Preface

About This Guide

The Advanced Configuration Guide is divided into three volumes, the Part I Guide, the Part II Guide, and the Part III Guide.

- Part I provides advanced configurations for basic systems, system management, interface configuration, router configuration, unicast routing protocols, MPLS, OAM and diagnostics, and VSR Installation and Setup.
- Part II provides advanced configurations for services overview, Layer 2 and EVPN services, Layer 3 services, and Quality of Service.
- Part III provides advanced configurations for Multi-Service Integrated Service Adapter (MS-ISA) – Extended Services Appliance (ESA), and Triple Play Service Delivery Architecture (TPSDA).

The MD-CLI Advanced Configuration Guide is divided into two volumes, the Part I Guide and the Part II Guide.

- Part I provides advanced configurations for basic systems, system management, interface configuration, router configuration, unicast routing protocols, MPLS, OAM and diagnostics, and VSR Installation and Setup.
- Part II provides advanced configurations for services overview, Layer 2 and EVPN services, Layer 3 services, Multi-Service Integrated Service Adapter (MS-ISA) – Extended Services Appliance (ESA), and Triple Play Service Delivery Architecture (TPSDA).

The guide is organized alphabetically within each category and provides feature and configuration explanations, CLI descriptions and overall solutions. The chapters in the Advanced Configuration Guide are written for and based on several Releases, up to 23.7.R2. The Applicability section in each chapter specifies on which release the configuration is based.

The Advanced Configuration Guide supplements the user configuration guides listed in the 7450 ESS, 7750 SR, and 7950 XRS Guide to Documentation.

Audience

This manual is intended for network administrators who are responsible for configuring the routers. It is assumed that the network administrators have a detailed understanding of networking principles and configurations.

Services Overview

This section provides configuration information for the following topics:

- BGP Selective Label-IPv4 Route Installation
- G.8032 Ethernet Ring Protection Multiple Ring Topology
- G.8032 Ethernet Ring Protection Single Ring Topology
- GRE Tunnel Origination and Termination Using Non-system IP Addresses
- Network Group Encryption Helper
- Seamless BFD Application — Auto-bind tunnel

BGP Selective Label-IPv4 Route Installation

This chapter provides information about BGP selective label-IPv4 route installation.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 23.3.R1. BGP selective label-IPv4 route installation is supported in SR OS Release 19.10.R2, and later.

Overview

Many service providers use BGP label-unicast (BGP-LU) to build network designs that connect multiple domains into unified and scalable network fabrics. However, the number of BGP-LU IPv4 routes that are distributed in the control plane can exceed the capacity of the Forwarding Information Base (FIB) and Label Forwarding Information Base (LFIB) of small access routers.

One solution is to apply import policies on the access router to limit the number of BGP-LU IPv4 routes accepted in the RIB-IN, but this is labor-intensive and prone to errors. A better solution is selective BGP-LU IPv4 route installation in the base routing instance, which addresses these issues.

When the **selective-label-ipv4-install** command is configured in the **bgp** context of the base router, BGP-LU IPv4 routes in the RIB-IN are made invalid if they are received from a base router BGP peer and not needed by any eligible service. When a BGP-LU IPv4 route is invalid in the RIB-IN, the BGP decision process prefers any valid route over this route, and the invalid BGP-LU IPv4 route is not programmed as a next-hop (primary next-hop, ECMP next-hop, or backup next-hop) of any IP route or tunnel.

The **selective-label-ipv4-install** command can be configured in the **bgp** context of the base router: in the global **bgp** context, the group context, or the neighbor context, as follows:

```
A:PE-1# tree flat detail | match selective-label-ipv4-install
configure router bgp group neighbor selective-label-ipv4-install
configure router bgp group neighbor no selective-label-ipv4-install
configure router bgp group no selective-label-ipv4-install
configure router bgp group selective-label-ipv4-install
configure router bgp no selective-label-ipv4-install
configure router bgp selective-label-ipv4-install
```

When a BGP-LU IPv4 route is invalid in the RIB-IN, it is marked with the flag Label-Unicast-No-Svc and the invalid route is handled as follows:

- No route for the IPv4 prefix is added to the route table from the BGP-LU RIB.
- No BGP tunnel for the /32 IPv4 prefix is added to the tunnel table.

- No RIB-OUT is generated for the invalid BGP-LU route, so this invalid route does not trigger a label-swap (incoming label map - ILM) entry to be programmed.

Note:
Configuring the **selective-label-ipv4-install** command on a BGP session unconditionally invalidates all non-/32 BGP-LU IPv4 routes received on that session, because those non-/32 routes are never used to resolve service endpoints.

Table 1: Selective BGP-LU installation logic by service type shows how BGP-LU IPv4 routes are handled when the selective-label-ipv4-install command is configured.

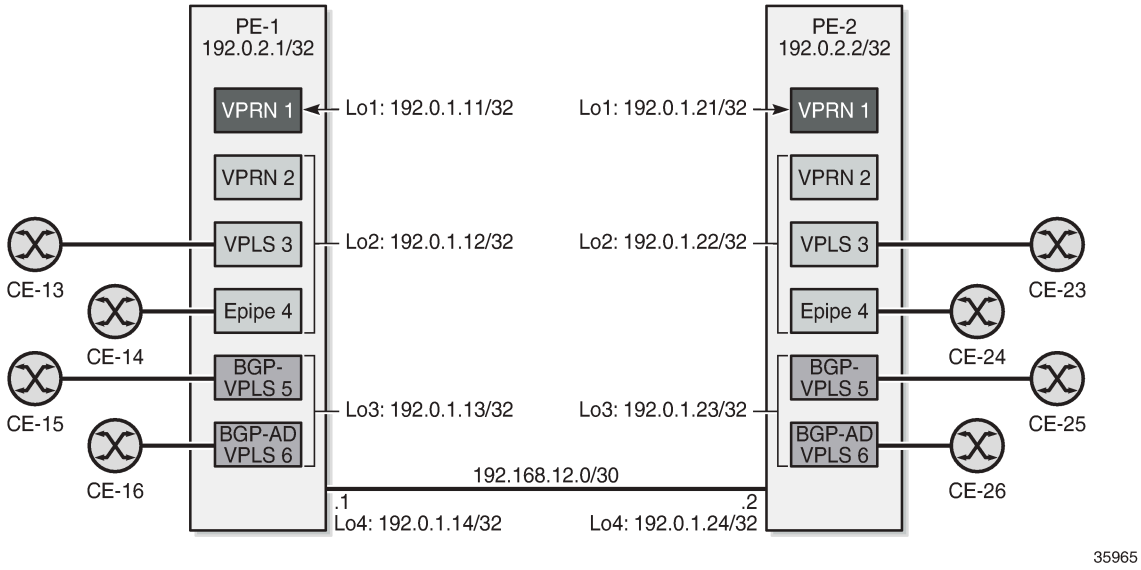
Table 1: Selective BGP-LU installation logic by service type

Service type	Logic marks BGP label-IPv4 routes as invalid except
L2 services with user-provisioned SDPs	When the user-provisioned SDP has a BGP tunnel as transport and the far end matches a /32 BGP-LU IPv4 route, that route is not marked as invalid, regardless of the operational state of the SDP.
L2 services with auto-created SDPs (BGP-AD, BGP-VPLS, BGP-EVPN)	If an L2 service imports a BGP-AD, BGP-VPLS, or BGP-EVPN route, /32 BGP-LU IPv4 routes matching the BGP next-hop address of this BGP route are not marked as invalid.
EVPN next-hop-self route reflector or model-B ASBR	If the base router BGP instance is configured as a next-hop-self RR or a model-B ASBR, BGP-LU IPv4 routes matching any IPv4 address in the BGP next-hop field of a received EVPN route are not marked as invalid, regardless of whether the transport-tunnel resolution filter allows BGP tunnels.
VPRN with explicitly configured SDP	BGP-LU IPv4 routes matching the SDP far-end address are not marked as invalid, regardless of the operational state of the SDP.
VPRN with auto-bind-tunnel	If the auto-bind VPRN service imports VPN-IPv4 or VPN-IPv6 routes where the BGP next-hop matches a BGP-LU IPv4 route, that route is not marked as invalid, regardless of whether the auto-bind-tunnel resolution filter allows BGP tunnels.
VPN-IP next-hop-self RR or model-B ASBR	If the base router BGP instance is configured as a next-hop-self RR or a model-B ASBR, BGP-LU IPv4 routes matching any IPv4 address in the BGP next-hop field of a received VPN-IP route are not marked as invalid, regardless of whether the transport-tunnel resolution filter allows BGP tunnels.

Configuration

Figure 1: Example topology shows the example topology with two PEs with the services that are configured.

Figure 1: Example topology



Initial configuration

The initial configuration on the PEs includes:

- Cards, MDAs, ports
- Router interfaces
- SR-ISIS

On PE-2, four loopback interfaces are configured in the base router context with /32 IPv4 addresses: 192.0.1.21/32, 192.0.1.22/32, 192.0.1.23/32, and 192.0.1.24/32. The list of router interfaces on PE-2 is as follows:

```
*A:PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
int-PE-2-PE-1                    Up        Up/Down     Network 1/1/c1/2:100

===============================================================================
```

These prefixes are exported as BGP-LU routes and the next-hop resolution filter for label-IPv4 routes is configured with SR-ISIS. The configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            prefix-list "192.0.1.0/24"
                prefix 192.0.1.0/24 prefix-length-range 32-32
            exit
            policy-statement "export-svc-lu-bgp"
                entry 10
                    from
                        prefix-list "192.0.1.0/24"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
        bgp
            split-horizon
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family label-ipv4
                            resolution-filter
                                no ldp
                                sr-isis
                            exit
                            resolution filter
                        exit
                    exit
                exit
            exit
            group "iBGPv4"
                family vpn-ipv4 label-ipv4
                peer-as 64500
                neighbor 192.0.2.1
                    export "export-svc-lu-bgp"
                exit
            exit
        exit
```

PE-1 receives four valid label-IPv4 routes, as follows:

```
*A:PE-1# show router bgp routes label-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500

      No As-Path                                                   524285
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

The tunnel table on PE-1 includes four BGP tunnels toward the loopback interfaces on PE-2:

```
*A:PE-1# show router tunnel-table protocol bgp

===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination           Owner     Encap TunnelId  Pref   Nexthop        Metric
   Color
-------------------------------------------------------------------------------
192.0.1.21/32         bgp       MPLS  262148    12     192.0.2.2      1000
192.0.1.22/32         bgp       MPLS  262147    12     192.0.2.2      1000
192.0.1.23/32         bgp       MPLS  262146    12     192.0.2.2      1000
192.0.1.24/32         bgp       MPLS  262145    12     192.0.2.2      1000
-------------------------------------------------------------------------------
Flags: B = BGP or MPLS backup hop available
       L = Loop-Free Alternate (LFA) hop available
       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

The route table on PE-1 shows four BGP-LU IPv4 routes toward the loopback interfaces on PE-2, with next-hop resolved via an SR-ISIS tunnel:

```
*A:PE-1# show router route-table protocol bgp-label

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.1.21/32                                 Remote  BGP_LABEL 00h02m54s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                          10
192.0.1.22/32                                 Remote  BGP_LABEL 00h02m54s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                          10
192.0.1.23/32                                 Remote  BGP_LABEL 00h02m54s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                          10
192.0.1.24/32                                 Remote  BGP_LABEL 00h02m54s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                          10
-------------------------------------------------------------------------------
```

```
No. of Routes: 4
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The tunnel toward destination 192.0.2.2 is the following SR-ISIS tunnel:

```
*A:PE-1# show router tunnel-table 192.0.2.2

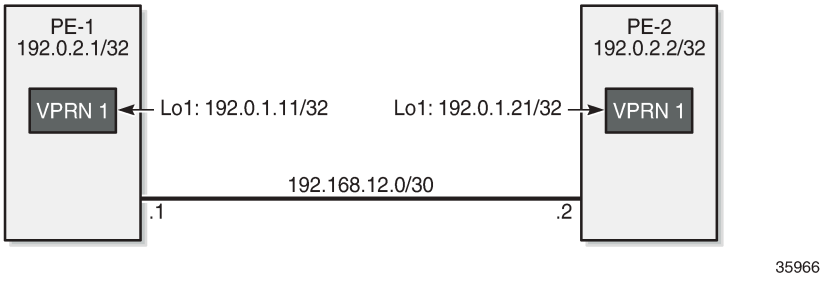
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination           Owner     Encap TunnelId  Pref   Nexthop        Metric
   Color
-------------------------------------------------------------------------------
192.0.2.2/32          isis (0)  MPLS  524290    11     192.168.12.2   10
-------------------------------------------------------------------------------
Flags: B = BGP or MPLS backup hop available
       L = Loop-Free Alternate (LFA) hop available
       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

In the following examples, services that use these BGP tunnels are configured .

VPRN 1 with auto-bind-tunnel

VPRN 1 in Figure 2: VPRN 1 uses a BGP transport tunnel with endpoint 192.0.1.21 on PE-2 uses the BGP transport tunnel between loopback interfaces "lo1" with IP address 192.0.1.11/32 on PE-1 and 192.0.1.21/32 on PE-2.

Figure 2: VPRN 1 uses a BGP transport tunnel with endpoint 192.0.1.21 on PE-2



VPRN 1 is configured with an auto-bind-tunnel and the next-hop must be resolved using a BGP tunnel. On PE-2, the policy "export-VPRN1" sets the next-hop to 192.0.1.21 and adds the community "target:64500:1", which matches the vrf-target of VPRN 1.

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            community "target:64500:1"
                members "target:64500:1"
```

```
            exit
            policy-statement "export-VPRN1"
                entry 10
                    action accept
                        next-hop 192.0.1.21
                        community add "target:64500:1"
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn 1 name "VPRN 1" customer 1 create
            interface "lo1" create
                address 172.31.1.2/32
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64500:1
                    vrf-export "export-VPRN1"
                    vrf-target target:64500:1
                    no shutdown
                exit
            exit
            no shutdown
```

The configuration is similar on PE-1, but the IP addresses are different.

VPRN 1 on PE-1 receives a BGP VPN-IPv4 route for prefix 172.31.1.2/32 from PE-2. The next-hop of this BGP-VPN route is 192.0.1.21:

```
*A:PE-1# show router bgp routes vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================

Flag  Network                                           LocalPref   MED
      Nexthop (Router)                                  Path-Id     IGP Cost
      As-Path                                                       Label
-------------------------------------------------------------------------------
u*>i  64500:1:172.31.1.2/32                             100         None
      192.0.1.21                                        None        0
      No As-Path                                                    524287
-------------------------------------------------------------------------------
Routes : 1
===============================================================================
```

VPRN 1 on PE-1 uses the BGP tunnel toward 192.0.1.21/32 while the other BGP tunnels are not required on PE-1. When BGP is configured with the **selective-label-ipv4-install** command, only the BGP-LU IPv4

route for 192.0.1.21/32 remains valid. The command can be configured in the global BGP context (as in the following configuration), per **group**, or per **neighbor**:

```
# on PE-1:
configure
    router Base
        bgp
            selective-label-ipv4-install
        exit
```

From the four BGP transport tunnels on PE-1, only the BGP tunnel with endpoint 192.0.1.21/32 is used by a service, so it remains valid, as follows:

```
*A:PE-1# show router bgp routes label-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -

u*>i  192.0.1.21/32                                     100         None
      192.0.2.2                                         None        10
      No As-Path                                                    524285
i     192.0.1.22/32                                     100         None
      192.0.2.2                                         None        10
      No As-Path                                                    524285
i     192.0.1.23/32                                     100         None
      192.0.2.2                                         None        10
      No As-Path                                                    524285
i     192.0.1.24/32                                     100         None
      192.0.2.2                                         None        10
      No As-Path                                                    524285
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

The first label-IPv4 route is valid; the other three label-IPv4 routes are marked invalid with flag Label-Unicast-No-Svc:

```
*A:PE-1# show router bgp routes label-ipv4 hunt | match Flags
Flags          : Used Valid Best IGP In-TTM In-RTM
Flags          : Invalid IGP Label-Unicast-No-Svc
Flags          : Invalid IGP Label-Unicast-No-Svc
Flags          : Invalid IGP Label-Unicast-No-Svc
```

In the route table on PE-1, only one BGP-LU IPv4 route remains:

```
*A:PE-1# show router route-table protocol bgp-label

===============================================================================
Route Table (Router: Base)
```

```
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.1.21/32                                 Remote  BGP_LABEL 00h04m01s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                          10
-------------------------------------------------------------------------------
No. of Routes: 1

===============================================================================
```

L2 and L3 services with user-provisioned SDP

When SDPs are configured to use a BGP transport tunnel, the corresponding BGP label-IPv4 route is not marked as invalid. The following TLDP-signaled SDP is configured with a BGP transport tunnel between the loopback interfaces "lo2" with IP address 192.0.1.12 on PE-1 and 192.0.1.22 on PE-2:

```
# on PE-2:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.1.12
                    local-lsr-id "lo2"
                exit
            exit
            no shutdown
        exit
    exit
    service
        sdp 1 mpls create
            signaling tldp      # default
            far-end 192.0.1.12
            bgp-tunnel
            no shutdown
        exit
    exit
```

The configuration is similar on PE-1; only the far-end and peer address is now 192.0.1.22:

```
*A:PE-1# show service sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId  AdmMTU  OprMTU  Far End          Adm  Opr         Del     LSP   Sig
-------------------------------------------------------------------------------
1      0       8970    192.0.1.22       Up   Up          MPLS    B     TLDP
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
Legend: R = RSVP, L = LDP, B = BGP, M = MPLS-TP, n/a = Not Applicable
        I = SR-ISIS, O = SR-OSPF, T = SR-TE, F = FPE
===============================================================================
```

When an SDP uses a BGP transport tunnel, the corresponding BGP label-IPv4 route is not marked as invalid, regardless of the operational state of the SDP. The following command shows that the second BGP label-IPv4 route is now valid:

```
*A:PE-1# show router bgp routes label-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

      No As-Path                                                   524285
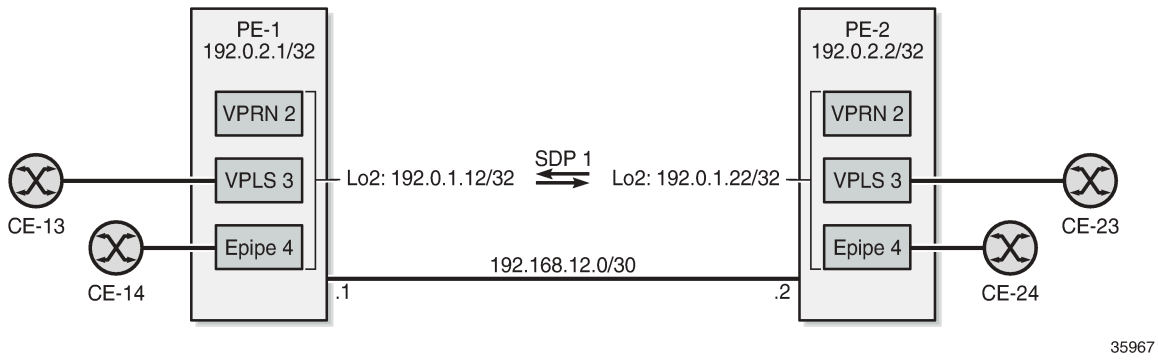
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

This SDP can be used by L2 and L3 services. Figure 3: VPRN 2, VPLS 3, and Epipe 4 use user-provisioned SDP 1 with BGP tunnel shows three services that use SDP 1: VPRN 2, VPLS 3, and Epipe 4.

Figure 3: VPRN 2, VPLS 3, and Epipe 4 use user-provisioned SDP 1 with BGP tunnel



VPRN 2 is similar to VPRN 1, but a spoke-SDP is configured instead of the auto-bind-tunnel. The configuration is as follows:

```
# on PE-1:
configure
```

```
    router Base
        policy-options
            begin
            community "target:64500:2"
                members "target:64500:2"
            exit
            policy-statement "export-VPRN2"
                entry 10
                    action accept
                        next-hop 192.0.1.12
                        community add "target:64500:2"
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn 2 name "VPRN 2" customer 1 create
            interface "lo1" create
                address 172.31.2.1/32
                loopback
            exit
            bgp-ipvpn
                mpls
                    route-distinguisher 64500:2
                    vrf-export "export-VPRN2"
                    vrf-target target:64500:2
                    no shutdown
                exit
            exit
            spoke-sdp 1:2 create
            exit
            no shutdown
        exit
    exit
```

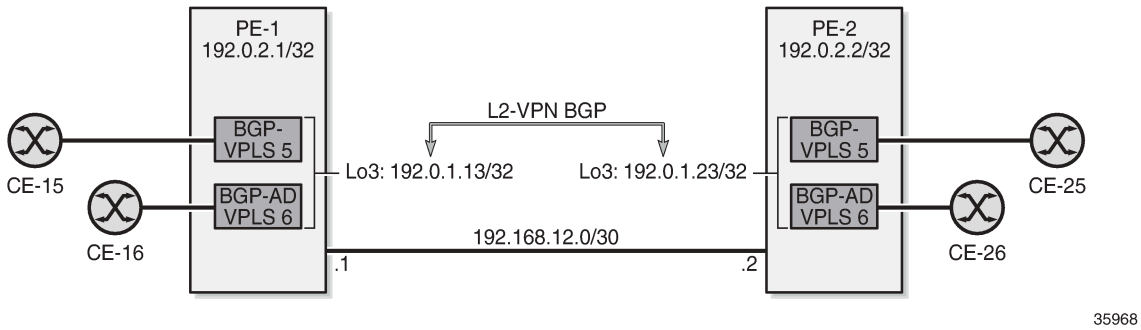
VPLS 3 and Epipe 4 only have a spoke-SDP and a SAP, as follows:

```
# on PE-1:
configure
    service
        vpls 3 name "VPLS 3" customer 1 create
            sap 1/1/c2/1:3 create
            exit
            spoke-sdp 1:3 create
            exit
            no shutdown
        exit
        epipe 4 name "Epipe 4" customer 1 create
            sap 1/1/c2/1:4 create
            exit
            spoke-sdp 1:4 create
            exit
            no shutdown
        exit
```

L2 services with auto-created SDPs

Figure 4: PE-1 receives BGP-VPLS and BGP-AD routes with next-hop 192.0.1.23 shows two VPLS services where the SDPs are auto-created between the loopback interfaces "lo3" on the PEs: BGP-VPLS 5 and BGP-AD VPLS 6.

Figure 4: PE-1 receives BGP-VPLS and BGP-AD routes with next-hop 192.0.1.23



For BGP-VPLS and BGP-AD, a BGP session is established for the L2-VPN address family between the loopback interfaces "lo3" on both PEs:

```
# on PE-2:
configure
    router Base
        bgp
            group "iBGP-L2"
                family l2-vpn
                type internal
                local-address 192.0.1.23
                neighbor 192.0.1.13
                exit
            exit
        exit
```

For BGP-AD, T-LDP signaling is used, so the following T-LDP session is established:

```
# on PE-2:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.1.13
                    local-lsr-id "lo3"
                exit
            exit
            no shutdown
        exit
```

The service configuration is as follows:

```
# on PE-2:
configure
    service
        pw-template 1 name "PW1" create
        exit
        vpls 5 name "BGP-VPLS 5" customer 1 create
```

```
            bgp
                route-distinguisher 64500:5
                route-target export target:64500:5 import target:64500:5
                pw-template-binding 1 import-rt "target:64500:5"
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            sap 1/1/c2/1:5 create
            exit
            no shutdown
        exit
        vpls 6 name "BGP-AD VPLS 6" customer 1 create
            bgp
                route-distinguisher 64500:6
                route-target export target:64500:6 import target:64500:6
                pw-template-binding 1
                exit
            exit
            bgp-ad
                vpls-id 64500:6
                vsi-id
                    prefix 192.0.1.23
                exit
                no shutdown
            exit
            sap 1/1/c2/1:6 create
            exit
            no shutdown
        exit
```

On PE-1, the received L2-VPN BGP routes have next-hop 192.0.1.23:

```
*A:PE-1# show router bgp routes l2-vpn

```

Conclusion

The **selective-label-ipv4-install** command allows BGP-LU IPv4 routes to be marked as invalid in the RIB-IN when these routes are received from a base router BGP peer and not needed by any eligible service. This is a technique to reduce the number of routes in the FIB/LFIB, which is mainly useful for small access routers having small FIB/LFIB sizes.

G.8032 Ethernet Ring Protection Multiple Ring Topology

This chapter provides information about G.8032 Ethernet ring protection multiple ring topologies.

Topics in this chapter include:

Applicability

Initially, this chapter was written for SR OS Release 12.0.R5, but the CLI in this edition is based on Release 23.3.R2.

Overview

G.8032 Ethernet ring protection is supported for data service SAPs within a regular VPLS service, a PBB VPLS (I/B-component), or a routed VPLS (R-VPLS). G.8032 is one of the fastest protection schemes for Ethernet networks. This chapter describes the advanced topic of multiple ring control, sometimes referred to as multi-chassis protection, with access rings being the most common form of multiple ring topologies. Single rings are covered in the G.8032 Ethernet Ring Protection Single Ring Topology chapter.This chapter will use a VPLS service to illustrate the configuration of G.8032. For very large ring topologies, provider backbone bridging (PBB) can also be used, but that is not configured in this chapter.

ITU-T G.8032v2 specifies protection switching mechanisms and a protocol for Ethernet layer network (ETH) Ethernet rings. Ethernet rings can provide wide-area multipoint connectivity more economically due to their reduced number of links. The mechanisms and protocol defined in ITU-T G.8032v2 are highly reliable with stable protection and never form loops, which would negatively affect network operation and service availability. Each ring node is connected to adjacent nodes participating in the same ring using two independent paths, which use ring links (configured on ports or link aggregation groups (LAGs)). A ring link is bounded by two adjacent nodes and a port for a ring link is called a ring port. The minimum number of nodes on a ring is two.

The fundamentals of this ring protection switching architecture are:

- the principle of loop avoidance and
- the utilization of learning, forwarding, and address table mechanisms defined in the ITU-T G.8032v2 Ethernet flow forwarding function (ETH_FF) (control plane).

Loop avoidance in the ring is achieved by guaranteeing that, at any time, traffic may flow on all but one of the ring links. This particular link is called the ring protection link (RPL) and under normal conditions this link is blocked, so it is not used for traffic. One designated node, the RPL owner, is responsible to block traffic over the one designated RPL. Under a ring failure condition, the RPL owner is responsible for unblocking the RPL, allowing the RPL to be used for traffic. The protocol ensures that even without an RPL owner defined, one link will be blocked and it operates as a *break before make* protocol, specifically the protocol guarantees that no link is restored until a different link in the ring is blocked. The other side of the RPL is configured as an RPL neighbor. An RPL neighbor blocks traffic on the RPL.

The event of a ring link or ring node failure results in protection switching of the traffic. This is achieved under the control of the ETH_FF functions on all ring nodes. A ring automatic protection switching (R-APS) protocol is used to coordinate the protection actions over the ring. The protection switching mechanisms and protocol supports a multi-ring/ladder network that consists of connected Ethernet rings.

Ring protection mechanism

The ring protection protocol is based on the following building blocks:

- ring status change on failure
  - idle → link failure → protection → recovery → idle
- ring control state changes
  - idle → protection → manual switch → forced switch → pending
- re-use existing ETH OAM
  - monitoring: ETH continuity check messages (CCM)
  - failure notification: Y.1731 signal failure
- forwarding database MAC flush on ring status change
- ring protection link (RPL)
  - defines blocked link in idle status

When subrings are used, they can either connect to a major ring (which is configured in the exact same way as a single ring) or another subring, or to a VPLS service. When connected to a major ring or to a subring, there is the option to extend the subring control service through the major ring or not. This gives the following three options for subring connectivity:

1. **subring to a major ring or to a subring with a virtual channel** — In this case, a data service on the major ring or subring is created which is used to forward the R-APS messages for the subring over the major ring or subring, between the interconnection points of the subring to the major ring or subring. This allows the subring to operate as a fully connected ring and is mandatory if the subring connects two major rings or subrings because the virtual channel is the only mechanism that the subrings can use to exchange control messages. It also could improve failover times if the subring was large as it provides two paths on the subring interconnection nodes to propagate the fault indication around the subring, whereas without a virtual channel the fault indication may need to traverse the entire subring. Each subring requires its own data service on the major ring or subring for the virtual channel.
2. **subring to a major ring or to a subring without a virtual channel** — In this case the subring is not fully connected and does not require any resources on the major ring or subring. This option requires that the R-APS messages are not blocked on the subring over its RPL.
3. **subring to a VPLS service** — This is similar to the preceding option, but it uses a VPLS service instead of a major ring or subring. In this option, subring failures can initiate the sending of an LDP MAC flush message into the VPLS service when spoke or MPLS mesh SDPs are used in the VPLS service.

Ethernet ring terminology

The implementation of Ethernet ring on SR OS uses a VPLS as the construct for a ring flow function (one for ETH_FF (solely for control) and one for each service_FF) and SAPs (on ports or LAGs) as ring links. The control VPLS must be a regular VPLS, but the data VPLS can be a regular VPLS, a PBB (B/I-) VPLS or a routed VPLS. The state of the data service SAPs is inherited from the state of the control

service SAPs. Table 2: Terminology comparison displays a comparison between the ITU-T and SR OS terminologies.

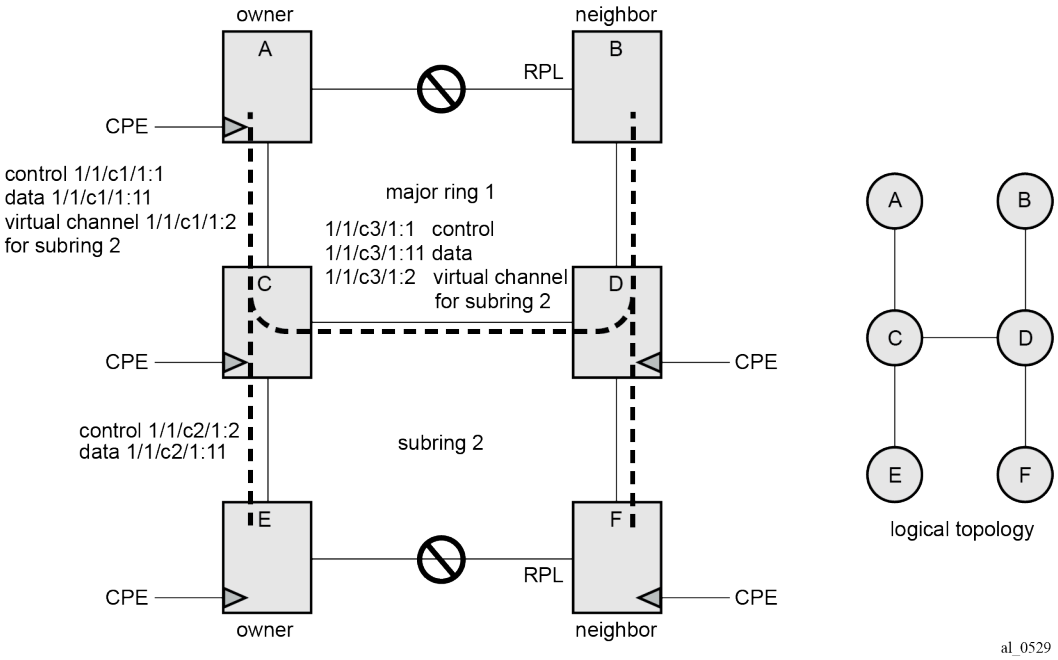
Table 2: Terminology comparison

ITU-T G.8032v2 terminology	SR OS terminology
ETH_FF	control vpls
service_FF	data vpls
east ring link	path a
west ring link	path b
RPL owner	rpl-node owner
RPL link	path {a|b} rpl-end
MEP	control-mep
ERP control process	eth-ring instance or ring-id
major ring	eth-ring
sub-ring	eth-ring sub-ring
ring node	ring node PE
ring-ID	not used; fixed at 1 per G.8032v2

There are various ways that multiple rings can be interconnected and the possible topologies may be large. Customers typically have two forms of networks: access ring edge networks or larger multiple ring networks. Both topologies require ring interconnection.

Figure 5: G.8032 major ring and subring shows a ring of six nodes, with a major ring (regular Ethernet ring) on the top four nodes and a subring on the bottom.

Figure 5: G.8032 major ring and subring



A major ring is a fully connected ring. A subring is a partial ring that depends on a major ring or a VPLS topology for part of the ring interconnect. Two major rings can be connected by a single subring. A subring can support other subrings.

In the major ring (on nodes A, B, C, and D), one path of the RPL owner is designated to be the RPL and the respective SAPs will be blocked in order to prevent a loop. The choice of where to put the RPL is up to the network administrator and can be different for different control instances of the ring allowing an RPL to be used for some other ring's traffic. In the subring, one path is designated as the RPL and will be blocked. Both the major ring and the subring have their own RPL. The subring interconnects to the major ring on nodes C and D and has a virtual channel on the major ring. SR OS supports both virtual channel and non-virtual channel rings. Schematics of the physical and logical topologies are also shown in Figure 5: G.8032 major ring and subring.

The G.8032 protocol defines a ring ID (1-255). The SR OS implementation only uses ring ID 1, which complies with G.8032v2. The configuration on a node uses a ring instance with a number but all rings use ring ID 1. This ring instance number is purely local and does not have to match on other ring nodes. Only the VLAN ID must match between SR OS ring nodes. For consistency in this example, VPLS instances and Ethernet ring instances are shown as matching for the same ring.

An RPL owner and RPL neighbor are configured for both the major ring and subring. The path and associated link will be the RPL when the ring is fully operational and will be blocked by the RPL owner whenever there is no fault on other ring links. Each ring RPL is independent. If a different ring link fails, then the RPL will be unblocked by the RPL owner. The link shared between a subring and the major ring is completely controlled by the major ring as if the subring were not there. Each ring can completely protect one fault within its ring. When the failed link recovers, it will initially be blocked by one of its adjacent nodes. The adjacent node sends an R-APS message across the ring to indicate the error is cleared and after a configurable time, if reversion is enabled, the RPL will revert to being blocked with all other links unblocked. This ensures that the ring topology when fully operational is predictable.

If a specific RPL owner is not configured (not recommended by G.8032 specification), then the last link to become active will be blocked and the ring will remain in this state until another link fails. This operation makes the selection of the blocked link non-deterministic.

The protection protocol uses a specific control VLAN, with the associated data VLANs taking their forwarding state from the control VLAN. The control VLAN cannot carry data.

Load balancing with multiple ring instances

Each control ring is independent of the other control rings on the same topology. Therefore, because the RPL is used by one control ring, it is often desirable to set up a second control ring that uses a different link as RPL. This spreads out traffic in the topology, but if there is a link failure in the ring, all traffic will be on the remaining links. In the following examples, only a single control ring instance is configured. Other control and data rings could be configured if desired.

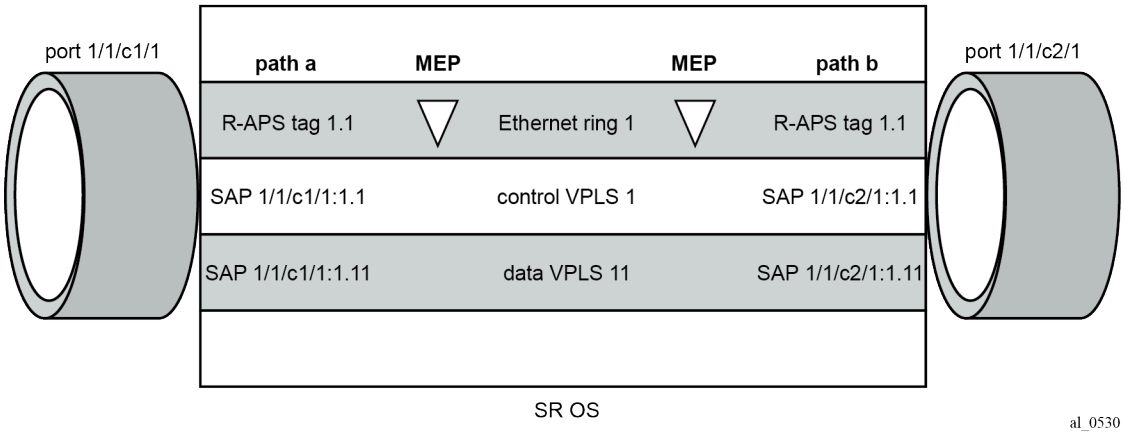
Provider backbone bridging (PBB)

PBB services also support G.8032 as data services (the services used for the control VPLS must be a regular VPLS). B/I-VPLS rings support both major rings and subrings. B-VPLS rings support multi-chassis link aggregation group (MC-LAG) as a dual homing option when aggregating I-VPLS traffic onto a B-VPLS ring. In other words, I-VPLS rings should not be dual-homed into two backbone edge bridge (BEB) nodes where the B-VPLS uses G.8032 to get connected to the rest of the B-VPLS network because the only mechanism that can propagate MAC flushes between an I-VPLS and B-VPLS is an LDP MAC flush.

SR OS implementation

G.8032 is built from VPLS components and each ring consists of the configuration components illustrated in Figure 6: G.8032 ring components .

Figure 6: G.8032 ring components



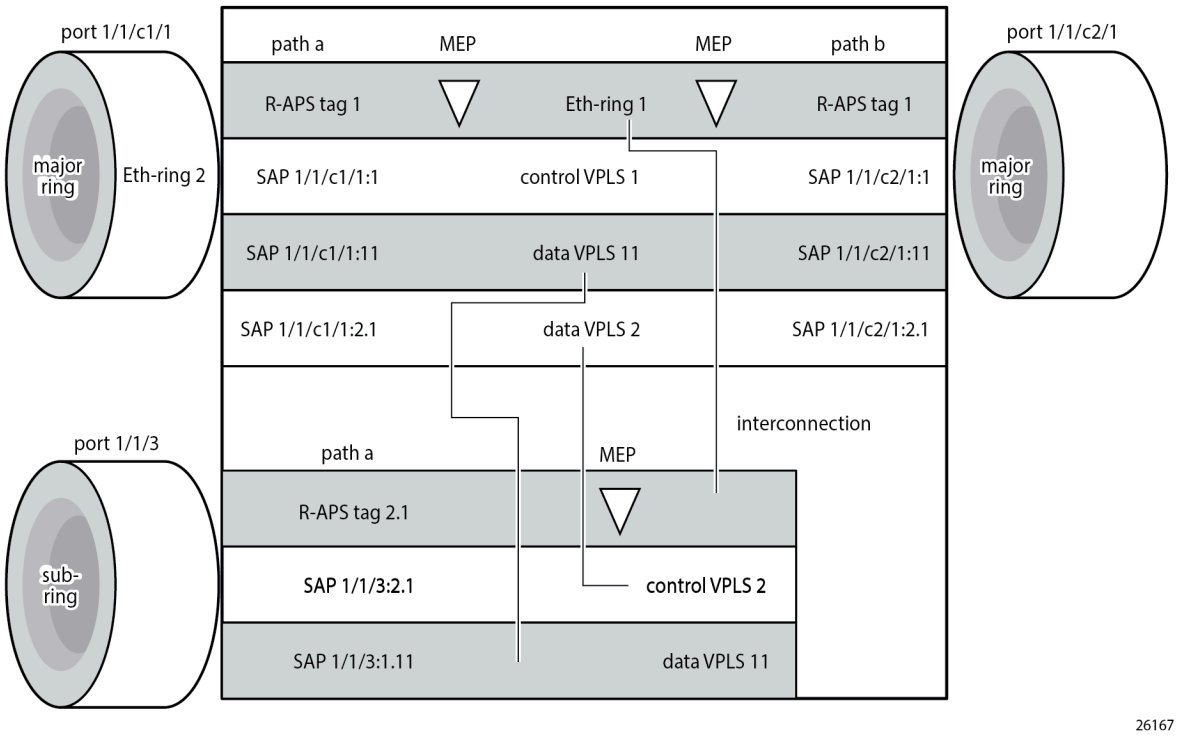
These components consist of:

- the Ethernet ring instance which defines the R-APS tags, the MEPs, and the ring behavior.
- the control VPLS which has SAPs with an encapsulation that matches the R-APS tags.

- the data VPLS which is linked to the ring. All of the data VPLS SAPs follow the operational state of the control VPLS SAPs in that each blocked SAP controlled by the ring is blocked for all control and data instances.

Figure 7: G.8032 subring interconnection components shows the major ring and subring interconnection components:

Figure 7: G.8032 subring interconnection components



For a subring, the configuration is the same as a single ring except at the junction of the major ring and the subring. The interconnection of a subring and a major ring links the control VPLS of the subring to a data VPLS of the major ring when a virtual link is used. Similarly the data VPLS of the subring is linked to a data VPLS of the major ring. Figure 7: G.8032 subring interconnection components illustrates the relationship of a subring and a major ring. Because this subring has a virtual channel, the data VPLS 2 has both data SAPs from the subring and data SAPs from the major ring. The virtual channel is also optional and in non-virtual-link cases, no VPLS instance is required (see non-virtual-link in the section Configuration of a subring to a VPLS service).

In Figure 7: G.8032 subring interconnection components, the inner tag values are kept the same for clarity, but in fact any encapsulation that is consistent with the next ring link will work. In other words, ring SAPs can perform VLAN ID translation and even when connecting a subring to a major ring. This also means that other ports may reuse the same tags when connecting independent services.

The R-APS tags and SAPs on the rings can either be dot1Q or QinQ encapsulated. It is also possible to have the control VPLS using single tagged frames with the data VPLSs using double tagged frames; this requires the system to be configured with the **new-qinq-untagged-sap** parameter (**configure system ethernet new-qinq-untagged-sap**), with the ring path R-APS tags and control VPLS SAPs configured as qtag.0, and the data VPLSs configured as QinQ SAP: qtag1.qtag2. Spanning tree protocol (STP) cannot be enabled on SAPs connected to Ethernet rings.

R-APS messages received from other nodes are normally blocked on the RPL interface but the subring case with non-virtual channel recommends that R-APS messages be propagated over the RPL. Configuring **sub-ring non-virtual-link** on all nodes on the subring is required to ensure propagation of R-APS messages around the subring.

R-APS messages are forwarded out of the egress using forwarding class network control (NC) and should be prioritized accordingly in the SAP egress QoS policy to ensure that congestion does not cause R-APS messages to be dropped which could cause the ring to switch to another path.

Configuration

This section describes the configuration of multiple rings. The Ethernet ring configuration commands are as follows.

```
configure
    eth-ring <ring-index [1..128]>
        ccm-hold-time { [down <down-timeout>] [up <up-timeout>] }
        compatible-version <version>            # [1..2] - Default: 2
        description <description-string>
        guard-time <time>       # [1..20] in deciseconds - Default: 5
        node-id <xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx>
        path {a|b} [ { <port-id>|<lag-id> } raps-tag <qtag1>[.<qtag2>] ]
            description <description-string>
            eth-cfm
                mep <mep-id> domain <md-index> association <ma-index>
                <...>
            rpl-end
            shutdown
        revert-time <time>      # [60..720] in seconds - Default: 300
        rpl-node {owner|nbr}
        shutdown
        sub-ring {virtual-link|non-virtual-link}
            interconnect { ring-id <ring-index> | vpls }
                propagate-topology-change
```

Parameters:

- **<ring-index>** — The ring index is the number by which the ring is referenced; values: 1 to128.
- **ccm-hold-time { [down <down-timeout>] [up <up-timeout>] }**
  - **down** — This command specifies the timer which controls the delay between detecting that ring path is down and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM. It does not apply to the ring port link state. To dampen ring port link state transitions, use the hold-time parameter from the physical member port. This is useful if the underlying path between two nodes is going across an optical system which implements its own protection.
  - **up** — This command specifies the timer which controls the delay between detecting that ring path is up and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM. It does not apply to the member port link state. To dampen member port link state transitions, use the hold-time parameter from the physical member port.

Values:

```
<down-timeout> : [0..5000] in centiseconds - default: 0; 1 centisecond = 10 ms
<up-timeout> : [0..5000] in deciseconds - default: 20; 1 decisecond = 100 ms
```

- The **compatible-version** command configures the Ethernet ring compatibility version for the G.8032 state machine and messages. The default is version 2 (ITU G.8032v2) and all SR OS systems use version 2. If there is a need to interwork with third party devices that only support version 1, this can be set to version 1 allowing the reception of version 1 PDUs. Version 2 is encoded as 1 in the R-APS messages. Compatibility allows the reception of version 1 (encoded as 0) R-APS PDUs but, as per the G.8032 specification, higher versions are ignored on reception. For SR OS, messages are always originated with version 2. Therefore if a third party switch supports version 3 (encoded as 2) or higher, interworking is also supported provided the other switch is compatible with version 2.
- The **description** includes a text string of maximum 80 characters that can be used to describe the use of the Ethernet ring.
- **guard-time** *<time>* — The forwarding method, in which R-APS messages are copied and forwarded at every Ethernet ring node, can result in a message corresponding to an old request, that is no longer relevant, being received by Ethernet ring nodes. Reception of an old R-APS message may result in erroneous ring state interpretation by some Ethernet ring nodes. The guard timer is used to prevent Ethernet ring nodes from acting upon outdated R-APS messages and prevents the possibility of forming a closed loop. Messages are not forwarded when the guard-timer is running.

  Values:

  ```
  [1..20] in deciseconds - default: 5; 1 decisecond = 100ms
  ```

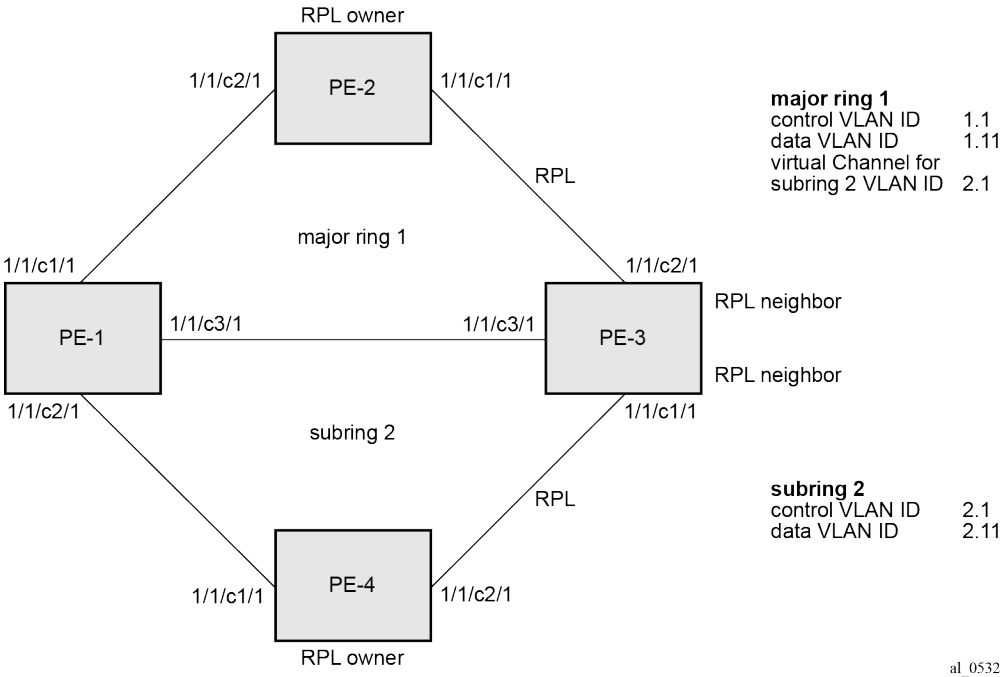
- The **node-id (<xx:xx:xx:xx:xx:xx>** or **<xx-xx-xx-xx-xx-xx>)** allows the node identifier to be explicitly configured. By default, the chassis MAC is used. The node ID is not required in typical configurations.
- **path {a | b} [{***<port-id>* **|** *<lag-id>***} raps-tag** *<qtag1>***[.***<qtag2>***]]** — The **path** parameter defines the paths around the ring, of which there are two in different directions on the ring: an "a" path and a "b" path, except on the interconnection node where a subring connects to another major ring or subring in which case there is one path (either a or b) configured together with the **sub-ring** command. The paths are configured on a dot1Q or QinQ encapsulated access or hybrid port or a LAG with the encapsulation used for the R-APS messages on the ring. These can be either single tagged or double tagged.
  - The **description** includes a text string of maximum 80 characters to describe the use of the path.
  - The **eth-cfm** context contains the associated Ethernet CFM parameters.
    - **mep** *<mep-id>* **domain** *<md-index>* **association** *<ma-index>* — The MEP defined under the path is used for the G.8032 protocol messages, which are based on IEEE 802.1ag/Y.1731 CFM frames.
  - When the **rpl-end** parameter is configured, the path is expected to be one end of the RPL. The **rpl-end** parameter must be configured in conjunction with the **rpl-node** parameter.
  - The **shutdown** command disables the path.
- The **revert-time** command configures the revert time for an Ethernet ring. The revert time is the time that the RPL will wait before returning to the blocked state, after a failure condition has been fixed. Configuring **no revert-time** disables reversion, effectively setting the revert time to zero. Values: [60..720] in seconds - Default: 300.
- **rpl-node {owner | nbr}** — A node can be designated as either the **owner** of the RPL, in which case this node is responsible for the RPL, or the **nbr** (neighbor), in which case this node is expected to be

the neighbor to the RPL owner across the RPL. The **nbr** is optional and is included to be compliant with the specification. This parameter must be configured in conjunction with the **rpl-end** command. On a subring without virtual channel it is mandatory to configure **sub-ring non-virtual-link** on all nodes on the subring to ensure propagation of the R-APS messages around the subring.

- **shutdown** — This command disables the ring.
- **sub-ring {virtual-link | non-virtual-link}** — This command is configured on the interconnection node between the subring and its major ring or subring to indicate that this ring is a subring. The parameter specifies whether it uses a virtual link through the major ring or subring for the R-APS messages or not. A ring configured as a subring can only be configured with a single path.
  - **interconnect [ring-id** *<ring-index>* **| vpls]** — A subring connects to either another ring or to a VPLS service. If it connects to another ring (either a major ring or another subring), the ring identifier must be specified and the ring to which it connects must be configured with both a path "a" and a path "b", meaning that it is not possible to connect a subring to another subring on an interconnection node. Alternatively, the **vpls** parameter is used to indicate the subring connects to a VPLS service. Interconnection using a VPLS service requires the subring to be configured with **non-virtual-link**.
    - **propagate-topology-change** — If a topology change event happens in the subring, it can be optionally propagated with the use of this parameter to either the major ring or subring it is connected to, using R-APS messages, or to the LDP VPLS SDP peers using an LDP "flush-all-from-me" message if the subring is connected to a VPLS service.

The example topology is shown in Figure 8: Ethernet example topology.

Figure 8: Ethernet example topology



The configuration is divided into the following sections:

- a subring connected to a major ring using a virtual link through the major ring
- a subring connected to a major ring without a virtual link

- a subring connected to a VPLS service (without a virtual link)

Configure a subring to a major ring with a virtual link

To configure an Ethernet ring using R-APS, there will be at least two VPLS services required for one Ethernet ring instance, one for the control channel and the others for data channels. The control channel is used for R-APS signaling while the data channel is for user data traffic. The state of the data channels is inherited from the state of the control channel.

The following needs to be configured:

- encapsulation type for each ring port
- ETH-CFM
- Ethernet ring for major ring 1
- Ethernet ring for subring 2
- control channel service and Ethernet ring SAPs
- user data channels

Configure the encapsulation for the ring ports.

Ethernet ring needs an R-APS tag to send and receive G.8032 signaling messages. To configure a control channel, an access SAP configuration is required on each path (a or b) port. The SAP configuration follows that of the port and must be either dot1Q or QinQ, consequently the control and data packets are either single tagged or double tagged.

Note:
Single tagged control frames are supported on a QinQ port by configuring the system with the **new-qinq-untagged-sap** parameter (**configure system ethernet new-qinq-untagged-sap**), and the ring path R -APS tags and control VPLS SAPs configured as qtag.0.

In this example, QinQ tags are used. For example, the port configuration on PE-1 is as follows:

```
# on PE-1:
configure
    port 1/1/c1/1
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    port 1/1/c2/1
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    port 1/1/c3/1
        ethernet
            mode access
            encap-type qinq
        exit
```

```
        no shutdown
    exit
```

Configure Ethernet CFM

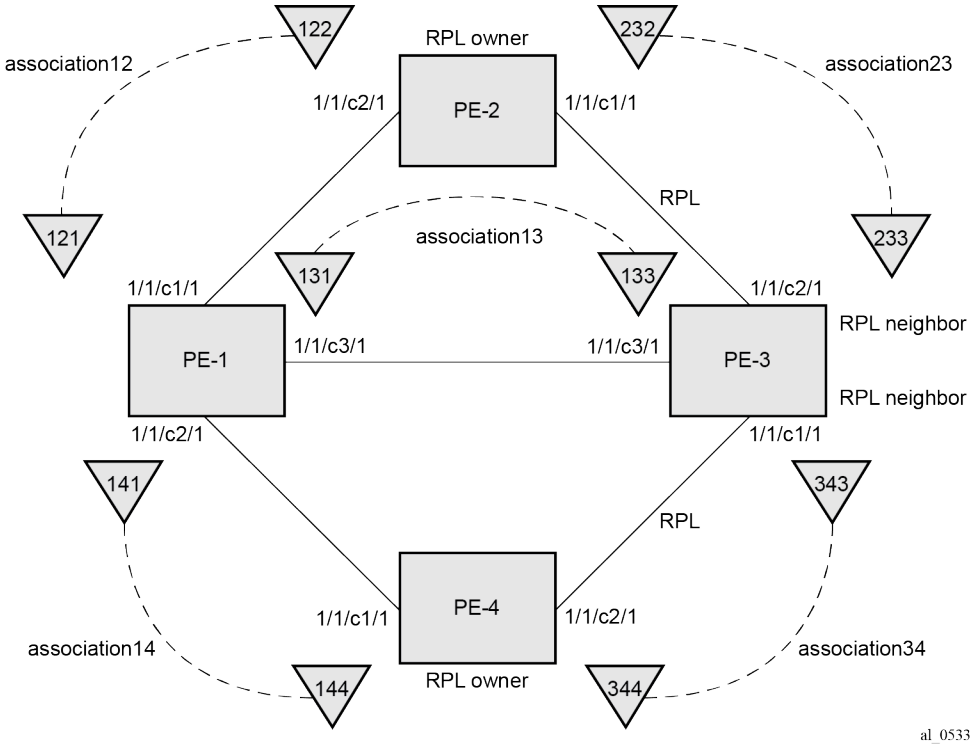
Configuring the Ethernet CFM domain, association, and MEP is required before configuring an Ethernet ring. The standard domain format is **none** and the association name must be ITU carrier code-based (ICC-based - Y.1731); however, the SR OS implementation is flexible in that it supports both IEEE and ICC formats. The Ethernet ring MEP requires a CCM interval with values such as 1s, 100ms, or 10ms to be configured.

The MEPs used for R-APS control normally will have CCM configured on the control channel path MEPs for failure detection. Alternatively, detecting a failure of the ring may be achieved by running Ethernet in the first mile (EFM) at the port level if CCM is not possible at 1s, 100ms, or 10ms. Also rings can be run without CFM although the Ethernet CFM association must be configured for R-APS messages to be exchanged. To omit the failure detecting CCMs, it is necessary to remove the **ccm-enable** from under the path MEPs and to remove the **remote-mepid** on the corresponding ETH CFM configuration.

Loss-of-signal, in conjunction with other OAM mechanisms, is applicable only when the nodes are directly connected.

Figure 9: ETH-CFM MEP associations shows the details of the MEPs and their associations configured when both the major rings and subrings are used. The associations only need to be pairwise unique but for clarity five unique associations are used. Any name format can be used, but it must be consistent on both adjacent nodes.

Figure 9: ETH-CFM MEP associations



The configuration of Ethernet CFM for the major and subrings on each node is as follows. The CCMs for failure detection are configured for 1 second intervals.

On ring node PE-1, the associations 12 and 13 are used for the major ring and association 14 is used for the subring.

```
# on PE-1:
configure
    eth-cfm
        domain 1 format none level 2 admin-name "domain-1"
            association 12 format icc-based name "Association12" admin-name "association-12"
                ccm-interval 1
                remote-mepid 122
            exit
            association 13 format icc-based name "Association13" admin-name "association-13"
                ccm-interval 1
                remote-mepid 133
            exit
            association 14 format icc-based name "Association14" admin-name "association-14"
                ccm-interval 1
                remote-mepid 144
            exit
        exit
```

On ring node PE-2, the associations 12 and 23 are used for the major ring.

```
# on PE-2:
configure
    eth-cfm
        domain 1 format none level 2 admin-name "domain-1"
            association 12 format icc-based name "Association12" admin-name "association-12"
                ccm-interval 1
                remote-mepid 121
            exit
            association 23 format icc-based name "Association23" admin-name "association-23"
                ccm-interval 1
                remote-mepid 233
            exit
        exit
```

On ring node PE-3, the associations 13 and 23 are used for the major ring and association 34 is used for the subring.

```
# on PE-3:
configure
    eth-cfm
        domain 1 format none level 2 admin-name "domain-1"
            association 13 format icc-based name "Association13" admin-name "association-13"
                ccm-interval 1
                remote-mepid 131
            exit
            association 23 format icc-based name "Association23" admin-name "association-23"
                ccm-interval 1
                remote-mepid 232
            exit
            association 34 format icc-based name "Association34" admin-name "association-34"
                ccm-interval 1
                remote-mepid 344
            exit
        exit
```

On ring node PE-4, the associations 14 and 34 are used for the subring.

```
# on PE-4
configure
    eth-cfm
        domain 1 format none level 2 admin-name "domain-1"
            association 14 format icc-based name "Association14" admin-name "association-14"
                ccm-interval 1
                remote-mepid 141
            exit
            association 34 format icc-based name "Association34" admin-name "association-34"
                ccm-interval 1
                remote-mepid 343
            exit
        exit
```

Configuring Ethernet ring – major ring 1

Two paths must be configured to form a ring. In this example, VLAN tag 1.1 is used as control channel for R-APS signaling for the major ring (Ethernet ring 1) on the ports shown in Figure 8: Ethernet example topology using the Ethernet CFM information shown in Figure 9: ETH-CFM MEP associations. The revert time is set to its minimum value of 60 seconds and CCM messages are enabled on the MEP. The **control-mep** parameter is required to indicate that this MEP is used for ring R-APS messages.

The configuration of Ethernet ring 1 on ring node PE-1 is as follows:

```
# on PE-1:
configure
    eth-ring 1
        description "Ethernet ring 1"
        revert-time 60
        path a 1/1/c1/1 raps-tag 1.1
            description "Ethernet ring 1 - pathA"
            eth-cfm
                mep 121 domain 1 association 12
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c3/1 raps-tag 1.1
            description "Ethernet Ring 1 - PathB"
            eth-cfm
                mep 131 domain 1 association 13
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

It is mandatory to configure a MEP in the path context, otherwise the following error is displayed:

```
*A:PE-1>config>eth-ring# path a 1/1/c1/1 raps-tag 1.1
```

```
*A:PE-1>config>eth-ring>path# no shutdown
INFO: ERMGR #1001 Not permitted - must configure eth-cfm MEP first
```

While MEPs are mandatory, enabling CCMs on the MEPs under the paths as a failure detection mechanism is optional as explained earlier.

Ring node PE-2 is configured as the RPL owner with the RPL being on path "a" as indicated by the **rpl-end** parameter. The revert time is 60 seconds.

```
# on PE-2:
configure
    eth-ring 1
        description "Ethernet Ring 1"
        revert-time 60
        rpl-node owner
        path a 1/1/c1/1 raps-tag 1.1
            description "Ethernet ring 1 - PathA"
            rpl-end
            eth-cfm
                mep 232 domain 1 association 23
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 1.1
            description "Ethernet ring 1 - PathB"
            eth-cfm
                mep 122 domain 1 association 12
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

It is not permitted to configure a path as an RPL end without having configured the node on this ring to be either the RPL **owner** or **nbr** otherwise the following error message is reported.

```
*A:PE-2>config>eth-ring>path# rpl-end
INFO: ERMGR #1001 Not permitted - path-type rpl-end is not consistent with eth-ring
'rpl-node' type
```

Ring node PE-3 is configured as the RPL neighbor with the RPL being on path "b" as indicated by the **rpl-end** parameter. The revert time is 60 seconds.

```
# on PE-3
configure
    eth-ring 1
        description "Ethernet ring 1"
        revert-time 60
        rpl-node nbr
        path a 1/1/c3/1 raps-tag 1.1
            description "Ethernet ring 1 - PathA"
            eth-cfm
                mep 133 domain 1 association 13
```

```
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 1.1
            description "Ethernet ring 1 - PathB"
            rpl-end
            eth-cfm
                mep 233 domain 1 association 23
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The link between PE-2 and PE-3 will be the RPL with PE-2 and PE-3 blocking that link when the ring is fully operational. In this example, the RPL is using path "a" on PE-2 and path "b" on PE-3.

Configuring Ethernet ring – subring 2

Ring nodes PE-1, PE-3, and PE-4 form a subring. The subring attaches to the major ring (ring 1). The subring in this case uses a virtual link. The interconnection ring instance identifier (**ring-id**) is specified and **propagate-topology-change** indicates that subring flushing will be propagated to the major ring. Only one path (path a) is specified because the other path (path b) is not required at an interconnection node. Subrings are almost identical to major rings in operation except that subrings send MAC flushes towards their connected ring (either a major ring or a subring). Major rings or subrings never send MAC flushes to their subrings. Therefore a couple of subrings connected to a major ring can cause MACs to flush on the major ring but the major ring will not propagate a subring MAC flush to other subrings.

Ring node PE-1 provides an interconnection between the major ring (ring 1) and the subring (ring 2). Ring 2 is configured to be a subring which interconnects to ring 1. It will use a virtual link on ring 1 to send R-APS messages to the other interconnection node and topology changes will be propagated from subring 2 to the major ring 1.

```
# on PE-1:
configure
    eth-ring 2
        description "Ethernet subring 2 on major ring 1"
        revert-time 60
        sub-ring virtual-link
            interconnect ring-id 1
                propagate-topology-change
            exit
        exit
        path a 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 141 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
```

```
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The configuration of PE-3 is similar to PE-1, but PE-3 is the RPL neighbor, with the RPL end on path "a", for the RPL between PE-3 and PE-4.

```
# on PE-3:
configure
    eth-ring 2
        description "Ethernet subring 2 on major ring 1"
        revert-time 60
        rpl-node nbr
        sub-ring virtual-link
            interconnect ring-id 1
                propagate-topology-change
            exit
        exit
        path a 1/1/c1/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            rpl-end
            eth-cfm
                mep 343 domain 1 association 34
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

Ring node PE-4 only has configuration for the subring 2. PE-4 is the RPL owner, with path "b" being the RPL end, for the RPL between PE-3 and PE-4.

```
# on PE-4
configure
    eth-ring 2
        description "Ethernet subring 2"
        revert-time 60
        rpl-node owner
        path a 1/1/c1/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 144 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathB"
            rpl-end
            eth-cfm
                mep 344 domain 1 association 34
                    ccm-enable
                    control-mep
```

```
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

Until the Ethernet ring instance is attached to a VPLS service, the ring operational status is down and the forwarding status of each port is blocked. This prevents the operator from creating a loop by misconfiguration. This state can be seen on ring node PE-1 as follows:

```
*A:PE-1# show eth-ring 1

===============================================================================

```

Configure the control channel VPLS service

Path "a" and "b" configured in the Ethernet ring must be added as SAPs into a VPLS service (standard VPLS) using the **eth-ring** parameter. The SAP encapsulation values must match the values of the R-APS tag configured for the associated path.

G.8032 uses the same R-APS tag value on all nodes on the ring, as configured in this example. However, the SR OS implementation relaxes this constraint by requiring the tag to match only on adjacent nodes.

In this example VPLS "control-VPLS-1" is configured on PE-1, PE-2, and PE-3 for the control channel for the major ring (ring 1), and VPLS "control-VPLS-2" is used on PE-1, PE-3, and PE-4 for the subring (ring 2).

VPLS "control-VPLS-1" is the control service for the major ring and is defined for PE-1, PE-2, and PE-3, as follows:

```
# on PE-1:
configure
```

```
    service
        vpls 1 name "control-VPLS-1" customer 1 create
            description "Control VID 1.1 for ring 1 - major ring"
            sap 1/1/c1/1:1.1 eth-ring 1 create
            exit
            sap 1/1/c3/1:1.1 eth-ring 1 create
            exit
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        vpls 1 name "control-VPLS-1" customer 1 create
            description "Control VID 1.1 for ring 1 - major ring"
            sap 1/1/c1/1:1.1 eth-ring 1 create
            exit
            sap 1/1/c2/1:1.1 eth-ring 1 create
            exit
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
        vpls 1 name "control-VPLS-1" customer 1 create
            description "Control VID 1.1 for ring 1 - major ring"
            sap 1/1/c2/1:1.1 eth-ring 1 create
            exit
            sap 1/1/c3/1:1.1 eth-ring 1 create
            exit
            no shutdown
        exit
```

SAPs or SDPs can be added to a control channel VPLS on condition the **eth-ring** parameter is present. Any attempt to add a SAP without this parameter to a control channel VPLS results in the following message being displayed.

```
*A:PE-1>config>service>vpls# sap 1/1/c4/1:1 create
MINOR: SVCMGR #1321 Service contains an Ethernet ring control SAP
```

For the subring, the configuration of a split horizon group for the virtual channel on the major ring on the interconnection nodes is recommended. This avoids the looping of control R-APS messages in the case there is a misconfiguration in the major ring.

On ring node PE-1, the control service for the subring "control-VPLS-2" is configured as follows. SAP 1/1/c1/1:2.1 and SAP 1/1/c3/1:2.1 connect to the major ring (ring 1) for the virtual channel, whereas SAP 1/1/c2/1:2.1 connects to the subring (ring 2).

```
# on PE-1:
configure
    service
        vpls 2 name "control-VPLS-2" customer 1 create
            description "control/virtual channel VID 2.1 for ring 2"
            split-horizon-group "shg-ring2" create
            exit
            sap 1/1/c1/1:2.1 split-horizon-group "shg-ring2" eth-ring 1 create
                description "ring 2 interconnection using ring 1"
            exit
            sap 1/1/c2/1:2.1 eth-ring 2 create
```

```
            exit
            sap 1/1/c3/1:2.1 split-horizon-group "shg-ring2" eth-ring 1 create
                description "ring 2 interconnection using ring 1"
            exit
            no shutdown
        exit
```

On ring node PE-2, subring 2 is not present. However, the control service "control-VPLS-2" for the subring must be configured on PE-2, because the virtual channel for subring 2 needs to exist throughout major ring 1.

```
# on PE-2:
configure
    service
        vpls 2 name "control-VPLS-2" customer 1 create
            description "virtual channel VID 2.1 for ring 2"
            sap 1/1/c1/1:2.1 eth-ring 1 create
            exit
            sap 1/1/c2/1:2.1 eth-ring 1 create
            exit
            no shutdown
        exit
```

If multiple virtual channels are used (due to the aggregation of multiple subrings into the same major ring), their configuration could be simplified on non-interconnection nodes on the major ring. To achieve this on a ring node such as PE-2, a default SAP could be used rather than configuring a VPLS per virtual channel. If QinQ SAPs are used then default SAPs 1/1/c1/1:qtag.* and 1/1/c2/1:qtag.* could be used but this requires all control channels for subrings to be using qtag as the outer VLAN ID, or 1/1/c1/1:* and 1/1/c2/1:* if dot1Q SAPs were used. This is because the SAPs match explicit SAP definitions first and the default SAP will handle any other traffic.

The following configuration for control service "control-VPLS-2" for the subring on ring node PE-3 is similar to the configuration of PE-1.

```
# on PE-3:
configure
    service
        vpls 2 name "control-VPLS-2" customer 1 create
            description "control/virtual channel VID 2.1 for ring 2"
            split-horizon-group "shg-ring2" create
            exit
            sap 1/1/c1/1:2.1 eth-ring 2 create
            exit
            sap 1/1/c2/1:2.1 split-horizon-group "shg-ring2" eth-ring 1 create
                description "ring 2 interconnection using ring 1"
            exit
            sap 1/1/c3/1:2.1 split-horizon-group "shg-ring2" eth-ring 1 create
                description "ring 2 interconnection using ring 1"
            exit
            no shutdown
        exit
```

On ring node PE-4, control service "control-VPLS-2" for the subring is configured as follows. Both SAPs are configured on the subring (ring 2).

```
# on PE-4
configure
    service
        vpls 2 name "control-VPLS-2" customer 1 create
            description "Control VID 2.1 for ring 2 Sub-ring"
```

```
            sap 1/1/c1/1:2.1 eth-ring 2 create
            exit
            sap 1/1/c2/1:2.1 eth-ring 2 create
            exit
            no shutdown
        exit
```

At this point, the Ethernet ring 1 is operationally up and the RPL is blocking successfully RPL end port 1/1/c1/1 on RPL owner PE-2 and RPL end port 1/1/c2/1 on RPL neighbor PE-3.

Show output

An overview of all of the rings can be shown using the following commands, in this case on PE-1.

The following command shows the Ethernet ring status on PE-1.

```
*A:PE-1# show eth-ring status

===============================================================================
Ethernet Ring (Status information)
===============================================================================
Ring   Admin  Oper       Path Information                MEP Information
ID     State  State  Path         Tag       State     Ctrl-MEP CC-Intvl Defects
-------------------------------------------------------------------------------
1      Up     Up     a - 1/1/c1/1     1.1   Up        Yes      1         -----
                     b - 1/1/c3/1     1.1   Up        Yes      1         -----
2      Up     Up     a - 1/1/c2/1     2.1   Up        Yes      1         -----
                     b - N/A           -        -        -        -----
===============================================================================
Ethernet Tunnel MEP Defect Legend:
R = Rdi, M = MacStatus, C = RemoteCCM, E = ErrorCCM, X = XconCCM
```

It is expected that the state is "up", even on ring paths which are blocked. The "Defects" column refers to the CFM defects of the MEPs. If there is a problem, these will be flagged.

The following command shows the ring and path forwarding states on PE-1.

```
*A:PE-1# show eth-ring

```

PE-2 is the RPL owner with port 1/1/c1/1 as an RPL end, which is blocked as expected. The revert time is also shown to be the configured value of 60 seconds. Detailed information is shown relating to the R-APS PDUs being transmitted on this ring because PE-2 is the RPL owner.

When a revert is pending after a link failure has been removed, the "Time to Revert" will show the number of seconds remaining before the revert occurs.

The following command shows specific information for major ring 1 on RPL neighbor PE-3:

```
*A:PE-3# show eth-ring 1

```

Configure the user data channel VPLS service

The user data channels are created on a separate VPLS, "VPLS-11" in this example, using VLAN tag 1.11. The ring data channels must be on the same ports as the corresponding control channels configured above. The access into the data services can use normal SAPs or SDPs, for example the SAP on port 1/1/c4/1 in the following output. Customer data traverses the ring on a data SAP. Multiple parallel data SAPs in different data services can be controlled by one control ring instance, Ethernet ring 1 in the example.

Data VPLS "VPLS-11" on ring node PE-1 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on major ring 1, while SAP 1/1/c2/1:1.11 is the data SAP on subring 2.

```
# on PE-1:
configure
    service
        vpls 11 name "VPLS-11" customer 1 create
            description "data VPLS"
            sap 1/1/c1/1:1.11 eth-ring 1 create
            exit
            sap 1/1/c2/1:1.11 eth-ring 2 create
            exit
            sap 1/1/c3/1:1.11 eth-ring 1 create
            exit
            sap 1/1/c4/1:11 create
                description "sample customer service SAP"
```

```
            exit
            no shutdown
        exit
```

The configuration of data VPLS "VPLS-11" on ring node PE-3 (not shown) is similar to ring node PE-1.

The configuration of data VPLS "VPLS-11" on ring node PE-2 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on major ring 1.

```
# on PE-2:
configure
    service
        vpls 11 name "VPLS-11" customer 1 create
            description "data VPLS"
            sap 1/1/c1/1:1.11 eth-ring 1 create
            exit
            sap 1/1/c2/1:1.11 eth-ring 1 create
            exit
            sap 1/1/c4/1:11 create
                description "sample customer service SAP"
            exit
            no shutdown
        exit
```

The configuration of data VPLS "VPLS-11" on ring node PE-4 has data SAPs 1/1/c1/1:1.11 and 1/1/c3/1:1.11 on subring 2.

```
# on PE-4:
configure
    service
        vpls 11 name "VPLS-11" customer 1 create
            description "data VPLS"
            sap 1/1/c1/1:1.11 eth-ring 2 create
            exit
            sap 1/1/c2/1:1.11 eth-ring 2 create
            exit
            sap 1/1/c4/1:11 create
                description "sample customer service SAP"
            exit
            no shutdown
        exit
```

All the SAPs which are configured to use Ethernet rings can be displayed. The following output is taken from PE-1, where there are:

- two SAPs in VPLS 1 for the control channel of ring 1 (VLAN ID 1.1)
- two SAPs in VPLS 2 on ring 1 for the virtual channel for ring 2 (VLAN ID 2.1)
- one SAP in VPLS 2 on ring 2 for the control channel for ring 2 (VLAN ID 2.1)
- three SAPs in VPLS 11, two on ring 1 and one on ring 2, for the data service (VLAN ID 1.11). This matches the information in Figure 7: G.8032 subring interconnection components.

```
*A:PE-1# show service sap-using eth-ring

"Eth-Ring 1 path b changed fwd state to blocked"

80 2023/05/10 07:54:01.300 UTC WARNING: SNMP #2004 Base 1/1/c2/1
"Interface 1/1/c2/1 is not operational"
```

For troubleshooting, the **tools dump eth-ring** <*ring-index*> command displays path information, the internal state of the control protocol, related statistics information, and up to the last 16 protocol events (including messages sent and received, and the expiration of timers). An associated **clear** parameter exists, which clears the event information in this output when the command is entered. The following is an example of the output on PE-2 after port 1/1/c2/1 has been enabled.

```
*A:PE-2# tools dump eth-ring 1

Configuration of a subring to a major ring with a non-virtual link

The differences from the preceding virtual link configuration with a non-virtual link for the subring are:

- The subring configuration on the interconnection nodes, PE-1 and PE-3, is modified to indicate that the subring is not using a virtual link, otherwise it remains the same.
- The subring configuration on the subring node PE-4 is also modified to indicate that this is part of a subring that is not using a virtual link. This is mandatory on all non-interconnection nodes on the subring in order to ensure the propagation of R-APS messages around the subring.
- The virtual link services and SAPs must be removed from PE-1, PE-2, and PE3, that is:
  - On PE-1 and PE-3, the SAPs in VPLS 2 around the major ring (configured with the parameter **eth-ring 1**) are removed.
  - The service VPLS 2 is removed completely from PE-2.

The new configuration of subring 2 on PE-1 is as follows, the configuration on PE-3 is similar.

```
# on PE-1:
configure
    eth-ring 2
        description "Ethernet subring 2 on major ring 1"
        revert-time 60
```

```
        sub-ring non-virtual-link
            interconnect ring-id 1
                propagate-topology-change
            exit
        exit
        path a 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 141 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The configuration of subring 2 on non-interconnection node PE-4 must include the **subring non-virtual-link** parameter, as follows:

```
# on PE-4:
configure
    eth-ring 2
        description "Ethernet subring 2"
        revert-time 60
        rpl-node owner
        sub-ring non-virtual-link
        exit
        path a 1/1/c1/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 144 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathB"
            rpl-end
            eth-cfm
                mep 344 domain 1 association 34
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The SAP usage on PE-1 is as follows with only the control and data SAPs to PE-4 now using subring 2.

```
*A:PE-1# show service sap-using eth-ring

===============================================================================

-------------------------------------------------------------------------------
Number of SAPs : 6
===============================================================================
```

The information relating to subring 2 is as follows and it can be seen that this is now not using a virtual link, but subring 2 is still connected to major ring 1 and propagation is still enabled from the subring to the major ring. The single ring path "a" is unblocked because the RPL is configured between PE-3 and PE-4.

```

Configuration of a subring to a VPLS service

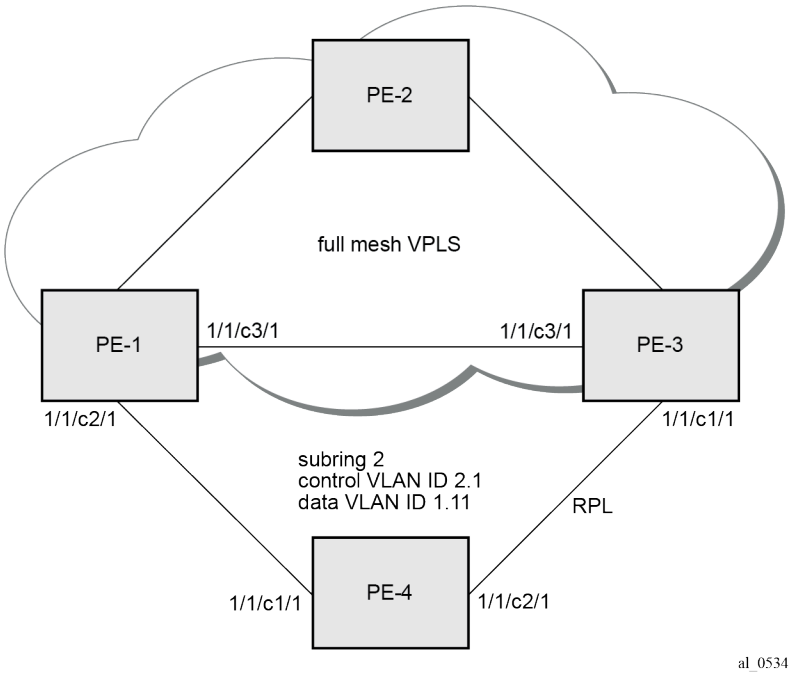
Subrings can be connected to VPLS services, in which case a virtual link is not used and is not configurable. While similar to the ring interconnect, there are a few differences.

Flush propagation is from the subring to the VPLS, in the same way as it was for the subring to the major ring. The same configuration parameter is used to propagate topology changes. In this case, LDP flush messages (flush-all-from-me) are sent into the LDP portion of the network to account for ring changes without the need to configure anything in the VPLS service.

As with other rings, until an Ethernet ring instance is attached to the VPLS service, the ring operational status is down and the forwarding status of each port is blocked. This prevents operators from creating a loop by misconfiguration.

The topology for this case is shown in Figure 10: Subring to VPLS topology. The configuration is very similar to the subring with a non-virtual link described earlier, but ring 1 is replaced by a VPLS service using LDP-signaled mesh SDPs between PE-1, PE-2, and PE-3 to create a fully meshed VPLS service. Both spoke and mesh SDPs using LDP can be used for the VPLS; however, only mesh SDPs have been used in this example.

Figure 10: Subring to VPLS topology



The differences for the VPLS service connection to the configuration when the subring is connected to a major ring without a virtual link are:

- The subring configuration on the interconnection nodes, PE-1 and PE-3, is modified to indicate that the subring is connected to a VPLS service.
- The subring configuration on the non-interconnection node PE-4 indicates that this is part of a subring that is not using a virtual link (same configuration as in the scenario when a subring is connected to a major ring without a virtual link). This is mandatory on all non-interconnection nodes on the subring in order to ensure the propagation of R-APS messages around the subring.
- The control VPLS "control-VPLS-1" and SAPs relating to the major ring 1 on PE-1, PE-2, and PE-3 are removed. These are replaced by routed IP interfaces configured with a routing protocol and LDP in order to signal the required MPLS labels, together with the necessary SDPs to provide interconnection at a service level.
- The data service "VPLS-11" is configured with mesh SDPs between PE-1, PE-2, and PE-3.

The configuration on PE-1 of the subring 2 is as follows with the interconnect indicating a VPLS service. The configuration on PE-3 is similar.

```
# on PE-1:
configure
    eth-ring 2
        description "Ethernet subring 2 on VPLS"
        revert-time 60
```

```
        sub-ring non-virtual-link
            interconnect vpls
                propagate-topology-change
            exit
        exit
        path a 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 141 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The following configuration of subring 2 on non-interconnection node PE-4 includes the **sub-ring non-virtual-link** parameter:

```
# on PE-4:
configure
    eth-ring 2
        description "Ethernet subring 2"
        revert-time 60
        rpl-node owner
        sub-ring non-virtual-link
        exit
        path a 1/1/c1/1 raps-tag 2.1
            description "Ethernet ring 2 - PathA"
            eth-cfm
                mep 144 domain 1 association 14
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 2.1
            description "Ethernet ring 2 - PathB"
            rpl-end
            eth-cfm
                mep 344 domain 1 association 34
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

The data service on PE-1 is as follows. The configuration on PE-3 is similar.

```
# on PE-1:
configure
    service
        vpls 11 name "VPLS-11" customer 1 create
```

```
            description "data VPLS"
            sap 1/1/c2/1:1.11 eth-ring 2 create
                no shutdown
            exit
            sap 1/1/c4/1:11 create
                description "sample customer service SAP"
                no shutdown
            exit
            mesh-sdp 12:11 create
                no shutdown
            exit
            mesh-sdp 13:11 create
                no shutdown
            exit
            no shutdown
        exit
```

The state of the subring is as follows and shows the subring is not using a virtual link, is connected to a VPLS service, and has propagation of topology change events enabled. As earlier, the single ring path "a" is unblocked because the RPL is configured between PE-3 and PE-4.

```
*A:PE-1# show eth-ring 2

===============================================================================
```

In this case, if a topology change event occurs in the subring, an LDP "flush-all-from-me" message is sent by PE-1 and PE-3 to their LDP peers. This can be seen by enabling the following debugging for PE-1, as follows:

```
*A:PE-1# debug router ldp peer 192.0.2.2 packet init
*A:PE-1# debug router ldp peer 192.0.2.3 packet init
```

```
# on PE-1:
debug
    router "Base"
        ldp
            peer 192.0.2.2
                event
```

```
                exit
                packet
                    init
                exit
            exit
            peer 192.0.2.3
                event
                exit
                packet
                    init
                exit
            exit
        exit
    exit
exit
```

The topology change is forced by disabling port 1/1/c2/1 on PE-1:

```
# on PE-1:
configure
    port 1/1/c2/1
        shutdown
```

The log shows the following messages on the console (combination of log 1 for debug-trace and log 2 for main), where packets 1 and 2 are the flush messages.

```

Operational procedures

Operators may wish to configure rings with or without control over reversion. Reversion can be controlled by timers or the ring can be run without reversion allowing the operator to choose when the ring reverts. To change a ring topology, the **manual** or **force** switch command may be used to block a specified ring path. A ring will still address failures when run without reversion but will not automatically revert to the RPL when resources are restored. A **clear** command can be used to clear the manual or force state of a ring.

The following **tools** commands are available to control the state of paths on a ring.

```
tools perform eth-ring clear <ring-index>
tools perform eth-ring force <ring-index> path {a|b}
tools perform eth-ring manual <ring-index> path {a|b}
```

In the following output, both ports of Ethernet ring 1 are unblocked.

```
*A:PE-1# show eth-ring 1

```

Both the **manual** and **force** command block the path specified, however, the **manual** command fails if there is an existing forced switch or signal fail event in the ring, as seen in the following output. The **force** command will block the port regardless of any existing ring state and there can be multiple force states simultaneously on a ring on different nodes.

```
*A:PE-1# tools perform eth-ring manual 1 path b
INFO: ERMGR #1001 Not permitted - The switch command is not compatible to the
current state (FS), effective priority (FS) or rpl-node type (None)
```

Conclusion

Ethernet ring APS provides an optimal solution for designing native Ethernet services with ring topology. With subrings, both multiple rings and access rings increase the versatility of G.8032. G.8032 has been expanded to more of the SR platforms by allowing R-APS with slower MEPs (including CCMs intervals of 1 second). This protocol provides simple configuration, operation, and guaranteed fast protection time. The implementation also has a flexible encapsulation that allows dot1Q, QinQ, or PBB for the ring traffic. It can be utilized on various services such as mobile backhaul, business VPN access, aggregation, and core.

G.8032 Ethernet Ring Protection Single Ring Topology

This chapter provides information about G.8032 Ethernet ring protection single ring topology.

Topics in this chapter include:

Applicability

The chapter was initially written for SR OS Release 8.0.R7, but the CLI in the current edition corresponds to SR OS Release 23.3.R2. This chapter describes ring protection for a single ring topology. Protection for multiple ring topologies is covered in G.8032 Ethernet Ring Protection Multiple Ring Topology.

Overview

G.8032 Ethernet ring protection is supported for data service SAPs within a regular VPLS service, a provider backbone bridging (PBB) VPLS (I/B-component), or a routed VPLS (R-VPLS). G.8032 is one of the fastest protection schemes for Ethernet networks.

ITU-T G.8032v2 specifies protection switching mechanisms and a protocol for Ethernet layer network (ETH) Ethernet rings. Ethernet rings can provide wide-area multi-point connectivity more economically due to their reduced number of links. The mechanisms and protocol defined in ITU-T G.8032v2 achieve highly reliable and stable protection and never form loops, which would negatively affect network operation and service availability. Each ring node is connected to adjacent nodes participating in the same ring using two independent paths, which use ring links that are configured on ports or link aggregation groups (LAGs). A ring link is bounded by two adjacent nodes and a port for a ring link is called a ring port. The minimum number of nodes on a ring is two.

The fundamentals of this ring protection switching architecture are:

- the principle of loop avoidance and
- the utilization of learning, forwarding, and address table mechanisms defined in the ITU-T G.8032v2 Ethernet flow forwarding function (ETH_FF) (control plane).

Loop avoidance in the ring is achieved by guaranteeing that, at any time, traffic may flow on all but one of the ring links. This particular link is called the ring protection link (RPL) and under normal conditions this link is blocked, so it is not used for traffic. One designated node, the RPL owner, is responsible to block traffic over the one designated RPL. Under a ring failure condition, the RPL owner is responsible for unblocking the RPL, allowing the RPL to be used for traffic. The protocol ensures that even without an RPL owner defined, one link will be blocked and it operates as a *break before make protocol*, specifically the protocol guarantees that no link is restored until a different link in the ring is blocked. The other side of the RPL is configured as an RPL neighbor. An RPL neighbor blocks traffic on the link.

The event of a ring link or ring node failure results in protection switching of the traffic. This is achieved under the control of the ETH_FF functions on all ring nodes. A ring automatic protection switching (R-APS) protocol is used to coordinate the protection actions over the ring. The protection switching mechanisms

and protocol supports a multi-ring/ladder network that consists of connected Ethernet rings, however, that is not covered in this chapter.

Ring protection mechanism

The ring protection protocol is based on the following building blocks:

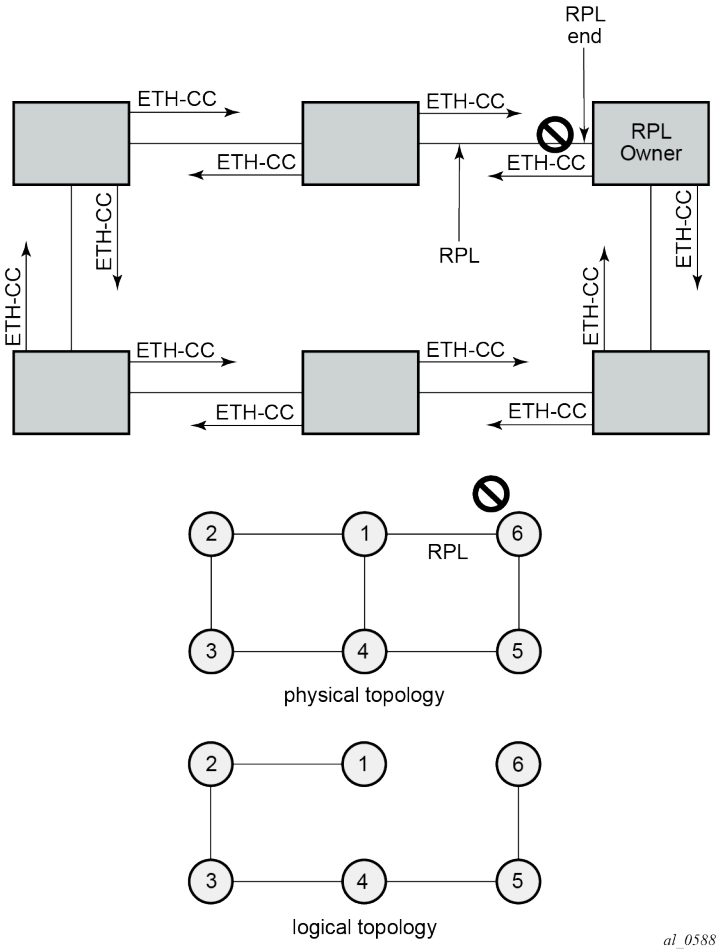
- ring status change on failure
  - idle → link failure → protection → recovery → idle
- ring control state changes
  - idle → protection → manual switch → forced switch → pending
- re-use existing ETH OAM
  - monitoring: ETH continuity check messages
  - failure notification: Y.1731 signal failure
- forwarding database MAC flush on ring status change
- ring protection link (RPL) defines blocked link in idle status

Figure 11: G.8032 operation and topologies shows a ring of six nodes, with the RPL owner on the top right. One link of the RPL owner is designated to be the RPL and will be blocked in order to prevent a loop. Schematics of the physical and logical topologies are also shown.

When an RPL owner and RPL end are configured, the associated link will be the RPL when the ring is fully operational and so be blocked by the RPL owner. If a different ring link fails, then the RPL will be unblocked by the RPL owner. When the failed link recovers, it will initially be blocked by one of its adjacent nodes. The adjacent node sends an R-APS message across the ring to indicate the error is cleared and after a configurable time, if reversion is enabled, the RPL will revert to being blocked with all other links unblocked. This ensures that the ring topology is predictable when fully operational.

If a specific RPL owner is not configured, then the last link to become active will be blocked and the ring will remain in this state until another link fails. However, this operation makes the selection of the blocked link non-deterministic.

Figure 11: G.8032 operation and topologies

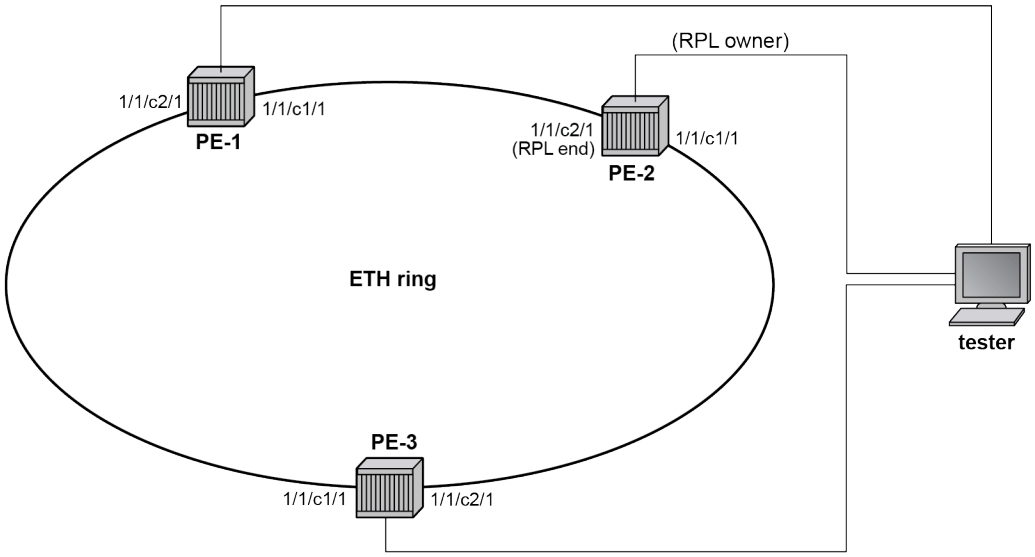


The protection protocol uses a specific control VLAN, with the associated data VLANs taking their forwarding state from the control VLAN.

Configuration

The example topology is shown in Figure 12: Example topology.

Figure 12: Example topology



** control channel: VPLS 1, tag 1
** data channel: VPLS 100, tag 100

al_0589

The Ethernet ring configuration commands are as follows:

```
configure
    eth-ring <ring-index [1..128]>
        ccm-hold-time { [down <down-timeout>] [up <up-timeout>] }
        compatible-version <version>            # [1..2] - Default: 2
        description <description-string>
        guard-time <time>       # [1..20] in deciseconds - Default: 5
        node-id <xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx>
        path {a|b} [ { <port-id>|<lag-id> } raps-tag <qtag1>[.<qtag2>] ]
            description <description-string>
            eth-cfm
                mep <mep-id> domain <md-index> association <ma-index>
                <...>
            rpl-end
            shutdown
        revert-time <time>      # [60..720] in seconds - Default: 300
        rpl-node {owner|nbr}
        shutdown
        sub-ring {virtual-link|non-virtual-link}       # beyond the scope
```

Parameters:

- *ring-index* — This is the number by which the ring is referenced, values: 1 to 128.
- **ccm-hold-time {[down** <*down-timeout*>**] [up** <*up-timeout*>**]}**
  - **down** — This command specifies the timer that controls the delay between detecting that ring path is down and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to the ring path continuity check message (CCM); it does not apply to the ring port link state. To dampen ring port link state transitions, use the **hold-**

time parameter from the physical member port. This is useful if the underlying path between two nodes is going across an optical system which implements its own protection.

– **up** — This command specifies the timer which controls the delay between detecting that the ring path is up and reporting it to the G.8032 protection module. If a non-zero value is configured, the system will wait for the time specified in the value parameter before reporting it to the G.8032 protection module. This parameter applies only to ring path CCM; it does not apply to the member port link state. To dampen member port link state transitions, use the **hold-time** parameter from the physical member port.

– timeout values:

```
<down-timeout>       : [0..5000] in 100ths of seconds - Default: 0
<up-timeout>         : [0..5000] in 10ths of seconds - Default: 20
```

- **compatible version** — This command configures the Ethernet ring compatibility version for the G.8032 state machine and messages. The default is version 2 (ITU G.8032v2) and all SR OS nodes use version 2. If there is a need to interwork with third party devices that only support version 1, this can be set to version 1 allowing the reception of version 1 PDUs. Version 2 is encoded as 1 in the R-APS messages. Compatibility allows the reception of version 1 (encoded as 0) R-APS PDUs but, as per the G.8032 specification, higher versions are ignored on reception. For SR OS nodes, messages are always originated with version 2. Therefore, if a third party switch supported version 3 (encoded as 2) or higher, interworking is also supported provided the other switch is compatible with version 2 (encoded as 1).
- **description <description-string>** — This configures a text string, up to 80 characters, which can be used to describe the use of the Ethernet ring.
- **guard-time <time>** — The forwarding method, in which R-APS messages are copied and forwarded at every Ethernet ring node, can result in a message corresponding to an old request, that is no longer relevant, being received by Ethernet ring nodes. Reception of an old R-APS message may result in erroneous ring state interpretation by some Ethernet ring nodes. The guard timer is used to prevent Ethernet ring nodes from acting upon outdated R-APS messages and prevents the possibility of forming a closed loop. Messages are not forwarded when the guard-timer is running.

  The guard time is configured in 10ths of seconds and the default guard time is 0.5 s:

  ```
  [1..20] in deciseconds - Default: 5
  ```

- **node-id <xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx>** — The node identifier can be explicitly configured. In typical configurations, the node ID is not configured; by default, the chassis MAC address is used as node ID.
- **path {a|b} [{<port-id>|<lag-id>} raps-tag <qtag1>[.<qtag2>]]** — The **path** parameter defines the paths around the ring, of which there are two in different directions on the ring: an "a" path and a "b" path. In addition, the path command configures the encapsulation used for the R-APS messages on the ring. These can be either single or double tagged.
  – **description <description-string>** — The description is a text string with up to 80 characters, that can be used to describe the use of the path.
  – **eth-cfm** — Configures the associated Ethernet connectivity fault management (CFM) parameters.
    - **mep <mep-id> domain <md-index> association <ma-index>** — The maintenance endpoint (MEP) defined under the path is used for the G.8032 protocol messages, which are based on IEEE 802.1ag/Y.1731 CFM frames.

  - **rpl-end** — When configured, this path is expected to be one end of the RPL. This parameter must be configured in conjunction with the **rpl-node**.
  - **shutdown** — This command disables the path.
- **revert-time <time>** — This command configures the revert time for an Ethernet ring. The revert time is the time that the RPL will wait before returning to the blocked state. Configuring **no revert-time** disables reversion, effectively setting the revert-time to zero.

  Values:

  ```
  [60..720] in seconds - Default: 300
  ```
- **rpl-node {owner|nbr}** — A node can be designated as either the **owner** of the RPL, in which case this node is responsible for the RPL, or the **nbr**, in which case this node is expected to be the neighbor to the RPL owner across the RPL. The neighbor is optional and is included to be compliant with the specification. This parameter must be configured in conjunction with the **rpl-end** parameter.
- **shutdown** — This command disables the ring.
- **sub-ring {virtual-link|non-virtual-link}** — The **sub-ring** command is beyond the scope of this chapter because it is only required for multiple ring topologies.

Logging

Create following log-id on PE-2 to see major events logged to the console on PE-2. This is an optional step; alternatively, log 99 can be consulted.

```
# on PE-2:
configure
    log
        log-id 1 name "log1"
            from main
            to console
        exit
    exit
```

Configure encapsulation for ring ports

To configure R-APS, there should be at least two VPLS services for one Ethernet ring instance, one VPLS for the control channel and the other VPLSs for data channels. The control channel is used for R-APS signaling while the data channel is for user data traffic. The state of the data channels is inherited from the state of the control channel.

- An Ethernet ring needs R-APS tags to send and receive G.8032 signaling messages. To configure a control channel, an access SAP configuration is required on each path a port and path b port. The SAP configuration follows that of the port and must be either dot1Q or QinQ, so the control and data packets are either single tagged or double tagged. It is also possible to have the control VPLS using single tagged frames with the data VPLSs using double tagged frames; this requires the system to be configured with the **new-qinq-untagged-sap** parameter (**configure system ethernet new-qinq-untagged-sap**), with the ring path R-APS tags and control VPLS SAPs configured as qtag.0, and the data VPLS SAPs configured as qtag1.qtag2.

In this example, single tags are used so the ports on the ring nodes are configured as follows:

```
# on PE-1, PE-2, PE-3:
configure
    port 1/1/c1/1
        ethernet
            mode access
            encap-type dot1q
        exit
        no shutdown
    exit
    port 1/1/c2/1
        ethernet
            mode access
            encap-type dot1q
        exit
        no shutdown
    exit
```

Configure Ethernet CFM

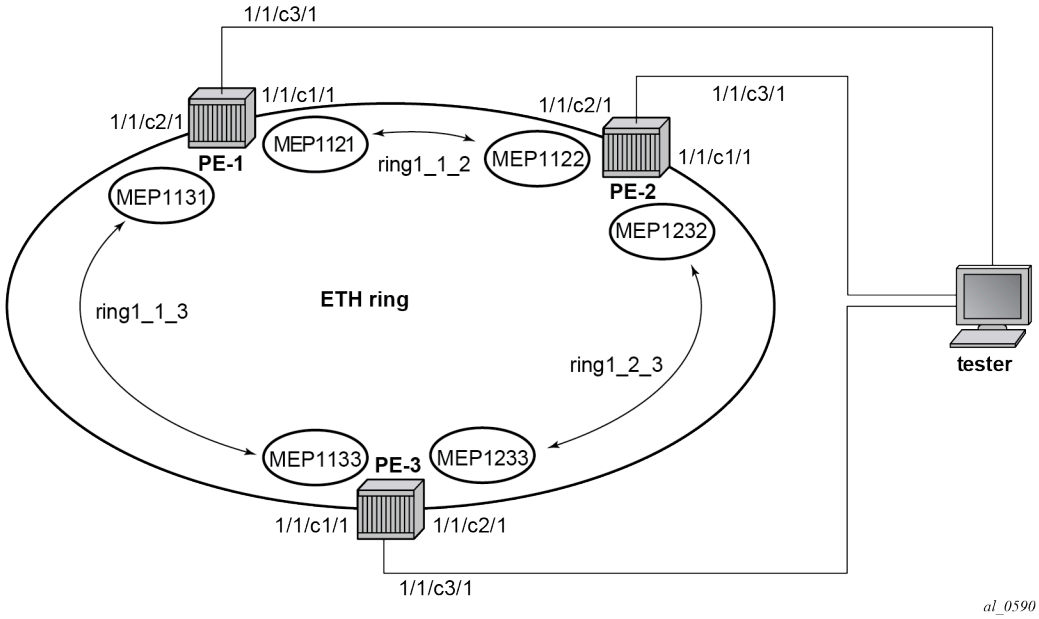
Ethernet ring requires Ethernet CFM domains, associations, and MEPs being configured. The domain format must be none and association name must be ITU-T carrier code-based (ICC-based - Y.1731). The minimum CCM interval for the SR OS nodes is 10ms. The Ethernet ring MEP requires a CCM interval, such as 10ms, 100ms, or 1s, to be configured.

The MEPs used for R-APS control normally have CCM configured on the control channel path MEPs for failure detection. Alternatively, detecting a failure of the ring may be achieved by running Ethernet in the first mile (EFM) at the port level if CCM is not possible at 10ms, 100ms, or 1s. Loss-of-signal, in conjunction with other OAM, is applicable only when the nodes are directly connected.

To omit the failure detecting CCMs, remove the **ccm-enable** from under the path MEPs and remove the **remote-mepid** from under the **eth-cfm>domain>association** on all nodes.

Figure 13: Ethernet CFM configuration shows the Ethernet CFM configuration used here.

Figure 13: Ethernet CFM configuration



The Ethernet CFM configuration of the nodes is as follows.

```
# on PE-1:
configure
    eth-cfm
        domain 1 format none level 3 admin-name "domain-1"
            association 1 format icc-based name "ring1_1_2" admin-name "association-1"
                ccm-interval 1
                remote-mepid 1122
            exit
            association 2 format icc-based name "ring1_1_3" admin-name "association-2"
                ccm-interval 1
                remote-mepid 1133
            exit
        exit
```

```
# on PE-2:
configure
    eth-cfm
        domain 1 format none level 3 admin-name "domain-1"
            association 1 format icc-based name "ring1_2_3" admin-name "association-1"
                ccm-interval 1
                remote-mepid 1233
            exit
            association 2 format icc-based name "ring1_1_2" admin-name "association-2"
                ccm-interval 1
                remote-mepid 1121
            exit
        exit
```

```
# on PE-3:
configure
    eth-cfm
```

```
        domain 1 format none level 3 admin-name "domain-1"
            association 1 format icc-based name "ring1_1_3" admin-name "association-1"
                ccm-interval 1
                remote-mepid 1131
            exit
            association 2 format icc-based name "ring1_2_3" admin-name "association-2"
                ccm-interval 1
                remote-mepid 1232
            exit
        exit
```

Configure Ethernet ring

Two paths need to be configured to form a ring. In this example, VLAN tag 1 is used as control channel for R-APS signaling in the ring.

```
# on PE-1:
configure
    eth-ring 1
        path a 1/1/c1/1 raps-tag 1
            eth-cfm
                 mep 1121 domain 1 association 1
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 1
            eth-cfm
                mep 1131 domain 1 association 2
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

It is mandatory to configure a MEP in the path context, otherwise the following error will be displayed:

```
*A:PE-1>config>eth-ring# path a 1/1/c1/1 raps-tag 1
*A:PE-1>config>eth-ring>path# no shutdown
INFO: ERMGR #1001 Not permitted - must configure eth-cfm MEP first
```

While MEPs are mandatory, enabling CCM on the MEP in the path context as a failure detection mechanism is optional.

In order to define the RPL, node PE-2 is configured as the RPL owner and path b as the RPL end. The link between nodes PE-1 and PE-2 will be the RPL with node PE-2 blocking that link when the ring is fully operational.

```
# on PE-2:
configure
    eth-ring 1
        revert-time 60
```

```
        rpl-node owner
        path a 1/1/c1/1 raps-tag 1
            eth-cfm
                mep 1232 domain 1 association 1
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
        path b 1/1/c2/1 raps-tag 1
            rpl-end
            eth-cfm
                mep 1122 domain 1 association 2
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

It is not allowed to configure a path as an RPL end without having configured the node on this ring to be either the RPL **owner** or **nbr** otherwise the following error message is reported.

```
*A:PE-2>config>eth-ring>path# rpl-end
INFO: ERMGR #1001 Not permitted - path-type rpl-end is not consistent with eth-ring 'rpl-node'
 type
```

```
# on PE-3:
configure
    eth-ring 1
        path a 1/1/c1/1 raps-tag 1
            eth-cfm
                mep 1133 domain 1 association 1
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        path b 1/1/c2/1 raps-tag 1
            eth-cfm
                mep 1233 domain 1 association 2
                    ccm-enable
                    control-mep
                    no shutdown
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

Until the Ethernet ring instance is attached to the service (VPLS in this case), the ring operational status is down and the forwarding status of each port is blocked. This prevents operators from creating a loop by misconfiguration. This state can be seen on ring node PE-1 as follows:

```
*A:PE-1# show eth-ring 1

```

Configure control channel VPLS service

Paths a and b defined in the Ethernet ring must be added as SAPs into a VPLS service (standard VPLS in this example) using the **eth-ring** parameter. The SAP encapsulation values must match the values of the **raps-tag** configured for the associated path.

G.8032 uses the same R-APS tag value on all nodes on the ring, as configured in this example. However, the SR OS implementation relaxes this constraint by requiring the tag to match only on adjacent nodes.

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS-1" customer 1 create
            description "control channel VPLS 1 tag 1"
            sap 1/1/c1/1:1 eth-ring 1 create
            exit
            sap 1/1/c2/1:1 eth-ring 1 create
            exit
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS-1" customer 1 create
            description "control channel VPLS 1 tag 1"
```

```
            sap 1/1/c1/1:1 eth-ring 1 create
            exit
            sap 1/1/c2/1:1 eth-ring 1 create
            exit
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS-1" customer 1 create
            description "control channel VPLS 1 tag 1"
            sap 1/1/c1/1:1 eth-ring 1 create
            exit
            sap 1/1/c2/1:1 eth-ring 1 create
            exit
            no shutdown
        exit
```

A normal SAP or SDP can be added in a control channel VPLS on condition the **eth-ring** parameter is present. Any attempt to add a SAP or SDP without this parameter into a control channel VPLS results in the following message being displayed. In the following example, SAP 1/1/c3/1:1 is added to control VPLS 1 without the **eth-ring** parameter.

```
*A:PE-1>config>service>vpls# sap 1/1/c3/1:1 create
MINOR: SVCMGR #1321 Service contains an Ethernet ring control SAP
```

In non-failure conditions, the Ethernet ring is operationally up and the RPL is blocking successfully on ring node PE-2 port 1/1/c2/1, as expected from the RPL owner and RPL end configuration.

An overview of all of the rings can be shown using the following commands, in this case on node PE-2.

The following command on PE-2 shows the Ethernet ring status.

```
*A:PE-2# show eth-ring status

===============================================================================

```

Configure user data channel VPLS service

The user data channels are created on a separate VPLS, "VPLS-100" in the example. The ring data channels must be on the same ports as the corresponding control channels configured above. The access into the data services can use SAPs and/or SDPs.

```
# on PE-1:
configure
    service
        vpls 100 name "VPLS-100" customer 1 create
            description "data channel VPLS 100"
            sap 1/1/c1/1:100 eth-ring 1 create
            exit
            sap 1/1/c2/1:100 eth-ring 1 create
            exit
            sap 1/1/c3/1:100 create
            exit
            no shutdown
        exit
```

```
# on PE-2:
```

```
configure
    service
        vpls 100 name "VPLS-100" customer 1 create
            description "data channel VPLS 100"
            sap 1/1/c1/1:100 eth-ring 1 create
            exit
            sap 1/1/c2/1:100 eth-ring 1 create
            exit
            sap 1/1/c3/1:100 create
            exit
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
        vpls 100 name "VPLS-100" customer 1 create
            description "data channel VPLS 100"
            sap 1/1/c1/1:100 eth-ring 1 create
            exit
            sap 1/1/c2/1:100 eth-ring 1 create
            exit
            sap 1/1/c3/1:100 create
            exit
            no shutdown
        exit
```

The following command on PE-1 shows all the SAPs which are configured to use Ethernet rings.

```
*A:PE-1# show service sap-using eth-ring

```

Debug

To emulate a failure on Ethernet ring 1, the unblocked port (1/1/c1/1) on node PE-2 is disabled, as follows.

```
# on PE-2:
configure
    port 1/1/c1/1
        shutdown
```

The following messages are logged in log 99 when the failure occurs:

```
85 2023/05/04 12:49:46.602 UTC MINOR: ETH_CFM #2001 Base
"MEP 1/1/1232 highest defect is now defRemoteCCM"
```

```
84 2023/05/04 12:49:43.312 UTC MAJOR: SVCMGR #2210 Base
"Processing of an access port state change event is finished and the status of all affected
SAPs on port 1/1/c1/1 has been updated."

"Eth-Ring 1 path b changed fwd state to unblocked"

82 2023/05/04 12:49:43.308 UTC MINOR: ERING #2001 Base eth-ring-1
"Eth-Ring 1 path a changed fwd state to blocked"

81 2023/05/04 12:49:43.308 UTC WARNING: SNMP #2004 Base 1/1/c1/1
"Interface 1/1/c1/1 is not operational"
```

For troubleshooting, the **tools dump eth-ring** <*ring-index*> command displays path information, the internal state of the control protocol, related statistics information and up to the last 20 protocol events (including messages sent and received, and the expiration of timers). An associated parameter **clear** exists, clearing the event information in this output when the command is entered. The following is an example of the output on node PE-2 with port 1/1/c1/1 disabled.

```
*A:PE-2# tools dump eth-ring 1

Conclusion

Ethernet ring APS provides an optimal solution for designing native Ethernet services with ring topology. This protocol provides simple configuration, operation, and guaranteed fast protection time. SR OS also has a flexible encapsulation that allows dot1Q, QinQ, or PBB for the ring traffic. Ethernet ring APS can be utilized for various services such as mobile backhaul, business VPN access, aggregation, and core.

GRE Tunnel Origination and Termination Using Non-system IP Addresses

This chapter provides information about GRE tunnel origination and termination using non-system IP addresses.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 16.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.3.R2. GRE SDPs and auto-bind GRE tunnels can originate and terminate on a non-system IP address in SR OS Release 16.0.R4 or later.

Overview

For scaling purposes, service providers typically deploy seamless MPLS or inter-AS scenarios. In many cases, the system IP address cannot be leaked between domains and a separate loopback address is used to terminate tunnels. GRE termination on a non-system IP address is supported in the following services:

- VPLS with manually configured GRE spoke-SDPs
- VPLS with BGP-AD using provisioned GRE SDPs (**use-provisioned-sdp** or **prefer-provisioned-sdp** CLI commands)
- BGP-VPLS using provisioned GRE SDPs
- Epipe with manually configured GRE spoke-SDPs
- Epipe with BGP-VPWS using provisioned GRE SDPs
- VPRN with manually configured GRE spoke-SDPs
- VPRN with auto-bind GRE tunnel
- IES with manually configured GRE spoke-SDPs

This chapter focuses on MPLS-over-GRE termination, but IP-over-GRE termination is also supported.

MPLS-over-GRE termination

GRE termination applies to GRE SDPs and auto-bind GRE tunnels concurrently on a system interface and on non-system interfaces with a subnet that is up to and including /16. In the following example, the non-system loopback address 10.0.1.1 with a subnet of /24 is configured as GRE termination on PE-1:

```
# on PE-1:
```

```
configure
    router Base
        interface "lo1"
            address 10.0.1.1/24
            loopback
            gre-termination
            no shutdown
        exit
```

Only one interface can be configured as GRE termination. The following error is raised when attempting to configure a second loopback interface "lo2" as GRE termination on PE-1:

```
*A:PE-1>config>router>if$ gre-termination
MINOR: CLI Could not set gre-termination for interface "lo2".
MINOR: PIP #2078 Cannot config GRE termination - already set on interface "lo1"
```

Although the preceding examples are for loopback interfaces, GRE termination can also be configured on other router interfaces, but only one per node. The following shows an attempt to configure interface "int-PE-1-PE-2" on PE-1 as GRE termination. The same error message is raised. However, if it were the first interface on the node to be configured as GRE termination, the configuration would be accepted.

```
*A:PE-1>config>router>if# gre-termination
MINOR: CLI Could not set gre-termination for interface "int-PE-1-PE-2".
MINOR: PIP #2078 Cannot config GRE termination - already set on interface "lo1"
```

The maximum size of the GRE termination subnet is /16.

GRE termination cannot be applied on the following interface types:

- Unnumbered network IP interfaces
- IES interfaces
- VPRN interfaces
- CSC VPRN interfaces

MPLS-over-GRE origination

GRE SDPs and auto-bind GRE tunnels can originate and terminate on a non-system IP address. Manually configured SDPs can be configured with a non-system IP address as the far-end address. Optionally, a non-system local-end address can be configured for generating GRE from an interface other than the system interface. In the following example on PE-1, GRE SDP 120 uses loopback address 10.0.1.1 as the local-end address and 10.0.2.1 on PE-2 as the far-end address.

```
# on PE-1:
configure
    service
        sdp 120 create
            far-end 10.0.2.1
            local-end 10.0.1.1
            no shutdown
        exit
```

The local-end IP address can only be configured for GRE SDPs; the following error message is raised when attempting to configure an MPLS SDP with a local-end address:

```
*A:PE-1>config>service# sdp 122 mpls create
```

```
*A:PE-1>config>service>sdp$ local-end 10.0.1.1
MINOR: SVCMGR #7825 Invalid local-end address - local-end not supported for this sdp type
```

The **local-end** parameter value complies with the following rules:

- A maximum of 15 distinct address values can be configured for all GRE SDPs in the **configure service sdp local-end** context, and all L2oGRE SDPs under the **configure service system gre-eth-bridged tunnel-termination** context.
- The same source address cannot be used in both contexts because an address configured for an L2oGRE SDP matches an internally created interface that is not available to other applications.
- The local-end address of a GRE SDP, when different from the system address, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

The primary IPv4 address of any local network IP interface, loopback or not, may be used. The following shows that IP address 192.168.12.1, as the IP address of the previously mentioned interface "int-PE-1-PE-2" toward PE-2, can be used as the local-end address:

```
# on PE-1:
configure
    service
        sdp 123 create
            far-end 10.0.2.1
            local-end 192.168.12.1
            no shutdown
        exit
```

The following shows that an error message is raised when attempting to configure an invalid local-end IP address, that is, an IP address that is not primary on a local router interface. In this case, local-end IP address 10.99.1.1 does not exist on PE-1.

```
*A:PE-1>config>service# sdp 120 create
*A:PE-1>config>service>sdp$ local-end 10.99.1.1
MINOR: SVCMGR #7827 Cannot configure local-end IP address - Local router interface with
address does not exist, or address is not primary
```

For services that support auto-binding to a GRE tunnel, the following command configures a single alternate source address (in this case, 10.0.1.1) per system:

```
# on PE-1:
configure
    service
        system
            vpn-gre-source-ip 10.0.1.1
        exit
```

The default value of the single source address is the primary IPv4 address of the system interface. The value of the **vpn-gre-source-ip** parameter can be changed at any time. After a new value is configured, the system address will not be used in services that bind to the GRE tunnel.

The **vpn-gre-source-ip** parameter value complies with the following rules:

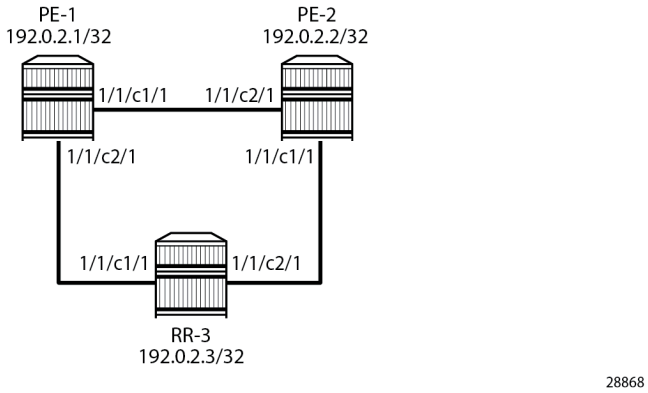
- This single source address counts toward the maximum of 15 distinct address values per system used by all GRE SDPs under the **configure service sdp local-end** context and all L2oGRE SDPs under the **configure service system gre-eth-bridged tunnel-termination** context.

- The same source address can be used in both **vpn-gre-source-ip** and **configure service sdp local-end** contexts.
- The same source address cannot be used in both **vpn-gre-source-ip** and **configure service system gre-eth-bridged tunnel-termination** contexts because an address configured for an L2oGRE SDP matches an internally created interface that is not available to other applications.
- The **vpn-gre-source-ip** address, when different from the system IP address, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

Configuration

Figure 14: Example topology shows the example topology with three SR OS nodes in AS 64500. Services will be configured on PE-1 and PE-2, while RR-3 is a route reflector (RR).

Figure 14: Example topology



The initial configuration on the three PEs includes:

- cards, MDAs, ports
- router interfaces. The IP addresses shown on the figure are the system IP addresses 192.0.2.x/32.
- IS-IS as IGP (alternatively, OSPF can be used)

GRE SDP termination on non-system IP addresses will be configured in the following use cases:

- VPLS with manually configured T-LDP signaled SDP
- Epipe with manually configured T-LDP signaled SDP
- BGP-VPLS using a provisioned BGP-signaled SDP
- BGP-AD in VPLS using a provisioned T-LDP signaled SDP
- BGP-VPWS using a provisioned BGP-signaled SDP
- VPRN with manually configured T-LDP signaled SDP
- VPRN with auto-bind to GRE tunnel
- IES with manually configured T-LDP signaled SDP

MPLS-over-GRE termination

On PE-1, PE-2, and RR-3, loopback interface "lo1" is configured as GRE termination with IPv4 address 10.0.x.1/24 for PE-x. The configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        interface "lo1"
            address 10.0.1.1/24
            loopback
            gre-termination
            no shutdown
        exit
```

This loopback interface will be used in the SDP configuration. With a /24 subnet, the SDP origination can be any address in the subnet. This is useful for providing entropy in the outer IPv4 header for load-balancing over the IP network.

MPLS-over-GRE origination: SDP local end

The local-end address must be reachable from the far-end router that terminates the GRE SDP. Therefore, the interface for this address can be added to IGP or BGP. Alternatively, a static route can be configured on the far-end router. In this example, IS-IS is enabled on the loopback interface with GRE termination, as follows:

```
# on PE-1, PE-2, RR-3:
configure
    router Base
        isis 0
            interface "lo1"
            exit
```

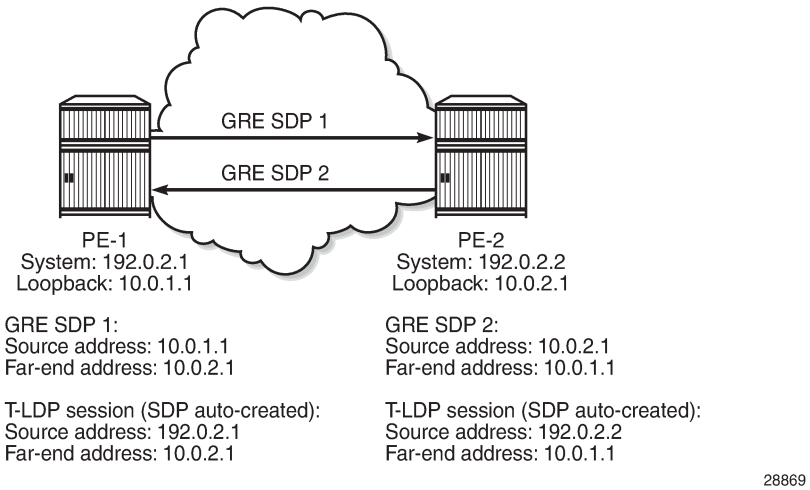
On PE-1, the following SDPs are configured with far-end 10.0.2.1 on PE-2 and local-end 10.0.1.1: SDP 120 with T-LDP signaling (default) and SDP 121 with BGP signaling.

```
# on PE-1:
configure
    service
        sdp 120 create
            signaling tldp       # default
            far-end 10.0.2.1
            local-end 10.0.1.1
            no shutdown
        exit
        sdp 121 create
            signaling bgp
            far-end 10.0.2.1
            local-end 10.0.1.1
            no shutdown
        exit
```

T-LDP signaled GRE SDPs

When T-LDP signaled SDPs, such as SDP 120 in the preceding example, are configured, T-LDP sessions are auto-created toward the far end of the SDPs. By default, LDP uses the system IP address as source address. However, if the source address for the T-LDP session does not match the destination transport address set by the remote PE, the T-LDP session will not come up and the GRE SDP will remain down.Figure 15: Mismatched T-LDP transport addresses shows an example where SDP auto-created T-LDP sessions use the local system addresses 192.0.2.x and far-end addresses 10.0.0.x, so the GRE SDPs will not come up.

Figure 15: Mismatched T-LDP transport addresses



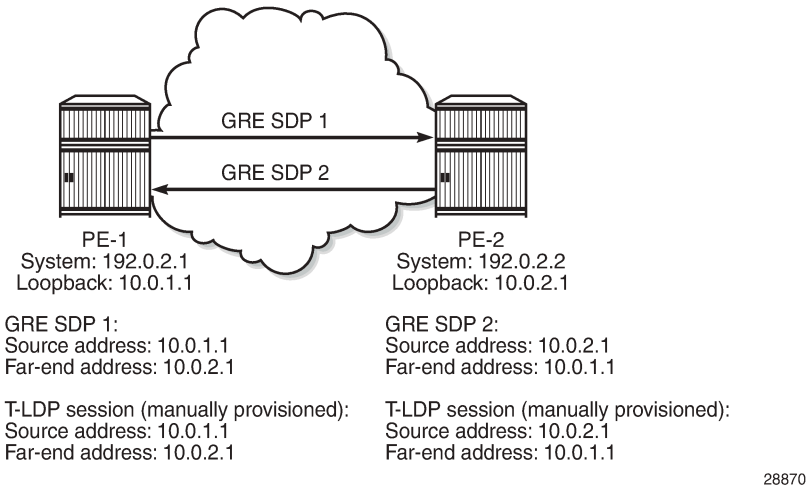
Therefore, the local transport address of the T-LDP session must match the local-end address of the GRE SDP in the PE. These T-LDP sessions can be manually provisioned or auto-created via peer templates. The following configures T-LDP sessions between the non-system IP addresses on PE-1 and PE-2.

```
# on PE-1:
configure
    router Base
        ldp
            targeted-session
                peer 10.0.2.1
                    local-lsr-id "lo1"
                exit

# on PE-2:
configure
    router Base
        ldp
            targeted-session
                peer 10.0.1.1
                    local-lsr-id "lo1"
                exit
```

Figure 16: Matching T-LDP transport addresses shows the GRE T-LDP signaled SDPs with matching addresses for the T-LDP sessions.

Figure 16: Matching T-LDP transport addresses



BGP configuration

In this example, the L2 and L3 services are configured on PE-1 and PE-2, while RR-3 acts as the RR. On PE-1, BGP is configured with neighbor 10.0.3.1 and local address 10.0.1.1, as follows. Address family L2-VPN is required for L2 services using BGP-VPLS, BGP-AD, and BGP-VPWS; address family VPN-IPv4 is used for VPRN services.

```
# on PE-1:
configure
    router Base
        bgp
            rapid-withdrawal
            split-horizon
            group "internal"
                family vpn-ipv4 l2-vpn
                type internal
                local-address 10.0.1.1
                neighbor 10.0.3.1
                exit
            exit
            no shutdown
```

On RR-3, the BGP configuration is as follows.

```
# on RR-3:
configure
    router Base
        bgp
            rapid-withdrawal
            split-horizon
            group "internal"
                family vpn-ipv4 l2-vpn
                type internal
                cluster 10.0.3.1
                local-address 10.0.3.1
                neighbor 10.0.1.1
```

```
            exit
            neighbor 10.0.2.1
            exit
        exit
        no shutdown
    exit
```

The loopback addresses 10.0.x.1 are configured for the local and neighbor addresses.

Note:
When the local address 10.0.x.1 is not configured, the system address 192.0.2.x will be used instead. However, in that case, no BGP sessions will be established and, therefore, no BGP routes will be exchanged between 192.0.2.x and 10.0.y.1, and no spoke-SDPs will be auto-created in L2 services using BGP-VPLS, BGP-AD, or BGP-VWPS. Likewise, no BGP-VPN routes will be exchanged between VPRNs on PE-1 and PE-2.

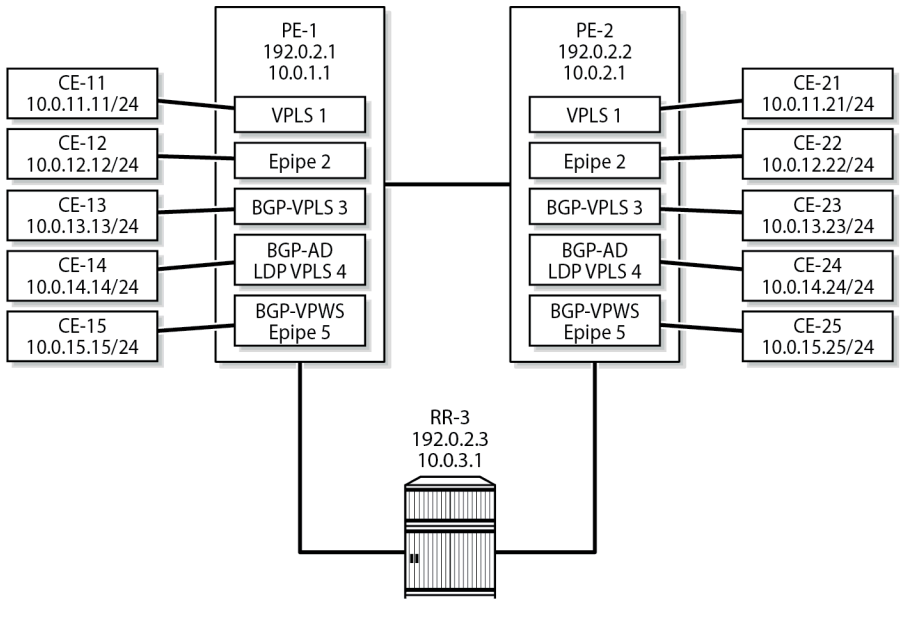
L2 services

Figure 17: L2 services on PE-1 and PE-2 shows the example topology with the following L2 services configured on PE-1 and PE-2:

- VPLS 1 with manually configured spoke-SDP 120:1
- Epipe 2 with manually configured spoke-SDP 120:2
- BGP-VPLS 3 using PW template 1 (BGP-signaled SDP 121 is used)
- LDP VPLS 4 with BGP-AD using PW template 1 (T-LDP signaled SDP 120 is used)
- BGP-VPWS Epipe 5 using PW template 1 (BGP-signaled SDP 121 is used)

The CEs are VPRNs configured on the PEs and connected to the VPLSs via port cross-connect (PXC).

Figure 17: L2 services on PE-1 and PE-2



For a description of the BGP-VPLS parameters, see the BGP VPLS chapter; for BGP-AD, see the LDP VPLS Using BGP Auto-Discovery chapter; for BGP-VPWS, see the BGP Virtual Private Wire Services chapter. For BGP-VPLS, BGP-AD, and BGP-VPWS, PW template 1 is configured with the **use-provisioned-sdp** command. The service configuration on PE-1 is as follows; the service configuration on PE-2 is similar.

```
# on PE-1:
configure
    service
        sdp 120 create
            far-end 10.0.2.1
            local-end 10.0.1.1
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        sdp 121 create
            signaling bgp
            far-end 10.0.2.1
            local-end 10.0.1.1
            keep-alive
                shutdown
            exit
            no shutdown

```

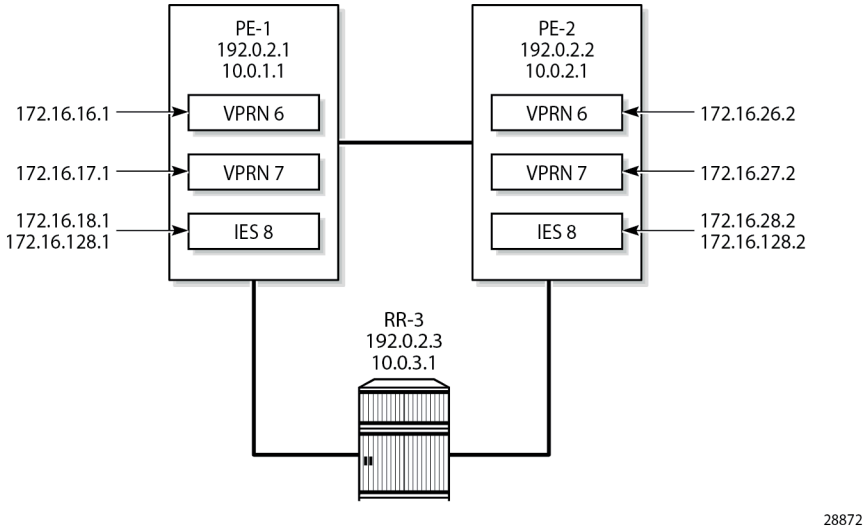
L3 services

Figure 18: L3 services on PE-1 and PE-2 shows the example topology with the following three L3 services configured on PE-1 and PE-2:

- VPRN 6 with manually configured spoke-SDP 120:6
- VPRN 7 with auto-bind to GRE tunnel
- IES 8 with manually configured spoke-SDP 120:8

Figure 18: L3 services on PE-1 and PE-2



VPRN 6 is configured with a loopback interface and a GRE spoke-SDP, as follows:

```
# on PE-1:
configure
    service
        system
            bgp-auto-rd-range 10.0.1.1 comm-val 60000 to 65000
        exit
        vprn 6 name "VPRN-6 with GRE spoke-SDP" customer 1 create
            interface "lo6" create
                address 172.16.16.1/32
                loopback
            exit
            bgp-ipvpn
                mpls
                    route-distinguisher auto-rd
                    vrf-target target:64500:6
                    no shutdown
                exit
            exit
            spoke-sdp 120:6 create
            exit
            no shutdown
        exit
```

The following forwarding information base (FIB) for VPRN 6 shows that the remote prefix is reachable via a transport tunnel using SDP 120:

```
*A:PE-1# show router 6 fib 1

===============================================================================
FIB Display
===============================================================================
Prefix [Flags]                                                  Protocol

-------------------------------------------------------------------------------
172.16.16.1/32                                                  LOCAL
```

```
  172.16.16.1 (lo6)
172.16.26.2/32                                                  BGP_VPN
  10.0.2.1 (VPRN Label:524274 Transport:SDP:120)
-------------------------------------------------------------------------------
Total Entries : 2
-------------------------------------------------------------------------------
===============================================================================
```

VPRN 7 is configured with **auto-bind-tunnel** and the tunnel needs to be resolved using GRE. For services that support auto-binding to a GRE tunnel, the **vpn-gre-source-ip** parameter defines a single alternate source address for all VPRNs on the system. On PE-1, the configuration is as follows:

```
# on PE-1:
configure
    service
        system
            vpn-gre-source-ip 10.0.1.1
        exit
        vprn 7 name "VPRN-7 with auto-bind GRE" customer 1 create
            interface "lo7" create
                address 172.16.17.1/24
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            gre
                        exit
                        resolution filter
                    exit
                    route-distinguisher auto-rd
                    vrf-target target:64500:7
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

The following FIB for VPRN 7 shows that the remote prefix is reachable via a GRE transport tunnel:

```
*A:PE-1# show router 7 fib 1

IES 8 has an interface with a manually configured GRE spoke-SDP, as follows:

```
# on PE-1:
configure
    service
        ies 8 name "IES-8" customer 1 create
            interface "lo8" create
                address 172.16.18.1/24
                loopback
            exit
            interface "int-IES8-PE-1-PE-2" create
                address 172.16.128.1/30
                spoke-sdp 120:8 create
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

On PE-1, the connectivity over the GRE spoke-SDP is verified as follows:

```
*A:PE-1# ping 172.16.128.2 rapid
PING 172.16.128.2 56 data bytes
!!!!!
---- 172.16.128.2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.44ms, avg = 2.54ms, max = 2.69ms, stddev = 0.081ms
```

Conclusion

By default, GRE SDPs and auto-bind GRE tunnels are originated and terminated on the system IP address, but it is possible to use non-system IP addresses. This is useful in cases where the system IP address cannot be leaked between domains and a separate loopback address must be used to terminate tunnels.

Network Group Encryption Helper

This chapter describes the network group encryption (NGE) helper.

Topics in this chapter include:

Applicability

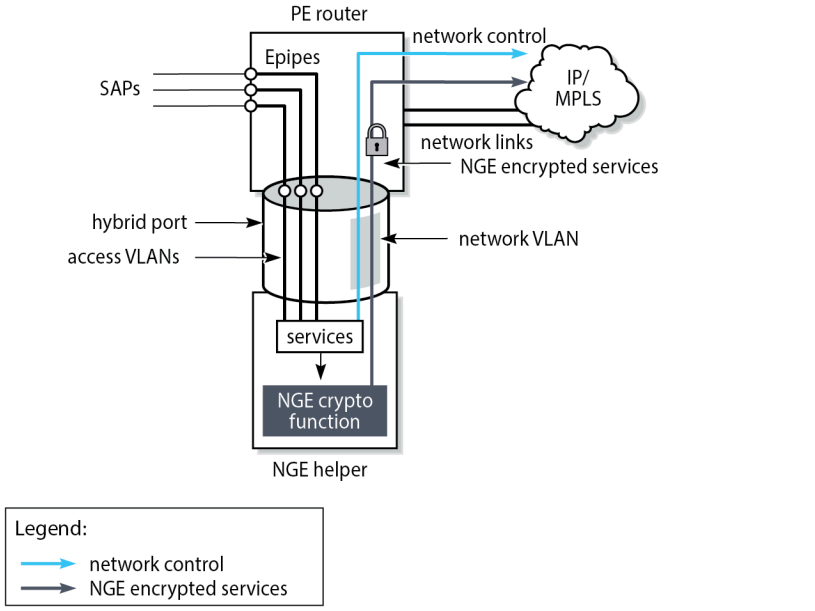
The information and configuration in this chapter are based on SR OS Release 23.3.R1. Network group encryption (NGE) helpers require use of the VSR-a or the VSR-I and can be deployed with 7750 SR and 7950 XRS.

Overview

The NGE helper enables NGE security for services configured on the 7750 SR or 7950 XRS (hereafter referred to as the router) that require additional confidentiality and integrity.

Multiple NGE helpers can be deployed with a router depending on the encrypted services throughput requirements required by the operator. Figure 19: General architecture using an NGE helper shows the general architecture using an NGE helper.

Figure 19: General architecture using an NGE helper



Each NGE helper is connected to the router using an access interface and a network interface, where both interfaces are configured on the NGE helper and on the router. A hybrid port can be used on the router and NGE helper to optimize the deployment, so one physical port is required on the router and NGE helper.

SAPs are configured on the router using an Epipe directed toward the NGE helper access interface. Unencrypted traffic that is received on the SAP interface is sent through the Epipe to the NGE helper which encrypts the traffic before sending it toward the network. The network interface on the NGE helper is enabled with minimal network control plane functions toward the router. The network control plane of the router performs the majority of network level processing and forwarding of NGE encrypted services.

The NGE helper supports services-based encryption, including:

- VPRN encryption
- SDP encryption
- PW-template encryption

Router interface encryption and port-level encryption are not supported by the NGE helper.

Scenarios for encrypting services

The following main services scenarios are supported:

- **VPRN encryption using auto-bind services for both MPLS (LDP or RSVP-TE signaled tunnels) and GRE transport**

  This scenario uses BGP to advertise the NGE helper IP address to remote NGE helpers. Remote NGE helpers can then send VPRN traffic to other NGE helpers to be processed for the associated destination SAP. This scenario uses VPRN-level NGE.

- **NG-MVPN with VPRN encryption using MLDP tunnels from the NGE helper to the router**

This scenario uses a similar setup to VPRN encryption, with the difference that MLDP tunnels are also established between the NGE helper and the router where the point-to-multipoint tree branches from for the NG-MVPN service. This scenario uses VPRN-level NGE.

- **T-LDP signaled Epipe or VPLS services using LDP or RSVP-TE transport tunnels**

  T-LDP sessions are established from the NGE helper to the remote PEs to establish Epipe or VPLS services. The transport of these services focuses on LDP or LDP with RSVP-TE. Where GRE is possible, GRE support of VPLS or VPWS mainly uses BGP VPLS or BGP VPWS with auto-GRE SDP, because this use case is prevalent with SAR-Hm/Hmc deployments. This scenario uses SDP-level NGE.

- **L2 services using BGP VPLS or BGP VPWS auto-GRE SDP**

  This scenario is similar to the VPRN auto-bind scenario, except that a BGP session is used to advertise L2 routes to and from the NGE helper where remote PEs can send GRE L2 packets encrypted with the associated NGE configuration under the **pw-template** context.

Configuration

NGE configuration

NGE configuration is managed by the Network Services Platform Network Functions Manager - Packet (NSP NFM-P). Operators use the NSP NFM-P to configure:

- global encryption labels
- key groups
- VPRN-level encryption – setting the inbound and outbound key groups on VPRN-based services, as shown in the VPRN or NG-MVPN using MP-BGP section
- SDP-level encryption – setting the inbound and outbound key groups on selected SDPs
- PW-template level encryption – setting the inbound and outbound key groups on selected PW templates

Group encryption configuration

In this example, the following two encryption keygroups are configured manually on NGE-1:

```
# on NGE-1:
configure
    group-encryption
        group-encryption-label 100
        encryption-keygroup 1 create
            keygroup-name "KG1"
            security-association spi 1 authentication-key 0x1111111100000000
             1111111100000000111111110000000011111111100000000 encryption-key
             0x11111111000000001111111100000000
            security-association spi 2 authentication-key 0x2222222200000000
             2222222200000000222222220000000022222222200000000 encryption-key
             0x22222222000000002222222200000000
            security-association spi 3 authentication-key 0x3333333300000000
             3333333300000000333333330000000033333333300000000 encryption-key
             0x33333333000000003333333300000000
```

```
            security-association spi 4 authentication-key 0x4444444400000000
             4444444400000000444444440000000044444444400000000 encryption-key
             0x4444444400000000444444440000000
            active-outbound-sa 1
        exit
        encryption-keygroup 2 create
            keygroup-name "KG2"
            security-association spi 5 authentication-key 0x5555555500000000
             5555555500000000555555550000000055555555500000000 encryption-key
             0x5555555500000000555555550000000
            security-association spi 6 authentication-key 0x6666666600000000
             6666666600000000666666660000000066666666600000000 encryption-key
             0x6666666600000000666666660000000
            security-association spi 7 authentication-key 0x7777777700000000
             7777777700000000777777770000000077777777700000000 encryption-key
             0x7777777700000000777777770000000
            security-association spi 8 authentication-key 0x8888888800000000
             8888888800000000888888880000000088888888800000000 encryption-key
             0x8888888800000000888888880000000
            active-outbound-sa 5
        exit
```

In this example, the authentication key and the encryption key are entered as cleartext. After configuration, they are never displayed in their cleartext form. The security parameter index (SPI) value in the security association is a node-wide unique value.

SDP configuration

On NGE-1, LDP SDP 1 is configured with encryption keygroup 1 and RSVP SDP 3 is configured with encryption keygroup 2:

```
# on NGE-1:
configure
    service
        sdp 1 mpls create
            description "LDP SDP with NGE"
            far-end 192.0.2.5
            ldp
            keep-alive
                shutdown
            exit
            encryption-keygroup 1 direction inbound
            encryption-keygroup 1 direction outbound
            no shutdown
        exit
        sdp 3 mpls create
            description "RSVP SDP with NGE"
            far-end 192.0.2.5
            lsp "LSP-NGE-1-NGE-2"
            keep-alive
                shutdown
            exit
            encryption-keygroup 2 direction inbound
            encryption-keygroup 2 direction outbound
            no shutdown
        exit
```

PW-template configuration

On NGE-1, PW template 2 is configured with encryption keygroup 1:

```
# on NGE-1:
configure
    service
        pw-template 2 name "2" auto-gre-sdp create
            description "PW template with NGE"
            vc-type vlan
            split-horizon-group "SHG"
            exit
            encryption-keygroup 1 direction inbound
            encryption-keygroup 1 direction outbound
        exit
```

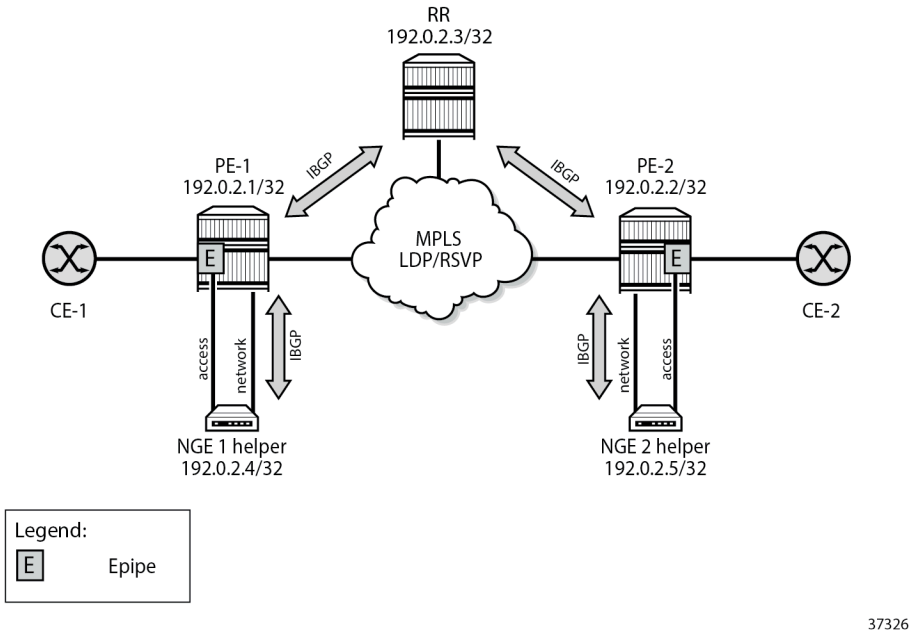
BGP configuration

BGP must be enabled on the router and the NGE helper for the following services:

- BGP VPWS with auto-GRE SDP (where NGE is configured under the **pw-template** context)
- BGP VPLS with auto-GRE SDP (where NGE is configured under the **pw-template** context)
- MP-BGP VPRN with auto-bind LDP or RSVP-TE (where NGE is configured under the **vprn** context)
- NG-MVPN with MLDP tunnels (where NGE is configured under the **vprn** context)

Figure 20: BGP topology for learning BGP label routes shows the BGP topology for learning BGP label routes for these services.

Figure 20: BGP topology for learning BGP label routes



The following configures BGP on PE-1 to support the NGE 1 helper function:

```
# on PE-1:
configure
    router Base
        bgp
            rapid-withdrawal
            group "core-RR"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.3      # RR
                exit
            exit
            group "PE-1-NGE-1-RR"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                cluster 192.0.2.1
                peer-as 64496
                neighbor 192.0.2.4      # NGE-1
                exit
            exit
            no shutdown
        exit
```

The following configures BGP on PE-2 to support the NGE 2 helper function:

```
# on PE-2:
configure
    router Base
        bgp
            rapid-withdrawal
            group "core-RR"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.3      # RR
                exit
            exit
            group "PE-2-NGE-2-RR"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                cluster 192.0.2.2
                peer-as 64496
                neighbor 192.0.2.5      # NGE-2
                exit
            exit
            no shutdown
        exit
```

The BGP configuration on the NGE-1 helper is as follows:

```
# on NGE-1:
configure
    router Base
        bgp
            rapid-withdrawal
            group "RR-PE-1"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.1    # PE-1
                exit
            exit
            no shutdown
        exit
```

The BGP configuration on the NGE-2 helper is as follows:

```
# on NGE-2:
configure
    router Base
        bgp
            rapid-withdrawal
            group "RR-PE-2"
                family vpn-ipv4 l2-vpn mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.2    # PE-2
                exit
            exit
            no shutdown
        exit
```

Operators can enable PE-CE control plane functionality such as EBGP from the NGE helper to learn routes from the CE and advertise them within the VPRN. The optional configuration required for PE-CE functionality is included in this chapter.

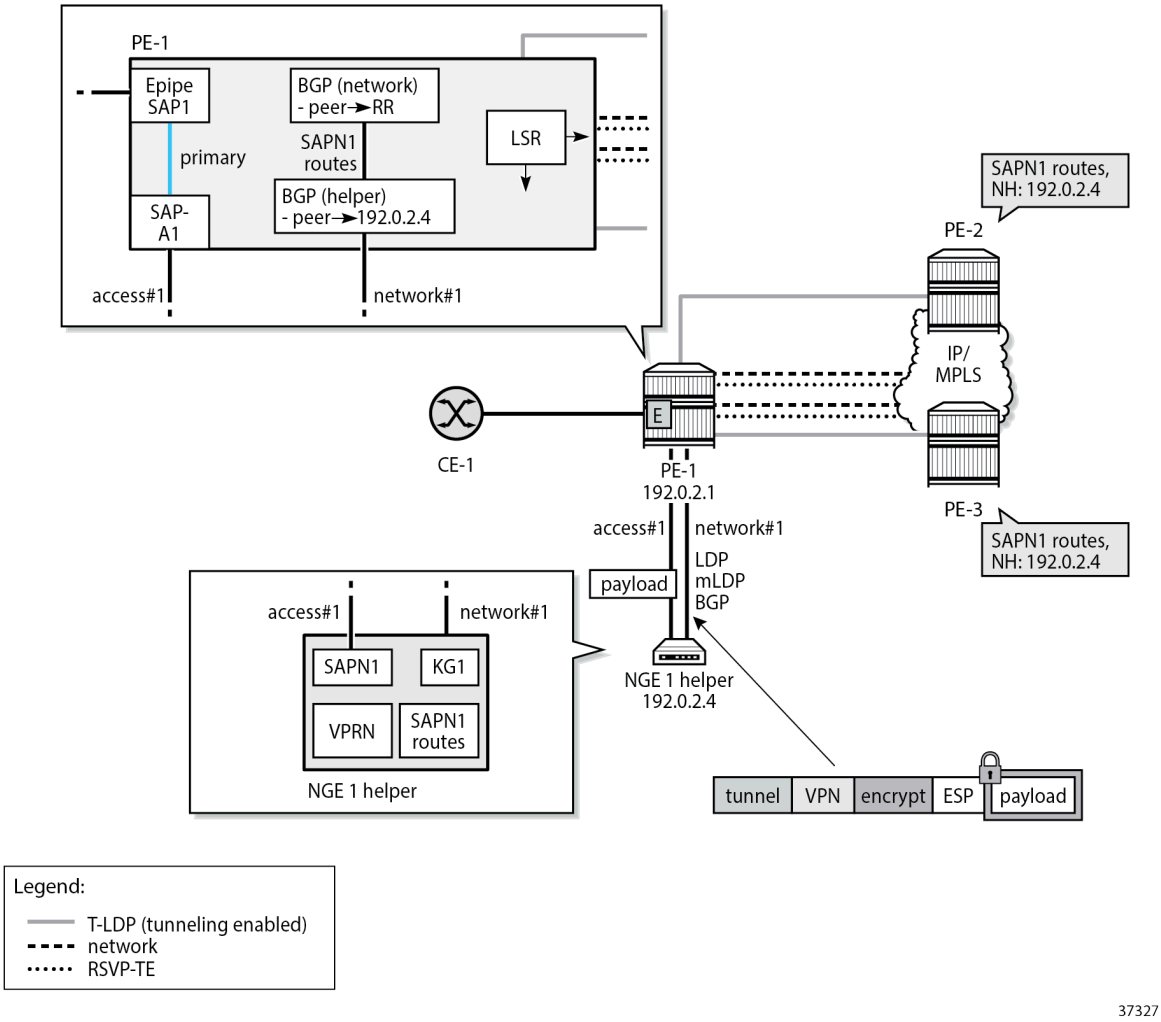
Services configuration

VPRN or NG-MVPN using MP-BGP

For these services, NGE is configured under the **vprn** context.

Figure 21: Operation of NGE helper for MP-BGP auto-bind VPRN or NG-MVPN multicast shows the operation of the NGE helper for MP-BGP auto-bind VPRN-based services or NG-MVPN multicast services.

Figure 21: Operation of NGE helper for MP-BGP auto-bind VPRN or NG-MVPN multicast



VPRN SAPs are typically configured on the router; however, in this case the VPRN and VPRN SAP are configured on the NGE helper. On PE-1, a local Epipe is configured that originates from the customer facing SAP1 and terminates on SAP-A1, connected to the access port on the NGE-1 helper. Traffic on this access port is not encrypted. In this example, Epipe 100301 is configured on PE-1 as follows:

```
# on PE-1:
configure
    service
        epipe 100301 name "Epipe-100301" customer 1 create
            sap lag-1:301 create
                description "toward NGE-1 VPRN 301"
                no shutdown
            exit
            sap lag-11:301.1 create
                description "toward CE"
                no shutdown
            exit
            no shutdown
```

```
        exit
```

In the VPRN on the NGE-1 helper, the traffic is encrypted. Traffic on the network port is encrypted.

On PE-1, the following network configurations are required to support encrypted services from the NGE-1 helper:

- optional RSVP-TE tunnels with fast reroute (FRR) to other remote PEs
  - If RSVP-TE tunnels are configured, then T-LDP sessions with tunneling enabled must also be configured to these same PEs. These sessions allow LDP packets from the NGE helper to use LDP to hop onto RSVP-TE tunnels.
- optional LDP, including MLDP, tunnels on core network interfaces for unicast and multicast traffic to other PEs
- BGP sessions for the VPN-IPv4 and MVPN-IPv4 address families, as described in the BGP configuration section
- LDP, including MLDP, is configured on the network interface to the NGE helper

On the NGE-1 helper, configuration is minimal and includes:

- VPRN SAPN1 where, optionally, PE-CE IGP protocols can be configured to learn routes from CE-1
- VPRN NG-MVPN for multicast services
- LDP, including MLDP, on the network interface to PE-1
- BGP session for the VPN-IPv4 and MVPN-IPv4 address families, as described in the BGP configuration section
- NGE enabled on the VPRN for encrypting unicast and multicast services

In this example, the configuration of VPRN 301 on NGE-1 is as follows:

```
# on NGE-1:
configure
    service
        vprn 301 name "VPRN-301" customer 1 create
            description "MP-BGP, NG MVPN, auto-bind LDP, VPRN NGE"
            autonomous-system 64501
            interface "toCE-1" create
                address 172.16.11.2/24
                sap lag-1:301 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 301:1
                    vrf-target target:301:1
                    no shutdown
                exit
            exit
            bgp
                group "CE"
                    export "exportBGP"
                    neighbor 172.16.11.1
                        family ipv4
```

```
                        type external
                        peer-as 64502
                    exit
                exit
                no shutdown
            exit
            pim
                interface "toCE-1"
                exit
                rp
                    static
                    exit
                    bsr-candidate
                        shutdown
                    exit
                    rp-candidate
                        shutdown
                    exit
                exit
                no shutdown
            exit
            mvpn
                auto-discovery default  # default auto-discovery via BGP
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            encryption-keygroup 1 direction inbound
            encryption-keygroup 1 direction outbound
            no shutdown
        exit
```

T-LDP signaled Epipe or VPLS services

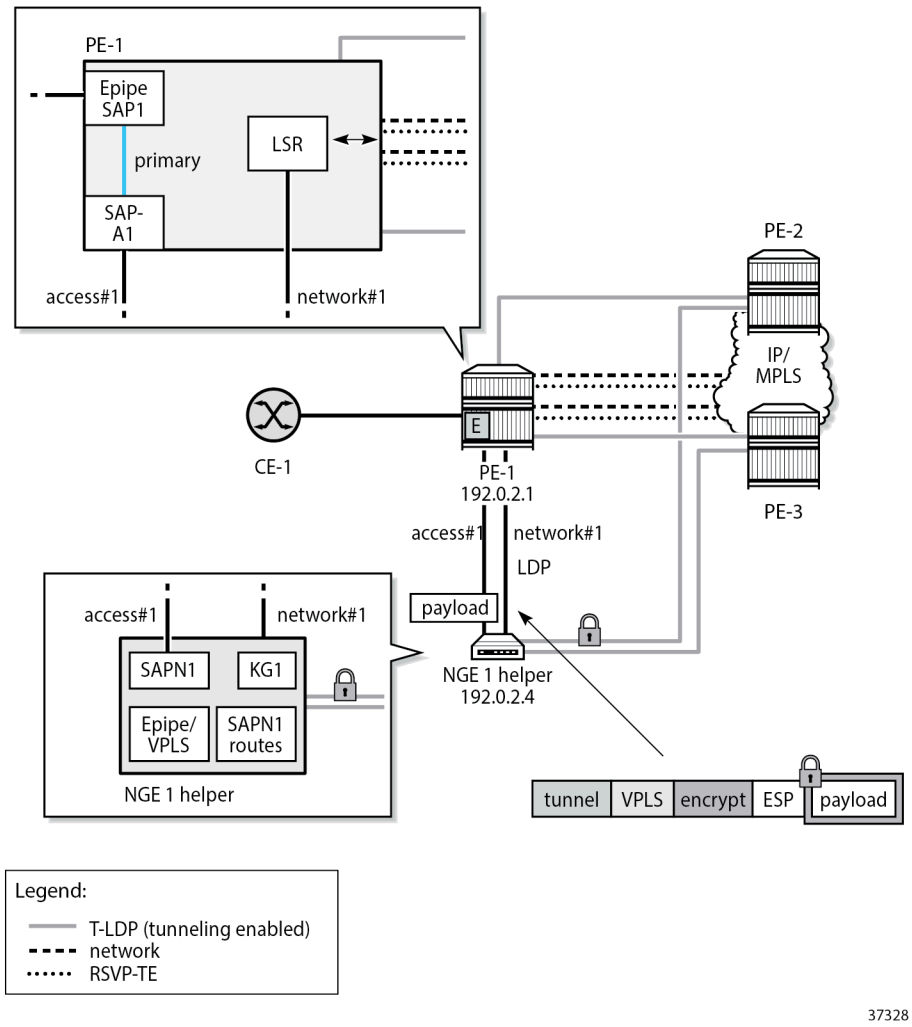
For these services, NGE is configured under the **sdp** context. On NGE-1, LDP SDP 1 is configured with encryption keygroup 1 and RSVP SDP 3 is configured with encryption keygroup 2, as follows:

```
# on NGE-1:
configure
    service
        sdp 1 mpls create
            description "LDP SDP with NGE"
            far-end 192.0.2.5
            ldp
            keep-alive
                shutdown
            exit
            encryption-keygroup 1 direction inbound
            encryption-keygroup 1 direction outbound
            no shutdown
        exit
        sdp 3 mpls create
            description "RSVP SDP with NGE"
            far-end 192.0.2.5
```

```
            lsp "LSP-NGE-1-NGE-2"
            keep-alive
                shutdown
            exit
            encryption-keygroup 2 direction inbound
            encryption-keygroup 2 direction outbound
            no shutdown
        exit
```

Figure 22: NGE helper for T-LDP signaled Epipe or VPLS services shows the operation of the NGE helper for T-LDP signaled Epipe or VPLS services.

Figure 22: NGE helper for T-LDP signaled Epipe or VPLS services



Similar to the VPRN scenario, the service SAPN1 of the Epipe or VPLS is configured on the NGE helper. On PE-1, a local Epipe is configured that is originating from the customer facing SAP1 and terminating on SAP-A1 connected to the NGE-1 helper on the access port where SAPN1 is configured. For example,

Epipe 100401 toward Epipe 101 on NGE-1 is configured as follows. Similar Epipes are configured toward other services on NGE-1, such as VPLS 501 and VPLS 601.

```
# on PE-1:
configure
    service
        epipe 100401 name "Epipe-100401" customer 1 create
            sap lag-1:401 create
                description "toward NGE-1 Epipe 401"
                no shutdown
            exit
            sap lag-11:401.1 create
                description "toward CE"
                no shutdown
            exit
            no shutdown
        exit
```

On PE-1, the following network configurations are required to support encrypted services from the NGE-1 helper:

- optional RSVP-TE tunnels with FRR to other remote PEs
  - If RSVP-TE tunnels are configured, then T-LDP sessions with tunneling enabled are also configured to these same PEs. These sessions allow LDP packets from the NGE-1 helper to use LDP to hop onto RSVP-TE tunnels.
- optional LDP tunnels if RSVP-TE tunnels are not used
- LDP on each network interface to the NGE-1 helper

On the NGE-1 helper, the configuration is minimal and includes:

- Epipe or VPLS SAPN1 configured on the NGE helper
- T-LDP configured from the NGE helper to each remote PE that needs to participate in the Epipe or VPLS service
- SDPs configured on the NGE helper toward each PE that is participating in the Epipe or VPLS service
- LDP configured on the network interface
- NGE enabled on the SDPs for encrypting the Epipe or VPLS services using the SDPs

Epipe 401 is configured with LDP SDP 1, which uses encryption keygroup 1:

```
# on NGE-1:
configure
    service
        epipe 401 name "Epipe-401" customer 1 create
            description "Epipe, LDP SDP, SDP NGE"
            sap lag-1:401 create
                no shutdown
            exit
            spoke-sdp 1:401 create
                no shutdown
            exit
            no shutdown
        exit
```

Likewise, VPLS 501 is configured with LDP SDP 1, which uses encryption keygroup 1:

```
# on NGE-1:
```

```
configure
    service
        vpls 501 name "VPLS-501" customer 1 create
            description "VPLS, LDP SDP, SDP NGE"
            sap lag-1:501 create
                no shutdown
            exit
            spoke-sdp 1:501 create
                no shutdown
            exit
            no shutdown
        exit
```

VPLS 601 is configured with RSVP SDP 3, which uses encryption keygroup 2:

```
# on NGE-1:
configure
    service
        vpls 601 name "VPLS-601" customer 1 create
            description "VPLS, RSVP SDP, SDP NGE"
            sap lag-1:601 create
                no shutdown
            exit
            mesh-sdp 3:601 create
                no shutdown
            exit
            no shutdown
        exit
```

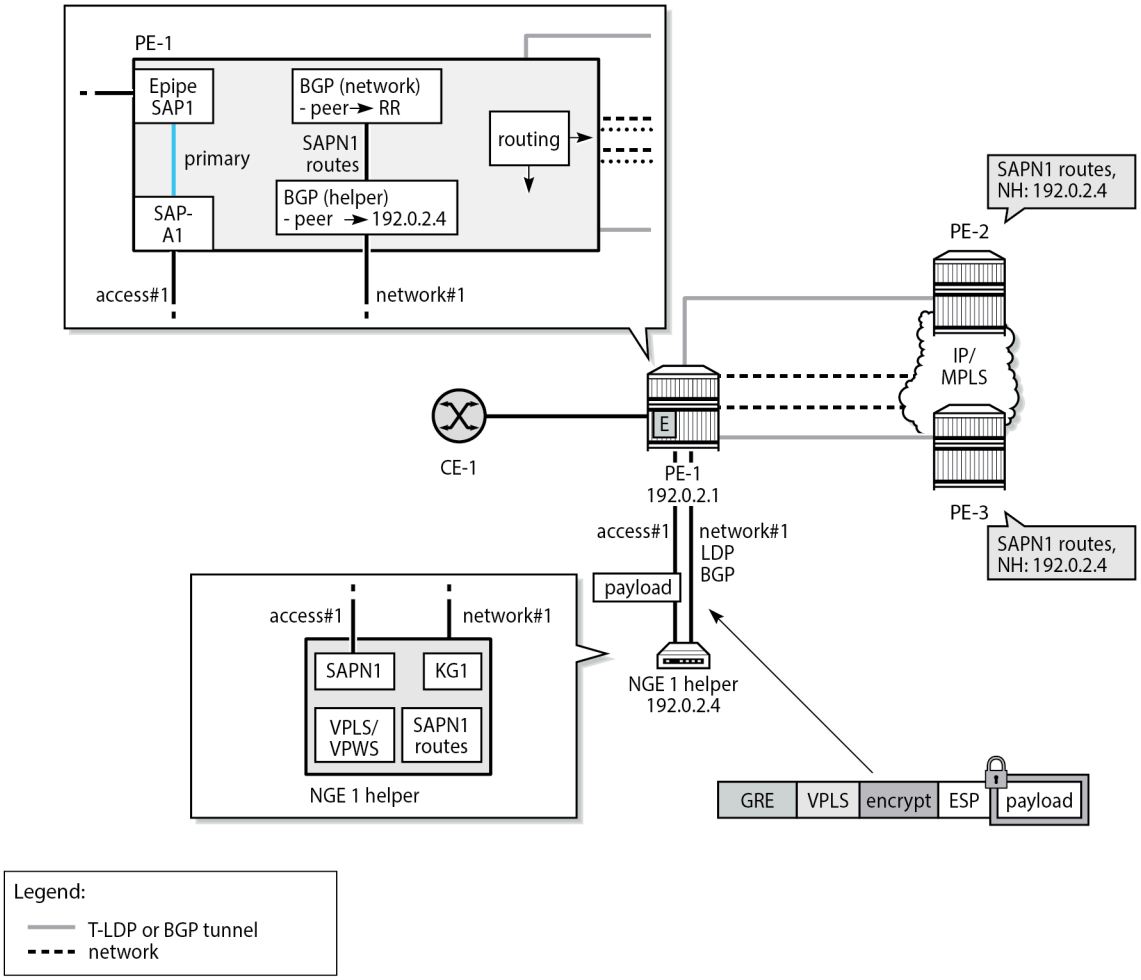
BGP VPLS or BGP VPWS with auto-GRE SDP

For these services, NGE is configured under the **pw-template** context, as in the following example:

```
# on NGE-1:
configure
    service
        pw-template 2 name "2" auto-gre-sdp create
            description "PW template with NGE"
            vc-type vlan
            split-horizon-group "SHG"
            exit
            encryption-keygroup 1 direction inbound
            encryption-keygroup 1 direction outbound
        exit
```

Figure 23: NGE helper for BGP VPLS or BGP VPWS using GRE SDPs with auto-GRE SDP shows the operation of the NGE helper for BGP VPLS and BGP VPWS services that use GRE SDPs when auto-GRE SDP is configured on the associated PW template.

Figure 23: NGE helper for BGP VPLS or BGP VPWS using GRE SDPs with auto-GRE SDP



Similar to the VPRN scenario, the VPLS or VPWS SAPN1 is configured on the NGE-1 helper. On PE-1, a local Epipe is configured that originates from the customer facing SAP1 and terminates on SAP-A1 connected to the NGE-1 helper. The configuration is similar to the preceding configuration of Epipe 100401 on PE-1.

On PE-1, the following network configurations are required to support encrypted services from the NGE-1 helper:

- any routing options that allow GRE packets received from the NGE helper to be routed to remote PEs
- BGP sessions for the L2-VPN address family, as described in the BGP configuration section

On the NGE-1 helper, the configuration includes:

- VPLS or VPWS SAPN1
- BGP session to PE-1 for the L2-VPN address family
- BGP VPLS or BGP VPWS using PW templates with auto-GRE SDP enabled

- NGE enabled on the PW templates for encrypting the VPLS or VPWS services using the PW templates

On NGE-1, Epipe 101 is a BGP VPWS with auto-GRE SDP. PW template 2 is configured with encryption keygroup 1. Epipe 101 is configured as follows:

```
# on NGE-1:
configure
    service
        epipe 101 name "Epipe-101" customer 1 create
            description "BGP VPWS auto-gre SDP_PW template 2"
            bgp
                route-distinguisher 101:1
                route-target export target:101:1 import target:101:1
                pw-template-binding 2
                exit
            exit
            bgp-vpws
                ve-name "pe-1"
                    ve-id 1
                exit
                remote-ve-name "pe-2"
                    ve-id 2
                exit
                no shutdown
            exit
            sap lag-1:101 create
            exit
            no shutdown
        exit
```

In a similar way, VPLS 201 is a BGP VPLS with auto-GRE SDP. PW template 2 is configured with encryption keygroup 1. VPLS 201 is configured as follows:

```
# on NGE-1:
configure
    service
        vpls 201 name "VPLS-201" customer 1 create
            description "BGP VPLS auto-gre SDP_PW template 2"
            bgp
                route-distinguisher 201:1
                route-target export target:201:1 import target:201:1
                pw-template-binding 2
                exit
            exit
            bgp-vpls
                max-ve-id 10
                ve-name "pe-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap lag-1:201 create
                no shutdown
            exit
            no shutdown
        exit
```

Configuration overview

Configuration on NGE-1 helper

On the NGE-1 helper, the configuration of the control plane and services for all preceding services is as follows:

```
#--------------------------------------------------
echo "Card Configuration"
#--------------------------------------------------
    card 1
        card-type iom-v
        mda 1
            mda-type m20-v
            no shutdown
        exit
        mda 2
            mda-type m20-v
            no shutdown
        exit
        mda 3
            mda-type m20-v
            no shutdown
        exit
        mda 4
            mda-type m20-v
            no shutdown
        exit
        no shutdown
    exit
#--------------------------------------------------
echo "Port Configuration"
#--------------------------------------------------
    port 1/1/1
        ethernet
            mode hybrid

Conclusion

NGE is a security solution for encrypting traffic flows on a per-service basis. The NGE helper extends the NGE solution to 7750 SR and 7950 XRS platforms where larger core and PE nodes are required to participate with other NGE-capable nodes.

Seamless BFD Application — Auto-bind tunnel

This chapter provides information about seamless BFD application — auto-bind tunnel.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 19.10.R3, but the CLI in the current edition corresponds to SR OS Release 23.3.R3.

A prerequisite is to read the "Seamless BFD for SR-TE LSPs" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*.

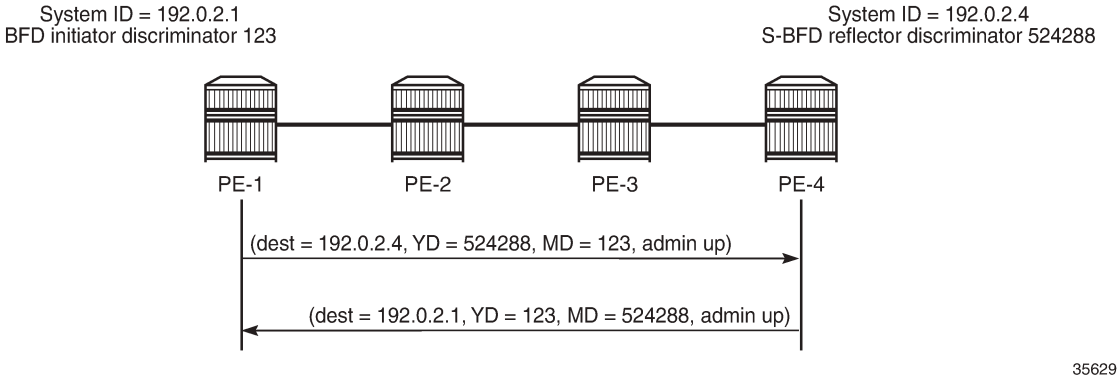
Overview

Bidirectional forwarding detection (BFD) is widely deployed in IP/MPLS networks to rapidly detect failures in the forwarding path between network elements.

Seamless BFD (S-BFD) is described in RFC 7880. S-BFD minimizes the time required to establish BFD sessions by removing the discovery of discriminators during the initial handshaking procedure, which contributes to its seamless operation. S-BFD relies on the fact that the discriminators needed to establish the BFD session are already known by the endpoints for each session, either through configuration or advertisement using unicast protocols.

Figure 24: S-BFD session establishment – continuity check shows the S-BFD session establishment between PE-1 and PE-4. The BFD discriminator used by the initiator is chosen by the system. On PE-1, the BFD (initiator) discriminator equals 123; on PE-4, the S-BFD (reflector) discriminator equals 524288. Through IGP advertisement or configuration, head-end router PE-1 is aware of the S-BFD discriminator of PE-4 (system ID 192.0.2.4; S-BFD discriminator 524288).

Figure 24: S-BFD session establishment – continuity check



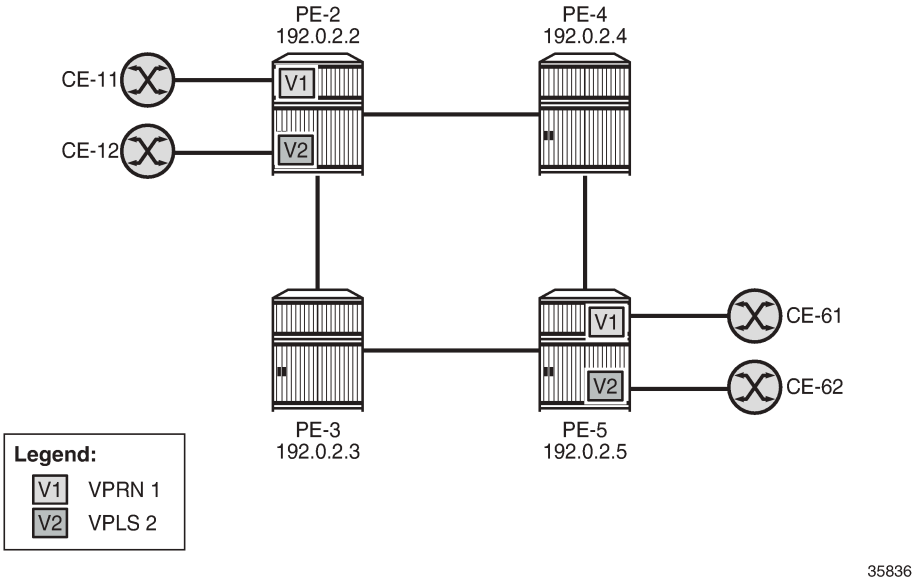
The state of the SR-TE LSP is linked to the state of the S-BFD session when failure action **failover-or-down** is configured. In the "Seamless BFD for SR-TE LSPs" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*, one of the examples illustrates the use of S-BFD with failure action **failover-or-down** in an SR-TE LSP with a primary path and a standby secondary path. When a link or node fails on the primary path, the S-BFD session goes down and the head-end node switches to a standby path that is operationally up.

In this chapter, S-BFD is configured in an SR-TE LSP with primary path only. Services such as VPRNs or EVPNs may have auto-bind tunnel configured with multiple tunnel resolution protocols, such as SR-TE and SR-ISIS. SR-TE tunnels are preferred to SR-ISIS tunnels. When a link or node fails on the primary path, the S-BFD session goes operationally down and the SR-TE LSP goes operationally down, and is removed from the tunnel table. The head-end node reverts to the best preference tunnel that is up; in this case, an SR-ISIS tunnel.

Configuration

Figure 25: Example topology shows the example topology. The VPRN and EVPN services will be configured on PE-2 and PE-5.

Figure 25: Example topology



Initial configuration

The initial configuration on the PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)
- SR-ISIS enabled
- Traffic engineering enabled on PE-2 and PE-5

The initial configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        interface "int-PE-2-PE-3"
            address 192.168.23.1/30
            port 1/1/c2/1:1000
        exit
        interface "int-PE-2-PE-4"
            address 192.168.24.1/30
            port 1/1/c1/1:1000
        exit
        interface "system"
            address 192.0.2.2/32
        exit
        mpls-labels
            sr-labels start 32000 end 32999
        exit
        isis 0
            area-id 49.0001
            traffic-engineering
```

```
            advertise-router-capability area
            segment-routing
                prefix-sid-range global
                no shutdown
            exit
            interface "system"
                ipv4-node-sid index 2
            exit
            interface "int-PE-2-PE-3"
                interface-type point-to-point
            exit
            interface "int-PE-2-PE-4"
                interface-type point-to-point
            exit
            no shutdown
        exit
```

S-BFD configuration

For S-BFD, the reflector BFD discriminator values must be configured in the range from 524288 to 526335. On far-end node PE-5, the global S-BFD configuration is as follows. This S-BFD discriminator will be advertised by IGP.

```
# on PE-5:
configure
    bfd
        seamless-bfd
            reflector "PE-5"
                discriminator 524291
                local-state up
                no shutdown
            exit
        exit
```

For S-BFD, a BFD template of type CPM-NP must be configured. On PE-2, the following BFD template is configured:

```
# on PE-2:
configure
    router Base
        bfd
            begin
            bfd-template "bfd-cpm-np-1s"
                type "cpm-np"
                transmit-interval 1000    # minimum value is 10 ms
                receive-interval 1000     # minimum value is 10 ms
            exit
            commit
```

Note:
Even though CPM-NP BFD can use intervals of minimum 10 ms, the used example setup has its limitations. The nodes in the used example setup are sims and the simulation for CPM-NP or central BFD sessions has the limitation that intervals that are configured with a value smaller than 1000 ms are always negotiated to intervals of 1000 ms. To avoid confusion when the configured intervals differ from the negotiated intervals on sims, a BFD template with intervals of 1000 ms is configured and used in this chapter.

On PE-2, the preceding BFD template is applied in the following SR-TE LSP to PE-5. For SR-TE LSPs, the only allowed failure action is **failover-or-down**.

```
# on PE-2:
configure
    router Base
        mpls
            path "empty"
                no shutdown
            exit
            lsp "LSP-PE-2-PE-5_empty_localCSPF" sr-te
                to 192.0.2.5

            exit
            no shutdown
```

The following tunnel table on PE-2 shows that two tunnels are available toward PE-5: an SR-TE tunnel with tunnel ID 655362 and default preference 8, and an SR-ISIS tunnel with tunnel ID 524293 and default preference 11. The SR-TE tunnel with preference 8 is preferred to the SR-ISIS tunnel with preference 11.

```
*A:PE-2# show router tunnel-table 192.0.2.5/32

VPRN and EVPN services with auto-bind tunnel

Both VPRN "VPRN-1" and an EVPN VPLS "VPLS-2" will be configured on PE-2 and PE-5. For advertising VPN-IPv4 and EVPN routes, BGP is configured on PE-2 and PE-5 for the VPN-IPv4 and EVPN address families. Both VPRN "VPRN-1" and EVPN VPLS "VPLS-2" have auto-bind tunnel enabled with resolution filter allowing SR-ISIS and SR-TE.

```
# on PE-2:

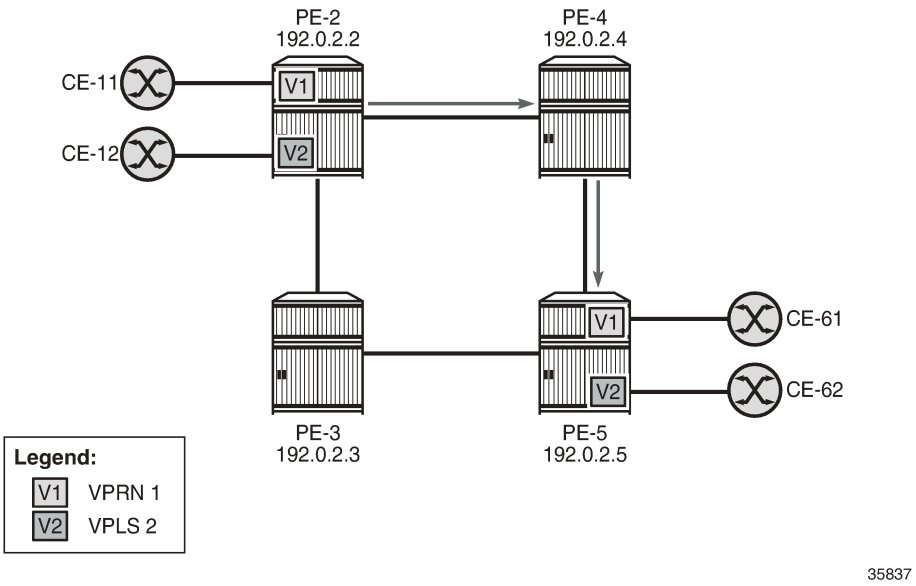
Failure of the SR-TE LSP

The following command shows that—without any failures—the primary path of the SR-TE LSP goes via PE-4:

```
*A:PE-2# show router mpls sr-te-lsp "LSP-PE-2-PE-5_empty_localCSPF" path detail
                                          | match "Actual Hops" post-lines 3
Actual Hops  :
    192.168.24.2(192.0.2.4)(A-SID)              Record Label        : 524286
 -> 192.168.45.2(192.0.2.5)(A-SID)              Record Label        : 524286
```

Figure 26: Primary path of SR-TE LSP via PE-4 shows the primary path of the SR-TE LSP.

Figure 26: Primary path of SR-TE LSP via PE-4



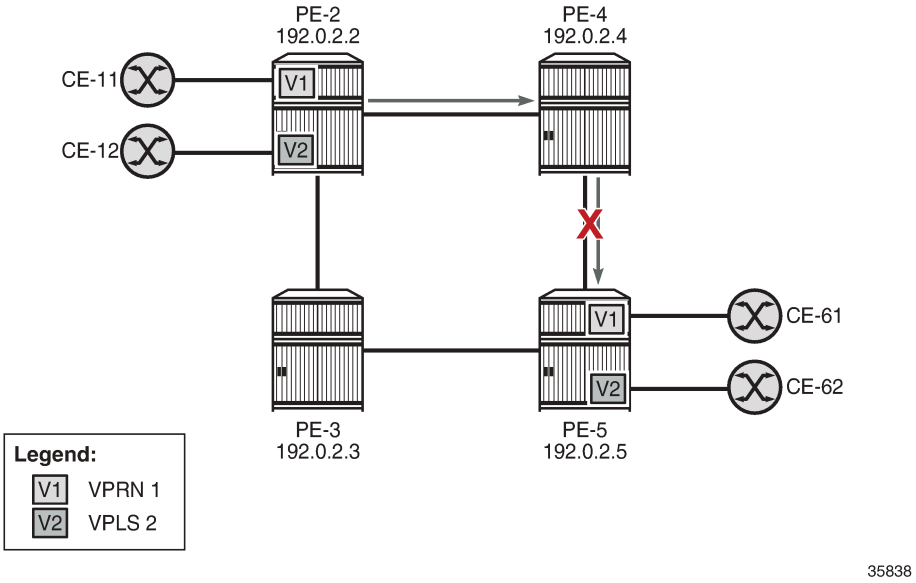
S-BFD is configured in the SR-TE LSP with failure action **failover-or-down**. If the SR-TE LSP fails, the S-BFD session will go down and it will bring the SR-TE tunnel down. The next-hop 192.0.2.5 cannot be resolved using the SR-TE tunnel, so an SR-ISIS tunnel will be used instead.

On PE-4, port 1/1/c1/1 to PE-5 is disabled to emulate a failure in the primary path of the SR-TE LSP, as follows:

```
# on PE-4:
configure
    port 1/1/c1/1      # port to PE-5
        shutdown
    exit
```

Figure 27: Remote failure in the primary path of the SR-TE LSP shows that a remote failure occurs in the primary path of the SR-TE LSP.

Figure 27: Remote failure in the primary path of the SR-TE LSP



The S-BFD session goes operationally down, as follows:

```
*A:PE-2# show router bfd seamless-bfd session lsp-path detail prefix 192.0.2.5/32

===============================================================================
BFD Session
===============================================================================

===============================================================================
```

Again, the SR-TE LSP will be preferred to the SR-ISIS LSP and both VPRN "VPRN-1" and EVPN VPLS "VPLS-2" will use the SR-TE tunnel to 192.0.2.5.

Conclusion

S-BFD can be used to determine the state of SR-TE LSPs that only have a primary path. The resiliency is at the service level for VPRN and EVPN services with auto-bind tunnel where several resolution protocols are configured and SR-TE has the lowest preference. When the S-BFD session for the SR-TE tunnel goes operationally down, the SR-TE tunnel goes operationally down. The VPRN and EVPN services will then use the best tunnel that is available; in this example, an SR-ISIS tunnel.

Layer 2 Services and EVPN

This section provides configuration information for the following topics:

- L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing
- L2 Services with Auto-GRE Spoke-SDPs
- Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication
- LDP VPLS Using BGP Auto-Discovery
- LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP
- Mobility for EVPN Hosts Within an R-VPLS
- Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire
- Multi-Segment Pseudowire Routing
- Operational Groups for EVPN-VXLAN VPWS Services
- Operational Groups in EVPN Services
- P2MP mLDP FEC Resolution for BGP-LU in EVPN
- P2MP mLDP Inter-AS Model C for EVPN-MPLS Services
- P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services
- PBB-Epipe
- PBB-EVPN ISID-based CMAC Flush
- PBB-EVPN ISID-based Route Targets
- PBB-VPLS
- PIM Snooping for IPv4 in EVPN-MPLS Services
- PIM Snooping for IPv4 in PBB-EVPN Services
- Preference-based and Non-revertive EVPN DF Election
- Proxy-ARP/ND MAC List for Dynamic Entries
- Shortest Path Bridging for MAC
- Static VXLAN Termination in Epipe Services
- Three-byte EVI in EVPN Services
- VCCV BFD for Epipe Services
- Virtual Ethernet Segments
- VLAN Range SAPs for VPLS and Epipe Services
- VXLAN Forwarding Path Extension

AC-Influenced DF Election on an ES

This chapter provides information about Attachment Circuit (AC) influenced Designated Forwarder (DF) election on an Ethernet Segment (ES).

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.5.R1. Attachment Circuit (AC) influenced Designated Forwarder (DF) election on an Ethernet Segment (ES) is always enabled in SR OS releases earlier than 21.5.R1. The AC-DF election capability can be disabled in SR OS Release 21.5.R1 and later.

Overview

RFC 8584, section "The AC-Influenced DF Election Capability", describes the AC-DF capability that modifies the EVPN DF election process in RFC 7432. RFC 8584 states that when PEs build their candidate DF election list, they do not include PEs when no Auto-Discovery (AD) per-ES or per-EVI routes for those PEs are present. In SR OS, this behavior is default for all ESs, configured as **ac-df-capability include**.

The **ac-df-capability** command is configurable in the **config>service>system>bgp-evpn>eth-seg** context:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg# ac-df-capability ?
  - ac-df-capability {include|exclude}
```

The command **ac-df-capability exclude** disables AC-DF on the ES, so the presence of an AD per-ES or per-EVI does not influence the candidate DF election list. When **ac-df-capability exclude** is configured:

- The candidate DF election list is not influenced by the presence or absence of AD per-ES/EVI routes (type 1) from the ES peers.
- PEs are only removed from the candidate DF election list when their ES route (type 4) is not present.
- The local ES route is active if there are active SAPs on the ES.
- When the local AC is operationally down, due to admin shutdown or reason other than Multi Homing (MH) standby, this does not trigger a DF switchover.

The **ac-df-capability exclude** option:

- is supported with any type of service-carving (DF Election)
- is recommended in ESs that use an operational group monitored by the access LAG to signal standby LACP or power-off

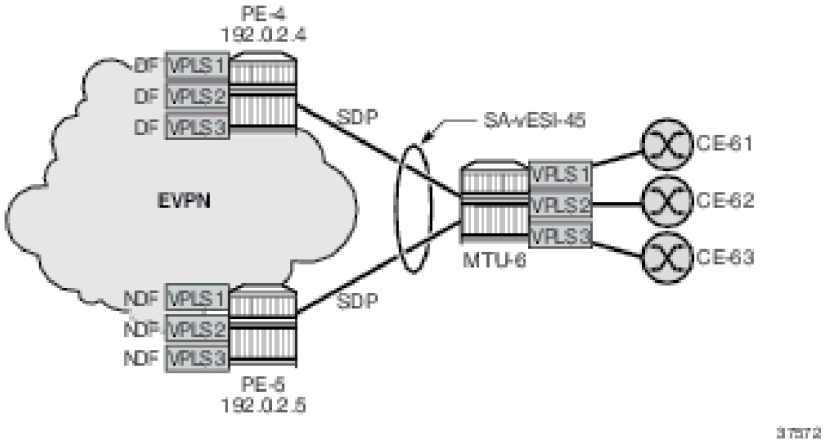
- must be configured consistently on all PEs attached to the same ES

AC-DF enabled – default

The following example illustrates the default behavior, where a PE builds the list of DF candidates with nodes that have sent EVPN AD per-ES/EVI routes. This behavior is compatible with the behavior in SR OS releases earlier than 21.5.R1.

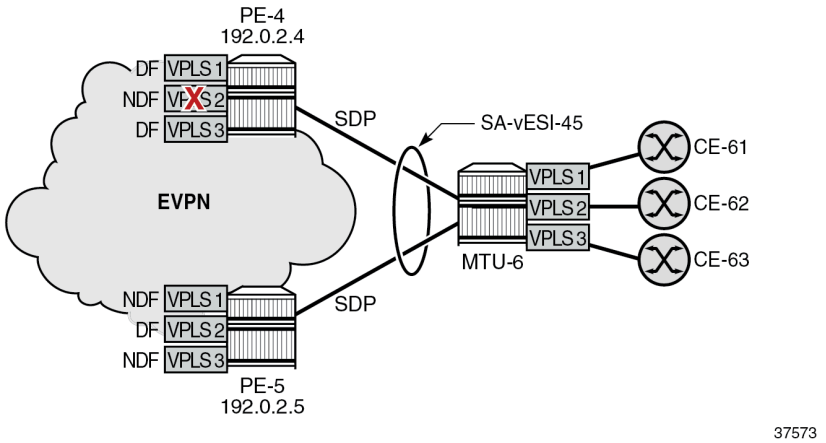
Figure 29: PE-4 as the DF on a single-active ES for three VPLSs shows a topology with MTU-6 connected via SDPs to the single-active ES "SA-vESI-45". PE-4 is the DF for three services: VPLS 1, VPLS 2, and VPLS 3. Traffic for these services passes via PE-4, while PE-5 is standby.

Figure 29: PE-4 as the DF on a single-active ES for three VPLSs



When a failure occurs on the spoke-SDP in VPLS 2 on PE-4, PE-4 sends an EVPN-AD per-EVI withdrawal and PE-4 becomes the Non-Designated Forwarder (NDF) for VPLS 2, while remaining the DF for VPLS 1 and VPLS 3, as shown in Figure 30: AC failure in VPLS 2 on PE-4 causes PE-5 to become the DF for VPLS 2.

Figure 30: AC failure in VPLS 2 on PE-4 causes PE-5 to become the DF for VPLS 2



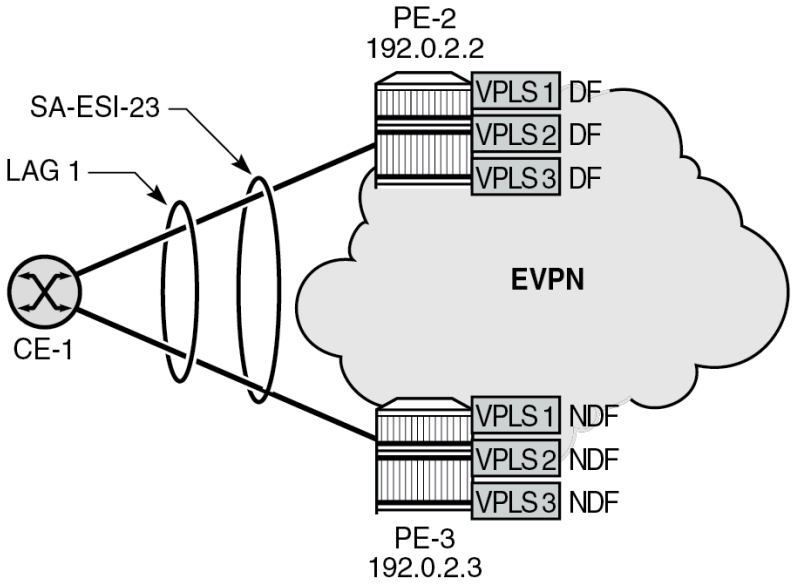
VPLS 2 traffic to and from MTU-6 passes via DF PE-5, while VPLS 1 and VPLS 3 traffic will pass via DF PE-4. No traffic is dropped. The AC failure in VPLS 2 does not have an impact on the other services.

Problem with AC-DF on ES with the operational group monitored by LAG

In this example, a failure in an access circuit of a particular service also impacts other services when the AC-DF capability is enabled.

Figure 31: PE-2 is DF on single-active ES for three VPLSs shows a single-active ES with LAG 1 associated with it. An operational group is assigned to the ES and monitored by the LAG to signal standby LACP (default) or power off. Three VPLSs are configured on PE-2 and PE-3. PE-2 is the DF for each of these VPLSs.

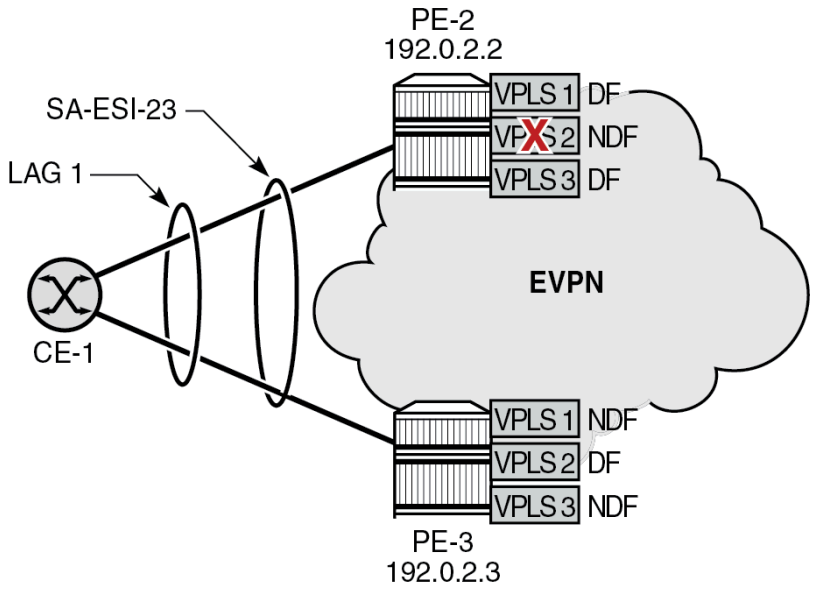
Figure 31: PE-2 is DF on single-active ES for three VPLSs



On NDF PE-3, the ES is inactive which causes the operational group in the ES to go down. LAG 1 monitors this operational group, so the LAG goes standby on NDF PE-3. LAG 1 has LACP standby-signaling enabled (default). On CE-1, only the LAG port to DF PE-2 is up and all traffic for the VPLSs goes via PE-2.

When the single-active ES has the default AC-DF setting (**ac-df-capability include**), a failure (or an unintended shutdown) on SAP lag-1:2 in VPLS 2 (or on the VPLS 2 service) on PE-2 can have an impact on all three services that share LAG 1. Figure 32: AC failure in VPLS 2 on PE-2 causes PE-3 to become DF for VPLS 2 shows that such an AC failure in VPLS 2 on PE-2 causes PE-3 to become the DF for VPLS 2 (after receiving an AD per-EVI withdrawal from PE-2).

Figure 32: AC failure in VPLS 2 on PE-2 causes PE-3 to become DF for VPLS 2

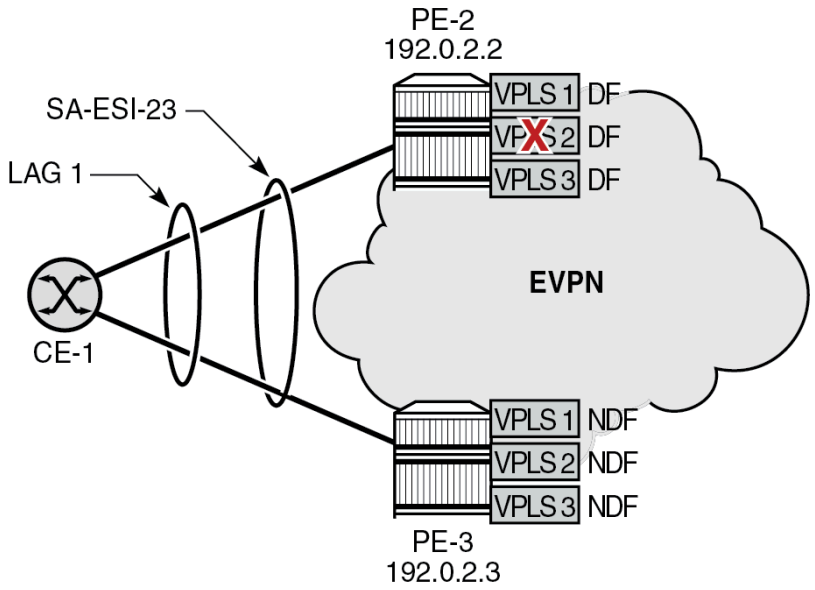


When PE-3 is the DF for VPLS 2, the ES operational group on PE-3 goes up. Therefore, the monitoring LAG is up on PE-3. On CE-1, both LAG ports to PE-2 and PE-3 are up. CE-1 can now send all VPLS traffic via either LAG port: DF PE-2 forwards the VPLS 1 and VPLS 3 traffic whereas NDF PE-3 drops it. PE-3 accepts VPLS 2 traffic, but PE-2 drops it. Approximately 50% of the traffic is lost.

AC-DF capability disabled

Nokia recommends disabling the AC-DF capability in ESs where the operational group is monitored by the LAG. Figure 33: AC failure in VPLS 2 on PE-2 has no impact on DF election shows the situation with the AC-DF disabled (**ac-df-capability exclude**): the PEs ignore the AD per-EVI withdrawal and PE-2 remains the DF for VPLS 2.

Figure 33: AC failure in VPLS 2 on PE-2 has no impact on DF election

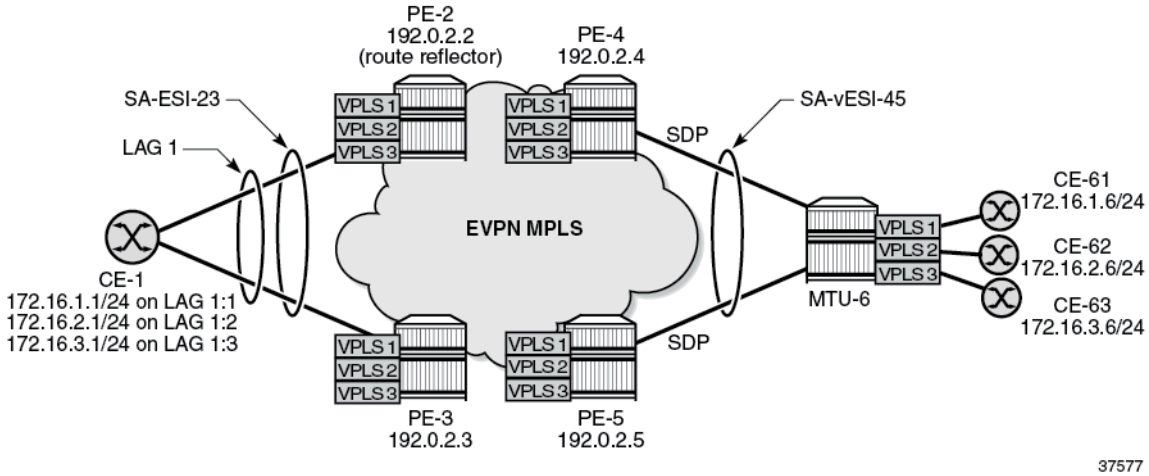


VPLS 2 traffic is dropped by PE-2, but the other services are not impacted.

Configuration

Figure 34: Example topology shows the example topology with four PEs in an EVPN-MPLS network.

Figure 34: Example topology



The initial configuration includes:

- cards, MDAs, ports

- router interfaces on the PEs and on MTU-6
- IS-IS on the router interfaces (alternatively, OSPF can be configured)
- LDP on the router interfaces

On the PEs, BGP is configured for the EVPN address family. In this example, PE-2 is the Route Reflector (RR) with the following BGP configuration:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                family evpn
                cluster 192.0.2.2
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

The BGP configuration on the clients PE-3, PE-4, and PE-5 is as follows:

```
# on PE-3, PE-4, PE-5:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
        exit
```

AC-DF capability enabled – default

On PE-2 and PE-3, operational group "op-grp-sa-es-23" is configured. This operational group is assigned to the single-active ES "SA-ESI-23" and monitored on LAG 1.

On PE-2, LAG 1 is configured as follows. The LAG configuration on PE-3 is similar, but with port 1/1/1 instead.

```
# on PE-2:
configure
    lag 1 name "lag-1"
        mode access
        encap-type dot1q
        monitor-oper-group "op-grp-sa-es-23"
        port 1/1/2
        lacp active administrative-key 1 system-id 00:00:00:00:23:01
        standby-signaling lacp      # default
        no shutdown
```

On PE-2 and PE-3, three VPLS services are configured with SAPs from LAG 1, which is associated with single-active ES "SA-ESI-23". This ES is configured with the operational group "op-grp-sa-es-23" that is monitored by LAG 1. The operational group triggers the LACP standby signaling from the NDF PE to CE-1 to avoid attracting traffic.

The service configuration on PE-2 and PE-3 is similar; only the preference value for the service carving in the ES is different.

Note:
When an operational group is associated with an ES, the hold timers for the operational group must be zero (the default value).

```
# on PE-2:
configure
    service
        oper-group "op-grp-sa-es-23" create
            hold-time
                group down 0    # default
                group up 0
            exit
        exit
        system
            bgp-evpn
                ethernet-segment "SA-ESI-23" create
                    esi 01:00:00:00:00:23:01:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 200         # on PE-3: preference value 100
                            exit
                        exit
                    exit
                    multi-homing single-active
                    ac-df-capability include    # default
                    lag 1
                    oper-group "op-grp-sa-es-23
                    no shutdown
                exit
            exit
        exit
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
```

```
                ingress-replication-bum-label
                ecmp 2
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap lag-1:1 create
            no shutdown
        exit
        no shutdown
    exit
    vpls 2 name "VPLS 2" customer 1 create
        bgp
        exit
        bgp-evpn
            evi 2
            mpls bgp 1
                ingress-replication-bum-label
                ecmp 2
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap lag-1:2 create
            no shutdown
        exit
        no shutdown
    exit
    vpls 3 name "VPLS 3" customer 1 create
        bgp
        exit
        bgp-evpn
            evi 3
            mpls bgp 1
                ingress-replication-bum-label
                ecmp 2
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap lag-1:3 create
            no shutdown
        exit
        no shutdown
    exit
```

On PE-4 and PE-5, single-active virtual ES "SA-vESI-45" is configured. No operational group is configured here. The service configuration on PE-4 is as follows. The configuration on PE-5 is similar, but with a different SDP and a different preference value for service carving.

```
# on PE-4:
configure
    service
        sdp 46 mpls create        # on PE-5: sdp 56
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "SA-vESI-45" virtual create
                    esi 01:00:00:00:00:45:01:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 200        # on PE-5: value 100
                            exit
                        exit
                    exit

```

The remainder of the chapter focuses on PE-2 and PE-3, where an AC failure in one of the services can have an impact on the other services using the same LAG.

DF election

PE-2 is the highest-preference PE in the ES and becomes the DF (preference value 200 on PE-2 versus preference value 100 on PE-3). In case of equal preference value between PE-2 and PE-3, the Don't Preempt (DP) bit is the tiebreaker (DP = 1 for non-revertive wins over DP = 0); if that is also a tie, the lowest PE IP address is the tiebreaker.

The following command shows that PE-2 is the DF for all three VPLSs. The candidate list contains both PE-2 and PE-3 for each of these VPLSs.

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "SA-ESI-23" all

LAG port status

On DF PE-2, LAG port 1/1/2 toward CE-1 is operationally up:

```
*A:PE-2# show lag "lag-1" port

===============================================================================
Lag Port States
LACP Status: e - Enabled, d - Disabled
===============================================================================
Name
Id     Port-id        Adm   Act/     Opr   Primary Sub-group      Forced Prio
                            Stdby
-------------------------------------------------------------------------------
lag-1
1(e)   1/1/2          up    active   up    yes     1              -      32768
===============================================================================
```

On NDF PE-3, LAG port 1/1/1 toward CE-1 is operationally down:

```
*A:PE-3# show lag "lag-1" port

===============================================================================
Lag Port States
LACP Status: e - Enabled, d - Disabled
===============================================================================
Name
Id     Port-id        Adm   Act/     Opr   Primary Sub-group      Forced Prio
                            Stdby
-------------------------------------------------------------------------------
```

```
lag-1
1(e)   1/1/1          up    active   down  yes     1              -      32768
===============================================================================
```

On CE-1, LAG port 1/1/1 toward DF PE-2 is operationally up while LAG port 1/1/2 toward NDF PE-3 is down:

```
*A:CE-1# show lag "lag-1" port

===============================================================================
Lag Port States
LACP Status: e - Enabled, d - Disabled
===============================================================================
Name
Id     Port-id        Adm   Act/     Opr   Primary Sub-group      Forced Prio
                            Stdby
-------------------------------------------------------------------------------
lag-1
1(e)   1/1/1          up    active   up    yes     1              -      32768
       1/1/2          up    active   down          1              -      32768
===============================================================================
```

AD per-EVI route withdrawal

A failure is simulated by disabling SAP lag-1:2 in VPLS 2 on PE-2:

```
# on PE-2:
configure
    service
        vpls "VPLS 2"
            sap lag-1:2
                shutdown
```

PE-2 withdraws the EVPN-AD per-EVI route. The following withdrawal is received by PE-3:

```
101 2022/06/03 08:54:07.346 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 69
    Flag: 0x90 Type: 15 Len: 65 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-MAC Len: 33 RD: 192.0.2.2:2 ESI: ESI-0, tag: 0, mac len: 48 mac:
 00:00:00:00:02:01, IP len: 0, IP: NULL, label1: 0
        Type: EVPN-AD Len: 25 RD: 192.0.2.2:2 ESI: 01:00:00:00:00:23:01:00:00:01, tag: 0 Label:

The following commands on PE-2 shows that SAP lag-1:1 in VPLS 1 is up, SAP lag-1:2 in VPLS 2 is down (as it might be due to a failure or misconfiguration), and SAP lag-1:3 in VPLS 3 is up:

```
*A:PE-2# show service id 1 sap

```

On CE-1, both ports in LAG 1 are up:

```
*A:CE-1# show lag "lag-1" port

===============================================================================
Lag Port States
LACP Status: e - Enabled, d - Disabled
===============================================================================
Name
Id     Port-id        Adm   Act/     Opr   Primary Sub-group      Forced Prio
                            Stdby
-------------------------------------------------------------------------------
lag-1
1(e)   1/1/1          up    active   up    yes     1              -      32768
       1/1/2          up    active   up            1              -      32768
===============================================================================
```

All traffic can take either LAG port, but PE-2 only forwards traffic for VPLS 1 and VPLS 3, while PE-3 only forwards traffic for VPLS 2. Traffic from VPLS 1 or VPLS 3 via port 1/1/2 to PE-3 is dropped by PE-3 because it is the NDF for VPLS 1 and VPLS 3. VPLS 2 traffic via LAG port 1/1/1 to PE-2 is dropped because SAP lag-1:2 is down (failure). This means that approximately 50% of the traffic is lost.

Potential loss on a single service under maintenance is acceptable but affecting other services on the same node is not acceptable. The solution is to disable the AC-DF capability.

AC-DF capability disabled

The default use of the AC-DF capability in SR OS is disabled on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "SA-ESI-23"
                    shutdown
                    ac-df-capability exclude
                    no shutdown
```

With AC-DF disabled, ES routes contain AC:0 in the DF-election extended community, as follows:

```
# on PE-3:
156 2022/06/03 08:55:53.529 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

        target:00:00:00:00:23:01
"
```

With the AC-DF capability disabled, the withdrawal of EVPN-AD routes does not influence the DF election. In this example, PE-2 remains the DF for all services, including VPLS 2, even when traffic for that service is dropped by PE-2. The following command shows that the DF candidate list on PE-3 contains six entries: even for VPLS 2, PE-2 is included in the list. PE-3 is the NDF for all three services.

```
*A:PE-3# show service system bgp-evpn ethernet-segment name "SA-ESI-23" all

---snip---
```

On NDF PE-3, the single-active ES "SA-ESI-23" is inactive and the ES operational group is down. The monitoring LAG is also operationally down.

On CE-1, LAG port 1/1/2 toward PE-3 is down:

```
*A:CE-1# show lag "lag-1" port

===============================================================================
Lag Port States
LACP Status: e - Enabled, d - Disabled
===============================================================================
Name
Id     Port-id        Adm   Act/     Opr   Primary Sub-group      Forced Prio
                            Stdby
-------------------------------------------------------------------------------
lag-1
1(e)   1/1/1          up    active   up    yes     1              -      32768
       1/1/2          up    active   down          1              -      32768
===============================================================================
```

CE-1 sends all traffic via LAG port 1/1/1 to PE-2. VPLS 1 and VPLS 3 traffic is forwarded by DF PE-2, whereas VPLS 2 traffic is dropped. Therefore, the failure does not have an impact on the other services.

On PE-2, SAP lag-1:1 in VPLS 1 and SAP lag-1:3 in VPLS 3 are operationally up:

```
*A:PE-2# show service id 1 sap

===============================================================================

Conclusion

By default, the AC-DF capability is enabled. Disabling the AC-DF capability is recommended in ESs that use an operational group monitored by the access LAG to signal standby LACP or power-off.

ARP-ND Host Routes in Data Centers

This chapter provides information about ARP-ND Host Routes in Data Centers.

Topics in this chapter include:

Applicability

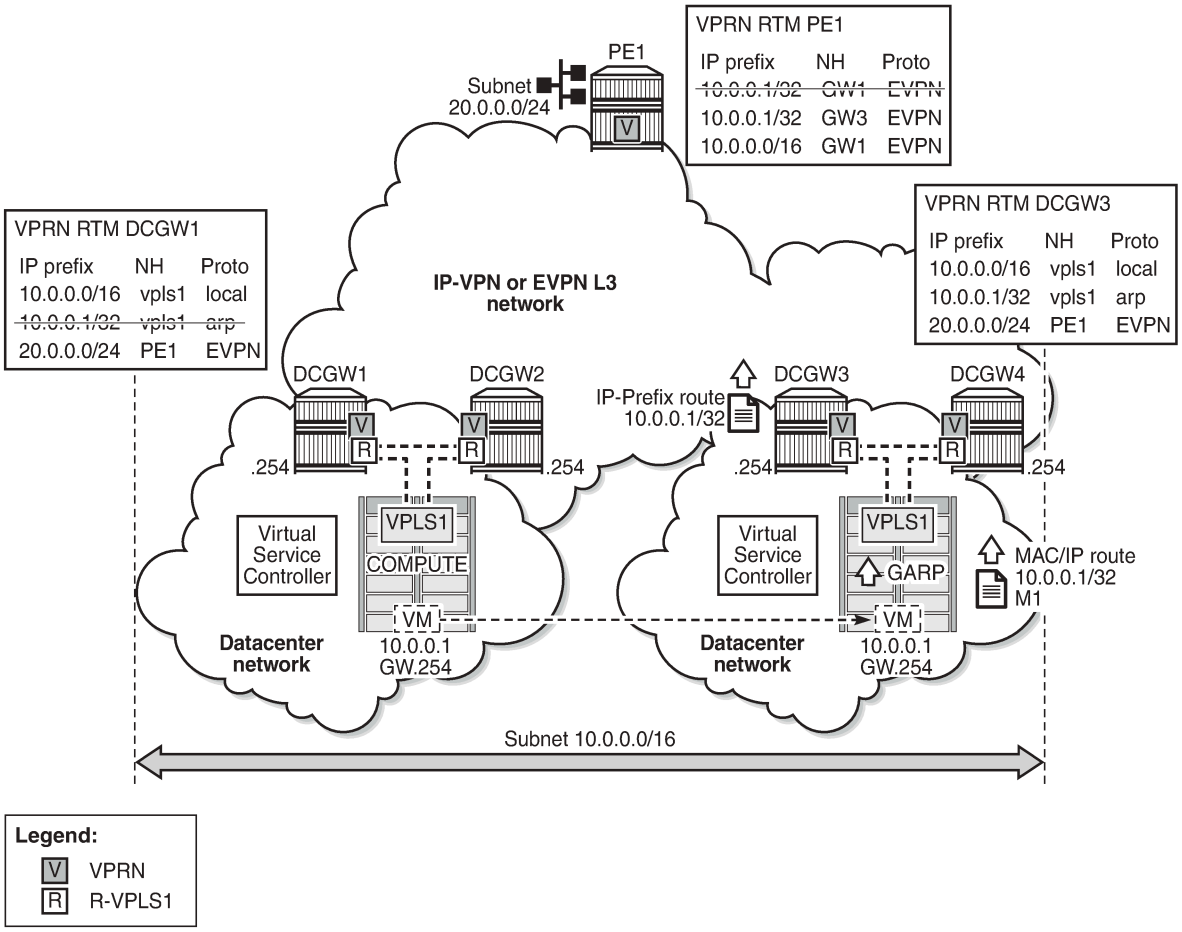
This chapter was initially written based on SR OS Release 16.0.R1, but the CLI in the current edition is based on SR OS Release 21.10.R3. Address Resolution Protocol - Neighbor Discovery (ARP-ND) host routes in VPRN and base router interfaces are supported in SR OS Release 15.0.R6 and later, but Nokia recommends using the feature in SR OS Release 15.0.R9, or later.

Chapters EVPN for MPLS Tunnels, EVPN for VXLAN Tunnels (Layer 2), EVPN for VXLAN Tunnels (Layer 3), and EVPN for MPLS Tunnels in Routed VPLS are prerequisite reading.

Overview

Inter-subnet forwarding (or simply routing) for a tenant domain in a Data Center (DC) must be efficient and avoid forwarding over the same path as arriving, known as tromboning or hairpinning. Figure 35: L2 broadcast domain extension across DCs shows an L2 broadcast domain (VPLS 1) extended across two DCs. This example is used to explain the requirement of upstream and downstream efficiency.

Figure 35: L2 broadcast domain extension across DCs



In Figure 35: L2 broadcast domain extension across DCs, subnet 10.0.0.0/16 is extended across two DCs and four DC Gateways (DCGWs), using VPLS 1 or R-VPLS 1 in the network nodes. The DCGWs are connected to the users of subnet 10.0.20.0/24 on PE1 via IP-VPN (or EVPN). In this scenario, there are two network characteristics that allow an efficient upstream and downstream routing:

- Anycast gateways
- ARP-ND host routes

Anycast Gateways provide upstream routing efficiency for the hosts connected to subnet 10.0.0.0/16, regardless of the DCGW to which they are connected. For example, if host 10.0.0.1 is in DC-1 and needs to forward traffic to subnet 10.0.20.0, DCGW1 and DCGW2 should be able to route the traffic upstream, without the need to go to DCGW3 or DCGW4. In the same way, if host 10.0.0.1 moves to DC-2, the upstream traffic to subnet 10.0.20.0 must be routed by the local DCGWs without changing the existing host default gateway IP and MAC configuration. To achieve this local default gateway routing, all the DCGWs of the extended broadcast domain need to have the same IP and MAC addresses in the R-VPLS interface (Integrated Routing and Bridging (IRB) interface in industry-standard terminology).

Anycast Gateways are implemented in SR OS by using passive VRRP. See the EVPN for MPLS Tunnels in Routed VPLS chapter for more information about passive VRRP.

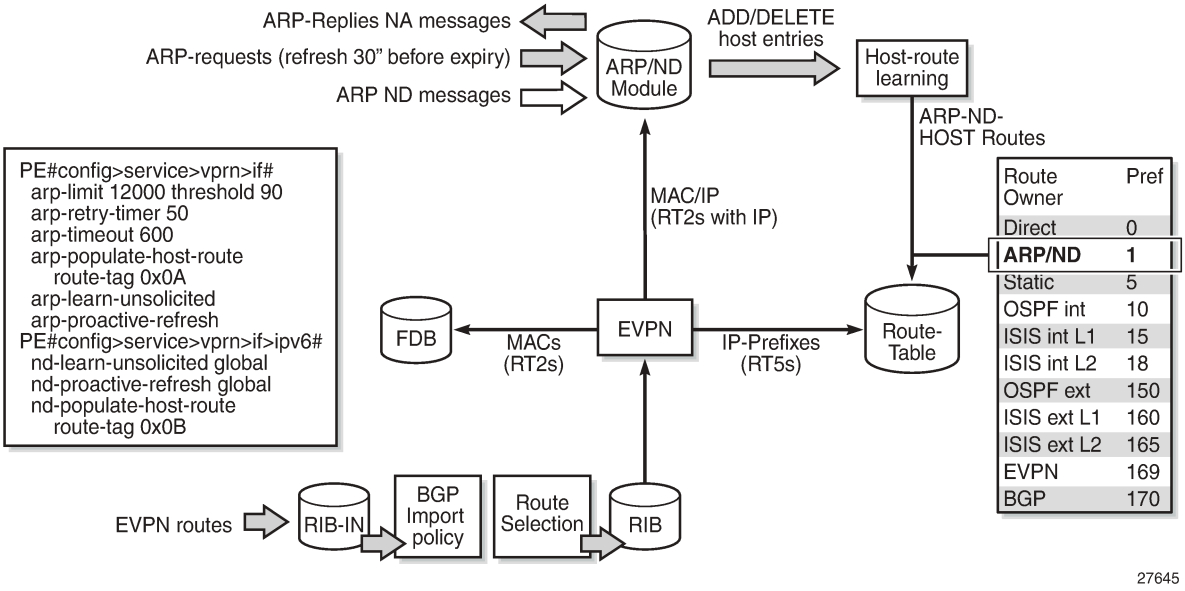
ARP-ND host routes learning and advertising are required to provide an efficient downstream routing from remote subnets to the hosts in the extended broadcast domain. Assuming virtual machine VM 10.0.0.1 (in Figure 35: L2 broadcast domain extension across DCs) is connected to DC-1 (left-side DC), when PE1 needs to send traffic to host 10.0.0.1, it will do a Longest Prefix Match (LPM) lookup on the VPRN route table. If the only IP prefix advertised by the four DCGWs were 10.0.0.0/16, PE1 could send the packets to a DC where the VM is not present. This would result in unnecessary tromboning; for example, PE1 could send the traffic to DCGW3, then DCGW3 would send it to DCGW2 to get to VM 10.0.0.1. However, PE1 could have forwarded directly to DCGW2.

To provide efficient downstream routing to the DC where the VM is located, DCGW1 and DCGW2 need to generate host routes for the VMs to which they are attached. Furthermore, when the VM moves to the other DC, DCGW3 and DCGW4 must be able to learn the VM host route and advertise it to PE1. Also, DCGW1 and DCGW2 will have to withdraw the route for 10.0.0.1, because the VM is no longer in the local DC.

To address this and other use cases, SR OS can learn the VM host route from the ARP or ND messages that it generates when it boots or when it moves. The host route can also be learned from EVPN routes type 2 (MAC/IP routes) that are installed in the ARP/ND caches, or in general, any ARP/ND entry can generate an ARP/ND host route.

A route owner type called "ARP-ND" is supported in the base router or a VPRN route table. The ARP-ND host routes have a preference of 1 and they are automatically created out of the ARP or ND Neighbor entries in the router instance. Figure 36: ARP-ND module and generated ARP-ND host routes shows how the ARP/ND software modules can generate ARP-ND host routes in the route table.

Figure 36: ARP-ND module and generated ARP-ND host routes



When **config>service>vprn/ies>interface>arp-host-route>populate [static | dynamic | evpn]** is enabled, the static, dynamic, and EVPN ARP entries of the routing context will create ARP-ND host routes in the route table. In the same way, ARP-ND host routes are created in the IPv6 route table out of static, dynamic, and EVPN neighbor entries, if **config>service>vprn/ies>interface>ipv6>nd-host-route>populate [static | dynamic | evpn]** is enabled.

Figure 36: ARP-ND module and generated ARP-ND host routes shows how the ARP/ND module populates its database from the usual dynamic and static entries, as well as from EVPN routes type 2 that include an IP address. Through the host-route learning action, ARP-ND host routes are handed over to the route table.

Figure 36: ARP-ND module and generated ARP-ND host routes also shows that the preference assigned to ARP-ND host routes is 1, which means that ARP-ND routes will be preferred over any other route owner, except for direct routes. For example, if the same host route gets to the route table from ARP-ND and VPN-IPv4 or EVPN, the ARP-ND host route will be preferred and added to the route table. Although they are added to the route table and advertised to routing protocols, ARP-ND host routes are never installed in the FIB. That helps preserve the FIB scale in the router.

The **arp/nd-host-route populate [static | dynamic | evpn]** commands are typically used along with other features:

- A route tag can be added to ARP-ND hosts by the command **route-tag**. This tag can be matched on BGP **vrf-export** and peer export policies.
- The ARP-ND host route will be kept in the route table while the corresponding ARP or Neighbor entry is active. The commands **arp-proactive-refresh** and **nd-proactive-refresh** help keep the entries active (even if there is no traffic destined to them) by sending an ARP refresh 30 seconds before the **arp-timeout** or starting Neighbor Unreachable Detection (NUD) when the **stale-time** expires.
- To speed up the learning of the ARP-ND host routes, the commands **arp-learn-unsolicited** and **nd-learn-unsolicited** can be configured. When **arp-learn-unsolicited** is enabled, received unsolicited ARP messages (typically, Gratuitous Address Resolution Protocol (GARP) messages) create an ARP entry, and therefore an ARP-ND route if **arp-host-route>populate [static | dynamic | evpn]** is added. Similarly, unsolicited Neighbor Advertisement messages will create a "stale" neighbor. If **nd-host-route>populate [static | dynamic | evpn]** is enabled, a confirmation message (NUD) is sent for all the neighbor entries created as stale, and, if confirmed, the corresponding ARP-ND routes are added to the route table.

In the example of Figure 35: L2 broadcast domain extension across DCs, **arp-host-route>populate [static | dynamic | evpn]** on the DCGWs allows them to learn/advertise the ARP-ND host route 10.0.0.1/32 when the VM is locally connected, and remove/withdraw it when the VM is no longer present in the local DC.

The following sections describe three typical DC scenarios in which the use of Anycast gateways and ARP-ND host routes is needed. The examples are focused on IPv4 and ARP; however, there is equivalent functionality for IPv6 and ND.

Configuration

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as an IGP

The following three scenarios are configured and presented in this document:

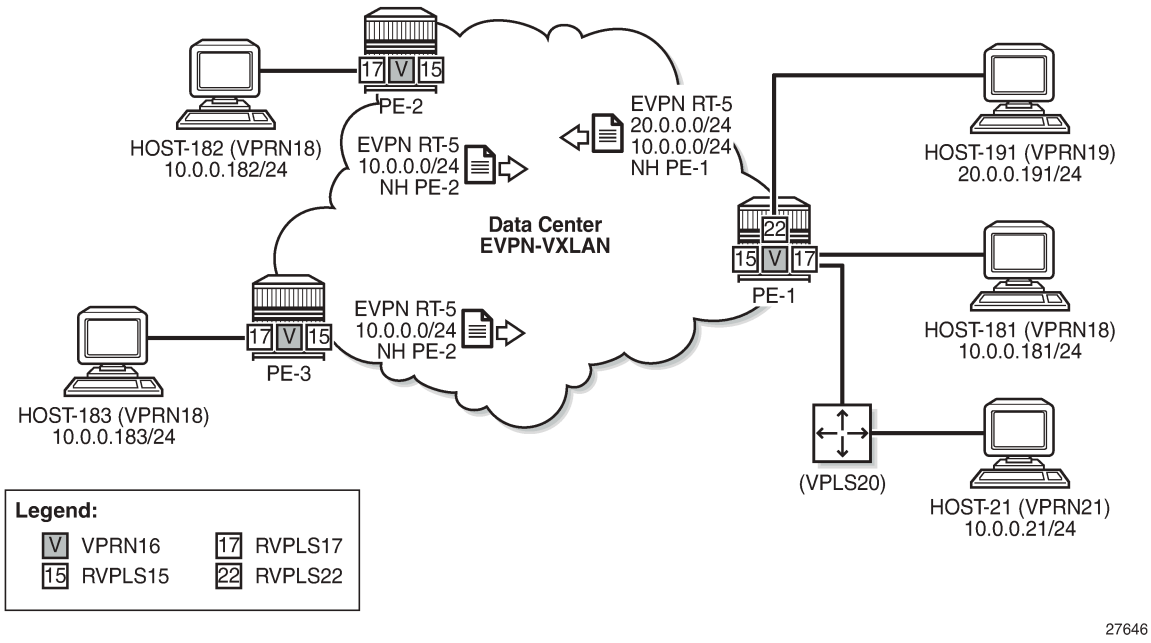
- DC inter-subnet forwarding with Anycast GWs (and no ARP-ND hosts)
- DC inter-subnet forwarding with Anycast GWs and ARP-ND hosts
- Data Center Interconnect (DCI) inter-subnet forwarding with Anycast GWs and ARP-ND hosts

DC inter-subnet forwarding with Anycast GWs

Figure 37: DC inter-subnet forwarding with Anycast GWs shows a typical DC network, where PE-1, PE-2, and PE-3 are leaf switches that use EVPN-VXLAN services to provide connectivity between two subnets of a tenant domain. Those two subnets are 10.0.0.0/24 and 10.0.20.0/24, respectively, and while the three PEs are attached to hosts in the 10.0.0.0/24 subnet, only PE-1 is attached to the 10.0.20.0/24 subnet. Subnet 10.0.0.0/24 uses R-VPLS 17 in the three PEs and subnet 10.0.20.0/24 uses R-VPLS 22 in PE-1. The distribution of the R-VPLS services does not have to be uniform in all the PEs, and those R-VPLS services are only created if there are hosts attached to them.

To provide inter-subnet forwarding for the tenant, each PE must be configured with a VPRN instance (VPRN 16) that has an interface to the subnet R-VPLS. In industry-standard terms, VPRN 16 represents the IP-VRF for the tenant, and R-VPLS 17 and R-VPLS 22 are user Broadcast Domains (BDs). R-VPLS 15 is not a user BD, but rather a backhaul R-VPLS that provides EVPN connectivity among the VPRN instances.

Figure 37: DC inter-subnet forwarding with Anycast GWs



The BGP configuration in the PEs is similar. As an example, the BGP configuration in PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "dc"
                type internal
                neighbor 192.0.2.2
```

```
                exit
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
        exit
```

PE-2 has the following service configuration. The service configuration on PE-3 is similar.

```
# on PE-2:
configure
    service
        vpls 15 name "sbd-15" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 15 create
            exit
            bgp
            exit
            bgp-evpn
                no mac-advertisement
                ip-route-advertisement
                evi 15
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vprn 16 name "ip-vrf-16" customer 1 create
            ecmp 2
            interface "evi-15" create
                mac 00:00:00:00:00:02
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-17" create
                address 10.0.0.2/24
                vrrp 1 passive
                    backup 10.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "evi-17"
                exit
            exit
            no shutdown
        exit
        vpls 17 name "evi-17" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 17 create
            exit
            bgp
            exit
            bgp-evpn
                evi 17
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap pxc-10.a:17 create
```

```
            no shutdown
        exit
        no shutdown
    exit
```

R-VPLS 17, "evi-17" in the configuration, is the BD used by subnet 10.0.0.0/24 in all the PEs. On the evi-17 interface in VPRN 16, a real IP address as well as a virtual (passive VRRP) IP address are configured. The real IP address is a unique address across the three PEs in R-VPLS 17 (10.0.0.2 in PE-2). This IP address will not be used by the R-VPLS 17 hosts as a default gateway, but rather will be used for troubleshooting purposes (ICMP or similar).

The backup IP address in the passive VRRP instance (10.0.0.254) is the Anycast GW IP address, and the same IP address is configured in all the PEs attached to R-VPLS 17. Because the virtual MAC is auto-derived from the VRRP instance, all the PEs will also have the same virtual MAC for this Anycast GW:

```

All the hosts attached to R-VPLS 17, such as host-181, host-182, and host-183, are configured with the Anycast GW as default gateway (10.0.0.254). The use of passive VRRP (or Anycast GW in standard terminology) has the following benefits:

- All the hosts use the same default gateway configuration, regardless of what PE they are attached to.
- When the hosts send traffic destined to a remote subnet, the local PE can route it directly, without any tromboning.
- In the case of a host moving to a different leaf switch, the host does not need to change its IP or default gateway, or even its ARP cache.

For completeness, the service configuration in PE-1 follows:

```
# on PE-1:
configure
    service
        vpls 15 name "sbd-15" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 15 create
            exit
            bgp
            exit
            bgp-evpn
                no mac-advertisement
                ip-route-advertisement
                evi 15
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
        vprn 16 name "ip-vrf-16" customer 1 create
            ecmp 2

            exit
            vxlan instance 1 vni 17 create
            exit
            bgp
            exit
            bgp-evpn
                evi 17
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:17 create
                no shutdown
            exit
            sap pxc-10.b:20 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 22 name "evi-22" customer 1 create
            allow-ip-int-bind
            exit
            stp
                shutdown
            exit
            sap pxc-10.b:19 create
                no shutdown
            exit
            no shutdown
        exit
```

See the EVPN for VXLAN Tunnels (Layer 3) chapter for more information about the EVPN-related configuration in the R-VPLS services. When there is no need for a recursive resolution of the EVPN IP prefix routes to a MAC/IP route, **no mac-advertisement** is used in the R-VPLS 15, compared to the examples in EVPN for VXLAN Tunnels (Layer 3).

With the described configuration, as an example, the intra-subnet and inter-subnet forwarding connectivity from host-182 is tested (host-182 is simulated with VPRN 18 that is connected to R-VPLS 17 via PXC SAP):

```
*A:PE-2# traceroute router 18 10.0.0.183 source 10.0.0.182
traceroute to 10.0.0.183 from 10.0.0.182, 30 hops max, 40 byte packets
  1  10.0.0.183 (10.0.0.183)    2.49 ms  2.31 ms  2.41 ms
```

```
*A:PE-2# traceroute router 18 10.0.20.191 source 10.0.0.182
traceroute to 10.0.20.191 from 10.0.0.182, 30 hops max, 40 byte packets
  1  10.0.0.2 (10.0.0.2)    0.979 ms  0.890 ms  0.875 ms
```

```
  2  10.0.20.1 (10.0.20.1)    2.02 ms  1.98 ms  1.92 ms
  3  10.0.20.191 (10.0.20.191)    2.61 ms  2.73 ms  2.74 ms
```

When host-182 sends traffic to host-191, it will ARP for the Anycast GW IP and will receive the virtual MAC as a reply. The virtual MAC is always associated with the local CPM on the local PE; therefore, the local PE can always route the traffic directly while it has a route for the IP destination.

Host-182 (VPRN 18) resolves the Anycast GW to the virtual MAC:

```
*A:PE-2# show router 18 arp 10.0.0.254

===============================================================================
ARP Table (Service: 18)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface

```

DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes

While the configuration shown in the preceding section is common in DCs, there is a variation that eliminates the flooding among PEs that are attached to the same BD, typically caused by ARP messages and ND. The configuration described in this section is recommended only if all the following conditions are met:

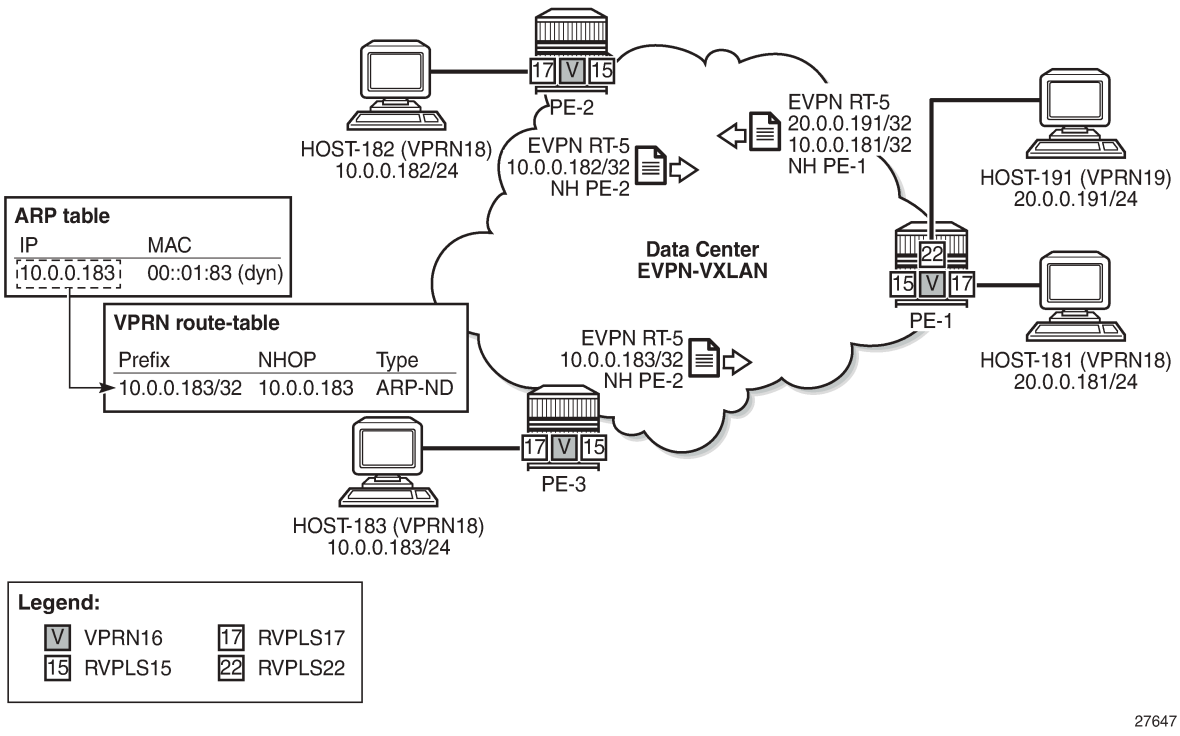
- All the hosts are directly connected to the leaf switches (PEs in Figure 37: DC inter-subnet forwarding with Anycast GWs).
- All the hosts announce themselves by issuing a GARP (or unsolicited NA for IPv6) whenever they boot up or move to a different leaf switch.

  Note: This is the case for virtual machines.
- All the traffic among hosts is IP unicast or non-IP unicast (if the hosts are in the same BD), and there is no Broadcast, Unknown unicast, or Multicast (BUM) traffic from the hosts in the tenant domain, other than ARP/ND.

If the preceding conditions are true, the ARP-ND host route feature can help eliminate BUM traffic completely.

Figure 38: DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes shows the scenario used in this section.

Figure 38: DC inter-subnet forwarding with Anycast GWs and ARP-ND host routes



Compared to the configuration used in the preceding section, VPRN 16 is modified in the three PEs as follows (changes in bold):

```
# on PE-2:
configure
```

```
    service
        vprn "ip-vrf-16"
            ecmp 2
            interface "evi-15" create
                mac 00:00:00:00:00:02
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-17" create
                address 10.0.0.2/24
                arp-host-route
                    populate static
                    populate dynamic
                    populate evpn
                exit
                arp-timeout 300
                arp-learn-unsolicited
                arp-proactive-refresh
                vrrp 1 passive
                    backup 10.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                remote-proxy-arp
                vpls "evi-17"
                exit
            exit
            no shutdown
```

```
# on PE-3:
configure
    service
        vprn "ip-vrf-16"
            ecmp 2
            interface "evi-15" create
                mac 00:00:00:00:00:03
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-17" create

                exit
            exit
            no shutdown
```

The behavior due to the newly added commands is as follows:

- **arp-host-route>populate [static | dynamic | evpn]** makes the router create an ARP-ND host route per ARP entry in the route table of VPRN "ip-vrf-16".
- **arp-learn-unsolicited** makes the router learn ARP entries for the hosts out of the GARP messages that they send when they boot up or move. Without this command, ARP entries are only created after the router receives packets with the host as the destination, issues an ARP request, and the host replies to this solicited ARP request.

- **arp-proactive-refresh** makes the router refresh every dynamic ARP entry even if there is no traffic destined to the owner. Without the command, host IP addresses will not be maintained in the ARP cache unless they receive traffic from remote hosts.
- **arp-timeout 300** is the timeout selected in this example (in seconds). The ARP timeout has an impact on how often the router will try to refresh an entry (30 seconds before the timeout expires). In environments where the hosts are subject to mobility (VMs moving between leaves), having a shorter ARP timeout will speed up the removal of the old ARP entry, that is, the old ARP-ND host route entry. However, in scaled environments with tens of thousands of ARP entries, Nokia does not recommend lowering the ARP timeout under 10 minutes.
- **remote-proxy-arp** allows the router to reply to any ARP request looking for an IP address in the same subnet as the source, with its virtual MAC (00:00:5e:00:01:01), and route the traffic, as long as there is a route for the destination in the route table.

In addition, the following commands will be executed in the three PEs:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vpls "evi-17"
            bgp-evpn
                vxlan
                    shutdown
                exit
                no ingress-repl-inc-mcast-advertisement
                vxlan
                    no shutdown
                exit
            exit
```

By disabling the advertisement of the Inclusive Multicast Ethernet Tag (IMET) route in R-VPLS 17, the PEs will not create a VXLAN BUM destination among each other, preventing the exchange of BUM traffic. Only known unicast traffic can be now exchanged in the context of R-VPLS 17. The three PEs will show VXLAN destinations that have Mcast "-", as opposed to "BUM":

```
*A:PE-3# show service id 17 vxlan destinations

```

With the described configuration, when the hosts boot up and generate a GARP message, the ARP entries will be created, and subsequently ARP-ND hosts and EVPN IP-prefix advertisements for them. The host bootup is simulated by disabling and re-enabling the VPRN that emulates the host. As an example, some debug commands are used to see the behavior when host-181 boots up and sends a GARP:

```
*A:PE-1# configure service vprn 18 shutdown
*A:PE-1# configure service vprn 18 no shutdown

1 2022/02/18 14:58:30.128 UTC MINOR: DEBUG #2001 vprn18 PIP
"PIP: ARP
instance 3 (18), interface index 7 (local),
ARP egressing on local
   Who has 10.0.0.181 ? Tell 10.0.0.181
"

2 2022/02/18 14:58:30.129 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 5 (evi-17),
ARP ingressing on evi-17
   Who has 10.0.0.181 ? Tell 10.0.0.181
"

4 2022/02/18 14:58:30.129 UTC MINOR: DEBUG #2001 vprn21 PIP
"PIP: ARP
instance 5 (21), interface index 9 (local),
ARP ingressing on local
   Who has 10.0.0.181 ? Tell 10.0.0.181
"
```

The GARP creates an ARP entry and, subsequently, an ARP-ND host route in the route table of VPRN 16. Host-181 MAC/IP and IP-prefix routes are advertised too:

```
3 2022/02/18 14:58:30.129 UTC MINOR: DEBUG #2001 vprn16 PIP

```

A side effect of this scenario is that traffic between hosts in the same BD (R-VPLS 17) is routed instead of switched. This can be shown on the traceroute from host-181 to host-182 (there are three hops instead of two), or the TTL on the ping packets (62 instead of 64):

```
*A:PE-1# traceroute router 18 10.0.0.182
traceroute to 10.0.0.182, 30 hops max, 40 byte packets
  1  10.0.0.1 (10.0.0.1)    2.02 ms  2.29 ms  2.26 ms
  2  10.0.0.2 (10.0.0.2)    3.35 ms  3.39 ms  3.17 ms
  3  10.0.0.182 (10.0.0.182)    4.10 ms  3.95 ms  3.56 ms
```

```
*A:PE-1# ping router 18 10.0.0.182 source 10.0.0.181

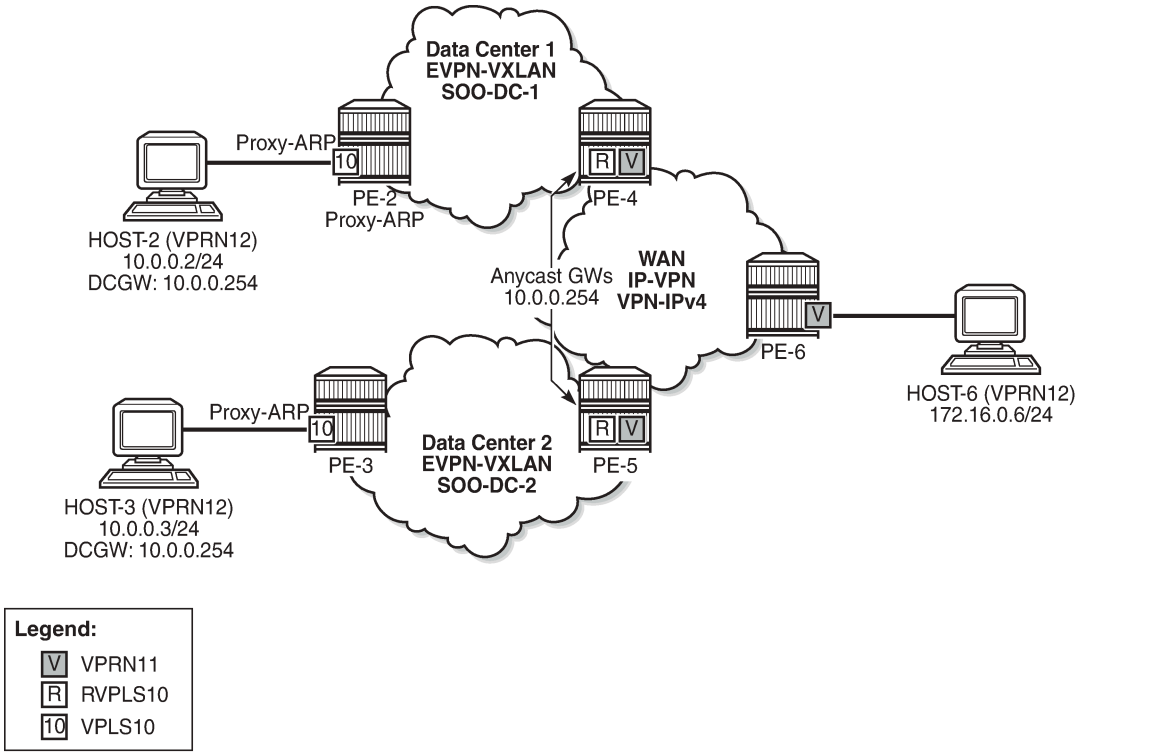
```

This extension of a subnet across a pure routing domain is compliant with the virtual subnet concept described in RFC 7814.

DCI inter-subnet forwarding with Anycast GWs and ARP-ND hosts

Figure 39: DCI inter-subnet forwarding with Anycast GWs and ARP-ND host routes shows a DCI scenario where the use of Anycast GWs, ARP-ND hosts, and some additional configuration provide efficient inter-subnet forwarding within the tenant domain.

Figure 39: DCI inter-subnet forwarding with Anycast GWs and ARP-ND host routes



In this example, VPLS 10 is extended across DC-1 and DC-2, via PE-4 and PE-5 (which are DC GWs). PE-4 and PE-5 are also connected to the WAN and use IP-VPN for inter-subnet forwarding connectivity to the remote host-6. In this network, PE-4 and PE-5 provide the Anycast GW functionality to host-2 and host-3, so that they can move between the two DCs without having to change their IP/MAC/default GW or ARP cache, and efficient upstream forwarding is provided.

PE-4 and PE-5 learn the ARP-ND host route of their respective host and advertise it to the WAN, so that downstream routing from PE-6 can be efficient and without tromboning.

To avoid unnecessary ARP flooding between DCs, proxy-ARP is used in PE-2 and PE-3. The configuration of VPLS 10 in the PE-2 and PE-3 is as follows:

```
# on PE-2:
configure
    service
        vpls 10 name "centralized-gw-bd" customer 1 create
            vxlan instance 1 vni 10 create
            exit
            bgp
            exit
            bgp-evpn
                evi 10
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
```

```
            sap pxc-10.a:10 create
                no shutdown
            exit
            proxy-arp
                send-refresh 120
                no unknown-arp-request-flood-evpn
                dynamic-arp-populate
                no garp-flood-evpn
                evpn-route-tag 1
                no shutdown
            exit
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
       vpls 10 name "centralized-gw-bd" customer 1 create
            vxlan instance 1 vni 10 create
            exit
            bgp
            exit
            bgp-evpn
                evi 10
                vxlan bgp 1 vxlan-instance 1

                exit
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:10 create
                no shutdown
            exit
            proxy-arp
                send-refresh 120
                no unknown-arp-request-flood-evpn
                dynamic-arp-populate
                no garp-flood-evpn
                evpn-route-tag 1
                no shutdown
            exit
            no shutdown
        exit
```

Because the hosts are directly connected to PE-2 and PE-3, and they announce themselves to the network through a GARP when they boot up or move, the proxy-ARP configuration includes the parameters **no unknown-arp-request-flood-evpn** and **no garp-flood-evpn**. Those two commands prevent unnecessary ARP flooding between DCs.

The two PEs also include the **proxy-arp evpn-route-tag 1** command. This command allows the proxy-ARP module to tag the routes when sent to BGP for advertisement of a MAC/IP route with non-zero IP. In this example, the tag is used in an export policy to add a Site-Of-Origin (SOO) extended community to the MAC/IP routes with non-zero IP. This, for example, allows PE-4 to accept MAC/IP routes from its own DC-1 and drop MAC/IP routes from DC-2 so that PE-4 only advertises ARP-ND host routes attached to DC-1. Vice versa for PE-5. The MAC/IP routes with zero-IP (that are also sent for every MAC) will not be tagged with the SOO and, therefore, will be imported by all the PEs in VPLS 10. This allows normal L2 connectivity among the four PEs, while the ARP-ND routes are only generated for the local hosts.

On PE-2, BGP is configured as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        policy-options
            begin
            community "SOO-DC-1"
                members "origin:64500:1"
            exit
            policy-statement "export-add-SOO"
                entry 10
                    from
                        tag 1
                    exit
                    action accept
                        community add "SOO-DC-1"
                    exit
                exit
            exit
            policy-statement "import-prefer-DC-1"
                entry 10
                    from
                        community "SOO-DC-1"
                    exit
                    action accept
                        local-preference 200
                    exit
                exit
            exit
            commit
        exit
        bgp
            family vpn-ipv4 vpn-ipv6 evpn
            vpn-apply-import
            vpn-apply-export
            import "import-prefer-DC-1"
            export "export-add-SOO"
            rapid-withdrawal
            rapid-update evpn
            group "dc"
                type internal
                neighbor 192.0.2.3
                exit
            exit
            group "dcgws"
                type internal
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

On PE-3, BGP is configured as follows:

```
# on PE-3:
configure
    router
        autonomous-system 64500
        policy-options
            begin
```

```
            community "SOO-DC-2"
                members "origin:64500:2"
            exit
            policy-statement "export-add-SOO"
                entry 10
                    from
                        tag 1
                    exit
                    action accept
                        community add "SOO-DC-2"
                    exit
                exit
            exit
            policy-statement "import-prefer-DC-2"
                entry 10
                    from
                        community "SOO-DC-2"
                    exit
                    action accept
                        local-preference 200
                    exit
                exit
            exit
            commit
        exit
        bgp
            family vpn-ipv4 vpn-ipv6 evpn
            vpn-apply-import
            vpn-apply-export
            import "import-prefer-DC-2"
            export "export-add-SOO"
            rapid-withdrawal
            rapid-update evpn
            group "dc"
                type internal
                neighbor 192.0.2.2
                exit
            exit
            group "dcgws"
                type internal
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

As an example, the following **show** commands prove that PE-2 does not add an SOO to MAC/IP routes with zero-IP, but it does add SOO-DC-1 for MAC/IP routes with non-zero IP:

```
*A:PE-2# show router bgp routes evpn mac rd 192.0.2.2:10 hunt
===============================================================================

The VPLS 10 configuration on PE-4 and the corresponding import policy to drop non-local SOO follow. PE-5 has a similar configuration (not shown), including the same RD 64500:10 in VPLS 10 as PE-4. The policy will drop routes tagged with SOO-DC-1 instead of SOO-DC-2.

```
# on PE-4:
configure
    service
        vpls 10 name "centralized-gw-bd" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 10 create
            exit
            bgp
                route-distinguisher 64500:10
            exit
            bgp-evpn
                evi 10
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

On PE-4, the BGP configuration is as follows:

```
# on PE-4:
configure
    router Base
        autonomous-system 64500
        policy-options
            begin
            community "SOO-DC-1"
                members "origin:64500:1"
            exit
            community "SOO-DC-2"
                members "origin:64500:2"
            exit
            policy-statement "export-add-SOO"
                entry 10
                    from
                    exit
                    action accept
                        community add "SOO-DC-1"
                    exit
                exit
            exit
            policy-statement "import-drop-DC-2"
                entry 10
                    from
                        community "SOO-DC-2"

            rapid-update evpn
            group "dc"
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "wan"
                type internal
                neighbor 192.0.2.5
                exit
                neighbor 192.0.2.6
                exit
            exit
            no shutdown
        exit
```

There is another aspect for which policies are used: on PE-2 and PE-3, two MAC/IP routes with the Anycast GW virtual MAC are received (one from PE-4 and another from PE5). To provide efficient upstream routing with no tromboning, it is important that PE-2 prefers the PE-4 virtual MAC route (its own DGW) over that of PE-5, and vice versa for PE-3. This is achieved by:

- Configuring the same RD on PE-4 and PE-5 for VPLS10.
- Configuring an import policy on PE-2 and PE-3 that modifies the local preference of the routes, so that each one prefers the local DGW.

PE-2 and PE-3 could have dropped the routes from the non-local DCGW, but with this configuration, DCGW redundancy is provided in case of failure:

```
*A:PE-2# show router policy "import-prefer-DC-1"
    entry 10
        from
            community "SOO-DC-1"
        exit
        action accept
            local-preference 200
        exit
    exit
```

```
*A:PE-2# show router bgp routes evpn mac community target:64500:10
                                                    mac-address 00:00:5e:00:01:01

            exit
            no shutdown
        exit
```

The passive VRRP commands, as well as the ARP commands, have already been discussed in preceding sections. The only new command in the configuration is **route-tag 1**. This command tags all the ARP-ND host routes learned on the interface, so that export policies can match on that tag and modify the routes before they are advertised. The command is included for completeness, however, in this configuration, there is no export policy using this tag.

When the configuration is in place and the hosts are connected, the FDBs, proxy-ARP, ARP caches, and route tables are checked with the following commands (example for host-2 and host-6).

When host-2 ARPs for its default gateway (10.0.0.254), PE-2 will reply with the information from its proxy-ARP table:

```
*A:PE-2# show service id 10 proxy-arp detail 10.0.0.254

===============================================================================
```

If PE-4 receives packets with MAC Destination Address (DA) equal to the virtual MAC and IP DA of host-6 (172.16.0.6), the forwarding is based on the information in the R-VPLS FDB first, and afterward on the VPRN 11 route table, as follows.

```
*A:PE-4# show service id 10 fdb mac 00:00:5e:00:01:01

===============================================================================
```

When the traffic goes back from host-6 to host-2, PE-6 will forward to PE-4 due to a Longest Prefix Match (LPM) lookup on the VPRN route table. The advertisement of the ARP-ND routes on PE-4 and PE-6 ensures that PE-6 can forward downstream traffic to the correct PE:

```
*A:PE-6# show router 11 route-table

===============================================================================
Route Table (Service: 11)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref

10.0.0.0/16                                 Remote  BGP VPN   00h06m57s  170
       192.0.2.5 (tunneled)                                          10
10.0.0.2/32                                 Remote  BGP VPN   00h06m57s  170
       192.0.2.4 (tunneled)                                          10
10.0.0.3/32                                 Remote  BGP VPN   00h06m57s  170
       192.0.2.5 (tunneled)                                          10
172.16.0.0/24                               Local   Local     00h07m01s  0
       local                                                         0
-------------------------------------------------------------------------------
No. of Routes: 5
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Traceroute commands from host-6 provide information about the path to each remote host (VPRN 12 on PE-6 simulates host-6):

```
*A:PE-6# traceroute router 12 10.0.0.2
traceroute to 10.0.0.2, 30 hops max, 40 byte packets
  1  172.16.0.254 (172.16.0.254)    3.09 ms  2.23 ms  2.31 ms
  2  10.0.0.4 (10.0.0.4)    3.27 ms  3.24 ms  3.28 ms
  3  10.0.0.2 (10.0.0.2)    5.64 ms  5.77 ms  5.86 ms
```

```
*A:PE-6# traceroute router 12 10.0.0.3
traceroute to 10.0.0.3, 30 hops max, 40 byte packets
  1  172.16.0.254 (172.16.0.254)    1.96 ms  2.19 ms  2.20 ms
  2  10.0.0.5 (10.0.0.5)    3.44 ms  3.27 ms  3.04 ms
  3  10.0.0.3 (10.0.0.3)    8.40 ms  5.63 ms  5.48 ms
```

Communication between host-2 and host-3 uses regular L2 switching, as expected, because there are EVPN-VXLAN destinations created between PE-2 and PE-3 for VPLS 10:

```
*A:PE-2# show service id 10 vxlan destinations

```

Troubleshooting and debugging

The following commands can be used when troubleshooting these scenarios:

- **show router** <*id*> **route table** and **show router** <*id*> **fib** <*slot*> (and their corresponding commands for IPv6)
- **show router** <*id*> **arp / neighbor**
- **show service** <*id*> **fdb detail**
- **show service** <*id*> **proxy-arp/nd detail**
- **show router bgp routes evpn / vpn-ipv4 / vpn-ipv6**

The following debug commands are also important to analyze the scenarios:

```
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-16"
        ip
            arp
            route-table
        exit
    exit
    router service-name "VM-test-anycast-gw"
        ip
            arp
        exit
    exit
    service
        id 10
            proxy-arp
                 all
            exit
        exit
    exit
exit
```

Conclusion

ARP-ND host routes are generated out of ARP-ND entries in a router context. These ARP-ND host routes, along with passive VRRP (for Anycast GWs), provide the correct solution for efficient inter-subnet forwarding in DCs and DCI networks.

Auto-Learn MAC Protect in EVPN

This chapter provides information about Auto-Learn MAC Protect in EVPN.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R5, but the CLI in the current edition is based on SR OS Release 21.2.R1. Auto-Learn MAC Protect (ALMP) is supported for EVPN in SR OS Release 14.0.R1, and later.

Overview

MAC protection is needed in Layer 2 services to safeguard business-critical MAC addresses against the possibility of being learned on the wrong SAP/SDP-binding. When a MAC address is learned on the wrong SAP/SDP-binding, traffic would be diverted from its intended destination. This could be caused by misconfiguration or by a malicious source launching a Denial of Service (DoS) attack. MAC protect can also be used to prevent loops in certain topologies.

Chapter EVPN for VXLAN Tunnels (Layer 2) describes MAC protection for static MAC addresses that are configured on SAPs or spoke-SDPs. The command to configure static MAC addresses in a VPLS service is as follows:

```
*A:PE-2>conf>serv>vpls>static-mac$ mac ?
  - mac <ieee-address> [create] black-hole
  - mac <ieee-address> [create] sap <sap-id> monitor {fwd-status}
  - no mac <ieee-address>
  - mac <ieee-address> [create] spoke-sdp <sdp-id:vc-id> monitor {fwd-status}
---snip---
```

Configuring static MAC addresses is not scalable if large numbers of MAC addresses need to be protected. Also, configuring static MAC addresses is not an option when the MAC addresses are unknown. Auto-Learn MAC Protect (ALMP) offers the same protection for learned MAC addresses in services such as EVPN VPLS and EVPN R-VPLS. However, ALMP is not supported for PBB-EVPN.

ALMP can be enabled with the **auto-learn-mac-protect** command in EVPN with VXLAN or MPLS bindings on the following:

- SAPs
- Mesh-SDPs
- Spoke-SDPs
- Pseudowire (PW) templates
- Split Horizon Groups (SHGs)

- SHGs in PW templates

When enabled, all MAC addresses learned on those objects become protected.

The following commands can be used to enable ALMP on objects in VPLS 1:

```
configure
    service
        pw-template 1 name "PW1" create
            auto-learn-mac-protect
        exit
        vpls 1 name "VPLS 1" customer 1 create
            split-horizon-group "SHG1" create
                auto-learn-mac-protect
            exit
            sap 1/2/1:1 create
                auto-learn-mac-protect
                no shutdown
            exit
            spoke-sdp 23:1 create
                auto-learn-mac-protect
                no shutdown
            exit
            mesh-sdp 24:1 create
                auto-learn-mac-protect
                no shutdown
            exit
```

When enabled on an SHG, it is only applicable to the SAPs within the SHG, not to spoke-SDPs. If ALMP is required on spoke-SDPs in the SHG, the parameter must be configured on each spoke-SDP individually. All MAC Source Addresses (SAs) learned on these objects will be protected and advertised with the sticky bit set. The sticky bit indicates that these MAC addresses should be treated as protected on the remote PEs, where these protected MAC addresses are considered to have been learned on the EVPN MPLS/VXLAN destinations. The remote EVPN peers then use the MAC protection functionality in the same way as the local peer to protect the MAC address.

ALMP enables an implicit **restrict-protected-src discard-frame** (RPS-DF) by default on SAPs and spoke/mesh-SDPs. When enabled, frames with a protected MAC SA are discarded if received on objects where they were not learned and protected. This configuration is the default and cannot be configured on objects where MAC addresses are learned, such as SAPs, spoke/mesh-SDPs, and SHGs.

However, RPS-DF can optionally be configured on destinations in EVPN MPLS or EVPN VXLAN, where data plane MAC learning is never performed for incoming traffic. For EVPN MPLS, the RPS-DF configuration is in the BGP EVPN context, as follows:

```
*A:PE-2>config>service>vpls>bgp-evpn>mpls# restrict-protected-src ?
  - no restrict-protected-src
  - restrict-protected-src discard-frame

 <discard-frame>      : keyword - discard frame and  trap on a protected MAC
```

For EVPN VXLAN, the RPS-DF configuration is in the VXLAN context, as follows:

```
*A:PE-2>config>service>vpls>vxlan$ restrict-protected-src ?
  - no restrict-protected-src
  - restrict-protected-src discard-frame
```

Instead of discarding the frame, the SAP or spoke/mesh-SDP can be brought operationally down when a frame is received with a protected MAC SA that has not been learned on the object, by configuring

restrict-protected-src (RPS) without any parameter on the object in EVPN services. After the object has been brought down, an operator needs to disable (**shutdown**) and enable (**no shutdown**) the object in order to make it operational again.

RPS can be enabled without any parameter on SAPs, spoke/mesh-SDPs, SHGs, and PW templates, but not on EVPN MPLS/VXLAN destinations, using following commands:

```
configure
    service
        pw-template 1 name "PW1" create
            restrict-protected-src
        exit
        pw-template 2 name "PW2" create
            split-horizon-group "SHG1"
                restrict-protected-src
            exit
        exit
        vpls "VPLS 1"
            split-horizon-group "SHG1"
                restrict-protected-src
            exit
            sap 1/2/1:1
                restrict-protected-src
            exit
            spoke-sdp 23:1
                restrict-protected-src
            exit
            mesh-sdp 24:1
                restrict-protected-src
            exit
```

The operation for an object is reverted to **restrict-protected-src discard-frame** after configuring the **no restrict-protected-src** command.

RPS cannot be configured without any parameter on EVPN MPLS destinations; if attempted, the following error will be raised:

```
*A:PE-2>config>service>vpls>bgp-evpn>mpls# restrict-protected-src
                                                                 ^
Error: Missing parameter
```

Likewise, RPS cannot be configured without any parameter on EVPN VXLAN destinations; if attempted, the following error will be raised:

```
*A:PE-2>config>service>vpls>vxlan# restrict-protected-src
                                                        ^
Error: Missing parameter
```

Note:
The configuration of restrict-protected-src alarm-only and restrict-unprotected-dst are not allowed in EVPN.

Protection is provided at the point where a MAC address first enters the EVPN part of the network. Therefore, the preference for an auto-learned protected MAC address is higher than that of a MAC address received in a BGP update with the sticky bit set.

The following list shows the MAC learning priority, with the highest priority first:

1. Local MAC address (including AS-MAC without static-black-hole, es-bmac, src-bmac, OAM, and so on)

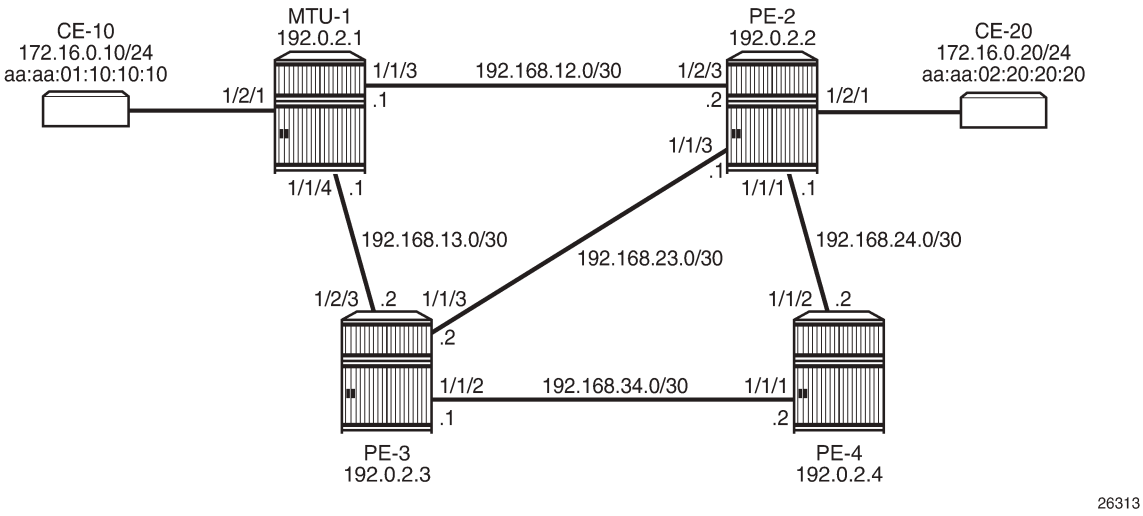
2. Conditional static MAC address (including AS-MAC with static-black-hole)
3. **Auto-Learn Protected MAC address**
4. EVPN MAC address with sticky/static bit set
5. Data plane learned MAC address (regular learning on SAP/SDP-binding)
6. EVPN MAC address without sticky/static bit set

Note:
ALMP MAC addresses have a higher priority but do not overwrite EVPN static MAC addresses.

Configuration

Figure 40: Example topology - no LAG shows the example topology with one MTU and three PEs.

Figure 40: Example topology - no LAG



- Cards, MDAs
- The ports between the PEs are configured as network ports; the other ports are access ports. No LAG is configured initially.
- IGP (IS-IS is used in this example) between the PEs
- LDP between the PEs
- BGP with address family EVPN on the PEs

PE-2 is the BGP route reflector. The BGP configuration on the PEs is similar. BGP is configured on PE-3 as follows:

```
# on PE-3:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
```

```
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
        exit
```

VPLS 1 is configured on all nodes. Initially, ALMP is disabled. On MTU-1, the VPLS 1 contains three SAPs: one toward CE-10, one toward PE-2, and one toward PE-3.

On PE-2, VPLS 1 is configured with EVPN MPLS and contains a SAP toward CE-20 and a SAP toward MTU-1, as follows:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            sap 1/2/3:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-3, VPLS 1 is configured with EVPN MPLS and contains a SAP toward MTU-1, as follows:

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
```

```
            exit
        exit
        stp
            shutdown
        exit
        sap 1/2/3:1 create
            no shutdown
        exit
        no shutdown
    exit
```

The following use cases will be described in this section:

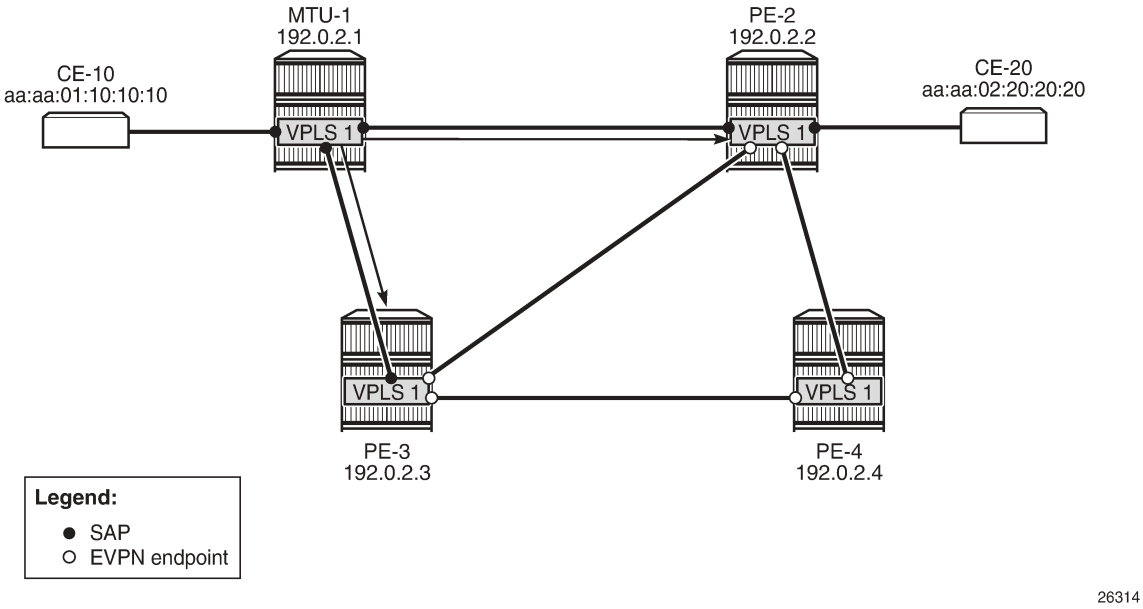
- EVPN MPLS without multi-homing.
  - Default behavior: no ALMP on SAPs, no protected MAC addresses
  - No ALMP on SAPs, RPS-DF on EVPN MPLS destinations
  - ALMP and implicit RPS-DF on SAPs.
    - RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2
    - RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
    - No RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
  - ALMP and RPS on SAPs.
    - RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2
    - RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
    - No RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3
- EVPN MPLS with ALMP in all-active multi-homing.
  - RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations

Default behavior: no protected MAC addresses

The following example is not a recommended configuration because it causes a loop. By default, ALMP is disabled and no static MAC addresses are configured. As described in chapter EVPN for VXLAN Tunnels (Layer 2), duplicate MAC addresses are detected in BGP EVPN and the MAC address will be put in a hold-down state on the EVPN destinations after a configurable threshold is reached. This applies to EVPN-MPLS as well as to EVPN-VXLAN. By default, the maximum number of MAC address moves is five in a time window of 3 minutes.

Figure 41: MAC address learned simultaneously on SAPs on PE-2 and PE-3 shows that the MAC address from CE-10 is learned simultaneously on the SAPs in VPLS 1 on PE-2 and PE-3.

Figure 41: MAC address learned simultaneously on SAPs on PE-2 and PE-3



CE-10 sends frames to CE-20 with MAC Destination Address (DA) aa:aa:02:20:20:20. MTU-1 has not learned that MAC DA, so the frames are flooded to PE-2 and PE-3, where they enter the SAPs simultaneously. PE-2 and PE-3 have not learned the MAC DA either, so the frames are flooded to all potential destinations. The frames received on PE-2 will be sent (among others) to PE-3, and vice versa. These frames are forwarded back out of the SAP toward MTU-1. This causes a loop.

Both PEs send a BGP update for the MAC SA aa:aa:01:10:10:10 to the other PEs with no sticky bit set. That MAC SA is learned, but not protected on the destination to the other PE. The stream of frames will cause the learned MAC SA to oscillate between the SAP and EVPN destinations on PE-2 and PE-3, and between the EVPN destinations on PE-4.

After a configurable number of BGP EVPN MAC address moves in a time span (by default, after five MAC address moves in a period of 3 minutes), the MAC address is put in a hold-down state on the EVPN destinations for a specific duration (until the next MAC address duplication detection retry; by default, after 9 minutes).

The following message in log 99 on PE-2 (and also on PE-3) indicates that duplicate MAC addresses have been detected:

```
74 2021/03/19 08:14:13.100 UTC MINOR: SVCMGR #2331 Base
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

The following shows the settings for EVPN MAC address duplication detection, which are the default. It also lists the detected duplicate MAC addresses of CE-10 and CE-20:

```
*A:PE-3# show service id 1 bgp-evpn

RPS is disabled (by default) on the EVPN destinations (**RestProtSrcMacAct** : *none*).

The MAC addresses are in a hold-down state on the EVPN destinations and no MAC address moves take place until the next MAC address duplication detection retry after 9 minutes. After 9 minutes, the EVPN MAC address duplication alarm is cleared, but after the next five MAC address moves within a time span of 3 minutes, the alarm is raised again and this threshold is reached soon after the alarm has been cleared.

The MAC addresses of both CEs are learned on the SAP of PE-3 (CE-20's MAC address is also learned on the SAP toward MTU-1), not on the EVPN destinations, because of the MAC address duplication detection and hold-down state in EVPN, as follows:

```
*A:PE-3# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
```

```

A similar output can be shown for PE-2.

Both PE-2 and PE-3 learn the MAC addresses locally and send BGP EVPN MAC address route updates to their BGP peers. PE-3 received the following BGP EVPN MAC address routes from PE-2, with the MAC address mobility sequence number representing the number of MAC address moves:

```
*A:PE-3# show router bgp routes evpn mac
===============================================================================
 BGP Router ID:192.0.2.3        AS:64500       Local AS:64500
===============================================================================

```

VPLS 1 on MTU-1 does not have EVPN configured and no MAC address duplication detection mechanism implemented. The MAC address from CE-10 is last learned on the SAP toward PE-3 (it might equally have been the SAP toward PE-2) instead of the SAP toward CE-10, resulting from the loop, as follows:

```
*A:MTU-1# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1          aa:aa:01:10:10:10 sap:1/1/4:1             L/0      03/19/21 08:18:05
1          aa:aa:02:20:20:20 sap:1/1/3:1             L/0      03/19/21 08:14:13
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

No ALMP on SAPs, RPS-DF on EVPN destinations

When there are no protected MAC addresses (ALMP is disabled and no static MAC addresses are configured), the behavior is as described earlier. RPS-DF discards frames with protected MAC addresses that were not learned on the object, but there are no protected MAC addresses, because ALMP is not configured. RPS-DF does not discard frames with MAC SAs that are not protected.

RPS-DF is enabled on EVPN destinations on all PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                mpls bgp 1
                    restrict-protected-src discard-frame
                exit
            exit
```

The state of RPS is now "discard-frame" instead of "none", as follows:

```
*A:PE-3# show service id 1 bgp-evpn | match RestProtSrcMacAct
RestProtSrcMacAct  : Discard-frame
```

It is also allowed to configure RPS without parameters on the SAPs, but that does not change the behavior when ALMP is disabled and there are no protected MAC addresses. RPS will not bring down a SAP after receiving a frame with an unprotected MAC SA.

ALMP and implicit RPS-DF on SAPs

ALMP is enabled on the SAPs in PE-2 as follows:

```
# on PE-2:
configure
    service
```

```
        vpls "VPLS 1"
            sap 1/2/1:1          # SAP toward CE-20
                auto-learn-mac-protect
                no shutdown
            exit
            sap 1/2/3:1          # SAP toward MTU-1
                auto-learn-mac-protect
                no shutdown
            exit
```

The configuration is similar on PE-3.

The following shows that ALMP is enabled on the SAP and that the default RPS-DF is used:

```
*A:PE-2# show service id 1 sap 1/2/3:1 detail

===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 1
SAP                : 1/2/3:1                  Encap             : q-tag
Description        : (Not Specified)
Admin State        : Up                       Oper State        : Up
Flags              : None
---snip---

Restr MacUnpr Dst  : Disabled
Auto Learn Mac Prot: Enabled
ALMP Exclude List  : <none>
RestMacProtSrc Act : none (oper: Discard-frame)
---snip---
```

ALMP and RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2

Initially, the SAP on PE-3 is disabled to ensure that the MAC address will first be learned on PE-2, then on PE-3, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/3:1
                shutdown
```

Each learned MAC address on the SAPs on PE-2 will be protected; therefore, a BGP update with the static/sticky bit set will be sent to the BGP EVPN peers. In this example, the MAC aa:aa:01:10:10:10 of CE-10 is learned first on SAP 1/2/3:1 on PE-2, and MAC aa:aa:02:20:20:20 is learned on SAP 1/2/1:1 on PE-2. Consequently, PE-2 sends BGP updates with the static/sticky bit set to PE-3 for both MAC aa:aa:01:10:10:10 and MAC aa:aa:02:20:20:20, as follows:

```
67 2021/03/19 08:23:22.782 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

"
```

Note:
The MPLS label is label1 in the BGP update divided by 16 (2^4), as follows:

$$\frac{8388544}{16} = 524284$$

PE-2 sends similar BGP EVPN updates to peer PE-4.

After these BGP EVPN updates have been sent to PE-3 (and PE-4), the SAP on PE-3 is enabled again, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/3:1
                no shutdown
```

The MAC addresses in the FDB on PE-2, where these MAC addresses are learned, get the indication "L" for learned and "P" for protected MAC address, as follows:

```
*A:PE-2# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
```

===============================================================================
```

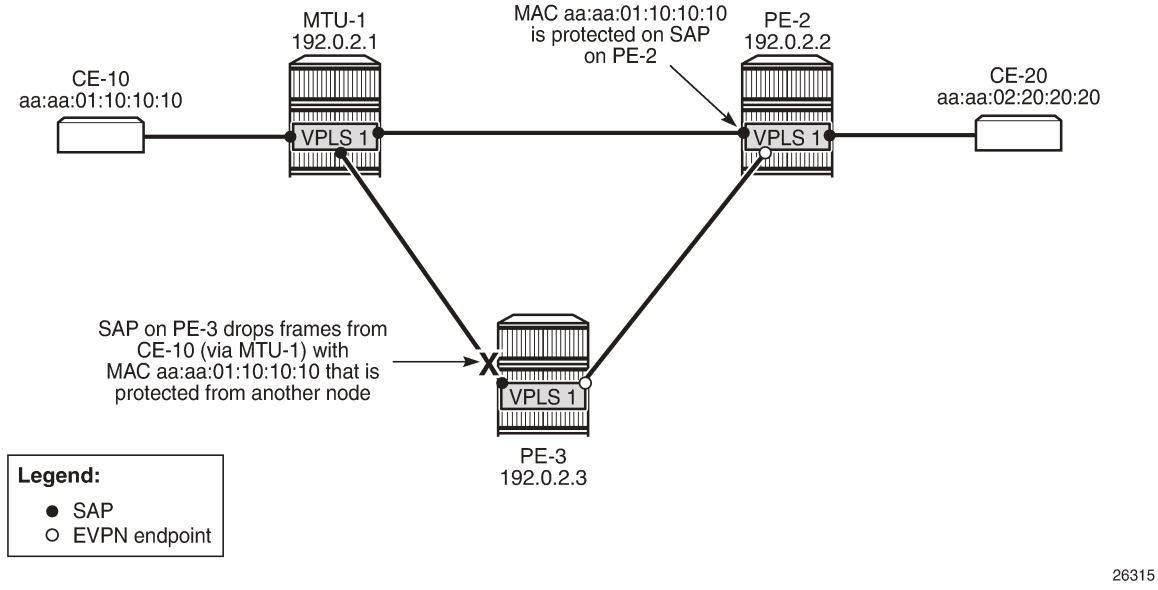
The BGP EVPN MAC routes on PE-4 are similar.

When a stream of frames with MAC SA aa:aa:01:10:10:10 enters the SAP on PE-3, these frames will be dropped by this SAP because of the implicit RPS-DF behavior in the SAP for protected MAC addresses, as shown in Figure 42: Default RPS-DF on SAPs - MAC learned and protected on SAP on PE-2.

Figure 42: Default RPS-DF on SAPs - MAC learned and protected on SAP on PE-2



Because the MAC address was protected on the SAP on PE-2 and the BGP EVPN MAC route update had been received by PE-3 before any frame was received with this MAC SA, there will be no temporary loop. The frames with the protected MAC SA will be discarded at the SAP on PE-3, not on the EVPN MPLS

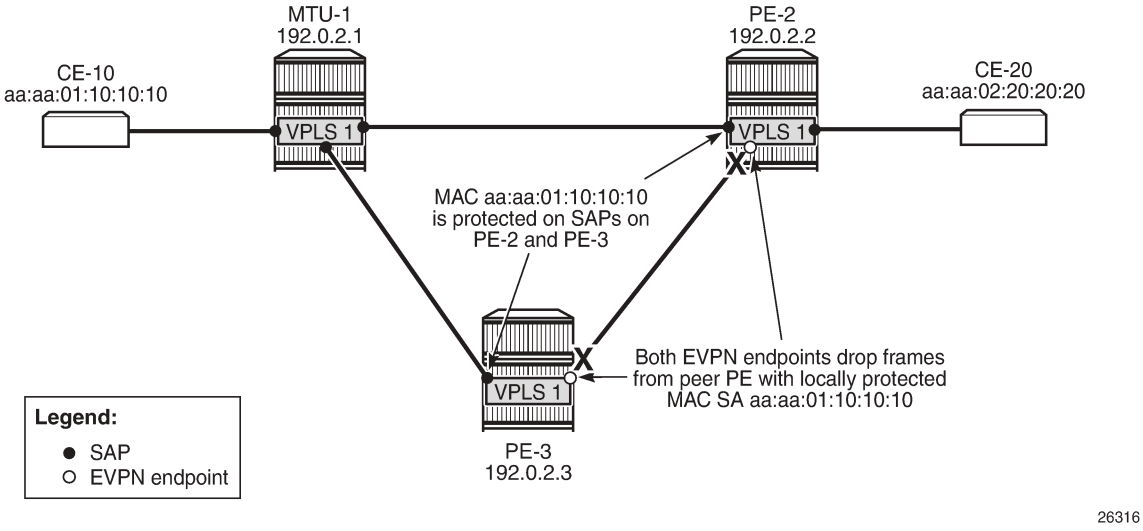
destination on PE-2. In this case, there is no need to configure RPS-DF on the EVPN MPLS destinations, but it will make a difference when the MAC address is learned on both SAPs simultaneously.

ALMP and RPS-DF on SAPs, RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

In the preceding example, the MAC addresses of CE-10 and CE-20 were first learned and protected on PE-2 and received on PE-3's SAP after the BGP update with static/sticky bit was received by PE-3. However, when the MAC address of CE-10 is learned simultaneously on both PEs, for example, because the MAC DA aa:aa:02:20:20:20 is unknown, there is a temporary loop until the MAC addresses are protected. Initially, the frames enter a SAP, are forwarded to the EVPN peer, and forwarded out of the remote SAP.

After the MAC addresses are learned and protected on the SAPs on both PEs, new frames received on a SAP with the protected MAC address will be sent to the other PE. However, they will be discarded due to RPS-DF on destination, as shown in Figure 43: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints, because the destination PE has that same MAC address protected on its local SAP. This prevents a loop. BGP updates with the static/sticky bit set are sent to the BGP EVPN peer, but the locally learned and protected MAC address is preferred to the MAC address in a BGP update. Therefore, the FDB contains the locally learned MAC address aa:aa:01:10:10:10, not the BGP EVPN MAC address update for MAC address aa:aa:01:10:10:10.

Figure 43: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints



The MAC addresses of the CEs are cleared from the FDBs on all nodes, as follows:

```
clear service id 1 fdb mac aa:aa:01:10:10:10
clear service id 1 fdb mac aa:aa:02:20:20:20
```

This clear command for the FDB only works for auto-learned MAC addresses, not for BGP EVPN MAC address updates. BGP EVPN MAC address withdraw updates need to be sent. In this example, BGP is configured with **rapid-update evpn**, as shown previously.

When traffic is sent from CE-10 to CE-20, MAC address aa:aa:01:10:10:10 of CE-10 is learned simultaneously on SAP 1/2/3:1 in PE-2 and PE-3 and protected on both SAPs. MAC address aa:aa:02:20:20:20 is, in this case, first learned via MAC address learning on PE-2 and advertised via a BGP EVPN MAC address route update. However, it might happen that it was learned and protected on the SAP on PE-3 first, before the MAC address was learned and protected on PE-2 and the BGP EVPN MAC address route update sent by PE-2 was received at PE-3. In the latter case, both MAC address aa:aa:01:10:10:10 and MAC address aa:aa:02:20:20:20 are learned and protected on the SAPs on both PE-2 and PE-3, and RPS-DF on the EVPN-MPLS destinations prevents loops.

However, in the present case, MAC address aa:aa:02:20:20:20 is only protected on the SAP on PE-2, because PE-3 received the EVPN MAC address update before it received a frame with MAC SA aa:aa:02:20:20:20. Therefore, the SAP on PE-3 will discard any frames with MAC SA aa:aa:02:20:20:20.

The FDB for VPLS 1 on PE-2 shows that both MAC addresses are learned locally and protected, as follows:

```
*A:PE-2# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1          aa:aa:01:10:10:10 sap:1/2/3:1             LP/0     03/19/21 08:33:32
1          aa:aa:02:20:20:20 sap:1/2/1:1             LP/0     03/19/21 08:33:32
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The FDB for VPLS 1 on PE-3 shows that MAC address aa:aa:01:10:10:10 is learned and protected locally, but MAC address aa:aa:02:20:20:20 is protected on PE-2, which has been advertised by PE-2 in a BGP EVPN MAC update, as follows:

```
*A:PE-3# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

"
```

Similar BGP EVPN updates are sent to the remote PE (PE-4). The FDB for VPLS 1 on PE-4 only contains entries learned from BGP EVPN updates, as follows:

```
*A:PE-4# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1          aa:aa:01:10:10:10 mpls:                   EvpnS:P  03/19/21 08:33:32
                             192.0.2.2:524284
           ldp:65538
1          aa:aa:02:20:20:20 mpls:                   EvpnS:P  03/19/21 08:33:32
                             192.0.2.2:524284
           ldp:65538
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

PE-4 received BGP EVPN MAC address route updates from PE-2 and PE-3, but only installs the MAC address routes to PE-2 in its FDB, based on the lowest next-hop IP of the EVPN NLRI (192.0.2.2).

ALMP and RPS-DF on SAPs, no RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

RPS-DF is disabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                mpls bgp 1
                    no restrict-protected-src
```

When a frame is received at SAP 1/2/3:1 on PE-3 with protected MAC SA aa:aa:01:10:10:10, it is not dropped by the SAP, because this MAC SA has been learned and protected on this SAP on PE-3. The frame is forwarded to PE-2 where it will not be discarded by the EVPN MPLS destination because RPS-DF is disabled. The frame will be forwarded to other objects in the VPLS in PE-2. For BUM traffic, there will be a loop, because all frames will be flooded to all objects in VPLS 1 on PE-2, including the SAP toward MTU-1.

ALMP and RPS on SAPs

When ALMP is enabled on an object, the default behavior is that frames with a protected MAC SA are discarded (RPS-DF). However, it is possible to configure RPS without any parameter on the object, in this case on the SAPs on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/3:1
                restrict-protected-src
```

Instead of discarding frames with MAC SAs that are protected on another object or node, the entire object (here: SAP) can be brought operationally down after a frame has been received with a MAC SA that is protected on another node.

The RPS configuration on the SAP can be shown as follows. The SAP has not been brought down yet.

```
*A:PE-2# show service id 1 sap 1/2/3:1 detail

===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 1
SAP                : 1/2/3:1                  Encap             : q-tag
Description        : (Not Specified)
Admin State        : Up                       Oper State        : Up
Flags              : None
---snip---

Restr MacUnpr Dst  : Disabled
Auto Learn Mac Prot: Enabled
ALMP Exclude List  : <none>
RestMacProtSrc Act : SAP-oper-down
---snip---
```

The **RestMacProtSrc Act** parameter is set to *SAP-oper-down*, meaning that RPS is configured without any parameter, which causes the system to bring down the SAP when a duplicate MAC address is received that is protected on another object or node. When a SAP is brought down because of this, the *RxProtSrcMAC* flag will be raised and can be shown in the detailed SAP show output.

ALMP and RPS on SAPs, RPS-DF on EVPN MPLS destinations, MAC first learned on PE-2

RPS-DF is enabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
```

```
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                mpls bgp 1
                    restrict-protected-src discard-frame
```

To simulate a scenario where the MAC addresses are first learned on PE-2, the SAP on PE-3 is disabled until the BGP EVPN MAC route updates are sent, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/3:1
                shutdown
```

The FDBs are cleared on the nodes, as follows:

```
clear service id 1 fdb mac aa:aa:01:10:10:10
clear service id 1 fdb mac aa:aa:02:20:20:20
```

Traffic is sent between CE-10 and CE-20, and the MAC addresses are learned and protected on the SAP on PE-2, as follows:

```
*A:PE-2# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1

-------------------------------------------------------------------------------
Number of SAPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The FDB is cleared for MAC address aa:aa:02:20:20:20 on MTU-1, as follows:

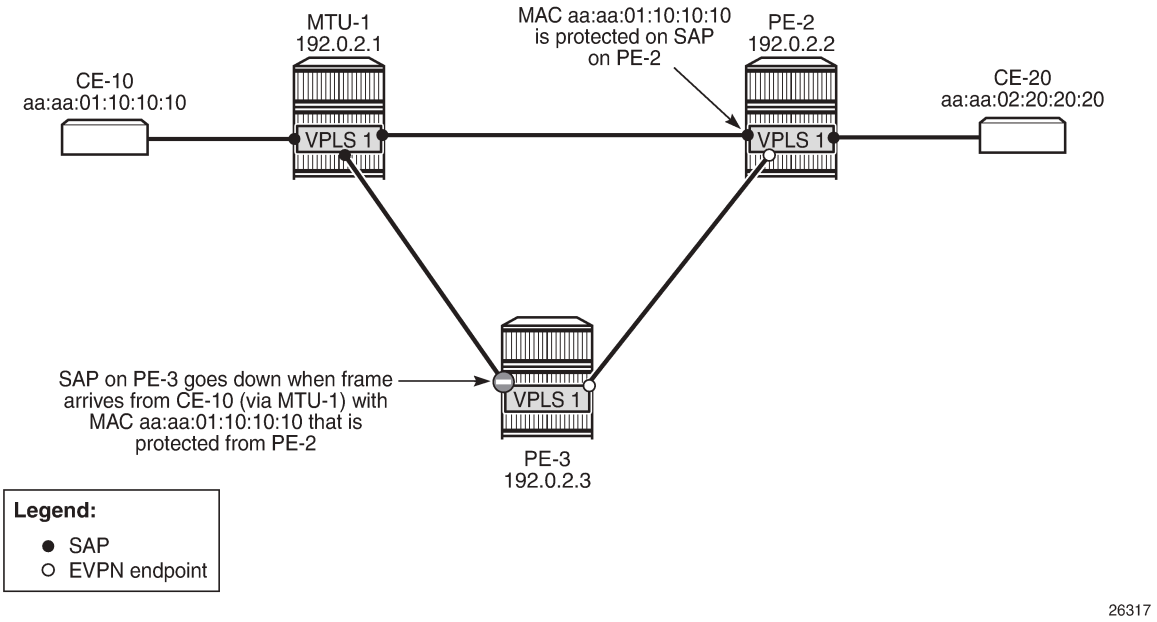
```
# on MTU-1:
clear service id 1 fdb mac aa:aa:02:20:20:20
```

Traffic from CE-10 toward the unknown MAC address aa:aa:02:20:20:20 reaches the SAPs on PE-2 and PE-3. When MAC SA aa:aa:01:10:10:10, which is protected on PE-2, is received on PE-3, SAP 1/2/3:1 will be brought operationally down, as shown in Figure 44: MAC learned and protected on SAP on PE-2 - RPS enabled on SAP on PE-3, and the following alarms will be raised in log 99:

```
85 2021/03/19 08:41:17.636 UTC MINOR: SVCMGR #2208 Base
"Protected MAC aa:aa:01:10:10:10 received on SAP 1/2/3:1 in service 1. The SAP will be
 disabled."

86 2021/03/19 08:41:17.636 UTC MINOR: SVCMGR #2203 Base
"Status of SAP 1/2/3:1 in service 1 (customer 1) changed to admin=up oper=down flags=RxProtSrc
Mac "
```

Figure 44: MAC learned and protected on SAP on PE-2 - RPS enabled on SAP on PE-3



The operational state of SAP 1/2/3:1 is now down. Detailed information about this SAP shows the *RxProtSrcMAC* flag, indicating that a duplicate MAC address that is protected on a remote node has been received, as follows:

```
*A:PE-3# show service id 1 sap 1/2/3:1

===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 1

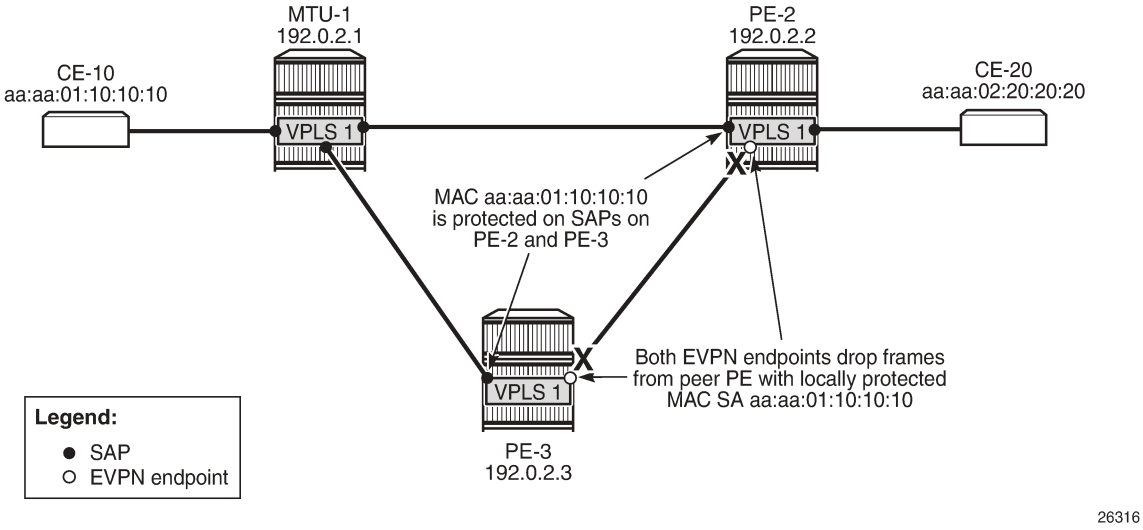
ALMP and RPS on SAPs, RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

When CE-10 sends traffic to CE-20 and the destination MAC address is unknown, MAC address aa:aa:01:10:10:10 is simultaneously learned and protected on PE-2 and PE-3. No SAP will be brought down when MAC address aa:aa:01:10:10:10 is received on PE-2 or PE-3. This scenario is identical to the one with ALMP and (default) RPS-DF on the SAPs, as shown in Figure 45: RPS enabled on SAPs - RPS-DF on EVPN endpoints, MACs learned simultaneously (which is identical to Figure 43: MAC learned and protected simultaneously on PEs - RPS-DF on EVPN endpoints).

Figure 45: RPS enabled on SAPs - RPS-DF on EVPN endpoints, MACs learned simultaneously



A temporary loop is possible until the MAC address is protected on the SAPs. Initially, the frames enter the SAP, are forwarded to the other PEs, and are forwarded out of the other SAP (unless the MAC address is protected). When the MAC address is protected, any other frames received on the SAP will be sent to the other PE (for example, from PE-3 to PE-2, or vice versa), but they will be discarded by the receiving PE, because RPS-DF is applied on the EVPN destination. BGP EVPN updates are sent to the peer PEs with the sticky bit set. This MAC route will not be installed in the FDB of PE-2 and PE-3 because the MAC address has already been learned locally, which has a higher preference.

The FDB on PE-2 contains locally learned and protected MAC addresses, as follows:

```
*A:PE-2# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
```

```
1          aa:aa:01:10:10:10 sap:1/2/3:1             LP/0     03/19/21 08:47:53
1          aa:aa:02:20:20:20 sap:1/2/1:1             LP/0     03/19/21 08:47:53
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The FDB on PE-3 contains MAC address aa:aa:01:10:10:10 that is learned locally and protected before a BGP-EVPN MAC was received and MAC address aa:aa:02:20:20:20 that is protected on PE-2, as follows.

```
*A:PE-3# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1          aa:aa:01:10:10:10 sap:1/2/3:1             LP/0     03/19/21 08:47:53
1          aa:aa:02:20:20:20 mpls:                   EvpnS:P  03/19/21 08:47:53
                             192.0.2.2:524284
           ldp:65537
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

SAP 1/2/3:1 will not be brought down if frames are received with MAC address aa:aa:01:10:10:10 that is locally learned and protected. However, MAC address aa:aa:02:20:20:20 was learned and protected first on PE-2 and the BGP update was received by PE-3 before the MAC address was received on PE-3. Therefore, MAC address aa:aa:02:20:20:20 will not be learned and protected on PE-3 and, if frames with a MAC SA aa:aa:02:20:20:20 were received on SAP 1/2/3:1 on PE-3, the SAP would be brought down.

ALMP and RPS on SAPs, no RPS-DF on EVPN MPLS destinations, MAC simultaneously learned on PE-2 and PE-3

RPS-DF is disabled on the EVPN MPLS destinations on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                mpls bgp 1
                    no restrict-protected-src
```

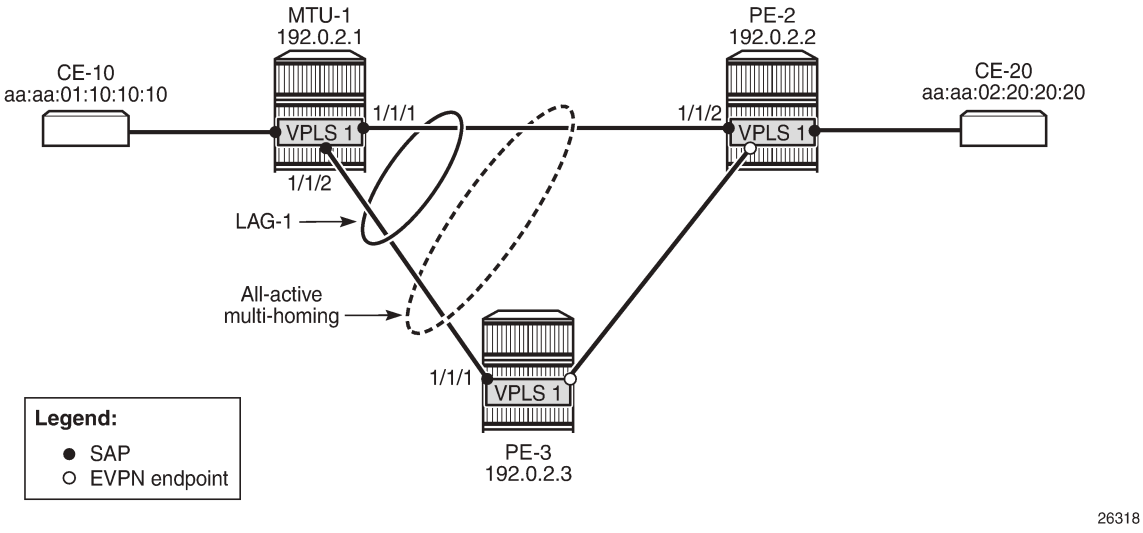
When frames are received at SAP 1/2/3:1 on PE-3 with protected MAC SA aa:aa:01:10:10:10, the SAP is not brought down, because this MAC SA has been learned and protected on this SAP. The frame is forwarded to PE-2 where it will not be discarded by the EVPN MPLS destination because RPS-DF is disabled. It will be forwarded to other objects in the VPLS. For BUM traffic, there will be a loop, because the frames will be flooded to all objects, including the SAP on PE-2 toward MTU-1.

ALMP in all-active multi-homing SAPs

All-active multi-homing for EVPN MPLS is explained in chapter EVPN for MPLS Tunnels. ALMP is not required on all-active multi-homing SAPs. The following example shows that traffic can be dropped when ALMP is enabled on the SAPs and RPS-DF is enabled on the EVPN-MPLS destinations.

Figure 46: ALMP in all-active multi-homing SAPs shows the example topology for all-active multi-homing.

Figure 46: ALMP in all-active multi-homing SAPs



VPLS is configured with SAP lag-1:1 on the three nodes in the topology, as follows:

```
# on MTU-1, PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            sap lag-1:1 create
                no shutdown
            exit
```

The SAPs used in the preceding scenarios are removed.

All-active multi-homing is configured on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23" create
                    esi 01:00:00:00:00:23:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
```

```
            exit
```

ALMP is enabled on the SAPs on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            sap lag-1:1
                auto-learn-mac-protect
                no shutdown
            exit
```

MAC address aa:aa:01:10:10:10 is learned and protected on PE-2 and PE-3, as follows:

```
*A:PE-2# show service id 1 fdb detail

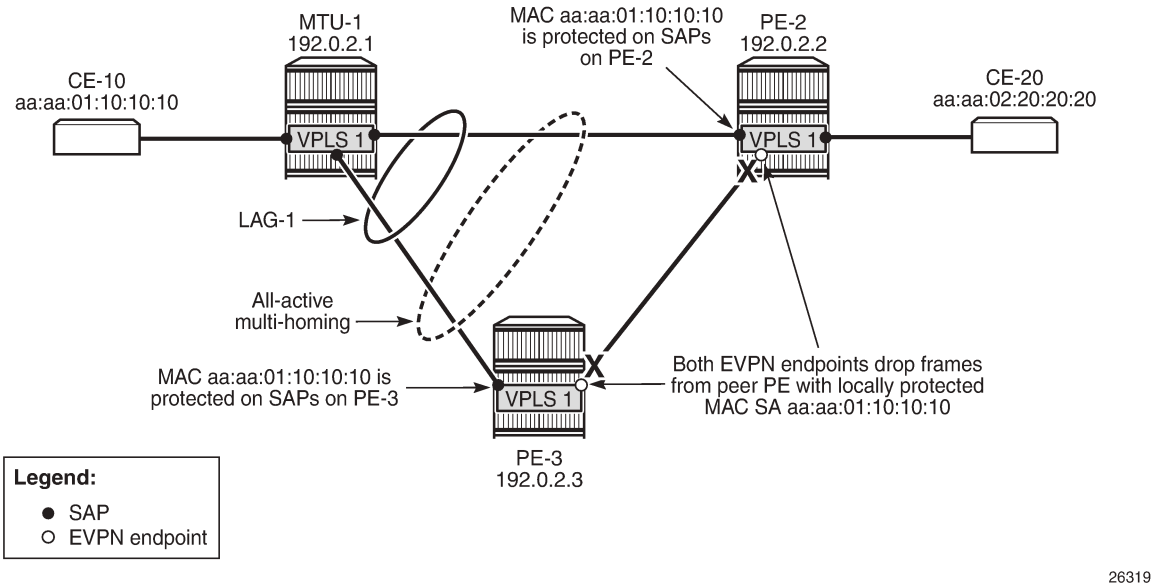
ALMP in all-active multi-homing, RPS-DF on EVPN MPLS destinations

ALMP is not recommended in all-active multi-homing because it can cause traffic loss. The following example shows when frames are dropped.

Figure 47: All-active multi-homing - RPS-DF on SAPs and EVPN endpoints shows the example setup with MAC address aa:aa:01:10:10:10 protected on SAP lag-1:1 on both PE-2 and PE-3, and RPS-DF enabled on the EVPN endpoints.

Figure 47: All-active multi-homing - RPS-DF on SAPs and EVPN endpoints



When frames with MAC address aa:aa:01:10:10:10 are sent between PE-2 and PE-3, these frames will be dropped by the EVPN MPLS destination that has RPS-DF enabled.

The traffic flows from CE-10 and CE-20 are hashed over both links in the LAG. When the frames are sent out on MTU-1 on port 1/1/1 toward PE-2, the traffic reaches CE-20, and traffic can be sent back from CE-20 to CE-10 via the direct link between PE-2 and MTU-1. However, when traffic is sent out from MTU-1 on port 1/1/2 toward PE-3, the frames will be forwarded from PE-3 to PE-2, where they will be discarded at the EVPN MPLS destination on PE-2 because of RPS-DF. No traffic flow is possible for frames with the protected MAC SA aa:aa:01:10:10:10 via PE-3 to PE-2, or vice versa. If the MAC address is not protected yet on PE-2, the first few messages get through until the MAC address is protected on PE-2. Both multi-homing PEs, PE-2 and PE-3, protect the MAC address aa:aa:01:10:10:10 on their local all-active SAP. Therefore, PE-2 discards all frames with the MAC SA aa:aa:01:10:10:10 when they are received on the EVPN MPLS destination from the other multi-homing PE (PE-3).

An improved mechanism for EVPN loop protection in all-active multi-homing is black-hole MAC duplication, as described in chapter Black-hole MAC for EVPN Loop Protection.

For single-active multi-homing, this problem does not arise: only the designated forwarder in the Ethernet segment receives and forwards traffic. Therefore, the CE MAC addresses will not be learned and protected on different PEs in the same Ethernet segment.

Conclusion

For security, MAC addresses learned on objects, such as SAPs, spoke/mesh-SDPs, and SHGs in EVPN services can be protected and advertised by BGP with the sticky bit set. By default, frames with a protected MAC SA are discarded if received on objects where the MAC address was not learned. Objects can be configured to be shut down when a frame is received with a protected MAC SA that has not been learned locally.

BGP Multi-Homing for VPLS Networks

This chapter describes BGP Multi-Homing (BGP-MH) for VPLS network configurations.

Topics in this chapter include:

Applicability

Initially, the information in this chapter was based on SR OS Release 8.0.R5, with additions for SR OS Release 9.0.R1. The CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports the use of Border Gateway Protocol Multi-Homing for VPLS (hereafter called BGP-MH). BGP-MH is described in *draft-ietf-bess-vpls-multihoming, BGP based Multi-homing in Virtual Private LAN Service*, and provides a network-based resiliency mechanism (no interaction from the Provider Edge routers (PEs) to Multi-Tenant Units/Customer Equipment (MTU/CE)) that can be applied on service access points (SAPs) or network (pseudowires) topologies. The BGP-MH procedures will run between the PEs and will provide a loop-free topology from the network perspective (only one logical active path will be provided per VPLS among all the objects SAPs or pseudowires which are part of the same Multi-Homing site).

Each multi-homing site connected to two or more peers is represented by a site ID (2 bytes long) which is encoded in the BGP MH Network Layer Reachability Information (NLRI). The BGP peer holding the active path for a particular multi-homing site will be named as the Designated Forwarder (DF), whereas the rest of the BGP peers participating in the BGP MH process for that site will be named as non-DF and will block the traffic (in both directions) for all the objects belonging to that multi-homing site.

BGP MH uses the following rules to determine which PE is the DF for a particular multi-homing site:

1. A BGP MH NLRI with D flag = 0 (multi-homing object up) always takes precedence over a BGP MH NLRI with D flag = 1 (multi-homing object down). If there is a tie, then:
2. The BGP MH NLRI with the highest BGP Local Preference (LP) wins. If there is a tie, then:
3. The BGP MH NLRI issued from the PE with the lowest PE ID (system address) wins.

The main advantages of using BGP-MH as opposed to other resiliency mechanisms for VPLS are:

- Flexibility: BGP-MH uses a common mechanism for access and core resiliency. The designer has the flexibility of using BGP-MH to control the active/standby status of SAPs, spoke SDPs, Split Horizon Groups (SHGs) or even mesh SDP bindings.
- The standard protocol is based on BGP, a standard, scalable, and well-known protocol.
- Specific benefits at the access:

  - It is network-based, independent of the customer CE and, as such, it does not need any customer interaction to determine the active path. Consequently, the operator will spend less effort on provisioning and will minimize both operation costs and security risks (in particular, this removes the requirement for spanning tree interaction between the PE and CE).
  - Easy load balancing per service (no service fate-sharing) on physical links.
- Specific benefits in the core:
  - It is a network-based mechanism, independent of the MTU resiliency capabilities and it does not need MTU interaction, therefore operational advantages are achieved as a result of the use of BGP-MH: less provisioning is required and there will be minimal risks of loops. In addition, simpler MTUs can be used.
  - Easy load balancing per service (no service fate-sharing) on physical links.
  - Less control plane overhead: there is no need for an additional protocol running the pseudowire redundancy when BGP is already used in the core of the network. BGP-MH just adds a separate NLRI in the L2-VPN family (AFI=25, SAFI=65).

This chapter describes how to configure and troubleshoot BGP-MH for VPLS.

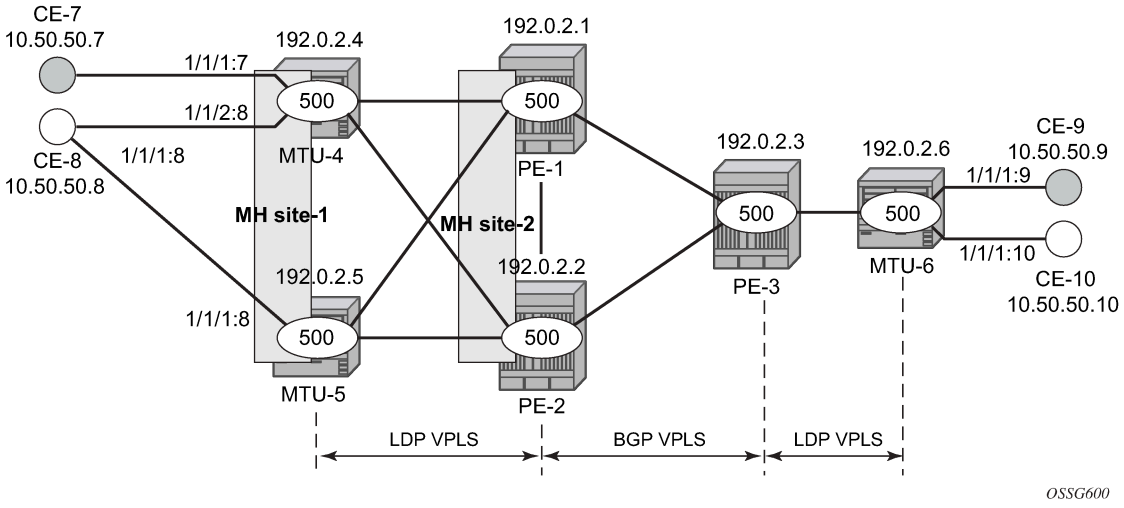
Knowledge of the LDP/BGP VPLS (RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, and RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*) architecture and functionality is assumed throughout this document. For further information, see the relevant Nokia documentation.

Figure 48: Example topology shows the example topology that will be used throughout the rest of the chapter.

The initial configuration includes:

- IGP — IS-IS, Level 2 on all routers; area 49.0001
- RSVP-TE for transport tunnels
- Fast reroute (FRR) protection in the core; no FRR protection at the access.

Figure 48: Example topology



The topology consists of three core nodes (PE-1, PE-2, and PE-3) and three MTUs connected to the core.

The VPLS service 500 is configured on all the six nodes with the following characteristics:

- The core VPLS instances are connected by a full mesh of BGP-signaled pseudowires (that is, pseudowires among PE-1, PE-2, and PE-3 will be signaled by BGP VPLS).
- As shown in Figure 48: Example topology, the MTUs are connected to the BGP VPLS core by TLDP pseudowires. MTU-6 is connected to PE-3 by a single pseudowire, whereas MTU-4 and MTU-5 are dual-homed to PE-1 and PE-2. The following resiliency mechanisms are used on the dual-homed MTUs:
  - MTU-4 is dual-connected to PE-1 and PE-2 by an active/standby pseudowire (A/S pseudowire hereafter).
  - MTU-5 is dual-connected to PE-1 and PE-2 by two active pseudowires, one of them being blocked by BGP MH running between PE-1 and PE-2. The PE-1 and PE-2 pseudowires, set up from MTU-5, will be part of the BGP MH site MH-site-2.
  - MTU-4 and MTU-5 are running BGP MH, being SHG site-1 and SAP 1/1/1:8 on MTU-5 part of the same BGP MH site, MH-site-1.
- The CEs are connected to the network in the following way:
  - CE-7, CE-9, and CE-10 are single-connected to the network
  - CE-8 is dual connected to MTU-4 and MTU-5.
  - CE-7 and CE-8 are part of the split-horizon group (SHG) site-1(SAPs 1/1/4:500 and 1/1/3:500 on MTU-4). Assume that CE-7 and CE-8 have a backdoor link between them so that when MTU-5 is elected as DF, CE-7 does not get isolated. This configuration highlights the use of a SHG within a site configuration.

For each BGP MH site, MH-site-1 and MH-site-2, the BGP MH process will elect a DF, blocking the site objects for the non-DF nodes. In other words, based on the specific configuration explained throughout the chapter:

- For MH-site-1, MTU-4 will be elected as the DF. The non-DF-MTU-5 will block the SAP 1/1/1:8.
- For MH-site-2, PE-1 will be elected as the DF. The non-DF PE-1 will block the spoke-SDP to MTU-5.

Configuration

This section describes all the relevant configuration tasks for the setup shown in Figure 48: Example topology. The appropriate associated IP/MPLS configuration is out of the scope of this chapter. In this example, the following protocols will be configured beforehand:

- ISIS-TE as IGP with all the interfaces being level-2 (OSPF-TE could have been used instead).
- RSVP-TE as the MPLS protocol to signal the transport tunnels (LDP could have been used instead).
- LSPs between core PEs will be FRR protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.

Note:
The designer can choose whether to protect access link failures by means of MPLS FRR or A/S pseudowire or BGP MH. Whereas FRR provides a faster convergence (around 50ms) and stability (it does not impact on the service layer, therefore, link failures do not trigger MAC flush and flooding), some interim inefficiencies can be introduced compared to A/S pseudowire or BGP MH.

Once the IP/MPLS infrastructure is up and running, the specific service configuration including the support for BGP MH can begin.

Global BGP configuration

BGP is used in this configuration guide for these purposes:

1. Auto-discovery and signaling of the pseudowires in the core, as per RFC 4761.
2. Exchange of multi-homing site NLRIs and redundancy handling from MTU-5 to the core.
3. Exchange of multi-homing site NLRIs and redundancy handling at the access for CE-7/CE-8.

A BGP route reflector (RR), PE-3, is used for the reflection of BGP updates corresponding to the preceding uses **a** and **b**.

A direct peering is established between MTU-4 and MTU-5 for use **c**. The same RR could have been used for the three cases, however, like in this example, the designer may choose to have a direct BGP peering between access devices. The reasons for this are:

- By having a direct BGP peering between MTU-4 and MTU-5, the BGP updates do not have to travel back and forth.
- On MTU-4 and MTU-5, BGP is exclusively used for multi-homing, therefore there will not be more BGP peers for either MTUs and a RR adds nothing in terms of control plane scalability.

On all nodes, the autonomous system number must be configured.

```
# on all nodes:
configure
    router Base
        autonomous-system 65000
```

The following CLI output shows the global BGP configuration required on MTU-4. The 192.0.2.5 address will be replaced by the corresponding peer or the RR system address for PE-1 and PE-2.

```
# on MTU-4:
configure
    router Base
        bgp
            family l2-vpn
            rapid-withdrawal
            rapid-update l2-vpn
            group "Multi-Homing"
                neighbor 192.0.2.5
                    peer-as 65000
                exit
            exit
```

In this example, PE-3 is the BGP RR, therefore its BGP configuration will contain a cluster with all its peers included (PE-1 and PE-2):

```
# on PE-3:
configure
    router Base
        bgp
            family l2-vpn
            rapid-withdrawal
            rapid-update l2-vpn
            group "internal"
```

```
            cluster 1.1.1.1
            neighbor 192.0.2.1
                peer-as 65000
            exit
            neighbor 192.0.2.2
                peer-as 65000
            exit
        exit
```

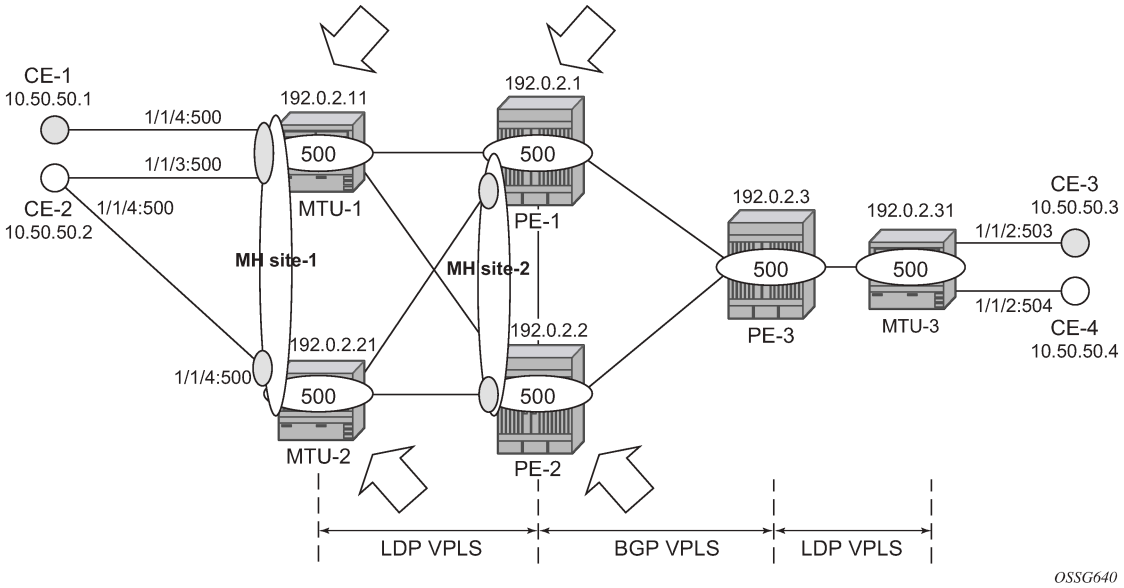
The relevant BGP commands for BGP-MH are in bold. Some considerations about those:

- It is required to specify **family l2-vpn** in the BGP configuration. That statement will allow the BGP peers to agree on the support for the family AFI=25 (Layer 2 VPN), SAFI=65 (VPLS). This family is used for BGP VPLS as well as for BGP MH and BGP AD.
- The **rapid-update l2-vpn** statement allows BGP MH to send BGP updates immediately after detecting link failures, without having to wait for the Minimum Route Advertisement Interval (MRAI) to send the updates in batches. This statement is required to guarantee a fast convergence for BGP MH.
- Optionally, **rapid-withdrawal** can also be added. In the context of BGP MH, this command is only useful if a particular multi-homing site is cleared. In that case, a BGP withdrawal is sent immediately without having to wait for the MRAI. A multi-homing site is cleared when the BGP MH site is removed or even the entire VPLS service.

Service level configuration

Once the IP/MPLS infrastructure is configured, including BGP, this section shows the configuration required at service level (VPLS 500). The focus is on the nodes involved on BGP MH, that is, MTU-4, MTU-5, PE-1, and PE-2. These nodes are highlighted in Figure 49: Nodes involved in BGP MH.

Figure 49: Nodes involved in BGP MH



Core PE service configuration

The following CLI excerpt shows the service level configuration on PE-1. The import/export policies configured on the PE nodes are identical:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            community "comm_core"
                members "target:65000:500"
            exit
            policy-statement "vsi500_export"
                entry 10
                    action accept
                        community add "comm_core"
                    exit
                exit
            exit
            policy-statement "vsi500_import"
                entry 10
                    from
                        community "comm_core"
                        family l2-vpn
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            commit
```

The configuration of the SDPs, PW template, and VPLS on PE-1 is as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP to transport BGP-signaled PWs"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            path-mtu 8000
            no shutdown
        exit
        sdp 13 mpls create
            description "SDP to transport BGP-signaled PWs"
            signaling bgp
            far-end 192.0.2.3
            lsp "LSP-PE-1-PE-3"
            path-mtu 8000
            no shutdown
        exit
        sdp 14 mpls create
            far-end 192.0.2.4
            lsp "LSP-PE-1-MTU-4"
            path-mtu 8000
            no shutdown
        exit
        sdp 15 mpls create
            far-end 192.0.2.5
```

```
            lsp "LSP-PE-1-MTU-5"
            path-mtu 8000
            no shutdown
        exit
        pw-template 500 use-provisioned-sdp create
        exit
        vpls 500 name "VLPS 500" customer 1 create
            bgp
                route-distinguisher 65000:501
                vsi-export "vsi500_export"
                vsi-import "vsi500_import"
                pw-template-binding 500 split-horizon-group "CORE"
                exit
            exit
            bgp-vpls
                max-ve-id 65535
                ve-name 501
                    ve-id 501
                exit
                no shutdown
            exit
            site "MH-site-2" create
                site-id 2
                spoke-sdp 15:500
                no shutdown
            exit
            spoke-sdp 14:500 create
            exit
            spoke-sdp 15:500 create
            exit
            no shutdown
        exit
```

The following are general comments about the configuration of VPLS 500:

- As seen in the preceding CLI output for PE-1, there are four provisioned SDPs that the service VPLS 500 will use in this example. SDP 14 and SDP 15 are tunnels over which the TLDP FEC128 pseudowires for service 500 will be carried (according to RFC 4762), whereas SDP 12 and SDP 13 are the tunnels for the core BGP pseudowires (based on RFC 4761).
- The BGP context provides the general service BGP configuration that will be used by BGP VPLS and BGP MH:
  - Route distinguisher (notation chosen is based on <AS_number:500 + node_id>)
  - VSI export policies are used to add the export route-targets included in all the BGP updates sent to the BGP peers.
  - VSI import policies are used to control the NLRIs accepted in the RIB, normally based on the route targets.
  - Both VSI-export and VSI-import policies can be used to modify attributes such as the Local Preference (LP) that will be used to influence the BGP MH Designated Forwarder (DF) election (LP is the second rule in the BGP MH election process, as previously discussed). The use of these policies will be described later in the chapter.
  - The **pw-template-binding** command maps the previously defined pw-template 500 to the SHG "CORE". In this way, all the BGP-signaled pseudowires will be part of this SHG. Although not shown in this example, the **pw-template-binding** command can also be used to instantiate pseudowires within different SHGs, based on different import route targets:

Note:
Detailed BGP-VPLS configuration is out of the scope of this chapter. For more information, see chapter *BGP-VPLS*.

```
*A:PE-1# configure service vpls 500 bgp pw-template-binding ?
  - pw-template-binding <policy-id> [split-horizon-group <group-name>]
                                      [import-rt {ext-community,...(upto 5 max)}]
  - no pw-template-binding <policy-id>

---snip---
```

- The BGP-signaled pseudowires (from PE-1 to PE-2 and PE-3) are set up according to the configuration in the **bgp** context. Beside those pseudowires, the VPLS 500 also has two more pseudowires signaled by TLDP: spoke-SDP 14:500 (to MTU-4) and spoke-SDP 15:500 (to MTU-5).

The general BGP MH configuration parameters for a particular multi-homing site are shown in the following output:

```
*A:PE-1# configure service vpls ?
  - no vpls <service-id>
  - vpls <service-id> [customer <customer-id>] [create] [vpn <vpn-id>] [m-vpls]
                                            [b-vpls|i-vpls] [etree] [name <name>]

---snip---
```

```
*A:PE-1# configure service vpls 500 site ?
  - no site <name>
  - site <name> [create]

 <name>               : [32 chars max]

 [no] boot-timer      - Configure/Override site boot-timer
      failed-thresho* - Configure threshold for the site to be declared down
 [no] mesh-sdp-bindi* - Enable/Disable application to all Mesh-SDP
 [no] monitor-oper-g* - Configure an Operational-Group to monitor
 [no] sap             - Configure a SAP for the site
 [no] shutdown        - Administratively enable/disable the site
 [no] site-activatio* - Configure/Override site activation timer
 [no] site-id         - Configure site identifier
 [no] site-min-down-* - Configure minimum down timer for the site
 [no] split-horizon-* - Configure a split-horizon-group
 [no] spoke-sdp       - Configure a spoke-SDP
```

Where:

- The **site** *name* is defined by a string of up to 32 characters.
- The **site-id** is an integer that identifies the multi-homing site and is encoded in the BGP MH NLRI. This ID must be the same one used on the peer node where the same multi-homing site is connected to. That is, MH-site-2 must use the same site-id in PE-1 and PE-2 (value = 2 in the PE-1 site configuration).
- Out of the four potential objects in a site—spoke SDP, SAP, SHG, and mesh SDP binding—only one can be used at the time on a particular site. To add more than just one SAP/spoke-SDP to the same site, an SHG composed of the SAP/spoke-SDP objects must be used in the site configuration.

Otherwise, only one object—spoke SDP, SAP, SHG, or mesh SDP binding—is allowed per site. A CLI log message warns the operator of such fact:

```
*A:PE-1>config>service>vpls>site# mesh-sdp-binding
MINOR: SVCMGR #5855 only one object is allowed per site
```

- The **failed-threshold** command defines how many objects should be down for the site to be declared down. This command is obviously only valid for multi-object sites (SHGs and mesh-SDP bindings). By default, all the objects in a site must be down for the site to be declared as operationally down.

```
*A:PE-1>config>service>vpls>site# failed-threshold ?
  - failed-threshold <[1..1000]>
  - failed-threshold all
```

- The **boot-timer** specifies for how long the service manager waits after a node reboot before running the MH procedures. The boot-timer value should be configured to allow for the BGP sessions to come up and for the NLRI information to be refreshed/exchanged. In environments with the default BGP MRAI (30 seconds), it is highly recommended to increase this value (for instance, 120 seconds for a normal configuration). The **boot-timer** is only important when a node comes back up and would become the DF. Default value: 10 seconds.

```
*A:PE-1>config>service>vpls>site# boot-timer ?
  - boot-timer <seconds>
  - no boot-timer

 <seconds>            : [0..600]
```

- The **site-activation-timer** command defines the amount of time the service manager will keep the local objects in standby (in the absence of BGP updates from remote PEs) before running the DF election algorithm to decide whether the site should be unblocked. The timer is started when one of the following events occurs only if the site is operationally up:
  - Manual site activation using the **no shutdown** command at the site-id level or at member object(s) level (SAP(s) or pseudowire(s))
  - Site activation after a failure
  - The BGP MH election procedures will be resumed upon expiration of this timer or the arrival of a BGP MH update for the multi-homing site. Default value: 2 seconds.

```
*A:PE-1>config>service>vpls>site# site-activation-timer ?
  - no site-activation-timer
  - site-activation-timer <seconds>

 <seconds>            : [0..100]
```

- When a BGP MH site goes down, it may be preferred that it stays down for a minimum time. This is configurable by the **site-min-down-timer**. When set to zero, this timer is disabled.

```
*A:PE-1>config>service>vpls>site# site-min-down-timer ?
  - no site-min-down-timer
  - site-min-down-timer <seconds>

 <seconds>            : [0..100]
```

- The **boot-timer**, **site-activation-timer**, and **site-min-down-timer** commands can be provisioned at service level or at global level. The service level settings have precedence and override the global

configuration. The **no** form of the commands at global level, sets the value back to the default values. The **no** form of the commands at service level, makes the timers inherit the global values.

```
*A:PE-1# configure redundancy bgp-multi-homing ?
  - bgp-multi-homing

 [no] boot-timer      - Configure BGP multi-homing boot-timer
 [no] site-activatio* - Configure BGP multi-homing site activation timer
 [no] site-min-down-* - Configure minimum down timer for the site
```

- The **shutdown** command controls the admin state of the site. Each site has three possible states:
  - Admin state — controlled by the shutdown command.
  - Operational state — controlled by the operational status of the individual site objects.
  - Designated Forwarder (DF) state — controlled by the BGP MH election algorithm.

The following CLI output shows the three states for BGP MH site "MH-site-1" on MTU-5:

```
*A:MTU-5# show service id 500 site "MH-site-1"

===============================================================================
Site Information

```

For this example, MH-site " MH-site-2" is configured in PE-1, where the site-id is 2 and the object in the site is spoke-SDP 15:500 (pseudowire established from PE-1 to MTU-5).

The following CLI shows the service configuration for PE-2. The site-id is 2, that is, the same value configured in PE-1. The object defined in PE-2's site is spoke-SDP 25:500 (pseudowire established from PE-2 to MTU-5).

```
# on PE-2:
configure
    service
        sdp 21 mpls create
            description "SDP to transport BGP-signaled PWs"
            signaling bgp
            far-end 192.0.2.1
            lsp "LSP-PE-2-PE-1"
            path-mtu 8000
            no shutdown
        exit
        sdp 23 mpls create
            description "SDP to transport BGP-signaled PWs"
            signaling bgp
            far-end 192.0.2.3
            lsp "LSP-PE-2-PE-3"
```

```
            path-mtu 8000
            no shutdown
        exit
        sdp 24 mpls create
            far-end 192.0.2.4
            lsp "LSP-PE-2-MTU-4"
            path-mtu 8000
            no shutdown
        exit
        sdp 25 mpls create
            far-end 192.0.2.5
            lsp "LSP-PE-2-MTU-5"
            path-mtu 8000
            no shutdown
        exit
        pw-template 500 use-provisioned-sdp create
        exit
        vpls 500 name "VPLS 500" customer 1 create
            bgp
                route-distinguisher 65000:502
                vsi-export "vsi500_export"
                vsi-import "vsi500_import"
                pw-template-binding 500 split-horizon-group "CORE"
                exit
            exit
            bgp-vpls
                max-ve-id 65535
                ve-name 502
                    ve-id 502
                exit
                no shutdown
            exit
            site "MH-site-2" create
                site-id 2
                spoke-sdp 25:500
                no shutdown
            exit
            spoke-sdp 24:500 create
            exit
            spoke-sdp 25:500 create
            exit
            no shutdown
        exit
```

MTU service configuration

The service configuration in MTU-4 is as follows:

```
# on MTU-4:
configure
    service
        sdp 41 mpls create
            far-end 192.0.2.1
            lsp "LSP-MTU-4-PE-1"
            path-mtu 8000
            no shutdown
        exit
        sdp 42 mpls create
            far-end 192.0.2.2

```

MTU-4 is configured with the following characteristics:

- The BGP context provides the general BGP parameters for service 500 in MTU-4. The **route-target** command is now used instead of the **vsi-import** and **vsi-export** commands. The intent in this example is to configure only the export and import route-targets. There is no need to modify any other attribute. If the local preference is to be modified (to influence the DF election), a **vsi-policy** must be configured.
- An A/S pseudowire configuration is used to control the pseudowire redundancy towards the core.
- The multi-homing site, MH-site-1 has a site-id = 1 and an SHG as an object. The SHG site-1 is composed of SAP 1/1/1:7 and SAP 1/1/2:8. As previously discussed, the site will not be declared operationally down until the two SAPs belonging to the site are down. This behavior can be changed by the **failed-threshold** command (for instance, in order to bring the site down when only one object has failed even though the second SAP is still up).
- As an example, a Y.1731 MEP with fault-propagation has been defined in SAP 1/1/2:8. As discussed later in the chapter, this MEP will signal the status of the SAP (as a result of the BGP MH process) to CE-8.

The service configuration in MTU-5 is as follows:

```
# on MTU-5:
configure
    service
        sdp 51 mpls create
            far-end 192.0.2.1
```

```
            lsp "LSP-MTU-5-PE-1"
            path-mtu 8000
            no shutdown
        exit
        sdp 52 mpls create
            far-end 192.0.2.2
            lsp "LSP-MTU-5-PE-2"
            path-mtu 8000
            no shutdown
        exit
        vpls 500 name "VPLS 500" customer 1 create
            bgp
                route-distinguisher 65000:505
                route-target export target:65000:500 import target:65000:500
            exit
            site "MH-site-1" create
                site-id 1
                sap 1/1/1:8
                no shutdown
            exit
            sap 1/1/1:8 create
            exit
            spoke-sdp 51:500 create
            exit
            spoke-sdp 52:500 create
            exit
            no shutdown
        exit
```

Influencing the DF election

As previously explained, assuming that the sites on the two nodes taking part of the same multi-homing site are both up, the two tie-breakers for electing the DF are (in this order):

1. Highest LP
2. Lowest PE ID

The LP by default is 100 in all the routers. Under normal circumstances, if the LP in any router is not changed, MTU-4 will be elected the DF for MH-site-1, whereas PE-1 will be the DF for MH-site-2. Assume in this section that this behavior is changed for MH-site-2 to make PE-2 the DF. Because changing the system address (to make PE-2's ID the lower of the two IDs) is usually not an easy task to accomplish, the vsi-export policy on PE-2 is modified with an LP of 150 with which the MH-site-2 NLRI is announced to PE-1. Because LP 150 is greater than the default 100 in PE-1, PE-2 will be elected as the DF for MH-site-2. The vsi-import policy remains unchanged and the vsi-export policy is modified as follows:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            community "comm_core"
                members "target:65000:500"
            exit
            policy-statement "vsi500_export"
                entry 10
                    action accept
                        community add "comm_core"
                        local-preference 150
                    exit
```

```
            exit
        exit
        policy-statement "vsi500_import"
            entry 10
                from
                    community "comm_core"
                    family l2-vpn
                exit
                action accept
                exit
            exit
            default-action drop
            exit
        exit
        commit
```

In PE-1, the import and export policies are not modified. The policies were already applied in the **bgp** context of VPLS 500, as follows:

```
# on PE-2:
configure
    service
        vpls "VPLS 500"
            bgp
                route-distinguisher 65000:502
                vsi-export "vsi500_export"
                vsi-import "vsi500_import"
                pw-template-binding 500 split-horizon-group "CORE"
                exit
            exit
---snip---
```

The DF state of PE-2 can be verified as follows:

```
*A:PE-2# show service id 500 site "MH-site-2"

===============================================================================
Site Information
===============================================================================

Monitor Oper Grp     : (none)
===============================================================================
```

The import and export policies are applied at service 500 level, which means that the LP changes for all the potential multi-homing sites configured under service 500. Therefore, load balancing can be achieved on a per-service basis, but not within the same service.

These policies are applied on the VPLS 500 for all the potential BGP applications: BGP VPLS, BGP MH, and BGP AD. In the example, the LP for the PE-2 BGP updates for BGP MH and BGP VPLS will be set to 150. However, this has no impact on BGP VPLS because a PE cannot receive two BGP VPLS NLRIs with the same VE-ID, which implies that a different VE-ID per PE within the same VPLS is required.

The vsi-export policy is restored to its original settings on PE-2, as follows:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            policy-statement "vsi500_export"
                entry 10
                    action accept
                        community add "comm_core"
                        no local-preference
                    exit
                exit
            exit
            commit
```

In all the PE nodes, the import and export policies applied in the **bgp** context of VPLS 500 have identical settings again, and PE-1 is the DF.

Black-hole avoidance

SR OS supports the appropriate MAC flush mechanisms for BGP MH, regardless of the protocol being used for the pseudowire signaling:

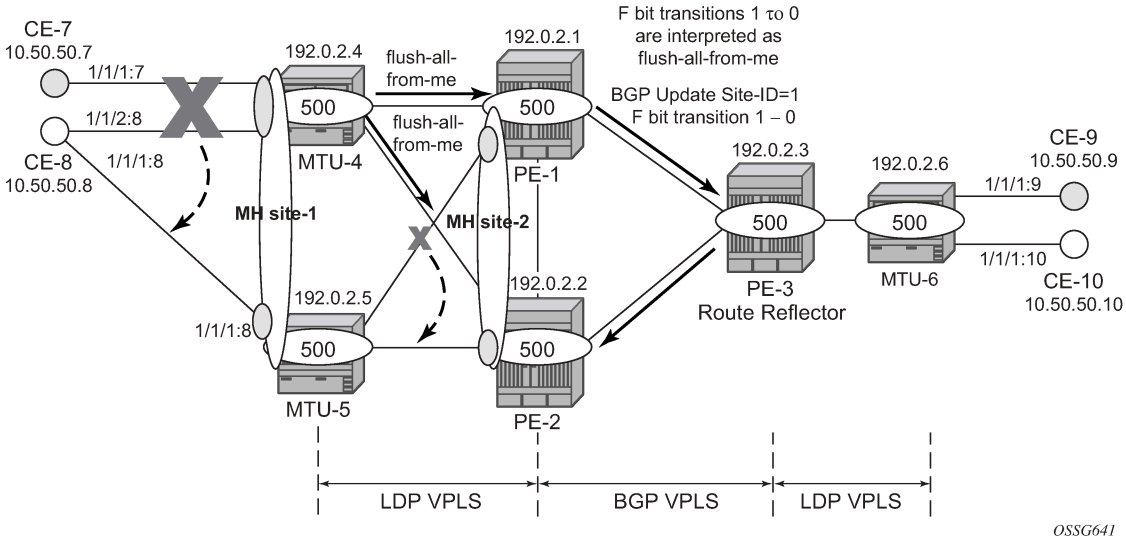
- LDP VPLS — The PE that contains the old DF site (the site that just experienced a DF to non-DF transition) always sends a LDP MAC flush-all-from-me to all LDP pseudowires in the VPLS, including the LDP pseudowires associated with the new DF site. No specific configuration is required.
- BGP VPLS — The remote BGP VPLS PEs interpret the F bit transitions from 1 to 0 as an implicit MAC flush-all-from-me indication. If a BGP update with the flag F=0 is received from the previous DF PE, the remote PEs perform MAC flush-all-from-me, flushing all the MACs associated with the pseudowire to the old DF PE. No specific configuration is required.

Double flushing will not happen because it is expected that between any pair of PEs there will exist only one type of pseudowires—either BGP or LDP pseudowire—, but not both types.

In the example, assuming MTU-4 and PE-1 are the DF nodes:

- When MH-site-1 is brought operationally down on MTU-4 (so by default, the two SAPs must go down unless the **failed-threshold** parameter is changed so that the site is down when only one SAP is brought down), MTU-4 will issue a flush-all-from-me message.
- When MH-site-2 is brought operationally down on PE-1, a BGP update with F=0 and D=1 is issued by PE-1. PE-2 and PE-3 will receive the update and will flush the MAC addresses learned on the pseudowire to PE-1.

Figure 50: MAC flush for BGP MH



Node failures implicitly trigger a MAC flush on the remote nodes, because the TLDP/BGP session to the failed node goes down.

Access CE/PE signaling

BGP MH works at service level, therefore no physical ports are torn down on the non-DF, but rather the objects are brought down operationally, while the physical port will stay up and used for any other services existing on that port. Due to this reason, there is a need for signaling the standby status of an object to the remote PE or CE.

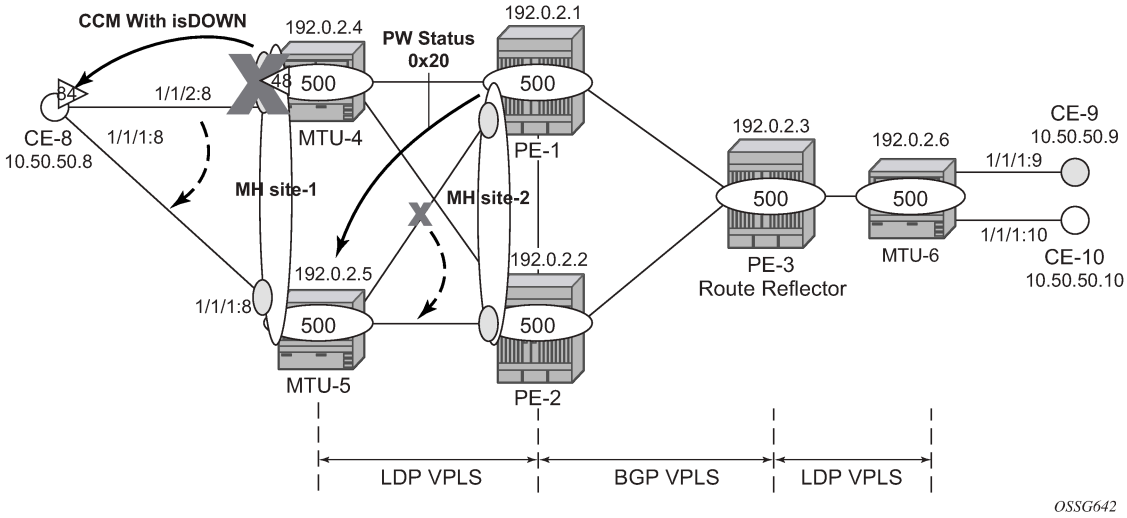
- Access PEs running BGP MH on spoke SDPs and elected non-DF, will signal pseudowire standby status (0x20) to the other end. If no pseudowire status is supported on the remote MTU, a label withdrawal is performed. If there is more than one spoke SDP on the site (part of the same SHG), the signaling is sent for all the pseudowires of the site.

  Note:
  The **configure service vpls x spoke-sdp y:z no pw-status-signaling** parameter allows to send a TLDP label-withdrawal instead of pseudowire status bits, even though the peer supports pseudowire status.

- Multi-homed CEs connected through SAPs to the PEs running BGP MH, are signaled by the PEs using Y.1731 CFM, either by stopping the transmission of CCMs or by sending CCMs with isDown (interface status down encoding in the interface status TLV).

In this example, down MEPs on MTU-4 SAP 1/1/2:8 and CE-8 SAP 1/1/2:8 are configured. In a similar way, other MEPs can be configured on MTU-4 SAP 1/1/1:7, MTU-5 SAP 1/1/1:8, and CE-8 SAP 1/1/1:7 and SAP 1/1/1:8. Figure 51: Access PE/CE signaling shows the MEPs on MTU-4 SAP 1/1/2:8 and CE-8. Upon failure on the MTU-4 site MH-site-1, the MEP 48 will start sending CCMs with interface status down.

Figure 51: Access PE/CE signaling



The CFM configuration required at SAP 1/1/2:8 is as follows. Down MEPs will be configured on CE-8 and MTU-5 SAPs in the same way, but in a different association. The option **fault-propagation-enable use-if-tlv** must be added. In case the CE does not understand the CCM interface status TLV, the **fault-propagation-enable suspend-ccm** option can be enabled instead. This will stop the transmission of CCMs upon site failures. Detailed configuration guidelines for Y.1731 are beyond the scope of this chapter.

```
# on MTU-4:
configure
    eth-cfm
        domain 1 format none level 3 admin-name "domain-1"
            association 1 format icc-based name "Association48" admin-name "assoc-1"
                bridge-identifier 500
                exit
                ccm-interval 1
                remote-mepid 84
            exit
        exit
```

```
# on MTU-4:
configure
    service
        vpls "VPLS 500"
            sap 1/1/2:8 split-horizon-group "site-1" create
                eth-cfm
                    mep 48 domain 1 association 1 direction down
                        fault-propagation-enable use-if-tlv
                        ccm-enable
                        no shutdown
                    exit
                exit
            exit
```

If CE-8 is a service router, upon receiving a CCM with isDown, an alarm will be triggered and the SAP will be brought down:

```
# on CE-8:
67 2021/01/19 09:13:19.447 UTC WARNING: OSPF #2047 vprn8 VR:  2 OSPFv2 (0)
```

```
"LCL_RTR_ID 10.50.50.8: Interface int-CE-8-MTU-4 state changed to down
(event IF_DOWN)"

66 2021/01/19 09:13:19.447 UTC WARNING: SNMP #2004 vprn8 int-CE-8-MTU-4

===============================================================================
```

As also depicted in Figure 51: Access PE/CE signaling, PE-1 will signal pseudowire status standby (code 0x20) when PE-1 goes to non-DF state for MH-site-2. MTU-5 will receive that signaling and, based on the **ignore-standby-signaling** parameter, will decide whether to send the broadcast, unknown unicast, and multicast (BUM) traffic to PE-1. In case MTU-5 uses in its configuration **ignore-standby-signaling**, it will be sending BUM traffic on both pseudowires at the same time (which is not normally desired), ignoring the pseudowire status bits. The following output shows the MTU-5 spoke-SDP receiving the pseudowire status signaling. Although the spoke SDP stays operationally up, the Peer Pw Bits field shows *pwFwdingStandby* and MTU-5 will not send any traffic if the **ignore-standby-signaling** parameter is disabled.

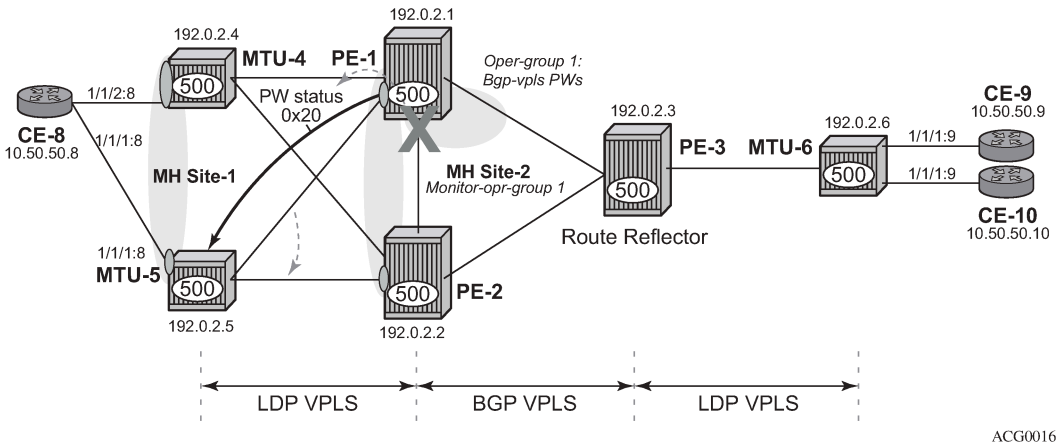
Operational groups for BGP-MH

Operational groups (**oper-group**) introduce the capability of grouping objects into a generic group object and associating its status to other service endpoints (pseudowires, SAPs, IP interfaces) located in the same or in different service instances. The operational group status is derived from the status of the individual components using certain rules specific to the application using the concept. A number of other service entities—the monitoring objects—can be configured to monitor the operational group status and to drive their own status based on the **oper-group** status. In other words, if the operational group goes down, the monitoring objects will be brought down. When one of the objects included in the operational group comes up, the entire group will also come up, and therefore so will the monitoring objects.

This concept can be used to enhance the BGP-MH solution for avoiding black-holes on the PE selected as the DF if the rest of the VPLS endpoints fail (pseudowire spoke(s)/pseudowire mesh and/or SAP(s)). Figure 52: Oper-groups and BGP-MH illustrates the use of operational groups together with BGP-MH. On PE-1 (and PE-2) all of the BGP-VPLS pseudowires in the core are configured under the same **oper-group group-1**. MH-site-2 is configured as a monitoring object. When the two BGP-VPLS pseudowires go down, **oper-group group-1** will be brought down, therefore MH-site-2 on PE-1 will go down as well (PE-2 will become DF and PE-1 will signal standby to MTU-5).

Figure 52: Oper-groups and BGP-MH



In the preceding example, this feature provides a solution to avoid a black-hole when PE-1 loses its connectivity to the core.

Operational groups are configured in two steps:

1. Identify a set of objects whose forwarding state should be considered as a whole group, then group them under an operational group (in this case **oper-group group-1**, which is configured in the **bgp pw-template-binding** context).
2. Associate other existing objects (clients) with the oper-group using the **monitor-group** command (configured, in this case, in the **site MH-site-2**).

The following CLI excerpt shows the commands required (**oper-group**, **monitor-oper-group**).

```
# on PE-1:
configure
    service
        oper-group "group-1" create
        exit
        vpls 500
            bgp
                pw-template-binding 500 split-horizon-group "CORE"
                    oper-group "group-1"
                exit
            exit
            site "MH-site-2"
                monitor-oper-group "group-1"
            exit
```

When all the BGP-VPLS pseudowires go down, **oper-group group-1** will go down and therefore the monitoring object, **site MH-site-2**, will also go down and PE-2 will then be elected as DF. The log 99 gives information about this sequence of events:

```
# on PE-1:
configure
    service
        sdp 12
            shutdown
        exit
        sdp 13
            shutdown
        exit
```

```

"Service-id 500 site MH-site-2 is not the designated-forwarder"

146 2021/01/19 09:20:08.753 UTC MAJOR: SVCMGR #2316 Base
"Processing of a SDP state change event is finished and the status of all affected SDP Bindings
 on SDP 13 has been updated."

145 2021/01/19 09:20:08.752 UTC MINOR: SVCMGR #2306 Base
"Status of SDP Bind 15:500 in service 500 (customer 1) changed to admin=up oper=down flags="

144 2021/01/19 09:20:08.752 UTC MINOR: SVCMGR #2326 Base
"Status of SDP Bind 15:500 in service 500 (customer 1) local PW status bits changed to pwFwding
Standby "

143 2021/01/19 09:20:08.752 UTC MINOR: SVCMGR #2542 Base
```

```
"Oper-group group-1 changed status to down"
```

PE-1 is no longer the DF, as follows:

```
*A:PE-1# show service id 500 site

===============================================================================
VPLS Sites
===============================================================================
Site                Site-Id   Dest               Mesh-SDP  Admin   Oper  Fwdr
-------------------------------------------------------------------------------
MH-site-2           2         sdp:15:500         no        Enabled down  No
-------------------------------------------------------------------------------
Number of Sites : 1
-------------------------------------------------------------------------------
===============================================================================
```

PE-2 becomes the DF:

```
*A:PE-2# show service id 500 site

===============================================================================
VPLS Sites
===============================================================================
Site                Site-Id   Dest               Mesh-SDP  Admin   Oper  Fwdr
-------------------------------------------------------------------------------
MH-site-2           2         sdp:25:500         no        Enabled up    Yes
-------------------------------------------------------------------------------
Number of Sites : 1
-------------------------------------------------------------------------------
===============================================================================
```

The process reverts when at least one BGP-VPLS pseudowire comes back up.

Show commands and debugging options

The main command to find out the status of a site is the **show service id x site** command.

```
*A:MTU-5# show service id 500 site

===============================================================================
VPLS Sites
===============================================================================
Site                Site-Id   Dest               Mesh-SDP  Admin   Oper  Fwdr
-------------------------------------------------------------------------------
MH-site-1           1         sap:1/1/1:8        no        Enabled up    No
-------------------------------------------------------------------------------
Number of Sites : 1
-------------------------------------------------------------------------------
===============================================================================
```

A **detail** modifier is available:

```
*A:MTU-5# show service id 500 site detail

===============================================================================
Site Information
===============================================================================
Site Name            : MH-site-1
```

```
-------------------------------------------------------------------------------
Site Id              : 1
Dest                 : sap:1/1/1:8          Mesh-SDP Bind    : no
Admin Status         : Enabled              Oper Status      : up
Designated Fwdr      : No
DF UpTime            : 0d 00:00:00          DF Chg Cnt       : 1
Boot Timer           : default              Timer Remaining  : 0d 00:00:00
Site Activation Timer: default              Timer Remaining  : 0d 00:00:00
Min Down Timer       : default              Timer Remaining  : 0d 00:00:00
Failed Threshold     : default(all)
Monitor Oper Grp     : (none)
-------------------------------------------------------------------------------
Number of Sites : 1
===============================================================================
```

The **detail** view of the command displays information about the BGP MH timers. The values are only shown if the global values are overridden by specific ones at service level (and will be tagged with *Ovr* if they have been configured at service level). The **Timer Remaining** field reflects the count down from the boot/site activation timers down to the moment when this router tries to become DF again. Again, this is only shown when the global timers have been overridden by the ones at service level.

The objects on the non-DF site will be brought down operationally and flagged with *StandByForMHProtocol*, for example, for SAP 1/1/1:8 on non-DF MTU-5:

```
*A:MTU-5# show service id 500 sap 1/1/1:8

===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 500
SAP                : 1/1/1:8                 Encap            : q-tag
Description        : (Not Specified)
Admin State        : Up                      Oper State       : Down
Flags              : StandByForMHProtocol
Multi Svc Site     : None
Last Status Change : 01/19/2021 08:30:37
Last Mgmt Change   : 01/19/2021 08:47:52
===============================================================================
```

For spoke SDP 25:500 on non-DF PE-2:

```
*A:PE-2# show service id 500 sdp 25:500 detail

===============================================================================
Service Destination Point (Sdp Id : 25:500) Details
===============================================================================
-------------------------------------------------------------------------------
 Sdp Id 25:500  -(192.0.2.5)
-------------------------------------------------------------------------------
Description     : (Not Specified)

---snip---

Admin State        : Up                      Oper State       : Down
---snip---

Flags              : StandbyForMHProtocol
---snip---
```

The BGP MH routes in the RIB, RIB-In and RIB-Out can be shown by using the corresponding **show router bgp routes** and **show router bgp neighbor x.x.x.x received-routes|advertised-routes**

commands. The BGP MH routes are only shown when the operator uses the **l2-vpn** family modifier. Should the operator want to filter only the BGP MH routes out of the l2-vpn routes, the **multi-homing** filter has to be added to the **show router bgp routes** commands.

```
*A:PE-3# show router bgp routes l2-vpn
===============================================================================

```

For debugging, the following CLI sources can be used:

- **log-id 99** — Provides information about the site object changes and DF changes.
- **debug router bgp update** command — Shows the BGP updates for BGP MH, including the sent and received BGP MH NLRIs and flags.

```
# on MTU-4:
debug
    router
        bgp
            update
```

- **debug router ldp** command — Provides information about the pseudowire status bits being signaled as well as the MAC flush messages.

```
# on MTU-4:
debug
    router
        ldp
            peer 192.0.2.1
                packet
                    init detail
                    label detail
```

As an example, log-id 99 shows the following debug output after disabling MH-site-1 on MTU-4:

```
# on MTU-4:
configure
    service
        vpls "VPLS 500"
            sap 1/1/1:7
                shutdown
            exit
            sap 1/1/2:8
                shutdown
            exit
```

```
*A:MTU-4# show log log-id 99

Assuming all the recommended tools are enabled, a DF to non-DF transition can be shown as well as the corresponding MAC flush messages and related BGP processing.

If MH-site-2 is torn down on PE-1, the **debug router bgp update** command would allow us to see two BGP updates from PE-1:

- A BGP MH update for site-id 2 with flag D set (because the site is down).

- A BGP VPLS update for veid=501 and flag D set. This is due to the fact that there are no more active objects on the VPLS, besides the BGP pseudowires.

```
# on PE-1:
configure
    service
        vpls "VPLS 500"
            spoke-sdp 14:500
                shutdown
            exit
            spoke-sdp 15:500
                shutdown
            exit
```

```
*A:PE-1# show log log-id 2

```

Conclusion

SR OS supports a wide range of service resiliency options as well as the best-of-breed system level HA and MPLS mechanisms for the access and the core. BGP MH for VPLS completes the service resiliency tool set by adding a mechanism that has some good advantages over the alternative solutions:

- BGP MH provides a common resiliency mechanism for attachment circuits (SAPs), pseudowires (spoke SDPs), split horizon groups and mesh bindings
- BGP MH is a network-based technique which does not need interaction to the CE or MTU to which it is providing redundancy to.

The examples used in this chapter illustrate the configuration of BGP MH for access CEs and MTUs. Show and debug commands have also been suggested so that the operator can verify and troubleshoot the BGP MH procedures.

BGP Virtual Private Wire Services

This chapter describes BGP Virtual Private Wire Service (VPWS) configurations.

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 11.0.R4. The CLI in the current edition is based on SR OS Release 21.2.R1. There are no prerequisites for this configuration.

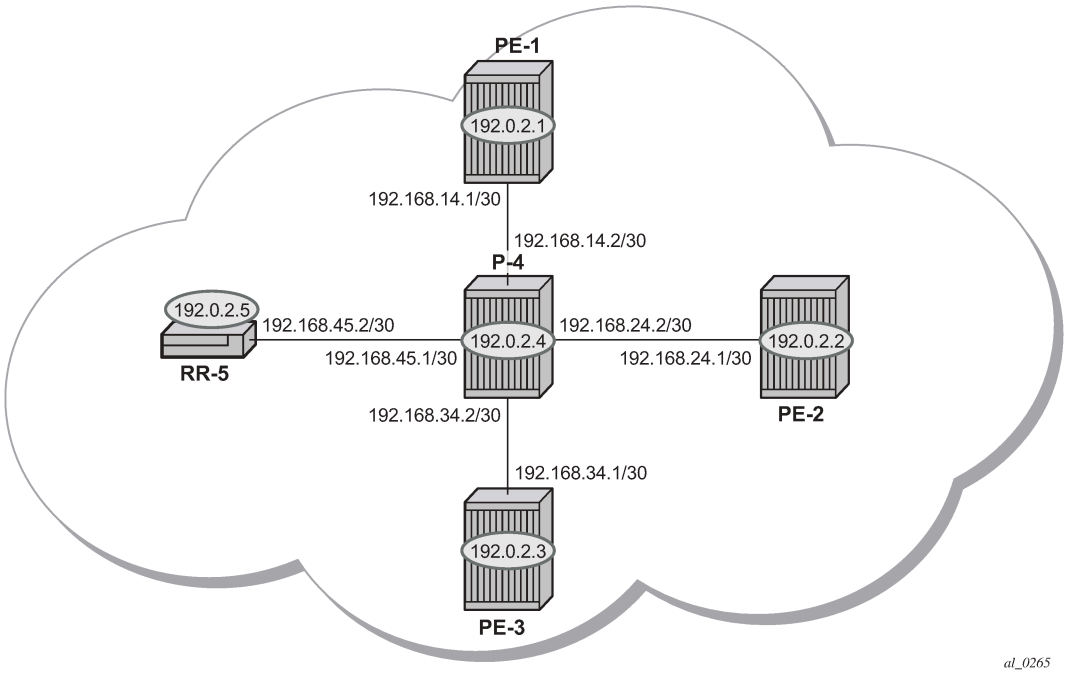
Overview

The following two IETF standards describe the provisioning of Virtual Private Wire Services (VPWS):

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*, describes Label Distribution Protocol (LDP) VPWS, where VPWS pseudowires are signaled using LDP between Provider Edge (PE) Routers.
- RFC 6624, *Layer 2 Virtual Private Networks Using BGP for Auto-Discovery and Signaling*, describes the use of Border Gateway Protocol (BGP) for signaling of pseudowires between such PEs.

Figure 53: Example topology shows the example topology with five SR OS routers located in the same Autonomous System (AS). There are three PE routers connected to a single P router and a route reflector (RR) for the AS. The PE routers are all BGP VPWS-aware. The Provider (P) router is BGP VPWS-unaware and does not take part in the BGP process.

Figure 53: Example topology



The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is configured on each of the network interfaces between the PE/P routers and route reflector.
- MPLS is configured on all interfaces between PE routers and P routers. It is not required between P-4 and RR-5.
- LDP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-5.
- RSVP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-5.

BGP VPWS

In this architecture, a VPWS is a collection of two (or three in case of redundancy) BGP VPWS service instances present on different PEs in a provider network.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP VPWS Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other BGP VPWS instances on peering PEs and to set up pseudowire connectivity for data flow between peers containing the same BGP VPWS service. Therefore, auto-discovery and pseudowire signaling is achieved using a single BGP update message.

Each PE with a BGP VPWS instance is identified by a VPWS edge identifier (VE-ID) and the presence of other BGP VPWS instances is determined using the exchange of standard BGP extended community route targets (RTs) between PEs.

Each PE will advertise, via the RR, the presence of its BGP VPWS instance to all other PEs, along with a block of multiplexer labels (for BGP VPWS, one label per block) that can be used to communicate between each instance, plus a BGP next-hop that determines a labeled transport tunnel to be used between PEs.

Each BGP VPWS instance is configured with import and export route target extended communities for topology control, along with VE identification.

Configuration

The following examples show the configuration of four BGP VPWS scenarios:

- Single homed BGP VPWS
  - using auto-provisioned SDPs
  - using pre-provisioned SDPs
- Dual homed BGP VPWS
  - with single pseudowire
  - with active/standby pseudowire

Configure MP-iBGP

The first step is to configure an MP-iBGP session between each of the PEs and the RR. The configuration for all PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure
    router Base
        autonomous-system 65536
        bgp
            group "INTERNAL"
                family l2-vpn
                peer-as 65536
                neighbor 192.0.2.5
                exit
            exit
        exit
```

The IP addresses can be derived from Figure 53: Example topology.

On RR-5, the BGP configuration is as follows:

```
# on RR-5:
configure
    router Base
        autonomous-system 65536
        bgp
            group "INTERNAL"
                family l2-vpn
                peer-as 65536
                cluster 1.1.1.1
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
```

```
               exit
            exit
         exit
```

The following command on RR-5 shows that BGP sessions with each PE are established and have a negotiated L2 VPN address family capability.

```
*A:RR-5# show router bgp summary all

===============================================================================

                            5    0

-------------------------------------------------------------------------------
```

Pseudowire templates

BGP VPWS utilizes pseudowire (PW) templates to dynamically instantiate SDP bindings for a service to signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, such as vc-type, vlan-vc-tag, hash-label, filters, and so on. The following parameters are recognized by BGP VPWS; the remainder is ignored.

```
configure
  service
  - pw-template <policy-id> [create] [prefer-provisioned-sdp] [name <name>]
                                                              [auto-gre-sdp]
  - no pw-template <policy-id>
  - pw-template <policy-id> use-provisioned-sdp [create] [name <name>]
       accounting-policy acct-policy-id
       no accounting-policy
       [no] collect-stats
       [no] controlword
       egress
         filter ipv6 <filter-id>
         filter ip <filter-id>
         filter mac <filter-id>
         no filter [ip <filter-id>] [mac <filter-id>] [ipv6 <filter-id>]
         [no] filter-name [ip name] [mac name] [ipv6 name]
         no qos [<network-policy-id>]
         qos <network-policy-id> port-redirect-group <queue-group-name>
                                                     instance <instance-id>
         qos name <network-policy-name> port-redirect-group <queue-group-name>
                                                     instance <instance-id>
```

```
        [no] force-vlan-vc-forwarding
        hash-label [signal-capability]
        no hash-label
        entropy-label
        ingress
          filter ipv6 <filter-id>
          filter ip <filter-id>
          filter mac <filter-id>
          no filter [ip <filter-id>] [mac <filter-id>] [ipv6 <filter-id>]
          [no] filter-name [ip name] [mac name] [ipv6 name]
          qos <network-policy-id> fp-redirect-group <queue-group-name>
                                                    instance <instance-id>
          qos name <network-policy-name> fp-redirect-group <queue-group-name>
                                                    instance <instance-id>
          no qos [<network-policy-id>]
        [no] sdp-exclude group-name
        [no] sdp-include group-name
        vc-type {ether | vlan}
        vlan-vc-tag 0..4094
        [no] vlan-vc-tag
```

Note:

- The encapsulation type in the Layer-2 extended community is either 4 (Ethernet VLAN tagged mode) or 5 (Ethernet raw mode), depending on the **vc-type** parameter.
- The **force-vlan-vc-forwarding** function will add a tag (equivalent to vc-type vlan) and will allow for customer QoS transparency (dot1p + Drop Eligibility (DE) bits).

The MPLS transport tunnel between PEs can be signaled using LDP or RSVP-TE.

LDP-based SDPs can be automatically instantiated or pre-provisioned. RSVP-TE-based SDPs have to be pre-provisioned. If pre-provisioned pseudowires are used, the PW template must be created with the **use-provisioned-sdp** parameter. Alternatively, the **prefer-provisioned-sdp** parameter can be used, in which case a pre-provisioned SDP will be used if available; if not, LDP-based SDPs can be automatically instantiated, see chapter LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, link layer LDP needs to be configured between all PEs/Ps so that a transport label for each PE system interface is available. For example, on PE-1:

```
# on PE-1:
configure
    router Base
        ldp
            interface-parameters
                interface "int-PE-1-P-4" dual-stack
                    ipv4
                        no shutdown
                    exit
```

Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at the higher end of the SDP numbering range, such as 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required. The following example is created using the default values:

```
# on PE-1, PE-2, and PE-3:
configure
    service
        pw-template 3 name "PW3" create
        exit
```

Pseudowire templates for provisioned SDPs using RSVP-TE

RSVP-TE LSPs need to be created between the PE routers on which provisioned SDPs will be used as prerequisite.

The MPLS interface and LSP configuration for PE-1 are:

```
# on PE-1:
configure
    router Base
        mpls
            interface "int-PE-1-P-4"
            exit
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                primary "dyn"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-3"
                to 192.0.2.3
                primary "dyn"
                exit
                no shutdown
            exit
            no shutdown
```

The MPLS and LSP configuration for PE-2 are similar to that of PE-1 with the appropriate interfaces and LSP names configured.

To use an RSVP-TE tunnel as transport between PEs, it is necessary to bind the RSVP-TE LSP between PEs to an SDP.

On PE-1, the SDP toward PE-2 is configured as follows. Similar SDPs are required on each PE to the remote PEs in the service where provisioned SDPs are to be used.

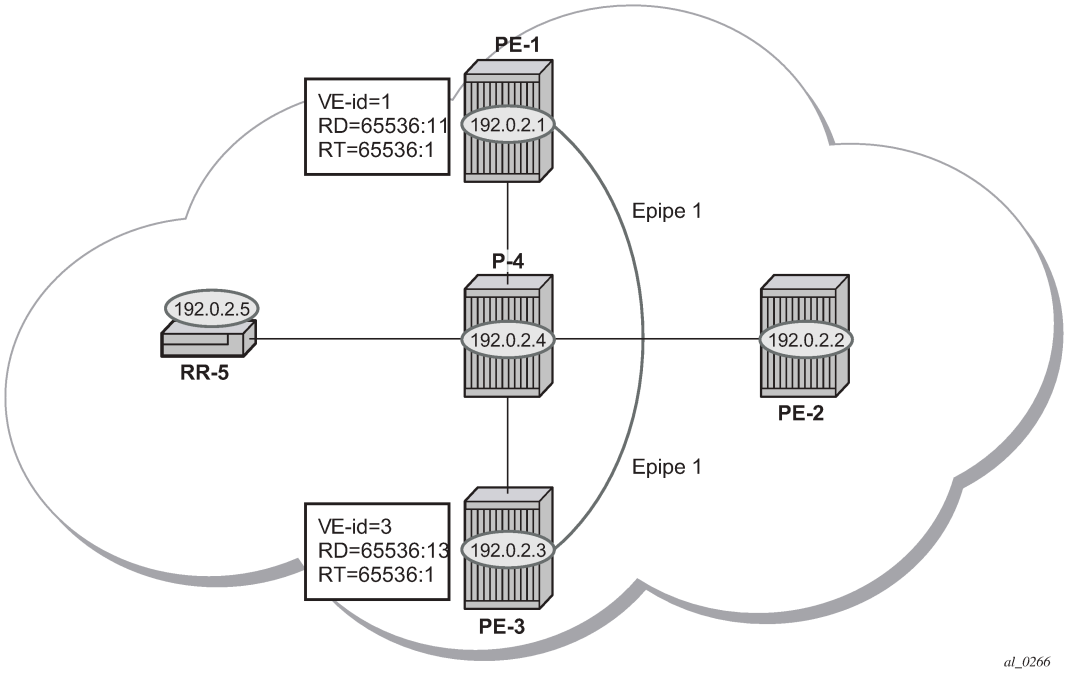
```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP-PE-1-PE-2_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
```

The **signaling bgp** parameter is required. BGP VPWS instances using BGP VPWS signaling can use BGP-signaled SDPs. However, TLDP-signaled (default) SDPs that are bound to RSVP-based LSPs will not be used as SDPs within BGP VPWS.

Single-homed BGP VPWS using auto-provisioned SDPs

Figure 54: Single-homed BGP VPWS using auto-provisioned SDPs shows a schematic of a single homed BGP VPWS between PE-1 and PE-3 where SDPs are auto-provisioned. In this case, the transport tunnels are LDP-signaled.

Figure 54: Single-homed BGP VPWS using auto-provisioned SDPs



The following shows the configuration required on PE-1 for a BGP VPWS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            vc-type vlan
        exit
        epipe 1 name "Epipe1" customer 1 create
            bgp
                route-distinguisher 65536:11
                route-target export target:65536:1 import target:65536:1
                pw-template-binding 1
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
```

```
                remote-ve-name "PE-3"
                    ve-id 3
                exit
                no shutdown
            exit
            sap 1/1/4:1 create
            exit
            no shutdown
        exit
```

The **bgp** context specifies parameters that are required for BGP VPWS.

Within the **bgp** context, parameters are configured that are used by the neighboring PEs to determine the membership of a BGP VPWS, in other words, the auto-discovery of PEs in the same BGP VPWS. Within the **bgp** context, the RD is configured, along with the route target extended communities. Route target communities are used to determine membership of a BGP VPWS. The import and export route targets at the BGP level are mandatory. The PW template binding is then applied and its parameters are used for both the routes sent by this PE and the received routes matching the route target value.

Within the **bgp-vpws** context, the signaling parameters are configured. These determine the service labels required for the data plane of the VPWS instance.

The VPWS Edge ID (VE-ID) is a numerical value assigned to each PE within a BGP VPWS. This value must be unique for a BGP VPWS, with the exception of multi-homed scenarios, where two dual-homed PEs can have the same VE-ID and are distinguishable by the site preference (or by the tie breaking rules from the *draft-ietf-bess-vpls-multihoming-03*).

Changes to the pseudowire template are not taken into account once the pseudowire has been set up (changes of RT are refreshed though). PW-templates can be re-evaluated with the **tools perform service eval-pw-template** command. The **eval-pw-template** checks if all of the bindings using this PW template policy are still meant to be using this policy. If the template has changed and **allow-service-impact** is true, then the old binding is removed and it is re-added using the new template.

```
*A:PE-1# tools perform service eval-pw-template 1
eval-pw-template succeeded for Svc 1 Tx L2 ExtComm, Policy 1
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 1
```

VE-ID and BGP label allocations

For a point-to-point VPWS, there are only two members within the BGP VPWS service, so only one label entry is required by each remote service. For dual-homed scenarios, there are two labels for the redundant site, one from each dual-homed PE.

Each PE allocates a label per BGP VPWS instance for the remote PEs, so it signals blocks with one label. It achieves this by advertising three parameters in a BGP update message. For more information about these parameters, see chapter BGP VPLS.

- A Label Base (LB) which is the lowest label in the block.
- A VE Block size (VBS) which is always 1 and cannot be changed.
- A VE Base Offset (VBO) corresponding to the first label in the label block.

PE-3 service creation

On PE-3, Epipe 1 is configured using PW template 1, as follows. PE-3 has been allocated a VE-ID of 3. For completeness, the PW template is also shown.

```
# on PE-3:
configure
    service
        pw-template 1 name "PW1" create
            vc-type vlan
        exit
        epipe 1 name "Epipe1" customer 1 create
            bgp
                route-distinguisher 65536:13
                route-target export target:65536:1 import target:65536:1
                pw-template-binding 1
                exit
            exit
            bgp-vpws
                ve-name "PE-3"
                    ve-id 3
                exit
                remote-ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap 1/1/4:1 create
            exit
            no shutdown
        exit
```

PE-1 service operation verification

The following command shows that the BGP VPWS service is enabled on PE-1:

```
*A:PE-1# show service id 1 bgp-vpws

===============================================================================
BGP VPWS Information
===============================================================================
Admin State          : Enabled
VE Name              : PE-1                VE Id           : 1
PW Tmpl used         : 1

Remote-Ve Information
-------------------------------------------------------------------------------

    Flag: 0x90 Type: 14 Len: 32 Multiprotocol Reachable NLRI:
        Address Family L2VPN
        NextHop len 4 NextHop 192.0.2.1
        [VPLS/VPWS] preflen 21, veid: 1, vbo: 3, vbs: 1, label-base: 524281,
                    RD 65536:11, csv: 0x00000000, type 1, len 1,
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x80 Type: 4 Len: 4 MED: 0
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:65536:1
        l2-vpn/vrf-imp:Encap=4: Flags=none: MTU=1514: PREF=0
"
```

The control flags within the extended community indicate the status of the BGP VPWS instance.

The control flags are the following:

```
0 1 2 3 4 5 6 7
+-+-+-+-+-+-+-+-+
|D|A|F|Z|Z|Z|C|S| (Z = MUST Be Zero)
+-+-+-+-+-+-+-+-+
```

- D: access circuit down indicator. D is 1 if all access circuits are down, otherwise D is 0.
- A: automatic site ID allocation, which is not supported. This is ignored on receipt and set to 0 on sending.
- F: MAC flush indicator, this relates to VPLS. This is set to 0 and ignored on receipt.
- C: presence of a control word. Control word usage is not supported. This is set to 0 on sending (control word not present) and if a non-zero value is received (indicating a control word is required), the pseudowire will not be created.
- S: sequenced delivery. Sequenced delivery is not supported. This is set to 0 on sending (no sequenced delivery) and if a non-zero value is received (indicating sequenced delivery required), the pseudowire will not be created.

The BGP VPWS NLRI is based on the BGP VPLS NLRI, but is extended with a Circuit Status Vector (CSV). The circuit status vector is used to indicate the status of both the SAP and the spoke-SDP within

the local service. Because the VE block size used is 1, the most significant bit in the circuit status vector TLV value will be set to 1 if either the SAP or spoke-SDP is down; otherwise, it will be set to 0.

```
# on PE-1:
configure
    service
        epipe "Epipe1"
            sap 1/1/4:1
                shutdown
```

```

```

On PE-1, SAP 1/1/4:1 is re-enabled as follows:

```
# on PE-1:
configure
    service
        epipe "Epipe1"
            sap 1/1/4:1
```

```
            no shutdown
        exit
```

PE-3 service operation verification

Similar to PE-1, the service operation should be validated on PE-3.

Single-homed BGP VPWS using pre-provisioned SDP

It is possible to configure BGP VPWS instances that use RSVP-TE transport tunnels. In this case, the SDPs must be created with the MPLS LSPs mapped and with the signaling set to BGP, because the service labels are signaled using BGP. The PW template configured within the BGP VPWS instance must use the keyword **use-provisioned-sdp** (or **prefer-provisioned-sdp**).

Figure 55: Single-homed BGP VPWS using pre-provisioned SDP

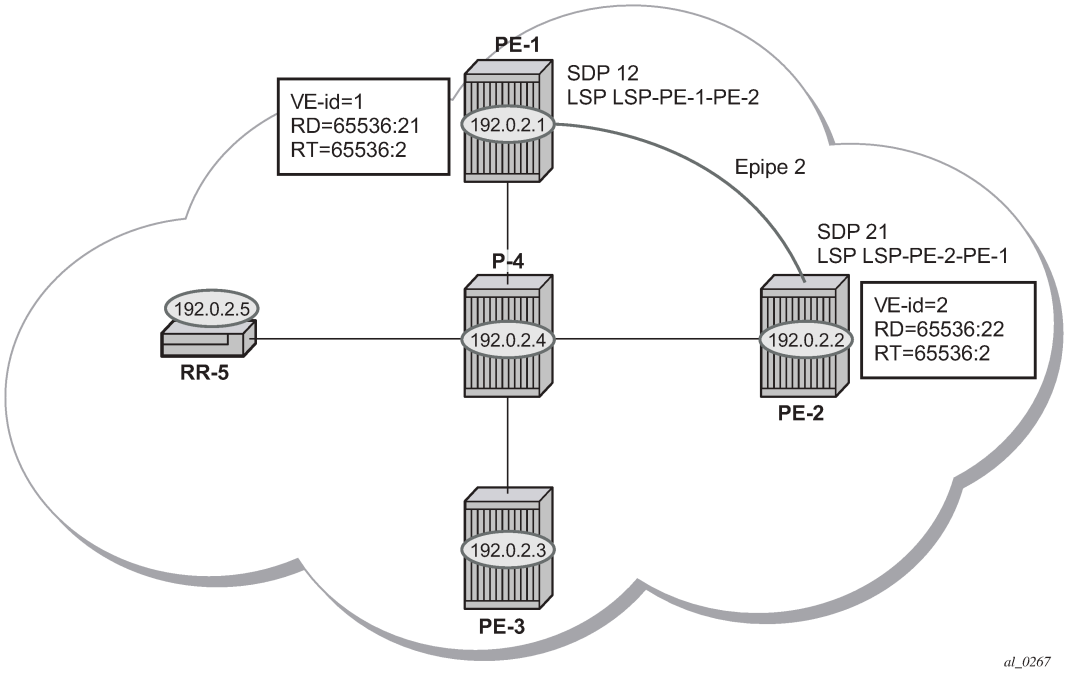

Figure 55: Single-homed BGP VPWS using pre-provisioned SDP shows a schematic of a BGP VPWS where SDPs are pre-provisioned with RSVP-TE signaled transport tunnels.

On PE-1, SDP 12 toward PE-2 is configured as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP-PE-1-PE-2_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
```

```
        exit
```

On PE-2, SDP 21 toward PE-1 is configured as follows:

```
# on PE-2:
configure
    service
        sdp 21 mpls create
            description "SDP-PE-2-PE-1_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.1
            lsp "LSP-PE-2-PE-1"
            no shutdown
        exit
```

To create a spoke SDP within a service that uses the RSVP-TE transport tunnel, a pseudowire template is required that has the **use-provisioned-sdp** parameter set.

The PW template is provisioned on both PEs as follows:

```
# on PE-1 and PE-2:
configure
    service
        pw-template 2 name "PW2" use-provisioned-sdp create
        exit
```

The following output shows the configuration required for a BGP VPWS service using a PW template configured for using pre-provisioned RSVP-TE SDPs.

```
# on PE-1:
configure
    service
        epipe 2 name "Epipe2" customer 1 create
            bgp
                route-distinguisher 65536:21
                route-target export target:65536:2 import target:65536:2
                pw-template-binding 2
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            sap 1/1/4:2 create
            exit
            no shutdown
```

The route distinguisher and route target extended community values for Epipe 2 are different from that in Epipe 1. This is to differentiate between the two as their visibility is global within the BGP domain. The VE-ID values can be reused in each Epipe instance, as long as they are unique within the instance.

Similarly, the configuration is as follows on PE-2, where the VE-ID is 2:

```
# on PE-2:
configure
```

```
    service
         epipe 2 name "Epipe2" customer 1 create
            bgp
                route-distinguisher 65536:22
                route-target export target:65536:2 import target:65536:2
                pw-template-binding 2
                exit
            exit
            bgp-vpws
                ve-name "PE-2"
                    ve-id 2
                exit
                remote-ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap 1/1/4:2 create
            exit
            no shutdown
```

The service Epipe 2 is operationally up on PE-1, as follows:

```
*A:PE-1# show service id 2 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 2                   Vpn Id            : 0
Service Type      : Epipe
---snip---

Admin State       : Up                  Oper State        : Up
---snip---

-------------------------------------------------------------------------------
Service Access & Destination Points
-------------------------------------------------------------------------------
Identifier                              Type         AdmMTU  OprMTU  Adm  Opr
-------------------------------------------------------------------------------
sap:1/1/4:2                             q-tag        1578    1578    Up   Up

==============================================================================
```

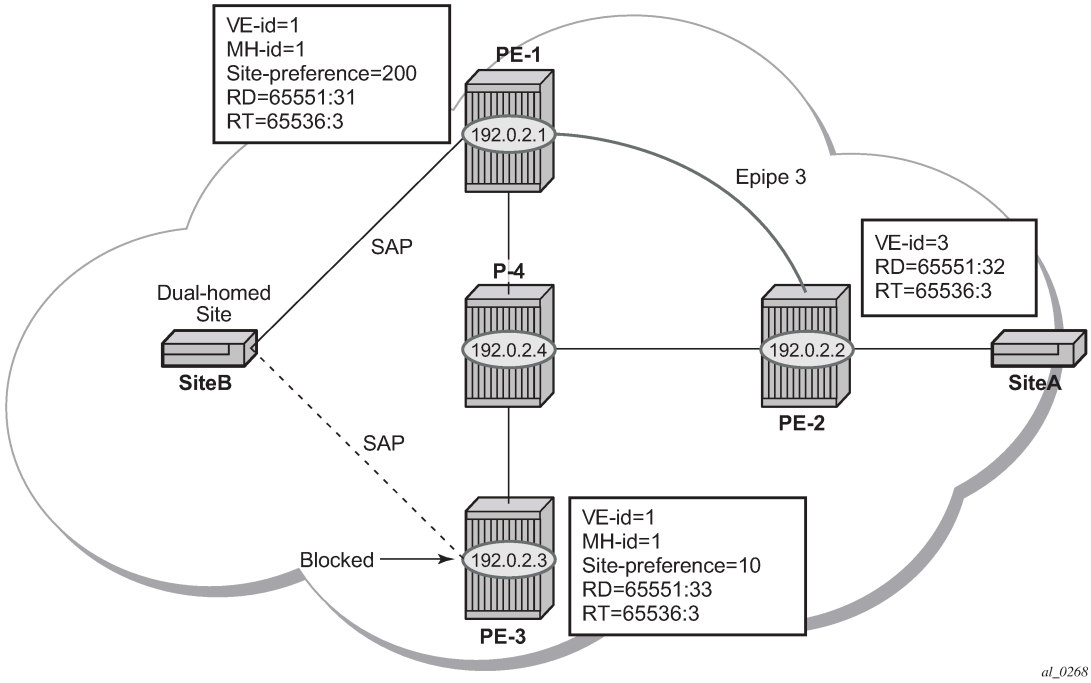
The SDP-ID used is the pre-provisioned SDP 21.

Dual-homed BGP VPWS with single pseudowire

For access redundancy, an Epipe using a BGP VPWS service can be configured as dual-homed, as described in *draft-ietf-bess-vpls-multihoming-03*. It can be configured with a single pseudowire setup, where the redundant pseudowire is not created until the initially active pseudowire is removed.

The following diagram shows a setup where an Epipe is configured on each PE. Site B is dual-homed to PE-1 and PE-3 with the remote PE-2 connected to site A; each site connection uses a SAP. A single pseudowire using Ethernet Raw Mode encapsulation connects PE-2 to PE-1 or PE-3 (but not both at the same time). The pseudowire is signaled using BGP VPWS over a tunnel LSP between the PEs.

Figure 56: Dual-homed BGP VPWS with single pseudowire



BGP multi-homing is configured for the dual-homed site B using a site-ID=1. The site-preference on PE-1 is set to 200 and to 10 on PE-3, this ensures that PE-1 will be the site's Designated Forwarder (DF) and the pseudowire from PE-2 will be created to PE-1 when PE-1 is fully operational (no pseudowire is created on PE-2 to PE-3). If PE-1 fails, or the multi-homing site fails over to PE-3, then the pseudowire from PE-2 to PE-1 will be removed and a new pseudowire will be created from PE-2 to PE-3.

On PE-1, Epipe 3 is configured as follows:

```
# on PE-1:
configure
```

```
    service
         pw-template 3 name "PW3" create
         exit
         epipe 3 name "Epipe3" customer 1 create
            bgp
                route-distinguisher 65536:31
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            site "SITEB" create
                site-id 1
                sap 1/1/4:3
                site-preference 200
                no shutdown
            exit
            sap 1/1/4:3 create
            exit
            no shutdown
        exit
```

Epipe 3 is configured on PE-3 with the same VE-ID as on PE-1, as follows:

```
# on PE-3:
configure
    service
        pw-template 3 name "PW3" create
        exit
        epipe 3 name "Epipe3" customer 1 create
            bgp
                route-distinguisher 65536:33
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-3"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            site "SITEB" create
                site-id 1
                sap 1/1/4:3
                site-preference 10
                no shutdown
            exit
            sap 1/1/4:3 create
            exit
            no shutdown
        exit
```

In the preceding configurations, the **remote-ve-name** for PE-2 uses VE-ID 2 on both PE-1 and PE-3.

Epipe 3 is configured on PE-2 as follows:

```
# on PE-2:
configure
    service
        pw-template 3 name "PW3" create
        exit
        epipe 3 name "Epipe3" customer 1 create
            bgp
                route-distinguisher 65536:32
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-2"
                    ve-id 2
                exit
                remote-ve-name "PE-1 or PE-3"
                    ve-id 1
                exit
                no shutdown
            exit
            sap 1/1/4:3 create
            exit
            no shutdown
        exit
```

On PE-2, the **remote-ve-name** is configured as "PE-1 or PE-3"; this is because both of these PEs are configured with VE-ID 1.

As a result of this configuration, there are multiple route entries for RD 65536:31 on PE-2. In the BGP routing table, there are two entries per partner PE, one for the BGP-MH update (with site-ID=1) and the other for the BGP-VPWS update (with VE-ID=1).

```
*A:PE-2# show router bgp routes l2-vpn rd 65536:31

```

After disabling the SAP in the service on PE-1, BGP update messages are received. The VPLS/VPWS message received on PE-2 from PE-1 shows in the CSV that the access circuit is down (the CSV has the

most-significant bit set to 1 (0x80)), so PE-2 selects the update from PE-3 to create the pseudowire. The BGP-MH update received by PE-2 from PE-1 also shows that the local site is down as indicated by the flags=D.

Note in the following debug output:

- BGP MH (multi-homing) entry uses encap-type=19.
- BGP VPWS entry uses encap-type=5 (Ethernet raw mode).

```
# Disable SAP in Epipe 3 on PE-1:
configure
    service
        epipe "Epipe3"
            sap 1/1/4:3
                shutdown
```

```

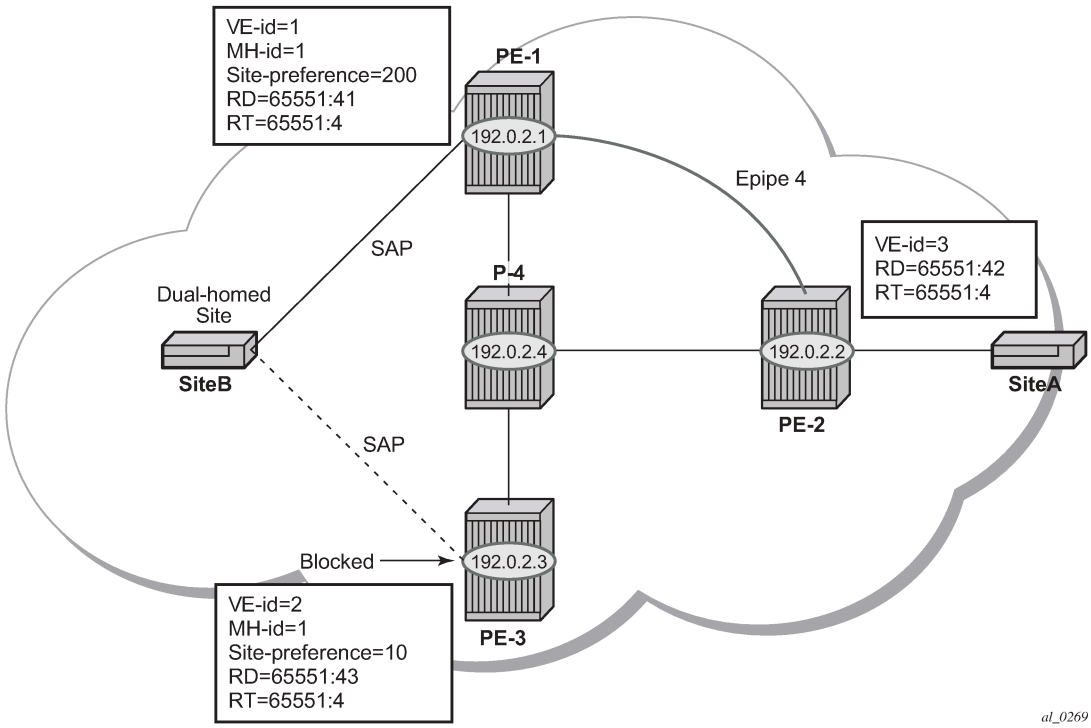
Dual-homed BGP VPWS with active/standby pseudowire

The second method for BGP VPWS pseudowire redundancy is an active/standby configuration. Whereas in the solution with one pseudowire, the redundant nodes use the same VE-ID for the remote PE and different preferences; in the active/standby solution, the redundant nodes use different VE-IDs for the remote PE and different preferences. The node connecting to both pseudowires (PE-2 in this example) has both remote VE-IDs configured. This allows for faster failover because the standby pseudowire is instantiated in addition to the active pseudowire. If more than two applicable BGP updates are received, at most one standby pseudowire is created (based on the BGP VPWS tie breaking rules).

Figure 57: Dual-homed BGP VPWS with active/standby pseudowire shows a setup where an Epipe is configured on each PE. Site B is dual-homed to PE-1 and PE-3 with the remote PE-2 connected to site A; each site connection uses a SAP. The active/standby pseudowires using Ethernet raw mode encapsulation connect PE-2 to PE-1 and PE-3. The pseudowires are signaled using BGP VPWS over tunnel LSPs between the PEs.

Figure 57: Dual-homed BGP VPWS with active/standby pseudowire



BGP Multi-Homing (MH) is configured for the dual-homed site B using a site-ID=1. The site preference on PE-1 is set to 200 and to 10 on PE-3; this ensures that PE-1 will be the site's DF for the MH site. The active pseudowire from PE-2 will be created to PE-1 with the standby pseudowire being created to PE-3. If PE-1 fails, or the multi-homing site fails over to PE-3, then the pseudowire from PE-2 to PE-3 will become active (used as the data path between site A and B).

Epipe 4 is configured on PE-1 as follows:

```
# on PE-1:
configure
    service
         pw-template 3 name "PW3" create
         exit
         epipe 4 name "Epipe4" customer 1 create
            bgp
                route-distinguisher 65536:41
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            site "SITEB" create
                site-id 1
```

```
                sap 1/1/4:4
                site-preference 200
                no shutdown
            exit
            sap 1/1/4:4 create
            exit
            no shutdown
        exit
```

Epipe 4 is configured on PE-3 with local VE-ID is 3 (different from previous example), as follows:

```
# on PE-3:
configure
    service
         pw-template 3 name "PW3" create
         exit
         epipe 4 name "Epipe4" customer 1 create
            bgp
                route-distinguisher 65536:43
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-3"
                    ve-id 3
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            site "SITEB" create
                site-id 1
                sap 1/1/4:4
                site-preference 10
                no shutdown
            exit
            sap 1/1/4:4 create
            exit
            no shutdown
        exit
```

Epipe 4 is configured on PE-2 as follows. Two remote VE names are configured, PE-1 and PE-3 (this is the maximum number allowed).

```
# on PE-2:
configure
    service
         pw-template 3 name "PW3" create
         exit
         epipe 4 name "Epipe4" customer 1 create
            bgp
                route-distinguisher 65536:42
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-2"
                    ve-id 2
                exit
```

```
                remote-ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-3"
                    ve-id 3
                exit
                no shutdown
            exit
            sap 1/1/4:4 create
            exit
            no shutdown
```

Compared with the single pseudowire solution, both pseudowires are signaled and up on all PEs. The pseudowire with the higher preference is forwarding traffic (to PE-1), while the Tx status to the standby PE-3 is set to inactive, as follows:

```
*A:PE-2# show service l2-route-table bgp-vpws detail

The choice of pseudowire to be used to transmit traffic from PE-2 to PE-1 can also be seen in the endpoint created in the BGP VPWS service. Endpoints are automatically created for the pseudowires within a BGP VPWS service, regardless of whether active/standby pseudowires are used; these endpoints are created with a system generated name that ends with the BGP VPWS service id.

```
tools perform service id <service-id> endpoint <endpoint-name> force-switchover <..>
```

Conclusion

BGP VPWS allows the delivery of Layer 2 virtual private wire services to customers where BGP is commonly used. This chapter shows the configuration of single and dual-homed BGP VPWS services together with the associated show output, which can be used to verify and troubleshoot them.

BGP VPLS

This chapter describes advanced BGP VPLS configurations.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The CLI in the current edition corresponds to SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Overview

The following two IETF standards describe the provisioning of Virtual Private LAN Services (VPLS).

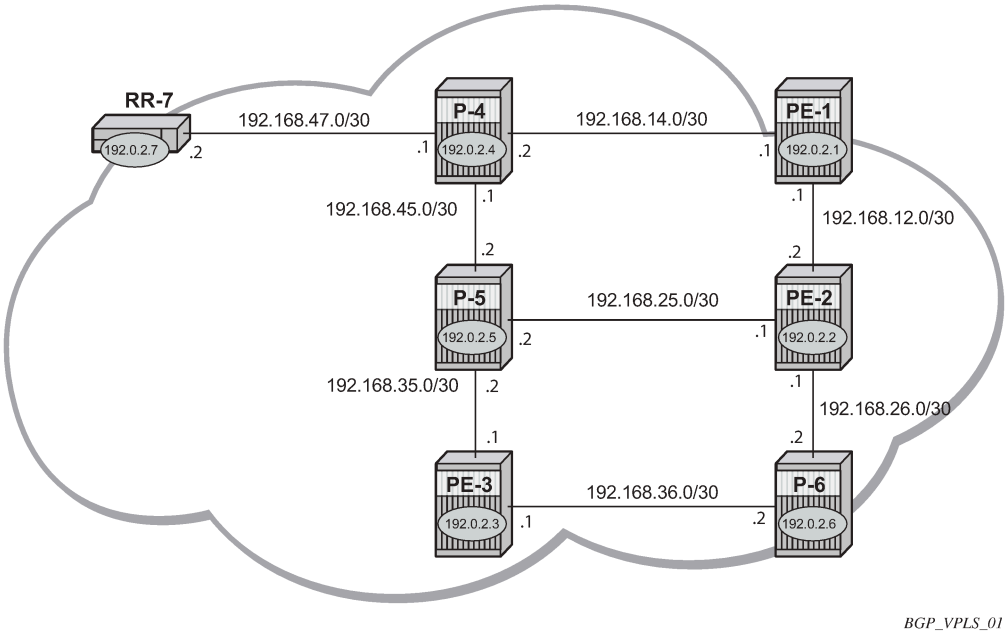
- RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, describes Label Distribution Protocol (LDP) VPLS, where VPLS pseudowires are signaled using LDP between VPLS Provider Edge (PE) routers, either configured manually or auto-discovered using BGP.
- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*, describes the use of Border Gateway Protocol (BGP) for both the auto-discovery of VPLS PEs and signaling of pseudowires between such PEs.

The purpose of this chapter is to describe the configuration and troubleshooting for BGP-VPLS.

Knowledge of BGP-VPLS RFC 4761 architecture and functionality is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

Figure 58: Example topology shows the example topology with seven SR OS nodes located in the same Autonomous System (AS).

Figure 58: Example topology



There are three Provider Edge (PE) routers, and RR-7 acts as a Route Reflector (RR) for the AS. The PE routers are all VPLS-aware, the Provider (P) routers are VPLS-unaware and do not take part in the BGP process.

The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF on each of the network interfaces between the PE/P routers and RR.
- MPLS is configured on all interfaces between PE routers and P routers. MPLS is not required between P-4 and RR-7.
- LDP is configured on interfaces between PE and P routers. It is not required between P-4 and the RR-7.
- The RSVP protocol is enabled.

BGP VPLS

In this architecture, a VPLS instance is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, any VPLS-aware PE is also known as a VPLS Edge (VE) device.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP-VPLS Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs and to set up pseudowire connectivity for data flow between peers containing a local VPLS within the same VPLS instance. Therefore, auto-discovery and pseudowire signaling are achieved using a single BGP update message.

Each PE within a VPLS instance is identified by a VPLS Edge identifier (VE-ID) and the presence of a VPLS instance is determined using the exchange of standard BGP extended community RTs between PEs.

Each PE will advertise, via the route reflectors, the presence of each VPLS instance to all other PEs, along with a block of multiplexer labels that can be used to communicate between such instances plus a BGP next hop that determines a labeled transport tunnel between PEs.

Each VPLS instance is configured with import and export RT extended communities for topology control, along with VE identification.

Configuration

The first step is to configure an MP-iBGP session between each of the PEs and the RR for the L2-VPN address family, as follows:

```
# on PE-1, PE-2, and PE-3:
configure
    router Base
        autonomous-system 65536
        bgp
            group "INTERNAL"
                family l2-vpn
                peer-as 65536
                neighbor 192.0.2.7
                exit
            exit
            no shutdown
        exit
```

The IP addresses can be derived from Figure 58: Example topology.

The configuration for RR-7 is as follows:

```
# on RR-7:
configure
    router Base
        autonomous-system 65536
        bgp
            cluster 1.1.1.1
            group "RR-INTERNAL"
                family l2-vpn
                peer-as 65536
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
        exit
```

On PE-1, the BGP session with RR-7 is established with the L2-VPN address family capability negotiated, as follows:

```
*A:PE-1# show router bgp neighbor 192.0.2.7

===============================================================================
BGP Neighbor
===============================================================================
-------------------------------------------------------------------------------
Peer                 : 192.0.2.7
```

```
Description          : (Not Specified)
Group                : INTERNAL
-------------------------------------------------------------------------------

Preference           : 170             Num of Update Flaps : 0
---snip---

Local Capability     : RtRefresh MPBGP 4byte ASN
Remote Capability    : RtRefresh MPBGP 4byte ASN
---snip---
```

On RR-7, the BGP sessions with each PE are established, and have negotiated the L2-VPN address family capability, as follows:

```
*A:RR-7# show router bgp summary all

===============================================================================
BGP Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================

                            7    0

-------------------------------------------------------------------------------
```

A full mesh of RSVP-TE LSPs is configured between the PE routers. On PE-1, the MPLS interface and LSP configuration are as follows:

```
# on PE-1:
configure
    router Base
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-P-4"
            exit
```

```
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                primary "loose"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-3"
                to 192.0.2.3
                primary "loose"
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The MPLS and LSP configuration for PE-2 and PE-3 are similar to that of PE-1 with the appropriate interfaces and LSP names configured.

BGP VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate SDP bindings for a service to signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, MAC-pinning, filters, and so on, plus other usage characteristics such as split horizon groups (SHGs).

The MPLS transport tunnel between PEs can be signaled using LDP or RSVP-TE.

LDP based pseudowires can be automatically instantiated. RSVP-TE based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, link layer LDP must be configured between all PEs/Ps, so that a transport label for each PE’s system interface is available.

```
# on PE-1:
configure
    router Base
        ldp
            interface-parameters
                interface "int-PE-1-PE-2" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
                interface "int-PE-1-P-4" dual-stack
                    ipv4
                        no shutdown
                    exit
```

```
                    no shutdown
                exit
            exit
        exit
```

Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at the higher end of the SDP numbering range, such as 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required containing an SHG. Each SDP created with this template is contained within an SHG so that traffic cannot be forwarded between them.

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            split-horizon-group "VPLS-SHG"
            exit
        exit
```

The pseudowire template also has the following options available when used for BGP-VPLS:

```
*A:PE-1>config>service# pw-template ?

  ---snip---
  [no] controlword
  ---snip---
  [no] force-vlan-vc-forwarding
  ---snip---
   vc-type {ether | vlan}
  ---snip---
```

- The control word will determine whether the C flag is set in the Layer 2 extended community and, therefore, if a control word is used in the pseudowire.
- The encap type in the Layer 2 extended community is always 19 (VPLS encap), therefore, the vc-type will always be **ether** regardless of the configured value on the vc-type.
- The **force-vlan-vc-forwarding** command will add a tag (equivalent to **vc-type vlan**) and will allow for customer QoS transparency (dot1p + Drop Eligibility (DE) bits).

Pseudowire templates for provisioned SDPs using RSVP-TE

To use an RSVP-TE tunnel as transport between PEs, it is necessary to bind the RSVP-TE LSP between PEs to an SDP.

The following SDP is created from PE-1 to PE-2:

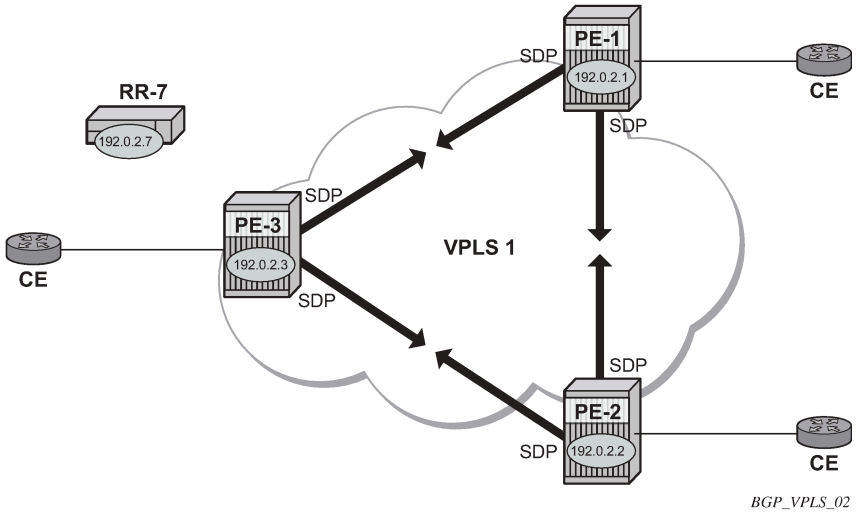
```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP-PE-1-PE-2_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
```

The **signaling bgp** parameter is required for BGP-VPLS to be able to use this SDP. Conversely, SDPs that are bound to RSVP-based LSPs with signaling set to the default value of **tldp** will not be used as SDPs within BGP-VPLS.

BGP VPLS using auto-provisioned SDPs

Figure 59: BGP VPLS using auto-provisioned SDPs shows a VPLS instance where SDPs are auto-provisioned. In this case, the transport tunnels are LDP-signaled.

Figure 59: BGP VPLS using auto-provisioned SDPs



The following shows the configuration required on PE-1 for a BGP-VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            split-horizon-group "VPLS-SHG"
            exit
        exit
        vpls 1 name "VPLS1_PE-1" customer 1 create
            bgp
                route-distinguisher 65536:1
                route-target export target:65536:1 import target:65536:1
                pw-template-binding 1
                exit
            exit
            bgp-vpls
                max-ve-id 10
                ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap 1/1/4:1.0 create
            exit
            no shutdown
```

```
        exit
```

The **bgp** context specifies parameters which are valid for all of the VPLS BGP applications, such as BGP multi-homing (BGP-MH), BGP auto-discovery (BGP-AD), and BGP-VPLS.

Within the **bgp** context, parameters are configured that are used by neighboring PEs to determine membership of a VPLS instance, such as the auto-discovery of PEs containing the same VPLS instance; the route distinguisher (RD) is configured, along with the route target (RT) extended communities.

RT communities are used to determine membership of a VPLS instance. The import RT at the BGP level is mandatory. The pseudowire template bind is then applied by the service manager on the received routes matching the RT value.

Within the **bgp-vpls** context, the signaling parameters are configured. These determine the service labels required for the data plane of the VPLS instance.

The VPLS edge ID (VE-ID) is a numerical value assigned to each PE within a VPLS instance. This value should be unique for a VPLS instance; no two PEs within the same instance should have the same VE-ID values.

A more specific RT can be applied to a pseudowire template in order to define a specific pseudowire topology, rather than only a full mesh, using the command within the **bgp** context:

pw-template *template-id* **[split-horizon-group** *groupname***] [import-rt** *import-rt-value (up to 5 max)***]**

Changes to the import policies are not taken once the pseudowire has been set up (changes on RT are refreshed though). Pseudowire templates can be re-evaluated with the command **tools perform service eval-pw-template**. The **eval-pw-template** command checks whether all the bindings using this pseudowire template policy are still meant to use this policy.

If the policy has changed and **allow-service-impact** is true, then the old binding is removed and it is re-added with the new template.

VE-ID and BGP label allocations

The choice of VE-ID is crucial in ensuring efficient allocation of de-multiplexer labels. The most efficient choice is for VE-IDs to be allocated starting at 1 and incrementing for each PE as the following section explains.

The **max-ve-id** *value* determines the range of the VE-ID value that can be configured. If a PE receives a BGP-VPLS update containing a VE-ID with a greater value than the configured **max-ve-id**, then the update is dropped and no service labels are installed for this VE-ID.

The **max-ve-id** command also checks the locally-configured VE-ID, and prevents a higher value from being used.

Each PE allocates blocks of labels per VPLS instance to remote PEs, in increments of eight labels. It achieves this by advertising three parameters in a BGP update message,

- A label base (LB) which is the lowest label in the block
- A VE Block Size (VBS) which is always eight labels, and cannot be changed
- A VE Base Offset (VBO).

This defines a block of labels in the range (LB, LB+1, ..., LB+VBS-1).

As an example, if the label base (LB) = 524272, then the range for the block is 524272 to 524279, which is exactly eight labels, as per the block size. (The last label in the block is calculated as 524272+8-1 = 524279)

The label allocated by the PE to each remote PE within the VPLS is chosen from this block and is determined by its VE-ID. In this way, each remote PE has a unique de-multiplexer label for that VPLS.

To reduce label wastage, contiguous VE-IDs in the range (N..N+7) per VPLS should be chosen, where N>0.

Assuming a collection of PEs with contiguous VE-IDs, the following labels will be chosen by PEs from the label block allocated by PE-1 which has a VE-ID =1.

Table 3: VE-IDs and Labels

VE-ID	Label
2	524273
3	524274
4	524275
5	524276
6	524277
7	524278
8	524279

This shows that the label allocated to a PE is (LB+VEID-1). The "1" is the VE block offset (VBO).

This means that the label allocated to a PE router within the VPLS can now be written as (LB + VEID - VBO), which means that (VEID - VBO) calculation must always be at least zero and be less than the block size, which is always 8.

For VE-ID < 8, a label will be allocated from this block.

For the next block of 8 VE-IDs (VE-ID 9 to VE-ID 16) a new block of 8 labels must be allocated, so a new BGP update is sent, with a new label base, and a block offset of 9.

Table 4: VE-IDs and Number of Labels shows how the choice of VE-IDs can affect the number of label blocks allocated, and therefore the number of labels:

Table 4: VE-IDs and Number of Labels

VE-ID	Block Offset	Labels Allocated
1-8	1	8
9-16	9	8
17-24	17	8
25-32	25	8
33-40	33	8
41-48	41	8

VE-ID	Block Offset	Labels Allocated
49-56	49	8

This shows that the most efficient use of labels occurs when the VE-IDs for a set of PEs are chosen from the same block offset.

If VE-IDs are chosen that map to different block offsets, then each PE will have to send multiple BGP updates to signal service labels. Each PE sends label blocks in BGP updates to each of its BGP neighbors for all label blocks in which at least one VE-ID has been seen by this PE (it does not advertise label blocks which do not contain an active VE-ID, where active VE-ID means the VE-ID of this PE or any other PE in this VPLS).

The **max-ve-id** must be configured first, and determines the maximum value of the VE-ID that can be configured within the PE. The VE-ID value cannot be higher than this within the PE configuration, VE-ID <= max-VE-ID. Similarly, if the VE-ID within a received NLRI is higher than the **max-ve-id** *value*, it will not be accepted as valid consequently the max-ve-id configured on all PEs must be greater than or equal to any VE-ID used in the VPLS.

Only one VE-ID value can be configured. If the VE-ID value is changed, BGP withdraws the NLRI and sends a route-refresh.

If the same VE-ID is used in different PEs for the same VPLS, a Designated Forwarder (DF) election takes place.

Executing the **shutdown** command triggers an MP-UNREACH-NLRI from the PE to all BGP peers.

The **no shutdown** command triggers an MP-REACH-NLRI to the same peers.

PE-2 service creation

On PE-2, a VPLS service using pseudowire template 1 is created. In order to make the label allocation more efficient, PE-2 has been allocated a VE-ID value of 2. For completeness, the pseudowire template is also shown.

```
# on PE-2:
configure
    service
        pw-template 1 name "PW1" create
            split-horizon-group "VPLS-SHG"
            exit
        exit
        vpls 1 name "VPLS1_PE-2" customer 1 create
            bgp
                route-distinguisher 65536:1
                route-target export target:65536:1 import target:65536:1
                pw-template-binding 1
                exit
            exit
            bgp-vpls
                max-ve-id 10
                ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            sap 1/1/4:1.0 create
            exit
```

```
            no shutdown
        exit
```

The **max-ve-id** *value* is set to 10 to allow an increase in the number of PEs that could be a part of this VPLS instance.

PE-3 service creation

The following configuration creates a VPLS instance on PE-3, using a VE-ID value of 3.

```
# on PE-3:
configure
    service
        pw-template 1 name "PW1" create
            split-horizon-group "VPLS-SHG"
            exit
        exit
        vpls 1 name "VPLS1_PE-3" customer 1 create
            bgp
                route-distinguisher 65536:1
                route-target export target:65536:1 import target:65536:1
                pw-template-binding 1
                exit
            exit
            bgp-vpls
                max-ve-id 10
                ve-name "PE-3"
                    ve-id 3
                exit
                no shutdown
            exit
            sap 1/1/4:1.0 create
            exit
            no shutdown
        exit
```

PE-1 service operation verification

The following command shows that the BGP-VPLS site is enabled on PE-1.

```
*A:PE-1# show service id 1 bgp-vpls

===============================================================================
BGP VPLS Information
===============================================================================
Max Ve Id            : 10                  Admin State      : Enabled
VE Name              : PE-1                VE Id            : 1
PW Tmpl used         : 1
===============================================================================
```

The following command shows that the service is operationally up on PE-1:

```
*A:PE-1# show service id 1 base

===============================================================================
Service Basic Information
===============================================================================
```

```
Service Id        : 1                   Vpn Id            : 0
Service Type      : VPLS
MACSec enabled    : no
Name              : VPLS1_PE-1
---snip---

Admin State       : Up                  Oper State        : Up

32767:4294967295 BgpVpls  192.0.2.2       Up      Up        524273    524270
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

As can be seen from the following output, a BGP-VPLS NLRI update is sent to the route reflector (192.0.2.7) and is received by each PE.

On PE-1, debugging is enabled for BGP updates:

```
# on PE-1:
debug
    router "Base"
        bgp
            update
```

PE-1 has sent the following BGP NLRI update for VPLS 1 to RR-7:

```
1 2021/01/25 15:27:27.169 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.7
"Peer 1: 192.0.2.7: UPDATE
Peer 1: 192.0.2.7 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 72
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family L2VPN
        NextHop len 4 NextHop 192.0.2.1
        [VPLS/VPWS] preflen 17, veid: 1, vbo: 1, vbs: 8, label-base: 524272, RD 65536:1
```

```
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x80 Type: 4 Len: 4 MED: 0
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:65536:1
        l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
"
```

The control flags within the extended community indicate the status of the VPLS instance.

The control flag D indicates that all attachment circuits are Down, or the VPLS is disabled. The flags are used in BGP-MH when determining which PEs are DF, see chapter BGP Multi-Homing for VPLS Networks.

When flags=none, then all attachment circuits are up. In the preceding example, no flags are present, but should all SAPs become operationally down, then the control flag D would be seen in the debug message. To simulate this, the SAP 1/1/4:1 is disabled on PE-1:

```
# on PE-1:
configure
    service
        vpls "VPLS1_PE-1"
            sap 1/1/4:1.0
                shutdown
```

All SAPs in VPLS 1 on PE-1 are operationally down, so PE-1 sends a BGP update message with control flag D set, as follows:

```
5 2021/01/25 15:40:08.169 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.7
"Peer 1: 192.0.2.7: UPDATE
Peer 1: 192.0.2.7 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 72
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family L2VPN
        NextHop len 4 NextHop 192.0.2.1
        [VPLS/VPWS] preflen 17, veid: 1, vbo: 1, vbs: 8, label-base: 524272, RD 65536:1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x80 Type: 4 Len: 4 MED: 0
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:65536:1
        l2-vpn/vrf-imp:Encap=19: Flags=D: MTU=1514: PREF=0
"
```

The SAP is re-enabled with the following command on PE-1:

```
# on PE-1:
configure
    service
        vpls "VPLS1_PE-1"
            sap 1/1/4:1.0
                no shutdown
```

The BGP VPLS signaling parameters are also present in the BGP update message, namely the VE-ID of the PE within the VPLS instance, the VBO and VBS, and the label base. The target indicates the VPLS instance, which must be matched against the import RTs of the receiving PEs.

The signaling parameters can be seen within the BGP update with following command:

```
*A:PE-1# show router bgp routes l2-vpn rd 65536:1 hunt

===============================================================================
```

In this configuration example, PE-1 (192.0.2.1) with VE-ID =1 has sent an update with base offset (VBO) =1, block size (VBS) = 8, and label base 524272. This means that labels 524272 (LB) to 524279 (LB +VBS-1) are available as de-multiplexer labels, egress labels to be used to reach PE-1 for VPLS 1.

PE-2 receives this update from PE-1. This is seen as a valid VPLS BGP route from PE-1 through the route reflector with next-hop 192.0.2.1.

```
*A:PE-2# show router bgp routes l2-vpn rd 65536:1

Routes : 3
===============================================================================
```

PE-2 uses this information in conjunction with its own VE-ID to calculate the egress label toward PE-1, using the condition VBO < VE-ID < (VBO+VBS).

The VE-ID of PE-2 is in the Label Block covered by VBO =1, thus,

Label calculation = label base + local VE-ID - Base offset

= 524272 + 2 - 1

Egress label used = 524273

This is verified using the following command on PE-2 where the egress label toward PE-1 (192.0.2.1) is 524273.

```
*A:PE-2# show service id 1 sdp

PE-3 de-multiplexer label verification

PE-3 also allocates the required parameters for PE-1 and PE-2 to calculate the egress service label required to reach PE-3.

This is verified using the following command on PE-1 to show the egress label toward PE-3 (192.0.2.3) (524272) where egress label toward PE-2 = 524270. The Label Base equals 524272 on PE-3 and 524270 on PE-2.

```
*A:PE-1# show service id 1 sdp

===============================================================================

===============================================================================
```

This example has shown that for VPLS instance with 3 PEs, not all labels allocated by a PE will be used by remote PEs as de-multiplexer service labels. There will be some wastage of label space, so there is a necessity to choose VE-IDs that keep this waste to a minimum.

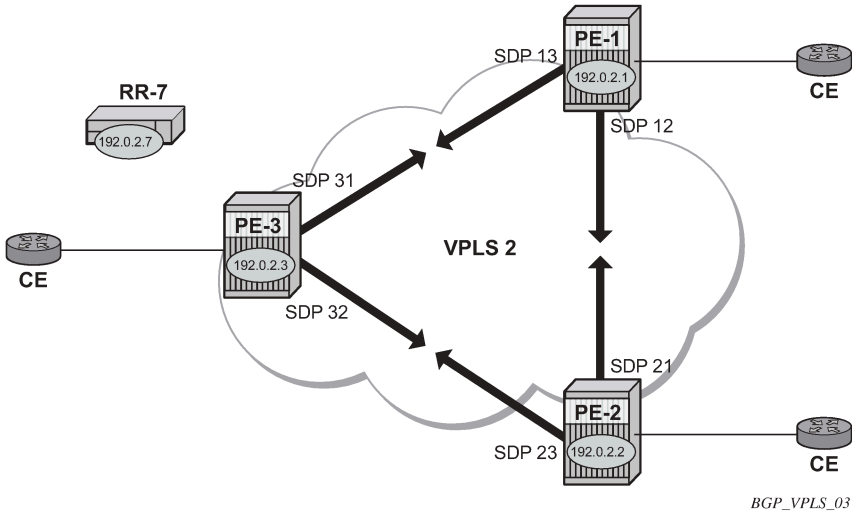
The next example will show an even more wasteful use of labels by using a random choice of VE-IDs.

BGP VPLS using pre-provisioned SDP

It is possible to configure BGP-VPLS instances that use RSVP-TE transport tunnels. In this case, the SDP must be created with the MPLS LSPs mapped and with signaling set to BGP, as the service labels are signaled using BGP. The pseudowire template configured within the BGP-VPLS instance must use the **use-provisioned-sdp** keyword. This example also examines the effect of using VE-IDs that are not all within the same contiguous block.

Figure 60: BGP VPLS using pre-provisioned SDP shows an example of a VPLS instance where SDPs are pre-provisioned with RSVP-TE signaled transport tunnels.

Figure 60: BGP VPLS using pre-provisioned SDP



On the PEs, the following SDPs are configured with RSVP transport tunnels.

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP-PE-1-PE-2_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
        sdp 13 mpls create
            description "SDP-PE-1-PE-3_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.3
            lsp "LSP-PE-1-PE-3"
            no shutdown
```

```
        exit
```

```
# on PE-2:
configure
    service
        sdp 21 mpls create
            description "SDP-PE-2-PE-1_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.1
            lsp "LSP-PE-2-PE-1"
            no shutdown
        exit
        sdp 23 mpls create
            description "SDP-PE-2-PE-3_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.3
            lsp "LSP-PE-2-PE-3"
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
        sdp 31 mpls create
            description "SDP-PE-3-PE-1_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.1
            lsp "LSP-PE-3-PE-1"
            no shutdown
        exit
        sdp 32 mpls create
            description "SDP-PE-3-PE-2_RSVP_BGP"
            signaling bgp
            far-end 192.0.2.2
            lsp "LSP-PE-3-PE-2"
            no shutdown
        exit
```

Pre-provisioned BGP-SDPs can also be used with BGP-VPLS. For reference, they are configured as follows:

```
# on PE-3:
configure
    service
        sdp 332 mpls create
            signaling bgp
            far-end 192.0.2.2
            no shutdown
        exit
```

To create an SDP within a service that uses the RSVP transport tunnel, a pseudowire template is required that has the **use-provisioned-sdp** parameter set. It is also possible to configure the **prefer-provisioned-sdp** parameter, see chapter *LDP VPLS Using BGP Auto-Discovery – Prefer Provisioned SDP*.

Once again, an SHG is included to prevent forwarding between pseudowires.

The following pseudowire template is provisioned on all PEs:

```
# on PE-1, PE-2, and PE-3:
configure
```

```
    service
        pw-template 2 name "PW2" use-provisioned-sdp create
            split-horizon-group "VPLS-SHG"
            exit
        exit
```

The following output shows the configuration required for a BGP-VPLS service using a pseudowire template configured for using pre-provisioned RSVP-TE SDPs.

```
# on PE-1:
configure
    service
        vpls 2 name "VPLS2_PE-1" customer 1 create
            bgp
                route-distinguisher 65536:2
                route-target export target:65536:2 import target:65536:2
                pw-template-binding 2
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap 1/1/4:2.0 create
            exit
            no shutdown
        exit
```

The RD and RT extended community values for VPLS 2 are different from the ones in VPLS 1. The VE-ID value for PE-1 can be the same as the one in VPLS 1, but these must be different within the same VPLS instance on the other PEs — PE-2 should not have VE-ID = 1.

On PE-2, the configuration is as follows with the VE-ID value equal to 20, which will result in a label from a different block:

```
# on PE-2:
configure
    service
        vpls 2 name "VPLS2_PE-2" customer 1 create
            bgp
                route-distinguisher 65536:2
                route-target export target:65536:2 import target:65536:2
                pw-template-binding 2
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-2"
                    ve-id 20
                exit
                no shutdown
            exit
            sap 1/1/4:2.0 create
            exit
            no shutdown
        exit
```

On PE-3, the configuration is as follows with the VE-ID value equal to 3:

```
# on PE-3:
configure
    service
        vpls 2 name "VPLS2_PE-3" customer 1 create
            bgp
                route-distinguisher 65536:2
                route-target export target:65536:2 import target:65536:2
                pw-template-binding 2
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-3"
                    ve-id 3
                exit
                no shutdown
            exit
            sap 1/1/4:2.0 create
            exit
            no shutdown
        exit
```

The service is operationally up on PE-1, as follows:

```

PE-1 de-multiplexer label calculation

In the case of VPLS 1, all VE-IDs are in the range of a single label block. In the case of VPLS 2, the VE-IDs are in different blocks, for example, the VE-ID 20 is in a different block to VE-IDs 1 and 3.

As the label allocation is block-dependent, multiple label blocks must be advertised by each PE to encompass this.

Consider PE-1's BGP update NLRIs.

-------------------------------------------------------------------------------
Routes : 8
===============================================================================
```

Two NLRIs updates are sent to the route reflector, with the following label parameters:

1. LB = 524264, VBS = 8, VBO = 1

2. LB = 524256, VBS = 8, VBO = 17

PE-2 has a VE-ID of 20. Applying the condition VBO < VE-ID < (VBO+VBS)

- Update 1: LB = 524264, VBS = 8, VBO = 1
- VBO < VE-ID for VE-ID = 20 is true
- VE-ID < (VBO+VBS) for VE-ID = 20 is false.
- PE-2 cannot choose a label from this block.
- Update 2: LB = 524256, VBS = 8, VBO = 17
- VBO < VE-ID for VE-ID = 20 is true
- VE-ID < (VBO+VBS) for VE-ID = 20 is true.
- PE-2 chooses label 524256 + 20 - 17 = 524259 (LB + VEID - VBO)

The egress label chosen is verified by examining the egress label toward PE-1 (192.0.2.1) on PE-2.

```
*A:PE-2# show service id 2 sdp

- Update 2: LB = 524256, VBS = 8, VBO = 17
- VBO < VE-ID for VE-ID = 3 is false
- VE-ID < (VBO+VBS) for VE-ID = 3 is true.
- PE-3 cannot choose a label from this block.

The egress label chosen is verified by examining the egress label toward PE-1 (192.0.2.1) on PE-3.

```
*A:PE-3# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================

32:4294967291    BgpVpls  192.0.2.2       Up      Up        524259    524256
```

```
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

To illustrate the allocation of label blocks by a PE, against the actual use of the same labels, consider the following. When BGP updates from each PE signal the multiplexer labels in blocks of eight, the allocated label values are added to the in-use pool. First check what label range can be allocated dynamically.

```
*A:PE-1# show router mpls-labels label-range

===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          18431       -           18400       18400
Dynamic         18432       524287      0           505824      505856
    Seg-Route   0           0           -           0           0
===============================================================================
```

Verify which labels in the dynamic range are in use. The label pool of PE-1 can be verified as per the following output which shows labels used along with the associated protocol:

```
*A:PE-1# show router mpls-labels label 18432 524287 in-use

===========================================================
MPLS Labels from 18432 to 524287 (In-use)

524286              dynamic             ILDP
```

```
524287              dynamic             ILDP
-------------------------------------------------------------------
In-use labels (Owner: All) in specified range   : 32
In-use labels in entire range                   : 32
===================================================================
```

This shows that 24 labels have been allocated for use by BGP. Of this number, 16 labels have been allocated for use by PEs within VPLS 2 to communicate with PE-1, the blocks with label base 524256 and with label base 524264.

There are only two neighboring PEs within this VPLS instance, so only two labels will ever be used in the data plane for traffic destined to PE-1. These are 524259 and 524266. The remaining labels have no PE with the associated VE-ID that can use them.

Once again, this case emphasizes that to reduce label wastage, contiguous VE-IDs in the range (N..N+7) per VPLS should be chosen, where N>0.

Conclusion

BGP-VPLS allows the delivery of Layer 2 VPN services to customers where BGP is commonly used. The examples presented in this chapter show the configuration of BGP-VPLS together with the associated show outputs which can be used for verification and troubleshooting.

Black-hole MAC for EVPN Loop Protection

This chapter provides information about Black-hole MAC for EVPN Loop Protection.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the CLI in the current edition corresponds to SR OS Release 21.2.R2. Black-hole MAC for EVPN loop protection is supported in SR OS Release 15.0.R1, and later.

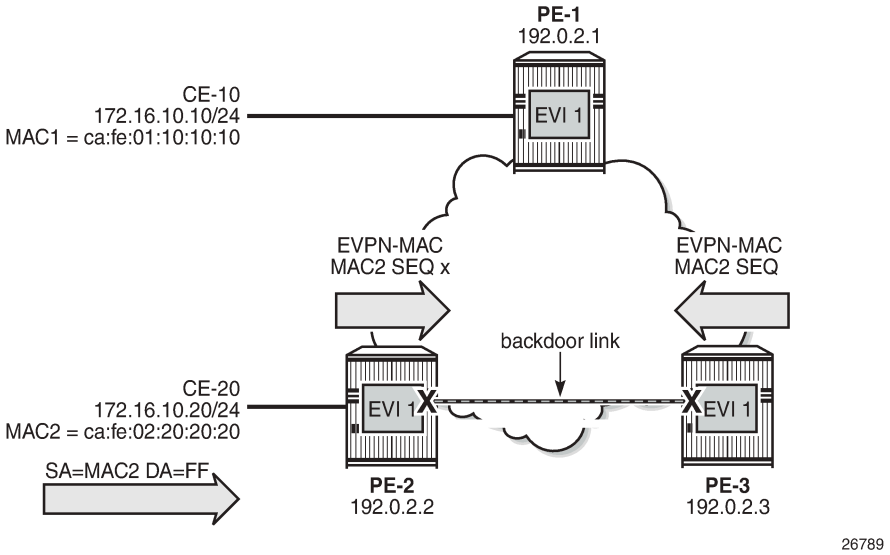
Chapters Auto-Learn MAC Protect in EVPN and Conditional Static Black-Hole MAC in EVPN are prerequisite reading.

Overview

Service providers are migrating VPLS networks to EVPN and require the same or better loop protection mechanisms, such as **mac-move** or **auto-learn-mac-protect** (ALMP). Chapter Auto-Learn MAC Protect in EVPN describes how traffic is protected in "static" networks, where the CEs do not move to a different port or PE, and MAC addresses are always learned first on the correct SAP/SDP-bindings. However, ALMP does not provide a loop protection solution in EVPN networks that require mobility and ALMP has issues with all-active multi-homing. Since mobility and all-active multi-homing are two of the key advantages of EVPN compared to VPLS, an alternate loop protection mechanism is required. This chapter describes an example for the black-hole based loop protection solution, based on *draft-snr-bess-evpn-loop-protect*.

Figure 61: Black-hole MAC for EVPN loop protection shows a topology using black-hole MAC for EVPN loop protection.

Figure 61: Black-hole MAC for EVPN loop protection



VPLS 1 with EVI 1 is configured on all PEs. A backdoor link exists between PE-2 and PE-3 (in this case, caused by misconfiguration: additional SAPs are configured in VPLS 1). When CE-20 sends Broadcast, Unknown unicast, or Multicast (BUM) traffic, its source address MAC2 is learned by PE-2, which sends an EVPN-MAC route for MAC2 to its BGP peers. PE-2 floods the frame to its EVPN-MPLS destinations (PE-1 and PE-3) as well as its local SAPs (including the backdoor link to PE-3).

PE-3 receives the EVPN-MAC route from PE-2, but due to the backdoor link, it also learns MAC2 on its local SAP. Following the MAC mobility procedures, PE-3 advertises MAC2 with a higher sequence number to its BGP peers. PE-3 floods the frame to its EVPN-MPLS destinations and to its local SAPs.

Note:
The preceding simplified description assumes that PE-3 receives the EVPN-MAC route prior to learning MAC2 from the backdoor link, which may or may not be the case. Regardless of how MAC2 is learned, the MAC duplication procedures are invoked.

PE-2 and PE-3 keep learning and advertising MAC2 until the configured number of MAC moves (**num-moves**) has been reached. Then, MAC2 is detected as duplicate and will not be advertised again until the **retry** interval has expired.

If the **mac-duplication black-hole-dup-mac** option is configured, MAC2 will be added to the FDB as black-hole MAC, so traffic with MAC DA = MAC2 will be discarded. Also, MAC addresses assigned to a black-hole destination are considered as protected, so traffic with MAC SA = MAC2 will not be forwarded due to one of the following reasons:

- When the SAPs/SDP-bindings or BGP-EVPN MPLS/VXLAN destinations are configured with **restrict-protected-source discard-frame**, the frames are discarded before any MAC SA is learned or the MAC DA is looked up.
- When the SAP/SDP-binding is configured with **restrict-protected-source**, an incoming frame with MAC SA = black-hole MAC causes the system to bring down the corresponding SAP/SDP-binding.

Assuming PE-3 detects MAC2 as duplicate and installs it as black-hole MAC, PE-3 will discard the broadcast frames with MAC SA = MAC2, so the loop is broken, whereas the legitimate traffic between CE-10 and CE-20 is allowed (assuming PE-2 does not black-hole MAC2).

Black-hole MAC duplication is enabled with the **black-hole-dup-mac** keyword in the **mac-duplication** context, as follows:

```
*A:PE-3>config>service>vpls>bgp-evpn# mac-duplication ?
  - mac-duplication

 [no] black-hole-dup* - Enable/disable BGP-EVPN black-hole duplicate MAC traffic
      detect          - Configure BGP EVPN Mac Duplication Detection
 [no] retry           - Configure BGP EVPN Mac Duplication Retry
```

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                mac-duplication
                    black-hole-dup-mac
```

When enabled, the operation is as follows:

- Each node that learns a MAC address that has been advertised by a BGP peer will send an EVPN-MAC route for that MAC address with a higher sequence number. When the number of MAC moves exceeds the configured threshold (by default, five MAC moves in three minutes), the MAC address is detected as duplicate and no EVPN-MAC routes will be sent for that MAC address until the retry interval (default nine minutes) has elapsed.
- When MAC2 is detected as duplicate, the system will:
  - Add MAC2 to the duplicate MAC list
  - Add MAC2 in the FDB as protected MAC associated with a black-hole endpoint (type *EvpnD:P* and source identifier *black-hole*)
    - Incoming frames with MAC DA = MAC2 will be discarded based on a MAC lookup in the FDB.
    - MAC addresses assigned to a black-hole destination are protected and incoming frames with MAC SA = MAC2 will be discarded or the system will bring down the SAP/SDP-binding, depending on the **restrict-protected-src** setting on the SAP/SDP/EVPN endpoint.

The following output shows the FDB with black-hole MAC address ca:fe:02:20:20:20 (type EvpnD:P):

```
*A:PE-3# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1          ca:fe:01:10:10:10 mpls:                   Evpn     04/28/21 09:59:12
                             192.0.2.1:524284
           ldp:65537
1          ca:fe:02:20:20:20 black-hole              EvpnD:P  04/28/21 09:59:12
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

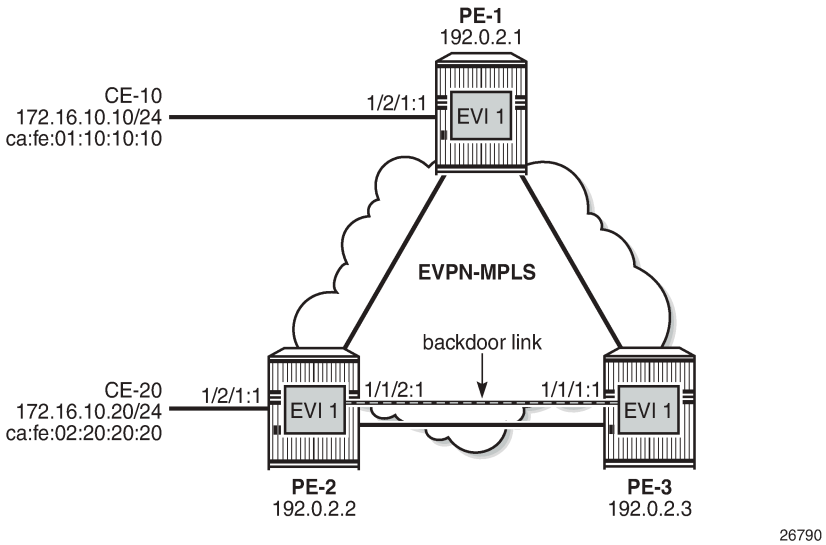
The duplicate MAC address will be removed from the FDB and the process will be restarted in the following cases:

- Retry interval events:
  - When the retry interval expires.
  - When the user configures **no retry** on the service that detected the duplicate MAC address.
- MAC relearning events:
  - When the remote PE withdraws the MAC address (due to aging or **clear service fdb**). Local attempts to clear a black-hole MAC (via **clear service fdb**) will fail because the type of the MAC entry is not "learned", but "EvpnD:P".
  - When configuring a local conditional static MAC address (CStatic:P) prevents the EvpnD:P entry for the same MAC address from being installed in the FDB as black-hole, if the SAP/SDP-binding where the MAC is configured is operationally up.
- CPM switchover event

Configuration

Figure 62: Example topology shows the example topology with three PEs and two CEs. A loop will occur when CE-20 sends Broadcast, Unknown unicast, or Multicast (BUM) traffic. Traffic between PE-2 and PE-3 will be sent over the regular router interfaces between the PEs, but also over the backdoor link (SAP 1/1/2:1 in VPLS 1 on PE-2 and SAP 1/1/1:1 in VPLS 1 on PE-3).

Figure 62: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces (alternatively, OSPF can be used)
- LDP on all router interfaces

Enable black-hole MAC duplication detection in EVPN

BGP is configured for address family EVPN on all PEs with PE-3 as route reflector. The following is the BGP configuration on PE-3:

```
# on PE-3:
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 192.0.2.3
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
            exit
        exit
```

VPLS 1 is configured on all PEs with BGP-EVPN and MAC duplication enabled; on PE-2, as follows:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mac-duplication
                    detect num-moves 3 window 1
                    retry 2
                    black-hole-dup-mac
                exit
                mpls bgp 1
                    restrict-protected-src discard-frame
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/1/2:1 create                          # backdoor link to PE-3
            exit
            sap 1/2/1:1 create                          # to CE-20
            exit
            no shutdown
        exit
```

To speed up MAC duplication detection, MAC duplication is detected after three MAC moves (default: five MAC moves). To shorten the retry interval, the time window is reduced to one minute (default: three minutes). When a MAC address has been detected as duplicated, the system removes the duplicate MAC entry after a retry interval of two minutes (default: nine minutes). The retry interval must be at least twice the time window for MAC duplication detection.

On the EVPN-MPLS endpoints, **restrict-protected-src discard-frame** must be configured. When MAC address ca:fe:02:20:20:20 is detected on PE-3 as a duplicate MAC address that is black-holed, the EVPN-MPLS endpoints on PE-3 should discard all frames with MAC SA ca:fe:02:20:20:20.

The configuration on the other PEs is similar; only the SAPs are different. VPLS 1 on PE-1 has SAP 1/2/1:1 to CE-10, but no SAP to a backdoor link; VPLS 1 on PE-3 has SAP 1/1/1:1 to the backdoor link to PE-2, but no SAP to a CE.

When CE-20 sends BUM traffic, its MAC SA ca:fe:02:20:20:20 is learned by PE-2 and advertised in EVPN-MAC routes. Because of the backdoor link to PE-3, PE-3 also learns MAC SA ca:fe:02:20:20:20 and advertises it to its BGP peers. The MAC-mobility sequence number is increased until the threshold of three MAC moves is reached. The following BGP EVPN-MAC route with sequence number 2 is sent by PE-2 to PE-3:

```
# on PE-2:
17 2021/04/28 09:59:11.599 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

===============================================================================
---snip---
```

The following message is logged in log "99" on PE-3 when VPLS 1 has detected duplicate MACs:

```
# on PE-3:
69 2021/04/28 10:04:40.266 UTC MINOR: SVCMGR #2331 Base
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

MAC address ca:fe:02:20:20:20 remains in the FDB as duplicate and black-holed until the retry interval expires, as follows:

```
*A:PE-3>config>service>vpls>bgp-evpn>mac-duplication# retry ?
  - no retry
  - retry <minutes>

 <minutes>            : [2..60]
```

By default, the retry interval is nine minutes, but in this example, it is set to two minutes, which is the minimum value. The retry interval must be at least twice the time window for MAC duplication detection,

which is by default three minutes, but reduced to one minute in this example. The following error is raised when attempting to configure a retry interval of two minutes for a detection time window of three minutes:

```
*A:PE-3>config>service>vpls>bgp-evpn>mac-duplication# retry 2
MINOR: SVCMGR #1003 Inconsistent value - mac-duplication detection retry time should be atleast
 twice that of detect window
```

After the retry interval expires, the MAC duplication is released.

Log "99" shows the following message when VPLS 1 no longer has duplicate MAC addresses:

```
# on PE-3:
70 2021/04/28 10:06:43.398 UTC MINOR: SVCMGR #2332 Base
"VPLS Service 1 no longer has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

MAC address ca:fe:02:20:20:20 remains in the FDB with type Evpn instead of EvpnD:P. BGP routes only disappear after a withdraw message has been received, whereas locally learned MAC addresses are flushed.

```
*A:PE-3# show service id 1 fdb mac ca:fe:02:20:20:20

Clear commands

The following FDB entry on PE-3 of type EvpnD:P cannot be cleared with a normal FDB **clear** command:

```
*A:PE-3# show service id 1 fdb mac ca:fe:02:20:20:20

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1          ca:fe:02:20:20:20 black-hole              EvpnD:P  04/28/21 10:07:52
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The following error is raised when attempting to clear this FDB entry:

```
*A:PE-3# clear service id 1 fdb mac ca:fe:02:20:20:20
MAJOR: LOG #1202 Cannot perform clear operation - Entry is not of learned type
```

Log "99" shows the following message:

```
72 2021/04/28 10:08:17.960 UTC INDETERMINATE: LOGGER #2010 Base Clear SVCMGR
"Clear function clearSvcIdFdbMac has been run with parameters: svc-id="1" mac=
"ca:fe:02:20:20:20".  The completion result is: failure.  Additional error text, if any, is:
 Entry is not of learned type"
```

The following **clear** command releases the MAC duplication from the entry in the FDB, but it does not remove the entry from the FDB if it was learned from EVPN. The type is changed from EvpnD:P to Evpn.

```
*A:PE-3# clear service id 1 evpn mac-dup-detect ca:fe:02:20:20:20
```

```
*A:PE-3# show service id 1 fdb mac ca:fe:02:20:20:20

```

Restrict Protected Source option

By default, the frames with MAC SA or DA equal to the duplicate MAC address are discarded, but the SAP/SDP-binding where the frame enters the VPLS remains operationally up. With the **restrict-protected-src** option, the system will bring the SAP/SDP-binding down where the frame with duplicate source MAC enters. The configuration on PE-2 and PE-3 is modified with **restrict-protected-src** on the SAP to the backdoor link, as follows:

```
# on PE-2:
configure
    service
        vpls "VPLS 1"
            sap 1/1/2:1
                restrict-protected-src

# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/1/1:1
                restrict-protected-src
```

When CE-20 sends BUM traffic, PE-3 detects MAC ca:fe:02:20:20:20 as duplicate. Log "99" shows that a duplicate MAC address has been detected, that protected MAC address ca:fe:02:20:20:20 has been received on SAP 1/1/1:1 in VPLS 1, and that the status of SAP 1/1/1:1 in VPLS 1 is changed to operationally down, with flag *RxProtSrcMac* indicating that a protected source MAC has been received.

```
80 2021/04/28 10:11:40.885 UTC MINOR: SVCMGR #2203 Base
"Status of SAP 1/1/1:1 in service 1 (customer 1) changed to admin=up oper=down flags=RxProtSrc
Mac "

79 2021/04/28 10:11:40.885 UTC MINOR: SVCMGR #2208 Base
"Protected MAC ca:fe:02:20:20:20 received on SAP 1/1/1:1 in service 1. The SAP will be
 disabled."

78 2021/04/28 10:11:39.886 UTC MINOR: SVCMGR #2331 Base
"VPLS Service 1 has MAC(s) detected as duplicates by EVPN mac-duplication detection."
```

The following shows that SAP 1/1/1:1 in VPLS 1 on PE-3 is operationally down with flag RxProtSrcMac:

```
*A:PE-3# show service id 1 sap 1/1/1:1

===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 1

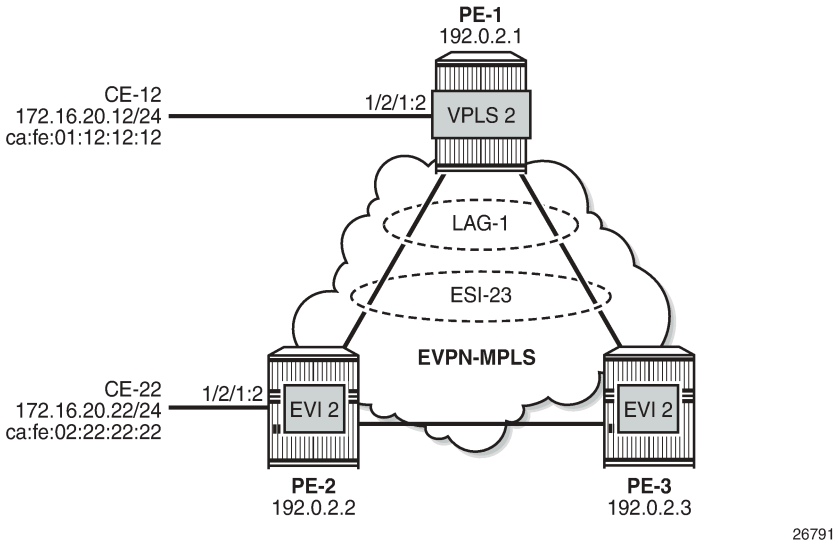
Black-hole MAC duplication in all-active multi-homing

Figure 63: Example topology with all-active multi-homing shows the example topology with all-active multi-homing.

Figure 63: Example topology with all-active multi-homing



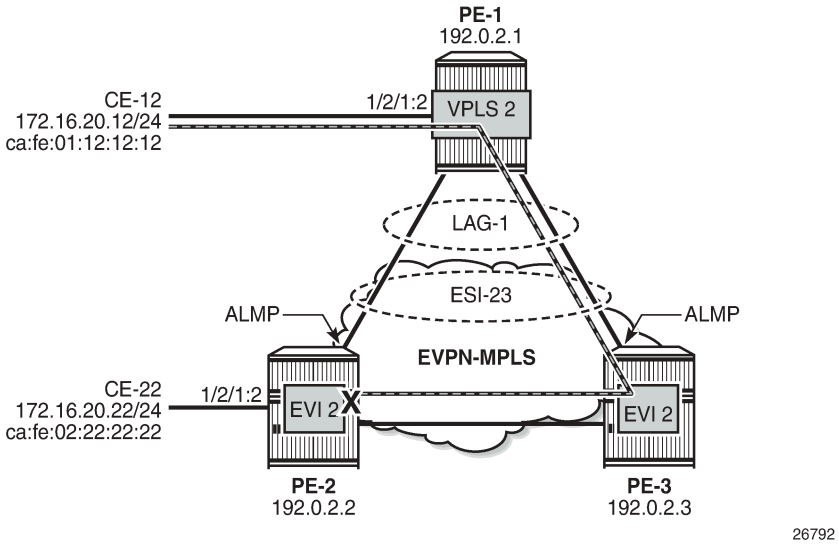
In this topology, the backdoor link is removed. On PE-1, VPLS 2 is configured without EVPN; on PE-2 and PE-3, VPLS 2 is configured with EVPN-MPLS. LAG 1 is configured on the PEs and Ethernet Segment (ES) ESI-23 is created on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
```

```
        system
            bgp-evpn
                ethernet-segment "ESI-23" create
                    esi 01:00:00:00:00:23:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
```

The reason why black-hole MAC duplication should be configured instead of ALMP is the following. When ALMP is configured on SAP lag-1:2 on PE-2 and PE-3, MAC address ca:fe:01:12:12:12 of CE-12 is learned and protected on the SAP on both PEs. Traffic sent from CE-12 to CE-22 that is hashed over the direct link between PE-1 and PE-2 will reach its destination. Traffic that is hashed over the link between PE-1 and PE-3 will be forwarded by PE-3 to PE-2, but PE-2 will drop the traffic because it contains a MAC SA that is protected locally, as shown in Figure 64: Traffic dropped when ALMP is configured in all-active multi-homing.

Figure 64: Traffic dropped when ALMP is configured in all-active multi-homing



When black-hole MAC duplication is configured instead of ALMP, traffic hashed on the link to PE-3 is forwarded to PE-2 and to CE-22. This is because MAC duplication is ES-aware and the same MAC seen on the same ES in two different PEs will never be detected as duplicate.

The configuration of VPLS 2 in PE-2 is as follows:

```
# on PE-2:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 2
                mac-duplication
```

```
                black-hole-dup-mac
            exit
            mpls bgp 1
                restrict-protected-src discard-frame
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/2/1:2 create
            no shutdown
        exit
        sap lag-1:2 create
            no shutdown
        exit
        no shutdown
```

The configuration of VPLS 2 on PE-3 is similar.

Conclusion

Black-hole MAC for EVPN MAC duplication protects EVPN services against customer-created backdoors or loops, while supporting MAC mobility and all-active multi-homing.

Conditional Static Black-Hole MAC in EVPN

This chapter provides information about Conditional Static Black-Hole MAC in EVPN.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the CLI in the current edition is based on SR OS Release 21.2.R1. Conditional static black-hole MAC is supported on EVPN services only, including EVPN-VXLAN and EVPN-MPLS, in SR OS Release 14.0.R1, and later.

Overview

A static black-hole MAC address is a local FDB record associated with a black-hole instead of a SAP or SDP-binding. Black-hole MAC addresses offer a scalable way to filter frames in the data plane based on MAC DA or SA, regardless of how the frame is arriving in the system. Black-hole MAC addresses can be configured in EVPN in the following ways:

- Static configured black-hole MAC address
- Anti-spoof MAC address in proxy Address Resolution Protocol/Neighbor Discovery (proxy-ARP/ND)
- MAC-duplication black-hole (supported in SR OS Release 15.0.R1, and later), see chapter Black-hole MAC for EVPN Loop Protection

When a specific MAC address is configured as a static black-hole MAC address, all frames with MAC DA equal to this black-hole MAC address will be dropped. Also, black-hole MAC addresses are treated as protected MAC addresses, which allows filtering on MAC SA; see chapter Auto-Learn MAC Protect in EVPN.

The default behavior on the SAP/SDP-bindings is Restricted Protected Source Discard Frame (RPS-DF). Therefore, all frames with MAC SA equal to the black-hole MAC address will, by default, be dropped on the SAP/SDP-binding where the frames enter the service. Instead of dropping the frames, the entire SAP/SDP-binding can be brought operationally down, if the SAP/SDP-binding is explicitly configured with Restricted Protected Source (RPS) without any parameter. The SAP/SDP-binding can only be brought up manually by disabling (shutdown) and re-enabling (no shutdown) the SAP/SDP-binding. On the EVPN endpoints between PEs, it is possible to configure RPS-DF, not RPS. When configured, the EVPN endpoint will drop frames with MAC SA equal to the black-hole MAC address.

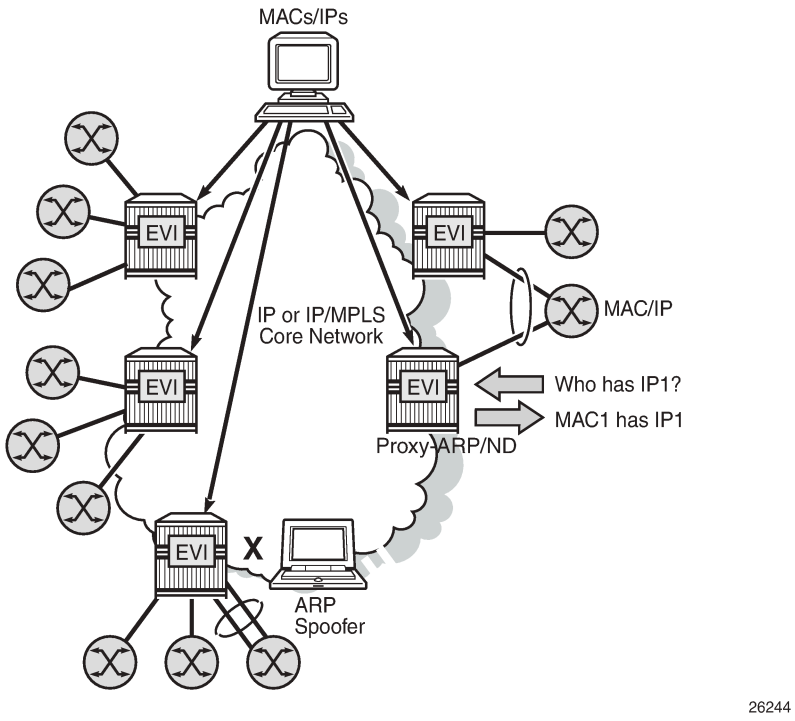
Black-hole MAC addresses can be used as an alternative to MAC filters, which simplifies the deployment of proxy-ARP/ND with anti-spoof MAC addresses. ARP/ND spoofing is a technique whereby an attacker sends fake ARP/ND messages to a broadcast domain. Generally, the aim is to get the routers in the broadcast domain to associate the attacker's MAC address with the IP address of another host, causing any traffic destined to that IP address to be sent to the attacker instead. To prevent this from happening, a proxy-ARP/ND with duplicate IP detection monitors the number of times the MAC changes for an offending

IP address. When a certain number of MAC moves are detected in a defined period, the system flags the proxy-ARP entry as duplicate for a defined hold time and an alarm is sent to log 99.

Chapter EVPN for MPLS Tunnels describes the proxy-ARP/ND configuration with the option to define an anti-spoof MAC (AS-MAC) address for EVPN-MPLS networks using MAC filters, including some recommended settings. The AS-MAC address will be advertised with the duplicate IP address in gratuitous ARP (GARP) and ARP replies to all CEs in the EVPN (in the case of proxy-ND, unsolicited Neighbor Advertisement messages are sent instead of GARP messages).

ARP/ND broadcast traffic is a security issue for Internet eXchange Providers (IXPs) and service providers with large Layer 2 domains. In such networks, administrators try to avoid ARP/ND flooding. Figure 65: Proxy-ARP/ND and ARP spoofing shows the proxy-ARP/ND feature where local ARP/ND requests are responded by the system on behalf of the IP interface owners.

Figure 65: Proxy-ARP/ND and ARP spoofing



EVPN can suppress ARP/ND flooding within an EVPN service if all the attached hosts advertise their presence. Therefore, EVPN is preferred in IXPs to mitigate and even eliminate the ARP/ND flooding issue. The proxy-ARP/ND agent responds to local ARP/ND requests using a proxy-ARP/ND table per service. This table is populated by EVPN entries (MAC-IP pairs), static entries configured in the service, and dynamic entries snooped from ARP/GARP/ND messages sent by the ISP routers. The static entries and snooped dynamic entries are also advertised in EVPN-MAC routes.

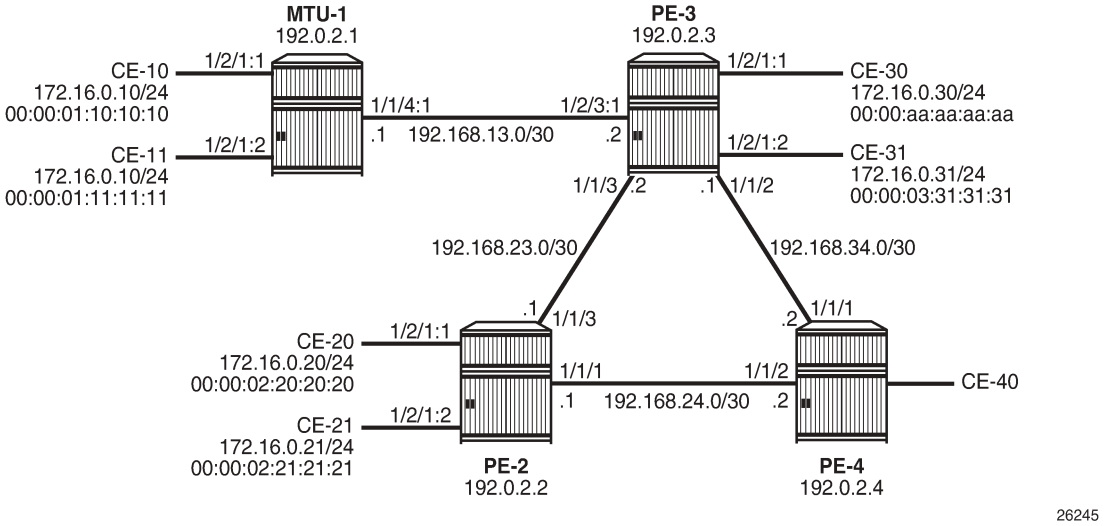
As well as the proxy-ARP/ND, SR OS supports an anti-spoofing mechanism that can detect and block an ARP spoofing attack or a misconfigured duplicated IP address. When using MAC filters, the same anti-spoof-mac option must be configured in all the PEs and this filter may be configured on all the PE SAPs/SDP-bindings to discard all the frames with MAC DA equal to the anti-spoof MAC address. This requires a lot of configuration and is prone to configuration errors.

Conditional static black-hole MAC addresses can be configured for the anti-spoof MAC address so that frames with MAC DA equal to the anti-spoof MAC address can be discarded based on a MAC address lookup in the FDB, as opposed to a MAC filter entry. Less configuration is required and this simplifies the deployment of proxy-ARP/ND with AS-MAC. The configuration example in this chapter includes proxy-ARP, but the behavior is similar for proxy-ND.

Configuration

Figure 66: Example topology shows the example topology. Traffic will be sent between the CEs and may be dropped in the PEs if the MAC DA or MAC SA matches a black-hole MAC address. IP address 172.16.0.10/24 is duplicate (CE-10 and CE-11).

Figure 66: Example topology



The initial configuration on the nodes includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PEs
- LDP between PEs

BGP is configured between the PEs for address family EVPN with PE-2 as route reflector (RR). Instead of an RR, a full mesh can also be configured between the PEs. The BGP configuration on PE-2 is as follows:

```
# on RR PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
```

```
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
        exit
```

VPLS 1 is configured on all PEs and on MTU-1 (MTU-1's VPLS 1 is connected to PE-3 by a SAP). The VPLS configuration on the PEs includes EVPN-MPLS, as follows:

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            sap 1/2/3:1 create
                no shutdown
            exit
            no shutdown
        exit
```

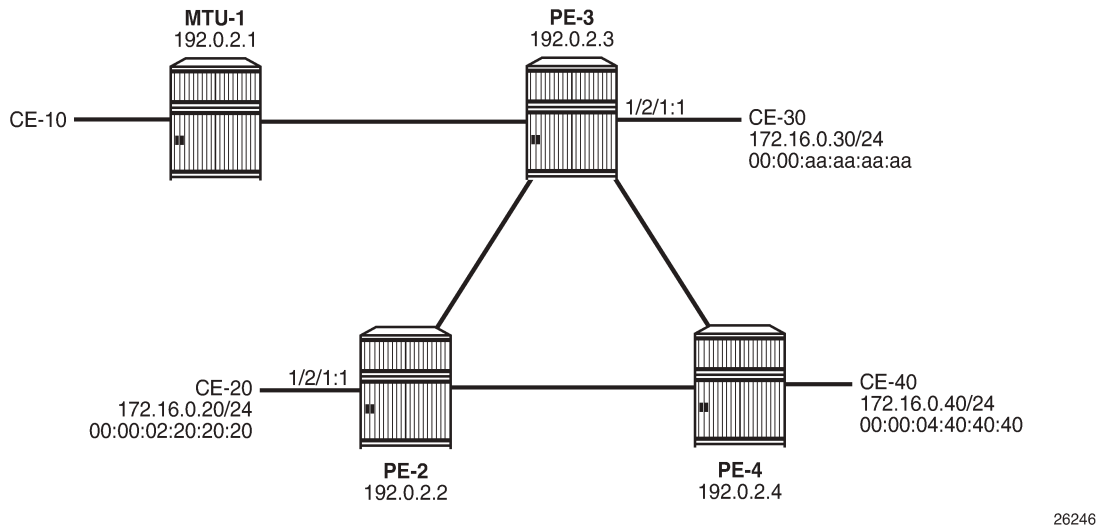
Conditional static black-hole MAC

Conditional static black-hole MAC address is an extension to the conditional static MAC address, but with the **black-hole** keyword. It is a scalable way to filter MAC DA or SA in the data plane, regardless of how the frame is arriving at the system (SAP/SDP-bindings or EVPN termination endpoints).

When the static black-hole MAC is added to the FDB, all Ethernet frames with MAC DA equal to the black-hole MAC are dropped. Filtering based on the MAC SA is explained in the next section: Conditional static black-hole MAC in combination with restrict protected source.

Figure 67: Conditional static black-hole MAC shows the example setup with conditional static black-hole MAC 00:00:aa:aa:aa:aa.

Figure 67: Conditional static black-hole MAC



When no conditional static black-hole MAC is configured, CE-30 can receive and send traffic from and to the other CEs; for instance, from and toward CE-20, as follows:

```
*A:PE-2# ping router 10 172.16.0.30
PING 172.16.0.30 56 data bytes
64 bytes from 172.16.0.30: icmp_seq=1 ttl=64 time=0.836ms.
64 bytes from 172.16.0.30: icmp_seq=2 ttl=64 time=0.841ms.
---snip---

*A:PE-3# ping router 10 172.16.0.20
PING 172.16.0.20 56 data bytes
64 bytes from 172.16.0.20: icmp_seq=1 ttl=64 time=3.69ms.
64 bytes from 172.16.0.20: icmp_seq=2 ttl=64 time=0.814ms.
---snip---
```

In this example, CE-20 and CE-30 correspond to VPRN 10 configured on PE-2 and PE-3 (using a hairpin to loop the traffic back to the PE).

Conditional static black-hole MAC 00:00:aa:aa:aa:aa (which corresponds to the MAC address of CE-30) is configured in VPLS 1 on PE-3 as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                mac 00:00:aa:aa:aa:aa create black-hole
```

The black-hole MAC is added as a conditional static (CStatic) MAC that is protected (P), as follows:

```
*A:PE-3# show service id 1 fdb mac 00:00:aa:aa:aa:aa

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
```

```
            Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1          00:00:aa:aa:aa:aa black-hole              CStatic: 03/24/21 15:46:33
                                                     P
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The source identifier is black-hole and it is applicable to frames that enter the VPLS on this node, regardless of how they enter the VPLS (SAP, SDP-binding, or EVPN endpoint).

The conditional static black-hole MAC is advertised to the BGP peers in a BGP-EVPN MAC route with the sticky/static bit set, as follows:

```
# on PE-3:
9 2021/03/24 15:46:32.883 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"
```

The MAC route is added to the FDB on the other PEs as a static (S) and protected (P) MAC; for example, on PE-2, as follows:

```
*A:PE-2# show service id 1 fdb mac 00:00:aa:aa:aa:aa

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age

-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

When CE-20 sends an ICMP request to CE-30, the MAC DA 00:00:aa:aa:aa:aa is black-holed on PE-3, and no ICMP request succeeds, as follows:

```
*A:PE-2# ping router 10 172.16.0.30
PING 172.16.0.30 56 data bytes
Request timed out. icmp_seq=1.
Request timed out. icmp_seq=2.
Request timed out. icmp_seq=3.
Request timed out. icmp_seq=4.
```

```
Request timed out. icmp_seq=5.

---- 172.16.0.30 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

The port statistics show that the traffic was sent from PE-2 to PE-3, where it entered on port 1/1/3, then got discarded. To verify this, the port statistics are cleared on PE-2 and PE-3, then 1000 ICMP packets are sent from CE-20, as follows:

```
*A:PE-2# clear port 1/[1..2]/[1..4] statistics
*A:PE-3# clear port 1/[1..2]/[1..4] statistics
*A:PE-2# ping router 10 172.16.0.30 rapid count 1000
---snip---
1000 packets transmitted, 0 packets received, 100% packet loss
```

The 1000 packets are received at SAP 1/2/1:1 on PE-2, as follows:

```
*A:PE-2# show port 1/2/1 statistics

===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                        Ingress Packets                 Ingress Octets
Id                           Egress Packets                  Egress Octets
-------------------------------------------------------------------------------
1/2/1                                  1000                          106000
                                          0                               0
===============================================================================
```

These packets are forwarded to port 1/1/3 toward PE-3, as follows:

```
*A:PE-2# show port 1/1/3 statistics

===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                        Ingress Packets                 Ingress Octets
Id                           Egress Packets                  Egress Octets
-------------------------------------------------------------------------------
1/1/3                                    13                            1306
                                       1013                          125254
===============================================================================
```

On the interfaces between the PEs, other packets are sent besides the ICMP requests, such as IS-IS messages; therefore, the number of packets is slightly greater than 1000.

On PE-3, these packets are received on port 1/1/3, as follows:

```
*A:PE-3# show port 1/1/3 statistics

===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                        Ingress Packets                 Ingress Octets
Id                           Egress Packets                  Egress Octets
-------------------------------------------------------------------------------
1/1/3                                  1024                          126444
                                         24                            2351
===============================================================================
```

The FDB entry for this MAC DA is black-holed and no traffic is received on SAP 1/2/1:1 toward CE-30; therefore, the statistics for port 1/2/1 are empty and nothing is displayed, as follows:

```
*A:PE-3# show port 1/2/1 statistics
*A:PE-3#
```

It is possible to configure the black-hole MAC address on a different PE; for example, on PE-4 instead of PE-3. The conditional static black-hole MAC address configuration in VPLS 1 on PE-3 is removed, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                no mac 00:00:aa:aa:aa:aa
```

The conditional static black-hole MAC is configured on PE-4 instead, as follows:

```
# on PE-4:
configure
    service
        vpls "VPLS 1"
            static-mac
                mac 00:00:aa:aa:aa:aa create black-hole
```

PE-4 sends EVPN-MAC updates to its peers. PE-2 learns that all traffic with MAC DA 00:00:aa:aa:aa:aa should be redirected to PE-4, as shown in the FDB on PE-2:

```
*A:PE-2# show service id 1 fdb mac 00:00:aa:aa:aa:aa

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

                                         24                           2351
===============================================================================
```

The configuration is restored with conditional static black-hole MAC in VPLS 1 on PE-3, not on PE-4, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                mac 00:00:aa:aa:aa:aa create black-hole
```

```
# on PE-4:
configure
    service
        vpls "VPLS 1"
            static-mac
                no mac 00:00:aa:aa:aa:aa
```

Conditional static black-hole MAC in combination with restrict protected source

For Ethernet frames with MAC SA equal to the static black-hole MAC, the treatment is the same as for protected MACs (see chapter Auto-Learn MAC Protect in EVPN), but for conditional static black-hole MACs, ALMP need not be enabled on the SAP or SDP-binding:

- When a frame is received with MAC SA equal to the black-hole MAC, it is dropped, because RPS-DF is enabled on the SAP or SDP-binding, by default. RPS-DF need not be enabled explicitly. The default is **no restrict-protected-src**, which operates as RPS-DF. An error message is raised when the following command is entered:

```
*A:PE-3>config>service>vpls>sap# restrict-protected-src discard-frame
MINOR: SVCMGR #7888 Cannot be configured/enabled with EVPN
```

- When RPS is enabled instead of RPS-DF, the SAP or SDP-binding where the frame was received, with MAC SA equal to the black-hole MAC, is brought operationally down. The SAP or SDP-binding can be brought up manually by disabling (shutdown) and re-enabling (no shutdown) the SAP or SDP-binding. RPS is enabled on SAP 1/2/1:1 as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/1:1
                restrict-protected-src
```

- Optionally, RPS-DF can be enabled on the EVPN-MPLS endpoint or EVPN-VXLAN endpoint. When enabled, the EVPN endpoint will discard frames with MAC SA equal to the black-hole MAC. RPS cannot be configured instead of RPS-DF on EVPN endpoints. It is not an option to bring the EVPN endpoint down when a frame is received with MAC SA equal to the static black-hole MAC. The commands to enable RPS-DF on the EVPN-MPLS endpoints and EVPN-VXLAN endpoints are as follows:

```
*A:PE-3>config>service>vpls>bgp-evpn>mpls# restrict-protected-src ?
  - no restrict-protected-src
  - restrict-protected-src discard-frame

 <discard-frame>      : keyword - discard frame and  trap on a protected MAC
```

```
*A:PE-3>config>service>vpls>vxlan$ restrict-protected-src ?
  - no restrict-protected-src
  - restrict-protected-src discard-frame
```

With the default configuration (RPS-DF on SAP/SDP-bindings), the behavior is as follows for conditional static black-hole MAC 00:00:aa:aa:aa:aa configured in VPLS 1 on PE-3. All traffic from CE-30 with MAC SA 00:00:aa:aa:aa:aa is black-holed on SAP 1/2/1:1 on PE-3, because the default behavior on SAP 1/2/1:1 is RPS-DF, and the frame is discarded. The packets are received on port 1/2/1 (SAP 1/2/1:1) and dropped. No packets are forwarded to port 1/1/3 toward PE-2 or any other port.

```
*A:PE-3# clear port 1/[1..2]/[1..4] statistics
*A:PE-3# ping router 10 172.16.0.20 rapid count 1000
---snip---
1000 packets transmitted, 0 packets received, 100% packet loss
*A:PE-3# show port 1/[1..2]/[1..4] statistics
```

```

===============================================================================
```

If the static MAC is configured in VPLS 1 on PE-4 and not on PE-3, PE-3 will still discard the packets with MAC SA 00:00:aa:aa:aa:aa arriving on SAP 1/2/1:1, because it learned from the EVPN-MAC updates that MAC 00:00:aa:aa:aa:aa is a protected MAC on PE-4. Therefore, traffic with this MAC SA is not expected and not allowed on PE-3, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                no mac 00:00:aa:aa:aa:aa
```

```
# on PE-3:
configure

                no mac 00:00:aa:aa:aa:aa
```

Optionally, RPS-DF can be configured on the EVPN-MPLS endpoints on the PEs, as follows:

```
# on PE-2, PE-3, PE-4:
configure
    service
```

```
        vpls "VPLS 1"
            bgp-evpn
                mpls bgp 1
                    restrict-protected-src discard-frame
```

When RPS-DF is configured on the EVPN-MPLS endpoints, frames with MAC SA 00:00:aa:aa:aa:aa can be discarded by the EVPN endpoints between the PEs. However, in this example this is not required, because any frame with MAC SA 00:00:aa:aa:aa:aa will be dropped by the local SAP before it can be forwarded to an EVPN endpoint.

It is possible to configure RPS without any parameters on SAP 1/2/1:1 on PE-3, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/1:1
                restrict-protected-src
```

When CE-30 sends traffic with MAC SA equal to a protected MAC address (black-hole or not), the entire SAP 1/2/1:1 will be brought operationally down, as follows:

```
*A:PE-3# ping router 10 172.16.0.20
PING 172.16.0.20 56 data bytes
Request timed out. icmp_seq=1.
Request timed out. icmp_seq=2.
---snip---
---- 172.16.0.20 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

```
*A:PE-3# show service id 1 sap

===============================================================================

```

Log 99 shows that a protected MAC was received on SAP 1/2/1:1 and the SAP went operationally down with flag RxProtSrcMac, as follows:

```
107 2021/03/24 15:54:05.661 UTC MINOR: SVCMGR #2208 Base
"Protected MAC 00:00:aa:aa:aa:aa received on SAP 1/2/1:1 in service 1. The SAP will be
 disabled."

108 2021/03/24 15:54:05.662 UTC MINOR: SVCMGR #2203 Base
"Status of SAP 1/2/1:1 in service 1 (customer 1) changed to admin=up oper=down flags=RxProtSrc
Mac "
```

The SAP can only be brought up manually by disabling and re-enabling the SAP, as follows:

```
*A:PE-3# configure service vpls "VPLS 1" sap 1/2/1:1 shutdown
*A:PE-3# configure service vpls "VPLS 1" sap 1/2/1:1 no shutdown
```

```
*A:PE-3# show service id 1 sap

===============================================================================

===============================================================================
```

The default behavior of SAP 1/2/1:1 is RPS-DF, which is configured by removing the RPS configuration, as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            sap 1/2/1:1
                no restrict-protected-src
```

The conditional static black-hole MAC configuration is removed as follows:

```
# on PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                no mac 00:00:aa:aa:aa:aa
```

Black-hole MAC in services with proxy-ARP/ND

In this example, only proxy-ARP is shown, not proxy-ND. However, the configuration and procedures for proxy-ND would be equivalent.

First, the implementation of proxy-ARP and AS-MAC is described without static black-hole MAC addresses. MAC filters will be required to drop or redirect traffic, but these are not shown in the example. Configuring MAC filters and applying them on SAP/SDP-bindings is labor-intensive and can be error-prone. Afterward, the implementation with AS-MAC as static black-hole is described.

Services with proxy-ARP and AS-MAC - no static black-hole MAC

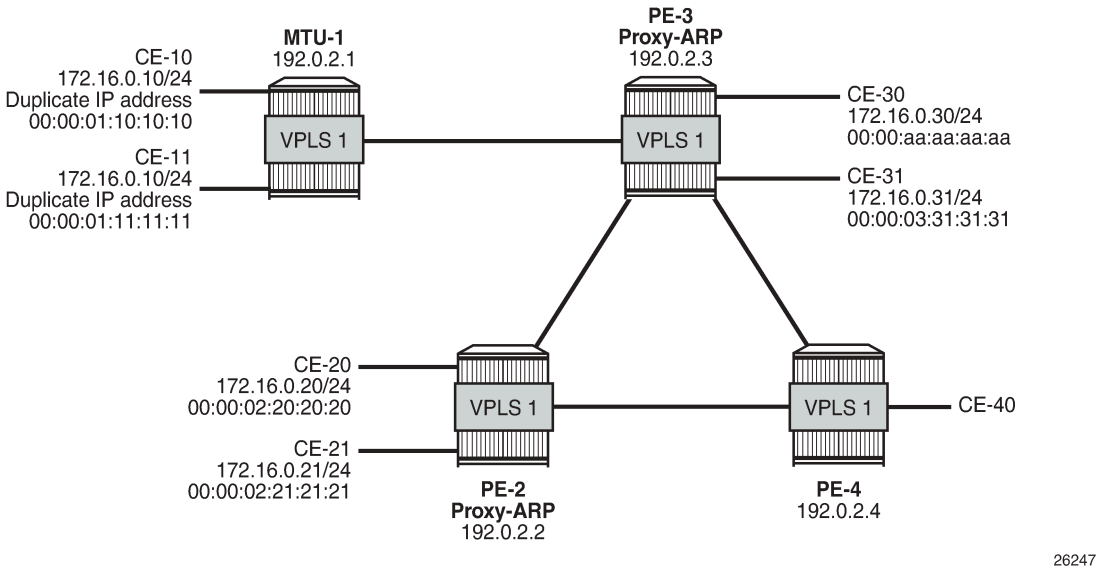
IP duplication works when the IP address moves between:

- Dynamic (learned on SAP) and EVPN
- EVPN and dynamic
- Dynamic and dynamic

The following example shows IP address moves from dynamic to dynamic between SAP 1/2/1:1 (to CE-10) and SAP 1/2/1:2 (to CE-11) in VPLS 1 on MTU-1. However, the duplicate IP address could have been in PE-3 and MTU-1 instead (EVPN or dynamic) and still the IP address would have been detected as duplicate.

Figure 68: VPLS 1 with proxy-ARP and AS-MAC shows the example setup with duplicate IP address 172.16.0.10/24 for CE-10 and CE-11. VPLS 1 is configured with proxy-ARP with duplicate IP detection in PE-2 and PE-3 (and possibly also in other PEs). MAC address 00:00:bb:bb:bb:bb is configured as AS-MAC, which will be used when a duplicate IP address has been detected.

Figure 68: VPLS 1 with proxy-ARP and AS-MAC



For IP duplication detection, the following parameters can be customized so that the system can react to particular conditions in the network. The syntax is as follows:

```
*A:PE-3>config>service>vpls>proxy-arp$ dup-detect ?
  - dup-detect [anti-spoof-mac <mac-address>] window <minutes> num-moves <count>
               hold-down <minutes|max>
  - dup-detect anti-spoof-mac <mac-address> window <minutes> num-moves <count>
               hold-down <minutes|max> [static-black-hole]
```

```
 <mac-address>        : xx-xx-xx-xx-xx-xx or xx:xx:xx:xx:xx:xx (hex chars)
 <minutes>            : [1..15] minutes - default:3
 <count>              : [3..10] - default:5
 <minutes|max>        : [2..60] default=9 | max - permanent hold
 <static-black-hole>  : keyword
```

In VPLS 1 on PE-3, a proxy-ARP with duplicate IP detection is configured, including an optional anti-spoof MAC (AS-MAC) 00:00:bb:bb:bb:bb for offending IP addresses, as follows:

```
#on PE-3:
configure
    service
        vpls "VPLS 1"
            proxy-arp
                dup-detect window 3 num-moves 3 hold-down max
                           anti-spoof-mac 00:00:bb:bb:bb:bb
                dynamic-arp-populate
                static 172.16.0.20 00:00:02:20:20:20
                no shutdown
            exit
```

The proxy-ARP table contains one static entry (for IP 172.16.0.20). In this case, dynamic ARP populate is enabled. Therefore, the proxy-ARP table will be updated with ARP entries for IP 172.16.0.10 and MAC 00:00:01:10:10:10 or MAC 00:00:01:11:11:11 for frames originating from CE-10 or CE-11.

When a duplicate IP is detected for IP 172.16.0.10 (after three changes of MAC for IP 172.16.0.10 in a period of three minutes), the corresponding ARP entry contains the duplicate IP address 172.16.0.10 and the AS-MAC 00:00:bb:bb:bb:bb and its type is duplicate (dup). Therefore, this ARP entry is always active until it is removed. Until now, this configuration does not include a static black-hole MAC, and this option is by default disabled. This configuration for duplicate IP detection can be used in combination with MAC filters. The configuration with static black-hole MAC is shown in the section Services with proxy-ARP and AS-MAC configured as static black-hole MAC.

The configured AS-MAC will be advertised in an EVPN-MAC route with the sticky/static bit set and without any IP address (because there is no IP duplication detected yet), as follows:

```
# on PE-3:
28 2021/03/24 16:01:30.827 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

Debugging is enabled for proxy-ARP for IP address 172.16.0.10 in VPLS 1 on PE-3, as follows:

```
# on PE-3:
debug
    service
        id 1
            proxy-arp ip 172.16.0.10
```

When traffic is sent from CE-11 to CE-21, a dynamic ARP entry for IP address 172.16.0.10 and MAC 00:00:01:11:11:11 is added to the proxy-ARP table for VPLS 1 in PE-3, and an EVPN-MAC update is sent to the peer PEs, as follows:

```
# on PE-3:
35 2021/03/24 16:06:02.919 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 evpn advertise"

        bgp-tunnel-encap:MPLS
"
```

There is no duplicate IP detected yet.

CE-10 and CE-11 have the same IP address for different MAC addresses. When CE-10 sends traffic to CE-20, the ARP entry for IP 172.16.0.10 changes MAC from 00:00:01:11:11:11 to 00:00:01:10:10:10, and an EVPN-MAC withdraw message is sent, as follows:

```
# on PE-3:
38 2021/03/24 16:06:07.137 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 evpn withdraw"

39 2021/03/24 16:06:07.137 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:01:10:10:10 "

40 2021/03/24 16:06:07.137 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 46
    Flag: 0x90 Type: 15 Len: 42 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48
                   mac: 00:00:01:11:11:11, IP len: 4, IP: 172.16.0.10, label1: 0
"
```

When the MAC changes, the system sends an ARP request for confirmation of the old MAC 00:00:01:11:11:11 for IP 172.16.0.10, as follows:

```
# on PE-3:
41 2021/03/24 16:06:07.290 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 confirm"
```

When MAC 00:00:01:11:11:11 is confirmed, the MAC in the ARP entry is changed once again to 00:00:01:11:11:11 and another ARP request is sent asking to confirm MAC 00:00:01:10:10:10 for IP 172.16.0.10, as follows:

```
# on PE-3:
42 2021/03/24 16:06:11.147 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:10:10:10->00:00:01:11:11:11 "

43 2021/03/24 16:06:11.290 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 confirm"
```

When CE-10 confirms MAC 00:00:01:10:10:10 for IP 172.16.0.10, IP duplication is detected for IP address 172.16.0.10 (after three MAC moves in a detection period of three minutes), and the following message is raised in log 99 after a duplicate proxy-ARP entry was detected for IP 172.16.0.10:

```
# log "99" on PE-3:
136 2021/03/24 16:06:15.358 UTC MINOR: SVCMGR #2346 Base
"A duplicate proxy ARP entry was detected with new MAC 00:00:01:10:10:10 for entry
IP 172.16.0.10 MAC 00:00:01:11:11:11 in service 1"
```

The following proxy-ARP debug messages show that the ARP entry for IP 172.16.0.10 in the proxy-ARP table changed MAC to the AS-MAC 00:00:bb:bb:bb:bb, and the type from dynamic to duplicate:

```
# on PE-3:
```

```
44 2021/03/24 16:06:15.357 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn advertise"

45 2021/03/24 16:06:15.358 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:bb:bb:bb:bb Type Change: Dyn->Dup "

46 2021/03/24 16:06:15.358 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup    Dup Detected"
```

If a duplicate IP is detected, AS-MAC 00:00:bb:bb:bb:bb is advertised with duplicate IP address 172.16.0.10 in an EVPN-MAC update to the BGP peers with the sticky/static bit set, as follows:

```
47 2021/03/24 16:06:15.358 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 93
    Flag: 0x90 Type: 14 Len: 48 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48
                  mac: 00:00:bb:bb:bb:bb, IP len: 4, IP: 172.16.0.10, label1: 8388544
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:1
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:0/Static
"
```

The difference with the first EVPN-MAC update for AS-MAC is the IP address. Immediately after the AS-MAC was configured, it was also advertised to the BGP-EVPN peers, but without any IP address.

The proxy-ARP entry is shown with type duplicate (dup) and active status in the proxy-ARP table for VPLS 1 on PE-3, as follows:

```
*A:PE-3# show service id 1 proxy-arp detail

===============================================================================
```

A duplicate entry is always active, regardless of the AS-MAC. When the entry with the duplicate IP address and the AS-MAC address are installed in the proxy-ARP table as active, every ARP request for the duplicate IP address will be replied by the system. The entry in the proxy-ARP table is treated as active, even if the AS-MAC address is not in the FDB (AS-MAC addresses do not consume FDB space). The AS-MAC address, along with the duplicate IP address, is advertised in EVPN with the sticky/static bit set, as shown earlier. GARP messages with AS-MAC/IP information are flooded locally to make the CEs update their ARP caches to use the AS-MAC address for traffic to the duplicate IP 172.16.0.10, as follows.

```
# on PE-3:
48 2021/03/24 16:06:15.490 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Gratuitous Update"
```

Note:
The AS-MAC address will always be "unique" in the system. When the AS-MAC is configured, the system will flush any entry with the same MAC address learned through EVPN or dynamic sources. Conditional static MAC addresses or OAM MAC addresses with the same value as the AS-MAC address are only allowed when they are configured as black-hole, which is not the case yet.

When the duplicate proxy-ARP entry is cleared from the list (hold-down timer expires, or clear command, or replacement of the duplicate entry for a static entry), an ARP request asking who has IP 172.16.0.10 is flooded by the proxy-ARP agent. This ARP refresh triggers an ARP reply from the IP owner, which will be learned in the proxy-ARP table and advertised in EVPN. The system will also send a GARP to local SAP/SDP-bindings. This will correct all host ARP caches in the network. In this example, the duplicate proxy-ARP entry is manually cleared, as follows:

```
*A:PE-3# clear service id 1 proxy-arp duplicate
```

Log "99" shows that the clear function has been run and the duplicate proxy-ARP entry 172.16.0.10 is cleared. The system forces a refresh and, if the condition with the duplicate IP address remains, this is detected almost immediately and a message is logged that a duplicate proxy-ARP entry was detected, as follows:

```
# on PE-3:
137 2021/03/24 16:08:51.964 UTC INDETERMINATE: LOGGER #2010 Base Clear SVCMGR
"Clear function clearSvcIdProxyArpDups has been run with parameters: svc-id="1"
ip-address="".  The completion result is: success.  Additional error text, if any, is: "

138 2021/03/24 16:08:51.965 UTC MINOR: SVCMGR #2347 Base
"A duplicate proxy ARP entry 172.16.0.10 is cleared in service 1"

139 2021/03/24 16:08:52.193 UTC MINOR: SVCMGR #2346 Base
```

```
"A duplicate proxy ARP entry was detected with new MAC 00:00:01:11:11:11 for entry
IP 172.16.0.10 MAC 00:00:01:10:10:10 in service 1"
```

The following debug messages for proxy-ARP on PE-3 show the process in more detail. Initially, an EVPN-MAC route withdraw message is sent and the proxy-ARP entry is deleted.

```
# on PE-3:
49 2021/03/24 16:08:51.964 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn withdraw"

50 2021/03/24 16:08:51.964 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Deleted"
```

The following BGP-EVPN MAC update is sent by PE-3 to indicate that the AS-MAC is withdrawn for IP 172.16.0.10 (multiprotocol unreachable NLRI):

```
# on PE-3:
52 2021/03/24 16:08:51.965 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 46
    Flag: 0x90 Type: 15 Len: 42 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-MAC Len: 37 RD: 192.0.2.3:1 ESI: ESI-0, tag: 0, mac len: 48
                       mac: 00:00:bb:bb:bb:bb, IP len: 4, IP: 172.16.0.10, label1: 0
"
```

Removing the active duplicate entry from the proxy-ARP table triggers an ARP flooding request asking who has IP 172.16.0.10 in VPLS 1, as follows:

```
# on PE-3:
51 2021/03/24 16:08:51.964 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 flood request"
```

The result of the ARP flooding request is that the IP owners reply with their MAC, at the local or a remote PE. In this case, the reply from CE-10 is received first (IP 172.16.0.10 - MAC 00:00:01:10:10:10), a dynamic proxy-ARP entry is added, and the MAC/IP route is advertised, as follows:

```
# on PE-3:
53 2021/03/24 16:08:51.967 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 evpn advertise"

54 2021/03/24 16:08:51.967 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dyn mac: 00:00:01:10:10:10 Added"
```

When CE-11 answers with its MAC 00:00:01:11:11:11, the MAC/IP route is withdrawn for IP 172.16.0.10, and the MAC address in the proxy-ARP entry for IP 172.16.0.10 is changed from MAC 00:00:01:10:10:10 to MAC 00:00:01:11:11:11, as follows:

```
# on PE-3:
55 2021/03/24 16:08:51.967 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
```

```
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 evpn withdraw"

56 2021/03/24 16:08:51.967 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:10:10:10->00:00:01:11:11:11 "
```

Any change of MAC address in a proxy-ARP entry triggers an ARP request asking for confirmation of the old MAC address for IP 172.16.0.10, in this case for MAC 00:00:01:10:10:10, as follows:

```
# on PE-3:
57 2021/03/24 16:08:52.090 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:10:10:10 confirm"
```

MAC address 00:00:01:10:10:10 is confirmed for IP address 172.16.0.10; therefore, the MAC address is changed in the proxy-ARP entry from 00:00:01:11:11:11 to 00:00:01:10:10:10, and an ARP confirmation is asked for the old MAC address 00:00:01:11:11:11, as follows:

```
# on PE-3:
58 2021/03/24 16:08:52.093 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 Mac Change: 00:00:01:11:11:11->00:00:01:10:10:10 "

59 2021/03/24 16:08:52.190 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:01:11:11:11 confirm"
```

MAC address 00:00:01:11:11:11 is confirmed and, therefore, three MAC moves occurred within three minutes. Duplicate IP 172.16.0.10 is detected and the proxy-ARP entry has the AS-MAC 00:00:bb:bb:bb:bb and type duplicate (Dup), as follows:

```
# on PE-3:
60 2021/03/24 16:08:52.193 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 mac: 00:00:bb:bb:bb:bb evpn advertise"

```

```
"
```

A GARP update is sent for IP 172.16.0.10 and AS-MAC 00:00:bb:bb:bb:bb, as follows:

```
# on PE-3:
64 2021/03/24 16:08:52.290 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.10 type: Dup mac: 00:00:bb:bb:bb:bb Gratuitous Update"
```

The AS-MAC address is optionally configured and populates all the host ARP caches when a duplicate IP address is detected. All traffic destined to the suspicious IP address 172.16.0.10 will have the AS-MAC address 00:00:bb:bb:bb:bb as MAC DA. The user can configure MAC filters on all SAP/SDP-bindings where the CEs are connected to drop, log, or redirect traffic destined to the AS-MAC. This will block any interception or man-in-the-middle attack (due to ARP-spoofing) in the network.

The AS-MAC address is independently configured on each PE for the same service. When a different AS-MAC address is configured per PE for the same service, the user will need to filter all the AS-MAC addresses in the service at each PE, which increases the complexity of the filters. Nokia recommends using the same AS-MAC address for the same service in all the PES where duplicate detect is active and MAC filters need to be configured. However, this recommendation is suspended when the AS-MAC address is configured as static black-hole MAC address, as described in the following section.

Services with proxy-ARP and AS-MAC configured as static black-hole MAC

With the AS-MAC address configured as static black-hole MAC address, MAC-filters do not need to be configured to discard frames with MAC DA equal to the AS-MAC address. Instead, the user can decide whether to use the same AS-MAC address on all the PEs. This scalability is not limited by the number of filters, but by the number of FDB entries.

The **static-black-hole** parameter is optional and disabled by default. In the example, the static-black-hole option is not configured yet for the AS-MAC address and the behavior is as follows:

- The AS-MAC address is added to the MAC DB as local, but not programmed in the FDB.
- The AS-MAC address is advertised in EVPN (initially without an IP address, and with an IP address as soon as the IP is detected as duplicate).
- The AS-MAC address cannot be overridden by any other MAC address.
- The AS-MAC address value cannot be configured on a static MAC address, because that MAC address is reserved for the proxy-ARP, as follows:

```
*A:PE-3>conf>serv>vpls>static-mac# mac 00:00:bb:bb:bb:bb create sap 1/2/3:1 monitor fwd-status
MINOR: SVCMGR #7875 Cannot create conditional static mac - Mac reserved by proxy

*A:PE-3>conf>serv>vpls>static-mac# mac 00:00:bb:bb:bb:bb create black-hole
MINOR: SVCMGR #7875 Cannot create conditional static mac - Mac reserved by proxy
```

When the static-black-hole option is not configured, the AS-MAC address is considered as a local MAC address and cannot be overridden. The MAC address priority is as follows:

1. Local MAC address (including AS-MAC addresses without static-black-hole, es-bmacs, src-bmacs, OAM, and so on)
2. Conditional static MAC addresses (including AS-MAC addresses with static-black-hole)
3. Auto-Learn Protected MAC addresses

4. EVPN-MAC addresses with sticky/static bit set
5. Data plane learned MAC addresses (regular learning on SAP/SDP-binding)
6. EVPN-MAC addresses without sticky/static bit set

To configure an AS-MAC address with static-black-hole option, a static black-hole MAC address needs to be configured first. The following error is raised when no static black-hole MAC has been configured for AS-MAC 00:00:bb:bb:bb:bb:

```
*A:PE-3>config>service>vpls>proxy-arp# dup-detect window 3 num-moves 5 hold-down max anti-
spoof-mac 00:00:bb:bb:bb:bb static-black-hole
MINOR: SVCMGR #8007 Cannot modify proxy arp - black-hole mac not configured on service
```

In that case, the AS-MAC address needs to be removed from the proxy-ARP configuration, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            proxy-arp
                shutdown
                dup-detect window 3 num-moves 5 hold-down max
            exit
```

Then, the static black-hole MAC address can be created as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                mac 00:00:bb:bb:bb:bb create black-hole
```

After the conditional static black-hole MAC address is configured, duplicate IP address detection cannot be configured with AS-MAC address, unless the static-black-hole option is added, as follows:

```
*A:PE-3>config>service>vpls>proxy-arp# dup-detect window 3 num-moves 5 hold-down max anti-
spoof-mac 00:00:bb:bb:bb:bb
MINOR: SVCMGR #8007 Cannot modify proxy arp - conditional static mac configured on service
```

When the static black-hole MAC 00:00:bb:bb:bb:bb is configured, the AS-MAC address can only be configured with the **static-black-hole** option in VPLS 1 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            static-mac
                mac 00:00:bb:bb:bb:bb create black-hole
            exit
            proxy-arp
                dup-detect window 3 num-moves 5 hold-down max
                            anti-spoof-mac 00:00:bb:bb:bb:bb static-black-hole
                dynamic-arp-populate
                static 172.16.0.20 00:00:02:20:20:20
                no shutdown
            exit
```

When the AS-MAC address is configured with the static black-hole option, the AS-MAC will be added not only to the MAC DB, but also to the FDB as CStatic, and associated with a black-hole endpoint, as follows:

```
*A:PE-3# show service id 1 fdb mac 00:00:bb:bb:bb:bb
===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1          00:00:bb:bb:bb:bb black-hole               CStatic: 03/24/21 16:13:59
                                                      P
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

Any frame with MAC DA equal to the AS-MAC with static black-hole will be dropped, regardless of the ingress endpoint and without any need for a filter. This mechanism is the only way to filter MAC DAs on EVPN endpoints, because MAC filters cannot be configured on EVPN endpoints.

The AS-MAC with static black-hole will be advertised in EVPN with the sticky/static bit set, as follows:

```
# on PE-3:
75 2021/03/24 16:13:58.752 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

-------------------------------------------------------------------------------
No. of ARP Entries: 2
===============================================================================
```

CE-30 and CE-31 cannot reach CE-10 or CE-11, because the MAC DA will be the AS-MAC address and all traffic to this MAC DA is black-holed instead of forwarded to SAP 1/2/3:1 toward CE-10 or CE-11. When 1000 ICMP packets are sent by CE-30, they arrive in SAP 1/2/1:1 on PE-3 and are then discarded, as follows:

```
*A:PE-3# clear port 1/[1..2]/[1..4] statistics

*A:PE-3# ping router 10 172.16.0.10 rapid count 1000
PING 172.16.0.10 56 data bytes

```

No packets were forwarded to SAP 1/2/3:1 toward MTU-1; therefore, there are no statistics for port 1/2/3.

Conclusion

Static black-hole MAC addresses can be applied in EVPN for security as a scalable alternative to MAC filters. Static black-hole MAC addresses are programmed in the FDB and all frames with MAC DA equal to the static black-hole MAC address are dropped, regardless of how the frame arrived at the system (SAP/SDP-binding or EVPN endpoint). Also, static black-hole MAC addresses are treated like protected MAC addresses and, in combination with RPS(-DF), filtering on MAC SA is performed in the data plane. Black-hole MAC addresses can be an option for an AS-MAC address in services with proxy-ARP/ND enabled, which simplifies the configuration because MAC filters are not required.

Data Center Interconnect Using Dual EVPN-VXLAN Instance VPLS

This chapter provides information about Data Center Interconnect using dual EVPN-VXLAN instance VPLS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R7, but the CLI in the current edition is based on SR OS Release 21.7.R1. Dual EVPN-VXLAN instances are supported in SR OS Release 16.0.R2, or later.

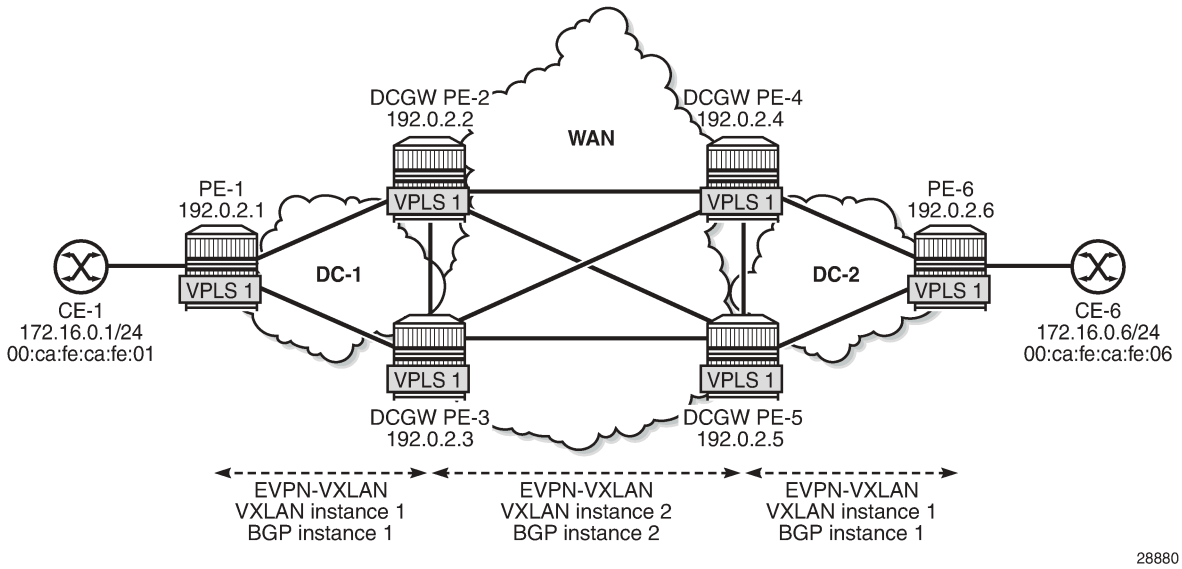
This chapter describes the redundancy based on an Anycast solution, as supported in SR OS Release 16.0, and later. For I-ES based redundancy scenarios as supported in SR OS Release 19.10, and later, see the EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services chapter.

Overview

Chapter EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services describes a Data Center Interconnect (DCI) scenario using VXLAN in the DCs and MPLS in the WAN. This chapter describes a similar scenario, where the core is an IP network that does not use MPLS, and where end-to-end VXLAN is used instead. The DC Gateways (GWs) contain VPLS services with two EVPN-VXLAN instances and two BGP instances: one EVPN-VXLAN instance faces the DC and the other EVPN-VXLAN instance faces the WAN.

Figure 69: Dual EVPN-VXLAN instance VPLS 1 shows the example topology with two DCs. On PE-1 and PE-6, VPLS 1 is configured with one VXLAN instance and one BGP instance. On the DC GWs, VPLS 1 is configured with two VXLAN instances and two BGP instances: one toward the DC and one toward the WAN.

Figure 69: Dual EVPN-VXLAN instance VPLS 1



For example, on DC GW PE-2, VPLS 1 is configured with VXLAN instance 1 using BGP instance 1 and VXLAN 2 using BGP instance 2. In this example, the BGP instance ID matches the VXLAN instance ID, but that is not required. Each VXLAN instance has a different VNI and a different BGP instance.

```
# on PE-2:
configure
    service
        system
            bgp-auto-rd-range 10.0.0.1 comm-val 60000 to 65000
        exit
        vpls 1 name "VPLS 1" customer 1 create
            description "dual evpn-vxlan VPLS"
            vxlan instance 1 vni 11 create
            exit
            vxlan instance 2 vni 12 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:11 import target:64500:11
            exit
            bgp 2
                route-distinguisher auto-rd
                route-target export target:64500:12 import target:64500:12
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                vxlan bgp 2 vxlan-instance 2
                    no shutdown
                exit
            exit
            no shutdown
```

When different BGP instances are configured, the auto-derived route distinguishers (RDs) in BGP instance 1 and BGP instance 2 are different, as follows:

```
*A:PE-2# show service id 1 bgp 1 | match "Route Dist"
Route Dist           : auto-rd
Oper Route Dist      : 10.0.0.1:60000
*A:PE-2# show service id 1 bgp 2 | match "Route Dist"
Route Dist           : auto-rd
Oper Route Dist      : 10.0.0.1:60001
```

Dual EVPN-VXLAN instance VPLSs can contain SAPs in SR OS Release 19.10.R1, and later. However, dual EVPN-VXLAN instance VPLSs cannot contain any SDP bindings in SR OS Release 21.7.R1, as follows:

```
*A:PE-2>config>service>vpls# spoke-sdp 21:1 create
MINOR: SVCMGR #1997 Cannot create sdp binding - not supported with multiple vxlan instances
```

Note:
This chapter describes the redundancy based on an Anycast solution, as supported in SR OS Release 16.0, and later. For I-ES based redundancy scenarios as supported in SR OS Release 19.10, and later, see chapter EVPN Multi-Homing on Dual EVPN-VXLAN BGP Instance VPLS.

To provide DC GW redundancy, an anycast IP address can be configured for the dual EVPN-VXLAN instance VPLSs on the DC GWs.

EVPN route types 2 and 3 are processed by dual EVPN-VXLAN VPLS services as follows:

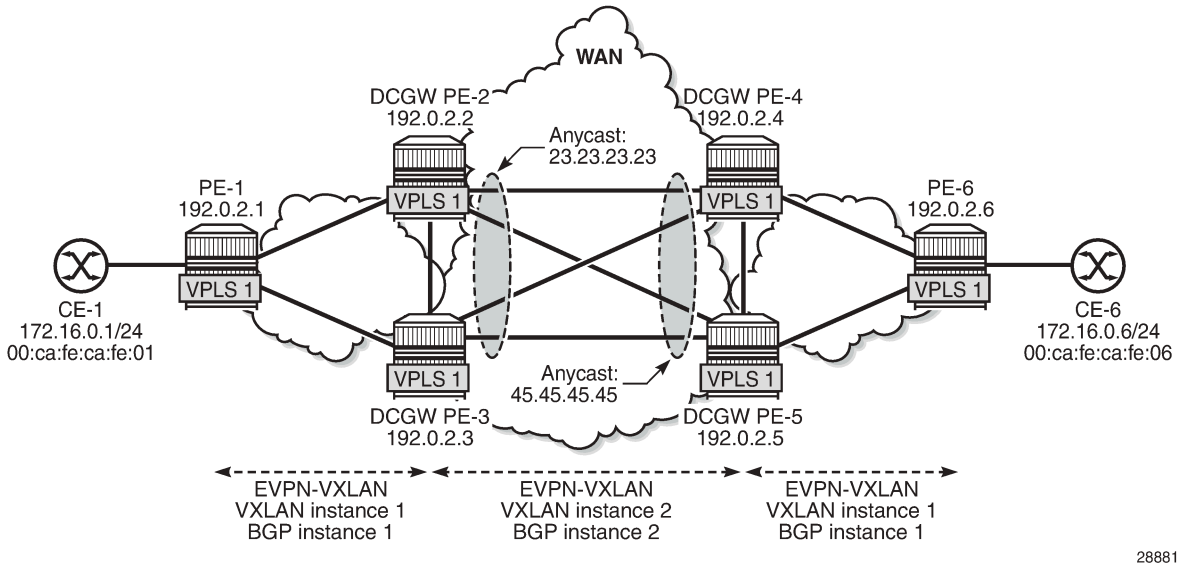
- Route type 2: MAC/IP routes
  - MAC/IP routes received in a BGP instance will be imported and—according to the selection rules—installed in the FDB.
  - Active MAC routes are re-advertised in the other BGP instance with new BGP attributes (RD, route target (RT), and so on).
    - Only the best EVPN MAC route is redistributed.
    - The MAC/IP information and the sticky bit are propagated. The only exception is the Ethernet Segment Identifier (ESI). A non-zero ESI will be reset unless the auto-disc-route-advertisement command is configured.
    - When an attribute has changed for a redistributed MAC route, the MAC route will be updated if it is still the best route. For example, an update of the sequence number or the sticky bit can trigger a redistribution.
- Route type 3: inclusive multicast routes
  - EVPN inclusive multicast routes are generated independently for each instance with the proper BGP extended communities.
  - Ingress Replication (IR) or Assisted Replication (AR) Inclusive Multicast Ethernet Tag (IMET) routes are supported.
  - The inclusive multicast originating IP can be configured with an anycast address:
    - The configured originating IP address is encoded in the originating IP field of the IMET-IR routes; the originating IP field of the IMET-AR routes is still derived from the assisted replication IP value in the service system settings for VXLAN.

- If a router receives two IMET routes with the same originating IP address, different RDs, and different next-hops, it sets up two bindings: one to each next-hop.
- If a router receives two IMET routes with the same originating IP address, the same RD, but different next-hops, it sets up one binding to the next-hop with the lowest IP address.
- If a router receives two IMET routes with the same originating IP address, different RDs, but the same next-hop, it sets up one binding to the next-hop.
- A DC GW will not set up a binding to its DC GW peer if the received originating IP equals its own originating IP, regardless of whether the local RD and the remote RD are the same or different.

Configuration

Figure 70: Example topology with VPLS 1 and anycast addresses shows the example topology. Redundancy is based on anycast: on the DC GWs PE-2 and PE-3, anycast address 23.23.23.23 is configured as inclusive multicast originating IP; on PE-4 and PE-5 in DC-2, the anycast address is 45.45.45.45. However, no Ethernet segments are used in this example.

Figure 70: Example topology with VPLS 1 and anycast addresses



The initial configuration includes:

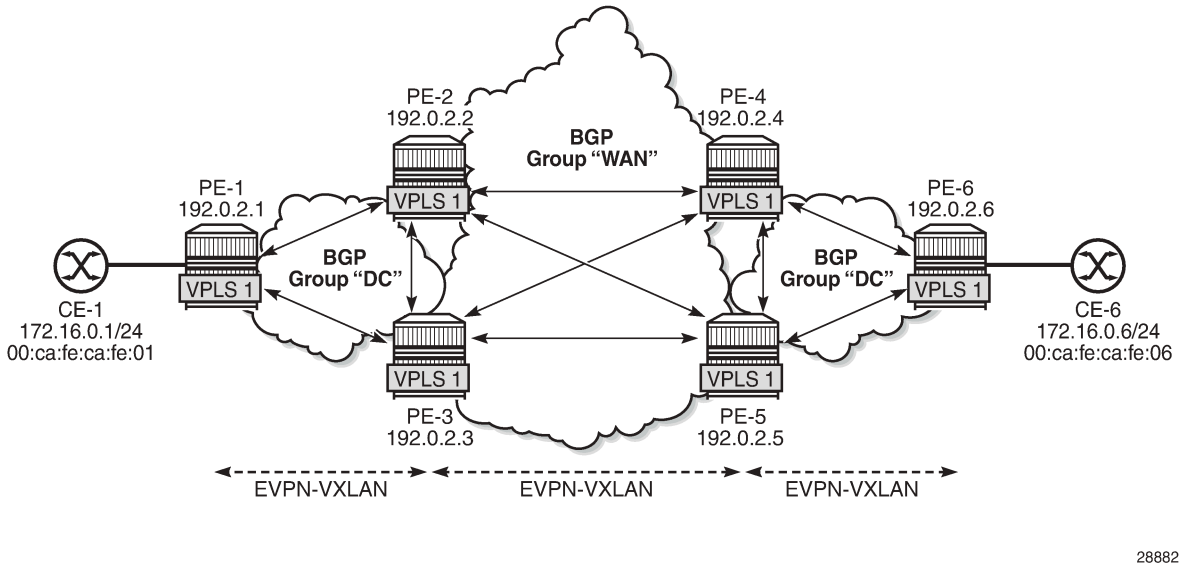
- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (level 1 in the DCs and level 2 in the WAN)

MPLS is not configured in any of these networks.

BGP configuration

BGP is configured for the EVPN address family on all nodes. Figure 71: Example topology with BGP groups shows the BGP groups: on the DC GWs, both BGP group "DC" and "WAN" are defined. Route policies ensure that only DC routes are forwarded to DC neighbors and only WAN routes are forwarded to WAN neighbors. Also, DC GWs need to drop BGP-EVPN routes from the local peer DC GW.

Figure 71: Example topology with BGP groups



The BGP configuration on PE-1 is as follows. The configuration on PE-6 is similar.

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

On the DC GWs, two BGP groups are defined: one for the DC group and one for the WAN group. Export policies ensure that only DC routes are exported to the DC group and only WAN routes are exported to the WAN group. Import policies ensure that routes from the local DC GW are dropped; for example, PE-2 drops routes from PE-3, and vice versa. The policies will be described later. The BGP configuration on PE-2 is as follows. The BGP configuration on the other DC GWs is similar.

```
# on PE-2:
```

```
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only DC and add SOO"
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "WAN"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only WAN and add SOO"
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

Route policies

The route policies are equivalent to the policies described in the chapter EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services. In this example, no filtering can be done based on the encapsulation extended community (VXLAN versus MPLS), because only VXLAN is used in the DCs and the WAN. Therefore, the route tag is used as a criterion instead in the route policies "allow only DC and add SOO" (Site of Origin) and "allow only WAN and add SOO". When two BGP instances for the same encapsulation are configured in a VPLS, different route tags in each BGP instance are required. In this example, route tag 11 is used in BGP instance 1 in the DCs and route tag 12 is used in BGP instance 2 in the WAN.

When redistributing to the other BGP instance, route filtering toward DC or WAN will be based on the route tags. Export policy "allow only DC and add SOO" drops routes with WAN route tag 12. Likewise, export policy "allow only WAN and add SOO" drops routes with DC route tag 11. Filtering matching on route tags on EVPN BGP instances is scalable, because only two route tags are required per PE. Filtering matching on route target (RT) is also possible, but in that case, two RTs per service are required. This does not scale well and is cumbersome.

The export policy "allow only DC and add SOO" ensures that EVPN routes with route tag 12 are dropped and only DC routes are forwarded. This route policy is applied in the BGP group "DC" context. Likewise, the export policy "allow only WAN and add SOO" drops EVPN routes with route tag 11, so that only WAN EVPN routes are forwarded.

Both policies also add a site of origin, such as "SOO-23" for PE-2 and PE-3, and "SOO-45" for PE-4 and PE-5. This SOO is used for filtering in the import policies "drop SOO-DCGW-23" and "drop SOO-DCGW-45" to ensure that, for instance, PE-2 drops routes advertised by the local peer PE-3 with the same SOO-23, and vice versa. Likewise, PE-4 drops routes advertised by its local peer PE-5 with the same SOO-45, and vice versa.

The following policies are configured on DC GWs PE-2 and PE-3:

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            community "SOO-23"
                members "origin:64500:23"
            exit
            policy-statement "drop SOO-DCGW-23"
                entry 10
                    from
                        community "SOO-23"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
            policy-statement "allow only DC and add SOO"
                entry 10
                    from
                        tag 12
                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        family evpn
                    exit
                    action accept
                        community add "SOO-23"
                    exit
                exit
            exit
            policy-statement "allow only WAN and add SOO"
                entry 10
                    from
                        tag 11
                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        family evpn
                    exit
                    action accept
                        community add "SOO-23"
                    exit
                exit
            exit
            commit
```

The following policies are configured on DC GWs PE-4 and PE-5:

```
# on PE-4, PE-5:
configure
    router Base
```

```
        policy-options
            begin
            community "SOO-45"
                members "origin:64500:45"
            exit
            policy-statement "drop SOO-DCGW-45"
                entry 10
                    from
                        community "SOO-45"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
            policy-statement "allow only DC and add SOO"
                entry 10
                    from
                        tag 12
                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        family evpn
                    exit
                    action accept
                        community add "SOO-45"
                    exit
                exit
            exit
            policy-statement "allow only WAN and add SOO"
                entry 10
                    from
                        tag 11
                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        family evpn
                    exit
                    action accept
                        community add "SOO-45"
                    exit
                exit
            exit
            commit
```

VPLS configuration

On PE-2 and PE-3, the service configuration is identical and VPLS 1 is configured as follows. For redundancy, the anycast IP address 23.23.23.23 is configured as inclusive multicast originating IP on PE-2 and PE-3. The RT is the same in all nodes: the RT is 64500:11 in BGP instance 1 of VPLS 1; in BGP instance 2, the RT is 64500:12. The RD is 64500:2311 in BGP instance 1 of VPLS 1 and 64500:2312 in

BGP instance 2 of VPLS 1 on PE-2 and PE-3. The RD must be the same in PE-2 and PE-3 because they are part of the anycast group, but the RD in PE-1 must be different.

```
# on PE-2, PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 11 create
            exit
            vxlan instance 2 vni 12 create
            exit
            bgp
                route-distinguisher 64500:2311
                route-target export target:64500:11 import target:64500:11
            exit
            bgp 2
                route-distinguisher 64500:2312
                route-target export target:64500:12 import target:64500:12
            exit
            bgp-evpn
                incl-mcast-orig-ip 23.23.23.23
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    default-route-tag 11
                    no shutdown
                exit
                vxlan bgp 2 vxlan-instance 2
                    default-route-tag 12
                    no shutdown
                exit
            exit
            no shutdown
```

On PE-1, VPLS 1 is configured with VXLAN instance 1 and BGP instance 1, as follows. The RT is 64500:11 in BGP instance 1 of VPLS 1 on PE-1. The RD (64500:111) in PE-1 is different from the RD (64500:2311) in PE-2 and PE-3.

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 11 create
            exit
            bgp
                route-distinguisher 64500:111
                route-target export target:64500:11 import target:64500:11
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit

                    no shutdown
                exit
            exit
            no shutdown
```

Verification

On PE-2, the following EVPN inclusive multicast routes are received. The first route has RD 64500:111, so it applies to BGP instance 1; the last two have RD 64500:4512, so they apply to BGP instance 2. Toward anycast address 45.45.45.45, the lowest IP next-hop 192.0.2.4 (PE-4) is preferred over 192.0.2.5 (PE-5).

Routes : 2
===============================================================================
```

On PE-2, the following three EVPN MAC routes are accepted. The first route has PE-1 (192.0.2.1) as next-hop and is received in BGP instance 1, which corresponds to VXLAN 1 and VNI 11. The latter two routes are received in BGP instance 2 for VXLAN instance 2 with VNI 12. These routes both have RD 64500:4512 and the route with the lowest IP next-hop is preferred, so the route to PE-4 (192.0.2.4) is used. The EVPN MAC routes on PE-3 are similar.

```
*A:PE-2# show router bgp routes evpn mac

Conclusion

With dual EVPN-VXLAN instance VPLS services, service providers can deploy DCI scenarios with end-to-end VXLAN.

Domain Path Attribute for VPRN BGP Routes

This chapter provides information about the domain path attribute for VPRN BGP routes.

Topics in this chapter include:

Applicability

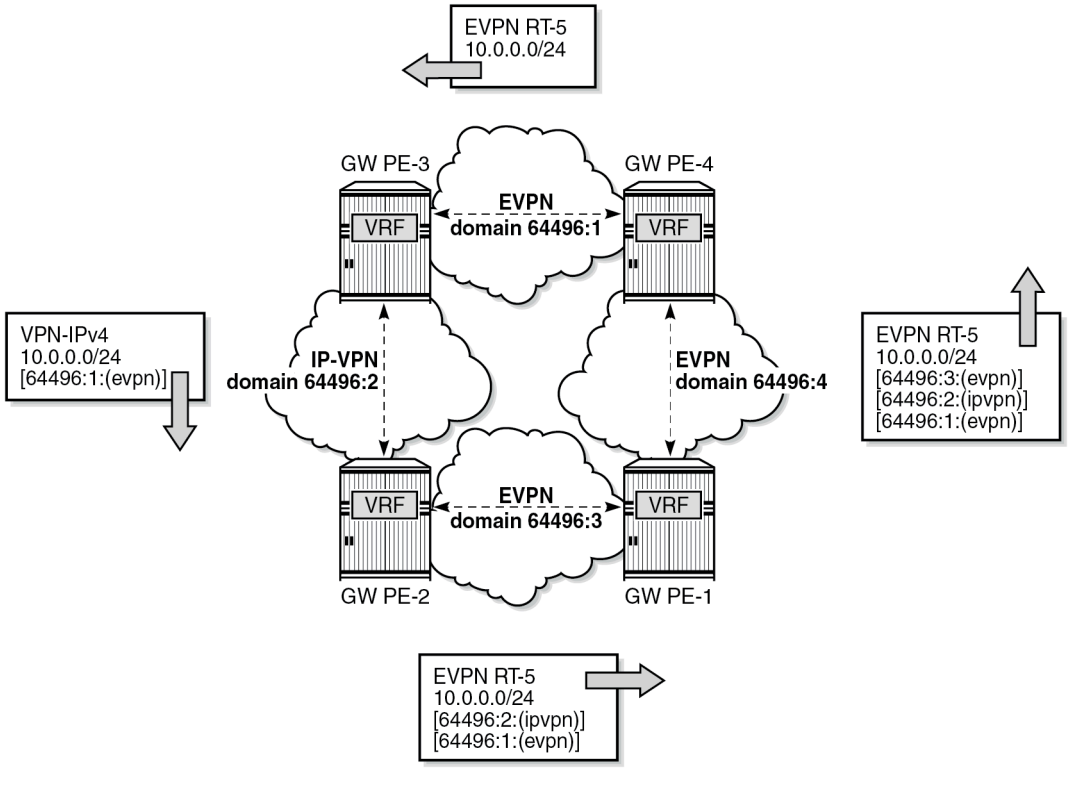
The information and configuration in this chapter are based on SR OS Release 22.7.R1. The domain path (D-path) attribute is supported in SR OS Release 21.10.R1 and later.

Overview

The D-path attribute can be used for route traceability, BGP best path selection, and loop prevention in networks that expand multiple IP-VPN and EVPN domains.

The D-path attribute is a sequence of domain segments, where each domain segment is represented by a domain ID in combination with an inter-subnet forwarding (ISF) subaddress family indicator (SAFI). The D-path attribute is added or modified by gateways (GWs) that import BGP-EVPN route type 5 (RT-5) or IP-VPN routes into a VPRN route table and export these prefixes as RT-5 or IP-VPN routes to their neighbors. Any PE that imports a prefix route does not install the route in the VPRN route table if the D-path attribute contains a domain segment where the domain ID matches a local domain ID, as shown in Figure 72: Loop prevention in networks with multiple IP-VPN and EVPN domains.

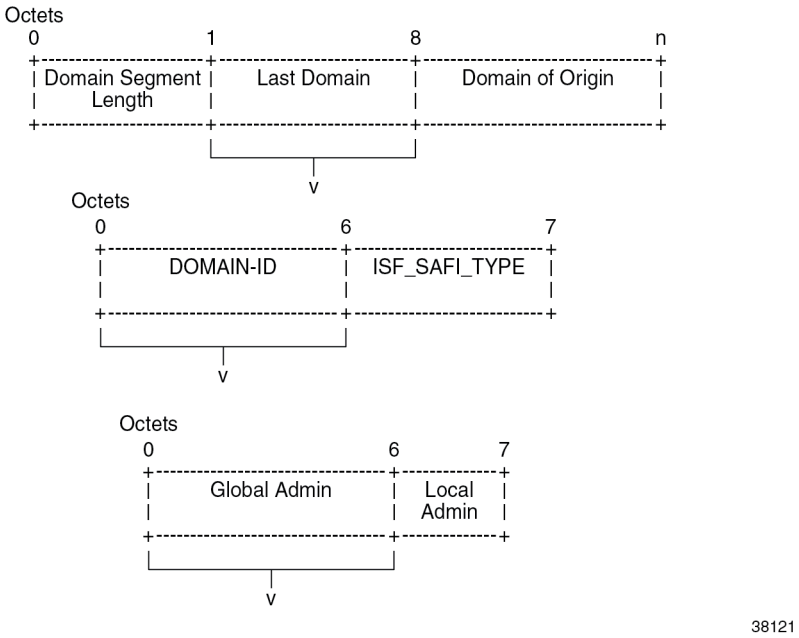
Figure 72: Loop prevention in networks with multiple IP-VPN and EVPN domains



All PEs in Figure 72: Loop prevention in networks with multiple IP-VPN and EVPN domains are GWs. PE-4 exports local prefix 10.0.0.0/24 as an EVPN RT-5 route without the D-path attribute when no domain ID is configured for local routes. PE-3 accepts this route. Domain ID 64496:1 is defined in PE-4 and PE-3, but the domain segment 64496:1:(evpn) is only added by GW PE-3 where the prefix is exported as an IP-VPN route instead of an EVPN RT-5 route. GW PE-2 accepts this route and modifies the D-path attribute by prepending domain segment 64496:2:(ipvpn) when exporting prefix 10.0.0.0/24 as an EVPN RT-5 route. PE-1 accepts this route. When PE-1 exports the prefix as an EVPN RT-5 route to PE-4, it prepends domain segment 64496:3:(evpn) to the D-path attribute. The VRF on PE-4 cannot import this prefix because the D-path attribute contains domain ID 64496:1, which is defined on PE-4.

Figure 73: D-path attribute shows the D-path attribute as defined in *draft-ietf-bess-evpn-ipvpn-interworking*.

Figure 73: D-path attribute



The D-path attribute is composed of a sequence of domain segments. Each domain segment consists of a domain ID and a SAFI type. The domain ID represents the domain and is composed of a 4-octet global administrator subfield and a 2-octet local administrator subfield. The global administrator subfield must have a value that is unique for the domain; for example, an autonomous system number (ASN). The 1-octet SAFI field can have the following values:

- 0 for local ISF routes
- 1 for PE-CE BGP domains
- 70 for EVPN domains
- 128 for IP-VPN domains

The domain ID can be configured on:

- VPRN BGP-EVPN MPLS and BGP-EVPN SRv6 instances (EVPN interface-less (EVPN-IFL))
- VPRN BGP-IPVPN MPLS and BGP-IPVPN SRv6 instances
- R-VPLS BGP-EVPN MPLS and BGP-EVPN VXLAN instances (EVPN interface-ful (EVPN-IFF))
- VPRN BGP neighbors (PE-CE)
- VPRN level (for local routes). When configured on the VPRN level, using the optional **local-routes-domain-id** command, the PE advertises its direct, static, or IGP routes with a D-path attribute.

Domain IDs can be modified while the service is operational. Modifying the domain ID initiates a route refresh for all address families associated with the VPRN.

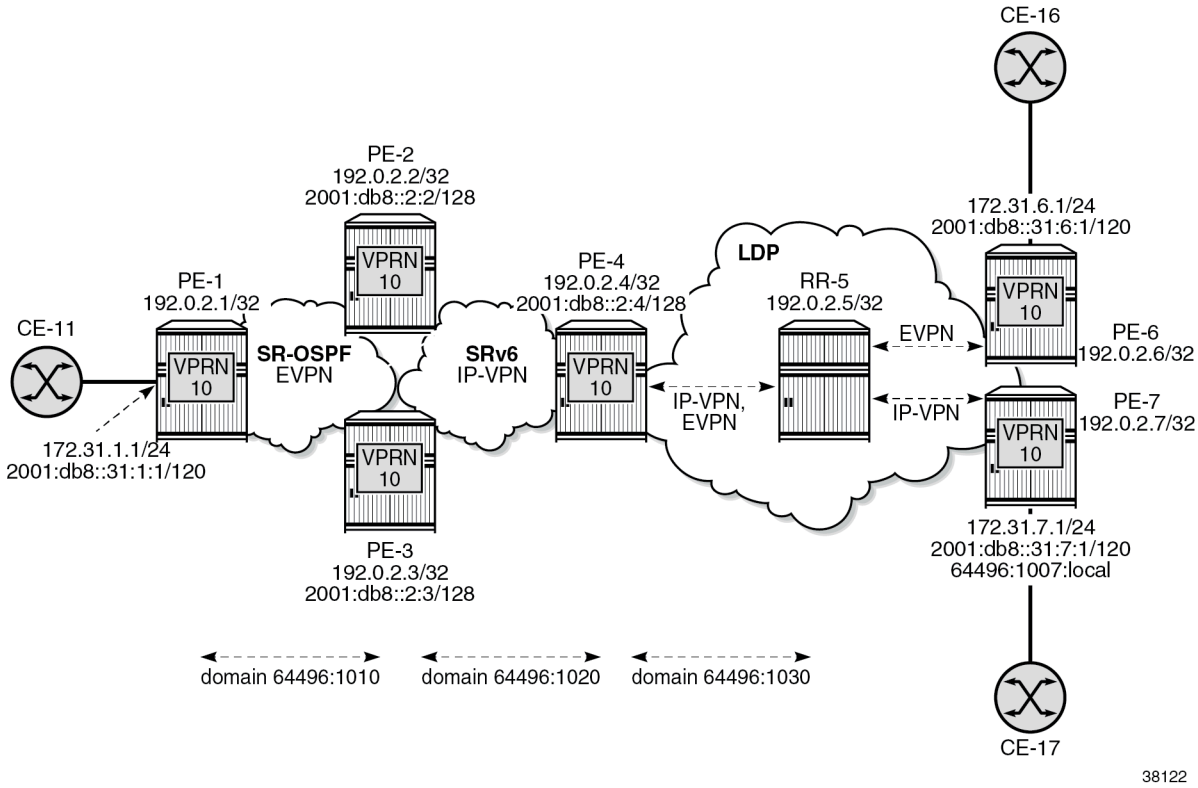
A PE receiving a prefix route with a D-path attribute containing one of its own domain IDs detects a routing loop and does not install the route in the VPRN route table.

The D-path attribute length can influence the BGP best path selection. In the BGP decision process, the shorter D-path is preferred, unless the **d-path-length-ignore** command is configured.

Configuration

Figure 74: Example topology with VPRN 10 and its domain IDs shows an example topology where PE-6 exports EVPN RT-5 routes 172.31.6.0/24 and 2001:db8::31:6:0/120 to route reflector RR-5, whereas PE-7 exports IP-VPN routes 172.31.7.0/24 and 2001:db8::31:7:0/120 to RR-5. LDP tunnels are used between PE-4, RR-5, PE-6, and PE-7; SRv6 tunnels are used between PE-2, PE-3, and PE-4; SR-OSPF tunnels are used between PE-1, PE-2, and PE-3.

Figure 74: Example topology with VPRN 10 and its domain IDs



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- OSPF as IGP on PE-1, PE-2, and PE-3
- IS-IS as IGP on PE-2, PE-3, PE-4, RR-5, PE-6, and PE-7
- SR-OSPF on PE-1, PE-2, and PE-3
- SRv6 on PE-2, PE-3, and PE-4, configured as in chapter "Segment Routing over IPv6" in the Segment Routing and PCE volume of *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Book I*.
- LDP on PE-4, RR-5, PE-6, and PE-7

The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal1"
                family evpn
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

```
# on PE-2 (similar configuration on PE-3):
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import

Domain IDs in VPRN BGP-EVPN MPLS and SRv6 instances

On PE-1, VPRN 10 is configured without domain ID in the **bgp-evpn mpls** context:

```
# on PE-1:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            autonomous-system 64496
            interface "int-PE-1-CE-11" create
                address 172.31.1.1/24
                ipv6
                    address 2001:db8::31:1:1/120
                exit
                sap 1/1/c5/1:10 create
                exit
            exit
            bgp-evpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            sr-ospf
                        exit
                        resolution filter
                    exit
                    route-distinguisher 192.0.2.1:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

Domain ID 64496:1010 is configured in the **bgp-evpn mpls** context on GWs PE-2 and PE-3, whereas domain ID 64496:1020 is configured in the **bgp-ipvpn segment-routing-v6** context on PE-2, PE-3, and PE-4. Domain ID 64496:1030 is configured for IP-VPN and for BGP-EVPN on PE-4.

On PE-2, VPRN 10 is configured as follows. The configuration on PE-3 is similar.

```
# on GW PE-2:
configure
    service
         vprn 10 name "VPRN 10" customer 1 create
            autonomous-system 64496
            segment-routing-v6 1 create
                locator "PE-2_loc"                      # on PE-3:"PE-3_loc"
                    function
                        end-dt4
                        end-dt6
                    exit
                exit
            exit
            bgp-ipvpn
                segment-routing-v6
                    domain-id 64496:1020
                    route-distinguisher 192.0.2.2:16     # on PE-3: 192.0.2.3:16
                    srv6-instance 1 default-locator "PE-2_loc"  # on PE-3:"PE-3_loc"
                    source-address 2001:db8::2:2         # on PE-3: 2001:db8::2:3
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            bgp-evpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            sr-ospf
                        exit
                        resolution filter
                    exit
                    domain-id 64496:1010
                    route-distinguisher 192.0.2.2:10     # on PE-3: 192.0.2.3:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            no shutdown
```

On GW PE-4, VPRN 10 is configured with two domain IDs: domain ID 1020 for IP-VPN over SRv6 and domain ID 1030 for IP-VPN over MPLS and for EVPN over MPLS.

```
# on GW PE-4:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            autonomous-system 64496
            segment-routing-v6 1 create
                locator "PE-4_loc"
                    function
                        end-dt4
                        end-dt6
                    exit
                exit
            exit
            bgp-ipvpn
```

```
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    domain-id 64496:1030
                    route-distinguisher 192.0.2.4:10
                    vrf-target target:64496:10
                    no shutdown
                exit
                segment-routing-v6
                    domain-id 64496:1020
                    route-distinguisher 192.0.2.4:16
                    srv6-instance 1 default-locator "PE-4_loc"
                    source-address 2001:db8::2:4          ## system IP@
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            bgp-evpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    domain-id 64496:1030
                    route-distinguisher 192.0.2.4:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            allow-export-bgp-vpn
            no shutdown
```

For completeness, the configuration on VPRN 10 on PE-6 and PE-7 is also shown. PE-6 has no domain ID configured:

```
# on PE-6:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            autonomous-system 64496
            interface "int-PE-6-CE-16" create
                address 172.31.6.1/24
                ipv6
                    address 2001:db8::31:6:1/120
                exit
                sap 1/1/c5/1:10 create
                exit
            exit
            bgp-evpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 192.0.2.6:10
```

```
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            no shutdown
```

PE-7 does not have a domain ID configured in the **bgp-ipvpn mpls** context, but it has a local domain ID configured: 64496:1007:

```
# on PE-7:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            local-routes-domain-id 64496:1007
            autonomous-system 64496
            interface "int-PE-7-CE-17" create
                address 172.31.7.1/24
                ipv6
                    address 2001:db8::31:7:1/120
                exit
                sap 1/1/c5/1:10 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 192.0.2.7:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            no shutdown
```

The following commands on PE-4 display the domain ID for BGP-IPVPN and BGP-EVPN. For BGP-IPVPN, domain ID 64496:1030 is configured in the EVPN-MPLS domain and domain ID 64496:1020 is configured in the SRv6 domain:

```
*A:PE-4# show service id 10 bgp-ipvpn

```

Figure 75: VPRN BGP routes for prefix 172.31.6.0/24 shows the D-path attribute in the BGP routes for prefix 172.31.6.0/24:

Figure 75: VPRN BGP routes for prefix 172.31.6.0/24

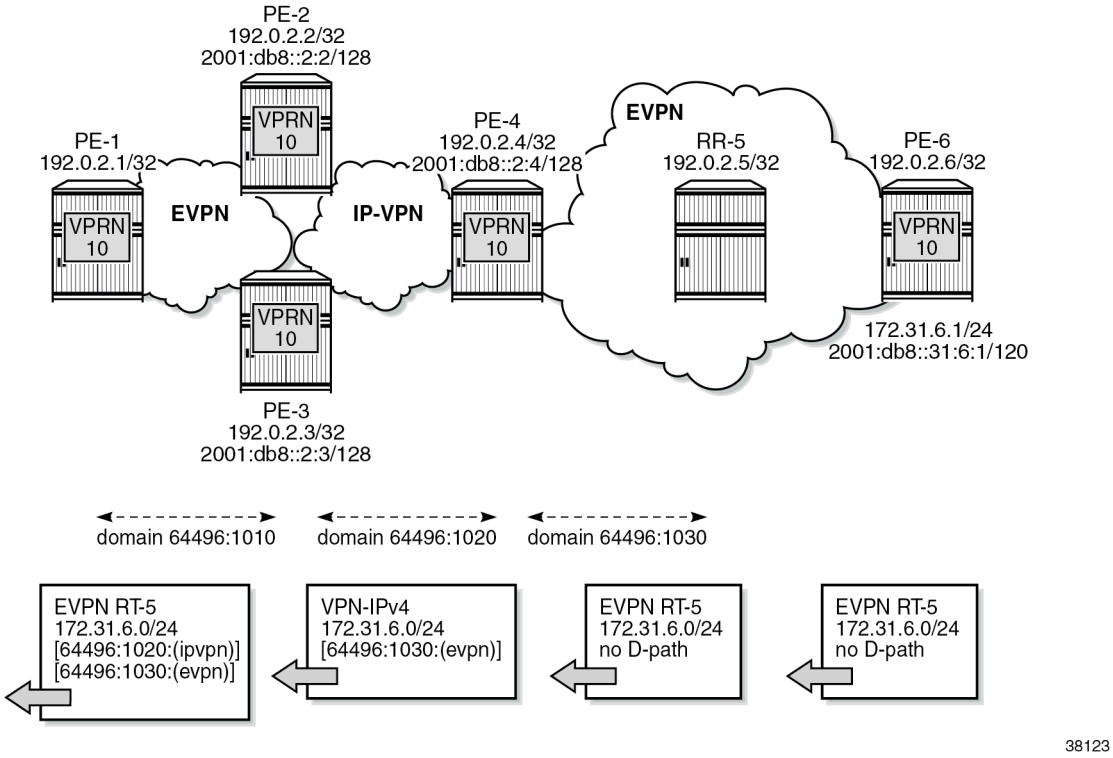

Figure 76: VPRN BGP routes for prefix 172.31.7.0/24 similarly shows the D-path attribute in the BGP routes for prefix 172.31.7.0/24:

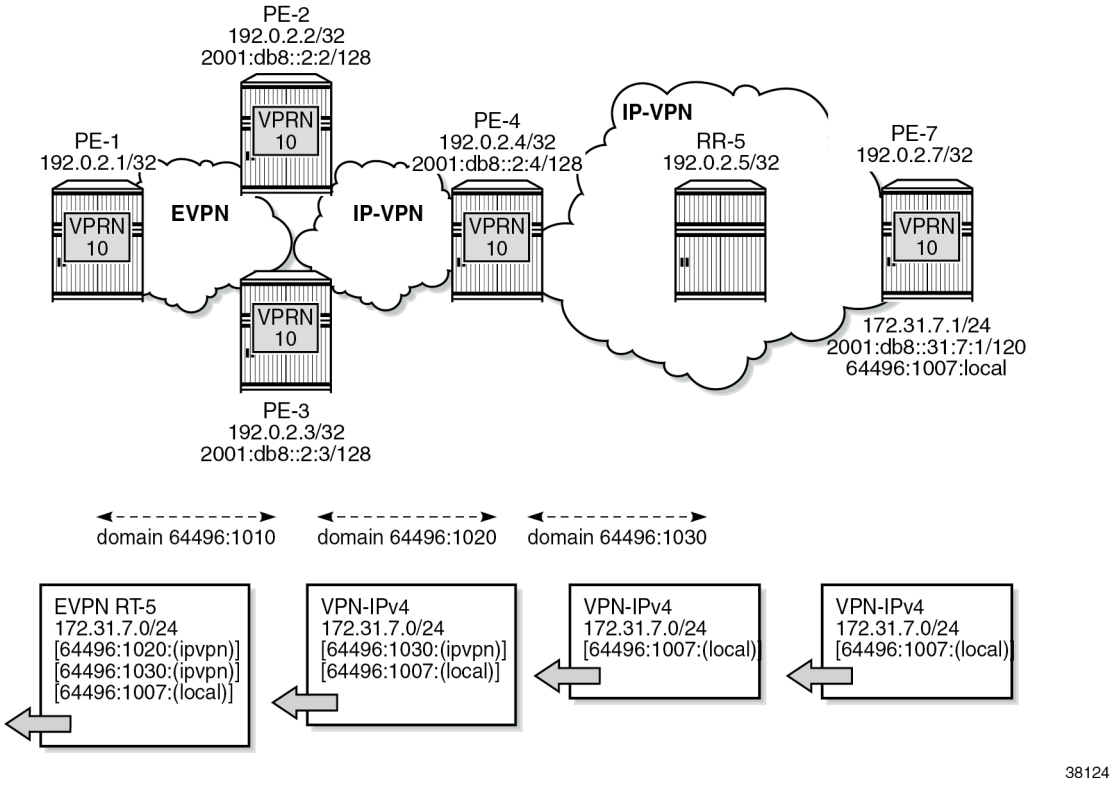
Figure 76: VPRN BGP routes for prefix 172.31.7.0/24



In VPRN 10 on PE-6, no local domain ID is configured, whereas in VPRN 10 on PE-7, the local domain ID 64496:1007 is configured for the routes local to PE-7.

The following BGP update shows that PE-7 advertises prefix 172.31.7.0/24 as a VPN-IPv4 route with a D-path attribute containing the domain segment 64496:1007:(local).

```
# on PE-7:
1 2022/09/05 14:07:07.879 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE

"
```

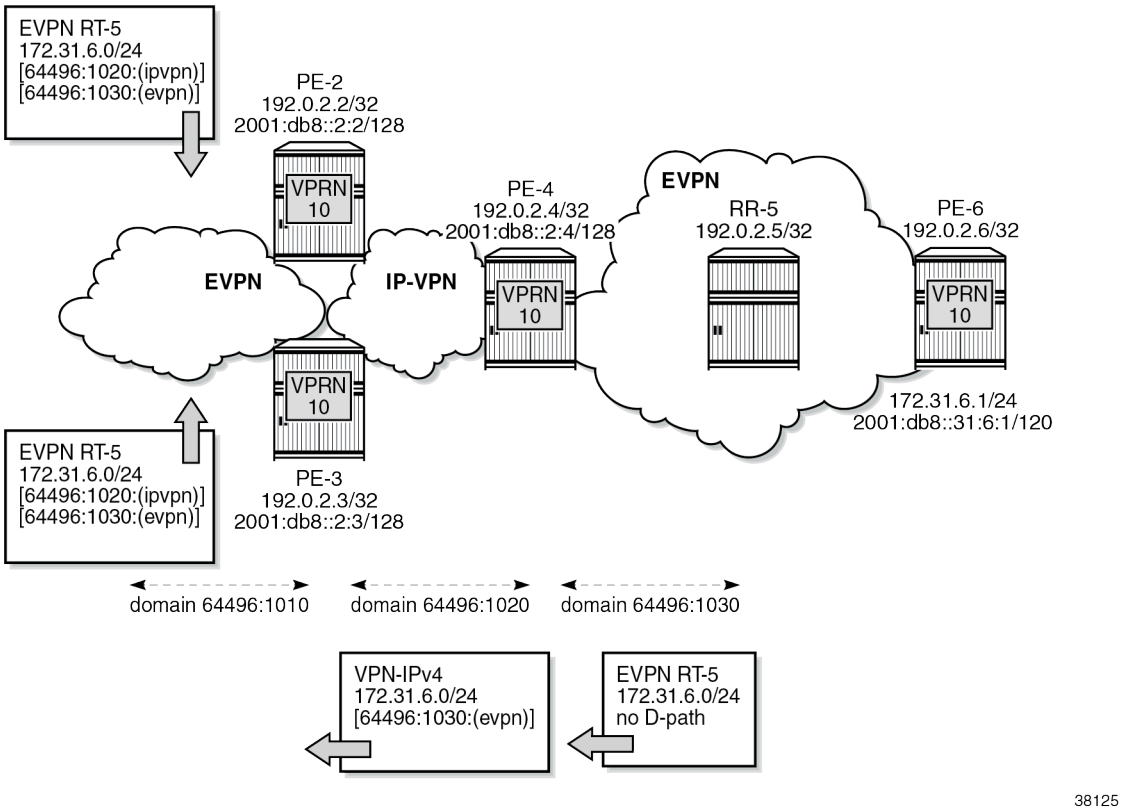
Loop prevention

Besides traceability, the D-path attribute provides loop prevention in the control plane. Redundant GWs PE-2 and PE-3 cause routing loops and the D-path attribute helps preventing these loops. When PE-2 receives the EVPN-IFL route from PE-3 with a D-path containing domain IDs configured on PE-2, such as 64496:1020, it does not install the route in the VPRN route table, as shown in Figure 77: Loop prevention between PE-2 and PE-3:

Figure 77: Loop prevention between PE-2 and PE-3



The following command on PE-2 shows that in the EVPN-IFL route for prefix 172.31.6.0/24 that was received from PE-3, a D-path loop has been detected in VPRN 10:

```
*A:PE-2# show router bgp routes evpn ip-prefix prefix 172.31.6.0/24 hunt

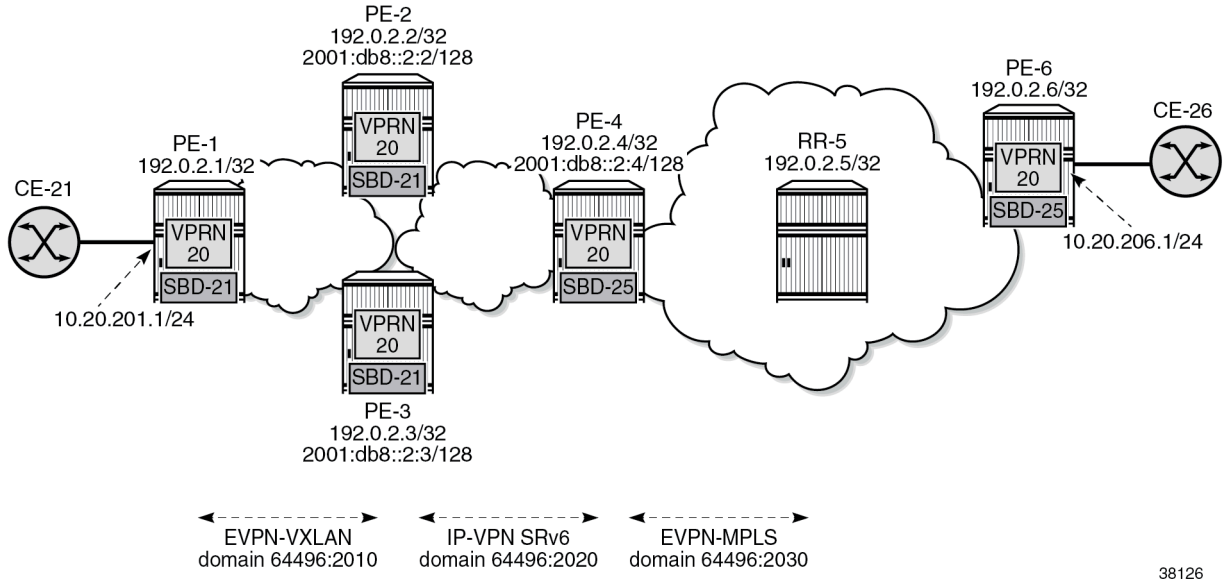
Domain IDs in R-VPLS BGP-EVPN MPLS and BGP-EVPN VXLAN instances

Loops can also be prevented in Layer 3 EVPN data center gateway (DC GW) scenarios where EVPN-IFF routes are translated into IP-VPN routes, and vice versa. Because redundant GWs are used, the scenario is subject to Layer 3 routing loops and the D-path attribute helps preventing these loops without the need for extra routing policies to tag or drop routes. Figure 78: Example topology with R-VPLS shows a slightly modified example topology with R-VPLS with PE-2 and PE-3 acting as redundant DC GWs. PE-1 advertises an EVPN-IFF route for prefix 10.20.201.0/24 and PE-6 advertises an EVPN-IFF route for prefix 10.20.206.0/24.

Figure 78: Example topology with R-VPLS



The service configuration on PE-1 does not include a domain ID, as follows:

```
# on PE-1:
configure
    service
        vprn 20 name "VPRN 20" customer 1 create
            autonomous-system 64496
            interface "int-SBD-21" create
                vpls "SBD-21"
                    evpn-tunnel
                exit
            exit
            interface "int-PE-1-CE-21" create
                address 10.20.201.1/24
                sap 1/1/c5/1:20 create
                exit
            exit
            no shutdown
        exit
        vpls 21 name "SBD-21" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                ip-route-advertisement
                evi 21
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

```
        exit
```

On DC GW PE-2, domain ID 64496:2010 is configured in VPLS "SBD-21" whereas domain ID 64496:2020 is configured in VPRN 20. The configuration on DC GW PE-3 is similar.

```
# on PE-2:
configure
    service
        vprn 20 name "VPRN 20" customer 1 create
            autonomous-system 64496
            interface "int-SBD-21" create
                vpls "SBD-21"
                    evpn-tunnel
                exit
            exit
            segment-routing-v6 1 create
                locator "PE-2_loc"        # on PE-3: "PE3_loc"
                    function
                        end-dt46
                    exit
                exit
            exit
            bgp-ipvpn
                segment-routing-v6
                    domain-id 64496:2020
                    route-distinguisher 192.0.2.2:26        # on PE-3; 192.0.2.3:26
                    srv6-instance 1 default-locator "PE-2_loc"  # on PE-3: "PE3_loc"
                    source-address 2001:db8::2:2            # on PE-3: 2001:db8::2:3
                    vrf-target target:64496:20
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vpls 21 name "SBD-21" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                ip-route-advertisement domain-id 64496:2010
                evi 21
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

The service configuration examples for PE-1, PE-2, and PE-3 show how a loop is detected at the DC GWs in VPN-IPv4 routes for prefix 10.20.201.0/24 received from the other DC GW. The following command on DC GW PE-2 shows that a D-path loop is detected in VPRN 20 in a VPN-IPv4 route for prefix 10.20.201.0/24 received from DC GW PE-3:

```
*A:PE-2# show router bgp routes vpn-ipv4 rd 192.0.2.3:26 hunt
===============================================================================
 BGP Router ID:192.0.2.2        AS:64496       Local AS:64496
```

```

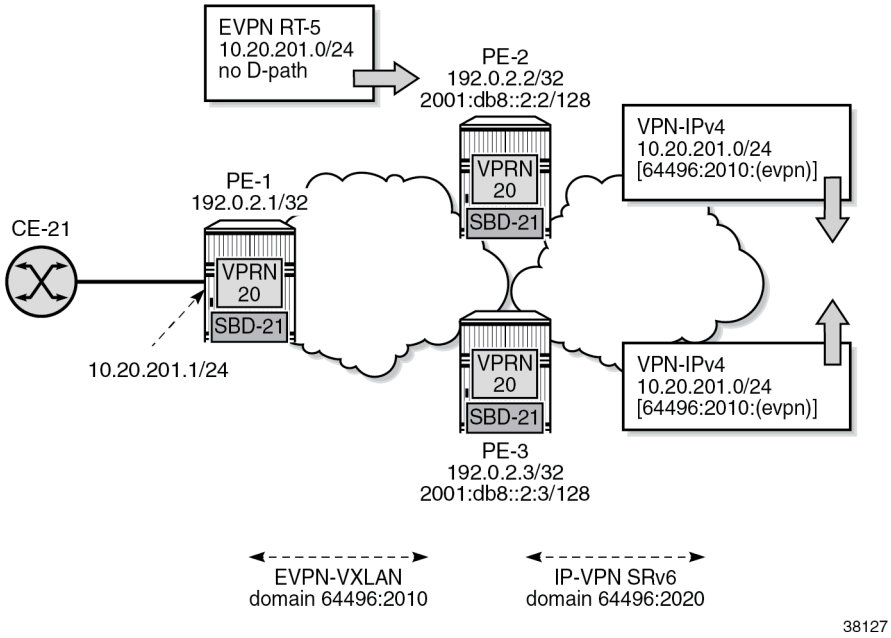
Figure 79: Loop prevention between DC GW PE-2 and DC GW PE-3 shows that PE-1 sends an EVPN-IFF route for prefix 10.20.201.0/24 without D-path attribute to PE-2 and PE-3. Both PE-2 and PE-3 re-advertise prefix 10.20.201.0/24 as a VPN-IPv4 route with D-path attribute 64496:2010:(evpn). When PE-2 receives this VPN-IPv4 route from PE-3, it detects a loop based on the D-path attribute with domain segment 64496:2010:(evpn) and does not install the route in the VPRN route table. Likewise, PE-3 receives the VPN-IPv4 route from PE-2 and does not install it in the VPRN route table.

Figure 79: Loop prevention between DC GW PE-2 and DC GW PE-3



PE-2 does not use the VPN-IPv4 route for prefix 10.20.201.0/24 from PE-3. The VPRN route table on PE-2 contains the EVPN-IFF route received from PE-1 for prefix 10.20.201.0/24:

```
*A:PE-2# show router 20 route-table

===============================================================================
```

Conclusion

The D-path attribute provides traceability for VPRN BGP routes and can be used for BGP best path selection. The D-path attribute for VPRN routes also helps preventing loops without the need for dedicated routing policies to tag and drop routes.

Dual EVPN-MPLS Instance VPLS Services

This chapter provides information about the dual EVPN-MPLS instance VPLS services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. Dual EVPN-MPLS instance in VPLS is supported in SR OS Release 21.10.R1 and later.

Overview

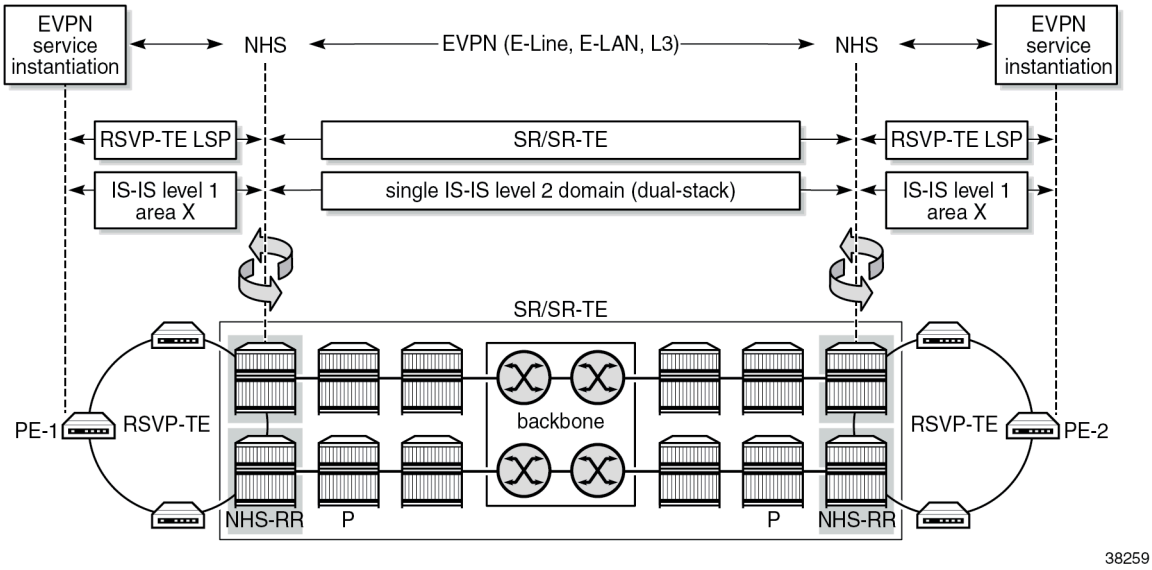
One of the scale issues that low-scale access nodes or leaf PEs face in high-scale architectures is the limited number of EVPN/IP-VPN next hops, tunnels, and service labels that they support.

The following solutions reduce the number of EVPN next hops exposed to the access nodes:

- inter-AS model B, as described in the Inter-AS VPRN Model B chapter
- next-hop-self route reflectors (NHS-RRs)

Figure 80: Access nodes receive next hops from the NHS-RRs shows the NHS-RR solution reducing the number of EVPN next hops that are sent to the low-scale access nodes PE-1 and PE-2. Only the two NHS-RRs are exposed as next hops to PE-1.

Figure 80: Access nodes receive next hops from the NHS-RRs



The number of EVPN next hops is reduced, but the number of service labels to be learned is not. PE-1 still learns one service label per remote PE for each service it is attached to. In case of EVPN E-LAN services and broadcast, unknown unicast, and multicast (BUM) traffic, the ingress PE still needs one copy of every BUM packet per egress PE that exists in the remote domains, even if all the BUM traffic goes through one of the two NHS-RRs (or ASBRs in the case of model B).

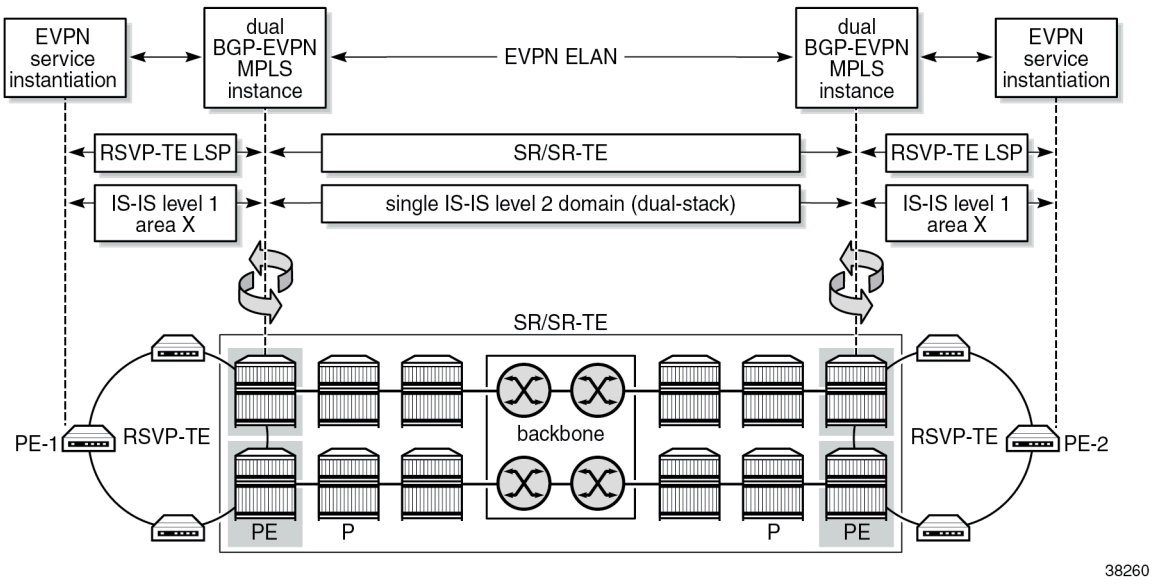
The following solutions reduce the number of service labels:

- VPRN services on the NHS-RRs with **allow-export-bgp-vpn** configured
- dual EVPN-MPLS instance VPLS services on the NHS-RRs

The **allow-export-bgp-vpn** command applies to VPRN services using EVPN-IFL, VPN-IPv4, and VPN-IPv6 families. Routes from the WAN are imported to the VPRN service and exported to the access nodes as new VPN-IP routes. The values of the service labels, route targets (RTs), and BGP next hops of the re-advertised routes are based on the configuration of the exporting VPRN.

Figure 81: Access nodes receive one service label per service from each NHS-RR shows a dual EVPN-MPLS instance VPLS service on the NHS-RRs, which offers a similar solution for EVPN-VPLS services to the **allow-export-bgp-vpn** solution for VPRN services. EVPN-MPLS routes received from the WAN are imported to the network EVPN-MPLS instance and redistributed to the access EVPN-MPLS instance with a new route distinguisher (RD), next hop, service label, and possibly a new RT. The ingress PE learns only one service label for each NHS-RR per service, as opposed to one service label per remote PE that is attached to the same EVPN service. With this solution, the replication of BUM traffic is also optimized because the ingress PE sends a single copy of each BUM packet to the NHS-RR, as opposed to one copy per egress PE.

Figure 81: Access nodes receive one service label per service from each NHS-RR



In the example, redundant NHS-RRs are used. Redundancy is handled via anycast multihoming, which implies that two or more PEs are configured with the same service parameters as part of the same redundancy group: identical route distinguishers and RTs per instance, and the same anycast IP address. The ingress PEs set up EVPN destinations to only one PE in the anycast group for a specific service. EVPN BUM destinations are not established between PEs in the same anycast group because the received anycast peer inclusive multicast Ethernet tag (IMET) routes have the same local originating IP address. In anycast multihoming scenarios, policies are required to prevent control-plane loops.

Configuration

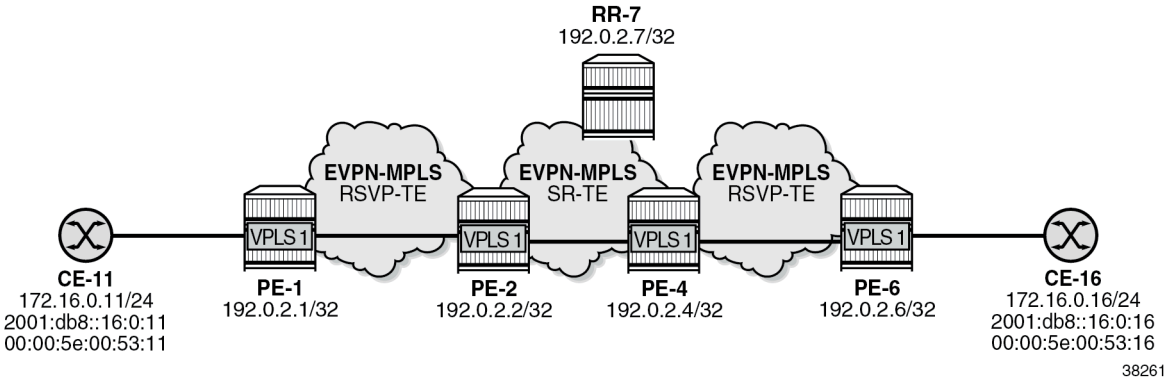
The following scenarios are described in this section:

- dual EVPN-MPLS instance VPLS without multihoming
- dual EPVN-MPLS instance VPLS with anycast multihoming

Dual EVPN-MPLS instance VPLS without multihoming

Figure 82: Example topology 1 shows EVPN-MPLS VPLS 1 configured on four PEs. PE-2 and PE-4 are EVPN gateways (GWs). RR-7 is the route reflector for PE-2 and PE-4 in the WAN network.

Figure 82: Example topology 1



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 1 between PE-1 and PE-2 and between PE-4 and PE-6
- IS-IS level 2 between PE-2, PE-4, and RR-7
- SR-TE tunnels between PE-2 and PE-4
- MPLS LSPs between PE-1 and PE-2 and between PE-4 and PE-6

BGP is configured on all nodes for the EVPN address family. PE-1 peers with the dual-homed EVPN GW PE-2. In a similar way, PE-6 peers with EVPN GW PE-4. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "access1"
                family evpn
                peer-as 64496
                neighbor 192.0.2.2
                exit
            exit
```

EVPN GW PE-2 peers with PE-1 in BGP group "access1" and with RR-7 in BGP group "WAN":

```
# on PE-2:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
```

```
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "access1"
                family evpn
                next-hop-self
                cluster 192.0.2.2
                export "drop-tag-20"
                peer-as 64496
                neighbor 192.0.2.1
                exit
            exit
            group "WAN"
                family evpn
                next-hop-self
                export "drop-tag-10"
                peer-as 64496
                neighbor 192.0.2.7
                exit
            exit
```

The BGP configuration on PE-4 is similar. The export policies use tags to avoid loops in topologies with redundant EVPN GWs, as described in the section Dual EVPN-MPLS instance VPLS with anycast multihoming.

RR-7 peers with PE-2 and PE-4 in BGP group "WAN":

```
# on RR-7:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "WAN"
                family evpn
                cluster 192.0.2.7
                peer-as 64496
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.4
                exit
            exit
```

On PE-1, VPLS 1 is configured with a single EVPN-MPLS instance. The RD 192.0.2.1:1 for BGP 1 is auto-derived from the values for the IPv4 system address and the EVI. PE-1 imports and exports routes with RT 64496:101.

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
                # route-distinguisher 192.0.2.1:1  # will be auto-derived
                route-target export target:64496:101 import target:64496:101
            exit
            bgp-evpn
```

```
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/1/c10/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, VPLS 1 is configured with two EVPN-MPLS instances: instance 1 is configured with multihoming mode access and instance 2 with the (default) multihoming mode network, as follows:

```
# on PE-2:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.2 comm-val 2000 to 2999
        exit
        vpls 1 name "VPLS 1" customer 1  create
            description "dual BGP-EVPN MPLS instance VPLS 1"
            bgp
                # route-distinguisher 192.0.2.2:1    # will be auto-derived
                route-target export target:64496:101 import target:64496:101
            exit
            bgp 2
                route-distinguisher auto-rd    # different RD (must be configured)
                route-target export target:64496:100 import target:64496:100
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    mh-mode access
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
                mpls bgp 2
                    # mh-mode network               # default MH mode
                    auto-bind-tunnel
                        resolution-filter
                            sr-te
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            stp
```

```
            shutdown
        exit
        no shutdown
```

Note: The RD for BGP 1 can be auto-derived from the values for the IPv4 system address and the EVI, for example, 192.0.2.2:1 on PE-2. The RD for BGP 2 cannot be auto-derived from the values for the IPv4 system address and the EVI, because the RD for BGP 2 must be different from the RD for BGP 1, so it must be configured manually or with **auto-rd**.

On PE-4, the configuration is similar:

```
# on PE-4:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.4 comm-val 2000 to 2999
        exit
        vpls 1 name "VPLS 1" customer 1 create
            description "dual BGP-EVPN MPLS instance VPLS"
            bgp
                # route-distinguisher 192.0.2.4:1    # will be auto-derived
                route-target export target:64496:102 import target:64496:102
            exit
            bgp 2
                route-distinguisher auto-rd    # different RD
                route-target export target:64496:100 import target:64496:100
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    mh-mode access
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
                mpls bgp 2
                    # mh-mode network               # default MH mode
                    auto-bind-tunnel
                        resolution-filter
                            sr-te
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

The following command on PE-2 shows BGP instances 1 and 2 in VPLS 1. RD 192.0.2.2:1 for BGP instance 1 is auto-derived from the IPv4 system address and the EVI; the RD for BGP instance 2 is configured with **auto-rd** and has the value 192.0.2.2:2000. The RT values are configured.

```
*A:PE-2# show service id 1 bgp
```

```

When traffic is sent between CE-11 and CE-16, MAC address 00:00:5e:00:53:11 of CE-11 is learned on the local SAP in VPLS 1 on PE-1 and MAC address 00:00:5e:00:53:16 of CE-16 is learned on the local SAP in VPLS 1 on PE-6. EVPN MAC routes are advertised to the BGP-EVPN peers.

The forwarding database (FDB) on PE-1 is as follows:

```
*A:PE-1# show service id 1 fdb detail

===============================================================================

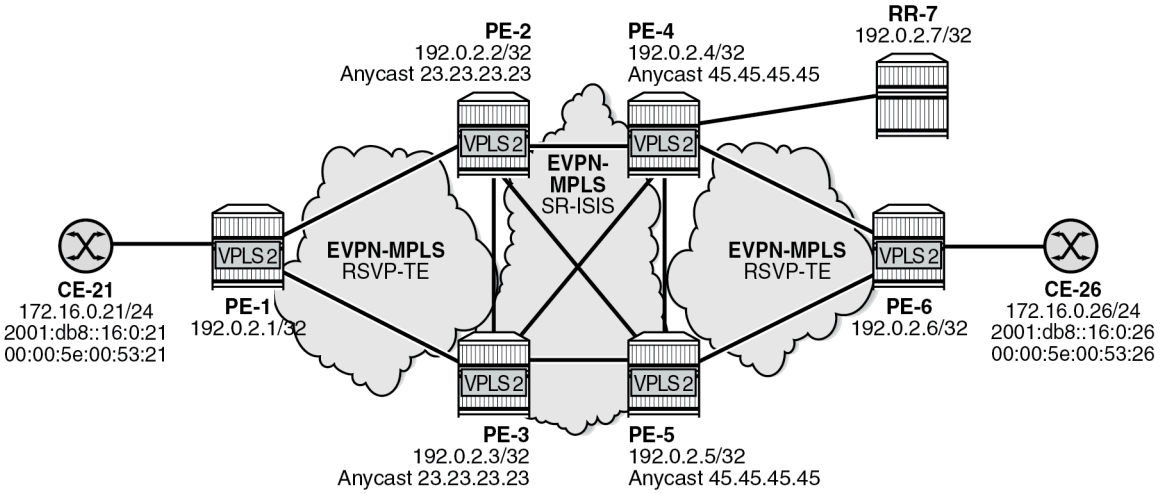
Dual EVPN-MPLS instance VPLS with anycast multihoming

Figure 83: Example topology 2 shows example topology 2 with VPLS 2 configured on six PEs. PE-2 and PE-3 are redundant EVPN GWs with anycast address 23.23.23.23; PE-4 and PE-5 are redundant EVPN GWs with anycast address 45.45.45.45. RR-7 is the route reflector for PE-2, PE-3, PE-4, and PE-5 in the WAN network.

Figure 83: Example topology 2



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 1 between PE-1, PE-2, and PE-3
- IS-IS level 1 between PE-4, PE-5, and PE-6
- IS-IS level 2 between PE-2, PE-3, PE-4, PE-5, and RR-7
- SR-ISIS between PE-2, PE-3, PE-4, and PE-5
- MPLS LSPs between PE-1 and PE-2, between PE-1 and PE-3, between PE-4 and PE-6, and between PE-5 and PE-6

The BGP configuration on PE-1 and PE-6 is similar.

```
# on PE-1:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "access1"
                family evpn
                peer-as 64496
                neighbor 192.0.2.2        # on PE-6: 192.0.2.4
                exit
                neighbor 192.0.2.3        # on PE-6: 192.0.2.5
                exit
            exit
```

The BGP configuration on PE-3 is:

```
# on PE-3:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "WAN"
                family evpn
                next-hop-self
                export "drop-tag-10"
                peer-as 64496
                neighbor 192.0.2.7
                exit
            exit
            group "access1"
                family evpn
                next-hop-self
                cluster 192.0.2.3
                export "drop-tag-20"
                peer-as 64496
                neighbor 192.0.2.1
                exit
            exit
```

The BGP configuration on PE-2, PE-4, and PE-5 is similar.

On PE-1, VPLS 2 is configured with a single EVPN-MPLS instance. PE-1 imports and exports routes with RT 64496:501. The configuration is as follows:

```
# on PE-1:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            bgp
                # route-distinguisher 192.0.2.1:2  # will be auto-derived
                route-target export target:64496:501 import target:64496:501
            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/1/c10/1:2 create
                no shutdown
            exit
            no shutdown
```

```
        exit
```

On PE-2 and PE-3, the following policies are used in VPLS 2:

- Export policy "vsi-501-export" adds the communities "SOO-23" for the site of origin (SOO) and "RT64496:501" for the RT.
- Export policy "vsi-502-export" adds the communities "SOO-23" and "RT64496:502".
- Import policy "vsi-501-import" prevents loops based on the SOO and accepts routes with RT 64496:501.
- Import policy "vsi-502-import" prevent loops based on the SOO and accepts routes with RT 64496:502.

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            community "SOO-23"
                members "origin:23:23"
            exit
            community "RT64496:501"
                members "target:64496:501"
            exit
            community "RT64496:502"
                members "target:64496:502"
            exit
            policy-statement "vsi-501-export"
                default-action accept
                    community add "RT64496:501" "SOO-23"
                exit
            exit
            policy-statement "vsi-501-import"
                entry 10
                    from
                        community "SOO-23"
                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        community "RT64496:501"
                        family evpn
                    exit
                    action accept
                    exit
                exit
            exit
            policy-statement "vsi-502-export"
                default-action accept
                    community add "RT64496:502" "SOO-23"
                exit
            exit
            policy-statement "vsi-502-import"
                entry 10
                    from
                        community "SOO-23"
                        family evpn
                    exit
                    action drop
                    exit
```

```
                exit
                entry 20
                    from
                        community "RT64496:502"
                        family evpn
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

On PE-2 and PE-3, VPLS 2 is configured with two EVPN-MPLS instances: instance 1 is configured with multihoming mode access and instance 2 with multihoming mode network. For redundancy, anycast multihoming is configured with anycast address 23.23.23.23 and identical RDs and RTs for the same instance. The RD for BGP 1 is 192.0.2.23:2 and the RD for BGP 2 is 192.0.2.32:2. The **default-route-tag 10** command is configured for service instance 1, while **default-route-tag 20** is configured for service instance 2. These route tags are used in the BGP peer export policies to differentiate the different routes.On PE-2 and PE-3, VPLS 2 is configured as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            description "dual BGP-EVPN MPLS instance VPLS"
            bgp
                route-distinguisher 192.0.2.23:2
                vsi-export "vsi-501-export"
                vsi-import "vsi-501-import"
            exit
            bgp 2
                route-distinguisher 192.0.2.32:2
                vsi-export "vsi-502-export"
                vsi-import "vsi-502-import"
            exit
            bgp-evpn
                incl-mcast-orig-ip 23.23.23.23
                evi 2
                mpls bgp 1
                    mh-mode access
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    default-route-tag 10
                    no shutdown
                exit
                mpls bgp 2
                    # mh-mode network               # default MH mode
                    auto-bind-tunnel
                        resolution-filter
                            sr-isis
                        exit
                        resolution filter
                    exit
                    default-route-tag 20
                    no shutdown
                exit
            exit
            stp
```

```
            shutdown
        exit
        no shutdown
```

Note: For anycast multihoming, the RDs must be identical, so all RDs are configured manually.

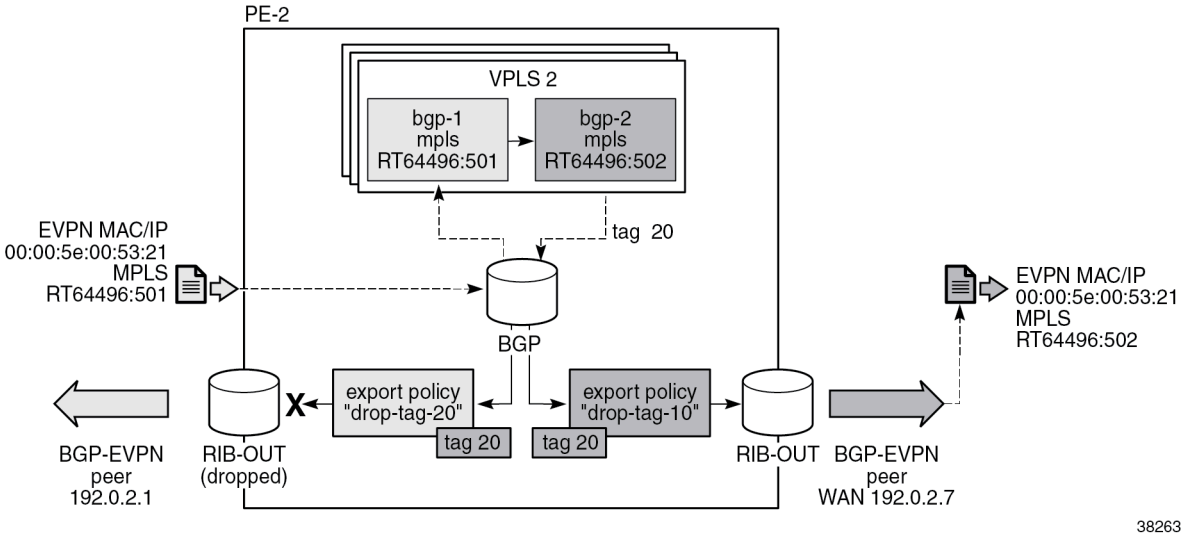
In datacenter GWs (DC GWs) with EVPN-VXLAN and EVPN-MPLS instances, route policies can match on the encapsulation type VXLAN or MPLS. In DC GWs with two EVPN-MPLS instances, the default route tag is used instead. The default route tag prevents a MAC/IP route that is installed in instance 1 (access) from being readvertised back to the access peers. In a similar way, MAC/IP routes installed in instance 2 are not readvertised back to peers in instance 2. On PE-2 and PE-3, the BGP peer export policy "drop-tag-10" drops routes with tag 10 and is configured in BGP group "WAN" with neighbor RR-7; BGP peer export policy "drop-tag-20" drops routes with tag 20 and is configured in BGP group "access1" with neighbor PE-1.

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            policy-statement "drop-tag-10"
                description "used as export policy toward WAN BGP peers"
                entry 10
                    from
                        tag 10
                    exit
                    action drop
                    exit
                exit
                default-action accept
                exit
            exit
            policy-statement "drop-tag-20"
                description "used as export policy toward DC BGP peers"
                entry 10
                    from
                        tag 20
                    exit
                    action drop
                    exit
                exit
                default-action accept
                exit
            exit
            commit
        exit
        bgp
            group "access1"
                export "drop-tag-20"
            exit
            group "WAN"
                export "drop-tag-10"
            exit
```

Figure 84: Export policies on PE-2 drop routes based on tag shows an incoming EVPN MAC route on PE-2 for CE-21's MAC address 00:00:5e:00:53:21. PE-2 receives the EVPN MAC route with RT target:64496:501 from PE-1 (BGP-EVPN peer 192.0.2.1). On PE-2, BGP 1 in VPLS 2 imports routes with this RT and the MAC address is installed in the FDB. The EVPN MAC route is redistributed to BGP 2

where the communities "RT64496:502" and "SOO-23", as well as internal tag 20, are added to the route. When PE-2's BGP process sends an EVPN MAC route with tag 20 to BGP peer PE-1, the BGP export policy "drop-tag-20" drops the route, preventing PE-2 from re-advertising the EVPN MAC route back to the access peer 192.0.2.1. PE-2 can only send the EVPN MAC route to WAN neighbor 192.0.2.7 because the BGP export policy toward the WAN only drops the routes with tag 10, not the ones with tag 20.

Figure 84: Export policies on PE-2 drop routes based on tag



For completeness, the configuration on PE-4 and PE-5 is as follows:

```
# on PE-4, PE-5:
configure
    router Base
        policy-options
            begin
            community "SOO-45"
                members "origin:45:45"
            exit
            community "RT64496:502"
                members "target:64496:502"
            exit
            community "RT64496:503"
                members "target:64496:503"
            exit

Conclusion

Dual-instance EVPN-MPLS GWs reduce the number of service labels to be learned at the access nodes, and optimizes the replication of BUM traffic from the access nodes.

EVPN E-LAN Services with SRv6 Transport

This chapter provides information about SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services is supported on FP-based platforms with FP4-based network ports in SR OS Release 22.7.R1 and later.

Overview

On FP-based platforms with FP4-based network ports, SR OS provides SRv6 support for distributed EVPN-enabled VPLS Layer 2 multipoint overlay services. SRv6 tunnels carry EVPN data between the PEs on which the EVPN service is provisioned. As usual in EVPN services, a full mesh of SRv6 tunnels is set up among all PEs that participate in the EVPN-enabled VPLS service. This supports the flooding of Broadcast, Unknown unicast, or Multicast (BUM) traffic to all remote destinations in the service, while ensuring that the PEs receive the traffic without looping or duplication of frames. Two or more routers may participate in a single EVPN-enabled VPLS service; a single router may participate in multiple EVPN-enabled VPLS services. The PE routers attached to an EVPN-enabled VPLS service with SRv6 transport use SRv6 End.DT2U behavior to terminate and forward unicast traffic, and SRv6 End.DT2M behavior to terminate and forward BUM traffic.

An SRv6 L2 Service TLV, which is carried in a BGP Prefix-SID attribute, signals the SRv6 Service SID for the End.DT2U or End.DT2M behavior for an EVPN-enabled VPLS Layer 2 overlay service, as per RFC 9252. The SRv6 Service SID is equivalent to an MPLS label for EVPN service routes in RFC 7432.

When a PE is attached to an EVPN-enabled VPLS service with SRv6 transport, the PE advertises its originating IP address in an Inclusive Multicast Ethernet Tag (IMET) route (also known as en EVPN type 3 route), along with the service attributes and the SRv6 SID corresponding to the End.DT2M behavior for the service. A remote PE attached to the same EVPN-enabled VPLS service imports the IMET route based on the import route target and adds an SRv6 destination entry to its flooding list for the EVPN-enabled VPLS service. In this way, all PEs that participate in an EVPN-enabled VPLS service learn about each other.

As in any other type of EVPN-enabled VPLS service, a PE learns the MAC address of a locally connected CE, either via data plane MAC learning or static provisioning. In the case of data plane MAC learning, a PE learns the source MAC address from data frames that it receives from the CE and adds a temporary entry for it in a VPLS forwarding database (FDB), which, on each PE, is private for each EVPN-enabled VPLS service.

A local MAC address is advertised in an EVPN MAC/IP advertisement route (EVPN type 2 route) for the EVPN-enabled VPLS service, along with the service parameters and an SRv6 SID corresponding to the

End.DT2U behavior for the service. A remote PE that imports the EVPN MAC/IP advertisement route adds an entry for the advertised MAC addresses to the FDB, pointing at an SRv6 destination based on the received SRv6 SID. In this way, remote PEs that participate in an EVPN-enabled VPLS service with SRv6 transport learn how to unicast return traffic to the remote (source) MAC address.

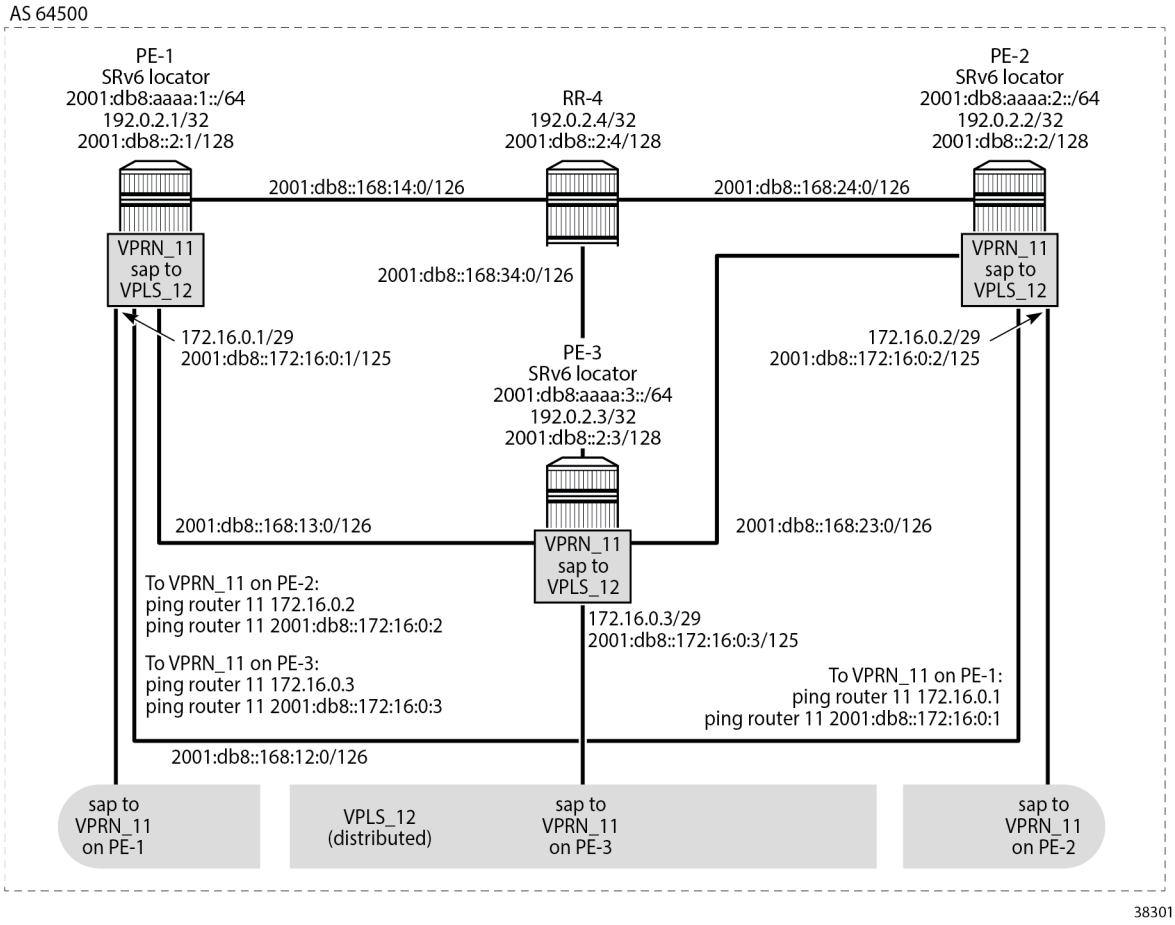
The **locator** command in the **service vpls <service-id> segment-routing-v6 <instance>** context configures the SRv6 locator that the PE uses to terminate SRv6 traffic for the EVPN-enabled VPLS service.

The base SRv6 configuration is as described in the SRv6 Encapsulation in the Base Routing Instance chapter.

Configuration

Figure 85: Example topology shows the example topology with three PE routers. The SRv6-enabled network that it represents comprises PE-1, PE-2, and PE-3 in the control and data planes, and a BGP route reflector RR-4 in the control plane only. The SRv6-enabled network has only IPv6 addresses and interfaces. IS-IS and BGP are configured on all routers. The system interfaces have also an IPv4 address, from which a unique router-id is automatically derived for IS-IS and BGP respectively.

Figure 85: Example topology



For the traffic of data frames from the EVPN-enabled VPLS service on a local PE to the same EVPN-enabled VPLS service on a remote PE, the local PE acts as the SRv6 ingress PE node, while the remote PE acts as the SRv6 egress PE node. SRv6 and forwarding port extensions (FPE) are configured only on the PE routers.

The **ping** commands between IPv4 and IPv6 interface addresses in the EVPN-enabled VPLS service simulate IPv4 and IPv6 data traffic respectively.

Configure the router

This configuration includes:

- on PE-1, PE-2, PE-3, and RR-4:
  - ports, IPv6-only interfaces, and system interfaces
  - IS-IS:
    - level 2 capability with wide metrics (for the 128-bit identifiers)
    - native IPv6 routing
    - the **traffic-engineering** and **traffic-engineering-options** commands, as a best practice to advertise the router capability within the autonomous system (AS)
  - BGP, with internal group "gr_v6_internal" that includes:
    - the EVPN family
    - BGP neighbor system IPv6 addresses
- on PE-1, PE-2, and PE-3, port cross-connect (PXC), using internal loopbacks on an FP4 MAC chip, as described in the Segment Routing over IPv6 chapter

The following example configuration applies for PE-1. A similar configuration applies for PE-2, PE-3, and RR-4. RR-4 has PE-1, PE-2 and PE-3 as BGP neighbors in a cluster.

```
*A:PE-1# configure
    port 1/1/c2/1
        ethernet

Configure the VPRNs to simulate CEs

On each PE, the VPRN configuration includes an IPv4 address and an IPv6 address for an interface from the local VPRN to the EVPN-enabled VPLS service. These IPv4 and IPv6 addresses must be in the same address range on all PEs, because the same EVPN-enabled VPLS service is provisioned on each PE. Each interface to the (local) EVPN-enabled VPLS service also includes a SAP.

The VPRNs are introduced only to simulate CEs from where the **ping** commands can be launched.

The following example configuration applies for VPRN 11 on PE-1. A similar configuration applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

```
*A:PE-1# configure
    service
        vprn 11 name "VPRN_11" customer 1 create
            description "CE_1"
            interface "local" create
                mac 00:00:5e:00:53:01
                address 172.16.0.1/29
                ipv6
                    address 2001:db8::172:16:0:1/125
                exit
                sap 1/1/c1/2:11 create
                exit
            exit
            no shutdown
        exit
    exit all
```

For example, VPRN 11 on PE-2 has the following interface, with corresponding IPv4 and IPv6 addresses. Similar output applies for VPRN 11 on PE-1 and for VPRN 11 on PE-3.

```
*A:PE-2# show router 11 interface

===============================================================================
Interface Table (Service: 11)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
local                            Up        Up/Up       VPRN    1/1/c2/2:11
   172.16.0.2/29                                               n/a
   2001:db8::172:16:0:2/125                                    PREFERRED
   fe80::200:22ff:fe22:2222/64                                 PREFERRED
-------------------------------------------------------------------------------
Interfaces : 1
===============================================================================
```

VPRN 11 on PE-1 has the following IPv4 and IPv6 routes. Similar output applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

For IPv4:

```
*A:PE-1# show router 11 route-table

===============================================================================
Route Table (Service: 11)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
172.16.0.0/29                                 Local   Local     00h15m44s  0
       local                                                        0
-------------------------------------------------------------------------------
No. of Routes: 1
---snip---
===============================================================================
```

For IPv6:

```
*A:PE-1# show router 11 route-table ipv6

===============================================================================
IPv6 Route Table (Service: 11)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8::172:16:0:0/125                      Local   Local     00h15m43s  0
       local                                                        0
-------------------------------------------------------------------------------
No. of Routes: 1
---snip---
===============================================================================
```

VPRN 11 on PE-1 has one locally learned MAC address for the locally configured interface. Similar output applies for VPRN 11 on PE-2 and for VPRN 11 on PE-3.

```
*A:PE-1# show router 11 arp summary
```

```
===============================================================
ARP Table Summary (Service: 11)
===============================================================
Local ARP Entries    : 1
---snip---
Dynamic ARP Entries  : 0
---snip---
---------------------------------------------------------------
No. of ARP Entries   : 1
===============================================================
```

The **show router 11 arp** command shows the association between the IP address and the MAC address, and the interface that the MAC address belongs to. The MAC address for the local interface to the EVPN-enabled VPLS service corresponds with that of the SAP that is configured for it in VPRN 11. Because the interface is statically configured, the association between the IP address and the MAC address does not expire. Similar output applies for PE-2 and for PE-3.

```
*A:PE-1# show router 11 arp

===============================================================================
ARP Table (Service: 11)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface

-------------------------------------------------------------------------------
No. of ARP Entries: 1
===============================================================================
```

Configure data path support, FPE, and SRv6

Configure data path support (PXC) and FPE identically on PE-1, PE2, and PE-3.

```
*A:PE-1# configure
    card 1
        mda 1
            xconnect
                mac 1 create
                    loopback 1 create
                    exit
                    loopback 2 create
                    exit
                exit
            exit
            no shutdown
        exit
    exit
    port-xc
        pxc 1 create
            port 1/1/m1/1
            no shutdown
        exit
        pxc 2 create
            port 1/1/m1/2
            no shutdown
        exit
    exit
    port pxc-1.a
        no shutdown
```

```
        exit
    port pxc-1.b
        no shutdown
    exit
    port pxc-2.a
        no shutdown
    exit
    port pxc-2.b
        no shutdown
    exit
    port 1/1/m1/1
        no shutdown
    exit
    port 1/1/m1/2
        no shutdown
    exit
    fwd-path-ext
        fpe 1 create
            path pxc 1
            srv6 origination
                interface-a
                exit
                interface-b
                exit
            exit
        exit
        fpe 2 create
            path pxc 2
            srv6 termination
                interface-a
                exit
                interface-b
                exit
            exit
        exit
    exit all
```

Configure the SRv6 locator *"PE-1_loc_VPLS"* with **ip-prefix** *2001:db8:aaaa:1::/64* in the **router Base segment-routing segment-routing-v6** context on PE-1 and similar on PE-2, with **ip-prefix** *2001:db8:aaaa:2::/64* for SRv6 locator *"PE-2_loc_VPLS"*, and on PE-3, with **ip-prefix** *2001:db8:aaaa:3::/64* for SRv6 locator *"PE-3_loc_VPLS"*.

```
*A:PE-1# configure router Base segment-routing segment-routing-v6
                source-address 2001:db8::2:1
                locator "PE-1_loc_VPLS"
                    block-length 48
                    prefix
                        ip-prefix 2001:db8:aaaa:1::/64
                    exit
                    no shutdown
                exit all
```

Use FPE 1 as the SRv6 origination FPE and FPE 2 as the SRv6 termination FPE on PE-1, and similar on PE-2 for SRv6 locator *"PE-2_loc_VPLS"*, and on PE-3 for SRv6 locator *"PE-3_loc_VPLS"*. For more information, see the Segment Routing over IPv6 chapter.

```
*A:PE-1# config# router Base segment-routing
        segment-routing-v6
            origination-fpe 1
```

```
            locator "PE-1_loc_VPLS"
                termination-fpe 2
                no shutdown
            exit
        exit all
```

Advertise the SRv6 locator *"PE-1_loc_VPLS"* in IS-IS while ensuring level 2 capability on PE-1, and similar on PE-2 for SRv6 locator *"PE-2_loc_VPLS"*, and on PE-3 for SRv6 locator *"PE-3_loc_VPLS"*.

```
*A:PE-1# configure router Base
        isis 0
            segment-routing-v6
                locator "PE-1_loc_VPLS"
                    level-capability level-2
                    level 1
                    exit
                    level 2
                    exit
                exit
                no shutdown
            exit
        exit all
```

Verify the IS-IS data base on PE-1 with the **show router isis 0 database detail** command. The output of this command (shortened here for PE-1, PE-3 and RR-4) provides information about each IS-IS-enabled router. For each uniquely identified IS-IS-enabled router, the SRv6 information indicates:

- the IS-IS-advertised router capabilities
- the IS-IS topology details
- the IPv4 and IPv6 reachability details
- the advertised SRv6 locator TLV
- the advertised configured SRv6 End SID and SRv6 End-X SIDs

```
*A:PE-1# show router isis 0 database detail

Verify data traffic

At this point, verify that IPv4 and IPv6 data traffic is not possible between the local VPRN 11 on PE-1 and the remote VPRN 11 on PE-2 and PE-3. PE-1 is not aware of the remote MAC addresses that are associated with IPv4 address 172.16.0.2 and IPv4 address 172.16.0.3 (or IPv6 address 2001:db8::172:16:0:2 and IPv6 address 2001:db8::172:16:0:3), because only interfaces that are locally connected to the EVPN-enabled VPLS service on PE-1 reply on the ARP request. Perform a similar verification for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-2 and the remote VPRN 11 on PE-1 and PE-3, and for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-3 and the remote VPRN 11 on PE-1 and PE-2.

For example, for IPv4 data traffic to the remote VPRN 11 on PE-2:

```
*A:PE-1# ping router 11 172.16.0.2
PING 172.16.0.2 56 data bytes
Request timed out. icmp_seq=1.
---snip---
---- 172.16.0.2 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

For example, for IPv6 data traffic to the remote VPRN 11 on PE-2:

```
*A:PE-1# ping router 11 2001:db8::172:16:0:2
PING 2001:db8::172:16:0:2 56 data bytes

---- 2001:db8::172:16:0:2 PING Statistics ----
5 packets transmitted, 5 packets bounced, 0 packets received, 100% packet loss
```

Configure the EVPN- and SRv6-enabled VPLS service on PE-1, PE-2, and PE-3

On each PE, this configuration includes a SAP to the local VPRN.

On PE-1, create an SRv6 instance *1* for the EVPN-enabled VPLS service. Use the SRv6 locator *"PE-1_loc_VPLS"* from the **router Base segment-routing segment-routing-v6** context in the **service vpls 12 segment-routing-v6 1** context and configure End.DT2U and End.DT2M behavior for it.

Use the configured SRv6 locator *"PE-1_loc_VPLS"* as the default locator in the **service vpls 12 bgp-evpn segment-routing-v6 1** context. In the **service vpls 12 bgp-evpn segment-routing-v6 1 locator "PE-1_loc_VPLS"** context, use the unique PE-1 system IPv6 address as the route next hop. This configuration can be verified with the **show service id 12 bgp** command (not shown). Perform a similar

configuration on PE-2 (and PE-3), with the configured SRv6 locator *"PE-2_loc_VPLS"* (*"PE-3_loc_VPLS"*) as the default locator, and the PE-2 (PE-3) system IPv6 address as route next hop.

```
*A:PE-1# configure service
        vpls 12 name "VPLS_12" customer 1 create
            description "VPLS_12 on PE-1"
            segment-routing-v6 1 create
                locator "PE-1_loc_VPLS"
                    function
                        end-dt2u
                        end-dt2m
                    exit
                exit
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                segment-routing-v6 bgp 1 srv6-instance 1 default-locator "PE-1_loc_VPLS" create
                    route-next-hop system-ipv6
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/1/c1/1:11 create
                description "sap to VPRN_11 on PE-1"
                no shutdown
            exit
            no shutdown
        exit all
```

The **show service id 12 fdb expiry** command shows that MAC learning and MAC aging are enabled. For example, the VPLS FDB entries that are locally learned expire after 300 seconds.

```
*A:PE-1# show service id 12 fdb expiry

The configuration of the SRv6 End.DT2U and End.DT2M behavior for the SRv6 locator that is used in the EVPN-enabled VPLS service results in corresponding SRv6 full SIDs. For example, the **show service id 12 segment-routing-v6 instance 1** command on PE-2 shows them. For the SRv6 End.DT2U behavior, the SRv6 function is 524288 (0x80000) and the corresponding SRv6 full SID is 2001:db8::aaaa:2:8000::. For the SRv6 End.DT2M behavior, the SRv6 function is 524287 (0x7ffff) and the corresponding SRv6 full SID is 2001:db8::aaaa:2:7fff:f000::. Similar output applies for PE-1 and for PE-3.

```
*A:PE-2# show service id 12 segment-routing-v6 instance 1

===============================================================================
```

Enabling the SRv6 End.DT2M behavior allows the exchange of EVPN IMET BGP update messages for the EVPN family. The **show log log-id <log-id>** command on PE-1 shows the BGP update message that PE-1 receives from PE-2, via the RR. It indicates the remote source address (orig_addr: 2001:db8::2:2), and the route distinguisher (RD: 192.0.2.2:1), tag (tag: 0), route target (Extended Community: target:64500:1), and next hop (Global NextHop 2001:db8::2:2) that PE-1 must use while sending IPv4 or IPv6 data traffic to PE-2. In addition, it indicates the Provicer Multicast Service Interface (PMSI) information about tunnel type (Tunnel-type Ingress Replication), MPLS label (MPLS Label 8388592 (0x7fffff)), and tunnel endpoint (Tunnel-Endpoint 2001:db8::2:2). Finally, it indicates that PE-1 must send the frames to the SRv6 locator (SRv6 SID: 2001:db8:aaaa:2::) with End.DT2M behavior (Behavior: 0x18 (24)). Similar output applies for the BGP update that PE-1 receives from PE-3, via the RR. PE-1 advertises a similar BGP update message to the RR, which forwards it to PE-2 and PE-3 (not shown here). PE-2 and PE-3 receive and advertise similar BGP update messages.

```

The reception of the EVPN IMET BGP update messages triggers PE-1 to install learned inclusive multicast routes as shown with the **show router bgp neighbor <ip-address> received-routes evpn** command. Because PE-1 receives EVPN IMET BGP update messages from PE-2 and from PE-3 with different route distinguishers, PE-1 installs a learned inclusive multicast route for each one of them. Similar output applies for PE-2 and for PE-3. The BGP EVPN inclusive multicast routes that are received, can also be displayed with the **show router bgp routes evpn incl-mcast** command.

```
*A:PE-1# show router bgp neighbor 2001:db8::2:4 received-routes evpn

From the received EVPN IMET BGP update messages, PE-1 learns the SRv6 tunnel endpoints for multicast traffic, as shown with the **show service id 12 segment-routing-v6 instance 1 destinations** command. The segment ID (SRv6 SID) corresponds with the expected End.DT2M behavior on PE-2 and PE-3 respectively. Similar output applies for PE-2 and for PE-3.

```
*A:PE-1# show service id 12 segment-routing-v6 instance 1 destinations

===============================================================================

The list of next hops for the EVPN family can be shown with the **show router bgp next-hop evpn** command. For each next hop, the details can be shown. The **show router bgp next-hop evpn 2001:db8::2:2 detail** command on PE-1 shows the details on PE-1 for next hop 2001:db8::2:2. It indicates that IPv4 and IPv6 data for the EVPN family uses the SRv6 tunnel for locator 2001:db8:aaaa:2::/64 and is

sent to the next hop 2001:db8::2:2 via the resolved next hop fe80::60e:1ff:fe01:1, which corresponds with the "int-PE-1-PE-2" interface on PE-1. Similar output applies on PE-1 for next hop 2001:db8::2:3. Similar output applies for PE-2 and for PE-3.

```
*A:PE-1# show router bgp next-hop evpn 2001:db8::2:2 detail

The **show router bgp routes evpn incl-mcast hunt** command shows a consolidated view on the inclusive multicast routes for the EVPN family. On PE-1, in the RIB In Entries section, it shows for each learned next hop how PE-1 must handle the BUM traffic destined for it. In the RIB Out Entries section, it shows for each local next hop how PE-1 expects the remote routers to handle BUM traffic destined for it. Similar output applies for PE-2 and for PE-3.

```
*A:PE-1# show router bgp routes evpn incl-mcast hunt

Verify data traffic

At this point, verify that IPv4 and IPv6 data traffic is possible between the local VPRN 11 on PE-1 and the remote VPRN 11 on PE-2 and PE-3. Perform a similar verification for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-2 and the remote VPRN 11 on PE-1 and PE-3, and for IPv4 and IPv6 data traffic between the local VPRN 11 on PE-3 and the remote VPRN 11 on PE-1 and PE-2.

For example, for IPv4 data traffic to the remote VPRN 11 on PE-2:

```
*A:PE-1# ping router 11 172.16.0.2
PING 172.16.0.2 56 data bytes
64 bytes from 172.16.0.2: icmp_seq=1 ttl=64 time=6.89ms.
---snip---
---- 172.16.0.2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.94ms, avg = 3.04ms, max = 6.89ms, stddev = 1.93ms
```

For example, for IPv6 data traffic to the remote VPRN 11 on PE-2:

```
*A:PE-1# ping router 11 2001:db8::172:16:0:2
PING 2001:db8::172:16:0:2 56 data bytes
64 bytes from 2001:db8::172:16:0:2 icmp_seq=1 hlim=64 time=14.4ms.
---snip---
---- 2001:db8::172:16:0:2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.09ms, avg = 4.63ms, max = 14.4ms, stddev = 4.88ms
```

When the SRv6 End.DT2U behavior is enabled, the sending of IPv4 or IPv6 data traffic triggers the exchange of EVPN MAC/IP BGP update messages for the EVPN family. The **show log log-id <log-id>** command on PE-1 shows the BGP update message that PE-1 receives from PE-2, via the RR. It indicates the remote MAC address (mac: 00:00:5e:00:53:02), and the route distinguisher (RD: 192.0.2.2:1), ESI (ESI: ESI-0), tag (tag: 0), label (label1: 8388608 (0x800000)), route target (Extended Community: target:64500:1), and next hop (Global NextHop 2001:db8::2:2) that PE-1 must use while sending IPv4 or IPv6 data traffic to PE-2. In addition, it indicates that PE-1 must send the frames to the SRv6 locator (SRv6 SID: 2001:db8:aaaa:2::) with End.DT2U behavior (Behavior: 0x17 (23)). PE-1 derives the SRv6 full

SID that is needed for this (2001:db8:aaaa:2:8000::). Similar output applies for the BGP update that PE-1 receives from PE-3, via the RR. PE-1 advertises a similar BGP update message to the RR, which forwards it to PE-2 and PE-3 (not shown here). PE-2 and PE-3 receive and advertise similar BGP update messages.

```
*A:PE-1# show log log-id 2

The reception of the EVPN MAC/IP BGP update messages triggers PE-1 to install learned MAC routes, as shown with the **show router bgp neighbor <ip-address> received-routes evpn** command. In contrast to the learned inclusive multicast routes, the learned MAC routes expire in accordance with the configuration that is shown with the **show service id 12 fdb expiry** command. PE-1 installs a learned MAC/IP route for each of the remote CEs. PE-1 derives the SRv6 function (524288) from the received label field. The earlier installed inclusive multicast routes remain in place (not shown). The BGP EVPN MAC/IP advertisement routes that are received, can also be displayed with the **show router bgp routes evpn mac** command. Similar output applies for PE-2 and for PE-3.

```
*A:PE-1# show router bgp neighbor 2001:db8::2:4 received-routes evpn

From the received EVPN MAC/IP BGP update messages, PE-1 learns the SRv6 tunnel endpoints for unicast traffic, as shown with the **show service id 12 segment-routing-v6 instance 1 destinations** command. The segment ID (SRv6 SID) corresponds with the expected End.DT2U behavior on PE-2 and PE-3 respectively. The earlier learned SRv6 tunnel endpoints for BUM traffic remain in place. Similar output applies for PE-2 and for PE-3.

```

---snip---
===============================================================================
```

The locally learned MAC address belongs to the originator of the **ping** commands in the VPRN 11 context on PE-1, while the BGP EVPN learned MAC addresses belong to the destinations for those **ping** commands, which are in the VPRN 11 context on PE-2 and in the VPRN 11 context on PE-3 respectively. The Transport:Tnl-Id (for example 2001:db8:aaaa:2:8000::) indicates that PE-1 transports frames to the destination (on or connected to PE-2) via the SRv6 full SID to PE-2 for the End.DT2U behavior. The VPLS FDB entries that PE-1 learns locally expire after 300 seconds. The removal of a locally learned entry from the local VPLS FDB triggers the removal of the corresponding BGP EVPN learned entries in the remote VPLS FDBs. Similar output applies for the **ping** commands in the VPRN 11 context on PE-2 and for the **ping** commands in the VPRN 11 context on PE-3.

```

Conclusion

Distributed EVPN-enabled VPLS services can be transported over SRv6 tunnels that are automatically set up between PEs. PEs attached to the same EVPN-enabled VPLS service exchange EVPN IMET routes and MAC/IP advertisement routes that contain the SRv6 SIDs. Those SRv6 SIDs are required so that PEs can create SRv6 destinations to send unicast and BUM traffic to the other PEs in the service.

EVPN ESI Type 1

This chapter provides information about EVPN ESI Type 1.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.5.R1.

Overview

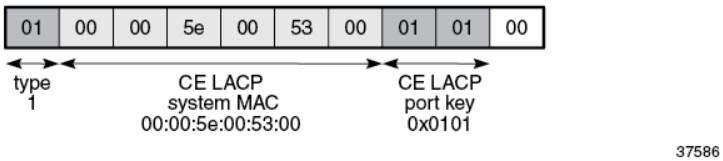
In SR OS releases earlier than 21.5.R1, the 10-byte Ethernet Segment Identifier (ESI) can only be configured manually; the auto-derived EVPN ESI type 1 (as per RFC 7432) is supported in SR OS Release 21.5.R1 and later. The **auto-esi** command is used to configure the ESI mode.

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg$ auto-esi ?
  - auto-esi {none|type-1}
```

The default **auto-esi** value is **none**, which forces the user to configure the 10-byte ESI manually. When **type-1** is configured, a manual ESI cannot be configured and the ESI is auto-derived, as per RFC 7432.

ESI type 1 is auto-derived from the CE's Link Aggregation Control Protocol (LACP) system MAC address and port key. Figure 86: ESI type 1 example shows an example of ESI type 1 for LACP system MAC address 00:00:5e:00:53:00 and administrative key 257 (= 0x0101).

Figure 86: ESI type 1 example



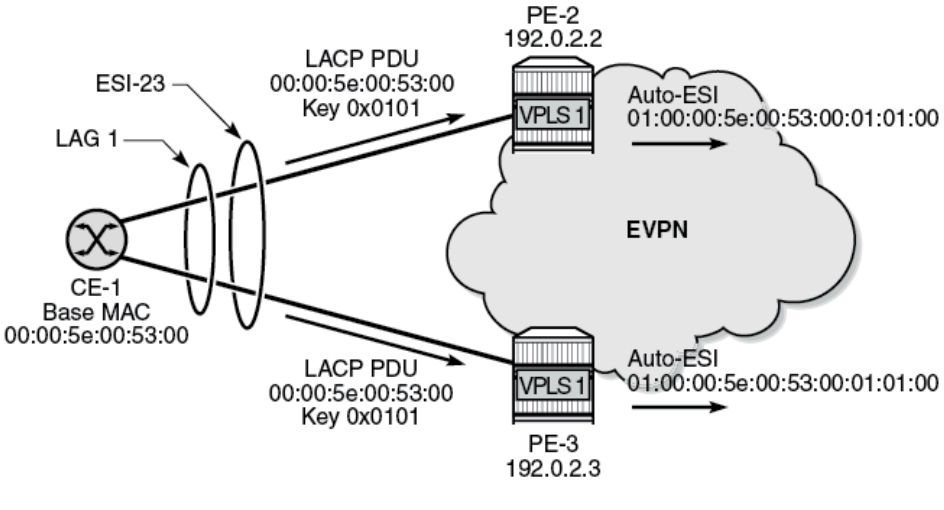
RFC 7432, section "Ethernet Segment", defines ESI type 1 as follows:

- Type 0x01 (byte 0)
- CE LACP system MAC address (bytes 1 through 6); for example, 00:00:5e:00:53:00
- CE LACP port key (bytes 7 and 8); for example, 0x0101
- 0x00 (byte 9 must be zero)

As per RFC 7432, this mechanism can only be used if the ESIs are unique, so the CE LACP system MAC and LACP port key combinations must be unique in the network.

Figure 87: ESI auto-configuration example shows the example where CE-1 has LACP system MAC address 00:00:5e:00:53:00 and LACP port key 257 (= 0x0101). CE-1 sends Link Aggregation Control Protocol Data Units (LACPDUs) to PE-2 and PE-3 with these values. Both PE-2 and PE-3 use ESI 01:00:00:5e:00:53:00:01:01:00 in ES "ESI-23". This applies both to all-active and to single-active ESs.

Figure 87: ESI auto-configuration example



The CE treats both PE-2 and PE-3 as the same switch. This allows the CE to aggregate links that are attached to different PEs in the same bundle.

When the ES LAG goes operationally down, due to the ports going down or LACP going down or standby, the previously auto-derived ESI is retained. However, when the LACP information on the CE is changed, such as a different LACP port key, the ES goes down and a new ESI will be generated.

The all-active ES "AA-ESI-23" with ESI type 1 is configured as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "AA-ESI-23" create
                    auto-esi type-1
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    ac-df-capability exclude
                    lag 1
                    no shutdown
                exit
```

The following restrictions apply for ESI type 1:

- ESI type 1 is only supported on non-virtual (regular) ESs. The following error message is raised when attempting to configure **auto-esi type-1** for a virtual ES:

```
*A:PE-2>config>service>system>bgp-evpn# ethernet-segment "vES-23" virtual create
```

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg$ auto-esi type-1
MINOR: SVCMGR #8050 Ethernet segment config cannot be modified - auto-esi not supported with
 virtual ethernet-segment
```

- ESI type 1 is not supported in ESs with associations other than LAG:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg$ port 1/2/1
MINOR: SVCMGR #8048 Ethernet segment association is not valid - not allowed with auto-esi

*A:PE-2>config>service>system>bgp-evpn>eth-seg# sdp 24
MINOR: SVCMGR #8048 Ethernet segment association is not valid - not allowed with auto-esi
```

- An ES with ESI type 1 can only be enabled if the LAG has LACP enabled:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg$ lag 4
*A:PE-2>config>service>system>bgp-evpn>eth-seg$ no shutdown
MINOR: SVCMGR #8057 Ethernet segment cannot change admin state - LACP not enabled on LAG for
 auto-esi type 1 ethernet-segment
```

- ESI type 1 is allowed with all-active and single-active ESs. When used in single-active mode, the CE must use a single LAG to connect to the multi-homed PEs.
- It is not possible to manually configure an ESI when **auto-esi type-1** is configured:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg# esi 01:00:00:00:00:23:00:00:00:01
MINOR: SVCMGR #8050 Ethernet segment config cannot be modified - esi value and auto-esi type
 incompatible
```

- An ES with a manually configured ESI cannot be created with the same ESI value as the auto-derived ESI type 1 in another ES.

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg# esi 01:00:00:5e:00:53:00:01:01:00
MINOR: SVCMGR #8047 Ethernet segment id is not valid - ESI already in use by another
 ethernet segment
```

- If an ES with manual ESI is active and another ES is configured with an auto-derived ESI with the same value as the manual ESI, the auto-ESI value is deleted, and a log event is added to log "99":

```
# in log "99":
97 2022/05/20 15:21:23.873 UTC MINOR: SVCMGR #2610 Base
"The Auto Ethernet segment identifier type-1 has been deleted for Ethernet Segment AA-ESI-23
 because the new ID 01:00:00:5e:00:53:00:01:01:00 conflicts with ES AA-ESI-23-5"
```

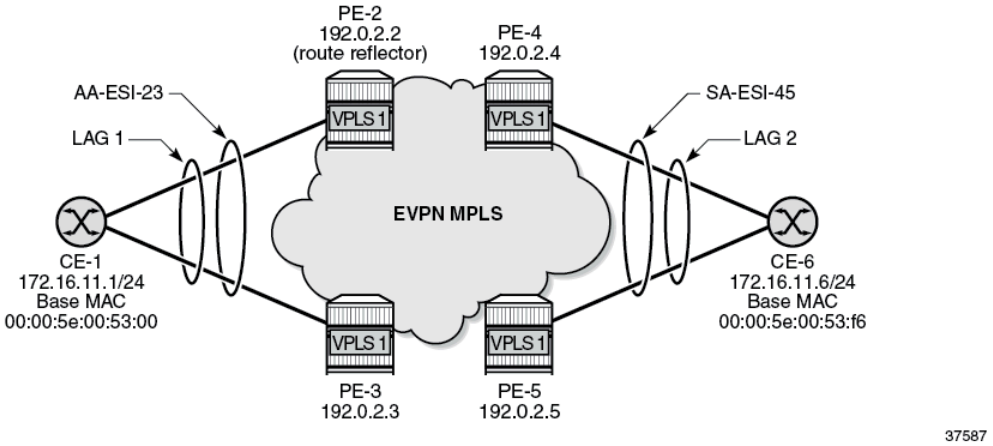
Configuration

In this section, ESI type 1 is configured in the following use cases:

- ESI type 1 in all-active ESs
- ESI type 1 in single-active ESs

Figure 88: Example topology shows the example topology with four PEs and two CEs. CE-1 is connected via LAG 1 to the all-active ES "AA-ESI-23" on PE-2 and PE-3; CE-6 is connected via LAG-2 to the single-active ES "SA-ESI-45" on PE-4 and PE-5. In this example, an EVPN-MPLS VPLS is configured, but other services are also supported.

Figure 88: Example topology



The initial configuration includes:

- cards, MDAs, ports
- on PEs: router interfaces, IS-IS, LDP

On the PEs, BGP is configured for the EVPN address family. PE-2 acts as the route reflector with the following configuration:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

On CE-1, LAG 1 is configured with LACP enabled and administrative key 257, as follows:

```
# on CE-1:
configure
    lag 1 name "lag-1"
        mode hybrid
        encap-type dot1q
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 257
```

```
        no shutdown
```

The LACP system MAC address of CE-1 can be retrieved with the following command:

```
*A:CE-1# show chassis | match MAC
  Base MAC address                 : 00:00:5e:00:53:00
```

ESI type 1 in all-active ESs

On PE-2 and PE-3, the all-active ES "AA-ESI-23" is configured with **auto-esi type-1** and LAG 1:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "AA-ESI-23" create
                    auto-esi type-1
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
```

The EVPN-MPLS VPLS 1 is configured as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

The operational ESI on PE-2 is 01:00:00:5e:00:53:00:01:01:00 for CE LACP system MAC address 00:00:5e:00:53:00 and administrative key 0x0101, as can be verified with the following command:

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "AA-ESI-23"
```

```
===============================================================================
Service Ethernet Segment
===============================================================================
Name                    : AA-ESI-23

```

ESI type 1 in single-active ESs

CE-6 is connected via LAG 2 to the single-active ES "SA-ESI-45" on PE-4 and PE-5. An ES operational group and LAG monitor operational group is required in this use case.

On CE-6, LAG 2 is configured with LACP enabled and administrative key 32768 (= 0x8000), as follows:

```
# on CE-6:
configure
    lag 2 name "lag-2"
        mode hybrid
        encap-type dot1q
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 32768
        no shutdown
```

The LACP system MAC address of CE-6 is the following:

```
*A:CE-6# show chassis | match MAC
  Base MAC address                 : 00:00:5e:00:53:f6
```

On PE-4 and PE-5, operational group "op-grp-2" is configured and assigned to single-active ES "SA-ESI-45".

Note: When an operational group is associated to an ES, the hold timers for the operational group must be zero (the default value for the group down timer).

LAG 2 monitors this operational group. The configuration is as follows:

```
# on PE-4:
configure
    service
        oper-group "op-grp-2" create
            hold-time
                group down 0    # default
                group up 0
            exit
       exit
    exit
    lag 2 name "lag-2"
        mode access
        encap-type dot1q
        monitor-oper-group "op-grp-2"
        port 1/1/1
        lacp active administrative-key 1 system-id 00:00:00:00:45:02
        no shutdown
    exit
    service
        system
            bgp-evpn
                ethernet-segment "SA-ESI-45" create
                    auto-esi type-1
                    service-carving
                        mode manual        # required for oper-group
                        manual
                            preference non-revertive create
                                value 200
                            exit
                        exit
                    exit
```

```
                    multi-homing single-active
                    ac-df-capability exclude
                    lag 2

===============================================================================
```

Auto-derived ESI changes when LACP port key on CE is modified

When the LAG goes operationally down due to ports going down or LACP going down, the auto-derived ESI is preserved. However, when the CE LACP configuration is changed— for example, with a different LACP port key—a new ESI is auto-derived.

In this example, the initial operational ESI on PE-4 is 01:00:00:5e:00:53:f6:80:00:00, as follows:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "SA-ESI-45" | match ESI
Name                    : SA-ESI-45
ESI                     : auto-esi
Oper ESI                : 01:00:00:5e:00:53:f6:80:00:00
Auto-ESI Type           : Type 1
```

On CE-6, the initial configuration of LAG 2 has LACP active with administrative key 32768:

```
*A:CE-6>config>lag# info
----------------------------------------------
        mode hybrid
        encap-type dot1q
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 32768
        no shutdown
----------------------------------------------
```

On CE-6, LAG 2 is reconfigured with administrative key 4095 (= 0x0fff), as follows:

```
# on CE-6:
configure
    lag 2 name "lag-2"
        mode hybrid
        encap-type dot1q
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 4095
        no shutdown
```

As a result, the operational ESI on PE-4 is 01:00:00:5e:00:53:f6:0f:ff:00, as follows:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "SA-ESI-45" | match ESI
Name                    : SA-ESI-45
ESI                     : auto-esi
Oper ESI                : 01:00:00:5e:00:53:f6:0f:ff:00
Auto-ESI Type           : Type 1
```

When debugging is enabled for BGP updates, the following ES routes are seen: initially with ESI 01:00:00:5e:00:53:f6:**80:00**:00 and later with ESI 01:00:00:5e:00:53:f6:**0f:ff**:00, as follows:

```

Conclusion

To simplify the configuration of single-active and all-active ESs with LAG association, ESI type 1 can be used to auto-derive the ESI from the CE's LACP system MAC address and LACP port key.

EVPN for MPLS Tunnels

This chapter provides information about EVPN for MPLS tunnels.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 13.0.R6, but the CLI in the current edition corresponds to SR OS Release 21.2.R1. A prerequisite is to read the EVPN for VXLAN Tunnels (Layer 2) chapter.

Overview

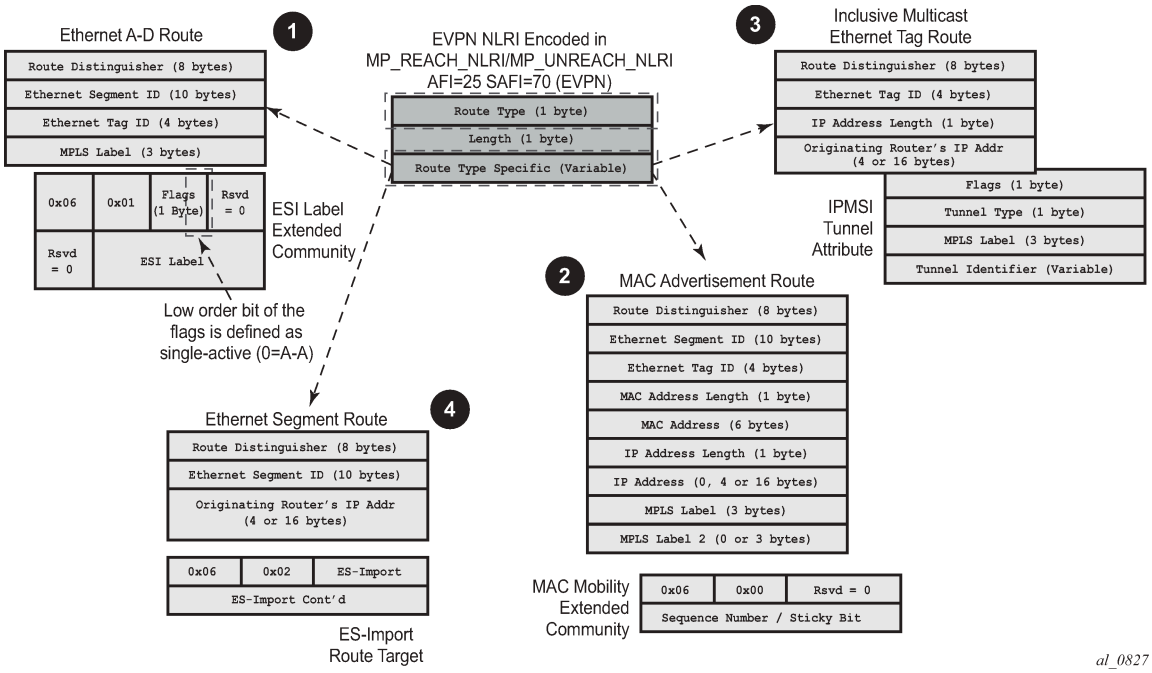
EVPN-MPLS is standardized in RFC 7432, *BGP MPLS-Based Ethernet VPN*, as a Layer 2 VPN technology that can supplement VPLS for E-LAN services. Besides the optimizations introduced by EVPN, a significant number of service providers offering E-LAN services today are requesting EVPN for their multi-homing capabilities. EVPN supports all-active multi-homing (per-flow load-balancing multi-homing) as well as single-active multi-homing (per-service load-balancing multi-homing). In addition to those superior multi-homing capabilities, EVPN also provides a number of significant benefits, such as:

- IP-VPN-like operation and control for E-LAN services.
- Reduction and (in some cases) suppression of the Broadcast, Unknown unicast, and Multicast (BUM) traffic in the network.
- Simple provisioning and management.
- New set of tools to control the distribution of MAC addresses and Address Resolution Protocol (ARP) entries in the network.

The EVPN for Virtual eXtensible Local Area Network (VXLAN) tunnels (Layer 2) chapter focuses on the use of EVPN as a control plane for VXLAN tunnels, whereas this chapter provides configuration guidelines for EVPN when used for MPLS tunnels. Similar to EVPN-VXLAN services, VPLS services with EVPN for MPLS tunnels are referred to as EVPN-MPLS services.

As a reference, the EVPN route types and NLRIs (Network Layer Reachability Information messages) used by the EVPN family in RFC 7432 are shown in Figure 89: EVPN route types and NLRIs.

Figure 89: EVPN route types and NLRIs



When no EVPN multi-homing is used in the network, only the base routes are used. Route types 2 and 3 are considered the base and mandatory routes:

- Route type 2 - MAC/IP route: This route advertises MAC addresses to be installed in the remote FDBs, or MAC/IP address pairs to be installed in the remote proxy-ARP/ND (Neighbor Discovery) tables.
- Route type 3 - Inclusive multicast route: This route advertises the multicast tree that the advertising PE intends to use for sending BUM traffic for an EVPN Instance (EVI). Ingress Replication, Point-to-multipoint multicast Label Distribution Protocol (P2MP mLDP), and composite tunnels are supported as tunnel types in route type 3 when BGP-EVPN MPLS is enabled. The ingress replication information, as well as the downstream MPLS label (for remote PEs to send BUM traffic to the advertising PE) are encoded in the Provider Multicast Service Interface Tunnel Attribute (PTA).

When EVPN multi-homing is used in an EVI, routes type 1 and 4 are used (where type 1 has two different purposes):

- Route type 1 - Auto-discovery per Ethernet segment (AD per ES) route: This route is advertised per ES from the PE, carries the Ethernet Segment Identifier (ESI) label (used for split-horizon) in multi-homing mode, and can affect procedures such as the Designated Forwarder (DF) election, as well as the aliasing/backup path/mass withdrawal on remote PEs.
- Route type 1 - Auto-discovery per EVPN instance (AD per-EVI) route: This route allows the remote PEs to provide aliasing and a backup path to the PEs part of the ES.
- Route type 4 - Ethernet Segment (ES) route: This route advertises a local configured ES. The exchange of this route can discover remote PEs that are part of the same ES and the DF election algorithm among them.

The AD per-EVI, MAC/IP, and inclusive multicast routes are considered service-level BGP-EVPN routes. Their RT/RD (Route-Target/Route-Distinguisher) are taken from the VPLS configuration.

The AD per-ES and the ES routes are considered base-level BGP-EVPN routes. However, their RT/RD are taken differently:

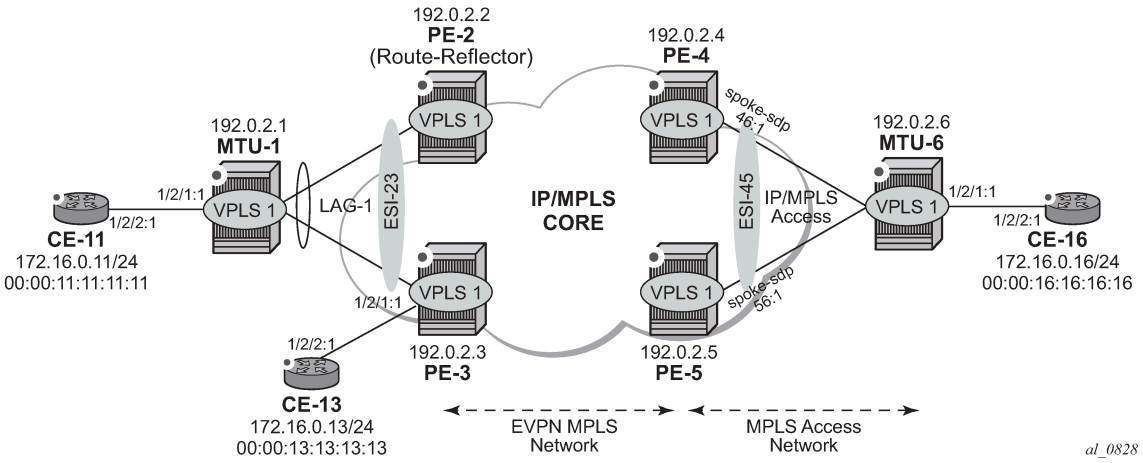
- The ES route RD is taken from the **service>system>bgp-evpn** configuration. The ES route RT is auto-derived from the Ethernet segment.
- The AD per-ES route RD is taken from the system level RD or service level RD. The RT extended community is taken from the service level RT or an RT set for the services defined on the Ethernet segment.

Configuration

This section describes the configuration of EVPN-MPLS for Layer 2 services on SR OS, as well as the available troubleshooting and show commands, and EVPN multi-homing.

Figure 90: EVPN-MPLS for VPLS services shows the topology used throughout this chapter. The network consists of a core with four EVPN PEs (PE-2, PE-3, PE-4, and PE-5) and two MTU devices that are dual-homed to the EVPN network. For MTU-1, all-active multi-homing is used, whereas MTU-6 is connected via single-active multi-homing to the EVPN network. Three CEs are connected to VPLS 1 in MTU-1, PE-3, and MTU-6 in order to test the connectivity.

Figure 90: EVPN-MPLS for VPLS services



As part of the network infrastructure configuration, the following settings and protocols must be added to the configuration before starting with the EVPN-specific configuration for the services:

- The ports interconnecting the four PEs in the core are configured as network ports (or hybrid) and will have router network interfaces defined in them. The ports on PE-2/PE-3 connected to MTU-1 can be access or hybrid ports, whereas the ports on PE-4/PE-5 connected to MTU-6 can be network or hybrid ports. In case of hybrid ports, no LACP can be configured.
- The four PEs in the core (as well as MTU-6 in the access MPLS network) are running IS-IS and establishing point-to-point adjacencies for the exchange of the system IP addresses.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, PE-5, and MTU-6. There is no LDP running between MTU-1 and the rest of the network, that is, MTU-1 is a pure Ethernet aggregation device.

- EVPN uses MP-BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although typically a separate router is used, in this chapter, PE-2 is used as BGP RR (route reflector) for EVPN routes. For example, the following output shows the configuration of BGP in the RR and one of the BGP clients. The relevant commands for EVPN are shown in bold.

  The configuration on the route reflector PE-2 is as follows:

```
# on RR PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

  The BGP configuration on the clients PE-3, PE-4, and PE-5 is as follows:

```
# on RR clients PE-3, PE-4, PE-5:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
```

Note:
The **def-recv-evpn-encap** command is not used in the preceding configuration because the default MPLS configuration is sufficient to have a correct interpretation of the received EVPN encapsulations.

The EVPN encapsulation type can be configured as MPLS or VXLAN, as follows:

```
*A:PE-3# configure router bgp group "internal" neighbor 192.0.2.2
                                                        def-recv-evpn-encap ?
```

```
- no def-recv-evpn-encap
- def-recv-evpn-encap <encap-type>

<encap-type>         : mpls|vxlan
```

EVPN routes type 1 (auto-discovery per-EVI route), type 2 (MAC/IP route), type 3 (inclusive multicast route), and type 5 (IP-prefix route) are always sent with the RFC 5512, *the BGP Encapsulation Subsequent Address Family Identifier (SAFI) and the BGP Tunnel Encapsulation Attribute*, BGP encapsulation extended community that indicates the associated encapsulation of the route. Because the use of this extended community is not mandatory in RFC 7432, the **def-recv-evpn-encap** command indicates to the system what encapsulation is associated with routes received without any encapsulation. When interoperating with third-party EVPN vendors in mixed MPLS and EVPN-VXLAN networks, this command should be revised accordingly.

EVPN-MPLS configuration without multi-homing

After the base infrastructure (interfaces, IGP, LDP, BGP protocols) is configured, the service and EVPN can be enabled. When no multi-homing is used, the EVPN-MPLS configuration in a VPLS service looks similar to the configuration of EVPN-VXLAN for Layer 2, except for the commands related to the MPLS data plane. The following output shows the VPLS-1 configuration on PE-3 as an example:

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            sap lag-1:1 create
                no shutdown
            exit
            no shutdown
```

Where the following commands are relevant for a basic EVPN configuration:

- **bgp** enables the context for the BGP configuration relevant to the service. If a manual (non-auto-derived) RD/RT, as well as import/export policies, are needed for the service, the commands in the **bgp** context must be configured. When **bgp-evpn** is enabled in a VPLS instance, other families are supported within the same service (bgp-ad, bgp-mh, bgp-vpls). This **bgp** context configures the

common BGP parameters for all the BGP families in the service. Even if the general BGP parameters for the service are auto-derived (as in this example), the **bgp** context must be enabled.

```
*A:PE-3>config>service>vpls# bgp ?
  - bgp [<bgp-instance>]
  - no bgp [<bgp-instance>]

 <bgp-instance>       : [1..2]

 [no] pw-template-bi* + Configure pw-template bind policy
 [no] route-distingu* - Configure route distinguisher
 [no] route-target    - Configure route target
 [no] vsi-export      - VSI export route policies
 [no] vsi-import      - VSI import route policies
```

- **bgp-evpn evi <1..65535>** — The EVPN instance or EVI is a 2-byte identifier used for the auto-derivation of the service RD, service RT, and for the service-carving algorithm when multi-homing is used. The EVI can be used for both **bgp-evpn vxlan** and **bgp-evpn mpls** when the user needs to auto-derive the RD and RT for the service. The auto-derivation is always based on:
  - RD system-ip:evi
  - RT autonomous-system:evi

  The configured and operating RD/RT values can be checked with the following show command (in this example, the evi value is 1):

```
*A:PE-3# show service id 1 bgp

-------------------------------------------------------------------------------
===============================================================================
```

Although not required for a basic BGP-EVPN MPLS configuration, some other parameters may be used at the **bgp-evpn** context level, when EVPN-MPLS services are deployed. Some examples are listed here:

- **bgp-evpn cfm-mac-advertisement** must be enabled when eth-cfm is used across an EVPN-MPLS service among different PEs. If a Maintenance Endpoint (MEP) or Maintenance domain Intermediate Point (MIP) is configured in any of the SAP/SDP bindings in the VPLS and has to exchange eth-cfm packets with a remote MEP/MIP across the EVPN-MPLS core, this command must be enabled. In that way, the MEP/MIP MAC address can be advertised in EVPN (otherwise, the MEP/MIP MAC address would not be learned on remote EVPN-MPLS PEs and eth-cfm would not work correctly).
- **bgp-evpn mac-advertisement** and **bgp-evpn mac-duplication** — See the EVPN for VXLAN Tunnels (Layer 2) chapter for a description of these two commands.

- **bgp-evpn mpls** must be enabled.

When two BGP instances are added to a VPLS service, both BGP-EVPN MPLS and BGP-EVPN VXLAN can be configured at the same time in the service. A maximum of two BGP instances are supported in the same VPLS. In this chapter, only one BGP instance will be used: BGP-EVPN MPLS uses the default BGP instance 1.

After the relevant **VPLS** parameters, **BGP** and **BGP-EVPN** attributes are added, the specific commands for **bgp-evpn mpls** can be configured as follows:

```
*A:PE-3>config>service>vpls>bgp-evpn>mpls# info
----------------------------------------------
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
----------------------------------------------
```

- **ingress-replication-bum-label** controls whether the system will advertise different service labels for unicast and BUM traffic. If no EVPN multi-homing is configured in the network, this command can be disabled (**no ingress-replication-bum-label**) and the same MPLS label will be advertised for the unicast and BUM traffic for the VPLS instance. If EVPN multi-homing is configured in the PE, this command is strongly recommended to avoid potential transient issues. See the EVPN-MPLS multi-homing section.
- **ecmp** controls the number of remote PEs to which the local PE can load balance the unicast traffic. See the EVPN multi-homing section.
- **auto-bind-tunnel** controls the resolution of EVPN destinations to MPLS transport tunnels. This command is also in VPRN services and works in the same way.
  - If the **auto-bind-tunnel resolution any** is configured, as in the example, EVPN destinations in the service are resolved based on the best tunnel in the Tunnel Table Manager (TTM). For instance, the following command shows the existing EVPN destinations for VPLS 1 in PE-3. The EVPN-MPLS destination (Termination Endpoint (TEP) 192.0.2.2, label 524282) is resolved to an LDP transport tunnel because the (best) LDP tunnel to 192.0.2.2 shown in the **show router tunnel-table** is LDP. If there was more than one tunnel type in the TTM to 192.0.2.2, the system would pick the lowest **Pref** (preference) tunnel.

```

===============================================================================
```

  - If resolution is set to **any**, the following tunnel types are selected in order of preference: RSVP, LDP, Segment Routing, and BGP. The user can configure the preference of the segment-routing tunnel type in the TTM for a specific IGP instance.
  - If one or more explicit tunnel types are specified using the resolution-filter option, then only these tunnel types will be selected again following the TTM preference.
  - The user must set the resolution to filter to activate the list of tunnel-types configured under resolution-filter.

Although not shown in the **bgp-evpn mpls** basic configuration for PE-3, there are other parameters that can be modified:

```
*A:PE-3>config>service>vpls>bgp-evpn# mpls ?
  - no mpls [bgp <bgp>]
  - mpls [bgp <bgp>]

 <bgp>                : [1..2]

      auto-bind-tunn* + Configure BGP EVPN mpls auto-bind-tunnel
 [no] control-word    - Enable/disable setting the CW bit in the label message
 [no] default-route-* - Configure default-route-tag to match against export policies
      ecmp            - Configure maximum ECMP routes information
 [no] entropy-label   - Enable/disable use of entropy-label
 [no] force-vlan-vc-* - Forces vlan-vc-type forwarding in the data-path
 [no] ingress-replic* - Use the same label as the one advertised for unicast traffic
 [no] oper-group      - Configure oper-group
 [no] restrict-prote* - Enable/disable protected src MAC restriction
      route-next-hop  - Configure route next-hop
 [no] send-tunnel-en* - Configure encapsulation for this service
 [no] shutdown        - Administratively Enable/Disable BGP-EVPN mpls
 [no] split-horizon-* - Configure a split-horizon-group
```

- **bgp** instance defines the BGP instance: default **bgp** or **bgp 1** can be used for either BGP-EVPN MPLS or BGP-EPVN VXLAN; **bgp 2** can only be used for BGP-EVPN MPLS.
- **control-word** enables/disables the insertion of the control-word in the data path. The control-word is disabled by default and is not signaled in EVPN (based on RFC 7432) and has to be consistently configured in all the PEs in the network. The use of the **control-word** prevents packet reordering from

happening in P routers that misinterpret the first nibble of the payload in the packets they receive. In some third-party EVPN vendors, the control-word is enabled by default, so it is recommended to enable it when interoperating with other vendors.

- **entropy-label** enables the use of entropy labels, as described in the *Entropy Label* chapter.
- **force-vlan-vc-forwarding** allows the system to preserve the VLAN ID and p-bits of the service-delimiting q-tag in a new tag added in the customer frame before sending it to the EVPN core. This command may be used with the **sap ingress vlan-translation** command: the configured translated VLAN ID will be sent to the EVPN binds, as opposed to the service-delimiting tag VLAN ID. If the ingress SAP/SDP-binding is null encapsulated, the output VLAN ID and p-bits will be zero.
- **restrict-protected-src** is by default disabled. When enabled, all packets entering the object will be verified not to contain a protected source MAC address. In combination with the parameter **discard-frame**, the packets that contain a protected MAC address will be discarded and an alarm is generated.
- **send-tunnel-encap** configures the encapsulation to be advertised with the EVPN routes for the service. The encapsulation is encoded in RFC 5512-based tunnel encapsulation extended communities. When configured in the **bgp-evpn>mpls** context, the supported options are none (no send-tunnel-encap), mpls, mplsoudp, or both.
- **shutdown** enables/disables the use of MPLS for EVPN. When **mpls no shutdown** is issued, a BGP route-refresh message is sent for the EVPN family.
- **split-horizon-group** *<group-name>* configures an explicit split-horizon-group (SHG) for all the EVPN destinations that can be shared with other SAP/SDP-bindings. See the VPLS to EVPN-MPLS integration section.

After **bgp-evpn mpls** is configured and enabled in the service, an inclusive multicast route is sent to the RR. The remote PEs receiving and importing that route will create an EVPN destination to the sending PE. An EVPN destination is identified by a TEP and MPLS label. Use the following show commands to view the service and the EVPN destinations created:

- **show service evpn-mpls**
- **show service id 1 evpn-mpls**
- **show service id 1 bgp-evpn**

An example of the output is shown for PE-2 when there is no traffic in the network. Therefore, only inclusive multicast routes have been exchanged among the four PEs.

```
*A:PE-2# show service evpn-mpls

When traffic is generated, the PEs will start learning MAC addresses and advertising them in BGP so that the remote PEs learn those MAC addresses against EVPN destinations. For instance, when CE-13 sends traffic, PE-3 learns its MAC address and advertises it. The remote PEs (for instance, PE-2) will learn the MAC address and associate it with their EVPN destination to PE-3 (192.0.2.3:524280 in this example):

```

When the **ingress-replication-bum-label** is enabled in the PEs, the advertisement of MAC addresses will create new EVPN destinations, because the label is different from the one previously sent by the inclusive multicast route that created an EVPN destination. In the preceding example, when PE-3 advertises the CE-13 MAC address, PE-2 will create a new binding (see in the following output in bold) that shows one MAC address that is not Mcast (multicast) capable:

```

```

If the route is successfully imported, it can be shown in the RIB (**show router bgp routes** commands). The route shown in the debug and the same route in a show command do not necessarily have the same label value. The reason for this expected mismatch is that the debug command shows the complete 24-bit field value because the route is shown before BGP can decide and decipher whether the label value is an MPLS label (high-order 20-bits of the label field) or a VNI (all 24 bits of the Label field for VXLAN). When the label in the debug command (8388512) is divided by 16 (2^4), the result is the MPLS label (524282), as follows: 8388512:16=524282.

VPLS to EVPN-MPLS integration

The SR OS EVPN implementation supports RFC 8560, *(PBB-)EVPN Seamless Integration with (PBB-)EVPN*, so that EVPN-MPLS and VPLS can be integrated into the same network and within the same service.

The following behavior enables the integration of EVPN and SDP-bindings in the same VPLS network:

- Systems with EVPN endpoints and SDP-bindings to the same far-end bring down the SDP-bindings.
  - SR OS will allow the establishment of an EVPN destination and an SDP-binding to the same far-end but the SDP-binding will be kept operationally down. Only the EVPN endpoint will be operationally up. This is true for spoke-SDPs (manual and BGP-AD) and mesh-SDPs. It is also true between VXLAN and SDP-bindings.
  - If there is an EVPN endpoint to a specified far-end and a spoke-SDP establishment is attempted, the spoke-SDP will be set up but kept down with an operational flag indicating that there is an EVPN route to the same far-end.
  - If there is a spoke-SDP and a valid/used EVPN route arrives, the EVPN endpoint will be set up and the spoke-SDP will be brought down with an operational flag indicating that there is an EVPN route to the same far-end.
  - In the case of an SDP-binding and EVPN endpoint to different far-end IP addresses on the same remote PE, both links will be up. This can happen if the SDP-binding is terminated in an IPv6 address or IPv4 address different from the system address where the EVPN endpoint is terminated.

  The following example illustrates the preceding description. A spoke-SDP is added to the VPLS 1 configuration on PE-2:

```
# on PE-2:
configure
    service
        sdp 24 mpls create
            far-end 192.0.2.4
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        vpls "VPLS1"
            spoke-sdp 24:1 create
                no shutdown
            exit
        exit
```

  The service configuration on PE-4 is as follows:

```
# on PE-4:
```

```
configure
    service
        sdp 42 mpls create
            far-end 192.0.2.2
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        vpls 1 name "VPLS1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 42:1 create
                no shutdown
            exit
            spoke-sdp 46:1 create
                no shutdown
            exit
            no shutdown
```

Spoke SDP 24:1 is operationally down, as can be verified as follows:

```
*A:PE-2# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
24:1             Spok     192.0.2.4       Up      Down      524282    524282
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

Spoke SDP 24:1 is down because of an EVPN route conflict, as indicated by the flags:

```
*A:PE-2# show service id 1 sdp 24 detail | match Flag context all
Flags              : PWPeerFaultStatusBits
                     EvpnRouteConflict
```

- The user can add spoke-SDPs and all the EVPN-MPLS endpoints in the same SHG.

  - A CLI command exists in the **bgp-evpn>mpls** context so that the EVPN-MPLS endpoints can be added to an SHG.
  - The **bgp-evpn mpls split-horizon-group** must reference a user-configured SHG. User-configured SHGs can be configured within the service context.
  - The same group name can be associated with SAPs, spoke-SDPs, PW-templates, PW-template-bindings, and EVPN-MPLS endpoints.
  - If the **split-horizon-group** command in **bgp-evpn>mpls** is not used, the default SHG (in which all the EVPN endpoints are) is still used, but it will not be possible to refer to it on SAPs/spoke-SDPs.
- The system disables the advertisement of MAC addresses learned on spoke- SDPs/SAPs that are part of an EVPN SHG.
  - When the SAPs or spoke-SDPs (manual or BGP-AD-discovered) are configured within the same SHG as the EVPN endpoints, MAC addresses will still be learned on them, but will not be advertised in EVPN.
  - The preceding statement is also true if proxy-ARP/ND is enabled and an IP-->MAC address pair is learned on a SAP/SDP-binding that belongs to the EVPN SHG.
  - The SAPs and/or spoke-SDPs added to an EVPN SHG should not be part of any EVPN multi-homed ES. If that happened, the PE would still advertise the AD per-EVI route for the SAP and/or spoke-SDP, attracting EVPN traffic that could not be forwarded to that SAP and/or SDP-binding.
  - Similar to the preceding statement, an SHG composed of SAPs/SDP-bindings used in a BGP-MH site should not be configured under **bgp-evpn>mpls>split-horizon-group**. This misconfiguration would prevent traffic being forwarded from the EVPN to the BGP-MH site, regardless of the DF/Non-DF state.

An example of a shared SHG configuration on PE-2 is as follows. Because the SAP and EVPN-MPLS are in the same SHG, no MAC addresses learned over SAP 1/2/1:2 will be advertised in EVPN (not even static MACs).

```
# on PE-2:
configure
    service
        vpls 2 name "VPLS2" customer 1 create
            split-horizon-group "CORE" create
            exit
            bgp
            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    split-horizon-group "CORE"
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/2/1:2 split-horizon-group "CORE" create
                no shutdown
            exit
            sap lag-1:2 create
                no shutdown
            exit
```

```
            no shutdown
```

EVPN-MPLS multi-homing

SR OS supports EVPN multi-homing as per RFC 7432.

The EVPN multi-homing implementation is based on the concept of the ES. An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multi-homed to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects.

Each ES has a unique identifier called ESI (Ethernet Segment Identifier) that is 10 bytes and is manually configured. The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homed CEs are assumed to be connected to an ES with ESI = 0 (single-homed ESs are not explicitly configured).

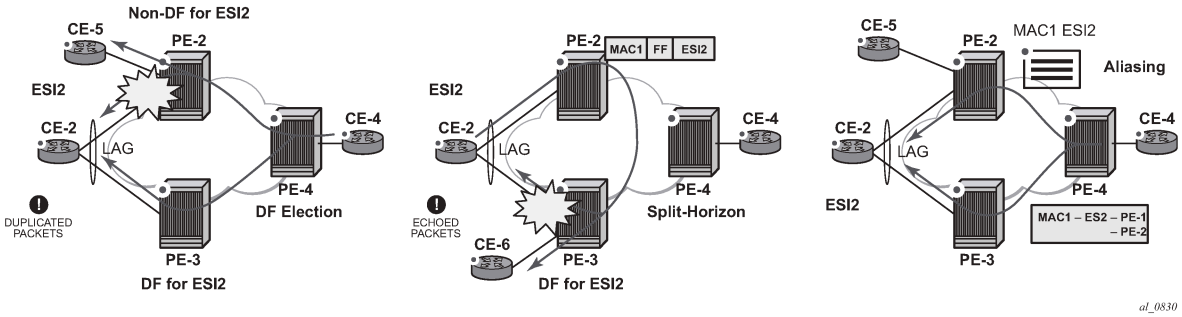
The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-MPLS service, by default. An ES can be shared by multiple services; the association of a specific SAP or spoke-SDP to an ES is automatically made when the SAP is defined in the same LAG or port configured in the ES, or when the spoke-SDP is defined in the same SDP configured in the ES. The following sections show the configuration of:

- an all-active multi-homing ES with a LAG associated with it
- a single-active multi-homing ES linked to an SDP

All-active multi-homing concepts

EVPN all-active multi-homing is built around three concepts: DF election, split-horizon (with an ESI-label), and aliasing, as shown in Figure 91: EVPN-MPLS all-active multi-homing concepts, from left to right.

Figure 91: EVPN-MPLS all-active multi-homing concepts



- With DF election, when PE-4 sends BUM traffic to the remote ES (CE-2), only one PE segment sends the BUM packets to the ES (PE-3 is the DF in the preceding example, and is elected to send BUM packets to CE-2). The non-DF, PE-2, removes the LAG SAP from the default multicast list (PE-2 does not bring CE-2 down, because it still needs to send upstream/downstream unicast traffic). PE-2 and PE-3 elect a DF for each service, based on the ES routes and the service-carving algorithm.
- With split-horizon, the PE part of the ES (PE-3 in the preceding example) identifies the BUM packets coming from the PE for the remote (PE-2), but within the same ES (ESI-2), and filters the packets so that they are not sent back to the ES, creating duplication. When PE-2 (non-DF) sends BUM traffic to

PE-3 (DF), it uses a special MPLS label in the data path that PE-3 previously advertised for ESI-2 in an AD per-ES route. When PE-3 does an ingress lookup, it recognizes the ESI-label and filters the traffic (PE-3 still sends the BUM traffic to other SAPs/SDP-bindings).

- With aliasing, remote PEs that are not part of the ES can load-balance unicast traffic to all the PEs that are part of the ES, irrespective of from which PE a destination MAC address was learned. PE-4 will create an EVPN destination to ESI-2 that will be resolved to the two next-hops: PE-2 and PE-3. Unicast load-balancing will happen as long as ECMP > 1 is enabled in PE-4.

Nokia recommends the use of **ingress-replication-bum-label** on the PEs that are part of an all-active ES. In an all-active multi-homing scenario, if a specified MAC address (for example, the CE-2 MAC address in the left-hand-side diagram), is not learned yet in a remote PE (for example, PE-4), but is known in the two PEs of the ES (for example, PE-2 and PE-3), the latter PEs might send duplicated packets to the CE.

This issue is solved by the use of **ingress-replication-bum-label** in PE-2 and PE-3. If configured, PE-2/PE-3 will know that the received packet is an unknown unicast packet; therefore, the Non-DF (PE-2) will not send the packet to CE-2 and there will not be duplication.

All-active multi-homing configuration

The all-active multi-homing configuration example is based on Figure 90: EVPN-MPLS for VPLS services.

MTU-1 is connected to the EVPN network using all-active multi-homing. According to RFC 7432, MTU-1 will be able to send traffic to both PEs for VPLS-1. Regular LAG load-balancing is used in MTU-1. Remote PEs such as PE-4 or PE-5 will be able to load-balance the unicast traffic to PE-2 and PE-3. PE-2 and PE-3 will discover that both are part of ESI-23 (due to the exchange of ES routes) and will elect a DF for VPLS-1. The non-DF for VPLS-1, in this case PE-2, will remove lag-1:1 from the VPLS-1 default multicast list. Also, when PE-2 and PE-3 send BUM traffic to each other, they will insert an ESI-label so that they can identify that the source of the BUM packet is ESI-23.

The following output shows the configuration of ESI-23 in PE-2 and PE-3, as well as the LAG interfaces for all-active multi-homing (see Figure 90: EVPN-MPLS for VPLS services). The configuration of LAG-1 in MTU-1 is also shown. Per RFC 7432, only a CE/MTU with a LAG can be connected to an all-active multi-homing ES. No other configuration is permitted on the CE for all-active multi-homing.

LAG 1 is configured on MTU-1, PE-2, PE-3, as follows:

```
# on MTU-1:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 32768
        no shutdown
```

```
# on PE-2:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/2
        lacp active administrative-key 1 system-id 00:00:00:00:02:03
```

```
        no shutdown
```

```
# on PE-3:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/1
        lacp active administrative-key 1 system-id 00:00:00:00:02:03
        no shutdown
```

Ethernet segment "ESI-23" is configured in the service **system bgp-evpn** context on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23" create
                    esi 01:00:00:00:00:23:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
```

When configuring an ES, the following must be considered:

- Any EVPN parameter that is not specific to any particular VPLS service, and is common to all the EVIs, is configured in a base BGP-EVPN instance located at **config>service>system>bgp-evpn**. In this base instance, the following attributes may be configured:
  - ethernet-segments
  - the base BGP-EVPN instance **route-distinguisher** that will be used for the ES routes. If this **route-distinguisher** is not configured, by default a type-1 RD will be derived as system-ip:0, as shown in the command help:

```
*A:PE-2>config>service>system>bgp-evpn# route-distinguisher ?
  - no route-distinguisher
  - route-distinguisher <rd>

 <rd>                : <ip-addr:comm-val>
                       ip-addr        - a.b.c.d
                       comm-val       - [0..65535]
                       default: system-ip:0
```

- The ES must be configured with a name and can contain the following parameters when configured for all-active multi-homing:
  - **esi** — 10-byte identifier that represents the ES in the BGP control plane. The same ESI must be configured in all the PEs connected to the same CE/MTU (using a unique value that cannot be associated with any other CE/MTU/access network). RFC 7432 defines five different types of ESI. In SR OS, the **type** byte, as well as the other 9 bytes can be arbitrarily configured.
  - **multi-homing all-active** — This command indicates that the ES is in all-active mode.

  - **lag** <*lag-id*> — The LAG connected to the CE/MTU must be added to the ES. In this example, lag-1 is added to ESI-23, on both PE-2 and PE-3. Although a different LAG-id may have been assigned to the same ES on PE-2 and PE-3, PE-2 and PE-3 must have the same configuration on the ES LAG; that is, encap-type. Also, if LACP is added (it is not mandatory), both PEs must have the same admin-key, system-id, and system-priority. MTU-1 will see PE-2 and PE-3 as a single LAG peer. For all-active multi-homing, only the **lag** option is accepted by the system; **port** or **sdp** are not accepted.
  - **[no] shutdown** — This command controls the administrative state of the ES.

- The preceding parameters are the minimum necessary so that the ES can be activated. In addition to those parameters, there are a few more that the user can configure if requiring values different from the default ones:
  - **es-activation-timer** *[0..100]* can be configured at **redundancy>bgp-evpn-multi-homing>es-activation-timer** or at **service>system>bgp-evpn>eth-seg>es-activation-timer** level (the most specific value is used).

    The **es-activation-timer** operation is as follows:

    - Upon reception of an ES, AD per-ES/EVI route update/withdrawal for a local ESI, the DF-candidate list of IPs is updated and the DF election algorithm is run without waiting for any timer.
    - If the result of the DF election requires the PE to be promoted from non-DF to DF, the **es-activation-timer** will start, and only after its expiration will the PE add the SAP to the default-multicast list. Transitions from non-DF to non-DF, or from DF to non-DF, are immediate and do not wait for any timer.
    - This use of an **es-activation-timer** value minimizes the risks of loops and packet duplication due to **transient** multiple DFs.
    - The same **es-activation-timer** must be configured in all the PEs that are part of the same ESI. The user must configure either a long timer to minimize the risks of loops/duplication, or **es-activation-timer** = 0 to speed up the convergence for NDF to DF transitions. The default value is 3 seconds.
  - **service-carving** — As defined in RFC 7432, service-carving controls the distribution of DF/non-DF roles across the different services defined in an ES.

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>service-carving# mode ?
 - mode {auto|manual|off}

 <auto|manual|off>    : auto|manual|off
```

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>service-carving# manual ?
  - manual

 [no] evi             - Configure EVI range (primary for non-preference based DF
                        election and lowest-preference for preference based DF
                        election)
 [no] isid            - Configure ISID range (primary for non-preference based DF
                        election and lowest-preference for preference based DF
                        election)
 [no] preference      + Configure DF preference election information
```

    As shown above, **service-carving** has three different modes:
  - **service-carving mode auto** (default) — The DF election algorithm will run the function [V(evi) mod N(peers) = i(ordinal)] to know who the DF for a specified service and ESI is. In this example, ESI-23 is configured with mode **auto**; therefore, for VPLS-1 (with EVI-1), PE-3 will be elected as DF

because evi(1) mod (2)peers = 1, and the ordinal 1 corresponds to the second lowest IP, PE-3. The algorithm takes the configured **evi** in the service; therefore, the **evi** is mandatory, and for the same service must match in all the PEs that are part of the ES. This guarantees that the election algorithm is consistent across all the PEs of the ESI.

  - **service-carving mode manual** — The user can manually decide for which **evi** identifiers the PE is DF: **service-carving mode manual / manual evi** <*start*> **[to** <*to*>**]**. The PE will be non-DF for the non-specified EVIs. If **service-carving mode manual** is configured, but no range is defined, all the services are considered to be non-DF. If a range is configured, but the **service-carving** is not **mode manual**, the range has no effect. Only two PEs are supported when **service-carving mode manual** is configured.
  - **service-carving mode off** — The lowest originator IP will win the election for a specified service and ES.
  - Because the **evi** is used for the service-carving algorithm, it must always be configured in a service with SAPs/SDP bindings created in an ES, regardless of the service-carving mode (service-carving off, auto, or manual).

Although not configured as part of the ES, the **config>redundancy>bgp-evpn-multi-homing>boot-timer** allows the necessary time for the control plane protocols to come up after the PE has rebooted, and before bringing up the ESs and running the DF algorithm. Some considerations about the boot timer:

- The boot timer should use a value long enough to allow the IOMs and BGP sessions to come up before exchanging ES routes and run the DF election for each EVI (it is 10 s, by default).
- The boot timer runs per EVI on the ESs in the system. While **system-up-time** <*boot-timer*>, the system will not run the DF election for any EVI. When the boot timer expires, the DF election for the EVI is run and, if the system is elected DF for the EVI, the **es-activation-timer** will start.
- The system will not advertise ES routes until the boot timer expires. This guarantees that the peer ES PEs do not run the DF election either, until the PE is ready to become the DF, if needed.
- The following show command displays the configured boot timer, as well as the remaining timer if the system is still in boot stage.

```
*A:PE-2# show redundancy bgp-evpn-multi-homing

===============================================================================
Redundancy BGP EVPN Multi-homing Information
===============================================================================
Boot-Timer              : 10 secs
Boot-Timer Remaining    : 0 secs
ES Activation Timer     : 3 secs
===============================================================================
```

After ESI-23 is configured in PE-2 and PE-3, the lag-1 SAPs in both PEs can be added to the VPLS-1 service. Until the ESI-23 is successfully enabled, the LAG SAPs will be kept down with a *StandByForMHProtocol* flag. This is illustrated in the following example for PE-2.

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23"
                    shutdown
                exit
            exit
```

```
        exit
    exit
    service
        vpls "VPLS1"
            sap lag-1:1 create
                no shutdown
            exit
```

```
*A:PE-2# show service id 1 sap lag-1:1 detail | match "  Oper State"

```

All-active multi-homing operation

To confirm that all-active multi-homing is working correctly for ESI-23, the user can use the following commands:

- **show service system bgp-evpn** — Shows the RD is used for the ES route.
- **show service system bgp-evpn ethernet-segment** — Shows all the ESs configured in the PE and their admin/operational status.
- **show service system bgp-evpn ethernet-segment name ESI-23 evi 1** — Shows the DF candidate PEs for EVI 1 and whether the system is DF for EVI.
- **show service system bgp-evpn ethernet-segment name ESI-23 all** — Shows all the information related to a specific ESI.

The base BGP-EVPN information includes the RD:

```
*A:PE-2# show service system bgp-evpn

===============================================================================
System BGP EVPN Information
===============================================================================

"
```

The ES RT as shown as target:00:00:00:00:23:00 in the extended community is auto-derived from the ESI bytes 2 to 7 (with the type byte being byte 1). Only PE-2 and PE-3 generate this RT and therefore import each other's ES route.

The following message in log 99 on PE-3 shows the result of the DF election for EVI 1.

```
86 2021/02/17 14:31:34.395 UTC MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-23, EVI:1, Designated Forwarding state changed to:true"
```

The **show service system bgp-evpn ethernet-segment name ESI-23 all** command shows the ESI-label allocated to the PE: **ES SHG Label** *524280* in the CLI output for PE-3. In this example, this label is allocated by PE-3 for ESI-23 (a different one is allocated per ESI) and advertised in the AD per-ES route for ESI-23. The following output shows the AD per-ES and AD per-EVI (for evi 1) routes sent by PE-3 and received by PE-2.

- The AD per-ES route can be identified by the *MAX-ET* in the Ethernet-tag field (as per RFC 7432) and carries the ESI-label as well as the multi-homing mode (all-active in this case) in the ESI-label extended community (see Figure 89: EVPN route types and NLRIs).

  The user can enable the aggregation of AD per-ES routes by using the following command: **config service system bgp-evpn ad-per-es-route-target evi-rt-set route-distinguisher ip-address**. If enabled, a single AD per-ES route with the associated RD and a set of EVI route-targets will be advertised (to a maximum of 128). When there are more than 128 EVIs defined in the Ethernet-segment, more than one route will be sent by the system.

- The AD per-EVI route will have an eth-tag 0 and will carry the service label in the NLRI.

```

From a service perspective, as soon as CE-11 sends some traffic, the PE learning the CE-11 MAC address will advertise it to the network. The remote PEs (PE-4 and PE-5) will create a new EVPN-MPLS ES destination to ESI-23, with two next-hops: PE-2 and PE-3. The following outputs on PE-4 show the following information:

- PE-4 has learned AD per-EVI/ES routes for ESI-23 from PE-2 and PE-3, as well as the CE-11 MAC address from PE-3 (because MTU-1 picked up its link to PE-3 to send CE-11 frames).

- PE-2 will show the CE-11 MAC address as learned locally in SAP lag-1:1 (because the data plane learning of the CE-11 MAC address happened in PE-2). For PE-3, even though it learned the MAC address from EVPN, it will install it as associated with SAP lag-1:1 because the EVPN route came with ESI-23, which is a local ESI. Because of this, whenever PE-3 receives a frame with MAC DA equal to the CE-11 MAC address, it will be able to forward the frame locally to the SAP lag-1:1. The following output shows the CE-11 MAC address as it is installed in PE-2 and PE-3:

```

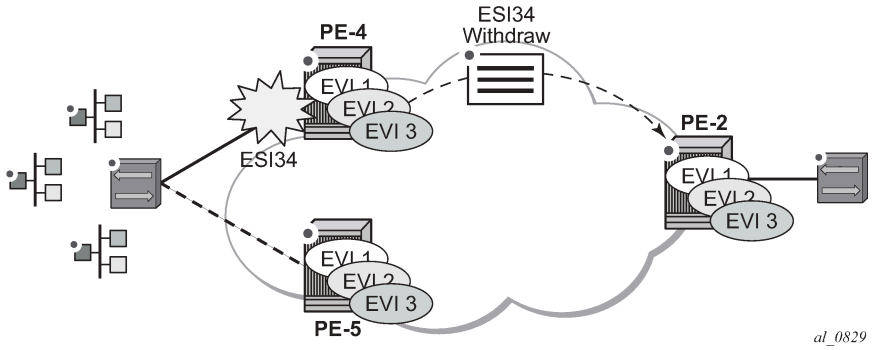
Single-active multi-homing concepts

Figure 92: EVPN-MPLS single-active multi-homing: mass-withdraw, backup path illustrates two concepts in EVPN single-active multi-homing: mass-withdraw and backup path.

Figure 92: EVPN-MPLS single-active multi-homing: mass-withdraw, backup path



- With mass-withdraw, when ESI-45 goes down, PE-2 does not have to wait for all the MAC routes to be withdrawn to converge all the services. Instead, PE-4 will withdraw the AD per-ES routes (also the AD per-EVI and MAC routes) and that will be used at PE-2 as a notification to stop sending traffic to PE-4 for any MAC address associated with ESI-45.
- With backup path, when PE-2 is notified of the ESI-45 failure due to the withdrawn AD routes, it will not flush any MAC address associated with ESI-45. Instead, it will change the next-hop of the EVPN-MPLS ES destination to the remaining PE in the ESI-45. Backup path only works when there are two PEs in the same ES. If there were more than two PEs in ESI-45, PE-2 would flush all the MAC addresses upon receiving a mass-withdraw notification, because it would not know who the new active PE is.

Single-active multi-homing configuration

The single-active multi-homing configuration example is based on Figure 90: EVPN-MPLS for VPLS services:

MTU-6 is connected to the EVPN network using single-active multi-homing. With the MTU-6 configuration, a VPLS service with active-standby spoke-sdp to PE-4 and PE-5 is configured. In PE-4 and PE-5, the SDP connected to MTU-6 is linked to ESI-45. Both will run the DF election algorithm for EVI 1, and the non-DF PE (PE-4 in this example) will bring down the spoke-SDP and notify MTU-6.

The following output shows the configuration of ESI-45 in PE-4 and PE-5, as well as the SDPs. The configuration of MTU-6 is also shown for completeness. It is important to keep the default **no ignore-standby-signaling** command on MTU-6 spoke-SDPs because the PW switchover in MTU-6 will be triggered based on the PW status bits sent by PE-4 and PE-5.

SDP 46 with far-end MTU-6 is configured on PE-4:

```
# on PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
```

Ethernet segment "ESI-45" is configured on PE-4 as follows:

```
# on PE-4:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
```

On PE-5, SDP 56 is configured as follows:

```
# on PE-5:
configure
    service
        sdp 56 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
```

Ethernet segment "ESI-45" is configured as follows on PE-5:

```
# on PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 56
                    no shutdown
                exit
```

On MTU-6, the service configuration is as follows:

```
# on MTU-6:
configure
    service
        sdp 64 mpls create
            far-end 192.0.2.4
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        sdp 65 mpls create
            far-end 192.0.2.5
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        vpls 1 name "VPLS1" customer 1 create
            endpoint "CORE" create
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
```

```
            spoke-sdp 64:1 endpoint "CORE" create
                stp
                    shutdown
                exit
                no shutdown
            exit
            spoke-sdp 65:1 endpoint "CORE" create
                stp
                    shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
```

For a detailed description of the base BGP-EVPN instance and ES configuration, see the All-active multi-homing configuration section. The **es-activation-timer**, **esi**, **service-carving**, **boot-timer**, and **shutdown** commands are used in the same way as for all-active multi-homing. Only the differences compared to all-active multi-homing are described here:

- **multi-homing single-active** must be configured so that the ES acts as single-active. Optionally, the **no-esi-label** attribute can be added to the **multi-homing single-active** command. This attribute controls the use of the ESI-label for single-active multi-homing. Although the ESI-label is always used in all-active multi-homing when sending BUM traffic between the PEs in the ES, it is configurable for single-active. However, Nokia recommends to use the default option (using ESI-label) to avoid potential transient issues when there is a DF switchover.
- **sdp** <*sdp-id*> is configured so that the ES can be associated with the SDP connected to MTU-6. Although all-active multi-homing only allows LAG associations to the ES, single-active allows LAG, port, and SDP. In this example, SDP is the option, because the access network is MPLS-based.

Similar to the all-active multi-homing case, when configuring the service in PE-4 and PE-5, the service objects are automatically associated with the ESI-45, because they are defined in the SDPs linked to the ESI. The configuration for VPLS 1 on PE-5 is as follows:

```
# on PE-5:
configure
    service
        vpls 1 name "VPLS1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 56:1 create
                no shutdown
            exit
            no shutdown
```

In all-active multi-homing, the non-DF does not bring down the service SAP associated with the ES (it only removes it from the default-multicast-list). However, in single-active multi-homing, the service spoke-SDP (or SAP, if that was the object associated) is brought operationally down. The following output shows the

spoke-SDP state in PE-4 (non-DF), as operationally down with the *StandbyForMHProtocol* flag and the **Local Pw Bits** that are signaled to MTU-6:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "ESI-45" evi 1

```

The local PW bits (*pwFwdingStandby*) are sent to MTU-6:

```
*A:PE-4# show service id 1 sdp 46:1 detail | match Pw
Local Pw Bits      : pwFwdingStandby
Peer Pw Bits       : None
```

Single-active multi-homing operation

The same commands used in the All-active multi-homing operation section can be used for single-active; see that section.

The **show service system bgp-evpn ethernet-segment name "ESI-45"** command shows an Ethernet-segment **Oper Multi-homing** in addition to the configured **Multi-homing** mode. This occurs because, in spite of configuring the ES as all-active, it may operate as single-active if there is a mismatch between

the modes advertised by PE-4 and PE-5 in the AD per-ES routes (per RFC 7432). In this example, the configured and the operational value are the same:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "ESI-45"

===============================================================================

===============================================================================
```

As soon as CE-16 sends some traffic, the DF PE (PE-5) will learn the CE-16 MAC address and will advertise it to the network. The remote PEs (PE-2 and PE-3) will create a new EVPN-MPLS ES destination to ESI-45, but this time with only one next-hop, PE-5, because this is single-active multi-homing. The following outputs show the following information:

- PE-2 has learned AD per-EVI/ES routes for ESI-45 from PE-4 and PE-5, as well as the CE-16 MAC address from an ES EVPN-MPLS destination, which is resolved to PE-5 (the DF for ESI-45).

```

Ethernet segment failures

If either ES fails, a DF re-election will happen and the corresponding AD per-ES/EVI routes will be withdrawn, causing the remote PEs to modify the list of next-hops for the EVPN-MPLS ES destination. The following example illustrates a failure on the SDP between MTU-6 and PE-5 (the DF).

1. A failure occurs in the LSP between MTU-6 and PE-5. This can be any event that brings the SDP down.

   ```
   # log 99 on PE-5:
   85 2021/02/17 15:14:45.918 UTC MINOR: SVCMGR #2303 Base
   "Status of SDP 56 changed to admin=up oper=down"
   ```

2. Immediately, PE-5 gives up the DF role and withdraws the ES route, as well as the AD routes and MAC routes. As soon as PE-4 receives any ES or AD withdraw, it will re-run the DF algorithm and, when the es-activation-timer expires, it will become the DF and activate its spoke-SDP.

   ```
   # log 99 on PE-5:
   87 2021/02/17 15:14:45.920 UTC MINOR: SVCMGR #2094 Base
   ```

```
"Ethernet Segment:ESI-45, EVI:1, Designated Forwarding state changed to:false"
```

The ES in PE-5 is operational down:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "ESI-45"

```

The following must be considered:

- The DF election procedure is revertive, that is, when the failed SDP comes back up, PE-5 will take over again as DF and the network will re-converge.
- The DF election is triggered by the following events:
  - **configure service system bgp-evpn ethernet-segment ESI-45 no shutdown** triggers the DF election for all the services in the ES.
  - A new update/withdrawal of an ES route (containing an ESI configured locally) triggers the DF election for all the services in the ESI.
  - A new update/withdrawal of an AD per-ES route (containing an ESI configured locally) triggers the DF election for all the services associated with the list of RTs received along with the route.
  - A new update of an AD per-ES route with a change in the ESI-label extended community (single-active bit or MPLS label) triggers the DF election for all the services associated with the list of RTs received along with the route.
  - A new update/withdrawal of an AD route per-EVI (containing an ESI configured locally) triggers the DF election for that service.

BGP-EVPN route selection in EVPN networks

The selection of the best route for a MAC address is as follows:

- If a PE receives more than one route for the same MAC address, the best MAC route is chosen:
  - If the route key is equal in two or more routes (that is, the mac, mac-length, ip, ip-length, RD, eth-tag), then regular BGP selection applies:
    - If local-pref, AS-path, origin, and MED are equal, the lowest IGP distance to the BGP next-hop is chosen (unless **ignore-nh-metric** is configured). If the BGP next-hop is resolved by an LSP, the cost from the tunnel-table is used.
    - As a last resort tie-breaker, the route with the lowest originator ID, or received from the peer with the lowest BGP Identifier, is chosen (unless **ignore-router-id** is configured and the routes being compared are EBGP routes).
  - If the mac-length, mac, ip-length, ip, eth-tag are equal, and the RD is different, the EVPN selection process is applied in the following order:
    - Conditional static MAC addresses (local protected MAC addresses)
    - EVPN static MAC addresses (remote protected MAC addresses)

    - Data plane learned MAC addresses (regular learning on SAPs/SDP-bindings)
    - EVPN MAC addresses with higher sequence number
    - Lowest IP address (next-hop IP of the EVPN NLRI)
    - Lowest Ethernet tag (will be normally zero)
    - Lowest RD
- After a MAC route is selected, the system checks for an associated ES.
  – If it has an ES, the system uses the MAC address as the EVPN-MPLS ES destination. The ES destination is constructed based on the AD per-EVI routes received for that ES (regardless of MAC address priorities with the ES).
  – The system selects the first ECMP number of AD per-EVI routes arranged by the IP address of PEs (lower IPs are selected first).
  – If the same PE has advertised multiple RDs, the system selects the route with the lowest RD for that PE.

In the example of Figure 90: EVPN-MPLS for VPLS services, PE-4 resolves the next-hops for ESI-23 as described in the second choice above, that is, because ECMP=2, the two available next-hops are chosen. If ECMP is changed to 1, PE-4 will pick up the lower IP (in the BGP next-hop). This is illustrated in the following output:

```
*A:PE-4# show service id 1 evpn-mpls esi 01:00:00:00:00:23:00:00:00:01

Comparing EVPN multi-homing and BGP multi-homing

EVPN-MPLS services support EVPN-MH (EVPN multi-homing) and also BGP-MH as in chapter BGP Multi-Homing for VPLS Networks. While EVPN-MH is the standard way of providing access resiliency in RFC 7432, BGP-MH is also a standard mechanism supported in VPLS or EVPN networks. The following table provides some comparison between both technologies.

Table 5: Comparing EVPN multi-homing and BGP multi-homing

VPN Requirements	EVPN-MH	BGP-MH	Comments
All-active MH (flow-based load-balancing)	Yes	No	EVPN-MH provides better bandwidth utilization
Single-active MH (service-based load-balancing)	Yes	Yes	
DF PE election - automatic service balancing	Yes Service-carving	No Requires vsi policies and LP manipulation	EVPN-MH provides better automation
DF PE election – manual configuration per service	Yes	No	EVPN-MH allows for manual DF config for EVIs and ISIDs (2 PEs)
Split-horizon indication in the data plane	Yes ESI-label	No	Prevents transient loops when dual-active DFs show up
DF indication in the control plane	No	Yes	BGP MH guarantees one DF at a time. EVPN relies on Timers to ensure one DF at a time

VPN Requirements	EVPN-MH	BGP-MH	Comments
Allows multiple SAPs or SDP-bindings per service on the same site	No	Yes Through the use of SHGs	
Boot timer and site(es)-activation-timers	Yes	Yes	BGP-MH supports more granular configuration (service level)
Support for oper-groups	No	Yes	
Non-DF notification to the CE (MPLS and CFM)	Yes	Yes	Avoids blackholing

In addition to the preceding comparison, the following configuration excerpt compares EVPN-MH with BGP-MH on a bgp-evpn VPLS service and shows that, while EVPN-MH does not have any configuration at service level, BGP-MH is configured within the VPLS context, which gives a more granular control over the redundancy provided. See the BGP Multi-Homing for VPLS Networks chapter for more information about BGP-MH.

```

Proxy-ARP/ND configuration for EVPN-MPLS networks

Although not strictly a BGP-EVPN configuration, **vpls>proxy-arp** and **vpls>proxy-nd** functions are typically enabled along with EVPN-MPLS in order to reduce the amount of flooding in the network. The proxy-ARP/ND agent in the VPLS service will snoop ARP-requests and/or Neighbor Solicitation messages and will reply to those messages locally (if the information is known) without having to flood the requests to the network.

The configuration options for proxy-ARP are the following:

```
*A:PE-2>config>service>vpls# proxy-arp ?
  - no proxy-arp
  - proxy-arp

 [no] age-time        - Configure aging timer for proxy ARP entries
      dup-detect      - Configure anti-spoofing MAC address information
 [no] dynamic         + Configure dynamic entry information
 [no] dynamic-arp-po* - Configure population of dynamic proxy ARP entries
 [no] evpn-route-tag  - Configure EVPN Route Tag information
 [no] garp-flood-evpn - Configure to flood GARP request/replys into EVPN
 [no] send-refresh    - Configure send refresh time
 [no] shutdown        - Administratively enable/disable proxy ARP configuration
 [no] static          - Configure static IP address to MAC address associations
      table-size      - Configure the maximum number of entries in the proxy ARP table
 [no] unknown-arp-re* - Configure to flood unknown ARP request
```

The configuration options for proxy-ND are the following:

```
*A:PE-2>config>service>vpls# proxy-nd ?
  - no proxy-nd
  - proxy-nd

 [no] age-time        - Configure aging timer for proxy ND entries
      dup-detect      - Configure anti-spoofing MAC address information
 [no] dynamic         + Configure dynamic entry information
 [no] dynamic-nd-pop* - Configure population of dynamic proxy ND entries
      evpn-nd-advert* - Configure EVPN Neighbor Discovery advertisements
 [no] evpn-route-tag  - Configure EVPN Route Tag information
 [no] host-unsolicit* - Configure whether to flood evpn with host  neighbor
                        advertisement
 [no] router-unsolic* - Configure whether to flood evpn with router neighbor
                        advertisement
 [no] send-refresh    - Configure send refresh time
 [no] shutdown        - Administratively enable/disable proxy ND configuration
 [no] static          - Configure static IP address to MAC address associations
      table-size      - Configure the maximum number of entries in the proxy ND table
 [no] unknown-ns-flo* - Configure to flood unknown ND solicitation
```

When proxy-ARP/ND is enabled, the following configuration guidelines must be followed:

- **dynamic-arp-populate** or **dynamic-nd-populate** should be used only in networks with a consistent configuration of this command in all PEs.
- When using **dynamic-arp-populate**/**dynamic-nd-populate**, the **age-time** value should be configured to a value equal to three times the **send-refresh** value. This will help reduce the EVPN withdrawals and re-advertisements in the network.
- With large **age-time** values, it would be sufficient to configure the **send-refresh** value to half of the proxy-ARP/ND **age-time** or FDB **age-time**.
- In scaled environments (with thousands of services), it is not recommended to set the send-refresh value to less than 300 s. In such scenarios, Nokia recommends using a minimum proxy-ARP/ND **age-time** and FDB **age-time** of 900 s.
- The use of the following commands reduces or suppresses the ARP/ND flooding in an EVPN network, because EVPN MAC routes replace the function of the regular data plane ARP/ND messages:
  - **no garp-flood-evpn**
  - **no unknown-arp-request-flood-evpn**
  - **no unknown-ns-flood-evpn**
  - **no host-unsolicited-na-flood-evpn**
  - **no router-unsolicited-na-flood-evpn**
- Nokia recommends using the preceding commands only in EVPN networks where the CEs are routers directly connected to an SR OS node acting as the PE. Networks using aggregation switches between the host/routers and the PEs should flood GARP/ND messages in EVPN to make sure the remote caches are updated and BGP does not miss the advertisement of these entries.
- When the **anti-spoof-mac** is used with proxy-ARP/ND, ingress filters (in the access SAPs/SDP-bindings) should be configured to drop all traffic with destination anti-spoof-mac. The same MAC address should be configured in all PEs where dup-detect is active.
- When proxy-ND is used, the configuration of the following commands should be consistent in all the PEs in the network:

  - **router-unsolicited-na-flood-evpn**
  - **host-unsolicited-na-flood-evpn**
  - **evpn-nd-advertise**
- Because EVPN does not propagate the **router** flag in IPv6--> MAC address advertisements, in a mixed network with hosts and routers where **evpn-nd-advertise router** is configured, unsolicited host NA messages should be flooded so that the entire network gets to learn all of the host and router ND entries. In the same way, **evpn-nd-advertise host** should be configured so that unsolicited router NA messages are flooded.

Finally, along with proxy-ARP/ND, **vpls>discard-unknown** may be used in some EVPN-MPLS deployments where all the CEs are routers and they announce themselves to the network by sending GARPs or NAs (Neighbor Solicitation messages). According to RFC 7432, whether or not to flood packets to unknown destination MAC addresses should be an administrative choice, depending on how learning happens between CEs and PEs. **Discard-unknown** provides that administrative choice in case all the MAC addresses in an EVI can be learned even before any traffic is exchanged.

Proxy-ARP/ND along with **discard-unknown** helps reduce the BUM traffic in an EVPN network significantly; however, their use must be analyzed and considered, depending on the type of CEs in the EVI.

An example of proxy-ARP configuration is as follows. This configuration should be added to all PEs. When a new ARP message is received on any of the PEs, they will learn the IP-MAC address pair and will advertise it to the network.

```
# on PE-2, PE-3, PE-4, PE-5:
configure
    service
        vpls "VPLS1"
            proxy-arp
                age-time 900
                send-refresh 300
                dynamic-arp-populate
                no shutdown
            exit
```

Enabling proxy-ARP increases the number of MAC/IP routes being sent by the PEs. This is due to the following reasons:

- An additional MAC/IP route will be advertised per new learned IP-MAC address pair, regardless of having advertised the same MAC address already.
- A MAC per VPLS service will be advertised with a system MAC address. That MAC address will be used as MAC SA for proxy-ARP confirm messages when an IP moves to a different PE.

The following output shows the MAC/IP routes on PE-2 when proxy-ARP is enabled in the network.

```
*A:PE-2# show router bgp routes evpn mac

Troubleshooting and debug commands

When troubleshooting an EVPN-MPLS network, the following show commands and debug commands are recommended, as already discussed throughout this chapter:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service evpn-mpls [**<*TEP ip-address*>**]**
- **show service id bgp-evpn**
- **show service id evpn-mpls** (and modifiers)
- **show service id fdb** (and modifiers)
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **log-id 99**

In addition to the preceding commands, the following tools dump commands may also help:

- **tools dump service evpn usage** — This command shows the amount of EVPN-MPLS (and EVPN-VXLAN) destinations consumed in the system.
- **tools dump service system bgp-evpn ethernet-segment** <*name*> **evi <[1..65535]> df** — This command computes the DF election for a specific ESI and EVI. Note: The **show service system bgp-evpn ethernet-segment** commands shows whether the local PE is DF or non-DF for a specific EVI,

but it does not show who the DF is if it is not the local PE. In case of more than 2 PEs in the ES, this command may be especially useful.

Some examples are provided below for PE-2. PE-2 is showing seven EVPN-MPLS destinations due to the following:

- Each remote PE consumes one EVPN-MPLS destination for unicast (if they advertise MAC/IP routes to PE-2 and the ingress-replication-bum-label is configured in all the PEs). PE-2 has three remote unicast EVPN-MPLS destinations.
- Each remote PE consumes one EVPN-MPLS destination for multicast (if they advertise inclusive multicast routes to PE-2). PE-2 has three remote multicast EVPN-MPLS destinations.
- Each remote ES consumes one EVPN-MPLS destination (it is only one per ES, regardless of the multi-homing mode and the number of PEs in the ES). PE-2 has one remote ES (ESI-45).

```
*A:PE-2# tools dump service evpn usage

vxlan-evpn-mpls usage statistics at 02/17/2021 15:38:31:

MPLS-TEP                                        :             3
VXLAN-TEP                                       :             0
Total-TEP                                       :      3/ 16383

Sdp Bind +  Evpn Dests                          :      8/245759
ES L2/L3 PBR                                    :      0/ 32767
Evpn Etree Remote BUM Leaf Labels               :             0
```

To compute the DF election for EVI 1:

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-23" evi 1 df

[02/17/2021 15:39:51] Computed DF: 192.0.2.3 (Remote) (Boot Timer Expired: Yes)
```

Conclusion

SR OS has a full RFC 7432 EVPN-MPLS implementation including single-active and all-active multi-homing. This example has shown how to configure and operate EVPN-MPLS for a simple non multi-homing configuration as well as a multi-homing configuration. Other topics, such as the integration of VPLS objects with EVPN-MPLS and proxy-ARP/ND, have also been discussed.

EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS)

This chapter provides information about EVPN for MPLS tunnels in Epipe services (EVPN-VPWS).

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 22.10.R1. Ethernet Virtual Private Network - Virtual Private Wire Service (EVPN-VPWS) is supported in SR OS Release 14.0.R1 and later. EVPN-VPWS in multi-homing scenarios is supported in SR OS Release 14.0.R4 and later.

Chapter EVPN for MPLS Tunnels is prerequisite reading.

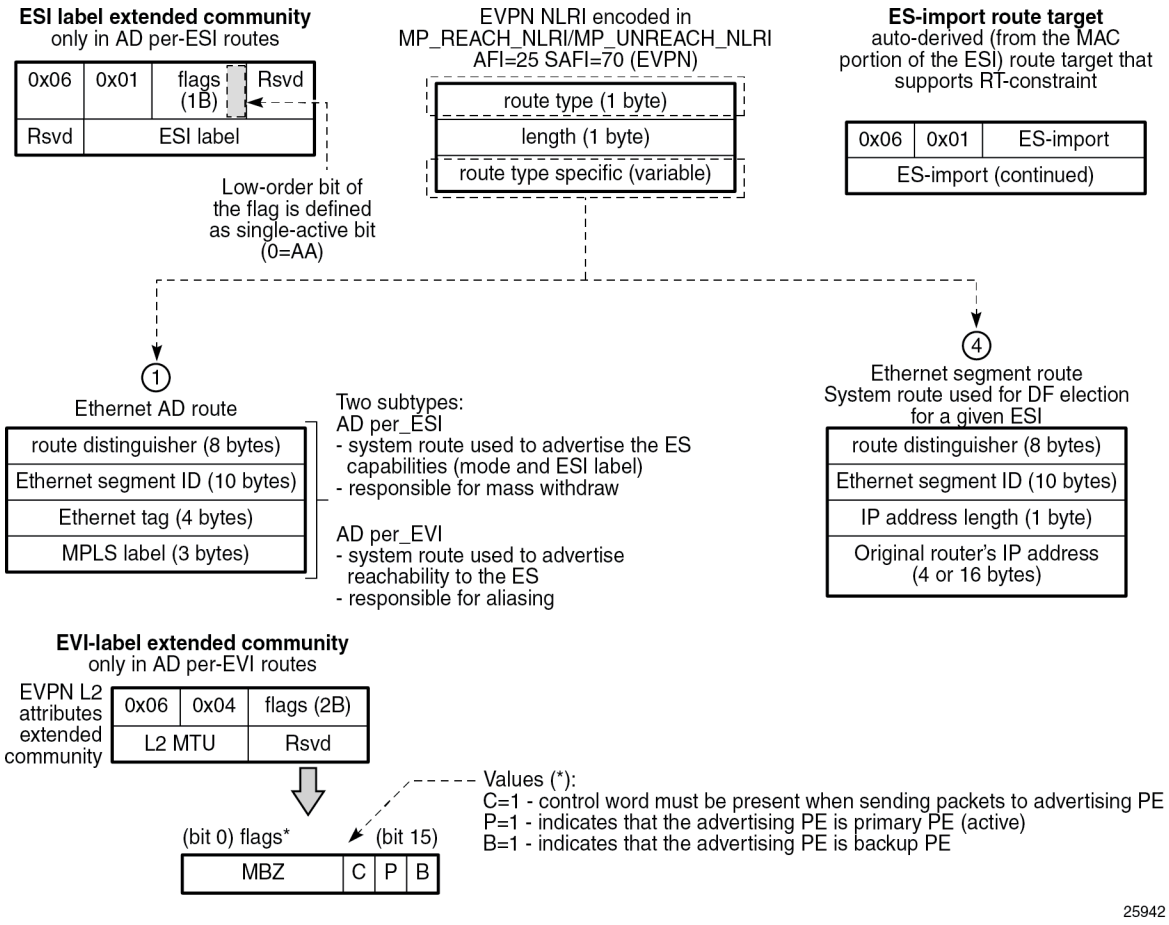
Overview

Service providers prefer an optimized, standardized, and unified control plane for VPNs. EVPN-VPWS is supported in MPLS networks that also run EVPN-MPLS in VPLS services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432, *BGP MPLS-Based Ethernet VPN*, because there is no need to advertise MAC routes in VPWS. EVPN-VPWS is described in RFC 8214, *Virtual Private Wire Service Support in Ethernet VPN*.

EVPN-VPWS supports all-active multi-homing (per-flow load-balancing multi-homing) as well as single-active multi-homing (per-service load-balancing multi-homing), using the same Ethernet segments (ESs) used for EVPN-MPLS VPLS services. EVPN-VPWS uses route-type 1 and route-type 4; it does not use route-types 2, 3, or 5, because MAC/IP routes, inclusive multicast, or IP-prefix routes are not required.

Figure 93: Route types and NLRIs for EVPN-VPWS shows the encoding of the required extensions for the route-types 1 and 4 for EVPN-VPWS.

Figure 93: Route types and NLRIs for EVPN-VPWS



Two sub-types are defined for route-type 1. Route-type 4 has no sub-types. The route types used for EVPN-VPWS have the following purposes:

- Route-type 1 - Auto-discovery per EVPN instance (AD per-EVI). This route type is used in all EVPN-VPWS scenarios, with or without multi-homing. For EVPN-VPWS, the Ethernet tag field is encoded with the local Attachment Circuit (AC) of the advertising PE. This value is configured using the **service epipe bgp-evpn local-attachment-circuit eth-tag** *<value>* command. The route distinguisher (RD), MPLS label, and the Ethernet segment ID (ESI) are encoded as for EVPN-MPLS. The MPLS label field is used as service label. In case of multi-homing, AD per-EVI routes containing the same ESI are used to provide aliasing and a backup path to the PEs part of the ES. The L2 MTU is encoded with the service MTU configured in the Epipe. The following flags are used for EVPN-VPWS:
  - Flag C is set if a control word is configured in the service.
  - Flag P is set if the advertising PE is primary PE.
    - If no multi-homing is used, there is no primary PE (P=0).
    - In all-active multi-homing, all PEs in the ES are primary (P=1).
    - In single-active multi-homing, only one PE per-EVI in the ES is primary (P=1).

– Flag B is set if the advertising PE is backup PE.
  - The B-flag is only set in case of single-active multi-homing and only for one PE, even if more than two PEs are present in the same single-active ES. The backup PE is the winner of the second Designated Forwarder (DF) election (excluding the DF). The remaining non-DF PEs send B=0.

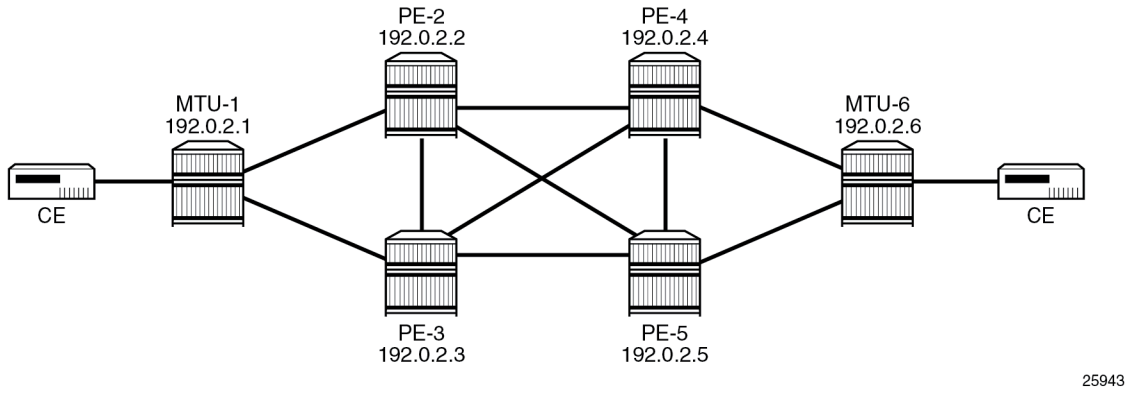
If there is no multi-homing, the ESI, flag P, and flag B will be zero.

- Route-type 1 - AD per Ethernet segment (AD per-ES). Same encoding as for EVPN-MPLS. AD per-ES is only used in multi-homing scenarios where it is advertised per ES from the PE. It carries the ESI label (used for split-horizon, but only for VPLS services and not for Epipe services) and can affect procedures such as the DF election, as well as the aliasing on remote PEs.
- Route-type 4 - ES route. Same encoding as for EVPN-MPLS. Route-type 4 is only used in multi-homing scenarios. This route advertises a local configured ES. The exchange of this route can discover remote PEs that are part of the same ES and the DF election algorithm among them.

Configuration

Figure 94: EVPN-VPWS example topology shows the example topology that will be used throughout this chapter.

Figure 94: EVPN-VPWS example topology



The example topology consists of six SR OS nodes with the following initial configuration:

- Network (or hybrid) ports interconnect the core PEs with configured router interfaces.
- MTU-1 is a pure Ethernet aggregator. The ports toward the core PEs are access ports. Likewise, the ports on PE-2 and PE-3 toward MTU-1 are access ports.
- Core PEs and MTU-6 run IS-IS on all router interfaces. Point-to-point adjacencies are established for the exchange of system IP addresses.
- Link LDP is configured between all PEs, and toward/from MTU-6.
- EVPN uses BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although typically a separate router is used, in this chapter, PE-2 is used as route reflector with the following BGP configuration:

```
# on PE-2:
configure
```

```
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 192.0.2.2
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

The BGP configuration on the other PEs is as follows:

```
# on PE-3, PE-4, PE-5:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
        exit
```

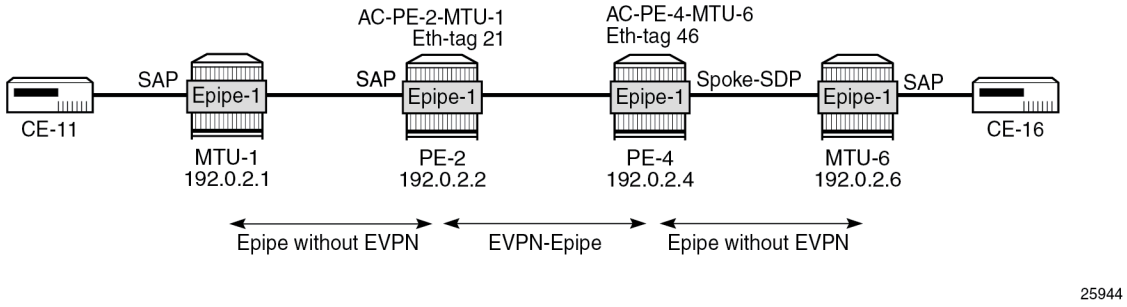
The following EVPN-VPWS scenarios are described in the following sections:

- EVPN for MPLS tunnels in Epipe services without multi-homing
- EVPN for MPLS tunnels in Epipe services with all-active multi-homing
- EVPN for MPLS tunnels in Epipe services with single-active multi-homing

EVPN for MPLS tunnels in Epipe services without multi-homing

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke-SDPs at the access, as shown in Figure 95: Example topology for EVPN-VPWS without multi-homing.

Figure 95: Example topology for EVPN-VPWS without multi-homing



On PE-2, Epipe 1 is configured as follows:

```
# on PE-2:
configure
    service
        epipe 1 name "Epipe-1" customer 1 create
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-PE-2-MTU-1 create
                    eth-tag 21
                exit
                remote-attachment-circuit AC-PE-4-MTU-6 create
                    eth-tag 46
                exit
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/1/c11/1:1 create
                no shutdown
            exit
            no shutdown
```

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure
    service
        sdp 460 create
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 1 name "Epipe-1" customer 1 create
            bgp
            exit
```

```
            bgp-evpn
                local-attachment-circuit AC-PE-4-MTU-6 create
                    eth-tag 46
                exit
                remote-attachment-circuit AC-PE-2-MTU-1 create
                    eth-tag 21
                exit
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 460:1 create
                no shutdown
            exit
            no shutdown
```

Where the following commands are relevant for the EVPN-VPWS configuration:

- **bgp** enables the context for the BGP configuration relevant to the service. The **bgp** context configures the common BGP parameters for all BGP families in the service, such as route distinguisher and route target. Even if the general BGP parameters for the service are auto-derived, the **bgp** context must be enabled.

```
*A:PE-2>config>service>epipe# bgp ?
  - bgp
  - no bgp

 [no] adv-service-mtu - Configure service-mtu to be advertised
 [no] pw-template-bi* + Configure pw-template bind policy
 [no] route-distingu* - Configure route distinguisher
 [no] route-target    - Configure route target
 [no] vsi-export      - VSI export route policies
 [no] vsi-import      - VSI import route policies
```

- The following parameters can be configured in the **bgp-evpn** context:

```
*A:PE-2>config>service>epipe# bgp-evpn ?
  - bgp-evpn
  - no bgp-evpn

 [no] evi             - EVPN Identifier
 [no] local-attachme* + Configure local attachment circuit information
 [no] mpls            + Configure BGP EVPN mpls
 [no] remote-attachm* + Configure remote attachment circuit information
 [no] segment-routin* + Configure SRv6 instance
 [no] vxlan           + Configure BGP EVPN vxlan
```

  – The **evi** is a two-byte or three-byte identifier used for auto-deriving the service RD (only for two-byte EVI), service RT, and for the DF election in multi-homing. The auto-derivation of RD and RT for a two-byte EVI is as follows:

    - RD <system IP address>:<evi>
    - RT <autonomous system number>:<evi>

    The EVI values must be unique in the system, regardless of the type of service they are assigned to (Epipe or VPLS).

Note: Three-byte EVI values are supported in SR OS Release 21.10.R1 and later. For auto-derived RT as per RFC 8365, the **evi-three-byte-auto-rt** command must be configured, as described in the Three-byte EVI in EVPN Services chapter.

– The **local-attachment-circuit** and **remote-attachment-circuit** identify the two attachment circuits connected by the EVPN-VPWS service. The configured Ethernet tag for the local AC is advertised in the Ethernet tag field of the AD per-EVI route for the Epipe, along with the corresponding RD, RT, and MPLS label. Both local and remote Ethernet tags are mandatory to bring up the Epipe service. If the received Ethernet tag for the Epipe service matches the configured remote AC Ethernet tag, it will create an EVPN-MPLS destination to the next hop.

  The local Ethernet tag cannot be modified without disabling **bgp-evpn mpls** in the Epipe, as shown in the following output:

```
*A:PE-2>config>service>epipe>bgp-evpn>local-att-cir# eth-tag 221
MINOR: SVCMGR #8036 evpn-vpws ac eth-tag not allowed - cannot change while evpn mpls/
vxlan/srv6 is enabled
```

  Unlike local Ethernet tags, remote Ethernet tags can be modified without disabling **bgp-evpn**.

– The following configuration options are available for Epipes in the **bgp-evpn>mpls** context:

```
*A:PE-2>config>service>epipe>bgp-evpn# mpls ?
  - mpls [bgp <bgp>]
  - no mpls [bgp <bgp>]

 <bgp>                : [1..1]

      auto-bind-tunn* + Configure BGP EVPN mpls auto-bind-tunnel
 [no] control-word    - Enable/disable setting the CW bit in the label message
 [no] default-route-* - Configure default-route-tag to match against export policies
 [no] dynamic-egress* - Enable/disable Dynamic Egress Label Limit
      ecmp            - Configure maximum ECMP routes information
 [no] entropy-label   - Enable/disable use of entropy-label
 [no] evi-three-byte* - Enable/Disable evi-three-byte-auto-rt
 [no] force-qinq-vc-* - Forces qinq-vc-type forwarding in the data-path
 [no] force-vlan-vc-* - Forces vlan-vc-type forwarding in the data-path
 [no] oper-group      - Configure oper-group
      route-next-hop  - Configure route next-hop
 [no] send-tunnel-en* - Configure encapsulation for this service
 [no] shutdown        - Administratively Enable/Disable BGP-EVPN mpls
```

  This is a subset of the options for VPLS services; see chapter EVPN for MPLS Tunnels.

When the local AC (SAP 1/1/c11/1:1) is up, PE-2 sends a BGP EVPN AD per-EVI route that contains Ethernet tag 21 for the local AC:

```
# on PE-2:
2 2022/11/29 09:33:44.668 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 81
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2
        Type: EVPN-AD Len: 25 RD: 192.0.2.2:1 ESI: ESI-0, tag: 21 Label: 8388512 (Raw Label:
 0x7fffa0) PathId:
```

```
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:1
        l2-attribute:MTU: 1514 C: 0 P: 0 B: 0
        bgp-tunnel-encap:MPLS
"
```

The auto-derived RD for EVI 1 is 192.0.2.2:1 and the RT is 64500:1.

When the remote AC on PE-4 (spoke-SDP 460:1) is up, PE-2 receives the following EVPN-AD per-EVI route with Ethernet tag 46 from PE-4:

```
# on PE-2:
4 2022/11/29 09:33:54.253 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 81
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:1 ESI: ESI-0, tag: 46 Label: 8388512 (Raw Label:
 0x7fffa0) PathId:
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:1
        l2-attribute:MTU: 1514 C: 0 P: 0 B: 0
        bgp-tunnel-encap:MPLS
"
```

When the received RT 64500:1 matches and the received Ethernet tag 46 matches the configured remote AC on PE-2, the following EVPN-MPLS destination (comprised of a termination endpoint (TEP) 192.0.2.4 and egress label 524282) is created on PE-2. In a similar way, an EVPN-MPLS destination is created on PE-4.

```
*A:PE-2# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address                     Egr Label               Last Change
                                 Transport:Tnl-id
-------------------------------------------------------------------------------
192.0.2.4                       524282                  11/29/2022 09:33:54
                                ldp:65538
-------------------------------------------------------------------------------

-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

The MPLS label in the debug message is not the same as in the service, because the router will strip the extra four lowest bits to get the 20-bit MPLS label. The egress label for the EVPN-MPLS destination on PE-4 is 524282. The 24-bit label value in the BGP update debug is 16 (2^4) times as high: 524282*16 = 8388512. This is because the debug message is shown before the router can parse the label field and see if it corresponds to a 20-bit MPLS label or a 24-bit VXLAN VNI.

The BGP AD per-EVI routes for Ethernet tag 46 can be shown with the following command:

```
*A:PE-2# show router bgp routes evpn auto-disc tag 46
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500
===============================================================================

Note: Each PE will send its service MTU into the L2 MTU field in the L2-attribute in the AD per-EVI route for the Epipe service. The received L2 MTU will be checked. In case of a mismatch between the received MTU and the configured service MTU, the router will not set up the EVPN destination and, therefore, the service will not come up.

EVPN for MPLS tunnels in Epipe services with multi-homing

SR OS supports EVPN multi-homing as per RFC 8214.

The EVPN multi-homing implementation is based on the concept of the Ethernet segment (ES). An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multi-homed to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects. It can also be shared between Epipe and VPLS services.

Each ES has a unique Ethernet segment Identifier (ESI) that is 10 bytes and is manually configured.

Note: Auto-derived EVPN ESI type 1 as per RFC 7432 is supported in SR OS Release 21.5.R1 and later, as described in the EVPN ESI Type 1 chapter.

The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homed CEs are assumed to be connected to an ES with ESI = 0 (single-homed ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-MPLS service, by default. An ES can be shared by multiple services; the association of a specific SAP or spoke-SDP to an ES is automatically made when the SAP is defined in the same LAG or port configured in the ES, or when the spoke-SDP is defined in the same SDP configured in the ES.

Regardless of the multi-homing mode, the local Ethernet tag values must match on all the PEs that are part of the same ES. The PEs in the ES will use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for an EVI. The DF election is only relevant for single-active multi-homing ESs. For Epipes defined in an all-active multi-homing ES, there is no DF election required, because all PEs are forwarding traffic and all traffic is treated as unicast.

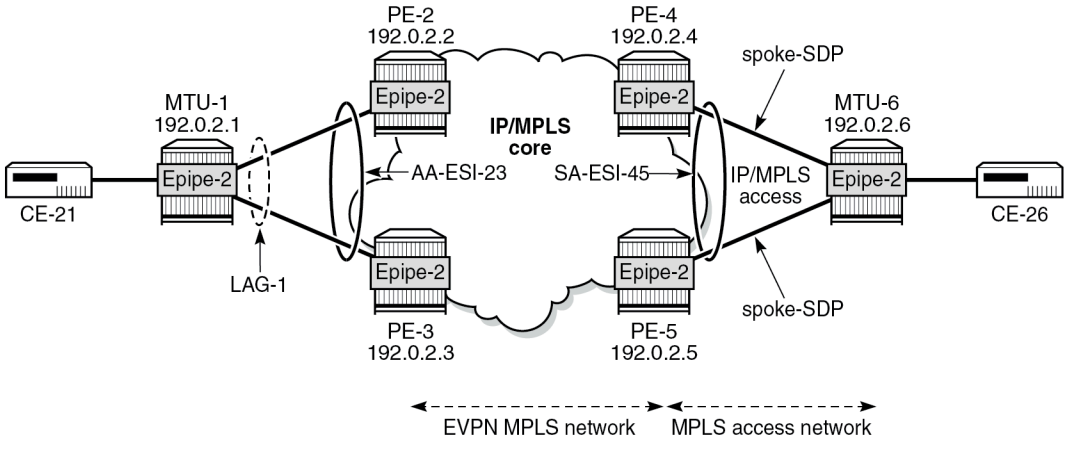
Aliasing is supported when sending traffic to an ES destination. Assuming ECMP is enabled on the ingress PE (and shared queuing or ingress policing), per-flow load-balancing will be performed among all the PEs that advertised P=1. PEs advertising P=0 are not considered as next hops for an ES destination.

The following sections show the configuration of:

- an all-active multi-homing ES with a LAG associated with it
- a single-active multi-homing ES linked to an SDP

Figure 96: Example topology EVPN-VPWS with multi-homing shows an all-active ES and a single-active ES. The all-active multi-homing ES "AA-ESI-23" in PE-2 and PE-3 has a LAG associated to it; the single-active multi-homing ES "SA-ESI-45" in PE-4 and PE-5 has an SDP associated to it.

Figure 96: Example topology EVPN-VPWS with multi-homing



EVPN for MPLS tunnels in Epipe services with all-active multi-homing

All-active multi-homing allows for per-flow load-balancing. Unlike EVPN-MPLS in VPLS services, EVPN-VPWS has no DF election in all-active multi-homing. All PEs in the ES are active and the remote PE will do per-flow load-balancing. AA-ESI-23 is configured on PE-2 and PE-3 in all-active multi-homing with LAG 1 associated to it. This LAG is used as a SAP in Epipe 2 on both PE-2 and PE-3. The configuration of the ES and Epipe 2 is identical on PE-2 and PE-3, including the local AC and remote AC names and Ethernet tags:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "AA-ESI-23" create
                    esi 01:00:00:00:00:23:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
```

```
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
            exit
        exit
        epipe 2 name "Epipe 2" customer 1 create
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-AA-ESI-23-MTU-1 create
                    eth-tag 231
                exit
                remote-attachment-circuit AC-SA-ESI-45-MTU-6 create
                    eth-tag 456
                exit
                evi 2
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap lag-1:2 create
                no shutdown
            exit
            no shutdown
```

See chapter EVPN for MPLS Tunnels for a detailed explanation of the configuration parameters of the ES.

In EVPN-VPWS multi-homing scenarios, three route types are exchanged: AD per-EVI, AD per-ES, and ES routes. The following ES route (route-type 4) for ESI 01:00:00:00:00:23:00:00:00:01 sent by PE-2 is imported at PE-3:

```
# on PE-3:
5 2022/11/29 09:42:41.537 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 71
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2
        Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.2:0 ESI: 01:00:00:00:00:23:00:00:00:01, IP-Len:
 4 Orig-IP-Addr: 192.0.2.2
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:

        esi-label:524282/All-Active
        bgp-tunnel-encap:MPLS
"
```

The ESI label is in the extended community, as well as the indication that the multi-homing is all-active. Epipe services do not require ESI labels because BUM traffic is not recognized as such in EVPN-VPWS services. However, because the ES can be shared by Epipe and VPLS services, the AD per-ES route still includes a non-zero ESI label.

The following AD per-EVI routes (route-type 1) with Ethernet tag 231 sent by RR PE-2 are received and imported on PE-4:

```
# PE-4 receives EVPN AD per-ES with Ethernet tag 231 (originator PE-2):

```

EVPN for MPLS tunnels in Epipe services with single-active multi-homing

Single-active multi-homing allows for per-service load-balancing. Single-active multi-homing is configured on PE-4 and PE-5 with ES "SA-ESI-45". Both PEs have an SDP to MTU-6, which is associated with the ES and to the Epipe service. The configuration of the local and remote AC names and Ethernet tags is identical on PE-4 and PE-5.

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "SA-ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
            exit
        exit
        epipe 2 name "Epipe 2" customer 1 create
            bgp
```

```
            exit
            bgp-evpn
                local-attachment-circuit AC-SA-ESI-45-MTU-6 create
                    eth-tag 456
                exit
                remote-attachment-circuit AC-AA-ESI-23-MTU-1 create
                    eth-tag 231
                exit
                evi 2
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 46:2 create
                no shutdown
            exit
            no shutdown
```

On PE-5, the configuration is similar, but with a different SDP:

```
# on PE-5:
configure
    service
        sdp 56 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "SA-ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 56
                    no shutdown
                exit
            exit
        exit
        epipe 2 name "Epipe 2" customer 1 create
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-SA-ESI-45-MTU-6 create
                    eth-tag 456
                exit
                remote-attachment-circuit AC-AA-ESI-23-MTU-1 create
                    eth-tag 231
                exit
                evi 2
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
```

```
                    resolution any
                exit
                no shutdown
            exit
        exit
        spoke-sdp 56:2 create
            no shutdown
        exit
        no shutdown
    exit
```

Three route types will be exchanged between the core PEs: AD per-EVI, AD per-ES, and ES routes.

PE-4 and PE-5 advertise ES routes that are only imported by them. As an example, the following is the ES route with originator PE-4 sent by RR PE-2 to PE-5. It contains a target 00:00:00:00:45:00 in the extended community that is derived from the ESI:

```
# on PE-2:
64 2022/11/29 09:43:18.845 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 85
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0 ESI: 01:00:00:00:00:45:00:00:00:01, IP-Len:
 4 Orig-IP-Addr: 192.0.2.4
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
        192.0.2.2
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:

        target:00:00:00:00:45:00
"
```

The AD per-ES route has a maximum Ethernet tag (MAX-ET) and an ESI label in the extended community. The multi-homing mode is single-active. As in the case of all-active multi-homing, the ESI label is not used in Epipe services. The following BGP update with originator PE-5 is sent by RR PE-2 to its client PE-4:

```
# on PE-2:
67 2022/11/29 09:43:18.970 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 95
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.5
        Type: EVPN-AD Len: 25 RD: 192.0.2.5:2 ESI: 01:00:00:00:00:45:00:00:00:01, tag: MAX-ET

```

```
        esi-label:524282/Single-Active
        bgp-tunnel-encap:MPLS
"
```

The AD per-EVI route contains flags for primary and backup, which will be different for routes received from PE-4 and PE-5. In this case, PE-4 is primary in the single-active multi-homing ES (P=1):

```
# on PE-2:
70 2022/11/29 09:43:21.801 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 95
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:2 ESI: 01:00:00:00:00:45:00:00:00:01, tag:
 456 Label: 8388464 (Raw Label: 0x7fff70) PathId:

```

The DF election is key for the forwarding and backup functions in single-active multi-homing ESs. The PE elected as DF will be the primary for the ES in the Epipe and will unblock the SAP/spoke-SDP for upstream and downstream traffic. The rest of the PEs in the ES will bring their ES SAPs or spoke-SDPs operationally down.

PE-5 is a non-DF, as follows:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "SA-ESI-45" evi 2

===============================================================================
EVI DF and Candidate List
===============================================================================

Number of entries: 2
===============================================================================
* indicates that the corresponding row element may have been truncated.
```

In single-active multi-homing, the service spoke-SDP (or SAP) is brought operationally down on the non-DF, as shown in the following output:

```
*A:PE-5# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
56:2             Spok     192.0.2.6       Up      Down      524280    524280
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The spoke-SDP 56:2 is operationally down with a StandbyForMHProtocol flag:

```
*A:PE-5# show service id 2 sdp 56:2 detail | match Flag
Flags              : StandbyForMHProtocol
```

Two consecutive DF elections take place: the first DF election includes all PEs in the ES for that Epipe and determines which PE is the primary PE (flags P=1, B=0). The second DF election excludes this DF and determines which PE is the backup (P=0, B=1). All other PEs signal flags P=0 and B=0.

When the primary PE fails, AD per-ES/EVI withdrawal messages are sent to the remote PE, which will update its next hop to the backup. The backup PE takes over immediately without waiting for the **es-activation-timer** to bring up its SAP/spoke-SDP.

Ethernet segment failures

When the SDP toward the primary (DF) fails, the backup PE needs to take over. An SDP failure is emulated and log 99 on PE-4 shows that SDP 46 is operational down and PE-4 is no longer the DF:

```
140 2022/11/29 10:05:00.118 UTC MINOR: SVCMGR #2303 Base
"Status of SDP 46 changed to admin=up oper=down"

142 2022/11/29 10:05:00.119 UTC MINOR: SVCMGR #2094 Base
"Ethernet Segment:SA-ESI-45, EVI:2, Designated Forwarding state changed to:false"
```

Remote PEs receive route withdrawal updates (unreachable NLRI) from former DF PE-4, for example on PE-2:

```
# on PE-2:
82 2022/11/29 10:05:00.122 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:

"
```

The backup PE-5 is promoted to primary (P=1, B=0) and sends BGP updates accordingly. The following AD per-EVI is received on PE-2:

```
# on PE-2:
85 2022/11/29 10:05:00.124 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE

        bgp-tunnel-encap:MPLS
"
```

PE-5 brings up its spoke-SDP without waiting for the **es-activation-timer** and takes over immediately. It is now the only DF candidate, and therefore the DF, as follows:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "SA-ESI-45" evi 2

===============================================================================
EVI DF and Candidate List
===============================================================================

-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
```

This process is revertive; as soon as the SDP 46 is operationally up again, a new DF election is triggered with two DF candidates and PE-4 will be elected as DF.

Troubleshooting and debugging

The following show and debug commands can be used in EVPN-VPWS:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service evpn-mpls [<TEP ip-address>]**
- **show service id bgp-evpn**
- **show service id evpn-mpls** (and modifiers)
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **show log log-id 99**

Most of these commands have been shown in the preceding sections; some commands are shown in this section.

Information about the configured boot timers (before DF election) and ES activation timer (after the system has been elected DF) can be shown as follows:

```
*A:PE-2# show redundancy bgp-evpn-multi-homing

===============================================================================
Redundancy BGP EVPN Multi-homing Information
===============================================================================
Boot-Timer              : 10 secs
Boot-Timer Remaining    : 0 secs
ES Activation Timer     : 3 secs
===============================================================================
```

See chapter EVPN for MPLS Tunnels for a description of these timers.

The following command shows that the BGP route-type 4 (ES route) messages are only imported by the PEs in the same ES; for example, on PE-3:

```
*A:PE-3# show router bgp routes evpn eth-seg

===============================================================================
```

In addition to the preceding commands, the following tools dump commands may be useful:

- **tools dump service evpn usage** - This command shows the number of EVPN-MPLS (and EVPN-VXLAN) destinations in the system.
- **tools dump service system bgp-evpn ethernet-segment** <*name*> **evi <..> df** - This command computes the DF election for a specific ESI and EVI. For all-active, there is no DF election and all PEs forward traffic. For single-active, one PE will be active for a service while another PE will be backup. This command shows the DF (primary), even if it is not the local PE.

The usage of EVPN resources can be shown as follows:

```
*A:PE-2# tools dump service evpn usage

vxlan-srv6-evpn-mpls usage statistics at 11/29/2022 10:13:11:

MPLS-TEP                                        :             1

Mpls Dests (TEP, Egress Label + ES + ES-BMAC)   :             2
Mpls Etree Leaf Dests                           :             0
Vxlan Dests (TEP, Egress VNI + ES)              :             0
Srv6 Dests (TEP, SID  + ES)                     :             0
Total-Dest                                      :      2/196607

Sdp Bind +  Evpn Dests                          :      2/245759
ES L2/L3 PBR                                    :      0/ 32767
Evpn Etree Remote BUM Leaf Labels               :             0
```

On PE-2, there is one MPLS-TEP (192.0.2.4 in Epipe 1 and Epipe 2) and there are two MPLS destinations: 192.0.2.4 and ESI 01:00:00:00:00:45:00:00:00:01. PE-5 is not an MPLS-TEP for PE-2, because it is not a primary and, therefore, not forwarding any traffic.

In all-active multi-homing, the DF election is not applicable:

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "AA-ESI-23" evi 2 df

[11/29/2022 10:13:29] All Active VPWS or IP-ALIASING - DF N/A
```

In single-active multi-homing, the following command shows which PE is the DF and which PE is the backup:

```
*A:PE-5# tools dump service system bgp-evpn ethernet-segment "SA-ESI-45" evi 2 df
```

```
[11/29/2022 10:13:49] Computed DF: 192.0.2.4 (Remote) (Boot Timer Expired: Yes)
[11/29/2022 10:13:49] Computed Backup: 192.0.2.5 (This Node)
```

The command is launched on PE-5, which is a backup. The computed DF is PE-4 and the boot timer has expired, meaning there is no DF re-election pending.

Conclusion

EVPN-VPWS is a simplified point-to-point version of RFC 7432, *BGP MPLS-Based Ethernet VPN*. When used for Epipe and VPLS services, EVPN provides a unified control plane mechanism that simplifies the network deployment and operation. Single-active and all-active multi-homing can be used in Epipes; EVPN-VPWS is a differentiator of EVPN compared to traditional TLDP or BGP Epipe redundancy mechanisms. The Ethernet segments used for multi-homing can be shared between EVPN VPLS and EVPN Epipes.

EVPN for MPLS Tunnels in Routed VPLS

This chapter provides information about EVPN for MPLS tunnels in routed VPLS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R4, but the CLI in the current edition is based on SR OS Release 21.10.R3. EVPN-MPLS and IP-prefix advertisement in routed VPLS (R-VPLS) without Multi-homing (MH) is supported in SR OS Release 14.0.R1, and later. EVPN-MPLS and IP-prefix advertisement in R-VPLS with all-active and single-active MH is supported in SR OS Release 14.0.R4, and later. Virtual Router Redundancy Protocol (VRRP) in passive mode is also supported in SR OS Release 14.0.R4, and later.

Chapter EVPN for VXLAN Tunnels (Layer 3) is prerequisite reading.

Overview

The EVPN-MPLS in R-VPLS feature matches the EVPN-VXLAN in R-VPLS feature, which is described in chapter EVPN for VXLAN Tunnels (Layer 3). The following capabilities are supported in an R-VPLS service where **bgp-evpn mpls** is enabled:

- R-VPLS with Virtual Router Redundancy Protocol (VRRP) support on the VPRN interfaces
- R-VPLS support including **ip-route-advertisement** (IP prefix routes—BGP-EVPN route type 5) with regular interfaces
- R-VPLS support including **ip-route-advertisement** with **evpn-tunnel** interfaces
- R-VPLS with IPv6 support on the VPRN IP interface

All-active and single-active MH Ethernet segments (ESs) are supported in R-VPLS. When Ethernet Segments (ESs) are used along with R-VPLS services in two or more PEs, passive VRRP provides an "anycast default gateway" that optimizes inter-subnet forwarding for hosts in the R-VPLS. Passive VRRP is described in the following section.

Passive VRRP

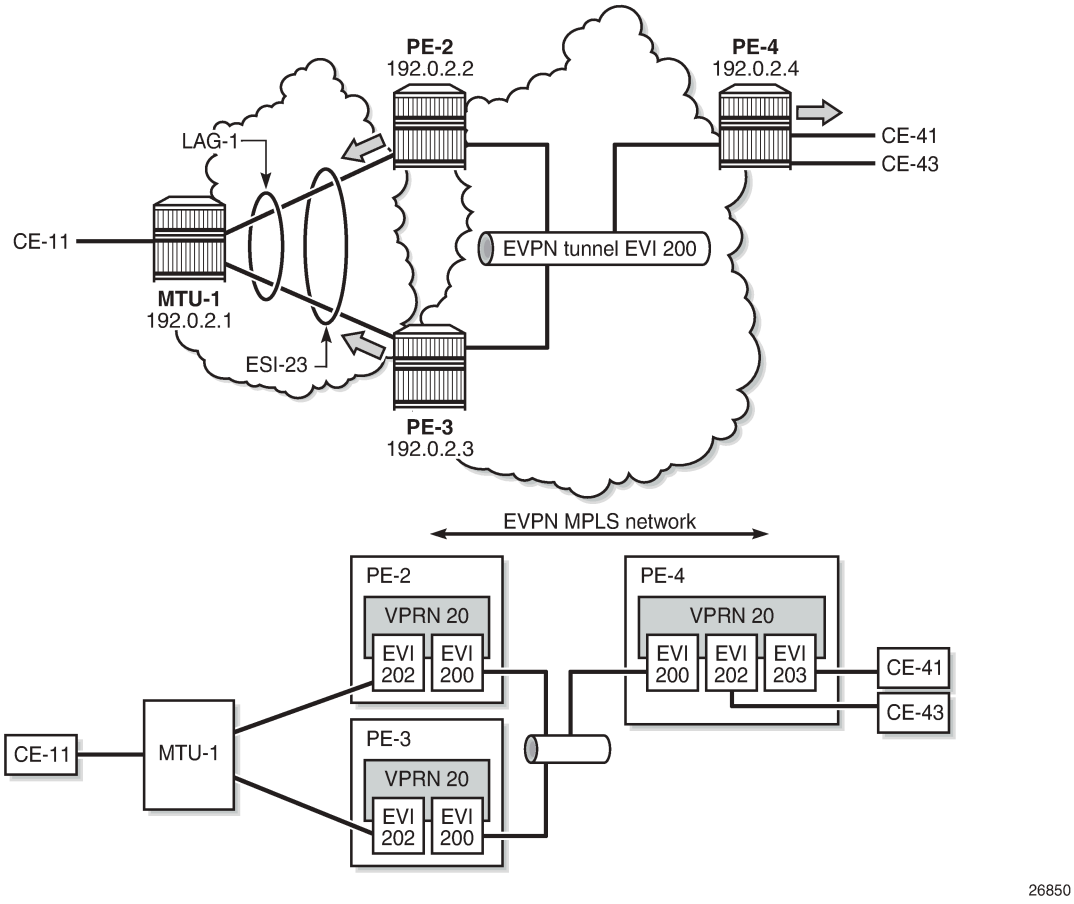
VRRP can be configured in passive mode, which suppresses the transmission and reception of keepalive messages. Passive mode can be enabled by adding the keyword **passive** at creation time. Passive mode cannot be enabled or disabled on the fly. Passive VRRP can be configured in the base router, in an IES, or in a VPRN, using the following commands:

```
*A:PE-2# tree flat detail | match vrrp | match passive
```

```
configure router interface ipv6 vrrp <virtual-router-id> [owner] [passive]
configure router interface vrrp <virtual-router-id> [owner] [passive]
configure service ies interface ipv6 vrrp <virtual-router-id> [owner] [passive]
configure service ies interface vrrp <virtual-router-id> [owner] [passive]
configure service vprn interface ipv6 vrrp <virtual-router-id> [owner] [passive]
configure service vprn interface vrrp <virtual-router-id> [owner] [passive]
```

All PEs configured with passive VRRP become VRRP master and take ownership of the virtual IP and MAC addresses. Figure 97: Passive VRRP - vMAC/vIP advertised by GARP shows the use of passive VRRP where the VRID and default gateway (GW) are identical for all nodes, and therefore, the vMAC/vIP are identical. Each PE sends Gratuitous Address Resolution Protocol (GARP) messages with the same vMAC/vIP.

Figure 97: Passive VRRP - vMAC/vIP advertised by GARP



Ethernet VPN instance (EVI) 202 is configured on all PEs as an R-VPLS with passive VRRP. Each individual R-VPLS interface has a unique MAC/IP, but they all have the same vMAC/vIP because they share the same VRID and backup IP address. The vMAC address is auto-derived out of 00:00:5e:00:00:<VRID>, as per RFC 3768.

The behavior is as follows:

- PEs advertise their real MAC/IP and their vMAC/vIP in EVPN for EVI 202.
- All hosts in EVI 202 have a unique configured default GW.

- When a CE sends upstream traffic to a remote subnet, the packets are routed by the closest PE because the vMAC address is local on each PE.
- In case of ES failure, or in case of single-active MH if the traffic arrives at the non-Designated Forwarder (NDF) PE, the traffic will not be discarded at the peer ES PE. Virtual MAC addresses bypass the R-VPLS interface protection, so traffic can be forwarded between the PEs without being dropped. Note that if passive VRRP was not used in this case and the same regular interface anycast MAC/IP was used instead, the peer PE would discard the traffic due to the MAC Source Address (SA).

Passive VRRP provides an efficient anycast default gateway solution, with the following advantages compared to regular VRRP:

- No need for multiple VRRP instances to achieve default GW load-balancing. Only one VRRP instance is in the R-VPLS, so only one default GW is needed for all hosts.
- Fast convergence because all the nodes in the VRID are master.
- Better scalability because there is no need for keepalive messages or BFD to detect failures.

Passive VRRP provides the following advantages compared to using the same anycast MAC/IP in all the Integrated Routing Bridging (IRB) interfaces:

- VRRP vMAC SA bypasses the protection in the receiving R-VPLS service; therefore, frames with MAC SA matching the local vMAC address are not discarded, and VRRP vMAC SAs can be used in combination with EVPN multi-homing.
- PEs will not show traps claiming duplicate IP addresses.
- vMAC addresses are auto-derived from the VRID, so no need to configure the same MAC address in all the IRB interfaces.
- PEs can still use their real (unique) IRB IP addresses when sending ICMP packets for troubleshooting purposes.

Configuration

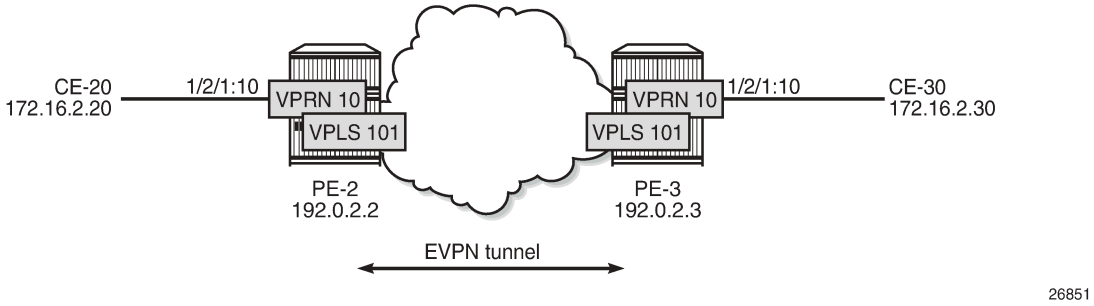
In this section, the following use cases are described:

- EVPN-MPLS R-VPLS without multi-homing
- EVPN-MPLS R-VPLS with all-active multi-homing ES
- EVPN-MPLS R-VPLS with single-active multi-homing ES

EVPN-MPLS R-VPLS without multi-homing

The first scenario describes R-VPLS support including IP route advertisement (BGP-EVPN route type 5) with EVPN tunnel interfaces, without multi-homing. VPLS 101 does not have any connected host, but the linked VPRN has SAP 1/2/1:10. Figure 98: R-VPLS with EVPN tunnel, without multi-homing shows the example topology used for R-VPLS with EVPN tunnel but without multi-homing. IP prefixes are advertised.

Figure 98: R-VPLS with EVPN tunnel, without multi-homing



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interface between PE-2 and PE-3
- IS-IS (or OSPF)
- LDP enabled on the router interface between PE-2 and PE-3

BGP is configured for address family EVPN on PE-2 and PE-3. The BGP configuration on PE-2 is as follows. The BGP configuration on PE-3 is similar.

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                peer-as 64500
                neighbor 192.0.2.3
                exit
            exit
        exit
```

The CEs are connected to SAP 1/2/1:10 in VPRN 10. R-VPLS 101 is bound to VPRN 10 and VPRN 10 has a dedicated interface "int-evi-101" for the EVPN tunnel. In general, if only one route-target (RT) is used for import and export in the EVPN-VPLS, it is good to add the EVI and have the route distinguisher (RD) and RT auto-derived from the EVI. It is simpler and avoids configuration mistakes. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            interface "int-PE-2-CE-20" create
                address 172.16.2.1/24
                sap 1/2/1:10 create
                exit
            exit
```

```
            interface "int-evi-101" create
                vpls "evi-101"
                    evpn-tunnel
                exit
            exit

            exit
            no shutdown
        exit
```

- The **allow-ip-int-binding** command is required so that R-VPLS 101 can be bound to VPRN 10.
- The service name is required and the configured name "evi-101" must match the name in the VPRN 10 VPLS interface. The service name is configured at service creation time.
- The VPRN 10 VPLS interface is configured with the keyword **evpn-tunnel**. This configuration has the advantage of not having to allocate IP addresses to the R-VPLS interfaces, however, it cannot be used when the R-VPLS has local SAPs.

The configuration is similar on PE-3. It is important that the RD is different on PE-2 and PE-3, but it is automatically the case when the RD is auto-derived from the configured EVI, as in the example. The RD on PE-2 is 192.0.2.2:101; on PE-3, the RD is 192.0.2.3:101.

PE-3 receives the following BGP-EVPN IP prefix route for prefix 172.16.2.0/24 from PE-2:

```
2 2022/02/24 11:00:28.145 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"
```

GW IP 0.0.0.0 is an indication that an EVPN tunnel is in use. With EVPN tunnels, no IRB IP address needs to be configured in the VPRN. EVPN tunnels make provisioning easier to automate and save IP addresses from the tenant IP space.

The BGP tunnel encapsulation is MPLS, but the MPLS label in the debug message is not the same as in the service, because the router will strip the extra four lowest bits to get the 20-bit MPLS label. In the debug message, the label is 8388496. This is because the debug message is shown before the router can parse the label field and see if it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits). The MPLS label is calculated by dividing the label value by 24 (16), as follows: 8388496/16 = 524281.

The MAC next-hop extended community 02:13:ff:ff:ff:a2 is the MAC address of the interface "int-evi-101" in VPRN 10 on PE-2, as follows:

```
*A:PE-2# show router 10 interface "int-evi-101" detail | match "MAC Address"
MAC Address      : 02:13:ff:ff:ff:a2    Mac Accounting    : Disabled
```

The routing table for VPRN 10 on PE-3 contains the route for prefix 172.16.2.0/24 as the EVPN-IFF (IFF stands for Interface-ful) route with next-hop "int-evi-101" and interface name "ET-02:13:ff:ff:ff:a2" (ET stands for EVPN Tunnel), as follows:

```
*A:PE-3# show router 10 route-table

When the CEs have IPv6 addresses, the VPRN configuration is similar on the PEs, but the **ipv6** context must be enabled in the EVPN tunnel interface, so that the router can advertise and process BGP-EVPN routes type 5 with IPv6 prefixes. The configuration of the VPLS is identical for IPv4 and IPv6.

```
# on PE-2:
configure
    service
        vprn 16 name "VPRN 16" customer 1 create
            interface "int-PE-2-CE-26" create
                ipv6
                    address 2001:db8:16::2:1/120
                exit
                sap 1/2/1:16 create
                exit
            exit
            interface "int-evi-106" create
                ipv6
                exit
                vpls "evi-106"
                    evpn-tunnel
                exit
            exit
            no shutdown
        exit
        vpls 106 name "evi-106" customer 1 create
            allow-ip-int-bind
            exit
            bgp
            exit
            bgp-evpn
                ip-route-advertisement
                evi 106
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

When advertising IPv6 prefixes, the GW IP field in the route type 5 is always populated with the IPv6 address of the R-VPLS interface. In this example, because no specific IPv6 global address is configured, the GW IP will be populated with the auto-created link local address. The following BGP update is received by PE-3 for IPv6 prefix 2001:db8:16::2:0/120:

```
# on PE-3:
9 2022/02/24 11:00:35.338 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

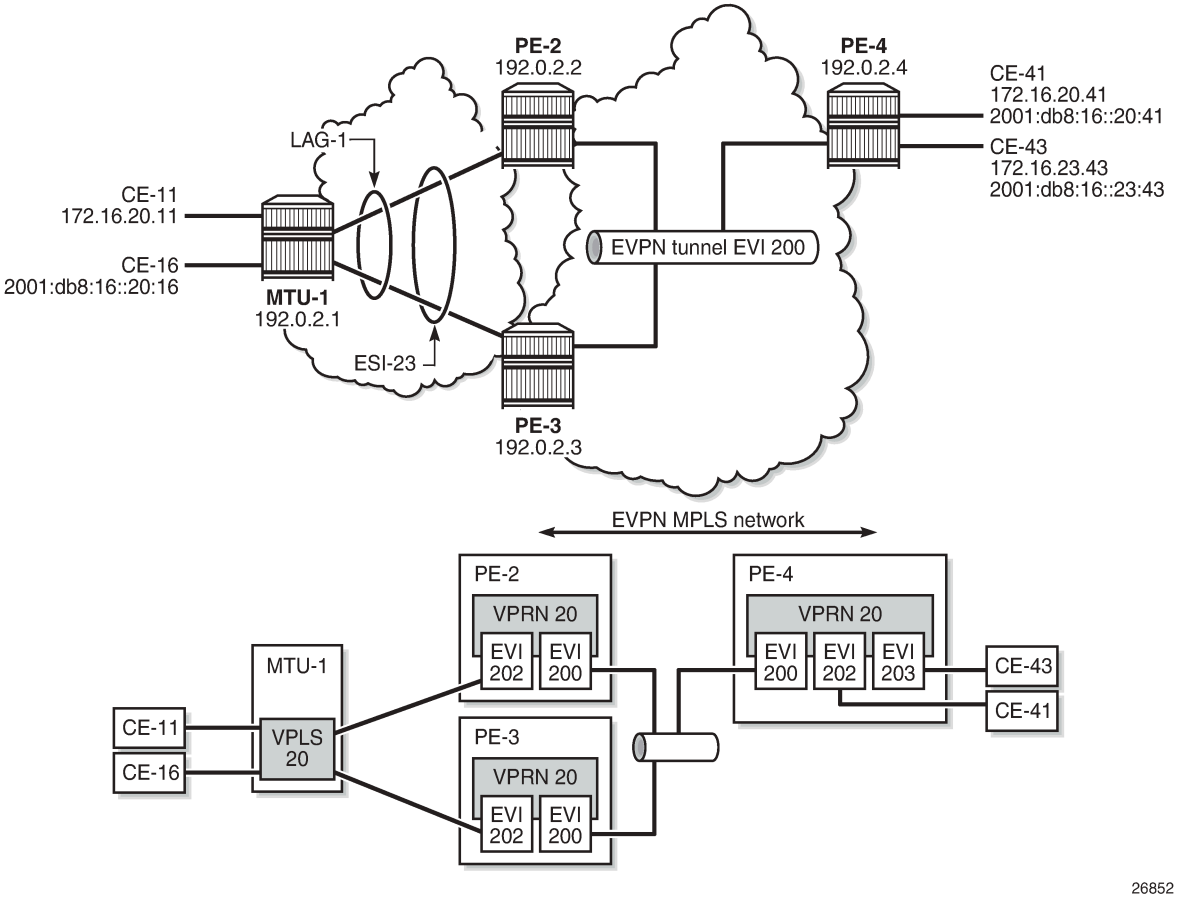
EVPN-MPLS R-VPLS with all-active MH

Figure 99: EVPN-MPLS R-VPLS with all-active MH ES shows the example topology with all-active multi-homing ES "AA-ESI-23".

Figure 99: EVPN-MPLS R-VPLS with all-active MH ES



BGP is configured between PE-2, PE-3, and PE-4 for address family EVPN. The configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
        exit
```

All-active multi-homing Ethernet segment "AA-ESI-23" is configured on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "AA-ESI-23" create
                    esi 01:00:00:00:00:23:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
```

The following services are configured on the PEs:

- VPRN 20 has interfaces bound to VPLS 200 and VPLS 202. On PE-4, VPRN 20 also has an interface bound to VPLS 203.
- VPLS 200 is configured as an EVPN tunnel that connects the PEs.
- VPLS 202 and VPLS 203 have attachment circuits to CEs.

The services are configured on PE-2 as follows. The configuration on PE-3 and PE-4 is similar.

```
# on PE-2:
configure
    service
        vprn 20 name "VPRN 20" customer 1 create
            interface "int-evi-202" create
                address 172.16.20.2/24
                mac 00:ca:fe:00:02:02
                vrrp 1 passive
                    backup 172.16.20.254
                    ping-reply
                    traceroute-reply
                exit
                ipv6

        exit
        no shutdown
    exit
```

The IPv6 VRRP backup address is in the same subnet as the link local address of the interface "int-evi-202". The option **dad-disable** is configured on the link local address to disable Duplicate Address Detection (DAD) and set the IPv6 address as preferred. Also for IPv6, router advertisement must be enabled and configured to use the virtual MAC address.

Passive VRRP

EVI 202 is configured as an R-VPLS with passive VRRP. A passive-VRRP VRID instance suppresses the transmission and reception of keepalive messages. All PEs configured with passive VRRP become VRRP master and take ownership of the virtual IP and MAC address.

Each individual R-VPLS interface has a different MAC/IP on each PE. The MAC/IPs for "int-evi-202" on PE-2 are MAC 00:ca:fe:00:02:02 and IP 172.16.20.2/24 for IPv4 and the same MAC address with IPv6 2001:db8:16::20:2 and fe80::16:20:2. However, the R-VPLS interfaces on all PEs share the same VRID 1 and backup IP address 172.16.20.254, so the same vMAC/vIP 00:00:5e:00:01:01/172.16.20.254 and

vMAC/vIP 00:00:5e:00:02:01/ fe80::16:20:fe are advertised by all PEs. PE-2 advertises the following EVPN MAC routes:

```

"
```

The three PEs advertise the same (anycast) vMAC/vIP in EVI 202 as protected, but each PE keeps its own MAC entry in the FDB. The following FDB shows that the source identifier for vMAC 00:00:5e:00:01:01 and vMAC 00:00:5e:00:02:01 is the CPM. These two vMAC entries with source identifier CPM are seen on all PEs.

```

===============================================================================
```

The interface MAC 00:ca:fe:00:02:02 is local, so it also has the CPM as source identifier. MAC 00:ca:fe:00:02:03 is the PE-3's R-VPLS interface MAC and it is learned via EVPN-MPLS (mpls-1) as static (S) and protected (P). MAC address 00:ca:fe:00:02:04 on PE-4 is also static and protected.

PE-4 sends the following IP prefix route (BGP-EVPN route type 5) for prefix 172.16.23.0/24 to the other PEs:

```
37 2022/02/24 15:09:13.665 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

===============================================================================
```

The following IPv6 routing table for VPRN 20 on PE-2 contains prefix 2001:db8:16::23:0/120, which has also been advertised by PE-4. The next-hop is again "int-evi-200", only this time the link local ipv6 address is displayed (GW IP) instead of the MAC address. The next-hop is the GW IP value in the route type 5, as

long as it is non-zero. When the GW IP address is zero, the route type 5 is expected to contain a mac-nh extended community. The MAC encoded in the extended community is used as next-hop in that case.

```
*A:PE-2# show router 20 route-table ipv6

Operation

On PE-4, VPRN 20 has one interface bound to VPLS 202 and another interface bound to VPLS 203. CE-41 is attached to VPLS 202, whereas CE-43 is attached to VPLS 203. When ping messages are sent from CE-41 to CE-43, or vice versa, the messages go via VPRN 20, which has routes to both CEs, as follows:

```
*A:PE-4# show router 20 route-table

===============================================================================
Route Table (Service: 20)
===============================================================================
```

```
Dest Prefix[Flags]                              Type    Proto     Age        Pref

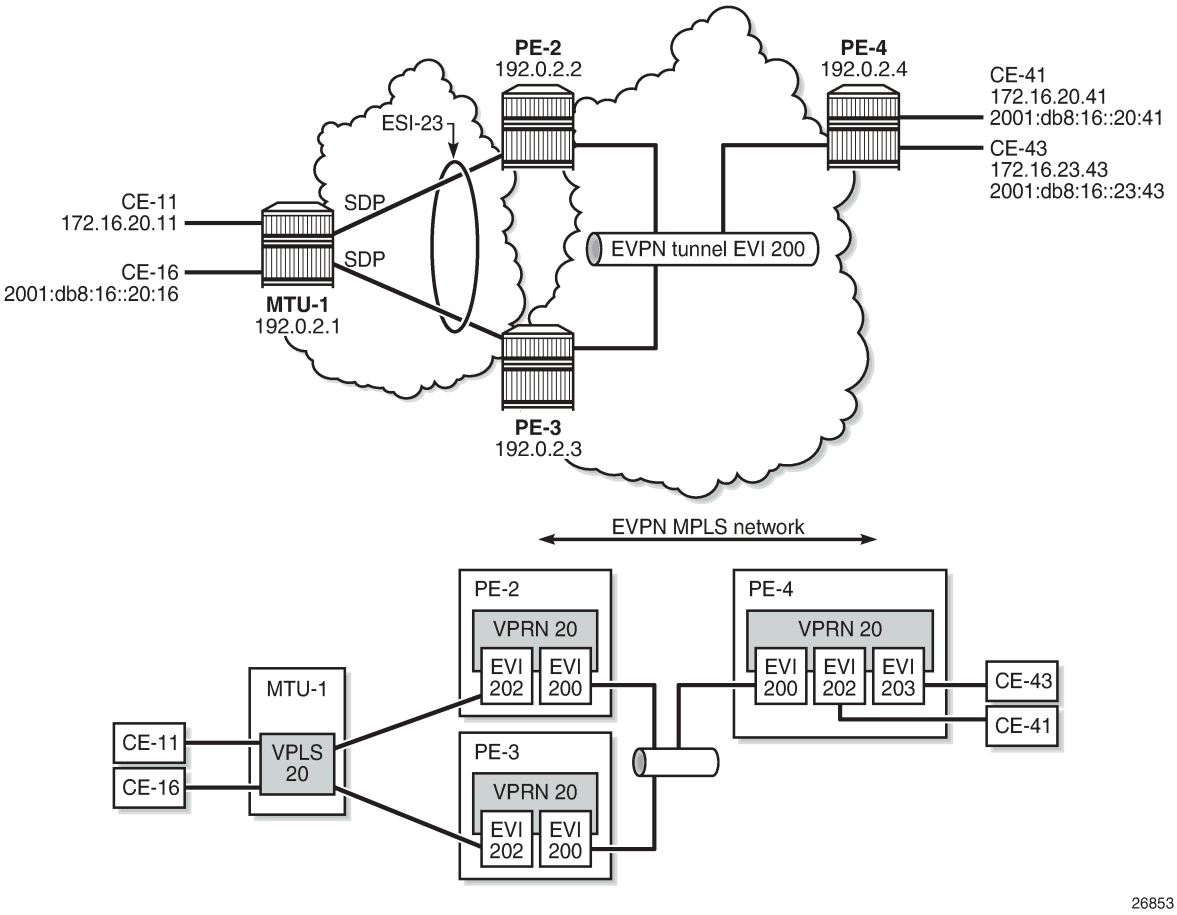
EVPN-MPLS R-VPLS with single-active MH

Figure 100: EVPN-MPLS R-VPLS with single-active multi-homing shows the example topology with single-active multi-homing ES "SA-ESI-23". The difference is that the ES is single-active and SDPs are used instead of a LAG.

Figure 100: EVPN-MPLS R-VPLS with single-active multi-homing



The configuration is modified as follows:

- LAG 1 is removed from MTU-1, PE-2, and PE-3.
- Network interfaces are configured between MTU-1 and PE-2/PE-3 with IS-IS and LDP enabled.
- SDPs are configured.
- Ethernet segment "SA-ESI-23" is defined as single-active multi-homing. The SDP is associated with this ES.
- VPLS 202 on PE-2 and PE-3 no longer has a SAP, but a spoke-SDP instead.
- No changes are required on VPRN 20 or VPLS 200.

The service configuration on PE-2 is as follows. The configuration on PE-3 is similar. No changes are required on PE-4.

```
# on PE-2:

```

When the SDP between MTU-1 and DF PE-2 goes down, traffic from CE-41 to CE-11 is forwarded by PE-4 to DF PE-2. PE-2 cannot forward the packets to CE-11 directly, and will forward the packets to its ES peer PE-3. PE-3 will forward to CE-11 even if the MAC SA matches its own vMAC. Virtual MACs bypass the R-VPLS interface protection, so traffic can be forwarded between the PEs without being dropped.

Conclusion

EVPN can be used as the unified control plane VPN technology, not only for providing Layer 2 connectivity, but also Layer 3 (inter-subnet forwarding). EVPN for MPLS tunnels, along with multi-homing and passive VRRP, provides efficient layer-2/layer-3 connectivity to distributed hosts and routers.

EVPN for PBB over MPLS (PBB-EVPN)

This chapter provides information about EVPN for PBB over MPLS (PBB-EVPN).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 13.0.R6. The CLI in the current edition is based on SR OS Release 21.2.R1.

Important note: A prerequisite is to read the EVPN for MPLS Tunnels chapter.

Overview

EVPN for Provider Backbone Bridging (PBB) over MPLS (hereafter called PBB-EVPN) is specified in RFC 7623, *Provider Backbone Bridging Combined with Ethernet VPN (PBB-EVPN)*. It provides a simplified version of EVPN-MPLS for cases where the network requires very high scalability and does not need all the advanced features supported by EVPN-MPLS (but still requires single-active and all-active multi-homing capabilities). Table 6: EVPN and PBB-EVPN SR OS feature comparison provides a comparison between the capabilities of EVPN and PBB-EVPN in SR OS, and may help to choose between them when designing a VPN service.

Table 6: EVPN and PBB-EVPN SR OS feature comparison

VPN requirements	EVPN	PBB-EVPN	Comments
All-active Multi-Homing (MH) (flow-based load-balancing)	Yes	Yes	Allows better bandwidth utilization
Single-active MH (service-based load-balancing)	Yes	Yes	
Ethernet Local Area Network (E-LAN) and point-to-point E-Line services	Yes	Yes	
Inter-subnet-forwarding	Yes	No	Allows combined Layer 2 / Layer 3 services. EVPN
Proxy-Address Resolution Protocol / Neighbor Discovery (Proxy-ARP/ND) and IP-duplication protection	Yes	No	Allows Broadcast, Unknown unicast and Multicast (BUM) traffic reduction and better security

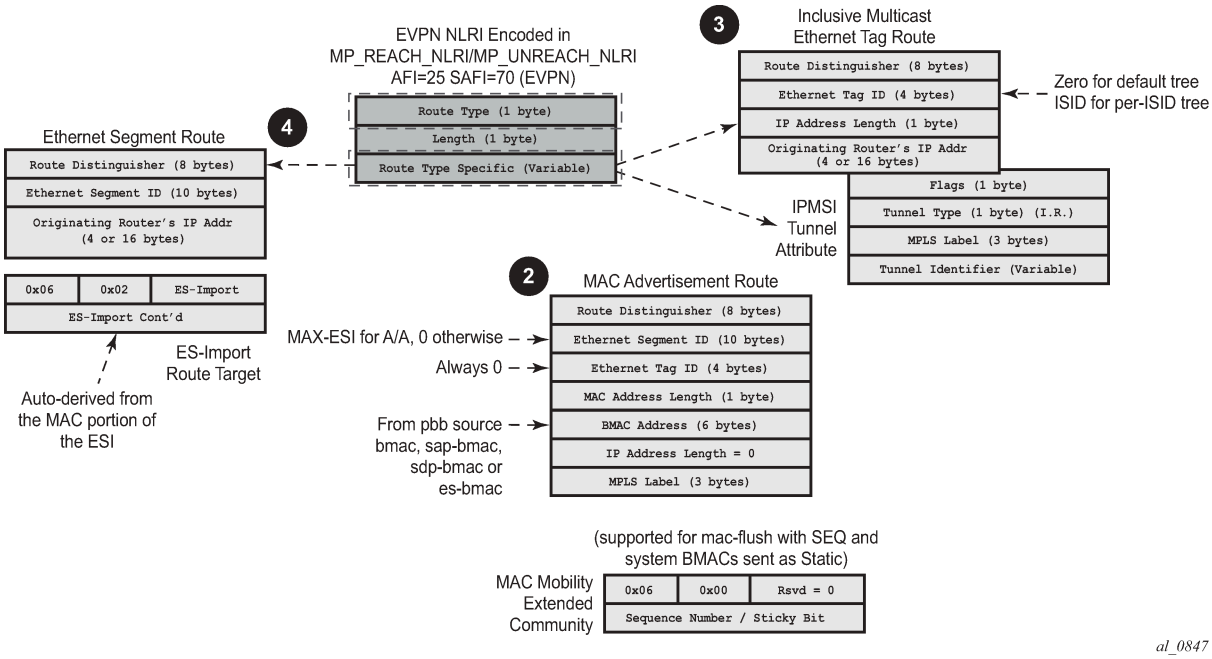
VPN requirements	EVPN	PBB-EVPN	Comments
Customer MAC (CMAC) protection	Yes	No	Allows protecting key static CMACs
Data Center integration	Yes	No	Integration with VXLAN and Nuage Virtualized Services Directory (VSD)
Control plane overhead	Medium	Low	PBB-EVPN only advertises Backbone MACs (BMACs) and no route type 1s
Confinement of CMAC learning	No	Yes	CMACs are only learned on PEs with flows using those CMACs
CMAC summarization	No	Yes	Aggregation of CMACs into BMACs

PBB-EVPN is a combination of 802.1ah PBB and RFC 7432, *BGP MPLS-Based Ethernet VPN* (EVPN-MPLS), and reuses the PBB-Virtual Private LAN Service (VPLS) service model, where Border Gateway Protocol BGP-EVPN is enabled in the backbone VPLS (B-VPLS) domain. EVPN is used as the control plane in the B-VPLS domain to control the distribution of BMACs and set up per-backbone service instance identifier (ISID) flooding trees for service instance VPLS (I-VPLS) services. The learning of the CMACs, either on local SAPs/SDP-bindings or associated with remote BMACs, is still performed in the data plane. Only the learning of BMACs in the B-VPLS is performed through BGP.

The SR OS PBB-EVPN implementation supports I-VPLS and PBB-Epipe services, including single-active and all-active multi-homing.

Because PBB-EVPN is based on the same control plane model as EVPN for MPLS, it is recommended to read the EVPN for MPLS Tunnels chapter before configuring PBB-EVPN. PBB-EVPN uses a subset of the BGP-EVPN routes described in EVPN for MPLS Tunnels as shown in Figure 101: EVPN route types.

Figure 101: EVPN route types



When no EVPN multi-homing is used in the network, only the base routes are used. Route types 2 and 3 are considered the base and mandatory routes:

- Route type 2 — (B) MAC route — In PBB-EVPN, this route type is used for the advertisement of BMACs that will be installed in the remote Forwarding Data Bases (FDBs). There are no IP addresses advertised in PBB-EVPN. The MAC mobility extended community is used for advertising system BMACs as **protected** (with the sticky bit set) and it is also used for CMAC flush in some single-homing scenarios that will be described later.
- Route type 3 — Inclusive Multicast route — This route type is used for the advertisement of the I-VPLS ISIDs (no Epipes) and the desired multicast tree for each of them. The ISIDs are encoded in the Ethernet-tag field of the Network Layer Reachability Information (NLRI). When the B-VPLS is created and enabled, an Inclusive Multicast route with ISID = 0 is advertised. This is for the creation of the default multicast tree.

When EVPN multi-homing is used in an ISID, route type 4 (Ethernet Segment (ES) route) is used. In PBB-EVPN, there is no route type 1 advertised when multi-homing is used on the ISID services (I-VPLS and Epipes). Only route type 4 is used, and in the same way as it is for EVPN-MPLS. See the EVPN for MPLS Tunnels example for more information about ES routes, how they are formed, and how their RT/RD values are populated.

Configuration

This example describes the basic PBB-EVPN configuration first (without multi-homing) and how the flood containment is handled in PBB-EVPN. Flood containment refers to the efficient distribution of the BUM traffic generated for an ISID.

Networks are not always greenfield, so a smooth migration of PBB-EVPN from PBB-VPLS is required to minimize the effect on existing services. This example also describes this migration, starting from a common PBB-VPLS configuration.

Finally, this example describes the configuration of PBB-EVPN multi-homing.

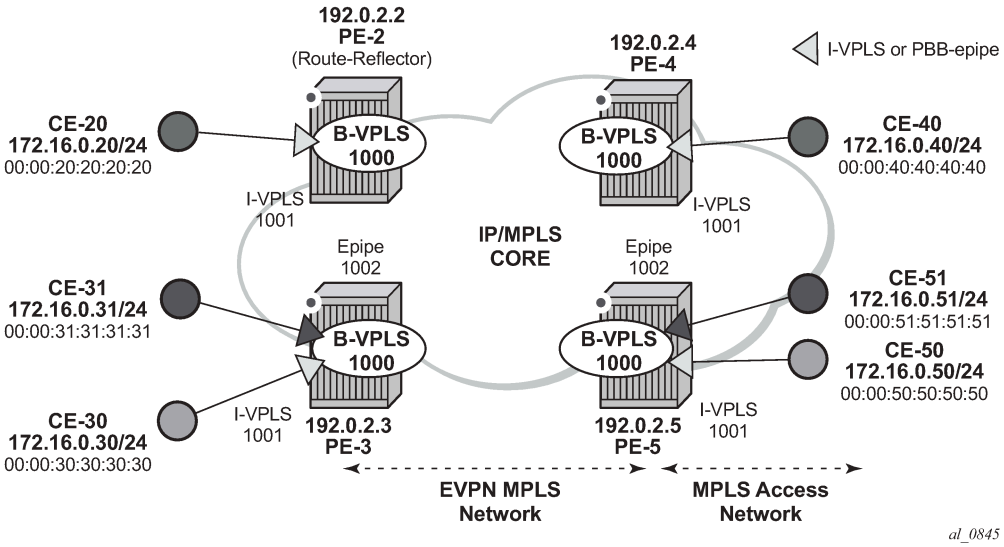
The same setup described in the EVPN for MPLS Tunnels example is used:

- Four PEs in the core (PE-2, PE-3, PE-4, and PE-5).
- The PEs are interconnected in the same way as explained in EVPN for MPLS Tunnels with the same IP addressing, IS-IS, transport LDP, and BGP peering configuration. There is not any difference with the basic infrastructure. See the EVPN for MPLS Tunnels chapter if more information is required.
- When configuring multi-homing, MTU-1 and MTU-6 are connected to the core.

PBB-EVPN configuration without multi-homing

Figure 102: PBB-EVPN network without multi-homing shows the example topology used in this chapter.

Figure 102: PBB-EVPN network without multi-homing



When configuring PBB-EVPN:

- There is no difference at the access side (I-VPLS and Epipe configuration) compared to other PBB technologies supported in SR OS, such as Shortest Path Bridging for MAC (SPBM) or PBB-VPLS.
- The B-VPLS becomes an EVPN-MPLS service, where bgp-evpn mpls is added.

The following output shows an example of a basic configuration in PE-3. B-VPLS 1000 is bgp-evpn enabled and I-VPLS 1001 and Epipe 1002 are linked to B-VPLS 1000.

```
# on PE-3:
configure
    service
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:03
```

```
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1

                no shutdown
            exit
            no shutdown
        exit
        epipe 1002 name "Epipe 1002" customer 1 create
            pbb
                tunnel 1000 backbone-dest-mac 00:00:00:00:00:05 isid 1002
            exit
            sap 1/2/1:1002 create
                no shutdown
            exit
            no shutdown
        exit
```

In the preceding output, there is no new configuration needed for I-VPLS/Epipe services. As for the B-VPLS, the output shows the minimum configuration required. If needed, the following parameters can be modified under **bgp-evpn**:

```
*A:PE-2>config>service>vpls# bgp-evpn ?
  - bgp-evpn
  - no bgp-evpn

 [no] accept-ivpls-e* - Configure to accept non-zero ethernet-tag MAC routes and
                        process for CMAC flushing
 [no] cfm-mac-advert* - Enable/disable the advertisement of MEP, MIP, and VMEP MAC
                        addresses over the BGP EVPN
 [no] evi             - EVPN Identifier
 [no] incl-mcast-ori* - Configure originating IP address
 [no] ingress-repl-i* - Configure BGP EVPN IMET-IR route advertisement
 [no] ip-route-adver* - Configure BGP EVPN IP Route Advertisement
      isid-route-tar* + configure ISID route target information
 [no] mac-advertisem* - Configure BGP EVPN MAC Advertisement
      mac-duplication + Configure BGP EVPN MAC Duplication
 [no] mpls            + Configure BGP EVPN mpls
 [no] sel-mcast-adve* - Enable/disable selective multicast advertisements
 [no] unknown-mac-ro* - Configure BGP EVPN Unknown MAC Route
```

```
 [no] vxlan           + Configure BGP EVPN vxlan
```

```
*A:PE-2>config>service>vpls>bgp-evpn# mpls ?
  - no mpls [bgp <bgp>]
  - mpls [bgp <bgp>]

 <bgp>               : [1..2]

      auto-bind-tunn* + Configure BGP EVPN mpls auto-bind-tunnel
 [no] control-word    - Enable/disable setting the CW bit in the label message
 [no] default-route-* - Configure default-route-tag to match against export policies
      ecmp            - Configure maximum ECMP routes information
 [no] entropy-label   - Enable/disable use of entropy-label
 [no] force-vlan-vc-* - Forces vlan-vc-type forwarding in the data-path
 [no] ingress-replic* - Use the same label as the one advertised for unicast traffic
 [no] oper-group      - Configure oper-group
 [no] restrict-prote* - Enable/disable protected src MAC restriction
      route-next-hop  - Configure route next-hop
 [no] send-tunnel-en* - Configure encapsulation for this service
 [no] shutdown        - Administratively Enable/Disable BGP-EVPN mpls
 [no] split-horizon-* - Configure a split-horizon-group
```

A detailed description of these commands is included in the EVPN for MPLS Tunnels chapter. In addition to the preceding commands, the following **service (b-)vpls pbb** commands are relevant for PBB-EVPN in the B-VPLS service:

- **force-qtag-forwarding** allows the transparent transport of the customer 802.1p bits across the B-VPLS services.
- **source-bmac** can modify the source BMAC for all the PBB packets containing traffic from non-multi-homed I-VPLS and Epipe services.
- **use-es-bmac** instructs the system to use an ES-specific BMAC for traffic coming from an ES on an I-VPLS or Epipe.
- **use-sap-bmac** instructs the system to use a SAP-specific BMAC for traffic coming from an MC-LAG I-VPLS/Epipe SAP.

Flood containment for I-VPLS services

In general, PBB technologies in SR OS support a way to contain flooding for a specified I-VPLS ISID, so that BUM traffic for that ISID only reaches the PEs where the ISID is locally defined. Each PE creates a Multicast Forwarding Information Base (MFIB) per I-VPLS ISID on the B-VPLS instance. That MFIB supports SAP/SDP-binding endpoints that can be populated by:

- Multiple MAC Registration Protocol (MMRP) in regular PBB-VPLS
- IS-IS in SPBM

In PBB-EVPN, B-VPLS EVPN destinations can be added to the MFIBs using EVPN Inclusive Multicast Ethernet tag routes when they include the ISID in the Ethernet-tag. By default, when a B-VPLS is successfully enabled (**no shutdown**), the PE advertises:

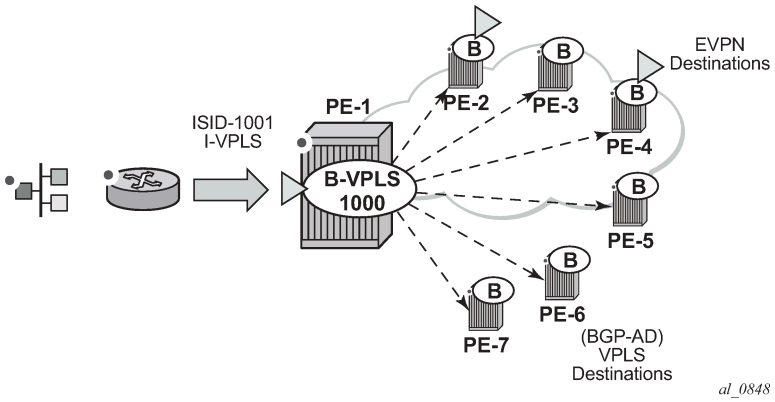
- An Inclusive Multicast route for ISID = 0 — This allows the remote PEs to add the advertising PE to the default-multicast-list for the B-VPLS.

- An Inclusive Multicast route for each local ISID defined in the system (a local ISID includes configured I-VPLS and static-ISIDs) — This allows the remote PEs to create MFIB entries in the B-VPLS for the received ISIDs.

Because EVPN destinations, B-SAPs, and B-spoke-SDPs can coexist in the same B-VPLS, be aware of the different flooding lists created and how they are used in a B-VPLS. Figure 103: PBB-EVPN — flooding lists illustrates this concept with an example for B-VPLS 1000 in PE-1. The assumptions are:

- I-VPLS 1001 is created in PE-1, PE-2, and PE-4 only.
- PE-1, PE-2, PE-3, PE-4, and PE-5 support BGP-EVPN in B-VPLS 1000.
- PE-6 and PE-7 only support spoke-SDPs.
- PE-1 is connected to all six PEs.

Figure 103: PBB-EVPN — flooding lists



In this situation, PE-1 creates two flooding lists in B-VPLS 1000:

- Default-multicast-list — composed of:
  - All the EVPN PEs that advertised ISID = 0 (PE-2, PE-3, PE-4, PE-5).
  - All the B-spoke-SDPs (or B-SAPs) (PE-6, PE-7).
  - All the EVPN PEs that advertised ISID 1001 and no ISID 0 (if an isid-policy is created in PE-1 stating **use-def-mcast** for ISID 1001). Note: third-party PEs may not advertise ISID = 0, but only non-zero ISIDs.
- MFIB for ISID 1001 is composed of:
  - All the EVPN PEs that advertised ISID 1001 (PE-2 and PE-4) unless there is an ISID-policy in PE-1 stating **use-def-mcast** for ISID 1001.
  - Static-ISIDs defined in manual B-spoke-SDPs and B-SAPs (static-ISIDs cannot be created on BGP-AD auto-discovered B-spoke-SDPs).

Based on the above, when BUM traffic is sent to I-VPLS 1001 on PE-1:

- The traffic is encapsulated in PBB with the group BMAC for ISID 1001 and sent (by default) to the MFIB created for ISID 1001 (PE-2 and PE-4).
- If an ISID-policy is added with **use-def-mcast** for ISID 1001, the BUM traffic is encapsulated in PBB with the group BMAC for ISID 1001 and sent to the default-multicast-list, that is, all six remote PEs.

Referring to Figure 102: PBB-EVPN network without multi-homing, the following output illustrates the use of the ISID-policy in PBB-EVPN. PE-2 does not have any ISID-policy configured; when it receives BUM traffic from the local I-VPLS 1001, it uses the MFIB for ISID 1001:

```
# on PE-2:
configure
    service
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:02
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

```
*A:PE-2# show service id 1000 mfib

===============================================================================
Multicast FIB, Service 1000
===============================================================================

                                                                          Blk
-------------------------------------------------------------------------------
*               01:1e:83:00:03:e9     b-mpls:192.0.2.3:524279      Local    Fwd
                                      b-mpls:192.0.2.4:524280      Local    Fwd
                                      b-mpls:192.0.2.5:524279      Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

An ISID-policy can be added to modify this behavior and allow PE-2 to use the default multicast list. If I-VPLS 1001 exists in all the remote PEs (as in this example), using the default multicast list is as efficient as using the MFIB and saves expensive MFIB resources. In the following output, as soon as the ISID-policy is added, the MFIB entries for ISID 1001 are removed and PE-2 starts using the default multicast list.

```
# on PE-2:
configure
    service
        vpls "B-VPLS 1000"
            isid-policy
                entry 10 create
                    use-def-mcast
                    range 1001 to 2000
                exit
            exit
```

The MFIB on PE-2 does not contain any entries for ISID 1001 anymore, as follows:

```
*A:PE-2# show service id 1000 mfib

PBB-VPLS to PBB-EVPN migration

The principles required for migrating a PBB-VPLS network to PBB-EVPN are explained in the *VPLS to EVPN-MPLS Integration* section of the EVPN for MPLS Tunnels chapter. Those principles are also applicable to EVPN destinations and spoke-SDPs in the B-VPLS and can be summarized in three points:

- Systems with an EVPN destination and SDP-binding to the same far-end IP bring down the SDP-binding. This avoids loops when both constructs exist in the same network.
- SDP-bindings and EVPN destinations can be placed in the same Split-Horizon Group (SHG). When traffic from an SDP-binding/EVPN destination belonging to that SHG is received on a PE, it is never forwarded to another SDP-binding or EVPN destination on the same SHG.
- MAC addresses learned on an SDP-binding or SAP, that belong to an SHG where EVPN destinations are also created, are not advertised in BGP-EVPN.

Based on those principles, this section describes how to migrate a PBB-VPLS network to PBB-EVPN. The network in Figure 102: PBB-EVPN network without multi-homing represents a regular PBB-VPLS network that needs to be migrated to PBB-EVPN.

In that network, the four PEs are running BGP-AD and TLDP for the discovery and setup of the pseudowires in the B-VPLS instance. The advantage of this configuration is that the migration can be done node by node and with minimum impact on customer service.

Initial configuration

Initially, the network is configured for PBB-VPLS with BGP-AD in B-VPLS 1000. The EVPN family is to be added. At the access, I-VPLS 1001 is connected to the CEs. As an example, the configuration in PE-3 is shown. An equivalent configuration exists in the other three PEs.

Note:
The EVPN family is added to the BGP configuration because PBB-EVPN uses this address family. Assuming there are redundant Route Reflectors (RRs), the addition of EVPN can be done without service impact. In this example, the assumption is that the PEs are already configured with the EVPN family.

```
*A:PE-3#
configure

```

Multiple MAC Registration Protocol (MMRP) is not used in the B-VPLS instance. If it were enabled, MMRP would have to be disabled in the network before this migration. If there are ISIDs using B-VPLS SDP-bindings to reach some remote locations and B-VPLS EVPN destinations to reach others, the default multicast list must be used in the current release (the MFIB cannot be used if there is a mix of both types). Therefore, during the migration process, the ISIDs must be added to the default multicast list.

1. Add service-level SHG (if not already there).

   From the first node being migrated to PBB-EVPN to all nodes migrated, PBB-VPLS and PBB-EVPN have to coexist within the same meshed network. That is, EVPN-MPLS destinations and SDP-bindings need to be defined in the same split-horizon group. Therefore, if there is no split-horizon group defined in the B-VPLS, the first step is to add it. In this example, the split-horizon group is defined at the **config>service>pw-template>level**; therefore, it has to be added at the B-VPLS level.

   Note:
   When the **service>split-horizon-group** is removed, an eval-pw-template must be performed.

   Note:
   After adding the **split-horizon-group** at the service level, an eval-pw-template must be performed again so that the SDP-bindings take the new SHG configuration.

   Note:
   During the time between the **split-horizon-group** being removed and added back again, the SDP-bindings can forward BUM traffic to each other, so this operation must be done carefully to avoid loops.

   Assuming that the first node to be migrated is PE-3, the following output shows the procedure for adding the **split-horizon-group** at the service level.

```
# on PE-3:
configure
    service
        pw-template 1
            no split-horizon-group
```

```
*A:PE-3# tools perform service id 1000 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1000 32765:4294967293 Policy 1
eval-pw-template succeeded for Svc 1000 32766:4294967294 Policy 1
eval-pw-template succeeded for Svc 1000 32767:4294967295 Policy 1
```

```
# on PE-3:
configure
    service
```

```
        vpls "B-VPLS 1000"
            split-horizon-group "CORE" create
            exit
            bgp
                pw-template-binding 1 split-horizon-group "CORE"
                exit
            exit
```

```
*A:PE-3# tools perform service id 1000 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1000 32765:4294967293 Policy 1
eval-pw-template succeeded for Svc 1000 32766:4294967294 Policy 1
eval-pw-template succeeded for Svc 1000 32767:4294967295 Policy 1
```

```
*A:PE-3>config>service>vpls# info
----------------------------------------------
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:03
            exit
            split-horizon-group "CORE" create
            exit
            bgp
                pw-template-binding 1 split-horizon-group "CORE"
                exit
            exit
            bgp-ad
                vpls-id 64500:1000
                no shutdown
            exit
            stp
                shutdown
            exit
            no shutdown
```

2. Add BGP-EVPN and ISID-policy configuration to the B-VPLS.

   After the B-VPLS is configured with the split horizon group, the BGP-EVPN configuration (still in **shutdown**) and an ISID-policy can be added, as follows.

```
# on PE-2, PE-3, PE-4, PE-5:
configure
    service
        vpls "B-VPLS 1000"
            bgp-evpn
                evi 1000
                mpls bgp 1
                    shutdown
                    split-horizon-group "CORE"
                    auto-bind-tunnel
                        resolution any
                    exit
                exit
            exit
            isid-policy
                entry 10 create
                    use-def-mcast
                    range 1001 to 3000
                exit
            exit
```

3. Enable BGP-EVPN MPLS on the PE.

When the configuration is ready, the **bgp-evpn mpls bgp 1** context can be enabled, as follows:

```
# on PE-3:
configure
    service
        vpls "B-VPLS 1000"
            bgp-evpn
                mpls bgp 1
                    no shutdown
```

Enabling the **bgp-evpn mpls bgp 1** context triggers a route-refresh message for the EVPN family from PE-3, but no changes happen because PE-3 does not create any EVPN destinations until it imports EVPN routes from the other PEs. The three spoke-SDPs to the remote PEs are still up.

4. Repeat steps 1 to 3 for the second PE (PE-5).

   The same steps 1 to 3 are repeated for PE-5. When the **bgp-evpn mpls bgp 1** context is enabled, PE-5 sends a route-refresh and gets the BGP-EVPN routes from PE-3. As a result of that, PE-3 brings down the spoke-SDP to PE-5 and creates an EVPN destination to PE-5. The same process happens in PE-5. The following CLI output shows the received routes in PE-3 and spoke-SDP going down.

```

===============================================================================
* indicates that the corresponding row element may have been truncated.
```

The reason why the spoke SDP toward PE-5 is down is an EVPN route conflict:

```
*A:PE-3# show service id 1000 sdp 32765:4294967293 detail | match Flag context all
Flags              : PWPeerFaultStatusBits
                     EvpnRouteConflict
```

An EVPN destination to PE-5 is created:

```
*A:PE-3# show service id 1000 evpn-mpls

```

5. Repeat Steps 1 to 3 for the rest of the PEs (PE-2, PE-4).

   The same process is repeated in all the PEs, node by node. The service impact for the I-VPLS 1001 is minimal.

6. (Optional) Remove the ISID policy.

   When all the PEs in the B-VPLS 1000 are migrated, the ISID policy can optionally be removed, node by node. This forces the B-VPLS instance to start using the MFIB to send I-VPLS BUM traffic to the remote nodes. This has no effect on Epipes (traffic is always unicast for Epipes).

   Before removing the ISID policy and starting to use the MFIB, it is recommended to check that the Inclusive Multicast routes for an ISID to the remote PEs are all active. Otherwise, connectivity for BUM traffic could be interrupted if any of the expected routes are not active. This is illustrated for PE-3.

```

===============================================================================
```

7. (Optional) Remove the BGP-AD configuration.

   The BGP-AD configuration can stay in the B-VPLS services. However, when the entire network is migrated to PBB-EVPN, all the spoke-SDPs will be operationally down and, even if they are not forwarding traffic, they consume resources in the system. Consider removing the BGP-AD configuration and, therefore, the spoke-SDPs.

   The following example shows the removal of BGP-AD in PE-4. Be aware that when BGP-AD is removed from the configuration, if the RD/RT was derived from the VPLS ID (as in this example), a new RD/RT must be auto-derived for the service. Therefore, new updates will be sent for all the EVPN NLRIs, as shown in the following output.

```
*A:PE-4# show service id 1000 bgp

===============================================================================

-------------------------------------------------------------------------------
===============================================================================
```

BGP-AD is disabled as follows:

```
# on PE-4:
configure
    service
        vpls "B-VPLS 1000"
            bgp-ad
                shutdown
```

After BGP-AD is disabled, the spoke SDP bindings are deleted.

```
# log "99" on PE-4:
163 2021/03/03 11:05:42.890 UTC MAJOR: SVCMGR #2319 Base
"Dynamic bgp-l2vpn SDP 32765 (192.0.2.5) was deleted."

162 2021/03/03 11:05:42.890 UTC MINOR: SVCMGR #2303 Base
"Status of SDP 32765 changed to admin=down oper=down"

161 2021/03/03 11:05:42.890 UTC MAJOR: SVCMGR #2320 Base
"Service Id 1000, Dynamic bgp-l2vpn SDP Bind Id 32765:4294967293 was deleted."

"Status of SDP Bind 32765:4294967293 in service 1000 (customer 1) changed to admin=down
 oper=down flags="
```

The PW template binding is removed as follows:

```
# on PE-4:
configure
    service
        vpls "B-VPLS 1000"
            bgp
                no pw-template-binding 1
```

The BGP-AD configuration is removed as follows:

```
# on PE-4:
configure
    service
        vpls "B-VPLS 1000"
            no bgp-ad
```

Initially, the RD/RT was derived from the VPLS ID (64500:1000). After the BGP-AD configuration is removed, a new RD and RT must be auto-derived from the EVI:

```
*A:PE-4# show service id 1000 bgp

===============================================================================
BGP Information
===============================================================================
Bgp Instance         : 1
Vsi-Import           : None
Vsi-Export           : None
Route Dist           : None
Oper Route Dist      : 192.0.2.4:1000
Oper RD Type         : derivedEvi
```

```
Rte-Target Import    : None                 Rte-Target Export: None

Oper RT Exp Origin   : derivedEvi           Oper RT Export   : 64500:1000

PW-Template Id       : None
-------------------------------------------------------------------------------
===============================================================================
```

In this case, the system picks up the RD in the following order:

a. Manual RD or auto-RD always take precedence when configured.

b. If no manual/auto-RD, the RD is derived from the **bgp-ad vpls-id**.

c. If no manual/auto-rd/vpls-id configuration, the RD is derived from the **bgp evpn evi**.

d. If no manual/auto-rd/vpls-id/evi configuration, there will be no RD and the service will fail.

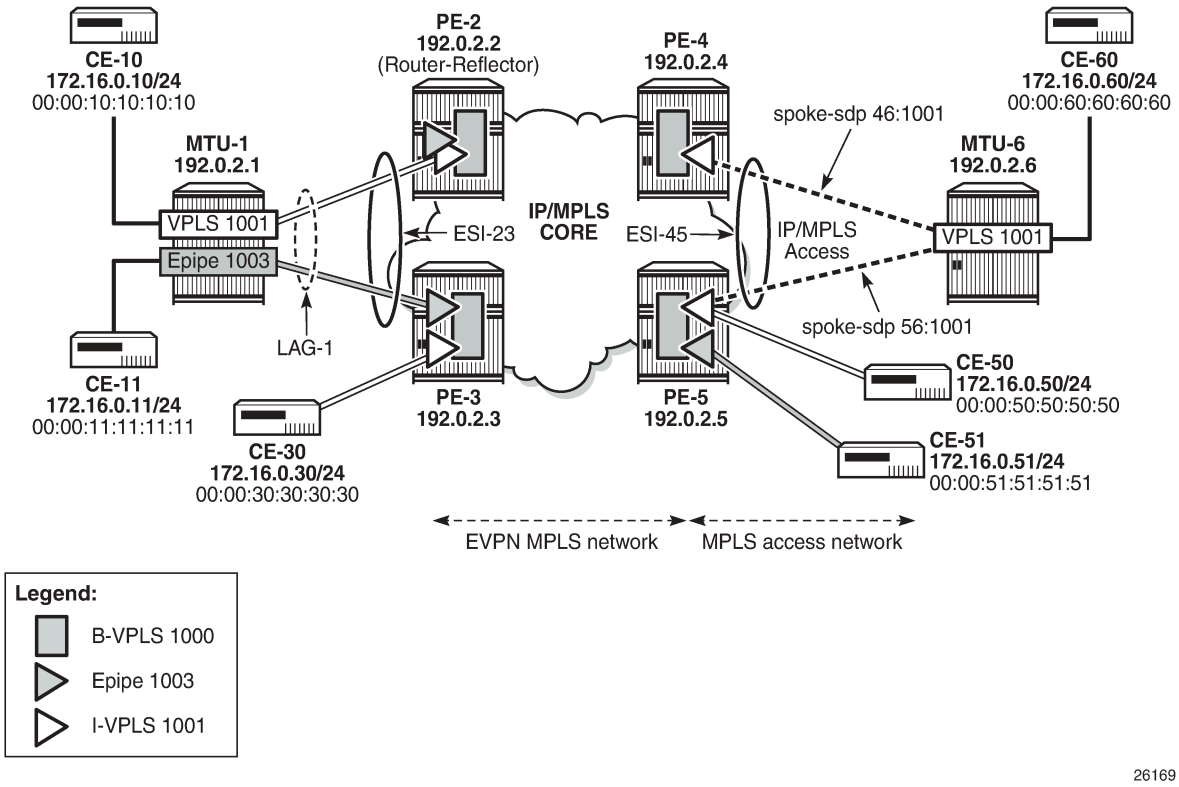
If in the migration from BGP-AD to BGP-EVPN, the advertisement of new updates is not needed, the initial configuration must include manual/auto-RDs. If manual/auto-RDs were not included, disabling BGP-AD would not cause the change of RD and the consequent BGP updates.

PBB-EVPN multi-homing

This section provides configuration guidelines for PBB-EVPN multi-homing. In the same way that EVPN-MPLS supports single-active and all-active multi-homing, PBB-EVPN can also be configured to support both modes. The same Ethernet segment that is used for regular EVPN-MPLS service SAPs and spoke-SDPs can be shared with I-VPLS/Epipe SAPs and spoke-SDPs.

Figure 104: PBB-EVPN multi-homing shows the example topology used in this section.

Figure 104: PBB-EVPN multi-homing



MTU-1 and MTU-6 have been added to the network (compared to Figure 102: PBB-EVPN network without multi-homing). I-VPLS 1001 has two new sites that are multi-homed to the PBB-EVPN network. MTU-1 uses all-active multi-homing, whereas MTU-6 is connected to a single-active ES. As with EVPN-MPLS, all-active multi-homing is only supported when a LAG is used at the access. Single-active multi-homing can be supported with regular Ethernet ports (that can form an independent LAG per PE) or SDPs.

RFC 7623 describes two types of system BMAC assignments that a PE can implement in a B-VPLS when ESs are present:

- Shared BMAC addresses that can be used for all the single-homed CEs and a number of multi-homed CEs connected to Ethernet-segments.
- Dedicated BMAC addresses per Ethernet-segment.

In this chapter and in SR OS terminology:

- A shared BMAC address (in IETF) is a source BMAC address as configured in **service>(b)vpls>pbb>source-bmac**. All the I-VPLS/Epipe traffic coming from single-homed CEs is sent encapsulated in a PBB packet with that source BMAC address.
- A dedicated-BMAC per ES (in IETF) is an ES BMAC address as activated in **service>(b)vpls>pbb>use-es-bmac** and generated from the combination of **vpls>pbb>source-bmac** plus **ethernet-segment>source-bmac-lsb**. If configured, any I-VPLS/Epipe traffic coming from an ES is encapsulated in a PBB packet with the ES-BMAC address as the source BMAC address.

The system allows the following user choices per B-VPLS and ES:

- A dedicated ES BMAC address per ES can be used. In that case, the **pbb use-es-bmac** command is configured in the B-VPLS. In all-active multi-homing, all the PEs that are part of the ES source the PBB packets with the same source ES BMAC address; single-active multi-homing requires the use of a different ES BMAC address per PE.
- A non-dedicated source BMAC address can be used (this is only possible in single-active multi-homing). In this case, the user does not configure **pbb>use-es-bmac** and the regular source BMAC address is used for the traffic. A different source BMAC address has to be advertised per PE.

As discussed, single-active multi-homing can use source BMAC addresses or ES BMAC addresses. Using one type or another has a different impact on CMAC flushing, as illustrated in Figure 105: The use of ES BMAC to minimize CMAC flush.

- If ES BMAC addresses are used, as shown on the right-hand side of Figure 105: The use of ES BMAC to minimize CMAC flush, a less-impacting CMAC flush is achieved, therefore minimizing the flooding after ES failures. In the case of ES failure, PE-1 withdraws the ES BMAC address 00:12 and the remote PE-3 only flushes the CMACs associated with that ES BMAC address (only the CMAC addresses behind the CE are flushed).
- If source BMAC addresses are used, as shown on the left-hand side of Figure 105: The use of ES BMAC to minimize CMAC flush, in the case of ES failure, a BGP update with higher sequence number is issued by PE-1 and the remote PE-3 flushes all the CMAC addresses associated with the source BMAC address. Therefore, all the CMAC addresses behind the B-VPLS of the PEs will be flushed, as opposed to only the CMAC addresses behind the CE of the Ethernet Service Instances (ESIs).

Figure 105: The use of ES BMAC to minimize CMAC flush

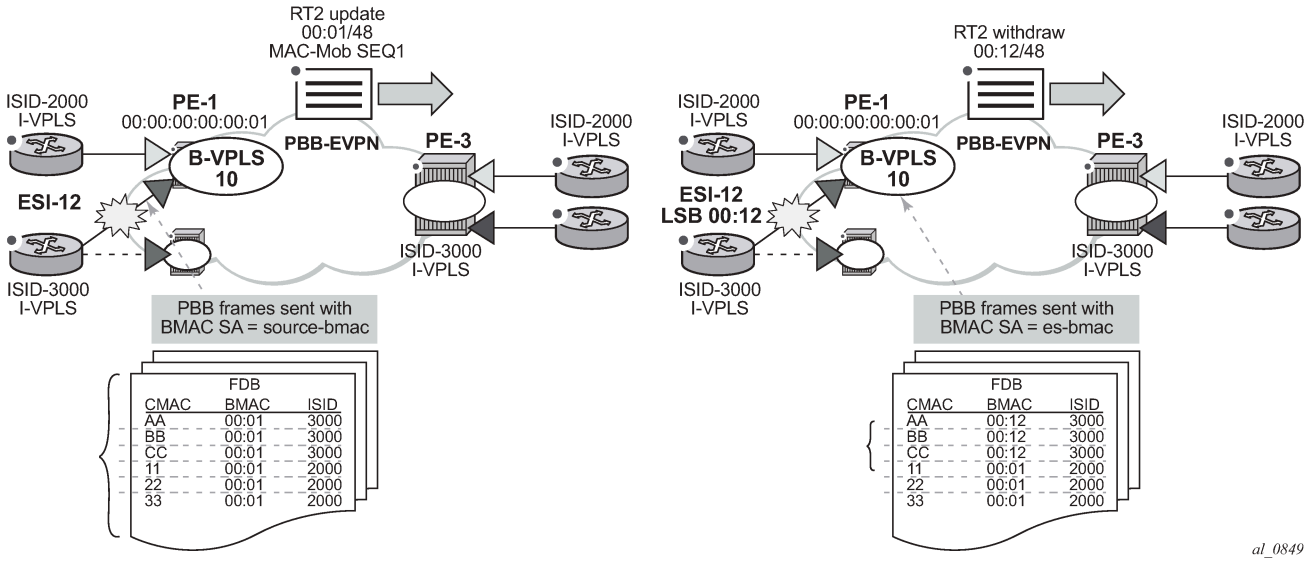


Table 7: PBB-EVPN multi-homing supported combinations in SR OS shows the PBB-EVPN multi-homing combinations supported in the current release in the topology of Figure 104: PBB-EVPN multi-homing.

Table 7: PBB-EVPN multi-homing supported combinations in SR OS

CE Connectivity	PE Connectivity	PE Redundancy	BMAC Assignment	I-VPLS Support	Epipe Support
LAG (LACP optional)	LAG SAP	EVPN MH all-active	use-es-bmac (shared BMAC)	Yes	Yes
Ethernet ports (no LAG)	LAG SAP or port SAP	EVPN MH single-active	use-es-bmac (dedicated per PE)	Yes	No
Ethernet ports (no LAG)	LAG SAP or port SAP	EVPN MH single-active	source-bmac (dedicated per PE)	Yes	No
MPLS	spoke-SDP	EVPN MH single-active	source-bmac (dedicated per PE)	Yes	No
MPLS	spoke-SDP	EVPN MH single-active	use-es-bmac (dedicated per PE)	Yes	No

As an example, the configurations of the first, and last two, rows (LAG SAP all-active, MPLS source-BMAC, and MPLS ES-BMAC, respectively) will be discussed in the following three sections.

PBB-EVPN all-active multi-homing for I-VPLS and Epipes

Figure 104: PBB-EVPN multi-homing shows a PBB-EVPN network where ESI-23 is configured as an all-active multi-homing ES on PE-2 and PE-3. Two services are using ESI-23: I-VPLS 1001 and Epipe 1003. The following output shows the relevant configuration in PE-2:

```
# on PE-2:

            no shutdown
        exit
        no shutdown
    exit
```

The preceding configuration shows that Epipe 1003 has a PBB tunnel pointing at the PE-5 source-BMAC. Epipe 1003 has the following configuration in PE-5 (the PBB tunnel points at the ESI-23 ES-BMAC):

```
# on PE-5:
configure
    service
        pbb
            mac-name "ES-MAC-23" 00:00:00:00:23:23
```

```
        exit
        epipe 1003 name "Epipe 1003" customer 1 create
            pbb
                tunnel 1000 backbone-dest-mac "ES-MAC-23" isid 1003
            exit
            sap 1/2/1:1003 create
                no shutdown
            exit
            no shutdown
        exit
```

Source-BMAC addresses and ES-BMAC addresses are distributed in BGP-EVPN. PE-2 and PE-3 will each advertise their own source-BMAC in a MAC route with ESI-0 and the shared ES-BMAC address with ESI-MAX (as per the RFC 7623). The ES-BMAC address that each PE uses in a B-VPLS is derived from the configured **service>(b)vpls>pbb>source-bmac** (four high-order bytes) and the ESI-23 configured **source-bmac-lsb**. In this example, PE-2 and PE-3 will both derive ES-BMAC 00:00:00:00:23:23. For both PEs to derive the required same ES-BMAC address, the four high-order bytes of the source-BMAC address must match on both PEs.

The **es-bmac-table-size** parameter modifies the default value (8) for the maximum number of ES-BMAC addresses that can be associated with the Ethernet segment across different B-VPLS services. When **source-bmac-lsb** is configured, the associated **es-bmac-table-size** is reserved out of the total FDB space.

The following outputs show the source-BMAC addresses and ES-BMAC address and how they are advertised and installed in the B-VPLS FDB.

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "ESI-23" | match BMAC
Source BMAC LSB         : 23-23
```

The following output shows that ES-BMAC is used and that the operational source-BMAC is 00:00:00:00:00:02.

```
*A:PE-2# show service id 1000 base

===============================================================================

PBB-EVPN all-active multi-homing is based on the same concepts as EVPN-MPLS all-active multi-homing: DF election, split-horizon, and aliasing.

Designated forwarder (DF) election

Only the DF PE for an ISID will send multicast traffic to the ES. The following command shows that PE-3 is the DF PE in ES “ESI-23” for ISID 1003:

```
*A:PE-3# show service system bgp-evpn ethernet-segment name "ESI-23" isid 1003

===============================================================================
ISID DF and Candidate List
===============================================================================
Isid          SvcId         Actv Timer Rem      DF  DF Last Change

```

The DF PE identifies multicast traffic by looking at either the destination BMAC or the EVPN label (which can be unicast or multicast).

In the case of Epipes, there are also DF and non-DF PEs. However, traffic is usually unicast (sent to the PBB tunnel backbone-destination BMAC). The non-DF PE will usually not discard Epipe traffic to the ES, unless the packet comes with an EVPN multicast label. To avoid packet duplication at the CE for Epipes, it is recommended to either:

- configure **discard-unknown** on all the B-VPLS instances where there are PBB-Epipes. This will prevent the ingress PE from flooding Epipe traffic if the PBB tunnel BMAC is unknown in the FDB.
- configure **ingress-replication-bum-label** so that, when the PBB tunnel BMAC is unknown in the FDB, the ingress PE sends traffic with a multicast label. The non-DF will discard traffic identified as multicast at Epipes.

Ethernet segment split-horizon

In PBB-EVPN all-active multi-homing, the split-horizon function is not based in the ESI label but in a source BMAC check. When BUM traffic is received on an I-VPLS, the PE will encapsulate it in PBB using the ES-BMAC as source BMAC and the group BMAC for the ISID. When the DF PE for the ISID receives that

packet, it will not send it back to the ES if the packet is identified as being originated from the ES itself (based on the ES-BMAC shared between the PEs).

Aliasing

Aliasing is based on the advertisement of the same ES-BMAC with MAX-ESI from the PEs part of the same ES. PE-2 and PE-3 advertise the ES-BMAC 00:00:00:00:23:23 with MAX-ESI (ESI = all FFs, as per the RFC 7623) and as Static (protected). When the remote PEs, PE-4, and PE-5, receive the two routes for the same BMAC and MAX-ESI, they will create a single EVPN-MPLS destination that will give more than one next-hop (in this case 2), as long as ECMP > 1:

```

A similar output will be obtained in PE-5. Unicast traffic entering I-VPLS 1001 in either PE-4 or PE-5 will be hashed and load-balanced to PE-2 and PE-3 if the destination CMAC lookup yields an **es-bmac-dest**:

```

```

If a failure occurs in the ES, the PE will withdraw the ES-BMAC and the remote PEs will remove one next-hop of the ES-BMAC EVPN-MPLS destination.

For PBB-Epipes, aliasing will also work, as long as shared-queuing or policing are enabled on the ingress PE Epipe. In Figure 104: PBB-EVPN multi-homing, Epipe 1003 on PE-5 requires shared-queuing or policing at the ingress SAP. Otherwise, the traffic will be sent to only one PE of the ES (usually to the lower-IP PE).

For more information about the configuration of the Ethernet segment and its parameters, see the EVPN for MPLS Tunnels chapter.

PBB-EVPN single-active multi-homing for I-VPLS with source BMAC addresses

ESI-45 is a single-active Ethernet-segment (see Figure 104: PBB-EVPN multi-homing) with SDPs linked to it. As indicated in Table 7: PBB-EVPN multi-homing supported combinations in SR OS , only I-VPLS services can be used in this configuration. As described in section PBB-EVPN multi-homing, single-active ES and B-VPLS services can be configured to either use source-BMAC addresses or ES-BMAC addresses. The following configuration shows the former option on PE-4:

```
# on PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    source-bmac-lsb 45-04 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
            exit
        exit
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:04
            exit
            split-horizon-group "CORE" create
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1
                    split-horizon-group "CORE"
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
```

```
            no shutdown
        exit
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                shutdown
            exit
            spoke-sdp 46:1001 create
            exit
            no shutdown
        exit
```

The configuration on PE-5 is similar:

```
# on PE-5:
configure
    service
        sdp 56 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    source-bmac-lsb 45-05 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 56
                    no shutdown
                exit
            exit
        exit
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:05
            exit
            split-horizon-group "CORE" create
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1
                    split-horizon-group "CORE"
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
```

```
            stp
                no shutdown
            exit
            no shutdown
        exit
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                no shutdown
            exit
            sap 1/2/1:1001 create
                no shutdown
            exit
            spoke-sdp 56:1001 create
                no shutdown
            exit
            no shutdown
        exit
```

With the preceding configuration, PE-4 and PE-5 will not advertise ES-BMAC addresses with MAX-ESI. Therefore, all the remote BMACs on PE-2 and PE-3 are associated with regular backbone EVPN-MPLS destinations. The CMAC addresses will be learned in the data plane associated with local SAP/SDP-bindings or remote BMAC addresses. An example for the I-VPLS and B-VPLS FDB in PE-2 follows:

```
*A:PE-2# show service id 1001 fdb detail pbb

===============================================================================
Forwarding Database, i-Vpls Service 1001
===============================================================================
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------

```

```
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

In the preceding example, the DF for ISID 1001 is PE-5. With a failure event on the SDP to MTU-6, PE-5 will not withdraw the advertised source BMAC (because it is still being used as source BMAC for other services and even CEs within the same service). PE-5 will send an update of the same source BMAC instead, increasing the sequence number in the MAC mobility extended community. That will be a **flush-all-from-me** indication for the remote PEs (they will flush all the CMACs associated with the updated source BMAC, regardless of the service).

When the former DF (PE-5) comes back up, PE-4 will become non-DF and will send a CMAC flush indication using the same mechanism as described above.

The following example shows a failure of SDP 56 in PE-5 and the corresponding DF switchover and CMAC flush.

```
# on PE-5:
186 2021/03/03 11:18:28.912 UTC MINOR: SVCMGR #2095 Base
"Ethernet Segment:ESI-45, ISID:1001, Designated Forwarding state changed to:false"

185 2021/03/03 11:18:28.912 UTC MINOR: SVCMGR #2303 Base
"Status of SDP 56 changed to admin=up oper=down"
```

PE-5 sends a BGP update with the same source BMAC, increasing the sequence number in the MAC mobility extended community—CMAC flush:

```
# on PE-5:
73 2021/03/03 11:18:28.912 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:2/Static
"
```

Individual SAP or spoke-SDP failures do not trigger any MAC flush or DF re-election. This is as per RFC 7623. In EVPN-MPLS, individual SAP/spoke-SDP failures are captured by the AD per-EVI withdrawal, which triggers a DF switchover.

PBB-EVPN single-active multi-homing for I-VPLS with ES-BMACs

As discussed throughout this chapter, the use of ES-BMACs for single-active multi-homing can minimize the number of CMACs flushed in a network. A simple change is necessary: activate the **use-es-bmac**

command and ensure that the generated ES-BMACs in PE-4 and PE-5 are different (the **source-bmac-lsb** in the previous configuration had different values for PE-4 and PE-5 already):

```
# on PE-4, PE-5:
configure
    service
        vpls "B-VPLS 1000"
            pbb
                use-es-bmac
```

On PE-4, the source BMAC LSB in ESI-45 is configured with a value of 45-04:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "ESI-45" | match BMAC
Source BMAC LSB         : 45-04
```

On PE-5, the source BMAC LSB in ESI-45 is configured with a value of 45-05:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" | match BMAC
Source BMAC LSB         : 45-05
```

The remote PEs (such as PE-2 in the following output) will receive additional BGP EVPN-MAC routes for the ES-BMACs. The following FDB on PE-2 shows the source BMAC addresses of PE-4 and PE-5 and the ES BMAC address of DF PE-5.

```
*A:PE-2# show service id 1000 fdb detail

===============================================================================
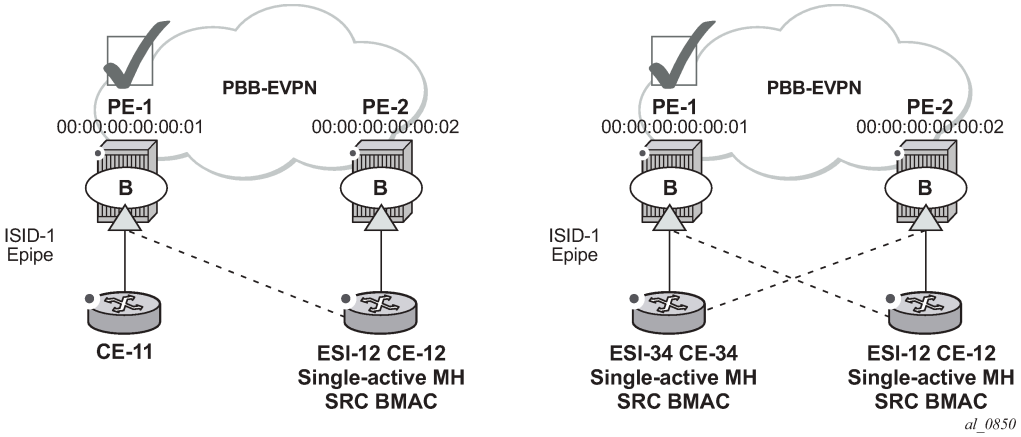
```

The benefit is that in case of a failure in ESI-45 (as before) the ES-BMAC is withdrawn and the remote PEs will only flush the CMACs associated with the remote ESI-45, as opposed to all the CMACs associated with PE-5.

PBB-EVPN single-active multi-homing for Epipes

In the network in Figure 104: PBB-EVPN multi-homing, Epipes can only support single-homing or all-active multi-homing but not single-active. For non-local-switching PBB-Epipes (there is a single SAP per Epipe), only all-active multi-homing is supported. Single-active multi-homing for local-switching enabled PBB-Epipes (two SAPs are defined within the PBB-Epipe instance) is only supported in the following scenarios.

Figure 106: PBB-EVPN single-active support for Epipes



Single-active multi-homing is supported for redundancy in a two-node, three or four SAP, scenario, as displayed in Figure 106: PBB-EVPN single-active support for Epipes. In these two cases, the Epipe PBB tunnel will be configured with the source BMAC of the remote PE node. When two SAPs are active in the same Epipe, local-switching is used to exchange frames between the CEs.

All-active multi-homing is not supported for redundancy in this scenario because the PE-1 PBB tunnel cannot point at a locally defined ES-BMAC.

PBB-EVPN multi-homing operation

See the EVPN for MPLS Tunnels chapter for the commands to operate Ethernet-segments. Consider that there are no AD routes in PBB-EVPN. Also, the DF election algorithm will be based on the ISID values as opposed to EVIs.

Troubleshooting and debug commands

When troubleshooting PBB-EVPN networks, most of the troubleshooting commands discussed in EVPN for MPLS Tunnels can be used in the B-VPLS service and the base **service>system>bgp-evpn** instance. Some examples of useful commands are:

- show redundancy bgp-evpn-multi-homing
- show router bgp routes evpn (and filters)
- show service evpn-mpls [<TEP ip-address>]
- show service id bgp-evpn
- show service id evpn-mpls (and modifiers)
- show service id fdb pbb (and modifiers)

- show service system bgp-evpn
- show service system bgp-evpn ethernet-segment (and modifiers)
- debug router bgp update
- log-id 99

In addition, the following **tools dump** commands also discussed in EVPN for MPLS Tunnels can help too:

- tools dump service evpn usage
- tools dump service system bgp-evpn ethernet-segment <name> isid <isid> df (Note: **isid** is used instead of **evi**.)

There are two aspects that are specific to PBB-EVPN and not EVPN:

1. Consumption of virtual BMAC addresses in the system— source BMACs, SAP BMACs, SDP BMACs, and ES BMACs are system BMACs that use FDB space but are not shown in the FDB together with the rest of the learned MAC addresses. The following command provides information about the virtual system MAC addresses consumed in the system.

```
*A:PE-3# tools dump redundancy src-bmac-lsb
Src-bmac-lsb:      3 (00-03) User: B-Vpls - 1 service(s)
Src-bmac-lsb:   8995 (23-23) User: Evpn Mpls

Total Src-bmac-lsbs = 2
```

2. Consumption of MFIBs — when ISIDs are not using the default-multicast list in the B-VPLS context for sending BUM traffic, an MFIB is consumed per ISID. The following command provides information about the consumption of MFIBs per system and per B-VPLS.

```
*A:PE-3# tools dump service vpls-pbb-mfib-stats detail

Service Manager VPLS PBB MFIB statistics at 03/03/2021 11:21:15:

Conclusion

In addition to a full RFC 7432 EVPN-MPLS implementation, SR OS supports PBB-EVPN as per RFC 7623 for large Layer 2 deployments, including single-active and all-active multi-homing. This example has shown how to configure and operate a PBB-EVPN network focusing on the specific aspects of PBB-EVPN compared to EVPN-MPLS.

EVPN for VXLAN Tunnels (Layer 2)

This chapter provides information about Ethernet Virtual Private Network (EVPN) for Virtual eXtensible Local Area Network (VXLAN) tunnels in VPLS services.

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 12.0.R4. The CLI in the current edition is based on SR OS Release 21.2.R1. Ethernet Virtual Private Network (EVPN) is a control plane technology and does not have line card hardware dependencies.

Overview

SR OS supports the EVPN control plane with Virtual eXtensible Local Area Network (VXLAN) data plane in VPLS services.

EVPN (RFC 7432) is an IETF technology that uses a dedicated BGP address family which allows VPLS services to be operated in a similar way to IP-VPNs, where the MAC addresses, IP addresses, and the information to set up the flooding tree are distributed by BGP. EVPN can be used as the control plane for different data plane encapsulations, such as VXLAN and MPLS.

VXLAN (RFC 7348) is an overlay IP tunneling technology used to carry Ethernet traffic over any IP network, and it is becoming the de facto standard for overlay data centers and networks. Compared to other IP overlay tunneling technologies, such as GRE, VXLAN supports multi-tenancy and multi-pathing:

- A tenant identifier, the VXLAN Network Identifier (VNI), is encoded in the VXLAN header and allows each tenant to have an isolated Layer 2 domain.
- VXLAN supports multi-pathing scalability through ECMP. VXLAN uses the outer source UDP port as an entropy field that can be used by the core IP routers to balance the load across different paths.

In SR OS, EVPN and VXLAN can be enabled in VPLS or R-VPLS services. In this chapter, EVPN-VXLAN services will refer to VPLS or R-VPLS services with EVPN and VXLAN enabled. These services can terminate/originate VXLAN tunnels and may have SAPs and/or SDP bindings at the same time. Some other SR OS implementation-specific considerations are the following:

- VXLAN is only supported on network or hybrid ports on Ethernet/LAG/POS/APS interfaces.
- VXLAN packets are originated/terminated with the system IPv4 address, in other words, a system originating VXLAN packets will use the system IP address as source outer IPv4 address and systems will only process VXLAN packets if their destination outer IPv4 address matches its own system IP address.
- Data plane MAC learning is not supported over VXLAN bindings. Only the control plane (EVPN) will be used for populating the FDB with MAC addresses associated to VXLAN bindings.

- EVPN provides support for the following features that are described in this chapter:
  - The BGP advertisement of the MAC addresses learned on SAPs, SDP-bindings and conditional static MACs to the remote BGP peers. The advertisement of MAC addresses in BGP can optionally be disabled.
  - The optional advertisement of an unknown MAC route, that allows the remote EVPN PEs or Network Virtualization Edge devices (NVEs) to suppress the unknown unicast flooding and send any unknown unicast frame to the owner of the unknown MAC route.
  - Ingress replication of Broadcast, Unknown unicast, and Multicast (BUM) packets over VXLAN.
  - A proxy-ARP table per service populated by the MAC-IP pairs received in BGP MAC advertisements. When an ARP request is received on a SAP or SDP-binding, the system will perform a lookup on this table and will reply to the ARP request if the lookup yields a valid result.
  - MAC mobility and static-MAC protection as described in RFC 7432, as well as MAC duplication detection.
- Multi-homing redundancy for SAPs and SDP-bindings in EVPN-VXLAN services is supported through BGP Multi-homing (L2VPN BGP address family). Only one BGP-MH site is supported in an EVPN-VXLAN service.

One of the main applications for EVPN-VXLAN services in SR OS is the Data Center Gateway (DC GW) function. In such an application, EVPN and VXLAN are expected to be used within the data center and VPLS SDP-bindings or SAPs are expected to be used for the connectivity to the WAN. When the system is used as a DC GW, a VPLS service is configured per Layer 2 domain that has to be extended to the WAN. In those VPLS services, BGP EVPN automatically sets up the VXLAN auto-bindings that connect the DC GW to the data center Network Virtual Edge devices (NVEs). The WAN connectivity is based on regular VPLS constructs where SAPs (null, dot1q, and QinQ), spoke-SDPs (FEC type 128 and 129, BGP-VPLS), and mesh-SDPs are supported. B-VPLS or I-VPLS services are not supported.

Although the DC GW application is one of the most common uses for this feature, this chapter focuses on the configuration and operation of EVPN-VXLAN for Layer 2 services in general, and its integration with regular VPLS services in MPLS networks.

Configuration

This section describes the configuration of EVPN-VXLAN on SR OS as well as the available troubleshooting and show commands. This example focuses on the following configuration aspects:

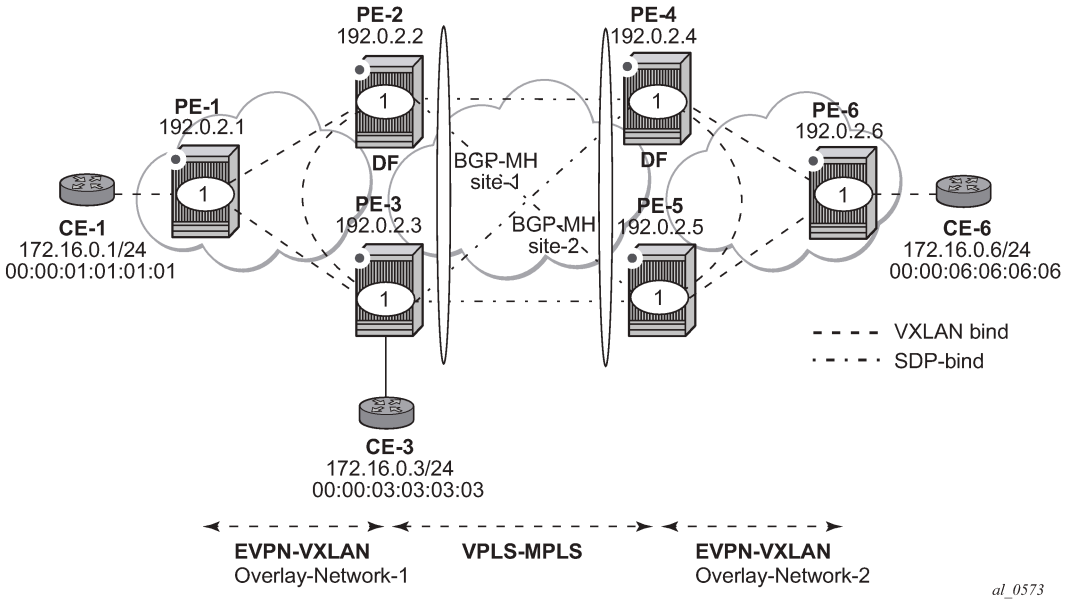
- Enabling EVPN and VXLAN in a VPLS service, including the use of BGP-EVPN, BGP Auto-discovery (BGP-AD), and BGP-Multi-homing (BGP-MH) in the same VPLS instance.
- Scaling BGP-MH resiliency with the use of operational groups (oper-groups).
- Use of proxy-ARP in EVPN-VXLAN services
- MAC mobility, MAC duplication, and MAC protection in EVPN-VXLAN services.

The configuration will be shown for PE-1, PE-2, and PE-3 only; the PEs in Overlay-Network-2 (Figure 107: EVPN-VXLAN example topology) have an equivalent configuration.

Enabling EVPN-VXLAN in a VPLS service

Figure 107: EVPN-VXLAN example topology shows the topology used in this example.

Figure 107: EVPN-VXLAN example topology



The example topology shows two overlay (VXLAN) networks interconnected by an MPLS network:

- PE-1, PE-2, and PE-3 are part of Overlay-Network-1
- PE-4, PE-5, and PE-6 are part of Overlay-Network-2

CE-1, CE-3, and CE-6 belong to the same IP subnet, therefore, Layer 2 connectivity must be provided to them.

The example topology can illustrate a Data Center Interconnect (DCI) example, where Overlay-Network-1 and Overlay-Network-2 are two data centers interconnected through an MPLS WAN. In this application, CE-1, CE-3, and CE-6 simulate virtual machines or appliances, PE-2/3/4/5 act as DC GWs and PE-1/6 as NVEs (or virtual PEs running on compute infrastructure).

The following protocols and objects are configured beforehand:

- The ports interconnecting the six PEs in Figure 107: EVPN-VXLAN example topology are configured as network ports (or hybrid) and have router network interfaces defined on them. Only the ports connected to the CEs are configured as access ports.
- The six PEs shown in the Figure 107: EVPN-VXLAN example topology are running IS-IS for the global routing table with the four core PEs interconnected using IS-IS Level-2 point-to-point interfaces and each overlay network is using IS-IS Level-1 point-to-point interfaces.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, and PE-5. There is no LDP running in the two overlay networks.
- The network port MTU (in all the ports sending/receiving VXLAN packets) must be at least 50 bytes (54 if dot1q encapsulation is used) greater than the service MTU in order to accommodate the size of the VXLAN header.

Once the IGP infrastructure and LDP are enabled in the core, BGP has to be configured. In this example, two BGP families have to be enabled: EVPN within each overlay network for the exchange of MAC/IP

addresses and setting up the flooding domains, and L2-VPN for the use of BGP-MH and BGP-AD in the VPLS-MPLS network.

As an example, the following CLI output shows the relevant BGP configuration of PE-1, which only needs the EVPN family. PE-6 would have a similar BGP configuration. The use of route reflectors (RRs) in this type of scenarios is common. Although this example does not use RRs, an EVPN RR could have been used in Overlay-Network-1 and Overlay-Network-2 and an L2-VPN RR could have been used in the core VPLS-MPLS network.

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
        exit
```

The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update l2-vpn evpn
            group "DC"
                family l2-vpn evpn
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "WAN"
                family l2-vpn
                peer-as 64500
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

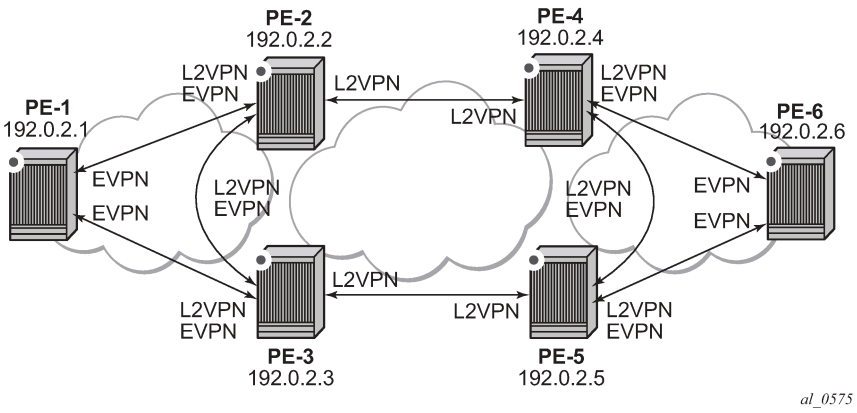
The BGP configuration on PE-3 is as follows:

```
# on PE-3:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update l2-vpn evpn
            group "DC"
                family l2-vpn evpn
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
            exit
            group "WAN"
                family l2-vpn
                peer-as 64500
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

The BGP configuration on PE-4 and PE-5 is equivalent.

Figure 108: BGP adjacencies and enabled families shows the BGP peering sessions among the PEs and the enabled BGP families. PE-1 will only establish an EVPN peering session with its peers (only the EVPN family is enabled on PE-1), even though PE-2 and PE-3 have EVPN and L2-VPN families configured.

Figure 108: BGP adjacencies and enabled families



Once the network infrastructure is running properly, the actual service configuration can be carried out. The following CLI outputs show the configuration of VPLS 1 in PE-1, PE-2, and PE-3 as per the topology illustrated in Figure 107: EVPN-VXLAN example topology.

VPLS 1 in those three PEs are interconnected using VXLAN bindings, whereas PE-2 and PE-3 are connected to the remote PEs by means of BGP-AD SDP-bindings. Although BGP-AD SDP-bindings are

used in this example for the connectivity of the EVPN-VXLAN PEs to a regular VPLS network, SAPs, BGP-VPLS spoke-SDPs, manual spoke-SDPs, or mesh-SDPs could have been used instead.

VPLS 1 is configured on PE-1, as follows:

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64500:1
                route-target export target:64500:12 import target:64500:12
            exit
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
```

EVPN-VXLAN is enabled by the configuration of a valid VXLAN Network Identifier (VNI) and the **bgp-evpn vxlan no shutdown** command. These two commands, along with the required BGP Route Distinguisher (RD) and Route Target (RT) information, are the minimum mandatory attributes:

- The VNI is a 24-bit identifier with valid values in the [1..16777215] range. This defines the VNI that SR OS will use in the EVPN routes generated for the VPLS service, and therefore the VNI that the system expects to see in the VXLAN packets destined to that particular VPLS service. The configured VNI determines the VNI that has to be received in the packets for the VPLS service, but not the VNI that will be sent in VXLAN packets to remote PEs for the service. In other words, in this example, VPLS 1 is configured with VNI=1 in all the PEs; however, each PE could have used a different VNI. The VNI is a system-wide significant value and two VPLS services cannot be configured with the same VNI.
- The **bgp-evpn vxlan no shutdown** command enables the use of EVPN for VXLAN. It requires the previous configuration of the VNI, RD, and RT. As soon as this command is executed, EVPN will advertise an inclusive multicast route to all of the BGP EVPN peers (regardless of the existing SAP/SDP-binding operational status). The exchange of inclusive multicast routes allows the establishment of the VXLAN bindings among the PEs.

Upon the reception of the EVPN inclusive multicast routes from PE-2 and PE-3, PE-1 will automatically set up its VXLAN bindings for VPLS 1. A VXLAN binding is represented by an (egress VTEP, egress VNI) pair, where VTEP is a VXLAN Termination End Point. This can be shown with the following show commands on PE-1:

```
*A:PE-1# show service vxlan

===============================================================================

```

To actually see this output, the VPLS service needs to be configured on all PEs, with import and export policy "vsi-policy-1" defined on the core PEs; see further. As can be seen in the CLI output, PE-1 has two VXLAN bindings: one to PE-2 and one to PE-3. Both use egress VNI=1 (the actual VNI used in its egress VXLAN packets) and both are part of the flooding multicast list (BUM) for VPLS 1 and are up. There is no layer 2 Policy-Based Routing (L2 PBR).

- The **Mcast**=*BUM* entry is set when the proper inclusive multicast route is received from the remote VTEP. The VXLAN binding will be used to flood BUM packets.
- The **Oper State** is based on the existence of the VTEP in the global routing table.

The VPLS 1 configuration of PE-2 and PE-3 is as follows:

```
# on PE-2:
configure
    service
        pw-template 1 name "PW1" create
        exit
        vpls 1 name "VPLS1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 192.0.2.2:1
                vsi-export "vsi-policy-1"
                vsi-import "vsi-policy-1"
                pw-template-binding 1 split-horizon-group "CORE"
                exit
            exit
            bgp-ad
                vpls-id 64500:1
                no shutdown
            exit
```

```
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            site "site-1" create
                site-id 1
                split-horizon-group CORE
                no shutdown
            exit
            no shutdown
```

```
# on PE-3:
configure
    service
        pw-template 1 name "PW1" create
        exit
        vpls 1 name "VPLS1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 192.0.2.3:1
                vsi-export "vsi-policy-1"
                vsi-import "vsi-policy-1"
                pw-template-binding 1 split-horizon-group "CORE"
                exit
            exit
            bgp-ad
                vpls-id 64500:1
                no shutdown
            exit
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            site "site-1" create
                site-id 1
                split-horizon-group CORE
                no shutdown
            exit
            sap 1/2/1:1 create
            exit
            no shutdown
```

In addition to the VNI and **bgp-evpn vxlan no shutdown** commands for enabling EVPN-VXLAN in VPLS 1, PE-2 and PE-3 require the configuration of BGP-AD for the discovery and establishment of FEC129 spoke-SDPs to the remote PEs in the core, as well as BGP-MH for redundancy. As outlined in Figure 107: EVPN-VXLAN example topology, there are two BGP-MH sites defined in the network: site-1 is used on PE-2/PE-3 and site-2 is used on PE-4/PE-5. Only one of the two gateway PEs in each overlay network will be the designated forwarder (DF) for VPLS 1, and only the DF will send/receive traffic for VPLS 1 in the overlay network. The following considerations must be taken into account when configuring the connectivity of EVPN-VXLAN services to regular VPLS objects:

- As discussed, in this example, BGP-AD spoke-SDPs are used, but SAPs, BGP-VPLS spoke-SDPs, manual spoke-SDPs, or mesh-SDPs are also supported.
- In this example, BGP-AD spoke-SDPs are auto-instantiated using **pw-template-binding 1 split-horizon-group "CORE".**
  - This requires the creation of the pw-template 1 (**config service pw-template 1 name <..> create**).
- The split-horizon group CORE is added to the BGP-MH site "site-1". This statement will ensure that all the spoke-SDPs automatically established to the remote PEs are part of the BGP-MH site.
- Although the route targets for the overlay network and the VPLS-MPLS network can have the same value for the same VPLS service, they are usually different. This example assumes the use of RT-DC-1 in Overlay-Network-1 and RT-WAN-1 in the VPLS-MPLS core for VPLS 1. The "vsi-policy-1" allows the system to export and import the right RTs for VPLS 1 on the core PEs:

```
# on PE-2 and PE-3:
configure
    router Base
        policy-options
            begin
            community "RT-DC-1"
                members "target:64500:12"
            exit
            community "RT-WAN-1"
                members "target:64500:11"
            exit
            policy-statement "vsi-policy-1"
                entry 10     # to import all the EVPN routes with RT-DC-1
                    from
                        community "RT-DC-1"
                        family evpn
                    exit
                    action accept

Once PE-2 and PE-3 are configured as shown, they will set up the spoke-SDPs and will run the DF election algorithm to determine the operational status of those spoke-SDPs. See chapters LDP VPLS Using BGP Auto-Discovery and BGP Multi-Homing for VPLS Networks for more information about the use of BGP-AD and BGP-MH.

In the configuration for VPLS 1, both gateway PEs, PE-2 and PE-3, will attempt to establish two parallel Layer 2 paths between each other (a BGP-AD spoke-SDP and an EVPN VXLAN binding). Because that would create a Layer 2 loop, the SR OS implementation gives priority to the EVPN path and only the VXLAN binding will be active. In other words, when a VXLAN (egress VTEP, VNI) and a spoke-SDP are attempted to be set up to the same far-end IP address at the same time, the VXLAN path will prevail and the spoke-SDP will be kept down. The spoke-SDP will only be brought up if the VXLAN (egress VTEP, VNI) goes down.

This behavior can be easily observed in this setup by using the following **show** commands. In PE-2, the spoke-SDP to far-end PE-3 will be down with a *EvpnRouteConflict* Flag. The (egress VTEP, VNI) = (192.0.2.3, 1) VXLAN bind will be up.

```

MAC learning and unknown-mac-route

Once the VPLS service (VPLS 1) is configured, the network allows the CEs to exchange unicast and BUM traffic over the overlay and VPLS-MPLS service infrastructure. BUM traffic sent by CE-1 will be ingress-replicated by PE-1 to PE-2 and PE-3, and propagated by PE-2 (the DF) to the remote network. From this point on, MAC addresses will be learned on active SAPs and spoke-SDPs and advertised in EVPN MAC routes. No data plane MAC learning is carried out on VXLAN bindings. MACs associated with (egress VTEP, VNI) bindings will always be learned through EVPN.

The following CLI output shows the reception of an EVPN MAC route on PE-1 and how the (CE-3) MAC address appears in the FDB for VPLS 1.

```

```

When a frame destined to 00:00:03:03:03:03 enters SAP 1/2/1:1, it is encapsulated into a VXLAN packet with outer destination IP 192.0.2.3 and VNI 1, and sent on the wire.

In virtualized data center networks where all the MACs are known beforehand (all the virtual machine and appliance MACs are distributed by EVPN before any traffic flows), unknown MAC addresses are always outside the data center. If that is the case, the DC GWs can make use of the **unknown-mac-route** so that the DC NVEs supporting the concept of this route send the unknown unicast traffic only to the DC GW. This minimizes the flooding within the data center, as explained in draft-ietf-bess-dci-evpn-overlay.

In this example, the unknown MAC route is configured in the gateway PEs (in Overlay-Network-1: PE-2 and PE-3) in the following way:

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS1"
            bgp-evpn
                unknown-mac-route
```

```
            exit
```

```
# on PE-2:
47 2021/02/10 16:00:36.068 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 88
    Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2
        Type: EVPN-MAC Len: 33 RD: 192.0.2.2:1 ESI: ESI-0, tag: 0, mac len: 48
                       mac: 00:00:00:00:00:00, IP len: 0, IP: NULL, label1: 1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x80 Type: 4 Len: 4 MED: 0
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100

        target:64500:12
        bgp-tunnel-encap:VXLAN
"
```

Note that:

- Although SR OS can generate the unknown MAC route, it will never honor it and normal flooding applies when an unknown unicast packet arrives at an ingress SAP/SDP-binding.
- When **unknown-mac-route** is configured, it will only be generated when: a) no BGP-MH site is configured within the same VPLS service or b) a site is configured and the site is DF (Designated Forwarder) in the PE. If the site becomes a non-DF site, the unknown MAC route will be withdrawn.
- If the **unknown-mac-route** is used in the DC GW and all the NVEs in the DC understand it, the advertisement of MAC addresses can be disabled with the **[no] mac-advertisement** command. If so, SR OS will only advertise the unknown MAC route.

```
# on DC GWs PE-2 and PE-3:
configure
    service
        vpls "VPLS1"
            bgp-evpn
                unknown-mac-route
                no mac-advertisement
            exit
```

Scaling BGP-MH resiliency with the use of operational groups

In Figure 107: EVPN-VXLAN example topology, VPLS 1 in PE-2 and PE-3 is configured with a BGP-MH site that controls which of the two PEs forwards the traffic to the remote PEs (in this case, PE-2 is the DF and the GW responsible for forwarding packets to the remote PEs).

When new VPLS services are required in PE-2 and PE-3, the same BGP-MH configuration can be used. However, if the number of VPLS services grows significantly, the use of individual BGP-MH sites per service will not scale. Because all the services in these two PEs share the same physical topology, the use of operational groups can provide a simple and scalable way of providing resiliency to as many services as the user needs (up to the maximum number of VPLS services per system).

The way operational groups can be used to scale this type of deployments is the following (using the network topology in Figure 107: EVPN-VXLAN example topology and focusing on Overlay-Network-1):

- A control-VPLS service is defined in PE-2 and PE-3. For instance, VPLS 1.
  - This service is configured with a BGP-MH site in both PEs.
  - An oper-group "control-vpls-1" is created and associated to the pw-template-binding 1 in VPLS 1.
- Data VPLS services are defined in both PEs. For instance: VPLS 2, VPLS 3,... VPLS 999.
  - In all these services, the pw-template-binding is configured with **monitor-oper-group "control-vpls-1"**.
  - The status of the spoke-SDPs in the data VPLS services depends on the status of the operational group. If there is a DF switchover in VPLS 1 and VPLS 1 spoke-SDPs go down on PE-2, all the spoke-SDPs in all the data VPLS services controlled by "control-vpls-1" in PE-2 will go down too. In the same way, the spoke-SDPs in PE-3 will come up.
- To allow per-service load balancing, a second control-VPLS service with a different BGP-MH site should be configured.
  - For instance, VPLS 1 might have PE-2 as the DF and VPLS 1000 might be a second control-VPLS service with PE-3 as the DF.
  - Each control-VPLS would control a group of data VPLS services based on the definition and association of a second operational group.

The following example shows the modification of VPLS 1 as the control-VPLS and the configuration of VPLS 2 as a data-VPLS on PE-2. VPLS 1 controls the VPLS 2 spoke-SDP status.

```
# on PE-2:
configure
    service
        oper-group "control-vpls-1" create
        exit
        vpls 1 name "VPLS1" customer 1 create
            description "control-VPLS"
            bgp
                pw-template-binding 1 split-horizon-group "CORE"
                    oper-group "control-vpls-1"
                exit
            exit
        exit
        vpls 2 name "VPLS2" customer 1 create
            description "data-VPLS"
            vxlan instance 1 vni 2 create
            exit
            bgp
                route-distinguisher 192.0.2.2:2
                vsi-export "vsi-policy-2"
                vsi-import "vsi-policy-2"
                pw-template-binding 1
                    monitor-oper-group "control-vpls-1"
                exit
            exit
            bgp-ad
                vpls-id 64500:2
                no shutdown
            exit
            bgp-evpn
                unknown-mac-route
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            no shutdown
```

```
        exit
```

Use of proxy-ARP in EVPN-VXLAN services

EVPN-VXLAN services support proxy-ARP functionality that is enabled by the **proxy-arp [no] shutdown** command. By default, proxy-ARP is disabled. When proxy-ARP is enabled, the following applies:

- MAC and IP addresses contained in the received valid EVPN MAC routes are populated in the proxy-ARP table.
- ARP-request messages received on SAPs and SDP-bindings are intercepted and the target IP address is looked up. If the IP address is found, an ARP reply will be issued based on the information found in the proxy-ARP table, otherwise the ARP request would be flooded in the VPLS service (except for the source SAP/SDP binding).
- ARP-reply messages received on SAPs and SDP-bindings are also intercepted and sent to the CPM. These ARP-reply messages are re-injected in the data plane and forwarded based on the FDB information to the destination MAC address. If the destination MAC address is not in the FDB, the ARP-reply message will be flooded in the VPLS service (except for the source SAP/SDP binding).

The following CLI output shows the proxy-ARP configuration in PE-3 and a received valid MAC route that includes the MAC address 00:00:01:01:01:01 and IP address 172.16.0.1 of CE-1. This MAC-IP pair is installed in the proxy-ARP table for VPLS 1.

```
# on PE-3:
configure
    service
        vpls "VPLS1"
            proxy-arp
                no shutdown
            exit
```

```

SR OS does not include a host IP address in any EVPN MAC advertisement for a MAC learned on a SAP or SDP-binding. Host IP addresses are only included in the EVPN MAC advertisements corresponding to R-VPLS IP interfaces. When deployed as DC GW in a Nuage architecture, the Nuage Networks Virtual Services Controller (VSC) or Virtual Services Gateway (VSG) will send virtual machine and host MAC/IP pairs in EVPN MAC routes. See the Nokia Nuage documentation for more information about the Nuage DC architecture. The 7x50 DC GW will populate the proxy-ARP tables with those MAC/IP pairs.

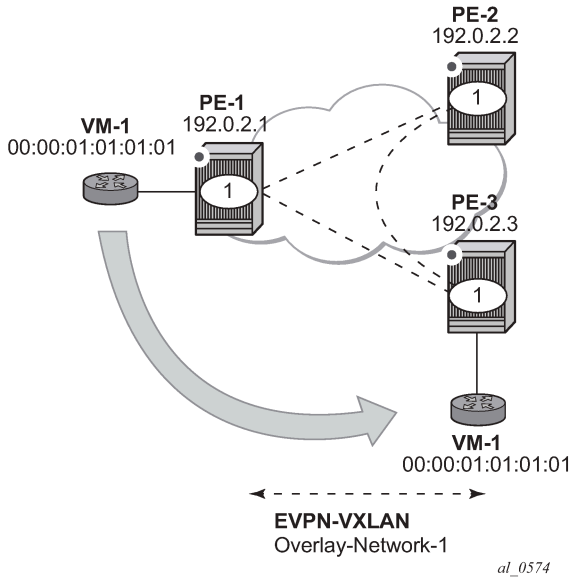
In the preceding CLI excerpt, assume that PE-1 is replaced by a Nuage VSC that sends the pair <172.16.0.1, 00:00:01:01:01:01> in an EVPN MAC route. PE-3 receives the advertisement and adds the entry to its proxy-ARP table for VPLS 1.

The proxy-ARP feature was significantly improved in SR OS Release 13.0; see chapter EVPN for MPLS Tunnels.

MAC mobility, MAC duplication, and MAC protection in EVPN

MAC mobility, duplication and protection are fully supported as specified in RFC 7432. Figure 109: EVPN MAC mobility illustrates the concept of mobility (Virtual Machine VM-1 moves from PE-1 to PE-3).

Figure 109: EVPN MAC mobility



MAC mobility is handled in EVPN by the use of sequence numbers in the MAC routes. When 00:00:01:01:01:01 moves from PE-1 to PE-3, SR OS will gracefully handle it in this way:

- 00:00:01:01:01:01 moves to PE-3 SAP 1/2/1:1
- PE-3 advertises 00:00:01:01:01:01 using a higher sequence number (the first time a MAC is advertised, EVPN uses sequence number 0).
- PE-2 at this point has two valid MAC routes for 00:00:01:01:01:01. It picks up the one coming from PE-3 because the sequence number is higher.
- PE-1 receives the MAC route, and because the sequence number is higher than the one for its own route, it updates the FDB and withdraws its own MAC route.

However, if MAC 00:00:01:01:01:01 is constantly learned on the PE-1 and PE-3 SAPs, the preceding process causes an endless exchange of MAC route advertisements and withdraws that has a negative impact on all the PEs in the EVPN network. This issue is known as “MAC duplication” and is originated by a loop at the access or a duplicated MAC address in two hosts of the same service. SR OS solves this issue through the use of the MAC duplication detection feature. MAC duplication is always enabled with the following default settings:

```
*A:PE-1>config>service>vpls>bgp-evpn# info detail | match mac-duplication context all
----------------------------------------------
                mac-duplication
                    detect num-moves 5 window 3
                    retry 9
                    no black-hole-dup-mac
```

Where:

- **num-moves** — Identifies the number of MAC moves in a VPLS service. The counter is incremented when a MAC is locally relearned in the FDB or flushed from the FDB due to the reception of a better

remote EVPN route for that MAC. When the threshold is reached for a MAC address, this MAC address is put in hold-down state (this hold-down state is described below). Range: <3..10>. Default value: 5.

- **window** — Identifies the timer within which a MAC is considered duplicate if it reaches the configured num-moves. Range: <1..15> minutes. Default value: 3 minutes.
- **Retry** — The timer after which the MAC in hold-down state is automatically flushed and the mac-duplication process starts again. This value is expected to be equal to two times or more than the window. If no retry is configured, this implies that, once MAC duplication is detected, MAC updates for that MAC will be held down until the user intervenes or a network event (that flushes the MAC) occurs. Range: <2..60> minutes. Default value: 9 minutes.
- **black-hole-dup-mac** — If enabled and a duplicate MAC address is detected, the router adds the MAC address to the duplicate MAC list and it programs the MAC in the FDB as a protected MAC associated with a black-hole (with type EvpnD:P and source ID "black-hole")

When a MAC address is considered a duplicate or in the hold-down state, no further BGP advertisements are issued for this MAC and an alarm is triggered (by the first MAC address in hold-down state). The following CLI output shows how PE-3 detects that MAC 00:00:01:01:01:01 is a duplicate (after reaching the **num-moves** in **window**) and the corresponding alarm.

```

00:00:01:01:01:01                           02/10/2021 16:18:58
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

SR OS stops sending and processing any BGP MAC advertisement routes for that MAC address until:

- The MAC is flushed due to a local event (SAP/SDP-binding associated to the MAC fails) or the reception of a remote withdraw for the MAC (due to a MAC flush at the remote 7x50) or
- The **retry <in_minutes>** timer expires, which flushes the MAC and restart the process.

When the last duplicate MAC address is removed from the duplicate list, log 99 on PE-3 will show the following message:

```
155 2021/02/10 16:21:58.885 UTC MINOR: SVCMGR #2332 Base
"VPLS Service 1 no longer has MAC(s) detected as duplicates by EVPN mac-duplication
detection."
```

EVPN also provides a mechanism to protect certain MAC addresses that do not move for which connectivity must be guaranteed. These addresses must be protected in case there is an attempt to dynamically learn them in a different place in the EVPN-VXLAN VPLS service (on the same or different PE).

The protected MAC addresses are configured in SR OS as conditional static MAC addresses. A conditional static MAC address defined in an EVPN-VXLAN VPLS service is advertised by BGP-EVPN as a static address. An example of the configuration of a conditional static MAC addressis as follows:

```
# on PE-1:
configure
    service
        vpls "VPLS1"
            static-mac
                mac 00:00:05:05:05:05 create sap 1/2/1:1 monitor fwd-status
            exit
        exit
```

The protected MAC addresses advertised in EVPN are shown in the receiving BGP RIB as Static (MAC mobility extended community with Sequence 0 and sticky bit set) and *EvpnS:P* (Evpn Static: Protected) in the FDB. The advertising PE shows the protected MAC as *CStatic:P* (Conditional Static: Protected) in the FDB:

On the advertising PE:

```
*A:PE-1# show service id 1 fdb mac 00:00:05:05:05:05

The following procedures are supported in order to protect the configured static MAC addresses:

- All the SAP/SDP-bindings are internally configured as MAC protect restrict-protected-src as soon as BGP-EVPN is enabled in the VPLS service.
- Local static MAC addresses or remote EVPN static MAC addresses are considered as protected.
- If a frame with a source MAC address matching one of the protected MAC addresses is received on a different SAP/SDP-binding than the owner of the protected MAC address, the frame is discarded and an alarm triggered. This MAC protection is not performed for frames received on VXLAN bindings.
- The same throttled alarm mechanism used in MAC protect for restrict-protected-src with discard-frame is used here: the offending frames are captured to a list to be polled by the CPM every ~10min.

In this example, PE-3 has 00:00:05:05:05:05 in its FDB as EvpnS. If SAP 1/2/1:1 on PE-3 receives a frame with source MAC address 00:00:05:05:05:05, the frame is discarded and an alarm triggered. The following is logged in log 99 on PE-3:

```
164 2021/02/10 16:44:03.736 UTC MINOR: SVCMGR #2208 Base Slot 1
"Protected MAC 00:00:05:05:05:05 received on SAP 1/2/1:1 in service 1. "
```

Debug and show commands

In addition to the previously mentioned **show service id vxlan destinations**, **show service id bgp-evpn** and **show service id fdb detail** commands, the following commands provide valuable information when troubleshooting an EVPN-VXLAN VPLS service.

The **show router bgp routes evpn** command supports filtering by route type as well as many other route fields.

```
# on any PE:
show router bgp routes evpn ?
  - evpn <evpn-type>

      auto-disc       - Display BGP EVPN Auto-Disc Routes
      eth-seg         - Display BGP EVPN Eth-Seg Routes
      incl-mcast      - Display BGP EVPN Inclusive-Mcast Routes

Conclusion

SR OS supports the EVPN control plane for VXLAN tunnels terminated in VPLS services. VXLAN is an overlay IP tunneling mechanism that is being used in data centers, data center interconnect, and other applications. EVPN is a scalable and flexible control plane that provides control over the MAC addresses being learned and advertised, as well as other mechanisms to optimize Layer 2 services such as proxy-ARP, MAC mobility, MAC duplication detection, and MAC protection. SR OS provides a resilient and

scalable EVPN-VXLAN solution for Layer 2 services, including interoperability to existing VPLS networks. This chapter showed all of those functions and how they are configured and operated.

EVPN for VXLAN Tunnels (Layer 3)

This chapter provides information about EVPN for VXLAN tunnels (Layer 3).

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS and was initially written for Release 12.0.R4. The CLI in the current edition is based on SR OS Release 21.10.R3. Ethernet Virtual Private Network (EVPN) is a control plane technology and does not have line card hardware dependencies.

Chapter EVPN for VXLAN Tunnels (Layer 2) is prerequisite reading.

Overview

As discussed in the EVPN for VXLAN Tunnels (Layer 2) chapter, EVPN and VXLAN can be enabled on VPLS or R-VPLS services in SR OS. Where that chapter focuses on the use of EVPN-VXLAN layer 2 services, in other words, how EVPN-VXLAN is configured in VPLS services, this chapter describes how EVPN-VXLAN can be used to provide inter-subnet forwarding in R-VPLS and VPRN services. Inter-subnet forwarding can be provided by regular R-VPLS and VPRN services. However, EVPN provides an efficient and unified way to populate Forwarding Databases (FDBs), Address Resolution Protocol (ARP) tables and routing tables using a single BGP address family. Inter-subnet forwarding in overlay networks would otherwise require data plane learning and the use of routing protocols on a per VPRN basis.

The SR OS solution for inter-subnet forwarding using EVPN is based on building blocks described in *draft-ietf-bess-evpn-inter-subnet-forwarding* and the use of the EVPN IP-prefix routes (route type 5) as explained in RFC 9136. This example describes three supported common scenarios and provides the CLI configuration and required tools to troubleshoot EVPN-VXLAN in each case. The scenarios configured and explained are:

- EVPN-VXLAN in R-VPLS services
- EVPN-VXLAN in Integrated Routing Bridging (IRB) backhaul R-VPLS services
- EVPN-VXLAN in EVPN tunnel R-VPLS services

In all these scenarios, redundant PEs are usually deployed. If that is the case, the interaction of EVPN, IP-VPN, and the Routing Table Manager (RTM) may lead to some routing loop situations that must be avoided by using routing policies (this also may happen in traditional IP-VPN deployments when eBGP and MP-BGP interact to populate VPRN routing tables in multi-homed networks). This chapter explains when those routing loops can happen and how to avoid them.

The term IRB interface refers to an R-VPLS service bound to a VPRN IP interface. The terms IRB interface and R-VPLS interface are used interchangeably throughout this chapter.

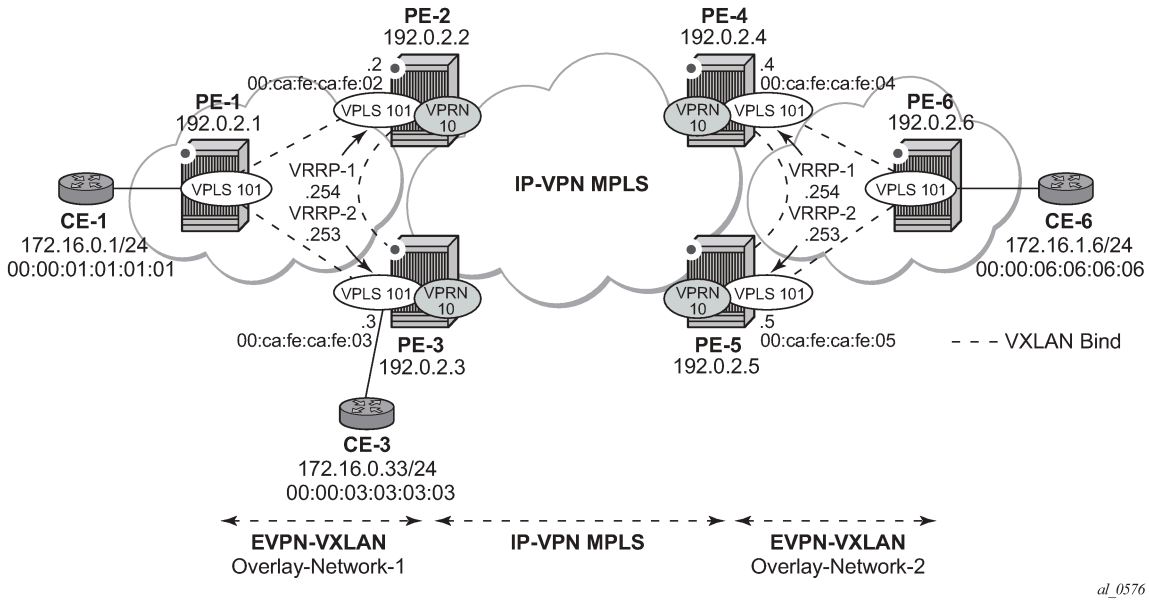
Configuration

This section describes the configuration of EVPN-VXLAN for Layer 3 services on SR OS, as well as the available troubleshooting and show commands. The three scenarios described in the overview are analyzed independently.

EVPN-VXLAN in an R-VPLS service

Figure 110: EVPN-VXLAN for R-VPLS services shows the topology used in the first scenario.

Figure 110: EVPN-VXLAN for R-VPLS services



The network topology shows two overlay (VXLAN) networks interconnected by an MPLS network:

- PE-1, PE-2, and PE-3 are part of Overlay-Network-1
- PE-4, PE-5, and PE-6 are part of Overlay-Network-2

A Layer 2/Layer 3 service is provided to a customer to connect CE-1, CE-3, and CE-6. In this scenario, Layer 2 connectivity is provided within each overlay network and inter-subnet connectivity (Layer 3) is provided between the overlay networks. VPLS 101 is defined within each overlay network and VPRN 10 connects both Layer 2 services through an IP-VPN MPLS network.

This topology can illustrate a Data Center Interconnect (DCI) example, where Overlay-Network-1 and Overlay-Network-2 are two data centers interconnected through an MPLS WAN. In this application, CE-1, CE-3, and CE-6 simulate virtual machines or appliances, PE-2/3/4/5 act as Data Center Gateways (DC GWs) and PE-1/6 as Network Virtualization Edge devices (or virtual PEs running on a compute infrastructure).

The following protocols and objects are configured beforehand:

- The ports interconnecting the six PEs in Figure 110: EVPN-VXLAN for R-VPLS services are configured as network or hybrid ports and have router network interfaces defined in them. Only the ports connected to the CEs are configured as access ports.
- The six PEs are running IS-IS for the global routing table with the four core PEs interconnected using IS-IS Level-2 point-to-point interfaces and each overlay network using IS-IS Level-1 point-to-point interfaces.
- LDP is used as the MPLS protocol to signal transport tunnel labels among PE-2, PE-3, PE-4, and PE-5. There is no LDP running within each overlay network.
- The network port MTU (in all the ports sending/receiving VXLAN packets) must be at least 50 bytes (54 if dot1q encapsulation is used) greater than the service MTU to accommodate the size of the VXLAN header.

Once the IGP infrastructure and LDP in the core are enabled, BGP is configured. In this scenario, two BGP families must be enabled: EVPN within each overlay network for the exchange of MAC/IP addresses and setting up the flooding domains, and VPN-IPv4 among the four core PEs so that IP prefixes can be exchanged and resolved to MPLS tunnels in the core.

The following CLI output shows the BGP configuration of PE-1, which only needs the EVPN family. PE-6 has a similar BGP configuration, that is, only EVPN family is configured for its peers. The use of Route Reflectors (RRs) in these scenarios is common. Although this scenario does not use RRs, an EVPN RR could have been used in Overlay-Network-1 and Overlay-Network-2 and a separate VPN-IPv4 RR could have been used in the core IP-VPN MPLS network.

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
        exit
```

The BGP configuration on the DC GWs is as follows:

```
# on PE-2:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                family vpn-ipv4 evpn
```

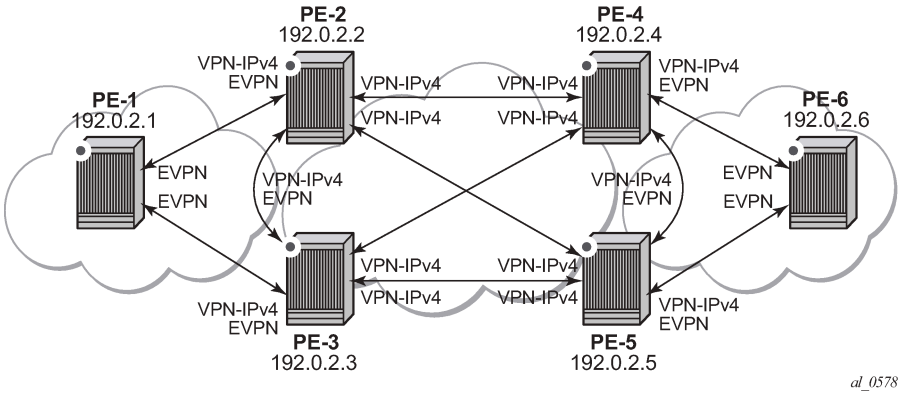
```
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "WAN"
                family vpn-ipv4
                peer-as 64500
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
        exit
```

```
# on PE-3:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                family vpn-ipv4 evpn
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
            exit
            group "WAN"
                family vpn-ipv4
                peer-as 64500
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
        exit
```

The DC GWs PE-4 and PE-5 have an equivalent BGP configuration.

Figure 111: BGP adjacencies and enabled families shows the BGP peering sessions among the PEs and the enabled BGP families. PE-1 and PE-6 only establish an EVPN peering session with their peers (only the EVPN family is enabled on PE-1 and PE-6, even if the peer PEs are VPN-IPv4 capable as well).

Figure 111: BGP adjacencies and enabled families



Once the network infrastructure is running properly, the actual service configuration, as illustrated in Figure 110: EVPN-VXLAN for R-VPLS services, can be carried out. The following CLI shows the configuration for VPLS 101 and VPRN 10 in PE-1, PE-2, and PE-3. The other overlay network has a similar configuration.

```
# on PE-1:
configure
    service
        vpls 101 name "evi-101" customer 1 create
            vxlan instance 1 vni 101 create
            exit
            bgp
                route-distinguisher 192.0.2.1:101
                route-target export target:64500:101 import target:64500:101
            exit
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/2/1:101 create
                no shutdown
            exit
            proxy-arp
                no shutdown
            exit
            no shutdown
```

Proxy-ARP is disabled (default) on PE-2, as well as on the other core PEs:

```
# on PE-2:
configure
    service
        vpls 101 name "evi-101" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 101 create
            exit
            bgp
                route-distinguisher 192.0.2.2:101
                route-target export target:64500:101 import target:64500:101
            exit
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1
```

```
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vprn 10 name "VPRN10" customer 1 create
            ecmp 2
            interface "int-1" create
                address 172.16.0.2/24
                mac 00:ca:fe:ca:fe:02

                    no shutdown
                exit
            exit
            no shutdown
        exit
```

For details about the EVPN and VXLAN configuration on PE-1 VPLS 101, see chapter EVPN for VXLAN Tunnels (Layer 2). The configuration of VPLS 101 on PE-2 and PE-3 has the following important aspects:

- The **allow-ip-int-bind** command is required so that the R-VPLS can be bound to VPRN 10.
- The service name "evi-101" is configured when the service is created and cannot be modified afterward. The service name must match the name configured in the VPRN 10 VPLS interface.
- Even though EVPN and VXLAN are properly configured, proxy-ARP cannot be enabled in VPLS 101. In an R-VPLS with EVPN-VXLAN, proxy-ARP is not supported and the VPRN ARP table is used instead. When an EVPN MAC route that includes an IP address is received in an R-VPLS, the MAC-IP pair encoded in the route is added to the ARP table of the VPRN, as opposed to the proxy-ARP table.

```
*A:PE-2>config>service>vpls>proxy-arp$ no shutdown
MINOR: SVCMGR #8007 Cannot modify proxy arp - service is routed
```

When configuring VPRN 10 on PE-2 and PE-3, the following considerations must be taken into account:

- When trying to enable existing VPRN features on interfaces linked to EVPN-VXLAN R-VPLS interfaces, the authentication-policy command is not supported:

```
*A:PE-2>config>service>vprn>if# authentication-policy "authPol1"
INFO: PIP #1875 Cannot configure auth-policy on routed-vpls interface
```

- Dynamic routing protocols such as IS-IS, RIP, or OSPF are not supported.
- In general, no SR OS control plane generated packets are sent to the egress VXLAN bindings except for ARP, VRRP, ICMP, BFD, and Eth-CFM.
- As shown in Figure 110: EVPN-VXLAN for R-VPLS services and in the CLI excerpts, VRRP can be configured on the VPRN 10 VPLS interfaces to provide default gateway redundancy to the hosts connected to VPLS 101. Two VRRP instances are configured so that VPLS 101 upstream traffic can be load-balanced to PE-2 and PE-3. With VRRP on EVPN-VXLAN R-VPLS interfaces:
  - **Ping-reply** and **traceroute-reply** can be configured and are supported. BFD is also supported to speed up the fault detection.
  - **standby-forwarding**, even if it were configured for VRRP, would not have any effect in this configuration: the standby PE will never see any flooded traffic sent to it, so this command is not applicable to this scenario.
- When a VPRN 10 VPLS interface is bound to VPLS 101, EVPN advertises all the IP addresses configured for that VPLS interface as MAC routes with a static MAC indication. For the remote EVPN peers, that means that those MAC addresses linked to remote IP interfaces are protected. VRRP virtual IP/MACs are also advertised by EVPN as "static" and so protected. In the example of Figure 110: EVPN-VXLAN for R-VPLS services, the VPLS 101 FDB in PE-1 shows the IP interface MAC addresses and VRRP MAC addresses as *EvpnS:P* (Static and protected MAC) as shown in the following output:

```
*A:PE-1# show service id 101 fdb detail

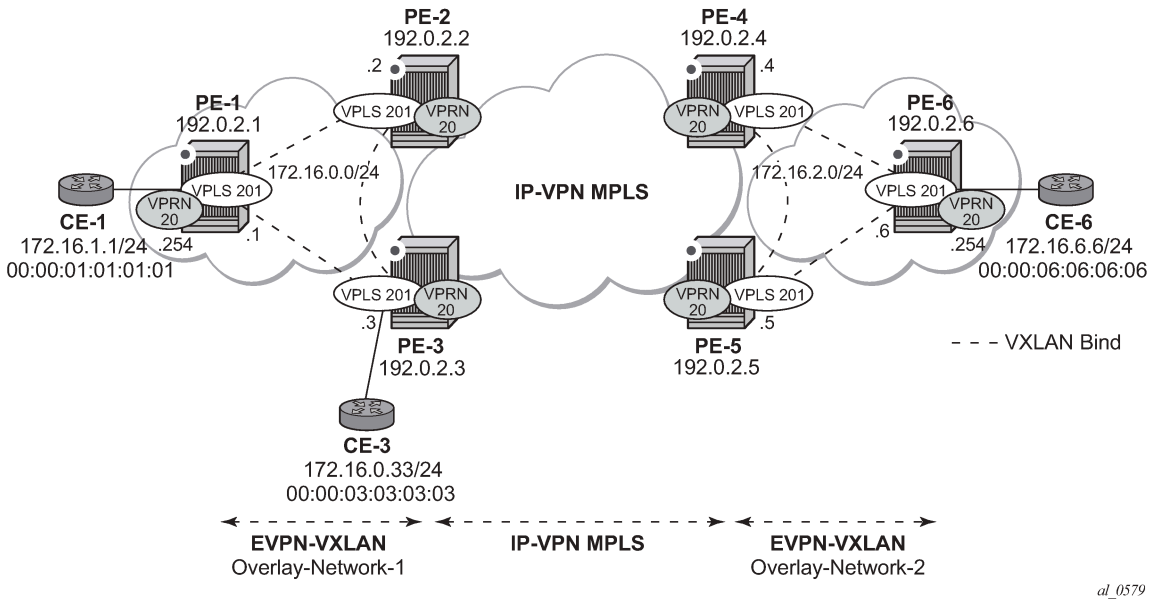
EVPN-VXLAN in IRB backhaul R-VPLS services

Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services illustrates the second inter-subnet forwarding scenario, where Layer 3 connectivity must be provided not only between the overlay networks but also within each overlay network. In the example shown in Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services, a customer (tenant) has different subnets and connectivity must be provided across all of them (CE-1, CE-3, and CE-6 must be able to communicate), bearing in mind that EVPN-VXLAN is enabled in each overlay network and IP-VPN MPLS is used to interconnect both overlay networks. VPLS 201 is an IRB Backhaul R-VPLS service because it provides connectivity to the VPRN instances.

Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services



From a BGP peering perspective, there is no change in this scenario compared to the previous one: PE-1 and PE-6 only support the EVPN address family. However, in this scenario, CE-1 is now connected to an R-VPLS directly linked to the VPRN instances in PE-2/PE-3. As a result of that, IP prefixes must be exchanged between PE-1 and PE-2/PE-3. EVPN can advertise not only MAC routes and Inclusive Multicast routes, but also IP prefix routes that contain IP prefixes that can be installed in the attached VPRN routing table.

As an example, the VPRN 20 and VPLS "evi-201" configurations on PE-1, PE-2, and PE-3 are shown. Similar configurations are needed in PE-4, PE-5, and PE-6.

On PE-1, VPRN 20 and VPLS "evi-201" are configured as follows:

```
# on PE-1:
configure
    service
        vprn 20 name "VPRN20" customer 1 create
            interface "int-evi-201" create
                address 172.16.0.1/24
                vpls "evi-201"
                exit
            exit
            interface "int-PE-1-CE-1" create
                address 172.16.1.254/24
                sap 1/2/1:20 create
                exit
            exit
            no shutdown
        exit
        vpls 201 name "evi-201" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 201 create
            exit
            bgp
```

```
                route-distinguisher 192.0.2.1:201
                route-target export target:64500:201 import target:64500:201
            exit
            bgp-evpn
                ip-route-advertisement
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

On PE-2, VPRN 20 and VPLS "evi-201" are configured as follows:

```
# on PE-2:
configure
    service
        vprn 20 name "VPRN20" customer 1 create
            interface "int-evi-201" create
                address 172.16.0.2/24
                vpls "evi-201"
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 192.0.2.2:20
                    vrf-target target:64500:20
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vpls 201 name "evi-201" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 201 create
            exit
            bgp
                route-distinguisher 192.0.2.2:201
                route-target export target:64500:201 import target:64500:201
            exit
            bgp-evpn
                ip-route-advertisement
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

On PE-3, VPRN 20 and VPLS "evi-201" are configured as follows:

```
# on PE-3:
configure
    service
        vprn 20 name "VPRN20" customer 1 create
            interface "int-evi-201" create
```

```
                address 172.16.0.3/24
                vpls "evi-201"
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 192.0.2.3:20
                    vrf-target target:64500:20
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vpls 201 name "evi-201" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 201 create
            exit
            bgp
                route-distinguisher 192.0.2.3:201
                route-target export target:64500:201 import target:64500:201
            exit
            bgp-evpn
                ip-route-advertisement
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/2/1:20 create
                no shutdown
            exit
            no shutdown
        exit
```

As shown in the CLI excerpt, the configuration in the three nodes (PE-1, PE-2, and PE-3) for VPLS "evi-201" and VPRN 20 is very similar. The main difference is the **auto-bind-tunnel** command in VRPN 20 on PE-2 and PE-3. This command allows the VPRN 20 on PE-2 and PE-3 to receive IP-VPN routes from the core and resolve them to MPLS tunnels. VPRN 20 on PE-1 does not require such command because all its IP prefixes are resolved to local interfaces or to EVPN peers.

The **ip-route-advertisement** command enables:

- The advertisement of IP prefixes in EVPN, in routes type 5. All the existing IP prefixes in the attached VPRN 20 routing table are advertised in EVPN within the VPLS 201 context (except for the ones associated to VPLS 201 itself).
- The installation of IP prefixes in the attached VPRN 20 routing table with a preference of 169 (BGP-VPN routes for IP-VPN have a preference of 170) and a next-hop of the gateway IP (GW IP) address included in the EVPN IP prefix route.

For instance, the following output shows that PE-1 advertises the IP prefix 172.16.1.0/24 as an EVPN route to PE-3 (a similar route is sent to PE-2), captured by a **debug router bgp update** session.

```

The VPRN 20 routing table in PE-1 includes two EVPN Interface-ful (EVPN-IFF) routes with preference 169, as follows:

```
*A:PE-1# show router 20 route-table

===============================================================================
Route Table (Service: 20)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
172.16.0.0/24                                 Local   Local     00h22m22s  0
       int-evi-201                                                 0
172.16.1.0/24                                 Local   Local     00h22m22s  0
       int-PE-1-CE-1                                               0
172.16.2.0/24                                 Remote  EVPN-IFF  00h01m41s  169
       172.16.0.2                                                  0
172.16.6.0/24                                 Remote  EVPN-IFF  00h01m41s  169
       172.16.0.2                                                  0
-------------------------------------------------------------------------------
No. of Routes: 4
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The subnet 172.16.0.0/24 is used on the interfaces "int-evi-201" in overlay network 1 and subnet 172.16.2.0/24 is used on similar interfaces in overlay network 2. CE-1 has an IP address in subnet 172.16.1.0/24 and CE-6 has an IP address in subnet 172.16.6.0/24. The next hop to reach 172.16.2.0/24 (overlay network 2) or CE-6, is 172.16.0.2 (PE-2), but it could have been PE-3.

There is redundancy in the example setup and therefore, loops can occur. To avoid loops, routing policies need to be configured on the core PEs (PE-2, PE-3, PE-4, and PE-5). These policies are described in the Use of routing policies to avoid routing loops in redundant PEs section for routing loop use case 1.

The routing table on PE-2 shows a EVPN-IFF route toward CE-1 (subnet 172.16.1.0/24) via PE-1. The route toward CE-6 uses a tunnel toward PE-4 in overlay network 2.

```
*A:PE-2# show router 20 route-table

===============================================================================
Route Table (Service: 20)

       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

When checking the operation of EVPN in this scenario, it is important to observe that the right next hops and prefixes are successfully installed in the VPRN 20 routing table:

- EVPN IP prefixes are sent using a GW IP matching the primary IP interface address of the R-VPLS for which the routes are sent. For instance, as shown above, IP prefix 172.16.1.0/24 is advertised from PE-1 with GW IP 172.16.0.1, which is the IP address configured for the VPRN 20 VPLS interface in PE-1. In the VPRN 20 routing tables on PE-2 and PE-3, IP prefix 172.16.1.0/24 is installed with next hop 172.16.0.1. Traffic arriving at PE-2 or PE-3 on VPRN 20 with IP Destination Address (DA) in the 172.16.1.0/24 subnet matches the mentioned routing table entry. As usual, the next-hop is resolved by the ARP table to a MAC address and the MAC address resolved by the FDB table to an egress VTEP, VNI.
- IP prefixes in the VPRN 20 routing table are advertised in IP-VPN to the remote IP-VPN MPLS peers. Received IP-VPN prefixes are installed in the VPRN 20 routing table using the remote PE system IP address as the next hop, as usual. For instance, 172.16.6.0/24 is installed in the routing table of VPRN 20 on PE-2 with next-hop (tunneled) 192.0.2.4 and preference 170.

The following considerations of how the routing table manager (RTM) handles EVPN and IP-VPN prefixes must be taken into account:

- Only VPRN interface primary addresses are advertised as GW IP in EVPN IP prefix routes. Secondary addresses are never sent as GW IP addresses.
- EVPN IP prefixes are advertised by default as soon as the **ip-route-advertisement** command is enabled and there are active IP prefixes in the attached VPRN routing table.
- If the same IP prefix is received on a PE via EVPN and IP-VPN at the same time for the same VPRN, by default, the EVPN prefix is selected because its preference (169) is better than the IP-VPN preference (170).
- Because EVPN has a better preference compared to IP-VPN, when the VPRNs on redundant PEs are attached to the same R-VPLS service, routing loops may occur. The use case described here is an example where routing loops can occur. Check Use of routing policies to avoid routing loops in redundant PEs to avoid routing loops in redundant PEs for more information.
- When the command **ip-route-advertisement** is enabled, the subnet IP prefixes are advertised in EVPN but not the host IP prefixes (/32 prefixes associated with the local interfaces). If the user wants to advertise the host IP prefixes as well, the **incl-host** keyword must be added to the **ip-route-advertisement** command. The following example illustrates this.

```
*A:PE-1# show router 20 route-table

===============================================================================
Route Table (Service: 20)

       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

- ECMP is fully supported for the VPRN for EVPN IP prefix routes coming from different GW IP next-hops. However, ECMP is not supported for IP prefixes routes belonging to different owners (EVPN and IP-VPN). ECMP is enabled in VPRN 20 on PE-1, as follows:

  ```
  # on PE-1:
  configure
      service
          vprn "VPRN20"
  ```

```
            ecmp 2
```

When policies are applied that prevent routing loops, as described in section Use of routing policies to avoid routing loops in redundant PEs, both PE-2 and PE-3 have IP-VPN tunnels for IP prefixes 172.16.2.0/24 and 172.16.6.0/24. In that case, an additional route with a different GW IP as next hop is installed in the routing table for these IP prefixes:

```
*A:PE-1# show router 20 route-table

===============================================================================

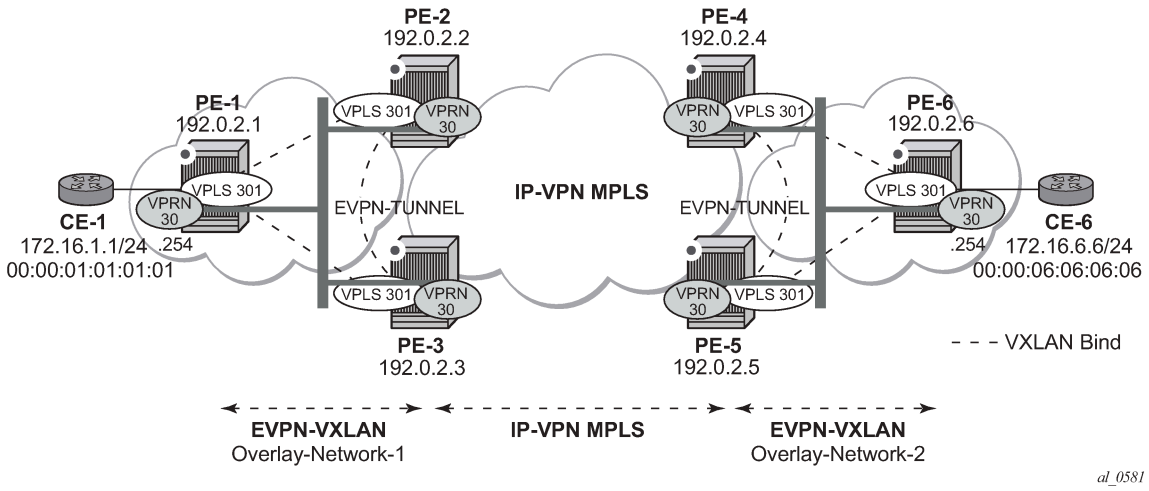
```

EVPN-VXLAN in EVPN tunnel R-VPLS services

The previous scenario shows how to use EVPN-VXLAN to provide inter-subnet forwarding for a tenant, where R-VPLS services can contain hosts and also offer transit services between VPRN instances. For example, in the use case shown in Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services, VPLS 201 in Overlay-Network-1 is an R-VPLS that can provide intra-subnet connectivity to all the hosts in subnet 172.16.0.0/24 (for example, CE-3 belongs to this subnet) but it can also provide transit or backhaul connectivity to hosts in subnet 172.16.1.0/24 (for example, CE-1) sending packets to subnets 172.16.2.0/24 or 172.16.6.0/24.

In some cases, the R-VPLS where EVPN-VXLAN is enabled does not need to provide intra-subnet connectivity and it is purely a transit or backhaul service where VPRN IRB interfaces are connected. Figure 113: EVPN-VXLAN in EVPN-tunnel R-VPLS services illustrates this use case.

Figure 113: EVPN-VXLAN in EVPN-tunnel R-VPLS services



Compared to the preceding use case in Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services, in this case the R-VPLS connecting the IRB interfaces in Overlay-Network-1 (VPLS 301) does not have any connected host. If that is the case, VPLS 301 can be configured as an EVPN tunnel.

EVPN tunnels are enabled using the **evpn-tunnel** command under the R-VPLS interface configured on the VPRN. EVPN tunnels bring the following benefits to EVPN-VXLAN IRB backhaul R-VPLS services:

- Easier and simpler provisioning of the tenant service: if an EVPN tunnel is configured in an IRB backhaul R-VPLS, there is no need to provision the IRB IP addresses in the VPRN. This makes the provisioning easier to automate and saves IP addresses from the tenant IP space.
- Higher scalability of the IRB backhaul R-VPLS: if EVPN tunnels are enabled, BUM traffic is suppressed in the EVPN-VXLAN IRB backhaul R-VPLS service (it is not required). As a result, the number of VXLAN bindings in IRB backhaul R-VPLS services with EVPN tunnels can be much higher.

As an example, the VPRN 30 and VPLS 301 configurations on PE-1, PE-2, and PE-3 are shown. Similar configurations are needed in PE-4, PE-5, and PE-6.

```
# on PE-1:
configure
    service
        vprn 30 name "VPRN30" customer 1 create
            interface "int-PE-1-CE-1" create
                address 172.16.0.254/24
                sap 1/2/1:30 create
                exit
            exit
            interface "int-evi-301" create
                vpls "evi-301"
                    evpn-tunnel
                exit
            exit
            no shutdown
        exit
        vpls 301 name "evi-301" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 301 create
            exit
```

            stp
                shutdown
            exit
            no shutdown
        exit
```

As shown in the preceding output, the configuration in the three nodes (PE-1/2/3) for VPLS 301 and VPRN 30 is similar to the configuration of VPLS 201 and VPRN 20 in the previous scenario, however, when the **evpn-tunnel** command is added to the VPRN interface, there is no need to configure an IP interface address. The option **evpn-tunnel** can be enabled independently of **ip-route-advertisement** (although no route type 5 advertisements are sent in that case).

A VPRN supports regular IRB backhaul R-VPLS services as well as EVPN tunnel R-VPLS services. A maximum of eight R-VPLS services with **ip-route-advertisement** enabled per VPRN is supported (in any combination of regular IRB R-VPLS or EVPN tunnel R-VPLS services). EVPN tunnel R-VPLS services do not support SAPs or SDP-bindings. No frames are flooded in an EVPN tunnel R-VPLS service, and, in fact no inclusive multicast routes are exchanged in R-VPLS services that are configured as EVPN tunnels.

The **show service id vxlan destinations** command for an R-VPLS service configured as an EVPN tunnel shows <egress VTEP, VNI> bindings excluded from Mcast, in other words, the VXLAN bindings are not used to flood BUM traffic:

```
*A:PE-2# show service id 301 vxlan destinations
```

```

The process followed upon receiving a route type 5 on a regular IRB R-VPLS interface (previous scenario) differs from the one for an EVPN tunnel type (this scenario):

- IRB backhaul R-VPLS VPRN interface:
  - When a route type 2 that includes an IP address is received and it becomes active, the MAC/IP information is added to the FDB and ARP tables. This can be checked with the **show router arp** command and the **show service id fdb detail** command.
  - When a route type 5 is received on (for instance) PE-2, and becomes active for the R-VPLS service, the IP prefix is added to the VPRN routing table regardless of the existence of a route type 2 that can resolve the GW IP address. If a packet is received from the WAN side and the IP lookup hits an entry for which the GW IP (IP next-hop) does not have an active ARP entry, the system will ARP to get the MAC. If the ARP is resolved but the MAC is unknown in the FDB table, the system will flood the ARP message into the R-VPLS multicast list. Routes type 5 can be checked in the routing table with the **show router route-table** command and the **show router fib** command.
- EVPN tunnel R-VPLS VPRN interface:
  - When a route type 2 is received and becomes active, the MAC address is added to the FDB (only). This MAC address is normally a GW MAC.
  - When a route type 5 is received on (for instance) PE-1, the system looks for the GW MAC. The IP prefix is added to the VPRN routing table with next hop equal to EVPN-tunnel GW MAC; for example, ET-02:13:ff:00:00:6a is an EVPN tunnel with GW MAC 02:13:ff:00:00:6a. The GW MAC is added from the GW MAC extended community sent along with the route type 5 for prefix 172.16.6.0/24. If a packet is received from CE-1 and the IP lookup hits an entry for which the next hop is an EVPN tunnel: GW MAC, the system looks up the GW MAC in the FDB. Normally a route type 2 with the GW MAC has already been received so that the GW MAC has been added to the FDB. If the GW MAC is not present in the FDB, the packet will be dropped.
  - The IP prefixes with GW MACs as next hops for the setup in Figure 113: EVPN-VXLAN in EVPN-tunnel R-VPLS services are displayed in the **show router route-table** command, as follows:

```
*A:PE-1# show router 30 route-table
```

```
===============================================================================
Route Table (Service: 30)
===============================================================================

```

IP prefix routes sent for EVPN tunnel R-VPLS services do not contain a GW IP (the GW IP will be zero) but convey a GW MAC address that is used in the peer VPRN routing table. The following output shows PE-2's VPRN 30 interface MAC address sent to PE-1:

```
*A:PE-2# show router 30 interface "int-evi-301" detail | match "MAC "
MAC Address      : 02:13:ff:00:00:6a    Mac Accounting    : Disabled
```

When **ip-route-advertisement** is configured, PE-2 sends route type 5 messages to PE-1, as can be seen in the following BGP update for the route toward subnet 172.16.6.0/24 in overlay network 2, using the MAC as GW MAC:

```
# on PE-2:
configure
    service
        vpls "evi-301"
            bgp-evpn
                ip-route-advertisement
```

```
            exit
```

```
221 2022/03/02 11:54:51.734 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1

```

In the VPRN 30 routing table on PE-2, IP prefixes are shown with an EVPN tunnel next-hop (GW MAC) as opposed to an IP next-hop, therefore, the user may think that no ARP entries are consumed by VPRN 30. However, internal ARP entries are still consumed in VPRN 30. Although not shown in the **show router 30 arp** command, the **summary** option shows the consumption of internal ARP entries for EVPN.

```
*A:PE-2# show router 30 route-table

===============================================================================
Route Table (Service: 30)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric

       int-evi-301 (ET-02:0f:ff:00:00:6a)                          0
172.16.6.0/24                                 Remote  BGP VPN   00h02m40s  170
       192.0.2.4 (tunneled)                                        10
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

There are no entries in the ARP table:

```
*A:PE-2# show router 30 arp

===============================================================================
ARP Table (Service: 30)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
No Matching Entries Found
===============================================================================
```

One internal BGP-EVPN ARP entry is consumed, as can be seen as follows:

```
*A:PE-2# show router 30 arp summary

===============================================================
ARP Table Summary (Service: 30)
===============================================================
Local ARP Entries    : 1
Static ARP Entries   : 0
Dynamic ARP Entries  : 0
Managed ARP Entries  : 0
Internal ARP Entries : 0
BGP-EVPN ARP Entries : 1
---------------------------------------------------------------
No. of ARP Entries   : 2
===============================================================
```

The number of BGP-EVPN ARP entries in the **show router 30 arp summary** command matches the number of remote valid GW MACs for VPRN 30.

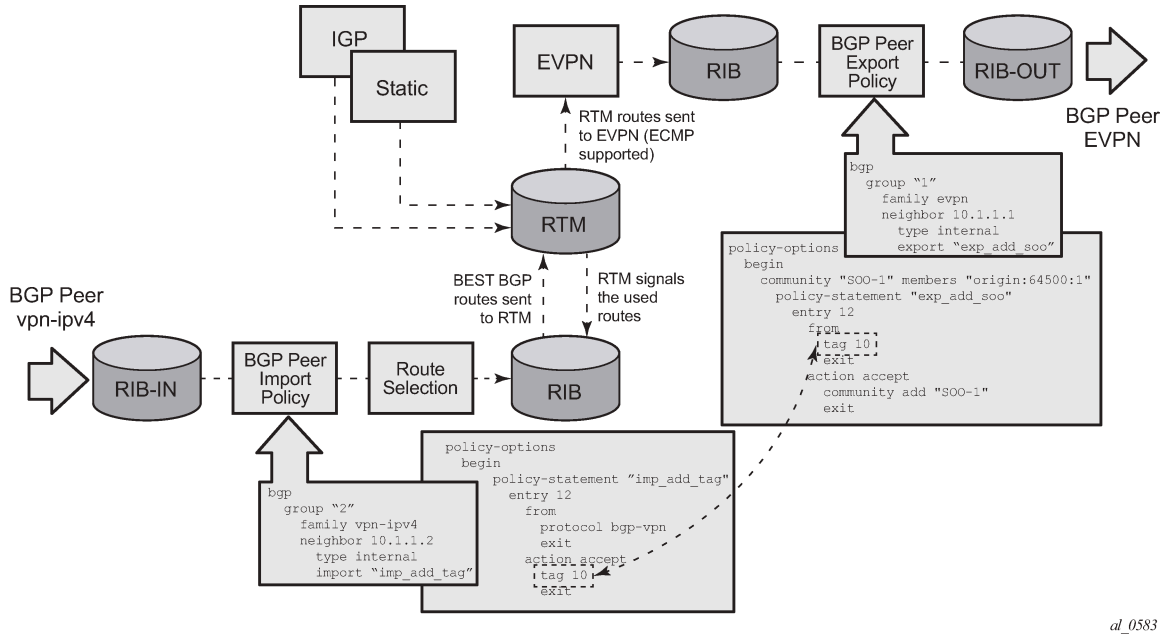
Routing policies for IP prefixes in EVPN

Routing policies are supported for IP prefixes imported or exported through BGP EVPN. The default import and export behavior for IP prefixes in EVPN can be modified by the use of routing policies applied either at peer level (**config router bgp group/group neighbor import/export**) or VPLS level (**config service vpls bgp vsi-import/vsi-export**).

When applying routing policies to control the distribution of prefixes between EVPN and IP-VPN, the user must take into account that both families are completely separated as far as BGP is concerned and that when prefixes from a family are imported in the RTM, the BGP attributes are lost to the other family. The use of tags allows the controlled distribution of prefixes across the two families.

Figure 114: Routing policies for egress EVPN routes illustrates how VPN-IPv4 routes are imported into the RTM and then passed onto EVPN for its own processing. VPN-IPv4 routes can be tagged at ingress and this tag is preserved throughout the RTM and EVPN processing so that the tag can be matched by the egress BGP routing policy. In this example, egress EVPN routes matching tag 10, are modified to add a site-of-origin (SOO) community origin:64500:1.

Figure 114: Routing policies for egress EVPN routes



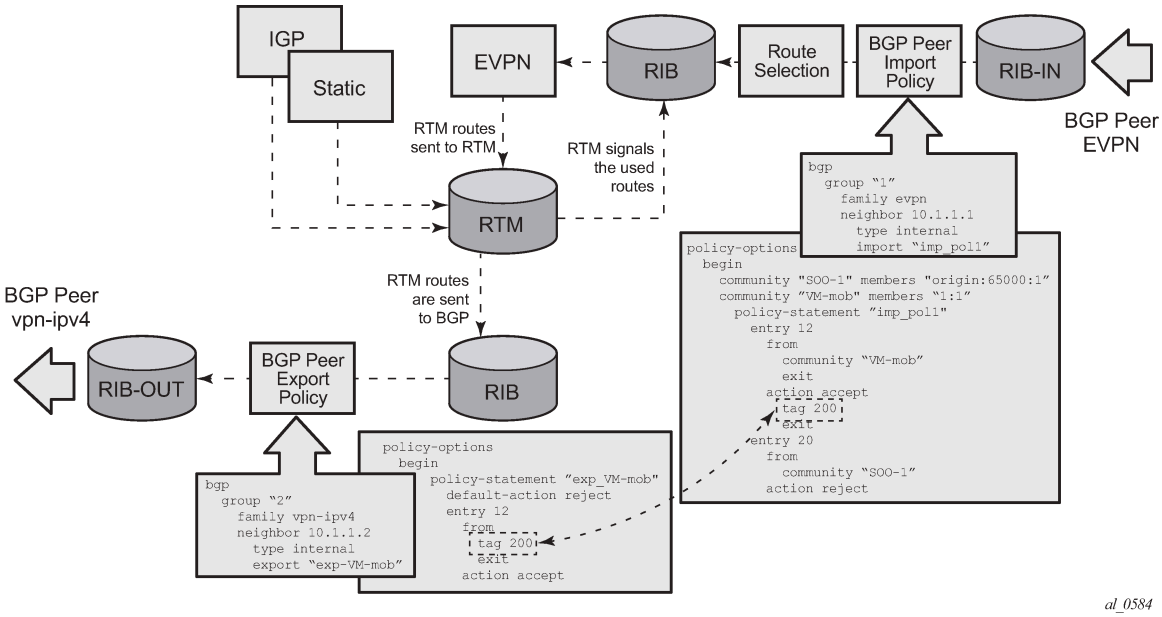
Policy tags can be used to match EVPN IP-prefixes that were learned not only from BGP VPN-IPv4 but also from other routing protocols. The tag range supported for each protocol is different:

```
*A:PE-2>config>router>policy-options>policy-statement>entry>action$ tag ?
  - no tag
  - tag <tag>

 <tag>                : tag-value      - accepts in decimal or hex
                                         [0x1..0xFFFFFFFF]H (for OSPF and ISIS)
                                         [0x1..0xFFFF]H (for RIP)
                                         [0x1..0xFFFFFFFF]H (for BGP)
                        param-name     - [32 chars max] - Must start and end with an at-sign
                                         (@)
```

Figure 115: Routing policies for ingress EVPN routes illustrates the reverse workflow: routes imported from EVPN and exported from RTM to BGPVPN-IPv4. In this example, EVPN routes received with community VM-mob are tagged with tag 200. At the egress VPN-IPv4 peers, only the routes with tag 200 are advertised.

Figure 115: Routing policies for ingress EVPN routes



The preceding behavior and the use of tags is also valid for **vsi-import** and **vsi-export** policies. The behavior can be summarized in the following statements:

- For EVPN prefix routes received and imported in RTM:
  - Routes can be matched on communities and tags can be added to them. This works at peer level or vsi-import level.
  - Well-known communities **[no-export | no-export-subconfed | no-advertise]** also require that the routing policies add a tag if the user wants to modify the behavior when exporting to BGP.
  - Routes can be matched based on family EVPN.
  - Routes cannot be matched on prefix list.
- For exporting RTM to EVPN prefix routes:
  - Routes can be matched on tags and based on that, communities added, or routes accepted or rejected (dropped), and so on. This works at peer level or vsi-export level.
  - Tags can be added for static routes, RIP, OSPF, IS-IS, and BGP and then be matched in the vsi-export policy for EVPN IP-prefix route advertisement.
  - Tags cannot be added for direct routes.

Use of routing policies to avoid routing loops in redundant PEs

When redundant PE VPRN instances are connected to the same R-VPLS service (IRB backhaul or EVPN tunnel R-VPLS) with the **ip-route-advertisement** command enabled, routing loops can occur in two different use cases:

1. Routing loop caused by EVPN and IP-VPN interaction in the RTM.
2. Routing loop caused by EVPN in parallel R-VPLS services.

Policy configuration examples for both cases are provided in the following sections.

Routing loop use-case 1: EVPN and IP-VPN interaction

This use case refers to scenarios with redundant PEs and VPRNs connected to the same R-VPLS with **ip-route-advertisement**. The scenarios in Figure 112: EVPN-VXLAN for IRB backhaul R-VPLS services (EVPN-VXLAN for IRB Backhaul R-VPLS services) and Figure 113: EVPN-VXLAN in EVPN-tunnel R-VPLS services (EVPN-VXLAN in EVPN tunnel R-VPLS services) are examples of this use case. In both scenarios, the following process causes a routing loop:

1. PE-4 advertises IP prefix 172.16.6.0/24 with preference 170 (IP-VPN) to PE-2 and PE-3.
2. PE-2 and PE-3 import prefix 172.16.6.0/24 in the VPRN routing table. PE-2 re-advertises prefix 172.16.6.0/24 with preference 169 (EVPN) to PE-1 and PE-3; PE-3 re-advertises the IP prefix in EVPN to PE-1 and PE-2.
3. PE-2 and PE-3 already have the 172.16.6.0/24 prefix in the VPRN routing table with preference 170 (IP-VPN) but because the IP prefix from EVPN has a lower preference (169), the RTM installs the EVPN prefix in the VPRN routing table.
4. PE-2 advertises the EVPN-learned IP prefix 172.16.6.0/24 to all MP-BGP VPN-IPv4 peers, including PE-3; PE-3 advertises the prefix 172.16.6.0/24 to all MP-BGP VPN-IPv4 peers, including PE-2.
5. PE-2 receives the IP prefix 172.16.6.0/24 again from PE-3 and advertises it in EVPN again, creating a routing loop. The same thing happens in PE-3.

This routing loop also happens in traditional multi-homed IP-VPN scenarios where the PE-CE eBGP and MP-BGP VPN-IPv4/v6 protocols interact in the same VPRN RTM, with different router preferences. In either case (EVPN or eBGP interaction with MP-BGP) the issue can be solved by using routing policies and site-of-origin communities.

Routing policies are applied to PE-2 and PE-3 (also to PE-4 and PE-5) and allow the redundant PEs to reject their own generated routes to avoid the loops. These routing policies can be applied at vsi-import/export level or BGP group/neighbor level. The following output shows an example of routing policies applied at BGP neighbor level for PE-2 (similar policies are applied on PE-3/4/5). Neighbor or group level policies are the preferred way in this kind of use case: a single set of policies is sufficient, as opposed to a set of policies per service (if the policies are applied at vsi-import/export level).

The following policies are applied in the BGP group or BGP group/neighbor context on PE-2:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            community "SOO-PE-2"
                members "origin:2:1"
            exit
            community "SOO-PE-3"
                members "origin:3:1"
            exit
            policy-statement "add-SOO_on_export"
                entry 10
                    from
                        tag 2
                    exit
                    action accept
                        community add "SOO-PE-2"
                    exit
                exit
                entry 20
                    from
```

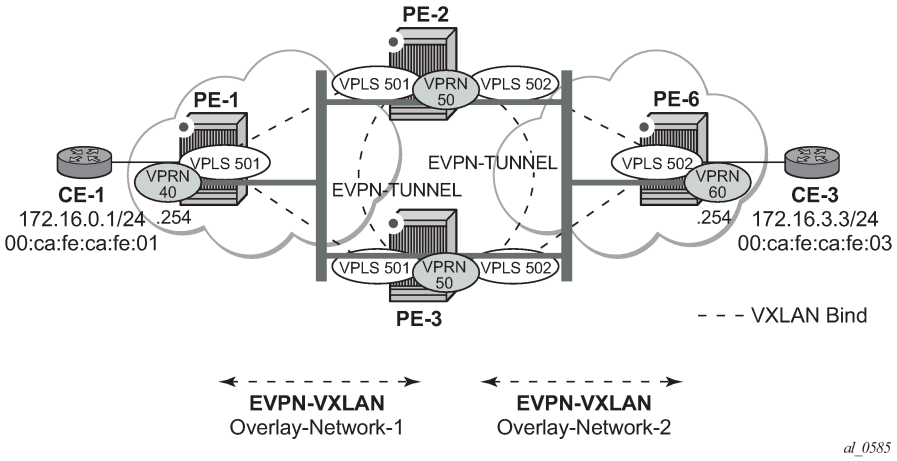
```
                    tag 3
                exit
                action accept
                    community add "SOO-PE-3"
                exit
            exit
        exit
        policy-statement "reject_based_on_SOO"
            entry 10
                from
                    community "SOO-PE-2"
                exit
                action drop
                exit
            exit
            entry 20
                from
                    community "SOO-PE-3"
                exit
                action drop
                exit
            exit
        exit
        policy-statement "add-tag_to_bgp-vpn_routes"
            entry 10
                from
                    protocol bgp-vpn
                exit
                action accept
                    tag 2
                exit
            exit
        exit
        policy-statement "add-tag_to_bgp-evpn_routes"
            entry 10
                from
                    family evpn
                exit
                action accept
                    tag 2
                exit
            exit
        exit
        commit
    exit
    bgp
        group "DC"
            neighbor 192.0.2.1
                import "add-tag_to_bgp-evpn_routes"
            exit
            neighbor 192.0.2.3
                import "reject_based_on_SOO"
                export "add-SOO_on_export"
            exit
        exit
        group "WAN"
            import "add-tag_to_bgp-vpn_routes"
        exit
```

EVPN and MP-BGP routes are tagged at import; on export, a site-of-origin community is added. Routes exchanged between the two redundant PEs are dropped if they are received by a PE with its own site-of-origin.

Routing loop use-case 2: EVPN in parallel R-VPLS services

If a VPRN is connected to more than one R-VPLS with **ip-route-advertisement** enabled, IP prefixes that belong to one R-VPLS are advertised into the other R-VPLS and vice versa. When redundant PEs are used, a routing loop will occur. Figure 116: EVPN in parallel R-VPLS services illustrates this use case. The example shows R-VPLS with an EVPN tunnel configuration, but the same routing loop occurs for regular IRB backhaul R-VPLS services.

Figure 116: EVPN in parallel R-VPLS services



The configuration of VPRN 50 as well as VPLS 501/502 and the required policies are as follows. For this use case, policies must be applied at vsi-import/export level because more granularity is required when modifying the imported/exported routes.

```
# on PE-2:
configure
    service
        vprn 50 name "VPRN50" customer 1 create
            interface "int-evi-501" create
                vpls "evi-501"
                    evpn-tunnel
                exit
            exit
            interface "int-evi-502" create
                vpls "evi-502"
                    evpn-tunnel
                exit
            exit
            no shutdown
        exit
        vpls 501 name "evi-501" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 501 create
            exit
            bgp
                route-distinguisher 192.0.2.2:501
                vsi-export "vsi-export-policy-501"
                vsi-import "vsi-import-policy-501"
            exit
            bgp-evpn
```

```
            ip-route-advertisement
            vxlan bgp 1 vxlan-instance 1
                no shutdown
            exit
        exit
        no shutdown
    exit
    vpls 502 name "evi-502" customer 1 create
        allow-ip-int-bind
        exit
        vxlan instance 1 vni 502 create
        exit
        bgp
            route-distinguisher 192.0.2.2:502
            vsi-export "vsi-export-policy-502"
            vsi-import "vsi-import-policy-502"
        exit
        bgp-evpn
            ip-route-advertisement

Troubleshooting and debug commands

For general information on EVPN and VXLAN troubleshooting and debug commands, see chapter EVPN for VXLAN Tunnels (Layer 2). The following information focuses on specific commands for Layer-3 applications.

When troubleshooting and operating an EVPN-VXLAN scenario with inter-subnet forwarding, it is important to check the IP prefixes and next-hops, as well as ARP tables and FDB tables:

- **show router** <*..*> **route-table**
- **show router** <*..*> **arp**
- **show service id** <*..*> **fdb detail**

ICMP commands can also help checking the connectivity. When traceroute is used on EVPN-VXLAN in EVPN tunnel interfaces, EVPN tunnel interface hops in the traceroute commands are showing the VPRN loopback address or the other non EVPN-tunnel interface address. In VPRN services where all the interfaces are EVPN tunnels, ICMP packets fail until an IP address is configured. The following output shows a traceroute from VPRN 30 in PE-1 to CE-6 and from PE-2 to CE-1 (see Figure 113: EVPN-VXLAN in EVPN-tunnel R-VPLS services):

```
*A:PE-1# traceroute router 30 172.16.6.6
traceroute to 172.16.6.6, 30 hops max, 40 byte packets
  1  0.0.0.0  * * *
  2  0.0.0.0  * * *
  3  172.16.6.254 (172.16.6.254)    4.98 ms  4.77 ms  4.97 ms
  4  172.16.6.6 (172.16.6.6)    7.64 ms  4.88 ms  5.14 ms
```

```
*A:PE-2# traceroute router 30 172.16.1.1
traceroute to 172.16.1.1, 30 hops max, 0 byte packets
No route to destination. Address: 172.16.1.1, Service: 30
```

When troubleshooting R-VPLS services, specifically R-VPLS services configured as EVPN tunnels, the limit of peer PEs per EVPN tunnel service is much higher than for a regular R-VPLS service because the egress <VTEP, VNI> bindings do not have to be added to the multicast flooding list. For this reason, the following **tools dump** command has been added to check the consumed/total EVPN tunnel next hops. The number of EVPN tunnel next hops matches the number of remote GW MAC addresses per EVPN tunnel R-VPLS service.

```
*A:PE-1# tools dump service id 501 evpn usage

Evpn Tunnel Interface IP Next Hop: 2/8189
```

Finally, when troubleshooting EVPN routes and routing policies, the **show router bgp routes evpn** command and its filters can help:

- Check that the expected routes are received, properly imported, and communities/tags added/replaced/removed.
- Check that the expected routes are sent, properly exported, and communities added/replaced/removed.

Examples of EVPN IP prefix routes including communities and tags are the following.

```
*A:PE-2# show router bgp routes evpn ?
  - evpn <evpn-type>

      auto-disc       - Display BGP EVPN Auto-Disc Routes
      eth-seg         - Display BGP EVPN Eth-Seg Routes
      incl-mcast      - Display BGP EVPN Inclusive-Mcast Routes
      ip-prefix       - Display BGP EVPN IPv4-Prefix Routes
      ipv6-prefix     - Display BGP EVPN IPv6-Prefix Routes
      mac             - Display BGP EVPN Mac Routes
      mcast-join-syn* - Display BGP EVPN Mcast Join Sync Routes
      mcast-leave-sy* - Display BGP EVPN Mcast Leave Sync Routes
      smet            - Display BGP EVPN Smet Routes
```

```
      spmsi-ad        - Display BGP EVPN Spmsi AD Routes
```

```
*A:PE-2# show router bgp routes evpn ip-prefix ?
  - ip-prefix [hunt|detail] [rd <rd>] [prefix <ip-prefix/ip-prefix-length>]
      [community <comm-id>] [tag <tag>] [next-hop <next-hop>] [aspath-regex <reg-exp>]

 <hunt|detail>        : keywords
 <rd>                 : {<ip-addr:comm-val>|
                        <2byte-asnumber:ext-comm-val>|
                        <4byte-asnumber:comm-val>}
 <ip-prefix/ip-pref*> : ip-address     - a.b.c.d (host bits must be 0)
                        mask           - [0..32]
 <comm-id>            : <as-number1:comm-val1>|<ext-comm>|
                        <well-known-comm>
                        ext-comm        - <type>:{<ip-address:comm-val1>|

Conclusion

SR OS supports not only the EVPN control plane for VXLAN tunnels in Layer 2 applications but also the simultaneous use of EVPN and VXLAN for VPN customers (tenants) with intra and inter-subnet connectivity requirements. R-VPLS services can be configured to provide default gateway connectivity to hosts, IRB backhaul connectivity to VPRN services, and EVPN tunnel connectivity to VPRN services.

When configured to do so, EVPN can advertise IP prefixes and interact with the VPRN RTM to propagate IP prefix connectivity between EVPN and other routing protocols in the VPRN, including IP-VPN. This example has shown how to configure R-VPLS services for all these functions, as well as how to configure routing policies for EVPN-based IP prefixes.

EVPN Interconnect Ethernet Segments

This chapter provides information about EVPN Interconnect Ethernet Segments.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the CLI in the current edition corresponds to SR OS Release 21.2.R2.

Chapters EVPN for MPLS Tunnels, EVPN for VXLAN Tunnels (Layer 2) and EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services are prerequisite reading.

Overview

SR OS supports Interconnect Ethernet Segments (I-ESs) for VXLAN as per the IETF *draft-ietf-bess-dci-evpn-overlay*. An I-ES is a virtual Ethernet Segment (vES) that allows Data Center Gateways (DCGWs) with two BGP instances (one for EVPN-MPLS and one for EVPN-VXLAN) to handle redundancy in VXLAN access networks. I-ESs support the RFC 7432 multi-homing functions, including single-active and all-active, ESI-label based split-horizon filtering, Designated Forwarder (DF) election, aliasing, and backup functions on remote EVPN-MPLS PEs.

The chapter EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services describes how VPLS services with two BGP instances are configured and describes a redundant mechanism referred to as Multi-homed anycast configuration for dual BGP-instance VPLS services. The use of I-ESs is recommended over this anycast configuration.

In addition to the EVPN multi-homing features, the main advantages of the I-ES solution compared to the redundant solution (described in Anycast Redundant Solution for Dual BGP-instance Services) are as follows:

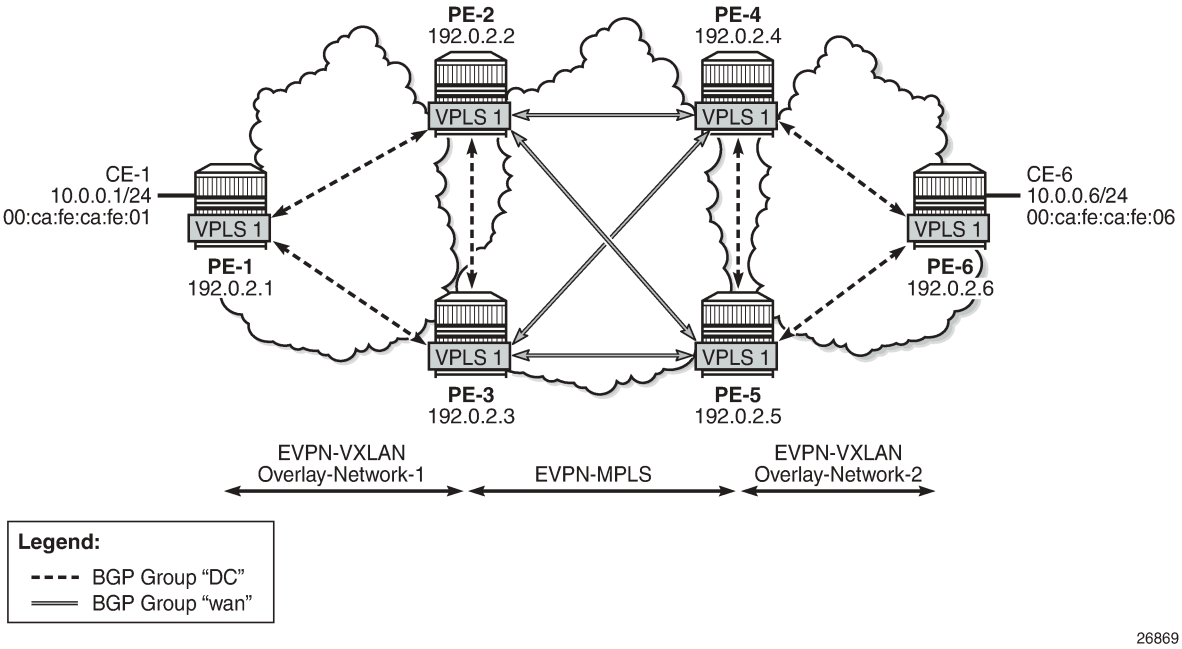
- The use of I-ES for redundancy in dual BGP-instance services allows local SAPs on the DCGWs. This is not supported in the anycast solution.
- P2MP mLDP can be provisioned to transport Broadcast, Unknown unicast, and Multicast (BUM) traffic between DCs that use I-ES, without any risk of packet duplication. As described in The use of provider tunnels on multi-homed anycast solutions, packet duplication may occur in the anycast DCGW solution when mLDP is used in the WAN.

When EVPN-MPLS networks are interconnected to EVPN-VXLAN networks, the I-ES concept and procedures apply only to the access VXLAN network; the EVPN-MPLS network does not modify its existing behavior compared to any other ES.

Configuration

Figure 117: EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology shows the topology and infrastructure configuration, which are the same as in chapter EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services. Read that chapter to see how the PEs are configured at port, IS-IS, and base BGP level.

Figure 117: EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology



PE-1, PE-2, and PE-3 simulate a data center (DC), shown as Overlay-Network-1, where PE-2 and PE-3 are DCGWs. In the same way, PE-4, PE-5, and PE-6 simulate a remote DC, Overlay-Network-2. Inside each DC, EVPN-VXLAN is used and the two DCGW pairs are connected by EVPN-MPLS. CE-1 and CE-6 are end-to-end connected by EVPN without any VLAN or Pseudowire (PW) hand-off, maintaining all the EVPN advantages across the DC Interconnect (DCI) network.

Interconnect Ethernet Segment (I-ES) configuration

After the base infrastructure is configured (interfaces, IGP, LDP in the core, and BGP EVPN peering sessions, as per Figure 117: EVPN-MPLS interconnect for EVPN-VXLAN - BGP topology), two I-ESs configured on the DCGWs show the use of the Interconnect Ethernet Segments.

The I-ES "I-ES231" is configured on PE-2 and PE-3 as follows:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES231" virtual create
                    esi 00:23:23:23:23:23:23:00:00:01
                    service-carving
                        mode manual
                        manual
```

```
                            preference non-revertive create
                                value 150
                            exit
                            evi 101 to 200
                        exit
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1 to 100
                        service-range 101 to 200
                    exit
                    no shutdown
                exit
```

```
# on PE-3:
configure
    service
        system

                            exit
                            evi 101 to 200
                        exit
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1 to 100
                        service-range 101 to 200
                    exit
                    no shutdown
                exit
```

On PE-1 and PE-2, the preceding configuration associates I-ES "I-ES231" with the VXLAN instance 1 in services contained in the range VPLS 1 to 100 and 101 to 200. The I-ES is modeled as a virtual ES, where:

- Two commands are needed within the ethernet-segment context: **network-interconnect-vxlan** and **service-id service-range** <*svc-id*> **[to** <*svc-id*>**]**.
  - The **[no] network-interconnect-vxlan** command identifies the VXLAN instance associated with the virtual ES. Only value 1 is supported in SR OS Release 21.2.R2.

    ```
    *A:PE-2>config>service>system>bgp-evpn>eth-seg# network-interconnect-vxlan ?
      - no network-interconnect-vxlan
      - network-interconnect-vxlan <instance>

     <instance>          : [1..1]
    ```

    The **[no] network-interconnect-vxlan** command is rejected in non-virtual ESs:

    ```
    *A:PE-2>config>service>system>bgp-evpn# ethernet-segment "ES-23" create
    *A:PE-2>config>service>system>bgp-evpn>eth-seg# network-interconnect-vxlan 1
    MINOR: SVCMGR #8065 Supported only on virtual ethernet segments
    ```

  - The **[no] service-range** command associates the specific service range with the ES. The ES must be configured as **network-interconnect-vxlan** before any service range can be added.
  - The other ES association options (port, lag, sdp, vc-id-range, dot1q, and qinq) are blocked in the ES when a **network-interconnect-vxlan** instance is configured.
  - The rest of the ES configuration options are supported. The **source-bmac-lsb** is blocked because the I-ES cannot be associated with I-VPLS or PBB-Epipe services.
  - All the services with two BGP instances associate the VXLAN destinations and ingress VXLAN instance with the ES.
- Multiple services (for example, 1 to 200 in the CLI above) can be associated with the same ES.
  - Up to eight service ranges per VXLAN instance can be configured. Ranges may overlap within the same ES (and not between different ESs). In this example, two non-overlapping ranges are configured to show the service range configuration, although a single range containing all the services could have been configured.
  - The service range may be configured before the service is, and it can be changed on the fly without having to disable the ES first.
- When the **network-interconnect-vxlan** I-ES is configured, the ES operational state depends exclusively on the ES admin state.
  - Because the I-ES is not associated with a physical port or SDP, when testing the non-revertive service-carving manual mode, an ethernet-segment shutdown/no shutdown will result in the node sending its own administrative preference and "Do not preempt" (pref/DP) values, and taking over if pref/DP is higher than the current DF. This is because when the ES is no shutdown, the peer ES routes are not present at the EVPN application layer, so the PE will send its own admin pref/DP values. Therefore, for I-ESs, the non-revertive mode will only work for node failures. See the chapter for more information about the preference-based and non-revertive DF election modes.
- There are no restrictions in the service-carving mode supported by I-ESs. In this example, preference-based service-carving is configured, but modes auto and (non-preference-based) manual are also supported.
- As described in the Preference-based and Non-revertive EVPN DF Election chapter, the service-carving context is configured with an EVI range that will pick up the lowest preference value when electing a DF for the service, whereas the non-configured EVI services will pick up the highest value when electing a DF. In this example, this means that, of the services allowed in the I-ES, that is, 1 to 200, services 1 to 100 will elect the highest Preference PE as DF, whereas services 101 to 200 will elect the lowest Preference PE.

PE-4 and PE-5 are configured with I-ES "I-ES451". The configuration of I-ES451 is similar to that of I-ES231; only single-active mode is configured, instead of all-active mode.

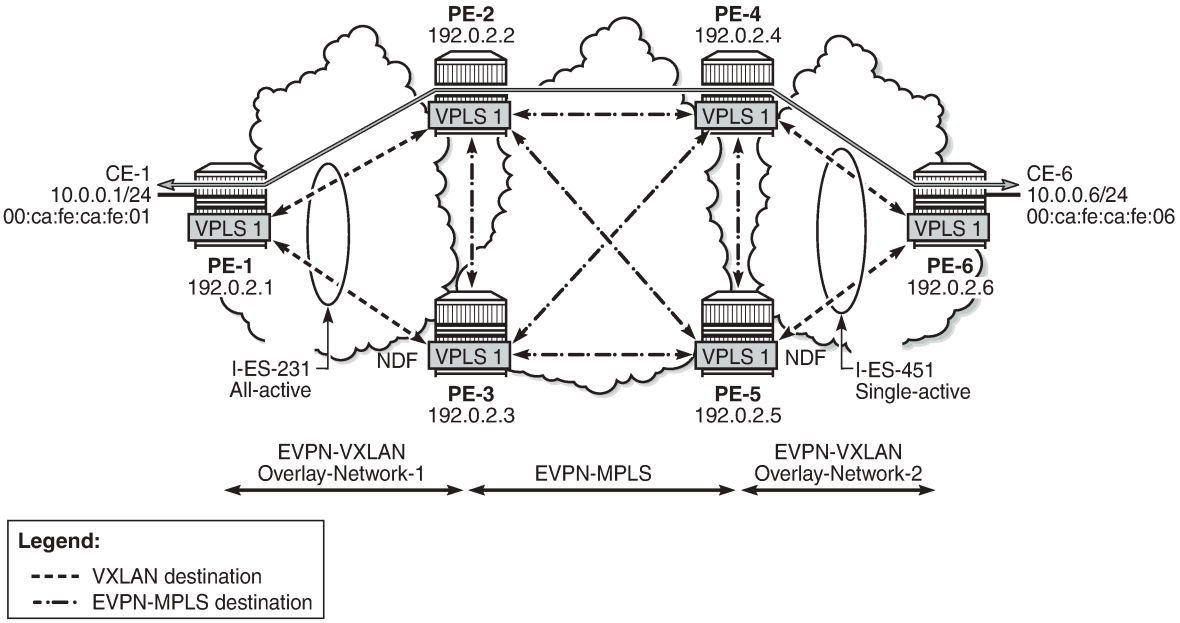
```
# on PE-4:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES451" virtual create
                    esi 00:45:45:45:45:45:45:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 150
                            exit
```

```
                        evi 101 to 200
                    exit
                exit
                multi-homing single-active
                network-interconnect-vxlan 1
                service-id
                    service-range 1 to 100
                    service-range 101 to 200
                exit
                no shutdown
            exit
```

```
# on PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES451" virtual create
                    esi 00:45:45:45:45:45:45:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 50
                            exit
                            evi 101 to 200
                        exit
                    exit
                    multi-homing single-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1 to 100
                        service-range 101 to 200
                    exit
                    no shutdown
                exit
```

In this example, VPLS 1 will be configured and associated with the preceding I-ESs. Figure 118: VPLS service and association with I-ESs shows an example of VPLS 1 and how it is associated with the I-ESs.

Figure 118: VPLS service and association with I-ESs



The configuration of VPLS 1 for PE-1, PE-2, and PE-3 is as follows. VPLS 101 is also configured in all the PEs in a similar way as VPLS 1, but not shown here. Also, the VPLS 1 configuration on the rest of the PEs is equivalent to the one in PE-1, PE-2, and PE-3, as follows:

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls
                    shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
```

```
# on PE-2:
```

```
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 192.0.2.2:1
            exit
            bgp 2
                route-distinguisher 192.0.2.2:2
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 192.0.2.3:1
            exit
            bgp 2
                route-distinguisher 192.0.2.3:2
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

As in the case of any other ESs, the association of instance and service is based on the ES configuration and there is no extra configuration required at the service level to make that association. The existing

show commands that are used to check the status of the ES can be used to check the I-ESs. For example, on I-ES231:

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "I-ES231" all

===============================================================================

The **show service id 1 vxlan instance 1 oper-flags** command shows the status of a VXLAN instance in the service. A service VXLAN instance will raise the oper-flag **MhStandby** (multi-homing standby) due to any of the following reasons:

- The PE is (single-active) non-Designated Forwarder (NDF) for that I-ES.
- The VXLAN service is added to the I-ES and either the ES is **shutdown** or **bgp-evpn>mpls** is **shutdown** in all the services included in the ES.

For example, because PE-5 is an NDF in I-ES451, the MhStandby flag will show "true":

```
*A:PE-5# show service id 1 vxlan instance 1 oper-flags

===============================================================================
VPLS VXLAN oper flags
===============================================================================
MhStandby                          : true
===============================================================================
```

EVPN route handling in dual BGP-instance VPLSs with I-ES

The configuration of I-ESs on DCGWs with two BGP instances has the following impact on the advertisement and process of the BGP-EVPN routes:

- EVPN MAC/IP routes:
  - MAC/IP routes received on the EVPN-MPLS BGP instance will be re-advertised to the EVPN-VXLAN BGP instance with the ESI set to zero in SR OS Release 21.2.R2.
  - EVPN-VXLAN PE/NVEs (Network Virtual Edge devices) in the DC will receive the same MAC address from two (or more) different MAC/IP routes from the DCGWs. The EVPN-VXLAN PE/NVEs will perform regular EVPN MAC/IP route selection.
  - MAC/IP routes received on the EVPN-VXLAN BGP instance will be re-advertised to the EVPN-MPLS BGP instance with the configured non-zero I-ESI value, assuming the VXLAN instance is not in the MhStandby operational state. MAC/IP routes received on the EVPN-VXLAN BGP instance will be dropped if the VXLAN instance is in the MhStandby state.
  - EVPN-MPLS PEs in the WAN will receive the same MAC address from two (or more) DCGWs, set with the same ESI. EVPN-MPLS PEs will perform regular aliasing and backup functions.
- ES routes are exchanged for the I-ES. They should be sent only to the MPLS network and not to the VXLAN side. This can be achieved by using router policies. In any case, because ES routes use an ES-import route-target extended community, they should not be imported by VXLAN PEs.

- Auto-discover per ES (AD per-ES) and AD per-EVI routes are also advertised for the I-ES. They should be sent only to the MPLS network and not to the VXLAN network. As for ES routes, router policies can be used to prevent AD routes being sent to VXLAN peers.

Required BGP policies to avoid control plane loops

Usually, the use of router policies is required when I-ESs are used for redundancy, to avoid control plane loops with MAC/IP routes. The control plane loops to be avoided are as follows:

1. Loops created by remote MAC addresses (learned on remote PE SAPs):
   a. Remote EVPN-MPLS MAC/IP routes are re-advertised into EVPN-VXLAN with a Site of Origin (SOO) extended community (added by a BGP peer or vsi-export policy) identifying the DCGW pair. The other DCGW in the pair will drop EVPN-VXLAN MAC routes tagged with the self SOO. Router policies to add SOO and drop routes received with self SOO are needed.
   b. Also, when remote EVPN-VXLAN MAC/IP routes are re-advertised into EVPN-MPLS, the DCGWs will automatically drop EVPN-MPLS MAC/IP routes received with their own non-zero I-ESI. No router policies are needed for this.
2. Loops created by local SAP MAC addresses:
   a. Local SAP MACs are learned and MAC/IP routes are advertised into both BGP instances. The MAC/IP routes advertised in the EVPN-VXLAN instance will be dropped by the peer based on the SOO router policies, as described in (1a) above, and DCGW local MACs will always be learned over the EVPN-MPLS destinations between the DCGWs.
   b. Because only EVPN-MPLS destinations exist between the DCGWs, EVPN-VXLAN MAC/IP and IMET routes exchanged between the DCGWs will be discarded and EVPN-VXLAN destinations will not be created between them.

As an example, the following BGP peer policies on PE-2 and PE-3 achieve the goals described above (similar policies would be configured on PE-4 and PE-5) and summarized as follows:

- Avoid sending service VXLAN routes to MPLS peers, and service MPLS routes to VXLAN peers.
- Avoid sending AD and ES routes to VXLAN peers.
- Add SOO to VXLAN routes to be sent to the ES peer.
- Drop VXLAN routes received from the ES peer.

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            community "mpls"
                members "bgp-tunnel-encap:MPLS"
            exit
            community "vxlan"
                members "bgp-tunnel-encap:VXLAN"
            exit
            community "SOO-DCGW-23"
                members "origin:64500:23"
            exit
```

The following policy prevents the router from sending service VXLAN routes to MPLS peers:

```
            policy-statement "allow only mpls"
```

```
                entry 10
                    from
                        community "vxlan"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
```

The following policy makes sure the router exports only routes that include the VXLAN encapsulation:

```
            policy-statement "allow only vxlan"
                entry 10
                    from
                        community "vxlan"
                        family evpn
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
```

The following import policy avoids importing routes with self SOO:

```
            policy-statement "drop SOO-DCGW-23"
                entry 10
                    from
                        community "SOO-DCGW-23"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
```

The following export policy adds SOO but only to VXLAN routes. This allows the peer to drop routes based on the SOO, without affecting the MPLS routes.

```
            policy-statement "add SOO to vxlan routes"
                entry 10
                    from
                        community "vxlan"
                        family evpn
                    exit
                    action accept
                        community add "SOO-DCGW-23"
                    exit
                exit
                default-action accept
                exit
            exit
```

The BGP configuration for PE-2 and PE-3 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
```

```
        router-id 192.0.2.2

                export "allow only vxlan"
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                    import "drop SOO-DCGW-23"
                    export "add SOO to vxlan routes"
                exit
            exit
            group "wan"
                type internal
                export "allow only mpls"
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

Single-active multi-homing operation

When the I-ES is configured as **single-active** and **no shutdown** (assuming at least one service is associated), the DCGWs will send ES and AD routes as usual for any ES, and run DF election based on the ES routes, with the candidate list being pruned by the AD routes.

In Figure 118: VPLS service and association with I-ESs, PE-4 and PE-5 are configured with I-ES451, which is a single-active ES. The NDF for a service (PE-5 for VPLS 1 in the example) will perform the following tasks:

- The VXLAN instance on the NDF will enter the MhStandby state and will block ingress and egress traffic on the VXLAN destinations associated with the I-ES.

```
A:PE-5# show service id 1 vxlan instance 1 oper-flags

===============================================================================
VPLS VXLAN oper flags
===============================================================================
MhStandby                          : true
===============================================================================
```

- MAC/IP routes and FDB process:
  - Advertised MAC/IP routes that are associated with the VXLAN instance are withdrawn.
  - Advertised MAC/IP routes corresponding to local SAP MAC addresses or EVPN-MPLS binding MAC addresses are withdrawn if they were advertised to the EVPN-VXLAN instance.
  - Received MAC/IP routes associated with the VXLAN instance are not installed in FDB. The MAC routes will show as "used" in the **show router bgp routes evpn mac** commands; however, only the MAC addresses received from MPLS (in particular from the ES peer) will be programmed. As an example, the following CLI output shows how MAC address 00:ca:fe:ca:fe:06 is learned on PE-4 (DF) and associated with the VXLAN destination to PE-6, whereas the MAC address is installed associated with an MPLS destination (remote ES) on PE-5 (NDF).

```

- Inclusive Multicast Ethernet Tag (IMET) routes process:
  - IMET-Assisted Replication with replicator role (IMET-AR-R) routes are withdrawn if the VXLAN instance enters the MhStandby state. Only the DF will advertise the IMET-AR-R routes. For more information on AR, see chapter Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.
  - IMET-Ingress Replication advertisements (IMET-IR) routes, in case of NDF (or the MhStandby state), are controlled by the **config>service>vpls>bgp-evpn>vxlan# [no] send-imet-ir-on-ndf** command.
    - By default, the command is enabled and the router will advertise IMET-IR routes even if the PE is NDF (MhStandby). This will attract BUM traffic (even if the NDF ends up dropping it); however, attracting BUM traffic will also speed up convergence in case of DF switchover. The command works for single-active and all-active.
    - If disabled, the router will withdraw the IMET-IR routes when the PE is NDF and will not attract BUM traffic.

In spite of not sending BUM or unicast traffic, the NDF for a service still creates the VXLAN bindings; however, they are not associated with any MAC addresses and they are flagged as non-multicast capable, or "-" in the Mcast column of the following command:

```
*A:PE-5# show service id 1 vxlan destinations

```

The I-ES DF PE for the service (PE-4) will continue advertising IMET and MAC/IP routes for the associated VXLAN instance. Forwarding will also happen as usual on the DF VXLAN bindings. When the DF PE receives BUM traffic from VXLAN, it will send it, adding the egress ESI label if needed.

All-active multi-homing operation

The same considerations as in single-active for ES and AD routes and DF election apply to all-active multi-homing. In Figure 118: VPLS service and association with I-ESs, PE-2 and PE-3 are configured with I-ES231, which is an all-active ES. The NDF PE for a service (PE-3 for VPLS 1, in the example) will show the following behavior:

- The VXLAN instance on the NDF will not enter the MhStandby state because it will still forward unicast traffic:

```
*A:PE-3# show service id 1 vxlan instance 1 oper-flags

===============================================================================
VPLS VXLAN oper flags
===============================================================================
MhStandby                           : false
===============================================================================
```

- MAC/IP routes and FDB process: MAC/IP routes are received, installed, and advertised as in the DF router.
- IMET routes process:
  - As in the single-active case, IMET-AR-R routes are withdrawn on the NDF. Only the DF will advertise the IMET-AR-R routes.
  - Also, as in the single-active case, IMET-IR advertisement from the NDF will be controlled by the **config>service>vpls>bgp-evpn>vxlan# [no] send-imet-ir-on-ndf** command. Advertising the IMET-IR route from the NDF will attract BUM traffic from the VXLAN PEs to the NDF, even though the unknown unicast traffic will be forwarded only when it is safe to do so. See section All-active multi-homing and unknown unicast forwarding on the NDF for more information about unknown unicast forwarding.

Contrary to the behavior in single-active multi-homing, in all-active, the NDF will forward unknown unicast to the VXLAN PEs as usual, but block broadcast and multicast in the upstream and downstream direction. In our example, the NDF for VPLS 1 (PE-3) will show the VXLAN destinations created as "U" (Unknown unicast) in the Mcast column of the **show service id 1 vxlan** command, as follows:

```
*A:PE-3# show service id 1 vxlan destinations

All-active multi-homing and unknown unicast forwarding on the NDF

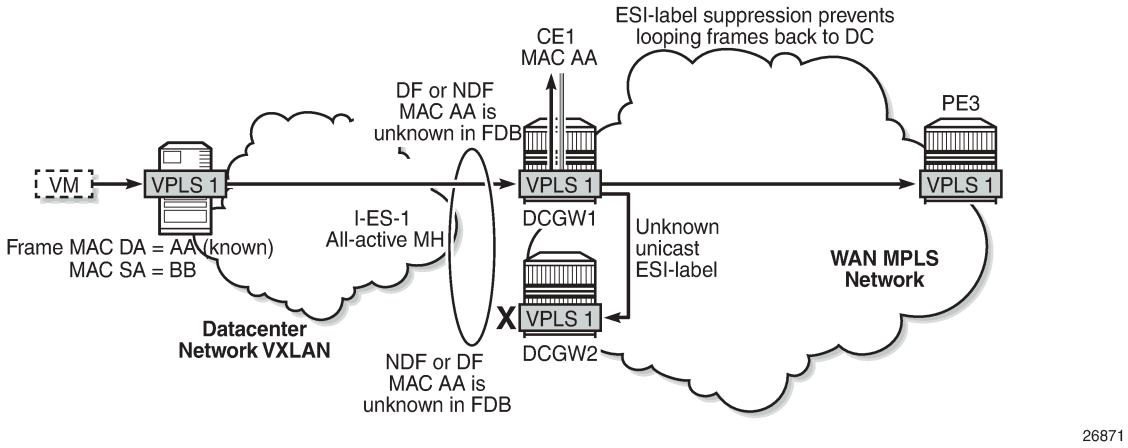
The unknown unicast traffic will be transmitted on the (all-active multi-homing) NDF in the upstream and downstream directions only in those cases where there is no risk of packet duplication. The router considers there is no risk when transmitting an unknown unicast packet on the NDF if:

- Unknown unicast packet arrives without an ESI label.
- Unknown unicast packet arrives without a BUM label (label advertised by an IMET route as opposed to a MAC/IP route).
- Unknown unicast packet passes a MAC Source Address (MAC SA) suppression (MAC SA lookup does not yield an entry associated with the I-ES).

The following examples show how unknown unicast traffic is handled in all-active I-ESs.

Figure 119: All-active multi-homing and unknown unicast example 1 shows an example with two DCGWs where (all-active) I-ES-1 is defined.

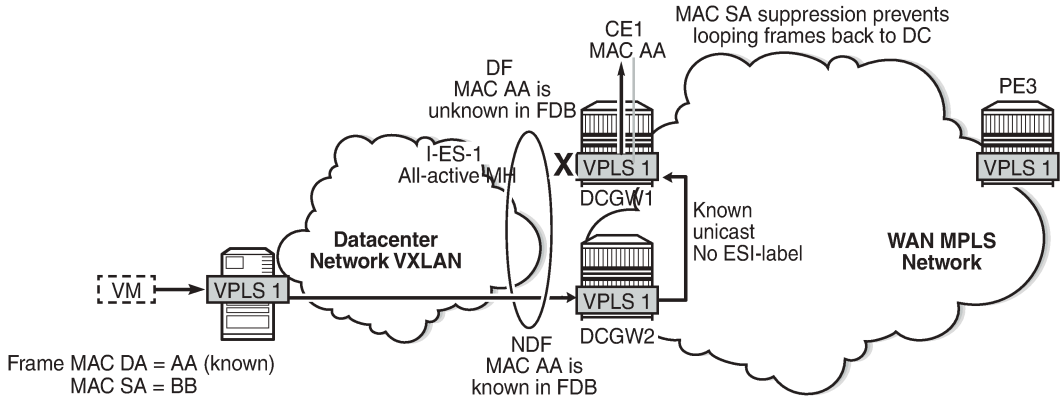
Figure 119: All-active multi-homing and unknown unicast example 1



The VXLAN PE/NVE transmits known unicast traffic, whereas DCGW1 has not learned the MAC address yet. Regardless of the DCGW1 being DF or NDF, it will accept unknown unicast and will flood to local SAPs and EVPN destinations. When sending to DCGW2, the router will send the ESI label identifying the I-ES. DCGW2 will not send unknown traffic back to the DC due to the ESI-label suppression on the I-ES.

Figure 120: All-active multi-homing and unknown unicast example 2 shows a similar example where the VXLAN node sends known unicast with MAC Destination Address (MAC DA) "AA" to DCGW2.

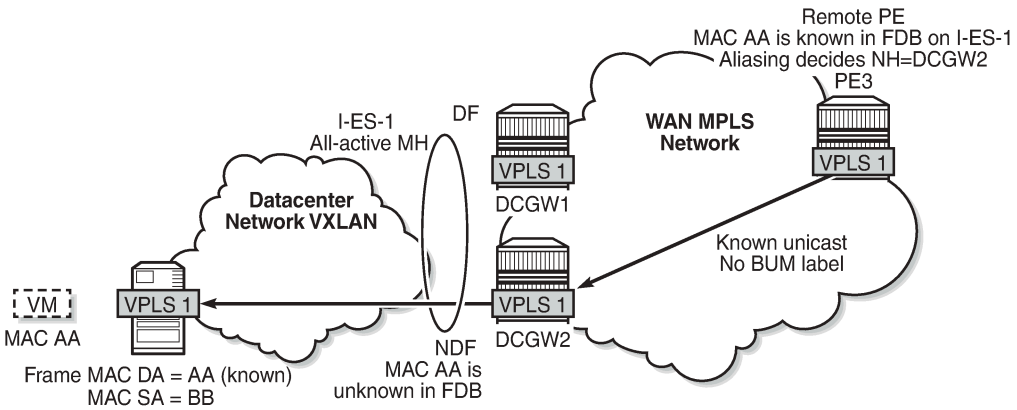
Figure 120: All-active multi-homing and unknown unicast example 2



DCGW2 does a MAC lookup and sends the frame as known unicast to DCGW1 via the EVPN-MPLS destination. However, MAC AA is unknown in DCGW1 for some reason (such as FDB limit exceeded, SAP failure, and so on). In this case, DCGW1 will flood the frame to CE1 and not to the VXLAN network. Even though the frame is not coming with an ESI label, the DCGW1 router does a MAC SA suppression and will not send unknown unicast frames to the I-ES. MAC SA suppression means that the router will do a MAC SA lookup on the FDB and will suppress the flooding to the I-ES if the MAC SA is learned on the I-ES (as in Figure 120: All-active multi-homing and unknown unicast example 2).

Figure 121: All-active multi-homing and unknown unicast example 3 shows an example in which the NDF forwards "no-risk" unknown unicast traffic to avoid black-holes.

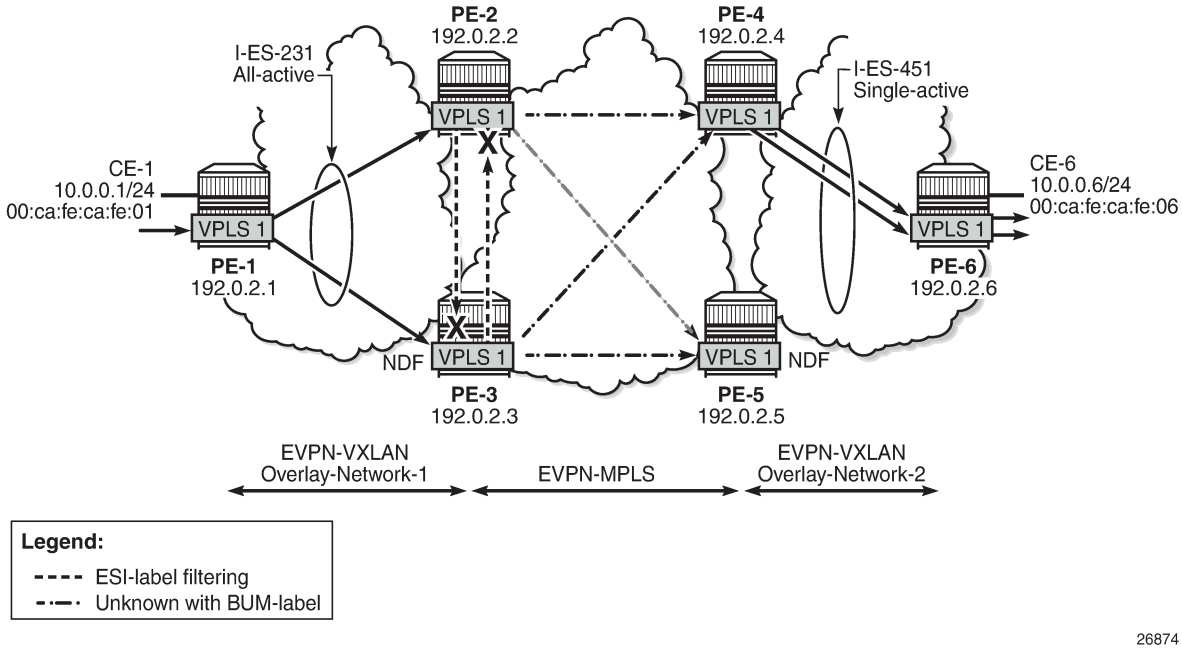
Figure 121: All-active multi-homing and unknown unicast example 3



PE3 receives unicast traffic with MAC DA = AA. The MAC address is known in the FDB and associated with I-ES-1; therefore, because PE3 is configured to do aliasing to DCGW1 and DCGW2 (bgp-evpn>mpls# ecmp 2), a packet hash determines that it has to be sent to DCGW2 (NDF). The packet arrives at DCGW2 with a unicast label. DCGW2 does a lookup and MAC AA is unknown for some reason (such as FDB limit exceeded, MAC not learned yet, and so on). In this case, DCGW2 will forward the packet to the I-ES VXLAN bindings, even if it is NDF. This behavior avoids black-hole periods in the network for unicast traffic.

Finally, in some cases, the unknown unicast forwarding behavior on the NDF may cause some transient packet duplication that can be avoided by configuring the **no send-imet-ir-on-ndf** command. The following example shows the use of this command to avoid transient packet duplication. Figure 122: All-active multi-homing and send-imet-ir-on-ndf shows how transient packet duplication may occur with the default setting **send-imet-ir-on-ndf**.

Figure 122: All-active multi-homing and send-imet-ir-on-ndf



Transient packet duplication may occur when sending unknown unicast from CE-1 to CE-6, if **send-imet-ir-on-ndf** is configured in PE-3 and PE-2. To show this, we clear the FDBs in all the PEs in the example as well as the ARP caches on the CEs.

The following command is executed in all the PEs and CEs:

```
*A:PE-1# clear service id 1 fdb all
*A:PE-1#
*A:PE-1# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

-------------------------------------------------------------------------------
No. of ARP Entries: 1
===============================================================================
```

When ICMP traffic is sent from CE-1 to CE-6, a duplicate entry occurs on CE-1:

```
*A:PE-1# ping router 300 10.0.0.6
PING 10.0.0.6 56 data bytes
64 bytes from 10.0.0.6: icmp_seq=1 ttl=64 time=13.2ms.
64 bytes from 10.0.0.6: icmp_seq=1 ttl=64, duplicate.
64 bytes from 10.0.0.6: icmp_seq=2 ttl=64 time=5.27ms.
64 bytes from 10.0.0.6: icmp_seq=3 ttl=64 time=5.25ms.
64 bytes from 10.0.0.6: icmp_seq=4 ttl=64 time=4.73ms.
64 bytes from 10.0.0.6: icmp_seq=5 ttl=64 time=4.80ms.

---- 10.0.0.6 PING Statistics ----
5 packets transmitted, 5 packets received, 1 duplicate
round-trip min = 4.73ms, avg = 6.66ms, max = 13.2ms, stddev = 3.29ms
```

This duplicate entry occurs because the packet gets to CE-6 twice and CE-6 sends two unicast ICMP reply messages back. From the CE-1 packet walkthrough:

- PE-1 floods the packet to PE-2 and PE-3 because the CE-6 MAC DA is unknown and it has VXLAN multicast destinations to them.
- PE-2 floods the unknown unicast packet to all the remote PEs because it is DF for I-ES231. PE-2 will add an ESI label when sending to PE-3, and a BUM label when sending to all of them.
- PE-3 is NDF for I-ES231, but it floods the packet because the I-ES is all-active and the unknown unicast packet is considered low risk. The packet arrives with no ESI label, no BUM label (in VXLAN, VNIs are the same for unicast and BUM), and the MAC SA suppression passes because the packet is coming from the I-ES and not from MPLS. PE-3 uses a BUM label when flooding the packet and an ESI label when sending to PE-2.
- PE-4 receives two unknown unicast packets and forwards both to PE-6.
- PE-5 does not forward because it is NDF. This is true regardless of the I-ES being single-active or all-active (if all-active, the packet will not be forwarded because it arrives with a BUM label).

This packet duplication situation is transient and it will stop as soon as the two MAC addresses are learned on the PEs. However, if needed, this situation can be avoided by configuring **no send-imet-ir-on-ndf** (the BGP-EVPN VXLAN must be disabled first):

```
# on PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            bgp-evpn
                vxlan
                    shutdown
                    no send-imet-ir-on-ndf
                    no shutdown
```

This command will make the NDF (PE-3) withdraw the IMET-IR route; therefore, PE-1 will only flood unknown unicast packets to the DF (PE-2). The following IMET-IR routes are received on PE-1: one route sent by DF PE-2 for VPLS 1 and two routes for VPLS 101.

```
*A:PE-1# show router bgp routes evpn incl-mcast

```

If a DF switchover occurs in the I-ES, the new DF would advertise the IMET-IR route and the new NDF would withdraw it.

After clearing FDBs and ARP caches again, the test is repeated with no packet duplication. Figure 123: All-active multi-homing and no send-imet-ir-on-ndf shows how PE-1 does not send unknown unicast to PE-3 (NDF) anymore and, therefore, there is no duplication.

```

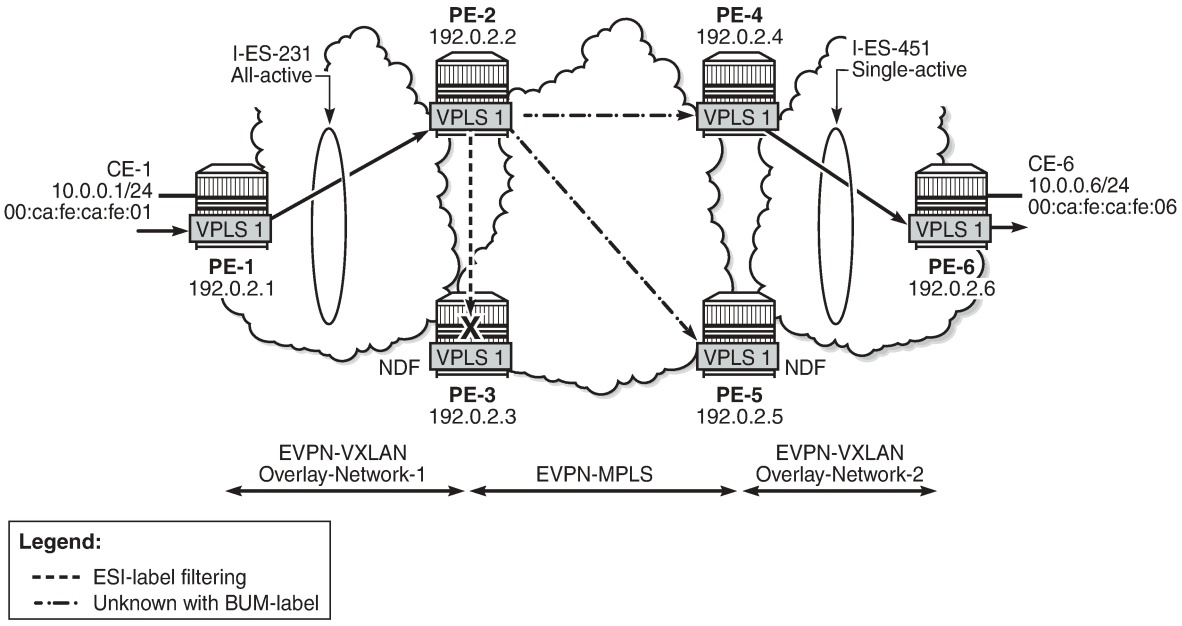
Figure 123: All-active multi-homing and no send-imet-ir-on-ndf



Local SAPs and provider tunnels along with I-ES

As described in the Overview section, the main advantages of the I-ES solution over the anycast redundant solution for dual BGP-instance services are the support of local SAPs and P2MP mLDP trees without packet duplication. This section shows the configuration of local SAPs and provider tunnels along with I-ES in VPLS services. The local SAPs can, at the same time, belong to an ES or a vES.

As an example, VPLS 1 on PE-2 is reconfigured as follows (similar configuration on PE-3, with provider tunnel also configured on PE-4 and PE-5):

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 192.0.2.2:1
            exit
            bgp 2
                route-distinguisher 192.0.2.2:2
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
```

```
                    resolution any
                exit
                no shutdown
            exit
        exit
        provider-tunnel
            inclusive
                owner bgp-evpn-mpls
                root-and-leaf
                mldp
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap lag-1:1 create
            no shutdown
        exit
        no shutdown
```

To have EVPN multi-homing from a CE locally connected to PE-2 and PE-3, an additional ES is configured on PE-2 and PE-3 that will include the local SAPs in VPLS 1, as follows:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES231" virtual create
                    esi 00:23:23:23:23:23:23:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 150
                            exit
                            evi 101 to 200
                        exit
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1 to 100
                        service-range 101 to 200
                    exit
                    no shutdown
                exit
                ethernet-segment "vES232" virtual create
                    esi 00:23:23:23:23:23:23:00:00:02
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 1
                    exit
                    no shutdown
                exit
```

Troubleshooting and debugging

Common troubleshooting commands to operate dual BGP-instance VPLS services are in the corresponding section of EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services. Also, ES and virtual ES can be troubleshot by using the commands described in chapter EVPN for MPLS Tunnels.

As well, the following **show** commands are specific to the use of I-ES in the router:

```
*A:PE-2# show service id 1 vxlan instance 1 oper-flags

===============================================================================
VPLS VXLAN oper flags
===============================================================================
MhStandby                           : false
===============================================================================
```

```
*A:PE-2# show service vxlan-instance-using ethernet-segment

===============================================================================
VXLAN Ethernet-Segment Information
===============================================================================
SvcId       VXLAN Instance      ES Name                         Status
-------------------------------------------------------------------------------
1           1                   I-ES231                         DF
101         1                   I-ES231                         NDF
===============================================================================
```

```
*A:PE-2# show service vxlan-instance-using ethernet-segment "I-ES231"

===============================================================================
VXLAN Ethernet-Segment Information
===============================================================================
SvcId                            VXLAN Instance                 Status
-------------------------------------------------------------------------------
1                                1                              DF
101                              1                              NDF
===============================================================================
```

Conclusion

Based on *draft-ietf-bess-dci-evpn-overlay*, SR OS supports the connectivity of Layer 2 EVPN-VXLAN services to an EVPN-MPLS network. This chapter complements the chapter EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services by describing how redundancy can be improved with the use of I-ES multi-homing, a concept standardized in *draft-ietf-bess-dci-evpn-overlay*.

EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services

This chapter provides information about EVPN Interconnect Ethernet Segments in Dual EVPN-VXLAN Instance VPLS Services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 21.7.R1. EVPN multi-homing on dual VXLAN instance VPLS services is supported on SR OS Release 19.10.R1, and later.

Overview

Some service providers are deploying large Data Centers (DCs) where SR OS routers are used as leaf switches in a VXLAN fabric. In those cases, all-active multi-homing can provide redundancy and maximize the bandwidth utilization.

SR OS supports Interconnect Ethernet Segments (I-ESs) for VXLAN as per RFC 9014. Chapter EVPN Interconnect Ethernet Segments (I-ESs) describes how I-ESs allow Data Center Gateways (DCGWs) with two BGP instances (one for EVPN-MPLS and one for EVPN-VXLAN) to handle redundancy in VXLAN access networks, as supported in SR OS 15.0.R4, and later.

This chapter describes similar scenarios with EVPN-VXLAN in the core network instead of EVPN-MPLS. The following scenarios are supported with I-ES in VXLAN instance 1:

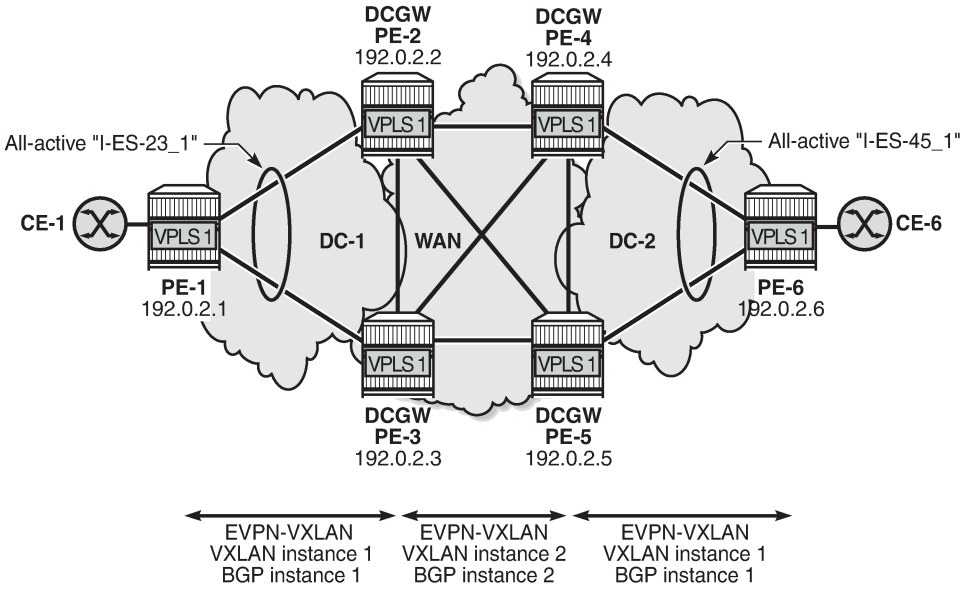
- dual instance VPLS with two EVPN-VXLAN instances
- dual instance VPLS with one EVPN-VXLAN instance and one static VXLAN instance
- dual instance VPLS with one EVPN-VXLAN instance and one EVPN-MPLS instance

The first two of these scenarios are described in this chapter.

CLI

Figure 124: Sample topology shows VPLS 1 with different EVPN-VXLAN instances: VXLAN instance 1 in DC 1 (and DC2) and VXLAN instance 2 in the WAN.

Figure 124: Sample topology



On DCGW PE-2, the following all-active I-ES is configured for VXLAN instance 1 and service id 1:

```
# on DCGW PE-2:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.2 comm-val 1 to 1000
            bgp-evpn
                ethernet-segment "I-ES-23_1" virtual create
                    esi 00:23:23:23:23:23:23:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100
                            exit
                            evi 1
                        exit
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1
                    exit
                    no shutdown
                exit
            exit
```

The following command configures VPLS 1 with dual EVPN-VXLAN instance. VXLAN instance 1 is a member of the I-ES and VXLAN instance 2 is configured with **mh-mode network** and **auto-disc-route-advertisement**:

```
# on DCGW PE-2:
configure
```

```
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 11 create
                rx-discard-on-ndf bum
            exit
            vxlan instance 2 vni 12 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:11 import target:64500:11
            exit
            bgp 2
                route-distinguisher auto-rd
                route-target export target:64500:12 import target:64500:12
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    default-route-tag 11
                    auto-disc-route-advertisement
                    no shutdown
                exit
                vxlan bgp 2 vxlan-instance 2
                    ecmp 2
                    default-route-tag 12
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

By default, the multi-homing mode for EVPN-VXLAN is access, but for VXLAN instance 2, it is modified to **mh-mode network**. The following error is raised when attempting to configure VXLAN instance 1—as a member of an I-ES—with **mh-mode network**:

```
*A:PE-2>config>service>vpls>bgp-evpn>vxlan# mh-mode network
MINOR: SVCMGR #7886 cannot modify evpn - not supported when vxlan instance is a member of an
 ethernet-segment
```

With **mh-mode network** configured, it is mandatory to configure **auto-disc-route-advertisement**; for **mh-mode access**, it is optional. When **auto-disc-route-advertisement** is enabled in an access instance associated to an I-ES, AD per-ES/EVI routes and MAC/IP routes are advertised for the I-ES.

The following AD per-EVI route is sent by DCGW PE-2:

```
13 2021/09/07 14:35:47.456 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 81
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2
```

```
        Type: EVPN-AD Len: 25 RD: 192.0.2.2:1 ESI: 00:23:23:23:23:23:23:00:00:01,
                      tag: 0 Label: 11 (Raw Label: 0xb) PathId:
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        origin:64500:23
        target:64500:11
        bgp-tunnel-encap:VXLAN
"
```

For MAC routes and their ESI value for an access VXLAN instance, the following redistribution considerations apply.

- With **mh-mode access** and **auto-disc-route-advertisement** configured, MAC routes are redistributed from the instance network to the instance access with the I-ESI if present, regardless of the original ESI.
- With **mh-mode access** and **no auto-disc-route-advertisement**, MAC routes are redistributed with zero ESI, regardless of the original ESI.

The following EVPN-MAC route is sent by DCGW PE-2 with I-ESI 00:23:23:23:23:23:23:00:00:01 of "I-ES-23_1":

```
79 2021/09/07 14:36:18.380 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 89
    Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2

        target:23:23:23:23:23:23
"
```

The following commands are not supported when **mh-mode network** is configured:

- proxy-arp/nd
- assisted replication
- source-vtep-security

Attempting to enable these unsupported commands while a BGP-EVPN VXLAN instance has **mh-mode network** triggers error messages, as follows:

```
*A:PE-2>config>service>vpls# proxy-arp
MINOR: SVCMGR #8005 Cannot create proxy arp - not supported when a bgp-evpn vxlan instance has
 mh-mode network
```

```
*A:PE-2>config>service>vpls# proxy-nd
MINOR: SVCMGR #8008 Cannot create proxy nd - not supported when a bgp-evpn vxlan instance has
 mh-mode network
```

```
*A:PE-2>config>service>vpls>vxlan# assisted-replication replicator
MINOR: SVCMGR #8111 Cannot change assisted-replicated role - not supported when vxlan instance
 is in use by bgp-evpn with mh-mode network
```

```
*A:PE-2>config>service>vpls>vxlan# source-vtep-security
MINOR: SVCMGR #7897 Cannot modify vxlan instance - not supported when vxlan instance is in use
 by bgp-evpn with mh-mode network
```

Local bias

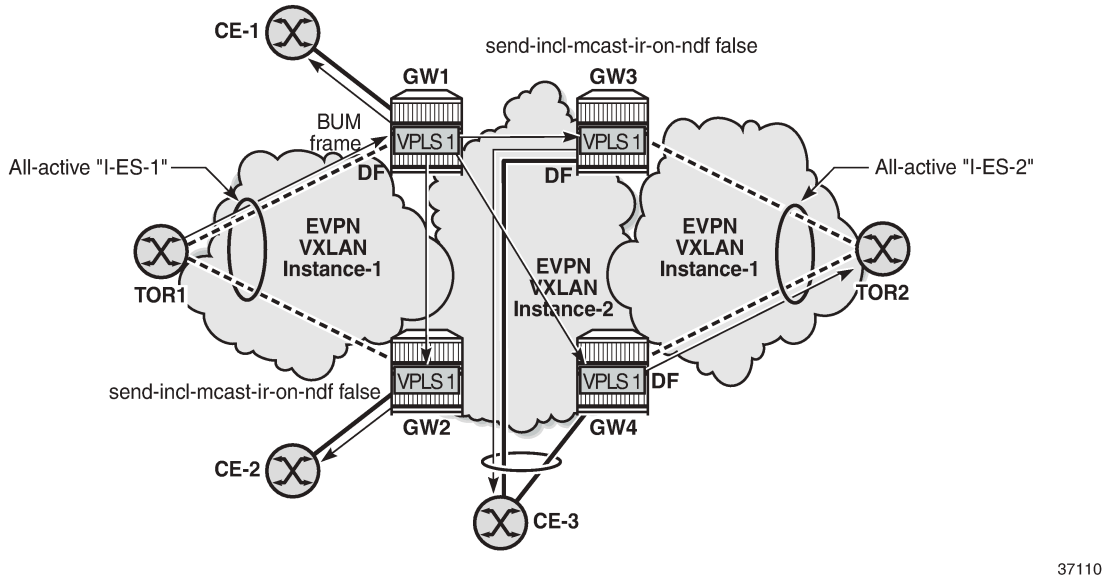
When EVPN-VXLAN is used in the instance network of a dual-instance VPLS service, local bias—as described in RFC 8365—is used for split horizon in all-active I-ESs. In VXLAN, there is no multicast label or multicast BMAC, so BUM traffic is identified by the MAC destination address. The modified forwarding rules for the I-ES-sourced BUM traffic for ingress PE and egress PE are as follows:

- ingress PE
  - The Non-Designated Forwarder (NDF) must discard BUM traffic, so one of the following two commands must be configured in VXLAN instance 1.
    - **no send-imet-ir-on-ndf**
    - **rx-discard-on-ndf bum**
  - BUM frames received on any SAP or I-ES VXLAN binding are flooded to:
    - local non-ES and single-active DF ES SAPs
    - local all-active ES SAPs (DF and NDF)
    - EVPN-VXLAN destinations (BUM frames received on an I-ES VXLAN binding follow SHG rules, so they can only be forwarded to EVPN-VXLAN destinations belonging to the other VXLAN instance.)
- egress PE
  - Look up source VTEP for BUM frames received on EVPN-VXLAN.

- If the source VTEP matches a PE with which the local PE shares an ES and a VXLAN service, then the local PE does not forward to the shared local ESs (this includes port, lag, and network-interconnect-VXLAN ESs).
- The local PE forwards to local ESs that are not shared but only when in DF state.

Figure 125: EVPN-VXLAN network interconnect VXLAN multi-homing and local bias shows the BUM forwarding with local bias procedures in multi-instance VPLS services.

Figure 125: EVPN-VXLAN network interconnect VXLAN multi-homing and local bias



In the example, GW1 and GW2 are configured with **no send-imet-ir-on-ndf**. TOR1 generates BUM traffic that will only reach DF GW1 and is forwarded as follows.

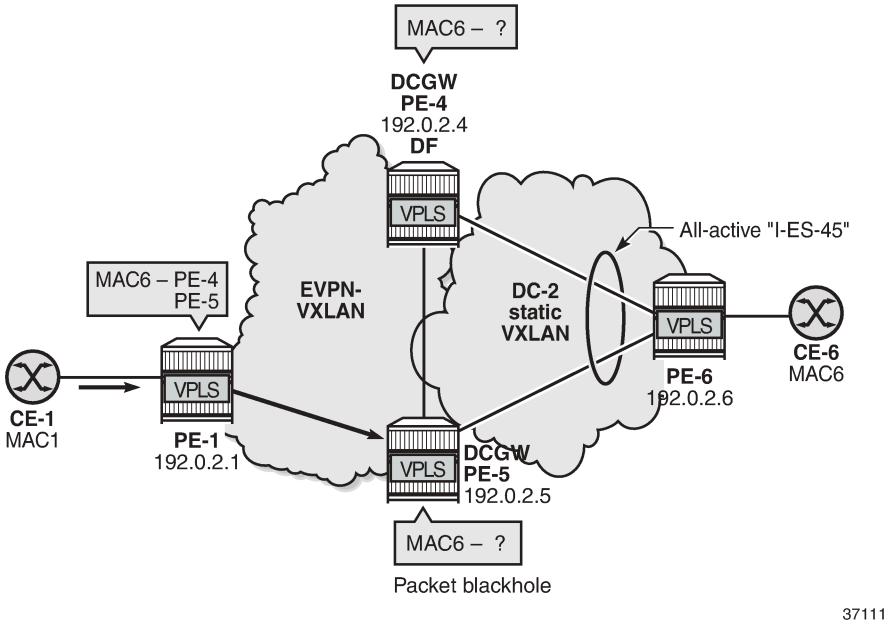
- Ingress PE GW1 forwards to CE-1 and EVPN-VXLAN destinations GW2, GW3, and GW4.
- Egress PE GW2 identifies the source VTEP as a PE with which I-ES-1 is shared, so it does not forward the BUM frames to the local I-ES. PE GW2 forwards only to the non-shared ES and local SAPs, in this case, to CE-2.
- Egress PE GW3 receives the BUM traffic with a source VTEP that does not match any PE with which GW3 shares an ES, so it forwards to all ESs that are DF, in this case, to CE-3.
- Egress PE GW4 receives the BUM traffic with a source VTEP that does not match any PE with which GW4 shares an ES, so it forwards to all ESs that are DF, in this case, to TOR2 through I-ES-2.

Local bias with static VXLAN on I-ES

When a static VXLAN instance coexists with an EVPN-VXLAN instance in the same VPLS service, traffic blackholes may occur when the static VXLAN instance is associated to an all-active I-ES. This is because, when multi-homing is used with an EVPN-VXLAN network instance, the NDF PE always discards unknown unicast traffic to the static VXLAN instance (this is not the case with EVPN-MPLS if the unknown traffic has a BUM label).

Figure 126: All-active I-ES NDF PE-5 drops unknown unicast traffic shows the packet blackhole for unknown unicast traffic at all-active I-ES NDF PE-5.

Figure 126: All-active I-ES NDF PE-5 drops unknown unicast traffic



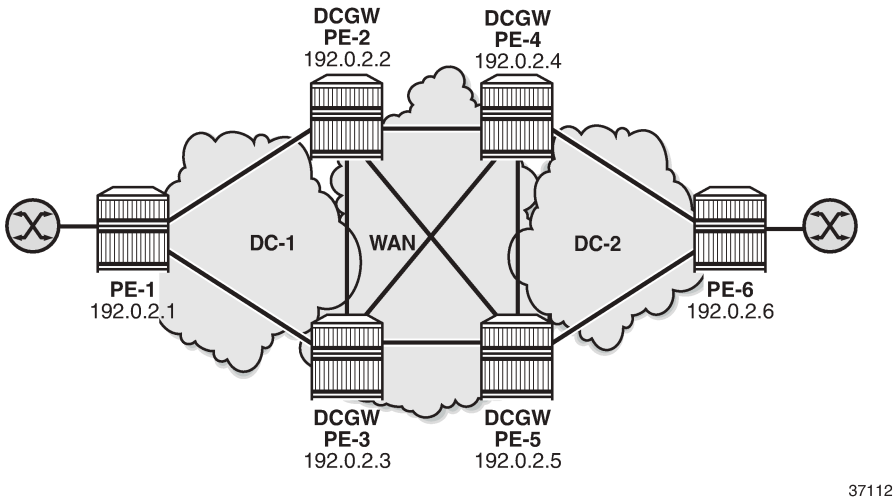
In the event that the remote PE-1 has learned the destination MAC address MAC6 via I-ES-45 EVPN destination, but the DCGWs PE-4 and PE-5 do not know MAC6, regular aliasing procedures allow that PE-1 sends unicast traffic with destination MAC6 to the NDF PE-5, which does not know MAC6 and drops all unknown unicast traffic, creating a blackhole for the flow.

When a static VXLAN instance coexists with an EVPN-VXLAN instance in the same VPLS service, Nokia recommends using a single-active I-ES or an anycast solution without I-ES instead of an all-active I-ES.

Configuration

Figure 127: Sample topology shows the sample topology with six SR OS nodes:

Figure 127: Sample topology



The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS on all interfaces (level 1 in the DCs; level 2 in the WAN)

BGP is configured for the EVPN address family. PE-1 acts as Route Reflector (RR) in DC 1 and PE-6 as RR in DC 2; no RR is used in the WAN.

The BGP configuration on RR PE-1 in DC 1 is as follows. The BGP configuration on RR PE-6 in DC2 is similar.

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            cluster 192.0.2.1
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

On DCGWs PE-2 and PE-3, BGP is configured as follows. The policies are explained in the next section.

```
# on PE-2, PE-3:
configure
    router Base
        autonomous-system 64500
        bgp
```

```
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                import "drop SOO-DCGW-23"
                export "export DC routes and add SOO"
                neighbor 192.0.2.1
                exit
            exit
            group "WAN"
                type internal
                export "export WAN routes only"
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

On DCGWs PE-4 and PE-5, BGP is configured as follows. The policies are explained in the next section.

```
# on PE-4, PE-5:
configure
    router
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                import "drop SOO-DCGW-45"
                export "export DC routes and add SOO"
                neighbor 192.0.2.6
                exit
            exit
            group "WAN"
                type internal
                export "export WAN routes only"
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

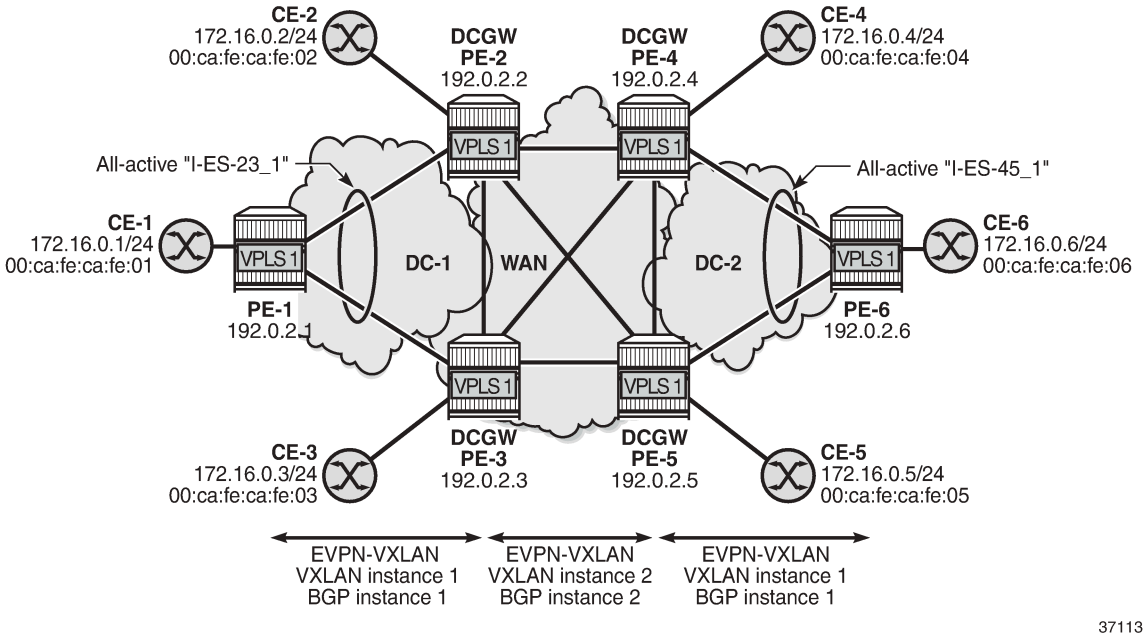
The following examples are configured:

- All-active multi-homing I-ESs in dual EVPN-VXLAN instance VPLS
- Single-active multi-homing I-ES when static VXLAN coexists with EVPN-VXLAN in the same VPLS

All-active multi-homing I-ESs in dual EVPN-VXLAN instance VPLS

Figure 128: All-active multi-homing for I-ESs shows the example topology with the service VPLS 1 on all nodes and two all-active I-ESs:

Figure 128: All-active multi-homing for I-ESs



On PE-1, VPLS 1 is configured as follows. The configuration on PE-6 is similar.

```
# on PE-1:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.1 comm-val 1 to 1000     # on PE-6: 192.0.2.6
        exit
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 11 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:11 import target:64500:11
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    no shutdown
                exit
            exit
            sap 1/2/1:1 create
            exit
            no shutdown
        exit
```

On DCGW PE-2, the following all-active multi-homing I-ES is configured for VXLAN instance 1 and service id 1. The configuration on DCGW PE-3 is similar, but the preference value is 150 instead of 100.

```
# on PE-2:
configure
    service
```

```
        system
            bgp-evpn
                ethernet-segment "I-ES-23_1" virtual create
                    esi 00:23:23:23:23:23:23:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100            # on PE-3: preference value 150
                            exit
                            evi 1
                        exit
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1
                    exit
                    no shutdown
                exit
            exit
```

On DCGWs PE-4 and PE-5, the following I-ES is configured:

```
# on PE-4, PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES-45_1" virtual create
                    esi 00:45:45:45:45:45:45:00:00:01
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 1
                    exit
                    no shutdown
                exit
            exit
        exit
```

On DCGWs PE-2, PE-3, PE-4, and PE-5, VPLS 1 is configured as follows. The **rx-discard-on-ndf bum** command makes the NDF drop any BUM traffic in VXLAN instance 1. VXLAN instance 2 is configured with **mh-mode network and auto-disc-route-advertisement**.

```
# on PE-2, PE-3, PE-4, PE-5:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 11 create
                rx-discard-on-ndf bum
            exit
            vxlan instance 2 vni 12 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:11 import target:64500:11
            exit
            bgp 2
```

```
                route-distinguisher auto-rd
                route-target export target:64500:12 import target:64500:12
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    default-route-tag 11
                    auto-disc-route-advertisement
                    no shutdown
                exit
                vxlan bgp 2 vxlan-instance 2
                    ecmp 2
                    default-route-tag 12
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2 and PE-3, the following policies are configured.

- The import policy "drop SOO-DCGW-23" in group "DC" is used to drop all VXLAN instance 1 routes between PE-2 and PE-3.
- The export policy "export WAN routes only" in group "WAN" is applied to avoid sending VXLAN instance 1 routes to the WAN PEs.
- The export policy "export DC routes and add SOO" in group "DC" is used to tag VXLAN instance 1 routes with community "SOO-23".

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            community "SOO-23"
                members "origin:64500:23"
            exit
            policy-statement "drop SOO-DCGW-23"         # import in group "DC"
                entry 10
                    from
                        community "SOO-23"
                        family evpn
                    exit
                    action drop
                    exit
                exit
                default-action accept
                exit
            exit
            policy-statement "export WAN routes only"   # export in group "WAN"
                entry 10
                    from
                        tag 11
```

```
                    family evpn
                exit
                action drop
                exit
            exit
            default-action accept
            exit
        exit
        policy-statement "export DC routes and add SOO"   # export in group "DC"
            entry 10
                from
                    tag 11
                    family evpn
                exit
                action accept
                    community add "SOO-23"
                exit
            exit
            default-action accept
            exit
        exit
        commit
```

On PE-4 and PE-5, the following policies are configured:

```
# on PE-4, PE-5:
configure
    router Base
        policy-options
            begin
            community "SOO-45"
                members "origin:64500:45"
            exit
            policy-statement "drop SOO-DCGW-45"         # import in group "DC"
                entry 10
                    from
                        community "SOO-45"
                        family evpn
                    exit
                    action drop
                    exit
                exit
                default-action accept
                exit
            exit
            policy-statement "export WAN routes only"   # export in group "WAN"
                entry 10
                    from
                        tag 11
                        family evpn
                    exit
                    action drop
                    exit
                exit
                default-action accept
                exit
            exit
            policy-statement "export DC routes and add SOO"   # export in group "DC"
                entry 10
                    from
                        tag 11
                        family evpn
                    exit
```

```
                    action accept
                        community add "SOO-45"
                    exit
                exit
                default-action accept
                exit
            exit
            commit
```

For VPLS 1, PE-2 is DF and PE-3 is NDF in the I-ES "I-ES-23_1":

```
*A:PE-2# show service id 1 ethernet-segment

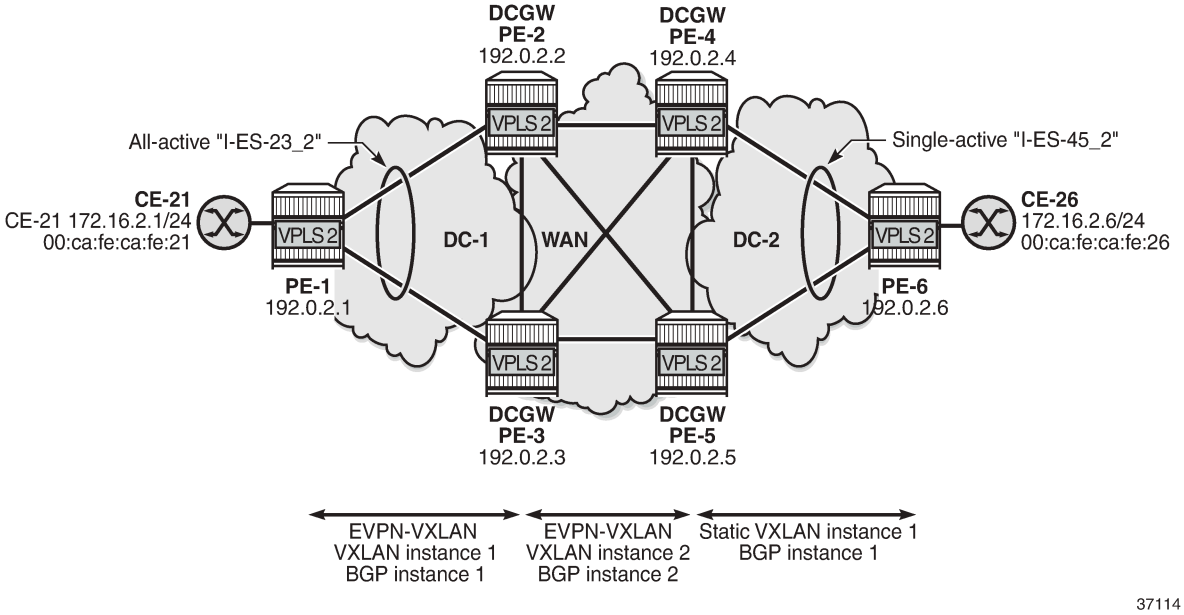
Single-active multi-homing I-ES when static VXLAN coexists with EVPN-VXLAN in the same VPLS

Figure 129: I-ES with EVPN-VXLAN in DC 1 and static VXLAN in DC2 shows the sample topology for VPLS 2 with static VXLAN in DC 2 and the single-active "I-ES-45_2" on PE-4 and PE-5.

Figure 129: I-ES with EVPN-VXLAN in DC 1 and static VXLAN in DC2



The configuration for VPLS 2 on PE-1, PE-2, and PE-3 is similar to the configuration for VPLS 1, so only the configuration on PE-4, PE-5, and PE-6 is shown.

On PE-6, VPLS 2 is configured with static VXLAN using non-anycast VTEP addresses:

```
# on PE-6:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.6 comm-val 1 to 1000
        exit
        vpls 2 name "VPLS 2" customer 1 create
            vxlan instance 1 vni 21 create
                egr-vtep 192.0.2.4 create
                exit
                egr-vtep 192.0.2.5 create
                exit
            exit
            sap 1/2/1:2 create
                no shutdown
            exit
            no shutdown
        exit
```

To avoid blackholes, the I-ES between DCGWs PE-4 and PE-5 must not be all-active.

On PE-4 and PE-5, the single-active I-ES "I-ES-45_2" is configured as follows:

```
# on PE-4, PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "I-ES-45_2" virtual create
```

```
                    esi 00:45:45:45:45:45:45:00:00:02
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    network-interconnect-vxlan 1
                    service-id
                        service-range 2
                    exit
                    no shutdown
                exit
            exit
```

On PE-4 and PE-5, VPLS 2 is configured as follows:

```
# on PE-4, PE-5:
configure
    service
       vpls 2 name "VPLS 2" customer 1 create
            vxlan instance 1 vni 21 create
                egr-vtep 192.0.2.6 create
                exit
            exit
            vxlan instance 2 vni 22 create
            exit
            bgp 2
                route-distinguisher auto-rd
                route-target export target:64500:22 import target:64500:22
            exit
            bgp-evpn
                evi 2
                vxlan bgp 2 vxlan-instance 2
                    ecmp 2
                    default-route-tag 22
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:2 create        # optional SAP toward local CE
                no shutdown
            exit
            no shutdown
        exit
```

The policies on all DCGWs must be modified with tag 21 for VXLAN instance 1 in VPLS 2, as follows:

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            policy-statement "export WAN routes only"
                entry 20
                    from
                        tag 21
                        family evpn
                    exit
                    action drop
                    exit
```

```
                exit
                default-action accept
                exit
            exit
            policy-statement "export DC routes and add SOO"
                entry 20
                    from
                        tag 21
                        family evpn
                    exit
                    action accept
                        community add "SOO-23"
                    exit
                exit
                default-action accept
                exit
            exit
            commit
```

DCGW PE-5 is NDF for "I-ES-45_2":

```
*A:PE-5# show service id 2 ethernet-segment

Note:
An anycast solution without I-ES can also be configured when an EVPN-VXLAN coexists with a static VXLAN.

Conclusion

Service providers can use I-ESs for better bandwidth utilization and redundancy in large DCs. EVPN all-active multi-homing I-ESs can be used in dual EVPN-VXLAN instance VPLS services. However, when a static VXLAN instance coexists with EVPN-VXLAN in the same VPLS, a single-active multi-homing I-ES (or an anycast solution without I-ES) is required to avoid blackholes.

EVPN IP-VRF-to-IP-VRF Models

This chapter provides information about EVPN IP-VRF-to-IP-VRF Models.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 16.0.R3. SR OS supports the three EVPN IP-VRF-to-IP-VRF models described in *draft-ietf-bess-evpn-prefix-advertisement*. The two interface-ful models for IPv4 are supported for EVPN-VXLAN in SR OS Release 12.0.R4, and later, and for EVPN-MPLS in SR OS Release 14.0.R1. The interface-less model is supported for IPv4 in EVPN-VXLAN and EVPN-MPLS in SR OS Release 16.0.R2, and later. Interface-less and interface-ful models for IPv6 are supported in SR OS Release 16.0.R4, and later.

Overview

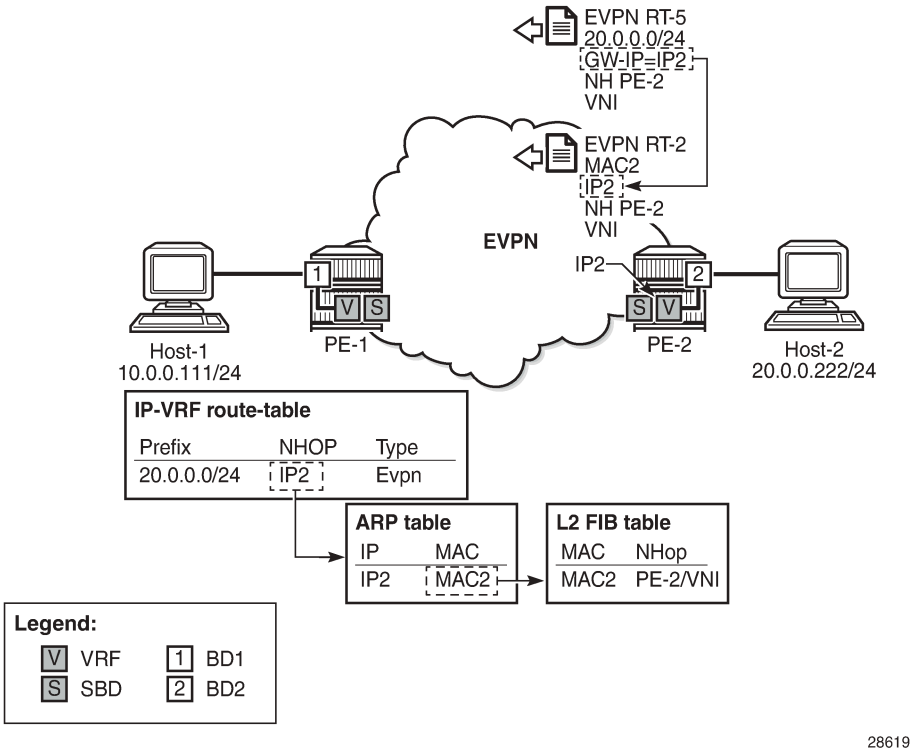
EVPN is considered the standard for Data Centers (DCs) and DC Interconnect (DCI) for layer 2 and layer 3 services. *Draft-ietf-bess-evpn-prefix-advertisement* describes the following three IP-VRF-to-IP-VRF models:

- Interface-less model (mandatory)
- Interface-ful model with Supplementary Broadcast Domain (SBD) Interworking Routing and Bridging (IRB) (mandatory)
- Interface-ful model with unnumbered SRB IRB (optional)

In standard terminology, SBD is the Broadcast Domain (BD) that joins two IP-VRFs. In SR OS, the SBD is a "backhaul" R-VPLS service that connects two PEs attached to VPRNs of the same VPN. For IP prefix advertisement in the SBD, **ip-route-advertisement** needs to be enabled in the BGP-EVPN context, whereas mac-advertisement is enabled by default. BGP-EVPN IP prefix route type 5 (RT-5) updates are used in all models; MAC/IP routes (RT-2) are used in the interface-ful models only. In the interface-less model, **mac-advertisement** must be disabled.

Figure 130: Interface-ful SBD IRB and Figure 131: Interface-ful Unnumbered SBD IRB show the two interface-ful IP-VRF-to-IP-VRF models: SBD IRB and unnumbered SBD IRB. Both interface-ful SBD IRB models require BGP-EVPN IP prefix routes (RT-5) with recursive lookup to MAC/IP routes (RT-2). Host 1 is located in broadcast domain 1 (BD1 corresponds to an R-VPLS) linked to the VRF in PE-1 and host 2 is located in BD2 linked to the VRF in PE-2. The VRFs correspond to VPRNs that are linked to an SBD, which is a backhaul R-VPLS.

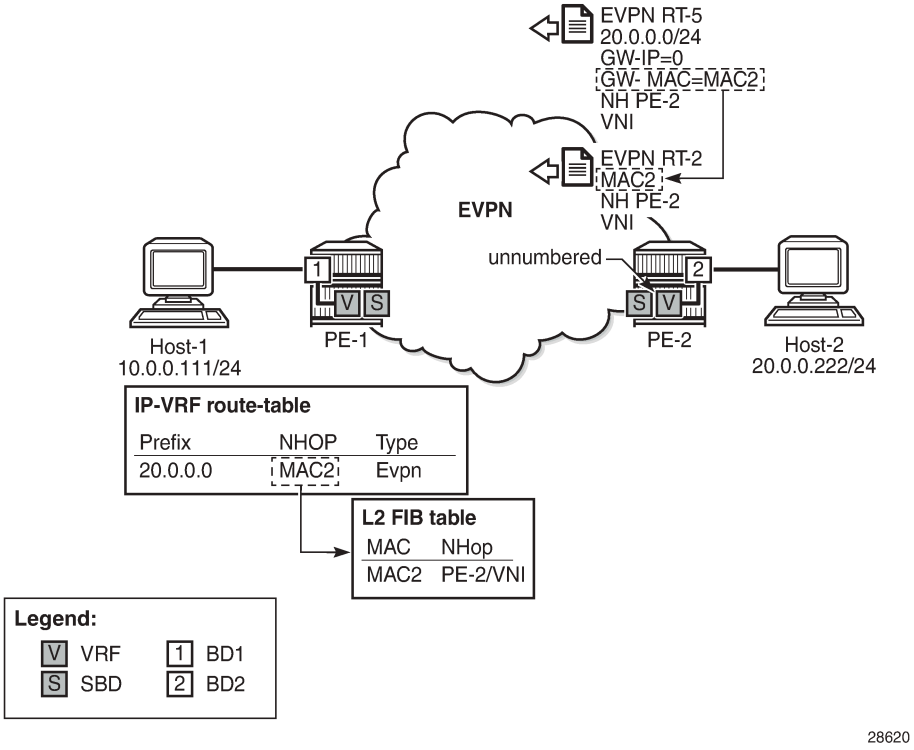
Figure 130: Interface-ful SBD IRB



The interface-ful SBD IRB model requires an IP address on the VPRN interface for the SBD (IP2 on PE-2); no EVPN tunnel can be used. Both PEs will send BGP-EVPN RT-5 (IP prefix) and BGP-EVPN RT-2 (MAC/IP) updates. PE-2 sends an RT-5 update for IP prefix 20.0.0.0/24 with GW IP address IP2 and an RT-2 update for GW IP address IP2 with MAC2 and next-hop PE-2. On PE-1, the prefix 20.0.0.0/24 appears in the VRF route table as an EVPN route with next-hop GW IP2. The ARP table for the VRF contains the corresponding MAC address MAC2 for the GW IP address IP2. The FDB of the SBD includes an EVPN entry for GW MAC address MAC2 with next-hop PE-2.

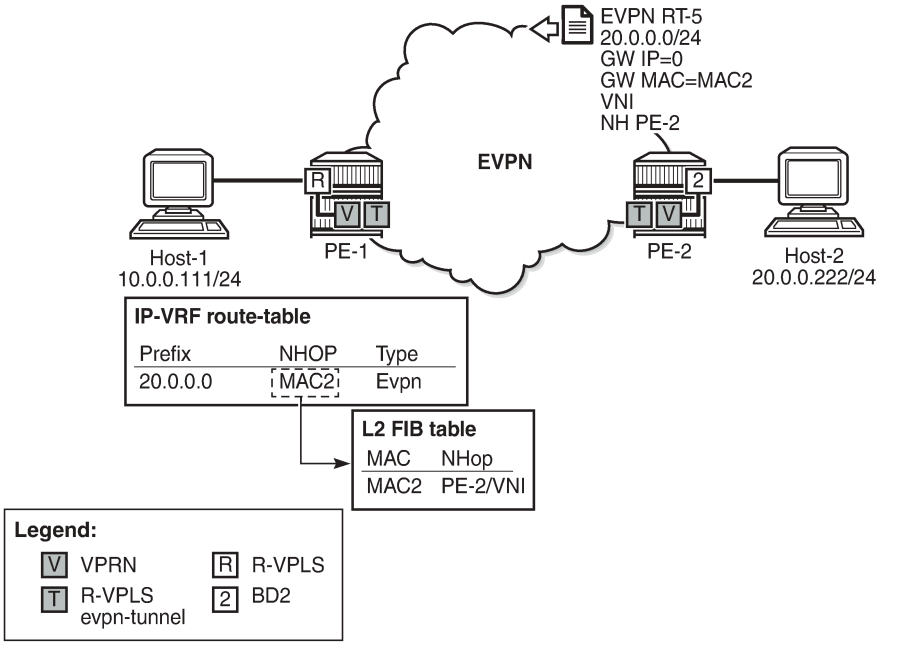
When the VPRN is configured toward the SBD with an EVPN tunnel rather than a numbered IP interface, the RT-5 update will contain the GW MAC address MAC2 instead of the GW IP address IP2. Figure 131: Interface-ful Unnumbered SBD IRB shows that PE-2 sends an RT-5 update for IP prefix 20.0.0.0/24 with GW MAC address MAC2 and an RT-2 update for GW MAC address MAC2 with next-hop PE-2. Again, a recursive lookup is done.

Figure 131: Interface-ful Unnumbered SBD IRB



Finally, in the interface-less IP-VRF-to-IP-VRF model, **mac-advertisement** is disabled in the BGP-EVPN context of the backhaul R-VPLS. BGP-EVPN RT-5 updates will contain the GW MAC address, and no RT-2 updates will be sent; therefore, the number of BGP-EVPN updates is reduced and no recursive lookup is done on PE-1. PE-1 adds an entry in its FDB based on an RT-5 route instead of an RT-2 route from PE-2. Figure 132: Interface-less IP-VRF-to-IP-VRF Model shows the interface-less IP-VRF-to-IP-VRF model where PE-2 sends an RT-5 update with GW MAC address MAC2.

Figure 132: Interface-less IP-VRF-to-IP-VRF Model



Note:
Other vendors do not use a service context as the R-VPLS EVPN tunnel shown in Figure 3, and they configure the route targets used for the RT-5 updates in the VPRN (or VRF) instances. When interoperating with those vendors, ensure that the 7x50 R-VPLS route targets match the route targets in the VRF of the third-party router.

The preceding examples are based on EVPN-VXLAN, but IP-VRF-to-IP-VRF also works for EVPN-MPLS. Instead of the VNI, the MPLS label is then included in the RT-5 and RT-2 updates.

EVPN MAC Selection Criteria

In the interface-less scenario, the MAC address entry in the R-VPLS FDB that is required to forward packets to the remote PE is obtained from an internal MAC/IP route. This internal route is obtained from the router MAC extended community in the BGP-EVPN RT-5 update. In case the same MAC address is received in multiple ways, the following MAC selection criteria apply. Beginning with criterion (1), the MAC is selected if the criterion is met, or the next criterion is applied. As indicated in (8), a MAC received from an RT-2 has higher priority than a MAC populated by the router MAC extended community in an RT-5 update.

1. Conditional static MAC addresses (locally protected MAC addresses)
2. Auto-learned protected MAC addresses (locally learned MAC addresses on SAPs or SDP-bindings due to the configuration of **auto-learn-mac-protect**)
3. EVPN ES PBR MAC addresses
4. EVPN static MAC addresses (remotely protected MAC addresses)

5. Data plane learned MAC addresses (regular learning on SAPs or SDP-bindings)
6. EVPN MAC routes with a higher sequence number
7. EVPN E-Tree root MAC addresses
8. EVPN non-RT-5 MAC addresses (this tie-breaking rule is only applied if the selection algorithm is comparing received MAC routes (RT-2) and internal MAC routes derived from the MAC addresses in IP-prefix routes, such as RT-5 MACs)
9. Lowest IP address for the next-hop of the EVPN NLRI
10. Lowest Ethernet tag (that will be zero for MPLS and might be different from zero for VXLAN)
11. Lowest route distinguisher
12. Lowest BGP instance (this tie-breaking rule is only applied if the preceding rules fail to select a unique MAC address and the service has two BGP instances of the same encapsulation)

EVPN IP-VRF-to-IP-VRF Model Comparison

Each model has its advantages. Table 8: EVPN IP-VRF-to-IP-VRF Model Comparison compares the three IP-VRF-to-IP-VRF models.

Table 8: EVPN IP-VRF-to-IP-VRF Model Comparison

Advantage	Model 1 Interface-less	Model 2 Interface-ful SBD IRB	Model 3 Interface-ful unnumbered SBD IRB
Reduced number of EVPN routes	Yes	No	No
Ease of provisioning (no IP address on core IRB)	Yes	No	Yes
Mass withdrawal due to recursive resolution	No	Yes	Yes

Configuration

The following use cases are documented in this chapter:

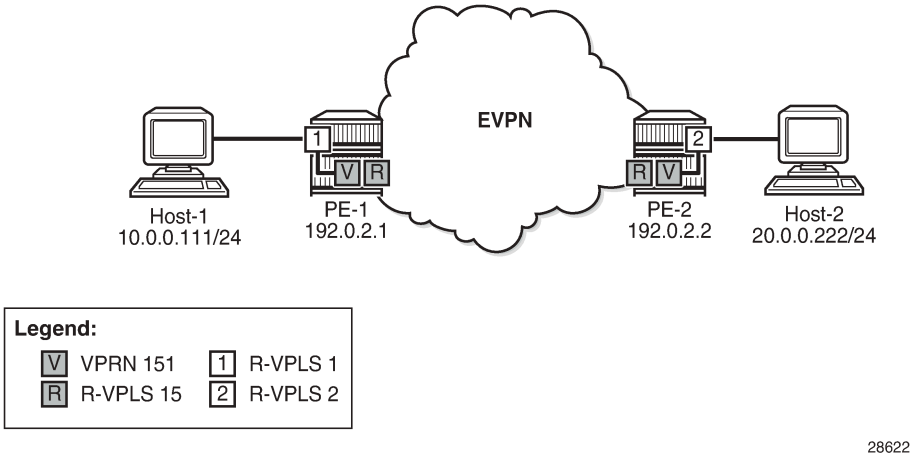
- IP-VRF-to-IP-VRF Models in EVPN-VXLAN
  - Interface-ful model with SBD IRB in EVPN-VXLAN
  - Interface-ful model with unnumbered SBD IRB in EVPN-VXLAN
  - Interface-less model in EVPN-VXLAN
- IP-VRF-to-IP-VRF Models in EVPN-MPLS
  - Interface-ful model with SBD IRB in EVPN-MPLS
  - Interface-ful model with unnumbered SBD IRB in EVPN-MPLS

– Interface-less model in EVPN-MPLS

IP-VRF-to-IP-VRF Model in EVPN-VXLAN

Figure 133: Example Topology with Services - EVPN-VXLAN shows the example topology with two PEs. Hosts 1 and 2-emulated through VPRNs 11 and 22-are attached to R-VPLS 1 and 2 respectively.

Figure 133: Example Topology with Services - EVPN-VXLAN



The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- BGP for address family EVPN

On PE-1, the BGP configuration is as follows. The BGP configuration on PE-2 is similar.

```
*A:PE-1#
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "dc"
                family evpn
                type internal
                neighbor 192.0.2.2
                exit
            exit
        exit
```

Interface-ful Model with SBD IRB in EVPN-VXLAN

The service configuration on PE-1 includes the SBD R-VPLS 15, VPRN 151, and R-VPLS 1. The service configuration on PE-2 is similar, but R-VPLS 2 is configured instead of R-VPLS 1.

On PE-1, SBD R-VPLS 15 is configured with VNI 15, as follows. MAC advertisement is enabled by default, but IP route advertisement must be enabled explicitly. Only one BGP instance and one VXLAN instance are configured.

```
*A:PE-1#
configure
    service
        vpls 15 name "sbd-15" customer 1 create
            description "backhaul R-VPLS 15"
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 15 create
            exit
            bgp
            exit
            bgp-evpn
                ip-route-advertisement
                evi 15
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

VPRN 151 has two interfaces: one toward the SBD R-VPLS 15 and one toward BD R-VPLS 1. The interface toward the SBD has GW IP address 172.16.151.1/24 and MAC address 00:00:00:01:51:01. The interface toward R-VPLS 1 has IP address 10.0.0.1/24 and MAC address 00:00:00:1e:01:01. VRRP is configured in passive mode, so PE-1 uses the backup IP address as an anycast gateway. The backup IP address is 10.0.0.254 and the auto-derived virtual MAC address is 00:00:5e:00:00:01 for VRID 1. On PE-1, VPRN 151 is configured as follows:

```
*A:PE-1#
configure
    service
        vprn 151 name "ip-vrf-151" customer 1 create
            ecmp 2
            route-distinguisher auto-rd
            interface "sbd-15" create
                address 172.16.151.1/24
                mac 00:00:00:01:51:01
                vpls "sbd-15"
                exit
            exit
            interface "bd-1" create
                address 10.0.0.1/24
                mac 00:00:00:1e:01:01
                vrrp 1 passive
                    backup 10.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "bd-1"
                exit
            exit
            no shutdown
```

```
        exit
```

On PE-1, R-VPLS 1 is configured as follows. Host 1 is attached to the SAP.

```
*A:PE-1#
configure
    service
        vpls 1 name "bd-1" customer 1 create
            description "R-VPLS 1 - BD 1"
            allow-ip-int-bind
            exit
            sap pxc-10.a:1 create
                no shutdown
            exit
            no shutdown
        exit
```

In this example, host 1 is simulated by VPRN 11, as follows. The default route has next-hop 10.0.0.254, which is the VRRP backup address in VPRN 151.

```
*A:PE-1#
configure
    service
        vprn 11 name "host1" customer 1 create
            description "Host-1 attached to R-VPLS 1"
            route-distinguisher auto-rd
            interface "local" create
                address 10.0.0.111/24
                mac 00:00:00:10:11:01
                sap pxc-10.b:1 create
                exit
            exit
            static-route-entry 0.0.0.0/0
                next-hop 10.0.0.254
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

The service configuration on PE-2 is similar, with R-VPLS 2 instead of R-VPLS 1 and VPRN 22 instead of VPRN 11. The GW IP address on PE-2 is 172.16.151.2/24, interface "bd-2" in VPRN 151 has IP address 20.0.0.2/24, and host 2 has IP address 20.0.0.222/24.

PE-1 receives a BGP-EVPN RT-5 update from PE-2 for IP prefix 20.0.0.0/24, as follows. The GW IP address is 172.16.151.2 and the next-hop is PE-2.

```
*A:PE-1# show router bgp routes evpn ip-prefix rd 192.0.2.2:15

```

Interface-ful Model with Unnumbered SBD IRB in EVPN-VXLAN

On both PEs, the GW IP addresses 172.16.151.x/24 are removed from interface "sbd-15" in VPRN 151 and an EVPN tunnel is configured instead. The changes in the configuration of VPRN 151 on PE-1 are the following:

```
*A:PE-1#
configure
    service
        vprn 151
            interface "sbd-15"
                no address 172.16.151.1/24
```

```
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
```

Similarly, the following is configured in VPRN 151 on PE-2:

```
*A:PE-2#
configure
    service
        vprn 151
            interface "sbd-15"
                no address 172.16.151.2/24
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
```

The configuration of VPRN 151 on PE-2 is as follows:

```
*A:PE-2>config>service>vprn# info
----------------------------------------------
            ecmp 2
            route-distinguisher auto-rd
            interface "sbd-15" create
                mac 00:00:00:01:51:02
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "bd-2" create
                address 20.0.0.2/24
                mac 00:00:00:2e:02:02
                vrrp 1 passive
                    backup 20.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "bd-2"
                exit
            exit
            no shutdown
----------------------------------------------
```

The provisioning is easier with unnumbered SBD IRB because no IRB IP addresses need to be configured in the VPRN.

PE-1 receives the following RT-5 update for IP prefix 20.0.0.0/24 with GW MAC address 00:00:00:01:51:02, because there is no GW IP address. The GW MAC address is used in the VPRN route table, where the EVPN tunnel leads toward this GW MAC address.

```
*A:PE-1# show router bgp routes evpn ip-prefix rd 192.0.2.2:15
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================

                          192.0.2.2
                          VNI 15

-------------------------------------------------------------------------------
Routes : 1
```

MAC advertisement is by default enabled, so PE-1 also receives the following RT-2 update for the GW MAC address. The interface is unnumbered, so there is no corresponding IP address.

```
*A:PE-1# show router bgp routes evpn mac rd 192.0.2.2:15
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================

                          n/a
                          192.0.2.2

-------------------------------------------------------------------------------
Routes : 1
```

The following traceroute from host 1 to host 2 shows that the second hop now is 20.0.0.2, which corresponds to the "bd-2" interface in VPRN 151 on PE-2. The other hops remain the same as in the preceding case.

```
*A:PE-1# traceroute router 11 20.0.0.222 source 10.0.0.111
traceroute to 20.0.0.222 from 10.0.0.111, 30 hops max, 40 byte packets
  1  10.0.0.1 (10.0.0.1)    0.804 ms  0.518 ms  0.493 ms
  2  20.0.0.2 (20.0.0.2)    1.01 ms  1.39 ms  1.04 ms
  3  20.0.0.222 (20.0.0.222)    1.26 ms  1.27 ms  1.10 ms
```

The following route table of VPRN 151 on PE-1 shows a BGP-EVPN route for IP prefix 20.0.0.0/24 with EVPN tunnel (ET) to GW MAC address 00:00:00:01:51:02:

```
*A:PE-1# show router 151 route-table

===============================================================================
Route Table (Service: 151)
===============================================================================
```

```
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.0/24                                     Local   Local     04h42m30s  0
       bd-1                                                         0
20.0.0.0/24                                     Remote  BGP EVPN  00h14m14s  169
       sbd-15 (ET-00:00:00:01:51:02)                                0
-------------------------------------------------------------------------------
No. of Routes: 2
```

The following ARP table for VPRN 151 does not contain any entries for interface "sbd-15", because they are unnumbered:

```
*A:PE-1# show router 151 arp "sbd-15"

===============================================================================
ARP Table (Service: 151)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
No Matching Entries Found
```

However, internally, ARP entries are created. The following command shows that the same number of ARP entries are consumed as in the preceding use case with the numbered interface "sbd-15". The BGP-EVPN ARP entry corresponds to the GW interface "sbd-15" on the BGP peer.

```
*A:PE-1# show router 151 arp summary

===========================================================
ARP Table Summary (Service: 151)
===========================================================
Local ARP Entries    : 3
Static ARP Entries   : 0
Dynamic ARP Entries  : 1
Managed ARP Entries  : 0
Internal ARP Entries : 0
BGP-EVPN ARP Entries : 1
-----------------------------------------------------------
No. of ARP Entries   : 5
===========================================================
*A:PE-1#
```

The FDB for R-VPLS 15 on PE-1 is as follows:

```
*A:PE-1# show service id 15 fdb detail

===============================================================================
Forwarding Database, Service 15
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

15         00:00:00:01:51:01 cpm                     Intf     10/11/18 06:55:47
15         00:00:00:01:51:02 vxlan-1:                EvpnS    10/11/18 12:03:16
                                                     P
                             192.0.2.2:15
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

```
*A:PE-1#
```

Interface-less Model in EVPN-VXLAN

The only difference from the preceding configuration is that MAC route advertisement is disabled in the backhaul R-VPLS 15 on both PEs, as follows:

```
*A:PE-1#
configure
    service
        vpls 15
            bgp-evpn
                no mac-advertisement
            exit
```

The configuration of R-VPLS 16 on PE-2 is as follows:

```
*A:PE-2# configure service vpls 15
*A:PE-2>config>service>vpls# info
----------------------------------------------
            description "backhaul R-VPLS 15"
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 15 create
            exit
            bgp
            exit
            bgp-evpn
                no mac-advertisement
                ip-route-advertisement
                evi 15
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
----------------------------------------------
```

Again, the provisioning is easier with unnumbered SBD IRB because no IRB IP addresses need to be configured in the VPRN.

PE-1 receives the following BGP-EVPN RT-5 update for IP prefix 20.0.0.0/24 with GW MAC address 00:00:00:01:51:02, which is the same as in the preceding use case:

```
*A:PE-1# show router bgp routes evpn ip-prefix rd 192.0.2.2:15
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP EVPN IP-Prefix Routes
===============================================================================
```

```
Flag  Route Dist.         Prefix
      Tag                 Gw Address
                          NextHop
                          Label
-------------------------------------------------------------------------------
u*>i  192.0.2.2:15        20.0.0.0/24
      0                   00:00:00:01:51:02
                          192.0.2.2
                          VNI 15

-------------------------------------------------------------------------------
Routes : 1
```

PE-1 does not receive any BGP-EVPN RT-2 updates because PE-2 does not advertise any MAC addresses in R-VPLS 15, as follows:

```
*A:PE-1# show router bgp routes evpn mac rd 192.0.2.2:15
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP EVPN MAC Routes
===============================================================================
Flag  Route Dist.         MacAddr           ESI
      Tag                 Mac Mobility      Label1
                          Ip Address
                          NextHop
-------------------------------------------------------------------------------
No Matching Entries Found.
```

The following traceroute from host 1 to host 2 shows that the second hop is the IP address of the "bd-2" interface in VPRN 151 on PE-2, as in the preceding use case:

```
*A:PE-1# traceroute router 11 20.0.0.222 source 10.0.0.111
traceroute to 20.0.0.222 from 10.0.0.111, 30 hops max, 40 byte packets
  1  10.0.0.1 (10.0.0.1)    0.643 ms  0.554 ms  0.549 ms
  2  20.0.0.2 (20.0.0.2)    1.08 ms  1.13 ms  0.988 ms
  3  20.0.0.222 (20.0.0.222)    1.31 ms  1.22 ms  1.29 ms
```

The following route table for VPRN 151 on PE-1 shows a BGP-EVPN route for IP prefix 20.0.0.0/24 with EVPN tunnel:

```
*A:PE-1# show router 151 route-table

===============================================================================
Route Table (Service: 151)
===============================================================================

       bd-1                                                         0
20.0.0.0/24                                   Remote  BGP EVPN  00h38m10s  169
       sbd-15 (ET-00:00:00:01:51:02)                                0
-------------------------------------------------------------------------------
```

```
No. of Routes: 2
```

The following FDB in R-VPLS 15 on PE-1 shows an EVPN entry for GW MAC address 00:00:00:01:51:02, which is created out of the RT-5 GW MAC (router MAC extended community):

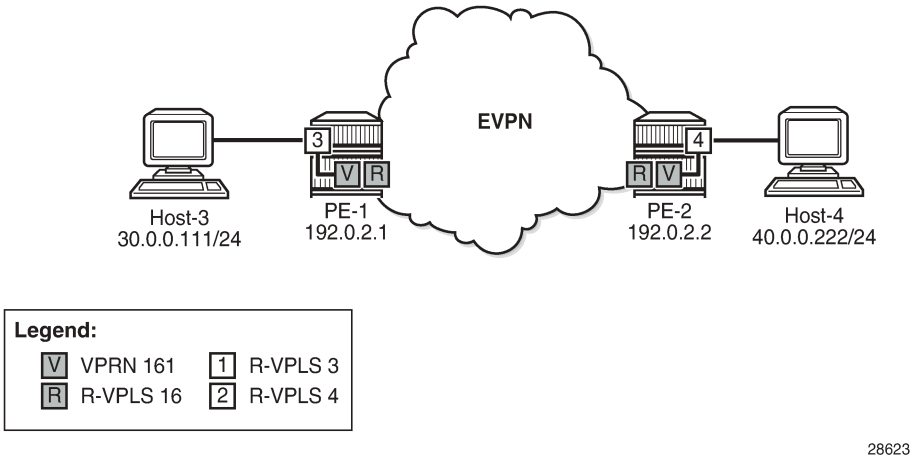
```
*A:PE-1# show service id 15 fdb detail

===============================================================================
Forwarding Database, Service 15
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
                                                     Age
-------------------------------------------------------------------------------
15         00:00:00:01:51:01 cpm                     Intf     10/11/18 06:55:47
15         00:00:00:01:51:02 vxlan-1:                Evpn     10/11/18 12:29:36
                             192.0.2.2:15
-------------------------------------------------------------------------------
No. of MAC Entries: 2
```

IP-VRF-to-IP-VRF Models in EVPN-MPLS

The three IP-VRF-to-IP-VRF models are also supported in EVPN-MPLS. Figure 134: Example Topology with Services - EVPN-MPLS shows the example topology with the services R-VPLS 16, VPRN 161, R-VPLS 3 (or 4), and VPRN 31 for host 3 (or VPRN 42 for host 4).

Figure 134: Example Topology with Services - EVPN-MPLS



For MPLS, LDP is configured on the interface between PE-1 and PE-2.

Interface-ful Model with SBD IRB in EVPN-MPLS

The following services are configured on PE-1 and PE-2:

- Backhaul R-VPLS 16
- VPRN 161
- R-VPLS 3 on PE-1; R-VPLS 4 on PE-2

- VPRN 31 (host 3) on PE-1; VPRN 42 (host 4) on PE-2

The service configuration on PE-1 is as follows. MAC route advertisement is enabled by default. The configuration on PE-2 is similar.

```
*A:PE-1#
configure
    service
        vpls 16 name "sbd-16" customer 1 create
            description "backhaul EVPN-MPLS R-VPLS 16"
            allow-ip-int-bind
            exit
            bgp
            exit
            bgp-evpn
                ip-route-advertisement
                evi 16
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
        vprn 161 name "ip-vrf-161" customer 1 create
            ecmp 2
            route-distinguisher auto-rd
            interface "sbd-16" create
                address 172.16.161.1/24
                mac 00:00:00:01:61:01
                vpls "sbd-16"
                exit
            exit
            interface "bd-3" create
                address 30.0.0.1/24
                mac 00:00:00:3e:03:01
                vrrp 1 passive
                    backup 30.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "bd-3"
                exit
            exit
            no shutdown
        exit
        vpls 3 name "bd-3" customer 1 create
            description "R-VPLS 3 - BD 3"
            allow-ip-int-bind
            exit
            sap pxc-10.a:3 create
                no shutdown
            exit
            no shutdown
        exit
        vprn 31 name "host3" customer 1 create
            description "Host-3 attached to R-VPLS 3"
            route-distinguisher auto-rd
            interface "local" create
                address 30.0.0.111/24
                mac 00:00:00:30:11:01
                sap pxc-10.b:3 create
```

```
                exit
            exit
            static-route-entry 0.0.0.0/0

The following traceroute from host 3 to host 4 shows that the GW IP address is the second hop:

```
*A:PE-1# traceroute router 31 40.0.0.222 source 30.0.0.111
traceroute to 40.0.0.222 from 30.0.0.111, 30 hops max, 40 byte packets
  1  30.0.0.1 (30.0.0.1)    1.62 ms  0.569 ms  0.531 ms
  2  172.16.161.2 (172.16.161.2)    2.08 ms  1.19 ms  0.943 ms
  3  40.0.0.222 (40.0.0.222)    2.64 ms  1.30 ms  1.18 ms
```

The route table and ARP table in VPRN 161 and the FDB in R-VPLS 16 are similar to the ones in theInterface-ful Model with SBD IRB in EVPN-VXLAN section.

Interface-ful Model with Unnumbered SBD IRB in EVPN-MPLS

The GW IP addresses are removed from the "sbd-16" interface in VPRN 161 and an EVPN-tunnel is configured instead. On PE-2, VPRN 161 is configured as follows:

```
*A:PE-2# configure service vprn 161
*A:PE-2>config>service>vprn# info
----------------------------------------------
            ecmp 2
            route-distinguisher auto-rd
            interface "sbd-16" create
                mac 00:00:00:01:61:02
                vpls "sbd-16"
                    evpn-tunnel
                exit
            exit
            interface "bd-4" create
                address 40.0.0.2/24
                mac 00:00:00:2e:04:02
                vrrp 1 passive
                    backup 40.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "bd-4"
                exit
            exit
            no shutdown
----------------------------------------------
```

The route table in VPRN 161 and the FDB in R-VPLS 16 are similar to the ones in the Interface-ful Model with Unnumbered SBD IRB in EVPN-VXLAN section.

Interface-less Model in EVPN-MPLS

MAC route advertisement is disabled in backhaul R-VPLS 16, as follows:

```
*A:PE-1# configure service vpls 16
*A:PE-1>config>service>vpls# info
----------------------------------------------
            description "backhaul EVPN-MPLS R-VPLS 16"
            allow-ip-int-bind
            exit
```

```
            bgp
            exit
            bgp-evpn
                no mac-advertisement
                ip-route-advertisement
                evi 16
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
-----------------------------------------------
```

The following route table for VPRN 161 contains a BGP-EVPN entry for prefix 40.0.0.0/24 with an EVPN tunnel to GW MAC address 00:00:00:01:61:02:

```
*A:PE-1# show router 161 route-table

Conclusion

The three EVPN IP-VRF-to-IP-VRF models each have advantages. Different vendors have chosen different models in the first phases of their EVPN implementations. SR OS supports all three EVPN IP-VRF-to-IP-VRF models, so they can be deployed in all environments where third-party vendors are deployed already.

EVPN Multi-Homing for VXLAN VPLS Services

This chapter provides information about EVPN Multi-Homing for VXLAN VPLS Services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 21.7.R1.

EVPN multi-homing has been supported in SR OS for EVPN-MPLS and PBB-EVPN in SR OS Release 13.0.R4 and later. SR OS Release 16.0 introduced EVPN multi-homing for EVPN-VXLAN on Epipe services. EVPN-VXLAN multi-homing in a single VXLAN instance VPLS or R-VPLS service—as specified in RFC 8365—is supported in SR OS Release 19.5.R1, and later.

Before you read this chapter, ensure you are familiar with the concepts in the EVPN for VXLAN Tunnels (Layer 2) chapter.

Overview

Some Service Providers are deploying large Telco cloud Data Centers (DCs) where SR OS nodes are used as leaf switches in a VXLAN fabric. In those cases, all-active multi-homing can provide redundancy and maximize the bandwidth use.

The multi-homing procedures consist of three components:

- Designated Forwarder (DF) election
  - The PEs attached to the same Ethernet Segment (ES) elect a single PE as DF to:
    - forward all traffic, in case of single-active mode
    - forward all Broadcast, Unknown unicast, Multicast (BUM) traffic, in case of all-active mode
- split-horizon
  - BUM traffic received from a peer ES PE is filtered so that it is not looped back to the CE that first transmitted the frame.
  - in EVPN-VXLAN services, split-horizon is only used with all-active mode and makes use of the local bias procedure described in RFC 8365.
- aliasing
  - PEs that are not attached to the ES can process non-zero Ethernet Segment Identifier (ESI) MAC/IP routes and AD routes and create ES destinations to which per-flow Equal Cost Multi-Path (ECMP) can be applied.
  - Aliasing only applies to all-active mode.

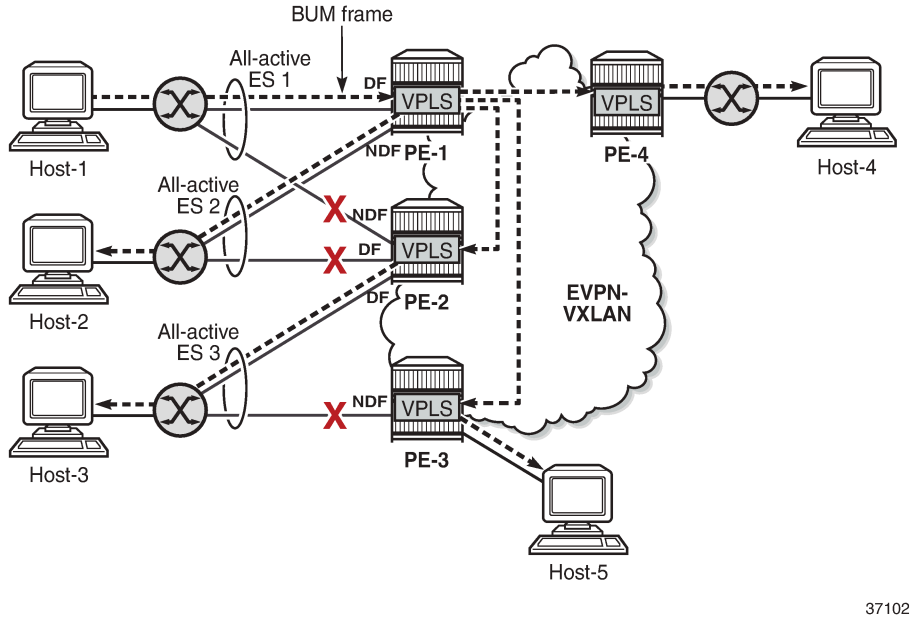
Split-horizon using local bias

In EVPN-MPLS services, split-horizon filtering uses ESI labels. VXLAN does not support ESI labels or MPLS labels. In EVPN-VXLAN services, the split-horizon filtering is based on the tunnel source IP address. In RFC 8365, this forwarding is referred to as local bias. Local bias works as follows:

- Every PE knows the IP addresses associated with the other PEs with which it has shared multi-homed ESs.
- The ingress PE replicates locally to all directly attached ESs, regardless of the DF state, for all flooded traffic coming from the access interfaces. BUM frames received on any SAP are flooded to:
  - local non-ES SAPs and non-ES SDP bindings
  - local all-active ES SAPs (DF and NDF)
  - local single-active ES SDP bindings and SAPs (DF only)
  - EVPN-VXLAN destinations
- When an egress PE receives a BUM frame from a VXLAN binding, it looks up the source IP address in the tunnel header and filters out the frame on all local interfaces connected to ESs that are shared with the ingress PE. The following rules apply to egress PE forwarding for EVPN-VXLAN services.
  1. The source VTEP is looked up for BUM frames received on EVPN-VXLAN.
  2. The router checks if the source VTEP matches one of the PEs with which the egress PE shared both an ES and a VXLAN service.
     - If there is a match, the egress PE is not forwarding to the shared ES local SAPs.
     - If there is no match, the egress PE forwards to ES SAPs in DF state (as usual).

Figure 135: Split-horizon filtering based on tunnel source IP address shows an example of local bias forwarding for BUM frames.

Figure 135: Split-horizon filtering based on tunnel source IP address



In this example, BUM frames sent by Host-1 are treated as follows.

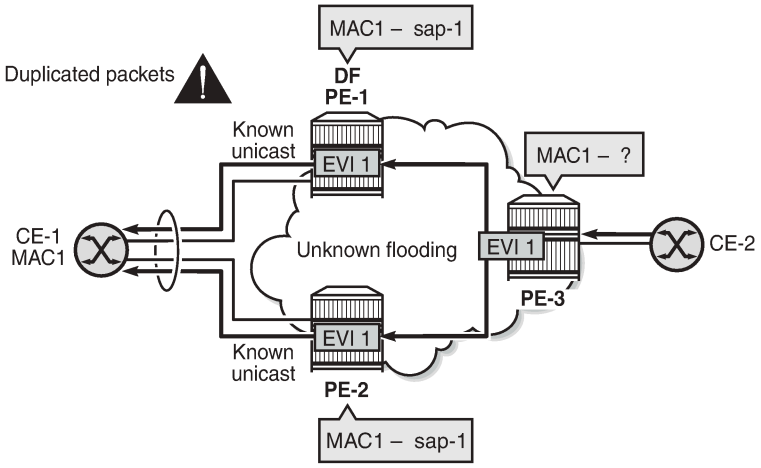
- Ingress node PE-1 receives BUM frames from Host-1 and forwards them to the other PEs (EVPN-VXLAN destinations) and the local all-active ES SAP toward Host-2, even though the SAP is in NDF state.
- Egress node PE-2 receives BUM frames on VXLAN. PE-2 identifies the source VTEP as a PE with which two all-active ESs are shared, so it does not forward the BUM frames to the two shared ESs. PE-2 forwards the BUM frames to the non-shared ES toward Host-3 because it is in DF state.
- Egress node PE-3 receives BUM traffic from PE-1, with which it does not share any ESs, so it forwards the BUM frames based on normal rules: it does not forward them toward Host-3, because the ES SAP is in NDF state. PE-3 only forwards toward Host-5.
- PE-4 does not share any ESs with PE-1, so the normal rules apply. PE-4 forwards the BUM frames toward Host-4.

Known limitations for local bias

In VXLAN, there are no BUM labels or any tunnel indication that can identify BUM traffic. The egress PE must solely rely on the Customer MAC (CMAC) destination address and this may create transient issues.

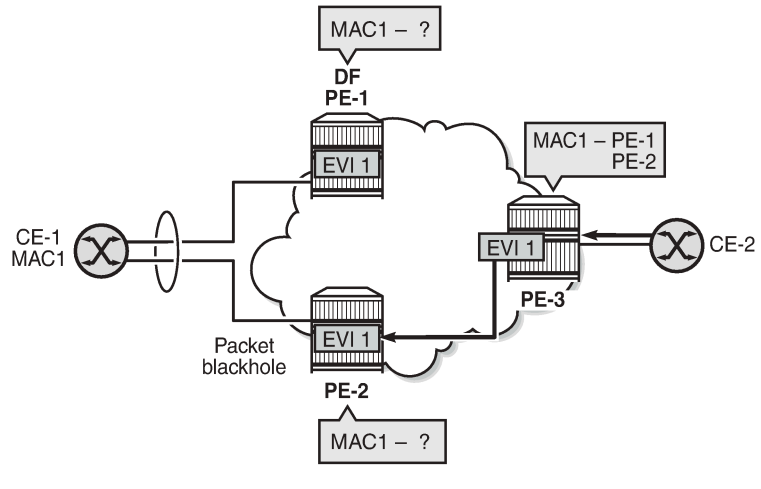
- Duplicate unicast traffic may occur when the CMAC destination address MAC1 is unknown on the ingress PE-3, while known on the egress PEs (PE-1 and PE-2). Figure 136: Duplicate unicast packets when MAC1 is unknown on PE-3 only shows that a packet with destination MAC1 arrives at PE-3, where it is flooded via ingress replication to PE-1 and PE-2, where MAC1 is known. PE-1 and PE-2 both forward the packets with CMAC destination MAC1 to CE-1, so multiple copies are sent to CE-1.

Figure 136: Duplicate unicast packets when MAC1 is unknown on PE-3 only



- A blackhole may occur when the CMAC destination address MAC1 is known on PE-3, but unknown on PE-1 and PE-2 and the aliasing hashing on PE-3 picks up the path to the NDF, where unknown unicast traffic is dropped, as shown in Figure 137: Packet blackhole for traffic on NDF PE-2 when MAC1 is known on PE-3 only. When the path to the DF is picked, no problem occurs, because the DF forwards BUM traffic.

  Figure 137: Packet blackhole for traffic on NDF PE-2 when MAC1 is known on PE-3 only

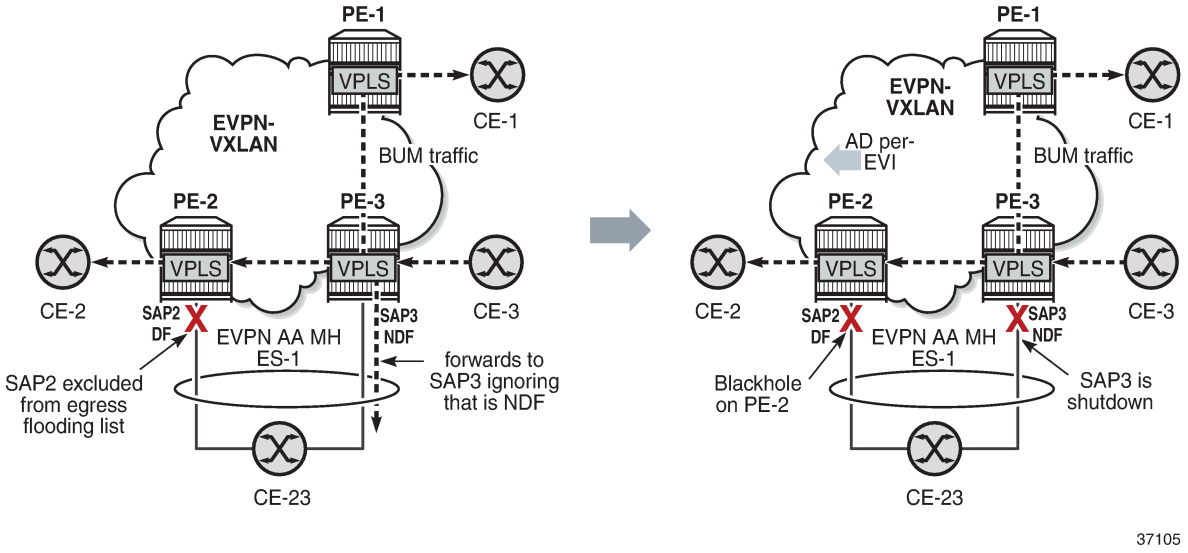


- A blackhole can be created when a remote SAP is disabled (**shutdown**), as shown in Figure 138: Blackhole created when a remote SAP is disabled.

  Under normal circumstances, when CE-3 sends BUM traffic to ingress node PE-3, the local bias mechanism on PE-3 forwards the BUM packets to SAP3, even though it is NDF for the ES. The BUM traffic is also flooded to PE-2, where it is forwarded to CE-2, but not to SAP2, because the ES is shared with PE-3.

When SAP3 is manually disabled, PE-3 withdraws the AD per-EVI route corresponding to SAP3. This does not change the local bias filtering for SAP2 on PE-2, so when CE-3 sends BUM traffic, it can neither be forwarded to CE-23 via SAP3 nor by PE-2.

Figure 138: Blackhole created when a remote SAP is disabled



CLI

The multi-homing capabilities are enabled in all the PEs attached to the VPLS service by configuring the options **auto-disc-route-advertisement** and **mh-mode network** in the **vpls bgp-evpn vxlan** context.

The **auto-disc-route-advertisement** option is by default disabled, but it can be enabled as follows:

```
*A:PE-2>config>service>vpls>bgp-evpn>vxlan$ auto-disc-route-advertisement
```

This **auto-disc-route-advertisement** command is only configurable for EVPN-VXLAN VPLS services and is implicitly enabled on all instances where it is not configurable. **Auto-disc-route-advertisement** is required in nodes with local ESs and remote ESs to process and enable the creation of ES destinations.

When auto-disc-route-advertisement is enabled, BGP-EVPN:

- processes Auto-Discovery per EVPN instance (AD per-EVI) routes and AD per-ES routes
- processes MAC/IP routes with non-zero Ethernet Segment Identifier (ESI) — without resetting the ESI to zero
- creates ES destinations upon receiving MAC/IP routes and AD per-ES/EVI routes with non-zero ESI

The **mh-mode** option can be configured with the values **access** or **network**. For EVPN-VXLAN services, the default value is **access**. The following command configures **mh-mode network**:

```
*A:PE-2>config>service>vpls>bgp-evpn>vxlan$ mh-mode network
```

When **mh-mode network** is configured, BGP-EVPN:

- activates multi-homing for the local ES SAPs or SDP-bindings and creates ES associations and related processes, such as:
  - the local bias mode allowing the system to add all-active SAPs to the flooding list regardless of the DF state
  - the source VTEP lookup mode
- runs DF election for the ESs associated to the service
- triggers the advertisement of AD per-ES routes, AD per-EVI routes, and non-zero MAC/IP routes for the ESs in the service

Configuration

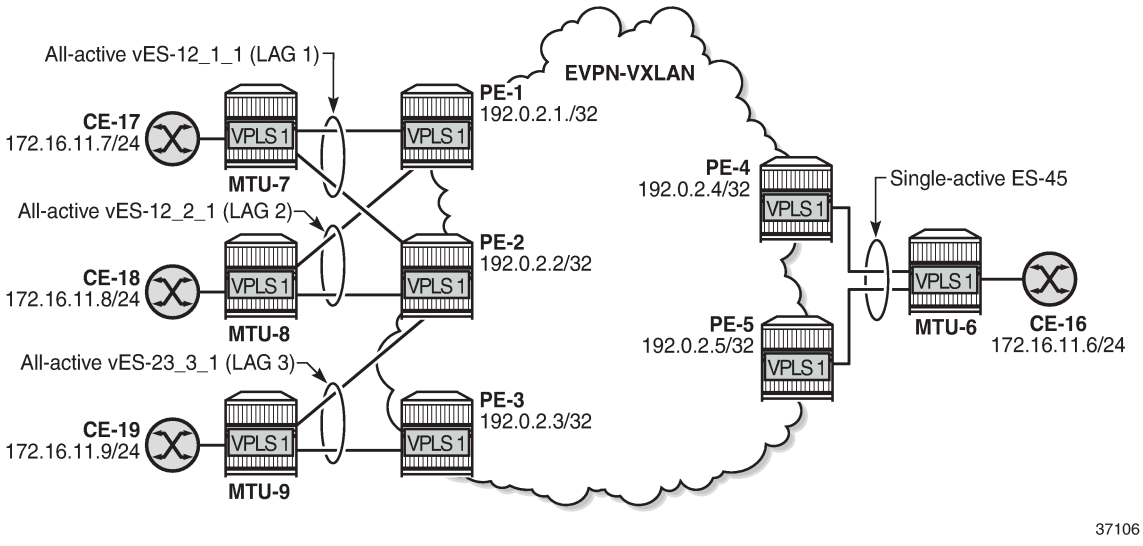
The following examples are configured:

- EVPN-VXLAN multi-homing with system IPv4 VTEP addresses
- EVPN-VXLAN multi-homing with non-system IPv4 VTEP addresses
- EVPN-VXLAN multi-homing with non-system IPv6 VTEP addresses

EVPN-VXLAN multi-homing with system IPv4 VTEP addresses

Figure 139: Example topology shows the topology with three all-active multi-homing ESs and one single-active multi-homing ES. This example shows the configuration for virtual Ethernet Segments, as described in the Virtual Ethernet Segments chapter, but non-virtual ES can also be used.

Figure 139: Example topology



The initial configuration on the PEs includes:

- cards, MDAs, ports
- LAG 1 on MTU-7, PE-1, PE-2

LAG 2 on MTU-8, PE-1, PE-2

LAG 3 on MTU-9, PE-2, PE-3

- router interfaces
- IS-IS between the PEs
- SR-ISIS between PE-4 and MTU-6 and between PE-5 and MTU-6 (and TLDP for SDP signaling)

BGP is configured between the PEs for the EVPN address family. PE-1 acts as route reflector, as follows:

```
# on RR PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                family evpn
                cluster 192.0.2.1
                peer-as 64500
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

ES configuration

The all-active ESs "vES-12_1_1" and "vES-12_2_1" are configured on PE-1 and PE-2. The configuration on PE-1 is as follows. The configuration on PE-2 is similar, but with different preference values.

```
# on PE-1:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES-12_1_1" virtual create
                    esi 00:12:12:12:12:12:12:00:01:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100           # on PE-2: preference value 150
                            exit
                            evi 1
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
```

```
                    q-tag-range 1
                exit
                no shutdown
            exit
            ethernet-segment "vES-12_2_1" virtual create
                esi 00:12:12:12:12:12:12:00:02:01
                service-carving
                    mode manual
                    manual
                        preference create
                            value 150           # on PE-2: preference value 100
                        exit
                        evi 1
                    exit
                exit
                multi-homing all-active
                lag 2
                dot1q
                    q-tag-range 1
                exit
                no shutdown
            exit
        exit
    exit
```

On PE-2 and PE-3, the all-active ES "vES-23_3_1" is configured in a similar way:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES-23_3_1" virtual create
                    esi 00:23:23:23:23:23:23:00:03:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100           # on PE-3: preference value 150
                            exit
                            evi 1
                        exit
                    exit
                    multi-homing all-active
                    lag 3
                    dot1q
                        q-tag-range 1
                    exit
                    no shutdown
                exit
```

On PE-4 and PE-5, the single-active ES "ES-45" is configured, as follows:

```
# on PE-4:
configure
    service
        sdp 46 mpls create                          # on PE-5: sdp 56
            far-end 192.0.2.6
            sr-isis
            keep-alive
                shutdown
            exit
            no shutdown
```

```
        exit
        system
            bgp-evpn
                ethernet-segment "ES-45" create
                    esi 00:45:45:45:45:45:00:00:01
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100           # on PE-5: preference value 150
                            exit
                            evi 1
                        exit
                    exit
                    multi-homing single-active
                    sdp 46                          # on PE-5: sdp 56
                    no shutdown
                exit
            exit
        exit
```

VPLS configuration

VPLS 1 is configured on PE-2 as follows. The configuration is similar on PE-1 and PE-3.

```
# on PE-2:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.2 comm-val 1 to 1000   # different values on PEs
        exit
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:1 import target:64500:1
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:1 create                      # LAG 1 also on PE-1, not on PE-3
                no shutdown
            exit
            sap lag-2:1 create                      # LAG 2 also on PE-1, not on PE-3
                no shutdown
            exit
            sap lag-3:1 create                      # LAG 3 also on PE-3, not on PE-1
                no shutdown
            exit
            no shutdown
        exit
```

The EVPN-VXLAN multi-homing capabilities are enabled in the PEs attached to VPLS 1 by the commands **auto-disc-route-advertisement** and **mh-mode network**. The **auto-disc-route-advertisement** command enables the advertisement and processing of multi-homing routes, and the **mh-mode network** command activates the DF election procedures.

ECMP is required for per-flow load balancing for VXLAN ES destinations with two or more next hops. In this example, ECMP is configured with a value of 2.

On PE-4, VPLS 1 is configured as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:1 import target:64500:1
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            spoke-sdp 46:1 create                   # on PE-5: spoke-sdp 56:1
            exit
            no shutdown
        exit
```

Show commands

The following command shows that the commands **mh-mode network** and **auto-disc-route-advertisement** are enabled:

```
*A:PE-2# show service id 1 bgp-evpn

Tools command to check local bias

The following **tools** command on PE-2 checks whether local bias is enabled for the peers in ES "vES-12_1_1". The output lists the PEs that are in the candidate DF election list for the ES and whether local bias procedures are enabled on them. In this case, only peer 192.0.2.1 is in the list and local bias is enabled. The output is similar for ES "vES-12_2_1".

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "vES-12_1_1" local-bias
-------------------------------------------------------------------------------
[08/26/2021 07:20:48] Vxlan Local Bias Information
-------------------------------------------------------------------+--------
Peer                                                               | Enabled
-------------------------------------------------------------------+--------
192.0.2.1                                                          | Yes
-------------------------------------------------------------------------------
```

The PE can only enable local bias procedures on a maximum of three PEs that are attached to the same ES and use multi-homed VXLAN services. If more than three PEs exist, the PEs are ordered by preference or IP address and only the top three PEs are considered for local bias. The order is as follows:

- lowest IP address (automatic service-carving)
- lowest preference (manual service-carving with configured EVI)

- highest preference (manual service-carving without configured EVI)

The following **tools** command on PE-2 shows that local bias is enabled for peer 192.0.2.3 in ES "vES-23_3_1":

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "vES-23_3_1" local-bias
-------------------------------------------------------------------------------
[08/26/2021 07:20:48] Vxlan Local Bias Information
-------------------------------------------------------------------+-------
Peer                                                               | Enabled
-------------------------------------------------------------------+-------
192.0.2.3                                                          | Yes
-------------------------------------------------------------------------------
```

Verify local bias for BUM traffic in all-active multi-homing ESs

Unknown unicast traffic is generated on MTU-7. This traffic is received in ingress queue 11 for SAP lag-1:1 on ingress node PE-1, as follows:

```
*A:PE-1# monitor service id 1 sap lag-1:1

===============================================================================
```

On the ingress node PE-1, the local bias mechanism forwards this BUM traffic toward EVPN-VXLAN destinations, and also to the local SAPs of all-active ESs, regardless of the DF state. In this case, the

local bias mechanism forwards the BUM traffic to lag-2:1 toward MTU-8, even though PE-1 is NDF in ES "vES-12_2_1".

```

For. Out/ExcProf      : 6                       408
-------------------------------------------------------------------------------
```

The egress PEs PE-2 and PE-3 receive the BUM traffic on the EVPN-VXLAN terminations. On egress PEs, the local bias mechanism filters BUM traffic based on the source IP address 192.0.2.1 of PE-1. PE-2 does not forward the traffic to the local SAPs lag-1:1 and lag-2:1, because PE-2 shares the all-active ESs "vES-12_1_1" and "vES-12_2_1" with PE-1. However, PE-2 forwards the BUM traffic to the non-shared ES "vES-23_3_1" because it is DF.

The following **monitor** commands show that PE-2 does not send any traffic toward SAP lag-1:1 or SAP lag-2:1.

```
*A:PE-2# monitor service id 1 sap lag-1:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf    : 0                       0
Dro. Out/ExcProf      : 0                       0
For. In/InplusProf    : 0                       0
For. Out/ExcProf      : 0                       0
---snip---
```

```
*A:PE-2# monitor service id 1 sap lag-2:1
---snip---

Queueing Stats(Egress QoS Policy 1)
```

```
Dro. In/InplusProf    : 0                       0
Dro. Out/ExcProf      : 0                       0
For. In/InplusProf    : 0                       0
For. Out/ExcProf      : 0                       0
---snip---
```

The following **monitor** command shows that PE-2 forwards the traffic to SAP lag-3:1 toward MTU-9:

```
*A:PE-2# monitor service id 1 sap lag-3:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf    : 0                       0
Dro. Out/ExcProf      : 0                       0
For. In/InplusProf    : 0                       0
For. Out/ExcProf      : 6                       408
---snip---
```

Egress node PE-3 receives BUM traffic on VXLAN and filters on IP address 192.0.2.1, but there are no shared ESs with PE-1. PE-3 is NDF for the non-shared ES vES-23_3_1, so it does not forward the traffic to SAP lag-3:1, as follows:

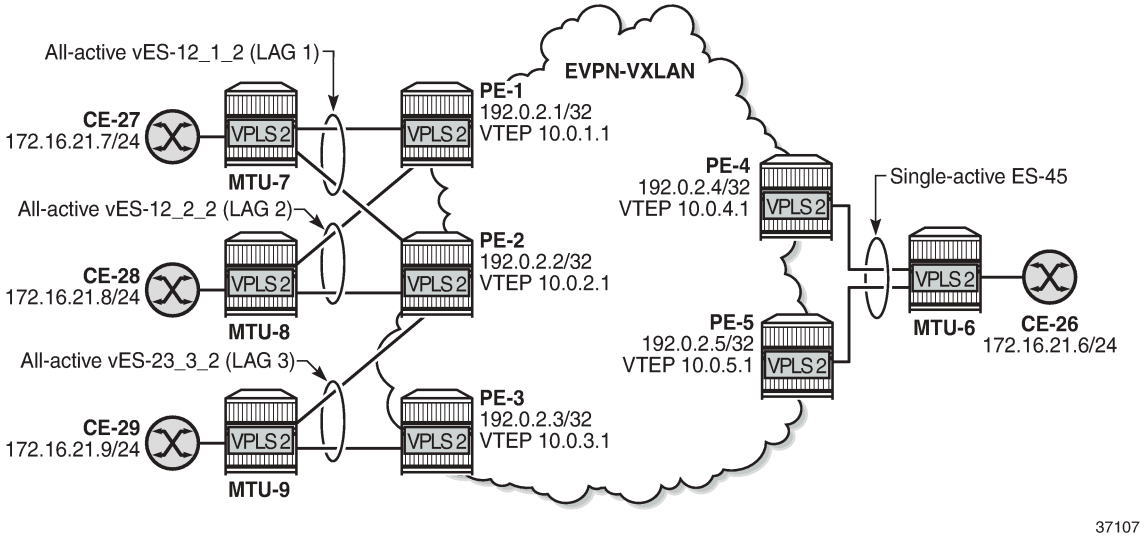
```
*A:PE-3# monitor service id 1 sap lag-3:1
---snip---

Queueing Stats(Egress QoS Policy 1)
Dro. In/InplusProf    : 0                       0
Dro. Out/ExcProf      : 0                       0
For. In/InplusProf    : 0                       0
For. Out/ExcProf      : 0                       0
---snip---
```

EVPN-VXLAN multi-homing with non-system IPv4 VTEP addresses

Figure 140: Non-system IPv4 VTEP multi-homing for VXLAN VPLS 2 shows the non-system IPv4 addresses to be used as VTEP addresses.

Figure 140: Non-system IPv4 VTEP multi-homing for VXLAN VPLS 2



Forwarding Path Extension (FPE), as described in the VXLAN Forwarding Path Extension chapter, is configured on all PEs. The configuration on PE-1 is as follows:

```
# on PE-1:
configure
    port-xc
        pxc 1 create
            port 1/2/6
            no shutdown
        exit
    exit
    port pxc-1.a
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port pxc-1.b
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port 1/2/6
        no shutdown
    exit
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 1 create
            path pxc 1
            vxlan-termination
        exit
    exit
    router Base
        interface "loopback1"
            address 10.0.1.0/31
            loopback
            ipv6
```

```
                address 2001:db8::10:0/127
            exit
            no shutdown
        exit
        isis 0
            interface "loopback1"
                passive
                no shutdown
            exit
        exit
    exit
    service
        system
            vxlan
                tunnel-termination 10.0.1.1 fpe 1 create
                tunnel-termination 2001:db8::10:1 fpe 1 create
            exit
        exit
    exit
```

The configuration on the other PEs is similar but with different IP addresses, for example, 10.0.2.1 on PE-2, 10.0.3.1 on PE-3, and so on.

The non-system IP address in each of the PEs in the ES must match in the following three commands for the local PE to be considered suitable for DF election:

- **es-orig-ip** 10.0.x.1 (ES)

  The **es-orig-ip** command modifies the originating IP address in the ES routes advertised for the ES and makes the system use this IP address when adding the local PE as DF candidate.

- **route-next-hop** 10.0.x.1 (ES)

  The **route-next-hop** command changes the next hop of the ES routes and AD per-ES routes to the configured address.

- **vxlan-src-vtep** 10.0.x.1 (VPLS)

  The **vxlan-src-vtep** command makes the router use the configured IP address as the VXLAN tunnel source IP address (source VTEP) for originating VXLAN-encapsulated frames for the service. The source VTEP is also used to set the BGP NLRI next hop in EVPN route advertisements for the services.

The following all-active multi-homing ESs are configured on PE-2 with non-system IPv4 address 10.0.2.1:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES-12_1_2" virtual create
                    esi 00:12:12:12:12:12:12:00:01:02
                    es-orig-ip 10.0.2.1
                    route-next-hop 10.0.2.1
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 150
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
```

```
                    q-tag-range 2
                exit
                no shutdown
            exit
            ethernet-segment "vES-12_2_2" virtual create
                esi 00:12:12:12:12:12:12:00:02:02
                es-orig-ip 10.0.2.1
                route-next-hop 10.0.2.1
                service-carving
                    mode manual
                    manual
                        preference create
                            value 100
                        exit
                    exit
                exit
                multi-homing all-active
                lag 2
                dot1q
                    q-tag-range 2
                exit
                no shutdown
            exit
            ethernet-segment "vES-23_3_2" virtual create
                esi 00:23:23:23:23:23:23:00:03:02
                es-orig-ip 10.0.2.1
                route-next-hop 10.0.2.1
                service-carving
                    mode manual
                    manual
                        preference create
                            value 100
                        exit
                    exit
                exit
                multi-homing all-active
                lag 3
                dot1q
                    q-tag-range 2
                exit
                no shutdown
            exit
        exit
    exit
```

The ES configuration on the other PEs is similar, but with different IP addresses and preference values.

VPLS 2 is configured with source VTEP 10.0.2.1 on PE-2:

```
# on PE-2:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            vxlan-src-vtep 10.0.2.1                 # different IP address on different PEs
            vxlan instance 1 vni 2 create
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:2 import target:64500:2
            exit
            bgp-evpn
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
```

```
                    auto-disc-route-advertisement
                    mh-mode network
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:2 create                      # lag-1 is shared with PE-1
                no shutdown
            exit
            sap lag-2:2 create                      # lag-2 is shared with PE-1
                no shutdown
            exit
            sap lag-3:2 create                      # lag-3 is shared with PE-3
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on the other PEs is similar.

Verification

The following command shows the DF status for the different ESs in VPLS 2 on PE-1:

```
*A:PE-1# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                           Status
-------------------------------------------------------------------------------
lag-1:2               vES-12_1_2                        NDF
lag-2:2               vES-12_2_2                        DF
===============================================================================
No sdp entries
No vxlan instance entries
```

The following command on PE-1 shows that the source VTEP for VPLS 2 is 10.0.1.1:

```
*A:PE-1# show service id 2 vxlan

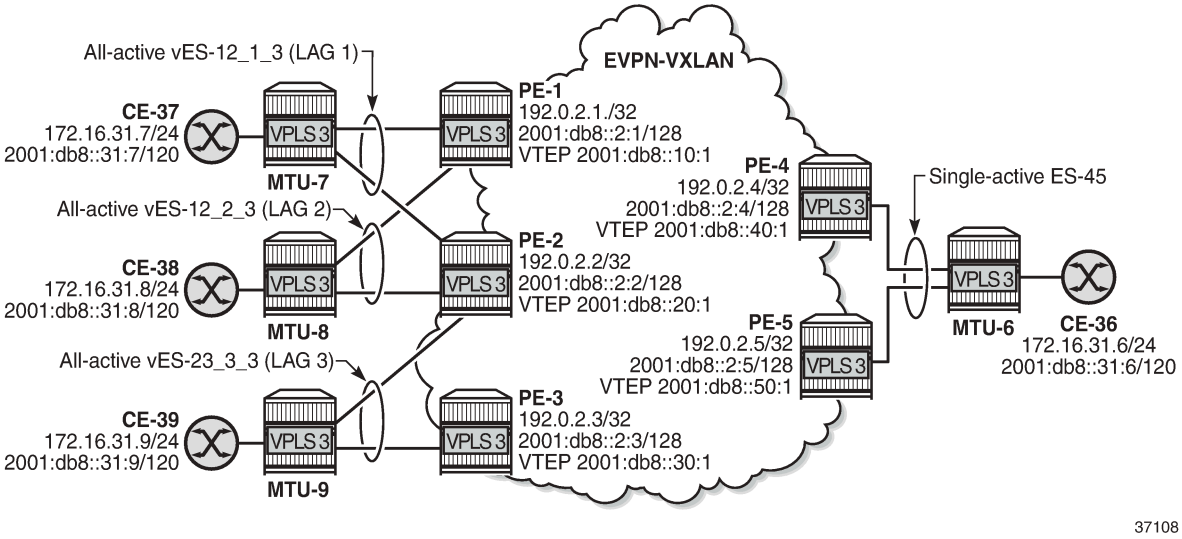
EVPN-VXLAN multi-homing with non-system IPv6 VTEP addresses

Figure 141: Non-system IPv6 VTEP multi-homing for VXLAN VPLS 2 shows the non-system IPv6 addresses to be used as VTEP addresses.

Figure 141: Non-system IPv6 VTEP multi-homing for VXLAN VPLS 2



Between the PEs, the router interfaces have IPv6 addresses as well as IPv4 addresses, and **ipv6-routing native** is configured in IS-IS on the PEs. FPE is configured with VXLAN termination 2001:db8::x0:1 on PE-x.

The following all-active multi-homing ESs with non-system IPv6 addresses are configured on PE-2:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES-12_1_3" virtual create        # same ES on PE-1
                    esi 00:12:12:12:12:12:12:00:01:03
                    es-orig-ip 2001:db8::20:1
                    route-next-hop 2001:db8::20:1
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1

```

Conclusion

All-active and single-active multi-homing can be configured for EVPN-VXLAN VPLSs. On all-active ESs, split-horizon for BUM traffic is based on local-bias, as described in RFC 8365.

EVPN R-VPLS Attached to IES

This chapter provides information about EVPN R-VPLS Attached to IES.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 16.0.R3. Routed VPLS (R-VPLS) services using EVPN-MPLS or EVPN-VXLAN can be attached to Internet Enhanced Services (IESs) in SR OS Release 16.0.R1, and later. R-VPLS using EVPN multi-homing is supported for EVPN-MPLS in SR OS Release 16.0.R1, and later. R-VPLS using multi-homing for EVPN-VXLAN will be supported in a later release; see the Release Notes.

Overview

R-VPLS services are often terminated on VPRN services. However, in some cases, R-VPLS services need to be terminated on IES services so that the traffic can be routed via the GRT. This is also supported for EVPN R-VPLS services.

In SR OS Release 16.0.R1, the following features are not supported for EVPN R-VPLSs attached to IESs:

- Dynamic IGPs (such as IS-IS, OSPF, RIP) on the R-VPLS interface
- EVPN tunnel on the IES interface
- IP route advertisement on R-VPLS (for the IP/IPv6 prefix BGP-EVPN RT-5 routes)

Configuration

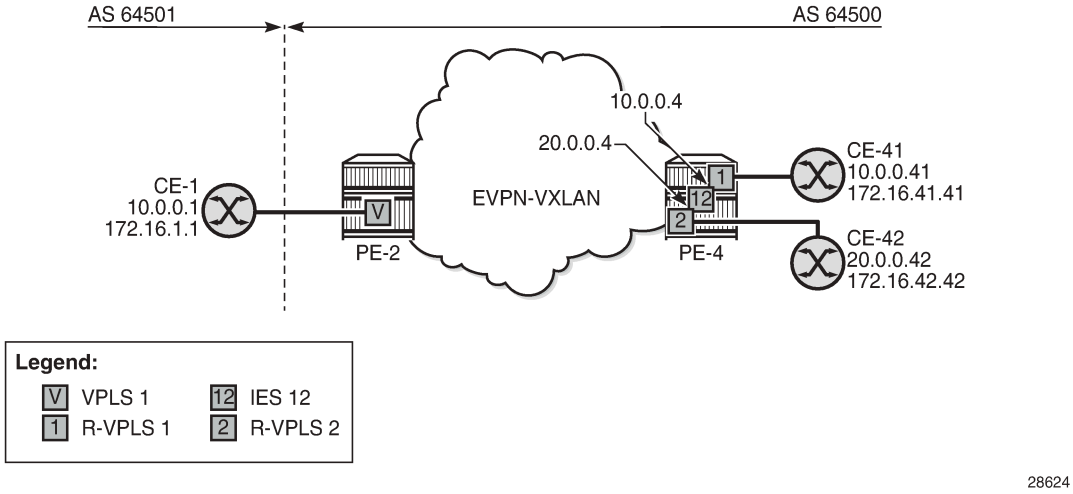
In this section, the following examples are configured:

- EVPN-VXLAN R-VPLS attached to IES without multi-homing
- EVPN-MPLS R-VPLS attached to IES with all-active and single-active multi-homing

EVPN-VXLAN R-VPLS attached to IES

Figure 142: EVPN-VXLAN R-VPLS attached to IES shows the example topology with EVPN-VXLAN configured on PE-2 and PE-4 and EVPN-VXLAN R-VPLSs 1 and 2 attached to IES 12 on PE-4.

Figure 142: EVPN-VXLAN R-VPLS attached to IES



CE-1 is in Autonomous System (AS) 64501 and the other nodes are in AS 64500.

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-2 and PE-4

Configuration on PE-2

On PE-2, BGP is configured for the EVPN address family, as follows:

```
*A:PE-2#
configure
    router
        bgp
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                type internal
                peer-as 64500
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
```

EVPN-VXLAN VPLS 1 is an ordinary VPLS on PE-2, not an R-VPLS, and configured as follows. CE-1 is attached to SAP 1/1/2:1 on PE-2.

```
*A:PE-2#
configure
    service
```

```
        vpls 1 name "VPLS-1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/1/2:1 create
            exit
            no shutdown
        exit
```

Configuration on PE-4

On PE-4, R-VPLS 1 is configured with service name "evi-1", as follows. CE-41 is attached to the SAP. The configuration of R-VPLS 2 is similar.

```
*A:PE-4#
configure
    service
        vpls 1 name "evi-1" customer 1 create
            description "EVPN-VXLAN R-VPLS 1"
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap pxc-1.a:1 create
                no shutdown
            exit
            no shutdown
        exit
```

Both R-VPLSs are attached to IES 12, which is configured as follows. Interface "evi-1" gets IP address 10.0.0.4/24 and interface "evi-2" gets IP address 20.0.0.4/24; these addresses are used as next-hop in default static routes on CE-1, CE-41, and CE-42.

```
*A:PE-4#
configure
    service
        ies 12 name "IES-12" customer 1 create
            interface "evi-1" create
                address 10.0.0.4/24
                mac 00:00:00:10:00:04
                vpls "evi-1"
                exit
            exit
            interface "evi-2" create
                address 20.0.0.4/24
```

```
                mac 00:00:00:20:00:04
                vpls "evi-2"
                exit
            exit
            no shutdown
        exit
```

The BGP configuration on PE-4 includes an EVPN session with PE-2 (neighbor 192.0.2.2), an internal IPv4 session with CE-42 (neighbor 20.0.0. 42), and an external IPv4 session with CE-1 (neighbor 10.0.0.1), as follows:

```
*A:PE-4#
configure
    router
        bgp
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "external-ipv4"
                family ipv4
                type external
                local-as 64500
                peer-as 64501
                neighbor 10.0.0.1
                exit
            exit
            group "internal-evpn"
                family evpn
                type internal
                neighbor 192.0.2.2
                exit
            exit
            group "internal-ipv4"
                family ipv4
                type internal
                neighbor 20.0.0.42
                exit
            exit
            no shutdown
        exit
```

In this example, CE-41 is emulated as VPRN 41 on PE-4. CE-41 is attached via port cross-connect (PXC) to R-VPLS 1. The default static route has next-hop 10.0.0.4 on interface "evi-1" in IES 12. CE-41 has an eBGP-IPv4 session configured with neighbor CE-1 (10.0.0.1); CE-41 exports prefix 172.16.41.0/24 to CE-1. The configuration of VPRN 41 on PE-4 is as follows:

```
*A:PE-4#
configure
    service
        vprn 41 name "CE-41" customer 1 create
            description "CE-41 attached to R-VPLS-1 on PE-4"
            autonomous-system 64500
            route-distinguisher 64500:41
            interface "int-1_41" create
                address 10.0.0.41/24
                mac 00:00:00:10:00:41
                sap pxc-1.b:1 create
                exit
            exit
            interface "lo1" create
```

```
                address 172.16.41.41/24
                mac 00:00:00:04:41:41
                loopback
            exit
            static-route-entry 0.0.0.0/0
                next-hop 10.0.0.4

```

CE-42 is emulated as VPRN 42 on PE-4. CE-42 is attached via PXC to R-VPLS 2. The default static route has next-hop equal to 20.0.0.4 on interface "evi-2" in IES 12. An iBGP-IPv4 session is configured to this IES interface (neighbor 20.0.0.4). CE-42 exports prefix 172.16.42.0/24 to this IES interface on PE-4. The configuration of VPRN 42 on PE-4 is as follows:

```
*A:PE-4#
configure
    service
         vprn 42 name "CE-42" customer 1 create
            description "CE-42 attached to R-VPLS-2 on PE-4"
            autonomous-system 64500
            route-distinguisher 64500:42
            interface "int-1_42" create
                address 20.0.0.42/24
                mac 00:00:00:20:00:42
                sap pxc-1.b:2 create
                exit
            exit
            interface "test42" create
                address 172.16.42.42/24
                mac 00:00:00:04:42:42
                sap pxc-1.b:42 create
            exit
            static-route-entry 0.0.0.0/0
                next-hop 20.0.0.4
                    no shutdown
                exit
            exit
            bgp
                router-id 20.0.0.42
                enable-peer-tracking
                rapid-withdrawal
                split-horizon
                group "internal-ipv4"
                    family ipv4
                    type internal
```

```
                    export "export-bgp-ipv4-42"
                    neighbor 20.0.0.4
                    exit
                exit
            exit
            no shutdown
        exit
```

The export policies are configured as follows:

```
*A:PE-4#
configure
    router
        policy-options
            begin
            prefix-list "172.16.41.x"
                prefix 172.16.41.0/24 exact
            exit
            prefix-list "172.16.42.x"
                prefix 172.16.42.0/24 exact
            exit
            policy-statement "export-bgp-ipv4-41"
                entry 10
                    from
                        prefix-list "172.16.41.x"
                    exit
                    action accept
                    exit
                exit
            exit
            policy-statement "export-bgp-ipv4-42"
                entry 10
                    from
                        prefix-list "172.16.42.x"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

Configuration on CE-1

On CE-1, the following static route is configured with next-hop 10.0.0. 4, which is the address on the interface "evi-1" in IES 12 on PE-4:

```
*A:CE-1#
configure
    router
        static-route-entry 0.0.0.0/0
            next-hop 10.0.0.4
                no shutdown
            exit
        exit
```

The following loopback address is configured on CE-1 for test purposes:

```
*A:CE-1#
```

```
configure
    router
        interface "lo1"
            address 172.16.1.1/24
            loopback
            no shutdown
        exit
```

On CE-1, eBGP-IPv4 sessions are configured to the IES interface "evi-1" on PE-4 (neighbor 10.0.0.4) and to CE-41 (neighbor 10.0.0.41) for the IPv4 address family. CE-1 exports prefix 172.16.1.0/24 to its peers. The BGP configuration is as follows:

```
*A:CE-1#
configure
    router
        policy-options
            begin
            prefix-list "172.16.1.x"
                prefix 172.16.1.0/24 exact
            exit
            policy-statement "export-bgp-ipv4"
                entry 10
                    from
                        prefix-list "172.16.1.x"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
        bgp
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "external"
                family ipv4
                type external
                export "export-bgp-ipv4"
                local-as 64501
                peer-as 64500
                neighbor 10.0.0.4
                exit
                neighbor 10.0.0.41
                exit
            exit
            no shutdown
        exit
```

Verification

On PE-4, the following shows that five BGP sessions are established:

- eBGP-IPv4 session with neighbor 10.0.0.1 (CE-1) from the base router
- iBGP-IPv4 session with neighbor 20.0.0.42 (CE-42) from the base router
- iBGP-EVPN session with neighbor 192.0.2.2 (PE-2) from the base router
- eBGP-IPv4 session with neighbor 10.0.0.1 (CE-1) from VPRN 41 (CE-41)

- iBGP-IPv4 session to IES interface "evi-2" (20.0.0.4) from VPRN 42 (CE-42)

Routes have been exchanged between the peers. The eBGP-IPv4 sessions are established using R-VPLS 1.

```

-------------------------------------------------------------------------------
No. of Routes: 4
```

Likewise, the following route table for CE-42 includes the remote prefix 172.16.1.0/24 received as BGP IPv4 route, but the next-hop is 20.0.0.4 instead of 10.0.0.1, because CE-42 is in subnet 20.0.0.0/24 whereas CE-1 is in subnet 10.0.0.0/24. Routing between the subnets 20.0.0.0/24 and 10.0.0.0/24 needs to be done in IES 12 on PE-4.

```

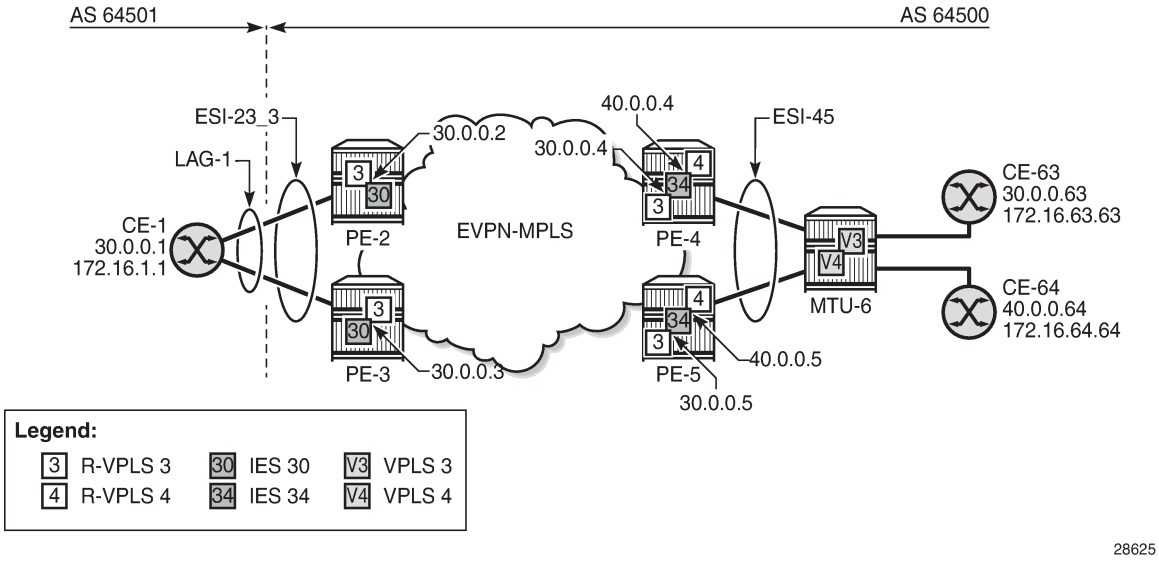
EVPN-MPLS R-VPLS attached to IES

Figure 143: Example Topology for EVPN-MPLS R-VPLS attached to IES shows the example topology for EVPN-MPLS R-VPLS attached to IES. All-active multi-homing (AA MH) is configured on PE-2 and PE-3, while single-active (SA) MH is configured on PE-4 and PE-5. R-VPLS 3 is configured on all PEs. IES 30 is configured on PE-2 and PE-3, whereas IES 34 is configured on PE-4 and PE-5. On MTU-6, VPLS 3 and 4 are regular VPLSs, not routed.

Figure 143: Example Topology for EVPN-MPLS R-VPLS attached to IES



The initial configuration on the nodes includes:

- Cards, MDAs, ports
- LAG 1 on CE-1, PE-2, PE-3
- Router interfaces between the PEs and toward MTU-6
- IS-IS on these interfaces (alternatively, OSPF can be configured)
- LDP on these interfaces

- BGP configured for the EVPN address family on the PEs. PE-2 is the RR and has the following BGP configuration:

```
*A:PE-2#
configure
    router
        bgp
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal-evpn"
                family evpn
                cluster 192.0.2.2
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

Configuration on PE-2 and PE-3

The service configuration on PE-2 and PE-3 is almost identical; only the IP address on the IES interface "evi-3" is different. The AA MH ES "ESI-23_3" is configured as follows, with LAG 1 and dot1q tag 3, so it is only applicable to VPLS 3.

```
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23_3" virtual create
                    esi 01:00:00:00:00:23:00:03:03:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 3
                    exit
                    no shutdown
                exit
```

R-VPLS 3 has EVPN-MPLS enabled and is configured on PE-2 and PE-3, as follows. SAP lag-1:3 matches the configured LAG and the q-tag range for ESI-23_3.

```
configure
    service
        vpls 3 name "evi-3" customer 1 create
            allow-ip-int-bind
            exit
            bgp
            exit
            bgp-evpn
```

```
                evi 3
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap lag-1:3 create
                no shutdown
            exit
            no shutdown
        exit
```

The following is the IES configuration on PE-2. In this example, IES 30 is only configured to demonstrate EVPN all-active multi-homing on R-VPLS with IES. If it were removed, everything still works and the connectivity between the CEs remains.

```
*A:PE-2#
configure
    service
        ies 30 name "IES-30" customer 1 create
            interface "evi-3" create
                address 30.0.0.2/24
                mac 00:00:00:30:00:02
                vpls "evi-3"
                exit
            exit
            no shutdown
        exit
```

The IES configuration on PE-3 is similar, only using IP address 30.0.0.3/24.

Configuration on PE-4 and PE-5

On PE-4, SDP 46 is configured toward MTU-6. An SA MH ES "ESI-45" is configured using this SDP, as follows:

```
*A:PE-4#
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
```

The configuration is similar on PE-5. SDP 56 is configured toward MTU-6 and ES "ESI-45" is configured with SDP 56 instead.

On PE-4, R-VPLSs 3 and 4 are configured with EVPN-MPLS, as follows:

```
*A:PE-4#
configure
    service
        vpls 3 name "evi-3" customer 1 create
            description "EVPN-MPLS R-VPLS 3"
            allow-ip-int-bind
            exit
            bgp
            exit
            bgp-evpn
                evi 3
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 46:3 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 4 name "evi-4" customer 1 create
            description "EVPN-MPLS R-VPLS 4"
            allow-ip-int-bind
            exit
            bgp
            exit
            bgp-evpn
                evi 4
                mpls bgp 1
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            spoke-sdp 46:4 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration is similar on PE-5; only the spoke-SDPs are different (spoke-SDP 56:3 and 56:4).

On PE-4, IES 34 is configured with interfaces "evi-3" and "evi-4", as follows. Passive VRRP is configured on both interfaces. With passive VRRP configured on both PE-4 and PE-5, both PEs behave as master.

```
*A:PE-4#
configure
    service
        ies 34 name "IES-34" customer 1 create
            interface "evi-3" create
                address 30.0.0.4/24
                mac 00:00:00:30:00:04
```

```
                vrrp 1 passive
                    backup 30.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "evi-3"
                exit
            exit
            interface "evi-4" create
                address 40.0.0.4/24
                mac 00:00:00:40:00:04
                vrrp 1 passive
                    backup 40.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                vpls "evi-4"
                exit
            exit
            no shutdown
        exit
```

The configuration of IES 34 is similar on PE-5, but the interface IP addresses are different: 30.0.0.5/24 and 40.0.0.5/24. The MAC addresses are also different.

To enable routing between CE-1 and CE-64 in a different subnet, BGP sessions are established with CE-1 (neighbor 30.0.0.1 in AS 64501) and CE-64 (neighbor 40.0.0.64 in AS 64500) for the IPv4 address family. The CEs export prefixes, but no export policy needs to be configured on PE-4 and PE-5. The BGP configuration on PE-4 is as follows:

```
*A:PE-4#
configure
    router
        bgp
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "external"
                family ipv4
                type external
                local-as 64500
                peer-as 64501
                neighbor 30.0.0.1
                exit
            exit
            group "internal-evpn"
                family evpn
                type internal
                neighbor 192.0.2.2
                exit
            exit
            group "internal-ipv4"
                family ipv4
                peer-as 64500
                local-address 30.0.0.4
                neighbor 40.0.0.64
                exit
            exit
            no shutdown
```

The BGP configuration on PE-5 is almost identical; the local address is 30.0.0.5 instead.

Configuration on CE-1

The configuration on CE-1 includes the following:

- Router interface to VPLS 3 (ESI-23_3) with IP address 30.0.0.1/24 and LAG-1:3 assigned to it
- Loopback interface with IP address 172.16.1.1/24 for test purposes
- Static default route with next-hop 30.0.0.254, which is the VRRP backup address for IES interface "evi-3" on PE-4 and PE-5
- Export policy to export prefix 172.16.1.0/24
- BGP sessions for the IPv4 address family toward PE-4 (30.0.0.4), PE-5 (30.0.0.5), and CE-63 (30.0.0.63)

The router configuration on CE-1 is as follows:

```
*A:CE-1>config>router# info
----------------------------------------------
#--------------------------------------------------
echo "IP Configuration"
#--------------------------------------------------
        interface "int-CE-1-VPLS1_ES-23"
            address 30.0.0.1/24
            port lag-1:3
            no shutdown
        exit
        interface "lo1"
            address 172.16.1.1/24
            loopback
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
            no shutdown
        exit
        autonomous-system 64501
#--------------------------------------------------
echo "Static Route Configuration"
#--------------------------------------------------
        static-route-entry 0.0.0.0/0
            next-hop 30.0.0.254
                no shutdown
            exit
        exit
#--------------------------------------------------
echo "Policy Configuration"
#--------------------------------------------------
        policy-options
            begin
            prefix-list "172.16.1.x"
                prefix 172.16.1.0/24 exact
            exit
            policy-statement "export-bgp-ipv4"
                entry 10
                    from
                        prefix-list "172.16.1.x"
                    exit
                    action accept
                    exit
                exit
            exit
```

```
            commit
        exit
#--------------------------------------------------
echo "BGP Configuration"
#--------------------------------------------------
        bgp
            router-id 30.0.0.1
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "external"
                family ipv4
                type external
                export "export-bgp-ipv4"
                local-as 64501
                peer-as 64500
                neighbor 30.0.0.4
                exit
                neighbor 30.0.0.5
                exit
                neighbor 30.0.0.63
                exit
            exit
            no shutdown
        exit
-------------------------------------------
```

Configuration on MTU-6

The configuration on MTU-6 includes the following:

- Router interfaces
- IS-IS
- LDP
- One policy to export prefix 172.16.63.0/24 and another policy to export prefix 172.16.64.0/24
- BGP is not configured in the base router

The following service configuration on MTU-6 includes the SDP configuration and the VPLSs 3 and 4, which are not routed:

```
*A:MTU-6#
configure
    service
        sdp 64 mpls create
            far-end 192.0.2.4
            ldp
            no shutdown
        exit
        sdp 65 mpls create
            far-end 192.0.2.5
            ldp
            no shutdown
        exit
        vpls 3 name "VPLS3" customer 1 create
            endpoint "CORE" create
            exit
            sap pxc-1.a:3 create
```

```
            exit
            spoke-sdp 64:3 endpoint "CORE" create
            exit
            spoke-sdp 65:3 endpoint "CORE" create
            exit
           no shutdown
        exit
        vpls 4 name "VPLS4" customer 1 create
            endpoint "CORE" create
            exit
            sap pxc-1.a:4 create
            exit
            sap pxc-1.a:64 create
            exit
            spoke-sdp 64:4 endpoint "CORE" create
            exit
            spoke-sdp 65:4 endpoint "CORE" create
            exit
           no shutdown
        exit
```

In this example, CE-63 and CE-64 are simulated by VPRN 63 and VPRN 64. The default static route has next-hop 30.0.0.254, which is the VRRP backup address on interface "evi-3" in IES 34 on both PE-4 and PE-5. BGP is configured within VPRN 63 and 64. The prefix 172.16.63.0/24 is exported by BGP in VPRN 63 (CE-63) and prefix 172.16.64.0/24 is exported by BGP in VPRN 64 (CE-64). The configuration of VPRN 63 and VPRN 64 is as follows:

```
*A:MTU-6#
configure
    service
        vprn 63 name "CE-63" customer 1 create
            autonomous-system 64500

Verification

In the AA MH ES "ESI-23_3", PE-3 is the designated forwarder (DF) for R-VPLS 3 and PE-2 is NDF, as follows:

```
*A:PE-2# show service id 3 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-1:3               ESI-23_3                        NDF
===============================================================================
No sdp entries
No vxlan instance entries
*A:PE-2#
```

```
*A:PE-3# show service id 3 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-1:3               ESI-23_3                        DF
===============================================================================
No sdp entries
No vxlan instance entries
*A:PE-3#
```

In the SA MH ES "ESI-45", PE-4 is NDF for R-VPLS 3 and DF for R-VPLS4, as follows:

```
*A:PE-4# show service id 3 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
46:3                  ESI-45                          NDF
===============================================================================
No vxlan instance entries
```

```
*A:PE-4# show service id 4 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                   Eth-Seg                         Status

-------------------------------------------------------------------------------
*A:MTU-6#
```

The difference is that CE-63 (with IP address 30.0.0.63) is in the same subnet as CE-1 (30.0.0.1), whereas CE-64 is not (40.0.0.64). Routing between these subnets can be done in IES 34 on PE-4 and PE-5. CE-63 exports prefix 172.16.63.0/24 directly to CE-1, whereas CE-64 exports prefix 172.16.64.0/24 to PE-4 and PE-5 instead, which will advertise prefix 172.16.64.0/24 to their BGP peer CE-1. The following route table on CE-1 shows BGP route 172.16.63.0/63 with next-hop 30.0.0.63 (CE-63) and BGP route 172.16.64.0/64 with next-hop 30.0.0.4 (interface "evi-3" on PE-4):

```
*A:CE-1# show router route-table

       system                                                        0
```

```
-------------------------------------------------------------------------------
No. of Routes: 6
```

In IES 34 on PE-4 (and PE-5), routing can be done between subnet 30.0.0.0/24 and 40.0.0.0/24. The following route table on PE-4 shows BGP route 172.16.1.0/24 with next-hop CE-1 (30.0.0.1) and BGP route 172.16.64.0/24 with next-hop CE-64 (40.0.0.64). The same entries occur in the route table on PE-5.

```
*A:PE-4# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
30.0.0.0/24                                   Local   Local     00h32m24s  0
       evi-3                                                        0
40.0.0.0/24                                   Local   Local     00h32m24s  0
       evi-4                                                        0
172.16.1.0/24                                 Remote  BGP       00h25m47s  170
       30.0.0.1                                                     0
172.16.64.0/24                                Remote  BGP       00h30m23s  170
       40.0.0.64                                                    0
---snip---
```

The route table of CE-63 (VPRN 63 on MTU-6) shows a BGP route for prefix 172.16.1.0/24 with next-hop 30.0.0.1 (CE-1), as follows:

```
*A:MTU-6# show router 63 route-table protocol bgp

===============================================================================
Route Table (Service: 63)

```

```
No. of Routes: 4
```

The connectivity between CE-1 and CE-63 is verified as follows:

```
*A:CE-1# ping 172.16.63.63 source 172.16.1.1
PING 172.16.63.63 56 data bytes
64 bytes from 172.16.63.63: icmp_seq=1 ttl=64 time=4.67ms.
64 bytes from 172.16.63.63: icmp_seq=2 ttl=64 time=4.97ms.
---snip---
```

The following traceroute command verifies the connectivity between CE-1 and CE-64. The intermediate hop is 30.0.0.4, the IP address of the IES interface "evi-3" on PE-4:

```
*A:CE-1# traceroute 172.16.64.64 source 172.16.1.1
traceroute to 172.16.64.64 from 172.16.1.1, 30 hops max, 40 byte packets
  1  30.0.0.4 (30.0.0.4)    3.81 ms  3.79 ms  3.13 ms
  2  172.16.64.64 (172.16.64.64)    4.55 ms  5.29 ms  5.08 ms
```

When the traceroute is launched from CE-64, the intermediate hop is 40.0.0.4, the IP address of the IES interface "evi-4" on PE-4:

```
*A:MTU-6# traceroute router 64 172.16.1.1
traceroute to 172.16.1.1, 30 hops max, 40 byte packets
  1  40.0.0.4 (40.0.0.4)    3.08 ms  2.97 ms  2.93 ms
  2  172.16.1.1 (172.16.1.1)    4.61 ms  4.37 ms  4.91 ms
```

The following ARP table on CE-1 contains entries for different nodes in the 30.0.0.0/24 subnet:

```
*A:CE-1# show router arp

Conclusion

With EVPN R-VPLS attached to IES services, EVPN services are connected to the base router, so the traffic can be routed in the global routing table (GRT).

EVPN VPWS Services with SRv6 Transport

This chapter provides information about SRv6 support for EVPN-VPWS overlay services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. SRv6 support for EVPN-VPWS overlay services is supported on FP-based platforms with FP4-based network ports in SR OS Release 22.7.R1 and later.

Chapter EVPN for MPLS Tunnels is prerequisite reading.

Overview

Service providers prefer an optimized, standardized, and unified control plane for VPNs. EVPN-VPWS is supported in SRv6 networks that may also run other EVPN-based services, such as EVPN-based VPLS services or Layer 3 EVPN IFL (interface-less) services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432, because there is no need to advertise MAC/IP advertisement routes in VPWS. EVPN-VPWS is described in RFC 8214, and the signaling aspects to support SRv6 are specified in RFC 9252.

EVPN-VPWS supports all-active multihoming (per-flow load-balancing multihoming) as well as single-active multihoming (per-service load-balancing multihoming), using the same Ethernet segments (ESs) used for EVPN-based VPLS services. EVPN-VPWS uses route type 1 and route type 4; it does not use route types 2, 3, or 5, because MAC/IP routes, inclusive multicast routes, or IP-prefix routes are not required.

EVPN-VPWS uses AD per-EVI routes, and optionally, if multihoming is used, AD per-ES and ES routes are required:

- route type 1 - Auto-discovery per EVPN instance (AD per-EVI). This route type is used in all EVPN-VPWS scenarios, with or without multihoming. For EVPN-VPWS, the Ethernet tag field is encoded with the local attachment circuit (AC) of the advertising PE. This value is configured using the **configure service epipe** *<service-id>* **bgp-evpn local-attachment-circuit** *<ac-name>* **eth-tag** *<tag-value>* command. The route distinguisher (RD), label, and the Ethernet segment identifier (ESI) are encoded as for EVPN-based VPLS. The label field is used as service label. In case of multihoming, AD per-EVI routes containing the same ESI are used to provide aliasing and a backup path to the PEs part of the ES. The L2 MTU field is encoded with the service MTU configured in the Epipe. The flags used for EVPN-VPWS are:
  - Flag C: this flag is set if a control word is configured in the service; however, this does not apply if the transport is SRv6.
  - Flag P: this flag is set if the advertising PE is a primary PE.

- If no multihoming is used, there is no primary PE (P = 0).
- In all-active multihoming, all PEs in the ES are primary (P = 1).
- In single-active multihoming, only one PE per-EVI in the ES is a primary (P = 1).

– Flag B: this flag is set if the advertising PE is a backup PE.

- Flag B is only set in case of single-active multihoming and only for one PE, even if more than two PEs are present in the same single-active ES. The backup PE is the winner of the second designated forwarder (DF) election (excluding the DF). The remaining non-DF PEs send B = 0.

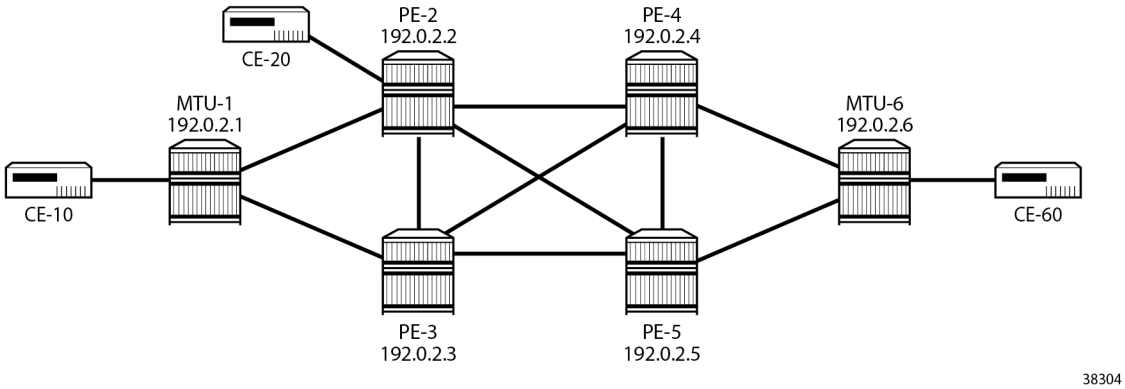
If there is no multihoming, the ESI, flag P, and flag B are set to zero.

- route type 1 - Auto-discovery per Ethernet segment (AD per-ES). This route type has the same encoding as for EVPN-based VPLS. The AD per-ES route is only used in multihoming scenarios where it is advertised from the PE for each ES. This route type carries the ESI label (used for split-horizon, but only for VPLS services and not for Epipe services) and can affect procedures such as the DF election, as well as the aliasing on remote PEs.
- route type 4 - ES route. This route type has the same encoding as for EVPN-based VPLS. The ES route is only used in multihoming scenarios. This route type advertises a local configured ES. The exchange of this route type can discover remote PEs that are part of the same ES and the DF election algorithm among them.

Configuration

Figure 144: EVPN-VPWS example topology shows the example topology that is used throughout this chapter.

Figure 144: EVPN-VPWS example topology



The example topology consists of six SR OS nodes with the following initial configuration:

- Network (or hybrid) ports interconnect the core PEs with configured router interfaces.
- MTU-1 is a pure Ethernet aggregator. The ports toward the core PEs are access ports. Likewise, the ports on PE-2 and PE-3 toward MTU-1 are access ports.
- Core PEs and MTU-6 run IS-IS on all interfaces.
- Link LDP is configured between all PEs, and toward and from MTU-6.

- EVPN uses BGP for exchanging reachability information at the service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although a separate router is typically used, in this chapter, PE-2 is used as route reflector with the following BGP configuration:

```
*A:PE-2# configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "gr_v6_internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                extended-nh-encoding ipv4 vpn-ipv4
                advertise-ipv6-next-hops evpn
                neighbor 2001:db8::2:3
                exit
                neighbor 2001:db8::2:4
                exit
                neighbor 2001:db8::2:5
                exit
            exit
        exit all
```

The BGP configuration on the other PEs is as follows:

```
*A:PE-3#, *A:PE-4#, *A:PE-5# configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "gr_v6_internal"
                family evpn
                peer-as 64500
                extended-nh-encoding ipv4 vpn-ipv4
                advertise-ipv6-next-hops evpn
                neighbor 2001:db8::2:2
                exit
            exit
        exit all
```

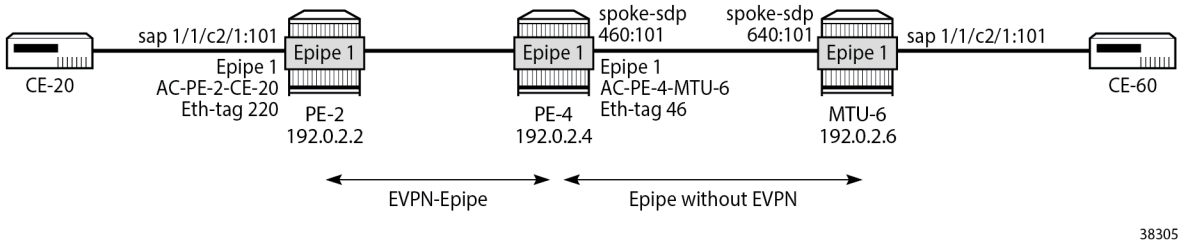
The following sections describe the EVPN-VPWS scenarios:

- SRv6 tunnels in EVPN-VPWS services without multihoming
- SRv6 tunnels in EVPN-VPWS services with all-active multihoming
- SRv6 tunnels in EVPN-VPWS services with single-active multihoming

SRv6 tunnels in EVPN-VPWS services without multihoming

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke SDPs at the access, as shown in Figure 145: Example topology for EVPN-VPWS without multihoming.

Figure 145: Example topology for EVPN-VPWS without multihoming



On PE-2, Epipe 1 is configured as follows:

```
*A:PE-2# configure
    service
        epipe 1 name "Epipe-1" customer 1 create
            segment-routing-v6 1 create
                locator "loc_Epipe-1"
                    function
                        end-dx2
                    exit
                exit
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-PE-2-CE-20 create
                    eth-tag 220
                exit
                remote-attachment-circuit AC-PE-4-MTU-6 create
                    eth-tag 46
                exit
                evi 10
                segment-routing-v6 bgp 1 srv6-instance 1 default-locator "loc_Epipe-1" create
                    # source-address 2001:db8::2:2    # defined for SRv6 on router level
                    no shutdown
                exit
            exit
            sap 1/1/c2/1:101 create
                no shutdown
            exit
            no shutdown
        exit all
```

On PE-4, the service configuration is as follows:

```
*A:PE-4# configure
    service
        sdp 460 create
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
```

```
        exit
        epipe 1 name "Epipe-1" customer 1 create
            segment-routing-v6 1 create
                locator "loc_Epipe-1"
                    function
                        end-dx2
                    exit
                exit
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-PE-4-MTU-6 create
                    eth-tag 46
                exit
                remote-attachment-circuit AC-PE-2-CE-20 create
                    eth-tag 220
                exit
                evi 10
                segment-routing-v6 bgp 1 srv6-instance 1 default-locator "loc_Epipe-1" create
                    # source-address 2001:db8::2:4    # defined for SRv6 on router level
                    no shutdown
                exit
            exit
            spoke-sdp 460:101 create
                no shutdown
            exit
            no shutdown
        exit all
```

The following commands are relevant for the EVPN-VPWS configuration:

- the **bgp** command enables the context for the BGP configuration relevant to the service. The **bgp** context configures the common BGP parameters for all BGP families in the service, such as the RD and the route target (RT). Even if the general BGP parameters for the service are auto-derived, the **bgp** context must be enabled.

```
*A:PE-2# configure service epipe 1 bgp ?
  - bgp
  - no bgp

 [no] adv-service-mtu - Configure service-mtu to be advertised
 [no] pw-template-bi* + Configure pw-template bind policy
 [no] route-distingu* - Configure route distinguisher
 [no] route-target    - Configure route target
 [no] vsi-export      - VSI export route policies
 [no] vsi-import      - VSI import route policies
```

- The following commands can be configured in the **bgp-evpn** context:

```
*A:PE-2# configure service epipe 1 bgp-evpn ?
  - bgp-evpn
  - no bgp-evpn

 [no] evi             - EVPN Identifier
 [no] local-attachme* + Configure local attachment circuit information
 [no] mpls            + Configure BGP EVPN mpls
 [no] remote-attachm* + Configure remote attachment circuit information
 [no] segment-routin* + Configure SRv6 instance
 [no] vxlan           + Configure BGP EVPN vxlan
```

– The **evi** command configures a 2-byte or 3-byte EVPN identifier (EVI) used for auto-deriving the service RD, service RT, and for the service carving (or DF election) when multihoming is used. For 2-byte EVIs, the auto-derivation of RD and RT is as follows:

  • RD system-ip:evi

  • RT autonomous-system:evi

  The EVI values must be unique in the system, regardless of the type of service they are assigned to (Epipe or VPLS).

– The **local-attachment-circuit** and **remote-attachment-circuit** commands configure the two attachment circuits connected by the EVPN-VPWS service. The configured Ethernet tag for the local AC is advertised in the Ethernet tag field of the AD per-EVI route for the Epipe, along with the corresponding RD, RT, and label. Both local and remote Ethernet tags are necessary to bring up the Epipe service. If the received Ethernet tag for the Epipe service matches the configured remote AC Ethernet tag, an EVPN-SRv6 destination is created to the next hop.

  The local Ethernet tag cannot be modified without disabling **bgp-evpn segment-routing-v6** in the Epipe, as shown in the following output:

```
*A:PE-2# configure service epipe "Epipe-1" bgp-evpn local-attachment-circuit AC-PE-2-CE-
20 eth-tag 221
MINOR: SVCMGR #8036 evpn-vpws ac eth-tag not allowed - cannot change while evpn mpls/
vxlan/srv6 is enabled
```

  Unlike local Ethernet tags, remote Ethernet tags can be modified without disabling bgp-evpn.

– The following configuration options are available for Epipes in the **configure service epipe 1 bgp-evpn segment-routing-v6** context:

```
*A:PE-2# configure service epipe 1 bgp-evpn segment-routing-v6 ?
  - no segment-routing-v6 [bgp <bgp-instance>]
  - segment-routing-v6 [bgp <bgp-instance>] [srv6-instance <[1..1]>] [default-locator
    <name>] [create]

 <bgp-instance>       : [1..1]
 <name>               : [64 chars max]
 <create>             : keyword

 [no] default-route-* - Configure default-route-tag to match against export policies
      ecmp            - Configure maximum ECMP routes information
 [no] evi-three-byte* - Enable/Disable evi-three-byte-auto-rt
 [no] force-qinq-vc-* - Forces qinq-vc-type forwarding in the data-path
 [no] force-vlan-vc-* - Forces vlan-vc-type forwarding in the data-path
 [no] oper-group      - Configure oper-group
      resolution      - Configure route resolution options
      route-next-hop  - Configure route next-hop
 [no] shutdown        - Enable/disable SRV6
 [no] source-address  - Configure source IPv6 address
```

  This output shows a subset of the options for VPLS services; see chapter EVPN for MPLS Tunnels for a longer list of options.

When the local AC (sap 1/1/c2/1:101) is up, PE-2 sends a BGP EVPN AD per-EVI route that contains Ethernet tag 220 for the local AC:

```
# on PE-2:
4 2022/11/30 09:46:56.704 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
```

```
"Peer 1: 2001:db8::2:4: UPDATE

When the received RT matches and the received Ethernet tag matches the configured remote AC Ethernet tag, the EVPN-SRv6 destination, which consists of a termination endpoint (TEP) and a SID) is created on PE-2 and PE-4:

```
*A:PE-2# show service id 1 segment-routing-v6 instance 1 destinations

===============================================================================
TEP, SID
===============================================================================
Instance  TEP Address                       Segment Id
-------------------------------------------------------------------------------
1         192.0.2.4                         2001:db8:aaaa:104:7fff:6000::
-------------------------------------------------------------------------------
Number of TEP, SID: 1
-------------------------------------------------------------------------------

===============================================================================
Instance  Eth SegId                     Num. Macs     Last Change
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

Note:
The egress label for the EVPN-SRv6 destination on PE-4 is 524278. The 24-bit label value in the BGP update debug is 16 (2^4) times as high:

524 278 * 16 = 8 388 448

because the debug message is shown before the router can parse the label field and determine if it corresponds to an MPLS label or a transposed function (20 bits), or to a VXLAN VNI (24 bits).

The BGP AD per-EVI routes for Ethernet tag 46 are shown with the following command:

```
*A:PE-2# show router bgp routes evpn auto-disc tag 46
===============================================================================

Note:
Each PE sends its service MTU into the L2 MTU field in the l2-attribute in the AD per-EVI route for the Epipe service. The received L2 MTU is checked. In case of a mismatch between the received MTU and the configured service MTU, the router does not set up the EVPN destination and, therefore, the service does not come up.

SRv6 tunnels in EVPN-VPWS services with multihoming

SR OS supports EVPN multihoming as per RFC 8214.

The EVPN multihoming implementation is based on the concept of the ES. An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multihoming to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects. It can also be shared between Epipe and VPLS services.

Each ES has a unique ESI that is 10 bytes and is manually configured. The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homing CEs are assumed to be connected to an ES with ESI = 0 (single-homing ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-based VPLS service by default. An ES can be shared by multiple services; a specific SAP or spoke SDP is automatically associated with an ES when the SAP is defined in the same LAG or port configured in the ES, or when the spoke SDP is defined in the same SDP configured in the ES.

Regardless of the multihoming mode, the local Ethernet tag values must match on all the PEs that are part of the same ES. The PEs in the ES use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for an EVI. The DF election is only relevant for single-active multihoming ESs. For Epipes defined in an all-active multihoming ES, there is no DF election required, because all PEs are forwarding traffic and all traffic is treated as unicast.

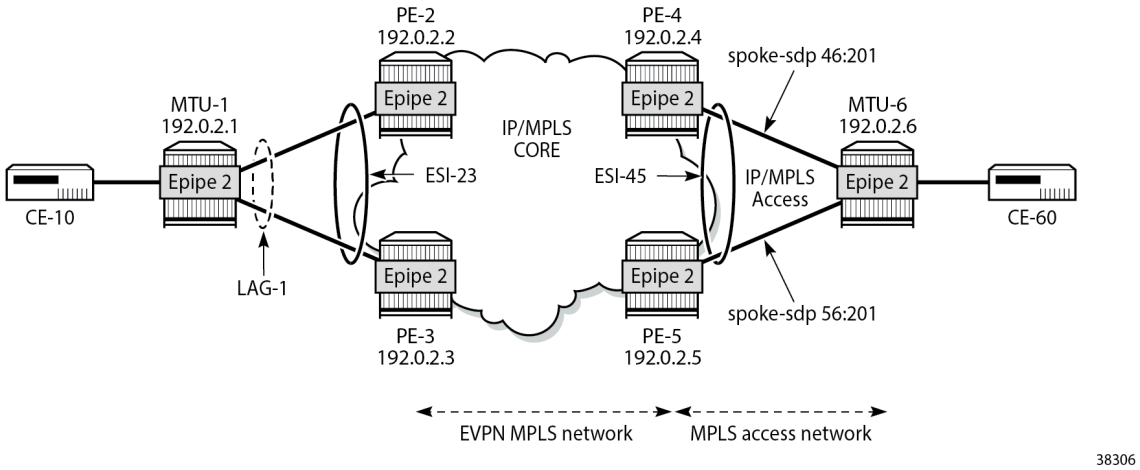
Aliasing is supported when sending traffic to an ES destination. Assuming ECMP is enabled on the ingress PE (and shared queuing or ingress policing are configured), per-flow load-balancing is performed among all the PEs that advertise P = 1. PEs advertising P = 0 are not considered as next hops for an ES destination.

The following sections show the configuration of:

- an all-active multihoming ES with a LAG associated with it
- a single-active multihoming ES linked to an SDP

Figure 146: Example topology EVPN-VPWS with multihoming shows the example topology has an all-active multihoming ES "ESI-23" with a LAG associated with it in PE-2 and PE-3. A single-active multihoming ES "ESI-45" with an SDP associated with it is configured in PE-4 and PE-5.

Figure 146: Example topology EVPN-VPWS with multihoming



SRv6 tunnels in EVPN-VPWS services with all-active multihoming

All-active multihoming allows for per-flow load-balancing. Unlike EVPN-based VPLS services, EVPN-VPWS has no DF election in all-active multihoming. All PEs in the ES are active and the remote PE performs per-flow load-balancing. ESI-23 is configured on PE-2 and PE-3 as all-active multihoming and is

associated with LAG 1. This LAG is used as a SAP in Epipe 2 on both PE-2 and PE-3. The configuration of the ES and Epipe 2 is identical on PE-2 and PE-3, including the local AC and remote AC names and Ethernet tags:

```
*A:PE-2#, *A:PE-3# configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23" create

                no shutdown
            exit
            no shutdown
        exit
    exit all
```

See chapter EVPN for MPLS Tunnels for a detailed explanation of the configuration parameters of the ES.

In EVPN-VPWS multihoming scenarios, three route types are exchanged: AD per-EVI, AD per-ES, and ES routes. The following ES route (route type 4) for ESI 01:00:00:00:00:23:00:00:00:01, sent by PE-2, is imported at PE-3:

```
# on PE-3:
8 2022/11/30 10:02:59.056 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:2
"Peer 1: 2001:db8::2:2: UPDATE
Peer 1: 2001:db8::2:2 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 71
```

```
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:

        target:00:00:00:00:23:00
"
```

The target 00:00:00:00:23:00 in the extended community is derived from the ESI (bytes 2 to 7) and is only imported by the PEs that are part of the same ES; that is, PE-2 and PE-3 in this example.

At the same time, the following AD per-ES route (route type 1) with maximum Ethernet (MAX-ET) tag (all Fs) and label 0 is sent by RR PE-2 and imported by the rest of the PEs. The following two BGP updates with MAX-ET are received by PE-4:

```
# on PE-4:
15 2022/11/30 10:03:42.705 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:2

    Flag: 0xc0 Type: 40 Len: 37 Prefix-SID-attr:
       SRv6 Services TLV (37 bytes):-
           Type: SRV6 L2 Service TLV (6)
                Type: 1 Len: 6
                BL:0 NL:0 FL:0 AL:0 TL:0 TO:0
"
```

The ESI label is in the extended community, as well as the indication that the multihoming is all-active. Epipe services do not require ESI labels because BUM traffic is not recognized in EVPN-VPWS services. However, because the ES can be shared by Epipe and VPLS services, the AD per-ES route still includes a non-zero ESI label. In this case, the transport is SRv6, so there are no ESI labels. The label field in the ESI-label extended community is an implicit-null value (3) and the included SRv6 Services TLV encodes a SID with value 0.

The following two AD per-EVI routes (route type 1) with Ethernet tag 231 sent by RR PE-2 are received and imported on PE-4:

```
# on PE-4:
14 2022/11/30 10:03:42.705 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:2

```

When ECMP is greater than 1 on the ingress PE, multiple TEPs can correspond to a specific ESI (aliasing). In this case, ECMP = 2 and PE-4 and PE-5 have two TEP addresses and SIDs for ESI 01:00:00:00:00:23:00:00:00:01, as shown for PE-4:

```
*A:PE-4# show service id 2 segment-routing-v6 esi 01:00:00:00:00:23:00:00:00:01

* indicates that the corresponding row element may have been truncated.
```

Note:
Even if ECMP is configured, the ingress router (where a SAP is configured) does not load-balance the traffic unless shared queuing or ingress policing is configured in the SAP. This is not specific to EVPN, but is generic to the way Epipes forward traffic.

In all-active multihoming for EVPN-VPWS, there is no DF election and all PEs in the ES are active. For ESI-23, both PE-2 and PE-3 are active primary DF, but there are no DF candidates, because there is no DF election:

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "ESI-23" evi 20

===============================================================================
EVI DF and Candidate List

SRv6 tunnels in EVPN-VPWS services with single-active multihoming

Single-active multihoming allows for per-service load-balancing. Single-active multihoming is configured on PE-4 and PE-5 with ES "ESI-45". Both PEs have an SDP to MTU-6, which is associated with the ES and to the Epipe service. The configuration of the local and remote AC names and Ethernet tags is identical on PE-4 and PE-5.

On PE-4, the service configuration is as follows:

```
*A:PE-4# configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
            exit
        exit
        epipe 2 name "Epipe-2" customer 1 create
            segment-routing-v6 1 create
                locator "loc_Epipe-2"
                    function
                        end-dx2
                    exit
                exit
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-ESI-45-MTU-6 create
                    eth-tag 456
                exit
                remote-attachment-circuit AC-ESI-23-MTU-1 create
                    eth-tag 231
                exit
                evi 20
                segment-routing-v6 bgp 1 srv6-instance 1 default-locator "loc_Epipe-2" create
                    # source-address 2001:db8::2:4    # defined for SRv6 on router level
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 46:201 create
```

```
                no shutdown
            exit
            no shutdown
        exit
    exit all
```

On PE-5, the configuration is similar, but with a different SDP:

```
*A:PE-5# configure
    service
        sdp 56 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 56
                    no shutdown
                exit
            exit
        exit
        epipe 2 name "Epipe-2" customer 1 create
            segment-routing-v6 1 create
                locator "loc_Epipe-2"
                    function
                        end-dx2
                    exit
                exit
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-ESI-45-MTU-6 create
                    eth-tag 456
                exit
                remote-attachment-circuit AC-ESI-23-MTU-1 create
                    eth-tag 231
                exit
                evi 20
                segment-routing-v6 bgp 1 srv6-instance 1 default-locator "loc_Epipe-2" create
                    # source-address 2001:db8::2:5    # defined for SRv6 on router level
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 56:201 create
                no shutdown
            exit
            no shutdown
        exit
    exit all
```

The core PEs exchange three route types: AD per-EVI, AD per-ES, and ES routes.

As an example, the following is the ES route with originator PE-4 sent by RR PE-2 to PE-5. It contains a target 00:00:00:00:45:00 in the extended community that is derived from the ESI:

```
# on PE-2:
56 2022/11/30 10:04:09.636 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5
"Peer 1: 2001:db8::2:5: UPDATE
Peer 1: 2001:db8::2:5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 85
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0 ESI: 01:00:00:00:00:45:00:00:00:01, IP-Len:
 4 Orig-IP-Addr: 192.0.2.4
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:

        target:00:00:00:00:45:00
"
```

The AD per-ES route has a MAX-ET tag and an ESI label in the extended community. The multihoming mode is single-active. As in the case of all-active multihoming, the ESI label is not used in Epipe services. The following BGP update with originator PE-5 is sent by RR PE-2 to its client PE-4:

```
# on PE-2:
53 2022/11/30 10:04:09.634 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
"Peer 1: 2001:db8::2:4: UPDATE
Peer 1: 2001:db8::2:4 - Send BGP UPDATE:

                BL:0 NL:0 FL:0 AL:0 TL:0 TO:0
"
```

The AD per-EVI route contains flags for primary and backup, which are different for routes received from PE-4 and PE-5. In this case, PE-4 is the primary in the single-active multihoming ES (P = 1):

```
# on PE-2:
67 2022/11/30 10:04:13.745 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5
"Peer 1: 2001:db8::2:5: UPDATE
Peer 1: 2001:db8::2:5 - Send BGP UPDATE:

Routes : 4
===============================================================================
```

For each PE in the single-active ES, there are two AD routes: the routes with MAX-ET are AD per-ES routes and the routes with a configured Ethernet tag are AD per-EVI routes.

The EVPN VPWS destination for Epipe 2 on PE-2 is ESI-45, as shown in the following output:

```
*A:PE-2# show service id 2 segment-routing-v6 instance 1 destinations

===============================================================================
TEP, SID
===============================================================================
Instance  TEP Address                       Segment Id

```

The DF election is key for the forwarding and backup functions in single-active multihoming ESs. The PE elected as DF is the primary for the ES in the Epipe and unblocks its SAP and spoke SDP for upstream and downstream traffic. The rest of the PEs in the ES bring their ES SAPs or spoke SDPs operationally down.

PE-5 is a non-DF, as follows:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" evi 20

===============================================================================

192.0.2.5                                  11/30/2022 10:04:11  0          Disabl*
-------------------------------------------------------------------------------
Number of entries: 2
===============================================================================
* indicates that the corresponding row element may have been truncated.
```

In single-active multihoming, the service SAP or spoke SDP is brought operationally down on the non-DF, as shown in the following output:

```
*A:PE-5# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
56:201           Spok     192.0.2.6       Up      Down      524275    524275
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
```

```
===============================================================================
```

The spoke sdp 56:201 is operationally down with a StandbyForMHProtocol flag:

```
*A:PE-5# show service id 2 sdp 56:201 detail | match Flag
Flags              : StandbyForMHProtocol
```

Two consecutive DF elections take place: the first DF election includes all PEs in the ES for that Epipe and determines which PE is the primary PE (flags P = 1, B = 0). The second DF election excludes this DF and determines which PE is the backup (P = 0, B = 1). All other PEs signal flags P = 0 and B = 0.

When the primary PE fails, AD per-ES and AD per-EVI withdrawal messages are sent to the remote PE, which updates its next hop to the backup. The backup PE takes over immediately without waiting for the ES activation timer (configured with the **es-activation-timer** command) to bring up its SAP and spoke SDP.

ES failures

When the SDP toward the primary (DF) fails, the backup PE needs to take over. An SDP failure is emulated and log 99 on PE-4 shows that SDP 46 is operationally down and PE-4 is no longer the DF:

```
155 2022/11/30 10:11:25.583 UTC MINOR: SVCMGR #2303 Base
"Status of SDP 46 changed to admin=up oper=down"

157 2022/11/30 10:11:25.584 UTC MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-45, EVI:20, Designated Forwarding state changed to:false"
```

Remote PEs receive route withdrawal updates (unreachable NLRI) from the former DF PE-4, for example on PE-2:

```
# on PE-2:
2 2022/11/30 10:11:25.585 UTC MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4

"
```

PE-5 brings up its spoke SDP without waiting for the ES activation timer and takes over immediately. It is now the only DF candidate, and therefore the DF, as follows:

```
*A:PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" evi 20

===============================================================================
EVI DF and Candidate List

-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
* indicates that the corresponding row element may have been truncated.
```

Because of the default DF election algorithm, this process is revertive; as soon as the SDP 46 is operationally up again, a new DF election is triggered with two DF candidates and PE-4 is elected as DF. A non-revertive mode is also available if preference-based DF election is configured.

Troubleshooting and debugging

The following **show** and **debug** commands can be used in EVPN-VPWS:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service segment-routing-v6 [**<*ip-address*>**]**
- **show service id** <*service-id*> **bgp-evpn**
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **show log log-id** *99*

Most of these commands have been shown in the preceding sections; some commands are shown in this section.

Information about the configured boot timers (before DF election) and ES activation timer (after the system has been elected DF) is shown as follows:

```
*A:PE-2# show redundancy bgp-evpn-multi-homing

===============================================================================
Redundancy BGP EVPN Multi-homing Information
===============================================================================
Boot-Timer              : 10 secs
Boot-Timer Remaining    : 0 secs
ES Activation Timer     : 3 secs
===============================================================================
```

See chapter EVPN for MPLS Tunnels for a description of these timers.

The following command shows that the BGP route type 4 (ES route) messages are only imported by the PEs in the same ES; for example, on PE-3:

```
*A:PE-3# show router bgp routes evpn eth-seg

```

In addition to the preceding commands, the following **tools dump** commands may be useful:

- **tools dump service evpn usage** - This command shows the number of EVPN-SRv6 (and EVPN-MPLS and EVPN-VXLAN) destinations in the system.
- **tools dump service system bgp-evpn ethernet-segment** <*name*> **evi** <*value*> **df** - This command computes the DF election for a specific ESI and EVI. For all-active multihoming, there is no DF election and all PEs forward traffic. For single-active multihoming, one PE is active for a service while another PE is a backup. This command shows the DF (primary), even if it is not the local PE.

The usage of EVPN resources is shown as follows:

```
*A:PE-2# tools dump service evpn usage

vxlan-srv6-evpn-mpls usage statistics at 11/30/2022 10:08:31:

Evpn Etree Remote BUM Leaf Labels               :             0
```

On PE-2, there is one SRv6 TEP (192.0.2.4 in Epipe 1 and in Epipe 2) and there are two SRv6 destinations: 192.0.2.4 and ESI 01:00:00:00:00:45:00:00:00:01. PE-5 is not an SRv6 TEP for PE-2 because it is not a primary and, therefore, is not forwarding any traffic.

In all-active multihoming, the DF election is not applicable:

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-23" evi 20 df

[11/30/2022 10:08:31] All Active VPWS or IP-ALIASING - DF N/A
```

In single-active multihoming, the following command shows which PE is the DF:

```
*A:PE-5# tools dump service system bgp-evpn ethernet-segment "ESI-45" evi 20 df

[11/30/2022 10:08:36] Computed DF: 192.0.2.4 (Remote) (Boot Timer Expired: Yes)
[11/30/2022 10:08:36] Computed Backup: 192.0.2.5 (This Node)
```

The command is launched on PE-5, which is a backup. The computed DF is PE-4 and the boot timer has expired, meaning there is no DF re-election pending.

Conclusion

EVPN-VPWS is a simplified point-to-point version of RFC 7432. EVPN provides a unified control plane mechanism that simplifies the network deployment and operation. Single-active and all-active multihoming can be used in Epipes; EVPN-VPWS is a differentiator of EVPN compared to traditional TLDP or BGP Epipe redundancy mechanisms.

EVPN-IFF BGP Attribute Propagation Between Families

This chapter provides information about EVPN-IFF BGP attribute propagation between families .

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 22.7.R1. EVPN Interface-ful (EVPN-IFF) BGP attribute propagation between BGP families based on uniform propagation is supported in SR OS Release 21.2.R1 and later.

For more information on routed VPLS in EVPN, see chapters EVPN for VXLAN Tunnels (Layer 3) and EVPN for MPLS Tunnels in Routed VPLS .

Overview

SR OS allows multiple BGP owners in the same VPRN service to receive or advertise IP prefixes contained in the VPRN route table. A VPRN route table can simultaneously install and process IPv4 or IPv6 prefixes for the following owners:

- EVPN Interface-ful (EVPN-IFF)
- EVPN Interface-less (EVPN-IFL)
- VPN-IP (also referred to as IP-VPN routes)
- IP (also referred to as BGP PE-CE routes)

EVPN-IFF routes are EVPN IP-prefix routes, otherwise known as route type 5 (RT-5) routes, that are imported and exported based on the configuration of the R-VPLS services attached to the VPRN. To enable the EVPN-IFF model, the command **config>service>vpls>bgp-evpn>ip-route-advertisement** needs to be configured. By default, BGP attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. However, BGP attributes can be used to influence routing (for example, local preference, Autonomous System (AS) path, communities, and so on), and therefore, SR OS supports EVPN-IFF BGP attribute propagation to other BGP families (uniform propagation), as described in *draft-ietf-bess-evpn-ipvpn-interworking*.

The following CLI command is used to enable EVPN-IFF BGP attribute propagation and EVPN-IFF best path selection:

```
*A:PE-4>config>service>system>bgp-evpn# ip-prefix-routes ?
  - ip-prefix-routes

 [no] iff-attribute-* - Enable attribute uniform propagation
 [no] iff-bgp-path-s* - Enable bgp path selection
```

The **iff-bgp-path-selection** command cannot be enabled when **iff-attribute-uniform-propagation** is disabled.

When **iff-attribute-uniform-propagation** is enabled on a node:

- the following BGP path attributes are propagated:
  - AS path
  - domain path (D-PATH), supported in SR OS Release 21.10.R1 and later
  - IBGP-only attributes, when advertising to an IBGP neighbor: local preference, originator ID, cluster ID
  - Multiple Exit Discriminator (MED)
  - communities, large communities, extended communities
- the following BGP path attributes are not propagated across families:
  - any type 0x06 extended communities supported by RT-5 routes:
    - MAC mobility extended community
    - EVPN router MAC extended community
  - BGP encapsulation extended community
  - Route Target extended community
  - BGP tunnel encapsulation attribute
  - BGP prefix-SID attribute used in RT-5 routes and VPN-IP routes for Segment Routing over IPv6 dataplane (SRv6) services
- IBGP-only attributes are only propagated to IBGP neighbors; EBGP-only attributes only to EBGP neighbors
- routes received with well-known communities, such as no-advertise or no-export(-subconfed), are sent or not sent depending on the community values
- BGP path attributes are propagated even when doing route leaking between routing instances

If multiple EVPN-IFF routes for the same prefix are received for the same VPRN, they are by default ordered and selected based on the lowest R-VPLS Ifindex, Route Distinguisher (RD), and Ethernet tag.

When **iff-bgp-path-selection** is enabled, EVPN-IFF routes with the same or different RD are selected based on regular BGP path selection rules in the following order:

1. valid route wins over invalid route (invalid routes are looped routes or routes where the originator ID matches the receiving router)
2. lowest origin validation state (origin validation state: valid is preferred to origin validation state: not found; origin validation state: not found is preferred to origin validation state: invalid) – applicable to IPv4, IPv6, or BGP Labeled Unicast (BGP-LU) routes
3. lowest Routing Table Manager (RTM) preference
4. highest local preference
5. shortest D-PATH
6. lowest Accumulated Interior Gateway Protocol (AIGP) metric (AIGP is not supported for EVPN-IFL, EVPN-IFF, or IP-VPN routes)
7. shortest AS path

8. lowest origin (origin: IGP is preferred to origin: EGP; origin: EGP is preferred to origin: incomplete)
9. lowest MED (routes without MED are considered as zero or infinity based on the configuration of the **always-compare-med** command)
10. lowest owner type (owner type: BGP-label is preferred to owner type: BGP; owner type: BGP is preferred to owner type: BGP-VPN) with BGP-VPN referring to VPN-IP and EVPN-IFL
11. EBGP wins over IBGP
12. lowest route-table or tunnel-table cost to the next-hop

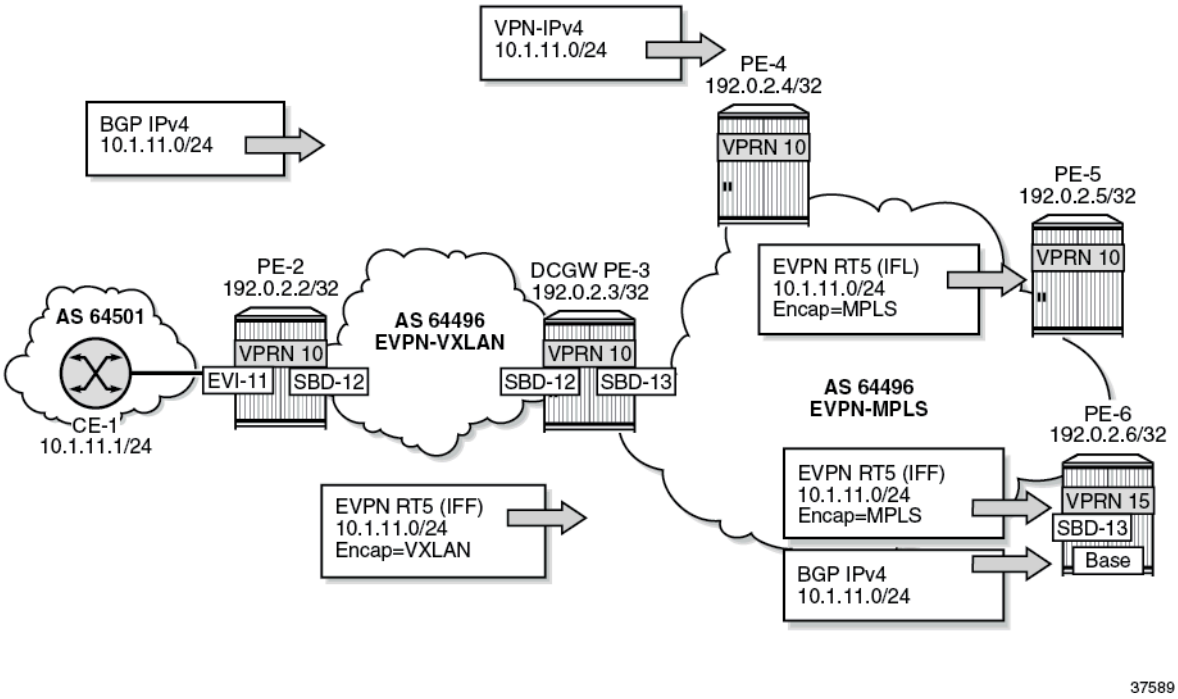
    Note: The **ignore-nh-metric** command is not supported for EVPN-IFF.

13. lowest next-hop type – a next-hop resolved to a tunnel-table entry is considered as a lower type than a next-hop resolved to a route-table entry
14. lowest router ID – applicable to IBGP peers
15. shortest cluster list length – applicable to IBGP peers
16. lowest IP address – IP address refers to the peer that advertised the route
17. EVPN-IFL wins over IPVPN
18. next-hop check (IPv4 next-hop wins over IPv6, then lowest next-hop wins) - The next-hop check is a tiebreaker if BGP receives the same prefix for VPN-IPv6 and EVPN-IFL. An IPv6 prefix received as VPN-IPv6 has an IPv6 next-hop whereas the same IPv6 prefix received as EVPN-IFL can have an IPv4 next-hop.
19. lowest RD for route-table selection
20. lowest path ID (add-path)

Configuration

Figure 147: Example topology shows the example topology with PE-3 as Data Center Gateway (DCGW) between an EVPN-VXLAN network and an EVPN-MPLS network. Routed VPLS is configured on PE-2, PE-3, and PE-6. Supplementary broadcast domain "SBD-12" is configured in the EVPN-VXLAN network between PE-2 and PE-3; "SBD-13" in the EVPN-MPLS network between PE-3 and PE-6. On PE-2, Ethernet VPN instance "EVI-11" is configured toward CE-1.

Figure 147: Example topology



CE-1 advertises prefix 10.1.11.0/24 to BGP neighbor 10.0.0.2 in VPRN 10 on PE-2. PE-2 sends an EVPN-IFF route to DCGW PE-3. PE-3 forwards the prefix 10.1.11.0/24 as VPN-IPv4 route to PE-4, as EVPN-IFL route to PE-5, as EVPN-IFF route to PE-6, and as IPv4 route to PE-6.

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces on all PEs
- IS-IS on the router interfaces
- LDP on the router interfaces on PE-3, PE-4, PE-5, and PE-6

On the PEs, BGP is configured for the EVPN address family. Between PE-3 and PE-4, both the VPN-IPv4 and the EVPN address family are configured. The configuration on PE-3 is as follows:

```
# on PE-3:
configure
    router Base
        autonomous-system 64496
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            rapid-update evpn
            group "internal1"
                family evpn
                peer-as 64496
                neighbor 192.0.2.2
                exit
```

```
            exit
            group "internal"
                peer-as 64496
                neighbor 192.0.2.4
                    family vpn-ipv4 evpn
                exit
                neighbor 192.0.2.5
                    family evpn
                exit
                neighbor 192.0.2.6
                    family evpn
                exit
            exit
        exit
```

On CE-1, BGP is configured in VPRN 11 for the IPv4 address family. The export policy adds communities "1:1" and "2:2" and sets the MED to a value of 81.

```
# on CE-1:
configure
    router Base
        policy-options
            begin
            community "1:1_2:2"
                members "1:1" "2:2"
            exit
            policy-statement "export-vnf-to-all"
                entry 10
                    from
                        protocol direct direct-interface
                    exit
                    action accept
                        community add "1:1_2:2"
                        bgp-med set 81
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn 11 name "VPRN 11" customer 1 create
            autonomous-system 64501
            interface "int-CE-1-PE-2" create
                address 10.0.0.1/24
                sap 1/1/2:11 create
                exit
            exit
            interface "test" create
                address 10.1.11.1/24
                sap 1/1/2:12 create
                exit
            exit
            bgp
                export "export-vnf-to-all"
                split-horizon
                group "CE-1-PE-2"
                    type external
                    peer-as 64496
                    neighbor 10.0.0.2
                    exit
                exit
            exit
```

```
            no shutdown
```

On PE-2, VPRN 10 has R-VPLS interface "int-EVI-11" toward CE-1 and R-VPLS interface "int-SBD-12" toward PE-3. BGP is configured toward neighbor 10.0.0.1 on CE-1 and the import policy sets the local preference (LP) to 200, as follows:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            policy-statement "local-preference-200"
                entry 10
                    action accept
                        local-preference 200
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn 10 name "VPRN 10" customer 1 create
            autonomous-system 64496
            interface "int-SBD-12" create
                vpls "SBD-12"
                    evpn-tunnel
                exit
            exit
            interface "int-EVI-11" create
                address 10.0.0.2/24
                vrrp 1 owner passive
                    backup 10.0.0.2
                exit
                vpls "EVI-11"
                exit
            exit
            bgp
                import "local-preference-200"
                local-as 64496
                split-horizon
                group "PE-2-CE-1"
                    type external
                    peer-as 64501
                    neighbor 10.0.0.1
                    exit
                exit
            exit
            no shutdown
        exit
        vpls 11 name "EVI-11" customer 1 create
            allow-ip-int-bind
            exit
            stp
                shutdown
            exit
            sap 1/1/1:11 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 12 name "SBD-12" customer 1 create
            allow-ip-int-bind
```

```
            exit
            vxlan instance 1 vni 12 create
            exit
            bgp-evpn
                no mac-advertisement
                ip-route-advertisement
                evi 12
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

On PE-3, VPRN 10 is configured with:

- three interfaces:
  - R-VPLS interface "int-SBD-12" toward PE-2
  - R-VPLS interface "int-SBD-13" toward PE-6
  - interface "int-VPRN10-PE-3-to-PE-6" to the base router of PE-6.
- BGP-IPVPN for the exchange of VPN-IPv4 routes with PE-4
- BGP-EVPN to propagate EVPN-IFL routes to PE-5 and EVPN-IFF routes to PE-6
- BGP to propagate BGP IPv4 routes to the base router on PE-6. The export policy is only required in the BGP configuration.

```
# on PE-3:
configure
    router Base
        policy-options
            begin
            prefix-list "10.1.0.0"
                prefix 10.1.0.0/16 longer
            exit
            policy-statement "export-bgp"
                entry 10
                    from
                        prefix-list "10.1.0.0"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
    exit
    service

            no shutdown
        exit
```

On PE-4, VPRN 10 is configured with BGP-IPVPN, as follows. BGP between PE-3 and PE-4 is configured for the VPN-IPv4 address family.

```
# on PE-4:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 192.0.2.4:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

On PE-5, VPRN 10 is configured with BGP-EVPN, as follows:

```
# on PE-5:
configure
    service
        vprn 10 name "VPRN 10" customer 1 create
            bgp-evpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 192.0.2.5:10
                    vrf-target target:64496:10
                    no shutdown
                exit
            exit
            bgp
                no shutdown
            exit
            no shutdown
        exit
```

In the base router of PE-6, BGP is configured to neighbor 10.15.16.3 on PE-3. VPRN 15 is configured with R-VPLS interface "int-SBD-13" toward PE-3. The configuration is as follows:

```
# on PE-6:
configure
    router Base
        interface "int-PE-6-to-VPRN10-PE-3"
            address 10.15.16.6/24
            port 1/1/1:13
        exit
```

```
        bgp
            group "PE-6-CE"
                family ipv4
                neighbor 10.15.16.3
                    type internal
                    local-as 64496
                    peer-as 64496
                exit
            exit
        exit
    exit
    service
        vprn 15 name "VPRN 15" customer 1 create
            autonomous-system 64502
            interface "int-SBD-13" create
                vpls "SBD-13"
                    evpn-tunnel
                exit
            exit
            no shutdown
        exit
        vpls 13 name "SBD-13" customer 1 create
            allow-ip-int-bind
            exit
            bgp
            exit

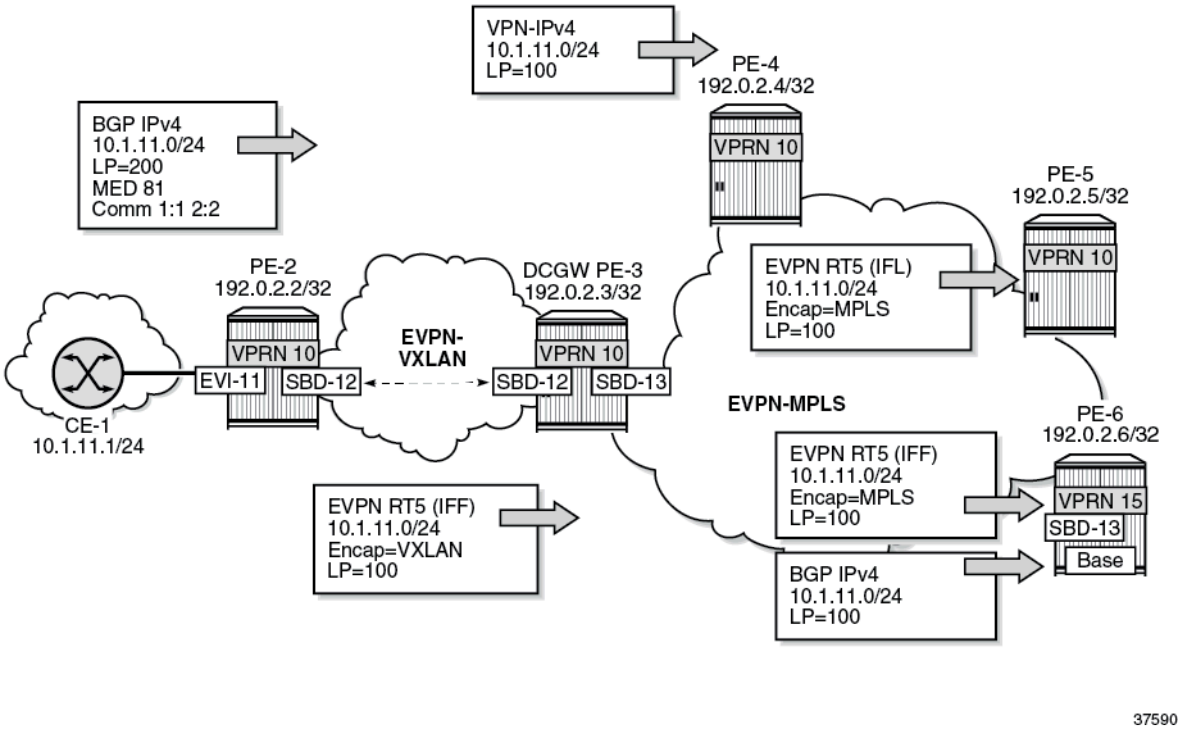
                no mac-advertisement
                ip-route-advertisement
                evi 13
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

Default behavior

By default, BGP path attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. Figure 148: EVPN-IFF BGP path attributes are re-originated by PE-2 and PE-3 shows that PE-2 receives an IPv4 route for prefix 10.1.11.0/24 with non-default BGP path attributes, whereas PE-2 propagates the prefix as an EVPN-IFF route with default path attributes.

Figure 148: EVPN-IFF BGP path attributes are re-originated by PE-2 and PE-3



VPRN 10 on PE-2 received a BGP IPv4 route for prefix 10.1.11.0/24 with LP 200, MED 81, and communities "1:1" and "2:2":

```
*A:PE-2# show router 10 bgp routes 10.1.11.0/24 hunt
===============================================================================

Uniform propagation for EVPN-IFF BGP path attributes to different BGP families

Enabling **iff-attribute-uniform-propagation** is not allowed when there are services enabled with **bgp-evpn ip-route-advertisement**:

```
*A:PE-2>config>service>system>bgp-evpn>ip-prefix-routes# iff-attribute-uniform-propagation
MINOR: SVCMGR #1003 Inconsistent value - iff-attribute-uniform-propagation cannot be enabled/
disabled when there are "bgp-evpn ip-route-advertisement" enabled services
```

To enable **iff-attribute-uniform-propagation** and **iff-best-path-selection** on PE-2, **ip-route-advertisement** must be temporarily disabled in VPLS "SBD-12", as follows:

```
# on PE-2
configure
    service
        vpls "SBD-12"
            bgp-evpn
                no ip-route-advertisement
            exit
        exit
        system
            bgp-evpn
                ip-prefix-routes
                    iff-attribute-uniform-propagation
                    iff-bgp-path-selection
                exit
            exit
        exit
        vpls "SBD-12"
            bgp-evpn
                ip-route-advertisement
            exit
        exit
```

In a similar configuration, **iff-attribute-uniform-propagation** and **iff-bgp-path-selection** are enabled on the other PEs.

The following command shows that uniform propagation for EVPN-IFF BGP path attributes and BGP path selection are enabled:

```
*A:PE-2# show service system bgp-evpn

PE-3 propagates BGP IPv4 route 10.1.11.0/24 to PE-6 with LP 200, MED 81, and communities "1:1" and "2:2". The following IPv4 route is received at PE-6:

```
*A:PE-6# show router bgp routes 10.1.11.0/24 hunt

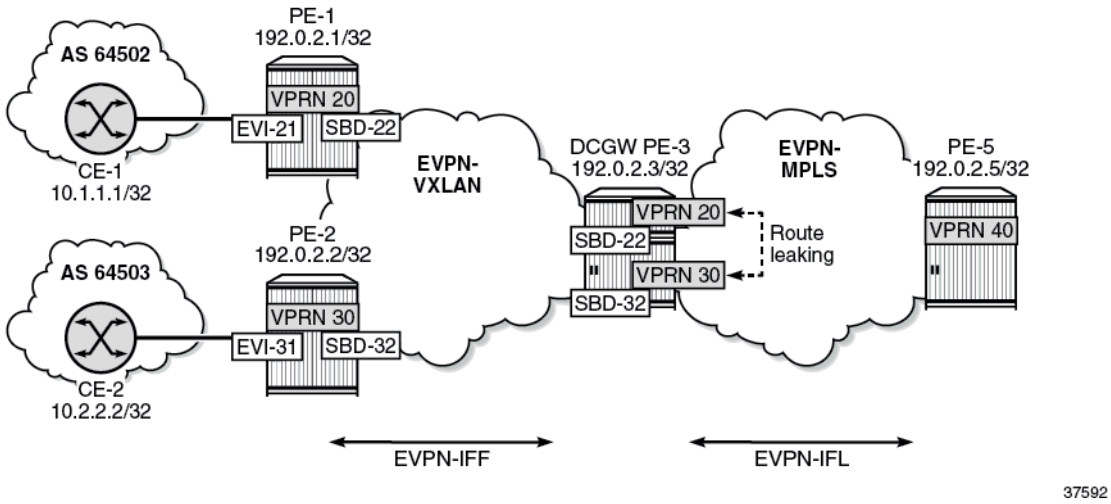
EVPN-IFF BGP path attributes exported to leaked EVPN routes

Figure 150: Example topology shows the example topology with two VPRNs on DCGW PE-3 where routes are leaked.

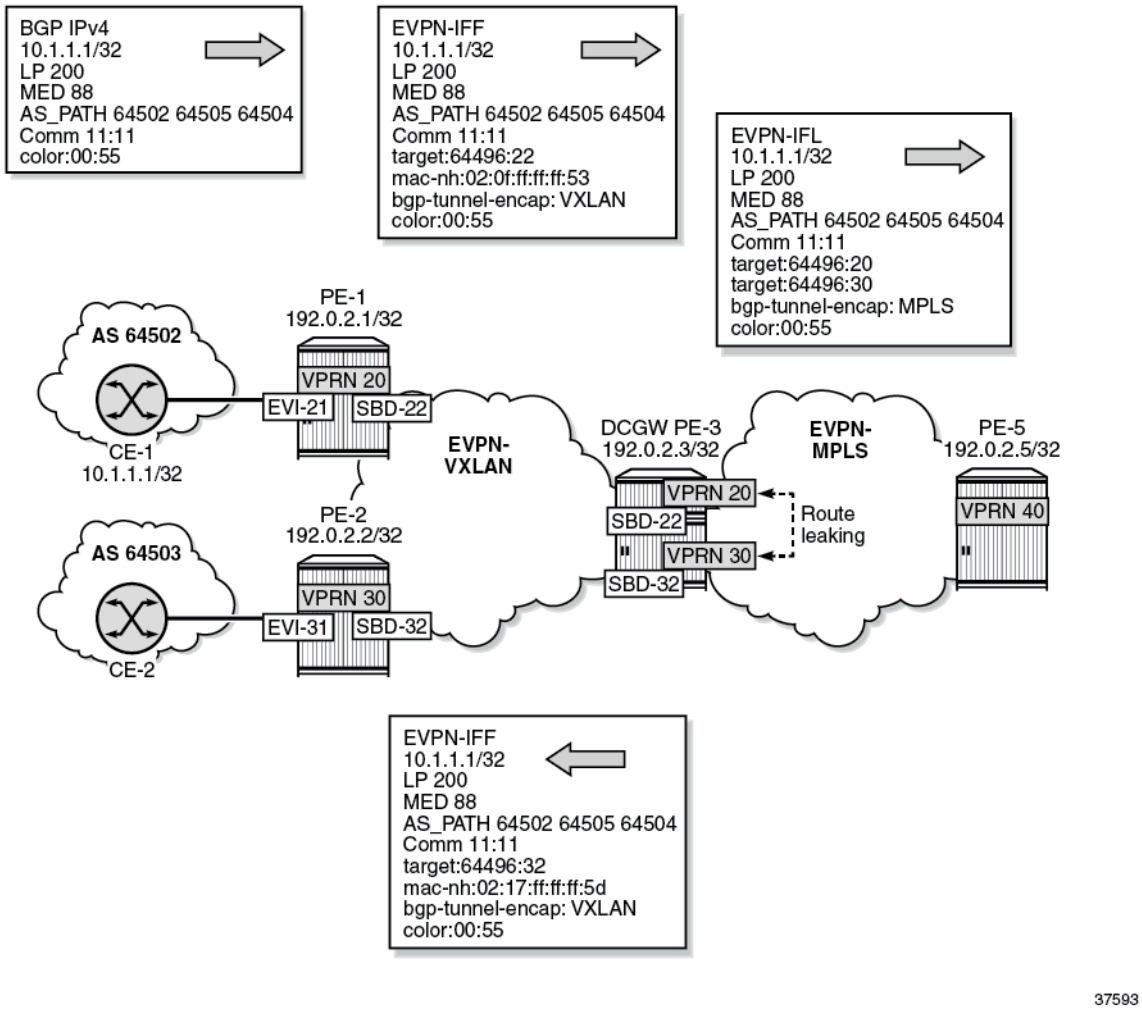
Figure 150: Example topology



The uniform propagation for EVPN-IFF BGP path attributes is enabled on all PEs.

Figure 151: BGP path attributes are propagated in leaked EVPN routes shows that CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1. This route has non-default BGP attributes; for example, MED 88, AS path 64502 64505 64504, and community "11:11" "color:00:55". PE-1 exports this route as an EVPN-IFF route to PE-3. PE-3 forwards this route as EVPN-IFL route to PE-5. On PE-3, the route is leaked from VPRN 20 to VPRN 30. The BGP path attributes are propagated to the leaked EVPN routes, except those attributes that are not expected to be propagated, such as the router's MAC extended community. PE-3 advertises an EVPN-IFF route for prefix 10.1.1.1/32 to PE-2.

Figure 151: BGP path attributes are propagated in leaked EVPN routes



In a similar way, CE-2 exports IPv4 prefix 10.2.2.2/32 to PE-2 with non-default BGP path attributes. PE-2 advertises this prefix as an EVPN-IFF route with the same BGP path attributes. PE-3 leaks the route from VPRN 30 to VPRN 20 while preserving the BGP path attributes. PE-3 advertises an EVPN-IFF route for prefix 10.2.2.2/32 to PE-1 with the same BGP path attributes. PE-3 also advertises the prefix as EVPN-IFL route to PE-5 with the same BGP path attributes. For brevity, the routes for prefix 10.2.2.2/32 are not shown here.

In this example, VPRN "CE-1" is configured as follows. The export policy sets the MED, prepends some AS numbers to the AS path, and adds the communities "11:11" and "color:00:55".

```
# CE-1:
configure
    router Base
        policy-options
            begin
            community "11:11"
                members "11:11"
            exit
```

```
            community "color:00:55"
                members "color:00:55"
            exit
            policy-statement "export-vnf-to-all-2"
                entry 10
                    from
                        protocol direct direct-interface
                    exit
                    action next-entry
                        community add "11:11" "color:00:55"
                        as-path-prepend 64504
                        bgp-med set 88
                    exit
                exit
                entry 20
                    from
                        protocol direct direct-interface
                    exit
                    action accept
                        as-path-prepend 64505
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn 23 name "CE-1" customer 1 create
            autonomous-system 64502
            interface "int-CE-1-PE-1" create
                address 10.2.0.1/24
                sap 1/2/2:21 create
                exit
            exit
            interface "loopback" create
                address 10.1.1.1/32
                loopback
            exit
            bgp
                export "export-vnf-to-all-2"
                local-as 64502
                group "PE-1-CE-1"
                    neighbor 10.2.0.254
                        type external
                        peer-as 64496
                    exit
                exit
            exit
            no shutdown
        exit
```

On PE-1, an import policy sets the LP to a value of 200. VPRN 20 has R-VPLS interface "int-EVI-21" toward CE-1 and R-VPLS interface "int-SBD-22" toward PE-2.

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "local-preference-200"

```

The configuration on PE-2 is similar with VPRN 30, R-VPLS "EVI-31", and R-VPLS "SBD-32".

PE-3 has two VPRNs: "VPRN 20" and "VPRN 30". Export policy "leak-color-55-into-30" is used to leak routes with color community "color:00:55" from VPRN 20 to VPRN 30. The configuration is as follows:

```
# on PE-3:
configure
    router Base
        policy-options
            begin
            community "color:00:55"
                members "color:00:55"
            exit
            community "RT64496:20"
                members "target:64496:20"
            exit
            community "RT64496:30"
                members "target:64496:30"
            exit
            policy-statement "leak-color-55-into-20"
                entry 10
                    from
                        community "color:00:55"
                    exit
                    action accept
                        community add "RT64496:20" "RT64496:30"
                    exit
                exit

                exit
            exit
            no shutdown
```

CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1 with community "color:00:55" and other non-default BGP path attributes. The route table for VPRN 20 on PE-1 includes an BGP IPv4 route for prefix 10.1.1.1/32:

```
*A:PE-1# show router 20 route-table 10.1.1.1/32

===============================================================================
Route Table (Service: 20)
```

```
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.1.1.1/32                                     Remote  BGP       00h01m57s  170
       10.2.0.1                                                        0
-------------------------------------------------------------------------------
No. of Routes: 1
```

PE-1 propagates prefix 10.1.1.1/32 in an EVPN-IFF route. On PE-3, the route table includes an EVPN-IFF route for prefix 10.1.1.1/32:

```
*A:PE-3# show router 20 route-table 10.1.1.1/32

===============================================================================
Route Table (Service: 20)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.1.1.1/32                                     Remote  EVPN-IFF  00h01m58s  169
       int-SBD-22 (ET-02:0f:ff:ff:ff:53)                              0
-------------------------------------------------------------------------------
No. of Routes: 1
```

PE-3 forwards prefix 10.1.1.1/32 as an EVPN-IFL to PE-5. On PE-5, the route table includes an EVPN-IFL route for prefix 10.1.1.1/32:

```
*A:PE-5# show router 40 route-table

===============================================================================
Route Table (Service: 40)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.1.1.1/32                                     Remote  EVPN-IFL  00h02m07s  170
       192.0.2.3 (tunneled)                                           10
10.2.2.2/32                                     Remote  EVPN-IFL  00h02m39s  170
       192.0.2.3 (tunneled)                                           10
10.5.5.5/32                                     Local   Local     00h03m24s  0
       loopback                                                       0
-------------------------------------------------------------------------------
No. of Routes: 3
```

In a similar way, PE-5 received an EVPN-IFL route for prefix 10.2.2.2/32. Prefix 10.5.5.5/32 is local to VPRN 40 on PE-5 and is advertised to PE-3 as EVPN-IFL route.

On PE-3, routes with community "color:00:55" are leaked between VPRN 20 and VPRN 30. PE-1 and PE-3 have forwarded the route with the original BGP path attributes, so this community is preserved and the route for prefix 10.1.1.1/32 is leaked to VPRN 30, as shown in the following route table. The next hop is R-VPLS "SBD-22" in local VPRN 20.

```
*A:PE-3# show router 30 route-table

===============================================================================
Route Table (Service: 30)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
```

```
10.1.1.1/32                                       Remote  EVPN-IFL  00h02m19s  169
       Local VRF [20:int-SBD-22]                                        0
10.2.2.2/32                                       Remote  EVPN-IFF  00h02m52s  169
       int-SBD-32 (ET-02:13:ff:ff:ff:5d)                                0
10.3.0.0/24                                       Remote  EVPN-IFF  00h03m42s  169
       int-SBD-32 (ET-02:13:ff:ff:ff:5d)                                0
10.5.5.5/32                                       Remote  EVPN-IFL  00h03m36s  170
       192.0.2.5 (tunneled)                                             10
-------------------------------------------------------------------------------
No. of Routes: 4
```

PE-3 propagates prefix 10.1.1.1/32 as an EVPN-IFF route to PE-2, so the route table for VPRN 30 on PE-2 includes an entry for prefix 10.1.1.1/32 with next hop "SBD-32" toward VPRN 30 on PE-3:

```
*A:PE-2# show router 30 route-table

===============================================================================
Route Table (Service: 30)
===============================================================================
Dest Prefix[Flags]                                Type    Proto     Age        Pref
      Next Hop[Interface Name]                                       Metric
-------------------------------------------------------------------------------
10.1.1.1/32                                       Remote  EVPN-IFF  00h02m30s  169
       int-SBD-32 (ET-02:17:ff:ff:ff:5d)                                0
10.2.2.2/32                                       Remote  BGP       00h03m02s  170
       10.3.0.1                                                         0
10.3.0.0/24                                       Local   Local     00h04m00s  0
       int-EVI-31                                                       0
10.5.5.5/32                                       Remote  EVPN-IFF  00h03m47s  169
       int-SBD-32 (ET-02:17:ff:ff:ff:5d)                                0
-------------------------------------------------------------------------------
No. of Routes: 4
```

The following show commands illustrate that the BGP path attributes are propagated. VPRN 20 on PE-1 receives an IPv4 route for prefix 10.1.1.1/32 from CE-1 with LP 200, MED 88, AS path 64502 64505 64504, and communities "1:1" "color:00:55", as follows:

```
*A:PE-1# show router 20 bgp routes 10.1.1.1/32 hunt

Conclusion

SR OS nodes can be configured to propagate EVPN-IFF BGP path attributes between families to influence the path selection, as per *draft-ietf-bess-evpn-ipvpn-interworking*.

EVPN-MPLS E-Tree

This chapter provides information about EVPN-MPLS E-Tree.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the CLI in the current edition is based on SR OS Release 23.7.R1. VPLS E-Tree without EVPN is supported in SR OS Release 12.0.R4, and later. EVPN-MPLS E-Tree is supported in SR OS Release 15.0.R1, and later.

Overview

Ethernet Tree (E-Tree) is a rooted multipoint Ethernet service defined by the Metro Ethernet Forum (MEF). E-Tree can be implemented based on the following:

- RFC 7796, *Ethernet-Tree Support in Virtual Private LAN Services* (VPLS E-Tree without EVPN)
- RFC 8317, *E-Tree Support in EVPN and PBB-EVPN* (EVPN-MPLS E-Tree)

VPLS E-Tree without EVPN

The E-Tree implementation is based on RFC 7796 and is supported for unicast and broadcast, unknown unicast, and multicast (BUM) traffic. Interfaces can be defined as root attachment circuit (AC) or leaf AC, or both, as described in Table 9: Interfaces in E-Tree . A VPLS E-Tree can have multiple root ACs. Access and network interfaces are both supported on SAPs and SDP bindings.

Table 9: Interfaces in E-Tree

Interface	Tag
Access interface (user-to-network interface - UNI)	Root tag
	Leaf tag
Network interface (network-to-network interface - NNI)	Root-leaf tag

On the ingress access interfaces, all frames are tagged and forwarded. On the network interfaces, no traffic is dropped based on the root or leaf tag. On the egress access interfaces, all traffic toward a root AC is forwarded, whereas traffic toward a leaf AC is only forwarded when it originates from a root AC, as summarized in Table 10: E-Tree Forwarding on Access Interfaces . Traffic from leaf AC to leaf AC is blocked.

Table 10: E-Tree Forwarding on Access Interfaces

	To root AC	To leaf AC
From root AC	Allowed	Allowed
From leaf AC	Allowed	Not allowed

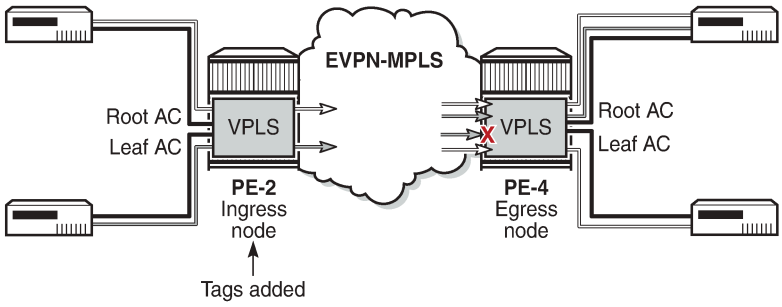
Within an E-Tree, the split horizon group capability is inherent for leaf SAPs and leaf SDP bindings and extends to all the remote nodes that are part of the same VPLS E-Tree service.

Ingress Tagging and Egress Filtering

Figure 152: Frame Forwarding in a VPLS E-Tree without EVPN shows how frames are forwarded in an E-Tree. The ingress node PE-2 knows whether the frame comes from a leaf AC or a root AC and adds a tag indicating "from root" or "from leaf". Specific VLAN IDs are used to indicate "from root" or "from leaf". The egress node PE-4 forwards the frame based on the "from root" or "from leaf" tag, as follows:

- A frame with the "from root" tag can be forwarded to any AC, leaf or root.
- A frame with the "from leaf" tag can only be forwarded to a root AC, not to a leaf AC.

Figure 152: Frame Forwarding in a VPLS E-Tree without EVPN



SAPs and SDP bindings are considered as root AC automatically (in the following example, SAP 1/2/c1/1:4 is a root AC); leaf ACs get the keyword **leaf-ac**, and NNI SAPs and SDP bindings get the keyword **root-leaf-tag**. The root tag equals the service delimiting VLAN ID (VID) in the SAP and the leaf tag can only be configured with a different value.

```
On PE-2:
configure
    service
        vpls 4 name "VPLS 4" customer 1 etree create
            sap 1/2/c1/1:4 create
            exit
            sap 1/2/c3/1:4 leaf-ac create
            exit
            sap 1/2/c5/1:4 root-leaf-tag leaf-tag 44 create
            exit
            spoke-sdp 24:4 vc-type vlan root-leaf-tag create
            exit
            spoke-sdp 210:4 leaf-ac create
```

```
            exit
            no shutdown
        exit
    exit
exit
```

VLAN ranges are not allowed in a VPLS E-Tree, as shown for the following connection profile VLAN, which is configured on PE-2:

```
On PE-2:
configure
    connection-profile-vlan 10 create
        vlan-range 10 to 19
        vlan-range 110
    exit
exit
```

The following error is raised when attempting to configure a SAP with VLAN range cp-10:

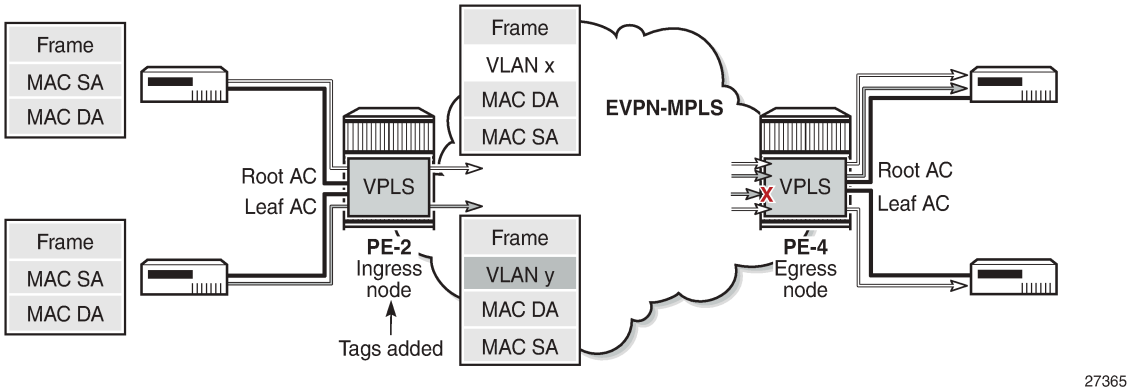
```
configure service vpls 4 sap 1/2/c3/1:cp-10 create
MINOR: SVCMGR #8303 vlan-range not allowed - etree configured

configure service vpls 4 sap 1/2/c3/1:cp-10.* leaf-ac create
MINOR: CLI SAP-id has an invalid port number or encapsulation value.
```

All incoming frames on a SAP or SDP binding in a VPLS have their dot1q/qinq encapsulation removed by the local PE. In a VPLS E-Tree, the local PE then adds a VLAN tag with a dedicated VID indicating whether the frame originates from a root AC or a leaf AC.

- For dot1q/qinq-based L2 services, a VLAN tag with VID x is added for root and VID y for leaf. Frames with VID x are forwarded to any type of AC, while frames with VID y are only forwarded to root ACs at the remote node, as shown in Figure 153: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree.
- For pseudowire-based L2 services, a VLAN tag with VID 1 is hard-coded for frames received on a root AC and a VLAN tag with VID 2 for frames received on a leaf AC.

Figure 153: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree



EVPN-MPLS E-Tree

Operators migrate their regular VPLS services to EVPN services because of the advantages offered by EVPN, such as all-active multi-homing, scalability, and easy provisioning. EVPN-MPLS E-Trees block leaf-to-leaf traffic, while allowing all traffic from and to root ACs. The following is a configuration example of an EVPN-MPLS E-Tree. The **evpn-etree-leaf-label** command is only relevant for EVPN E-Tree services and allocates an E-Tree leaf label on the system, which is used for egress filtering of BUM traffic.

```
configure
    service
        system
            bgp-evpn
                evpn-etree-leaf-label
            exit
        exit
        vpls 1 name "VPLS 1" customer 1 etree create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/2/c1/1:1 create
            exit
            sap 1/2/c3/1:1 leaf-ac create
            exit
            spoke-sdp 210:1 leaf-ac create
            exit
            no shutdown
        exit
    exit
exit
```

SAPs or SDP bindings are by default root AC objects. MAC addresses learned on root AC objects are advertised as usual, while MAC addresses learned on a SAP or SDP binding configured as leaf AC are advertised with an BGP EVPN E-Tree extended community with leaf indication bit L=1.

BGP EVPN VXLAN is not supported in E-Tree services; only EVPN-MPLS E-Tree is supported. The following error is raised when attempting to configure VXLAN in an E-Tree enabled service:

```
configure
    service
        vpls 3 name "VPLS 3" customer 1 etree create
            vxlan vni 3 create
MINOR: SVCMGR #7890 Cannot configure vxlan - not supported on etree enabled services
```

In an EVPN-MPLS E-Tree, it is not required and not even possible to configure the **root-leaf-tag** option on interfaces. The following error is raised when attempting to configure a spoke SDP or SAP with **root-leaf-tag** option:

```
configure
    service
        vpls 1
            spoke-sdp 24:1 vc-type vlan root-leaf-tag create
```

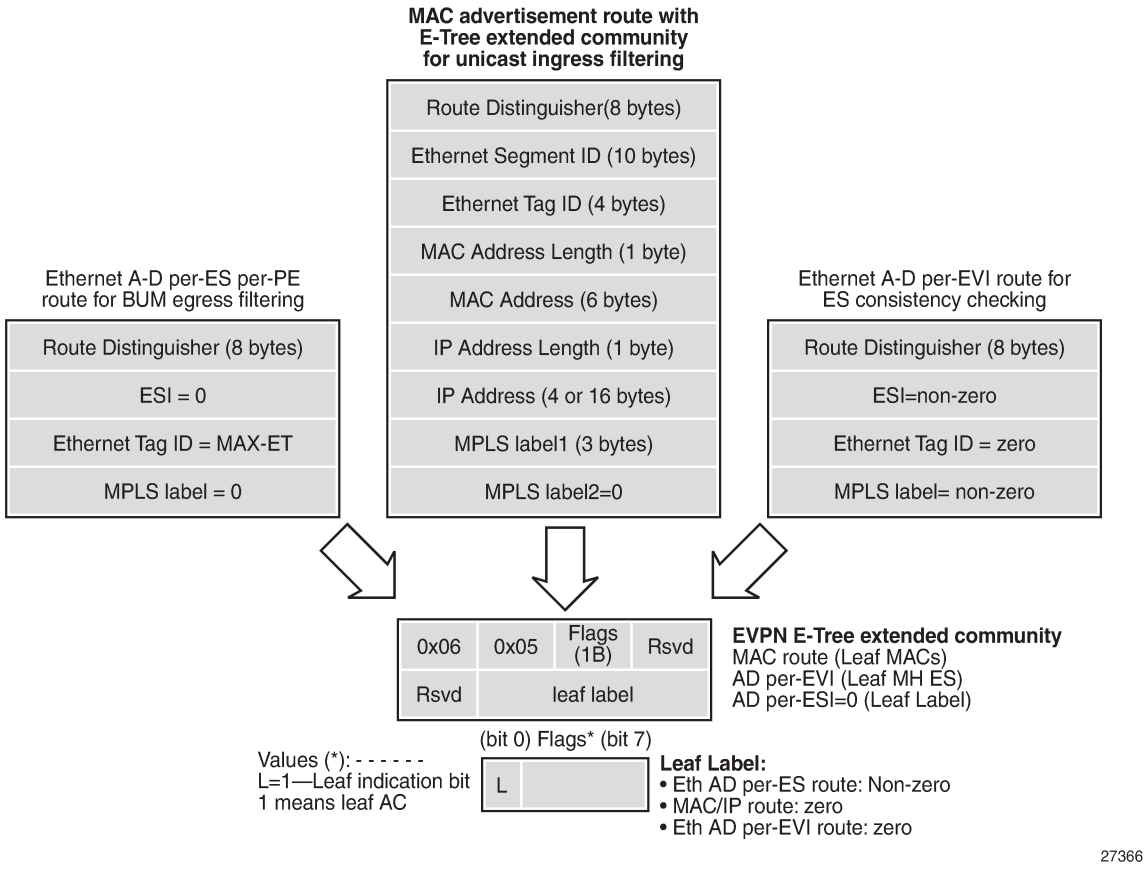
```
MINOR: SVCMGR #7883 evpn configured in service

configure
    service
        vpls 1
            sap 1/2/c3/1:200 create root-leaf-tag leaf-tag 22
MINOR: SVCMGR #7883 evpn configured in service
```

BGP EVPN Control Plane for EVPN E-Tree

No leaf tag needs to be added to frames forwarded to EVPN destinations. Instead, the BGP EVPN control plane for EVPN E-Tree advertises a leaf indication bit and a leaf label in the E-tree extended community, as shown in Figure 154: BGP EVPN Control Plane for EVPN E-Tree.

Figure 154: BGP EVPN Control Plane for EVPN E-Tree



The BGP EVPN control plane is extended with the EVPN E-Tree extended community, as per RFC 8317. The low-order bit of the flags field contains the L-bit (L=1 indicates a leaf AC). The leaf label contains a 20-bit MPLS label that is non-zero for Ethernet Auto Discovery (AD) per Ethernet Segment (per-ES) routes (tag MAX-ET), but it equals zero for MAC/IP routes and Ethernet AD per EVPN Instance (per-EVI) routes (tag 0). The following BGP EVPN AD per-ES route contains an EVPN E-Tree extended community with

L=0 and leaf label 524282, and is used for egress BUM filtering. RFC 8317 states that the leaf indication bit L must be ignored on reception and should be zero on transmission.

```

===============================================================================
```

If receiving the same MAC route as root from PE-1 and as leaf from PE-2, the MAC route from PE-1 is selected: root MAC routes have higher priority than leaf MAC routes. Root static MAC routes take precedence over leaf static MAC routes.

EVPN MAC routes with a higher sequence number have a higher priority than root or leaf MAC routes. MAC mobility procedures take precedence to first identify the location of the MAC before associating that MAC with a root or a leaf site. The EVPN MAC route selection criteria in tie-break order are as follows:

1. Conditional static MACs (local protected MACs)
2. Auto-learned protected MACs (locally learned MACs on SAPs or mesh/spoke SDPs because of the configuration of auto-learn-mac-protect)
3. EVPN ES PBR MACs
4. EVPN static MACs (remote protected MACs)
5. Data plane learned MACs (regular MAC learning on SAPs/SDP-bindings)
6. EVPN MACs with a higher sequence number
7. EVPN E-Tree root MACs
8. Lowest IP (next-hop IP of the EVPN NLRI)
9. Lowest Ethernet tag (Ethernet tag is zero for MPLS and non-zero for VXLAN)
10. Lowest RD

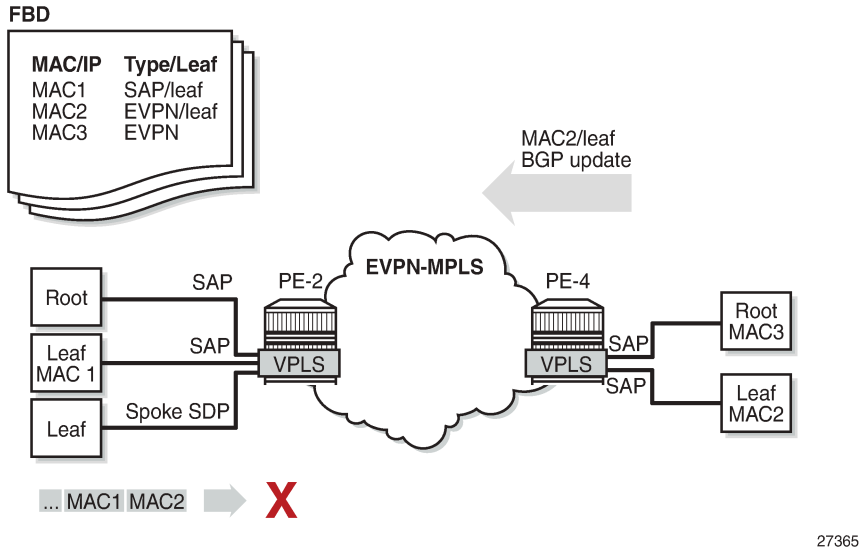
Ingress Leaf Filtering for Unicast Traffic

EVPN-MPLS E-Tree is the only E-Tree technology able to do unicast ingress filtering, as opposed to the usual unicast egress filtering that, for example, VPLS does. Remote MAC addresses are learned in the control plane, so EVPN can optimize the forwarding by filtering known unicast traffic at the ingress:

- Unicast frames entering a root AC at the ingress PE are not filtered. The MAC destination address (DA) is looked up in the FDB and the frames are forwarded. The MAC source address (SA) is learned and advertised in BGP EVPN without the E-Tree extended community.
- Unicast frames entering a leaf AC at the ingress PE are filtered. The MAC DA is looked up in the FDB. When the MAC DA is learned from an EVPN leaf (or a leaf AC), the frame is dropped. When the MAC DA is learned from an EVPN root (or root AC), the frame is forwarded. The MAC SA is learned and advertised in BGP EVPN with leaf indication bit L=1.

Figure 155: Ingress Leaf Filtering for Known Unicast Traffic shows that PE-4 advertises MAC2 with leaf indication bit L=1. When a frame is sent with MAC SA MAC1 on a leaf AC of PE-2, PE-2 does a MAC lookup in the FDB to find out that the DA MAC2 is learned from an EVPN leaf. Therefore, PE-2 does not forward the frame to PE-4, but drops it at the ingress.

Figure 155: Ingress Leaf Filtering for Known Unicast Traffic



The ingress filtering blocks E-Tree leaf-to-leaf traffic and requires the implementation of an extra leaf EVPN-MPLS destination per remote PE containing leaf ACs per E-Tree service. Therefore, a dedicated EVPN-MPLS binding is created per leaf unicast traffic in the service. This additional internal EVPN-MPLS destination is created per remote PE that contains a leaf and that advertises at least one leaf MAC. The MPLS E-Tree leaf destination is created when a MAC route with L=1 is received. Any EVPN E-Tree service could potentially use one additional EVPN-MPLS destination for leaf unicast traffic per remote PE. This additional EVPN-MPLS leaf destination in the E-Tree is only unicast and not part of the flooding list. The EVPN-MPLS leaf destination consumes EVPN resources, as can be verified as follows:

```
*A:PE-2# tools dump service evpn usage | match "Mpls Etree"
```

```
Mpls Etree Leaf Dests                          :            1
```

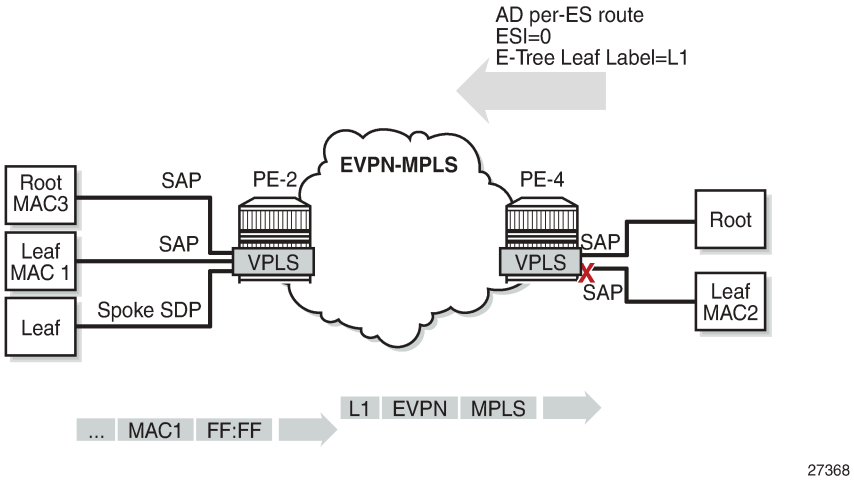
All MAC addresses received with L=1 point to this EVPN-MPLS E-Tree leaf destination, whereas root MAC addresses point to the root destination.

Egress Leaf Filtering for BUM Traffic

Figure 156: Egress Leaf Filtering for BUM Traffic shows that leaf-to-leaf BUM traffic is filtered at the egress, based on the EVPN leaf label advertised in the E-Tree extended community of the zero ESI AD per-ES route (tag=MAX-ET).

- BUM frames that enter a root AC at the ingress PE are not filtered; the BUM frames follow regular EVPN data plane procedures.
- BUM frames that enter a leaf AC at the ingress PE are marked as leaf and forwarded or replicated to the egress IOM. At the egress IOM, the frame is flooded in the default multicast list, subject to the following:
  - Leaf entries are skipped when BUM traffic is forwarded, so no BUM traffic is forwarded to local leaf ACs.
  - BUM traffic to remote BGP EVPN PEs is encapsulated with the EVPN label stack.
    - If the remote PE has advertised an AD per-ES route with E-Tree leaf label L1, this leaf label L1 is added at the bottom of the stack. At the egress PE, when the leaf label L1 matches the leaf label of the PE, the BUM traffic is only forwarded to the root ACs, not to the leaf ACs.
    - If the egress PE does not have any E-Tree enabled service, it has not advertised any AD per-ES route with E-Tree leaf label. The local PE forwards the BUM traffic with BGP EVPN encapsulation, but without an additional label. Even when the egress PE does not have E-Tree enabled, it can still work with the VPLS E-Tree service available in the ingress PE. No traffic is dropped at the egress PE where no E-Tree is configured.

Figure 156: Egress Leaf Filtering for BUM Traffic



The following command is used to monitor the ESI label entries consumed by the EVPN E-Tree application:

```
*A:PE-2# tools dump service evpn usage | match "BUM"
Evpn Etree Remote BUM Leaf Labels              :            1
```

Configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- LDP between the PEs
- BGP for the EVPN address family (between the PEs)

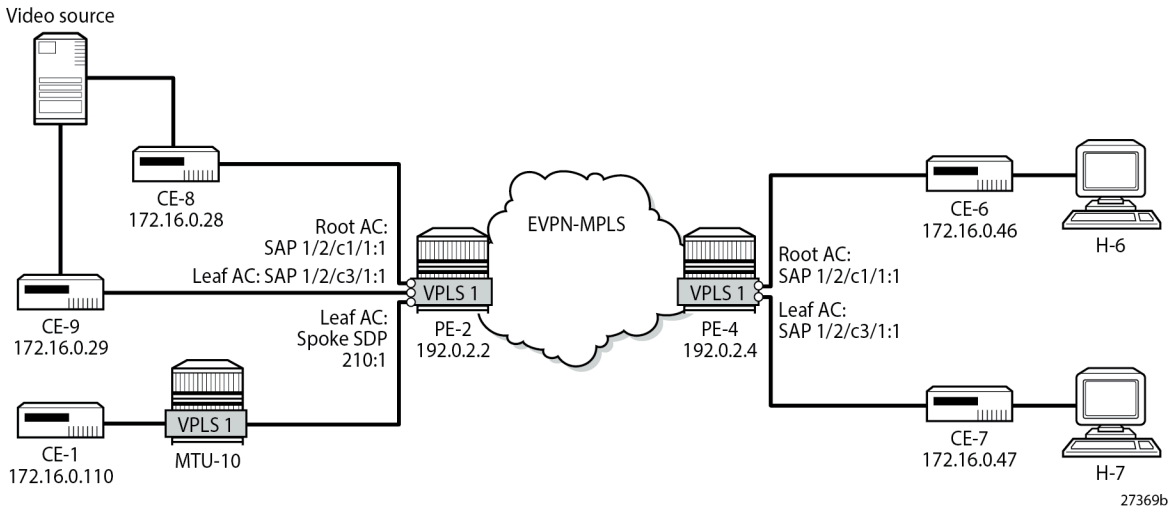
In this section, the following cases are described:

- EVPN-MPLS E-Tree without multi-homing
- EVPN-MPLS E-Tree with all-active and single-active multi-homing

EVPN-MPLS E-Tree without Multi-homing

Figure 157: Example Topology for EVPN-MPLS E-Tree without Multi-homing shows an example topology with two PEs in an EVPN-MPLS network with VPLS 1 configured as E-Tree. CE-6 and CE-8 have root ACs and are able to send and receive traffic to and from all other CEs, whereas CE-7, CE-9, and CE-1 are only able to exchange traffic with CE-6 and CE-8, but not with each other. The video source can be connected to CE-8 (root AC) or CE-9 (leaf AC).

Figure 157: Example Topology for EVPN-MPLS E-Tree without Multi-homing



The service configuration on PE-2 is as follows:

```
On PE-2:
configure
    service
        sdp 210 mpls create
            far-end 192.0.2.10
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                evpn-etree-leaf-label
            exit
        exit
        vpls 1 name "VPLS 1" customer 1 etree create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/2/c1/1:1 create
            exit
            sap 1/2/c3/1:1 leaf-ac create
            exit
            spoke-sdp 210:1 leaf-ac create
            exit
            no shutdown
        exit
    exit
exit
```

The service configuration on PE-4 is similar, with SAP 1/2/c1/1:1 as root AC and SAP 1/2/c3/1:1 as leaf AC.

The following command on PE-2 shows that SAP 1/2/c1/1:1 is a root AC (default), SAP 1/2/c3/1:1 is a leaf AC (indicated by "L"), and spoke SDP 210:1 is also a leaf AC.

```
*A:PE-2# show service id 1 etree

```

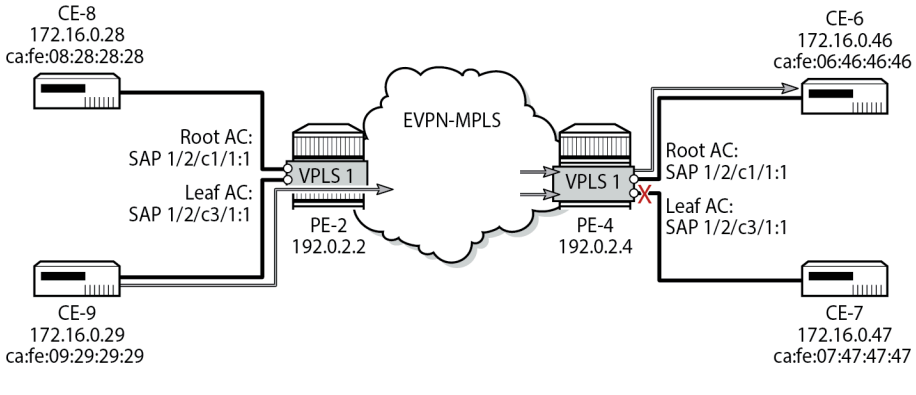
EVPN E-Tree Egress Filtering Based on MAC SA

Egress filtering on MAC SA is required to cover cases when the ingress PE sends traffic received on a leaf AC, but without leaf indication. Figure 158: EVPN E-Tree Egress Filtering Based on MAC SA shows that CE-9 sends traffic with MAC SA ca:fe:09:29:29:29 on a leaf AC.

Figure 158: EVPN E-Tree Egress Filtering Based on MAC SA



When CE-9 sends unicast traffic to CE-6 with root MAC DA ca:fe:06:46:46:46, the ingress PE-2 forwards the frames to this root MAC DA to egress PE-4. However, if PE-4 does not have the MAC DA in its FDB (because of aging or MAC flush and the MAC route has not made it yet to PE-2), it may flood the frame to all the root and leaf ACs, even if the frame originated from a leaf AC. EVPN E-Tree egress filtering based on MAC SA prevents this from happening, so the traffic is only forwarded to the root AC.

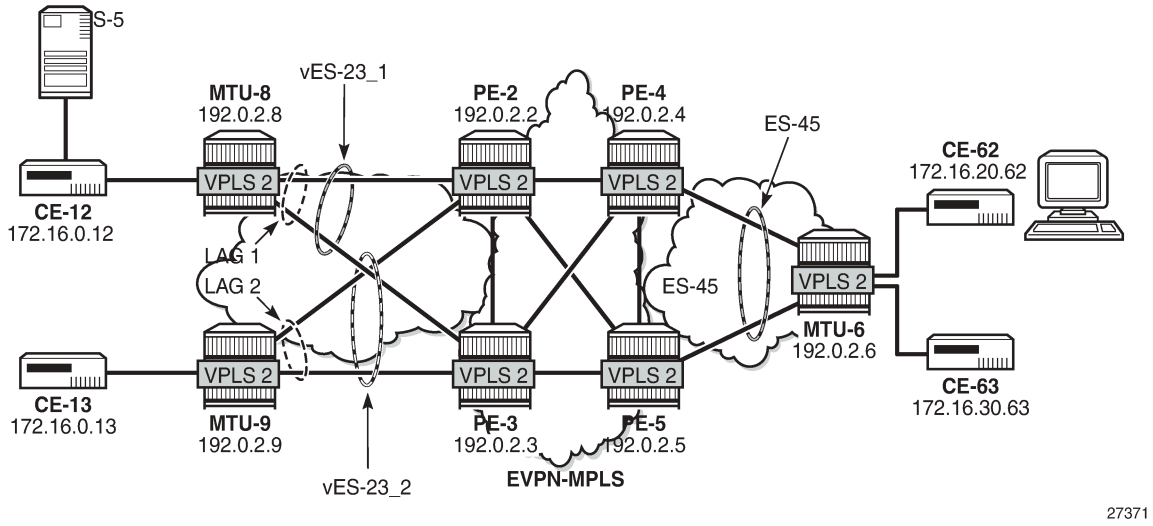
The data path does the egress filtering based on MAC SA as follows:

- First, frames are identified as leaf frames in one of the following cases:
  - Frames arriving on a leaf SAP
  - EVPN traffic arriving with a leaf label
  - Frames arriving with a MAC SA that is flagged as being a leaf SA
- At the egress PE, frames identified as leaf are filtered depending on the type of traffic:
  - For known unicast traffic, the FDB is consulted. If the MAC DA FDB entry is marked as being from a leaf, the frame is dropped to prevent leaf-to-leaf forwarding.
  - For BUM traffic, the leaf frames are filtered at the egress IOM to suppress leaf-to-leaf forwarding.

EVPN-MPLS E-Tree with Multi-homing

Figure 159: Example Topology with All-active ESs and Single-active ES shows the example topology with two all-active multi-homing vESs on PE-2 and PE-3 and one single-active multi-homing ES on PE-4 and PE-5.

Figure 159: Example Topology with All-active ESs and Single-active ES



On PE-2, two all-active multi-homing vESs are configured. VPLS 2 is configured as EVPN-MPLS E-Tree with LAG 1 as root AC and LAG 2 as leaf AC. RD 2.2.2.2 is configured and used in the non-zero AD per-ES routes, while the zero ESI routes (AD per-ES) use the IP address 192.0.2.2. The service configuration on PE-2 is as follows:

```
On PE-2:
configure
    service
        system
            bgp-evpn
                ad-per-es-route-target evi-rt-set route-distinguisher 2.2.2.2
                evpn-etree-leaf-label
                ethernet-segment "vESI-23_1" virtual create
                    esi 01:00:00:00:00:23:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 2
                    exit

            sap lag-2:2 leaf-ac create
            exit
            no shutdown
        exit
    exit
exit
```

The service configuration on PE-3 is identical, but with **evi-rt-set route-distinguisher** 3.3.3.3 instead.

Note:
The command **config service system bgp-evpn ad-per-es-route-target evi-rt-set** is not supported for EVPN E-Tree services. When the command is configured on a router, the AD per-ES routes (with ESI=0) used for EVPN E-Tree services are always advertised with the service route target and route distinguisher, regardless of the **ad-per-es-route-target** configuration. AD per-ES routes for non-zero ESIs (used for regular multi-homing) is usually sent using either **evi-rt-set** or **evi-rt**, based on the router configuration.

It is important that all the ACs in each EVI for an ES must either be root ACs or leaf ACs in both PEs where the ES is defined, not a mix. In this example, SAP lag-1:2 is assigned to vES-23_1 and defined as root AC in both PE-2 and PE-3. Likewise, SAP lag-2:2 is assigned to vES-23_2 and configured as leaf AC in PE-2 and PE-3. However, if the configuration were a mix of root and leaf ACs in different PEs of the same ES, a remote PE (PE-4 or PE-5) would receive the AD per-EVI routes with inconsistent leaf indication and would treat the AC as root AC.

PE-2 sends the following BGP EVPN AD routes: an AD per-ES route with zero ESI and RD 192.0.2.2:2 (for egress filtering of BUM traffic) and an EVPN AD per-EVI route with non-zero ESI and RD 2.2.2.2:1 (to verify the ES consistency).

```

The following command shows the EVI RT set RD ranging from 2.2.2.2:1 to 2.2.2.2:512. In VPLS 2, the configured EVI is 2 and needs to be divided by 128, the number of EVI RT sets that are advertised. This value is rounded up to 1; therefore, the RD in the preceding AD per-EVI equals 2.2.2.2:1. The minimum EVI RT set RD equals 2.2.2.2:1 and the maximum is 2.2.2.2:512, because the EVI ranges from 1 to 65535 and 65536/128=512.

The FDB for VPLS 2 on PE-3 shows the same EVPN leaf MAC addresses. For all PEs in the all-active MH ESs, the MAC addresses ca:fe:06:00:20:12 and ca:fe:06:00:30:13 from the locally attached ACs can be learned on the SAPs or via EVPN from the ES peer where they are learned on the SAPs. In this case, they are learned on the SAPs on PE-2 and PE-3.

Egress Filtering for BUM Traffic

Each PE advertises zero ESI AD per-ES routes (with tag MAX-ET) that are needed for egress BUM filtering.

BUM frames received on an ES root AC are flooded to the EVPN, based on regular EVPN procedures. The regular ESI label is sent for split horizon when frames are sent to the DF or NDF PEs in the same ES.

BUM frames received on an ES leaf AC are flooded in the default multicast list. The egress PE does not forward BUM traffic to any leaf ACs, including the ES leaf ACs. However, in the unlikely event that some ACs in a specific ES for an EVI have an inconsistent E-Tree configuration, these ACs are treated as root ACs, and the traffic is forwarded.

The remote PE-4 receives the following EVPN AD routes from DF PE-2: a zero ESI AD per-ES (tag MAX-ET), two AD per-EVI (tag 0) routes with a non-zero label, and two AD per-ES routes (tag MAX-ET).

Conclusion

E-Trees can be used for enterprise business services, for the distribution of IPTV multicast content, for centralized backup BNGs, and so on. In a VPLS E-Tree, leaf SAPs or leaf SDP bindings cannot exchange traffic with each other, similar to split horizon group behavior. The E-Tree restrictions apply to all remote PEs that are part of the same service. E-Trees can be applied in an EVPN-MPLS VPLS as well as in a regular VPLS.

EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services

This chapter provides information about EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R5, but the CLI in the current edition is based on SR OS Release 21.2.R1.

Chapters EVPN for MPLS Tunnels and EVPN for VXLAN Tunnels (Layer 2) are prerequisite reading.

Overview

When EVPN-MPLS is deployed in the WAN, many service providers are looking for a way to integrate existing Layer 2 EVPN-VXLAN based data center services into the WAN, while keeping the end-to-end advantages of EVPN. The IETF draft-ietf-bess-dci-evpn-overlay describes how to provide Layer 2 connectivity for EVPN-overlay data centers in different ways. This chapter follows section 4.4 of that document, in which EVPN-MPLS is used in the same VPLS service that terminates overlay (VXLAN) tunnels.

To provide EVPN-MPLS connectivity to VPLS services terminating EVPN-VXLAN, SR OS supports the configuration of BGP-EVPN MPLS and BGP-EVPN VXLAN at the same time by adding two BGP instances to the service. Two BGP instances are supported in the same VPLS at most. BGP-EVPN MPLS and BGP-EVPN VXLAN can both use BGP instance 1 or 2, but they must use different instances.

In a service with EVPN-VXLAN and EVPN-MPLS, the **config service vpls bgp-evpn mpls bgp 2** command allows the user to associate BGP-EVPN MPLS to a different instance than BGP-EVPN VXLAN, and therefore, have both encapsulations simultaneously enabled in the same service. When the two BGP instances are successfully added to the same VPLS service, the service behaves as follows:

- MAC/IP routes received on one instance will be "consumed" (accepted, imported, and installed in FDB) and re-advertised in the other instance, as long as the route is the best route for a specific MAC or MAC/IP.
- Inclusive multicast routes are independently generated for each BGP instance.
- From a data plane perspective, EVPN-MPLS and EVPN-VXLAN destinations are instantiated in different implicit Split-Horizon Groups (SHGs) so that traffic can be forwarded between the two SHGs, but not between destinations of the same kind. For example, traffic coming from EVPN-MPLS cannot be forwarded to other destinations in the EVPN-MPLS SHG.

The following example shows a VPLS service configured on PE-2 with two BGP instances and both encapsulations, VXLAN and MPLS, configured at the same time:

```
# on PE-2:
```

```
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            description "evpn-mpls and evpn-vxlan in the same service"
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 10:1
                route-target export target:64500:1 import target:64500:1
            exit
            bgp 2
                route-distinguisher 10:2
                route-target export target:64500:1 import target:64500:1
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

In the preceding example

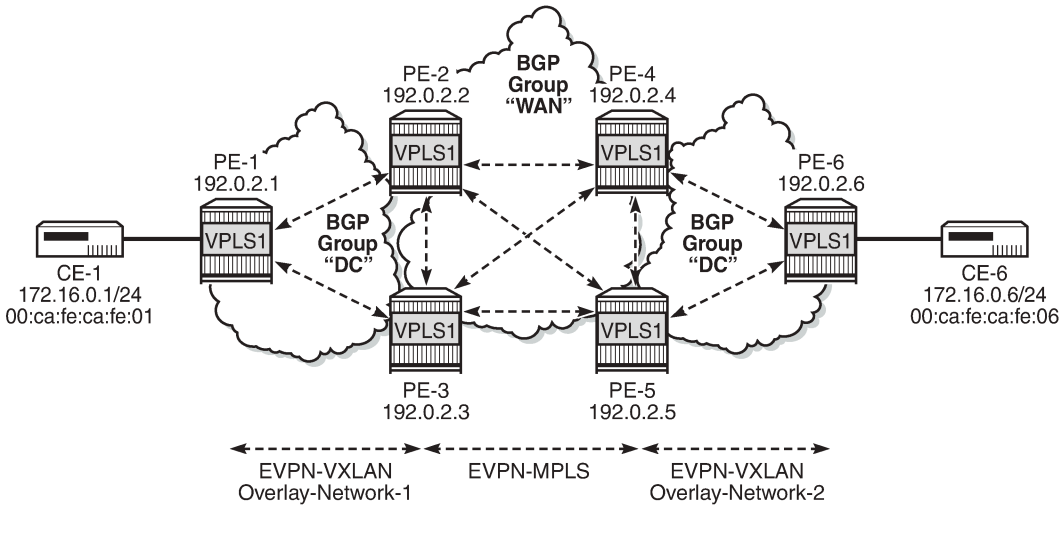
- **bgp 1** or simply **bgp** is the default BGP instance.
- **bgp 2** is the additional instance that is required when both BGP-EVPN VXLAN and BGP-EVPN MPLS are enabled in the service.
- The same commands supported under BGP instance 1 exist for this second BGP instance, with the following considerations:
  - **pw-template-binding** – the pseudowire (PW) template binding can only exist in BGP instance 1; it is not supported in BGP instance 2. Because no SDP-bindings can exist in a VPLS service with two BGP instances, the **pw-template-binding** command is ineffective in this configuration.
  - **route-distinguisher** – the route distinguisher in both BGP instances must be different.
  - **route-target** – the route target in both instances can be the same or different.
  - **vsi-import** and **vsi-export** – import and export policies can also be defined for either BGP instance.
- The **mpls bgp 2** command will assign BGP instance 2 to MPLS. The **bgp-evpn vxlan bgp 1 vxlan-instance 1 no shutdown** command will only be allowed if **bgp-evpn** is **shutdown** or if the BGP instance associated with MPLS has a different route distinguisher than the VXLAN instance (and vice versa).
- The **evi** can still be used for auto-derivation of RD/RT on BGP instance 1 and auto-derivation of RT (not RD) on BGP instance 2. Auto-RD or an explicitly configured RD is needed in BGP instance 2.

Configuration

Figure 160: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the example topology that will be used throughout this chapter, as well as the BGP peering topology. PE-1, PE-2, and PE-3 simulate a data center, shown as Overlay-Network-1, where PE-2 and PE-3 are DC GWs. In the same way, PE-4, PE-5, and PE-6 simulate a remote data center, Overlay-Network-2. Inside each DC, EVPN-VXLAN is used.

The two DC GW pairs are connected by EVPN-MPLS; therefore, CE-1 and CE-6 are end-to-end connected by EVPN without any VLAN or PW hand-off, maintaining all the EVPN advantages across the DC Interconnect (DCI) network.

Figure 160: EVPN-MPLS interconnect for EVPN-VXLAN - example topology



The example topology consists of six 7750 SR routers with the following initial configuration:

- Hybrid ports (they could have been network type too) are interconnecting the six PEs with configured router interfaces.
- The six PEs are running IS-IS and creating point-to-point adjacencies.
- Link LDP is configured in the core, among PE-2, PE-3, PE-4, and PE-5, while PE-1 and PE-6 are only running VXLAN.
- EVPN uses MP-BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the PEs for the EVPN family. Figure 160: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the peering sessions established among the six PEs. Although usually a Route-Reflector (RR) is used in each DC and another RR in the WAN, in this example, there are direct peering sessions in each DC and in the WAN.

The following output shows the BGP configuration of PE-2. The BGP configuration on the rest of the DC GWs (PE-3, PE-4, and PE-5) is similar:

```
# on PE-2:
configure
    router Base
        bgp
            family evpn
```

```
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only vxlan and add SOO"
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "WAN"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only mpls and add SOO"
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

Two different BGP groups are configured: DC and WAN. The DC group contains the DC neighbors (including the peer DC GW) and the WAN group contains the WAN neighbors. This grouping makes the use of policies easier. These policies will be explained in the section The mandatory use of BGP policies in the multi-homed anycast solution.

The following output shows the BGP configuration of PE-1. PE-6 has a similar BGP configuration.

```
# on PE-1:
configure
    router Base
        bgp
            family evpn
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
```

VPLS service configuration

After the base infrastructure (interfaces, IGP, LDP in the core, and BGP) is configured, the services can be added. The configuration example in this section will use VPLS 1 as the service to be interconnected across the two DCs.

PE-1 and PE-6 have a regular EVPN-VXLAN configuration; DCI connectivity provided by EVPN-MPLS is completely transparent to them. The configuration of VPLS 1 in PE-1 is as follows:

```
# on PE-1:
configure
    service
```

```
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

See the EVPN for VXLAN Tunnels (Layer 2) chapter for a complete description of the EVPN-VXLAN commands.

The configuration on PE-2, PE-3, PE-4, and PE-5 (see Figure 160: EVPN-MPLS interconnect for EVPN-VXLAN - example topology) enables EVPN-VXLAN and EVPN-MPLS in the same VPLS service. As an example, the VPLS 1 configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64500:1
            exit
            bgp 2
                route-distinguisher 64500:2
            exit
            bgp-evpn
                incl-mcast-orig-ip 23.23.23.23
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

As described in the Overview section, the preceding configuration enables the router to create EVPN-VXLAN and EVPN-MPLS destinations in the same VPLS service, but in different SHGs. In addition to the **bgp 2** commands already described in the Overview section, the **incl-mcast-orig-ip command** is added

in the configuration. If configured, this command will change the originating IP address in the inclusive multicast routes (from the default system IP) for both BGP instances. The section Multi-homed anycast configuration for dual BGP-instance VPLS services describes why this command is added.

The following section provides a detailed description of the expected behavior for EVPN routes that are imported and exported on dual BGP instance VPLS services.

EVPN route handling in dual BGP-instance VPLS services

This section describes how the BGP-EVPN routes are processed in dual BGP instance services.

Usually, the router validates the received tunnel encapsulation (from the RFC 5512 Extended Community) with the configured encapsulation of the service/BGP-instance. Therefore, an EVPN-VXLAN route will not get imported into the BGP-EVPN MPLS instance and vice-versa. This is also how the different EVPN route types are handled in dual BGP instance services:

- *Route type 1 - auto-discovery routes*

  AD per-EVI routes are never generated by services with two BGP instances (because no Ethernet Segment (ES) can be associated with the dual BGP instance service). However, AD per-EVI routes can still be received from the EVPN-MPLS peers and are processed as usual. Therefore, a VPLS service with two BGP instances will still support aliasing/backup and AD per-ES checking procedures for a remote multi-homed ES, as described in the EVPN for MPLS Tunnels chapter. However, in the example in Figure 160: EVPN-MPLS interconnect for EVPN-VXLAN - example topology, PE-6 does not have any local multi-homed ES configured; therefore, no AD per-EVI routes are present in this example.

- *Route type 2 - MAC/IP routes*

  MAC/IP routes received on one of the two BGP instances will be imported and the MAC addresses added to the FDB according to the existing selection rules. If the MAC address is active (therefore installed in the FDB), it will be re-advertised in the other BGP instance with the BGP attributes of the other BGP instance (new route target if different, new route distinguisher, and so on). The **mac-advertisement** command will govern the advertisement of MAC addresses in either BGP instance.

  The MAC/IP route redistribution across BGP instances is performed according to the following rules:

  – A MAC route is redistributed only if it is the best route according to the EVPN selection rules in the EVPN for MPLS Tunnels chapter.

  – Assuming a specific MAC route is the best one and has to be redistributed, the MAC/IP information along with the sticky bit is propagated in the redistribution.

  – A change in the MAC/IP route sequence number or sticky bit in one instance is updated in the other instance, as long as that route is the best MAC route for the route key.

  – When a MAC address moves within the EVPN-VXLAN (or the EVPN-MPLS) network, the MAC route is received on the same BGP instance where it was previously received, but now with a higher sequence number. In this case, the MAC route will be redistributed with the new sequence number. However, a router with two BGP instances in the same service will not detect any duplicate MAC on the EVPN-VXLAN and EVPN-MPLS networks.

  As an example, the following output shows the debug of a MAC/IP route received on PE-2, on the BGP instance for EVPN-VXLAN on VPLS 1, and how the route is re-advertised to the BGP instance used for MPLS (with a different next-hop, route distinguisher, label, and BGP tunnel encapsulation):

```

- *Route type 3 - inclusive multicast routes*

  EVPN Inclusive Multicast Ethernet Tag (IMET) routes are generated independently for each BGP instance with the correct BGP tunnel encapsulation extended community and the tunnel type associated to the BGP instance; for example, Ingress Replication (IR), P2MP mLDP, or Assisted Replication (AR):

  – On the EVPN-VXLAN BGP instance, IR or AR IMET routes are supported.

- When **assisted-replication replicator** is enabled and the received VXLAN broadcast and multicast packets contain an IP DA = AR-IP, the DC GW will send the packets back to VXLAN (but not to the VXLAN termination end-point (VTEP) from where the packet is received) in addition to the EVPN-MPLS destinations.
- If **assisted-replication replicator** is used on the DC GWs, the AR-IP (**configure>service>system>vxlan>assisted-replication-ip**) must be a loopback different from the router's system IP and the configured **bgp-evpn>incl-mcast-orig-ip**. The two AR-IP addresses in the DC GW pair do not need to be the same IP address.

– On the EVPN-MPLS BGP instance, IR, P2MP mLDP, or composite IMET routes are supported.

– Following is the behavior when the **incl-mcast-orig-ip** command is used:

- The configured IP in the **incl-mcast-orig-ip** command is encoded in the originating IP field of the IMET routes for IR, P2MP, and composite routes for both BGP instances.
- The originating IP field of the IMET AR routes is still derived from the configured **service>system>vxlan>assisted-replication-ip** value.

– The received IMET routes will be processed in the following way depending on their type:

- IMET-IR routes: the EVPN destination (MPLS or VXLAN) is set up based on the NLRI next-hop.
- IMET-P2MP routes: the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PTA) tunnel ID will be used to join the mLDP tree (as mLDP FEC in the LDP mapping messages).
- IMET-P2MP-IR (composite) routes: the PTA tunnel ID is used to join the mLDP tree. The NLRI next-hop is used to build the EVPN destination.
- IMET-AR routes: the NLRI next-hop is used to build the EVPN-VXLAN destination.

– Upon reception of two IMET routes with similar information, the router behaves as follows:

- If the router receives two IMET routes with the same originating IP, different RDs, and different NLRI next-hops, it will set up two EVPN destinations, one to each next-hop.
- If the router gets two IMET routes with the same originating IP, different RDs, but the same next-hop, it will set up only one EVPN destination.
- The router will not set up an EVPN destination to its DC GW peer if the received originating IP matches its own originating IP, regardless of whether the local RD and the remote RD are the same or different. This enables the use of the redundant anycast solution that is described in the following section: Multi-homed anycast configuration for dual BGP-instance VPLS services.

- *Route type 4 - ES routes*

  ESs are supported in routers where dual BGP-instance services exist. However, because dual BGP-instance VPLS services do not support SDP-bindings, ESs and ES routes are not relevant to these types of services.

- *Route type 5 - IP-prefix routes*

  R-VPLS services are not supported along with dual BGP instances; therefore, IP-prefix routes are neither generated nor processed by the service.

Multi-homed anycast configuration for dual BGP-instance VPLS services

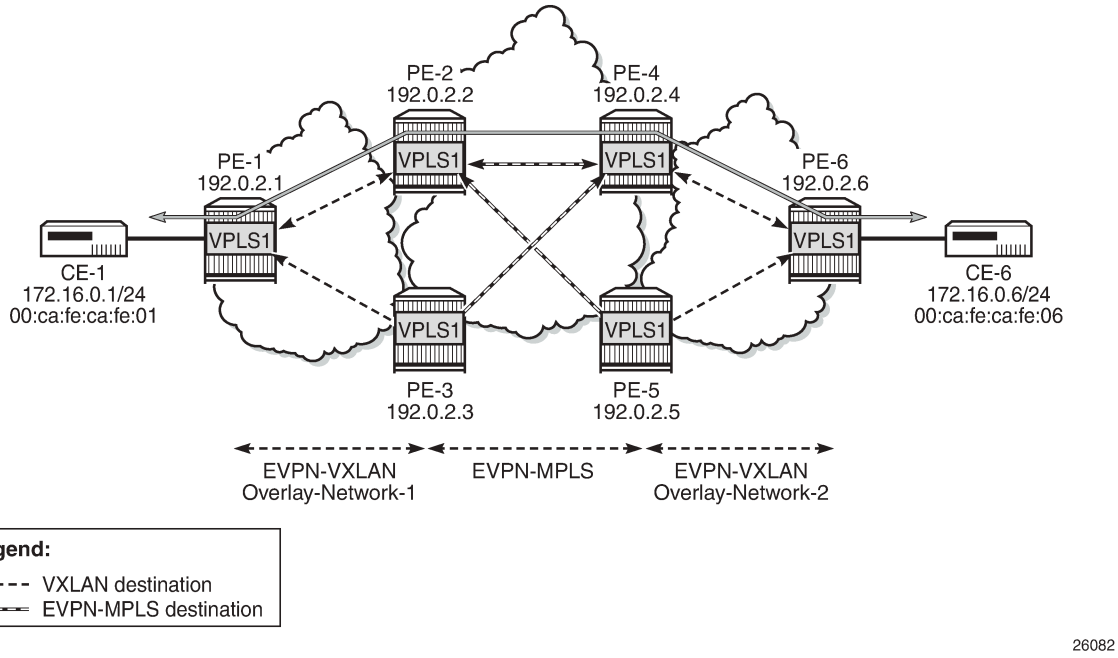
Services with EVPN-MPLS and EVPN-VXLAN SHGs are specified in *draft-ietf-bess-dci-evpn-overlay* and the associated multi-homing solution is also described in the same draft. That multi-homing solution is

based on an interconnect ES that allows all-active and single-active multi-homed EVPN networks as well as local attachment circuits in the DC GWs (SAP/SDP-bindings).

This chapter was initially written for SR OS Release 14.0.R5 and interconnect ESs were not supported in that release. Therefore, an anycast solution is used to provide redundancy. This anycast solution is based on the two PE DC GWs in the redundant pair being configured to advertised MAC/IP and IMET routes with the same route key, so that the remote PEs will only pick up one of the two anycast DC GWs when sending unicast or BUM traffic, and no loop or packet duplication is created.

Figure 161: EVPN destinations created on multi-homed anycast DC GWs is an example of how multi-homing can be achieved for dual BGP-instance VPLS services. The figure also shows the EVPN destinations created and their direction (see the arrows). For instance, only one EVPN multicast destination is created for PE-1, PE-2, or PE-4. Therefore, BUM traffic sent by CE-1 will be sent via PE-2, PE-4, and PE-6 only, and no duplication or loops occur.

Figure 161: EVPN destinations created on multi-homed anycast DC GWs



The following output shows the VPLS 1 configuration on PE-2 and PE-3 so that this anycast redundancy can be realized. The route distinguishers as well as the **incl-mcast-orig-ip** addresses must match between the two PEs in the redundant pair. VPLS 1 is configured on PE-2 as follows:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64500:1
            exit
            bgp 2
                route-distinguisher 64500:2
            exit
```

```
            bgp-evpn
                incl-mcast-orig-ip 23.23.23.23
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

The VPLS 1 configuration on PE-3 is as follows:

```
# on PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64500:1
            exit
            bgp 2
                route-distinguisher 64500:2
            exit
            bgp-evpn
                incl-mcast-orig-ip 23.23.23.23
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

The VPLS 1 configuration on PE-4 is as follows:

```
# on PE-4:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64501:1
            exit
```

```
            bgp 2
                route-distinguisher 64501:2
            exit
            bgp-evpn
                incl-mcast-orig-ip 45.45.45.45
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

The VPLS 1 configuration on PE-5 is as follows:

```
# on PE-5:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
                route-distinguisher 64501:1
            exit
            bgp 2
                route-distinguisher 64501:2
            exit
            bgp-evpn
                incl-mcast-orig-ip 45.45.45.45
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
                mpls bgp 2
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

Based on the preceding configuration example, the DC GWs behavior in this scenario is as follows:

- PE-2 and PE-3 both send IMET IR routes to the other PEs with the same route key but a different next-hop. The route key in IMET routes comprises [RD, Ethernet tag, originator-IP/length], which in this case will be [64500:1, 0, 23.23.23.23/32] for the EVPN-VXLAN IMET routes and [64500:2, 0, 23.23.23.23/32] for the EVPN-MPLS IMET routes.

- In the same way, PE-2 and PE-3 both send MAC/IP routes to the other PEs with the same route key but a different next-hop. The route key comprises [RD, Ethernet tag, MAC/MAC-length, IP/IP-length].

The configuration of the same **incl-mcast-orig-ip** address and RDs in both DC GWs enables the anycast solution due to the following:

- The configured originating IP (for example, 23.23.23.23 in PE-2 and PE-3) is not required to be a reachable IP address, which forces the remote PEs (or RRs if they exist) to select only one of the two DC GWs for BUM traffic (based on regular BGP selection). In this example, the remote PEs will select the PE-2 IMET route and create only one destination. The following output shows the IMET routes received by PE-1 (only the PE-2 route is used) and the created EVPN-VXLAN destination to PE-2. The same behavior could have been shown in the rest of the PEs.

```

- Due to the same RD and originating IP configured on PE-2 and PE3 (similarly in PE-4 and PE-5), the DC GW redundant PEs will never establish an EVPN destination between each other. PE-2 only sets up EVPN multicast destinations to PE-1 and PE-4, as follows:

```
*A:PE-2# show service id 1 vxlan destinations

===============================================================================

```

- Likewise, when the two redundant PEs receive the same MAC/IP route, they will both re-advertise it with the same route key, forcing the remote PEs to pick up only one of the two (based on regular BGP selection) and create only one EVPN destination (if different from the multicast destination). In the following example, PE-6 advertised the CE-6 MAC address, that is, re-advertised by PE-4/PE-5 and then by PE-2/PE-3, but only one of the routes is selected at each hop. The following output shows that PE-1 selects the PE-2 MAC/IP route (see the "used" flag) and uses the existing EVPN destination to PE-2:

```

- As shown in the preceding outputs, the EVPN destinations are always created to the IMET or MAC/IP route's BGP next-hops, which are still the system IP address of the routers (they could have also been a loopback address). The BGP next-hops need to be reachable in their respective network: DC or WAN.

The mandatory use of BGP policies in the multi-homed anycast solution

BGP policies must be configured in a multi-homed anycast solution, such as the one described in the previous section. Without policies, the following undesired behavior would happen:

- IMET routes with VXLAN encapsulation would be sent to the BGP peers in the MPLS network and IMET routes with MPLS encapsulation sent to BGP peers in the DC. The configured BGP policies will avoid that and make sure that the VXLAN routes are only sent to the DC and MPLS routes only to the WAN.
- MAC/IP routes received in the VXLAN BGP instance of a DC GW would be re-advertised to the redundant DC GW in the MPLS BGP instance and the redundant DC GW would re-advertise the same MAC again into the VXLAN instance, creating a control plane loop. The same thing would happen for MAC/IP routes received in an MPLS BGP instance. The configured BGP policies will prevent a DC GW from re-advertising MAC/IP routes received from the redundant DC GW.

While service-level BGP policies (**config>service>vpls>bgp>vsi-import/export**) may have been configured to prevent these loops and misbehavior, the use of BGP peer-level policies (**config>router>bgp>group>import/export**) is recommended due to the following reasons:

- Simplicity - BGP peer-level policies do not require any extra configuration at the service level, only at the BGP level.
- Scalability - BGP peer-level policies scale better than VSI-level policies, because the number of services where the VSI policies should be configured may be significant.

The following policies are configured in the example used in this chapter. No policies are needed in PE-1 and PE-6; only the DC GWs must be configured.

Following are the policies on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure
    router Base
        policy-options
            begin
            community "mpls"
                members "bgp-tunnel-encap:MPLS"
            exit
            community "vxlan"

                        family evpn
                    exit
                    action drop
                    exit
                exit
                entry 20
                    from
                        family evpn
                    exit
                    action accept
                        community add "SOO-DCGW-23"
                    exit
                exit
            exit
            commit
        exit
```

The policies are properly applied at BGP group level.

```
# on PE-2:
configure
    router Base
        bgp
            family evpn
            vpn-apply-import
```

```
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "DC"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only vxlan and add SOO"
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
            group "WAN"
                type internal
                import "drop SOO-DCGW-23"
                export "allow only mpls and add SOO"
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
        exit
```

The same policies are configured and applied on PE-3 (including the addition and filtering of the same Site-Of-Origin because PE-3 is part of the same DC GW pair).

PE-4 and PE-5 use the same BGP peer policies, but using a Site Of Origin extended community identifying the PE-4/PE-5 pair instead of the PE-2/PE-3 pair:

```
# on PE-4, PE-5:
configure
    router
        policy-options
            begin
            community "mpls"
                members "bgp-tunnel-encap:MPLS"
            exit
            community "vxlan"
                members "bgp-tunnel-encap:VXLAN"
            exit
            community "SOO-DCGW-45"
                members "origin:64500:45"
            exit
---snip---
```

Dual BGP instance VPLS service caveats

When two BGP instances are enabled on the same VPLS service, the following considerations apply:

- SDP-bindings are not supported (therefore, no pw-template-binding is needed in the service). Any attempt to add an SDP-binding to a service with two BGP instances will be blocked by the CLI, as follows:

  ```
  *A:PE-2>config>service>vpls# spoke-sdp 21:1 create
  MINOR: SVCMGR #7888 Cannot be configured/enabled with EVPN - sdp-binds not allowed when both
   vxlan and evpn-mpls are enabled
  ```

- Services that are not supported: R-VPLS, M-VPLS, I-VPLS, B-VPLS, or E-Tree VPLS

  - A consequence of not supporting R-VPLS is that no routes type 5 (IP-Prefix routes) are supported on dual BGP-instance services.
- Proxy-ARP/ND is not supported.
- BGP multi-homing is not supported.
- Although the Assisted-Replication feature is supported on dual BGP-instance VPLS services, the Assisted-Replication configuration is only relevant to the VXLAN destinations. See section EVPN route handling in dual BGP-instance VPLS services for some considerations about how EVPN handles IMET AR routes.

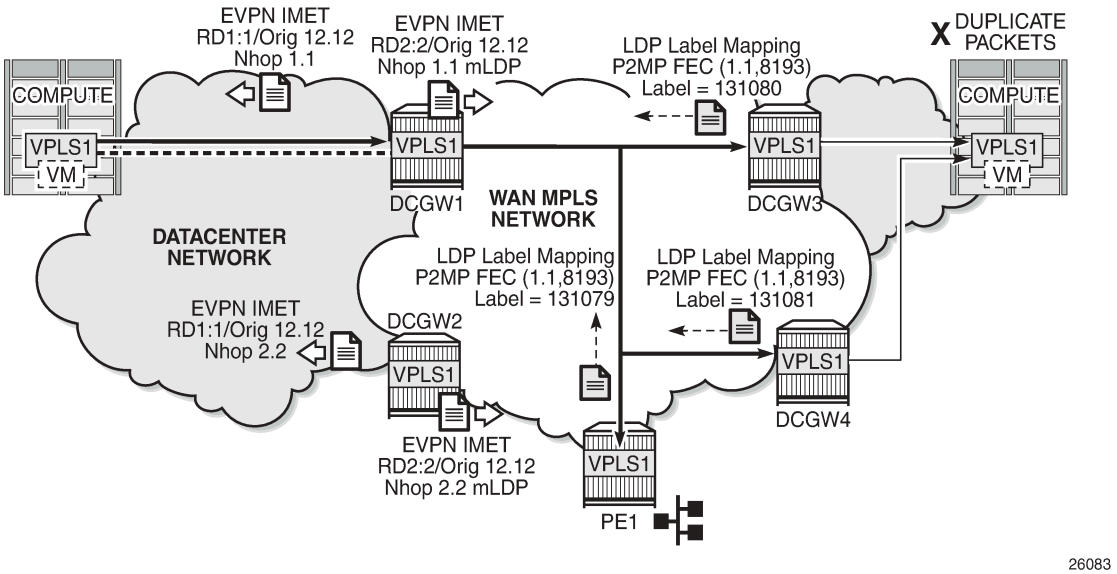
In addition to the preceding restrictions, some commands have a specific behavior when two BGP instances are configured:

- **config>service>vpls>bgp-evpn>[no] mac-advertisement** enables/disables the re-advertisement of MAC/IP routes in a BGP instance for MAC addresses that have been learned in the other BGP instance in the service.
- **config>service>vpls>bgp-evpn>[no] unknown-mac-route** enables/disables the advertisement of the unknown MAC route (MAC 00:..:00) on the BGP-EVPN VXLAN instance. The unknown MAC route is never sent to the BGP-EVPN MPLS instance.

The use of provider tunnels on multi-homed anycast solutions

The use of provider tunnels in dual BGP-instance VPLS services connecting multiple DCs is not recommended. Figure 162: Use of provider-tunnels between anycast DC GWs create packet duplication shows the case where the same BGP-EVPN service is configured in redundant anycast DC GWs and mLDP is used in the MPLS instance. In this case, packet duplication may occur if the configuration is not done carefully.

Figure 162: Use of provider-tunnels between anycast DC GWs create packet duplication



When mLDP is used along with multiple anycast multi-homing DC GWs to send BUM traffic to remote PEs, but no BUM traffic between DCs is needed, the same originating IP must be used on all the DC GWs; otherwise, packet duplication may happen. In the example in Figure 162: Use of provider-tunnels between anycast DC GWs create packet duplication, each pair of DC GWs, DCGW1/DCGW2 and DCGW3/DCGW4, is configured with a different originating IP (**config>service>vpls>bgp-evpn> incl-mcast-orig-ip**):

- DCGW3 and DCGW4 will receive the IMET route with the same route key from DCGW1 and DCGW2.
- DCGW3 and DCGW4 will select only one route, which will usually be the same; for example, the DCGW1 IMET route.
- Because of that, both DCGW3 and DCGW4 will join the mLDP tree with root in DCGW1, creating packet duplication when DCGW1 sends BUM traffic.
- Remote PE nodes with a single MPLS instance will join the mLDP tree without any issue.

To avoid the packet duplication shown by the example of Figure 162: Use of provider-tunnels between anycast DC GWs create packet duplication, the same originating IP may be configured in the four DCGWs, while the RD is still different per pair. By doing that:

- In the example of Figure 162: Use of provider-tunnels between anycast DC GWs create packet duplication, DCGW3 and DCGW4 will never join any mLDP tree sourced from DCGW1 or DCGW2. This will prevent any packet duplication because a router will ignore IMET routes received with its own originating IP, regardless of the RD.
- PE-1 (a remote EVPN-MPLS PE) will still join the mLDP trees from the two DCs.
- The preceding configuration allows the use of mLDP as long as no BUM traffic is required between the two DCs. If BUM traffic is required between DCs, IR must be used.

Troubleshooting and debugging

The following show and debug commands can be used in dual BGP-instance VPLS services:

- show router bgp routes evpn (and filters)
- show service evpn-mpls [<TEP ip-address>]
- show service vxlan [<TEP ip-address>]
- show service id bgp-evpn
- show service id evpn-mpls (and modifiers)
- show service id vxlan destinations
- debug router bgp update
- show log log-id "99"

See chapter EVPN for MPLS Tunnels and EVPN for VXLAN Tunnels (Layer 2) for a detailed description of these commands.

Also, in dual BGP-instance VPLS services, the **show service id** <*service-id*> **bgp** <*bgp-instance*> command may help see the BGP parameters of each individual BGP instance:

```
*A:PE-2# show service id 1 bgp ?
  - bgp [<bgp-instance>]
```

```
 <bgp-instance>       : [1..2]
```

```
*A:PE-2# show service id 1 bgp 1

Conclusion

As service providers deploy EVPN-MPLS in the network for Ethernet local area network (E-LAN) and Ethernet point-to-point (E-Line) services, the use of EVPN-MPLS to interconnect data centers is becoming a popular option. Based on *draft-ietf-bess-dci-evpn-overlay*, SR OS supports the connectivity of Layer 2 EVPN-VXLAN services to an EVPN-MPLS network. To implement that EVPN-MPLS Data Center Interconnect (DCI) solution, VPLS services support dual BGP instances, where EVPN-VXLAN and EVPN-MPLS can coexist simultaneously in the same VPLS service. This chapter describes the configuration of such dual BGP-instance VPLS services and how to deploy them in a redundant anycast DC GW configuration.

EVPN-VXLAN VPWS

This chapter provides information about EVPN-VXLAN VPWS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R7, but the CLI in the current edition is based on SR OS Release 21.5.R2.

Overview

Some service providers use VXLAN as a next-generation access technology between Multi-Service Access Node (MSAN) PE and core PE routers. VXLAN allows any IP router in the aggregation core and provides a simple alternative to MPLS. Static VXLAN bindings can be used when the MSAN PEs do not support any control plane. However, EVPN offers a control plane protocol for the VXLAN bindings for faster convergence and fault propagation. In this chapter, the focus is on EVPN-VPWS, which provides a lighter control plane compared to full-blown EVPN when point-to-point services need to be extended to the Data Center (DC).

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, including support of Equal Cost Multi-Path (ECMP), and EVPN All-Active (AA) and Single-Active (SA) Multi-Homing (MH). The configuration resembles the EVPN-MPLS Epipe configuration, as described in the EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS) chapter. As an example, the following configures EVPN-VXLAN Epipe 4 with SA MH.

```
# on PE-4:
configure
    service
        sdp 460 create
            description "GRE SDP for SA MH"
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ES45" create
                    esi 01:00:00:00:00:45:00:00:00:04
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 460
```

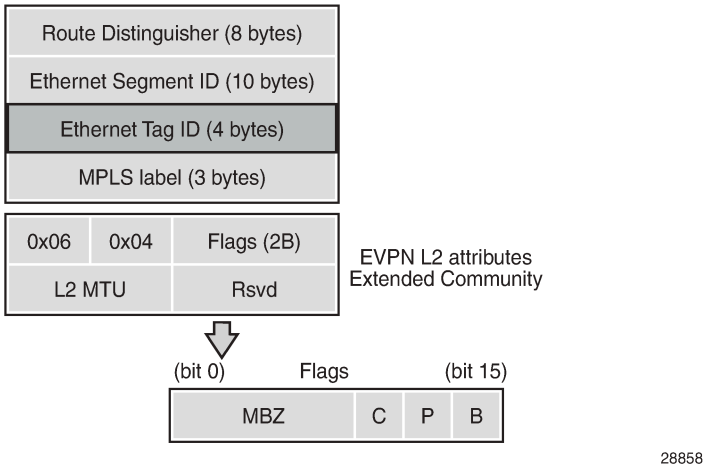
```
                no shutdown
            exit
        exit
    exit
    epipe 4 name "Epipe-4" customer 1 create
        vxlan instance 1 vni 4 create
        exit
        bgp
        exit
        bgp-evpn
            local-attachment-circuit AC-45 create
                eth-tag 145
            exit
            remote-attachment-circuit AC-23 create
                eth-tag 123
            exit
            evi 4
            vxlan bgp 1 vxlan-instance 1
                ecmp 2
                send-tunnel-encap     # default
                no shutdown
            exit
        exit
        spoke-sdp 460:4 create
            no shutdown
        exit
        no shutdown
    exit
```

The SDP is a GRE SDP, because no MPLS is configured in the network. The VNI is 4, and the local Attachment Circuit (AC) name is "AC-45" with Ethernet tag 145, whereas the remote AC name is "AC-23" with Ethernet tag 123. An ES can contain up to four nodes. Each of these nodes will have the same local Ethernet tag.

On Epipe services, the BGP instance is 1 and the VXLAN instance is 1. ECMP is configured with a value of 2, so the traffic flows can be sprayed over two paths with equal cost (a value greater than 2 can be configured if aliasing to more than two nodes is needed). By default, **send-tunnel-encap** is enabled, which determines whether the RFC 5512 encapsulation extended community is sent with VXLAN value (if enabled) or not sent.

EVPN-VPWS uses BGP-EVPN route type 1 (autodiscovery (AD) per-EVI routes and AD per-ES routes) and route type 4 (Ethernet Segment (ES) routes); it does not use route types 2 (MAC/IP routes), 3 (Inclusive Multicast routes), or 5 (IP Prefix routes). Figure 163: BGP-EVPN AD per-EVI route shows the fields in a BGP-EVPN AD per-EVI route.

Figure 163: BGP-EVPN AD per-EVI route



The Route Distinguisher (RD) is encoded as specified in RFC 7432; in this example, the system IP address is followed by the service ID, such as 192.0.2.2:1 for Epipe 1 on PE-2. The MPLS label field is encoded as the VXLAN Network Identifier (VNI) and the Ethernet tag field defines the local Attachment Circuit (AC) ID. The ES ID (ESI) is the 10 bytes configured ESI for MH and equals zero for single-homed services.

The EVPN L2 attributes extended community has type 0x06 (EVPN) and subtype 0x04 (EVPN L2 attributes). The flags are defined as follows:

- Flag C (control word) is set if control word is configured in the service. For EVPN-MPLS VPWS, the control word can be configured in the **bgp-evpn>mpls** context, but for EVPN-VXLAN VPWS, the control word cannot be configured in the **bgp-evpn>vxlan** context, so flag C is always zero (C=0).
- Flag P (primary) is set in MH scenarios: all nodes in an AA MH ES send P=1, but in an SA MH ES, only the Designated Forwarder (DF) sends P=1, while the NDFs send P=0. In single-homed scenarios, all nodes send P=0.
- Flag B (backup) is set in SA MH scenarios: the NDF that will take the primary role after the original primary node has failed is the backup, so it sends B=1. All other NDFs have B=0. In AA MH scenarios, all nodes send B=0. Also, in single-homed scenarios, all nodes except for the backup DF send B=0.

If the received L2 MTU does not match the configured service MTU, the EVPN binding is not set up. However, if the received L2 MTU is zero, the MTU is ignored.

AD per-EVI routes are responsible for aliasing. The following BGP update shows an AD per-EVI route received from DF 192.0.2.4 (PE-4) in an SA MH ES with ESI 01:00:00:00:00:45:00:00:00:04, Ethernet tag 145 for the local AC on PE-4, and MPLS label 4 for Epipe 4. The primary flag is set: P=1.

```
50 2021/06/29 12:03:54.278 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

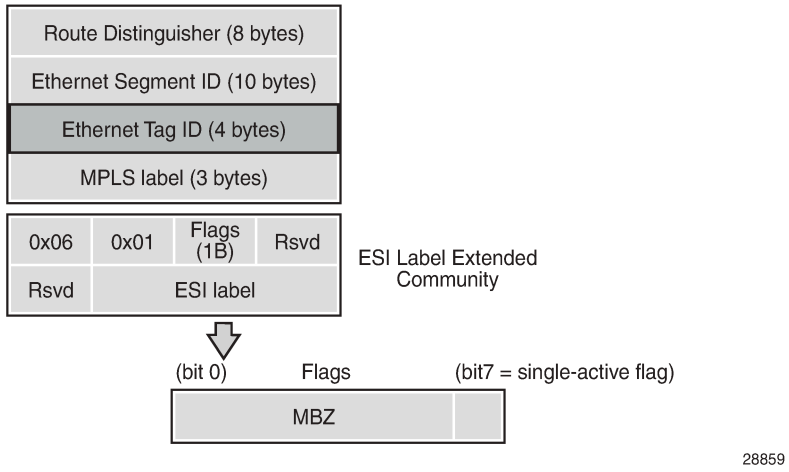
"
```

As per RFC 8214, in an AD per-ES route, the Ethernet tag is MAX-ET (all bits are set), the MPLS label is zero, and the BGP extended community contains the single-active flag (1 for SA and 0 for AA) and ESI label. Figure 164: BGP-EVPN AD per-ES route shows the fields in a BGP-EVPN AD per-ES route.

Figure 164: BGP-EVPN AD per-ES route



The following AD per-ES route is received by PE-2 from PE-4, which is in an SA MH ES with ESI 01:00:00:00:00:45:00:00:00:04.

```
52 2021/06/29 12:03:18.185 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

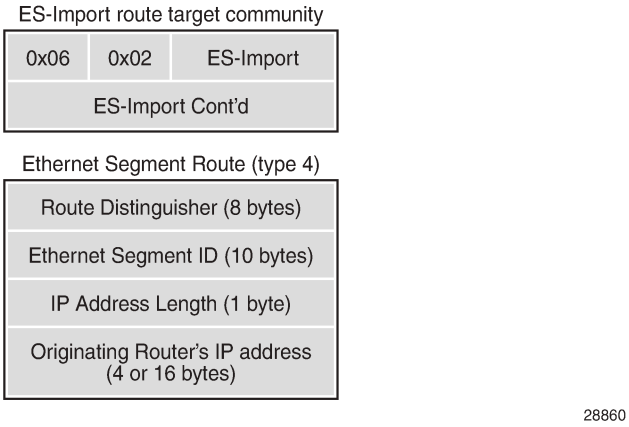
"
```

Figure 165: BGP-EVPN ES route shows a BGP-EVPN route type 4 (ES route) that is used for MH ES discovery and DF election.

Figure 165: BGP-EVPN ES route



The RD is taken from the system level RD; by default, the RD is derived as system-IP:0, such as 192.0.2.4:0 for PE-4. The ESI contains the 10-byte identifier as configured in the ES. The ES import route target community has type 0x06 (EVPN) and subtype 0x02 (ES import route target), and is derived from the MAC address portion of the ESI. This extended community is treated as a route target, such as: target:00:00:00:00:45:00. Only the PEs attached to the ES will import the ES route.

The following BGP update shows a BGP-EVPN ES route sent by PE-4. The RD is defined as 192.0.2.4:0, the ESI is 01:00:00:00:00:45:00:00:00:04, and the originating IP address is 192.0.2.4 for PE-4. The ES import route target is target:00:00:00:00:45:00.

```

By default, the system IP addresses are used for the VXLAN tunnel termination. However, it is possible to use non-system IPv4 or IPv6 termination for EVPN-VXLAN VPWS, both for single-homed and multi-homed services. In that case, Forwarding Path Extension (FPE) needs to be defined with VXLAN termination, as described in chapter Static VXLAN Termination in Epipe Services.

The following shows the configuration of the single-homed Epipe 2 using non-system IPv4 source VXLAN Tunnel Endpoint (VTEP) 10.0.3.1 on PE-3. Likewise, it is possible to use a non-system IPv6 source VTEP, such as **vxlan-src-vtep 2001::3:1**. Unlike the source VTEP, the egress VTEP cannot be configured when BGP-EVPN is enabled. The egress VTEP is dynamically learned via BGP instead.

```
# on PE-3:
```

```
configure
    service
        epipe 2 name "Epipe-2" customer 1 create
            vxlan-src-vtep 10.0.3.1
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-3 create
                    eth-tag 103
                exit
                remote-attachment-circuit AC-5 create
                    eth-tag 105
                exit
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    no shutdown
                exit
            exit
            sap 1/1/1:2 create
                no shutdown
            exit
            no shutdown
```

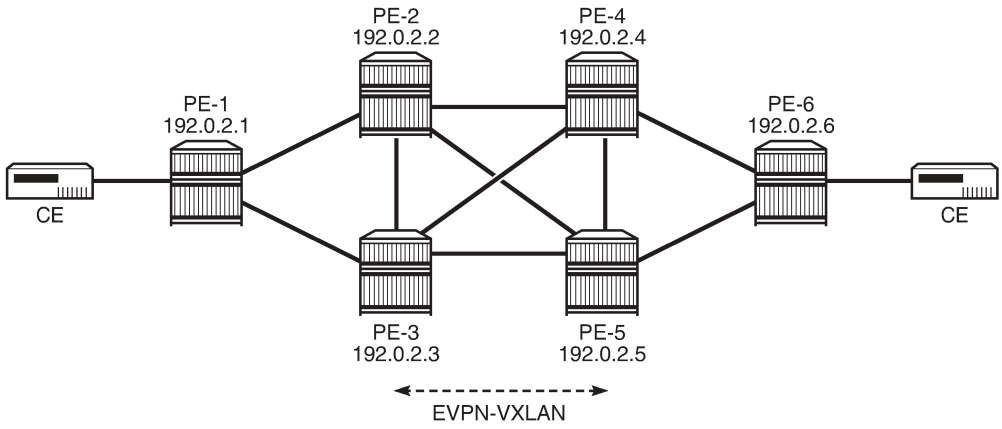
Configuration

The following use cases are included in the configuration section:

- Single-homed EVPN-VXLAN Epipe using IPv4 system addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using IPv4 system addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

Figure 166: Example topology shows the example topology with six PEs. EVPN-VXLAN Epipe services will be configured on the core PEs PE-2, PE-3, PE-4, and PE-5. On the access nodes PE-1 and PE-6, ordinary Epipe services will be configured, without EVPN-VXLAN. The CEs are emulated by VPRN services configured on PE-1 or PE-6.

Figure 166: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces: level 2 between the core PEs and level 1 in the access networks

No MPLS protocol is configured.

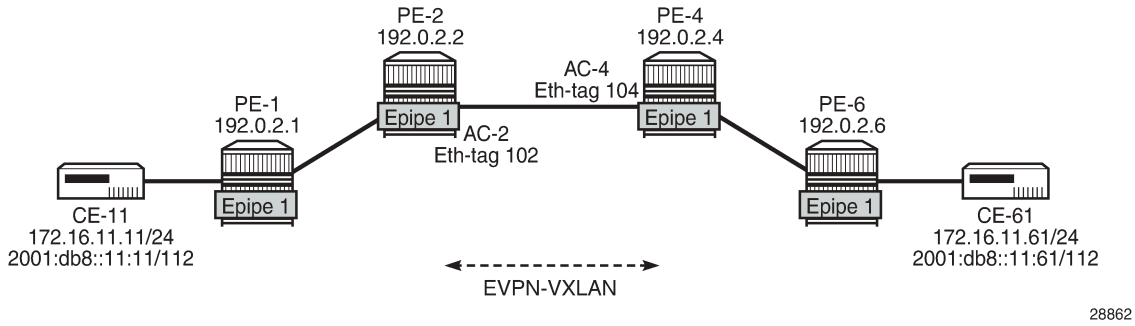
BGP is configured on the core PEs for the EVPN address family with RR PE-2. The BGP configuration on RR PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            rapid-update evpn
            group "iBGP"
                family evpn
                type internal
                cluster 192.0.2.2
                split-horizon
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

Single-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 167: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses shows the routers PE-1, PE-2, PE-4, and PE-6 configured with Epipe 1. VXLAN-EVPN is only configured on the core PEs PE-2 and PE-4.

Figure 167: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses



Configuration of Epipe 1

On PE-1, Epipe 1 is configured without EVPN-VXLAN, as follows.

```
# on PE-1:
configure
    service
        epipe 1 name "Epipe-1" customer 1 create
            sap 1/1/1:1 create
                no shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, Epipe 1 is configured with EVPN-VXLAN. The local AC "AC-2" has Ethernet tag 102 and the remote AC is "AC-4" with Ethernet tag 104, as follows:

```
# on PE-2:
configure
    service
        epipe 1 name "Epipe-1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-2 create
                    eth-tag 102
                exit
                remote-attachment-circuit AC-4 create
                    eth-tag 104
                exit
                evi 1
                vxlan bgp 1 vxlan-instance 1
```

```
                    no shutdown
                exit
            exit
            sap 1/1/2:1 create
                no shutdown
            exit
            no shutdown
        exit
```

The Epipe configuration on PE-4 is similar, but the local AC and remote AC are swapped, as follows. Instead of a SAP, a spoke-SDP is configured toward PE-6. The SDP itself is GRE-based.

```
# on PE-4:
configure
    service
        sdp 46 create
            description "GRE SDP for single-homing"
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 1 name "Epipe-1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-4 create
                    eth-tag 104
                exit
                remote-attachment-circuit AC-2 create
                    eth-tag 102
                exit
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    no shutdown
                exit
            exit
            spoke-sdp 46:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-6, Epipe 1 is an ordinary Epipe with spoke-SDP 64:1 toward PE-4 and SAP 1/2/1:1 toward a CE, as follows:

```
# on PE-6:
configure
    service
        sdp 64 create
            description "GRE SDP for single-homing"
            far-end 192.0.2.4
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 1 name "Epipe-1" customer 1 create
```

```
            sap 1/2/1:1 create
                no shutdown
            exit
            spoke-sdp 64:1 create
                no shutdown
            exit
            no shutdown
        exit
```

Verification

VPRN 11 on PE-1 and PE-6 simulates the CEs CE-11 and CE-61. The connectivity between the CEs can be verified as follows:

```
*A:PE-1# ping router 11 172.16.11.61 rapid
PING 172.16.11.61 56 data bytes
!!!!!
---- 172.16.11.61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.26ms, avg = 4.40ms, max = 4.54ms, stddev = 0.099ms
```

```
*A:PE-1# ping router 11 2001:db8::11:61 rapid
PING 2001:db8::11:61 56 data bytes
!!!!!
---- 2001:db8::11:61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 3.80ms, avg = 3.96ms, max = 4.22ms, stddev = 0.153ms
```

On PE-2, the VXLAN destination for Epipe 1 is the system address of PE-4: 192.0.2.4, as follows. There are no VXLAN ES destinations for Epipe 1, because the service is single-homed.

```
*A:PE-2# show service id 1 vxlan destinations

PE-2 has received the following BGP-EVPN AD per-EVI route with RD 192.0.2.4:1 and Ethernet tag 104 from PE-4. Epipe 1 is single-homed, so ESI=0 and there is no primary or backup node (P=B=0). Also, no control word is used, so C=0.

```

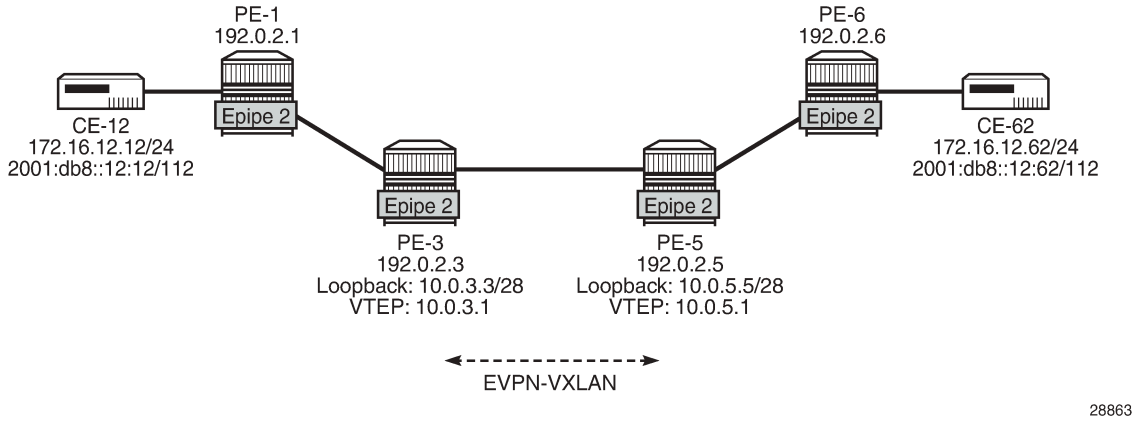
Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 168: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses shows the single-homed service Epipe 2 configured on PE-1, PE-3, PE-5, and PE-6. On PE-3, a loopback interface is created in the base router with IPv4 address 10.0.3.3/28. Epipe 2 uses VXLAN termination 10.0.3.1 from the same subnet.

Figure 168: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses



Configuration of Epipe 2

On PE-1 and PE-6, the configuration of Epipe 2 is similar to the configuration of Epipe 1.

On PE-3, FPE needs to be configured using PXC, as described in chapter Static VXLAN Termination in Epipe Services. The following configuration is included without further explanation about FPE or PXC. The same configuration is required on PE-5.

```
# on PE-3:
configure
    port-xc
        pxc 1 create
            port 1/2/5
            no shutdown
        exit
    exit
    port 1/2/5
        ethernet
            dot1x
                tunneling
            exit
            mode hybrid
            encap-type dot1q
        exit
```

```
        no shutdown
    exit
    port pxc-1.a
        ethernet
        exit
        no shutdown
    exit
    port pxc-1.b
        ethernet
        exit
        no shutdown
    exit
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 1 create
            path pxc 1
            vxlan-termination
        exit
```

On PE-3, the following loopback interface is created and IS-IS is enabled on it. The subnet must allow multiple IP addresses; one other IP address from the subnet will be defined as VXLAN tunnel termination. The IPv6 address is only required in the next use-case, but this configuration will not be repeated in that section.

```
# on PE-3:
configure
    router Base
        interface "lo1"
            address 10.0.3.3/28
            loopback
            ipv6
                address 2001::3:3/124
            exit
        exit
        isis 0
            interface "lo1"
                passive
            exit
        exit
```

Up to three VXLAN tunnel terminations can be defined per system. On PE-3, the following two VXLAN tunnel terminations are configured. For Epipe 2, only the first VXLAN tunnel termination is required; the second (IPv6) VXLAN tunnel termination is used in Epipe 3. The VXLAN tunnel termination is used as VXLAN source VTEP in Epipe 2. No egress VTEP can be defined when BGP-EVPN is configured in the service; egress VTEPs are configured in static VXLAN tunnels instead.

```
# on PE-3:
configure
    service
        system
            vxlan
                tunnel-termination 10.0.3.1 fpe 1 create
                tunnel-termination 2001::3:1 fpe 1 create
            exit
        exit
        epipe 2 name "Epipe-2" customer 1 create
            vxlan-src-vtep 10.0.3.1
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
```

```
            bgp-evpn
                local-attachment-circuit AC-3 create
                    eth-tag 103
                exit
                remote-attachment-circuit AC-5 create
                    eth-tag 105
                exit
                evi 2
                vxlan bgp 1 vxlan-instance 1
