

7450 Ethernet Service Switch
7750 Service Router
7950 Extensible Routing System
Releases Up To 23.10.R2

MD-CLI Advanced Configuration Guide - Part II

3HE 19550 AAAC TQZZA
Edition: 01
March 2024

Nokia is committed to diversity and inclusion. We are continuously reviewing our customer documentation and consulting with standards bodies to ensure that terminology is inclusive and aligned with the industry. Our future customer documentation will be updated accordingly.

This document includes Nokia proprietary and confidential information, which may not be distributed or disclosed to any third parties without the prior written consent of Nokia.

This document is intended for use by Nokia's customers ("You"/"Your") in connection with a product purchased or licensed from any company within Nokia Group of Companies. Use this document as agreed. You agree to notify Nokia of any errors you may find in this document; however, should you elect to use this document for any purpose(s) for which it is not intended, You understand and warrant that any determinations You may make or actions You may take will be based upon Your independent judgment and analysis of the content of this document.

Table of contents

List of tables	7
List of figures	9
Preface	29
About This Guide.....	29
Services Overview	30
BGP Selective Label-IPv4 Route Installation.....	31
G.8032 Ethernet Ring Protection Multiple Ring Topology.....	47
G.8032 Ethernet Ring Protection Single Ring Topology.....	86
GRE Tunnel Origination and Termination Using Non-system IP Addresses.....	106
Network Group Encryption Helper.....	122
Seamless BFD Application — Auto-bind tunnel.....	134
Layer 2 Services and EVPN	148
AC-Influenced DF Election on an ES.....	150
ARP-ND Host Routes in Data Centers.....	175
Auto-Learn MAC Protect in EVPN.....	210
BGP Multi-Homing for VPLS Networks.....	239
BGP Virtual Private Wire Services.....	270
BGP VPLS.....	296
Black-hole MAC for EVPN Loop Protection.....	326
Conditional Static Black-Hole MAC in EVPN.....	340
Data Center Interconnect Using Dual EVPN-VXLAN Instance VPLS.....	369
Domain Path Attribute for VPRN BGP Routes.....	385
Dual EVPN-MPLS Instance VPLS Services.....	410
EVPN E-LAN services with SRv6 transport.....	433
EVPN ESI Type 1.....	462
EVPN for MPLS Tunnels.....	476
EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS).....	526
EVPN for MPLS Tunnels in Routed VPLS.....	555
EVPN for PBB over MPLS (PBB-EVPN).....	578
EVPN for VXLAN Tunnels (Layer 2).....	616

EVPN for VXLAN Tunnels (Layer 3).....	641
EVPN Interconnect Ethernet Segments.....	681
EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services.....	706
EVPN IP-VRF-to-IP-VRF Models.....	732
EVPN Multi-Homing for VXLAN VPLS Services.....	758
EVPN R-VPLS Attached to IES.....	786
EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 Stitching.....	816
EVPN VPWS Multihoming on PW ports.....	847
EVPN VPWS Services with SRv6 Transport.....	880
EVPN-IFF BGP Attribute Propagation Between Families.....	910
EVPN-MPLS E-Tree.....	944
EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services.....	974
EVPN-VXLAN VPWS.....	996
Inter-AS Model C for VLL.....	1031
L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing.....	1050
L2 Services with Auto-GRE Spoke-SDPs.....	1069
Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.....	1087
LDP VPLS Using BGP Auto-Discovery.....	1110
LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP.....	1131
Mobility for EVPN Hosts Within an R-VPLS.....	1143
Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire.....	1179
Multi-Instance VPRN with EVPN-IFL Using SRv6 Transport.....	1202
Operational Groups for EVPN-VXLAN VPWS Services.....	1243
Operational Groups in EVPN Services.....	1266
P2MP mLDP FEC Resolution for BGP-LU in EVPN.....	1289
P2MP mLDP Inter-AS Model C for EVPN-MPLS Services.....	1313
P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services.....	1338
PBB-Epipe.....	1362
PBB-EVPN ISID-based CMAC Flush.....	1381
PBB-EVPN ISID-based Route Targets.....	1407
PBB-VPLS.....	1425
PIM Snooping for IPv4 in EVPN-MPLS Services.....	1457
PIM Snooping for IPv4 in PBB-EVPN Services.....	1507
Preference-based and Non-revertive EVPN DF Election.....	1540
Proxy-ARP/ND MAC List for Dynamic Entries.....	1564
Shortest Path Bridging for MAC.....	1580

Static VXLAN Termination in Epipe Services.....	1610
Three-byte EVI in EVPN Services.....	1648
VCCV BFD for Epipe Services.....	1664
Virtual Ethernet Segments.....	1675
VLAN Range SAPs for VPLS and Epipe Services.....	1689
VXLAN Forwarding Path Extension.....	1707
Layer 3 Services.....	1726
BGP Best External in a VPRN.....	1727
Carrier Supporting Carrier IP VPNs.....	1752
Flexible Algorithms for SRv6-based VPRNs.....	1774
Inter-AS VPRN Model B.....	1809
Inter-AS VPRN Model B Using MPLS over UDP.....	1829
Inter-AS VPRN Model C.....	1843
Layer 3 VPN: VPRN Type Spoke.....	1858
NG-MVPN Configuration with MPLS.....	1873
NG-MVPN Configuration with PIM.....	1927
NG-MVPN Inter-AS Model B Using Non-Segmented mLDP Tunnels.....	1971
NG-MVPN Inter-AS Model C Using Non-Segmented mLDP Tunnels.....	2001
NG-MVPN Sender-Only, Receiver-Only.....	2035
NG-MVPN Source Redundancy.....	2086
NG-MVPN Wildcard S-PMSI.....	2117
Rosen MVPN Core Diversity.....	2144
Rosen MVPN Inter-AS Option B.....	2170
Spoke Termination for IPv6-6VPE.....	2195
Traffic Leaking from VPRN to GRT.....	2218
Weighted ECMP for VPRN over RSVP-TE or SR-TE LSPs.....	2238
Multi-Service Integrated Service Adapter and Extended Services Appliance.....	2259
Multi-Chassis IPsec Redundancy.....	2260
N:M MC-IPsec Redundancy.....	2298
Triple Play Service Delivery Architecture.....	2317
BNG Dual-Homing with EVPN VPWS in the Access Network and SRv6 Transport.....	2318
Diameter Base Protocol: Establishing a Diameter Peer Connection.....	2598
L2TP for Subscriber Access — LAC.....	2611

Vport-Based Load Balancing on a LAG.....	2659
--	------

List of tables

Table 1: Selective BGP-LU installation logic by service type.....	32
Table 2: Terminology comparison.....	49
Table 3: VE-IDs and Labels.....	305
Table 4: VE-IDs and Number of Labels.....	305
Table 5: Comparing EVPN multi-homing and BGP multi-homing.....	518
Table 6: EVPN and PBB-EVPN SR OS feature comparison.....	578
Table 7: PBB-EVPN multi-homing supported combinations in SR OS.....	598
Table 8: EVPN IP-VRF-to-IP-VRF model comparison.....	736
Table 9: Interfaces in E-Tree.....	944
Table 10: E-Tree Forwarding on Access Interfaces.....	945
Table 11: Inclusive multicast route information sent by different AR roles.....	1089
Table 12: IMET routes and Tunnel Types advertised based on the configuration.....	1346
Table 13: CMAC flush transmission behavior.....	1385
Table 14: CMAC flush reception behavior.....	1386
Table 15: Supported examples for Q-tag values between 1 and 4094.....	1677
Table 16: Supported examples for Q-tag values 0, *, and null.....	1677
Table 17: VLAN manipulation in SAPs.....	1689
Table 18: SAP lookup order for dot1q ports.....	1693
Table 19: SAP lookup order for QinQ ports.....	1693
Table 20: NG MVPN Components.....	1928
Table 21: mLDP Message Opaque Value Types in MVPN Model B.....	1973

Table 22: mLDP Message Opaque Value Types in MVPN inter-AS Model C.....	2003
Table 23: S-PMSI Auto-Discovery BGP NLRI.....	2119
Table 24: SRv6 endpoint behaviors.....	2324
Table 25: L2TPv2 header fields and descriptions.....	2614
Table 26: AVP header fields and descriptions.....	2615
Table 27: Generic L2TP RADIUS attributes.....	2621
Table 28: Nokia specific L2TP RADIUS attributes.....	2621
Table 29: Subscriber association with Vports.....	2663
Table 30: Vport distribution over member ports.....	2679
Table 31: Vport distribution over member ports.....	2686

List of figures

Figure 1: Example topology.....	33
Figure 2: VPRN 1 uses a BGP transport tunnel with endpoint 192.0.1.21 on PE-2.....	37
Figure 3: VPRN 2, VPLS 3, and Epipe 4 use user-provisioned SDP 1 with BGP tunnel.....	41
Figure 4: PE-1 receives BGP-VPLS and BGP-AD routes with next-hop 192.0.1.23.....	43
Figure 5: G.8032 major ring and subring.....	50
Figure 6: G.8032 ring components.....	51
Figure 7: G.8032 subring interconnection components.....	52
Figure 8: Ethernet example topology.....	56
Figure 9: ETH-CFM MEP associations.....	58
Figure 10: Subring to VPLS topology.....	80
Figure 11: G.8032 operation and topologies.....	88
Figure 12: Example topology.....	89
Figure 13: Ethernet CFM configuration.....	93
Figure 14: Example topology.....	109
Figure 15: Mismatched T-LDP transport addresses.....	111
Figure 16: Matching T-LDP transport addresses.....	112
Figure 17: L2 services on PE-1 and PE-2.....	114
Figure 18: L3 services on PE-1 and PE-2.....	118
Figure 19: General architecture using an NGE helper.....	123
Figure 20: BGP topology for learning BGP label routes.....	126
Figure 21: NGE helper for BGP VPLS or BGP VPWS using GRE SDPs with auto-GRE SDP.....	128

Figure 22: S-BFD session establishment – continuity check.....	135
Figure 23: Example topology.....	136
Figure 24: Primary path of SR-TE LSP via PE-4.....	143
Figure 25: Remote failure in the primary path of the SR-TE LSP.....	144
Figure 26: SR-TE LSP reconnects after retry timer expires.....	146
Figure 27: PE-4 as the DF on a single-active ES for three VPLSs.....	151
Figure 28: AC failure in VPLS 2 on PE-4 causes PE-5 to become the DF for VPLS 2.....	152
Figure 29: PE-2 is DF on single-active ES for three VPLSs.....	153
Figure 30: AC failure in VPLS 2 on PE-2 causes PE-3 to become DF for VPLS 2.....	154
Figure 31: AC failure in VPLS 2 on PE-2 has no impact on DF election.....	155
Figure 32: Example topology.....	155
Figure 33: L2 broadcast domain extension across DCs.....	176
Figure 34: ARP-ND module and generated ARP-ND host routes.....	177
Figure 35: DC inter-subnet forwarding with Anycast GWs.....	179
Figure 36: DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes.....	186
Figure 37: DCI inter-subnet forwarding with Anycast GWs and ARP-ND host routes.....	194
Figure 38: Example topology - no LAG.....	214
Figure 39: MAC address learned simultaneously on SAPs on PE-2 and PE-3.....	216
Figure 40: Default RPS-DF on SAPs - MAC learned and protected on SAP on PE-2.....	225
Figure 41: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints.....	226
Figure 42: MAC learned and protected on SAP on PE-2 - RPS enabled on SAP on PE-3.....	232
Figure 43: RPS enabled on SAPs - RPS-DF on EVPN endpoints, MACs learned simultaneously.....	233
Figure 44: ALMP in all-active multi-homing SAPs.....	235

Figure 45: All-active multi-homing - RPS-DF on SAPs and EVPN endpoints.....	237
Figure 46: Example topology.....	240
Figure 47: Nodes involved in BGP MH.....	244
Figure 48: MAC flush for BGP MH.....	256
Figure 49: Access PE/CE signaling.....	257
Figure 50: Oper-groups and BGP-MH.....	260
Figure 51: Example topology.....	271
Figure 52: Single-homed BGP VPWS using auto-provisioned SDPs.....	276
Figure 53: Single-homed BGP VPWS using pre-provisioned SDP.....	282
Figure 54: Dual-homed BGP VPWS with single pseudowire.....	286
Figure 55: Dual-homed BGP VPWS with active/standby pseudowire.....	292
Figure 56: Example topology.....	297
Figure 57: BGP VPLS using auto-provisioned SDPs.....	303
Figure 58: BGP VPLS using pre-provisioned SDP.....	317
Figure 59: Black-hole MAC for EVPN loop protection.....	327
Figure 60: Example topology.....	329
Figure 61: Example topology with all-active multi-homing.....	337
Figure 62: Traffic dropped when ALMP is configured in all-active multi-homing.....	338
Figure 63: Proxy-ARP/ND and ARP spoofing.....	341
Figure 64: Example topology.....	342
Figure 65: Conditional static black-hole MAC.....	344
Figure 66: VPLS 1 with proxy-ARP and AS-MAC.....	356
Figure 67: Dual EVPN-VXLAN instance VPLS 1.....	370

Figure 68: Example topology with VPLS 1 and anycast addresses.....	373
Figure 69: Example topology with BGP groups.....	374
Figure 70: Loop prevention in networks with multiple IP-VPN and EVPN domains.....	386
Figure 71: D-path attribute.....	387
Figure 72: Example topology with VPRN 10 and its domain IDs.....	388
Figure 73: VPRN BGP routes for prefix 172.31.6.0/24.....	400
Figure 74: VPRN BGP routes for prefix 172.31.7.0/24.....	401
Figure 75: Loop prevention between PE-2 and PE-3.....	403
Figure 76: Example topology with R-VPLS.....	405
Figure 77: Loop prevention between DC GW PE-2 and DC GW PE-3.....	408
Figure 78: Access nodes receive next hops from the NHS-RRs.....	411
Figure 79: Access nodes receive one service label per service from each NHS-RR.....	412
Figure 80: Example topology 1.....	413
Figure 81: Example topology 2.....	421
Figure 82: Export policies on PE-2 drop routes based on tag.....	427
Figure 83: Example topology.....	435
Figure 84: ESI type 1 example.....	462
Figure 85: ESI auto-configuration example.....	463
Figure 86: Example topology.....	465

Preface

About This Guide

The Advanced Configuration Guide is divided into three volumes, the Part I Guide, the Part II Guide, and the Part III Guide.

- Part I provides advanced configurations for basic systems, system management, interface configuration, router configuration, unicast routing protocols, MPLS, OAM and diagnostics, and VSR Installation and Setup.
- Part II provides advanced configurations for services overview, Layer 2 and EVPN services, Layer 3 services, and Quality of Service.
- Part III provides advanced configurations for Multi-Service Integrated Service Adapter (MS-ISA) – Extended Services Appliance (ESA), and Triple Play Service Delivery Architecture (TPSDA).

The MD-CLI Advanced Configuration Guide is divided into two volumes, the Part I Guide and the Part II Guide.

- Part I provides advanced configurations for basic systems, system management, interface configuration, router configuration, unicast routing protocols, MPLS, OAM and diagnostics, and VSR Installation and Setup.
- Part II provides advanced configurations for services overview, Layer 2 and EVPN services, Layer 3 services, Multi-Service Integrated Service Adapter (MS-ISA) – Extended Services Appliance (ESA), and Triple Play Service Delivery Architecture (TPSDA).

The guide is organized alphabetically within each category and provides feature and configuration explanations, CLI descriptions and overall solutions. The chapters in the Advanced Configuration Guide are written for and based on several Releases, up to 23.10.R2. The Applicability section in each chapter specifies on which release the configuration is based.

The Advanced Configuration Guide supplements the user configuration guides listed in the 7450 ESS, 7750 SR, and 7950 XRS Guide to Documentation.

Audience

This manual is intended for network administrators who are responsible for configuring the routers. It is assumed that the network administrators have a detailed understanding of networking principles and configurations.

Services Overview

This section provides configuration information for the following topics:

- [BGP Selective Label-IPv4 Route Installation](#)
- [G.8032 Ethernet Ring Protection Multiple Ring Topology](#)
- [G.8032 Ethernet Ring Protection Single Ring Topology](#)
- [GRE Tunnel Origination and Termination Using Non-system IP Addresses](#)
- [Network Group Encryption Helper](#)
- [Seamless BFD Application — Auto-bind tunnel](#)

BGP Selective Label-IPv4 Route Installation

This chapter provides information about BGP selective label-IPv4 route installation.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 23.3.R1. BGP selective label-IPv4 route installation is supported in SR OS Release 19.10.R2, and later.

Overview

Many service providers use BGP label-unicast (BGP-LU) to build network designs that connect multiple domains into unified and scalable network fabrics. However, the number of BGP-LU IPv4 routes that are distributed in the control plane can exceed the capacity of the Forwarding Information Base (FIB) and Label Forwarding Information Base (LFIB) of small access routers.

One solution is to apply import policies on the access router to limit the number of BGP-LU IPv4 routes accepted in the RIB-IN, but this is labor-intensive and prone to errors. A better solution is selective BGP-LU IPv4 route installation in the base routing instance, which addresses these issues.

When the **selective-label-ipv4-install** command is configured in the **bgp** context of the base router, BGP-LU IPv4 routes in the RIB-IN are made invalid if they are received from a base router BGP peer and not needed by any eligible service. When a BGP-LU IPv4 route is invalid in the RIB-IN, the BGP decision process prefers any valid route over this route, and the invalid BGP-LU IPv4 route is not programmed as a next-hop (primary next-hop, ECMP next-hop, or backup next-hop) of any IP route or tunnel.

The **selective-label-ipv4-install** command can be configured in the **bgp** context of the base router: in the global **bgp** context, the group context, or the neighbor context, as follows:

```
[/]
A:admin@PE-1# tree flat detail | match selective-label-ipv4-install
configure groups group <string> router <string> bgp group <string> selective-label-ipv4-install
<boolean>
configure groups group <string> router <string> bgp neighbor <string | ipv4-address-with-zone
| ipv4-address | ipv6-address-linklocal-with-zone | ipv6-address | ipv6-address-with-zone>
selective-label-ipv4-install <boolean>
configure groups group <string> router <string> bgp selective-label-ipv4-install <boolean>
configure router <string> bgp group <string> selective-label-ipv4-install <boolean>
configure router <string> bgp neighbor <ipv4-address-with-zone | ipv4-address | ipv6-address-
linklocal-with-zone | ipv6-address | ipv6-address-with-zone> selective-label-ipv4-install
<boolean>
configure router <string> bgp selective-label-ipv4-install <boolean>
```

When a BGP-LU IPv4 route is invalid in the RIB-IN, it is marked with the flag Label-Unicast-No-Svc and the invalid route is handled as follows:

- No route for the IPv4 prefix is added to the route table from the BGP-LU RIB.
- No BGP tunnel for the /32 IPv4 prefix is added to the tunnel table.
- No RIB-OUT is generated for the invalid BGP-LU route, so this invalid route does not trigger a label-swap (incoming label map - ILM) entry to be programmed.

Note:

Configuring the **selective-label-ipv4-install** command on a BGP session unconditionally invalidates all non-/32 BGP-LU IPv4 routes received on that session, because those non-/32 routes are never used to resolve service endpoints.

[Table 1: Selective BGP-LU installation logic by service type](#) shows how BGP-LU IPv4 routes are handled when the selective-label-ipv4-install command is configured.

Table 1: Selective BGP-LU installation logic by service type

Service type	Logic marks BGP label-IPv4 routes as invalid except
L2 services with user-provisioned SDPs	When the user-provisioned SDP has a BGP tunnel as transport and the far end matches a /32 BGP-LU IPv4 route, that route is not marked as invalid, regardless of the operational state of the SDP.
L2 services with auto-created SDPs (BGP-AD, BGP-VPLS, BGP-EVPN)	If an L2 service imports a BGP-AD, BGP-VPLS, or BGP-EVPN route, /32 BGP-LU IPv4 routes matching the BGP next-hop address of this BGP route are not marked as invalid.
EVPN next-hop-self route reflector or model-B ASBR	If the base router BGP instance is configured as a next-hop-self RR or a model-B ASBR, BGP-LU IPv4 routes matching any IPv4 address in the BGP next-hop field of a received EVPN route are not marked as invalid, regardless of whether the transport-tunnel resolution filter allows BGP tunnels.
VPRN with explicitly configured SDP	BGP-LU IPv4 routes matching the SDP far-end address are not marked as invalid, regardless of the operational state of the SDP.
VPRN with auto-bind-tunnel	If the auto-bind VPRN service imports VPN-IPv4 or VPN-IPv6 routes where the BGP next-hop matches a BGP-LU IPv4 route, that route is not marked as invalid, regardless of whether the auto-bind-tunnel resolution filter allows BGP tunnels.
VPN-IP next-hop-self RR or model-B ASBR	If the base router BGP instance is configured as a next-hop-self RR or a model-B ASBR, BGP-LU IPv4 routes matching any IPv4 address in the BGP next-hop field of a received VPN-IP route are not marked as invalid, regardless of whether the transport-tunnel resolution filter allows BGP tunnels.

Configuration

Figure 1: Example topology shows the example topology with two PEs with the services that are configured.

Figure 1: Example topology

35965

Initial configuration

The initial configuration on the PEs includes:

- Cards, MDAs, ports
- Router interfaces
- SR-ISIS

On PE-2, four loopback interfaces are configured in the base router context with /32 IPv4 addresses: 192.0.1.21/32, 192.0.1.22/32, 192.0.1.23/32, and 192.0.1.24/32. The list of router interfaces on PE-2 is as follows:

```
[/]
A:admin@PE-2# show router interface
```

```
=====
Interface Table (Router: Base)

=====

```

These prefixes are exported as BGP-LU routes and the next-hop resolution filter for label-IPv4 routes is configured with SR-ISIS. The configuration on PE-2 is as follows:

```

# on PE-2:
configure {
  policy-options {
    prefix-list "192.0.1.0/24" {
      prefix 192.0.1.0/24 type range {
        start-length 32
        end-length 32
      }
    }
  }
  policy-statement "export-svc-lu-bgp" {
    entry 10 {
      from {
        prefix-list ["192.0.1.0/24"]
      }
      action {
        action-type accept
      }
    }
  }
}
router "Base" {
  bgp {
    split-horizon true
    ebgp-default-reject-policy {
      import false
      export false
    }
  }
  next-hop-resolution {
    labeled-routes {
      transport-tunnel {
        family label-ipv4 {
          resolution-filter {
            ldp false
            sr-isis true
          }
        }
      }
    }
  }
}
group "iBGPv4" {
  peer-as 64500
  family {
    vpn-ipv4 true
    label-ipv4 true
  }
}
neighbor "192.0.2.1" {

  Color
-----
192.0.2.2/32     isis (0)  MPLS  524290   11    192.168.12.2  10
-----
Flags: B = BGP or MPLS backup hop available
      L = Loop-Free Alternate (LFA) hop available
      E = Inactive best-external BGP route
      k = RIB-API or Forwarding Policy backup hop
=====
```

In the following examples, services that use these BGP tunnels are configured .

VPRN 1 with auto-bind-tunnel

VPRN 1 in [Figure 2: VPRN 1 uses a BGP transport tunnel with endpoint 192.0.1.21 on PE-2](#) uses the BGP transport tunnel between loopback interfaces "lo1" with IP address 192.0.1.11/32 on PE-1 and 192.0.1.21/32 on PE-2.

Figure 2: VPRN 1 uses a BGP transport tunnel with endpoint 192.0.1.21 on PE-2

35966

VPRN 1 is configured with an auto-bind-tunnel and the next-hop must be resolved using a BGP tunnel. On PE-2, the policy "export-VPRN1" sets the next-hop to 192.0.1.21 and adds the community "target:64500:1", which matches the vrf-target of VPRN 1.

```
# on PE-2:
configure {
  policy-options {
    community "target:64500:1" {
      member "target:64500:1" { }
    }
    policy-statement "export-VPRN1" {
      entry 10 {
        action {
          action-type accept
          next-hop 192.0.1.21
          community {
            add ["target:64500:1"]
          }
        }
      }
    }
  }
  service {
    vprn "VPRN 1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp-ipvpn {
        mpls {
          admin-state enable
          route-distinguisher "64500:1"
          vrf-target {
            community "target:64500:1"
          }
          vrf-export {
            policy ["export-VPRN1"]
          }
          auto-bind-tunnel {
            resolution filter
          }
        }
      }
    }
  }
  interface "lo1" {
    loopback true
    ipv4 {
      primary {
        address 172.31.1.2
        prefix-length 32
      }
    }
  }
}
```

```

    }
  }
}

```

The configuration is similar on PE-1, but the IP addresses are different.

VPRN 1 on PE-1 receives a BGP VPN-IPv4 route for prefix 172.31.1.2/32 from PE-2. The next-hop of this BGP-VPN route is 192.0.1.21:

```

[/]
A:admin@PE-1# show router bgp routes vpn-ipv4

      No As-Path                              524285
-----
Routes : 1
=====

```

VPRN 1 on PE-1 uses the BGP tunnel toward 192.0.1.21/32 while the other BGP tunnels are not required on PE-1. When BGP is configured with the **selective-label-ipv4-install** command, only the BGP-LU IPv4 route for 192.0.1.21/32 remains valid. The command can be configured in the global BGP context (as in the following configuration), per **group**, or per **neighbor**:

```

# on PE-1:
configure {
  router "Base" {
    bgp {
      selective-label-ipv4-install true
    }
  }
}

```

From the four BGP transport tunnels on PE-1, only the BGP tunnel with endpoint 192.0.1.21/32 is used by a service, so it remains valid, as follows:

```

[/]
A:admin@PE-1# show router bgp routes label-ipv4
=====
BGP Router ID:192.0.2.1          AS:64500          Local AS:64500
=====
Legend -
Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                l - leaked, x - stale, > - best, b - backup, p - purge
Origin codes  : i - IGP, e - EGP, ? - incomplete
=====

```

```

BGP LABEL-IPv4 Routes
=====
Flag Network                               LocalPref MED

      No As-Path                             524286
-----
Routes : 4
=====

```

The first label-IPv4 route is valid; the other three label-IPv4 routes are marked invalid with flag Label-Unicast-No-Svc:

```

[/]
A:admin@PE-1# show router bgp routes label-ipv4 hunt | match Flags
Flags          : Used Valid Best IGP In-TTM In-RTM
Flags          : Invalid IGP Label-Unicast-No-Svc
Flags          : Invalid IGP Label-Unicast-No-Svc
Flags          : Invalid IGP Label-Unicast-No-Svc

```

In the route table on PE-1, only one BGP-LU IPv4 route remains:

```

[/]
A:admin@PE-1# show router route-table protocol bgp-label

=====
Route Table (Router: Base)
=====
Dest Prefix[Flags]                Type   Proto   Age           Pref
      Next Hop[Interface Name]                    Metric
-----

Flags: n = Number of times nexthop is repeated
      B = BGP backup route available
      L = LFA nexthop available
      S = Sticky ECMP requested
=====

```

L2 and L3 services with user-provisioned SDP

When SDPs are configured to use a BGP transport tunnel, the corresponding BGP label-IPv4 route is not marked as invalid. The following TLDP-signaled SDP is configured with a BGP transport tunnel between the loopback interfaces "lo2" with IP address 192.0.1.12 on PE-1 and 192.0.1.22 on PE-2:

```
# on PE-2:
configure {
  router "Base" {
    ldp {
      targeted-session {
        peer 192.0.1.12 {
          local-lsr-id {
            interface-name "lo2"
          }
        }
      }
    }
  }
}
service {
  sdp 1 {
    admin-state enable
    delivery-type mpls
    bgp-tunnel true
    far-end {
      ip-address 192.0.1.12
    }
  }
}
```

The configuration is similar on PE-1; only the far-end and peer address is now 192.0.1.22:

```
[/]
A:admin@PE-1# show service sdp

=====
Services: Service Destination Points
=====
SdpId  AdmMTU  OprMTU  Far End           Adm  Opr           Del  LSP  Sig
-----
1      0       8970    192.0.1.22       Up   Up            MPLS B    TLDP
-----
Number of SDPs : 1
-----

This SDP can be used by L2 and L3 services. [Figure 3: VPRN 2, VPLS 3, and Epipe 4 use user-provisioned SDP 1 with BGP tunnel](#) shows three services that use SDP 1: VPRN 2, VPLS 3, and Epipe 4.

Figure 3: VPRN 2, VPLS 3, and Epipe 4 use user-provisioned SDP 1 with BGP tunnel

VPRN 2 is similar to VPRN 1, but a spoke-SDP is configured instead of the auto-bind-tunnel. The configuration is as follows:

```

# on PE-1:
configure {
  policy-options {
    community "target:64500:2" {
      member "target:64500:2" { }
    }
  }
  policy-statement "export-VPRN2" {
    entry 10 {
      action {
        action-type accept
        next-hop 192.0.1.12
        community {
          add ["target:64500:2"]
        }
      }
    }
  }
}

```

```

    }
  }
}
service {
  vprn "VPRN 2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp-ipvpn {
      mpls {
        admin-state enable
        route-distinguisher "64500:2"
        vrf-target {
          community "target:64500:2"
        }
        vrf-export {
          policy ["export-VPRN2"]
        }
      }
    }
  }
  interface "lo1" {
    loopback true
    ipv4 {
      primary {
        address 172.31.2.1
        prefix-length 32
      }
    }
  }
  spoke-sdp 1:2 {
  }
}
}

```

VPLS 3 and Epipe 4 only have a spoke-SDP and a SAP, as follows:

```

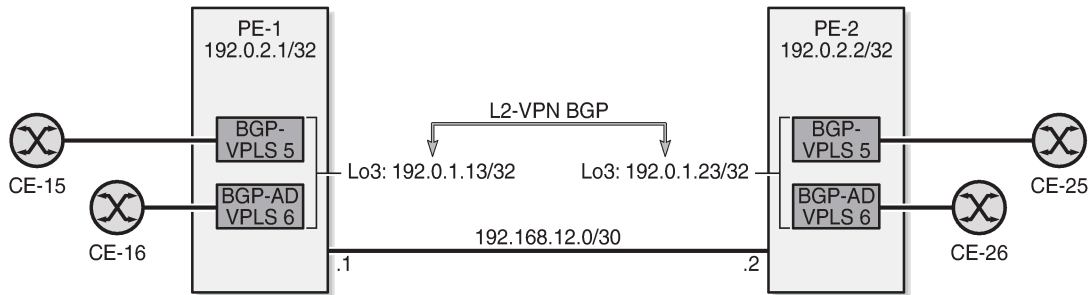

# on PE-1:
configure {
  service {
    vpls "VPLS 3" {
      admin-state enable
      service-id 3
      customer "1"
      spoke-sdp 1:3 {
      }
      sap 1/1/c2/1:3 {
      }
    }
    epipe "Epipe 4" {
      admin-state enable
      service-id 4
      customer "1"
      spoke-sdp 1:4 {
      }
      sap 1/1/c2/1:4 {
      }
    }
  }
}

```

L2 services with auto-created SDPs

Figure 4: PE-1 receives BGP-VPLS and BGP-AD routes with next-hop 192.0.1.23 shows two VPLS services where the SDPs are auto-created between the loopback interfaces "lo3" on the PEs: BGP-VPLS 5 and BGP-AD VPLS 6.

Figure 4: PE-1 receives BGP-VPLS and BGP-AD routes with next-hop 192.0.1.23

35968

For BGP-VPLS and BGP-AD, a BGP session is established for the L2-VPN address family between the loopback interfaces "lo3" on both PEs:

```
# on PE-2:
configure {
  router "Base" {
    bgp {
      group "iBGP-L2" {
        type internal
        local-address 192.0.1.23
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.1.13" {
        group "iBGP-L2"
      }
    }
  }
}
```

For BGP-AD, T-LDP signaling is used, so the following T-LDP session is established:

```
# on PE-2:
configure {
  router "Base" {
    ldp {
      targeted-session {
        peer 192.0.1.13 {
          local-lsr-id {
            interface-name "lo3"
          }
        }
      }
    }
  }
}
```

The service configuration is as follows:

```
# on PE-2:

MED          : None
IGP Cost     : 10
```

Conclusion

The **selective-label-ipv4-install** command allows BGP-LU IPv4 routes to be marked as invalid in the RIB-IN when these routes are received from a base router BGP peer and not needed by any eligible service. This is a technique to reduce the number of routes in the FIB/LFIB, which is mainly useful for small access routers having small FIB/LFIB sizes.

G.8032 Ethernet Ring Protection Multiple Ring Topology

This chapter provides information about G.8032 Ethernet ring protection multiple ring topologies.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

Initially, this chapter was written for SR OS Release 12.0.R5, but the MD-CLI in this edition is based on Release 23.3.R2.

Overview

G.8032 Ethernet ring protection is supported for data service SAPs within a regular VPLS service, a PBB VPLS (I/B-component), or a routed VPLS (R-VPLS). G.8032 is one of the fastest protection schemes for Ethernet networks. This chapter describes the advanced topic of multiple ring control, sometimes referred to as multi-chassis protection, with access rings being the most common form of multiple ring topologies. Single rings are covered in the [G.8032 Ethernet Ring Protection Single Ring Topology](#) chapter. This chapter will use a VPLS service to illustrate the configuration of G.8032. For very large ring topologies, provider backbone bridging (PBB) can also be used, but that is not configured in this chapter.

ITU-T G.8032v2 specifies protection switching mechanisms and a protocol for Ethernet layer network (ETH) Ethernet rings. Ethernet rings can provide wide-area multipoint connectivity more economically due to their reduced number of links. The mechanisms and protocol defined in ITU-T G.8032v2 are highly reliable with stable protection and never form loops, which would negatively affect network operation and service availability. Each ring node is connected to adjacent nodes participating in the same ring using two independent paths, which use ring links (configured on ports or link aggregation groups (LAGs)). A ring link is bounded by two adjacent nodes and a port for a ring link is called a ring port. The minimum number of nodes on a ring is two.

The fundamentals of this ring protection switching architecture are:

- the principle of loop avoidance and
- the utilization of learning, forwarding, and address table mechanisms defined in the ITU-T G.8032v2 Ethernet flow forwarding function (ETH_FF) (control plane).

Loop avoidance in the ring is achieved by guaranteeing that, at any time, traffic may flow on all but one of the ring links. This particular link is called the ring protection link (RPL) and under normal conditions this link is blocked, so it is not used for traffic. One designated node, the RPL owner, is responsible to block traffic over the one designated RPL. Under a ring failure condition, the RPL owner is responsible for unblocking the RPL, allowing the RPL to be used for traffic. The protocol ensures that even without an RPL owner defined, one link will be blocked and it operates as a *break before make* protocol, specifically the protocol guarantees that no link is restored until a different link in the ring is blocked. The other side of the RPL is configured as an RPL neighbor. An RPL neighbor blocks traffic on the RPL.

The event of a ring link or ring node failure results in protection switching of the traffic. This is achieved under the control of the ETH_FF functions on all ring nodes. A ring automatic protection switching (R-APS) protocol is used to coordinate the protection actions over the ring. The protection switching mechanisms and protocol supports a multi-ring/ladder network that consists of connected Ethernet rings.

Ring protection mechanism

The ring protection protocol is based on the following building blocks:

- ring status change on failure
 - idle → link failure → protection → recovery → idle
- ring control state changes
 - idle → protection → manual switch → forced switch → pending
- re-use existing ETH OAM
 - monitoring: ETH continuity check messages (CCM)
 - failure notification: Y.1731 signal failure
- forwarding database MAC flush on ring status change
- ring protection link (RPL)
 - defines blocked link in idle status

When subrings are used, they can either connect to a major ring (which is configured in the exact same way as a single ring) or another subring, or to a VPLS service. When connected to a major ring or to a subring, there is the option to extend the subring control service through the major ring or not. This gives the following three options for subring connectivity:

- 1. subring to a major ring or to a subring with a virtual channel** — In this case, a data service on the major ring or subring is created which is used to forward the R-APS messages for the subring over the major ring or subring, between the interconnection points of the subring to the major ring or subring. This allows the subring to operate as a fully connected ring and is mandatory if the subring connects two major rings or subrings because the virtual channel is the only mechanism that the subrings can use to exchange control messages. It also could improve failover times if the subring was large as it provides two paths on the subring interconnection nodes to propagate the fault indication around the subring, whereas without a virtual channel the fault indication may need to traverse the entire subring. Each subring requires its own data service on the major ring or subring for the virtual channel.
- 2. subring to a major ring or to a subring without a virtual channel** — In this case the subring is not fully connected and does not require any resources on the major ring or subring. This option requires that the R-APS messages are not blocked on the subring over its RPL.
- 3. subring to a VPLS service** — This is similar to the preceding option, but it uses a VPLS service instead of a major ring or subring. In this option, subring failures can initiate the sending of an LDP MAC flush message into the VPLS service when spoke or MPLS mesh SDPs are used in the VPLS service.

Ethernet ring terminology

The implementation of Ethernet ring on SR OS uses a VPLS as the construct for a ring flow function (one for ETH_FF (solely for control) and one for each service_FF) and SAPs (on ports or LAGs) as ring links. The control VPLS must be a regular VPLS, but the data VPLS can be a regular VPLS, a PBB (B/I-) VPLS or a routed VPLS. The state of the data service SAPs is inherited from the state of the control

service SAPs. [Table 2: Terminology comparison](#) displays a comparison between the ITU-T and SR OS terminologies.

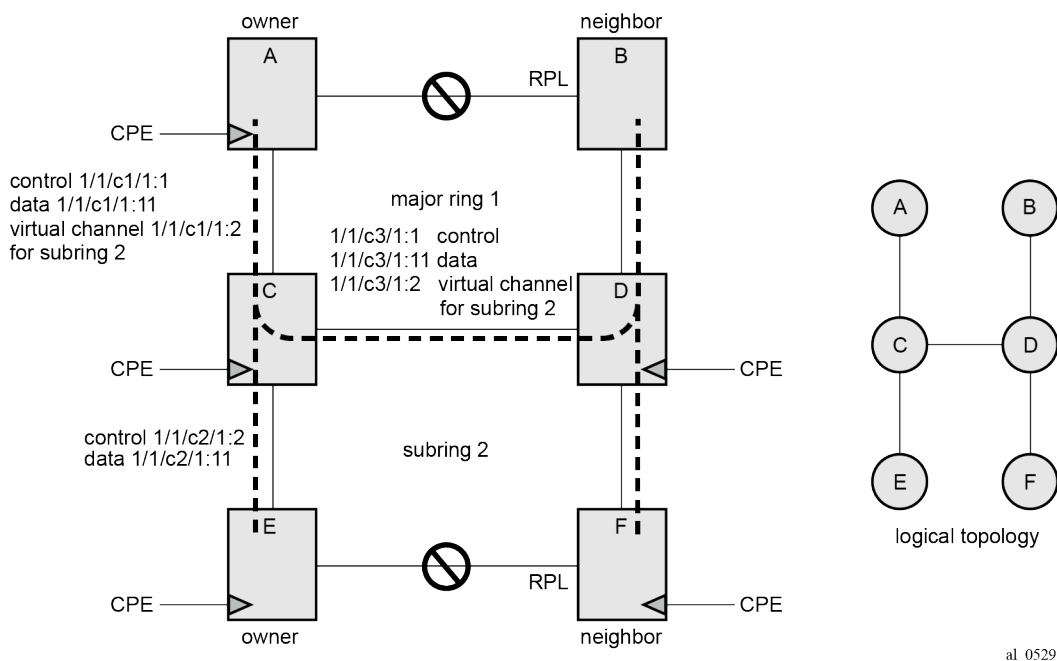

Table 2: Terminology comparison

ITU-T G.8032v2 terminology	SR OS terminology
ETH_FF	control vpls
service_FF	data vpls
east ring link	path a
west ring link	path b
RPL owner	rpl-node owner
RPL link	path {a b} rpl-end
MEP	control-mep
ERP control process	eth-ring instance or ring-id
major ring	eth-ring
sub-ring	eth-ring sub-ring
ring node	ring node PE
ring-ID	not used; fixed at 1 per G.8032v2

There are various ways that multiple rings can be interconnected and the possible topologies may be large. Customers typically have two forms of networks: access ring edge networks or larger multiple ring networks. Both topologies require ring interconnection.

[Figure 5: G.8032 major ring and subring](#) shows a ring of six nodes, with a major ring (regular Ethernet ring) on the top four nodes and a subring on the bottom.

Figure 5: G.8032 major ring and subring

A major ring is a fully connected ring. A subring is a partial ring that depends on a major ring or a VPLS topology for part of the ring interconnect. Two major rings can be connected by a single subring. A subring can support other subrings.

In the major ring (on nodes A, B, C, and D), one path of the RPL owner is designated to be the RPL and the respective SAPs will be blocked in order to prevent a loop. The choice of where to put the RPL is up to the network administrator and can be different for different control instances of the ring allowing an RPL to be used for some other ring's traffic. In the subring, one path is designated as the RPL and will be blocked. Both the major ring and the subring have their own RPL. The subring interconnects to the major ring on nodes C and D and has a virtual channel on the major ring. SR OS supports both virtual channel and non-virtual channel rings. Schematics of the physical and logical topologies are also shown in [Figure 5: G.8032 major ring and subring](#).

The G.8032 protocol defines a ring ID (1-255). The SR OS implementation only uses ring ID 1, which complies with G.8032v2. The configuration on a node uses a ring instance with a number but all rings use ring ID 1. This ring instance number is purely local and does not have to match on other ring nodes. Only the VLAN ID must match between SR OS ring nodes. For consistency in this example, VPLS instances and Ethernet ring instances are shown as matching for the same ring.

An RPL owner and RPL neighbor are configured for both the major ring and subring. The path and associated link will be the RPL when the ring is fully operational and will be blocked by the RPL owner whenever there is no fault on other ring links. Each ring RPL is independent. If a different ring link fails, then the RPL will be unblocked by the RPL owner. The link shared between a subring and the major ring is completely controlled by the major ring as if the subring were not there. Each ring can completely protect one fault within its ring. When the failed link recovers, it will initially be blocked by one of its adjacent nodes. The adjacent node sends an R-APS message across the ring to indicate the error is cleared and after a configurable time, if reversion is enabled, the RPL will revert to being blocked with all other links unblocked. This ensures that the ring topology when fully operational is predictable.

If a specific RPL owner is not configured (not recommended by G.8032 specification), then the last link to become active will be blocked and the ring will remain in this state until another link fails. This operation makes the selection of the blocked link non-deterministic.

The protection protocol uses a specific control VLAN, with the associated data VLANs taking their forwarding state from the control VLAN. The control VLAN cannot carry data.

Load balancing with multiple ring instances

Each control ring is independent of the other control rings on the same topology. Therefore, because the RPL is used by one control ring, it is often desirable to set up a second control ring that uses a different link as RPL. This spreads out traffic in the topology, but if there is a link failure in the ring, all traffic will be on the remaining links. In the following examples, only a single control ring instance is configured. Other control and data rings could be configured if desired.

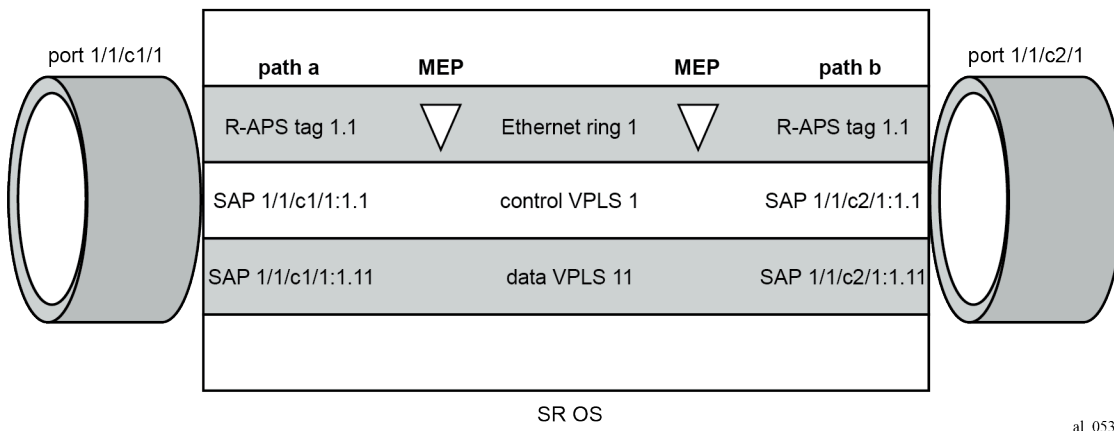

Provider backbone bridging (PBB)

PBB services also support G.8032 as data services (the services used for the control VPLS must be a regular VPLS). B/I-VPLS rings support both major rings and subrings. B-VPLS rings support multi-chassis link aggregation group (MC-LAG) as a dual homing option when aggregating I-VPLS traffic onto a B-VPLS ring. In other words, I-VPLS rings should not be dual-homed into two backbone edge bridge (BEB) nodes where the B-VPLS uses G.8032 to get connected to the rest of the B-VPLS network because the only mechanism that can propagate MAC flushes between an I-VPLS and B-VPLS is an LDP MAC flush.

SR OS implementation

G.8032 is built from VPLS components and each ring consists of the configuration components illustrated in [Figure 6: G.8032 ring components](#).

Figure 6: G.8032 ring components

These components consist of:

- the Ethernet ring instance which defines the R-APS tags, the MEPs, and the ring behavior.
- the control VPLS which has SAPs with an encapsulation that matches the R-APS tags.

- the data VPLS which is linked to the ring. All of the data VPLS SAPs follow the operational state of the control VPLS SAPs in that each blocked SAP controlled by the ring is blocked for all control and data instances.

Figure 7: G.8032 subring interconnection components shows the major ring and subring interconnection components:

Figure 7: G.8032 subring interconnection components

26167

For a subring, the configuration is the same as a single ring except at the junction of the major ring and the subring. The interconnection of a subring and a major ring links the control VPLS of the subring to a data VPLS of the major ring when a virtual link is used. Similarly, the data VPLS of the subring is linked to a data VPLS of the major ring. Figure 7: G.8032 subring interconnection components illustrates the relationship of a subring and a major ring. Because this subring has a virtual channel, the data VPLS 2 has both data SAPs from the subring and data SAPs from the major ring. The virtual channel is also optional and in non-virtual-link cases, no VPLS instance is required (see non-virtual-link in the section Configuration of a subring to a VPLS service).

In Figure 7: G.8032 subring interconnection components, the inner tag values are kept the same for clarity, but in fact any encapsulation that is consistent with the next ring link will work. In other words, ring SAPs can perform VLAN ID translation and even when connecting a subring to a major ring. This also means that other ports may reuse the same tags when connecting independent services.

The R-APS tags and SAPs on the rings can either be dot1Q or QinQ encapsulated. It is also possible to have the control VPLS using single tagged frames with the data VPLSs using double tagged frames; this requires the system to be configured with the **extended-default-qinq-sap-lookup** parameter (**configure service system extended-default-qinq-sap-lookup true**), with the ring path R-APS tags and control VPLS SAPs configured as qtag.0, and the data VPLSs configured as QinQ SAP: qtag1.qtag2. Spanning tree protocol (STP) cannot be enabled on SAPs connected to Ethernet rings.

R-APS messages received from other nodes are normally blocked on the RPL interface but the subring case with non-virtual channel recommends that R-APS messages be propagated over the RPL. Configuring **sub-ring type non-virtual-link** on all nodes on the subring is required to ensure propagation of R-APS messages around the subring.

R-APS messages are forwarded out of the egress using forwarding class network control (NC) and should be prioritized accordingly in the SAP egress QoS policy to ensure that congestion does not cause R-APS messages to be dropped which could cause the ring to switch to another path.

Configuration

This section describes the configuration of multiple rings. The Ethernet ring configuration commands are as follows.

```
configure {
  eth-ring <ring-index [1..128]> {
    ccm-hold-time {
      down <number> # Hold timer for down event dampening in centiseconds
      up <number> # Hold timer for recovery reporting in deciseconds
    }
    compatible-version <number> # [1..2] - Default: 2
    description <string>
    guard-time <number> # [1..20] in deciseconds - Default: 5
    node-id <mac-address> # MAC address of the RPL <xx:xx:xx:xx:xx:xx>
    path <string> # path ID: string of 1 character
    admin-state <keyword> # default: disable
    description <string>
    port-and-raps-tag <port-and-encap> # Port ID and ring APS tag ID
    eth-cfm {
      mep md-admin-name <reference> ma-admin-name <reference> mep-id <number> {
        admin-state <keyword> # default: disable
        ccm <boolean> # default: false
        control-mep <boolean> # default: false
      }
    }
    rpl-end <boolean> # default: false
  }
  revert-time <number> # <0,60..720> in seconds - Default: 300
  rpl-node <keyword> # owner | neighbor
  sub-ring
    interconnect {
      propagate-topology-change <boolean> # default: false
      ring-id # Ring instance of the connection ring for the subring
      vpls # Connect subring to VPLS ID that contains subring SAP
    }
    type # Subring type (virtual-link|non-virtual-link)
  }
}
```

Parameters:

- **<ring-index>** — The ring index is the number by which the ring is referenced; values: 1 to128.
- **ccm-hold-time { [down <down-timeout>] [up <up-timeout>] }**
 - **down** — This command specifies the timer which controls the delay between detecting that ring path is down and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM. It does not apply to the ring port link state. To dampen ring port link state transitions, use the hold-time parameter from the physical

member port. This is useful if the underlying path between two nodes is going across an optical system which implements its own protection.

- **up** — This command specifies the timer which controls the delay between detecting that ring path is up and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM. It does not apply to the member port link state. To dampen member port link state transitions, use the hold-time parameter from the physical member port.

Values:

```
*[ex:/configure eth-ring 1 ccm-hold-time]
A:admin@PE-1# down ?

down <number>
<number> - <1..5000> - centiseconds

    Hold timer for down event dampening

*[ex:/configure eth-ring 1 ccm-hold-time]
A:admin@PE-1# up ?

up <number>
<number> - <0..5000> - deciseconds
Default - 20

    Hold timer for recovery reporting
```

- The **admin-state** command allows to enable or disable the Ethernet ring.
- The **compatible-version** command configures the Ethernet ring compatibility version for the G.8032 state machine and messages. The default is version 2 (ITU G.8032v2) and all SR OS systems use version 2. If there is a need to interwork with third party devices that only support version 1, this can be set to version 1 allowing the reception of version 1 PDUs. Version 2 is encoded as 1 in the R-APS messages. Compatibility allows the reception of version 1 (encoded as 0) R-APS PDUs but, as per the G.8032 specification, higher versions are ignored on reception. For SR OS, messages are always originated with version 2. Therefore, if a third party switch supports version 3 (encoded as 2) or higher, interworking is also supported provided the other switch is compatible with version 2.
- The **description** includes a text string of maximum 80 characters to describe the use of the Ethernet ring.
- **guard-time <time>** — The forwarding method, in which R-APS messages are copied and forwarded at every Ethernet ring node, can result in a message corresponding to an old request, that is no longer relevant, being received by Ethernet ring nodes. Reception of an old R-APS message may result in erroneous ring state interpretation by some Ethernet ring nodes. The guard timer is used to prevent Ethernet ring nodes from acting upon outdated R-APS messages and prevents the possibility of forming a closed loop. Messages are not forwarded when the guard-timer is running.

Values:

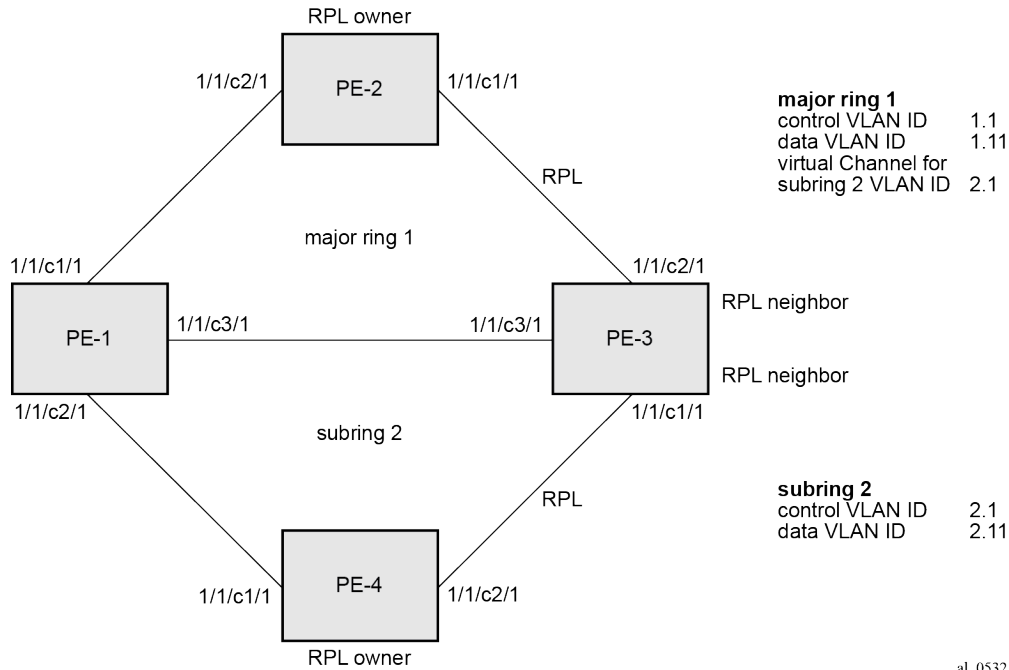

```
*[ex:/configure eth-ring 1]
A:admin@PE-1# guard-time ?

guard-time <number>
<number> - <1..20> - deciseconds
Default - 5
```

- The **node-id** `<xx-xx-xx-xx-xx-xx>` allows the node identifier to be explicitly configured. By default, the chassis MAC is used. The node ID is not required in typical configurations.
- The **path** parameter defines the paths around the ring, of which there are two in different directions on the ring: an "a" path and a "b" path, except on the interconnection node where a subring connects to another major ring or subring in which case there is one path (either a or b) configured together with the **sub-ring** command. The paths are configured on a dot1Q or QinQ encapsulated access or hybrid port or a LAG with the encapsulation used for the R-APS messages on the ring. These can be either single tagged or double tagged.
 - The **admin-state** command allows to enable or disable the path.
 - The **port-and-raps-tag** specifies the port ID and the R-APS tag.
 - The **description** includes a text string of maximum 80 characters to describe the use of the path.
 - The **eth-cfm** context includes the associated Ethernet CFM parameters.
 - **mep md-domain-name** `<reference>` **ma-domain-name** `<reference>` **mep-id** `<number>` — The MEP defined under the path is used for the G.8032 protocol messages, which are based on IEEE 802.1ag/Y.1731 CFM frames.
 - **rpl-end** — When configured, this path is expected to be one end of the RPL. This parameter must be configured in conjunction with the **rpl-node** parameter.
- The **revert-time** command configures the revert time for an Ethernet ring. The revert time is the time that the RPL will wait before returning to the blocked state, after a failure condition has been fixed. Values: [0, 60..720] in seconds - Default: 300.
- When the **rpl-node** parameter is configured, a node can be designated as either the **owner** of the RPL, in which case this node is responsible for the RPL, or the **neighbor**, in which case the node is expected to be the neighbor to the RPL owner across the RPL. The **neighbor** parameter is optional and is included to be compliant with the specification. The **rpl-node** parameter must be configured in conjunction with the **rpl-end** command. On a subring without virtual channel it is mandatory to configure **sub-ring type non-virtual-link** on all nodes on the subring to ensure propagation of the R-APS messages around the subring.
- The **sub-ring** command is configured on the interconnection node between the subring and its major ring or subring to indicate that this ring is a subring. A ring configured as a subring can only be configured with a single path.
 - The **type** `{virtual-link|non-virtual-link}` parameter specifies whether it uses a virtual link through the major ring or subring for the R-APS messages or not.
 - **interconnect** `[ring-id <ring-index> | vpls]` — A subring connects to either another ring or to a VPLS service. If it connects to another ring (either a major ring or another subring), the ring identifier must be specified and the ring to which it connects must be configured with both a path "a" and a path "b", meaning that it is not possible to connect a subring to another subring on an interconnection node. Alternatively, the **vpls** parameter is used to indicate the subring connects to a VPLS service. Interconnection using a VPLS service requires the subring to be configured with **type non-virtual-link**.
 - **propagate-topology-change** — If a topology change event happens in the subring, it can be optionally propagated with the use of this parameter to either the major ring or subring it is connected to, using R-APS messages, or to the LDP VPLS SDP peers using an LDP "flush-all-from-me" message if the subring is connected to a VPLS service.

The example topology is shown in [Figure 8: Ethernet example topology](#).

Figure 8: Ethernet example topology

The configuration is divided into the following sections:

- a subring connected to a major ring using a virtual link through the major ring
- a subring connected to a major ring without a virtual link
- a subring connected to a VPLS service (without a virtual link)

Configure a subring to a major ring with a virtual link

To configure an Ethernet ring using R-APS, there will be at least two VPLS services required for one Ethernet ring instance, one for the control channel and the others for data channels. The control channel is used for R-APS signaling while the data channel is for user data traffic. The state of the data channels is inherited from the state of the control channel.

The following needs to be configured:

- encapsulation type for each ring port
- Ethernet CFM
- Ethernet ring for major ring 1
- Ethernet ring for subring 2
- control channel service and Ethernet ring SAPs
- user data channel services

Configure the encapsulation for the ring ports.

An Ethernet ring needs an R-APS tag to send and receive G.8032 signaling messages. To configure a control channel, an access SAP configuration is required on each path (a or b) port. The SAP configuration follows that of the port and must be either dot1Q or QinQ, consequently the control and data packets are either single tagged or double tagged.

Note:

Single tagged control frames are supported on a QinQ port by configuring the system with the **extended-default-qinq-sap-lookup** parameter (**configure service system extended-default-qinq-sap-lookup true**), and the ring path R-APS tags and control VPLS SAPs configured as qtag.0.

In this example, QinQ tags are used. For example, the port configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  port 1/1/c1/1 {
    admin-state enable
    ethernet {
      mode access
      encap-type qinq
    }
  }
  port 1/1/c2/1 {
    admin-state enable
    ethernet {
      mode access
      encap-type qinq
    }
  }
  port 1/1/c3/1 {
    admin-state enable
    ethernet {
      mode access
      encap-type qinq
    }
  }
}
```

Configure Ethernet CFM

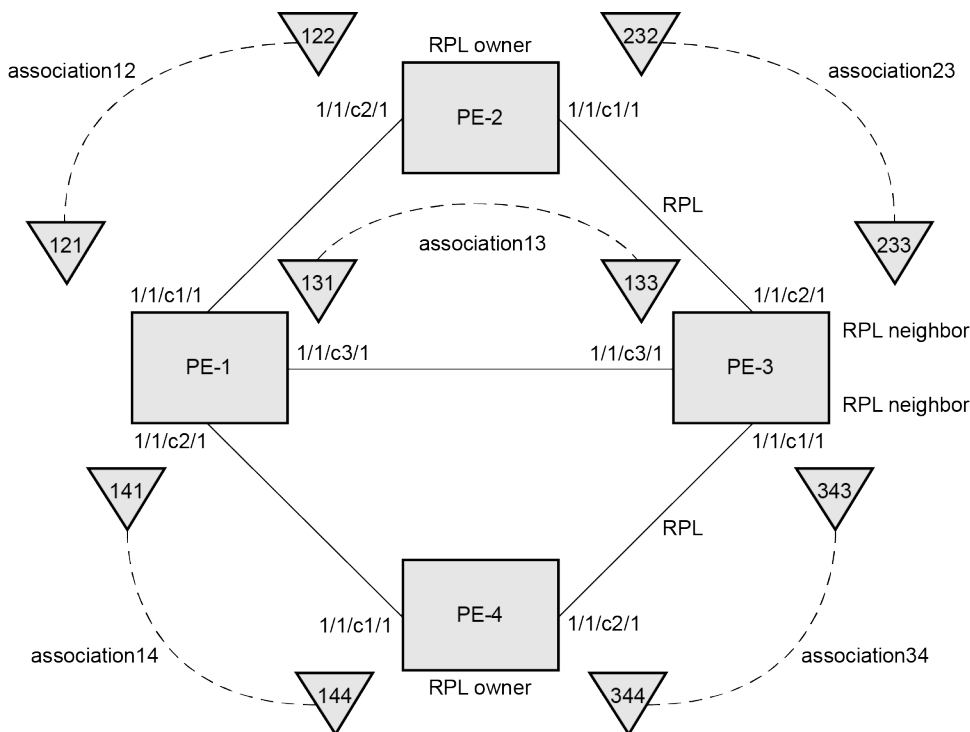

Configuring the Ethernet CFM domain, association, and MEP is required before configuring an Ethernet ring. The standard domain format is **none** and the association name must be ITU carrier code-based (ICC-based - Y.1731); however, the SR OS implementation is flexible in that it supports both IEEE and ICC formats. The Ethernet ring MEP requires a CCM interval with values such as 1s, 100ms, or 10ms to be configured.

The MEPs used for R-APS control normally will have CCM configured on the control channel path MEPs for failure detection. Alternatively, detecting a failure of the ring may be achieved by running Ethernet in the first mile (EFM) at the port level if CCM is not possible at 1s, 100ms, or 10ms. Also rings can be run without CFM although the Ethernet CFM association must be configured for R-APS messages to be exchanged. To omit the failure detecting CCMs, it is necessary to remove the **ccm true** from under the path MEPs and to remove the **remote-mep** on the corresponding ETH CFM configuration.

Loss-of-signal, in conjunction with other OAM mechanisms, is applicable only when the nodes are directly connected.

Figure 9: ETH-CFM MEP associations shows the details of the MEPs and their associations configured when both the major rings and subrings are used. The associations only need to be pairwise unique but for clarity five unique associations are used. Any name format can be used, but it must be consistent on both adjacent nodes.

Figure 9: ETH-CFM MEP associations

al_0533

The configuration of Ethernet CFM for the major and subrings on each node is as follows. The CCMs for failure detection are configured for 1 second intervals.

On ring node PE-1, the associations "association-12" and "association-13" are used for the major ring and association "association-14" is used for the subring.

```
# on PE-1:
configure {
  eth-cfm {
    domain "domain-1" {
      level 2
      format none
      md-index 1
      association "association-12" {
        icc-based "Association12"
        ma-index 12
        ccm-interval 1s
        remote-mep 122 {
        }
      }
      association "association-13" {
        icc-based "Association13"
        ma-index 13
        ccm-interval 1s
        remote-mep 133 {
        }
      }
    }
  }
}
```

```
    }  
  }  
  association "association-14" {  
    icc-based "Association14"  
    ma-index 14  
    ccm-interval 1s  
    remote-mep 144 {  
    }  
  }  
}
```

On ring node PE-2, the associations "association-12" and "association-23" are used for the major ring.

```
# on PE-2:  
configure {  
  eth-cfm {  
    domain "domain-1" {  
      level 2  
      format none  
      md-index 1  
      association "association-12" {  
        icc-based "Association12"  
        ma-index 12  
        ccm-interval 1s  
        remote-mep 121 {  
        }  
      }  
      association "association-23" {  
        icc-based "Association23"  
        ma-index 23  
        ccm-interval 1s  
        remote-mep 233 {  
        }  
      }  
    }  
  }  
}
```

On ring node PE-3, the associations "association-13" and "association-23" are used for the major ring and association "association-34" is used for the subring.

```
# on PE-3:  
configure {  
  eth-cfm {  
    domain "domain-1" {  
      level 2  
      format none  
      md-index 1  
      association "association-13" {  
        icc-based "Association13"  
        ma-index 13  
        ccm-interval 1s  
        remote-mep 131 {  
        }  
      }  
      association "association-23" {  
        icc-based "Association23"  
        ma-index 23  
        ccm-interval 1s  
        remote-mep 232 {  
        }  
      }  
    }  
  }  
  association "association-34" {  
    icc-based "Association34"  
  }  
}
```

```

        ma-index 34
        ccm-interval 1s
        remote-mep 344 {
        }
    }
}

```

On ring node PE-4, the associations 14 and 34 are used for the subring.

```

# on PE-4
configure {
  eth-cfm {
    domain "domain-1" {
      level 2
      format none
      md-index 1
      association "association-14" {
        icc-based "Association14"
        ma-index 14
        ccm-interval 1s
        remote-mep 141 {
        }
      }
      association "association-34" {
        icc-based "Association34"
        ma-index 34
        ccm-interval 1s
        remote-mep 343 {
        }
      }
    }
  }
}

```

Configuring Ethernet ring – major ring 1

Two paths must be configured to form a ring. In this example, VLAN tag 1.1 is used as control channel for R-APS signaling for the major ring (Ethernet ring 1) on the ports shown in [Figure 8: Ethernet example topology](#) using the Ethernet CFM information shown in [Figure 9: ETH-CFM MEP associations](#). The revert time is set to the value of 60 seconds and CCM messages are enabled on the MEP. The **control-mep true** command indicates that this MEP is used for ring R-APS messages.

The configuration of Ethernet ring 1 on ring node PE-1 is as follows:

```

# on PE-1:
configure {
  eth-ring 1 {
    admin-state enable
    description "Ethernet ring 1_major ring"
    revert-time 60
    path "a" {
      admin-state enable
      description "Ethernet ring 1_path a"
      port-and-raps-tag 1/1/cl/1:1.1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-12" mep-id 121 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
}

```

```

path "b" {
  admin-state enable
  description "Ethernet ring 1_path b"
  port-and-raps-tag 1/1/c3/1:1.1
  eth-cfm {
    mep md-admin-name "domain-1" ma-admin-name "association-13" mep-id 131 {
      admin-state enable
      ccm true
      control-mep true
    }
  }
}

```

It is mandatory to configure a MEP in the path context, otherwise the following error is displayed:

```

*[ex:/configure eth-ring 1 path "a"]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure eth-ring 1 path "a" admin-state - Cannot enable path
without eth-cfm mep configured - configure eth-ring 1 path "a" admin-state

```

While MEPs are mandatory, enabling CCMs on the MEPs under the paths as a failure detection mechanism is optional as explained earlier.

Ring node PE-2 is configured as the RPL owner with the RPL being on path "a" as indicated by the **rpl-end** parameter. The revert time is 60 seconds.

```

# on PE-2:
configure {
  eth-ring 1 {
    admin-state enable
    description "Ethernet ring 1_major ring"
    revert-time 60
    rpl-node owner
    path "a" {
      admin-state enable
      description "Ethernet ring 1_path a"
      port-and-raps-tag 1/1/c1/1:1.1
      rpl-end true
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-23" mep-id 232 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
  path "b" {
    admin-state enable
    description "Ethernet ring 1_path b"
    port-and-raps-tag 1/1/c2/1:1.1
    eth-cfm {
      mep md-admin-name "domain-1" ma-admin-name "association-12" mep-id 122 {
        admin-state enable
        ccm true
        control-mep true
      }
    }
  }
}

```

It is not permitted to configure a path as an RPL end without having configured the node on this ring to be either the RPL owner or RPL neighbor, otherwise the following error message is reported.

```
*[ex:/configure eth-ring 1 path "a"]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure eth-ring 1 path "a" rpl-end - rpl-node must be set -
configure eth-ring 1 rpl-node
```

Ring node PE-3 is configured as the RPL neighbor with the RPL being on path "b" as indicated by the **rpl-end** parameter. The revert time is 60 seconds.

```
# on PE-3:
configure {
  eth-ring 1 {
    admin-state enable
    description "Ethernet ring 1_major ring"
    revert-time 60
    rpl-node neighbor
    path "a" {
      admin-state enable
      description "Ethernet ring 1_path a"
      port-and-raps-tag 1/1/c3/1:1.1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-13" mep-id 133 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
  path "b" {
    admin-state enable
    description "Ethernet ring 1_path b"
    port-and-raps-tag 1/1/c2/1:1.1
    rpl-end true
    eth-cfm {
      mep md-admin-name "domain-1" ma-admin-name "association-23" mep-id 233 {
        admin-state enable
        ccm true
        control-mep true
      }
    }
  }
}
```

The link between PE-2 and PE-3 will be the RPL with PE-2 and PE-3 blocking that link when the ring is fully operational. In this example, the RPL is using path "a" on PE-2 and path "b" on PE-3.

Configuring Ethernet ring – subring 2

Ring nodes PE-1, PE-3, and PE-4 form a subring. The subring attaches to the major ring (Ethernet ring 1). The subring in this case uses a virtual link. The interconnection ring instance identifier (**ring-id 1**) is specified and **propagate-topology-change true** indicates that subring flushing will be propagated to the major ring. Only one path (path a) is specified because the other path (path b) is not required at an interconnection node. Subrings are almost identical to major rings in operation except that subrings send MAC flushes towards their connected ring (either a major ring or a subring). Major rings or subrings never send MAC flushes to their subrings. Therefore a couple of subrings connected to a major ring can

cause MACs to flush on the major ring but the major ring will not propagate a subring MAC flush to other subrings.

Ring node PE-1 provides an interconnection between the major ring (ring 1) and the subring (ring 2). Ring 2 is configured to be a subring which interconnects to ring 1. It will use a virtual link on ring 1 to send R-APS messages to the other interconnection node and topology changes will be propagated from subring 2 to the major ring 1.

```
# on PE-1:
configure {
  eth-ring 2 {
    admin-state enable
    description "Ethernet subring 2 on major ring 1"
    revert-time 60
    sub-ring {
      type virtual-link
      interconnect {
        ring-id 1
        propagate-topology-change true
      }
    }
  }
  path "a" {
    admin-state enable
    description "Ethernet subring 2_path a"
    port-and-raps-tag 1/1/c2/1:2.1
    eth-cfm {
      mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 141 {
        admin-state enable
        ccm true
        control-mep true
      }
    }
  }
}
```

Subring 2 is not configured on PE-2.

The configuration of subring 2 on PE-3 is similar to PE-1, but PE-3 is the RPL neighbor, with the RPL end on path "a", for the RPL between PE-3 and PE-4.

```
# on PE-3:
configure {
  eth-ring 2
    admin-state enable
    description "Ethernet subring 2 on major ring 1"
    revert-time 60
    rpl-node neighbor
    sub-ring {
      type virtual-link
      interconnect {
        ring-id 1
        propagate-topology-change true
      }
    }
  }
  path "a" {
    admin-state enable
    description "Ethernet subring 2_path a"
    port-and-raps-tag 1/1/c1/1:2.1
    rpl-end true
    eth-cfm {
      mep md-admin-name "domain-1" ma-admin-name "association-34" mep-id 343 {
        admin-state enable
        ccm true
      }
    }
  }
}
```

```

        control-mep true
    }
}

```

Ring node PE-4 only has configuration for the subring 2, not for major ring 1. PE-4 is the RPL owner, with path "b" being the RPL end, for the RPL between PE-3 and PE-4.

```

# on PE-4:
configure {
  eth-ring 2
    admin-state enable
    description "Ethernet subring 2"
    revert-time 60
    rpl-node owner
    path "a" {
      admin-state enable
      description "Ethernet subring 2_path a"
      port-and-raps-tag 1/1/c1/1:2.1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 144 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
    path "b" {
      admin-state enable
      description "Ethernet subring 2_path b"
      port-and-raps-tag 1/1/c2/1:2.1
      rpl-end true
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-34" mep-id 344 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
}

```

Until the Ethernet ring instance is attached to a VPLS service, the ring operational status is down and the forwarding status of each port is blocked. This prevents the operator from creating a loop by misconfiguration. This state can be seen on ring node PE-1 as follows:

```

[/]
A:admin@PE-1# show eth-ring 1

Configure the control channel VPLS service

Path "a" and "b" configured in the Ethernet ring must be added as SAPs into a VPLS service (standard VPLS) using the **eth-ring** parameter. The SAP encapsulation values must match the values of the R-APS tag configured for the associated path.

G.8032 uses the same R-APS tag value on all nodes on the ring, as configured in this example. However, the SR OS implementation relaxes this constraint by requiring the tag to match only on adjacent nodes.

In this example VPLS "control-VPLS-1" is configured on PE-1, PE-2, and PE-3 for the control channel for the major ring (ring 1), and VPLS "control-VPLS-2" is used on PE-1, PE-3, and PE-4 for the subring (ring 2).

VPLS "control-VPLS-1" is the control service for the major ring and is defined for PE-1, PE-2, and PE-3, as follows:

```
# on PE-1:
configure {
  service {
    vpls "control-VPLS-1" {
      admin-state enable
      description "Control channel VID 1.1 for ring 1 - major ring"
      service-id 1
      customer "1"
      sap 1/1/c1/1:1.1 {
        eth-ring 1
      }
      sap 1/1/c3/1:1.1 {
        eth-ring 1
      }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    vpls "control-VPLS-1" {
      admin-state enable
      description "Control channel VID 1.1 for ring 1 - major ring"
      service-id 1
      customer "1"
      sap 1/1/c1/1:1.1 {
        eth-ring 1
      }
      sap 1/1/c2/1:1.1 {
        eth-ring 1
      }
    }
  }
}
```

```

    }

# on PE-3:
configure {
  service {
    vpls "control-VPLS-1" {
      admin-state enable
      description "Control channel VID 1.1 for ring 1 - major ring"
      service-id 1
      customer "1"
      sap 1/1/c2/1:1.1 {
        eth-ring 1
      }
      sap 1/1/c3/1:1.1 {
        eth-ring 1
      }
    }
  }
}

```

SAPs or SDPs can be added to a control channel VPLS on condition the **eth-ring** parameter is present. Any attempt to add a SAP without the **eth-ring** parameter to a control channel VPLS results in the following messages being displayed.

```

*[ex:/configure service vpls "control-VPLS-1" sap 1/1/c4/1:1]
A:admin@PE-1# commit
MINOR: SVCMgr #2590: configure service vpls "control-VPLS-1" sap 1/1/c3/1:1.1 - Invalid
Ethernet ring configuration - Ring control SAP cannot be added to service that contains non-
ring SAPs or SDP bindings - configure service vpls "control-VPLS-1" sap 1/1/c3/1:1.1 eth-ring
MINOR: SVCMgr #2590: configure service vpls "control-VPLS-1" sap 1/1/c3/1:1.1 - Invalid
Ethernet ring configuration - Ethernet Ring Control service should only have controls saps
from same ring - configure service vpls "control-VPLS-1" sap 1/1/c3/1:1.1 eth-ring
MINOR: SVCMgr #2590: configure service vpls "control-VPLS-1" sap 1/1/c1/1:1.1 - Invalid
Ethernet ring configuration - Ring control SAP cannot be added to service that contains non-
ring SAPs or SDP bindings - configure service vpls "control-VPLS-1" sap 1/1/c1/1:1.1 eth-ring
MINOR: SVCMgr #2590: configure service vpls "control-VPLS-1" sap 1/1/c1/1:1.1 - Invalid
Ethernet ring configuration - Ethernet Ring Control service should only have controls saps
from same ring - configure service vpls "control-VPLS-1" sap 1/1/c1/1:1.1 eth-ring

```

For the subring, the configuration of a split horizon group for the virtual channel on the major ring on the interconnection nodes is recommended. This avoids the looping of control R-APS messages in the case there is a misconfiguration in the major ring.

On ring node PE-1, the control service for the subring "control-VPLS-2" is configured as follows. SAP 1/1/c1/1:2.1 and SAP 1/1/c3/1:2.1 connect to the major ring (ring 1) for the virtual channel, whereas SAP 1/1/c2/1:2.1 connects to the subring (ring 2).

```

# on PE-1:
configure {
  service {
    vpls "control-VPLS-2" {
      admin-state enable
      description "Control/virtual channel VID 2.1 for ring 2"
      service-id 2
      customer "1"
      split-horizon-group "shg-ring2" {
      }
      sap 1/1/c1/1:2.1 {
        description "ring 2 interconnection using ring 1"
        eth-ring 1
        split-horizon-group "shg-ring2"
      }
    }
  }
}

```

```

    sap 1/1/c2/1:2.1 {
      eth-ring 2
    }
    sap 1/1/c3/1:2.1 {
      description "ring 2 interconnection using ring 1"
      eth-ring 1
      split-horizon-group "shg-ring2"
    }
  }

```

On ring node PE-2, subring 2 is not present. However, the control service "control-VPLS-2" for the subring must be configured on PE-2, because the virtual channel for subring 2 needs to exist throughout major ring 1.

```

# on PE-2:
configure {
  service {
    vpls "control-VPLS-2" {
      admin-state enable
      description "virtual channel VID 2.1 for ring 2"
      service-id 2
      customer "1"
      sap 1/1/c1/1:2.1 {
        eth-ring 1
      }
      sap 1/1/c2/1:2.1 {
        eth-ring 1
      }
    }
  }
}

```

If multiple virtual channels are used (due to the aggregation of multiple subrings into the same major ring), their configuration could be simplified on non-interconnection nodes on the major ring. To achieve this on a ring node such as PE-2, a default SAP could be used rather than configuring a VPLS per virtual channel. If QinQ SAPs are used then default SAPs 1/1/c1/1:qtag.* and 1/1/c2/1:qtag.* could be used but this requires all control channels for subrings to be using qtag as the outer VLAN ID, or 1/1/c1/1:* and 1/1/c2/1:* if dot1Q SAPs were used. This is because the SAPs match explicit SAP definitions first and the default SAP will handle any other traffic.

The following configuration for control service "control-VPLS-2" for the subring on ring node PE-3 is similar to the configuration of PE-1.

```

# on PE-3:
configure {
  service {
    vpls "control-VPLS-2" {
      admin-state enable
      description "control/virtual channel VID 2.1 for ring 2"
      service-id 2
      customer "1"
      split-horizon-group "shg-ring2" {
      }
      sap 1/1/c1/1:2.1 {
        eth-ring 2
      }
      sap 1/1/c2/1:2.1 {
        description "ring 2 interconnection using ring 1"
        eth-ring 1
        split-horizon-group "shg-ring2"
      }
      sap 1/1/c3/1:2.1 {
        description "ring 2 interconnection using ring 1"
      }
    }
  }
}

```

```

        eth-ring 1
        split-horizon-group "shg-ring2"
    }
}

```

On ring node PE-4, control service "control-VPLS-2" for the subring is configured as follows. Both SAPs are configured on the subring (ring 2).

```

# on PE-4:
configure {
    service {
        vpls "control-VPLS-2" {
            admin-state enable
            description "control VID 2.1 for subring 2"
            service-id 2
            customer "1"
            sap 1/1/c1/1:2.1 {
                eth-ring 2
            }
            sap 1/1/c2/1:2.1 {
                eth-ring 2
            }
        }
    }
}

```

At this point, the Ethernet ring 1 is operationally up and the RPL is blocking successfully RPL end port 1/1/c1/1 on RPL owner PE-2 and RPL end port 1/1/c2/1 on RPL neighbor PE-3.

Show output

An overview of all of the rings can be shown using the following commands, in this case on PE-1.

The following command shows the Ethernet ring status on PE-1.

```

[/]
A:admin@PE-1# show eth-ring status
=====
Ethernet Ring (Status information)
=====
Ring  Admin  Oper   Path Information          MEP Information

Configure the user data channel VPLS service

The user data channels are created on a separate VPLS, "VPLS-11" in this example, using VLAN tag 1.11. The ring data channels must be on the same ports as the corresponding control channels configured above. The access into the data services can use normal SAPs or SDPs, for example the SAP on port 1/1/c4/1 in the following output. Customer data traverses the ring on a data SAP. Multiple parallel data SAPs in different data services can be controlled by one control ring instance, Ethernet ring 1 in the example.

Data VPLS "VPLS-11" on ring node PE-1 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on major ring 1, while SAP 1/1/c2/1:1.11 is the data SAP on subring 2.

```
# on PE-1:
configure {
  service {
    vpls "VPLS-11" {
      admin-state enable
      description "data VPLS"
      service-id 11
      customer "1"
      sap 1/1/c1/1:1.11 {
        eth-ring 1
      }
      sap 1/1/c2/1:1.11 {
        eth-ring 2
      }
      sap 1/1/c3/1:1.11 {
        eth-ring 1
      }
      sap 1/1/c4/1:11 {
        description "sample customer service SAP"
      }
    }
  }
}
```

The configuration of data VPLS "VPLS-11" on ring node PE-3 (not shown) is similar to ring node PE-1.

The configuration of data VPLS "VPLS-11" on ring node PE-2 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on major ring 1.

```
# on PE-2:
configure {
  service {
    vpls "VPLS-11" {
      admin-state enable
      description "data VPLS"
      service-id 11
      customer "1"
      sap 1/1/c1/1:1.11 {
        eth-ring 1
      }
      sap 1/1/c2/1:1.11 {
        eth-ring 1
      }
      sap 1/1/c4/1:11 {
        description "sample customer service SAP"
      }
    }
  }
}
```

The configuration of data VPLS "VPLS-11" on ring node PE-4 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on subring 2.

```
# on PE-4:
configure {
  service {
    vpls "VPLS-11" {
      admin-state enable
      description "data VPLS"
      service-id 11
      customer "1"
      sap 1/1/c1/1:1.11 {
        eth-ring 2
      }
      sap 1/1/c2/1:1.11 {
        eth-ring 2
      }
      sap 1/1/c4/1:11 {
        description "sample customer service SAP"
      }
    }
  }
}
```

All the SAPs which are configured to use Ethernet rings can be displayed. The following output is taken from PE-1, where there are:

- two SAPs in VPLS 1 for the control channel of ring 1 (VLAN ID 1.1)
- two SAPs in VPLS 2 on ring 1 for the virtual channel for ring 2 (VLAN ID 2.1)
- one SAP in VPLS 2 on ring 2 for the control channel for ring 2 (VLAN ID 2.1)
- three SAPs in VPLS 11, two on ring 1 and one on ring 2, for the data service (VLAN ID 1.11). This matches the information in [Figure 7: G.8032 subring interconnection components](#).

```

To see an example of the messages in log "99" on a ring failure, when the unblocked port 1/1/c2/1 on PE-2 is disabled, the following messages are displayed. When logging is enabled from main to console, the same messages can be seen on the console.

```

# on PE-2:
configure {
  port 1/1/c2/1
  admin-state disable
}

```

```

74 2023/05/16 08:43:40.190 CEST MINOR: ETH_CFM #2001 Base
"MEP 1/12/122 highest defect is now defRemoteCCM"

```

```

73 2023/05/16 08:43:36.641 CEST MAJOR: SVCMGR #2210 Base
"Processing of an access port state change event is finished and the status of all
affected SAPs on port 1/1/c2/1 has been updated."

```

```

72 2023/05/16 08:43:36.640 CEST MINOR: ERING #2001 Base eth-ring-1
"Eth-Ring 1 path a changed fwd state to unblocked"

```

```

71 2023/05/16 08:43:36.640 CEST MINOR: ERING #2001 Base eth-ring-1

```

```
"Eth-Ring 1 path b changed fwd state to blocked"
```

```
70 2023/05/16 08:43:36.640 CEST WARNING: SNMP #2004 Base 1/1/c2/1  
"Interface 1/1/c2/1 is not operational"
```

For troubleshooting, the **tools dump eth-ring <ring-index>** command displays path information, the internal state of the control protocol, related statistics information, and up to the last 16 protocol events (including messages sent and received, and the expiration of timers). An associated **clear** parameter exists, which clears the event information in this output when the command is entered. The following is an example of the output on PE-2 after port 1/1/c2/1 has been enabled.

```
[/]

Configuration of a subring to a major ring with a non-virtual link

The differences from the preceding virtual link configuration with a non-virtual link for the subring are:

- The subring configuration on the interconnection nodes, PE-1 and PE-3, is modified to indicate that the subring is not using a virtual link, otherwise it remains the same.
- The subring configuration on the subring node PE-4 is also modified to indicate that this is part of a subring that is not using a virtual link. This is mandatory on all non-interconnection nodes on the subring in order to ensure the propagation of R-APS messages around the subring.
- The virtual link services and SAPs must be removed from PE-1, PE-2, and PE3, that is:
 - On PE-1 and PE-3, the SAPs in VPLS 2 around the major ring (configured with the parameter **eth-ring 1**) are removed.
 - The service "control-VPLS-2" is removed completely from PE-2.

The new configuration of subring 2 on PE-1 is as follows, the configuration on PE-3 is similar.

```

# on PE-1:
configure {
  eth-ring 2 {
    admin-state enable
    description "Ethernet subring 2 on major ring 1"
    revert-time 60
    sub-ring {
      type non-virtual-link
      interconnect {
        ring-id 1
        propagate-topology-change true
      }
    }
    path "a" {
      admin-state enable
      description "Ethernet subring 2_path a"
      port-and-raps-tag 1/1/c2/1:2.1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 141 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
}

```

The configuration of subring 2 on non-interconnection node PE-4 must include the **type non-virtual-link** parameter, as follows:

```
# on PE-4:
configure {
  eth-ring 2 {
    admin-state enable
    description "Ethernet subring 2"
    revert-time 60
    rpl-node owner
    sub-ring {
      type non-virtual-link
    }
    path "a" {
      admin-state enable
      description "Ethernet subring 2_path a"
      port-and-raps-tag 1/1/c1/1:2.1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 144 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
    path "b" {
      admin-state enable
      description "Ethernet subring 2_path b"
      port-and-raps-tag 1/1/c2/1:2.1
      rpl-end true
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-34" mep-id 344 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
}
```

The SAP usage on PE-1 is as follows with only the control and data SAPs to PE-4 now using subring 2.

```
[/]
A:admin@PE-1# show service sap-using eth-ring

=====
Service Access Points (Ethernet Ring)
=====
```

SapId	SvcId	Eth-Ring	Path	Admin State	Oper State	Blocked	Control/Data
1/1/c1/1:1.1	1	1	a	Up	Up	No	Ctrl
1/1/c3/1:1.1	1	1	b	Up	Up	No	Ctrl
1/1/c2/1:2.1	2	2	a	Up	Up	No	Ctrl
1/1/c1/1:1.11	11	1	a	Up	Up	No	Data
1/1/c2/1:1.11	11	2	a	Up	Up	No	Data
1/1/c3/1:1.11	11	1	b	Up	Up	No	Data

```
-----
Number of SAPs : 6
=====
```

The information relating to subring 2 is as follows and it can be seen that this is now not using a virtual link, but subring 2 is still connected to major ring 1 and propagation is still enabled from the subring to the major ring. The single ring path "a" is unblocked because the RPL is configured between PE-3 and PE-4.

```
[/]
A:admin@PE-1# show eth-ring 2

Configuration of a subring to a VPLS service

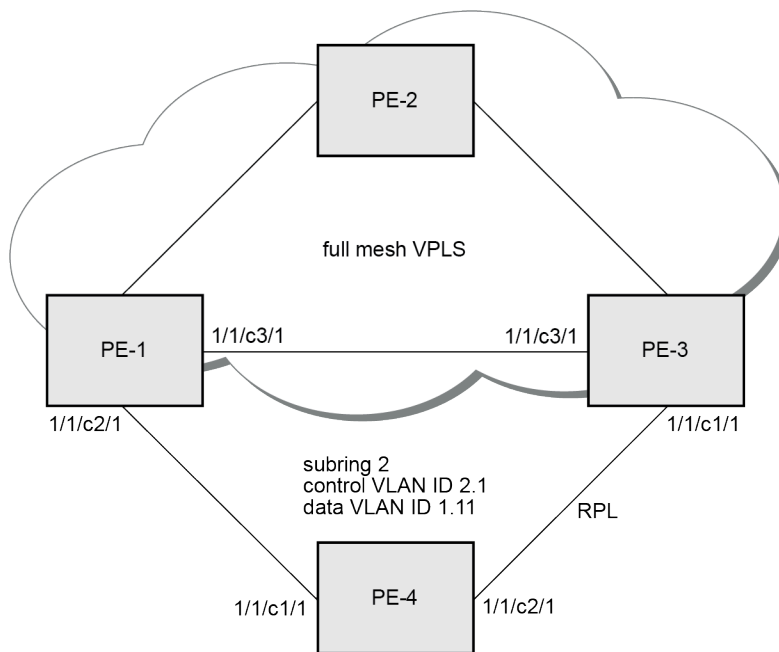

Subrings can be connected to VPLS services, in which case a virtual link is not used and is not configurable. While similar to the ring interconnect, there are a few differences.

Flush propagation is from the subring to the VPLS, in the same way as it was for the subring to the major ring. The same configuration parameter is used to propagate topology changes. In this case, LDP "flush-all-from-me" messages are sent into the LDP portion of the network to account for ring changes without the need to configure anything in the VPLS service.

As with other rings, until an Ethernet ring instance is attached to the VPLS service, the ring operational status is down and the forwarding status of each port is blocked. This prevents operators from creating a loop by misconfiguration.

The topology for this case is shown in [Figure 10: Subring to VPLS topology](#). The configuration is very similar to the subring with a non-virtual link described earlier, but ring 1 is replaced by a VPLS service using LDP-signaled mesh SDPs between PE-1, PE-2, and PE-3 to create a fully meshed VPLS service. Both spoke and mesh SDPs using LDP can be used for the VPLS; however, only mesh SDPs have been used in this example.

Figure 10: Subring to VPLS topology

al_0534

The differences for the VPLS service connection to the configuration when the subring is connected to a major ring without a virtual link are:

- The subring configuration on the interconnection nodes, PE-1 and PE-3, is modified to indicate that the subring is connected to a VPLS service.
- The subring configuration on the non-interconnection node PE-4 indicates that this is part of a subring that is not using a virtual link (same configuration as in the scenario when a subring is connected to a major ring without a virtual link). This is mandatory on all non-interconnection nodes on the subring in order to ensure the propagation of R-APS messages around the subring.
- The control VPLS "control-VPLS-1" and SAPs relating to the major ring 1 on PE-1, PE-2, and PE-3 are removed. These are replaced by routed IP interfaces configured with a routing protocol and LDP in order to signal the required MPLS labels, together with the necessary SDPs to provide interconnection at a service level.
- The data service "VPLS-11" is configured with mesh SDPs between PE-1, PE-2, and PE-3.

The configuration on PE-1 of the subring 2 is as follows with the interconnect indicating a VPLS service. The configuration on PE-3 is similar.

```
# on PE-1:
configure {
  eth-ring 2 {
    admin-state enable
    description "Ethernet subring 2 on VPLS"
    revert-time 60
    sub-ring {
      type non-virtual-link
      interconnect {
        vpls
        propagate-topology-change true
      }
    }
  }
}
```

```

    }
    path "a" {
        admin-state enable
        description "Ethernet subring 2_path a"
        port-and-raps-tag 1/1/c2/1:2.1
        eth-cfm {
            mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 141 {
                admin-state enable
                ccm true
                control-mep true
            }
        }
    }
}

```

The following configuration of subring 2 on non-interconnection node PE-4 includes the **type non-virtual-link** parameter:

```

# on PE-4:
configure {
    eth-ring 2 {
        admin-state enable
        description "Ethernet subring 2"
        revert-time 60
        rpl-node owner
        sub-ring {
            type non-virtual-link
        }
        path "a" {
            admin-state enable
            description "Ethernet subring 2_path a"
            port-and-raps-tag 1/1/c1/1:2.1
            eth-cfm {
                mep md-admin-name "domain-1" ma-admin-name "association-14" mep-id 144 {
                    admin-state enable
                    ccm true
                    control-mep true
                }
            }
        }
        path "b" {
            admin-state enable
            description "Ethernet subring 2_path b"
            port-and-raps-tag 1/1/c2/1:2.1
            rpl-end true
            eth-cfm {
                mep md-admin-name "domain-1" ma-admin-name "association-34" mep-id 344 {
                    admin-state enable
                    ccm true
                    control-mep true
                }
            }
        }
    }
}

```

The data service on PE-1 is as follows. The configuration on PE-3 is similar.

```

# on PE-1:
configure {
    service {
        vpls "VPLS-11" {
            admin-state enable
            description "data VPLS"
            service-id 11
        }
    }
}

```

```

customer "1"
mesh-sdp 12:11 {
}
mesh-sdp 13:11 {
}
sap 1/1/c2/1:1.11 {
    eth-ring 2
}
sap 1/1/c4/1:11 {
    description "sample customer service SAP"
}
    
```

The state of the subring is as follows and shows the subring is not using a virtual link, is connected to a VPLS service, and has propagation of topology change events enabled. As earlier, the single ring path "a" is unblocked because the RPL is configured between PE-3 and PE-4.

```

[/]
A:admin@PE-1# show eth-ring 2

=====
    
```

In this case, if a topology change event occurs in the subring, an LDP "flush-all-from-me" message is sent by PE-1 and PE-3 to their LDP peers. This can be seen by enabling the following debugging for PE-1:

```

# on PE-1:
debug {
    router "Base" {
        ldp {
            peer 192.0.2.2 {
                packet {
                    init {
                    }
                }
            }
            peer 192.0.2.3 {
                packet {
                    init {
                    }
                }
            }
        }
    }
}
    
```

```
}
```

The topology change is forced by disabling port 1/1/c2/1 on PE-1.

```
# on PE-1:
configure {
  port 1/1/c2/1
    admin-state disable
}
```

The log shows the following messages on the console (combination of log 1 for debug-trace and log 2 for main), where packets 1 and 2 are the LDP flush messages.

```

Operational procedures

Operators may wish to configure rings with or without control over reversion. Reversion can be controlled by timers or the ring can be run without reversion allowing the operator to choose when the ring reverts. To change a ring topology, the **manual** or **force** switch command may be used to block a specified ring path. A ring will still address failures when run without reversion but will not automatically revert to the RPL when resources are restored. A **clear** command can be used to clear the manual or force state of a ring.

The following **tools** commands are available to control the state of paths on a ring.

```
tools perform eth-ring clear <ring-index>
tools perform eth-ring force <ring-index> path {a|b}
tools perform eth-ring manual <ring-index> path {a|b}
```

In the following output, both ports of Ethernet ring 1 are unblocked.

```
[/]
A:admin@PE-1# show eth-ring 1
```

```

```

Conclusion

Ethernet ring APS provides an optimal solution for designing native Ethernet services with ring topology. With subrings, both multiple rings and access rings increase the versatility of G.8032. G.8032 has been expanded to more of the SR platforms by allowing R-APS with slower MEPs (including CCMs intervals of 1 second). This protocol provides simple configuration, operation, and guaranteed fast protection time. The implementation also has a flexible encapsulation that allows dot1Q, QinQ, or PBB for the ring traffic. It can be utilized on various services such as mobile backhaul, business VPN access, aggregation, and core.

G.8032 Ethernet Ring Protection Single Ring Topology

This chapter provides information about G.8032 Ethernet ring protection single ring topology.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The chapter was initially written for SR OS Release 8.0.R7, but the MD-CLI in the current edition corresponds to SR OS Release 23.3.R2. This chapter describes ring protection for a single ring topology. Protection for multiple ring topologies is covered in [G.8032 Ethernet Ring Protection Multiple Ring Topology](#).

Overview

G.8032 Ethernet ring protection is supported for data service SAPs within a regular VPLS service, a provider backbone bridging (PBB) VPLS (I/B-component), or a routed VPLS (R-VPLS). G.8032 is one of the fastest protection schemes for Ethernet networks.

ITU-T G.8032v2 specifies protection switching mechanisms and a protocol for Ethernet layer network (ETH) Ethernet rings. Ethernet rings can provide wide-area multi-point connectivity more economically due to their reduced number of links. The mechanisms and protocol defined in ITU-T G.8032v2 achieve highly reliable and stable protection and never form loops, which would negatively affect network operation and service availability. Each ring node is connected to adjacent nodes participating in the same ring using two independent paths, which use ring links that are configured on ports or link aggregation groups (LAGs). A ring link is bounded by two adjacent nodes and a port for a ring link is called a ring port. The minimum number of nodes on a ring is two.

The fundamentals of this ring protection switching architecture are:

- the principle of loop avoidance and
- the utilization of learning, forwarding, and address table mechanisms defined in the ITU-T G.8032v2 Ethernet flow forwarding function (ETH_FF) (control plane).

Loop avoidance in the ring is achieved by guaranteeing that, at any time, traffic may flow on all but one of the ring links. This particular link is called the ring protection link (RPL) and under normal conditions this link is blocked, so it is not used for traffic. One designated node, the RPL owner, is responsible to block traffic over the one designated RPL. Under a ring failure condition, the RPL owner is responsible for unblocking the RPL, allowing the RPL to be used for traffic. The protocol ensures that even without an RPL owner defined, one link will be blocked and it operates as a *break before make protocol*, specifically the protocol guarantees that no link is restored until a different link in the ring is blocked. The other side of the RPL is configured as an RPL neighbor. An RPL neighbor blocks traffic on the link.

The event of a ring link or ring node failure results in protection switching of the traffic. This is achieved under the control of the ETH_FF functions on all ring nodes. A ring automatic protection switching (R-APS)

protocol is used to coordinate the protection actions over the ring. The protection switching mechanisms and protocol supports a multi-ring/ladder network that consists of connected Ethernet rings, however, that is not covered in this chapter.

Ring protection mechanism

The ring protection protocol is based on the following building blocks:

- ring status change on failure
 - idle → link failure → protection → recovery → idle
- ring control state changes
 - idle → protection → manual switch → forced switch → pending
- re-use existing ETH OAM
 - monitoring: Ethernet continuity check messages
 - failure notification: Y.1731 signal failure
- forwarding database MAC flush on ring status change
- ring protection link (RPL) defines blocked link in idle status

[Figure 11: G.8032 operation and topologies](#) shows a ring of six nodes, with the RPL owner on the top right. One link of the RPL owner is designated to be the RPL and will be blocked in order to prevent a loop. Schematics of the physical and logical topologies are also shown.

When an RPL owner and RPL end are configured, the associated link will be the RPL when the ring is fully operational and so be blocked by the RPL owner. If a different ring link fails, then the RPL will be unblocked by the RPL owner. When the failed link recovers, it will initially be blocked by one of its adjacent nodes. The adjacent node sends an R-APS message across the ring to indicate the error is cleared and after a configurable time, if reversion is enabled, the RPL will revert to being blocked with all other links unblocked. This ensures that the ring topology is predictable when fully operational.

If a specific RPL owner is not configured, then the last link to become active will be blocked and the ring will remain in this state until another link fails. However, this operation makes the selection of the blocked link non-deterministic.

Figure 11: G.8032 operation and topologies

ai_0588

The protection protocol uses a specific control VLAN, with the associated data VLANs taking their forwarding state from the control VLAN.

Configuration

The example topology is shown in [Figure 12: Example topology](#).

Figure 12: Example topology

** control channel: VPLS 1, tag 1
** data channel: VPLS 100, tag 100

al_0589

The Ethernet ring configuration commands are as follows:

```
configure {
  eth-ring <ring-index [1..128]> {
    ccm-hold-time {
      down <number> # Hold timer for down event dampening
      up <number> # Hold timer for recovery reporting
    }
    compatible-version <number> # [1..2] - Default: 2
    description <string>
    guard-time <number> # [1..20] in deciseconds - Default: 5
    node-id <mac-address> # MAC address of the RPL <xx:xx:xx:xx:xx:xx>
    path <string> # path ID: string of 1 character
    admin-state <keyword> # default: disable
    description <string>
    port-and-raps-tag <port-and-encap> # Port ID and Ring APS tag ID
    eth-cfm {
      mep md-admin-name <reference> ma-admin-name <reference> mep-id <number> {
        admin-state <keyword> # default: disable
        ccm <boolean> # default: false
        control-mep <boolean> # default: false
      }
    }
    rpl-end <boolean> # default: false
  }
  revert-time <number> # <0,60..720> in seconds - Default: 300
  rpl-node <keyword> # owner | neighbor
  sub-ring # beyond the scope
}
```

Parameters:

- *ring-index* — This is the number by which the ring is referenced, values: 1 to 128.

- **ccm-hold-time** **{[down <hold timer for down event dampening>] [up <hold timer for recovery reporting>]}**
 - **down** — This command specifies the timer that controls the delay between detecting that ring path is down and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to the ring path continuity check message (CCM); it does not apply to the ring port link state. To dampen ring port link state transitions, use the **hold-time** parameter from the physical member port. This is useful if the underlying path between two nodes is going across an optical system which implements its own protection.
 - **up** — This command specifies the timer which controls the delay between detecting that the ring path is up and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM; it does not apply to the member port link state. To dampen member port link state transitions, use the **hold-time** parameter from the physical member port.
 - hold timer values:

```
*[ex:/configure eth-ring 1 ccm-hold-time]
A:admin@PE-1# down ?

down <number>
<number> - <1..5000> - centiseconds

    Hold timer for down event dampening

*[ex:/configure eth-ring 1 ccm-hold-time]
A:admin@PE-1# up ?

up <number>
<number> - <0..5000> - deciseconds
Default - 20

    Hold timer for recovery reporting
```

- **compatible version** — This command configures the Ethernet ring compatibility version for the G.8032 state machine and messages. The default is version 2 (ITU G.8032v2) and all SR OS nodes use version 2. If there is a need to interwork with third party devices that only support version 1, this can be set to version 1 allowing the reception of version 1 PDUs. Version 2 is encoded as 1 in the R-APS messages. Compatibility allows the reception of version 1 (encoded as 0) R-APS PDUs but, as per the G.8032 specification, higher versions are ignored on reception. For SR OS nodes, messages are always originated with version 2. Therefore, if a third party switch supported version 3 (encoded as 2) or higher, interworking is also supported provided the other switch is compatible with version 2 (encoded as 1).
- **description <string>** — This configures a text string, up to 80 characters, which can be used to describe the use of the Ethernet ring.
- **guard-time <number>** — The forwarding method, in which R-APS messages are copied and forwarded at every Ethernet ring node, can result in a message corresponding to an old request, that is no longer relevant, being received by Ethernet ring nodes. Reception of an old R-APS message may result in erroneous ring state interpretation by some Ethernet ring nodes. The guard timer is used to prevent Ethernet ring nodes from acting upon outdated R-APS messages and prevents the possibility of forming a closed loop. Messages are not forwarded when the guard-timer is running.

The guard time is configured in 10ths of seconds and the default guard time is 0.5 s:

```
*[ex:/configure eth-ring 1]
A:admin@PE-1# guard-time ?

guard-time <number>
<number> - <1..20> - deciseconds
Default - 5

Ethernet ring guard time
```

- **node-id <mac-address>** — The node identifier can be explicitly configured. In typical configurations, the node ID is not configured; by default, the chassis MAC address is used as node ID.
- **path [path-index] <1-character string> [port-and-raps-tag]** — The **path** parameter defines the paths around the ring, of which there are two in different directions on the ring: an "a" path and a "b" path. In addition, the path command configures the encapsulation used for the R-APS messages on the ring. These can be either single or double tagged.
 - **description <string>** — The description is a text string with up to 80 characters, that can be used to describe the use of the path.
 - **eth-cfm** — Configures the associated Ethernet connectivity fault management (CFM) parameters.
 - **mep md-admin-name <reference> ma-admin-name <reference> <mep-id>** — The maintenance endpoint (MEP) defined under the path is used for the G.8032 protocol messages, which are based on IEEE 802.1ag/Y.1731 CFM frames.
 - **rpl-end** — When configured, this path is expected to be one end of the RPL. This parameter must be configured in conjunction with the **rpl-node**.
 - **admin-state <keyword>** — This command enables or disables the path.
- **revert-time <number>** — This command configures the revert time for an Ethernet ring. The revert time is the time that the RPL will wait before returning to the blocked state.

Values:

```
*[ex:/configure eth-ring 1]
A:admin@PE-1# revert-time ?

revert-time <number>
<number> - <0,60..720> - seconds
Default - 300
```

- **rpl-node <keyword{owner|neighbor}>** — A node can be designated as either the **owner** of the RPL, in which case this node is responsible for the RPL, or the **neighbor**, in which case this node is expected to be the neighbor to the RPL owner across the RPL. The neighbor is optional and is included to be compliant with the specification. This parameter must be configured in conjunction with the **rpl-end** parameter.
- **admin-state <keyword>** — This command enables or disables the Ethernet ring.
- **sub-ring** — The **sub-ring** command is beyond the scope of this chapter because it is only required for multiple ring topologies.

Logging

Create following log-id on PE-2 to see major events logged to the console on PE-2. This is an optional step; alternatively, log 99 can be consulted.

```
# on PE-2:
configure {
  log {
    log-id "log1" {
      source {
        main true
      }
      destination {
        console
      }
    }
  }
}
```

Configure encapsulation for ring ports

To configure R-APS, there should be at least two VPLS services for one Ethernet ring instance, one VPLS for the control channel and the other VPLSs for data channels. The control channel is used for R-APS signaling while the data channel is for user data traffic. The state of the data channels is inherited from the state of the control channel.

- An Ethernet ring needs R-APS tags to send and receive G.8032 signaling messages. To configure a control channel, an access SAP configuration is required on each path a port and path b port. The SAP configuration follows that of the port and must be either dot1Q or QinQ, so the control and data packets are either single tagged or double tagged. It is also possible to have the control VPLS using single tagged frames with the data VPLSs using double tagged frames; this requires the system to be configured with the **extended-default-qinq-sap-lookup** parameter (**configure service system extended-default-qinq-sap-lookup true**), with the ring path R-APS tags and control VPLS SAPs configured as qtag.0, and the data VPLS SAPs configured as qtag1.qtag2.

In the example in this chapter, single tags are used so the ports on the ring nodes are configured as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  port 1/1/c1/1 {
    admin-state enable
    ethernet {
      mode access
      encap-type dot1q
    }
  }
  port 1/1/c2/1 {
    admin-state enable
    ethernet {
      mode access
      encap-type dot1q
    }
  }
}
```

Configure Ethernet CFM

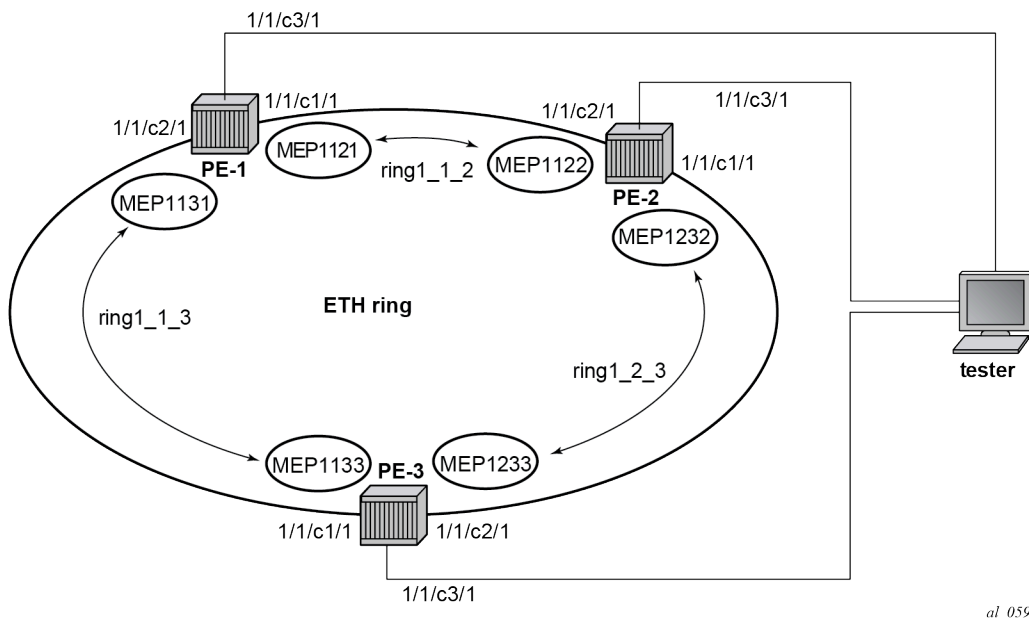

Ethernet ring requires Ethernet CFM domains, associations, and MEPs being configured. The domain format must be none and association name must be ITU-T carrier code-based (ICC-based - Y.1731). The minimum CCM interval for the SR OS nodes is 10ms. The Ethernet ring MEP requires a CCM interval, such as 10ms, 100ms, or 1s, to be configured.

The MEPs used for R-APS control normally have CCM configured on the control channel path MEPs for failure detection. Alternatively, detecting a failure of the ring may be achieved by running Ethernet in the first mile (EFM) at the port level if CCM is not possible at 10ms, 100ms, or 1s. Loss-of-signal, in conjunction with other OAM, is applicable only when the nodes are directly connected.

To omit the failure detecting CCMs, remove the **ccm true** from under the path MEPs and remove the **remote-mep** from under the **eth-cfm>domain>association** on all nodes.

Figure 13: Ethernet CFM configuration shows the Ethernet CFM configuration used here.

Figure 13: Ethernet CFM configuration

al_0590

The Ethernet CFM configuration of the nodes is as follows.

```
# on PE-1:
configure {
  eth-cfm {
    domain "domain-1" {
      level 3
      format none
      md-index 1
      association "association-1" {
        icc-based "ring1_1_2"
        ma-index 1
        ccm-interval 1s
        remote-mep 1122 {
        }
      }
      association "association-2" {
```

```
        icc-based "ring1_1_3"  
        ma-index 2  
        ccm-interval 1s  
        remote-mep 1133 {  
        }  
    }  
}
```

```
# on PE-2:  
configure {  
    eth-cfm {  
        domain "domain-1" {  
            level 3  
            format none  
            md-index 1  
            association "association-1" {  
                icc-based "ring1_2_3"  
                ma-index 1  
                ccm-interval 1s  
                remote-mep 1233 {  
                }  
            }  
            association "association-2" {  
                icc-based "ring1_1_2"  
                ma-index 2  
                ccm-interval 1s  
                remote-mep 1121 {  
                }  
            }  
        }  
    }  
}
```

```
# on PE-3:  
configure {  
    eth-cfm {  
        domain "domain-1" {  
            level 3  
            format none  
            md-index 1  
            association "association-1" {  
                icc-based "ring1_1_3"  
                ma-index 1  
                ccm-interval 1s  
                remote-mep 1131 {  
                }  
            }  
            association "association-2" {  
                icc-based "ring1_2_3"  
                ma-index 2  
                ccm-interval 1s  
                remote-mep 1232 {  
                }  
            }  
        }  
    }  
}
```

Configure Ethernet ring

Two paths need to be configured to form a ring: path a and path b. In this example, VLAN tag 1 is used as control channel for R-APS signaling in the ring.

```
# on PE-1:
configure {
  eth-ring 1 {
    admin-state enable
    path "a" {
      admin-state enable
      port-and-raps-tag 1/1/c1/1:1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-1" mep-id 1121 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
    path "b" {
      admin-state enable
      port-and-raps-tag 1/1/c2/1:1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-2" mep-id 1131 {
          admin-state enable
          ccm true
          control-mep true
        }
      }
    }
  }
}
```

It is mandatory to configure a MEP in the path context, otherwise the following error is displayed:

```
*[ex:/configure eth-ring 1]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure eth-ring 1 path "a" admin-state - Cannot enable path
without eth-cfm mep configured - configure eth-ring 1 path "a" admin-state
MINOR: MGMT_CORE #4001: configure eth-ring 1 path "b" admin-state - Cannot enable path
without eth-cfm mep configured - configure eth-ring 1 path "b" admin-state
```

While MEPs are mandatory, enabling CCM on the MEP in the path context as a failure detection mechanism is optional.

In order to define the RPL, node PE-2 is configured as the RPL owner and path b as the RPL end. The link between nodes PE-1 and PE-2 will be the RPL with node PE-2 blocking that link when the ring is fully operational.

```
# on PE-2:
configure {
  eth-ring 1 {
    admin-state enable
    revert-time 60
    rpl-node owner
    path "a" {
      admin-state enable
      port-and-raps-tag 1/1/c1/1:1
      eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-1" mep-id 1232 {
          admin-state enable
          ccm true
        }
      }
    }
  }
}
```

```

        control-mep true
    }
}
path "b" {
    admin-state enable
    port-and-raps-tag 1/1/c2/1:1
    rpl-end true
    eth-cfm {
        mep md-admin-name "domain-1" ma-admin-name "association-2" mep-id 1122 {
            admin-state enable
            ccm true
            control-mep true
        }
    }
}
}

```

It is not allowed to configure a path as an RPL end without having configured the node on this ring to be either the RPL **owner** or **neighbor** otherwise the following error message is reported.

```

*[ex:/configure eth-ring 1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure eth-ring 1 path "b" rpl-end - rpl-node must be set -
configure eth-ring 1 rpl-node

```

```

# on PE-3:
configure {
    eth-ring 1 {
        admin-state enable
        path "a" {
            admin-state enable
            port-and-raps-tag 1/1/c1/1:1
            eth-cfm {
                mep md-admin-name "domain-1" ma-admin-name "association-1" mep-id 1133 {
                    admin-state enable
                    ccm true
                    control-mep true
                }
            }
        }
    }
    path "b" {
        admin-state enable
        port-and-raps-tag 1/1/c2/1:1
        eth-cfm {
            mep md-admin-name "domain-1" ma-admin-name "association-2" mep-id 1233 {
                admin-state enable
                ccm true
                control-mep true
            }
        }
    }
}
}

```

Until the Ethernet ring instance is attached to the service (VPLS in this case), the ring operational status is down and the forwarding status of each port is blocked. This prevents operators from creating a loop by misconfiguration. This state can be seen on ring node PE-1 as follows:

```

[/]
A:admin@PE-1# show eth-ring 1

```

```

Configure control channel VPLS service

Paths a and b defined in the Ethernet ring must be added as SAPs into a VPLS service (standard VPLS in this example) using the **eth-ring** parameter. The SAP encapsulation values must match the values of the **port-and-raps-tag** configured for the associated path.

G.8032 uses the same R-APS tag value on all nodes on the ring, as configured in this example. However, the SR OS implementation relaxes this constraint by requiring the tag to match only on adjacent nodes.

```

# on PE-1:
configure {
  service {
    vpls "VPLS-1" {
      admin-state enable
      description "control channel VPLS 1 tag 1"
      service-id 1
      customer "1"
      sap 1/1/c1/1:1 {
        eth-ring 1
      }
      sap 1/1/c2/1:1 {
        eth-ring 1
      }
    }
  }
}

```

```

# on PE-2:
configure {
  service {
    vpls "VPLS-1" {
      admin-state enable
      description "control channel VPLS 1 tag 1"
      service-id 1
      customer "1"
      sap 1/1/c1/1:1 {
        eth-ring 1
      }
    }
  }
}

```

```

        sap 1/1/c2/1:1 {
            eth-ring 1
        }

# on PE-3:
configure {
    service {
        vpls "VPLS-1" {
            admin-state enable
            description "control channel VPLS 1 tag 1"
            service-id 1
            customer "1"
            sap 1/1/c1/1:1 {
                eth-ring 1
            }
            sap 1/1/c2/1:1 {
                eth-ring 1
            }
        }
    }
}

```

A normal SAP or SDP can be added in a control channel VPLS on condition the **eth-ring** parameter is present. Any attempt to add a SAP or SDP without this parameter into a control channel VPLS results in error messages being displayed. To trigger the following error messages, SAP 1/1/c3/1:1 is added without the eth-ring parameter.

```

*[ex:/configure service vpls "VPLS-1" sap 1/1/c3/1:1]
A:admin@PE-1# commit
MINOR: SVCMGR #2590: configure service vpls "VPLS-1" sap 1/1/c1/1:1 - Invalid Ethernet ring
configuration - Ring control SAP cannot be added to service that contains non-ring SAPs or SDP
bindings - configure service vpls "VPLS-1" sap 1/1/c1/1:1 eth-ring

bindings - configure service vpls "VPLS-1" sap 1/1/c2/1:1 eth-ring
MINOR: SVCMGR #2590: configure service vpls "VPLS-1" sap 1/1/c2/1:1 - Invalid Ethernet ring
configuration - Ethernet Ring Control service should only have controls saps from same ring -
configure service vpls "VPLS-1" sap 1/1/c2/1:1 eth-ring

```

In non-failure conditions, the Ethernet ring is operationally up and the RPL is blocking successfully on ring node PE-2 port 1/1/c2/1, as expected from the RPL owner and RPL end configuration.

An overview of all of the rings can be shown using the following commands, in this case on node PE-2.

The following command on PE-2 shows the Ethernet ring status.

```

[/]
A:admin@PE-2# show eth-ring status

Configure user data channel VPLS service

The user data channels are created on a separate VPLS, "VPLS-100" in the example. The ring data channels must be on the same ports as the corresponding control channels configured above. The access into the data services can use SAPs or SDPs.

```
# on PE-1:
configure {
  service {
    vpls "VPLS-100" {
      admin-state enable
      description "data channel VPLS 100"
      service-id 100
      customer "1"
      sap 1/1/c1/1:100 {
        eth-ring 1
      }
      sap 1/1/c2/1:100 {
        eth-ring 1
      }
      sap 1/1/c3/1:100 {
      }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    vpls "VPLS-100" {
      admin-state enable
      description "data channel VPLS 100"
      service-id 100
      customer "1"
      sap 1/1/c1/1:100 {
        eth-ring 1
      }
      sap 1/1/c2/1:100 {
        eth-ring 1
      }
      sap 1/1/c3/1:100 {
      }
    }
  }
}
```

```
# on PE-3:
configure {
  service {
    vpls "VPLS-100" {
      admin-state enable
      description "data channel VPLS 100"
      service-id 100
      customer "1"
      sap 1/1/c1/1:100 {
        eth-ring 1
      }
      sap 1/1/c2/1:100 {
        eth-ring 1
      }
      sap 1/1/c3/1:100 {
      }
    }
  }
}
```

The following command on PE-1 shows all the SAPs that are configured to use Ethernet rings.

```
[/]
A:admin@PE-1# show service sap-using eth-ring

"Interface 1/1/c1/1 is not operational"
```

For troubleshooting, the **tools dump eth-ring <ring-index>** command displays path information, the internal state of the control protocol, related statistics information and up to the last 20 protocol events (including messages sent and received, and the expiration of timers). An associated parameter **clear** exists, clearing the event information in this output when the command is entered. The following is an example of the output on node PE-2 with port 1/1/c1/1 disabled.

```

Conclusion

Ethernet ring APS provides an optimal solution for designing native Ethernet services with ring topology. This protocol provides simple configuration, operation, and guaranteed fast protection time. SR OS also has a flexible encapsulation that allows dot1Q, QinQ, or PBB for the ring traffic. Ethernet ring APS can be utilized for various services such as mobile backhaul, business VPN access, aggregation, and core.

GRE Tunnel Origination and Termination Using Non-system IP Addresses

This chapter provides information about GRE tunnel origination and termination using non-system IP addresses.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 16.0.R5, but the MD-CLI in the current edition corresponds to SR OS Release 23.3.R2. GRE SDPs and auto-bind GRE tunnels can originate and terminate on a non-system IP address in SR OS Release 16.0.R4 or later.

Overview

For scaling purposes, service providers typically deploy seamless MPLS or inter-AS scenarios. In many cases, the system IP address cannot be leaked between domains and a separate loopback address is used to terminate tunnels. GRE termination on a non-system IP address is supported in the following services:

- VPLS with manually configured GRE spoke-SDPs
- VPLS with BGP-AD using provisioned GRE SDPs (**provisioned-sdp use** or **provisioned-sdp prefer** commands)
- BGP-VPLS using provisioned GRE SDPs
- Epipe with manually configured GRE spoke-SDPs
- Epipe with BGP-VPWS using provisioned GRE SDPs
- VPRN with manually configured GRE spoke-SDPs
- VPRN with auto-bind GRE tunnel
- IES with manually configured GRE spoke-SDPs

This chapter focuses on MPLS-over-GRE termination, but IP-over-GRE termination is also supported.

MPLS-over-GRE termination

GRE termination applies to GRE SDPs and auto-bind GRE tunnels concurrently on a system interface and on non-system interfaces with a subnet that is up to and including /16. In the following example, the non-system loopback address 10.0.1.1 with a subnet of /24 is configured as GRE termination on PE-1:

```
# on PE-1:
```

```
configure {
  router "Base" {
    interface "lo1" {
      loopback
      gre-termination true
      ipv4 {
        primary {
          address 10.0.1.1
          prefix-length 24
        }
      }
    }
  }
}
```

Only one interface can be configured as GRE termination. The following error is raised when attempting to configure a second loopback interface "lo2" as GRE termination on PE-1:

```
*[ex:/configure router "Base" interface "lo2"]
A:admin@Dut-A# commit
MINOR: COMMON #238: configure router "Base" interface "lo2" - Configuration change failed
validation - Multiple interfaces with gre-termination set in the router
```

Although the preceding examples are for loopback interfaces, GRE termination can also be configured on other router interfaces, but only one per node. The following shows an attempt to configure interface "int-PE-1-PE-2" on PE-1 as GRE termination. The same error message is raised. However, if it were the first interface on the node to be configured as GRE termination, the configuration would be accepted.

```
*[ex:/configure router "Base" interface "int-PE-1-PE-2"]
A:admin@Dut-A# commit
MINOR: COMMON #238: configure router "Base" interface "int-PE-1-PE-2" - Configuration change
failed validation - Multiple interfaces with gre-termination set in the router
```

The maximum size of the GRE termination subnet is /16.

GRE termination cannot be applied on the following interface types:

- Unnumbered network IP interfaces
- IES interfaces
- VPRN interfaces
- CSC VPRN interfaces

MPLS-over-GRE origination

GRE SDPs and auto-bind GRE tunnels can originate and terminate on a non-system IP address. Manually configured SDPs can be configured with a non-system IP address as the far-end address. Optionally, a non-system local-end address can be configured for generating GRE from an interface other than the system interface. In the following example on PE-1, GRE SDP 120 uses loopback address 10.0.1.1 as the local-end address and 10.0.2.1 on PE-2 as the far-end address.

```
# on PE-1:
configure {
  service {
    sdp 120 {
      admin-state enable
      local-end 10.0.1.1
      far-end {
        ip-address 10.0.2.1
      }
    }
  }
}
```

```
}
}
```

The local-end IP address can only be configured for GRE SDPs; the following error message is raised when attempting to configure an MPLS SDP with a local-end address:

```
*[ex:/configure service sdp 122]
A:admin@PE-1# commit
MINOR: SVCMGR #7720: configure service sdp 122 local-end - Invalid SDP configuration -
local-end is not supported for this sdp delivery-type.
```

The **local-end** parameter value complies with the following rules:

- A maximum of 15 distinct address values can be configured for all GRE SDPs in the **configure service sdp local-end** context, and all L2oGRE SDPs under the **configure service system gre-eth-bridged tunnel-termination** context.
- The same source address cannot be used in both contexts because an address configured for an L2oGRE SDP matches an internally created interface that is not available to other applications.
- The local-end address of a GRE SDP, when different from the system address, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

The primary IPv4 address of any local network IP interface, loopback or not, may be used. The following shows that IP address 192.168.12.1, as the IP address of the previously mentioned interface "int-PE-1-PE-2" toward PE-2, can be used as the local-end address:

```
# on PE-1:
configure {
  service {
    sdp 123 {
      admin-state enable
      local-end 192.168.12.1
      far-end {
        ip-address 10.0.2.1
      }
    }
  }
}
```

The following shows that an error message is raised when attempting to configure an invalid local-end IP address, that is, an IP address that is not primary on a local router interface. In this case, local-end IP address 10.99.1.1 does not exist on PE-1.

```
*[ex:/configure service sdp 120]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service sdp 120 - sdp 120: router interface with address
10.99.1.1 does not exist, or is not primary IPv4 address - configure router "Base" description
```

For services that support auto-binding to a GRE tunnel, the following command configures a single alternate source address (in this case, 10.0.1.1) per system:

```
# on PE-1:
configure {
  service {
    system {
      vpn-gre-source-ip 10.0.1.1
    }
  }
}
```

The default value of the single source address is the primary IPv4 address of the system interface. The value of the **vpn-gre-source-ip** parameter can be changed at any time. After a new value is configured, the system address will not be used in services that bind to the GRE tunnel.

The **vpn-gre-source-ip** parameter value complies with the following rules:

- This single source address counts toward the maximum of 15 distinct address values per system used by all GRE SDPs under the **configure service sdp local-end** context and all L2oGRE SDPs under the **configure service system gre-eth-bridged tunnel-termination** context.
- The same source address can be used in both **vpn-gre-source-ip** and **configure service sdp local-end** contexts.
- The same source address cannot be used in both **vpn-gre-source-ip** and **configure service system gre-eth-bridged tunnel-termination** contexts because an address configured for an L2oGRE SDP matches an internally created interface that is not available to other applications.
- The **vpn-gre-source-ip** address, when different from the system IP address, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

Configuration

Figure 14: Example topology shows the example topology with three SR OS nodes in AS 64500. Services will be configured on PE-1 and PE-2, while RR-3 is a route reflector (RR).

Figure 14: Example topology

28868

The initial configuration on the three PEs includes:

- cards, MDAs, ports
- router interfaces. The IP addresses shown on the figure are the system IP addresses 192.0.2.x/32.
- IS-IS as IGP (alternatively, OSPF can be used)

GRE SDP termination on non-system IP addresses will be configured in the following use cases:

- VPLS with manually configured T-LDP signaled SDP
- Epipe with manually configured T-LDP signaled SDP
- BGP-VPLS using a provisioned BGP-signaled SDP

- BGP-AD in VPLS using a provisioned T-LDP signaled SDP
- BGP-VPWS using a provisioned BGP-signaled SDP
- VPRN with manually configured T-LDP signaled SDP
- VPRN with auto-bind to GRE tunnel
- IES with manually configured T-LDP signaled SDP

MPLS-over-GRE termination

On PE-1, PE-2, and RR-3, loopback interface "lo1" is configured as GRE termination with IPv4 address 10.0.x.1/24 for PE-x. The configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  router "Base" {
    interface "lo1" {
      loopback
      gre-termination true
      ipv4 {
        primary {
          address 10.0.1.1
          prefix-length 24
        }
      }
    }
  }
}
```

This loopback interface will be used in the SDP configuration. With a /24 subnet, the SDP origination can be any address in the subnet. This is useful for providing entropy in the outer IPv4 header for load-balancing over the IP network.

MPLS-over-GRE origination: SDP local end

The local-end address must be reachable from the far-end router that terminates the GRE SDP. Therefore, the interface for this address can be added to IGP or BGP. Alternatively, a static route can be configured on the far-end router. In this example, IS-IS is enabled on the loopback interface with GRE termination, as follows:

```
# on PE-1, PE-2, RR-3:
configure {
  router "Base" {
    isis 0 {
      interface "lo1" {
      }
    }
  }
}
```

On PE-1, the following SDPs are configured with far-end 10.0.2.1 on PE-2 and local-end 10.0.1.1: SDP 120 with T-LDP signaling (default) and SDP 121 with BGP signaling.

```
# on PE-1:
configure exclusive
service {
  sdp 120 {
    admin-state enable
    local-end 10.0.1.1
    far-end {
```

```

        ip-address 10.0.2.1
    }
}
sdp 121 {
    admin-state enable
    local-end 10.0.1.1
    signaling bgp
    far-end {
        ip-address 10.0.2.1
    }
}
}

```

T-LDP signaled GRE SDPs

When T-LDP signaled SDPs, such as SDP 120 in the preceding example, are configured, T-LDP sessions are auto-created toward the far end of the SDPs. By default, LDP uses the system IP address as source address. However, if the source address for the T-LDP session does not match the destination transport address set by the remote PE, the T-LDP session will not come up and the GRE SDP will remain down. [Figure 15: Mismatched T-LDP transport addresses](#) shows an example where SDP auto-created T-LDP sessions use the local system addresses 192.0.2.x and far-end addresses 10.0.0.x, so the GRE SDPs will not come up.

Figure 15: Mismatched T-LDP transport addresses

28869

Therefore, the local transport address of the T-LDP session must match the local-end address of the GRE SDP in the PE. These T-LDP sessions can be manually provisioned or auto-created via peer templates. The following configures T-LDP sessions between the non-system IP addresses on PE-1 and PE-2.

```

# on PE-1:
configure {
    router "Base" {
        ldp {
            targeted-session {
                peer 10.0.2.1 {
                    local-lsr-id {
                        interface-name "lo1"
                    }
                }
            }
        }
    }
}

```

```

}
# on PE-2:
configure {
  router "Base" {
    ldp {
      targeted-session {
        peer 10.0.1.1 {
          local-lsr-id {
            interface-name "lo1"
          }
        }
      }
    }
  }
}

```

Figure 16: Matching T-LDP transport addresses shows the GRE T-LDP signaled SDPs with matching addresses for the T-LDP sessions.

Figure 16: Matching T-LDP transport addresses

28870

BGP configuration

In this example, the L2 and L3 services are configured on PE-1 and PE-2, while RR-3 acts as the RR. On PE-1, BGP is configured with neighbor 10.0.3.1 and local address 10.0.1.1, as follows. Address family L2-VPN is required for L2 services using BGP-VPLS, BGP-AD, and BGP-VPWS; address family VPN-IPv4 is used for VPRN services.

```

# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "internal" {
        type internal
        local-address 10.0.1.1
        family {
          vpn-ipv4 true
          l2-vpn true
        }
      }
    }
  }
}

```

```

    }
  }
  neighbor "10.0.3.1" {
    group "internal"
  }
}

```

The BGP configuration on PE-2 is similar with neighbor 10.0.3.1 and local address 10.0.2.1.

On RR-3, the BGP configuration is as follows.

```

# on RR-3:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "internal" {
        type internal
        local-address 10.0.3.1
        family {
          vpn-ipv4 true
          l2-vpn true
        }
        cluster {
          cluster-id 10.0.3.1
        }
      }
      neighbor "10.0.1.1" {
        group "internal"
      }
      neighbor "10.0.2.1" {
        group "internal"
      }
    }
  }
}

```

The loopback addresses 10.0.x.1 are configured for the local and neighbor addresses.

Note:

When the local address 10.0.x.1 is not configured, the system address 192.0.2.x will be used instead. However, in that case, no BGP sessions will be established and, therefore, no BGP routes will be exchanged between 192.0.2.x and 10.0.y.1, and no spoke-SDPs will be auto-created in L2 services using BGP-VPLS, BGP-AD, or BGP-VWPS. Likewise, no BGP-VPN routes will be exchanged between VPRNs on PE-1 and PE-2.

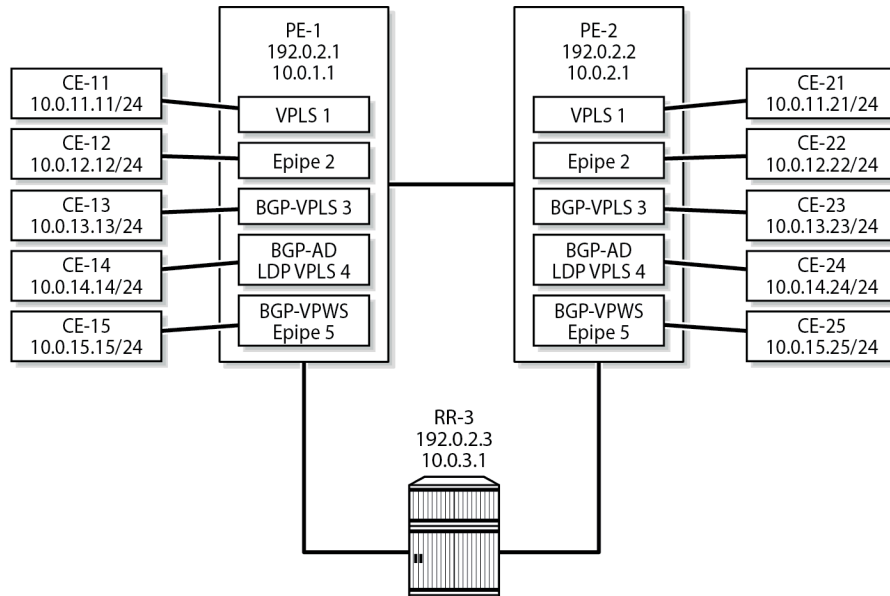

L2 services

Figure 17: L2 services on PE-1 and PE-2 shows the example topology with the following L2 services configured on PE-1 and PE-2:

- VPLS 1 with manually configured spoke-SDP 120:1
- Epipe 2 with manually configured spoke-SDP 120:2
- BGP-VPLS 3 using PW template 1 (BGP-signaled SDP 121 is used)
- LDP VPLS 4 with BGP-AD using PW template 1 (T-LDP signaled SDP 120 is used)
- BGP-VPWS Epipe 5 using PW template 1 (BGP-signaled SDP 121 is used)

The CEs are VPRNs configured on the PEs and connected to the VPLSs via port cross-connect (PXC).

Figure 17: L2 services on PE-1 and PE-2

28871

For a description of the BGP-VPLS parameters, see the [BGP VPLS](#) chapter; for BGP-AD, see the [LDP VPLS Using BGP Auto-Discovery](#) chapter; for BGP-VPWS, see the [BGP Virtual Private Wire Services](#) chapter. For BGP-VPLS, BGP-AD, and BGP-VPWS, PW template 1 is configured with the **provisioned-sdp use** command. The service configuration on PE-1 is as follows; the service configuration on PE-2 is similar.

```
# on PE-1:
configure {
  service {
    sdp 120 {
      admin-state enable
      local-end 10.0.1.1
      far-end {
        ip-address 10.0.2.1
      }
    }
    sdp 121 {
      admin-state enable
      local-end 10.0.1.1
      signaling bgp
      far-end {
        ip-address 10.0.2.1
      }
    }
  }
  pw-template "PW1-use-prov-SDP" {
    pw-template-id 1
    provisioned-sdp use
  }
  vpls "VPLS-1" {
    admin-state enable
    description "VPLS 1 with manually configured spoke-SDP"
    service-id 1
  }
}
```

```
customer "1"

L3 services

Figure 18: L3 services on PE-1 and PE-2 shows the example topology with the following three L3 services configured on PE-1 and PE-2:

- VPRN 6 with manually configured spoke-SDP 120:6
- VPRN 7 with auto-bind to GRE tunnel
- IES 8 with manually configured spoke-SDP 120:8

Figure 18: L3 services on PE-1 and PE-2

28872

VPRN 6 is configured with a loopback interface and a GRE spoke-SDP, as follows:

```
# on PE-1:
configure {
  service {
    system {
      bgp-auto-rd-range {
        ip-address 10.0.1.1
        community-value {
          start 60000
          end 65000
        }
      }
    }
  }
  vprn "VPRN-6 with GRE spoke-SDP" {
    admin-state enable
    service-id 6
    customer "1"
    bgp-ipvpn {
      mpls {
        admin-state enable
        route-distinguisher auto-rd
        vrf-target {
          community "target:64500:6"
        }
      }
    }
    interface "lo6" {
      loopback true
      ipv4 {
        primary {
          address 172.16.16.1
          prefix-length 32
        }
      }
    }
    spoke-sdp 120:6 {
    }
  }
}
```

The following forwarding information base (FIB) for VPRN 6 shows that the remote prefix is reachable via a transport tunnel using SDP 120:

```
[/]
A:admin@PE-1# show router 6 fib 1

=====

-----
Total Entries : 2
=====
```

VPRN 7 is configured with **auto-bind-tunnel** and the tunnel needs to be resolved using GRE. For services that support auto-binding to a GRE tunnel, the **vpn-gre-source-ip** parameter defines a single alternate source address for all VPRNs on the system. On PE-1, the configuration is as follows:

```
# on PE-1:
configure {
  service {
    system {
      vpn-gre-source-ip 10.0.1.1
    }
    vprn "VPRN-7 with auto-bind GRE" {
      admin-state enable
      service-id 7
      customer "1"
      bgp-ipvpn {
        mpls {
          admin-state enable
          route-distinguisher auto-rd
          vrf-target {
            community "target:64500:7"
          }
          auto-bind-tunnel {
            resolution filter
            resolution-filter {
              gre true
            }
          }
        }
      }
      interface "lo7" {
        loopback true
        ipv4 {
          primary {
            address 172.16.17.1
            prefix-length 24
          }
        }
      }
    }
  }
}
```

The following FIB for VPRN 7 shows that the remote prefix is reachable via a GRE transport tunnel:

```
[/]
A:admin@PE-1# show router 7 fib 1

=====
FIB Display

=====
```

IES 8 has an interface with a manually configured GRE spoke-SDP, as follows:

```
# on PE-1:
configure {
  service {
    ies "IES-8" {
      admin-state enable
      service-id 8
      customer "1"
      interface "int-IES8-PE-1-PE-2" {
        spoke-sdp 120:8 {
        }
        ipv4 {
          primary {
            address 172.16.128.1
            prefix-length 30
          }
        }
      }
      interface "lo8" {
        loopback true
        ipv4 {
          primary {
            address 172.16.18.1
            prefix-length 24
          }
        }
      }
    }
  }
}
```

On PE-1, the connectivity over the GRE spoke-SDP is verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.128.2 interval 0.1 output-format summary
PING 172.16.128.2 56 data bytes
!!!!
---- 172.16.128.2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.57ms, avg = 2.73ms, max = 3.01ms, stddev = 0.168ms
```

Conclusion

By default, GRE SDPs and auto-bind GRE tunnels are originated and terminated on the system IP address, but it is possible to use non-system IP addresses. This is useful in cases where the system IP address cannot be leaked between domains and a separate loopback address must be used to terminate tunnels.

Network Group Encryption Helper

This chapter describes the network group encryption (NGE) helper.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

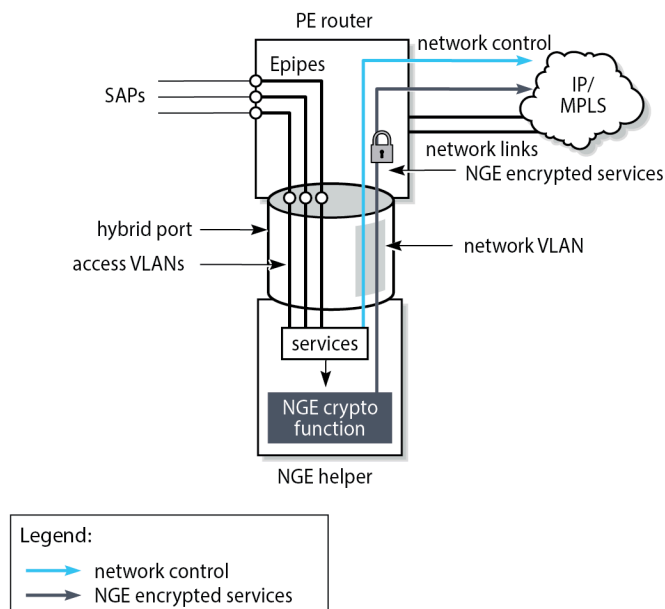

The information and configuration in this chapter are based on SR OS Release 23.3.R1. Network group encryption (NGE) helpers require use of the VSR-a or the VSR-I and can be deployed with 7750 SR and 7950 XRS.

Overview

The NGE helper enables NGE security for services configured on the 7750 SR or 7950 XRS (hereafter referred to as the router) that require additional confidentiality and integrity.

Multiple NGE helpers can be deployed with a router depending on the encrypted services throughput requirements required by the operator. [Figure 19: General architecture using an NGE helper](#) shows the general architecture using an NGE helper.

Figure 19: General architecture using an NGE helper

37325

Each NGE helper is connected to the router using an access interface and a network interface, where both interfaces are configured on the NGE helper and on the router. A hybrid port can be used on the router and NGE helper to optimize the deployment, so one physical port is required on the router and NGE helper.

SAPs are configured on the router using an Epipe directed toward the NGE helper access interface. Unencrypted traffic that is received on the SAP interface is sent through the Epipe to the NGE helper which encrypts the traffic before sending it toward the network. The network interface on the NGE helper is enabled with minimal network control plane functions toward the router. The network control plane of the router performs the majority of network level processing and forwarding of NGE encrypted services.

The NGE helper supports services-based encryption, including:

- VPRN encryption
- SDP encryption
- PW-template encryption

Note: In SR OS Release 23.3.R1, all services-based encryption can be configured in classic CLI, whereas in MD-CLI, only PW-template encryption can be configured.

Router interface encryption and port-level encryption are not supported by the NGE helper.

Scenarios for encrypting services

The following main services scenarios are supported:

- **VPRN encryption using auto-bind services for both MPLS (LDP or RSVP-TE signaled tunnels) and GRE transport**

This scenario uses BGP to advertise the NGE helper IP address to remote NGE helpers. Remote NGE helpers can then send VPRN traffic to other NGE helpers to be processed for the associated destination SAP. This scenario uses VPRN-level NGE.

- **NG-MVPN with VPRN encryption using MLDP tunnels from the NGE helper to the router**

This scenario uses a similar setup to VPRN encryption, with the difference that MLDP tunnels are also established between the NGE helper and the router where the point-to-multipoint tree branches from for the NG-MVPN service. This scenario uses VPRN-level NGE.

- **T-LDP signaled Epipe or VPLS services using LDP or RSVP-TE transport tunnels**

T-LDP sessions are established from the NGE helper to the remote PEs to establish Epipe or VPLS services. The transport of these services focuses on LDP or LDP with RSVP-TE. Where GRE is possible, GRE support of VPLS or VPWS mainly uses BGP VPLS or BGP VPWS with auto-GRE SDP, because this use case is prevalent with SAR-Hm/Hmc deployments. This scenario uses SDP-level NGE.

- **L2 services using BGP VPLS or BGP VPWS auto-GRE SDP**

This scenario is similar to the VPRN auto-bind scenario, except that a BGP session is used to advertise L2 routes to and from the NGE helper where remote PEs can send GRE L2 packets encrypted with the associated NGE configuration under the **pw-template** context.

Configuration

NGE configuration

NGE configuration is managed by the Network Services Platform Network Functions Manager - Packet (NSP NFM-P). Operators use the NSP NFM-P to configure:

- global encryption labels
- key groups
- VPRN-level encryption – setting the inbound and outbound key groups on VPRN-based services
- SDP-level encryption – setting the inbound and outbound key groups on selected SDPs
- PW-template level encryption – setting the inbound and outbound key groups on selected PW templates

Note: In this chapter, the NSP NFM-P is not used. Therefore, the remainder of the chapter focuses on PW-template level encryption, that can be configured in MD-CLI in SR OS Release 23.3.R1.

Group encryption configuration

In this example, encryption keygroup 1 is configured manually on NGE-1:

```
# on NGE-1:
configure {
  group-encryption {
    group-encryption-label 100
    encryption-keygroup 1 {
```

```

keygroup-name "KG1"
active-outbound-security-association 1
security-association 1 {
  authentication-key
0x1111111100000000111111110000000011111111000000001111111100000000
  encryption-key 0x11111111000000001111111100000000
}
security-association 2 {
  authentication-key
0x2222222200000000222222220000000022222222000000002222222200000000
  encryption-key 0x22222222000000002222222200000000
}
security-association 3 {
  authentication-key
0x3333333300000000333333330000000033333333000000003333333300000000
  encryption-key 0x33333333000000003333333300000000
}
security-association 4 {
  authentication-key
0x4444444400000000444444440000000044444444000000004444444400000000
  encryption-key 0x44444444000000004444444400000000
}
}

```

The authentication key and the encryption key are configured as cleartext. After configuration, they are never displayed in their cleartext form. The security parameter index (SPI) value in the security association is a node-wide unique value.

PW-template configuration

On NGE-1, PW template 2 is configured with encryption keygroup 1:

```

# on NGE-1:
service {
  pw-template "2" {
    auto-gre-sdp true
    vc-type vlan
    split-horizon-group {
      name "SHG"
    }
    encryption-keygroup {
      inbound 1
      outbound 1
    }
  }
}

```

BGP configuration

BGP must be enabled on the router and the NGE helper for the L2-VPN address family for the following services:

- BGP VPWS with auto-GRE SDP (where NGE is configured under the **pw-template** context)
- BGP VPLS with auto-GRE SDP (where NGE is configured under the **pw-template** context)

[Figure 20: BGP topology for learning BGP label routes](#) shows the BGP topology for learning BGP label routes for those services.

Figure 20: BGP topology for learning BGP label routes

37326

The following configures BGP on PE-1 to support the NGE 1 helper function:

```
# on PE-1:
configure {
  router "Base" {
    bgp {
      rapid-withdrawal true
      group "PE-1-NGE-1-RR" {
        peer-as 64496
        family {
          l2-vpn true
        }
        cluster {
          cluster-id 192.0.2.1
        }
      }
      group "core-RR" {
        peer-as 64496
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.3" {
        group "core-RR"
      }
      neighbor "192.0.2.4" {
        group "PE-1-NGE-1-RR"
      }
    }
  }
}
```

The following configures BGP on PE-2 to support the NGE 2 helper function:

```
# on PE-2:
configure {
```

```
router "Base" {
  bgp {
    rapid-withdrawal true
    group "PE-2-NGE-2-RR" {
      peer-as 64496
      family {
        l2-vpn true
      }
      cluster {
        cluster-id 192.0.2.2
      }
    }
    group "core-RR" {
      peer-as 64496
      family {
        l2-vpn true
      }
    }
    neighbor "192.0.2.3" {
      group "core-RR"
    }
    neighbor "192.0.2.5" {
      group "PE-2-NGE-2-RR"
    }
  }
}
```

The BGP configuration on the NGE-1 helper is as follows:

```
# on NGE-1:
configure {
  router "Base" {
    bgp {
      rapid-withdrawal true
      group "RR-PE-1" {
        peer-as 64496
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.1" {
        group "RR-PE-1"
      }
    }
  }
}
```

The BGP configuration on the NGE-2 helper is as follows:

```
# on NGE-2:
configure {
  router "Base" {
    bgp {
      rapid-withdrawal true
      group "RR-PE-2" {
        peer-as 64496
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.2" {
        group "RR-PE-2"
      }
    }
  }
}
```

Services configuration

BGP VPLS or BGP VPWS with auto-GRE SDP

Figure 21: NGE helper for BGP VPLS or BGP VPWS using GRE SDPs with auto-GRE SDP shows the operation of the NGE helper for BGP VPLS and BGP VPWS services that use GRE SDPs when auto-GRE SDP is configured on the associated PW template.

Figure 21: NGE helper for BGP VPLS or BGP VPWS using GRE SDPs with auto-GRE SDP

 - - - network

37329

In this scenario, the VPLS or VPWS SAPN1 is configured on the NGE-1 helper. On PE-1, a local Epipe is configured that originates from the customer facing SAP1 and terminates on SAP-A1 connected to the NGE-1 helper. On PE-1, Epipes 100101 and 100201 are configured as follows:

```
# on PE-1:
configure {
```

```

service {
  epipe "Epipe-100101" {
    admin-state enable
    service-id 100101
    customer "1"
    sap lag-1:101 {
      description "toward NGE-1 Epipe 101"
    }
    sap lag-11:101.1 {
      description "toward CE"
    }
  }
  epipe "Epipe-100201" {
    admin-state enable
    service-id 100201
    customer "1"
    sap lag-1:201 {
      description "toward NGE-1 VPLS 201"
    }
    sap lag-11:201.1 {
      description "toward CE"
    }
  }
}

```

On PE-1, the following network configurations are required to support encrypted services from the NGE-1 helper:

- any routing options that allow GRE packets received from the NGE helper to be routed to remote PEs
- BGP sessions for the L2-VPN address family, as described in the [BGP configuration](#) section

On the NGE-1 helper, the configuration includes:

- VPLS or VPWS SAPN1
- BGP session to PE-1 for the L2-VPN address family
- BGP VPLS or BGP VPWS using PW templates with auto-GRE SDP enabled
- NGE enabled on the PW templates for encrypting the VPLS or VPWS services using the PW templates

On NGE-1, Epipe 101 is a BGP VPWS with auto-GRE SDP. PW template 2 is configured with encryption keygroup 1. Epipe 101 is configured as follows:

```

# on NGE-1:
configure {
  service {
    pw-template "2" {
      auto-gre-sdp true
      vc-type vlan
      split-horizon-group {
        name "SHG"
      }
      encryption-keygroup {
        inbound 1
        outbound 1
      }
    }
  }
  epipe "Epipe-101" {
    admin-state enable
    description "BGP VPWS auto-gre SDP_PW template 2"
    service-id 101
    customer "1"
    bgp 1 {
      route-distinguisher "101:1"
    }
  }
}

```

```

        route-target {
            export "target:101:1"
            import "target:101:1"
        }
        pw-template-binding "2" {
        }
    }
    bgp-vpws {
        admin-state enable
        local-ve {
            name "pe-1"
            id 1
        }
        remote-ve "pe-2" {
            id 2
        }
    }
}
sap lag-1:101 {
}
}

```

In a similar way, VPLS 201 is a BGP VPLS with auto-GRE SDP. PW template 2 is configured with encryption keygroup 1. VPLS 201 is configured as follows:

```

# on NGE-1:
configure {
    service {
        vpls "VPLS-201" {
            admin-state enable
            description "BGP VPLS auto-gre SDP_PW template 2"
            service-id 201
            customer "1"
            bgp 1 {
                route-distinguisher "201:1"
                route-target {
                    export "target:201:1"
                    import "target:201:1"
                }
                pw-template-binding "2" {
                }
            }
        }
        bgp-vpls {
            admin-state enable
            maximum-ve-id 10
            ve {
                name "pe-1"
                id 1
            }
        }
    }
    sap lag-1:201 {
    }
}
}

```

Verification

The following base information for the services shows that the services are operationally up, as well as their SAPs and SDP bindings:

```

Conclusion

NGE is a security solution for encrypting traffic flows on a per-service basis. The NGE helper extends the NGE solution to 7750 SR and 7950 XRS platforms where larger core and PE nodes are required to participate with other NGE-capable nodes.

Seamless BFD Application — Auto-bind tunnel

This chapter provides information about seamless BFD application — auto-bind tunnel.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 19.10.R3, but the MD-CLI in the current edition corresponds to SR OS Release 23.3.R3.

A prerequisite is to read the "Seamless BFD for SR-TE LSPs" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

Overview

Bidirectional forwarding detection (BFD) is widely deployed in IP/MPLS networks to rapidly detect failures in the forwarding path between network elements.

Seamless BFD (S-BFD) is described in RFC 7880. S-BFD minimizes the time required to establish BFD sessions by removing the discovery of discriminators during the initial handshaking procedure, which contributes to its seamless operation. S-BFD relies on the fact that the discriminators needed to establish the BFD session are already known by the endpoints for each session, either through configuration or advertisement using unicast protocols.

[Figure 22: S-BFD session establishment – continuity check](#) shows the S-BFD session establishment between PE-1 and PE-4. The BFD discriminator used by the initiator is chosen by the system. On PE-1, the BFD (initiator) discriminator equals 123; on PE-4, the S-BFD (reflector) discriminator equals 524288. Through IGP advertisement or configuration, head-end router PE-1 is aware of the S-BFD discriminator of PE-4 (system ID 192.0.2.4; S-BFD discriminator 524288).

Figure 22: S-BFD session establishment – continuity check

35629

The state of the SR-TE LSP is linked to the state of the S-BFD session when failure action **failover-or-down** is configured. In the "Seamless BFD for SR-TE LSPs" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*, one of the examples illustrates the use of S-BFD with failure action **failover-or-down** in an SR-TE LSP with a primary path and a standby secondary path. When a link or node fails on the primary path, the S-BFD session goes down and the head-end node switches to a standby path that is operationally up.

In this chapter, S-BFD is configured in an SR-TE LSP with primary path only. Services such as VPRNs or EVPNs may have auto-bind tunnel configured with multiple tunnel resolution protocols, such as SR-TE and SR-ISIS. SR-TE tunnels are preferred to SR-ISIS tunnels. When a link or node fails on the primary path, the S-BFD session goes operationally down and the SR-TE LSP goes operationally down, and is removed from the tunnel table. The head-end node reverts to the best preference tunnel that is up; in this case, an SR-ISIS tunnel.

Configuration

Figure 23: [Example topology](#) shows the example topology. The VPRN and EVPN services will be configured on PE-2 and PE-5.

Figure 23: Example topology

35836

Initial configuration

The initial configuration on the PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)
- SR-ISIS enabled
- Traffic engineering enabled on PE-2 and PE-5

The initial configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  router "Base" {
    interface "int-PE-2-PE-3" {
      port 1/1/c2/1:1000
      ipv4 {
        primary {
          address 192.168.23.1
          prefix-length 30
        }
      }
    }
    interface "int-PE-2-PE-4" {
      port 1/1/c1/1:1000
      ipv4 {
        primary {
          address 192.168.24.1
          prefix-length 30
        }
      }
    }
  }
}
```

```
}
interface "system" {
  ipv4 {
    primary {
      address 192.0.2.2
      prefix-length 32
    }
  }
}
mpls-labels {
  sr-labels {
    start 32000
    end 32999
  }
}
isis 0 {
  admin-state enable
  advertise-router-capability area
  traffic-engineering true
  area-address [49.0001]
  segment-routing {
    admin-state enable
    prefix-sid-range {
      global
    }
  }
  interface "int-PE-2-PE-3" {
    interface-type point-to-point
  }
  interface "int-PE-2-PE-4" {
    interface-type point-to-point
  }
  interface "system" {
    ipv4-node-sid {
      index 2
    }
  }
}
}
```

S-BFD configuration

For S-BFD, the reflector BFD discriminator values must be configured in the range from 524288 to 526335. On far-end node PE-5, the global S-BFD configuration is as follows. This S-BFD discriminator will be advertised by IGP.

```
# on PE-5:
configure {
  bfd {
    seamless-bfd {
      reflector "PE-5" {
        admin-state enable
        discriminator 524291
      }
    }
  }
}
```

For S-BFD, a BFD template of type CPM-NP must be configured. On PE-2, the following BFD template is configured:

```
# on PE-2:
configure {
```

```
bfd {
  bfd-template "bfd-cpm-np-1s" {
    receive-interval 1000    # minimum value is 10 ms
    transmit-interval 1000  # minimum value is 10 ms
    type cpm-np
  }
}
```

Note:

Even though CPM-NP BFD can use intervals of minimum 10 ms, the used example setup has its limitations. The nodes in the used example setup are sims and the simulation for CPM-NP or central BFD sessions has the limitation that intervals that are configured with a value smaller than 1000 ms are always negotiated to intervals of 1000 ms. To avoid confusion when the configured intervals differ from the negotiated intervals on sims, a BFD template with intervals of 1000 ms is configured and used in this chapter.

On PE-2, the preceding BFD template is applied in the following SR-TE LSP to PE-5. For SR-TE LSPs, the only allowed failure action is **failover-or-down**.

```
# on PE-2:
configure {
  router "Base" {
    mpls {
      admin-state enable
      path "empty" {
        admin-state enable
      }
      lsp "LSP-PE-2-PE-5_empty_localCSPF" {
        admin-state enable
        type p2p-sr-te
        to 192.0.2.5
        path-computation-method local-cspf
        bfd {
          bfd-liveness true
          bfd-template "bfd-cpm-np-1s"
          failure-action failover-or-down
        }
        primary "empty" {
        }
      }
    }
  }
}
```

The following tunnel table on PE-2 shows that two tunnels are available toward PE-5: an SR-TE tunnel with tunnel ID 655362 and default preference 8, and an SR-ISIS tunnel with tunnel ID 524293 and default preference 11. The SR-TE tunnel with preference 8 is preferred to the SR-ISIS tunnel with preference 11.

```

VPRN and EVPN services with auto-bind tunnel

Both VPRN "VPRN-1" and an EVPN VPLS "VPLS-2" will be configured on PE-2 and PE-5. For advertising VPN-IPv4 and EVPN routes, BGP is configured on PE-2 and PE-5 for the VPN-IPv4 and EVPN address families. Both VPRN "VPRN-1" and EVPN VPLS "VPLS-2" have auto-bind tunnel enabled with resolution filter allowing SR-ISIS and SR-TE.

```
# on PE-2:
configure {
```

```
router "Base" {
  autonomous-system 64496
  bgp {
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    split-horizon true
    rapid-update {
      vpn-ipv4 true
      evpn true
    }
    group "internal" {
      peer-as 64496
      family {
        vpn-ipv4 true
        evpn true
      }
    }
    neighbor "192.0.2.5" {
      group "internal"
    }
  }
}
service {
  vpls "VPLS-2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    bgp-evpn {
      evi 2
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution filter
          resolution-filter {
            sr-isis true
            sr-te true
          }
        }
      }
    }
    sap 1/1/c3/1:2 {
    }
  }
}
vprn "VPRN-1" {
  admin-state enable
  service-id 1
  customer "1"
  bgp-ipvpn {
    mpls {
      admin-state enable
      route-distinguisher "64496:1"
      vrf-target {
        community "target:64496:1"
      }
      auto-bind-tunnel {
        resolution filter
        resolution-filter {
          sr-isis true
          sr-te true
        }
      }
    }
  }
}
```

```

    }
  }
  interface "int-VPRN-1_PE-2_CE-11" {
    mac 00:00:5e:00:53:11
    ipv4 {
      primary {
        address 172.31.2.2
        prefix-length 30
      }
    }
    sap 1/1/c4/1:1 {
    }
  }
}

```

The following route table for VPRN "VPRN-1" on PE-2 shows that the SR-TE tunnel with tunnel ID 655362 is used toward next-hop 192.0.2.5:

```

[/]

Failure of the SR-TE LSP

The following command shows that—without any failures—the primary path of the SR-TE LSP goes via PE-4:

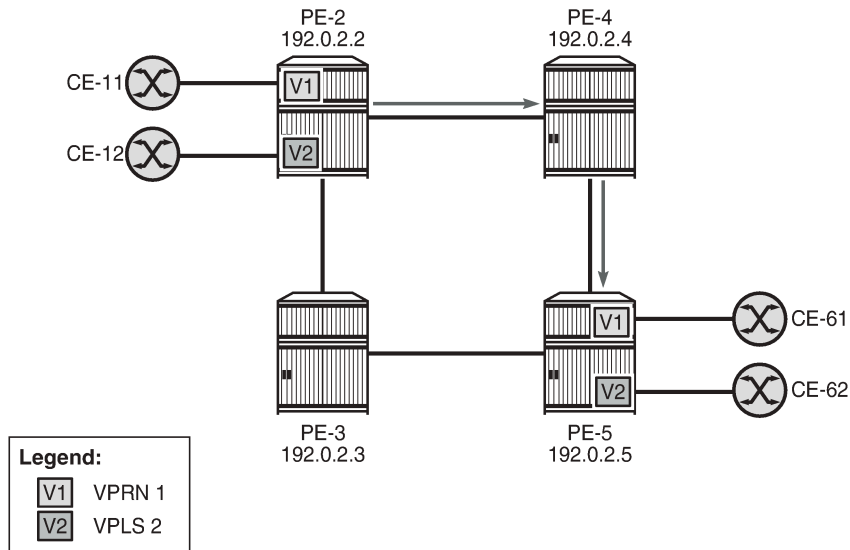

```

[/]
A:admin@PE-2# show router mpls sr-te-lsp "LSP-PE-2-PE-5_empty_localCSPF" path detail
| match "Actual Hops" post-lines 3
Actual Hops      :
  192.168.24.2(192.0.2.4) (A-SID)      Record Label      : 524286
-> 192.168.45.2(192.0.2.5) (A-SID)      Record Label      : 524286

```

Figure 24: Primary path of SR-TE LSP via PE-4 shows the primary path of the SR-TE LSP.

Figure 24: Primary path of SR-TE LSP via PE-4

35837

S-BFD is configured in the SR-TE LSP with failure action **failover-or-down**. If the SR-TE LSP fails, the S-BFD session will go down and it will bring the SR-TE tunnel down. The next-hop 192.0.2.5 cannot be resolved using the SR-TE tunnel, so an SR-ISIS tunnel will be used instead.

On PE-4, port 1/1/c1/1 to PE-5 is disabled to emulate a failure in the primary path of the SR-TE LSP, as follows:

```
# on PE-4:
configure {
  port 1/1/c1/1 {      # port to PE-5
    admin-state disable
```

Figure 25: Remote failure in the primary path of the SR-TE LSP shows that a remote failure occurs in the primary path of the SR-TE LSP.

       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
=====
```

Again, the SR-TE LSP will be preferred to the SR-ISIS LSP and both VPRN "VPRN-1" and EVPN VPLS "VPLS-2" will use the SR-TE tunnel to 192.0.2.5.

Conclusion

S-BFD can be used to determine the state of SR-TE LSPs that only have a primary path. The resiliency is at the service level for VPRN and EVPN services with auto-bind tunnel where several resolution protocols are configured and SR-TE has the lowest preference. When the S-BFD session for the SR-TE tunnel goes operationally down, the SR-TE tunnel goes operationally down. The VPRN and EVPN services will then use the best tunnel that is available; in this example, an SR-ISIS tunnel.

AC-Influenced DF Election on an ES

This chapter provides information about Attachment Circuit (AC) influenced Designated Forwarder (DF) election on an Ethernet Segment (ES).

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 22.5.R1. Attachment Circuit (AC) influenced Designated Forwarder (DF) election on an Ethernet Segment (ES) is always enabled in SR OS releases earlier than 21.5.R1. The AC-DF election capability can be disabled in SR OS Release 21.5.R1 and later.

Overview

RFC 8584, section "The AC-Influenced DF Election Capability", describes the AC-DF capability that modifies the EVPN DF election process in RFC 7432. RFC 8584 states that when PEs build their candidate DF election list, they do not include PEs when no Auto-Discovery (AD) per-ES or per-EVI routes for those PEs are present. In SR OS, this behavior is default for all ESs, configured as **ac-df-capability include**.

The **ac-df-capability** command is configurable in the **configure service system bgp evpn ethernet-segment** context:

```
[ex:/configure service system bgp evpn ethernet-segment "SA-ESI-23"]
A:admin@PE-2# ac-df-capability ?

ac-df-capability <keyword>
<keyword> - (include|exclude)
Default   - include

AC-influenced DF election capability

Warning: Modifying this element toggles
'configure service system bgp evpn ethernet-segment "SA-ESI-23" admin-state'
automatically for the new value to take effect.
```

The command **ac-df-capability exclude** disables AC-DF on the ES, so the presence of an AD per-ES or per-EVI does not influence the candidate DF election list. When **ac-df-capability exclude** is configured:

- The candidate DF election list is not influenced by the presence or absence of AD per-ES/EVI routes (type 1) from the ES peers.
- PEs are only removed from the candidate DF election list when their ES route (type 4) is not present.
- The local ES route is active if there are active SAPs on the ES.

- When the local AC is operationally down, due to **admin-state disable** or reason other than Multi Homing (MH) standby, this does not trigger a DF switchover.

The **ac-df-capability exclude** option:

- is supported with any type of service-carving (DF Election)
- is recommended in ESs that use an operational group monitored by the access LAG to signal standby LACP or power-off
- must be configured consistently on all PEs attached to the same ES

AC-DF enabled – default

The following example illustrates the default behavior, where a PE builds the list of DF candidates with nodes that have sent EVPN AD per-ES/EVI routes. This behavior is compatible with the behavior in SR OS releases earlier than 21.5.R1.

[Figure 27: PE-4 as the DF on a single-active ES for three VPLSs](#) shows a topology with MTU-6 connected via SDPs to the single-active ES "SA-vESI-45". PE-4 is the DF for three services: VPLS 1, VPLS 2, and VPLS 3. Traffic for these services passes via PE-4, while PE-5 is standby.

Figure 27: PE-4 as the DF on a single-active ES for three VPLSs

When a failure occurs on the spoke-SDP in VPLS 2 on PE-4, PE-4 sends an EVPN-AD per-EVI withdrawal and PE-4 becomes the Non-Designated Forwarder (NDF) for VPLS 2, while remaining the DF for VPLS 1 and VPLS 3, as shown in [Figure 28: AC failure in VPLS 2 on PE-4 causes PE-5 to become the DF for VPLS 2](#).

Figure 28: AC failure in VPLS 2 on PE-4 causes PE-5 to become the DF for VPLS 2

37573

VPLS 2 traffic to and from MTU-6 passes via DF PE-5, while VPLS 1 and VPLS 3 traffic will pass via DF PE-4. No traffic is dropped. The AC failure in VPLS 2 does not have an impact on the other services.

Problem with AC-DF on ES with the operational group monitored by LAG

In this example, a failure in an access circuit of a particular service also impacts other services when the AC-DF capability is enabled.

Figure 29: PE-2 is DF on single-active ES for three VPLSs shows a single-active ES with LAG 1 associated with it. An operational group is assigned to the ES and monitored by the LAG to signal standby LACP (default) or power off. Three VPLSs are configured on PE-2 and PE-3. PE-2 is the DF for each of these VPLSs.

Figure 29: PE-2 is DF on single-active ES for three VPLSs

37574

On NDF PE-3, the ES is inactive which causes the operational group in the ES to go down. LAG 1 monitors this operational group, so the LAG goes standby on NDF PE-3. LAG 1 has LACP standby-signaling enabled (default). On CE-1, only the LAG port to DF PE-2 is up and all traffic for the VPLSs goes via PE-2.

When the single-active ES has the default AC-DF setting (**ac-df-capability include**), a failure (or an unintended **admin-state disable**) on SAP lag-1:2 in VPLS 2 (or on the VPLS 2 service) on PE-2 can have an impact on all three services that share LAG 1. [Figure 30: AC failure in VPLS 2 on PE-2 causes PE-3 to become DF for VPLS 2](#) shows that such an AC failure in VPLS 2 on PE-2 causes PE-3 to become the DF for VPLS 2 (after receiving an AD per-EVI withdrawal from PE-2).

Figure 30: AC failure in VPLS 2 on PE-2 causes PE-3 to become DF for VPLS 2

37575

When PE-3 is the DF for VPLS 2, the ES operational group on PE-3 goes up. Therefore, the monitoring LAG is up on PE-3. On CE-1, both LAG ports to PE-2 and PE-3 are up. CE-1 can now send all VPLS traffic via either LAG port: DF PE-2 forwards the VPLS 1 and VPLS 3 traffic whereas NDF PE-3 drops it. PE-3 accepts VPLS 2 traffic, but PE-2 drops it. Approximately 50% of the traffic is lost.

AC-DF capability disabled

Nokia recommends disabling the AC-DF capability in ESs where the operational group is monitored by the LAG. [Figure 31: AC failure in VPLS 2 on PE-2 has no impact on DF election](#) shows the situation with the AC-DF disabled (**ac-df-capability exclude**): the PEs ignore the AD per-EVI withdrawal and PE-2 remains the DF for VPLS 2.

Figure 31: AC failure in VPLS 2 on PE-2 has no impact on DF election

37576

VPLS 2 traffic is dropped by PE-2, but the other services are not impacted.

Configuration

Figure 32: Example topology shows the example topology with four PEs in an EVPN-MPLS network.

Figure 32: Example topology

37577

The initial configuration includes:

- cards, MDAs, ports
- router interfaces on the PEs and on MTU-6

- IS-IS on the router interfaces (alternatively, OSPF can be configured)
- LDP on the router interfaces

On the PEs, BGP is configured for the EVPN address family. In this example, PE-2 is the Route Reflector (RR) with the following BGP configuration:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
        cluster {
          cluster-id 192.0.2.2
        }
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
      neighbor "192.0.2.4" {
        group "internal"
      }
      neighbor "192.0.2.5" {
        group "internal"
      }
    }
  }
}
```

The BGP configuration on the clients PE-3, PE-4, and PE-5 is as follows:

```
# on PE-3, PE-4, PE-5:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
      }
      neighbor "192.0.2.2" {
        group "internal"
      }
    }
  }
}
```

```
}

```

AC-DF capability enabled – default

On PE-2 and PE-3, operational group "op-grp-sa-es-23" is configured. This operational group is assigned to the single-active ES "SA-ESI-23" and monitored on LAG 1.

On PE-2, LAG 1 is configured as follows. The LAG configuration on PE-3 is similar, but with port 1/1/1 instead.

```
# on PE-2:
configure {
  lag "lag-1" {
    admin-state enable
    encap-type dot1q
    mode access
    # standby-signaling lacp      # default
    monitor-oper-group "op-grp-sa-es-23"
    max-ports 64
    lacp {
      mode active
      system-id 00:00:00:00:23:01
      administrative-key 1
    }
    port 1/1/2 {
    }
  }
}
```

On PE-2 and PE-3, three VPLS services are configured with SAPs from LAG 1, which is associated with single-active ES "SA-ESI-23". This ES is configured with the operational group "op-grp-sa-es-23" that is monitored by LAG 1. The operational group triggers the LACP standby signaling from the NDF PE to CE-1 to avoid attracting traffic.

The service configuration on PE-2 and PE-3 is similar; only the preference value for the service carving in the ES is different.

Note:

When an operational group is associated with an ES, the hold timers for the operational group must be zero (the default value).

```
# on PE-2:
configure {
  service {
    oper-group "op-grp-sa-es-23" {
      hold-time {
        ## down # default 0
        up 0
      }
    }
  }
  system {
    bgp {
      evpn {
        ethernet-segment "SA-ESI-23" {
          admin-state enable
          esi 01:00:00:00:00:23:01:00:00:01
          multi-homing-mode single-active
          oper-group "op-grp-sa-es-23"
          # ac-df-capability include      # default
          df-election {

```

```

    }
}
}

```

With the AC-DF capability enabled (default), the PEs send ES routes with **AC:1** in the extended community for DF election. The following ES route is received by PE-3 from PE-2:

```

10 2022/06/08 15:38:15.005 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
    Withdrawn Length = 0

```

```

  Flag: 0xc0 Type: 16 Len: 16 Extended Community:
  df-election::DF-Type:Preference/DP:1/DF-Preference:200/AC:1
  target:00:00:00:00:23:01
```

The remainder of the chapter focuses on PE-2 and PE-3, where an AC failure in one of the services can have an impact on the other services using the same LAG.

DF election

PE-2 is the highest-preference PE in the ES and becomes the DF (preference value 200 on PE-2 versus preference value 100 on PE-3). In case of equal preference value between PE-2 and PE-3, the Don't Preempt (DP) bit is the tiebreaker (DP = 1 for non-revertive wins over DP = 0); if that is also a tie, the lowest PE IP address is the tiebreaker.

The following command shows that PE-2 is the DF for all three VPLSs. The candidate list contains both PE-2 and PE-3 for each of these VPLSs.

```

		1/1/2	up	active	down		1	-	32768

AD per-EVI route withdrawal

A failure is simulated by disabling SAP lag-1:2 in VPLS 2 on PE-2:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 2" {
      sap lag-1:2 {
        admin-state disable
      }
    }
  }
}
```

PE-2 withdraws the EVPN-AD per-EVI route. The following withdrawal is received by PE-3:

```
77 2022/06/08 15:44:59.536 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
```

```
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 69
  Flag: 0x90 Type: 15 Len: 65 Multiprotocol Unreachable NLRI:

=====
```

All traffic can take either LAG port, but PE-2 only forwards traffic for VPLS 1 and VPLS 3, while PE-3 only forwards traffic for VPLS 2. Traffic from VPLS 1 or VPLS 3 via port 1/1/2 to PE-3 is dropped by PE-3 because it is the NDF for VPLS 1 and VPLS 3. VPLS 2 traffic via LAG port 1/1/1 to PE-2 is dropped because SAP lag-1:2 is down (failure). This means that approximately 50% of the traffic is lost.

Potential loss on a single service under maintenance is acceptable but affecting other services on the same node is not acceptable. The solution is to disable the AC-DF capability.

AC-DF capability disabled

The default use of the AC-DF capability in SR OS is disabled on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "SA-ESI-23" {
            ac-df-capability exclude
          }
        }
      }
    }
  }
}
```

With AC-DF disabled, ES routes contain AC:0 in the DF-election extended community, as follows:

```
# on PE-3:
142 2022/06/08 15:54:10.390 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:

  4 Orig-IP-Addr: 192.0.2.2
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
      df-election::DF-Type:Preference/DP:1/DF-Preference:200/AC:0
      target:00:00:00:00:23:01
"
```

With the AC-DF capability disabled, the withdrawal of EVPN-AD routes does not influence the DF election. In this example, PE-2 remains the DF for all services, including VPLS 2, even when traffic for that service

is dropped by PE-2. The following command shows that the DF candidate list on PE-3 contains six entries: even for VPLS 2, PE-2 is included in the list. PE-3 is the NDF for all three services.

```

Conclusion

By default, the AC-DF capability is enabled. Disabling the AC-DF capability is recommended in ESs that use an operational group monitored by the access LAG to signal standby LACP or power-off.

ARP-ND Host Routes in Data Centers

This chapter provides information about ARP-ND Host Routes in Data Centers.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

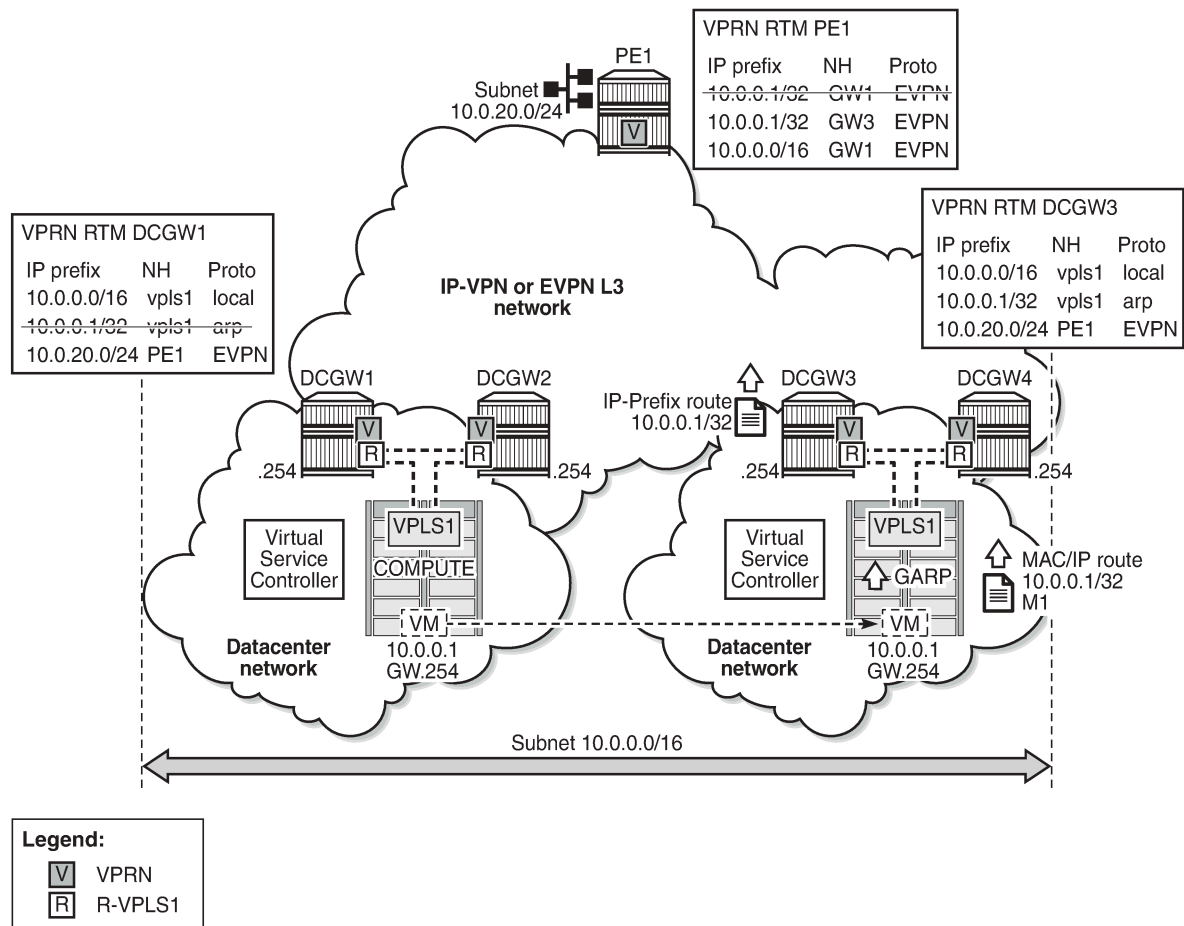

This chapter was initially written based on SR OS Release 16.0.R1, but the MD-CLI in the current edition is based on SR OS Release 21.10.R3. Address Resolution Protocol - Neighbor Discovery (ARP-ND) host routes in VPRN and base router interfaces are supported in SR OS Release 15.0.R6 and later, but Nokia recommends using the feature in SR OS Release 15.0.R9, or later.

Chapters [EVPN for MPLS Tunnels](#), [EVPN for VXLAN Tunnels \(Layer 2\)](#), [EVPN for VXLAN Tunnels \(Layer 3\)](#), and [EVPN for MPLS Tunnels in Routed VPLS](#) are prerequisite reading.

Overview

Inter-subnet forwarding (or simply routing) for a tenant domain in a Data Center (DC) must be efficient and avoid forwarding over the same path as arriving, known as tromboning or hairpinning. [Figure 33: L2 broadcast domain extension across DCs](#) shows an L2 broadcast domain (VPLS 1) extended across two DCs. This example is used to explain the requirement of upstream and downstream efficiency.

Figure 33: L2 broadcast domain extension across DCs

27644

In [Figure 33: L2 broadcast domain extension across DCs](#), subnet 10.0.0.0/16 is extended across two DCs and four DC Gateways (DCGWs), using VPLS 1 or R-VPLS 1 in the network nodes. The DCGWs are connected to the users of subnet 10.0.20.0/24 on PE1 via IP-VPN (or EVPN). In this scenario, there are two network characteristics that allow an efficient upstream and downstream routing:

- Anycast gateways
- ARP-ND host routes

Anycast Gateways provide upstream routing efficiency for the hosts connected to subnet 10.0.0.0/16, regardless of the DCGW to which they are connected. For example, if host 10.0.0.1 is in DC-1 and needs to forward traffic to subnet 10.0.20.0, DCGW1 and DCGW2 should be able to route the traffic upstream, without the need to go to DCGW3 or DCGW4. In the same way, if host 10.0.0.1 moves to DC-2, the upstream traffic to subnet 10.0.20.0 must be routed by the local DCGWs without changing the existing host default gateway IP and MAC configuration. To achieve this local default gateway routing, all the DCGWs of the extended broadcast domain need to have the same IP and MAC addresses in the R-VPLS interface (Integrated Routing and Bridging (IRB) interface in industry-standard terminology).

Anycast Gateways are implemented in SR OS by using passive VRRP. See [EVPN for MPLS Tunnels in Routed VPLS](#) for more information about passive VRRP.

ARP-ND host routes learning and advertising are required to provide an efficient downstream routing from remote subnets to the hosts in the extended broadcast domain. Assuming virtual machine VM 10.0.0.1 (in [Figure 33: L2 broadcast domain extension across DCs](#)) is connected to DC-1 (left-side DC), when PE1 needs to send traffic to host 10.0.0.1, it will do a Longest Prefix Match (LPM) lookup on the VPRN route table. If the only IP prefix advertised by the four DCGWs were 10.0.0.0/16, PE1 could send the packets to a DC where the VM is not present. This would result in unnecessary tromboning; for example, PE1 could send the traffic to DCGW3, then DCGW3 would send it to DCGW2 to get to VM 10.0.0.1. However, PE1 could have forwarded directly to DCGW2.

To provide efficient downstream routing to the DC where the VM is located, DCGW1 and DCGW2 need to generate host routes for the VMs to which they are attached. Furthermore, when the VM moves to the other DC, DCGW3 and DCGW4 must be able to learn the VM host route and advertise it to PE1. Also, DCGW1 and DCGW2 will have to withdraw the route for 10.0.0.1, because the VM is no longer in the local DC.

To address this and other use cases, SR OS can learn the VM host route from the ARP or ND messages that it generates when it boots or when it moves. The host route can also be learned from EVPN routes type 2 (MAC/IP routes) that are installed in the ARP/ND caches, or in general, any ARP/ND entry can generate an ARP/ND host route.

A route owner type called "ARP-ND" is supported in the base router or a VPRN route table. The ARP-ND host routes have a preference of 1 and they are automatically created out of the ARP or ND Neighbor entries in the router instance. [Figure 34: ARP-ND module and generated ARP-ND host routes](#) shows how the ARP/ND software modules can generate ARP-ND host routes in the route table.

Figure 34: ARP-ND module and generated ARP-ND host routes

When `configure>service>vprn/ies>interface>ipv4>neighbor-discovery>host-route>populate [static | dynamic | evpn]` is enabled, the static, dynamic, and EVPN ARP entries of the routing context will create ARP-ND host routes in the route table. In the same way, ARP-ND host routes are created in the IPv6 route table out of static, dynamic, and EVPN neighbor entries, if `configure>service>vprn/ies>interface>ipv6>neighbor-discovery>host-route>populate[static | dynamic | evpn]` is enabled.

[Figure 34: ARP-ND module and generated ARP-ND host routes](#) shows how the ARP/ND module populates its database from the usual dynamic and static entries, as well as from EVPN routes type 2 that include an IP address. Through the host-route learning action, ARP-ND host routes are handed over to the route table.

[Figure 34: ARP-ND module and generated ARP-ND host routes](#) also shows that the preference assigned to ARP-ND host routes is 1, which means that ARP-ND routes will be preferred over any other route owner, except for direct routes. For example, if the same host route gets to the route table from ARP-ND and VPN-IPv4 or EVPN, the ARP-ND host route will be preferred and added to the route table. Although they are added to the route table and advertised to routing protocols, ARP-ND host routes are never installed in the FIB. That helps preserve the FIB scale in the router.

The **neighbor-discovery>host-route>populate [static | dynamic | evpn]** commands are typically used along with other features:

- A route tag can be added to ARP-ND hosts by the command **route-tag**. This tag can be matched on BGP **vrf-export** and peer export policies.
- The ARP-ND host route will be kept in the route table while the corresponding ARP or Neighbor entry is active. The command **proactive-refresh** helps keep the entries active (even if there is no traffic destined to them) by sending an ARP refresh 30 seconds before the **timeout** or starting Neighbor Unreachable Detection (NUD) when the **stale-time** expires.
- To speed up the learning of the ARP-ND host routes, the command **learn-unsolicited** can be configured. When **learn-unsolicited** is enabled, received unsolicited ARP messages (typically, Gratuitous Address Resolution Protocol (GARP) messages) create an ARP entry, and therefore an ARP-ND route if **ipv4>neighbor-discovery>host-route>populate [static | dynamic | evpn]** is added. Similarly, unsolicited Neighbor Advertisement messages will create a "stale" neighbor. If **ipv6>neighbor-discovery>host-route>populate [static | dynamic | evpn]** is enabled, a confirmation message (NUD) is sent for all the neighbor entries created as stale, and, if confirmed, the corresponding ARP-ND routes are added to the route table.

In the example of [Figure 33: L2 broadcast domain extension across DCs](#), **ipv4>neighbor-discovery>host-route>populate [static | dynamic | evpn]** on the DCGWs allows them to learn/advertise the ARP-ND host route 10.0.0.1/32 when the VM is locally connected, and remove/withdraw it when the VM is no longer present in the local DC.

The following sections describe three typical DC scenarios in which the use of Anycast gateways and ARP-ND host routes is needed. The examples are focused on IPv4 and ARP; however, there is equivalent functionality for IPv6 and ND.

Configuration

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as an IGP

The following three scenarios are configured and presented in this document:

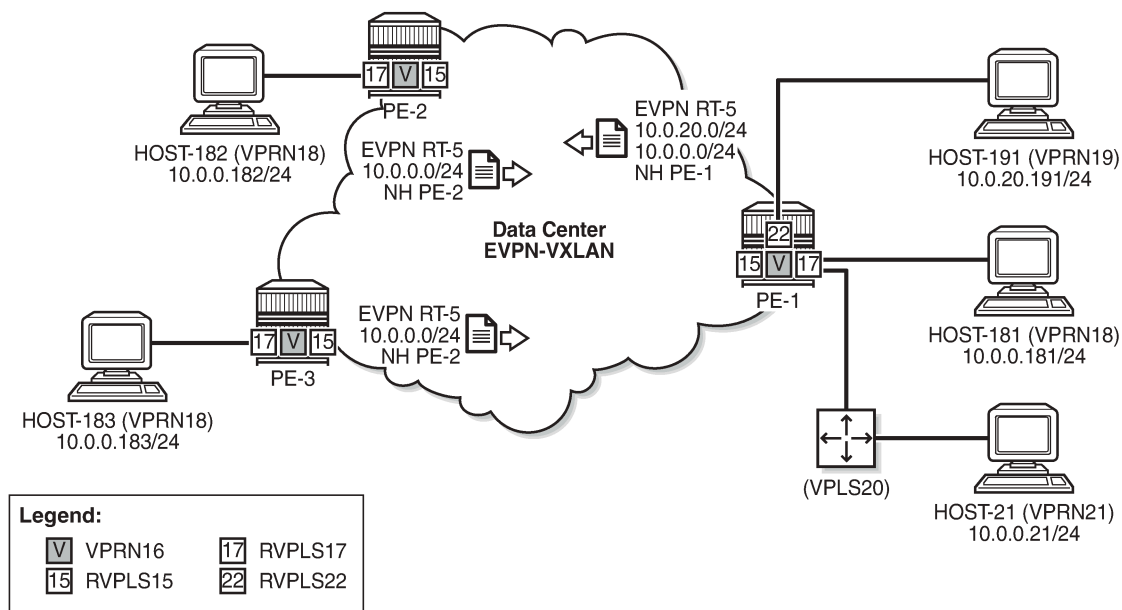

- DC inter-subnet forwarding with Anycast GWs (and no ARP-ND hosts)
- DC inter-subnet forwarding with Anycast GWs and ARP-ND hosts
- Data Center Interconnect (DCI) inter-subnet forwarding with Anycast GWs and ARP-ND hosts

DC inter-subnet forwarding with Anycast GWs

Figure 35: DC inter-subnet forwarding with Anycast GWs shows a typical DC network, where PE-1, PE-2, and PE-3 are leaf switches that use EVPN-VXLAN services to provide connectivity between two subnets of a tenant domain. Those two subnets are 10.0.0.0/24 and 10.0.20.0/24, respectively, and while the three PEs are attached to hosts in the 10.0.0.0/24 subnet, only PE-1 is attached to the 10.0.20.0/24 subnet. Subnet 10.0.0.0/24 uses R-VPLS 17 in the three PEs and subnet 10.0.20.0/24 uses R-VPLS 22 in PE-1. The distribution of the R-VPLS services does not have to be uniform in all the PEs, and those R-VPLS services are only created if there are hosts attached to them.

To provide inter-subnet forwarding for the tenant, each PE must be configured with a VPRN instance (VPRN 16) that has an interface to the subnet R-VPLS. In industry-standard terms, VPRN 16 represents the IP-VRF for the tenant, and R-VPLS 17 and R-VPLS 22 are user Broadcast Domains (BDs). R-VPLS 15 is not a user BD, but rather a backhaul R-VPLS that provides EVPN connectivity among the VPRN instances.

Figure 35: DC inter-subnet forwarding with Anycast GWs

27646

The BGP configuration in the PEs is similar. As an example, the BGP configuration in PE-1 is as follows:

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        evpn true
      }
    }
    rapid-update {
```

```

        evpn true
    }
    group "dc" {
        type internal
    }
    neighbor "192.0.2.2" {
        group "dc"
    }
    neighbor "192.0.2.3" {
        group "dc"
    }
}

```

PE-2 has the following service configuration. The service configuration on PE-3 is similar.

```

# on PE-2:
configure {
    service {
        vpls "sbd-15" {
            admin-state enable
            description "R-VPLS 15"
            service-id 15
            customer "1"
            vxlan {
                instance 1 {
                    vni 15
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 15
                routes {
                    mac-ip {
                        advertise false
                    }
                    ip-prefix {
                        advertise true
                    }
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            ecmp 2
            interface "evi-15" {
                mac 00:00:00:00:00:02
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
            interface "evi-17" {
                ipv4 {
                    primary {

```

```

        address 10.0.0.2
        prefix-length 24
    }
    vrrp 1 {
        backup [10.0.0.254]
        passive true
        ping-reply true
        traceroute-reply true
    }
}
vpls "evi-17" {
}
}

vpls "evi-17" {
    admin-state enable
    description "R-VPLS 17"
    service-id 17
    customer "1"
    vxlan {
        instance 1 {
            vni 17
        }
    }
    routed-vpls {
    }
    bgp 1 {
    }
    bgp-evpn {
        evi 17
        vxlan 1 {
            admin-state enable
            vxlan-instance 1
        }
    }
    sap pxc-10.a:17 {
    }
}
}

```

R-VPLS 17, "evi-17" in the configuration, is the BD used by subnet 10.0.0.0/24 in all the PEs. On the evi-17 interface in VPRN 16, a real IP address as well as a virtual (passive VRRP) IP address are configured. The real IP address is a unique address across the three PEs in R-VPLS 17 (10.0.0.2 in PE-2). This IP address will not be used by the R-VPLS 17 hosts as a default gateway, but rather will be used for troubleshooting purposes (ICMP or similar).

The backup IP address in the passive VRRP instance (10.0.0.254) is the Anycast Gateway IP address, and the same IP address is configured in all the PEs attached to R-VPLS 17. Because the virtual MAC is auto-derived from the VRRP instance, all the PEs will also have the same virtual MAC for this Anycast Gateway:

```

All the hosts attached to R-VPLS 17, such as host-181, host-182, and host-183, are configured with the Anycast Gateway as default gateway (10.0.0.254). The use of passive VRRP (or Anycast Gateway in standard terminology) has the following benefits:

- All the hosts use the same default gateway configuration, regardless of what PE they are attached to.
- When the hosts send traffic destined to a remote subnet, the local PE can route it directly, without any tromboning.
- In the case of a host moving to a different leaf switch, the host does not need to change its IP or default gateway, or even its ARP cache.

For completeness, the service configuration in PE-1 follows:

```

# on PE-1:
configure {
    service {
        vpls "sbd-15" {
            admin-state enable
        }
    }
}

```

See the [EVPN for VXLAN Tunnels \(Layer 3\)](#) for more information about the EVPN-related configuration in the R-VPLS services. When there is no need for a recursive resolution of the EVPN IP prefix routes to a MAC/IP route, **mac-ip>advertisement false** is configured in the R-VPLS 15, compared to the examples in [EVPN for VXLAN Tunnels \(Layer 3\)](#).

With the described configuration, as an example, the intra-subnet and inter-subnet forwarding connectivity from host-182 is tested (host-182 is simulated with VPRN "VM-test-anycast-gw" that is connected to R-VPLS 17 via PXC SAP):

```

[/]
A:admin@PE-2# traceroute 10.0.0.183 router-instance "VM-test-anycast-gw"
                                     source-address 10.0.0.182
traceroute to 10.0.0.183 from 10.0.0.182, 30 hops max, 40 byte packets
 1 10.0.0.183 (10.0.0.183)  6.61 ms  3.90 ms  3.79 ms

```

```
[/]
```

```
A:admin@PE-2# traceroute 10.0.20.191 router-instance "VM-test-anycast-gw"
                                                    source-address 10.0.0.182
traceroute to 10.0.20.191 from 10.0.0.182, 30 hops max, 40 byte packets
 1 10.0.0.2 (10.0.0.2)    1.71 ms  2.31 ms  2.34 ms
 2 10.0.20.1 (10.0.20.1) 3.09 ms  4.56 ms  2.99 ms
 3 10.0.20.191 (10.0.20.191) 3.91 ms  3.85 ms  3.78 ms
```

When host-182 sends traffic to host-191, it will ARP for the Anycast Gateway IP and will receive the virtual MAC as a reply. The virtual MAC is always associated with the local CPM on the local PE; therefore, the local PE can always route the traffic directly while it has a route for the IP destination.

Host-182 (VPRN 18) resolves the Anycast Gateway to the virtual MAC:

```
[/]
A:admin@PE-2# show router 18 arp 10.0.0.254

=====
ARP Table (Service: 18)
=====
IP Address      MAC Address      Expiry      Type      Interface
-----
10.0.0.254     00:00:5e:00:01:01 03h59m18s  Dyn[I]  local
=====
```

In PE-2, the virtual MAC is associated with a local IP interface:

```
[/]
A:admin@PE-2# show service id 17 fdb mac 00:00:5e:00:01:01

=====

DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes

While the configuration shown in the preceding section is common in DCs, there is a variation that eliminates the flooding among PEs that are attached to the same BD, typically caused by ARP messages and ND. The configuration described in this section is recommended only if all the following conditions are met:

- All the hosts are directly connected to the leaf switches (PEs in [Figure 35: DC inter-subnet forwarding with Anycast GWs](#)).
- All the hosts announce themselves by issuing a GARP (or unsolicited NA for IPv6) whenever they boot up or move to a different leaf switch.

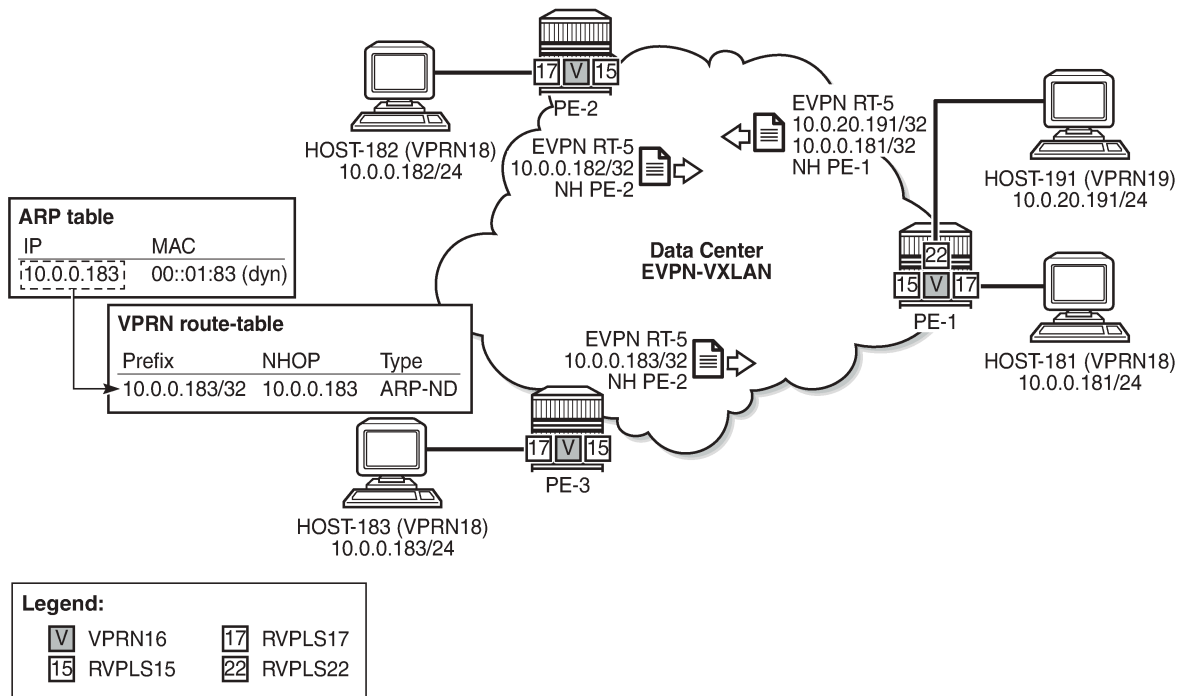

Note: This is the case for virtual machines.

- All the traffic among hosts is IP unicast or non-IP unicast (if the hosts are in the same BD), and there is no Broadcast, Unknown unicast, or Multicast (BUM) traffic from the hosts in the tenant domain, other than ARP/ND.

If the preceding conditions are true, the ARP-ND host route feature can help eliminate BUM traffic completely.

[Figure 36: DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes](#) shows the scenario used in this section.

Figure 36: DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes

27647

Compared to the configuration used in the preceding section, VPRN 16 is modified in the three PEs as follows (changes in **neighbor-discovery** context):

```
# on PE-2:
configure {
  service {
    vprn "ip-vrf-16" {
      admin-state enable
      service-id 16
      customer "1"
      ecmp 2
      interface "evi-15" {
        mac 00:00:00:00:00:02
        vpls "sbd-15" {
          evpn-tunnel {
          }
        }
      }
    }
    interface "evi-17" {
      mac 00:00:00:00:00:2e:17
      ipv4 {
        primary {
          address 10.0.0.2
          prefix-length 24
        }
        neighbor-discovery {
          timeout 300
          learn-unsolicited true
          proactive-refresh true
          remote-proxy-arp true
          host-route {
            populate static {
            }
            populate dynamic {
            }
            populate evpn {
            }
          }
        }
      }
      vrrp 1 {
        backup [10.0.0.254]
        passive true
        ping-reply true
        traceroute-reply true
      }
    }
    vpls "evi-17" {
    }
  }
}
```

```
# on PE-3:
configure {
  service {
    vprn "ip-vrf-16" {
      admin-state enable
      service-id 16
      customer "1"
      ecmp 2
      interface "evi-15" {
        mac 00:00:00:00:00:00:03
        vpls "sbd-15" {
          evpn-tunnel {
          }
        }
      }
    }
  }
}
```

```
    }  
  }  
  interface "evi-17" {  
    mac 00:00:00:00:3e:17  
    ipv4 {  
      primary {  
        address 10.0.0.3  
        prefix-length 24  
      }  
      neighbor-discovery {  
        timeout 300  
        learn-unsolicited true  
        proactive-refresh true  
        remote-proxy-arp true  
        host-route {  
          populate static {  
          }  
          populate dynamic {  
          }  
          populate evpn {  
          }  
        }  
      }  
    }  
    vrrp 1 {  
      backup [10.0.0.254]  
      passive true  
      ping-reply true  
      traceroute-reply true  
    }  
  }  
  vpls "evi-17" {  
  }  
}
```

```
# on PE-1:  
configure {  
  service {  
    vprn "ip-vrf-16" {

            traceroute-reply true
        }
    }
    vpls "evi-22" {
    }
}
}

```

The behavior due to the added commands in the **neighbor-discovery** context is as follows:

- **host-route>populate [static | dynamic | evpn]** makes the router create an ARP-ND host route per ARP entry in the route table of VPRN "ip-vrf-16".
- **learn-unsolicited** makes the router learn ARP entries for the hosts out of the GARP messages that they send when they boot up or move. Without this command, ARP entries are only created after the router receives packets with the host as the destination, issues an ARP request, and the host replies to this solicited ARP request.
- **proactive-refresh** makes the router refresh every dynamic ARP entry even if there is no traffic destined to the owner. Without the command, host IP addresses will not be maintained in the ARP cache unless they receive traffic from remote hosts.

- **timeout 300** is the timeout selected in this example (in seconds). The ARP timeout has an impact on how often the router will try to refresh an entry (30 seconds before the timeout expires). In environments where the hosts are subject to mobility (VMs moving between leaves), having a shorter ARP timeout will speed up the removal of the old ARP entry, that is, the old ARP-ND host route entry. However, in scaled environments with tens of thousands of ARP entries, Nokia does not recommend lowering the ARP timeout under 10 minutes.
- **remote-proxy-arp** allows the router to reply to any ARP request looking for an IP address in the same subnet as the source, with its virtual MAC (00:00:5e:00:01:01), and route the traffic, as long as there is a route for the destination in the route table.

In addition, the following command will be executed in the three PEs:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    vpls "evi-17" {
      bgp-evpn {
        routes {
          incl-mcast {
            advertise-ingress-replication false
          }
        }
      }
    }
  }
}
```

By disabling the advertisement of the Inclusive Multicast Ethernet Tag (IMET) route in R-VPLS 17, the PEs will not create a VXLAN BUM destination among each other, preventing the exchange of BUM traffic. Only known unicast traffic can be now exchanged in the context of R-VPLS 17. The three PEs will show VXLAN destinations that have Mcast "-", as opposed to "BUM":

```
[/]
A:admin@PE-3# show service id 17 vxlan destinations

```

With the described configuration, when the hosts boot up and generate a GARP message, the ARP entries will be created, and subsequently ARP-ND hosts and EVPN IP-prefix advertisements for them. The host

bootup is simulated by disabling and re-enabling the VPRN that emulates the host. As an example, some debug commands are used to see the behavior when host-181 boots up and sends a GARP:

```

1 2022/02/21 16:47:36.844 CET MINOR: DEBUG #2001 vprn18 PIP
"PIP: ARP
instance 2 (18), interface index 4 (local),
ARP egressing on local
  Who has 10.0.0.181 ? Tell 10.0.0.181
"

2 2022/02/21 16:47:36.845 CET MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 5 (16), interface index 8 (evi-17),
ARP ingressing on evi-17
  Who has 10.0.0.181 ? Tell 10.0.0.181
"

4 2022/02/21 16:47:36.845 CET MINOR: DEBUG #2001 vprn21 PIP
"PIP: ARP
instance 4 (21), interface index 6 (local),
ARP ingressing on local
  Who has 10.0.0.181 ? Tell 10.0.0.181
"

```

The GARP creates an ARP entry and, subsequently, an ARP-ND host route in the route table of VPRN 16. Host-181 MAC/IP and IP-prefix routes are advertised too:

```

3 2022/02/21 16:47:36.845 CET MINOR: DEBUG #2001 vprn16 PIP

A side effect of this scenario is that traffic between hosts in the same BD (R-VPLS "evi-17") is routed instead of switched. This can be shown on the traceroute from host-181 to host-182 (there are three hops instead of two), or the TTL on the ping packets (62 instead of 64):

```
[/]
A:admin@PE-1# traceroute 10.0.0.182 router-instance "H-181" source-address 10.0.0.181
traceroute to 10.0.0.182 from 10.0.0.181, 30 hops max, 40 byte packets
 1 10.0.0.1 (10.0.0.1)  1.53 ms  2.37 ms  2.42 ms
 2 10.0.0.2 (10.0.0.2)  3.42 ms  3.26 ms  3.29 ms
 3 10.0.0.182 (10.0.0.182)  3.80 ms  3.54 ms  3.76 ms
```

```
[/]

```

This extension of a subnet across a pure routing domain is compliant with the virtual subnet concept described in RFC 7814.

DCI inter-subnet forwarding with Anycast GWs and ARP-ND hosts

[Figure 37: DCI inter-subnet forwarding with Anycast GWs and ARP-ND host routes](#) shows a DCI scenario where the use of Anycast GWs, ARP-ND hosts, and some additional configuration provide efficient inter-subnet forwarding within the tenant domain.

Figure 37: DCI inter-subnet forwarding with Anycast GWs and ARP-ND host routes

27648

In this example, VPLS 10 is extended across DC-1 and DC-2, via PE-4 and PE-5 (which are DC GWs). PE-4 and PE-5 are also connected to the WAN and use IP-VPN for inter-subnet forwarding connectivity to the remote host-6. In this network, PE-4 and PE-5 provide the Anycast GW functionality to host-2 and host-3, so that they can move between the two DCs without having to change their IP/MAC/default GW or ARP cache, and efficient upstream forwarding is provided.

PE-4 and PE-5 learn the ARP-ND host route of their respective host and advertise it to the WAN, so that downstream routing from PE-6 can be efficient and without tromboning.

To avoid unnecessary ARP flooding between DCs, proxy-ARP is used in PE-2 and PE-3. The configuration of VPLS 10 in the PE-2 and PE-3 is as follows:

```
# on PE-2:
configure {
  service {
    vpls "centralized-gw-bd" {
      admin-state enable
      service-id 10
      customer "1"
      vxlan {
        instance 1 {
          vni 10
        }
      }
    }
    proxy-arp {
      admin-state enable
      dynamic-populate true
      send-refresh 120
      evpn {
```

The two PEs also include the **proxy-arp>evpn>route-tag 1** command. This command allows the proxy-ARP module to tag the routes when sent to BGP for advertisement of a MAC/IP route with non-zero IP. In this example, the tag is used in an export policy to add a Site-Of-Origin (SOO) extended community to the MAC/IP routes with non-zero IP. This, for example, allows PE-4 to accept MAC/IP routes from its own DC-1 and drop MAC/IP routes from DC-2 so that PE-4 only advertises ARP-ND host routes attached to DC-1. Vice versa for PE-5. The MAC/IP routes with zero-IP (that are also sent for every MAC) will not be tagged with the SOO and, therefore, will be imported by all the PEs in VPLS 10. This allows normal L2 connectivity among the four PEs, while the ARP-ND routes are only generated for the local hosts.

On PE-2, BGP is configured with the export policy "export-add-SOO" and import policy "import-prefer-DC-1", as follows:

```
# on PE-2:
configure {
  policy-options {
    community "S00-DC-1" {
      member "origin:64500:1" { }
    }
    policy-statement "export-add-S00" {
      entry 10 {
        from {
          tag 1
        }
        action {
          action-type accept
          community {
            add ["S00-DC-1"]
          }
        }
      }
    }
    policy-statement "import-prefer-DC-1" {
      entry 10 {
        from {
          community {
            name "S00-DC-1"
          }
        }
        action {
          action-type accept
          local-preference 200
        }
      }
    }
  }
}
router "Base" {
  autonomous-system 64500
  bgp {
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    family {

}

```

As an example, the following show commands prove that PE-2 does not add an SOO to MAC/IP routes with zero-IP, but it does add SOO-DC-1 for MAC/IP routes with non-zero IP:

```

[/]
A:admin@PE-2# show router bgp routes evpn mac rd 192.0.2.2:10 hunt

```

The VPLS 10 configuration on PE-4 and the corresponding import policy to drop non-local SOO follow. PE-5 has a similar configuration (not shown), including the same RD 64500:10 in VPLS 10 as PE-4. The policy will drop routes tagged with SOO-DC-1 instead of SOO-DC-2.

```

# on PE-4:
configure {
  service {
    vpls "centralized-gw-bd" {
      admin-state enable
      service-id 10
      customer "1"
    }
  }
}

```

```
    vxlan {
        instance 1 {
            vni 10
        }
    }
    routed-vpls {
    }
    bgp 1 {
        route-distinguisher "64500:10"
    }
    bgp-evpn {
        evi 10
        vxlan 1 {
            admin-state enable
            vxlan-instance 1
        }
    }
}
```

On PE-4, the BGP configuration is as follows:

```
# on PE-4:
configure {
    policy-options {
        community "S00-DC-1" {
            member "origin:64500:1" { }
        }
        community "S00-DC-2" {
            member "origin:64500:2" { }
        }
    }
    policy-statement "export-add-S00" {
        entry 10 {
            from {
            }
            action {
                action-type accept
                community {
                    add ["S00-DC-1"]
                }
            }
        }
    }
    policy-statement "import-drop-DC-2" {
        entry 10 {
            from {
                community {
                    name "S00-DC-2"
                }
            }
            action {
                action-type reject
            }
        }
    }
}
router "Base" {
    autonomous-system 64500
    bgp {
        vpn-apply-export true
        vpn-apply-import true
        rapid-withdrawal true
        family {
            ipv4 false
        }
    }
}
```

```

        vpn-ipv4 true
        vpn-ipv6 true
        evpn true
    }

        group "dc"
    }
    neighbor "192.0.2.3" {
        group "dc"
    }
    neighbor "192.0.2.5" {
        group "wan"
    }
    neighbor "192.0.2.6" {
        group "wan"
    }
}

```

There is another aspect for which policies are used: on PE-2 and PE-3, two MAC/IP routes with the Anycast GW virtual MAC are received (one from PE-4 and another from PE5). To provide efficient upstream routing with no tromboning, it is important that PE-2 prefers the PE-4 virtual MAC route (its own DGW) over that of PE-5, and vice versa for PE-3. This is achieved by:

- Configuring the same RD on PE-4 and PE-5 for VPLS10.
- Configuring an import policy on PE-2 and PE-3 that modifies the local preference of the routes, so that each one prefers the local DGW.

PE-2 and PE-3 could have dropped the routes from the non-local DCGW, but with this configuration, DCGW redundancy is provided in case of failure:

```

[/]
A:admin@PE-2# show router policy plcy-name "import-prefer-DC-1"
  entry 10
    from
      community "S00-DC-1"
    exit
    action accept
      local-preference 200
    exit
  exit

```

```

[/]

                backup [10.0.0.254]
                passive true
                ping-reply true
                traceroute-reply true
            }
        }
        vpls "centralized-gw-bd" {
        }
    }
}

```

The passive VRRP commands, as well as the ARP commands, have already been discussed in preceding sections. The only new command in the configuration is **route-tag 1**. This command tags all the ARP-ND host routes learned on the interface, so that export policies can match on that tag and modify the routes before they are advertised. The command is included for completeness, however, in this configuration, there is no export policy using this tag.

When the configuration is in place and the hosts are connected, the FDBs, proxy-ARP, ARP caches, and route tables are checked with the following commands (example for host-2 and host-6).

When host-2 ARPs for its default gateway (10.0.0.254), PE-2 will reply with the information from its proxy-ARP table:

```
[/]

=====
```

If PE-4 receives packets with MAC Destination Address (DA) equal to the virtual MAC and IP DA of host-6 (172.16.0.6), the forwarding is based on the information in the R-VPLS FDB first, and afterward on the VPRN 11 route table, as follows.

```
[/]
A:admin@PE-4# show service id 10 fdb mac 00:00:5e:00:01:01

=====

```

Traceroute commands from host-6 provide information about the path to each remote host (VPRN 12 in PE-6 simulates host-6):

```

[/]
A:admin@PE-6# traceroute 10.0.0.2 router-instance "CE-PE-6"
traceroute to 10.0.0.2, 30 hops max, 40 byte packets
 1 172.16.0.254 (172.16.0.254)  1.85 ms 2.30 ms 2.26 ms
 2 10.0.0.4 (10.0.0.4)         3.38 ms 3.20 ms 5.66 ms
 3 10.0.0.2 (10.0.0.2)        4.80 ms 4.41 ms 4.73 ms

```

```

[/]
A:admin@PE-6# traceroute 10.0.0.3 router-instance "CE-PE-6"
traceroute to 10.0.0.3, 30 hops max, 40 byte packets
 1 172.16.0.254 (172.16.0.254)  1.55 ms 2.34 ms 2.28 ms
 2 10.0.0.5 (10.0.0.5)         3.53 ms 3.58 ms 3.43 ms
 3 10.0.0.3 (10.0.0.3)        7.18 ms 5.05 ms 4.74 ms

```

Communication between host-2 and host-3 uses regular L2 switching, as expected, because there are EVPN-VXLAN destinations created between PE-2 and PE-3 for VPLS 10:

```

[/]
A:admin@PE-2# show service id 10 vxlan destinations

```

Troubleshooting and debugging

The following commands can be used when troubleshooting these scenarios:

- **show router <id> route table** and **show router <id> fib <id>** (and their corresponding commands for IPv6)
- **show router <id> arp / neighbor**
- **show service <id> fdb detail**
- **show service <id> proxy-arp/nd detail**
- **show router bgp routes evpn / vpn-ipv4 / vpn-ipv6**

The following debug commands—in classic CLI—are also important to analyze the scenarios:

```
debug
  router "Base"
    bgp
      update
    exit
  exit
  router service-name "ip-vrf-16"
    ip
      arp
      route-table
    exit
  exit
  router service-name "VM-test-anycast-gw"
    ip
      arp
    exit
  exit
  service
    id 10
      proxy-arp
      all
    exit
  exit
  exit
exit
```

Conclusion

ARP-ND host routes are generated out of ARP-ND entries in a router context. These ARP-ND host routes, along with passive VRRP (for Anycast GWs), provide the correct solution for efficient inter-subnet forwarding in DCs and DCI networks.

Auto-Learn MAC Protect in EVPN

This chapter provides information about Auto-Learn MAC Protect in EVPN.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R5, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. Auto-Learn MAC Protect (ALMP) is supported for EVPN in SR OS Release 14.0.R1, and later.

Overview

MAC protection is needed in Layer 2 services to safeguard business-critical MAC addresses against the possibility of being learned on the wrong SAP/SDP-binding. When a MAC address is learned on the wrong SAP/SDP-binding, traffic would be diverted from its intended destination. This could be caused by misconfiguration or by a malicious source launching a Denial of Service (DoS) attack. MAC protect can also be used to prevent loops in certain topologies.

Chapter [EVPN for VXLAN Tunnels \(Layer 2\)](#) describes MAC protection for static MAC addresses that are configured on SAPs or spoke-SDPs. The command to configure static MAC addresses in a VPLS service is as follows:

```
*[ex:configure service vpls "1" fdb static-mac]
A:admin@PE-4# mac ?

[mac-address] <unicast-mac-address-no-zero>
<unicast-mac-address-no-zero> - <xx:xx:xx:xx:xx:xx>

Static MAC address to SAP/SDP-binding or black-hole
```

Configuring static MAC addresses is not scalable if large numbers of MAC addresses need to be protected. Also, configuring static MAC addresses is not an option when the MAC addresses are unknown. Auto-Learn MAC Protect (ALMP) offers the same protection for learned MAC addresses in services such as EVPN VPLS and EVPN R-VPLS. However, ALMP is not supported for PBB-EVPN.

ALMP can be enabled with the **auto-learn-mac-protect** command in EVPN with VXLAN or MPLS bindings on the following:

- SAPs
- Mesh-SDPs
- Spoke-SDPs
- Pseudowire (PW) templates

- Split Horizon Groups (SHGs)
- SHGs in PW templates

When enabled, all MAC addresses learned on those objects become protected.

The following commands can be used to enable ALMP on objects in VPLS 1:

```
configure {
  service {
    pw-template "PW1" {
      fdb {
        auto-learn-mac-protect true
      }
    }
    vpls "VPLS 1" {
      split-horizon-group "SHG1" {
        fdb {
          saps {
            auto-learn-mac-protect true
          }
        }
      }
      spoke-sdp 23:1 {
        fdb {
          auto-learn-mac-protect true
        }
      }
      mesh-sdp 24:1 {
        fdb {
          auto-learn-mac-protect true
        }
      }
      sap 1/2/1:1 {
        fdb {
          auto-learn-mac-protect true
        }
      }
    }
  }
}
```

When enabled on an SHG, it is only applicable to the SAPs within the SHG, not to spoke-SDPs. If ALMP is required on spoke-SDPs in the SHG, the parameter must be configured on each spoke-SDP individually. All MAC Source Addresses (SAs) learned on these objects will be protected and advertised with the sticky bit set. The sticky bit indicates that these MAC addresses should be treated as protected on the remote PEs, where these protected MAC addresses are considered to have been learned on the EVPN MPLS/VXLAN destinations. The remote EVPN peers then use the MAC protection functionality in the same way as the local peer to protect the MAC address.

By default, ALMP enables an implicit **protected-src-mac-violation-action discard** (restrict protected source discard frame (RPS-DF)) on SAPs and spoke/mesh-SDPs. When enabled, frames with a protected MAC SA are discarded if received on objects where they were not learned and protected. This configuration is the default and cannot be configured on objects where MAC addresses are learned, such as SAPs, spoke/mesh-SDPs, and SHGs.

However, protected-src-mac-violation-action discard can optionally be configured on destinations in EVPN MPLS or EVPN VXLAN, where data plane MAC learning is never performed for incoming traffic. The only configurable protected source MAC violation action is discard; it is not an option to bring down the entire EVPN destination. For EVPN MPLS, this configuration is in the BGP EVPN context, as follows:

```
*[ex:configure service vpls "VPLS 1" bgp-evpn mpls 1 fdb]
A:admin@PE-2# protected-src-mac-violation-action ?
```

```
protected-src-mac-violation-action <keyword>
<keyword> - discard

Action when a relearn request for a protected MAC is received
```

```
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mpls 1 {
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
    }
  }
}
```

For EVPN VXLAN, this configuration is in the VXLAN context, as follows:

```
*[ex:configure service vpls "VPLS 1" vxlan instance 1 fdb]
A:admin@PE-2# protected-src-mac-violation-action ?

protected-src-mac-violation-action <keyword>
<keyword> - discard

Action when a relearn request for a protected MAC is received
```

```
configure {
  service {
    vpls "VPLS 1" {
      vxlan {
        instance 1 {
          vni 1
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
    }
  }
}
```

Instead of discarding the frame, the SAP or spoke/mesh-SDP can be brought operationally down when a frame is received with a protected MAC SA that has not been learned on the object, by configuring **protected-src-mac-violation-action sap-oper-down** or **sdp-bind-oper-down** on the object in EVPN services. After the object has been brought down, an operator needs to disable and re-enable the object in order to make it operational again.

The protected source MAC violation action can be configured as **sap-oper-down** on SAPs and SHGs, or **sdp-bind-oper-down** on spoke/mesh-SDPs, and PW templates, but not on EVPN MPLS/VXLAN destinations, using following commands:

```
configure {
  service {
    pw-template "PW1" {
      fdb {
        auto-learn-mac-protect true
        protected-src-mac-violation-action sdp-bind-oper-down
      }
    }
    pw-template "PW2" {
      split-horizon-group {
        name "SHG1"
        fdb {
          saps {
```

```

        auto-learn-mac-protect true
        protected-src-mac-violation-action sap-oper-down
    }
}
}
vpls "VPLS 1" {
    split-horizon-group "SHG1" {
        fdb {
            saps {
                auto-learn-mac-protect true
                protected-src-mac-violation-action sap-oper-down
            }
        }
    }
    spoke-sdp 23:1 {
        fdb {
            auto-learn-mac-protect true
            protected-src-mac-violation-action sdp-bind-oper-down
        }
    }
    mesh-sdp 24:1 {
        fdb {
            auto-learn-mac-protect true
            protected-src-mac-violation-action sdp-bind-oper-down
        }
    }
    sap 1/2/1:1 {
        fdb {
            auto-learn-mac-protect true
            protected-src-mac-violation-action sap-oper-down
        }
    }
}
}

```

Note:

The configuration of protected-src-mac-violation-action alarm-only is not allowed in BGP-EVPN.

Protection is provided at the point where a MAC address first enters the EVPN part of the network. Therefore, the preference for an auto-learned protected MAC address is higher than that of a MAC address received in a BGP update with the sticky bit set.

The following list shows the MAC learning priority, with the highest priority first:

1. Local MAC address (including AS-MAC without static-black-hole, es-bmac, src-bmac, OAM, and so on)
2. Conditional static MAC address (including AS-MAC with static-black-hole)
3. **Auto-learn protected MAC address**
4. EVPN MAC address with sticky/static bit set
5. Data plane learned MAC address (regular learning on SAP/SDP-binding)
6. EVPN MAC address without sticky/static bit set

Note:

ALMP MAC addresses have a higher priority but do not overwrite EVPN static MAC addresses.

Configuration

Figure 38: Example topology - no LAG shows the example topology with one MTU and three PEs.

Figure 38: Example topology - no LAG

26313

- Cards, MDAs
- The ports between the PEs are configured as network ports; the other ports are access ports. No LAG is configured initially.
- IGP (IS-IS is used in this example) between the PEs
- LDP between the PEs
- BGP with address family EVPN on the PEs

PE-2 is the BGP route reflector. The BGP configuration on the PEs is similar. The BGP configuration on the clients PE-3 and PE-4 is as follows:

```
# on PE-3, PE-4:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
      }
      neighbor "192.0.2.2" {
        group "internal"
      }
    }
  }
}
```

VPLS 1 is configured on all nodes. Initially, ALMP is disabled. On MTU-1, the VPLS 1 contains three SAPs: one toward CE-10, one toward PE-2, and one toward PE-3.

On PE-2, VPLS 1 is configured with EVPN MPLS and contains a SAP toward CE-20 and a SAP toward MTU-1, as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        mpls 1 {
          admin-state enable
          ingress-replication-bum-label true
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
    sap 1/2/1:1 {
    }
    sap 1/2/3:1 {
    }
  }
}
```

On PE-3, VPLS 1 is configured with EVPN MPLS and contains a SAP toward MTU-1, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        mpls 1 {
          admin-state enable
          ingress-replication-bum-label true
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
    sap 1/2/3:1 {
    }
  }
}
```

The following use cases will be described in this section:

- EVPN MPLS without multi-homing.
 - Default behavior: no ALMP on SAPs, no protected MAC addresses
 - No ALMP on SAPs, RPS-DF on EVPN MPLS destinations

- ALMP and implicit RPS-DF on SAPs.
 - RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2
 - RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
 - No RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
- ALMP and RPS on SAPs.
 - RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2
 - RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
 - No RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
- EVPN MPLS with ALMP in all-active multi-homing.
 - RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations

Default behavior: no protected MAC addresses

The following example is not a recommended configuration because it causes a loop. By default, ALMP is disabled and no static MAC addresses are configured. As described in chapter [EVPN for VXLAN Tunnels \(Layer 2\)](#), duplicate MAC addresses are detected in BGP EVPN and the MAC address will be put in a hold-down state on the EVPN destinations after a configurable threshold is reached. This applies to EVPN-MPLS as well as to EVPN-VXLAN. By default, the maximum number of MAC address moves is five in a time window of 3 minutes.

[Figure 39: MAC address learned simultaneously on SAPs on PE-2 and PE-3](#) shows that the MAC address from CE-10 is learned simultaneously on the SAPs in VPLS 1 on PE-2 and PE-3.

Figure 39: MAC address learned simultaneously on SAPs on PE-2 and PE-3

26314

CE-10 sends frames to CE-20 with MAC Destination Address (DA) aa:aa:02:20:20:20. MTU-1 has not learned that MAC DA, so the frames are flooded to PE-2 and PE-3, where they enter the SAPs

simultaneously. PE-2 and PE-3 have not learned the MAC DA either, so the frames are flooded to all potential destinations. The frames received on PE-2 will be sent (among others) to PE-3, and vice versa. These frames are forwarded back out of the SAP toward MTU-1. This causes a loop.

Both PEs send a BGP update for the MAC SA aa:aa:01:10:10:10 to the other PEs with no sticky bit set. That MAC SA is learned, but not protected on the destination to the other PE. The stream of frames will cause the learned MAC SA to oscillate between the SAP and EVPN destinations on PE-2 and PE-3, and between the EVPN destinations on PE-4.

After a configurable number of BGP EVPN MAC address moves in a time span (by default, after five MAC address moves in a period of 3 minutes), the MAC address is put in a hold-down state on the EVPN destinations for a specific duration (until the next MAC address duplication detection retry; by default, after 9 minutes).

The following message in log 99 on PE-2 (and also on PE-3) indicates that duplicate MAC addresses have been detected:

```
77 2021/03/23 09:42:59.410 CET MINOR: SVCMGR #2331 Base
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

The following shows the settings for EVPN MAC address duplication detection, which are the default. It also lists the detected duplicate MAC addresses of CE-10 and CE-20:

```
[/]
A:admin@PE-3# show service id 1 bgp-evpn

=====

```

By default, there is no protected source MAC violation action on the EVPN destinations (**RestProtSrcMacAct : none**).

The MAC addresses are in a hold-down state on the EVPN destinations and no MAC address moves take place until the next MAC address duplication detection retry after 9 minutes. After 9 minutes, the EVPN MAC address duplication alarm is cleared, but after the next five MAC address moves within a time span of 3 minutes, the alarm is raised again and this threshold is reached soon after the alarm has been cleared.

The MAC addresses of both CEs are learned on the SAP of PE-3 (CE-20's MAC address is also learned on the SAP toward MTU-1), not on the EVPN destinations, because of the MAC address duplication detection and hold-down state in EVPN, as follows:

```

[/]
A:admin@PE-3# show service id 1 fdb detail

```

PE-3 does not use these BGP EVPN MAC address routes in its FDB, because locally learned MAC addresses are preferred.

The remote PE (PE-4) received the following BGP EVPN MAC routes from PE-2 and PE-3:

```

[/]
A:admin@PE-4# show router bgp routes evpn mac

In the preceding output, MAC aa:aa:01:10:10:10 is learned from BGP peer 192.0.2.3 with MAC mobility sequence number 3, and from BGP peer 192.0.2.2 with sequence number 4. MAC aa:aa:02:20:20:20 is learned from BGP peer 192.0.2.2 with sequence number 4 and from BGP peer 192.0.2.3 with sequence number 5. The FDB for VPLS 1 on PE-4 contains the MAC addresses learned from BGP EVPN MAC updates with the highest MAC mobility sequence number, as follows:

```

[/]
A:admin@PE-4# show service id 1 fdb detail

VPLS 1 on MTU-1 does not have EVPN configured and no MAC address duplication detection mechanism implemented. The MAC address from CE-10 is last learned on the SAP toward PE-2 (it might equally have been the SAP toward PE-3) instead of the SAP toward CE-10, resulting from the loop, as follows:

```

[/]
A:admin@MTU-1# show service id 1 fdb detail

=====
Forwarding Database, Service 1
=====

```

ServId	MAC Transport:Tnl-Id	Source-Identifier	Type Age	Last Change

=====

```

No ALMP on SAPs, RPS-DF on EVPN destinations

When there are no protected MAC addresses (ALMP is disabled and no static MAC addresses are configured), the behavior is as described earlier. RPS-DF discards frames with protected MAC addresses that were not learned on the object, but there are no protected MAC addresses, because ALMP is not configured. RPS-DF does not discard frames with MAC SAs that are not protected.

RPS-DF is enabled on EVPN destinations on all PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mpls 1 {
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
    }
  }
}
```

The state of RPS is now "discard-frame" instead of "none", as follows:

```
[/]
A:admin@PE-3# show service id 1 bgp-evpn | match RestProtSrcMacAct
RestProtSrcMacAct : Discard-frame
```

It is also allowed to configure RPS (**protected-src-mac-violation-action sap-oper-down**) on the SAPs, but that does not change the behavior when ALMP is disabled and there are no protected MAC addresses. RPS will not bring down a SAP after receiving a frame with an unprotected MAC SA.

ALMP and implicit RPS-DF on SAPs

ALMP is enabled on the SAPs in PE-2 as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/1:1 {          # SAP toward CE-20
        fdb {
          auto-learn-mac-protect true
        }
      }
      sap 1/2/3:1 {        # SAP toward MTU-1
        fdb {
          auto-learn-mac-protect true
        }
      }
    }
  }
}
```

The configuration is similar on PE-3.

The following shows that ALMP is enabled on the SAP and that the default RPS-DF is used:

```
[/]
A:admin@PE-2# show service id 1 sap 1/2/3:1 detail
=====
```

```

Service Access Points(SAP)
=====

---snip---

```

ALMP and RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2

Initially, the SAP on PE-3 is disabled to ensure that the MAC address will first be learned on PE-2, then on PE-3, as follows:

```

# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/3:1 {          # SAP toward MTU-1
        admin-state disable
      }
    }
  }
}

```

Each learned MAC address on the SAPs on PE-2 will be protected; therefore, a BGP update with the static/sticky bit set will be sent to the BGP EVPN peers. In this example, the MAC aa:aa:01:10:10:10 of CE-10 is learned first on SAP 1/2/3:1 on PE-2, and MAC aa:aa:02:20:20:20 is learned on SAP 1/2/1:1 on PE-2. Consequently, PE-2 sends BGP updates with the static/sticky bit set to PE-3 for both MAC aa:aa:01:10:10:10 and MAC aa:aa:02:20:20:20, as follows:

```

95 2021/03/23 09:55:45.486 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

Flag: 0xc0 Type: 16 Len: 24 Extended Community:
  target:64500:1
  bgp-tunnel-encap:MPLS
  mac-mobility:Seq:0/Static
"
```

Note:

The MPLS label is label1 in the BGP update divided by 16 (2⁴), as follows:

$$\frac{8388544}{16} = 524284$$

PE-2 sends similar BGP EVPN updates to peer PE-4.

After these BGP EVPN updates have been sent to PE-3 (and PE-4), the SAP on PE-3 is enabled again, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/3:1 { # SAP toward MTU-1
        admin-state enable
      }
    }
  }
}
```

The MAC addresses in the FDB on PE-2, where these MAC addresses are learned, get the indication "L" for learned and "P" for protected MAC address, as follows:

```
[/]
A:admin@PE-2# show service id 1 fdb detail

```

The BGP EVPN MAC routes on PE-4 are similar.

When a stream of frames with MAC SA aa:aa:01:10:10:10 enters the SAP on PE-3, these frames will be dropped by this SAP because of the implicit RPS-DF behavior in the SAP for protected MAC addresses, as shown in [Figure 40: Default RPS-DF on SAPs - MAC learned and protected on SAP on PE-2](#).

Figure 40: Default RPS-DF on SAPs - MAC learned and protected on SAP on PE-2

26315

Because the MAC address was protected on the SAP on PE-2 and the BGP EVPN MAC route update had been received by PE-3 before any frame was received with this MAC SA, there will be no temporary loop. The frames with the protected MAC SA will be discarded at the SAP on PE-3, not on the EVPN MPLS destination on PE-2. In this case, there is no need to configure RPS-DF on the EVPN MPLS destinations, but it will make a difference when the MAC address is learned on both SAPs simultaneously.

ALMP and RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

In the preceding example, the MAC addresses of CE-10 and CE-20 were first learned and protected on PE-2 and received on PE-3's SAP after the BGP update with static/sticky bit was received by PE-3. However, when the MAC address of CE-10 is learned simultaneously on both PEs, for example, because the MAC DA aa:aa:02:20:20:20 is unknown, there is a temporary loop until the MAC addresses are protected. Initially, the frames enter a SAP, are forwarded to the EVPN peer, and forwarded out of the remote SAP.

After the MAC addresses are learned and protected on the SAPs on both PEs, new frames received on a SAP with the protected MAC address will be sent to the other PE. However, they will be discarded due to RPS-DF on destination, as shown in [Figure 41: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints](#), because the destination PE has that same MAC address protected on its local SAP. This prevents a loop. BGP updates with the static/sticky bit set are sent to the BGP EVPN peer, but the locally learned and protected MAC address is preferred to the MAC address in a BGP update. Therefore, the FDB contains the locally learned MAC address aa:aa:01:10:10:10, not the BGP EVPN MAC address update for MAC address aa:aa:01:10:10:10.

Figure 41: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints

26316

The MAC addresses of the CEs are cleared from the FDBs on all nodes, as follows:

```
clear service id 1 fdb mac aa:aa:01:10:10:10
clear service id 1 fdb mac aa:aa:02:20:20:20
```

This clear command for the FDB only works for auto-learned MAC addresses, not for BGP EVPN MAC address updates. BGP EVPN MAC address withdraw updates need to be sent. In this example, BGP is configured with **rapid-update evpn**, as shown previously.

When traffic is sent from CE-10 to CE-20, MAC address aa:aa:01:10:10:10 of CE-10 is learned simultaneously on SAP 1/2/3:1 in PE-2 and PE-3 and protected on both SAPs. MAC address aa:aa:02:20:20:20 is, in this case, first learned via MAC address learning on PE-2 and advertised via a BGP EVPN MAC address route update. However, it might happen that it was learned and protected on the SAP on PE-3 first, before the MAC address was learned and protected on PE-2 and the BGP EVPN

MAC address route update sent by PE-2 was received at PE-3. In the latter case, both MAC address aa:aa:01:10:10:10 and MAC address aa:aa:02:20:20:20 are learned and protected on the SAPs on both PE-2 and PE-3, and RPS-DF on the EVPN-MPLS destinations prevents loops.

However, in the present case, MAC address aa:aa:02:20:20:20 is only protected on the SAP on PE-2, because PE-3 received the EVPN MAC address update before it received a frame with MAC SA aa:aa:02:20:20:20. Therefore, the SAP on PE-3 will discard any frames with MAC SA aa:aa:02:20:20:20.

The FDB for VPLS 1 on PE-2 shows that both MAC addresses are learned locally and protected, as follows:

```
[/]
A:admin@PE-2# show service id 1 fdb detail

=====
```

PE-4 received BGP EVPN MAC address route updates from PE-2 and PE-3, but only installs the MAC address routes to PE-2 in its FDB, based on the lowest next-hop IP of the EVPN NLRI (192.0.2.2).

ALMP and RPS-DF on SAPs, no RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

RPS-DF is disabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mpls 1 {
          fdb {
            delete protected-src-mac-violation-action
          }
        }
      }
    }
  }
}
```

When a frame is received at SAP 1/2/3:1 on PE-3 with protected MAC SA aa:aa:01:10:10:10, it is not dropped by the SAP, because this MAC SA has been learned and protected on this SAP on PE-3. The frame is forwarded to PE-2 where it will not be discarded by the EVPN MPLS destination because RPS-DF is disabled. The frame will be forwarded to other objects in the VPLS in PE-2. For BUM traffic, there will be a loop, because all frames will be flooded to all objects in VPLS 1 on PE-2, including the SAP toward MTU-1.

ALMP and RPS on SAPs

When ALMP is enabled on an object, the default behavior is that frames with a protected MAC SA are discarded (RPS-DF). However, it is possible to configure RPS with **sap-oper-down** (or **sdp-bind-oper-down**), in this case on the SAPs on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/3:1 {
        fdb {
          protected-src-mac-violation-action sap-oper-down
        }
      }
    }
  }
}
```

Instead of discarding frames with MAC SAs that are protected on another object or node, the entire object (here: SAP) can be brought operationally down after a frame has been received with a MAC SA that is protected on another node.

The RPS configuration on the SAP can be shown as follows. The SAP has not been brought down yet.

```
[/]
A:admin@PE-2# show service id 1 sap "1/2/3:1" detail

=====
Service Access Points(SAP)
=====
Service Id       : 1
SAP              : 1/2/3:1           Encap           : q-tag
Description     : (Not Specified)
Admin State     : Up                Oper State      : Up
Flags           : None
---snip---

Restr MacUnpr Dst : Disabled
Auto Learn Mac Prot: Enabled
ALMP Exclude List : <none>
RestMacProtSrc Act : SAP-oper-down
---snip---
```

The **RestMacProtSrc Act** parameter is set to **SAP-oper-down**, meaning that RPS is configured, which causes the system to bring down the SAP when a duplicate MAC address is received that is protected on another object or node. When a SAP is brought down because of this, the **RxProtSrcMAC** flag will be raised and can be shown in the detailed SAP show output.

ALMP and RPS on SAPs, RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2

RPS-DF is enabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mpls 1 {
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
    }
  }
}
```

To simulate a scenario where the MAC addresses are first learned on PE-2, the SAP on PE-3 is disabled until the BGP EVPN MAC route updates are sent, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/3:1 {
        admin-state disable
      }
    }
  }
}
```

The FDBs are cleared on the nodes, as follows:

```
clear service id 1 fdb mac aa:aa:01:10:10:10
clear service id 1 fdb mac aa:aa:02:20:20:20
```

Traffic is sent between CE-10 and CE-20, and the MAC addresses are learned and protected on the SAP on PE-2, as follows:

```
[/]

ALMP and RPS on SAPs, RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

When CE-10 sends traffic to CE-20 and the destination MAC address is unknown, MAC address aa:aa:01:10:10:10 is simultaneously learned and protected on PE-2 and PE-3. No SAP will be brought down when MAC address aa:aa:01:10:10:10 is received on PE-2 or PE-3. This scenario is identical to the one with ALMP and (default) RPS-DF on the SAPs, as shown in [Figure 43: RPS enabled on SAPs - RPS-DF on EVPN endpoints, MACs learned simultaneously](#) (which is identical to [Figure 41: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints](#)).

Figure 43: RPS enabled on SAPs - RPS-DF on EVPN endpoints, MACs learned simultaneously

26316

A temporary loop is possible until the MAC address is protected on the SAPs. Initially, the frames enter the SAP, are forwarded to the other PEs, and are forwarded out of the other SAP (unless the MAC address is protected). When the MAC address is protected, any other frames received on the SAP will be sent to the other PE (for example, from PE-3 to PE-2, or vice versa), but they will be discarded by the receiving PE, because RPS-DF is applied on the EVPN destination. BGP EVPN updates are sent to the peer PEs

with the sticky bit set. This MAC route will not be installed in the FDB of PE-2 and PE-3 because the MAC address has already been learned locally, which has a higher preference.

The FDB on PE-2 contains locally learned and protected MAC addresses, as follows:

```
[/]
A:admin@PE-2# show service id 1 fdb detail

=====
Forwarding Database, Service 1

      Transport:Tnl-Id
-----
1           aa:aa:01:10:10:10  sap:1/2/3:1       LP/0      03/23/21 10:09:54
1           aa:aa:02:20:20:20  mpls:             EvpnS:P   03/23/21 10:09:54
                        192.0.2.2:524284
                        ldp:65537
-----
No. of MAC Entries: 2
-----
Legend:  L=Learned O=0am P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
```

SAP 1/2/3:1 will not be brought down if frames are received with MAC address aa:aa:01:10:10:10 that is locally learned and protected. However, MAC address aa:aa:02:20:20:20 was learned and protected first on PE-2 and the BGP update was received by PE-3 before the MAC address was received on PE-3. Therefore, MAC address aa:aa:02:20:20:20 will not be learned and protected on PE-3 and, if frames with a MAC SA aa:aa:02:20:20:20 were received on SAP 1/2/3:1 on PE-3, the SAP would be brought down.

ALMP and RPS on SAPs, no RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

RPS-DF is disabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure {
  service {
```

```

vpls "VPLS 1" {
  bgp-evpn {
    mpls 1 {
      fdb {
        delete protected-src-mac-violation-action
      }
    }
  }
}

```

When frames are received at SAP 1/2/3:1 on PE-3 with protected MAC SA aa:aa:01:10:10:10, the SAP is not brought down, because this MAC SA has been learned and protected on this SAP. The frame is forwarded to PE-2 where it will not be discarded by the EVPN MPLS destination because RPS-DF is disabled. It will be forwarded to other objects in the VPLS. For BUM traffic, there will be a loop, because the frames will be flooded to all objects, including the SAP on PE-2 toward MTU-1.

ALMP in all-active multi-homing SAPs

All-active multi-homing for EVPN MPLS is explained in chapter [EVPN for MPLS Tunnels](#). ALMP is not required on all-active multi-homing SAPs. The following example shows that traffic can be dropped when ALMP is enabled on the SAPs and RPS-DF is enabled on the EVPN-MPLS destinations.

Figure 44: ALMP in all-active multi-homing SAPs shows the example topology for all-active multi-homing.

Figure 44: ALMP in all-active multi-homing SAPs

26318

VPLS is configured with SAP lag-1:1 on the three nodes in the topology, as follows:

```

# on MTU-1, PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap lag-1:1 {
      }
    }
  }
}

```

The SAPs used in the preceding scenarios are removed.

All-active multi-homing is configured on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-12" {
            admin-state enable
            esi 01:00:00:00:00:23:00:00:00:01
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
            }
          }
        }
      }
    }
  }
}
```

ALMP is enabled on the SAPs on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap lag-1:1 {
        fdb {
          auto-learn-mac-protect true
        }
      }
    }
  }
}
```

MAC address aa:aa:01:10:10:10 is learned and protected on PE-2 and PE-3, as follows:

```

ALMP in all-active multi-homing, RPS-DF on EVPN MPLS destinations

ALMP is not recommended in all-active multi-homing because it can cause traffic loss. The following example shows when frames are dropped.

Figure 45: All-active multi-homing - RPS-DF on SAPs and EVPN endpoints shows the example setup with MAC address aa:aa:01:10:10:10 protected on SAP lag-1:1 on both PE-2 and PE-3, and RPS-DF enabled on the EVPN endpoints.

Figure 45: All-active multi-homing - RPS-DF on SAPs and EVPN endpoints

26319

When frames with MAC address aa:aa:01:10:10:10 are sent between PE-2 and PE-3, these frames will be dropped by the EVPN MPLS destination that has RPS-DF enabled.

The traffic flows from CE-10 and CE-20 are hashed over both links in the LAG. When the frames are sent out on MTU-1 on port 1/1/1 toward PE-2, the traffic reaches CE-20, and traffic can be sent back from CE-20 to CE-10 via the direct link between PE-2 and MTU-1. However, when traffic is sent out from MTU-1 on port 1/1/2 toward PE-3, the frames will be forwarded from PE-3 to PE-2, where they will be discarded at the EVPN MPLS destination on PE-2 because of RPS-DF. No traffic flow is possible for frames with the protected MAC SA aa:aa:01:10:10:10 via PE-3 to PE-2, or vice versa. If the MAC address is not protected yet on PE-2, the first few messages get through until the MAC address is protected on PE-2. Both multi-homing PEs, PE-2 and PE-3, protect the MAC address aa:aa:01:10:10:10 on their local all-active SAP.

Therefore, PE-2 discards all frames with the MAC SA aa:aa:01:10:10:10 when they are received on the EVPN MPLS destination from the other multi-homing PE (PE-3).

An improved mechanism for EVPN loop protection in all-active multi-homing is black-hole MAC duplication, as described in chapter [Black-hole MAC for EVPN Loop Protection](#).

For single-active multi-homing, this problem does not arise: only the designated forwarder in the Ethernet segment receives and forwards traffic. Therefore, the CE MAC addresses will not be learned and protected on different PEs in the same Ethernet segment.

Conclusion

For security, MAC addresses learned on objects, such as SAPs, spoke/mesh-SDPs, and SHGs in EVPN services can be protected and advertised by BGP with the sticky bit set. By default, frames with a protected MAC SA are discarded if received on objects where the MAC address was not learned. Objects can be configured to be brought operationally down when a frame is received with a protected MAC SA that has not been learned locally.

BGP Multi-Homing for VPLS Networks

This chapter describes BGP Multi-Homing (BGP-MH) for VPLS network configurations.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

Initially, the information in this chapter was based on SR OS Release 8.0.R5, with additions for SR OS Release 9.0.R1. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports the use of Border Gateway Protocol Multi-Homing for VPLS (hereafter called BGP-MH). BGP-MH is described in *draft-ietf-bess-vpls-multihoming, BGP based Multi-homing in Virtual Private LAN Service*, and provides a network-based resiliency mechanism (no interaction from the Provider Edge routers (PEs) to Multi-Tenant Units/Customer Equipment (MTU/CE)) that can be applied on service access points (SAPs) or network (pseudowires) topologies. The BGP-MH procedures will run between the PEs and will provide a loop-free topology from the network perspective (only one logical active path will be provided per VPLS among all the objects SAPs or pseudowires which are part of the same Multi-Homing site).

Each multi-homing site connected to two or more peers is represented by a site ID (2 bytes long) which is encoded in the BGP MH Network Layer Reachability Information (NLRI). The BGP peer holding the active path for a particular multi-homing site will be named as the Designated Forwarder (DF), whereas the rest of the BGP peers participating in the BGP MH process for that site will be named as non-DF and will block the traffic (in both directions) for all the objects belonging to that multi-homing site.

BGP MH uses the following rules to determine which PE is the DF for a particular multi-homing site:

1. A BGP MH NLRI with D flag = 0 (multi-homing object up) always takes precedence over a BGP MH NLRI with D flag = 1 (multi-homing object down). If there is a tie, then:
2. The BGP MH NLRI with the highest BGP Local Preference (LP) wins. If there is a tie, then:
3. The BGP MH NLRI issued from the PE with the lowest PE ID (system address) wins.

The main advantages of using BGP-MH as opposed to other resiliency mechanisms for VPLS are:

- **Flexibility:** BGP-MH uses a common mechanism for access and core resiliency. The designer has the flexibility of using BGP-MH to control the active/standby status of SAPs, spoke SDPs, Split Horizon Groups (SHGs) or even mesh SDP bindings.
- The standard protocol is based on BGP, a standard, scalable, and well-known protocol.
- Specific benefits at the access:

- It is network-based, independent of the customer CE and, therefore, it does not need any customer interaction to determine the active path. Consequently, the operator will spend less effort on provisioning and will minimize both operation costs and security risks (in particular, this removes the requirement for spanning tree interaction between the PE and CE).
- Easy load balancing per service (no service fate-sharing) on physical links.
- Specific benefits in the core:
 - It is a network-based mechanism, independent of the MTU resiliency capabilities and it does not need MTU interaction, therefore operational advantages are achieved as a result of the use of BGP-MH: less provisioning is required and there will be minimal risks of loops. In addition, simpler MTUs can be used.
 - Easy load balancing per service (no service fate-sharing) on physical links.
 - Less control plane overhead: there is no need for an additional protocol running the pseudowire redundancy when BGP is already used in the core of the network. BGP-MH just adds a separate NLRI in the L2-VPN family (AFI=25, SAFI=65).

This chapter describes how to configure and troubleshoot BGP-MH for VPLS

Knowledge of the LDP/BGP VPLS (RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, and RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*) architecture and functionality is assumed throughout this chapter. For further information, see the relevant Nokia documentation.

Figure 46: Example topology shows the example topology that will be used throughout the rest of the chapter.

The initial configuration includes:

- IGP — IS-IS, Level 2 on all routers; area 49.0001
- RSVP-TE for transport tunnels
- Fast reroute (FRR) protection in the core; no FRR protection at the access.

Figure 46: Example topology

OSSG600

The topology consists of three core nodes (PE-1, PE-2, and PE-3) and three MTUs connected to the core.

The VPLS service VPLS-500 is configured on the six nodes with the following characteristics:

- The core VPLS instances are connected by a full mesh of BGP-signaled pseudowires (that is, pseudowires among PE-1, PE-2, and PE-3 will be signaled by BGP VPLS).
- As shown in [Figure 46: Example topology](#), the MTUs are connected to the BGP VPLS core by T-LDP pseudowires. MTU-6 is connected to PE-3 by a single pseudowire, whereas MTU-4 and MTU-5 are dual-homed to PE-1 and PE-2. The following resiliency mechanisms are used on the dual-homed MTUs:
 - MTU-4 is dual-connected to PE-1 and PE-2 by an active/standby pseudowire (A/S pseudowire hereafter).
 - MTU-5 is dual-connected to PE-1 and PE-2 by two active pseudowires, one of them being blocked by BGP MH running between PE-1 and PE-2. The PE-1 and PE-2 pseudowires, set up from MTU-5, will be part of the BGP MH site MH-site-2.
 - MTU-4 and MTU-5 are running BGP MH, being SHG site-1 and SAP 1/1/1:8 on MTU-5 part of the same BGP MH site, MH-site-1.
- The CEs are connected to the network in the following way:
 - CE-7, CE-9, and CE-10 are single-connected to the network
 - CE-8 is dual connected to MTU-4 and MTU-5.
 - CE-7 and CE-8 are part of the split-horizon group (SHG) site-1(SAPs 1/1/4:500 and 1/1/3:500 on MTU-4). Assume that CE-7 and CE-8 have a backdoor link between them so that when MTU-5 is elected as DF, CE-7 does not get isolated. This configuration highlights the use of a SHG within a site configuration.

For each BGP MH site, MH-site-1 and MH-site-2, the BGP MH process will elect a DF, blocking the site objects for the non-DF nodes. In other words, based on the specific configuration described throughout the chapter:

- For MH-site-1, MTU-4 will be elected as the DF. The non-DF-MTU-5 will block the SAP 1/1/1:8.
- For MH-site-2, PE-1 will be elected as the DF. The non-DF PE-1 will block the spoke-SDP to MTU-5.

Configuration

This section describes all the relevant configuration tasks for the setup shown in [Figure 46: Example topology](#). The appropriate associated IP/MPLS configuration is out of the scope of this chapter. In this example, the following protocols will be configured beforehand:

- ISIS-TE as IGP with all the interfaces being level-2 (OSPF-TE could have been used instead).
- RSVP-TE as the MPLS protocol to signal the transport tunnels (LDP could have been used instead).
- LSPs between core PEs will be FRR protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.

Note:

The designer can choose whether to protect access link failures by means of MPLS FRR or A/S pseudowire or BGP MH. Whereas FRR provides a faster convergence (around 50ms) and stability (it does not impact on the service layer, therefore, link failures do not trigger MAC flush and flooding), some interim inefficiencies can be introduced compared to A/S pseudowire or BGP MH.

When the IP/MPLS infrastructure is up and running, the specific service configuration including the support for BGP MH can begin.

Global BGP configuration

BGP is used in this configuration guide for these purposes:

1. Exchange of multi-homing site NLRIs and redundancy handling from MTU-5 to the core.
2. Auto-discovery and signaling of the pseudowires in the core, as per RFC 4761.
3. Exchange of multi-homing site NLRIs and redundancy handling at the access for CE-7/CE-8.

A BGP route reflector (RR), PE-3, is used for the reflection of BGP updates corresponding to the preceding uses **1** and **2**.

A direct peering is established between MTU-4 and MTU-5 for use **3**. The same RR could have been used for the three cases, however, like in this example, the designer may choose to have a direct BGP peering between access devices. The reasons for this are:

- By having a direct BGP peering between MTU-4 and MTU-5, the BGP updates do not have to travel back and forth.
- On MTU-4 and MTU-5, BGP is exclusively used for multi-homing, therefore there will not be more BGP peers for either MTUs and a RR adds nothing in terms of control plane scalability.

On all nodes, the autonomous system number must be configured, as follows:

```
# on all nodes:
configure {
  router "Base" {
    autonomous-system 65000
  }
}
```

The following CLI output shows the global BGP configuration required on MTU-4. The 192.0.2.5 address will be replaced by the corresponding peer or the RR system address for PE-1 and PE-2.

```
# on MTU-4:
configure {
  router "Base" {
    autonomous-system 65000
    bgp {
      router-id 192.0.2.4
      rapid-withdrawal true
      family {
        ipv4 false
        l2-vpn true
      }
      rapid-update {
        l2-vpn true
      }
      group "Multi-Homing" {
      }
      neighbor "192.0.2.5" {
        group "Multi-Homing"
        peer-as 65000
      }
    }
  }
}
```

In this example, PE-3 is the BGP RR with clients PE-1 and PE-2, as follows:

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 65000
    bgp {
      router-id 192.0.2.3
      rapid-withdrawal true
      family {
        ipv4 false
        l2-vpn true
      }
      rapid-update {
        l2-vpn true
      }
      group "internal" {
        cluster {
          cluster-id 1.1.1.1
        }
      }
      neighbor "192.0.2.1" {
        group "internal"
        peer-as 65000
      }
      neighbor "192.0.2.2" {
        group "internal"
        peer-as 65000
      }
    }
  }
}
```

Some considerations about the relevant BGP commands for BGP-MH:

- It is required to specify **family l2-vpn** in the BGP configuration. That statement will allow the BGP peers to agree on the support for the family AFI=25 (Layer 2 VPN), SAFI=65 (VPLS). This family is used for BGP VPLS as well as for BGP MH and BGP AD.
- The **rapid-update l2-vpn** statement allows BGP MH to send BGP updates immediately after detecting link failures, without having to wait for the Minimum Route Advertisement Interval (MRAI) to send the updates in batches. This statement is required to guarantee a fast convergence for BGP MH.
- Optionally, **rapid-withdrawal** can also be added. In the context of BGP MH, this command is only useful if a particular multi-homing site is cleared. In that case, a BGP withdrawal is sent immediately without having to wait for the MRAI. A multi-homing site is cleared when the BGP MH site is removed or even the entire VPLS service.

Service level configuration

After the IP/MPLS infrastructure is configured, including BGP, this section shows the configuration required at service level (VPLS-500). The focus is on the nodes involved on BGP MH, that is, MTU-4, MTU-5, PE-1, and PE-2. These nodes are highlighted in [Figure 47: Nodes involved in BGP MH](#).

Figure 47: Nodes involved in BGP MH

OSSG640

Core PE service configuration

The following CLI excerpt shows the service level configuration on PE-1. The import/export policies configured on the PE nodes are identical:

```
# on PE-1:
configure {
  policy-options {
    community "comm_core" {
      member "target:65000:500" { }
    }
    policy-statement "vsi500_export" {
      entry 10 {
        action {
          action-type accept
          community {
            add ["comm_core"]
          }
        }
      }
    }
    policy-statement "vsi500_import" {
      entry 10 {
        from {
          family [l2-vpn]
          community {
            name "comm_core"
          }
        }
        action {
          action-type accept
        }
      }
    }
    default-action {
      action-type reject
    }
  }
}
```

```
}
}
```

The configuration of the SDPs, PW template, and VPLS on PE-1 is as follows:

```
# on PE-1:
configure {
  service {
    pw-template "PW500" {
      pw-template-id 500
      provisioned-sdp use
    }
    sdp 12 {
      admin-state enable
      description "SDP to transport BGP-signaled PWs"
      delivery-type mpls
      path-mtu 8000
      signaling bgp
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-1-PE-2" { }
    }
    sdp 13 {
      admin-state enable
      description "SDP to transport BGP-signaled PWs"
      delivery-type mpls
      path-mtu 8000
      signaling bgp
      far-end {
        ip-address 192.0.2.3
      }
      lsp "LSP-PE-1-PE-3" { }
    }
    sdp 14 {
      admin-state enable
      delivery-type mpls
      path-mtu 8000
      far-end {
        ip-address 192.0.2.4
      }
      lsp "LSP-PE-1-MTU-4" { }
    }
    sdp 15 {
      admin-state enable
      delivery-type mpls
      path-mtu 8000
      far-end {
        ip-address 192.0.2.5
      }
      lsp "LSP-PE-1-MTU-5" { }
    }
  }
  vpls "VPLS-500" {
    admin-state enable
    service-id 500
    customer "1"
    bgp 1 {
      route-distinguisher "65000:501"
      vsi-import ["vsi500_import"]
      vsi-export ["vsi500_export"]
      pw-template-binding "PW500" {
        split-horizon-group "CORE"
      }
    }
  }
}
```

```

    }
    bgp-vpls {
        admin-state enable
        maximum-ve-id 65535
        ve {
            name "501"
            id 501
        }
    }
    spoke-sdp 14:500 {
    }
    spoke-sdp 15:500 {
    }
    bgp-mh-site "MH-site-2" {
        admin-state enable
        id 2
        spoke-sdp 15:500
    }
}

```

The following are general comments about the configuration of VPLS-500:

- As seen in the preceding CLI output for PE-1, there are four provisioned SDPs that the service VPLS-500 will use in this example. SDP 14 and SDP 15 are tunnels over which the T-LDP FEC128 pseudowires for VPLS-500 will be carried (according to RFC 4762), whereas SDP 12 and SDP 13 are the tunnels for the core BGP pseudowires (based on RFC 4761).
- The BGP context provides the general service BGP configuration that will be used by BGP VPLS and BGP MH:
 - Route distinguisher (notation chosen is based on <AS_number:500 + node_id>)
 - VSI export policies are used to add the export route-targets included in all the BGP updates sent to the BGP peers.
 - VSI import policies are used to control the NLRIs accepted in the RIB, normally based on the route targets.
 - Both VSI-export and VSI-import policies can be used to modify attributes such as the Local Preference (LP) that will be used to influence the BGP MH Designated Forwarder (DF) election (LP is the second rule in the BGP MH election process, as previously discussed). The use of these policies will be described later in the chapter.
 - The **pw-template-binding** command maps the previously defined pw-template PW500 to the SHG "CORE". In this way, all the BGP-signaled pseudowires will be part of this SHG. Although not shown in this example, the **pw-template-binding** command can also be used to instantiate pseudowires within different SHGs, based on different import route targets:

Note:

Detailed BGP-VPLS configuration is out of the scope of this chapter. For more information, see chapter [BGP VPLS](#).

```

[ex:configure service vpls "VPLS-500" bgp 1]
A:admin@PE-1# pw-template-binding "PW500" ?

pw-template-binding

apply-groups          - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
bfd-liveness          - Enable BFD

```

```

bfd-template      - BFD template name for PW-Template binding
import-rt         - Import route-target communities
split-horizon-group - Split horizon group

Choice: oper-group-association
monitor-oper-group :- Operational group to monitor
oper-group        :- Operational group
    
```

- The BGP-signaled pseudowires (from PE-1 to PE-2 and PE-3) are set up according to the configuration in the BGP context. Beside those pseudowires, the VPLS-500 also has two more pseudowires signaled by TLDP: spoke-SDP 14:500 (to MTU-4) and spoke-SDP 15:500 (to MTU-5).

The MH site name is defined by a string of up to 32 characters:

```

[ex:configure service vpls "VPLS-500"]
A:admin@PE-1# bgp-mh-site ?

[site-name] <string>
<string> - <1..32 characters>

Name for the specific site
    
```

The general BGP MH configuration parameters for a particular multi-homing site are as follows:

```

[ex:configure service vpls "VPLS-500"]
A:admin@PE-1# bgp-mh-site "MH-site-2" ?

bgp-mh-site

activation-timer - Time that the local sites are in standby status, waiting for
                  BGP updates
admin-state      - Administrative state of the VPLS BGP multi-homing site
apply-groups     - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
boot-timer       - Time that system waits after node reboot and before it runs
                  DF election algorithm
failed-threshold - Threshold for the site to be declared down
id               - ID for the site
min-down-timer  - Minimum downtime for BGP multi-homing site after transition
                  from up to down
monitor-oper-group - Operational group to monitor

Choice: site-object
mesh-sdp-binds  :- Specify if a mesh-sdp-binding is associated with this site
sap             :- SAP to be associated with this site
shg-name        :- Split horizon group to be associated with this site
spoke-sdp       :- SDP to be associated with this site
    
```

Where:

- The site **name** is defined by a string of up to 64 characters.
- The **id** is an integer that identifies the multi-homing site and is encoded in the BGP MH NLRI. This ID must be the same one used on the peer node where the same multi-homing site is connected to. That is, MH-site-2 must use the same site-id in PE-1 and PE-2 (value = 2 in the PE-1 site configuration).
- Out of the four potential objects in a site—spoke SDP, SAP, SHG, and mesh SDP binding—only one can be used at the time on a particular site. To add more than just one SAP/spoke-SDP to the same site, an SHG composed of the SAP/spoke-SDP objects must be used in the site configuration. Otherwise, only one object—spoke SDP, SAP, SHG, or mesh SDP binding—is allowed per site. When a new object is configured in a site, it replaces the previous object in that site.

- The **failed-threshold** command defines how many objects should be down for the site to be declared down. This command is obviously only valid for multi-object sites (SHGs and mesh-SDP bindings). By default, all the objects in a site must be down for the site to be declared as operationally down.

```
[ex:configure service vpls "VPLS-500" bgp-mh-site "MH-site-2"]
A:admin@PE-1# failed-threshold ?

failed-threshold (<number> | <keyword>)
<number> - <1..1000>
<keyword> - all
Default - all
```

Threshold for the site to be declared down

- The **boot-timer** specifies for how long the service manager waits after a node reboot before running the MH procedures. The boot-timer value should be configured to allow for the BGP sessions to come up and for the NLRI information to be refreshed/exchanged. In environments with the default BGP MRAI (30 seconds), it is highly recommended to increase this value (for instance, 120 seconds for a normal configuration). The **boot-timer** is only important when a node comes back up and would become the DF. Default value: 10 seconds.

```
[ex:configure service vpls "VPLS-500" bgp-mh-site "MH-site-2"]
A:admin@PE-1# boot-timer ?

boot-timer <number>
<number> - <0..600> - seconds
```

Time that system waits after node reboot and before it runs DF election algorithm

- The **activation-timer** command defines the amount of time the service manager will keep the local objects in standby (in the absence of BGP updates from remote PEs) before running the DF election algorithm to decide whether the site should be unblocked. The timer is started when one of the following events occurs only if the site is operationally up:
 - Manual site activation by enabling the admin-state at the **id** level or at member objects level (SAPs or pseudowires)
 - Site activation after a failure
 - The BGP MH election procedures will be resumed upon expiration of this timer or the arrival of a BGP MH update for the multi-homing site. Default value: 2 seconds.

```
[ex:configure service vpls "VPLS-500" bgp-mh-site "MH-site-2"]
A:admin@PE-1# activation-timer ?

activation-timer <number>
<number> - <0..100> - seconds
```

Time that the local sites are in standby status, waiting for BGP updates

- When a BGP MH site goes down, it may be preferred that it stays down for a minimum time. This is configurable by the **min-down-timer**. When set to zero, this timer is disabled.

```
[ex:configure service vpls "VPLS-500" bgp-mh-site "MH-site-2"]
A:admin@PE-1# min-down-timer ?

min-down-timer <number>
<number> - <0..100> - seconds
```

Minimum downtime for BGP multi-homing site after transition from up to down

- The **boot-timer**, **activation-timer**, and **min-down-timer** commands can be provisioned at service level or at global level. The service level settings have precedence and override the global configuration. When no timer values are provisioned at global level, the default values apply; when no timer values are provisioned at service level, the timers inherit the global values.

```
[ex:configure redundancy bgp-mh]
A:admin@PE-1# site ?

site

activation-timer    - Time to keep local sites in standby status before running DF
                    election algorithm
boot-timer          - Time that system waits after node reboot and before it runs
                    DF election algorithm
min-down-timer     - Minimum downtime for BGP multi-homing site after transition
                    from up to down
```

- Each site has three possible states:
 - Admin state — controlled by the admin-state command.
 - Operational state — controlled by the operational status of the individual site objects.
 - Designated Forwarder (DF) state — controlled by the BGP MH election algorithm.

The following CLI output shows the three states for BGP MH site "MH-site-1" on MTU-5:

```
[]
A:admin@MTU-5# show service id 500 site MH-site-1

```

On PE-1, MH-site "MH-site-2" is configured with site ID 2 and object spoke-SDP 15:500 (pseudowire established from PE-1 to MTU-5).

The following CLI shows the service configuration for PE-2. The site ID is 2, that is, the same value configured in PE-1. The object defined in PE-2's site is spoke-SDP 25:500 (pseudowire established from PE-2 to MTU-5).

```
# on PE-2:
service {
  pw-template "PW500" {
    pw-template-id 500
    provisioned-sdp use
  }
}
```

```
sdp 21 {
  admin-state enable
  description "SDP to transport BGP-signaled PWS"
  delivery-type mpls
  path-mtu 8000
  signaling bgp
  far-end {
    ip-address 192.0.2.1
  }
  lsp "LSP-PE-2-PE-1" { }
}
sdp 23 {
  admin-state enable
  description "SDP to transport BGP-signaled PWS"
  delivery-type mpls
  path-mtu 8000
  signaling bgp
  far-end {

                ccm true
            }
        }
    }
}

```

MTU-4 is configured with the following characteristics:

- The BGP context provides the general BGP parameters for service 500 in MTU-4. The **route-target** command is now used instead of the vsi-import and vsi-export commands. The intent in this example is to configure only the export and import route-targets. There is no need to modify any other attribute. If the local preference is to be modified (to influence the DF election), a **vsi-policy** must be configured.
- An A/S pseudowire configuration is used to control the pseudowire redundancy towards the core.
- The multi-homing site, MH-site-1 has a site-id = 1 and an SHG as an object. The SHG site-1 is composed of SAP 1/1/1:7 and SAP 1/1/2:8. As previously discussed, the site will not be declared operationally down until the two SAPs belonging to the site are down. This behavior can be changed by the **failed-threshold** command (for instance, in order to bring the site down when only one object has failed even though the second SAP is still up).
- As an example, a Y.1731 MEP with fault-propagation has been defined in SAP 1/1/2:8. As discussed later in the chapter, this MEP will signal the status of the SAP (as a result of the BGP MH process) to CE-8.

The service configuration in MTU-5 is as follows:

```

# on MTU-5:
configure {
    service {
        sdp 51 {
            admin-state enable
            delivery-type mpls
            path-mtu 8000
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-MTU-5-PE-1" { }
        }
        sdp 52 {
            admin-state enable
            delivery-type mpls
            path-mtu 8000
        }
    }
}

```

```

        far-end {
            ip-address 192.0.2.2
        }
        lsp "LSP-MTU-5-PE-2" { }
    }
    vpls "VPLS-500" {
        admin-state enable
        service-id 500
        customer "1"
        bgp 1 {
            route-distinguisher "65000:505"
            route-target {
                export "target:65000:500"
                import "target:65000:500"
            }
        }
        spoke-sdp 51:500 {
        }
        spoke-sdp 52:500 {
        }
        bgp-mh-site "MH-site-1" {
            admin-state enable
            id 1
            sap 1/1/1:8
        }
        sap 1/1/1:8 {
        }
    }
}

```

Influencing the DF election

As previously described, assuming that the sites on the two nodes taking part of the same multi-homing site are both up, the two tie-breakers for electing the DF are (in this order):

1. Highest LP
2. Lowest PE ID

The LP by default is 100 in all the routers. Under normal circumstances, if the LP in any router is not changed, MTU-4 will be elected the DF for MH-site-1, whereas PE-1 will be the DF for MH-site-2. Assume in this section that this behavior is changed for MH-site-2 to make PE-2 the DF. Because changing the system address (to make PE-2's ID the lower of the two IDs) is usually not an easy task to accomplish, the vsi-export policy on PE-2 is modified with an LP of 150 with which the MH-site-2 NLRI is announced to PE-1. Because LP 150 is greater than the default 100 in PE-1, PE-2 will be elected as the DF for MH-site-2. The vsi-import policy remains unchanged and the vsi-export policy is modified as follows:

```

# on PE-2:
configure {
    policy-options {
        community "comm_core" {
            member "target:65000:500" { }
        }
    }
    policy-statement "vsi500_export" {
        entry 10 {
            action {
                action-type accept
                local-preference 150
                community {
                    add ["comm_core"]
                }
            }
        }
    }
}

```

```

    }
  }
}

```

On PE-1, the import and export policies are not modified. The policies were already applied in the **bgp** context of VPLS-500, as follows:

```

# on PE-2:
configure {
  service {
    vpls "VPLS-500" {
      admin-state enable
      service-id 500
      customer "1"
      bgp 1 {
        route-distinguisher "65000:502"
        vsi-import ["vsi500_import"]
        vsi-export ["vsi500_export"]
        pw-template-binding "PW500" {
          split-horizon-group "CORE"
        }
      }
    }
  }
}
---snip---

```

The DF state of PE-2 can be verified as follows:

```

[]
A:admin@PE-2# show service id 500 site MH-site-2

=====

```

The import and export policies are applied at service 500 level, which means that the LP changes for all the potential multi-homing sites configured under service 500. Therefore, load balancing can be achieved on a per-service basis, but not within the same service.

These policies are applied on VPLS-500 for all the potential BGP applications: BGP VPLS, BGP MH, and BGP AD. In the example, the LP for the PE-2 BGP updates for BGP MH and BGP VPLS will be set to 150. However, this has no impact on BGP VPLS because a PE cannot receive two BGP VPLS NLRIs with the same VE-ID, which implies that a different VE-ID per PE within the same VPLS is required.

The vsi-export policy is restored to its original settings on PE-2, as follows:

```

# on PE-2:
configure {
  policy-options {
    community "comm_core" {

```

```
        member "target:65000:500" { }
    }
    policy-statement "vsi500_export" {
        entry 10 {
            action {
                action-type accept
                delete local-preference
                community {
                    add ["comm_core"]
                }
            }
        }
    }
}
```

In all the PE nodes, the import and export policies applied in the **bgp** context of VPLS-500 have identical settings again, and PE-1 is the DF.

Black-hole avoidance

SR OS supports the appropriate MAC flush mechanisms for BGP MH, regardless of the protocol being used for the pseudowire signaling:

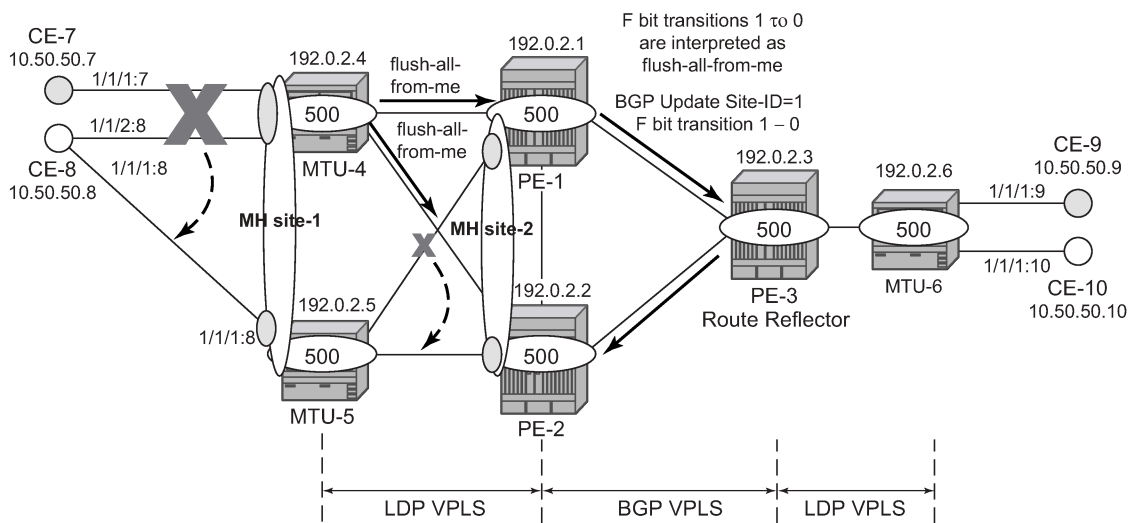

- LDP VPLS — The PE that contains the old DF site (the site that just experienced a DF to non-DF transition) always sends an LDP MAC flush-all-from-me to all LDP pseudowires in the VPLS, including the LDP pseudowires associated with the new DF site. No specific configuration is required.
- BGP VPLS — The remote BGP VPLS PEs interpret the F bit transitions from 1 to 0 as an implicit MAC flush-all-from-me indication. If a BGP update with the flag F=0 is received from the previous DF PE, the remote PEs perform MAC flush-all-from-me, flushing all the MACs associated with the pseudowire to the old DF PE. No specific configuration is required.

Double flushing will not happen because it is expected that between any pair of PEs there will exist only one type of pseudowires—either BGP or LDP pseudowire—, but not both types.

In the example, assuming MTU-4 and PE-1 are the DF nodes:

- When MH-site-1 is brought operationally down on MTU-4 (so by default, the two SAPs must go down unless the **failed-threshold** parameter is changed so that the site is down when only one SAP is brought down), MTU-4 will issue a flush-all-from-me message.
- When MH-site-2 is brought operationally down on PE-1, a BGP update with F=0 and D=1 is issued by PE-1. PE-2 and PE-3 will receive the update and will flush the MAC addresses learned on the pseudowire to PE-1.

Figure 48: MAC flush for BGP MH

OSSG641

Node failures implicitly trigger a MAC flush on the remote nodes, because the TLDP/BGP session to the failed node goes down.

Access CE/PE signaling

BGP MH works at service level, therefore no physical ports are torn down on the non-DF, but rather the objects are brought down operationally, while the physical port will stay up and used for any other services existing on that port. Because of this reason, there is a need for signaling the standby status of an object to the remote PE or CE.

- Access PEs running BGP MH on spoke SDPs and elected non-DF, will signal pseudowire standby status (0x20) to the other end. If no pseudowire status is supported on the remote MTU, a label withdrawal is performed. If there is more than one spoke SDP on the site (part of the same SHG), the signaling is sent for all the pseudowires of the site.

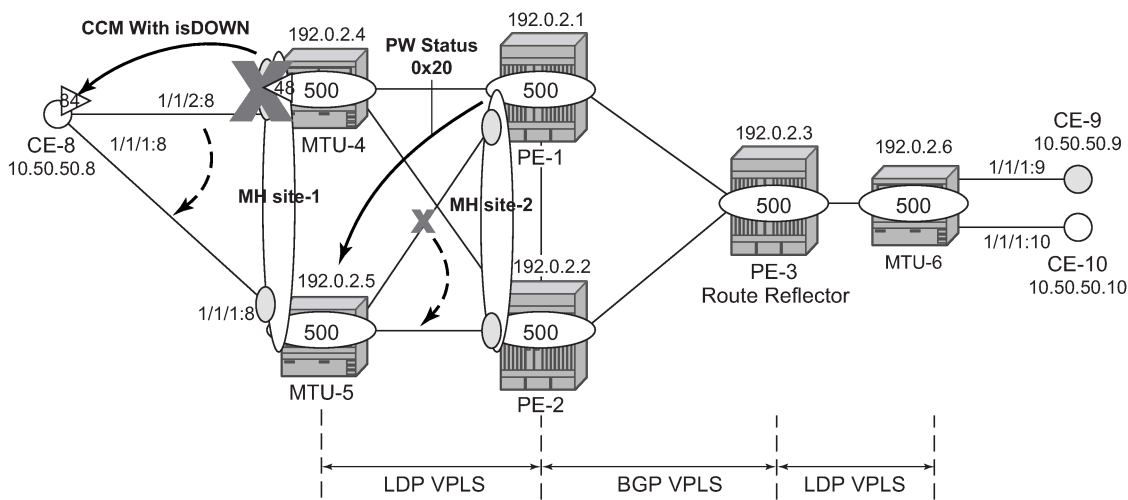

Note:

The **configure service vpls x spoke-sdp y:z pw-status signaling false** parameter allows to send a TLDP label-withdrawal instead of pseudowire status bits, even though the peer supports pseudowire status.

- Multi-homed CEs connected through SAPs to the PEs running BGP MH, are signaled by the PEs using Y.1731 CFM, either by stopping the transmission of CCMs or by sending CCMs with isDown (interface status down encoding in the interface status TLV).

In this example, down MEPs on MTU-4 SAP 1/1/2:8 and CE-8 SAP 1/1/2:8 are configured. In a similar way, other MEPs can be configured on MTU-4 SAP 1/1/1:7, MTU-5 SAP 1/1/1:8, and CE-8 SAP 1/1/1:7 and SAP 1/1/1:8. [Figure 49: Access PE/CE signaling](#) shows the MEPs on MTU-4 SAP 1/1/2:8 and CE-8. Upon failure on the MTU-4 site MH-site-1, the MEP 48 will start sending CCMs with interface status down.

Figure 49: Access PE/CE signaling

OSSG642

The CFM configuration required at SAP 1/1/2:8 is as follows. Down MEPs will be configured on CE-8 and MTU-5 SAPs in the same way, but in a different association. The option **fault-propagation use-if-status-tlv** must be added. In case the CE does not understand the CCM interface status TLV, the **fault-propagation suspend-ccm** option can be enabled instead. This will stop the transmission of CCMs upon site failures. Detailed configuration guidelines for Y.1731 are beyond the scope of this chapter.

```
# on MTU-4:
configure {
  eth-cfm {
    domain "domain-1" {
      level 3
      name "domain-1"
      md-index 1
      association "assoc-1" {
        icc-based "Association48"
        ma-index 1
        ccm-interval 1s
        bridge-identifier "VPLS-500" {
        }
        remote-mep 84 {
        }
      }
    }
  }
}
```

```
# on MTU-4:
configure {
  service {
    vpls "VPLS-500" {
      sap 1/1/2:8 {
        split-horizon-group "site-1"
        eth-cfm {
          mep md-admin-name "domain-1" ma-admin-name "assoc-1" mep-id 48 {
            admin-state enable
            direction down
            fault-propagation use-if-status-tlv
            ccm true
          }
        }
      }
    }
  }
}
```

```
}  
}
```

If CE-8 is a service router, upon receiving a CCM with isDown, an alarm will be triggered and the SAP will be brought down:

```
# on CE-8:  
71 2021/01/20 16:09:02.701 CET WARNING: OSPF #2047 vprn8 VR: 2 OSPFv2 (0)  
"LCL_RTR_ID 10.50.50.8: Interface int-CE-8-MTU-4 state changed to down (event  
IF_DOWN)"  
  
70 2021/01/20 16:09:02.701 CET WARNING: SNMP #2004 vprn8 int-CE-8-MTU-4  
"Interface int-CE-8-MTU-4 is not operational"

```
=====
```

As also depicted in [Figure 49: Access PE/CE signaling](#), PE-1 will signal pseudowire status standby (code 0x20) when PE-1 goes to non-DF state for MH-site-2. MTU-5 will receive that signaling and, based on the **ignore-standby-signaling** parameter, will decide whether to send the broadcast, unknown unicast, and multicast (BUM) traffic to PE-1. In case MTU-5 uses in its configuration **ignore-standby-signaling**, it will be sending BUM traffic on both pseudowires at the same time (which is not normally desired), ignoring the pseudowire status bits. The following output shows the MTU-5 spoke-SDP receiving the pseudowire status signaling. Although the spoke SDP stays operationally up, the Peer Pw Bits field shows **pwFwdingStandby** and MTU-5 will not send any traffic if the **ignore-standby-signaling** parameter is disabled.

```

Operational groups for BGP-MH

Operational groups (**oper-group**) introduce the capability of grouping objects into a generic group object and associating its status to other service endpoints (pseudowires, SAPs, IP interfaces) located in the same or in different service instances. The operational group status is derived from the status of the individual components using certain rules specific to the application using the concept. A number of other service entities—the monitoring objects—can be configured to monitor the operational group status and to drive their own status based on the **oper-group** status. In other words, if the operational group goes down, the monitoring objects will be brought down. When one of the objects included in the operational group comes up, the entire group will also come up, and therefore so will the monitoring objects.

This concept can be used to enhance the BGP-MH solution for avoiding black-holes on the PE selected as the DF if the rest of the VPLS endpoints fail (pseudowire spoke(s)/pseudowire mesh and/or SAP(s)). [Figure 50: Oper-groups and BGP-MH](#) illustrates the use of operational groups together with BGP-MH. On PE-1 (and PE-2) all of the BGP-VPLS pseudowires in the core are configured under the same **oper-groupgroup-1**. MH-site-2 is configured as a monitoring object. When the two BGP-VPLS pseudowires go down, **oper-groupgroup-1** will be brought down, therefore MH-site-2 on PE-1 will go down as well (PE-2 will become DF and PE-1 will signal standby to MTU-5).

Figure 50: Oper-groups and BGP-MH

ACG0016

In the preceding example, this feature provides a solution to avoid a black-hole when PE-1 loses its connectivity to the core.

Operational groups are configured in two steps:

1. Identify a set of objects whose forwarding state should be considered as a whole group, then group them under an operational group (in this case **oper-groupgroup-1**, which is configured in the **bgp pw-template-binding** context).
2. Associate other existing objects (clients) with the oper-group using the **monitor-group** command (configured, in this case, in the **site MH-site-2**).

The following CLI excerpt shows the commands required (**oper-group**, **monitor-oper-group**).

```
# on PE-1:
configure {
  service {
    oper-group "group-1" {
    }
    vpls "VPLS-500"
    bgp 1 {
      pw-template-binding "PW500" {
        split-horizon-group "CORE"
        oper-group "group-1"
      }
    }
    bgp-mh-site "MH-site-2"
    monitor-oper-group "group-1"
  }
}
```

When all the BGP-VPLS pseudowires go down, **oper-groupgroup-1** will go down and therefore the monitoring object, **site MH-site-2**, will also go down and PE-2 will then be elected as DF. The log 99 gives information about this sequence of events:

```
# on PE-1:
configure {
  service {
    sdp 12 {
      admin-state disable
    }
  }
}
```

```

sdp 13 {
    admin-state disable
}

Site Activation Timer: default          Timer Remaining     : 0d 00:00:00
Min Down Timer       : default          Timer Remaining     : 0d 00:00:00
Failed Threshold     : default(all)
Monitor Oper Grp    : (none)
-----
Number of Sites : 1
-----
=====
```

The **detail** view of the command displays information about the BGP MH timers. The values are only shown if the global values are overridden by specific ones at service level (and will be tagged with **Ovr** if they have been configured at service level). The **Timer Remaining** field reflects the count down from the boot timer and activation timer down to the moment when this router tries to become DF again. Again, this is only shown when the global timers have been overridden by the ones at service level.

The objects on the non-DF site will be brought down operationally and flagged with **StandByForMHProtocol**, for example, for SAP 1/1/1:8 on non-DF MTU-5:

```
[ ]
A:admin@MTU-5# show service id 500 sap 1/1/1:8

=====
```

```

```

The BGP MH routes in the RIB, RIB-In and RIB-Out can be shown by using the corresponding **show router bgp routes l2-vpn** and **show router bgp neighbor x.x.x.x filter1 received-routes|advertised-routes family l2-vpn** commands. The BGP MH routes are only shown when the operator uses the **l2-vpn** family modifier. Should the operator want to filter only the BGP MH routes out of the l2-vpn routes, the **l2vpn-type multi-homing** filter has to be added to the **show router bgp routes** commands.

```

For debugging, the following CLI sources can be used:

- **log-id 99** — Provides information about the site object changes and DF changes.
- **debug router bgp update** (in classic CLI) — Shows the BGP updates for BGP MH, including the sent and received BGP MH NLRIs and flags.

```

# on MTU-4 (classic CLI):
debug
  router "Base"
    bgp
      update

```

- **debug router ldp** commands (in classic CLI) — Provides information about the pseudowire status bits being signaled as well as the MAC flush messages.

```

# on MTU-4 (classic CLI):
debug
  router "Base"

```

```

ldp
  peer 192.0.2.1
    packet
      init detail
      label detail

```

As an example, log-id 99 shows the following debug output after disabling MH-site-1 on MTU-4:

```

# on MTU-4:
configure {
  service {
    vpls "VPLS-500"
    sap 1/1/1:7 {
      admin-state disable
    }
    sap 1/1/2:8 {
      admin-state disable
    }
  }
}

```

```

    target:65000:500
    l2-vpn/vrf-imp:Encap=19: Flags=D: MTU=0: PREF=0
"

```

As described earlier, debugging is enabled on MTU-4 for LDP messages between MTU-4 and PE-1. The following MAC flush-all-from-me message is sent by MTU-4 to PE-1.

```

1 2021/01/20 16:38:54.686 CET MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Address Withdraw packet (msgId 383) to 192.0.2.1:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/500 Group ID = 0 cBit = 0
"

```

Assuming all the recommended tools are enabled, a DF to non-DF transition can be shown as well as the corresponding MAC flush messages and related BGP processing.

On PE-1, MH-site-2 is brought down by disabling the spoke-SDP 15:500 object. A BGP-MH update will be sent when the MH site goes down. When all objects on the VPLS are disabled as in the following configuration, a BGP VPLS update will be sent as well.

```

# on PE-1:
configure {
    service {
        vpls "VPLS-500" {
            spoke-sdp 14:500 {
                admin-state disable
            }
            spoke-sdp 15:500 {
                admin-state disable
            }
        }
    }
}

```

When MH-site-2 is torn down on PE-1, the **debug router bgp update** command allows us to see two BGP updates from PE-1:

- A BGP MH update for site ID 2 with flag D set (because the site is down).
- A BGP VPLS update for veid=501 and flag D set. This is due to the fact that there are no more active objects on the VPLS, besides the BGP pseudowires.

```

Conclusion

SR OS supports a wide range of service resiliency options as well as the best-of-breed system level HA and MPLS mechanisms for the access and the core. BGP MH for VPLS completes the service resiliency tool set by adding a mechanism that has some good advantages over the alternative solutions:

- BGP MH provides a common resiliency mechanism for attachment circuits (SAPs), pseudowires (spoke SDPs), split horizon groups and mesh bindings
- BGP MH is a network-based technique which does not need interaction to the CE or MTU to which it is providing redundancy to.

The examples used in this chapter illustrate the configuration of BGP MH for access CEs and MTUs. Show and debug commands have also been suggested so that the operator can verify and troubleshoot the BGP MH procedures.

BGP Virtual Private Wire Services

This chapter describes BGP Virtual Private Wire Service (VPWS) configurations.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 11.0.R4. The MD-CLI in the current edition is based on SR OS Release 21.2.R1. There are no prerequisites for this configuration.

Overview

The following two IETF standards describe the provisioning of Virtual Private Wire Services (VPWS):

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*, describes Label Distribution Protocol (LDP) VPWS, where VPWS pseudowires are signaled using LDP between Provider Edge (PE) Routers.
- RFC 6624, *Layer 2 Virtual Private Networks Using BGP for Auto-Discovery and Signaling*, describes the use of Border Gateway Protocol (BGP) for signaling of pseudowires between such PEs.

[Figure 51: Example topology](#) shows the example topology with five SR OS routers located in the same Autonomous System (AS). There are three PE routers connected to a single P router and a route reflector (RR) for the AS. The PE routers are all BGP VPWS-aware. The Provider (P) router is BGP VPWS-unaware and does not take part in the BGP process.

Figure 51: Example topology

al_0265

The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is configured on each of the network interfaces between the PE/P routers and route reflector.
- MPLS is configured on all interfaces between PE routers and P routers. It is not required between P-4 and RR-5.
- LDP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-5.
- RSVP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-5.

BGP VPWS

In this architecture, a VPWS is a collection of two (or three in case of redundancy) BGP VPWS service instances present on different PEs in a provider network.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP VPWS Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other BGP VPWS instances on peering PEs and to set up pseudowire connectivity for data flow between peers containing the same BGP VPWS service. Therefore, auto-discovery and pseudowire signaling is achieved using a single BGP update message.

Each PE with a BGP VPWS instance is identified by a VPWS edge identifier (VE-ID) and the presence of other BGP VPWS instances is determined using the exchange of standard BGP extended community route targets (RTs) between PEs.

Each PE will advertise, via the RR, the presence of its BGP VPWS instance to all other PEs, along with a block of multiplexer labels (for BGP VPWS, one label per block) that can be used to communicate between each instance, plus a BGP next-hop that determines a labeled transport tunnel to be used between PEs.

Each BGP VPWS instance is configured with import and export route target extended communities for topology control, along with VE identification.

Configuration

The following examples show the configuration of four BGP VPWS scenarios:

- Single homed BGP VPWS
 - using auto-provisioned SDPs
 - using pre-provisioned SDPs
- Dual homed BGP VPWS
 - with single pseudowire
 - with active/standby pseudowire

Configure MP-iBGP

The first step is to configure an MP-iBGP session between each of the PEs and the RR. The configuration for all PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure {
  router "Base"{
    autonomous-system 65536
    bgp {
      group "INTERNAL" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.5" {
        group "INTERNAL"
      }
    }
  }
}
```

The IP addresses can be derived from [Figure 51: Example topology](#).

On RR-5, the BGP configuration is as follows:

```
# on RR-5:
configure {
  router "Base"{
    autonomous-system 65536
    bgp {
      group "INTERNAL" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      cluster {
        cluster-id 1.1.1.1
      }
    }
  }
}
```

```

    }
  }
  neighbor "192.0.2.1" {
    group "INTERNAL"
  }
  neighbor "192.0.2.2" {
    group "INTERNAL"
  }
  neighbor "192.0.2.3" {
    group "INTERNAL"
  }
}

```

The following command on RR-5 shows that BGP sessions with each PE are established and have a negotiated L2 VPN address family capability.

```

```

Pseudowire templates

BGP VPWS utilizes pseudowire (PW) templates to dynamically instantiate SDP bindings for a service to signal the egress service de-multiplexer labels used by remote PEs to reach the local PE. The template determines the signaling parameters of the pseudowire, such as vc-type, vlan-vc-tag, hash-label, filters, and so on.

- The encapsulation type in the Layer-2 extended community is either 4 (Ethernet VLAN tagged mode) or 5 (Ethernet raw mode), depending on the **vc-type** parameter.
- The **force-vc-forwarding** function will add a tag (equivalent to vc-type vlan) and will allow for customer QoS transparency (dot1p + Drop Eligibility (DE) bits).

The MPLS transport tunnel between PEs can be signaled using LDP or RSVP-TE.

LDP-based SDPs can be automatically instantiated or pre-provisioned. RSVP-TE-based SDPs have to be pre-provisioned. If pre-provisioned pseudowires are used, the PW template must be created with the **provisioned-sdp use** parameter. Alternatively, the **provisioned-sdp prefer** parameter can be used, in

which case a pre-provisioned SDP will be used if available; if not, LDP-based SDPs can be automatically instantiated, see chapter [LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP](#).

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, link layer LDP needs to be configured between all PEs/Ps so that a transport label for each PE system interface is available. For example, on PE-1:

```
# on PE-1:
configure {
  router "Base" {
    ldp {
      interface-parameters {
        interface "int-PE-1-P-4" {
          ipv4 {
          }
        }
      }
    }
  }
}
```

Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at the higher end of the SDP numbering range, such as 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required. The following example is created using the default values:

```
# on PE-1, PE-2, and PE-3:
configure {
  service {
    pw-template "PW3" {
      pw-template-id 3
    }
  }
}
```

Pseudowire templates for provisioned SDPs using RSVP-TE

RSVP-TE LSPs need to be created between the PE routers on which provisioned SDPs will be used as prerequisite.

The MPLS interface and LSP configuration for PE-1 are:

```
# on PE-1:
configure {
  router "Base" {
    mpls {
      admin-state enable
      interface "int-PE-1-P-4" {
      }
      path "dyn" {
        admin-state enable
      }
    }
    lsp "LSP-PE-1-PE-2" {
      admin-state enable
      type p2p-rsvp
      to 192.0.2.2
      primary "dyn" {
      }
    }
  }
}
```

```
    }  
    lsp "LSP-PE-1-PE-3" {  
        admin-state enable  
        type p2p-rsvp  
        to 192.0.2.3  
        primary "dyn" {  
        }  
    }  
}
```

The MPLS and LSP configuration for PE-2 are similar to that of PE-1 with the appropriate interfaces and LSP names configured.

To use an RSVP-TE tunnel as transport between PEs, it is necessary to bind the RSVP-TE LSP between PEs to an SDP.

On PE-1, the SDP toward PE-2 is configured as follows. Similar SDPs are required on each PE to the remote PEs in the service where provisioned SDPs are to be used.

```
# on PE-1:  
configure {  
    service {  
        sdp 12 {  
            admin-state enable  
            description "SDP-PE-1-PE-2_RSVP_BGP"  
            delivery-type mpls  
            signaling bgp  
            far-end {  
                ip-address 192.0.2.2  
            }  
            lsp "LSP-PE-1-PE-2" { }  
        }  
    }  
}
```

The **signaling bgp** parameter is required. BGP VPWS instances using BGP VPWS signaling can use BGP-signaled SDPs. However, TLDP-signaled (default) SDPs that are bound to RSVP-based LSPs will not be used as SDPs within BGP VPWS.

Single-homed BGP VPWS using auto-provisioned SDPs

[Figure 52: Single-homed BGP VPWS using auto-provisioned SDPs](#) shows a schematic of a single homed BGP VPWS between PE-1 and PE-3 where SDPs are auto-provisioned. In this case, the transport tunnels are LDP-signaled.

Figure 52: Single-homed BGP VPWS using auto-provisioned SDPs

al_0266

The following shows the configuration required on PE-1 for a BGP VPWS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      vc-type vlan
    }
    epipe "Epipe-1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
        route-distinguisher "65536:11"
        route-target {
          export "target:65536:1"
          import "target:65536:1"
        }
        pw-template-binding "PW1" {
        }
      }
    }
    bgp-vpws {
      admin-state enable
      local-ve {
        name "PE-1"
        id 1
      }
      remote-ve "PE-3" {
        id 3
      }
    }
  }
}
```

```
        sap 1/1/4:1 {  
            admin-state enable  
        }  
    }
```

The **bgp** context specifies parameters that are required for BGP VPWS.

Within the **bgp** context, parameters are configured that are used by the neighboring PEs to determine the membership of a BGP VPWS, in other words, the auto-discovery of PEs in the same BGP VPWS. Within the **bgp** context, the RD is configured, along with the route target extended communities. Route target communities are used to determine membership of a BGP VPWS. The import and export route targets at the BGP level are mandatory. The PW template binding is then applied and its parameters are used for both the routes sent by this PE and the received routes matching the route target value.

Within the **bgp-vpws** context, the signaling parameters are configured. These determine the service labels required for the data plane of the VPWS instance.

The VPWS Edge ID (VE-ID) is a numerical value assigned to each PE within a BGP VPWS. This value must be unique for a BGP VPWS, with the exception of multi-homed scenarios, where two dual-homed PEs can have the same VE-ID and are distinguishable by the site preference (or by the tie breaking rules from the *draft-ietf-bess-vpls-multihoming-03*).

Changes to the pseudowire template are not taken into account once the pseudowire has been set up (changes of RT are refreshed though). PW-templates can be re-evaluated with the **tools perform service eval-pw-template** command. The **eval-pw-template** checks if all of the bindings using this PW template policy are still meant to be using this policy. If the template has changed and **allow-service-impact** is true, then the old binding is removed and it is re-added using the new template.

```
[/]  
A:admin@PE-1# tools perform service eval-pw-template 1  
eval-pw-template succeeded for Svc 1 Tx L2 ExtComm, Policy 1  
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 1
```

VE-ID and BGP label allocations

For a point-to-point VPWS, there are only two members within the BGP VPWS service, so only one label entry is required by each remote service. For dual-homed scenarios, there are two labels for the redundant site, one from each dual-homed PE.

Each PE allocates a label per BGP VPWS instance for the remote PEs, so it signals blocks with one label. It achieves this by advertising three parameters in a BGP update message. For more information about these parameters, see chapter [BGP VPLS](#).

- A Label Base (LB) which is the lowest label in the block.
- A VE Block size (VBS) which is always 1 and cannot be changed.
- A VE Base Offset (VBO) corresponding to the first label in the label block.

PE-3 service creation

On PE-3, Epipe 1 is configured using PW template 1, as follows. PE-3 has been allocated a VE-ID of 3. For completeness, the PW template is also shown.

```
# on PE-3:  
configure {
```

```
service {
  pw-template "PW1" {
    pw-template-id 1
    vc-type vlan
  }
  epipe "Epipe-1" {
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
      route-distinguisher "65536:13"
      route-target {
        export "target:65536:1"
        import "target:65536:1"
      }
      pw-template-binding "PW1" {
      }
    }
    bgp-vpws {
      admin-state enable
      local-ve {
        name "PE-3"
        id 3
      }
      remote-ve "PE-1" {
        id 1
      }
    }
    sap 1/1/4:1 {
    }
  }
}
```

The control flags within the extended community indicate the status of the BGP VPWS instance.

The control flags are the following:

```
0 1 2 3 4 5 6 7
+---+---+---+---+
|D|A|F|Z|Z|Z|C|S| (Z = MUST Be Zero)
+---+---+---+---+
```

- D: access circuit down indicator. D is 1 if all access circuits are down, otherwise D is 0.
- A: automatic site ID allocation, which is not supported. This is ignored on receipt and set to 0 on sending.
- F: MAC flush indicator, this relates to VPLS. This is set to 0 and ignored on receipt.
- C: presence of a control word. Control word usage is not supported. This is set to 0 on sending (control word not present) and if a non-zero value is received (indicating a control word is required), the pseudowire will not be created.
- S: sequenced delivery. Sequenced delivery is not supported. This is set to 0 on sending (no sequenced delivery) and if a non-zero value is received (indicating sequenced delivery required), the pseudowire will not be created.

The BGP VPWS NLRI is based on the BGP VPLS NLRI, but is extended with a Circuit Status Vector (CSV). The circuit status vector is used to indicate the status of both the SAP and the spoke-SDP within

the local service. Because the VE block size used is 1, the most significant bit in the circuit status vector TLV value will be set to 1 if either the SAP or spoke-SDP is down; otherwise, it will be set to 0.

```
# on PE-1:
configure {
  service {
    epipe "Epipe-1"
    sap 1/1/4:1 {
      admin-state disable
    }
  }
}
```

```

On PE-1, SAP 1/1/4:1 is re-enabled as follows:

```
# on PE-1:
configure {
  service {
    epipe "Epipe-1"
  }
}
```

```
sap 1/1/4:1 {
    admin-state enable
}
```

PE-3 service operation verification

Similar to PE-1, the service operation should be validated on PE-3.

Single-homed BGP VPWS using pre-provisioned SDP

It is possible to configure BGP VPWS instances that use RSVP-TE transport tunnels. In this case, the SDPs must be created with the MPLS LSPs mapped and with the signaling set to BGP, because the service labels are signaled using BGP. The PW template configured within the BGP VPWS instance must use the keyword `provisioned-sdp use` (or `provisioned-sdp prefer`).

Figure 53: Single-homed BGP VPWS using pre-provisioned SDP

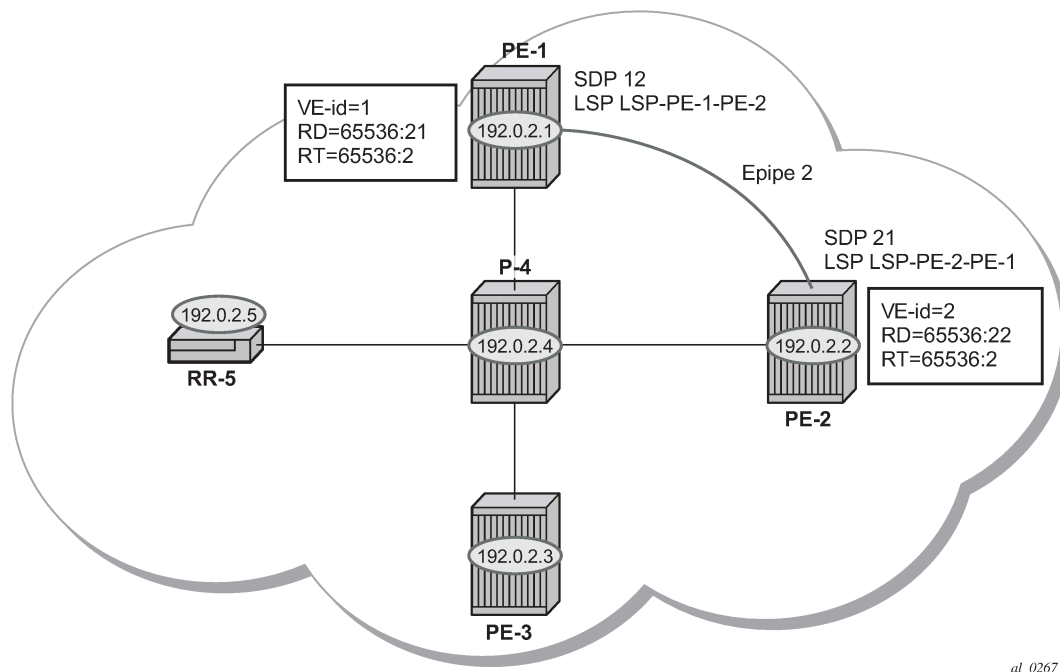

Figure 53: Single-homed BGP VPWS using pre-provisioned SDP shows a schematic of a BGP VPWS where SDPs are pre-provisioned with RSVP-TE signaled transport tunnels.

On PE-1, SDP 12 toward PE-2 is configured as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "SDP-PE-1-PE-2_RSVP_BGP"
            delivery-type mpls
            signaling bgp
        }
    }
}
```

```

        far-end {
            ip-address 192.0.2.2
        }
        lsp "LSP-PE-1-PE-2" { }
    }

```

On PE-2, SDP 21 toward PE-1 is configured as follows:

```

# on PE-2:
configure {
    service {
        sdp 21 {
            admin-state enable
            description "SDP-PE-2-PE-1_RSVP_BGP"
            delivery-type mpls
            signaling bgp
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-PE-2-PE-1" { }
        }
    }
}

```

To create a spoke SDP within a service that uses the RSVP-TE transport tunnel, a pseudowire template is required that has the **provisioned-sdp use** parameter set.

The PW template is provisioned on both PEs as follows:

```

# on PE-1 and PE-2:
configure {
    service {
        pw-template "PW2" {
            pw-template-id 2
            provisioned-sdp use
        }
    }
}

```

The following output shows the configuration required for a BGP VPWS service using a PW template configured for using pre-provisioned RSVP-TE SDPs.

```

# on PE-1:
configure {
    service {
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "65536:21"
                route-target {
                    export "target:65536:2"
                    import "target:65536:2"
                }
            }
            pw-template-binding "PW2" {
            }
        }
        bgp-vpws {
            admin-state enable
            local-ve {
                name "PE-1"
                id 1
            }
            remote-ve "PE-2" {
                id 2
            }
        }
    }
}

```

```

    }
  }
  sap 1/1/4:2 {
  }
}

```

The route distinguisher and route target extended community values for Epipe 2 are different from those in Epipe 1. This is to differentiate between the two as their visibility is global within the BGP domain. The VE-ID values can be reused in each Epipe instance, as long as they are unique within the instance.

Similarly, the configuration is as follows on PE-2, where the VE-ID is 2:

```

# on PE-2:
configure {
  service {
    epipe "Epipe-2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
        route-distinguisher "65536:22"
        route-target {
          export "target:65536:2"
          import "target:65536:2"
        }
        pw-template-binding "PW2" {
        }
      }
    }
    bgp-vpws {
      admin-state enable
      local-ve {
        name "PE-2"
        id 2
      }
      remote-ve "PE-1" {
        id 1
      }
    }
  }
  sap 1/1/4:2 {
  }
}

```

The service Epipe 2 is operationally up on PE-1, as follows:

```

[/]
A:admin@PE-1# show service id 2 base
=====

```

The SDP-ID used is the pre-provisioned SDP 21.

Dual-homed BGP VPWS with single pseudowire

For access redundancy, an Epipe using a BGP VPWS service can be configured as dual-homed, as described in *draft-ietf-bess-vpls-multihoming-03*. It can be configured with a single pseudowire setup, where the redundant pseudowire is not created until the initially active pseudowire is removed.

The following diagram shows a setup where an Epipe is configured on each PE. Site B is dual-homed to PE-1 and PE-3 with the remote PE-2 connected to site A; each site connection uses a SAP. A single pseudowire using Ethernet Raw Mode encapsulation connects PE-2 to PE-1 or PE-3 (but not both at the same time). The pseudowire is signaled using BGP VPWS over a tunnel LSP between the PEs.

Figure 54: Dual-homed BGP VPWS with single pseudowire

al_0268

BGP multi-homing is configured for the dual-homed site B using a site-ID=1. The site-preference on PE-1 is set to 200 and to 10 on PE-3, this ensures that PE-1 will be the site's Designated Forwarder (DF) and the pseudowire from PE-2 will be created to PE-1 when PE-1 is fully operational (no pseudowire is created on PE-2 to PE-3). If PE-1 fails, or the multi-homing site fails over to PE-3, then the pseudowire from PE-2 to PE-1 will be removed and a new pseudowire will be created from PE-2 to PE-3.

On PE-1, Epipe 3 is configured as follows:

```
# on PE-1:
configure {
  service {
    pw-template "PW3" {
      pw-template-id 3
    }
  }
  epipe "Epipe-3" {
    admin-state enable
    service-id 3
    customer "1"
    bgp 1 {
      route-distinguisher "65536:31"
      route-target {
        export "target:65536:3"
        import "target:65536:3"
      }
    }
    pw-template-binding "PW3" {
    }
  }
  bgp-vpws {
    admin-state enable
    local-ve {
      name "PE-1"
      id 1
    }
  }
}
```

```

    }
    remote-ve "PE-2" {
        id 2
    }
}
bgp-mh-site "SITEB" {
    admin-state enable
    id 1
    sap 1/1/4:3
    preference 200
}
sap 1/1/4:3 {
    admin-state enable
}
}
}

```

Epipe 3 is configured on PE-3 with the same local VE-ID as on PE-1, as follows:

```

# on PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
        }
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:33"
                route-target {
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW3" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-3"
                    id 1
                }
                remote-ve "PE-2" {
                    id 2
                }
            }
        }
        bgp-mh-site "SITEB" {
            admin-state enable
            id 1
            sap 1/1/4:3
            preference 10
        }
        sap 1/1/4:3 {
        }
    }
}

```

In the preceding configurations, the **remote-ve** for PE-2 uses VE-ID 2 on both PE-1 and PE-3.

Epipe 3 is configured on PE-2 as follows:

```

# on PE-2:
configure {

```

```

service {
  pw-template "PW3" {
    pw-template-id 3
  }
  epipe "Epipe-3" {
    admin-state enable
    service-id 3
    customer "1"
    bgp 1 {
      route-distinguisher "65536:32"
      route-target {
        export "target:65536:3"
        import "target:65536:3"
      }
      pw-template-binding "PW3" {
      }
    }
    bgp-vpws {
      admin-state enable
      local-ve {
        name "PE-2"
        id 2
      }
      remote-ve "PE-1 or PE-3" {
        id 1
      }
    }
  }
  sap 1/1/4:3 {
  }
}

```

On PE-2, the **remote-ve** is configured as "PE-1 or PE-3"; this is because both of these PEs are configured with VE-ID 1.

As a result of this configuration, there are multiple route entries for RD 65536:31 on PE-2. In the BGP routing table, there are two entries per partner PE, one for the BGP-MH update (with site-ID=1) and the other for the BGP-VPWS update (with VE-ID=1).

```

```

After disabling the SAP in the service "Epipe3" on PE-1, BGP update messages are received. The VPLS/VPWS message received on PE-2 from PE-1 shows in the CSV that the access circuit is down (the CSV has the most-significant bit set to 1 (0x80)), so PE-2 selects the update from PE-3 to create the pseudowire. The BGP-MH update received by PE-2 from PE-1 also shows that the local site is down as indicated by the flags=D.

Note in the following debug output:

- BGP MH (multi-homing) entry uses encap-type=19.
- BGP VPWS entry uses encap-type=5 (Ethernet raw mode).

```
# Disable SAP in Epipe 3 on PE-1:
configure {
  service {
    epipe "Epipe-3"
      sap 1/1/4:3 {
        admin-state disable
      }
  }
}

Dual-homed BGP VPWS with active/standby pseudowire

The second method for BGP VPWS pseudowire redundancy is an active/standby configuration. Whereas in the solution with one pseudowire, the redundant nodes use the same VE-ID for the remote PE and different preferences; in the active/standby solution, the redundant nodes use different VE-IDs for the remote PE and different preferences. The node connecting to both pseudowires (PE-2 in this example) has both remote VE-IDs configured. This allows for faster failover because the standby pseudowire is instantiated in addition to the active pseudowire. If more than two applicable BGP updates are received, at most one standby pseudowire is created (based on the BGP VPWS tie breaking rules).

[Figure 55: Dual-homed BGP VPWS with active/standby pseudowire](#) shows a setup where an Epipe is configured on each PE. Site B is dual-homed to PE-1 and PE-3 with the remote PE-2 connected to site A; each site connection uses a SAP. The active/standby pseudowires using Ethernet raw mode encapsulation connect PE-2 to PE-1 and PE-3. The pseudowires are signaled using BGP VPWS over tunnel LSPs between the PEs.

Figure 55: Dual-homed BGP VPWS with active/standby pseudowire

BGP Multi-Homing (MH) is configured for the dual-homed site B using site ID 1. The site preference on PE-1 is set to 200 and to 10 on PE-3; this ensures that PE-1 will be the site's DF for the MH site. The active pseudowire from PE-2 will be created to PE-1 with the standby pseudowire being created to PE-3. If PE-1 fails, or the multi-homing site fails over to PE-3, then the pseudowire from PE-2 to PE-3 will become active (used as the data path between site A and B).

Epipe 4 is configured on PE-1 as follows:

```
# on PE-1:
configure {
  service {
    pw-template "PW3" {
      pw-template-id 3
    }
  }
  epipe "Epipe-4" {
    admin-state enable
    service-id 4
    customer "1"
    bgp 1 {
      route-distinguisher "65536:41"
      route-target {
        export "target:65536:4"
        import "target:65536:4"
      }
      pw-template-binding "PW3" {
      }
    }
  }
  bgp-vpws {
    admin-state enable
    local-ve {
      name "PE-1"
    }
  }
}
```

```

        id 1
    }
    remote-ve "PE-2" {
        id 2
    }
}
bgp-mh-site "SITEB" {
    admin-state enable
    id 1
    sap 1/1/4:4
    preference 200
}
sap 1/1/4:4 {
}
}

```

Epipe 4 is configured on PE-3 with local VE-ID 3 (different from the previous example), as follows:

```

# on PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
        }
    }
    epipe "Epipe-4" {
        admin-state enable
        service-id 4
        customer "1"
        bgp 1 {
            route-distinguisher "65536:43"
            route-target {
                export "target:65536:4"
                import "target:65536:4"
            }
            pw-template-binding "PW3" {
            }
        }
    }
    bgp-vpws {
        admin-state enable
        local-ve {
            name "PE-3"
            id 3
        }
        remote-ve "PE-2" {
            id 2
        }
    }
}
bgp-mh-site "SITEB" {
    admin-state enable
    id 1
    sap 1/1/4:4
    preference 10
}
sap 1/1/4:4 {
}
}

```

Epipe 4 is configured on PE-2 as follows. Two remote VE names are configured, PE-1 and PE-3 (this is the maximum number allowed).

```

# on PE-2:
configure {

```

```

service {
  pw-template "PW3" {
    pw-template-id 3
  }
  epipe "Epipe-4" {
    admin-state enable
    service-id 4
    customer "1"
    bgp 1 {
      route-distinguisher "65536:42"
      route-target {
        export "target:65536:4"
        import "target:65536:4"
      }
      pw-template-binding "PW3" {
      }
    }
    bgp-vpws {
      admin-state enable
      local-ve {
        name "PE-2"
        id 2
      }
      remote-ve "PE-1" {
        id 1
      }
      remote-ve "PE-3" {
        id 3
      }
    }
  }
  sap 1/1/4:4 {
  }
}

```

Compared with the single pseudowire solution, both pseudowires are signaled and up on all PEs. The pseudowire with the higher preference is forwarding traffic (to PE-1), while the Tx status to the standby PE-3 is set to inactive, as follows:

```

The choice of pseudowire to be used to transmit traffic from PE-2 to PE-1 can also be seen in the endpoint created in the BGP VPWS service. Endpoints are automatically created for the pseudowires within a BGP VPWS service, regardless of whether active/standby pseudowires are used; these endpoints are created with a system generated name that ends with the BGP VPWS service id.

Conclusion

BGP VPWS allows the delivery of Layer 2 virtual private wire services to customers where BGP is commonly used. This chapter shows the configuration of single and dual-homed BGP VPWS services together with the associated show output, which can be used to verify and troubleshoot them.

BGP VPLS

This chapter describes advanced BGP VPLS configurations.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Overview

The following two IETF standards describe the provisioning of Virtual Private LAN Services (VPLS).

- RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, describes Label Distribution Protocol (LDP) VPLS, where VPLS pseudowires are signaled using LDP between VPLS Provider Edge (PE) routers, either configured manually or auto-discovered using BGP.
- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*, describes the use of Border Gateway Protocol (BGP) for both the auto-discovery of VPLS PEs and signaling of pseudowires between such PEs.

The purpose of this chapter is to describe the configuration and troubleshooting for BGP-VPLS.

Knowledge of BGP-VPLS RFC 4761 architecture and functionality is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

[Figure 56: Example topology](#) shows the example topology with seven SR OS nodes located in the same Autonomous System (AS).

Figure 56: Example topology

BGP_VPLS_01

There are three Provider Edge (PE) routers, and RR-7 acts as a Route Reflector (RR) for the AS. The PE routers are all VPLS-aware, the Provider (P) routers are VPLS-unaware and do not take part in the BGP process.

The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF on each of the network interfaces between the PE/P routers and RR.
- MPLS is configured on all interfaces between PE routers and P routers. MPLS is not required between P-4 and RR-7.
- LDP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-7.
- The RSVP protocol is enabled.

BGP VPLS

In this architecture, a VPLS instance is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, any VPLS-aware PE is also known as a VPLS Edge (VE) device.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP-VPLS Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs and to set up pseudowire connectivity for data flow between peers containing a local VPLS within the same VPLS instance. Therefore, auto-discovery and pseudowire signaling are achieved using a single BGP update message.

Each PE within a VPLS instance is identified by a VPLS Edge identifier (VE-ID) and the presence of a VPLS instance is determined using the exchange of standard BGP extended community RTs between PEs.

Each PE will advertise, via the route reflectors, the presence of each VPLS instance to all other PEs, along with a block of multiplexer labels that can be used to communicate between such instances plus a BGP next hop that determines a labeled transport tunnel between PEs.

Each VPLS instance is configured with import and export RT extended communities for topology control, along with VE identification.

Configuration

The first step is to configure an MP-iBGP session between each of the PEs and the RR for the L2-VPN address family, as follows:

```
# on PE-1, PE-2, and PE-3:
configure {
  router "Base" {
    autonomous-system 65536
    bgp {
      group "INTERNAL" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.7" {
        group "INTERNAL"
      }
    }
  }
}
```

The IP addresses can be derived from [Figure 56: Example topology](#).

The BGP configuration for RR-7 is as follows:

```
# on RR-7:
configure {
  router "Base" {
    autonomous-system 65536
    bgp {
      cluster {
        cluster-id 1.1.1.1
      }
      group "RR-INTERNAL" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.1" {
        group "RR-INTERNAL"
      }
      neighbor "192.0.2.2" {
        group "RR-INTERNAL"
      }
      neighbor "192.0.2.3" {
        group "RR-INTERNAL"
      }
    }
  }
}
```

On PE-1, the BGP session with RR-7 is established with the L2-VPN address family capability negotiated, as follows:

```
[ ]
```

```
A:admin@PE-1# show router bgp neighbor 192.0.2.7

=====
BGP Neighbor

-----
```

A full mesh of RSVP-TE LSPs is configured between the PE routers. On PE-1, the MPLS interface and LSP configuration are as follows:

```
# on PE-1:
configure {
  router "Base" {
    mpls {
      admin-state enable
      interface "int-PE-1-P-4" {
      }
      interface "int-PE-1-PE-2" {
      }
      path "loose" {
        admin-state enable
      }
      lsp "LSP-PE-1-PE-2" {
        admin-state enable
        type p2p-rsvp
        to 192.0.2.2
        primary "loose" {
        }
      }
      lsp "LSP-PE-1-PE-3" {
        admin-state enable
        type p2p-rsvp
        to 192.0.2.3
        primary "loose" {
        }
      }
    }
  }
}
```

The MPLS and LSP configuration for PE-2 and PE-3 are similar to that of PE-1 with the appropriate interfaces and LSP names configured.

BGP VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate SDP bindings for a service to signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, MAC-pinning, filters, and so on, plus other usage characteristics such as split horizon groups (SHGs).

The MPLS transport tunnel between PEs can be signaled using LDP or RSVP-TE.

LDP based pseudowires can be automatically instantiated. RSVP-TE based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, link layer LDP must be configured between all PEs/Ps, so that a transport label for each PE's system interface is available.

```
# on PE-1:
configure (
  router "Base" {
```

```

    ldp {
      interface-parameters {
        interface "int-PE-1-P-4" {
          ipv4 {
          }
        }
        interface "int-PE-1-PE-2" {
          ipv4 {
          }
        }
      }
    }
  }
}

```

Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at the higher end of the SDP numbering range, such as 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required containing an SHG. Each SDP created with this template is contained within an SHG so that traffic cannot be forwarded between them.

```

# on PE-1:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      split-horizon-group {
        name "VPLS-SHG"
      }
    }
  }
}

```

The pseudowire template also has the following options available when used for BGP-VPLS:

```

[ex:configure service]
A:admin@PE-1# pw-template "PW1" ?

---snip---

control-word          - Enable/Disable the use of ControlWord
---snip---

force-vc-forwarding  - VC forwarding action
---snip---

vc-type               - Type of virtual circuit associated with the SDP bind.
---snip---

```

- The control word will determine whether the C flag is set in the Layer 2 extended community and, therefore, if a control word is used in the pseudowire.
- The **force-vlan-vc-forwarding** command will add a tag (equivalent to **vc-type vlan**) and will allow for customer QoS transparency (dot1p + Drop Eligibility (DE) bits).

```

[ex:configure service pw-template "PW1"]
A:admin@PE-1# force-vc-forwarding ?

force-vc-forwarding <keyword>
<keyword> - (vlan|qinq-c-tag-c-tag|qinq-s-tag-c-tag)

```

- The encap type in the Layer 2 extended community is always 19 (VPLS encap), therefore, the **vc-type** will always be **ether** regardless of the configured value on the vc-type.

```
[ex:configure service pw-template "PW1"]
A:admin@PE-1# vc-type ?

vc-type <keyword>
<keyword> - (ether|vlan)
Default   - ether

Type of virtual circuit associated with the SDP bind.
```

Pseudowire templates for provisioned SDPs using RSVP-TE

To use an RSVP-TE tunnel as transport between PEs, it is necessary to bind the RSVP-TE LSP between PEs to an SDP.

The following SDP is created from PE-1 to PE-2:

```
# on PE-1:
configure {
  service {
    sdp 12 {
      admin-state enable
      description "SDP-PE-1-PE-2_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-1-PE-2" { }
    }
  }
}
```

The **signaling bgp** parameter is required for BGP-VPLS to be able to use this SDP. Conversely, SDPs that are bound to RSVP-based LSPs with signaling set to the default value of **ldp** will not be used as SDPs within BGP-VPLS.

BGP VPLS using auto-provisioned SDPs

[Figure 57: BGP VPLS using auto-provisioned SDPs](#) shows a VPLS instance where SDPs are auto-provisioned. In this case, the transport tunnels are LDP-signaled.

Figure 57: BGP VPLS using auto-provisioned SDPs

The following shows the configuration required on PE-1 for a BGP-VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      split-horizon-group {
        name "VPLS-SHG"
      }
    }
  }
  vpls "VPLS1_PE-1" {
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
      route-distinguisher "65536:1"
      route-target {
        export "target:65536:1"
        import "target:65536:1"
      }
      pw-template-binding "PW1" {
      }
    }
  }
  bgp-vpls {
    admin-state enable
    maximum-ve-id 10
    ve {
      name "PE-1"
      id 1
    }
  }
  sap 1/1/4:1.0 {
  }
}
```

The **bgp** context specifies parameters which are valid for all of the VPLS BGP applications, such as BGP multi-homing (BGP-MH), BGP auto-discovery (BGP-AD), and BGP-VPLS.

Within the **bgp** context, parameters are configured that are used by neighboring PEs to determine membership of a VPLS instance, such as the auto-discovery of PEs containing the same VPLS instance; the route distinguisher (RD) is configured, along with the route target (RT) extended communities.

RT communities are used to determine membership of a VPLS instance. The import RT at the BGP level is mandatory. The pseudowire template bind is then applied by the service manager on the received routes matching the RT value.

Within the **bgp-vpls** context, the signaling parameters are configured. These determine the service labels required for the data plane of the VPLS instance.

The VPLS edge ID (VE-ID) is a numerical value assigned to each PE within a VPLS instance. This value should be unique for a VPLS instance; no two PEs within the same instance should have the same VE-ID values.

A more specific RT can be applied to a pseudowire template in order to define a specific pseudowire topology, rather than only a full mesh, using the command within the **bgp** context:

```
[ex:configure service vpls "VPLS1_PE-1" bgp 1 pw-template-binding "PW1"]
A:admin@PE-1# import-rt ?

import-rt <value>
import-rt [<value>...] - 0..5 system-ordered values separated by spaces enclosed by
brackets

<value> - <string>
<string> - <10..28 characters>

Import route-target communities
```

Changes to the import policies are not taken once the pseudowire has been set up (changes on RT are refreshed though). Pseudowire templates can be re-evaluated with the command **tools perform service eval-pw-template**. The **eval-pw-template** command checks whether all the bindings using this pseudowire template policy are still meant to use this policy.

If the policy has changed and **allow-service-impact** is true, then the old binding is removed and it is re-added with the new template.

VE-ID and BGP label allocations

The choice of VE-ID is crucial in ensuring efficient allocation of de-multiplexer labels. The most efficient choice is for VE-IDs to be allocated starting at 1 and incrementing for each PE as the following section explains.

The **maximum-ve-id** *value* determines the range of the VE-ID value that can be configured. If a PE receives a BGP-VPLS update containing a VE-ID with a greater value than the configured **maximum-ve-id**, then the update is dropped and no service labels are installed for this VE-ID.

The **maximum-ve-id** command also checks the locally-configured VE-ID, and prevents a higher value from being used.

Each PE allocates blocks of labels per VPLS instance to remote PEs, in increments of eight labels. It achieves this by advertising three parameters in a BGP update message,

- A label base (LB) which is the lowest label in the block

- A VE Block Size (VBS) which is always eight labels, and cannot be changed
- A VE Base Offset (VBO).

This defines a block of labels in the range (LB, LB+1, ..., LB+VBS-1).

As an example, if the label base (LB) = 524272, then the range for the block is 524272 to 524279, which is exactly eight labels, as per the block size. (The last label in the block is calculated as 524272+8-1 = 524279)

The label allocated by the PE to each remote PE within the VPLS is chosen from this block and is determined by its VE-ID. In this way, each remote PE has a unique de-multiplexer label for that VPLS.

To reduce label wastage, contiguous VE-IDs in the range (N..N+7) per VPLS should be chosen, where N>0.

Assuming a collection of PEs with contiguous VE-IDs, the following labels will be chosen by PEs from the label block allocated by PE-1 which has a VE-ID =1.

Table 3: VE-IDs and Labels

VE-ID	Label
2	524273
3	524274
4	524275
5	524276
6	524277
7	524278
8	524279

This shows that the label allocated to a PE is (LB+VEID-1). The "1" is the VE block offset (VBO).

This means that the label allocated to a PE router within the VPLS can now be written as (LB + VEID - VBO), which means that (VEID - VBO) calculation must always be at least zero and be less than the block size, which is always 8.

For VE-ID < 8, a label will be allocated from this block.

For the next block of 8 VE-IDs (VE-ID 9 to VE-ID 16) a new block of 8 labels must be allocated, so a new BGP update is sent, with a new label base, and a block offset of 9.

Table 4: VE-IDs and Number of Labels shows how the choice of VE-IDs can affect the number of label blocks allocated, and therefore the number of labels:

Table 4: VE-IDs and Number of Labels

VE-ID	Block Offset	Labels Allocated
1-8	1	8
9-16	9	8

VE-ID	Block Offset	Labels Allocated
17-24	17	8
25-32	25	8
33-40	33	8
41-48	41	8
49-56	49	8

This shows that the most efficient use of labels occurs when the VE-IDs for a set of PEs are chosen from the same block offset.

If VE-IDs are chosen that map to different block offsets, then each PE will have to send multiple BGP updates to signal service labels. Each PE sends label blocks in BGP updates to each of its BGP neighbors for all label blocks in which at least one VE-ID has been seen by this PE (it does not advertise label blocks which do not contain an active VE-ID, where active VE-ID means the VE-ID of this PE or any other PE in this VPLS).

The **maximum-ve-id** must be configured first, and determines the maximum value of the VE-ID that can be configured within the PE. The VE-ID value cannot be higher than this within the PE configuration, VE-ID <= maximum VE-ID. Similarly, if the VE-ID within a received NLRI is higher than the maximum VE-ID value, it will not be accepted as valid consequently the maximum VE-ID configured on all PEs must be greater than or equal to any VE-ID used in the VPLS.

Only one VE-ID value can be configured. If the VE-ID value is changed, BGP withdraws the NLRI and sends a route-refresh.

If the same VE-ID is used in different PEs for the same VPLS, a Designated Forwarder (DF) election takes place.

Executing the **admin-state disable** command triggers an MP-UNREACH-NLRI from the PE to all BGP peers.

The **admin-state enable** command triggers an MP-REACH-NLRI to the same peers.

PE-2 service creation

On PE-2, a VPLS service using pseudowire template 1 is created. In order to make the label allocation more efficient, PE-2 has been allocated a VE-ID value of 2. For completeness, the pseudowire template is also shown.

```
# on PE-2:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      split-horizon-group {
        name "VPLS-SHG"
      }
    }
  }
  vpls "VPLS1_PE-2" {
    admin-state enable
    service-id 1
    customer "1"
  }
}
```

```
    bgp 1 {
      route-distinguisher "65536:1"
      route-target {
        export "target:65536:1"
        import "target:65536:1"
      }
      pw-template-binding "PW1" {
      }
    }
  }
  bgp-vpls {
    admin-state enable
    maximum-ve-id 10
    ve {
      name "PE-2"
      id 2
    }
  }
  sap 1/1/4:1.0 {
  }
}
```

The **maximum-ve-id** value is set to 10 to allow an increase in the number of PEs that could be a part of this VPLS instance.

PE-3 service creation

The following configuration creates a VPLS instance on PE-3, using a VE-ID value of 3.

```
# on PE-3:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      split-horizon-group {
        name "VPLS-SHG"
      }
    }
  }
  vpls "VPLS1_PE-3" {
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
      route-distinguisher "65536:1"
      route-target {
        export "target:65536:1"
        import "target:65536:1"
      }
      pw-template-binding "PW1" {
      }
    }
    bgp-vpls {
      admin-state enable
      maximum-ve-id 10
      ve {
        name "PE-3"
        id 3
      }
    }
  }
  sap 1/1/4:1.0 {
  }
}
```

```
}

```

PE-1 service operation verification

The following command shows that the BGP-VPLS site is enabled on PE-1.

```
[ ]
A:admin@PE-1# show service id 1 bgp-vpls

=====

=====
```

As can be seen from the following output, a BGP-VPLS NLRI update is sent to the route reflector (192.0.2.7) and is received by each PE.

PE-1 has sent the following BGP NLRI update for VPLS 1 to RR-7.

```
1 2021/01/26 10:54:39.689 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.7
"Peer 1: 192.0.2.7: UPDATE
Peer 1: 192.0.2.7 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 72
  Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
    Address Family L2VPN
    NextHop len 4 NextHop 192.0.2.1
    [VPLS/VPWS] preflen 17, veid: 1, vbo: 1, vbs: 8, label-base: 524272, RD 65536:1
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x80 Type: 4 Len: 4 MED: 0
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 16 Extended Community:
    target:65536:1
    l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
"
```

The control flags within the extended community indicate the status of the VPLS instance.

The control flag D indicates that all attachment circuits are Down, or the VPLS is disabled. The flags are used in BGP-MH when determining which PEs are DF, see chapter [BGP Multi-Homing for VPLS Networks](#).

When flags=none, then all attachment circuits are up. In the preceding example, no flags are present, but should all SAPs become operationally down, then the control flag D would be seen in the debug message. To simulate this, the SAP 1/1/4:1 is disabled on PE-1:

```
# on PE-1:
configure {
  service {
    vpls "VPLS1_PE-1" {
      sap 1/1/4:1.0 {
        admin-state disable
      }
    }
  }
}
```

All SAPs in VPLS 1 on PE-1 are operationally down, so PE-1 sends a BGP update message with control flag D set, as follows:

```
5 2021/01/26 11:09:10.688 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.7
"Peer 1: 192.0.2.7: UPDATE
Peer 1: 192.0.2.7 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 72
  Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
    Address Family L2VPN
    NextHop len 4 NextHop 192.0.2.1
    [VPLS/VPWS] preflen 17, veid: 1, vbo: 1, vbs: 8, label-base: 524272, RD 65536:1
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x80 Type: 4 Len: 4 MED: 0
```

```

Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
Flag: 0xc0 Type: 16 Len: 16 Extended Community:
target:65536:1
l2-vpn/vrf-imp:Encap=19: Flags=D: MTU=1514: PREF=0
"

```

The SAP is re-enabled with the following command on PE-1:

```

# on PE-1:
configure {
  service {
    vpls "VPLS1_PE-1" {
      sap 1/1/4:1.0 {
        admin-state enable
      }
    }
  }
}

```

The BGP VPLS signaling parameters are also present in the BGP update message, namely the VE-ID of the PE within the VPLS instance, the VBO and VBS, and the label base. The target indicates the VPLS instance, which must be matched against the import RTs of the receiving PEs.

The signaling parameters can be seen within the BGP update with following command:

```

```

In this configuration example, PE-1 (192.0.2.1) with VE-ID =1 has sent an update with base offset (VBO) =1, block size (VBS) = 8, and label base 524272. This means that labels 524272 (LB) to 524279 (LB +VBS-1) are available as de-multiplexer labels, egress labels to be used to reach PE-1 for VPLS 1.

PE-2 receives this update from PE-1. This is seen as a valid VPLS BGP route from PE-1 through the route reflector with next-hop 192.0.2.1.

```

PE-2 uses this information in conjunction with its own VE-ID to calculate the egress label toward PE-1, using the condition $VBO < VE-ID < (VBO+VBS)$.

The VE-ID of PE-2 is in the Label Block covered by $VBO = 1$, thus,

Label calculation = label base + local VE-ID - Base offset

$$= 524272 + 2 - 1$$

Egress label used = 524273

This is verified using the following command on PE-2 where the egress label toward PE-1 (192.0.2.1) is 524273.

```

PE-2 de-multiplexer label calculation

In the same way that PE-1 allocates a label base (LB), block size (VBS), and base offset (VBO), PE-2 also allocates the same parameters for PE-1 and PE-3 to calculate the egress service label required to reach PE-2.

```

```

This example has shown that for VPLS instance with 3 PEs, not all labels allocated by a PE will be used by remote PEs as de-multiplexer service labels. There will be some wastage of label space, so there is a necessity to choose VE-IDs that keep this waste to a minimum.

The next example will show an even more wasteful use of labels by using a random choice of VE-IDs.

BGP VPLS using pre-provisioned SDP

It is possible to configure BGP-VPLS instances that use RSVP-TE transport tunnels. In this case, the SDP must be created with the MPLS LSPs mapped and with signaling set to BGP, as the service labels are signaled using BGP. The pseudowire template configured within the BGP-VPLS instance must be configured with **provisioned-sdp use**. This example also examines the effect of using VE-IDs that are not all within the same contiguous block.

[Figure 58: BGP VPLS using pre-provisioned SDP](#) shows an example of a VPLS instance where SDPs are pre-provisioned with RSVP-TE signaled transport tunnels.

Figure 58: BGP VPLS using pre-provisioned SDP

On the PEs, the following SDPs are configured with RSVP transport tunnels.

```
# on PE-1:
configure {
  service {
    sdp 12 {
      admin-state enable
      description "SDP-PE-1-PE-2_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-1-PE-2" { }
    }
    sdp 13 {
      admin-state enable
      description "SDP-PE-1-PE-3_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.3
      }
      lsp "LSP-PE-1-PE-3" { }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    sdp 21 {
      admin-state enable
      description "SDP-PE-2-PE-1_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.1
      }
      lsp "LSP-PE-2-PE-1" { }
    }
  }
}
```

```

}
sdp 23 {
  admin-state enable
  description "SDP-PE-2-PE-3_RSVP_BGP"
  delivery-type mpls
  signaling bgp
  far-end {
    ip-address 192.0.2.3
  }
  lsp "LSP-PE-2-PE-3" { }
}

```

```

# on PE-3:
configure {
  service {
    sdp 31 {
      admin-state enable
      description "SDP-PE-3-PE-1_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.1
      }
      lsp "LSP-PE-3-PE-1" { }
    }
    sdp 32 {
      admin-state enable
      description "SDP-PE-3-PE-2_RSVP_BGP"
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-3-PE-2" { }
    }
  }
}

```

Pre-provisioned BGP-SDPs can also be used with BGP-VPLS. For reference, they are configured as follows:

```

# on PE-3:
configure {
  service {
    sdp 332 {
      admin-state enable
      delivery-type mpls
      signaling bgp
      far-end {
        ip-address 192.0.2.2
      }
    }
  }
}

```

To create an SDP within a service that uses the RSVP transport tunnel, a pseudowire template is required that has the **provisioned-sdp use** parameter set. It is also possible to configure the **provisioned-sdp prefer** parameter, see chapter [LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP](#).

Once again, an SHG is included to prevent forwarding between pseudowires.

The following pseudowire template is provisioned on all PEs:

```

# on PE-1, PE-2, and PE-3:
configure {

```

```

service {
  pw-template "PW2" {
    pw-template-id 2
    provisioned-sdp use
    split-horizon-group {
      name "VPLS-SHG"
    }
  }
}

```

The following output shows the configuration required for a BGP-VPLS service using a pseudowire template configured for using pre-provisioned RSVP-TE SDPs.

```

# on PE-1:
configure {
  service {
    vpls "VPLS2_PE-1" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
        route-distinguisher "65536:2"
        route-target {
          export "target:65536:2"
          import "target:65536:2"
        }
        pw-template-binding "PW2" {
        }
      }
    }
    bgp-vpls {
      admin-state enable
      maximum-ve-id 100
      ve {
        name "PE-1"
        id 1
      }
    }
    sap 1/1/4:2.0 {
    }
  }
}

```

The RD and RT extended community values for VPLS 2 are different from the ones in VPLS 1. The VE-ID value for PE-1 can be the same as the one in VPLS 1, but these must be different within the same VPLS instance on the other PEs — PE-2 should not have VE-ID = 1.

On PE-2, the configuration is as follows with the VE-ID value equal to 20, which will result in a label from a different block:

```

# on PE-2:
configure {
  service {
    vpls "VPLS2_PE-2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
        route-distinguisher "65536:2"
        route-target {
          export "target:65536:2"
          import "target:65536:2"
        }
        pw-template-binding "PW2" {
        }
      }
    }
  }
}

```

```

    }
    bgp-vpls {
        admin-state enable
        maximum-ve-id 100
        ve {
            name "PE-2"
            id 20
        }
    }
    sap 1/1/4:2.0 {
    }
}

```

On PE-3, the configuration is as follows with the VE-ID value equal to 3:

```

# on PE-3:
configure {
    service {
        vpls "VPLS2_PE-3" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "65536:2"
                route-target {
                    export "target:65536:2"
                    import "target:65536:2"
                }
                pw-template-binding "PW2" {
                }
            }
        }
        bgp-vpls {
            admin-state enable
            maximum-ve-id 100
            ve {
                name "PE-3"
                id 3
            }
        }
    }
    sap 1/1/4:2.0 {
    }
}

```

The service is operationally up on PE-1, as follows:

PE-1 de-multiplexer label calculation

In the case of VPLS 1, all VE-IDs are in the range of a single label block. In the case of VPLS 2, the VE-IDs are in different blocks, for example, the VE-ID 20 is in a different block to VE-IDs 1 and 3.

As the label allocation is block-dependent, multiple label blocks must be advertised by each PE to encompass this.

Consider PE-1's BGP update NLRIs.

Routes : 8
=====
    
```

Two NLRIs updates are sent to the route reflector, with the following label parameters:

1. LB = 524264, VBS = 8, VBO = 1
2. LB = 524256, VBS = 8, VBO = 17

PE-2 has a VE-ID of 20. Applying the condition $VBO < VE-ID < (VBO+VBS)$

- Update 1: LB = 524264, VBS = 8, VBO = 1
- $VBO < VE-ID$ for $VE-ID = 20$ is true
- $VE-ID < (VBO+VBS)$ for $VE-ID = 20$ is false.
- PE-2 cannot choose a label from this block.
- Update 2: LB = 524256, VBS = 8, VBO = 17
- $VBO < VE-ID$ for $VE-ID = 20$ is true
- $VE-ID < (VBO+VBS)$ for $VE-ID = 20$ is true.
- PE-2 chooses label $524256 + 20 - 17 = 524259$ (LB + VEID - VBO)

The egress label chosen is verified by examining the egress label toward PE-1 (192.0.2.1) on PE-2.

```

To illustrate the allocation of label blocks by a PE, against the actual use of the same labels, consider the following. When BGP updates from each PE signal the multiplexer labels in blocks of eight, the allocated label values are added to the in-use pool. First check what label range can be allocated dynamically.

```
[ ]
A:admin@PE-1# show router mpls-labels label-range

=====
Label Ranges
=====
Label Type      Start Label  End Label    Aging      Available  Total
-----
Static          32           18431        -          18400     18400
Dynamic         18432        524287       0          505824    505856

```

This shows that 24 labels have been allocated for use by BGP. Of this number, 16 labels have been allocated for use by PEs within VPLS 2 to communicate with PE-1, the blocks with label base 524256 and with label base 524264.

There are only two neighboring PEs within this VPLS instance, so only two labels will ever be used in the data plane for traffic destined for PE-1. These are 524259 and 524266. The remaining labels have no PE with the associated VE-ID that can use them.

Once again, this case emphasizes that to reduce label wastage, contiguous VE-IDs in the range (N..N+7) per VPLS should be chosen, where N>0.

Conclusion

BGP-VPLS allows the delivery of Layer 2 VPN services to customers where BGP is commonly used. The examples presented in this chapter show the configuration of BGP-VPLS together with the associated show outputs which can be used for verification and troubleshooting.

Black-hole MAC for EVPN Loop Protection

This chapter provides information about Black-hole MAC for EVPN Loop Protection.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2. Black-hole MAC for EVPN loop protection is supported in SR OS Release 15.0.R1, and later.

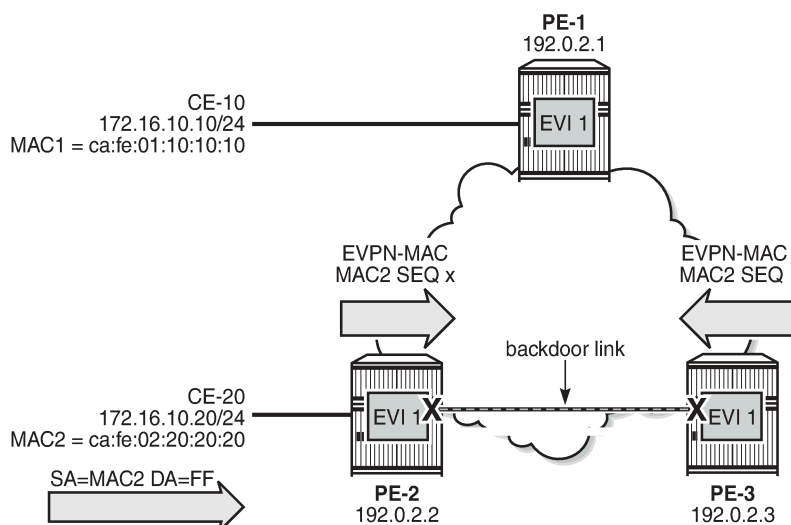

Chapters [Auto-Learn MAC Protect in EVPN](#) and [Conditional Static Black-Hole MAC in EVPN](#) are prerequisite reading.

Overview

Service providers are migrating VPLS networks to EVPN and require the same or better loop protection mechanisms, such as **mac-move** or **auto-learn-mac-protect** (ALMP). Chapter [Auto-Learn MAC Protect in EVPN](#) describes how traffic is protected in "static" networks, where the CEs do not move to a different port or PE, and MAC addresses are always learned first on the correct SAP/SDP-bindings. However, ALMP does not provide a loop protection solution in EVPN networks that require mobility and ALMP has issues with all-active multi-homing. Since mobility and all-active multi-homing are two of the key advantages of EVPN compared to VPLS, an alternate loop protection mechanism is required. This chapter describes an example for the black-hole based loop protection solution, based on *draft-snr-bess-evpn-loop-protect*.

[Figure 59: Black-hole MAC for EVPN loop protection](#) shows a topology using black-hole MAC for EVPN loop protection.

Figure 59: Black-hole MAC for EVPN loop protection

26789

VPLS 1 with EVI 1 is configured on all PEs. A backdoor link exists between PE-2 and PE-3 (in this case, caused by misconfiguration: additional SAPs are configured in VPLS 1). When CE-20 sends Broadcast, Unknown unicast, or Multicast (BUM) traffic, its source address MAC2 is learned by PE-2, which sends an EVPN-MAC route for MAC2 to its BGP peers. PE-2 floods the frame to its EVPN-MPLS destinations (PE-1 and PE-3) as well as its local SAPs (including the backdoor link to PE-3).

PE-3 receives the EVPN-MAC route from PE-2, but due to the backdoor link, it also learns MAC2 on its local SAP. Following the MAC mobility procedures, PE-3 advertises MAC2 with a higher sequence number to its BGP peers. PE-3 floods the frame to its EVPN-MPLS destinations and to its local SAPs.

Note:

The preceding simplified description assumes that PE-3 receives the EVPN-MAC route prior to learning MAC2 from the backdoor link, which may or may not be the case. Regardless of how MAC2 is learned, the MAC duplication procedures are invoked.

PE-2 and PE-3 keep learning and advertising MAC2 until the configured number of MAC moves (**num-moves**) has been reached. Then, MAC2 is detected as duplicate and will not be advertised again until the **retry** interval has expired.

If the **mac-duplication blackhole** option is enabled, MAC2 will be added to the FDB as black-hole MAC, so traffic with MAC DA = MAC2 will be discarded. Also, MAC addresses assigned to a black-hole destination are considered as protected, so traffic with MAC SA = MAC2 will not be forwarded due to one of the following reasons:

- When the SAPs/SDP-bindings or BGP-EVPN MPLS/VXLAN destinations are configured with **fdb>protected-src-mac-violation-action discard**, the frames are discarded before any MAC SA is learned or the MAC DA is looked up.
- When the SAP is configured with **fdb>protected-src-mac-violation-action sap-oper-down**, an incoming frame with MAC SA = black-hole MAC causes the system to bring down the corresponding SAP.

Assuming PE-3 detects MAC2 as duplicate and installs it as black-hole MAC, PE-3 will discard the broadcast frames with MAC SA = MAC2, so the loop is broken, whereas the legitimate traffic between CE-10 and CE-20 is allowed (assuming PE-2 does not black-hole MAC2).

Black-hole MAC duplication is enabled with **blackhole true** in the **mac-duplication** context, as follows:

```
[ex:/configure service vpls "VPLS 1" bgp-evpn]
A:admin@PE-3# mac-duplication ?

mac-duplication

blackhole          - Enable black hole dup MAC configuration
detect             + Enter the detect context
retry              - BGP EVPN MAC duplication retry
```

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mac-duplication {
          blackhole true
        }
      }
    }
  }
}
```

When enabled, the operation is as follows:

- Each node that learns a MAC address that has been advertised by a BGP peer will send an EVPN-MAC route for that MAC address with a higher sequence number. When the number of MAC moves exceeds the configured threshold (by default, five MAC moves in three minutes), the MAC address is detected as duplicate and no EVPN-MAC routes will be sent for that MAC address until the retry interval (default nine minutes) has elapsed.
- When MAC2 is detected as duplicate, the system will:
 - Add MAC2 to the duplicate MAC list
 - Add MAC2 in the FDB as protected MAC associated with a black-hole endpoint (type **EvpnD:P** and source identifier **black-hole**)
 - Incoming frames with MAC DA = MAC2 will be discarded based on a MAC lookup in the FDB.
 - MAC addresses assigned to a black-hole destination are protected and incoming frames with MAC SA = MAC2 will be discarded or the system will bring down the SAP/SDP-binding, depending on the **protected-src-mac-violation-action** on the SAP/SDP/EVPN endpoint.

The following output shows the FDB with black-hole MAC address ca:fe:02:20:20:20 (type EvpnD:P):

```
[/]
A:admin@PE-3# show service id 1 fdb detail

=====

-----
Legend:  L=Learned O=0am P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
```

The duplicate MAC address will be removed from the FDB and the process will be restarted in the following cases:

- Retry interval events:
 - When the retry interval expires.
 - When the user configures **retry never** on the service that detected the duplicate MAC address.
- MAC relearning events:
 - When the remote PE withdraws the MAC address (due to aging or **clear service fdb**). Local attempts to clear a black-hole MAC (via **clear service fdb**) will fail because the type of the MAC entry is not "learned", but "EvpnD:P".
 - When configuring a local conditional static MAC address (CStatic:P) prevents the EvpnD:P entry for the same MAC address from being installed in the FDB as black-hole, if the SAP/SDP-binding where the MAC is configured is operationally up.
- CPM switchover event

Configuration

Figure 60: Example topology shows the example topology with three PEs and two CEs. A loop will occur when CE-20 sends Broadcast, Unknown unicast, or Multicast (BUM) traffic. Traffic between PE-2 and PE-3 will be sent over the regular router interfaces between the PEs, but also over the backdoor link (SAP 1/1/2:1 in VPLS 1 on PE-2 and SAP 1/1/1:1 in VPLS 1 on PE-3).

Figure 60: Example topology

26790

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces (alternatively, OSPF can be used)
- LDP on all router interfaces

Enable black-hole MAC duplication detection in EVPN

BGP is configured for address family EVPN on all PEs with PE-3 as route reflector. The following is the BGP configuration on PE-3:

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "internal" {
      peer-as 64500
      family {
        evpn true
      }
      cluster {
        cluster-id 192.0.2.3
      }
    }
    neighbor "192.0.2.1" {
      group "internal"
    }
    neighbor "192.0.2.2" {
      group "internal"
    }
  }
}
```

VPLS 1 is configured on all PEs with BGP-EVPN and MAC duplication enabled; on PE-2, as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        mac-duplication {
          retry 2      # Duplicate MACs are released after retry interval
          blackhole true
          detect {
            num-moves 3      # speed up MAC-duplication detection
            window 1        # speed up MAC-duplication detection
          }
        }
      }
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution any
        }
        fdb {
          protected-src-mac-violation-action discard
        }
      }
    }
  }
}
```

```

    }
  }
  sap 1/1/2:1 {          # backdoor link to PE-3
  }
  sap 1/2/1:1 {          # to CE-20
  }
}

```

To speed up MAC duplication detection, MAC duplication is detected after three MAC moves (default: five MAC moves). To shorten the retry interval, the time window is reduced to one minute (default: three minutes). When a MAC address has been detected as duplicated, the system removes the duplicate MAC entry after a retry interval of two minutes (default: nine minutes). The retry interval must be at least twice the time window for MAC duplication detection.

On the EVPN-MPLS endpoints, **protected-src-mac-violation-action discard** must be configured. When MAC address ca:fe:02:20:20:20 is detected on PE-3 as a duplicate MAC address that is black-holed, the EVPN-MPLS endpoints on PE-3 should discard all frames with MAC SA ca:fe:02:20:20:20.

The configuration on the other PEs is similar; only the SAPs are different. VPLS 1 on PE-1 has SAP 1/2/1:1 to CE-10, but no SAP to a backdoor link; VPLS 1 on PE-3 has SAP 1/1/1:1 to the backdoor link to PE-2, but no SAP to a CE.

When CE-20 sends BUM traffic, its MAC SA ca:fe:02:20:20:20 is learned by PE-2 and advertised in EVPN-MAC routes. Because of the backdoor link to PE-3, PE-3 also learns MAC SA ca:fe:02:20:20:20 and advertises it to its BGP peers. The MAC-mobility sequence number is increased until the threshold of three MAC moves is reached. The following BGP EVPN-MAC route with sequence number 2 is sent by PE-2 to PE-3:

```

# on PE-2:

Detected Duplicate MAC Addresses           Time Detected
-----
ca:fe:02:20:20:20                         04/28/2021 09:59:12
-----
---snip---

```

The following message is logged in log "99" on PE-3 when VPLS 1 has detected duplicate MACs:

```

# on PE-3:
69 2021/04/28 10:04:40.266 UTC MINOR: SVCMGR #2331 Base

```

```
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

MAC address ca:fe:02:20:20:20 remains in the FDB as duplicate and black-holed until the retry interval expires, as follows:

```
[ex:/configure service vpls "VPLS 1" bgp-evpn mac-duplication]
A:admin@PE-3# retry ?

retry (<number> | <keyword>)
<number>   - <2..60>   - minutes
<keyword>  - never     - minutes
Default    - 9

      BGP EVPN MAC duplication retry
```

By default, the retry interval is nine minutes, but in this example, it is set to two minutes, which is the minimum value. The retry interval must be at least twice the time window for MAC duplication detection, which is by default three minutes, but reduced to one minute in this example. The following error is raised when attempting to configure a retry interval of two minutes for a detection time window of three minutes:

```
*[ex:/configure service vpls "VPLS 1" bgp-evpn mac-duplication]
A:admin@PE-3# commit
MINOR: MGMT_CORE #3001: configure service vpls "VPLS 1" bgp-evpn mac-duplication retry - mac-duplication detection window should be less than or equal to half of retry time
```

After the retry interval expires, the MAC duplication is released.

Log "99" shows the following message when VPLS 1 no longer has duplicate MAC addresses:

```
# on PE-3:
70 2021/04/28 10:06:43.398 UTC MINOR: SVCNMR #2332 Base
"VPLS Service 1 no longer has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

MAC address ca:fe:02:20:20:20 remains in the FDB with type Evpn instead of EvpnD:P. BGP routes only disappear after a withdraw message has been received, whereas locally learned MAC addresses are flushed.

```
[/]

```

Restrict Protected Source option

By default, the frames with MAC SA or DA equal to the duplicate MAC address are discarded, but the SAP/SDP-binding where the frame enters the VPLS remains operationally up. With the **protected-src-mac-violation-action sap-oper-down**, the system will bring the SAP down where the frame with duplicate source MAC enters. The configuration on PE-2 and PE-3 is modified with **protected-src-mac-violation-action sap-oper-down** on the SAP to the backdoor link, as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/1/2:1 {
        fdb {
          protected-src-mac-violation-action sap-oper-down
        }
      }
    }
  }
}

# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/1/1:1 {
        fdb {
          protected-src-mac-violation-action sap-oper-down
        }
      }
    }
  }
}
```

When CE-20 sends BUM traffic, PE-3 detects MAC ca:fe:02:20:20:20 as duplicate. Log "99" shows that a duplicate MAC address has been detected, that protected MAC address ca:fe:02:20:20:20 has been received on SAP 1/1/1:1 in VPLS 1, and that the status of SAP 1/1/1:1 in VPLS 1 is changed to operationally down, with flag **RxProtSrcMac** indicating that a protected source MAC has been received.

```
80 2021/04/28 10:11:40.885 UTC MINOR: SVCMgr #2203 Base
"Status of SAP 1/1/1:1 in service 1 (customer 1) changed to admin=up oper=down flags=RxProtSrc
Mac "

79 2021/04/28 10:11:40.885 UTC MINOR: SVCMgr #2208 Base
```

```
"Protected MAC ca:fe:02:20:20:20 received on SAP 1/1/1:1 in service 1. The SAP will be disabled."
```

```
78 2021/04/28 10:11:39.886 UTC MINOR: SVCMGR #2331 Base  
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

The following shows that SAP 1/1/1:1 in VPLS 1 on PE-3 is operationally down with flag RxProtSrcMac:

```
[/]
A:admin@PE-3# show service id 1 sap 1/1/1:1

Black-hole MAC duplication in all-active multi-homing

Figure 61: Example topology with all-active multi-homing shows the example topology with all-active multi-homing.

Figure 61: Example topology with all-active multi-homing

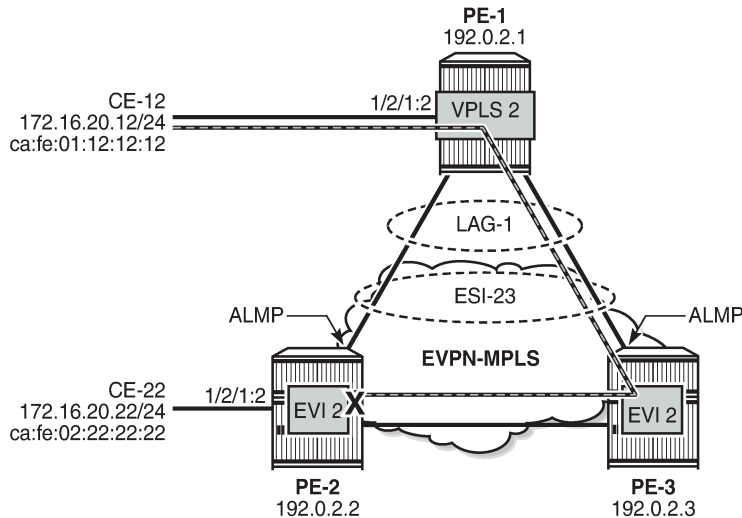

26791

In this topology, the backdoor link is removed. On PE-1, VPLS 2 is configured without EVPN; on PE-2 and PE-3, VPLS 2 is configured with EVPN-MPLS. LAG 1 is configured on the PEs and Ethernet Segment (ES) ESI-23 is created on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-23" {
            admin-state enable
            esi 01:00:00:00:00:23:00:00:00:01
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
            }
          }
        }
      }
    }
  }
}
```

The reason why black-hole MAC duplication should be configured instead of ALMP is the following. When ALMP is configured on SAP lag-1:2 on PE-2 and PE-3, MAC address ca:fe:01:12:12:12 of CE-12 is learned and protected on the SAP on both PEs. Traffic sent from CE-12 to CE-22 that is hashed over the direct link between PE-1 and PE-2 will reach its destination. Traffic that is hashed over the link between PE-1 and PE-3 will be forwarded by PE-3 to PE-2, but PE-2 will drop the traffic because it contains a MAC SA that is protected locally, as shown in [Figure 62: Traffic dropped when ALMP is configured in all-active multi-homing](#).

Figure 62: Traffic dropped when ALMP is configured in all-active multi-homing

26792

When black-hole MAC duplication is configured instead of ALMP, traffic hashed on the link to PE-3 is forwarded to PE-2 and to CE-22. This is because MAC duplication is ES-aware and the same MAC seen on the same ES in two different PEs will never be detected as duplicate.

The configuration of VPLS 2 in PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 2
        mac-duplication {
          blackhole true
        }
        mpls 1 {
          admin-state enable
          auto-bind-tunnel {
            resolution any
          }
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
      sap 1/2/1:2 {
      }
      sap lag-1:2 {
      }
    }
  }
}
```

The configuration of VPLS 2 on PE-3 is similar.

Conclusion

Black-hole MAC for EVPN MAC duplication protects EVPN services against customer-created backdoors or loops, while supporting MAC mobility and all-active multi-homing.

Conditional Static Black-Hole MAC in EVPN

This chapter provides information about Conditional Static Black-Hole MAC in EVPN.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. Conditional static black-hole MAC is supported on EVPN services only, including EVPN-VXLAN and EVPN-MPLS, in SR OS Release 14.0.R1, and later.

Overview

A static black-hole MAC address is a local FDB record associated with a black-hole instead of a SAP or SDP-binding. Black-hole MAC addresses offer a scalable way to filter frames in the data plane based on MAC DA or SA, regardless of how the frame is arriving in the system. Black-hole MAC addresses can be configured in EVPN in the following ways:

- Static configured black-hole MAC address
- Anti-spoof MAC address in proxy Address Resolution Protocol/Neighbor Discovery (proxy-ARP/ND)
- MAC-duplication black-hole (supported in SR OS Release 15.0.R1, and later), see chapter [Black-hole MAC for EVPN Loop Protection](#)

When a specific MAC address is configured as a static black-hole MAC address, all frames with MAC DA equal to this black-hole MAC address will be dropped. Also, black-hole MAC addresses are treated as protected MAC addresses, which allows filtering on MAC SA; see chapter [Auto-Learn MAC Protect in EVPN](#).

The default behavior on the SAP/SDP-bindings is Restricted Protected Source Discard Frame (RPS-DF). Therefore, all frames with MAC SA equal to the black-hole MAC address will, by default, be dropped on the SAP/SDP-binding where the frames enter the service. Instead of dropping the frames, the entire SAP/SDP-binding can be brought operationally down, if the SAP/SDP-binding is explicitly configured with Restricted Protected Source (RPS) with **sap-oper-down/sdp-bind-oper-down**. The SAP/SDP-binding can only be brought up manually by disabling and re-enabling the SAP/SDP-binding. On the EVPN endpoints between PEs, it is possible to configure RPS-DF, not RPS. When configured, the EVPN endpoint will drop frames with MAC SA equal to the black-hole MAC address.

Black-hole MAC addresses can be used as an alternative to MAC filters, which simplifies the deployment of proxy-ARP/ND with anti-spoof MAC addresses. ARP/ND spoofing is a technique whereby an attacker sends fake ARP/ND messages to a broadcast domain. Generally, the aim is to get the routers in the broadcast domain to associate the attacker's MAC address with the IP address of another host, causing any traffic destined to that IP address to be sent to the attacker instead. To prevent this from happening, a proxy-ARP/ND with duplicate IP detection monitors the number of times the MAC changes for an offending

IP address. When a certain number of MAC moves are detected in a defined period, the system flags the proxy-ARP entry as duplicate for a defined hold time and an alarm is sent to log 99.

Chapter [EVPN for MPLS Tunnels](#) describes the proxy-ARP/ND configuration with the option to define an anti-spoof MAC (AS-MAC) address for EVPN-MPLS networks using MAC filters, including some recommended settings. The AS-MAC address will be advertised with the duplicate IP address in gratuitous ARP (GARP) and ARP replies to all CEs in the EVPN (in the case of proxy-ND, unsolicited Neighbor Advertisement messages are sent instead of GARP messages).

ARP/ND broadcast traffic is a security issue for Internet eXchange Providers (IXPs) and service providers with large Layer 2 domains. In such networks, administrators try to avoid ARP/ND flooding. [Figure 63: Proxy-ARP/ND and ARP spoofing](#) shows the proxy-ARP/ND feature where local ARP/ND requests are responded by the system on behalf of the IP interface owners.

Figure 63: Proxy-ARP/ND and ARP spoofing

26244

EVPN can suppress ARP/ND flooding within an EVPN service if all the attached hosts advertise their presence. Therefore, EVPN is preferred in IXPs to mitigate and even eliminate the ARP/ND flooding issue. The proxy-ARP/ND agent responds to local ARP/ND requests using a proxy-ARP/ND table per service. This table is populated by EVPN entries (MAC-IP pairs), static entries configured in the service, and dynamic entries snooped from ARP/GARP/ND messages sent by the ISP routers. The static entries and snooped dynamic entries are also advertised in EVPN-MAC routes.

As well as the proxy-ARP/ND, SR OS supports an anti-spoofing mechanism that can detect and block an ARP spoofing attack or a misconfigured duplicated IP address. When using MAC filters, the same anti-spoof-mac option must be configured in all the PEs and this filter may be configured on all the PE SAPs/SDP-bindings to discard all the frames with MAC DA equal to the anti-spoof MAC address. This requires a lot of configuration and is prone to configuration errors.

Conditional static black-hole MAC addresses can be configured for the anti-spoof MAC address so that frames with MAC DA equal to the anti-spoof MAC address can be discarded based on a MAC address lookup in the FDB, as opposed to a MAC filter entry. Less configuration is required and this simplifies the deployment of proxy-ARP/ND with AS-MAC. The configuration example in this chapter includes proxy-ARP, but the behavior is similar for proxy-ND.

Configuration

Figure 64: Example topology shows the example topology. Traffic will be sent between the CEs and may be dropped in the PEs if the MAC DA or MAC SA matches a black-hole MAC address. IP address 172.16.0.10/24 is duplicate (CE-10 and CE-11).

Figure 64: Example topology

26245

The initial configuration on the nodes includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PEs
- LDP between PEs

BGP is configured between the PEs for address family EVPN with PE-2 as route reflector (RR). Instead of an RR, a full mesh can also be configured between the PEs. The BGP configuration on PE-2 is as follows:

```
# on RR PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "internal" {
```

```

    peer-as 64500
    family {
        evpn true
    }
    cluster {
        cluster-id 1.1.1.1
    }
}
neighbor "192.0.2.3" {
    group "internal"
}
neighbor "192.0.2.4" {
    group "internal"
}
}

```

VPLS 1 is configured on all PEs and on MTU-1 (MTU-1's VPLS 1 is connected to PE-3 by a SAP). The VPLS configuration on the PEs includes EVPN-MPLS, as follows:

```

# on PE-3:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        sap 1/2/1:1 {
        }
        sap 1/2/3:1 {
        }
    }
}

```

Conditional static black-hole MAC

Conditional static black-hole MAC address is an extension to the conditional static MAC address, but with the blackhole keyword. It is a scalable way to filter MAC DA or SA in the data plane, regardless of how the frame is arriving at the system (SAP/SDP-bindings or EVPN termination endpoints).

When the static black-hole MAC is added to the FDB, all Ethernet frames with MAC DA equal to the black-hole MAC are dropped. Filtering based on the MAC SA is explained in the next section: [Conditional static black-hole MAC in combination with restrict protected source](#).

[Figure 65: Conditional static black-hole MAC](#) shows the example setup with conditional static black-hole MAC 00:00:aa:aa:aa:aa.

Figure 65: Conditional static black-hole MAC

26246

When no conditional static black-hole MAC is configured, CE-30 can receive and send traffic from and to the other CEs; for instance, from and toward CE-20, as follows:

```
[/]
A:admin@PE-2# ping 172.16.0.30 router-instance "VPRN 10"
PING 172.16.0.30 56 data bytes
64 bytes from 172.16.0.30: icmp_seq=1 ttl=64 time=7.31ms.
64 bytes from 172.16.0.30: icmp_seq=2 ttl=64 time=3.33ms.
---snip---
```

```
[/]
A:admin@PE-3# ping 172.16.0.20 router-instance "VPRN 10"
PING 172.16.0.20 56 data bytes
64 bytes from 172.16.0.20: icmp_seq=1 ttl=64 time=3.45ms.
64 bytes from 172.16.0.20: icmp_seq=2 ttl=64 time=3.13ms.
---snip---
```

In this example, CE-20 and CE-30 correspond to VPRN 10 configured on PE-2 and PE-3 (using a hairpin to loop the traffic back to the PE).

Conditional static black-hole MAC 00:00:aa:aa:aa:aa (which corresponds to the MAC address of CE-30) is configured in VPLS 1 on PE-3 as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:aa:aa:aa:aa {
            blackhole
          }
        }
      }
    }
  }
}
```

The black-hole MAC is added as a conditional static (CStatic) MAC that is protected (P), as follows:

```
[/]
A:admin@PE-3# show service id 1 fdb mac 00:00:aa:aa:aa:aa

=====
Forwarding Database, Service 1
=====
ServId      MAC                Source-Identifier    Type      Last Change
          Transport:Tnl-Id
-----
1           00:00:aa:aa:aa:aa black-hole           CStatic: 03/26/21 11:49:43
                                     P
-----
Legend:  L=Learned O=0am P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
```

The source identifier is black-hole and it is applicable to frames that enter the VPLS on this node, regardless of how they enter the VPLS (SAP, SDP-binding, or EVPN endpoint).

The conditional static black-hole MAC is advertised to the BGP peers in a BGP-EVPN MAC route with the sticky/static bit set, as follows:

```
# on PE-3:
9 2021/03/26 11:49:42.675 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 89
  Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:
    Address Family EVPN

=====
```

When CE-20 sends an ICMP request to CE-30, the MAC DA 00:00:aa:aa:aa:aa is black-holed on PE-3, and no ICMP request succeeds, as follows:

```
[/]
A:admin@PE-2# ping 172.16.0.30 router-instance "VPRN 10"
PING 172.16.0.30 56 data bytes
Request timed out. icmp_seq=1.
Request timed out. icmp_seq=2.
Request timed out. icmp_seq=3.
Request timed out. icmp_seq=4.
Request timed out. icmp_seq=5.

---- 172.16.0.30 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

The port statistics show that the traffic was sent from PE-2 to PE-3, where it entered on port 1/1/3, then got discarded. To verify this, the port statistics are cleared on PE-2 and PE-3, then 1000 ICMP packets are sent from CE-20, as follows:

```
[/]
A:admin@PE-2# ping 172.16.0.30 router-instance "VPRN 10" count 1000 interval 0.1 output-format
summary
---snip---
1000 packets transmitted, 0 packets received, 100% packet loss
```

The 1000 packets are received at SAP 1/2/1:1 on PE-2, as follows:

```
[/]
A:admin@PE-2# show port 1/2/1 statistics

=====
Port Statistics on Slot 1
=====
Port          Ingress Packets      Ingress Octets

=====
```

On the interfaces between the PEs, other packets are sent besides the ICMP requests, such as IS-IS messages; therefore, the number of packets is slightly greater than 1000.

On PE-3, these packets are received on port 1/1/3, as follows:

```
[/]
A:admin@PE-3# show port 1/1/3 statistics

=====
Port Statistics on Slot 1
=====
Port          Ingress Packets      Ingress Octets
Id            Egress Packets      Egress Octets
-----
1/1/3                1024                126444
                        24                  2351
=====
```

The FDB entry for this MAC DA is black-holed and no traffic is received on SAP 1/2/1:1 toward CE-30; therefore, the statistics for port 1/2/1 are empty and nothing is displayed, as follows:

```
[/]
A:admin@PE-3# show port 1/2/1 statistics
```

It is possible to configure the black-hole MAC address on a different PE; for example, on PE-4 instead of PE-3. The conditional static black-hole MAC address configuration in VPLS 1 on PE-3 is removed, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          delete mac 00:00:aa:aa:aa:aa {
          }
        }
      }
    }
  }
}
```

The conditional static black-hole MAC is configured on PE-4 instead, as follows:

```
# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:aa:aa:aa:aa {
            blackhole
          }
        }
      }
    }
  }
}
```

PE-4 sends EVPN-MAC updates to its peers. PE-2 learns that all traffic with MAC DA 00:00:aa:aa:aa:aa should be redirected to PE-4, as shown in the FDB on PE-2:

```
[/]
A:admin@PE-2# show service id 1 fdb mac 00:00:aa:aa:aa:aa

=====
Forwarding Database, Service 1
=====
```

ServId	MAC Transport:Tnl-Id	Source-Identifier	Type Age	Last Change
1	00:00:aa:aa:aa:aa ldp:65538	mpls: 192.0.2.4:524284	EvpnS:P	03/26/21 11:51:59

Legend: L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf

The port statistics are cleared on all PEs and 1000 ICMP packets are sent from CE-20 to CE-30, as follows:

```
[/]
A:admin@PE-2# ping 172.16.0.30 router-instance "VPRN 10" count 1000 interval 0.1 output-format
summary
---snip---
1000 packets transmitted, 0 packets received, 100% packet loss
```

On PE-2, traffic is not forwarded on the direct link (port 1/1/3) toward PE-3, but redirected to PE-4 (port 1/1/1) instead, as follows:

```
[/]
A:admin@PE-2# show port 1/1/1 statistics

```

The configuration is restored with conditional static black-hole MAC in VPLS 1 on PE-3, not on PE-4, as follows:

```

# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:aa:aa:aa:aa {
            blackhole
          }
        }
      }
    }
  }
}

# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          delete mac 00:00:aa:aa:aa:aa {
          }
        }
      }
    }
  }
}

```

Conditional static black-hole MAC in combination with restrict protected source

For Ethernet frames with MAC SA equal to the static black-hole MAC, the treatment is the same as for protected MACs (see chapter [Auto-Learn MAC Protect in EVPN](#)), but for conditional static black-hole MACs, ALMP need not be enabled on the SAP or SDP-binding:

- When a frame is received with MAC SA equal to the black-hole MAC, it is dropped, because RPS-DF is enabled on the SAP or SDP-binding, by default. RPS-DF need not be enabled explicitly. An error message is raised when the following command is entered:

```

[ex:/configure service vpls "VPLS 1" sap 1/2/1:1 fdb]
A:admin@PE-3# protected-src-mac-violation-action discard

*[ex:/configure service vpls "VPLS 1" sap 1/2/1:1 fdb]
A:admin@PE-3# commit

```

```
MINOR: SVCMGR #12: configure service vpls "VPLS 1" sap 1/2/1:1 fdb protected-src-mac-
violation-action - Inconsistent Value error - not supported on bgp-evpn services - configure
service vpls "VPLS 1" bgp-evpn
```

- When RPS is enabled instead of RPS-DF, the SAP or SDP-binding where the frame was received, with MAC SA equal to the black-hole MAC, is brought operationally down. The SAP or SDP-binding can be brought up manually by disabling and re-enabling the SAP or SDP-binding. RPS is enabled on SAP 1/2/1:1 as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/1:1 {
        fdb {
          protected-src-mac-violation-action sap-oper-down
        }
      }
    }
  }
}
```

- Optionally, RPS-DF can be enabled on the EVPN-MPLS endpoint or EVPN-VXLAN endpoint. When enabled, the EVPN endpoint will discard frames with MAC SA equal to the black-hole MAC. RPS cannot be configured instead of RPS-DF on EVPN endpoints. It is not an option to bring the EVPN endpoint down when a frame is received with MAC SA equal to the static black-hole MAC. The commands to enable RPS-DF on the EVPN-MPLS endpoints and EVPN-VXLAN endpoints are as follows:

```
[ex:configure service vpls "VPLS 1" bgp-evpn mpls 1 fdb]
A:admin@PE-3# protected-src-mac-violation-action ?

protected-src-mac-violation-action <keyword>
<keyword> - discard

Action when a relearn request for a protected MAC is received
```

```
*[ex:configure service vpls "VPLS 1" vxlan instance 1 fdb]
A:admin@PE-3# protected-src-mac-violation-action ?

protected-src-mac-violation-action <keyword>
<keyword> - discard

Action when a relearn request for a protected MAC is received
```

With the default configuration (RPS-DF on SAP/SDP-bindings), the behavior is as follows for conditional static black-hole MAC 00:00:aa:aa:aa:aa configured in VPLS 1 on PE-3. All traffic from CE-30 with MAC SA 00:00:aa:aa:aa:aa is black-holed on SAP 1/2/1:1 on PE-3, because the default behavior on SAP 1/2/1:1 is RPS-DF, and the frame is discarded. The packets are received on port 1/2/1 (SAP 1/2/1:1) and dropped. No packets are forwarded to port 1/1/3 toward PE-2 or any other port.

```

```

If the static MAC is configured in VPLS 1 on PE-4 and not on PE-3, PE-3 will still discard the packets with MAC SA 00:00:aa:aa:aa:aa arriving on SAP 1/2/1:1, because it learned from the EVPN-MAC updates that MAC 00:00:aa:aa:aa:aa is a protected MAC on PE-4. Therefore, traffic with this MAC SA is not expected and not allowed on PE-3, as follows:

```

# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:aa:aa:aa:aa {
            blackhole
          }
        }
      }
    }
  }
}

```

```

# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          delete mac 00:00:aa:aa:aa:aa {

```

```

}
}
}

                                     0                               0
=====
```

The configuration is restored as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:aa:aa:aa:aa {
            blackhole
          }
        }
      }
    }
  }
}
```

```
# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          delete mac 00:00:aa:aa:aa:aa {
          }
        }
      }
    }
  }
}
```

Optionally, RPS-DF can be configured on the EVPN-MPLS endpoints on the PEs, as follows:

```
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        mpls 1 {
          fdb {
            protected-src-mac-violation-action discard
          }
        }
      }
    }
  }
}
```

When RPS-DF is configured on the EVPN-MPLS endpoints, frames with MAC SA 00:00:aa:aa:aa:aa can be discarded by the EVPN endpoints between the PEs. However, in this example this is not required, because any frame with MAC SA 00:00:aa:aa:aa:aa will be dropped by the local SAP before it can be forwarded to an EVPN endpoint.

It is possible to configure RPS with **sap-oper-down** on SAP 1/2/1:1 on PE-3, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/1:1 {
        fdb {
          protected-src-mac-violation-action sap-oper-down
        }
      }
    }
  }
}
```

When CE-30 sends traffic with MAC SA equal to a protected MAC address (black-hole or not), the entire SAP 1/2/1:1 will be brought operationally down, as follows:

```
[/]
A:admin@PE-3# ping 172.16.0.20 router-instance "VPRN 10"
PING 172.16.0.20 56 data bytes
Request timed out. icmp_seq=1.
Request timed out. icmp_seq=2.
---snip---
---- 172.16.0.20 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

```
[/]
A:admin@PE-3# show service id 1 sap

```

Log 99 shows that a protected MAC was received on SAP 1/2/1:1 and the SAP went operationally down with flag RxProtSrcMac, as follows:

```
90 2021/03/26 11:54:35.164 CET MINOR: SVCNMR #2208 Base
"Protected MAC 00:00:aa:aa:aa:aa received on SAP 1/2/1:1 in service 1. The SAP will be
disabled."

91 2021/03/26 11:54:35.164 CET MINOR: SVCNMR #2203 Base
"Status of SAP 1/2/1:1 in service 1 (customer 1) changed to admin=up oper=down flags=RxProtSrc
Mac "
```

The SAP can only be brought up manually by disabling and re-enabling the SAP, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/1:1 {
        admin-state disable
        commit
        admin-state enable
        commit
      }
    }
  }
}
```

```
[/]
A:admin@PE-3# show service id 1 sap
```

```

```

The default behavior of SAP 1/2/1:1 is RPS-DF, which is configured by removing the RPS configuration, as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/1:1 {
        fdb {
          delete protected-src-mac-violation-action
        }
      }
    }
  }
}
```

The conditional static black-hole MAC configuration is removed as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          delete mac 00:00:aa:aa:aa:aa {
          }
        }
      }
    }
  }
}
```

Black-hole MAC in services with proxy-ARP/ND

In this example, only proxy-ARP is shown, not proxy-ND. However, the configuration and procedures for proxy-ND would be equivalent.

First, the implementation of proxy-ARP and AS-MAC is described without static black-hole MAC addresses. MAC filters will be required to drop or redirect traffic, but these are not shown in the example. Configuring MAC filters and applying them on SAP/SDP-bindings is labor-intensive and can be error-prone. Afterward, the implementation with AS-MAC as static black-hole is described.

Services with proxy-ARP and AS-MAC - no static black-hole MAC

IP duplication works when the IP address moves between:

- Dynamic (learned on SAP) and EVPN
- EVPN and dynamic
- Dynamic and dynamic

The following example shows IP address moves from dynamic to dynamic between SAP 1/2/1:1 (to CE-10) and SAP 1/2/1:2 (to CE-11) in VPLS 1 on MTU-1. However, the duplicate IP address could have been in PE-3 and MTU-1 instead (EVPN or dynamic) and still the IP address would have been detected as duplicate.

Figure 66: VPLS 1 with proxy-ARP and AS-MAC shows the example setup with duplicate IP address 172.16.0.10/24 for CE-10 and CE-11. VPLS 1 is configured with proxy-ARP with duplicate IP detection in PE-2 and PE-3 (and possibly also in other PEs). MAC address 00:00:bb:bb:bb:bb is configured as AS-MAC, which will be used when a duplicate IP address has been detected.

Figure 66: VPLS 1 with proxy-ARP and AS-MAC

26247

For IP duplication detection, the following parameters can be customized so that the system can react to particular conditions in the network. The syntax is as follows:

```
*[ex:/configure service vpls "VPLS 1" proxy-arp]
A:admin@PE-3# duplicate-detect ?

duplicate-detect
anti-spoof-mac      - MAC address to replace the proxy-ARP/ND offending entry's MAC
```

```

hold-down-time    - Hold down time for a duplicate entry
num-moves         - Number of moves required to declare a duplicate entry
static-blackhole - Consider anti-spoof MAC as black-hole static MAC in FDB
window           - Time to monitor the MAC address in the anti-spoofing mechanism
    
```

In VPLS 1 on PE-2 and PE-3, a proxy-ARP with duplicate IP detection is configured, including an optional anti-spoof MAC (AS-MAC) 00:00:bb:bb:bb:bb for offending IP addresses, as follows:

```

# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      proxy-arp {
        admin-state enable
        dynamic-populate true
        duplicate-detect {
          anti-spoof-mac 00:00:bb:bb:bb:bb
          window 3
          num-moves 3
          hold-down-time max
        }
      }
      static-arp {
        ip-address 172.16.0.20 {
          mac 00:00:02:20:20:20
        }
      }
    }
  }
}
    
```

The proxy-ARP table contains one static entry (for IP 172.16.0.20). In this case, dynamic ARP populate is enabled. Therefore, the proxy-ARP table will be updated with ARP entries for IP 172.16.0.10 and MAC 00:00:01:10:10:10 or MAC 00:00:01:11:11:11 for frames originating from CE-10 or CE-11.

When a duplicate IP is detected for IP 172.16.0.10 (after three changes of MAC for IP 172.16.0.10 in a period of three minutes), the corresponding ARP entry contains the duplicate IP address 172.16.0.10 and the AS-MAC 00:00:bb:bb:bb:bb and its type is duplicate (dup). Therefore, this ARP entry is always active until it is removed. Until now, this configuration does not include a static black-hole MAC, and this option is by default disabled. This configuration for duplicate IP detection can be used in combination with MAC filters. The configuration with static black-hole MAC is shown in the section [Services with proxy-ARP and AS-MAC configured as static black-hole MAC](#).

The configured AS-MAC will be advertised in an EVPN-MAC route with the sticky/static bit set and without any IP address (because there is no IP duplication detected yet), as follows:

```

# on PE-3:
25 2021/03/26 11:59:16.417 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

```

Debugging is enabled for proxy-ARP for IP address 172.16.0.10 in VPLS 1 on PE-3, as follows (in classic CLI):

```

A:PE-3# debug service id 1 proxy-arp ip 172.16.0.10

```

When traffic is sent from CE-11 to CE-21, a dynamic ARP entry for IP address 172.16.0.10 and MAC 00:00:01:11:11:11 is added to the proxy-ARP table for VPLS 1 in PE-3, and an EVPN-MAC update is sent to the peer PEs, as follows:

```

# on PE-3:
36 2021/03/26 12:06:35.179 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 evpn advertise"

37 2021/03/26 12:06:35.179 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:

"

```

There is no duplicate IP detected yet.

CE-10 and CE-11 have the same IP address for different MAC addresses. When CE-10 sends traffic to CE-20, the ARP entry for IP 172.16.0.10 changes MAC from 00:00:01:11:11:11 to 00:00:01:10:10:10, and an EVPN-MAC withdraw message is sent, as follows:

```
# on PE-3:
39 2021/03/26 12:06:35.489 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 evpn withdraw"

40 2021/03/26 12:06:35.489 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:01:10:10:10 "
```

```
41 2021/03/26 12:06:35.489 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 46
  Flag: 0x90 Type: 15 Len: 42 Multiprotocol Unreachable NLRI:
    Address Family EVPN
      Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48
        mac: 00:00:01:11:11:11, IP len: 4, IP: 172.16.0.10, label1: 0
"
```

When the MAC changes, the system sends an ARP request for confirmation of the old MAC 00:00:01:11:11:11 for IP 172.16.0.10, as follows:

```
# on PE-3:
42 2021/03/26 12:06:35.542 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 confirm"
```

When MAC 00:00:01:11:11:11 is confirmed, the MAC in the ARP entry is changed once again to 00:00:01:10:10:10 and another ARP request is sent asking to confirm MAC 00:00:01:10:10:10 for IP 172.16.0.10, as follows:

```
# on PE-3:
43 2021/03/26 12:06:35.798 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:10:10:10->00:00:01:11:11:11 "
```

```
44 2021/03/26 12:06:35.842 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 confirm"
```

When CE-10 confirms MAC 00:00:01:10:10:10 for IP 172.16.0.10, IP duplication is detected for IP address 172.16.0.10 (after three MAC moves in a detection period of three minutes), and the following message is raised in log 99 after a duplicate proxy-ARP entry was detected for IP 172.16.0.10:

```
# log "99" on PE-3:
107 2021/03/26 12:06:36.108 CET MINOR: SVCMGR #2346 Base
"A duplicate proxy ARP entry was detected with new MAC 00:00:01:10:10:10 for entry IP
172.16.0.10 MAC 00:00:01:11:11:11 in service 1"
```

The following proxy-ARP debug messages show that the ARP entry for IP 172.16.0.10 in the proxy-ARP table changed MAC to the AS-MAC 00:00:bb:bb:bb:bb, and the type from dynamic to duplicate:

```
# on PE-3:
```

```

45 2021/03/26 12:06:36.108 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn advertise"

46 2021/03/26 12:06:36.108 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:bb:bb:bb:bb Type Change:
  Dyn->Dup "

47 2021/03/26 12:06:36.108 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup    Dup Detected"

```

If a duplicate IP is detected, AS-MAC 00:00:bb:bb:bb:bb is advertised with duplicate IP address 172.16.0.10 in an EVPN-MAC update to the BGP peers with the sticky/static bit set, as follows:

```

48 2021/03/26 12:06:36.108 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 93
  Flag: 0x90 Type: 14 Len: 48 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.3
    Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48
      mac: 00:00:bb:bb:bb:bb, IP len: 4, IP: 172.16.0.10, label1: 8388544
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 24 Extended Community:
    target:64500:1
    bgp-tunnel-encap:MPLS
    mac-mobility:Seq:0/Static
"

```

The difference with the first EVPN-MAC update for AS-MAC is the IP address. Immediately after the AS-MAC was configured, it was also advertised to the BGP-EVPN peers, but without any IP address.

The proxy-ARP entry is shown with type duplicate (dup) and active status in the proxy-ARP table for VPLS 1 on PE-3, as follows:

```

=====

```

A duplicate entry is always active, regardless of the AS-MAC. When the entry with the duplicate IP address and the AS-MAC address are installed in the proxy-ARP table as active, every ARP request for the duplicate IP address will be replied by the system. The entry in the proxy-ARP table is treated as active, even if the AS-MAC address is not in the FDB (AS-MAC addresses do not consume FDB space). The AS-MAC address, along with the duplicate IP address, is advertised in EVPN with the sticky/static bit set, as shown earlier. GARP messages with AS-MAC/IP information are flooded locally to make the CEs update their ARP caches to use the AS-MAC address for traffic to the duplicate IP 172.16.0.10, as follows.

```

# on PE-3:
49 2021/03/26 12:06:36.142 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Gratuitous Update"

```

Note:

The AS-MAC address will always be "unique" in the system. When the AS-MAC is configured, the system will flush any entry with the same MAC address learned through EVPN or dynamic sources. Conditional static MAC addresses or OAM MAC addresses with the same value as the AS-MAC address are only allowed when they are configured as black-hole, which is not the case yet.

When the duplicate proxy-ARP entry is cleared from the list (hold-down timer expires, or clear command, or replacement of the duplicate entry for a static entry), an ARP request asking who has IP 172.16.0.10 is flooded by the proxy-ARP agent. This ARP refresh triggers an ARP reply from the IP owner, which will be learned in the proxy-ARP table and advertised in EVPN. The system will also send a GARP to local SAP/SDP-bindings. This will correct all host ARP caches in the network. In this example, the duplicate proxy-ARP entry is manually cleared, as follows:

```

[/]
A:admin@PE-3# clear service id 1 proxy-arp duplicate

```

Log 99 shows that the clear function has been run and the duplicate proxy-ARP entry 172.16.0.10 is cleared. The system forces a refresh and, if the condition with the duplicate IP address remains, this is detected almost immediately and a message is logged that a duplicate proxy-ARP entry was detected, as follows:

```

# on PE-3:
108 2021/03/26 12:07:54.958 CET INDETERMINATE: LOGGER #2010 Base Clear SVCGR
"Clear function clearSvcIdProxyArpDups has been run with parameters: svc-id="1" ip-address="".
The completion result is: success. Additional error text, if any, is: "
109 2021/03/26 12:07:54.958 CET MINOR: SVCGR #2347 Base

```

```
"A duplicate proxy ARP entry 172.16.0.10 is cleared in service 1"
```

```
110 2021/03/26 12:07:55.146 CET MINOR: SVCNMR #2346 Base  
"A duplicate proxy ARP entry was detected with new MAC 00:00:01:11:11:11 for entry IP  
172.16.0.10 MAC 00:00:01:10:10:10 in service 1"
```

The following debug messages for proxy-ARP on PE-3 show the process in more detail. Initially, an EVPN-MAC route withdraw message is sent and the proxy-ARP entry is deleted.

```
# on PE-3:  
50 2021/03/26 12:07:54.958 CET MINOR: DEBUG #2001 Base proxy arp  
"proxy arp:  
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn withdraw"  
  
51 2021/03/26 12:07:54.958 CET MINOR: DEBUG #2001 Base proxy arp  
"proxy arp:  
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Deleted"
```

The following BGP-EVPN MAC update is sent by PE-3 to indicate that the AS-MAC is withdrawn for IP 172.16.0.10 (multiprotocol unreachable NLRI):

```
# on PE-3:  
53 2021/03/26 12:07:54.958 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2  
"Peer 1: 192.0.2.2: UPDATE  
Peer 1: 192.0.2.2 - Send BGP UPDATE:  
  Withdrawn Length = 0  
  Total Path Attr Length = 46  
  Flag: 0x90 Type: 15 Len: 42 Multiprotocol Unreachable NLRI:  
    Address Family EVPN  
      Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48  
        mac: 00:00:bb:bb:bb:bb, IP len: 4, IP: 172.16.0.10, label1: 0  
"
```

Removing the active duplicate entry from the proxy-ARP table triggers an ARP flooding request asking who has IP 172.16.0.10 in VPLS 1, as follows:

```
# on PE-3:  
52 2021/03/26 12:07:54.958 CET MINOR: DEBUG #2001 Base proxy arp  
"proxy arp:  
svc: 1 ip: 172.16.0.10 flood request"
```

The result of the ARP flooding request is that the IP owners reply with their MAC, at the local or a remote PE. In this case, the reply from CE-10 is received first (IP 172.16.0.10 - MAC 00:00:01:10:10:10), a dynamic proxy-ARP entry is added, and the MAC/IP route is advertised, as follows:

```
# on PE-3:  
54 2021/03/26 12:07:54.961 CET MINOR: DEBUG #2001 Base proxy arp  
"proxy arp:  
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 evpn advertise"  
  
55 2021/03/26 12:07:54.961 CET MINOR: DEBUG #2001 Base proxy arp  
"proxy arp:  
svc: 1 ip: 172.16.0.10 type: Dyn mac: 00:00:01:10:10:10 Added"
```

When CE-11 answers with its MAC 00:00:01:11:11:11, the MAC/IP route is withdrawn for IP 172.16.0.10, and the MAC address in the proxy-ARP entry for IP 172.16.0.10 is changed from MAC 00:00:01:10:10:10 to MAC 00:00:01:11:11:11, as follows:

```
# on PE-3:
56 2021/03/26 12:07:54.961 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 evpn withdraw"

57 2021/03/26 12:07:54.961 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:10:10:10->00:00:01:11:11:11 "
```

Any change of MAC address in a proxy-ARP entry triggers an ARP request asking for confirmation of the old MAC address for IP 172.16.0.10, in this case for MAC 00:00:01:10:10:10, as follows:

```
# on PE-3:
58 2021/03/26 12:07:55.042 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 confirm"
```

MAC address 00:00:01:10:10:10 is confirmed for IP address 172.16.0.10; therefore, the MAC address is changed in the proxy-ARP entry from 00:00:01:11:11:11 to 00:00:01:10:10:10, and an ARP confirmation is asked for the old MAC address 00:00:01:11:11:11, as follows:

```
# on PE-3:
59 2021/03/26 12:07:55.045 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:01:10:10:10 "
```

```
60 2021/03/26 12:07:55.142 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 confirm"
```

MAC address 00:00:01:11:11:11 is confirmed and, therefore, three MAC moves occurred within three minutes. Duplicate IP 172.16.0.10 is detected and the proxy-ARP entry has the AS-MAC 00:00:bb:bb:bb:bb and type duplicate (Dup), as follows:

```
# on PE-3:
61 2021/03/26 12:07:55.146 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn advertise"

```

A GARP update is sent for IP 172.16.0.10 and AS-MAC 00:00:bb:bb:bb:bb, as follows:

```

# on PE-3:
65 2021/03/26 12:07:55.242 CET MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Gratuitous Update"

```

The AS-MAC address is optionally configured and populates all the host ARP caches when a duplicate IP address is detected. All traffic destined to the suspicious IP address 172.16.0.10 will have the AS-MAC address 00:00:bb:bb:bb:bb as MAC DA. The user can configure MAC filters on all SAP/SDP-bindings where the CEs are connected to drop, log, or redirect traffic destined to the AS-MAC. This will block any interception or man-in-the-middle attack (due to ARP spoofing) in the network.

The AS-MAC address is independently configured on each PE for the same service. When a different AS-MAC address is configured per PE for the same service, the user will need to filter all the AS-MAC addresses in the service at each PE, which increases the complexity of the filters. Nokia recommends using the same AS-MAC address for the same service in all the PES where duplicate detect is active and MAC filters need to be configured. However, this recommendation is suspended when the AS-MAC address is configured as static black-hole MAC address, as described in the following section.

Services with proxy-ARP and AS-MAC configured as static black-hole MAC

With the AS-MAC address configured as static black-hole MAC address, MAC-filters do not need to be configured to discard frames with MAC DA equal to the AS-MAC address. Instead, the user can decide whether to use the same AS-MAC address on all the PEs. This scalability is not limited by the number of filters, but by the number of FDB entries.

The **static-blackhole** parameter is optional and disabled by default. In the example, the static-black-hole option is not configured yet for the AS-MAC address and the behavior is as follows:

- The AS-MAC address is added to the MAC DB as local, but not programmed in the FDB.
- The AS-MAC address is advertised in EVPN (initially without an IP address, and with an IP address as soon as the IP is detected as duplicate).
- The AS-MAC address cannot be overridden by any other MAC address.
- The AS-MAC address value cannot be configured on a static MAC address, because that MAC address is reserved for the proxy-ARP, as follows:

```

# on PE-3:
*[ex:/configure service vpls "VPLS 1" fdb static-mac mac 00:00:bb:bb:bb:bb]
A:admin@PE-3# sap 1/2/3:1 monitor forward-status

*[ex:/configure service vpls "VPLS 1" fdb static-mac mac 00:00:bb:bb:bb:bb]
A:admin@PE-3# commit

```

```
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" proxy-arp duplicate-detect anti-spoof-
mac - antispoof-mac conflicts with static-mac - configure service vpls "VPLS 1" fdb static-mac
mac 00:00:bb:bb:bb:bb

# on PE-3:
*[ex:/configure service vpls "VPLS 1" fdb static-mac mac 00:00:bb:bb:bb:bb]
A:admin@PE-3# blackhole

*[ex:/configure service vpls "VPLS 1" fdb static-mac mac 00:00:bb:bb:bb:bb]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" proxy-arp duplicate-detect anti-spoof-
mac - antispoof-mac conflicts with static-mac - configure service vpls "VPLS 1" fdb static-mac
mac 00:00:bb:bb:bb:bb
```

When the **static-blackhole** option is not configured, the AS-MAC address is considered as a local MAC address and cannot be overridden. The MAC address priority is as follows:

1. Local MAC address (including AS-MAC addresses without static-black-hole, es-bmacs, src-bmacs, OAM, and so on)
2. Conditional static MAC addresses (including AS-MAC addresses with static-black-hole)
3. Auto-Learn Protected MAC addresses
4. EVPN-MAC addresses with sticky/static bit set
5. Data plane learned MAC addresses (regular learning on SAP/SDP-binding)
6. EVPN-MAC addresses without sticky/static bit set

To configure an AS-MAC address with static-black-hole option, a static black-hole MAC address needs to be configured. The following error is raised when no static black-hole MAC has been configured for AS-MAC 00:00:bb:bb:bb:bb:

```
# on PE-3:
*[ex:/configure service vpls "VPLS 1" proxy-arp duplicate-detect]
A:admin@PE-3# static-blackhole true

*[ex:/configure service vpls "VPLS 1" proxy-arp duplicate-detect]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" proxy-arp duplicate-detect static-
blackhole - blackhole conditional static mac needs to be configured - configure service vpls
"VPLS 1"
```

The VPLS service is configured with proxy-ARP and AS-MAC as static black-hole on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      fdb {
        static-mac {
          mac 00:00:bb:bb:bb:bb {
            blackhole
          }
        }
      }
      proxy-arp {
        admin-state enable
        dynamic-populate true
        duplicate-detect {
          anti-spoof-mac 00:00:bb:bb:bb:bb
        }
      }
    }
  }
}
```

```

        window 3
        num-moves 5
        hold-down-time max
        static-blackhole true
    }
    static-arp {
        ip-address 172.16.0.20 {
            mac 00:00:02:20:20:20
        }
    }
}

```

When the AS-MAC address is configured with the static black-hole option, the AS-MAC will be added not only to the MAC DB, but also to the FDB as CStatic, and associated with a black-hole endpoint, as follows:

```

[/]
A:admin@PE-3# show service id 1 fdb mac 00:00:bb:bb:bb:bb
=====
Forwarding Database, Service 1
=====
ServId      MAC                Source-Identifier      Type      Last Change
          Transport:Tnl-Id
-----
1           00:00:bb:bb:bb:bb  black-hole            CStatic:  03/26/21 12:09:35
                                     P
-----
Legend:  L=Learned O=0am P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====

```

Any frame with MAC DA equal to the AS-MAC with static black-hole will be dropped, regardless of the ingress endpoint and without any need for a filter. This mechanism is the only way to filter MAC DAs on EVPN endpoints, because MAC filters cannot be configured on EVPN endpoints.

The AS-MAC with static black-hole will be advertised in EVPN with the sticky/static bit set, as follows:

```

# on PE-3:
87 2021/03/26 12:09:34.970 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

=====

```

CE-30 and CE-31 cannot reach CE-10 or CE-11, because the MAC DA will be the AS-MAC address and all traffic to this MAC DA is black-holed instead of forwarded to SAP 1/2/3:1 toward CE-10 or CE-11. When 1000 ICMP packets are sent by CE-30, they arrive in SAP 1/2/1:1 on PE-3 and are then discarded, as follows:

```

[/]
A:admin@PE-3# ping 172.16.0.10 router-instance "VPRN 10" count 1000 interval 0.1 output-format
summary

```
[/]  
A:admin@PE-3# show port 1/1/3 statistics
```

```
=====  
Port Statistics on Slot 1  
=====
```

Port Id	Ingress Packets Egress Packets	Ingress Octets Egress Octets
1/1/3	16 16	1537 1537

```
[/]  
A:admin@PE-3# show port 1/2/1 statistics
```

```
=====  
Port Statistics on Slot 1  
=====
```

Port Id	Ingress Packets Egress Packets	Ingress Octets Egress Octets
1/2/1	1000 0	106000 0

No packets were forwarded to SAP 1/2/3:1 toward MTU-1; therefore, there are no statistics for port 1/2/3.

Conclusion

Static black-hole MAC addresses can be applied in EVPN for security as a scalable alternative to MAC filters. Static black-hole MAC addresses are programmed in the FDB and all frames with MAC DA equal to the static black-hole MAC address are dropped, regardless of how the frame arrived at the system (SAP/SDP-binding or EVPN endpoint). Also, static black-hole MAC addresses are treated like protected MAC addresses and, in combination with RPS(-DF), filtering on MAC SA is performed in the data plane. Black-hole MAC addresses can be an option for an AS-MAC address in services with proxy-ARP/ND enabled, which simplifies the configuration because MAC filters are not required.

Data Center Interconnect Using Dual EVPN-VXLAN Instance VPLS

This chapter provides information about Data Center Interconnect using dual EVPN-VXLAN instance VPLS.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 16.0.R7, but the MD-CLI in the current edition is based on SR OS Release 21.7.R1. Dual EVPN-VXLAN instances are supported in SR OS Release 16.0.R2, or later.

This chapter describes the redundancy based on an Anycast solution, as supported in SR OS Release 16.0, and later. For I-ES based redundancy scenarios as supported in SR OS Release 19.10, and later, see the [EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services](#) chapter.

Overview

Chapter [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#) describes a Data Center Interconnect (DCI) scenario using VXLAN in the DCs and MPLS in the WAN. This chapter describes a similar scenario, where the core is an IP network that does not use MPLS, and where end-to-end VXLAN is used instead. The DC Gateways (GWs) contain VPLS services with two EVPN-VXLAN instances and two BGP instances: one EVPN-VXLAN instance faces the DC and the other EVPN-VXLAN instance faces the WAN.

[Figure 67: Dual EVPN-VXLAN instance VPLS 1](#) shows the example topology with two DCs. On PE-1 and PE-6, VPLS 1 is configured with one VXLAN instance and one BGP instance. On the DC GWs, VPLS 1 is configured with two VXLAN instances and two BGP instances: one toward the DC and one toward the WAN.

Figure 67: Dual EVPN-VXLAN instance VPLS 1

28880

For example, on DC GW PE-2, VPLS 1 is configured with VXLAN instance 1 using BGP instance 1 and VXLAN 2 using BGP instance 2. In this example, the BGP instance ID matches the VXLAN instance ID, but that is not required. Each VXLAN instance has a different VNI and a different BGP instance.

```
# on PE-2:
configure {
  service {
    system {
      bgp-auto-rd-range {
        ip-address 10.0.0.1
        community-value {
          start 60000
          end 65000
        }
      }
    }
  }
  vpls "VPLS 1" {
    admin-state enable
    description "dual evpn-vxlan VPLS"
    service-id 1
    customer "1"
    vxlan {
      instance 1 {
        vni 11
      }
      instance 2 {
        vni 12
      }
    }
  }
  bgp 1 {
    route-distinguisher auto-rd
    route-target {
      export "target:64500:11"
      import "target:64500:11"
    }
  }
  bgp 2 {
```

```

        route-distinguisher auto-rd
        route-target {
            export "target:64500:12"
            import "target:64500:12"
        }
    }
    bgp-evpn {
        evi 1
        vxlan 1 {
            admin-state enable
            vxlan-instance 1
        }
        vxlan 2 {
            admin-state enable
            vxlan-instance 2
        }
    }
}

```

When different BGP instances are configured, the auto-derived route distinguishers (RDs) in BGP instance 1 and BGP instance 2 are different, as follows:

```

[/]
A:admin@PE-2# show service id 1 bgp 1 | match "Route Dist"
Route Dist      : auto-rd
Oper Route Dist : 10.0.0.1:60000

[/]
A:admin@PE-2# show service id 1 bgp 2 | match "Route Dist"
Route Dist      : auto-rd
Oper Route Dist : 10.0.0.1:60001

```

Dual EVPN-VXLAN instance VPLSs can contain SAPs in SR OS Release 19.10.R1, and later. However, dual EVPN-VXLAN instance VPLSs cannot contain any SDP bindings in SR OS Release 21.7.R1, as follows:

```

*[ex:/configure service vpls "VPLS 1" spoke-sdp 21:1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" - multiple bgp-evpn instances not
supported with local mesh or spoke sdp
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" - multi-instance vxlan not supported
with sdp-bindings in service

```

Note:

This chapter describes the redundancy based on an Anycast solution, as supported in SR OS Release 16.0, and later. For I-ES based redundancy scenarios as supported in SR OS Release 19.10, and later, see chapter *EVPN Multi-Homing on Dual EVPN-VXLAN BGP Instance VPLS*.

To provide DC GW redundancy, an anycast IP address can be configured for the dual EVPN-VXLAN instance VPLSs on the DC GWs.

EVPN route types 2 and 3 are processed by dual EVPN-VXLAN VPLS services as follows:

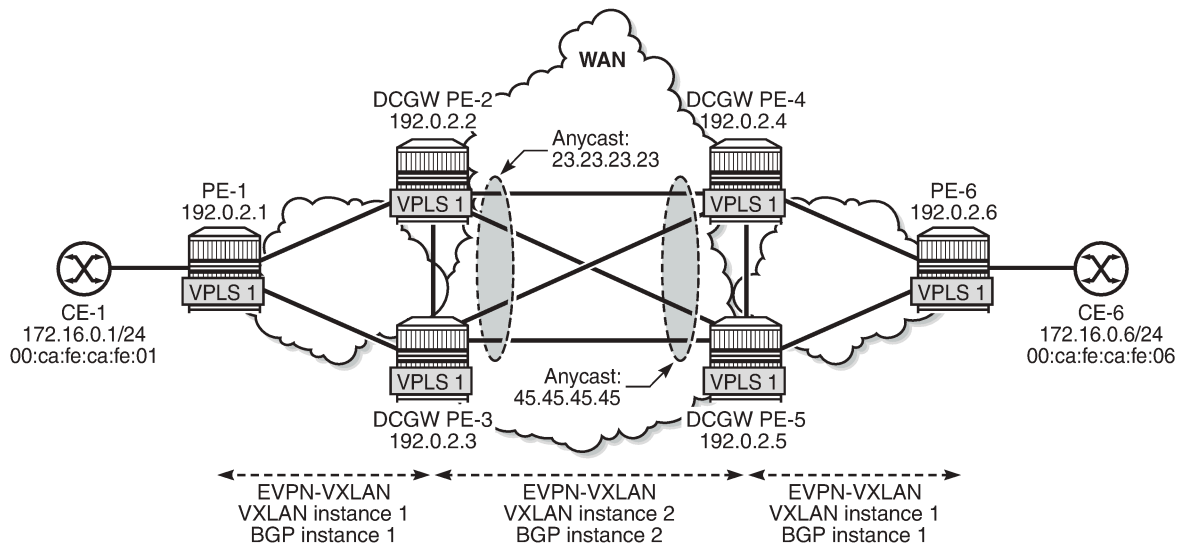

- Route type 2: MAC/IP routes
 - MAC/IP routes received in a BGP instance will be imported and — according to the selection rules — installed in the FDB.
 - Active MAC routes are re-advertised in the other BGP instance with new BGP attributes (RD, route target (RT), and so on).

- Only the best EVPN MAC route is redistributed.
- The MAC/IP information and the sticky bit are propagated. The only exception is the Ethernet Segment Identifier (ESI). A non-zero ESI will be reset unless the auto-disc advertise command is enabled.
- When an attribute has changed for a redistributed MAC route, the MAC route will be updated if it is still the best route. For example, an update of the sequence number or the sticky bit can trigger a redistribution.
- Route type 3: inclusive multicast routes
 - EVPN inclusive multicast routes are generated independently for each instance with the proper BGP extended communities.
 - Ingress Replication (IR) or Assisted Replication (AR) Inclusive Multicast Ethernet Tag (IMET) routes are supported.
 - The inclusive multicast originating IP can be configured with an anycast address:
 - The configured originating IP address is encoded in the originating IP field of the IMET-IR routes; the originating IP field of the IMET-AR routes is still derived from the assisted replication IP value in the service system settings for VXLAN.
 - If a router receives two IMET routes with the same originating IP address, different RDs, and different next-hops, it sets up two bindings: one to each next-hop.
 - If a router receives two IMET routes with the same originating IP address, the same RD, but different next-hops, it sets up one binding to the next-hop with the lowest IP address.
 - If a router receives two IMET routes with the same originating IP address, different RDs, but the same next-hop, it sets up one binding to the next-hop.
 - A DC GW will not set up a binding to its DC GW peer if the received originating IP equals its own originating IP, regardless of whether the local RD and the remote RD are the same or different.

Configuration

[Figure 68: Example topology with VPLS 1 and anycast addresses](#) shows the example topology. Redundancy is based on anycast: on the DC GWs PE-2 and PE-3, anycast address 23.23.23.23 is configured as inclusive multicast originating IP; on PE-4 and PE-5 in DC-2, the anycast address is 45.45.45.45. However, no Ethernet segments are used in this example.

Figure 68: Example topology with VPLS 1 and anycast addresses

28881

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (level 1 in the DCs and level 2 in the WAN)

MPLS is not configured in any of these networks.

BGP configuration

BGP is configured for the EVPN address family on all nodes. [Figure 69: Example topology with BGP groups](#) shows the BGP groups: on the DC GWs, both BGP group "DC" and "WAN" are defined. Route policies ensure that only DC routes are forwarded to DC neighbors and only WAN routes are forwarded to WAN neighbors. Also, DC GWs need to drop BGP-EVPN routes from the local peer DC GW.

Figure 69: Example topology with BGP groups

28882

The BGP configuration on PE-1 is as follows. The configuration on PE-6 is similar.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
      group "DC" {
        type internal
      }
      neighbor "192.0.2.2" {
        group "DC"
      }
      neighbor "192.0.2.3" {
        group "DC"
      }
    }
  }
}
```

On the DC GWs, two BGP groups are defined: one for the DC group and one for the WAN group. Export policies ensure that only DC routes are exported to the DC group and only WAN routes are exported to the WAN group. Import policies ensure that routes from the local DC GW are dropped; for example, PE-2 drops routes from PE-3, and vice versa. The policies will be described later. The BGP configuration on PE-2 is as follows. The BGP configuration on the other DC GWs is similar.

```
# on PE-2:
configure {
```

```

router "Base" {
  autonomous-system 64500
  bgp {
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    family {
      ipv4 false
      evpn true
    }
    rapid-update {
      evpn true
    }
    group "DC" {
      type internal
      import {
        policy ["drop S00-DCGW-23"]
      }
      export {
        policy ["allow only DC and add S00"]
      }
    }
    group "WAN" {
      type internal
      import {
        policy ["drop S00-DCGW-23"]
      }
      export {
        policy ["allow only WAN and add S00"]
      }
    }
  }
  neighbor "192.0.2.1" {
    group "DC"
  }
  neighbor "192.0.2.3" {
    group "DC"
  }
  neighbor "192.0.2.4" {
    group "WAN"
  }
  neighbor "192.0.2.5" {
    group "WAN"
  }
}

```

Route policies

The route policies are equivalent to the policies described in the chapter [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#). In this example, no filtering can be done based on the encapsulation extended community (VXLAN versus MPLS), because only VXLAN is used in the DCs and the WAN. Therefore, the route tag is used as a criterion instead in the route policies "allow only DC and add SOO" (Site of Origin) and "allow only WAN and add SOO". When two BGP instances for the same encapsulation are configured in a VPLS, different route tags in each BGP instance are required. In this example, route tag 11 is used in BGP instance 1 in the DCs and route tag 12 is used in BGP instance 2 in the WAN.

When redistributing to the other BGP instance, route filtering toward DC or WAN will be based on the route tags. Export policy "allow only DC and add SOO" drops routes with WAN route tag 12. Likewise, export policy "allow only WAN and add SOO" drops routes with DC route tag 11. Filtering matching on route tags on EVPN BGP instances is scalable, because only two route tags are required per PE. Filtering matching

on route target (RT) is also possible, but in that case, two RTs per service are required. This does not scale well and is cumbersome.

The export policy "allow only DC and add SOO" ensures that EVPN routes with route tag 12 are dropped and only DC routes are forwarded. This route policy is applied in the BGP group "DC" context. Likewise, the export policy "allow only WAN and add SOO" drops EVPN routes with route tag 11, so that only WAN EVPN routes are forwarded.

Both policies also add a site of origin, such as "SOO-23" for PE-2 and PE-3, and "SOO-45" for PE-4 and PE-5. This SOO is used for filtering in the import policies "drop SOO-DCGW-23" and "drop SOO-DCGW-45" to ensure that, for instance, PE-2 drops routes advertised by the local peer PE-3 with the same SOO-23, and vice versa. Likewise, PE-4 drops routes advertised by its local peer PE-5 with the same SOO-45, and vice versa.

The following policies are configured on DC GWs PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
  policy-options {
    community "SOO-23" {
      member "origin:64500:23" { }
    }
  }
  policy-statement "allow only DC and add SOO" {
    entry 10 {
      from {
        family [evpn]
        tag 12
      }
      action {
        action-type reject
      }
    }
    entry 20 {
      from {
        family [evpn]
      }
      action {
        action-type accept
        community {
          add ["SOO-23"]
        }
      }
    }
  }
  policy-statement "allow only WAN and add SOO" {
    entry 10 {
      from {
        family [evpn]
        tag 11
      }
      action {
        action-type reject
      }
    }
    entry 20 {
      from {
        family [evpn]
      }
      action {
        action-type accept
        community {
          add ["SOO-23"]
        }
      }
    }
  }
}
```

```
    }  
  }  
}  
policy-statement "drop S00-DCGW-23" {  
  entry 10 {  
    from {  
      family [evpn]  
      community {  
        name "S00-23"  
      }  
    }  
    action {  
      action-type reject  
    }  
  }  
}
```

The following policies are configured on DC GWs PE-4 and PE-5:

```
# on PE-4, PE-5:  
configure {  
  policy-options {  
    community "S00-45" {  
      member "origin:64500:45" { }  
    }  
  }  
  policy-statement "allow only DC and add S00" {  
    entry 10 {  
      from {  
        family [evpn]  
        tag 12  
      }  
      action {  
        action-type reject  
      }  
    }  
    entry 20 {  
      from {  
        family [evpn]  
      }  
      action {  
        action-type accept  
        community {  
          add ["S00-45"]  
        }  
      }  
    }  
  }  
  policy-statement "allow only WAN and add S00" {  
    entry 10 {  
      from {  
        family [evpn]  
        tag 11  
      }  
      action {  
        action-type reject  
      }  
    }  
    entry 20 {  
      from {  
        family [evpn]  
      }  
      action {
```

```

        action-type accept
        community {
            add ["S00-45"]
        }
    }
}
policy-statement "drop S00-DCGW-45" {
    entry 10 {
        from {
            family [evpn]
            community {
                name "S00-45"
            }
        }
        action {
            action-type reject
        }
    }
}
}

```

VPLS configuration

On PE-2 and PE-3, the service configuration is identical and VPLS 1 is configured as follows. For redundancy, the anycast IP address 23.23.23.23 is configured as inclusive multicast originating IP on PE-2 and PE-3. The RT is the same in all nodes: the RT is 64500:11 in BGP instance 1 of VPLS 1; in BGP instance 2, the RT is 64500:12. The RD is 64500:2311 in BGP instance 1 of VPLS 1 and 64500:2312 in BGP instance 2 of VPLS 1 on PE-2 and PE-3. The RD must be the same in PE-2 and PE-3 because they are part of the anycast group, but the RD in PE-1 must be different.

```

# on PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 11
                }
                instance 2 {
                    vni 12
                }
            }
            bgp 1 {
                route-distinguisher "64500:2311"
                route-target {
                    export "target:64500:11"
                    import "target:64500:11"
                }
            }
            bgp 2 {
                route-distinguisher "64500:2312"
                route-target {
                    export "target:64500:12"
                    import "target:64500:12"
                }
            }
        }
        bgp-evpn {

```

```

    evi 1
    incl-mcast-orig-ip 23.23.23.23
    vxlan 1 {
        admin-state enable
        vxlan-instance 1
        default-route-tag 0xb          # default route tag 11
    }
    vxlan 2 {
        admin-state enable
        vxlan-instance 2
        default-route-tag 0xc          # default route tag 12
    }
}

```

On PE-1, VPLS 1 is configured with VXLAN instance 1 and BGP instance 1, as follows. The RT is 64500:11 in BGP instance 1 of VPLS 1 on PE-1. The RD (64500:111) in PE-1 is different from the RD (64500:2311) in PE-2 and PE-3.

```

# on PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 11
                }
            }
        }
        bgp 1 {
            route-distinguisher "64500:111"
            route-target {
                export "target:64500:11"
                import "target:64500:11"
            }
        }
        bgp-evpn {
            evi 1
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
            }
        }
        sap 1/2/1:1 {
        }
    }
}

```

On PE-4 and PE-5, the service configuration is identical and VPLS 1 is configured as follows. For redundancy, the anycast IP address 45.45.45.45 is configured as inclusive multicast originating IP.

```

# on PE-4, PE-5:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 11
                }
            }
        }
    }
}

```

```

    }
    instance 2 {
        vni 12
    }
}
bgp 1 {
    route-distinguisher "64500:4511"
    route-target {
        export "target:64500:11"
        import "target:64500:11"
    }
}
bgp 2 {
    route-distinguisher "64500:4512"
    route-target {
        export "target:64500:12"
        import "target:64500:12"
    }
}
bgp-evpn {
    evi 1
    incl-mcast-orig-ip 45.45.45.45
    vxlan 1 {
        admin-state enable
        vxlan-instance 1
        default-route-tag 0xb          # default route tag 11
    }
    vxlan 2 {
        admin-state enable
        vxlan-instance 2
        default-route-tag 0xc          # default route tag 12
    }
}
}

```

Verification

On PE-2, the following EVPN inclusive multicast routes are received. The first route has RD 64500:111, so it applies to BGP instance 1; the last two have RD 64500:4512, so they apply to BGP instance 2. Toward anycast address 45.45.45.45, the lowest IP next-hop 192.0.2.4 (PE-4) is preferred over 192.0.2.5 (PE-5).

-----
=====
```

The CEs are simulated by VPRN 11 configured on PE-1 and PE-6. Connectivity between CE-1 and CE-6 is verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.0.6 router-instance "VPRN 11" interval 0.1 output-format summary
PING 172.16.0.6 56 data bytes
!!!!
---- 172.16.0.6 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.19ms, avg = 4.56ms, max = 5.30ms, stddev = 0.393ms
```

The following two EVPN MAC routes are accepted on PE-1, which has only BGP instance 1 and VXLAN instance 1 enabled, and the VNI is 11. The used EVPN MAC route for MAC address 00:ca:fe:ca:fe:06 has PE-2 (192.0.2.2) as next-hop. The second route for the same MAC address has PE-3 (192.0.2.3) as next-hop, but it is not preferred, so it is not used.

```

=====

```

On PE-2, the following three EVPN MAC routes are accepted. The first route has PE-1 (192.0.2.1) as next-hop and is received in BGP instance 1, which corresponds to VXLAN 1 and VNI 11. The latter two routes are received in BGP instance 2 for VXLAN instance 2 with VNI 12. These routes both have RD 64500:4512 and the route with the lowest IP next-hop is preferred, so the route to PE-4 (192.0.2.4) is used. The EVPN MAC routes on PE-3 are similar.

=====
```

The EVPN MAC routes on the nodes in DC-2 are also similar.

The following FDB for VPLS 1 on PE-2 shows that MAC address 00:ca:fe:ca:fe:01 is learned from an EVPN MAC route in VXLAN 1 from 192.0.2.1 (PE-1); MAC address 00:ca:fe:ca:fe:06 is learned in VXLAN 2 from 192.0.2.4 (PE-4). For routes with the same RD but different next-hops, the router processes only the route with the lowest IP next-hop.

Conclusion

With dual EVPN-VXLAN instance VPLS services, service providers can deploy DCI scenarios with end-to-end VXLAN.

Domain Path Attribute for VPRN BGP Routes

This chapter provides information about the domain path attribute for VPRN BGP routes.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

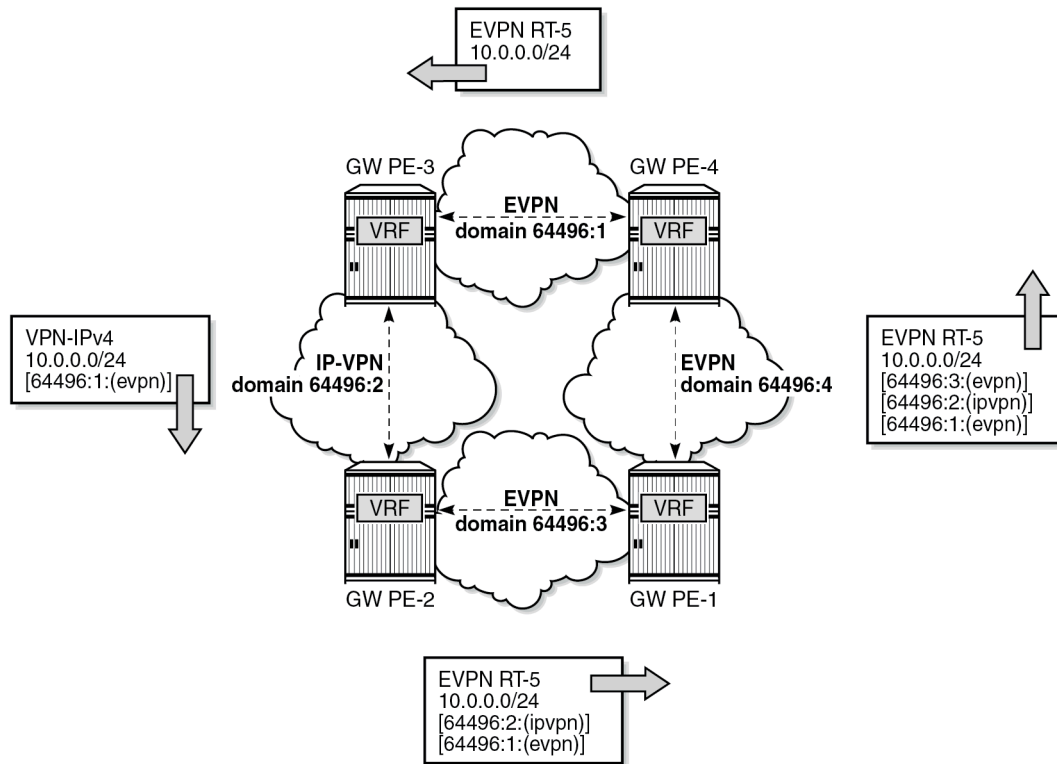

The information and configuration in this chapter are based on SR OS Release 22.7.R1. The domain path (D-path) attribute is supported in SR OS Release 21.10.R1 and later.

Overview

The D-path attribute can be used for route traceability, BGP best path selection, and loop prevention in networks that expand multiple IP-VPN and EVPN domains.

The D-path attribute is a sequence of domain segments, where each domain segment is represented by a domain ID in combination with an inter-subnet forwarding (ISF) subaddress family indicator (SAFI). The D-path attribute is added or modified by gateways (GWs) that import BGP-EVPN route type 5 (RT-5) or IP-VPN routes into a VPRN route table and export these prefixes as BGP-EVPN RT-5 or IP-VPN routes to their neighbors. Any PE that imports a prefix route does not install the route in the VPRN route table if the D-path attribute contains a domain segment where the domain ID matches a local domain ID, as shown in the figure [Figure 70: Loop prevention in networks with multiple IP-VPN and EVPN domains](#).

Figure 70: Loop prevention in networks with multiple IP-VPN and EVPN domains

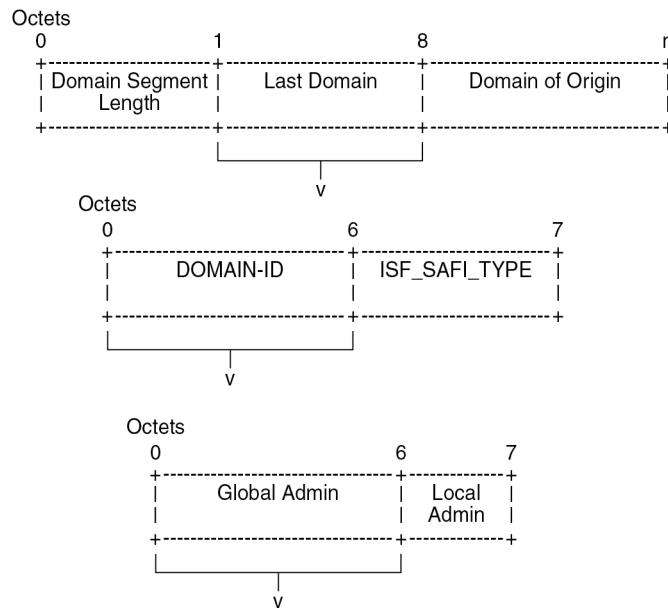

38120

All PEs in the figure [Figure 70: Loop prevention in networks with multiple IP-VPN and EVPN domains](#) are GWs. PE-4 exports local prefix 10.0.0.0/24 as an EVPN RT-5 route without the D-path attribute when no domain ID is configured for local routes. PE-3 accepts this route. Domain ID 64496:1 is defined in PE-4 and PE-3, but the domain segment 64496:1:(evpn) is only added by GW PE-3 where the prefix is exported as an IP-VPN route instead of an EVPN RT-5 route. GW PE-2 accepts this route and modifies the D-path attribute by prepending domain segment 64496:2:(ipvpn) when exporting prefix 10.0.0.0/24 as an EVPN RT-5 route. PE-1 accepts this route. When PE-1 exports the prefix as an EVPN RT-5 route to PE-4, it prepends domain segment 64496:3:(evpn) to the D-path attribute. The VRF on PE-4 cannot import this prefix because the D-path attribute contains domain ID 64496:1, which is defined on PE-4.

The figure [Figure 71: D-path attribute](#) shows the D-path attribute as defined in *draft-ietf-bess-evpn-ipvpn-interworking*.

Figure 71: D-path attribute

38121

The D-path attribute is composed of a sequence of domain segments. Each domain segment consists of a domain ID and a SAFI type. The domain ID represents the domain and is composed of a 4-octet global administrator subfield and a 2-octet local administrator subfield. The global administrator subfield must have a value that is unique for the domain; for example, an autonomous system number (ASN). The 1-octet SAFI field can have the following values:

- 0 for local ISF routes
- 1 for PE-CE BGP domains
- 70 for EVPN domains
- 128 for IP-VPN domains

The domain ID can be configured on:

- VPRN BGP-EVPN MPLS and BGP-EVPN SRv6 instances (EVPN interface-less (EVPN-IFL))
- VPRN BGP-IPVPN MPLS and BGP-IPVPN SRv6 instances
- R-VPLS BGP-EVPN MPLS and BGP-EVPN VXLAN instances (EVPN interface-ful (EVPN-IFF))
- VPRN BGP neighbors (PE-CE)
- VPRN level (for local routes). When configured on the VPRN level, using the optional **local-routes-domain-id** command, the PE advertises its direct, static, or IGP routes with a D-path attribute.

Domain IDs can be modified while the service is operational. Modifying the domain ID initiates a route refresh for all address families associated with the VPRN.

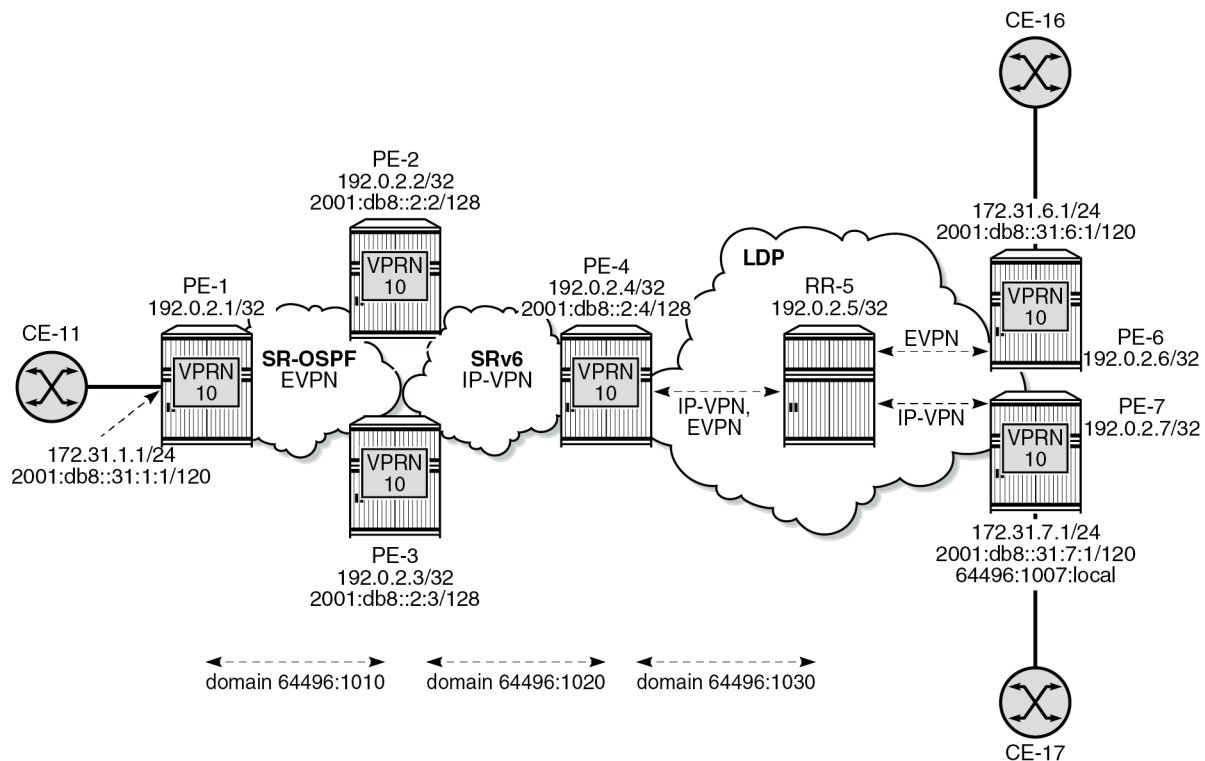

A PE receiving a prefix route with a D-path attribute containing one of its own domain IDs detects a routing loop and does not install the route in the VPRN route table.

The D-path attribute length can influence the BGP best path selection. In the BGP decision process, the shorter D-path is preferred, unless the **d-path-length-ignore** command is configured.

Configuration

The figure [Figure 72: Example topology with VPRN 10 and its domain IDs](#) shows an example topology where PE-6 exports EVPN RT-5 routes 172.31.6.0/24 and 2001:db8::31:6:0/120 to route reflector RR-5, whereas PE-7 exports IP-VPN routes 172.31.7.0/24 and 2001:db8::31:7:0/120 to RR-5. LDP tunnels are used between PE-4, RR-5, PE-6, and PE-7; SRv6 tunnels are used between PE-2, PE-3, and PE-4; SR-OSPF tunnels are used between PE-1, PE-2, and PE-3.

Figure 72: Example topology with VPRN 10 and its domain IDs

38122

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- OSPF as IGP on PE-1, PE-2, and PE-3
- IS-IS as IGP on PE-2, PE-3, PE-4, RR-5, PE-6, and PE-7
- SR-OSPF on PE-1, PE-2, and PE-3
- SRv6 on PE-2, PE-3, and PE-4, configured as in the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.
- LDP on PE-4, RR-5, PE-6, and PE-7

The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal1" {
        type internal
        family {
          evpn true
        }
      }
      neighbor "192.0.2.2" {
        group "internal1"
      }
      neighbor "192.0.2.3" {
        group "internal1"
      }
    }
  }
}
```

```
# on PE-2 (similar configuration on PE-3):
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      router-id 192.0.2.2           # on PE-3: 192.0.2.3
      advertise-inactive true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {

        }
      }
    }
  }
}
```

Domain IDs in VPRN BGP-EVPN MPLS and SRv6 instances

On PE-1, VPRN 10 is configured without domain ID in the **bgp-evpn mpls 1** context:

```
# on PE-1:
configure {
  service {
    vprn "VPRN 10" {
      admin-state enable
      service-id 10
      customer "1"
      autonomous-system 64496
      bgp-evpn {
        mpls 1 {
          admin-state enable
          route-distinguisher "192.0.2.1:10"
        }
      }
    }
  }
}
```

```

        vrf-target {
            community "target:64496:10"
        }
        auto-bind-tunnel {
            resolution filter
            resolution-filter {
                sr-ospf true
            }
        }
    }
}
interface "int-PE-1-CE-11" {
    ipv4 {
        primary {
            address 172.31.1.1
            prefix-length 24
        }
    }
    sap 1/1/c5/1:10 {
    }
    ipv6 {
        address 2001:db8::31:1:1 {
            prefix-length 120
        }
    }
}
}
}

```

Domain ID 64496:1010 is configured in the **bgp-evpn mpls 1** context on GWs PE-2 and PE-3, whereas domain ID 64496:1020 is configured in the **bgp-ipvpn segment-routing-v6** context on PE-2, PE-3, and PE-4. Domain ID 64496:1030 is configured for IP-VPN and for BGP-EVPN on PE-4.

On PE-2, VPRN 10 is configured as follows. The configuration on PE-3 is similar.

```

# on GW PE-2:
configure {
    service {
        vprn "VPRN 10" {
            admin-state enable
            service-id 10
            customer "1"
            autonomous-system 64496
            segment-routing-v6 1 {
                locator "PE-2_loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                    }
                }
            }
        }
    }
    bgp-evpn {

For completeness, the configuration on VPRN 10 on PE-6 and PE-7 is also shown. PE-6 has no domain ID configured:

```

# on PE-6:
configure {
    service {
        vprn "VPRN 10" {
            admin-state enable
            service-id 10
            customer "1"
            autonomous-system 64496
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.6:10"
                    vrf-target {
                        community "target:64496:10"
                    }
                }
                auto-bind-tunnel {
                    resolution filter
                    resolution-filter {
                        ldp true
                    }
                }
            }
        }
    }
    interface "int-PE-6-CE-16" {
        ipv4 {
            primary {
                address 172.31.6.1
                prefix-length 24
            }
        }
        sap 1/1/c5/1:10 {
        }
    }
}

```

```

        ipv6 {
            address 2001:db8::31:6:1 {
                prefix-length 120
            }
        }
    }
}

```

PE-7 does not have a domain ID configured in the **bgp-ipvpn mpls** context, but it has a local domain ID configured: 64496:1007:

```

# on PE-7:
configure {
    service {
        vprn "VPRN 10" {
            admin-state enable
            service-id 10
            customer "1"
            autonomous-system 64496
            local-routes-domain-id "64496:1007"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.7:10"
                    vrf-target {
                        community "target:64496:10"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            ldp true
                        }
                    }
                }
            }
        }
    }
    interface "int-PE-7-CE-17" {
        ipv4 {
            primary {
                address 172.31.7.1
                prefix-length 24
            }
        }
        sap 1/1/c5/1:10 {

VPNR BGP routes for prefix 172.31.6.0/24

PE-6 advertises prefix 172.31.6.0/24 as an EVPN-IFL route without the D-path attribute, as follows:

```
# on PE-6:
2 2022/09/06 10:46:07.053 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE

  Flag: 0xc0 Type: 36 Len: 16 D-PATH: [64496:1020: (ipvpn)][64496:1030: (evpn)]
"

```

The figure [Figure 73: VPRN BGP routes for prefix 172.31.6.0/24](#) shows the D-path attribute in the BGP routes for prefix 172.31.6.0/24:

Figure 73: VPRN BGP routes for prefix 172.31.6.0/24

38123

The figure [Figure 74: VPRN BGP routes for prefix 172.31.7.0/24](#) similarly shows the D-path attribute in the BGP routes for prefix 172.31.7.0/24:

Figure 74: VPRN BGP routes for prefix 172.31.7.0/24

38124

In VPRN 10 on PE-6, no local domain ID is configured, whereas in VPRN 10 on PE-7, the local domain ID 64496:1007 is configured for the routes local to PE-7.

The following BGP update shows that PE-7 advertises prefix 172.31.7.0/24 as a VPN-IPv4 route with a D-path attribute containing the domain segment 64496:1007:(local).

```
# on PE-7:
5 2022/09/06 10:46:12.896 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 72
  Flag: 0x90 Type: 14 Len: 32 Multiprotocol Reachable NLRI:
    Address Family VPN_IPV4
    NextHop len 12 NextHop 192.0.2.7
    172.31.7.0/24 RD 192.0.2.7:10 Label 524282 (Raw Label 0x7ffa1)
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 8 Extended Community:
    target:64496:10
  Flag: 0xc0 Type: 36 Len: 8 D-PATH: [64496:1007:(local)]
"
```

RR-5 advertises prefix 172.31.7.0/24 as a VPN-IPv4 route with the same D-path attribute. PE-4 prepends the domain segment 64496:1030:(ipvpn) to the D-path attribute of the VPN-IPv4 routes for prefix

172.31.7.0/24 to PE-2 (and PE-3). PE-2 advertises prefix 172.31.7.0/24 as an EVPN-IFL route to PE-1 with domain segment 64496:1020:(ipvpn) added to the D-path attribute:

```
# on PE-2:
31 2022/09/06 10:46:12.900 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:

(local)]
"
```

Loop prevention

Besides traceability, the D-path attribute provides loop prevention in the control plane. Redundant GWs PE-2 and PE-3 cause routing loops and the D-path attribute helps preventing these loops. When PE-2 receives the EVPN-IFL route from PE-3 with a D-path containing domain IDs configured on PE-2, such as 64496:1020, it does not install the route in the VPRN route table, as shown in the figure [Figure 75: Loop prevention between PE-2 and PE-3](#):

Figure 75: Loop prevention between PE-2 and PE-3

38125

The following command on PE-2 shows that in the EVPN-IFL route for prefix 172.31.6.0/24 that was received from PE-3, a D-path loop has been detected in VPRN 10:

```
[/]  
A:admin@PE-2# show router bgp routes evpn ip-prefix prefix 172.31.6.0/24 hunt  
=====
```

Domain IDs in R-VPLS BGP-EVPN MPLS and BGP-EVPN VXLAN instances

Loops can also be prevented in Layer 3 EVPN data center gateway (DC GW) scenarios where EVPN-IFF routes are translated into IP-VPN routes, and vice versa. Because redundant GWs are used, the scenario is subject to Layer 3 routing loops and the D-path attribute helps preventing these loops without the need for extra routing policies to tag or drop routes. The figure [Figure 76: Example topology with R-VPLS](#) shows a slightly modified example topology with R-VPLS with PE-2 and PE-3 acting as redundant DC GWs. PE-1 advertises an EVPN-IFF route for prefix 10.20.201.0/24 and PE-6 advertises an EVPN-IFF route for prefix 10.20.206.0/24.

Figure 76: Example topology with R-VPLS

38126

The service configuration on PE-1 does not include a domain ID, as follows:

```
# on PE-1:
configure {
  service {
    vpls "SBD-21" {
      admin-state enable
      service-id 21
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      routed-vpls {
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 21
        routes {
          ip-prefix {
            advertise true
          }
        }
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
    }
  }
  vprn "VPRN 20" {
    admin-state enable
    service-id 20
    customer "1"
    autonomous-system 64496
    interface "int-PE-1-CE-21" {
```

```

        ipv4 {
            primary {
                address 10.20.201.1
                prefix-length 24
            }
        }
        sap 1/1/c5/1:20 {
        }
    }
    interface "int-SBD-21" {
        vpls "SBD-21" {
            evpn-tunnel {
            }
        }
    }
}

```

On DC GW PE-2, domain ID 64496:2010 is configured in VPLS "SBD-21" whereas domain ID 64496:2020 is configured in VPRN 20. The configuration on DC GW PE-3 is similar.

```

# on PE-2:
configure {
    service {
        vpls "SBD-21" {
            admin-state enable
            service-id 21
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 21
                routes {
                    ip-prefix {
                        advertise true
                        domain-id "64496:2010"
                    }
                }
            }
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
            }
        }
    }
    vprn "VPRN 20" {
        admin-state enable
        service-id 20
        customer "1"
        autonomous-system 64496
        segment-routing-v6 1 {
            locator "PE-2_loc" {
                function {
                    end-dt46 {
                    }
                }
            }
        }
    }
}
# on PE-3: "PE-3_loc"

```

```

    bgp-ipvpn {
        segment-routing-v6 1 {
            admin-state enable
            route-distinguisher "192.0.2.2:26" # on PE-3; 192.0.2.3:26
            source-address 2001:db8::2:2 # on PE-3: 2001:db8::2:3
            domain-id "64496:2020"
            vrf-target {
                community "target:64496:20"
            }
            srv6 {
                instance 1
                default-locator "PE-2_loc" # on PE-3: "PE-3_loc"
            }
        }
    }
    interface "int-SBD-21" {
        vpls "SBD-21" {
            evpn-tunnel {
            }
        }
    }
}

```

The service configuration examples for PE-1, PE-2, and PE-3 show how a loop is detected at the DC GWs in VPN-IPv4 routes for prefix 10.20.201.0/24 received from the other DC GW. The following command on DC GW PE-2 shows that a D-path loop is detected in VPRN 20 in a VPN-IPv4 route for prefix 10.20.201.0/24 received from DC GW PE-3:

```

router bgp routes vpn-ipv4 rd 192.0.2.3:26 hunt

```

The figure [Figure 77: Loop prevention between DC GW PE-2 and DC GW PE-3](#) shows that PE-1 sends an EVPN-IFF route for prefix 10.20.201.0/24 without D-path attribute to PE-2 and PE-3. Both PE-2 and PE-3 re-advertise prefix 10.20.201.0/24 as a VPN-IPv4 route with D-path attribute 64496:2010:(evpn). When PE-2 receives this VPN-IPv4 route from PE-3, it detects a loop based on the D-path attribute with domain segment 64496:2010:(evpn) and does not install the route in the VPRN route table. Likewise, PE-3 receives the VPN-IPv4 route from PE-2 and does not install it in the VPRN route table.

Figure 77: Loop prevention between DC GW PE-2 and DC GW PE-3

38127

PE-2 does not use the VPN-IPv4 route for prefix 10.20.201.0/24 from PE-3. The VPRN route table on PE-2 contains the EVPN-IFF route received from PE-1 for prefix 10.20.201.0/24:

```
[/]
A:admin@PE-2# show router 20 route-table

=====
```

Conclusion

The D-path attribute provides traceability for VPRN BGP routes and can be used for BGP best path selection. The D-path attribute for VPRN routes also helps preventing loops without the need for dedicated routing policies to tag and drop routes.

Dual EVPN-MPLS Instance VPLS Services

This chapter provides information about the dual EVPN-MPLS instance VPLS services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and MD-CLI configuration in this chapter are based on SR OS Release 22.10.R1. Dual EVPN-MPLS instance in VPLS is supported in SR OS Release 21.10.R1 and later.

Overview

One of the scale issues that low-scale access nodes or leaf PEs face in high-scale architectures is the limited number of EVPN/IP-VPN next hops, tunnels, and service labels that they support.

The following solutions reduce the number of EVPN next hops exposed to the access nodes:

- inter-AS model B, as described in the [Inter-AS VPRN Model B](#) chapter
- next-hop-self route reflectors (NHS-RRs)

The figure [Figure 78: Access nodes receive next hops from the NHS-RRs](#) shows the NHS-RR solution reducing the number of EVPN next hops that are sent to the low-scale access nodes PE-1 and PE-2. Only the two NHS-RRs are exposed as next hops to PE-1.

Figure 78: Access nodes receive next hops from the NHS-RRs

38259

The number of EVPN next hops is reduced, but the number of service labels to be learned is not. PE-1 still learns one service label per remote PE for each service it is attached to. In case of EVPN E-LAN services and broadcast, unknown unicast, and multicast (BUM) traffic, the ingress PE still needs one copy of every BUM packet per egress PE that exists in the remote domains, even if all the BUM traffic goes through one of the two NHS-RRs (or ASBRs in the case of model B).

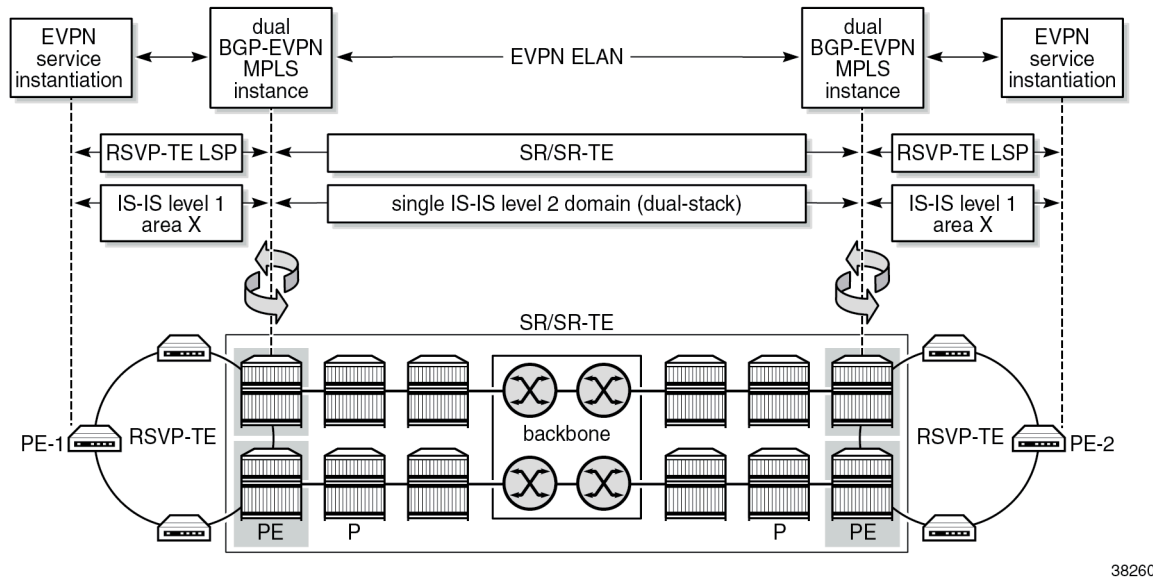

The following solutions reduce the number of service labels:

- VPRN services on the NHS-RRs with **allow-export-bgp-vpn** configured
- dual EVPN-MPLS instance VPLS services on the NHS-RRs

The **allow-export-bgp-vpn** command applies to VPRN services using EVPN-IFL, VPN-IPv4, and VPN-IPv6 families. Routes from the WAN are imported to the VPRN service and exported to the access nodes as new VPN-IP routes. The values of the service labels, route targets (RTs), and BGP next hops of the re-advertised routes are based on the configuration of the exporting VPRN.

The figure [Figure 79: Access nodes receive one service label per service from each NHS-RR](#) shows a dual EVPN-MPLS instance VPLS service on the NHS-RRs, which offers a similar solution for EVPN-VPLS services to the **allow-export-bgp-vpn** solution for VPRN services. EVPN-MPLS routes received from the WAN are imported to the network EVPN-MPLS instance and redistributed to the access EVPN-MPLS instance with a new route distinguisher (RD), next hop, service label, and possibly a new RT. The ingress PE learns only one service label for each NHS-RR per service, as opposed to one service label per remote PE that is attached to the same EVPN service. With this solution, the replication of BUM traffic is also optimized because the ingress PE sends a single copy of each BUM packet to the NHS-RR, as opposed to one copy per egress PE.

Figure 79: Access nodes receive one service label per service from each NHS-RR

In the example, redundant NHS-RRs are used. Redundancy is handled via anycast multihoming, which implies that two or more PEs are configured with the same service parameters as part of the same redundancy group: identical route distinguishers and RTs per instance, and the same anycast IP address. The ingress PEs set up EVPN destinations to only one PE in the anycast group for a specific service. EVPN BUM destinations are not established between PEs in the same anycast group because the received anycast peer inclusive multicast Ethernet tag (IMET) routes have the same local originating IP address. In anycast multihoming scenarios, policies are required to prevent control-plane loops.

Configuration

The following scenarios are described in this section:

- dual EVPN-MPLS instance VPLS without multihoming
- dual EPVN-MPLS instance VPLS with anycast multihoming

Dual EVPN-MPLS instance VPLS without multihoming

The figure [Figure 80: Example topology 1](#) shows EVPN-MPLS VPLS 1 configured on four PEs. PE-2 and PE-4 are EVPN gateways (GWs). RR-7 is the route reflector for PE-2 and PE-4 in the WAN network.

Figure 80: Example topology 1

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 1 between PE-1 and PE-2 and between PE-4 and PE-6
- IS-IS level 2 between PE-2, PE-4, and RR-7
- SR-TE tunnels between PE-2 and PE-4
- MPLS LSPs between PE-1 and PE-2 and between PE-4 and PE-6

BGP is configured on all nodes for the EVPN address family. PE-1 peers with the dual-homed EVPN GW PE-2. In a similar way, PE-6 peers with EVPN GW PE-4. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "access1" {
        peer-as 64496
        family {
          evpn true
        }
      }
      neighbor "192.0.2.2" {
        group "access1"
      }
    }
  }
}
```

EVPN GW PE-2 peers with PE-1 in BGP group "access1" and with RR-7 in BGP group "WAN":

```
# on PE-2:
```

```
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "WAN" {
        next-hop-self true
        peer-as 64496
        family {
          evpn true
        }
        export {
          policy ["drop-tag-10"]
        }
      }
      group "access1" {
        next-hop-self true
        peer-as 64496
        family {
          evpn true
        }
        cluster {
          cluster-id 192.0.2.2
        }
        export {
          policy ["drop-tag-20"]
        }
      }
      neighbor "192.0.2.1" {
        group "access1"
      }
      neighbor "192.0.2.7" {
        group "WAN"
      }
    }
  }
}
```

The BGP configuration on PE-4 is similar. The export policies use tags to avoid loops in topologies with redundant EVPN GWs, as described in the section [Dual EVPN-MPLS instance VPLS with anycast multihoming](#).

RR-7 peers with PE-2 and PE-4 in BGP group "WAN":

```
# on RR-7:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "WAN" {
```

```

        peer-as 64496
        family {
            evpn true
        }
        cluster {
            cluster-id 192.0.2.7
        }
    }
    neighbor "192.0.2.2" {
        group "WAN"
    }
    neighbor "192.0.2.4" {
        group "WAN"
    }
}

```

On PE-1, VPLS 1 is configured with a single EVPN-MPLS instance. The RD 192.0.2.1:1 for BGP 1 is auto-derived from the values for the IPv4 system address and the EVI. PE-1 imports and exports routes with RT 64496:101.

```

# on PE-1:
configure {
    service {
        vpls "VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                # route-distinguisher 192.0.2.1:1 # will be auto-derived
                route-target {
                    export "target:64496:101"
                    import "target:64496:101"
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            rsvp true
                        }
                    }
                }
            }
        }
        sap 1/1/c10/1:1 {
        }
    }
}

```

On PE-2, VPLS 1 is configured with two EVPN-MPLS instances: instance 1 is configured with multihoming mode access and instance 2 with the (default) multihoming mode network, as follows:

```

# on PE-2:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2
                community-value {
                    start 2000
                }
            }
        }
    }
}

```

```

        end 2999
    }
}
vpls "VPLS-1" {
    admin-state enable
    description "dual BGP-EVPN MPLS instance VPLS"
    service-id 1
    customer "1"
    bgp 1 {
        # route-distinguisher 192.0.2.2:1    # will be auto-derived
        route-target {
            export "target:64496:101"
            import "target:64496:101"
        }
    }
    bgp 2 {
        route-distinguisher auto-rd
        route-target {
            export "target:64496:100"
            import "target:64496:100"
        }
    }
    bgp-evpn {
        evi 1
        mpls 1 {
            admin-state enable
            mh-mode access
            auto-bind-tunnel {
                resolution filter
                resolution-filter {
                    rsvp true
                }
            }
        }
        mpls 2 {
            admin-state enable
            # mh-mode network                    # default MH mode
            auto-bind-tunnel {
                resolution filter
                resolution-filter {
                    sr-te true
                }
            }
        }
    }
}
}
}

```

Note: The RD for BGP 1 can be auto-derived from the values for the IPv4 system address and the EVI, for example, 192.0.2.2:1 on PE-2. The RD for BGP 2 cannot be auto-derived from the values for the IPv4 system address and the EVI, because the RD for BGP 2 must be different from the RD for BGP 1, so it must be configured manually or with **auto-rd**.

On PE-4, the configuration is similar:

```

# on PE-4:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.4
                community-value {

```

```

        start 2000
        end 2999
    }
}
vpls "VPLS-1" {
    admin-state enable
    description "dual BGP-EVPN MPLS instance VPLS"
    service-id 1
    customer "1"
    bgp 1 {
        # route-distinguisher 192.0.2.4:1    # will be auto-derived
        route-target {
            export "target:64496:102"
            import "target:64496:102"
        }
    }
    bgp 2 {
        route-distinguisher auto-rd        # different RD
        route-target {
            export "target:64496:100"
            import "target:64496:100"
        }
    }
    bgp-evpn {
        evi 1
        mpls 1 {
            admin-state enable
            mh-mode access
            auto-bind-tunnel {
                resolution filter
                resolution-filter {
                    rsvp true
                }
            }
        }
        mpls 2 {
            admin-state enable
            # mh-mode network                # default MH mode
            auto-bind-tunnel {
                resolution filter
                resolution-filter {
                    sr-te true
                }
            }
        }
    }
}
}
}

```

The following command on PE-2 shows BGP instances 1 and 2 in VPLS 1. RD 192.0.2.2:1 for BGP instance 1 is auto-derived from the IPv4 system address and the EVI; the RD for BGP instance 2 is configured with **auto-rd** and has the value 192.0.2.2:2000. The RT values are configured.

```

Dual EVPN-MPLS instance VPLS with anycast multihoming

Figure 81: Example topology 2 shows example topology 2 with VPLS 2 configured on six PEs. PE-2 and PE-3 are redundant EVPN GWs with anycast address 23.23.23.23; PE-4 and PE-5 are redundant EVPN GWs with anycast address 45.45.45.45. RR-7 is the route reflector for PE-2, PE-3, PE-4, and PE-5 in the WAN network.

Figure 81: Example topology 2

38262

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 1 between PE-1, PE-2, and PE-3
- IS-IS level 1 between PE-4, PE-5, and PE-6
- IS-IS level 2 between PE-2, PE-3, PE-4, PE-5, and RR-7
- SR-ISIS between PE-2, PE-3, PE-4, and PE-5
- MPLS LSPs between PE-1 and PE-2, between PE-1 and PE-3, between PE-4 and PE-6, and between PE-5 and PE-6

The BGP configuration on PE-1 and PE-6 is similar.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "access1" {
      peer-as 64496
      family {
        evpn true
      }
    }
  }
  neighbor "192.0.2.2" {
    # on PE-6: 192.0.2.4
```

```
        group "access1"
      }
      neighbor "192.0.2.3" {          # on PE-6: 192.0.2.5
        group "access1"
      }
    }
  }
```

The BGP configuration on PE-3 is:

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "WAN" {
        next-hop-self true
        peer-as 64496
        family {
          evpn true
        }
        export {
          policy ["drop-tag-10"]
        }
      }
      group "access1" {
        next-hop-self true
        peer-as 64496
        family {
          evpn true
        }
        cluster {
          cluster-id 192.0.2.3
        }
        export {
          policy ["drop-tag-20"]
        }
      }
      neighbor "192.0.2.1" {
        group "access1"
      }
      neighbor "192.0.2.7" {
        group "WAN"
      }
    }
  }
}
```

The BGP configuration on PE-2, PE-4, and PE-5 is similar.

On PE-1, VPLS 2 is configured with a single EVPN-MPLS instance. PE-1 imports and exports routes with RT 64496:501. The configuration is as follows:

```
# on PE-1:
configure {
  service {
    vpls "VPLS-2" {
      admin-state enable
    }
  }
}
```

```

service-id 2
customer "1"
bgp 1 {
    # route-distinguisher 192.0.2.1:2 # will be auto-derived
    route-target {
        export "target:64496:501"
        import "target:64496:501"
    }
}
bgp-evpn {
    evi 2
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution filter
            resolution-filter {
                rsvp true
            }
        }
    }
}
sap 1/1/c10/1:2 {
}
}

```

On PE-2 and PE-3, the following policies are used in VPLS 2:

- Export policy "vsi-501-export" adds the communities "SOO-23" for the site of origin (SOO) and "RT64496:501" for the RT.
- Export policy "vsi-502-export" adds the communities "SOO-23" and "RT64496:502".
- Import policy "vsi-501-import" prevents loops based on the SOO and accepts routes with RT 64496:501.
- Import policy "vsi-502-import" prevent loops based on the SOO and accepts routes with RT 64496:502.

```

# on PE-2, PE-3:
configure {
    policy-options {
        community "RT64496:501" {
            member "target:64496:501" { }
        }
        community "RT64496:502" {
            member "target:64496:502" { }
        }
        community "SOO-23" {
            member "origin:23:23" { }
        }
    }
    policy-statement "vsi-501-export" {
        default-action {
            action-type accept
            community {
                add ["RT64496:501" "SOO-23"]
            }
        }
    }
    policy-statement "vsi-501-import" {
        entry 10 {
            from {
                family [evpn]
                community {
                    name "SOO-23"
                }
            }
        }
    }
}

```

```

    }
    action {
        action-type reject
    }
}
entry 20 {
    from {
        family [evpn]
        community {
            name "RT64496:501"
        }
    }
    action {
        action-type accept
    }
}
}
policy-statement "vsi-502-export" {
    default-action {
        action-type accept
        community {
            add ["RT64496:502" "S00-23"]
        }
    }
}
}
policy-statement "vsi-502-import" {
    entry 10 {
        from {
            family [evpn]
            community {
                name "S00-23"
            }
        }
        action {
            action-type reject
        }
    }
    entry 20 {
        from {
            family [evpn]
            community {
                name "RT64496:502"
            }
        }
        action {
            action-type accept
        }
    }
}
}
}
}

```

On PE-2 and PE-3, VPLS 2 is configured with two EVPN-MPLS instances: instance 1 is configured with multihoming mode access and instance 2 with multihoming mode network. For redundancy, anycast multihoming is configured with anycast address 23.23.23.23 and identical RDs and RTs for the same instance. The RD for BGP 1 is 192.0.2.23:2 and the RD for BGP 2 is 192.0.2.32:2. The **default-route-tag 10** command is configured for service instance 1, while **default-route-tag 20** is configured for service instance 2. These route tags are used in the BGP peer export policies to differentiate the different routes. On PE-2 and PE-3, VPLS 2 is configured as follows:

```

# on PE-2, PE-3:
configure {
    service {
        vpls "VPLS-2" {

```

```

admin-state enable
description "dual BGP-EVPN MPLS instance VPLS"
service-id 2

    }
    mpls 2 {
        admin-state enable
        default-route-tag 0x14        # default route tag 20
        auto-bind-tunnel {
            resolution filter
            resolution-filter {
                sr-isis true
            }
        }
    }
}
}

```

Note: For anycast multihoming, the RDs must be identical, so all RDs are configured manually.

In datacenter GWs (DC GWs) with EVPN-VXLAN and EVPN-MPLS instances, route policies can match on the encapsulation type VXLAN or MPLS. In DC GWs with two EVPN-MPLS instances, the default route tag is used instead. The default route tag prevents a MAC/IP route that is installed in instance 1 (access) from being readvertised back to the access peers. In a similar way, MAC/IP routes installed in instance 2 are not readvertised back to peers in instance 2. On PE-2 and PE-3, the BGP peer export policy "drop-tag-10" drops routes with tag 10 and is configured in BGP group "WAN" with neighbor RR-7; BGP peer export policy "drop-tag-20" drops routes with tag 20 and is configured in BGP group "access1" with neighbor PE-1.

```

# on PE-2, PE-3:
configure {
    policy-options {
        policy-statement "drop-tag-10" {
            description "used as export policy toward WAN BGP peers"
            entry 10 {
                from {
                    tag 10
                }
            }
        }
    }
}

```

```

        }
        action {
            action-type reject
        }
    }
    default-action {
        action-type accept
    }
}
policy-statement "drop-tag-20" {
    description "used as export policy toward DC BGP peers"
    entry 10 {
        from {
            tag 20
        }
        action {
            action-type reject
        }
    }
    default-action {
        action-type accept
    }
}
}
info
}
router "Base" {
    bgp {
        group "WAN" {
            export {
                policy ["drop-tag-10"]
            }
        }
        group "access1" {
            export {
                policy ["drop-tag-20"]
            }
        }
    }
}

```

The figure [Figure 82: Export policies on PE-2 drop routes based on tag](#) shows an incoming EVPN MAC route on PE-2 for CE-21's MAC address 00:00:5e:00:53:21. PE-2 receives the EVPN MAC route with RT target:64496:501 from PE-1 (BGP-EVPN peer 192.0.2.1). On PE-2, BGP 1 in VPLS 2 imports routes with this RT and the MAC address is installed in the FDB. The EVPN MAC route is redistributed to BGP 2 where the communities "RT64496:502" and "SOO-23", as well as internal tag 20, are added to the route. When PE-2's BGP process sends an EVPN MAC route with tag 20 to BGP peer PE-1, the BGP export policy "drop-tag-20" drops the route, preventing PE-2 from re-advertising the EVPN MAC route back to the access peer 192.0.2.1. PE-2 can only send the EVPN MAC route to WAN neighbor 192.0.2.7 because the BGP export policy toward the WAN only drops the routes with tag 10, not the ones with tag 20.

Figure 82: Export policies on PE-2 drop routes based on tag

38263

For completeness, the configuration on PE-4 and PE-5 is as follows:

```
# on PE-4, PE-5:
configure {
  policy-options {
    community "RT64496:502" {
      member "target:64496:502" { }
    }

Conclusion

Dual-instance EVPN-MPLS GWs reduce the number of service labels to be learned at the access nodes, and optimizes the replication of BUM traffic from the access nodes.

EVPN E-LAN services with SRv6 transport

This chapter provides information about SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services is supported on FP-based platforms with FP4-based network ports in SR OS Release 22.7.R1 and later.

Overview

On FP-based platforms with FP4-based network ports, SR OS provides SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services. SRv6 tunnels carry EVPN data between the PEs on which the EVPN service is provisioned. As usual in EVPN services, a full mesh of SRv6 tunnels is set up among all PEs that participate in the EVPN-enabled VPLS service. This supports the flooding of Broadcast, Unknown unicast, or Multicast (BUM) traffic to all remote destinations in the service, while ensuring that the PEs receive the traffic without looping or duplication of frames. Two or more routers may participate in a single EVPN-enabled VPLS service; a single router may participate in multiple EVPN-enabled VPLS services. The PE routers attached to an EVPN-enabled VPLS service with SRv6 transport use SRv6 End.DT2U behavior to terminate and forward unicast traffic, and SRv6 End.DT2M behavior to terminate and forward BUM traffic.

An SRv6 L2 Service TLV, which is carried in a BGP Prefix-SID attribute, signals the SRv6 Service SID for the End.DT2U or End.DT2M behavior for an EVPN-enabled VPLS Layer 2 overlay service, as per RFC 9252. The SRv6 Service SID is equivalent to an MPLS label for EVPN service routes in RFC 7432.

When a PE is attached to an EVPN-enabled VPLS service with SRv6 transport, the PE advertises its originating IP address in an Inclusive Multicast Ethernet Tag (IMET) route (also known as an EVPN type 3 route), along with the service attributes and the SRv6 SID corresponding to the End.DT2M behavior for the service. A remote PE attached to the same EVPN-enabled VPLS service imports the IMET route based on the import route target and adds an SRv6 destination entry to its flooding list for the EVPN-enabled VPLS service. In this way, all PEs that participate in an EVPN-enabled VPLS service learn about each other.

As in any other type of EVPN-enabled VPLS service, a PE learns the MAC address of a locally connected CE, either via data plane MAC learning or static provisioning. In the case of data plane MAC learning, a PE learns the source MAC address from data frames that it receives from the CE and adds a temporary entry for it in a VPLS forwarding database (FDB), which, on each PE, is private for each EVPN-enabled VPLS service.

A local MAC address is advertised in an EVPN MAC/IP advertisement route (EVPN type 2 route) for the EVPN-enabled VPLS service, along with the service parameters and an SRv6 SID corresponding to the

End.DT2U behavior for the service. A remote PE that imports the EVPN MAC/IP advertisement route adds an entry for the advertised MAC addresses to the FDB, pointing at an SRv6 destination based on the received SRv6 SID. In this way, remote PEs that participate in an EVPN-enabled VPLS service with SRv6 transport learn how to unicast return traffic to the remote (source) MAC address.

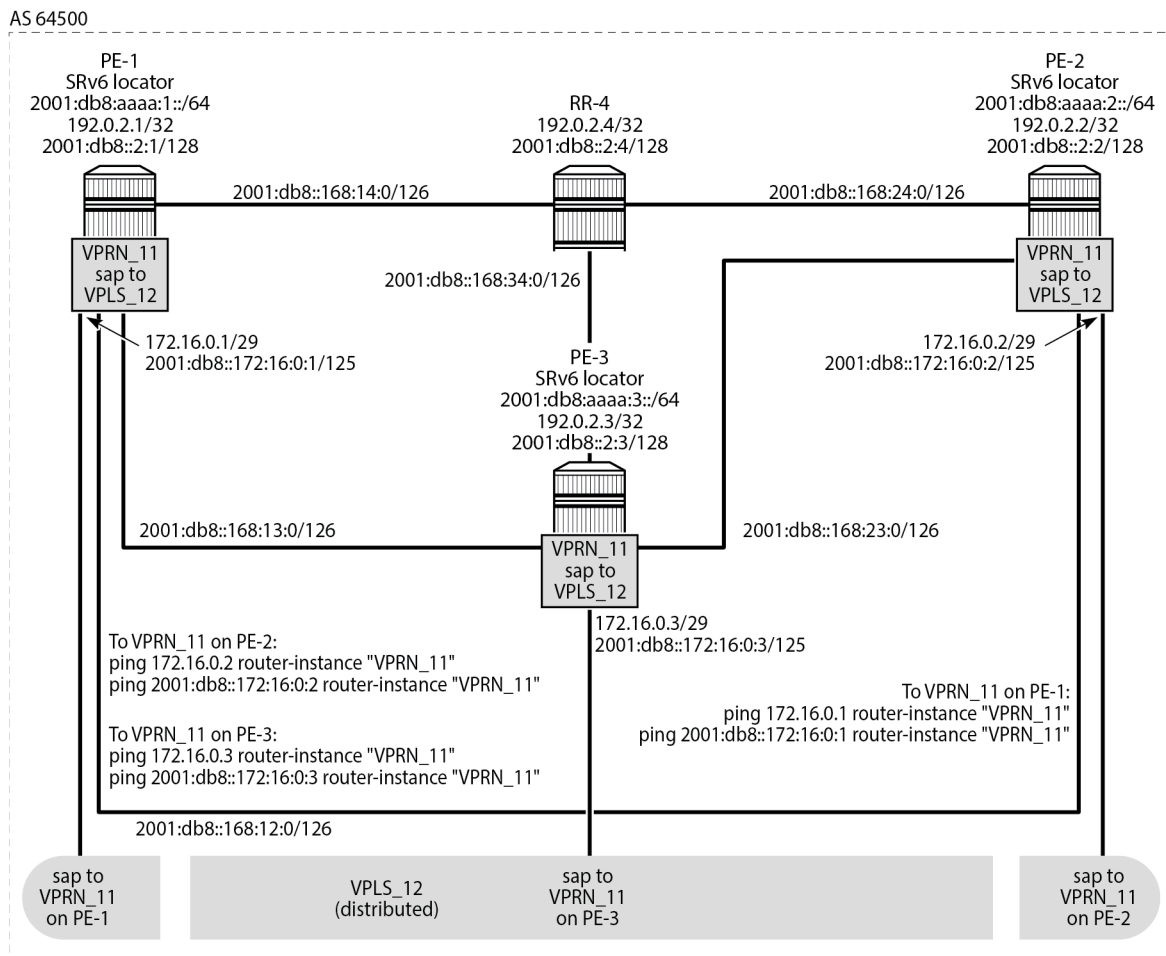

The **locator** command in the **service vpls <service-name> segment-routing-v6 <instance>** context configures the SRv6 locator that the PE uses to terminate SRv6 traffic for the EVPN-enabled VPLS service.

The base SRv6 configuration is as described in the "SRv6 Encapsulation in the Base Routing Instance" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

Configuration

[Figure 83: Example topology](#) shows the example topology with three PE routers. The SRv6-enabled network that it represents comprises PE-1, PE-2, and PE-3 in the control and data planes, and a BGP route reflector RR-4 in the control plane only. The SRv6-enabled network has only IPv6 addresses and interfaces. IS-IS and BGP are configured on all routers. The system interfaces have also an IPv4 address, from which a unique router-id is automatically derived for IS-IS and BGP respectively.

Figure 83: Example topology

38302

For the traffic of data frames from the EVPN-enabled VPLS service on a local PE to the same EVPN-enabled VPLS service on a remote PE, the local PE acts as the SRv6 ingress PE node, while the remote PE acts as the SRv6 egress PE node. SRv6 and forwarding port extensions (FPE) are configured only on the PE routers.

The **ping** commands between IPv4 and IPv6 interface addresses in the EVPN-enabled VPLS service simulate IPv4 and IPv6 data traffic respectively.

Configure the router

This configuration includes:

- on PE-1, PE-2, PE-3, and RR-4:
 - ports, IPv6-only interfaces, and system interfaces
 - IS-IS:
 - level 2 capability with wide metrics (for the 128-bit identifiers)

- native IPv6 routing
 - the **traffic-engineering** and **traffic-engineering-options** commands, as a best practice to advertise the router capability within the autonomous system (AS)
- BGP, with internal group "gr_v6_internal" that includes:
- the EVPN family
 - BGP neighbor system IPv6 addresses
- on PE-1, PE-2, and PE-3, port cross-connect (PXC), using internal loopbacks on an FP4 MAC chip, as described in the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*

The following example configuration applies for PE-1. A similar configuration applies for PE-2, PE-3, and RR-4. RR-4 has PE-1, PE-2 and PE-3 as BGP neighbors in a cluster.

```
A:admin@PE-1# configure {
  port 1/1/c2/1 {
    ethernet {
      mode hybrid
    }
    admin-state enable
  }
  port 1/1/c3/1 {
    ethernet {
      mode hybrid
    }
    admin-state enable
  }
  port 1/1/c4/1 {
    ethernet {
      mode hybrid
    }
    admin-state enable
  }
  port 1/1/c1/1 {
    ethernet {
      mode hybrid
    }
    admin-state enable
  }
  port 1/1/c1/2 {
    ethernet {
      mode hybrid
    }
    admin-state enable
  }
  router "Base" {

        group "gr_v6_internal"
    }
}
}
```

Configure the VPRNs to simulate CEs

On each PE, the VPRN configuration includes an IPv4 address and an IPv6 address for an interface from the local VPRN to the EVPN-enabled VPLS service. These IPv4 and IPv6 addresses must be in the same address range on all PEs, because the same EVPN-enabled VPLS service is provisioned on each PE. Each interface to the (local) EVPN-enabled VPLS service also includes a SAP.

The VPRNs are introduced only to simulate CEs from where the **ping** commands can be launched.

The following example configuration applies for VPRN 11 on PE-1. A similar configuration applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

```
A:admin@PE-1# configure {
  service {
    vprn "VPRN_11" {
      service-id 11
      customer "1"
      description "CE_1"
      interface "local" {
        mac 00:00:5e:00:53:01
        ipv4 {
          primary {
            address 172.16.0.1
            prefix-length 29
          }
        }
        ipv6 {
          address 2001:db8::172:16:0:1 {
            prefix-length 125
          }
        }
        sap 1/1/c1/2:11 {
        }
      }
      admin-state enable
    }
  }
}
```

For example, VPRN 11 on PE-2 has the following interface, with corresponding IPv4 and IPv6 addresses. Similar output applies for VPRN 11 on PE-1 and for VPRN 11 on PE-3.

```
A:admin@PE-2# show router 11 interface
```

```
=====
Interface Table (Service: 11)
=====
Interface-Name                Adm      Opr(v4/v6)  Mode    Port/SapId
```

IP-Address				PfxState
Local	Up	Up/Up	VPRN	1/1/c2/2:11
172.16.0.2/29				n/a
2001:db8::172:16:0:2/125				PREFERRED
fe80::200:22ff:fe22:2222/64				PREFERRED

Interfaces : 1				
=====				

VPRN 11 on PE-1 has the following IPv4 and IPv6 routes. Similar output applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

For IPv4:

```
A:admin@PE-1# show router 11 route-table
=====
Route Table (Service: 11)
=====
Dest Prefix[Flags]          Type  Proto  Age      Pref
Next Hop[Interface Name]   Metric
-----
172.16.0.0/29              Local Local  00h01m43s  0
local                      0
-----
No. of Routes: 1
---snip---
```

For IPv6:

```
A:admin@PE-1# show router 11 route-table ipv6
=====
IPv6 Route Table (Service: 11)
=====
Dest Prefix[Flags]          Type  Proto  Age      Pref
Next Hop[Interface Name]   Metric
-----
2001:db8::172:16:0:0/125   Local Local  00h01m42s  0
local                      0
-----
No. of Routes: 1
---snip---
```

VPRN 11 on PE-1 has one locally learned MAC address for the locally configured interface. Similar output applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

```
A:admin@PE-1# show router 11 arp summary
=====
ARP Table Summary (Service: 11)
=====
Local ARP Entries   : 1
---snip---
Dynamic ARP Entries : 0
---snip---
-----
No. of ARP Entries  : 1
```

The **show router 11 arp** command shows the association between the IP address and the MAC address, and the interface that the MAC address belongs to. The MAC address for the local interface to the EVPN-enabled VPLS service corresponds with that of the SAP that is configured for it in VPRN 11. Because the interface is statically configured, the association between the IP address and the MAC address does not expire. Similar output applies for PE-2 and for PE-3.

```
A:admin@PE-1# show router 11 arp
```

```
=====
ARP Table (Service: 11)
=====
```

IP Address	MAC Address	Expiry	Type	Interface
172.16.0.1	00:00:5e:00:53:01	00h00m00s	0th[I]	local

```
-----
No. of ARP Entries: 1
=====
```

Configure data path support, FPE, and SRv6

Configure data path support (PXC) and FPE identically on PE-1, PE2, and PE-3.

```
A:admin@PE-1# configure {
  card 1 {
    mda 1 {
      xconnect {
        mac 1 {
          loopback 1 {
          }
          loopback 2 {
          }
        }
      }
    }
  }
  port-xc {
    pxc 1 {
      port 1/1/m1/1
      admin-state enable
    }
    pxc 2 {
      port 1/1/m1/2
      admin-state enable
    }
  }
  port pxc-1.a {
    admin-state enable
  }
  port pxc-1.b {
    admin-state enable
  }
  port pxc-2.a {
    admin-state enable
  }
  port pxc-2.b {
    admin-state enable
  }
}
```

```

port 1/1/m1/1 {
    admin-state enable
}
port 1/1/m1/2 {
    admin-state enable
}
fwd-path-ext {
    fpe 1 {
        path {
            pxc 1
        }
        application {
            srv6 {
                type origination
            }
        }
    }
    fpe 2 {
        path {
            pxc 2
        }
        application {
            srv6 {
                type termination
            }
        }
    }
}
}
}

```

Configure the SRv6 locator *"PE-1_loc_VPLS"* with **ip-prefix 2001:db8:aaaa:1::/64** in the **router Base segment-routing segment-routing-v6** context on PE-1 and similar on PE-2, with **ip-prefix 2001:db8:aaaa:2::/64** for SRv6 locator *"PE-2_loc_VPLS"*, and on PE-3, with **ip-prefix 2001:db8:aaaa:3::/64** for SRv6 locator *"PE-3_loc_VPLS"*.

```

A:admin@PE-1# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                source-address 2001:db8::2:1
                locator "PE-1_loc_VPLS" {
                    block-length 48
                    prefix {
                        ip-prefix 2001:db8:aaaa:1::/64
                    }
                }
                admin-state enable
            }
        }
    }
}

```

Use FPE 1 as the SRv6 origination FPE and FPE 2 as the SRv6 termination FPE on PE-1, and similar on PE-2 for SRv6 locator *"PE-2_loc_VPLS"*, and on PE-3 for SRv6 locator *"PE-3_loc_VPLS"*. For more information, see the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

```

configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {

```

```

        origination-fpe [1]
        locator "PE-1_loc_VPLS" {
            termination-fpe [2]
            admin-state enable
        }
    }
}

```

Advertise the SRv6 locator "*PE-1_loc_VPLS*" in IS-IS while ensuring level 2 capability on PE-1, and similar on PE-2 for SRv6 locator "*PE-2_loc_VPLS*", and on PE-3 for SRv6 locator "*PE-3_loc_VPLS*".

```

A:admin@PE-1# configure {
    router "Base" {
        isis 0 {
            segment-routing-v6 {
                locator "PE-1_loc_VPLS" {
                    level-capability 2
                }
                admin-state enable
            }
        }
    }
}

```

Verify the IS-IS data base on PE-1 with the **show router isis 0 database detail** command. The output of this command (shortened here for PE-1, PE-3 and RR-4) provides information about each IS-IS-enabled router. For each uniquely identified IS-IS-enabled router, the SRv6 information indicates:

- the IS-IS-advertised router capabilities
- the IS-IS topology details
- the IPv4 and IPv6 reachability details
- the advertised SRv6 locator TLV
- the advertised configured SRv6 End SID and SRv6 End-X SIDs

```

A:admin@PE-1# show router isis 0 database detail

PE-1 transports IPv4 and IPv6 data to the remote SRv6 locator prefixes in an SRv6 encapsulated tunnel. For each SRv6 locator prefix destination, PE-1 sets up a different SRv6 tunnel with its specific label (TunnelId). Similar output applies for PE-2 and for PE-3.

```
A:admin@PE-1# show router tunnel-table ipv6

Verify data traffic

At this point, verify that IPv4 and IPv6 data traffic is not possible between the local VPRN 11 on PE-1 and the remote VPRN 11 on PE-2 and PE-3. PE-1 is not aware of the remote MAC addresses that are associated with IPv4 address 172.16.0.2 and IPv4 address 172.16.0.3 (or IPv6 address 2001:db8::172:16:0:2 and IPv6 address 2001:db8::172:16:0:3), because only interfaces that are locally connected to the EVPN-enabled VPLS service on PE-1 reply on the ARP request. Perform a similar verification for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-2 and the remote VPRN 11 on PE-1 and PE-3, and for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-3 and the remote VPRN 11 on PE-1 and PE-2.

For example, for IPv4 data traffic to the remote VPRN 11 on PE-2:

```
A:admin@PE-1# ping 172.16.0.2 router-instance "VPRN_11"
PING 172.16.0.2 56 data bytes
... .. . Request timed out. icmp_seq=1.
Request timed out. icmp_seq=2.
---snip---
---- 172.16.0.2 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

For example, for IPv6 data traffic to the remote VPRN 11 on PE-2:

```
A:admin@PE-1# ping 2001:db8::172:16:0:2 router-instance "VPRN_11"
PING 2001:db8::172:16:0:2 56 data bytes
... .. . 112 bytes from 2001:db8::172:16:0:1 Address unreachable
VR CLS  LEN NXT HLIM SRC
 6 00   64 58  64 2001:db8::172:16:0:1
                               DST
                               2001:db8::172:16:0:2
ICMP6: Echo request
---snip---
---- 2001:db8::172:16:0:2 PING Statistics ----
5 packets transmitted, 5 packets bounced, 0 packets received, 100% packet loss
```

Configure the EVPN- and SRv6-enabled VPLS service on PE-1, PE-2, and PE-3

On each PE, this configuration includes a SAP to the local VPRN.

On PE-1, create an SRv6 instance *1* for the EVPN-enabled VPLS service. Use the SRv6 locator "*PE-1_loc_VPLS*" from the **router Base segment-routing segment-routing-v6** context in the **service vpls "VPLS_12" segment-routing-v6 1** context and configure End.DT2U and End.DT2M behavior for it.

Use the configured SRv6 locator "*PE-1_loc_VPLS*" as the default locator in the **service vpls "VPLS_12" bgp-evpn segment-routing-v6 1 locator "PE-1_loc_VPLS"** context, use the unique PE-1 system IPv6 address as the route next hop. This configuration can be verified with the **show service id 12 bgp** command (not shown). Perform a similar configuration on PE-2 (and PE-3), with the configured SRv6 locator "*PE-2_loc_VPLS*" ("*PE-3_loc_VPLS*") as the default locator, and the PE-2 (PE-3) system IPv6 address as route next hop.

```
A:admin@PE-1# configure {
  service {
    vpls "VPLS_12" {
      service-id 12
      customer "1"
      description "VPLS_12 on PE-1"
      segment-routing-v6 1 {
        locator "PE-1_loc_VPLS" {
          function {
            end-dt2u {
            }
            end-dt2m {
            }
          }
        }
      }
    }
    bgp 1 {
    }
    bgp-evpn {
      evi 1
      segment-routing-v6 1 {
        srv6 {
          instance 1
          default-locator "PE-1_loc_VPLS"
        }
        route-next-hop {
          system-ipv6
        }
        admin-state enable
      }
    }
    sap 1/1/c1/1:11 {
      description "sap to VPRN_11 on PE-1"
    }
    admin-state enable
  }
}
```

The **show service id 12 fdb expiry** command shows that MAC learning and MAC aging are enabled. For example, the VPLS FDB entries that are locally learned expire after 300 seconds.

```
A:admin@PE-1# show service id 12 fdb expiry

The **show service id 12 bgp-evpn** command shows how BGP EVPN behavior is configured. MAC advertisement for EVPN MAC/IP advertisement routes (for **ping** commands) and inclusive multicast advertisement for EVPN IMET routes (for flooding and BUM traffic) are enabled. The next hop corresponds with the local system IPv6 address. The route resolution uses the route table of the VPRN that has a local interface to the EVPN-enabled VPLS service. Similar output applies for PE-2 and for PE-3.

```

A:admin@PE-1# show service id 12 bgp-evpn

```

The configuration of the SRv6 End.DT2U and End.DT2M behavior for the SRv6 locator that is used in the EVPN-enabled VPLS service results in corresponding SRv6 full SIDs. For example, the **show service id 12 segment-routing-v6 instance 1** command on PE-2 shows them. For the SRv6 End.DT2U behavior, the SRv6 function is 524288 (0x80000) and the corresponding SRv6 full SID is 2001:db8::aaaa:2:8000::

For the SRv6 End.DT2M behavior, the SRv6 function is 524287 (0x7ffff) and the corresponding SRv6 full SID is 2001:db8::aaaa:2:7fff:f000::. Similar output applies for PE-1 and for PE-3.

```
A:admin@PE-2# show service id 12 segment-routing-v6 instance 1

Enabling the SRv6 End.DT2M behavior allows the exchange of EVPN IMET BGP update messages for the EVPN family. The **show log log-id <log-id>** command on PE-1 shows the BGP update message that PE-1 receives from PE-2, via the RR. It indicates the remote source address (orig_addr: 2001:db8::2:2), and the route distinguisher (RD: 192.0.2.2:1), tag (tag: 0), route target (Extended Community: target:64500:1), and next hop (Global NextHop 2001:db8::2:2) that PE-1 must use while sending IPv4 or IPv6 data traffic to PE-2. In addition, it indicates the Provider Multicast Service Interface (PMSI) information about tunnel type (Tunnel-type Ingress Replication), MPLS label (MPLS Label 8388592 (0x7ffff)), and tunnel endpoint (Tunnel-Endpoint 2001:db8::2:2). Finally, it indicates that PE-1 must send the frames to the SRv6 locator (SRv6 SID: 2001:db8:aaaa:2::) with End.DT2M behavior (Behavior: 0x18 (24)). Similar output applies for the BGP update that PE-1 receives from PE-3, via the RR. PE-1 advertises a similar BGP update message to the RR, which forwards it to PE-2 and PE-3 (not shown here). PE-2 and PE-3 receive and advertise similar BGP update messages.

The reception of the EVPN IMET BGP update messages triggers PE-1 to install learned inclusive multicast routes as shown with the **show router bgp neighbor <ip-address> received-routes evpn** command. Because PE-1 receives EVPN IMET BGP update messages from PE-2 and from PE-3 with different route distinguishers, PE-1 installs a learned inclusive multicast route for each one of them. Similar output applies for PE-2 and for PE-3. The BGP EVPN inclusive multicast routes that are received, can also be displayed with the **show router bgp routes evpn incl-mcast** command.

```

The **show router bgp routes evpn incl-mcast hunt** command shows a consolidated view on the inclusive multicast routes for the EVPN family. On PE-1, in the RIB In Entries section, it shows for each learned next hop how PE-1 must handle the BUM traffic destined for it. In the RIB Out Entries section, it shows for each local next hop how PE-1 expects the remote routers to handle BUM traffic destined for it. Similar output applies for PE-2 and for PE-3.

```

Verify data traffic

At this point, verify that IPv4 and IPv6 data traffic is possible between the local VPRN 11 on PE-1 and the remote VPRN 11 on PE-2 and PE-3. Perform a similar verification for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-2 and the remote VPRN 11 on PE-1 and PE-3, and for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-3 and the remote VPRN 11 on PE-1 and PE-2.

For example, for IPv4 data traffic to the remote VPRN 11 on PE-2:

```

A:admin@PE-1# ping 172.16.0.2 router-instance "VPRN_11"
PING 172.16.0.2 56 data bytes
64 bytes from 172.16.0.2: icmp_seq=1 ttl=64 time=7.34ms.
---snip---
---- 172.16.0.2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.90ms, avg = 3.34ms, max = 7.34ms, stddev = 2.02ms

```

For example, for IPv6 data traffic to the remote VPRN 11 on PE-2:

```

A:admin@PE-1# ping 2001:db8::172:16:0:2 router-instance "VPRN_11"
PING 2001:db8::172:16:0:2 56 data bytes
64 bytes from 2001:db8::172:16:0:2 icmp_seq=1 hlim=64 time=5.50ms.
---snip---
---- 2001:db8::172:16:0:2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss

```

```
round-trip min = 1.76ms, avg = 2.79ms, max = 5.50ms, stddev = 1.37ms
```

When the SRv6 End.DT2U behavior is enabled, the sending of IPv4 or IPv6 data traffic triggers the exchange of EVPN MAC/IP BGP update messages for the EVPN family. The **show log log-id <log-id>** command on PE-1 shows the BGP update message that PE-1 receives from PE-2, via the RR. It indicates the remote MAC address (mac: 00:00:5e:00:53:02), and the route distinguisher (RD: 192.0.2.2:1), ESI (ESI: ESI-0), tag (tag: 0), label (label1: 8388608 (0x800000)), route target (Extended Community: target:64500:1), and next hop (Global NextHop 2001:db8::2:2) that PE-1 must use while sending IPv4 or IPv6 data traffic to PE-2. In addition, it indicates that PE-1 must send the frames to the SRv6 locator (SRv6 SID: 2001:db8:aaaa:2::) with End.DT2U behavior (Behavior: 0x17 (23)). PE-1 derives the SRv6 full SID that is needed for this (2001:db8:aaaa:2:8000::). Similar output applies for the BGP update that PE-1 receives from PE-3, via the RR. PE-1 advertises a similar BGP update message to the RR, which forwards it to PE-2 and PE-3 (not shown here). PE-2 and PE-3 receive and advertise similar BGP update messages.

```

The reception of the EVPN MAC/IP BGP update messages triggers PE-1 to install learned MAC routes, as shown with the **show router bgp neighbor <ip-address> received-routes evpn** command. In contrast to the learned inclusive multicast routes, the learned MAC routes expire in accordance with the configuration that is shown with the **show service id 12 fdb expiry** command. PE-1 installs a learned MAC/IP route for each of the remote CEs. PE-1 derives the SRv6 function (524288) from the received label field. The earlier

installed inclusive multicast routes remain in place (not shown). The BGP EVPN MAC/IP advertisement routes that are received, can also be displayed with the **show router bgp routes evpn mac** command. Similar output applies for PE-2 and for PE-3.

```

From the received EVPN MAC/IP BGP update messages, PE-1 learns the SRv6 tunnel endpoints for unicast traffic, as shown with the **show service id 12 segment-routing-v6 instance 1 destinations** command. The segment ID (SRv6 SID) corresponds with the expected End.DT2U behavior on PE-2 and PE-3 respectively. The earlier learned SRv6 tunnel endpoints for BUM traffic remain in place. Similar output applies for PE-2 and for PE-3.

```

=====
```

The locally learned MAC address belongs to the originator of the **ping** commands in the VPRN 11 context on PE-1, while the BGP EVPN learned MAC addresses belong to the destinations for those **ping** commands, which are in the VPRN 11 context on PE-2 and in the VPRN 11 context on PE-3 respectively. The Transport:Tnl-Id (for example 2001:db8:aaaa:2:8000::) indicates that PE-1 transports frames to the destination (on or connected to PE-2) via the SRv6 full SID to PE-2 for the End.DT2U behavior. The VPLS FDB entries that PE-1 learns locally expire after 300 seconds. The removal of a locally learned entry from the local VPLS FDB triggers the removal of the corresponding BGP EVPN learned entries in the remote VPLS FDBs. Similar output applies for the **ping** commands in the VPRN 11 context on PE-2 and for the **ping** commands in the VPRN 11 context on PE-3.

```

Conclusion

Distributed EVPN-enabled VPLS services can be transported over SRv6 tunnels that are automatically set up between PEs. PEs attached to the same EVPN-enabled VPLS service exchange EVPN IMET routes and MAC/IP advertisement routes that contain the SRv6 SIDs. Those SRv6 SIDs are required so that PEs can create SRv6 destinations to send unicast and BUM traffic to the other PEs in the service.

EVPN ESI Type 1

This chapter provides information about EVPN ESI Type 1.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 22.5.R1.

Overview

In SR OS releases earlier than 21.5.R1, the 10-byte Ethernet Segment Identifier (ESI) can only be configured manually; the auto-derived EVPN ESI type 1 (as per RFC 7432) is supported in SR OS Release 21.5.R1 and later. The **auto-esi** command is used to configure the ESI mode.

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23"]
A:admin@PE-2# auto-esi ?

auto-esi <keyword>
<keyword> - (none|type-1)
Default   - none

EVPN Ethernet segment auto-ESI type

Warning: Modifying this element toggles
'configure service system bgp evpn ethernet-segment "ESI-23" admin-state'
automatically for the new value to take effect.
```

The default **auto-esi** value is **none**, which forces the user to configure the 10-byte ESI manually. When **type-1** is configured, a manual ESI cannot be configured and the ESI is auto-derived, as per RFC 7432.

ESI type 1 is auto-derived from the CE's Link Aggregation Control Protocol (LACP) system MAC address and port key. [Figure 84: ESI type 1 example](#) shows an example of ESI type 1 for LACP system MAC address 00:00:5e:00:53:00 and administrative key 257 (= 0x0101).

Figure 84: ESI type 1 example

37586

RFC 7432, section "Ethernet Segment", defines ESI type 1 as follows:

- Type 0x01 (byte 0)
- CE LACP system MAC address (bytes 1 through 6); for example, 00:00:5e:00:53:00
- CE LACP port key (bytes 7 and 8); for example, 0x0101
- 0x00 (byte 9 must be zero)

As per RFC 7432, this mechanism can only be used if the ESIs are unique, so the CE LACP system MAC and LACP port key combinations must be unique in the network.

Figure 85: ESI auto-configuration example shows the example where CE-1 has LACP system MAC address 00:00:5e:00:53:00 and LACP port key 257 (= 0x0101). CE-1 sends Link Aggregation Control Protocol Data Units (LACPDU)s to PE-2 and PE-3 with these values. Both PE-2 and PE-3 use ESI 01:00:00:5e:00:53:00:01:01:00 in ES "ESI-23". This applies both to all-active and to single-active ESs.

Figure 85: ESI auto-configuration example

37588

The CE treats both PE-2 and PE-3 as the same switch. This allows the CE to aggregate links that are attached to different PEs in the same bundle.

When the ES LAG goes operationally down, due to the ports going down or LACP going down or standby, the previously auto-derived ESI is retained. However, when the LACP information on the CE is changed, such as a different LACP port key, the ES goes down and a new ESI will be generated.

The all-active ES "AA-ESI-23" with ESI type 1 is configured as follows:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-ESI-23" {
            admin-state enable
            multi-homing-mode all-active
            auto-esi type-1
            association {
              lag "lag-1" {
            }
          }
        }
      }
    }
  }
}
```

```
}  
}
```

The following restrictions apply for ESI type 1:

- ESI type 1 is only supported on non-virtual (regular) ESs. The following error message is raised when attempting to configure **auto-esi type-1** for a virtual ES:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23"]  
A:admin@PE-2# commit  
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23" auto-esi -  
Inconsistent value - not supported along with virtual ethernet-segment
```

- ESI type 1 is not supported in ESs with associations other than LAG:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23" association port 1/2/1]  
A:admin@PE-2# commit  
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "ESI-23" auto-esi  
- Inconsistent value - not supported with association - configure service system bgp evpn  
ethernet-segment "ESI-23"
```

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23" association sdp 24]  
A:admin@PE-2# commit  
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "ESI-23" auto-esi  
- Inconsistent value - not supported with association - configure service system bgp evpn  
ethernet-segment "ESI-23"
```

- An ES with ESI type 1 can only be enabled if the LAG has LACP enabled:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23" association lag "lag-4"]  
A:admin@PE-2# commit  
MINOR: MGMT_CORE #4001: configure service system bgp evpn ethernet-segment "ESI-23" auto-esi  
- lacp needs to be enabled on lag for auto-esi type 1 - configure lag "lag-4" lacp
```

- ESI type 1 is allowed with all-active and single-active ESs. When used in single-active mode, the CE must use a single LAG to connect to the multi-homed PEs.
- It is not possible to manually configure an ESI when **auto-esi type-1** is configured:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23"]  
A:admin@PE-2# auto-esi type-1  
  
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23"]  
A:admin@PE-2# esi 01:00:00:00:00:23:00:00:00:01  
  
*[ex:/configure service system bgp evpn ethernet-segment "ESI-23"]  
A:admin@PE-2# commit  
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "ESI-23" auto-esi -  
Inconsistent value - not supported along with esi configuration
```

- An ES with a manually configured ESI cannot be created with the same ESI value as the auto-derived ESI type 1 in another ES.

```
*[ex:/configure service system bgp evpn ethernet-segment "AA-ESI-23-5"]  
A:admin@PE-2# esi 01:00:00:5e:00:53:00:01:01:00  
  
*[ex:/configure service system bgp evpn ethernet-segment "AA-ESI-23-5"]  
A:admin@PE-2# commit
```

```
MINOR: SVCMGR #8047: configure service system bgp evpn ethernet-segment "AA-ESI-23-5" -
Ethernet segment id is not valid - ESI already in use by another ethernet segment
```

- If an ES with manual ESI is active and another ES is configured with an auto-derived ESI with the same value as the manual ESI, the auto-ESI value is deleted, and a log event is added to log "99":

```
# in log "99":
110 2022/05/25 15:28:44.361 CEST MINOR: SVCMGR #2610 Base
"The Auto Ethernet segment identifier type-1 has been deleted for Ethernet Segment AA-ESI-23
because the new ID 01:00:00:5e:00:53:00:01:01:00 conflicts with ES AA-ESI-23-5"
```

Configuration

In this section, ESI type 1 is configured in the following use cases:

- ESI type 1 in all-active ESs
- ESI type 1 in single-active ESs

Figure 86: Example topology shows the example topology with four PEs and two CEs. CE-1 is connected via LAG 1 to the all-active ES "AA-ESI-23" on PE-2 and PE-3; CE-6 is connected via LAG-2 to the single-active ES "SA-ESI-45" on PE-4 and PE-5. In this example, an EVPN-MPLS VPLS is configured, but other services are also supported.

Figure 86: Example topology

37587

The initial configuration includes:

- cards, MDAs, ports
- on PEs: router interfaces, IS-IS, LDP

On the PEs, BGP is configured for the EVPN address family. PE-2 acts as the route reflector with the following configuration:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
```

```
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
        cluster {
          cluster-id 1.1.1.1
        }
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
      neighbor "192.0.2.4" {
        group "internal"
      }
      neighbor "192.0.2.5" {
        group "internal"
      }
    }
  }
```

On CE-1, LAG 1 is configured with LACP enabled and administrative key 257, as follows:

```
# on CE-1:
configure {
  lag "lag-1" {
    admin-state enable
    mode hybrid
    max-ports 64
    lacp {
      mode active
      administrative-key 257
    }
    port 1/1/1 {
    }
    port 1/1/2 {
    }
  }
}
```

The LACP system MAC address of CE-1 can be retrieved with the following command:

```
[/]
A:admin@CE-1# show chassis | match MAC
Base MAC address           : 00:00:5e:00:53:00
```

ESI type 1 in all-active ESs

On PE-2 and PE-3, the all-active ES "AA-ESI-23" is configured with **auto-esi type-1** and LAG 1:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
```

```

evpn {
  ethernet-segment "AA-ESI-23" {
    admin-state enable
    multi-homing-mode all-active
    auto-esi type-1
    association {
      lag "lag-1" {
      }
    }
  }
}

```

The EVPN-MPLS VPLS 1 is configured as follows:

```

# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        mpls 1 {
          admin-state enable
          ingress-replication-bum-label true
          ecmp 2
          auto-bind-tunnel {
            resolution any
          }
        }
      }
      sap lag-1:1 {
      }
    }
  }
}

```

The operational ESI on PE-2 is 01:00:00:5e:00:53:00:01:01:00 for CE LACP system MAC address 00:00:5e:00:53:00 and administrative key 0x0101, as can be verified with the following command:

```

[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "AA-ESI-23"

=====
Service Ethernet Segment
=====
Name                : AA-ESI-23
Eth Seg Type        : None
Admin State         : Enabled           Oper State           : Up
ESI                : auto-esi

ESI type 1 in single-active ESs

CE-6 is connected via LAG 2 to the single-active ES "SA-ESI-45" on PE-4 and PE-5. An ES operational group and LAG monitor operational group is required in this use case.

On CE-6, LAG 2 is configured with LACP enabled and administrative key 32768 (= 0x8000), as follows:

```
# on CE-6:
configure {
  lag "lag-2" {
    admin-state enable
    mode hybrid
    max-ports 64
    lacp {
      mode active
      administrative-key 32768
    }
  }
}
```

```

port 1/1/1 {
}
port 1/1/2 {
}
}

```

The LACP system MAC address of CE-6 is the following:

```

[/]
A:admin@CE-6# show chassis | match MAC
Base MAC address           : 00:00:5e:00:53:f6

```

On PE-4 and PE-5, operational group "op-grp-2" is configured and assigned to single-active ES "SA-ESI-45".

Note: When an operational group is associated to an ES, the hold timers for the operational group must be zero (the default value for the group down timer).

LAG 2 monitors this operational group. The configuration is as follows:

```

# on PE-4:
configure {
  lag "lag-2" {
    admin-state enable
    encap-type dot1q
    mode access
    monitor-oper-group "op-grp-2"
    max-ports 64
    lacp {
      mode active
      system-id 00:00:00:00:45:02
      administrative-key 1
    }
    port 1/1/1 {
    }
  }
}
service {
  oper-group "op-grp-2" {
    hold-time {
      ## down # default 0
      up 0
    }
  }
}
system {
  bgp {
    evpn {
      ethernet-segment "SA-ESI-45" {
        admin-state enable
        multi-homing-mode single-active
        oper-group "op-grp-2"
        auto-esi type-1
        ac-df-capability exclude
        service-carving-mode manual # required for oper-group
        manual {
          preference {
            mode non-revertive
            value 200
          }
        }
      }
    }
  }
  association {
    lag "lag-2" {

```

```

}
}
}
}
}
}
}
vpls "VPLS 1" {
  admin-state enable
  service-id 1
  customer "1"
  bgp 1 {
  }
  bgp-evpn {
    evi 1
    mpls 1 {
      admin-state enable
      ingress-replication-bum-label true
      ecmp 2
      auto-bind-tunnel {
        resolution any
      }
    }
  }
  sap lag-2:1 {
  }
}

```

The following command on Designated Forwarder (DF) PE-4 shows that the operational ESI is 01:00:00:5e:00:53:f6:80:00:00:

```

Auto-derived ESI changes when LACP port key on CE is modified

When the LAG goes operationally down due to ports going down or LACP going down, the auto-derived ESI is preserved. However, when the CE LACP configuration is changed— for example, with a different LACP port key—a new ESI is auto-derived.

In this example, the initial operational ESI on PE-4 is 01:00:00:5e:00:53:f6:80:00:00, as follows:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "SA-ESI-45" | match ESI
Name                : SA-ESI-45
ESI                 : auto-esi
Oper ESI           : 01:00:00:5e:00:53:f6:80:00:00
Auto-ESI Type       : Type 1
```

On CE-6, the initial configuration of LAG 2 has LACP active with administrative key 32768:

```
[ex:/configure lag "lag-2"]
A:admin@CE-6# info
admin-state enable
mode hybrid
max-ports 64
lACP {
    mode active
    administrative-key 32768
}
port 1/1/1 {
}
port 1/1/2 {
}
```

On CE-6, LAG 2 is reconfigured with administrative key 4095 (= 0x0fff), as follows:

```
# on CE-6:
configure {
    lag "lag-2" {
        admin-state enable
        mode hybrid
        max-ports 64
        lACP {
            mode active
            administrative-key 4095
        }
        port 1/1/1 {
        }
        port 1/1/2 {
        }
    }
}
```

As a result, the operational ESI on PE-4 is 01:00:00:5e:00:53:f6:0f:ff:00, as follows:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "SA-ESI-45" | match ESI
Name                : SA-ESI-45
ESI                 : auto-esi
Oper ESI           : 01:00:00:5e:00:53:f6:0f:ff:00
Auto-ESI Type       : Type 1
```

When debugging is enabled for BGP updates, the following ES routes are seen: initially with ESI 01:00:00:5e:00:53:f6:80:00:00 and later with ESI 01:00:00:5e:00:53:f6:0f:ff:00, as follows:

```

Conclusion

To simplify the configuration of single-active and all-active ESs with LAG association, ESI type 1 can be used to auto-derive the ESI from the CE's LACP system MAC address and LACP port key.

EVPN for MPLS Tunnels

This chapter provides information about EVPN for MPLS tunnels.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 13.0.R6, but the MD-CLI in the current edition corresponds to Release 21.2.R1. A prerequisite is to read the [EVPN for VXLAN Tunnels \(Layer 2\)](#) chapter.

Overview

EVPN-MPLS is standardized in RFC 7432, *BGP MPLS-Based Ethernet VPN*, as a Layer 2 VPN technology that can supplement VPLS for E-LAN services. Besides the optimizations introduced by EVPN, a significant number of service providers offering E-LAN services today are requesting EVPN for their multi-homing capabilities. EVPN supports all-active multi-homing (per-flow load-balancing multi-homing) as well as single-active multi-homing (per-service load-balancing multi-homing). In addition to those superior multi-homing capabilities, EVPN also provides a number of significant benefits, such as:

- IP-VPN-like operation and control for E-LAN services.
- Reduction and (in some cases) suppression of the Broadcast, Unknown unicast, and Multicast (BUM) traffic in the network.
- Simple provisioning and management.
- New set of tools to control the distribution of MAC addresses and Address Resolution Protocol (ARP) entries in the network.

The EVPN for Virtual eXtensible Local Area Network (VXLAN) tunnels (Layer 2) chapter focuses on the use of EVPN as a control plane for VXLAN tunnels, whereas this chapter provides configuration guidelines for EVPN when used for MPLS tunnels. Similar to EVPN-VXLAN services, VPLS services with EVPN for MPLS tunnels are referred to as EVPN-MPLS services.

As a reference, the EVPN route types and NLRIs (Network Layer Reachability Information messages) used by the EVPN family in RFC 7432 are shown in [Figure 87: EVPN route types and NLRIs](#).

Figure 87: EVPN route types and NLRIs

al_0827

When no EVPN multi-homing is used in the network, only the base routes are used. Route types 2 and 3 are considered the base and mandatory routes:

- Route type 2 - MAC/IP route: This route advertises MAC addresses to be installed in the remote FDBs, or MAC/IP address pairs to be installed in the remote proxy-ARP/ND (Neighbor Discovery) tables.
- Route type 3 - Inclusive multicast route: This route advertises the multicast tree that the advertising PE intends to use for sending BUM traffic for an EVPN Instance (EVI). Ingress Replication, Point-to-multipoint multicast Label Distribution Protocol (P2MP mLDP), and composite tunnels are supported as tunnel types in route type 3 when BGP-EVPN MPLS is enabled. The ingress replication information, as well as the downstream MPLS label (for remote PEs to send BUM traffic to the advertising PE) are encoded in the Provider Multicast Service Interface Tunnel Attribute (PTA).

When EVPN multi-homing is used in an EVI, routes type 1 and 4 are used (where type 1 has two different purposes):

- Route type 1 - Auto-discovery per Ethernet segment (AD per ES) route: This route is advertised per ES from the PE, carries the Ethernet Segment Identifier (ESI) label (used for split-horizon) in multi-homing mode, and can affect procedures such as the Designated Forwarder (DF) election, as well as the aliasing/backup path/mass withdrawal on remote PEs.
- Route type 1 - Auto-discovery per EVPN instance (AD per-EVI) route: This route allows the remote PEs to provide aliasing and a backup path to the PEs part of the ES.
- Route type 4 - Ethernet Segment (ES) route: This route advertises a local configured ES. The exchange of this route can discover remote PEs that are part of the same ES and the DF election algorithm among them.

The AD per-EVI, MAC/IP, and inclusive multicast routes are considered service-level BGP-EVPN routes. Their RT/RD (Route-Target/Route-Distinguisher) are taken from the VPLS configuration.

The AD per-ES and the ES routes are considered base-level BGP-EVPN routes. However, their RT/RD are taken differently:

- The ES route RD is taken from the **service>system>bgp>evpn** configuration. The ES route RT is auto-derived from the Ethernet segment.
- The AD per-ES route RD is taken from the system level RD or service level RD. The RT extended community is taken from the service level RT or an RT set for the services defined on the Ethernet segment.

Configuration

This section describes the configuration of EVPN-MPLS for Layer 2 services on SR OS, as well as the available troubleshooting and show commands, and EVPN multi-homing.

Figure 88: EVPN-MPLS for VPLS services shows the topology used throughout this chapter. The network consists of a core with four EVPN PEs (PE-2, PE-3, PE-4, and PE-5) and two MTU devices that are dual-homed to the EVPN network. For MTU-1, all-active multi-homing is used, whereas MTU-6 is connected via single-active multi-homing to the EVPN network. Three CEs are connected to VPLS 1 in MTU-1, PE-3, and MTU-6 in order to test the connectivity.

Figure 88: EVPN-MPLS for VPLS services

As part of the network infrastructure configuration, the following settings and protocols must be added to the configuration before starting with the EVPN-specific configuration for the services:

- The ports interconnecting the four PEs in the core are configured as network ports (or hybrid) and will have router network interfaces defined in them. The ports on PE-2/PE-3 connected to MTU-1 can be access or hybrid ports, whereas the ports on PE-4/PE-5 connected to MTU-6 can be network or hybrid ports. In case of hybrid ports, no LACP can be configured.
- The four PEs in the core (as well as MTU-6 in the access MPLS network) are running IS-IS and establishing point-to-point adjacencies for the exchange of the system IP addresses.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, PE-5, and MTU-6. There is no LDP running between MTU-1 and the rest of the network, that is, MTU-1 is a pure Ethernet aggregation device.

- EVPN uses MP-BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although typically a separate router is used, in this chapter, PE-2 is used as BGP RR (route reflector) for EVPN routes. For example, the following output shows the configuration of BGP in the RR and one of the BGP clients. The relevant commands for EVPN are shown in bold.

The configuration on the route reflector PE-2 is as follows:

```
# on RR PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
        cluster {
          cluster-id 1.1.1.1
        }
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
      neighbor "192.0.2.4" {
        group "internal"
      }
      neighbor "192.0.2.5" {
        group "internal"
      }
    }
  }
}
```

The BGP configuration on the RR clients is as follows:

```
# on RR clients PE-3, PE-4, PE-5:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
      }
    }
  }
}
```

```

neighbor "192.0.2.2" {
    group "internal"
}

```

**Note:**

The **def-recv-evpn-encap** command is not used in the preceding configuration because the default MPLS configuration is sufficient to have a correct interpretation of the received EVPN encapsulations.

The EVPN encapsulation type can be configured as MPLS or VXLAN in the general BGP configuration, the BGP group, or the BGP neighbor. For example, on PE-3, the EVPN encapsulation type for neighbor 192.0.2.2 can be configured using the following command:

```

[ex:configure router "Base" bgp neighbor "192.0.2.2"]
A:admin@PE-3# def-recv-evpn-encap

def-recv-evpn-encap <keyword>
<keyword> - (mpls|vxlan)

Default EVPN encapsulation type

```

EVPN routes type 1 (auto-discovery per-EVI route), type 2 (MAC/IP route), type 3 (inclusive multicast route), and type 5 (IP-prefix route) are always sent with the RFC 5512, *the BGP Encapsulation Subsequent Address Family Identifier (SAFI) and the BGP Tunnel Encapsulation Attribute*, BGP encapsulation extended community that indicates the associated encapsulation of the route. Because the use of this extended community is not mandatory in RFC 7432, the **def-recv-evpn-encap** command indicates to the system what encapsulation is associated with routes received without any encapsulation. When interoperating with third-party EVPN vendors in mixed MPLS and EVPN-VXLAN networks, this command should be revised accordingly.

EVPN-MPLS configuration without multi-homing

After the base infrastructure (interfaces, IGP, LDP, BGP protocols) is configured, the service and EVPN can be enabled. When no multi-homing is used, the EVPN-MPLS configuration in a VPLS service looks similar to the configuration of EVPN-VXLAN for Layer 2, except for the commands related to the MPLS data plane. The following output shows the VPLS-1 configuration on PE-3 as an example:

```

# on PE-3:
configure {
    service {
        vpls "VPLS1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
    }
}

```

```

    }
  }
  sap 1/2/1:1 {
  }
  sap lag-1:1 {
  }
}

```

Where the following commands are relevant for a basic EVPN configuration:

- **bgp** enables the context for the BGP configuration relevant to the service. Two BGP instances can be configured, but only BGP instance 1 is configured in this example. If a manual (non-auto-derived) RD/RT, as well as import/export policies, are needed for the service, the commands in the **bgp** context must be configured. When **bgp-evpn** is enabled in a VPLS instance, other families are supported within the same service (bgp-ad, bgp-mh, bgp-vpls). This **bgp** context configures the common BGP parameters for all the BGP families in the service. Even if the general BGP parameters for the service are auto-derived (as in this example), the **bgp** context must be enabled.

```

[ex:configure service vpls "VPLS1"]
A:admin@PE-3# bgp ?

  [bgp-instance] <number>
  <number> - <1..2>

  BGP instance

[ex:configure service vpls "VPLS1"]
A:admin@PE-3# bgp 1 ?

  bgp

  apply-groups          - Apply a configuration group at this level
  apply-groups-exclude - Exclude a configuration group at this level
  pw-template-binding  + Enter the pw-template-binding list instance
  route-distinguisher  - High-order 6 bytes that are used as string to compose
                       VSI-ID for use in NLRI
  route-target          + Enter the route-target context
  vsi-export            - VSI export policies
  vsi-import            - VSI import policies

```

- **bgp-evpn evi <1..65535>** — The EVPN instance or EVI is a 2-byte identifier used for the auto-derivation of the service RD, service RT, and for the service-carving algorithm when multi-homing is used. The EVI can be used for both **bgp-evpn vxlan** and **bgp-evpn mpls** when the user needs to auto-derive the RD and RT for the service. The auto-derivation is always based on:
 - RD system-ip:evi
 - RT autonomous-system:evi

The configured and operating RD/RT values can be checked with the following show command (in this example, the evi value is 1):

```

[/]
A:admin@PE-3# show service id 1 bgp

```

Although not required for a basic BGP-EVPN MPLS configuration, some other parameters may be used at the **bgp-evpn** context level, when EVPN-MPLS services are deployed. Some examples are listed here:

- **bgp-evpn>routes>mac-ip>cfm-mac** must be enabled when eth-cfm is used across an EVPN-MPLS service among different PEs. If a Maintenance Endpoint (MEP) or Maintenance domain Intermediate Point (MIP) is configured in any of the SAP/SDP bindings in the VPLS and has to exchange eth-cfm packets with a remote MEP/MIP across the EVPN-MPLS core, this command must be enabled. In that way, the MEP/MIP MAC address can be advertised in EVPN (otherwise, the MEP/MIP MAC address would not be learned on remote EVPN-MPLS PEs and eth-cfm would not work correctly).
- **bgp-evpn>routes>mac-ip>advertise** and **bgp-evpn>mac-duplication** — See the [EVPN for VXLAN Tunnels \(Layer 2\)](#) chapter for a description of these two commands.
- **bgp-evpn>mpls <bgp-instance>** must be enabled.

When two BGP instances are added to a VPLS service, both BGP-EVPN MPLS and BGP-EVPN VXLAN can be configured at the same time in the service. A maximum of two BGP instances are supported in the same VPLS. In this chapter, only BGP instance 1 is used.

After the relevant **VPLS** parameters, **BGP** and **BGP-EVPN** attributes are added, the specific commands for **bgp-evpn mpls <bgp-instance>** can be configured as follows:

```

[ex:configure service vpls "VPLS1" bgp-evpn mpls 1]
A:admin@PE-3# info
  admin-state enable
  ingress-replication-bum-label true
  ecmp 2
  auto-bind-tunnel {
    resolution any
  }
    
```

- **ingress-replication-bum-label** controls whether the system will advertise different service labels for unicast and BUM traffic. If no EVPN multi-homing is configured in the network, this command can be disabled (**ingress-replication-bum-label false**) and the same MPLS label will be advertised for the unicast and BUM traffic for the VPLS instance. If EVPN multi-homing is configured in the PE, this command is strongly recommended to avoid potential transient issues. See the [EVPN-MPLS multi-homing](#) section.
- **ecmp** controls the number of remote PEs to which the local PE can load balance the unicast traffic. See the [EVPN-MPLS multi-homing](#) section.
- **auto-bind-tunnel** controls the resolution of EVPN destinations to MPLS transport tunnels. This command is also in VPRN services and works in the same way.
 - If the **auto-bind-tunnel resolution any** is configured, as in the example, EVPN destinations in the service are resolved based on the best tunnel in the Tunnel Table Manager (TTM). For instance, the following command shows the existing EVPN destinations for VPLS 1 in PE-3. The EVPN-MPLS

destination (Termination Endpoint (TEP) 192.0.2.2, label 524281) is resolved to LDP transport tunnel 65537 because the (best) LDP tunnel to 192.0.2.2 shown in the **show router tunnel-table** is LDP. If there was more than one tunnel type in the TTM to 192.0.2.2, the system would pick the lowest **Pref** (preference) tunnel.

=====
```

- If resolution is set to **any**, the following tunnel types are selected in order of preference: RSVP, LDP, Segment Routing, and BGP. The user can configure the preference of the segment-routing tunnel type in the TTM for a specific IGP instance.
- If one or more explicit tunnel types are specified using the resolution-filter option, then only these tunnel types will be selected again following the TTM preference.
- The user must set the resolution to filter to activate the list of tunnel-types configured under resolution-filter.

Although not shown in the **bgp-evpn mpls** basic configuration for PE-3, there are other parameters that can be modified:

```
[ex:/configure service vpls "VPLS1" bgp-evpn]
A:admin@PE-3# mpls 1 ?
```

```
mpls

admin-state          - Administrative state of BGP EVPN MPLS

route-next-hop      + Enter the route-next-hop context
send-tunnel-encap   + Enter the send-tunnel-encap context
split-horizon-group - Split horizon group
```

bgp <bgp>

defines the BGP instance: 1 or 2.

control-word

enables/disables the insertion of the control-word in the data path. The control-word is disabled by default and is not signaled in EVPN (based on RFC 7432) and has to be consistently configured in all the PEs in the network. The use of the **control-word** prevents packet reordering from happening in P routers that misinterpret the first nibble of the payload in the packets they receive. In some third-party EVPN vendors, the control-word is enabled by default, so it is recommended to enable it when interoperating with other vendors.

entropy-label

enables the use of entropy labels, as described in the *Entropy Label* chapter in the MPLS volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Book I*.

force-vc-forwarding <vlan>

allows the system to preserve the VLAN ID and p-bits of the service-delimiting q-tag in a new tag added in the customer frame before sending it to the EVPN core. This command may be used with the **sap ingress qtag-manipulation** command: the configured translated VLAN ID will be sent to the EVPN binds, as opposed to the service-delimiting tag VLAN ID. If the ingress SAP/SDP-binding is null encapsulated, the output VLAN ID and p-bits will be zero.

fdb protected-src-mac-violation-action

is by default disabled. When enabled, all packets entering the object will be verified not to contain a protected source MAC address. In combination with the keyword discard, the packets that contain a protected MAC address will be discarded and an alarm is generated.

send-tunnel-encap

configures the encapsulation to be advertised with the EVPN routes for the service. The encapsulation is encoded in RFC 5512-based tunnel encapsulation extended communities. When configured in the **bgp-evpn>mpls** context, the supported options are none (delete send-tunnel-encap), mpls, mpls-over-udp, or both.

admin-state

enables/disables the use of MPLS for EVPN. When enabled, a BGP route-refresh message is sent for the EVPN family.

split-horizon-group <group-name>

configures an explicit split-horizon-group (SHG) for all the EVPN destinations that can be shared with other SAP/SDP-bindings. See the [VPLS to EVPN-MPLS integration](#) section.

After **bgp-evpn mpls** is configured and enabled in the service, an inclusive multicast route is sent to the RR. The remote PEs receiving and importing that route will create an EVPN destination to the sending PE. An EVPN destination is identified by a TEP and MPLS label. Use the following show commands to view the service and the EVPN destinations created:

- **show service evpn-mpls**
- **show service id 1 evpn-mpls**
- **show service id 1 bgp-evpn**

An example of the output is shown for PE-2 when there is no traffic in the network. Therefore, only inclusive multicast routes have been exchanged among the four PEs.

When traffic is generated, the PEs will start learning MAC addresses and advertising them in BGP so that the remote PEs learn those MAC addresses against EVPN destinations. For instance, when CE-13 sends traffic, PE-3 learns its MAC address and advertises it. The remote PEs (for instance, PE-2) will learn the MAC address and associate it with their EVPN destination to PE-3 (192.0.2.3:524282 in this example):

```

When the **ingress-replication-bum-label** is enabled in the PEs, the advertisement of MAC addresses will create new EVPN destinations, because the label is different from the one previously sent by the inclusive multicast route that created an EVPN destination. In the preceding example, when PE-3 advertises the CE-13 MAC address, PE-2 will create a new binding (see in the following output in bold) that shows one MAC address that is not Mcast (multicast) capable:

```

```

If the route is successfully imported, it can be shown in the RIB (**show router bgp routes** commands). The route shown in the debug and the same route in a show command do not necessarily have the same label value. The reason for this expected mismatch is that the debug command shows the complete 24-bit field value because the route is shown before BGP can decide and decipher whether the label value is an MPLS label (high-order 20-bits of the label field) or a VNI (all 24 bits of the Label field for VXLAN). When the label in the debug command (8388512) is divided by 16 (2^4), the result is the MPLS label (524282), as follows: $8388512:16=524282$.

VPLS to EVPN-MPLS integration

The SR OS EVPN implementation supports RFC 8560, *(PBB-)EVPN Seamless Integration with (PBB-)EVPN*, so that EVPN-MPLS and VPLS can be integrated into the same network and within the same service.

The following behavior enables the integration of EVPN and SDP-bindings in the same VPLS network:

- Systems with EVPN endpoints and SDP-bindings to the same far-end bring down the SDP-bindings.
 - SR OS will allow the establishment of an EVPN destination and an SDP-binding to the same far-end but the SDP-binding will be kept operationally down. Only the EVPN endpoint will be operationally up. This is true for spoke-SDPs (manual and BGP-AD) and mesh-SDPs. It is also true between VXLAN and SDP-bindings.
 - If there is an EVPN endpoint to a specified far-end and a spoke-SDP establishment is attempted, the spoke-SDP will be set up but kept down with an operational flag indicating that there is an EVPN route to the same far-end.
 - If there is a spoke-SDP and a valid/used EVPN route arrives, the EVPN endpoint will be set up and the spoke-SDP will be brought down with an operational flag indicating that there is an EVPN route to the same far-end.
 - In the case of an SDP-binding and EVPN endpoint to different far-end IPs on the same remote PE, both links will be up. This can happen if the SDP-binding is terminated in an IPv6 address or IPv4 address different from the system address where the EVPN endpoint is terminated.

The following example illustrates the preceding description. A spoke-SDP is added to the VPLS 1 configuration on PE-2:

```
# on PE-2:
configure {
  service {
    sdp 24 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.4
      }
    }
    vpls "VPLS1" {
      spoke-sdp 24:1 {
      }
    }
  }
}
```

The service configuration on PE-4 is as follows:

```
# on PE-4:
configure {
  service {
    sdp 42 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.2
      }
    }
    sdp 46 {
      admin-state enable
    }
  }
}
```

```

        delivery-type mpls
        ldp true
        far-end {
            ip-address 192.0.2.6
        }
    }
    vpls "VPLS1" {
        admin-state enable
        service-id 1
        customer "1"
        bgp 1 {
        }
        bgp-evpn {
            evi 1
            mpls 1 {
                admin-state enable
                ingress-replication-bum-label true
                ecmp 2
                auto-bind-tunnel {
                    resolution any
                }
            }
        }
        spoke-sdp 42:1 {
        }
        spoke-sdp 46:1 {
        }
    }
}

```

Spoke SDP 24:1 is operationally down, as can be verified as follows:

```

[/]
A:admin@PE-2# show service id 1 sdp
=====
Services: Service Destination Points
=====
SdpId          Type      Far End addr  Adm   Opr      I.Lbl  E.Lbl
-----
24:1           Spok     192.0.2.4    Up    Down    524280 524279
-----
Number of SDPs : 1
-----
=====

```

Spoke SDP 24:1 is down because of an EVPN route conflict, as indicated by the flags:

```

[/]
A:admin@PE-2# show service id 1 sdp 24 detail | match Flag post-lines 1
Flags          : PWPeerFaultStatusBits
               EvpnRouteConflict

```

- The user can add spoke-SDPs and all the EVPN-MPLS endpoints in the same SHG.
 - A CLI command exists in the **bgp-evpn>mpls** context so that the EVPN-MPLS endpoints can be added to an SHG.
 - The **bgp-evpn mpls split-horizon-group** must reference a user-configured SHG. User-configured SHGs can be configured within the service context.
 - The same group name can be associated with SAPs, spoke-SDPs, PW-templates, PW-template-bindings, and EVPN-MPLS endpoints.

- If the **split-horizon-group** command in **bgp-evpn>mpls** is not used, the default SHG (in which all the EVPN endpoints are) is still used, but it will not be possible to refer to it on SAPs/spoke-SDPs.
- The system disables the advertisement of MAC addresses learned on spoke- SDPs/SAPs that are part of an EVPN SHG.
 - When the SAPs or spoke-SDPs (manual or BGP-AD-discovered) are configured within the same SHG as the EVPN endpoints, MAC addresses will still be learned on them, but will not be advertised in EVPN.
 - The preceding statement is also true if proxy-ARP/ND is enabled and an IP-->MAC address pair is learned on a SAP/SDP-binding that belongs to the EVPN SHG.
 - The SAPs and/or spoke-SDPs added to an EVPN SHG should not be part of any EVPN multi-homed ES. If that happened, the PE would still advertise the AD per-EVI route for the SAP and/or spoke-SDP, attracting EVPN traffic that could not be forwarded to that SAP and/or SDP-binding.
 - Similar to the preceding statement, an SHG composed of SAPs/SDP-bindings used in a BGP-MH site should not be configured under **bgp-evpn>mpls>split-horizon-group**. This misconfiguration would prevent traffic being forwarded from the EVPN to the BGP-MH site, regardless of the DF/Non-DF state.

An example of a shared SHG configuration on PE-2 is as follows. Because the SAP and EVPN-MPLS are in the same SHG, no MAC addresses learned over SAP 1/2/1:2 will be advertised in EVPN (not even static MAC addresses).

```
# on PE-2:
configure {
  service {
    vpls "VPLS2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 2
        mpls 1 {
          admin-state enable
          split-horizon-group "CORE"
          ingress-replication-bum-label true
          ecmp 2
          auto-bind-tunnel
            resolution any
        }
      }
    }
    split-horizon-group "CORE" {
    }
    sap 1/2/1:2 {
      split-horizon-group "CORE"
    }
    sap lag-1:2 {
    }
  }
}
```

EVPN-MPLS multi-homing

SR OS supports EVPN multi-homing as per RFC 7432.

The EVPN multi-homing implementation is based on the concept of the ES. An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multi-homed to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects.

Each ES has a unique identifier called ESI (Ethernet Segment Identifier) that is 10 bytes and is manually configured. The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homed CEs are assumed to be connected to an ES with ESI = 0 (single-homed ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-MPLS service, by default. An ES can be shared by multiple services; the association of a specific SAP or spoke-SDP to an ES is automatically made when the SAP is defined in the same LAG or port configured in the ES, or when the spoke-SDP is defined in the same SDP configured in the ES. The following sections show the configuration of:

- an all-active multi-homing ES with a LAG associated with it
- a single-active multi-homing ES linked to an SDP

All-active multi-homing concepts

EVPN all-active multi-homing is built around three concepts: DF election, split-horizon (with an ESI-label), and aliasing, as shown in [Figure 89: EVPN-MPLS all-active multi-homing concepts](#), from left to right.

Figure 89: EVPN-MPLS all-active multi-homing concepts

- With DF election, when PE-4 sends BUM traffic to the remote ES (CE-2), only one PE segment sends the BUM packets to the ES (PE-3 is the DF in the preceding example, and is elected to send BUM packets to CE-2). The non-DF, PE-2, removes the LAG SAP from the default multicast list (PE-2 does not bring CE-2 down, because it still needs to send upstream/downstream unicast traffic). PE-2 and PE-3 elect a DF for each service, based on the ES routes and the service-carving algorithm.
- With split-horizon, the PE part of the ES (PE-3 in the preceding example) identifies the BUM packets coming from the PE for the remote (PE-2), but within the same ES (ESI-2), and filters the packets so that they are not sent back to the ES, creating duplication. When PE-2 (non-DF) sends BUM traffic to PE-3 (DF), it uses a special MPLS label in the data path that PE-3 previously advertised for ESI-2 in an AD per-ES route. When PE-3 does an ingress lookup, it recognizes the ESI-label and filters the traffic (PE-3 still sends the BUM traffic to other SAPs/SDP-bindings).
- With aliasing, remote PEs that are not part of the ES can load-balance unicast traffic to all the PEs that are part of the ES, irrespective of from which PE a destination MAC address was learned. PE-4 will

create an EVPN destination to ESI-2 that will be resolved to the two next-hops: PE-2 and PE-3. Unicast load-balancing will happen as long as ECMP > 1 is enabled in PE-4.

Nokia recommends the use of **ingress-replication-bum-label** on the PEs that are part of an all-active ES. In an all-active multi-homing scenario, if a specified MAC address (for example, the CE-2 MAC address in the left-hand-side diagram), is not learned yet in a remote PE (for example, PE-4), but is known in the two PEs of the ES (for example, PE-2 and PE-3), the latter PEs might send duplicated packets to the CE.

This issue is solved by the use of **ingress-replication-bum-label** in PE-2 and PE-3. If configured, PE-2/PE-3 will know that the received packet is an unknown unicast packet; therefore, the Non-DF (PE-2) will not send the packet to CE-2 and there will not be duplication.

All-active multi-homing configuration

The all-active multi-homing configuration example is based on [Figure 88: EVPN-MPLS for VPLS services](#).

MTU-1 is connected to the EVPN network using all-active multi-homing. According to RFC 7432, MTU-1 will be able to send traffic to both PEs for VPLS-1. Regular LAG load-balancing is used in MTU-1. Remote PEs such as PE-4 or PE-5 will be able to load-balance the unicast traffic to PE-2 and PE-3. PE-2 and PE-3 will discover that both are part of ESI-23 (due to the exchange of ES routes) and will elect a DF for VPLS-1. The non-DF for VPLS-1, in this case PE-2, will remove lag-1:1 from the VPLS-1 default multicast list. Also, when PE-2 and PE-3 send BUM traffic to each other, they will insert an ESI-label so that they can identify that the source of the BUM packet is ESI-23.

The following output shows the configuration of ESI-23 in PE-2 and PE-3, as well as the LAG interfaces for all-active multi-homing (see [Figure 88: EVPN-MPLS for VPLS services](#)). The configuration of LAG-1 in MTU-1 is also shown. Per RFC 7432, only a CE/MTU with a LAG can be connected to an all-active multi-homing ES. No other configuration is permitted on the CE for all-active multi-homing.

LAG 1 is configured on MTU-1, PE-2, and PE-3, as follows:

```
# on MTU-1:
configure {
  lag "lag-1" {
    admin-state enable
    encap-type dot1q
    mode access
    max-ports 64
    lacp {
      mode active
      administrative-key 32768
    }
    port 1/1/1 {
    }
    port 1/1/2 {
    }
  }
}
```

```
# on PE-2:
configure {
  lag "lag-1" {
    admin-state enable
    encap-type dot1q
    mode access
    max-ports 64
    lacp {
      mode active
      system-id 00:00:00:00:02:03
    }
  }
}
```

```

        administrative-key 1
    }
    port 1/1/2 {
    }
}

# on PE-3:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            mode active
            system-id 00:00:00:00:02:03
            administrative-key 1
        }
    }
    port 1/1/1 {
    }
}

```

Ethernet segment "ESI-23" is configured in the service **system bgp-evpn** context on PE-2 and PE-3, as follows:

```

# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23" {
                        admin-state enable
                        esi 01:00:00:00:00:23:00:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            lag "lag-1" {
                            }
                        }
                    }
                }
            }
        }
    }
}

```

When configuring an ES, the following must be considered:

- Any EVPN parameter that is not specific to any particular VPLS service, and is common to all the EVIs, is configured in a base BGP-EVPN instance located at **config>service>system>bgp-evpn**. In this base instance, the following attributes may be configured:
 - **ethernet-segments**
 - the base BGP-EVPN instance **route-distinguisher** that will be used for the ES routes. If this **route-distinguisher** is not configured, by default a type-1 RD will be derived as system-ip:0. The ES route distinguisher can be configured using the following command:

```

[ex:configure service system bgp evpn]
A:admin@PE-2# route-distinguisher ?

```

```
route-distinguisher <string>
<string> - <0..255 characters>
```

Route distinguisher for ES routes

- The ES must be configured with a name and can contain the following parameters when configured for all-active multi-homing:
 - **esi** — 10-byte identifier that represents the ES in the BGP control plane. The same ESI must be configured in all the PEs connected to the same CE/MTU (using a unique value that cannot be associated with any other CE/MTU/access network). RFC 7432 defines five different types of ESI. In SR OS, the **type** byte, as well as the other 9 bytes can be arbitrarily configured.
 - **multi-homing-mode all-active** — This command indicates that the ES is in all-active mode.
 - **association>lag <lag-id>** — The LAG connected to the CE/MTU must be added to the ES. In this example, LAG "lag-1" is added to ESI-23, on both PE-2 and PE-3. Although a different LAG-id may have been assigned to the same ES on PE-2 and PE-3, PE-2 and PE-3 must have the same configuration on the ES LAG; that is, encap-type. Also, if LACP is added (it is not mandatory), both PEs must have the same admin-key, system-id, and system-priority. MTU-1 will see PE-2 and PE-3 as a single LAG peer. For all-active multi-homing, only the **lag** option is accepted by the system; **port** or **sdp** are not accepted.
 - **admin-state** — This command controls the administrative state of the ES.
- The preceding parameters are the minimum necessary so that the ES can be activated. In addition to those parameters, there are a few more that the user can configure if requiring values different from the default ones:
 - **activation-timer [0..100]** can be configured at **redundancy>bgp-evpn-ethernet-segment>activation-timer** or at **service>system>bgp>evpn>ethernet-segment>df-election>es-activation-timer** level (the most specific value is used).

The ES activation timer operation is as follows:

- Upon reception of an ES, AD per-ES/EVI route update/withdrawal for a local ESI, the DF-candidate list of IP addresses is updated and the DF election algorithm is run without waiting for any timer.
- If the result of the DF election requires the PE to be promoted from non-DF to DF, the ES activation timer will start, and only after its expiration will the PE add the SAP to the default multicast list. Transitions from non-DF to non-DF, or from DF to non-DF, are immediate and do not wait for any timer.
- This use of an ES activation timer value minimizes the risks of loops and packet duplication due to transient multiple DFs.
- The same ES activation timer must be configured in all the PEs that are part of the same ESI. The user must configure either a long timer to minimize the risks of loops/duplication, or **(es-)activation-timer=0** to speed up the convergence for NDF to DF transitions. The default value is 3 seconds.
- **service-carving-mode** — As defined in RFC 7432, service carving controls the distribution of DF/non-DF roles across the different services defined in an ES.

```
[ex:configure service system bgp evpn ethernet-segment "ESI-23" df-election]
A:admin@PE-2# service-carving-mode ?
```

```
service-carving-mode <keyword>
```

```
<keyword> - (auto|manual|off)
Default   - auto

Mode of service carving enabled per EVPN associated with this Ethernet segment
entry
```

```
[ex:configure service system bgp evpn ethernet-segment "ESI-23" df-election]
A:admin@PE-2# manual ?

manual

evi          + Enter the evi context
isis         + Enter the isid context
preference   + Enter the preference context
```

As shown above, **service-carving** has three different modes:

- **service-carving-mode auto** (default) — The DF election algorithm will run the function $[V(\text{evi}) \bmod N(\text{peers}) = i(\text{ordinal})]$ to know who the DF for a specified service and ESI is. In this example, ESI-23 is configured with mode **auto**; therefore, for VPLS-1 (with EVI-1), PE-3 will be elected as DF because $\text{evi}(1) \bmod (2)\text{peers} = 1$, and the ordinal 1 corresponds to the second lowest IP, PE-3. The algorithm takes the configured **evi** in the service; therefore, the **evi** is mandatory, and for the same service must match in all the PEs that are part of the ES. This guarantees that the election algorithm is consistent across all the PEs of the ESI.
- **service-carving-mode manual** — The user can manually decide for which **evi** identifies the PE is DF: **service-carving-mode manual / manual evi <start> end <to>**. The PE will be non-DF for the non-specified EVIs. If **service-carving-mode manual** is configured, but no range is defined, all the services are considered to be non-DF. If a range is configured, but the **service-carving-mode** is not **manual**, the range has no effect. Only two PEs are supported when **service-carving-mode manual** is configured.
- **service-carving-mode off** — The lowest originator IP will win the election for a specified service and ES.
- Because the **evi** is used for the service carving algorithm, it must always be configured in a service with SAPs/SDP bindings created in an ES, regardless of the service-carving mode (service-carving off, auto, or manual).

Although not configured as part of the ES, the **config>redundancy>bgp-evpn-ethernet-segment>boot-timer** allows the necessary time for the control plane protocols to come up after the PE has rebooted, and before bringing up the ESs and running the DF algorithm. Some considerations about the boot timer:

- The boot timer should use a value long enough to allow the IOMs and BGP sessions to come up before exchanging ES routes and run the DF election for each EVI (it is 10 s, by default).
- The boot timer runs per EVI on the ESs in the system. While **system-up-time < boot-timer**, the system will not run the DF election for any EVI. When the boot timer expires, the DF election for the EVI is run and, if the system is elected DF for the EVI, the ES activation timer will start.
- The system will not advertise ES routes until the boot timer expires. This guarantees that the peer ES PEs do not run the DF election either, until the PE is ready to become the DF, if needed.
- The following show command displays the configured boot timer, as well as the remaining timer if the system is still in boot stage.

```
[/]
A:admin@PE-2# show redundancy bgp-evpn-multi-homing
```

```

=====

```

After ESI-23 is configured in PE-2 and PE-3, the lag-1 SAPs in both PEs can be added to the VPLS-1 service. Until the ESI-23 is successfully enabled, the LAG SAPs will be kept down with a StandByForMHPProtocol flag. This is illustrated in the following example for PE-2 where the LAG SAP is added and ESI-23 is disabled:

```

# on PE-2:
configure exclusive
  service {
    vpls "VPLS1" {
      sap lag-1:1 {
      }
    }
  }
  system {
    bgp {
      evpn {
        ethernet-segment "ESI-23" {
          admin-state disable
        }
      }
    }
  }
  commit

```

```

[/]
A:admin@PE-2# show service id 1 sap lag-1:1 detail | match " Oper State"
Admin State      : Up
Oper State       : Down

```

```

[/]
A:admin@PE-2# show service id 1 sap lag-1:1 detail | match Flag
Flags            : StandByForMHPProtocol

```

ESI-23 is enabled and SAP lag-1:1 is operationally up, as follows:

```

# on PE-2:
configure exclusive
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-23" {
            admin-state enable
          }
        }
      }
    }
  }
  commit

```

```

[/]

All-active multi-homing operation

To confirm that all-active multi-homing is working correctly for ESI-23, the user can use the following commands:

- **show service system bgp-evpn** — Shows the RD is used for the ES route.
- **show service system bgp-evpn ethernet-segment** — Shows all the ESs configured in the PE and their admin/operational status.
- **show service system bgp-evpn ethernet-segment name ESI-23 evi evi-1 1** — Shows the DF candidate PEs for EVI 1 and whether the system is DF for EVI.
- **show service system bgp-evpn ethernet-segment name ESI-23 all** — Shows all the information related to a specific ESI.

The base BGP-EVPN information includes the RD:

```
[/]
A:admin@PE-2# show service system bgp-evpn

  target:00:00:00:00:23:00
"

```

The ES RT as shown as target:00:00:00:00:23:00 in the extended community is auto-derived from the ESI bytes 2 to 7 (with the type byte being byte 1). Only PE-2 and PE-3 generate this RT and therefore import each other's ES route.

The following message in log 99 on PE-3 shows the result of the DF election for EVI 1.

```
# log "99" on PE-3:
99 2021/02/25 17:04:27.467 CET MINOR: SVCNMR #2094 Base
"Ethernet Segment:ESI-23, EVI:1, Designated Forwarding state changed to:true"
```

The **show service system bgp-evpn ethernet-segment name ESI-23 all** command shows the ESI-label allocated to the PE: ES SHG Label 524282 in the CLI output for PE-3. In this example, this label is allocated by PE-3 for ESI-23 (a different one is allocated per ESI) and advertised in the AD per-ES route for ESI-23. The following output shows the AD per-ES and AD per-EVI (for evi 1) routes sent by PE-3 and received by PE-2.

- The AD per-ES route can be identified by the **MAX-ET** in the ethernet-tag field (as per RFC 7432) and carries the ESI-label as well as the multi-homing mode (all-active in this case) in the ESI-label extended community (see [Figure 87: EVPN route types and NLRIs](#)).

The user can enable the aggregation of AD per-ES routes by using the following command:

configure service system bgp evpn ad-per-es-route route-target-type evi-route-target-set route-distinguisher-ip-address ip-address. If enabled, a single AD per-ES route with the associated RD and a set of EVI route-targets will be advertised (to a maximum of 128). When there are more than 128 EVIs defined in the ES, more than one route will be sent by the system.

```
[ex:/configure service system bgp evpn ad-per-es-route]
A:admin@PE-2# route-distinguisher-ip-address ?

route-distinguisher-ip-address <ipv4-address>
<ipv4-address> - <d.d.d.d>

IP address for route distinguisher for EVPN AD-ES routes
```

The following AD per-ES route is received on PE-2:

```
# AD per-ES route received on PE-2:

From a service perspective, as soon as CE-11 sends some traffic, the PE learning the CE-11 MAC address will advertise it to the network. The remote PEs (PE-4 and PE-5) will create a new EVPN-MPLS ES destination to ESI-23, with two next-hops: PE-2 and PE-3. The following outputs show the following information:

- PE-4 has learned AD per-EVI/ES routes for ESI-23 from PE-2 and PE-3, as well as the CE-11 MAC address from PE-3 (because MTU-1 picked up its link to PE-3 to send CE-11 frames).

- PE-2 will show the CE-11 MAC address as learned locally in SAP lag-1:1 (because the data plane learning of the CE-11 MAC address happened in PE-2). For PE-3, even though it learned the MAC address from EVPN, it will install it as associated with SAP lag-1:1 because the EVPN route came with ESI-23, which is a local ESI. Because of this, whenever PE-3 receives a frame with MAC DA equal to the CE-11 MAC address, it will be able to forward the frame locally to the SAP lag-1:1. The following output shows the CE-11 MAC address as it is installed in PE-2 and PE-3:

```

[/]
A:admin@PE-2# show service id 1 fdb mac 00:00:11:11:11:11

Single-active multi-homing concepts

Figure 90: EVPN-MPLS single-active multi-homing: mass-withdraw, backup path illustrates two concepts in EVPN single-active multi-homing: mass-withdraw and backup path.

Figure 90: EVPN-MPLS single-active multi-homing: mass-withdraw, backup path

- With mass-withdraw, when ESI-45 goes down, PE-2 does not have to wait for all the MAC routes to be withdrawn to converge all the services. Instead, PE-4 will withdraw the AD per-ES routes (also the AD per-EVI and MAC routes) and that will be used at PE-2 as a notification to stop sending traffic to PE-4 for any MAC address associated with ESI-45.
- With backup path, when PE-2 is notified of the ESI-45 failure due to the withdrawn AD routes, it will not flush any MAC address associated with ESI-45. Instead, it will change the next-hop of the EVPN-MPLS ES destination to the remaining PE in the ESI-45. Backup path only works when there are two PEs in the same ES. If there were more than two PEs in ESI-45, PE-2 would flush all the MAC addresses upon receiving a mass-withdraw notification, because it would not know who the new active PE is.

Single-active multi-homing configuration

The single-active multi-homing configuration example is based on [Figure 88: EVPN-MPLS for VPLS services](#):

MTU-6 is connected to the EVPN network using single-active multi-homing. With the MTU-6 configuration, a VPLS service with active-standby spoke-SDP to PE-4 and PE-5 is configured. In PE-4 and PE-5, the SDP connected to MTU-6 is linked to ESI-45. Both will run the DF election algorithm for EVI 1, and the non-DF PE (PE-4 in this example) will bring down the spoke-SDP and notify MTU-6.

The following output shows the configuration of ESI-45 in PE-4 and PE-5, as well as the SDPs. The configuration of MTU-6 is also shown for completeness. It is important to keep the default — **ignore-standby-signaling false** — on MTU-6 spoke-SDPs because the PW switchover in MTU-6 will be triggered based on the PW status bits sent by PE-4 and PE-5.

SDP 46 with far-end MTU-6 is configured on PE-4:

```
# on PE-4:
configure {
  service {
    sdp 46 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.6
      }
    }
  }
}
```

Ethernet segment "ESI-45" is configured on PE-4 as follows:

```
# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-45" {
            admin-state enable
            esi 01:00:00:00:00:45:00:00:00:01
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              sdp 46 {
            }
          }
        }
      }
    }
  }
}
```

On PE-5, SDP 56 is configured as follows:

```
# on PE-5:
configure {
  service {
    sdp 56 {
```

```
    admin-state enable
    delivery-type mpls
    ldp true
    far-end {
        ip-address 192.0.2.6
    }
}
```

Ethernet segment "ESI-45" is configured as follows on PE-5:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 56 {
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

On MTU-6, the service configuration is as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.4
            }
        }
        sdp 65 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.5
            }
        }
    }
    vpls "VPLS1" {
        admin-state enable
        service-id 1
        customer "1"
        endpoint "CORE" {
        }
        spoke-sdp 64:1 {
            endpoint {
                name "CORE"
            }
        }
    }
}
```

```

        stp {
            admin-state disable
        }
    }
    spoke-sdp 65:1 {
        endpoint {
            name "CORE"
        }
        stp {
            admin-state disable
        }
    }
    sap 1/2/1:1 {
    }
}

```

For a detailed description of the base BGP-EVPN instance and ES configuration, see the [All-active multi-homing configuration](#) section. The **es-activation-timer**, **esi**, **service-carving-mode**, **boot-timer**, and **admin-state** commands are used in the same way as for all-active multi-homing. Only the differences compared to all-active multi-homing are described here:

- **multi-homing-mode single-active** must be configured so that the ES acts as single-active. Optionally, **multi-homing-mode single-active-no-esi-label** can be configured, which controls the use of the ESI-label for single-active multi-homing. Although the ESI-label is always used in all-active multi-homing when sending BUM traffic between the PEs in the ES, it is configurable for single-active. However, Nokia recommends to use the default option (using ESI-label) to avoid potential transient issues when there is a DF switchover.
- **association>sdp <sdp-id>** is configured so that the ES can be associated with the SDP connected to MTU-6. Although all-active multi-homing only allows LAG associations to the ES, single-active allows LAG, port, and SDP. In this example, SDP is the option, because the access network is MPLS-based.

Similar to the all-active multi-homing case, when configuring the service in PE-4 and PE-5, the service objects are automatically associated with the ESI-45, because they are defined in the SDPs linked to the ESI. The configuration for VPLS 1 on PE-5 is as follows:

```

# on PE-5:
configure {
    service {
        vpls "VPLS1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        spoke-sdp 56:1 {
        }
    }
}

```

In all-active multi-homing, the non-DF does not bring down the service SAP associated with the ES (it only removes it from the default multicast list). However, in single-active multi-homing, the service spoke-SDP (or SAP, if that was the object associated) is brought operationally down. The following output shows the spoke-SDP state in PE-4 (non-DF), as operationally down with the **StandbyForMHPProtocol** flag and the **Local Pw Bits** that are signaled to MTU-6:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "ESI-45" evi evi-1 1

Spoke-SDP 46:1 is operationally down with the StandbyForMHPProtocol flag:

```
[/]
A:admin@PE-4# show service id 1 sdp 46:1 detail | match Flag
Flags                : StandbyForMHPProtocol
```

The local PW bits (**pwFwdingStandby**) are sent to MTU-6:

```
[/]
A:admin@PE-4# show service id 1 sdp 46:1 detail | match Pw
Local Pw Bits       : pwFwdingStandby
Peer Pw Bits       : None
```

Single-active multi-homing operation

The same commands used in the [All-active multi-homing operation](#) section can be used for single-active; see that section.

The **show service system bgp-evpn ethernet-segment name ESI-45** command shows an Ethernet-segment **Oper Multi-homing** in addition to the configured **Multi-homing** mode. This occurs because, in spite of configuring the ES as all-active, it may operate as single-active if there is a mismatch between the modes advertised by PE-4 and PE-5 in the AD per-ES routes (per RFC 7432). In this example, the configured and the operational value are the same:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "ESI-45"

As soon as CE-16 sends some traffic, the DF PE (PE-5) will learn the CE-16 MAC address and will advertise it to the network. The remote PEs (PE-2 and PE-3) will create a new EVPN-MPLS ES destination to ESI-45, but this time with only one next-hop, PE-5, because this is single-active multi-homing. The following outputs show the following information:

- PE-2 has learned AD per-EVI/ES routes for ESI-45 from PE-4 and PE-5, as well as the CE-16 MAC address from an ES EVPN-MPLS destination, which is resolved to PE-5 (the DF for ESI-45).

=====

```

Ethernet-segment failures

If either ES fails, a DF re-election will happen and the corresponding AD per-ES/EVI routes will be withdrawn, causing the remote PEs to modify the list of next-hops for the EVPN-MPLS ES destination. The following example illustrates a failure on the SDP between MTU-6 and PE-5 (the DF).

1. A failure occurs in the LSP between MTU-6 and PE-5. This can be any event that brings the SDP down.

```
# log "99" on PE-5:
```

```
94 2021/02/25 17:25:00.632 CET MINOR: SVCMGR #2303 Base
"Status of SDP 56 changed to admin=up oper=down"
```

2. Immediately, PE-5 gives up the DF role and withdraws the ES route, as well as the AD routes and MAC routes. As soon as PE-4 receives any ES or AD withdraw, it will re-run the DF algorithm and, when the es-activation-timer expires, it will become the DF and activate its spoke-SDP.

```
# log 99 on PE-5:
96 2021/02/25 17:25:00.633 CET MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-45, EVI:1, Designated Forwarding state changed to:false"
```

The ES in PE-5 is operational down:

```

The following must be considered:

- The DF election procedure is revertive, that is, when the failed SDP comes back up, PE-5 will take over again as DF and the network will re-converge.
- The DF election is triggered by the following events:
 - Enabling an ES (**admin-state enable**) triggers the DF election for all the services in the ES.
 - A new update/withdrawal of an ES route (containing an ESI configured locally) triggers the DF election for all the services in the ESI.
 - A new update/withdrawal of an AD per-ES route (containing an ESI configured locally) triggers the DF election for all the services associated with the list of RTs received along with the route.
 - A new update of an AD per-ES route with a change in the ESI-label extended community (single-active bit or MPLS label) triggers the DF election for all the services associated with the list of RTs received along with the route.
 - A new update/withdrawal of an AD route per-EVI (containing an ESI configured locally) triggers the DF election for that service.

BGP-EVPN route selection in EVPN networks

The selection of the best route for a MAC address is as follows:

- If a PE receives more than one route for the same MAC address, the best MAC route is chosen:
 - If the route key is equal in two or more routes (that is, the mac, mac-length, ip, ip-length, RD, eth-tag), then regular BGP selection applies:

- If local-pref, AS-path, origin, and MED are equal, the lowest IGP distance to the BGP next-hop is chosen (unless **ignore-nh-metric** is configured). If the BGP next-hop is resolved by an LSP, the cost from the tunnel-table is used.
- As a last resort tie-breaker, the route with the lowest originator ID, or received from the peer with the lowest BGP Identifier, is chosen (unless **ignore-router-id** is configured and the routes being compared are EBGp routes).
- If the mac-length, mac, ip-length, ip, eth-tag are equal, and the RD is different, the EVPN selection process is applied in the following order:
 - Conditional static MAC addresses (local protected MAC addresses)
 - EVPN static MAC addresses (remote protected MAC addresses)
 - Data plane learned MAC addresses (regular learning on SAPs/SDP-bindings)
 - EVPN MAC addresses with higher sequence number
 - Lowest IP address (next-hop IP of the EVPN NLRI)
 - Lowest Ethernet tag (will be normally zero)
 - Lowest RD
- After a MAC route is selected, the system checks for an associated ES.
 - If it has an ES, the system uses the MAC address as the EVPN-MPLS ES destination. The ES destination is constructed based on the AD per-EVI routes received for that ES (regardless of MAC address priorities with the ES).
 - The system selects the first ECMP number of AD per-EVI routes arranged by the IP address of PEs (lower IPs are selected first).
 - If the same PE has advertised multiple RDs, the system selects the route with the lowest RD for that PE.

In the example of [Figure 88: EVPN-MPLS for VPLS services](#), PE-4 resolves the next-hops for ESI-23 as described in the second choice above, that is, because ECMP=2, the two available next-hops are chosen. If ECMP is changed to 1, PE-4 will pick up the lower IP (in the BGP next-hop). This is illustrated in the following output:

```
[/]
A:admin@PE-4# show service id 1 evpn-mpls esi esi-1 01:00:00:00:00:23:00:00:00:01

Comparing EVPN multi-homing and BGP multi-homing

EVPN-MPLS services support EVPN-MH (EVPN multi-homing) and also BGP-MH as in chapter [BGP Multi-Homing for VPLS Networks](#). While EVPN-MH is the standard way of providing access resiliency in RFC 7432, BGP-MH is also a standard mechanism supported in VPLS or EVPN networks. The following table provides some comparison between both technologies.

Table 5: Comparing EVPN multi-homing and BGP multi-homing

VPN Requirements	EVPN-MH	BGP-MH	Comments
All-active MH (flow-based load-balancing)	Yes	No	EVPN-MH provides better bandwidth utilization
Single-active MH (service-based load-balancing)	Yes	Yes	

VPN Requirements	EVPN-MH	BGP-MH	Comments
DF PE election - automatic service balancing	Yes Service-carving	No Requires vsi policies and LP manipulation	EVPN-MH provides better automation
DF PE election – manual configuration per service	Yes	No	EVPN-MH allows for manual DF config for EVIs and ISIDs (2 PEs)
Split-horizon indication in the data plane	Yes ESI-label	No	Prevents transient loops when dual-active DFs show up
DF indication in the control plane	No	Yes	BGP MH guarantees one DF at a time. EVPN relies on timers to ensure one DF at a time
Allows multiple SAPs or SDP-bindings per service on the same site	No	Yes Through the use of SHGs	
Boot timer and site(es)-activation-timers	Yes	Yes	BGP-MH supports more granular configuration (service level)
Support for oper-groups	No	Yes	
Non-DF notification to the CE (MPLS and CFM)	Yes	Yes	Avoids blackholing

In addition to the preceding comparison, the following configuration excerpt compares EVPN-MH with BGP-MH on a `bgp-evpn` VPLS service and shows that, while EVPN-MH does not have any configuration at service level, BGP-MH is configured within the VPLS context, which gives a more granular control over the redundancy provided. See the [BGP Multi-Homing for VPLS Networks](#) chapter for more information about BGP-MH.

```

Proxy-ARP/ND configuration for EVPN-MPLS networks

Although not strictly a BGP-EVPN configuration, **vpls>proxy-arp** and **vpls>proxy-nd** functions are typically enabled along with EVPN-MPLS in order to reduce the amount of flooding in the network. The proxy-ARP/ND agent in the VPLS service will snoop ARP-requests and/or Neighbor Solicitation messages and will reply to those messages locally (if the information is known) without having to flood the requests to the network.

The configuration options for proxy-ARP are the following:

```
[ex:/configure service vpls "VPLS1"]
A:admin@PE-2# proxy-arp ?

proxy-arp

admin-state          - Administrative state of the proxy
age-time             - Aging timer for proxy entries, where entries are flushed
                    upon timer expiry
apply-groups         - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
duplicate-detect     + Enter the duplicate-detect context
dynamic-arp          + Enter the dynamic-arp context
dynamic-populate     - Populate proxy ARP entries from snooped GARP/ARP/ND
                    messages on SAPs/SDP-bindings
evpn                 + Enter the evpn context
send-refresh         - Time at which to send a refresh message
static-arp           + Enter the static-arp context
table-size           - Maximum number of learned and static entries allowed in
                    the proxy table of this service
```

The configuration options for proxy-ND are the following:

```
[ex:/configure service vpls "VPLS1"]
A:admin@PE-2# proxy-nd ?

proxy-nd

admin-state          - Administrative state of the proxy
age-time             - Aging timer for proxy entries, where entries are flushed
                    upon timer expiry
apply-groups         - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
duplicate-detect     + Enter the duplicate-detect context
dynamic-neighbor     + Enter the dynamic-neighbor context
dynamic-populate     - Populate proxy ARP entries from snooped GARP/ARP/ND
                    messages on SAPs/SDP-bindings
evpn                 + Enter the evpn context
send-refresh         - Time at which to send a refresh message
static-neighbor      + Enter the static-neighbor context
table-size           - Maximum number of learned and static entries allowed in
                    the proxy table of this service
```

When proxy-ARP/ND is enabled, the following configuration guidelines must be followed:

- **dynamic-populate** should be used only in networks with a consistent configuration of this command in all PEs.
- When using **dynamic-populate**, the **age-time** value should be configured to a value equal to three times the **send-refresh** value. This will help reduce the EVPN withdrawals and re-advertisements in the network.
- With large **age-time** values, it would be sufficient to configure the **send-refresh** value to half of the **proxy-ARP/ND age-time** or **FDB age-time**.
- In scaled environments (with thousands of services), it is not recommended to set the send-refresh value to less than 300 s. In such scenarios, Nokia recommends using a minimum proxy-ARP/ND **age-time** and **FDB age** of 900 s.
- The use of the following commands reduces or suppresses the ARP/ND flooding in an EVPN network, because EVPN MAC routes replace the function of the regular data plane ARP/ND messages:

- **proxy-arp>evpn>flood> gratuitous-arp false**
- **proxy-arp>evpn>flood> unknown-arp-req false**
- **proxy-nd>evpn>flood> unknown-neighbor-solicitation false**
- **proxy-nd>evpn>flood> unknown-neighbor-advertise-router false**
- **proxy-nd>evpn>flood> unknown-neighbor-advertise-host false**
- Nokia recommends using the preceding commands only in EVPN networks where the CEs are routers directly connected to an SR OS node acting as the PE. Networks using aggregation switches between the host/routers and the PEs should flood GARP/ND messages in EVPN to make sure the remote caches are updated and BGP does not miss the advertisement of these entries.
- When **duplicate-detect anti-spoof-mac** is used with proxy-ARP/ND, ingress filters (in the access SAPs/SDP-bindings) should be configured to drop all traffic with destination anti-spoof-mac. The same MAC address should be configured in all PEs where duplicate-detect is active.
- When proxy-ND is used, the configuration of the following commands should be consistent in all the PEs in the network:
 - **proxy-nd>evpn>flood> unknown-neighbor-advertise-router**
 - **proxy-nd>evpn>flood> unknown-neighbor-advertise-host**
 - **proxy-nd>evpn>advertise-neighbor-type**
- Because EVPN does not propagate the **router** flag in IPv6--> MAC address advertisements, in a mixed network with hosts and routers where **evpn>advertise-neighbor-type router** is configured, unsolicited host NA messages should be flooded so that the entire network gets to learn all of the host and router ND entries. In the same way, **evpn>advertise-neighbor-type host** should be configured so that unsolicited router NA messages are flooded.

Finally, along with proxy-ARP/ND, **vpls>fdb>discard-unknown true** may be used in some EVPN-MPLS deployments where all the CEs are routers and they announce themselves to the network by sending GARPs or NAs (Neighbor Solicitation messages). According to RFC 7432, whether or not to flood packets to unknown destination MAC addresses should be an administrative choice, depending on how learning happens between CEs and PEs. **Discard-unknown** provides that administrative choice in case all the MAC addresses in an EVI can be learned even before any traffic is exchanged.

Proxy-ARP/ND along with **discard-unknown** helps reduce the BUM traffic in an EVPN network significantly; however, their use must be analyzed and considered, depending on the type of CEs in the EVI.

An example of proxy-ARP configuration is as follows. This configuration should be added to all PEs. When a new ARP message is received on any of the PEs, they will learn the IP-MAC address pair and will advertise it to the network.

```
# on PE-2, PE-3, PE-4, PE-5:
configure {
  service {
    vpls "VPLS1" {
      proxy-arp {
        admin-state enable
        dynamic-populate true
        age-time 900
        send-refresh 300
      }
    }
  }
}
```

Enabling proxy-ARP increases the number of MAC/IP routes being sent by the PEs. This is due to the following reasons:

- An additional MAC/IP route will be advertised per new learned IP-MAC address pair, regardless of having advertised the same MAC address already.
- A MAC per VPLS service will be advertised with a system MAC address. That MAC address will be used as MAC SA for proxy-ARP confirm messages when an IP moves to a different PE.

The following output shows the MAC/IP routes on PE-2 when proxy-ARP is enabled in the network.

```

Troubleshooting and debug commands

When troubleshooting an EVPN-MPLS network, the following show commands and debug commands are recommended, as already discussed throughout this chapter:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn (and filters)**

- **show service evpn-mpls** [<TEP ip-address>]
- **show service id bgp-evpn**
- **show service id evpn-mpls** (and modifiers)
- **show service id fdb** (and modifiers)
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update** (in classic CLI)
- **log-id "99"**

In addition to the preceding commands, the following tools dump commands may also help:

- **tools dump service evpn usage** — This command shows the amount of EVPN-MPLS (and EVPN-VXLAN) destinations consumed in the system.
- **tools dump service system bgp-evpn ethernet-segment <name> evi <[1..65535]> df** — This command computes the DF election for a specific ESI and EVI. Note: The **show service system bgp-evpn ethernet-segment** commands shows whether the local PE is DF or non-DF for a specific EVI, but it does not show who the DF is if it is not the local PE. In case of more than 2 PEs in the ES, this command may be especially useful.

Some examples are provided below for PE-2. PE-2 is showing seven EVPN-MPLS destinations due to the following:

- Each remote PE consumes one EVPN-MPLS destination for unicast (if they advertise MAC/IP routes to PE-2 and the ingress-replication-bum-label is configured in all the PEs). PE-2 has three remote unicast EVPN-MPLS destinations.
- Each remote PE consumes one EVPN-MPLS destination for multicast (if they advertise inclusive multicast routes to PE-2). PE-2 has three remote multicast EVPN-MPLS destinations.
- Each remote ES consumes one EVPN-MPLS destination (it is only one per ES, regardless of the multi-homing mode and the number of PEs in the ES). PE-2 has one remote ES (ESI-45).

```
[/]
A:admin@PE-2# tools dump service evpn usage

vxlan-evpn-mpls usage statistics at 02/25/2021 17:40:37:

```

To compute the DF election for EVI 1:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-23" evi 1 df
```

```
[02/25/2021 17:40:47] Computed DF: 192.0.2.3 (Remote) (Boot Timer Expired: Yes)
```

Conclusion

SR OS has a full RFC 7432 EVPN-MPLS implementation including single-active and all-active multi-homing. This example has shown how to configure and operate EVPN-MPLS for a simple non multi-homing configuration as well as a multi-homing configuration. Other topics, such as the integration of VPLS objects with EVPN-MPLS and proxy-ARP/ND, have also been discussed.

EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS)

This chapter provides information about EVPN for MPLS tunnels in Epipe services (EVPN-VPWS).

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the MD-CLI in the current edition is based on SR OS Release 22.10.R1. Ethernet Virtual Private Network - Virtual Private Wire Service (EVPN-VPWS) is supported in SR OS Release 14.0.R1 and later. EVPN-VPWS in multi-homing scenarios is supported in SR OS Release 14.0.R4 and later.

Chapter [EVPN for MPLS Tunnels](#) is prerequisite reading.

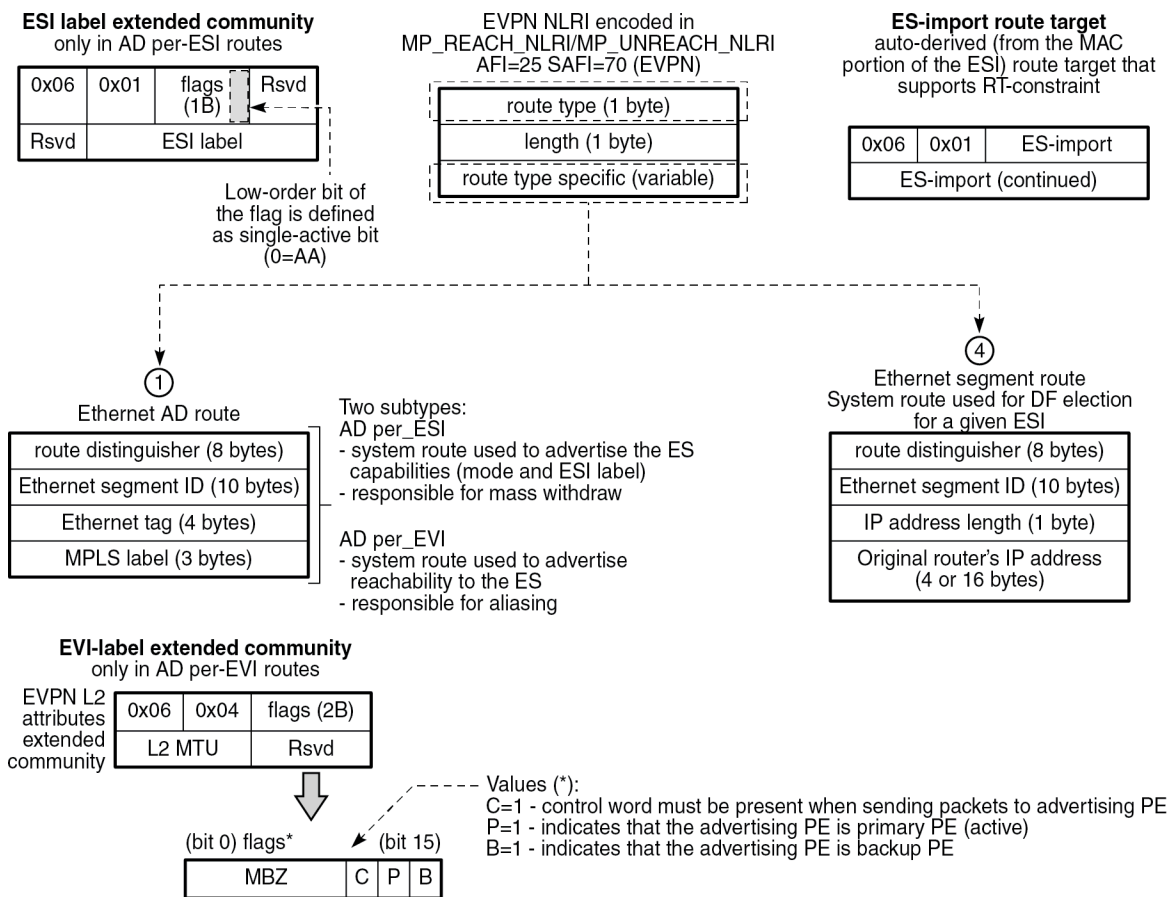

Overview

Service providers prefer an optimized, standardized, and unified control plane for VPNs. EVPN-VPWS is supported in MPLS networks that also run EVPN-MPLS in VPLS services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432 – *BGP MPLS-Based Ethernet VPN*, because there is no need to advertise MAC routes in VPWS. EVPN-VPWS is described in RFC 8214 – *Virtual Private Wire Service Support in Ethernet VPN*.

EVPN-VPWS supports all-active multi-homing (per-flow load-balancing multi-homing) as well as single-active multi-homing (per-service load-balancing multi-homing), using the same Ethernet segments (ESs) used for EVPN-MPLS VPLS services. EVPN-VPWS uses route-type 1 and route-type 4; it does not use route-types 2, 3, or 5, because MAC/IP routes, inclusive multicast, or IP-prefix routes are not required.

The figure [Figure 91: Route types and NLRIs for EVPN-VPWS](#) shows the encoding of the required extensions for the route-types 1 and 4 for EVPN-VPWS.

Figure 91: Route types and NLRIs for EVPN-VPWS

25942

Two sub-types are defined for route-type 1. Route-type 4 has no sub-types. The route types used for EVPN-VPWS have the following purposes:

- Route-type 1 - Auto-discovery per EVPN instance (AD per-EVI). This route type is used in all EVPN-VPWS scenarios, with or without multi-homing. For EVPN-VPWS, the Ethernet tag field is encoded with the local Attachment Circuit (AC) of the advertising PE. This value is configured using the **service>epipe>bgp-evpn>local-attachment-circuit>eth-tag <value>** command. The route distinguisher (RD), MPLS label, and the Ethernet segment ID (ESI) are encoded as for EVPN-MPLS. The MPLS label field is used as service label. In case of multi-homing, AD per-EVI routes containing the same ESI are used to provide aliasing and a backup path to the PEs part of the ES. The L2 MTU is encoded with the service MTU configured in the Epipe. The following flags are used for EVPN-VPWS:
 - Flag C is set if a control word is configured in the service.
 - Flag P is set if the advertising PE is primary PE.
 - If no multi-homing is used, there is no primary PE (P=0).
 - In all-active multi-homing, all PEs in the ES are primary (P=1).
 - In single-active multi-homing, only one PE per-EVI in the ES is primary (P=1).

- Flag B is set if the advertising PE is backup PE.
 - The B-flag is only set in case of single-active multi-homing and only for one PE, even if more than two PEs are present in the same single-active ES. The backup PE is the winner of the second Designated Forwarder (DF) election (excluding the DF). The remaining non-DF PEs send B=0.

If there is no multi-homing, the ESI, flag P, and flag B will be zero.

- Route-type 1 - AD per Ethernet segment (AD per-ES). Same encoding as for EVPN-MPLS. AD per-ES is only used in multi-homing scenarios where it is advertised per ES from the PE. It carries the ESI label (used for split-horizon, but only for VPLS services and not for Epipe services) and can affect procedures such as the DF election, as well as the aliasing on remote PEs.
- Route-type 4 - ES route. Same encoding as for EVPN-MPLS. Route-type 4 is only used in multi-homing scenarios. This route advertises a local configured ES. The exchange of this route can discover remote PEs that are part of the same ES and the DF election algorithm among them.

Configuration

The figure [Figure 92: EVPN-VPWS example topology](#) shows the example topology that will be used throughout this chapter.

Figure 92: EVPN-VPWS example topology

25943

The example topology consists of six SR OS nodes with the following initial configuration:

- Network (or hybrid) ports interconnect the core PEs with configured router interfaces.
- MTU-1 is a pure Ethernet aggregator. The ports toward the core PEs are access ports. Likewise, the ports on PE-2 and PE-3 toward MTU-1 are access ports.
- Core PEs and MTU-6 run IS-IS on all router interfaces. Point-to-point adjacencies are established for the exchange of system IP addresses.
- Link LDP is configured between all PEs, and toward/from MTU-6.
- EVPN uses BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although typically a separate router is used, in this chapter, PE-2 is used as route reflector (RR) with the following BGP configuration:

```
# on RR PE-2:
configure {
```

```
router "Base" {
  autonomous-system 64500
  bgp {
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    peer-ip-tracking true
    split-horizon true
    rapid-update {
      evpn true
    }
    group "internal" {
      peer-as 64500
      family {
        evpn true
      }
      cluster {
        cluster-id 192.0.2.2
      }
    }
    neighbor "192.0.2.3" {
      group "internal"
    }
    neighbor "192.0.2.4" {
      group "internal"
    }
    neighbor "192.0.2.5" {
      group "internal"
    }
  }
}
```

The BGP configuration on the other PEs is as follows:

```
# on PE-3, PE-4, PE-5:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
      }
      neighbor "192.0.2.2" {
        group "internal"
      }
    }
  }
}
```

The following EVPN-VPWS scenarios are described in the following sections:

- [EVPN for MPLS tunnels in Epipe services without multi-homing](#)
- [EVPN for MPLS tunnels in Epipe services with all-active multi-homing](#)
- [EVPN for MPLS tunnels in Epipe services with single-active multi-homing](#)

EVPN for MPLS tunnels in Epipe services without multi-homing

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke-SDPs at the access, as shown in the figure [Figure 93: Example topology for EVPN-VPWS without multi-homing](#).

Figure 93: Example topology for EVPN-VPWS without multi-homing

25944

On PE-2, Epipe 1 is configured as follows:

```
# on PE-2:
configure {
  service {
    epipe "Epipe-1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      sap 1/1/c11/1:1 {
      }
      bgp-evpn {
        evi 1
        local-attachment-circuit "AC-PE-2-MTU-1" {
          eth-tag 21
        }
        remote-attachment-circuit "AC-PE-4-MTU-6" {
          eth-tag 46
        }
        mpls 1 {
          admin-state enable
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}
```

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure {
  service {
    epipe "Epipe-1" {
```

```

    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
    }
    spoke-sdp 460:1 {
    }
    bgp-evpn {
        evi 1
        local-attachment-circuit "AC-PE-4-MTU-6" {
            eth-tag 46
        }
        remote-attachment-circuit "AC-PE-2-MTU-1" {
            eth-tag 21
        }
    }
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution any
        }
    }
    }
}
sdp 460 {
    admin-state enable
    far-end {
        ip-address 192.0.2.6
    }
}

```

Where the following commands are relevant for the EVPN-VPWS configuration:

- **bgp 1** enables the context for the BGP configuration relevant to the service. The **bgp** context configures the common BGP parameters for all BGP families in the service, such as route distinguisher and route target. Even if the general BGP parameters for the service are auto-derived, the **bgp** context must be enabled.

```

[ex:/configure service epipe "Epipe-1"]
A:admin@PE-2# bgp 1 ?

```

```

bgp

adv-service-mtu      - Advertised service MTU value
apply-groups        - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
pw-template-binding  + Enter the pw-template-binding list instance
route-distinguisher  - High-order 6 bytes that are used as string to compose VSI-ID for
                    use in NLRI
route-target         + Enter the route-target context
vsi-export          - VSI export policies
vsi-import          - VSI import policies

```

- The following parameters can be configured in the **bgp-evpn** context:

```

[ex:/configure service epipe "Epipe-1"]
A:admin@PE-2# bgp-evpn ?

```

```

bgp-evpn

apply-groups        - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
evi                 - EVPN ID

```

local-attachment-circuit	+ Enter the local-attachment-circuit list instance
mpls	+ Enter the mpls list instance
remote-attachment-circuit	+ Enter the remote-attachment-circuit list instance
segment-routing-v6	+ Enter the segment-routing-v6 list instance
vxlan	+ Enter the vxlan list instance

- The **evi** is a two-byte or three-byte identifier used for auto-deriving the service RD (only for two-byte EVI), service RT, and for the DF election in multi-homing. The auto-derivation of RD and RT for a two-byte EVI is as follows:

- RD <system IP address>:<evi>
- RT <autonomous system number>:<evi>

The EVI values must be unique in the system, regardless of the type of service they are assigned to (Epipe or VPLS).

Note: Three-byte EVI values are supported in SR OS Release 21.10.R1 and later. For auto-derived RT as per RFC 8365, the **evi-three-byte-auto-rt** command must be configured, as described in the [Three-byte EVI in EVPN Services](#) chapter.

- The **local-attachment-circuit** and **remote-attachment-circuit** identify the two attachment circuits connected by the EVPN-VPWS service. The configured Ethernet tag for the local AC is advertised in the Ethernet tag field of the AD per-EVI route for the Epipe, along with the corresponding RD, RT, and MPLS label. Both local and remote Ethernet tags are mandatory to bring up the Epipe service. If the received Ethernet tag for the Epipe service matches the configured remote AC Ethernet tag, it will create an EVPN-MPLS destination to the next hop.
- The following configuration options are available for Epipes in the **bgp-evpn>mpls <bgp-instance>** context:

```
[ex:/configure service epipe "Epipe-1" bgp-evpn]
A:admin@PE-2# mpls 1 ?

mpls

admin-state          - Administrative state of BGP EVPN MPLS
apply-groups         - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
auto-bind-tunnel     + Enter the auto-bind-tunnel context
control-word         - Enable the CW bit in the label message
default-route-tag    - Default route tag
dynamic-egress-label-limit - Enables dynamic egress label limit
ecmp                 - Maximum ECMP routes information
entropy-label        - Enable use of entropy-labels
evi-three-byte-auto-rt - Auto-derive the BGP EVPN route target
force-vc-forwarding - VC forwarding action
oper-group           - Operational group identifier
route-next-hop       + Enter the route-next-hop context
send-tunnel-encap    + Enter the send-tunnel-encap context
```

This is a subset of the options for VPLS services; see chapter [EVPN for MPLS Tunnels](#).

When the local AC (SAP 1/1/c11/1:1) is up, PE-2 sends a BGP EVPN AD per-EVI route that contains Ethernet tag 21 for the local AC:

```
# on PE-2:
3 2022/11/30 11:33:31.729 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 81
  Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
  Address Family EVPN
  NextHop len 4 NextHop 192.0.2.2
  Type: EVPN-AD Len: 25 RD: 192.0.2.2:1 ESI: ESI-0, tag: 21 Label: 8388512 (Raw Label:
0x7fffa0) PathId:
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 24 Extended Community:
  target:64500:1
  l2-attribute:MTU: 1514 C: 0 P: 0 B: 0
  bgp-tunnel-encap:MPLS
"
```

The auto-derived RD is 192.0.2.2:1 and the RT is 64500:1.

When the remote AC on PE-4 (spoke-SDP 460:1) is up, PE-2 receives the following BGP update from PE-4:

```
# on PE-2:
5 2022/11/30 11:33:50.377 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 81
  Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
  Address Family EVPN
  NextHop len 4 NextHop 192.0.2.4
  Type: EVPN-AD Len: 25 RD: 192.0.2.4:1 ESI: ESI-0, tag: 46 Label: 8388512 (Raw Label:
0x7fffa0) PathId:
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 24 Extended Community:
  target:64500:1
  l2-attribute:MTU: 1514 C: 0 P: 0 B: 0
  bgp-tunnel-encap:MPLS
"
```

When the received RT matches and the received Ethernet tag matches the configured remote AC, the EVPN-MPLS destination (comprised of a termination endpoint (TEP) and egress label) is created on PE-2 and PE-4:

```
[/]
A:admin@PE-2# show service id 1 evpn-mpls

=====
BGP EVPN-MPLS Dest
=====
TEP Address                               Egr Label                               Last Change
                                         Transport:Tnl-id
-----
```

```

192.0.2.4                524282                11/30/2022 11:33:50
                        ldp:65538

BGP EVPN-MPLS Ethernet Segment Dest
=====
Eth SegId                Last Change
-----
No Matching Entries
=====

```

The MPLS label in the debug message is not the same as in the service, because the router will strip the extra four lowest bits to get the 20-bit MPLS label. The egress label for the EVPN-MPLS destination on PE-4 is 524282. The 24-bit label value in the BGP update debug is 16 (2⁴) times as high: 524282*16 = 8388512. This is because the debug message is shown before the router can parse the label field and see if it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits).

The BGP AD per-EVI routes for Ethernet tag 46 can be shown with the following command:

```

[/]
A:admin@PE-2# show router bgp routes evpn auto-disc tag 46

Note: Each PE sends its service MTU into the L2 MTU field in the L2-attribute in the AD per-EVI route for the Epipe service. The received L2 MTU will be checked. In case of a mismatch between the received MTU and the configured service MTU, the router will not set up the EVPN destination and, therefore, the service will not come up.

EVPN for MPLS tunnels in Epipe services with multi-homing

SR OS supports EVPN multi-homing as per RFC 8214.

The EVPN multi-homing implementation is based on the concept of the Ethernet segment (ES). An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multi-homed to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects. It can also be shared between Epipe and VPLS services.

Each ES has a unique Ethernet Segment Identifier (ESI) that is 10 bytes and is manually configured.

Note: Auto-derived EVPN ESI type 1 as per RFC 7432 is supported in SR OS Release 21.5.R1 and later, as described in the [EVPN ESI Type 1](#) chapter.

The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homed CEs are assumed to be connected to an ES with ESI = 0 (single-homed ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-MPLS service, by default. An ES can be shared by multiple services; the association of a specific SAP or spoke-SDP to an ES is automatically made when the SAP is defined in the same LAG or port configured in the ES, or when the spoke-SDP is defined in the same SDP configured in the ES.

Regardless of the multi-homing mode, the local Ethernet tag values must match on all the PEs that are part of the same ES. The PEs in the ES will use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for an EVI. The DF election is only relevant for single-active multi-homing ESs. For Epipes defined in an all-active multi-homing ES, there is no DF election required, because all PEs are forwarding traffic and all traffic is treated as unicast.

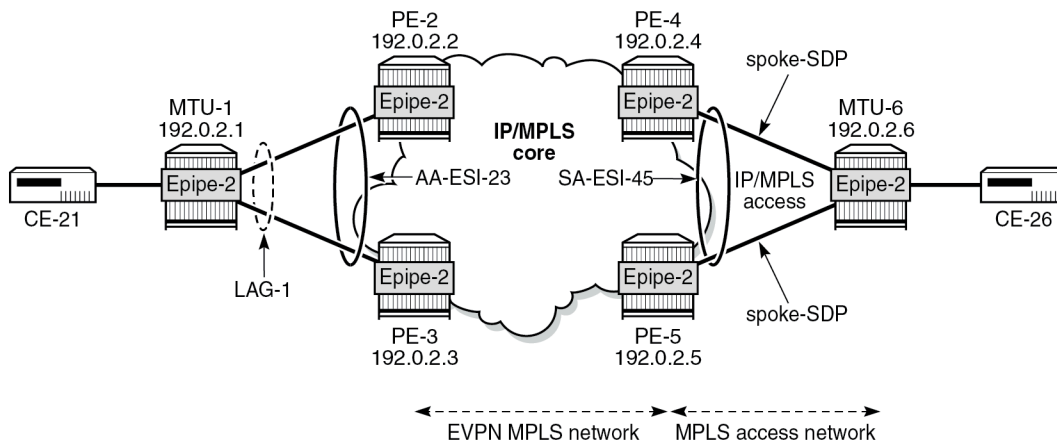

Aliasing is supported when sending traffic to an ES destination. Assuming ECMP is enabled on the ingress PE (and shared queuing or ingress policing), per-flow load-balancing will be performed among all the PEs that advertised P=1. PEs advertising P=0 are not considered as next hops for an ES destination.

The following sections show the configuration of:

- an all-active multi-homing ES with a LAG associated with it
- a single-active multi-homing ES linked to an SDP

The figure [Figure 94: Example topology EVPN-VPWS with multi-homing](#) shows an all-active ES and a single-active ES. The all-active multi-homing ES "AA-ESI-23" on PE-2 and PE-3 has a LAG associated to it; the single-active multi-homing ES "SA-ESI-45" on PE-4 and PE-5 has an SDP associated to it.

Figure 94: Example topology EVPN-VPWS with multi-homing

25945

EVPN for MPLS tunnels in Epipe services with all-active multi-homing

All-active multi-homing allows for per-flow load-balancing. Unlike EVPN-MPLS in VPLS services, EVPN-VPWS has no DF election in all-active multi-homing. All PEs in the ES are active and the remote PE will

do per-flow load-balancing. ES "AA-ESI-23" is configured on PE-2 and PE-3 in all-active multi-homing with LAG 1 associated to it. This LAG is used as a SAP in Epipe 2 on both PE-2 and PE-3. The configuration of the ES and Epipe 2 is identical on PE-2 and PE-3, including the local AC and remote AC names and Ethernet tags:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-ESI-23" {
            admin-state enable
            esi 01:00:00:00:00:23:00:00:00:01
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
            }
          }
        }
      }
    }
  }
  epipe "Epipe-2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    sap lag-1:2 {
    }
    bgp-evpn {
      evi 2
      local-attachment-circuit "AC-AA-ESI-23-MTU-1" {
        eth-tag 231
      }
      remote-attachment-circuit "AC-SA-ESI-45-MTU-6" {
        eth-tag 456
      }
      mpls 1 {
        admin-state enable
        ecmp 2
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}
```

See chapter [EVPN for MPLS Tunnels](#) for a detailed explanation of the configuration parameters of the ES.

In EVPN-VPWS multi-homing scenarios, three route types are exchanged: AD per-EVI, AD per-ES, and ES routes. The following ES route (route-type 4) for ESI 01:00:00:00:00:23:00:00:00:01 sent by PE-2 is imported at PE-3:

```
# on PE-3:
3 2022/11/30 11:44:28.466 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
```

```

Withdrawn Length = 0
Total Path Attr Length = 71
Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
  Address Family EVPN

```

"

The ESI label is in the extended community, as well as the indication that the multi-homing is all-active. Epipe services do not require ESI labels because BUM traffic is not recognized as such in EVPN-VPWS services. However, because the ES can be shared by Epipe and VPLS services, the AD per-ES route still includes a non-zero ESI label.

The following AD per-EVI routes (route-type 1) with Ethernet tag 231 sent by RR PE-2 are received and imported on PE-4:

```
# on PE-4:

```

Note: Even if ECMP is configured, the ingress router will not load-balance the traffic unless shared queuing or ingress policing is configured. This is not specific to EVPN, but generic to the way Epipe forward traffic.

In all-active multi-homing for EVPN-VPWS, there is no DF election and all PEs in the ES are active. For AA-ESI-23, both PE-2 and PE-3 are active/primary/DF, but there are no DF candidates, because there is no DF election:

```

[/]

```

EVPN for MPLS tunnels in Epipe services with single-active multi-homing

Single-active multi-homing allows for per-service load-balancing. Single-active multi-homing is configured on PE-4 and PE-5 with ES "SA-ESI-45". Both PEs have an SDP to MTU-6, which is associated with the ES and to the Epipe service. The configuration of the local and remote AC names and Ethernet tags is identical on PE-4 and PE-5.

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure {
  service {
    system {
      bgp {
```

```
        evpn {
            ethernet-segment "SA-ESI-45" {
                admin-state enable
                esi 01:00:00:00:00:45:00:00:00:01
                multi-homing-mode single-active
                df-election {
                    es-activation-timer 3
                }
                association {
                    sdp 46 {
                    }
                }
            }
        }
    }
}
epipe "Epipe-2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    spoke-sdp 46:2 {
    }
    bgp-evpn {
        evi 2
        local-attachment-circuit "AC-SA-ESI-45-MTU-6" {
            eth-tag 456
        }
        remote-attachment-circuit "AC-AA-ESI-23-MTU-1" {
            eth-tag 231
        }
        mpls 1 {
            admin-state enable
            ecmp 2
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
sdp 46 {
    admin-state enable
    delivery-type mpls
    ldp true
    far-end {
        ip-address 192.0.2.6
    }
}
}
```

On PE-5, the configuration is similar, but with a different SDP:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "SA-ESI-45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:01
                        multi-homing-mode single-active
                        df-election {
```

```
                es-activation-timer 3
            }
            association {
                sdp 56 {
                }
            }
        }
    }
}
epipe "Epipe 2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    spoke-sdp 56:2 {
    }
    bgp-evpn {
        evi 2
        local-attachment-circuit "AC-SA-ESI-45-MTU-6" {
            eth-tag 456
        }
        remote-attachment-circuit "AC-AA-ESI-23-MTU-1" {
            eth-tag 231
        }
        mpls 1 {
            admin-state enable
            ecmp 2
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
}
sdp 56 {
    admin-state enable
    delivery-type mpls
    ldp true
    far-end {
        ip-address 192.0.2.6
    }
}
```

Three route types will be exchanged between the core PEs: AD per-EVI, AD per-ES, and ES routes.

PE-4 and PE-5 advertise ES routes that are only imported by them. As an example, the following is the ES route with originator PE-4 sent by RR PE-2 to PE-5. It contains a target 00:00:00:00:45:00 in the extended community that is derived from the ESI:

```
# on PE-2:
56 2022/11/30 11:45:03.406 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 85
  Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.4
    Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0 ESI: 01:00:00:00:00:45:00:00:00:01, IP-Len:
  4 Orig-IP-Addr: 192.0.2.4
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
```

```

Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
Flag: 0x80 Type: 10 Len: 4 Cluster ID:
    192.0.2.2
Flag: 0xc0 Type: 16 Len: 16 Extended Community:
    df-election::DF-Type:Auto/DP:0/DF-Preference:0/AC:1
    target:00:00:00:00:45:00
"
    
```

The AD per-ES route has a maximum Ethernet tag (MAX-ET) and an ESI label in the extended community. The multi-homing mode is single-active. As in the case of all-active multi-homing, the ESI label is not used in Epipe services. The following BGP update with originator PE-4 is sent by RR PE-2 to its client PE-5:

```

# on PE-2:
36 2022/11/30 11:44:47.394 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 95
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:2 ESI: 01:00:00:00:00:45:00:00:00:01, tag: MAX-ET
Label: 0 (Raw Label: 0x0) PathId:
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
        192.0.2.2
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:2
        esi-label:524279/Single-Active
        bgp-tunnel-encap:MPLS
"
    
```

The AD per-EVI route contains flags for primary and backup, which will be different for routes received from PE-4 and PE-5. In this case, PE-4 is primary in the single-active multi-homing ES (P=1):

```

# on PE-2:
64 2022/11/30 11:45:06.415 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 95
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN

The DF election is key for the forwarding and backup functions in single-active multi-homing ESs. The PE elected as DF will be the primary for the ES in the Epipe and will unblock the SAP/spoke-SDP for upstream and downstream traffic. The rest of the PEs in the ES will bring their ES SAPs or spoke-SDPs operationally down.

PE-5 is a non-DF, as follows:

```
[/]
A:admin@PE-5# show service system bgp-evpn ethernet-segment name "SA-ESI-45" evi evi-1 2

=====
EVI DF and Candidate List
=====

=====
* indicates that the corresponding row element may have been truncated.

```

In single-active multi-homing, the service spoke-SDP (or SAP) is brought operationally down on the non-DF, as shown in the following output:

```

[/]
A:admin@PE-5# show service id 2 sdp
=====
Services: Service Destination Points
=====
SdpId          Type          Far End addr  Adm    Opr          I.Lbl          E.Lbl
-----
56:2          Spok          192.0.2.6    Up     Down         524280         524280
-----
Number of SDPs : 1
-----
=====

```

The spoke-SDP 56:2 is operationally down with a StandbyForMHPProtocol flag:

```

[/]
A:admin@PE-5# show service id 2 sdp 56:2 detail | match Flag
Flags          : StandbyForMHPProtocol

```

Two consecutive DF elections take place: the first DF election includes all PEs in the ES for that Epipe and determines which PE is the primary PE (flags P=1, B=0). The second DF election excludes this DF and determines which PE is the backup (P=0, B=1). All other PEs signal flags P=0 and B=0.

When the primary PE fails, AD per-ES/EVI withdrawal messages are sent to the remote PE, which will update its next hop to the backup. The backup PE takes over immediately without waiting for the **es-activation-timer** to bring up its SAP/spoke-SDP.

Ethernet segment failures

When the SDP toward the primary (DF) fails, the backup PE needs to take over. An SDP failure is emulated and log 99 on PE-4 shows that SDP 46 is operational down and PE-4 is no longer the DF:

```

140 2022/11/30 12:09:36.765 CET MINOR: SVCMGR #2094 Base
"Ethernet Segment:SA-ESI-45, EVI:2, Designated Forwarding state changed to:false"

139 2022/11/30 12:09:36.764 CET MINOR: SVCMGR #2326 Base
"Status of SDP Bind 46:2 in service 2 (customer 1) local PW status bits changed to psnIngress
Fault psnEgressFault "

```

```
138 2022/11/30 12:09:36.764 CET MINOR: SVCNMR #2303 Base
"Status of SDP 46 changed to admin=up oper=down"
```

Remote PEs receive route withdrawal updates (unreachable NLRI) from former DF PE-4, for example on RR PE-2:

```
# on PE-2:
76 2022/11/30 12:09:36.765 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

=====

```

This process is revertive; as soon as the SDP 46 is operationally up again, a new DF election is triggered with two DF candidates and PE-4 will be elected as DF.

Troubleshooting and debugging

The following show and debug commands can be used in EVPN-VPWS:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service evpn-mpls** [*<TEP ip-address>*]
- **show service id bgp-evpn**
- **show service id evpn-mpls** (and modifiers)
- **show service system bgp-evpn**

- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **show log log-id 99**

Most of these commands have been shown in the preceding sections; some commands are shown in this section.

Information about the configured boot timers (before DF election) and ES activation timer (after the system has been elected DF) can be shown as follows:

```
[/]
A:admin@PE-2# show redundancy bgp-evpn-multi-homing

=====
Redundancy BGP EVPN Multi-homing Information
=====
Boot-Timer           : 10 secs
Boot-Timer Remaining : 0 secs
ES Activation Timer   : 3 secs
=====
```

See chapter [EVPN for MPLS Tunnels](#) for a description of these timers.

The following command shows that the BGP route-type 4 (ES route) messages are only imported by the PEs in the same ES; for example, on PE-3:

```
[/]
A:admin@PE-3# show router bgp routes evpn eth-seg

=====

```

In addition to the preceding commands, the following tools dump commands may be useful:

- **tools dump service evpn usage** – This command shows the number of EVPN-MPLS (and EVPN-VXLAN) destinations in the system.
- **tools dump service system bgp-evpn ethernet-segment <name> evi <.> df** – This command computes the DF election for a specific ESI and EVI. For all-active, there is no DF election and all PEs forward traffic. For single-active, one PE will be active for a service while another PE will be backup. This command shows the DF (primary), even if it is not the local PE.

The usage of EVPN resources can be shown as follows:

```
[/]
A:admin@PE-2# tools dump service evpn usage

vxlan-srv6-evpn-mpls usage statistics at 11/30/2022 12:15:35:

MPLS-TEP                :          1
VXLAN-TEP                :          0
SRV6-TEP                :          0
Total-TEP                :        1/ 16383

Vxlan Dests (TEP, Egress VNI + ES)           :          0
Srv6 Dests (TEP, SID + ES)                   :          0
Total-Dest                :       2/196607

Sdp Bind + Evpn Dests   :       2/245759
ES L2/L3 PBR            :       0/ 32767
Evpn Etree Remote BUM Leaf Labels            :          0
```

On PE-2, there is one MPLS-TEP (192.0.2.4 in Epipe 1 and Epipe 2) and there are two MPLS destinations: 192.0.2.4 and ESI 01:00:00:00:00:45:00:00:01. PE-5 is not an MPLS-TEP for PE-2, because it is not a primary and, therefore, not forwarding any traffic.

In all-active multi-homing, the DF election is not applicable:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "AA-ESI-23" evi 2 df

[11/30/2022 12:15:50] All Active VPWS or IP-ALIASING - DF N/A
```

In single-active multi-homing, the following command shows which PE is the DF:

```
[/]
A:admin@PE-5# tools dump service system bgp-evpn ethernet-segment "SA-ESI-45" evi 2 df

[11/30/2022 12:16:04] Computed DF: 192.0.2.4 (Remote) (Boot Timer Expired: Yes)
[11/30/2022 12:16:04] Computed Backup: 192.0.2.5 (This Node)
```

The command is launched on PE-5, which is a backup. The computed DF is PE-4 and the boot timer has expired, meaning there is no DF re-election pending.

Conclusion

EVPN-VPWS is a simplified point-to-point version of RFC 7432 - *BGP MPLS-Based Ethernet VPN*. When used for Epipe and VPLS services, EVPN provides a unified control plane mechanism that simplifies the network deployment and operation. Single-active and all-active multi-homing can be used in Epipes; EVPN-VPWS is a differentiator of EVPN compared to traditional TLDP or BGP Epipe redundancy mechanisms. The Ethernet Segments used for multi-homing can be shared between EVPN VPLS and EVPN Epipes.

EVPN for MPLS Tunnels in Routed VPLS

This chapter provides information about EVPN for MPLS tunnels in routed VPLS.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 15.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.10.R3. EVPN-MPLS and IP-prefix advertisement in routed VPLS (R-VPLS) without Multi-homing (MH) is supported in SR OS Release 14.0.R1, and later. EVPN-MPLS and IP-prefix advertisement in R-VPLS with all-active and single-active MH is supported in SR OS Release 14.0.R4, and later. Virtual Router Redundancy Protocol (VRRP) in passive mode is also supported in SR OS Release 14.0.R4, and later.

Chapter [EVPN for VXLAN Tunnels \(Layer 3\)](#) is prerequisite reading.

Overview

The EVPN-MPLS in R-VPLS feature matches the EVPN-VXLAN in R-VPLS feature, which is described in chapter [EVPN for VXLAN Tunnels \(Layer 3\)](#) The following capabilities are supported in an R-VPLS service where **bgp-evpn mpls** is enabled:

- R-VPLS with Virtual Router Redundancy Protocol (VRRP) support on the VPRN interfaces
- R-VPLS support including IP route advertisement (IP prefix routes — BGP-EVPN route type 5) with regular interfaces
- R-VPLS support including IP route advertisement with **evpn-tunnel** interfaces
- R-VPLS with IPv6 support on the VPRN IP interface

All-active and single-active MH Ethernet segments (ESs) are supported in R-VPLS. When Ethernet Segments (ESs) are used along with R-VPLS services in two or more PEs, passive VRRP provides an "anycast default gateway" that optimizes inter-subnet forwarding for hosts in the R-VPLS. Passive VRRP is described in the following section.

Passive VRRP

VRRP can be configured in passive mode, which suppresses the transmission and reception of keepalive messages. Passive VRRP can be configured in the base router, in an IES, or in a VPRN, using the following commands:

```
[/]  
A:admin@PE-2# tree flat detail | match vrrp | match passive  
configure groups group <string> router <string> interface <string> ipv4 vrrp <string>
```

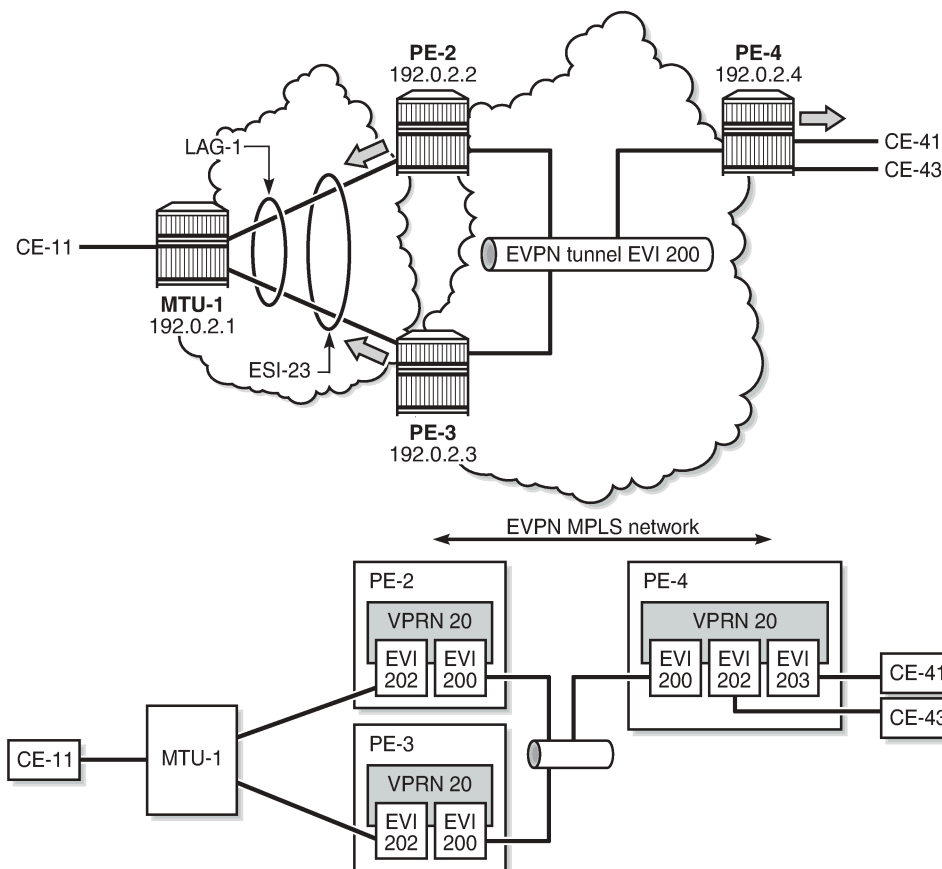

```

| number> passive <boolean>
configure groups group <string> router <string> interface <string> ipv6 vrrp <string | number>
passive <boolean>
configure groups group <string> service ies <string> interface <string> ipv4 vrrp <string |
number> passive <boolean>
configure groups group <string> service ies <string> interface <string> ipv6 vrrp <string |
number> passive <boolean>
configure groups group <string> service vprn <string> interface <string> ipv4 vrrp <string |
number> passive <boolean>
configure groups group <string> service vprn <string> interface <string> ipv6 vrrp <string |
number> passive <boolean>
configure router <string> interface <string> ipv4 vrrp <number> passive <boolean>
configure router <string> interface <string> ipv6 vrrp <number> passive <boolean>
configure service ies <string> interface <string> ipv4 vrrp <number> passive <boolean>
configure service ies <string> interface <string> ipv6 vrrp <number> passive <boolean>
configure service vprn <string> interface <string> ipv4 vrrp <number> passive <boolean>
configure service vprn <string> interface <string> ipv6 vrrp <number> passive <boolean>

```

All PEs configured with passive VRRP become VRRP master and take ownership of the virtual IP and MAC addresses. [Figure 95: Passive VRRP - vMAC/vIP advertised by GARP](#) shows the use of passive VRRP where the VRID and default gateway (GW) are identical for all nodes, and therefore, the vMAC/vIP are identical. Each PE sends Gratuitous Address Resolution Protocol (GARP) messages with the same vMAC/vIP.

Figure 95: Passive VRRP - vMAC/vIP advertised by GARP

26850

Ethernet VPN instance (EVI) 202 is configured on all PEs as an R-VPLS with passive VRRP. Each individual R-VPLS interface has a unique MAC/IP, but they all have the same vMAC/vIP because they share the same VRID and backup IP address. The vMAC address is auto-derived out of 00:00:5e:00:00:<VRID>, as per RFC 3768.

The behavior is as follows:

- PEs advertise their real MAC/IP and their vMAC/vIP in EVPN for EVI 202.
- All hosts in EVI 202 have a unique configured default GW.
- When a CE sends upstream traffic to a remote subnet, the packets are routed by the closest PE because the vMAC address is local on each PE.
- In case of ES failure, or in case of single-active MH if the traffic arrives at the non-Designated Forwarder (NDF) PE, the traffic will not be discarded at the peer ES PE. Virtual MAC addresses bypass the R-VPLS interface protection, so traffic can be forwarded between the PEs without being dropped. Note that if passive VRRP was not used in this case and the same regular interface anycast MAC/IP was used instead, the peer PE would discard the traffic due to the MAC Source Address (SA).

Passive VRRP provides an efficient anycast default gateway solution, with the following advantages compared to regular VRRP:

- No need for multiple VRRP instances to achieve default GW load-balancing. Only one VRRP instance is in the R-VPLS, so only one default GW is needed for all hosts.
- Fast convergence because all the nodes in the VRID are master.
- Better scalability because there is no need for keepalive messages or BFD to detect failures.

Passive VRRP provides the following advantages compared to using the same anycast MAC/IP in all the Integrated Routing Bridging (IRB) interfaces:

- VRRP vMAC SA bypasses the protection in the receiving R-VPLS service; therefore, frames with MAC SA matching the local vMAC address are not discarded, and VRRP vMAC SAs can be used in combination with EVPN multi-homing.
- PEs will not show traps claiming duplicate IP addresses.
- vMAC addresses are auto-derived from the VRID, so no need to configure the same MAC address in all the IRB interfaces.
- PEs can still use their real (unique) IRB IP addresses when sending ICMP packets for troubleshooting purposes.

Configuration

In this section, the following use cases are described:

- EVPN-MPLS R-VPLS without multi-homing
- EVPN-MPLS R-VPLS with all-active multi-homing ES
- EVPN-MPLS R-VPLS with single-active multi-homing ES

EVPN-MPLS R-VPLS without multi-homing

The first scenario describes R-VPLS support including IP route advertisement (BGP-EVPN route type 5) with EVPN tunnel interfaces, without multi-homing. VPLS 101 does not have any connected host, but the

linked VPRN has SAP 1/2/1:10. [Figure 96: R-VPLS with EVPN tunnel, without multi-homing](#) shows the example topology used for R-VPLS with EVPN tunnel but without multi-homing. IP prefixes are advertised.

Figure 96: R-VPLS with EVPN tunnel, without multi-homing

26851

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interface between PE-2 and PE-3
- IS-IS (or OSPF)
- LDP enabled on the router interface between PE-2 and PE-3

BGP is configured for the EVPN address family on PE-2 and PE-3. The BGP configuration on PE-2 is as follows. The BGP configuration on PE-3 is similar.

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
    }
  }
}
```

The CEs are connected to SAP 1/2/1:10 in VPRN 10. R-VPLS 101 is bound to VPRN 10 and VPRN 10 has a dedicated interface "int-evi-101" for the EVPN tunnel. In general, if only one route-target (RT) is used for import and export in the EVPN-VPLS, it is good to add the EVI and have the route distinguisher (RD) and

RT auto-derived from the EVI. It is simpler and avoids configuration mistakes. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    vpls "evi-101" {
      admin-state enable
      service-id 101
      customer "1"
      routed-vpls {
      }
      bgp 1 {          # RD and RT are not manually configured in BGP context
      }
      bgp-evpn {
        evi 101      # RD and RT will be auto-derived from the EVI
        routes {
          ip-prefix {
            advertise true
          }
        }
        mpls 1 {
          admin-state enable
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
  vprn "VPRN 10" {
    admin-state enable
    service-id 10
    customer "1"
    interface "int-PE-2-CE-20" {
      ipv4 {
        primary {
          address 172.16.2.1
          prefix-length 24
        }
      }
      sap 1/2/1:10 {
      }
    }
    interface "int-evi-101" {
      vpls "evi-101" {
        evpn-tunnel {
        }
      }
    }
  }
}
```

- The **routed-vpls** command is required so that R-VPLS "evi-101" can be bound to VPRN 10.
- The service name "evi-101" must match the name in the VPRN 10 VPLS interface.
- The VPRN 10 VPLS interface is configured with the keyword **evpn-tunnel**. This configuration has the advantage of not having to allocate IP addresses to the R-VPLS interfaces, however, it cannot be used when the R-VPLS has local SAPs.

The configuration is similar on PE-3. It is important that the RD is different on PE-2 and PE-3, but it is automatically the case when the RD is auto-derived from the configured EVI, as in the example. The RD on PE-2 is 192.0.2.2:101; on PE-3, the RD is 192.0.2.3:101.

PE-3 receives the following BGP-EVPN IP prefix route for prefix 172.16.2.0/24 from PE-2:

```

2 2022/02/24 11:00:28.145 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"

```

GW IP 0.0.0.0 is an indication that an EVPN tunnel is in use. With EVPN tunnels, no IRB IP address needs to be configured in the VPRN. EVPN tunnels make provisioning easier to automate and save IP addresses from the tenant IP space.

The BGP tunnel encapsulation is MPLS, but the MPLS label in the debug message is not the same as in the service, because the router will strip the extra four lowest bits to get the 20-bit MPLS label. In the debug message, the label is 8388496. This is because the debug message is shown before the router can parse the label field and see if it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits). The MPLS label is calculated by dividing the label value by 24 (16), as follows: $8388496/16 = 524281$.

The MAC next-hop extended community 02:13:ff:ff:ff:a2 is the MAC address of the interface "int-evi-101" in VPRN 10 on PE-2, as follows:

```

[/]
A:admin@PE-2# show router 10 interface "int-evi-101" detail | match "MAC Address"
MAC Address      : 02:13:ff:ff:ff:a2   Mac Accounting   : Disabled

```

The routing table for VPRN 10 on PE-3 contains the route for prefix 172.16.2.0/24 as the EVPN-IFF (IFF stands for Interface-ful) route with next-hop "int-evi-101" and interface name "ET-02:13:ff:ff:a2" (ET stands for EVPN Tunnel), as follows:

```

[/]
A:admin@PE-3# show router 10 route-table

```

When the CEs have IPv6 addresses, the VPRN configuration is similar on the PEs, but the **ipv6** context must be enabled in the EVPN tunnel interface, so that the router can advertise and process BGP-EVPN routes type 5 with IPv6 prefixes. The configuration of the VPLS is identical for IPv4 and IPv6.

```
# on PE-2:
configure {
  service {
    vpls "evi-106" {
      admin-state enable
      service-id 106
      customer "1"
      routed-vpls {
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 106
        routes {
          ip-prefix {
            advertise true
          }
        }
        mpls 1 {
          admin-state enable
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
  vprn "VPRN 16" {
    admin-state enable
    service-id 16
    customer "1"
    interface "int-PE-2-CE-26" {
      sap 1/2/1:16 {
      }
    }
  }
}
```

```

        ipv6 {
            address 2001:db8:16::2:1 {
                prefix-length 120
            }
        }
    }
    interface "int-evi-106" {
        vpls "evi-106" {
            evpn-tunnel {
            }
        }
        ipv6 {
        }
    }
}

```

When advertising IPv6 prefixes, the GW IP field in the route type 5 is always populated with the IPv6 address of the R-VPLS interface. In this example, because no specific IPv6 global address is configured, the GW IP will be populated with the auto-created link local address. The following BGP update is received by PE-3 for IPv6 prefix 2001:db8:16::2:0/120:

```

# on PE-3:
9 2022/02/24 11:00:35.338 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

EVPN-MPLS R-VPLS with all-active MH

Figure 97: EVPN-MPLS R-VPLS with all-active MH ES shows the example topology with all-active multi-homing ES "AA-ESI-23".

Figure 97: EVPN-MPLS R-VPLS with all-active MH ES

26852

BGP is configured between PE-2, PE-3, and PE-4 for address family EVPN. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      family {
        ipv4 false
      }
    }
  }
}
```

```

    evpn true
  }
  rapid-update {
    evpn true
  }
  group "internal" {
    peer-as 64500
  }
  neighbor "192.0.2.3" {
    group "internal"
  }
  neighbor "192.0.2.4" {
    group "internal"
  }
}

```

All-active multi-homing Ethernet segment "AA-ESI-23" is configured on PE-2 and PE-3, as follows:

```

# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-ESI-23" {
            admin-state enable
            esi 01:00:00:00:00:23:00:00:00:01
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
            }
          }
        }
      }
    }
  }
}

```

The following services are configured on the PEs:

- VPRN 20 has interfaces bound to VPLS 200 and VPLS 202. On PE-4, VPRN 20 also has an interface bound to VPLS 203.
- VPLS 200 is configured as an EVPN tunnel that connects the PEs.
- VPLS 202 and VPLS 203 have attachment circuits to CEs.

The services are configured on PE-2 as follows. The configuration on PE-3 and PE-4 is similar.

```

# on PE-2:
configure {
  service {
    vpls "evi-200" {
      admin-state enable
      service-id 200
      customer "1"
      routed-vpls {
    }
      bgp 1 {
    }
      bgp-evpn {
        evi 200
      }
    }
  }
}

```

```
        routes {
            ip-prefix {
                advertise true
            }
        }
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
vpls "evi-202" {
    admin-state enable
    service-id 202
    customer "1"
    routed-vpls {
    }
    bgp 1 {
    }
    bgp-evpn {
        evi 202
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
    sap lag-1:20 {
    }
}
vprn "VPRN 20" {
    admin-state enable
    service-id 20
    customer "1"
    interface "int-evi-200" {
        vpls "evi-200" {
            evpn-tunnel {
            }
        }
        ipv6 {
        }
    }
    interface "int-evi-202" {
        mac 00:ca:fe:00:02:02
        ipv4 {
            primary {
                address 172.16.20.2
                prefix-length 24
            }
            vrrp 1 {
                backup [172.16.20.254]
                passive true
                ping-reply true
                traceroute-reply true
            }
        }
        vpls "evi-202" {
        }
        ipv6 {
            link-local-address {
                address fe80::16:20:2
            }
        }
    }
}
```

```

        duplicate-address-detection false
    }
    address 2001:db8:16::20:2 {
        prefix-length 120
    }
    vrrp 1 {
        backup [fe80::16:20:fe]
        passive true
        ping-reply true
        traceroute-reply true
    }
}
}
ipv6 {
    router-advertisement {
        interface "int-evi-202" {
            admin-state enable
            use-virtual-mac true
        }
    }
}
}
}

```

The IPv6 VRRP backup address is in the same subnet as the link local address of the interface "int-evi-202". The option **duplicate-address-detection false** is configured on the link local address to disable Duplicate Address Detection (DAD) and set the IPv6 address as preferred. Also for IPv6, router advertisement must be enabled and configured to use the virtual MAC address.

Passive VRRP

EVI 202 is configured as an R-VPLS with passive VRRP. A passive-VRRP VRID instance suppresses the transmission and reception of keepalive messages. All PEs configured with passive VRRP become VRRP master and take ownership of the virtual IP and MAC address.

Each individual R-VPLS interface has a different MAC/IP on each PE. The MAC/IPs for "int-evi-202" on PE-2 are MAC 00:ca:fe:00:02:02 and IP 172.16.20.2/24 for IPv4 and the same MAC address with IPv6 2001:db8:16::20:2 and fe80::16:20:2. However, the R-VPLS interfaces on all PEs share the same VRID 1 and backup IP address 172.16.20.254, so the same vMAC/vIP 00:00:5e:00:01:01/172.16.20.254 and vMAC/vIP 00:00:5e:00:02:01/ fe80::16:20:fe are advertised by all PEs. PE-2 advertises the following EVPN MAC routes:

```

```

The three PEs advertise the same (anycast) vMAC/vIP in EVI 202 as protected, but each PE keeps its own MAC entry in the FDB. The following FDB shows that the source identifier for vMAC 00:00:5e:00:01:01 and vMAC 00:00:5e:00:02:01 is the CPM. These two vMAC entries with source identifier CPM are seen on all PEs.

=====

```

The interface MAC 00:ca:fe:00:02:02 is local, so it also has the CPM as source identifier. MAC 00:ca:fe:00:02:03 is the PE-3's R-VPLS interface MAC and it is learned via EVPN-MPLS (mpls-1) as static (S) and protected (P). MAC address 00:ca:fe:00:02:04 on PE-4 is also static and protected.

PE-4 sends the following IP prefix route (BGP-EVPN route type 5) for prefix 172.16.23.0/24 to the other PEs:

```

37 2022/02/24 15:09:13.665 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

=====
    
```

The following IPv6 routing table for VPRN 20 on PE-2 contains prefix 2001:db8:16::23:0/120, which has also been advertised by PE-4. The next-hop is again "int-evi-200", only this time the link local IPv6 address is displayed (GW IP) instead of the MAC address. The next-hop is the GW IP value in the route type 5, as long as it is non-zero. When the GW IP address is zero, the route type 5 is expected to contain a mac-nh extended community. The MAC encoded in the extended community is used as next-hop in that case.

```

Operation

On PE-4, VPRN 20 has one interface bound to VPLS 202 and another interface bound to VPLS 203. CE-41 is attached to VPLS 202, whereas CE-43 is attached to VPLS 203. When ping messages are sent from CE-41 to CE-43, or vice versa, the messages go via VPRN 20, which has routes to both CEs, as follows:

```

[/]
A:admin@PE-4# show router 20 route-table

EVPN-MPLS R-VPLS with single-active MH

Figure 98: EVPN-MPLS R-VPLS with single-active multi-homing shows the example topology with single-active multi-homing ES "SA-ESI-23". The difference is that the ES is single-active and SDPs are used instead of a LAG.

Figure 98: EVPN-MPLS R-VPLS with single-active multi-homing

26853

The configuration is modified as follows:

- LAG 1 is removed from MTU-1, PE-2, and PE-3.
- Network interfaces are configured between MTU-1 and PE-2/PE-3 with IS-IS and LDP enabled.
- SDPs are configured.
- Ethernet segment "SA-ESI-23" is configured as single-active multi-homing. The SDP is associated with this ES.
- VPLS 202 on PE-2 and PE-3 no longer has a SAP, but a spoke-SDP instead.
- No changes are required on VPRN 20 or VPLS 200.

The service configuration on PE-2 is as follows. The configuration on PE-3 is similar. No changes are required on PE-4.

```
# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "SA-ESI-23" {
```

```
    traceroute-reply true
  }
}
ipv6 {
  router-advertisement {
    interface "int-evi-202" {
      admin-state enable
      use-virtual-mac true
    }
  }
}
vpls "evi-200" {
  admin-state enable
  service-id 200
  customer "1"
  routed-vpls {
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 200
    routes {
      ip-prefix {
        advertise true
      }
    }
    mpls 1 {
      admin-state enable
      auto-bind-tunnel {
        resolution any
      }
    }
  }
}
vpls "evi-202" {
  admin-state enable
  service-id 202
  customer "1"
  routed-vpls {
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 202
    mpls 1 {
      admin-state enable
      auto-bind-tunnel {
        resolution any
      }
    }
  }
}
spoke-sdp 21:20 {
}
}
```

PE-2 is the Designated Forwarder (DF) in the single-active ES, as shown in the following output:

```

```

When the SDP between MTU-1 and DF PE-2 goes down, traffic from CE-41 to CE-11 is forwarded by PE-4 to DF PE-2. PE-2 cannot forward the packets to CE-11 directly, and will forward the packets to its ES peer PE-3. PE-3 will forward to CE-11 even if the MAC SA matches its own vMAC. Virtual MACs bypass the R-VPLS interface protection, so traffic can be forwarded between the PEs without being dropped.

Conclusion

EVPN can be used as the unified control plane VPN technology, not only for providing Layer 2 connectivity, but also Layer 3 (inter-subnet forwarding). EVPN for MPLS tunnels, along with multi-homing and passive VRRP, provides efficient layer-2/layer-3 connectivity to distributed hosts and routers.

EVPN for PBB over MPLS (PBB-EVPN)

This chapter provides information about EVPN for PBB over MPLS (PBB-EVPN).

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 13.0.R6. The MD-CLI in the current edition is based on SR OS Release 21.2.R1.

Note:

A prerequisite is to read the [EVPN for MPLS Tunnels](#) chapter.

Overview

EVPN for Provider Backbone Bridging (PBB) over MPLS (hereafter called PBB-EVPN) is specified in RFC 7623, *Provider Backbone Bridging Combined with Ethernet VPN (PBB-EVPN)*. It provides a simplified version of EVPN-MPLS for cases where the network requires very high scalability and does not need all the advanced features supported by EVPN-MPLS (but still requires single-active and all-active multi-homing capabilities). [Table 6: EVPN and PBB-EVPN SR OS feature comparison](#) provides a comparison between the capabilities of EVPN and PBB-EVPN in SR OS, and may help to choose between them when designing a VPN service.

Table 6: EVPN and PBB-EVPN SR OS feature comparison

VPN requirements	EVPN	PBB-EVPN	Comments
All-active Multi-Homing (MH) (flow-based load-balancing)	Yes	Yes	Allows better bandwidth utilization
Single-active MH (service-based load-balancing)	Yes	Yes	
Ethernet Local Area Network (E-LAN) and point-to-point E-Line services	Yes	Yes	
Inter-subnet-forwarding	Yes	No	Allows combined Layer 2 / Layer 3 services. EVPN

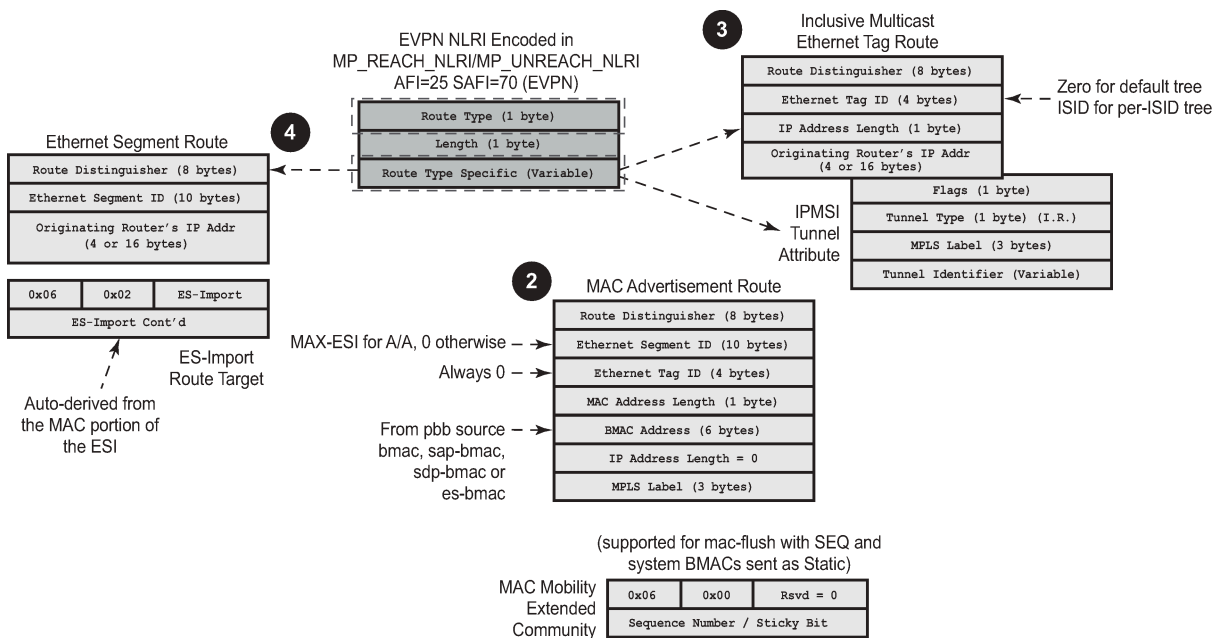

VPN requirements	EVPN	PBB-EVPN	Comments
Proxy-Address Resolution Protocol / Neighbor Discovery (Proxy-ARP/ND) and IP-duplication protection	Yes	No	Allows Broadcast, Unknown unicast and Multicast (BUM) traffic reduction and better security
Customer MAC (CMAC) protection	Yes	No	Allows protecting key static CMACs
Data Center integration	Yes	No	Integration with VXLAN and Nuage Virtualized Services Directory (VSD)
Control plane overhead	Medium	Low	PBB-EVPN only advertises Backbone MACs (BMACs) and no route type 1s
Confinement of CMAC learning	No	Yes	CMACs are only learned on PEs with flows using those CMACs
CMAC summarization	No	Yes	Aggregation of CMACs into BMACs

PBB-EVPN is a combination of 802.1ah PBB and RFC 7432, *BGP MPLS-Based Ethernet VPN* (EVPN-MPLS), and reuses the PBB-Virtual Private LAN Service (VPLS) service model, where Border Gateway Protocol BGP-EVPN is enabled in the backbone VPLS (B-VPLS) domain. EVPN is used as the control plane in the B-VPLS domain to control the distribution of BMACs and set up per-backbone service instance identifier (ISID) flooding trees for service instance VPLS (I-VPLS) services. The learning of the CMACs, either on local SAPs/SDP-bindings or associated with remote BMACs, is still performed in the data plane. Only the learning of BMACs in the B-VPLS is performed through BGP.

The SR OS PBB-EVPN implementation supports I-VPLS and PBB-Epipe services, including single-active and all-active multi-homing.

Because PBB-EVPN is based on the same control plane model as EVPN for MPLS, it is recommended to read the [EVPN for MPLS Tunnels](#) chapter before configuring PBB-EVPN. PBB-EVPN uses a subset of the BGP-EVPN routes described in [EVPN for MPLS Tunnels](#) as shown in [Figure 99: EVPN route types](#).

Figure 99: EVPN route types

al_0847

When no EVPN multi-homing is used in the network, only the base routes are used. Route types 2 and 3 are considered the base and mandatory routes:

- Route type 2 — (B) MAC route — In PBB-EVPN, this route type is used for the advertisement of BMAC addresses that will be installed in the remote Forwarding Data Bases (FDBs). There are no IP addresses advertised in PBB-EVPN. The MAC mobility extended community is used for advertising system BMACs as **protected** (with the sticky bit set) and it is also used for CMAC flush in some single-homing scenarios that will be described later.
- Route type 3 — Inclusive Multicast route — This route type is used for the advertisement of the I-VPLS ISIDs (no Epipecs) and the desired multicast tree for each of them. The ISIDs are encoded in the Ethernet-tag field of the Network Layer Reachability Information (NLRI). When the B-VPLS is created and enabled, an Inclusive Multicast route with ISID = 0 is advertised. This is for the creation of the default multicast tree.

When EVPN multi-homing is used in an ISID, route type 4 (Ethernet Segment (ES) route) is used. In PBB-EVPN, there is no route type 1 advertised when multi-homing is used on the ISID services (I-VPLS and Epipecs). Only route type 4 is used, and in the same way as it is for EVPN-MPLS. See the [EVPN for MPLS Tunnels](#) example for more information about ES routes, how they are formed, and how their RT/RD values are populated.

Configuration

This example describes the basic PBB-EVPN configuration first (without multi-homing) and how the flood containment is handled in PBB-EVPN. Flood containment refers to the efficient distribution of the BUM traffic generated for an ISID.

Networks are not always greenfield, so a smooth migration of PBB-EVPN from PBB-VPLS is required to minimize the effect on existing services. This example also describes this migration, starting from a common PBB-VPLS configuration.

Finally, this example describes the configuration of PBB-EVPN multi-homing.

The same setup described in the VPN for MPLS tunnels example is used:

- Four PEs in the core (PE-2, PE-3, PE-4, and PE-5).
- The PEs are interconnected in the same way as explained in [EVPN for MPLS Tunnels](#) with the same IP addressing, IS-IS, transport LDP, and BGP peering configuration. There is not any difference with the basic infrastructure. See the [EVPN for MPLS Tunnels](#) chapter if more information is required.
- When configuring multi-homing, MTU-1 and MTU-6 are connected to the core.

PBB-EVPN configuration without multi-homing

Figure 100: PBB-EVPN network without multi-homing shows the example topology used in this chapter.

Figure 100: PBB-EVPN network without multi-homing

When configuring PBB-EVPN:

- There is no difference at the access side (I-VPLS and Epipe configuration) compared to other PBB technologies supported in SR OS, such as Shortest Path Bridging for MAC (SPBM) or PBB-VPLS.
- The B-VPLS becomes an EVPN-MPLS service, where `bgp-evpn mpls` is added.

The following output shows an example of a basic configuration in PE-3. B-VPLS 1000 is `bgp-evpn` enabled and I-VPLS 1001 and Epipe 1002 are linked to B-VPLS 1000.

```
# on PE-3:
configure {
  service {
    vpls "B-VPLS 1000" {
      admin-state enable
      service-id 1000
      customer "1"
    }
  }
}
```

```

service-mtu 2000
pbb-type b-vpls
pbb {
    source-bmac {
        address 00:00:00:00:00:03
    }
}
bgp 1 {
}
bgp-evpn {
    evi 1000
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution any
        }
    }
}
}
vpls "I-VPLS 1001" {
    admin-state enable
    service-id 1001
    customer "1"
    pbb-type i-vpls
    pbb {
        backbone-vpls "B-VPLS 1000" {
            isid 1001
        }
    }
    sap 1/2/1:1001 {
    }
}
epipe "Epipe 1002" {
    admin-state enable
    service-id 1002
    customer "1"
    pbb {
        tunnel {
            backbone-vpls-service-name "B-VPLS 1000"
            isid 1002
            backbone-dest-mac 00:00:00:00:00:05
        }
    }
    sap 1/2/1:1002 {
    }
}
}

```

In the preceding output, there is no new configuration needed for I-VPLS/Epipe services. As for the B-VPLS, the output shows the minimum configuration required. If needed, the following parameters can be modified in the **bgp-evpn** context:

```

[ex:/configure service vpls "B-VPLS 1000"]
A:admin@PE-2# bgp-evpn ?

```

```

bgp-evpn

```

```

accept-ivpls-evpn-flush - Accept non-zero ethernet-tag MAC routes and process for CMAC
                        flushing
apply-groups             - Apply a configuration group at this level
apply-groups-exclude    - Exclude a configuration group at this level
evi                      - EVPN ID
incl-mcast-orig-ip      - Originating IP address
isid-route-target       + Enter the isid-route-target context

```

```

mac-duplication + Enter the mac-duplication context
mpls            + Enter the mpls list instance
routes         + Enter the routes context
vxlan          + Enter the vxlan list instance
    
```

The following parameters can be modified in the **bgp-evpn mpls 1** context:

```

[ex:/configure service vpls "B-VPLS 1000" bgp-evpn]
A:admin@PE-2# mpls 1 ?

mpls

admin-state      - Administrative state of BGP EVPN MPLS
apply-groups     - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
auto-bind-tunnel + Enter the auto-bind-tunnel context
control-word     - Enable/disable setting the CW bit in the label message.
default-route-tag - Default route tag
ecmp             - Maximum ECMP routes information
entropy-label    - Enable/disable use of entropy-label.
fdb             + Enter the fdb context
force-vc-forwarding - VC forwarding action
ingress-replication-bum-label - Use the same label as the one advertised for unicast traffic
oper-group       - Operational-Group identifier.
route-next-hop   + Enter the route-next-hop context
send-tunnel-encap + Enter the send-tunnel-encap context
split-horizon-group - Split horizon group
    
```

A detailed description of these commands is included in the [EVPN for MPLS Tunnels](#) chapter. In addition to the preceding commands, the following **service>(b)-vpls>pbp** commands are relevant for PBB-EVPN in the B-VPLS service:

- **force-qtag-forwarding** allows the transparent transport of the customer 802.1p bits across the B-VPLS services.
- **source-bmac>address** can modify the source BMAC for all the PBB packets containing traffic from non-multi-homed I-VPLS and Epipe services.
- **source-bmac>use-es-bmac-lsb true** instructs the system to use an ES-specific BMAC for traffic coming from an ES on an I-VPLS or Epipe.
- **source-bmac>use-mclag-bmac-lsb true** instructs the system to use a SAP-specific BMAC for traffic coming from an MC-LAG I-VPLS/Epipe SAP.

Flood containment for I-VPLS services

In general, PBB technologies in SR OS support a way to contain flooding for a specified I-VPLS ISID, so that BUM traffic for that ISID only reaches the PEs where the ISID is locally defined. Each PE creates a Multicast Forwarding Information Base (MFIB) per I-VPLS ISID on the B-VPLS instance. That MFIB supports SAP/SDP-binding endpoints that can be populated by:

- Multiple MAC Registration Protocol (MMRP) in regular PBB-VPLS
- IS-IS in SPBM

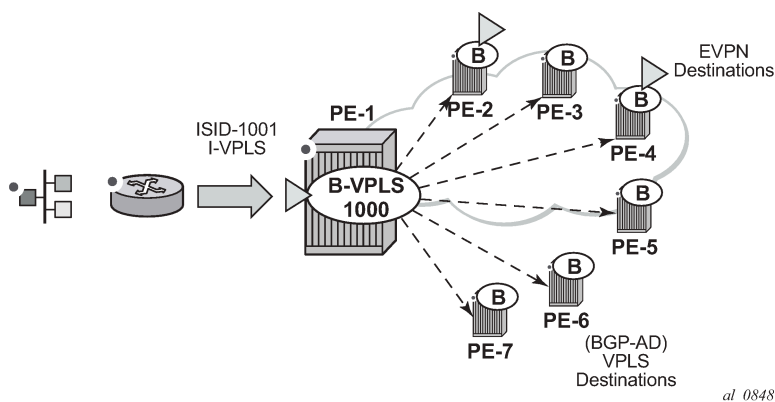

In PBB-EVPN, B-VPLS EVPN destinations can be added to the MFIBs using EVPN Inclusive Multicast Ethernet tag routes when they include the ISID in the Ethernet-tag. By default, when a B-VPLS is successfully enabled (**admin-state enable**), the PE advertises:

- An Inclusive Multicast route for ISID = 0 — This allows the remote PEs to add the advertising PE to the default-multicast-list for the B-VPLS.
- An Inclusive Multicast route for each local ISID defined in the system (a local ISID includes configured I-VPLS and static-ISIDs) — This allows the remote PEs to create MFIB entries in the B-VPLS for the received ISIDs.

Because EVPN destinations, B-SAPs, and B-spoke-SDPs can coexist in the same B-VPLS, be aware of the different flooding lists created and how they are used in a B-VPLS. [Figure 101: PBB-EVPN — flooding lists](#) illustrates this concept with an example for B-VPLS 1000 in PE-1. The assumptions are:

- I-VPLS 1001 is created in PE-1, PE-2, and PE-4 only.
- PE-1, PE-2, PE-3, PE-4, and PE-5 support BGP-EVPN in B-VPLS 1000.
- PE-6 and PE-7 only support spoke-SDPs.
- PE-1 is connected to all six PEs.

Figure 101: PBB-EVPN — flooding lists

In this situation, PE-1 creates two flooding lists in B-VPLS 1000:

- Default-multicast-list — composed of:
 - All the EVPN PEs that advertised ISID = 0 (PE-2, PE-3, PE-4, PE-5).
 - All the B-spoke-SDPs (or B-SAPs) (PE-6, PE-7).
 - All the EVPN PEs that advertised ISID 1001 and no ISID 0 (if an isid-policy is created in PE-1 stating **use-def-mcast** for ISID 1001). Note: third-party PEs may not advertise ISID = 0, but only non-zero ISIDs.
- MFIB for ISID 1001 is composed of:
 - All the EVPN PEs that advertised ISID 1001 (PE-2 and PE-4) unless there is an ISID-policy in PE-1 stating **use-def-mcast** for ISID 1001.
 - Static-ISIDs defined in manual B-spoke-SDPs and B-SAPs (static-ISIDs cannot be created on BGP-AD auto-discovered B-spoke-SDPs).

Based on the above, when BUM traffic is sent to I-VPLS 1001 on PE-1:

- The traffic is encapsulated in PBB with the group BMAC for ISID 1001 and sent (by default) to the MFIB created for ISID 1001 (PE-2 and PE-4).
- If an ISID-policy is added with **use-def-mcast** for ISID 1001, the BUM traffic is encapsulated in PBB with the group BMAC for ISID 1001 and sent to the default-multicast-list, that is, all six remote PEs.

Referring to [Figure 100: PBB-EVPN network without multi-homing](#), the following output illustrates the use of the ISID-policy in PBB-EVPN. PE-2 does not have any ISID-policy configured; when it receives BUM traffic from the local I-VPLS 1001, it uses the MFIB for ISID 1001:

```
# on PE-2:
configure {
  service {
    vpls "B-VPLS 1000" {
      admin-state enable
      service-id 1000
      customer "1"
      service-mtu 2000
      pbb-type b-vpls
      pbb {
        source-bmac {
          address 00:00:00:00:00:02
        }
      }
    }
    bgp 1 {
    }
    bgp-evpn {
      evi 1000
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}
```

```
[/]A:admin@PE-2# show service id 1000 mfib
```

```

                                     b-mpls:192.0.2.5:524282  Local   Fwd
-----
Number of entries: 1
=====
```

An ISID-policy can be added to modify this behavior and allow PE-2 to use the default multicast list. If I-VPLS 1001 exists in all the remote PEs (as in this example), using the default multicast list is as efficient as using the MFIB and saves expensive MFIB resources. In the following output, as soon as the ISID-policy is added, the MFIB entries for ISID 1001 are removed and PE-2 starts using the default multicast list.

```
# on PE-2:
configure {
  service {
    vpls "B-VPLS 1000" {
      isid-policy {
        entry 10 {
          use-def-mcast true
          range {
            start 1001
            end 2000
          }
        }
      }
    }
  }
}
```

```
}  
}
```

The MFIB on PE-2 does not contain any entries for ISID 1001 anymore, as follows:

```
[/]
A:admin@PE-2# show service id 1000 mfib

PBB-VPLS to PBB-EVPN migration

The principles required for migrating a PBB-VPLS network to PBB-EVPN are explained in the [VPLS to EVPN-MPLS integration](#) section of the [EVPN for MPLS Tunnels](#) chapter. Those principles are also applicable to EVPN destinations and spoke-SDPs in the B-VPLS and can be summarized in three points:

- Systems with an EVPN destination and SDP-binding to the same far-end IP bring down the SDP-binding. This avoids loops when both constructs exist in the same network.
- SDP-bindings and EVPN destinations can be placed in the same Split-Horizon Group (SHG). When traffic from an SDP-binding/EVPN destination belonging to that SHG is received on a PE, it is never forwarded to another SDP-binding or EVPN destination on the same SHG.
- MAC addresses learned on an SDP-binding or SAP, that belong to an SHG where EVPN destinations are also created, are not advertised in BGP-EVPN.

Based on those principles, this section describes how to migrate a PBB-VPLS network to PBB-EVPN. The network in [Figure 100: PBB-EVPN network without multi-homing](#) represents a regular PBB-VPLS network that needs to be migrated to PBB-EVPN.

In that network, the four PEs are running BGP-AD and TLDP for the discovery and setup of the pseudowires in the B-VPLS instance. The advantage of this configuration is that the migration can be done node by node and with minimum impact on customer service.

Initial configuration

Initially, the network is configured for PBB-VPLS with BGP-AD in B-VPLS 1000. The EVPN family is to be added. At the access, I-VPLS 1001 is connected to the CEs. As an example, the configuration in PE-3 is shown. An equivalent configuration exists in the other three PEs.

Note:

The EVPN family is added to the BGP configuration because PBB-EVPN uses this address family. Assuming there are redundant Route Reflectors (RRs), the addition of EVPN can be done without service impact. In this example, the assumption is that the PEs are already configured with the EVPN family.

```
# on PE-3:
```

```
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true

```

Multiple MAC Registration Protocol (MMRP) is not used in the B-VPLS instance. If it were enabled, MMRP would have to be disabled in the network before this migration. If there are ISIDs using B-VPLS SDP-bindings to reach some remote locations and B-VPLS EVPN destinations to reach others, the default multicast list must be used in the current release (the MFIB cannot be used if there is a mix of both types). Therefore, during the migration process, the ISIDs must be added to the default multicast list.

1. Add service-level SHG (if not already there).

From the first node being migrated to PBB-EVPN to all nodes migrated, PBB-VPLS and PBB-EVPN have to coexist within the same meshed network. That is, EVPN-MPLS destinations and SDP-bindings need to be defined in the same split-horizon group. Therefore, if there is no split-horizon group defined in the B-VPLS, the first step is to add it. In this example, the split-horizon group is defined at the **config>service>pw-template>level**; therefore, it has to be added at the B-VPLS level.

Note:

When the **service>split-horizon-group** is removed, an eval-pw-template must be performed.

Note:

After adding the **split-horizon-group** at the service level, an eval-pw-template must be performed again so that the SDP-bindings take the new SHG configuration.

Note:

During the time between the **split-horizon-group** being removed and added back again, the SDP-bindings can forward BUM traffic to each other, so this operation must be done carefully to avoid loops.

Assuming that the first node to be migrated is PE-3, the following output shows the procedure for adding the **split-horizon-group** at the service level.

```
# on PE-3:
configure exclusive
service {
  pw-template "PW1" {
    pw-template-id 1
    delete split-horizon-group
  }
}

  pw-template-binding "PW1" {
    split-horizon-group "CORE"
  }
}
bgp-ad {
  admin-state enable
  vpls-id "64500:1000"
}
split-horizon-group "CORE" {
```

```
}

```

2. Add BGP-EVPN and ISID-policy configuration to the B-VPLS.

After the B-VPLS is configured with the split horizon group, the BGP-EVPN configuration (with admin-state disabled) and ISID-policy can be added, as follows.

```
# on PE-3:
configure {
  service {
    vpls "B-VPLS 1000" {
      bgp-evpn {
        evi 1000
        mpls 1 {
          admin-state disable      # must be disabled
          split-horizon-group "CORE"
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
    isid-policy {
      entry 10 {
        use-def-mcast true
        range {
          start 1001
          end 3000
        }
      }
    }
  }
}
```

3. Enable BGP-EVPN MPLS on the PE.

When the configuration is ready, the **bgp-evpn mpls 1** context can be enabled, as follows:

```
# on PE-3:
configure {
  service {
    vpls "B-VPLS 1000" {
      bgp-evpn {
        mpls 1 {
          admin-state enable
        }
      }
    }
  }
}
```

Enabling the **bgp-evpn mpls 1** context triggers a route-refresh message for the EVPN family from PE-3, but no changes happen because PE-3 does not create any EVPN destinations until it imports EVPN routes from the other PEs. The three spoke-SDPs to the remote PEs are still up.

4. Repeat steps 1 to 3 for the second PE (PE-5).

The same steps 1 to 3 are repeated for PE-5. When the **bgp-evpn mpls 1** context is enabled, PE-5 sends a route-refresh and gets the BGP-EVPN routes from PE-3. As a result of that, PE-3 brings down the spoke-SDP to PE-5 and creates an EVPN destination to PE-5. The same process happens in PE-5. The following CLI output shows the received routes in PE-3 and spoke-SDP going down.

```

=====
* indicates that the corresponding row element may have been truncated.

```

The reason why the spoke SDP toward PE-5 is down is an EVPN route conflict:

```

[/]
A:admin@PE-3# show service id 1000 sdp 32765:4294967293 detail | match Flag post-lines 1
Flags                : PWPeerFaultStatusBits
                    EvpnRouteConflict

```

An EVPN destination to PE-5 is created:

```
[/]
A:admin@PE-3# show service id 1000 evpn-mpls

```

5. Repeat Steps 1 to 3 for the rest of the PEs (PE-2, PE-4).

The same process is repeated in all the PEs, node by node. The service impact for the I-VPLS 1001 is minimal.

6. (Optional) Remove the ISID policy.

When all the PEs in the B-VPLS 1000 are migrated, the ISID policy can optionally be removed, node by node. This forces the B-VPLS instance to start using the MFIB to send I-VPLS BUM traffic to the remote nodes. This has no effect on Epipes (traffic is always unicast for Epipes).

Before removing the ISID policy and starting to use the MFIB, it is recommended to check that the Inclusive Multicast routes for an ISID to the remote PEs are all active. Otherwise, connectivity for BUM traffic could be interrupted if any of the expected routes are not active. This is illustrated for PE-3.

```

```

7. (Optional) Remove the BGP-AD configuration.

The BGP-AD configuration can stay in the B-VPLS services. However, when the entire network is migrated to PBB-EVPN, all the spoke-SDPs will be operationally down and, even if they are not forwarding traffic, they consume resources in the system. Consider removing the BGP-AD configuration and, therefore, the spoke-SDPs.

The following example shows the removal of BGP-AD in PE-4. Be aware that when BGP-AD is removed from the configuration, if the RD/RT was derived from the VPLS ID (as in this example), a new RD/RT must be auto-derived for the service. Therefore, new updates will be sent for all the EVPN NLRIs, as shown in the following output.

```

[/]
A:admin@PE-4# show service id 1000 bgp

"Status of SDP Bind 32765:4294967292 in service 1000 (customer 1) changed to admin=down
oper=down flags="
```

Initially, the RD/RT was derived from the VPLS ID (64500:1000). After the BGP-AD configuration is removed, a new RD and RT must be auto-derived from the EVI:

```
[/]
A:admin@PE-4# show service id 1000 bgp

=====
BGP Information
=====
Bgp Instance           : 1
Vsi-Import             : None
Vsi-Export             : None
Route Dist             : None
Oper Route Dist       : 192.0.2.4:1000

Oper RT Exp Origin    : derivedEvi
Oper RT Import       : 64500:1000
Oper RT Export       : 64500:1000

PW-Template Id       : None
-----
=====
```

In this case, the system picks up the RD in the following order:

- a. Manual RD or auto-RD always take precedence when configured.
- b. If no manual/auto-RD, the RD is derived from the **bgp-ad vpls-id**.
- c. If no manual/auto-rd/vpls-id configuration, the RD is derived from the **bgp evpn evi**.
- d. If no manual/auto-rd/vpls-id/evi configuration, there will be no RD and the service will fail.

If in the migration from BGP-AD to BGP-EVPN, the advertisement of new updates is not needed, the initial configuration must include manual/auto-RDs. If manual/auto-RDs were not included, disabling BGP-AD would not cause the change of RD and the consequent BGP updates.

PBB-EVPN multi-homing

This section provides configuration guidelines for PBB-EVPN multi-homing. In the same way that EVPN-MPLS supports single-active and all-active multi-homing, PBB-EVPN can also be configured to support both modes. The same Ethernet segment that is used for regular EVPN-MPLS service SAPs and spoke-SDPs can be shared with I-VPLS/Epipe SAPs and spoke-SDPs.

[Figure 102: PBB-EVPN multi-homing](#) shows the example topology used in this section.

Figure 102: PBB-EVPN multi-homing

26169

MTU-1 and MTU-6 have been added to the network (compared to [Figure 100: PBB-EVPN network without multi-homing](#)). I-VPLS 1001 has two new sites that are multi-homed to the PBB-EVPN network. MTU-1 uses all-active multi-homing, whereas MTU-6 is connected to a single-active ES. As with EVPN-MPLS, all-active multi-homing is only supported when a LAG is used at the access. Single-active multi-homing can be supported with regular Ethernet ports (that can form an independent LAG per PE) or SDPs.

RFC 7623 describes two types of system BMAC assignments that a PE can implement in a B-VPLS when ESs are present:

- Shared BMAC addresses that can be used for all the single-homed CEs and a number of multi-homed CEs connected to Ethernet-segments.
- Dedicated BMAC addresses per Ethernet segment.

In this chapter and in SR OS terminology:

- A shared BMAC address (in IETF) is a source BMAC address as configured in **service>(b)vpls>pbb>source-bmac**. All the I-VPLS/Epipe traffic coming from single-homed CEs is sent encapsulated in a PBB packet with that source BMAC address.
- A dedicated-BMAC per ES (in IETF) is an ES BMAC address as activated in **service>(b)vpls>pbb>source-bmac>use-es-bmac-lsb** and generated from the combination of **vpls>pbb>source-bmac** plus **ethernet-segment>pbb>source-bmac-lsb**. If configured, any I-VPLS/Epipe traffic coming from an ES is encapsulated in a PBB packet with the ES-BMAC address as the source BMAC address.

The system allows the following user choices per B-VPLS and ES:

- A dedicated ES BMAC address per ES can be used. In that case, the **pbbsource-bmac>use-es-bmac-lsb** command is configured in the B-VPLS. In all-active multi-homing, all the PEs that are part of the ES source the PBB packets with the same source ES BMAC address; single-active multi-homing requires the use of a different ES BMAC address per PE.
- A non-dedicated source BMAC address can be used (this is only possible in single-active multi-homing). In this case, the user does not configure **pbbsource-bmac>use-es-bmac-lsb** and the regular source BMAC address is used for the traffic. A different source BMAC address has to be advertised per PE.

As discussed, single-active multi-homing can use source BMAC addresses or ES BMAC addresses. Using one type or another has a different impact on CMAC flushing, as illustrated in [Figure 103: The use of ES BMAC to minimize CMAC flush](#).

- If ES BMAC addresses are used, as shown on the right-hand side of [Figure 103: The use of ES BMAC to minimize CMAC flush](#), a less-impacting CMAC flush is achieved, therefore minimizing the flooding after ES failures. In the case of ES failure, PE-1 withdraws the ES BMAC address 00:12 and the remote PE-3 only flushes the CMACs associated with that ES BMAC address (only the CMAC addresses behind the CE are flushed).
- If source BMAC addresses are used, as shown on the left-hand side of [Figure 103: The use of ES BMAC to minimize CMAC flush](#), in the case of ES failure, a BGP update with higher sequence number is issued by PE-1 and the remote PE-3 flushes all the CMAC addresses associated with the source BMAC address. Therefore, all the CMAC addresses behind the B-VPLS of the PEs will be flushed, as opposed to only the CMAC addresses behind the CE of the Ethernet Service Instances (ESIs).

Figure 103: The use of ES BMAC to minimize CMAC flush

al_0849

[Table 7: PBB-EVPN multi-homing supported combinations in SR OS](#) shows the PBB-EVPN multi-homing combinations supported in the current release in the topology of [Figure 102: PBB-EVPN multi-homing](#).

Table 7: PBB-EVPN multi-homing supported combinations in SR OS

CE Connectivity	PE Connectivity	PE Redundancy	BMAC Assignment	I-VPLS Support	Epipe Support
LAG (LACP optional)	LAG SAP	EVPN MH all-active	use-es-bmac-lsb (shared BMAC)	Yes	Yes
Ethernet ports (no LAG)	LAG SAP or port SAP	EVPN MH single-active	use-es-bmac-lsb (dedicated per PE)	Yes	No
Ethernet ports (no LAG)	LAG SAP or port SAP	EVPN MH single-active	source-bmac address (dedicated per PE)	Yes	No
MPLS	spoke-SDP	EVPN MH single-active	source-bmac address (dedicated per PE)	Yes	No
MPLS	spoke-SDP	EVPN MH single-active	use-es-bmac-lsb (dedicated per PE)	Yes	No

As an example, the configurations of the first, and last two, rows (LAG SAP all-active, MPLS source-BMAC, and MPLS ES-BMAC, respectively) will be discussed in the following three sections.

PBB-EVPN all-active multi-homing for I-VPLS and Epipes

Figure 102: PBB-EVPN multi-homing shows a PBB-EVPN network where ESI-23 is configured as an all-active multi-homing ES on PE-2 and PE-3. Two services are using ESI-23: I-VPLS 1001 and Epipe 1003. The following output shows the relevant configuration in PE-2:

```
# on PE-2:
configure {
  service {
    pbb {
      mac "PE-5" {
        address 00:00:00:00:00:05
      }
    }
  }
  system {
    bgp {
      evpn {
        ethernet-segment "ESI-23" {
          admin-state enable
          esi 01:00:00:00:00:23:00:00:00:01
          multi-homing-mode all-active
          df-election {
            es-activation-timer 3
          }
          association {
            lag "lag-1" {
            }
          }
        }
        pbb {
          source-bmac-lsb 23-23
        }
      }
    }
  }
}
```

```
    }
  }
  vpls "B-VPLS 1000" {
    admin-state enable
    service-id 1000
    customer "1"
    service-mtu 2000
    pbb-type b-vpls
    pbb {
      source-bmac {
        address 00:00:00:00:00:02
        use-es-bmac-lsb true
      }
    }
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 1000
    mpls 1 {
      admin-state enable
      split-horizon-group "CORE"
      ecmp 2
      auto-bind-tunnel {
        resolution any
      }
    }
  }
  split-horizon-group "CORE" {
  }
}
vpls "I-VPLS 1001" {
  admin-state enable
  service-id 1001
  customer "1"
  pbb-type i-vpls
  pbb {

    service-mtu 2000
    pbb-type b-vpls
    pbb {
      source-bmac {
        address 00:00:00:00:00:03
        use-es-bmac-lsb true
      }
    }
    bgp 1 {
    }
    bgp-evpn {
      evi 1000
      mpls 1 {
        admin-state enable
        split-horizon-group "CORE"
        ecmp 2
        auto-bind-tunnel {
          resolution any
        }
      }
    }
    split-horizon-group "CORE" {
    }
  }
  vpls "I-VPLS 1001" {
    admin-state enable
    service-id 1001
    customer "1"
    pbb-type i-vpls
    pbb {
      backbone-vpls "B-VPLS 1000" {
        isid 1001
      }
    }
  }
}
```

```

        sap 1/2/1:1001 {
        }
        sap lag-1:1001 {
        }
    }
    epipe "Epipe 1003" {
        admin-state enable
        service-id 1003
        customer "1"
        pbb {
            tunnel {
                backbone-vpls-service-name "B-VPLS 1000"
                isid 1003
                backbone-dest-mac-name "PE-5"
            }
        }
        sap lag-1:1003 {
        }
    }
}

```

The preceding configuration shows that Epipe 1003 has a PBB tunnel pointing at the PE-5 source-BMAC. Epipe 1003 has the following configuration in PE-5 (the PBB tunnel points at the ESI-23 ES-BMAC):

```

# on PE-5:
configure {
    service {
        pbb {
            mac "ES-MAC-23" {
                address 00:00:00:00:23:23
            }
        }
        epipe "Epipe 1003" {
            admin-state enable
            service-id 1003
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 1000"
                    isid 1003
                    backbone-dest-mac-name "ES-MAC-23"
                }
            }
            sap 1/2/1:1003 {
            }
        }
    }
}

```

Source-BMAC addresses and ES-BMAC addresses are distributed in BGP-EVPN. PE-2 and PE-3 will each advertise their own source-BMAC in a MAC route with ESI-0 and the shared ES-BMAC address with ESI-MAX (as per the RFC 7623). The ES-BMAC address that each PE uses in a B-VPLS is derived from the configured **service>(b)vpls>pbb>source-bmac** (four high-order bytes) and the ESI-23 configured **source-bmac-lsb**. In this example, PE-2 and PE-3 will both derive ES-BMAC 00:00:00:00:23:23. For both PEs to derive the required same ES-BMAC address, the four high-order bytes of the source-BMAC address must match on both PEs.

The **es-bmac-table-size** parameter modifies the default value (8) for the maximum number of ES-BMAC addresses that can be associated with the Ethernet segment across different B-VPLS services. When **source-bmac-lsb** is configured, the associated **es-bmac-table-size** is reserved out of the total FDB space.

The following outputs show the source-BMAC addresses and ES-BMAC address and how they are advertised and installed in the B-VPLS FDB.

```
[/]  
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "ESI-23" | match BMAC  
Source BMAC LSB      : 23-23
```

The following output shows that ES-BMAC is used and that the operational source-BMAC is 00:00:00:00:00:02.

```
[/]  
A:admin@PE-2# show service id 1000 base  
  
=====
```

PBB-EVPN all-active multi-homing is based on the same concepts as EVPN-MPLS all-active multi-homing: DF election, split-horizon, and aliasing.

Designated forwarder (DF) election

Only the DF PE for an ISID will send multicast traffic to the ES. The following command shows that PE-3 is the DF PE in ES "ESI-23" for ISID 1003:

```

[/]
A:admin@PE-3# show service system bgp-evpn ethernet-segment name "ESI-23"
                                                    isid isid-2 1003

```

The DF PE identifies multicast traffic by looking at either the destination BMAC or the EVPN label (which can be unicast or multicast).

In the case of Epipes, there are also DF and non-DF PEs. However, traffic is usually unicast (sent to the PBB tunnel backbone-destination BMAC). The non-DF PE will usually not discard Epipe traffic to the ES, unless the packet comes with an EVPN multicast label. To avoid packet duplication at the CE for Epipes, it is recommended to either:

- configure **discard-unknown** on all the B-VPLS instances where there are PBB-Epipes. This will prevent the ingress PE from flooding Epipe traffic if the PBB tunnel BMAC is unknown in the FDB.
- configure **ingress-replication-bum-label true** so that, when the PBB tunnel BMAC is unknown in the FDB, the ingress PE sends traffic with a multicast label. The non-DF will discard traffic identified as multicast at Epipes.

Ethernet segment split-horizon

In PBB-EVPN all-active multi-homing, the split-horizon function is not based in the ESI label but in a source BMAC check. When BUM traffic is received on an I-VPLS, the PE will encapsulate it in PBB using the ES-BMAC as source BMAC and the group BMAC for the ISID. When the DF PE for the ISID receives that packet, it will not send it back to the ES if the packet is identified as being originated from the ES itself (based on the ES-BMAC shared between the PEs).

Aliasing

Aliasing is based on the advertisement of the same ES-BMAC with MAX-ESI from the PEs part of the same ES. PE-2 and PE-3 advertise the ES-BMAC 00:00:00:00:23:23 with MAX-ESI (ESI = all FFs, as per the RFC 7623) and as Static (protected). When the remote PEs, PE-4, and PE-5, receive the two routes for the same BMAC and MAX-ESI, they will create a single EVPN-MPLS destination that will give more than one next-hop (in this case 2), as long as ECMP > 1:

If a failure occurs in the ES, the PE will withdraw the ES-BMAC and the remote PEs will remove one next-hop of the ES-BMAC EVPN-MPLS destination.

For PBB-Epipes, aliasing will also work, as long as shared-queuing or policing are enabled on the ingress PE Epipe. In [Figure 102: PBB-EVPN multi-homing](#), Epipe 1003 on PE-5 requires shared-queuing or policing at the ingress SAP. Otherwise, the traffic will be sent to only one PE of the ES (usually to the lower-IP PE).

For more information about the configuration of the Ethernet segment and its parameters, see the [EVPN for MPLS Tunnels](#) chapter.

PBB-EVPN single-active multi-homing for I-VPLS with source BMAC addresses

ESI-45 is a single-active Ethernet-segment (see [Figure 102: PBB-EVPN multi-homing](#)) with SDPs linked to it. As indicated in [Table 7: PBB-EVPN multi-homing supported combinations in SR OS](#), only I-VPLS services can be used in this configuration. As described in section [PBB-EVPN multi-homing](#), single-

active ES and B-VPLS services can be configured to either use source-BMAC addresses or ES-BMAC addresses. The following configuration shows the former option on PE-4:

```
# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-45" {
            admin-state enable
            esi 01:00:00:00:00:45:00:00:00:01
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              sdp 46 {
            }
          }
        }
        pbb {
          source-bmac-lsb 45-04
        }
      }
    }
  }
  sdp 46 {
    admin-state enable
    delivery-type mpls
    ldp true
    far-end {
      ip-address 192.0.2.6
    }
  }
  vpls "B-VPLS 1000" {
    admin-state enable
    service-id 1000
    customer "1"
    service-mtu 2000
    pbb-type b-vpls
    pbb {
      source-bmac {
        address 00:00:00:00:00:04
      }
    }
    bgp 1 {
    }
    bgp-evpn {
      evi 1000
      mpls 1 {
        admin-state enable
        split-horizon-group "CORE"
        ecmp 2
        auto-bind-tunnel {
          resolution any
        }
      }
    }
    split-horizon-group "CORE" {
    }
  }
  vpls "I-VPLS 1001" {
```

```

    }
}
spoke-sdp 46:1001 {
}
sap 1/2/1:1001 {
}
}

```

The configuration on PE-5 is similar:

```

# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 56 {
                                }
                            }
                        }
                        pbb {
                            source-bmac-lsb 45-05
                        }
                    }
                }
            }
        }
        sdp 56 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {

    pbb {
        backbone-vpls "B-VPLS 1000" {
            isid 1001
        }
    }
    spoke-sdp 56:1001 {
    }
    sap 1/2/1:1001 {
    }
}
}

```

With the preceding configuration, PE-4 and PE-5 will not advertise ES-BMAC addresses with MAX-ESI. Therefore, all the remote BMACs on PE-2 and PE-3 are associated with regular backbone EVPN-MPLS destinations. The CMAC addresses will be learned in the data plane associated with local SAP/SDP-bindings or remote BMAC addresses. An example for the I-VPLS and B-VPLS FDB in PE-2 follows:

```

[/]
A:admin@PE-2# show service id 1001 fdb detail pbb

=====

```

In the preceding example, the DF for ISID 1001 is PE-5. With a failure event on the SDP to MTU-6, PE-5 will not withdraw the advertised source BMAC (because it is still being used as source BMAC for other services and even CEs within the same service). PE-5 will send an update of the same source BMAC instead, increasing the sequence number in the MAC mobility extended community. That will be a *flush-all-from-me* indication for the remote PEs (they will flush all the CMACs associated with the updated source BMAC, regardless of the service).

When the former DF (PE-5) comes back up, PE-4 will become non-DF and will send a CMAC flush indication using the same mechanism as described above.

The following example shows a failure of SDP 56 in PE-5 and the corresponding DF switchover and CMAC flush.

```

# on PE-5:
221 2021/03/05 10:34:56.487 CET MINOR: SVCMGR #2095 Base
"Ethernet Segment:ESI-45, ISID:1001, Designated Forwarding state changed to:false"

219 2021/03/05 10:34:56.486 CET MINOR: SVCMGR #2303 Base
"Status of SDP 56 changed to admin=up oper=down"

```

PE-5 sends a BGP update with the same source BMAC, increasing the sequence number in the MAC mobility extended community—CMAC flush:

```

# on PE-5:
97 2021/03/05 10:34:56.487 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"

```

Individual SAP or spoke-SDP failures do not trigger any MAC flush or DF re-election. This is as per RFC 7623. In EVPN-MPLS, individual SAP/spoke-SDP failures are captured by the AD per-EVI withdrawal, which triggers a DF switchover.

PBB-EVPN single-active multi-homing for I-VPLS with ES-BMACs

As discussed throughout this chapter, the use of ES-BMACs for single-active multi-homing can minimize the number of CMACs flushed in a network. A simple change is necessary: configure the **use-es-bmac-lsb true** command and ensure that the generated ES-BMACs in PE-4 and PE-5 are different (the **source-bmac-lsb** in the previous configuration had different values for PE-4 and PE-5 already):

```
# on PE-4 and PE-5:
configure {
  service {
    vpls "B-VPLS 1000" {
      pbb {
        source-bmac {
          use-es-bmac-lsb true
        }
      }
    }
  }
}
```

On PE-4, the source BMAC LSB in ESI-45 is configured with a value of 45-04:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "ESI-45" | match BMAC
Source BMAC LSB      : 45-04
```

On PE-5, the source BMAC LSB in ESI-45 is configured with a value of 45-05:

```
[/]
A:admin@PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" | match BMAC
Source BMAC LSB      : 45-05
```

The remote PEs (such as PE-2 in the following output) will receive additional BGP EVPN-MAC routes for the ES-BMACs. The following FDB on PE-2 shows the source BMAC addresses of PE-4 and PE-5 and the ES BMAC address of DF PE-5.

```
[/]
A:admin@PE-2# show service id 1000 fdb detail

1000	00:00:00:00:00:05	mpls: 192.0.2.5:524279	EvpnS:P	03/05/21 10:05:42
	ldp:65539			
1000	00:00:00:00:45:05	mpls: 192.0.2.5:524279	EvpnS:P	03/05/21 10:37:14
	ldp:65539			

```
-----
No. of MAC Entries: 4
-----
Legend: L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
```

The benefit is that in case of a failure in ESI-45 (as before) the ES-BMAC is withdrawn and the remote PEs will only flush the CMACs associated with the remote ESI-45, as opposed to all the CMACs associated with PE-5.

PBB-EVPN single-active multi-homing for Epipes

In the network in [Figure 102: PBB-EVPN multi-homing](#), Epipes can only support single-homing or all-active multi-homing but not single-active. For non-local-switching PBB-Epipes (there is a single SAP per Epipe), only all-active multi-homing is supported. Single-active multi-homing for local-switching enabled PBB-Epipes (two SAPs are defined within the PBB-Epipe instance) is only supported in the following scenarios.

Figure 104: PBB-EVPN single-active support for Epipes

Single-active multi-homing is supported for redundancy in a two-node, three or four SAP, scenario, as displayed in [Figure 104: PBB-EVPN single-active support for Epipes](#). In these two cases, the Epipe PBB tunnel will be configured with the source BMAC of the remote PE node. When two SAPs are active in the same Epipe, local-switching is used to exchange frames between the CEs.

All-active multi-homing is not supported for redundancy in this scenario because the PE-1 PBB tunnel cannot point at a locally defined ES-BMAC.

PBB-EVPN multi-homing operation

See the [EVPN for MPLS Tunnels](#) chapter for the commands to operate Ethernet segments. Consider that there are no AD routes in PBB-EVPN. Also, the DF election algorithm will be based on the ISID values as opposed to EVIs.

Troubleshooting and debug commands

When troubleshooting PBB-EVPN networks, most of the troubleshooting commands discussed in [EVPN for MPLS Tunnels](#) can be used in the B-VPLS service and the base `service>system>bgp-evpn` instance. Some examples of useful commands are:

- `show redundancy bgp-evpn-multi-homing`

- show router bgp routes evpn (and filters)
- show service evpn-mpls [<TEP ip-address>]
- show service id bgp-evpn
- show service id evpn-mpls (and modifiers)
- show service id fdb pbb (and modifiers)
- show service system bgp-evpn
- show service system bgp-evpn ethernet-segment (and modifiers)
- debug router bgp update (in classic CLI)
- log-id "99"

In addition, the following **tools dump** commands also discussed in [EVPN for MPLS Tunnels](#) can help too:

- tools dump service evpn usage
- tools dump service system bgp-evpn ethernet-segment <name> isid <isid> df (Note: **isid** is used instead of **evi**.)

There are two aspects that are specific to PBB-EVPN and not EVPN:

1. Consumption of virtual BMAC addresses in the system— source BMACs, SAP BMACs, SDP BMACs, and ES BMACs are system BMACs that use FDB space but are not shown in the FDB together with the rest of the learned MAC addresses. The following command provides information about the virtual system MAC addresses consumed in the system.

```
[/]
A:admin@PE-3# tools dump redundancy src-bmac-lsb
Src-bmac-lsb:      3 (00-03) User: B-Vpls - 1 service(s)
Src-bmac-lsb:    8995 (23-23) User: Evpn Mpls

Total Src-bmac-lsbs = 2
```

2. Consumption of MFIBs — when ISIDs are not using the default-multicast list in the B-VPLS context for sending BUM traffic, an MFIB is consumed per ISID. The following command provides information about the consumption of MFIBs per system and per B-VPLS.

```
[/]
A:admin@PE-3# tools dump service vpls-pbb-mfib-stats detail

Conclusion

In addition to a full RFC 7432 EVPN-MPLS implementation, SR OS supports PBB-EVPN as per RFC 7623 for large Layer 2 deployments, including single-active and all-active multi-homing. This example has shown how to configure and operate a PBB-EVPN network focusing on the specific aspects of PBB-EVPN compared to EVPN-MPLS.

EVPN for VXLAN Tunnels (Layer 2)

This chapter provides information about Ethernet Virtual Private Network (EVPN) for Virtual eXtensible Local Area Network (VXLAN) tunnels in VPLS services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 12.0.R4. The MD-CLI in the current edition is based on SR OS Release 21.2.R1. Ethernet Virtual Private Network (EVPN) is a control plane technology and does not have line card hardware dependencies.

Overview

SR OS supports the EVPN control plane with Virtual eXtensible Local Area Network (VXLAN) data plane in VPLS services.

EVPN (RFC 7432) is an IETF technology that uses a dedicated BGP address family which allows VPLS services to be operated in a similar way to IP-VPNs, where the MAC addresses, IP addresses, and the information to set up the flooding tree are distributed by BGP. EVPN can be used as the control plane for different data plane encapsulations, such as VXLAN and MPLS.

VXLAN (RFC 7348) is an overlay IP tunneling technology used to carry Ethernet traffic over any IP network, and it is becoming the de facto standard for overlay data centers and networks. Compared to other IP overlay tunneling technologies, such as GRE, VXLAN supports multi-tenancy and multi-pathing:

- A tenant identifier, the VXLAN Network Identifier (VNI), is encoded in the VXLAN header and allows each tenant to have an isolated Layer 2 domain.
- VXLAN supports multi-pathing scalability through ECMP. VXLAN uses the outer source UDP port as an entropy field that can be used by the core IP routers to balance the load across different paths.

In SR OS, EVPN and VXLAN can be enabled in VPLS or R-VPLS services. In this chapter, EVPN-VXLAN services will refer to VPLS or R-VPLS services with EVPN and VXLAN enabled. These services can terminate/originate VXLAN tunnels and may have SAPs and/or SDP bindings at the same time. Some other SR OS implementation-specific considerations are the following:

- VXLAN is only supported on network or hybrid ports on Ethernet/LAG/POS/APS interfaces.
- VXLAN packets are originated/terminated with the system IPv4 address, in other words, a system originating VXLAN packets will use the system IP address as source outer IPv4 address and systems will only process VXLAN packets if their destination outer IPv4 address matches its own system IP address.
- Data plane MAC learning is not supported over VXLAN bindings. Only the control plane (EVPN) will be used for populating the FDB with MAC addresses associated with VXLAN bindings.

- EVPN provides support for the following features that are described in this chapter:
 - The BGP advertisement of the MAC addresses learned on SAPs, SDP-bindings and conditional static MACs to the remote BGP peers. The advertisement of MAC addresses in BGP can optionally be disabled.
 - The optional advertisement of an unknown MAC route, that allows the remote EVPN PEs or Network Virtualization Edge devices (NVEs) to suppress the unknown unicast flooding and send any unknown unicast frame to the owner of the unknown MAC route.
 - Ingress replication of Broadcast, Unknown unicast, and Multicast (BUM) packets over VXLAN.
 - A proxy-ARP table per service populated by the MAC-IP pairs received in BGP MAC advertisements. When an ARP request is received on a SAP or SDP-binding, the system will perform a lookup on this table and will reply to the ARP request if the lookup yields a valid result.
 - MAC mobility and static-MAC protection as described in RFC 7432, as well as MAC duplication detection.
- Multi-homing redundancy for SAPs and SDP-bindings in EVPN-VXLAN services is supported through BGP Multi-homing (L2VPN BGP address family). Only one BGP-MH site is supported in an EVPN-VXLAN service.

One of the main applications for EVPN-VXLAN services in SR OS is the Data Center Gateway (DC GW) function. In such an application, EVPN and VXLAN are expected to be used within the data center and VPLS SDP-bindings or SAPs are expected to be used for the connectivity to the WAN. When the system is used as a DC GW, a VPLS service is configured per Layer 2 domain that has to be extended to the WAN. In those VPLS services, BGP EVPN automatically sets up the VXLAN auto-bindings that connect the DC GW to the data center Network Virtual Edge devices (NVEs). The WAN connectivity is based on regular VPLS constructs where SAPs (null, dot1q, and QinQ), spoke-SDPs (FEC type 128 and 129, BGP-VPLS), and mesh-SDPs are supported. B-VPLS or I-VPLS services are not supported.

Although the DC GW application is one of the most common uses for this feature, this chapter focuses on the configuration and operation of EVPN-VXLAN for Layer 2 services in general, and its integration with regular VPLS services in MPLS networks.

Configuration

This section describes the configuration of EVPN-VXLAN on SR OS as well as the available troubleshooting and show commands. This example focuses on the following configuration aspects:

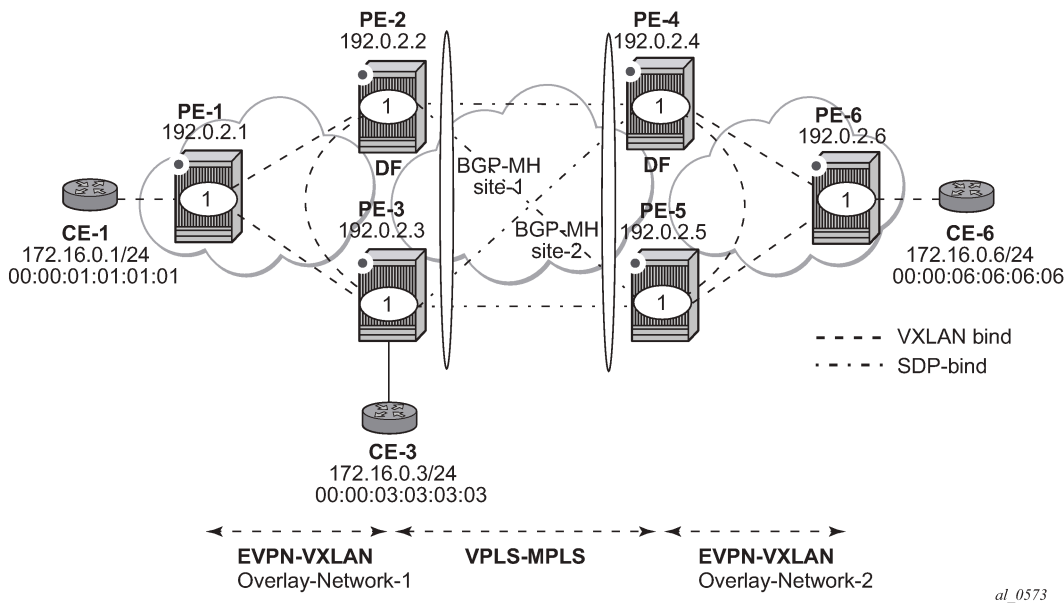

- Enabling EVPN and VXLAN in a VPLS service, including the use of BGP-EVPN, BGP Auto-discovery (BGP-AD), and BGP-Multi-homing (BGP-MH) in the same VPLS instance.
- Scaling BGP-MH resiliency with the use of operational groups (oper-groups).
- Use of proxy-ARP in EVPN-VXLAN services
- MAC mobility, MAC duplication, and MAC protection in EVPN-VXLAN services.

The configuration will be shown for PE-1, PE-2, and PE-3 only; the PEs in Overlay-Network-2 ([Figure 105: EVPN-VXLAN example topology](#)) have an equivalent configuration.

Enabling EVPN-VXLAN in a VPLS service

[Figure 105: EVPN-VXLAN example topology](#) shows the topology used in this example.

Figure 105: EVPN-VXLAN example topology

at_0573

The example topology shows two overlay (VXLAN) networks interconnected by an MPLS network:

- PE-1, PE-2, and PE-3 are part of Overlay-Network-1
- PE-4, PE-5, and PE-6 are part of Overlay-Network-2

CE-1, CE-3, and CE-6 belong to the same IP subnet, therefore, Layer 2 connectivity must be provided to them.

The example topology can illustrate a Data Center Interconnect (DCI) example, where Overlay-Network-1 and Overlay-Network-2 are two data centers interconnected through an MPLS WAN. In this application, CE-1, CE-3, and CE-6 simulate virtual machines or appliances, PE-2/3/4/5 act as DC GWs and PE-1/6 as NVEs (or virtual PEs running on compute infrastructure).

The following protocols and objects are configured beforehand:

- The ports interconnecting the six PEs in [Figure 105: EVPN-VXLAN example topology](#) are configured as network ports (or hybrid) and have router network interfaces defined on them. Only the ports connected to the CEs are configured as access ports.
- The six PEs shown in the [Figure 105: EVPN-VXLAN example topology](#) are running IS-IS for the global routing table with the four core PE nodes interconnecting using IS-IS Level-2 point-to-point interfaces and each overlay network is using IS-IS Level-1 point-to-point interfaces.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, and PE-5. There is no LDP running in the two overlay networks.
- The network port MTU (in all the ports sending/receiving VXLAN packets) must be at least 50 bytes (54 if dot1q encapsulation is used) greater than the service MTU in order to accommodate the size of the VXLAN header.

Once the IGP infrastructure and LDP are enabled in the core, BGP has to be configured. In this example, two BGP families have to be enabled: EVPN within each overlay network for the exchange of MAC/IP

addresses and setting up the flooding domains, and L2-VPN for the use of BGP-MH and BGP-AD in the VPLS-MPLS network.

As an example, the following CLI output shows the relevant BGP configuration of PE-1, which only needs the EVPN family. PE-6 would have a similar BGP configuration. The use of route reflectors (RRs) in this type of scenarios is common. Although this example does not use RRs, an EVPN RR could have been used in Overlay-Network-1 and Overlay-Network-2 and an L2-VPN RR could have been used in the core VPLS-MPLS network.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
    }
    group "DC" {
      peer-as 64500
      family {
        evpn true
      }
    }
    neighbor "192.0.2.2" {
      group "DC"
    }
    neighbor "192.0.2.3" {
      group "DC"
    }
  }
}
```

The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        l2-vpn true
        evpn true
      }
    }
    group "DC" {
      peer-as 64500
      family {
        l2-vpn true
        evpn true
      }
    }
    group "WAN" {
      peer-as 64500
      family {
        l2-vpn true
      }
    }
  }
}
```

```

    }
    neighbor "192.0.2.1" {
        group "DC"
    }
    neighbor "192.0.2.3" {
        group "DC"
    }
    neighbor "192.0.2.4" {
        group "WAN"
    }
    neighbor "192.0.2.5" {
        group "WAN"
    }
}

```

The BGP configuration on PE-3 is as follows:

```

# on PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            rapid-update {
                l2-vpn true
                evpn true
            }
        }
        group "DC" {
            peer-as 64500
            family {
                l2-vpn true
                evpn true
            }
        }
        group "WAN" {
            peer-as 64500
            family {
                l2-vpn true
            }
        }
        neighbor "192.0.2.1" {
            group "DC"
        }
        neighbor "192.0.2.2" {
            group "DC"
        }
        neighbor "192.0.2.4" {
            group "WAN"
        }
        neighbor "192.0.2.5" {
            group "WAN"
        }
    }
}

```

The BGP configuration on PE-4 and PE-5 is equivalent.

Figure 106: BGP adjacencies and enabled families shows the BGP peering sessions among the PEs and the enabled BGP families. PE-1 will only establish an EVPN peering session with its peers (only the EVPN family is enabled on PE-1), even though PE-2 and PE-3 have EVPN and L2-VPN families configured.

Figure 106: BGP adjacencies and enabled families

al_0575

Once the network infrastructure is running properly, the actual service configuration can be carried out. The following CLI outputs show the configuration of VPLS 1 in PE-1, PE-2, and PE-3 as per the topology illustrated in [Figure 105: EVPN-VXLAN example topology](#).

VPLS 1 in those three PEs are interconnected using VXLAN bindings, whereas PE-2 and PE-3 are connected to the remote PEs by means of BGP-AD SDP-bindings. Although BGP-AD SDP-bindings are used in this example for the connectivity of the EVPN-VXLAN PEs to a regular VPLS network, SAPs, BGP-VPLS spoke-SDPs, manual spoke-SDPs, or mesh-SDPs could have been used instead.

VPLS 1 is configured on PE-1, as follows:

```
# on PE-1:
configure {
  service {
    vpls "VPLS1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.1:1"
        route-target {
          export "target:64500:12"
          import "target:64500:12"
        }
      }
    }
    bgp-evpn {
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
    }
    sap 1/2/1:1 {
    }
  }
}
```

EVPN-VXLAN is enabled by the configuration of a valid VXLAN Network Identifier (VNI) and the **bgp-evpn>vxlan>admin-state enable** command. These two commands, along with the required BGP Route Distinguisher (RD) and Route Target (RT) information, are the minimum mandatory attributes:

- The VNI is a 24-bit identifier with valid values in the [1..16777215] range. This defines the VNI that SR OS will use in the EVPN routes generated for the VPLS service, and therefore the VNI that the system expects to see in the VXLAN packets destined to that particular VPLS service. The configured VNI determines the VNI that has to be received in the packets for the VPLS service, but not the VNI that will be sent in VXLAN packets to remote PEs for the service. In other words, in this example, VPLS 1 is configured with VNI=1 in all the PEs; however, each PE could have used a different VNI. The VNI is a system-wide significant value and two VPLS services cannot be configured with the same VNI.
- The **bgp-evpn>vxlan>admin-state enable** command enables the use of EVPN for VXLAN. It requires the previous configuration of the VNI, RD, and RT. As soon as this command is executed, EVPN will advertise an inclusive multicast route to all the BGP EVPN peers (regardless of the existing SAP/SDP-binding operational status). The exchange of inclusive multicast routes allows the establishment of the VXLAN bindings among the PEs.

Upon the reception of the EVPN inclusive multicast routes from PE-2 and PE-3, PE-1 will automatically set up its VXLAN bindings for VPLS 1. A VXLAN binding is represented by an (egress VTEP, egress VNI) pair, where VTEP is a VXLAN Termination End Point. This can be shown with the following show commands on PE-1:

```
[/]
A:admin@PE-1# show service vxlan

=====
VXLAN Tunnel Endpoints (VTEPs)
=====
VTEP Address                VXLAN Dest    ES Dest
-----
192.0.2.2                    1              0
192.0.2.3                    1              0
-----
Number of VTEPs: 2
-----
=====
```

```
[/]
A:admin@PE-1# show service id 1 vxlan instance 1 destinations

=====
Egress VTEP, VNI
=====
Instance  VTEP Address      Egress VNI  EvpnStatic Num
Mcast    Oper State        L2 PBR      SupBcasDom  MACs
-----
1         192.0.2.2         1           evpn        1
BUM      Up
1         192.0.2.3         1           evpn        1
BUM      Up
-----
Number of Egress VTEP, VNI : 2
-----
-----snip-----
```

To actually see this output, the VPLS service needs to be configured on all PEs, with import and export policy "vsi-policy-1" defined on the core PEs; see further. As can be seen in the CLI output, PE-1 has two

VXLAN bindings: one to PE-2 and one to PE-3. Both use egress VNI=1 (the actual VNI used in its egress VXLAN packets) and both are part of the flooding multicast list (BUM) for VPLS 1 and are up. There is no layer 2 Policy-Based Routing (L2 PBR).

- The **Mcast= BUM** entry is set when the proper inclusive multicast route is received from the remote VTEP. The VXLAN binding will be used to flood BUM packets.
- The **Oper State** is based on the existence of the VTEP in the global routing table.

The VPLS 1 configuration of PE-2 and PE-3 is as follows:

```
# on PE-2:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
    }
    vpls "VPLS1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.2:1"
        vsi-import ["vsi-policy-1"]
        vsi-export ["vsi-policy-1"]
        pw-template-binding "PW1" {
          split-horizon-group "CORE"
        }
      }
      bgp-ad {
        admin-state enable
        vpls-id "64500:1"
      }
      bgp-evpn {
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      bgp-mh-site "site-1" {
        admin-state enable
        id 1
        shg-name "CORE"
      }
    }
  }
}
```

```
# on PE-3:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
    }
    vpls "VPLS1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
```

```

        vni 1
    }
}
bgp 1 {
    route-distinguisher "192.0.2.3:1"
    vsi-import ["vsi-policy-1"]
    vsi-export ["vsi-policy-1"]
    pw-template-binding "PW1" {
        split-horizon-group "CORE"
    }
}
bgp-ad {
    admin-state enable
    vpls-id "64500:1"
}
bgp-evpn {
    vxlan 1 {
        admin-state enable
        vxlan-instance 1
    }
}
bgp-mh-site "site-1" {
    admin-state enable
    id 1
    shg-name "CORE"
}
}
sap 1/2/1:1 {
}

```

In addition to the VNI and **bgp-evpn>vxlan>admin-state enable** commands for enabling EVPN-VXLAN in VPLS 1, PE-2 and PE-3 require the configuration of BGP-AD for the discovery and establishment of FEC129 spoke-SDPs to the remote PEs in the core, as well as BGP-MH for redundancy. As described in [Figure 105: EVPN-VXLAN example topology](#), there are two BGP-MH sites defined in the network: site-1 is used on PE-2/PE-3 and site-2 is used on PE-4/PE-5. Only one of the two gateway PEs in each overlay network will be the Designated Forwarder (DF) for VPLS 1, and only the DF will send/receive traffic for VPLS 1 in the overlay network. The following considerations must be taken into account when configuring the connectivity of EVPN-VXLAN services to regular VPLS objects:

- As discussed, in this example, BGP-AD spoke-SDPs are used, but SAPs, BGP-VPLS spoke-SDPs, manual spoke-SDPs, or mesh-SDPs are also supported.
- In this example, BGP-AD spoke-SDPs are auto-instantiated using **pw-template-binding "PW1" split-horizon-group "CORE"**.
 - This requires the creation of the pw-template "PW1" (**config>service>pw-template "PW1"**).
- The split-horizon group CORE is added to the BGP-MH site "site-1". This statement will ensure that all the spoke-SDPs automatically established to the remote PEs are part of the BGP-MH site.
- Although the route targets for the overlay network and the VPLS-MPLS network can have the same value for the same VPLS service, they are usually different. This example assumes the use of RT-DC-1 in Overlay-Network-1 and RT-WAN-1 in the VPLS-MPLS core for VPLS 1. The "vsi-policy-1" allows the system to export and import the right RTs for VPLS 1 on the core PEs:

```

# on PE-2 and PE-3:
configure {
    policy-options {
        community "RT-DC-1" {
            member "target:64500:12" { }
        }
    }
}

```

```

community "RT-WAN-1" {
  member "target:64500:11" { }
}
policy-statement "vsi-policy-1" {
  entry 10 {          # to import all the EVPN routes with RT-DC-1
    from {
      family [evpn]
      community {
        name "RT-DC-1"
      }
    }
    action {
      action-type accept
    }
  }
  entry 20 {          # to import all the BGP-AD/MH routes from the WAN
    from {
      family [l2-vpn]
      community {
        name "RT-WAN-1"
      }
    }
    action {
      action-type accept
    }
  }
  entry 30 {          # to export all the EVPN routes with "RT-DC-1"
    from {
      family [evpn]
    }
    action {
      action-type accept
      community {
        add ["RT-DC-1"]
      }
    }
  }
  entry 40 {          # to export all the BGP-AD/MH routes with "RT-WAN-1"
    from {
      family [l2-vpn]
    }
    action {
      action-type accept
      community {
        add ["RT-WAN-1"]
      }
    }
  }
  default-action {
    action-type reject
  }
}
}

```

Once PE-2 and PE-3 are configured as shown, they will set up the spoke-SDPs and will run the DF election algorithm to determine the operational status of those spoke-SDPs. See chapters [LDP VPLS Using BGP Auto-Discovery](#) and [BGP Multi-Homing for VPLS Networks](#) for more information about the use of BGP-AD and BGP-MH.

In the configuration for VPLS 1, both gateway PEs, PE-2 and PE-3, will attempt to establish two parallel Layer 2 paths between each other (a BGP-AD spoke-SDP and an EVPN VXLAN binding). Because that would create a Layer 2 loop, the SR OS implementation gives priority to the EVPN path and only the VXLAN binding will be active. In other words, when a VXLAN (egress VTEP, VNI) and a spoke-SDP are

attempted to be set up to the same far-end IP address at the same time, the VXLAN path will prevail and the spoke-SDP will be kept down. The spoke-SDP will only be brought up if the VXLAN (egress VTEP, VNI) goes down.

This behavior can be easily observed in this setup by using the following **show** commands. In PE-2, the spoke-SDP to far-end PE-3 will be down with an **EvpnRouteConflict** Flag. The (egress VTEP, VNI) = (192.0.2.3, 1) VXLAN bind will be up.

MAC learning and unknown-mac

Once the VPLS service (VPLS 1) is configured, the network allows the CEs to exchange unicast and BUM traffic over the overlay and VPLS-MPLS service infrastructure. BUM traffic sent by CE-1 will be ingress-replicated by PE-1 to PE-2 and PE-3, and propagated by PE-2 (the DF) to the remote network. From this point on, MAC addresses will be learned on active SAPs and spoke-SDPs and advertised in EVPN MAC routes. No data plane MAC learning is carried out on VXLAN bindings. MACs associated with (egress VTEP, VNI) bindings will always be learned through EVPN.

The following CLI output shows the reception of an EVPN MAC route on PE-1 and how the (CE-3) MAC address appears in the FDB for VPLS 1.

```

```

When a frame destined to 00:00:03:03:03:03 enters SAP 1/2/1:1, it is encapsulated into a VXLAN packet with outer destination IP 192.0.2.3 and VNI 1, and sent on the wire.

In virtualized data center networks where all the MACs are known beforehand (all the virtual machine and appliance MACs are distributed by EVPN before any traffic flows), unknown MAC addresses are always outside the data center. If that is the case, the DC GWs can make use of the **unknown-mac true** so that the DC NVEs supporting the concept of this route send the unknown unicast traffic only to the DC GW. This minimizes the flooding within the data center, as described in draft-ietf-bess-dci-evpn-overlay.

In this example, the unknown MAC route is configured in the gateway PEs (in Overlay-Network-1: PE-2 and PE-3) in the following way:

```

# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS1" {
      bgp-evpn {
        routes {
          mac-ip {
            unknown-mac true
          }
        }
      }
    }
  }
}

```

```

47 2021/02/10 16:00:36.068 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

      bgp-tunnel-encap:VXLAN
"

```

Note that:

- Although SR OS can generate the unknown MAC route, it will never honor it and normal flooding applies when an unknown unicast packet arrives at an ingress SAP/SDP-binding.
- When **unknown-mac true** is configured, it will only be generated when: a) no BGP-MH site is configured within the same VPLS service or b) a site is configured and the site is DF in the PE. If the site becomes a non-DF site, the unknown MAC route will be withdrawn.
- If the **unknown-mac true** is used in the DC GW and all the NVEs in the DC understand it, the advertisement of MAC addresses can be disabled with the **routes>mac-ip>advertise false** command. If so, SR OS will only advertise the unknown MAC route.

```

# on DC GWs PE-2 and PE-3:
configure {
  service {
    vpls "VPLS1" {
      bgp-evpn {
        routes {
          mac-ip {
            advertise false
            unknown-mac true
          }
        }
      }
    }
  }
}

```

Scaling BGP-MH resiliency with the use of operational groups

In [Figure 105: EVPN-VXLAN example topology](#), VPLS 1 in PE-2 and PE-3 is configured with a BGP-MH site that controls which of the two PEs forwards the traffic to the remote PEs (in this case, PE-2 is the DF and the GW responsible for forwarding packets to the remote PEs).

When new VPLS services are required in PE-2 and PE-3, the same BGP-MH configuration can be used. However, if the number of VPLS services grows significantly, the use of individual BGP-MH sites per service will not scale. Because all the services in these two PEs share the same physical topology, the use of operational groups can provide a simple and scalable way of providing resiliency to as many services as the user needs (up to the maximum number of VPLS services per system).

The way operational groups can be used to scale this type of deployments is the following (using the network topology in [Figure 105: EVPN-VXLAN example topology](#) and focusing on Overlay-Network-1):

- A control-VPLS service is defined in PE-2 and PE-3. For instance, VPLS 1.
 - This service is configured with a BGP-MH site in both PEs.
 - An oper-group “control-vpls-1” is created and associated with the pw-template-binding 1 in VPLS 1.
- Data VPLS services are defined in both PEs. For instance: VPLS 2, VPLS 3,... VPLS 999.

- In all these services, the pw-template-binding is configured with **monitor-oper-group "control-vpls-1"**.
- The status of the spoke-SDPs in the data VPLS services depends on the status of the operational group. If there is a DF switchover in VPLS 1 and VPLS 1 spoke-SDPs go down on PE-2, all the spoke-SDPs in all the data VPLS services controlled by "control-vpls-1" in PE-2 will go down too. In the same way, the spoke-SDPs in PE-3 will come up.
- To allow per-service load balancing, a second control-VPLS service with a different BGP-MH site should be configured.
 - For instance, VPLS 1 may have PE-2 as the DF and VPLS 1000 may be a second control-VPLS service with PE-3 as the DF.
 - Each control-VPLS would control a group of data VPLS services based on the definition and association of a second operational group.

The following example shows the modification of VPLS 1 as the control-VPLS and the configuration of VPLS 2 as a data-VPLS on PE-2. VPLS 1 controls the VPLS 2 spoke-SDP status.

```
# on PE-2:
configure {
  service {
    oper-group "control-vpls-1" {
    }
    vpls "VPLS1" {
      description "control-VPLS"
      bgp 1 {
        pw-template-binding "PW1" {
          oper-group "control-vpls-1"
        }
      }
    }
    vpls "VPLS2" {
      admin-state enable
      description "data-VPLS"
      service-id 2
      customer "1"
      vxlan {
        instance 1 {
          vni 2
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.2:2"
        vsi-import ["vsi-policy-2"]
        vsi-export ["vsi-policy-2"]
        pw-template-binding "PW1" {
          monitor-oper-group "control-vpls-1"
        }
      }
    }
    bgp-ad {
      admin-state enable
      vpls-id "64500:2"
    }
    bgp-evpn {
      routes {
        mac-ip {
          unknown-mac true
        }
      }
    }
    vxlan 1 {

```

```
    admin-state enable
    vxlan-instance 1
  }
}
```

Use of proxy-ARP in EVPN-VXLAN services

EVPN-VXLAN services support proxy-ARP functionality that is enabled by the **proxy-arp admin-state** command. By default, proxy-ARP is disabled. When proxy-ARP is enabled, the following applies:

- MAC and IP addresses contained in the received valid EVPN MAC routes are populated in the proxy-ARP table.
- ARP-request messages received on SAPs and SDP-bindings are intercepted and the target IP address is looked up. If the IP address is found, an ARP reply will be issued based on the information found in the proxy-ARP table, otherwise the ARP request would be flooded in the VPLS service (except for the source SAP/SDP binding).
- ARP-reply messages received on SAPs and SDP-bindings are also intercepted and sent to the CPM. These ARP-reply messages are re-injected in the data plane and forwarded based on the FDB information to the destination MAC address. If the destination MAC address is not in the FDB, the ARP-reply message will be flooded in the VPLS service (except for the source SAP/SDP binding).

The following CLI output shows the proxy-ARP configuration in PE-3 and a received valid MAC route that includes the MAC address 00:00:01:01:01:01 and IP address 172.16.0.1 of CE-1. This MAC-IP pair is installed in the proxy-ARP table for VPLS 1.

```
# on PE-3:
configure {
  service {
    vpls "VPLS1" {
      proxy-arp {
        admin-state enable
      }
    }
  }
}
```

```

SR OS does not include a host IP address in any EVPN MAC advertisement for a MAC learned on a SAP or SDP-binding. Host IP addresses are only included in the EVPN MAC advertisements corresponding to R-VPLS IP interfaces. When deployed as DC GW in a Nuage architecture, the Nuage Networks Virtual Services Controller (VSC) or Virtual Services Gateway (VSG) will send virtual machine and host MAC/IP pairs in EVPN MAC routes. See the Nokia Nuage documentation for more information about the Nuage DC architecture. The 7x50 DC GW will populate the proxy-ARP tables with those MAC/IP pairs.

In the preceding CLI excerpt, assume that PE-1 is replaced by a Nuage VSC that sends the pair <172.16.0.1, 00:00:01:01:01:01> in an EVPN MAC route. PE-3 receives the advertisement and adds the entry to its proxy-ARP table for VPLS 1.

The proxy-ARP feature was significantly improved in SR OS Release 13.0; see the [EVPN for MPLS Tunnels](#) chapter.

MAC mobility, MAC duplication, and MAC protection in EVPN

MAC mobility, duplication and protection are fully supported as specified in RFC 7432. [Figure 107: EVPN MAC mobility](#) illustrates the concept of mobility (Virtual Machine VM-1 moves from PE-1 to PE-3).

Figure 107: EVPN MAC mobility

MAC mobility is handled in EVPN by the use of sequence numbers in the MAC routes. When 00:00:01:01:01:01 moves from PE-1 to PE-3, SR OS will gracefully handle it in this way:

- 00:00:01:01:01:01 moves to PE-3 SAP 1/2/1:1
- PE-3 advertises 00:00:01:01:01:01 using a higher sequence number (the first time a MAC is advertised, EVPN uses sequence number 0).
- PE-2 at this point has two valid MAC routes for 00:00:01:01:01:01. It picks up the one coming from PE-3 because the sequence number is higher.
- PE-1 receives the MAC route, and because the sequence number is higher than the one for its own route, it updates the FDB and withdraws its own MAC route.

However, if MAC 00:00:01:01:01:01 is constantly learned on the PE-1 and PE-3 SAPs, the preceding process causes an endless exchange of MAC route advertisements and withdraws that has a negative impact on all the PEs in the EVPN network. This issue is known as *MAC duplication* and is originated by a loop at the access or a duplicated MAC address in two hosts of the same service. SR OS solves this issue through the use of the MAC duplication detection feature. MAC duplication is always enabled with the following default settings:

```
[ex:/configure service vpls "VPLS1" bgp-evpn]
A:admin@PE-3# info detail | match 'mac-duplication' post-lines 7
  mac-duplication {
    retry 9
    blackhole false
    detect {
      num-moves 5
      window 3
    }
  }
```

Where:

num-moves

Identifies the number of MAC moves in a VPLS service. The counter is incremented when a MAC is locally relearned in the FDB or flushed from the FDB because of the reception of a better remote EVPN route for that MAC. When the threshold is reached for a MAC address, this MAC address is put in hold-down state (this 'hold-down' state is described below). Range: <3..10>. Default value: 5.

window

Identifies the timer within which a MAC is considered duplicate if it reaches the configured num-moves. Range: <1..15> minutes. Default value: 3 minutes.

retry

The timer after which the MAC in hold-down state is automatically flushed and the mac-duplication process starts again. This value is expected to be equal to two times or more than the window. If no retry is configured, this implies that, once MAC duplication is detected, MAC updates for that MAC will be held down until the user intervenes or a network event (that flushes the MAC) occurs. Range: <2..60> minutes. Default value: 9 minutes.

blackhole

If enabled and a duplicate MAC address is detected, the router adds the MAC address to the duplicate MAC list and it programs the MAC in the FDB as a protected MAC associated with a black-hole (with type EvpnD:P and source ID "black-hole")

When a MAC address is considered a duplicate or in the hold-down state, no further BGP advertisements are issued for this MAC and an alarm is triggered (by the first MAC address in hold-down state). The following CLI output shows how PE-3 detects that MAC 00:00:01:01:01:01 is a duplicate (after reaching the **num-moves** in **window**) and the corresponding alarm.

Log 99 on PE-3 shows the following message when EVPN has detected a duplicate MAC address in VPLS 1:

```
# on PE-3:
154 2021/02/10 16:18:58.902 UTC MINOR: SVCMGR #2331 Base
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

The **show service id bgp-evpn** command shows the MAC duplication settings and the list of duplicate MAC addresses on hold-down.

```

---snip---
```

SR OS stops sending and processing any BGP MAC advertisement routes for that MAC address until:

- The MAC is flushed because of a local event (SAP/SDP-binding associated with the MAC fails) or the reception of a remote withdraw for the MAC (because of a MAC flush at the remote 7x50).
- The **retry** *<in_minutes>* timer expires, which flushes the MAC and restart the process.

When the last duplicate MAC address is removed from the duplicate list, log 99 on PE-3 will show the following message:

```
155 2021/02/10 16:21:58.885 UTC MINOR: SVCNMR #2332 Base
"VPLS Service 1 no longer has MAC(s) detected as duplicates by EVPN mac-duplication
detection."
```

EVPN also provides a mechanism to protect specific MAC addresses that do not move for which connectivity must be guaranteed. These addresses must be protected in case there is an attempt to dynamically learn them in a different place in the EVPN-VXLAN VPLS service (on the same or different PE).

The protected MAC addresses are configured in SR OS as conditional static MAC addresses. A conditional static MAC address defined in an EVPN-VXLAN VPLS service is advertised by BGP-EVPN as a static address. An example of the configuration of a conditional static MAC address is as follows:

```
# on PE-1:
configure {
  service {
    vpls "VPLS1"
    fdb {
      static-mac {
        mac 00:00:05:05:05:05 {
          sap 1/2/1:1
```

```

```

The following procedures are supported to protect the configured static MAC addresses:

- All the SAP/SDP-bindings are internally configured as MAC protect restrict-protected-src as soon as BGP-EVPN is enabled in the VPLS service.
- Local static MAC addresses or remote EVPN static MAC addresses are considered as protected.
- If a frame with a source MAC address matching one of the protected MAC addresses is received on a different SAP/SDP-binding than the owner of the protected MAC address, the frame is discarded and an alarm triggered. This MAC protection is not performed for frames received on VXLAN bindings.
- The same throttled alarm mechanism used in MAC protect for restrict-protected-src with discard-frame is used here: the offending frames are captured to a list to be polled by the CPM every ~10min.

In this example, PE-3 has 00:00:05:05:05:05 in its FDB as EvpnS. If SAP 1/2/1:1 on PE-3 receives a frame with source MAC address 00:00:05:05:05:05, the frame is discarded and an alarm triggered. The following is logged in log 99 on PE-3:

```

164 2021/02/10 16:44:03.736 UTC MINOR: SVCNMR #2208 Base Slot 1
"Protected MAC 00:00:05:05:05:05 received on SAP 1/2/1:1 in service 1. "
    
```

Debug and show commands

In addition to the previously mentioned **show service id vxlan destinations**, **show service id bgp-evpn** and **show service id fdb detail** commands, the following commands provide valuable information when troubleshooting an EVPN-VXLAN VPLS service.

The **show router bgp routes evpn** command supports filtering by route type as well as many other route fields.

Conclusion

SR OS supports the EVPN control plane for VXLAN tunnels terminated in VPLS services. VXLAN is an overlay IP tunneling mechanism that is being used in data centers, data center interconnect, and other applications. EVPN is a scalable and flexible control plane that provides control over the MAC addresses being learned and advertised, as well as other mechanisms to optimize Layer 2 services such as proxy-ARP, MAC mobility, MAC duplication detection, and MAC protection. SR OS provides a resilient and scalable EVPN-VXLAN solution for Layer 2 services, including interoperability to existing VPLS networks. This chapter showed all of those functions and how they are configured and operated.

EVPN for VXLAN Tunnels (Layer 3)

This chapter provides information about EVPN for VXLAN tunnels (Layer 3).

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter is applicable to SR OS and was initially written for Release 12.0.R4. The MD-CLI in the current edition is based on SR OS Release 21.10.R3. Ethernet Virtual Private Network (EVPN) is a control plane technology and does not have line card hardware dependencies.

Chapter [EVPN for VXLAN Tunnels \(Layer 2\)](#) is prerequisite reading.

Overview

As discussed in the [EVPN for VXLAN Tunnels \(Layer 2\)](#) chapter, EVPN and VXLAN can be enabled on VPLS or R-VPLS services in SR OS. Where that chapter focuses on the use of EVPN-VXLAN layer 2 services, in other words, how EVPN-VXLAN is configured in VPLS services, this chapter describes how EVPN-VXLAN can be used to provide inter-subnet forwarding in R-VPLS and VPRN services. Inter-subnet forwarding can be provided by regular R-VPLS and VPRN services. However, EVPN provides an efficient and unified way to populate Forwarding Databases (FDBs), Address Resolution Protocol (ARP) tables, and routing tables using a single BGP address family. Inter-subnet forwarding in overlay networks would otherwise require data plane learning and the use of routing protocols on a per VPRN basis.

The SR OS solution for inter-subnet forwarding using EVPN is based on building blocks described in *draft-ietf-bess-evpn-inter-subnet-forwarding* and the use of the EVPN IP-prefix routes (route type 5) as described in RFC 9136. This example describes three supported common scenarios and provides the CLI configuration and required tools to troubleshoot EVPN-VXLAN in each case. The scenarios configured and described are:

- EVPN-VXLAN in R-VPLS services
- EVPN-VXLAN in Integrated Routing Bridging (IRB) backhaul R-VPLS services
- EVPN-VXLAN in EVPN tunnel R-VPLS services

In all these scenarios, redundant PEs are usually deployed. If that is the case, the interaction of EVPN, IP-VPN, and the Routing Table Manager (RTM) may lead to some routing loop situations that must be avoided by using routing policies (this also may happen in traditional IP-VPN deployments when eBGP and MP-BGP interact to populate VPRN routing tables in multi-homed networks). This chapter describes when those routing loops can happen and how to avoid them.

The term IRB interface refers to an R-VPLS service bound to a VPRN IP interface. The terms IRB interface and R-VPLS interface are used interchangeably throughout this chapter.

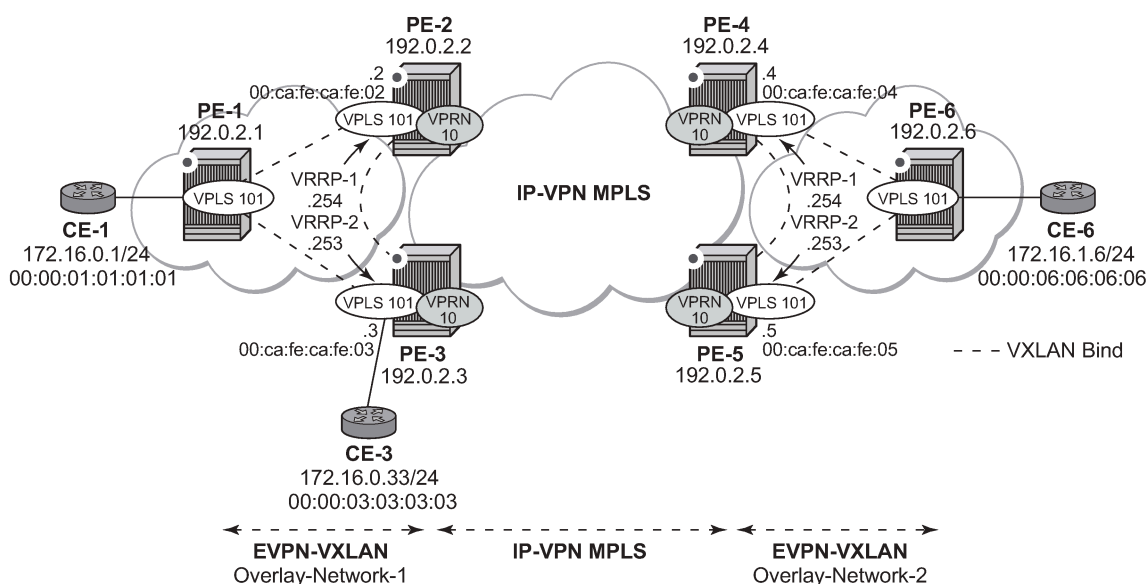

Configuration

This section describes the configuration of EVPN-VXLAN for Layer 3 services on SR OS, as well as the available troubleshooting and show commands. The three scenarios described in the overview are analyzed independently.

EVPN-VXLAN in an R-VPLS service

Figure 108: EVPN-VXLAN for R-VPLS services shows the topology used in the first scenario.

Figure 108: EVPN-VXLAN for R-VPLS services

al_0576

The network topology shows two overlay (VXLAN) networks interconnected by an MPLS network:

- PE-1, PE-2, and PE-3 are part of Overlay-Network-1
- PE-4, PE-5, and PE-6 are part of Overlay-Network-2

A Layer 2/Layer 3 service is provided to a customer to connect CE-1, CE-3, and CE-6. In this scenario, Layer 2 connectivity is provided within each overlay network and inter-subnet connectivity (Layer 3) is provided between the overlay networks. VPLS "evi-101" is defined within each overlay network and VPRN "VPRN10" connects both Layer 2 services through an IP-VPN MPLS network.

This topology can illustrate a Data Center Interconnect (DCI) example, where Overlay-Network-1 and Overlay-Network-2 are two data centers interconnected through an MPLS WAN. In this application, CE-1, CE-3, and CE-6 simulate virtual machines or appliances, PE-2/3/4/5 act as Data Center Gateways (DC GWs) and PE-1/6 as Network Virtualization Edge devices (or virtual PEs running on a compute infrastructure).

The following protocols and objects are configured beforehand:

- The ports interconnecting the six PEs in [Figure 108: EVPN-VXLAN for R-VPLS services](#) are configured as network or hybrid ports and have router network interfaces defined in them. Only the ports connected to the CEs are configured as access ports.
- The six PEs are running IS-IS for the global routing table with the four core PEs interconnected using IS-IS Level-2 point-to-point interfaces and each overlay network using IS-IS Level-1 point-to-point interfaces.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, and PE-5. There is no LDP running within the overlay networks.
- The network port MTU (in all the ports sending/receiving VXLAN packets) must be at least 50 bytes (54 if dot1q encapsulation is used) greater than the service MTU to accommodate the size of the VXLAN header.

Once the IGP infrastructure and LDP in the core are enabled, BGP is configured. In this scenario, two BGP families must be enabled: EVPN within each overlay network for the exchange of MAC/IP addresses and setting up the flooding domains, and VPN-IPv4 among the four core PEs so that IP prefixes can be exchanged and resolved to MPLS tunnels in the core.

The following MD-CLI shows the BGP configuration of PE-1, which only needs the EVPN family. PE-6 has a similar BGP configuration, that is, only EVPN family is configured for its peers. The use of Route Reflectors (RRs) in these scenarios is common. Although this scenario does not use RRs, an EVPN RR could have been used in Overlay-Network-1 and Overlay-Network-2 and a separate VPN-IPv4 RR could have been used in the core IP-VPN MPLS network.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true

            peer-ip-tracking true
            rapid-update {
                evpn true
            }
        }
        group "DC" {
            peer-as 64500
            family {
                vpn-ipv4 true
                evpn true
            }
        }
        group "WAN" {
            peer-as 64500
            family {
                vpn-ipv4 true
            }
        }
        neighbor "192.0.2.1" {
            group "DC"
        }
        neighbor "192.0.2.2" {
            group "DC"
        }
    }
}
```

```

neighbor "192.0.2.4" {
  group "WAN"
}
neighbor "192.0.2.5" {
  group "WAN"
}
}

```

The DC GWs PE-4 and PE-5 have an equivalent BGP configuration.

[Figure 109: BGP adjacencies and enabled families](#) shows the BGP peering sessions among the PEs and the enabled BGP families. PE-1 and PE-6 only establish an EVPN peering session with their peers (only the EVPN family is enabled on PE-1 and PE-6, even if the peer PEs are VPN-IPv4 capable as well).

Figure 109: BGP adjacencies and enabled families

al_0578

When the network infrastructure is running properly, the actual service configuration, as illustrated in [Figure 108: EVPN-VXLAN for R-VPLS services](#), can be carried out. The following MD-CLI shows the configuration for VPLS "evi-101" and VPRN "VPRN10" in PE-1, PE-2, and PE-3. The other overlay network has a similar configuration.

```

# on PE-1:
configure {
  service {
    vpls "evi-101" {
      admin-state enable
      service-id 101
      customer "1"
      vxlan {
        instance 1 {
          vni 101
        }
      }
    }
    proxy-arp {
      admin-state enable
    }
    bgp 1 {
      route-distinguisher "192.0.2.1:101"
      route-target {
        export "target:64500:101"
        import "target:64500:101"
      }
    }
    bgp-evpn {
      vxlan 1 {

```

```

        admin-state enable
        vxlan-instance 1
    }
}
sap 1/2/1:101 {
}
}

```

Proxy-ARP is disabled (default) on PE-2, as well as on the other core PEs:

```

# on PE-2:
configure {
    service {
        vpls "evi-101" {
            admin-state enable
            service-id 101
            customer "1"
            vxlan {
                instance 1 {
                    vni 101
                }
            }
        }
        routed-vpls {
        }
        bgp 1 {
            route-distinguisher "192.0.2.2:101"
            route-target {
                export "target:64500:101"
                import "target:64500:101"
            }
        }
        bgp-evpn {
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
            }
        }
    }
    vprn "VPRN10" {
        admin-state enable
        service-id 10
        customer "1"
        ecmp 2
        bgp-ipvpn {

For details about the EVPN and VXLAN configuration in VPLS "evi-101" on PE-1, see chapter [EVPN for VXLAN Tunnels \(Layer 2\)](#). The configuration of VPLS "evi-101" on PE-2 and PE-3 has the following important aspects:

- The **routed-vpls** command is required so that the R-VPLS can be bound to VPRN "VPRN10".
- The service name "evi-101" is configured when the service is created and cannot be modified afterward. The service name must match the name configured in the VPLS interface in VPRN "VPRN10".
- Even though EVPN and VXLAN are properly configured, proxy-ARP cannot be enabled in VPLS "evi-101". In an R-VPLS with EVPN-VXLAN, proxy-ARP is not supported and the VPRN ARP table is used instead. When an EVPN MAC route that includes an IP address is received in an R-VPLS, the MAC-IP pair encoded in the route is added to the ARP table of the VPRN, as opposed to the proxy-ARP table.

```

*[ex:/configure service vpls "evi-101" proxy-arp]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "evi-101" proxy-arp admin-state -
configuration not supported on routed-vpls - configure service vpls "evi-101" routed-vpls

```

When configuring VPRN "VPRN10" on PE-2 and PE-3, the following considerations must be taken into account:

- When trying to enable existing VPRN features on interfaces linked to EVPN-VXLAN R-VPLS interfaces, the **radius-auth-policy** command is not supported:

```

*[ex:/configure service vprn "VPRN10" interface "int-1"]

```

```
A:admin@PE-2# radius-auth-policy "authPol1"

*[ex:/configure service vprn "VPRN10" interface "int-1"]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vprn "VPRN10" interface "int-1" radius-auth-policy
- Combination of radius authentication policy and vpls binding not supported - configure
service vprn "VPRN10" interface "int-1"
```

- Dynamic routing protocols such as IS-IS, RIP, or OSPF are not supported.
- In general, no SR OS control plane generated packets are sent to the egress VXLAN bindings except for ARP, VRRP, ICMP, BFD, and Eth-CFM.
- As shown in [Figure 108: EVPN-VXLAN for R-VPLS services](#) and in the CLI excerpts, VRRP can be configured on the VPLS interfaces in VPRN "VPRN10" to provide default gateway redundancy to the hosts connected to VPLS "evi-101". Two VRRP instances are configured so that VPLS "evi-101" upstream traffic can be load-balanced to PE-2 and PE-3. With VRRP on EVPN-VXLAN R-VPLS interfaces:
 - **Ping-reply** and **traceroute-reply** can be configured and are supported. BFD is also supported to speed up the fault detection.
 - **standby-forwarding**, even if it were configured for VRRP, would not have any effect in this configuration: the standby PE will never see any flooded traffic sent to it, so this command is not applicable to this scenario.
- When a VPRN "VPRN10" VPLS interface is bound to VPLS "evi-101", EVPN advertises all the IP addresses configured for that VPLS interface as MAC routes with a static MAC indication. For the remote EVPN peers, that means that those MAC addresses linked to remote IP interfaces are protected. VRRP virtual IP/MACs are also advertised by EVPN as "static" and so protected. In the example of [Figure 108: EVPN-VXLAN for R-VPLS services](#), the VPLS "evi-101" FDB in PE-1 shows the IP interface MAC addresses and VRRP MAC addresses as **EvpnS:P** (Static and protected MAC) as shown in the following output:

```

EVPN-VXLAN in IRB backhaul R-VPLS services

[Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services](#) illustrates the second inter-subnet forwarding scenario, where Layer 3 connectivity must be provided not only between the overlay networks but also within each overlay network. In the example shown in [Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services](#), a customer (tenant) has different subnets and connectivity must be provided across all of them (CE-1, CE-3, and CE-6 must be able to communicate), bearing in mind that EVPN-VXLAN is enabled in each overlay network and IP-VPN MPLS is used to interconnect both overlay networks. VPLS "evi-201" is an IRB Backhaul R-VPLS service because it provides connectivity to the VPRN instances.

Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services

al_0579

From a BGP peering perspective, there is no change in this scenario compared to the previous one: PE-1 and PE-6 only support the EVPN address family. However, in this scenario, CE-1 is now connected to an R-VPLS directly linked to the VPRN instances in PE-2/PE-3. As a result of that, IP prefixes must be exchanged between PE-1 and PE-2/PE-3. EVPN can advertise not only MAC routes and Inclusive Multicast routes, but also IP prefix routes that contain IP prefixes that can be installed in the attached VPRN routing table.

As an example, the VPRN "VPRN20" and VPLS "evi-201" configurations on PE-1, PE-2, and PE-3 are shown. Similar configurations are needed in PE-4, PE-5, and PE-6.

On PE-1, VPRN "VPRN20" and VPLS "evi-201" are configured as follows:

```
# on PE-1:
configure {
  service {
    vpls "evi-201" {
      admin-state enable
      service-id 201
      customer "1"
      vxlan {
        instance 1 {
          vni 201
        }
      }
    }
    routed-vpls {
    }
  }
  bgp 1 {
    route-distinguisher "192.0.2.1:201"
    route-target {
      export "target:64500:201"
      import "target:64500:201"
    }
  }
  bgp-evpn {
  }
}
```

```

        routes {
            ip-prefix {
                advertise true
            }
        }
        vxlan 1 {
            admin-state enable
            vxlan-instance 1
        }
    }
}
vprn "VPRN20" {
    admin-state enable
    service-id 20
    customer "1"
    interface "int-PE-1-CE-1" {
        ipv4 {
            primary {
                address 172.16.1.254
                prefix-length 24
            }
        }
        sap 1/2/1:20 {
        }
    }
    interface "int-evi-201" {
        ipv4 {
            primary {
                address 172.16.0.1
                prefix-length 24
            }
        }
        vpls "evi-201" {
        }
    }
}
}

```

On PE-2, VPRN "VPRN20" and VPLS "evi-201" are configured as follows:

```

# on PE-2:
configure {
    service {
        vpls "evi-201" {
            admin-state enable
            service-id 201
            customer "1"
            vxlan {
                instance 1 {
                    vni 201
                }
            }
        }
        routed-vpls {
        }
        bgp 1 {
            route-distinguisher "192.0.2.2:201"
            route-target {
                export "target:64500:201"
                import "target:64500:201"
            }
        }
    }
    bgp-evpn {
        routes {
            ip-prefix {

```

```

        advertise true
    }
}
vxlان 1 {
    admin-state enable
    vxlan-instance 1
}
}
vprn "VPRN20" {
    admin-state enable
    service-id 20
    customer "1"
    bgp-ipvpn {
        mpls {
            admin-state enable
            route-distinguisher "192.0.2.2:20"
            vrf-target {
                community "target:64500:20"
            }
            auto-bind-tunnel {
                resolution any
            }
        }
    }
    interface "int-evi-201" {
        ipv4 {
            primary {
                address 172.16.0.2
                prefix-length 24
            }
        }
        vpls "evi-201" {
        }
    }
}
}

```

On PE-3, VPRN "VPRN20" and VPLS "evi-201" are configured as follows:

```

# on PE-3:
configure {
    service {
        vpls "evi-201" {
            admin-state enable
            service-id 201
            customer "1"
            vxlan {
                instance 1 {
                    vni 201
                }
            }
        }
        routed-vpls {
        }
        bgp 1 {
            route-distinguisher "192.0.2.3:201"
            route-target {
                export "target:64500:201"
                import "target:64500:201"
            }
        }
    }
    bgp-evpn {
        routes {
            ip-prefix {

```

```

        advertise true
    }
}
vxlان 1 {
    admin-state enable
    vxlan-instance 1
}
}
sap 1/2/1:20 {
}
}
vprn "VPRN20" {
    admin-state enable
    service-id 20
    customer "1"
    bgp-ipvpn {
        mpls {
            admin-state enable
            route-distinguisher "192.0.2.3:20"
            vrf-target {
                community "target:64500:20"
            }
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
interface "int-evi-201" {
    ipv4 {
        primary {
            address 172.16.0.3
            prefix-length 24
        }
    }
    vpls "evi-201" {
    }
}
}
}

```

As shown in the CLI excerpt, the configuration in the three nodes (PE-1, PE-2, and PE-3) for VPLS "evi-201" and VPRN "VPRN20" is very similar. The main difference is the **auto-bind-tunnel** command in VPRN 20 on PE-2 and PE-3. This command allows the VPRN "VPRN20" on PE-2 and PE-3 to receive IP-VPN routes from the core and resolve them to MPLS tunnels. VPRN "VPRN20" on PE-1 does not require such command because all its IP prefixes are resolved to local interfaces or to EVPN peers.

The **routes>ip-prefix>advertise** command enables:

- The advertisement of IP prefixes in EVPN, in routes type 5. All the existing IP prefixes in the attached VPRN "VPRN20" routing table are advertised in EVPN within the VPLS "evi-201" context (except for the ones associated with VPLS "evi-201" itself).
- The installation of IP prefixes in the attached VPRN "VPRN20" routing table with a preference of 169 (BGP-VPN routes for IP-VPN have a preference of 170) and a next-hop of the gateway IP (GW IP) address included in the EVPN IP prefix route.

For instance, the following output shows that PE-1 advertises the IP prefix 172.16.1.0/24 as an EVPN route to PE-3 (a similar route is sent to PE-2), captured by a **//debug router bgp update** session.

```

=====

```

The subnet 172.16.0.0/24 is used on the interfaces "int-evi-201" in overlay network 1 and subnet 172.16.2.0/24 is used on similar interfaces in overlay network 2. CE-1 has an IP address in subnet 172.16.1.0/24 and CE-6 has an IP address in subnet 172.16.6.0/24. The next hop to reach 172.16.2.0/24 (overlay network 2) or CE-6, is 172.16.0.2 (PE-2), but it could have been PE-3.

There is redundancy in the example setup and therefore, loops can occur. To avoid loops, routing policies need to be configured on the core PEs (PE-2, PE-3, PE-4, and PE-5). These policies are described in the [Use of routing policies to avoid routing loops in redundant PEs](#) section for routing loop use case 1.

The routing table on PE-2 shows a EVPN-IFF route toward CE-1 (subnet 172.16.1.0/24) via PE-1. The route toward CE-6 uses a tunnel toward PE-4 in overlay network 2.

```

=====

```

When checking the operation of EVPN in this scenario, it is important to observe that the right next hops and prefixes are successfully installed in the routing table of VPRN "VPRN20":

- EVPN IP prefixes are sent using a GW IP address matching the primary IP interface address of the R-VPLS for which the routes are sent. For instance, as shown above, IP prefix 172.16.1.0/24 is advertised from PE-1 with GW IP address 172.16.0.1, which is the IP address configured for the VPLS interface in VPRN "VPRN20" on PE-1. In the routing tables of VPRN "VPRN20" on PE-2 and PE-3, IP prefix 172.16.1.0/24 is installed with next hop 172.16.0.1. Traffic arriving at PE-2 or PE-3 on VPRN "VPRN20" with IP Destination Address (DA) in the 172.16.1.0/24 subnet matches the mentioned routing table entry. As usual, the next-hop is resolved by the ARP table to a MAC address and the MAC address resolved by the FDB table to an egress VTEP, VNI.
- IP prefixes in the routing table of VPRN "VPRN20" are advertised in IP-VPN to the remote IP-VPN MPLS peers. Received IP-VPN prefixes are installed in the routing table of VPRN "VPRN20" using the

remote PE system IP address as the next hop, as usual. For instance, 172.16.6.0/24 is installed in the routing table of VPRN "VPRN20" on PE-2 with next-hop (tunneled) 192.0.2.4 and preference 170.

The following considerations of how the routing table manager (RTM) handles EVPN and IP-VPN prefixes must be taken into account:

- Only VPRN interface primary addresses are advertised as GW IP in EVPN IP prefix routes. Secondary addresses are never sent as GW IP addresses.
- EVPN IP prefixes are advertised by default as soon as the **routes>ip-prefix>advertise** command is enabled and there are active IP prefixes in the attached VPRN routing table.
- If the same IP prefix is received on a PE via EVPN and IP-VPN at the same time for the same VPRN, by default, the EVPN prefix is selected because its preference (169) is better than the IP-VPN preference (170).
- Because EVPN has a better preference compared to IP-VPN, when the VPRNs on redundant PEs are attached to the same R-VPLS service, routing loops may occur. The use case described here is an example where routing loops can occur. Check the [Use of routing policies to avoid routing loops in redundant PEs](#) section to avoid routing loops in redundant PEs for more information.
- When the command **routes>ip-prefix>advertise** is enabled, the subnet IP prefixes are advertised in EVPN but not the host IP prefixes (/32 prefixes associated with the local interfaces). If the user wants to advertise the host IP prefixes as well, the **routes>ip-prefix>include-direct-interface-host** command must be configured. The following example illustrates this.

```
[/]
A:admin@PE-1# show router 20 route-table

When the **routes>ip-prefix>include-direct-interface-host** command is enabled on VPLS "evi-201" on PE-1, PE-1 advertises the host routes as well and these are installed in the routing tables on the remote PEs.

```
# on PE-1:
configure {
  service {
    vpls "evi-201" {
      bgp-evpn {
        routes {
          ip-prefix {
            advertise true
            include-direct-interface-host true
          }
        }
      }
    }
  }
}
```

```
[/]
A:admin@PE-2# show router 20 route-table
```

Route Table (Service: 20)

Dest Prefix[Flags] Next Hop[Interface Name]	Type	Proto	Age	Metric	Pref
172.16.0.0/24 int-evi-201	Local	Local	00h11m40s	0	0

172.16.1.254/32 172.16.0.1	Remote	EVPN-IFF	00h00m11s	169	0
172.16.2.0/24 192.0.2.4 (tunneled)	Remote	BGP VPN	00h04m27s	170	10
172.16.6.0/24 192.0.2.4 (tunneled)	Remote	BGP VPN	00h04m27s	170	10

No. of Routes: 5
Flags: n = Number of times nexthop is repeated

```
B = BGP backup route available
L = LFA nexthop available
S = Sticky ECMP requested
```

- ECMP is fully supported for the VPRN for EVPN IP prefix routes coming from different GW IP next-hops. However, ECMP is not supported for IP prefixes routes belonging to different owners (EVPN and IP-VPN). ECMP is enabled in VPRN "VPRN20" on PE-1, as follows:

```
# on PE-1:
configure {
  service {
    vprn "VPRN20" {
      ecmp 2
    }
  }
}
```

When policies are applied that prevent routing loops, as described in section [Use of routing policies to avoid routing loops in redundant PEs](#), both PE-2 and PE-3 have IP-VPN tunnels for IP prefixes 172.16.2.0/24 and 172.16.6.0/24. In that case, an additional route with a different GW IP as next hop is installed in the routing table for these IP prefixes:

```
[/]
A:admin@PE-1# show router 20 route-table

```

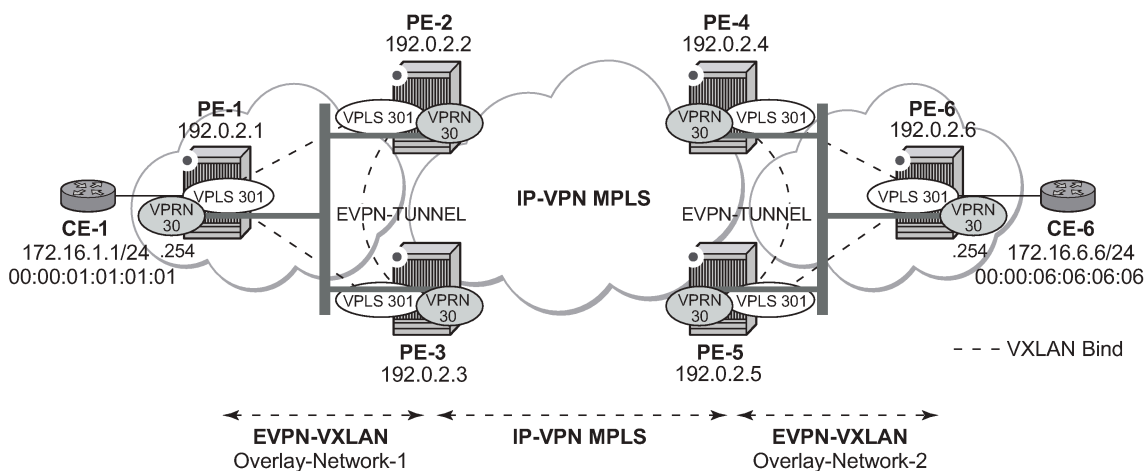

EVPN-VXLAN in EVPN tunnel R-VPLS services

The previous scenario shows how to use EVPN-VXLAN to provide inter-subnet forwarding for a tenant, where R-VPLS services can contain hosts and also offer transit services between VPRN instances. For example, in the use case shown in [Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services](#), VPLS "evi-201" in Overlay-Network-1 is an R-VPLS that can provide intra-subnet connectivity to all the hosts in subnet 172.16.0.0/24 (for example, CE-3 belongs to this subnet) but it can also provide transit or

backhaul connectivity to hosts in subnet 172.16.1.0/24 (for example, CE-1) sending packets to subnets 172.16.2.0/24 or 172.16.6.0/24.

In some cases, the R-VPLS where EVPN-VXLAN is enabled does not need to provide intra-subnet connectivity and it is purely a transit or backhaul service where VPRN IRB interfaces are connected. [Figure 111: EVPN-VXLAN in EVPN-tunnel R-VPLS services](#) illustrates this use case.

Figure 111: EVPN-VXLAN in EVPN-tunnel R-VPLS services

Compared to the preceding use case in [Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services](#), in this case the R-VPLS connecting the IRB interfaces in Overlay-Network-1 (VPLS "evi-301") does not have any connected host. If that is the case, VPLS "evi-301" can be configured as an EVPN tunnel.

EVPN tunnels are enabled using the **evpn-tunnel** command under the R-VPLS interface configured on the VPRN. EVPN tunnels bring the following benefits to EVPN-VXLAN IRB backhaul R-VPLS services:

- Easier and simpler provisioning of the tenant service: if an EVPN tunnel is configured in an IRB backhaul R-VPLS, there is no need to provision the IRB IP addresses in the VPRN. This makes the provisioning easier to automate and saves IP addresses from the tenant IP space.
- Higher scalability of the IRB backhaul R-VPLS: if EVPN tunnels are enabled, BUM traffic is suppressed in the EVPN-VXLAN IRB backhaul R-VPLS service (it is not required). As a result, the number of VXLAN bindings in IRB backhaul R-VPLS services with EVPN tunnels can be much higher.

As an example, the VPRN "VPRN30" and VPLS "evi-301" configurations on PE-1, PE-2, and PE-3 are shown. Similar configurations are needed in PE-4, PE-5, and PE-6.

```
# on PE-1:
configure {
  service {
    vpls "evi-301" {
      admin-state enable
      service-id 301
      customer "1"
      vxlan {
        instance 1 {
          vni 301
        }
      }
    }
  }
  routed-vpls {
```

```
    }
    bgp 1 {
        route-distinguisher "192.0.2.1:301"

                resolution filter
                resolution-filter {
                    ldp true
                }
            }
        }
    }
    interface "int-evi-301" {
        vpls "evi-301" {
            evpn-tunnel {
            }
        }
    }
}
}
}

```

As shown in the preceding output, the configuration in the three nodes (PE-1/2/3) for VPLS "evi-301" and VPRN "VPRN30" is similar to the configuration of VPLS "evi-201" and VPRN "VPRN20" in the preceding scenario. When the **evpn-tunnel** command is added to the VPRN interface, there is no need to configure an IP interface address. The option **evpn-tunnel** can be enabled independently of **routes>ip-prefix>advertise** (although no route type 5 advertisements are sent when **routes>ip-prefix>advertise false** is configured).

A VPRN supports regular IRB backhaul R-VPLS services as well as EVPN tunnel R-VPLS services. A maximum of eight R-VPLS services with **routes>ip-prefix>advertise** enabled per VPRN is supported (in any combination of regular IRB R-VPLS or EVPN tunnel R-VPLS services). EVPN tunnel R-VPLS services do not support SAPs or SDP-bindings. No frames are flooded in an EVPN tunnel R-VPLS service, and, in fact no inclusive multicast routes are exchanged in R-VPLS services that are configured as EVPN tunnels.

The **show service id vxlan destinations** command for an R-VPLS service configured as an EVPN tunnel shows <egress VTEP, VNI> bindings excluded from Mcast, in other words, the VXLAN bindings are not used to flood BUM traffic:

```

The process followed upon receiving a route type 5 on a regular IRB R-VPLS interface (preceding scenario) differs from the one for an EVPN tunnel type (this scenario):

- IRB backhaul R-VPLS VPRN interface:
 - When a route type 2 that includes an IP address is received and it becomes active, the MAC/IP information is added to the FDB and ARP tables. This can be checked with the **show router 30 arp** command and the **show service id 301 fdb detail** command.
 - When a route type 5 is received on (for instance) PE-2, and becomes active for the R-VPLS service, the IP prefix is added to the VPRN routing table regardless of the existence of a route type 2 that can resolve the GW IP address. If a packet is received from the WAN side and the IP lookup hits an entry for which the GW IP (IP next-hop) does not have an active ARP entry, the system will ARP to get the MAC. If the ARP is resolved but the MAC is unknown in the FDB table, the system floods the ARP message into the R-VPLS multicast list. Routes type 5 can be checked in the routing table with the **show router 30 route-table** command and the **show router 30 fib 1** command.
- EVPN tunnel R-VPLS VPRN interface:
 - When a route type 2 is received and becomes active, the MAC address is added to the FDB (only). This MAC address is normally a GW MAC address.
 - When a route type 5 is received on (for instance) PE-1, the system looks for the GW MAC address. The IP prefix is added to the VPRN routing table with next hop equal to EVPN-tunnel GW MAC; for example, ET-02:13:ff:00:00:6a is an EVPN tunnel with GW MAC 02:13:ff:00:00:6a. The GW MAC address is added from the GW MAC extended community sent along with the route type 5 for prefix 172.16.6.0/24. If a packet is received from CE-1 and the IP lookup hits an entry for which the next hop is an EVPN tunnel: GW MAC, the system looks up the GW MAC address in the FDB. Normally a route type 2 with the GW MAC address has already been received so that the GW MAC address has been added to the FDB. If the GW MAC address is not present in the FDB, the packet will be dropped.
 - The IP prefixes with GW MAC addresses as next hops for the setup in [Figure 111: EVPN-VXLAN in EVPN-tunnel R-VPLS services](#) are displayed in the **show router 30 route-table** command, as follows:

```

[/]
A:admin@PE-1# show router 30 route-table

```

IP prefix routes sent for EVPN tunnel R-VPLS services do not contain a GW IP address (the GW IP address is zero) but convey a GW MAC address that is used in the peer VPRN routing table. The following output shows PE-2's VPRN "VPRN30" interface MAC address sent to PE-1:

```

[/]
A:admin@PE-2# show router 30 interface "int-evi-301" detail | match "MAC "
MAC Address      : 02:13:ff:00:00:6a   Mac Accounting   : Disabled

```

When **routes>ip-prefix>advertise true** is configured, PE-2 sends route type 5 messages to PE-1, as can be seen in the following BGP update for the route toward subnet 172.16.6.0/24 in overlay network 2, using the MAC address as GW MAC address:

```

# on PE-2:
configure {
  service {
    vpls "evi-301" {
      bgp-evpn {
        routes {

```

```

        ip-prefix {
            advertise true
        }
    }
}

221 2022/03/02 11:54:51.734 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1

```

In the routing table of VPRN "VPRN30" on PE-2, IP prefixes are shown with an EVPN tunnel next-hop (GW MAC) as opposed to an IP next-hop, therefore, the user may think that no ARP entries are consumed by VPRN "VPRN30". However, internal ARP entries are still consumed in VPRN "VPRN30". Although not shown in the **show router 30 arp** command, the **summary** option shows the consumption of internal ARP entries for EVPN.

```

[/]
A:admin@PE-2# show router 30 route-table

```

One internal BGP-EVPN ARP entry is consumed, as can be seen as follows:

```
[/]  
A:admin@PE-2# show router 30 arp summary  
  
=====  
ARP Table Summary (Service: 30)  
=====  
Local ARP Entries      : 1  
Static ARP Entries     : 0  
Dynamic ARP Entries    : 0  
Managed ARP Entries   : 0  
Internal ARP Entries   : 0  
BGP-EVPN ARP Entries  : 1  
-----  
No. of ARP Entries    : 2  
=====
```

The number of BGP-EVPN ARP entries in the **show router 30 arp summary** command matches the number of remote valid GW MAC addresses for VPRN "VPRN30".

Routing policies for IP prefixes in EVPN

Routing policies are supported for IP prefixes imported or exported through BGP EVPN. The default import and export behavior for IP prefixes in EVPN can be modified by using routing policies applied either at peer level (**config>router>bgp>group/neighbor>import/export**) or VPLS level (**config>service>vpls>bgp>vsi-import/vsi-export**).

When applying routing policies to control the distribution of prefixes between EVPN and IP-VPN, the user must take into account that both families are completely separated as far as BGP is concerned and that when prefixes from a family are imported in the RTM, the BGP attributes are lost to the other family. The use of tags allows the controlled distribution of prefixes across the two families.

[Figure 112: Routing policies for egress EVPN routes](#) illustrates how VPN-IPv4 routes are imported into the RTM and then passed onto EVPN for its own processing. VPN-IPv4 routes can be tagged at ingress and this tag is preserved throughout the RTM and EVPN processing so that the tag can be matched by the egress BGP routing policy. In this example, egress EVPN routes matching tag 10, are modified to add a site-of-origin (SOO) community origin:64500:1.

Figure 112: Routing policies for egress EVPN routes

al_0583

Policy tags can be used to match EVPN IP-prefixes that were learned not only from BGP VPN-IPv4 but also from other routing protocols.

```

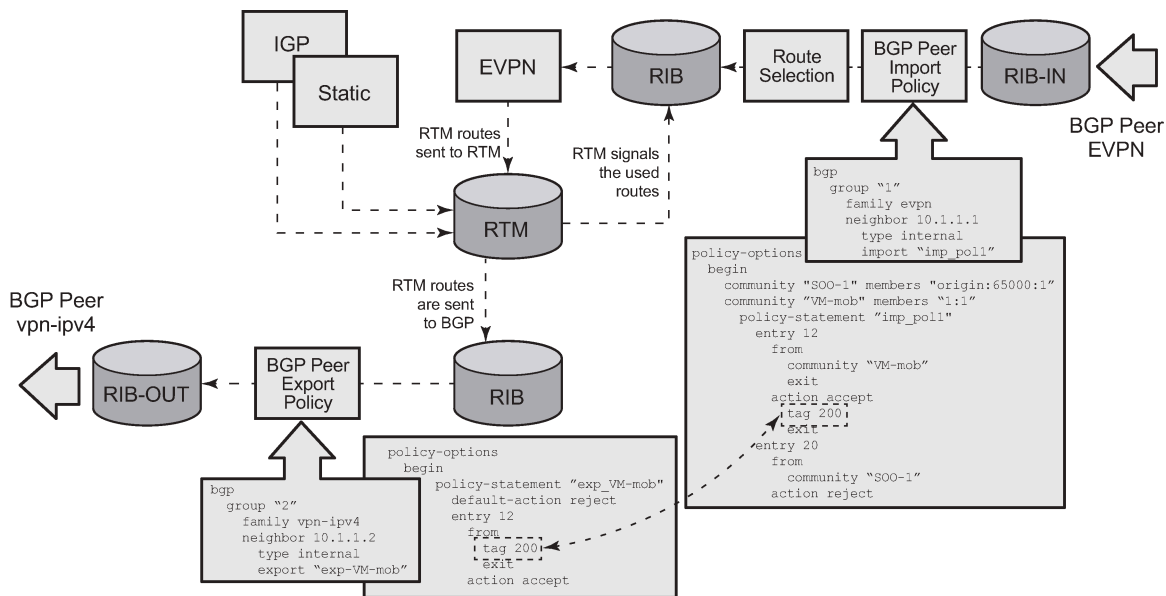

*[ex:/configure policy-options policy-statement "test" entry 10 action]
A:admin@PE-1# tag ?

tag (<number> | <string>)
<number> - <1..4294967295>
<string> - <1..32 characters>

OSPF RIP or IS-IS tag applied to routes
    
```

Figure 113: Routing policies for ingress EVPN routes illustrates the reverse workflow: routes imported from EVPN and exported from RTM to BGP VPN-IPv4. In this example, EVPN routes received with community VM-mob are tagged with tag 200. At the egress VPN-IPv4 peers, only the routes with tag 200 are advertised.

Figure 113: Routing policies for ingress EVPN routes

al_0584

The preceding behavior and the use of tags is also valid for **vsi-import** and **vsi-export** policies. The behavior can be summarized in the following statements:

- For EVPN prefix routes received and imported in RTM:
 - Routes can be matched on communities and tags can be added to them. This works at peer level or vsi-import level.
 - Well-known communities [**no-export** | **no-export-subconfed** | **no-advertise**] also require that the routing policies add a tag if the user wants to modify the behavior when exporting to BGP.
 - Routes can be matched based on family EVPN.
 - Routes cannot be matched on prefix list.
- For exporting RTM to EVPN prefix routes:
 - Routes can be matched on tags and based on that, communities added, or routes accepted or rejected, and so on. This works at peer level or vsi-export level.
 - Tags can be added for static routes, RIP, OSPF, IS-IS, and BGP and then be matched in the vsi-export policy for EVPN IP-prefix route advertisement.
 - Tags cannot be added for direct routes.

Use of routing policies to avoid routing loops in redundant PEs

When redundant PE VPRN instances are connected to the same R-VPLS service (IRB backhaul or EVPN tunnel R-VPLS) with the **routes>ip-prefix>advertise true** command enabled, routing loops can occur in two different use cases:

1. Routing loop caused by EVPN and IP-VPN interaction in the RTM.
2. Routing loop caused by EVPN in parallel R-VPLS services.

Policy configuration examples for both cases are provided in the following sections.

Routing loop use-case 1: EVPN and IP-VPN interaction

This use case refers to scenarios with redundant PEs and VPRNs connected to the same R-VPLS with **routes>ip-prefix>advertise true**. The scenarios in [Figure 110: EVPN-VXLAN for IRB backhaul R-VPLS services](#) (EVPN-VXLAN for IRB Backhaul R-VPLS services) and [Figure 111: EVPN-VXLAN in EVPN-tunnel R-VPLS services](#) (EVPN-VXLAN in EVPN tunnel R-VPLS services) are examples of this use case. In both scenarios, the following process causes a routing loop:

1. PE-4 advertises IP prefix 172.16.6.0/24 with preference 170 (IP-VPN) to PE-2 and PE-3.
2. PE-2 and PE-3 import prefix 172.16.6.0/24 in the VPRN routing table. PE-2 re-advertises prefix 172.16.6.0/24 with preference 169 (EVPN) to PE-1 and PE-3; PE-3 re-advertises the IP prefix in EVPN to PE-1 and PE-2.
3. PE-2 and PE-3 already have the 172.16.6.0/24 prefix in the VPRN routing table with preference 170 (IP-VPN) but because the IP prefix from EVPN has a lower preference (169), the RTM installs the EVPN prefix in the VPRN routing table.
4. PE-2 advertises the EVPN-learned IP prefix 172.16.6.0/24 to all MP-BGP VPN-IPv4 peers, including PE-3; PE-3 advertises the prefix 172.16.6.0/24 to all MP-BGP VPN-IPv4 peers, including PE-2.
5. PE-2 receives the IP prefix 172.16.6.0/24 again from PE-3 and advertises it in EVPN again, creating a routing loop. The same thing happens in PE-3.

This routing loop also happens in traditional multi-homed IP-VPN scenarios where the PE-CE eBGP and MP-BGP VPN-IPv4/v6 protocols interact in the same VPRN RTM, with different router preferences. In either case (EVPN or eBGP interaction with MP-BGP) the issue can be solved by using routing policies and site-of-origin communities.

Routing policies are applied to PE-2 and PE-3 (also to PE-4 and PE-5) and allow the redundant PEs to reject their own generated routes to avoid the loops. These routing policies can be applied at vsi-import/export level or BGP group/neighbor level. The following output shows an example of routing policies applied at BGP neighbor level for PE-2 (similar policies are applied on PE-3, PE-4, and PE-5). Neighbor or group level policies are the preferred way in this kind of use case: a single set of policies is sufficient, as opposed to a set of policies per service (if the policies are applied at vsi-import or vsi-export level).

The following policies are applied in the BGP group or BGP neighbor context on PE-2:

```
# on PE-2:
configure {
  policy-options {
    community "S00-PE-2" {
      member "origin:2:1" {}
    }
    community "S00-PE-3" {
      member "origin:3:1" {}
    }
  }
  policy-statement "add-S00_on_export" {
    entry 10 {
      from {
        tag 2
      }
      action {
        action-type accept
        community {
          add ["S00-PE-2"]
        }
      }
    }
    entry 20 {
```

```
        from {
            tag 3
        }
        action {
            action-type accept
            community {
                add ["S00-PE-3"]
            }
        }
    }
}
policy-statement "reject_based_on_S00" {
    entry 10 {
        from {
            community {
                name "S00-PE-2"
            }
        }
        action {
            action-type reject
        }
    }
    entry 20 {
        from {
            community {
                name "S00-PE-3"
            }
        }
        action {
            action-type reject
        }
    }
}
policy-statement "add-tag_to_bgp-evpn_routes" {
    entry 10 {
        from {
            family [evpn]
        }
        action {
            action-type accept
            tag 2
        }
    }
}
policy-statement "add-tag_to_bgp-vpn_routes" {
    entry 10 {
        from {
            protocol {
                name [bgp-vpn]
            }
        }
        action {
            action-type accept
            tag 2
        }
    }
}
}
router "Base" {
    bgp {
        vpn-apply-export true
        vpn-apply-import true
        rapid-withdrawal true
        peer-ip-tracking true
    }
}
```

```

rapid-update {
  evpn true
}
group "DC" {
  peer-as 64500
  family {

  import {
    policy ["add-tag_to_bgp-evpn_routes"]
  }
}
neighbor "192.0.2.3" {
  group "DC"
  import {
    policy ["reject_based_on_S00"]
  }
  export {
    policy ["add-S00_on_export"]
  }
}
neighbor "192.0.2.4" {
  group "WAN"
}
neighbor "192.0.2.5" {
  group "WAN"
}

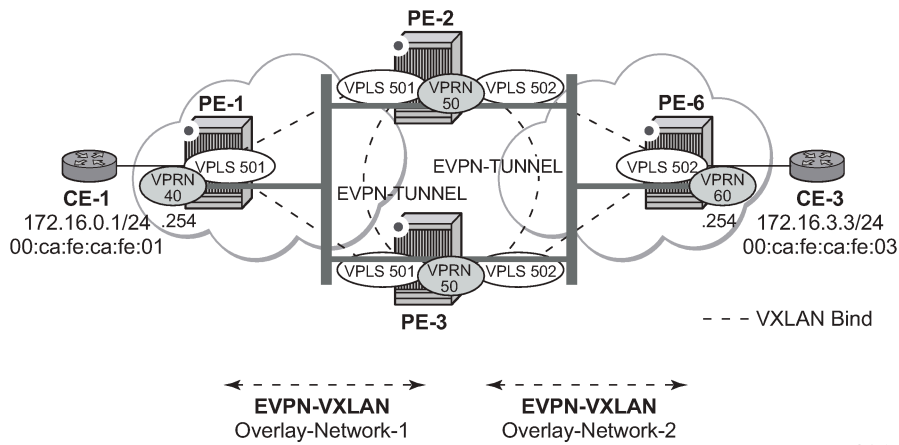

```

EVPN and MP-BGP routes are tagged at import; on export, a site-of-origin community is added. Routes exchanged between the two redundant PEs are dropped if they are received by a PE with its own site-of-origin.

Routing loop use-case 2: EVPN in parallel R-VPLS services

If a VPRN is connected to more than one R-VPLS with `routes>ip-prefix>advertise true` configured, IP prefixes that belong to one R-VPLS are advertised into the other R-VPLS and vice versa. When redundant PEs are used, a routing loop will occur. [Figure 114: EVPN in parallel R-VPLS services](#) illustrates this use case. The example shows R-VPLS with an EVPN tunnel configuration, but the same routing loop occurs for regular IRB backhaul R-VPLS services.

Figure 114: EVPN in parallel R-VPLS services

al_0585

The configuration of VPRN "VPRN50" as well as VPLSs "evi-501" and "evi-502" and the required policies are as follows. For this use case, policies must be applied at vsi-import/export level because more granularity is required when modifying the imported/exported routes.

```
# on PE-2:
configure {
  policy-options {
    community "S00-PE-2-RVPLS" {
      member "origin:2:11" { }
    }
    community "S00-PE-3-RVPLS" {
      member "origin:3:11" { }
    }
    community "S00_PE-3_RVPLS501" {
      member "origin:3:11" { }
      member "target:64500:501" { }
    }
    community "S00_PE-3_RVPLS502" {
      member "origin:3:11" { }
      member "target:64500:502" { }
    }
    community "exp_RVPLS501" {
      member "origin:2:11" { }
      member "target:64500:501" { }
    }
    community "exp_RVPLS502" {
      member "origin:2:11" { }
      member "target:64500:502" { }
    }
  }
  policy-statement "vsi-export-policy-501" {
    entry 10 {
      from {
        tag 12
      }
      action {
        action-type accept
        community {
          add ["S00_PE-3_RVPLS501"]
        }
      }
    }
  }
}
```

```
    }
  }
  entry 20 {
    action {
      action-type accept
      community {
        add ["exp_RVPLS501"]
      }
    }
  }
}
policy-statement "vsi-export-policy-502" {

Troubleshooting and debug commands

For general information about EVPN and VXLAN troubleshooting and debug commands, see chapter [EVPN for VXLAN Tunnels \(Layer 2\)](#). The following information focuses on specific commands for Layer-3 applications.

When troubleshooting and operating an EVPN-VXLAN scenario with inter-subnet forwarding, it is important to check the IP prefixes and next-hops, as well as ARP tables and FDB tables:

- **show router <.> route-table**
- **show router <.> arp**
- **show service id <.> fdb detail**

ICMP commands can also help checking the connectivity. When **traceroute** is used on EVPN-VXLAN in EVPN tunnel interfaces, EVPN tunnel interface hops in the **traceroute** commands are showing the VPRN loopback address or the other non EVPN-tunnel interface address. In VPRN services where all the interfaces are EVPN tunnels, ICMP packets fail until an IP address is configured. The following output shows a traceroute from VPRN "VPRN30" in PE-1 to CE-6 and from PE-2 to CE-1 (see [Figure 111: EVPN-VXLAN in EVPN-tunnel R-VPLS services](#)):

```

[/]
A:admin@PE-1# traceroute 172.16.6.6 router-instance "VPRN30"
traceroute to 172.16.6.6, 30 hops max, 40 byte packets
 1  0.0.0.0  * * *
 2  0.0.0.0  * * *
 3  172.16.6.254 (172.16.6.254)    4.79 ms  4.65 ms  4.80 ms

```

```
4 172.16.6.6 (172.16.6.6) 5.32 ms 5.12 ms 4.86 ms
```

```
[/]
A:admin@PE-2# traceroute 172.16.1.1 router-instance "VPRN30"
traceroute to 172.16.1.1, 30 hops max, 0 byte packets
No route to destination. Address: 172.16.1.1, Router Instance:VPRN30
```

When troubleshooting R-VPLS services, specifically R-VPLS services configured as EVPN tunnels, the limit of peer PEs per EVPN tunnel service is much higher than for a regular R-VPLS service because the egress <VTEP, VNI> bindings do not have to be added to the multicast flooding list. For this reason, the following **tools dump** command has been added to check the consumed/total EVPN tunnel next hops. The number of EVPN tunnel next hops matches the number of remote GW MAC addresses per EVPN tunnel R-VPLS service.

```
[/]
A:admin@PE-1# tools dump service id 501 evpn usage
```

Evpn Tunnel Interface IP Next Hop: 2/8189

Finally, when troubleshooting EVPN routes and routing policies, the **show router bgp routes evpn** command and its filters can help:

- Check that the expected routes are received, properly imported, and communities/tags added/replaced/removed.
- Check that the expected routes are sent, properly exported, and communities added/replaced/removed.

Examples of EVPN IP prefix routes including communities and tags are the following.

```
[/]
A:admin@PE-2# show router bgp routes evpn ?

auto-disc          - Display BGP EVPN Auto-Disc Routes

Conclusion

SR OS supports not only the EVPN control plane for VXLAN tunnels in Layer 2 applications but also the simultaneous use of EVPN and VXLAN for VPN customers (tenants) with intra and inter-subnet connectivity requirements. R-VPLS services can be configured to provide default gateway connectivity to hosts, IRB backhaul connectivity to VPRN services, and EVPN tunnel connectivity to VPRN services.

When configured to do so, EVPN can advertise IP prefixes and interact with the VPRN RTM to propagate IP prefix connectivity between EVPN and other routing protocols in the VPRN, including IP-VPN. This example has shown how to configure R-VPLS services for all these functions, as well as how to configure routing policies for EVPN-based IP prefixes.

EVPN Interconnect Ethernet Segments

This chapter provides information about EVPN Interconnect Ethernet Segments.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2.

Chapters [EVPN for MPLS Tunnels](#), [EVPN for VXLAN Tunnels \(Layer 2\)](#) and [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#) are prerequisite reading.

Overview

SR OS supports Interconnect Ethernet Segments (I-ESs) for VXLAN as per the IETF *draft-ietf-bess-dci-evpn-overlay*. An I-ES is a virtual Ethernet Segment (vES) that allows Data Center Gateways (DCGWs) with two BGP instances (one for EVPN-MPLS and one for EVPN-VXLAN) to handle redundancy in VXLAN access networks. I-ESs support the RFC 7432 multi-homing functions, including single-active and all-active, ESI-label based split-horizon filtering, Designated Forwarder (DF) election, aliasing, and backup functions on remote EVPN-MPLS PEs.

The chapter [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#) describes how VPLS services with two BGP instances are configured and describes a redundant mechanism referred to as [Multi-homed anycast configuration for dual BGP-instance VPLS services](#). The use of I-ESs is recommended over this anycast configuration.

In addition to the EVPN multi-homing features, the main advantages of the I-ES solution compared to the redundant solution (described in [Anycast Redundant Solution for Dual BGP-instance Services](#)) are as follows:

- The use of I-ES for redundancy in dual BGP-instance services allows local SAPs on the DCGWs. This is not supported in the anycast solution.
- P2MP mLDP can be provisioned to transport Broadcast, Unknown unicast, and Multicast (BUM) traffic between DCs that use I-ES, without any risk of packet duplication. As described in [The use of provider tunnels on multi-homed anycast solutions](#), packet duplication may occur in the anycast DCGW solution when mLDP is used in the WAN.

When EVPN-MPLS networks are interconnected to EVPN-VXLAN networks, the I-ES concept and procedures apply only to the access VXLAN network; the EVPN-MPLS network does not modify its existing behavior compared to any other ES.

Configuration

Figure 115: [EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology](#) shows the topology and infrastructure configuration, which are the same as in chapter [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#). Read that chapter to see how the PEs are configured at port, IS-IS, and base BGP level.

Figure 115: EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology

26869

PE-1, PE-2, and PE-3 simulate a data center (DC), shown as Overlay-Network-1, where PE-2 and PE-3 are DCGWs. In the same way, PE-4, PE-5, and PE-6 simulate a remote DC, Overlay-Network-2. Inside each DC, EVPN-VXLAN is used and the two DCGW pairs are connected by EVPN-MPLS. CE-1 and CE-6 are end-to-end connected by EVPN without any VLAN or Pseudowire (PW) hand-off, maintaining all the EVPN advantages across the DC Interconnect (DCI) network.

Interconnect Ethernet Segment (I-ES) configuration

After the base infrastructure is configured (interfaces, IGP, LDP in the core, and BGP EVPN peering sessions, as per [Figure 115: EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology](#)), two I-ESs configured on the DCGWs show the use of the Interconnect Ethernet Segments.

The I-ES "I-ES231" is configured on PE-2 and PE-3 as follows:

```
# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES231" {
            admin-state enable
            type virtual
            esi 00:23:23:23:23:23:00:00:01
          }
        }
      }
    }
  }
}
```

```
multi-homing-mode all-active
df-election {
  service-carving-mode manual
  manual {
    evi 101 {
      end 200
    }
  }
  preference {
    mode non-revertive
    value 150
  }
}
association {
  network-interconnect-vxlan 1 {
    virtual-ranges {
      service-id 1 {
        end 100
      }
      service-id 101 {
        end 200
      }
    }
  }
}
}
```

```
# on PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES231" {
            admin-state enable
            type virtual
            esi 00:23:23:23:23:23:00:00:01
            multi-homing-mode all-active
            df-election {
              service-carving-mode manual
              manual {
                evi 101 {
                  end 200
                }
              }
              preference {
                mode non-revertive
                value 50
              }
            }
          }
        }
      }
    }
  }
  association {
    network-interconnect-vxlan 1 {
      virtual-ranges {
        service-id 1 {
          end 100
        }
        service-id 101 {
          end 200
        }
      }
    }
  }
}
}
```

On PE-1 and PE-2, the preceding configuration associates I-ES "I-ES231" with the VXLAN instance 1 in services contained in the range VPLS 1 to 100 and 101 to 200. The I-ES is modeled as a virtual ES, where:

- Two commands are needed within the ethernet-segment context: **network-interconnect-vxlan** and **virtual-ranges service-id <svc-id> end <svc-id>**.
 - The **network-interconnect-vxlan** command identifies the VXLAN instance associated with the virtual ES. Only value 1 is supported in SR OS Release 21.2.R2.

```
*[ex:/configure service system bgp evpn ethernet-segment "vES-23" association]
A:admin@PE-1# network-interconnect-vxlan ?

[network-interconnect-vxlan-id] <number>
<number> - <1>

Vxlan instance id multi-homed with this Ethernet segment entry.
```

The **network-interconnect-vxlan** command is rejected in non-virtual ESs:

```
*[ex:/configure service system bgp evpn ethernet-segment "ES-23" association]
A:admin@PE-1# network-interconnect-vxlan 1
MINOR: MGMT_CORE #2203: configure service system bgp evpn ethernet-segment "ES-23"
association network-interconnect-vxlan 1 - Invalid element - network-interconnect-vxlan
allowed only on virtual ethernet-segments
```

- The **service-id** command associates the specific service range with the ES.
- The other ES association options (port, lag, sdp, vc-id-range, dot1q, and qinq) cannot be combined with a **network-interconnect-vxlan** instance in an ES.
- The rest of the ES configuration options are supported. The **source-bmac-lsb** is blocked because the I-ES cannot be associated with I-VPLS or PBB-Epipe services.
- All the services with two BGP instances associate the VXLAN destinations and ingress VXLAN instance with the ES.
- Multiple services (for example, 1 to 200 in the CLI above) can be associated with the same ES.
 - Up to eight service ranges per VXLAN instance can be configured. Ranges may overlap within the same ES (and not between different ESs). In this example, two non-overlapping ranges are configured to show the service range configuration, although a single range containing all the services could have been configured.
 - The service range may be configured before the service is, and it can be changed on the fly.
- When the **network-interconnect-vxlan** I-ES is configured, the ES operational state depends exclusively on the ES admin state.
 - Because the I-ES is not associated with a physical port or SDP, when testing the non-revertive service-carving manual mode, an ethernet-segment admin-state disable/enable will result in the node sending its own administrative preference and "Do not preempt" (pref/DP) values, and taking over if pref/DP is higher than the current DF. This is because when the ES is enabled, the peer ES routes are not present at the EVPN application layer, so the PE will send its own admin pref/DP values. Therefore, for I-ESs, the non-revertive mode will only work for node failures. See the chapter for more information about the preference-based and non-revertive DF election modes.
- There are no restrictions in the service-carving mode supported by I-ESs. In this example, preference-based service-carving is configured, but modes auto and (non-preference-based) manual are also supported.

- As described in the [Preference-based and Non-revertive EVPN DF Election](#) chapter, the service-carving context is configured with an EVI range that will pick up the lowest preference value when electing a DF for the service, whereas the non-configured EVI services will pick up the highest value when electing a DF. In this example, this means that, of the services allowed in the I-ES, that is, 1 to 200, services 1 to 100 will elect the highest Preference PE as DF, whereas services 101 to 200 will elect the lowest Preference PE.

PE-4 and PE-5 are configured with I-ES "I-ES451". The configuration of I-ES451 is similar to that of I-ES231; only single-active mode is configured, instead of all-active mode.

```
# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES451" {
            admin-state enable
            type virtual
            esi 00:45:45:45:45:45:00:00:01
            multi-homing-mode single-active
            df-election {
              service-carving-mode manual
              manual {
                evi 101 {
                  end 200
                }
              }
              preference {
                mode non-revertive
                value 150
              }
            }
          }
          association {
            network-interconnect-vxlan 1 {
              virtual-ranges {
                service-id 1 {
                  end 100
                }
                service-id 101 {
                  end 200
                }
              }
            }
          }
        }
      }
    }
  }
}
```

```
# on PE-5:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES451" {
            admin-state enable
            type virtual
            esi 00:45:45:45:45:45:00:00:01
            multi-homing-mode single-active
            df-election {
              service-carving-mode manual
              manual {
```

```
evi 101 {
  end 200
}
preference {
  mode non-revertive
  value 50
}
}
}
}
association {
  network-interconnect-vxlan 1 {
    virtual-ranges {
      service-id 1 {
        end 100
      }
      service-id 101 {
        end 200
      }
    }
  }
}
}
}
}
}
```

In this example, VPLS 1 will be configured and associated with the preceding I-ESs. [Figure 116: VPLS service and association with I-ESs](#) shows an example of VPLS 1 and how it is associated with the I-ESs.

Figure 116: VPLS service and association with I-ESs

26870

The configuration of VPLS 1 for PE-1, PE-2, and PE-3 is as follows. VPLS 101 is also configured in all the PEs in a similar way as VPLS 1, but not shown here. Also, the VPLS 1 configuration on the rest of the PEs is equivalent to the one in PE-1, PE-2, and PE-3, as follows:

```
# on PE-1:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      sap 1/2/1:1 {
      }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.2:1"
      }
      bgp 2 {
        route-distinguisher "192.0.2.2:2"
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      mpls 2 {
        admin-state enable
        ingress-replication-bum-label true
        ecmp 2
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}
```

```

}

# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.3:1"
      }
      bgp 2 {
        route-distinguisher "192.0.2.3:2"
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
        mpls 2 {
          admin-state enable
          ingress-replication-bum-label true
          ecmp 2
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}

```

As in the case of any other ESs, the association of instance and service is based on the ES configuration and there is no extra configuration required at the service level to make that association. The existing **show** commands that are used to check the status of the ES can be used to check the I-ESs. For example, on I-ES231:

```

[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "I-ES231" all

=====

The **show service id 1 vxlan instance 1 oper-flags** command shows the status of a VXLAN instance in the service. A service VXLAN instance will raise the oper-flag **MhStandby** (multi-homing standby) due to any of the following reasons:

- The PE is (single-active) non-Designated Forwarder (NDF) for that I-ES.
- The VXLAN service is added to the I-ES and either the ES is disabled or **bgp-evpn>mpls** is disabled in all the services included in the ES.

For example, because PE-5 is an NDF in I-ES451, the MhStandby flag will show "true":

```
[/]
A:admin@PE-5# show service id 1 vxlan instance 1 oper-flags

=====
VPLS VXLAN oper flags

MhStandby                : true
=====
```

EVPN route handling in dual BGP-instance VPLSs with I-ES

The configuration of I-ESs on DCGWs with two BGP instances has the following impact on the advertisement and process of the BGP-EVPN routes:

- EVPN MAC/IP routes:
 - MAC/IP routes received on the EVPN-MPLS BGP instance will be re-advertised to the EVPN-VXLAN BGP instance with the ESI set to zero in SR OS Release 21.2.R2.
 - EVPN-VXLAN PE/NVEs (Network Virtual Edge devices) in the DC will receive the same MAC address from two (or more) different MAC/IP routes from the DCGWs. The EVPN-VXLAN PE/NVEs will perform regular EVPN MAC/IP route selection.
 - MAC/IP routes received on the EVPN-VXLAN BGP instance will be re-advertised to the EVPN-MPLS BGP instance with the configured non-zero I-ESI value, assuming the VXLAN instance is not in the MhStandby operational state. MAC/IP routes received on the EVPN-VXLAN BGP instance will be dropped if the VXLAN instance is in the MhStandby state.
 - EVPN-MPLS PEs in the WAN will receive the same MAC address from two (or more) DCGWs, set with the same ESI. EVPN-MPLS PEs will perform regular aliasing and backup functions.
- ES routes are exchanged for the I-ES. They should be sent only to the MPLS network and not to the VXLAN side. This can be achieved by using router policies. In any case, because ES routes use an ES-import route-target extended community, they should not be imported by VXLAN PEs.
- Auto-discover per ES (AD per-ES) and AD per-EVI routes are also advertised for the I-ES. They should be sent only to the MPLS network and not to the VXLAN network. As for ES routes, router policies can be used to prevent AD routes being sent to VXLAN peers.

Required BGP policies to avoid control plane loops

Usually, the use of router policies is required when I-ESs are used for redundancy, to avoid control plane loops with MAC/IP routes. The control plane loops to be avoided are as follows:

1. Loops created by remote MAC addresses (learned on remote PE SAPs):
 - a. Remote EVPN-MPLS MAC/IP routes are re-advertised into EVPN-VXLAN with a Site of Origin (SOO) extended community (added by a BGP peer or vsi-export policy) identifying the DCGW pair. The other DCGW in the pair will drop EVPN-VXLAN MAC routes tagged with the self SOO. Router policies to add SOO and drop routes received with self SOO are needed.
 - b. Also, when remote EVPN-VXLAN MAC/IP routes are re-advertised into EVPN-MPLS, the DCGWs will automatically drop EVPN-MPLS MAC/IP routes received with their own non-zero I-ESI. No router policies are needed for this.

2. Loops created by local SAP MAC addresses:

- a.** Local SAP MACs are learned and MAC/IP routes are advertised into both BGP instances. The MAC/IP routes advertised in the EVPN-VXLAN instance will be dropped by the peer based on the SOO router policies, as described in (1a) above, and DCGW local MACs will always be learned over the EVPN-MPLS destinations between the DCGWs.
- b.** Because only EVPN-MPLS destinations exist between the DCGWs, EVPN-VXLAN MAC/IP and IMET routes exchanged between the DCGWs will be discarded and EVPN-VXLAN destinations will not be created between them.

As an example, the following BGP peer policies on PE-2 and PE-3 achieve the goals described above (similar policies would be configured on PE-4 and PE-5) and summarized as follows:

- Avoid sending service VXLAN routes to MPLS peers, and service MPLS routes to VXLAN peers.
- Avoid sending AD and ES routes to VXLAN peers.
- Add SOO to VXLAN routes to be sent to the ES peer.
- Drop VXLAN routes received from the ES peer.

```
# on PE-2, PE-3:
configure {
  policy-options {
    community "SOO-DCGW-23" {
      member "origin:64500:23" { }
    }
    community "mpls" {
      member "bgp-tunnel-encap:MPLS" { }
    }
    community "vxlan" {
      member "bgp-tunnel-encap:VXLAN" { }
    }
  }
}
```

The following policy prevents the router from sending service VXLAN routes to MPLS peers:

```
policy-statement "allow only mpls" {
  entry 10 {
    from {
      family [evpn]
      community {
        name "vxlan"
      }
    }
    action {
      action-type reject
    }
  }
}
```

The following policy makes sure the router exports only routes that include the VXLAN encapsulation:

```
policy-statement "allow only vxlan" {
  entry 10 {
    from {
      family [evpn]
      community {
        name "vxlan"
      }
    }
    action {
```

```

        action-type accept
    }
}
default-action {
    action-type reject
}
}

```

The following import policy avoids importing routes with self SOO:

```

policy-statement "drop S00-DCGW-23" {
    entry 10 {
        from {
            family [evpn]
            community {
                name "S00-DCGW-23"
            }
        }
        action {
            action-type reject
        }
    }
}

```

The following export policy adds SOO but only to VXLAN routes. This allows the peer to drop routes based on the SOO, without affecting the MPLS routes.

```

policy-statement "add S00 to vxlan routes" {
    entry 10 {
        from {
            family [evpn]
            community {
                name "vxlan"
            }
        }
        action {
            action-type accept
            community {
                add ["S00-DCGW-23"]
            }
        }
    }
    default-action {
        action-type accept
    }
}

```

The BGP configuration for PE-2 and PE-3 is as follows:

```

# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        router-id 192.0.2.2
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            family {
                ipv4 false
                evpn true
            }
        }
    }
}

```

```
    rapid-update {
      evpn true
    }
  group "dc" {
    type internal
    export {
      policy ["allow only vxlan"]
    }
  }

    }
    export {
      policy ["add S00 to vxlan routes"]
    }
  }
  neighbor "192.0.2.4" {
    group "wan"
  }
  neighbor "192.0.2.5" {
    group "wan"
  }
}
```

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 64500
    router-id 192.0.2.3
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
    }
    group "dc" {
      type internal
      export {
        policy ["allow only vxlan"]
      }
    }
    group "wan" {
      type internal
      export {
        policy ["allow only mpls"]
      }
    }
  }
  neighbor "192.0.2.1" {
```

```

    group "dc"
  }
  neighbor "192.0.2.2" {
    group "dc"
    import {
      policy ["drop S00-DCGW-23"]
    }
    export {
      policy ["add S00 to vxlan routes"]
    }
  }
  neighbor "192.0.2.4" {
    group "wan"
  }
  neighbor "192.0.2.5" {
    group "wan"
  }
}

```

Single-active multi-homing operation

When the I-ES is configured as **single-active** and **admin-state enabled** (assuming at least one service is associated), the DCGWs will send ES and AD routes as usual for any ES, and run DF election based on the ES routes, with the candidate list being pruned by the AD routes.

In [Figure 116: VPLS service and association with I-ESs](#), PE-4 and PE-5 are configured with I-ES451, which is a single-active ES. The NDF for a service (PE-5 for VPLS 1 in the example) will perform the following tasks:

- The VXLAN instance on the NDF will enter the MhStandby state and will block ingress and egress traffic on the VXLAN destinations associated with the I-ES.

```

[/]
A:admin@PE-5# show service id 1 vxlan instance 1 oper-flags

```

```

=====
VPLS VXLAN oper flags
=====

```

```

MhStandby                : true
=====

```

- MAC/IP routes and FDB process:
 - Advertised MAC/IP routes that are associated with the VXLAN instance are withdrawn.
 - Advertised MAC/IP routes corresponding to local SAP MAC addresses or EVPN-MPLS binding MAC addresses are withdrawn if they were advertised to the EVPN-VXLAN instance.
 - Received MAC/IP routes associated with the VXLAN instance are not installed in FDB. The MAC routes will show as "used" in the **show router bgp routes evpn mac** commands; however, only the MAC addresses received from MPLS (in particular from the ES peer) will be programmed. As an example, the following CLI output shows how MAC address 00:ca:fe:ca:fe:06 is learned on PE-4 (DF) and associated with the VXLAN destination to PE-6, whereas the MAC address is installed associated with an MPLS destination (remote ES) on PE-5 (NDF).

```

```

- Inclusive Multicast Ethernet Tag (IMET) routes process:
 - IMET-Assisted Replication with replicator role (IMET-AR-R) routes are withdrawn if the VXLAN instance enters the MhStandby state. Only the DF will advertise the IMET-AR-R routes. For more information on AR, see chapter "Layer 2 Multicast Optimization for EVPN-VXLAN - Assisted Replication" in the Layer 2 Services and EVPN section of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part II*.
 - IMET-Ingress Replication advertisements (IMET-IR) routes, in case of NDF (or the MhStandby state), are controlled by the **config>service>vpls>bgp-evpn>vxlan# send-incl-mcast-ir-on-ndf** command.
 - By default, the command is enabled and the router will advertise IMET-IR routes even if the PE is NDF (MhStandby). This will attract BUM traffic (even if the NDF ends up dropping it); however, attracting BUM traffic will also speed up convergence in case of DF switchover. The command works for single-active and all-active.
 - If disabled, the router will withdraw the IMET-IR routes when the PE is NDF and will not attract BUM traffic.

In spite of not sending BUM or unicast traffic, the NDF for a service still creates the VXLAN bindings; however, they are not associated with any MAC addresses and they are flagged as non-multicast capable, or "-" in the Mcast column of the following command:

```

[/]
A:admin@PE-5# show service id 1 vxlan destinations
=====

```

```

```

The I-ES DF PE for the service (PE-4) will continue advertising IMET and MAC/IP routes for the associated VXLAN instance. Forwarding will also happen as usual on the DF VXLAN bindings. When the DF PE receives BUM traffic from VXLAN, it will send it, adding the egress ESI label if needed.

All-active multi-homing operation

The same considerations as in single-active for ES and AD routes and DF election apply to all-active multi-homing. In [Figure 116: VPLS service and association with I-ESs](#), PE-2 and PE-3 are configured with I-ES231, which is an all-active ES. The NDF PE for a service (PE-3 for VPLS 1, in the example) will show the following behavior:

- The VXLAN instance on the NDF will not enter the MhStandby state because it will still forward unicast traffic:

```

[/]
A:admin@PE-3# show service id 1 vxlan instance 1 oper-flags
=====
VPLS VXLAN oper flags
=====
MhStandby                : false
=====

```

- MAC/IP routes and FDB process: MAC/IP routes are received, installed, and advertised as in the DF router.
- IMET routes process:
 - As in the single-active case, IMET-AR-R routes are withdrawn on the NDF. Only the DF will advertise the IMET-AR-R routes.
 - Also, as in the single-active case, IMET-IR advertisement from the NDF will be controlled by the `config>service>vpls>bgp-evpn>vxlan# send-incl-mcast-ir-on-ndf` command. Advertising the IMET-IR route from the NDF will attract BUM traffic from the VXLAN PEs to the NDF, even though the unknown unicast traffic will be forwarded only when it is safe to do so. See section [All-active multi-homing and unknown unicast forwarding on the NDF](#) for more information about unknown unicast forwarding.

Contrary to the behavior in single-active multi-homing, in all-active, the NDF will forward unknown unicast to the VXLAN PEs as usual, but block broadcast and multicast in the upstream and downstream direction. In our example, the NDF for VPLS 1 (PE-3) will show the VXLAN destinations created as "U" (Unknown unicast) in the Mcast column of the **show service id 1 vxlan** command, as follows:

```
[/]
A:admin@PE-3# show service id 1 vxlan destinations

All-active multi-homing and unknown unicast forwarding on the NDF

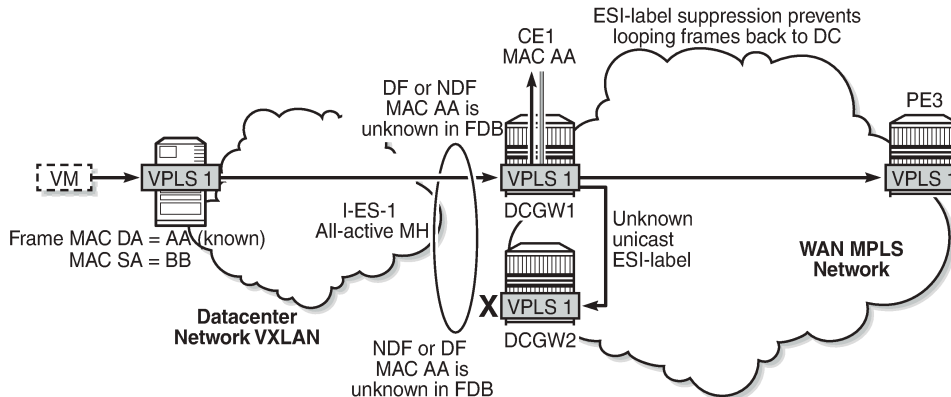

The unknown unicast traffic will be transmitted on the (all-active multi-homing) NDF in the upstream and downstream directions only in those cases where there is no risk of packet duplication. The router considers there is no risk when transmitting an unknown unicast packet on the NDF if:

- Unknown unicast packet arrives without an ESI label.
- Unknown unicast packet arrives without a BUM label (label advertised by an IMET route as opposed to a MAC/IP route).
- Unknown unicast packet passes a MAC Source Address (MAC SA) suppression (MAC SA lookup does not yield an entry associated with the I-ES).

The following examples show how unknown unicast traffic is handled in all-active I-ESs.

Figure 117: All-active multi-homing and unknown unicast example 1 shows an example with two DCGWs where (all-active) I-ES-1 is defined.

Figure 117: All-active multi-homing and unknown unicast example 1

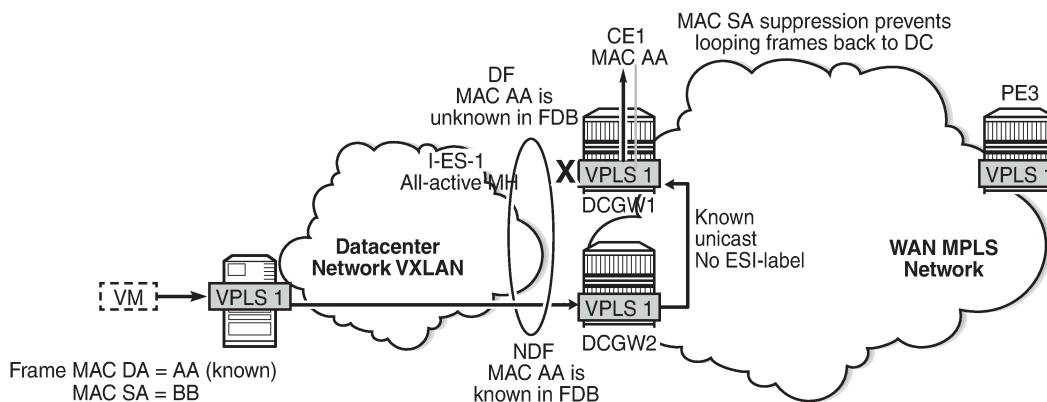

26871

The VXLAN PE/NVE transmits known unicast traffic, whereas DCGW1 has not learned the MAC address yet. Regardless of the DCGW1 being DF or NDF, it will accept unknown unicast and will flood to local SAPs and EVPN destinations. When sending to DCGW2, the router will send the ESI label identifying the I-ES. DCGW2 will not send unknown traffic back to the DC due to the ESI-label suppression on the I-ES.

Figure 118: All-active multi-homing and unknown unicast example 2 shows a similar example where the VXLAN node sends known unicast with MAC Destination Address (MAC DA) "AA" to DCGW2.

Figure 118: All-active multi-homing and unknown unicast example 2

26871

DCGW2 does a MAC lookup and sends the frame as known unicast to DCGW1 via the EVPN-MPLS destination. However, MAC AA is unknown in DCGW1 for some reason (such as FDB limit exceeded, SAP failure, and so on). In this case, DCGW1 will flood the frame to CE1 and not to the VXLAN network. Even though the frame is not coming with an ESI label, the DCGW1 router does a MAC SA suppression and will not send unknown unicast frames to the I-ES. MAC SA suppression means that the router will do a MAC SA lookup on the FDB and will suppress the flooding to the I-ES if the MAC SA is learned on the I-ES (as in Figure 118: All-active multi-homing and unknown unicast example 2).

Figure 119: All-active multi-homing and unknown unicast example 3 shows an example in which the NDF forwards "no-risk" unknown unicast traffic to avoid black-holes.

Figure 119: All-active multi-homing and unknown unicast example 3

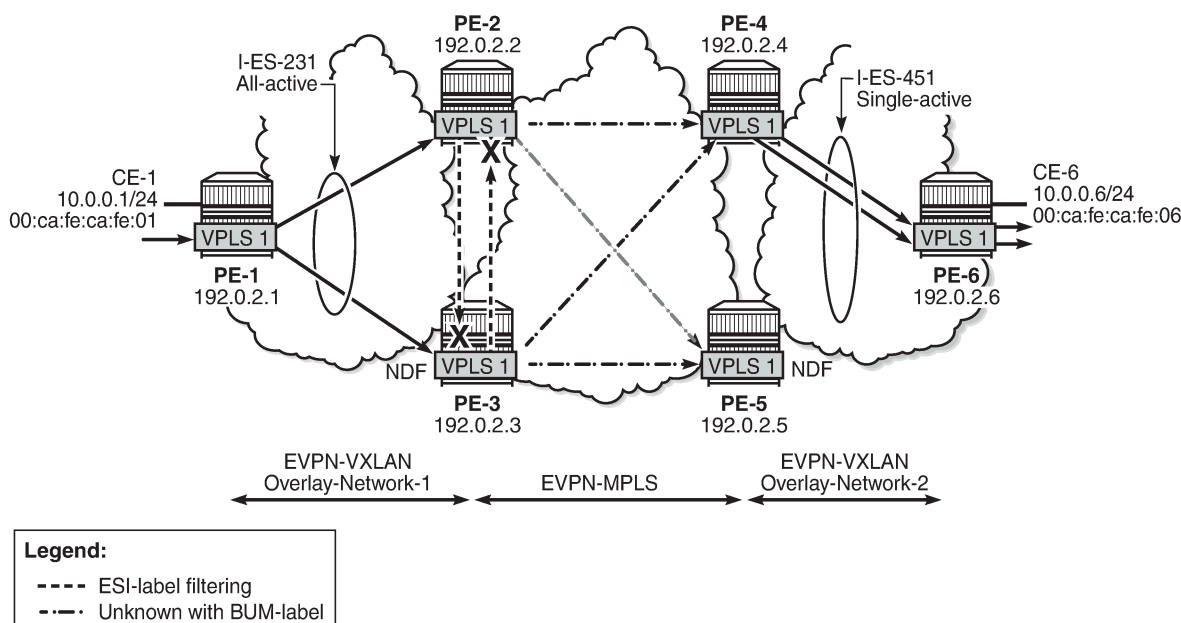

26873

PE3 receives unicast traffic with MAC DA = AA. The MAC address is known in the FDB and associated with I-ES-1; therefore, because PE3 is configured to do aliasing to DCGW1 and DCGW2 (bgp-evpn>mpls# ecmp 2), a packet hash determines that it has to be sent to DCGW2 (NDF). The packet arrives at DCGW2 with a unicast label. DCGW2 does a lookup and MAC AA is unknown for some reason (such as FDB limit exceeded, MAC not learned yet, and so on). In this case, DCGW2 will forward the packet to the I-ES VXLAN bindings, even if it is NDF. This behavior avoids black-hole periods in the network for unicast traffic.

Finally, in some cases, the unknown unicast forwarding behavior on the NDF may cause some transient packet duplication that can be avoided by configuring the **send-incl-mcast-ir-on-ndf** command. The following example shows the use of this command to avoid transient packet duplication. [Figure 120: All-active multi-homing and send-incl-mcast-ir-on-ndf true](#) shows how transient packet duplication may occur with the default setting (**send-incl-mcast-ir-on-ndf true**).

Figure 120: All-active multi-homing and send-incl-mcast-ir-on-ndf true

26874

Transient packet duplication may occur when sending unknown unicast from CE-1 to CE-6, if **send-incl-mcast-ir-on-ndf true** is configured in PE-3 and PE-2. To show this, we clear the FDBs in all the PEs in the example as well as the ARP caches on the CEs.

The following command is executed in all the PEs and CEs:

```
[/]
A:admin@PE-1# clear service id 1 fdb all

[/]
A:admin@PE-1# show service id 1 fdb detail
```

```

=====
```

When ICMP traffic is sent from CE-1 to CE-6, a duplicate entry occurs on CE-1:

```
[/]
A:admin@PE-1# ping 10.0.0.6 router-instance "VPRN 300"
PING 10.0.0.6 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=1 ttl=64 time=13.2ms.
64 bytes from 10.0.0.6: icmp_seq=1 ttl=64, duplicate.
64 bytes from 10.0.0.6: icmp_seq=2 ttl=64 time=5.27ms.
64 bytes from 10.0.0.6: icmp_seq=3 ttl=64 time=5.25ms.
64 bytes from 10.0.0.6: icmp_seq=4 ttl=64 time=4.73ms.
64 bytes from 10.0.0.6: icmp_seq=5 ttl=64 time=4.80ms.

---- 10.0.0.6 PING Statistics ----
5 packets transmitted, 5 packets received, 1 duplicate
round-trip min = 4.73ms, avg = 6.66ms, max = 13.2ms, stddev = 3.29ms
```

This duplicate entry occurs because the packet gets to CE-6 twice and CE-6 sends two unicast ICMP reply messages back. From the CE-1 packet walkthrough:

- PE-1 floods the packet to PE-2 and PE-3 because the CE-6 MAC DA is unknown and it has VXLAN multicast destinations to them.
- PE-2 floods the unknown unicast packet to all the remote PEs because it is DF for I-ES231. PE-2 will add an ESI label when sending to PE-3, and a BUM label when sending to all of them.
- PE-3 is NDF for I-ES231, but it floods the packet because the I-ES is all-active and the unknown unicast packet is considered low risk. The packet arrives with no ESI label, no BUM label (in VXLAN, VNIs are the same for unicast and BUM), and the MAC SA suppression passes because the packet is coming from the I-ES and not from MPLS. PE-3 uses a BUM label when flooding the packet and an ESI label when sending to PE-2.
- PE-4 receives two unknown unicast packets and forwards both to PE-6.
- PE-5 does not forward because it is NDF. This is true regardless of the I-ES being single-active or all-active (if all-active, the packet will not be forwarded because it arrives with a BUM label).

This packet duplication situation is transient and it will stop as soon as the two MAC addresses are learned on the PEs. However, if needed, this situation can be avoided by configuring **send-incl-mcast-ir-on-ndf false**:

```
# on PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      bgp-evpn {
        vxlan 1 {
          send-incl-mcast-ir-on-ndf false
        }
      }
    }
  }
}
```

This command will make the NDF (PE-3) withdraw the IMET-IR route; therefore, PE-1 will only flood unknown unicast packets to the DF (PE-2). The following IMET-IR routes are received on PE-1: one route sent by DF PE-2 for VPLS 1 and two routes for VPLS 101.

```
[/]

-----
Routes : 3
=====
```

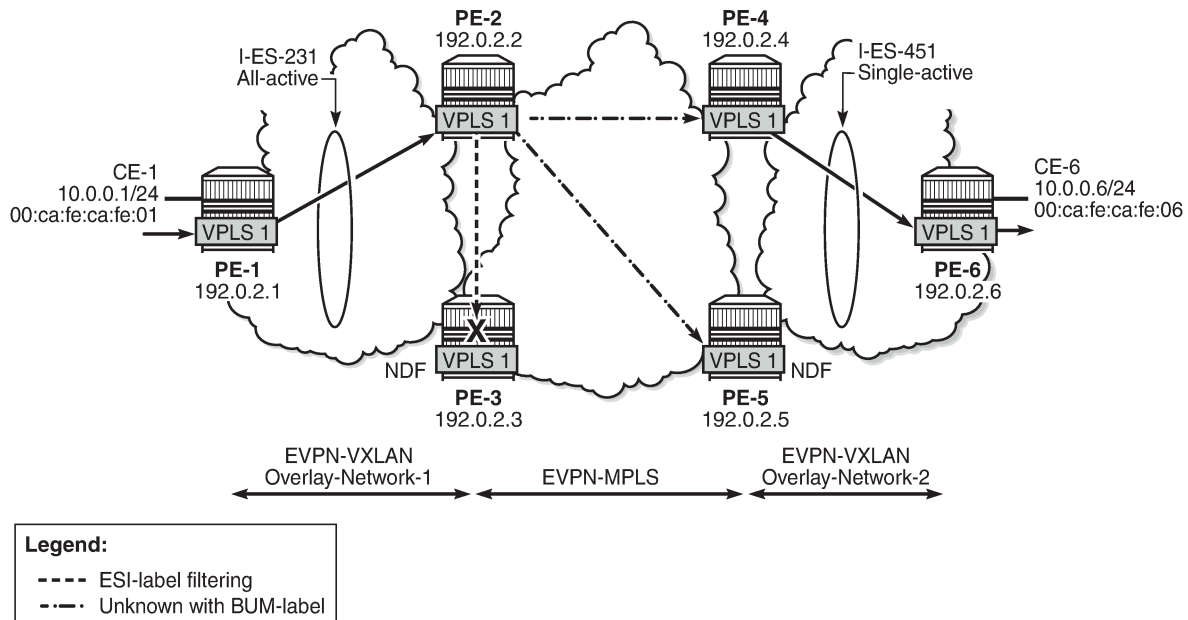

If a DF switchover occurs in the I-ES, the new DF would advertise the IMET-IR route and the new NDF would withdraw it.

After clearing FDBs and ARP caches again, the test is repeated with no packet duplication. [Figure 121: All-active multi-homing and send-incl-mcast-ir-on-ndf false](#) shows how PE-1 does not send unknown unicast to PE-3 (NDF) anymore and, therefore, there is no duplication.

```

Local SAPs and provider tunnels along with I-ES

As described in the [Overview](#) section, the main advantages of the I-ES solution over the anycast redundant solution for dual BGP-instance services are the support of local SAPs and P2MP mLDP trees without packet duplication. This section shows the configuration of local SAPs and provider tunnels along with I-ES in VPLS services. The local SAPs can, at the same time, belong to an ES or a vES.

As an example, VPLS 1 on PE-2 is reconfigured as follows (similar configuration on PE-3, with provider tunnel also configured on PE-4 and PE-5):

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "192.0.2.2:1"
      }
      bgp 2 {
        route-distinguisher "192.0.2.2:2"
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
```

```

        admin-state enable
        vxlan-instance 1
    }
    mpls 2 {
        admin-state enable
        ingress-replication-bum-label true
        ecmp 2
        auto-bind-tunnel {
            resolution any
        }
    }
}
sap lag-1:1 {
}
provider-tunnel {
    inclusive {
        admin-state enable
        owner bgp-evpn-mpls
        root-and-leaf true
        mldp
    }
}

```

To have EVPN multi-homing from a CE locally connected to PE-2 and PE-3, an additional ES is configured on PE-2 and PE-3 that will include the local SAPs in VPLS 1, as follows:

```

# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES232" {
                        admin-state enable
                        type virtual
                        esi 00:23:23:23:23:23:00:00:02
                        multi-homing-mode all-active
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 1 {
                                            end 1
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}

```

Troubleshooting and debugging

Common troubleshooting commands to operate dual BGP-instance VPLS services are in the corresponding section of [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#). Also, ES and virtual ES can be troubleshot by using the commands described in chapter [EVPN for MPLS Tunnels](#).

As well, the following **show** commands are specific to the use of I-ES in the router:

```

[/]
A:admin@PE-2# show service id 1 vxlan instance 1 oper-flags

```

```

Conclusion

Based on *draft-ietf-bess-dci-evpn-overlay*, SR OS supports the connectivity of Layer 2 EVPN-VXLAN services to an EVPN-MPLS network. This chapter complements the chapter [EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services](#) by describing how redundancy can be improved with the use of I-ES multi-homing, a concept standardized in *draft-ietf-bess-dci-evpn-overlay*.

EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services

This chapter provides information about EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 21.7.R1. EVPN multi-homing on dual VXLAN instance VPLS services is supported on SR OS Release 19.10.R1, and later.

Overview

Some service providers are deploying large Data Centers (DCs) where SR OS routers are used as leaf switches in a VXLAN fabric. In those cases, all-active multi-homing can provide redundancy and maximize the bandwidth utilization.

SR OS supports Interconnect Ethernet Segments (I-ESs) for VXLAN as per RFC 9014. Chapter [EVPN Interconnect Ethernet Segments](#) (I-ESs) describes how I-ESs allow Data Center Gateways (DCGWs) with two BGP instances (one for EVPN-MPLS and one for EVPN-VXLAN) to handle redundancy in VXLAN access networks, as supported in SR OS 15.0.R4, and later.

This chapter describes similar scenarios with EVPN-VXLAN in the core network instead of EVPN-MPLS. The following scenarios are supported with I-ES in VXLAN instance 1:

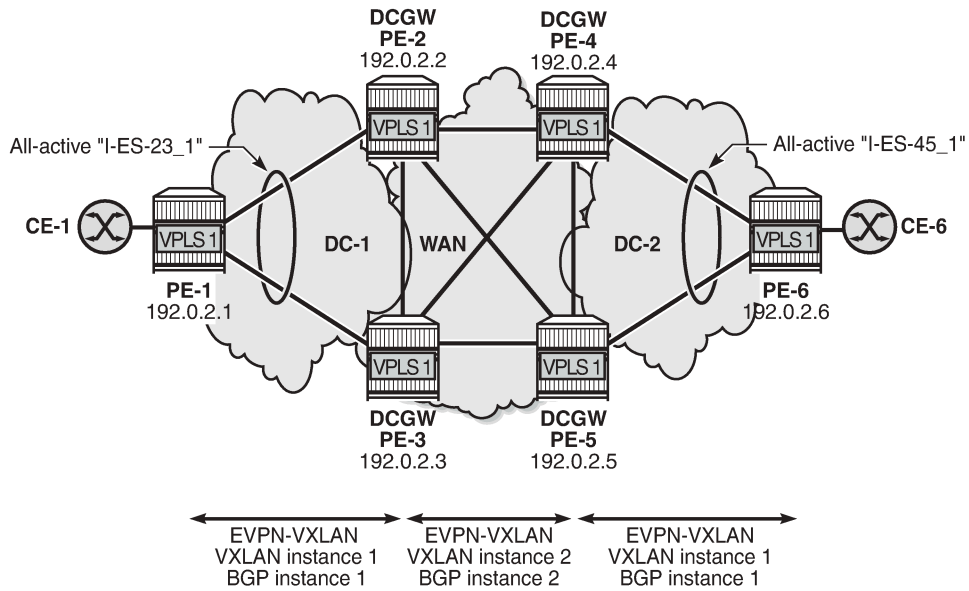

- dual instance VPLS with two EVPN-VXLAN instances
- dual instance VPLS with one EVPN-VXLAN instance and one static VXLAN instance
- dual instance VPLS with one EVPN-VXLAN instance and one EVPN-MPLS instance

The first two of these scenarios are described in this chapter.

CLI

[Figure 122: Sample topology](#) shows VPLS 1 with different EVPN-VXLAN instances: VXLAN instance 1 in DC 1 (and DC2) and VXLAN instance 2 in the WAN.

Figure 122: Sample topology

37109

On DCGW PE-2, the following all-active I-ES is configured for VXLAN instance 1 and service id 1:

```
# on DCGW PE-2:
configure {
  service {
    system {
      bgp-auto-rd-range {
        ip-address 192.0.2.2
        community-value {
          start 1
          end 1000
        }
      }
    }
    bgp {
      evpn {
        ethernet-segment "I-ES-23_1" {
          admin-state enable
          type virtual
          esi 00:23:23:23:23:23:00:00:01
          multi-homing-mode all-active
          df-election {
            service-carving-mode manual
            manual {
              evi 1 {
                end 1
              }
              preference {
                value 100
              }
            }
          }
        }
        association {
          network-interconnect-vxlan 1 {
            virtual-ranges {
              service-id 1 {

```

```
        }
    }
}
end 1
```

The following command configures VPLS 1 with dual EVPN-VXLAN instance. VXLAN instance 1 is a member of the I-ES and VXLAN instance 2 is configured with **mh-mode network** and **routes>auto-disc>advertise true**:

```
# on DCGW PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 11
          rx-discard-on-ndf bum
        }
        instance 2 {
          vni 12
        }
      }
    }
    bgp 1 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:11"
        import "target:64500:11"
      }
    }
    bgp 2 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:12"
        import "target:64500:12"
      }
    }
  }
  bgp-evpn {
    evi 1
    vxlan 1 {
      admin-state enable
      vxlan-instance 1
      default-route-tag 0xb
      ecmp 2
      routes {
        auto-disc {
          advertise true
        }
      }
    }
    vxlan 2 {
      admin-state enable
      vxlan-instance 2
      default-route-tag 0xc
      ecmp 2
      mh-mode network
      routes {
        auto-disc {
```

```
        advertise true
      }
    }
  }
  sap 1/2/1:1 {
  }
}
```

By default, the multi-homing mode for EVPN-VXLAN is access, but for VXLAN instance 2, it is modified to **mh-mode network**. The following error is raised when attempting to configure VXLAN instance 1—as a member of an I-ES—with **mh-mode network**:

```
[ex:/configure service vpls "VPLS 1" bgp-evpn vxlan 1]
A:admin@PE-2# mh-mode network

*[ex:/configure service vpls "VPLS 1" bgp-evpn vxlan 1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" bgp-evpn vxlan 1 mh-mode - mh-mode
network not supported when vxlan instance is member of ethernet-segment - configure service
system bgp evpn ethernet-segment "I-ES-23_1" association network-interconnect-vxlan 1 virtual-
ranges service-id 1
```

With **mh-mode network** configured, it is mandatory to configure **routes>auto-disc>advertise true**; for **mh-mode access**, it is optional. When **routes>auto-disc>advertise** is enabled in an access instance associated to an I-ES, AD per-ES/EVI routes and MAC/IP routes are advertised for the I-ES.

The following AD per-EVI route is sent by DCGW PE-2:

```
10 2021/09/29 17:53:31.575 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 81
  Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.2
    Type: EVPN-AD Len: 25 RD: 192.0.2.2:1 ESI: 00:23:23:23:23:23:00:00:01,
      tag: 0 Label: 11 (Raw Label: 0xb) PathId:
  Flag: 0x40 Type: 1 Len: 1 Origin: 0

    target:64500:11
    bgp-tunnel-encap:VXLAN
"
```

For MAC routes and their ESI value for an access VXLAN instance, the following redistribution considerations apply.

- With **mh-mode access** and **routes>auto-disc>advertise true** configured, MAC routes are redistributed from the instance network to the instance access with the I-ESI if present, regardless of the original ESI.
- With **mh-mode access** and **routes>auto-disc>advertise false**, MAC routes are redistributed with zero ESI, regardless of the original ESI.

The following EVPN-MAC route is sent by DCGW PE-2 with I-ESI 00:23:23:23:23:23:00:00:01 of "I-ES-23_1":

```
20 2021/09/29 17:53:31.577 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1

source-vtep-security on vxlan instance not supported when it is in use by bgp-evpn with mh-
mode network - configure service vpls "VPLS 1" vxlan instance 2 source-vtep-security
```

Local bias

When EVPN-VXLAN is used in the instance network of a dual-instance VPLS service, local bias—as described in RFC 8365—is used for split horizon in all-active I-ESs. In VXLAN, there is no multicast label or multicast BMAC, so BUM traffic is identified by the MAC destination address. The modified forwarding rules for the I-ES-sourced BUM traffic for ingress PE and egress PE are as follows:

- ingress PE
 - The Non-Designated Forwarder (NDF) must discard BUM traffic, so one of the following two commands must be configured in VXLAN instance 1.
 - **send-incl-mcast-ir-on-ndf false**
 - **rx-discard-on-ndf bum**
 - BUM frames received on any SAP or I-ES VXLAN binding are flooded to:
 - local non-ES and single-active DF ES SAPs
 - local all-active ES SAPs (DF and NDF)
 - EVPN-VXLAN destinations (BUM frames received on an I-ES VXLAN binding follow split-horizon rules, so they can only be forwarded to EVPN-VXLAN destinations belonging to the other VXLAN instance.)
- egress PE

- Look up source VTEP for BUM frames received on EVPN-VXLAN.
 - If the source VTEP matches a PE with which the local PE shares an ES and a VXLAN service, then the local PE does not forward to the shared local ESs (this includes port, lag, and network-interconnect-VXLAN ESs).
 - The local PE forwards to local ESs that are not shared but only when in DF state.

Figure 123: EVPN-VXLAN network interconnect VXLAN multi-homing and local bias shows the BUM forwarding with local bias procedures in multi-instance VPLS services.

Figure 123: EVPN-VXLAN network interconnect VXLAN multi-homing and local bias

37110

In the example, GW1 and GW2 are configured with **send-incl-mcast-ir-on-ndf false**. TOR1 generates BUM traffic that will only reach DF GW1 and is forwarded as follows.

- Ingress PE GW1 forwards to CE-1 and EVPN-VXLAN destinations GW2, GW3, and GW4.
- Egress PE GW2 identifies the source VTEP as a PE with which I-ES-1 is shared, so it does not forward the BUM frames to the local I-ES. PE GW2 forwards only to the non-shared ES and local SAPs, in this case, to CE-2.
- Egress PE GW3 receives the BUM traffic with a source VTEP that does not match any PE with which GW3 shares an ES, so it forwards to all ESs that are DF, in this case, to CE-3.
- Egress PE GW4 receives the BUM traffic with a source VTEP that does not match any PE with which GW4 shares an ES, so it forwards to all ESs that are DF, in this case, to TOR2 through I-ES-2.

Local bias with static VXLAN on I-ES

When a static VXLAN instance coexists with an EVPN-VXLAN instance in the same VPLS service, traffic blackholes may occur when the static VXLAN instance is associated to an all-active I-ES. This is because, when multi-homing is used with an EVPN-VXLAN network instance, the NDF PE always discards unknown unicast traffic to the static VXLAN instance (this is not the case with EVPN-MPLS if the unknown traffic has a BUM label).

Figure 124: All-active I-ES NDF PE-5 drops unknown unicast traffic shows the packet blackhole for unknown unicast traffic at all-active I-ES NDF PE-5.

Figure 124: All-active I-ES NDF PE-5 drops unknown unicast traffic

37111

In the event that the remote PE-1 has learned the destination MAC address MAC6 via I-ES-45 EVPN destination, but the DCGWs PE-4 and PE-5 do not know MAC6, regular aliasing procedures allow that PE-1 sends unicast traffic with destination MAC6 to the NDF PE-5, which does not know MAC6 and drops all unknown unicast traffic, creating a blackhole for the flow.

When a static VXLAN instance coexists with an EVPN-VXLAN instance in the same VPLS service, Nokia recommends using a single-active I-ES or an anycast solution without I-ES instead of an all-active I-ES.

Configuration

Figure 125: Sample topology shows the sample topology with six SR OS nodes:

Figure 125: Sample topology

37112

The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS on all interfaces (level 1 in the DCs; level 2 in the WAN)

BGP is configured for the EVPN address family. PE-1 acts as Route Reflector (RR) in DC 1 and PE-6 as RR in DC 2; no RR is used in the WAN.

The BGP configuration on RR PE-1 in DC 1 is as follows. The BGP configuration on RR PE-6 in DC2 is similar.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      cluster {
        cluster-id 192.0.2.1
      }
      rapid-update {
        evpn true
      }
      group "DC" {
        type internal
      }
      neighbor "192.0.2.2" {
        group "DC"
      }
      neighbor "192.0.2.3" {
        group "DC"
      }
    }
  }
}
```

```
}
```

On DCGWs PE-2 and PE-3, BGP is configured as follows. The policies are explained in the next section.

```
# on PE-2, PE-3:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
    }
    group "DC" {
      type internal
      import {
        policy ["drop S00-DCGW-23"]
      }
      export {
        policy ["export DC routes and add S00"]
      }
    }
    group "WAN" {
      type internal
      export {
        policy ["export WAN routes only"]
      }
    }
  }
  neighbor "192.0.2.1" {
    group "DC"
  }
  neighbor "192.0.2.4" {
    group "WAN"
  }
  neighbor "192.0.2.5" {
    group "WAN"
  }
}
```

On DCGWs PE-4 and PE-5, BGP is configured as follows. The policies are explained in the next section.

```
# on PE-4, PE-5:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
    }
    group "DC" {
```

```
        type internal
        import {
            policy ["drop S00-DCGW-45"]
        }
        export {
            policy ["export DC routes and add S00"]
        }
    }
    group "WAN" {
        type internal
        export {
            policy ["export WAN routes only"]
        }
    }
    neighbor "192.0.2.6" {
        group "DC"
    }
    neighbor "192.0.2.2" {
        group "WAN"
    }
    neighbor "192.0.2.3" {
        group "WAN"
    }
}
```

The following examples are configured:

- [All-active multi-homing I-ESs in dual EVPN-VXLAN instance VPLS](#)
- [Single-active multi-homing I-ES when static VXLAN coexists with EVPN-VXLAN in the same VPLS](#)

All-active multi-homing I-ESs in dual EVPN-VXLAN instance VPLS

[Figure 126: All-active multi-homing for I-ESs](#) shows the example topology with the service VPLS 1 on all nodes and two all-active I-ESs:

Figure 126: All-active multi-homing for I-ESs

37113

On PE-1, VPLS 1 is configured as follows. The configuration on PE-6 is similar.

```
# on PE-1:
configure {
  service {
    system {
      bgp-auto-rd-range {
        ip-address 192.0.2.1
        community-value {
          start 1
          end 1000
        }
      }
    }
  }
  vpls "VPLS 1" {
    admin-state enable
    service-id 1
    customer "1"
    vxlan {
      instance 1 {
        vni 11
      }
    }
    bgp 1 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:11"
        import "target:64500:11"
      }
    }
  }
  bgp-evpn {
    evi 1
    vxlan 1 {
      admin-state enable
    }
  }
}
```

```

        vxlan-instance 1
        ecmp 2
    }
}
sap 1/2/1:1 {
}
}

```

On DCGW PE-2, the following all-active multi-homing I-ES is configured for VXLAN instance 1 and service id 1. The configuration on DCGW PE-3 is similar, but the preference value is 150 instead of 100.

```

# on PE-2:
configure {
  service {
    system {
      bgp-auto-rd-range {
        ip-address 192.0.2.2
        community-value {
          start 1
          end 1000
        }
      }
    }
    bgp {
      evpn {
        ethernet-segment "I-ES-23_1" {
          admin-state enable
          type virtual
          esi 00:23:23:23:23:23:00:00:01
          multi-homing-mode all-active
          df-election {
            service-carving-mode manual
            manual {
              evi 1 {
                end 1
              }
            }
            preference {
              value 100          # on PE-3: preference value 150
            }
          }
        }
      }
      association {
        network-interconnect-vxlan 1 {
          virtual-ranges {
            service-id 1 {
              end 1
            }
          }
        }
      }
    }
  }
}

```

On DCGWs PE-4 and PE-5, the following I-ES is configured:

```

# on PE-4, PE-5:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES-45_1" {

```

```
admin-state enable
type virtual
esi 00:45:45:45:45:45:00:00:01
multi-homing-mode all-active
association {
  network-interconnect-vxlan 1 {
    virtual-ranges {
      service-id 1 {
        end 1
      }
    }
  }
}
```

On DCGWs PE-2, PE-3, PE-4, and PE-5, VPLS 1 is configured as follows. The **rx-discard-on-ndf bum** command makes the NDF drop any BUM traffic in VXLAN instance 1. VXLAN instance 2 is configured with **mh-mode network** and **routes>auto-disc>advertise true**.

```
# on PE-2, PE-3, PE-4, PE-5:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 11
          rx-discard-on-ndf bum
        }
        instance 2 {
          vni 12
        }
      }
    }
    bgp 1 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:11"
        import "target:64500:11"
      }
    }
    bgp 2 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:12"
        import "target:64500:12"
      }
    }
  }
  bgp-evpn {
    evi 1
    vxlan 1 {
      admin-state enable
      vxlan-instance 1
      default-route-tag 0xb
      ecmp 2
      routes {
        auto-disc {
          advertise true
        }
      }
    }
  }
}
```

```

    }
    vxlan 2 {
        admin-state enable
        vxlan-instance 2
        default-route-tag 0xc
        ecmp 2
        mh-mode network
        routes {
            auto-disc {
                advertise true
            }
        }
    }
}
sap 1/2/1:1 {
}
}

```

On PE-2 and PE-3, the following policies are configured.

- The import policy "drop SOO-DCGW-23" in group "DC" is used to drop all VXLAN instance 1 routes between PE-2 and PE-3.
- The export policy "export WAN routes only" in group "WAN" is applied to avoid sending VXLAN instance 1 routes to the WAN PEs.
- The export policy "export DC routes and add SOO" in group "DC" is used to tag VXLAN instance 1 routes with community "SOO-23".

```

# on PE-2, PE-3:
configure {
    policy-options {
        community "SOO-23" {
            member "origin:64500:23" { }
        }
    }
    policy-statement "drop SOO-DCGW-23" {           # import in group "DC"
        entry 10 {
            from {
                family [evpn]
                community {
                    name "SOO-23"
                }
            }
            action {
                action-type reject
            }
        }
        default-action {
            action-type accept
        }
    }
    policy-statement "export WAN routes only" {     # export in group "WAN"
        entry 10 {
            from {
                family [evpn]
                tag 11
            }
            action {
                action-type reject
            }
        }
        default-action {
            action-type accept
        }
    }
}

```

```

    }
  }
  policy-statement "export DC routes and add S00" {      # export in group "DC"
    entry 10 {
      from {
        family [evpn]
        tag 11
      }
      action {
        action-type accept
        community {
          add ["S00-23"]
        }
      }
    }
    default-action {
      action-type accept
    }
  }
}

```

On PE-4 and PE-5, the following policies are configured:

```

# on PE-4, PE-5:
configure {
  policy-options {
    community "S00-45" {
      member "origin:64500:45" { }
    }
  }
  policy-statement "drop S00-DCGW-45" {                # import in group "DC"
    entry 10 {
      from {
        family [evpn]
        community {
          name "S00-45"
        }
      }
      action {
        action-type reject
      }
    }
    default-action {
      action-type accept
    }
  }
  policy-statement "export WAN routes only" {          # export in group "WAN"
    entry 10 {
      from {
        family [evpn]
        tag 11
      }
      action {
        action-type reject
      }
    }
    default-action {
      action-type accept
    }
  }
  policy-statement "export DC routes and add S00" {   # export in group "DC"
    entry 10 {
      from {
        family [evpn]
        tag 11
      }
    }
  }
}

```

```

    }
    action {
      action-type accept
      community {
        add ["S00-45"]
      }
    }
  }
  default-action {
    action-type accept
  }
}

```

For VPLS 1, PE-2 is DF and PE-3 is NDF in the I-ES "I-ES-23_1":

```

```

Single-active multi-homing I-ES when static VXLAN coexists with EVPN-VXLAN in the same VPLS

Figure 127: I-ES with EVPN-VXLAN in DC 1 and static VXLAN in DC2 shows the sample topology for VPLS 2 with static VXLAN in DC 2 and the single-active "I-ES-45_2" on PE-4 and PE-5.

Figure 127: I-ES with EVPN-VXLAN in DC 1 and static VXLAN in DC2

37114

The configuration for VPLS 2 on PE-1, PE-2, and PE-3 is similar to the configuration for VPLS 1, so only the configuration on PE-4, PE-5, and PE-6 is shown.

On PE-6, VPLS 2 is configured with static VXLAN using non-anycast VTEP addresses:

```
# on PE-6:
configure {
  service {
    vpls "VPLS 2" {
      admin-state enable
      service-id 2
      customer "1"
      vxlan {
        instance 1 {
          vni 21
          egress-vtep 192.0.2.4 { }
          egress-vtep 192.0.2.5 { }
        }
      }
      sap 1/2/1:2 {
      }
    }
  }
}
```

To avoid blackholes, the I-ES between DCGWs PE-4 and PE-5 must not be all-active.

On PE-4 and PE-5, the single-active I-ES "I-ES-45_2" is configured as follows:

```
# on PE-4, PE-5:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "I-ES-45_2" {
            admin-state enable
            type virtual
            esi 00:45:45:45:45:45:00:00:02
            multi-homing-mode single-active
            association {
              network-interconnect-vxlan 1 {
                virtual-ranges {
                  service-id 2 {
                    end 2
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

On PE-4 and PE-5, VPLS 2 is configured as follows:

```
# on PE-4, PE-5:
configure {
  service {
    vpls "VPLS 2" {
      admin-state enable
      service-id 2
      customer "1"
      vxlan {
        instance 1 {
          vni 21
          egress-vtep 192.0.2.6 { }
        }
        instance 2 {
          vni 22
        }
      }
    }
    bgp 2 {
      route-distinguisher auto-rd
      route-target {
        export "target:64500:22"
        import "target:64500:22"
      }
    }
    bgp-evpn {
      evi 2
      vxlan 2 {
        admin-state enable
        vxlan-instance 2
        default-route-tag 0x16      # default route tag 22
        ecmp 2
        mh-mode network
        routes {
          auto-disc {
```

```

        advertise true
    }
}
}
sap 1/2/1:2 {
}
}

```

The policies on all DCGWs must be modified with tag 21 for VXLAN instance 1 in VPLS 2, as follows:

```

# on PE-2, PE-3:
configure {
  policy-options {
    policy-statement "export WAN routes only" {
      entry 20 {
        from {
          family [evpn]
          tag 21
        }
        action {
          action-type reject
        }
      }
      default-action {
        action-type accept
      }
    }
    policy-statement "export DC routes and add S00" {
      entry 20 {
        from {
          family [evpn]
          tag 21
        }
        action {
          action-type accept
          community {
            add ["S00-23"]
          }
        }
      }
      default-action {
        action-type accept
      }
    }
  }
}

```

DCGW PE-5 is NDF for "I-ES-45_2":

```

[/]
A:admin@PE-5# show service id 2 ethernet-segment
No sap entries
No sdp entries

```

```

=====
VXLAN Ethernet-Segment Information
=====

```

VXLAN Instance	Eth-Seg	Status
1	I-ES-45_2	NDF

```

=====

```

On PE-5, the status of VXLAN instance 1 in VPLS 2 is mhStandby, as follows:

```

Note:

An anycast solution without I-ES can also be configured when an EVPN-VXLAN coexists with a static VXLAN.

Conclusion

Service providers can use I-ESs for better bandwidth utilization and redundancy in large DCs. EVPN all-active multi-homing I-ESs can be used in dual EVPN-VXLAN instance VPLS services. However, when a static VXLAN instance coexists with EVPN-VXLAN in the same VPLS, a single-active multi-homing I-ES (or an anycast solution without I-ES) is required to avoid blackholes.

EVPN IP-VRF-to-IP-VRF Models

This chapter provides information about EVPN IP-VRF-to-IP-VRF models.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 16.0.R3, but the MD-CLI in the current edition corresponds to SR OS Release 23.7.R2. SR OS supports the three EVPN IP-VRF-to-IP-VRF models described in *draft-ietf-bess-evpn-prefix-advertisement*.

Overview

EVPN is considered the standard for Data Centers (DCs) and DC Interconnect (DCI) for layer 2 and layer 3 services. *Draft-ietf-bess-evpn-prefix-advertisement* describes the following three IP-VRF-to-IP-VRF models:

- Interface-less model (mandatory)
- Interface-ful model with Supplementary Broadcast Domain (SBD) Interworking Routing and Bridging (IRB) (mandatory)
- Interface-ful model with unnumbered SBD IRB (optional)

In standard terminology, SBD is the Broadcast Domain (BD) that joins two IP-VRFs. In SR OS, the SBD is a "backhaul" R-VPLS service that connects two PEs attached to VPRNs of the same VPN. For IP prefix advertisement in the SBD, IP route advertisement needs to be enabled in the BGP-EVPN context, whereas MAC advertisement is enabled by default. BGP-EVPN IP prefix route type 5 (RT-5) updates are used in all models; MAC/IP routes (RT-2) are used in the interface-ful models only. In the interface-less model, MAC advertisement must be disabled.

[Figure 128: Interface-ful SBD IRB](#) and [Figure 129: Interface-ful unnumbered SBD IRB](#) show the two interface-ful IP-VRF-to-IP-VRF models: SBD IRB and unnumbered SBD IRB. Both interface-ful SBD IRB models require BGP-EVPN IP prefix routes (RT-5) with recursive lookup to MAC/IP routes (RT-2). Host 1 is located in broadcast domain 1 (BD1 corresponds to an R-VPLS) linked to the VRF in PE-1 and host 2 is located in BD2 linked to the VRF in PE-2. The VRFs correspond to VPRNs that are linked to an SBD, which is a backhaul R-VPLS.

The following examples are based on EVPN-VXLAN, but IP-VRF-to-IP-VRF also works for EVPN-MPLS. Instead of the VNI, the MPLS label is then included in the RT-5 and RT-2 updates.

Figure 128: Interface-ful SBD IRB

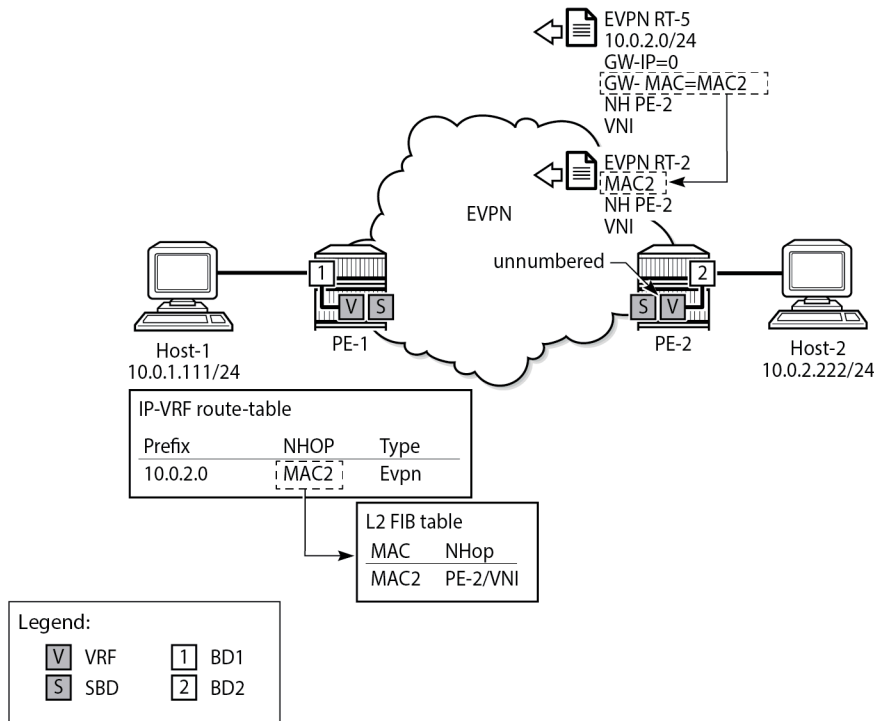

28619

The interface-ful SBD IRB model requires an IP address on the VPRN interface for the SBD (IP2 on PE-2); no EVPN tunnel can be used. Both PEs will send BGP-EVPN RT-5 (IP prefix) and BGP-EVPN RT-2 (MAC/IP) updates. PE-2 sends an RT-5 update for IP prefix 10.0.2.0/24 with GW IP address IP2 and an RT-2 update for GW IP address IP2 with MAC2 and next-hop PE-2. On PE-1, the prefix 10.0.2.0/24 appears in the VRF route table as an EVPN route with next-hop GW IP2. The ARP table for the VRF contains the corresponding MAC address MAC2 for the GW IP address IP2. The FDB of the SBD includes an EVPN entry for GW MAC address MAC2 with next-hop PE-2.

When the VPRN is configured toward the SBD with an EVPN tunnel rather than a numbered IP interface, the RT-5 update will contain the GW MAC address MAC2 instead of the GW IP address IP2. [Figure 129: Interface-ful unnumbered SBD IRB](#) shows that PE-2 sends an RT-5 update for IP prefix 10.0.2.0/24 with GW MAC address MAC2 and an RT-2 update for GW MAC address MAC2 with next-hop PE-2. Again, a recursive lookup is done.

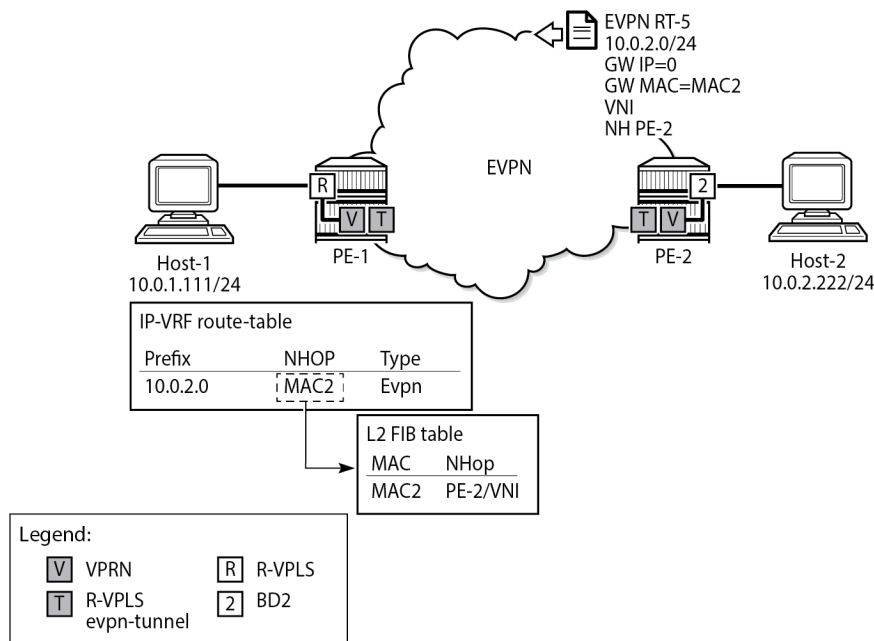

Figure 129: Interface-ful unnumbered SBD IRB

28620

Finally, in the interface-less IP-VRF-to-IP-VRF model, MAC advertisement is disabled in the BGP-EVPN context of the backhaul R-VPLS. BGP-EVPN RT-5 updates will contain the GW MAC address, and no RT-2 updates will be sent; therefore, the number of BGP-EVPN updates is reduced and no recursive lookup is done on PE-1. PE-1 adds an entry in its FDB based on an RT-5 route instead of an RT-2 route from PE-2. [Figure 130: Interface-less IP-VRF-to-IP-VRF model](#) shows the interface-less IP-VRF-to-IP-VRF model where PE-2 sends an RT-5 update with GW MAC address MAC2.

Figure 130: Interface-less IP-VRF-to-IP-VRF model

28621

Note:

Other vendors do not use a service context as the R-VPLS EVPN tunnel shown in [Figure 130: Interface-less IP-VRF-to-IP-VRF model](#), and they configure the route targets used for the RT-5 updates in the VPRN (or VRF) instances. When interoperating with those vendors, ensure that the R-VPLS route targets match the route targets in the VRF of the third-party router.

The standard specification *draft-ietf-bess-evpn-ip-prefix* supports two variants of the interface-less model that are not interoperable with each other:

- EVPN interface-less (EVPN IFL) for Ethernet Network Virtualization Overlay (NVO) tunnels
Ethernet NVO indicates that the EVPN packets contain an inner Ethernet header. The ingress PE uses the received router's MAC extended community address in the IP prefix route as the inner destination MAC address for the EVPN packets sent to the prefix. This corresponds to the scenario described in [Figure 130: Interface-less IP-VRF-to-IP-VRF model](#).
- EVPN IFL for IP NVO tunnels
IP NVO indicates that the EVPN packets contain an inner IP packet, but no Ethernet header. This is similar to the IP-VPN packets exchanged between PEs. In this scenario, the IP prefix route does not contain any GW (IP or MAC) address. The IP packets are directly encapsulated with an EVPN service label and the transport labels. This model is described further in [Interface-less model in EVPN-MPLS with IP encapsulation](#).

EVPN MAC selection criteria

In the EVPN IFL for Ethernet NVO scenario, the MAC address entry in the R-VPLS FDB that is required to forward packets to the remote PE is obtained from an internal MAC/IP route. This internal route is obtained

from the router MAC extended community in the BGP-EVPN RT-5 update. In case the same MAC address is received in multiple ways, the following MAC selection criteria apply. Beginning with criterion (1), the MAC is selected if the criterion is met, or the next criterion is applied. As indicated in (8), a MAC received from an RT-2 has higher priority than a MAC populated by the router MAC extended community in an RT-5 update.

1. Conditional static MAC addresses (locally protected MAC addresses)
2. Auto-learned protected MAC addresses (locally learned MAC addresses on SAPs or SDP-bindings due to the configuration of **auto-learn-mac-protect**)
3. EVPN ES PBR MAC addresses
4. EVPN static MAC addresses (remotely protected MAC addresses)
5. Data plane learned MAC addresses (regular learning on SAPs or SDP-bindings)
6. EVPN MAC routes with a higher sequence number
7. EVPN E-Tree root MAC addresses
8. EVPN non-RT-5 MAC addresses (this tie-breaking rule is only applied if the selection algorithm is comparing received MAC routes (RT-2) and internal MAC routes derived from the MAC addresses in IP-prefix routes, such as RT-5 MACs)
9. Lowest IP address for the next-hop of the EVPN NLRI
10. Lowest Ethernet tag (that will be zero for MPLS and might be different from zero for VXLAN)
11. Lowest route distinguisher
12. Lowest BGP instance (this tie-breaking rule is only applied if the preceding rules fail to select a unique MAC address and the service has two BGP instances of the same encapsulation)

EVPN IP-VRF-to-IP-VRF model comparison

Each model has its advantages. [Table 8: EVPN IP-VRF-to-IP-VRF model comparison](#) compares the three IP-VRF-to-IP-VRF models.

Table 8: EVPN IP-VRF-to-IP-VRF model comparison

Advantage	Model 1 Interface-less	Model 2 Interface-ful SBD IRB	Model 3 Interface-ful unnumbered SBD IRB
Reduced number of EVPN routes	Yes	No	No
Ease of provisioning (no IP address on core IRB)	Yes	No	Yes
Mass withdrawal due to recursive resolution	No	Yes	Yes

Configuration

The following use cases are documented in this chapter:

- [IP-VRF-to-IP-VRF Models in EVPN-VXLAN](#)
 - [Interface-ful model with SBD IRB in EVPN-VXLAN](#)
 - [Interface-ful model with unnumbered SBD IRB in EVPN-VXLAN](#)
 - [Interoperable interface-less model in EVPN-VXLAN](#)
- [IP-VRF-to-IP-VRF Models in EVPN-MPLS](#)
 - [Interface-ful model with SBD IRB in EVPN-MPLS](#)
 - [Interface-ful model with unnumbered SBD IRB in EVPN-MPLS](#)
 - [Interface-less model in EVPN-MPLS](#)
 - [Interoperable interface-less model with Ethernet encapsulation](#)
 - [Interface-less model with IP encapsulation for MPLS tunnels](#)

IP-VRF-to-IP-VRF model in EVPN-VXLAN

[Figure 131: Example topology with services - EVPN-VXLAN](#) shows the example topology with two PEs. Hosts 1 and 2—emulated through VPRNs—are attached to R-VPLS 1 and 2 respectively.

Figure 131: Example topology with services - EVPN-VXLAN

28622

The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- BGP for address family EVPN

On PE-1, the BGP configuration is as follows. The BGP configuration on PE-2 is similar.

```
# on PE-1:
```

```
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      rapid-update {
        evpn true
      }
    }
    group "dc" {
      type internal
      family {
        evpn true
      }
    }
    neighbor "192.0.2.2" {
      group "dc"
      ebgp-default-reject-policy {
        import false
        export false
      }
    }
  }
}
```

Interface-ful model with SBD IRB in EVPN-VXLAN

The service configuration on PE-1 includes the SBD R-VPLS "sbd-15", VPRN "ip-vrf-151", and R-VPLS "bd-1". The service configuration on PE-2 is similar, but R-VPLS "bd-2" is configured instead of R-VPLS "bd-1".

On PE-1, SBD R-VPLS "sbd-15" is configured with VNI 15, as follows. MAC advertisement is enabled by default, but IP route advertisement must be enabled explicitly. Only one BGP instance and one VXLAN instance are configured.

```
# on PE-1:
configure {
  service {
    vpls "sbd-15" {
      admin-state enable
      description "backhaul R-VPLS 15"
      service-id 15
      customer "1"
      vxlan {
        instance 1 {
          vni 15
        }
      }
      routed-vpls {
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 15
        routes {
          ip-prefix {
            advertise true
          }
        }
      }
      vxlan 1 {
      }
    }
  }
}
```

```

        admin-state enable
        vxlan-instance 1
    }
}

```

VPRN "ip-vrf-151" has two interfaces: one toward the SBD R-VPLS "sbd-15" and one toward BD R-VPLS "bd-1". The interface toward the SBD has GW IP address 172.16.151.1/24 and MAC address 00:00:00:01:51:01. The interface toward R-VPLS 1 has IP address 10.0.1.1/24 and MAC address 00:00:00:1e:01:01. VRRP is configured in passive mode, so PE-1 uses the backup IP address as an anycast gateway. The backup IP address is 10.0.1.254 and the auto-derived virtual MAC address is 00:00:5e:00:00:01 for VRID 1. On PE-1, VPRN "ip-vrf-151" is configured as follows:

```

# on PE-1:
configure {
  service {
    vprn "ip-vrf-151" {
      admin-state enable
      service-id 151
      customer "1"
      ecmp 2
      interface "int-bd-1" {
        mac 00:00:00:1e:01:01
        ipv4 {
          primary {
            address 10.0.1.1
            prefix-length 24
          }
          vrrp 1 {
            backup [10.0.1.254]
            passive true
            ping-reply true
            traceroute-reply true
          }
        }
        vpls "bd-1" {
        }
      }
      interface "int-sbd-15" {
        mac 00:00:00:01:51:01
        ipv4 {
          primary {
            address 172.16.151.1
            prefix-length 24
          }
          vpls "sbd-15" {
          }
        }
      }
    }
  }
}

```

On PE-1, R-VPLS "bd-1" is configured as follows. Host 1 is attached to the SAP.

```

# on PE-1:
configure {
  service {
    vpls "bd-1" {
      admin-state enable
      description "R-VPLS 1 - BD 1"
      service-id 1
      customer "1"
    }
  }
}

```

```

        routed-vpls {
        }
        sap pxc-10.a:1 {
        }
    }

```

In this example, host 1 is simulated by VPRN "host1", as follows. The default route has next-hop 10.0.1.254, which is the VRRP backup address in VPRN "ip-vrf-151".

```

# on PE-1:
configure {
  service {
    vprn "host1" {
      admin-state enable
      description "Host-1 attached to R-VPLS 1"
      service-id 11
      customer "1"
      interface "local" {
        mac 00:00:00:10:11:01
        ipv4 {
          primary {
            address 10.0.1.111
            prefix-length 24
          }
        }
        sap pxc-10.b:1 {
        }
      }
      static-routes {
        route 0.0.0.0/0 route-type unicast {
          next-hop "10.0.1.254" {
            admin-state enable
          }
        }
      }
    }
  }
}

```

The service configuration on PE-2 is similar, with R-VPLS "bd-2" instead of R-VPLS "bd-1" and VPRN "host2" instead of VPRN "host1". The GW IP address on PE-2 is 172.16.151.2/24, interface "int-bd-2" in VPRN "ip-vrf-151" has IP address 10.0.2.2/24, and host "host2" has IP address 10.0.2.222/24.

PE-1 receives a BGP-EVPN RT-5 update from PE-2 for IP prefix 10.0.2.0/24, as follows. The GW address is IP address 172.16.151.2 and the next-hop is PE-2.

```

Interface-ful model with unnumbered SBD IRB in EVPN-VXLAN

On both PEs, the GW IP addresses 172.16.151.x/24 are removed from interface "int-sbd-15" in VPRN "ip-vrf-151" and an EVPN tunnel is configured instead. The changes in the configuration of VPRN "ip-vrf-151" are the following:

```
# on PE-1, PE-2:
configure {
  service {
    vprn "ip-vrf-151" {
      interface "int-sbd-15" {
        delete ipv4
        vpls "sbd-15" {
          evpn-tunnel {
          }
        }
      }
    }
  }
}
```

The configuration of VPRN "ip-vrf-151" on PE-1 is as follows:

```
[ex:/configure service vprn "ip-vrf-151"]
A:admin@PE-1# info
  admin-state enable
  service-id 151
  customer "1"
  ecmp 2
  interface "int-bd-1" {
    mac 00:00:00:1e:01:01
    ipv4 {
      primary {
        address 10.0.1.1
        prefix-length 24
      }
      vrrp 1 {
        backup [10.0.1.254]
        passive true
        ping-reply true
        traceroute-reply true
      }
    }
  }
  vpls "bd-1" {
  }
}
interface "int-sbd-15" {
  mac 00:00:00:01:51:01
  vpls "sbd-15" {
    evpn-tunnel {
    }
  }
}
}
```

The provisioning is easier with unnumbered SBD IRB because no IRB IP addresses need to be configured in the VPRN.

PE-1 receives the following RT-5 update for IP prefix 10.0.2.0/24 with GW MAC address 00:00:00:01:51:02, because there is no GW IP address. The GW MAC address is used in the VPRN route table, where the EVPN tunnel leads toward this GW MAC address.

```
[/]

```

Interoperable interface-less model in EVPN-VXLAN

This model is interface-less because no SBD is required to connect the VPRNs and no recursive resolution is required upon receiving an IP prefix route. The next-hop of the IP prefix route is directly resolved to an EVPN tunnel, without the need for any other route.

The only difference from the preceding configuration is that MAC route advertisement is disabled in the backhaul R-VPLS on both PEs, as follows:

```
# on PE-1, PE-2:
configure {
  service {
    vpls "sbd-15" {
      bgp-evpn {
        routes {
          mac-ip {
            advertise false
          }
        }
      }
    }
  }
}
```

The configuration of the backhaul R-VPLS is as follows:

```
[ex:/configure service vpls "sbd-15"]
A:admin@PE-1# info
  admin-state enable
  description "backhaul R-VPLS 15"
  service-id 15
  customer "1"
  vxlan {
    instance 1 {
      vni 15
    }
  }
  routed-vpls {
```

```

}
bgp 1 {
}
bgp-evpn {
  evi 15
  routes {
    mac-ip {
      advertise false
    }
    ip-prefix {
      advertise true
    }
  }
  vxlan 1 {
    admin-state enable
    vxlan-instance 1
  }
}
}

```

Again, the provisioning is easier with unnumbered SBD IRB because no IRB IP addresses need to be configured in the VPRN.

PE-1 receives the following BGP-EVPN RT-5 update for IP prefix 10.0.2.0/24 with GW MAC address 00:00:00:01:51:02, which is the same as in the preceding use case:

```

[/]
A:admin@PE-1# show router bgp routes evpn ip-prefix

IP-VRF-to-IP-VRF models in EVPN-MPLS

The three IP-VRF-to-IP-VRF models are also supported in EVPN-MPLS. [Figure 132: Example topology with services - EVPN-MPLS](#) shows the example topology with the services R-VPLS "sbd-16", VPRN "ip-vrf-161", R-VPLS "bd-3" (or "bd-4"), and VPRN "host3" for host 3 (or VPRN "host4" for host 4).

Figure 132: Example topology with services - EVPN-MPLS

28623

For MPLS, LDP is configured on the interface between PE-1 and PE-2.

Interface-ful model with SBD IRB in EVPN-MPLS

The following services are configured on PE-1 and PE-2:

- Backhaul R-VPLS "sbd-16"
- VPRN "ip-vrf-161"
- R-VPLS "bd-3" on PE-1; R-VPLS "bd-4" on PE-2
- VPRN "host3" on PE-1; VPRN "host4" on PE-2

The service configuration on PE-1 is as follows. MAC route advertisement is enabled by default. The configuration on PE-2 is similar.

```

# on PE-1:
configure {
  service {
    vpls "sbd-16" {

```

```
admin-state enable
description "backhaul EVPN-MPLS R-VPLS 16"
service-id 16
customer "1"
routed-vpls {
}
bgp 1 {
}
bgp-evpn {
  evi 16
  routes {          # MAC advertisement is by default enabled
    ip-prefix {
      advertise true
    }
  }
  mpls 1 {
    admin-state enable
    auto-bind-tunnel {
      resolution any
    }
  }
}
}
vprn "ip-vrf-161" {
  admin-state enable
  service-id 161
  customer "1"
  ecmp 2
  interface "int-bd-3" {
    mac 00:00:00:3e:03:01
    ipv4 {
      primary {
        address 10.0.3.1
        prefix-length 24
      }
    }
    vrrp 1 {
      backup [10.0.3.254]
      passive true
      ping-reply true
      traceroute-reply true
    }
  }
  vpls "bd-3" {
  }
}
interface "int-sbd-16" {
  mac 00:00:00:01:61:01
  ipv4 {
    primary {
      address 172.16.161.1
      prefix-length 24
    }
  }
  vpls "sbd-16" {
  }
}
}
vpls "bd-3" {
  admin-state enable

  service-id 3
  customer "1"
  routed-vpls {
  }
}
```

```

        sap pxc-10.a:3 {
        }
    }
    vprn "host3" {
        admin-state enable
        description "Host-3 attached to R-VPLS 3"
        service-id 31
        customer "1"
        interface "local" {
            mac 00:00:00:30:11:01
            ipv4 {
                primary {
                    address 10.0.3.111
                    prefix-length 24
                }
            }
            sap pxc-10.b:3 {
            }
        }
        static-routes {
            route 0.0.0.0/0 route-type unicast {
                next-hop "10.0.3.254" {
                    admin-state enable
                }
            }
        }
    }
}

```

PE-1 receives the following BGP-EVPN IP prefix route for prefix 10.0.4.0/24:

```

[/]
A:admin@PE-1# show router bgp routes evpn ip-prefix

The following traceroute from host 3 to host 4 shows that the GW IP address is the second hop:

```
[/]
A:admin@PE-1# traceroute 10.0.4.222 router-instance "host3" source-address 10.0.3.111
traceroute to 10.0.4.222 from 10.0.3.111, 30 hops max, 40 byte packets
 1 10.0.3.1 (10.0.3.1)  2.45 ms 1.03 ms 1.41 ms
 2 172.16.161.2 (172.16.161.2)  2.27 ms 2.39 ms 2.32 ms
 3 10.0.4.222 (10.0.4.222)  5.39 ms 2.62 ms 2.77 ms
```

The route table and ARP table in VPRN 161 and the FDB in R-VPLS 16 are similar to the ones in the [Interface-ful model with SBD IRB in EVPN-VXLAN](#) section.

Interface-ful model with unnumbered SBD IRB in EVPN-MPLS

The GW IP addresses are removed from the "int-sbd-16" interface in VPRN "ip-vrf-161" and an EVPN tunnel is configured instead. On PE-1, VPRN "ip-vrf-161" is configured as follows:

```
[ex:/configure service vprn "ip-vrf-161"]
A:admin@PE-1# info
admin-state enable
service-id 161
customer "1"
ecmp 2
interface "int-bd-3" {
  mac 00:00:00:3e:03:01
  ipv4 {
    primary {
      address 10.0.3.1
      prefix-length 24
    }
  }
}
```

```
    }
    vrrp 1 {
        backup [10.0.3.254]
        passive true
        ping-reply true
        traceroute-reply true
    }
}
vpls "bd-3" {
}
}
interface "int-sbd-16" {
    mac 00:00:00:01:61:01
    vpls "sbd-16" {
        evpn-tunnel {
        }
    }
}
}
```

The route table in VPRN "ip-vrf-161" and the FDB in R-VPLS "sbd-16" are similar to the ones in the [Interface-ful model with unnumbered SBD IRB in EVPN-VXLAN](#) section.

Interoperable interface-less model in EVPN-MPLS with Ethernet encapsulation

In the EVPN interface-less (EVPN IFL) model, the next hop of the IP prefix route is directly resolved to an EVPN tunnel, without the need for any other route.

MAC route advertisement is disabled in backhaul R-VPLS "sbd-16", as follows:

```
[ex:/configure service vpls "sbd-16"]
A:admin@PE-1# info
admin-state enable
description "backhaul EVPN-MPLS R-VPLS 16"
service-id 16
customer "1"
routed-vpls {

```

The interoperable interface-less model in EVPN-MPLS with Ethernet encapsulation is interface-ful although compatible with EVPN interface-less.

Interface-less model in EVPN-MPLS with IP encapsulation

In this IP NVO model, the ingress PE no longer pushes an inner Ethernet header, but the IP packet is directly encapsulated with an EVPN service label and the transport labels.

The PEs advertise IP prefixes without router MAC extended community. The route lookup in the VPRN does not point at an SBD R-VPLS, but rather to an MPLS tunnel terminated in the other PE. The packets are sent with an EVPN service label that was received in the IP prefix route.

The configuration of VPRN "ip-vrf-161" is modified: the interface "int-sbd-16" is removed and a BGP-EVPN context is added with route distinguisher, VRF target, and auto-bind tunnel. VPLS "sbd-16" is not used at all. The following shows the configuration of VPRN "ip-vrf-161" on PE-1:

```

[ex:/configure service vprn "ip-vrf-161"]
A:admin@PE-1# info
  admin-state enable
  service-id 161

```

```

customer "1"
  ecmp 2
  bgp-evpn {
    mpls 1 {
      admin-state enable
      route-distinguisher "192.0.2.1:161"
      vrf-target {
        community "target:64500:161"
      }
      auto-bind-tunnel {
        resolution any
      }
    }
  }
  interface "int-bd-3" {
    mac 00:00:00:3e:03:01
    ipv4 {
      primary {
        address 10.0.3.1
        prefix-length 24
      }
      vrrp 1 {
        backup [10.0.3.254]
        passive true
        ping-reply true
        traceroute-reply true
      }
    }
    vpls "bd-3" {
    }
  }
}

```

The configuration on PE-2 is similar.

The following route table shows that the EVPN route is interface-less, the next hop is the IP address of PE-2, and the tunnel is an MPLS (LDP) tunnel instead of an EVPN tunnel:

```

Conclusion

The three EVPN IP-VRF-to-IP-VRF models each have advantages. Different vendors have chosen different models in the first phases of their EVPN implementations. SR OS supports all three EVPN IP-VRF-to-IP-VRF models, so they can be deployed in all environments where third-party vendors are deployed already.

EVPN Multi-Homing for VXLAN VPLS Services

This chapter provides information about EVPN Multi-Homing for VXLAN VPLS Services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 21.7.R1.

EVPN multi-homing has been supported in SR OS for EVPN-MPLS and PBB-EVPN in SR OS Release 13.0.R4 and later. SR OS Release 16.0 introduced EVPN multi-homing for EVPN-VXLAN on Epipe services. EVPN-VXLAN multi-homing in a single VXLAN instance VPLS or R-VPLS service—as specified in RFC 8365—is supported in SR OS Release 19.5.R1, and later.

Before you read this chapter, ensure you are familiar with the concepts in the [EVPN for VXLAN Tunnels \(Layer 2\)](#) chapter.

Overview

Some Service Providers are deploying large Telco cloud Data Centers (DCs) where SR OS nodes are used as leaf switches in a VXLAN fabric. In those cases, all-active multi-homing can provide redundancy and maximize the bandwidth use.

The multi-homing procedures consist of three components:

- Designated Forwarder (DF) election
 - The PEs attached to the same Ethernet Segment (ES) elect a single PE as DF to:
 - forward all traffic, in case of single-active mode
 - forward all Broadcast, Unknown unicast, Multicast (BUM) traffic, in case of all-active mode
- split-horizon
 - BUM traffic received from a peer ES PE is filtered so that it is not looped back to the CE that first transmitted the frame.
 - in EVPN-VXLAN services, split-horizon is only used with all-active mode and makes use of the local bias procedure described in RFC 8365.
- aliasing
 - PEs that are not attached to the ES can process non-zero Ethernet Segment Identifier (ESI) MAC/IP routes and AD routes and create ES destinations to which per-flow Equal Cost Multi-Path (ECMP) can be applied.
 - Aliasing only applies to all-active mode.

Split-horizon using local bias

In EVPN-MPLS services, split-horizon filtering uses ESI labels. VXLAN does not support ESI labels or MPLS labels. In EVPN-VXLAN services, the split-horizon filtering is based on the tunnel source IP address. In RFC 8365, this forwarding is referred to as local bias. Local bias works as follows:

- Every PE knows the IP addresses associated with the other PEs with which it has shared multi-homed ESs.
- The ingress PE replicates locally to all directly attached ESs, regardless of the DF state, for all flooded traffic coming from the access interfaces. BUM frames received on any SAP are flooded to:
 - local non-ES SAPs and non-ES SDP bindings
 - local all-active ES SAPs (DF and NDF)
 - local single-active ES SDP bindings and SAPs (DF only)
 - EVPN-VXLAN destinations
- When an egress PE receives a BUM frame from a VXLAN binding, it looks up the source IP address in the tunnel header and filters out the frame on all local interfaces connected to ESs that are shared with the ingress PE. The following rules apply to egress PE forwarding for EVPN-VXLAN services.
 1. The source VTEP is looked up for BUM frames received on EVPN-VXLAN.
 2. The router checks if the source VTEP matches one of the PEs with which the egress PE shared both an ES and a VXLAN service.
 - If there is a match, the egress PE is not forwarding to the shared ES local SAPs.
 - If there is no match, the egress PE forwards to ES SAPs in DF state (as usual).

[Figure 133: Split-horizon filtering based on tunnel source IP address](#) shows an example of local bias forwarding for BUM frames.

Figure 133: Split-horizon filtering based on tunnel source IP address

37102

In this example, BUM frames sent by Host-1 are treated as follows.

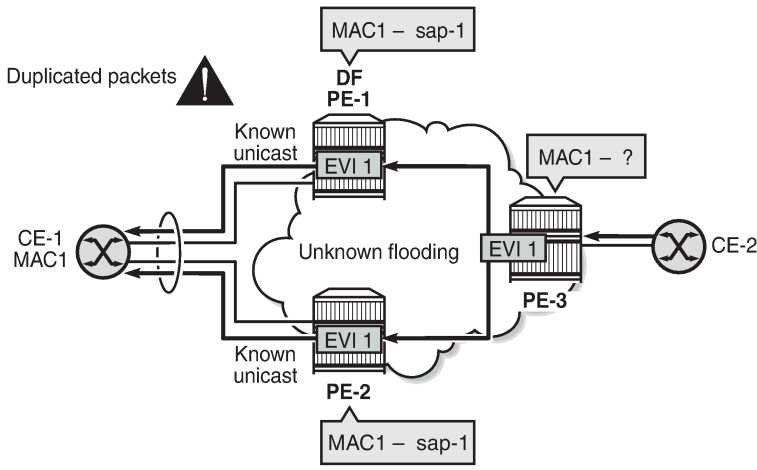

- Ingress node PE-1 receives BUM frames from Host-1 and forwards them to the other PEs (EVPN-VXLAN destinations) and the local all-active ES SAP toward Host-2, even though the SAP is in NDF state.
- Egress node PE-2 receives BUM frames on VXLAN. PE-2 identifies the source VTEP as a PE with which two all-active ESs are shared, so it does not forward the BUM frames to the two shared ESs. PE-2 forwards the BUM frames to the non-shared ES toward Host-3 because it is in DF state.
- Egress node PE-3 receives BUM traffic from PE-1, with which it does not share any ESs, so it forwards the BUM frames based on normal rules: it does not forward them toward Host-3, because the ES SAP is in NDF state. PE-3 only forwards toward Host-5.
- PE-4 does not share any ESs with PE-1, so the normal rules apply. PE-4 forwards the BUM frames toward Host-4.

Known limitations for local bias

In VXLAN, there are no BUM labels or any tunnel indication that can identify BUM traffic. The egress PE must solely rely on the Customer MAC (CMAC) destination address and this may create transient issues.

- Duplicate unicast traffic may occur when the CMAC destination address MAC1 is unknown on the ingress PE-3, while known on the egress PEs (PE-1 and PE-2). [Figure 134: Duplicate unicast packets when MAC1 is unknown on PE-3 only](#) shows that a packet with destination MAC1 arrives at PE-3, where it is flooded via ingress replication to PE-1 and PE-2, where MAC1 is known. PE-1 and PE-2 both forward the packets with CMAC destination MAC1 to CE-1, so multiple copies are sent to CE-1.

Figure 134: Duplicate unicast packets when MAC1 is unknown on PE-3 only

37103

- A blackhole may occur when the CMAC destination address MAC1 is known on PE-3, but unknown on PE-1 and PE-2 and the aliasing hashing on PE-3 picks up the path to the NDF, where unknown unicast traffic is dropped, as shown in [Figure 135: Packet blackhole for traffic on NDF PE-2 when MAC1 is known on PE-3 only](#). When the path to the DF is picked, no problem occurs, because the DF forwards BUM traffic.

Figure 135: Packet blackhole for traffic on NDF PE-2 when MAC1 is known on PE-3 only

37104

- A blackhole can be created when a remote SAP is disabled, as shown in [Figure 136: Blackhole created when a remote SAP is disabled](#).

Under normal circumstances, when CE-3 sends BUM traffic to ingress node PE-3, the local bias mechanism on PE-3 forwards the BUM packets to SAP3, even though it is NDF for the ES. The BUM traffic is also flooded to PE-2, where it is forwarded to CE-2, but not to SAP2, because the ES is shared with PE-3.

When SAP3 is manually disabled (**admin-state disable**), PE-3 withdraws the AD per-EVI route corresponding to SAP3. This does not change the local bias filtering for SAP2 on PE-2, so when CE-3 sends BUM traffic, it can neither be forwarded to CE-23 via SAP3 nor by PE-2.

Figure 136: Blackhole created when a remote SAP is disabled

37105

CLI

The multi-homing capabilities are enabled in all the PEs attached to the VPLS service by configuring the options **routes auto-disc advertise** and **mh-mode network** in the **vpls bgp-evpn vxlan** context.

The **routes auto-disc advertise** option is by default disabled, but it can be enabled as follows:

```
*[ex:/configure service vpls "VPLS 2" bgp-evpn vxlan 1 routes auto-disc]
A:admin@PE-2# advertise true
```

This **routes auto-disc advertise** command is only configurable for EVPN-VXLAN VPLS services and is implicitly enabled on all instances where it is not configurable. **routes auto-disc advertise** is required in nodes with local ESs and remote ESs to process and enable the creation of ES destinations.

When **routes auto-disc advertise** is enabled, BGP-EVPN:

- processes Auto-Discovery per EVPN instance (AD per-EVI) routes and AD per-ES routes
- processes MAC/IP routes with non-zero Ethernet Segment Identifier (ESI) — without resetting the ESI to zero
- creates ES destinations upon receiving MAC/IP routes and AD per-ES/EVI routes with non-zero ESI.

The **mh-mode** option can be configured with the values **access** or **network**. For EVPN-VXLAN services, the default value is **access**. The following command configures **mh-mode network**:

```
*[ex:/configure service vpls "VPLS 2" bgp-evpn vxlan 1]
A:admin@PE-2# mh-mode network
```

When **mh-mode network** is configured, BGP-EVPN:

- activates multi-homing for the local ES SAPs or SDP-bindings and creates ES associations and related processes, such as:
 - the local bias mode allowing the system to add all-active SAPs to the flooding list regardless of the DF state
 - the source VTEP lookup mode
- runs DF election for the ESs associated with the service
- triggers the advertisement of AD per-ES routes, AD per-EVI routes, and non-zero MAC/IP routes for the ESs in the service.

Configuration

The following examples are configured:

- [EVPN-VXLAN multi-homing with system IPv4 VTEP addresses](#)
- [EVPN-VXLAN multi-homing with non-system IPv4 VTEP addresses](#)
- [EVPN-VXLAN multi-homing with non-system IPv6 VTEP addresses](#)

EVPN-VXLAN multi-homing with system IPv4 VTEP addresses

Figure 137: Example topology shows the topology with three all-active multi-homing ESs and one single-active multi-homing ES. This example shows the configuration for virtual Ethernet Segments, as described in the [Virtual Ethernet Segments](#) chapter, but non-virtual ES can also be used.

Figure 137: Example topology

37106

The initial configuration on the PEs includes:

- cards, MDAs, ports

- LAG 1 on MTU-7, PE-1, PE-2
LAG 2 on MTU-8, PE-1, PE-2
LAG 3 on MTU-9, PE-2, PE-3
- router interfaces
- IS-IS between the PEs
- SR-ISIS between PE-4 and MTU-6 and between PE-5 and MTU-6 (and TLDP for SDP signaling)

BGP is configured between the PEs for the EVPN address family. PE-1 acts as route reflector, as follows:

```
# on RR PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
        cluster {
          cluster-id 192.0.2.1
        }
      }
      neighbor "192.0.2.2" {
        group "internal"
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
      neighbor "192.0.2.4" {
        group "internal"
      }
      neighbor "192.0.2.5" {
        group "internal"
      }
    }
  }
}
```

ES configuration

The all-active ESs "vES-12_1_1" and "vES-12_2_1" are configured on PE-1 and PE-2. The configuration on PE-1 is as follows. The configuration on PE-2 is similar, but with different preference values.

```
# on PE-1:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "vES-12_1_1" {
            admin-state enable
          }
        }
      }

      }
    }
  }
}
}
}
```

On PE-2 and PE-3, the all-active ES "vES-23_3_1" is configured in a similar way:

```
# on PE-2:
configure {
  service {
    system {
      bgp {
```

```

evpn {
  ethernet-segment "vES-23_3_1" {
    admin-state enable
    type virtual
    esi 00:23:23:23:23:23:00:03:01
    multi-homing-mode all-active
    df-election {
      service-carving-mode manual
      manual {
        evi 1 {
          end 1
        }
      }
      preference {
        value 100          # on PE-3: preference value 150
      }
    }
  }
  association {
    lag "lag-3" {
      virtual-ranges {
        dot1q {
          q-tag 1 {
            end 1
          }
        }
      }
    }
  }
}

```

On PE-4 and PE-5, the single-active ES "ES-45" is configured, as follows:

```

# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ES-45" {
            admin-state enable
            esi 00:45:45:45:45:45:00:00:01
            multi-homing-mode single-active
            df-election {
              service-carving-mode manual
              manual {
                evi 1 {
                  end 1
                }
              }
              preference {
                value 100          # on PE-5: preference value 150
              }
            }
          }
          association {
            sdp 46 {              # on PE-5: sdp 56
            }
          }
        }
      }
    }
  }
  sdp 46 {                      # on PE-5: sdp 56

```

```

    admin-state enable
    delivery-type mpls
    sr-isis true
    far-end {
        ip-address 192.0.2.6
    }
}

```

VPLS configuration

VPLS 1 is configured on PE-2 as follows. The configuration is similar on PE-1 and PE-3.

```

# on PE-2:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2           # different values on different PEs
                community-value {
                    start 1
                    end 1000
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                    mh-mode network
                    routes {
                        auto-disc {
                            advertise true
                        }
                    }
                }
            }
        }
        sap lag-1:1 {
        }
        sap lag-2:1 {
        }
        sap lag-3:1 {
        }
    }
}

```

The EVPN-VXLAN multi-homing capabilities are enabled in the PEs attached to VPLS 1 by the commands **routes auto-disc advertise** and **mh-mode network**. The **routes auto-disc advertise** command enables the advertisement and processing of multi-homing routes, and the **mh-mode network** command activates the DF election procedures.

ECMP is required for per-flow load balancing for VXLAN ES destinations with two or more next hops. In this example, ECMP is configured with a value of 2.

On PE-4, VPLS 1 is configured as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher auto-rd
        route-target {
          export "target:64500:1"
          import "target:64500:1"
        }
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
          ecmp 2
          mh-mode network
          routes {
            auto-disc {
              advertise true
            }
          }
        }
      }
      spoke-sdp 46:1 {
    }
  }
}

# on PE-5: spoke-sdp 56:1
```

Show commands

The following command shows that the commands **mh-mode network** and **routes auto-disc advertise** are enabled:

```
[/]
A:admin@PE-2# show service id 1 bgp-evpn

Tools command to check local bias

The following **tools** command on PE-2 checks whether local bias is enabled for the peers in ES "vES-12_1_1". The output lists the PEs that are in the candidate DF election list for the ES and whether

local bias procedures are enabled on them. In this case, only peer 192.0.2.1 is in the list and local bias is enabled. The output is similar for ES "vES-12_2_1".

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vES-12_1_1" local-bias
-----
[09/27/2021 16:45:44] Vxlan Local Bias Information
-----+-----
Peer                                     | Enabled
-----+-----
192.0.2.1                               | Yes
-----
```

The PE can only enable local bias procedures on a maximum of three PEs that are attached to the same ES and use multi-homed VXLAN services. If more than three PEs exist, the PEs are ordered by preference or IP address and only the top three PEs are considered for local bias. The order is as follows:

- lowest IP address (automatic service-carving)
- lowest preference (manual service-carving with configured EVI)
- highest preference (manual service-carving without configured EVI)

The following **tools** command on PE-2 shows that local bias is enabled for peer 192.0.2.3 in ES "vES-23_3_1":

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vES-23_3_1" local-bias
-----
[09/27/2021 16:45:44] Vxlan Local Bias Information
-----+-----
Peer                                     | Enabled
-----+-----
192.0.2.3                               | Yes
-----
```

Verify local bias for BUM traffic in all-active multi-homing ESs

Unknown unicast traffic is generated on MTU-7. This traffic is received in ingress queue 11 for SAP lag-1:1 on ingress node PE-1. The following **monitor** command — in classic CLI — monitors SAP lag-1:1 in VPLS 1 on PE-1:

```
*A:PE-1# monitor service id 1 sap lag-1:1

=====

```

On the ingress node PE-1, the local bias mechanism forwards this BUM traffic toward EVPN-VXLAN destinations, and also to the local SAPs of all-active ESs, regardless of the DF state. In this case, the local bias mechanism forwards the BUM traffic to lag-2:1 toward MTU-8, even though PE-1 is NDF in ES "vES-12_2_1".

```

-----

```

The egress PEs PE-2 and PE-3 receive the BUM traffic on the EVPN-VXLAN terminations. On egress PEs, the local bias mechanism filters BUM traffic based on the source IP address 192.0.2.1 of PE-1. PE-2 does not forward the traffic to the local SAPs lag-1:1 and lag-2:1, because PE-2 shares the all-active ESs

"vES-12_1_1" and "vES-12_2_1" with PE-1. However, PE-2 forwards the BUM traffic to the non-shared ES "vES-23_3_1" because it is DF.

The following **monitor** commands show that PE-2 does not send any traffic toward SAP lag-1:1 or SAP lag-2:1.

```
*A:PE-2# monitor service id 1 sap lag-1:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf      : 0           0
Dro. Out/ExcProf        : 0           0
For. In/InplusProf      : 0           0
For. Out/ExcProf        : 0           0
---snip---
```

```
*A:PE-2# monitor service id 1 sap lag-2:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf      : 0           0
Dro. Out/ExcProf        : 0           0
For. In/InplusProf      : 0           0
For. Out/ExcProf        : 0           0
---snip---
```

The following **monitor** command shows that PE-2 forwards the traffic to SAP lag-3:1 toward MTU-9:

```
*A:PE-2# monitor service id 1 sap lag-3:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf      : 0           0
Dro. Out/ExcProf        : 0           0
For. In/InplusProf      : 0           0
For. Out/ExcProf        : 6           408
---snip---
```

Egress node PE-3 receives BUM traffic on VXLAN and filters on IP address 192.0.2.1, but there are no shared ESs with PE-1. PE-3 is NDF for the non-shared ES vES-23_3_1, so it does not forward the traffic to SAP lag-3:1, as follows:

```
*A:PE-3# monitor service id 1 sap lag-3:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf      : 0           0
Dro. Out/ExcProf        : 0           0
For. In/InplusProf      : 0           0
For. Out/ExcProf        : 0           0
---snip---
```

EVPN-VXLAN multi-homing with non-system IPv4 VTEP addresses

Figure 138: Non-system IPv4 VTEP multi-homing for VXLAN VPLS 2 shows the non-system IPv4 addresses to be used as VTEP addresses.

Figure 138: Non-system IPv4 VTEP multi-homing for VXLAN VPLS 2

37107

Forwarding Path Extension (FPE), as described in the [VXLAN Forwarding Path Extension](#) chapter, is configured on all PEs. The configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  fwd-path-ext {
    sdp-id-range {
      start 10000
      end 10127
    }
  }
  fpe 1 {
    path {
      pxc 1
    }
    application {
      vxlan-termination {
      }
    }
  }
}
port 1/2/6 {
  admin-state enable
  ethernet {
    mode hybrid
    dot1x {
      tunneling true
    }
  }
}
port pxc-1.a {
  admin-state enable
}
port pxc-1.b {
  admin-state enable
}
port-xc {
  pxc 1 {
    admin-state enable
  }
}
```

```

        port-id 1/2/6
    }
}
router "Base" {
    interface "loopback1" {
        loopback
        ipv4 {
            primary {
                address 10.0.1.0
                prefix-length 31
            }
        }
        ipv6 {
            address 2001:db8::10:0 {
                prefix-length 127
            }
        }
    }
    isis 0 {
        interface "loopback1"
        passive true
    }
}
}
service {
    system {
        vxlan {
            tunnel-termination 10.0.1.1 {
                fpe-id 1
            }
            tunnel-termination 2001:db8::10:1 {
                fpe-id 1
            }
        }
    }
}

```

The configuration on the other PEs is similar but with different IP addresses, for example, 10.0.2.1 on PE-2, 10.0.3.1 on PE-3, and so on.

The non-system IP address in each of the PEs in the ES must match in the following three commands for the local PE to be considered suitable for DF election:

- **orig-ip 10.0.x.1 (ES)**

The **orig-ip** command modifies the originating IP address in the ES routes advertised for the ES and makes the system use this IP address when adding the local PE as DF candidate.

- **route-next-hop 10.0.x.1 (ES)**

The **route-next-hop** command changes the next hop of the ES routes and AD per-ES routes to the configured address.

- **vxlan source-vtep 10.0.x.1 (VPLS)**

The **vxlan source-vtep** command makes the router use the configured IP address as the VXLAN tunnel source IP address (source VTEP) for originating VXLAN-encapsulated frames for the service. The source VTEP is also used to set the BGP NLRI next hop in EVPN route advertisements for the services.

The following all-active multi-homing ESs are configured on PE-2 with non-system IPv4 address 10.0.2.1:

```

# on PE-2:
configure {
    service {
        system {

```

```
bgp {
  evpn
    ethernet-segment "vES-12_1_2" {
      admin-state enable
      type virtual
      esi 00:12:12:12:12:12:12:00:01:02
      orig-ip 10.0.2.1
      route-next-hop 10.0.2.1
      multi-homing-mode all-active
      df-election {
        service-carving-mode manual
        manual {
          preference {
            value 150
          }
        }
      }
      association {
        lag "lag-1" {
          virtual-ranges {
            dot1q {
              q-tag 2 {
                end 2
              }
            }
          }
        }
      }
    }
    ethernet-segment "vES-12_2_2" {
      admin-state enable
      type virtual
      esi 00:12:12:12:12:12:12:00:02:02
      orig-ip 10.0.2.1
      route-next-hop 10.0.2.1
      multi-homing-mode all-active
      df-election {
        service-carving-mode manual
        manual {
          preference {
            value 100
          }
        }
      }
      association {
        lag "lag-2" {
          virtual-ranges {
            dot1q {
              q-tag 2 {
                end 2
              }
            }
          }
        }
      }
    }
  }
  ethernet-segment "vES-23_3_2" {
    admin-state enable
    type virtual
    esi 00:23:23:23:23:23:23:00:03:02
    orig-ip 10.0.2.1
    route-next-hop 10.0.2.1
    multi-homing-mode all-active
    df-election {
```

```
        service-carving-mode manual
        manual {
            preference {
                value 100
            }
        }
    }
    association {
        lag "lag-3" {
            virtual-ranges {
                dot1q {
                    q-tag 2 {
                        end 2
                    }
                }
            }
        }
    }
}
}
```

The ES configuration on the other PEs is similar, but with different IP addresses and preference values.
VPLS 2 is configured with source VTEP 10.0.2.1 on PE-2:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 10.0.2.1        # different IP address on different PEs
                instance 1 {
                    vni 2
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:2"
                    import "target:64500:2"
                }
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                    mh-mode network
                    routes {
                        auto-disc {
                            advertise true
                        }
                    }
                }
            }
        }
        sap lag-1:2 {                # lag-1 is shared with PE-1
        }
        sap lag-2:2 {                # lag-2 is shared with PE-1
        }
    }
}
```

```

        sap lag-3:2 {          # lag-3 is shared with PE-3
        }
    }

```

The configuration on the other PEs is similar.

Verification

The following command shows the DF status for the different ESs in VPLS 2 on PE-1:

```

[/]
A:admin@PE-1# show service id 2 ethernet-segment
=====

EVPN-VXLAN multi-homing with non-system IPv6 VTEP addresses

Figure 139: Non-system IPv6 VTEP multi-homing for VXLAN VPLS 2 shows the non-system IPv6 addresses to be used as VTEP addresses.

Figure 139: Non-system IPv6 VTEP multi-homing for VXLAN VPLS 2

37108

Between the PEs, the router interfaces have IPv6 addresses as well as IPv4 addresses, and **ipv6-routing native** is configured in IS-IS on the PEs. FPE is configured with VXLAN termination 2001:db8::x0:1 on PE-X.

The following all-active multi-homing ESs with non-system IPv6 addresses are configured on PE-2:

```
# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "vES-12_1_3" {
            admin-state enable
            type virtual
            esi 00:12:12:12:12:12:12:00:01:03
            orig-ip 2001:db8::20:1
            route-next-hop 2001:db8::20:1
            multi-homing-mode all-active
            association {
              lag "lag-1" {
                virtual-ranges {
                  dot1q {
                    q-tag 3 {
                      end 3
                    }
                  }
                }
              }
            }
          }
          ethernet-segment "vES-12_2_3" {
            admin-state enable
            type virtual
            esi 00:12:12:12:12:12:12:00:02:03
            orig-ip 2001:db8::20:1
            route-next-hop 2001:db8::20:1
            multi-homing-mode all-active
          }
        }
      }
    }
  }
}
```

```

        routes {
            auto-disc {
                advertise true
            }
        }
    }
}
sap lag-1:3 {          # lag-1 shared with PE-1
}
sap lag-2:3 {          # lag-2 shared with PE-1
}
sap lag-3:3 {          # lag-3 shared with PE-3
}
}

```

Verification

The following command on PE-1 shows that the source VTEP is 2001:db8::10:1 for VPLS 3:

```

Debug

With debugging enabled for BGP updates, the following debug message on PE-3 shows that the NextHop value is changed in the EVPN-AD routes:

```

29 2021/09/27 17:36:42.781 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE

```

Conclusion

All-active and single-active multi-homing can be configured for EVPN-VXLAN VPLSs. On all-active ESs, split-horizon for BUM traffic is based on local-bias, as described in RFC 8365.

EVPN R-VPLS Attached to IES

This chapter provides information about EVPN R-VPLS attached to IES.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written based on SR OS Release 16.0.R3, but the MD-CLI configuration in the current edition corresponds to SR OS Release 23.10.R1.

Overview

R-VPLS services are often terminated on VPRN services. However, in some cases, R-VPLS services need to be terminated on IES services so that the traffic can be routed via the GRT. This is also supported for EVPN R-VPLS services.

Configuration

In this section, the following examples are configured:

- EVPN-VXLAN R-VPLS attached to IES without multi-homing
- EVPN-MPLS R-VPLS attached to IES with all-active and single-active multi-homing

EVPN-VXLAN R-VPLS attached to IES

[Figure 140: EVPN-VXLAN R-VPLS attached to IES](#) shows the example topology with EVPN-VXLAN configured on PE-2 and PE-4 and EVPN-VXLAN R-VPLSs 1 and 2 attached to IES 12 on PE-4.

Figure 140: EVPN-VXLAN R-VPLS attached to IES

28624b

CE-1 is in Autonomous System (AS) 64501 and the other nodes are in AS 64500.

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-2 and PE-4

Configuration on PE-2

On PE-2, BGP is configured for the EVPN address family, as follows:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "internal-evpn" {
      type internal
      peer-as 64500
      family {
        evpn true
      }
    }
    neighbor "192.0.2.4" {
      group "internal-evpn"
    }
  }
}
```

EVPN-VXLAN VPLS 1 is an ordinary VPLS on PE-2, not an R-VPLS, and configured as follows. CE-1 is attached to SAP 1/1/c2/1:1 on PE-2.

```
# on PE-2:
configure {
  service {
    vpls "VPLS-1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      sap 1/1/c2/1:1 {
      }
    }
  }
}
```

Configuration on PE-4

On PE-4, R-VPLS "evi-1" is configured as follows. CE-41 is attached to the SAP. The configuration of R-VPLS "evi-2" is similar.

```
# on PE-4:
configure {
  service {
    vpls "evi-1" {
      admin-state enable
      description "EVPN-VXLAN R-VPLS evi-1"
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      routed-vpls {
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      sap pxc-1.a:1 {
      }
    }
  }
}
```

Both R-VPLSs are attached to IES 12, which is configured as follows. Interface "int-evi-1" gets IP address 10.0.1.4/24 and interface "int-evi-2" gets IP address 10.0.2.4/24; these addresses are used as next-hop in default static routes on CE-1, CE-41, and CE-42.

```
# on PE-4:
configure {
  service {
    ies "IES-12" {
      admin-state enable
      service-id 12
      customer "1"
      interface "int-evi-1" {
        mac 00:00:00:00:01:04
        vpls "evi-1" {
        }
        ipv4 {
          primary {
            address 10.0.1.4
            prefix-length 24
          }
        }
      }
      interface "int-evi-2" {
        mac 00:00:00:00:02:04
        vpls "evi-2" {
        }
        ipv4 {
          primary {
            address 10.0.2.4
            prefix-length 24
          }
        }
      }
    }
  }
}
```

The BGP configuration on PE-4 includes an internal EVPN session with PE-2 (neighbor 192.0.2.2), an internal IPv4 session with CE-42 (neighbor 10.0.2.42), and an external IPv4 session with CE-1 (neighbor 10.0.1.1), as follows:

```
# on PE-4:
configure {
  router "Base" {
    bgp {
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "external-ipv4" {
      type external
      peer-as 64501
      family {
        ipv4 true
      }
      local-as {
        as-number 64500
      }
    }
    group "internal-evpn" {
      type internal
      family {

```

```

        evpn true
    }
}
group "internal-ipv4" {
    type internal
    family {
        ipv4 true
    }
}
neighbor "10.0.1.1" {
    group "external-ipv4"
    ebgp-default-reject-policy {
        import false
        export false
    }
}
neighbor "10.0.2.42" {
    group "internal-ipv4"
}
neighbor "192.0.2.2" {
    group "internal-evpn"
}
}
}

```

In this example, CE-41 is emulated as VPRN "CE-41" on PE-4. CE-41 is attached via port cross-connect (PXC) to R-VPLS "evi-1". The default static route has next-hop 10.0.1.4 on interface "int-evi-1" in IES 12. CE-41 has an EBGP-IPv4 session configured with neighbor CE-1 (10.0.1.1); CE-41 exports prefix 172.16.41.0/24 to CE-1. The configuration of VPRN "CE-41" on PE-4 is as follows:

```

# on PE-4:
configure {
    service {
        vprn "CE-41" {
            admin-state enable
            description "CE-41 attached to R-VPLS evi-1 on PE-4"
            service-id 41
            customer "1"
            autonomous-system 64500
            bgp {
                router-id 10.0.1.41
                rapid-withdrawal true
                peer-ip-tracking true
                split-horizon true
                group "external" {
                    type external
                    peer-as 64501
                    family {
                        ipv4 true
                    }
                    local-as {
                        as-number 64500
                    }
                    export {
                        policy ["export-bgp-ipv4-41"]
                    }
                }
            }
            neighbor "10.0.1.1" {
                group "external"
                ebgp-default-reject-policy {
                    import false
                }
            }
        }
    }
}

```

```

interface "int-1_41" {
    mac 00:00:00:00:01:41
    ipv4 {
        primary {
            address 10.0.1.41
            prefix-length 24
        }
    }
    sap pxc-1.b:1 {
    }
}
interface "lol" {
    loopback true
    mac 00:00:00:04:41:41
    ipv4 {
        primary {
            address 172.16.41.41
            prefix-length 24
        }
    }
}
static-routes {
    route 0.0.0.0/0 route-type unicast {
        next-hop "10.0.1.4" {
            admin-state enable
        }
    }
}
}

```

CE-42 is emulated as VPRN "CE-42" on PE-4. CE-42 is attached via PXC to R-VPLS "evi-2". The default static route has next-hop equal to 10.0.2.4 on interface "int-evi-2" in IES 12. An IBGP-IPv4 session is configured to this IES interface (neighbor 10.0.2.4). CE-42 exports prefix 172.16.42.0/24 to this IES interface on PE-4. The configuration of VPRN "CE-42" on PE-4 is as follows:

```

# on PE-4:
configure {
    service {
        vprn "CE-42" {
            admin-state enable
            description "CE-42 attached to R-VPLS evi-2 on PE-4"
            service-id 42
            customer "1"
            autonomous-system 64500
            bgp {
                router-id 10.0.2.42
                rapid-withdrawal true
                peer-ip-tracking true
                split-horizon true
                group "internal-ipv4" {
                    type internal
                    family {
                        ipv4 true
                    }
                    export {
                        policy ["export-bgp-ipv4-42"]
                    }
                }
                neighbor "10.0.2.4" {
                    group "internal-ipv4"
                }
            }
        }
    }
    interface "int-2_42" {

```

```

        mac 00:00:00:00:02:42
        ipv4 {
            primary {
                address 10.0.2.42
                prefix-length 24
            }
        }
        sap pxc-1.b:2 {
        }
    }
    interface "int-test42" {
        mac 00:00:00:04:42:42
        ipv4 {
            primary {
                address 172.16.42.42
                prefix-length 24
            }
        }
        sap pxc-1.b:42 {
        }
    }
    static-routes {
        route 0.0.0.0/0 route-type unicast {
            next-hop "10.0.2.4" {
                admin-state enable
            }
        }
    }
}

```

The export policies are configured as follows:

```

# on PE-4:
configure {
    policy-options {
        prefix-list "172.16.41.x" {
            prefix 172.16.41.0/24 type exact {
            }
        }
        prefix-list "172.16.42.x" {
            prefix 172.16.42.0/24 type exact {
            }
        }
    }
    policy-statement "export-bgp-ipv4-41" {
        entry 10 {
            from {
                prefix-list ["172.16.41.x"]
            }
            action {
                action-type accept
            }
        }
    }
    policy-statement "export-bgp-ipv4-42" {
        entry 10 {
            from {
                prefix-list ["172.16.42.x"]
            }
            action {
                action-type accept
            }
        }
    }
}

```

```
}

```

Configuration on CE-1

On CE-1, the following static route is configured with next-hop 10.0.1. 4, which is the address on the interface "int-evi-1" in IES 12 on PE-4:

```
# on CE-1:
configure {
  router "Base" {
    static-routes {
      route 0.0.0.0/0 route-type unicast {
        next-hop "10.0.1.4" {
          admin-state enable
        }
      }
    }
  }
}
```

The following loopback address is configured on CE-1 for test purposes:

```
# on CE-1:
configure
  router "Base" {
    interface "lo1" {
      loopback
      ipv4 {
        primary {
          address 172.16.1.1
          prefix-length 24
        }
      }
    }
  }
}
```

On CE-1, EBGP-IPv4 sessions are configured to the IES interface "int-evi-1" on PE-4 (neighbor 10.0.1.4) and to CE-41 (neighbor 10.0.1.41) for the IPv4 address family. CE-1 exports prefix 172.16.1.0/24 to its peers. The BGP configuration is as follows:

```
# on CE-1:
configure {
  policy-options {
    prefix-list "172.16.1.x" {
      prefix 172.16.1.0/24 type exact {
      }
    }
  }
  policy-statement "export-bgp-ipv4" {
    entry 10 {
      from {
        prefix-list ["172.16.1.x"]
      }
      action {
        action-type accept
      }
    }
  }
}
router "Base" {
  bgp {
    rapid-withdrawal true
    peer-ip-tracking true
  }
}
```

```

split-horizon true
group "external" {
  type external
  peer-as 64500
  family {
    ipv4 true
  }
  ebgp-default-reject-policy {
    import false
  }
  local-as {
    as-number 64501
  }
  export {
    policy ["export-bgp-ipv4"]
  }
}
neighbor "10.0.1.4" {
  group "external"
}
neighbor "10.0.1.41" {
  group "external"
}
}

```

Verification

On PE-4, the following shows that five BGP sessions are established:

- EBGP-IPv4 session with neighbor 10.0.1.1 (CE-1) from the base router
- IBGP-IPv4 session with neighbor 10.0.2.42 (CE-42) from the base router
- IBGP-EVPN session with neighbor 192.0.2.2 (PE-2) from the base router
- EBGP-IPv4 session with neighbor 10.0.1.1 (CE-1) from VPRN "CE-41"
- IBGP-IPv4 session to IES interface "int-evi-2" (10.0.2.4) from VPRN "CE-42"

Routes have been exchanged between the peers. The EBGP-IPv4 sessions are established using R-VPLS "evi-1".

```

On PE-4, the following route table includes the prefixes 10.0.1.0/24 of interface "int-evi-1" and 10.0.2.0/24 of "int-evi-2" in IES 12. Also, it includes the remote prefixes 172.16.1.0/24 and 172.16.42.0, which are received as BGP IPv4 routes from CE-1 and CE-42.

```
[/]
A:admin@PE-4# show router route-table

=====

```

Likewise, the following route table for CE-42 includes the remote prefix 172.16.1.0/24 received as BGP IPv4 route, but the next-hop is 10.0.2.4 instead of 10.0.1.1, because CE-42 is in subnet 10.0.2.0/24 whereas CE-1 is in subnet 10.0.1.0/24. Routing between the subnets 10.0.2.0/24 and 10.0.1.0/24 needs to be done in IES 12 on PE-4.

```

EVPN-MPLS R-VPLS attached to IES

Figure 141: Example topology for EVPN-MPLS R-VPLS attached to IES shows the example topology for EVPN-MPLS R-VPLS attached to IES. All-active multi-homing (AA MH) is configured on PE-2 and PE-3, while single-active (SA) MH is configured on PE-4 and PE-5. R-VPLS "evi-3" is configured on all PEs. IES 30 is configured on PE-2 and PE-3, whereas IES 34 is configured on PE-4 and PE-5. On MTU-6, "VPLS-3" and "VPLS-4" are regular VPLSs, not routed.

Figure 141: Example topology for EVPN-MPLS R-VPLS attached to IES

28625

The initial configuration on the nodes includes:

- Cards, MDAs, ports
- LAG "lag-1" on CE-1, PE-2, PE-3
- Router interfaces between the PEs and toward MTU-6
- IS-IS on these interfaces (alternatively, OSPF can be configured)
- LDP on these interfaces

- BGP configured for the EVPN address family on the PEs. PE-2 is the RR and has the following BGP configuration:

```
# on PE-2:
configure {
  router "Base" {
    bgp {
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "internal-evpn" {
      peer-as 64500
      family {
        evpn true
      }
      cluster {
        cluster-id 192.0.2.2
      }
    }
    neighbor "192.0.2.3" {
      group "internal-evpn"
    }
    neighbor "192.0.2.4" {
      group "internal-evpn"
    }
    neighbor "192.0.2.5" {
      group "internal-evpn"
    }
  }
}
```

Configuration on PE-2 and PE-3

The service configuration on PE-2 and PE-3 is almost identical; only the IP address on the IES interface "int-evi-3" is different. The AA MH ES "ESI-23_3" is configured as follows, with LAG 1 and dot1q tag 3, so it is only applicable to VPLS "evi-3".

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-23_3" {
            admin-state enable
            type virtual
            esi 0x01000000002300030301
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
          }
          association {
            lag "lag-1" {
              virtual-ranges {
                dot1q {
                  q-tag 3 {
                    end 3
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

```
    }  
  }  
}
```

R-VPLS "evi-3" has EVPN-MPLS enabled and is configured on PE-2 and PE-3, as follows. SAP lag-1:3 matches the configured LAG and the q-tag range for ESI-23_3.

```
# on PE-2, PE-3:  
configure {  
  service {  
    vpls "evi-3" {  
      admin-state enable  
      service-id 3  
      customer "1"  
      routed-vpls {  
      }  
      bgp 1 {  
      }  
      bgp-evpn {  
        evi 3  
        mpls 1 {  
          admin-state enable  
          ecmp 2  
          auto-bind-tunnel {  
            resolution any  
          }  
        }  
      }  
      sap lag-1:3 {  
      }  
    }  
  }  
}
```

The following is the IES configuration on PE-2. In this example, IES 30 is only configured to demonstrate EVPN all-active multi-homing on R-VPLS with IES. If it were removed, everything still works and the connectivity between the CEs remains.

```
# on PE-2:  
configure {  
  service {  
    ies "IES-30" {  
      admin-state enable  
      service-id 30  
      customer "1"  
      interface "int-evi-3" {  
        mac 00:00:00:00:03:02  
        vpls "evi-3" {  
        }  
        ipv4 {  
          primary {  
            address 10.0.3.2  
            prefix-length 24  
          }  
        }  
      }  
    }  
  }  
}
```

The IES configuration on PE-3 is similar, only using IP address 10.0.3.3/24.

Configuration on PE-4 and PE-5

On PE-4, SDP 46 is configured toward MTU-6. An SA MH ES "ESI-45" is configured using this SDP, as follows:

```
# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-45" {
            admin-state enable
            esi 0x01000000004500000001
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              sdp 46 {
            }
          }
        }
      }
    }
  }
  sdp 46 {
    admin-state enable
    delivery-type mpls
    ldp true
    far-end {
      ip-address 192.0.2.6
    }
  }
}
```

The configuration is similar on PE-5. SDP 56 is configured toward MTU-6 and ES "ESI-45" is configured with SDP 56 instead.

On PE-4, R-VPLSs "evi-3" and "evi-4" are configured with EVPN-MPLS, as follows:

```
# on PE-4:
configure {
  service {
    vpls "evi-3" {
      admin-state enable
      description "EVPN-MPLS R-VPLS 3"
      service-id 3
      customer "1"
      routed-vpls {
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 3
        mpls 1 {
          admin-state enable
          ecmp 2
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}
```

```

    }
  }
  spoke-sdp 46:3 {
  }
}
vpls "evi-4" {
  admin-state enable
  description "EVPN-MPLS R-VPLS 4"
  service-id 4
  customer "1"
  routed-vpls {
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 4
    mpls 1 {
      admin-state enable
      ecmp 2
      auto-bind-tunnel {
        resolution any
      }
    }
  }
}
  spoke-sdp 46:4 {
  }
}
}

```

The configuration is similar on PE-5; only the spoke-SDPs are different (spoke-SDP 56:3 and 56:4).

On PE-4, IES 34 is configured with interfaces "int-evi-3" and "int-evi-4", as follows. Passive VRRP is configured on both interfaces. With passive VRRP configured on both PE-4 and PE-5, both PEs behave as primary.

```

# on PE-4:
configure {
  service {
    ies "IES-34" {
      admin-state enable
      service-id 34
      customer "1"
      interface "int-evi-3" {
        mac 00:00:00:00:03:04
        vpls "evi-3" {
        }
      }
      ipv4 {
        primary {
          address 10.0.3.4
          prefix-length 24
        }
        vrrp 1 {
          backup [10.0.3.254]
          passive true
          ping-reply true
          traceroute-reply true
        }
      }
    }
  }
  interface "int-evi-4" {
    mac 00:00:00:00:04:04
    vpls "evi-4" {
    }
  }
}

```

```

        ipv4 {
            primary {
                address 10.0.4.4
                prefix-length 24
            }
            vrrp 1 {
                backup [10.0.4.254]
                passive true
                ping-reply true
                traceroute-reply true
            }
        }
    }
}

```

The configuration of IES 34 is similar on PE-5, but the interface IP addresses are different: 10.0.3.5/24 and 10.0.4.5/24. The MAC addresses are also different.

To enable routing between CE-1 and CE-64 in a different subnet, BGP sessions are established with CE-1 (neighbor 10.0.3.1 in AS 64501) and CE-64 (neighbor 10.0.4.64 in AS 64500) for the IPv4 address family. The CEs export prefixes, but no export policy needs to be configured on PE-4 and PE-5. The BGP configuration on PE-4 is as follows:

```

# on PE-4:
configure {
    router "Base" {
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
        }
        group "external" {
            type external
            peer-as 64501
            family {
                ipv4 true
            }
            local-as {
                as-number 64500
            }
        }
        group "internal-evpn" {
            type internal
            family {
                evpn true
            }
        }
        group "internal-ipv4" {
            peer-as 64500
            local-address 10.0.3.4
            family {
                ipv4 true
            }
        }
        neighbor "10.0.3.1" {
            group "external"
            ebgp-default-reject-policy {
                import false
                export false
            }
        }
    }
}

```

```
neighbor "10.0.4.64" {
    group "internal-ipv4"
}
neighbor "192.0.2.2" {
    group "internal-evpn"
}
}
```

The BGP configuration on PE-5 is almost identical; the local address is 10.0.3.5 instead.

Configuration on CE-1

The configuration on CE-1 includes the following:

- Router interface to VPLS "evi-3" (ESI-23_3) with IP address 10.0.3.1/24 and LAG-1:3 assigned to it
- Loopback interface with IP address 172.16.1.1/24 for test purposes
- Static default route with next-hop 10.0.3.254, which is the VRRP backup address for IES interface "int-evi-3" on PE-4 and PE-5
- Export policy to export prefix 172.16.1.0/24
- BGP sessions for the IPv4 address family toward PE-4 (10.0.3.4), PE-5 (10.0.3.5), and CE-63 (10.0.3.63)

The router configuration on CE-1 is as follows:

```
# on CE-1:
configure {
    policy-options {
        prefix-list "172.16.1.x" {
            prefix 172.16.1.0/24 type exact {
            }
        }
        policy-statement "export-bgp-ipv4" {
            entry 10 {
                from {
                    prefix-list ["172.16.1.x"]
                }
                action {
                    action-type accept
                }
            }
        }
    }
}
router "Base" {
    autonomous-system 64501
    interface "int-CE-1-evi-3_ES-23" {
        port lag-1:3
        ipv4 {
            primary {
                address 10.0.3.1
                prefix-length 24
            }
        }
    }
    interface "lo1" {
        loopback
        ipv4 {
            primary {
                address 172.16.1.1
            }
        }
    }
}
```

```
        prefix-length 24
    }
}
interface "system" {
    ipv4 {
        primary {
            address 192.0.2.1
            prefix-length 32
        }
    }
}
bgp {
    router-id 10.0.3.1
    rapid-withdrawal true
    peer-ip-tracking true
    split-horizon true
    group "external" {
        type external
        peer-as 64500
        family {
            ipv4 true
        }
        ebgp-default-reject-policy {
            import false
        }
        local-as {
            as-number 64501
        }
        export {
            policy ["export-bgp-ipv4"]
        }
    }
    neighbor "10.0.3.4" {
        group "external"
    }
    neighbor "10.0.3.5" {
        group "external"
    }
    neighbor "10.0.3.63" {
        group "external"
    }
}
static-routes {
    route 0.0.0.0/0 route-type unicast {
        next-hop "10.0.3.254" {
            admin-state enable
        }
    }
}
}
```

Configuration on MTU-6

The configuration on MTU-6 includes the following:

- Router interfaces
- IS-IS
- LDP
- One policy to export prefix 172.16.63.0/24 and another policy to export prefix 172.16.64.0/24

- BGP is not configured in the base router

The following service configuration on MTU-6 includes the SDP configuration and the VPLSs "VPLS-3" and "VPLS-4", which are not routed:

```
# on MTU-6:
configure {
  service {
    sdp 64 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.4
      }
    }
    sdp 65 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.5
      }
    }
  }
  vpls "VPLS-3" {
    admin-state enable
    service-id 3
    customer "1"
    endpoint "CORE" {
    }
    spoke-sdp 64:3 {
      endpoint {
        name "CORE"
      }
      stp {
        admin-state disable
      }
    }
    spoke-sdp 65:3 {
      endpoint {
        name "CORE"
      }
      stp {
        admin-state disable
      }
    }
    sap pxc-1.a:3 {
    }
  }
  vpls "VPLS-4" {
    admin-state enable
    service-id 4
    customer "1"
    endpoint "CORE" {
    }
    spoke-sdp 64:4 {
      endpoint {
        name "CORE"
      }
      stp {
        admin-state disable
      }
    }
    spoke-sdp 65:4 {

```

```

        endpoint {
            name "CORE"
        }
        stp {
            admin-state disable
        }
    }
    sap pxc-1.a:4 {
    }
    sap pxc-1.a:64 {
    }
}

```

In this example, CE-63 and CE-64 are simulated by VPRNs "CE-63" and "CE-64". The default static route has next-hop 10.0.3.254, which is the VRRP backup address on interface "int-evi-3" in IES 34 on both PE-4 and PE-5. BGP is configured within CE-63 and CE-64. The prefix 172.16.63.0/24 is exported by BGP in CE-63 and prefix 172.16.64.0/24 is exported by BGP in CE-64. The configuration of CE-63 and CE-64 is as follows:

```

# on MTU-6:
configure {
    service {
        vprn "CE-63" {
            admin-state enable
            service-id 63
            customer "1"
            autonomous-system 64500
            bgp {
                router-id 10.0.3.63
                rapid-withdrawal true
                peer-ip-tracking true
                split-horizon true
                group "external" {
                    type external
                    peer-as 64501
                    family {
                        ipv4 true
                    }
                    ebgp-default-reject-policy {
                        import false
                    }
                }
                local-as {
                    as-number 64500
                }
                export {
                    policy ["export-bgp-ipv4-63"]
                }
            }
            neighbor "10.0.3.1" {
                group "external"
            }
        }
    }
    interface "int-1_63" {
        mac 00:00:00:00:03:63
        ipv4 {
            primary {
                address 10.0.3.63
                prefix-length 24
            }
        }
        sap pxc-1.b:3 {
        }
    }
}

```

```
}
interface "lo1" {
  loopback true
  ipv4 {

-----

```

The difference is that CE-63 (with IP address 10.0.3.63) is in the same subnet as CE-1 (10.0.3.1), whereas CE-64 is not (10.0.4.64). Routing between these subnets can be done in IES 34 on PE-4 and PE-5. CE-63 exports prefix 172.16.63.0/24 directly to CE-1, whereas CE-64 exports prefix 172.16.64.0/24 to PE-4 and PE-5 instead, which will advertise prefix 172.16.64.0/24 to their BGP peer CE-1. The following route table on CE-1 shows BGP route 172.16.63.0/63 with next-hop 10.0.3.63 (CE-63) and BGP route 172.16.64.0/64 with next-hop 10.0.3.4 (interface "int-evi-3" on PE-4):

```

The connectivity between CE-1 and CE-63 is verified as follows:

```

[/]
A:admin@CE-1# ping 172.16.63.63 source-address 172.16.1.1
PING 172.16.63.63 56 data bytes
64 bytes from 172.16.63.63: icmp_seq=1 ttl=64 time=5.75ms.

```

```
64 bytes from 172.16.63.63: icmp_seq=2 ttl=64 time=5.80ms.
---snip---
```

The following traceroute command verifies the connectivity between CE-1 and CE-64. The intermediate hop is 10.0.3.4, the IP address of the IES interface "int-evi-3" on PE-4:

```
[/]
A:admin@CE-1# traceroute 172.16.64.64 source-address 172.16.1.1
traceroute to 172.16.64.64 from 172.16.1.1, 30 hops max, 40 byte packets
 1 10.0.3.4 (10.0.3.4) 3.48 ms 3.87 ms 4.24 ms
 2 172.16.64.64 (172.16.64.64) 6.28 ms 6.28 ms 6.13 ms
```

When the traceroute is launched from CE-64, the intermediate hop is 10.0.4.4, the IP address of the IES interface "int-evi-4" on PE-4:

```
[/]
A:admin@MTU-6# traceroute 172.16.1.1 router-instance "CE-64"
traceroute to 172.16.1.1, 30 hops max, 40 byte packets
 1 10.0.4.4 (10.0.4.4) 2.91 ms 3.65 ms 3.98 ms
 2 172.16.1.1 (172.16.1.1) 5.77 ms 6.44 ms 5.80 ms
```

The following ARP table on CE-1 contains entries for different nodes in the 10.0.3.0/24 subnet:

```

Conclusion

With EVPN R-VPLS attached to IES services, EVPN services are connected to the base router, so the traffic can be routed in the global routing table (GRT).

EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 Stitching

This chapter provides information about the EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 stitching.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 23.10.R2. MPLS to SRv6 stitching within an EVPN VPLS is supported in SR OS Release 22.10.R1 and later; VXLAN to SRv6 stitching within an EVPN VPLS is supported in SR OS Release 22.10.R3 and later.

Overview

SRv6 to MPLS stitching or SRv6 to VXLAN stitching is required in hybrid networks where MPLS PEs and SRv6 PEs are both attached to the same EVPN VPLS service. This concept follows the RFC 9014 standard and it is implemented in SR OS by using two EVPN instances in the same EVPN VPLS service. Also, a migration from MPLS tunnels to SRv6 tunnels in EVPN VPLS services requires the support of an SRv6 instance and an MPLS instance in the same EVPN VPLS service. EVPN destinations of different transport types (MPLS, VXLAN, or SRv6) can be placed in the same Split Horizon Groups (SHGs) to avoid loops.

[Figure 142: The need for MPLS to SRv6 stitching in an EVPN VPLS](#) shows an EVPN VPLS service configured in all PEs where the gateways (GWs) PE-4 and PE-5 have two service instances in the EVPN VPLS: BGP instance 1 uses MPLS transport and BGP instance 2 uses SRv6. For GW redundancy on PE-4 and PE-5, the anycast multihoming concept is applied.

Figure 142: The need for MPLS to SRv6 stitching in an EVPN VPLS

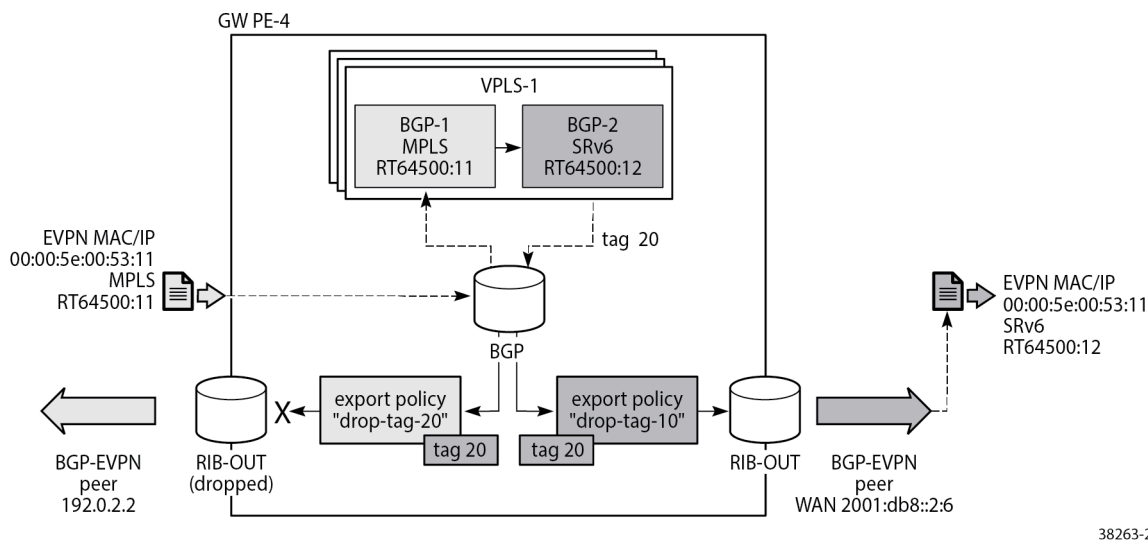

39235

The following applies for multi-instance EVPN VPLS services with SRv6:

- SHGs are supported:
 - EVPN VXLAN cannot be configured with an explicit SHG
 - SHG associated to the EVPN MPLS instance can be the same as or different from the SHG associated to the EVPN SRv6 instance:
 - when the same SHG is configured across two instances, no routes are redistributed between the instances
 - when different SHGs are configured across two instances, routes are redistributed between the instances
- when one of the instances is SRv6, SAPs can be configured only if the two instances are configured with the same explicit SHG
- no SDP bindings are supported on multi-instance VPLS services:
 - the configuration of spoke SDPs or mesh SDPs is blocked
 - BGP VPLS and BGP AD can be configured, but the spoke SDPs are not auto-created
- the **mh-mode access | network** command is supported to configure multihoming:
 - access or network mode can be configured in an SRv6 instance, with network being the default mode
 - the following combinations are supported:
 - SRv6 mh-mode network with MPLS instance mh-mode access
 - SRv6 mh-mode access with MPLS instance mh-mode network (Note: If provider-tunnel is needed on the multi-instance service, the MPLS instance must be configured as mh-mode network)
 - two mh-mode access instances in the same EVPN VPLS are allowed for the combinations VXLAN/MPLS, VXLAN/SRv6, and MPLS/SRv6 (but not for the combination MPLS/MPLS)
- Anycast multihoming can be applied:

- two or more PEs can be configured with the same service parameters as part of the same redundancy group:
 - same Route Distinguisher (RD) for the same BGP instance
 - same Route Target (RT) for the same BGP instance
 - same inclusive multicast originator IP address
- remote PEs set up EVPN destinations to only one PE in the anycast group for a service
- no EVPN BUM destinations are established among the PEs in the anycast group because the received anycast peer inclusive multicast Ethernet tag (IMET) routes have the same inclusive multicast originator IP address
- policies are applied on the GW PEs to avoid loops:
 - export policies add route target and site-of-origin (SOO) extended communities to the redistributed MAC/IP routes and the peer GW PEs drop the routes received with the group SOO
 - default route tags per service instance differentiate the allowed non-redistributed MAC/IP routes from the rest, so that these MAC/IP routes are not advertised between access and network peers, as shown in [Figure 143: Default route tags per service instance avoid loops](#).

Figure 143: Default route tags per service instance avoid loops

The figure shows that an incoming MAC/IP route with RT 64500:11 is accepted in VPLS-1 on GW PE-4 by service instance 1 and passed on to service instance 2 where it gets RT 64500:12 and default route tag 20. Routes with route tag 20 are accepted for routes sent to peer 2001:db8::2:6 in the network, but not for routes sent back to access peer 192.0.2.2. Likewise (but not shown in the figure), routes coming from peer 2001:db8::2:6 with RT 64500:12 are accepted by service instance 2 and passed on to service instance 1 where default route tag 10 is added. Routes with route tag 10 are forwarded to peer 192.0.2.2, but are not sent back to the network peer 2001:db8::2:6.

38263-251

Configuration

The following use cases are described in this section:

- [EVPN VPLS with MPLS to SRv6 stitching](#)
- [EVPN VPLS with VXLAN to SRv6 stitching](#)

EVPN VPLS with MPLS to SRv6 stitching

Figure 144: Example topology with VPLS-1 shows the example topology for VPLS-1 with MPLS to SRv6 stitching in the GWs PE-4 and PE-5.

Figure 144: Example topology with VPLS-1

39236

The initial configuration on the nodes includes:

- cards, MDAs, ports, LAG
- router interfaces
- IS-IS as IGP
- LDP between PE-2, PE-3, PE-4, PE-5

SRv6 configuration

The SRv6 configuration on PE-4 is as follows:

```
# on PE-4:
configure {
  card 1 {
    mda 1 {
      xconnect {
```

```
        mac 1 {
            loopback 1 {
            }
            loopback 2 {
            }
        }
    }
}
fwd-path-ext {
    fpe 1 {
        path {
            pxc 1
        }
        application {
            srv6 {
                type origination
            }
        }
    }
    fpe 2 {
        path {
            pxc 2
        }
        application {
            srv6 {
                type termination
            }
        }
    }
}
port pxc-1.a {

                }
            }
        }
    }
}
    ---snip---

```

The SRv6 configuration on PE-5 and PE-6 is similar.

BGP configuration

In the MPLS access network, PE-2 acts as the route reflector (RR) with clients PE-3, PE-4, and PE-5. The BGP configuration is as follows:

```

# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
        }
    }
}

```

```

vpn-apply-import true
rapid-withdrawal true
peer-ip-tracking true
split-horizon true
rapid-update {
    evpn true
}
group "access-mpls" {
    peer-as 64500
    family {
        evpn true
    }
    cluster {
        cluster-id 192.0.2.2
    }
}
neighbor "192.0.2.3" {
    group "access-mpls"
}
neighbor "192.0.2.4" {
    group "access-mpls"
}
neighbor "192.0.2.5" {
    group "access-mpls"
}

```

The BGP configuration on PE-3 is as follows:

```

# on PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "access-mpls"
            }
        }
    }
}

```

In the SRv6 network, PE-6 acts as the RR. The BGP configuration on the GWs PE-4 and PE-5 is as follows. The export policy "drop-tag-10" is used to avoid loops within the core SRv6 network and the export policy "drop-tag-20" is used to avoid loops within the access MPLS network, as shown in [Figure 143: Default route tags per service instance avoid loops](#).

```

# on GWs PE-4 and PE-5:
configure {
    policy-options {
        policy-statement "drop-tag-10" {
            description "route tag in VPLSs to avoid loops"
            entry 10 {

```

```
        from {
            tag 10
        }
        action {
            action-type reject
        }
    }
}
policy-statement "drop-tag-20" {
    description "route tag in VPLSs to avoid loops"
    entry 10 {
        from {
            tag 20
        }
        action {
            action-type reject
        }
    }
}
}
router "Base" {
    autonomous-system 64500
    bgp {
        vpn-apply-export true
        vpn-apply-import true
        rapid-withdrawal true
        peer-ip-tracking true
        split-horizon true
        rapid-update {
            evpn true
        }
        group "access-mpls" {
            peer-as 64500
            family {
                evpn true
            }
            export {
                policy ["drop-tag-20"]
            }
        }
        group "core-srv6" {
            peer-as 64500
            family {
                evpn true
            }
            export {
                policy ["drop-tag-10"]
            }
        }
        neighbor "192.0.2.2" {
            group "access-mpls"
        }
        neighbor "2001:db8::2:6" {
            group "core-srv6"
        }
    }
}
```

The BGP configuration on RR PE-6 is as follows:

```
# on RR PE-6:

    }
    neighbor "2001:db8::2:5" {
      group "core-srv6"
    }
  }

```

Service configuration

VPLS-1 is configured on all nodes. On PE-2, PE-3, PE-4, and PE-5, service instance 1 of VPLS-1 uses MPLS tunnels. The service configuration on PE-2 and PE-3 is identical, except for the preference value in the all-active Ethernet segment (ES). Route target 64500:11 is accepted in service instance 1 of VPLS-1 on the GW PEs PE-4 and PE-5. The service configuration on PE-2 is as follows:

```

# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-vES-23-1" {
            admin-state enable
            type virtual
            esi 0x01000000002300000101
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
              service-carving-mode manual
              manual {
                preference {
                  mode non-revertive
                  value 100
                }
              }
            }
          }
        }
      }
    }
  }
}

```

\# on PE-3: preference 150

```

}
vpls "VPLS-1" {
  admin-state enable
  service-id 1
  customer "1"
  bgp 1 {
    route-target {

        resolution any
      }
    }
  }
  sap lag-1:1 {
  }
}
}

```

On PE-6, VPLS-1 uses SRv6 transport and route target 64500:12 is accepted in service instance 2 of VPLS-1 on the GW PEs PE-4 and PE-5. SAP 1/1/c10/1:1 is connected to CE-61. The configuration on PE-6 is as follows.

```

# on PE-6:
configure {
  service {
    vpls "VPLS-1" {
      admin-state enable
      service-id 1
      customer "1"
      segment-routing-v6 1 {
        locator "PE6-loc" {
          function {
            end-dt2u {
            }
            end-dt2m {
            }
          }
        }
      }
    }
  }
  bgp 1 {
    route-target {
      export "target:64500:12"
      import "target:64500:12"
    }
  }
  bgp-evpn {
    evi 1
    segment-routing-v6 1 {
      admin-state enable
      srv6 {
        instance 1
        default-locator "PE6-loc"
      }
    }
    route-next-hop {
      system-ipv6
    }
  }
}

```

```

    }
  }
  sap 1/1/c10/1:1 {
  }
}

```

The following configuration on the anycast GW PE-4 shows that the EVPN VPLS is configured with two instances: service instance 1 uses MPLS transport and service instance 2 uses SRv6. The configuration on GW PE-5 is identical with only a different SRv6 locator name. The VSI policies are used to accept EVPN routes with the matching route target and to avoid loops between GWs PE-4 and PE-5 based on the SOO.

```

# on PE-4:
configure {
  policy-options {

        route-distinguisher "192.0.2.45:1"
        vsi-import ["vsi-11-import"]
        vsi-export ["vsi-11-export"]
    }
    bgp 2 {
        route-distinguisher "192.0.2.54:1"
        vsi-import ["vsi-12-import"]
        vsi-export ["vsi-12-export"]
    }
    bgp-evpn {
        evi 1
        incl-mcast-orig-ip 145.145.145.145
        segment-routing-v6 2 {
            admin-state enable
            default-route-tag 0x14          # default route tag 20
            split-horizon-group "SHG-2"
        }
    }
}
```

```

        srv6 {
            instance 1
                default-locator "PE4-loc"
            }
            route-next-hop {
                system-ipv6
            }
        }
        mpls 1 {
            admin-state enable
            split-horizon-group "SHG-1"
            ecmp 2
            default-route-tag 0xa           # default route tag 10
            mh-mode access
            auto-bind-tunnel {
                resolution any
            }
        }
    }
    split-horizon-group "SHG-1" {
    }
    split-horizon-group "SHG-2" {
    }
}

```

The configuration of SHGs is optional. In this example, different SHGs are applied to the two service instances, so the routes can be redistributed between the instances.

In the anycast solution, the RDs, RTs, and the originator IP address must be identical on the GWs PE-4 and PE-5:

- originator IP address: 145.145.145.145
- for instance 1: RD 192.0.2.45:1, RT 64500:11
- for instance 2: RD 192.0.2.54:1, RT 64500:12

Service instance 1 has default route tag 10 and service instance 2 has default route tag 20. These route tags allow to differentiate routes and avoid loops as shown in [Figure 143: Default route tags per service instance avoid loops](#).

The MPLS multihoming mode is access in this example; the SRv6 multihoming mode is network (default).

Show commands

After VPLS-1 is configured on all nodes, traffic is sent between CE-11 and CE-61. The FDB for VPLS-1 on PE-2 is as follows:

```

The GWs PE-4 and PE-5 redistribute EVPN MAC routes between MPLS and SRv6 domains. The FDB on PE-4 shows that MAC address 00:00:5e:00:53:11 of CE-11 can be reached via the all-active ES with ESI 01:00:00:00:00:23:00:00:01:01, which is in the MPLS domain. MAC address 00:00:5e:00:53:61 of CE-61 can be reached using an SRv6 tunnel to PE-6. The FDB table on PE-5 is similar.

```

EVPN VPLS with VXLAN to SRv6 stitching

Figure 145: Example topology with VPLS-2 shows the example topology for VPLS-2 with VXLAN to SRv6 stitching in the GWs PE-4 and PE-5.

Figure 145: Example topology with VPLS-2

39237

Initial configuration

The initial configuration is similar to the one for EVPN VPLS with MPLS to SRv6 stitching, but LDP is not required between PE-2, PE-3, PE-4, and PE-5. The BGP configuration remains the same with the export policies using route tags to avoid loops.

Service configuration

In the VXLAN domain, all-active multihoming is used between PE-2 and PE-3. The service configuration on PE-2 and PE-3 is identical. Route tag 64500:21 accepted in instance 1 of VPLS-2 on GWs PE-4 and PE-5:

```
# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-vES-23-2" {
            admin-state enable
            type virtual
            esi 01:00:00:00:00:23:02:00:01:01
            multi-homing-mode all-active
            association {
              lag "lag-1" {
                virtual-ranges {
                  dot1q {
                    q-tag 2 {
                      end 2
                    }
                  }
                }
              }
            }
          }
        }
      }
    }
  }
  vpls "VPLS-2" {
    admin-state enable
    service-id 2
    customer "1"
    vxlan {
      instance 1 {
        vni 2
      }
    }
    bgp 1 {
      route-target {
        export "target:64500:21"
        import "target:64500:21"
      }
    }
    bgp-evpn {
      evi 2
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
        ecmp 2
        mh-mode network # required for VXLAN MH
        routes {
          auto-disc {
            advertise true # required for VXLAN MH
          }
        }
      }
    }
  }
  sap lag-1:2 {
  }
}
```

```
}

```

In the SRv6 domain, no multihoming is used. The configuration of VPLS-2 on PE-6 is as follows:

```
# on PE-6:
configure {
  service {
    vpls "VPLS-2" {
      admin-state enable
      service-id 2
      customer "1"
      segment-routing-v6 1 {
        locator "PE6-loc" {
          function {
            end-dt2u {
            }
            end-dt2m {
            }
          }
        }
      }
    }
  }
  bgp 1 {
    route-target {
      export "target:64500:22"
      import "target:64500:22"
    }
  }
  bgp-evpn {
    evi 2
    segment-routing-v6 1 {
      admin-state enable
      srv6 {
        instance 1
        default-locator "PE6-loc"
      }
      route-next-hop {
        system-ipv6
      }
    }
  }
  sap 1/1/c10/1:2 {
  }
}

```

On the GW PEs, service instance 1 uses VXLAN and service instance 2 uses SRv6 transport. VSI policies are used to accept routes with the matching RT and to avoid loops based on the SOO. In the VXLAN service instance, the multihoming mode is access (multihoming mode network is not supported on VXLAN) and no explicit SHG can be configured. For anycast, the same RD and RT values are used on both GW PEs and the originator IP address is 45.45.45.45. The configuration on PE-4 is as follows:

```
# on PE-4:
configure {
  policy-options {
    community "RT64500:21" {
      member "target:64500:21" { }
    }
    community "RT64500:22" {
      member "target:64500:22" { }
    }
    community "SOO-45" {
      member "origin:45:45" { }
    }
  }
}

```

```
policy-statement "drop-tag-10" {
  description "default-route-tag in VPLSs to avoid loops"
  entry 10 {
    from {
      tag 10
    }
    action {
      action-type reject
    }
  }
}
policy-statement "drop-tag-20" {
  description "default-route-tag in VPLSs to avoid loops"
  entry 10 {
    from {
      tag 20
    }
    action {
      action-type reject
    }
  }
}
policy-statement "vsi-21-export" {
  entry 10 {
    action {
      action-type accept

Conclusion

SRv6 to MPLS stitching and SRv6 to VXLAN stitching are required to interwork with non-SRv6 networks.

EVPN VPWS Multihoming on PW ports

This chapter provides information about EVPN-VPWS multihoming on PW ports.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 23.10.R1.

Prerequisite reading: [EVPN for MPLS Tunnels in Epipe Services \(EVPN-VPWS\)](#) and [EVPN VPWS Services with SRv6 Transport](#).

Overview

Service providers are migrating active/standby pseudowire (PW) aggregation networks to EVPN-VPWS. This architecture is commonly known as "Pseudowire Headend" architecture. In SR OS, the PW headend PE uses PW ports to map ingress traffic from the access into Layer 2 or Layer 3 services in the core. PW ports provide PW termination with the following characteristics:

- provide SAP-based capabilities to a PW which has traditionally been a network-port-based concept within SR OS. PW payload can be extracted onto PW-port-based SAPs with granular queuing capabilities (per SAP).
- look up dot1q and qinq VLAN tags underneath the PW labels and map the traffic to different services.
- terminate subscriber traffic carried within the PW on a Broadband Network Gateway (BNG): PW-port-based SAPs are instantiated under a group interface with Enhanced Subscriber Management (ESM).

PW ports can operate in two modes:

- PW port bound to a specific physical input/output port (I/O port)
- PW port independent of the I/O port on which the PW is terminated: Forwarding Path Extension (FPE) based PW port

In this chapter, FPE-based PW ports are used. The benefit of FPE-based PW ports is that they can provide services when traffic within the PW is rerouted between I/O ports because of a network failure.

Both all-active and single-active EVPN multihoming modes are supported. [Figure 146: EVPN-MPLS single-active multihoming on Epipe PW ports](#) shows the example topology with stitching Epipe "Epipe-123" in the access network and single-active multihoming between PE-2 and PE-3. The single-active Ethernet segment (ES) has a PW port associated to it.

Figure 146: EVPN-MPLS single-active multihoming on Epipe PW ports

39229

In the aggregation network, the stitching EVPN-VPWS "Epipe-123" backhauls the traffic. The SAP of the stitching Epipe on access node PE-1 is 1/1/c10/1:*, so it accepts packets with VID 1 for core service "Epipe-1" and packets with VID 2 for core service "Epipe-2". The stitching between Epipe "Epipe-123" and the service Epipes is done at the Designated Forwarder (DF) PE-3. PE-2 is the Non-Designated Forwarder (NDF) which brings the PW port operationally down due to the MHStandby flag (unless the **oper-up-on-mhstandby** option is enabled). On the NDF PE-2, the PW SAPs pw-23:1 and pw-23:2 (in the core services "Epipe-1" and "Epipe-2") are brought operationally down when the PW port is down. If the PW port is down only due to the MHStandby flag, the AD per-ES route and AD per-EVI route for the service Epipes are still advertised, so PE-1 receives EVPN-AD routes from DF PE-3 and NDF PE-2.

Figure 147: Internal connectivity between switching Epipe and service Epipes shows how internal VPLS "_tmnx_InternalVplsService" with ID 2147483649 is used for the internal cross-connect between the stitching Epipe and the service Epipes.

Figure 147: Internal connectivity between switching Epipe and service Epipes

39230a

Configuration

Figure 148: Example topology shows the example topology used throughout this section.

Figure 148: Example topology

39231

The initial configuration on the PEs and RR includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on the router interfaces (alternatively, OSPF can be used)

The following scenarios are described in this section:

- [EVPN-MPLS all-active multihoming on Epipe PW ports](#)
- [EVPN-MPLS single-active multihoming on Epipe PW ports](#)
- [EVPN-SRv6 single-active multihoming on Epipe PW ports](#)

In the EVPN-MPLS scenarios, MPLS is used in the aggregation network (between PE-1, PE-2, and PE-3) and in the core network (between PE-2, PE-3, and PE-4). In this example, LDP is applied in the aggregation network and SR-ISIS in the core network.

In the EVPN-MPLS scenarios, the BGP configuration is as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
    }
    group "internal" {
      peer-as 64500
      family {
        evpn true
      }
    }
  }
  neighbor "192.0.2.5" {
    group "internal"
  }
}
```

```
}

```

In the EVPN-MPLS scenarios, the BGP configuration on RR-5 is the following:

```
# on RR-5:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64500
        family {
          evpn true
        }
        cluster {
          cluster-id 192.0.2.5
        }
      }
      neighbor "192.0.2.1" {
        group "internal"
      }
      neighbor "192.0.2.2" {
        group "internal"
      }
      neighbor "192.0.2.3" {
        group "internal"
      }
      neighbor "192.0.2.4" {
        group "internal"
      }
    }
  }
}
```

In all scenarios, FPE 5 is configured with PW port extension on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
  fwd-path-ext {
    sdp-id-range {
      start 10000
      end 10127
    }
  }
  fpe 5 {
    path {
      pxc 5
    }
    application {
      pw-port-extension {
      }
    }
  }
}
port pxc-5.a {
  admin-state enable
}
port pxc-5.b {
  admin-state enable
}
```

```

}
port 1/1/c5/1 {
  admin-state enable
  ethernet {
    mode hybrid
    dot1x {
      tunneling true
    }
  }
}
port-xc {
  pxc 5 {
    admin-state enable
    port-id 1/1/c5/1
  }
}
}

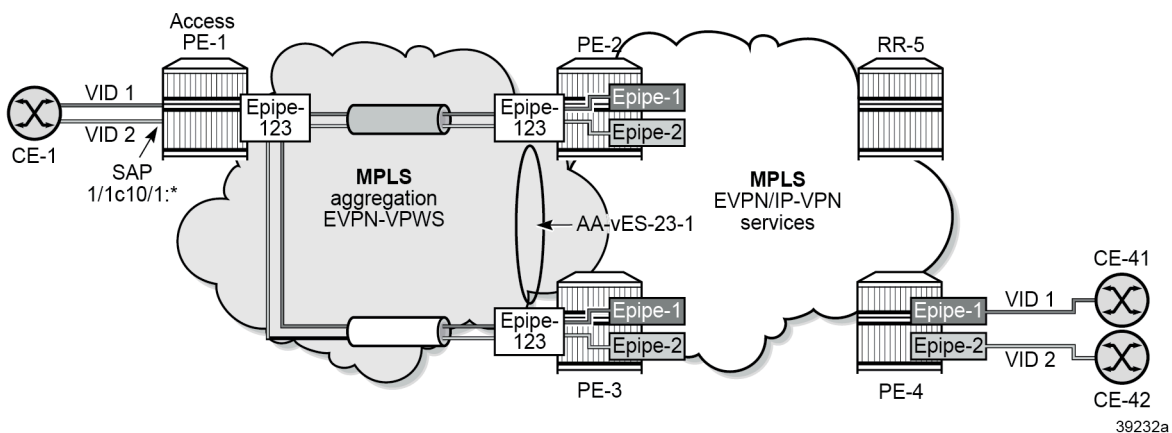

```

The preceding configuration is similar to the VXLAN FPE configuration, as described in the [VXLAN Forwarding Path Extension](#) chapter.

EVPN-MPLS all-active multihoming on Epipe PW ports

[Figure 149: EVPN-MPLS all-active multi-homing on Epipe PW ports](#) shows the stitching Epipe in the aggregation network and the core Epipe services in an all-active multihoming scenario.

Figure 149: EVPN-MPLS all-active multi-homing on Epipe PW ports

The stitching EVPN-VPWS service is configured on PE-1, PE-2, and PE-3. The configuration on PE-1 is as follows:

```

# on PE-1:
configure {
  service {
    epipe "Epipe-123" {
      admin-state enable
      service-id 123
      customer "1"
      bgp 1 {
      }
    }
    sap 1/1/c10/1:* {

```

```

        description "SAP to CEs"
    }
    bgp-evpn {
        evi 123
        local-attachment-circuit "ac-1" {
            eth-tag 1
        }
        remote-attachment-circuit "ac-23" {
            eth-tag 23
        }
    }
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution any
        }
    }
}
}
}

```

CE-1 is connected to this Epipe on PE-1. In this setup, CE-1 is emulated by a VPRN service: on one interface, it sends traffic with VID 1 and on another interface, it sends traffic with VID 2. Both are accepted on SAP 1/1/c10/1:* in EVPN-VPWS "Epipe-123" on PE-1.

The stitching EVPN-VPWS on PE-2 and PE-3 is assigned to FPE-based PW port 23, as follows:

```

# on PE-2, PE-3:
configure {
    pw-port 23 {
        epipe "stitching-Epipe-123" {
            fpe-id 5
        }
    }
    service {
        epipe "stitching-Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            bgp 1 {
            }
        }
        bgp-evpn {
            evi 123
            local-attachment-circuit "ac-23" {
                eth-tag 23
            }
            remote-attachment-circuit "ac-1" {
                eth-tag 1
            }
        }
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
}
}

```

The aggregation network uses EVPN-VPWS to backhaul the traffic. The network nodes PE-2 and PE-3 apply the same Ethernet tag (23) on the local attachment circuit in the stitching Epipe. Optionally, PE-2 and PE-3 can use the same route distinguisher on the stitching service. AD per-EVI routes for the stitching service are advertised with ESI 0.

The FPE-based PW port is associated to a virtual all-active ES on PE-2 and PE-3. The configuration on PE-2 is as follows; the configuration on PE-3 is identical, but with a different preference value.

```
# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "AA-vES-23-1" {
            admin-state enable
            type virtual
            esi 0x01000000002300000101
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
              service-carving-mode manual
              manual {
                preference {
                  mode non-revertive
                  value 100
                }
              }
            }
          }
          association {
            pw-port 23 {
              virtual-ranges {
                dot1q {
                  q-tag 1 {
                    end 200
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

PE-2 and PE-3 receive tagged traffic inside the EVPN-VPWS stitching Epipe and map each tag to a different service in the core, such as ESM services, Epipe services, or VPRN services. In this example, the following services are configured:

```
# on PE-2, PE-3:
configure {
  service {
    epipe "service-Epipe-1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      sap pw-23:1 {
      }
      bgp-evpn {
        evi 1
        local-attachment-circuit "ac-23" {
          eth-tag 23
        }
        remote-attachment-circuit "ac-4" {
          eth-tag 4
        }
      }
    }
  }
}
```

```
    }
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution any
        }
    }
}
epipe "service-Epipe-2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    sap pw-23:2 {
    }
    bgp-evpn {
        evi 2
        local-attachment-circuit "ac-23" {
            eth-tag 23
        }
        remote-attachment-circuit "ac-4" {
            eth-tag 4
        }
    }
    mpls 1 {
        admin-state enable
        auto-bind-tunnel {
            resolution any
        }
    }
}
}
```

These Epipe services are also configured on PE-4:

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:1 {
                description "SAP to CE-41"
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-4" {
                    eth-tag 4
                }

      remote-attachment-circuit "ac-23" {
        eth-tag 23
      }
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}

```

Forwarding from CE-1 to CE-41 or CE-42 works as follows:

- Access node PE-1 forwards traffic based on the best AD per-EVI route advertised by PE-2 and PE-3 for the stitching Epipe. This selection can be either BGP-based if PE-2 and PE-3 use the same route distinguisher (RD) in the stitching service or EVPN-based if different RDs are used. The EVPN-based selection when the RDs are different is based on the lowest IP address of the route. In the example, the RDs are auto-derived, such as 192.0.2.2:123, 192.0.2.3:123.

Note:

BGP-based selection is also possible when the RDs are different if the command **configure service system bgp evpn ad-per-evi-routes bgp-path-selection** is configured. For example, in the case of regular BGP best path selection, it is possible to modify the local preference to influence which path is selected.

- When access node PE-1 selects the route to PE-2, PE-2 receives the traffic on the local PW SAP for Epipes "Epipe-1" or "Epipe-2" and forwards it based on the EVPN-VPWS rules in the network to PE-4.

Forwarding from CE-41 or CE-42 to CE-1 works as follows:

- PE-4 forwards the traffic based on the configuration of ECMP and aliasing rules for Epipes "Epipe-1" or "Epipe-2".
- PE-4 may send the traffic to PE-3 and PE-3 to the access node PE-1.

Traffic from the core to the access network may follow an asymmetric path because the multihoming procedures are run on the PW SAPs of the core services, not on the stitching Epipe service. The AD per-EVI routes advertised in the context of the stitching Epipe use ESI 0.

The following command shows that the all-active ES applies to EVI 1 and EVI 2, not to the stitching Epipe with EVI 123:

```

[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "AA-vES-23-1" all

```

```

EVPN-MPLS single-active multihoming on Epipe PW ports

EVPN-MPLS single-active multihoming support on Epipe PW ports is supported in SR OS Release 22.2.R1 and later.

[Figure 146: EVPN-MPLS single-active multihoming on Epipe PW ports](#) shows the EVPN-MPLS single-active multihoming on Epipe PW ports.

Figure 150: EVPN-MPLS single-active multihoming on Epipe PW ports

Service configuration on PE-2 and PE-3

On PE-2 and PE-3, the stitching Epipe is configured as follows:

```
# on PE-2, PE-3:
configure {
  pw-port 23 {
    epipe "stitching-Epipe-123" {
      fpe-id 5
    }
  }
  service {
    epipe "stitching-Epipe-123" {
      admin-state enable
      service-id 123
      customer "1"
      bgp 1 {
      }
      bgp-evpn {
        evi 123
        local-attachment-circuit "ac-23" {
          eth-tag 23
        }
        remote-attachment-circuit "ac-1" {
          eth-tag 1
        }
      }
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}
```

The following (non-virtual) single-active ES is configured on PE-2 and PE-3.

```
# on PE-2, PE-3:
```

```

configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "SA-ES-23" {
            admin-state enable
            esi 0x01000000002300000001
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              pw-port 23 {
                pw-port-headend true
              }
            }
          }
        }
      }
    }
  }
}

```

The **pw-headend** keyword allows PW ports to be associated with ESs in single-active mode. The **pw-headend** keyword ensures that the stitching Epipe is running the ES and DF election procedures similar to the mh-mode network in VPLS services. The NDF on the stitching Epipe brings the PW port down with reason MHStandby. The AD per-ES routes and AD per-EVI routes are advertised with the RD and RT of the service Epipe and the configured ESI of the ES associated with the PW port. If the PW port is down only due to MHStandby, the AD per-ES routes and AD per-EVI routes are still advertised. The **oper-up-on-mhstandby** option allows to keep the PW port up on the NDF, which can speed up convergence in case a large number of PW SAPs is configured on the same PW port.

The DF receives tagged traffic inside EVPN-VPWS circuits and maps each tag to a different service in the core network, such as ESM services, Epipe services, or VPRN services. In this example, the following Epipe services are configured with PW SAPs:

```

# on PE-2, PE-3:
configure {
  service {
    epipe "service-Epipe-1" {
      admin-state enable
      service-id 1
      customer "1"
      bgp 1 {
      }
      sap pw-23:1 {
      }
      bgp-evpn {
        evi 1
        local-attachment-circuit "ac-23" {
          eth-tag 23
        }
        remote-attachment-circuit "ac-4" {
          eth-tag 4
        }
      }
      mpls 1 {
        admin-state enable
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}

```

```

    }
    epipe "service-Epipe-2" {
        admin-state enable
        service-id 2
        customer "1"
        bgp 1 {
        }
        sap pw-23:2 {
        }
        bgp-evpn {
            evi 2
            local-attachment-circuit "ac-23" {
                eth-tag 23
            }
            remote-attachment-circuit "ac-4" {
                eth-tag 4
            }
            mpls 1 {
                admin-state enable
                auto-bind-tunnel {
                    resolution any
                }
            }
        }
    }
}

```

The configuration on PE-1 and PE-4 is similar to the configuration in the all-active multihoming scenario.

ES and DF election procedures on stitching Epipe

The stitching Epipe associated with the PW port is running the ES and DF election procedures. The following ES command on PE-3 shows the state for the stitching Epipe EVI 123, not for the contained PW SAP services with EVI 1 and EVI 2. PE-3 is the DF.

```

[/]
A:admin@PE-3# show service system bgp-evpn ethernet-segment name "SA-ES-23" all
=====

The following command shows that PE-2 is NDF for the stitching Epipe:

```

[/]
A:admin@PE-2# show service id 123 ethernet-segment
No sap entries
No sdp entries
No vxlan instance entries

=====
SDP Ethernet-Segment Information
=====
Pw-Port            Eth-Seg                Status
-----
23                 SA-ES-23                NDF
=====
    
```

The NDF PE-2 will bring the PW port down because of the MHStandby flag, but the AD per-ES route for the stitching Epipe service is still advertised (if MHStandby is the only reason for the PW port to be down). Therefore, PE-1 receives an AD per-ES route for the stitching Epipe from PE-2 and from PE-3:

```

# on PE-1:6 2023/12/04 15:26:36.888 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5

NDF behavior

The following command on NDF PE-2 shows that the PW port is operationally down with flag StandbyForMHPProtocol:

```
[/]
A:admin@PE-2# show pw-port 23 detail

```

The following command configures the **oper-up-on-mhstandby** option for the stitching Epipe on NDF PE-2:

```

# on PE-2:
configure {
  pw-port 23 {
    epipe "stitching-Epipe-123" {
      fpe-id 5
      oper-up-on-mh-standby true
    }
  }
}

```

With the **oper-up-on-mhstandby** option enabled, the PW port is operationally up on NDF PE-2:

```

[/]
A:admin@PE-2# show pw-port 23 detail

```

```

EVPN-SRv6 single-active multihoming on Epipe PW ports

EVPN-SRv6 single-active multihoming support on Epipe PW ports is supported in SR OS Release 22.5.R1 and later.

[Figure 151: EVPN-SRv6 single-active multihoming on Epipe PW ports](#) shows the topology with EVPN-SRv6 in the aggregation network and both EVPN-MPLS and EVPN-SRv6 in the core network.

Figure 151: EVPN-SRv6 single-active multihoming on Epipe PW ports

The stitching Epipe in the aggregation network uses SRv6 transport. Epipe 1 in the core network uses SRv6 transport, while Epipe 2 in the core network uses MPLS transport.

SRv6 configuration

The SRv6 configuration is as described in the [EVPN VPWS Services with SRv6 Transport](#) chapter:

```
# on PE-2:
configure {
  card 1 {
    mda 1 {
      xconnect {
        mac 1 {
          loopback 1 {
          }
          loopback 2 {
          }
        }
      }
    }
  }
  fwd-path-ext {
    fpe 1 {
      path {
        pxc 1
      }
      application {
        srv6 {
          type origination
        }
      }
    }
    fpe 2 {
      path {
        pxc 2
      }
      application {
        srv6 {
          type termination
        }
      }
    }
  }
}
```

```
    }
  }
}
port pxc-1.a {
  admin-state enable
}
port pxc-1.b {
  admin-state enable
}
port pxc-2.a {
  admin-state enable
}
port pxc-2.b {
  admin-state enable
}
port 1/1/m1/1 {
  admin-state enable
}
port 1/1/m1/2 {
  admin-state enable
}
port-xc {
  pxc 1 {
    admin-state enable
    port-id 1/1/m1/1
  }
  pxc 2 {
    admin-state enable
    port-id 1/1/m1/2
  }
}
router "Base" {
  isis 0 {
    admin-state enable
    advertise-passive-only true
    advertise-router-capability as
    ipv6-multicast-routing false
    ipv6-routing native
    traffic-engineering true
    area-address [49.0001]
    traffic-engineering-options {
      ipv6 true
      application-link-attributes {
      }
    }
  }
  segment-routing-v6 {
    admin-state enable
    locator "loc_Epipe" {
      level-capability 2
    }
  }
}
---snip---
segment-routing {
  segment-routing-v6 {
    origination-fpe [1]
    source-address 2001:db8::2:2
    locator "loc_Epipe" {
      admin-state enable
      block-length 48
      termination-fpe [2]
      prefix {
        ip-prefix 2001:db8:aaaa:102::/64
      }
    }
  }
}
```

```
    }
    base-routing-instance {
        locator "loc_Epipe" {
            function {
                end 1 {
                    srh-mode usp
                }
            }
            end-x-auto-allocate psp protection unprotected { }
        }
    }
}
}
```

The configuration on the other PEs is similar. IPv6 addresses are configured on all interfaces. The BGP configuration uses IPv6 addresses, as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
        }
        group "internal" {
            peer-as 64500
            family {
                evpn true
            }
        }
        neighbor "2001:db8::2:5" {
            group "internal"
        }
    }
}
```

```
# on RR-5:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
        }
        group "internal" {
            peer-as 64500
            family {
                evpn true
            }
        }
        cluster {
            cluster-id 192.0.2.5
        }
        extended-nh-encoding {

```

```
        vpn-ipv4 true
        ipv4 true
    }
    advertise-ipv6-next-hops {
        evpn true
    }
}
neighbor "2001:db8::2:1" {
    group "internal"
}
neighbor "2001:db8::2:2" {
    group "internal"
}
neighbor "2001:db8::2:3" {
    group "internal"
}
neighbor "2001:db8::2:4" {
    group "internal"
}
}
```

Service configuration

On PE-1, the EVPN-VPWS "Epipe-123" is configured as follows:

```
# on access node PE-1:
configure {
    service {
        epipe "Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
        }
        bgp 1 {
        }
        sap 1/1/c10/1:* {
            description "SAP to CEs"
        }
        bgp-evpn {
            evi 123
            local-attachment-circuit "ac-1" {
                eth-tag 1
            }
            remote-attachment-circuit "ac-23" {
                eth-tag 23
            }
        }
        segment-routing-v6 1 {
            admin-state enable
            srv6 {
                instance 1
                default-locator "loc_Epipe"
            }
        }
    }
}
```

On PE-2 and PE-3, the stitching Epipe and the single-active ES are configured as follows:

```
# on PE-2, PE-3:
configure {
  pw-port 23 {
    epipe "stitching-Epipe-123" {
      fpe-id 5
    }
  }
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "SA-ES-23" {
            admin-state enable
            esi 0x01000000002300000001
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              pw-port 23 {
                pw-port-headend true
              }
            }
          }
        }
      }
    }
  }
  epipe "stitching-Epipe-123" {
    admin-state enable
    service-id 123
    customer "1"
    segment-routing-v6 1 {
      locator "loc_Epipe" {
        function {
          end-dx2 {
          }
        }
      }
    }
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 123
    local-attachment-circuit "ac-23" {
      eth-tag 23
    }
    remote-attachment-circuit "ac-1" {
      eth-tag 1
    }
  }
  segment-routing-v6 1 {
    admin-state enable
    ecmp 2
    srv6 {
      instance 1
      default-locator "loc_Epipe"
    }
  }
}
}
```

The core service "service-Epipe-1" uses SRV6 transport:

```
# on PE-2, PE-3:
configure {
  service {
    epipe "service-Epipe-1" {
      admin-state enable
      service-id 1
      customer "1"
      segment-routing-v6 1 {
        locator "loc_Epipe" {
          function {
            end-dx2 {
            }
          }
        }
      }
    }
    bgp 1 {
    }
    sap pw-23:1 {
    }
    bgp-evpn {
      evi 1
      local-attachment-circuit "ac-23" {
        eth-tag 23
      }
      remote-attachment-circuit "ac-4" {
        eth-tag 4
      }
      segment-routing-v6 1 {
        admin-state enable
        ecmp 2
        srv6 {
          instance 1
          default-locator "loc_Epipe"
        }
      }
    }
  }
}
```

The core service "service-Epipe-2" uses MPLS transport:

```
# on PE-2, PE-3:
configure {
  service {
    epipe "service-Epipe-2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
      }
      sap pw-23:2 {
      }
      bgp-evpn {
        evi 2
        local-attachment-circuit "ac-23" {
          eth-tag 23
        }
        remote-attachment-circuit "ac-4" {
          eth-tag 4
        }
      }
      mpls 1 {
        admin-state enable
      }
    }
  }
}
```

```
        ecmp 2
        auto-bind-tunnel {
            resolution any
        }
    }
}
}
```

On PE-4, the corresponding Epipe services are configured as follows:

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
        }
        bgp 1 {
        }
        sap 1/1/c10/1:1 {
            description "SAP to CE-41"
        }
        bgp-evpn {
            evi 1
            local-attachment-circuit "ac-4" {
                eth-tag 4
            }
            remote-attachment-circuit "ac-23" {
                eth-tag 23
            }
            segment-routing-v6 1 {
                admin-state enable
                ecmp 2
                srv6 {
                    instance 1
                    default-locator "loc_Epipe"
                }
            }
        }
    }
    epipe "Epipe-2" {
        admin-state enable
        service-id 2
        customer "1"
        bgp 1 {
        }
        sap 1/1/c10/1:2 {
            description "SAP to CE-42"
        }
        bgp-evpn {
            evi 2
            local-attachment-circuit "ac-4" {
                eth-tag 4
            }
            remote-attachment-circuit "ac-23" {
            }
        }
    }
}
```

```

        eth-tag 23
    }
    mpls 1 {
        admin-state enable
        ecmp 2

}
}

```

Verification

The stitching Epipe associated with the PW port is running the ES and DF election procedures. The following service configuration output shows that the ES is applied for EVI 123 of the stitching Epipe, not for EVI 1 or EVI 2.

```

PE-1 receives the following AD per-ES route with RD 192.0.2.2:123 of the stitching Epipe on PE-2. This AS per-ES route contains:

- an ESI-label extended community with the multihomed mode (single-active) and an ESI label
- an SRv6 L2 service TLV with:
 - an SRv6 SID value of zero (the locator, function, and argument equal zero)
 - the used endpoint behavior code point 0x18 for End.DT2M

```

```

The AD per-EVI routes contain an SRv6 L2 service TLV with:

- an SRv6 SID value of 2001:db8:aaaa:103:: with:

- block length (BL) 48
- node length (NL) 16
- function length (FL) 20
- argument length (AL) 0
- transposition length (TL) 20 (for EVPN and IP-VPN) - transposition of 20 bits of the function field to the ESI label field
- transposition offset (TO) 0
- the used endpoint behavior code point 0x15 for End.DX2

Conclusion

EVPN-VPWS multihoming on PW ports is supported for all-active and for single-active multihoming. The transport on the stitching (and service) Epipe services can be MPLS or SRv6.

EVPN VPWS Services with SRv6 Transport

This chapter provides information about SRv6 support for EVPN-VPWS overlay services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R2. SRv6 support for EVPN-VPWS overlay services is supported on FP-based platforms with FP4-based network ports in SR OS Release 22.7.R1 and later.

Chapter [EVPN for MPLS Tunnels](#) is prerequisite reading.

Overview

Service providers prefer an optimized, standardized, and unified control plane for VPNs. EVPN-VPWS is supported in SRv6 networks that may also run other EVPN-based services, such as EVPN-based VPLS services or Layer 3 EVPN IFL (interface-less) services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432, because there is no need to advertise MAC/IP advertisement routes in VPWS. EVPN-VPWS is described in RFC 8214, and the signaling aspects to support SRv6 are specified in RFC 9252.

EVPN-VPWS supports all-active multihoming (per-flow load-balancing multihoming) as well as single-active multihoming (per-service load-balancing multihoming), using the same Ethernet segments (ESs) used for EVPN-based VPLS services. EVPN-VPWS uses route type 1 and route type 4; it does not use route types 2, 3, or 5, because MAC/IP routes, inclusive multicast routes, or IP-prefix routes are not required.

EVPN-VPWS uses AD per-EVI routes, and optionally, if multihoming is used, AD per-ES and ES routes are required:

- route type 1 - Auto-discovery per EVPN instance (AD per-EVI). This route type is used in all EVPN-VPWS scenarios, with or without multihoming. For EVPN-VPWS, the Ethernet tag field is encoded with the local attachment circuit (AC) of the advertising PE. This value is configured using the **configure service epipe <service-name> bgp-evpn local-attachment-circuit <name> eth-tag <eth-tag>** command. The route distinguisher (RD), label, and the Ethernet segment identifier (ESI) are encoded as for EVPN-based VPLS. The label field is used as service label. In case of multihoming, AD per-EVI routes containing the same ESI are used to provide aliasing and a backup path to the PEs part of the ES. The L2 MTU field is encoded with the service MTU configured in the Epipe. The flags used for EVPN-VPWS are:
 - Flag C: this flag is set if a control word is configured in the service; however, this does not apply if the transport is SRv6.
 - Flag P: this flag is set if the advertising PE is a primary PE.

- If no multihoming is used, there is no primary PE (P = 0).
 - In all-active multihoming, all PEs in the ES are primary (P = 1).
 - In single-active multihoming, only one PE per-EVI in the ES is a primary (P = 1).
- Flag B: this flag is set if the advertising PE is a backup PE.
- Flag B is only set in case of single-active multihoming and only for one PE, even if more than two PEs are present in the same single-active ES. The backup PE is the winner of the second designated forwarder (DF) election (excluding the DF). The remaining non-DF PEs send B = 0.

If there is no multihoming, the ESI, flag P, and flag B are set to zero.

- route type 1 - Auto-discovery per Ethernet segment (AD per-ES). This route type has the same encoding as for EVPN-based VPLS. The AD per-ES route is only used in multihoming scenarios where it is advertised from the PE for each ES. This route type carries the ESI label (used for split-horizon, but only for VPLS services and not for Epipe services) and can affect procedures such as the DF election, as well as the aliasing on remote PEs.
- route type 4 - ES route. This route type has the same encoding as for EVPN-based VPLS. The ES route is only used in multihoming scenarios. This route type advertises a local configured ES. The exchange of this route type can discover remote PEs that are part of the same ES and the DF election algorithm among them.

Configuration

Figure 152: EVPN-VPWS example topology shows the example topology that is used throughout this chapter.

Figure 152: EVPN-VPWS example topology

38304

The example topology consists of six SR OS nodes with the following initial configuration:

- Network (or hybrid) ports interconnect the core PEs with configured router interfaces.
- MTU-1 is a pure Ethernet aggregator. The ports toward the core PEs are access ports. Likewise, the ports on PE-2 and PE-3 toward MTU-1 are access ports.
- Core PEs and MTU-6 run IS-IS on all interfaces.
- Link LDP is configured between all PEs, and toward and from MTU-6.

- EVPN uses BGP for exchanging reachability information at the service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although a separate router is typically used, in this chapter, PE-2 is used as route reflector with the following BGP configuration:

```
[/]
A:admin@PE-2# configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-import true
      vpn-apply-export true
      peer-ip-tracking true
      rapid-withdrawal true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "gr_v6_internal" {
        family {
          evpn true
        }
        cluster {
          cluster-id 1.1.1.1
        }
        peer-as 64500
        extended-nh-encoding {
          ipv4 true
          vpn-ipv4 true
        }
        advertise-ipv6-next-hops {
          evpn true
        }
      }
      neighbor 2001:db8::2:3 {
        group "gr_v6_internal"
      }
      neighbor 2001:db8::2:4 {
        group "gr_v6_internal"
      }
      neighbor 2001:db8::2:5 {
        group "gr_v6_internal"
      }
    }
  }
}
```

The BGP configuration on the other PEs is as follows:

```
[/]
A:admin@PE-3#, A:admin@PE-4#,A:admin@PE-5# configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-import true
      vpn-apply-export true
      peer-ip-tracking true
      rapid-withdrawal true
      split-horizon true
      rapid-update {
        evpn true
      }
      group "gr_v6_internal" {
```

```
family {
  evpn true
}
peer-as 64500
extended-nh-encoding {
  ipv4 true
  vpn-ipv4 true
}
advertise-ipv6-next-hops {
  evpn true
}
}
neighbor 2001:db8::2:2 {
  group "gr_v6_internal"
}
}
}
```

The following sections describe the EVPN-VPWS scenarios:

- [SRv6 tunnels in EVPN-VPWS services without multihoming](#)
- [SRv6 tunnels in EVPN-VPWS services with all-active multihoming](#)
- [SRv6 tunnels in EVPN-VPWS services with single-active multihoming](#)

SRv6 tunnels in EVPN-VPWS services without multihoming

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke SDPs at the access, as shown in [Figure 153: Example topology for EVPN-VPWS without multihoming](#).

Figure 153: Example topology for EVPN-VPWS without multihoming

38305

On PE-2, Epipe 1 is configured as follows:

```
[/]
A:admin@PE-2# configure {
  service {
    epipe "Epipe-1" {
      customer "1"
      service-id 1
      segment-routing-v6 1 {
        locator "loc_Epipe-1" {
          function {
            end-dx2 {
            }
          }
        }
      }
    }
  }
}
```

```
    bgp 1 {
    }
    bgp-evpn {
        local-attachment-circuit AC-PE-2-CE-20 {
            eth-tag 220
        }
        remote-attachment-circuit AC-PE-4-MTU-6 {
            eth-tag 46
        }
        evi 10
        segment-routing-v6 1 {
            srv6 {
                instance 1
                default-locator "loc_Epipe-1"
            }
            # source-address 2001:db8::2:2 # defined for SRv6 on router level
            admin-state enable
        }
    }
    sap 1/1/c2/1:101 {
    }
    admin-state enable
}
}
```

On PE-4, the service configuration is as follows:

```
[/]
A:admin@PE-4# configure {
    service {
        sdp 460 {
            far-end {
                ip-address 192.0.2.6
            }
            admin-state enable
        }
        epipe "Epipe-1" {
            customer "1"
            service-id 1
            segment-routing-v6 1 {
                locator "loc_Epipe-1" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
        }
        bgp 1 {
        }
        bgp-evpn {
            local-attachment-circuit AC-PE-4-MTU-6 {
                eth-tag 46
            }
            remote-attachment-circuit AC-PE-2-CE-20 {
                eth-tag 220
            }
            evi 10
            segment-routing-v6 1 {
                srv6 {
                    instance 1
                    default-locator "loc_Epipe-1"
                }
            }
        }
    }
}
```

```

# source-address 2001:db8::2:4 # defined for SRv6 on router level
admin-state enable
    }
    }
    spoke-sdp 460:101 {
    }
    admin-state enable
    }
}
}
}

```

The following commands are relevant for the EVPN-VPWS configuration:

- the **bgp** *<bgp-instance>* command enables the context for the BGP configuration relevant to the service. The **bgp** context configures the common BGP parameters for all BGP families in the service, such as the RD and the route target (RT). Even if the general BGP parameters for the service are auto-derived, the **bgp** context must be enabled.

```

[/]
A:admin@PE-2# configure {
  service {
    epipe "Epipe-1" {
      bgp 1 ?

      bgp

      adv-service-mtu      - Advertised service MTU value
      apply-groups         - Apply a configuration group at this level
      apply-groups-exclude - Exclude a configuration group at this level
      pw-template-binding  + Enter the pw-template-binding list instance
      route-distinguisher  - High-order 6 bytes that are used as string to compose VSI-ID for
                           use in NLRI
      route-target         + Enter the route-target context
      vsi-export           - VSI export policies
      vsi-import           - VSI import policies
    }
  }
}

```

- The following parameters can be configured in the **bgp-evpn** context:

```

[/]
A:admin@PE-2# configure {
  service {
    epipe "Epipe-1" {
      bgp-evpn ?

      bgp-evpn

      apply-groups         - Apply a configuration group at this level
      apply-groups-exclude - Exclude a configuration group at this level
      evi                  - EVPN ID
      local-attachment-   + Enter the local-attachment-circuit list instance
        circuit
      mpls                 + Enter the mpls list instance
      remote-attachment-  + Enter the remote-attachment-circuit list instance
        circuit
      segment-routing-v6  + Enter the segment-routing-v6 list instance
      vxlan                + Enter the vxlan list instance
    }
  }
}

```

- The **evi** command configures a 2-byte or 3-byte EVPN identifier (EVI) used for auto-deriving the service RD, service RT, and for the service carving (or DF election) when multihoming is used. For 2-byte EVIs, the auto-derivation of RD and RT is as follows:

- RD system-ip:evi
- RT autonomous-system:evi

The EVI values must be unique in the system, regardless of the type of service they are assigned to (Epipe or VPLS).

- The **local-attachment-circuit** and **remote-attachment-circuit** commands configure the two attachment circuits connected by the EVPN-VPWS service. The configured Ethernet tag for the local AC is advertised in the Ethernet tag field of the AD per-EVI route for the Epipe, along with the corresponding RD, RT, and label. Both local and remote Ethernet tags are necessary to bring up the Epipe service. If the received Ethernet tag for the Epipe service matches the configured remote AC Ethernet tag, an EVPN-SRv6 destination is created to the next hop.

The local Ethernet tag cannot be modified without disabling **bgp-evpn segment-routing-v6** in the Epipe, as shown in the following output:

```
[/]
A:admin@PE-2# configure {
  service {
    epipe "Epipe-1" {
      bgp-evpn {
        local-attachment-circuit AC-PE-2-CE-20 {
          eth-tag 221
        }
      }
    }
  }
}
MINOR: SVCNMR #8036: configure service epipe "Epipe-1" bgp-evpn local-attachment-circuit
"AC-PE-2-CE-20" - evpn-vpws ac eth-tag not allowed - cannot change while evpn mpls/
vxlan/srv6 is enabled
```

Unlike local Ethernet tags, remote Ethernet tags can be modified without disabling bgp-evpn.

- The following configuration options are available for Epipes in the **configure service epipe 1 bgp-evpn segment-routing-v6** context:

```
[/]
A:admin@PE-2# configure {
  service {
    epipe "Epipe-1" {
      bgp-evpn {
        segment-routing-v6 1 ?

segment-routing-v6

admin-state           - Administrative state of segment routing over IPv6
apply-groups          - Apply a configuration group at this level
apply-groups-exclude - Exclude a configuration group at this level
default-route-tag     - Default route tag
ecmp                 - Maximum ECMP value configured on the service
evi-three-byte-auto-rt - Auto-derive the BGP EVPN route target
force-vc-forwarding  - Datapath forwarding to force vlan-vc-type
oper-group            - Operational group
resolution            - Resolution options for routes
route-next-hop       + Enter the route-next-hop context
source-address      - Source IPv6 address
srv6                + Enter the srv6 context
```

This output shows a subset of the options for VPLS services; see chapter [EVPN for MPLS Tunnels](#) for a longer list of options.

When the local AC (sap 1/1/c2/1:101) is up, PE-2 sends a BGP EVPN AD per-EVI route that contains Ethernet tag 220 for the local AC:

```
# on PE-2:

```

When the received RT matches and the received Ethernet tag matches the configured remote AC Ethernet tag, the EVPN-SRv6 destination, which consists of a termination endpoint (TEP) and a SID, is created on PE-2 and PE-4:

```
[/]
A:admin@PE-2# show service id 1 segment-routing-v6 instance 1 destinations
=====
TEP, SID
=====
Instance  TEP Address                Segment Id
-----
1         192.0.2.4                   2001:db8:aaaa:104:7fff:6000::
-----
Number of TEP, SID: 1
-----

Segment Routing v6 Ethernet Segment Dest
=====
Instance  Eth SegId                Num. Macs    Last Change
-----
No Matching Entries
=====
```

Note:

The egress label for the EVPN-SRv6 destination on PE-4 is 524278. The 24-bit label value in the BGP update debug is 16 (2⁴) times as high:

$$524\ 278 * 16 = 8\ 388\ 448$$

because the debug message is shown before the router can parse the label field and determine if it corresponds to an MPLS label or a transposed function (20 bits), or to a VXLAN VNI (24 bits).

The BGP AD per-EVI routes for Ethernet tag 46 are shown with the following command:

```
[/]
A:admin@PE-2# show router bgp routes evpn auto-disc tag 46
=====
BGP Router ID:192.0.2.2      AS:64500      Local AS:64500

```

Note:

Each PE sends its service MTU into the L2 MTU field in the I2-attribute in the AD per-EVI route for the Epipe service. The received L2 MTU is checked. In case of a mismatch between the received MTU and the configured service MTU, the router does not set up the EVPN destination and, therefore, the service does not come up.

SRv6 tunnels in EVPN-VPWS services with multihoming

SR OS supports EVPN multihoming as per RFC 8214.

The EVPN multihoming implementation is based on the concept of the ES. An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multihoming to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects. It can also be shared between Epipe and VPLS services.

Each ES has a unique ESI that is 10 bytes and is manually configured. The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homing CEs are assumed to be connected to an ES with ESI = 0 (single-homing ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-based VPLS service by default. An ES can be shared by multiple services; a specific SAP or spoke SDP is automatically associated with an ES when the SAP is defined in the same LAG or port configured in the ES, or when the spoke SDP is defined in the same SDP configured in the ES.

Regardless of the multihoming mode, the local Ethernet tag values must match on all the PEs that are part of the same ES. The PEs in the ES use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for an EVI. The DF election is only relevant for single-active multihoming ESs. For Epipes defined in an all-active multihoming ES, there is no DF election required, because all PEs are forwarding traffic and all traffic is treated as unicast.

Aliasing is supported when sending traffic to an ES destination. Assuming ECMP is enabled on the ingress PE (and shared queuing or ingress policing are configured), per-flow load-balancing is performed among all the PEs that advertise P = 1. PEs advertising P = 0 are not considered as next hops for an ES destination.

The following sections show the configuration of:

- an all-active multihoming ES with a LAG associated with it
- a single-active multihoming ES linked to an SDP

Figure 154: Example topology EVPN-VPWS with multihoming shows the example topology has an all-active multihoming ES "ESI-23" with a LAG associated with it in PE-2 and PE-3. A single-active multihoming ES "ESI-45" with an SDP associated with it is configured in PE-4 and PE-5.

Figure 154: Example topology EVPN-VPWS with multihoming

38306

SRv6 tunnels in EVPN-VPWS services with all-active multihoming

All-active multihoming allows for per-flow load-balancing. Unlike EVPN-based VPLS services, EVPN-VPWS has no DF election in all-active multihoming. All PEs in the ES are active and the remote PE performs per-flow load-balancing. ESI-23 is configured on PE-2 and PE-3 as all-active multihoming and is associated with LAG 1. This LAG is used as a SAP in Epipe 2 on both PE-2 and PE-3. The configuration of the ES and Epipe 2 is identical on PE-2 and PE-3, including the local AC and remote AC names and Ethernet tags:

```
[/]
A:admin@PE-2#, A:admin@PE-3# configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-23" {
            esi 01:00:00:00:00:23:00:00:00:01
            df-election {
              es-activation-timer 3
            }
            multi-homing-mode all-active
            association {
              lag "lag-1" {
            }
          }
          admin-state enable
        }
      }
    }
  }
  epipe "Epipe-2" {
    customer "1"
    service-id 2
    segment-routing-v6 1 {
      locator "loc_Epipe-2" {
        function {
          end-dx2 {
        }
      }
    }
  }
  }
  bgp 1 {
  }
  bgp-evpn {
    local-attachment-circuit AC-ESI-23-MTU-1 {
      eth-tag 231
    }
    remote-attachment-circuit AC-ESI-45-MTU-6 {
      eth-tag 456
    }
    evi 20
    segment-routing-v6 1 {
      srv6 {
        instance 1
        default-locator "loc_Epipe-2"
      }
      ecmp 2
      # source-address 2001:db8::2:2 # defined for SRv6 on router level
      admin-state enable
    }
  }
}
```

```

        sap lag-1:201 {
        }
        admin-state enable
    }
}

```

See chapter [EVPN for MPLS Tunnels](#) for a detailed explanation of the configuration parameters of the ES.

In EVPN-VPWS multihoming scenarios, three route types are exchanged: AD per-EVI, AD per-ES, and ES routes. The following ES route (route type 4) for ESI 01:00:00:00:00:23:00:00:00:01, sent by PE-2, is imported at PE-3:

```

# on PE-3:
8 2023/01/10 23:27:55.229 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:2
"Peer 1: 2001:db8::2:2: UPDATE

        Type: 1 Len: 6
        BL:0 NL:0 FL:0 AL:0 TL:0 T0:0
"

```

The ESI label is in the extended community, as well as the indication that the multihoming is all-active. Epipe services do not require ESI labels because BUM traffic is not recognized in EVPN-VPWS services. However, because the ES can be shared by Epipe and VPLS services, the AD per-ES route still includes a non-zero ESI label. In this case, the transport is SRv6, so there are no ESI labels. The label field in the ESI-label extended community is an implicit-null value (3) and the included SRv6 Services TLV encodes a SID with value 0.

The following two AD per-EVI routes (route type 1) with Ethernet tag 231 sent by RR PE-2 are received and imported on PE-4:

```

# on PE-4:

* indicates that the corresponding row element may have been truncated.

Note:

Even if ECMP is configured, the ingress router (where a SAP is configured) does not load-balance the traffic unless shared queuing or ingress policing is configured in the SAP. This is not specific to EVPN, but is generic to the way Epipes forward traffic.

In all-active multihoming for EVPN-VPWS, there is no DF election and all PEs in the ES are active. For ESI-23, both PE-2 and PE-3 are active primary DF, but there are no DF candidates, because there is no DF election:

```
[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "ESI-23" evi evi-1 20

SRv6 tunnels in EVPN-VPWS services with single-active multihoming

Single-active multihoming allows for per-service load-balancing. Single-active multihoming is configured on PE-4 and PE-5 with ES "ESI-45". Both PEs have an SDP to MTU-6, which is associated with the ES and to the Epipe service. The configuration of the local and remote AC names and Ethernet tags is identical on PE-4 and PE-5.

On PE-4, the service configuration is as follows:

```

[/]
A:admin@PE-4# configure {
  service {
    sdp 46 {
      delivery-type mpls
      far-end {
        ip-address 192.0.2.6
      }
      ldp true
      admin-state enable
    }
    system {
      bgp {
        evpn {
          ethernet-segment "ESI-45" {
            esi 01:00:00:00:00:45:00:00:00:01
            df-election {
              es-activation-timer 3
            }
            multi-homing-mode single-active
            association {
              sdp 46 {
            }
          }
        }
      }
    }
  }
}

```

```
        admin-state enable
      }
    }
  }
}
epipe "Epipe-2" {
  customer "1"
  service-id 2
  segment-routing-v6 1 {
    locator "loc_Epipe-2" {
      function {
        end-dx2 {
        }
      }
    }
  }
}
bgp 1 {
}
bgp-evpn {
  local-attachment-circuit AC-ESI-45-MTU-6 {
    eth-tag 456
  }
  remote-attachment-circuit AC-ESI-23-MTU-1 {
    eth-tag 231
  }
  evi 20
  segment-routing-v6 1 {
    srv6 {
      instance 1
      default-locator "loc_Epipe-2"
    }
    ecmp 2
    # source-address 2001:db8::2:4 # defined for SRv6 on router level
    admin-state enable
  }
}
spoke-sdp 46:201 {
}
admin-state enable
}
}
}
```

On PE-5, the configuration is similar, but with a different SDP:

```
[/]
A:admin@PE-5# configure {
  service {
    sdp 56 {
      delivery-type mpls
      far-end {
        ip-address 192.0.2.6
      }
      ldp true
      admin-state enable
    }
  }
  system {
    bgp {
      evpn {
        ethernet-segment "ESI-45" {
          esi 01:00:00:00:00:45:00:00:00:01
          df-election {
            es-activation-timer 3
          }
        }
      }
    }
  }
}
```

```
    }
    multi-homing-mode single-active
    association {
      sdp 56 {
      }
    }
    admin-state enable
  }
}
}
epipe "Epipe-2" {
  customer "1"
  service-id 2
  segment-routing-v6 1 {
    locator "loc_Epipe-2" {
      function {
        end-dx2 {
        }
      }
    }
  }
}
}
bgp 1 {
}
}
bgp-evpn {
  local-attachment-circuit AC-ESI-45-MTU-6 {
    eth-tag 456
  }
  remote-attachment-circuit AC-ESI-23-MTU-1 {
    eth-tag 231
  }
}
evi 20
segment-routing-v6 1 {
  srv6 {
    instance 1
    default-locator "loc_Epipe-2"
  }
  ecmp 2
  # source-address 2001:db8::2:5    # defined for SRv6 on router level
  admin-state enable
}
}
spoke-sdp 56:201 {
}
}
admin-state enable
}
}
}
```

Three route types are exchanged between the core PEs: AD per-EVI, AD per-ES, and ES routes.

As an example, the following is the ES route with originator PE-4 sent by RR PE-2 to PE-5. It contains a target 00:00:00:00:45:00 in the extended community that is derived from the ESI:

```
# on PE-2:
45 2023/01/10 23:29:07.514 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5
"Peer 1: 2001:db8::2:5: UPDATE
Peer 1: 2001:db8::2:5 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 85
  Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.4
```

```

Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0 ESI: 01:00:00:00:00:45:00:00:00:01, IP-Len:
4 Orig-IP-Addr: 192.0.2.4
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
  Flag: 0x80 Type: 10 Len: 4 Cluster ID:
    1.1.1.1
  Flag: 0xc0 Type: 16 Len: 16 Extended Community:
    df-election::DF-Type:Auto/DP:0/DF-Preference:0/AC:1
    target:00:00:00:00:45:00
"

```

The AD per-ES route has a MAX-ET tag and an ESI label in the extended community. The multihoming mode is single-active. As in the case of all-active multihoming, the ESI label is not used in Epipe services. The following BGP update with originator PE-5 is sent by RR PE-2 to its client PE-4:

```

# on PE-2:
51 2023/01/10 23:29:07.669 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
"Peer 1: 2001:db8::2:4: UPDATE
Peer 1: 2001:db8::2:4 - Send BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 127
  Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.5
    Type: EVPN-AD Len: 25 RD: 192.0.2.5:20 ESI: 01:00:00:00:00:45:00:00:00:01, tag: MAX-ET
  Label: 0 (Raw Label: 0x0) PathId:
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.5
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
      1.1.1.1
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:

          Type: 1 Len: 6
          BL:0 NL:0 FL:0 AL:0 TL:0 TO:0
"

```

The AD per-EVI route contains flags for primary and backup, which are different for routes received from PE-4 and PE-5. In this case, PE-4 is the primary in the single-active multihoming ES (P = 1):

```

# on PE-2:
53 2023/01/10 23:29:10.550 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5

MAX-ET                                0
-----
Routes : 4
=====

```

For each PE in the single-active ES, there are two AD routes: the routes with MAX-ET are AD per-ES routes and the routes with a configured Ethernet tag are AD per-EVI routes.

The EVPN VPWS destination for Epipe 2 on PE-2 is ESI-45, as shown in the following output:

```

[/]
A:admin@PE-2# show service id 2 segment-routing-v6 instance 1 destinations

```

The DF election is key for the forwarding and backup functions in single-active multihoming ESs. The PE elected as DF is the primary for the ES in the Epipe and unblocks its SAP and spoke SDP for upstream and downstream traffic. The rest of the PEs in the ES bring their ES SAPs or spoke SDPs operationally down.

PE-5 is a non-DF, as follows:

```

[/]
A:admin@PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" evi evi-1 20
=====
EVI DF and Candidate List

=====
Number of SDPs : 1
=====

```

The spoke sdp 56:201 is operationally down with a StandbyForMHPProtocol flag:

```

[/]
A:admin@PE-5# show service id 2 sdp 56:201 detail | match Flag
Flags          : StandbyForMHPProtocol

```

Two consecutive DF elections take place: the first DF election includes all PEs in the ES for that Epipe and determines which PE is the primary PE (flags P = 1, B = 0). The second DF election excludes this DF and determines which PE is the backup (P = 0, B = 1). All other PEs signal flags P = 0 and B = 0.

When the primary PE fails, AD per-ES and AD per-EVI withdrawal messages are sent to the remote PE, which updates its next hop to the backup. The backup PE takes over immediately without waiting for the ES activation timer (configured with the **es-activation-timer** command) to bring up its SAP and spoke SDP.

ES failures

When the SDP toward the primary (DF) fails, the backup PE needs to take over. An SDP failure is emulated and log 99 on PE-4 shows that SDP 46 is operationally down and PE-4 is no longer the DF:

```
191 2023/01/10 23:38:55.867 CET MINOR: SVCMGR #2303 Base
"Status of SDP 46 changed to admin=up oper=down"

193 2023/01/10 23:38:55.868 CET MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-45, EVI:20, Designated Forwarding state changed to:false"
```

Remote PEs receive route withdrawal updates (unreachable NLRI) from the former DF PE-4, for example on PE-2:

```
# on PE-2:
1 2023/01/10 23:38:55.869 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
"Peer 1: 2001:db8::2:4: UPDATE

=====
* indicates that the corresponding row element may have been truncated.
    
```

Because of the default DF election algorithm, this process is revertive; as soon as the SDP 46 is operationally up again, a new DF election is triggered with two DF candidates and PE-4 is elected as DF. A non-revertive mode is also available if preference-based DF election is configured.

Troubleshooting and debugging

The following **show** and **debug** commands can be used in EVPN-VPWS:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service segment-routing-v6** [*<ip-address>*]
- **show service id** *<service-id>* **bgp-evpn**
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **show log log-id** *<log-id>*

Most of these commands have been shown in the preceding sections; some commands are shown in this section.

Information about the configured boot timers (before DF election) and ES activation timer (after the system has been elected DF) is shown as follows:

```
[/]
A:admin@PE-2# show redundancy bgp-evpn-multi-homing

=====
Redundancy BGP EVPN Multi-homing Information
=====
Boot-Timer           : 10 secs
Boot-Timer Remaining : 0 secs
ES Activation Timer  : 3 secs
=====
```

See chapter [EVPN for MPLS Tunnels](#) for a description of these timers.

The following command shows that the BGP route type 4 (ES route) messages are only imported by the PEs in the same ES; for example, on PE-3:

```
[/]
A:admin@PE-3# show router bgp routes evpn eth-seg

```

In addition to the preceding commands, the following **tools dump** commands may be useful:

- **tools dump service evpn usage** - This command shows the number of EVPN-SRv6 (and EVPN-MPLS and EVPN-VXLAN) destinations in the system.
- **tools dump service system bgp-evpn ethernet-segment <name> evi <evi> df** - This command computes the DF election for a specific ESI and EVI. For all-active multihoming, there is no DF election and all PEs forward traffic. For single-active multihoming, one PE is active for a service while another PE is a backup. This command shows the DF (primary), even if it is not the local PE.

The usage of EVPN resources is shown as follows:

```
[/]
A:admin@PE-2# tools dump service evpn usage

vxlan-srv6-evpn-mpls usage statistics at 01/10/2023 23:35:05:

MPLS-TEP           :           0
VXLAN-TEP          :           0
SRV6-TEP         :           2
Total-TEP          :       2/ 16383

Mpls Dests (TEP, Egress Label + ES + ES-BMAC) :           0
Mpls Etree Leaf Dests :           0
Vxlan Dests (TEP, Egress VNI + ES)           :           0
Srv6 Dests (TEP, SID + ES)                 :           2
Total-Dest                    :       2/196607

Sdp Bind + Evpn Dests                       :       2/245759
ES L2/L3 PBR                   :       0/ 32767
Evpn Etree Remote BUM Leaf Labels :           0
```

On PE-2, there is one SRv6 TEP (192.0.2.4 in Epipe 1 and in Epipe 2) and there are two SRv6 destinations: 192.0.2.4 and ESI 01:00:00:00:00:45:00:00:00:01. PE-5 is not an SRv6 TEP for PE-2 because it is not a primary and, therefore, is not forwarding any traffic.

In all-active multihoming, the DF election is not applicable:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-23" evi 20 df

[01/10/2023 23:35:05] All Active VPWS or IP-ALIASING - DF N/A
```

In single-active multihoming, the following command shows which PE is the DF:

```
[/]
```

```
A:admin@PE-5# tools dump service system bgp-evpn ethernet-segment "ESI-45" evi 20 df
[01/10/2023 23:35:10] Computed DF: 192.0.2.4 (Remote) (Boot Timer Expired: Yes)
[01/10/2023 23:35:10] Computed Backup: 192.0.2.5 (This Node)
```

The command is launched on PE-5, which is a backup. The computed DF is PE-4 and the boot timer has expired, meaning there is no DF re-election pending.

Conclusion

EVPN-VPWS is a simplified point-to-point version of RFC 7432. EVPN provides a unified control plane mechanism that simplifies the network deployment and operation. Single-active and all-active multihoming can be used in Epipes; EVPN-VPWS is a differentiator of EVPN compared to traditional TLDP or BGP Epipe redundancy mechanisms.

EVPN-IFF BGP Attribute Propagation Between Families

This chapter provides information about EVPN-IFF BGP attribute propagation between families .

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and MD-CLI configuration in this chapter are based on SR OS Release 22.7.R1. EVPN Interface-ful (EVPN-IFF) BGP attribute propagation between BGP families based on uniform propagation is supported in SR OS Release 21.2.R1 and later.

For more information on routed VPLS in EVPN, see chapters [EVPN for VXLAN Tunnels \(Layer 3\)](#) and [EVPN for MPLS Tunnels in Routed VPLS](#) .

Overview

SR OS allows multiple BGP owners in the same VPRN service to receive or advertise IP prefixes contained in the VPRN route table. A VPRN route table can simultaneously install and process IPv4 or IPv6 prefixes for the following owners:

- EVPN Interface-ful (EVPN-IFF)
- EVPN Interface-less (EVPN-IFL)
- VPN-IP (also referred to as IP-VPN routes)
- IP (also referred to as BGP PE-CE routes)

EVPN-IFF routes are EVPN IP-prefix routes, otherwise known as route type 5 (RT-5) routes, that are imported and exported based on the configuration of the R-VPLS services attached to the VPRN. To enable the EVPN-IFF model, the command **configure service vpls <.> bgp-evpn routes ip-prefix advertise true** needs to be configured. By default, BGP attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. However, BGP attributes can be used to influence routing (for example, local preference, Autonomous System (AS) path, communities, and so on), and therefore, SR OS supports EVPN-IFF BGP attribute propagation to other BGP families (uniform propagation), as described in *draft-ietf-bess-evpn-ipvpn-interworking*.

The following CLI command is used to enable EVPN-IFF BGP attribute propagation and EVPN-IFF best path selection:

```
[ex:/configure service system bgp evpn]
A:admin@PE-4# ip-prefix-routes ?

ip-prefix-routes

d-path-length-ignore - Ignore D-PATH length for BGP path selection of EVPN-IFF
iff-attribute-       - Enable uniform propagation of BGP attributes
```

```
uniform-propagation
iff-bgp-path-      - Enable BGP path selection for EVPN-IFF routes
selection
```

The **iff-bgp-path-selection** command cannot be enabled when **iff-attribute-uniform-propagation** is disabled.

When **iff-attribute-uniform-propagation** is enabled on a node:

- the following BGP path attributes are propagated:
 - AS path
 - domain path (D-PATH), supported in SR OS Release 21.10.R1 and later
 - IBGP-only attributes, when advertising to an IBGP neighbor: local preference, originator ID, cluster ID
 - Multiple Exit Discriminator (MED)
 - communities, large communities, extended communities
- the following BGP path attributes are not propagated across families:
 - any type 0x06 extended communities supported by RT-5 routes:
 - MAC mobility extended community
 - EVPN router MAC extended community
 - BGP encapsulation extended community
 - Route Target extended community
 - BGP tunnel encapsulation attribute
 - BGP prefix-SID attribute used in RT-5 routes and VPN-IP routes for Segment Routing over IPv6 dataplane (SRv6) services
- IBGP-only attributes are only propagated to IBGP neighbors; EBGP-only attributes only to EBGP neighbors
- routes received with well-known communities, such as no-advertise or no-export(-subconfed), are sent or not sent depending on the community values
- BGP path attributes are propagated even when doing route leaking between routing instances

If multiple EVPN-IFF routes for the same prefix are received for the same VPRN, they are by default ordered and selected based on the lowest R-VPLS Iindex, Route Distinguisher (RD), and Ethernet tag.

When **iff-bgp-path-selection** is enabled, EVPN-IFF routes with the same or different RD are selected based on regular BGP path selection rules in the following order:

1. valid route wins over invalid route (invalid routes are looped routes or routes where the originator ID matches the receiving router)
2. lowest origin validation state (origin validation state: valid is preferred to origin validation state: not found; origin validation state: not found is preferred to origin validation state: invalid) – applicable to IPv4, IPv6, or BGP Labeled Unicast (BGP-LU) routes
3. lowest Routing Table Manager (RTM) preference
4. highest local preference
5. shortest D-PATH

6. lowest Accumulated Interior Gateway Protocol (AIGP) metric (AIGP is not supported for EVPN-IFL, EVPN-IFF, or IP-VPN routes)
7. shortest AS path
8. lowest origin (origin: IGP is preferred to origin: EGP; origin: EGP is preferred to origin: incomplete)
9. lowest MED (routes without MED are considered as zero or infinity based on the configuration of the **always-compare-med** command)
10. lowest owner type (owner type: BGP-label is preferred to owner type: BGP; owner type: BGP is preferred to owner type: BGP-VPN) with BGP-VPN referring to VPN-IP and EVPN-IFL
11. EBGP wins over IBGP
12. lowest route-table or tunnel-table cost to the next-hop

Note: The **ignore-nh-metric** command is not supported for EVPN-IFF.

13. lowest next-hop type – a next-hop resolved to a tunnel-table entry is considered as a lower type than a next-hop resolved to a route-table entry
14. lowest router ID – applicable to IBGP peers
15. shortest cluster list length – applicable to IBGP peers
16. lowest IP address – IP address refers to the peer that advertised the route
17. EVPN-IFL wins over IPVPN
18. next-hop check (IPv4 next-hop wins over IPv6, then lowest next-hop wins) - The next-hop check is a tiebreaker if BGP receives the same prefix for VPN-IPv6 and EVPN-IFL. An IPv6 prefix received as VPN-IPv6 has an IPv6 next-hop whereas the same IPv6 prefix received as EVPN-IFL can have an IPv4 next-hop.
19. lowest RD for route-table selection
20. lowest path ID (add-path)

Configuration

[Figure 155: Example topology](#) shows the example topology with PE-3 as Data Center Gateway (DCGW) between an EVPN-VXLAN network and an EVPN-MPLS network. Routed VPLS is configured on PE-2, PE-3, and PE-6. Supplementary broadcast domain "SBD-12" is configured in the EVPN-VXLAN network between PE-2 and PE-3; "SBD-13" in the EVPN-MPLS network between PE-3 and PE-6. On PE-2, Ethernet VPN instance "EVI-11" is configured toward CE-1.

Figure 155: Example topology

37589

CE-1 advertises prefix 10.1.11.0/24 to BGP neighbor 10.0.0.2 in VPRN 10 on PE-2. PE-2 sends an EVPN-IFF route to DCGW PE-3. PE-3 forwards the prefix 10.1.11.0/24 as VPN-IPv4 route to PE-4, as EVPN-IFL route to PE-5, as EVPN-IFF route to PE-6, and as IPv4 route to PE-6.

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces on all PEs
- IS-IS on the router interfaces
- LDP on the router interfaces on PE-3, PE-4, PE-5, and PE-6

On the PEs, BGP is configured for the EVPN address family. Between PE-3 and PE-4, both the VPN-IPv4 and the EVPN address family are configured. The configuration on PE-3 is as follows:

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      rapid-update {
        evpn true
      }
      group "internal" {
        peer-as 64496
      }
    }
  }
}
```

```

    group "internal1" {
        peer-as 64496
        family {
            evpn true
        }
    }
    neighbor "192.0.2.2" {
        group "internal1"
    }
    neighbor "192.0.2.4" {
        group "internal"
        family {
            vpn-ipv4 true
            evpn true
        }
    }
    neighbor "192.0.2.5" {
        group "internal"
        family {
            evpn true
        }
    }
    neighbor "192.0.2.6" {
        group "internal"
        family {
            evpn true
        }
    }
}

```

On CE-1, BGP is configured in VPRN 11 for the IPv4 address family. The export policy adds communities "1:1" and "2:2" and sets the MED to a value of 81.

```

# on CE-1:
configure {
    policy-options {
        community "1:1_2:2" {
            member "1:1" { }
            member "2:2" { }
        }
        policy-statement "export-vnf-to-all" {
            entry 10 {
                from {
                    protocol {
                        name [direct direct-interface]
                    }
                }
                action {
                    action-type accept
                    bgp-med {
                        set 81
                    }
                    community {
                        add ["1:1_2:2"]
                    }
                }
            }
        }
    }
}
service {
    vprn "VPRN 11" {
        admin-state enable
        service-id 11
    }
}

```

```

customer "1"
autonomous-system 64501
bgp {
  split-horizon true
  export {
    policy ["export-vnf-to-all"]
  }
  group "CE-1-PE-2" {
    type external
    peer-as 64496
  }
  neighbor "10.0.0.2" {
    group "CE-1-PE-2"
    ebgp-default-reject-policy {
      import false
    }
  }
}
interface "int-CE-1-PE-2" {

  }
  sap 1/1/2:12 {
  }
}
}

```

On PE-2, VPRN 10 has R-VPLS interface "int-EVI-11" toward CE-1 and R-VPLS interface "int-SBD-12" toward PE-3. BGP is configured toward neighbor 10.0.0.1 on CE-1 and the import policy sets the local preference (LP) to 200, as follows:

```

# on PE-2:
configure {
  policy-options {
    policy-statement "local-preference-200" {
      entry 10 {
        action {
          action-type accept
          local-preference 200
        }
      }
    }
  }
}
service {
  vprn "VPRN 10" {
    admin-state enable
    service-id 10
    customer "1"
    autonomous-system 64496
    bgp {
      split-horizon true
    }
  }
}

```

```
        local-as {
            as-number 64496
        }
        import {
            policy ["local-preference-200"]
        }
        group "PE-2-CE-1" {
            type external
            peer-as 64501
        }
        neighbor "10.0.0.1" {
            group "PE-2-CE-1"
            ebgp-default-reject-policy {
                export false
            }
        }
    }
    interface "int-EVI-11" {
        ipv4 {
            primary {
                address 10.0.0.2
                prefix-length 24
            }
            vrrp 1 {
                backup [10.0.0.2]
                owner true
                passive true
            }
        }
        vpls "EVI-11" {

}
}
}

```

On PE-3, VPRN 10 is configured with:

- three interfaces:
 - R-VPLS interface "int-SBD-12" toward PE-2
 - R-VPLS interface "int-SBD-13" toward PE-6
 - interface "int-VPRN10-PE-3-to-PE-6" to the base router of PE-6.
- BGP-IPVPN for the exchange of VPN-IPv4 routes with PE-4
- BGP-EVPN to propagate EVPN-IFL routes to PE-5 and EVPN-IFF routes to PE-6
- BGP to propagate BGP IPv4 routes to the base router on PE-6. The export policy is only required in the BGP configuration.

```

# on PE-3:
configure {
    policy-options {
        prefix-list "10.1.0.0" {
            prefix 10.1.0.0/16 type longer {
            }
        }
        policy-statement "export-bgp" {

}
}
}

```

On PE-4, VPRN 10 is configured with BGP-IPVPN, as follows. BGP between PE-3 and PE-4 is configured for the VPN-IPv4 address family.

```

# on PE-4:
configure {
  service {
    vprn "VPRN 10" {
      admin-state enable
      service-id 10
      customer "1"
      bgp-ipvpn {
        mpls {
          admin-state enable
          route-distinguisher "192.0.2.4:10"
          vrf-target {
            community "target:64496:10"
          }
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}

```

```
    }  
  }
```

On PE-5, VPRN 10 is configured with BGP-EVPN, as follows:

```
# on PE-5:  
configure {  
  service {  
    vprn "VPRN 10" {  
      admin-state enable  
      service-id 10  
      customer "1"  
      bgp-evpn {  
        mpls 1 {  
          admin-state enable  
          route-distinguisher "192.0.2.5:10"  
          vrf-target {  
            community "target:64496:10"  
          }  
          auto-bind-tunnel {  
            resolution any  
          }  
        }  
      }  
    }  
  }  
  bgp {  
  }
```

In the base router of PE-6, BGP is configured to neighbor 10.15.16.3 on PE-3. VPRN 15 is configured with R-VPLS interface "int-SBD-13" toward PE-3. The configuration is as follows:

```
# on PE-6:  
configure {  
  router "Base" {  
    interface "int-PE-6-to-VPRN10-PE-3" {  
      port 1/1/1:13  
      ipv4 {  
        primary {  
          address 10.15.16.6  
          prefix-length 24  
        }  
      }  
    }  
  }  
  bgp {  
    group "PE-6-CE" {  
      family {  
        ipv4 true  
      }  
    }  
    neighbor "10.15.16.3" {  
      group "PE-6-CE"  
      type internal  
      peer-as 64496  
      local-as {  
        as-number 64496  
      }  
    }  
  }  
}  
  service {  
    vpls "SBD-13" {  
      admin-state enable  
      service-id 13  
    }  
  }
```

```

      }
      ip-prefix {
        advertise true
      }
    }
    mpls 1 {
      admin-state enable
      auto-bind-tunnel {
        resolution any
      }
    }
  }
}
vprn "VPRN 15" {
  admin-state enable
  service-id 15
  customer "1"
  autonomous-system 64502
  interface "int-SBD-13" {
    vpls "SBD-13" {
      evpn-tunnel {
      }
    }
  }
}
```

Default behavior

By default, BGP path attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. [Figure 156: EVPN-IFF BGP path attributes are re-originated by PE-2 and PE-3](#) shows that PE-2 receives an IPv4 route for prefix 10.1.11.0/24 with non-default BGP path attributes, whereas PE-2 propagates the prefix as an EVPN-IFF route with default path attributes.

Figure 156: EVPN-IFF BGP path attributes are re-originated by PE-2 and PE-3

37590

VPRN 10 on PE-2 received a BGP IPv4 route for prefix 10.1.11.0/24 with LP 200, MED 81, and communities "1:1" and "2:2":

```
[/]

Uniform propagation for EVPN-IFF BGP path attributes to different BGP families

Enable **iff-attribute-uniform-propagation** and **iff-best-path-selection** on PE-2 as follows:

```

# on PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ip-prefix-routes
            iff-attribute-uniform-propagation
            iff-bgp-path-selection
          }
        }
      }
    }
  }
}

```

In a similar configuration, **iff-attribute-uniform-propagation** and **iff-bgp-path-selection** are enabled on the other PEs.

The following command shows that uniform propagation for EVPN-IFF BGP path attributes and BGP path selection are enabled:

```

[/]
A:admin@PE-2# show service system bgp-evpn

EVPN-IFF BGP path attributes exported to leaked EVPN routes

Figure 158: Example topology shows the example topology with two VPRNs on DCGW PE-3 where routes are leaked.

Figure 158: Example topology

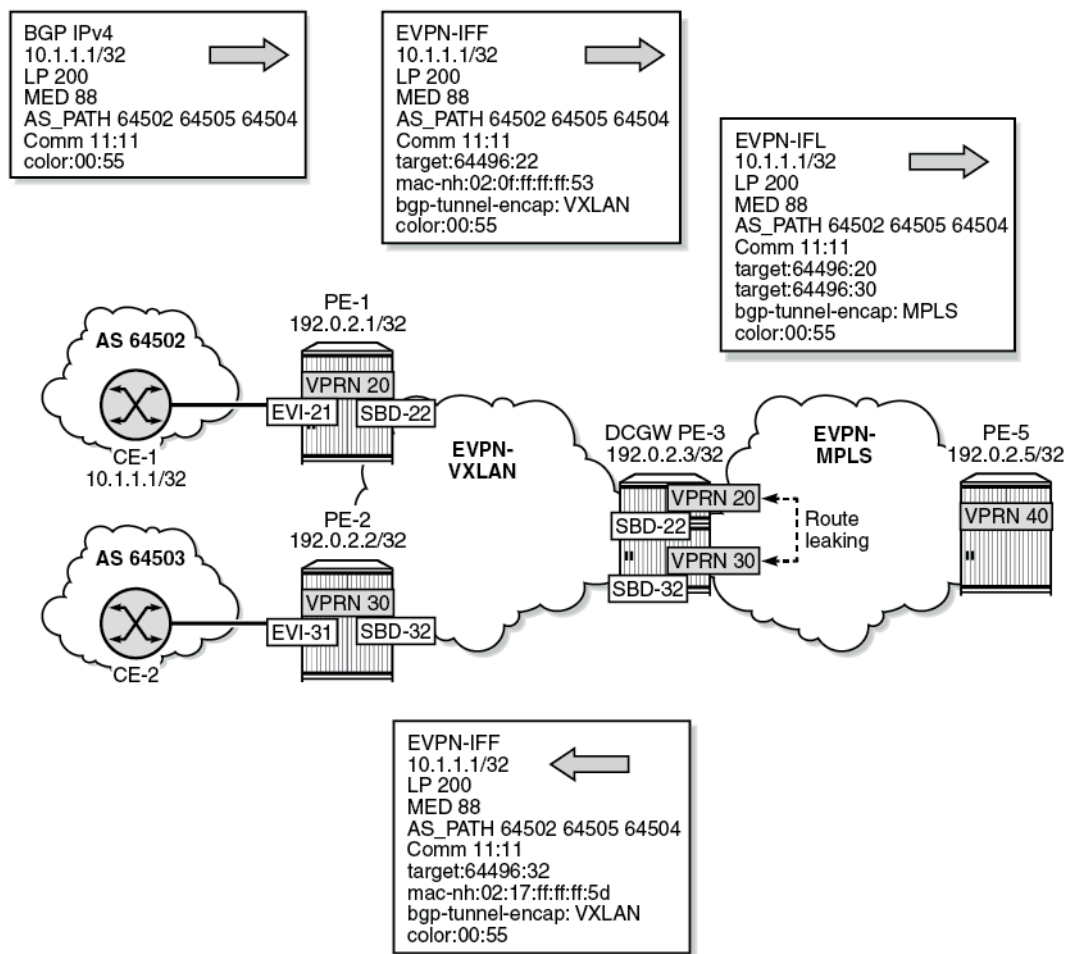

37592

The uniform propagation for EVPN-IFF BGP path attributes is enabled on all PEs.

Figure 159: BGP path attributes are propagated in leaked EVPN routes shows that CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1. This route has non-default BGP attributes; for example, MED 88, AS path 64502 64505 64504, and community "11:11" "color:00:55". PE-1 exports this route as an EVPN-IFF route to PE-3. PE-3 forwards this route as EVPN-IFL route to PE-5. On PE-3, the route is leaked from VPRN 20 to VPRN 30. The BGP path attributes are propagated to the leaked EVPN routes, except those attributes that are not expected to be propagated, such as the router's MAC extended community. PE-3 advertises an EVPN-IFF route for prefix 10.1.1.1/32 to PE-2.

Figure 159: BGP path attributes are propagated in leaked EVPN routes

37593

In a similar way, CE-2 exports IPv4 prefix 10.2.2.2/32 to PE-2 with non-default BGP path attributes. PE-2 advertises this prefix as an EVPN-IFF route with the same BGP path attributes. PE-3 leaks the route from VPRN 30 to VPRN 20 while preserving the BGP path attributes. PE-3 advertises an EVPN-IFF route for prefix 10.2.2.2/32 to PE-1 with the same BGP path attributes. PE-3 also advertises the prefix as EVPN-IFL route to PE-5 with the same BGP path attributes. For brevity, the routes for prefix 10.2.2.2/32 are not shown here.

In this example, VPRN "CE-1" is configured as follows. The export policy sets the MED, prepends some AS numbers to the AS path, and adds the communities "11:11" and "color:00:55".

```
# on CE-1:
configure {
  policy-options {
    community "11:11" {
      member "11:11" { }
    }
  }
  community "color:00:55" {
    member "color:00:55" { }
  }
}
```

```
    }
    policy-statement "export-vnf-to-all-2" {
        entry 10 {
            from {
                protocol {
                    name [direct direct-interface]
                }
            }
            action {
                action-type next-entry
                as-path-prepend {
                    as-path 64504
                }
                bgp-med {
                    set 88
                }
                community {
                    add ["11:11" "color:00:55"]
                }
            }
        }
        entry 20 {

            prefix-length 32
        }
    }
}
}
}

```

On PE-1, an import policy sets the LP to a value of 200. VPRN 20 has R-VPLS interface "int-EVI-21" toward CE-1 and R-VPLS interface "int-SBD-22" toward PE-2.

```

# on PE-1:
configure {
    policy-options {
        policy-statement "local-preference-200" {

The configuration on PE-2 is similar with VPRN 30, R-VPLS "EVI-31", and R-VPLS "SBD-32".

PE-3 has two VPRNs: "VPRN 20" and "VPRN 30". Export policy "leak-color-55-into-30" is used to leak routes with color community "color:00:55" from VPRN 20 to VPRN 30. The configuration is as follows:

```

# on PE-3:
configure {
  policy-options {
    community "RT64496:20" {

```

```
        member "target:64496:20" { }
    }
    community "RT64496:30" {
        member "target:64496:30" { }
    }
    community "color:00:55" {
        member "color:00:55" { }
    }
    policy-statement "leak-color-55-into-20" {
        entry 10 {
            from {
                community {
                    name "color:00:55"
                }
            }
            action {
                action-type accept
                community {
                    add ["RT64496:20" "RT64496:30"]
                }
            }
        }
    }
    policy-statement "leak-color-55-into-30" {
        entry 10 {
            from {
                community {
                    name "color:00:55"
                }
            }
            action {
                action-type accept
                community {
                    add ["RT64496:20" "RT64496:30"]
                }
            }
        }
    }
}

PE-3 exports the prefix route as EVPN-IFL to PE-5. On PE-5, VPRN 40 is configured as follows:

```

# on PE-5:
configure {
    policy-options {
        community "RT64496:20" {
            member "target:64496:20" { }
        }
        community "RT64496:30" {
            member "target:64496:30" { }
        }
    }
    policy-statement "vrf-40-export" {
        entry 10 {
            from {
                protocol {
                    name [direct direct-interface]
                }
            }
            action {
                action-type accept
                community {
                    add ["RT64496:20" "RT64496:30"]
                }
            }
        }
    }
    policy-statement "vrf-40-import" {
        entry 10 {
            from {
                community {
                    name "RT64496:20"
                }
            }
            action {
                action-type accept
            }
        }
        entry 20 {
            from {
                community {
                    name "RT64496:30"
                }
            }
        }
    }
}

```

```
        }
        action {
            action-type accept
        }
    }
}
}
}
}
service {

            }
        }
        interface "loopback" {
            loopback true
            ipv4 {
                primary {
                    address 10.5.5.5
                    prefix-length 32
                }
            }
        }
    }
}
}
```

CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1 with community "color:00:55" and other non-default BGP path attributes. The route table for VPRN 20 on PE-1 includes an BGP IPv4 route for prefix 10.1.1.1/32:

```
[/]
A:admin@PE-1# show router 20 route-table 10.1.1.1/32

=====
Route Table (Service: 20)
=====
Dest Prefix[Flags]                               Type  Proto  Age        Pref
  Next Hop[Interface Name]                       Metric
-----
10.1.1.1/32                                       Remote BGP   00h03m25s  170
   10.2.0.1                                         0
-----
No. of Routes: 1
```

PE-1 propagates prefix 10.1.1.1/32 in an EVPN-IFF route. On PE-3, the route table includes an EVPN-IFF route for prefix 10.1.1.1/32:

```
[/]
A:admin@PE-3# show router 20 route-table 10.1.1.1/32
```

```

=====
Route Table (Service: 20)
=====

  Next Hop[Interface Name]                        Metric
-----
10.1.1.1/32                                       Remote EVPN-IFF 00h03m28s 169
  int-SBD-22 (ET-02:0f:ff:ff:ff:53)              0
-----
No. of Routes: 1

```

PE-3 forwards prefix 10.1.1.1/32 as an EVPN-IFL to PE-5. On PE-5, the route table includes an EVPN-IFL route for prefix 10.1.1.1/32:

```

[/]
A:admin@PE-5# show router 40 route-table

=====
Route Table (Service: 40)
=====
Dest Prefix[Flags]                                Type  Proto  Age      Pref
  Next Hop[Interface Name]                        Metric
-----
10.1.1.1/32                                       Remote EVPN-IFL 00h03m59s 170
  192.0.2.3 (tunneled)                             10
10.2.2.2/32                                       Remote EVPN-IFL 00h03m56s 170
  192.0.2.3 (tunneled)                             10
10.5.5.5/32                                       Local  Local  00h04m03s 0
  loopback                                          0
-----
No. of Routes: 3

```

In a similar way, PE-5 received an EVPN-IFL route for prefix 10.2.2.2/32. Prefix 10.5.5.5/32 is local to VPRN 40 on PE-5 and is advertised to PE-3 as EVPN-IFL route.

On PE-3, routes with community "color:00:55" are leaked between VPRN 20 and VPRN 30. PE-1 and PE-3 have forwarded the route with the original BGP path attributes, so this community is preserved and the route for prefix 10.1.1.1/32 is leaked to VPRN 30, as shown in the following route table. The next hop is R-VPLS "SBD-22" in local VPRN 20.

```

[/]
A:admin@PE-3# show router 30 route-table

=====
Route Table (Service: 30)
=====

Conclusion

SR OS nodes can be configured to propagate EVPN-IFF BGP path attributes between families to influence the path selection, as per *draft-ietf-bess-evpn-ipvpn-interworking*.

EVPN-MPLS E-Tree

This chapter provides information about EVPN-MPLS E-Tree.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the CLI in the current edition is based on SR OS Release 23.7.R1. VPLS E-Tree without EVPN is supported in SR OS Release 12.0.R4, and later. EVPN-MPLS E-Tree is supported in SR OS Release 15.0.R1, and later.

Overview

Ethernet Tree (E-Tree) is a rooted multipoint Ethernet service defined by the Metro Ethernet Forum (MEF). E-Tree can be implemented based on the following:

- RFC 7796, *Ethernet-Tree Support in Virtual Private LAN Services* (VPLS E-Tree without EVPN)
- RFC 8317, *E-Tree Support in EVPN and PBB-EVPN* (EVPN-MPLS E-Tree)

VPLS E-Tree without EVPN

The E-Tree implementation is based on RFC 7796 and is supported for unicast and broadcast, unknown unicast, and multicast (BUM) traffic. Interfaces can be defined as root attachment circuit (AC) or leaf AC, or both, as described in [Table 9: Interfaces in E-Tree](#). A VPLS E-Tree can have multiple root ACs. Access and network interfaces are both supported on SAPs and SDP bindings.

Table 9: Interfaces in E-Tree

Interface	Tag
Access interface (user-to-network interface - UNI)	Root tag
	Leaf tag
Network interface (network-to-network interface - NNI)	Root-leaf tag

On the ingress access interfaces, all frames are tagged and forwarded. On the network interfaces, no traffic is dropped based on the root or leaf tag. On the egress access interfaces, all traffic toward a root AC is forwarded, whereas traffic toward a leaf AC is only forwarded when it originates from a root AC, as summarized in [Table 10: E-Tree Forwarding on Access Interfaces](#). Traffic from leaf AC to leaf AC is blocked.

Table 10: E-Tree Forwarding on Access Interfaces

	To root AC	To leaf AC
From root AC	Allowed	Allowed
From leaf AC	Allowed	Not allowed

Within an E-Tree, the split horizon group capability is inherent for leaf SAPs and leaf SDP bindings and extends to all the remote nodes that are part of the same VPLS E-Tree service.

Ingress Tagging and Egress Filtering

Figure 160: Frame Forwarding in a VPLS E-Tree without EVPN shows how frames are forwarded in an E-Tree. The ingress node PE-2 knows whether the frame comes from a leaf AC or a root AC and adds a tag indicating "from root" or "from leaf". Specific VLAN IDs are used to indicate "from root" or "from leaf". The egress node PE-4 forwards the frame based on the "from root" or "from leaf" tag, as follows:

- A frame with the "from root" tag can be forwarded to any AC, leaf or root.
- A frame with the "from leaf" tag can only be forwarded to a root AC, not to a leaf AC.

Figure 160: Frame Forwarding in a VPLS E-Tree without EVPN

27364

SAPs and SDP bindings are considered as root AC automatically (in the following example, SAP 1/2/c1/1:4 is a root AC); leaf ACs get the keyword **leaf-ac**, and NNI SAPs and SDP bindings get the keyword **root-leaf-tag**. The root tag equals the service delimiting VLAN ID (VID) in the SAP and the leaf tag can only be configured with a different value.

```
On PE-2:
configure {
  service {
    vpls "VPLS 4" {
      admin-state enable
      service-id 4
      customer "1"
      etree true
      sap 1/2/c1/1:4 { }
      sap 1/2/c3/1:4 {
        etree-leaf true
      }
    }
    sap 1/2/c5/1:4 {
```

```

        etree-root-leaf-tag {
            leaf 44
        }
    }
    spoke-sdp 24:4 {
        etree-root-leaf-tag true
        vc-type vlan
    }
    spoke-sdp 210:4 {
        etree-leaf true
    }
}
}
}

```

VLAN ranges are not allowed in a VPLS E-Tree, as shown for the following connection profile VLAN, which is configured on PE-2:

```

On PE-2:
configure {
    connection-profile {
        vlan 10 {
            qtag-range 10 {
                end 19
            }
            qtag-range 110 {
                end 110
            }
        }
    }
}

```

The following error is raised when attempting to configure a SAP with VLAN range cp-10:

```

configure {
    service {
        vpls "VPLS 4" {
            sap 1/2/c3/1:cp-10 { }
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 4" sap 1/2/c3/1:cp-10
- vlan-range not allowed with etree vpls
        }
    }
}

configure {
    service {
        vpls "VPLS 4" {
            sap 1/2/c3/1:cp-10.* {
                etree-leaf true
            }
        }
    }
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 4" sap 1/2/c3/1:cp-10.*
- SAP and port encapsulation values are incompatible
- configure port 1/2/c3/1 ethernet encap-type
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 4" sap 1/2/c3/1:cp-10.*
- vlan-range not allowed with etree vpls
- configure service vpls "VPLS 4" etree
}

```

All incoming frames on a SAP or SDP binding in a VPLS have their dot1q/qinq encapsulation removed by the local PE. In a VPLS E-Tree, the local PE then adds a VLAN tag with a dedicated VID indicating whether the frame originates from a root AC or a leaf AC.

- For dot1q/qinq-based L2 services, a VLAN tag with VID x is added for root and VID y for leaf. Frames with VID x are forwarded to any type of AC, while frames with VID y are only forwarded to root ACs at

the remote node, as shown in [Figure 161: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree](#).

- For pseudowire-based L2 services, a VLAN tag with VID 1 is hard-coded for frames received on a root AC and a VLAN tag with VID 2 for frames received on a leaf AC.

Figure 161: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree

27365

EVPN-MPLS E-Tree

Operators migrate their regular VPLS services to EVPN services because of the advantages offered by EVPN, such as all-active multi-homing, scalability, and easy provisioning. EVPN-MPLS E-Trees block leaf-to-leaf traffic, while allowing all traffic from and to root ACs. The following is a configuration example of an EVPN-MPLS E-Tree. The `evpn-etree-leaf-label` command is only relevant for EVPN E-Tree services and allocates an E-Tree leaf label on the system, which is used for egress filtering of BUM traffic.

```
configure {
  service {
    system {
      bgp {
        evpn {
          etree-leaf-label true
        }
      }
    }
  }
  vpls "VPLS 1" {
    admin-state enable
    service-id 1
    customer "1"
    etree true
    bgp 1 { }
    bgp-evpn {
      evi 1
      mpls 1 {
        admin-state enable
        ingress-replication-bum-label true
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
  sap 1/2/c1/1:1 { }
  sap 1/2/c3/1:1 { }
```

```

        etree-leaf true
    }
    spoke-sdp 210:1 {
        etree-leaf true
    }
}
}
}
}

```

SAPs or SDP bindings are by default root AC objects. MAC addresses learned on root AC objects are advertised as usual, while MAC addresses learned on a SAP or SDP binding configured as leaf AC are advertised with an BGP EVPN E-Tree extended community with leaf indication bit L=1.

BGP EVPN VXLAN is not supported in E-Tree services; only EVPN-MPLS E-Tree is supported. The following error is raised when attempting to configure VXLAN in an E-Tree enabled service:

```

configure {
  service {
    vpls "VPLS 3" {
      admin-state enable
      service-id 3
      customer "1"
      etree true
      vxlan {
        instance 1
      }
    }
  }
}
MINOR: MGMT_CORE #2203: configure service vpls "VPLS 3" vxlan instance 1
- Invalid element - etree or m-vpls must be unset

```

In an EVPN-MPLS E-Tree, it is not required and not even possible to configure the **etree-root-leaf-tag** option on interfaces. The following error is raised when attempting to configure a spoke SDP or SAP with **etree-root-leaf-tag** option:

```

configure {
  service {
    vpls "VPLS 1" {
      spoke-sdp 24:1 {
        etree-root-leaf-tag true
        vc-type vlan
      }
    }
  }
}
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" spoke-sdp 24:1 etree-root-leaf-tag
- Not supported with bgp-evpn
- configure service vpls "VPLS 1" bgp-evpn

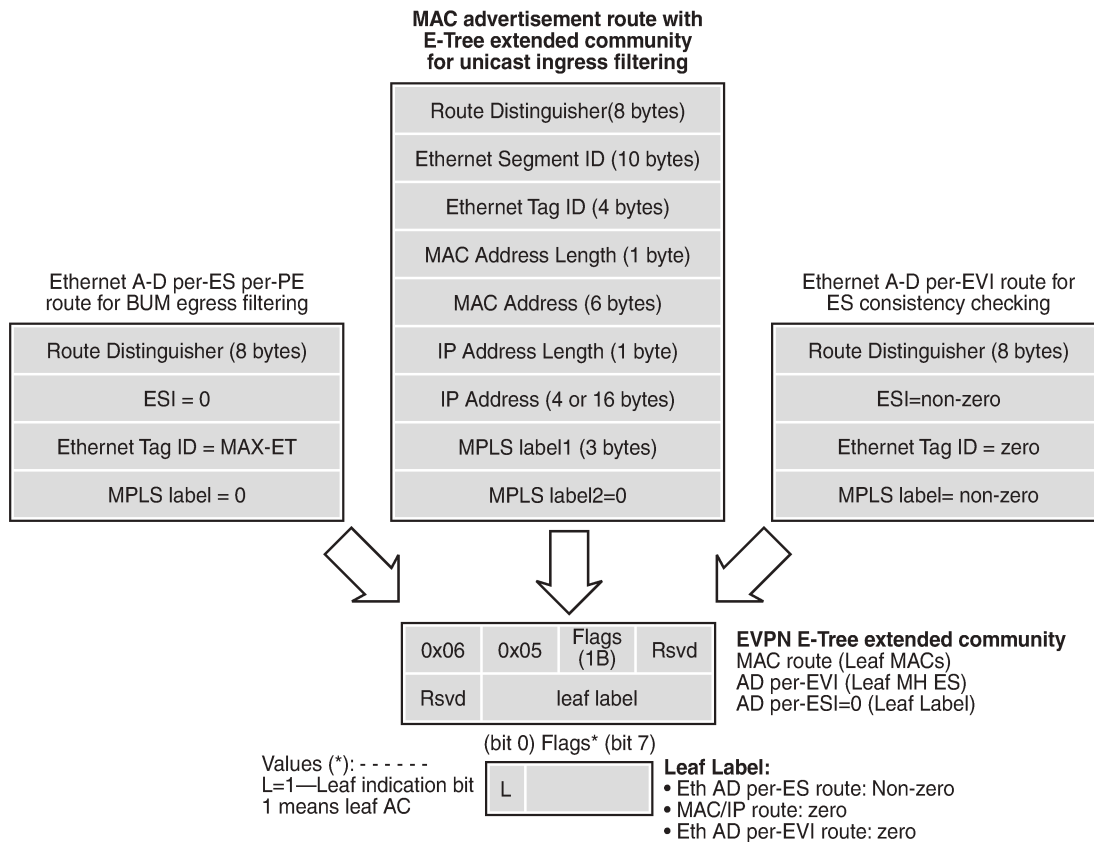

configure {
  service {
    vpls "VPLS 1" {
      sap 1/2/c3/1:200 {
        etree-root-leaf-tag {
          leaf 22
        }
      }
    }
  }
}
MINOR: SVC_MGR #12: configure service vpls "VPLS 1" sap 1/2/c3/1:200 etree-root-leaf-tag
- Inconsistent Value error
- not supported with bgp-evpn
- configure service vpls "VPLS 1" bgp-evpn

```

BGP EVPN Control Plane for EVPN E-Tree

No leaf tag needs to be added to frames forwarded to EVPN destinations. Instead, the BGP EVPN control plane for EVPN E-Tree advertises a leaf indication bit and a leaf label in the E-tree extended community, as shown in [Figure 162: BGP EVPN Control Plane for EVPN E-Tree](#).

Figure 162: BGP EVPN Control Plane for EVPN E-Tree

The BGP EVPN control plane is extended with the EVPN E-Tree extended community, as per RFC 8317. The low-order bit of the flags field contains the L-bit (L=1 indicates a leaf AC). The leaf label contains a 20-bit MPLS label that is non-zero for Ethernet Auto Discovery (AD) per Ethernet Segment (per-ES) routes (tag MAX-ET), but it equals zero for MAC/IP routes and Ethernet AD per EVPN Instance (per-EVI) routes (tag 0). The following BGP EVPN AD per-ES route contains an EVPN E-Tree extended community with L=0 and leaf label 524282, and is used for egress BUM filtering. RFC 8317 states that the leaf indication bit L must be ignored on reception and should be zero on transmission.

```

=====
```

If receiving the same MAC route as root from PE-1 and as leaf from PE-2, the MAC route from PE-1 is selected: root MAC routes have higher priority than leaf MAC routes. Root static MAC routes take precedence over leaf static MAC routes.

EVPN MAC routes with a higher sequence number have a higher priority than root or leaf MAC routes. MAC mobility procedures take precedence to first identify the location of the MAC before associating that MAC with a root or a leaf site. The EVPN MAC route selection criteria in tie-break order are as follows:

1. Conditional static MACs (local protected MACs)
2. Auto-learned protected MACs (locally learned MACs on SAPs or mesh/spoke SDPs because of the configuration of auto-learn-mac-protect)
3. EVPN ES PBR MACs
4. EVPN static MACs (remote protected MACs)
5. Data plane learned MACs (regular MAC learning on SAPs/SDP-bindings)
6. EVPN MACs with a higher sequence number
7. EVPN E-Tree root MACs
8. Lowest IP (next-hop IP of the EVPN NLRI)
9. Lowest Ethernet tag (Ethernet tag is zero for MPLS and non-zero for VXLAN)
10. Lowest RD

Ingress Leaf Filtering for Unicast Traffic

EVPN-MPLS E-Tree is the only E-Tree technology able to do unicast ingress filtering, as opposed to the usual unicast egress filtering that, for example, VPLS does. Remote MAC addresses are learned in the control plane, so EVPN can optimize the forwarding by filtering known unicast traffic at the ingress:

- Unicast frames entering a root AC at the ingress PE are not filtered. The MAC destination address (DA) is looked up in the FDB and the frames are forwarded. The MAC source address (SA) is learned and advertised in BGP EVPN without the E-Tree extended community.
- Unicast frames entering a leaf AC at the ingress PE are filtered. The MAC DA is looked up in the FDB. When the MAC DA is learned from an EVPN leaf (or a leaf AC), the frame is dropped. When the MAC DA is learned from an EVPN root (or root AC), the frame is forwarded. The MAC SA is learned and advertised in BGP EVPN with leaf indication bit L=1.

Figure 163: Ingress Leaf Filtering for Known Unicast Traffic shows that PE-4 advertises MAC2 with leaf indication bit L=1. When a frame is sent with MAC SA MAC1 on a leaf AC of PE-2, PE-2 does a MAC lookup in the FDB to find out that the DA MAC2 is learned from an EVPN leaf. Therefore, PE-2 does not forward the frame to PE-4, but drops it at the ingress.

Figure 163: Ingress Leaf Filtering for Known Unicast Traffic

27365

The ingress filtering blocks E-Tree leaf-to-leaf traffic and requires the implementation of an extra leaf EVPN-MPLS destination per remote PE containing leaf ACs per E-Tree service. Therefore, a dedicated EVPN-MPLS binding is created per leaf unicast traffic in the service. This additional internal EVPN-MPLS destination is created per remote PE that contains a leaf and that advertises at least one leaf MAC. The MPLS E-Tree leaf destination is created when a MAC route with L=1 is received. Any EVPN E-Tree service could potentially use one additional EVPN-MPLS destination for leaf unicast traffic per remote PE. This additional EVPN-MPLS leaf destination in the E-Tree is only unicast and not part of the flooding list. The EVPN-MPLS leaf destination consumes EVPN resources, as can be verified as follows:

```
[/]
A:admin@PE-2# tools dump service evpn usage | match "Mpls Etree"
Mpls Etree Leaf Dests          :          1
```

All MAC addresses received with L=1 point to this EVPN-MPLS E-Tree leaf destination, whereas root MAC addresses point to the root destination.

Egress Leaf Filtering for BUM Traffic

Figure 164: Egress Leaf Filtering for BUM Traffic shows that leaf-to-leaf BUM traffic is filtered at the egress, based on the EVPN leaf label advertised in the E-Tree extended community of the zero ESI AD per-ES route (tag=MAX-ET).

- BUM frames that enter a root AC at the ingress PE are not filtered; the BUM frames follow regular EVPN data plane procedures.
- BUM frames that enter a leaf AC at the ingress PE are marked as leaf and forwarded or replicated to the egress IOM. At the egress IOM, the frame is flooded in the default multicast list, subject to the following:
 - Leaf entries are skipped when BUM traffic is forwarded, so no BUM traffic is forwarded to local leaf ACs.
 - BUM traffic to remote BGP EVPN PEs is encapsulated with the EVPN label stack.
 - If the remote PE has advertised an AD per-ES route with E-Tree leaf label L1, this leaf label L1 is added at the bottom of the stack. At the egress PE, when the leaf label L1 matches the leaf label of the PE, the BUM traffic is only forwarded to the root ACs, not to the leaf ACs.
 - If the egress PE does not have any E-Tree enabled service, it has not advertised any AD per-ES route with E-Tree leaf label. The local PE forwards the BUM traffic with BGP EVPN encapsulation, but without an additional label. Even when the egress PE does not have E-Tree enabled, it can still work with the VPLS E-Tree service available in the ingress PE. No traffic is dropped at the egress PE where no E-Tree is configured.

Figure 164: Egress Leaf Filtering for BUM Traffic

The following command is used to monitor the ESI label entries consumed by the EVPN E-Tree application:

```
[/]  
A:admin@PE-2# tools dump service evpn usage | match "BUM"
```

Evpn Etree Remote BUM Leaf Labels : 1

Configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- LDP between the PEs
- BGP for the EVPN address family (between the PEs)

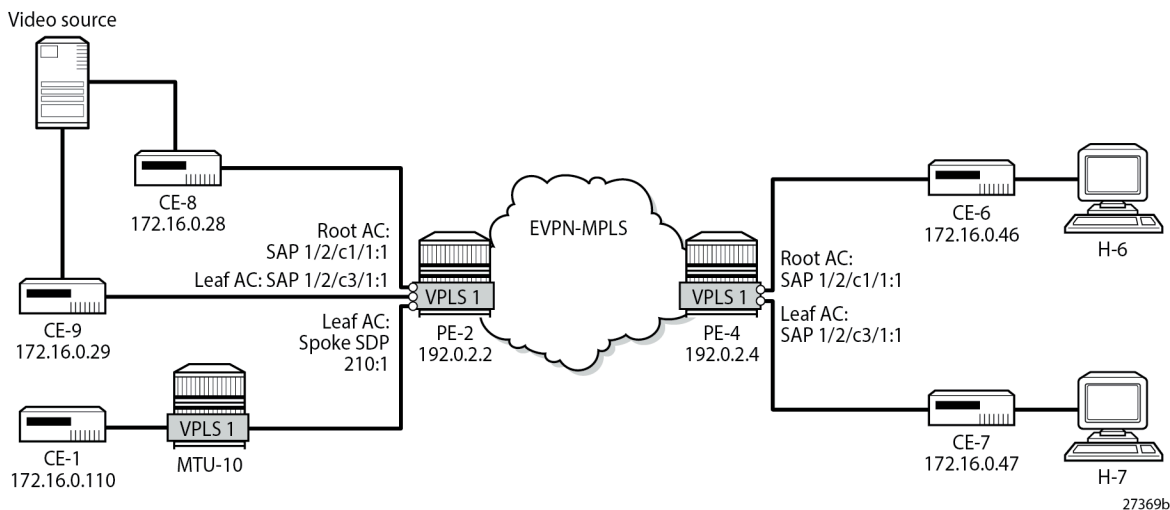

In this section, the following cases are described:

- EVPN-MPLS E-Tree without multi-homing
- EVPN-MPLS E-Tree with all-active and single-active multi-homing

EVPN-MPLS E-Tree without Multi-homing

Figure 165: Example Topology for EVPN-MPLS E-Tree without Multi-homing shows an example topology with two PEs in an EVPN-MPLS network with VPLS 1 configured as E-Tree. CE-6 and CE-8 have root ACs and are able to send and receive traffic to and from all other CEs, whereas CE-7, CE-9, and CE-1 are only able to exchange traffic with CE-6 and CE-8, but not with each other. The video source can be connected to CE-8 (root AC) or CE-9 (leaf AC).

Figure 165: Example Topology for EVPN-MPLS E-Tree without Multi-homing

The service configuration on PE-2 is as follows:

```
On PE-2:
configure {
  service {
```

```

sdp 210 {
  admin-state enable
  delivery-type mpls
  ldp true
  far-end {
    ip-address 192.0.2.10
  }
}
system {
  bgp {
    evpn {
      etree-leaf-label true
    }
  }
}
vpls "VPLS 1" {
  admin-state enable
  service-id 1
  customer "1"
  etree true
  bgp 1 { }
  bgp-evpn {
    evi 1
    mpls 1 {
      admin-state enable
      ingress-replication-bum-label true
      auto-bind-tunnel {
        resolution any
      }
    }
  }
  sap 1/2/c1/1:1 { }
  sap 1/2/c3/1:1 {
    etree-leaf true
  }
  spoke-sdp 210:1 {
    etree-leaf true
  }
}
}
}

```

The service configuration on PE-4 is similar, with SAP 1/2/c1/1:1 as root AC and SAP 1/2/c3/1:1 as leaf AC.

The following command on PE-2 shows that SAP 1/2/c1/1:1 is a root AC (default), SAP 1/2/c3/1:1 is a leaf AC (indicated by "L"), and spoke SDP 210:1 is also a leaf AC.

```

[/]

EVPN E-Tree Egress Filtering Based on MAC SA

Egress filtering on MAC SA is required to cover cases when the ingress PE sends traffic received on a leaf AC, but without leaf indication. [Figure 166: EVPN E-Tree Egress Filtering Based on MAC SA](#) shows that CE-9 sends traffic with MAC SA ca:fe:09:29:29:29 on a leaf AC.

Figure 166: EVPN E-Tree Egress Filtering Based on MAC SA

27370b

When CE-9 sends unicast traffic to CE-6 with root MAC DA ca:fe:06:46:46:46, the ingress PE-2 forwards the frames to this root MAC DA to egress PE-4. However, if PE-4 does not have the MAC DA in its FDB (because of aging or MAC flush and the MAC route has not made it yet to PE-2), it may flood the frame to all the root and leaf ACs, even if the frame originated from a leaf AC. EVPN E-Tree egress filtering based on MAC SA prevents this from happening, so the traffic is only forwarded to the root AC.

The data path does the egress filtering based on MAC SA as follows:

- First, frames are identified as leaf frames in one of the following cases:
 - Frames arriving on a leaf SAP
 - EVPN traffic arriving with a leaf label
 - Frames arriving with a MAC SA that is flagged as being a leaf SA
- At the egress PE, frames identified as leaf are filtered depending on the type of traffic:
 - For known unicast traffic, the FDB is consulted. If the MAC DA FDB entry is marked as being from a leaf, the frame is dropped to prevent leaf-to-leaf forwarding.
 - For BUM traffic, the leaf frames are filtered at the egress IOM to suppress leaf-to-leaf forwarding.

EVPN-MPLS E-Tree with Multi-homing

Figure 167: Example Topology with All-active ESs and Single-active ES shows the example topology with two all-active multi-homing vESs on PE-2 and PE-3 and one single-active multi-homing ES on PE-4 and PE-5.

Figure 167: Example Topology with All-active ESs and Single-active ES

27371

On PE-2, two all-active multi-homing vESs are configured. VPLS 2 is configured as EVPN-MPLS E-Tree with LAG 1 as root AC and LAG 2 as leaf AC. RD 2.2.2.2 is configured and used in the non-zero AD per-ES routes, while the zero ESI routes (AD per-ES) use the IP address 192.0.2.2. The service configuration on PE-2 is as follows:

```
On PE-2:
configure {
  service {
    system {
      bgp {
        evpn {
          ad-per-es-route {
            route-target-type evi-route-target-set
            route-distinguisher-ip-address 2.2.2.2
          }
          etree-leaf-label true
          ethernet-segment "vESI-23_1" {
            admin-state enable
            type virtual
            esi 0x01000000002301000001
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
                virtual-ranges {
                  dot1q {
                    q-tag 2 {
                      end 2
                    }

          }
        }
      }
    }
  }
}
```

remote PE (PE-4 or PE-5) would receive the AD per-EVI routes with inconsistent leaf indication and would treat the AC as root AC.

PE-2 sends the following BGP EVPN AD routes: an AD per-ES route with zero ESI and RD 192.0.2.2 (for egress filtering of BUM traffic) and an EVPN AD per-EVI route with non-zero ESI and RD 2.2.2.2:1 (to verify the ES consistency).

```

On PE-2:

```

The following command shows the EVI RT set RD ranging from 2.2.2.2:1 to 2.2.2.2:512. In VPLS VPLS 2, the configured EVI is 2 and needs to be divided by 128, the number of EVI RT sets that are advertised. This value is rounded up to 1; therefore, the RD in the preceding AD per-EVI equals 2.2.2.2:1. The minimum EVI RT set RD equals 2.2.2.2:1 and the maximum is 2.2.2.2:512, because the EVI ranges from 1 to 65535 and 65536/128=512.

Egress Filtering for BUM Traffic

Each PE advertises zero ESI AD per-ES routes (with tag MAX-ET) that are needed for egress BUM filtering.

BUM frames received on an ES root AC are flooded to the EVPN, based on regular EVPN procedures. The regular ESI label is sent for split horizon when frames are sent to the DF or NDF PEs in the same ES.

BUM frames received on an ES leaf AC are flooded in the default multicast list. The egress PE does not forward BUM traffic to any leaf ACs, including the ES leaf ACs. However, in the unlikely event that some ACs in a specific ES for an EVI have an inconsistent E-Tree configuration, these ACs are treated as root ACs, and the traffic is forwarded.

The remote PE-4 receives the following EVPN AD routes from DF PE-2: a zero ESI AD per-ES (tag MAX-ET), two AD per-EVI (tag 0) routes with a non-zero label, and two AD per-ES routes (tag MAX-ET).

Conclusion

E-Trees can be used for enterprise business services, for the distribution of IPTV multicast content, for centralized backup BNGs, and so on. In a VPLS E-Tree, leaf SAPs or leaf SDP bindings cannot exchange traffic with each other, similar to split horizon group behavior. The E-Tree restrictions apply to all remote PEs that are part of the same service. E-Trees can be applied in an EVPN-MPLS VPLS as well as in a regular VPLS.

EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services

This chapter provides information about EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R5, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1.

Chapters [EVPN for MPLS Tunnels](#) and [EVPN for VXLAN Tunnels \(Layer 2\)](#) are prerequisite reading.

Overview

When EVPN-MPLS is deployed in the WAN, many service providers are looking for a way to integrate existing Layer 2 EVPN-VXLAN based data center services into the WAN, while keeping the end-to-end advantages of EVPN. The IETF *draft-ietf-bess-dci-evpn-overlay* describes how to provide Layer 2 connectivity for EVPN-overlay data centers in different ways. This chapter follows section 4.4 of that document, in which EVPN-MPLS is used in the same VPLS service that terminates overlay (VXLAN) tunnels.

To provide EVPN-MPLS connectivity to VPLS services terminating EVPN-VXLAN, SR OS supports the configuration of BGP-EVPN MPLS and BGP-EVPN VXLAN at the same time by adding two BGP instances to the service. Two BGP instances are supported in the same VPLS at most. BGP-EVPN MPLS and BGP-EVPN VXLAN can both use BGP instance 1 or 2, but they must use different instances.

In a service with EVPN-VXLAN and EVPN-MPLS, the `config>service>vpls>bgp-evpn>mpls 2` command allows the user to associate BGP-EVPN MPLS to BGP instance 2, while BGP-EVPN VXLAN is associated to BGP instance 1, and therefore, have both encapsulations simultaneously enabled in the same service. Either BGP instance 1 or 2 can be associated to BGP-EVPN VXLAN or MPLS, but they must be different. When the two BGP instances are successfully added to the same VPLS service, the service behaves as follows:

- MAC/IP routes received on one instance will be "consumed" (accepted, imported, and installed in FDB) and re-advertised in the other instance, as long as the route is the best route for a specific MAC or MAC/IP.
- Inclusive multicast routes are independently generated for each BGP instance.
- From a data plane perspective, EVPN-MPLS and EVPN-VXLAN destinations are instantiated in different implicit Split-Horizon Groups (SHGs) so that traffic can be forwarded between the two SHGs, but not between destinations of the same kind. For example, traffic coming from EVPN-MPLS cannot be forwarded to other destinations in the EVPN-MPLS SHG.

The following example shows a VPLS service configured on PE-2 with two BGP instances and both encapsulations, VXLAN and MPLS, configured at the same time:

```
configure {
  service {
    vpls "VPLS 1" {
      description "evpn-mpls and evpn-vxlan in the same service"
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "10:1"
        route-target {
          export "target:64500:1"
          import "target:64500:1"
        }
      }
      bgp 2 {
        route-distinguisher "10:2"
        route-target {
          export "target:64500:1"
          import "target:64500:1"
        }
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
        mpls 2 {
          admin-state enable
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}
```

In the preceding example

- **bgp 1** is the default BGP instance.
- **bgp 2** is the additional instance that is required when both BGP-EVPN VXLAN and BGP-EVPN MPLS are enabled in the service.
- The same commands supported under BGP instance 1 exist for this second BGP instance, with the following considerations:
 - **pw-template-binding** – the pseudowire (PW) template binding can only exist in BGP instance 1; it is not supported in BGP instance 2. Because no SDP-bindings can exist in a VPLS service with two BGP instances, the **pw-template-binding** command is ineffective in this configuration.
 - **route-distinguisher** – the route distinguisher in both BGP instances must be different.
 - **route-target** – the route target in both instances can be the same or different.
 - **vsi-import** and **vsi-export** – import and export policies can also be defined for either BGP instance.

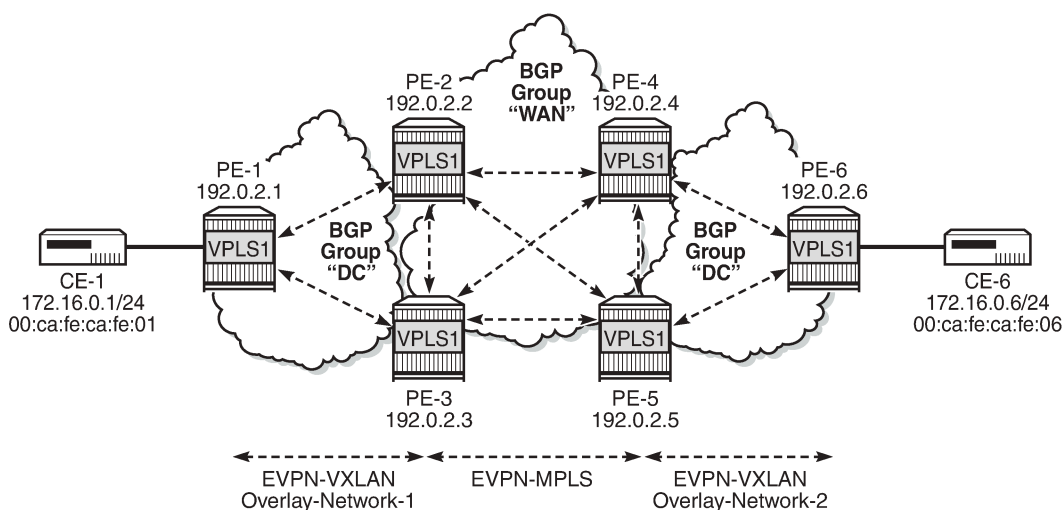

- The **mpls 2** command will assign BGP instance 2 to MPLS. The VPLS configuration can only be committed if the BGP instance associated with MPLS has a different route distinguisher than the BGP instance associated with VXLAN.
- The **evi** can still be used for auto-derivation of RD/RT on BGP instance 1 and auto-derivation of RT (not RD) on BGP instance 2. Auto-RD or an explicitly configured RD is needed in BGP instance 2.

Configuration

Figure 168: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the example topology that will be used throughout this chapter, as well as the BGP peering topology. PE-1, PE-2, and PE-3 simulate a data center, shown as Overlay-Network-1, where PE-2 and PE-3 are DC GWs. In the same way, PE-4, PE-5, and PE-6 simulate a remote data center, Overlay-Network-2. Inside each DC, EVPN-VXLAN is used.

The two DC GW pairs are connected by EVPN-MPLS; therefore, CE-1 and CE-6 are end-to-end connected by EVPN without any VLAN or PW hand-off, maintaining all the EVPN advantages across the DC Interconnect (DCI) network.

Figure 168: EVPN-MPLS interconnect for EVPN-VXLAN - example topology

26081

The example topology consists of six 7750 SR routers with the following initial configuration:

- Hybrid ports (they could have been network type ethernet too) are interconnecting the six PEs with configured router interfaces.
- The six PEs are running IS-IS and creating point-to-point adjacencies.
- Link LDP is configured in the core, among PE-2, PE-3, PE-4, and PE-5, while PE-1 and PE-6 are only running VXLAN.
- EVPN uses MP-BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the PEs for the EVPN family. Figure 168: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the peering sessions established among the six PEs. Although usually a Route-Reflector (RR) is used in each DC and another RR in the WAN, in this example, there are direct peering sessions in each DC and in the WAN.

The following output shows the BGP configuration of PE-2. The BGP configuration on the rest of the DC GWs (PE-3, PE-4, and PE-5) is similar:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
    }
    group "DC" {
      type internal
      import {
        policy ["drop S00-DCGW-23"]
      }
      export {
        policy ["allow only vxlan and add S00"]
      }
    }
    group "WAN" {
      type internal
      import {
        policy ["drop S00-DCGW-23"]
      }
      export {
        policy ["allow only mpls and add S00"]
      }
    }
    neighbor "192.0.2.1" {
      group "DC"
    }
    neighbor "192.0.2.3" {
      group "DC"
    }
    neighbor "192.0.2.4" {
      group "WAN"
    }
    neighbor "192.0.2.5" {
      group "WAN"
    }
  }
}
```

Two different BGP groups are configured: DC and WAN. The DC group contains the DC neighbors (including the peer DC GW) and the WAN group contains the WAN neighbors. This grouping makes the use of policies easier. These policies will be explained in the section [The mandatory use of BGP policies in the multi-homed anycast solution](#).

The following output shows the BGP configuration of PE-1. PE-6 has a similar BGP configuration.

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
```

```

    rapid-withdrawal true
    family {
        ipv4 false
        evpn true
    }
    rapid-update {
        evpn true
    }
    group "DC" {
        type internal
    }
    neighbor "192.0.2.2" {
        group "DC"
    }
    neighbor "192.0.2.3" {
        group "DC"
    }
}

```

VPLS service configuration

After the base infrastructure (interfaces, IGP, LDP in the core, and BGP) is configured, the services can be added. The configuration example in this section will use VPLS 1 as the service to be interconnected across the two DCs.

PE-1 and PE-6 have a regular EVPN-VXLAN configuration; DCI connectivity provided by EVPN-MPLS is completely transparent to them. The configuration of VPLS 1 in PE-1 is as follows:

```

# on PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/2/1:1 {
            }
        }
    }
}

```

See the [EVPN for VXLAN Tunnels \(Layer 2\)](#) chapter for a complete description of the EVPN-VXLAN commands.

The configuration on PE-2, PE-3, PE-4, and PE-5 (see [Figure 168: EVPN-MPLS interconnect for EVPN-VXLAN - example topology](#)) enables EVPN-VXLAN and EVPN-MPLS in the same VPLS service. As an example, the VPLS 1 configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "64500:1"
      }
      bgp 2 {
        route-distinguisher "64500:2"
      }
      bgp-evpn {
        evi 1
        incl-mcast-orig-ip 23.23.23.23
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
        mpls 2 {
          admin-state enable
          ingress-replication-bum-label true
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}
```

As described in the [Overview](#) section, the preceding configuration enables the router to create EVPN-VXLAN and EVPN-MPLS destinations in the same VPLS service, but in different SHGs. In addition to the **bgp 2** commands already described in the [Overview](#) section, the **incl-mcast-orig-ip** command is added in the configuration. If configured, this command will change the originating IP address in the inclusive multicast routes (from the default system IP) for both BGP instances. The section [Multi-homed anycast configuration for dual BGP-instance VPLS services](#) describes why this command is added.

The following section provides a detailed description of the expected behavior for EVPN routes that are imported and exported on dual BGP instance VPLS services.

EVPN route handling in dual BGP-instance VPLS services

This section describes how the BGP-EVPN routes are processed in dual BGP instance services.

Usually, the router validates the received tunnel encapsulation (from the RFC 5512 Extended Community) with the configured encapsulation of the service/BGP-instance. Therefore, an EVPN-VXLAN route will not get imported into the BGP-EVPN MPLS instance and vice-versa. This is also how the different EVPN route types are handled in dual BGP instance services:

- **Route type 1 - auto-discovery routes**

AD per-EVI routes are never generated by services with two BGP instances (because no Ethernet Segment (ES) can be associated with the dual BGP instance service). However, AD per-EVI routes can still be received from the EVPN-MPLS peers and are processed as usual. Therefore, a VPLS service with two BGP instances will still support aliasing/backup and AD per-ES checking procedures for a remote multi-homed ES, as described in the [EVPN for MPLS Tunnels](#) chapter. However, in the example in [Figure 168: EVPN-MPLS interconnect for EVPN-VXLAN - example topology](#), PE-6 does not have any local multi-homed ES configured; therefore, no AD per-EVI routes are present in this example.

- **Route type 2 - MAC/IP routes**

MAC/IP routes received on one of the two BGP instances will be imported and the MAC addresses added to the FDB according to the existing selection rules. If the MAC address is active (therefore installed in the FDB), it will be re-advertised in the other BGP instance with the BGP attributes of the other BGP instance (new route target if different, new route distinguisher, and so on). The **bgp-evpn>routes>mac-ip>advertise** command will govern the advertisement of MAC addresses in either BGP instance.

The MAC/IP route redistribution across BGP instances is performed according to the following rules:

- A MAC route is redistributed only if it is the best route according to the EVPN selection rules in the [EVPN for MPLS Tunnels](#) chapter.
- Assuming a specific MAC route is the best one and has to be redistributed, the MAC/IP information along with the sticky bit is propagated in the redistribution.
- A change in the MAC/IP route sequence number or sticky bit in one instance is updated in the other instance, as long as that route is the best MAC route for the route key.
- When a MAC address moves within the EVPN-VXLAN (or the EVPN-MPLS) network, the MAC route is received on the same BGP instance where it was previously received, but now with a higher sequence number. In this case, the MAC route will be redistributed with the new sequence number. However, a router with two BGP instances in the same service will not detect any duplicate MAC on the EVPN-VXLAN and EVPN-MPLS networks.

As an example, the following output shows the debug of a MAC/IP route received on PE-2, on the BGP instance for EVPN-VXLAN on VPLS 1, and how the route is re-advertised to the BGP instance used for MPLS (with a different next-hop, route distinguisher, label, and BGP tunnel encapsulation):

```

- **Route type 3 - inclusive multicast routes**

EVPN Inclusive Multicast Ethernet Tag (IMET) routes are generated independently for each BGP instance with the correct BGP tunnel encapsulation extended community and the tunnel type associated to the BGP instance; for example, Ingress Replication (IR), P2MP mLDP, or Assisted Replication (AR):

- On the EVPN-VXLAN BGP instance, IR or AR IMET routes are supported.
 - When **assisted-replication replicator** is enabled and the received VXLAN broadcast and multicast packets contain an IP DA = AR-IP, the DC GW will send the packets back to VXLAN (but not to the VXLAN termination end-point (VTEP) from where the packet is received) in addition to the EVPN-MPLS destinations.
 - If **assisted-replication replicator** is used on the DC GWs, the AR-IP (**configure>service>system>vxlan>assisted-replication>ip-address**) must be a loopback different from the router's system IP and the configured **bgp-evpn>incl-mcast-orig-ip**. The two AR-IP addresses in the DC GW pair do not need to be the same IP address.
- On the EVPN-MPLS BGP instance, IR, P2MP mLDP, or composite IMET routes are supported.
- Following is the behavior when the **incl-mcast-orig-ip** command is used:
 - The configured IP in the **incl-mcast-orig-ip** command is encoded in the originating IP field of the IMET routes for IR, P2MP, and composite routes for both BGP instances.

- The originating IP field of the IMET AR routes is still derived from the configured **service>system>vxlan>assisted-replication>ip-address** value.
- The received IMET routes will be processed in the following way depending on their type:
 - IMET-IR routes: the EVPN destination (MPLS or VXLAN) is set up based on the NLRI next-hop.
 - IMET-P2MP routes: the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PTA) tunnel ID will be used to join the mLDP tree (as mLDP FEC in the LDP mapping messages).
 - IMET-P2MP-IR (composite) routes: the PTA tunnel ID is used to join the mLDP tree. The NLRI next-hop is used to build the EVPN destination.
 - IMET-AR routes: the NLRI next-hop is used to build the EVPN-VXLAN destination.
- Upon reception of two IMET routes with similar information, the router behaves as follows:
 - If the router receives two IMET routes with the same originating IP, different RDs, and different NLRI next-hops, it will set up two EVPN destinations, one to each next-hop.
 - If the router gets two IMET routes with the same originating IP, different RDs, but the same next-hop, it will set up only one EVPN destination.
 - The router will not set up an EVPN destination to its DC GW peer if the received originating IP matches its own originating IP, regardless of whether the local RD and the remote RD are the same or different. This enables the use of the redundant anycast solution that is described in the following section: [Multi-homed anycast configuration for dual BGP-instance VPLS services](#).
- **Route type 4 - ES routes**

ESs are supported in routers where dual BGP-instance services exist. However, because dual BGP-instance VPLS services do not support SDP-bindings, ESs and ES routes are not relevant to these types of services.
- **Route type 5 - IP-prefix routes**

R-VPLS services are not supported along with dual BGP instances; therefore, IP-prefix routes are neither generated nor processed by the service.

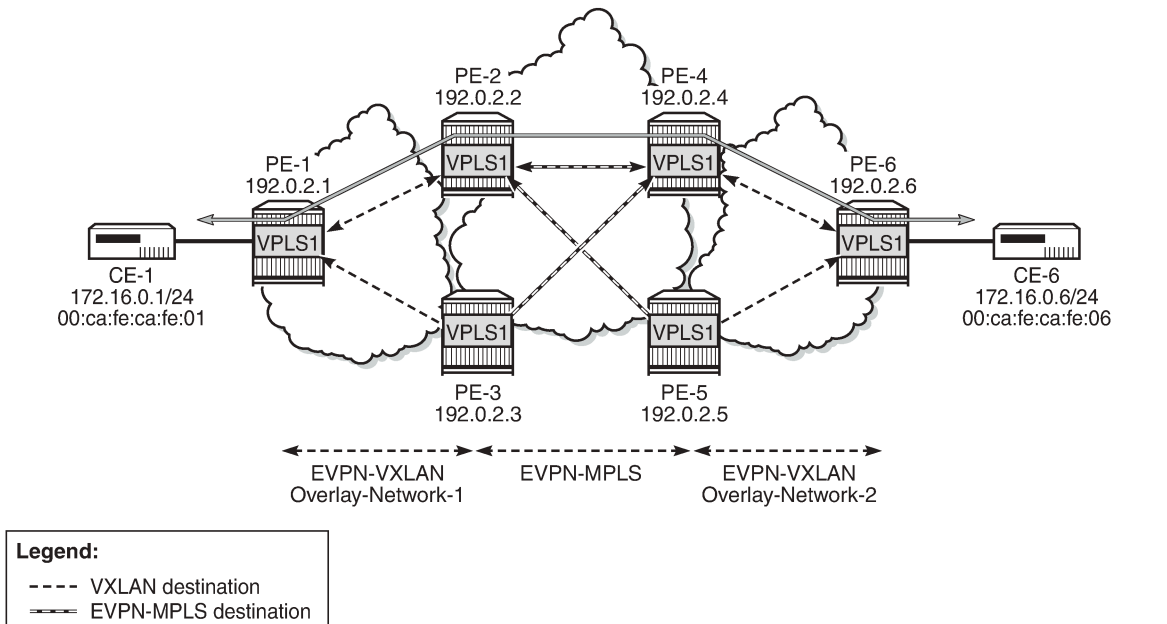

Multi-homed anycast configuration for dual BGP-instance VPLS services

Services with EVPN-MPLS and EVPN-VXLAN SHGs are specified in *draft-ietf-bess-dci-evpn-overlay* and the associated multi-homing solution is also described in the same draft. That multi-homing solution is based on an interconnect ES that allows all-active and single-active multi-homed EVPN networks as well as local attachment circuits in the DC GWs (SAP/SDP-bindings).

This chapter was initially written for SR OS Release 14.0.R5 and interconnect ESs were not supported in that release. Therefore, an anycast solution is used to provide redundancy. This anycast solution is based on the two PE DC GWs in the redundant pair being configured to advertised MAC/IP and IMET routes with the same route key, so that the remote PEs will only pick up one of the two anycast DC GWs when sending unicast or BUM traffic, and no loop or packet duplication is created.

[Figure 169: EVPN destinations created on multi-homed anycast DC GWs](#) is an example of how multi-homing can be achieved for dual BGP-instance VPLS services. The figure also shows the EVPN destinations created and their direction (see the arrows). For instance, only one EVPN multicast destination is created for PE-1, PE-2, or PE-4. Therefore, BUM traffic sent by CE-1 will be sent via PE-2, PE-4, and PE-6 only, and no duplication or loops occur.

Figure 169: EVPN destinations created on multi-homed anycast DC GWs

26082

The following output shows the VPLS 1 configuration on PE-2 and PE-3 so that this anycast redundancy can be realized. The route distinguishers as well as the **incl-mcast-orig-ip** addresses must match between the two PEs in the redundant pair. VPLS 1 is configured on PE-2 as follows:

```
# on PE-2:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
    }
    bgp 1 {
      route-distinguisher "64500:1"
    }
    bgp 2 {
      route-distinguisher "64500:2"
    }
  }
  bgp-evpn {
    evi 1
    incl-mcast-orig-ip 23.23.23.23
    vxlan 1 {
      admin-state enable
      vxlan-instance 1
    }
    mpls 2 {
      admin-state enable
      ingress-replication-bum-label true
      auto-bind-tunnel {
```

```
        resolution any
    }
}
}
```

The VPLS 1 configuration on PE-3 is as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "64500:1"
      }
      bgp 2 {
        route-distinguisher "64500:2"
      }
      bgp-evpn {
        evi 1
        incl-mcast-orig-ip 23.23.23.23
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
        mpls 2 {
          admin-state enable
          ingress-replication-bum-label true
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}
```

The VPLS 1 configuration on PE-4 is as follows:

```
# on PE-4:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "64501:1"
      }
      bgp 2 {
        route-distinguisher "64501:2"
      }
    }
  }
}
```

```

    bgp-evpn {
      evi 1
      incl-mcast-orig-ip 45.45.45.45
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
      mpls 2 {
        admin-state enable
        ingress-replication-bum-label true
        auto-bind-tunnel {
          resolution any
        }
      }
    }
  }
}

```

The VPLS 1 configuration on PE-5 is as follows:

```

# on PE-5:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
        route-distinguisher "64501:1"
      }
      bgp 2 {
        route-distinguisher "64501:2"
      }
      bgp-evpn {
        evi 1
        incl-mcast-orig-ip 45.45.45.45
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
        mpls 2 {
          admin-state enable
          ingress-replication-bum-label true
          auto-bind-tunnel {
            resolution any
          }
        }
      }
    }
  }
}

```

Based on the preceding configuration example, the DC GWs behavior in this scenario is as follows:

- PE-2 and PE-3 both send IMET IR routes to the other PEs with the same route key but a different next-hop. The route key in IMET routes comprises [RD, Ethernet tag, originator-IP/length], which in this case will be [64500:1, 0, 23.23.23.23/32] for the EVPN-VXLAN IMET routes and [64500:2, 0, 23.23.23.23/32] for the EVPN-MPLS IMET routes.

- In the same way, PE-2 and PE-3 both send MAC/IP routes to the other PEs with the same route key but a different next-hop. The route key comprises [RD, Ethernet tag, MAC/MAC-length, IP/IP-length].

The configuration of the same **incl-mcast-orig-ip** address and RDs in both DC GWs enables the anycast solution due to the following:

- The configured originating IP (for example, 23.23.23.23 in PE-2 and PE-3) is not required to be a reachable IP address, which forces the remote PEs (or RRs if they exist) to select only one of the two DC GWs for BUM traffic (based on regular BGP selection). In this example, the remote PEs will select the PE-2 IMET route and create only one destination. The following output shows the IMET routes received by PE-1 (only the PE-2 route is used) and the created EVPN-VXLAN destination to PE-2. The same behavior could have been shown in the rest of the PEs.

- Due to the same RD and originating IP configured on PE-2 and PE3 (similarly in PE-4 and PE-5), the DC GW redundant PEs will never establish an EVPN destination between each other. PE-2 only sets up EVPN multicast destinations to PE-1 and PE-4, as follows:

```
[/]

- Likewise, when the two redundant PEs receive the same MAC/IP route, they will both re-advertise it with the same route key, forcing the remote PEs to pick up only one of the two (based on regular BGP selection) and create only one EVPN destination (if different from the multicast destination). In the following example, PE-6 advertised the CE-6 MAC address, that is, re-advertised by PE-4/PE-5 and then by PE-2/PE-3, but only one of the routes is selected at each hop. The following output shows that PE-1 selects the PE-2 MAC/IP route (see the "used" flag) and uses the existing EVPN destination to PE-2:

```

- As shown in the preceding outputs, the EVPN destinations are always created to the IMET or MAC/IP route's BGP next-hops, which are still the system IP address of the routers (they could have also been a loopback address). The BGP next-hops need to be reachable in their respective network: DC or WAN.

The mandatory use of BGP policies in the multi-homed anycast solution

BGP policies must be configured in a multi-homed anycast solution, such as the one described in the previous section. Without policies, the following undesired behavior would happen:

- IMET routes with VXLAN encapsulation would be sent to the BGP peers in the MPLS network and IMET routes with MPLS encapsulation sent to BGP peers in the DC. The configured BGP policies will avoid that and make sure that the VXLAN routes are only sent to the DC and MPLS routes only to the WAN.
- MAC/IP routes received in the VXLAN BGP instance of a DC GW would be re-advertised to the redundant DC GW in the MPLS BGP instance and the redundant DC GW would re-advertise the same MAC again into the VXLAN instance, creating a control plane loop. The same thing would happen for MAC/IP routes received in an MPLS BGP instance. The configured BGP policies will prevent a DC GW from re-advertising MAC/IP routes received from the redundant DC GW.

While service-level BGP policies (**config>service>vpls>bgp>vsi-import/export**) may have been configured to prevent these loops and misbehavior, the use of BGP peer-level policies (**config>router>bgp>group>import/export**) is recommended due to the following reasons:

- Simplicity - BGP peer-level policies do not require any extra configuration at the service level, only at the BGP level.
- Scalability - BGP peer-level policies scale better than VSI-level policies, because the number of services where the VSI policies should be configured may be significant.

The following policies are configured in the example used in this chapter. No policies are needed in PE-1 and PE-6; only the DC GWs must be configured.

Following are the policies and how they are applied in PE-2 and PE-3:

```

# on PE-2, PE-3:
configure {
  policy-options {
    community "S00-DCGW-23" {
      member "origin:64500:23" { }
    }
    community "mpls" {
      member "bgp-tunnel-encap:MPLS" { }
    }
    community "vxlan" {
      member "bgp-tunnel-encap:VXLAN" { }
    }
  }

  /* "drop S00-DCGW-23" will drop any EVPN route that is received from PE-3,
  the other DC GW in the pair. */

  policy-statement "drop S00-DCGW-23" {
    
```

```

    entry 10 {
      from {
        family [evpn]
        community {
          name "S00-DCGW-23"
        }
      }
      action {
        action-type reject
      }
    }
  }
}

```

/* "allow only mpls and add S00" has a twofold objective: avoids sending EVPN-VXLAN routes to the MPLS network and marks the advertised EVPN routes with a Site-Of-Origin extended community that identifies the DC GW pair. */

```

policy-statement "allow only mpls and add S00" {
  entry 10 {
    from {
      family [evpn]
      community {
        name "vxlan"
      }
    }
    action {
      action-type reject
    }
  }
  entry 20 {
    from {
      family [evpn]
    }
    action {
      action-type accept
      community {
        add ["S00-DCGW-23"]
      }
    }
  }
}

```

/* In the same way, "allow only vxlan and add S00" avoids sending EVPN-MPLS routes to the VXLAN network and marks the EVPN routes with a Site-Of-Origin extended community that identifies the DC GW pair. */

```

policy-statement "allow only vxlan and add S00" {
  entry 10 {
    from {
      family [evpn]
      community {
        name "mpls"
      }
    }
    action {
      action-type reject
    }
  }
  entry 20 {
    from {
      family [evpn]
    }
    action {
      action-type accept
    }
  }
}

```

```

        community {
            add ["S00-DCGW-23"]
        }
    }
}

/* The policies are properly applied at group level, as follows: */

# on PE-2, PE-3:
configure {
    router "Base" {
        bgp {
            ---snip---
            group "DC" {
                type internal
                import {
                    policy ["drop S00-DCGW-23"]
                }
                export {
                    policy ["allow only vxlan and add S00"]
                }
            }
            group "WAN" {
                type internal
                import {
                    policy ["drop S00-DCGW-23"]
                }
                export {
                    policy ["allow only mpls and add S00"]
                }
            }
        }
    }
    ---snip---
}

```

PE-4 and PE-5 use the same BGP peer policies, but using a Site Of Origin extended community identifying the PE-4/PE-5 pair instead of the PE-2/PE-3 pair:

```

# on PE-4, PE-5:
configure {
    policy-options {
        community "S00-DCGW-45" {
            member "origin:64500:45" { }
        }
        community "mpls" {
            member "bgp-tunnel-encap:MPLS" { }
        }
        community "vxlan" {
            member "bgp-tunnel-encap:VXLAN" { }
        }
    }
    ---snip---
}

```

Dual BGP instance VPLS service caveats

When two BGP instances are enabled on the same VPLS service, the following considerations apply:

- SDP-bindings are not supported (therefore, no pw-template-binding is needed in the service). Any attempt to add an SDP-binding to a service with two BGP instances will be blocked by the CLI, as follows:

```
*[ex:/configure service vpls "VPLS 1" spoke-sdp 21:1]
```

```
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" - multiple bgp-evpn instances not
supported with local mesh or spoke sdp
```

- Services that are not supported: R-VPLS, M-VPLS, I-VPLS, B-VPLS, or E-Tree VPLS
 - A consequence of not supporting R-VPLS is that no routes type 5 (IP-Prefix routes) are supported on dual BGP-instance services.
- Proxy-ARP/ND is not supported.
- BGP multi-homing is not supported.
- Although the Assisted-Replication feature is supported on dual BGP-instance VPLS services, the Assisted-Replication configuration is only relevant to the VXLAN destinations. See section [EVPN route handling in dual BGP-instance VPLS services](#) for some considerations about how EVPN handles IMET AR routes.

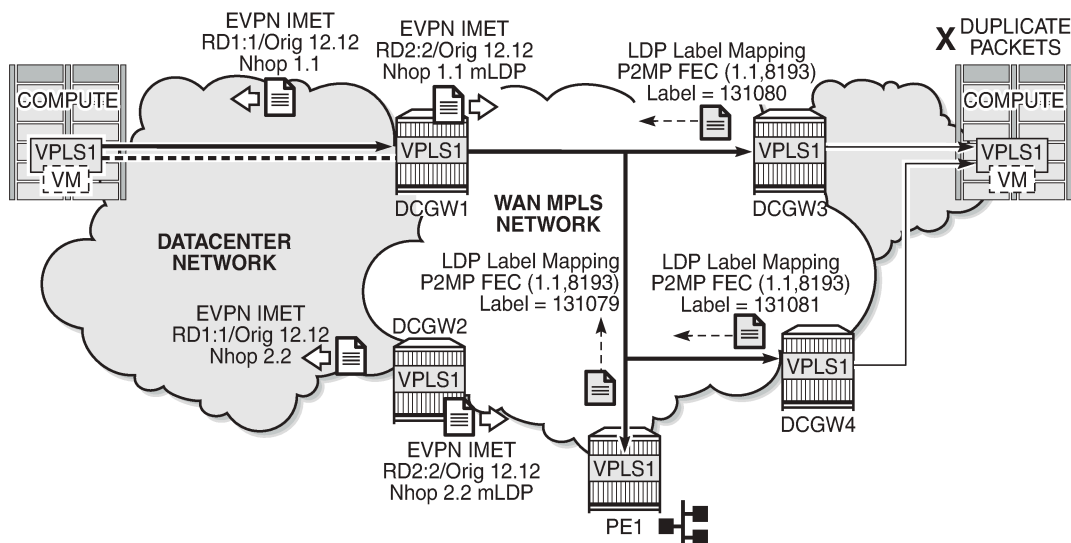

In addition to the preceding restrictions, some commands have a specific behavior when two BGP instances are configured:

- **config>service>vpls>bgp-evpn>routes>mac-ip>advertise** enables/disables the re-advertisement of MAC/IP routes in a BGP instance for MAC addresses that have been learned in the other BGP instance in the service.
- **config>service>vpls>bgp-evpn>routes>mac-ip>unknown-mac <boolean>** enables/disables the advertisement of the unknown MAC route (MAC 00:...:00) on the BGP-EVPN VXLAN instance. The unknown MAC route is never sent to the BGP-EVPN MPLS instance.

The use of provider tunnels on multi-homed anycast solutions

The use of provider tunnels in dual BGP-instance VPLS services connecting multiple DCs is not recommended. [Figure 170: Use of provider-tunnels between anycast DC GWs create packet duplication](#) shows the case where the same BGP-EVPN service is configured in redundant anycast DC GWs and mLDP is used in the MPLS instance. In this case, packet duplication may occur if the configuration is not done carefully.

Figure 170: Use of provider-tunnels between anycast DC GWs create packet duplication

26083

When mLDP is used along with multiple anycast multi-homing DC GWs to send BUM traffic to remote PEs, but no BUM traffic between DCs is needed, the same originating IP must be used on all the DC GWs; otherwise, packet duplication may happen. In the example in [Figure 170: Use of provider-tunnels between anycast DC GWs create packet duplication](#), each pair of DC GWs, DCGW1/DCGW2 and DCGW3/DCGW4, is configured with a different originating IP (`config>service>vpls>bgp-evpn>incl-mcast-orig-ip`):

- DCGW3 and DCGW4 will receive the IMET route with the same route key from DCGW1 and DCGW2.
- DCGW3 and DCGW4 will select only one route, which will usually be the same; for example, the DCGW1 IMET route.
- Because of that, both DCGW3 and DCGW4 will join the mLDP tree with root in DCGW1, creating packet duplication when DCGW1 sends BUM traffic.
- Remote PE nodes with a single MPLS instance will join the mLDP tree without any issue.

To avoid the packet duplication shown by the example of [Figure 170: Use of provider-tunnels between anycast DC GWs create packet duplication](#), the same originating IP may be configured in the four DCGWs, while the RD is still different per pair. By doing that:

- In the example of [Figure 170: Use of provider-tunnels between anycast DC GWs create packet duplication](#), DCGW3 and DCGW4 will never join any mLDP tree sourced from DCGW1 or DCGW2. This will prevent any packet duplication because a router will ignore IMET routes received with its own originating IP, regardless of the RD.
- PE-1 (a remote EVPN-MPLS PE) will still join the mLDP trees from the two DCs.
- The preceding configuration allows the use of mLDP as long as no BUM traffic is required between the two DCs. If BUM traffic is required between DCs, IR must be used.

Troubleshooting and debugging

The following show and debug commands can be used in dual BGP-instance VPLS services:

- show router bgp routes evpn (and filters)
- show service evpn-mpls [<TEP ip-address>]
- show service vxlan [<TEP ip-address>]
- show service id bgp-evpn
- show service id evpn-mpls (and modifiers)
- show service id vxlan destinations
- debug router bgp update (in classic CLI)
- show log log-id 99

See chapter [EVPN for MPLS Tunnels](#) and [EVPN for VXLAN Tunnels \(Layer 2\)](#) for a detailed description of these commands.

Also, in dual BGP-instance VPLS services, the **show service id bgp <bgp-instance>** command may help see the BGP parameters of each individual BGP instance:

```
[/]
A:admin@PE-2# show service id 1 bgp ?

bgp [<number>]

[bgp-instance] <number>
<number> - <1..2>

<number> - <1..2>
```

```
[/]
A:admin@PE-2# show service id 1 bgp 1

Conclusion

As service providers deploy EVPN-MPLS in the network for Ethernet local area network (E-LAN) and Ethernet point-to-point (E-Line) services, the use of EVPN-MPLS to interconnect data centers is becoming a popular option. Based on *draft-ietf-bess-dci-evpn-overlay*, SR OS supports the connectivity of Layer 2 EVPN-VXLAN services to an EVPN-MPLS network. To implement that EVPN-MPLS Data Center Interconnect (DCI) solution, VPLS services support dual BGP instances, where EVPN-VXLAN and EVPN-MPLS can coexist simultaneously in the same VPLS service. This chapter describes the configuration of such dual BGP-instance VPLS services and how to deploy them in a redundant anycast DC GW configuration.

EVPN-VXLAN VPWS

This chapter provides information about EVPN-VXLAN VPWS.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 16.0.R7, but the MD-CLI in the current edition is based on SR OS Release 21.5.R2.

Overview

Some service providers use VXLAN as a next-generation access technology between Multi-Service Access Node (MSAN) PE and core PE routers. VXLAN allows any IP router in the aggregation core and provides a simple alternative to MPLS. Static VXLAN bindings can be used when the MSAN PEs do not support any control plane. However, EVPN offers a control plane protocol for the VXLAN bindings for faster convergence and fault propagation. In this chapter, the focus is on EVPN-VPWS, which provides a lighter control plane compared to full-blown EVPN when point-to-point services need to be extended to the Data Center (DC).

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, including support of Equal Cost Multi-Path (ECMP), and EVPN All-Active (AA) and Single-Active (SA) Multi-Homing (MH). The configuration resembles the EVPN-MPLS Epipe configuration, as described in the [EVPN for MPLS Tunnels in Epipe Services \(EVPN-VPWS\)](#) chapter. As an example, the following configures EVPN-VXLAN Epipe 4 with SA MH.

```
# on PE-4:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "ES45" {
            admin-state enable
            esi 01:00:00:00:00:45:00:00:00:04
            multi-homing-mode single-active
            df-election {
              es-activation-timer 3
            }
            association {
              sdp 460 {
            }
          }
        }
      }
    }
  }
}
```

```

epipe "Epipe-4" {
  admin-state enable
  service-id 4
  customer "1"
  bgp 1 {
  }
  spoke-sdp 460:4 {
  }
  vxlan {
    instance 1 {
      vni 4
    }
  }
  bgp-evpn {
    evi 4
    local-attachment-circuit "AC-45" {
      eth-tag 145
    }
    remote-attachment-circuit "AC-23" {
      eth-tag 123
    }
    vxlan 1 {
      admin-state enable
      vxlan-instance 1
      ecmp 2
    }
  }
}
sdp 460 {
  admin-state enable
  description "GRE SDP for SA MH"
  far-end {
    ip-address 192.0.2.6
  }
}

```

The SDP is a GRE SDP, because no MPLS is configured in the network. The VNI is 4, and the local Attachment Circuit (AC) name is "AC-45" with Ethernet tag 145, whereas the remote AC name is "AC-23" with Ethernet tag 123. An ES can contain up to four nodes. Each of these nodes will have the same local Ethernet tag.

On Epipe services, the BGP instance is 1 and the VXLAN instance is 1. ECMP is configured with a value of 2, so the traffic flows can be sprayed over two paths with equal cost (a value greater than 2 can be configured if aliasing to more than two nodes is needed). By default, **send-tunnel-encap** is enabled, which determines whether the RFC 5512 encapsulation extended community is sent with VXLAN value (if enabled) or not sent.

EVPN-VPWS uses BGP-EVPN route type 1 (autodiscovery (AD) per-EVI routes and AD per-ES routes) and route type 4 (Ethernet Segment (ES) routes); it does not use route types 2 (MAC/IP routes), 3 (Inclusive Multicast routes), or 5 (IP Prefix routes). [Figure 171: BGP-EVPN AD per-EVI route](#) shows the fields in a BGP-EVPN AD per-EVI route.

Figure 171: BGP-EVPN AD per-EVI route

28858

The Route Distinguisher (RD) is encoded as specified in RFC 7432; in this example, the system IP address is followed by the service ID, such as 192.0.2.2:1 for Epipe 1 on PE-2. The MPLS label field is encoded as the VXLAN Network Identifier (VNI) and the Ethernet tag field defines the local Attachment Circuit (AC) ID. The ES ID (ESI) is the 10 bytes configured ESI for MH and equals zero for single-homed services.

The EVPN L2 attributes extended community has type 0x06 (EVPN) and subtype 0x04 (EVPN L2 attributes). The flags are defined as follows:

- Flag C (control word) is set if control word is configured in the service. For EVPN-MPLS VPWS, the control word can be configured in the **bgp-evpn>mpls** context, but for EVPN-VXLAN VPWS, the control word cannot be configured in the **bgp-evpn>vxlan** context, so flag C is always zero (C=0).
- Flag P (primary) is set in MH scenarios: all nodes in an AA MH ES send P=1, but in an SA MH ES, only the Designated Forwarder (DF) sends P=1, while the NDFs send P=0. In single-homed scenarios, all nodes send P=0.
- Flag B (backup) is set in SA MH scenarios: the NDF that will take the primary role after the original primary node has failed is the backup, so it sends B=1. All other NDFs have B=0. In AA MH scenarios, all nodes send B=0. Also, in single-homed scenarios, all nodes except for the backup DF send B=0.

If the received L2 MTU does not match the configured service MTU, the EVPN binding is not set up. However, if the received L2 MTU is zero, the MTU is ignored.

AD per-EVI routes are responsible for aliasing. The following BGP update shows an AD per-EVI route received from DF 192.0.2.4 (PE-4) in an SA MH ES with ESI 01:00:00:00:00:45:00:00:00:04, Ethernet tag 145 for the local AC on PE-4, and MPLS label 4 for Epipe 4. The primary flag is set: P=1.

```

```

Figure 173: BGP-EVPN ES route shows a BGP-EVPN route type 4 (ES route) that is used for MH ES discovery and DF election.

Figure 173: BGP-EVPN ES route

28860

The RD is taken from the system level RD; by default, the RD is derived as system-IP:0, such as 192.0.2.4:0 for PE-4. The ESI contains the 10-byte identifier as configured in the ES. The ES import route target community has type 0x06 (EVPN) and subtype 0x02 (ES import route target), and is derived from the MAC address portion of the ESI. This extended community is treated as a route target, such as: target:00:00:00:00:45:00. Only the PEs attached to the ES will import the ES route.

The following BGP update shows a BGP-EVPN ES route sent by PE-4. The RD is defined as 192.0.2.4:0, the ESI is 01:00:00:00:00:45:00:00:00:04, and the originating IP address is 192.0.2.4 for PE-4. The ES import route target is target:00:00:00:00:45:00.

```

```

By default, the system IP addresses are used for the VXLAN tunnel termination. However, it is possible to use non-system IPv4 or IPv6 termination for EVPN-VXLAN VPWS, both for single-homed and multi-homed services. In that case, Forwarding Path Extension (FPE) needs to be defined with VXLAN termination, as described in chapter [Static VXLAN Termination in Epipe Services](#).

The following shows the configuration of the single-homed Epipe 2 using non-system IPv4 source VXLAN Tunnel Endpoint (VTEP) 10.0.3.1 on PE-3. Likewise, it is possible to use a non-system IPv6 source VTEP, such as `vxlan>source-vtep 2001::3:1`. Unlike the source VTEP, the egress VTEP cannot be configured when BGP-EVPN is enabled. The egress VTEP is dynamically learned via BGP instead.

```
# on PE-3:
```

```
configure {
  service {
    epipe "Epipe-2" {
      admin-state enable
      service-id 2
      customer "1"
      bgp 1 {
      }
      sap 1/1/1:2 {
      }
      vxlan {
        source-vtep 10.0.3.1
        instance 1 {
          vni 2
        }
      }
    }
    bgp-evpn {
      evi 2
      local-attachment-circuit "AC-3" {
        eth-tag 103
      }
      remote-attachment-circuit "AC-5" {
        eth-tag 105
      }
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
    }
  }
}
```

Configuration

The following use cases are included in the configuration section:

- Single-homed EVPN-VXLAN Epipe using IPv4 system addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using IPv4 system addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

[Figure 174: Example topology](#) shows the example topology with six PEs. EVPN-VXLAN Epipe services will be configured on the core PEs PE-2, PE-3, PE-4, and PE-5. On the access nodes PE-1 and PE-6, ordinary Epipe services will be configured, without EVPN-VXLAN. The CEs are emulated by VPRN services configured on PE-1 or PE-6.

Figure 174: Example topology

28861

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces: level 2 between the core PEs and level 1 in the access networks

No MPLS protocol is configured.

BGP is configured on the core PEs for the EVPN address family with RR PE-2. The BGP configuration on RR PE-2 is as follows:

```
# on PE-2:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-update {
        evpn true
      }
    }
    group "iBGP" {
      type internal
      split-horizon true
      family {
        evpn true
      }
    }
    cluster {
      cluster-id 192.0.2.2
    }
  }
  neighbor "192.0.2.3" {
    group "iBGP"
  }
  neighbor "192.0.2.4" {
    group "iBGP"
  }
}
```

```
neighbor "192.0.2.5" {
    group "iBGP"
}
```

Single-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 175: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses shows the routers PE-1, PE-2, PE-4, and PE-6 configured with Epipe 1. VXLAN-EVPN is only configured on the core PEs PE-2 and PE-4.

Figure 175: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses

Configuration of Epipe 1

On PE-1, Epipe 1 is configured without EVPN-VXLAN, as follows.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/1:1 {
            }
            sap 1/2/1:1 {
            }
        }
    }
}
```

On PE-2, Epipe 1 is configured with EVPN-VXLAN. The local AC "AC-2" has Ethernet tag 102 and the remote AC is "AC-4" with Ethernet tag 104, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/2:1 {
            }
        }
    }
}
```

```

    }
    vxlan {
        instance 1 {
            vni 1
        }
    }
    bgp-evpn {
        evi 1
        local-attachment-circuit "AC-2" {
            eth-tag 102
        }
        remote-attachment-circuit "AC-4" {
            eth-tag 104
        }
        vxlan 1 {
            admin-state enable
            vxlan-instance 1
        }
    }
}

```

The Epipe configuration on PE-4 is similar, but the local AC and remote AC are swapped, as follows. Instead of a SAP, a spoke-SDP is configured toward PE-6. The SDP itself is GRE-based.

```

# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            spoke-sdp 46:1 {
            }
            vxlan {
                instance 1 {
                    vni 1
                }
            }
        }
        bgp-evpn {
            evi 1
            local-attachment-circuit "AC-4" {
                eth-tag 104
            }
            remote-attachment-circuit "AC-2" {
                eth-tag 102
            }
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
            }
        }
    }
}
sdp 46 {
    admin-state enable
    description "GRE SDP for single-homing"
    far-end {
        ip-address 192.0.2.6
    }
}

```

On PE-6, Epipe 1 is an ordinary Epipe with spoke-SDP 64:1 toward PE-4 and SAP 1/2/1:1 toward a CE, as follows:

```
# on PE-6:
configure {
  service {
    epipe "Epipe 1" {
      admin-state enable
      service-id 1
      customer "1"
      spoke-sdp 64:1 {
      }
      sap 1/2/1:1 {
      }
    }
    sdp 64 {
      admin-state enable
      description "GRE SDP for single-homing"
      far-end {
        ip-address 192.0.2.4
      }
    }
  }
}
```

Verification

VPRN 11 on PE-1 and PE-6 simulates the CEs CE-11 and CE-61. The connectivity between the CEs can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.11.61 router-instance "VPRN 11" interval 0.1
                                                    output-format summary
PING 172.16.11.61 56 data bytes
!!!!!!
---- 172.16.11.61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.42ms, avg = 5.89ms, max = 10.9ms, stddev = 2.49ms
```

```
[/]
A:admin@PE-1# ping 2001:db8::11:61 router-instance "VPRN 11" interval 0.1
                                                    output-format summary
PING 2001:db8::11:61 56 data bytes
!!!!!!
---- 2001:db8::11:61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.14ms, avg = 5.63ms, max = 11.2ms, stddev = 2.79ms
```

On PE-2, the VXLAN destination for Epipe 1 is the system address of PE-4: 192.0.2.4, as follows. There are no VXLAN ES destinations for Epipe 1, because the service is single-homed.

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 176: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses shows the single-homed service Epipe 2 configured on PE-1, PE-3, PE-5, and PE-6. On PE-3, a loopback interface is created in the base router with IPv4 address 10.0.3.3/28. Epipe 2 uses VXLAN termination 10.0.3.1 from the same subnet.

Figure 176: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses

28863

Configuration of Epipe 2

On PE-1 and PE-6, the configuration of Epipe 2 is similar to the configuration of Epipe 1.

On PE-3, FPE needs to be configured using PXC, as described in chapter [Static VXLAN Termination in Epipe Services](#). The following configuration is included without further explanation about FPE or PXC. The same configuration is required on PE-5.

```
# on PE-3:
configure {
  fwd-path-ext {
    sdp-id-range {
      start 10000
      end 10127
    }
  }
  fpe 1 {
    path {
      pxc 1
    }
    application {
      vxlan-termination {
      }
    }
  }
}
port 1/2/5 {
  admin-state enable
  ethernet {
    mode hybrid
    encap-type dot1q
    dot1x {
      tunneling true
    }
  }
}
port pxc-1.a {
  admin-state enable
}
port pxc-1.b {
  admin-state enable
}
port-xc {
  pxc 1 {
    admin-state enable
    port 1/2/5
  }
}
}
```

On PE-3, the following loopback interface is created and IS-IS is enabled on it. The subnet must allow multiple IP addresses; one other IP address from the subnet will be defined as VXLAN tunnel termination. The IPv6 address is only required in the next use-case, but this configuration will not be repeated in that section.

```
# on PE-3:
configure {
  router "Base" {
    interface "lo1" {
      loopback
      ipv4 {
        primary {
          address 10.0.3.3
          prefix-length 28
        }
      }
      ipv6 {
        address 2001::3:3 {

```

```

        prefix-length 124
    }
}
isis 0 {
    interface "lo1" {
        passive true
    }
}

```

Up to three VXLAN tunnel terminations can be defined per system. On PE-3, the following two VXLAN tunnel terminations are configured. For Epipe 2, only the first VXLAN tunnel termination is required; the second (IPv6) VXLAN tunnel termination is used in Epipe 3. The VXLAN tunnel termination is used as VXLAN source VTEP in Epipe 2. No egress VTEP can be defined when BGP-EVPN is configured in the service; egress VTEPs are configured in static VXLAN tunnels instead.

```

# on PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.3.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::3:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:2 {
            }
            vxlan {
                source-vtep 10.0.3.1
                instance 1 {
                    vni 2
                }
            }
        }
        bgp-evpn {
            evi 2
            local-attachment-circuit "AC-3" {
                eth-tag 103
            }
            remote-attachment-circuit "AC-5" {
                eth-tag 105
            }
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
            }
        }
    }
}

```

The configuration on PE-5 is similar. The following is the service configuration on PE-5.

```

# on PE-5:
configure {

```

```

service {
  system {
    vxlan {
      tunnel-termination 10.0.5.1 {
        fpe-id 1
      }
      tunnel-termination 2001::5:1 {
        fpe-id 1
      }
    }
  }
  epipe "Epipe-2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
    }
    spoke-sdp 56:2 {
    }
    vxlan {
      source-vtep 10.0.5.1
      instance 1 {
        vni 2
      }
    }
    bgp-evpn {
      evi 2
      local-attachment-circuit "AC-5" {
        eth-tag 105
      }
      remote-attachment-circuit "AC-3" {
        eth-tag 103
      }
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
    }
  }
  sdp 56 {
    admin-state enable
    description "GRE SDP for single-homing"
    far-end {
      ip-address 192.0.2.6
    }
  }
}

```

It is possible to use a system IPv4 address as a VXLAN tunnel termination on one of the nodes and a non-system IPv4 address on another, but that is not configured here.

Verification

The connectivity between the CEs that are emulated by VPRN 12 can be verified as follows:

```

[/]
A:admin@PE-1# ping 172.16.12.62 router-instance "VPRN 12" interval 0.1
                                     output-format summary
PING 172.16.12.62 56 data bytes
!!!!
---- 172.16.12.62 PING Statistics ----

Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

Figure 177: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses shows the example topology for single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses for VXLAN tunnel termination.

Figure 177: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses

28864

Configuration of Epipe 3

The following single-homed Epipe 3 using non-system IPv6 addresses for the VXLAN tunnel terminations is configured on PE-3.

```
# on PE-3:
configure {
  service {
    system {
      vxlan {
        tunnel-termination 10.0.3.1 {
          fpe-id 1
        }
        tunnel-termination 2001::3:1 {
          fpe-id 1
        }
      }
    }
  }
  epipe "Epipe-3" {
    admin-state enable
    service-id 3
    customer "1"
    bgp 1 {
    }
    sap 1/1/1:3 {
    }
    vxlan {
      source-vtep 2001::3:1
      instance 1 {
        vni 3
      }
    }
    bgp-evpn {
      evi 3
      local-attachment-circuit "AC-3_v6" {
        eth-tag 163
      }
      remote-attachment-circuit "AC-5_v6" {
        eth-tag 165
      }
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
    }
  }
}
```

The service configuration on PE-5 is similar, as follows:

```
# on PE-5:
configure {
  service {
    system {
      vxlan {
        tunnel-termination 10.0.5.1 {
          fpe-id 1
        }
        tunnel-termination 2001::5:1 {

AA and SA multi-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 178: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 4 with AA MH ES "vES23_4" between PE-2 and PE-3 and SA MH ES "ES45" between PE-4 and PE-5.

Figure 178: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses

28865

Configuration of Epipe 4

On PE-1, Epipe 4 is configured as follows:

```

# on PE-1:
configure {
  service {
    epipe "Epipe-4" {
      admin-state enable
      service-id 4
      customer "1"
      sap 1/2/1:4 {

```

```

    }
    sap lag-1:4 {
    }
}

```

On PE-2 and PE-3, the AA MH ES "vES23_4" is configured as a virtual ES for LAG 1 and dot1q-tag 4, so it only affects Epipe 4.

```

# on PE-2, PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "vES23_4" {
            admin-state enable
            type virtual
            esi 01:00:00:00:00:23:00:00:00:04
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
            }
            association {
              lag "lag-1" {
                virtual-ranges {
                  dot1q {
                    q-tag 4 {
                      end 4
                    }
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}

```

On PE-2 and PE-3, Epipe 4 is configured as follows. The system IPv4 address is used as VXLAN termination, the local AC Ethernet tag is 123, and the remote AC Ethernet tag is 145.

```

# on PE-2, PE-3:
configure {
  service {
    epipe "Epipe-4" {
      admin-state enable
      service-id 4
      customer "1"
      bgp 1 {
      }
      sap lag-1:4 {
      }
      vxlan {
        instance 1 {
          vni 4
        }
      }
      bgp-evpn {
        evi 4
        local-attachment-circuit "AC-23" {
          eth-tag 123
        }
        remote-attachment-circuit "AC-45" {
          eth-tag 145
        }
      }
    }
  }
}

```

```

        vxlan 1 {
            admin-state enable
            vxlan-instance 1
            ecmp 2
        }
    }
}

```

On PE-4 and PE-5, the SA MH ES "ES45" is configured with a GRE SDP toward PE-6: SDP 460 on PE-4 and SDP 560 on PE-6. The following is the configuration of "ES45" on PE-4:

```

# on PE-4:
configure {
    service {
        sdp 460 {
            admin-state enable
            description "GRE SDP for SA MH"
            far-end {
                ip-address 192.0.2.6
            }
        }
    }
    system {
        bgp {
            evpn {
                ethernet-segment "ES45" {
                    admin-state enable
                    esi 01:00:00:00:00:45:00:00:00:04
                    multi-homing-mode single-active
                    df-election {
                        es-activation-timer 3
                    }
                    association {
                        sdp 460 {
                        }
                    }
                }
            }
        }
    }
}

```

On PE-4, Epipe 4 is configured as follows. The configuration on PE-5 is similar, but with spoke-SDP 560:4 instead.

```

# on PE-4:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
            }
            spoke-sdp 460:4 {
            }
            vxlan {
                instance 1 {
                    vni 4
                }
            }
        }
    }
    bgp-evpn {
        evi 4
        local-attachment-circuit "AC-45" {
        }
    }
}

```

```
        eth-tag 145
      }
      remote-attachment-circuit "AC-23" {
        eth-tag 123
      }
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
        ecmp 2
      }
    }
  }
```

On PE-6, Epipe 4 is configured as follows:

```
# on PE-6:
configure {
  service {
    epipe "Epipe-4" {
      admin-state enable
      description "Epipe-4 with active/standby pseudowire"
      service-id 4
      customer "1"
      endpoint "EP" {
      }
      spoke-sdp 640:4 {
        endpoint {
          name "EP"
        }
      }
      spoke-sdp 650:4 {
        endpoint {
          name "EP"
        }
      }
      sap 1/2/1:4 {
      }
    }
  }
}
```

Verification

The connectivity between the CEs emulated by VPRN 14 can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.14.64 router-instance "VPRN 14" interval 0.1
                                                    output-format summary

AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 179: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 5 with AA MH ES "vES23_5" between PE-2 and PE-3 and SA MH ES "ES45_5" between PE-4 and PE-5.

Figure 179: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses

28866

The configuration of Epipe 5 on PE-1 is similar to the configuration of Epipe 4 on PE-1, so it is not shown here. The same applies for Epipe 5 on PE-6.

On PE-2, VTEP 10.0.2.1 is used instead of the system IP address. The ES must include two additional parameters for the DF selection: **orig-ip** and **route-next-hop**, which are both equal to the VTEP. Without these parameters, the DF selection will not work. The **orig-ip** command modifies the originator IP address of the ES route and the **route-next-hop** modifies the next-hop of the AD per-ES routes for the ES. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    system {
      vxlan {
        tunnel-termination 10.0.2.1 {
          fpe-id 1
        }
        tunnel-termination 2001::2:1 {
          fpe-id 1
        }
      }
    }
    bgp {
      evpn {
        ethernet-segment "vES23_5" {
          admin-state enable
          type virtual
          esi 01:00:00:00:00:23:00:00:00:05
          orig-ip 10.0.2.1
          route-next-hop 10.0.2.1
          multi-homing-mode all-active
          association {
            lag "lag-1" {
              virtual-ranges {
                dot1q {
                  q-tag 5 {
                    end 5
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
epipe "Epipe-5" {
  admin-state enable
  service-id 5
  customer "1"
  bgp 1 {
  }
  sap lag-1:5 {
  }

Conclusion

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, and can be used in networks without MPLS.

Inter-AS Model C for VLL

This chapter describes advanced inter-AS model C for Virtual Leased Line (VLL) configurations.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 8.0.R4. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports RFC 3107, *Carrying Label Information in BGP-4*, including VLL/VPLS. BGP SDPs can also be used with PBB-VPLS services.

Internet service providers are looking for mechanisms to implement the VLL and VPLS services across Autonomous Systems (ASs). Service providers may have inter-AS operation as a consequence of delivering inter-provider VLL/VPLS or because they use multiple ASs as a result of acquisitions and mergers.

The objective of this chapter is to describe the interconnection of VLL services across multiple ASs, using inter-AS model C. Inter-AS Model C involves eBGP redistribution of internal system addresses to the neighboring AS using labeled IPv4 routes.

Example topology

[Figure 181: Example topology – Inter-AS model C for VLL](#) shows the example topology used for Inter-AS Model C VLL.

Figure 181: Example topology – Inter-AS model C for VLL

al_0126

The example topology shown in [Figure 181: Example topology – Inter-AS model C for VLL](#) consists of three sites in different ASes with each site using SR OS nodes.

AS 64500 contains PE-1 and PE-2, AS 64501 contains PE-3, and AS 64502 contains PE-4 and PE-5. There is a business customer with two remote locations, Site A and Site B, with Customer Edge (CE) devices CE-1 connected to the AS 64500 via PE-1 and CE-5 connected to the AS 64502 via PE-5. A VLL Epipe service is configured between PE-1 and PE-5 to connect site A and site B.

Figure 182: Inter-AS model C for VLL

al_0127

Configuration

This section describes all of the relevant configuration tasks for the detailed setup shown in [Figure 183: Network setup configuration](#). In this particular example, the following protocols are assumed to be already configured.

- IS-IS as the IGP with all the nodes being level Level1/Level 2.
- LDP as the MPLS protocol to signal the transport tunnels within AS 64500 and AS 64502.

Figure 183: Network setup configuration

aL_0128

BGP configuration

A BGP tunnel must be established between PE-1 and PE-5, therefore, labeled BGP routes must be exchanged for prefixes 192.0.2.1/32 and 192.0.2.5/32 across the ASs. The following shows the BGP configuration — iBGP and eBGP — required for the PE routers to implement an Inter-AS VLL.

The BGP configuration on PE-3 in AS 64501 is as follows:

```
# on PE-3:
configure {
  router "Base" {
    autonomous-system 64501
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "EBGP" {
        local-as {
          as-number 64501
        }
      }
      neighbor "192.168.23.1" {
        group "EBGP"
        peer-as 64500
        family {
          label-ipv4 true
        }
        import {
          policy ["import-from64500"]
        }
        export {
          policy ["export-from64502"]
        }
      }
      neighbor "192.168.34.2" {
        group "EBGP"
        peer-as 64502
        family {
          label-ipv4 true
        }
        import {
          policy ["import-from64502"]
        }
      }
    }
  }
}
```

```
        export {
            policy ["export-from64500"]
        }
    }
```

The address family **label-ipv4** must be configured so that MPLS labels are carried along with MP-BGP Network Layer Reachability Information (NLRIs), see chapter "Separate BGP RIBs for Labeled Routes" in the Unicast Routing Protocols volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*. The setting **split-horizon** is optional and prevents that a received route is sent back to the originator, which may result in multiple routes for a certain prefix.

To export the prefixes of the nodes where the Epipe is configured (PE-1 and PE-5) to another AS, a common scenario is to advertise the prefix to be exported within the AS as labeled BGP. Therefore, an export policy is defined for prefix 192.0.2.1/32 on PE-1 and this prefix will be advertised with community "64500:0" to the ASBR in AS 64500, in this case to PE-2.

On PE-2, the labeled BGP route for prefix 192.0.2.1/32 is inactive, because the IGP route for that prefix is preferred. The setting **advertise-inactive** will allow the inactive labeled BGP routes from AS 64500 to be advertised to PE-3 in AS 64501. However, for EBGP sessions on Autonomous System Border Routers (ASBRs) such as PE-2, RFC 8212 is supported, so that routes are neither imported nor exported unless specifically enabled by configuration. Export policy "export-from64500" exports all routes with community "64500:0" and import policy "import-from64502" imports all routes with community "64502:0" which is the community added by the export policy on PE-5.

On PE-5, an export policy is configured to advertise prefix 192.0.2.5/32 with community "64502:0" to ASBR PE-4 in AS 64502.

On PE-4, BGP is configured with **advertise-inactive** to advertise the labeled BGP route to its EBGP peer, PE-3. Export policy "export-64502:0" exports routes with community "64502:0" to PE-3. Import policy "import-64500:0" imports routes with community "64500:0".

On PE-3, import and export policies are configured toward the EBGP peers. PE-3 imports routes with community "64500:0" from PE-2 and exports these routes to PE-4. Simultaneously, PE-3 imports routes with community "64502:0" from PE-4 and exports these routes to PE-2.

Labeled BGP is used end-to-end between PE-1 and PE-5 and no IGP routes are to be redistributed into BGP, which would be the case if no local BGP labeled routes were advertised within AS 64500 or AS 64502 and only IGP routes were defined within these ASs.

The ASBRs PE-2, PE-3, and PE-4 will swap the BGP labels. PE-3 will advertise the labeled BGP routes learned from AS 64500 to AS 64502 and vice versa and the ASBRs will advertise these labeled routes for remote PE prefixes to their BGP peers. Eventually, PE-1 will have learned a labeled BGP route for prefix 192.0.2.5/32 and PE-5 will have learned a labeled BGP route for prefix 192.0.2.1/32 and a VLL Epipe can be established between PE-1 and PE-5.

The following policies are configured on ASBR PE-2:

```
# on PE-2:
configure {
    policy-options {
        community "64500:0" {
            member "64500:0" { }
        }
        community "64502:0" {
            member "64502:0" { }
        }
    }
    policy-statement "export-from64500" {
        entry 10 {
```

```
        from {
            community {
                name "64500:0"
            }
        }
        action {
            action-type accept
        }
    }
}
policy-statement "import-from64502" {
    entry 10 {
        from {
            community {
                name "64502:0"
            }
        }
        action {
            action-type accept
        }
    }
}
```

The BGP configuration of PE-2 in AS 64500 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64500
                }
            }
            group "IBGP" {
            }
            neighbor "192.0.2.1" {
                group "IBGP"
                next-hop-self true
                peer-as 64500
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.23.2" {
                advertise-inactive true
                group "EBGP"
                peer-as 64501
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64502"]
                }
                export {
                    policy ["export-from64500"]
                }
            }
        }
    }
}
```

The BGP configuration of ASBR PE-4 in AS 64502 is as follows. The import and export policies are similar to the policies on PE-2.

```
# on PE-4:
configure {
  router "Base" {
    autonomous-system 64502
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "EBGP" {
        local-as {
          as-number 64502
        }
      }
      group "IBGP" {
      }
      neighbor "192.0.2.5" {
        group "IBGP"
        next-hop-self true
        peer-as 64502
        family {
          label-ipv4 true
        }
      }
      neighbor "192.168.34.1" {
        advertise-inactive true
        group "EBGP"
        peer-as 64501
        family {
          label-ipv4 true
        }
        import {
          policy ["import-from64500"]
        }
        export {
          policy ["export-from64502"]
        }
      }
    }
  }
}
```

PE-1 and PE-5 are the PEs to which the CEs are connected in AS 64500 and AS 64502. PE-1 and PE-5 advertise their system prefixes as labeled BGP routes to their BGP peers within the AS.

The BGP configuration of PE-1 is as follows:

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "IBGP" {
        export {
          policy ["export-PE-1"]
        }
      }
      neighbor "192.0.2.2" {
        group "IBGP"
        next-hop-self true
        peer-as 64500
        family {

```

```
        label-ipv4 true
    }
}
```

The BGP configuration of PE-5 in AS 64502 is as follows:

```
# on PE-5:
configure {
  router "Base" {
    autonomous-system 64502
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "IBGP" {
        export {
          policy ["export-PEsys"]
        }
      }
      neighbor "192.0.2.4" {
        group "IBGP"
        next-hop-self true
        peer-as 64502
        family {
          label-ipv4 true
        }
      }
    }
  }
}
```

Policy configuration

The export policies on PE-1 and PE-5 advertise the system addresses to the remote AS. The added communities are used by the export and import policies on PE-2, PE-3, and PE-4. The export policy on PE-1 has a prefix list that only contains prefix 192.0.2.1/32 as follows:

```
# on PE-1:
configure {
  policy-options {
    community "64500:0" {
      member "64500:0" { }
    }
    prefix-list "PE-1" {
      prefix 192.0.2.1/32 type exact {
      }
    }
  }
  policy-statement "export-PE-1" {
    entry 10 {
      from {
        prefix-list ["PE-1"]
      }
      action {
        action-type accept
        origin igp
        community {
          add ["64500:0"]
        }
      }
    }
  }
}
```

A similar export policy can be configured for prefix 192.0.2.5/32 on PE-5. However, the export policy on PE-5 is slightly different: the policy has a prefix list that can be applied for prefixes on multiple PEs, but in this case, only prefix 192.0.2.5/32 will be exported:

```
# on PE-5:
configure {
  policy-options {
    community "64502:0" {
      member "64502:0" { }
    }
    prefix-list "PEsys" {
      prefix 192.0.2.0/29 type longer {
      }
    }
  }
  policy-statement "export-PEsys" {
    entry 10 {
      from {
        prefix-list ["PEsys"]
        protocol {
          name [direct]
        }
      }
      action {
        action-type accept
        origin igp
        community {
          add ["64502:0"]
        }
      }
    }
  }
}
```

The same policy could have been applied on PE-1.

Service configuration

Once BGP is configured, the configuration requires the service to be defined (Epipe 1). The focus here is a VLL service, however, it is also possible to have a similar configuration with VPLS services.

The following shows the service level configuration on PE-1:

```
# on PE-1:
configure {
  service {
    epipe "Epipe 1" {
      admin-state enable
      description "Tunnel-PE-1-PE-5"
      service-id 1
      customer "1"
      spoke-sdp 15:1 {
      }
      sap 1/1/3:1 {
      }
    }
    sdp 15 {
      admin-state enable
      delivery-type mpls
      bgp-tunnel true
      far-end {
        ip-address 192.0.2.5
      }
    }
  }
}
```

```
}
}
```

The following CLI shows the service level configuration on PE-5:

```
# on PE-5:
configure {
  service {
    epipe "Epipe 1" {
      admin-state enable
      description "Tunnel-PE-5-PE-1"
      service-id 1
      customer "1"
      spoke-sdp 51:1 {
      }
      sap 1/1/3:1 {
      }
    }
    sdp 51 {
      admin-state enable
      delivery-type mpls
      bgp-tunnel true
      far-end {
        ip-address 192.0.2.1
      }
    }
  }
}
```

Show commands and troubleshooting

On PE-5, BGP tunnels exist to the remote AS system addresses that are using LDP as a transport mechanism and the configuration of end-to-end SDPs over which T-LDP service labels are exchanged.

In the following sections, the same commands are launched on the nodes in the following order: first on PE-1 and PE-5; then on PE-3, and finally, on PE-2 and PE-4.

Show commands and troubleshooting on PE-1

The following shows information about SDP 15 on PE-1:

```
[ ]
A:admin@PE-1# show service sdp

Conclusion

The BGP tunnel-based SDP binding is allowed for VLL and VPLS services, including PBB-VPLS. Using RFC 3107, it is possible to implement inter-AS Model C VLLs.

The example used in this chapter illustrates the configuration of an Inter-AS VLL providing access to CE sites. Troubleshooting commands also have been shown to verify all the procedures.

L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing

This chapter provides information about L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 23.7.R1.

Overview

IPv4 multicast traffic can be forwarded from an EVPN-MPLS service into an attached R-VPLS service in which the receiving devices are using EVPN all-active multi-homing.

The routed service to which the R-VPLS service attaches can be an IES or a VPRN service. In this way, IPv4 multicast traffic can be transported using native IP for the IES case or NG-MVPN technologies for the VPRN case.

This feature requires:

- IGMP support on the R-VPLS IP interface
- Forwarding IPv4 multicast traffic from the IP interface of a VPRN or IES to its EVPN-MPLS R-VPLS service
- IGMP snooping within the VPLS of the R-VPLS service
- IGMP snooping state synchronization based on the ESI label to synchronize the IGMP snooping state between the all-active (R-)VPLS LAG SAPs

The configuration used in this chapter is the NG-MVPN scenario as shown in [Figure 184: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing](#).

Figure 184: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing

28641b

A multicast stream is emitted by the source connected to PE-2 with group address 225.70.1.1. A multicast receiver connected to MTU-4 joins group 225.70.1.1. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. On MTU-4, LAG 1 comprises port 1/1/c1/1 and 1/1/c2/1, and this LAG is used in VPLS 10. On PE-1 and PE-3, VPLS 10 is interconnected with VPRN 1 through an Integrated Routing and Bridging (IRB) interface. VPRN 1 is defined in PE-1, PE-2, and PE-3, and uses NG-MVPN for transporting the multicast traffic through the core of the network. See the [EVPN for MPLS Tunnels](#) and [EVPN for MPLS Tunnels in Routed VPLS](#) chapters for more information about EVPN. See the "NG-MVPN Configuration with MPLS" and "NG-MVPN Configuration with PIM" chapters in the Layer 3 Services volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part II* for more information about NG-MVPN.

Configuration

The initial configuration on the PE nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- MPLS tunnels between the PEs: LDP- or RSVP-based

BGP is required at the core of the network, using the VPN IPv4 and MVPN IPv4 address families between all PEs, for supporting unicast and multicast traffic on VPRN services, and additionally using the EVPN address family between PE-1 and PE-3 to support EVPN services. The BGP configurations for PE-1, PE-2, and PE-3 are as follows:

```
# on PE-1:
configure {
  router {
    autonomous-system 64496
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      family {
        ipv4 false
      }
    }
  }
}
```

```
        vpn-ipv4 true
        mvpn-ipv4 true
        evpn true
    }
    ebgp-default-reject-policy {
        import false
        export false
    }
    rapid-update {
        evpn true
    }
    group "iBGP" { }
    neighbor "192.0.2.2" {
        group "iBGP"
        peer-as 64496
    }
    neighbor "192.0.2.3" {
        group "iBGP"
        peer-as 64496
    }
}
}
```

```
# on PE-2:
configure {
    router {
        autonomous-system 64496
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            family {
                ipv4 false
                vpn-ipv4 true
                mvpn-ipv4 true
            }
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "iBGP" { }
            neighbor "192.0.2.1" {
                group "iBGP"
                peer-as 64496
            }
            neighbor "192.0.2.3" {
                group "iBGP"
                peer-as 64496
            }
        }
    }
}
```

```
# on PE-3:
configure {
    router {
        autonomous-system 64496
    }
}
```

```

    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      peer-ip-tracking true
      family {
        ipv4 false
        vpn-ipv4 true
        mvpn-ipv4 true
        evpn true
      }
      ebgp-default-reject-policy {
        import false
        export false
      }
      rapid-update {
        evpn true
      }
      group "iBGP" { }
      neighbor "192.0.2.1" {
        group "iBGP"
        peer-as 64496
      }
      neighbor "192.0.2.2" {
        group "iBGP"
        peer-as 64496
      }
    }
  }
}

```

The receiver connected to MTU-4 joins group 225.70.1.1, and the corresponding multicast stream is emitted by the source that is connected to PE-2. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. The VPLS and the LAG on MTU-4 are defined as follows:

```

# on MTU-4:
configure {
  service {
    vpls "mcast-vpls" {
      admin-state enable
      service-id 10
      customer "1"
      igmp-snooping {
        admin-state enable
      }
      sap 1/2/c1/1 { }
      sap lag-1:10 { }
    }
  }
}

configure {
  lag "lag-1" {
    admin-state enable
    encap-type dot1q
    mode access
    port 1/1/c1/1 { }
    port 1/1/c2/1 { }
  }
}

```

The all-active multi-homing Ethernet segment esi-13 is configured identically on PE-1 and PE-3, as follows. See the [EVPN for MPLS Tunnels](#) and [EVPN for MPLS Tunnels in Routed VPLS](#) chapters for more information.

```
# on PE-1 and PE-3:
configure {
  service {
    system {
      bgp {
        evpn {
          ethernet-segment "esi-13" {
            admin-state enable
            esi 0x01000000001300000001
            multi-homing-mode all-active
            df-election {
              es-activation-timer 3
              service-carving-mode manual
              manual {
                preference {
                  mode non-revertive
                  value 30
                }
              }
            }
            association {
              lag "lag-1" { }
            }
          }
        }
      }
    }
  }
}
```

The multi-homed access circuits of esi-13 are located on port 1/1/c3/1 for PE-1 and PE-3, so the LAG is configured identically, as follows:

```
# on PE-1 and PE-3:
configure {
  lag "lag-1" {
    admin-state enable
    encap-type dot1q
    mode access
    port 1/1/c3/1 { }
  }
}
```

Also, the EVPN VPLS service with ID 10 is configured identically on PE-1 and PE-3, as follows. The *mcast-vpls* name is needed to link VPLS 10 to VPRN 1 at a later stage, without requiring a physical loop or hairpin. The **routed-vpls** command enables the VPLS to become an R-VPLS. The **igmp-snooping** and **mrouter-port true** commands are required for multicast to work correctly in an all-active multi-homed scenario.

```
# on PE-1 and PE-3:
configure {
  service {
    vpls "mcast-vpls" {
      admin-state enable
      service-id 10
      customer "1"
    }
  }
}
```

```

routed-vpls {
  multicast {
    ipv4 {
      igmp-snooping {
        mrouter-port true
      }
    }
  }
}
bgp 1 { }
igmp-snooping {
  admin-state enable
}
bgp-evpn {
  evi 111
  mpls 1 {
    admin-state enable
    ingress-replication-bum-label true
    auto-bind-tunnel {
      resolution any
    }
  }
}
sap lag-1:10 { }
}
}
}

```

The VPRN service with ID 1 provides the connection toward MTU-4 via VPLS 10, through the *int-MCAST-VPLS* interface with address 10.1.4.1/24 on PE-1, and with address 10.1.4.3/24 on PE-3. This L3 interface is linked to VPLS 10 with the **vpls "mcast-vpls" { }** command. The *int-MCAST-VPLS* interface is also included in the IGMP and PIM configurations of VPRN 1. The full configuration of VPRN 1 on PE-1 is as follows. The configuration of VPRN 1 on PE-3 is similar.

```

# on PE-1:
configure {
  service {
    vprn "VPRN 1" {
      admin-state enable
      service-id 1
      customer "1"
      igmp {
        ssm-translate {
          group-range start 225.70.1.1 end 225.70.255.255 {
            source 10.1.2.222 { }
          }
        }
      }
      interface "int-MCAST-VPLS" { }
      interface "int-PE-1-CE-1" { }
    }
    pim {
      interface "int-MCAST-VPLS" { }
      interface "system" { }
    }
    mvpn {
      c-mcast-signaling bgp
      mdt-type receiver-only
      auto-discovery {
        type bgp
      }
      vrf-target {
        unicast true
      }
    }
  }
}

```

```
    }
    provider-tunnel {
        inclusive {
            mldp {
                admin-state enable
            }
        }
        selective {
            data-threshold {
                group-prefix 224.0.0.0/4 {
                    threshold 1
                }
            }
            mldp {

A stream with group address 225.70.1.1 is started by the multicast source and joined by the multicast receiver connected to MTU-4. This stream is forwarded from PE-2 to PE-3; PE-1 is not involved in the forwarding.

PE-1 maintains IGMP state for group 225.70.1.1 in VPRN 1, and so does PE-3. PE-1 and PE-3 synchronize IGMP state using a data-driven mechanism. The forwarding list includes the *int-MCAST-VPLS* interface, as follows:

```
[/]
A:admin@PE-1# show router 1 igmp group 225.70.1.1 interfaces
=====
IGMP Interface Groups

PE-3 sends this multicast stream to MTU-4, which in turn sends it to the receiver that sent the join, so the path taken by the multicast stream runs via PE-2, PE-3, and MTU-4.

In the example from [Figure 184: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing](#), and the commands and traces that follow, PE-1 is the active IGMP querier using address 10.1.4.1, sending out the queries across the L2 domain. The group queries are sent by PE-1 to PE-3 across the EVPN-MPLS tunnel because PE-3 is DF for *esi-13*, then forwarded onto MTU-4 to reach the (potential) receiver. MTU-4 relays the IGMP responses from the receiver to one of the links; in this example, the link between MTU-4 and PE-1. When the IGMP response for joining the 225.1.70.1 stream is received on PE-1, this event is signaled across the EVPN-MPLS tunnel because it is received over *esi-13*. This way, the IGMP state is synchronized between PE-3 and PE-1 in a data-driven way.

The basic IGMP snooping state for VPLS 10 on PE-1 and PE-3 is as follows. The output shows that IGMP snooping is enabled on ports *sap:lag-1:10*, *rvpls*, and *evpn-mpls*.

```

PE-1 sends the IGMP queries on VPRN 1 via the *int-MCAST-VPLS* interface, so the VPLS that is referenced in the *int-MCAST-VPLS* interface registers the ports on which the IGMP queries are received as multicast router ports. EVPN-MPLS tunnels are always multicast router ports. The following output displays the source addresses of the multicast routers:

```

Debug

Debugging is useful for troubleshooting purposes, and the debug configuration used on PE-1 and PE-3 for checking IGMP and IGMP snooping functionalities is as follows:

```

debug {
  router "VPRN 1" {
    igmp {
      packet {
        dropped true
        ingress true
        egress true
      }
    }
  }
  service {
    vpls "mcast-vpls" {
      igmp-snooping {
        packet {
          dropped true
          ingress true
          egress true
          evpn-mpls true
          sap lag-1:10 { }
        }
      }
    }
  }
}
    
```

When group 225.70.1.1 is joined, the trace on PE-1 is as follows. Event 4 is the IGMPv3 join message for group 225.70.1.1 received on SAP lag-1:10 in VPLS 10 from the receiver. The reception of this message is synchronized across the EVPN-MPLS tunnel for VPLS 10, as indicated by event 5. Event 6 is the IGMPv3 join message as received on interface *int-MCAST-VPLS* by VPRN 1.

```

4 2023/07/20 11:42:52.720 CEST MINOR: DEBUG #2001 Base IGMP

"

Similar events are logged when the multicast receiver leaves the 225.70.1.1 group.

Conclusion

By connecting customers to EVPN-MPLS VPRN/IES routed services via an R-VPLS, service providers can offer IPv4 multicast services to customers in an all-active multi-homing scenario.

L2 Services with Auto-GRE Spoke-SDPs

This chapter provides information about L2 Services with Auto-GRE Spoke-SDPs.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 16.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Auto-GRE spoke-SDPs are supported in L2 services in SR OS Release 16.0.R1, and later.

Overview

When the connectivity between nodes is IP-based (not MPLS), VPWS and VPLS services can use manually provisioned or auto-generated GRE transport tunnels. For auto-GRE transport tunnels, the signaling can be BGP or Targeted LDP (T-LDP). BGP signaling is more scalable than T-LDP, because T-LDP requires point-to-point sessions between communicating peers.

Auto-GRE spoke-SDPs can be used in the following services:

- BGP-VPLS with BGP signaling
- LDP VPLS using BGP-AD with T-LDP signaling
- BGP-VPWS with BGP signaling
- Dynamic Multi-segment Pseudowire (MS-PW) spoke-SDP Forwarding Equivalence Class (FEC) 129 with T-LDP signaling (*not* supported in MD-CLI for SR OS Release 21.5.R1)

PW templates for auto-GRE spoke-SDPs are configured with **auto-gre-sdp true**.

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# auto-gre-sdp ?

auto-gre-sdp <boolean>
<boolean> - ([true]|false)
Default   - false

'auto-gre-sdp' is: immutable

    Use a GRE tunnel to automatically create an SDP

    Warning: Modifying this element recreates 'configure service pw-template "PW3"'
    automatically for the new value to take effect.

Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

The **auto-gre-sdp** parameter can be combined with the parameter **provisioned-sdp prefer**, but not with **provisioned-sdp use** (because that might contradict the use of auto-GRE spoke-SDPs), as follows:

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# commit
MINOR: SVCNOR #5626: configure service pw-template "PW3" auto-gre-sdp - not compatible with
auto-gre-sdp - auto-gre-sdp is not allowed with used-provisioned-sdp
```

The auto-GRE SDP and SDP binding are created after a matching BGP route has been received. Subsequent requests for an auto-GRE SDP of the same type and to the same destination as an existing auto-GRE SDP will use the existing auto-GRE SDP.

Downstream fragmentation is allowed for auto-GRE SDPs by clearing the Don't Fragment (DF) bit in the GRE IP header. The following command controls fragmentation for a PW template:

```
configure {
  service {
    pw-template "PW40" {
      pw-template-id 40
      allow-fragmentation true
      auto-gre-sdp true
    }
  }
}
```

The following PW template parameters are not supported with GRE tunnels and will be ignored when a GRE SDP is auto-created:

- Hash label
- Entropy label
- SDP include/exclude (there is no mechanism to configure an SDP admin group for auto-GRE SDPs)

However, these parameters are relevant for provisioned MPLS SDPs when the PW template is configured with **provisioned-sdp prefer**.

The **pw-template-binding** parameter in the **bgp <.>** context of the L2 service allows to configure the PW template to be used. It is possible to define multiple PW template bindings within a service. The mechanism for selecting the PW template is as follows:

- In BGP-VPWS, BGP-VPLS, and BGP-AD services, the PW template binding selection is based on matching the configured import Route Targets (RTs) for a PW template binding with the RTs in the received routes.
- The binding with the first matching RT is chosen. If no import RTs are configured, the lowest PW template binding ID is used.
- It is not possible to add RTs to BGP-VPWS BGP updates using import or export policies, because they are ignored. However, the RT exported to select the destination service can be used on the receiving PE with PW template binding statement to influence the PW template to be selected; see the first use case in the [Configuration](#) section.
- If the selected PW template is configured with **provisioned-sdp prefer** and an SDP with a matching far-end address exists, the system chooses the SDP with the lowest metric from the tunnel table. If multiple matching SDPs with the same metric occur, the highest SDP ID that is operationally up is chosen.

The following **tools** command allows for PW template bindings to change:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template
```

```
[policy-id] <number>
<number> - <1..2147483647>

<number> - <1..2147483647>
```

The policy ID refers to the PW template currently in use. With the **allow-service-impact** option, the current binding will be torn down and re-signaled.

Configuration

Figure 185: Example topology shows the example topology with three PEs in AS 64500. Services will be configured on PE-1 and PE-2, and PE-3 is the route reflector (RR).

Figure 185: Example topology

28652

The initial configuration on the three PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)

Auto-GRE spoke-SDPs are configured in the following use cases:

1. BGP-VPLS with BGP signaling
2. BGP-AD in VPLS with T-LDP signaling
3. BGP-VPWS with BGP signaling

In these three use cases (BGP-VPLS, BGP-AD, BGP-VPWS), BGP is configured for the L2-VPN address family. In each of the use cases, two L2 services will be configured using different PW templates with **auto-gre-sdp**: one with **provisioned-sdp prefer** and one without.

Auto-GRE spoke-SDPs in BGP-VPLS

Figure 186: BGP-VPLS with auto-GRE spoke-SDPs shows the example topology with BGP-VPLSs 1 and 2 configured on PE-1 and PE-2. BGP is configured for the L2-VPN address family with PE-3 as Route Reflector (RR). The CEs are emulated through VPRNs configured on the PEs and connected to the VPLSs via Port Cross-connect (PXC).

Figure 186: BGP-VPLS with auto-GRE spoke-SDPs

28653

BGP configuration

For the BGP-VPLS, BGP-AD, and BGP-VPWS use cases, BGP is configured with the L2-VPN address family. The BGP configuration on PE-1 and PE-2 is identical, as follows:

```
# on PE-1, PE-2::
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "WAN" {
        type internal
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.3" {
        group "WAN"
      }
    }
  }
}
```

On RR PE-3, BGP is configured as follows:

```
# on RR PE-3:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      rapid-withdrawal true
      split-horizon true
      group "WAN" {
        type internal
        family {
          l2-vpn true
        }
      }
      cluster {
        cluster-id 192.0.2.3
      }
    }
  }
  neighbor "192.0.2.1" {
    group "WAN"
  }
}
```

```

    }
    neighbor "192.0.2.2" {
        group "WAN"
    }
}

```

Service configuration

The configuration of BGP-VPLS services is described in the [BGP VPLS](#) chapter.

PW template 10 is configured with **auto-gre-sdp**; PW template 20 is configured with **provisioned-sdp prefer** and **auto-gre-sdp**. Because only IP connectivity is present between the nodes (no MPLS), the provisioned SDP is GRE-based using BGP signaling (no T-LDP). VPLS 1 has PW template bindings with IDs 10 and 20; VPLS 2 is configured with PW template binding 20. The service configuration on PE-1 is as follows:

```

# on PE-1:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
    }
    sdp 12 {
        admin-state enable
        signaling bgp
        far-end {
            ip-address 192.0.2.2
        }
    }
    vpls "BGP-VPLS-1" {
        admin-state enable
        description "BGP-VPLS with auto-GRE spoke-SDP"
        service-id 1
        customer "1"
        bgp 1 {
            route-distinguisher "64500:1"
            route-target {
                export "target:64500:1"
                import "target:64500:1"
            }
            pw-template-binding "PW10-auto-GRE" {
            }
            pw-template-binding "PW20-auto-GRE_prefer-prov" {
            }
        }
    }
    bgp-vpls {
        admin-state enable
        maximum-ve-id 100
        ve {
            name "PE-1"
            id 1
        }
    }
    sap pxc-10.a:1 {          # SAP to connect to CE-11
    }
}

```

```

}
vpls "BGP-VPLS-2" {
  admin-state enable
  description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
  service-id 2
  customer "1"
  bgp 1 {
    route-distinguisher "64500:2"
    route-target {
      export "target:64500:2"
      import "target:64500:2"
    }
    pw-template-binding "PW20-auto-GRE_prefer-prov" {
    }
  }
  bgp-vpls {
    admin-state enable
    maximum-ve-id 100
    ve {
      name "PE-1"
      id 1
    }
  }
  sap pxc-10.a:2 {      # SAP to connect to CE-12
  }
}

```

The service configuration on PE-2 is similar, but the VE name is "PE-2" and the VE ID equals 2 instead, as follows:

```

# on PE-2:
configure {
  service {
    pw-template "PW10-auto-GRE" {
      pw-template-id 10
      auto-gre-sdp true
    }
    pw-template "PW20-auto-GRE_prefer-prov" {
      pw-template-id 20
      provisioned-sdp prefer
      auto-gre-sdp true
    }
  }
  sdp 21 {
    admin-state enable
    signaling bgp
    far-end {
      ip-address 192.0.2.1
    }
  }
}
vpls "BGP-VPLS-1" {
  admin-state enable
  description "BGP-VPLS with auto-GRE spoke-SDP"
  service-id 1
  customer "1"
  bgp 1 {
    route-distinguisher "64500:1"
    route-target {
      export "target:64500:1"
      import "target:64500:1"
    }
    pw-template-binding "PW10-auto-GRE" {
    }
    pw-template-binding "PW20-auto-GRE_prefer-prov" {
    }
  }
}

```

```

    }
  }
  bgp-vpls {
    admin-state enable
    maximum-ve-id 100
    ve {
      name "PE-2"
      id 2
    }
  }
  sap pxc-10.a:1 {      # SAP to connect to CE-21
  }
}
vpls "BGP-VPLS-2" {
  admin-state enable
  description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
  service-id 2
  customer "1"
  bgp 1 {
    route-distinguisher "64500:2"
    route-target {
      export "target:64500:2"
      import "target:64500:2"
    }
    pw-template-binding "PW20-auto-GRE_prefer-prov" {
    }
  }
  bgp-vpls {
    admin-state enable
    maximum-ve-id 100
    ve {
      name "PE-2"
      id 2
    }
  }
  sap pxc-10.a:2 {      # SAP to connect to CE-22
  }
}
}

```

The following L2-VPN routes are received on PE-1: one for VPLS 1 with RD 64500:1 and another for VPLS 2 with RD 64500:2.

```

```

VPLS 1 is configured with two PW template bindings without import RT. Because the PW template binding with the lowest ID is preferred, PW template 10 is used and therefore, the following GRE SDP 32767 is auto-created:

```

[/]
A:admin@PE-1# show service id 1 sdp detail

=====

```

In VPLS 1, the PW template binding selection can be changed by configuring a non-matching import RT to PW template 10, as follows:

```
# on PE-1:
configure {
  service {
    vpls "BGP-VPLS-1" {
      bgp 1 {
        pw-template-binding "PW10-auto-GRE" {
          import-rt ["target:64500:999"]
        }
      }
    }
  }
}
```

This does not change the selected PW template during service operation and PW template 10 remains in use, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id      : 10
```

The following **tools** command forces the system to re-evaluate the PW template binding:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 10 allow-service-impact
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 10
```

When the PW template binding is re-evaluated, PW template binding 20 is selected and the provisioned SDP 12 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id      : 20
```

```
[/]
A:admin@PE-1# show service id 1 sdp
```

```

Auto-GRE spoke-SDPs in LDP-VPLS using BGP-AD

[Figure 187: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs](#) shows the example topology with VPLSs 3 and 4 configured with BGP-AD on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

Figure 187: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs

28654

The following T-LDP session is configured between PE-1 and PE-2:

```
# on PE-1:
configure {
  router "Base" {
    ldp {
      targeted-session {
        peer 192.0.2.2 {
        }
      }
    }
  }
}
```

```
# on PE-2:
configure {
  router "Base" {
    ldp {
      targeted-session {
        peer 192.0.2.1 {
        }
      }
    }
  }
}
```

The following T-LDP signaled SDP is configured on PE-1 and PE-2:

```
# on PE-1:
configure {
  service {
    sdp 120 {
      admin-state enable
      far-end {
        ip-address 192.0.2.2
      }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    sdp 210 {
      admin-state enable
      far-end {
        ip-address 192.0.2.1
      }
    }
  }
}
```

The service configuration on PE-1 and PE-2 is as follows; see chapter [LDP VPLS Using BGP Auto-Discovery](#) for a description of BGP-AD in LDP VPLS. PW templates 10 and 20 are the same as in the preceding example.

```
# on PE-1, PE-2:
configure {
  service {
    pw-template "PW10-auto-GRE" {
      pw-template-id 10
      auto-gre-sdp true
    }
    pw-template "PW20-auto-GRE_prefer-prov" {
      pw-template-id 20
      provisioned-sdp prefer
      auto-gre-sdp true
    }
    vpls "BGP-AD VPLS-3" {
      admin-state enable
      description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP"
      service-id 3
      customer "1"
      bgp 1 {
        route-distinguisher "64500:3"
        route-target {
          export "target:64500:3"
          import "target:64500:3"
        }
        pw-template-binding "PW10-auto-GRE" {
        }
        pw-template-binding "PW20-auto-GRE_prefer-prov" {
        }
      }
      bgp-ad {
        admin-state enable
        vpls-id "64500:3"
      }
      sap pxc-10.a:3 {          # SAP to connect to CE-13 (PE-1) or CE-23 (PE-2)
      }
    }
    vpls "BGP-AD VPLS-4" {
      admin-state enable
      description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP pref-prov-SDP"
      service-id 4
      customer "1"
      bgp 1 {
        route-distinguisher "64500:4"
        route-target {
          export "target:64500:4"
          import "target:64500:4"
        }
        pw-template-binding "PW20-auto-GRE_prefer-prov" {
        }
      }
      bgp-ad {
        admin-state enable
        vpls-id "64500:4"
      }
      sap pxc-10.a:4 {          # SAP to connect to CE-14 (PE-1) or CE-24 (PE-2)
      }
    }
  }
}
```

PE-1 has received the following L2-VPN BGP-AD routes:

```

Auto-GRE spoke-SDPs in BGP-VPWS

Figure 188: BGP-VPWS with auto-GRE spoke-SDPs shows the example topology with BGP-VPWS Epipes 5 and 6 on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

Figure 188: BGP-VPWS with auto-GRE spoke-SDPs

28655

Chapter [BGP Virtual Private Wire Services](#) describes the configuration of BGP VPWS. The configuration of Epipe 5 and 6 on PE-1 is as follows:

```
# on PE-1:
configure {
  service {
    pw-template "PW10-auto-GRE" {
      pw-template-id 10
      auto-gre-sdp true
    }
    pw-template "PW20-auto-GRE_prefer-prov" {
      pw-template-id 20
      provisioned-sdp prefer
      auto-gre-sdp true
    }
  }
  epipe "BGP-VPWS-5" {
    admin-state enable
    description "BGP-VPWS with auto-GRE spoke-SDP"
    service-id 5
    customer "1"
    bgp 1 {
      route-distinguisher "64500:5"
      route-target {
        export "target:64500:5"
        import "target:64500:5"
      }
      pw-template-binding "PW10-auto-GRE" {
      }
      pw-template-binding "PW20-auto-GRE_prefer-prov" {
      }
    }
  }
  bgp-vpws {
    admin-state enable
    local-ve {
      name "PE-1"
      id 1
    }
    remote-ve "PE-2" {
      id 2
    }
  }
  sap pxc-10.a:5 {      # SAP to connect to CE-15
  }
}
epipe "BGP-VPWS-6" {
```

```

admin-state enable
description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
service-id 6
customer "1"
bgp 1 {
  route-distinguisher "64500:6"
  route-target {
    export "target:64500:6"
    import "target:64500:6"
  }
  pw-template-binding "PW20-auto-GRE_prefer-prov" {
  }
}
bgp-vpws {
  admin-state enable
  local-ve {
    name "PE-1"
    id 1
  }
  remote-ve "PE-2" {
    id 2
  }
}
sap pxc-10.a:6 {          # SAP to connect to CE-16
}
}

```

The configuration of the Epipes is similar on PE-2, but the VE names and VE IDs are different, as follows:

```

# on PE-2:
configure {
  service {
    pw-template "PW10-auto-GRE" {
      pw-template-id 10
      auto-gre-sdp true
    }
    pw-template "PW20-auto-GRE_prefer-prov" {
      pw-template-id 20
      provisioned-sdp prefer
      auto-gre-sdp true
    }
  }
  epipe "BGP-VPWS-5" {
    admin-state enable
    description "BGP-VPWS with auto-GRE spoke-SDP"
    service-id 5
    customer "1"
    bgp 1 {
      route-distinguisher "64500:5"
      route-target {
        export "target:64500:5"
        import "target:64500:5"
      }
      pw-template-binding "PW10-auto-GRE" {
      }
      pw-template-binding "PW20-auto-GRE_prefer-prov" {
      }
    }
  }
  bgp-vpws {
    admin-state enable
    local-ve {
      name "PE-2"
      id 2
    }
  }
}

```

```

        remote-ve "PE-1" {
            id 1
        }
    }
    sap pxc-10.a:5 {          # SAP to connect to CE-25
    }
}
epipe "BGP-VPWS-6" {
    admin-state enable
    description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
    service-id 6
    customer "1"
    bgp 1 {
        route-distinguisher "64500:6"
        route-target {
            export "target:64500:6"
            import "target:64500:6"
        }
        pw-template-binding "PW20-auto-GRE_prefer-prov" {
        }
    }
    bgp-vpws {
        admin-state enable
        local-ve {
            name "PE-2"
            id 2
        }
        remote-ve "PE-1" {
            id 1
        }
    }
}
    sap pxc-10.a:6 {          # SAP to connect to CE-26
    }
}

```

PE-1 receives the following BGP-VPWS routes from PE-2:

```

[/]
A:admin@PE-1# show router bgp routes l2-vpn bgp-vpws

Conclusion

In IP-based networks, auto-GRE spoke-SDPs can be used in VPWS and VPLS services. Manually configured GRE tunnels are not an option in networks — such as LTE networks — where it is common to assign IP addresses dynamically from a pool of addresses, but auto-GRE spoke-SDPs can be applied instead.

Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication

This chapter provides information about Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3. Layer 2 multicast optimization for EVPN-VXLAN - Assisted Replication (AR) is supported in SR OS Release 14.0.R4, and later.

Overview

Typically, EVPN-VXLAN can use either Ingress Replication (IR) or Protocol Independent Multicast (PIM) for Broadcast, Unknown unicast, and Multicast (BUM) traffic (although SR OS does not support PIM along with EVPN-VXLAN). PIM requires keeping multicast state awareness per subnet per tenant in the core routers, which may not scale. Not all core routers support PIM.

IR inefficiency is usually tolerable in EVPN networks for broadcast and unknown unicast traffic; however, it is not tolerable for multicast traffic:

- Broadcast traffic can be reduced by the proxy-ARP and proxy-ND capabilities supported by EVPN.
- Unknown unicast traffic is greatly reduced in virtualized Data Center (DC) networks where all MAC and IP addresses are learned in the control or management planes. In such cases, unknown MAC addresses are always outside the DC. An **unknown-mac-route** can be enabled to ensure that the unknown unicast traffic is sent only to the DC gateway, which minimizes flooding within the DC.
- Multicast traffic may be an issue for the hypervisors holding the multicast sources, because the hypervisors need to replicate the multicast traffic to the remote VXLAN Tunnel Endpoints (VTEPs). The multicast replication at the hypervisors is a software process and the throughput can be heavily impacted. This is also true when VPLS services are used in the Virtual Service Router (VSR) and many replicas must be done from the VSR. Using a dedicated service node to replicate the multicast traffic on behalf of the hypervisors can help, but the replication capabilities of such service nodes are limited too.

SR OS supports the Assisted Replication (AR) feature for IPv4 VXLAN tunnels (both replicator and leaf functions) in compliance with the non-selective mode described in *draft-ietf-bess-evpn-optimized-ir*. AR is a Layer 2 multicast optimization feature that helps software-based PEs and Network Virtualization Edge (NVE) devices with low-performance replication capabilities to deliver Broadcast and Multicast (BM) Layer 2 traffic to remote VTEPs in the VPLS.

SR OS nodes support the AR-Replicator (AR-R) and AR-Leaf (AR-L) functions, although not simultaneously on the same service. Nodes configured as AR-L select an AR-R within a service and send

all BM packets to this AR-R. AR-Rs replicate traffic to all the VTEPs in the VPLS on behalf of the AR-Ls, so BM traffic is delivered to all VPLS participants without any packet loss caused by performance issues. Unknown unicast packets follow the same path as known unicast packets to avoid packet reordering. Therefore, no AR-R is used for unknown unicast traffic.

When multiple AR-Rs exist in a service, the AR-L performs per-service load-balancing of the BM traffic. The AR-L lists the candidate AR-Rs, ordered by IP address and VXLAN Network Identifier (VNI); candidate 0 having the lowest IP address and VNI. The replicator is selected using a modulo function of the service ID and the number of candidate AR-Rs. For example, assume that VPLS 1 has two candidate AR-Rs: because 1 modulo 2 equals 1, the second AR-R in the list is selected. In case of failure, a new AR-R is selected. If there are no more AR-Rs, the system falls back to IR.

Figure 189: PMSI Tunnel Attribute - Flags shows an EVPN route-type 3, an Inclusive Multicast Ethernet Tag (IMET) route containing a PMSI tunnel attribute with a flags octet. Flag L was already defined in RFC 6514. *Draft-ietf-bess-evpn-optimized-ir* defines additional flags: type, BM, and U. The BM and U flags are used for Pruned Flood Lists (PFL) signaling and they are not supported.

Figure 189: PMSI Tunnel Attribute - Flags

26626b

The type field has two bits that define the AR role of the advertising router, as follows:

- Type 00 = Regular Network Virtualization Edge (RNVE) - indicates that AR is not supported and IR is applied instead (for backward compatibility)
- Type 01 = AR-R
- Type 10 = AR-L
- Type 11 = reserved

The tunnel type in the PMSI tunnel attribute can be configured with the following options for IR and AR:

- Tunnel type 0x06 = (non-optimized) IR, sent by AR-R and AR-L if **ingress-repl-inc-mcast-advertisement** is enabled, which is the default option
- Tunnel type 0x0A = type AR, originated by AR-R

For regular IR routes, the originating router's IP address equals the system IP address. The MPLS label and tunnel identifier must be used as described in RFC 7432. The tunnel identifier is set to a routable address of the PE.

For AR routes, the originating router's IP address and the tunnel identifier are both set to the AR IP address (AR-IP) configured in the **service system vxlan** context. The AR-IP must be previously defined as a loopback interface address in the base router and must be different from the IR IP address (IR-IP).

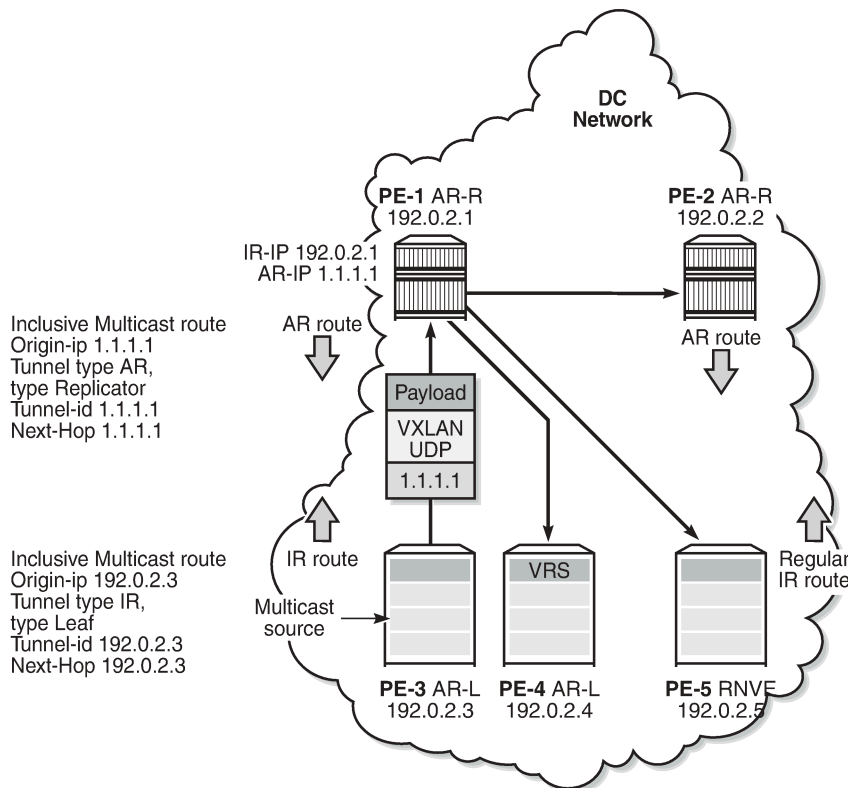

Note:

If the AR-IP loopback interface is down, the router does not withdraw the AR route. However, the remote AR-Ls is not able to resolve the AR route's BGP next-hop if the AR-IP is no longer propagated in the IGP.

Figure 190: EVPN Assisted Replication for VXLAN shows the example topology with the multicast source connected to a hypervisor PE-3 that acts as AR-L, which sends an IR route containing the system address of PE-3. The AR-R PE-1 sends an AR route that uses AR-IPs instead of IR-IPs; for example, PE-1 has AR-IP 1.1.1.1 and IR-IP 192.0.2.1.

Figure 190: EVPN Assisted Replication for VXLAN

26627

Hypervisor PE-3 sends the BM traffic to the AR-R, which replicates it to all the VTEPs in the VPLS, except to PE-3.

Table 11: Inclusive multicast route information sent by different AR roles shows the inclusive multicast route information sent by each role in an AR-capable service.

Table 11: Inclusive multicast route information sent by different AR roles

AR role	function	inclusive multicast route advertised
AR-R	assists AR-Ls	IR inclusive multicast route (tunnel = 0x06 = IR, IR-IP, type = 0 = none)

AR role	function	inclusive multicast route advertised
		AR inclusive multicast route (tunnel = 0x0A = AR, AR-IP, type = 1 = AR-R)
AR-L	sends BM only to AR-R	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 2 = AR-L)
RNVE	non-AR support	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 0 = none)

Unicast traffic (known or unknown) is processed as normal. For BM traffic, the AR-R uses AR or IR based on the IP destination address (DA):

- If IP DA equals the AR-IP, the AR-R replicates to the VTEPs in the VXLAN service, except for the VTEP over which the BM traffic was received.
- If IP DA equals the IR-IP, normal IR forwarding is done.

Non-optimized-IR nodes are unaware of the PMSI tunnel attribute flag definition with the additional flags for AR, so they ignore the information in the flags field.

The *draft-ietf-bess-evpn-optimized-ir* describes the following three types of IR optimizations:

- Non-selective AR - the chosen AR-R replicates the BM traffic to all NVEs in the Ethernet VPN Instance (EVI) except for the source NVE.
- Selective AR - AR-Rs replicate BM traffic to only their AR-L set and the rest of the AR-Rs. Selective AR allows a "multi-stage" AR replication, as opposed to a "single-stage" AR replication.
- Pruned Flood Lists - AR-Ls can signal PFL flags to be pruned from the flood lists for BM or for unknown unicast traffic. PFL may be used in combination with AR.

This chapter only describes non-selective AR.

Configure AR-R and AR-L

The AR-IP is configured on the AR-R, as follows:

```
configure {
  service {
    system {
      vxlan {
        assisted-replication {
          ip-address ?

ip-address <unicast-ipv4-address>
<unicast-ipv4-address> - <d.d.d.d>

          IP address for assisted replication in the router
        }
      }
    }
  }
}
```

The AR-IP is the IPv4 address of a loopback interface in the base router instance. When attempting to configure an AR-IP and the loopback address does not exist, the following error message is raised:

```
configure {
  service {
    system {
      vxlan {
```

```
    assisted-replication {  
        ip-address 1.1.1.1
```

```
MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address  
- loopback interface with address (max prefix) needed for assisted replication  
- configure router "Base"
```

The AR types replicator and leaf are configured in a VPLS with the following command:

```
configure {  
    service {  
        vpls "VPLS 10" {  
            vxlan {  
                instance 1 {  
                    vni 1  
                    assisted-replication ?  
  
                assisted-replication  
  
                Choice: role  
                leaf          :+ Enter the leaf context  
                replicator    :- AR role as replicator
```

When attempting to configure an AR-R before the AR-IP is set, the following error is raised:

```
configure {  
    service {  
        vpls "VPLS 10" {  
            customer "1"  
            service-id 10  
            vxlan {  
                instance 1 {  
                    vni 1  
                    assisted-replication {  
                        replicator  
  
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 10" vxlan instance 1 assisted-replication  
replicator  
- assisted-replication ip address needed for replication role  
- configure service system vxlan assisted-replication ip-address
```

The `assisted-replication-time` can only be configured on leaf nodes. The following error is raised after an attempt to configure the `assisted-replication-time` on an AR-R:

```
configure {  
    service {  
        vpls "VPLS 10" {  
            vxlan {  
                instance 1 {  
                    assisted-replication {  
                        replicator {  
                            acttime 5  
  
MINOR: MGMT_CORE #2201: Unknown element - 'acttime'
```

The **acttime** can optionally be activated, and works as follows. When the router creates an AR-R destination for the first time, the assisted replication time must expire before this AR-R destination is eligible as candidate AR-R to forward BM traffic. Upon expiration, the router runs the AR-R selection (service ID modulo the number of AR-Rs provides the selected AR-R in the ordered list of candidate AR-Rs). The AR-R EVPN destination is created as "BM" and the destinations to the remaining nodes is shown as "U".

The **acttime** allows the AR-R some time to program the leaf VTEPs in the following cases:

- Configuration of a new AR-R
- AR-R rebooting
- AR-R going operationally down and up again

If the timer is zero (default value), the AR-R may receive packets from a VTEP that has not been programmed yet, in which case the AR-R drops the packets.

With the AR-Rs and AR-Ls configured, IMET AR routes can be exchanged. IR can be enabled or disabled independently of the AR configuration. The following command is required to enable IR inclusive multicast routes, and is enabled by default:

```
configure {
  service {
    vpls "VPLS 10" {
      bgp-evpn {
        routes {
          incl-mcast {
            advertise-ingress-replication true
          }
        }
      }
    }
  }
}
```

BGP-EVPN routes

By default, IR is enabled in BGP-EVPN. The following IMET IR route is sent from PE-5 (RNVE) to Route Reflector (RR) PE-1. The flags in the PMSI Tunnel Attribute (PTA) indicate that regular IR is used to forward BUM traffic (tunnel type: 0x06). The AR type is "None", because AR is disabled on PE-5. The IR-IP 192.0.2.5 is used as next-hop, originator IP address, and tunnel endpoint. The MPLS label corresponds to the VNI.

```

Configuration

Figure 191: Example topology shows the example topology with PE-1 and PE-2 as AR-R nodes, PE-3 and PE-4 as AR-L nodes, and PE-5 as RNVE node. The multicast source is connected to PE-3, which is a low-performance node. PE-1 acts as an RR for all nodes.

Figure 191: Example topology

26628b

The initial configuration on the nodes includes:

- Cards, MDAs, ports
- Router interfaces between the nodes
- IS-IS as IGP (alternatively, OSPF can be used)

BGP is configured for address family EVPN with RR PE-1. The BGP configuration on PE-1 is as follows:

```

On PE-1:
configure {
  router "Base" {

```

```
autonomous-system 64500
  bgp {
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    split-horizon true
    ebgp-default-reject-policy {
      import false
      export false
    }
    rapid-update {
      evpn true
    }
    group "DC" {
      peer-as 64500
      family {
        evpn true
      }
      cluster {
        cluster-id 192.0.2.1
      }
    }
    neighbor "192.0.2.2" {
      group "DC"
    }
    neighbor "192.0.2.3" {
      group "DC"
    }
    neighbor "192.0.2.4" {
      group "DC"
    }
    neighbor "192.0.2.5" {
      group "DC"
    }
  }
}
```

The BGP configuration on the other nodes is as follows:

```
On the other PEs:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      split-horizon true
      ebgp-default-reject-policy {
        import false
        export false
      }
      rapid-update {
        evpn true
      }
    }
    group "DC" {
      peer-as 64500
      family {
        evpn true
      }
    }
    neighbor "192.0.2.1" {
      group "DC"
    }
  }
}
```

```
}

```

VPLS 10 is configured on all nodes. PE-1 is configured as AR-R with AR-IP 1.1.1.1, which must be configured as loopback IPv4 address in the base router and as AR-IP that can be shared between services. When attempting to configure an AR-IP with an IP address that does not exist in the base router, the following error is raised:

```
configure {
  service {
    system {
      vxlan {
        assisted-replication {
          ip-address 1.1.1.1
MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address
- loopback interface with address (max prefix) needed for assisted replication
- configure router "Base"
```

First, a loopback interface is configured in the base router. The IP address needs to be routable and, in this example, an export policy exporting this IP address is configured in IS-IS. Alternatively, a static route can be configured or an additional IS-IS passive interface can be configured for the loopback interface. The IP address is then configured as AR-IP in the **service system vxlan** context. PE-1 is configured as AR-R for VPLS 10, as follows:

```
On PE-1:
configure {
  policy-options {
    prefix-list "AR-IP" {
      prefix 1.1.1.1/32 type exact {
      }
    }
    policy-statement "export_AR-IP" {
      entry 10 {
        from {
          prefix-list ["AR-IP"]
        }
        action {
          action-type accept
        }
      }
    }
  }
  router "Base" {
    interface "AR-IP" {
      loopback
      ipv4 {
        primary {
          address 1.1.1.1
          prefix-length 32
        }
      }
    }
    isis 0 {
      export-policy ["export_AR-IP"]
    }
  }
  service {
    system {
      vxlan {
        assisted-replication {
          ip-address 1.1.1.1
        }
      }
    }
  }
}
```

```

    }
  }
  vpls "VPLS 10" {
    customer "1"
    service-id 10
    admin-state enable
    vxlan {
      instance 1 {
        vni 1
        assisted-replication {
          replicator
        }
      }
    }
    bgp 1 {
    }
    bgp-evpn {
      evi 1
      vxlan 1 {
        admin-state enable
        vxlan-instance 1
      }
    }
  }
}

```

The configuration is similar on PE-2, but with AR-IP 2.2.2.2 instead of 1.1.1.1.

PE-3 and PE-4 are configured as AR-L nodes for VPLS 10. No AR-IP needs to be configured. The configuration of VPLS 10 on PE-3 is as follows:

```

On PE-3:
configure {
  service {
    vpls "VPLS 10" {
      admin-state enable
      service-id 10
      customer "1"
      vxlan {
        instance 1 {
          vni 1
          assisted-replication {
            leaf { }
          }
        }
      }
    }
  }
  bgp 1 {
  }
  bgp-evpn {
    evi 1
    vxlan 1 {
      admin-state enable
      vxlan-instance 1
    }
  }
  }
  sap 1/1/c3/1 { # sap for ingress traffic from STC
  }
  sap 1/2/c1/1:1 { # sap for egress traffic to VPLS 10
  }
}

```

Multicast traffic enters SAP 1/1/c3/1, whereas receiving hosts can be connected to other SAPs, such as SAP 1/2/c1/1:1. The configuration of VPLS 10 on PE-4 is similar, but no multicast source is connected.

When a node is configured as AR-L, optionally the **acttime** can be configured to define the waiting time before the leaf can begin sending multicast traffic to a new replicator or a replicator that was rebooted. The default is zero seconds, in which case the AR-L starts sending packets to the AR-R without delay. Nokia recommends configuring a **acttime** value different from zero.

```
configure {
  service {
    vpls "VPLS 10" {
      vxlan {
        instance 1 {
          vni 1
          assisted-replication {
            leaf {
              acttime ?
            }
          }
        }
      }
    }
  }
}

acttime <number>
<number> - <1..255> - seconds

Time for the leaf to wait before sending traffic to a new replicator
```

PE-5 is configured as an RNVE node for VPLS 10, as follows:

```
On PE-5:
configure {
  service {
    vpls "VPLS 10" {
      admin-state enable
      service-id 10
      customer "1"
      vxlan {
        instance 1 {
          vni 1
        }
      }
      bgp 1 {
      }
      bgp-evpn {
        evi 1
        vxlan 1 {
          admin-state enable
          vxlan-instance 1
        }
      }
      sap 1/2/c1/1:1 { # sap for egress traffic to VPLS 10
      }
    }
  }
}
```

BGP-EVPN IMET routes are exchanged between the nodes. The following IMET routes are used on AR-L PE-3, with two routes from each AR-R: one IR route with BGP next-hop 192.0.2.x and one AR route with BGP next-hop x.x.x.x (with x equal to 1 or 2).

```

When the AR-R has no local attachment circuits, such as SAPs or SDP-bindings, it should not generate regular IR routes. This can be controlled by disabling **advertise-ingress-replication** on PE-1 and PE-2, as follows:

```

On PE-1 and PE-2:
configure {
  service {
    vpls "VPLS 10" {
      bgp-evpn {
        routes {
          incl-mcast {
            advertise-ingress-replication false
          }
        }
      }
    }
  }
}

```

When IR is disabled on the AR-Rs, no IR routes are sent to the other nodes and PE-3 only sees the AR routes from PE-1 and PE-2, as follows:

```

[/]

-----
Number of Egress VTEP, VNI : 4
---snip---
```

PE-3 is configured as AR-L and no **acttime** is defined (default). Four egress VTEPs are listed: the system IP addresses are used for IR routes and the AR-IPs are used for AR routes. All BM traffic is forwarded to AR-IP 1.1.1.1 on PE-1. The AR-R in use is selected by the modulo operation on the service ID (10). In this example, two AR-Rs are available, and the service ID modulo 2 equals zero: $10 \bmod 2 = 0$. This is the lowest possible outcome, so the first AR-R in the ordered candidate list is used. The AR-Rs are ordered by IP and VNI, with candidate 0 the lowest IP and VNI.

```
[/]
A:admin@PE-3# show service id 10 vxlan assisted-replication replicator

-----
Number of entries : 2
-----
```

Within a service, no load-sharing is done between the AR-Rs. However, different AR-Rs can be used for different services.

- If PE-3 were configured as AR-L in VPLS 11, the calculation would be as follows: $11 \bmod 2 = 1$; therefore, the second AR-R in the list would be selected.
- When three AR-Rs were available for VPLS 11, the calculation would be: $11 \bmod 3 = 2$, so the third AR-R in the list would be used.

In case different VNIs are configured for the AR-Rs, the lowest IP address is always higher in the list, even when the VNI is higher. This can be shown when the VPLS VXLAN configuration on PE-1 is modified with VNI 99 instead of VNI 1, as follows:

```
On PE-1:
configure {
  service {
    vpls "VPLS 10" {
```

```

        bgp-evpn {
            delete vxlan 1
        }
        delete vxlan

configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 99
                    assisted-replication {
                        replicator
                    }
                }
            }
        }
    }
}

configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
    }
}

```

The list of AR-Rs on PE-3 shows that the first entry is the VTEP with the lowest IP address (1.1.1.1), even though the VNI 99 is higher than 1:

```

[/]
A:admin@PE-3# show service id 10 vxlan assisted-replication replicator

```

```

=====
Vxlan AR Replicator Candidates
=====

```

Inst	VTEP Address	Egr VNI	In Use	In Candidate List	Pending Time
1	1.1.1.1	99	yes	yes	0
1	2.2.2.2	1	no	yes	0

```

-----
Number of entries : 2
-----
=====

```

Note:

If the AR-IP loopback interface is down, BGP does not withdraw the AR route. When the route to the AR-IP is signaled using IGP, the route is removed from the routing table and the AR-L selects another AR-R. However, when a static route is defined for the AR-IP, a black-hole exists when the AR-IP interface is down.

PE-5 is configured as an RNVE node that signals regular IMET IR routes and is unaware of the AR-R and AR-L roles in the EVI. RNVE nodes ignore IMET AR routes. In the example, only PE-3, PE-4, and PE-5 send IMET IR updates, so the list of VTEP addresses on PE-5 only contains PE-3 and PE-4, as follows:

```

[/]
A:admin@PE-5# show service id 10 vxlan destinations

```

```

```

Verification of multicast traffic

The multicast source connected to PE-3 generates multicast traffic. PE-3 acts as AR-L and forwards the multicast packets to AR-R PE-1. In this example topology, multicast traffic enters port 1/1/c3/1 on PE-3 and is forwarded to egress port 1/1/c1/1 toward PE-1. Port statistics are cleared and traffic is generated, then the port statistics are verified.

```

Id	Egress Packets	Egress Octets
1/1/c3/1	48809 0	73213500 0

Besides the multicast traffic, IGP signaling is sent and received on the network interfaces. This explains why the counters on the network interface 1/1/c1/1 toward PE-1 show a slightly higher value than on the interface 1/1/c3/1 toward the multicast source. No multicast traffic is forwarded to PE-2, which is an AR-R candidate, but not used. AR-L PE-3 selected PE-1 for VPLS 10.

When the AR-R PE-1 receives the multicast traffic from PE-3, it forwards the traffic to PE-4 and PE-5 within the VXLAN service. The VXLAN information for VPLS 10 on PE-1 shows that PE-2 is not in the list of egress VTEPs. The reason is that PE-2 does not have any SAPs or SDP-bindings and no IMET IR route is sent by PE-2 because **advertise-ingress-replication** is disabled.

AR-R PE-1 receives the multicast traffic from PE-3 on port 1/1/c2/1 and forwards it to the egress ports 1/1/c3/1 toward PE-5 and 1/1/c4/1 toward PE-4, as follows. No multicast traffic needs to be forwarded to egress port 1/1/c1/1 toward PE-2. Source squelching ensures that the traffic is not sent back to the originator AR-L PE-3. PE-1 has no local SAPs or SDP-bindings.

```

An egress AR-L or RNVE node performs regular egress BUM forwarding procedures. Packets are replicated to local SAPs or SDP-bindings, but not to VXLAN-bindings.

AR-R failure scenarios

When the AR-IP interface on the used AR-R is down for any kind of reason, the route to this AR-IP is removed from the routing table on AR-L PE-3, and PE-3 selects AR-R PE-2. To simulate an AR-R failure, the AR-IP interface on PE-1 is disabled, as follows:

```

On PE-1:
configure {
  router "Base" {
    interface "AR-IP" {
      admin-state disable
    }
  }
}

```

After a while, the routing table on PE-3 does not contain an entry for prefix 1.1.1.1/32 anymore, as follows:

```

[/]
A:admin@PE-3# show router route-table 1.1.1.1/32

=====
Route Table (Router: Base)
=====
Dest Prefix[Flags]          Type  Proto  Age  Pref
Next Hop[Interface Name]    Metric
-----
No. of Routes: 0
Flags: n = Number of times nexthop is repeated
      B = BGP backup route available

```

```
L = LFA nexthop available
S = Sticky ECMP requested
```

AR-R PE-1 is not eligible anymore when the AR-IP is not reachable. PE-2 is now selected as AR-R, so BM traffic is forwarded to PE-2. Log 99 on PE-3 shows the change in AR-R from PE-1 to PE-2, as follows:

```
On PE-3:
136 2023/07/12 11:34:57.482 CEST MINOR: SVCNMR #2090 Base
"Assisted replicator in service 10 changed to VTEP 2.2.2.2, Egress VNI 1 vxlan-instance 1."
```

The VXLAN destinations for VPLS 10 on PE-3 do not include VTEP 1.1.1.1 anymore, as follows:

```

```

In this case, IR is done for all BUM traffic toward PE-4 and PE-5.

Conclusion

AR uses replicators to forward broadcast and multicast traffic on behalf of less-performing nodes that are configured as AR-Ls. AR is primarily used for L2 multicast optimization in data centers, but may also be used in any network using overlay EVPN-VXLAN tunnels.

LDP VPLS Using BGP Auto-Discovery

This chapter provides information about LDP VPLS using BGP Auto-Discovery.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The MD-CLI in this edition is based on SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Knowledge of BGP-auto-discovery RFC 6074 architecture and functionality, RFC 4447 Pseudo-wire set-up using label distribution protocol is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

Overview

MPLS-based Virtual Private LAN Services (VPLS) may have many different provisioning models to allow the signaling of pseudowires between Provider Edge (PE) routers containing VPLS instances.

Network Management System (NMS) provisioning using Label Distribution Protocol (LDP) signaling is a well understood method of provisioning of Layer 2 VPLS services as described in RFC 4762. This relies on the provisioning of pseudowires between VPLS instances using LDP signaling with a common Virtual Circuit (VC) identifier within the label mapping message to instantiate pseudowires.

Border Gateway Protocol Auto-Discovery (BGP-AD), as specified in RFC 6074, is an alternative method of provisioning of Layer 2 PE routers containing VPLS service instances to those described above where PEs in a common VPLS instance are automatically discovered using BGP-AD techniques.

Each PE router advertises the presence of VPLS instances to other PE routers using defined parameters within a BGP update message.

LDP is used as the pseudowire signaling protocol and relies on the auto-discovery of VPLS endpoints to instantiate pseudowires instead of manually provisioning virtual circuits. Locally configured parameters, along with BGP learned parameters, are used to determine local and remote VPLS endpoints, which are used by LDP to signal service labels to peer routers.

[Figure 192: Example topology](#) shows the example topology with six SR OS nodes located in the same autonomous system (AS). There are three PEs and RR-6 acts as a route reflector for the AS. The PE routers are all VPLS-aware. The provider (P) routers are VPLS-unaware and do not take part in the BGP process. A full mesh VPLS between PE-1, PE-2, and PE-3 is described.

Figure 192: Example topology

al_0538

The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is enabled on all network interfaces between each of the PE/P routers and route reflector RR-6.
- MPLS is configured on all interfaces between PE and P routers; MPLS is not required between P-4 and RR-6.
- LDP is configured on interfaces between PE and P routers; LDP is not required between P-4 and RR-6.
- The RSVP protocol must be enabled.

BGP-AD

In this architecture, a VPLS service is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, VPLS-aware devices are PE routers. Each VPLS instance has a unique identifier known as the VPLS identifier (VPLS-ID). All PEs that have this VPLS instance present will have a common VPLS-ID configured.

Each VPLS instance within a PE contains a Virtual Switching Instance (VSI). The VPLS attachment circuits and pseudowires are associated with the VSI. Each VSI within a VPLS has a unique identifier called the VSI identifier (VSI-ID) and is a concatenation of the VPLS-ID plus an IP address, usually the system IP address.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP Layer 2 Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs. In turn, this allows peer PE routers to set up pseudowire connectivity using LDP signaling for data flow between peers containing a local VPLS within the same VPLS instances.

Each update contains parameters usually associated with Multi-Protocol BGP updates:

- NLRI encoded as route target (RT)—usually the VPLS-ID—and PE system address.
- Next-Hop — The system IP address of the sending PE router.
- Extended communities — Contains the RT extended community and the VPLS-ID as community values.

Each VPLS instance is configured with import and export RT extended communities to create the required pseudowire topology by controlling the distribution of each NLRI.

This chapter describes the provisioning of a VPLS instance across three PE routers. A full mesh of pseudowires interconnects the VSI of each PE within the VPLS instance. A single attachment circuit is also configured on each VSI.

Configuration

The first step is to configure an MP-iBGP session using the L2-VPN address family between each of the PEs and the RR.

The configuration on the PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure {
  router "Base"
    autonomous-system 65536
    bgp {
      group "internal" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      neighbor "192.0.2.6" {
        group "internal"
      }
    }
  }
}
```

The IP addresses can be derived from [Figure 192: Example topology](#).

The configuration for RR-6 is as follows:

```
# on RR-6:
configure {
  router "Base"
    autonomous-system 65536
    bgp {
      group "rr-internal" {
        peer-as 65536
        family {
          l2-vpn true
        }
      }
      cluster {
        cluster-id 1.1.1.1
      }
    }
    neighbor "192.0.2.1" {
      group "rr-internal"
    }
    neighbor "192.0.2.2" {
      group "rr-internal"
    }
    neighbor "192.0.2.3" {

```

```

    group "rr-internal"
}

```

On PE-1, the BGP session with RR-6 is established with address family L2-VPN capability negotiated, as follows:

```

[]
A:admin@PE-1# show router bgp neighbor 192.0.2.6

=====
BGP Neighbor
=====
-----

```

A full mesh of RSVP Label Switched Paths (LSPs) is configured between the PE routers. For reference, the MPLS interface configuration and LSPs for PE-1 to PE-2 and PE-3 is as follows:

```

# on PE-1:
configure {

```

```
router "Base"
  mpls {
    admin-state enable
    interface "int-PE-1-P-4" {
    }
    interface "int-PE-1-PE-2" {
    }
    path "loose" {
      admin-state enable
    }
    lsp "LSP-PE-1-PE-2" {
      admin-state enable
      type p2p-rsvp
      to 192.0.2.2
      primary "loose" {
      }
    }
    lsp "LSP-PE-1-PE-3" {
      admin-state enable
      type p2p-rsvp
      to 192.0.2.3
      primary "loose" {
      }
    }
  }
}
```

VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate Service Distribution Point (SDP) bindings. For a given service, pseudowire templates signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, plus other usage characteristics such as Split Horizon Groups (SHGs), MAC-pinning, filters, and so on.

The MPLS transport tunnel between PE routers can be signaled using either LDP or RSVP.

LDP-based pseudowires can be automatically instantiated; RSVP-based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, it is necessary for link layer LDP to be configured between all PEs/Ps so that a transport label for each PE system interface address is available. Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required which may contain an SHG. Each SDP created with this template is contained within the configured SHG so that traffic cannot be forwarded between them.

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    pw-template "PW1" {
      pw-template-id 1
      split-horizon-group {
```

```

        name "vpls-shg"
    }
}

```

A pseudowire template can also be created that does not contain a split horizon group. The split horizon group can then be specified when the pw-template is included within the service.

```

# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW2" {
            pw-template-id 2
        }
    }
}

```

Pseudowire templates for provisioned SDPs using RSVP

To use an RSVP tunnel as transport between PEs, it is necessary to bind the RSVP LSPs to the SDPs between each PE.

On PE-1, SDP 12 from PE-1 to PE-2 is configured as follows:

```

# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
    }
}

```

To create an SDP within a service that uses an RSVP transport tunnel, a pseudowire template is required that has the **provisioned-sdp use** parameter.

```

# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
            provisioned-sdp use
        }
    }
}

```

Alternatively, the **provisioned-sdp prefer** parameter can be used, see chapter [LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP](#).

VPLS BGP-AD using auto-provisioned SDPs

Figure 193: VPLS instance with auto-provisioned SDPs

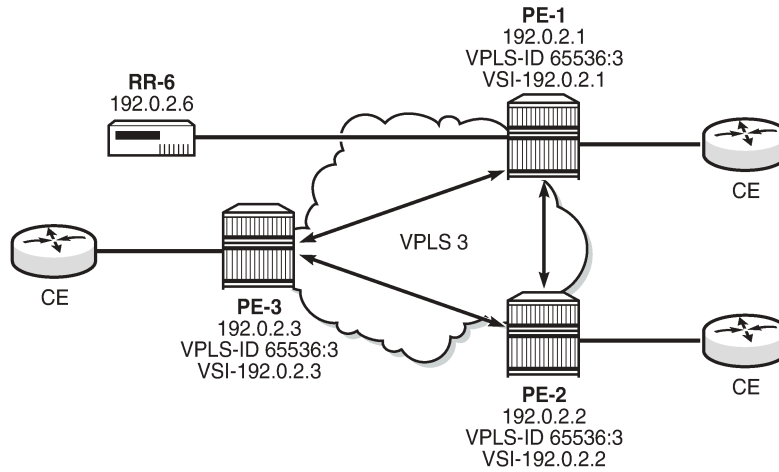

Figure 193: VPLS instance with auto-provisioned SDPs shows a schematic of a VPLS instance where the SDPs are auto-provisioned. SDPs are instantiated by a PE router using LDP signaling upon receipt of BGP Auto-Discovery (BGP-AD) updates from peer PE routers.

PE-1 configuration:

The following output shows the configuration required for a VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure {
  service {
    vpls "VPLS-3" {
      admin-state enable
      service-id 3
      customer "1"
      bgp 1 {
        route-distinguisher "65536:3"
        route-target {
          export "target:65536:3"
          import "target:65536:3"
        }
        pw-template-binding "PW2" {
          split-horizon-group "vpls-shg"
          import-rt ["target:65536:3"]
        }
      }
    }
  }
  bgp-ad {
    admin-state enable
    vpls-id "65536:3"
    vsi-id-prefix 192.0.2.1
  }
  sap 1/1/4:3.0 {
  }
}
```

Within the **bgp** context, the pseudowire template is referenced which can be linked to an SHG and an import RT, if required.

Within the **bgp-ad** context, the signaling parameters are configured. These are two parameters used by each PE to determine the presence of a VPLS instance on a PE router. In turn, these are translated into endpoint identifiers for LDP signaling of pseudowires. As previously discussed, these parameters are:

- VPLS-ID — a unique identifier of the VPLS instance. Each PE that is a member of a VPLS must share the same VPLS-ID. This is inserted as an extended community value in the format AS:n. In this case, the VPLS-ID for VPLS 3 is 65536:3. This is a mandatory parameter and if it is not configured, it is not possible to enable BGP-AD (admin-state enable).
- Virtual Switching Instance (VSI) prefix — This identifies a specific instance of the VPLS. This must be unique within the VPLS instance, and is encoded using the 4 byte dotted-decimal notation. Generally, the system address is used as the VSI prefix. If this parameter is not configured, then the system address is used automatically.

The VPLS-ID and VSI prefix for VPLS 3 on each PE is shown in [Figure 193: VPLS instance with auto-provisioned SDPs](#).

The VPLS-ID and VSI prefix are concatenated to form a unique VSI-ID. In this case, PE-1 has a VSI-ID of 65536:3:192.0.2.1. This uniquely identifies the VPLS instance on each individual PE and is advertised as an L2-VPN BGP update.

A BGP-AD update is transmitted to all other PEs via the RR, as follows:

```

Routes : 4
=====
```

The preceding BGP update is transmitted by PE-1 and has route type auto-discovery.

In this L2-VPN update, the VPLS-ID is encoded as the L2-VPN extended community 65536:3.

The VSI is seen as the prefix 192.0.2.1. The combination of the VPLS-ID and the VSI forms the VSI-ID and uniquely identifies the VPLS instance within this PE router.

The next-hop is also encoded as the local system IP address 192.0.2.1, which allows remote PEs to identify a suitable transport tunnel to PE-1 and for the targeted-LDP peer for instantiating the SDP.

As can be seen within the update, the VPLS-ID 65536:3 is also used to determine the RT extended community and the route distinguisher (RD).

PE-2 configuration

On PE-2, VPLS 3 is created using pseudowire template 1, with VPLS-ID 65536:3 and VSI-ID prefix 192.0.2.2 (system IP address), as follows”

```
# on PE-2:
configure {
  service {
    vpls "VPLS-3" {
      admin-state enable
      service-id 3
      customer "1"
      bgp 1 {
        route-distinguisher "65536:3"
        route-target {
          export "target:65536:3"
          import "target:65536:3"
        }
        pw-template-binding "PW2" {
          split-horizon-group "vpls-shg"
          import-rt ["target:65536:3"]
        }
      }
    }
    bgp-ad {
      admin-state enable
      vpls-id "65536:3"
      vsi-id-prefix 192.0.2.2
    }
    sap 1/1/4:3.0 {
    }
  }
}
```

PE-3 configuration

On PE-3, VPLS 3 is created using pseudowire template 2, with VPLS-ID 65536:3—identical to the VPLS-ID of PE-1 and PE-2—and VSI-ID 192.0.2.3 (system IP address), as follows:

```
# on PE-3:
configure {
  service {
    vpls "VPLS-3" {
      admin-state enable
      service-id 3
      customer "1"
      bgp 1 {
        route-distinguisher "65536:3"
        route-target {
```

```

        export "target:65536:3"
        import "target:65536:3"
    }
    pw-template-binding "PW2" {
        split-horizon-group "vpls-shg"
        import-rt ["target:65536:3"]
    }
}
bgp-ad {
    admin-state enable
    vpls-id "65536:3"
    vsi-id-prefix 192.0.2.3
}
sap 1/1/4:3.0 {
}

```

PE-1 service operation verification

The following output on PE-1 shows that the VPLS and its objects (SAP and auto-discovered spoke SDPs) are operationally up on PE-1:

```

[]
A:admin@PE-1# show service id 3 base

=====
* indicates that the corresponding row element may have been truncated.

```

The **SB** flag indicates that the SDP is of type spoke-SDP (S flag) BGP (B flag).

BGP is used to discover the VPLS endpoints and exchange network reachability information. LDP is used to signal the pseudowires between the PEs.

LDP signaling occurs when each PE has discovered the endpoints of the VPLS instance. This compares with the use of the provisioned virtual circuit IDs used in an NMS provisioned VPLS instances as per RFC 4762.

The ability of PE-1 to reach the other PE routers with VSIs within the VPLS instance is verified from the following L2-route table:

```

[]
A:admin@PE-1# show service l2-route-table bgp-ad

```

```

```

This output shows the presence of the signaled pseudowire SDPs. SDPs from PE-1 to PE-2 and PE-3 are signaled using LDP Forwarding Equivalence Class (FEC) Element 129.

Each PE router uses targeted LDP to signal the local and remote endpoints. If there is an endpoint match, then SDPs are instantiated. This compares with the use of LDP for NMS provisioned SDPs, which uses virtual circuit IDs to signal pseudowires using LDP FEC Element 128.

In order to signal the SDPs, the following parameters are required:

1. Attachment Group Identifier (AGI): this is used to carry the VPLS-ID of the local PE router VPLS instance. The VPLS-ID must be identical for all PEs in the same VPLS instance.
2. Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII): these use All type 1 (RFC 4446) and are used to carry the NLRI (VSI-ID minus the RD) of the remote PE router VPLS instance.

The AGI for each PE must be identical. SAII and TAII must be different.

The following shows the service LDP bindings for VPLS 3 on PE-1:

```

[]
A:admin@PE-1# show router ldp bindings services service-id 3

BGP AD using pre-provisioned SDPs

It is possible to configure BGP-AD instances that use RSVP transport tunnels. In this case, the LSPs and SDPs must be manually created.

Figure 194: VPLS instance using pre-provisioned SDPs

Figure 194: VPLS instance using pre-provisioned SDPs shows a VPLS instance configured across three PE routers as before.

The following SDPs are configured on the three PEs:

```
# on PE-1:
configure {
  service {
    sdp 12 {
      admin-state enable
      description "RSVP-based SDP from PE-1 to PE-2"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-1-PE-2" { }
    }
    sdp 13 {
      admin-state enable
      description "RSVP-based SDP from PE-1 to PE-3"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.3
      }
      lsp "LSP-PE-1-PE-3" { }
    }
  }
}
```

```
# on PE-2:
configure {
  service {
    sdp 21 {
      admin-state enable
      description "RSVP-based SDP from PE-2 to PE-1"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.1
      }
      lsp "LSP-PE-2-PE-1" { }
    }
  }
}
```

```

}
sdp 23 {
  admin-state enable
  description "RSVP-based SDP from PE-2 to PE-3"
  delivery-type mpls
  far-end {
    ip-address 192.0.2.3
  }
  lsp "LSP-PE-2-PE-3" { }
}

```

```

# on PE-3:
configure {
  service {
    sdp 31 {
      admin-state enable
      description "RSVP-based SDP from PE-3 to PE-1"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.1
      }
      lsp "LSP-PE-3-PE-1" { }
    }
    sdp 32 {
      admin-state enable
      description "RSVP-based SDP from PE-3 to PE-2"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-3-PE-2" { }
    }
  }
}

```

The PW template to be used within each VPLS instance must be provisioned on all PEs and must use the keyword `provisioned-sdp use`, as follows:

```

# on PE-1, PE-2, PE-3:
configure {
  service {
    pw-template "PW3" {
      pw-template-id 3
      provisioned-sdp use
    }
  }
}

```

The following output shows the configuration required for a VPLS service using a pseudowire template configured for pre-provisioned RSVP SDPs.

```

# on PE-1:
configure {
  service {
    vpls "VPLS-4" {
      admin-state enable
      service-id 4
      customer "1"
      bgp 1 {
        route-distinguisher "65536:4"
        route-target {
          export "target:65536:4"
          import "target:65536:4"
        }
        pw-template-binding "PW3" {

```

```
        split-horizon-group "vpls-shg"  
        import-rt ["target:65536:4"]  
    }  
}  
bgp-ad {  
    admin-state enable  
    vpls-id "65536:4"  
    vsi-id-prefix 192.0.2.1  
}  
sap 1/1/4:4.0 {  
}
```

Similarly, on PE-2 the configuration is as follows:

```
# on PE-2:  
configure {  
    service {  
        vpls "VPLS-4" {  
            admin-state enable  
            service-id 4  
            customer "1"  
            bgp 1 {  
                route-distinguisher "65536:4"  
                route-target {  
                    export "target:65536:4"  
                    import "target:65536:4"  
                }  
                pw-template-binding "PW3" {  
                    split-horizon-group "vpls-shg"  
                    import-rt ["target:65536:4"]  
                }  
            }  
        }  
        bgp-ad {  
            admin-state enable  
            vpls-id "65536:4"  
            vsi-id-prefix 192.0.2.2  
        }  
    }  
    sap 1/1/4:4.0 {  
    }  
}
```

On PE-3, VPLS 4 is configured as follows:

```
# on PE-3:  
configure {  
    service {  
        vpls "VPLS-4" {  
            admin-state enable  
            service-id 4  
            customer "1"  
            bgp 1 {  
                route-distinguisher "65536:4"  
                route-target {  
                    export "target:65536:4"  
                    import "target:65536:4"  
                }  
                pw-template-binding "PW3" {  
                    split-horizon-group "vpls-shg"  
                    import-rt ["target:65536:4"]  
                }  
            }  
        }  
        bgp-ad {  
            admin-state enable  
            vpls-id "65536:4"  
        }  
    }  
}
```

```

vsi-id-prefix 192.0.2.3
}
sap 1/1/4:4.0 {
}

```

The following output shows that the service and its objects are operationally up on PE-1.

```

Conclusion

BGP-AD coupled with LDP pseudowire signaling allows the delivery of L2-VPN services to customers where BGP is commonly used. This example shows the configuration of BGP-AD together with the associated show outputs which can be used for verification and troubleshooting.

LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP

This chapter provides information about LDP VPLS using BGP auto-discovery — prefer provisioned SDP.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. BGP Auto-Discovery (BGP-AD) based on RFC 6074 is supported in SR OS Release 6.0, and later. The **provisioned-sdp prefer** option is supported in SR OS Release 14.0.R1, and later.

Overview

As described in chapter [LDP VPLS Using BGP Auto-Discovery](#), BGP-AD based on RFC 6074 can auto-create SDP bindings, but an operator can force the system to use a provisioned SDP by specifying the **provisioned-sdp use** option. This chapter compares the **provisioned-sdp use** option with the **provisioned-sdp prefer** option. The chapter describes a migration scenario for a VPLS service with a pseudowire (PW) template binding, restricted to using provisioned SDPs toward a PW template binding preferring to use provisioned SDPs, but auto-creating SDPs in case there is no suitable manually created SDP available.

PW templates

PW templates can be configured with the following command:

```
[ex:/configure service]
A:admin@PE-1# pw-template "PW 1" ?

pw-template

Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

When provisioned SDPs are to be used, the **provisioned-sdp** context must be configured:

```
*[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# provisioned-sdp ?

provisioned-sdp <keyword>
<keyword> - (use|prefer)

'provisioned-sdp' is: immutable
```

Provisioned SDP type

Warning: Modifying this element recreates 'configure service pw-template "PW 1"' automatically for the new value to take effect.

- When the **provisioned-sdp use** option is configured, the tunnel manager is forced to look for a provisioned and active SDP to the far-end PE. The far-end PE is auto-discovered from the BGP next hop. If multiple SDPs are active to this far-end PE, the tunnel manager chooses the SDP template with the best metric. If there is a tie, the SDP ID is used as a tie-breaker and the highest SDP ID wins. However, if no provisioned SDP exists, the SDP binding will not be instantiated.
- When the **provisioned-sdp prefer** option is configured, the behavior is the same when a provisioned SDP exists. When the tunnel manager finds an existing matching SDP, it will use it even if it is operationally down. Only when no provisioned SDP exists, will the SDP binding be auto-created.
- When a PW template is configured without the **provisioned-sdp use** or **provisioned-sdp prefer** option, the SDP bindings will be auto-created.

Figure 195: LDP VPLS using BGP-AD with **provisioned-sdp use** option shows the following use case: the metro Ethernet networks were initially built with provisioned SDPs. Intra-metro services are provisioned using provisioned SDPs; for example, customer X has a VPLS service defined in the metro Ethernet networks, using BGP-AD with a PW template to use the provisioned SDPs in the metro Ethernet networks.

Figure 195: LDP VPLS using BGP-AD with **provisioned-sdp use** option

26302

The service provider initially started with PE-10 and PE-11 in metro Ethernet 1, but now wants to add PE-20 and PE-30 as new sites to the VPLS service. Therefore, the BGP-AD routes should propagate beyond the boundaries of the metro Ethernet network. The backbone network may be in a different AS, but in this example, all networks are in the same AS. VPLS 1 of customer X can have sites added to the service on PEs in different metro Ethernet networks. A new PW template is configured with the **provisioned-sdp prefer** option and applied to the VPLS service.

- When a new site within the metro Ethernet network is added, an SDP is already provisioned to this site and this SDP is used for the SDP binding in the VPLS.
- When a new site in a different metro Ethernet network is added, no SDP is available to the site in the remote metro Ethernet network and the SDP binding is auto-created.

Figure 196: LDP VPLS using BGP-AD with **provisioned-sdp prefer** option shows the SDP bindings in VPLS 1 between PE-10 and the other PEs. For simplicity, the SDP bindings between the other PEs are not shown.

Figure 196: LDP VPLS using BGP-AD with provisioned-sdp prefer option

When PW templates are in use, it is not possible to modify the **provisioned-sdp prefer** option to **provisioned-sdp use** and vice versa. To support migration from one PW template to another with minimal service impact, two PW templates can be applied in parallel, as shown in the [Configuration](#) section.

Configuration

Figure 197: Example topology shows the example topology. For simplicity, all nodes are in the same AS.

Figure 197: Example topology

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (or OSPF) on all interfaces
- MPLS and RSVP on all interfaces, except "int-P-4-P-6" and "int-P-5-P-6".
- LDP on all interfaces

BGP is configured on all PE routers for address family l2-vpn, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
```

```

router "Base" {
  autonomous-system 64496
  bgp {
    group "internal" {
      peer-as 64496
      family {
        l2-vpn true
      }
    }
    neighbor "192.0.2.6" {
      group "internal"
    }
  }
}

```

The BGP configuration on the route reflector (RR) P-6 is as follows:

```

# on P-6:
configure {
  router "Base" {
    autonomous-system 64496
    bgp {
      group "rr-internal" {
        peer-as 64496
        family {
          l2-vpn true
        }
        cluster {
          cluster-id 1.1.1.1
        }
      }
      neighbor "192.0.2.1" {
        group "rr-internal"
      }
      neighbor "192.0.2.2" {
        group "rr-internal"
      }
      neighbor "192.0.2.3" {
        group "rr-internal"
      }
    }
  }
}

```

On PE-1 and PE-2 in metro Ethernet network 1, an RSVP LSP is created that is used in a manually created SDP. The LSP configuration on PE-1 is as follows:

```

# on PE-1:
configure {
  router "Base" {
    mpls {
      admin-state enable
      path "loose" {
        admin-state enable
      }
    }
    lsp "LSP-PE-1-PE-2" {
      admin-state enable
      type p2p-rsvp
      to 192.0.2.2
      primary "loose" {
      }
    }
  }
}

```

On PE-1, SDP 12 is configured as follows:

```
# on PE-1:
configure {
  service {
    sdp 12 {
      admin-state enable
      description "SDP12 to 192.0.2.2"
      delivery-type mpls
      far-end {
        ip-address 192.0.2.2
      }
      lsp "LSP-PE-1-PE-2" { }
    }
  }
}
```

The configuration on PE-2 is similar.

LDP VPLS using AD without provisioned-sdp prefer option

Initially, the following two PW templates are configured on all PEs: PW template 1 has the **provisioned-sdp use** option and PW template 2 is configured without any option; therefore, SDP bindings will be auto-created.

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    pw-template "PW 1" {
      pw-template-id 1
      provisioned-sdp use
    }
    pw-template "PW 2" {
      pw-template-id 2
    }
  }
}
```

The following lists the PW templates configured on PE-1:

```
[/]
A:admin@PE-1# show service pw-template

=====
PW Template information
=====
PW Template Id      SDP                Last Update
-----
1                   Use-provisioned    04/01/2021 16:35:27

=====
```

On all PEs, two VPLS services are configured: VPLS 1 with BGP-AD PW template 1 and VPLS 2 with PW template 2, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      admin-state enable
      service-id 1
      customer "1"
    }
  }
}
```

```

    bgp 1 {
        route-distinguisher "64496:1"
        route-target {
            export "target:64496:1"
            import "target:64496:1"
        }
        pw-template-binding "PW 1" {
        }
    }
    bgp-ad {
        admin-state enable
        vpls-id "64496:1"
    }
    sap 1/2/1:1 {
    }
}
vpls "VPLS 2" {
    admin-state enable
    service-id 2
    customer "1"
    bgp 1 {
        route-distinguisher "64496:2"
        route-target {
            export "target:64496:2"
            import "target:64496:2"
        }
        pw-template-binding "PW 2" {
            import-rt ["target:64496:2"]
        }
    }
    bgp-ad {
        admin-state enable
        vpls-id "64496:2"
    }
    sap 1/2/1:2 {
    }
}
}

```

On PE-1, the following SDP bindings have been created:

```

[/]
A:admin@PE-1# show service sdp-using

=====
SDP Using
=====
SvcId      SdpId                Type   Far End                Opr   I.Label E.Label
State
-----
1          12:4294967295       BgpAd 192.0.2.2              Up    524280 524280
2          32766:4294967293    BgpAd 192.0.2.3              Up    524278 524280
2          32767:4294967294    BgpAd 192.0.2.2              Up    524279 524279
-----
Number of SDPs : 3
=====

```

The first SDP binding is created by BGP-AD in VPLS 1 and uses the configured SDP 12 with far-end PE-2; the other two SDP bindings have been auto-created by BGP-AD in VPLS 2 and have far-end PE-2 and PE-3.

The list of SDP bindings on PE-2 looks similar:

```
[/]
A:admin@PE-2# show service sdp-using

=====
SDP Using
=====
SvcId      SdpId                Type  Far End                Opr  I.Label E.Label

-----
=====
```

Log "99" on PE-3 shows that the system failed to create a dynamic BGP-L2VPN SDP binding because no provisioned SDP was found, as follows:

```
69 2021/04/01 16:36:44.405 CEST MAJOR: SVCMGR #2322 Base
"The system failed to create a dynamic bgp-l2vpn SDP Bind in service 1 with SDP pw-template
policy 1 for the following reason: suitable manual SDP not found."
```

[Figure 198: SDP bindings in VPLS 1 with provisioned-sdp use option](#) shows the SDPs used in VPLS 1. PE-1 and PE-2 both used the provisioned SDP. PE-3 has no SDP bindings in VPLS 1.

Figure 198: SDP bindings in VPLS 1 with provisioned-sdp use option

26305

Figure 199: Auto-created SDP bindings in VPLS 2 shows the auto-created SDP bindings in VPLS 2. Each PE has two auto-created SDP bindings to each other PE.

Figure 199: Auto-created SDP bindings in VPLS 2

26306

Migrate VPLS 1 to provisioned-sdp prefer option

VPLS 1 uses PW template 1 with the **provisioned-sdp use** option. This option cannot be modified when the PW template is in use, as follows:

```
[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# provisioned-sdp prefer

*[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# commit
MINOR: SVCMGR #5609: configure service vpls "VPLS 1" bgp 1 pw-template-binding "PW 1" - PW
Template is in use
```

The following steps are needed to migrate to another PW template with the **provisioned-sdp prefer** option without service outage:

1. Configure new PW template with **provisioned-sdp prefer** option.
2. Add new PW template binding to VPLS and verify which PW template is used.
3. Modify old PW template binding to make it not usable.
4. Launch tools command to re-evaluate old PW template in the VPLS.
5. When the old PW template is not used anymore, remove PW template binding from the VPLS configuration.

A new PW template with the provisioned-sdp prefer option is configured on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    pw-template "PW 10" {
      pw-template-id 10
      provisioned-sdp prefer
    }
  }
}
```

An additional PW template binding is configured in VPLS 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      bgp 1 {
        pw-template-binding "PW 10" {
        }
      }
    }
  }
}
```

The configuration of VPLS 1 includes two PW template bindings, as follows:

```
[ex:/configure service vpls "VPLS 1"]
A:admin@PE-1# info
  admin-state enable
  service-id 1
  customer "1"
  bgp 1 {
    route-distinguisher "64496:1"
    route-target {
      export "target:64496:1"
      import "target:64496:1"
    }
    pw-template-binding "PW 1" {
    }
    pw-template-binding "PW 10" {
    }
  }
  bgp-ad {
    admin-state enable
    vpls-id "64496:1"
  }
  sap 1/2/1:1 {
  }
```

The following shows that no additional SDP bindings have been created. The only SDP binding in VPLS 1 on PE-1 uses the provisioned SDP 12.

```
[/]
A:admin@PE-1# show service id 1 sdp

=====
Services: Service Destination Points
=====
SdpId          Type      Far End addr  Adm   Opr    I.Lbl  E.Lbl
-----
12:4294967295  BgpAd    192.0.2.2    Up    Up     524280 524280
-----
Number of SDPs : 1
-----
=====
```

The following shows that PW template 1 was used for the creation of the SDP binding:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id          : 12:4294967295          Type           : BgpAd
PW-Template Id : 1
```

The PW template 10 has a higher ID than PW template 1 and is not used. Re-evaluating the PW template binding for PW template 1 in VPLS 1 will make no difference if both PW templates are usable. However, PW template 1 can be made unusable by adding a dummy **import-rt** not matching any route in the VPLS, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      bgp 1 {
        pw-template-binding "PW 1" {
          import-rt "target:111:111"
        }
      }
    }
  }
}
```

As a result, PW template 10 with the **provisioned-sdp prefer** option is used for the automatic creation of SDP bindings where no provisioned SDP is available, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp

=====
Services: Service Destination Points
=====
SdpId          Type      Far End addr  Adm   Opr    I.Lbl  E.Lbl
-----
12:4294967295  BgpAd    192.0.2.2    Up    Up     524280 524280
32766:4294967292 BgpAd    192.0.2.3    Up    Up     524277 524279
-----
Number of SDPs : 2
-----
=====
```

For the first SDP binding, PW template 1 is used, and for the second SDP binding, PW template 10 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id      : 12:4294967295      Type      : BgpAd
PW-Template Id : 1
SDP Id      : 32766:4294967292   Type      : BgpAd
PW-Template Id : 10
```

The following command forces the system to re-evaluate PW template 1 in VPLS 1:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1 12:4294967295 Policy 1
```

As a result, only PW template 10 is used for the creation of SDP bindings in VPLS 1, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id      : 12:4294967291      Type      : BgpAd
PW-Template Id : 10
SDP Id      : 32766:4294967292   Type      : BgpAd
PW-Template Id : 10
```

PW template 1 is not used anymore and can be removed from the VPLS configuration, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
  service {
    vpls "VPLS 1" {
      bgp 1 {
        delete pw-template-binding "PW 1" {
        }
      }
    }
  }
}
```

The configuration of VPLS 1 on PE-1 contains only a PW template binding for PW template 10, as follows:

```
[ex:/configure service vpls "VPLS 1" bgp 1]
A:admin@PE-1# info
route-distinguisher "64496:1"
route-target {
  export "target:64496:1"
  import "target:64496:1"
}
pw-template-binding "PW 10" {
}
```

Figure 200: SDP bindings in VPLS 1 with provisioned-sdp prefer option shows the SDP bindings in VPLS 1 with the **provisioned-sdp prefer** option. Within metro Ethernet network 1, the provisioned SDP is used, and between metro Ethernet networks, auto-created SDP bindings are used.

Figure 200: SDP bindings in VPLS 1 with provisioned-sdp prefer option

26306

Conclusion

LDP VPLS using BGP-AD allows the creation of SDP bindings that are either auto-created or that use provisioned SDPs. When the **provisioned-sdp prefer** option is used, the tunnel manager will look for a provisioned and active SDP to the far end and use it, if available, even if it is down. When no provisioned SDP is available, the system will auto-create an SDP binding.

Mobility for EVPN Hosts Within an R-VPLS

This chapter provides information about Mobility for EVPN Hosts Within an R-VPLS.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R2. Efficient EVPN host mobility without tromboning or hairpinning in an R-VPLS is supported for IPv4 in SR OS Release 19.10.R3 and later and is supported for IPv6 in SR OS Release 20.5.R1 and later.

Overview

SR OS can populate a VPRN route table with host routes learned from the IPv4 Address Resolution Protocol (ARP) messages or IPv6 Neighbor Discovery (ND) protocol messages. The host routes can be advertised in the VPRN context as IP-VPN or EVPN route type 5 (RT5), to be used by an IP-VPN or EVPN core network for inter-subnet forwarding. SR OS supports *draft-ietf-bess-evpn-inter-subnet-forwarding* for a dynamic and efficient routing between remote hosts, avoiding hairpinning.

In SR OS releases earlier than Release 19.10.R3, inefficient hairpinning situations may occur when the VPRN is configured to advertise IPv4 host routes as IP-VPN or EVPN RT5 routes. [Figure 201: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3](#) shows hairpinning in an EVPN broadcast domain with PE-1, PE-2, and PE-3.

Figure 201: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3

37332

When host-100 comes up, it sends a Gratuitous Address Resolution Protocol (GARP) message that is then learned on PE-2 and PE-3. PE-2 and PE-3 are configured to advertise host routes, so they generate an RT5 host route for prefix 10.0.0.100/32 of host-100. PE-3 selects its best RT5 for 10.0.0.100/32 and traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-4, and PE-6. However, when the active path between PE-4 and PE-6 fails, the standby path between PE-5 and PE-6 takes over and hairpinning occurs when PE-1 continues selecting PE-2 as the next hop, while a more efficient path is possible via next-hop PE-3. Traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-3, PE-5, and PE-6.

In SR OS Release 19.10.R3 and later, the more efficient path from host-191 via PE-1, PE-3, PE-5, and PE-6 to host-100 is used, as shown in [Figure 202: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later](#).

Figure 202: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later

37333

In SR OS Release 19.10.R3 and later, EVPN host mobility is supported for IPv4 as described in section "Symmetric and Asymmetric IRB" of *draft-ietf-bess-evpn-inter-subnet-forwarding*. When a host moves from a source PE to a target PE in the same broadcast domain, the behavior for IPv4 hosts is one of the following.

1. The host initiates an ARP request or GARP.
2. The host sends a data packet without first initiating an ARP request or GARP.
3. The host does not send any traffic and the source PE generates an ARP request when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-100 from source PE-2 to target PE-3 is simulated.

For the first of these scenarios, the VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    vprn "ip-vrf-16" {
      admin-state enable
      service-id 16
      customer "1"
      interface "evi-15" {
        mac 00:00:00:00:00:02
        vpls "sbd-15" {
          evpn-tunnel {
          }
        }
      }
    }
  }
}
```

```

interface "evi-17" {
  mac 00:00:00:00:2f:17
  ipv4 {
    primary {
      address 10.0.0.2
      prefix-length 24
    }
    neighbor-discovery {
      timeout 300
      learn-unsolicited true
      proactive-refresh true
      local-proxy-arp true
      host-route {
        populate dynamic {
        }
      }
    }
  }
  vrrp 1 {
    backup [10.0.0.254]
    passive true
    ping-reply true
    traceroute-reply true
  }
}
vpls "evi-17" {
  evpn {
    arp {
      learn-dynamic false
      flood-garp-and-unknown-req false
      advertise dynamic {
      }
    }
  }
}
}
}

```

For IPv4, the behavior is controlled by the following commands.

- **ipv4>neighbor-discovery>host-route>populate [dynamic | evpn | static]** configures PE-2 to advertise host routes. The type of ARP entry that can create a host route can be dynamic, EVPN, static, or a combination of these.
- **ipv4>neighbor-discovery>learn-unsolicited** triggers the learning of an ARP entry upon receiving an ARP or GARP message that was not requested by the router.
- **ipv4>neighbor-discovery>proactive-refresh** triggers the refresh of the ARP entry 30 seconds before aging out.
- **ipv4>neighbor-discovery>local-proxy-arp** ensures that PE-2 replies to any received ARP request on behalf of the other hosts in the R-VPLS broadcast domain.
- **vpls>evpn>arp>learn-dynamic** controls whether data path ARP messages received on EVPN connections can populate the ARP tables.
- **vpls>evpn>arp>flood-garp-and-unknown-req** controls the flooding of Control Processing Module (CPM)-generated ARP requests to EVPN destinations.
- **vpls>evpn>arp>advertise [dynamic | static]** enables PE-2 to advertise MAC and IP in EVPN-MAC routes for ARP entries of the dynamic or static type.

For IPv6, the corresponding commands are as follows:

- **ipv6>neighbor-discovery>host-route>populate [dynamic | evpn | static]**

- `ipv6>neighbor-discovery>learn-unsolicited [global | link-local | both]`
- `ipv6>neighbor-discovery>proactive-refresh [global | link-local | both]` triggers the refresh of the ND entry upon aging out.
- `ipv6>neighbor-discovery>local-proxy-nd`
- `vpls>evpn>nd>learn-dynamic`
- `vpls>evpn>nd>advertise [dynamic | static]`

For IPv6, CPM-generated Neighbor Solicitation (NS) messages are always flooded to EVPN destinations. This is not configurable in the `vpls>evpn>nd` context of the VPRN service, in contrast to the `flood-garp-and-unknown-req` command in the `vpls>evpn>arp` context for IPv4.

The behavior for IPv6 hosts when moving from a source PE to a target PE is one of the following.

1. The host initiates an unsolicited Neighbor Advertisement (NA).
2. The host sends traffic, without first initiating NA or NS messages.
3. The host does not send any traffic, and the source PE generates an NS message when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-66 from source PE-2 to target PE-3 is simulated.

Configuration

[Figure 203: Example topology with system IP addresses](#) shows the example topology with PE-1, PE-2, and PE-3 in an EVPN-MPLS network and PE-4, PE-5, and PE-6 in an MPLS network.

Figure 203: Example topology with system IP addresses

37334

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- LDP between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- BGP configured for the EVPN address family on PE-1, PE-2, and PE-3

On PE-1, BGP is configured as follows:

```
# on PE-1:
configure {
  router "Base" {
    autonomous-system 64500
    bgp {
      vpn-apply-export true
      vpn-apply-import true
      rapid-withdrawal true
      family {
        ipv4 false
        evpn true
      }
      rapid-update {
        evpn true
      }
      group "dc" {
        type internal
      }
      neighbor "192.0.2.2" {
        group "dc"
      }
      neighbor "192.0.2.3" {
        group "dc"
      }
    }
  }
}
```

The BGP configuration is similar on PE-2 and PE-3.

IPv4 host mobility

The following use cases for IPv4 host mobility are described:

1. Host initiates ARP request or GARP after moving
2. Host initiates non-ARP traffic after moving
3. Host does not send any traffic after moving

IPv4 host mobility case 1: host initiates ARP request or GARP after moving

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  service {
    vpls "sbd-15" {
      admin-state enable
      description "R-VPLS 15"
      service-id 15
      customer "1"
      routed-vpls {
      }
      bgp 1 {
        route-distinguisher "192.0.2.1:15"
      }
      bgp-evpn {
        evi 15
      }
    }
  }
}
```

```

        routes {
            ip-prefix {
                advertise true
            }
        }
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
vprn "ip-vrf-16" {
    admin-state enable
    service-id 16
    customer "1"
    interface "evi-15" {
        mac 00:00:00:00:00:01
        vpls "sbd-15" {
            evpn-tunnel {
            }
        }
    }
    interface "evi-20" {
        mac 00:00:00:00:1e:20
        ipv4 {
            primary {
                address 10.0.20.1
                prefix-length 24
            }
        }
        vpls "evi-20" {
        }
    }
}
vpls "evi-20" {
    admin-state enable
    description "R-VPLS 20"
    service-id 20
    customer "1"
    routed-vpls {
    }
    sap pxc-10.a:20 {
    }
}
}

```

VPRN "ip-vrf-16" has two interfaces: interface "evi-15" toward R-VPLS "sbd-15" and interface "evi-20" toward R-VPLS "evi-20". Host-191 is connected to interface "evi-20" of R-VPLS "evi-20".

PE-2 and PE-3 are configured with an anycast gateway, that is, a VRRP passive instance with the same backup IP address 10.0.0.254 on interface "evi-17" in VPRN "ip-vrf-16". The MAC address under VRRP is by default derived from the Virtual Router ID (VRID), so both PE-2 and PE-3 get MAC address 00:00:5E:00:01:01. The service configuration on PE-2 and PE-3 is similar.

```

# on PE-2:
configure {
    service {
        vpls "evi-17" {
            admin-state enable
            description "R-VPLS 17"
            service-id 17
            customer "1"
        }
    }
}

```

```

    routed-vpls {
    }
    bgp 1 {
        route-distinguisher "192.0.2.2:17"          # on PE-3: 192.0.2.3:17
    }
    bgp-evpn {
        evi 17
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
    sap 1/1/1:17 {                                  # on PE-3: sap 1/1/2:17
    }
}
vpls "sbd-15" {
    admin-state enable
    description "R-VPLS 15"
    service-id 15
    customer "1"
    routed-vpls {
    }
    bgp 1 {
        route-distinguisher "192.0.2.2:15"        # on PE-3: 192.0.2.3:15
    }
    bgp-evpn {
        evi 15
        routes {
            ip-prefix {
                advertise true
            }
        }
        mpls 1 {
            admin-state enable
            auto-bind-tunnel {
                resolution any
            }
        }
    }
}
}
vprn "ip-vrf-16" {
    admin-state enable
    service-id 16
    customer "1"
    interface "evi-15" {
        mac 00:00:00:00:00:02                      # on PE-3: 00:00:00:00:00:03
        vpls "sbd-15" {
            evpn-tunnel {
            }
        }
    }
    interface "evi-17" {
        mac 00:00:00:00:2f:17                      # on PE-3: 00:00:00:00:3f:17
        ipv4 {
            primary {
                address 10.0.0.2                    # on PE-3: 10.0.0.3
                prefix-length 24
            }
        }
        neighbor-discovery {
            timeout 300
            learn-unsolicited true
            proactive-refresh true
        }
    }
}

```

```
        local-proxy-arp true
        host-route {
            populate dynamic {
            }
        }
    }
    vrrp 1 {
        backup [10.0.0.254]           # anycast IP address on PE-2, PE-3
        passive true
        ping-reply true
        traceroute-reply true
    }
}
vpls "evi-17" {
    evpn {
        arp {
            learn-dynamic false
            flood-garp-and-unknown-req false
            advertise dynamic {
            }
        }
    }
}
}
```

The `ipv4>neighbor-discovery>host-route>populate dynamic` ensures that route-table ARP-ND host routes are created for dynamic entries, not for static or EVPN entries. The `learn-dynamic false` command prevents PE-2 and PE-3 from learning ARP entries from ARP messages received on an EVPN destination. The `flood-garp-and-unknown-req false` command suppresses CPM-generated ARP to reduce unnecessary ARP flooding.

In this sample topology, an Epipe is used where a failover from the primary to the secondary path simulates a move of host-100 from PE-2 to PE-3. SAP 1/1/1:17 in R-VPLS "evi-17" on PE-2 is connected to a SAP of Epipe 17 on PE-4; SAP 1/1/2:17 in R-VPLS "evi-17" on PE-3 to a SAP of Epipe 17 on PE-5. The service configuration on PE-4 is as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure {
    service {
        oper-group "op-grp-1" {
        }
    }
    epipe "Epipe 17" {
        admin-state enable
        service-id 17
        customer "1"
        spoke-sdp 46:17 {
            oper-group "op-grp-1"
        }
        sap 1/1/2:17 {
            description "SAP connected to SAP 1/1/1:17 on PE-2"
            monitor-oper-group "op-grp-1"
        }
    }
    sdp 46 {
        admin-state enable
        delivery-type mpls
        ldp true
        far-end {
            ip-address 192.0.2.6
        }
    }
}
```

```
}
```

On PE-6, the service configuration is as follows:

```
# on PE-6:
configure {
  service {
    epipe "Epipe 17" {
      admin-state enable
      service-id 17
      customer "1"
      endpoint "EP17" {
      }
      spoke-sdp 64:17 {
        endpoint {
          name "EP17"
          precedence primary
        }
      }
      spoke-sdp 65:17 {
        endpoint {
          name "EP17"
        }
      }
      sap 1/2/1:17 {
      }
    }
    sdp 64 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.4
      }
    }
    sdp 65 {
      admin-state enable
      delivery-type mpls
      ldp true
      far-end {
        ip-address 192.0.2.5
      }
    }
  }
}
```

Host-100 is connected to SAP 1/2/1:17 in Epipe 17.

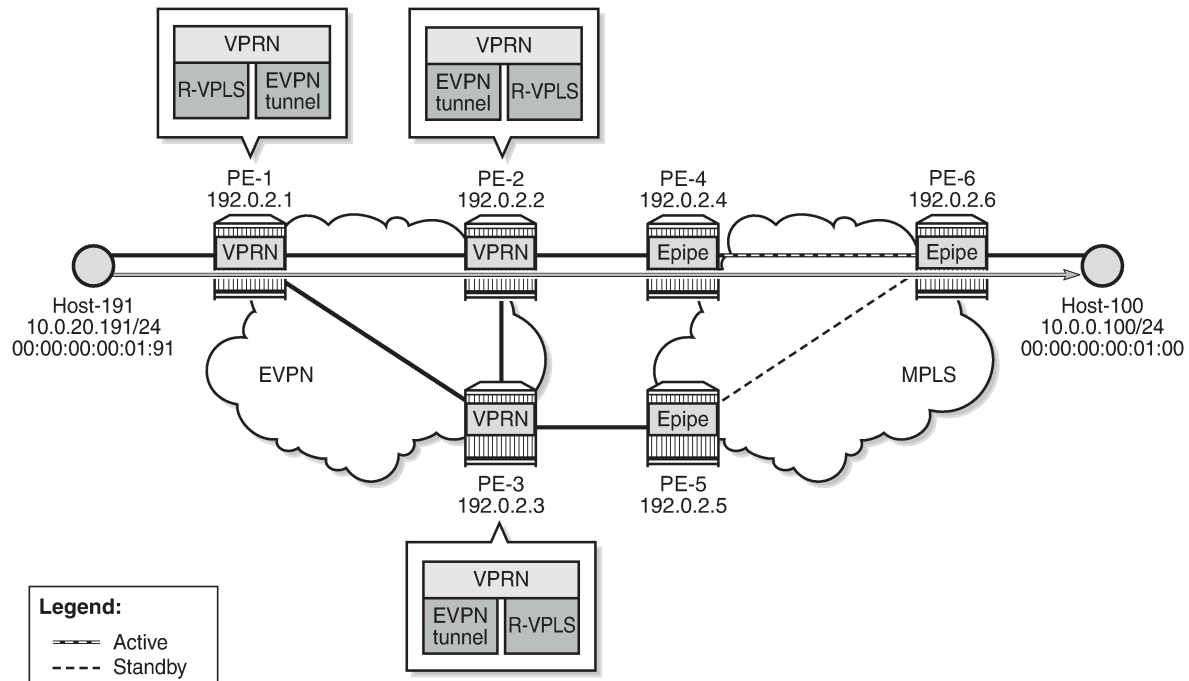

On PE-2 and PE-3, debugging is enabled (in classic CLI):

```
# on PE-2, PE-3:
debug
  router "Base"
    bgp
      update
    exit
  exit
  router service-name "ip-vrf-16"
    ip
      arp
      route-table
    exit
  exit
exit
```

Initial phase

Figure 204: Initial situation with forwarding path via PE-2 shows that traffic from host-191 to host-100 is forwarded via PE-1, PE-2, PE-4, and PE-6.

Figure 204: Initial situation with forwarding path via PE-2

37335

Host-191 sends a traceroute to host-100 via PE-2 (10.0.0.2):

```
[/]
A:admin@PE-1# traceroute 10.0.0.100 router-instance "H-191" source-address 10.0.20.191
traceroute to 10.0.0.100 from 10.0.20.191, 30 hops max, 40 byte packets
 1 10.0.20.1 (10.0.20.1) 3.96 ms 2.27 ms 2.07 ms
 2 10.0.0.2 (10.0.0.2) 2.96 ms 2.95 ms 2.82 ms
 3 10.0.0.100 (10.0.0.100) 10.9 ms 5.54 ms 5.07 ms
```

The ARP table for VPRN "ip-vrf-16" on PE-2 shows that IP address 10.0.0.100 corresponds to MAC address 00:00:00:00:01:00 and is learned dynamically:

```
[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

=====
ARP Table (Service: 16)
=====
IP Address      MAC Address      Expiry      Type      Interface
-----
10.0.0.100     00:00:00:00:01:00 00h04m49s  Dyn[I]  evi-17
=====
```

The ARP table for VPRN "ip-vrf-16" on PE-3 shows that IP address 10.0.0.100 is advertised through EVPN:

```
[/]
A:admin@PE-3# show router 16 arp 10.0.0.100

=====
ARP Table (Service: 16)
=====
IP Address      MAC Address      Expiry      Type      Interface

       L = LFA nexthop available
       S = Sticky ECMP requested
=====
```

PE-3 receives the IP and MAC addresses of host-100 as EVPN type. PE-3 must not learn these IP and MAC addresses as dynamic because PE-3 must be prevented from advertising an RT5 route. If PE-3 advertised prefix 10.0.0.100, then PE-1 could select PE-3 as next hop to reach host-100, causing an undesired hairpinning forwarding behavior.

Host-100 sends an ARP request or GARP after moving

[Figure 205: Host-100 sends an ARP request or GARP after switchover](#) shows a switchover from the active to the standby path where host-100 sends an ARP request or GARP and its IP and MAC addresses are learned on PE-3 instead of PE-2. The failure is simulated by disabling the SDP from PE-4 to PE-6.

Figure 205: Host-100 sends an ARP request or GARP after switchover

37336

Due to the SDP failure on PE-4, the initial path can no longer be used. Host-100 sends an ARP request or GARP with its IP and MAC addresses. In the following example, PE-3 receives the following ARP request and replies to it:

```

1 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP ingressing on evi-17
  Who has 10.0.0.254 ? Tell 10.0.0.100
"
2 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP

ARP egressing on evi-17
  10.0.0.254 is at 00:00:5e:00:01:01
"

```

The Route Table Manager (RTM) for prefix 10.0.0.100 in VPRN "ip-vrf-16" is modified with preference 1 and owner ARP-ND. This behavior is due to the `ipv4>neighbor-discovery>host-route>populate dynamic` command.

```

3 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP

=====

```

On PE-3, the ARP table for VPRN "ip-vrf-16" shows that IP address 10.0.0.100 is learned dynamically on interface "evi-17":

```

[/]
A:admin@PE-3# show router 16 arp 10.0.0.100

=====
ARP Table (Service: 16)
=====
IP Address      MAC Address      Expiry      Type      Interface
-----
10.0.0.100     00:00:00:00:01:00 00h04m40s  Dyn[I]   evi-17
=====

```

On PE-2, the ARP table for VPRN "ip-vrf-16" shows that the entry for IP address 10.0.0.100 is updated from dynamic to type EVPN:

```

[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

=====
ARP Table (Service: 16)
=====
IP Address      MAC Address      Expiry      Type      Interface
-----
10.0.0.100     00:00:00:00:01:00 00h00m00s  Evp[I]   evi-17
=====

```

An ARP entry's change from dynamic to EVPN triggers a CPM-generated ARP request from PE-2, but the configured **flood-garp-and-unknown-req false** command prevents PE-2 from flooding the ARP request to EVPN destinations such as PE-3.

On PE-3, the route table for VPRN "ip-vrf-16" shows an ARP-ND host route for prefix 10.0.0.100:

```

[/]

```

```
A:admin@PE-3# show router 16 route-table 10.0.0.100

=====
Route Table (Service: 16)
=====

  evi-15 (ET-00:00:00:00:00:03)        0
-----
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
=====
```

IPv4 host mobility case 2: host sends traffic without first initiating an ARP request or GARP after moving

In use cases 2 and 3, the configuration of VPRN "ip-vrf-16" is modified on PE-2 and PE-3. The only difference from case 1 is that the **flood-garp-and-unknown-req** is configured, which is the default setting. The VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
  service {
    vprn "ip-vrf-16" {
      admin-state enable
      service-id 16
      customer "1"
      interface "evi-15" {
        mac 00:00:00:00:00:02
        vpls "sbd-15" {
          evpn-tunnel {
          }
        }
      }
    }
  }
}
```

```

    }
  }
  interface "evi-17" {
    mac 00:00:00:00:2f:17
    ipv4 {
      primary {
        address 10.0.0.2
        prefix-length 24
      }
      neighbor-discovery {
        timeout 300
        learn-unsolicited true
        proactive-refresh true
        local-proxy-arp true
        host-route {
          populate dynamic {
          }
        }
      }
    }
    vrrp 1 {
      backup [10.0.0.254]
      passive true
      ping-reply true
      traceroute-reply true
    }
  }
  vpls "evi-17" {
    evpn {
      arp {
        learn-dynamic false
        flood-garp-and-unknown-req true # default behavior
        advertise dynamic {
        }
      }
    }
  }
}

```

Initial forwarding path

The initial forwarding path via PE-2 is restored by enabling the SDP from PE-4 to PE-6. The route table for VPRN "ip-vrf-16" on PE-2 shows the following ARP-ND host route for prefix 10.0.0.100/32:

```

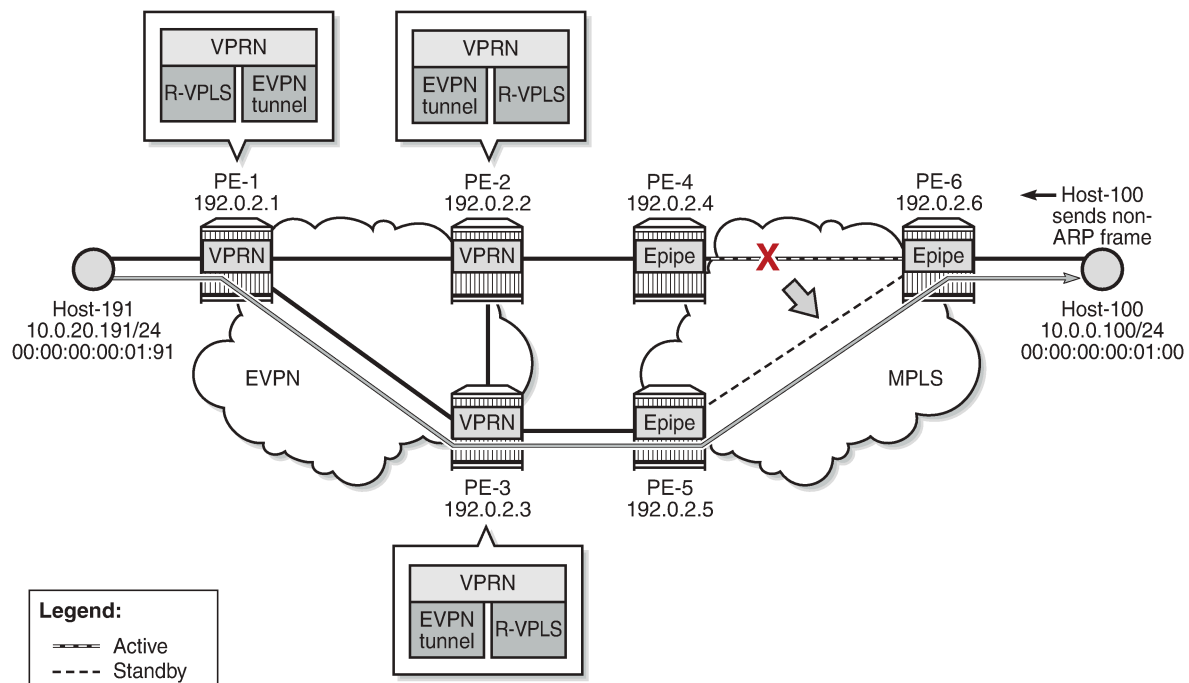

[/]
A:admin@PE-2# show router 16 route-table 10.0.0.100
=====
Route Table (Service: 16)
=====
Dest Prefix[Flags]                Type   Proto   Age           Pref
  Next Hop[Interface Name]                Metric
-----
10.0.0.100/32                      Remote ARP-ND  00h03m46s  1
  10.0.0.100                          0
-----
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested

```

Host-100 generates non-ARP traffic after moving

On PE-4, the SDP from PE-4 to PE-6 is disabled, causing a switchover to the standby path. [Figure 206: Host sends non-ARP frame after switchover](#) shows the path after switchover. Host-100 generates non-ARP traffic after moving.

Figure 206: Host sends non-ARP frame after switchover

37337

Host-100 sends a non-ARP frame with MAC source address 00:00:00:00:01:00 to host-191. The following steps occur:

1. PE-3 receives this frame with MAC 00:00:00:00:01:00 and updates its FDB.
2. PE-3 advertises an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address) with a higher sequence number.
3. PE-2 receives this EVPN MAC route, updates its FDB and withdraws its EVPN-MAC routes for MAC 00:00:00:00:01:00.
4. The FDB update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for MAC 00:00:00:00:01:00.
5. PE-2 is configured with **flood-garp-and-unknown-req**, so the ARP request is flooded to the EVPN destinations PE-1 and PE-3. PE-3 floods this ARP request to its SAPs and SDP-bindings; in this case, to SAP 1/1/2:17.
6. When the ARP request reaches host-100, it sends an ARP reply to the anycast IP address 10.0.0.254. This ARP reply is received by PE-3.

7. When PE-3 receives the ARP reply, it updates the ARP entry for 10.0.0.100 to type dynamic instead of type EVPN.
8. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. Also, MAC 00:00:00:00:01:00 is now learned in ARP as local, so PE-3 sends an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100.
9. PE-2 receives the EVPN routes and updates the ARP entry for prefix 10.0.0.100 from type dynamic to type EVPN. PE-2 also removes its ARP-ND host route from the route table and withdraws its RT5 for prefix 10.0.0.100/32.

On PE-3, the route for prefix 10.0.0.100/32 is an ARP-ND host route:

```
[/]
A:admin@PE-3# show router 16 route-table 10.0.0.100

```

IPv4 host mobility case 3: host does not send any traffic after moving

The service configuration on PE-2 and PE-3 remains the same as in use case 2.

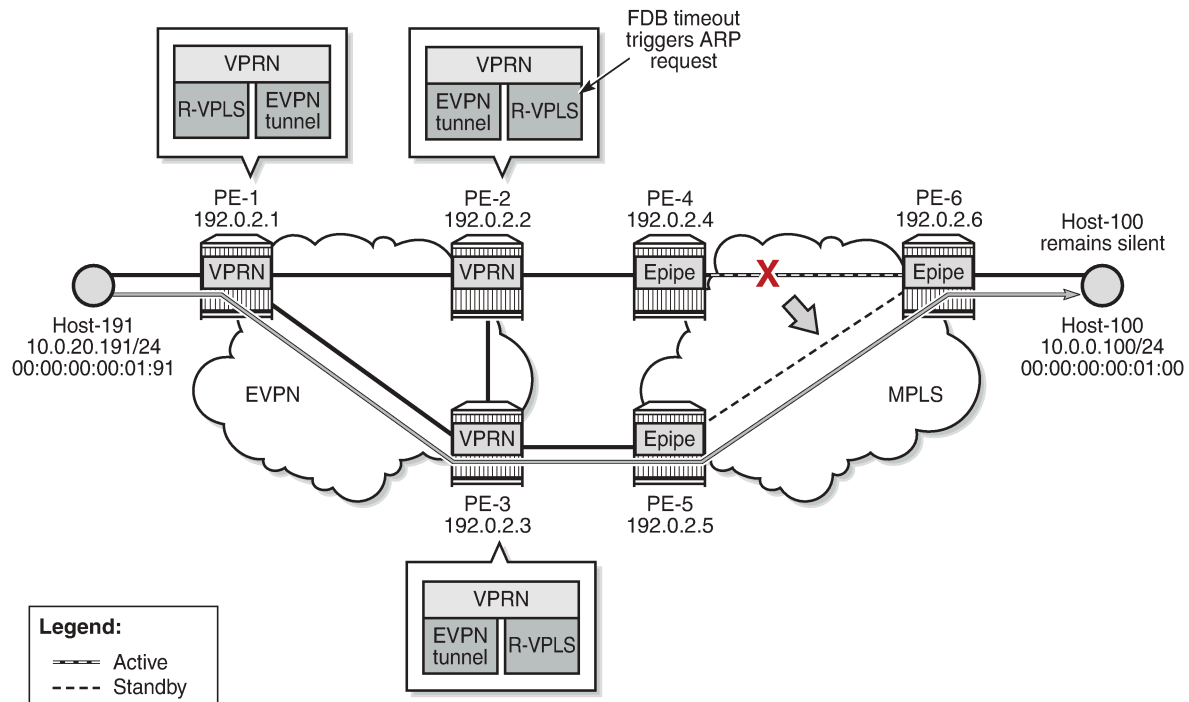

The forwarding path is restored by enabling the SDP from PE-4 to PE-6, so the initial situation is the same as in the preceding cases. PE-2 learns MAC address 00:00:00:00:01:00 on its local SAP 1/1/1:17, as follows:

```
[/]
A:admin@PE-2# show service id 17 fdb detail

=====
Forwarding Database, Service 17

```

The SDP from PE-4 to PE-6 is disabled and host-100 does not send any traffic, as shown in [Figure 207: Host does not send any traffic after switchover](#).

Figure 207: Host does not send any traffic after switchover

37338

The following steps occur:

1. When MAC 00:00:00:00:01:00 ages out in the FDB of R-VPLS 17 on PE-2, PE-2 withdraws the EVPN-MAC routes for MAC 00:00:00:00:01:00. The update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for 10.0.0.100.

```
# on PE-2:
99 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP egressing on evi-17
  Who has 10.0.0.100 ? Tell 10.0.0.254
"
```

```
101 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
Withdrawn Length = 0
Total Path Attr Length = 42

mac: 00:00:00:00:01:00, IP len: 0, IP: NULL, label: 0
```

"

2. PE-2 is configured with **flood-garp-and-unknown-req true**. PE-2 floods the CPM-generated ARP request to PE-3. PE-3 forwards the ARP request to host-100.
3. Host-100 sends an ARP reply that is received by PE-3. PE-3 updates its FDB and ARP tables.
4. The FDB update on PE-3 makes PE-3 advertise an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address). The ARP update makes PE-3 advertise an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100. PE-2 receives two EVPN-MAC routes from PE-3:

```
103 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

    target:64500:17
    bgp-tunnel-encap:MPLS
    mac-mobility:Seq:5
"
```

5. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. In the route table for VPRN "ip-vrf-16", the route for IP prefix 10.0.0.100/32 is ARP-ND host route. PE-2 receives the following RT5 route from PE-3:

```
102 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Received BGP UPDATE:
  Withdrawn Length = 0
  Total Path Attr Length = 90
  Flag: 0x90 Type: 14 Len: 45 Multiprotocol Reachable NLRI:
    Address Family EVPN
    NextHop len 4 NextHop 192.0.2.3
    Type: EVPN-IP-PREFIX Len: 34 RD: 192.0.2.3:15, tag: 0,
      ip_prefix: 10.0.0.100/32 gw_ip 0.0.0.0 Label: 8388544 (Raw Label: 0x7fffc0)
  Flag: 0x40 Type: 1 Len: 1 Origin: 0
  Flag: 0x40 Type: 2 Len: 0 AS Path:
  Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
  Flag: 0xc0 Type: 16 Len: 24 Extended Community:
    target:64500:15
    mac-nh:00:00:00:00:03
    bgp-tunnel-encap:MPLS
"
```

6. PE-2 receives the EVPN routes and updates its FDB and ARP tables. When the ARP entry changes its type from dynamic to EVPN, PE-2 withdraws its RT5 route.

On PE-2, the FDB for R-VPLS 17 shows an EVPN route for MAC 00:00:00:00:01:00:

[/]

IPv6 host mobility

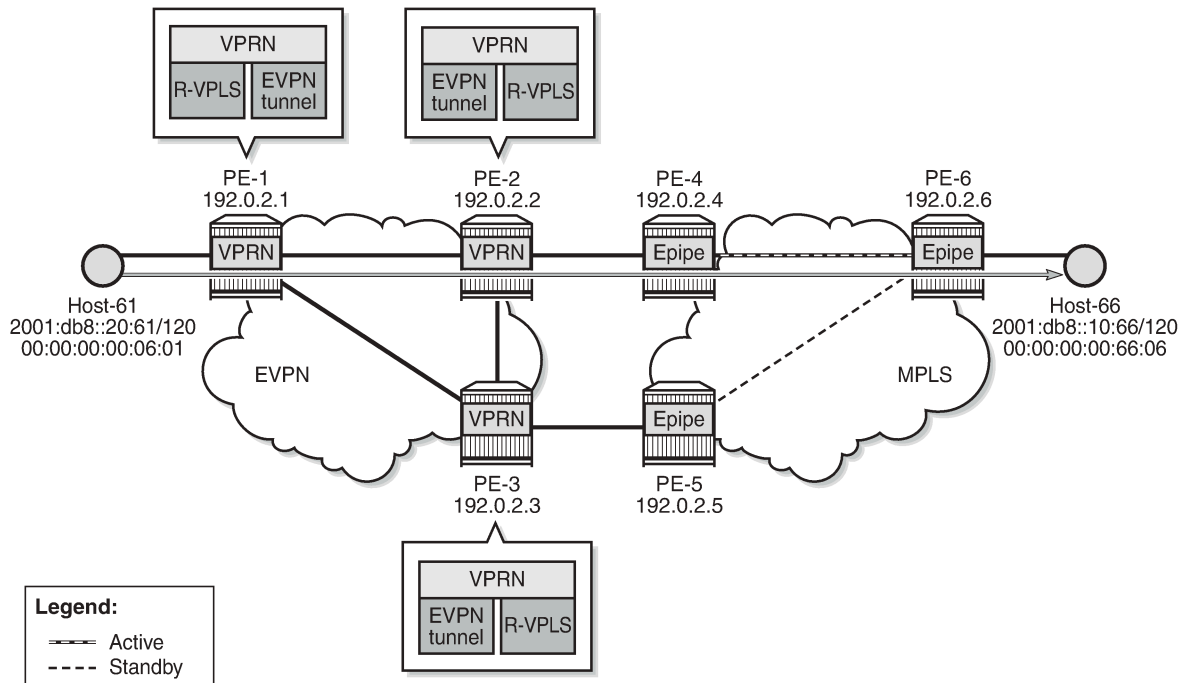

The following use cases for IPv6 host mobility are described:

1. Host initiates an unsolicited NA message after moving
2. Host sends non-ND traffic after moving
3. Host does not send any traffic after moving

The configuration is identical in these use cases.

[Figure 208: Example topology for initial forwarding path via PE-2 with IPv6 addresses](#) shows the topology with IPv6 addresses for host-61 and host-66.

Figure 208: Example topology for initial forwarding path via PE-2 with IPv6 addresses

37339

The services are the following:

- R-VPLS "sbd-5" on PE-1, PE-2, and PE-3
- VPRN "ip-vrf-6" on PE-1, PE-2, and PE-3
- R-VPLS "evi-10" on PE-1; R-VPLS "evi-7" on PE-2 and PE-3
- Epipe "Epipe 7" on PE-4, PE-5, and PE-6
- Host-61 is connected to R-VPLS "evi-10" on PE-1
- Host-66 is connected to Epipe "Epipe 7" on PE-6

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
  service {
    vpls "evi-10" {
      admin-state enable
      description "R-VPLS 10"
      service-id 10
      customer "1"
      routed-vpls {
      }
      sap pxc-10.a:10 {
      }
    }
    vpls "sbd-5" {
      admin-state enable
      description "R-VPLS 5"
      service-id 5
    }
  }
}
```

```

customer "1"
  routed-vpls {
  }
  bgp 1 {
    route-distinguisher "192.0.2.1:5"
  }
  bgp-evpn {
    evi 5
    routes {
      ip-prefix {
        advertise true
      }
    }
    mpls 1 {
      admin-state enable
      auto-bind-tunnel {
        resolution any
      }
    }
  }
}
vprn "ip-vrf-6" {
  admin-state enable
  service-id 6
  customer "1"
  interface "evi-10" {
    mac 00:00:00:06:1e:20
    vpls "evi-10" {
    }

  mpls 1 {
    admin-state enable
    auto-bind-tunnel {
      resolution any
    }
  }
}
sap 1/1/1:7 {                               # on PE-3: sap 1/1/2:7
}
}

```

Debugging is enabled on PE-2 and PE-3 (in classic CLI):

```

# on PE-2, PE-3:
debug
  router "Base"
    bgp
      update
    exit
  exit
  router service-name "ip-vrf-6"
    ip
      route-table
      icmp6 "evi-7"
      neighbor "evi-7"
    exit
  exit
exit

```

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```

[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
 1 2001:db8::10:2 (2001:db8::10:2)  1034 ms  2.80 ms  4.17 ms
 2  :: * * *
 3 2001:db8::20:61 (2001:db8::20:61)  11.1 ms  5.59 ms  4.95 ms

```

The following route table on PE-2 shows an ARP-ND host route for prefix 2001:db8::10:66/128:

```

[/]
A:admin@PE-2# show router 6 route-table 2001:db8::10:66

```

IPv6 host mobility case 1: host initiates an unsolicited NA message after moving

On PE-2 and PE-3, the **learn-unsolicited** command is configured on interface "evi-7" in VPRN "ip-vrf-6". When an unsolicited NA message is received, a stale neighbor is created. If **host-route>populate dynamic** is enabled, a confirmation message is sent for all the neighbor entries created as stale, and if confirmed, the corresponding ARP-ND routes are added to the route table.

Disabling SDP 46 on PE-4 causes a failover from the primary path via PE-4 to the secondary path via PE-5, simulating host-66 moving from PE-2 to PE-3. To trigger an unsolicited NA message from host-66, its MAC address 00:00:00:00:66:06 is replaced by MAC address 00:00:00:00:06:06. [Figure 209: Host-66 sends unsolicited NA message after switchover](#) shows that host-66 sends an unsolicited NA message.

Figure 209: Host-66 sends unsolicited NA message after switchover

37340

Host-66 advertises its new MAC address in unsolicited NA messages. PE-3 receives the following NA messages from host-66. PE-2 also receives the NA messages, but it rejects NA messages received on interface "evi-7" when **learn-dynamic false** is configured:

```

# on PE-3:
3 2022/01/28 13:19:55.747 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: ICMP6_PKT
    
```

```
ICMP6 ingressing on evi-7 (vprn6):
fe80::10:6 -> ff02::1
Type: Neighbor Advertisement (136)
Code: No Code (0)
  Tgt Addr: 2001:db8::10:66
  Flags   : Router Override
  Option  : Tgt Link Layer Addr 00:00:00:00:06:06
"
```

```
1 2022/01/28 13:19:55.747 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: ICMP6_PKT
ICMP6 ingressing on evi-7 (vprn6):
fe80::10:6 -> ff02::1
Type: Neighbor Advertisement (136)
Code: No Code (0)
  Tgt Addr: fe80::10:6
  Flags   : Router Override
  Option  : Tgt Link Layer Addr 00:00:00:00:06:06
"
```

PE-3 learns the MAC address dynamically:

```
[/]
A:admin@PE-3# show service id 7 fdb mac 00:00:00:00:06:06

=====
Forwarding Database, Service 7
=====
ServId    MAC                Source-Identifier    Type    Last Change
         Transport:Tnl-Id
-----
7         00:00:00:00:06:06  sap:1/1/2:7         L/90    01/28/22 13:19:56
-----
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
```

PE-3 sends CPM-generated NS messages that are also flooded to the EVPN destinations. The **learn-dynamic false** command prevents PE-2 from learning MAC addresses dynamically on an EVPN connection.

PE-3 sends an EVPN-MAC update to PE-2 and MAC address 00:00:00:00:06:06 appears in the FDB on PE-2 as an EVPN entry:

```
[/]

```

IPv6 host mobility case 2: host sends non-ND traffic after moving,

The service configuration is the same as in the use case 1. The only difference from use case 1 is the type of message that is sent by host-66 after moving.

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
 1 2001:db8::10:2 (2001:db8::10:2)  7.88 ms  3.85 ms  3.67 ms
 2  :: * * *
 3 2001:db8::20:61 (2001:db8::20:61) 11.0 ms  5.19 ms  5.30 ms
```

PE-3 advertises MAC address 00:00:00:00:06:06 from host-66 in three EVPN-MAC routes: one with the global IP address 2001:db8::10:66, one with the link local IP address fe80::200:ff:fe00:606, and one with a null IP address. PE-2 receives the following EVPN-MAC routes from PE-3:

```
# on PE-2:
59 2022/01/28 13:29:59.437 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

      S = Sticky ECMP requested
=====
```

IPv6 host mobility case 3: host does not send any traffic after moving

The service configuration is the same as use cases 1 and 2. SDP 46 is enabled on PE-4, so host-66 moves back to PE-2. The following traceroute shows that the forwarding path from host-66 to host-61 is via PE-2:

```
[/]
A:admin@PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
 1 2001:db8::10:2 (2001:db8::10:2)   3.76 ms 4.23 ms 4.00 ms
 2  :: * * *
```

```
3 2001:db8::20:61 (2001:db8::20:61) 5.89 ms 5.40 ms 5.61 ms
```

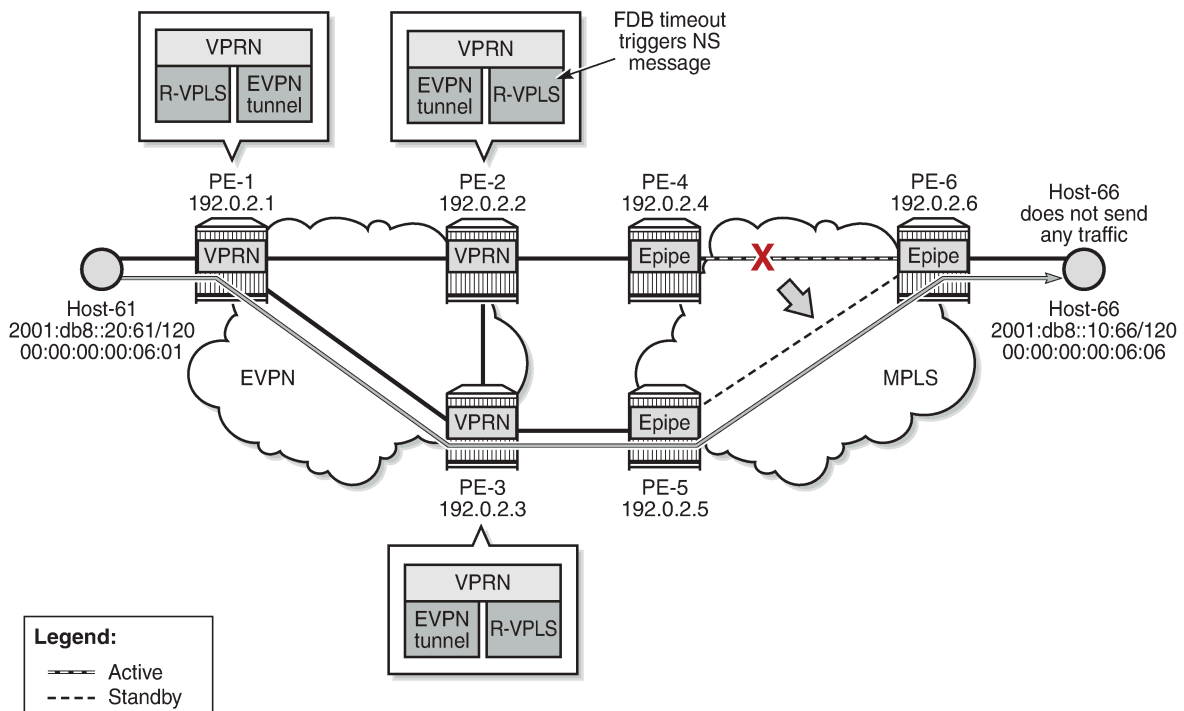

The FDB on PE-2 shows that MAC address 00:00:00:00:06:06 is learned on the local SAP 1/1/1:7, as follows:

```
[/]
A:admin@PE-2# show service id 7 fdb detail

=====
Forwarding Database, Service 7
=====
ServId   MAC                Source-Identifier   Type   Last Change
-----
7        00:00:00:00:06:06  sap:1/1/1:7        L/30   01/28/22 13:36:03

-----
No. of MAC Entries: 3
-----
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
```

A failure is simulated, causing a failover from the primary path via PE-4 to the secondary path via PE-5. Host-66 does not send any traffic after switchover. [Figure 211: Host does not send any traffic after switchover](#) shows that PE-2 sends an NS message when the FDB entry for host-66 ages out.

Figure 211: Host does not send any traffic after switchover

37342

On PE-2, MAC address 00:00:00:00:06:06 expires in the FDB for R-VPLS "evi-7", which triggers PE-2 to send an NS message for 2001:db8::10:66. This CPM-generated NS message is flooded to the EVPN destinations PE-1 and PE-3.

```
# on PE-2:
202 2022/01/28 13:37:34.634 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Sending NS for nbr addr 2001:db8::10:66 nbr type dynamic"
```

The NS message reaches host-66, which replies with an NA message. PE-3 receives the NA message and updates its FDB and ND tables. PE-2 also receives the NA message, but it rejects NA messages received on interface "evi-7" when no learn-dynamic is configured:

```
225 2022/01/28 13:37:34.638 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Ignore NA for target address 2001:db8::10:66 on evpn endpoint evi-7 because learn-dynamic is disabled."
```

PE-2 receives the following EVPN-MAC routes from PE-3:

```
237 2022/01/28 13:43:03.001 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

Conclusion

EVPN host mobility is supported in SR OS as described in draft-ietf-bess-evpn-inter-subnet-forwarding. This chapter describes several cases when a host moves from a source PE to a target PE within the same broadcast domain.

Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire

This chapter provides information about multi-chassis endpoint for VPLS active/standby pseudowire.

Topics in this chapter include:

- [Applicability](#)
- [Overview](#)
- [Configuration](#)
- [Conclusion](#)

Applicability

This chapter was initially written for SR OS Release 7.0.R6, but the MD-CLI in this edition is based on SR OS Release 23.7.R2.

Overview

When implementing a large VPLS, one of the limiting factors is the number of T-LDP sessions required for the full mesh of SDPs. Mesh-SDPs are required between all PEs participating in the VPLS with a full mesh of T-LDP sessions.

This solution is not scalable, because the number of sessions grows more rapidly than the number of participating PEs. Several options exist to reduce the number of T-LDP sessions required in a large VPLS.

The first option is hierarchical VPLS (H-VPLS) with spoke SDPs. By using spoke SDPs between two clouds of fully meshed PEs, any-to-any T-LDP sessions for all participating PEs are not required.

However, if spoke SDP redundancy is required, STP must be used to avoid a loop in the VPLS. Management VPLS can be used to reduce the number of STP instances and separate customer and STP traffic, as illustrated in [Figure 212: H-VPLS with STP](#).

Figure 212: H-VPLS with STP

OSSG432
