                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            sap 1/1/1:2 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on PE-5 is similar. The following is the service configuration on PE-5.

```
# on PE-5:
configure
    service
        sdp 56 create
            description "GRE SDP for single-homing"
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            vxlan
                tunnel-termination 10.0.5.1 fpe 1 create
                tunnel-termination 2001::5:1 fpe 1 create
            exit
        exit
        epipe 2 name "Epipe-2" customer 1 create
            vxlan-src-vtep 10.0.5.1
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-5 create
                    eth-tag 105
                exit
                remote-attachment-circuit AC-3 create
                    eth-tag 103
                exit
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 56:2 create
                no shutdown
            exit
            no shutdown
```

```
        exit
```

It is possible to use a system IPv4 address as a VXLAN tunnel termination on one of the nodes and a non-system IPv4 address on another, but that is not configured here.

Verification

The connectivity between the CEs that are emulated by VPRN 12 can be verified as follows:

```
*A:PE-1# ping router 12 172.16.12.62 rapid
PING 172.16.12.62 56 data bytes
!!!!!
---- 172.16.12.62 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.27ms, avg = 4.77ms, max = 5.72ms, stddev = 0.509ms
```

```
*A:PE-1# ping router 12 2001:db8::12:62 rapid
PING 2001:db8::12:62 56 data bytes
!!!!!
---- 2001:db8::12:62 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.58ms, avg = 4.87ms, max = 5.59ms, stddev = 0.367ms
```

On PE-3, the VXLAN destination for Epipe 2 is the non-system address 10.0.5.1 on PE-5, as follows:

```
*A:PE-3# show service id 2 vxlan destinations

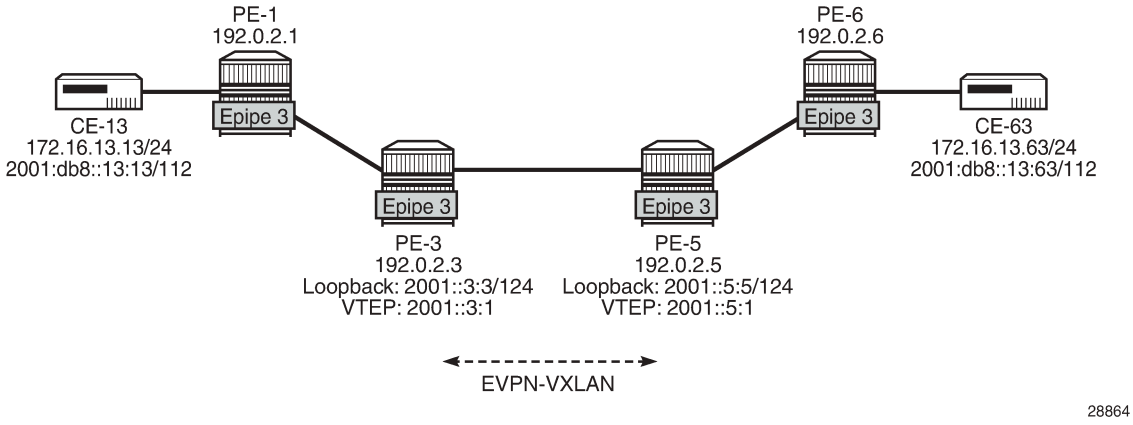
Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

Figure 169: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses shows the example topology for single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses for VXLAN tunnel termination.

Figure 169: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses



Configuration of Epipe 3

The following single-homed Epipe 3 using non-system IPv6 addresses for the VXLAN tunnel terminations is configured on PE-3.

```
# on PE-3:
configure
    service
        system
            vxlan
                tunnel-termination 10.0.3.1 fpe 1 create
                tunnel-termination 2001::3:1 fpe 1 create
            exit
        exit
        epipe 3 name "Epipe-3" customer 1 create
            vxlan-src-vtep 2001::3:1
            vxlan instance 1 vni 3 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-3_v6 create
                    eth-tag 163
                exit
                remote-attachment-circuit AC-5_v6 create
                    eth-tag 165
                exit
                evi 3
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            sap 1/1/1:3 create
            exit
            no shutdown
        exit
```

The service configuration on PE-5 is similar, as follows:

```
# on PE-5:
configure
    service
        system
            vxlan
                tunnel-termination 10.0.5.1 fpe 1 create
                tunnel-termination 2001::5:1 fpe 1 create
            exit
        exit
        epipe 3 name "Epipe-3" customer 1 create
            vxlan-src-vtep 2001::5:1
            vxlan instance 1 vni 3 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-5_v6 create
                    eth-tag 165
                exit
                remote-attachment-circuit AC-3_v6 create
                    eth-tag 163
                exit
                evi 3
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 56:3 create
                no shutdown
            exit
            no shutdown
        exit
```

Verification

The connectivity between the CEs that are emulated by VPRN 13 is verified as follows:

```
*A:PE-1# ping router 13 172.16.13.63 rapid
PING 172.16.13.63 56 data bytes
!!!!!
---- 172.16.13.63 PING Statistics ----

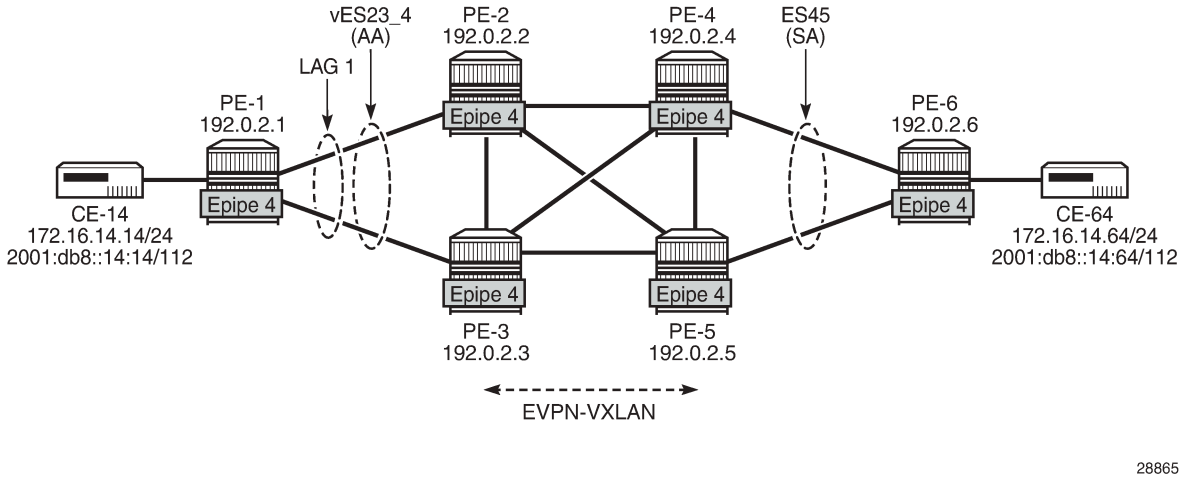
AA and SA multi-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 170: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 4 with AA MH ES "vES23_4" between PE-2 and PE-3 and SA MH ES "ES45" between PE-4 and PE-5.

Figure 170: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses



Configuration of Epipe 4

On PE-1, Epipe 4 is configured as follows:

```
# on PE-1:
configure
    service
        epipe 4 name "Epipe-4" customer 1 create
            sap 1/2/1:4 create
                no shutdown
            exit
            sap lag-1:4 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2 and PE-3, the AA MH ES "vES23_4" is configured as a virtual ES for LAG 1 and dot1q-tag 4, so it only affects Epipe 4.

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES23_4" virtual create
                    esi 01:00:00:00:00:23:00:00:00:04
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 4
                    exit
                    no shutdown
                exit
            exit
        exit
```

On PE-2 and PE-3, Epipe 4 is configured as follows. The system IPv4 address is used as VXLAN termination, the local AC Ethernet tag is 123, and the remote AC Ethernet tag is 145.

```
# on PE-2:
configure
    service
        epipe 4 name "Epipe-4" customer 1 create
            vxlan instance 1 vni 4 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                remote-attachment-circuit AC-45 create
                    eth-tag 145
                exit
                evi 4
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            sap lag-1:4 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-4 and PE-5, the SA MH ES "ES45" is configured with a GRE SDP toward PE-6: SDP 460 on PE-4 and SDP 560 on PE-6. The following is the configuration of "ES45" on PE-4:

```
# on PE-4:
configure
    service
```

```
        sdp 460 create
            description "GRE SDP for SA MH"
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ES45"  create
                    esi 01:00:00:00:00:45:00:00:00:04
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 460
                    no shutdown
                exit
            exit
        exit
```

On PE-4, Epipe 4 is configured as follows. The configuration on PE-5 is similar, but with spoke-SDP 560:4 instead.

```
# on PE-4:
configure
    service
        epipe 4 name "Epipe-4" customer 1 create
            vxlan instance 1 vni 4 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-45 create
                    eth-tag 145
                exit
                remote-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                evi 4
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 460:4 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-6, Epipe 4 is configured as follows:

```
# on PE-6:
configure
    service
        epipe 4 name "Epipe-4" customer 1 create
            endpoint "EP" create
            exit
            sap 1/2/1:4 create
```

```
            no shutdown
        exit
        spoke-sdp 640:4 endpoint "EP" create
            no shutdown
        exit
        spoke-sdp 650:4 endpoint "EP" create
            no shutdown
        exit
        no shutdown
    exit
```

Verification

The connectivity between the CEs emulated by VPRN 14 can be verified as follows:

```
*A:PE-1# ping router 14 172.16.14.64 rapid
PING 172.16.14.64 56 data bytes
!!!!!
---- 172.16.14.64 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 3.84ms, avg = 5.12ms, max = 9.41ms, stddev = 2.15ms
```

```
*A:PE-1# ping router 14 2001:db8::14:64 rapid
PING 2001:db8::14:64 56 data bytes
!!!!!
---- 2001:db8::14:64 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 3.80ms, avg = 5.19ms, max = 9.89ms, stddev = 2.36ms
```

The following BGP-EVPN information for Epipe 4 includes the EVI and the AC names and Ethernet tags:

```
*A:PE-2# show service id 4 bgp-evpn

===============================================================================

In AA MH ESs, the DF for VPLS services is the forwarder for Broadcast, Unknown unicast, and Multicast (BUM) traffic. In Epipes, however, all traffic is treated as unicast. The following tools commands on PE-2 and PE-3 show that DF is not applicable for AA MH ES "vES23_4.

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "vES23_4" evi 4 df

[06/29/2021 09:59:05] All Active VPWS - DF N/A
```

```
*A:PE-3# tools dump service system bgp-evpn ethernet-segment "vES23_4" evi 4 df

[06/29/2021 09:59:03] All Active VPWS - DF N/A
```

The following command on PE-2 shows no DF candidates for ES "vES23_4", even though PE-2 (as well as PE-3) is considered as DF (DF=yes):

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "vES23_4" evi 4

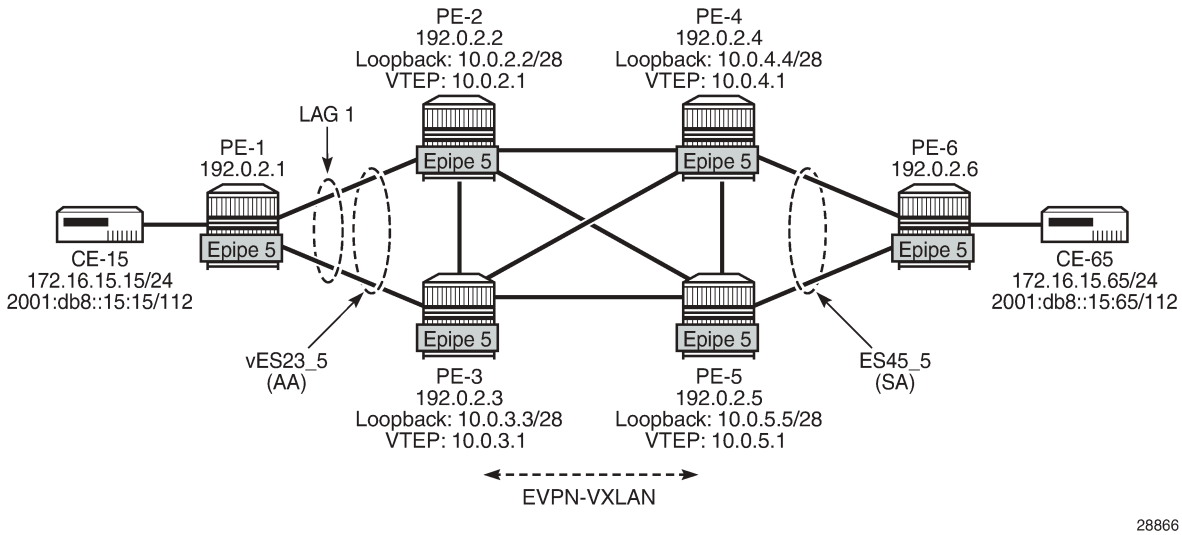
AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 171: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 5 with AA MH ES "vES23_5" between PE-2 and PE-3 and SA MH ES "ES45_5" between PE-4 and PE-5.

Figure 171: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses



The configuration of Epipe 5 on PE-1 is similar to the configuration of Epipe 4 on PE-1, so it is not shown here. The same applies for Epipe 5 on PE-6.

On PE-2, VTEP 10.0.2.1 is used instead of the system IP address. The ES must include two additional parameters for the DF selection: **es-orig-ip** and **route-next-hop**, which are both equal to the VTEP. Without these parameters, the DF selection will not work. The **es-orig-ip** command modifies the originator IP address of the ES route and the **route-next-hop** modifies the next-hop of the AD per-ES routes for the ES. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        system
            vxlan
                tunnel-termination 10.0.2.1 fpe 1 create
                tunnel-termination 2001::2:1 fpe 1 create
            exit
            bgp-evpn
                ethernet-segment "vES23_5" virtual create
                    esi 01:00:00:00:00:23:00:00:00:05
                    es-orig-ip 10.0.2.1
                    route-next-hop 10.0.2.1
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 5
                    exit
                    no shutdown
                exit
            exit
        exit
        epipe 5 name "Epipe-5" customer 1 create
            vxlan-src-vtep 10.0.2.1
            vxlan instance 1 vni 5 create
```

```
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-23_2 create
                    eth-tag 223
                exit
                remote-attachment-circuit AC-45_2 create
                    eth-tag 245
                exit
                evi 5
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    no shutdown
                exit
            exit
            sap lag-1:5 create
                no shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-3 is similar.

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure
    service
        sdp 465 create
            far-end 192.0.2.6
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            vxlan
                tunnel-termination 10.0.4.1 fpe 1 create
            exit
            bgp-evpn
                ethernet-segment "ES45_5" create
                    esi 01:00:00:00:00:45:00:00:00:05
                    es-orig-ip 10.0.4.1
                    route-next-hop 10.0.4.1
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 465
                    no shutdown
                exit
            exit
        exit
        epipe 5 name "Epipe-5" customer 1 create
            vxlan-src-vtep 10.0.4.1
            vxlan instance 1 vni 5 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-45_2 create
                    eth-tag 245
                exit
```

```
                remote-attachment-circuit AC-23_2 create
                    eth-tag 223
                exit
                evi 5
                vxlan bgp 1 vxlan-instance 1
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 465:5 create
                no shutdown
            exit
            no shutdown
        exit
```

In the AA MH ES, both PE-2 and PE-3 are DF. PE-4 receives BGP-EVPN autodiscovery routes with Ethernet tag 223 from PE-2 and PE-3 with the primary flag set to 1, as follows:

```
*A:PE-4# show router bgp routes evpn auto-disc tag 223 detail

            exit
        exit
        epipe 6 name "Epipe-6" customer 1 create
            vxlan-src-vtep 2001::4:1
            vxlan instance 1 vni 6 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-45_v6 create
                    eth-tag 645
                exit
                remote-attachment-circuit AC-23_v6 create
                    eth-tag 623
                exit
                evi 6
                vxlan bgp 1 vxlan-instance 1
                    send-tunnel-encap     # default
                    ecmp 2
                    no shutdown
                exit
            exit
            spoke-sdp 466:6 create
                no shutdown
            exit
            no shutdown
        exit
```

Conclusion

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, and can be used in networks without MPLS.

Fully Dynamic VSD Integration Model

This chapter provides information about fully dynamic virtualized service directory (VSD) integration model.

Topics in this chapter include:

Applicability

Software requirements for this feature are SR OS Release 13.0.R4 or later and Nuage Virtualized Services Platform (VSP) release 3.2.R1 or later. This configuration was tested on SR OS Release 13.0.R4 and Nuage VSP release 3.2.R3.

Note:
Fully dynamic extensible messaging and presence protocol (XMPP) provisioning is not supported along with the dynamic business services feature in Release 13.0. Both features are mutually exclusive.

Note:
Provisioning of filter entries from Virtualized Services Directory (VSD) is not supported in SR OS 13.0.

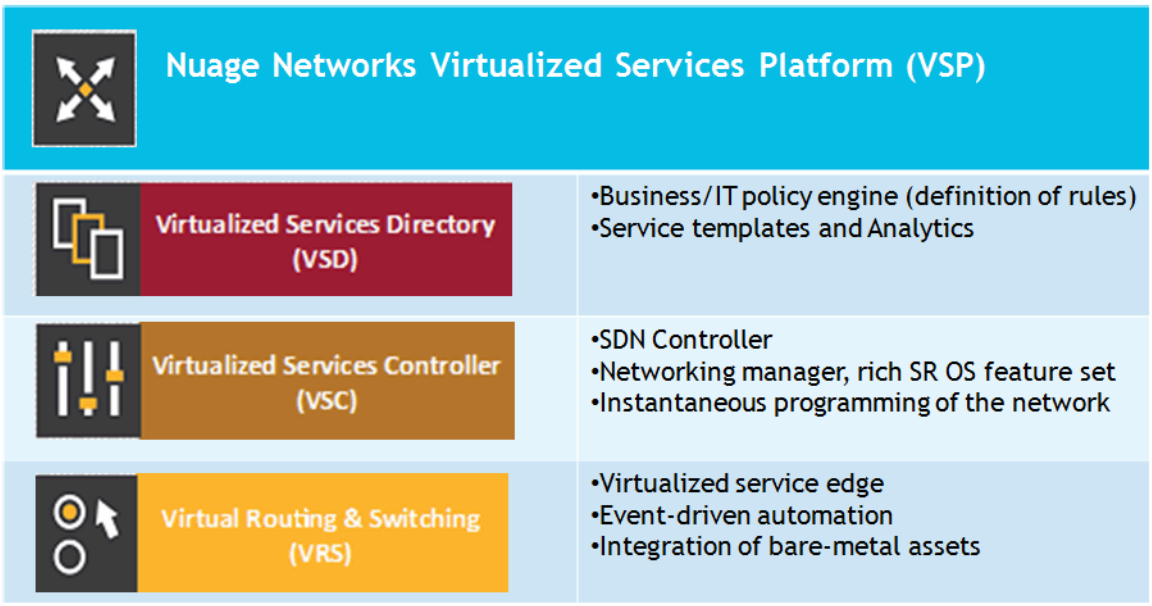
Nuage VSP conceptual knowledge and Nuage VSD operational knowledge are prerequisites. See the Nuage VSP user documentation for more information.

Overview

The Nuage VSP is a Software-Defined Networking (SDN) solution that provides data center (DC) network virtualization and automatically establishes connectivity between compute resources upon their creation. Leveraging programmable business logic and a powerful policy engine, the Nuage VSP provides an open and highly responsive solution that scales to meet the stringent needs of massive multi-tenant DCs. The Nuage VSP can be deployed over an existing DC IP network fabric, and has three main components:

Virtualized Services Directory (VSD), Virtualized Services Controller (VSC), and Virtual Routing and Switching (VRS), as displayed in Figure 173: Nuage VSP overview

Figure 173: Nuage VSP overview



Virtualized Services Directory (VSD)

The Nuage VSD is a programmable policy and analytics engine. It provides a flexible and hierarchical network policy framework that enables IT administrators to define and enforce resource policies in a user-friendly manner.

The VSD contains a multi-tenant service directory, which supports role-based administration of users, computing, and network resources. The VSD also manages network resource assignments such as IP addresses and ACLs.

For the purpose of service assurance, the VSD allows the definition of sophisticated statistics rules, such as collection frequencies, rolling averages, and samples, as well as Threshold Crossing Alerts (TCA). When a TCA occurs, it will trigger an event that can be exported to external systems through a generic messaging bus. Statistics are aggregated over hours, days, and months, and stored in a Hadoop® analytics cluster to facilitate data mining and performance reporting.

The VSD runs as a number of processes in a virtual machine (VM) environment.

Virtualized Services Controller (VSC)

The Nuage VSC is an SDN controller. It functions as the robust network control plane for DCs, maintaining a full view of per-tenant network and service topologies. Through the VSC, virtual routing and switching constructs are established to program the network forwarding plane, the Nuage VRS, using the OpenFlow protocol.

The VSC communicates with the VSD policy engine using Extensible Messaging and Presence Protocol (XMPP). An ejabberd XMPP server/cluster is used to distribute messages between the VSD and VSC entities. Multiple VSC instances can be interconnected within and across DCs by leveraging Multi-Protocol Border Gateway Protocol (MP-BGP).

The VSC is based on the Service Router Operating System (SR OS) and runs in a virtual machine environment.

Virtual Routing and Switching (VRS)

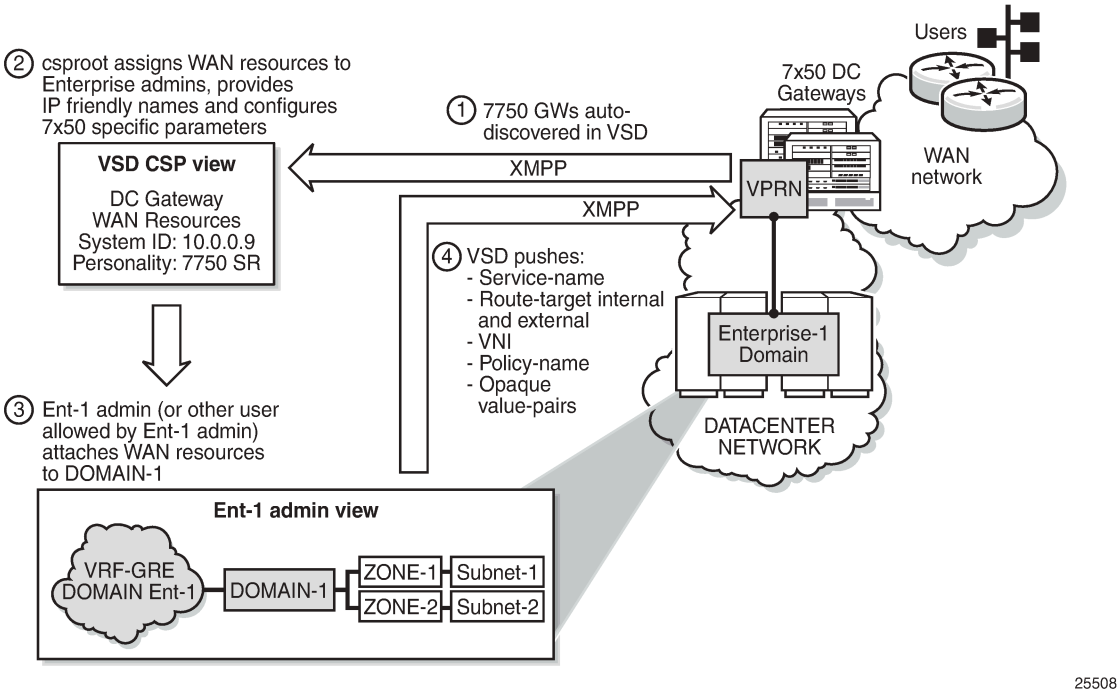
The Nuage VRS component is an enhanced Open vSwitch (OVS) implementation that constitutes the network forwarding plane. It encapsulates and de-encapsulates user traffic, enforcing L2 to L4 traffic policies as defined by the VSD. The VRS tracks Virtual Machine (VM) creation, migration, and deletion events in order to dynamically adjust network connectivity.

DC Gateway automated service provisioning

The first phase of VSD-7x50 integration was introduced in SR OS 12.0.R4. This phase included the development of an XMPP interface on the 7x50 SR and the integration in the Nuage XMPP architecture. This so-called Static + Dynamic (S-D) provisioning model allows the auto-provisioning of VPLS and VPRN route targets, as well as VPLS VNI (VXLAN Network Identifiers) on the 7x50 SR through the XMPP interface and the VSD interaction. The prerequisite in this model is the pre-configuration of the VPLS and VPRN services on the 7x50 through CLI or SNMP. This model is intended to be used in DC Gateways where the WAN and the DC are managed by different administrative entities. The DC administrator will use VSD to "attach" the already configured VPLS or VPRN service to the L2 or L3 domain in the DC.

The second phase of VSD-7x50 integration was introduced in SR OS 13.0.R4. This phase supports the Fully Dynamic (F-D) provisioning model. The goal of this model is to avoid the prerequisite of pre-configuring the services on the 7x50 SR existing in the S-D provisioning model, since this model assumes that the service is completely owned by the DC administrator. The entire service will be auto-generated on the 7x50 SR as a result of the interaction with the VSD. Figure 174: DC Gateway fully dynamic provisioning workflow shows the workflow of the F-D provisioning model.

Figure 174: DC Gateway fully dynamic provisioning workflow



1. As soon as the XMPP server is configured on the 7x50 DC Gateway, it is auto-discovered by the VSD.
2. The Cloud Service Provider (CSP) root user creates WAN services and assigns these resources to Enterprise administrators; for example, to the Ent-1 admin.
3. The Ent-1 admin sees the WAN service in the infrastructure resources and assigns permissions to certain user groups in Ent-1, who can consume these WAN resources by connecting to an L2/L3 domain.
4. As soon as the WAN service is added to an L2/L3 domain, the VSD pushes a list of parameters to the 7x50 DC Gateway, which uses a python script to construct the configuration of the WAN service. The list of parameters sent to the 7750 routers can include:
   - **service-name** (Service ID field in the WAN Service GUI) - used as VSD domain in the CLI
   - **config-type** (Config Type field in the WAN Service GUI) - DYNAMIC for F-D XMPP provisioning
   - **service-type** (based on combination of the Service Type field and IRB check box in the WAN Service GUI) - possible values: L2DOMAIN, L2DOMAIN-IRB, VRF-GRE, or VRF-VXLAN
   - **name** (name of the L2 domain in the VSD to which the WAN service is assigned, or BackHaulSubnet in the case of service-type VRF-VXLAN)
   - **service-policy** (service Policy in the WAN Service GUI field) - should match the python policy configured on the 7x50 DC Gateway
   - **vn-id** (VNI used for the Nuage overlay service) - dynamically supplied for VXLAN WAN services
   - **RT-I** (internal Route Target used for the Nuage overlay service)
   - **RT-E** (ext. Route Target in the WAN Service GUI field)
   - **metadata** (list of opaque parameters supplied in the Metadata section of the WAN Service GUI)

The dynamic provisioning of parameters is provided for the following VSD domain types (configured in the 7x50 DC Gateway):

l2-domain To attach a service at the gateway to an L2 (Ethernet) domain in the data center with no routing at the gateway, a VPLS service must be associated with a vsd-domain of type l2-domain.

l2-domain-irb To attach a service at the gateway to an L2 (Ethernet) domain in the data center with routing at the gateway, an R-VPLS service should be associated with a vsd-domain of type l2-domain-irb.

vrf-gre To attach a service at the gateway to an L3 domain (with GRE transport) in the data center, a VPRN service should be associated with a vsd-domain of type vrf-gre.

vrf-vxlan To attach a service at the gateway to an L3 domain (with VXLAN transport) in the data center, an R-VPLS service (with ip-route-advertisement enabled and linked to an EVPN-tunnel) should be associated with a vsd-domain of type vrf-vxlan.

This chapter will show examples of l2-domain, l2-domain-irb, and vrf-vxlan service type F-D provisioning, and focuses mostly on the 7x50 DC Gateway configuration. For a more detailed F-D provisioning workflow on the VSD UI, refer to the VSP User Guide.

Python script

The XMPP parameters supplied by the VSD are parsed by a python script on the 7x50 DC Gateway that dynamically provisions the VPLS and/or VPRN services provided for the Nuage overlay services.

The python script generates an executable CLI script based on the information received in the XMPP attributes. Three dynamic data service functions can be specified: **setup**, **modify**, or **teardown**. A fourth action, **revert**, is automatically invoked when the modify action fails:

- **setup** function: output = CLI to create a new dynamic data service.
- **teardown** function: output = CLI to delete an existing dynamic data service.
- **modify** function: output = CLI to change the parameters of an existing dynamic data service
- **revert** function: output = CLI to rollback the dynamic data service modify function actions in case of a modify failure

The python script uses the alc.dyn python module that contains a number of functions required to set up dynamic data services. To use the alc.dyn module, it must be imported into the python script:

```
from alc import dyn
```

The alc.dyn module contains a number of functions. Relevant alc.dyn functions for F-D XMPP provisioning are listed here:

- **dyn.action**(dictionary)
- **dyn.add_cli**(string)
- **dyn.select_free-id**(service-id)

The next sections provide a basic description of these functions. The alc.dyn module contains other functions that are not relevant for this feature. For a full list of the alc.dyn functions together with an extensive explanation of each function, refer to the RADIUS-Triggered Dynamic Data Service Provisioning chapter.

The trigger in the python script to execute a specific function is by calling the internal function **dyn.action**(d), where "d" is a python dictionary:

- d = { key : value, key : value, key : value, … , key : value }

For F-D XMPP provisioning, only 1 key:value pair is used and the key string must be set to "script".

The value is a tuple with the following comma separated values:

- (setup-function, modify-function, revert-function, teardown-function)

Setup and teardown functions are mandatory. Modify and revert functions are optional. If a modify function is defined, the revert function must also be defined. If no modify/revert function is required, the keyword **None** should be used instead.

The following two combinations are supported for F-D Dynamic XMPP provisioning:

1. without modify function:

```
d = {"script" : (setup_script, None, None, teardown_script)}
dyn.action(d)
```

2. with modify function (allows for changes in the WAN service on the VSD while the service is assigned to a domain):

```
d = {"script" : (setup_script, modify_script, revert_script, teardown_script)}
dyn.action(d)
```

When the configuration for a new service-name is received from the VSD, the vsd parameters and the opaque parameters string are concatenated into a single dictionary. The setup_script() is called and the dictionary is passed to the function. In this chapter, the dictionary will be named "vsdParams", but any other name would do. Within the python script:

- The VSD UI parameters are referenced as vsdParams['rt'], vsdParams['vni'], vsdParams['servicetype'], and so on.
- The metadata parameters are defined in an opaque string. For example, when the metadata string "rd=1:1,sap=1/1/1:1000" is supplied to the VSD WAN Service GUI, the format in the dictionary will be in the following format: "'metadata': 'rd=1:1,sap=1/1/1:1000 '".

To reference the metadata, the format is changed (trailing space is removed and parameters split up):

```
metadata = vsdParams['metadata']
    metadata = metadata.rstrip()
    metadata = dict(e.split('=') for e in metadata.split(','))
```

The individual metadata parameters can then be referenced in a similar way as the vsd parameters; for example, metadata['rd'], metadata['sap'], and so on.

When the startup script is executed, the **config>service>vsd>domain** is created outside the script context before running the actual script. The teardown script will remove the vsd domain. The domain-name is taken from the service-name supplied by the VSD ("Service ID" field in the WAN Service GUI - used as VSD domain in the CLI). When testing the script with the **tools perform python-script** command, the domain-name is taken from the domain-name command parameter (see Testing the python script section).

When subsequent configuration messages are received from the VSD, the new parameter list is again generated from the VSD message and compared to the last parameter list that was successfully executed.

- If the two strings are identical, no action is taken.
- If there is a difference between the strings, the **modify_script()** function is called. For example, the **modify_script()** function is set up to handle a change in the service-mtu.

If a configuration message is received from the VSD for an existing service-name with no VSD parameters, the **teardown_script()** is called.

If a **setup_script()** fails, the **teardown_script()** is called.

To generate CLI output in the python script, an internal function, **dyn.add_cli**(output-string), is available. It adds the specified output-string to the CLI script. Python enables the use of triple quotes to specify strings that span multiple lines. For example:

```
from alc import dyn
    dyn.add_cli("""
configure
    service
        ies %(svc_id)s customer 1 create
            service-name "%(inst)s"
            description "%(inst)s"
            no shutdown
        exit
    exit
exit
""" % d)
```

An internal function, **dyn.select_free_id**("service-id"), is available to select a free (unused) service identifier in the service-range specified in the dynamic-services context (see the Configuration section). If no service-range is configured, the python script fails when **dyn.select_free_id**("service-id") is called. The service-id is made available again after a successful teardown (removal) of the service.

XMPP

The Extensible Messaging and Presence Protocol (XMPP) is an open technology for real-time communication, using XML (Extensible Markup Language) as the base format for exchanging information. XMPP provides a way to send small pieces of XML from one entity to another in near real time. Although initially intended for Instant Messaging applications, it can be easily extended to be used in a DC environment.

In the Nuage solution, each XMPP client, including the 7x50 SR, is referred to with a JID(JabberID) in the following format: username@xmppserver.domain. The xmppserver.domainpoints to the XMPP server.

The Nuage VSP/7x50 DC Gateway solution uses the XMPP PubSub (Publish Subscribe) extension. This extension allows a user to subscribe to a node so that it can be notified whenever there is new or updated information available. The mechanism is used in this feature to auto-discover the username of the VSD JID. Additionally, the 7x50 will subscribe to a separate PubSub for each DC Gateway, to discover updates on specific domains. Subscriptions are confirmed periodically (every 15 min).

The 7x50 DC Gateway will periodically audit the VSD and request a DIFF list of F-D VSD domains. The VSD keeps a DIFF list of domains, which contains the F-D domain names for which the VSD has not received an info/query (IQ) request from the 7x50 for a long time. The DC Gateway periodically checks the info for each of its deployed dynamic services with an IQ request (every 16-24 min). A DIFF or FULL

domain list audit can also be triggered with the **tools perform service vsd fd-domain-sync <full> | <diff>** command.

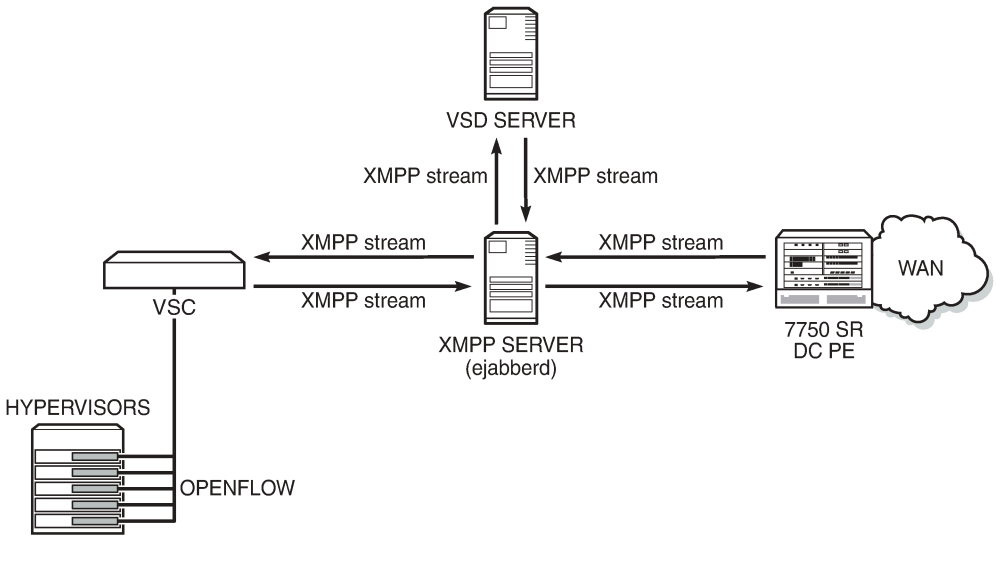
Configuration

This section describes the configuration that is required on the 7x50 DC Gateway for F-D XMPP provisioning.

The following figure shows the basic setup used and also illustrates the XMPP architecture in the data center. Although the VSD and XMPP servers are represented by a single server, a cluster of VSD servers (using the same database) and/or XMPP servers will be a very common configuration in a data center.

It is assumed that underlying IP connectivity and an IGP has already been configured in this setup.

Figure 175: F-D XMPP provisioning setup



XMPP configuration

To receive configuration parameters from the VSD, the 7x50 DC Gateway has to establish an XMPP client session with the XMPP server. Only one XMPP server can be configured.

When the XMPP server is properly configured, with no shutdown, the 7750 will try to establish a TCP session with the XMPP server through the management interface first. If it fails to establish communication, the 7750 will use in-band communication and will use its system IP as the source IP address.

To resolve the XMPP server fully qualified domain name (FQDN), provide a DNS server in the boot option file (bof) configuration and configure a dns-domain:

```
*A:pe-9>config>system# show bof
===============================================================================
BOF (Memory)
===============================================================================
---snip---
    primary-dns      138.203.39.47
```

```
    dns-domain       nuage.net
---snip---
===============================================================================
```

Then, configure the system-id of the DC Gateway that will be communicated to the VSD:

```
*A:pe-9>config>system# info
----------------------------------------------
#--------------------------------------------------
echo "vsd Configuration"
#--------------------------------------------------
        vsd
            system-id "pe9"
        exit
```

The next step is to configure the VSD server. The domain-name is the domain portion of the JID. The username is the username portion of the JID acting as an XMPP client. Ensure that the username uses all letters in lowercase (see SR OS 13.0 release notes). If no username is provided, an in-band registration will be provided, using the chassis MAC as username. The use of a password is optional:

```
*A:pe-9>config>system# info
#--------------------------------------------------
echo "Xmpp Configuration"
#--------------------------------------------------
        xmpp
            server vsd domain-name vsd1.nuage.net create username pe9
                no shutdown
            exit
        exit
----------------------------------------------
```

When the XMPP server has been configured, the state should move to "Functional":

```
*A:pe-9# show system xmpp server
===============================================================================
XMPP Server Table
===============================================================================
Name                            User Name          State
 XMPP FQDN                       Last State chgd    Admin State
-------------------------------------------------------------------------------
vsd                             pe9                Functional
 vsd1.nuage.net                  0d 00:37:01        inService
-------------------------------------------------------------------------------

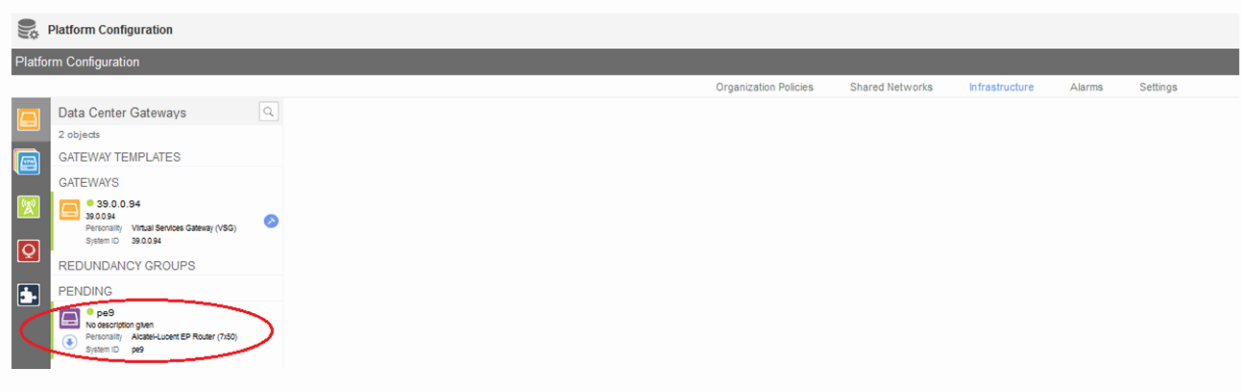
F-D XMPP provisioning uses the PubSub XMPP extension that allows each user to subscribe to a node, to be notified whenever that node gets new pieces of information or updated information.

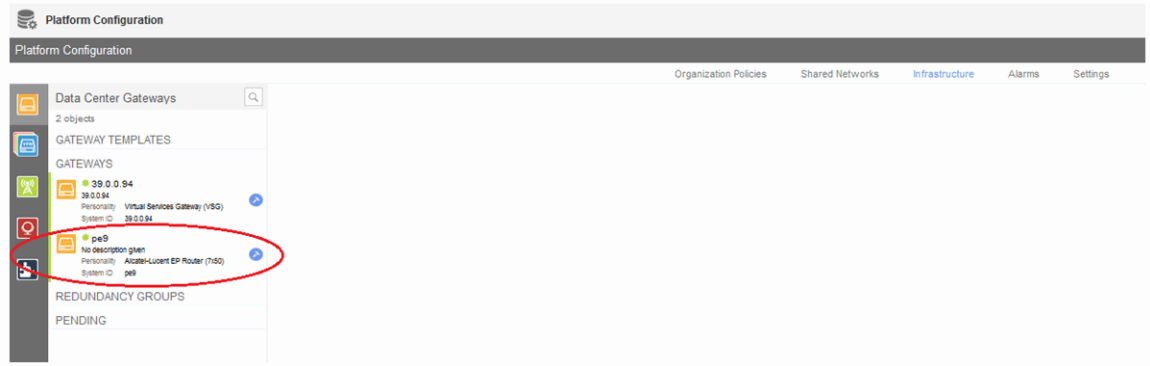
The DC Gateway PubSub subscription state and subscriber name can be shown:

```
*A:pe-9# show system vsd
===============================================================================
VSD Information
===============================================================================
System Id                : pe9
GW Last Audit Tx Time    : 10/13/2015 13:56:34
Gateway Publish-Subscribe Information
-------------------------------------------------------------------------------
Subscribed               : True
Subscriber Name          : nuage_gateway_id_pe9
Last Subscription Time   : 10/13/2015 13:56:34
===============================================================================
```

At the same time, the 7x50 DC Gateway will be announced as a pending gateway in the VSD:



The gateway will be promoted to the available gateways group by clicking on the arrow below the pending gateway icon:



BGP configuration

In the Nuage VSP solution, MP-BGP is used in the control plane to distribute MAC/IP information about the VMs. This information is distributed between the different VSCs, VSGs, and 7x50 DC Gateways. Configure MP-BGP on the 7x50 DC Gateway and the VSC/VSG (in this case, a VSG was used, but VSC is similar):

```
*A:pe-9>config>router# info
----------------------------------------------
#--------------------------------------------------
echo "IP Configuration"
#--------------------------------------------------
        interface "system"
            address 10.0.0.9/32
            no shutdown
        exit
---snip---
        autonomous-system 65000
---snip---
#--------------------------------------------------
echo "BGP Configuration"
#--------------------------------------------------
            min-route-advertisement 5
            rapid-withdrawal
            rapid-update evpn
            group "Nuage"
                family route-target evpn
                type internal
                neighbor 39.0.0.94
                exit
            exit
            no shutdown
```

```
*A:vsc1.nuage.net>config>router# info
------------------------------------------------
#--------------------------------------------------
echo "IP Configuration"
#--------------------------------------------------
---snip---
        interface "system"
            address 39.0.0.94/32
            no shutdown
        exit
        autonomous-system 65000
---snip---
#--------------------------------------------------
echo "BGP Configuration"
#--------------------------------------------------
        bgp
            family route-target evpn
            min-route-advertisement 5
            rapid-withdrawal
            rapid-update evpn
            group "internal"
                type internal
                neighbor 10.0.0.9
                    family evpn
                exit
            exit
            no shutdown
        exit
```

```
-----------------------------------------------
```

In this setup, the family type "evpn" and "route-target" is used. The former is used to learn the EVPN route updates while the latter is restricting the 7x50 to only learn those MB-BGP routes for which it has a route target configured.

Note:
To use vrf-gre domains, configure BGP family "vpn-ipv4" as well. Similarly, to use BGP-MH (for example, in case of redundant 7x50 DC Gateways with L2-domains), the use of BGP family "l2vpn" is required.

Verify that BGP peering is in the operational state:

```
*A:pe-9# show router bgp summary
===============================================================================
 BGP Router ID:10.0.0.9         AS:65000       Local AS:65000

-------------------------------------------------------------------------------
39.0.0.94
                65000   76287    0 00h04m14s 0/0/0 (RouteTarget)
                         2634    0           0/0/0 (Evpn)
-------------------------------------------------------------------------------
```

Dynamic VSD Services range

F-D XMPP provisioning requires a reserved range of Service-IDs that can be used for dynamic data services. This configured range is no longer available for regular services configured via CLI/SNMP:

```
*A:pe-9>config>service# info
----------------------------------------------
        vsd
            service-range 64000 to 64999
        exit
```

```
*A:pe-9# show service vsd summary
===============================================================================
VSD Information
===============================================================================
Service Range
Start              : 64000                        End           : 64999
===============================================================================
No domain entries found
```

Python script

The python script that will build the dynamic services based on the VSD parameters obtained via XMPP can be stored locally on the CF or on a remote FTP server:

```
*A:pe-9>config>python# info
----------------------------------------------
```

```
        python-script "l2domain_services" create
            primary-url "ftp://*:*@138.203.15.48/./l2domain_service.py"
            no shutdown
        exit
```

The script is loaded into memory as soon as a no shutdown is performed and is reloaded with each **shutdown**/**no shutdown** action. Alternatively, a tools command can be used to reload the script:

```
*A:pe-9# tools perform python-script reload "l2domain_services"
```

In case incorrect python syntax is used in the script, an error message is displayed after a **no shutdown** of the script (or a reload with the tools command), with an indication of the line where the error is located.

The details of the python script can be inspected:

```
*A:pe-9# show python python-script "l2domain_services"
===============================================================================
Python script "l2domain_services"
===============================================================================
Description   : (Not Specified)
Admin state   : inService
Oper state    : inService
Action on fail: drop
Protection    : none
Primary URL   : ftp://*:*@138.203.15.48/./l2domain_service.py
Secondary URL : (Not Specified)
Tertiary URL  : (Not Specified)
Active URL    : primary
Last changed  : 10/13/2015 09:54:26
===============================================================================
```

The contents of the python script can also be viewed. The contents of the script are shown in the "Test the python script" section:

```
*A:pe-9# show python python-script "l2domain_services" source-in-use
===============================================================================
Python script "l2domain_services"

    164 d = {"script" : (setup_script, modify_script, revert_script, teardown_script)}
    165
    166 dyn.action(d)
==============================================================================
```

A list of CLI command nodes that can be used with python script function dyn.add_cli is provided with the **tools dump service vsd-services command-list** command. In general, all the 'leaf' commands under the nodes shown in the tools dump command, can be used with the python script.

Further restriction of CLI commands is possible by creating a separate CLI user for the XMPP interface and associate that user with a profile where the commands are limited.

The CLI user for the XMPP interface is configurable:

```
config>system>security>cli-script>authorization>
        vsd
[no] cli-user <username>
```

Python policy

Python scripts are called by a python policy that will be referred to in the VSD WAN services GUI in the Service Policy field.

Create a python policy (that will be referred to in the VSD GUI) and link the python policy to the python script:

```
*A:pe-9>config>python# info
----------------------------------------------
        python-policy "py-l2" create
            description "Python script to create L2 domains"
            vsd script "l2domain_services"
        exit
```

```
*A:pe-9# show python python-script "l2domain_services" association
===============================================================================
Python Script Association
===============================================================================
Policy                          Type                                  Dir
-------------------------------------------------------------------------------
py-l2                           vsdAccessRequest                      ingress
-------------------------------------------------------------------------------
```

```
*A:pe-9# show python python-policy "py-l2"
===============================================================================
Python policy "py-l2"
===============================================================================
Description                : Python script to create L2 domains
-------------------------------------------------------------------------------
Messages
-------------------------------------------------------------------------------
Type                                Dir     Script
-------------------------------------------------------------------------------
vsdAccessRequest                    ingress l2domain_services
-------------------------------------------------------------------------------
```

Test the python script

The python script can be tested separately on the 7x50 DC Gateway; even before connecting it to the Nuage setup.

Some notes about the python script and creating dynamic services:

- The VSD (and **tools evaluate-script** command) will provide some compulsory parameters like:
  - domain-name
  - domain type (l2-domain|vrf-gre|vrf-vxlan|l2-domain-irb)
  - action (setup or teardown)
  - vni
  - RT (internal and external route-targets are provided)
- The VSD (and **tools evaluate-script** command) can provide extra metadata that is supplied in a text string and comma separated. For example, metadata "rd=1:1,sap=1/1/1:1000".
- The RT format supplied by the VSD though XMPP (that is, "x:x") differs from the RT format that can be used with the **tools evaluate-script** command (for example, "target:x:x"). For that reason, it can be useful to add the following check in the script:

```
if not rt.startswith ('target'):
     rt = "target:"+rt
```

- The VSD metadata string includes an empty space at the end. This can be removed with the following python command:

```
metadata = metadata.rstrip()
```

- If a configuration message is received from the VSD for an existing service-name with no VSD parameters, or if a setup_script() fails, the teardown_script() is called.
- At any point in the script, you can add **print** commands to check the status/content of various parameters.

The python policy and script can then be tested with the tools evaluate-script command. Example syntax has been added into the scripts for convenience.

Before testing the script, it will be useful to enable the following debugging:

```
debug
    python
        python-script "l2domain_services"
            script-all-info
        exit
    exit
    vsd
        scripts
            event
                cli
                errors
                executed-cmd
                warnings
                state-change
            exit
        exit
    exit
```

```
exit
```

In this section, a python example script for an l2-domain is used. The contents of the script are shown in the following text format. Examples for l2-domain-irb and vrf-vxlan type domains are shown in dedicated sections:

```
from alc import dyn
# example of metadata to be added in VSD WAN Service: "rd=1:1,sap=1/1/1:1000"
# example of tools cli to test this script: tools perform service vsd evaluate-script domain-
name "l2dom1" type l2-domain action setup policy "py-l2" vni 1234 rt-i target:1:1 rt-e
 target:1:1 metadata "rd=1:1,sap=1/1/1:1000"

# teardown example cli: tools perform service vsd evaluate-script domain-name "l2dom1" type l2-
domain action teardown policy "py-l2" vni 1234 rt-i target:1:1 rt-e target:1:1

def setup_script(vsdParams):

2147483649   intVpls   Up   Down 1          _tmnx_InternalVplsService
-------------------------------------------------------------------------------
Matching Services : 2
-------------------------------------------------------------------------------
===============================================================================
```

```
*A:pe-9# show service vsd domain
No domain entries found
```

Editing dynamic VSD services

As indicated in the previous section, the dynamic VSD services CLI configuration cannot be shown or edited normally. However, under certain circumstances, it might be necessary to inspect/change/remove the configuration of a dynamic VSD service; for example, when the python VSD script was not using the correct syntax and the creation/deletion of the dynamic VSD service failed.

It is possible to edit the dynamic VSD services configuration by entering the **enable-vsd-config** mode. First, create a password, which is required to enter this mode:

```
*A:pe-9# configure system security password
*A:pe-9>config>system>security>password# vsd-password *****
```

Then, enter the enable-vsd-config mode. You will be asked for the previously configured password:

```
*A:pe-9# enable-vsd-config
Password:
```

Now you can edit the dynamic VSD services configuration and change/add/remove configuration:

```
*A:pe-9# configure service
*A:pe-9>config>service# info
----------------------------------------------
        customer 1 create
            description "Default customer"
        exit
        vsd
            domain l2dom1 type l2-domain create
                description "l2dom1"
                no shutdown
            exit
            service-range 64000 to 64999
        exit
        vpls 64000 customer 1 create
            description "vpls64000"
            vxlan vni 1234 create
            exit
            bgp
```

```
                route-distinguisher 1:1
            exit
            bgp-evpn
                evi 64000
                vxlan
                    no shutdown
                exit
                mpls
                    shutdown
                exit
            exit
            proxy-arp
                dynamic-arp-populate
                no shutdown
            exit
            stp
                shutdown
            exit
            service-name "evi64000"
            sap 1/1/1:1000 create
            exit
            vsd-domain "l2dom1"
            no shutdown
        exit
----------------------------------------------
```

In the enable-vsd-config mode, only dynamic VSD services can be edited, not regular CLI-based services:

```
*A:pe-9# configure service vpls 100 customer 1 create
MINOR: SVCMGR #1201 Invalid service-id - not reserved
```

After inspecting/editing the dynamic VSD services configuration, you should exit this mode again:

```
*A:pe-9# no enable-vsd-config
```

L2 VXLAN

An example python script for F-D XMPP provisioning of an L2 VXLAN type service (l2-domain) was provided in the "Testing the python script" section. In this section, the same script is used for provisioning via the VSD.

To dynamically provision this type of service, a few things must be configured on the VSD: (screenshots of this workflow are available in the VSP User Guide)

Create an L2 WAN service in the VSD:

- under Platform Config/Infrastructure, select the DC Gateway to add a WAN service
- select Service Type "layer 2" (no IRB)
- select "Dynamic" configuration type to allow Fully Dynamic provisioning
- under Service Policy, provide the python policy configured on the DC Gateway
- provide a Name and Service-ID (the Service-ID will be the name of the dynamically created service domain on the DC Gateway)

Add the metadata to the WAN service:

- right-click the WAN service and select "inspect"

- a dialog box appears, select the "Metadata" tag and add the metadata info "rd=1:1,sap=1/1/1:1000"

Add permissions to Enterprise1. The WAN service should now be visible in Enterprise1. Add permissions for a group of users to use this WAN service. Instantiate the L2 domain and attach the WAN service.

As soon as the WAN service is attached to the L2 domain, the VSD will send a notification via XMPP to the DC Gateway about the new Service-ID. The VSD will send an XMPP IQ request to the VSD to obtain the VSD service parameters.

Note:
There is an 8 to 12 s delay. The command **tools perform service vsd domain refresh-config** can be used to expedite the request.

As soon as the DC Gateway receives this information, the python policy mentioned in the VSD service parameters is triggered and the VSD parameters are passed to the associated python script. The python script will then construct and execute the same configuration CLI and trigger similar debug information as is shown in the section "Testing the python script".

After the python script has completed successfully, the service can be inspected in a similar way as before.

- **show service service-using**
- **show service id** <*service-id*> **all**
- enter enable-vsd-config mode if required and inspect the service config

MAC addresses can now be learned in the Nuage VSC/VSG and sent via MP-BGP to the DC Gateway:

```
*A:pe-9# show service id 64000 fdb detail
===============================================================================
Forwarding Database, Service 64000
===============================================================================
ServId    MAC               Source-Identifier        Type     Last Change
                                                     Age
-------------------------------------------------------------------------------
64000     1e:50:01:01:00:01 vxlan:                   Evpn     10/14/15 16:10:44
                            39.0.0.94:1006636
-------------------------------------------------------------------------------
```

In case HyperVisors (HVs) with VRS are deployed or a Host vPORT has been connected to a VSG, the EVPN MAC/Route (type 2) will also include the IP address of the VM/Host, in which case the DC Gateway can perform a proxy-arp function. For more information about EVPN-VXLAN features, refer to the chapters EVPN for VXLAN Tunnels (Layer 2) and EVPN for VXLAN Tunnels (Layer 3).

```

-------------------------------------------------------------------------------
Number of entries : 1
===============================================================================
```

The svc-ID belonging to the Service-ID configured on the VSD can be easily obtained:

```
*A:pe-9# show service vsd domain "L2-service-1" association
============================================================
Service VSD Domain
============================================================
Svc Id      Svc Type  Domain Type    Domain Admin   Origin
------------------------------------------------------------
64000       vpls      l2Domain       inService      vsd
------------------------------------------------------------
Number of entries: 1
```

The associated RT/RD/VNI information can then be displayed with the **show service id** <*service-id*> **all** command, as shown previously.

An overview of the VTEPs that the DC Gateway shares this service with, and the corresponding VNIs is available:

```
*A:pe-9# show service id 64000 vxlan
===============================================================================
VPLS VXLAN, Ingress VXLAN Network Id: 1006636
===============================================================================
Egress VTEP, VNI
===============================================================================

```

The WAN service can be detached from the L2 domain in the VSD GUI, if required.

This triggers similar debug information on the DC Gateway as the **tools perform service vsd evaluate teardown** command shown in the "Testing the python script" section.

After deleting the WAN service in the VSD GUI, the VPLS service and the service domain is removed from the DC Gateway.

L2 VXLAN IRB

An example python script for F-D XMPP provisioning of an L2 VXLAN IRB type service (l2-domain-irb) is as follows:

```
from alc import dyn
# example of metadata to be added in VSD WAN Service: "rd=2:2,sap=1/1/1:1000,vprnAS=
65000,vprnRD=65000:1,vprnRT=target:65000:1,vprnLo=1.1.1.1,irbGW=10.32.78.1/24"
# example of tools cli to test this script: tools perform service vsd evaluate-script
 domain-name "l2domIRB1" type l2-domain-irb action setup policy "py-l2-irb" vni  1234 rt-i
 target:2:2 rt-e target:2:2 metadata "rd=2:2,sap=1/1/1:1000,vprnAS=65000,vprnRD=65000:1,vprnRT=
target:65000:1,vprnLo=1.1.1.1,irbGW=10.32.78.1/24"
# teardown example cli: tools perform service vsd evaluate-script domain-name "l2domIRB1" type
 l2-domain-irb action teardown policy "py-l2-irb" vni 1234 rt-i target:2:2  rt-e target:2:2
def setup_script(vsdParams):

      """ % {'vplsSvc_id' : setupParams['vplsSvc_id'], 'vprnSvc_id' : setupParams['vprnSvc_
id'], 'vni' : setupParams['vni'], 'sap_id' : setupParams['sap_id']})
      return setupParams
d = {"script" : (setup_script, None, None, teardown_script)}
dyn.action(d)
```

The python script and policy are configured in a similar way as the previous example:

```
*A:pe-9# configure python
*A:pe-9>config>python# info
----------------------------------------------
        python-script "l2domain-irb_services" create
            primary-url "ftp://*:*@138.203.15.48/./l2domainIRB_service.py"
            no shutdown
        exit
        python-policy "py-l2-irb" create
            description "Python script to create L2-IRB domains"
            vsd script "l2domain-irb_services"
        exit
----------------------------------------------
```

It is also possible to create a python script that covers different domain types. The relevant part of the script is then addressed by using the following if-statement in the script:

```
    servicetype = vsdParams.get('servicetype')
        if servicetype == "L2DOMAIN-IRB":
           ---snip---
```

On the VSD, the following has to be provided:

(screenshots of this workflow are available in the VSP User Guide)

Create an L2 WAN service in the VSD:

- under Platform Config/Infrastructure, select the DC Gateway to add a WAN service
- select Service Type "layer 2" and select "IRB"
- select "Dynamic" configuration type to allow Fully Dynamic provisioning
- under Service Policy, provide the python policy configured on the DC Gateway
- provide a Name and Service-ID (the Service-ID will be the name of the dynamically created service domain on the DC Gateway)

Add the metadata to the WAN service:

- right-click the WAN service and select "inspect"
- a pop-up dialog box appears; select the "Metadata" tag and add the metadata info; for example,

  "rd=2:2,sap=1/1/1:1000,vprnAS=65000,vprnRD=65000:1,vprnRT=target:65000:1,vprnLo=1.1.1.1, irbGW=10.32.78.1/24"

Add permissions to Enterprise1. The WAN service should now be visible in Enterprise1.

Add permissions for a group of users to use this WAN service. Instantiate an L2 domain and attach the WAN service.

After the script has completed, there should be two new services created:

```
*A:pe-9# show service service-using

            sap 1/1/1:1000 create
            exit
            vsd-domain "L2-IRB-Service-1"
            no shutdown
        exit
        vprn 64001 customer 1 create
            autonomous-system 65000
            route-distinguisher 65000:1
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:65000:1
            interface "irbvpls-64000" create
```

```
                address 10.32.78.1/24
                vpls "vpls64000"
                exit
            exit
            interface "lo1" create
                address 1.1.1.1/32
                loopback
            exit
            vsd-domain "L2-IRB-Service-1"
            no shutdown
        exit
----------------------------------------------
```

MAC addresses can now be learned in the Nuage VSP/VSG and sent via MP-BGP to the DC Gateway:

```
*A:pe-9# show service id 64000 fdb detail
===============================================================================
Forwarding Database, Service 64000
===============================================================================
ServId    MAC               Source-Identifier        Type     Last Change
                                                     Age
-------------------------------------------------------------------------------
64000     1e:50:01:01:00:01 vxlan:                   Evpn     07/22/15 11:26:15
                            39.0.0.94:1006636
64000     1e:e2:ff:00:f9:3d cpm                      Intf     07/22/15 11:15:36
-------------------------------------------------------------------------------
```

The second MAC address is the GW-MAC that the VM or VSG-connected host will use to reach the interface on the VPRN:

```
*A:pe-9# show router 64001 route-table
===============================================================================
Route Table (Service: 64001)
===============================================================================
Dest Prefix[Flags]                             Type    Proto     Age        Pref
      Next Hop[Interface Name]                                     Metric
-------------------------------------------------------------------------------
1.1.1.1/32                                     Local   Local     00h17m10s  0
       lo1                                                           0
10.32.78.0/24                                  Local   Local     00h17m10s  0
       irbvpls-64000                                                 0
```

```
*A:pe-9# show router 64001 arp
===============================================================================
ARP Table (Service: 64001)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.32.78.1      1e:e2:ff:00:f9:3d 00h00m00s Oth[I] irbvpls-64000
10.32.78.100    1e:50:01:01:00:01 03h53m22s Dyn[I] irbvpls-64000
1.1.1.1         1e:e2:ff:00:00:00 00h00m00s Oth    lo1
```

Similar commands as shown in the previous section are available to obtain relevant information:

- **show service vsd domain "L2-IRB-Service-1" association** to obtain svc-IDs
- **show service id <id> all** to obtain RT/RD/VNI values
- **show service id <id> vxlan** to obtain VTEPs in the VPLS service
- **show service vxlan <vtep-ip>** to obtain svc-ID and VNI information

- **show router bgp routes evpn mac** to obtain MAC/IP/VNI/RT/NH information

The VM or VSG-connected Host should be able to ping the loopback interface of the VPRN service:

```
*A:ce1# ping 1.1.1.1 source 10.32.78.100
PING 1.1.1.1 56 data bytes
64 bytes from 1.1.1.1: icmp_seq=1 ttl=64 time=1.67ms.
64 bytes from 1.1.1.1: icmp_seq=2 ttl=64 time=1.83ms.
```

L3 VXLAN

An example python script for F-D XMPP provisioning of an L3 VXLAN type service (vrf-vxlan) is:

```
from alc import dyn

# example of metadata to be added in VSD WAN Service: "rd=3:3,vprnAS=65000,vprnRD=
65000:1,vprnRT=target:65000:1,vprnLo=1.1.1.1"

# example of tools cli to test this script: tools perform service vsd evaluate-script domain-
name "l3dom1" type vrf-vxlan action setup policy "py-vrf-vxlan" vni 1234 rt-i target:3:3 rt-e
 target:3:3 metadata "rd=3:3,vprnAS=65000,vprnRD=65000:1,vprnRT=target:65000:1,vprnLo=1.1.1.1"

# teardown example cli: tools perform service vsd evaluate-script domain-name "l3dom1" type
 vrf-vxlan action teardown policy "py-vrf-vxlan" vni 1234 rt-i target:3:3 rt-e target:3:3

def setup_script(vsdParams):

    print ("These are the VSD params: " + str(vsdParams))
    servicetype = vsdParams['servicetype']
    vni = vsdParams['vni']
    rt = vsdParams['rt']

# add "target:" if provisioned by VSD (VSD uses x:x format whereas tools command uses
 target:x:x format)
    if not rt.startswith ('target'):
       rt = "target:"+rt
    metadata = vsdParams['metadata']

# remove trailing space at the end of the metadata
    metadata = metadata.rstrip()
    print ("VSD metadata" + str(metadata))
    metadata = dict(e.split('=') for e in metadata.split(','))
    print ("Modified metadata" + str(metadata))
    vplsSvc_id = dyn.select_free_id("service-id")
    vprnSvc_id = dyn.select_free_id("service-id")

id'], 'vni' : setupParams['vni']})
      return setupParams

d = {"script" : (setup_script, None, None, teardown_script)}
```

```
dyn.action(d)
```

The python script and policy are configured in a similar way as the previous example:

```
*A:pe-9# configure python
*A:pe-9>config>python# info
----------------------------------------------
        python-script "vrf-vxlan_services" create
            primary-url "ftp://*:*@138.203.15.48/./vrf-vxlan_service.py"
            no shutdown
        exit
        python-policy "py-vrf-vxlan" create
            description "Python script to create vrf-vxlan domains"
            vsd script "l3vxlan"
        exit
----------------------------------------------
```

The following steps are required on the VSD to provision the WAN service:

(screenshots of this workflow are available in the VSP User Guide)

Create an L3 WAN service in the VSD:

- under Platform Config / Infrastructure, select the DC Gateway to add a WAN service
- select Service Type "layer 3"
- select "Dynamic" configuration type to allow Fully Dynamic provisioning
- under Service Policy, provide the python policy configured on the DC Gateway
- provide a Name and Service-ID (the Service-ID will be the name of the dynamically created service domain on the DC Gateway)

Add the metadata to the WAN service:

- right-click the WAN service and select "inspect"
- a pop-up dialog box appears; select the "Metadata" tag and add the metadata info; for example,

  "rd=3:3,vprnAS=65000,vprnRD=65000:1,vprnRT=target:65000:1,vprnLo=1.1.1.1"

Add permissions to Enterprise1. The WAN service should now be visible in Enterprise1.

Add permissions for a group of users to use this WAN service. Instantiate an L3 domain and attach the WAN service.

After the script has completed, there should be two new services:

```
*A:pe-9# show service service-using

The dynamically created configuration can be inspected in enable-vsd-config mode (only enter the enable-vsd-config mode when required):

```
*A:pe-9>config>service# info
----------------------------------------------
        customer 1 create
            description "Default customer"
        exit
        vsd
            domain L3-service-1 type vrf-vxlan create
                description "L3-service-1"
                no shutdown
            exit
            service-range 64000 to 64999
        exit
        vpls 64000 customer 1 create
            description "vpls64000"
            allow-ip-int-bind
            exit
            vxlan vni 119281 create
            exit
            bgp
                route-distinguisher 3:3
                vsi-export "vsi_export_64000"
                vsi-import "vsi_import_64000"
            exit
            bgp-evpn
                ip-route-advertisement
                vxlan
                    no shutdown
                exit
                mpls
                    shutdown
                exit
            exit
            stp
                shutdown
            exit
            service-name "vpls64000"
            vsd-domain "L3-service-1"
            no shutdown
        exit
        vprn 64001 customer 1 create
            autonomous-system 65000
            route-distinguisher 65000:1
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:65000:1
            interface "vpls-64000" create
                vpls "vpls64000"
                    evpn-tunnel
                exit
            exit
            interface "lo1" create
                address 1.1.1.1/32
                loopback
            exit
            vsd-domain "L3-service-1"
            no shutdown
        exit
----------------------------------------------
```

The EVPN tunnel NH-MAC addresses can now be learned in the Nuage VSP/VSG and sent via MP-BGP to the DC Gateway:

```
*A:pe-9# show service id 64000 fdb detail
Forwarding Database, Service 64000
===============================================================================
ServId    MAC               Source-Identifier        Type     Last Change
                                                     Age
-------------------------------------------------------------------------------
64000     00:00:27:00:00:5e vxlan:                   Evpn     07/22/15 13:38:47
                            39.0.0.94:119281
64000     1e:e2:ff:00:f9:3d cpm                      Intf     07/22/15 13:38:44
-------------------------------------------------------------------------------
```

The first MAC entry address is the tunnel NH-MAC for the VSG and the second is the address for the DC Gateway for EVPN-tunnel service 64000:

```
*A:pe-9# show router 64001 route-table
===============================================================================
1.1.1.1/32                                  Local   Local     00h09m08s  0
       lo1                                                       0
10.32.78.0/24                               Remote  BGP EVPN  00h09m05s  169
       vpls-64000 (ET-00:00:27:00:00:5e)                         0
10.32.78.100/32                             Remote  BGP EVPN  00h00m04s  169
       vpls-64000 (ET-00:00:27:00:00:5e)                         0
-------------------------------------------------------------------------------
```

The following commands are useful to obtain relevant information:

- **show service vsd domain "L3-service-1" association** to obtain svc-IDs
- **show service id <id> all** to obtain RT/RD/VNI values
- **show service id <id> vxlan** to obtain VTEPs in the VPLS service
- **show service vxlan <vtep-ip>** to obtain svc-id and VNI information

Relevant EVPN tunnel NH-MAC/VNI/RT/NH information is also in the EVPN BGP RIB:

```
*A:pe-9# show router bgp routes evpn mac detail

The VM or VSG-connected Host should be able to ping the loopback interface of the VPRN service:

```
*A:ce1# ping 1.1.1.1 source 10.32.78.100
PING 1.1.1.1 56 data bytes
64 bytes from 1.1.1.1: icmp_seq=1 ttl=64 time=1.67ms.
64 bytes from 1.1.1.1: icmp_seq=2 ttl=64 time=1.83ms.
```

Troubleshooting and debug commands

When testing/troubleshooting F-D XMPP provisioning, the following show/tools/debug commands can be useful:

- tools perform service vsd evaluate-script
- tools perform service vsd fd-domain-sync <full|diff>
- tools perform service vsd domain refresh-config
- tools perform python-script reload
- tools dump service vsd-services command-list
- debug python python-script
- debug vsd scripts event/instance
- debug system xmpp
- debug router bgp update
- show service vsd domain
- show service vsd script
- show service vsd summary
- show system vsd
- show xmpp vsd
- show python python-policy <name> {association}
- show python python-script <name> {association|source-in-use}
- show service vxlan [<vtep-ip>]
- show service service-using {<service-type>}
- show service id route-table
- show service id fdb detail
- show service id proxy-arp detail
- show router [<router-instance>] route-table
- show router [<router-instance>] arp
- show router bgp routes bgp <mac|ip-prefix|inclusive-mcast> {detail}

- log-id 99

Conclusion

The fully dynamic VSD integration model allows for automated provisioning of breakout services on the 7x50 DC Gateway. Different domain types (l2-domain/l2-domain-irb/vrf-vxlan/vrf-gre) are supported. This chapter has shown how to construct, load, and test python scripts for this feature. It also described how to configure WAN services on the VSD and how to verify the dynamically created services.

Inter-AS Model C for VLL

This chapter describes advanced inter-AS model C for Virtual Leased Line (VLL) configurations.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 8.0.R4. The CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports RFC 3107, *Carrying Label Information in BGP-4*, including VLL/VPLS. BGP SDPs can also be used with PBB-VPLS services.

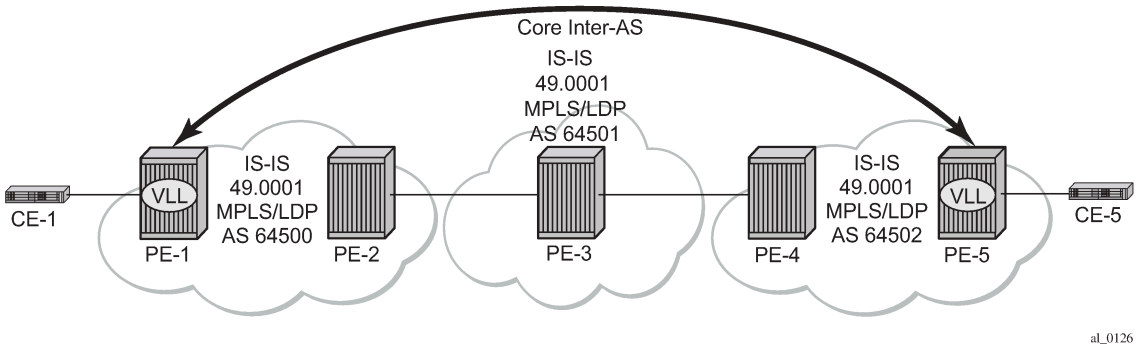
Internet service providers are looking for mechanisms to implement the VLL and VPLS services across Autonomous Systems (ASs). Service providers may have inter-AS operation as a consequence of delivering inter-provider VLL/VPLS or because they use multiple ASs as a result of acquisitions and mergers.

The objective of this chapter is to describe the interconnection of VLL services across multiple ASs, using inter-AS model C. Inter-AS Model C involves eBGP redistribution of internal system addresses to the neighboring AS using labeled IPv4 routes.

Example topology

Figure 176: Example topology – Inter-AS model C for VLL shows the example topology used for Inter-AS Model C VLL.

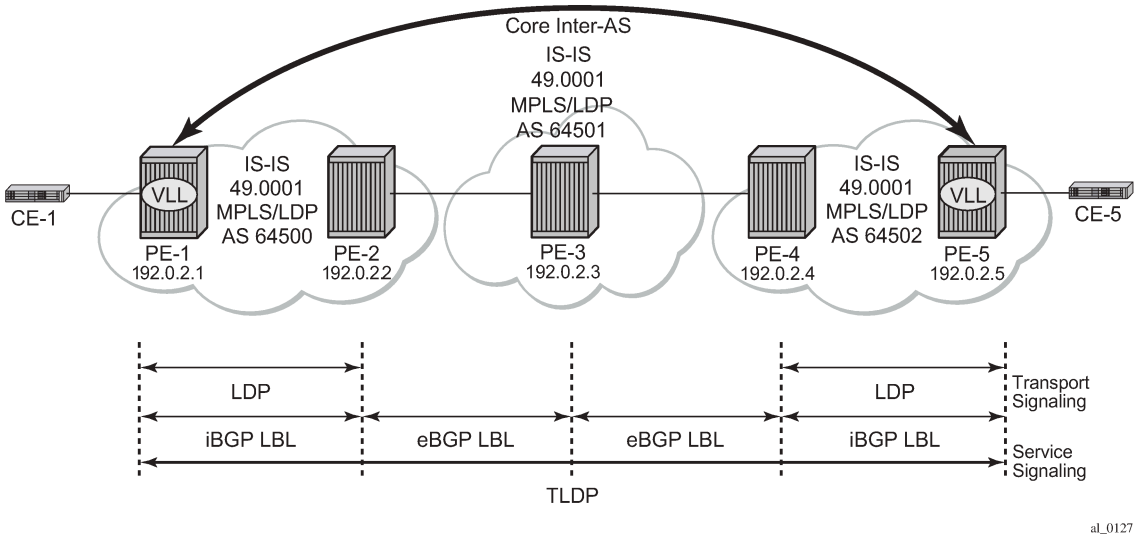
Figure 176: Example topology – Inter-AS model C for VLL



The example topology shown in Figure 176: Example topology – Inter-AS model C for VLL consists of three sites in different ASs with each site using SR OS nodes.

AS 64500 contains PE-1 and PE-2, AS 64501 contains PE-3, and AS 64502 contains PE-4 and PE-5. There is a business customer with two remote locations, Site A and Site B, with Customer Edge (CE) devices CE-1 connected to the AS 64500 via PE-1 and CE-5 connected to the AS 64502 via PE-5. A VLL Epipe service is configured between PE-1 and PE-5 to connect site A and site B.

Figure 177: Inter-AS model C for VLL

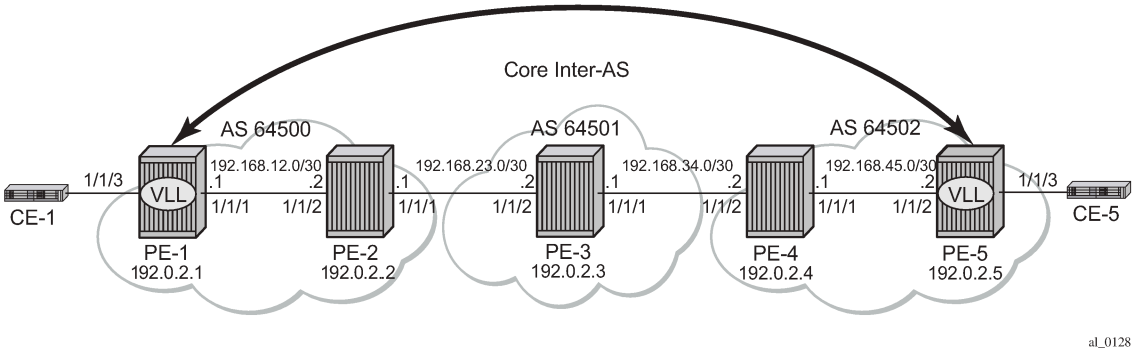


Configuration

This section describes all of the relevant configuration tasks for the detailed setup shown in Figure 178: Network setup configuration. In this particular example, the following protocols are assumed to be already configured.

- IS-IS as the IGP with all the nodes being level Level1/Level 2.
- LDP as the MPLS protocol to signal the transport tunnels within AS 64500 and AS 64502.

Figure 178: Network setup configuration



BGP configuration

A BGP tunnel must be established between PE-1 and PE-5, therefore, labeled BGP routes must be exchanged for prefixes 192.0.2.1/32 and 192.0.2.5/32 across the ASs. The following shows the BGP configuration — iBGP and eBGP — required for the PE routers to implement an Inter-AS VLL.

The BGP configuration on PE-3 in AS 64501 is as follows:

```
# on PE-3:
configure
    router Base
        autonomous-system 64501
        bgp
            rapid-withdrawal
            split-horizon
            group "EBGP"
                local-as 64501
                neighbor 192.168.23.1
                    family label-ipv4
                    peer-as 64500
                exit
                neighbor 192.168.34.2
                    family label-ipv4
                    peer-as 64502
                exit
            exit
        exit
```

The address family **label-ipv4** must be configured so that MPLS labels are carried along with MP-BGP Network Layer Reachability Information (NLRIs), see chapter *Separate BGP RIBs for Labeled Routes*. The setting **split-horizon** is optional and prevents that a received route is sent back to the originator, which might result in multiple routes for a certain prefix.

To export the prefixes of the nodes where the Epipe is configured (PE-1 and PE-5) to another AS, a common scenario is to advertise the prefix to be exported within the AS as labeled BGP. Therefore, an export policy is defined for prefix192.0.2.1/32 on PE-1 and this prefix will be advertised to the ASBR in AS 64500, in this case to PE-2.

On PE-2, the labeled BGP route for prefix 192.0.2.1/32 is inactive, because the IGP route for that prefix is preferred. No export policy needs to be configured in the Autonomous System Border Router (ASBR) PE-2

for the EBGP session with PE-3 in AS 64501. Rather, the setting **advertise-inactive** will allow the inactive labeled BGP routes from AS 64500 to be advertised to PE-3 in AS 64501.

Likewise, an export policy will be configured on PE-5 to advertise prefix 192.0.2.5/32 to ASBR PE-4 in AS 64502. On PE-4, BGP is configured with **advertise-inactive** to advertise the labeled BGP route to its EBGP peer, PE-3.

The advantage of this approach is that labeled BGP is used end-to-end between PE-1 and PE-5 and no IGP routes are to be redistributed into BGP, which would be the case if no local BGP labeled routes were advertised within AS 64500 or AS 64502 and only IGP routes were defined within these ASs.

The ASBRs PE-2, PE-3, and PE-4 will swap the BGP labels. PE-3 will advertise the labeled BGP routes learned from AS 64500 to AS 64502 and vice versa and the ASBRs will advertise these labeled routes for remote PE prefixes to their BGP peers. Eventually, PE-1 will have learned a labeled BGP route for prefix 192.0.2.5/32 and PE-5 will have learned a labeled BGP route for prefix 192.0.2.1/32 and a VLL Epipe can be established between PE-1 and PE-5.

The BGP configuration of ASBR PE-2 in AS 64500 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            group "EBGP"
                local-as 64500
                neighbor 192.168.23.2
                    family label-ipv4
                    peer-as 64501
                    advertise-inactive
                exit
            exit
            group "IBGP"
                neighbor 192.0.2.1
                    family label-ipv4
                    next-hop-self
                    peer-as 64500
                exit
            exit
        exit
```

The BGP configuration of ASBR PE-4 in AS 64502 is as follows:

```
# on PE-4:
configure
    router Base
         autonomous-system 64502
         bgp
            rapid-withdrawal
            split-horizon
            group "EBGP"
                local-as 64502
                neighbor 192.168.34.1
                    family label-ipv4
                    peer-as 64501
                    advertise-inactive
                exit
            exit
            group "IBGP"
                neighbor 192.0.2.5
```

```
                    family label-ipv4
                    next-hop-self
                    peer-as 64502
                exit
            exit
        exit
```

PE-1 and PE-5 are the PEs to which the CEs are connected in AS 64500 and AS 64502. PE-1 and PE-5 advertise their system prefixes as labeled BGP routes to their BGP peers within the AS.

The BGP configuration of PE-1 is as follows:

```
# on PE-1:
configure
    router Base
         autonomous-system 64500
         bgp
            rapid-withdrawal
            split-horizon
            group "IBGP"
                export "export-PE-1"
                neighbor 192.0.2.2
                    family label-ipv4
                    next-hop-self
                    peer-as 64500
                exit
            exit
        exit
```

The BGP configuration of PE-5 in AS 64502 is as follows:

```
# on PE-5:
configure
    router Base
         autonomous-system 64502
         bgp
            rapid-withdrawal
            split-horizon
            group "IBGP"
                export "export-PEsys"
                neighbor 192.0.2.4
                    family label-ipv4
                    next-hop-self
                    peer-as 64502
                exit
            exit
        exit
```

Policy configuration

The export policies on PE-1 and PE-5 advertise the system addresses to the remote AS.

The export policy on PE-1 has a prefix list that only contains prefix 192.0.2.1/32 as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            prefix-list "PE-1"
```

```
                prefix 192.0.2.1/32 exact
            exit
            policy-statement "export-PE-1"
                entry 10
                    from
                        prefix-list "PE-1"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

A similar export policy can be configured for prefix 192.0.2.5/32 on PE-5. However, the export policy on PE-5 is slightly different: the policy has a prefix list that can be applied for prefixes on multiple PEs, but in this case, only prefix 192.0.2.5/32 will be exported:

```
# on PE-5:
configure
    router Base
        policy-options
            begin
            prefix-list "PEsys"
                prefix 192.0.2.0/29 longer
            exit
            policy-statement "export-PEsys"
                entry 10
                    from
                        protocol direct
                        prefix-list "PEsys"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The same policy could have been applied on PE-1.

Service configuration

Once BGP is configured, the configuration requires the service to be defined (Epipe 1). The focus here is a VLL service, however, it is also possible to have a similar configuration with VPLS services.

The following shows the service level configuration on PE-1:

```
# on PE-1:
configure
     service
        sdp 15 mpls create
            far-end 192.0.2.5
            bgp-tunnel
            no shutdown
        exit
        epipe 1 name "Epipe 1" customer 1 create
            description "Tunnel-PE-1-PE-5"
            sap 1/1/3:1 create
            exit
            spoke-sdp 15:1 create
            exit
```

```
            no shutdown
        exit
```

The following CLI shows the service level configuration on PE-5:

```
# on PE-5:
configure
    service
        sdp 51 mpls create
            far-end 192.0.2.1
            bgp-tunnel
            no shutdown
        exit
        epipe 1 name "Epipe 1" customer 1 create
            description "Tunnel-PE-5-PE-1"
            sap 1/1/3:1 create
            exit
            spoke-sdp 51:1 create
            exit
            no shutdown
        exit
```

Show commands and troubleshooting

On PE-5, BGP tunnels exist to the remote AS system addresses that are using LDP as a transport mechanism and the configuration of end-to-end SDPs over which T-LDP service labels are exchanged.

In the following sections, the same commands are launched on the nodes in the following order: first on PE-1 and PE-5; then on PE-3, and finally, on PE-2 and PE-4.

Show commands and troubleshooting on PE-1

The following shows information about SDP 15 on PE-1:

```
*A:PE-1# show service sdp

===============================================================================
Services: Service Destination Points

Conclusion

The BGP tunnel-based SDP binding is allowed for VLL and VPLS services, including PBB-VPLS. Using RFC 3107, it is possible to implement inter-AS Model C VLLs.

The example used in this chapter illustrates the configuration of an Inter-AS VLL providing access to CE sites. Troubleshooting commands also have been shown to verify all the procedures.

L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing

This chapter provides information about L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 23.7.R1.

Overview

IPv4 multicast traffic can be forwarded from an EVPN-MPLS service into an attached R-VPLS service in which the receiving devices are using EVPN all-active multi-homing.

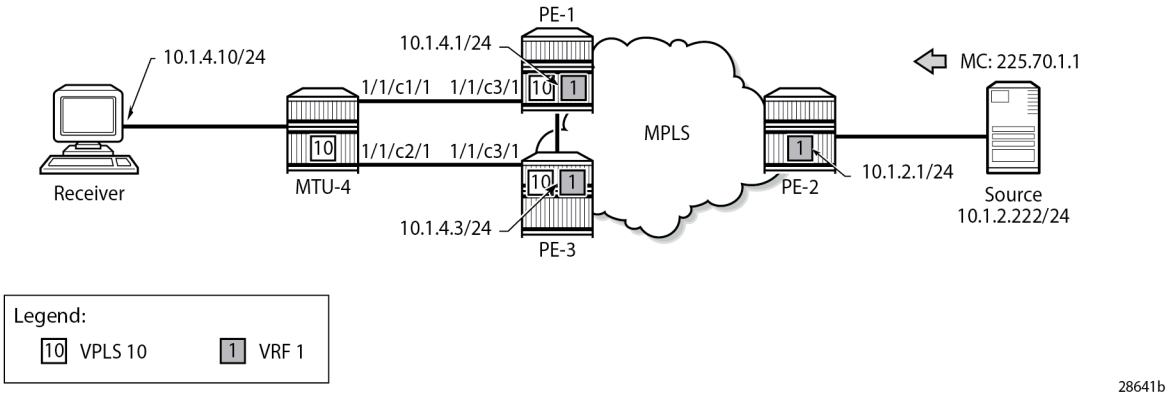
The routed service to which the R-VPLS service attaches can be an IES or a VPRN service. In this way, IPv4 multicast traffic can be transported using native IP for the IES case or NG-MVPN technologies for the VPRN case.

This feature requires:

- IGMP support on the R-VPLS IP interface
- Forwarding IPv4 multicast traffic from the IP interface of a VPRN or IES to its EVPN-MPLS R-VPLS service
- IGMP snooping within the VPLS of the R-VPLS service
- IGMP snooping state synchronization based on the ESI label to synchronize the IGMP snooping state between the all-active (R-)VPLS LAG SAPs

The configuration used in this chapter is the NG-MVPN scenario as shown in Figure 179: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing.

Figure 179: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing



A multicast stream is emitted by the source connected to PE-2 with group address 225.70.1.1. A multicast receiver connected to MTU-4 joins group 225.70.1.1. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. On MTU-4, LAG 1 comprises port 1/1/c1/1 and 1/1/c2/1, and this LAG is used in VPLS 10. On PE-1 and PE-3, VPLS 10 is interconnected with VPRN 1 through an Integrated Routing and Bridging (IRB) interface. VPRN 1 is defined in PE-1, PE-2, and PE-3, and uses NG-MVPN for transporting the multicast traffic through the core of the network. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information about EVPN. See the NG-MVPN Configuration with MPLS and the NG-MVPN Configuration with PIM chapters for more information about NG-MVPN.

Configuration

The initial configuration on the PE nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- MPLS tunnels between the PEs: LDP- or RSVP-based

BGP is required at the core of the network, using the VPN IPv4 and MVPN IPv4 address families between all PEs, for supporting unicast and multicast traffic on VPRN services, and additionally using the EVPN address family between PE-1 and PE-3 to support EVPN services. The BGP configurations for PE-1, PE-2, and PE-3 are as follows:

```
# on PE-1:
configure
    router
        autonomous-system 64496
        bgp
            family vpn-ipv4 mvpn-ipv4 evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "iBGP"
                neighbor 192.0.2.2
```

```
                    peer-as 64496
                exit
                neighbor 192.0.2.3
                    peer-as 64496
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
# on PE-2:
configure
    router
        autonomous-system 64496
        bgp
            family vpn-ipv4 mvpn-ipv4
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "iBGP"
                neighbor 192.0.2.1
                    peer-as 64496
                exit
                neighbor 192.0.2.3
                    peer-as 64496
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
# on PE-3:
configure
    router
        autonomous-system 64496
        bgp
            family vpn-ipv4 mvpn-ipv4 evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "iBGP"
                neighbor 192.0.2.1
                    peer-as 64496
                exit
                neighbor 192.0.2.2
                    peer-as 64496
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The receiver connected to MTU-4 joins group 225.70.1.1, and the corresponding multicast stream is emitted by the source that is connected to PE-2. MTU-4 is connected to PE-1 and PE-3 through an all-

active multi-homing EVPN Ethernet segment comprising LAG 1. The VPLS and the LAG on MTU-4 are defined as follows:

```
# on MTU-4:
configure
    service
        vpls 10 name "mcast-vpls" customer 1 create
            stp
                shutdown
            exit
            sap 1/2/c1/1 create
                no shutdown
            exit
            sap lag-1:10 create
                no shutdown
            exit
            igmp-snooping
                no shutdown

```

The all-active multi-homing Ethernet segment esi-13 is configured identically on PE-1 and PE-3, as follows. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information.

```
# on PE-1 and PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "esi-13" create
                    esi 01:00:00:00:00:13:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 30
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

The multi-homed access circuits of esi-13 are located on port 1/1/c3/1 for PE-1 and PE-3, so the LAG is configured identically, as follows:

```
# on PE-1 and PE-3:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/c3/1
        no shutdown
    exit
exit
```

Also, the EVPN VPLS service with ID 10 is configured identically on PE-1 and PE-3, as follows. The *mcast-vpls* name is needed to link VPLS 10 to VPRN 1 at a later stage, without requiring a physical loop or hairpin. The **allow-ip-int-bind** command enables the VPLS to become an R-VPLS. The **igmp-snooping** and **mrouter-port** commands are required for multicast to work correctly in an all-active multi-homed scenario.

```
# on PE-1 and PE-3:
configure
    service
        vpls 10 name "mcast-vpls" customer 1 create
            allow-ip-int-bind
                igmp-snooping
                    mrouter-port
                exit
            exit
            bgp
            exit
            bgp-evpn
                evi 111
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            igmp-snooping
                no shutdown
            exit
            sap lag-1:10 create
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

The VPRN service with ID 1 provides the connection toward MTU-4 via VPLS 10, through the *int-MCAST-VPLS* interface with address 10.1.4.1/24 on PE-1, and with address 10.1.4.3/24 on PE-3. This L3 interface is linked to VPLS 10 with the **vpls "mcast-vpls"** command. The *int-MCAST-VPLS* interface is also included in the IGMP and PIM configurations of VPRN 1. The full configuration of VPRN 1 on PE-1 is as follows. The configuration of VPRN 1 on PE-3 is similar.

```
# on PE-1:
configure
    service
```

```
        vprn 1 name "VPRN 1" customer 1 create
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:1
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            interface "int-MCAST-VPLS" create
                address 10.1.4.1/24
                vpls "mcast-vpls"
                exit
            exit
            interface "int-PE-1-CE-1" create
                address 10.1.1.1/24
                sap 1/2/c1/1 create
                exit
            exit
            interface "system" create
                address 192.0.2.101/32
                loopback
            exit
            igmp
                ssm-translate
                    grp-range 225.70.1.1 225.70.255.255
                        source 10.1.2.222
                    exit
                exit
                interface "int-MCAST-VPLS"
                    no shutdown
                exit

```

A stream with group address 225.70.1.1 is started by the multicast source and joined by the multicast receiver connected to MTU-4. This stream is forwarded from PE-2 to PE-3; PE-1 is not involved in the forwarding.

PE-1 maintains IGMP state for group 225.70.1.1 in VPRN 1, and so does PE-3. PE-1 and PE-3 synchronize IGMP state using a data-driven mechanism. The forwarding list includes the *int-MCAST-VPLS* interface, as follows:

```
*A:PE-1# show router 1 igmp group 225.70.1.1 interfaces
===============================================================================
IGMP Interface Groups
===============================================================================

(*,225.70.1.1)                                          UpTime: 0d 00:01:56
    Fwd List  : int-MCAST-VPLS
-------------------------------------------------------------------------------
Entries : 1
===============================================================================
```

PE-1 maintains PIM state for group 225.70.1.1, as follows. The outgoing interfaces list is empty and the forwarding rate is zero; both are indications that PE-1 is not forwarding any multicast traffic.

```
*A:PE-1# show router 1 pim group 225.70.1.1 detail

```

PE-3 sends this multicast stream to MTU-4, which in turn sends it to the receiver that sent the join, so the path taken by the multicast stream runs via PE-2, PE-3, and MTU-4.

In the example from Figure 179: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing, and the commands and traces that follow, PE-1 is the active IGMP querier using address 10.1.4.1, sending out the queries across the L2 domain. The group queries are sent by PE-1 to PE-3 across the EVPN-MPLS tunnel because PE-3 is DF for *esi-13*, then forwarded onto MTU-4 to reach the (potential) receiver. MTU-4 relays the IGMP responses from the receiver to one of the links; in this example, the link between MTU-4 and PE-1. When the IGMP response for joining the 225.1.70.1 stream is received on PE-1, this event is signaled across the EVPN-MPLS tunnel because it is received over esi-13. This way, the IGMP state is synchronized between PE-3 and PE-1 in a data-driven way.

The basic IGMP snooping state for VPLS 10 on PE-1 and PE-3 is as follows. The output shows that IGMP snooping is enabled on ports sap:lag-1:10, rvpls, and evpn-mpls.

```
*A:PE-1# show service id 10 igmp-snooping base

PE-1 sends the IGMP queries on VPRN 1 via the *int-MCAST-VPLS* interface, so the VPLS that is referenced in the *int-MCAST-VPLS* interface registers the ports on which the IGMP queries are received as

multicast router ports. EVPN-MPLS tunnels are always multicast router ports. The following output displays the source addresses of the multicast routers:

```
*A:PE-1# show service id 10 igmp-snooping mrouters

===============================================================================

Debug

Debugging is useful for troubleshooting purposes, and the debug configuration used on PE-1 and PE-3 for checking IGMP and IGMP snooping functionalities is as follows:

```
debug
    router "1"
        igmp
```

```
            packet mode egr-ingr-and-dropped
        exit
    exit
    service
        id 10
            igmp-snooping
                mode egr-ingr-and-dropped
                detail-level high
                sap lag-1:10
                evpn-mpls
            exit
        exit
    exit
exit
```

When group 225.70.1.1 is joined, the trace on PE-1 is as follows. Event 7 is the IGMPv3 join message for group 225.70.1.1 received on SAP lag-1:10 in VPLS 10 from the receiver. The reception of this message is synchronized across the EVPN-MPLS tunnel for VPLS 10, as indicated by event 8. Event 10 is the IGMPv3 join message as received on interface *int-MCAST-VPLS* by VPRN 1.

```

Similar events are logged when the multicast receiver leaves the 225.70.1.1 group.

Conclusion

By connecting customers to EVPN-MPLS VPRN/IES routed services via an R-VPLS, service providers can offer IPv4 multicast services to customers in an all-active multi-homing scenario.

L2 Services with Auto-GRE Spoke-SDPs

This chapter provides information about L2 Services with Auto-GRE Spoke-SDPs.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R4, but the CLI in the current edition is based on SR OS Release 21.5.R1. Auto-GRE spoke-SDPs are supported in BGP-VPLS, BGP-AD, BGP-VPWS, and with FEC 129 spoke-SDPs in SR OS Release 16.0.R1, and later.

Overview

When the connectivity between nodes is IP-based (not MPLS), VPWS and VPLS services can use manually provisioned or auto-generated GRE transport tunnels. For auto-GRE transport tunnels, the signaling can be BGP or Targeted LDP (T-LDP). BGP signaling is more scalable than T-LDP, because T-LDP requires point-to-point sessions between communicating peers.

Auto-GRE spoke-SDPs can be used in the following services:

- BGP-VPLS with BGP signaling
- LDP VPLS using BGP-AD with T-LDP signaling
- BGP-VPWS with BGP signaling
- Dynamic Multi-segment Pseudowire (MS-PW) spoke-SDP Forwarding Equivalence Class (FEC) 129 with T-LDP signaling

PW templates for auto-GRE spoke-SDPs are configured with the creation-time parameter **auto-gre-sdp**. The **auto-gre-sdp** parameter can be combined with the creation-time parameter **prefer-provisioned-sdp**, but not with **use-provisioned-sdp** (because that might contradict the use of auto-GRE spoke-SDPs), as follows:

```
*A:PE-1>config>service# pw-template 3 name "PW3" ?
  - pw-template <policy-id> [create] [prefer-provisioned-sdp] [name <name>]
    [auto-gre-sdp]
  - no pw-template <policy-id>
  - pw-template <policy-id> use-provisioned-sdp [create] [name <name>]
---snip---
```

The auto-GRE SDP and SDP binding are created after a matching BGP route has been received. Subsequent requests for an auto-GRE SDP of the same type and to the same destination as an existing auto-GRE SDP will use the existing auto-GRE SDP.

Downstream fragmentation is allowed for auto-GRE SDPs by clearing the Don't Fragment (DF) bit in the GRE IP header. The following command controls fragmentation for a PW template:

```
configure
    service
        pw-template 40 name "PW40" auto-gre-sdp create
            allow-fragmentation
        exit
```

The following PW template parameters are not supported with GRE tunnels and will be ignored when a GRE SDP is auto-created:

- Hash label
- Entropy label
- SDP include/exclude (there is no mechanism to configure an SDP admin group for auto-GRE SDPs)

However, these parameters are relevant for provisioned MPLS SDPs when the PW template is configured with **prefer-provisioned-sdp**.

The **pw-template-binding** parameter in the **bgp** context of the L2 service allows to configure the PW template to be used. It is possible to define multiple PW template bindings within a service. The mechanism for selecting the PW template is as follows:

- In BGP-VPWS, BGP-VPLS, and BGP-AD services, the PW template binding selection is based on matching the configured import Route Targets (RTs) for a PW template binding with the RTs in the received routes.
- The binding with the first matching RT is chosen. If no import RTs are configured, the lowest PW template binding ID is used.
- It is not possible to add RTs to BGP-VPWS BGP updates using import or export policies, because they are ignored. However, the RT exported to select the destination service can be used on the receiving PE with PW template binding statement to influence the PW template to be selected; see the first use case in the Configuration section.
- If the selected PW template is configured with **prefer-provisioned-sdp** and an SDP with a matching far-end address exists, the system chooses the SDP with the lowest metric from the tunnel table. If multiple matching SDPs with the same metric occur, the highest SDP ID that is operationally up is chosen.

The following **tools** command allows for PW template bindings to change:

```
*A:PE-1# tools perform service id 1 eval-pw-template ?
  - eval-pw-template <policy-id> [allow-service-impact]

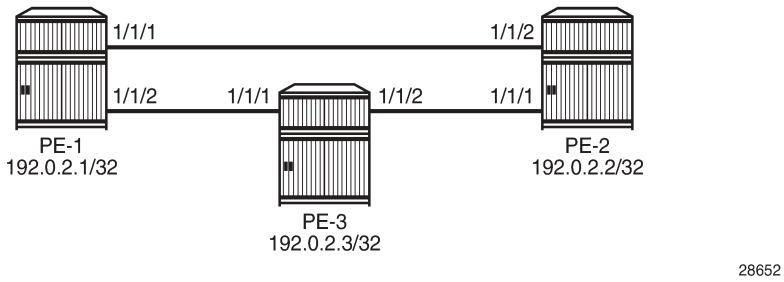
 <policy-id>          : [1..2147483647]
 <allow-service-imp*> : keyword
```

The policy ID refers to the PW template currently in use. With the **allow-service-impact** option, the current binding will be torn down and re-signaled.

Configuration

Figure 180: Example topology shows the example topology with three PEs in AS 64500. Services will be configured on PE-1 and PE-2, and PE-3 is the route reflector (RR).

Figure 180: Example topology



The initial configuration on the three PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)

Auto-GRE spoke-SDPs are configured in the following use cases:

1. BGP-VPLS with BGP signaling
2. BGP-AD in VPLS with T-LDP signaling
3. BGP-VPWS with BGP signaling
4. Dynamic MS-PW spoke-SDP FEC 129 with T-LDP signaling

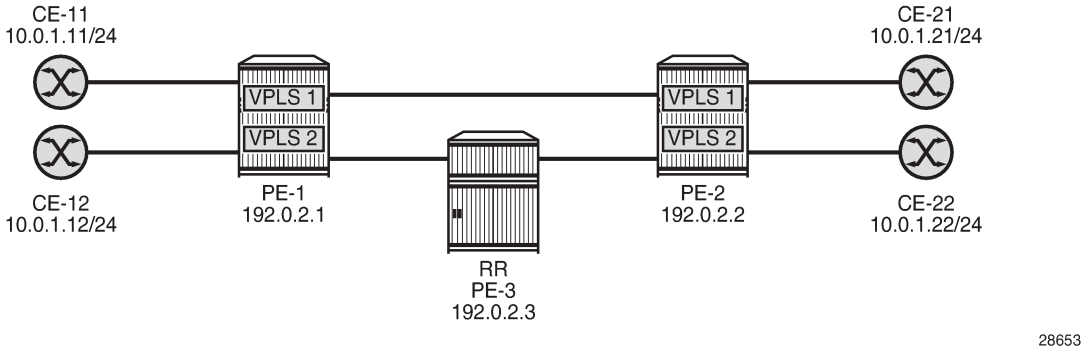
In the first three use cases (BGP-VPLS, BGP-AD, BGP-VPWS), BGP is configured for the L2-VPN address family; in the last use case (dynamic MS-PW), BGP is configured for the MS-PW address family.

In each of the use cases, two L2 services will be configured using different PW templates with **auto-gre-sdp**: one with **prefer-provisioned-sdp** and one without.

Auto-GRE spoke-SDPs in BGP-VPLS

Figure 181: BGP-VPLS with auto-GRE spoke-SDPs shows the example topology with BGP-VPLSs 1 and 2 configured on PE-1 and PE-2. BGP is configured for the L2-VPN address family with PE-3 as Route Reflector (RR). The CEs are emulated through VPRNs configured on the PEs and connected to the VPLSs via Port Cross-connect (PXC).

Figure 181: BGP-VPLS with auto-GRE spoke-SDPs



BGP configuration

For the BGP-VPLS, BGP-AD, and BGP-VPWS use cases, BGP is configured with the L2-VPN address family. The BGP configuration on PE-1 and PE-2 is identical, as follows:

```
# on PE-1, PE-2::
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            group "WAN"
                family l2-vpn
                type internal
                neighbor 192.0.2.3
                exit
            exit
```

On RR PE-3, BGP is configured as follows:

```
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            group "WAN"
                family l2-vpn
                cluster 192.0.2.3
                type internal
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
            exit
```

Service configuration

The configuration of BGP-VPLS services is described in the BGP VPLS chapter.

PW template 10 is configured with **auto-gre-sdp**; PW template 20 is configured with **prefer-provisioned-sdp** and **auto-gre-sdp**. Because only IP connectivity is present between the nodes (no MPLS), the provisioned SDP is GRE-based using BGP signaling (no T-LDP). VPLS 1 has PW template bindings with IDs 10 and 20; VPLS 2 is configured with PW template binding 20. The service configuration on PE-1 is as follows:

```
# on PE-1:
configure
    service
        sdp 12 create
            signaling bgp
            far-end 192.0.2.2
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        pw-template 10 name "PW10-auto-GRE" auto-gre-sdp create
        exit
        pw-template 20 name "PW20-auto-GRE_prefer-prov" prefer-provisioned-sdp
            auto-gre-sdp create
        exit
        vpls 1 name "BGP-VPLS-1" customer 1 create
            description "BGP-VPLS with auto-GRE spoke-SDP"
            bgp
                route-distinguisher 64500:1
                route-target export target:64500:1 import target:64500:1
                pw-template-binding 10
                exit
                pw-template-binding 20
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:1 create                # SAP to connect to CE-11
                no shutdown
            exit
            no shutdown
        exit
        vpls 2 name "BGP-VPLS-2" customer 1 create
            description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
            bgp
                route-distinguisher 64500:2
                route-target export target:64500:2 import target:64500:2
                pw-template-binding 20
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-1"
                    ve-id 1
```

```
                exit
                no shutdown
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:2 create               # SAP to connect to CE-12
                no shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-2 is similar, but the VE name is "PE-2" and the VE ID equals 2 instead, as follows:

```
# on PE-2:
configure
    service
        sdp 21 create
            signaling bgp
            far-end 192.0.2.1
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        pw-template 10 name "PW10-auto-GRE" auto-gre-sdp create
        exit
        pw-template 20 name "PW20-auto-GRE_prefer-prov" prefer-provisioned-sdp
            auto-gre-sdp create
        exit
        vpls 1 name "BGP-VPLS-1" customer 1 create
            description "BGP-VPLS with auto-GRE spoke-SDP"
            bgp
                route-distinguisher 64500:1
                route-target export target:64500:1 import target:64500:1
                pw-template-binding 10
                exit
                pw-template-binding 20
                exit
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:1 create               # SAP to connect to CE-21
                no shutdown
            exit
            no shutdown
        exit
        vpls 2 name "BGP-VPLS-2" customer 1 create
            description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
            bgp
                route-distinguisher 64500:2
                route-target export target:64500:2 import target:64500:2
                pw-template-binding 20
                exit
```

```
            exit
            bgp-vpls
                max-ve-id 100
                ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            stp
                shutdown
            exit
            sap pxc-10.a:2 create               # SAP to connect to CE-22
                no shutdown
            exit
            no shutdown
        exit
```

The following L2-VPN routes are received on PE-1: one for VPLS 1 with RD 64500:1 and another for VPLS 2 with RD 64500:2.

```
*A:PE-1# show router bgp routes l2-vpn
===============================================================================

-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

VPLS 1 is configured with two PW template bindings without import RT. Because the PW template binding with the lowest ID is preferred, PW template 10 is used and therefore, the following GRE SDP 32767 is auto-created:

```
*A:PE-1# show service id 1 sdp detail

===============================================================================
Services: Service Destination Points Details
===============================================================================
-------------------------------------------------------------------------------
 Sdp Id 32767:4294967295  -(192.0.2.2)
-------------------------------------------------------------------------------
```

```
Description     : (Not Specified)

```

VPLS 2 is configured with PW template binding 20, which prefers provisioned SDPs, so the provisioned SDP 12 is used, as follows:

```
*A:PE-1# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967294    BgpVpls  192.0.2.2       Up      Up        524273    524272
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

In VPLS 1, the PW template binding selection can be changed by configuring a non-matching import RT to PW template 10, as follows:

```
# on PE-1:
configure
    service
        vpls "BGP-VPLS-1"
            bgp
                pw-template-binding 10 import-rt "target:64500:999"
                exit
            exit
```

This does not change the selected PW template during service operation and PW template 10 remains in use, as follows:

```
*A:PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 10
```

The following **tools** command forces the system to re-evaluate the PW template binding:

```
*A:PE-1# tools perform service id 1 eval-pw-template 10 allow-service-impact
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 10
```

When the PW template binding is re-evaluated, PW template binding 20 is selected and the provisioned SDP 12 is used, as follows:

```
*A:PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 20
```

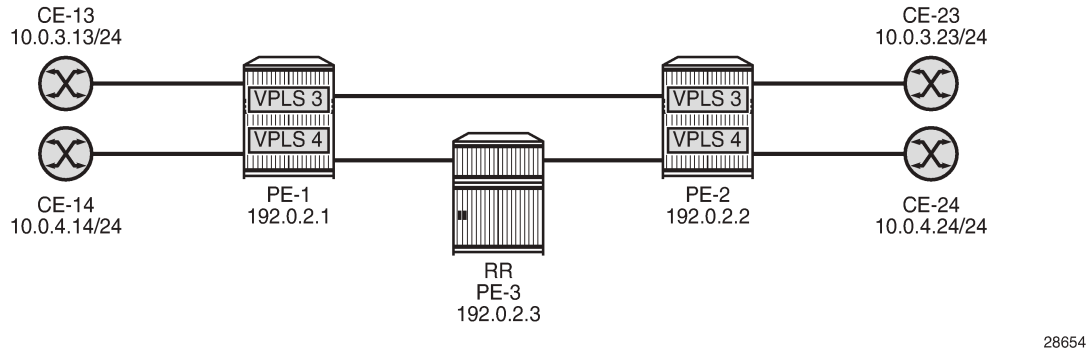
```
*A:PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967293    BgpVpls  192.0.2.2       Up      Up        524281    524280
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

Auto-GRE spoke-SDPs in LDP-VPLS using BGP-AD

Figure 182: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs shows the example topology with VPLSs 3 and 4 configured with BGP-AD on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

Figure 182: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs



The following T-LDP session is configured between PE-1 and PE-2:

```
# on PE-1:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.2.2
                    no shutdown
                exit
            exit
```

```
# on PE-2:
configure
    router Base
```

```
        ldp
            targeted-session
                peer 192.0.2.1
                    no shutdown
                exit
            exit
```

The following T-LDP signaled SDP is configured on PE-1 and PE-2:

```
# on PE-1:
configure
    service
        sdp 120 create
            far-end 192.0.2.2
            keep-alive
                shutdown
            exit
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        sdp 120 create
            far-end 192.0.2.1
            keep-alive
                shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-1 and PE-2 is as follows; see chapter LDP VPLS Using BGP Auto-Discovery for a description of BGP-AD in LDP VPLS. PW templates 10 and 20 are the same as in the preceding example.

```
# on PE-1, PE-2:
configure
    service
        pw-template 10 name "PW10-auto-GRE" auto-gre-sdp create
        exit
        pw-template 20 name "PW20-auto-GRE_prefer-prov" prefer-provisioned-sdp
                                                                auto-gre-sdp create
        exit
        vpls 3 name "BGP-AD VPLS-3" customer 1 create
            description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP"
            bgp
                route-distinguisher 64500:3
                route-target export target:64500:3 import target:64500:3
                pw-template-binding 10
                exit
                pw-template-binding 20
                exit
            exit
            bgp-ad
                vpls-id 64500:3
                no shutdown
            exit
            stp
                shutdown
            exit
```

```
            sap pxc-10.a:3 create                # SAP to connect to CE-13 (PE-1) or CE-23 (PE-
2)
                no shutdown
            exit
            no shutdown
        exit
        vpls 4 name "BGP-AD VPLS-4" customer 1 create
            description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP pref-prov-SDP"
            bgp
                route-distinguisher 64500:4
                route-target export target:64500:4 import target:64500:4
                pw-template-binding 20
                exit
            exit
            bgp-ad
                vpls-id 64500:4

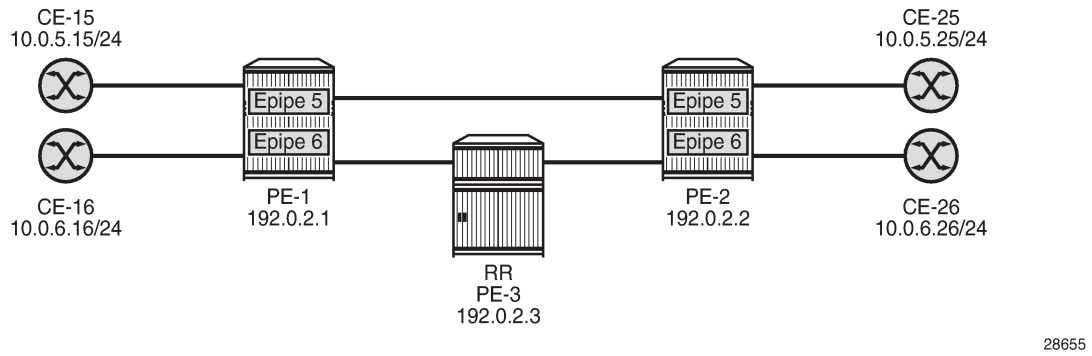
Auto-GRE spoke-SDPs in BGP-VPWS

Figure 183: BGP-VPWS with auto-GRE spoke-SDPs shows the example topology with BGP-VPWS Epipes 5 and 6 on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

Figure 183: BGP-VPWS with auto-GRE spoke-SDPs



Chapter BGP Virtual Private Wire Services describes the configuration of BGP VPWS. The configuration of Epipes 5 and 6 on PE-1 is as follows:

```
# on PE-1:
configure
    service
        pw-template 10 name "PW10-auto-GRE" auto-gre-sdp create
        exit
        pw-template 20 name "PW20-auto-GRE_prefer-prov" prefer-provisioned-sdp
                                                              auto-gre-sdp create
        exit
        epipe 5 name "BGP-VPWS-5" customer 1 create
            description "BGP-VPWS with auto-GRE spoke-SDP"
            bgp
                route-distinguisher 64500:5
                route-target export target:64500:5 import target:64500:5
                pw-template-binding 10
                exit
                pw-template-binding 20
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
```

```
            sap pxc-10.a:5 create                # SAP to connect to CE-15
                no shutdown
            exit
            no shutdown
        exit
        epipe 6 name "BGP-VPWS-6" customer 1 create
            description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
            bgp
                route-distinguisher 64500:6
                route-target export target:64500:6 import target:64500:6
                pw-template-binding 20
                exit
            exit
            bgp-vpws
                ve-name "PE-1"
                    ve-id 1
                exit
                remote-ve-name "PE-2"
                    ve-id 2
                exit
                no shutdown
            exit
            sap pxc-10.a:6 create                # SAP to connect to CE-16
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of the Epipes is similar on PE-2, but the VE names and VE IDs are different, as follows:

```
# on PE-2:
configure
    service
        epipe 5 name "BGP-VPWS-5" customer 1 create
            description "BGP-VPWS with auto-GRE spoke-SDP"
            bgp
                route-distinguisher 64500:5
                route-target export target:64500:5 import target:64500:5
                pw-template-binding 10
                exit
                pw-template-binding 20
                exit
            exit
            bgp-vpws
                ve-name "PE-2"
                    ve-id 2
                exit
                remote-ve-name "PE-1"
                    ve-id 1
                exit
                no shutdown
            exit
            sap pxc-10.a:5 create                # SAP to connect to CE-25
                no shutdown
            exit
            no shutdown
        exit
        epipe 6 name "BGP-VPWS-6" customer 1 create
            description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
            bgp
                route-distinguisher 64500:6
                route-target export target:64500:6 import target:64500:6
                pw-template-binding 20
```

```
            exit
        exit
        bgp-vpws
            ve-name "PE-2"
                ve-id 2
            exit
            remote-ve-name "PE-1"
                ve-id 1
            exit
            no shutdown
        exit
        sap pxc-10.a:6 create               # SAP to connect to CE-26
            no shutdown
        exit
        no shutdown
    exit
```

PE-1 receives the following BGP-VPWS routes from PE-2:

```
*A:PE-1# show router bgp routes l2-vpn bgp-vpws

```

Auto-GRE spoke-SDPs in dynamic MS-PW spoke-SDP FEC

Chapter Multi-Segment Pseudowire Routing describes the configuration for dynamic MS-PW spoke-SDP FEC.

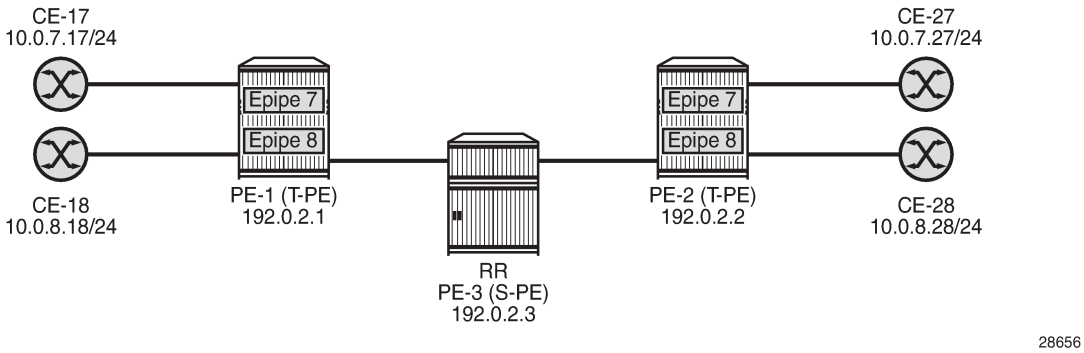
Figure 184: Dynamic MS-PW spoke-SDP FEC with auto-GRE spoke-SDPs shows the example topology with PE-1 and PE-2 as Terminating PEs (T-PEs) and PE-3 as Switching PE (S-PE). Port 1/1/1 on PE-1 (toward PE-2) and port 1/1/2 on PE-2 (toward PE-1) are disabled, as follows:

```
# on PE-1:
configure
    port 1/1/1
        shutdown
```

```
# on PE-2:
configure
    port 1/1/2
        shutdown
```

BGP-VPWS Epipes 7 and 8 are configured on PE-1 and PE-2.

Figure 184: Dynamic MS-PW spoke-SDP FEC with auto-GRE spoke-SDPs



T-LDP is configured between PE-1 and PE-3 and between PE-2 and PE-3, as follows:

```
# on PE-1, PE-2:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.2.3
                    no shutdown
```

```
# on PE-3:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.2.1
                    no shutdown
                exit
                peer 192.0.2.2
                    no shutdown
                exit
```

BGP configuration

BGP is configured for the MS-PW address family. On the T-PEs, an export policy is required to export MS-PW routes; in this case, a default policy matching all the MS-PW routes is configured. The configuration on PE-1 and PE-2 is as follows:

```
# on PE-1, PE-2:
configure
    router Base
        policy-options
            begin
            policy-statement "export ms-pw"
                entry 10
                    from
                        family ms-pw
                    exit
                    action accept
                        origin igp
                    exit
                exit
            exit
            commit
        exit
        bgp
            rapid-withdrawal
            group "WAN"
                family ms-pw
                type internal
                neighbor 192.0.2.3
                    export "export ms-pw"
                exit
            exit
        exit
```

S-PE (and RR) PE-3 is configured for the MS-PW address family and has next-hop-self enabled, as follows:

```
# on PE-3:
configure
    router Base
        bgp
            rapid-withdrawal
            split-horizon
            group "WAN"
                family ms-pw
                next-hop-self
                type internal
                cluster 192.0.2.3
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
            exit
        exit
```

Service configuration

Each T-PE and S-PE is configured with an SPE address. On S-PE PE-3, the SPE address is configured as follows:

```
# on PE-3:
configure
    service
        pw-routing
            spe-address 64500:192.0.2.3
        exit
```

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure
    service
        pw-routing
            spe-address 64500:192.0.2.1
            local-prefix 64500:192.0.2.1 create
                advertise-bgp route-distinguisher 64500:7
                advertise-bgp route-distinguisher 64500:8
            exit
        exit
        pw-template 10 name "PW10-auto-GRE" auto-gre-sdp create
        exit
        pw-template 20 name "PW20-auto-GRE_prefer-prov" prefer-provisioned-sdp
                                                              auto-gre-sdp create
        exit
        epipe 7 name "Epipe-7 MS-PW" customer 1 create
            description "Epipe with dynamic MS-PW spoke-SDP FEC"
            sap pxc-10.a:7 create                # SAP to connect to CE-17
                no shutdown
            exit
            spoke-sdp-fec 7 fec 129 aii-type 2 create
                pw-template-bind 10
                saii-type2 64500:192.0.2.1:7
                taii-type2 64500:192.0.2.2:7
                no shutdown
            exit
            no shutdown
        exit
        epipe 8 name "Epipe-8 MS-PW" customer 1 create
            description "Epipe with dynamic MS-PW spoke-SDP FEC_pref-prov"
            sap pxc-10.a:8 create                # SAP to connect to CE-18
                no shutdown
            exit
            spoke-sdp-fec 8 fec 129 aii-type 2 create
                pw-template-bind 20
                saii-type2 64500:192.0.2.1:8
                taii-type2 64500:192.0.2.2:8
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, the following service configuration is similar, with different SPE address, local prefix, Source Attachment Individual Identifier (SAII), and Target Attachment Individual Identifier (TAII). The SAIIs for the

Epipes on PE-2 match the TAIIs for the matching Epipes on PE-1 and the TAIIs on PE-2 match the SAIIs on PE-1.

```
# on PE-2:
configure
    service
        pw-routing
            spe-address 64500:192.0.2.2
            local-prefix 64500:192.0.2.2 create
                advertise-bgp route-distinguisher 64500:7
                advertise-bgp route-distinguisher 64500:8
            exit
        exit
        epipe 7 name "Epipe-7 MS-PW" customer 1 create
            description "Epipe with dynamic MS-PW spoke-SDP FEC"
            sap pxc-10.a:7 create               # SAP to connect to CE-27
                no shutdown
            exit
            spoke-sdp-fec 7 fec 129 aii-type 2 create
                pw-template-bind 10
                saii-type2 64500:192.0.2.2:7
                taii-type2 64500:192.0.2.1:7
                no shutdown
            exit
            no shutdown
        exit
        epipe 8 name "Epipe-8 MS-PW" customer 1 create
            description "Epipe with dynamic MS-PW spoke-SDP FEC_pref-prov"
            sap pxc-10.a:8 create               # SAP to connect to CE-28
                no shutdown
            exit
            spoke-sdp-fec 8 fec 129 aii-type 2 create
                pw-template-bind 20
                saii-type2 64500:192.0.2.2:8
                taii-type2 64500:192.0.2.1:8
                no shutdown
            exit
            no shutdown
        exit
```

Conclusion

In IP-based networks, auto-GRE spoke-SDPs can be used in VPWS and VPLS services. Manually configured GRE tunnels are not an option in networks—such as LTE networks—where it is common to assign IP addresses dynamically from a pool of addresses, but auto-GRE spoke-SDPs can be applied instead.

Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication

This chapter provides information about Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3. Layer 2 multicast optimization for EVPN-VXLAN - Assisted Replication (AR) is supported in SR OS Release 14.0.R4, and later.

Overview

Typically, EVPN-VXLAN can use either Ingress Replication (IR) or Protocol Independent Multicast (PIM) for Broadcast, Unknown unicast, and Multicast (BUM) traffic (although SR OS does not support PIM along with EVPN-VXLAN). PIM requires keeping multicast state awareness per subnet per tenant in the core routers, which may not scale. Not all core routers support PIM.

IR inefficiency is usually tolerable in EVPN networks for broadcast and unknown unicast traffic; however, it is not tolerable for multicast traffic:

- Broadcast traffic can be reduced by the proxy-ARP and proxy-ND capabilities supported by EVPN.
- Unknown unicast traffic is greatly reduced in virtualized Data Center (DC) networks where all MAC and IP addresses are learned in the control or management planes. In such cases, unknown MAC addresses are always outside the DC. An **unknown-mac-route** can be enabled to ensure that the unknown unicast traffic is sent only to the DC gateway, which minimizes flooding within the DC.
- Multicast traffic may be an issue for the hypervisors holding the multicast sources, because the hypervisors need to replicate the multicast traffic to the remote VXLAN Tunnel Endpoints (VTEPs). The multicast replication at the hypervisors is a software process and the throughput can be heavily impacted. This is also true when VPLS services are used in the Virtual Service Router (VSR) and many replicas must be done from the VSR. Using a dedicated service node to replicate the multicast traffic on behalf of the hypervisors can help, but the replication capabilities of such service nodes are limited too.

SR OS supports the Assisted Replication (AR) feature for IPv4 VXLAN tunnels (both replicator and leaf functions) in compliance with the non-selective mode described in *draft-ietf-bess-evpn-optimized-ir*. AR is a Layer 2 multicast optimization feature that helps software-based PEs and Network Virtualization Edge (NVE) devices with low-performance replication capabilities to deliver Broadcast and Multicast (BM) Layer 2 traffic to remote VTEPs in the VPLS.

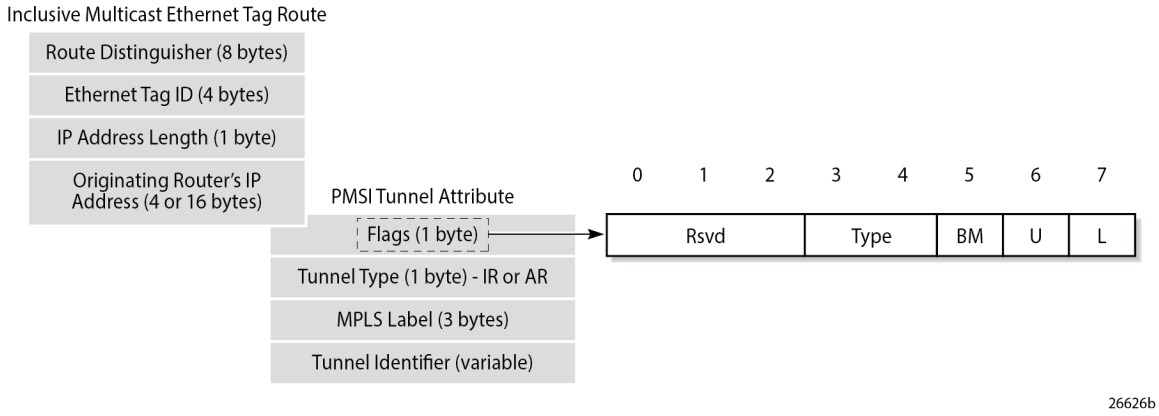
SR OS nodes support the AR-Replicator (AR-R) and AR-Leaf (AR-L) functions, although not simultaneously on the same service. Nodes configured as AR-L select an AR-R within a service and send

all BM packets to this AR-R. AR-Rs replicate traffic to all the VTEPs in the VPLS on behalf of the AR-Ls, so BM traffic is delivered to all VPLS participants without any packet loss caused by performance issues. Unknown unicast packets follow the same path as known unicast packets to avoid packet reordering. Therefore, no AR-R is used for unknown unicast traffic.

When multiple AR-Rs exist in a service, the AR-L performs per-service load-balancing of the BM traffic. The AR-L lists the candidate AR-Rs, ordered by IP address and VXLAN Network Identifier (VNI); candidate 0 having the lowest IP address and VNI. The replicator is selected using a modulo function of the service ID and the number of candidate AR-Rs. For example, assume that VPLS 1 has two candidate AR-Rs: because 1 modulo 2 equals 1, the second AR-R in the list is selected. In case of failure, a new AR-R is selected. If there are no more AR-Rs, the system falls back to IR.

Figure 185: PMSI Tunnel Attribute - Flags shows an EVPN route-type 3, an Inclusive Multicast Ethernet Tag (IMET) route containing a PMSI tunnel attribute with a flags octet. Flag L was already defined in RFC 6514. *Draft-ietf-bess-evpn-optimized-ir* defines additional flags: type, BM, and U. The BM and U flags are used for Pruned Flood Lists (PFL) signaling and they are not supported.

Figure 185: PMSI Tunnel Attribute - Flags



The type field has two bits that define the AR role of the advertising router, as follows:

- Type 00 = Regular Network Virtualization Edge (RNVE) - indicates that AR is not supported and IR is applied instead (for backward compatibility)
- Type 01= AR-R
- Type 10 = AR-L
- Type 11 = reserved

The tunnel type in the PMSI tunnel attribute can be configured with the following options for IR and AR:

- Tunnel type 0x06 = (non-optimized) IR, sent by AR-R and AR-L if **ingress-repl-inc-mcast-advertisement** is enabled, which is the default option
- Tunnel type 0x0A = type AR, originated by AR-R

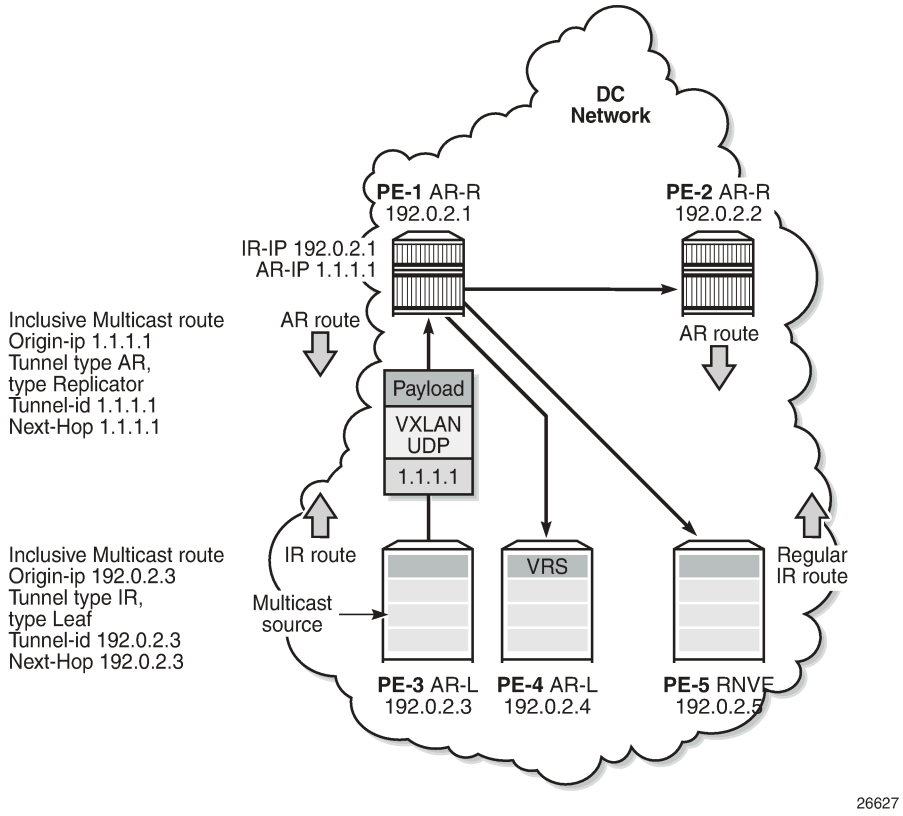
For regular IR routes, the originating router's IP address equals the system IP address. The MPLS label and tunnel identifier must be used as described in RFC 7432. The tunnel identifier is set to a routable address of the PE.

For AR routes, the originating router's IP address and the tunnel identifier are both set to the AR IP address (AR-IP) configured in the **service system vxlan** context. The AR-IP must be previously defined as a loopback interface address in the base router and must be different from the IR IP address (IR-IP).

Note:
If the AR-IP loopback interface is down, the router does not withdraw the AR route. However, the remote AR-Ls is not able to resolve the AR route's BGP next-hop if the AR-IP is no longer propagated in the IGP.

Figure 186: EVPN Assisted Replication for VXLAN shows the example topology with the multicast source connected to a hypervisor PE-3 that acts as AR-L, which sends an IR route containing the system address of PE-3. The AR-R PE-1 sends an AR route that uses AR-IPs instead of IR-IPs; for example, PE-1 has AR-IP 1.1.1.1 and IR-IP 192.0.2.1.

Figure 186: EVPN Assisted Replication for VXLAN



Hypervisor PE-3 sends the BM traffic to the AR-R, which replicates it to all the VTEPs in the VPLS, except to PE-3.

Table 11: Inclusive multicast route information sent by different AR roles shows the inclusive multicast route information sent by each role in an AR-capable service.

Table 11: Inclusive multicast route information sent by different AR roles

AR role	function	inclusive multicast route advertised
AR-R	assists AR-Ls	IR inclusive multicast route (tunnel = 0x06 = IR, IR-IP, type = 0 = none)

AR role	function	inclusive multicast route advertised
		AR inclusive multicast route (tunnel = 0x0A = AR, AR-IP, type = 1 = AR-R)
AR-L	sends BM only to AR-R	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 2 = AR-L)
RNVE	non-AR support	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 0 = none)

Unicast traffic (known or unknown) is processed as normal. For BM traffic, the AR-R uses AR or IR based on the IP destination address (DA):

- If IP DA equals the AR-IP, the AR-R replicates to the VTEPs in the VXLAN service, except for the VTEP over which the BM traffic was received.
- If IP DA equals the IR-IP, normal IR forwarding is done.

Non-optimized-IR nodes are unaware of the PMSI tunnel attribute flag definition with the additional flags for AR, so they ignore the information in the flags field.

The *draft-ietf-bess-evpn-optimized-ir* describes the following three types of IR optimizations:

- Non-selective AR - the chosen AR-R replicates the BM traffic to all NVEs in the Ethernet VPN Instance (EVI) except for the source NVE.
- Selective AR - AR-Rs replicate BM traffic to only their AR-L set and the rest of the AR-Rs. Selective AR allows a "multi-stage" AR replication, as opposed to a "single-stage" AR replication.
- Pruned Flood Lists - AR-Ls can signal PFL flags to be pruned from the flood lists for BM or for unknown unicast traffic. PFL may be used in combination with AR.

This chapter only describes non-selective AR.

Configure AR-R and AR-L

The AR-IP is configured on the AR-R, as follows:

```
*A:PE-1# configure service system vxlan assisted-replication-ip ?
  - assisted-replication-ip <ip-address>
  - no assisted-replication-ip

 <ip-address>         : a.b.c.d
```

The AR-IP is the IPv4 address of a loopback interface in the base router instance. When attempting to configure an AR-IP and the loopback address does not exist, the following error message is raised:

```
*A:PE-1# configure service system vxlan assisted-replication-ip 1.1.1.1
MINOR: SVCMGR #8110 Cannot change assisted-replicated address
 - loopback interface with address does not exist
```

The AR types replicator and leaf are configured in a VPLS with the following command:

```
*A:PE-1# configure service vpls 10 vxlan instance 1 vni 1 assisted-replication ?
  - assisted-replication {replicator|leaf} [replicator-activation-time <seconds>]
  - no assisted-replication
```

```
 <replicator|leaf>    : replicator|leaf
 <seconds>            : [1..255]
```

When attempting to configure an AR-R before the AR-IP is set, the following error is raised:

```
*A:PE-1# configure service vpls 10 name "VPLS 10" customer 1 create vxlan instance 1 vni 1
 create assisted-replication replicator
MINOR: SVCMGR #8111 Cannot change assisted-replicated role
 - assisted replicator ip not set
```

The AR type (AR-R or AR-L) cannot be changed while being used by any BGP-EVPN service. The following error is raised in such a case:

```
*A:PE-1# configure service vpls 10 vxlan instance 1 vni 1 assisted-replication leaf
MINOR: SVCMGR #8111 Cannot change assisted-replicated role - Evpn not shut
```

The assisted-replication-time can only be configured on leaf nodes. The following error is raised after an attempt to configure the assisted-replication-time on an AR-R:

```
*A:PE-1# configure service vpls 10 vxlan instance 1 vni 1 assisted-replication replicator
 replicator-activation-time 5
MINOR: SVCMGR #8112 Cannot change replicator activation time - valid only on leaf
```

The **replicator-activation-time** can optionally be activated, and works as follows. When the router creates an AR-R destination for the first time, the assisted-replication-timer must expire before this AR-R destination is eligible as candidate AR-R to forward BM traffic. Upon timer expiration, the router runs the AR-R selection (service ID modulo the number of AR-Rs provides the selected AR-R in the ordered list of candidate AR-Rs). The AR-R EVPN destination is created as "BM" and the destinations to the remaining nodes is shown as "U".

The **replicator-activation-time** allows the AR-R some time to program the leaf VTEPs in the following cases:

- Configuration of a new AR-R
- AR-R rebooting
- AR-R going operationally down and up again

If the timer is zero (default value), the AR-R may receive packets from a VTEP that has not been programmed yet, in which case the AR-R drops the packets.

With the AR-Rs and AR-Ls configured, IMET AR routes can be exchanged. IR can be enabled or disabled independently of the AR configuration. The following command is required to enable IR inclusive multicast routes, and is enabled by default:

```
*A:PE-1# configure service vpls 10 bgp-evpn ingress-repl-inc-mcast-advertisement
```

BGP-EVPN routes

By default, IR is enabled in BGP-EVPN. The following IMET IR route is sent from PE-5 (RNVE) to Route Reflector (RR) PE-1. The flags in the PMSI Tunnel Attribute (PTA) indicate that regular IR is used to forward BUM traffic (tunnel type: 0x06). The AR type is "None", because AR is disabled on PE-5. The IR-IP

192.0.2.5 is used as next-hop, originator IP address, and tunnel endpoint. The MPLS label corresponds to the VNI.

```
*A:PE-5# show debug
debug
    router "Base"
        bgp
            update
```

```
On PE-5:

"
```

A similar IMET IR route is sent from AR-L PE-3 toward RR PE-1, as follows. The difference is that the flags indicate that PE-3 is configured as an AR-L for the VPLS. The IR-IP 192.0.2.3 is used as next-hop, originator address, and tunnel endpoint.

```
On PE-3:
8 2023/07/07 09:55:54.883 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE

"
```

The IMET IR routes contain the system IP addresses of the nodes, not the AR-IPs.

The following AR route is advertised from AR-R PE-1. The tunnel type is AR and the flags indicate that PE-1 is configured as AR-R. The AR-IP 1.1.1.1 is the next-hop address, the originator address, and the tunnel endpoint.

```
On PE-1:
4 2023/07/07 09:55:29.613 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

"
```

Besides IMET AR routes, PE-1 may also advertise IMET IR routes to the other nodes using IR-IP 192.0.2.1 (system IP address). By default, BGP-EVPN has IR enabled. For example, the following IMET IR route is advertised to PE-4:

```
On PE-1:
3 2023/07/07 09:55:29.613 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

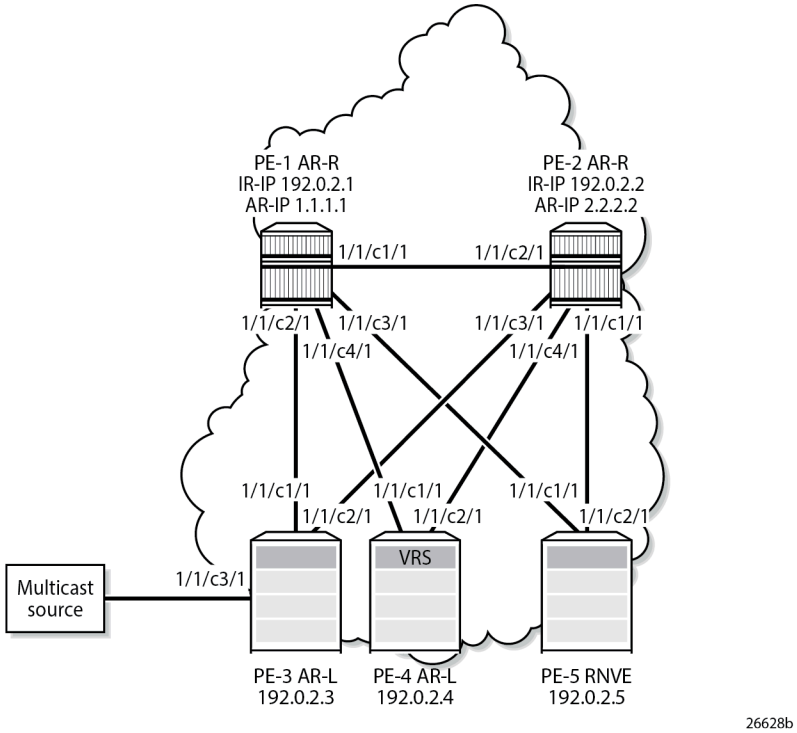
Configuration

Figure 187: Example topology shows the example topology with PE-1 and PE-2 as AR-R nodes, PE-3 and PE-4 as AR-L nodes, and PE-5 as RNVE node. The multicast source is connected to PE-3, which is a low-performance node. PE-1 acts as an RR for all nodes.

Figure 187: Example topology



The initial configuration on the nodes includes:

- Cards, MDAs, ports
- Router interfaces between the nodes
- IS-IS as IGP (alternatively, OSPF can be used)

BGP is configured for address family EVPN with RR PE-1. The BGP configuration on PE-1 is as follows:

```
On PE-1:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "DC"
                family evpn
                cluster 192.0.2.1
                peer-as 64500
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
```

```
                exit
            exit
        exit
```

The BGP configuration on the other nodes is as follows:

```
On the other PEs:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "DC"
                family evpn
                peer-as 64500
                neighbor 192.0.2.1
                exit
            exit
        exit
```

VPLS 10 is configured on all nodes. PE-1 is configured as AR-R with AR-IP 1.1.1.1, which must be configured as loopback IPv4 address in the base router and as AR-IP that can be shared between services. When attempting to configure an AR-IP with an IP address that does not exist in the base router, the following error is raised:

```
*A:PE-1# configure service system vxlan assisted-replication-ip 1.1.1.1
MINOR: SVCMGR #8110 Cannot change assisted-replicated address
 - loopback interface with address does not exist
```

First, a loopback interface is configured in the base router. The IP address needs to be routable and, in this example, an export policy exporting this IP address is configured in IS-IS. Alternatively, a static route can be configured or an additional IS-IS passive interface can be configured for the loopback interface. The IP address is then configured as AR-IP in the **service system vxlan** context. PE-1 is configured as AR-R for VPLS 10, as follows:

```
On PE-1:
configure
    router
        interface "AR-IP"
            address 1.1.1.1/32
            loopback
        exit
        policy-options
            begin
            prefix-list "AR-IP"
                prefix 1.1.1.1/32 exact
            exit
            policy-statement "export_AR-IP"
                entry 10
                    from
                        prefix-list "AR-IP"
                    exit
                    action accept
                    exit
                exit
            exit
```

```
            commit
        exit
        isis
            export "export_AR-IP"
        exit
    exit
    service
        system
            vxlan
                assisted-replication-ip 1.1.1.1
            exit
        exit
        vpls 10 name "VPLS 10" customer 1 create
            vxlan instance 1 vni 1 create
                assisted-replication replicator
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
```

The configuration is similar on PE-2, but with AR-IP 2.2.2.2 instead of 1.1.1.1.

PE-3 and PE-4 are configured as AR-L nodes for VPLS 10. No AR-IP needs to be configured. The configuration of VPLS 10 on PE-3 is as follows:

```
On PE-3:
configure
    service
        vpls 10 name "VPLS 10" customer 1 create
            vxlan instance 1 vni 1 create
                assisted-replication leaf
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/1/c3/1 create    # sap for ingress traffic from STC
            exit
            sap 1/2/c1/1:1 create    # sap for egress traffic to VPLS 10
            exit
            no shutdown
```

Multicast traffic enters SAP 1/1/c3/1, whereas receiving hosts can be connected to other SAPs, such as SAP 1/2/c1/1:1. The configuration of VPLS 10 on PE-4 is similar, but no multicast source is connected. When a node is configured as AR-L, optionally the **replicator-activation-time** can be configured to define the waiting time before the leaf can begin sending multicast traffic to a new replicator or a replicator that

was rebooted. The default is zero seconds, in which case the AR-L starts sending packets to the AR-R without delay. Nokia recommends configuring a **replicator-activation-time** value different from zero.

```
*A:PE-3# configure service vpls 10 vxlan instance 1 vni 1 assisted-replication leaf ?
  - assisted-replication {replicator|leaf} [replicator-activation-time <seconds>]
  - no assisted-replication

 <replicator|leaf>    : replicator|leaf
 <seconds>            : [1..255]
```

PE-5 is configured as an RNVE node for VPLS 10, as follows:

```
On PE-5:
configure
    service
        vpls 10 name "VPLS 10" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/2/c1/1:1 create    # sap for egress traffic to VPLS 10
            exit
            no shutdown
```

BGP-EVPN IMET routes are exchanged between the nodes. The following IMET routes are used on AR-L PE-3, with two routes from each AR-R: one IR route with BGP next-hop 192.0.2.x and one AR route with BGP next-hop x.x.x.x (with x equal to 1 or 2).

```

------------------------------------------------------------------------------
Routes : 6
==============================================================================
```

When the AR-R has no local attachment circuits, such as SAPs or SDP-bindings, it should not generate regular IR routes. This can be controlled by disabling **ingress-repl-inc-mcast-advertisement** on PE-1 and PE-2, as follows:

```
On PE-1 and PE-2:
configure
    service
        vpls 10
            bgp-evpn
                vxlan bgp 1 vxlan-instance 1 shutdown
                no ingress-repl-inc-mcast-advertisement
                vxlan bgp 1 vxlan-instance 1 no shutdown
```

When IR is disabled on the AR-Rs, no IR routes are sent to the other nodes and PE-3 only sees the AR routes from PE-1 and PE-2, as follows:

```
*A:PE-3# show router bgp routes evpn incl-mcast
==============================================================================
 BGP Router ID:192.0.2.3        AS:64500       Local AS:64500

===============================================================================
```

PE-3 is configured as AR-L and no **replicator-activation-time** is defined (default). Four egress VTEPs are listed: the system IP addresses are used for IR routes and the AR-IPs are used for AR routes. All BM traffic is forwarded to AR-IP 1.1.1.1 on PE-1. The AR-R in use is selected by the modulo operation on the service ID (10). In this example, two AR-Rs are available, and the service ID modulo 2 equals zero: 10 mod 2 = 0. This is the lowest possible outcome, so the first AR-R in the ordered candidate list is used. The AR-Rs are ordered by IP and VNI, with candidate 0 the lowest IP and VNI.

```
*A:PE-3# show service id 10 vxlan assisted-replication replicator

===============================================================================
Vxlan AR Replicator Candidates
===============================================================================
Inst  VTEP Address           Egr VNI  In Use  In Candidate List Pending Time

1     1.1.1.1                1        yes     yes               0
1     2.2.2.2                1        no      yes               0
-------------------------------------------------------------------------------
Number of entries : 2
-------------------------------------------------------------------------------
===============================================================================
```

Within a service, no load-sharing is done between the AR-Rs. However, different AR-Rs can be used for different services.

- If PE-3 were configured as AR-L in VPLS 11, the calculation would be as follows: 11 mod 2 = 1; therefore, the second AR-R in the list would be selected.
- When three AR-Rs were available for VPLS 11, the calculation would be: 11 mod 3 = 2, so the third AR-R in the list would be used.

In case different VNIs are configured for the AR-Rs, the lowest IP address is always higher in the list, even when the VNI is higher. This can be shown when the VPLS VXLAN configuration on PE-1 is modified with VNI 99 instead of VNI 1, as follows:

```
On PE-1:
configure service vpls 10 bgp-evpn vxlan bgp 1 vxlan-instance 1 shutdown
configure service vpls 10 bgp-evpn no vxlan
configure service vpls 10 no vxlan instance 1 vni 1
configure service vpls 10 vxlan instance 1 vni 99 create assisted-replication replicator
configure service vpls 10 bgp-evpn vxlan bgp 1 vxlan-instance 1 no shutdown
```

The list of AR-Rs on PE-3 shows that the first entry is the VTEP with the lowest IP address (1.1.1.1), even though the VNI 99 is higher than 1:

```
*A:PE-3# show service id 10 vxlan assisted-replication replicator

===============================================================================
Vxlan AR Replicator Candidates
===============================================================================
Inst  VTEP Address           Egr VNI  In Use  In Candidate List Pending Time
-------------------------------------------------------------------------------
1     1.1.1.1                99       yes     yes               0
1     2.2.2.2                1        no      yes               0
-------------------------------------------------------------------------------
Number of entries : 2
-------------------------------------------------------------------------------
```

```
===============================================================================
```

Note:
If the AR-IP loopback interface is down, BGP does not withdraw the AR route. When the route to the AR-IP is signaled using IGP, the route is removed from the routing table and the AR-L selects another AR-R. However, when a static route is defined for the AR-IP, a black-hole exists when the AR-IP interface is down.

PE-5 is configured as an RNVE node that signals regular IMET IR routes and is unaware of the AR-R and AR-L roles in the EVI. RNVE nodes ignore IMET AR routes. In the example, only PE-3, PE-4, and PE-5 send IMET IR updates, so the list of VTEP addresses on PE-5 only contains PE-3 and PE-4, as follows:

```
*A:PE-5# show service id 10 vxlan destinations

===============================================================================
Egress VTEP, VNI (Instance 1)
===============================================================================
VTEP Address                                        Egress VNI Oper  Mcast Num
                                                               State       MACs
-------------------------------------------------------------------------------
192.0.2.3                                           1          Up    BUM   0
192.0.2.4                                           1          Up    BUM   0
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 2
-------------------------------------------------------------------------------
---snip---
===============================================================================
```

The RNVE is unaware of AR-Rs; therefore, the list of AR-Rs is empty on PE-5:

```
*A:PE-5# show service id 10 vxlan assisted-replication replicator

===============================================================================
Vxlan AR Replicator Candidates
===============================================================================

-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

Verification of multicast traffic

The multicast source connected to PE-3 generates multicast traffic. PE-3 acts as AR-L and forwards the multicast packets to AR-R PE-1. In this example topology, multicast traffic enters port 1/1/c3/1 on PE-3 and is forwarded to egress port 1/1/c1/1 toward PE-1. Port statistics are cleared and traffic is generated, then the port statistics are verified.

```
*A:PE-3# show port 1/1/c1/1 statistics

                                            0                              0
===============================================================================
```

Besides the multicast traffic, IGP signaling is sent and received on the network interfaces. This explains why the counters on the network interface 1/1/c1/1 toward PE-1 show a slightly higher value than on the interface 1/1/c3/1 toward the multicast source. No multicast traffic is forwarded to PE-2, which is an AR-R candidate, but not used. AR-L PE-3 selected PE-1 for VPLS 10.

When the AR-R PE-1 receives the multicast traffic from PE-3, it forwards the traffic to PE-4 and PE-5 within the VXLAN service. The VXLAN information for VPLS 10 on PE-1 shows that PE-2 is not in the list of egress VTEPs. The reason is that PE-2 does not have any SAPs or SDP-bindings and no IMET IR route is sent by PE-2 because **ingress-repl-inc-mcast-advertisement** is disabled.

AR-R PE-1 receives the multicast traffic from PE-3 on port 1/1/c2/1 and forwards it to the egress ports 1/1/c3/1 toward PE-5 and 1/1/c4/1 toward PE-4, as follows. No multicast traffic needs to be forwarded to egress port 1/1/c1/1 toward PE-2. Source squelching ensures that the traffic is not sent back to the originator AR-L PE-3. PE-1 has no local SAPs or SDP-bindings.

```

An egress AR-L or RNVE node performs regular egress BUM forwarding procedures. Packets are replicated to local SAPs or SDP-bindings, but not to VXLAN-bindings.

AR-R failure scenarios

When the AR-IP interface on the used AR-R is down for any kind of reason, the route to this AR-IP is removed from the routing table on AR-L PE-3, and PE-3 selects AR-R PE-2. To simulate an AR-R failure, the AR-IP interface on PE-1 is disabled, as follows:

```
*A:PE-1# configure router interface "AR-IP" shutdown
```

After a while, the routing table on PE-3 does not contain an entry for prefix 1.1.1.1/32 anymore, as follows:

```
*A:PE-3# show router route-table 1.1.1.1/32

===============================================================================

```

When the AR-IP interface on AR-R PE-2 is also disabled, no AR-R is available anymore and PE-3 reverts to IR instead.

```
*A:PE-2# configure router interface "AR-IP" shutdown
```

The following log 99 message on AR-L PE-3 indicates that there is no AR-R anymore (VTEP 0.0.0.0, Egress VNI 0).

```
On PE-3:
125 2023/07/07 10:29:38.545 UTC MINOR: SVCMGR #2090 Base
"Assisted replicator in service 10 changed to VTEP 0.0.0.0, Egress VNI 0 vxlan-instance 1."
```

The list of VXLAN destinations for VPLS 10 on PE-3 does not include any AR-R (VTEP 1.1.1.1 or 2.2.2.2) anymore, as follows:

```
*A:PE-3# show service id 10 vxlan destinations

===============================================================================
Egress VTEP, VNI (Instance 1)
===============================================================================
VTEP Address                                    Egress VNI Oper  Mcast Num
                                                           State       MACs
-------------------------------------------------------------------------------
192.0.2.4                                       1          Up    BUM   0
192.0.2.5                                       1          Up    BUM   0
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 2
-------------------------------------------------------------------------------
---snip---
===============================================================================
```

```
*A:PE-3# show service id 10 vxlan assisted-replication replicator
```

```
===============================================================================
Vxlan AR Replicator Candidates
===============================================================================
Inst  VTEP Address           Egr VNI  In Use  In Candidate List Pending Time
-------------------------------------------------------------------------------

===============================================================================
```

In this case, IR is done for all BUM traffic toward PE-4 and PE-5.

Conclusion

AR uses replicators to forward broadcast and multicast traffic on behalf of less-performing nodes that are configured as AR-Ls. AR is primarily used for L2 multicast optimization in data centers, but may also be used in any network using overlay EVPN-VXLAN tunnels.

LDP VPLS Using BGP Auto-Discovery

This chapter provides information about LDP VPLS using BGP Auto-Discovery.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The CLI in this edition is based on SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Knowledge of BGP-auto-discovery RFC 6074 architecture and functionality, RFC 4447 Pseudo-wire set-up using label distribution protocol is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

Overview

MPLS-based Virtual Private LAN Services (VPLS) may have many different provisioning models to allow the signaling of pseudowires between Provider Edge (PE) routers containing VPLS instances.

Network Management System (NMS) provisioning using Label Distribution Protocol (LDP) signaling is a well understood method of provisioning of Layer 2 VPLS services as described in RFC 4762. This relies on the provisioning of pseudowires between VPLS instances using LDP signaling with a common Virtual Circuit (VC) identifier within the label mapping message to instantiate pseudowires.

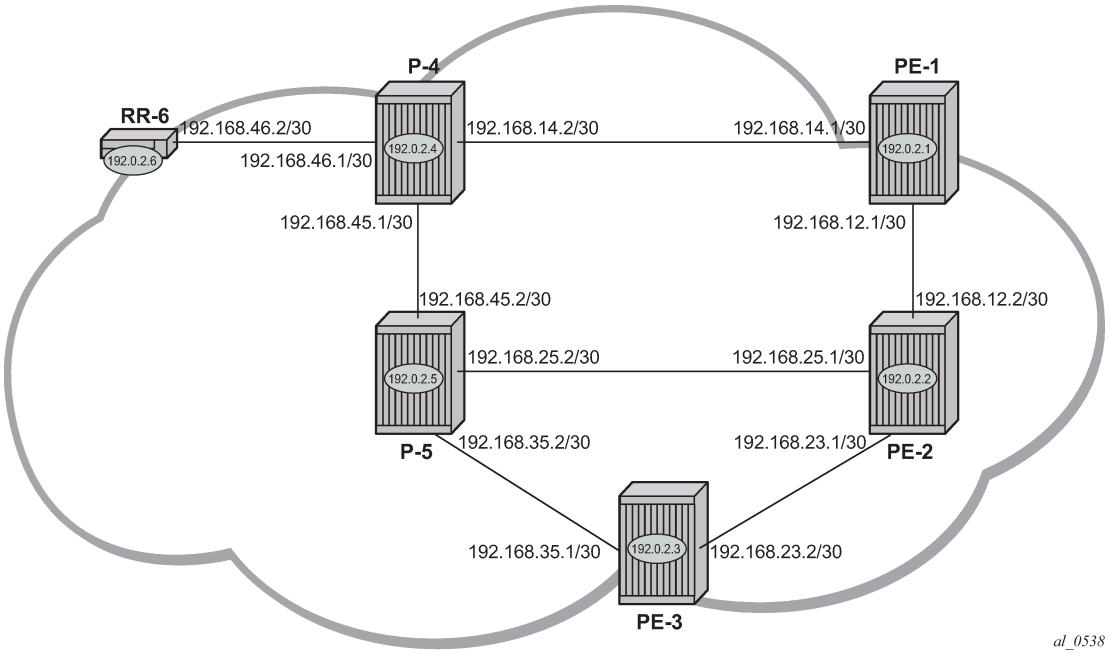
Border Gateway Protocol (BGP) Auto-Discovery (RFC 6074) is an alternative method of provisioning of Layer 2 PE routers containing VPLS service instances to those described above where PEs in a common VPLS instance are automatically discovered using BGP Auto-Discovery (BGP-AD) techniques.

Each PE router advertises the presence of VPLS instances to other PE routers using defined parameters within a BGP update message.

LDP is used as the pseudowire signaling protocol and relies on the auto-discovery of VPLS endpoints to instantiate pseudowires instead of manually provisioning virtual circuits. Locally configured parameters, along with BGP learned parameters, are used to determine local and remote VPLS endpoints, which are used by LDP to signal service labels to peer routers.

Figure 188: Example topology shows the example topology with six SR OS nodes located in the same autonomous system (AS).There are three PEs and RR-6 will act as a route reflector for the AS. The PE routers are all VPLS-aware. The provider (P) routers are VPLS-unaware and do not take part in the BGP process. A full mesh VPLS between PE-1, PE-2, and PE-3 is described.

Figure 188: Example topology



The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is enabled on all network interfaces between each of the PE/P routers and route reflector RR-6.
- MPLS is configured on all interfaces between PE and P routers; MPLS is not required between P-4 and RR-6.
- LDP is configured on interfaces between PE and P routers; LDP is not required between P-4 and RR-6.
- The RSVP protocol must be enabled.

BGP-AD

In this architecture, a VPLS service is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, VPLS-aware devices are PE routers. Each VPLS instance has a unique identifier known as the VPLS identifier (VPLS-ID). All PEs that have this VPLS instance present will have a common VPLS-ID configured.

Each VPLS instance within a PE contains a Virtual Switching Instance (VSI). The VPLS attachment circuits and pseudowires are associated with the VSI. Each VSI within a VPLS has a unique identifier called the VSI identifier (VSI-ID) and is a concatenation of the VPLS-ID plus an IP address, usually the system IP address.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP Layer 2 Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs. In turn, this allows peer PE routers to set up pseudowire connectivity using LDP signaling for data flow between peers containing a local VPLS within the same VPLS instances.

Each update contains parameters usually associated with Multi-Protocol BGP updates:

- NLRI encoded as route target (RT)—usually the VPLS-ID—and PE system address.
- Next-Hop — The system IP address of the sending PE router.
- Extended communities — Contains the RT extended community and the VPLS-ID as community values.

Each VPLS instance is configured with import and export RT extended communities to create the required pseudowire topology by controlling the distribution of each NLRI.

This chapter describes the provisioning of a VPLS instance across three PE routers. A full mesh of pseudowires interconnects the VSI of each PE within the VPLS instance. A single attachment circuit is also configured on each VSI.

Configuration

The first step is to configure an MP-iBGP session using the L2-VPN address family between each of the PEs and the RR.

The configuration for the PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure
     router Base
        autonomous-system 65536
        bgp
            group "internal"
                family l2-vpn
                peer-as 65536
                neighbor 192.0.2.6
                exit
            exit
            no shutdown
        exit
    exit
```

The IP addresses can be derived from Figure 188: Example topology.

The configuration for RR-6 is as follows:

```
# on RR-6:
configure
     router Base
     autonomous-system 65536
        bgp
            group "rr-internal"
                family l2-vpn
                cluster 1.1.1.1
                peer-as 65536
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
        exit
    exit
```

On PE-1, the BGP session with RR-6 is established with address family L2-VPN capability negotiated, as follows:

```
*A:PE-1# show router bgp neighbor 192.0.2.6

===============================================================================
BGP Neighbor
===============================================================================
-------------------------------------------------------------------------------
Peer                 : 192.0.2.6
Description          : (Not Specified)
Group                : internal
-------------------------------------------------------------------------------

-------------------------------------------------------------------------------
```

A full mesh of RSVP Label Switched Paths (LSPs) is configured between the PE routers. For reference, the MPLS interface configuration and LSPs for PE-1 to PE-2 and PE-3 is as follows:

```
# on PE-1:
configure
    router Base
        mpls
            interface "int-PE-1-PE-2"
                no shutdown
            exit
            interface "int-PE-1-P-4"
```

```
            no shutdown
        exit
        path "loose"
            no shutdown
        exit
        lsp "LSP-PE-1-PE-2"
            to 192.0.2.2
            primary "loose"
            exit
            no shutdown
        exit
        lsp "LSP-PE-1-PE-3"
            to 192.0.2.3
            primary "loose"
            exit
            no shutdown
        exit
        no shutdown
```

VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate Service Distribution Point (SDP) bindings. For a given service, pseudowire templates signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, plus other usage characteristics such as Split Horizon Groups (SHGs), MAC-pinning, filters, and so on.

The MPLS transport tunnel between PE routers can be signaled using either LDP or RSVP.

LDP-based pseudowires can be automatically instantiated; RSVP-based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, it is necessary for link layer LDP to be configured between all PEs/Ps so that a transport label for each PE system interface address is available. Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required which may contain an SHG. Each SDP created with this template is contained within the configured SHG so that traffic cannot be forwarded between them.

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 1 name "PW1" create
            split-horizon-group "vpls-shg"
            exit
        exit
```

A pseudowire template can also be created that does not contain a split horizon group. The split horizon group can then be specified when the pw-template is included within the service.

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 2 name "PW2" create
        exit
```

Pseudowire templates for provisioned SDPs using RSVP

To use an RSVP tunnel as transport between PEs, it is necessary to bind the RSVP LSPs to the SDPs between each PE.

On PE-1, SDP 12 from PE-1 to PE-2 is configured as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "RSVP-based SDP from PE-1 to PE-2"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
```

To create an SDP within a service that uses the RSVP transport tunnel, a pseudowire template is required that has the **use-provisioned-sdp** parameter.

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 3 name "PW3" use-provisioned-sdp create
            exit
        exit
```

Alternatively, the **prefer-provisioned-sdp** parameter can be used, see chapter LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP.

VPLS BGP-AD using auto-provisioned SDPs

Figure 189: VPLS instance with auto-provisioned SDPs

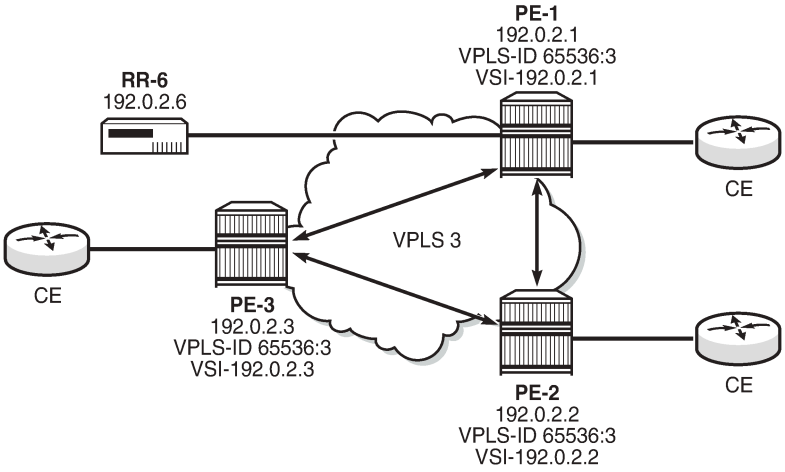

Figure 189: VPLS instance with auto-provisioned SDPs shows a schematic of a VPLS instance where the SDPs are auto-provisioned. SDPs are instantiated by a PE router using LDP signaling upon receipt of BGP Auto-Discovery (BGP-AD) updates from peer PE routers.

PE-1 configuration:

The following output shows the configuration required for a VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure
    service
        vpls 3 name "VPLS3" customer 1 create
            bgp
                route-distinguisher 65536:3
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 2 split-horizon-group "vpls-shg"
                    import-rt "target:65536:3"
                exit
            exit
            bgp-ad
                vpls-id 65536:3
                vsi-id
                    prefix 192.0.2.1
                exit
                no shutdown
            exit
            sap 1/1/4:3.0 create
            exit
            no shutdown
        exit
```

Within the **bgp** context, the pseudowire template is referenced which can be linked to an SHG and an import RT, if required.

Within the **bgp-ad** context, the signaling parameters are configured. These are two parameters used by each PE to determine the presence of a VPLS instance on a PE router. In turn, these are translated into endpoint identifiers for LDP signaling of pseudowires. As previously discussed, these parameters are:

- VPLS-ID — a unique identifier of the VPLS instance. Each PE that is a member of a VPLS must share the same VPLS-ID. This is inserted as an extended community value in the format AS:n. In this case, the VPLS-ID for VPLS 3 is 65536:3. This is a mandatory parameter and if it is not configured, it is not possible to enable BGP-AD using no shutdown.
- Virtual Switching Instance (VSI) prefix — This identifies a specific instance of the VPLS. This must be unique within the VPLS instance, and is encoded using the 4 byte dotted decimal notation. Generally, the system address is used as the VSI prefix. If this parameter is not configured, then the system address is used automatically.

The VPLS-ID and VSI prefix for VPLS 3 on each PE is shown in Figure 189: VPLS instance with auto-provisioned SDPs.

The VPLS-ID and VSI prefix are concatenated to form a unique VSI-ID. In this case, PE-1 has a VSI-ID of 65536:3:192.0.2.1. This uniquely identifies the VPLS instance on each individual PE and is advertised as an L2-VPN BGP update.

A BGP-AD update is transmitted to all other PEs via the RR, as follows:

```
*A:PE-1# show router bgp routes l2-vpn rd 65536:3 hunt

===============================================================================
```

The preceding BGP update is transmitted by PE-1 and has route type auto-discovery.

In this L2-VPN update, the VPLS-ID is encoded as the L2-VPN extended community 65536:3.

The VSI is seen as the prefix 192.0.2.1. The combination of the VPLS-ID and the VSI forms the VSI-ID and uniquely identifies the VPLS instance within this PE router.

The next-hop is also encoded as the local system IP address 192.0.2.1, which allows remote PEs to identify a suitable transport tunnel to PE-1 and for the targeted-LDP peer for instantiating the SDP.

As can be seen within the update, the VPLS-ID 65536:3 is also used to determine the RT extended community and the route distinguisher (RD).

PE-2 configuration

On PE-2, VPLS 3 is created using pseudowire template 1, with VPLS-ID 65536:3 and VSI-ID prefix 192.0.2.2 (system IP address), as follows”

```
# on PE-2:
configure
    service
        vpls 3 name "VPLS3" customer 1 create
            bgp
                route-distinguisher 65536:3
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 2 split-horizon-group "vpls-shg"
                    import-rt "target:65536:3"
                exit
            exit
            bgp-ad
                vpls-id 65536:3
                vsi-id
                    prefix 192.0.2.2
                exit
                no shutdown
            exit
            sap 1/1/4:3.0 create
            exit
            no shutdown
        exit
```

PE-3 configuration

On PE-3, VPLS 3 is created using pseudowire template 2, with VPLS-ID 65536:3—identical to the VPLS-ID of PE-1 and PE-2—and VSI-ID 192.0.2.3 (system IP address), as follows:

```
# on PE-3:
configure
    service
        vpls 3 name "VPLS3" customer 1 create
            bgp
                route-distinguisher 65536:3
                route-target export target:65536:3 import target:65536:3
                pw-template-binding 2 split-horizon-group "vpls-shg"
                    import-rt "target:65536:3"
                exit
            exit
            bgp-ad
                vpls-id 65536:3
                vsi-id
                    prefix 192.0.2.3
                exit
                no shutdown
            exit
            sap 1/1/4:3.0 create
```

```
            exit
            no shutdown
        exit
```

PE-1 service operation verification

The following output shows that the service is operationally up on PE-1:

```
*A:PE-1# show service id 3 base

===============================================================================
* indicates that the corresponding row element may have been truncated.
```

As seen from the output, the service is operationally up, with the SAPs and SDPs also up. The *SB* flag indicates that the SDP is of type spoke-SDP (S flag) BGP (B flag).

BGP is used to discover the VPLS endpoints and exchange network reachability information. LDP is used to signal the pseudowires between the PEs.

LDP signaling occurs when each PE has discovered the endpoints of the VPLS instance. This compares with the use of the provisioned virtual circuit IDs used in an NMS provisioned VPLS instances as per RFC 4762.

The ability of PE-1 to reach the other PE routers with VSIs within the VPLS instance is verified from the following L2-route table:

```
*A:PE-1# show service l2-route-table bgp-ad

===============================================================================

===============================================================================
```

This output shows the presence of the signaled pseudowire SDPs. SDPs from PE-1 to PE-2 and PE-3 are signaled using LDP Forwarding Equivalence Class (FEC) Element 129.

Each PE router uses targeted LDP to signal the local and remote endpoints. If there is an endpoint match, then SDPs are instantiated. This compares with the use of LDP for NMS provisioned SDPs, which uses virtual circuit IDs to signal pseudowires using LDP FEC Element 128.

In order to signal the SDPs, the following parameters are required:

1. Attachment Group Identifier (AGI): this is used to carry the VPLS-ID of the local PE router VPLS instance. The VPLS-ID must be identical for all PEs in the same VPLS instance.
2. Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII): these use AII type 1 (RFC 4446) and are used to carry the NLRI (VSI-ID minus the RD) of the remote PE router VPLS instance.

The AGI for each PE must be identical. SAII and TAII must be different.

The following shows the service LDP bindings for VPLS 3 on PE-1:

```
*A:PE-1# show router ldp bindings services service-id 3

BGP AD using pre-provisioned SDPs

It is possible to configure BGP-AD instances that use RSVP transport tunnels. In this case, the LSPs and SDPs must be manually created.

Figure 190: VPLS instance using pre-provisioned SDPs

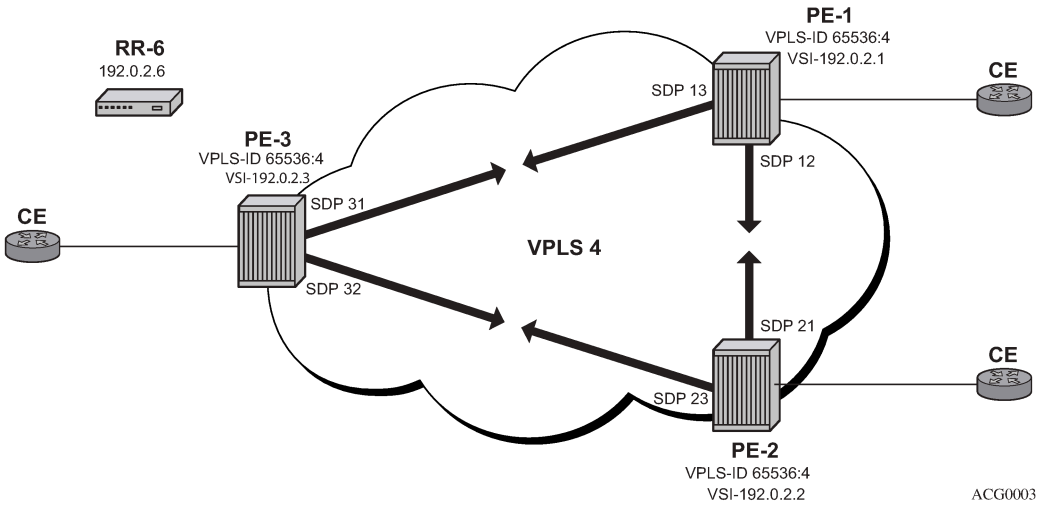

Figure 190: VPLS instance using pre-provisioned SDPs shows a VPLS instance configured across three PE routers as before.

The SDP configurations for the three PEs are as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "RSVP-based SDP from PE-1 to PE-2"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
```

```
            no shutdown
        exit
        sdp 13 mpls create
            description "RSVP-based SDP from PE-1 to PE-3"
            far-end 192.0.2.3
            lsp "LSP-PE-1-PE-3"
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        sdp 21 mpls create
            description "RSVP-based SDP from PE-2 to PE-1"
            far-end 192.0.2.1
            lsp "LSP-PE-2-PE-1"
            no shutdown
        exit
        sdp 23 mpls create
            description "RSVP-based SDP from PE-2 to PE-3"
            far-end 192.0.2.3
            lsp "LSP-PE-2-PE-3"
            no shutdown
        exit
```

```
# on PE-3:
configure
    service
        sdp 31 mpls create
            description "RSVP-based SDP from PE-3 to PE-1"
            far-end 192.0.2.1
            lsp "LSP-PE-3-PE-1"
            no shutdown
        exit
        sdp 32 mpls create
            description "RSVP-based SDP from PE-3 to PE-2"
            far-end 192.0.2.2
            lsp "LSP-PE-3-PE-2"
            no shutdown
        exit
```

The pw-template that is to be used within each VPLS instance must be provisioned on all PEs and must use the keyword **use-provisioned-sdp**. The pw-template is configured on all PEs with the following command:

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 3 name "PW3" use-provisioned-sdp create
        exit
```

The following output shows the configuration required for a VPLS service using a pseudowire template configured for pre-provisioned RSVP SDPs.

```
# on PE-1:
configure
    service
        vpls 4 name "VPLS4" customer 1 create
            bgp
                route-distinguisher 65536:4
```

```
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3 split-horizon-group "vpls-shg"
                    import-rt "target:65536:4"
                exit
            exit
            bgp-ad
                vpls-id 65536:4
                vsi-id
                    prefix 192.0.2.1
                exit
                no shutdown
            exit
            sap 1/1/4:4.0 create
            exit
            no shutdown
        exit
```

Similarly, on PE-2 the configuration is as follows:

```
# on PE-2:
configure
    service
        vpls 4 name "VPLS4" customer 1 create
            bgp
                route-distinguisher 65536:4
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3 split-horizon-group "vpls-shg"
                    import-rt "target:65536:4"
                exit
            exit
            bgp-ad
                vpls-id 65536:4
                vsi-id
                    prefix 192.0.2.2
                exit
                no shutdown
            exit
            sap 1/1/4:4.0 create
            exit
            no shutdown
        exit
```

On PE-3, VPLS 4 is configured as follows:

```
# on PE-3:
configure
    service
        vpls 4 name "VPLS4" customer 1 create
            bgp
                route-distinguisher 65536:4
                route-target export target:65536:4 import target:65536:4
                pw-template-binding 3 split-horizon-group "vpls-shg"
                    import-rt "target:65536:4"
                exit
            exit
            bgp-ad
                vpls-id 65536:4
                vsi-id
                    prefix 192.0.2.3
                exit
                no shutdown
            exit
            sap 1/1/4:4.0 create
```

```
            exit
            no shutdown
        exit
```

The following output shows that the service is operationally up on PE-1.

```
*A:PE-1# show service id 4 base

Conclusion

BGP-AD coupled with LDP pseudowire signaling allows the delivery of L2-VPN services to customers where BGP is commonly used. This example shows the configuration of BGP-AD together with the associated show outputs which can be used for verification and troubleshooting.

LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP

This chapter provides information about LDP VPLS using BGP auto-discovery — prefer provisioned SDP.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the CLI in the current edition is based on SR OS Release 21.2.R1. BGP Auto-Discovery (BGP-AD) based on RFC 6074 is supported in SR OS Release 6.0, and later. The **prefer-provisioned-sdp** option is supported in SR OS Release 14.0.R1, and later.

Overview

As described in chapter LDP VPLS Using BGP Auto-Discovery, BGP-AD based on RFC 6074 can auto-create SDP bindings, but an operator can force the system to use a provisioned SDP by specifying the **use-provisioned-sdp** option. This chapter compares the **use-provisioned-sdp** option with the **prefer-provisioned-sdp** option. The chapter describes a migration scenario for a VPLS service with a pseudowire (PW) template binding, restricted to using provisioned SDPs toward a PW template binding preferring to use provisioned SDPs, but auto-creating SDPs in case there is no suitable manually created SDP available.

PW templates

PW templates can be configured with the following command:

```
*A:PE-1>config>service# pw-template ?
  - pw-template <policy-id> [create] [prefer-provisioned-sdp] [name <name>]
                                                                [auto-gre-sdp]
  - no pw-template <policy-id>
  - pw-template <policy-id> use-provisioned-sdp [create] [name <name>]

 <policy-id>          : [1..2147483647]
 <use-provisioned-s*> : keyword
 <create>             : keyword - mandatory while creating an entry.
 <prefer-provisione*> : keyword
 <name>               : [64 chars max]
 <auto-gre-sdp>       : keyword
---snip---
```

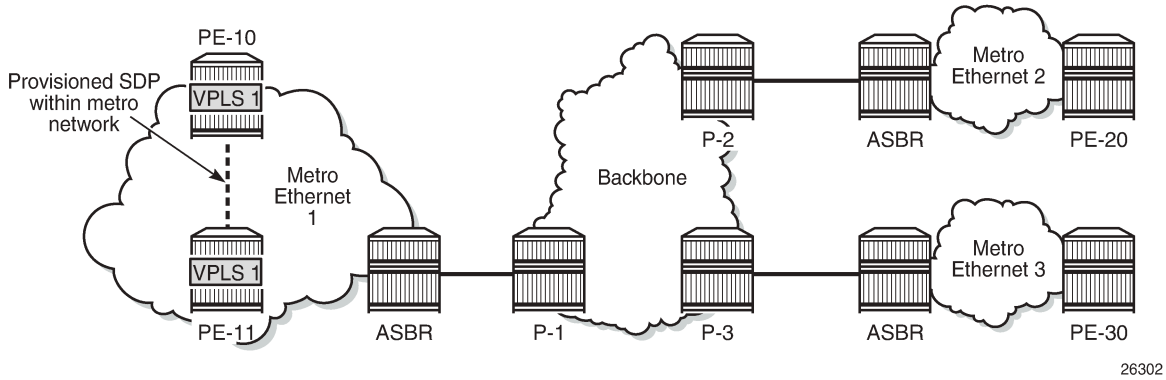
- When the **use-provisioned-sdp** keyword is added at creation time, the tunnel manager is forced to look for a provisioned and active SDP to the far-end PE. The far-end PE is auto-discovered from the BGP next hop. If multiple SDPs are active to this far-end PE, the tunnel manager chooses the SDP

template with the best metric. If there is a tie, the SDP ID is used as a tie-breaker and the highest SDP ID wins. However, if no provisioned SDP exists, the SDP binding will not be instantiated.

- When the **prefer-provisioned-sdp** keyword is added at creation time, the behavior is the same as when a provisioned SDP exists. When the tunnel manager finds an existing matching SDP, it will use it even if it is operationally down. Only when no provisioned SDP exists, will the SDP binding be auto-created.
- When a PW template is created without the **use-provisioned-sdp** or **prefer-provisioned-sdp** keyword, the SDP bindings will be auto-created.

Figure 191: LDP VPLS using BGP-AD with use-provisioned-sdp option shows the following use case: the metro Ethernet networks were initially built with provisioned SDPs. Intra-metro services are provisioned using provisioned SDPs; for example, customer X has a VPLS service defined in the metro Ethernet networks, using BGP-AD with a PW template to use the provisioned SDPs in the metro Ethernet networks.

Figure 191: LDP VPLS using BGP-AD with use-provisioned-sdp option

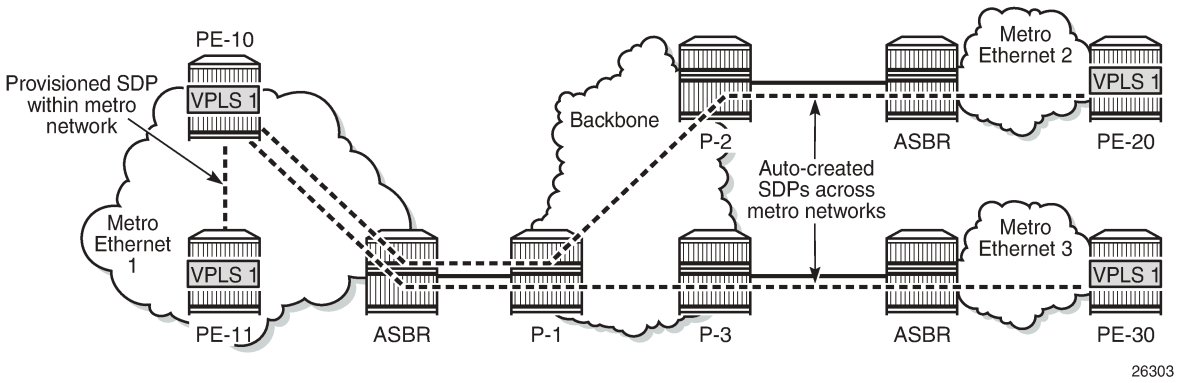


The service provider initially started with PE-10 and PE-11 in metro Ethernet 1, but now wants to add PE-20 and PE-30 as new sites to the VPLS service. Therefore, the BGP-AD routes should propagate beyond the boundaries of the metro Ethernet network. The backbone network may be in a different AS, but in this example, all networks are in the same AS. VPLS 1 of customer X can have sites added to the service on PEs in different metro Ethernet networks. A new PW template is created with the **prefer-provisioned-sdp** option and applied to the VPLS service.

- When a new site within the metro Ethernet network is added, an SDP is already provisioned to this site and this SDP is used for the SDP binding in the VPLS.
- When a new site in a different metro Ethernet network is added, no SDP is available to the site in the remote metro Ethernet network and the SDP binding is auto-created.

Figure 192: LDP VPLS using BGP-AD with prefer-provisioned-sdp option shows the SDP bindings in VPLS 1 between PE-10 and the other PEs. For simplicity, the SDP bindings between the other PEs are not shown.

Figure 192: LDP VPLS using BGP-AD with prefer-provisioned-sdp option

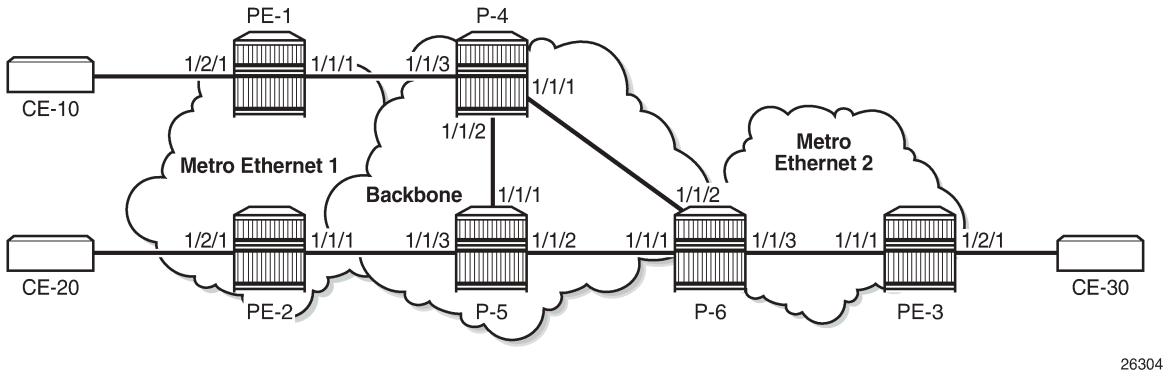


The **prefer-provisioned-sdp** and **use-provisioned-sdp** options can only be defined at creation time, implying that existing PW templates cannot be changed from prefer-provisioned-sdp to use-provisioned-sdp and vice versa. To support migration from one PW template to another with minimal service impact, two PW templates can be applied in parallel, as shown in the Configuration section.

Configuration

Figure 193: Example topology shows the example topology. For simplicity, all nodes are in the same AS.

Figure 193: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (or OSPF) on all interfaces
- MPLS and RSVP on all interfaces, except "int-P-4-P-6" and "int-P-5-P-6".
- LDP on all interfaces

BGP is configured on all PE routers for address family l2-vpn, as follows:

```
# on PE-1, PE-2, PE-3:
```

```
configure
    router Base
        autonomous-system 64496
        bgp
            group "internal"
                family l2-vpn
                peer-as 64496
                neighbor 192.0.2.6
                exit
            exit
```

The BGP configuration on the route reflector (RR) P-6 is as follows:

```
# on P-6:
configure
    router Base
        autonomous-system 64496
        bgp
            group "rr-internal"
                family l2-vpn
                cluster 1.1.1.1
                peer-as 64496
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

On PE-1 and PE-2 in metro Ethernet network 1, an RSVP LSP is created that is used in a manually created SDP. The LSP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                primary "loose"
                exit
                no shutdown
            exit
            no shutdown
```

On PE-1, SDP 12 is configured as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            description "SDP12 to 192.0.2.2"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            keep-alive
                shutdown
            exit
            no shutdown
```

```
        exit
```

The configuration on PE-2 is similar.

LDP VPLS using AD without prefer-provisioned-sdp option

Initially, the following two PW templates are created on all PEs: PW template 1 has the **use-provisioned-sdp** option and PW template 2 is created without any option; therefore, SDP bindings will be auto-created.

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 1 name "PW 1" use-provisioned-sdp create
        exit
        pw-template 2 name "PW 2" create
        exit
```

The following lists the PW templates configured on PE-1:

```
*A:PE-1# show service pw-template

===============================================================================
PW Template information
===============================================================================
PW Template Id      SDP                           Last Update
-------------------------------------------------------------------------------
1                   Use-provisioned               04/01/2021 08:47:29
2                   Auto-mpls                     04/01/2021 08:07:06
===============================================================================
```

On all PEs, two VPLS services are created: VPLS 1 with BGP-AD PW template 1 and VPLS 2 with PW template 2, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
                route-distinguisher 64496:1
                route-target export target:64496:1 import target:64496:1
                pw-template-binding 1
                exit
            exit
            bgp-ad
                vpls-id 64496:1
                no shutdown
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 2 name "VPLS 2" customer 1 create
            bgp
                route-distinguisher 64496:2
                route-target export target:64496:2 import target:64496:2
```

```
                pw-template-binding 2 import-rt "target:64496:2"
                exit
            exit
            bgp-ad
                vpls-id 64496:2
                no shutdown
            exit
            stp
                shutdown
            exit
            sap 1/2/1:2 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-1, the following SDP bindings have been created:

```
*A:PE-1# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
1          12:4294967295      BgpAd  192.0.2.2           Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3           Up    524278  524280
2          32767:4294967294   BgpAd  192.0.2.2           Up    524279  524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

The first SDP binding is created by BGP-AD in VPLS 1 and uses the configured SDP 12 with far-end PE-2; the other two SDP bindings have been auto-created by BGP-AD in VPLS 2 and have far-end PE-2 and PE-3.

The list of SDP bindings on PE-2 looks similar:

```
*A:PE-2# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
1          21:4294967295      BgpAd  192.0.2.1           Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3           Up    524278  524281
2          32767:4294967294   BgpAd  192.0.2.1           Up    524279  524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

On PE-3, there are only two SDP bindings, both in VPLS 2:

```
*A:PE-3# show service sdp-using

===============================================================================
SDP Using
```

```
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
2          32766:4294967294   BgpAd  192.0.2.1           Up    524280  524278
2          32767:4294967295   BgpAd  192.0.2.2           Up    524281  524278
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

Log "99" on PE-3 shows that the system failed to create a dynamic BGP-L2VPN SDP binding because no provisioned SDP was found, as follows:

```
77 2021/04/01 08:49:00.672 UTC MAJOR: SVCMGR #2322 Base
"The system failed to create a dynamic bgp-l2vpn SDP Bind  in service 1 with SDP
pw-template policy 1 for the following reason: suitable manual SDP not found."
```

Figure 194: SDP bindings in VPLS 1 with use-provisioned-sdp option shows the SDPs used in VPLS 1. PE-1 and PE-2 both used the provisioned SDP. PE-3 has no SDP bindings in VPLS 1.

Figure 194: SDP bindings in VPLS 1 with use-provisioned-sdp option

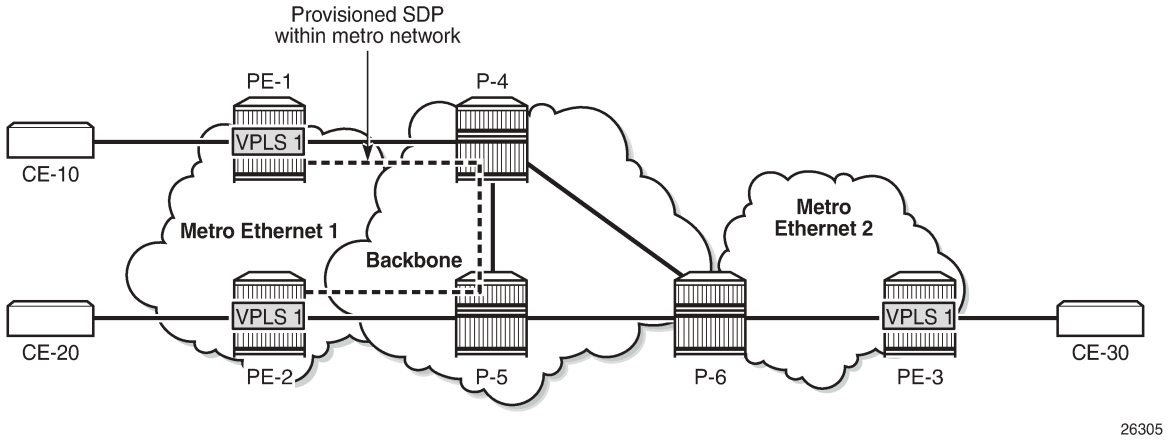


Figure 195: Auto-created SDP bindings in VPLS 2 shows the auto-created SDP bindings in VPLS 2. Each PE has two auto-created SDP bindings to each other PE.

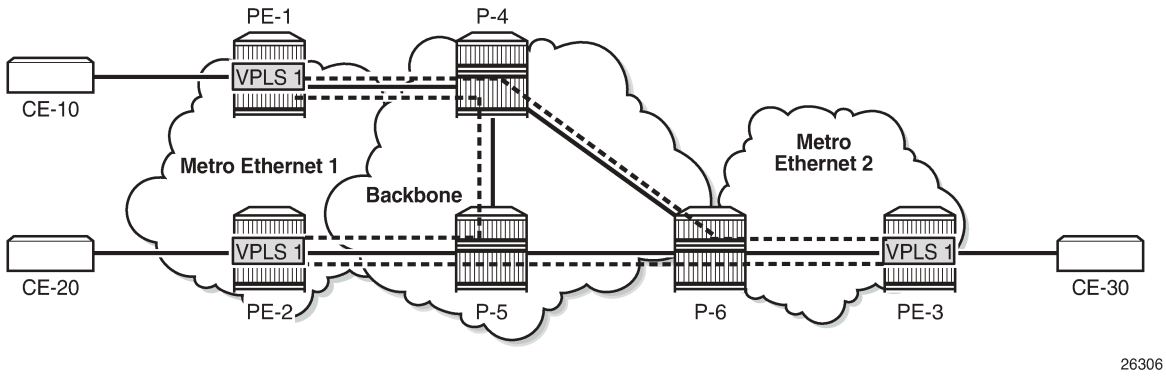
Figure 195: Auto-created SDP bindings in VPLS 2



Migrate VPLS 1 to prefer-provisioned-sdp option

VPLS 1 uses PW template 1 with the **use-provisioned-sdp** option. This option is defined at creation time and cannot be modified afterward, as follows:

```
*A:PE-1>config>service# pw-template 1 prefer-provisioned-sdp
MINOR: CLI The prefer-provisioned-sdp option cannot be modified after creation.
```

The following steps are needed to migrate to another PW template with the **prefer-provisioned-sdp** option without service outage:

1. Create new PW template with **prefer-provisioned-sdp** option.
2. Add new PW template binding to VPLS and verify which PW template is used.
3. Modify old PW template binding to make it not usable.
4. Launch tools command to re-evaluate old PW template in the VPLS.
5. When the old PW template is not used anymore, remove PW template binding from the VPLS configuration.

A new PW template with the prefer-provisioned-sdp option is configured on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        pw-template 10 name "PW 10" prefer-provisioned-sdp create
        exit
```

An additional PW template binding is configured in VPLS 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            bgp
                pw-template-binding 10
```

```
                exit
```

The configuration of VPLS 1 includes two PW template bindings, as follows:

```
*A:PE-1>config>service>vpls# info
----------------------------------------------
            bgp
                route-distinguisher 64496:1
                route-target export target:64496:1 import target:64496:1
                pw-template-binding 1
                exit
                pw-template-binding 10
                exit
            exit
            bgp-ad
                vpls-id 64496:1
                no shutdown
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
```

The following shows that no additional SDP bindings have been created. The only SDP binding in VPLS 1 on PE-1 uses the provisioned SDP 12.

```
*A:PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The following shows that PW template 1 was used for the creation of the SDP binding:

```
*A:PE-1# show service id 1 sdp detail | match "SDP Id|PW-Template Id" expression
SDP Id             : 12:4294967295            Type              : BgpAd
PW-Template Id     : 1
```

The PW template 10 has a higher ID than PW template 1 and is not used. Re-evaluating the PW template binding for PW template 1 in VPLS 1 will make no difference if both PW templates are usable. However, PW template 1 can be made unusable by adding a dummy **import-rt** not matching any route in the VPLS, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            bgp
                pw-template-binding 1 import-rt "target:111:111"
                exit
```

```
            exit
```

As a result, PW template 10 with the **prefer-provisioned-sdp** option is used for the automatic creation of SDP bindings where no provisioned SDP is available, as follows:

```
*A:PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
32766:4294967292 BgpAd    192.0.2.3       Up      Up        524277    524278
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

For the first SDP binding, PW template 1 is used, and for the second SDP binding, PW template 10 is used, as follows:

```
*A:PE-1# show service id 1 sdp detail | match "SDP Id|PW-Template Id" expression
SDP Id             : 12:4294967295            Type              : BgpAd
PW-Template Id     : 1
SDP Id             : 32766:4294967292         Type              : BgpAd
PW-Template Id     : 10
```

The following command forces the system to re-evaluate PW template 1 in VPLS 1:

```
*A:PE-1# tools perform service id 1 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1 12:4294967295 Policy 1
```

As a result, only PW template 10 is used for the creation of SDP bindings in VPLS 1, as follows:

```
*A:PE-1# show service id 1 sdp detail | match "SDP Id|PW-Template Id" expression
SDP Id             : 12:4294967291            Type              : BgpAd
PW-Template Id     : 10
SDP Id             : 32766:4294967292         Type              : BgpAd
PW-Template Id     : 10
```

PW template 1 is not used anymore and can be removed from the VPLS configuration, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vpls "VPLS 1"
            bgp
                no pw-template-binding 1
            exit
```

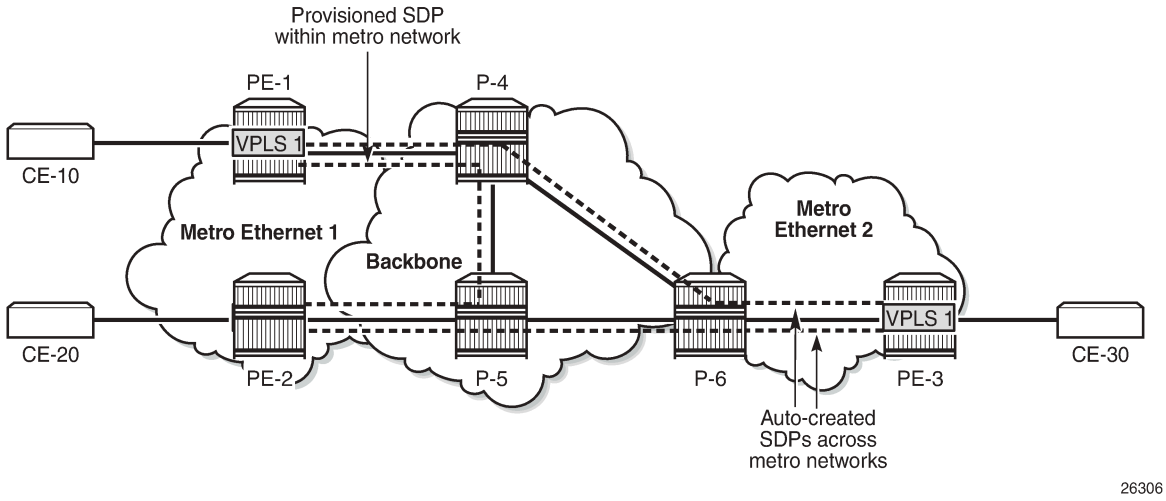
The configuration of VPLS 1 on PE-1 contains only a PW template binding for PW template 10, as follows:

```
*A:PE-1>config>service>vpls# info
----------------------------------------------
            bgp
                route-distinguisher 64496:1
                route-target export target:64496:1 import target:64496:1
                pw-template-binding 10
```

```
                exit
            exit
            bgp-ad
                vpls-id 64496:1
                no shutdown
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
----------------------------------------------
```

Figure 196: SDP bindings in VPLS 1 with prefer-provisioned-sdp option shows the SDP bindings in VPLS 1 with the **prefer-provisioned-sdp** option. Within metro Ethernet network 1, the provisioned SDP is used, and between metro Ethernet networks, auto-created SDP bindings are used.

Figure 196: SDP bindings in VPLS 1 with prefer-provisioned-sdp option



Conclusion

LDP VPLS using BGP-AD allows the creation of SDP bindings that are either auto-created or that use provisioned SDPs. When the **prefer-provisioned-sdp** option is used, the tunnel manager will look for a provisioned and active SDP to the far end and use it, if available, even if it is down. When no provisioned SDP is available, the system will auto-create an SDP binding.

Mobility for EVPN Hosts Within an R-VPLS

This chapter provides information about Mobility for EVPN Hosts Within an R-VPLS.

Topics in this chapter include:

Applicability

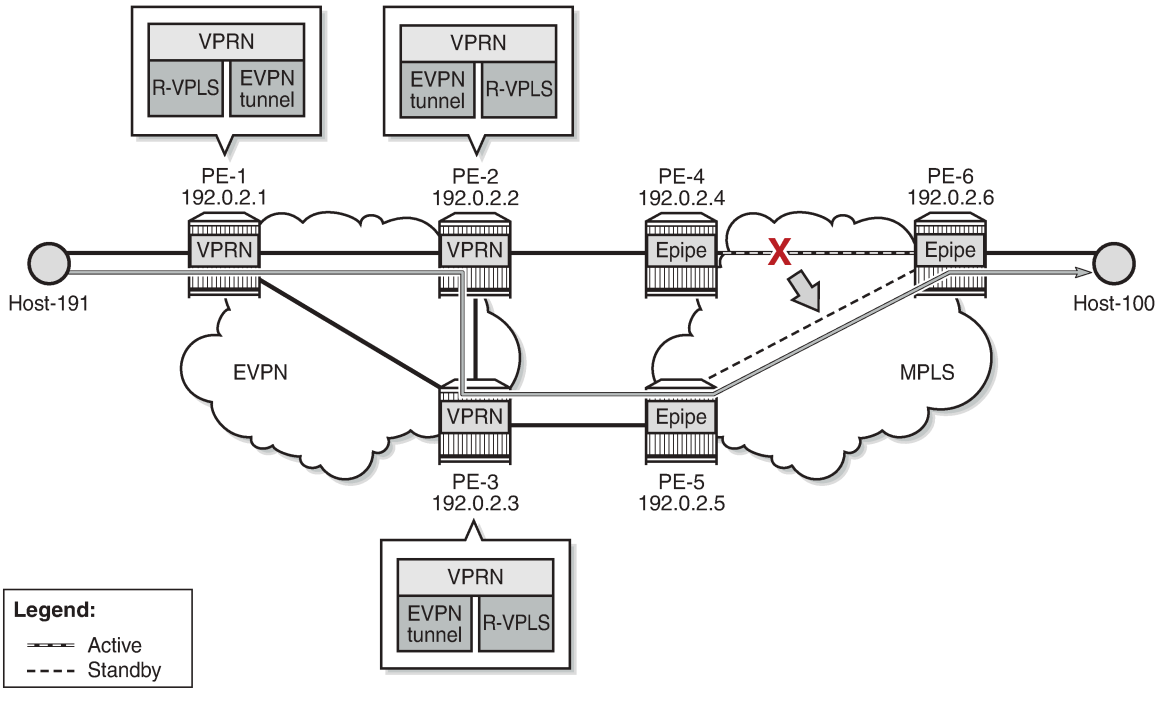
The information and configuration in this chapter are based on SR OS Release 21.10.R2. Efficient EVPN host mobility without tromboning or hairpinning in an R-VPLS is supported for IPv4 in SR OS Release 19.10.R3 and later and is supported for IPv6 in SR OS Release 20.5.R1 and later.

Overview

SR OS can populate a VPRN route table with host routes learned from the IPv4 Address Resolution Protocol (ARP) messages or IPv6 Neighbor Discovery (ND) protocol messages. The host routes can be advertised in the VPRN context as IP-VPN or EVPN route type 5 (RT5), to be used by an IP-VPN or EVPN core network for inter-subnet forwarding. SR OS supports *draft-ietf-bess-evpn-inter-subnet-forwarding* for a dynamic and efficient routing between remote hosts, avoiding hairpinning.

In SR OS Releases earlier than Release 19.10.R3, inefficient hairpinning situations may occur when the VPRN is configured to advertise IPv4 host routes as IP-VPN or EVPN RT5 routes. Figure 197: Hairpinning in a broadcast domain after switchover for SR OS Releases earlier than Release 19.10.R3 shows hairpinning in an EVPN broadcast domain with PE-1, PE-2, and PE-3.

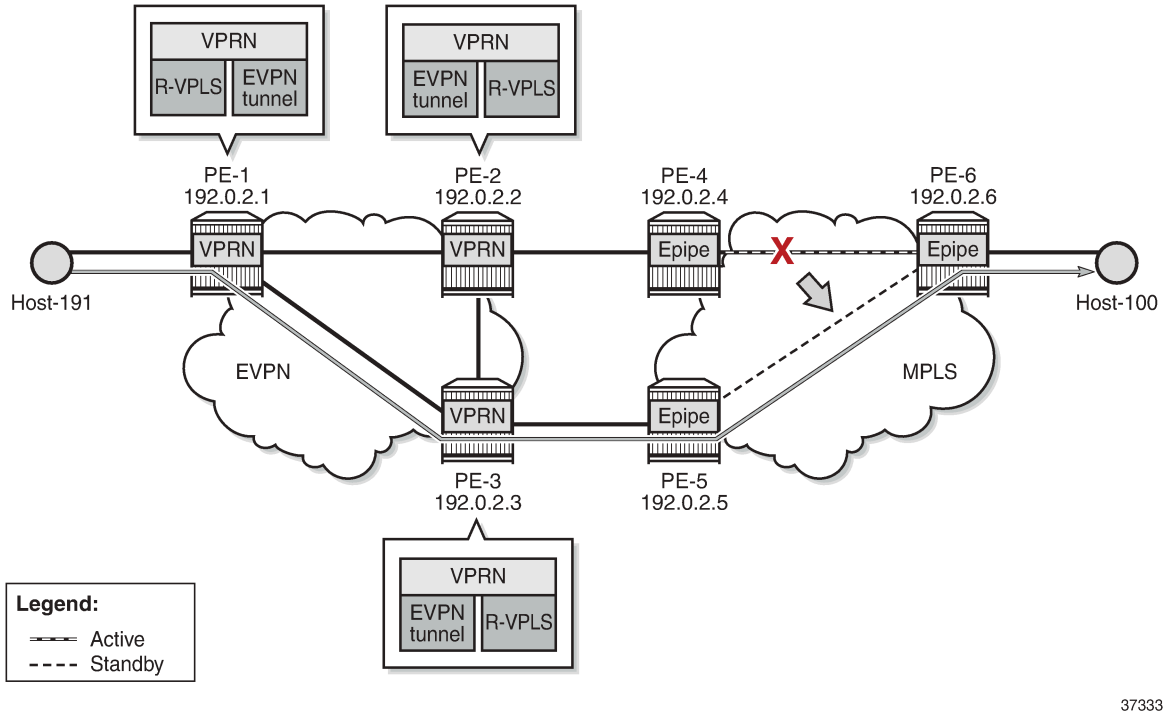
Figure 197: Hairpinning in a broadcast domain after switchover for SR OS Releases earlier than Release 19.10.R3



When host-100 comes up, it sends a Gratuitous Address Resolution Protocol (GARP) message that is then learned on PE-2 and PE-3. PE-2 and PE-3 are configured to advertise host routes, so they generate an RT5 host route for prefix 10.0.0.100/32 of host-100. PE-3 selects its best RT5 for 10.0.0.100/32 and traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-4, and PE-6. However, when the active path between PE-4 and PE-6 fails, the standby path between PE-5 and PE-6 takes over and hairpinning occurs when PE-1 continues selecting PE-2 as the next hop, while a more efficient path is possible via next-hop PE-3. Traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-3, PE-5, and PE-6.

In SR OS Release 19.10.R3 and later, the more efficient path from host-191 via PE-1, PE-3, PE-5, and PE-6 to host-100 is used, as shown in Figure 198: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later.

Figure 198: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later



In SR OS Release 19.10.R3 and later, EVPN host mobility is supported for IPv4 as described in section "Symmetric and Asymmetric IRB" of *draft-ietf-bess-evpn-inter-subnet-forwarding*. When a host moves from a source PE to a target PE in the same broadcast domain, the behavior for IPv4 hosts is one of the following.

1. The host initiates an ARP request or GARP.
2. The host sends a data packet without first initiating an ARP request or GARP.
3. The host does not send any traffic and the source PE generates an ARP request when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-100 from source PE-2 to target PE-3 is simulated.

For the first of these scenarios, the VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vprn 16 name "ip-vrf-16" customer 1 create
            interface "evi-15" create
                mac 00:00:00:00:00:02
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-17" create
                address 10.0.0.2/24
                mac 00:00:00:00:2e:17
                arp-host-route
```

```
                populate dynamic
            exit
            arp-timeout 300
            arp-learn-unsolicited
            arp-proactive-refresh
            vrrp 1 passive
                backup 10.0.0.254
                ping-reply
                traceroute-reply
            exit
            local-proxy-arp
            vpls "evi-17"
                evpn
                    arp
                        no learn-dynamic
                        no flood-garp-and-unknown-req
                        advertise dynamic
                    exit
                exit
            exit
        exit
        no shutdown
    exit
```

The behavior is controlled by the following commands.

- **arp-host-route>populate [dynamic | evpn | static]** configures PE-2 to advertise host routes. The type of ARP entry that can create a host route can be dynamic, EVPN, static, or a combination of these.
- **arp-learn-unsolicited** triggers the learning of an ARP entry upon receiving an ARP or GARP message that was not requested by the router.
- **arp-proactive-refresh** triggers the refresh of the ARP entry 30 seconds before aging out.
- **local-proxy-arp** ensures that PE-2 replies to any received ARP request on behalf of the other hosts in the R-VPLS broadcast domain.
- **vpls>evpn>arp>[no] learn-dynamic** controls whether data path ARP messages received on EVPN connections can populate the ARP tables.
- **vpls>evpn>arp>[no] flood-garp-and-unknown-req** controls the flooding of Control Processing Module (CPM)-generated ARP requests to EVPN destinations.
- **vpls>evpn>arp>advertise [dynamic | static]** enables PE-2 to advertise MAC and IP in EVPN-MAC routes for ARP entries of the dynamic or static type.

For IPv6, the corresponding commands are as follows:

- **ipv6>nd-host-route>populate [dynamic | evpn | static]**
- **ipv6>nd-learn-unsolicited [global | link-local | both]**
- **ipv6>nd-proactive-refresh [global | link-local | both]** triggers the refresh of the ND entry upon aging out.
- **ipv6>local-proxy-nd**
- **vpls>evpn>nd>[no] learn-dynamic**
- **vpls>evpn>nd>advertise [dynamic | static]**

For IPv6, CPM-generated Neighbor Solicitation (NS) messages are always flooded to EVPN destinations. This is not configurable in the **vpls>evpn>nd** context of the VPRN service, in contrast to the **[no] flood-garp-and-unknown-req** command in the **vpls>evpn>arp** context for IPv4.

The behavior for IPv6 hosts when moving from a source PE to a target PE is one of the following.

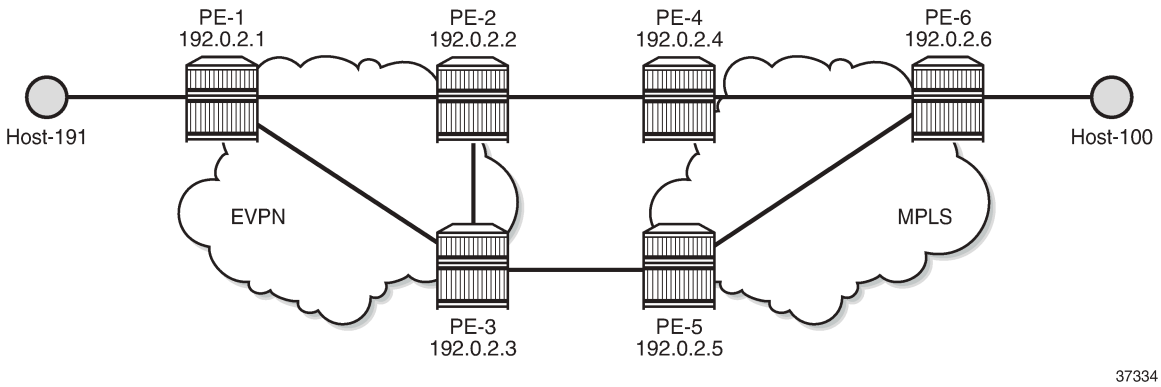
1. The host initiates an unsolicited Neighbor Advertisement (NA).
2. The host sends traffic, without first initiating NA or NS messages.
3. The host does not send any traffic, and the source PE generates an NS message when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-66 from source PE-2 to target PE-3 is simulated.

Configuration

Figure 199: Example topology with system IP addresses shows the example topology with PE-1, PE-2, and PE-3 in an EVPN-MPLS network and PE-4, PE-5, and PE-6 in an MPLS network.

Figure 199: Example topology with system IP addresses



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- LDP between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- BGP configured for the EVPN address family on PE-1, PE-2, and PE-3

On PE-1, BGP is configured as follows:

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            vpn-apply-import
            vpn-apply-export
            rapid-withdrawal
            rapid-update evpn
            group "dc"
                type internal
```

```
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
        exit
```

The BGP configuration is similar on PE-2 and PE-3.

IPv4 host mobility

The following use cases for IPv4 host mobility are described:

1. Host initiates ARP request or GARP after moving
2. Host initiates non-ARP traffic after moving
3. Host does not send any traffic after moving

IPv4 host mobility case 1: host initiates ARP request or GARP after moving

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure
    service
        vpls 15 name "sbd-15" customer 1 create
            description "R-VPLS 15"
            allow-ip-int-bind
            exit
            bgp
                route-distinguisher 192.0.2.1:15
            exit
            bgp-evpn
                ip-route-advertisement
                evi 15
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
        vprn 16 name "ip-vrf-16" customer 1 create
            interface "evi-15" create
                mac 00:00:00:00:00:01
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-20" create
                address 10.0.20.1/24
                mac 00:00:00:00:1e:20
                vpls "evi-20"
                exit
```

```
            exit
            no shutdown
        exit
        vpls 20 name "evi-20" customer 1 create
            description "R-VPLS 20"
            allow-ip-int-bind
            exit
            sap pxc-10.a:20 create
                no shutdown
            exit
            no shutdown
        exit
```

VPRN "ip-vrf-16" has two interfaces: interface "evi-15" toward R-VPLS "sbd-15" and interface "evi-20" toward R-VPLS "evi-20". Host-191 is connected to interface "evi-20" of R-VPLS "evi-20".

PE-2 and PE-3 are configured with an anycast gateway, that is, a VRRP passive instance with the same backup IP address 10.0.0.254 on interface "evi-17" in VPRN "ip-vrf-16". The MAC address under VRRP is by default derived from the Virtual Router ID (VRID), so both PE-2 and PE-3 get MAC address 00:00:5E:00:01:01. The service configuration on PE-2 and PE-3 is similar.

```
# on PE-2:
configure
    service
         vpls 15 name "sbd-15" customer 1 create
            description "R-VPLS 15"
            allow-ip-int-bind
            exit
            bgp
                route-distinguisher 192.0.2.2:15                # on PE-3: 192.0.2.3:15
            exit
            bgp-evpn
                ip-route-advertisement

            stp
                shutdown
            exit
            sap 1/1/1:17 create                                         # on PE-3: sap 1/1/2:17
                no shutdown
            exit
            no shutdown
        exit
```

The **arp-host-route>populate dynamic** ensures that route-table ARP-ND host routes are created for dynamic entries, not for static or EVPN entries. The **no learn-dynamic** command prevents PE-2 and PE-3 from learning ARP entries from ARP messages received on an EVPN destination. The **no flood-garp-and-unknown-req** command suppresses CPM-generated ARP to reduce unnecessary ARP flooding.

In this sample topology, an Epipe is used where a failover from the primary to the secondary path simulates a move of host-100 from PE-2 to PE-3. SAP 1/1/1:17 in R-VPLS "evi-17" on PE-2 is connected to a SAP of Epipe 17 on PE-4; SAP 1/1/2:17 in R-VPLS "evi-17" on PE-3 to a SAP of Epipe 17 on PE-5. The service configuration on PE-4 is as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure
    service
        oper-group "op-grp-1" create
        exit
        sdp 46 mpls create                                              # on PE-5: sdp 56
            far-end 192.0.2.6
            ldp
            keep-alive
```

```
                shutdown
            exit
            no shutdown
        exit
        epipe 17 name "Epipe 17" customer 1 create
            sap 1/1/2:17 create                                    # on PE-5: sap 1/1/1:17
                description "SAP connected to SAP 1/1/1:17 on PE-2"
                monitor-oper-group "op-grp-1"
                no shutdown
            exit
            spoke-sdp 46:17 create                                 # on PE-5: spoke-sdp 56:17
                oper-group "op-grp-1"
                no shutdown
            exit
            no shutdown
        exit
```

On PE-6, the service configuration is as follows:

```
# on PE-6:
configure
    service
        sdp 64 mpls create
            far-end 192.0.2.4
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        sdp 65 mpls create
            far-end 192.0.2.5
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 17 name "Epipe 17" customer 1 create
            endpoint "EP17" create
            exit
            sap 1/2/1:17 create                                    # toward host-100
                no shutdown
            exit
            spoke-sdp 64:17 endpoint "EP17" create
                precedence primary
                no shutdown
            exit
            spoke-sdp 65:17 endpoint "EP17" create
                no shutdown
            exit
            no shutdown
        exit
```

Host-100 is connected to SAP 1/2/1:17 in Epipe 17.

On PE-2 and PE-3, debugging is enabled:

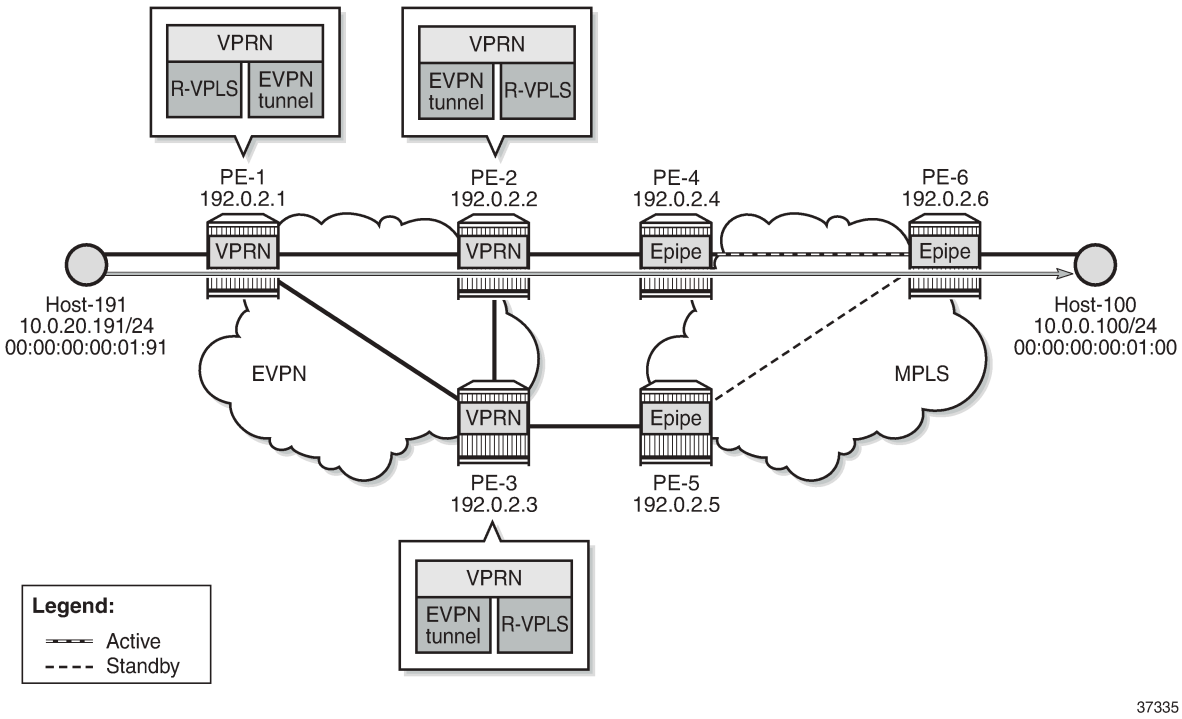
```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
```

```
        exit
    exit
    router service-name "ip-vrf-16"
        ip
            arp
            route-table
        exit
    exit
exit
```

Initial phase

Figure 200: Initial situation with forwarding path via PE-2 shows that traffic from host-191 to host-100 is forwarded via PE-1, PE-2, PE-4, and PE-6.

Figure 200: Initial situation with forwarding path via PE-2



Host-191 sends a traceroute to host-100 via PE-2 (10.0.0.2):

```
*A:PE-1# traceroute router 19 10.0.0.100 source 10.0.20.191
traceroute to 10.0.0.100 from 10.0.20.191, 30 hops max, 40 byte packets
  1  10.0.20.1 (10.0.20.1)    2.34 ms  2.35 ms  2.27 ms
  2  10.0.0.2 (10.0.0.2)    3.37 ms  3.29 ms  3.14 ms
  3  10.0.0.100 (10.0.0.100)    5.90 ms  5.28 ms  5.46 ms
```

The ARP table for VPRN "ip-vrf-16" on PE-2 shows that IP address 10.0.0.100 corresponds to MAC address 00:00:00:00:01:00 and is learned dynamically:

```
*A:PE-2# show router 16 arp 10.0.0.100
```

```
===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h04m49s Dyn[I] evi-17
===============================================================================
```

The ARP table for VPRN "ip-vrf-16" on PE-3 shows that IP address 10.0.0.100 is advertised through EVPN:

```
*A:PE-3# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

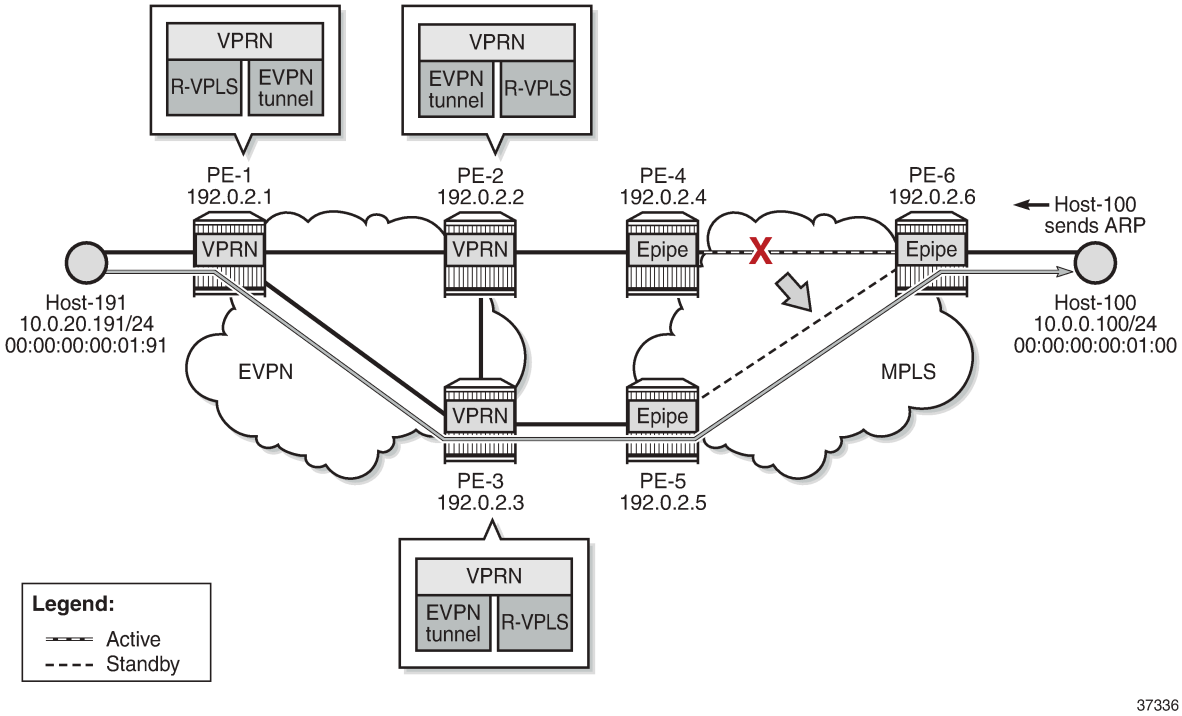
PE-3 receives the IP and MAC addresses of host-100 as EVPN type. PE-3 must not learn these IP and MAC addresses as dynamic because PE-3 must be prevented from advertising an RT5 route. If PE-3 advertised prefix 10.0.0.100, then PE-1 could select PE-3 as next hop to reach host-100, causing an undesired hairpinning forwarding behavior.

Host-100 sends an ARP request or GARP after moving

Figure 201: Host-100 sends an ARP request or GARP after switchover shows a switchover from the active to the standby path where host-100 sends an ARP request or GARP and its IP and MAC addresses are learned on PE-3 instead of PE-2. The failure is simulated by disabling the SDP from PE-4 to PE-6.

Figure 201: Host-100 sends an ARP request or GARP after switchover



Due to the SDP failure on PE-4, the initial path can no longer be used. Host-100 sends an ARP request or GARP with its IP and MAC addresses. In the following example, PE-3 receives the following ARP request and replies to it:

```
1 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),

===============================================================================
```

On PE-3, the ARP table for VPRN "ip-vrf-16" shows that IP address 10.0.0.100 is learned dynamically on interface "evi-17":

```
*A:PE-3# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h04m40s Dyn[I] evi-17
===============================================================================
```

On PE-2, the ARP table for VPRN "ip-vrf-16" shows that the entry for IP address 10.0.0.100 is updated from dynamic to type EVPN:

```
*A:PE-2# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h00m00s Evp[I] evi-17
===============================================================================
```

An ARP entry's change from dynamic to EVPN triggers a CPM-generated ARP request from PE-2, but the configured **no flood-garp-and-unknown-req** command prevents PE-2 from flooding the ARP request to EVPN destinations such as PE-3.

On PE-3, the route table for VPRN "ip-vrf-16" shows an ARP-ND host route for prefix 10.0.0.100:

```
*A:PE-3# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
```

```
-------------------------------------------------------------------------------
10.0.0.100/32                                 Remote  ARP-ND    00h01m32s  1
       10.0.0.100                                                    0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The route table for VPRN "ip-vrf-16" for prefix 10.0.0.100 shows that PE-2 removed its ARP-ND host route and the received EVPN route from PE-3 is used instead:

```
*A:PE-2# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv4 host mobility case 2: host sends traffic without first initiating an ARP request or GARP after moving

In use cases 2 and 3, the configuration of VPRN "ip-vrf-16" is modified on PE-2 and PE-3. The only difference from case 1 is that the **flood-garp-and-unknown-req** is configured, which is the default setting. The VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vprn 16 name "ip-vrf-16" customer 1 create
            interface "evi-15" create
                mac 00:00:00:00:00:02                          # on PE-3: 00:00:00:00:00:03
                vpls "sbd-15"
                    evpn-tunnel
                exit
            exit
            interface "evi-17" create
                address 10.0.0.2/24
                mac 00:00:00:00:2f:17
                arp-host-route
                    populate dynamic
                exit
                arp-timeout 300
                arp-learn-unsolicited
                arp-proactive-refresh
                vrrp 1 passive
```

```
                    backup 10.0.0.254
                    ping-reply
                    traceroute-reply
                exit
                local-proxy-arp
                vpls "evi-17"
                    evpn
                        arp
                            no learn-dynamic
                            flood-garp-and-unknown-req           # default
                            advertise dynamic
                        exit
                    exit
                exit
            exit
            no shutdown
```

Initial forwarding path

The initial forwarding path via PE-2 is restored by enabling the SDP from PE-4 to PE-6. The route table for VPRN "ip-vrf-16" on PE-2 shows the following ARP-ND host route for prefix 10.0.0.100/32:

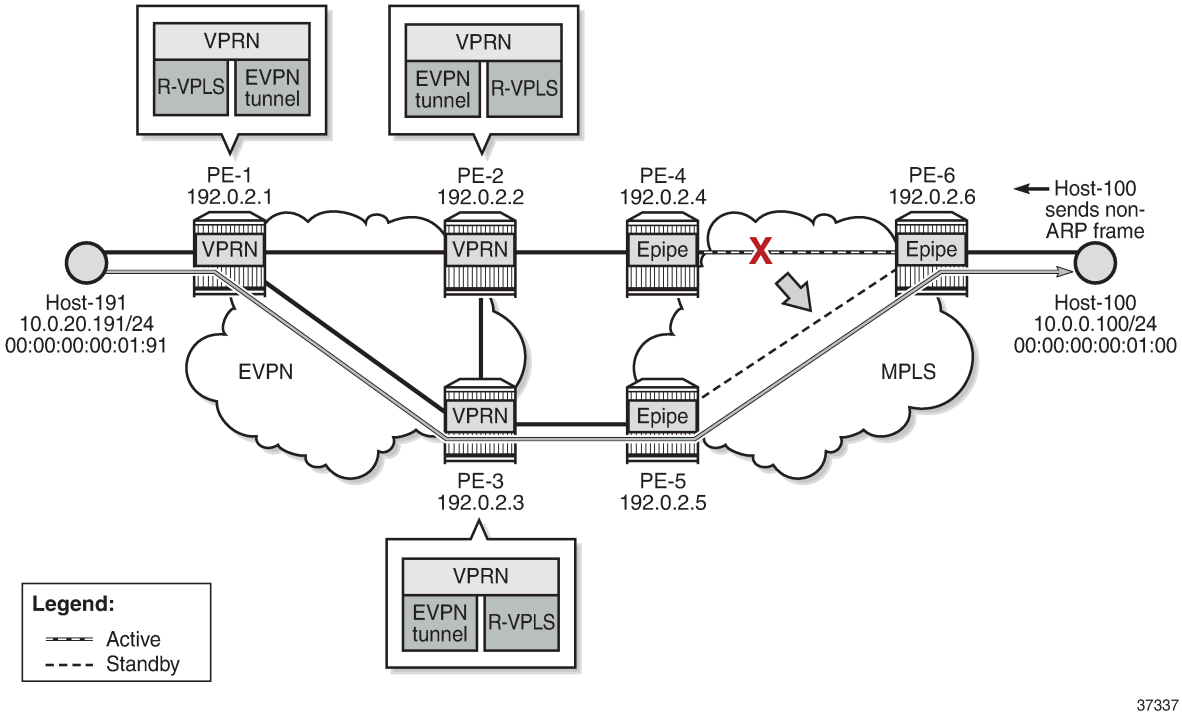
```
*A:PE-2# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.100/32                                 Remote  ARP-ND    00h03m46s  1
       10.0.0.100                                                 0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Host-100 generates non-ARP traffic after moving

On PE-4, the SDP from PE-4 to PE-6 is disabled, causing a switchover to the standby path. Figure 202: Host sends non-ARP frame after switchover shows the path after switchover. Host-100 generates non-ARP traffic after moving.

Figure 202: Host sends non-ARP frame after switchover



Host-100 sends a non-ARP frame with MAC source address 00:00:00:00:01:00 to host-191. The following steps occur:

1. PE-3 receives this frame with MAC 00:00:00:00:01:00 and updates its FDB.
2. PE-3 advertises an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address) with a higher sequence number.
3. PE-2 receives this EVPN MAC route, updates its FDB and withdraws its EVPN-MAC routes for MAC 00:00:00:00:01:00.
4. The FDB update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for MAC 00:00:00:00:01:00.
5. PE-2 is configured with **flood-garp-and-unknown-req**, so the ARP request is flooded to the EVPN destinations PE-1 and PE-3. PE-3 floods this ARP request to its SAPs and SDP-bindings; in this case, to SAP 1/1/2:17.
6. When the ARP request reaches host-100, it sends an ARP reply to the anycast IP address 10.0.0.254. This ARP reply is received by PE-3.
7. When PE-3 receives the ARP reply, it updates the ARP entry for 10.0.0.100 to type dynamic instead of type EVPN.
8. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. Also, MAC 00:00:00:00:01:00 is now learned in ARP as local, so PE-3 sends an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100.

9. PE-2 receives the EVPN routes and updates the ARP entry for prefix 10.0.0.100 from type dynamic to type EVPN. PE-2 also removes its ARP-ND host route from the route table and withdraws its RT5 for prefix 10.0.0.100/32.

On PE-3, the route for prefix 10.0.0.100/32 is an ARP-ND host route:

```
*A:PE-3# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.0.0.100/32                                   Remote  ARP-ND    00h01m05s  1
       10.0.0.100                                                      0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv4 host mobility case 3: host does not send any traffic after moving

The service configuration on PE-2 and PE-3 remains the same as in use case 2.

The forwarding path is restored by enabling the SDP from PE-4 to PE-6, so the initial situation is the same as in the preceding cases. PE-2 learns MAC address 00:00:00:00:01:00 on its local SAP 1/1/1:17, as follows:

```
*A:PE-2# show service id 17 fdb detail

===============================================================================
Forwarding Database, Service 17
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

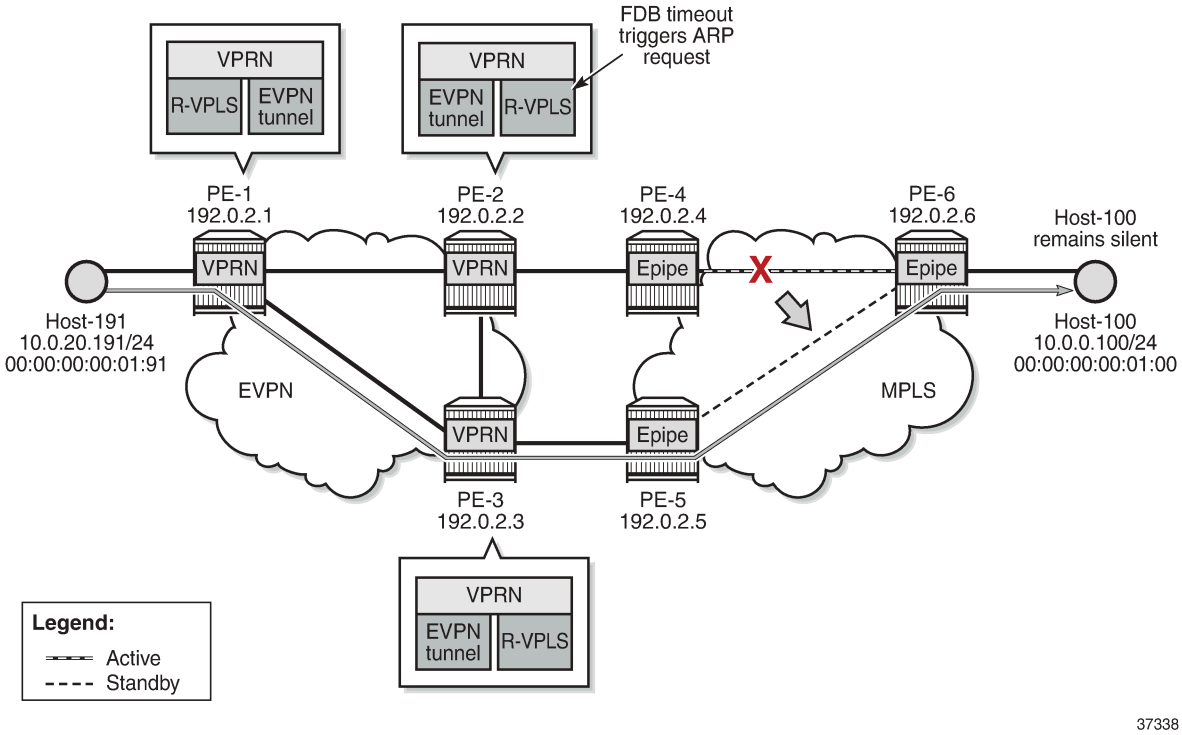
===============================================================================
```

The SDP from PE-4 to PE-6 is disabled and host-100 does not send any traffic, as shown in Figure 203: Host does not send any traffic after switchover.

Figure 203: Host does not send any traffic after switchover



The following steps occur:

1. When MAC 00:00:00:00:01:00 ages out in the FDB of R-VPLS 17 on PE-2, PE-2 withdraws the EVPN-MAC routes for MAC 00:00:00:00:01:00. The update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for 10.0.0.100.

```
# on PE-2:
99 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP egressing on evi-17
   Who has 10.0.0.100 ? Tell 10.0.0.254
"
```

```
101 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

                       mac: 00:00:00:00:01:00, IP len: 0, IP: NULL, label1: 0
"
```

2. PE-2 is configured with **flood-garp-and-unknown-req**. PE-2 floods the CPM-generated ARP request to PE-3. PE-3 forwards the ARP request to host-100.
3. Host-100 sends an ARP reply that is received by PE-3. PE-3 updates its FDB and ARP tables.

4. The FDB update on PE-3 makes PE-3 advertise an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address). The ARP update makes PE-3 advertise an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100. PE-2 receives two EVPN-MAC routes from PE-3:

```
103 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

6. PE-2 receives the EVPN routes and updates its FDB and ARP tables. When the ARP entry changes its type from dynamic to EVPN, PE-2 withdraws its RT5 route.

On PE-2, the FDB for R-VPLS 17 shows an EVPN route for MAC 00:00:00:00:01:00:

```

IPv6 host mobility

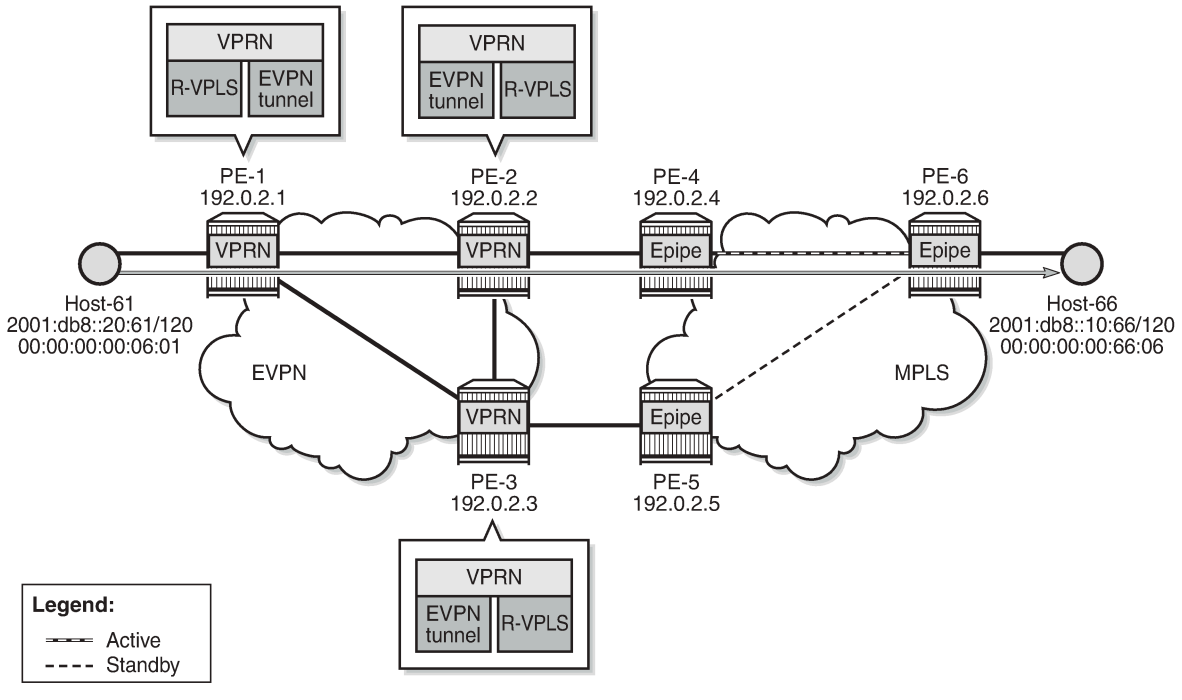
The following use cases for IPv6 host mobility are described:

1. Host initiates an unsolicited NA message after moving
2. Host sends non-ND traffic after moving
3. Host does not send any traffic after moving

The configuration is identical in these use cases.

Figure 204: Example topology for initial forwarding path via PE-2 with IPv6 addresses shows the topology with IPv6 addresses for host-61 and host-66.

Figure 204: Example topology for initial forwarding path via PE-2 with IPv6 addresses



The services are the following:

- R-VPLS "sbd-5" on PE-1, PE-2, and PE-3
- VPRN "ip-vrf-6" on PE-1, PE-2, and PE-3
- R-VPLS "evi-10" on PE-1; R-VPLS "evi-7" on PE-2 and PE-3
- Epipe "Epipe 7" on PE-4, PE-5, and PE-6
- Host-61 is connected to R-VPLS "evi-10" on PE-1
- Host-66 is connected to Epipe "Epipe 7" on PE-6

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure
    service
        vpls 5 name "sbd-5" customer 1 create
            description "R-VPLS 5"
            allow-ip-int-bind
            exit
            bgp
                route-distinguisher 192.0.2.1:5
            exit
            bgp-evpn
                ip-route-advertisement
                evi 5
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
        vprn 6 name "ip-vrf-6" customer 1 create
            interface "evi-5" create
                mac 00:00:00:00:06:01
                ipv6
                exit
                vpls "sbd-5"
                    evpn-tunnel
                exit
            exit
            interface "evi-10" create
                mac 00:00:00:06:1e:20
                ipv6
                    address 2001:db8::20:1/120
                exit
                vpls "evi-10"
                exit
            exit
            no shutdown
        exit
        vpls 10 name "evi-10" customer 1 create
            description "R-VPLS 10"
            allow-ip-int-bind
            exit
            stp
                shutdown
            exit
```

```
            sap pxc-10.a:10 create
                no shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-2 is as follows. The service configuration on PE-3 is similar.

```
# on PE-2:
configure
    service
        vpls 5 name "sbd-5" customer 1 create
            description "R-VPLS 5"
            allow-ip-int-bind
            exit
            bgp
                route-distinguisher 192.0.2.2:5                 # on PE-3: 192.0.2.3:5
            exit
            bgp-evpn
                ip-route-advertisement
                evi 5
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit

                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/1/1:7 create                                  # on PE-3: sap 1/1/2:7
            no shutdown
        exit
        no shutdown
    exit
```

Debugging is enabled on PE-2 and PE-3:

```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-6"
        ip
            route-table
            icmp6 "evi-7"
            neighbor "evi-7"
        exit
    exit
exit
```

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
*A:PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    8.86 ms  3.79 ms  4.00 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.5 ms  5.45 ms  5.52 ms
```

The following route table on PE-2 shows an ARP-ND host route for prefix 2001:db8::10:66/128:

```
*A:PE-2# show router 6 route-table 2001:db8::10:66
```

```
===============================================================================

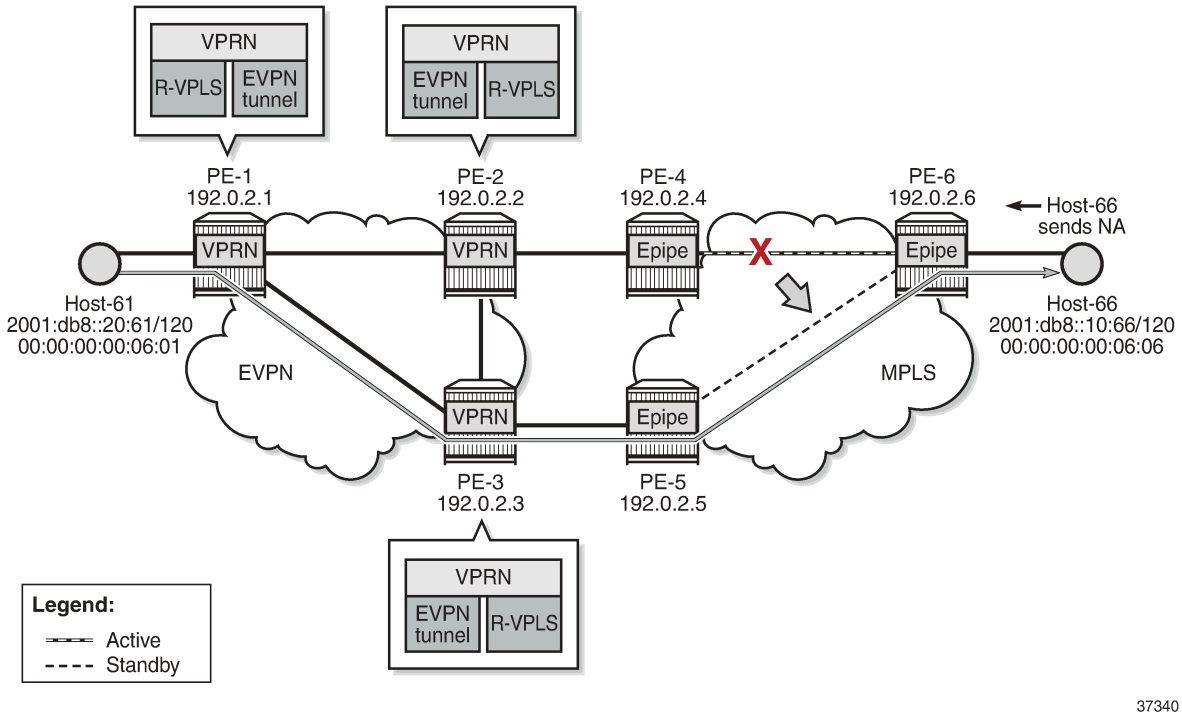
```

IPv6 host mobility case 1: host initiates an unsolicited NA message after moving

On PE-2 and PE-3, the **nd-learn-unsolicited** command is configured on interface "evi-7" in VPRN "ip-vrf-6". When an unsolicited NA message is received, a stale neighbor is created. If **nd-host-route>populate dynamic** is enabled, a confirmation message is sent for all the neighbor entries created as stale, and if confirmed, the corresponding ARP-ND routes are added to the route table.

Disabling SDP 46 on PE-4 causes a failover from the primary path via PE-4 to the secondary path via PE-5, simulating host-66 moving from PE-2 to PE-3. To trigger an unsolicited NA message from host-66, its MAC address 00:00:00:00:66:06 is replaced by MAC address 00:00:00:00:06:06. Figure 205: Host-66 sends unsolicited NA message after switchover shows that host-66 sends an unsolicited NA message.

Figure 205: Host-66 sends unsolicited NA message after switchover



Host-66 advertises its new MAC address in unsolicited NA messages. PE-3 receives the following NA messages from host-66. PE-2 also receives the NA messages, but it rejects NA messages received on interface "evi-7" when **no learn-dynamic** is configured:

```
3 2022/01/28 13:19:55.747 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: ICMP6_PKT
ICMP6 ingressing on evi-7 (vprn6):
   fe80::10:6 -> ff02::1
   Type: Neighbor Advertisement (136)
   Code: No Code (0)
      Tgt Addr: 2001:db8::10:66
      Flags   : Router Override
      Option  : Tgt Link Layer Addr 00:00:00:00:06:06
"
```

```
1 2022/01/28 13:19:55.747 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: ICMP6_PKT
ICMP6 ingressing on evi-7 (vprn6):
   fe80::10:6 -> ff02::1
   Type: Neighbor Advertisement (136)
   Code: No Code (0)
      Tgt Addr: fe80::10:6
      Flags   : Router Override
      Option  : Tgt Link Layer Addr 00:00:00:00:06:06
"
```

PE-3 learns the MAC address dynamically:

```
*A:PE-3# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================
Forwarding Database, Service 7
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
7          00:00:00:00:06:06 sap:1/1/2:7             L/90     01/28/22 13:19:56
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

PE-3 sends CPM-generated NS messages that are also flooded to the EVPN destinations. The **no learn-dynamic** command prevents PE-2 from learning MAC addresses dynamically on an EVPN connection.

PE-3 sends an EVPN-MAC update to PE-2 and MAC address 00:00:00:00:06:06 appears in the FDB on PE-2 as an EVPN entry:

```
*A:PE-2# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================
Forwarding Database, Service 7

-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv6 host mobility case 2: host sends non-ND traffic after moving,

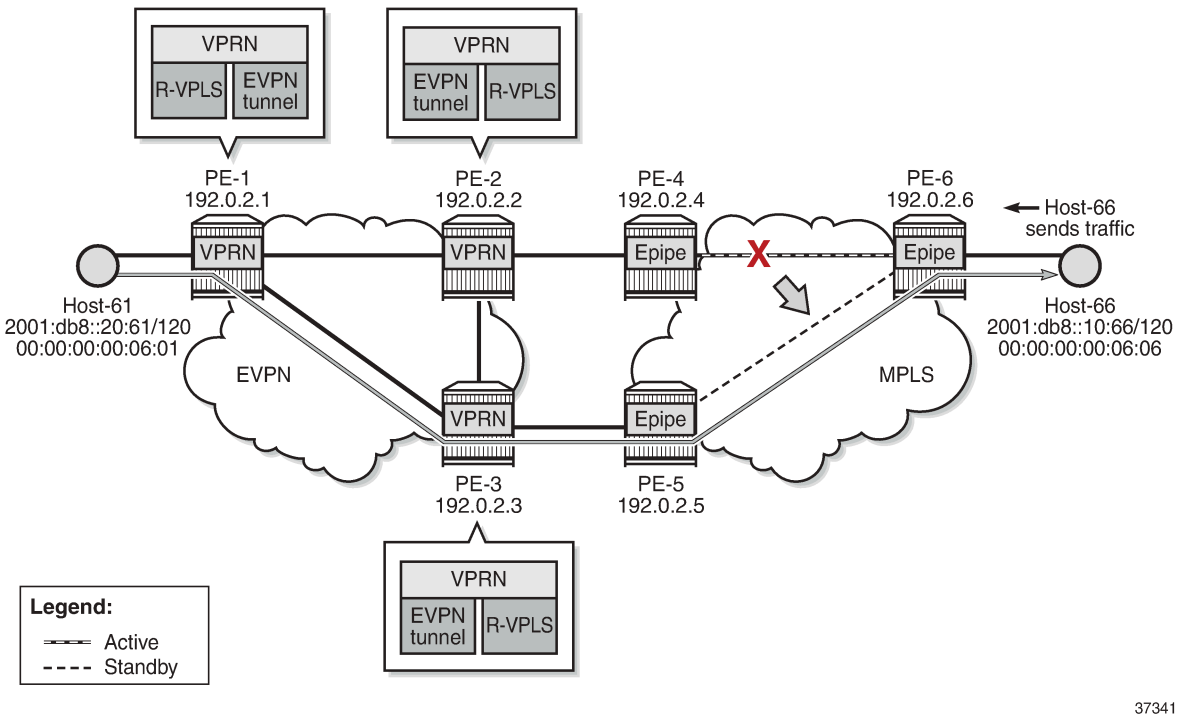
The service configuration is the same as in the use case 1. The only difference from use case 1 is the type of message that is sent by host-66 after moving.

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
*A:PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    7.88 ms  3.85 ms  3.67 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.0 ms  5.19 ms  5.30 ms
```

A switchover from the primary path to the secondary path takes place, so host-66 moves from PE-2 to PE-3. Figure 206: Host generates non-ND traffic after switchover shows that host-66 sends non-ND traffic after moving.

Figure 206: Host generates non-ND traffic after switchover



The traceroute from host-66 to host-61 is via PE-3 (2001:db8::10:3) instead of PE-2, as follows:

```
*A:PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:3 (2001:db8::10:3)    4.16 ms  4.11 ms  4.01 ms
  2  ::  * * *

IPv6 host mobility case 3: host does not send any traffic after moving

The service configuration is the same as use cases 1 and 2. SDP 46 is enabled on PE-4, so host-66 moves back to PE-2. The following traceroute shows that the forwarding path from host-66 to host-61 is via PE-2:

```
*A:PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    3.76 ms  4.23 ms  4.00 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    5.89 ms  5.40 ms  5.61 ms
```

The FDB on PE-2 shows that MAC address 00:00:00:00:06:06 is learned on the local SAP 1/1/1:7, as follows:

```
*A:PE-2# show service id 7 fdb detail

===============================================================================
Forwarding Database, Service 7

===============================================================================
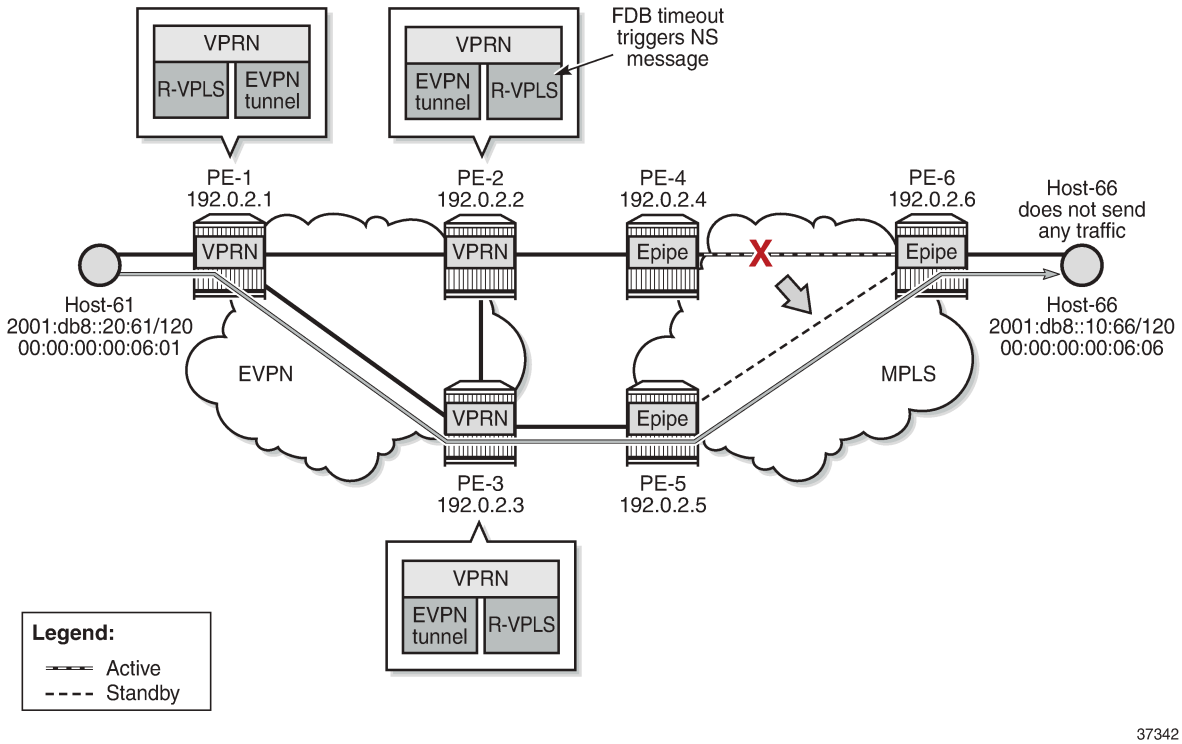
```

A failure is simulated, causing a failover from the primary path via PE-4 to the secondary path via PE-5. Host-66 does not send any traffic after switchover. Figure 207: Host does not send any traffic after switchover shows that PE-2 sends an NS message when the FDB entry for host-66 ages out.

Figure 207: Host does not send any traffic after switchover



On PE-2, MAC address 00:00:00:00:06:06 expires in the FDB for R-VPLS "evi-7", which triggers PE-2 to send an NS message for 2001:db8::10:66. This CPM-generated NS message is flooded to the EVPN destinations PE-1 and PE-3.

```
# on PE-2:
202 2022/01/28 13:37:34.634 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Sending NS for nbr addr 2001:db8::10:66 nbr type dynamic"
```

The NS message reaches host-66, which replies with an NA message. PE-3 receives the NA message and updates its FDB and ND tables. PE-2 also receives the NA message, but it rejects NA messages received on interface "evi-7" when no learn-dynamic is configured:

```
225 2022/01/28 13:37:34.638 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Ignore NA for target address 2001:db8::10:66 on evpn endpoint evi-7 because learn-dynamic is
 disabled."
```

PE-2 receives the following EVPN-MAC routes from PE-3:

```
237 2022/01/28 13:43:03.001 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

```

Conclusion

EVPN host mobility is supported in SR OS as described in draft-ietf-bess-evpn-inter-subnet-forwarding. This chapter describes several cases when a host moves from a source PE to a target PE within the same broadcast domain.

Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire

This chapter provides information about multi-chassis endpoint for VPLS active/standby pseudowire.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 7.0.R6, but the CLI in this edition is based on SR OS Release 19.5.R2.

Overview

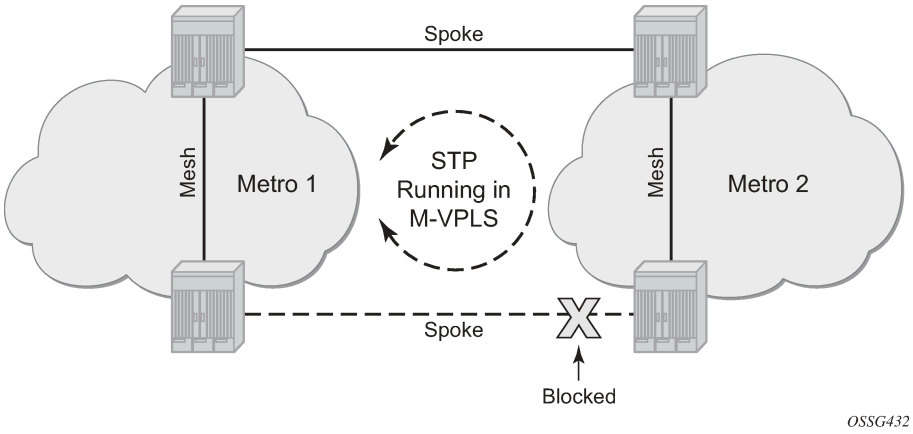
When implementing a large VPLS, one of the limiting factors is the number of T-LDP sessions required for the full mesh of SDPs. Mesh-SDPs are required between all PEs participating in the VPLS with a full mesh of T-LDP sessions.

This solution is not scalable, because the number of sessions grows more rapidly than the number of participating PEs. Several options exist to reduce the number of T-LDP sessions required in a large VPLS.

The first option is hierarchical VPLS (H-VPLS) with spoke-SDPs. By using spoke-SDPs between two clouds of fully meshed PEs, any-to-any T-LDP sessions for all participating PEs are not required.

However, if spoke-SDP redundancy is required, STP must be used to avoid a loop in the VPLS. Management VPLS can be used to reduce the number of STP instances and separate customer and STP traffic (Figure 208: H-VPLS with STP).

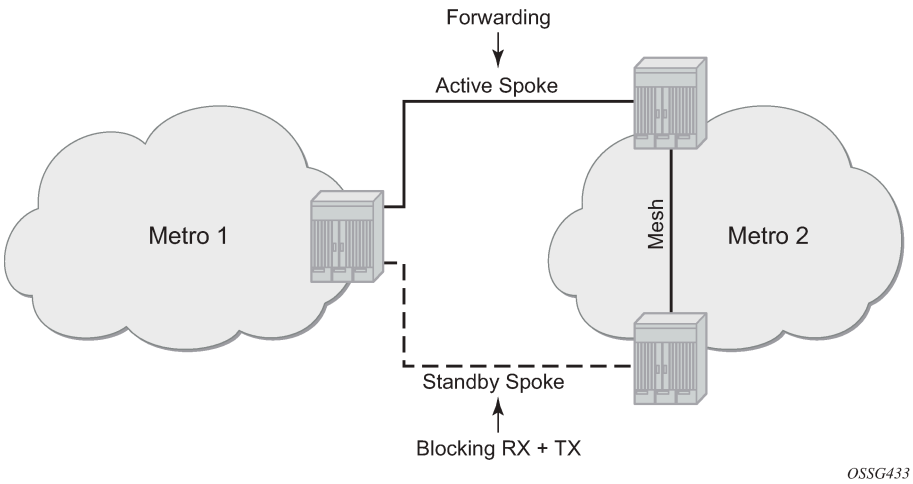
Figure 208: H-VPLS with STP



VPLS pseudowire redundancy provides H-VPLS redundant spoke connectivity. The active spoke is in forwarding state, while the standby spoke is in blocking state. Therefore, STP is not needed anymore to break the loop, as illustrated in Figure 209: VPLS pseudowire redundancy.

However, the PE implementing the active and standby spokes represents a single point of failure in the network.

Figure 209: VPLS pseudowire redundancy

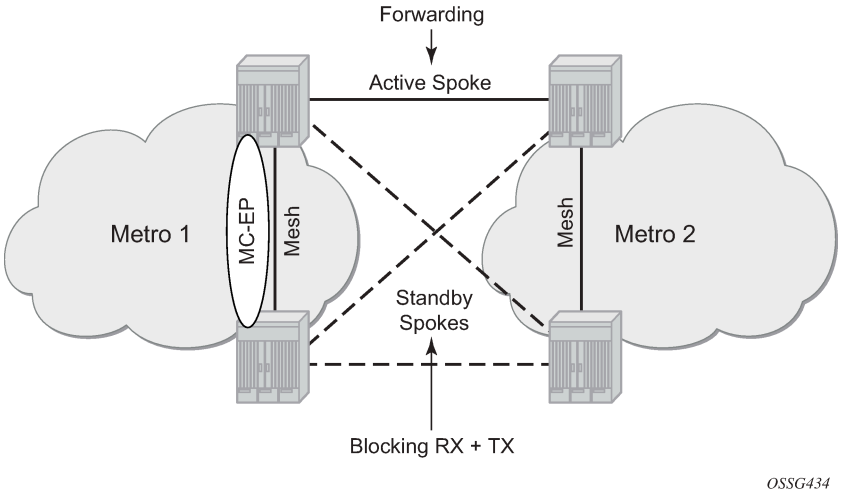


Multi-chassis endpoint (MC-EP) for VPLS active/standby pseudowire expands on the VPLS pseudowire redundancy and allows the removal of the single point of failure.

Only one spoke-SDP is in forwarding state; all standby spoke-SDPs are in blocking state. Mesh and square resiliency are supported.

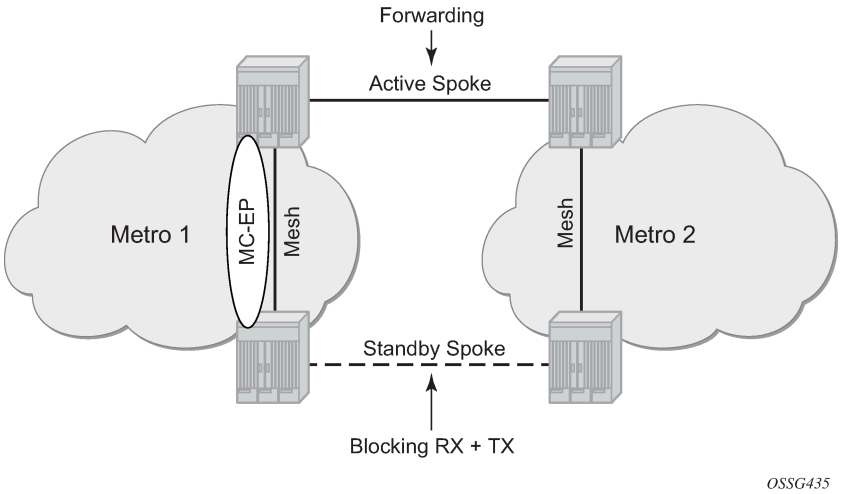
Mesh resiliency can protect against simultaneous node failure in the core and in the MC-EP (double failure), but requires more SDPs (and therefore more T-LDP sessions). Mesh resiliency is illustrated in Figure 210: Multi-chassis endpoint with mesh resiliency.

Figure 210: Multi-chassis endpoint with mesh resiliency



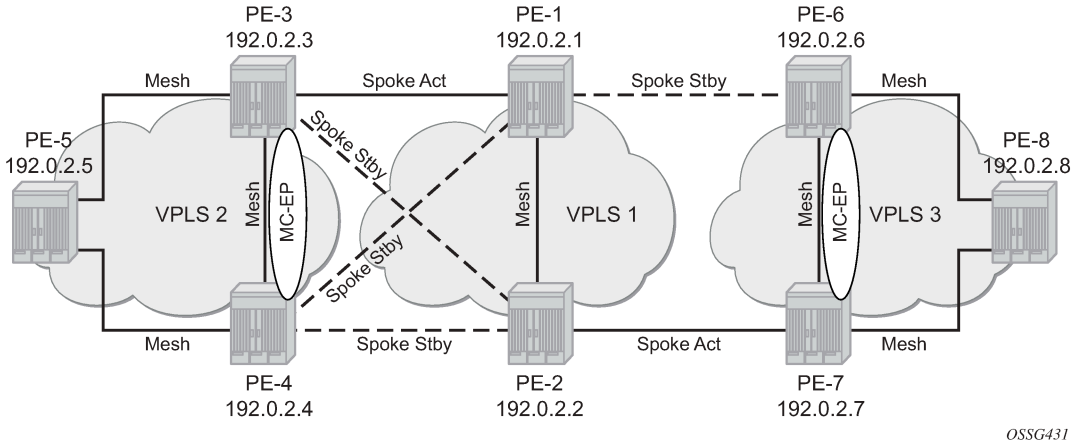
Square resiliency provides single failure node protection, and requires less SDPs (and thus less T-LDP sessions). Square resiliency is illustrated in Figure 211: Multi-chassis endpoint with square resiliency.

Figure 211: Multi-chassis endpoint with square resiliency



Example topology

Figure 212: Example topology



The network topology is displayed in Figure 212: Example topology.

The setup consists of:

- Two core nodes (PE-1 and PE-2), and three nodes for each metro area (PE-3, PE-4, PE-5 and PE-6, PE-7, PE-8, respectively).
- VPLS 1 is the core VPLS, used to interconnect the two metro areas represented by VPLS 2 and VPLS 3.
- VPLS 2 will be connected to the core VPLS in mesh resiliency.
- VPLS 3 will be connected to the core VPLS in square resiliency.

Three separate VPLS identifiers are used for clarity. However, the same identifier could be used for each. For interoperation, only the same VC-ID is required to be used on both ends of the spoke-SDPs.

The following configuration tasks should be done first:

- IS-IS or OSPF throughout the network.
- RSVP or LDP-signaled LSPs over the paths used for mesh/spoke-SDPs.

Configuration

SDP configuration

On each PE, SDPs are created to match the topology described in Figure 212: Example topology.

The convention for the SDP naming is: XY where X is the originating node and Y the target node.

An example of the SDP configuration in PE-3 (using LDP):

```
# on PE-3:
configure
    service
        sdp 31 mpls create
            far-end 192.0.2.1
            ldp
            no shutdown
        exit
        sdp 32 mpls create
            far-end 192.0.2.2
            ldp
            no shutdown
        exit
        sdp 34 mpls create
            far-end 192.0.2.4
            ldp
            no shutdown
        exit
        sdp 35 mpls create
            far-end 192.0.2.5
            ldp
            no shutdown
        exit
```

Verification of the SDPs on PE-3:

```
*A:PE-3# show service sdp

===============================================================================

===============================================================================
```

Full mesh VPLS configuration

Next, three fully meshed VPLS services are configured.

- VPLS 1 is the core VPLS, on PE-1 and PE-2
- VPLS 2 is the metro 1 VPLS, on PE-3, PE-4 and PE-5
- VPLS 3 is the metro 2 VPLS, on PE-6, PE-7 and PE-8

On PE-1 (similar configuration on PE-2):

```
# on PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            description "core VPLS"
            mesh-sdp 12:1 create
            exit
            no shutdown
        exit
```

On PE-3 (similar configuration on PE-4 and PE-5):

```
# on PE-3:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            description "Metro 1 VPLS"
            mesh-sdp 34:2 create
            exit
            mesh-sdp 35:2 create
            exit
            no shutdown
        exit
```

On PE-6 (similar configuration on PE-7 and PE-8):

```
configure
    service
        vpls 3 name "VPLS 3" customer 1 create
            description "Metro 2 VPLS"
            mesh-sdp 67:3 create
            exit
            mesh-sdp 68:3 create
            exit
            no shutdown
        exit
```

Verification of the VPLS:

- The service must be operationally up.
- All mesh-SDPs must be up in the VPLS service.

On PE-6 (similar on other nodes):

```
*A:PE-6# show service id 3 base

```

Multi-chassis configuration

Multi-chassis will be configured on the MC peers PE-3, PE-4 and PE-6, PE-7. The peer system address is configured, and **mc-endpoint** will be enabled.

On PE-3 (similar configuration on PE-4, PE-6, and PE-7):

```
configure
    redundancy
        multi-chassis
            peer 192.0.2.4 create
                mc-endpoint
                    no shutdown
                exit
                no shutdown
            exit
```

Verification of the multi-chassis synchronization (MCS):

If the MCS fails, both nodes will fall back to single-chassis mode. In that case, two spoke-SDPs could become active at the same time. It is important to verify the MCS before enabling the redundant spoke-SDPs.

```
*A:PE-3# show redundancy multi-chassis mc-endpoint peer 192.0.2.4

===============================================================================
Multi-Chassis MC-Endpoint
===============================================================================

===============================================================================
```

Mesh resiliency configuration

PE-3 and PE-4 will be connected to the core VPLS in mesh resiliency.

- First an endpoint is configured.
- The **no suppress-standby-signaling** is needed to block the standby spoke-SDP.
- The multi-chassis endpoint peer is configured. The mc-endpoint ID must match between the two peers.

On PE-3 (similar on PE-4):

```
configure
    service
        vpls 2
            endpoint "CORE" create
            no suppress-standby-signaling
            mc-endpoint 1
                mc-ep-peer 192.0.2.4
            exit
        exit
```

After this configuration, the MP-EP count in the preceding show command changes to 1, as follows:

```
*A:PE-3# show redundancy multi-chassis mc-endpoint peer 192.0.2.4

===============================================================================
Multi-Chassis MC-Endpoint
===============================================================================
Peer Addr       : 192.0.2.4           Peer Name            :
Admin State     : up                  Oper State           : up
Last State chg  :                     Source Addr          :
System Id       : 04:0d:ff:00:00:00   Sys Priority         : 0
Keep Alive Intvl: 10                  Hold on Nbr Fail     : 3

===============================================================================
```

Two spoke-SDPs are configured on each peer of the multi-chassis to the two nodes of the core VPLS (mesh resiliency). Each spoke-SDP refers to the endpoint CORE.

The precedence is defined on the spoke-SDPs as follows:

- Spoke-SDP 31 on PE-3 will be active. It is configured as primary (= precedence 0).
- Spoke-SDP 32 on PE-3 will be the first backup. It is configured with precedence 1.
- Spoke-SDP 41 on PE-4 will be the second backup. It is configured with precedence 2.
- Spoke-SDP 42 on PE-4 will be the third backup. It is configured with precedence 3.

On PE-3:

```
configure
    service
        vpls 2
            spoke-sdp 31:1 endpoint "CORE" create
                precedence primary
            exit
            spoke-sdp 32:1 endpoint "CORE" create
                precedence 1
            exit
```

On PE-4:

```
configure
    service
        vpls 2
            spoke-sdp 41:1 endpoint "CORE" create
                precedence 2
            exit
            spoke-sdp 42:1 endpoint "CORE" create
                precedence 3
            exit
```

Verification of the spoke-SDPs:

On PE-3 and PE-4, the spoke-SDPs must be up.

```
*A:PE-3# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================

35:2             Mesh     192.0.2.5       Up      Up        524278    524279
-------------------------------------------------------------------------------
Number of SDPs : 4
-------------------------------------------------------------------------------
===============================================================================
```

The endpoints on PE-3 and PE-4 can be verified. One spoke-SDP is in Tx-Active mode (31 on PE-1 because it is configured as primary).

```
*A:PE-3# show service id 2 endpoint "CORE" | match "Tx Active"
Tx Active (SDP)              : 31:1
```

```
Tx Active Up Time            : 0d 01:16:04
Tx Active Change Count       : 1
Last Tx Active Change        : 06/21/2019 08:10:41
```

There is no active spoke-SDP on PE-4.

```
*A:PE-4# show service id 2 endpoint "CORE" | match "Tx Active"
Tx Active                    : none
Tx Active Up Time            : 0d 00:00:00
Tx Active Change Count       : 0
Last Tx Active Change        : 06/21/2019 07:59:47
```

On PE-1 and PE-2, the spoke-SDPs are operationally up.

```
*A:PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:1             Mesh     192.0.2.2       Up      Up        524279    524279
13:1             Spok     192.0.2.3       Up      Up        524278    524277
14:1             Spok     192.0.2.4       Up      Up        524277    524277
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

However, because pseudowire signaling has been enabled, only one spoke-SDP will be active, the others are set in standby.

On PE-1, spoke-SDP 13:1 is active (no pseudowire bit signaled from peer PE-3) and the spoke-SDP 14:1 is signaled in standby by peer PE-4.

```
*A:PE-1# show service id 1 sdp 13:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : None
*A:PE-1# show service id 1 sdp 14:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

On PE-2, both spoke-SDPs are signaled in standby by peers PE-3 and PE-4.

```
*A:PE-2# show service id 1 sdp 23:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
*A:PE-2# show service id 1 sdp 24:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

There is one active and three standby spoke-SDPs.

Square resiliency configuration

PE-6 and PE-7 will be connected to the core VPLS in square resiliency.

- First an endpoint is configured.
- The **no suppress-standby-signaling** is needed to block the standby spoke-SDP.
- The multi-chassis endpoint peer is configured. The mc-endpoint ID must match between the two peers.

On PE-7 (similar on PE-6):

One spoke-SDP is configured on each peer of the multi-chassis to one node of the core VPLS (square resiliency). Each spoke-SDP refers to the endpoint CORE.

```
# on PE-7:
configure
    service
        vpls 3
            endpoint "CORE" create
                no suppress-standby-signaling
                mc-endpoint 1
                    mc-ep-peer 192.0.2.6
                exit
            exit
        exit
    exit
exit
```

The precedence will be defined on the spoke-SDPs as follows:

- Spoke-SDP 72:1 on PE-7 will be active. It is configured as primary (= precedence 0)
- Spoke-SDP 61:1 on PE-6 will be the first backup with precedence 1.

On PE-7:

```
configure
    service
        vpls 3
            spoke-sdp 72:1 endpoint "CORE" create
                precedence primary
            exit
        exit
    exit
```

On PE-6:

```
configure
    service
        vpls 3
            spoke-sdp 61:1 endpoint "CORE" create
                precedence 1
            exit
        exit
    exit
```

Verification of the spoke-SDPs.

```
*A:PE-7# show service id 3 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
72:1             Spok     192.0.2.2       Up      Up        524277    524276
76:3             Mesh     192.0.2.6       Up      Up        524279    524279
78:3             Mesh     192.0.2.8       Up      Up        524278    524278
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
```

```
===============================================================================
```

On PE-6 and PE-7, the spoke-SDPs must be up.

The endpoints on PE-7 and PE-6 can be verified. One spoke-SDP is in Tx-Active mode (72 on PE-7 because it is configured as primary).

```
*A:PE-7# show service id 3 endpoint | match "Tx Active"
Tx Active (SDP)              : 72:1
Tx Active Up Time            : 0d 00:17:24
Tx Active Change Count       : 1
Last Tx Active Change        : 06/21/2019 08:13:18
```

There are no active spoke-SDP on PE-6.

```
*A:PE-6# show service id 3 endpoint | match "Tx Active"
Tx Active                    : none
Tx Active Up Time            : 0d 00:00:00
Tx Active Change Count       : 2
Last Tx Active Change        : 06/21/2019 08:13:18
```

The output shows that on PE-1, spoke-SDP 16 is signaled with peer in standby mode.

```
*A:PE-1# show service id 1 sdp 16:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

On PE-2, the spoke-SDP 27 is signaled with peer active (no pseudowire bits).

```
*A:PE-2# show service id 1 sdp 27:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : None
```

There is one active and one standby spoke-SDP.

Additional parameters

Multi-chassis

```
*A:PE-3# configure redundancy multi-chassis peer 192.0.2.4 mc-endpoint
  - mc-endpoint
  - no mc-endpoint

 [no] bfd-enable      - Configure BFD
 [no] boot-timer      - Configure boot timer interval
 [no] hold-on-neighb* - Configure hold time applied on neighbor failure
 [no] keep-alive-int* - Configure keep alive interval for this MC-Endpoint
 [no] passive-mode    - Configure passive-mode
 [no] shutdown        - Administratively enable/disable the multi-chassis
                        peer end-point
 [no] system-priority - Configure system priority
```

These parameters will be explained in the following sections.

Peer failure detection

The default mechanism is based on the keep-alive messages exchanged between the peers.

The keep-alive interval is the interval at which keep-alive messages are sent to the MC peer. It is set in tenths of a second from 5 to 500), with a default value of 5.

Hold-on-neighbor failure is the number of keep-alive intervals that the node will wait for a packet from the peer before assuming it has failed. After this interval, the node will revert to single chassis behavior. It can be set from 2 to 25 with a default value of 3.

BFD session

BFD is another peer failure detection mechanism. It can be used to speed up the convergence in case of peer loss.

```
*A:PE-3# configure
    redundancy
        multi-chassis
            peer 192.0.2.4
                mc-endpoint
                    bfd-enable
                exit
            exit
```

It is using the centralized BFD session. BFD must be enabled on the system interface.

```
*A:PE-3# configure
    router
        interface "system"
            address 192.0.2.3/32
            bfd 100 receive 100 multiplier 3
        exit
```

Verification of the BFD session:

```
*A:PE-3# show router bfd session

===============================================================================
Legend:
  Session Id = Interface Name | LSP Name | Prefix | RSVP Sess Name | Service Id

-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
```

Boot timer

The **boot-timer** command specifies the time after a reboot that the node will try to establish a connection with the MC peer before assuming a peer failure. In case of failure, the node will revert to single chassis behavior.

System priority

The system priority influences the selection of the MC master. The lowest priority node will become the master.

In case of equal priorities, the lowest system ID (=chassis MAC address) will become the master.

VPLS endpoint and spoke-SDP

Ignore standby pseudowire bits

```
*A:PE-1# configure service vpls 1 spoke-sdp 14:1
---snip---
[no] ignore-standby* - Ignore 'standby-bit' received from LDP peer
---snip---
```

The peer pseudowire status bits are ignored and traffic is forwarded over the spoke-SDP.

It can speed up convergence for multicast traffic in case of spoke-SDP failure.

Traffic sent over the standby spoke-SDP will be discarded by the peer.

In this topology, if the **ignore-standby-signaling** command is enabled on PE-1, it sends MC traffic to PE-3 and PE-4 (and to PE-6). If PE-3 fails, PE-4 can start forwarding traffic in the VPLS as soon as it detects PE-3 being down. There is no signaling needed between PE-1 and PE-4.

Block-on-mesh failure

```
*A:PE-3# configure service vpls 2 endpoint "CORE"
---snip---
[no] block-on-mesh-* - Block traffic on mesh-SDP failure
---snip---
```

In case a PE loses all the mesh-SDPs of a VPLS, it should block the spoke-SDPs to the core VPLS, and inform the MC-EP peer that can activate one of its spoke-SDPs.

If **block-on-mesh-failure** is enabled, the PE will signal all the pseudowires of the endpoint in standby.

In this topology, if PE3 does not have any valid mesh-SDP to the VPLS 2 mesh, it will set the spoke-SDPs under endpoint CORE in standby.

When **block-on-mesh-failure** is activated under an endpoint, it is automatically set under the spoke-SDPs belonging to this endpoint.

```
*A:PE-3# configure service vpls 2
```

```
*A:PE-3>config>service>vpls# info
----------------------------------------------
            description "Metro 1 VPLS"
            stp
                shutdown
            exit
            endpoint "CORE" create
                no suppress-standby-signaling
                mc-endpoint 1
                    mc-ep-peer 192.0.2.4
                exit
            exit

                exit
                block-on-mesh-failure
                precedence 1
                no shutdown
            exit
```

```
            mesh-sdp 34:2 create
                no shutdown
            exit
            mesh-sdp 35:2 create
                no shutdown
            exit
            no shutdown
-----------------------------------------------
```

Precedence

```
*A:PE-3# configure service vpls 2 spoke-sdp 31:1
---snip---
 [no] precedence      - Configure the spoke-sdp precedence
---snip---
```

The precedence is used to indicate in which order the spoke-SDPs should be used. The value is from 0 to 4 (0 being primary), the lowest having higher priority. The default value is 4.

Revert time

```
*A:PE-3# configure service vpls 2 endpoint "CORE"
---snip---
 [no] revert-time     - Configure the time to wait before reverting to primary spoke-sdp
---snip---
```

If the precedence is equal between the spoke-SDPs, there is no revertive behavior. Changing the precedence of a spoke-SDP will not trigger a revert. The default is **no revert**.

MAC flush parameters

When a spoke-SDP goes from standby to active (due to the active spoke-SDP failure), the node will send a **flush-all-but-mine** message.

After a restoration of the spoke-SDP, a new **flush-all-but-mine** message will be sent.

```
*A:PE-1# configure service vpls 1 propagate-mac-flush
```

A node configured with **propagate MAC flush** will forward the flush messages received on the spoke-SDP to its other mesh/spoke-SDPs.

A node configured with **send flush on failure** will send a **flush-all-from-me** message when one of its SDPs goes down.

```
A:PE-1# configure service vpls 1 send-flush-on-failure
```

Failure scenarios

For the subsequent failure scenarios, the configuration of the nodes is as described in the Configuration section.

Core node failure

When the core node PE-1 fails, the spoke-SDPs from PE-3 and PE-4 go down.

Because the spoke-SDP 31 between PE-3 and PE-4 was active, the MC master (PE-3 in this case) will select the next best spoke-SDP, which will be 32 between PE-3 and PE-2 (precedence 1). See Figure 213: Core Node Failure.

Figure 213: Core Node Failure

Multi-chassis communication failure

If the multi-chassis communication is interrupted, both nodes will revert to single chassis mode.

To simulate a communication failure between the two nodes, define a static route on PE-3 that will black-hole the system address of PE-4.

```
# on PE-3:
configure
    router
        static-route-entry 192.0.2.4/32
            black-hole
                no shutdown
            exit
        exit
```

Verify that the MC synchronization is down.

```
*A:PE-4# show redundancy multi-chassis mc-endpoint peer 192.0.2.3

The spoke-SDPs are active on PE-3 and on PE-4.

```
*A:PE-3# show service id 2 endpoint | match "Tx Active"
Tx Active (SDP)              : 31:1
Tx Active Up Time            : 0d 00:05:58
Tx Active Change Count       : 6
Last Tx Active Change        : 06/21/2019 08:19:09
```

```
*A:PE-4# show service id 2 endpoint | match "Tx Active"
Tx Active (SDP)              : 41:1
Tx Active Up Time            : 0d 00:04:56
Tx Active Change Count       : 3
Last Tx Active Change        : 06/21/2019 08:19:05
```

This can potentially cause a loop in the system. The section Passive mode describes how to avoid this loop.

Passive mode

As in the preceding Multi-chassis communication failure subsection, if there is a failure in the multi-chassis communication, both nodes will assume that the peer is down and will revert to single-chassis mode. This can create loops because two spoke-SDPs can become active.

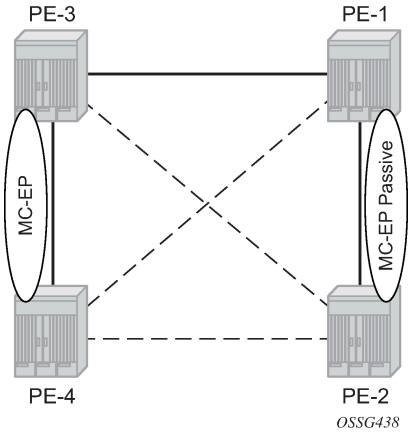
One solution is to synchronize the two core nodes, and configure them in passive mode. See Figure 215: Multi-chassis passive mode.

In passive mode, both peers will stay dormant as long as one active spoke-SDP is signaled from the remote end. If more than one spoke-SDP becomes active, the MC-EP algorithm will select the best SDP. All other spoke-SDPs are blocked locally (in Rx and Tx directions). There is no signaling sent to the remote PEs.

If one peer is configured in passive mode, the other peer will be forced to passive mode as well.

The **no suppress-standby-signaling** and **no ignore-standby-signaling** commands are required.

Figure 215: Multi-chassis passive mode



The following output shows the multi-chassis configuration on PE-1 (similar on PE-2).

```
# on PE-1:
configure
    redundancy
        multi-chassis
            peer 192.0.2.2 create
                mc-endpoint
                    no shutdown
                    passive-mode
                exit
                no shutdown
            exit
        exit
```

The following output shows the VPLS spoke-SDPs configuration on PE-1 (similar on PE-2)

```
# on PE-1:
configure
    service
        vpls 1
            endpoint "METRO1" create
                no suppress-standby-signaling
                mc-endpoint 1
                    mc-ep-peer 192.0.2.2
                exit
            exit
            spoke-sdp 13:1 endpoint "METRO1" create
            exit
            spoke-sdp 14:1 endpoint "METRO1" create
            exit
            no shutdown
        exit
```

To simulate a communication failure between the two nodes, a static route is defined on PE-3 that will black-hole the system address of PE-4.

```
# on PE-3:
configure
    router
        static-route-entry 192.0.2.4/32
```

```
            black-hole
                no shutdown
            exit
        exit
```

The spoke-SDPs are active on PE-3 and on PE-4.

```
*A:PE-3# show service id 2 endpoint | match "Tx Active"
Tx Active (SDP)              : 31:1
Tx Active Up Time            : 0d 00:00:28
Tx Active Change Count       : 8
Last Tx Active Change        : 06/21/2019 08:20:24
```

```
*A:PE-4# show service id 2 endpoint | match "Tx Active"
Tx Active (SDP)              : 41:1
Tx Active Up Time            : 0d 00:00:22
Tx Active Change Count       : 5
Last Tx Active Change        : 06/21/2019 08:20:25
```

PE-1 and PE-2 have blocked one spoke-SDP which avoids a loop in the VPLS.

```
*A:PE-1# show service id 1 endpoint "METRO1" | match "Tx Active"
Tx Active (SDP)              : 13:1
Tx Active Up Time            : 0d 00:00:58
Tx Active Change Count       : 5
Last Tx Active Change        : 06/21/2019 08:20:50
```

```
*A:PE-2# show service id 1 endpoint  "METRO1" | match "Tx Active"
Tx Active                    : none
Tx Active Up Time            : 0d 00:00:00
Tx Active Change Count       : 2
Last Tx Active Change        : 06/21/2019 08:20:15
```

The passive nodes do not set the pseudowire status bits; therefore, the nodes PE-3 and PE-4 are not aware that one spoke-SDP is blocked.

Conclusion

Multi-chassis endpoint for VPLS active/standby pseudowire allows the building of hierarchical VPLS without single point of failure, and without requiring STP to avoid loops.

Care must be taken to avoid loops. The multi-chassis peer communication is important and should be possible on different interfaces.

Passive mode can be a solution to avoid loops in case of multi-chassis communication failure.

Multi-Segment Pseudowire Routing

This chapter describes advanced multi-segment pseudowire routing configurations.

Topics in this chapter include:

Applicability

Multi-Segment Pseudowire (MS-PW) routing is supported in SR OS Release 9.0.R3, and later. This chapter was initially written for SR OS Release 10.0.R4. The CLI in this edition is based on SR OS Release 21.2.R1. There are no specific prerequisites for this configuration.

Overview

SR OS supports the use of Multi-Segment Pseudowire (MS-PW) routing for Epipe services. MS-PW routing is described in RFC 7267, *Dynamic Placement of Multi-Segment Pseudowires*, and it is an extension of the procedures proposed in RFC 6073 (static MS-PW) to enable multi-segment pseudowires to be dynamically placed. Ultimately, MS-PW Routing provides the capability of setting up MS-PWs without provisioning the Switching PEs (S-PEs).

This chapter will go through the configuration process required to set up MS-PW routing and will provide two configuration examples typically deployed by service providers: MS-PW within the same Autonomous System (AS) and MS-PW across two different ASs. Different configuration options are shown and described for each example.

MS-PW routing

From a data plane perspective, MS-PW routing does not introduce any changes with respect to the existing MS-PW architecture. However, from the control plane perspective, MS-PW routing brings a new information model and set of procedures to set up a MS-PW. These are the building blocks defined by the MS-PW routing feature:

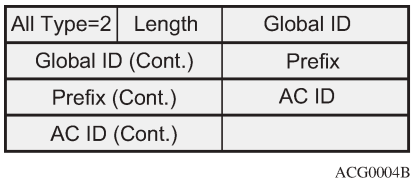
- A new information model is introduced for dynamic MS-PW based on the FEC129, Attachment Individual Identifier (AII) Type 2. Static MS-PW uses FEC128 whereas VPLS with BGP-AD uses FEC129, but with AII Type 1 instead.
  - FEC129 is suitable for applications where the local PE with a Source Attachment Individual Identifier (SAII) must automatically learn the remote Target Attachment Individual Identifier (TAII), normally through BGP, before launching the LDP mapping message for the pseudowire setup. Figure 216: FEC129 structure shows the FEC129 structure:

Figure 216: FEC129 structure

  - The Attachment Group Identifier (AGI) is not used in dynamic MS-PW signaling. In VPLS, it typically carries the instance identifier. It is zero in dynamic MS-PWs.
  - The SAII and TAII (or pseudowire end-point identifiers) are encoded in FEC129 and can have two different formats: AII Type 1 or AII Type 2.

- AII Type 1 is composed of a fixed 32-bit value unique on the local PE. This AII type is used by VPLS when BGP-AD is needed.
- Figure 217: AII type 2 format shows the AII type 2 format. AII type 2 is composed of global-ID:prefix: attachment-circuit-ID (GID:prefix:AC-ID) and allows for summarization, thereby enhancing scalability in large networks. The GID is normally derived from the AS number, the prefix from the node system address, and the AC-ID is the local pseudowire end-point identifier. The combination of the three identifiers gives us a globally unique 96-bit AII value. In general, the same global ID and prefix are assigned for all ACs belonging to the same Terminating PE (T-PE). This is not a strict requirement though.

Figure 217: AII type 2 format



- A MS-PW routing table must be built in all the T-PEs and S-PEs through one of the following two mechanisms:
  - Multi-protocol BGP (MP-BGP), using a dedicated NLRI and SAFI (pseudowire routing SAFI=6, with AFI=25 for L2-VPN). The FEC129 AII Type 2 global values are mapped in the pseudowire routing NLRI and advertised by BGP. SR OS supports an NLRI comprising a Length, RD, Global ID, and 32-bit prefix, that is, the AC ID is not included in the advertised NLRI. The AC ID is not included as indicated in RFC 7267 because the source T-PE knows by provisioning the AC ID on the terminating T-PE to use in signaling. Therefore, there is no need to advertise a "fully qualified" 96-bit address on a per pseudowire attachment circuit basis. Only the T-PE Global ID, Prefix, and prefix length need to be advertised as part of well-known BGP procedures. This also minimizes the amount of routing information that is advertised in BGP to only what is necessary to reach the far-end T-PE. Figure 218: Pseudowire routing NLRI (the AC ID is always zero) shows the MS-PW routing NLRI:

Figure 218: Pseudowire routing NLRI (the AC ID is always zero)

  - Static routes, configurable via CLI

- Once the MS-PW routing table is populated, Targeted LDP (T-LDP) will make use of it to signal the MS-PW all the way from the originating T-PE to the terminating T-PE as well as in the reverse direction. The following methods will be used:
  - At the originating T-PE, a longest-match lookup will be performed in the pseudowire routing table for the configured TAII. Based on the lookup outcome, a label mapping message will be sent to the Next Signaling Hop (NSH).

    Note:
    The "originating T-PE" will be the T-PE initiating the MS-PW signaling. See the Active/passive signaling and auto-configuration section for further information.

  - At the intermediate S-PEs and destination T-PE, a longest-match lookup between the TAII Type 2 included in the T-LDP signaling message and entries installed in the pseudowire routing table will be performed.
  - Alternatively to the pseudowire routing table lookup, T-LDP can also use explicit routing, as per section 7.4.2 of RFC 7267. If that is the case, a "path" must be configured on the T-PEs. The originating T-PE will include an Explicit Route Object (ERO) in the T-LDP label mapping, containing all the S-PE hops specified in the configured path. Each S-PE along the path will remove its own entry from the ERO and will forward the label mapping message to the next hop.

SR OS supports the information model and all the previously described methods:

- Dynamic placement through MP-BGP, with the pseudowire routing NLRI
- Static routes
- Explicit paths

In addition to the above, the following features are supported on dynamic MS-PW:

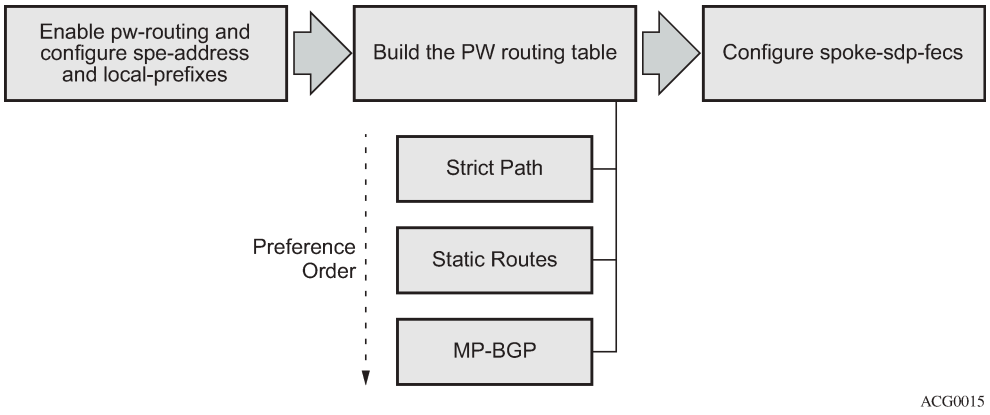
- Auto-configuration of spoke SDPs at T-PE (if enabled on a T-PE, there is no need for configuring the TAII of the remote T-PE, see Active/passive signaling and auto-configuration. The auto-configuration is typically used in hub-and-spoke scenarios. The TAII would only be configured on the spoke T-PE whereas the TAII would be automatically provisioned on the hub T-PE if the auto-config parameter is added.
- OAM using virtual circuit connectivity verification vccv-ping and vccv-trace
- Pseudowire redundancy
- Control word
- Hash label

- Standby-signaling-master and standby-signaling-slave commands
- Filters

Configuration

The following flowchart in Figure 219: Configuration flowchart shows the configuration process to be followed when setting up MS-PW routing. Base IGP and MPLS configuration is assumed to be in place before these configuration tasks can be carried out.

Figure 219: Configuration flowchart



The following subsections review these three steps, including all the options in detail.

- Pseudowire routing enablement
- Building the pseudowire routing table
- Spoke-SDP FEC timers

Pseudowire routing enablement

The first step in the configuration is to enable **pw-routing** and configure the required pseudowire routing basic parameters: the **spe-address** (in S-PEs and T-PEs) and the **local-prefix**/prefixes (only required in T-PEs). The following CLI examples show the configuration of the spe-address and local-prefixes.

```
# on PE-1:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.1
            local-prefix 65536:192.0.2.11 create
                advertise-bgp route-distinguisher 65536:11 community 65535:11
            exit
            local-prefix 65536:192.0.2.12 create
                advertise-bgp route-distinguisher 65536:12 community 65535:12
            exit
        exit
```

In order to enable support for MS-PW routing on an SR OS router, a single, globally unique, S-PE ID (known as the spe-address) is first configured in the **config>service>pw-routing** context on each SR OS

router to be used as a T-PE or S-PE. The S-PE address has the format global-id:prefix. It is not possible to configure any local prefixes used for pseudowire routing or to configure spoke SDPs using dynamic MS-PWs at a T-PE, unless an S-PE address has already been configured. The S-PE address is used as the address of a node when populating the switching point TLV in the LDP label mapping message and the pseudowire status notification sent for faults at an S-PE. The following output shows the spe-address configuration format:

```
*A:PE-1# configure service pw-routing spe-address ?
  - no spe-address
  - spe-address <global-id:prefix>

 <global-id:prefix>   : <global-id>:{<prefix>|<ipaddress>}
                        global-id - [1..4294967295]
                        prefix    - [1..4294967295]
                        ipaddress - a.b.c.d
```

Where:

- <global-id> is normally the 2 or 4-byte ASN identifying the network (although nothing prevents the operator from configuring any value here)
- <prefix> is normally the system address of the node (although any value in IP address or decimal format can be used)

If an S-PE is capable of dynamic MS-PW signaling, but is not assigned with an S-PE address, then on receiving a dynamic MS-PW label mapping message, the S-PE will return a label release with the "LDP_RESOURCES_UNAVAILABLE" (0x38)" status code. The S-PE address cannot be changed unless the dynamic MS-PW configuration is completely removed; therefore Nokia recommends to configure the spe-address carefully and keep it for the life of the services.

The second basic pw-routing context parameter is the local-prefix:

```
*A:PE-1# configure service pw-routing local-prefix ?
  - local-prefix <local-prefix> [create]
  - no local-prefix <local-prefix>

 <local-prefix>       : <global-id>:<ip-addr>|<raw-prefix>
                        ip-addr      - a.b.c.d
                        raw-prefix   - [1..4294967295]
                        global-id    - [1..4294967295]

 [no] advertise-bgp   - Configure BGP advertisement
```

One or more local (Layer 2) prefixes (up to a maximum of 16), which are formatted in the style of <global-id>:<ipv4-address>, are supported. A local prefix identifies a T-PE in the pseudowire routing domain. When using explicit paths or static routes, the definition of the local-prefixes without any further attribute is enough. However, when BGP is used, the **advertise-bgp** parameter along with a Route Distinguisher (RD) value and an optional BGP community is required.

```
A:PE-1# configure service pw-routing local-prefix 65536:192.0.2.11 advertise-bgp ?
  - advertise-bgp route-distinguisher <rd> [community <community>]
  - no advertise-bgp route-distinguisher <rd>

 <rd>                 : <ip-addr:comm-val>|<2byte-asnumber:ext-comm-val>|
                                          <4byte-asnumber:comm-val>
                        ip-addr        - a.b.c.d
                        comm-val       - [0..65535]
                        2byte-asnumber - [1..65535]
                        ext-comm-val   - [0..4294967295]
```

```
                          4byte-asnumber - [1..4294967295]
 <community>            : <asnumber:comm-val>
                          asnumber - [1..65535]
                          comm-val - [0..65535]
```

Up to four unique RDs (and communities) can be configured per each local prefix. Different RDs for the same prefix allow the operator to advertise the same prefix coming from up to four different Next Signaling Hops (NSHs). Route Reflectors (RRs) would reflect the four routes in that case, whereas only one would be reflected should the same RD be used.

```
*A:PE-1>config>service>pw-routing>local-prefix# info
----------------------------------------------
                advertise-bgp route-distinguisher 400:20
                advertise-bgp route-distinguisher 500:3
                advertise-bgp route-distinguisher 600:300
                advertise-bgp route-distinguisher 65536:11 community 65535:11
```

```
*A:PE-1>config>service>pw-routing>local-prefix# advertise-bgp route-distinguisher 700:100
MINOR: SVCMGR #6072 Maximum number of RD's has been reached
```

For each local prefix, BGP then advertises each global ID/prefix tuple and unique RD and community (if configured) using the MS-PW NLRI, based on the aggregated FEC129 AII Type 2 and the Layer 2 VPN/PW routing AFI/SAFI 25/6, to each BGP neighbor, subject to local BGP policies.

Building the pseudowire routing table

Once the S-PE address and the local prefixes have been configured and before configuring the Epipe service itself on the T-PE nodes, we need to populate the pseudowire routing table in all the participating T-PE and S-PE nodes, so that T-LDP knows what the Next Signaling Hop (NSH) is and sends LDP label mapping messages.

The pseudowire routing table will be populated with local prefixes, static routes, and BGP routes, where the static routes have preference over the BGP-learned routes. The pseudowire routing table can be overridden by the explicit paths, should the operator want to configure them. Therefore, when T-LDP signals an LDP Label Mapping for a TAII, it will:

- First check if there is an explicit path configured for that spoke-SDP FEC.
- Otherwise, it will look up the TAII prefix into the pseudowire routing table, where static routes take precedence over BGP routes.

An aggregation scheme, similar to that used for classless IPv4 addresses, can be employed in the pseudowire routing table, where a longest match is used to find a route. Except for the default pseudowire route, which is encoded with a zero mask, masks included in the pw-routing table are:

- /64 for regular prefixes, including a global ID and prefix (as previously mentioned; the AC-ID is not included in the BGP NLRI).
- /96 for local prefixes, including the AC-ID, as well as global-id and prefix.

Each S-PE and T-PE must have a pseudowire routing table that contains a reference to the T-LDP session to use to signal to a set of next hop S-PEs to reach a T-PE (or the T-PE if that is the next hop). For Epipes, this table contains aggregated AII Type 2 FECs and may be populated with routes that are learned through MP-BGP or that are statically configured.

Explicit paths

A set of default explicit routes to a remote T-PE prefix may be configured on a T-PE under **config>services>pw-routing** using the path name command. Explicit paths are used to populate the explicit route TLV used by MS-PW T-LDP signaling. Only strict (fully qualified) explicit paths are supported. It is possible to configure explicit paths independently of the configuration of BGP or static routing.

The following CLI excerpt shows an explicit path example for a MS-PW following the PE-1–PE-3–PE-5–PE-2 path (see the example topology in Figure 220: Intra-AS MS-PW example topology). The IP addresses are the system addresses of all the S-PE and T-PE along the path (except for PE-1).

```
# on PE-1:
configure
    service
        pw-routing
            path "path-1" create
                hop 1 192.0.2.3
                hop 2 192.0.2.5
                hop 3 192.0.2.2
                no shutdown
            exit
```

Static routes

In addition to support for BGP routing, static MS-PW routes may also be configured using the **config services pw-routing static-route** command. Each static route comprises of the target T-PE global ID and prefix, and the IP address of the T-LDP session to the next hop S-PE or T-PE that should be used:

```
*A:PE-1# configure service pw-routing static-route ?
  - no static-route <route-name>
  - static-route <route-name>

 <route-name>         : <global-id>:<prefix>:<next-hop-ip_addr>
                        global-id      - 0..4294967295
                        prefix         - a.b.c.d|0..4294967295
                        ip_addr        - a.b.c.d
```

If a static route <global-id>:<prefix> is set to 0, then this represents the default route.

```
# on PE-1:
configure
    service
        pw-routing
            static-route 0:0.0.0.0:192.0.2.3
            static-route 0:0.0.0.0:192.0.2.4
```

Even though several default routes can be configured, only one default route is added to the PW routing table. The following command shows the PW routing table content where only one default route (out of the two previously configured ones) is added. The default route added to the PW routing table is the first valid route added to the configuration.

```
*A:PE-1# show service pw-routing route-table all-routes

===============================================================================
Service PW L2 Routing Information
===============================================================================
AII-Type2/Prefix-Len                          Next-Hop       Owner  Age
```

```
 Route-Distinguisher                          Community      Best
-------------------------------------------------------------------------------
0:0.0.0.0:0/0                                192.0.2.3      static 00h00m11s
 0:0                                          0:0            yes
---snip---
```

If a static route exists to a T-PE, then this is used in preference to any BGP route that may exist.

BGP routes

As already mentioned, the dynamic advertisement of the PW routes is enabled for each prefix and RD using the **advertise-bgp** command in the **config>services>pw-routing>local-prefix** context. A BGP export policy is required in order to export MS-PW routes in MP-BGP. This can be done using a default policy matching all the MS-PW routes, such as the following:

```
# on PE-1:
configure
    router
        autonomous-system 65536
        policy-options
            begin
            policy-statement "export_ms-pw"
                entry 10
                    from
                        family ms-pw
                    exit
                    action accept
                        origin igp
                    exit
                exit
            exit
            commit
        exit
        bgp
            enable-peer-tracking
            rapid-withdrawal
            group "region"
                family ms-pw
                export "export_ms-pw"
                peer-as 65536
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
        exit
```

MS-PW routes advertised/received can be debugged and shown on the log sessions (**debug router bgp update**). A dedicated MS-PW address family and NLRI are used to distribute the MS-PW prefixes. The following BGP update is sent by PE-1 to PE-3:

```
# on PE-1:
2 2021/03/03 08:55:53.651 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

===============================================================================
```

If there are two (or more) equal cost BGP MS-PW routes with identical <global-ID:prefix> and different RDs in the RIB, they are both tagged as best/used and both will be added to the pseudowire routing table; however, only the one with a higher RD will be shown as "Best" and as a result of that, only that one will be used by T-LDP for the NSH.

The **pw-routing** context on PE-2 contains the following **advertise-bgp** entries with different RDs for local-prefix 65536:192.0.2.2:

```
# on PE-2:
configure
    service
        pw-routing
            local-prefix 65536:192.0.2.2 create
                advertise-bgp route-distinguisher 65536:21 community 65535:11
                advertise-bgp route-distinguisher 65536:22 community 65535:12
            exit
```

The following CLI output shows an example of two equal cost MS-PW routes. The route 65536:192.0.2.2 with RD 65536:21 and next-hop 192.0.2.3 is tagged as best and used; the route with RD 65536:22 and next-hop 192.0.2.4 is also best and used (u*>).

```
*A:PE-1# show router bgp routes ms-pw aii-type2 65536:192.0.2.2:0
```

```

65536:192.0.2.2:0/64                          192.0.2.4      bgp    00h01m31s
 65536:22                                      65535:12       yes
---snip---
```

In the preceding example, the routes have different RDs, but that need not be the case. When the originating T-PE or any intermediate S-PE receives two (or more) equal cost MS-PW routes with the *same RD* but from different Next-Hops (NHs), all the MS-PW routes will be added to the MS-PW routing table as "Best".

In case multiple equal-cost MS-PW routes are available, T-LDP will pick up the NSH out of an ECMP hashing algorithm applied to the <global-ID:prefix:AC-ID> for the SAII and the TAII of the pseudowires pointing at the same prefix. The output of that hashing algorithm will determine what the NSH will be for a spoke-SDP FEC.

When path diversity for an active and a standby pseudowire (hot standby pseudowire redundancy) is desired and the two pseudowires of the same Epipe endpoint are pointing at the same remote <global-

ID:prefix> coming from two different NHs, the operator has to make sure T-LDP chooses a different NSH for the standby pseudowire. Only in that case, hot standby pseudowire redundancy can be achieved. As a rule of thumb, if the SAII/TAII of the active and standby pseudowires are separated by 16 or more AC-ID values, T-LDP will select a different NSH for both pseudowires.

For example:

- Given the following SAII/TAII AC-ID values for the active/standby pseudowires on the originating T-PE, T-LDP will select the same NSH:
  - Active pseudowire: saii-type2 — 65536:192.0.2.1:1, taii-type2 — 65536:192.0.2.2:1
  - Standby pseudowire: saii-type2 — 65536:192.0.2.1:2, taii-type2 — 65536:192.0.2.2:2
- However, the following SAII/TAII AC-ID values for the active/standby pseudowires on the originating T-PE will allow the ECMP hashing algorithm to make T-LDP select different NSHs for the active and the standby pseudowires:
  - Active pseudowire: saii-type2 — 65536:192.0.2.1:1, taii-type2 — 65536:192.0.2.2:1
  - Standby pseudowire: saii-type2 — 65536:192.0.2.1:16, taii-type2 — 65536:192.0.2.2:16

Other AC-ID values greater than 16 (for the standby pseudowire) would also have achieved next hop diversity.

Configuring dynamic pseudowires on the T-PEs

Before any LDP signaling can take place, T-LDP sessions must be explicitly configured on T-PEs and S-PEs.

One or more spoke-SDPs may be configured for distributed Epipe VLL services. Dynamic MS-PWs use FEC129 (also known as the Generalized ID FEC) with AII Type 2 to identify the pseudowire, as opposed to FEC128 (also known as the PW ID FEC) used for traditional single segment pseudowires and for pseudowire switching. FEC129 spoke-SDPs are configured under the **spoke-sdp-fec** command in the CLI. Spoke-SDP FECs (or FEC129 spoke-SDPs) are by default FEC type 129 and AII type 2. Spoke-SDP FECs can be part of an endpoint and even an Inter-Chassis Backup (ICB) pseudowire.

```
*A:PE-1# configure service epipe "Epipe2" spoke-sdp-fec ?
  - no spoke-sdp-fec <spoke-sdp-fec-id>
  - spoke-sdp-fec <spoke-sdp-fec-id> [fec <fec-type>] [aii-type <aii-type>] [create]
  - spoke-sdp-fec <spoke-sdp-fec-id> no-endpoint
  - spoke-sdp-fec <spoke-sdp-fec-id> [fec <fec-type>] [aii-type <aii-type>] [create]
                  endpoint <name> [icb]

 <spoke-sdp-fec-id>   : [1..4294967295]
 <fec-type>           : [129..130]
 <aii-type>           : [1..2]
 <name>               : [32 chars max]
 <icb>                : keyword - configure spoke-sdp as inter-chassis backup
```

FEC129 AII Type 2 uses a SAII and a TAII to identify the ends of a PW at the T-PE. The SAII identifies the local end, while the TAII identifies the remote end. The SAII and TAII are each structured as follows:

- Global ID: this is a 4-byte identifier that uniquely identifies an operator or the local network. Normally, this matches the ASN
- Prefix: a 4-byte prefix, which should correspond to one of the local prefixes assigned under pw-routing
- AC ID: a 4-byte identifier for this end of the PW. This should be locally unique within the scope of the global-id:prefix

In terms of the SDP tunnel being used by each spoke-SDP FEC, PW routing chooses the MS-PW path in terms of the sequence of S-PEs to use to reach a T-PE. It does not select the SDP to use on each hop, which is instead determined at signaling time. When a label mapping is sent for a PW segment, an LDP SDP will be used to reach the next-hop S-PE/T-PE, if such an SDP exists. If not, and an RFC 3107 labeled BGP SDP is available, then that will be used. Otherwise, the label mapping will fail and a label release will be sent.

Note:
The RSVP SDPs might be picked at the T-PE through the use of pw-template <policy-id> [use-provisioned-sdp], however there is no way to select an RSVP SDP on an S-PE.

The following CLI output shows one example of two spoke-SDP FECs belonging to an endpoint:

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            controlword
        exit
        epipe 2 name "Epipe2" customer 1 create
            description "ms-pw epipe with bgp - using 2 prefixes"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
                standby-signaling-master
            exit
            sap 1/1/4:2 create
            exit
            spoke-sdp-fec 21 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.11:1
                taii-type2 65536:192.0.2.21:1
                no shutdown
            exit
            spoke-sdp-fec 22 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.12:1
                taii-type2 65536:192.0.2.22:1
                no shutdown
            exit
            no shutdown
        exit
```

The following options are available in the **spoke-sdp-fec** context:

```
*A:PE-1# configure service epipe "Epipe2" spoke-sdp-fec ?
  - no spoke-sdp-fec <spoke-sdp-fec-id>
  - spoke-sdp-fec <spoke-sdp-fec-id> [fec <fec-type>] [aii-type <aii-type>] [create]
  - spoke-sdp-fec <spoke-sdp-fec-id> no-endpoint
  - spoke-sdp-fec <spoke-sdp-fec-id> [fec <fec-type>] [aii-type <aii-type>] [create]
                                     endpoint <name> [icb]

 <spoke-sdp-fec-id>   : [1..4294967295]
 <fec-type>           : [129..130]
 <aii-type>           : [1..2]
 <name>               : [32 chars max]
 <icb>                : keyword - configure spoke-sdp as inter-chassis backup

 [no] auto-config     - Configure auto-configuration
 [no] path            - Configure path-name
```

```
 [no] precedence      - Configure precedence
 [no] pw-template-bi* - Configure Pseudo-Wire template-binding policy
 [no] retry-count     - Configure retry count
 [no] retry-timer     - Configure retry timer
 [no] saii-type2      - Configure Source Attachment Individual Identifier (SAII)
 [no] shutdown        - Administratively enable/disable the spoke SDP FEC binding
      signaling       - Configure Spoke-SDP FEC signaling
 [no] standby-signal* - Enable PW standby-signaling slave
 [no] taii-type2      - Configure Target Attachment Individual Identifier (TAII)
```

Active/passive signaling and auto-configuration

When an MS-PW is signaled, each T-PE might independently initiate signaling of the MS-PW. This could result in a different path being used in each direction of the PW. To avoid this situation, one of the T-PEs will start the PW signaling (active role), while the other T-PE waits to receive the LDP label mapping message before sending the LDP label mapping message for the reverse direction of the PW (passive role).

Debugging for LDP messages is enabled on PE-2, as follows:

```
# on PE-2:
debug
    router "Base"
        ldp
            peer 192.0.2.5
                packet
                    init detail
                    label detail
                exit
            exit
            peer 192.0.2.6
                packet
                    init detail
                    label detail
                exit
            exit
        exit
```

By default, the T-PE with SAII>TAII will have the active role and will send the label mapping first. When spoke-SDP FEC 21 is first disabled, and then enabled, PE-2 sends a label mapping to PE-5 first (message 77 in following output). Afterward, it receives a label mapping packet from PE-5 (message 78).

```
# on PE-2:
configure
    service
        epipe "Epipe2"
            spoke-sdp-fec 21
                shutdown
                no shutdown
```

```

"
```

For the other T-PE, it is the other way round. PE-1 receives a label mapping packet first before it sends a label mapping packet back.

This default behavior can be modified by the **signaling** command. When set to master, the T-PE will send a label mapping message regardless of the SAII and TAII. By default the parameter is set to auto (which means the T-PE will trigger label mapping if SAII>TAII).

```
*A:PE-1# configure service epipe "Epipe2" spoke-sdp-fec 21 signaling ?
  - signaling <signaling>

 <signaling>          : auto|master
```

```
# on PE-1:
configure
    service
        epipe "Epipe2"
            spoke-sdp-fec 21
                shutdown
                signaling master
                no shutdown
```

The MS-PW routing implementation on SR OS supports single-sided auto-provisioning. This allows it to have "hub" T-PEs where the TAII is not required to be configured and as such simplifies the provisioning. In this case, the spoke T-PE PWs would be configured with specific SAII and TAII as well as signaling master, whereas the hub T-PE PWs would be configured with only the SAII and the auto-config parameter. When the auto-config attribute is set for a spoke-SDP FEC, the T-PE always passively waits for the label

mapping to be received before issuing a label mapping message (because it does not know the TAII beforehand). This is a CLI example for a hub T-PE spoke-SDP FEC:

```
# on PE-2:
configure
    service
        epipe "Epipe2"
            spoke-sdp-fec 21 fec 129 aii-type 2 create
                auto-config
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.21:1
                no shutdown
            exit
```

Spoke-SDP FEC timers

MS-PW routing provides a few timers that can be configured at the global pw-routing level or at each specific spoke-SDP FEC level:

```
# on PE-1:
configure
    service
        pw-routing
            boot-timer 20
            retry-timer 40
            retry-count 50
```

```
# on PE-1:
configure
    service
        epipe "Epipe2"
            spoke-sdp-fec 21
                retry-timer 10
                retry-count 10
```

Where:

- **Boot-timer** (the default is 10 seconds with values 0 — 600 seconds allowed): Configures a hold-off timer for MS-PW routing advertisements and signaling that is used at boot time. This timer helps to make sure all the network infrastructure is up and running before setting up the PWs.
- **Retry-timer** (the default is 30 seconds with values 10 — 480 seconds allowed): The exponential back-off timer that determines the interval between consecutive retries to re-establish a spoke-SDP. The configured value gives the initial retry time. The attempt fails if a label withdrawal is received. If configured at global and spoke-SDP FEC level, the latter overrides the value set by the global settings.
- **Retry-count** (the default 30 with values 10 — 10000): Specifies the number of attempts the system should make to re-establish the spoke-SDP after it has failed. After each successful attempt, the counter is reset to zero. When the specified number is reached, no more attempts are made and the spoke-SDP is put into the disabled state. Use the **no shutdown** command to bring up the path after the retry limit is exceeded. It is present at the PW routing level as well as the spoke-SDP FEC level. If configured at global and spoke-SDP FEC level, the latter overrides the value set by the global settings.
- The usual endpoint level timers are also available for MS-PW routing:

- **Revert-time** <*time-value*> **| infinite** (default is 0, values 0 — 600 sec): configures the time to wait before reverting to the primary spoke-SDP FEC.
- **Active-hold-delay** (the default is 0, values 0 — 60 deci-seconds): It specifies that the node will delay sending the T-LDP status bits for VLL endpoint when the MC-LAG transitions the LAG subgroup which hosts the SAP from active to standby (MC-Ring or MC-APS are supported too) or when any object in the endpoint—SAP, ICB, or regular spoke SDP—transitions from up to down operational state. The active-hold-delay range starts from 1 (in units of deci-seconds) via CLI, and the only way to get the default value of zero is to use the **no active-hold-delay** command

Standby signaling

Just as with a regular endpoint with regular spoke-SDPs, there can also be standby-signaling-master and standby-signaling-slave parameters for spoke-SDP FECs.

The **standby-signaling-master** command is configured in the **endpoint** context and makes sure that standby signaling (T-LDP PW status bits 0x20) is sent for the selected standby PW.

```
# on PE-1:
configure
    service
        epipe "Epipe2"
            endpoint "CORE"
                standby-signaling-master
```

It is not allowed to add a SAP associated to an endpoint configured as standby-signaling-master to an Epipe.

```
*A:PE-1>config>service>epipe# sap 1/1/4:2 endpoint "CORE" create
MINOR: SVCMGR #6025 The endpoint has standby-signaling-master configured
```

The **standby-signaling-slave** can be configured at endpoint or spoke-SDP FEC level.

```
# at endpoint on PE-1:
configure
    service
        epipe "Epipe2"
            endpoint "CORE"
                no standby-signaling-master
                standby-signaling-slave
```

```
# at spoke-SDP FEC on PE-1:
configure
    service
        epipe "Epipe2"
            spoke-sdp-fec 21
                standby-signaling-slave
```

When **standby-signaling-slave** is configured, the node will block the transmit forwarding direction of a spoke-SDP based on the PW standby bit received from a T-LDP peer.

Spoke-SDP FEC templates and filters

PW templates are the way to configure the control word for this type of PW as well as ingress/egress filters (IPv4/MAC/IPv6). Filters are only supported on the T-PEs, because there is no provisioning of a PW template (or Epipe at all) on the S-PEs.

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            controlword
            egress
                filter ip 1
            exit
        exit
        epipe 2 name "Epipe2" customer 1 create
---snip---
            spoke-sdp-fec 22 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.12:1
                taii-type2 65536:192.0.2.22:1
                no shutdown
            exit
```

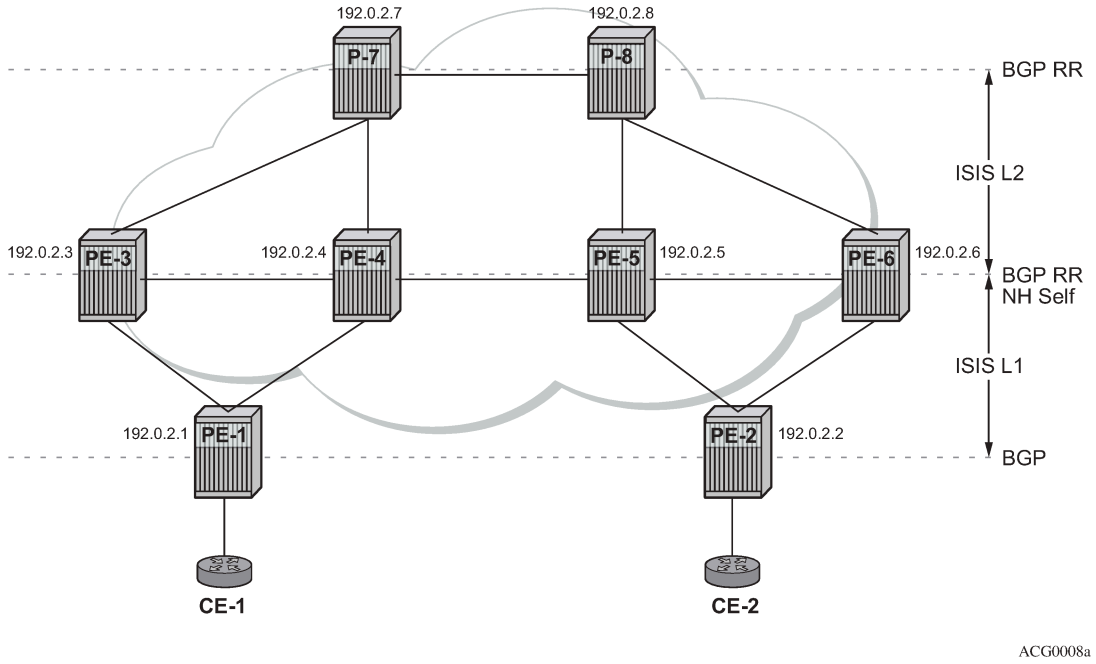
PW template changes (just like for VPLS with BGP-AD or BGP-VPLS) are not automatically propagated. A **tools perform** command is provided to evaluate and distribute the changes at the service level to one or all the services that use that template (if the service ID is omitted, then all the services will be updated).

```
# on PE-1:
tools perform service id 2 eval-pw-template 1 allow-service-impact
```

Intra-AS MS-PW routing

This section provides a configuration example for an intra-AS scenario. Figure 220: Intra-AS MS-PW example topology shows the example topology that will be used for this section.

Figure 220: Intra-AS MS-PW example topology



Multiple MS-PW routing Epipes are to be configured between PE-1 and PE-2, with PE-3, PE-4, PE-5, and PE-6 being S-PE routers. P-7 and P-8 are pure P routers from a data plane perspective.

All the PEs are pre-configured with IS-IS as the IGP, as shown in Figure 220: Intra-AS MS-PW example topology: PE-1 and PE-2 are level-1 routers, P-7 and P-8 are level-2 only routers and the rest of the routers are level-1/level-2. Link level LDP is also pre-configured on all the network interfaces and targeted LDP is configured between PE-1 and PE-3/PE-4, between PE-2 and PE-5/PE-6 and among PE-3, PE-4, PE-5, and PE-6. There are no targeted LDP sessions configured on P-7 and P-8.

As outlined in Figure 219: Configuration flowchart, the configuration is a three-step process where the pw-routing context is configured first, then the required configuration so that routing tables get populated accordingly and finally the services themselves.

MS-PW using BGP routing

In this subsection, Epipe 2 will be configured between PE-1 and PE-2, where T-LDP will use the BGP routes populated in the MS-PW routing table to signal the MS-PW.

The first step is the provisioning of the pw-routing context on all the T-PEs and S-PEs. The **spe-address** will be configured on all the T-PEs and S-PEs—all the routers except for P-7 and P-8—using the ASN as the global ID and the system address as the prefix. On PE-1 and PE-2, (only) the prefixes used for setting up Epipe 2 are configured. Two prefixes are configured per T-PE so that PW redundancy with path diversity for the standby PW can be carried out. The **spe-address** and local prefixes for the T-PEs are shown in the following CLI output. The **advertise-bgp** parameter is required because BGP is used here.

```
# on PE-1:
configure
    service
```

```
        pw-routing
            spe-address 65536:192.0.2.1
            local-prefix 65536:192.0.2.11 create
                advertise-bgp route-distinguisher 65536:11 community 65535:11
            exit
            local-prefix 65536:192.0.2.12 create
                advertise-bgp route-distinguisher 65536:12 community 65535:12
            exit
```

```
# on PE-2:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.2
            local-prefix 65536:192.0.2.21 create
                advertise-bgp route-distinguisher 65536:21 community 65535:11
            exit
            local-prefix 65536:192.0.2.22 create
                advertise-bgp route-distinguisher 65536:22 community 65535:12
            exit
```

The second step is the configuration of BGP.

As shown in Figure 220: Intra-AS MS-PW example topology, BGP is enabled in all the routers. The middle routers (PE-3, PE-4 and PE-5, PE-6) are BGP RRs for PE-1 and PE-2 and they reflect MS-PW routes while changing the next-hop to their own system address. This is required so that T-LDP knows where to send the label mapping message for a particular prefix. P-7 and P-8 are regular RRs reflecting routes among all the S-PEs. The BGP configuration of PE-1, PE-3, PE-4, and P-7 is as follows. Similar commands are configured on the other PEs depending on their T-PE, S-PE, or RR function.

The T-PEs have dual-homed BGP sessions to the S-PEs. Example for PE-1:

```
# on PE-1:
configure
    router
        autonomous-system 65536
        policy-options
            begin
            policy-statement "export_ms-pw"
                entry 10
                    from
                        family ms-pw
                    exit
                    action accept
                        origin igp
                    exit
                exit
            exit
            commit
        exit
        bgp
            enable-peer-tracking
            rapid-withdrawal
            group "region"
                family ms-pw
                export "export_ms-pw"
                peer-as 65536

                exit
                neighbor 192.0.2.4
                exit
            exit
```

```
        exit
```

The S-PEs are reflecting routes and also changing the NH and local preference based on the communities accordingly, so that PW diversity can be ensured.

```
# on PE-3:
configure
    router
        autonomous-system 65536
        policy-options
            begin

                        protocol bgp
                        community "65535:11"
                        family ms-pw
                    exit
                    action accept
```

```
                        origin igp
                        local-preference 100
                        next-hop-self
                    exit
                exit
            exit
            policy-statement "export_ms-pw_ABR-to-region"
                entry 10
                    from
                        protocol bgp
                        community "65535:12"
                        family ms-pw
                    exit
                    action accept
                        origin igp
                        local-preference 150
                        next-hop-self
                    exit
                exit
                entry 20
                    from
                        protocol bgp
                        community "65535:11"
                        family ms-pw
                    exit
                    action accept
                        origin igp
                        local-preference 100
                        next-hop-self
                    exit
                exit
            exit
            commit
        exit
        bgp
            rapid-withdrawal
            group "core"
                family ms-pw
                export "export_ms-pw_ABR-to-core"
                peer-as 65536
                neighbor 192.0.2.7
                exit
                neighbor 192.0.2.8
                exit
            exit
            group "region"
                family ms-pw
                cluster 4.4.4.4
                export "export_ms-pw_ABR-to-region"
                peer-as 65536
                enable-peer-tracking
                neighbor 192.0.2.1
                exit
            exit
        exit
```

The following is the BGP configuration for the RRs P-7 and P-8:

```
# on P-7 and P-8:
configure
    router
        autonomous-system 65536
        bgp
```

```
            enable-peer-tracking
            rapid-withdrawal
            group "core"
                family ms-pw
                cluster 1.1.1.1
                peer-as 65536
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
                neighbor 192.0.2.6
                exit
            exit
        exit
```

After BGP is properly configured and the BGP update exchange takes place, the RIBs are properly populated and the required prefixes uploaded into the MS-PW routing table.

The following command shows the BGP MS-PW routes on PE-1:

```
*A:PE-1# show router bgp routes ms-pw
===============================================================================
 BGP Router ID:192.0.2.1        AS:65536       Local AS:65536

-------------------------------------------------------------------------------
```

The two prefixes advertised by PE-2 are properly learned by PE-1 through two different next hops. Now, use each one with a different PW and make sure that the active and standby PW follow different paths in the network.

Once the routes are installed in the MS-PW routing table, the services are configured on PE-1 and PE-2, as follows:

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            controlword
        exit
        epipe 2 name "Epipe2" customer 1 create
            description "ms-pw epipe with bgp - using 2 prefixes"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
                standby-signaling-master
            exit
            sap 1/1/4:2 create
            exit
            spoke-sdp-fec 21 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.11:1
                taii-type2 65536:192.0.2.21:1
                no shutdown
            exit
            spoke-sdp-fec 22 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.12:1
                taii-type2 65536:192.0.2.22:1
                no shutdown
            exit
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        pw-template 1 name "PW1" create
            controlword
        exit
        epipe 2 name "Epipe2" customer 1 create
            description "ms-pw epipe with bgp - using 2 prefixes"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
```

```
            exit
            sap 1/1/4:2 create
            exit
            spoke-sdp-fec 21 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.21:1
                taii-type2 65536:192.0.2.11:1
                no shutdown
            exit
            spoke-sdp-fec 22 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.22:1
                taii-type2 65536:192.0.2.12:1
                no shutdown
            exit
            no shutdown
        exit
```

The following command can be executed to verify that the service and spoke-SDP FECs are up:

```
*A:PE-1# show service id 2 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 2                   Vpn Id            : 0

===============================================================================
```

The SDP-binding identifiers and SDP identifiers are automatically generated by the system.

Use **vccv-trace** to check that the spoke-SDP FECs for the active and standby pseudowires follow different and disjoint paths:

```
*A:PE-1# oam vccv-trace spoke-sdp-fec 21
VCCV-TRACE  with 120 bytes of MPLS payload

```

MS-PW using static routing

In this subsection, Epipe 3 will be configured between PE-1 and PE-2, where T-LDP will use static routes in the MS-PW routing table to signal the MS-PW.

On PE-1 and PE-2 (only), the prefixes used for setting up Epipe 3 are configured. These prefixes could be the same as used for Epipe 2, however, different prefixes are used in this example. The **no advertise-bgp** parameter is required now. The static routes for each remote prefix are also configured. Because we will also have PW redundancy for Epipe 3, two prefixes with static routes pointing at different next-hops will be used:

```
# on PE-1:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.1
            local-prefix 65536:192.0.2.13 create
            exit
            local-prefix 65536:192.0.2.14 create
            exit
            static-route 65536:192.0.2.23:192.0.2.3
            static-route 65536:192.0.2.24:192.0.2.4
```

```
# on PE-2:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.2
            local-prefix 65536:192.0.2.23 create
            exit
            local-prefix 65536:192.0.2.24 create
            exit
            static-route 65536:192.0.2.13:192.0.2.5
            static-route 65536:192.0.2.14:192.0.2.6
```

Static routes are also required at all S-PEs along the path (keeping the path diversity for the prefixes as well) and for both directions:

```
# on PE-3:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.3
            static-route 65536:192.0.2.13:192.0.2.1
            static-route 65536:192.0.2.23:192.0.2.5
```

```
# on PE-4:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.4
            static-route 65536:192.0.2.14:192.0.2.1
            static-route 65536:192.0.2.24:192.0.2.6
```

Finally, once the MS-PW routing tables are properly populated, the services can be configured and brought up:

```
# on PE-1:
configure
    service
        pw-template 1 name "PW1" create
            controlword
        exit
        epipe 3 name "Epipe3" customer 1 create
            description "ms-pw epipe with static routes"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
                standby-signaling-master
            exit
            sap 1/1/4:3 create
            exit
            spoke-sdp-fec 31 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.13:31
                taii-type2 65536:192.0.2.23:31
                no shutdown
            exit
            spoke-sdp-fec 32 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.14:32
                taii-type2 65536:192.0.2.24:32
                no shutdown
            exit
            no shutdown
        exit
```

```
# on PE-2:
configure
    service
        pw-template 1 name "PW1" create
            controlword
        exit
        epipe 3 name "Epipe3" customer 1 create
            description "ms-pw epipe with static routes"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
                standby-signaling-master
            exit
            sap 1/1/4:3 create
            exit
            spoke-sdp-fec 31 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                pw-template-bind 1
                saii-type2 65536:192.0.2.23:31
                taii-type2 65536:192.0.2.13:31
                no shutdown
            exit
            spoke-sdp-fec 32 fec 129 aii-type 2 create endpoint CORE
                pw-template-bind 1
                saii-type2 65536:192.0.2.24:32
                taii-type2 65536:192.0.2.14:32
                no shutdown
            exit
            no shutdown
```

```
        exit
```

Check the status and path of the spoke-SDP FECs with the proper **show** commands and **oam vccv-trace/ping** commands (see previous subsection MS-PW using BGP routing).

MS-PW using explicit paths

In this subsection, Epipe 4 will be configured between PE-1 and PE-2, where T-LDP will use explicit paths to signal the MS-PW, overriding the information given by the MS-PW routing table. Although this mode requires the specific configuration of the hops, one by one, the configuration is only done on the T-PEs, as opposed to the static routes where all the S-PEs must be configured with static routes (a mix of static routes and BGP routes can coexist). The local prefixes shown for Epipe 3 will be re-used here for Epipe 4.

Path-1 and path-2 will be configured hop by hop, using diverse paths. All the S-PE nodes as well as the terminating T-PE must be included in the path.

```
# on PE-1:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.1
            local-prefix 65536:192.0.2.13 create
            exit
            local-prefix 65536:192.0.2.14 create
            exit
            path "path-1" create
                hop 1 192.0.2.3
                hop 2 192.0.2.5
                hop 3 192.0.2.2
                no shutdown
            exit
            path "path-2" create
                hop 1 192.0.2.4
                hop 2 192.0.2.6
                hop 3 192.0.2.2
                no shutdown
            exit
        exit
```

```
# on PE-2:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.2
            local-prefix 65536:192.0.2.23 create
            exit
            local-prefix 65536:192.0.2.24 create
            exit
            path "path-1" create
                hop 1 192.0.2.5
                hop 2 192.0.2.3
                hop 3 192.0.2.1
                no shutdown
            exit
            path "path-2" create
                hop 1 192.0.2.6
                hop 2 192.0.2.4
                hop 3 192.0.2.1
                no shutdown
```

```
            exit
        exit
```

Those paths must be specified when configuring the Epipe:

```
# on PE-1:
configure
    service
        epipe 4 name "Epipe4" customer 1 create
            description "ms-pw epipe with explicit paths"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
                standby-signaling-master
            exit
            sap 1/1/4:4 create
            exit
            spoke-sdp-fec 41 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                saii-type2 65536:192.0.2.13:41
                taii-type2 65536:192.0.2.23:41
                path "path-1"
                no shutdown
            exit
            spoke-sdp-fec 42 fec 129 aii-type 2 create endpoint CORE
                saii-type2 65536:192.0.2.14:42
                taii-type2 65536:192.0.2.24:42
                path "path-2"
                no shutdown
            exit
            no shutdown
        exit
```

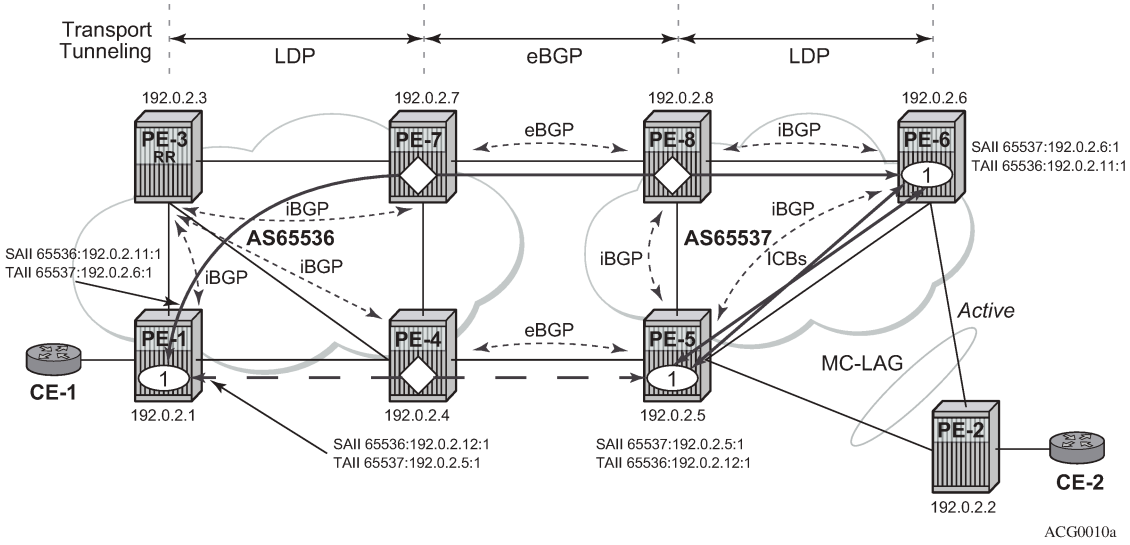
```
# on PE-2:
configure
    service
        epipe 4 name "Epipe4" customer 1 create
            description "ms-pw epipe with explicit paths"
            endpoint "CORE" create
                description "endpoint for epipe A/S PW redundancy"
                revert-time 10
            exit
            sap 1/1/4:4 create
            exit
            spoke-sdp-fec 41 fec 129 aii-type 2 create endpoint CORE
                precedence primary
                saii-type2 65536:192.0.2.23:41
                taii-type2 65536:192.0.2.13:41
                path "path-1"
                no shutdown
            exit
            spoke-sdp-fec 42 fec 129 aii-type 2 create endpoint CORE
                saii-type2 65536:192.0.2.24:42
                taii-type2 65536:192.0.2.14:42
                path "path-2"
                no shutdown
            exit
            no shutdown
        exit
```

Verify the status and path of the spoke-SDP FECs with the proper **show** commands and **oam vccv-trace/ping** commands (see subsection MS-PW using BGP routing).

Inter-AS MS-PW routing

This configuration example for an inter-AS scenario uses BGP tunnels between ASBRs and BGP as the MS-PW routing mechanism. Figure 221: Inter-AS MS-PW example topology shows the example topology used in this section.

Figure 221: Inter-AS MS-PW example topology



In this example, only one Epipe is configured (Epipe 1, using MS-PW BGP routing). The T-PEs are PE-1, PE-5, and PE-6; the S-PEs are PE-7, PE-8, and PE-4.

A/S pseudowire redundancy together with MC-LAG at one end will be used, as shown in Figure 221: Inter-AS MS-PW example topology. Inter-Chassis Backup (ICB) spoke-SDPs between PE-5 and PE-6 are required in order to forward the in-flight packets while MC-LAG and A/S pseudowire are converging, in case of network failures. Those ICBs will also be signaled following the MS-PW routing procedures.

The example topology in Figure 221: Inter-AS MS-PW example topology is pre-configured with the following settings:

- There are two ASs (65536 and 65537) which are connected by two ASBR pairs (PE-7/PE-4 and PE-8/PE-5) running eBGP between them. These eBGP sessions will be used to exchange IPv4-labels (to set up the transport BGP-LBL tunnel, according to the RFC 3107) and MS-PW NLRIs.
- Within AS65536, PE-3 is used as an RR to reflect the MS-PW routes. In AS65537, there is a full mesh of iBGP sessions to distribute the MS-PW routes.
- IS-IS is used within each AS.
- LDP is used as a transport MPLS signaling protocol within each AS and a BGP tunnel will be used between the ASBRs (MS-PW routing supports LDP or BGP tunnels as transport).
- A redundant MC-LAG access to PE-6 and PE-5 is configured.

The next section will go through the configuration required to set up a redundant Epipe between CE-1 and CE-2, by combining A/S pseudowire in the network and MC-LAG at the access.

MS-PW using BGP routing

Epipe 1 will be configured at the end of this section, including the active and redundant pseudowires from PE-1 to PE-5/PE-6, as well as the required ICBs and SAPs at the access.

As discussed, the first step is the provisioning of the pw-routing context. Again, the **spe-address** must be provisioned in all T-PEs and S-PEs whereas prefixes are mandatory only on the T-PEs involved in the service. The following shows the prefixes configured on PE-1, PE-5, and PE-6. Two prefixes are needed in PE-1 in order to make sure that active and standby pseudowires follow disjoint paths.

```
# on PE-1:
configure
    service
        pw-routing
            spe-address 65536:192.0.2.1
            local-prefix 65536:192.0.2.11 create
                advertise-bgp route-distinguisher 65536:11 community 65535:11
            exit
            local-prefix 65536:192.0.2.12 create
                advertise-bgp route-distinguisher 65536:12 community 65535:12
            exit
```

```
# on PE-5:
configure
    service
        pw-routing
            spe-address 65537:192.0.2.5
            local-prefix 65537:192.0.2.5 create
                advertise-bgp route-distinguisher 65537:5 community 65535:5
            exit
```

```
# on PE-6:
configure
    service
        pw-routing
            spe-address 65537:192.0.2.6
            local-prefix 65537:192.0.2.6 create
                advertise-bgp route-distinguisher 65537:6 community 65535:60
            exit
```

Note:
0xFFFF006 and 0xFFFF007 are the values that have been assigned by IANA to the well-known communities for Long-Lived Graceful Restart (LLGR): "LLGR_STALE" and "NO_LLGR". Therefore, on PE-6, the community value must not be 65535:6, because 65535:6 would be mapped to community "LLGR_STALE". The value 65535:60 is used instead.

Once the S-PE-addresses and prefixes have been provisioned, BGP must be configured accordingly. A simple BGP export policy is used to export all the local MS-PW prefixes. The configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router
        autonomous-system 65536
        policy-options
            begin
            policy-statement "export_ms-pw"
                entry 10
```

```
                    from
                        family ms-pw
                    exit
                    action accept
                        origin igp
                    exit
                exit
            exit
            commit
        exit
        bgp
            enable-peer-tracking
            rapid-withdrawal
            group "intra-AS"
                family ms-pw
                export "export_ms-pw"
                peer-as 65536
                neighbor 192.0.2.3
                exit
            exit
            no shutdown
        exit
    exit
```

The configuration on PE-6 is as follows:

```
# on PE-6:
configure
    router
        autonomous-system 65537
        policy-options
            begin
            policy-statement "export_ms-pw"
                entry 10
                    from
                        family ms-pw
                    exit
                    action accept
                        origin igp
                    exit
                exit
            exit
            commit
        exit
        bgp
            enable-peer-tracking
            rapid-withdrawal
            group "intra-AS"
                family ms-pw
                export "export_ms-pw"
                peer-as 65537
                neighbor 192.0.2.5
                exit
                neighbor 192.0.2.8
                exit
            exit
            no shutdown
        exit
    exit
```

At the ASBR, the BGP policies are more complex because the following tasks must be accomplished:

- ASBR IPv4 system addresses must be exported to the peer ASBR to establish the RFC 3107 BGP tunnel between ASBRs.
- BGP export policies must be used so that MS-PW NLRI exchange can be controlled and attributes like Multi Exit Discriminator (MED) toward the remote AS and/or local-preference (LP) toward the local AS can be modified.
- Finally, BGP import policies must also be used to modify the MS-PW route NH because the T-LDP next signaling hop must match a peer T-LDP system address.

The prefixes 65536:192.0.2.11 and 65537:192.0.2.6 must be preferred in the PE-7/PE-8 pair whereas the prefixes 65536:192.0.2.12 and 65537:192.0.2.5 must be preferred in the PE-4/PE-5 pair, so that the PWs are established as shown in Figure 221: Inter-AS MS-PW example topology. The preference can be propagated by using the BGP MED; the LP is used within the AS, but not relevant to eBGP. The following CLI excerpt shows an example of how to modify MED and LP, as well as changing the NH with an import policy. The configuration on ASBR PE-4 is as follows:

```
*A:PE-4#
configure
    router
        autonomous-system 65536
        policy-options
            begin
            prefix-list "system"
                prefix 192.0.2.4/32 exact
            exit
            community "65535:5"
                members "65535:5"
            exit
            community "65535:11"

            exit
        exit
        no shutdown
    exit
```

PE-5 and PE-8 have similar configurations to the ones shown. However, PE-5 is a T-PE as well as an ASBR, therefore a local MS-PW prefix must be exported as opposed to only remote prefixes (that is, some export entries for the local MS-PW routes will not contain **protocol bgp** in the matching criteria).

After BGP is properly configured and the updates get exchanged, the RIBs are populated and the prefixes uploaded onto the MS-PW routing table as shown for PE-1 in the following output:

```
*A:PE-1# show router bgp routes ms-pw

===============================================================================
```

As can be seen in the preceding **show** commands on PE-6, the two PE-1 prefixes are learned on (PE-5 and) PE-6 through different and disjoint paths. On PE-1, the PE-5 and PE-6 prefixes are learned through two different and disjoint paths.

After configuring the PW routing context and configuring BGP, the last step is the service configuration on the three T-PEs, as follows. T-LDP sessions must have been previously and explicitly configured between the T-PEs and S-PEs (between PE-1 and PE-4/7, between PE-4 and PE-5, PE-7 and PE-8, and between PE-6 and PE-5/8).

```
# on PE-1:
configure
    router Base
        ldp
            targeted-session
                peer 192.0.2.4
                exit
                peer 192.0.2.7
```

```
                exit
            exit
        exit
    exit
    service

       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

```
*A:PE-7# show service sdp 32766 detail | match "Active LSP"
Mixed LSP Mode       : Enabled               Active LSP Type    : LDP
```

```
*A:PE-7# show service sdp 32767 detail | match "Active LSP"
Mixed LSP Mode       : Enabled               Active LSP Type    : BGP
```

In addition to all of the recommended show commands, **vccv-ping** and **vccv-trace** are two extremely useful commands in this environment. **vccv-trace** can even help to trace the traffic going through the ICBs under failure situations.

Conclusion

Service Providers are always seeking highly scalable VLL services that can be deployed with the lowest operational cost. The SR OS supports MS-PW routing according to the draft-ietf-pwe3-dynamic-ms-pw.

MS-PW routing allows the Service Provider to deploy Epipe services without having to provision services in the core of the network. In other words, MS-PW enables end-point provisioning in highly scalable seamless MPLS networks, through the use of BGP. Alternatively, static MS-PW routes or explicit paths can also be used.

The examples used in this chapter illustrate the configuration of MS-PW routing in intra-AS and inter-AS scenarios. Show and OAM commands have also been suggested so that the operator can verify and troubleshoot the MS-PW routing paths and procedures.

Operational Groups for EVPN-VXLAN VPWS Services

This chapter describes the Operational Groups for EVPN-VXLAN VPWS Services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 16.0.R5, but the CLI in the current edition corresponds to SR OS Release 21.5.R2. EVPN-VXLAN VPWS and service-level operational groups for VPWS services are supported in SR OS Release 16.0.R1, or later.

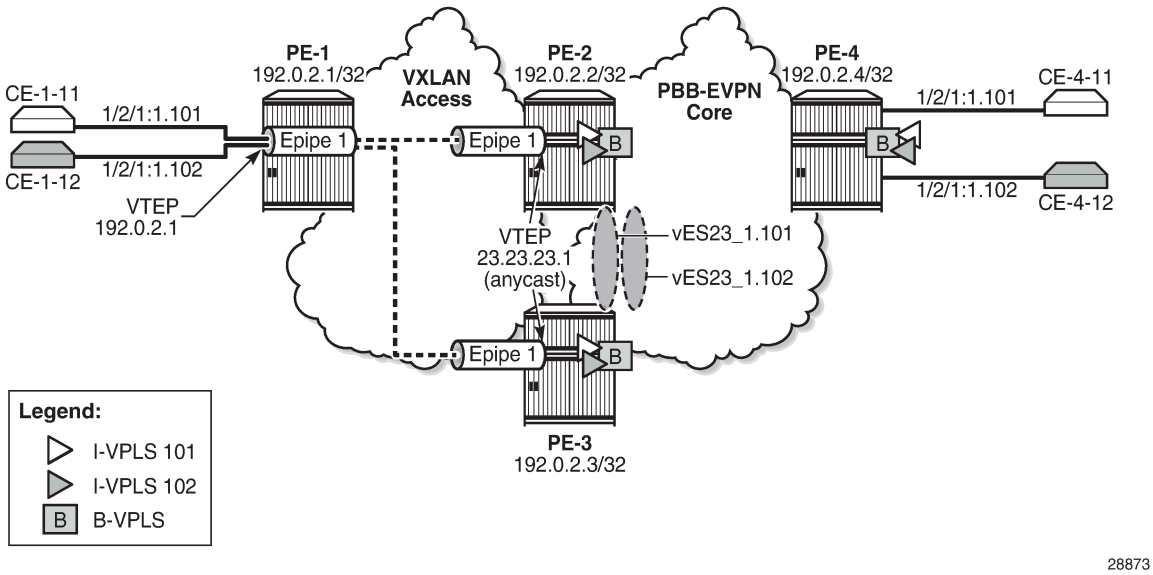
Overview

Operational groups on Epipe services are used for fault propagation to other services, such as I-VPLS or R-VPLS services. Epipes with VXLAN destinations are used in some edge PE applications along with port cross-connect (PXC) so that VXLAN networks can be terminated in other VPLS or VPRN services. In such cases, the operational status of the Epipe services terminating VXLAN must override the operational status of the SAPs of the VPLS or VPRN where the Epipe is stitched to.

Operational group on egress VTEP in Epipes with static VXLAN bindings

The Static VXLAN Termination in Epipe Services chapter describes how Epipes with static VXLAN termination are stitched to I-VPLS services. In Epipes with static VXLAN bindings, operational groups can be configured in the egress VTEP context. Figure 222: Epipe with static VXLAN termination shows the example topology with a static VXLAN tunnel between PE-1 and an anycast address on PE-2 and PE-3. The All-Active Multi-Homing Ethernet Segments (AA MH ESs) "vES23_1.101" and "vES23_1.102" are used by the I-VPLSs 101 and 102, which are both stitched to Epipe 1 in PE-2 and PE-3. The SAPs in these I-VPLSs monitor the operational group configured in the egress VTEP context of the Epipe service, so the SAPs will go operationally down when the operational group of the VTEP goes operationally down.

Figure 222: Epipe with static VXLAN termination



On PE-2 and PE-3, Epipe 1 is configured with static VXLAN bindings, as follows. The egress VTEP is 192.0.2.1, which is the system IP address of PE-1. Operational group "op-grp-1" in configured for this egress VTEP. LAG 2 combines PXC ports and is used to stitch Epipe 1 to the I-VPLS services 101 and 102. For a detailed description of the configuration, see the Static VXLAN Termination in Epipe Services chapter.

```
# on PE-2, PE-3:
configure
    service
        oper-group "op-grp-1" create
        exit
        epipe 1 name "Epipe 1" customer 1 create
            description "Epipe 1 with static VXLAN bindings"
            vxlan-src-vtep 23.23.23.1
            vxlan instance 1 vni 1 create
                egr-vtep 192.0.2.1
                    oper-group "op-grp-1"
                exit
            exit
            sap lag-2:1.* create
                no shutdown
            exit
            no shutdown
        exit
```

For failure propagation to the stitched I-VPLSs, the SAPs in the I-VPLSs can monitor the operational group "op-grp-1", for I-VPLS 101 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls 101 name "I-VPLS 101" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
```

```
            exit
            sap lag-1:1.101 create
                monitor-oper-group "op-grp-1"
                no shutdown
            exit
            no shutdown
        exit
```

When the egress VTEP prefix 192.0.2.1 disappears from the global route-table on PE-2, the VXLAN binding goes down, as follows:

```
*A:PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

When the egress VTEP 192.0.2.1 goes down, the operational group "op-grp-1" goes down too, as follows:

```
*A:PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

When the operational group "op-grp-1" goes down, the monitoring SAP in I-VPLS 101 goes operationally down with flag OperGroupDown, as follows:

```
*A:PE-2# show service id 101 sap lag-1:1.101 detail
                                          | match expression "Flags | Oper State"
Admin State        : Up                    Oper State        : Down
Flags              : OperGroupDown
Stp Admin State    : Up                    Stp Oper State    : Down
```

When this SAP goes down, the entire I-VPLS 101 service goes down on PE-2, as follows:

```
*A:PE-2# show service id 101 base | match "State"
Admin State       : Up                 Oper State        : Down
```

Epipes with static VXLAN bindings impose the following restrictions, which cannot be overcome unless a control plane protocol such as BGP-EVPN is used for the VXLAN bindings.

- When anycast VTEPs on the PEs are used, a change in the vES preference on the DF PE triggers a DF switchover for the I-VPLS service. However, the access PE (PE-1 in Figure 1) is unaware and keeps

sending the VXLAN traffic to the same PE, unless a change in DF comes with an automatic change in the underlay IGP metrics, which cannot be easily accomplished.

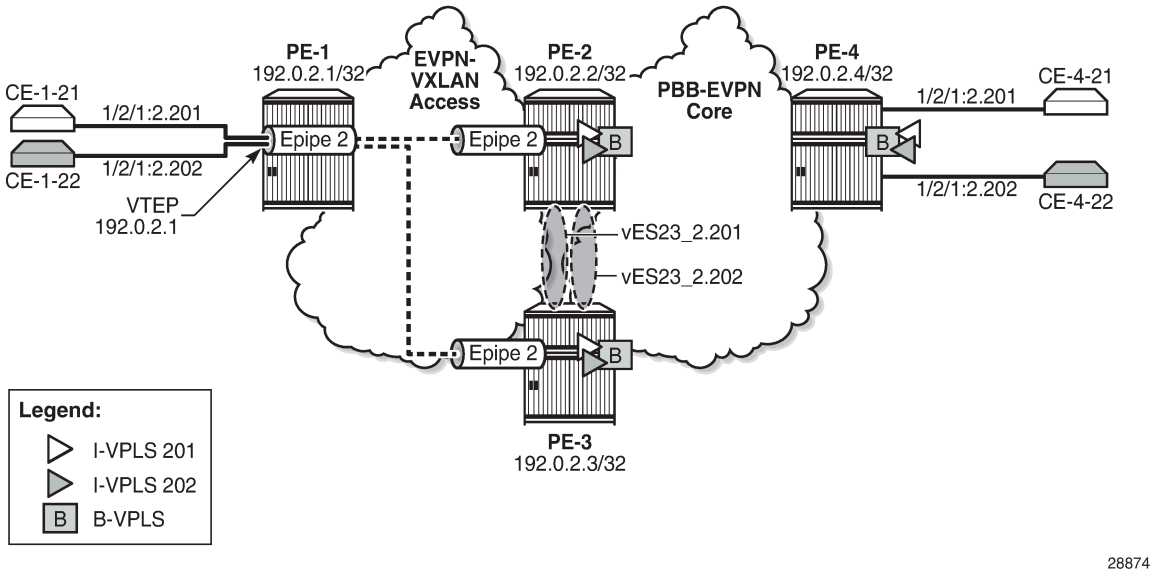
- Without a control plane, Eth-CFM must be used between PEs and access PEs to detect end-to-end service-level failures.
- Traffic from the access PE is forwarded to the anycast VTEP, based on underlay IGP metrics. There is no control on a per-service basis.
- The architecture does not support AA MH for the Epipe service, so the access PEs always send the traffic to one single PE.

The preceding challenges can be addressed by using different VTEPs on the PEs and adding a BGP-EVPN control plane on the Epipe, as described in the next section.

Operational groups in EVPN-VXLAN Epipes

Figure 223: Epipe 2 with EVPN-VXLAN and all-active multi-homing shows EVPN-VXLAN Epipe 2 stitched to I-VPLSs 201 and 202. AA MH ESs "vES23_2.201" and "vES23_2.202" are used by the I-VPLSs 201 and 202 respectively.

Figure 223: Epipe 2 with EVPN-VXLAN and all-active multi-homing



The EVPN-VXLAN VPWS chapter describes the configuration of Epipes with EVPN-VXLAN bindings instead of static VXLAN bindings. The egress VTEP is not configured manually, but dynamically learned through BGP-EVPN. Therefore, the operational group cannot be configured in the egress VTEP context. However, it is possible to configure an operational group in an Epipe at the service level, as follows:

```
# on PE-2:
configure
    service
        oper-group "op-grp-2" create
        exit
        epipe 2 name "Epipe 2" customer 1 create
            description "Epipe 2 with EVPN-VXLAN"
```

```
            oper-group "op-grp-2"
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                remote-attachment-circuit AC-1 create
                    eth-tag 101
                exit
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap lag-2:2.* create
                no shutdown
            exit
            no shutdown
```

The following shows the error raised when attempting to configure the egress VTEP manually in an Epipe service with BGP-EVPN enabled:

```
*A:PE-2>configure>service>epipe>vxlan# egr-vtep 192.0.2.1
MINOR: SVCMGR #7894 Cannot configure egr-vtep - service has bgp-evpn
```

An operational group can be associated with the entire Epipe or with specific objects, such as SAPs or spoke-SDPs, but not simultaneously. The following error is raised when attempting to associate the operational group "op-grp-2"—that is already associated with the Epipe with the SAP on PE-2:

```
*A:PE-2>config>service>epipe>sap# oper-group "op-grp-2"
MINOR: SVCMGR #1003 Inconsistent value - oper-group already in use as service oper group
```

The service-level operational group status is derived from the service operational status: when Epipe 2 is operationally down, the operational group "op-grp-2" will be down.

For fault propagation to the stitched I-VPLSs 201 and 202, the SAPs in the I-VPLSs monitor the operational group "op-grp-2", for I-VPLS 201 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls 201 name "I-VPLS 201" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-1:2.201 create
                monitor-oper-group "op-grp-2"
                no shutdown
            exit
            no shutdown
        exit
```

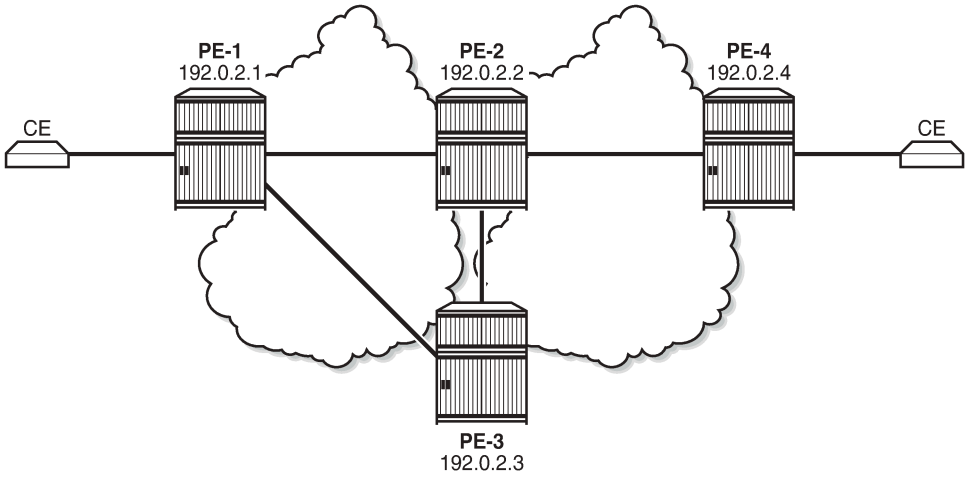
Configuration

In this section, the following use cases are described:

- operational group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using Single-Active (SA) MH ESs

Figure 224: Example topology shows the example topology with four PEs in an autonomous system.

Figure 224: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (level capability 2 in the core between PE-2, PE-3, and PE-4; level capability 1 in the access toward PE-1)
- LDP between the core routers PE-2, PE-3, and PE-4

Oper group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs

When static VXLAN bindings are used, no BGP-EVPN is required in the access network to and from PE-1; BGP is only configured in the core network. When PE-2 acts as the route reflector, its BGP configuration is as follows:

```
# on RR PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
```

```
            vpn-apply-import
            vpn-apply-export
            rapid-update evpn
            group "CORE"
                family evpn
                type internal
                cluster 192.0.2.2
                split-horizon
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
```

Figure 222: Epipe with static VXLAN termination shows that Epipe 1 is configured in the access network: on PE-1, the VTEP is the system address 192.0.2.1 (default), and on PE-2 and PE-3, the VTEP is a unicast address 23.23.23.1.

On PE-1, Epipe 1 is configured with egress VTEP 23.23.23.1, as follows:

```
# on PE-1:
configure
    service
        epipe 1 name "Epipe 1" customer 1 create
            description "Epipe 1 with static VXLAN bindings"
            vxlan instance 1 vni 1 create
                egr-vtep 23.23.23.1
                exit
            exit
            sap 1/2/1:1.* create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2 and PE-3, the following unicast address is configured:

```
# on PE-2, PE-3:
configure
    router
        interface "lo23"
            address 23.23.23.0/31
            loopback
        exit
```

On PE-2 and PE-3, three ports are configured as PXC. PXC 1 is used as Forwarding Path Extension (FPE) and the VXLAN tunnel termination 23.23.23.1 is configured with this FPE, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            vxlan
                tunnel-termination 23.23.23.1 fpe 1 create
            exit
```

PXCs 2 and 3 are used in the internal LAGs that are used to stitch Epipe 1 to I-VPLSs 101 and 102, as follows. LAG 1 will be used in the I-VPLS services; LAG 2 in the Epipe services.

```
# on PE-2, PE-3:
```

```
configure
    lag 1
        mode hybrid
        encap-type qinq
        port pxc-2.a
        port pxc-3.a
        no shutdown
    exit
    lag 2
        mode hybrid
        encap-type qinq
        port pxc-2.b
        port pxc-3.b
        no shutdown
    exit
```

On PE-2 and PE-3, Epipe 1 is configured with source VTEP 23.23.23.1 and egress VTEP 192.0.2.1, as follows. The operational group "op-grp-1" is associated with the egress VTEP. The SAP stitches Epipe 1 to the I-VPLSs 101 and 102.

```
# on PE-2, PE-3:
configure
    service
        oper-group "op-grp-1" create
        exit
        epipe 1 name "Epipe 1" customer 1 create
            description "Epipe 1 with static VXLAN bindings"
            vxlan-src-vtep 23.23.23.1
            vxlan instance 1 vni 1 create
                egr-vtep 192.0.2.1
                    oper-group "op-grp-1"
                exit
            exit
            sap lag-2:1.* create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, B-VPLS 100 is configured as follows. The configuration is similar on PE-3 and PE-4.

```
# on PE-2:
configure
    service
        vpls 100 name "B-VPLS-100" customer 1 b-vpls create
            service-mtu 1532
            pbb
                source-bmac 00:00:00:00:00:02
                use-es-bmac
            exit
            bgp
            exit
            bgp-evpn
                evi 100
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
```

```
            no shutdown
        exit
```

On PE-2, I-VPLS 101 is configured as follows. The SAP monitors the operational group "op-grp-1" that is configured in Epipe 1. The AA MH ES "vES23_1.101" is used. The configuration of I-VPLS 102 is similar, but it uses AA MH ES "vES23_1.102" with preference value 50 instead. On PE-3, the preference values are reversed: preference value 50 for "vES23_1.101" and 100 for "vES23_1.102".

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES23_1.101" virtual create
                    esi 01:00:00:00:00:23:00:00:01:11
                    source-bmac-lsb 23-11 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    qinq
                        s-tag 1 c-tag-range 101
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 101 name "I-VPLS 101" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-1:1.101 create
                monitor-oper-group "op-grp-1"
                no shutdown
            exit
            no shutdown
        exit
```

On PE-4, I-VPLS 101 is configured as follows:

```
# on PE-4:
configure
    service
        vpls 101 name "I-VPLS 101" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap 1/2/1:1.101 create
                no shutdown
            exit
            no shutdown
        exit
```

To emulate a failure that affects the operational state of the egress VTEP (and also of the Epipe service), the SAP of Epipe 1 on PE-2 is disabled, as follows:

```
# on PE-2:
configure
    service
        epipe "Epipe 1"
            sap lag-2:1.*
                shutdown
```

When the SAP is operationally down, Epipe 1 goes down, as follows:

```
*A:PE-2# show service id 1 base | match "State"
Admin State       : Up                 Oper State        : Down
```

The egress VTEP 192.0.2.1 is operationally down, as follows:

```
*A:PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The operational group "op-grp-1" is associated with the egress VTEP, so it goes operationally down, as follows:

```
*A:PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

This operational group is monitored by the SAPs in I-VPLSs 101 and 102, so these SAPs go down with flag OperGroupDown; for example, for I-VPLS 101 on PE-2:

```
*A:PE-2# show service id 101 sap lag-1:1.101 | match "Flags"
Flags              : OperGroupDown
```

When the SAP goes down, the I-VPLS service goes down, as follows:

```
*A:PE-2# show service id 101 base | match "State"
Admin State       : Up                 Oper State        : Down
```

Even though Epipe 1 on PE-2 is operationally down while Epipe 1 on PE-3 is up, PE-1 is unaware because the VXLAN destination in Epipe 1 remains up, as follows:

```
*A:PE-1# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
23.23.23.1                            1                   Up        static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

With ECMP=1, all traffic from PE-1 is directed to PE-2, regardless of the state of the Epipe on PE-2. The following route table on PE-1 shows that destination prefix 23.23.23.0/31 has next-hop 192.168.12.2, which is an interface address on PE-2.

```
*A:PE-1# show router route-table 23.23.23.0/31

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref

===============================================================================
```

Traffic from the CEs attached to PE-1 is forwarded by PE-1 to PE-2, where it is dropped.

Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using AA MH ESs

BGP must be enabled on all nodes for the EVPN address family, also in the access to and from PE-1. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            rapid-update evpn
            group "ACCESS"
                family evpn
```

```
                type internal
                split-horizon
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

On PE-1, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 101 and remote Ethernet tag 123.

```
# on PE-1:
configure
    service
        epipe 2 name "Epipe 2" customer 1 create
            description "Epipe 2 with EVPN-VXLAN"
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-1 create
                    eth-tag 101
                exit
                remote-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap 1/2/1:2.* create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 123 and remote Ethernet tag 101. The operational group "op-grp-2" is associated with Epipe 2. The configuration on PE-3 is identical.

```
# on PE-2:
configure
    service
        oper-group "op-grp-2" create
        exit
        epipe 2 name "Epipe 2" customer 1 create
            description "Epipe 2 with EVPN-VXLAN"
            oper-group "op-grp-2"
            vxlan instance 1 vni 2 create
            exit
            bgp
            exit
            bgp-evpn
                local-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                remote-attachment-circuit AC-1 create
                    eth-tag 101
                exit
                evi 2
```

```
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap lag-2:2.* create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of B-VPLS 100 remains unchanged and the configuration of the I-VPLSs 201 and 202 resembles the configuration of VPLSs 101.

When there is no failure, the egress VTEP for Epipe 2 on PE-1 is 192.0.2.2, which is the system IP address of PE-2, as follows:

```
*A:PE-1# show service id 2 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.2                             2                   Up        evpn
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

To emulate a failure that affects the operational state of the Epipe service, the SAP in Epipe 2 is disabled, as follows:

```
# on PE-2:
configure
    service
        epipe "Epipe 2"
            sap lag-2:2.*
                shutdown
```

When the SAP goes down, the Epipe goes down, as follows:

```
*A:PE-2# show service id 2 base | match "State"
Admin State       : Up                  Oper State        : Down
```

On PE-1, the egress VTEP for Epipe 2 is 192.0.2.3, which is the system IP address of PE-3, as follows:

```
*A:PE-1# show service id 2 vxlan destinations

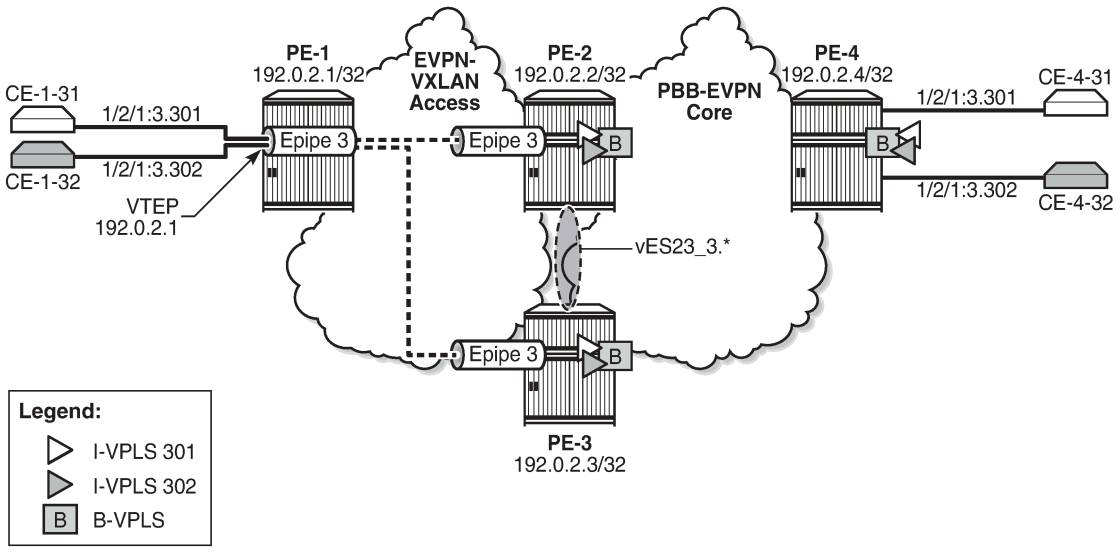
Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using SA MH ESs

Figure 225: Epipe 3 with EVPN-VXLAN and SA MH ES shows the example topology with an SA MH ES used by the I-VPLSs.

Figure 225: Epipe 3 with EVPN-VXLAN and SA MH ES



The configuration of Epipe 3 resembles the configuration of Epipe 2: the same Ethernet tags are used, only the VNI, EVI, and SAPs are different.

On PE-2 and PE-3, PXC 4 is configured to stitch Epipe 3 to I-VPLSs 301 and 302. The PXC port will be used in the SA MH ES.

On PE-2 and PE-3, Epipe 3 is configured as follows:

```
# on PE-2, PE-3:
configure
    service
        oper-group "op-grp-3" create
        exit
        epipe 3 name "Epipe 3" customer 1 create
            description "EVPN-VXLAN Epipe 3"
            oper-group "op-grp-3"
            vxlan instance 1 vni 3 create
            exit
            bgp-evpn
                local-attachment-circuit AC-23 create
                    eth-tag 123
                exit
                remote-attachment-circuit AC-1 create
                    eth-tag 101
                exit
                evi 3
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            sap pxc-4.b:3.* create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, I-VPLS 301 uses SA MH ES "vES23_3.*", and is configured as follows.

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES23_3.*" virtual create
                    esi 01:00:00:00:00:23:00:00:03:01
                    source-bmac-lsb 23-34 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100
                            exit
                        exit
                    exit
                    multi-homing single-active
                    port pxc-4.a
                    qinq
                        s-tag-range 3
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 301 name "I-VPLS 301" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
```

```
            stp
                shutdown
            exit
            sap pxc-4.a:3.301 create
                monitor-oper-group "op-grp-3"
                no shutdown
            exit
            no shutdown
        exit
```

The configuration is similar on PE-3, but with source-bmac-lsb 23-35 and preference 50.

When Epipe 3 on PE-2 is operationally up, the egress VTEP for Epipe 3 on PE-1 is 192.0.2.2, as follows:

```
*A:PE-1# show service id 3 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan

-------------------------------------------------------------------------------
192.0.2.2                             3                   Up        evpn
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

To emulate a failure on PE-2 that affects the operational state of the Epipe service, the SAP in Epipe 3 is disabled, as follows:

```
# on PE-2:
configure
    service
        epipe "Epipe 3"
            sap pxc-4.b:3.*
                shutdown
```

When the SAP goes down, Epipe 3 goes down on PE-2, as follows:

```
*A:PE-2# show service id 3 base | match "State"
Admin State       : Up                Oper State        : Down
```

When Epipe 3 on PE-2 goes operationally down, the egress VTEP for Epipe 3 on PE-1 is 192.0.2.3, as follows:

```
*A:PE-1# show service id 3 vxlan destinations

===============================================================================

Conclusion

Some service providers use VXLAN as a next-generation access technology used between the MSANs (or access PEs) and core PE routers. EVPN-VXLAN Epipes can be stitched using PXC to other services, such as I-VPLS. Operational groups can be defined in the Epipe for fault propagation to the SAPs of the services where the Epipe is stitched to.

Operational Groups in EVPN Services

This chapter provides information about Operational Groups in EVPN Services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R1. EVPN operational groups are supported in EVPN-VXLAN and EVPN-MPLS VPLS and R-VPLS services in SR OS Release 19.10.R2 and later; in EVPN-MPLS Epipes in SR OS Release 19.5.R1 and later.

Overview

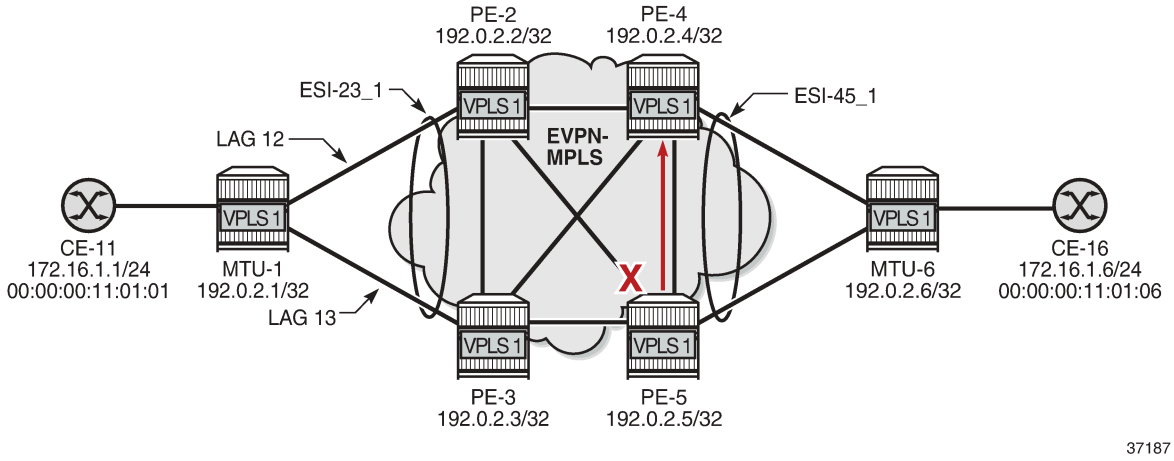
An operational group includes objects and drives the status of service endpoints (such as pseudowires, SAPs, IP interfaces) located in the same or in different service instances. The operational group status is derived from the status of the individual components. Other service objects can monitor the operational group status. The status of the operational group influences the status of the monitoring objects.

If the operational group goes down, the monitoring objects are also brought operationally down. When one of the objects included in the operational group comes up, the entire operational group comes up, as well as the monitoring objects.

Operational groups for EVPN destinations

Figure 226: EVPN mesh going down triggers DF switchover from PE-5 to PE-4 shows a sample topology with VPLS 1 configured on all nodes. PE-4 and PE-5 share a single-active Ethernet Segment (ES) "ESI-45_1" where PE-5 is the Designated Forwarder (DF).

Figure 226: EVPN mesh going down triggers DF switchover from PE-5 to PE-4



When the EVPN-VPLS service becomes isolated from the rest of the EVPN network (for example, all EVPN destinations are removed on DF PE-5), an operational group for EVPN destinations is required to trigger a DF switchover and bring the monitoring access SAP (or spoke SDP) down. EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. Ethernet Connectivity Fault Management (ETH-CFM) is enabled on a down Maintenance Endpoint (MEP) configured on the SAP to detect SAP failure. After the remote MEP on MTU-6 detects the failure, MTU-6 redirects its traffic to PE-4. This avoids blackholes when PE-5 is disconnected from the EVPN core.

On PE-5, VPLS 1 is configured with operational group "vpls-1_45" in EVPN-MPLS and SAP 1/1/2:1 monitoring this operational group. The operational group configured under a BGP-EVPN instance cannot be configured under any other object, such as SAPs or SDP-bindings.

```
# on PE-5:
configure
    service
        oper-group "vpls-1_45" create
            hold-time
                group down 0
                group up 0
            exit
        exit
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                cfm-mac-advertisement
                evi 1
                mpls bgp 1
                    oper-group "vpls-1_45"
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
```

```
            sap 1/1/2:1 create
                description "to MTU-6"
                eth-cfm
                    mep 56 domain 1 association 11 direction down
                        fault-propagation-enable suspend-ccm
                        ccm-enable
                        mac-address 00:00:00:00:56:05
                        no shutdown
                    exit
                exit
                monitor-oper-group "vpls-1_45"
                no shutdown
            exit
            no shutdown
        exit
```

Using operational groups in the EVPN service, it is possible to monitor if the PE is isolated and, if it is, trigger a Designated Forwarder switchover. The operational group associated to the EVPN-MPLS instance goes down in the following cases:

- bgp-evpn mpls is disabled (shutdown)
- VPLS is disabled (shutdown)
- all EVPN destinations associated to the instance are removed, for example, when:
  - no tunnels are available for auto-bind-tunnel resolution
  - the network ports facing the EVPN ports are down
  - the BGP sessions to the route reflector or PEs are down

Operational groups for Ethernet Segments (Port-active multi-homing)

Operational groups can be configured on single-active ESs that need to function as port-active multi-homing Ethernet Segments. 'Port-active' refers to a special single-active mode where the PE is DF or non-DF for all the services attached to the ES. The configuration of a port-active ES is as follows:

```
# on PE-2:
configure
    service
        oper-group "vpls-1_23" create
            hold-time
                group down 0
                group up 0
            exit
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-23_1" create
                    esi 01:23:00:00:00:00:01:00:00:00
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 150               # on PE-3: value 100
                            exit
                        exit
                    exit
                    multi-homing single-active
                    lag 12                              # on PE-3: lag 13
```

```
                    oper-group "vpls-1_23"
                    no shutdown
                exit
```

This ES operational group can be monitored on the LAG:

```
# on PE-2:
configure
    lag 12 name "lag-12"
        description "to MTU-1"
        mode access
        encap-type dot1q
        monitor-oper-group "vpls-1_23"
        port 1/1/2
        lacp active administrative-key 1 system-id 00:00:00:01:02:01
                                          system-priority 1
        standby-signaling lacp                          # default
        no shutdown
    exit
```

When the operational group is configured on the ES and monitored on the associated LAG:

- The status of the ES operational group is driven by the ES DF status.
  - When a node becomes NDF, the ES operational group goes down and all the SAPs in the ES go down.
- The ES operational group goes down when all the SAPs in the ES go down.
  - When all SAPs in the ES go down, the operational group goes down and the node becomes NDF.

The monitoring LAG goes down when the ES operational group is down. The LAG signals the LAG standby state to the access node. The LAG standby signaling can be configured as **lacp** or **power-off**.

```
*A:PE-2>config>lag# standby-signaling
  - no standby-signaling
  - standby-signaling {lacp|power-off}
```

- **standby-signaling lacp** signals LACP out-of-sync to the CE when the application layer instructs the LAG to become standby
- **standby-signaling power-off** brings the LAG members down, and hence the access SAPs down

The ES and AD routes for the ES are not withdrawn because the router recognizes that the LAG becomes standby due to the ES operational group.

Some restrictions:

- Multi-chassis LAG and ES are mutually exclusive:

  ```
  *A:PE-3>config>redundancy>mc>peer>mc-lag# lag 13
  MINOR: LAGMGR #1321 lag associated with ethernet segment
  ```

- LAG sub-groups are blocked:

  ```
  *A:PE-3>config>lag# port 1/1/1 sub-group 2
  MINOR: CLI Could not set subgroup for port "1/1/1".
  MINOR: LAGMGR #1031 Port settings incompatible - invalid combination port sub-group <->
   monitor-oper-group
  ```

- Only LAGs in access mode can monitor operational groups:

```
*A:PE-3>config>lag$ monitor-oper-group "vpls-1_23"
MINOR: LAGMGR #1031 Port settings incompatible - monitor-oper-group not allowed when lag is
 not access
```

- Operational groups cannot be assigned to virtual ESs:

```
*A:PE-3>config>service>system>bgp-evpn>eth-seg# oper-group "vpls-1_23"
MINOR: SVCMGR #8050 Ethernet segment config cannot be modified - oper-group not supported
 with virtual ethernet-segments
```

- Operational groups cannot be assigned to all-active ESs:

```
*A:PE-3>config>service>system>bgp-evpn>eth-seg$ oper-group "vpls-1_23"
MINOR: SVCMGR #8050 Ethernet segment config cannot be modified - oper-group not supported
 with all-active ethernet-segment
```

- Operational groups cannot be assigned to ESs with service-carving auto:

```
*A:PE-3>config>service>system>bgp-evpn>eth-seg$ oper-group "vpls-1_23"
MINOR: SVCMGR #8050 Ethernet segment config cannot be modified - oper-group not supported on
 ethernet-segments with service carving auto
```

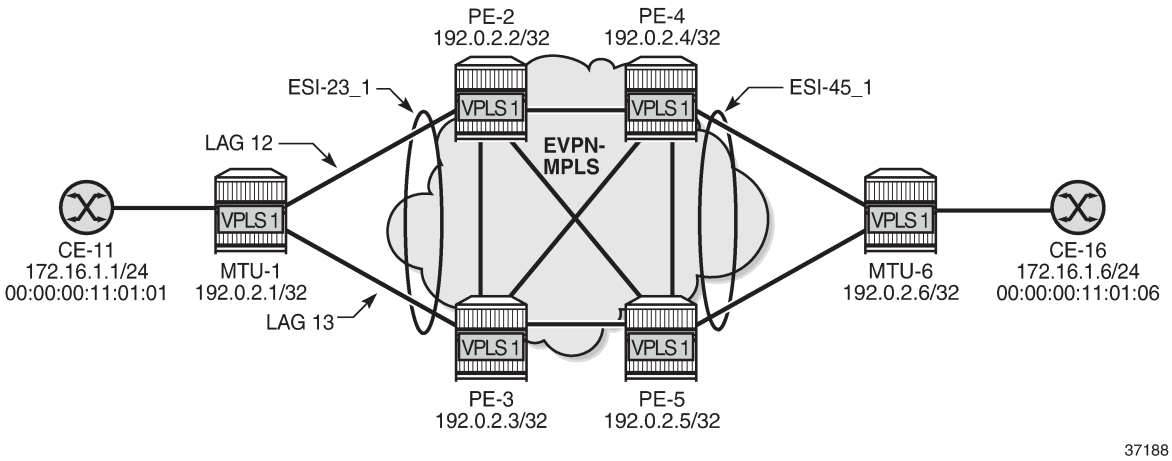
Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM. However, not all access nodes support ETH-CFM and, in that case, LAG **standby-signaling lacp** or **power-off** can be used instead.

Configuration

Figure 227: Sample topology with VPLS 1 shows the sample topology with VPLS 1 configured on all nodes.

Figure 227: Sample topology with VPLS 1



The initial configuration includes:

- Cards, MDAs, ports
- LAG 12 between PE-1 and PE-2; LAG 13 between PE-1 and PE-3
- Router interfaces between PE-2, PE-3, PE-4, and PE-5
- IS-IS on all router interfaces
- LDP between PE-2, PE-3, PE-4, and PE-5
- BGP between PE-2, PE-3, PE-4, and PE-5

For BGP, PE-2 acts as route reflector and the configuration is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 192.0.2.2
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
        exit
```

Operational groups for EVPN destinations

On PE-4, single-active ES "ESI-45_1" is configured with service carving auto. Operational group "vpls-1_45" is associated with EVPN-MPLS in VPLS 1 and SAP 1/1/1:1 is monitoring that operational group. ETH-CFM is enabled on a down MEP configured on the SAP to detect SAP failures. The service configuration is as follows:

```
# on PE-4:
configure
    service
        oper-group "vpls-1_45" create
            hold-time
                group down 0
                group up 0
            exit
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45_1" create
                    esi 01:45:00:00:00:00:01:00:00:00
                    es-activation-timer 3
                    service-carving
```

```
                    mode auto
                exit
                multi-homing single-active
                port 1/1/1
                no shutdown
            exit
        exit
    exit
    vpls 1 name "VPLS 1" customer 1 create
        bgp
        exit
        bgp-evpn
            cfm-mac-advertisement
            evi 1
            mpls bgp 1
                oper-group "vpls-1_45"
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/1/1:1 create
            description "to MTU-6"
            eth-cfm
                mep 46 domain 1 association 10 direction down
                    ccm-enable
                    mac-address 00:00:00:00:46:04
                    no shutdown
                exit
            exit
            monitor-oper-group "vpls-1_45"
            no shutdown
        exit
        no shutdown
    exit
```

The configuration on PE-5 is similar.

On MTU-6, VPLS 1 is configured with three SAPs: SAP 1/1/2:1 toward PE-4, SAP 1/1/1:1 toward PE-5, and SAP 1/2/1:1 toward CE-16. ETH-CFM MEPs are configured on SAP 1/1/1:1 and SAP 1/1/2:1. The service configuration is as follows:

```
# on MTU-6:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            stp
                shutdown
            exit
            sap 1/1/1:1 create
                description "to PE-5"
                eth-cfm
                    mep 65 domain 1 association 11
                        ccm-enable
                        mac-address 00:00:00:00:65:06
                        no shutdown
                    exit
                exit
                no shutdown
```

```
            exit
            sap 1/1/2:1 create
                description "to PE-4"
                eth-cfm
                    mep 64 domain 1 association 10
                        ccm-enable
                        mac-address 00:00:00:00:64:06
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            sap 1/2/1:1 create
                description "to CE-16"
                no shutdown
            exit
            no shutdown
        exit
```

Initial situation without failure

On MTU-6, ETH-CFM MEP 65 receives Continuity Check (CC) messages from its remote peer 56 on PE-5:

```
*A:MTU-6# show eth-cfm mep 65 domain 1 association 11 all-remote-mepids

===============================================================================
Eth-CFM Remote-Mep Table
===============================================================================
R-mepId AD Rx CC RxRdi Port-Tlv If-Tlv Peer Mac Addr     CCM status since
-------------------------------------------------------------------------------
56         True  False Absent   Absent 00:00:00:00:56:05 12/23/2021 13:51:58
===============================================================================
Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

The following command shows that PE-5 is DF for VPLS 1:

```
*A:PE-5# show service id 1 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
1/1/2:1               ESI-45_1                        DF
===============================================================================
No sdp entries
No vxlan instance entries
```

PE-5 has full mesh with all EVPN destinations in VPLS 1:

```
*A:PE-5# show service id 1 evpn-mpls

===============================================================================

Avoiding blackholes when EVPN destinations are removed

On PE-5, a failure is simulated by disabling LDP:

```
# on PE-5:
configure
    router Base
        ldp
            shutdown
```

With LDP disabled, PE-5 has no tunnels available for auto-bind-tunnel in VPLS 1 and all EVPN destinations are removed, as follows:

```
*A:PE-5# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address                     Egr Label     Num.   Mcast Last Change

```

Finally, the failure is restored by re-enabling LDP on PE-5:

```
# on PE-5:
configure
    router Base
        ldp
            no shutdown
```

Operational groups for ES (Port-Active Multi-Homing)

On PE-2 and PE-3, operational group vpls-1_23 is configured and associated with ES " ESI-23_1", but not configured or monitored in VPLS 1. The service configuration on PE-3 is as follows:

```
# on PE-3:
configure
    service
        oper-group "vpls-1_23" create
            hold-time
                group down 0
                group up 0
            exit
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-23_1" create
                    esi 01:23:00:00:00:00:01:00:00:00
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 100               # on PE-2: value 150
                            exit
                        exit
                    exit
                    multi-homing single-active
                    ac-df-capability exclude
                    lag 13
                    oper-group "vpls-1_23"
                    no shutdown
                exit
            exit
        exit
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-13:1 create                         # on PE-2: lag-12:1
                description "to MTU-1"
                no shutdown
            exit
            no shutdown
        exit
```

LAG 12 on PE-2 and LAG 13 on PE-3 monitor operational group "vpls-1_23". The **monitor-oper-group** command can be added to the LAG without the need to disable (shutdown) the LAG:

```
# on PE-3:
configure
```

```
    lag 13 name "lag-13"
        description "to MTU-1"
        mode access
        encap-type dot1q
        monitor-oper-group "vpls-1_23"
        port 1/1/1
        lacp active administrative-key 1 system-id 00:00:00:01:03:01
                                          system-priority 1
        standby-signaling lacp                    # default
        no shutdown
```

Note:
In this example, MTU-1 is connected to PE-2 and PE-3 through two different LAGs, however, this port-active multi-homing mode also supports the use of a single LAG on MTU-1. If a single LAG was used on MTU-1, the LAG ports on PE-2 and PE-3 must be configured with the same LACP parameters (administrative-key, system-id and system-priority) to ensure that PE-2 and PE-3 show themselves as a single system to MTU-1.

EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. In this port-active multi-homing mode, ETH-CFM is not used, and other notification mechanisms are needed, such as LAG standby signaling (**lacp** or **power-off**). When the EVPN application layer instructs the LAG to become standby as a result of the NDF status, the behavior is as follows:

- the **lacp** option signals LACP out-of-sync to MTU-1
- the power-off option brings down the LAG ports connected to MTU-1

MTU-1 is connected to PE-2 and PE-3 using two different access LAGs with encapsulation dot1q and at least one port in each LAG. Any encapsulation type is supported in the LAGs. The LAG configuration is as follows:

```
# on MTU-1:
configure
    lag 12 name "lag-12"
        description "to PE-2"
        mode access
        encap-type dot1q
        port 1/1/1
        lacp active administrative-key 32768
        no shutdown
    exit
    lag 13 name "lag-13"
        description "to PE-3"
        mode access
        encap-type dot1q
        port 1/1/2
        lacp active administrative-key 32769
        no shutdown
    exit
```

On MTU-1, VPLS 1 is configured as follows:

```
# on MTU-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            stp
                shutdown
            exit
```

```
            sap 1/2/1:1 create
                description "to CE-11"
                no shutdown
            exit
            sap lag-12:1 create
                description "to PE-2"
                no shutdown
            exit
            sap lag-13:1 create
                description "to PE-3"
                no shutdown
            exit
            no shutdown
        exit
```

Initial situation without failures

PE-2 is DF for VPLS 1:

```
*A:PE-2# show service id 1 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status

```

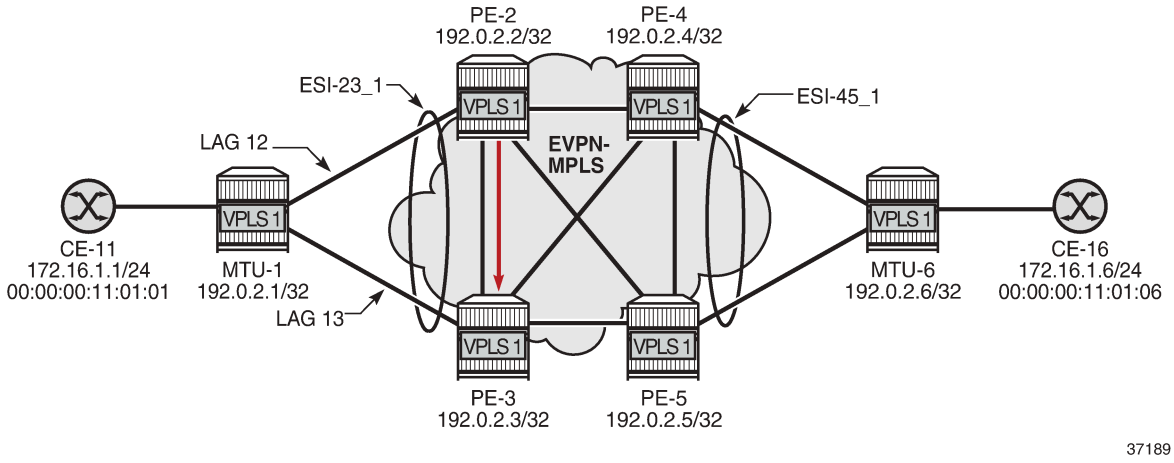
DF switchover

To trigger a DF switchover, the preference value is modified on PE-2, as follows:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-23_1"  create
                    service-carving
                        manual
                            preference create
                                value 50
                            exit
```

Figure 228: DF switchover in single-active ESI-23_1 shows a DF switchover from PE-2 to PE-3. PE-2 becomes the NDF and LAG 12 is in standby.

Figure 228: DF switchover in single-active ESI-23_1



Log 99 on PE-2 shows that SAP lag-12:1 goes down, the ES operational group goes down, the monitoring LAG 12 goes down, port 1/1/2 goes down, and subsequently an LACP out-of-sync message is sent:

```
93 2021/12/23 14:04:40.062 UTC WARNING: LAG #2007 Base LAG
"LAG lag-12 : partner oper state bits changed on member 1/1/2 : [sync FALSE -> TRUE] [expired
 TRUE -> FALSE] [defaulted TRUE -> FALSE]"
```

```
92 2021/12/23 14:04:40.062 UTC WARNING: LAG #2007 Base LAG
"LAG lag-12 : LACP RX state machine entered current state on member 1/1/2"

91 2021/12/23 14:04:40.058 UTC MAJOR: SVCMGR #2210 Base
"Processing of an access port state change event is finished and the status of all affected
 SAPs on port lag-12 has been updated."

```

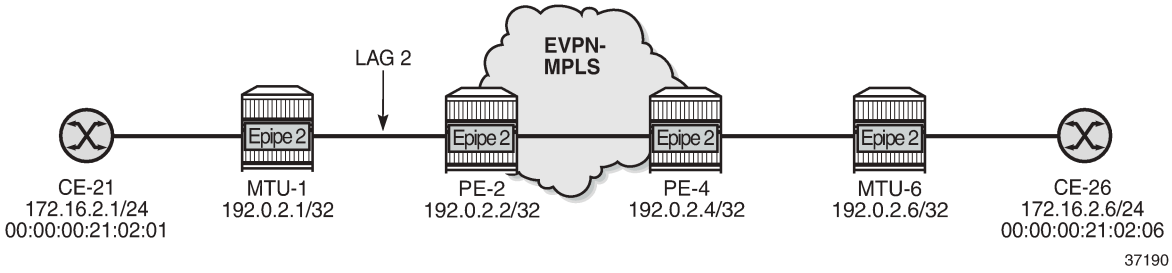
Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM, but also using LAG **standby-signaling lacp** or **power-off**.

Figure 229: Sample topology with Epipe 2 shows the sample topology with Epipe 2.

Figure 229: Sample topology with Epipe 2



The configuration on MTU-1 is as follows:

```
# on MTU-1:
configure
    lag 2
        mode access
        encap-type dot1q
        port 1/1/5
        lacp passive administrative-key 32769
        no shutdown
    exit
    service
        epipe 2 name "Epipe 2" customer 1 create
            sap 1/2/1:2 create
                no shutdown
            exit
            sap lag-2:2 create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, operational group "llf-1" is configured and associated to EVPN-MPLS. LAG 2 monitors this operational group.

```
# on PE-2:
configure
    service
        oper-group "llf-1" create
            hold-time
                group down 0
                group up 0
            exit
        exit
    exit
    lag 2
        mode access
        encap-type dot1q
        monitor-oper-group "llf-1"
        port 1/1/5
        lacp active administrative-key 2 system-id 00:00:00:00:12:01
                                          system-priority 1
        standby-signaling lacp                          # default
        no shutdown
    exit
    service
        epipe 2 name "Epipe 2" customer 1 create
```

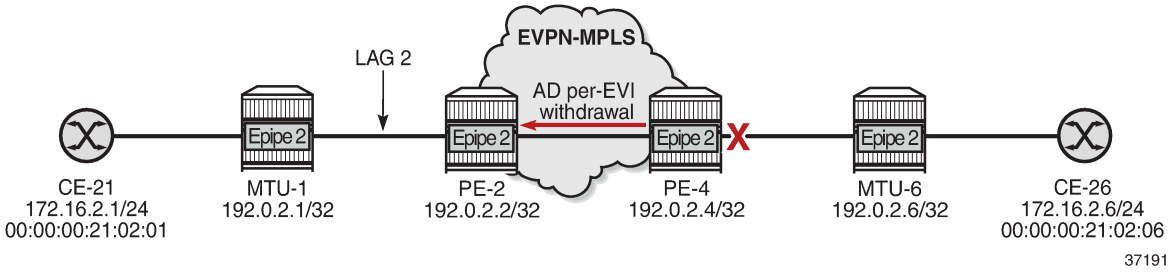
```
            bgp
            exit
            bgp-evpn
                local-attachment-circuit "ac-1_2" create
                    eth-tag 12
                exit
                remote-attachment-circuit "ac-6_2" create
                    eth-tag 62
                exit
                evi 2
                mpls bgp 1
                    oper-group "llf-1"
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap lag-2:2 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on PE-4 is as follows:

```
# on PE-4:
configure
    service
        epipe 2 name "Epipe 2" customer 1 create
            bgp
            exit
            bgp-evpn
                local-attachment-circuit "ac-6_2" create
                    eth-tag 62
                exit
                remote-attachment-circuit "ac-1_2" create
                    eth-tag 12
                exit
                evi 2
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            sap 1/1/5:2 create
                no shutdown
            exit
            no shutdown
        exit
```

Figure 230: LLF in Epipe 2 - PE-4 failure shows when a failure occurs on PE-4.

Figure 230: LLF in Epipe 2 - PE-4 failure



The failure is simulated on PE-4 by disabling port 1/1/5 toward MTU-6.

```
# on PE-4:
configure
    port 1/1/5
        shutdown
```

When the link between PE-4 and MTU-6 fails, PE-4 withdraws the AD per-EVI route for Epipe 2. PE-2 receives the following AD per-EVI withdrawal from PE-4:

```
159 2021/12/23 14:17:25.843 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 34
    Flag: 0x90 Type: 15 Len: 30 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:2 ESI: ESI-0, tag: 62
                      Label: 0 (Raw Label: 0x0) PathId:
"
```

Upon receiving this AD per-EVI route, Epipe 2 goes operationally down on PE-2:

```
*A:PE-2# show service id 2 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

Operational group "llf-1" goes down when the Epipe is operationally down:

```
*A:PE-2# show lag 2 detail | match "per group"
Monitor oper group  : llf-1
Oper group status   : down
```

On PE-2, the detailed information for operational group "llf-1" shows that the operational group and the monitoring LAG are down.

```
*A:PE-2# show service oper-group "llf-1" detail

```

PE-2 signals the fault based on the configuration of the LAG standby signaling:

- If the LAG standby signaling is power-off, PE-2 brings down the ports in the LAG.
- If the LACP standby signaling is configured, PE-2 signals an LACP out-of-sync on the LAG ports.

In either case, MTU-1 stops forwarding traffic to PE-2.

The following debug message in log 99 on MTU-1 shows that MTU-1 received an LACP out-of-sync message for port 1/1/5 of LAG 2:

```
181 2021/12/23 14:17:25.845 UTC WARNING: LAG #2007 Base LAG
"LAG lag-2 : partner oper state bits changed on member 1/1/5 : [sync TRUE -> FALSE] [collecting
 TRUE -> FALSE]"
```

The following debug messages in log 99 on MTU-1 show that LAG 2 and interface 1/1/5 are not operational:

```
183 2021/12/23 14:17:25.845 UTC WARNING: SNMP #2004 Base lag-2
"Interface lag-2 is not operational"

182 2021/12/23 14:17:25.845 UTC WARNING: SNMP #2004 Base 1/1/5

    lag-2
===============================================================================
```

Conclusion

Operational groups can be useful in EVPN services to avoid blackholes when a PE is disconnected from the EVPN core. Failures can be propagated by the PEs to access nodes, either by ETH-CFM or LAG standby signaling.

P2MP mLDP FEC Resolution for BGP-LU in EVPN

This chapter provides information about P2MP mLDP FEC Resolution for BGP-LU in EVPN.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R3, but the CLI in the current edition is based on SR OS Release 21.5.R1. Recursive and non-recursive multicast Label Distribution Protocol (mLDP) Forwarding Equivalence Class (FEC) resolution for BGP Labeled Unicast (BGP-LU) is supported in SR OS Release 15.0.R1 or later; see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

In SR OS Release 15.0.R4, and later, a leaf node in an MVPN can generate non-recursive mLDP mapping messages even if the root IP address is resolved using BGP-LU, without the need to leak BGP routes to IGP and LDP. In SR OS Release 16.0.R1, this is also supported for EVPN-MPLS services.

Overview

In inter-AS and intra-AS scenarios, recursive and non-recursive FEC label mapping messages can be used to set up the mLDP tree. In the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter, recursive and non-recursive mLDP FEC resolution is documented for inter-AS model C.

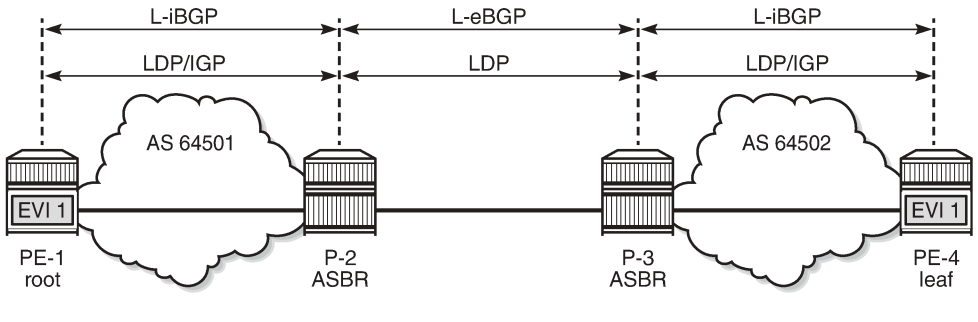
This chapter describes the following use cases for recursive and non-recursive mLDP FEC resolution for BGP-LU:

- P2MP mLDP FEC resolution for inter-AS model C
- P2MP mLDP FEC resolution for seamless MPLS

Some routers do not support recursive mLDP FEC, so basic non-recursive mLDP FEC is used instead. The non-recursive mLDP FEC resolution does not require the root IP address to be leaked from BGP to IGP and LDP. This is different from the configuration in the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

Figure 231: Example topology for inter-AS model C shows the example topology for inter-AS model C with the configured protocols (IGP, LDP, BGP). Root node PE-1 is situated in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are AS Border Routers (ASBRs) that are configured with next-hop-self (NHS). VPLS 1 is configured on root node PE-1 and leaf node PE-4, and is EVPN-MPLS enabled. The example topology for seamless MPLS is similar, but P-2 and P-3 will then act as Area Border Routers (ABRs) and IGP instance 0 is configured between them.

Figure 231: Example topology for inter-AS model C

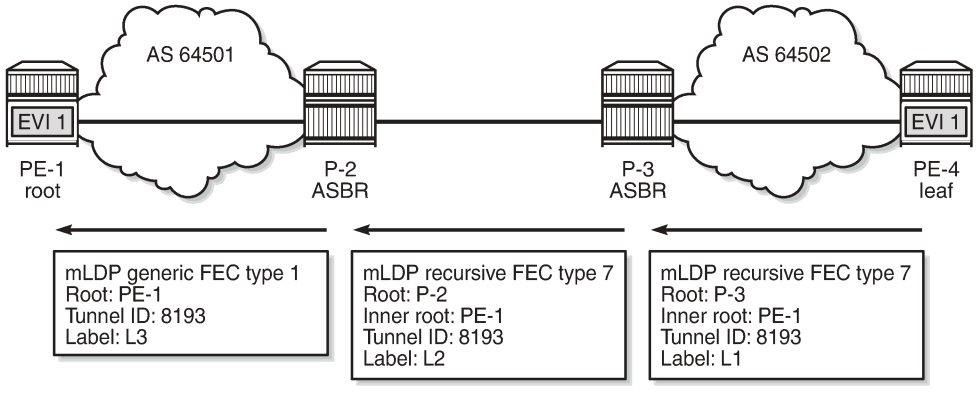


Recursive mLDP FEC resolution requires the nodes in a remote AS (or remote area in case of seamless MPLS) to support GRT recursive FEC type 7 to join the root node.

- PE-4 has a labeled BGP route to root PE-1 with next-hop P-3 in its route table. If PE-4 supports it, it sends a GRT recursive FEC type 7 label mapping message with inner root PE-1 and root P-3.
- P-3 has a labeled BGP route to PE-1 with next-hop P-2. When P-3 receives the mLDP label mapping message from PE-4, it generates its own GRT recursive FEC type 7 message with inner root PE-1 and root P-2.
- P-2 has an IGP route to root PE-1. When P-2 receives the mLDP label mapping message from P-3, it generates a non-recursive FEC type 1 message with root PE-1.

Figure 232: mLDP FEC label mapping messages for inter-AS model C shows the mLDP label mapping messages for inter-AS model C.

Figure 232: mLDP FEC label mapping messages for inter-AS model C



However, if the leaf node PE-4 does not support GRT recursive FEC type 7, it is possible to generate a non-recursive FEC type 1 label mapping message with root PE-1 to the local ASBR that supports GRT recursive FEC type 7. The following command generates only generic FEC type 1 label mapping messages with PE-1 as the root, on the leaf node PE-4:

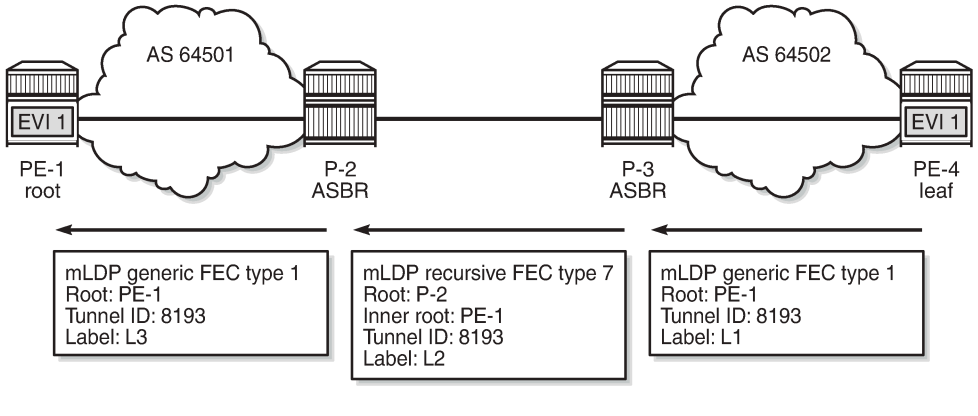
```
# on PE-4:
configure
    router Base
        ldp
```

```
            generate-basic-fec-only
```

Note:
SR OS always generates a recursive FEC if the root node is resolved via BGP; if the root node is resolved via IGP, basic FEC is generated instead. The only way to not generate a recursive FEC when the root is resolved via BGP is by configuring the **generate-basic-fec-only** command.

Figure 233: Non-recursive mLDP FEC for inter-AS model C shows the non-recursive mLDP label mapping messages for inter-AS model C.

Figure 233: Non-recursive mLDP FEC for inter-AS model C

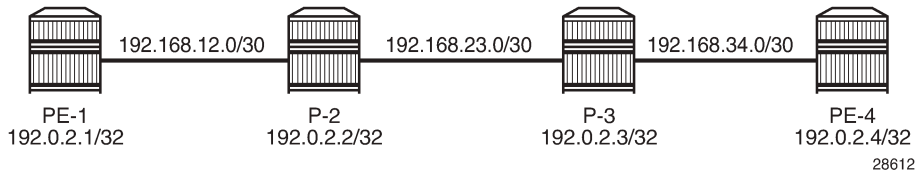


It is also possible that the ASBR routers do not support GRT recursive FEC either. The same **generate-basic-fec-only** command can be configured on all these nodes, which will then generate basic FEC type 1 label mapping messages with root address 192.0.2.1 to the next-hop.

Configuration

Figure 234: Example topology shows the example topology with four nodes.

Figure 234: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces

Inter-AS model C

Figure 231: Example topology for inter-AS model C showed the example topology for inter-AS model C. The following is configured for that topology. For a detailed explanation of the configuration, see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

- Within each AS, OSPF is configured as IGP (alternatively, IS-IS can be used).
- LDP is enabled within each AS.
- LDP is enabled between the ASBRs using the interface IP addresses 192.168.23.x.
- On the ASBRs, a static route 192.168.23.y/32 for the interface IP address on the ASBR peer is configured (with mask /32 instead of /30). When a label mapping message is received for an LDP FEC prefix, the next-hop for a FEC prefix is resolved using the routing table. The FEC is installed in the Label Information Base (LIB) if the next-hop matches a /32 route entry.
- BGP is configured on all nodes for the labeled IPv4 address family. An export policy exports the system IP addresses of the root and leaf nodes PE-1 and PE-4.
- A multi-hop BGP session is established between PE-1 and PE-4 for the EVPN address family, allowing inclusive multicast EVPN routes to be exchanged.
- EVPN-MPLS VPLS 1 is configured on PE-1 and PE-4 with mLDP enabled. PE-1 is configured as root node.

The BGP configuration on PE-1 is as follows. The BGP configuration on PE-4 is similar, but with different neighbors and AS numbers. The export policy is identical.

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            prefix-list "sysPE"
                prefix 192.0.2.0/24 prefix-length-range 32-32
            exit
            policy-statement "PE-sys-to-labeled-BGP"
                entry 10
                    from
                        protocol direct
                        prefix-list "sysPE"
                    exit
                    to
                        protocol bgp-label
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
        bgp
            split-horizon
            group "eBGP"
                family evpn
                type external
                multihop 10
                local-as 64501
                peer-as 64502
                neighbor 192.0.2.4
                exit
            exit
```

```
            group "iBGP"
                type internal
                neighbor 192.0.2.2
                    family label-ipv4
                    export "PE-sys-to-labeled-BGP"
                exit
            exit
            no shutdown
        exit
```

On PE-1, VPLS 1 is configured as follows. The service configuration on PE-4 is similar, but with different RT values and without the **root-and-leaf** parameter.

```
# on PE-1:
configure
    service
        vpls 1 name "EVI-1" customer 1 create
            bgp
                route-target export target:64501:1 import target:64502:1
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf        # PE-1 is configured as root node
                    mldp
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
        exit
```

On P-2, the following static route with mask /32 is configured for the interface IP address of the peer ASBR. The configuration on P-3 is similar.

```
# on P-2:
configure
    router Base
        static-route-entry 192.168.23.2/32
            next-hop 192.168.23.2
                no shutdown
            exit
        exit
```

On P-2, the LDP and BGP configuration is as follows. The configuration on P-3 is similar.

```
# on P-2:
configure
    router Base
        ldp
            interface-parameters
                interface "int-P-2-PE-1" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
                interface "int-P-2-P-3" dual-stack
                    ipv4
                        local-lsr-id interface
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
        exit
        bgp
            split-horizon
            group "eBGP"
                type external
                neighbor 192.168.23.2
                    family label-ipv4
                    next-hop-self
                    local-as 64501
                    peer-as 64502
                    advertise-inactive
                exit
            exit
            group "iBGP"
                type internal
                neighbor 192.0.2.1
                    family label-ipv4
                    cluster 192.0.2.2
                exit
            exit
            no shutdown
        exit
```

Leaf node PE-4 has a labeled BGP route toward root node PE-1 using next-hop 192.0.2.3, as follows:

```
*A:PE-4# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  BGP_LABEL 00h00m08s  170
       192.0.2.3 (tunneled)                                         10
192.0.2.3/32                                    Remote  OSPF      00h02m33s  10
       192.168.34.1                                                 10
192.0.2.4/32                                    Local   Local     00h02m34s  0
       system                                                       0
192.168.34.0/30                                 Local   Local     00h02m34s  0
       int-PE-4-P-3                                                 0
-------------------------------------------------------------------------------
```

```
No. of Routes: 4
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Likewise, ASBR P-3 has a labeled BGP route toward root node PE-1 using next-hop 192.168.23.1, as follows:

```
*A:P-3# show router route-table 192.0.2.1/32

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                  Remote  BGP_LABEL 00h01m35s  170
       192.168.23.1                                                 0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

P-2 has an IGP route toward root node PE-1, as follows:

```
*A:P-2# show router route-table 192.0.2.1/32

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                  Remote  OSPF      00h03m49s  10
       192.168.12.1                                                 10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Recursive mLDP FEC resolution for inter-AS model C

With the preceding configuration, leaf node PE-4 sends a recursive mLDP FEC label mapping message with PE-1 as inner root and P-3 as root. On PE-4, the number of GRT recursive mLDP bindings is 1, as follows:

```
*A:PE-4# show router ldp bindings active p2mp summary ipv4
 No. of Generic IPv4 P2MP Active Bindings: 0
 No. of In-Band-SSM IPv4 P2MP Active Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Active Bindings: 0
 No. of In-Band-SSM IPv4 P2MP Active Bindings: 0
```

```
 No. of VPN Recursive with Generic IPv4 P2MP Active Bindings: 0
 No. of GRT Recursive with Generic IPv4 P2MP Active Bindings: 1
```

```
*A:PE-4# show router ldp bindings p2mp opaque-type grt-recursive ipv4 detail

===============================================================================
LDP Bindings (IPv4 LSR ID 192.0.2.4)

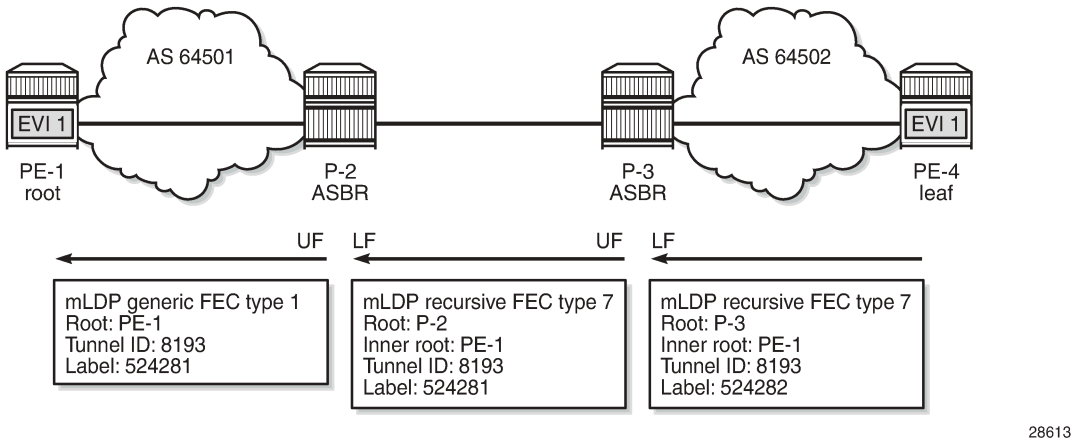
Figure 235: Recursive mLDP FEC for inter-AS model C shows the mLDP label mapping messages with the corresponding labels: label 524281 is used between PE-1 and P-2; label 524281 is used between P-2 and P-3; label 524282 is used between P-3 and PE-4.

Figure 235: Recursive mLDP FEC for inter-AS model C



Non-recursive mLDP FEC resolution for inter-AS model C

Some routers may not support GRT recursive FEC type 7. In that case, the router generates a non-recursive FEC type 1 with root PE-1 to the next-hop P-3. In this example, leaf node PE-4 does not support GRT recursive FEC type 7 and is configured to only send basic FEC type 1 messages. ASBR P-3 supports

GRT recursive type 7 and sends similar messages as in the preceding scenario. However, it is possible that none of the routers supports GRT recursive FEC type 7. In that case, the **generate-basic-fec-only** command is configured on all nodes.

The following command is configured on leaf node PE-4 to make the system send only basic FEC type 1 messages:

```
# on PE-4:
configure
    router Base
        ldp
            generate-basic-fec-only
        exit
```

When PE-4 is configured to only generate basic FEC type 1, PE-4 withdraws the GRT recursive type 7 (T:7) label mapping message with PE-1 as inner root and P-3 as root and sends a non-recursive generic type 1 (T:1) label mapping message with PE-1 as root instead. When debugging is enabled on PE-4 for LDP label mapping messages between P-3 and PE-4, the following messages are logged:

```
# on PE-4:
1 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Withdraw packet (msgId 96) to 192.0.2.3:0
Protocol version = 1
Label 524282 withdrawn for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"

2 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 97) to 192.0.2.3:0
Protocol version = 1
Label 524281 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"

3 2021/06/17 08:44:52.344 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Release packet (msgId 95) from 192.0.2.3:0
Protocol version = 1
Label 524282 released for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

On PE-4, there is one non-recursive generic mLDP binding, as follows:

```
*A:PE-4# show router ldp bindings p2mp summary ipv4

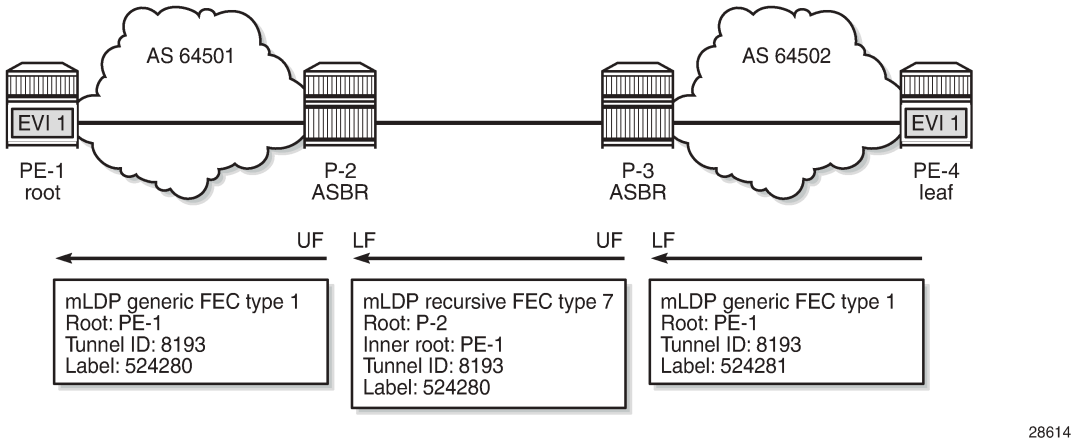
On P-2 and PE-1, the mLDP bindings are similar to the preceding scenario, but the labels are different. Figure 236: Non-recursive mLDP FEC for inter-AS model C shows the label mapping messages with label 524280 between PE-1 and P-2 and label 524280 between P-2 and P-3; label 524281 is used between P-3 and PE-4.

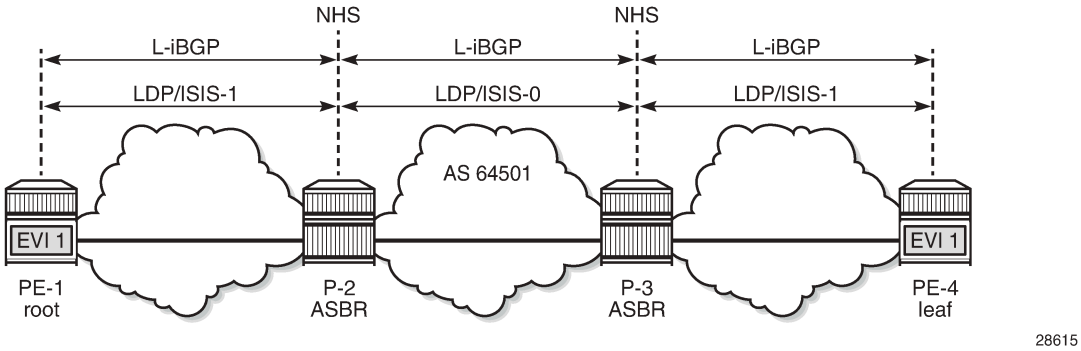
Figure 236: Non-recursive mLDP FEC for inter-AS model C



Seamless MPLS

Figure 237: Example topology for seamless MPLS shows the example topology for seamless MPLS.

Figure 237: Example topology for seamless MPLS



The configuration is according to the *Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP* chapter.

IS-IS is configured as IGP. IS-IS instance 0 is configured between P-2 and P-3, whereas IS-IS instance 1 is configured between P-2 and PE-1 and between P-3 and PE-4. On P-2, IS-IS is configured as follows:

```
# on P-2:
configure
    router
        isis 0
            level-capability level-2
            area 49.0001
            interface "system"
            exit
            interface "int-P-2-P-3"
                interface-type point-to-point
            exit
            no shutdown
        exit
        isis 1
            level-capability level-2
            area 49.0001
            interface "system"
            exit
            interface "int-P-2-PE-1"
                interface-type point-to-point
            exit
            no shutdown
        exit
```

Other characteristics of this example are as follows:

- Unlike the preceding use case for inter-AS model C, no static route is required between P-2 and P-3.
- LDP is configured on all interfaces.
- VPLS 1 is configured as before, but the route target is identical for import and export, and equal to 64501:1.
- All nodes are in AS 64501, so only iBGP is configured.

On PE-1, BGP is configured as follows, using the same policy as for inter-AS model C. The BGP configuration on PE-4 is similar, but the neighbors are different.

```
# on PE-1:
configure
    router Base
       autonomous-system 64501
       bgp
            split-horizon
            group "iBGP"
                type internal
                neighbor 192.0.2.2
                    family label-ipv4
                    export "PE-sys-to-labeled-BGP"
                exit
                neighbor 192.0.2.4
                    family evpn
                exit
            exit
        exit
```

On P-2, the BGP configuration is as follows. The ABRs are configured with **next-hop-self** in both directions. The BGP configuration is similar on P-3.

```
*A:P-2#
configure
    router Base
        autonomous-system 64501
        bgp
            split-horizon
            group "iBGP"
                type internal
                neighbor 192.0.2.1
                    family label-ipv4
                    next-hop-self
                    cluster 192.0.2.2
                exit
                neighbor 192.0.2.3
                    family label-ipv4
                    next-hop-self
                    advertise-inactive
                exit
            exit
```

The following route table on PE-4 shows a labeled BGP route to root node PE-1 with P-3 as the next-hop:

```
*A:PE-4# show router route-table 192.0.2.1

===============================================================================

===============================================================================
```

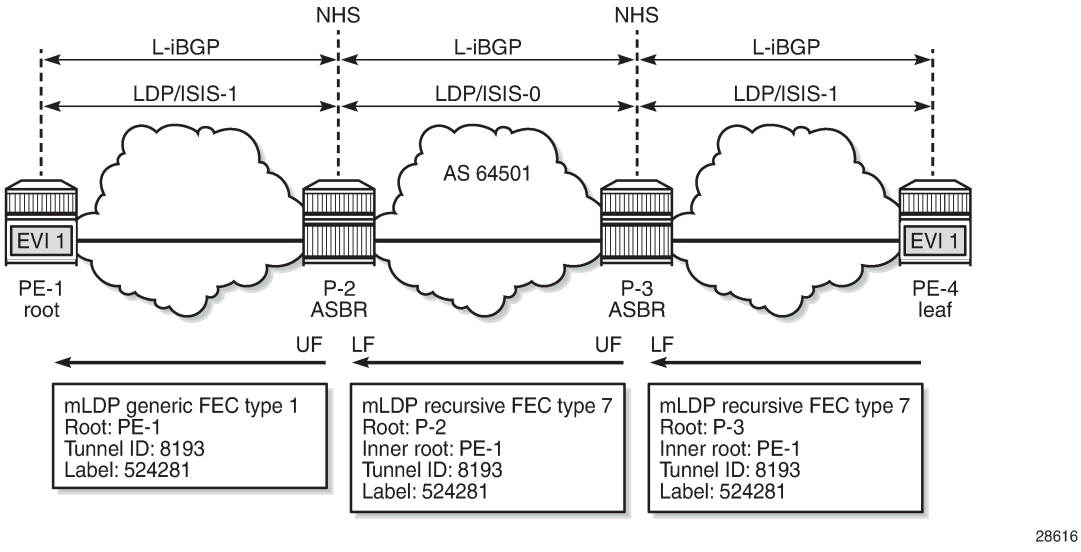
P-2 has one GRT recursive FEC binding with inner root PE-1 and root P-2 (LF). P-2 also has one non-recursive FEC binding with root PE-1 (UF). PE-1 only has a non-recursive FEC binding with root PE-1. Figure 238: Recursive mLDP FEC for seamless MPLS shows the mLDP label mapping messages that all have label 524281 in this example.

Figure 238: Recursive mLDP FEC for seamless MPLS



Non-recursive mLDP FEC resolution for seamless MPLS

For nodes that do not support GRT recursive mLDP FEC type 7, the following command ensures that only non-recursive mLDP type 1 label mapping messages will be sent. In this example, it is assumed that only PE-4 does not support GRT recursive mLDP FEC type 7.

```
# on PE-4:
configure
    router Base
        ldp
            generate-basic-fec-only
```

PE-4 sends a non-recursive mLDP label mapping message with PE-1 as the root to its peer P-3, as follows:

```
*A:PE-4# show router ldp bindings p2mp opaque-type generic detail ipv4
```

```

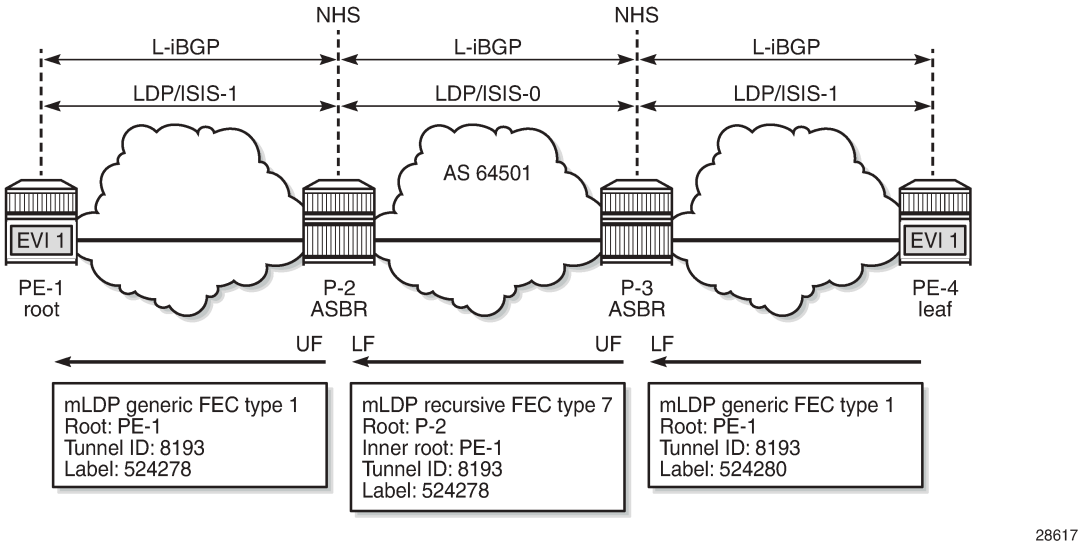
```

Figure 239: Leaf node sends basic FEC in seamless MPLS shows the label mapping messages when leaf node PE-4 only generates basic FEC type 1 messages.

Figure 239: Leaf node sends basic FEC in seamless MPLS



It is possible that ABR routers do not support GRT recursive either. The same command is configured on P-2 and P-3, as follows:

```
# on P-2, P-3:
configure
```

```
    router Base
        ldp
            generate-basic-fec-only
```

When **generate-basic-fec-only** is enabled in the ABRs, P-2 and P-3 will only generate basic FEC messages. On P-3, there are no GRT recursive mLDP bindings anymore, as follows:

```
*A:P-3# show router ldp bindings p2mp summary ipv4
 No. of Generic IPv4 P2MP Bindings: 2
 No. of In-Band-SSM IPv4 P2MP Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Bindings: 0
 No. of Recursive with In-Band-SSM IPv4 P2MP Bindings: 0
 No. of VPN Recursive with Generic IPv4 P2MP Bindings: 0
 No. of GRT Recursive with Generic IPv4 P2MP Bindings: 0
```

The two generic mLDP bindings on P-3 have root address 192.0.2.1, as follows. There is no UF or LF.

```
*A:P-3# show router ldp bindings p2mp opaque-type generic detail ipv4

===============================================================================
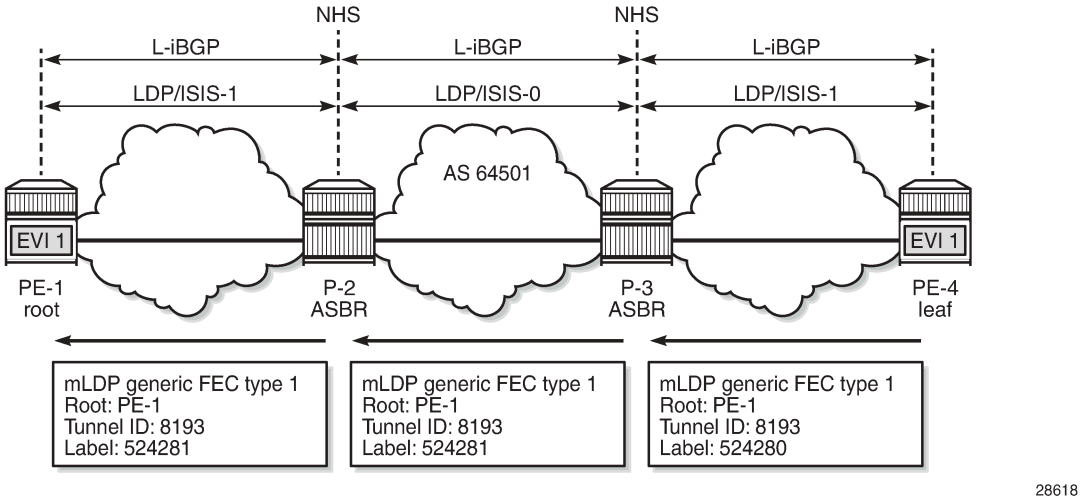
```

The output on P-2 is similar. Figure 240: ABRs and leaf node send basic FEC in seamless MPLS shows the label mapping messages when all nodes only generate basic FEC type 1 messages.

Figure 240: ABRs and leaf node send basic FEC in seamless MPLS



Conclusion

In inter-AS and intra-AS scenarios, mLDP trees can be set up using recursive or non-recursive label mapping messages. Routers not supporting recursive FEC can generate only non-recursive FEC, even if the system address of the root node is resolved via BGP. This feature is supported in MVPN and in EVPN.

P2MP mLDP Inter-AS Model C for EVPN-MPLS Services

This chapter provides information about P2MP mLDP Inter-AS Model C for EVPN-MPLS Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R5, but the CLI in the current edition is based on SR OS Release 21.5.R1.

Point-to-Multipoint Multicast Label Distribution Protocol (P2MP mLDP) for Broadcast, Unknown Unicast, and Multicast (BUM) traffic in EVPN-MPLS networks is supported in SR OS Release 14.0.R1, and later. EVPN with P2MP mLDP LSPs is supported in a seamless MPLS or inter-AS model C scenario in SR OS Release 15.0.R1, and later. This chapter describes the inter-AS model C scenario, but the configuration for seamless MPLS is similar.

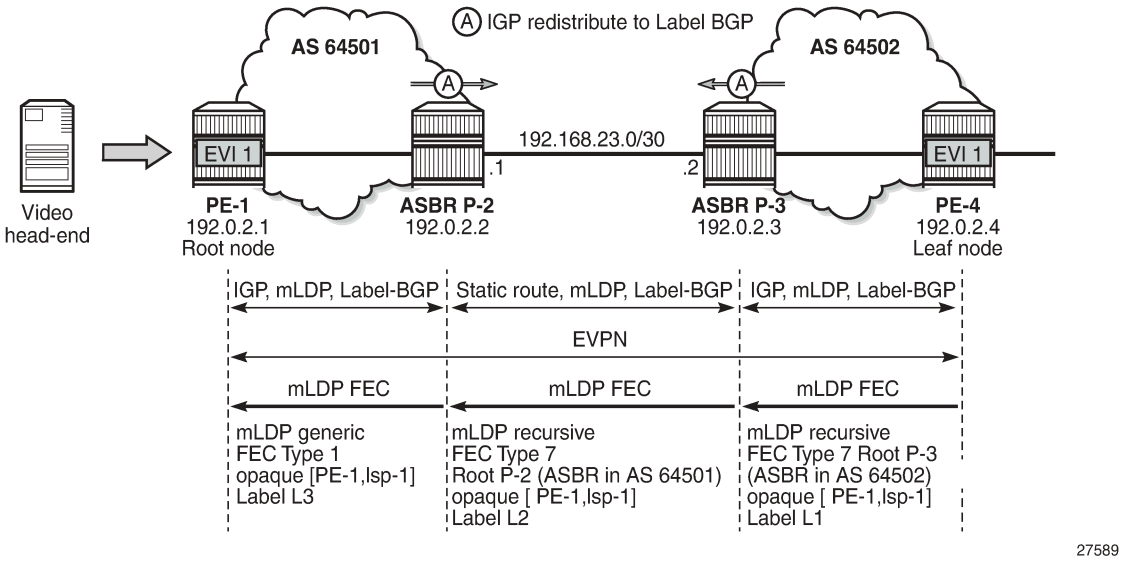
Overview

Chapter P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services describes P2MP mLDP within an Autonomous System (AS). PEs configured as root-and-leaf can send BUM traffic over P2MP mLDP tunnels; PEs configured as not root-and-leaf (that is, leaf-only) can only send BUM traffic over Ingress Replication (IR) tunnels. Both types of PEs (root-and-leaf and leaf-only) can receive BUM traffic over either P2MP mLDP tunnels or IR tunnels.

When **provider-tunnel inclusive mldp** is enabled in an EVPN-MPLS service in combination with **root-and-leaf** and **bgp-evpn>ingress-repl-inc-mcast-advertisement**, the system will send an Inclusive Multicast Ethernet Tag (IMET) route with a composite tunnel type (IMET-P2MP-IR) in the provider tunnel attributed.

Inter-AS VPN model C is described in chapters Inter-AS VPRN Model C and Inter-AS Model C for VLL. Labeled IPv4 unicast BGP is used to provide inter-AS connectivity. The system IP addresses within each AS are exported by the Autonomous System Border Routers (ASBRs) and a multi-hop BGP session is established between root node and leaf node for address family EVPN. The root node advertises a composite IMET-P2MP-IR route to the leaf nodes and the leaf nodes advertise an IMET-IR route to the root node. Figure 241: Inter-AS Model C for P2MP mLDP shows an example topology with root node PE-1 in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are ASBRs.

Figure 241: Inter-AS Model C for P2MP mLDP



The composite IMET-P2MP-IR route received by leaf node PE-4 contains the root node (192.0.2.1) and the LSP ID (0x2001) that will be used by the nodes to set up a P2MP mLDP tree toward the root.

```

        MPLS Label2 IR 8388544
        Root-Node 192.0.2.1, LSP-ID 0x2001
"
```

The Provider Multicast Service Interface (PMSI) tunnel attribute for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 always equals zero in SR OS Release 21.5.R1, because SR OS does not support aggregated P2MP tunnels. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388544 needs to be divided by 16 to get the MPLS label value: 8388544/16 = 524284. This is due to the debug message being shown before the router can parse the label field and see whether it corresponds to an

MPLS label (20 bits) or a VXLAN VNI (24 bits). The following command on PE-4 shows the EVPN-MPLS destination 192.0.2.1 with MPLS label 524284 using a BGP transport tunnel:

```
*A:PE-4# show service id 1 evpn-mpls

---snip---
```

The use of mLDP with recursive opaque values is specified in RFC 6512.

When the leaf node PE-4 receives the composite IMET-P2MP-IR route from the root node PE-1, a P2MP mLDP tree needs to be established from the leaf node to the root node. Leaf node PE-4 resolves the IP address of PE-1 to a labeled BGP route with next-hop ASBR P-3. PE-4 then sends an mLDP FEC with root node ASBR P-3 and an opaque value containing the root PE-1 and an LSP ID that was advertised in the IMET-P2MP-IR route, as follows:

```
# on PE-4:
4 2021/06/02 08:31:13.915 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 40) to 192.0.2.3:0
Protocol version = 1
Label 524283 advertised for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

T: 7 indicates the MLDP recursive FEC type 7. The tunnel ID 8193 corresponds to the hexadecimal value 0x2001 sent by the root node PE-1, which is the inner root 192.0.2.1 in the recursive opaque value.

When ASBR P-3 receives this mLDP FEC, it identifies itself as root node and resolves the recursive opaque value (PE-1, LSP ID) and creates a new mLDP FEC element with root node ASBR P-2 and an identical opaque value (PE-1, LSP ID). The following mLDP FEC is sent to ASBR P-2:

```
# on P-3:
12 2021/06/02 08:32:36.794 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 34) to 192.168.23.1:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.168.23.1, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

ASBR P-2 receives the mLDP FEC and finds that it is the root node. P-2 creates a new mLDP FEC, but no recursion is required because P-2 knows the IP address of PE-1 through the IGP. P-2 sends the following mLDP FEC with root node PE-1, LSP ID 8193, and mLDP FEC type 1.

```
# on P-2:
12 2021/06/02 08:32:36.814 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
```

```
Send Label Mapping packet (msgId 50) to 192.0.2.1:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"
```

Configuration

The example topology was already shown in Figure 241: Inter-AS Model C for P2MP mLDP. The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- OSPF as IGP within each AS (alternatively, IS-IS can be used)
- LDP enabled within each AS

The following two scenarios are configured:

- Inter-AS model C for mLDP
- Optimized inter-AS model C for mLDP

Inter-AS Model C for mLDP

The initial BGP configuration on the PEs only includes a label-IPv4 peering with the ASBRs. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router Base
        bgp
            group "iBGP"
                type internal
                neighbor 192.0.2.2
                    family label-ipv4
                exit
```

On the ASBRs, BGP is configured for address family label-IPv4, both internal to PE-1 and external to the peer ASBR. The BGP configuration on P-2 is as follows:

```
# on P-2:
configure
    router Base
        bgp
            group "eBGP"
                type external
                neighbor 192.168.23.2
                    family label-ipv4
                    export "PE-sys-to-labeled-BGP"
                    local-as 64501
                    peer-as 64502
                    split-horizon
                exit
            exit
            group "iBGP"
                type internal
```

```
                neighbor 192.0.2.1
                    family label-ipv4
                exit
            exit
```

The BGP configuration on ASBR P-3 is similar, but the IP addresses are different and the local AS and peer AS are swapped. The following export policy is identical on both ASBRs P-2 and P-3:

```
# on P-2, P-3:
configure
    router
        policy-options
            begin
            prefix-list "sysPE"
                prefix 192.0.2.0/24 longer
            exit
            policy-statement "PE-sys-to-labeled-BGP"
                entry 10
                    from
                        prefix-list "sysPE"
                    exit
                    to
                        protocol bgp-label
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This policy exports the system prefixes as label-IPv4 routes to the eBGP peer.

When a P2MP mLDP tree must be established across ASs, LDP needs to be enabled on the interface between the ASBRs with **local-lsr-id interface** instead of the default value "system". The LDP configuration on P-2 is as follows:

```
# on P-2:
configure
    router
        ldp
            interface-parameters
                interface "int-P-2-P-3"
                    ipv4
                        local-lsr-id interface
                    exit
                exit
```

With this LDP configuration, a link adjacency will be established toward the interface IP address instead of the system address, as follows:

```
*A:P-2# show router ldp session ipv4

===============================================================================
LDP IPv4 Sessions
===============================================================================
Peer LDP Id         Adj Type  State         Msg Sent  Msg Recv  Up Time
-------------------------------------------------------------------------------
192.0.2.1:0         Link      Established   229       229       0d 00:09:48
192.168.23.2:0      Link      Established   137       140       0d 00:05:46
-------------------------------------------------------------------------------
No. of IPv4 Sessions: 2
```

```
===============================================================================
```

However, this LDP configuration is insufficient for the resolution of mLDP FEC as link LSR ID. LDP needs a /32 route instead of a /30 route, so the following /32 static route is configured on P-2:

```
# on P-2:
configure
    router
        static-route-entry 192.168.23.2/32
            next-hop 192.168.23.2
                no shutdown
            exit
        exit
```

The configuration on ASBR P-3 is similar for static route 192.168.23.1/32. When this static route is not configured, no mLDP label mapping message will be sent from P-3 to P-2, so the mLDP P2MP tree cannot be established.

On PE-1, VPLS 1 is configured with mLDP root-and-leaf, as follows:

```
# on PE-1:
configure
    service
        vpls 1 name "EVI-1" customer 1 create
            bgp
                route-target export target:64501:1 import target:64502:1
            exit
            bgp-evpn
                ingress-repl-inc-mcast-advertisement
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf
                    mldp
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            no shutdown
```

On PE-4, VPLS 1 is configured with mLDP leaf-only (no root-and-leaf, which is default), as follows:

```
# on PE-4:
configure
    service
        vpls 1 name "EVI-1" customer 1 create
            bgp
```

```
            route-target export target:64502:1 import target:64501:1
        exit
        bgp-evpn
            evi 1
            mpls bgp 1
                ingress-replication-bum-label
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        provider-tunnel
            inclusive
                owner bgp-evpn-mpls
                mldp
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/2/1:1 create
            no shutdown
        exit
        no shutdown
```

The Route Distinguisher (RD) is auto-derived from EVI 1, but the route target (RT) should not be auto-derived, because the export RT on PE-1 must match the import RT on PE-4, and vice versa. It is an option to configure an identical RT on all PEs, such as 1:1, but in this example, the export RT on PE-1 is 64501:1, which equals the import RT on PE-4. When the RTs do not match, the BGP routes will be received at the PE in the peer AS, but they will not become active and no mLDP P2MP tree can be established.

Multi-hop BGP peering is configured between PE-1 and PE-4 for address family EVPN. The external BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure
    router
        bgp
            split-horizon
            group eBGP
                family evpn
                multihop 10
                local-as 64501
                peer-as 64502
                neighbor 192.0.2.4
                exit
            exit
```

The external BGP configuration on PE-4 is similar, but the local AS and peer AS are swapped, and the neighbor IP address is different.

Inter-AS Model C for mLDP - Verification

The following BGP summary shows that P-2 has sent and received two prefixes with its eBGP peer P-3 and has advertised two prefixes to its iBGP peer PE-1:

```
*A:P-2# show router bgp summary all
```

```
===============================================================================

-------------------------------------------------------------------------------
                                                8193    192.0.2.1

-------------------------------------------------------------------------------
```

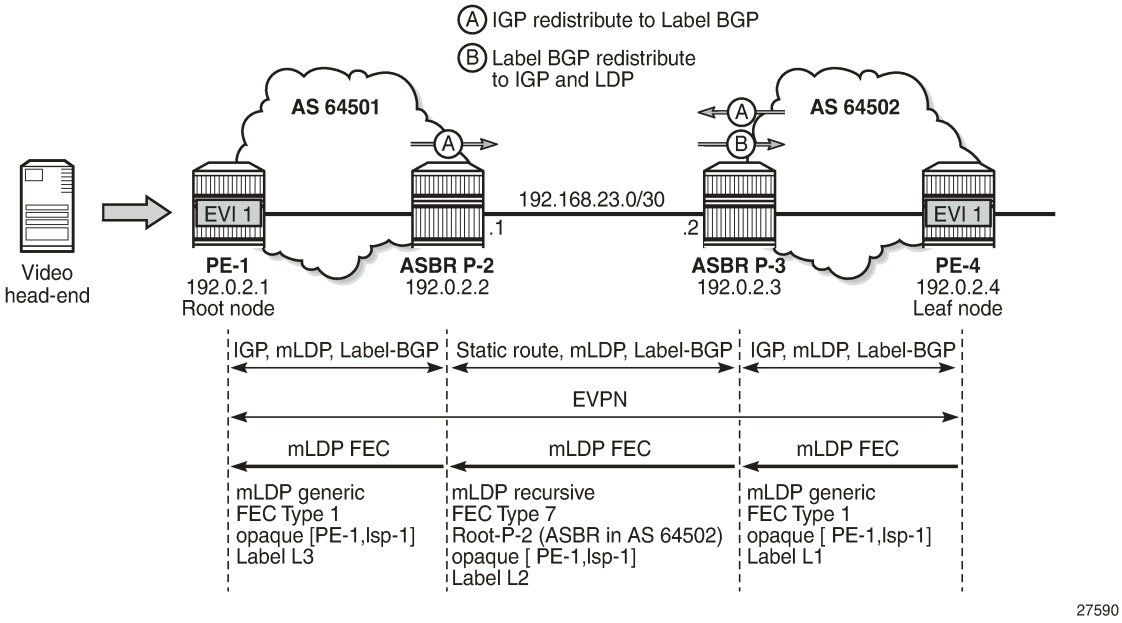
Optimized Inter-AS Model C for mLDP

When some leaf nodes do not support labeled BGP routes or recursive opaque mLDP label mapping, the ASBR in the AS where the leaf nodes are situated needs to leak the root IP address into the leaf PE IGP, which allows the leaf node PE-4 to send a generic FEC type 1 to join the root. The recursive opaque functionality is pushed to the local ASBR P-3.

Figure 242: Example topology for optimized Inter-AS Model C for mLDP shows the example topology for the optimized inter-AS model C for mLDP.

Figure 242: Example topology for optimized Inter-AS Model C for mLDP



The configuration starts with the configuration in the preceding section Inter-AS Model C for mLDP. The policy to export system prefixes from the ASs to labeled BGP is already configured and applied on both ASBRs. The following additional policies are defined on ASBR P-3 in the AS of the leaf node to export labeled BGP routes to OSPF and to LDP.

```
# on ASBR P-3:
configure
    router
        policy-options
            begin
            policy-statement "bgpToOspf"
                entry 10
                    from
                        protocol bgp-label
                    exit
                    to
                        protocol ospf
                    exit
                    action accept
                    exit
                exit
            exit
```

```
            policy-statement "bgpToLdp"
                entry 10
                    from
                        protocol bgp-label
                    exit
                    to
                        protocol ldp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

Policy "bgpToOspf" is configured in the OSPF context and policy "bgpToLdp" in the **ldp** context, as follows:

```
# on ASBR P-3:
configure
    router Base
        ospf
            export "bgpToOspf"
        exit
        ldp
            export-tunnel-table "bgpToLdp"
        exit
```

Optimized Inter-AS Model C for mLDP - Verification

The prefixes from AS 64501 are now exported to OSPF and LDP in AS 64502; therefore, leaf node PE-4 will no longer use the labeled BGP routes to a node in AS 64501.

```
*A:PE-4# show router bgp routes label-ipv4

===============================================================================
```

Root node PE-1 will send an IMET-P2MP-IR route to leaf node PE-4. PE-4 will send an mLDP label mapping message type 1 instead of type 7, because there is an LDP tunnel toward PE-1 instead of a BGP tunnel. The only P2MP mLDP binding on leaf node PE-4 is a generic P2MP binding, as follows:

```
*A:PE-4# show router ldp bindings p2mp summary ipv4
 No. of Generic IPv4 P2MP Bindings: 1
 No. of In-Band-SSM IPv4 P2MP Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Bindings: 0

===============================================================================
No. of GRT Recursive with Generic IPv4 P2MP Bindings: 1
===============================================================================
```

The P2MP mLDP bindings on P-2 and PE-1 are the same as in the previous non-optimized inter-AS model C for mLDP scenario. P-2 has one GRT recursive mLDP binding to P-3 and one generic mLDP binding to root node PE-1, whereas PE-1 only has a generic mLDP binding to P-2.

The following command on root node PE-1 shows that an EVPN-MPLS destination is created to the leaf node PE-4. This EVPN destination runs over a BGP tunnel and can transport multicast (BUM) traffic. However, as discussed in the preceding section, the EVPN destination is used for BUM traffic only in the case where the provider tunnel goes operationally down.

```
*A:PE-1# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address     Egr Label     Num. MACs   Mcast           Last Change
                Transport:Tnl                             Sup BCast Domain
-------------------------------------------------------------------------------
192.0.2.4       524284        0           bum             06/02/2021 08:31:14
                bgp:262146                                No
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The same command on the leaf node PE-4 shows an EVPN destination running on an LDP tunnel instead of a BGP tunnel. This destination is used whenever PE-4 needs to send BUM traffic to PE-1:

```
*A:PE-4# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================

-------------------------------------------------------------------------------
192.0.2.1       524284        0           bum             06/02/2021 08:31:14
                ldp:65538                                 No
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The other **show** commands in the Inter-AS Model C for mLDP section have an identical output for both scenarios.

Conclusion

P2MP mLDP is supported in inter-AS model C for EVPN-MPLS services with or without optimization. Optimization in this chapter refers to the ability to set up an end-to-end mLDP tunnel without the need for recursive opaque mLDP FECs on the leaf nodes. A similar configuration is applied in the case of seamless MPLS across different areas.

P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services

This chapter provides information about P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3.

Point-to-Multipoint (P2MP) multicast Label Distribution Protocol (mLDP) tunnels for Broadcast, Unknown unicast, and Multicast (BUM) traffic in Ethernet Virtual Private Network Multiprotocol Label Switching (EVPN-MPLS) networks are supported in SR OS Release 14.0.R1, and later. Internet Group Management Protocol (IGMP) snooping support for EVPN-MPLS services is supported in SR OS Release 14.0.R4, and later.

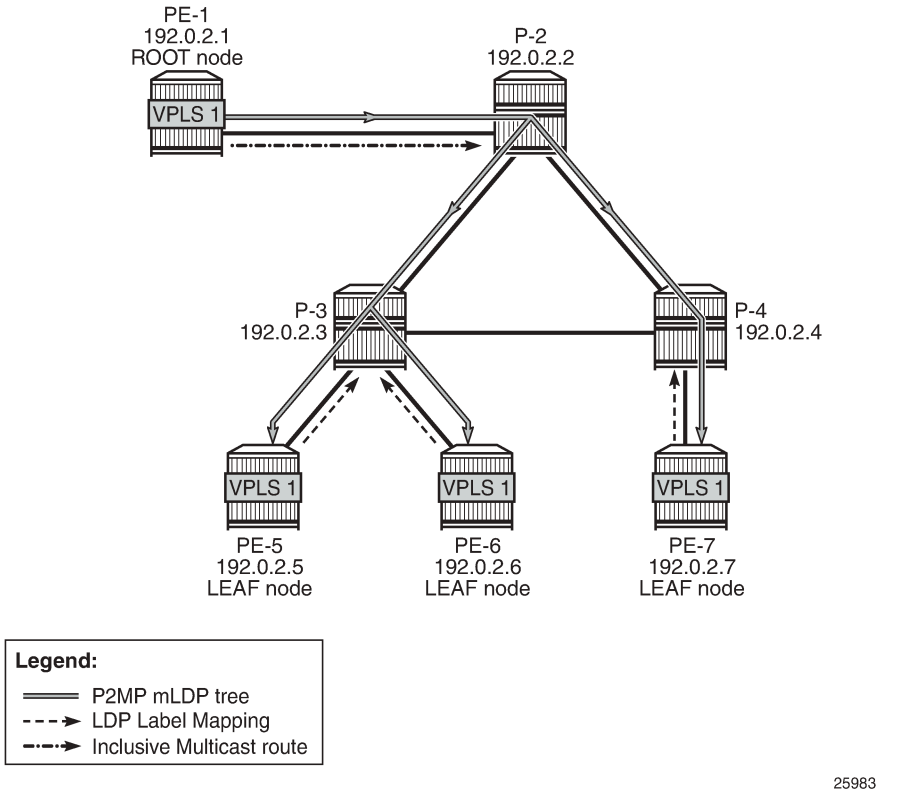
Overview

Service providers are moving their existing VPN services to EVPN. Providers using P2MP LSPs for VPLS services expect the same capabilities in EVPN. Before SR OS Release 14.0.R1, only Ingress Replication (IR) was supported. This works well for broadcast and unknown unicast traffic, but it is inefficient for multicast. Ingress replication does not use a multicast mechanism. Instead, the parent node makes n individual copies and unicasts each copy through an MPLS or IP tunnel to each child node.

BUM traffic is sent from a root node to a number of leaf nodes, but leaf nodes are also allowed to send BUM traffic to root nodes. If most BUM traffic is flowing from a few root nodes to leaf nodes, it would be inefficient to promote all leaf nodes to root-and-leaf nodes because of the amount of P2MP tunnels that would need to be set up. Another solution is to use a combination of P2MP mLDP and ingress replication (IR) tunnels in the service. The root nodes send BUM traffic using P2MP tunnels while the leaf nodes use IR tunnels to send BUM traffic to the root nodes. This avoids the need to set up a P2MP tree from each leaf, while it still allows leaf nodes to send BUM traffic to the root nodes.

Figure 243: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a multicast mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7.

Figure 243: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7



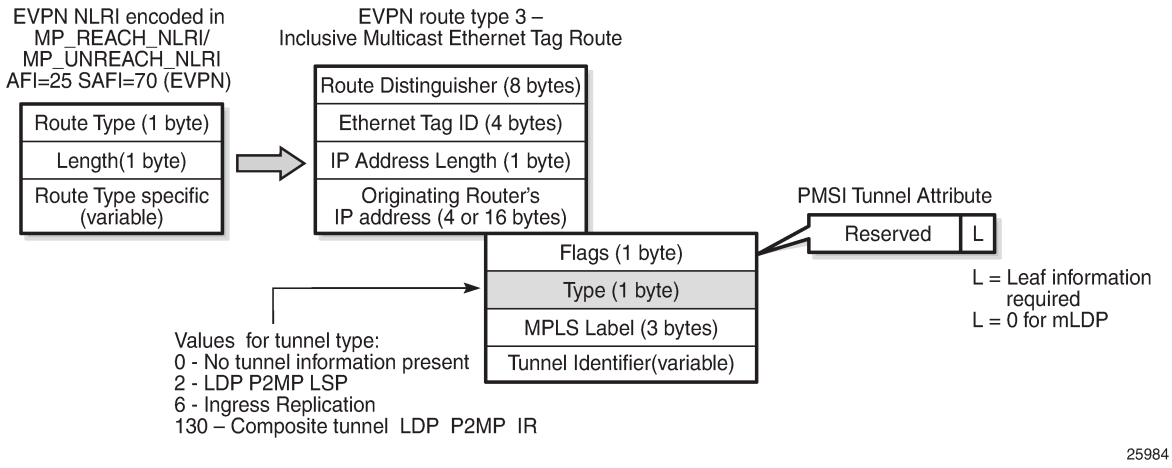
The Inclusive Multicast Ethernet Tag (IMET) route (EVPN route type 3) sent by root node PE-1 contains the required information to set up an mLDP tree, such as the root node IP address and an opaque value. As described in chapter "Multicast Label Distribution Protocol" in the MPLS volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*, the mLDP tree is set up from the leaf nodes toward the root.

The LDP label mapping message contains the root node address, an opaque value, and an MPLS label. The leaf nodes send an LDP label mapping message to their upstream next hop toward the root node of the tree. Each transit node that has received such LDP label mapping message generates a new LDP label mapping message to its upstream next hop toward the root. This is repeated until the root node receives an LDP label mapping message and the multicast tree is completed.

Figure 243: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a P2MP mLDP tree rooted in PE-1, which is optimal for multicast traffic. However, no P2MP mLDP tree needs to be rooted in PE-5, PE-6, and PE-7 for the reverse direction. These three PEs can use IR to send traffic to the root (and to the other leaf nodes if needed).

EVPN route type 3 is used for setting up the flooding tree for a specified VPLS service. EVPN route type 3 includes the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PMSI Tunnel Attribute = PTA), which can have different formats depending on the tunnel type; see Figure 244: BGP-EVPN route type 3 with PTA.

Figure 244: BGP-EVPN route type 3 with PTA



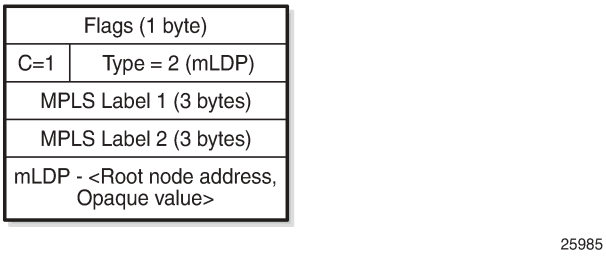
The following route values are used for EVPN-MPLS services:

- The route distinguisher (RD) is taken from the RD of the VPLS service, which can be configured in the BGP context or auto-derived from the BGP-EVPN EVPN Instance (EVI) value. In this case, the RD is auto-derived from the EVI, resulting in a value of 192.0.2.1:1 for VPLS 1 on PE-1.
- The Ethernet tag ID equals 0.
- The IP address length equals 32.
- The originating router's IP address carries the IPv4 system address.
- The PTA can have different formats depending on the tunnel type enabled in the service. The SR OS EVPN-MPLS implementation supports the following tunnel types (SR OS supports different tunnel types for EVPN-VXLAN):
  - Tunnel type 2 - P2MP mLDP
    - The route is referred to as an Inclusive Multicast Ethernet Tag Point-to-Multipoint (IMET-P2MP).
    - Flags: leaf not required.
    - The MPLS label is zero.
    - The tunnel identifier includes the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join to the mLDP P2MP tree.
  - Tunnel type 6 - Ingress Replication (IR)
    - The route is referred to as an Inclusive Multicast Ethernet Tag Ingress Replication (IMET-IR).
    - Flags: leaf not required.
    - The MPLS label is a non-zero, downstream allocated label. This MPLS label is allocated to the service and is the same for unicast MAC/IP routes for the same service, unless **ingress-replication-bum-label** is configured in the service.
    - The tunnel identifier is the tunnel endpoint and is equal to the originating IP address.
  - Tunnel type 130 - Composite tunnel: Type: C-bit (composite) + type 2 (mLDP)
    - The route is referred to as an IMET-P2MP-IR.
    - Flags: leaf not required.

- MPLS label 1 equals zero.
- MPLS label 2 is a non-zero, downstream allocated label (as any other IR label). The leaf nodes use the label to set up an EVPN-MPLS binding to the root and add it to the default multicast list.
- The mLDP tunnel identifier is the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join the mLDP P2MP tree.

Figure 245: PTA for composite tunnel IMET-P2MP-IR shows the PTA for tunnel type 130.

Figure 245: PTA for composite tunnel IMET-P2MP-IR



The composite bit C is set, indicating that the PTA identifies two tunnels: the transmit tunnel is a P2MP mLDP tunnel and the receive tunnel is an IR tunnel.

IMET-P2MP-IR routes

The composite tunnel type is an optimized solution that combines mLDP and IR within the same EVPN service so that each root node sends BUM traffic using the P2MP tunnel whereas each leaf-only node sends BUM traffic to the root node using IR.

- PEs configured with **root-and-leaf** can send all BUM traffic over P2MP mLDP tunnels while they receive BUM traffic either over P2MP mLDP tunnels (from other root-and-leaf nodes) or over ingress-replication tunnels (from leaf-only nodes).
- PEs configured with **no root-and-leaf** (default setting) can use IR to send BUM traffic to root nodes and other leaf-only nodes, while receiving BUM traffic over either P2MP mLDP tunnels (from root nodes) or ingress-replication tunnels (from leaf-only nodes).

The root PEs signal an IMET-P2MP-IR route, indicating that they intend to transmit BUM traffic using an mLDP P2MP tunnel, while they can receive traffic over an IR EVPN-MPLS binding. Composite tunnels reduce the number of P2MP mLDP tunnels that the PE/P routers in the EVI need to handle, because no full mesh of P2MP tunnels among all the PEs in the EVI is required. This is important (in terms of scaling) in services where there are just a pair of root nodes sending BUM in P2MP tunnels and hundreds of leaf nodes that only need to send BUM traffic to the root nodes using IR tunnels.

Configuration

Initial configuration

The PE and P nodes have the following initial configuration:

- The ports between the routers are configured as network ports and have router interfaces configured.

- IS-IS is enabled on all the router interfaces.
- LDP is enabled on all the router interfaces.
- BGP is enabled on all PEs with route reflector (RR) P-2. The BGP configuration on RR P-2 is as follows:

```
# On P-2:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.5
                exit
                neighbor 192.0.2.6
                exit
                neighbor 192.0.2.7
                exit
            exit
            no shutdown
        exit
    exit
```

Configure EVPN P2MP mLDP in VPLS Service

On the root node PE-1, VPLS 1 is configured as follows:

```
# On PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                ingress-repl-inc-mcast-advertisement    # default setting
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf
                    mldp
                    no shutdown
```

```
            exit
        exit
        stp
            shutdown
        exit
        sap 1/2/c3/1 create    # sap for ingress traffic from STC
        exit
        no shutdown
    exit
```

The configuration options in the **bgp-evpn** context of the VPLS are as follows:

```
*A:PE-1# configure service vpls 1 bgp-evpn ?
  - bgp-evpn
  - no bgp-evpn

 [no] accept-ivpls-e* - Configure to accept non-zero ethernet-tag MAC routes and process for
 CMAC flushing
 [no] arp-nd-extende* - Enable/disable ARP/ND Ext Community advertisement
 [no] cfm-mac-advert* - Enable/disable the advertisement of MEP, MIP, and VMEP MAC addresses
 over the BGP EVPN
 [no] evi             - EVPN Identifier
 [no] ignore-mtu-mis* - Configure ignore-mtu-mismatch
 [no] incl-mcast-l2-* - Configure BGP EVPN L2 attribute route advertisement
 [no] incl-mcast-ori* - Configure originating IP address
 [no] ingress-repl-i* - Configure BGP EVPN IMET-IR route advertisement
 [no] ip-route-adver* - Configure BGP EVPN IP Route Advertisement
      ip-route-link-* + Configure BGP EVPN IP Route Link Bandwidth
      isid-route-tar* + configure ISID route target information
 [no] mac-advertisem* - Configure BGP EVPN MAC Advertisement
      mac-duplication + Configure BGP EVPN MAC Duplication
 [no] mpls            + Configure BGP EVPN mpls
 [no] segment-routin* + Configure SRv6 instance
 [no] sel-mcast-adve* - Enable/disable selective multicast advertisements
 [no] unknown-mac-ro* - Configure BGP EVPN Unknown MAC Route
 [no] vxlan           + Configure BGP EVPN vxlan
```

By default, the advertisement of the inclusive multicast route with IR is enabled (**ingress-repl-inc-mcast-advertisement**). However, if it is disabled, the router does not send the IMET-IR or IMET-P2MP-IR routes, regardless of the service being enabled for BGP EVPN-MPLS or BGP EVPN-VXLAN.

For information about the other parameters in the **bgp-evpn** context of the VPLS, see chapters EVPN for VXLAN Tunnels (Layer 2) and EVPN for MPLS Tunnels.

The configuration options in the **provider-tunnel inclusive** context are as follows:

```
*A:PE-1# configure service vpls 1 provider-tunnel inclusive ?
  - inclusive

 [no] data-delay-int* - Configure data delay interval
 [no] mldp            - Enable/Disable MLDP
 [no] owner           - Configure provider-tunnel owner
 [no] root-and-leaf   - Configure LSP node type
 [no] rsvp            + Configure RSVP parameters
 [no] shutdown        - Administratively enable/disable the service
```

- The **data-delay-interval** is configured in seconds in the range from 3 to 180 seconds. A node configured with **root-and-leaf** sends all BUM packets (data plane and control plane: ARP, CCMs, and so on) to its provider tunnel after the delay-data-interval has expired. This timer keeps the provider tunnel operationally down until its expiration, and, during that time, the router can use the EVPN-MPLS destinations typically used for IR.

- mLDP is enabled by adding the keyword **mldp** and enabling the provider tunnel (**no shutdown**).
- The owner must be **bgp-evpn-mpls** if MPLS is enabled in the EVPN.

```
*A:PE-1# configure service vpls 1 provider-tunnel inclusive owner ?
  - no owner
  - owner {bgp-ad|bgp-vpls|bgp-evpn-mpls}
```

Only one of the three possible owner protocols supports the provider tunnel in the service and needs to be set before the provider tunnel can be enabled. By default, no owner is configured. The following error is raised when a user wants to enable the provider tunnel without an owner:

```
*A:PE-1>config>service>vpls>provider-tunnel>inclusive# no shutdown
INFO: SVCMGR #6732 No owner configured for provider-tunnel
```

After the provider tunnel has an owner and is enabled, the owner can only be changed when the provider tunnel is disabled.

```
*A:PE-1>config>service>vpls>provider-tunnel>inclusive# owner bgp-vpls
INFO: SVCMGR #6721 Provider tunnel is not shutdown
```

After the owner is set, the corresponding protocol is checked to see if it is enabled in the service configuration.

```
*A:PE-1>config>service>vpls>provider-tunnel>inclusive# shutdown
*A:PE-1>config>service>vpls>provider-tunnel>inclusive# owner bgp-vpls
*A:PE-1>config>service>vpls>provider-tunnel>inclusive# no shutdown
MINOR: SVCMGR #6730 provider-tunnel cannot be enabled - bgp-vpls not enabled
```

- If **ingress-repl-inc-mcast-advertisement** is enabled and the PE is configured with **root-and-leaf**, the router sends an IMET-P2MP-IR route; if the PE is configured with **no root-and-leaf** (default), the router sends an IMET-IR route. However, if **ingress-repl-inc-mcast-advertisement** is disabled and the PE is configured with **root-and-leaf**, the router only sends IMET-P2MP routes. Leaf-only nodes do not send any IMET routes at all in case no IR multicast advertisement is allowed.

  Root-and-leaf nodes only send BUM traffic to the P2MP tunnel as long as it is active. If the P2MP tunnel goes operationally down, it starts sending BUM traffic to IR tunnels (EVPN-MPLS destinations shown in the **show service id 1 evpn-mpls** command).
- If a provider tunnel is configured on a node, the router can join P2MP trees as a leaf, by generating an LDP label mapping message including the corresponding P2MP mLDP FEC. If no provider tunnel is configured, the node does not join P2MP mLDP trees, and can only use IR for BUM.
- If one node is configured as root, all other nodes must be configured with provider tunnels; otherwise, they do not receive BUM traffic sent on P2MP tunnels. The configuration of leaf-only node PE-5 is as follows, the main difference with the configuration for the root being the **no root-and-leaf** (default setting):

```
# On PE-5:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    auto-bind-tunnel
```

```
                    resolution any
                exit
                no shutdown
            exit
        exit
        provider-tunnel
            inclusive
                owner bgp-evpn-mpls
                mldp
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/2/c1/1:1 create    # sap for egress traffic to VPLS 1
        exit
        no shutdown
    exit
```

As described, the tunnel types for BUM traffic are controlled by **ingress-repl-inc-mcast-advertisement** and the **provider-tunnel** context (**root-and-leaf**). The IMET route sending behavior is summarized in Table 12: IMET routes and Tunnel Types advertised based on the configuration .

Table 12: IMET routes and Tunnel Types advertised based on the configuration

IMET route set	Root + Leaf PE	Leaf-only	No provider-tunnel
IR-mcast advertisement	Composite P2MP + IR	IR	IR
No IR-mcast advertisement	P2MP	-	-

Information about the provider tunnel can be retrieved as follows:

```
*A:PE-1# show service id 1 provider-tunnel

===============================================================================

===============================================================================
```

Note:
The same IMET-P2MP route cannot be imported by two services at the same time. If two VPLS services (where a provider tunnel is enabled) have the same import route-target, only one service joins the mLDP tree (whichever comes first).

EVPN P2MP mLDP operation

After the root node and leaf nodes are configured as shown, the root node sends BGP EVPN composite IMET-P2MP-IR routes, as follows:

```
# On PE-1:
1 2023/07/03 12:23:01.864 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:

        target:64500:1
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 25 PMSI:
        Tunnel-type Composite LDP P2MP IR (130)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label1 Ag  0
        MPLS Label2 IR 8388480
        Root-Node 192.0.2.1, LSP-ID 0x2001
"
```

The PTA for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 equals zero. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388480 needs to be divided by 16 to have the MPLS label: 8388480/16 = 524280. This is because the debug message is shown before the router can parse the label field and see whether it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits).

The tunnel identifier field contains the root node address 192.0.2.1 and the opaque value 0x2001, which corresponds to decimal value 8193. With this tunnel identifier, the leaf nodes can join the mLDP multicast tree toward the root node by sending LDP label mapping messages that contain the root node IP address and the opaque value.

Note:
When static P2MP mLDP tunnels and dynamic P2MP mLDP tunnels used by BGP-EVPN coexist on the same router, Nokia recommends that the static tunnels use a tunnel ID less than 8193. If a tunnel ID is statically configured with a value equal to or greater than 8193, BGP-EVPN may attempt to use the same tunnel ID for services with an enabled provider tunnel and fail to set up an mLDP tunnel.

The root node PE-1 receives IMET-IR routes from all leaf nodes, as shown for the BGP update sent by leaf node PE-5 (via RR P-2):

```
# On PE-1:
6 2023/07/03 12:26:12.751 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

        MPLS Label 8388480
        Tunnel-Endpoint 192.0.2.5
"
```

The PTA tunnel type 6 for IR has only one MPLS label, which corresponds to the MPLS label 524280 allocated for the service. The tunnel identifier is the tunnel endpoint 192.0.2.5, which is the system address of the originating leaf node.

On leaf node PE-5, three BGP EVPN inclusive multicast routes have been learned and are used, as follows:

```
*A:PE-5# show router bgp routes evpn incl-mcast

```

The MPLS label is 524280, as described. The LSP ID equals 8193, which corresponds to the hexadecimal value 0x2001 in the preceding BGP update message sent by the root node PE-1.

To set up the mLDP tree, leaf node PE-5 has generated an LDP label mapping message to the next hop router toward the root, P-3. The label mapping message includes the root address 192.0.2.1, the opaque value 8193, and MPLS label 524279, as follows:

```
*A:PE-5# show router ldp bindings active p2mp ipv4

===============================================================================
```

When the LDP label reaches the root node PE-1, the mLDP tree is complete and it can be used for BUM traffic.

The following **tools** command shows the provider tunnels for VPLS 1 on root node and leaf nodes. On root node PE-1, there is one originating inclusive provider tunnel and there are no terminating inclusive provider tunnels, as follows:

```
*A:PE-1# tools dump service id 1 provider-tunnels

===============================================================================
VPLS 1 Inclusive Provider Tunnels Originating
===============================================================================
ipmsi (LDP)                                 P2MP-ID  Root-Addr
-------------------------------------------------------------------------------
8193                                        8193    192.0.2.1

-------------------------------------------------------------------------------

===============================================================================
VPLS 1 Inclusive Provider Tunnels Terminating
===============================================================================
ipmsi (LDP)                                 P2MP-ID  Root-Addr
-------------------------------------------------------------------------------
```

```
No Tunnels Found
------------------------------------------------------------------------------
---snip---
```

On leaf node PE-5, no originating inclusive provider tunnels are established; only one terminating provider tunnel, as follows:

```
*A:PE-5# tools dump service id 1 provider-tunnels

==============================================================================
VPLS 1 Inclusive Provider Tunnels Originating
==============================================================================
ipmsi (LDP)                                     P2MP-ID  Root-Addr
------------------------------------------------------------------------------

No Tunnels Found
------------------------------------------------------------------------------

==============================================================================
VPLS 1 Inclusive Provider Tunnels Terminating
==============================================================================
ipmsi (LDP)                                     P2MP-ID  Root-Addr
------------------------------------------------------------------------------
                                                8193    192.0.2.1

------------------------------------------------------------------------------
---snip---
```

The inclusive provider tunnels are identified by the combination of the P2MP ID (opaque value) and the root address. These parameters are in every label mapping message and they are included in the PTA tunnel identifier for tunnel type 130 (IMET-P2MP-IR) and for tunnel type 2 (IMET-P2MP).

In VPLS 1 on root node PE-1, an SDP of type VplsPmsi is auto-created, as follows:

```
*A:PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl

IGMP snooping

When IGMP snooping is disabled and a multicast stream enters VPLS 1 on the root node, this stream is sent to all the leaf nodes, even if no receivers join the multicast group on the leaf nodes. In this example, a receiver connected to PE-5 joins a multicast group, but there are no receivers for any multicast group on PE-6 and PE-7. By default, IGMP is disabled and the multicast stream is flooded to all leaf PEs, as can be verified with the following monitor command on PE-6 where no receivers have joined any multicast stream:

```
*A:PE-6# monitor port 1/1/c1/1 1/2/c3/1 1/2/c1/1 1/2/c2/1 repeat 15 interval 4 | match "==|
Port|Input|--|time|Packets" expression
===============================================================================
Monitor statistics for Ports
===============================================================================
                                                    Input                 Output
-------------------------------------------------------------------------------
---snip---

Packets                                           3289                      0
-------------------------------------------------------------------------------
---snip---
===============================================================================
```

This implies that bandwidth is wasted, which can be prevented by enabling IGMP snooping. IGMP snooping ensures that multicast traffic is only sent to the receivers that joined a multicast group. IGMP snooping can be enabled in VPLS 1 on all PEs, as follows:

```
configure service vpls 1 igmp-snooping no shutdown
```

A receiver connected to PE-5 has sent an IGMP report whereas PE-6 has no receivers that joined a multicast group. The traffic counters are monitored on the outgoing port to the (potential) receivers. On PE-5, traffic is sent to the receiver, as follows:

```
*A:PE-5# monitor port 1/1/c1/1 1/2/c3/1 1/2/c1/1 1/2/c2/1 repeat 15 interval 4 | match "==|
Port|Input|--|time|Packets" expression
===============================================================================
Monitor statistics for Ports
===============================================================================
                                                    Input                Output
-------------------------------------------------------------------------------
---snip---
-------------------------------------------------------------------------------
At time t = 12 sec (Mode: Delta)
-------------------------------------------------------------------------------
Port 1/1/c1/1
-------------------------------------------------------------------------------
Packets                                           3294                      3
Port 1/2/c3/1
-------------------------------------------------------------------------------
Packets                                              0                      0
Port 1/2/c1/1
-------------------------------------------------------------------------------
Packets                                              0                   3290

---snip---
===============================================================================
```

IGMP snooping can be enabled in EVPN-MPLS services with IR or provider-tunnel mLDP trees. When IGMP snooping is enabled on the VPLS, all the EVPN-MPLS destinations are added to the MFIB as a single router interface. IGMP queries and reports are properly forwarded to and from EVPN-MPLS destinations.

The following shows the EVPN-MPLS destinations as part of the MFIB when IGMP snooping is enabled:

```
*A:PE-5# show service id 1 mfib

===============================================================================

On leaf node PE-5, the receiving host connected to SAP 1/2/c1/1:1 has IP address 172.16.0.5, as follows:

```
*A:PE-5# show service id 1 igmp-snooping mrouters

===============================================================================
IGMP Snooping Multicast Routers for service 1
===============================================================================
MRouter          Port Id                   Up Time        Expires   Version
-------------------------------------------------------------------------------
172.16.0.5       sap:1/2/c1/1:1            0d 00:04:19    160s      3
-------------------------------------------------------------------------------
Number of mrouters: 1
===============================================================================
```

On leaf node PE-6, SAP 1/2/c1/1:1 has no receiving host connected, but EVPN-MPLS is always added as an mrouter, as follows:

```
*A:PE-6# show service id 1 igmp-snooping base

===============================================================================
IGMP Snooping Base info for service 1
===============================================================================
Admin State : Up
Querier     : 172.16.0.5 on evpn-mpls

-------------------------------------------------------------------------------
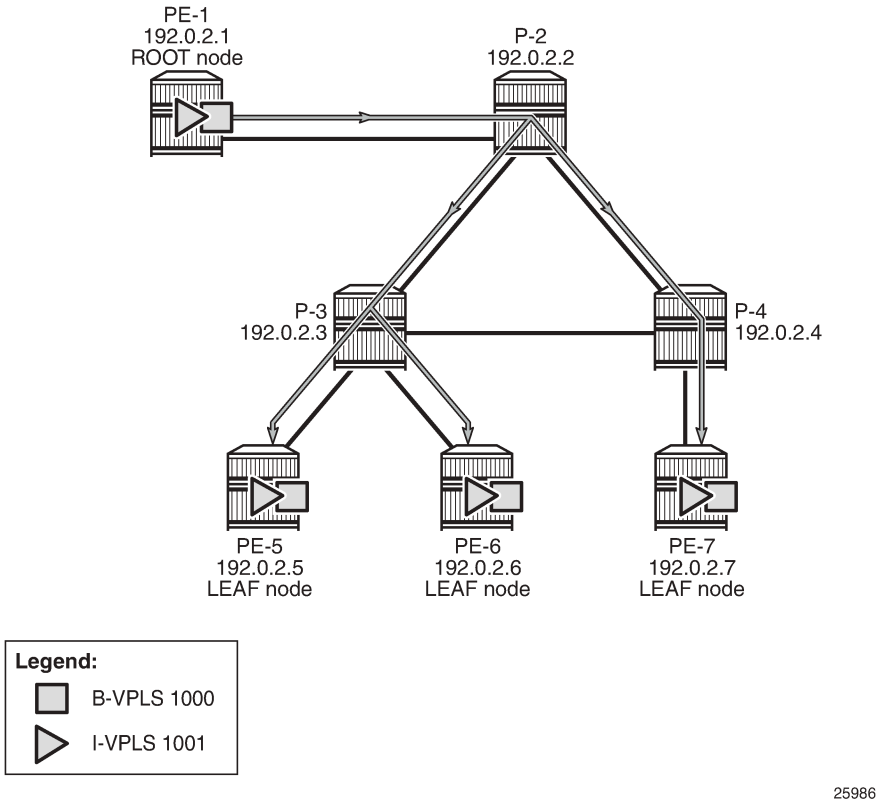
Number of mrouters: 1
===============================================================================
```

PBB-EVPN and P2MP mLDP

Provider Backbone Bridging (PBB) EVPN is described in chapter EVPN for PBB over MPLS (PBB-EVPN).

Figure 246: P2MP mLDP in PBB-EVPN shows the setup for P2MP mLDP in PBB-EVPN.

Figure 246: P2MP mLDP in PBB-EVPN



P2MP mLDP tunnels can also be used in PBB-EVPN services. In Release 14.0, the use of **provider-tunnel inclusive mldp** is only for the default multicast list; no per-ISID IMET-P2MP routes are supported.

The Backbone (B) -VPLS still uses Multicast Forwarding Information Bases (MFIBs) for ISIDs using IR.

If an ISID policy is configured in the B-VPLS, a range of ISIDs configured with **use-def-mcast** use the P2MP tree, and a range of ISIDs configured with **advertise-local** make the router advertise IMET-IR routes for the local ISIDs in the range.

PE-1 is configured with **root-and-leaf**. The configuration for B-VPLS and I-VPLS is as follows:

```
# On PE-1:
configure
    service
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:01
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
```

```
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf
                    mldp
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            isid-policy
                entry 10 create
                    use-def-mcast
                    no advertise-local
                    range 1001 to 2000
                exit
            exit
            no shutdown
        exit
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/c3/1 create    # sap for ingress traffic from STC
            exit
            no shutdown
        exit
    exit
```

In this example, ISIDs in the range from 1001 to 2000 use the P2MP tree (**use-def-mcast**) and the router does not advertise the IMET-IR routes for the local ISIDs included in that range (**no advertise-local**). Any other local ISID advertises an IMET-IR and uses the MFIB to forward BUM packets to the remote EVPN-MPLS bindings created by IMET-IR routes.

The configuration on the leaf nodes PE-5, PE-6, and PE-7 is similar to the one for the root node, except for the **no root-and-leaf** setting (which is default), as follows:

```
# On PE-5:
configure
    service
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:05
            exit
            bgp
            exit
            bgp-evpn
                evi 1000
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
```

```
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    mldp
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            isid-policy
                entry 10 create
                    use-def-mcast
                    no advertise-local
                    range 1001 to 2000
                exit
            exit
            no shutdown
        exit
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/c1/1:1001 create    # sap for egress traffic to VPLS 1001
            exit
            no shutdown
        exit
    exit
```

A VPLS-PMSI SDP is auto-created in the B-VPLS at the root node, as follows:

```
*A:PE-1# show service id 1000 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
32767:4294967288 VplsPmsi not applicable  Up      Up        None      3
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The default multicast list for the B-VPLS 1000 can be retrieved on root node and leaf nodes, for instance for leaf node PE-5, as follows:

```
*A:PE-5# tools dump service id 1000 evpn-mpls default-multicast-list
-------------------------------------------------------------------------
TEP Address                          Egr Label
                                     Transport
-------------------------------------------------------------------------
192.0.2.1                            524279
                                     ldp
192.0.2.6                            524279
                                     ldp
192.0.2.7                            524279
                                     ldp
```

```
-------------------------------------------------------------------------------
```

IGMP snooping can be enabled in the I-VPLS 1001 on all PEs, as follows:

```
configure service vpls 1001 igmp-snooping no shutdown
```

After IGMP snooping is enabled, the multicast stream is not flooded anymore to any receivers until they send an IGMP report for the multicast stream.

On each PE, the logical interface B-EVPN-MPLS is added as a single IGMP snooping interface and treated as an mrouter, as follows:

```
*A:PE-5# show service id 1001 igmp-snooping base

===============================================================================
IGMP Snooping Base info for service 1001
===============================================================================
Admin State : Up

172.16.0.55      evpn-mpls                 0d 00:03:43    197s      3
-------------------------------------------------------------------------------
Number of mrouters: 1
===============================================================================
```

Conclusion

Service providers are migrating their existing VPN services to EVPN and expect at least the same capabilities in EVPN, including the forwarding of BUM traffic. Ingress replication is a good mechanism for broadcast and unknown unicast traffic in EVPN networks, but not efficient for multicast applications. EVPN P2MP mLDP offers efficiency for multicast, using composite tunnels combining the benefits of P2MP mLDP and IR.

PBB-Epipe

This chapter provides information about Provider Backbone Bridging (PBB) — Ethernet Virtual Leased Line in an MPLS-based network which is applicable to SR OS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 7.0.R5. The CLI in the current edition corresponds to SR OS Release 20.10.R2. There are no specific prerequisites.

Overview

RFC 7041, *Extensions to VPLS PE model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

The PBB model is organized around a B-component (backbone instance) and an I-component (customer instance). In Nokia's implementation of the PBB model, the use of an Epipe as I-component is allowed for point-to-point services. Multiple I-VPLS and Epipe services can be all mapped to the same B-VPLS (backbone VPLS instance).

The use of Epipe scales the E-Line services because no MAC switching, learning, or replication is required in order to deliver the point-to-point service. All packets ingressing the customer SAP are PBB-encapsulated and unicasted through the B-VPLS tunnel using the backbone destination MAC of the remote PBB PE. All the packets egressing the B-VPLS destined for the Epipe are PBB de-encapsulated and forwarded to the customer SAP.

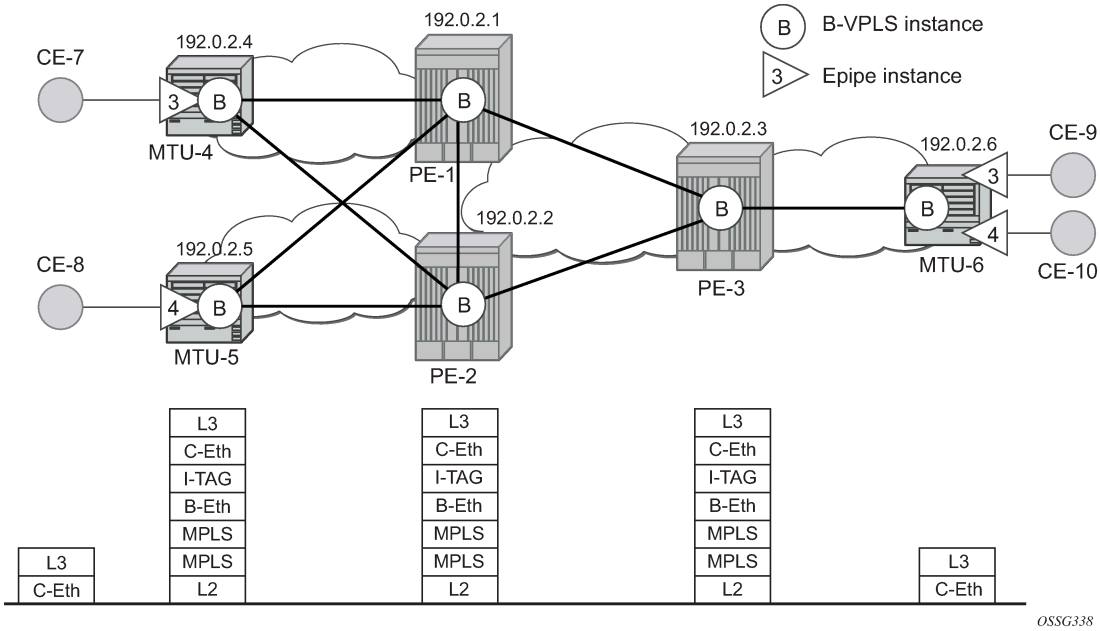
Some use cases for PBB-Epipe are:

- Get a more efficient and scalable solution for point-to-point services:
  - Up to 8K VPLS services per box are supported (including I-VPLS or B-VPLS) and using I-VPLS for point-to-point services takes VPLS resources as well as unnecessary customer MAC learning. A better solution is to connect a PBB-Epipe to a B-VPLS instance, where there is no customer MAC switching/learning.
- Take advantage of the pseudowire aggregation in the M:1 model:
  - Many Epipe services may use only a single service and set of pseudowires over the backbone.
- Have a uniform provisioning model for both point-to-point (Epipe) and multipoint (VPLS) services.
  - Using the PBB-Epipe, the core MPLS/pseudowire infrastructure does not need to be modified: the new Epipe inherits the existing pseudowire and MPLS structure already configured on the B-VPLS and there is no need for configuring new tunnels or pseudowire switching instances at the core.

Knowledge of the PBB-VPLS architecture and functionality on the service router family is assumed throughout this section. For additional information, see the relevant Nokia user documentation.

The following network setup will be used throughout the rest of the chapter.

Figure 247: Network topology



The setup consists of a three SR OS routers in the core (PE-1, PE-2, and PE-3) and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 101) will be defined in all the six nodes, whereas two Epipe services will be defined as illustrated in Figure 247: Network topology (Epipe 3 in nodes MTU-4 and MTU-6, Epipe 4 in nodes MTU-5 and MTU-6). Those Epipe services will be multiplexed into the common B-VPLS 101, using the I-Service ID (ISID) field within the I-TAG as the demultiplexer field required at the egress MTU to differentiate each specific customer. I-VPLS and Epipe services can be mapped to the same B-VPLS.

The B-VPLS domain constitutes a H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby (A/S) spoke-SDPs can be used from the MTUs to the PEs (like in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (like MTU-6).

The protocol stack being used along the path between the CEs is represented in Figure 247: Network topology.

Configuration

This section describes all the relevant PBB-Epipe configuration tasks for the setup shown in Figure 247: Network topology. The appropriate B-VPLS and associated IP/MPLS configuration is out of the scope of this document. In this particular example, the following protocols will be configured beforehand in the core:

- ISIS-TE as IGP with all the interfaces being level-2. Alternatively, OSPF could have been used.
- RSVP-TE as the MPLS protocol to signal the transport tunnels.
- LSPs between core PEs will be fast re-route protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.

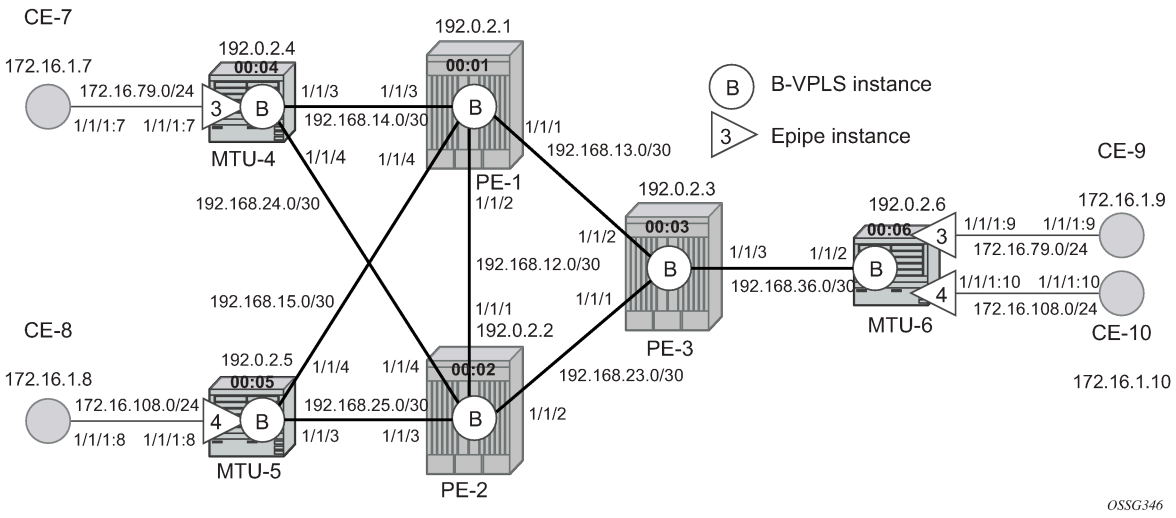
- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the A/S pseudowire protection configured in the B-VPLS.
- BGP is configured for auto-discovery—BGP-AD (Layer 2 VPN family), because FEC 129 will be used to establish the pseudowires between PEs in the core (FEC 128 between MTU and PE nodes).

Once the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB Epipe service configuration

In this particular example, the Epipes 3 and 4 are using the B-VPLS 101 in the core. The same B-VPLS which is multiplexing the Epipe services into a common service provider infrastructure can also be used to connect the I-VPLS instances existing in the network for multipoint services.

Figure 248: Setup detailed view



B-VPLS and PBB configuration

First, configure the B-VPLS instance that will carry the PBB traffic. There is no specific requirement on the B-VPLS to support Epipes. The following shows the B-VPLS configuration on MTU-4 and PE-1.

```
# on MTU-4:
configure
    service
        vpls 101 name "B-VPLS 101" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:04:04:04:04:04
            exit
            endpoint "core" create
                no suppress-standby-signaling
            exit
            spoke-sdp 41:101 endpoint "core" create
                precedence primary
            exit
            spoke-sdp 42:101 endpoint "core" create
```

```
            exit
            no shutdown
        exit
```

```
# on PE-1:
configure
    service
        pw-template 1 use-provisioned-sdp create
            split-horizon-group "CORE"
            exit
        exit
        vpls 101 name "B-VPLS 101" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:01:01:01:01:01
            exit
            bgp
                route-target export target:65000:101 import target:65000:101
                pw-template-binding 1
                exit
            exit
            bgp-ad
                vpls-id 65000:101
                no shutdown
            exit
            spoke-sdp 14:101 create
            exit
            spoke-sdp 15:101 create
            exit
            no shutdown
        exit
```

The relevant B-VPLS commands are in **bold**.

The keyword **b-vpls** is given at creation time and therefore it cannot be added to an existing regular VPLS instance. Besides the **b-vpls** keyword, the B-VPLS is a regular VPLS instance in terms of configuration, with the following exceptions:

- The B-VPLS service MTU must be at least 18 bytes greater than the Epipe MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1514 bytes), therefore, any MTU equal or greater than 1532 bytes must be configured. In this particular example, an MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.
- The source B-MAC is the MAC that will be used as a source when the PBB traffic is originated from that node. It is possible to configure a source B-MAC per B-VPLS instance (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. A common B-MAC is configured as follows:

```
# on MTU-4:
configure
    service
        pbb
            source-bmac 00:04:04:04:04:04
```

```
# on MTU-5:
configure
    service
        pbb
```

```
            source-bmac 00:05:05:05:05:05
```

```
# on MTU-6:
configure
    service
        pbb
            source-bmac 00:06:06:06:06:06
```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported.
  - Default SAP types are blocked in the CLI for the B-VPLS SAP.
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowire, the outgoing PBB frame on an SDP (for example, Bpseudowire) contains a BVID q-tag only if the pseudowire type is Ethernet VLAN (vc-type=vlan). If the pseudowire type is Ethernet (vc-type=ether), the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS, therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group has been configured to emulate the behavior of mesh SDPs in the core.
- While Multiple MAC Registration Protocol (MMRP) is useful to optimize the flooding in the B-VPLS domain and build a flooding tree on a per I-VPLS basis, it does not have any effect for Epipes because the destination B-MAC used for Epipes is always the destination B-MAC configured in the Epipe and never the group B-MAC corresponding to the ISID.
- If a local Epipe instance is associated with the B-VPLS, local frames originated or terminated on local Epipe(s) are PBB encapsulated or de-encapsulated using the PBB Etype provisioned under the related port or SDP component.

By default, the PBB Etype is 0x88e7 (which is the standard one defined in the 802.1ah, indicating that there is an I-TAG in the payload) but this PBB Etype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
A:MTU-4# configure port 1/1/3 ethernet pbb-etype
  - pbb-etype <0x0600..0xffff>
  - no pbb-etype

 <0x0600..0xffff>     : [1536..65535] - accepts in decimal or hex
```

```
A:MTU-4# configure service sdp 41 pbb-etype
  - no pbb-etype [<0x0600..0xffff>]
  - pbb-etype <0x0600..0xffff>

 <0x0600..0xffff>     : [1536..65535] - accepts in decimal or hex
```

The following commands are useful to check the actual PBB Etype.

```
A:MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                  PBB Etype          : 0x88e7
```

```
A:MTU-4# show port 1/1/3 | match PBB
```

```
PBB Ethertype      : 0x88e7
```

Before configuring the Epipe itself, the operator can optionally configure MAC names under the PBB context. MAC names will simplify the Epipe provisioning later on and in case of any change on the remote node MAC address, only one configuration modification is required as opposed as one change per affected Epipe (potentially thousands of Epipes which are terminated onto the same remote node). The MAC names are configured in the service PBB CLI context:

```
*A:MTU-4# configure service pbb mac-name
  - mac-name <name> <ieee-address>
  - no mac-name <name>

 <name>               : 32 char max
 <ieee-address>       : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
```

```
# on all nodes:
configure
    service
        pbb
            mac-name "MTU-4" 00:04:04:04:04:04
            mac-name "MTU-5" 00:05:05:05:05:05
            mac-name "MTU-6" 00:06:06:06:06:06
```

It is not required to configure a node with its own MAC address, so on MTU-4, the line defining the mac-name MTU-4 can be omitted.

Epipe configuration

Once the common B-VPLS is configured, the next step is the provisioning of the customer Epipe instances. For PBB-Epipes, the I-component or Epipe is composed of an I-SAP and a PBB tunnel endpoint which points to the backbone destination MAC address (B-DA).

The following outputs show the relevant CLI configuration for the two Epipe instances represented in Figure 248: Setup detailed view. The Epipe instances are configured on the MTU devices, whereas the core PEs are kept as customer-unaware nodes.

Epipes 3 and 4 are configured on MTU-6 as follows:

```
# on MTU-6:
configure
    service
        epipe 3 name "Epipe 3" customer 1 create
            description "pbb epipe number 3"
            pbb
                tunnel 101 backbone-dest-mac "MTU-4" isid 3
            exit
            sap 1/1/1:9 create
            exit
            no shutdown
        exit
        epipe 4 name "Epipe 4" customer 1 create
            description "pbb epipe number 4"
            pbb
                tunnel 101 backbone-dest-mac "MTU-5" isid 4
            exit
            sap 1/1/1:10 create
            exit
            no shutdown
```

```
        exit
```

```
# on MTU-4:
configure
    service
        epipe 3 name "Epipe 3" customer 1 create
            description "pbb epipe number 3"
            pbb
                tunnel 101 backbone-dest-mac "MTU-6" isid 3
            exit
            sap 1/1/1:7 create
            exit
            no shutdown
        exit
```

```
# on MTU-5:
configure
    service
        epipe 4 name "Epipe 4" customer 1 create
            description "pbb epipe number 4"
            pbb
                tunnel 101 backbone-dest-mac "MTU-6" isid 4
            exit
            sap 1/1/1:8 create
            exit
            no shutdown
        exit
```

All Ethernet SAPs supported by a regular Epipe are also supported in the PBB Epipe. spoke-SDPs are not supported in PBB-Epipes, for example, no spoke-SDP is allowed when PBB tunnels are configured on the Epipe.

The PBB tunnel links the SAP configured to the B-VPLS 101 existing in the core. The following parameters are accepted in the PBB tunnel configuration:

```
A:MTU-5# configure service epipe 4 pbb tunnel
  - no tunnel
  - tunnel <service-id> backbone-dest-mac <mac-name> isid <ISID>
  - tunnel <service-id> backbone-dest-mac <ieee-address> isid <ISID>

 <service-id>         : [1..2148007978]|<svc-name:64 char max>
 <mac-name>           : 32 char max
 <ieee-address>       : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
 <ISID>               : [0..16777215]
```

Where:

- The service-id matches the B-VPLS ID.
- The **backbone-dest-mac** can be given by a MAC name (as in this configuration example) or the MAC address itself. It is recommended to use MAC names, as explained in the previous section.
- The ISID must be specified.

Flood avoidance in PBB-Epipes

As already discussed in the previous section, when provisioning a PBB Epipe, the remote **backbone-dest-mac** must be explicitly configured on the PBB tunnel so that the ingress PBB node can build the 802.1ah encapsulation.

If the configured remote backbone destination MAC address is not known in the local FDB, the Epipe customer frames will be 802.1ah encapsulated and flooded into the B-VPLS until the MAC is learned. As previously stated, MMRP does not help to minimize the flooding because the PBB Epipes always use the configured **backbone-destination-mac** for flooding traffic as opposed to the group B-MAC derived from the ISID.

Flooding could be indefinably prolonged in the following cases:

- Configuration mistake of the **backbone-destination-mac**. The service will not work, but the operator will not detect the mistake, because the customer traffic is not dropped at the source node. Every single frame is turned into an unknown unicast PBB frame and therefore flooded into the B-VPLS domain.
- Change the **backbone-smac** in the remote PE B-VPLS instance.
- There is only unidirectional traffic in the Epipe service. In this case, the backbone-dest-mac will never be learned in the local FIB and the frames will always be flooded into the B-VPLS domain.
- The remote node owning the **backbone-destination-mac** simply goes down.

In any of those cases, the operator can easily check whether the PBB Epipe is flooding into the B-VPLS domain, just by looking at the flood flag in the following command output:

```
*A:MTU-4# show service id 3 base

===============================================================================

===============================================================================
```

In this particular example, the PBB Epipe 3 is flooding into the B-VPLS 101, as the flood flag indicates. The operator can also confirm that the operational destination B-MAC for the PBB tunnel, MTU-6, has not been learned in the B-VPLS FDB:

```
*A:MTU-4# show service id 101 fdb pbb
```

```
===============================================================================
Forwarding Database, b-Vpls Service 101
===============================================================================
MAC               Source-Identifier     iVplsMACs  Epipes     Type/Age
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

In small B-VPLS environments (up to 20 B-VPLSs, each with 10 MC-LAGs), it is possible to configure the PBB V-VPLS MAC notification mechanism to send notification messages at regular intervals (using the renotify parameter), rather than being only event-driven. This can avoid flooding into the B-VPLS.

Flooding cases 1 and 2 — Wrong backbone-dest-mac

Flooding cases 1 and 2 should be fixed after detecting the flooding (see previous commands) and checking the FDBs and PBB tunnel configurations.

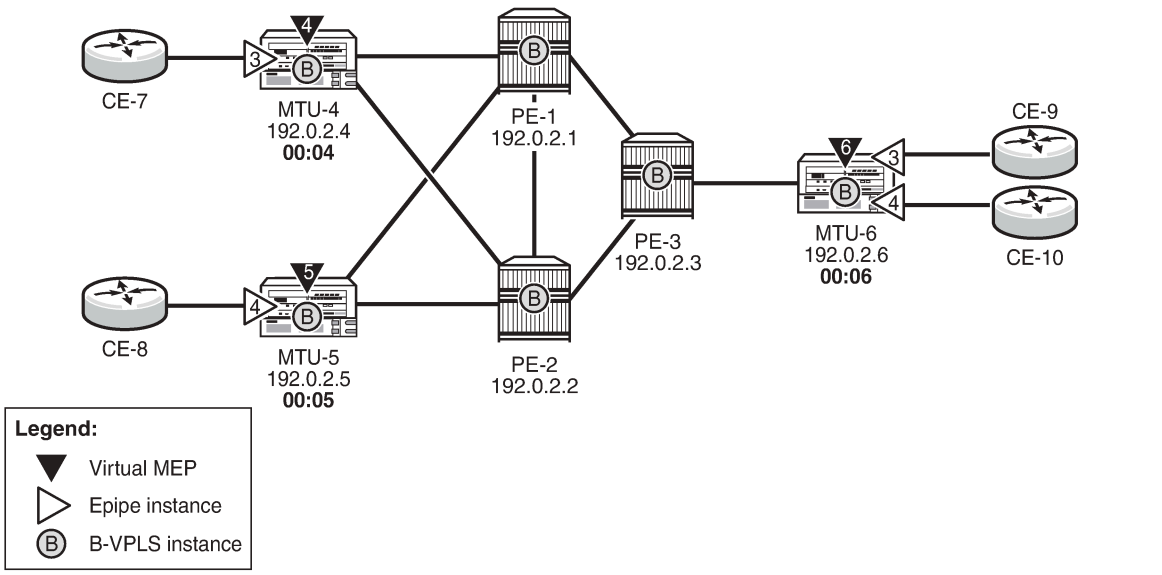
Flooding case 3 — Unidirectional traffic: virtual MEP and CCM configuration

For flooding case 3 (unidirectional traffic), Nokia recommends the use of ETH-CFM (802.1ag/Y.1731 Connectivity Fault Management) virtual Maintenance End Points (MEPs). By defining a virtual MEP per node terminating a PBB-Epipe, configuring the MEP MAC address to be the source-bmac value and activating continuity check messages (CCM), a twofold effect is achieved:

- The **pbb-tunnel backbone-destination-mac** will always be learned at the local FDB, as long as the remote virtual MEP is active and sending CC messages. As a result, there will not be flooding even if we have unidirectional traffic.
- An automatic proactive OAM mechanism exists to detect failures on remote nodes, which ultimately cause unnecessary flooding in the B-VPLS domain.

In the following network example, the virtual MEPs in B-VPLS 101: MEP4, MEP5, and MEP6 are configured.

Figure 249: Virtual MEPs for flooding avoidance



The following configuration example uses MTU-4. First, the general ETH-CFM configuration is made:

```
# on MTU-4:
configure
    eth-cfm
        domain 1 format none level 3 admin-name "domain 1"
            association 1 format icc-based name "B-VPLS-000101" admin-name "assoc-1"
                bridge-identifier 101
                exit
                remote-mepid 5
                remote-mepid 6
            exit
        exit
    exit
```

Then the actual virtual MEP configuration is made:

```
# on MTU-4:
configure
    service
        vpls 101
            eth-cfm
                mep 4 domain 1 association 1
                    ccm-enable
                    mac-address 00:04:04:04:04:04
                    no shutdown
                exit
            exit
        exit
```

The MAC address configured for the MEP4 matches the MAC address configured as the **source-bmac** on MTU-4, which is the **backbone-destination-mac** configured on the Epipe 3 PBB tunnel on MTU-6. The source-BMAC address on MTU-4 is 00:04:04:04:04:04, as follows:

```
# on MTU-4:
configure
    service
        pbb
            source-bmac 00:04:04:04:04:04
            mac-name "MTU-4" 00:04:04:04:04:04
            mac-name "MTU-5" 00:05:05:05:05:05
            mac-name "MTU-6" 00:06:06:06:06:06
        exit
```

The backbone destination MAC address configured on MTU-6 uses MAC name "MTU-4", which corresponds to MAC address 00:04:04:04:04:04, as follows:

```
# on MTU-6:
configure
    service
        pbb
            source-bmac 00:06:06:06:06:06
            mac-name "MTU-4" 00:04:04:04:04:04
            mac-name "MTU-5" 00:05:05:05:05:05
            mac-name "MTU-6" 00:06:06:06:06:06
        exit
        epipe 3 name " Epipe 3" customer 1 create
            description "pbb epipe number 3"
            pbb
                tunnel 101 backbone-dest-mac "MTU-4" isid 3
            exit
            sap 1/1/1:9 create
            exit
            no shutdown
        exit
```

Once MEP4 has been configured, check that MTU-6 is receiving CC messages from MEP4 with the following command:

```
*A:MTU-6# show eth-cfm mep 6 domain 1 association 1 all-remote-mepids

===============================================================================
Eth-CFM Remote-Mep Table
===============================================================================
R-mepId AD Rx CC RxRdi Port-Tlv If-Tlv Peer Mac Addr     CCM status since
-------------------------------------------------------------------------------
4          True  False Absent   Absent 00:04:04:04:04:04 01/05/2021 16:05:12
5          True  False Absent   Absent 00:05:05:05:05:05 01/05/2021 16:05:12
===============================================================================
Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

As a result of the CC messages coming from MEP4, the MTU-4 MAC is permanently learned in the B-VPLS 101 FDB on node MTU-6 and no flooding takes place. The following output shows that the flooding flag is not set.

```
*A:MTU-6# show service id 3 base

===============================================================================
Service Basic Information
===============================================================================
```

```

===============================================================================
```

Flooding case 4 — Remote node failure

If the node owner of the **backbone-dest-mac** fails or gets isolated, the node where the PBB Epipe is initiated will not detect the failure; that is, if MTU-4 fails, the Epipe 3 remote end will also fail but MTU-6 will not detect the failure and as a result of that, MTU-6 will flood the traffic to the network (flooding will occur after MTU-4 MAC is removed from the B-VPLS FDBs, due to either the B-VPLS flushing mechanisms or aging).

In order to avoid/reduce flooding in this case, the following mechanisms are recommended:

- Provision virtual MEPs in the B-VPLS instances terminating PBB Epipes, as already explained. This will guarantee there is no unknown B-MAC unicast being flooded under normal operation.
- CCM timers should be provisioned based on how long the service provider is willing to accept flooding.

```
*A:MTU-6# configure eth-cfm domain 1 association 1 ccm-interval
  - ccm-interval <interval>
  - no ccm-interval

 <interval>           : {10ms|100ms|1|10|60|600} - default 10 seconds
```

- It is possible to provision **discard-unknown** in the B-VPLS, so that flooded traffic due to the destination MAC being unknown in the B-VPLS is discarded immediately. This can be configured on the PEs and the MTUs. On the MTUs, it is important to configure this in conjunction with the CC messages from the virtual MEPs to ensure that the remote B-MACs are learned in both directions. If, for any reason, the remote B-MACs are not in the MTU B-VPLS, no traffic will be forwarded at all on the PBB-Epipe.

```
# on all nodes:
configure
    service
        vpls 101
            discard-unknown
```

As soon as the MTU node recovers, it will start sending CC messages and the backbone MAC address will be learned on the backbone nodes and MTU nodes again.

With the recommended configuration in place, in case MTU-4 fails, the **backbone-dest-mac** configured on the PBB tunnel for Epipe 3 on MTU-6 will be removed from the B-VPLS 101 on all the nodes (either by MAC flush mechanisms on the B-VPLS or by aging). From that point on, traffic originated from CE-9 will be discarded at MTU-6 and won't be flooded further.

As soon as MTU-4 comes back up, MEP4 will start sending CCM and as such the MTU-4 MAC will be learned throughout the B-VPLS 101 domain and in particular in PE-1, PE-3, and MTU-6 (CCM PDUs use a multicast address). From the moment MTU-4 MAC is known on the backbone nodes and MTU-6, the traffic will not be discarded any more, but forwarded to MTU-4.

PBB-Epipe show commands

The following commands can help to check the PBB Epipe configuration and their related parameters.

For the B-VPLS service:

```
*A:MTU-4# show service id 101 base

```

CCMs are no longer received from virtual MEP 6 (the one defined in MTU-6) since 01/05/2021 16:14:28. This conveys which node has failed and when it failed.

Conclusion

Point-to-Point Ethernet services can use the same operational model followed by PBB VPLS for multipoint services. In other words, Epipes can be linked to the same B-VPLS domain being used by I-VPLS instances and use the existing H-VPLS network infrastructure in the core. The use of PBB Epipes reduces dramatically the number of services and pseudowires in the core and therefore allows the service provider to scale the number of E-Line services in the network.

The example used in this chapter shows the configuration of the PBB Epipes as well as all the related features which are required for this environment. Show commands have also been suggested so that the operator can verify and troubleshoot the service.

PBB-EVPN ISID-based CMAC Flush

This chapter provides information about PBB-EVPN ISID-based CMAC Flush.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R4, but the CLI in the current edition is based on SR OS Release 21.2.R2. PBB-EVPN ISID-based CMAC flush is supported on the following objects in an I-VPLS:

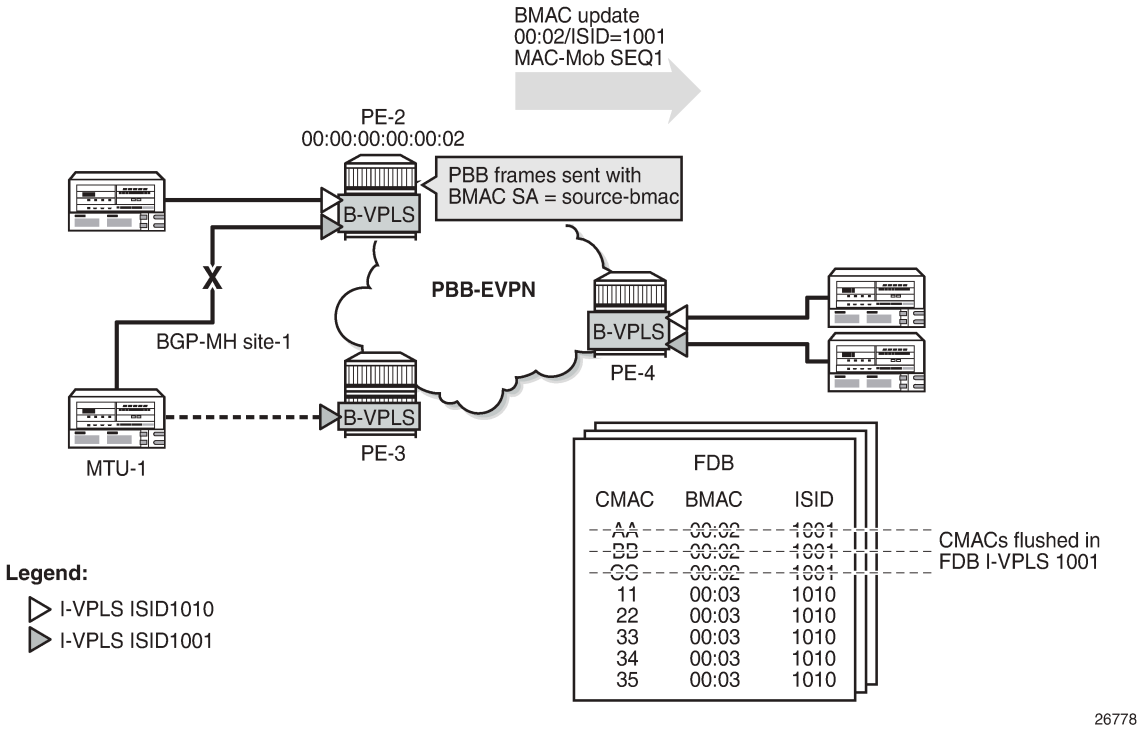
- SAPs in a BGP multi-homing site (no Ethernet Segment (ES))-supported in SR OS Release 14.0.R4, and later
- SAPs in ESs or virtual ESs (vESs)-SR OS Release 15.0.R1, and later
- Spoke-SDPs (that may be part of an ES/vES or not)-SR OS Release 15.0.R4, and later.

Chapter EVPN for PBB over MPLS (PBB-EVPN) is prerequisite reading.

Overview

Figure 250: CMAC flush when SAP in BGP multi-homing site fails shows an example topology with PBB-EVPN where a CMAC flush is triggered after a SAP in a BGP multi-homing site fails.

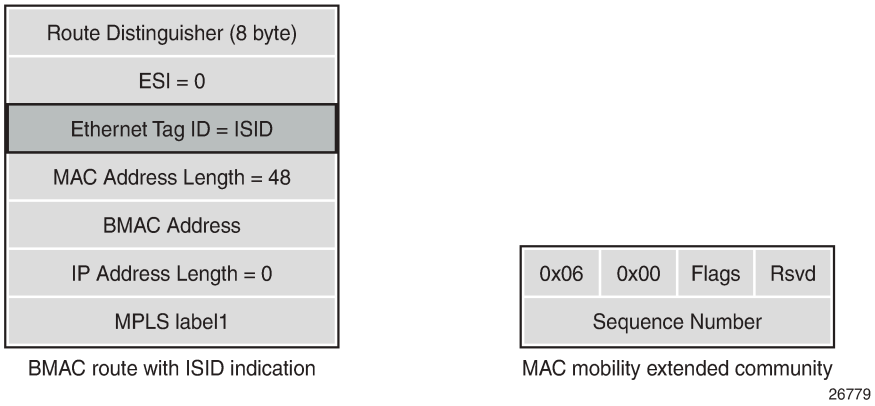
Figure 250: CMAC flush when SAP in BGP multi-homing site fails



I-VPLS 1001 is configured in PE-2 and PE-3 with **send-bvpls-evpn-flush** and connected to MTU-1. In the example, the SAP goes operationally down in I-VPLS 1001 on PE-2. To speed up convergence without flushing CMAC addresses in other I-VPLS services, PE-2 sends a BGP-EVPN BMAC route for ISID 1001 with increased sequence number to trigger a MAC-flush for I-VPLS 1001 on the remote PEs. All CMAC addresses in the FDB for other I-VPLS services, such as I-VPLS 1010 in this example, will be preserved. When PE-4 needs to send traffic to one of the flushed CMAC addresses in I-VPLS 1001, it will flood the frames until the CMAC address is learned again (via PE-3).

When SAPs or SDP-bindings-associated with ESs, vESs, or BGP-MH sites-in an I-VPLS service fail, a BGP-EVPN BMAC route (route type 2) can trigger an ISID-based CMAC flush on the remote PEs. For the CMAC addresses to be flushed from the FDB of the I-VPLS, the existing EVPN BMAC routes will be used with the Ethernet tag equal to the ISID. Figure 251: EVPN BMAC route with ISID indication shows the EVPN BMAC route with ISID indication (BMAC/ISID). A BMAC/ISID update may trigger a selective MAC-flush for a specific I-VPLS, whereas a BMAC/0 update (BMAC/ISID route where ISID=0) may trigger a MAC-flush for all I-VPLS services. This procedure is based on *draft-snr-bess-pbb-evpn-isid-cmacflush*.

Figure 251: EVPN BMAC route with ISID indication



By default, ISID-based CMAC flush is disabled: no I-VPLS will send a B-VPLS EVPN flush message and no B-VPLS will accept any I-VPLS EVPN flush messages. The router only installs CMAC entries corresponding to a zero Ethernet tag and ignores non-zero Ethernet tag MAC routes. However, when the B-VPLS is configured to accept BMAC/ISID routes, non-zero Ethernet tag BMAC routes can be processed for CMAC flush. The CMAC flush trigger will be an EVPN BMAC/ISID route with a sequence number that is higher than before. The receiving PE will then flush all CMACs associated with this BMAC address in the I-VPLS.

The first time that a BMAC/ISID route is received, it is added to the database as a baseline. It does not cause a CMAC flush. Only subsequent BMAC/ISID updates with increased sequence number or withdrawals will cause CMAC flush.

The following command shows that B-VPLS 1000 does not accept any I-VPLS EVPN flush messages. This is the default behavior.

```
*A:PE-2# show service id 1000 bgp-evpn | match "Accept IVPLS Flush"
Accept IVPLS Flush : Disabled
```

At the receiving node, B-VPLS 1000 will accept BMAC/ISID routes when the following command is configured:

```
# on PE-2:
configure
    service
        vpls "B-VPLS 1000"
            bgp-evpn
                accept-ivpls-evpn-flush
```

By default, I-VPLS 1001 will not send any B-VPLS EVPN flush messages, as follows:

```
*A:PE-2# show service id 1001 base | match SendBvplsEvpnFlush
SendBvplsEvpnFlush : Disabled
```

The following configuration allows I-VPLS 1001 to send B-VPLS EVPN flush messages when a SAP or SDP-binding fails:

```
# on PE-2:
configure
    service
```

```
        vpls "I-VPLS 1001"
            pbb
                send-bvpls-evpn-flush
```

When enabled, the I-VPLS will send a BMAC/ISID route and subsequent updates with a higher sequence number whenever a SAP fails in the I-VPLS on the node. The default setting for a SAP allows a B-VPLS EVPN flush message to be sent (when enabled in the I-VPLS itself):

```
*A:PE-2# show service id 1001 sap 1/2/1:1001 detail | match SendBvplsEvpnFlush
SendBvplsEvpnFlush : Enabled
```

When no alternative route via another node is available for specific SAPs (single-homed SAPs), no CMAC flush should be triggered. When no B-VPLS EVPN flush messages need to be sent from PE-4 when SAP 1/2/1:1001 goes down, the configuration is as follows:

```
# on PE-4:
configure
    service
        vpls "I-VPLS 1001"
            sap 1/2/1:1001
                disable-send-bvpls-evpn-flush
```

The router only installs the BMACs received in MAC routes that have Ethernet tag zero. When CMAC flush is enabled, MAC routes with Ethernet tag equal to the ISID (always non-zero) are for CMAC flush, but not for installing the conveyed BMACs.

BMAC/ISID routes have the following characteristics:

- BMAC/ISID routes are sent with the static bit flag set as for any other BMAC route. The static bit is ignored at reception because this route is never used to install a BMAC in the FDB.
- BMAC/ISID routes received with non-zero ESI and non-zero Ethernet tag are treated as withdraw by the router at application level. Route Reflectors (RRs) treat such BMAC/ISID routes as valid routes that can be forwarded.
- BMAC/ISID routes are shown as valid in the **show router bgp routes evpn mac** commands, as in the following output, even though they are not used to populate the FDB. This shows that BGP is sending the routes to the application layer for CMAC flush processing. The BMAC/0 route should be sent before the BMAC/ISID routes for the same BMAC. Also, when the B-VPLS goes operationally down, the BMAC/0 should be withdrawn before the BMAC/ISID routes.

When **send-bvpls-evpn-flush** is enabled in an I-VPLS that is associated with a B-VPLS, BGP-EVPN BMAC/ISID updates will be sent when certain events take place in the I-VPLS or B-VPLS. Table 13: CMAC flush transmission behavior shows the CMAC flush transmission behavior at the egress PE.

Table 13: CMAC flush transmission behavior

Local Event	Send-bvpls-evpn-flush	SAP disable-bvpls-evpn-flush	Action
Reconfigure I-VPLS: enable or disable send-bvpls-evpn-flush	Enable or disable	N/A	Send update/withdraw source BMAC/ISID with Seq=0
Associate/disassociate I-VPLS to/from B-VPLS	Enabled	N/A	Send update/withdraw source BMAC/ISID with Seq=0
I-VPLS oper-up/oper-down	Enabled	N/A	Send update/withdraw source BMAC/ISID with Seq=0
B-VPLS oper-up/oper-down	Enabled	N/A	Send update/withdraw source BMAC/ISID with Seq=0 Note: All BMACs are also advertised/withdrawn.
B-VPLS bgp-evpn mpls no shut/shut	Enabled	N/A	Send update/withdraw source BMAC/ISID with Seq=0
B-VPLS operational source BMAC change	Enabled	N/A	Send update/withdraw source BMAC/ISID with Seq=0
SAP oper-up	Enabled	N/A	No operation
SAP oper-down	Enabled	No disable	Send update source BMAC/ISID Seq=Seq+1
	Enabled	Disable	No operation

Table 14: CMAC flush reception behavior shows the reception behavior at the ingress PE. For the CMAC flush triggered by a BMAC/ISID update with increased sequence number, the B-VPLS in the receiving PE must be configured with **accept-ivpls-evpn-flush**. BMAC/0 refers to a BMAC route where the Ethernet Tag is 0.

Table 14: CMAC flush reception behavior

Received Route	Action
BMAC/0 withdraw	Flush all CMACs for that BMAC
BMAC/ISID withdraw	Flush all CMACs for that BMAC and ISID
BMAC/0 update + Seq change	Flush all CMACs for that BMAC
BMAC/ISID update + Seq change	Flush all CMACs for that BMAC and ISID
BMAC/0 update + PE (NHop) change	No CMAC-flush
BMAC/ISID update + PE (NHop) change	Flush all CMACs for that BMAC and ISID

BMAC/ISID updates will trigger CMAC flush procedures regardless of the Termination Endpoint (TEP) or Route Distinguisher (RD) with which the update is received. CMAC flush will be processed even if the BMAC-ISID comes from a TEP or RD different from the BMAC/0 route. Even when the sequence number is the same as in the previous BMAC/ISID update, CMAC flush will happen when the TEP is different. When the same BMAC/ISID is received from two PEs, both are accepted and any change in sequence number causes a MAC flush. However, when the same BMAC/ISID route is received from two PEs with the same RD, BGP will select only one, so the router only sees one.

CMAC flush for ES/vES

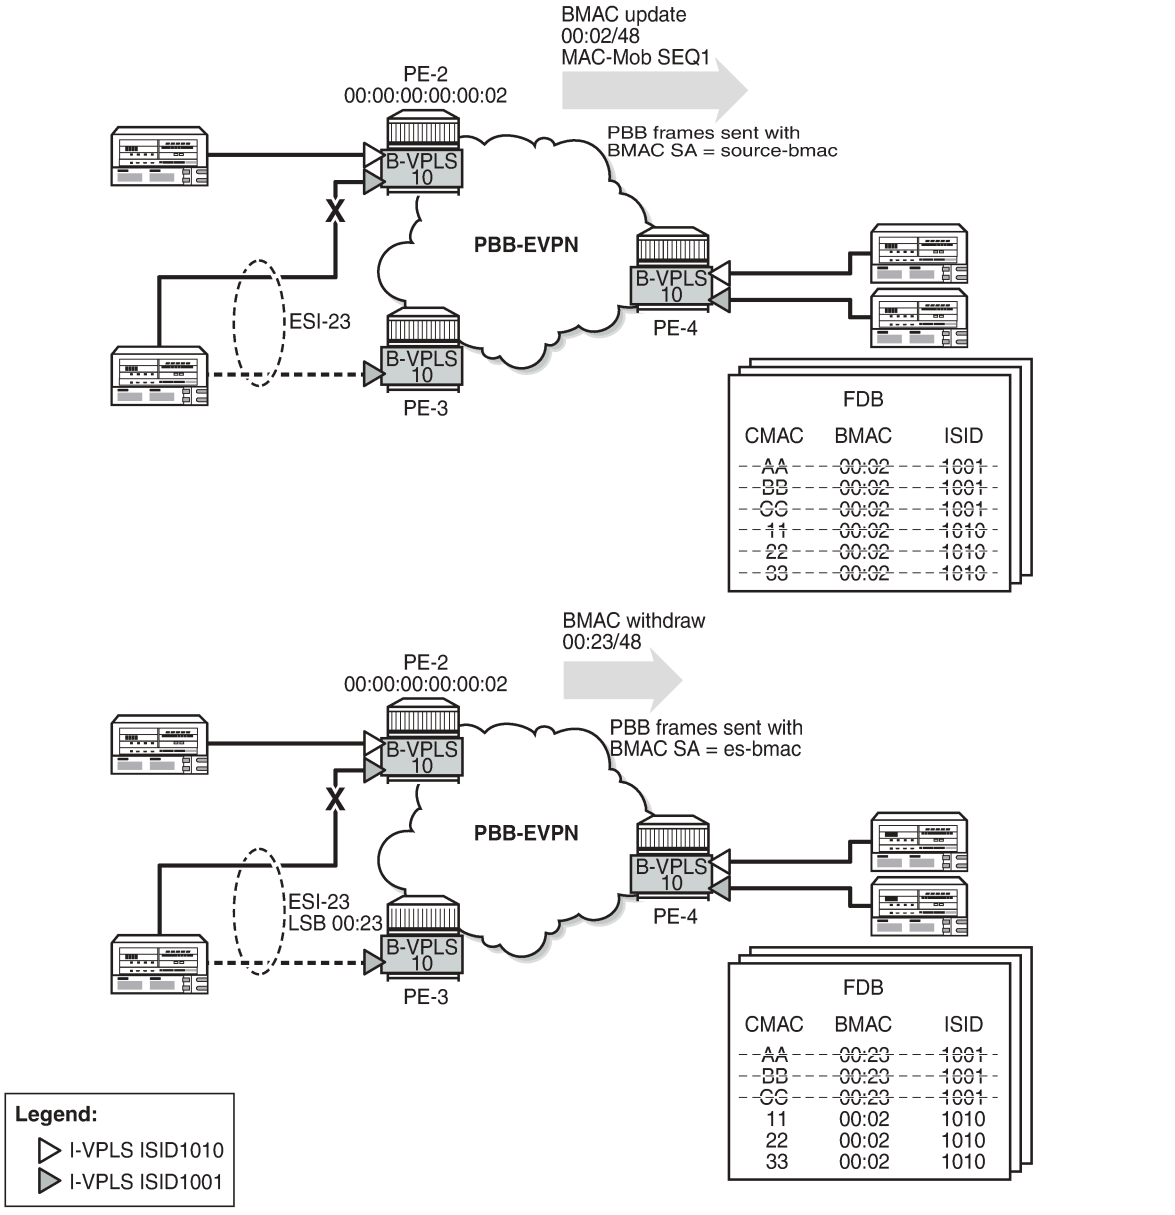
RFC 7623 (PBB-EVPN) defines the following CMAC Flush notification mechanisms for single-active multi-homing. These notifications do not include the local ISIDs:

- When ES-BMACs are used and the ES goes operationally down, the ES-BMAC will be withdrawn.
- When source-BMACs are used and the ES goes operationally down, a BGP-EVPN BMAC/0 is sent with a higher sequence number.

Figure 252: ISID-independent CMAC flush when ES fails shows the following two scenarios for ISID-independent CMAC flush that are supported in SR OS Release 13.0.R4, and later:

- PBB frames are sent with the source-BMAC. When the ES goes operationally down, a BMAC update is sent with an increased sequence number, triggering a CMAC flush for all CMAC addresses associated with the BMAC address in I-VPLS, regardless of the ISID.
- PBB frames are sent with the ES-BMAC address. When the ES goes operationally down, a BMAC withdraw message is sent, triggering the remote PEs to flush all CMAC addresses associated to the ES-BMAC address, regardless of the ISID.

Figure 252: ISID-independent CMAC flush when ES fails



In addition to the preceding ISID-independent CMAC flush mechanisms, ISID-based CMAC flush is also supported in I-VPLS services with SAP or spoke-SDPs that are part of an ES or vES. ISID-based CMAC flush is enabled in the I-VPLS with the **send-bvpls-evpn-flush** command. An I-VPLS that is configured with **send-bvpls-evpn-flush** requires one of the following conditions to be met:

- The SAP or spoke-SDP has **disable-send-bvpls-evpn-flush** configured.
- The SAP or spoke-SDP has **no disable-send-bvpls-evpn-flush** configured (default) and one of the following conditions is met:
  - The SAP or spoke-SDP is not on an ES.

  - The SAP or spoke-SDP is on an ES or vES with **no src-bmac-lsb** configured.
  - The B-VPLS has **no use-es-bmac** configured.

For ES SAPs with **no disable-send-bvpls-evpn-flush** in I-VPLS services that have **send-bvpls-evpn-flush** configured, the ISID-based CMAC flush replaces the RFC 7623-based CMAC flush mechanism.

For each ES/vES and B-VPLS, the system will check whether all I-VPLS services in the ES/B-VPLS have ISID-based MAC-flush enabled.

- If all I-VPLSs have **send-bvpls-evpn-flush** enabled:
  - No BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Only BMAC/ISID updates with increased sequence number will be sent when the I-VPLS attachment circuit goes operationally down.
- If at least one I-VPLS has **no send-bvpls-evpn-flush** enabled:
  - BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Also, BMAC/ISID updates with increased sequence number will be generated for those I-VPLS services that have **send-bvpls-evpn-flush** enabled.

The number of CMAC addresses that may be flushed at the remote nodes can be reduced by enabling ISID-based MAC-flush for all the I-VPLS services in the ES/vES.

When attempting to set **use-es-bmac** in B-VPLS 1000 on PE-4 when the SAP/SDP-binding has default settings (and **send-bvpls-evpn-flush** is enabled in the I-VPLS), the following error is raised:

```
*A:PE-4>config>service>vpls>pbb# use-es-bmac
MINOR: SVCMGR #1433 Cannot set use-es-bmac - spoke 46:1001 on ethernet-segment ESI-45 has "no
 disable-send-bvpls-evpn-flush"
```

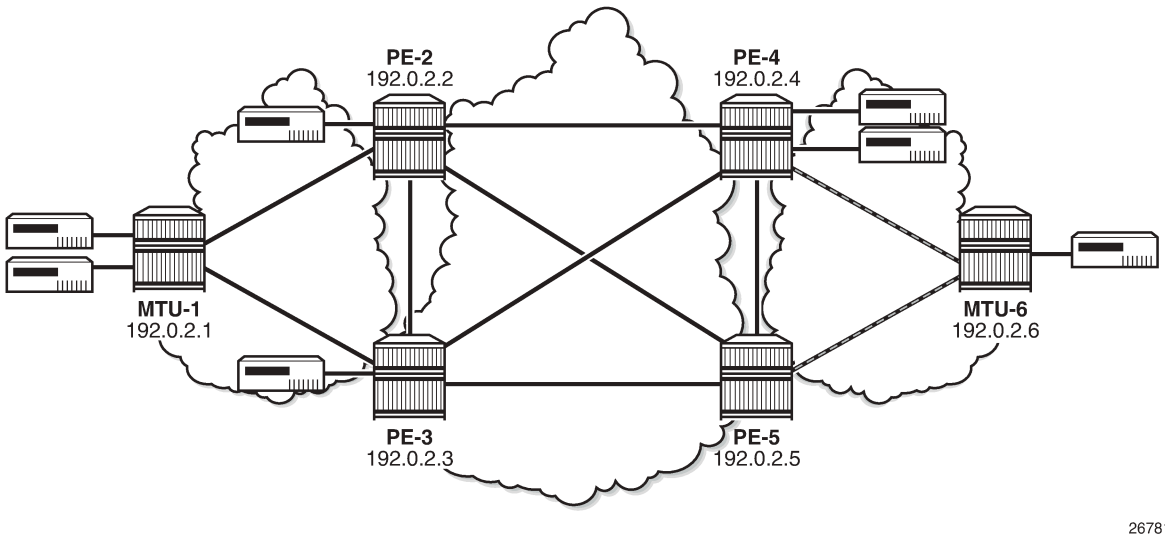
When the ES is disabled, the B-VPLS can be configured with **use-es-bmac**. When attempting to enable the ES afterward, the following error is raised.

```
*A:PE-4# configure service system bgp-evpn ethernet-segment "ESI-45" shutdown
*A:PE-4# configure service vpls "B-VPLS 1000" pbb use-es-bmac
*A:PE-4# configure service system bgp-evpn ethernet-segment "ESI-45" no shutdown
MINOR: SVCMGR #8057 Ethernet segment cannot change admin state -
spoke 46:1001 has "no disable-send-bvpls-evpn-flush"
```

Configuration

Figure 253: Example topology shows the example topology.

Figure 253: Example topology



The initial configuration includes the following:

- Cards, MDAs
- Ports: the ports between the MTUs and the PEs are hybrid or access ports with dot1q encapsulation; the ports between the PEs are network ports with null encapsulation
- Router interfaces
- IS-IS on all router interfaces (alternatively, OSPF could be used)
- LDP on all router interfaces

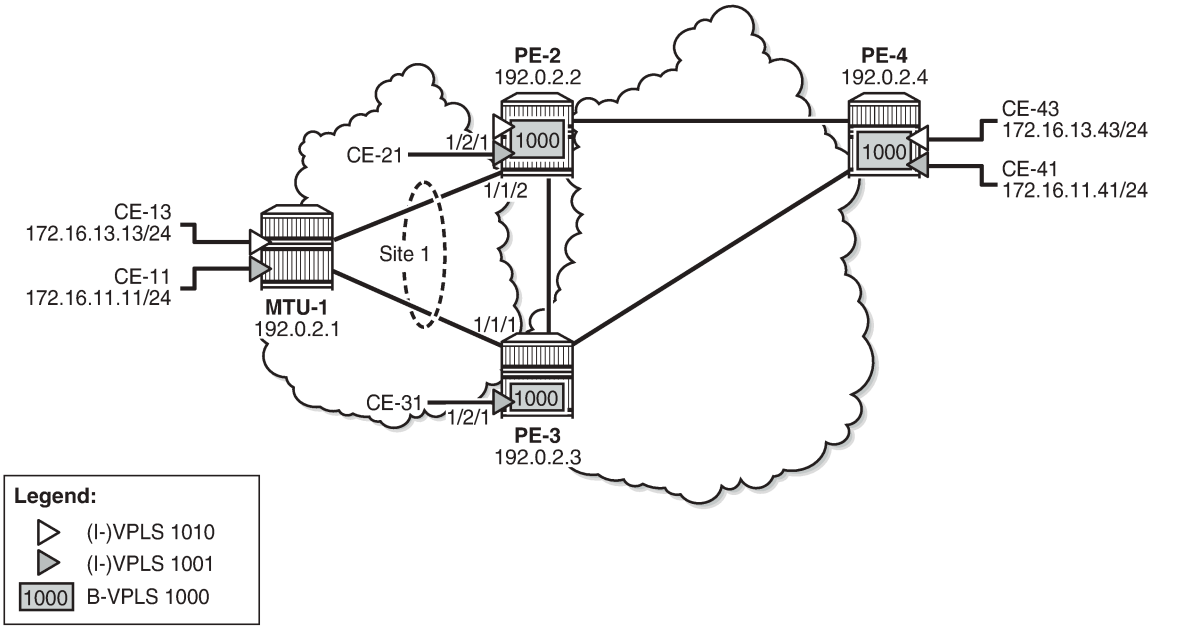
The following use cases are described in this section:

- ISID-based CMAC flush for BGP non-EVPN multi-homing (no ES)
- ISID-based CMAC flush for BGP-EVPN in a single-active ES

ISID-based CMAC flush for BGP multi-homing

Figure 254: Example topology with BGP multi-homing shows the example topology with BGP multi-homing site 1 between PE-2 and PE-3. B-VPLS 1000 is configured on all the core nodes (PEs) and I-VPLS 1001 and I-VPLS 1010 are associated with this B-VPLS in the PEs. On MTU-1, regular VPLSs are configured. For more information about BGP non-EVPN multi-homing, see chapter BGP Multi-Homing for VPLS Networks.

Figure 254: Example topology with BGP multi-homing



BGP is configured for address family EVPN on all PEs with PE-2 as RR. For BGP multi-homing, address family L2-VPN is enabled between PE-2 and PE-3. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update l2-vpn evpn
            group "internal"
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.3
                    family l2-vpn evpn
                exit
                neighbor 192.0.2.4
                    family evpn
                exit
            exit
        exit
```

The BGP configuration on PE-4 is as follows:

```
# on PE-4:
configure
    router Base
        autonomous-system 64500
        bgp
```

```
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
        exit
```

The configuration of B-VPLS 1000 and I-VPLS 1001 on PE-2 is as follows. ISID-based CMAC flush is disabled by default. BGP multi-homing site "site 1" is configured on PE-2 with SAP 1/1/2:1001 associated with it, whereas SAP 1/2/1:1001 is not associated to the MH site. CE-21 is attached to I-VPLS 1001 with SAP 1/2/1:1001.

```
# on PE-2:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.2 comm-val 1 to 999

                no shutdown
            exit
            no shutdown
        exit
        vpls 1010 name "I-VPLS 1010" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:1010 import target:64500:1010
            exit
            stp
                shutdown
            exit
            sap 1/1/2:1010 create
                no shutdown
            exit
            no shutdown
        exit
```

I-VPLS 1010 is configured without multi-homing. The configuration of VPLS 1001 on PE-3 is similar, but without I-VPLS 1010.

ISID-based CMAC flush is not enabled yet. The PEs exchange BGP-EVPN MAC routes with Ethernet tag zero. PE-3 has received BMAC/0 routes from PE-2 and PE-4, as follows:

```
*A:PE-3# show router bgp routes evpn mac
===============================================================================

-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

PE-2 and PE-4 have also received BMAC/0 routes from the other PEs.

ISID-based CMAC flush is enabled in I-VPLS 1001 on PE-2 and PE-3. PE-4 has no multi-homing in I-VPLS 1001, so it should not send any CMAC flush. I-VPLS 1010 has no multi-homing in any PE, so ISID-based MAC-flush should not be enabled in I-VPLS 1010.

```
# on PE-2, PE-3:
configure
    service
        vpls "I-VPLS 1001"
            pbb
                send-bvpls-evpn-flush
```

PE-2 and PE-3 will send BMAC/1001 updates with sequence number 0 to the other two PEs. As an example, the following EVPN-MAC route for BMAC 00:00:00:00:00:03 with tag 1001 is sent by PE-3:

```
22 2021/04/15 08:07:57.818 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

When a failure occurs on PE-2, PE-3, and PE-4 should accept the BMAC/ISID with increased sequence number; for a failure on PE-3, PE-2, and PE-4 should accept the BMAC/ISID update. Therefore, the B-VPLS on all PEs should accept the CMAC flush message for ISID 1001, and this is configured as follows:

```
# on PE-2, PE-3, PE-4, PE-5:
configure
    service
        vpls "B-VPLS 1000"
            bgp-evpn
                accept-ivpls-evpn-flush
```

The FDB for VPLS 1001 on PE-4 includes MAC address 00:00:11:11:11:11 with source-identifier 192.0.2.2:524282, so PE-4 will forward traffic toward that MAC address to PE-2.

```
*A:PE-4# show service id 1001 fdb detail

===============================================================================

-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

A failure is simulated on SAP 1/1/2:1001 in multi-homing site 1 on PE-2 as follows:

```
# on PE-2:
configure
    service
        vpls "I-VPLS 1001"
            sap 1/1/2:1001
                shutdown
```

SAP 1/1/2:1001 has the default **no disable-send-bvpls-evpn-flush** and I-VPLS 1001 is configured with **send-bvpls-evpn-flush**, so PE-2 will send BMAC/ISID updates for BMAC 00:00:00:00:00:02, ISID 1001, and sequence number 1 to its BGP peers. The following BGP update is sent by PE-2 to PE-4:

```
# on PE-2:
64 2021/04/15 08:12:55.058 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 89
    Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:
        Address Family EVPN

        Type: EVPN-MAC Len: 33 RD: 192.0.2.2:1000 ESI: ESI-0, tag: 1001, mac len: 48
                       mac: 00:00:00:00:00:02, IP len: 0, IP: NULL, label1: 8388512
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:1000
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:1/Static
"
```

This BMAC/ISID with sequence number 1 triggers a CMAC flush in the FDB for VPLS 1001, so the entry for 00:00:11:11:11:11 will be flushed, along with all other MAC addresses associated with BMAC 00:00:00:00:00:02. The FDB on PE-4 does not contain any entries with source-identifier BMAC 00:00:00:00:00:02, as follows:

```
*A:PE-4# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001

No. of MAC Entries: 1
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

When the MAC address 00:00:11:11:11:11 is learned via PE-3, the FDB is as follows:

```
*A:PE-4# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1001       00:00:11:11:11:11 b-mpls:                 L/0      04/15/21 08:15:16
                             192.0.2.3:524282
           ldp:65538
1001       00:00:41:41:41:41 sap:1/2/1:1001          L/0      04/15/21 08:11:36
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
```

```
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The CMAC flush is only applied for VPLS 1001, so the FDB for VPLS 1010 on PE-4 will keep entries learned from PE-2, as follows:

```
*A:PE-4# show service id 1010 fdb detail

===============================================================================
Forwarding Database, Service 1010
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1010       00:00:13:13:13:13 b-mpls:                 L/0      04/15/21 08:03:48

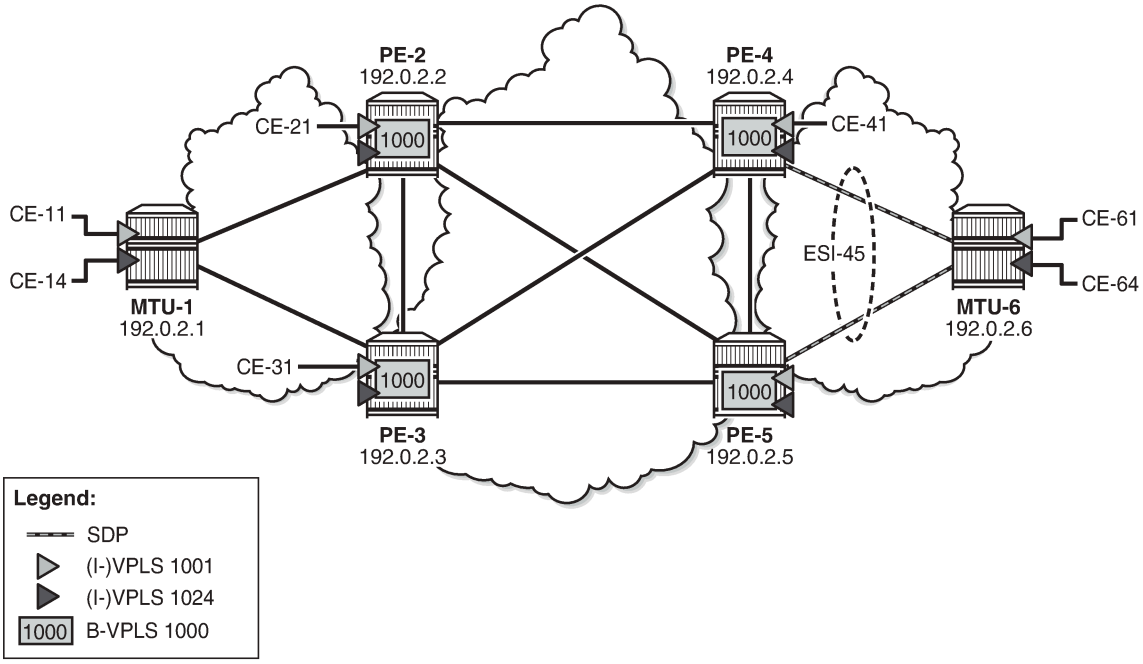
===============================================================================
```

ISID-based CMAC flush in single-active ES

CMAC flush only makes sense for single-active multi-homing. Also, CMAC flush only works for single-active multi-homing; not for all-active multi-homing, because ES-BMAC is required in all-active multi-homing. Figure 255: Example topology with single-active ES shows the example topology with a single-active ES "ESI-45" configured in PE-4 and PE-5.

Figure 255: Example topology with single-active ES



The multi-homing configuration has been removed from PE-2 and PE-3, so no CMAC flush should be sent by PE-2 or PE-3. VPLS 1001 is configured as follows on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure
    service
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:1001 import target:64500:1001
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1001 create
                no shutdown
            exit
            sap lag-1:1001 create
                no shutdown
            exit
            no shutdown
        exit
```

SDPs are configured between PE-4 and MTU-6, and between PE-5 and MTU-6. These SDPs are associated with the single-active ES "ESI-45".

The configuration of B-VPLS 1000 on PE-4 is as follows. The B-VPLS configuration on the other PEs is similar, but with a different source BMAC.

```
# on PE-4:
configure
    service
        vpls 1000 name "B-VPLS 1000" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:04
            exit
            bgp
            exit
            bgp-evpn
                accept-ivpls-evpn-flush
                evi 1000
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
```

The service configuration on PE-4 includes an SDP toward PE-6 and a single-active multi-homing ES, as follows:

```
# on PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-45" create
                    esi 01:00:00:00:00:45:00:00:00:01
                    source-bmac-lsb 45-04 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
            exit
        exit
```

The configuration on PE-5 is similar. The configuration of B-VPLS 1000 is similar to the one for PE-2, with only a different BMAC. The configuration of I-VPLS 1001 on PE-4 is as follows:

```
# on PE-4:
configure
    service
        vpls 1001 name "I-VPLS 1001" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
                send-bvpls-evpn-flush
            exit
            bgp
                route-distinguisher auto-rd
                route-target export target:64500:1001 import target:64500:1001
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1001 create
                no shutdown
            exit
            spoke-sdp 46:1001 create
                no shutdown
            exit
            no shutdown
        exit
```

ISID-based MAC-flush is enabled in B-VPLS 1000 and I-VPLS 1001 on all PEs.

I-VPLS 1024 is also associated with B-VPLS 1000 and contains one object (SAP or spoke-SDP) in each PE. The configuration of I-VPLS 1024 is identical on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure
    service
        vpls 1024 name "I-VPLS 1024" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:1024 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of I-VPLS 1024 on PE-4 has **send-bvpls-evpn-flush** enabled and contains a spoke-SDP instead of a SAP, as follows. The configuration on PE-5 is similar, but with a different SDP.

```
# on PE-4:
configure
    service
        vpls 1024 name "I-VPLS 1024" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
                send-bvpls-evpn-flush
            exit
```

```
            stp
                shutdown
            exit
            spoke-sdp 46:1024 create
                no shutdown
            exit
            no shutdown
        exit
```

ISID-based MAC-flush is enabled on PE-4 and PE-5 for both I-VPLS 1001 and I-VPLS 1024, and BMAC/ISID updates are sent for ISID 1001 and ISID 1024, as follows:

```
*A:PE-3# show router bgp routes evpn mac rd 192.0.2.4:1000

===============================================================================
```

PE-5 is the DF for VPLS 1001 in "ESI-45". A failure is simulated by disabling the SDP toward PE-5 on MTU-6, as follows:

```
# on MTU-6:
configure
    service
        sdp 65
            shutdown
```

PE-5 sends the following BMAC/ISID with increased sequence number for ISID 1001 to the RR PE-2:

```
50 2021/04/15 08:24:35.567 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
```

```
    Total Path Attr Length = 89
    Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:

Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

If MAC address 00:00:61:61:61:61 is learned again, the next hop will be PE-4 instead of PE-5.

The configuration is restored as follows:

```
# on MTU-6:
configure
    service
        sdp 65
            no shutdown
```

No CMAC/ISID update will be sent when the last SAP/SDP-binding in a service goes operationally down. VPLS 1024 only has one SAP/SDP-binding in DF PE-4: spoke-SDP 46:1024. A failure of the spoke-SDP is simulated as follows:

```
# on MTU-6:
configure
    service
        sdp 64
            shutdown
```

When the last SAP/SDP-binding is down, the service will be operationally down, as follows:

```
*A:PE-4# show service id 1024 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

PE-4 sends the following withdrawal message instead of a CMAC/ISID:

```
56 2021/04/15 08:26:10.691 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

                       mac: 00:00:00:00:00:04, IP len: 0, IP: NULL, label1: 0
"
```

The configuration is restored as follows:

```
# on MTU-6:
configure
    service
        sdp 64
            no shutdown
```

ISID-based and regular CMAC flush in ES

When ISID-based CMAC flush is not enabled in all I-VPLS services using the ES, a failure in the ES will trigger BMAC/0 updates and BMAC/ISID updates with increased sequence number. An additional I-VPLS is configured on the nodes with **no send-bvpls-evpn-flush** (default). The configuration of I-VPLS 1021 on PE-5 is as follows:

```
# on PE-5:
configure
    service
        vpls 1021 name "I-VPLS 1021" customer 1 i-vpls create
            pbb
                backbone-vpls 1000
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1021 create
                no shutdown
            exit
            spoke-sdp 56:1021 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on PE-4 is similar; PE-2 and PE-3 have SAP lag-1:1021 instead of the spoke-SDP.

On MTU-6, SDP 65 is disabled, which will cause an ES failure on PE-5:

```
# on MTU-6:
configure
    service
        sdp 65
```

```
            shutdown
```

The following BMAC updates are sent by PE-5:

- BMAC/0 with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for all I-VPLS services (ISID-independent)
- BMAC/ISID with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for VPLS 1001

```

Conclusion

ISID-based MAC-flush speeds up convergence after a SAP or spoke-SDP failure, triggering a selective CMAC flush on the receiving nodes, which flushes all CMAC entries associated with that ISID and BMAC. The feature can be enabled per I-VPLS and disabled for those SAPs or spoke-SDPs for which no alternative route is available, or for those SAPs that are contained in an all-active Ethernet Segment. The BMAC/ISID update always contains the source-BMAC, not the ES-BMAC. CMAC flush based on ES-BMAC is not performed per ISID.

PBB-EVPN ISID-based Route Targets

This chapter provides information about PBB-EVPN ISID-based Route Targets.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the CLI in the current edition corresponds to SR OS Release 21.5.R1. PBB-EVPN ISID-based route targets are supported in SR OS Release 15.0.R1, and later.

Overview

The following BGP-EVPN routes are used in PBB-EVPN according to RFC 7623:

- B-MAC routes—based on BGP-EVPN route type 2—are sent with the B-VPLS Route Target (RT), so they are sent to all the PEs where the B-VPLS is defined.
- Ethernet Segment (ES) routes—route type 4—are used for multi-homing. ES routes are sent with an RT auto-derived from the ES Identifier (ESI). If the RT-constraint is enabled, the routes are sent to only those PEs that are part of the ES.
- Inclusive Multicast Ethernet Tag (IMET) routes—route type 3—are used for the setup of per-ISID flooding domains and can be sent with a B-VPLS RT or with an ISID-based RT.
  - IMET routes are, by default, sent with a B-VPLS RT (referred to as IMET/0 routes), so they are imported by all the PEs where the B-VPLS is defined, as per RFC 7623, and supported in SR OS Release 13.0.R4, and later.
  - IMET routes with an ISID-based RT (referred to as IMET/ISID routes) are imported by only the PEs where the ISID is defined. RFC 7623 recommends these routes for deployments where the ISIDs are sparsely distributed in the network. This is supported in SR OS Release 15.0.R1, and later. The service ISID is encoded in the Ethernet tag field.

Figure 256: PBB-EVPN B-VPLS-based RT shows how the B-MAC and IMET routes with a B-VPLS RT sent by PE-1 are advertised to all other PEs (via the Route Reflector (RR)), regardless of the ISID.

Figure 256: PBB-EVPN B-VPLS-based RT

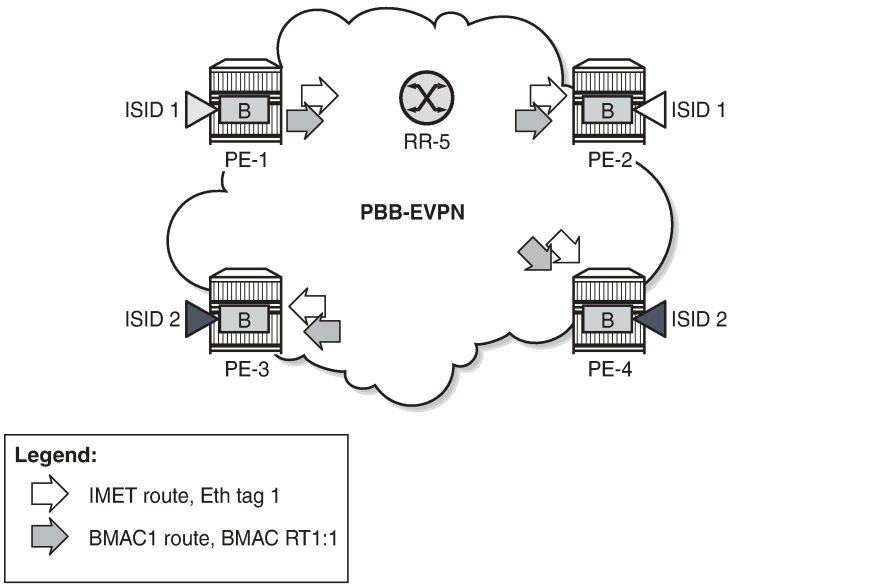

Figure 257: PBB-EVPN ISID-based RT shows how the B-MAC routes are sent to all PEs within the B-VPLS, whereas the IMET routes sent by PE-1 are selectively reflected by the RR (due to RT-constraints) and only sent to PE-2, which is the only PE with the same ISID.

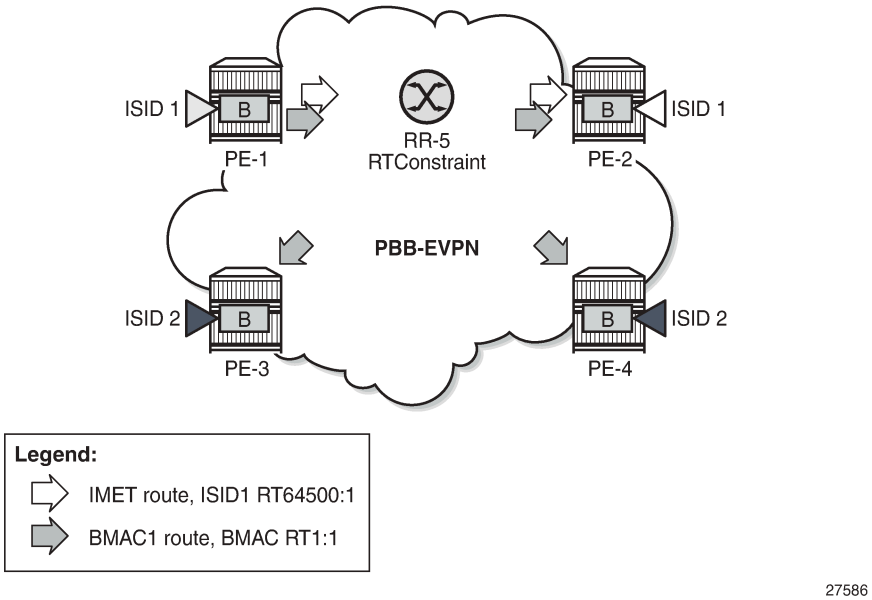
Figure 257: PBB-EVPN ISID-based RT



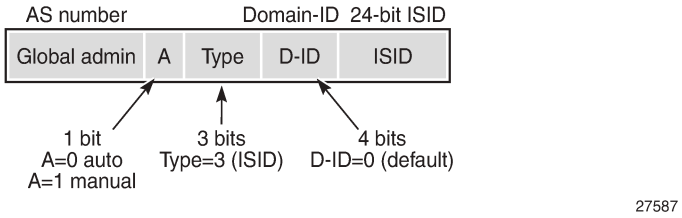
IMET routes with ISID-based RTs (IMET/ISID) can significantly reduce the number of IMET/ISID routes distributed by the RRs. The RT for the IMET/ISID route can be auto-derived from the corresponding Ethernet tag (ISID).

In addition to RFC 7623, the ISID-derived RTs can be used for BMAC/ISID routes if ISID-based CMAC flush is enabled, as per *draft-snr-bess-pbb-evpn-isid-cmacflush*. The service ISID is encoded in the Ethernet tag field.

PBB-EVPN ISID-based RT format

Figure 258: PBB-EVPN ISID-based RT format shows the ISID-based RT format:

Figure 258: PBB-EVPN ISID-based RT format



For an auto-derived ISID-based RT, the values are as follows:

- The Autonomous System (AS) number is obtained from the **config router autonomous-system** command:
  - Value = 2-byte AS number
  - For AS numbers with more than 2 bytes, the low-order 16-bit value is used.
- A = 0 for auto-derivation
- Type = 011 = 3 for ISID-based RT
- Domain ID = 0000 (default)
- ISID value

The auto-derived RT will be AS:00110000+ISID = AS:0x30+ISID Hex.

The type and sub-type of the BGP extended community is 0x00 and 0x02.

Enabling ISID-based RT

The following command is used to enable ISID-based RT for specific ISID ranges for IMET/ISID and BMAC/ISID routes.

```
*A:PE-1>config>service>vpls>bgp-evpn$ isid-route-target ?
  - isid-route-target

 [no] isid-range      - Configure ISID range information
```

The RT to be used for the I-VPLS can be auto-derived or explicitly configured.

```
*A:PE-1>configure>service>vpls>bgp-evpn>isid-route-target# isid-range ?
  - isid-range <from> [to <to>] auto-rt
  - isid-range <from> [to <to>] route-target <rt>
  - no isid-range <from>

 <from>               : [1..16777215]
```

```
 <to>                 : [1..16777215]
 <rt>                 : target:{<ip-addr:comm-val>|<2byte-asnumber:ext-comm-val>|
                        <4byte-asnumber:comm-val>}
                        ip-addr        - a.b.c.d
                        comm-val       - [0..65535]
                        2byte-asnumber - [0..65535]
                        ext-comm-val   - [0..4294967295]
                        4byte-asnumber - [0..4294967295]
```

The following configures an ISID range from 20 to 29 with auto-derived RT, whereas ISID 30 has a manually configured RT of 64500:30.

```
# on PE-1:
configure
    service
        vpls "B-VPLS 100"
            bgp-evpn
                isid-route-target
                    isid-range 20 to 29 auto-rt
                    isid-range 30 route-target target:64500:30
                exit
```

If **isid-route-target** is enabled, the IMET/ISID and BMAC/ISID route processing is modified in the export and import directions:

- "Exported IMET/ISID and BMAC/ISID routes:
  - IMET/ISID routes are sent with an ISID-based RT for the local I-VPLS ISIDs and static ISIDs, unless the ISID is contained in an ISID policy for which **no advertise-local** is configured.
  - When **isid-route-target** and **send-bvpls-evpn-flush** are both enabled for an I-VPLS, the BMAC/ISID route will also be sent with the ISID-based RT instead of the B-VPLS-based RT.
  - The **isid-route-target** command has impact only on IMET/ISID and BMAC/ISID, not on IMET/0, BMAC/0, or ES routes.
  - When a new ISID-based RT is added for an I-VPLS, a BGP update is sent for the existing IMET/ISID and BMAC/ISID routes. The new RT will be added when the routes are advertised.
- Imported IMET/ISID and BMAC/ISID routes:
  - When **isid-route-target** is enabled for an I-VPLS, BGP will start importing IMET/ISID routes and—if **bgp-evpn accept-ivpls-evpn-flush** is enabled—BMAC/ISID routes with ISID-based RTs.
  - ISID-based RTs are added for import operations when the I-VPLS is associated with the B-VPLS (regardless of the operational state of the I-VPLS) and/or when the static ISID has been added.
  - Ensure that the ISID-based RTs are configured consistently in the network. The system does not keep a mapping of RTs and ISIDs for imported routes.
  - The system will not check the format of the received auto-derived RTs. Routes will be imported when the RT is on the list of RTs for the B-VPLS.
- When **isid-route-target** is configured for an I-VPLS, VSI import/export policies are blocked in the B-VPLS, whereas BGP import/export policies are allowed and matching on the export ISID-based RT is supported.

Some other considerations:

- ISID ranges cannot overlap within a B-VPLS, but they can overlap across different B-VPLSs.
- The explicitly configured RT is meant to be used in two cases:

- ISID aggregation - when multiple ISIDs are using the same ISID RT
- Interoperability - in case the peer sends an RT in a different format

ISID-based RTs and RT-constraint

The use of the RT-constraint feature (BGP family route-target) maximizes the benefits of using different RTs per ISID; therefore, service providers are expected to enable both ISID-based RTs and RT-constraint. RT-constraint is enabled by adding the BGP address family route-target in the general BGP settings, per group, or per neighbor, as follows:

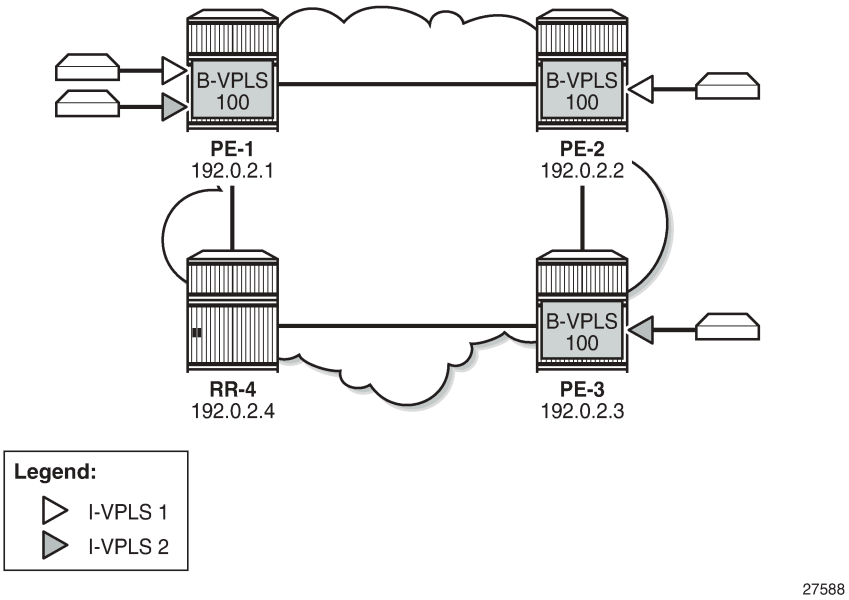
```
configure router bgp family route-target evpn
configure router bgp group "internal" family route-target evpn
configure router bgp group "internal" neighbor 192.0.2.4 family route-target evpn
```

The system will advertise the RT-constraint route when the I-VPLS is associated with the B-VPLS, regardless of the operational state of the I-VPLS. However, the IMET/ISID and the BMAC/ISID routes are sent based on the I-VPLS operational state.

Configuration

Figure 259: Example topology shows the example topology with three PEs and an RR.

Figure 259: Example topology



Initial configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on all router interfaces (alternatively, OSPF could be used)
- SR-ISIS enabled on the PEs (but disabled on the RR)

BGP is configured on all PEs for address family EVPN, as follows.

```
# on PE-1, PE-2, PE-3:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                peer-as 64500
                neighbor 192.0.2.4
                exit
            exit
        exit
```

On RR-4, BGP is configured as follows:

```
# on RR-4:
configure
    router Base
        autonomous-system 64500
        bgp
            family evpn
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
        exit
```

For the RT-constraint feature, the route-target address family can be configured in combination with the EVPN address family; see section ISID-based RTs and RT-constraint.

The initial service configuration on PE-1 without ISID-based RTs is as follows:

```
# on PE-1:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.1 comm-val 10 to 99
        exit
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            service-mtu 2000
            pbb
```

```
            source-bmac 00:00:00:00:00:01
        exit
        bgp
        exit
        bgp-evpn
            evi 100
            mpls bgp 1
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        no shutdown
    exit
    vpls 1 name "I-VPLS 1" customer 1 i-vpls create
        pbb
            backbone-vpls 100
            exit
        exit
        bgp
            route-distinguisher auto-rd
            route-target export target:64500:1 import target:64500:1
        exit
        stp
            shutdown
        exit
        sap 1/2/1:1 create
            no shutdown
        exit
        no shutdown
    exit
    vpls 2 name "I-VPLS 2" customer 1 i-vpls create
        pbb
            backbone-vpls 100
            exit
        exit
        bgp
            route-distinguisher auto-rd
            route-target export target:64500:2 import target:64500:2
        exit
        stp
            shutdown
        exit
        sap 1/2/1:2 create
            no shutdown
        exit
        no shutdown
    exit
```

The service configuration on PE-2 is similar, but only I-VPLS 1 is configured. On PE-3, only I-VPLS 2 is configured.

PE-1 sends the following default BGP-EVPN IMET/0 update to the RR:

```
2 2021/05/28 08:55:18.406 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

u*>i  192.0.2.2:100       192.0.2.2
      0                   192.0.2.2

u*>i  192.0.2.2:100       192.0.2.2
      1                   192.0.2.2

u*>i  192.0.2.3:100       192.0.2.3
      0                   192.0.2.3

u*>i  192.0.2.3:100       192.0.2.3
      2                   192.0.2.3

-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

All these routes have a B-VPLS-based RT equal to 64500:100, as follows:

```
*A:PE-1# show router bgp routes evpn incl-mcast detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
```

In the preceding output, each of the four inclusive multicast routes occurs twice: the first time with the original attributes, the second time with the modified attributes, but in this example, the attribute did not change.

For the EVPN MAC routes, the output is similar. ISID-based CMAC flush is not enabled yet, so there are only BMAC/0 routes, no BMAC/ISID routes, as follows:

```
*A:PE-1# show router bgp routes evpn mac
===============================================================================

                           n/a
                           192.0.2.3

-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

Both EVPN MAC routes have the same B-VPLS-based RT with value 64500:100, as follows:

```
*A:PE-1# show router bgp routes evpn mac detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
```

ISID-based RTs

On the PEs, B-VPLS 100 is configured with ISID-based RTs, but initially without ISID-based CMAC flush, as follows:

```
# on PE-1, PE-2:
configure
    service
        vpls "B-VPLS 100"
            bgp-evpn
                isid-route-target
                    isid-range 1 to 2 auto-rt
                    isid-range 10 to 11 route-target target:64500:10
```

```
            exit
        exit
```

B-VPLS 100 has two ISID-ranges configured:

- For ISIDs 1 and 2, the RT is auto-derived. The hexadecimal value for ISID 1 is 0x30000001, which corresponds to decimal value 805306369. The hexadecimal value for ISID 2 is 0x30000002 (decimal value 805306370). For ISID 1, the RT is 64500: 805306369; for ISID 2, the RT is 64500: 805306370.
- For ISIDs 10 and 11, the RT is manually configured as 64500:10.

The configuration is identical on PE-2. On PE-3, only ISID range 2 is configured, as follows:

```
# on PE-3:
configure
    service
        vpls "B-VPLS 100"
            bgp-evpn
                isid-route-target
                    isid-range 2 auto-rt
                exit
            exit
```

On PE-1, the same four BGP-EVPN IMET routes are shown, as follows:

```
*A:PE-1# show router bgp routes evpn incl-mcast
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP EVPN Inclusive-Mcast Routes
===============================================================================

-------------------------------------------------------------------------------
Routes : 4
```

The IMET route with Ethernet tag 1 now has RT 64500:805306369 (ISID 1) and the IMET route with Ethernet tag 2 has RT 64500:805306370 (ISID 2), as follows:

```
*A:PE-1# show router bgp routes evpn incl-mcast detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
```

```
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
```

Again, each route has two identical entries in the preceding command: one with the original attributes and another with the modified attributes.

The following BGP-EVPN IMET/ISID route is sent by PE-1 for ISID 1. The Ethernet tag is 1 and the RT is 64500:805306369.

```
# on PE-1:

```

```
"
```

When a SAP (or SDP binding) is added with static ISID 11, RT 64500:10 will be added. The service configuration on PE-1 is modified as follows:

```
# on PE-1:
configure
    service
        vpls "B-VPLS 100"
            bgp-evpn
                isid-route-target
                    isid-range 1 to 2 auto-rt
                    isid-range 10 to 11 route-target target:64500:10
                exit
            exit
            isid-policy
                entry 10 create
                    range 11
                exit
            exit
            sap 1/1/1:100 create
                static-isid
                    range 1 create isid 11
                    exit
                exit
            exit
```

The configuration is similar on PE-2. Only on PE-1 and PE-2, SAPs are configured, with static ISID 11. The following IMET/ISID route with RT 64500:10 is sent by PE-1:

```
# on PE-1:
13 2021/05/28 08:59:47.251 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 77
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.1
        Type: EVPN-INCL-MCAST Len: 17 RD: 192.0.2.1:100, tag: 11, orig_addr len: 32,
                              orig_addr: 192.0.2.1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:64500:10
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 9 PMSI:
        Tunnel-type Ingress Replication (6)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label 8388560
        Tunnel-Endpoint 192.0.2.1
"
```

This RT 64500:10 is not auto-derived, but configured manually for ISID range 10 to 11.

ISID-based CMAC flush

ISID-based CMAC flush is described in chapter PBB-EVPN ISID-based CMAC Flush and requires the following configuration on PE-1:

```
# on PE-1:
configure
    service
        vpls "I-VPLS 1"
            pbb
                send-bvpls-evpn-flush
            exit
        exit
        vpls "I-VPLS 2"
            pbb
                send-bvpls-evpn-flush
            exit
        exit
        vpls "B-VPLS 100"
            bgp-evpn
                accept-ivpls-evpn-flush
            exit
        exit
```

The configuration on PE-2 and PE-3 is similar, but only needs to be applied for I-VPLS 1 on PE-2 (I-VPLS 2 is not configured on PE-2) and for I-VPLS 2 on PE-3. The configuration for B-VPLS 100 is the same on all PEs.

When ISID-based CMAC flush is enabled on the PEs, additional BGP-EVPN MAC routes are sent by PE-1 for ISIDs 1 and 2:

```
27 2021/05/28 09:02:38.769 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

```

ISID-based RTs and RT-constraint

To show that RT BGP updates are sent when the I-VPLS is associated with the B-VPLS, the I-VPLSs are initially disassociated from B-VPLS 100 on PE-1, as follows:

```
# on PE-1:
configure
    service
        vpls "I-VPLS 1"
            pbb
                no backbone-vpls
            exit
        exit
        vpls "I-VPLS 2"
            pbb
                no backbone-vpls
            exit
        exit
```

The BGP configuration is modified on all nodes to include address families route-target and EVPN, as follows:

```
# on PE-1, PE-2, PE-3, RR-4:
configure
    router Base
        bgp
            family route-target evpn
```

The following RT-constraint route is sent by PE-1 after I-VPLS 1 is associated with B-VPLS 100. The RT is auto-derived from the ISID 1:

```
# on PE-1:
configure
    service
        vpls "I-VPLS 1"
            pbb
                backbone-vpls 100
            exit
        exit
        vpls "I-VPLS 2"
            pbb
                backbone-vpls 100
            exit
        exit
```

```
# on PE-1:
73 2021/05/28 09:09:34.587 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

        [RT-Const-V4] origin-as 64500, Target target:64500:805306369
"
```

Conclusion

PBB-EVPN ISID-based RTs, in combination with RT-constraint, reduce the number of advertised IMET routes to only those nodes where the ISID is configured. The ISID-based RT can be auto-derived from the ISID or configured manually. When ISID-based CMAC flush is also enabled, the BMAC/ISID routes will contain the same auto-derived RT.

PBB-VPLS

This chapter provides information about Provider Backbone Bridging (PBB) in a Multi-Protocol Label Switching (MPLS) based network.

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 7.0.R6. The CLI in the current edition is based on SR OS Release 20.10.R2.

Note:
Although it can be used in an MPLS-based PBB network as explained in this document, the MAC notification feature for dual-homed access is normally used in native PBB networks.

Overview

RFC 7041, *Extensions to the Virtual Private LAN Service (VPLS) Provider Edge (PE) Model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

PBB-VPLS combines the best of the PBB and VPLS technologies to deliver the most scalable multi-point Layer 2 VPN in the market. PBB-VPLS inherits all the benefits derived from MPLS (for example, sub-50ms Fast Reroute (FRR) protection, Traffic Engineering (TE), no need for Multiple Spanning Tree Protocol (MSTP) in the backbone) while greatly increasing the scalability of the network by providing MAC hiding, service multiplexing, and pseudowire aggregation.

The SR OS PBB-VPLS implementation also includes support for:

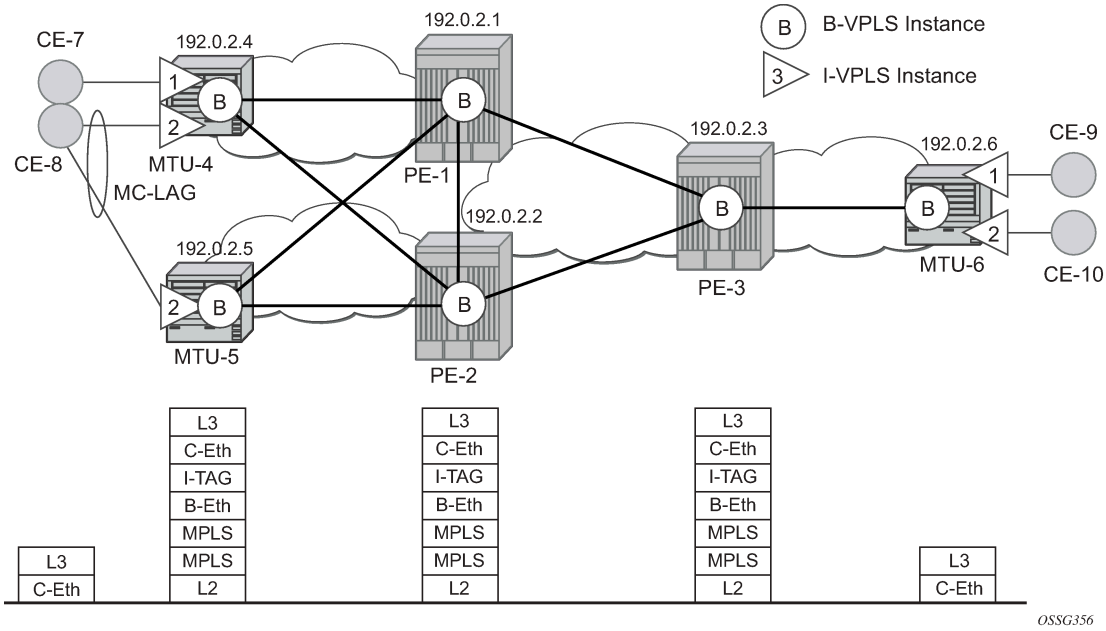
- Multiple MAC Registration Protocol (MMRP), application within IEEE 802.1ak for flood containment in the backbone instances, as specified in Section 6 of RFC 7041.
- Extensions to LDP signaling for PBB-VPLS, according to *draft-balus-l2vpn-pbb-ldp-ext-00*. These extensions will avoid network black-hole issues, as described in the Section 3 of the mentioned draft.

This chapter describes how to configure and troubleshoot a PBB-VPLS network.

Knowledge of the VPLS and H-VPLS (RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*) architecture and functionality is assumed throughout this chapter. The most relevant concepts will be briefly explained in this chapter. For further information, see the relevant Nokia documentation.

Figure 260: Example topology including B-VPLS, I-VPLSs, and protocol stacks shows the example topology that will be used throughout the rest of the chapter.

Figure 260: Example topology including B-VPLS, I-VPLSs, and protocol stacks



The topology consists of three core nodes (PE-1, PE-2, and PE-3) and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 100) will be defined in all the six nodes, whereas a few customer I-VPLS instances will be defined on the three MTU nodes.

Those I-VPLS instances will be multiplexed into the common B-VPLS, using the ISID field within the I-TAG as the demultiplexer field at the egress MTU to differentiate each specific customer.

The B-VPLS domain constitutes an H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby spoke-SDPs can be used from the MTUs to the PEs (for example, in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (for example, MTU-6). CE-8 is dual-connected to the service provider network through MC-LAG.

The protocol stack being used along the path between the CEs is shown in Figure 260: Example topology including B-VPLS, I-VPLSs, and protocol stacks.

Configuration

This section describes all the relevant PBB-VPLS configuration tasks for the setup shown in Figure 260: Example topology including B-VPLS, I-VPLSs, and protocol stacks. The appropriate associated IP/MPLS configuration is out of the scope of this example. In this particular example, the following protocols will be configured beforehand:

- ISIS-TE as IGP with all the interfaces being Level-2 (OSPF-TE could have been used instead).
- RSVP-TE as the MPLS protocol to signal the transport tunnels (LDP could have been used instead).
- LSPs between core PEs will be fast reroute protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.
- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the active/standby pseudowire protection configured in the B-VPLS.

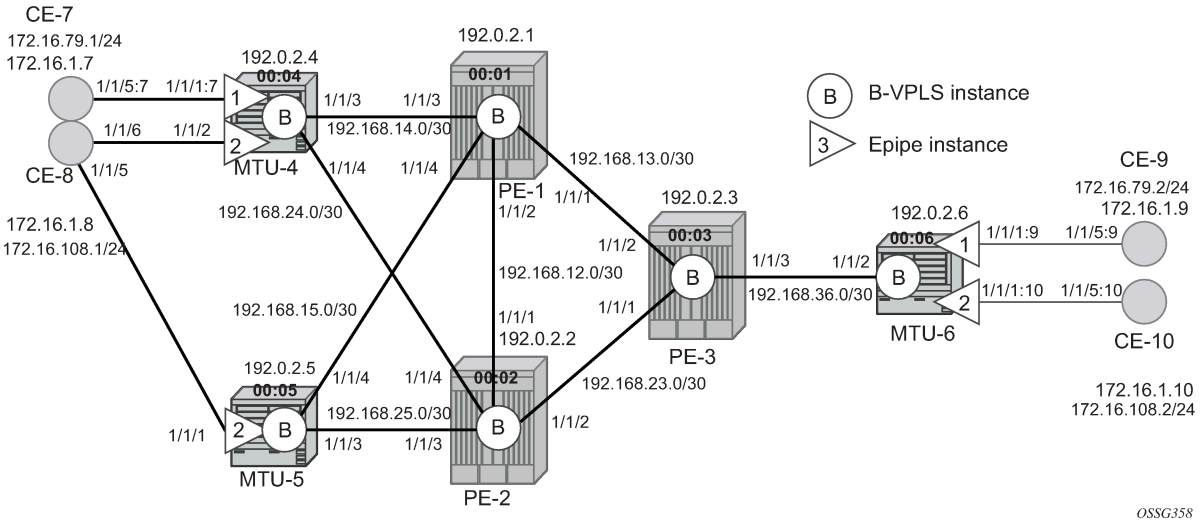
- BGP is configured for auto-discovery (Layer 2-VPN family), because FEC 129 will be used for the pseudowires between PEs in the core.

Once the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB-VPLS M:1 service configuration

This section explains the process to configure PBB-VPLS services in a M:1 fashion, M being the number of customer I-VPLS services multiplexed into the same B-VPLS instance (instance 100). An alternative configuration is 1:1, where each customer I-VPLS has its own B-VPLS. MTU-4 and PE-1 will be picked to show the relevant CLI configuration commands. The bold digits separated by colons *00:xx* are abbreviations for the backbone MAC addresses.

Figure 261: Example topology with port numbers and IP addresses



B-VPLS configuration

The first step is to configure the B-VPLS instance that will carry the PBB traffic. The following shows the B-VPLS configuration on MTU-4 and PE-1. The configuration on MTU-5 and MTU-6 resembles the configuration on MTU-4; the configuration on PE-2 and PE-3 resembles the configuration on PE-1.

The configuration for B-VPLS 100 on MTU-4 is as follows:

```
# on MTU-4:
configure
    service
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            endpoint "core" create
                no suppress-standby-signaling
            exit
            service-mtu 2000
            pbb
                source-bmac 00:04:04:04:04:04
            exit
            spoke-sdp 41:100 endpoint "core" create
```

```
                precedence primary
            exit
            spoke-sdp 42:100 endpoint "core" create
            exit
            no shutdown
        exit
```

On PE-1, B-VPLS 100 is configured as follows:

```
# on PE-1:
configure
    service
        pw-template 1 use-provisioned-sdp create
            split-horizon-group "CORE"
            exit
        exit
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:01:01:01:01:01
            exit
            bgp
                route-target export target:65000:100 import target:65000:100
                pw-template-binding 1
                exit
            exit
            bgp-ad
                vpls-id 65000:100
                no shutdown
            exit
            spoke-sdp 14:100 create
            exit
            spoke-sdp 15:100 create
            exit
            no shutdown
        exit
```

The keyword **b-vpls** is given at creation time and therefore it cannot be added to a regular existing VPLS instance. Besides the **b-vpls** keyword, the B-VPLS is a regular VPLS instance in terms of configuration, with the following exceptions:

- The B-VPLS service MTU must be at least 18 bytes greater than the I-VPLS MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1500 bytes); therefore, any MTU equal to or greater than 1518 bytes must be configured. In this particular example, a MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.
- The source B-MAC is the MAC address that will be sourced when the PBB traffic is originated from that node. A source B-MAC per B-VPLS instance can be configured (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. If no specific source B-MAC is provisioned, the system MAC address is used as the source B-MAC. When using the access multi-homing feature for native PBB, the source B-MAC must be a configured one and never the chassis MAC address. The way to configure a common B-MAC for all the B-VPLS instances on MTU-4 is as follows:

  ```
  # on MTU-4:
  configure
      service
          pbb
              source-bmac 00:04:04:04:04:04
  ```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported
  - Default SAP (:*) types are blocked in the CLI for the B-VPLS SAP
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowires, the outgoing PBB frame on an SDP (for example, B-pseudowire) contains a BVID qtag only if the pseudowire type is Ethernet VLAN. If the pseudowire type is *Ethernet*, the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS; therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group (SHG) has been configured to emulate the behavior of mesh-SDPs in the core.
- If a local I-VPLS instance is associated with the B-VPLS, local frames originated/terminated on local I-VPLS(s) are PBB encapsulated/de-encapsulated using the PBB Ethertype provisioned under the related port or SDP component.

By default, the PBB Ethertype is 0x88e7 (which is the standard one defined in 802.1ah for the I-TAG) but this PBB Ethertype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
*A:MTU-4# configure port 1/1/3 ethernet pbb-etype ?
  - pbb-etype <0x0600..0xffff>
  - no pbb-etype

 <0x0600..0xffff>     : [1536..65535] - accepts in decimal or hex
```

```
*A:MTU-4# configure service sdp 41 pbb-etype ?
  - no pbb-etype [<0x0600..0xffff>]
  - pbb-etype <0x0600..0xffff>

 <0x0600..0xffff>     : [1536..65535] - accepts in decimal or hex
```

The following commands are useful to check the actual PBB Ethertype:

```
*A:MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                  PBB Etype          : 0x88e7
```

```
*A:MTU-4# show port 1/1/3 | match PBB
PBB Ethertype      : 0x88e7
```

I-VPLS configuration

Once the common B-VPLS is configured, the next step is to provision the customer I-VPLS instances. The following shows the relevant configuration on MTU-4 for the two I-VPLS instances represented in Figure 261: Example topology with port numbers and IP addresses. The I-VPLS instances are configured on the MTU devices, whereas the core PEs are customer-unaware nodes.

```
# on MTU-4:
configure
```

```
    service
        vpls 1 name "I-VPLS 1" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap 1/1/1:7 create
            exit
            no shutdown
        exit
        vpls 2 name "I-VPLS 2" customer 1 i-vpls create
            pbb
                backbone-vpls 100 isid 2
                exit
            exit
            sap lag-1 create
            exit
            no shutdown
        exit
```

The keyword **i-vpls** is given at creation time and therefore it cannot be added to a regular existing VPLS instance. After creating the I-VPLS instance, it has to be linked to its corresponding transport B-VPLS instance. That link is given by the **backbone-vpls** <*b-vpls*> **isid** <*isid*> command. If no ISID (20 bit customer identification in the ITAG) is specified, the system will take the VPLS instance identifier as the ISID value.

The following considerations will be taken into account when configuring the I-VPLS:

- I-VPLS SAPs:
  - SAPs can be defined on ports with any Ethernet encapsulation type (null, dot1q, and qinq)
  - The I-VPLS SAPs can coexist on the same port with SAPs for other business services, for example, VLL and VPLS SAPs.
- I-VPLS SDPs:
  - GRE and MPLS SDPs are supported.
  - No mesh-SDPs are supported, only spoke-SDP. Mesh-SDPs can be emulated by using SHGs.

Existing SAP processing rules still apply for the I-VPLS case; the SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service that the packet belongs to:

- Null encapsulation defined on ingress — Any VLAN tags are ignored and the packet goes to a default service for the SAP;
- Dot1q encapsulation defined on ingress — only first VLAN tag is considered;
- QinQ encapsulation defined on ingress — both VLAN tags are considered; wildcard for the inner VLAN tag is supported.
- For dot1q/qinq encapsulations, traffic encapsulated with VLAN tags for which there is no definition is discarded.
- Any VLAN tag used for service selection on the I-SAP is stripped before the PBB encapsulation is added. Appropriate VLAN tags are added at the remote PBB PE when sending the packet out on the egress SAP.

MMRP for flooding optimization

When the M:1 model is used (as in this example), any I-VPLS broadcast, unknown unicast, or multicast (BUM) frame is flooded throughout the B-VPLS domain regardless of the nodes where the originating I-VPLS is defined. In other words, in our example in Figure 260: Example topology including B-VPLS, I-VPLSs, and protocol stacks, any BUM frame coming from CE-7 would be flooded in the B domain and would reach PE-2 and MTU-5, even though that traffic only needs to go to PE-3 and MTU-6. In order to build customer-based flooding trees and optimize the flooding, Multiple MAC Registration Protocol (MMRP) must be configured on the B-VPLS.

MMRP can be enabled with its default settings just by executing a **mrp no shutdown** command on all nodes:

```
# on all nodes:
configure
    service
        vpls "B-VPLS 100"
            mrp
                no shutdown
```

There are certain B-VPLS MRP settings that can be modified. These are the default values:

```
*A:MTU-4>config>service>vpls>mrp# info detail
----------------------------------------------
                mmrp
                    no end-station-only
                    attribute-table-size 2048
                    attribute-table-low-wmark 90
                    attribute-table-high-wmark 95
                    no flood-time
                    no shutdown
                exit
                no shutdown
----------------------------------------------
```

These attributes can be changed in order to control the number of MMRP attributes per B-VPLS and optimize the convergence time in case of failures in the B-VPLS:

- Controlling the number of attributes per B-VPLS

  The MMRP exchanges create one entry per attribute (group B-MAC) in the B-VPLS where MMRP protocol is running. PBB uses a group B-MAC address—built using a specific OUI (00:1e:83) with the multicast bit set, and the ISID value for the last 24 bits—as a destination MAC address for flooding any BUM frame into the B-domain.

  When the first registration is received for an attribute, an MFIB entry is created for it. The **attribute-table-size** allows the user to control the number of MMRP attributes (group B-MACs) created on a per B-VPLS basis, between 1 and 2048. Based on the configured size, high and low watermarks can be set (in percentage) so that alarms can be triggered upon exceeding the watermarks. This ensures that no B-VPLS will take up all the resources from the total pool. The maximum number of attributes per B-VPLS is 2048 and 4000 can be configured globally on the system.

- Optimizing the convergence time

  Assuming that MMRP is used in a certain B-VPLS, under failure conditions, the time it takes for the B-VPLS forwarding to resume may depend on the data plane and control plane convergence plus the time it takes for MMRP exchanges to stabilize the flooding trees on a per ISID basis. In order to minimize the convergence time, the PBB SR OS implementation offers the selection of a mode where B-VPLS forwarding reverts for a short time to flooding so that MMRP has enough time to converge. This mode

can be selected through configuration using the **flood-time** <*value*> command where value represents the amount of time in seconds (between 3 and 600) that flooding will be enabled. If this behavior is selected, the forwarding plane starts with B-VPLS flooding for a configurable time period, then it reverts back to the MFIB entries installed by MMRP. The following B-VPLS events initiate the switch from per I-VPLS (MMRP) MFIB entries to B-VPLS flooding:

- Reception or local triggering of a Spanning Tree Topology Change Notification (TCN)
- B-SAP failure
- Failure of a B-SDP binding
- Pseudowire activation in a primary/standby H-VPLS resiliency solution
- SF/CPM switchover due to STP reconvergence

The IEEE 802.1ak standard, which defines MRP, requires the implementation of different state machines with associated timers that can be tuned. A full MRP participant maintains the following state machines:

- Registrar state machine
- Applicant state machine
- LeaveAll state machine
- PeriodicTransmission state machine

The two first state machines are maintained for each attribute in which the participant is interested, whereas the two latter are global to all the attributes.

The job of the registrar function is to record declarations of the attribute made by other participants on the LAN. A registrar does not send any protocol messages, because the applicant looks after the interests of all would-be participants.

The job of the applicant is twofold: first, to ensure that this participant's declaration is correctly registered by other participants' registrars, and next, to prompt other participants to register again after one withdraws a declaration.

The associated timers can be tuned on a per SAP/SDP basis:

```
*A:MTU-4>config>service>vpls>spoke-sdp# mrp ?
  - mrp

 [no] join-time       - Configure timer value in 10th of seconds for sending
                        join-messages
 [no] leave-all-time  - Configure timer value in 10th of seconds for refreshing
                        all attributes
 [no] leave-time      - Configure timer value in 10th of seconds to hold
                        attribute in leave-state
 [no] mrp-policy      - Configure mrp-policy
 [no] periodic-time   - Configure timer value in 10th of seconds for
                        re-transmission of attribute declarations
 [no] periodic-timer  - Control re-transmission of attribute declarations
```

```
*A:MTU-4>config>service>vpls>spoke-sdp>mrp# info detail
----------------------------------------------
                    join-time 2
                    leave-time 30
                    leave-all-time 100
                    periodic-time 10
                    no periodic-timer
                    no mrp-policy
----------------------------------------------
```

A brief description of the MRP SAP/SDP attributes follows:

- **join-time** — This command controls the interval between transmit opportunities that are applied to the applicant state machine. An instance of this join period timer is required on a per-port, per-MRP participant basis. For additional information, see IEEE 802.1ak-2007 section 10.7.4.1.
- **leave-time** — This command controls the period of time that the registrar state machine will wait in the leave state before transitioning to the MT state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The leave period timer is set to the value leave-time when it is started. A registration is normally in "in" state where there is an MFIB entry and traffic being forwarded. When a "leave all" is performed (periodically around every 10-15 seconds per SAP/SDP binding – see leave-all-time below), a node sends a message to its peer indicating a leave all is occurring and puts all of its registrations in leave state. The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations. See IEEE 802.1ak-2007 section 10.7.4.2.
- **leave-all-time** — This command controls the frequency with which the leaveall state machine generates leaveall PDUs. The timer is required on a per-port, per-MRP participant basis. The leaveall period timer is set to a random value, T, in the range leave-all-time<T<1.5*leave-all-time when it is started. See IEEE 802.1ak-2007, section 10.7.4.3.
- **periodic-time** — This command controls the frequency the periodic transmission state machine generates periodic events if the periodic transmission timer is enabled. The timer is required on a per-port basis. The periodic transmission timer is set to one second when it is started.
- **periodic-timer** — This command enables or disables the periodic transmission timer.

The following command shows the MRP configuration and statistics on a per SAP/SDP basis within the B-VPLS:

```

In the example throughout the chapter, as soon as MMRP is enabled, an optimized flooding tree will be built for ISID 1, because the I-VPLS 1 is only defined in MTU-4 and MTU-6, but not in MTU-5. A good way to track the flooding tree for a particular ISID is the following command:

```
*A:MTU-4# show service id 100 mmrp mac
-------------------------------------------------------------------------------
SAP/SDP                               MAC Address       Registered  Declared

-------------------------------------------------------------------------------
Number of Entries=2 SAPs=0 SDPs=2
-------------------------------------------------------------------------------
```

The group B-MAC ending in *01* corresponds to the I-VPLS 1 whereas the one ending in *02* to the I-VPLS 2. MMRP PDUs for the two attributes are sent throughout the loop-tree topology (not over STP blocked ports or standby spoke-SDPs and observing the split-horizon rules). The two attributes are registered on every B-VPLS virtual port; however, the tree is only built on those ports where the attribute is also declared, and

not only registered. For instance, the spoke-SDP 52:100 in MTU-5 will not be part of the ISID 1 or ISID 2 flooding trees. Neither attribute is declared because I-VPLS 1 does not exist on MTU-5 and I-VPLS 2 is operationally down on MTU-5 (MC-LAG SAP is in standby state, so the I-VPLS is down).

As soon as a group B-MAC attribute is registered on a particular port, an MFIB entry is added for that B-MAC on that port, regardless of the declaration state for that attribute on the port. For instance, neither B-MAC is declared on MTU-5, however, the two MFIB entries are created as soon as the attributes are registered:

```
*A:MTU-5# show service id 100 mfib

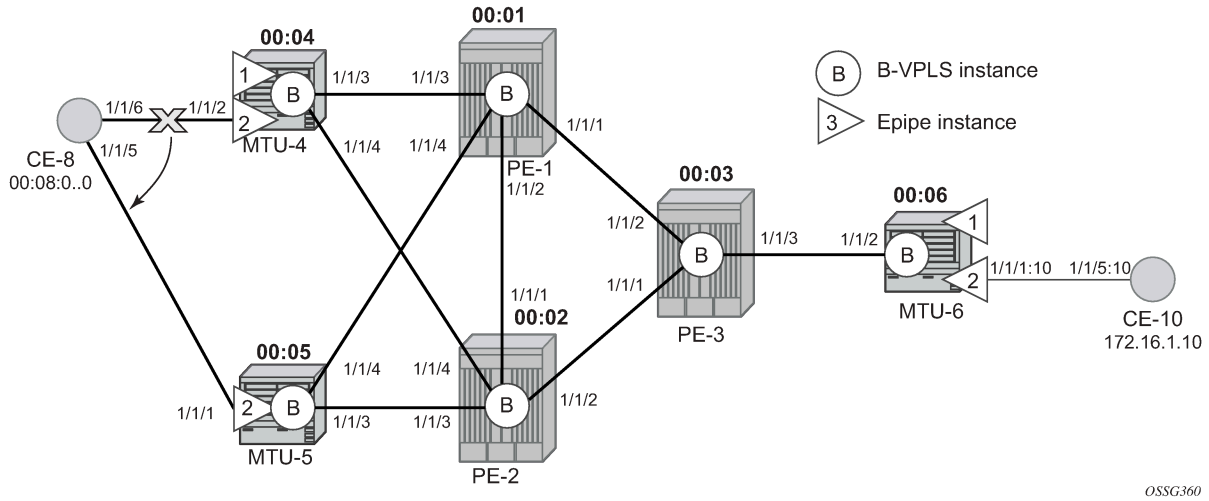
```

MAC flush: avoiding black-holes

Both the I-VPLS and B-VPLS components inherit the MAC flush capabilities of a regular VPLS clearing the related C-MAC and respectively B-MAC FIBs. All types of MAC flush—**flush-all-but-mine** and **flush-all-from-me**—are supported together with the related CLI. In addition to these features, some extensions have been added so that MAC flush can be triggered on the B-VPLS based on some events happening on the I-VPLS. The following diagram shows a potential scenario where black-holes can occur if the proper configuration is not added.

Figure 262: Black-hole



Under normal conditions, the I-VPLS 2 FIB on MTU-6 shows that CE-8 MAC address is learned through B-MAC 00:04 of MTU-4:

```
*A:MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2
===============================================================================
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:04:04:04:04:04 L/180
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/0
===============================================================================
```

When a failure happens in the CE-8 MC-LAG active link, the link to MTU-5 takes over. However, the FIB on MTU-6 still points at the BMAC of MTU-4 and that will still be the B-MAC used in the PBB encapsulation. Therefore, a black-hole occurs until either bidirectional traffic is sent or the FIB aging timer expires.

The configuration in the I-VPLS can be modified to trigger a MAC flush in the B-VPLS with the following command:

```
*A:MTU-4# configure service vpls "I-VPLS 2" pbb send-bvpls-flush ?
  - send-bvpls-flush {[all-but-mine] [all-from-me]}
  - no send-bvpls-flush

 <all-but-mine>       : keyword
 <all-from-me>        : keyword
```

The following command is executed on all MTUs to solve the black-hole:

```
# on all MTUs:
configure
    service
        vpls "I-VPLS 2"
            pbb
                send-bvpls-flush all-from-me
```

By enabling **send-bvpls-flush all-from-me** on I-VPLS 2, a failure on the MC-LAG active link on I-VPLS 2 will trigger an LDP MAC **flush-all-from-me** into the B-VPLS that will flush the FIB in MTU-6 for I-VPLS 2, avoiding the black-hole. A MC-LAG failure is emulated by disabling the LAG on MTU-4, as follows:

```
# on MTU-4:
configure
    lag 1
        shutdown
```

MTU-4 sends the following LDP MAC flush for all MAC addresses learned from MTU-4:

```
1 2021/01/12 17:02:25.211 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Address Withdraw packet (msgId 263) to 192.0.2.1:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
ISID 1 = 2
```

```
Number of Path Vectors : 1
Path Vector(  1) = 192.0.2.4
"
```

On MTU-6:

```
1 2021/01/12 17:02:25.227 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Address Withdraw packet (msgId 206) from 192.0.2.3:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
ISID 1 = 2
Number of Path Vectors : 3
Path Vector(  1) = 192.0.2.4
Path Vector(  2) = 192.0.2.1
Path Vector(  3) = 192.0.2.3
"
```

Immediately after receiving the MAC flush, the CE-8 MAC is flushed. The CE-8 MAC is learned again, but this time linked to the B-MAC 00:05, which is the B-MAC of MTU-5:

```
*A:MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2
===============================================================================
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:05:05:05:05:05 L/0
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/120
===============================================================================
```

The following I-VPLS events are propagated into the B-VPLS depending on the **flush-all-but-mine** or **flush-all-from-me** keywords used in the configuration:

If the **flush-all-but-mine** keyword is configured (positive flush), the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. TCN event in one or more of the related I-VPLS/M-VPLS.
2. Pseudowire/SDP binding activation with active/standby pseudowire (standby to active or down to up).
3. Reception of an LDP MAC withdraw flush-all-but-mine in the related I-VPLS.

If the **flush-all-from-me** keyword is configured (negative flush) the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. MC-LAG active link failure (in our example).
2. Failure of a local SAP – requires **send-flush-on-failure** to be enabled in I-VPLS.
3. Failure of a local pseudowire/SDP binding – requires **send-flush-on-failure** to be enabled in I-VPLS.
4. Reception of an LDP MAC withdraws flush-all-from-me in the related I-VPLS.

In addition to this and regardless of what type, MAC flush has been optimized to avoid flushing in the core PEs, flushing only the C-MACs mapped to a certain B-MAC (belonging to a specific ISID FIB) and the ability to indicate to core PEs which messages should always be forwarded endpoint-to-endpoint toward all

PBB PEs regardless of the propagate-mac-flush setting in B-VPLS. All of this is implemented without the need of any additional CLI commands and it is part of *draft-balus-l2vpn-pbb-ldp-ext-00*.

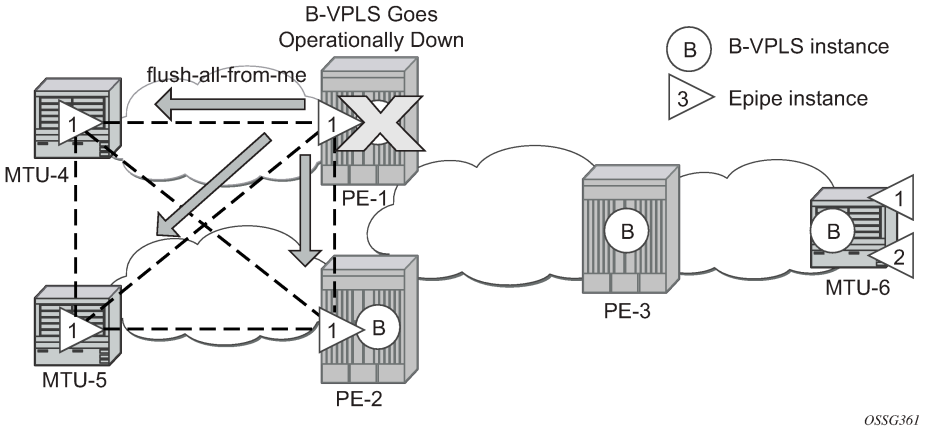
Another extension supported to avoid black-holes within this mix of I- and B-VPLS environments is the **block-on-mesh-failure** feature in PBB. When the VPLS mesh exists only in I-VPLS or in B-VPLS, and the **block-on-mesh-failure** feature is enabled, the regular VPLS behavior will apply (when all the mesh-SDPs go down an LDP notification with pseudowire status bits = 0x01—Pseudo Wire Not Forwarding—is sent over the spoke-SDPs). When the active/standby pseudowire resiliency is implemented in I-VPLS such that the PBB PE performs the role of a PE-rs, the B-VPLS core replaces the pseudowire (SDP binding) mesh. The block-on-mesh notification (LDP notification indicating pseudowire not forwarding) will be sent to the MTUs only when the related B-VPLS is operationally down. The B-VPLS core is operationally down only when all of its SAPs and SDPs are down.

The final feature that can be enabled in an I-VPLS with CLI is the **send-flush-on-bvpls-failure** feature.

```
*A:MTU-4# configure service vpls "I-VPLS 2" pbb send-flush-on-bvpls-failure ?
  - no send-flush-on-bvpls-failure
  - send-flush-on-bvpls-failure
```

This feature is required to avoid black-holes when there is a full mesh of pseudowires in the I-VPLS domain and the B-VPLS instance can go operationally down. The following figure shows a typical scenario where this feature is needed (normally when PBB-VPLS and multi-chassis end point are combined together).

Figure 263: Send flush on B-VPLS failure example



Access dual-homing and MAC notification

Although this section is focused on PBB in a MPLS based network, Nokia PBB implementation also allows the operator to use a native Ethernet infrastructure in the PBB core. Native Ethernet tunneling can be emulated using Ethernet SAPs to interconnect the related B-VPLS instances. In those cases, there is no LDP signaling available; therefore, there is no MAC flush sent when the active link in a multi-homed access device fails.

The SR OS supports a mechanism to avoid potential black-holes in native Ethernet PBB networks. In addition to the source B-MAC associated with each B-VPLS, an additional B-MAC is associated with each MC-LAG supporting Multi-homed I-VPLS SAPs. The nodes that are in a multi-homed MC-LAG configuration share a common B-MAC on the related MC-LAG interfaces. When the MAC notification is

enabled (**mac-notification no shutdown**), an Ethernet CFM notification message is sent from the node holding the active link. That message will be flooded in the B-VPLS domain using the MC-LAG SAP B-MAC as the source MAC address. The remote nodes will learn the customer MAC addresses behind the MC-LAG and will link them to this new SAP B-MAC. MC-LAG will keep track of the active link for each particular LAG associated to a SAP B-MAC. Should MC-LAG detect any new active link in a node, a new CFM notification message will be flooded from the new active node.

The following caveats and considerations must be taken into account:

- Only MC-LAG is supported as dual-home mechanism.
- This mechanism is supported for native PBB and/or MPLS-based PBB-VPLS. Although it is mostly beneficial when native PBB is used in the core, it can also help to optimize the re-learning process in a MPLS-based core in case of MC-LAG failures, in addition to the existing LDP MAC flush procedures.

The example of this configuration shows the setup being used in this configuration example. MAC-notification will be configured in MTU-4 and MTU-5 for the dual-homed CE-8.

The first step is to configure the SAP B-MAC that will be used for the MAC notification messages. The **source-bmac-lsb** (source backbone MAC least significant bits) command has been added to the MC-LAG branch so that the operator can decide the two last octets to be used in the SAP B-MAC. Those two last octets can be derived from the LACP key (if the **use-lacp-key** statement is used) or can be specifically defined.

```
*A:MTU-4# configure redundancy multi-chassis peer 192.0.2.5 mc-lag lag ?
  - lag <lag-id> lacp-key <admin-key> system-id <system-id> [remote-lag <remote-lag-    id>]
 system-priority <system-priority> source-bmac-lsb use-lacp-key
  - lag <lag-id> lacp-key <admin-key> system-id <system-id> [remote-lag <remote-lag-    id>]
 system-priority <system-priority> source-bmac-lsb <MAC-Lsb>
  - lag <lag-id> lacp-key <admin-key> system-id <system-id> [remote-lag <remote-lag-    id>]
 system-priority <system-priority>
  - lag <lag-id> [remote-lag <remote-lag-id>]
  - no lag <lag-id>

 <lag-id>             : [1..800]
 <admin-key>          : [1..65535]
 <system-id>          : xx:xx:xx:xx:xx:xx     - xx [00..FF]

 <system-priority>    : [1..65535]
 <MAC-Lsb>            : [1..65535] or xx-xx or xx:xx
```

There must be a different SAP B-MAC per MC-LAG. The use of the LACP key as a default for two least significant octets makes the operations simpler. In this example, the sap-bmac last two octets will come from the lacp-key. The configuration on MTU-4 is as follows:

```
# on MTU-4:
configure
    redundancy
        multi-chassis
            peer 192.0.2.5 create
                mc-lag
                    lag 1 lacp-key 15 system-id 00:00:00:00:00:01
                          system- priority 65535 source-bmac-lsb use-lacp-key
                    no shutdown
                exit
                no shutdown
```

Therefore, the SAP B-MAC will be formed in the following way:

[sap-bmac = 4 first bytes of the source bmac + 2 bytes from source-bmac-lsb]

MAC notification in B-VPLS 100 is enabled on all MTUs, as follows:

```
# on MTU-4, MTU-5, MTU-6:
configure
    service
        vpls "B-VPLS 100"
            mac-notification
                no shutdown
```

The **mac-notification** command activates the described mechanism and has the following parameters:

```
*A:MTU-4# configure service vpls "B-VPLS 100" mac-notification ?
  - mac-notification

 [no] count           - Configure count for MAC-notification messages
 [no] interval        - Configure interval for MAC-notification messages
 [no] renotify        - Configure re-notify interval for MAC-notification messages
 [no] shutdown        - Configure admin state for MAC-notification messages
```

Where:

- **interval** <*value*> controls how often the subsequent MAC notification messages are sent. Default = 100 ms. Required values: 100 ms – 10 sec, in increments of 100 ms.
- **count** <*value*> controls how often the MAC notification messages are sent. Default: 3. Range: 1–10.

The "count" and "interval" parameters can also be configured at the service context. The settings configured at the B-VPLS service context take precedence though.

```
*A:MTU-4# configure service mac-notification ?
  - mac-notification

 [no] count           - Configure count for MAC-notification messages
 [no] interval        - Configure interval for MAC-notification messages
```

Finally, the B-VPLS is instructed to use the SAP B-MAC. The **use-sap-bmac** statement enables the use of the source B-MAC allocated to the multi-homed SAPs (assigned to the MC-LAG) in the related I-VPLS service (could be Epipe service as well). The command will fail if the value of the source B-MAC assigned to the B-VPLS is the hardware (chassis) B-MAC. In other words, the source B-MAC must be a configured one. The **use-sap-bmac** statement is by default off.

```
# on MTU-4:
configure
    service
        vpls "B-VPLS 100"
            pbb
                source-bmac 00:aa:aa:aa:aa:04
                use-sap-bmac
            exit
```

```
*A:MTU-5# configure
    service
        vpls "B-VPLS 100"
            pbb
                source-bmac 00:aa:aa:aa:aa:05
                use-sap-bmac
            exit
```

```
*A:MTU-6# show service id 2 fdb pbb
```

```
===============================================================================
Forwarding Database, i-Vpls Service 2

===============================================================================
```

As soon as the **mac-notification** is enabled, an Ethernet CFM notification message is sent from MTU-4, which is the node where the active MC-LAG link resides. The CFM message will have the source mac "00:aa:aa:aa:00:0f" (4 first bytes of the configured source bmac + 2 bytes from the configured **source-bmac-lsb**, which is 15 in hex) and will be flooded throughout the B-VPLS domain. Should the link between CE-8 and MTU-4 fail, the MC-LAG protocol will activate the redundant link and MTU-5 will immediately issue a CFM message with the shared sourced SAP B-MAC that will be flooded in the B-VPLS domain.

PBB and IGMP snooping

IGMP snooping can be enabled on I-VPLS SAPs and SDPs (it cannot be enabled on B-VPLS). SR OS can keep track of IGMP joins received over individual B-SDPs or B-SAPs, and it starts flooding the multicast group (and only the multicast group) to all B-components (using the group B-MAC for I-SID) as soon as the first IGMP join for that multicast group is received in one of the B-SAP/SDP components.

The first IGMP join message received over the local B-VPLS will add all the B-VPLS SAP/SDP components into the related multicast table associated with the I-VPLS context. When the querier is connected to a remote I-VPLS instance, over the B-VPLS infrastructure, its location is identified by the B-VPLS SDP/SAP on which the query was received and also by the source B-MAC address used in the PBB header for the query message, the B-MAC associated with the B-VPLS instance on the remote PBB PE.

The following configuration on MTU-4 enables IGMP snooping in I-VPLS 1 and adds some static groups on a SAP. The location of the querier is configured by adding the B-MAC where the querier is connected to (in this example, MTU-6) and adding the two B-VPLS spoke-SDPs as mrouter ports (B-VPLS mrouter ports are added in the I-VPLS backbone-vpls context).

The **mac-name** command translates MAC address into strings so that the names can be used instead of typing the entire MAC address every time we need to.

```
# on MTU-4:
configure
    service
       pbb
            source-bmac 00:04:04:04:04:04
            mac-name "MTU-4" 00:04:04:04:04:04
            mac-name "MTU-5" 00:05:05:05:05:05
            mac-name "MTU-6" 00:06:06:06:06:06
        exit
        vpls 1 name "I-VPLS 1" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                    igmp-snooping
                        mrouter-dest "MTU-6"
                    exit
                    sdp 41:100
                        igmp-snooping
                            mrouter-port
                        exit
```

```
                    exit
                    sdp 42:100
                        igmp-snooping
                            mrouter-port
                        exit
                    exit
                exit
            exit
            igmp-snooping
                no shutdown
            exit
            sap 1/1/1:7 create
                igmp-snooping
                    static
                        group 228.0.0.1
                            starg
                        exit
                        group 228.0.0.2
                            starg
                        exit
                        group 239.0.0.1
                            source 172.16.99.99
                        exit
                    exit
                exit
            exit
            no shutdown
```

As in regular VPLS instances, mrouter ports are added to all the multicast groups:

```
*A:MTU-4# show service id 1 mfib

===============================================================================

```

MMRP policies and ISID-based filtering for PBB inter-domain expansion

As described in the MMRP for flooding optimization section, MMRP is used in the backbone VPLS instances to build per I-VPLS flooding trees. Each I-VPLS has an associated group B-MAC in the B-VPLS, which is derived from the ISID, and is advertised by MMRP throughout the whole B-VPLS context, regardless of whether a certain I-VPLS is present in one or all the B-VPLS PEs.

In an inter-domain environment, the same B-VPLS can be defined in different domains and as such MMRP will advertise all the group B-MACs in every domain. The group B-MACs are consuming resources in all the PEs no matter if a particular ISID—and therefore its group B-MAC—is required in one of the domains or not. When MMRP is enabled in a particular PE, data plane and control plane resources are consumed and they must be taken into consideration when designing PBB-VPLS networks:

- Control plane – MRRP processing takes CPU cycles and the number of attributes that can be advertised is not unlimited
- Data plane – each group B-MAC registration takes one MFIB entry (the MFIB is shared between MMRP and IGMP/PIM snooping)

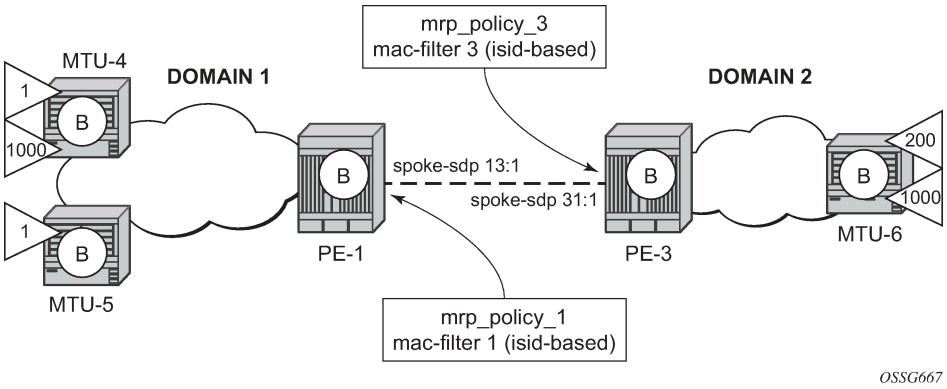
SR OS routers support MMRP policies and ISID-based filters so that control plane and data plane resources can be saved when I-VPLS instances are not defined in all the domains.

Figure 264: Inter-domain B-VPLS and MMRP policies/ISID-based filters example illustrates an example of usage for MMRP policies and ISID-based filters that will be configured in this section. "Domain 1” and "domain 2” will have a range of local ISIDs each and a range of "inter-domain” ISIDs:

- Domain 1 local ISIDs: from 1 to 100
- Domain 2 local ISIDs: from 101 to 200
- Inter-domain ISIDs: from 1000 to 2000

By applying the MMRP policies indicated in Figure 264: Inter-domain B-VPLS and MMRP policies/ISID-based filters example, domain 1 attributes will be prevented from being declared and registered in domain 2 and vice versa, domain 2 attributes from being declared and registered in domain 1. The egress MAC filters will drop any traffic sourced from a local ISID preventing it to be transmitted to the remote domain.

Figure 264: Inter-domain B-VPLS and MMRP policies/ISID-based filters example



MMRP policies

The following shows the MMRP policy configuration on node PE-1. This policy will block any registration/declaration except those for ISIDs 1000-2000. Packets will be compared against the configured matching ISIDs as long as the PBB Etype matches the one configured on the port or SDP.

```
# on PE-1:
configure
    service
        mrp
            mrp-policy "mrp_policy_1" create
                description "allow-inter-domain-isids"
                default-action block
                entry 10 create
                    action allow
                    match
                        isid 1000 to 2000
                    exit
                exit
            exit
        exit
    exit
```

Once the MMRP policy is configured, it must be applied on the corresponding SAP or SDP-binding. An MRP policy can be applied to a B-VPLS SAP, B-VPLS spoke-SDP or B-VPLS mesh-SDP:

```
# on PE-1:
configure
    service
        vpls "B-VPLS 100"
            spoke-sdp 14:100 create
                mrp
                    mrp-policy "mrp_policy_1"
                exit
            exit
            spoke-sdp 15:100 create
                mrp
                    mrp-policy "mrp_policy_1"
                exit
            exit
            no shutdown
```

```
        exit
```

In the same way, mrp_policy_3 will be configured in PE-3.

Some additional considerations about the MMRP policies:

- Different entries within the same MRP policy can have overlapping ISID ranges. The entries will be evaluated in the order of their IDs and the first match will cause the implementation to execute the associated action for that entry and then to exit the MRP policy.
- If no ISID is specified in the match condition then:
  - If the action is "end-station", no entry is added and the action is block.
  - If the action is different from "end-station", every ISID is considered for that action.
- The MRP policy specifies either a forward or a drop action for the group B-MAC attributes associated with the ISIDs specified in the match criteria.

```
     *A:PE-1# configure service mrp mrp-policy "mrp_policy_1" entry 10 action ?
       - action <action>
       - no action

      <action>             : none|block|allow|end-station
```

- There is an additional action called **end-station**. This action specifies that an end-station emulation is present on the SAP/SDP-binding where the policy has been applied. The matching ISIDs will not get declared/registered in the SAP/SDP-binding (just like the **block** action). However, those attributes will get mapped as static MMRP entries on the SAP/SDP-binding, which implicitly get instantiated in the data plane as MFIB entries associated with that SAP/SDP-binding for the related group B-MAC. When the action is "end-station", the default action must be block:

```
*A:PE-3>config>serv>mrp>mrp-policy# default-action allow
MINOR: SVCMGR #5904 Mrp-policy default-action must be block when end-station action
exists
```

- The **end-station** action can be used in the inter-domain gateways when, for instance, we do not want MMRP control plane exchanges between domains. The following output shows how to define the static MMRP entries 1000-2000 in PE-3 without receiving any declaration for any of those attributes or having any of those locally configured.

```
# on PE-3:
configure
    service
        mrp
            mrp-policy "mrp_policy_3" create
                default-action block
                entry 10 create
                    action end-station
                    match
                        isid 1000 to 2000
                    exit
                exit
            exit
        exit
    exit
```

```
*A:PE-3# show service id 100 mfib

===============================================================================

                                      b-sdp:36:100                Local    Fwd
---snip---
*               01:1e:83:00:07:ce     b-sdp:36:100                Local    Fwd
*               01:1e:83:00:07:cf     b-sdp:36:100                Local    Fwd
*               01:1e:83:00:07:d0     b-sdp:36:100                Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1002
===============================================================================
```

- The MRP policy can be applied to multiple B-VPLS services as long as the scope of the policy is *template* (the scope can also be *exclusive*).
- Any changes made to the existing policy will be applied immediately to all services where this policy is applied. For this reason, when many changes are required on a MRP policy, Nokia recommends copying the policy to a work-in-progress policy. That work-in-progress policy can be modified until complete and then written over the original MRP policy. You can use the **configure service mrp copy** command to work with the policies in this manner. The **renum** command can also help to change the entries sequence order.

```
*A:PE-3# configure service mrp copy ?
  - copy <src-mrp-policy> to <dst-mrp-policy>

 <src-mrp-policy>     : [32 chars max]
 <dst-mrp-policy>     : [32 chars max]
```

```
*A:PE-3# configure service mrp mrp-policy "mrp_policy_3" renum ?
  - renum <src-entry-id> to <dst-entry-id>

 <src-entry-id>       : [1..65535]
 <dst-entry-id>       : [1..65535]
```

- The **no** form of the **mrp-policy** command deletes the MRP policy. An MRP policy cannot be deleted until it is removed from all the SAPs/SDP-bindings where it is applied.

ISID-based filters

The MMRP policies help to control the exchange of group B-MAC attributes across domains. Based on the registration state of a specific group B-MAC on a SAP/SDP-binding, the BUM traffic for a particular I-VPLS will be allowed or dropped. However, to avoid that any local ISID packet is flooded to the remote B-VPLS domain, all the packets tagged with the local ISIDs at the gateway PEs need to be filtered at the data plane. ISID- based filters will prevent the local ISIDs from sending any packet with unicast B-MAC to the remote domain. This is particularly useful for PBB-Epipe services across domains, where all the frames use unicast B-MACs and MMRP policies cannot help because they only act on group B-MAC packets.

The following CLI output shows how to configure an ISID-based filter that drops all the traffic sourced from the local ISIDs on PE-1 (the default action is drop and it does not show up in the configuration).

```
# on PE-1:
configure
```

```
    filter
        mac-filter 1 name "MAC 1" create
            description "drop_local_isids"
            type isid
            entry 10 create
                match frame-type 802dot3
                    isid 1000 to 2000
                exit
                log 101
                action
                    forward
                exit
            exit
```

Once the filter is configured, it must be applied on a B-VPLS SAP or SDP-binding and always at egress.

```
# on PE-1:
configure
    service
        vpls 100
            spoke-sdp 14:100 create
                egress
                    filter mac 1
                exit
            exit
            spoke-sdp 15:100 create
                egress
                    filter mac 1
                exit
            exit
```

Some additional comments about ISID-based filters:

- The **type isid** statement must be added before introducing any ISID in the match command, otherwise the system will show an error:

  ```
  *A:PE-1>config>filter>mac-filter>entry>match$ isid 1000 to 2000
  MINOR: FILTER #1533 The match criteria entered are not compatible with the Mac
  filter type - On a normal filter no ISID or VID match criteria are allowed
  ```

  ```
  *A:PE-1>config>filter>mac-filter$ type isid
  MINOR: FILTER #1561 Cannot change filter type when filter contains entries
  ```

- Once the operator sets the "type isid", the filter cannot be applied at ingress. Only egress ISID-based filters are allowed:

  ```
  *A:PE-1>config>service>vpls>spoke-sdp# ingress filter mac 1
  MINOR: SVCMGR #2050 Can not apply filter of type 'isid' on ingress
  ```

- Like any filter or MMRP policy, the filter can be applied to multiple B-VPLS services as long as the scope of the policy is "template" (the scope can also be "exclusive").
- The following command shows the filter configuration and packets that have matched the filter (field "Egr. Matches"):

  ```
  *A:PE-1# show filter mac 1

  ===============================================================================
  Mac Filter
  ===============================================================================

B-VPLS and I-VPLS show and debug commands

For the following output, the MRP policies and ISID-based MAC filters have been removed from the spoke-SDPs on PE-1 and PE-3. The following commands can help to check the B-VPLS and I-VPLS configuration and their related parameters. The first is for the B-VPLS on MTU-4:

```
*A:MTU-4# show service id 100 base

===============================================================================
```

The following debug commands allow the operator to check the LDP label mapping, label withdrawal, messages and also the MAC-flush messages for regular VPLS, for I-VPLS and B-VPLS including the PBB extensions and TLVs.

```
*A:MTU-4# show debug
debug
    router "Base"
        ldp
            peer 192.0.2.1
                event
                exit
                packet
                    init detail
                    label detail
                exit
            exit
            peer 192.0.2.2
                event
                exit
                packet
                    init detail
                    label detail
                exit
            exit
        exit
    exit
exit
```

The following debug commands can help the operator to troubleshoot MMRP.

```
*A:MTU-4# debug service id 100 mrp ?
  - mrp
  - no mrp
```

```
     all-events      - Enable/disable MRP debugging for all events
[no] applicant-sm    - Enable/disable MRP debugging for applicant state machine
                       changes
[no] leave-all-sm    - Enable/disable MRP debugging for leave all state machine
                       changes
[no] mmrp-mac        - Enable/disable MRP debugging for a particular MAC address
[no] mrpdu           - Enable/disable MRP debugging for Rx/Tx MRP PDUs
[no] mvrp-vlan       - Enable/disable debugging for a particular vlan
[no] periodic-sm     - Enable/disable MRP debugging for periodic state machine
                       changes
[no] registrant-sm   - Enable/disable MRP debugging for registrant state machine
                       changes
[no] sap             - Enable/disable MRP debugging for a particular SAP
[no] sdp             - Enable/disable MRP debugging for a particular SDP
```

Conclusion

PBB-VPLS allows the service providers to scale VPLS services by multiplexing customer I-VPLS instances into one or more B-VPLS instances. This multiplexing dramatically reduces the number of services, pseudowires, and MAC addresses in the core and therefore allows the service provider to scale Layer 2 multi-point networks and provide services across international backbones.

The example used in this chapter shows the configuration of the customer and backbone VPLS instances as well as all the related features which are required for this environment. Show and debug commands have also been suggested so that the operator can verify and troubleshoot the service.

PIM Snooping for IPv4 in EVPN-MPLS Services

This chapter provides information about PIM snooping for IPv4 in EVPN-MPLS services.

Topics in this chapter include:

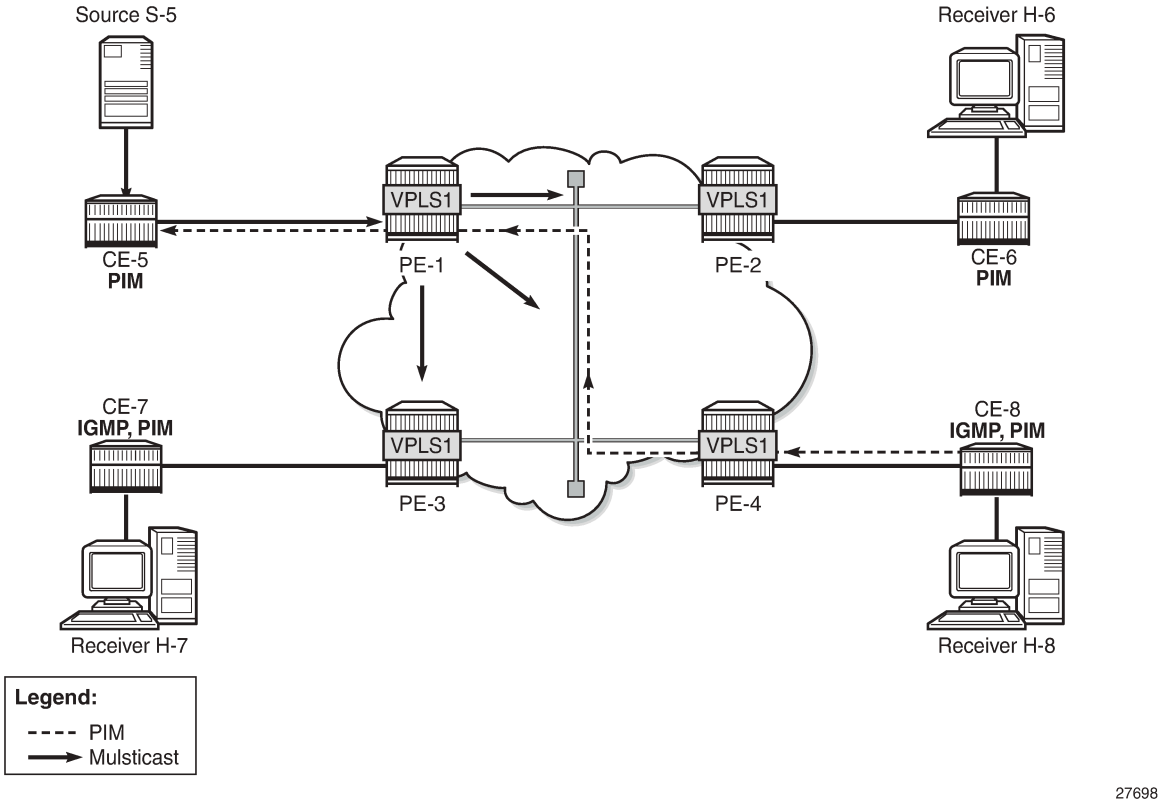
Applicability

This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. PIM snooping for IPv4 is supported in EVPN-MPLS services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing mode without ESI label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active multi-homing mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping in all-active multi-homing mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

Figure 265: Multicast in VPLS without PIM Snooping shows the example topology with four CEs that have IGMP and PIM enabled (L3) and four PEs configured with VPLS 1 (L2). Source-specific multicast is used in this example. The following description applies to all VPLSs, with or without EVPN.

Figure 265: Multicast in VPLS without PIM Snooping



The VPLS emulates a LAN interconnecting sites with L3-capable devices that use PIM to join or leave multicast groups. When receiver H-8 sends an IGMP report message to join a multicast group, CE-8 sends a PIM join message to CE-5. The PEs forward the PIM message without learning any PIM-related information, such as which CE sent the PIM join and for which multicast group.

The source S-5 is sending the multicast stream to CE-5. When CE-5 receives a PIM join message for this multicast group from CE-8, it forwards the multicast stream to CE-8. By default, all PEs flood the multicast stream on all their connections in the VPLS domain, regardless of whether a PIM join was received from that connection. L2 flooding is not aware of the PIM join/prune messages from the L3 edge routers, resulting in an inefficient use of network resources. To avoid this L2 flooding, PIM snooping can be enabled in the VPLS by the following command:

```
*A:PE-1# configure service vpls 1 pim-snooping ?
  - no pim-snooping
  - pim-snooping

 [no] group-policy    - Enable/Disable PIM snooping group policy
 [no] hold-time       - Configure PIM snooping hold time
 [no] ipv4-multicast* - Administratively disable/enable PIM operation for IPv4
 [no] ipv6-multicast* - Administratively disable/enable PIM operation for IPv6
      mode            - Administratively enable/disable PIM Snooping mode
```

The default mode is proxy, but PIM snooping can also use snooping mode, depending on the information in the received PIM hello messages. In snooping mode, the PE does not modify the PIM messages; in proxy mode, the PE terminates incoming PIM messages and generates its own PIM messages.

PIM snooping is used for router multicast registration, whereas IGMP snooping is used for host/client multicast registration. IGMP snooping in EVPN-MPLS services is described in chapter P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services. Optionally, PIM snooping and IGMP snooping can be enabled simultaneously.

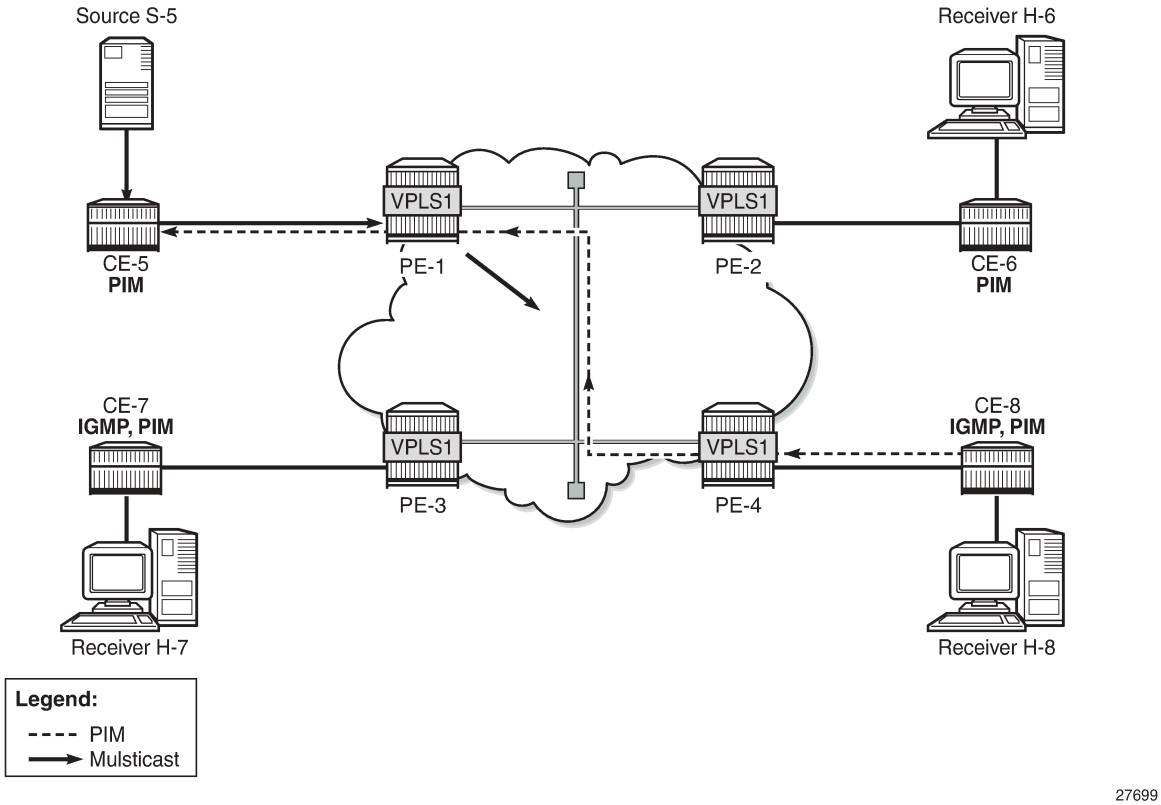
With PIM enabled, the CEs send PIM hello messages to the well-known multicast address for PIM, 224.0.0.13. PIM hello messages are used to form PIM neighbors and can be used to form the Forwarding Database (FDB). With PIM snooping enabled in the VPLS in the PEs, the PEs snoop PIM messages. The PEs only forward multicast traffic downstream when required, as determined from the received PIM messages. This provides a more efficient use of network resources.

PIM snooping states in a PE are maintained per VPLS instance. When PIM snooping is enabled, IP multicast traffic to a multicast group that is not learned via snooping is dropped by default, unless it is received from a directly connected source.

PIM Snooping in Snooping Mode

Figure 266: Multicast in VPLS with PIM Snooping in Snooping Mode shows that the multicast stream is not flooded in PE-1 when PIM snooping is enabled and operating in snooping mode.

Figure 266: Multicast in VPLS with PIM Snooping in Snooping Mode

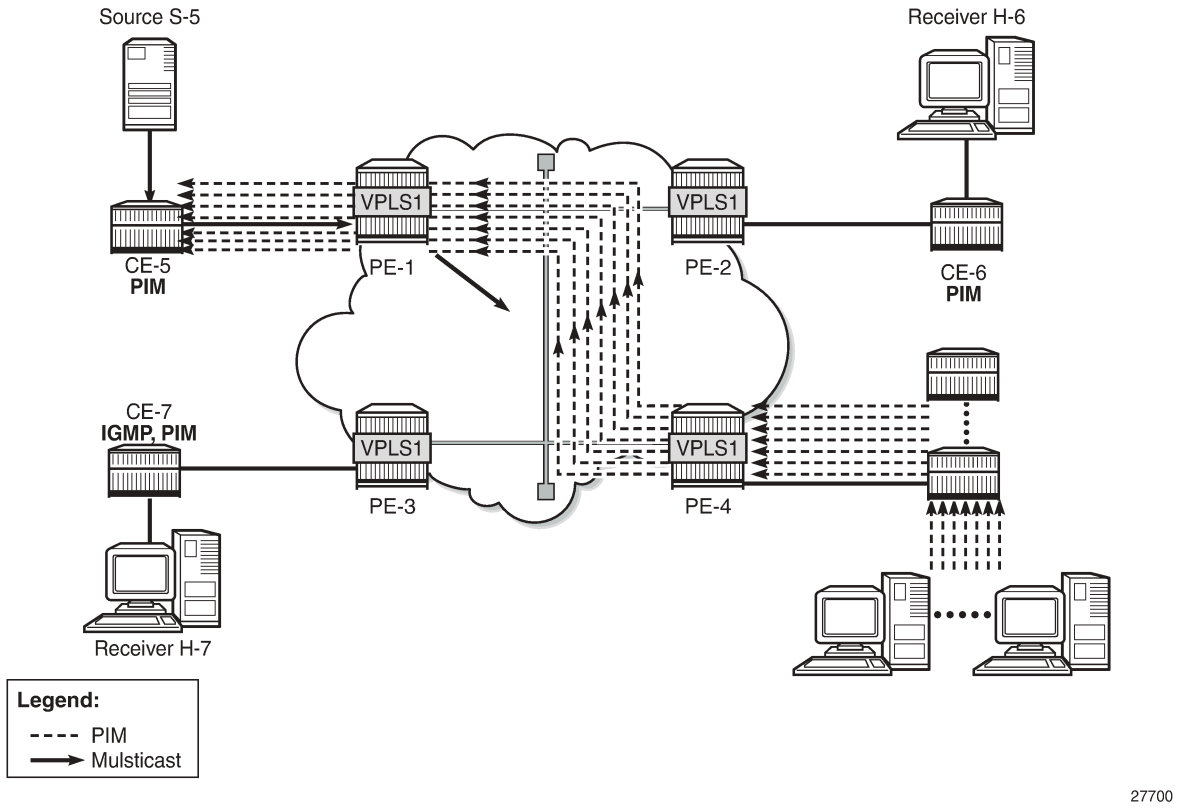


When H-8 sends an IGMP report message to join the multicast stream from source S-5 to CE-8, CE-8 sends a PIM join message to CE-5. PE-4 snoops the PIM join message and builds the FDB. PE-4 forwards the PIM join message to PE-1 by matching the upstream neighbor address in the join with the neighbor

database. PE-1 snoops the PIM join message, builds its Multicast Forwarding Information Base (MFIB), and performs a similar lookup in its FDB. PE-1 forwards the PIM join to CE-5. The Source Path Tree (SPT) between receiver CE-8 and sender CE-5 is now built and CE-5 forwards multicast data frames to CE-8. PE-1 does not flood multicast frames, but forwards them to CE-8 only, based on the MFIB.

Figure 267: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs shows how the number of PIM messages in the control plane increases when multiple client CEs are connected to PE-4.

Figure 267: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs



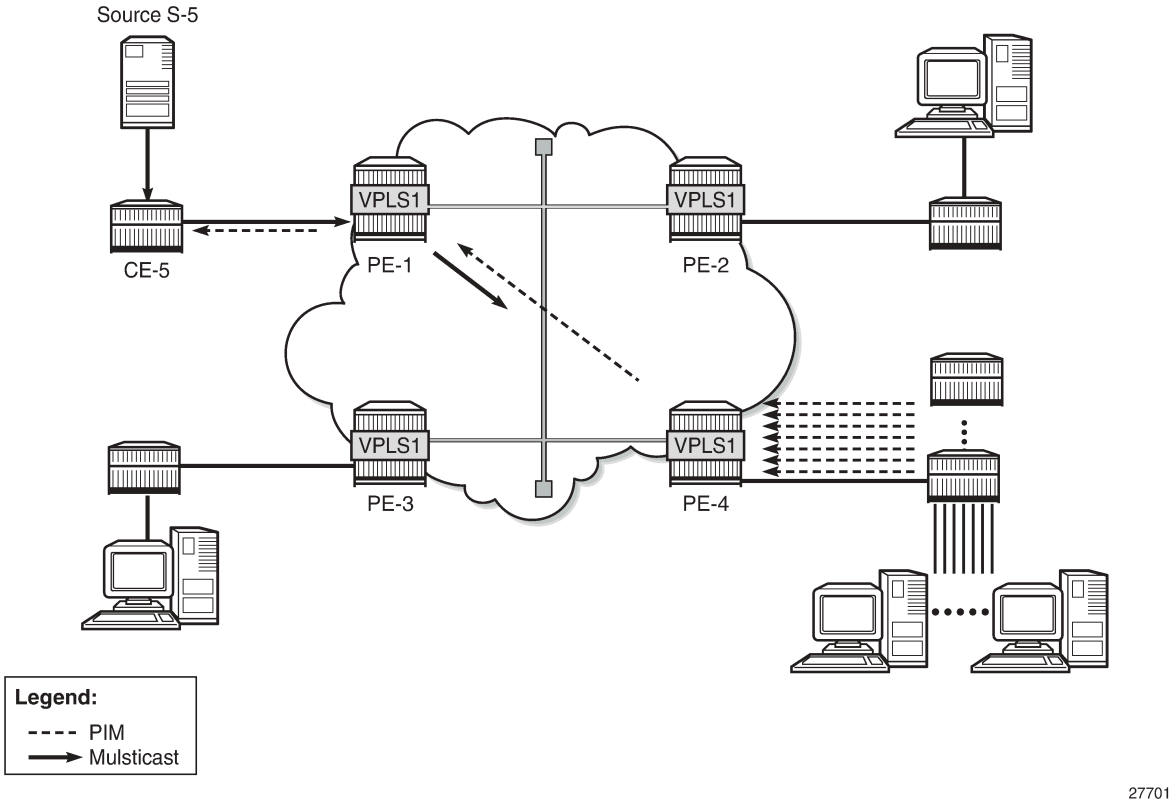
PIM Snooping in Proxy Mode

When H-8 sends an IGMP report message to join a multicast stream, CE-8 again sends a PIM join message to CE-5. PE-4 terminates the incoming PIM join message and generates its own PIM join message using CE-5 as the source address, learned from the PIM hello messages. PE-4 builds its MFIB and sends a new PIM join message to S-5. PE-1 terminates the incoming PIM join message and builds its MFIB. PE-1 generates its own PIM join message using CE-5 as the source address. PE-1 forwards the PIM join to CE-5. The SPT between CE-8 and CE-5 is now built and the multicast stream flows from source S-5 to receiver H-8. No multicast traffic is sent to CE-6 and CE-7, because they do not have receivers attached that joined the multicast stream.

The default mode for PIM snooping is proxy mode.

Figure 268: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs shows that the number of PIM messages in the control plane does not increase when multiple client CEs are connected to PE-4, compared to snooping mode.

Figure 268: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs



PIM snooping in proxy mode can be configured with a delay to avoid existing traffic interruption. PIM snooping in proxy mode does not program the MFIB until a hold timer has expired. This hold time is useful in the following cases:

- PIM snooping being enabled on the VPLS
- PIM snooping states being manually cleared by an operator

When the hold timer is started, but not expired yet, multicast traffic is flooded in the VPLS as if PIM snooping was not enabled. VPLS flooding ensures flow delivery during the hold time.

PIM Snooping in VPLS with EVPN-MPLS

PIM snooping in an EVPN-MPLS service supports the following:

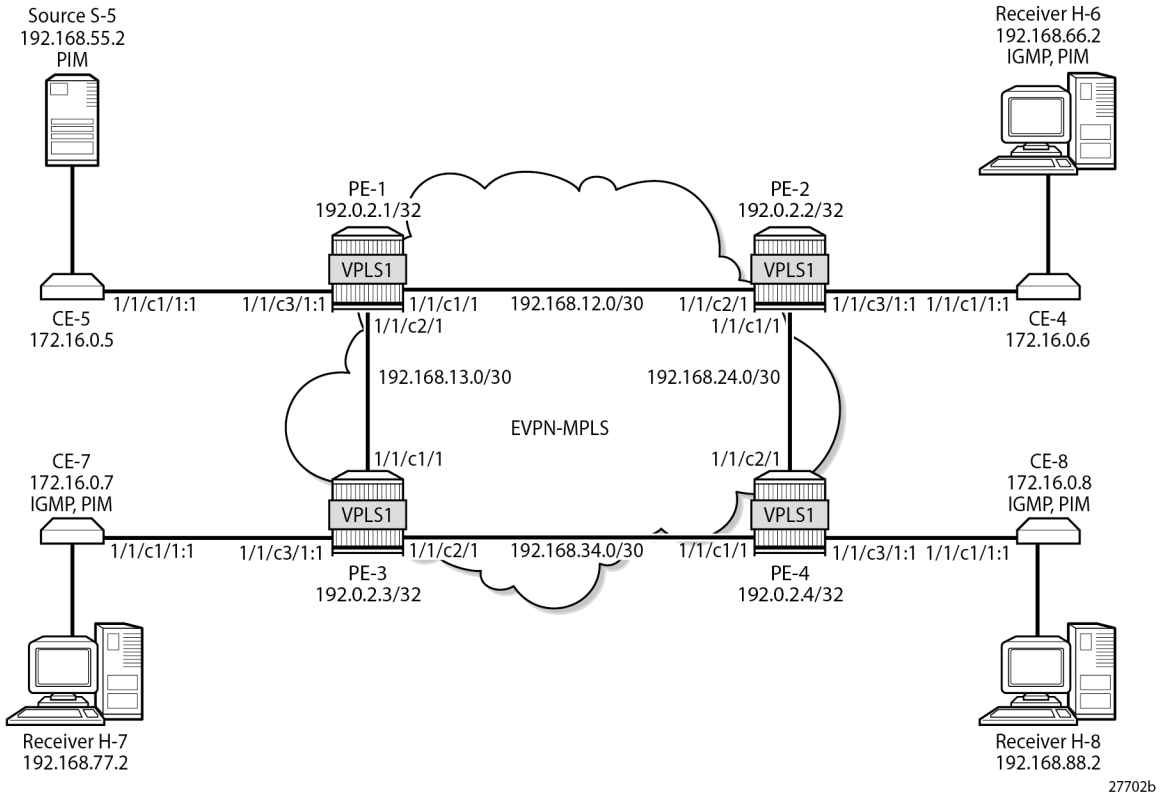
- Regular PIM snooping on SAPs/SDP-bindings
  - PIM messages received on EVPN-MPLS endpoints are forwarded to SAPs/SDP-bindings.
  - IP multicast traffic received on an EVPN-MPLS binding is forwarded to SAPs/SDP-bindings from which a PIM join was received, or to ports configured as mrouter ports.

- The EVPN-MPLS endpoints are treated as a single PIM interface:
  - IP multicast traffic and PIM messages received on an EVPN-MPLS endpoint are not forwarded to other EVPN-MPLS endpoints (split-horizon).
  - Hello and join/prune messages from SAPs/SDP-bindings are forwarded to all EVPN-MPLS destinations.
  - When a hello message is received from one PIM neighbor on an EVPN-MPLS destination, the single interface representing all EVPN-MPLS destinations has that neighbor.
    - Individual destinations appear in the MFIB, but the information for each EVPN-MPLS destination entry is identical.
- If a Point-to-Multipoint (P2MP) mLDP provider tunnel is configured:
  - If the PE is the root node of a P2MP LSP that is up, PIM messages and IP multicast traffic are only forwarded over the P2MP Label Switched Path (LSP) instead of being sent to the EVPN-MPLS endpoints. Therefore, the P2MP leaves must match the EVPN-MPLS endpoints, in this case, PE-2, PE-3, and PE-4.
  - If the PE is a leaf node of a P2MP LSP, it sends PIM messages and IP multicast traffic over its EVPN-MPLS endpoints.
  - The PEs can expect to receive IP multicast traffic and PIM messages from leaf nodes over their EVPN-MPLS endpoints, or over the P2MP LSPs for traffic from root nodes.
- PIM snooping is supported in inter-AS model B and inter-AS model C, as for IGMP snooping.
- All-active and single-active EVPN multi-homing are supported.
- Multi-chassis Synchronization (MCS) of PIM snooping state is supported on SAPs and spoke-SDPs in dual-homing.
  - The active (Designated Forwarder (DF)) PE sends the PIM states to the backup non-DF (NDF) PE.
  - In case of failure, the backup PE has the PIM states already, and the multicast traffic path can be re-established fast without any need to wait for PIM states to be snooped.
  - A sync-tag is configured on the ports or SDPs that need to be synchronized on both PEs.
  - MCS PIM snooping is restricted to two peers, even though MCS supports more peers for other types of information. An error is raised when attempting to configure a sync-tag on the same port or SDP to more than one peer.
- PIM snooping is supported for both IPv4 and IPv6 multicast. PIM snooping for IPv6 uses MAC-based forwarding by default, and can be configured to use (S,G)-based forwarding.
- PIM snooping is transparent to the underlying tunnel. PIM snooping works with RSVP, LDP, SR-ISIS, SR-OSPF, SR-TE, BGP, and MPLSoUDP.
- PIM snooping is not supported with routed VPLS with EVPN-MPLS, and its configuration is blocked.

Configuration

Figure 269: Example Topology shows the example topology. Source S-5 sends multicast streams to CE-5, which forwards those only after a PIM join message has been received. An mLDP P2MP LSP is used to distribute the multicast from the root node PE-1 to the other PEs. All CEs have PIM enabled and the receiving CEs (CE-6, CE-7, and CE-8) have IGMP configured on the interface toward the receivers (H-6, H-7, and H-8). EVPN-MPLS VPLS 1 is configured on the PEs. Initially, PIM snooping is disabled in the VPLS. Receiver H-8 joins multicast group 232.1.1.1 from source S-5.

Figure 269: Example Topology



The initial configuration includes the following:

- Cards, MDAs
- Ports
  - Ports between PEs are network ports with null encapsulation
  - Ports between CEs and PEs are hybrid ports with dot1q encapsulation
- IS-IS as IGP between the PEs (alternatively, OSPF can be used)
- LDP between the PEs
- BGP with address family EVPN between the PEs. PE-2 is the route reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
On PE-2:
configure
    router "Base"
        autonomous-system 64496
        bgp
            rapid-withdrawal
            rapid-update evpn
            group INTERNAL
                family evpn
                type internal
                cluster 192.0.2.2
                neighbor 192.0.2.1
```

```
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
        exit
    exit all
```

EVPN-MPLS VPLS without PIM Snooping

VPLS 1 is configured with EVPN-MPLS in the PEs. By default, PIM snooping is disabled. PE-1 is configured as **root-and-leaf** node for the P2MP mLDP multicast tree, while the other three PEs have the default **no root-and-leaf** configured, so they are leaf-only nodes. The configuration of VPLS 1 on PE-1 is as follows:

```
On PE-1:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf
                    mldp
                    no shutdown
                exit
            exit
            sap 1/1/c3/1:1 create
            exit
            no shutdown
        exit all
```

A P2MP mLDP multicast tree is created from root node PE-1 to the leaf nodes. On the root node PE-1, an SDP of type **VplsPmsi** is auto-created:

```
*A:PE-1# show service id 1 base

===============================================================================

PMSI Owner         : none
===============================================================================
```

When a P2MP mLDP provider tunnel is configured, the root node forwards PIM messages and IP multicast traffic over the provider tunnel instead of over the EVPN-MPLS endpoints. However, the leaf nodes of a P2MP mLDP provider tunnel send PIM messages and IP multicast traffic over the EVPN-MPLS endpoints.

The following P2MP mLDP bindings are active on root node PE-1: one toward PE-2 via port 1/1/c1/1 and one toward PE-3 via port 1/1/c2/1.

```
*A:PE-1# show router ldp bindings active p2mp opaque-type generic ipv4

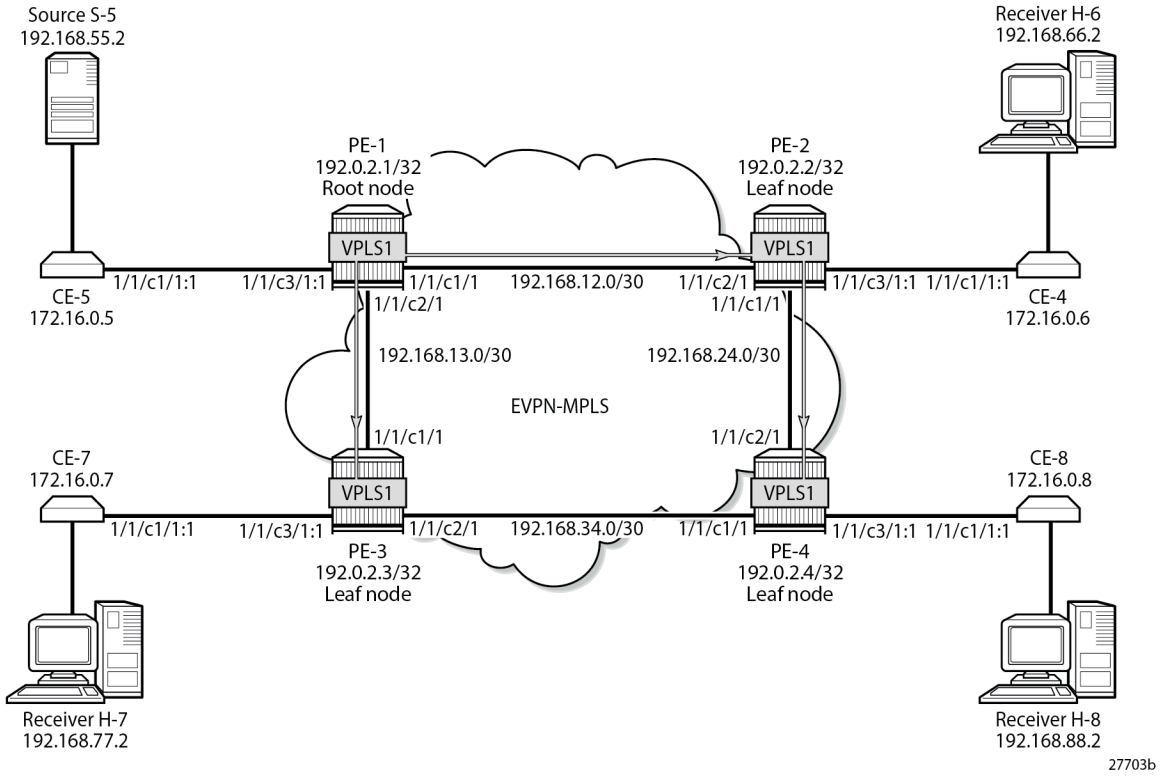
Figure 270: P2MP mLDP Multicast Tree shows the mLDP multicast tree. Multicast traffic from source S-5 uses the mLDP multicast tree from PE-1 to both PE-2 and PE-3. PE-2 is a transit node for multicast traffic to PE-4, and also a leaf node. PE-3 and PE-4 are leaf nodes.

Figure 270: P2MP mLDP Multicast Tree



CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. The configuration on CE-8 is as follows:

```
On CE-8:
configure
    router "Base"
        interface "int-CE-8-H-8"
            address 192.168.88.1/24
            port 1/1/c2/1
        exit
        interface "int-CE-8-PE-4"
            address 172.16.0.8/16
            port 1/1/c1/1:1
        exit
        interface "system"
            address 192.0.2.8/32
        exit
        static-route-entry 192.168.55.0/30
            next-hop 172.16.0.5
                no shutdown
            exit
        exit
        igmp
            interface "int-CE-8-H-8"
```

```
            exit
        exit
        pim
            apply-to all
        exit
    exit all
```

The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure
    router "Base"
        interface "int-CE-5-PE-1"
            address 172.16.0.5/16
            port 1/1/c1/1:1
        exit
        interface "int-CE-5-S-5"
            address 192.168.55.1/30
            port 1/1/c3/1
        exit
        interface "system"
            address 192.0.2.5/32
        exit
        static-route-entry 192.168.66.0/24
            next-hop 172.16.0.6
                no shutdown
            exit
        exit
        static-route-entry 192.168.77.0/24
            next-hop 172.16.0.7
                no shutdown
            exit
        exit
        static-route-entry 192.168.88.0/24
            next-hop 172.16.0.8
                no shutdown
            exit
        exit
        pim
            apply-to all
        exit
    exit all
```

The PIM neighbors of CE-5 are the receiving CEs: CE-6, CE-7, and CE-8, as follows:

```
*A:CE-5# show router pim neighbor

===============================================================================

```

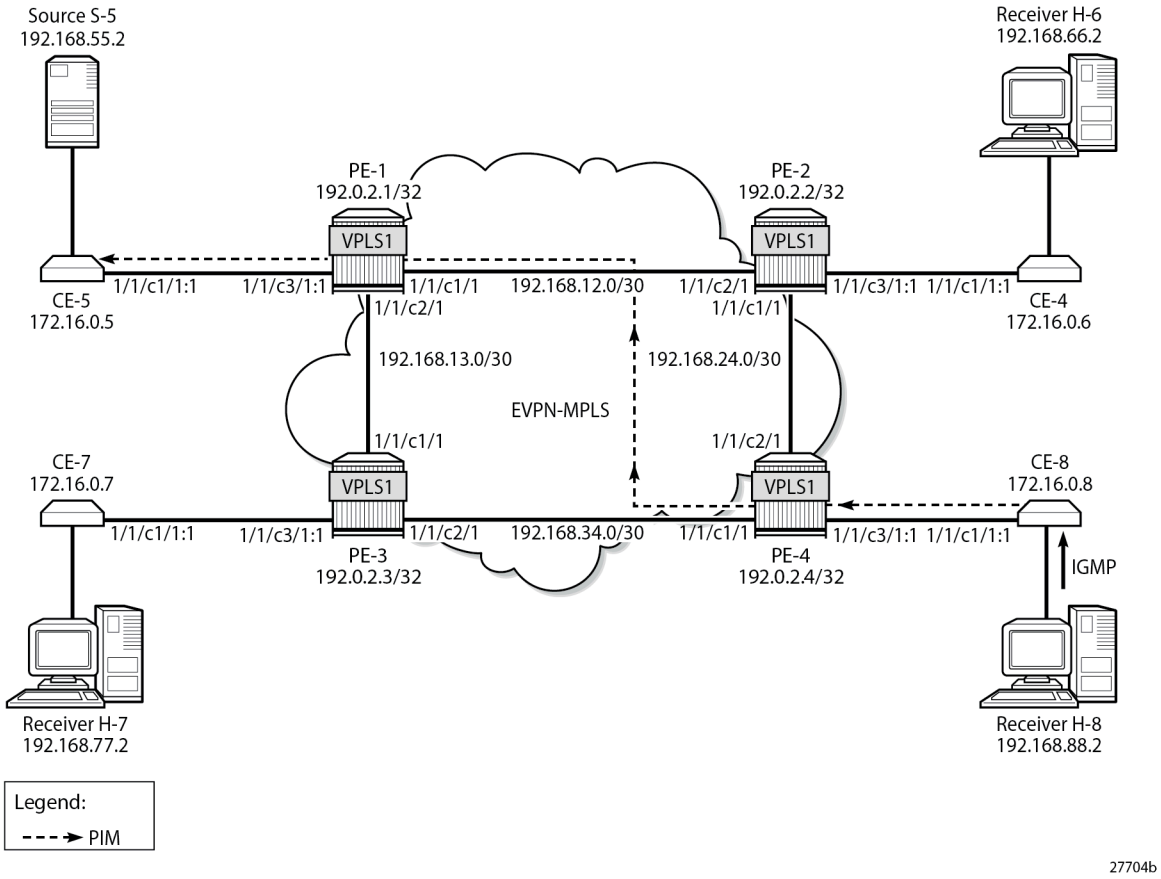
Figure 271: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled shows that receiver H-8 sends an IGMP report to CE-8 and CE-8 sends a PIM join message to CE-5 via PE-4. PE-4 floods the PIM join message to all PEs, and the message is not snooped by any intermediate PE.

Figure 271: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled



Alternatively, a static multicast group can be configured on IGMP interface int-CE-8-H-8 for multicast group (192.168.55.2, 232.1.1.1), as follows:

```
On CE-8:
configure
    router "Base"
        igmp
            interface "int-CE-8-H-8"
                ssm-translate
                    grp-range 232.0.0.0 232.255.255.255
                        source 192.168.55.2
                    exit
                exit
                static
                    group 232.1.1.1 source 192.168.55.2
                exit
                no shutdown
```

```
            exit
            no shutdown
        exit all
```

CE-8 sends the following PIM join message for multicast group (192.168.55.2, 232.1.1.1) to upstream IP address 172.16.0.5 on CE-5:

```
3 2023/08/08 09:26:05.675 UTC MINOR: DEBUG #2001 Base PIM[Instance 1 Base]
"PIM[Instance 1 Base]: Join/Prune
[000 00:23:23.670] PIM-TX ifId 3 ifName int-CE-8-PE-4 0.0.0.0 -> 224.0.0.13 Length: 34
PIM Version: 2 Msg Type: Join/Prune Checksum: 0x4828
Upstream Nbr IP : 172.16.0.5 Resvd: 0x0, Num Groups 1, HoldTime 210

Joined Srcs:
192.168.55.2/32 Flag S  <S,G>

"
```

Multicast stream 232.1.1.1 is sent from source S-5 to CE-5. When CE-5 has received the PIM join message, it floods the multicast stream to PE-1. Root node PE-1 sends the multicast stream to both PE-2 and PE-3. PE-2 forwards the multicast stream to PE-4 and to CE-6; PE-3 forwards the stream to CE-7, and PE-4 forwards to CE-8. The following PIM group for group address 232.1.1.1 is joined on CE-8:

```
*A:CE-8# show router pim group detail

CE-8 forwards the multicast stream to outgoing interface int-CE-8-H-8 toward receiver H-8, while CE-6 and CE-7 drop the traffic.

The following port statistics show that the incoming traffic on port 1/1/c3/1 on PE-1 is forwarded to port 1/1/c1/1 to PE-2 and to port 1/1/c2/1 to PE-3:

```

===============================================================================
```

Besides the multicast traffic, signaling messages (such as IS-IS or BGP) are sent, which explains the other counters on the ports being different from zero.

A similar result occurs on PE-2, where incoming traffic from PE-1 is forwarded to PE-4 and to CE-6.

The following port statistics on CE-6 show that the incoming traffic on port 1/1/c1/1 from PE-2 is not forwarded to port 1/1/c2/1 to H-6:

```
*A:CE-6# show port 1/1/c1/1 statistics

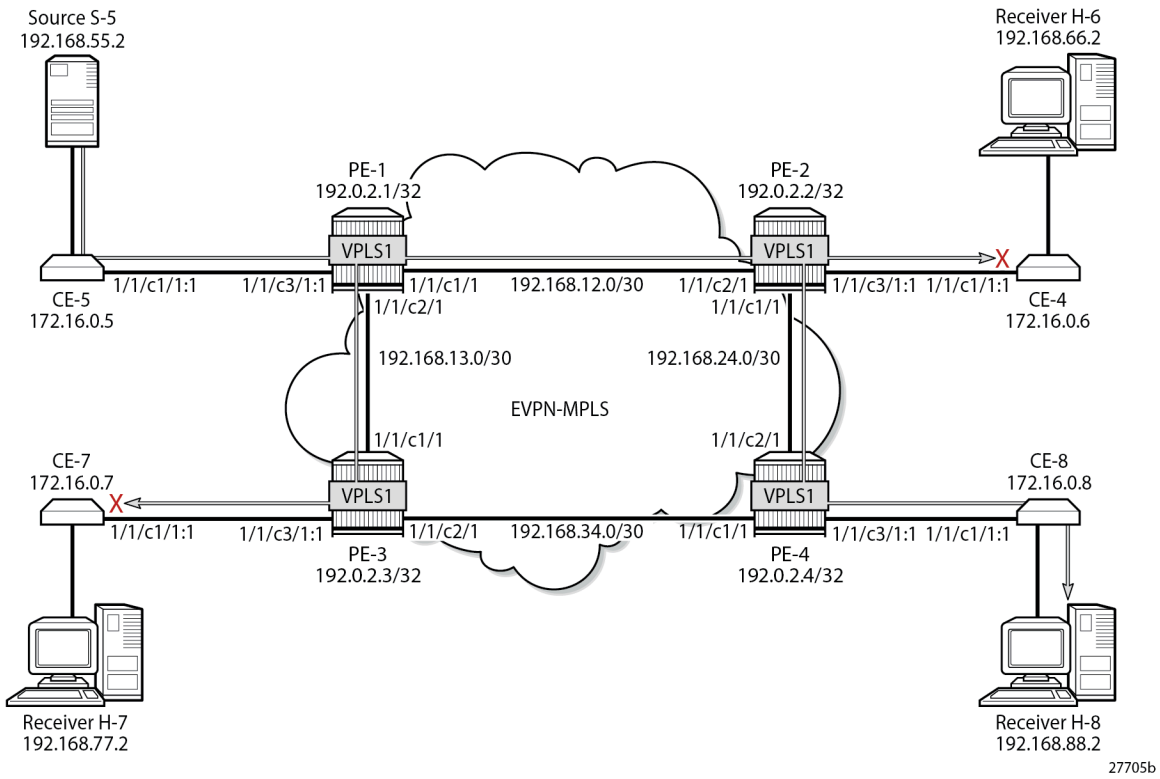
*A:CE-6# show port 1/1/c2/1 statistics
```

Without PIM snooping, multicast streams are forwarded to CEs that drop them, which wastes resources. Figure 272: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled shows the multicast data streams with receiver H-8 joined and PIM snooping disabled.

Figure 272: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled



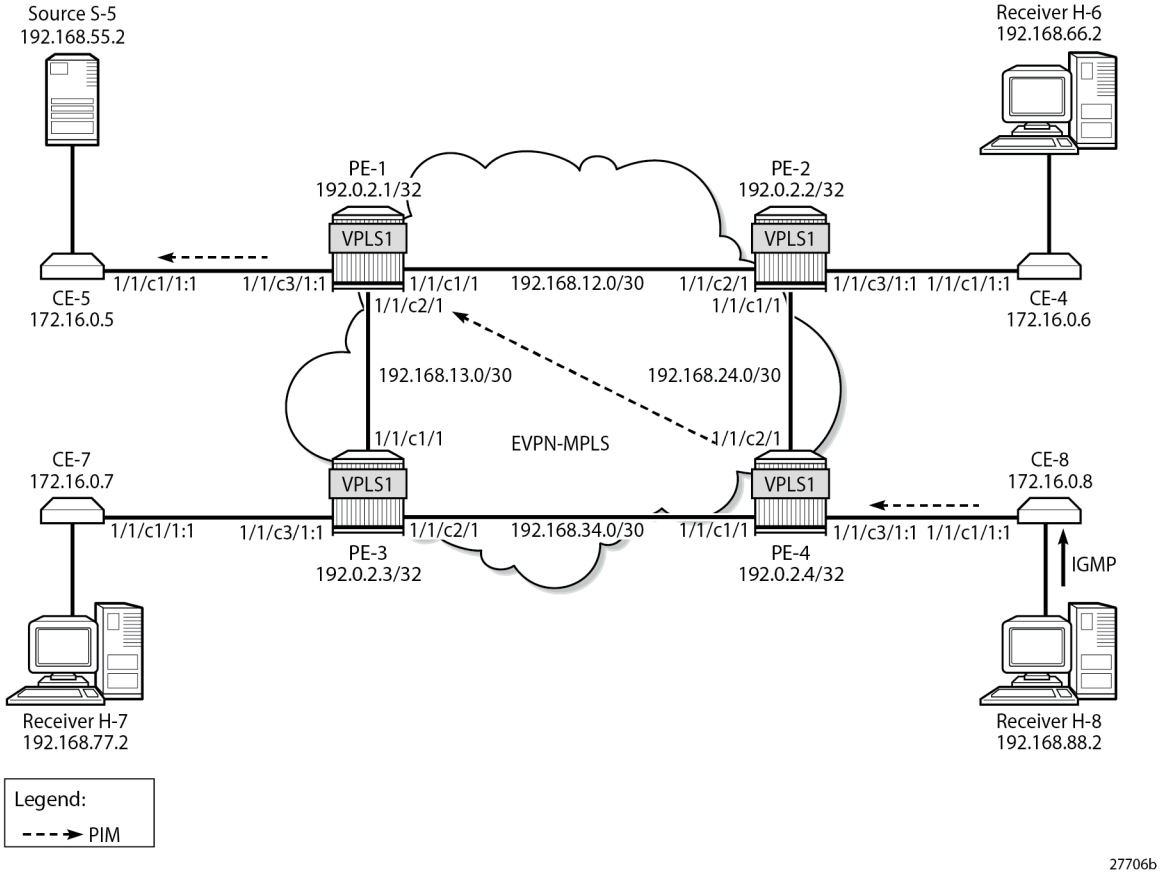
EVPN-MPLS VPLS with PIM Snooping Enabled

PIM snooping is enabled on all PEs as follows:

```
configure service vpls 1 pim-snooping
```

The default mode for PIM snooping is proxy mode, which allows the intermediate PEs to terminate the incoming PIM join or prune messages and create their own PIM join or prune message to be sent toward CE-5, as shown in Figure 273: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode:

Figure 273: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode



PE-4 receives the following PIM join message for multicast group (192.168.55.2, 232.1.1.1) from CE-8 to CE-5 on SAP 1/1/c3/1:1:

```
17 2023/08/08 09:31:26.206 UTC MINOR: DEBUG #2001 Base PIM[vpls 1 ]
"PIM[vpls 1 ]: Join/Prune
[000 00:28:47.290] PIM-RX ifId 1 ifName SAP:1/1/c3/1:1 172.16.0.8 -> 224.0.0.13 Length: 34

```

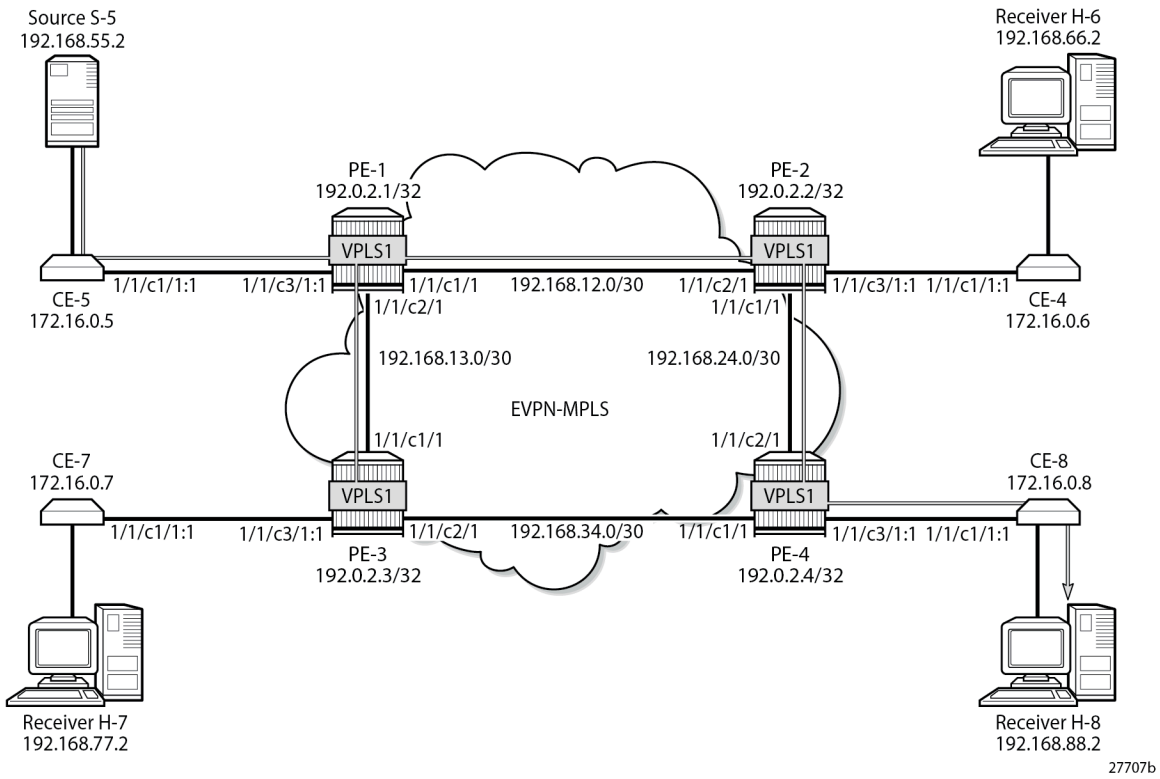
Figure 274: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled shows that the multicast stream still flows from the source S-5 to the receiver H-8, but is not forwarded to CE-6 and CE-7 when PIM snooping is enabled. The root node PE-1 sends the multicast traffic received on the SAP to all EVPN-MPLS destinations over the P2MP mLDP provider tunnel. The EVPN-MPLS interface is treated as a single interface.

Figure 274: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled

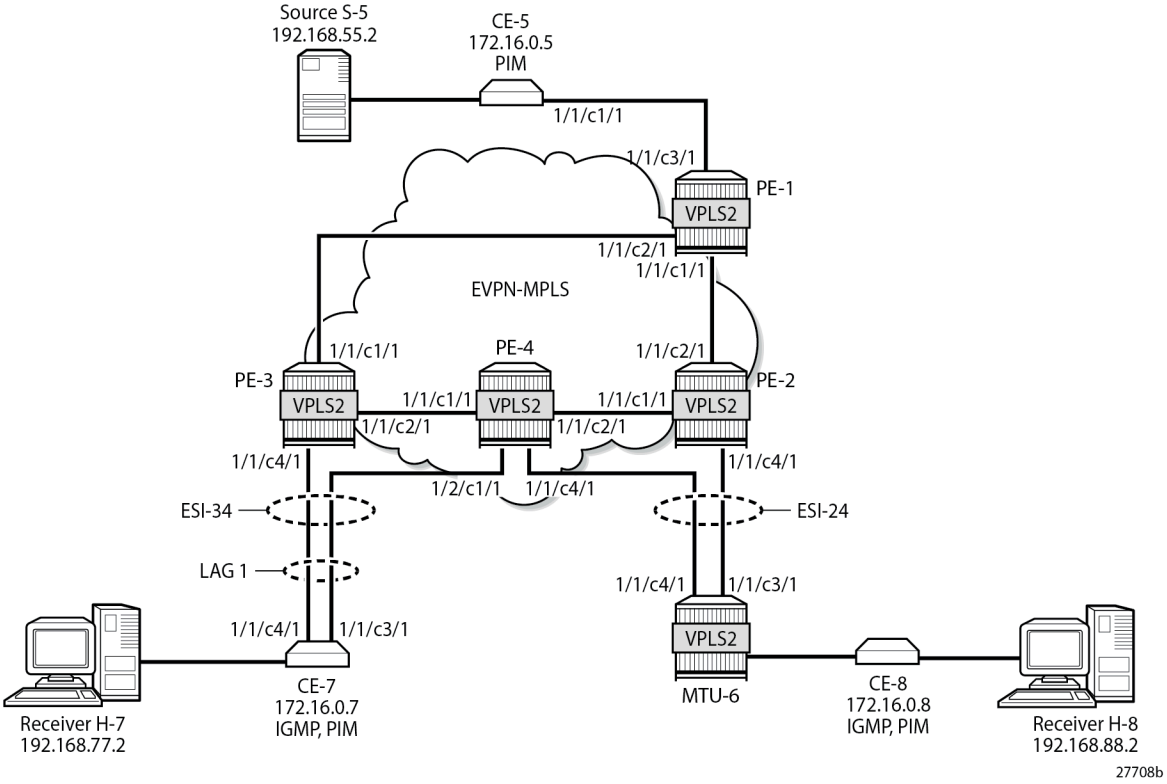


Multi-homed EVPN-MPLS VPLS without PIM Snooping

When CE-5 receives a PIM join message, it forwards the multicast stream to PE-1. All multicast traffic in VPLS 2 is sent to all receiving CEs, regardless of the received PIM join messages.

Figure 275: Example Topology with Multi-homing ESs shows the example topology with an all-active multi-homing virtual Ethernet Segment (ES) "ESI-34_2" between PE-3 and PE-4 using a LAG, and a single-active multi-homing ES "ESI-24" between PE-2 and PE-4 using SDPs.

Figure 275: Example Topology with Multi-homing ESs



The configuration of VPLS 2 is similar to the configuration of VPLS 1 on all PEs. An identical P2MP mLDP provider tunnel is established on the PEs for VPLS 2: PE-1 is the root node, PE-2 is a leaf node and a transit node, PE-3 is a leaf node, and PE-4 is also a leaf node.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active multi-homing ES "ESI-24". Spoke-SDP 26:2 is associated with VPLS 2.

```
On PE-2:
configure
    service
        sdp 26 mpls create
            far-end 192.0.2.6
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-24" create
                    esi 01:00:00:00:00:24:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 10000
                            exit
                        exit
```

```
                    exit
                    multi-homing single-active
                    sdp 26
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "VPLS 2" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    no root-and-leaf        # default
                    mldp
                    no shutdown
                exit
            exit
            spoke-sdp 26:2 create
            exit
            no shutdown
        exit
    exit all
```

The same ES is configured on PE-4, together with another ES-an all-active multi-homing virtual ES that applies to VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 5000 (which is lower than the preference 10000 on PE-3); see chapter Preference-based and Non-revertive EVPN DF Election. VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-24" create
                    esi 01:00:00:00:00:24:00:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 5000
                            exit
                        exit
                    exit
                    multi-homing single-active
```

```
                    sdp 46
                    no shutdown
                exit
                ethernet-segment "ESI-34_2" virtual create
                    esi 01:00:00:00:00:34:02:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 5000
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 2
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "VPLS 2" customer 1 create

            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    no root-and-leaf        # default
                    mldp
                    no shutdown
                exit
            exit
            sap lag-1:2 create
            exit
            spoke-sdp 46:2 create
            exit
            no shutdown
        exit
    exit all
```

The service configuration on PE-3 includes the same all-active multi-homing virtual ES with preference 10000, as follows:

```
On PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "ESI-34_2" virtual create
                    esi 01:00:00:00:00:34:02:00:00:01
                    es-activation-timer 3
```

```
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 10000
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 2
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "VPLS 2" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    no root-and-leaf        # default
                    mldp
                    no shutdown
                exit
            exit

            exit
            no shutdown
        exit
    exit all
```

The following is the service configuration on MTU-6:

```
On MTU-6:
configure
    service
        sdp 62 mpls create
            far-end 192.0.2.2
            ldp
            no shutdown
        exit
        sdp 64 mpls create
            far-end 192.0.2.4
            ldp
            no shutdown
        exit
        vpls 2 name "VPLS 2" customer 1 create
            endpoint "x" create
            exit
            sap 1/2/c1/1:2 create
```

```
            exit
            spoke-sdp 62:2 endpoint "x" create
            exit
            spoke-sdp 64:2 endpoint "x" create
            exit
            no shutdown
        exit
    exit all
```

For VPLS 2, PE-2 is the DF in ES "ESI-24", as follows:

```
*A:PE-2# show service id 2 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                         Status

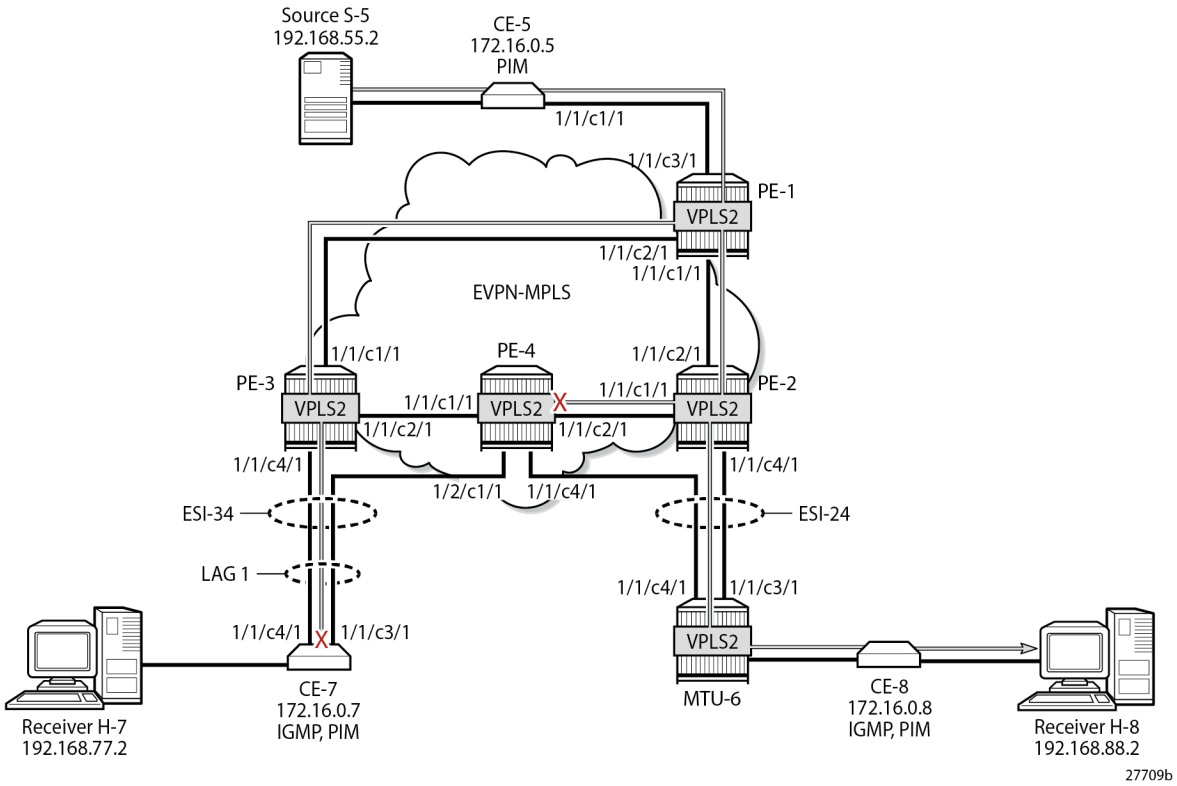
46:2                 ESI-24                          NDF
===============================================================================
No vxlan instance entries
```

When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tree to PE-2, PE-3, and PE-4. The DF PE-2 forwards the traffic to

MTU-6, and DF PE-3 forwards it to CE-7, even though a PIM join for this group has not been received from CE-7. PE-4 is NDF, so it does not forward the traffic to MTU-6 or CE-7. MTU-6 forwards the traffic to CE-8, which sends it to H-8. CE-7 drops the multicast traffic because no attached receiver has joined the multicast group. Figure 276: EVPN-MPLS with Multi-homing – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

Figure 276: EVPN-MPLS with Multi-homing – Receiver H-8 Joined



The static IGMP multicast is removed to emulate an IGMPv3 report from receiver H-8 to exclude multicast group 232.1.1.1 from source 192.168.55.2, as follows:

```
On CE-8:
configure
    router "Base"
        igmp
            interface "int-CE-8-H-8"
                static
                    no group 232.1.1.1
                exit
                no shutdown
            exit
            no shutdown
        exit all
```

Multi-homed EVPN-MPLS VPLS with PIM Snooping

PIM snooping is enabled in VPLS 2 on all PEs, including PE-1, which is not part of an ES-with the following command:

```
configure service vpls 2 pim-snooping
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
*A:PE-1# show service id 2 pim-snooping neighbor

===============================================================================
PIM Snooping Neighbors ipv4

  172.16.0.7
-------------------------------------------------------------------------------
Neighbors : 3
===============================================================================
```

PE-3 and PE-4 also have these three CEs as PIM snooping neighbors.

All-active MH EVPN-MPLS VPLS with PIM Snooping

On CE-7, the following static IGMP membership is configured on interface int-CE-7-H-7:

```
On CE-7:
configure
    router "Base"
        igmp
```

```
            interface "int-CE-7-H-7"
                ssm-translate
                    grp-range 232.0.0.0 232.255.255.255
                        source 192.168.55.2
                    exit
                exit
                static
                    group 232.1.1.1 source 192.168.55.2
                exit
                no shutdown
            exit
            no shutdown
        exit all
```

When H-7 joins the multicast group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2, with four port IDs: the local SAP to CE-5 and the EVPN-MPLS destinations, as follows:

```
*A:PE-1# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sap:1/1/c3/1:2              Local    Fwd
                                      mpls:192.0.2.2:524279       Local    Fwd
                                      mpls:192.0.2.3:524279       Local    Fwd
                                      mpls:192.0.2.4:524278       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

The MFIB on PE-2 is empty because no locally attached node has sent a PIM join for any multicast group:

```
*A:PE-2# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Number of entries: 0
===============================================================================
```

The MFIB on PE-3 contains an entry for the (S,G) with the local SAP lag-1:2 and the EVPN-MPLS destination, as follows:

```
*A:PE-3# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sap:lag-1:2                 Local    Fwd
```

```
                                    mpls:192.0.2.1:524280        Local    Fwd
                                    mpls:192.0.2.2:524279        Local    Fwd
                                    mpls:192.0.2.4:524278        Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

Data-driven PIM state synchronization between PE-3 and PE-4 in the ESI-34_2 results in the following MFIB entry on PE-4:

```
*A:PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                         Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sap:lag-1:2                 Local    Fwd
                                      mpls:192.0.2.1:524280       Local    Fwd
                                      mpls:192.0.2.2:524279       Local    Fwd
                                      mpls:192.0.2.3:524279       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

When debugging is enabled on the PEs as follows, the synchronization between peers in ES "ESI-34_2" is logged:

```
debug
    service
        id 2
            pim-snooping
                jp
                packet evpn-mpls
            exit all
```

For example, PE-4 sends the following PIM message to its remote peer PE-3 in ESI-34_2:

```
87 2023/08/08 09:47:08.842 UTC MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimVplsFwdJPToEvpn
Forwarding to remote peer on bgp-evpn ethernet-segment ESI-34_2"
```

PE-3 receives the following PIM message from its remote peer PE-4 in ESI-34_2:

```
65 2023/08/08 09:45:40.009 UTC MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimProcessPdu
Received from remote peer on bgp-evpn ethernet-segment ESI-34_2, will be applied on lag-1:2
"
```

On PE-1, the PIM snooping group (192.168.55.2, 232.1.1.1) has incoming interface SAP 1/1/c3/1:2 toward CE-5 and the EVPN-MPLS interface as outgoing interface, as follows:

```
*A:PE-1# show service id 2 pim-snooping group detail

===============================================================================
PIM Snooping Source Group ipv4
===============================================================================
Group Address      : 232.1.1.1
```

```

```

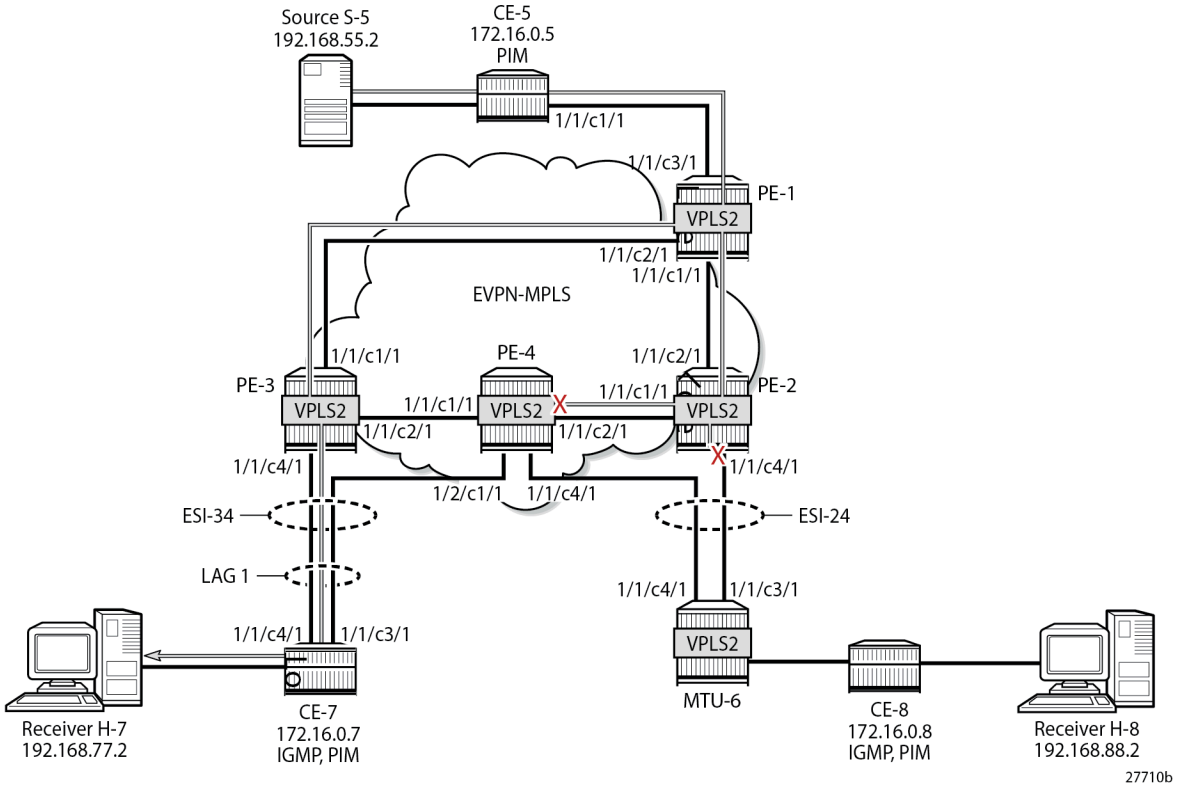
Figure 277: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined shows how the multicast traffic is forwarded when H-7 joins the multicast group and PIM snooping is enabled. DF PE-3 forwards the traffic toward CE-7. The multicast stream also reaches PE-2 and PE-4, where it is dropped.

Figure 277: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined



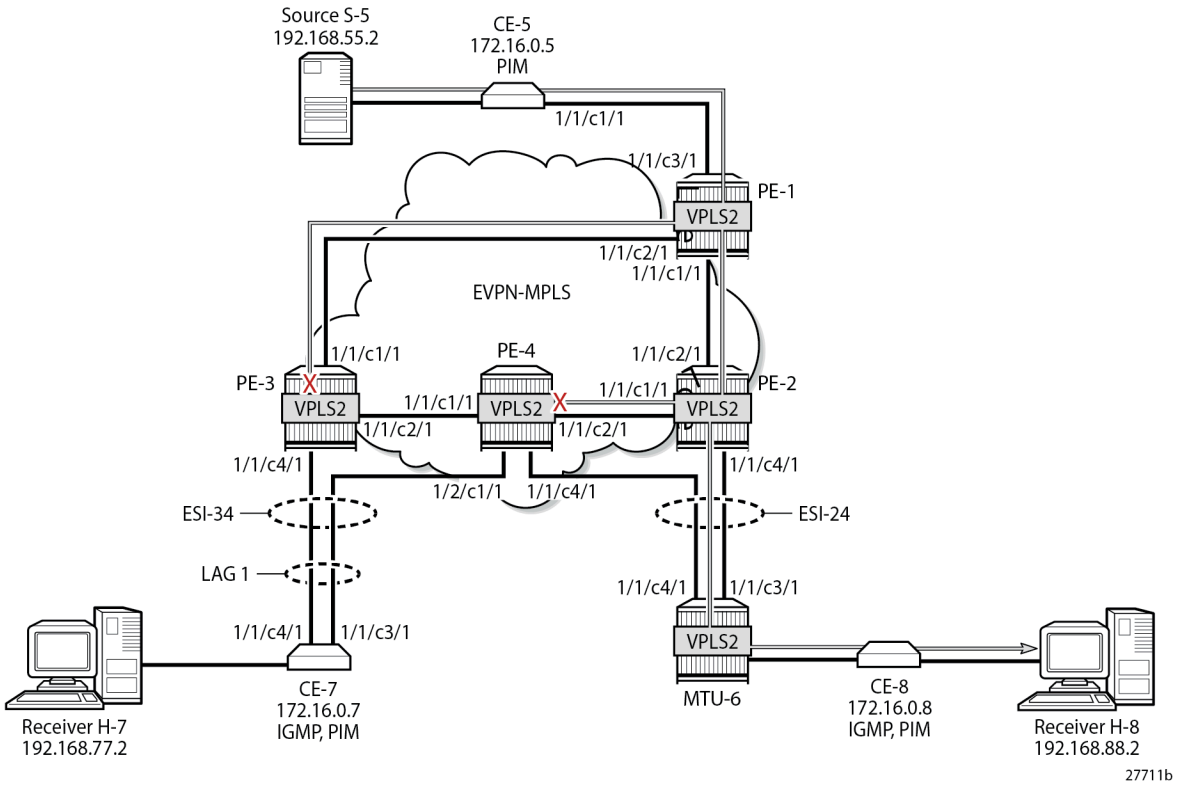
H-7 leaves the multicast group and H-8 joins it instead.

Single-active MH EVPN-MPLS VPLS with PIM Snooping

When H-8 joins the multicast group and PIM snooping is enabled, only DF PE-2 forwards traffic from the EVPN-MPLS toward a receiver. PE-3 does not forward traffic to CE-7 because no PIM join message was

received from CE-7. Figure 278: EVPN-MPLS with Single-active Multi-homing and PIM Snooping Enabled – Receiver H-8 Joined shows how the multicast traffic is forwarded when H-8 joins the multicast group and PIM snooping is enabled.

Figure 278: EVPN-MPLS with Single-active Multi-homing and PIM Snooping Enabled – Receiver H-8 Joined



On PE-1, the MFIB looks the same as in the preceding case, as follows:

```
*A:PE-1# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                      Svc Id   Fwd
                                                                          Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sap:1/1/c3/1:2               Local    Fwd
                                      mpls:192.0.2.2:524279        Local    Fwd
                                      mpls:192.0.2.3:524279        Local    Fwd
                                      mpls:192.0.2.4:524278        Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

On PE-2, the MFIB contains an entry for source address 192.168.55.2 and group address 232.1.1.1 with spoke-SDP 26:2 and the EVPN-MPLS destinations to the other PEs, as follows:

```
*A:PE-2# show service id 2 mfib
```

```
===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                         Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sdp:26:2                    Local    Fwd
                                      mpls:192.0.2.1:524280       Local    Fwd
                                      mpls:192.0.2.3:524279       Local    Fwd
                                      mpls:192.0.2.4:524278       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

The MFIB on PE-3 is empty, because multicast traffic toward H-8 is not sent via PE-3, as follows:

```
*A:PE-3# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                         Blk
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Number of entries: 0
===============================================================================
```

The data-driven PIM state synchronization ensures that DF PE-2 sends updates to NDF PE-4. With debugging enabled, the following debug message is displayed at PE-2:

```
203 2023/08/08 09:48:51.571 UTC MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimVplsFwdJPToEvpn
Forwarding to remote peer on bgp-evpn ethernet-segment ESI-24"
```

The following debug message is displayed at PE-4:

```
74 2023/08/08 09:45:40.499 UTC MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimProcessPdu
Received from remote peer on bgp-evpn ethernet-segment ESI-24, will be applied on 46:2
"
```

As a result, the MFIB on PE-4 is not empty, as follows:

```
*A:PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                         Blk
-------------------------------------------------------------------------------

===============================================================================
```

PIM state synchronization is data-driven, so the PIM states are not stored in a database. Therefore, the ESs must be configured as **non-revertive** to avoid reverting back to the preferred PE while this PE is unaware of the PIM states.

PIM Snooping with Multi-chassis Synchronization

Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later. The ES must be configured as non-revertive, so that after a failover, the new DF remains the DF even when the original DF is operational again. When data-driven PIM state synchronization cannot be used, for example, when the service carving is configured in auto mode, or when the SR OS Release is an earlier release of 15.0, Multi-chassis synchronization (MCS) can be configured for a faster failover. MCS of the PIM snooping state on SAPs and spoke-SDPs is supported between an active and a standby PE and the PIM states are stored in a synchronization database. This can be configured in case of single-active multi-homing (MH), for example on PE-2 for peer PE-4, with PIM snooping on spoke-SDPs, as follows:

```
On PE-2:
configure
    redundancy
        multi-chassis
            peer 192.0.2.4 create
                sync
                    pim-snooping spoke-sdps
                    sdp 26 create
                        range 2-2 sync-tag "syncSA"
                    exit
                    no shutdown
                exit
                no shutdown
            exit all
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure
    redundancy
        multi-chassis
            peer 192.0.2.2 create
                sync
                    pim-snooping spoke-sdps
                    sdp 46 create
                        range 2-2 sync-tag "syncSA"
                    exit
                    no shutdown
                exit
                no shutdown
            exit all
```

When H-8 joins the multicast group, the following entries are in the MCS synchronization database of the PEs. The MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
*A:PE-2# tools dump redundancy multi-chassis sync-database detail

If no entries are present for an application, no detail will be displayed.

FLAGS LEGEND: ld - local delete; da - delete alarm; pd - pending global delete;
              oal - omcr alarmed; ost - omcr standby

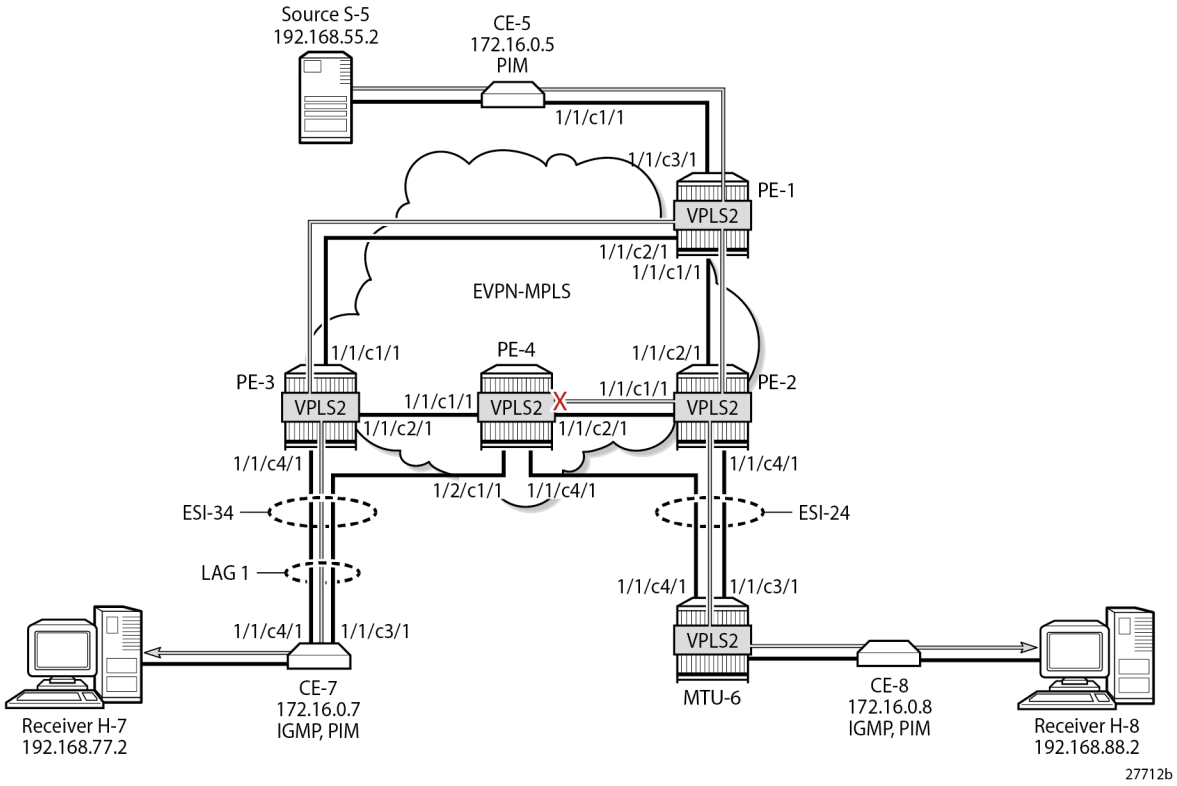
Failover

Figure 279: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined shows the multicast traffic flow in the case where both receivers H-7 and H-8 joined multicast group 232.1.1.1 from source 192.168.55.2 and no failures have occurred. For SR OS Release 15.0.R4, and later, MCS need not be configured for faster failover in single-active MH when the ES is non-revertive.

Figure 279: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined



NDF PE-4 has an MFIB table with the required information for a fast failover, as follows:

```
*A:PE-4# show service id 2 mfib

```

The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. On MTU-6, SDP 62 is disabled, as follows:

```
*A:MTU-6# configure service sdp 62 shutdown
```

On CE-7, port 1/1/c4/1 toward PE-3 is disabled, as follows:

```
*A:CE-7# configure port 1/1/c4/1 shutdown
```

Log 99 on PE-3 shows that the DF state in ESI-34_2 changed to false:

```
156 2023/08/08 09:51:51.762 UTC MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-34_2, EVI:2, Designated Forwarding state changed to:false"
```

PE-4 becomes the DF for both ESs, as follows:

```
*A:PE-4# show service id 2 ethernet-segment

                                        16479                       24755468
===============================================================================
```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. CE-7 forwards the traffic to H-7. PE-3 drops the multicast traffic because LAG-1 is down because of the failure that was introduced at CE-7 (port disabled).

Conclusion

PIM snooping in EVPN-MPLS services results in a more efficient use of network resources because multicast traffic no longer needs to be flooded. PIM snooping can be used in EVPN-MPLS services with all-active and single-active multi-homing with data-driven PIM state synchronization. Alternatively, MCS synchronization of the PIM snooping state on SAPs and spoke-SDPs is supported with single-active MH.

PIM Snooping for IPv4 in PBB-EVPN Services

This chapter describes PIM Snooping for IPv4 in PBB-EVPN Services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. Protocol Independent Multicast (PIM) snooping for IPv4 is supported in Provider Backbone Bridging - Ethernet Virtual Private Network (PBB-EVPN) services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing (MH) mode without Ethernet Segment Identifier (ESI) label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active MH mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping for IPv4 in all-active MH mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

PBB-EVPN services have EVPN-MPLS enabled in the B-VPLS. PIM snooping in PBB-EVPN I-VPLS provides the following:

- PIM snooping in SAPs and SDP-bindings: PIM messages received from SAPs, SDP-bindings, or the B-VPLS are forwarded to SAPs or SDP-bindings according to the PIM snooping.
- Multicast flooding between I-VPLS and B-VPLS is the same for a PBB-EVPN B-VPLS as for a B-VPLS without EVPN. The first PIM join message received over the local B-VPLS from a B-VPLS SAP/SDP-binding or EVPN endpoint results in adding the B-VPLS SAP/SDP-binding or EVPN interface into the Multicast Forwarding Information Base (MFIB) associated with the I-VPLS context. Multicast traffic is flooded throughout the B-VPLS on a per-ISID single tree.
- When the PIM router is connected to a remote I-VPLS instance over the B-VPLS infrastructure, its location is identified by the B-VPLS SAP/SDP-binding or by the set of all EVPN endpoints on which PIM hellos are received. The location is also identified by the source BMAC address in the PBB header for the PIM hello message, which is the BMAC address associated with the B-VPLS instance on the remote PBB PE.
- The set of all EVPN endpoints in the B-VPLS is treated as a single PIM interface.
  - Hello and join/prune messages from I-VPLS SAPs/SDP-bindings are always sent to all B-VPLS PBB-EVPN destinations.
  - When a hello message is received from one B-VPLS PBB-EVPN destination PIM neighbor, the single interface representing all B-VPLS PBB-EVPN destinations will have that PIM neighbor.
  - All individual B-VPLS PBB-EVPN destinations appear in the MFIB, but the information for each B-VPLS PBB-EVPN destination entry is identical.

  - The EVPN split-horizon logic ensures that IP multicast traffic and PIM messages received on a PBB-EVPN endpoint are not forwarded back to other PBB-EVPN endpoints.

- When a point-to-multipoint (P2MP) mLDP provider tunnel is configured in the B-VPLS, the provider tunnel only works for the default multicast list. Ingress Replication (IR) is used for the per-ISID MFIB trees. ISID policies can be configured to specify ISID ranges that will use the default multicast list. ISID policies can help reduce the per-ISID MFIB resources used.
- PIM snooping for IPv4 within a PBB-EVPN I-VPLS is supported with single-active MH and with all-active MH in the associated I-VPLS.
- Data-driven PIM state synchronization between remote peers in an all-active MH Ethernet Segment (ES) is supported.
- Multi-Chassis Synchronization (MCS) of PIM snooping state on SAPs and spoke-SDPs is supported in active/standby scenarios.

The following command enables PIM snooping in an I-VPLS:

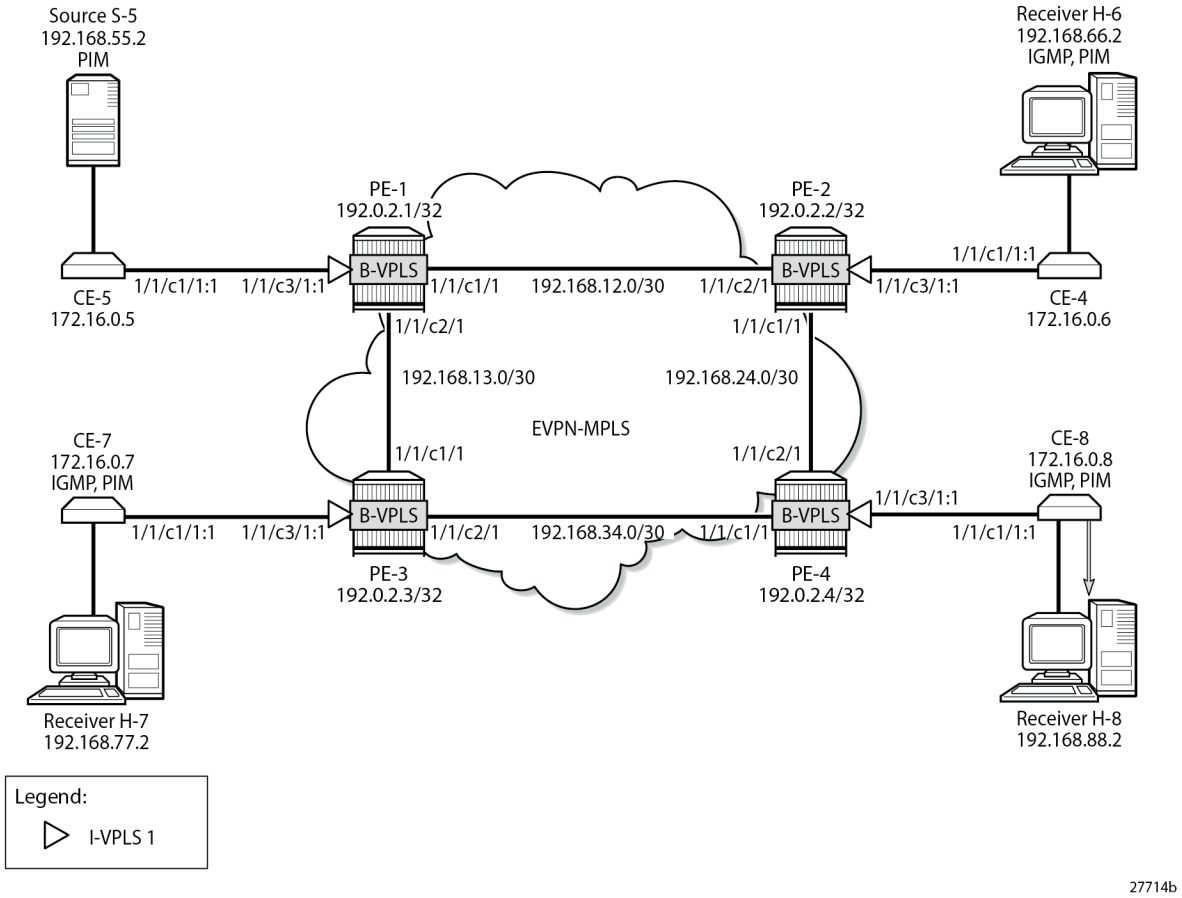
```
configure service vpls 1 pim-snooping
```

The default PIM snooping mode is proxy mode, which implies that the PE will terminate the PIM join/prune messages and generate its own PIM join/prune messages with the same (S,G). The advantage is that the number of PIM messages to be sent can be reduced: regardless of the number of PIM join messages received for a certain (S,G), the node only needs to send one PIM join message toward the source. PIM snooping can also use snooping mode based on the information in the received PIM hello messages; in snooping mode, the PE does not modify the PIM messages.

Configuration

Figure 281: Example Topology for PBB-EVPN without MH shows the example topology with source S-5 and receivers H-6, H-7, and H-8 attached to CEs that are connected to PEs. On the PEs, B-VPLS 100 is configured and I-VPLS 1 is associated with it. B-VPLS 100 has EVPN-MPLS enabled. An mLDP P2MP provider tunnel is used to distribute multicast traffic from PE-1 to the other PEs.

Figure 281: Example Topology for PBB-EVPN without MH



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on the PEs (alternatively, OSPF can be used)
- LDP enabled on the PEs

BGP is configured on the PEs with address family EVPN, and PE-2 is configured as route reflector (RR). The BGP configuration on PE-2 is as follows:

```
On PE-2:
configure
    router "Base"
        bgp
            rapid-withdrawal
            rapid-update evpn
            group INTERNAL
                family evpn
                type internal
                cluster 192.0.2.2
                neighbor 192.0.2.1
                exit
```

```
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
        exit all
```

PBB-EVPN without MH – No PIM Snooping

B-VPLS 100 is configured with EVPN-MPLS enabled on all PEs. Multicast LDP is configured in B-VPLS 100 with PE-1 as the P2MP tunnel root node (**root-and-leaf**) and the other PEs as leaf nodes (**no root-and-leaf** is default). An (optional) ISID policy defines that the default multicast tree -which is used by the P2MP mLDP tunnel- is used for ISIDs 1 and 2 (range 1 to 2). The configuration of B-VPLS 100 on PE-1 is as follows:

```
On PE-1:
configure
    service
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            description "B-VPLS 100"
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:01
            exit
            split-horizon-group "CORE" create
            exit
            bgp
            exit
            bgp-evpn
                evi 100
                mpls
                    split-horizon-group "CORE"
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            provider-tunnel
                inclusive
                    owner bgp-evpn-mpls
                    root-and-leaf
                    mldp
                    no shutdown
                exit
            exit
            isid-policy
                entry 1 create
                    use-def-mcast
                    no advertise-local
                    range 1 to 2
                exit
            exit
            no shutdown
        exit all
```

The configuration of B-VPLS on the other PEs is similar, but without the root-and-leaf option.

In B-VPLS 100 on root node PE-1, the following mLDP provider tunnel is created with Provider Multicast Service Interface (PMSI) owner bgpEvpnMpls. PE-1 is configured as root-and-leaf node.

```
*A:PE-1# show service id 100 provider-tunnel

===============================================================================
Service Provider Tunnel Information

===============================================================================
```

When the B-VPLS is created, I-VPLS 1 can be associated with it, as follows:

```
On PE-1:
configure
    service
        vpls 1 name "I-VPLS 1" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap 1/1/c3/1:1 create
            exit
            no shutdown
        exit all
```

The configuration of I-VPLS 1 on the other PEs is identical.

CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. Source-specific multicast is used in this example. The configuration on CE-8 is as follows:

```
On CE-8:
configure
    router "Base"
        interface "int-CE-8-H-8"
            address 192.168.88.1/24
            port 1/1/c2/1
        exit
        interface "int-CE-8-PE-4"
            address 172.16.0.8/16
            port 1/1/c1/1:1
        exit
        interface "system"
            address 192.0.2.8/32
        exit
        static-route-entry 192.168.55.0/30
            next-hop 172.16.0.5
                no shutdown
            exit
        exit
        igmp
            interface int-CE-8-H-8
```

```
            exit
        exit
        pim
            apply-to all
        exit
    exit all
```

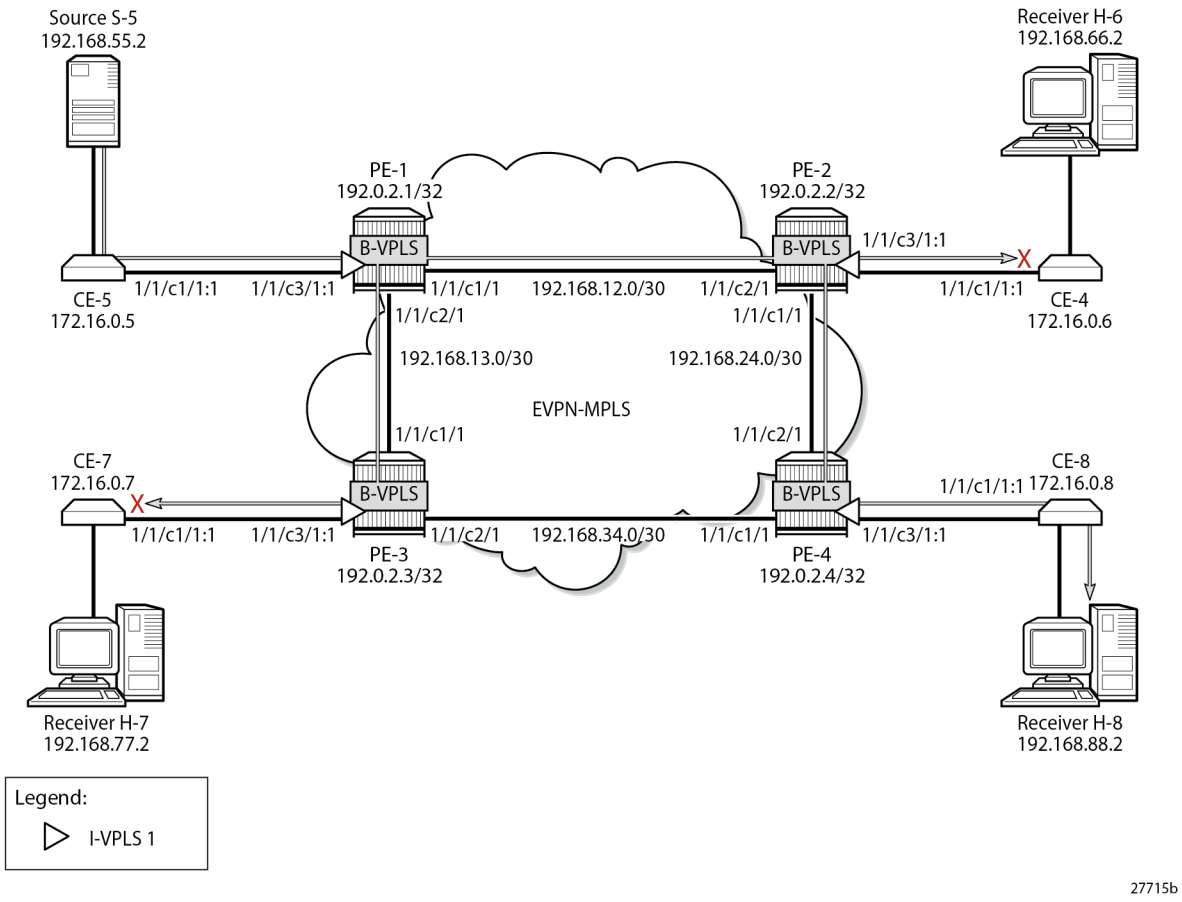
The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure
    router "Base"
        interface "int-CE-5-PE-1"
            address 172.16.0.5/16
            port 1/1/c1/1:1
        exit
        interface "int-CE-5-S-5"
            address 192.168.55.1/30
            port 1/1/c3/1
        exit
        interface "system"
            address 192.0.2.5/32
        exit
        static-route-entry 192.168.66.0/24
            next-hop 172.16.0.6
                no shutdown
            exit
        exit
        static-route-entry 192.168.77.0/24
            next-hop 172.16.0.7
                no shutdown
            exit
        exit
        static-route-entry 192.168.88.0/24
            next-hop 172.16.0.8
                no shutdown
            exit
        exit
        pim
            apply-to all
        exit
    exit all
```

When receiver H-8 sends an IGMP report to join multicast group (S,G), CE-8 sends a PIM join message to CE-5. This PIM join message is flooded by the PEs. When CE-5 receives the PIM join message, it forwards the multicast stream to receiver H-8. PIM snooping is disabled by default and the MFIB on each of the PEs remains empty, so the multicast stream is not only sent to CE-8, but also to CE-6 and CE-7. CE-6 and CE-7 drop this stream when no receiver is active, while CE-8 forwards the multicast stream to receiver H-8, as shown in Figure 282: Multicast Stream to Receiver H-8 with PIM Snooping Disabled.

Figure 282: Multicast Stream to Receiver H-8 with PIM Snooping Disabled



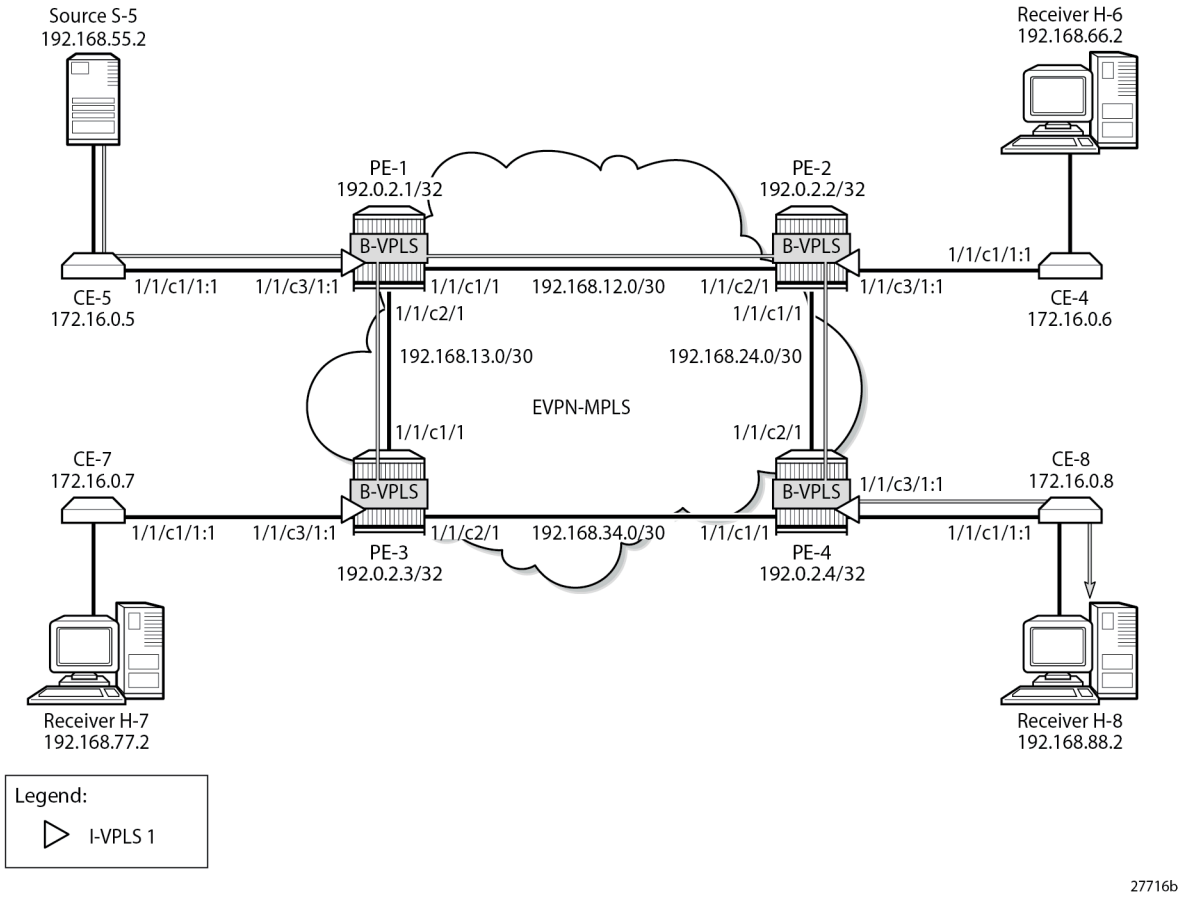
PBB-EVPN without MH – PIM Snooping for IPv4 Enabled

PIM snooping for IPv4 is enabled in I-VPLS 1 on all PEs as follows:

```
On all PEs:
configure service vpls 1 pim-snooping
```

When PIM snooping for IPv4 is enabled, the PEs only forward the multicast traffic to those CEs that have sent PIM join messages for that multicast group. This implies that PE-2 and PE-3 do not forward traffic to the CEs; only PE-4 forwards traffic toward CE-8 and CE-8 forwards to receiver H-8, as shown in Figure 283: Multicast Stream to Receiver H-8 with PIM Snooping Enabled.

Figure 283: Multicast Stream to Receiver H-8 with PIM Snooping Enabled



When PIM snooping for IPv4 is enabled, PE-1 has the following two PIM snooping ports: the SAP toward the source and the backbone b-EVPN-MPLS interface, which is treated as one entity for all PBB-EVPN destinations.

```
*A:PE-1# show service id 1 pim-snooping port

===============================================================================
PIM Snooping Port ipv4
===============================================================================
Port Id                                                    Opr   PW Fwding
-------------------------------------------------------------------------------
SAP:1/1/c3/1:1                                             Up    Actv
b-EVPN-MPLS                                                Up    Actv
===============================================================================
```

PE-1 has the following PIM snooping neighbors: CE-5 with IP address 172.16.0.5 is attached via SAP 1/1/c3/1:1, and the other CEs are attached to the b-EVPN-MPLS. Even though this b-EVPN-MPLS is treated as one entity, individual entries are shown for each B-VPLS PBB-EVPN destination, as follows:

```
*A:PE-1# show service id 1 pim-snooping neighbor
```

```

The following shows that PE-2 receives the multicast packets on port 1/1/c2/1 and forwards them to PE-4 on port 1/1/c1/1. With PIM snooping for IPv4 enabled, PE-2 does not forward the traffic to CE-6 on port 1/1/c3/1 because no PIM join message was received from CE-6. Besides the multicast traffic, some signaling messages (such as PIM, IS-IS, and so on) are sent on the ports, which explains why all counters have non-zero values.

```

The following PIM snooping group with group address 232.1.1.1 and source address 192.168.55.2 is shown on PE-1. The incoming interface is the SAP toward CE-5 and the outgoing interface is the b-EVPN-MPLS interface. A single b-EVPN-MPLS interface is shown in the outgoing interface list, regardless of the B-VPLS PBB-EVPN destination. The split-horizon mechanism ensures that all traffic from the incoming interface SAP 1/1/c3/1:1 is only forwarded on the b-EVPN-MPLS interface, not sent back on the SAP.

```

```

On PE-2 and PE-3, there are no PIM snooping groups.

On PE-4, the PIM snooping group with group address 232.1.1.1 and source address 192.168.55.2 has the b-EVPN-MPLS interface as incoming interface and SAP 1/1/c3/1:1 toward CE-8 as outgoing interface, as follows. The split-horizon mechanism ensures that traffic received from the b-EVPN-MPLS interface is not

forwarded on the b-EVPN-MPLS interface to the other PEs, so it is only forwarded on the SAP 1/1/c3/1:1 toward CE-8.

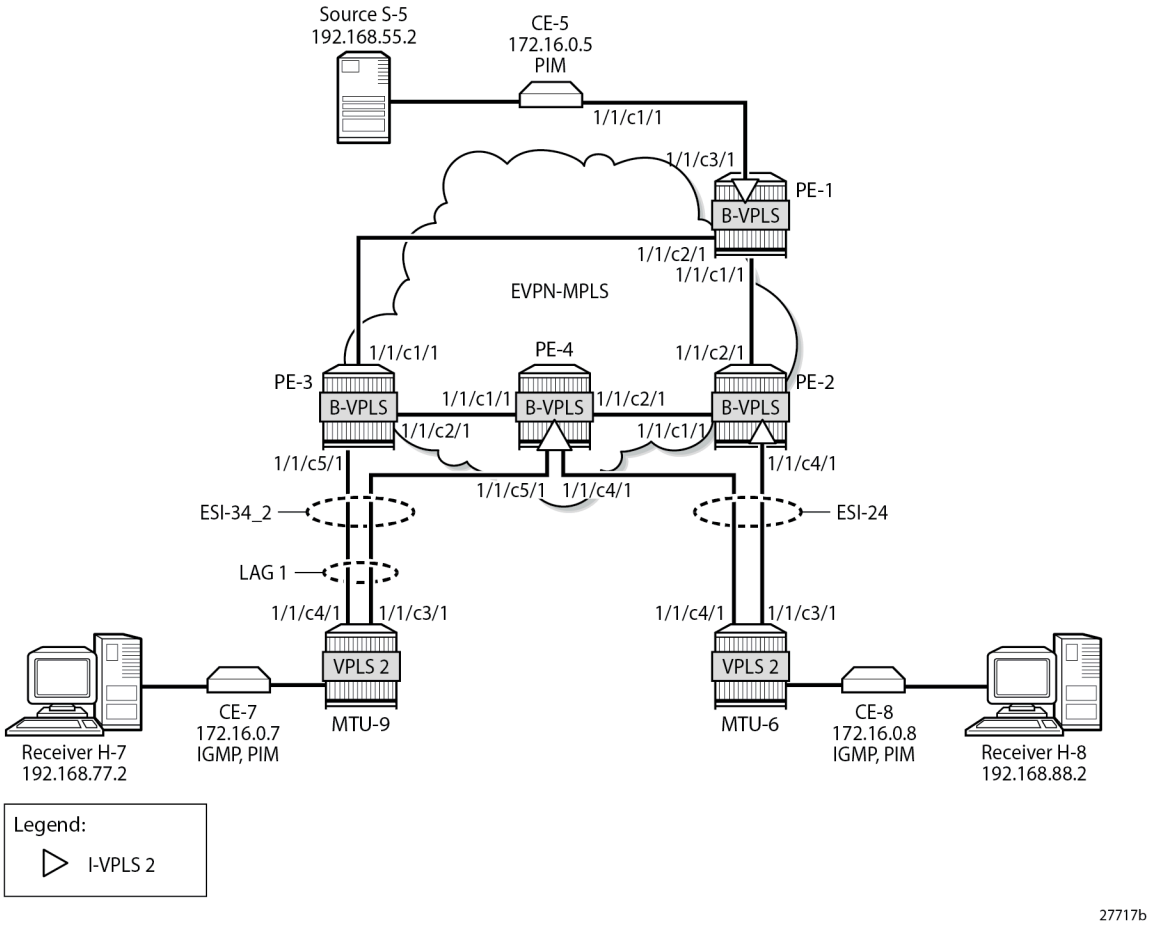
PBB-EVPN with MH – No PIM Snooping

Figure 284: Example Topology for PBB-EVPN with MH shows the example topology with CE-7 attached to MTU-9, which is connected to both PE-3 and PE-4 via LAG 1. Virtual ES (vES) ESI-34_2 is configured in all-active MH mode using LAG 1 for dot1q value 2. MTU-6 is connected to PE-2 and PE-4 with SDPs. These SDPs are associated with a single-active MH ES ESI-24.

Figure 284: Example Topology for PBB-EVPN with MH



The configuration of I-VPLS 2 is similar to the preceding configuration of I-VPLS 1 on all PEs.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active MH ES ESI-24, that is non-restrictive -after failover, it does not restore to the initial designated forwarder (DF) if available again; see chapter Preference-based and Non-revertive EVPN DF Election. The manually configured preference is 200 on PE-2, which is higher than preference 50 at PE-3, so PE-2 is the DF when no failover has occurred. Spoke-SDP 26:2 is associated with I-VPLS 2. The B-VPLS 100 remains unchanged and is not repeated here.

```
On PE-2:
configure
    service
        sdp 26 mpls create
            far-end 192.0.2.6
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-24" create
                    esi 01:00:00:00:00:24:00:00:00:01
```

```
                    source-bmac-lsb 24-02 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 200
                            exit
                        exit
                    exit
                    multi-homing single-active
                    sdp 26
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "I-VPLS 2" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            spoke-sdp 26:2 create
            exit
            no shutdown
        exit
    exit all
```

On PE-4, LAG 1 is configured in access mode with dot1q encapsulation on the port to MTU-9, as follows. The LAG configuration is similar on PE-3.

```
On PE-4:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/c5/1
        lacp active administrative-key 1 system-id 00:00:00:00:01:34
        no shutdown
    exit all
```

Single-active ES ESI-24 is configured on PE-4, together with a virtual ES ESI-34_2, which is an all-active MH virtual ES that applies to LAG 1 for I-VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 50 (which is lower than preference 200 on the remote peer in the ES). I-VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            no shutdown
        exit
        system
            bgp-evpn
                ethernet-segment "ESI-24" create
                    esi 01:00:00:00:00:24:00:00:00:01
                    source-bmac-lsb 24-04 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
```

```
                        mode manual
                        manual
                            preference non-revertive create
                                value 50
                            exit
                        exit
                    exit
                    multi-homing single-active
                    sdp 46
                    no shutdown
                exit
                ethernet-segment "ESI-34_2" virtual create
                    esi 01:00:00:00:00:34:02:00:00:01
                    source-bmac-lsb 34-34 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 50
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 2
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "I-VPLS 2" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-1:2 create
            exit
            spoke-sdp 46:2 create
            exit
            no shutdown
        exit
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            pbb
                use-es-bmac
            exit
        exit
    exit all
```

On PE-4, the source BMAC in the all-active MH ESI-34_2 is identical to the source BMAC on remote peer PE-3, but in the single-active MH ESI-24, the source BMAC must be different. Remote PEs might send traffic to the NDF PE based on the shared source BMAC, which is fine for all-active MH ESs, but not for single-active MH ESs.

The following service configuration on PE-3 includes an all-active virtual ES ESI-34_2 with preference 200, which makes PE-3 the DF for ESI-34_2 when no failover has occurred. After failover, PE-4 becomes DF, and it does not revert to PE-3 when available.

```
On PE-3:
configure
    service
```

```
        system
            bgp-evpn
                ethernet-segment "ESI-34_2" virtual create
                    esi 01:00:00:00:00:34:02:00:00:01
                    source-bmac-lsb 34-34 es-bmac-table-size 8
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 200
                            exit
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 2
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 2 name "I-VPLS 2" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-1:2 create
            exit

        exit
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            pbb
                use-es-bmac
            exit
        exit
    exit all
```

The following is the service configuration on MTU-6:

```
On MTU-6:
configure
    service
        sdp 62 mpls create
            far-end 192.0.2.2
            ldp
            no shutdown
        exit
        sdp 64 mpls create
            far-end 192.0.2.4
            ldp
            no shutdown
        exit
        vpls 2 name "VPLS 2" customer 1 create
            endpoint "x" create
            exit
            sap 1/2/c1/1:2 create
            exit
            spoke-sdp 62:2 endpoint "x" create
            exit
            spoke-sdp 64:2 endpoint "x" create
            exit
```

```
            no shutdown
        exit
    exit all
```

The following is the LAG configuration on MTU-9:

```
On MTU-9:
configure
    lag 1
        mode access
        encap-type dot1q
        port 1/1/c3/1
        port 1/1/c4/1
        lacp active administrative-key 32768
        no shutdown
    exit all
```

The configuration of VPLS 2 on MTU-9 is as follows:

```
On MTU-9:
configure
    service
        vpls 2 name "VPLS 2" customer 1 create
            sap lag-1:2 create
            exit
            sap 1/1/c1/1:2 create
            exit
            no shutdown
        exit all
```

For I-VPLS 2, PE-2 is the DF in ES ESI-24, as follows:

```
*A:PE-2# show service id 2 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                   Eth-Seg                           Status

===============================================================================
No vxlan instance entries
```

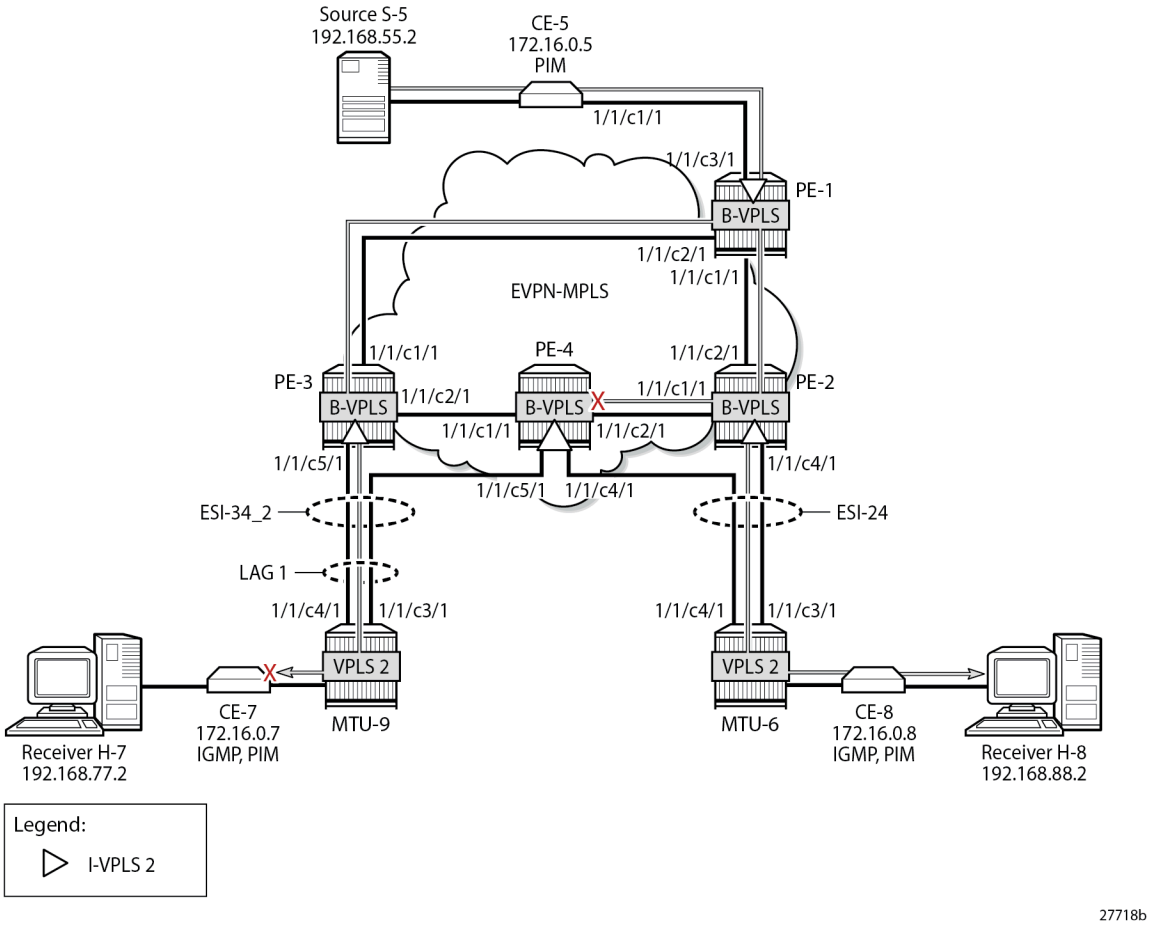
When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tunnel to all EVPN-MPLS destinations: PE-2, PE-3, and PE-4. PE-2 is the DF for ESI-24 and forwards the traffic to MTU-6, which forwards it to CE-8, where it is sent to the attached receiver H-8 that joined the multicast group. PE-3 is the DF for ESI-34_2 and sends the multicast stream to MTU-9, which forwards it to CE-7, where it is dropped because no attached receiver has joined the multicast group. PE-4 is the NDF for both ESs, so it does not forward the traffic to MTU-6 or MTU-9. Figure 285: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

Figure 285: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 Enabled

PIM snooping for IPv4 is enabled in I-VPLS 2 on all PEs with the following command:

```
On all PEs:
configure service vpls 2 pim-snooping
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
*A:PE-1# show service id 2 pim-snooping neighbor

===============================================================================
PIM Snooping Neighbors ipv4
===============================================================================
Port Id                 Nbr DR Prty     Up Time       Expiry Time     Hold Time
  Nbr Address
-------------------------------------------------------------------------------
SAP:1/1/c3/1:2          1               0d 00:00:59   0d 00:01:16     105
  172.16.0.5
```

```
b-EVPN-MPLS             1               0d 00:00:42   0d 00:01:33     105

===============================================================================
```

When H-7 and H-8 join the group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2 with four port IDs: the local SAP to CE-5 and the B-VPLS PBB-EVPN destinations, as follows:

```
*A:PE-1# show service id 2 mfib

===============================================================================

Furthermore, data-driven PIM state synchronization between PEs in an all-active MH ES allows the NDF PE-4 to build its MFIB, even when the NDF does not forward multicast traffic to the receivers. When the NDF has the MFIB information, the failover is faster and the loss of traffic is limited. For data-driven PIM state synchronization, the source BMAC must be identical within the ES, so it only works for all-active MH in PBB-EVPN, not for single-active MH. The MFIB on PE-4 contains the SAP from the all-active MH ESI-34_2, but not the spoke-SDP from the single-active MH ESI-24, as follows:

```
*A:PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2

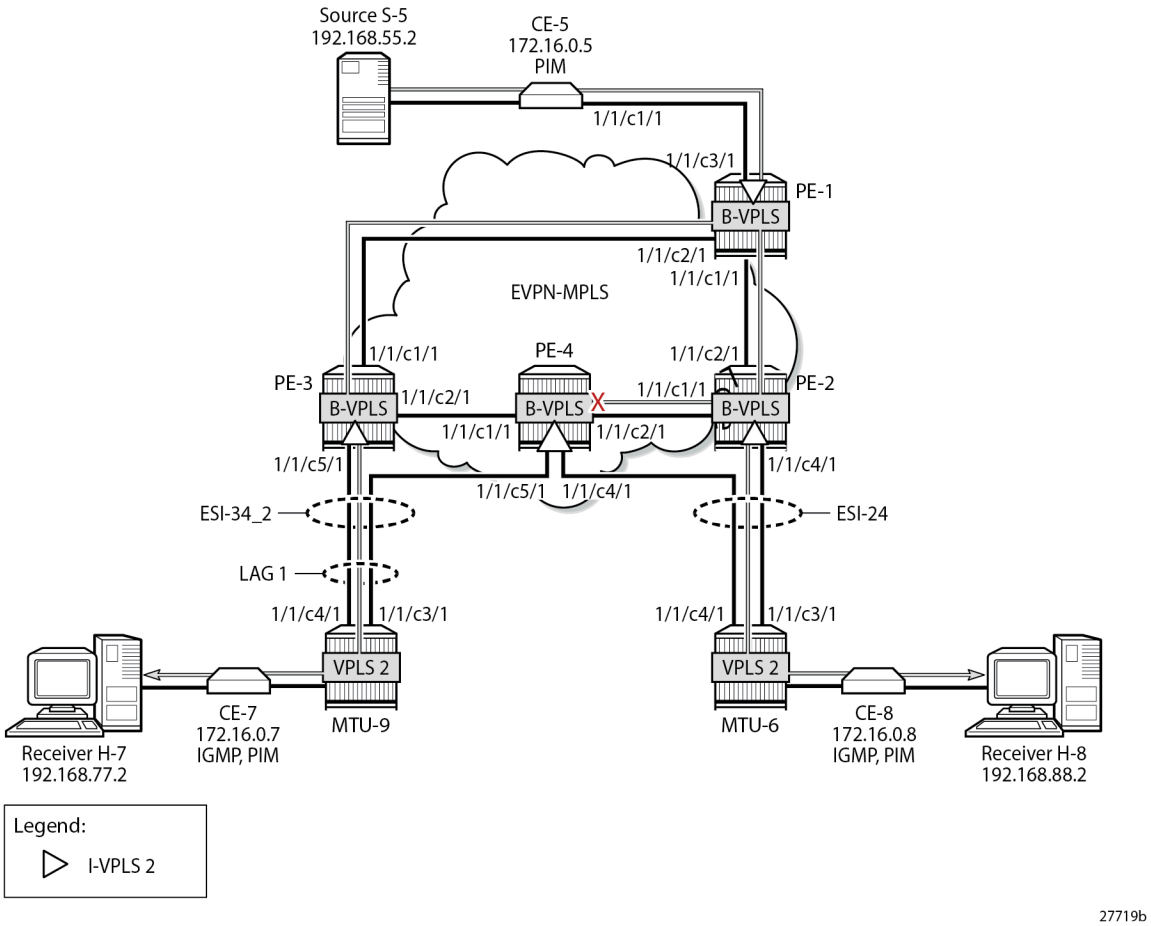
With the PIM snooping group information available on the NDF, the traffic loss is limited when the NDF PE-4 becomes the DF after failover. Data-driven PIM state synchronization does not store PIM states in a database, so the DF election in the ES should be configured as non-revertive, to prevent that when the preferred DF is restored after a failover, the system would revert to a DF that is unaware of the PIM state.

PE-4 is also NDF in the single-active MH ES ESI-24, but it received no PIM state synchronization information from DF PE-2. Data-driven PIM state synchronization is not supported for single-active MH in PBB-EVPN services, because it is not allowed to have two PEs in a single-active MH ES using the same source BMAC, with the potential risk of traffic sent by remote PEs to the NDF PE (based on it sending to the shared source BMAC) being dropped. However, for a faster failover in single-active MH, multi-chassis synchronization (MCS) can be configured, as described in the next section.

Figure 286: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined shows the multicast traffic flow when PIM snooping is enabled and both receivers H-7 and H-8 have joined the multicast group. All PEs receive the multicast traffic on the P2MP tunnel, but only DF PE-2 and DF PE-3 forward the multicast traffic to the MTUs, which forward the traffic to the CEs, where it is forwarded to the receivers.

Figure 286: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 with MCS

MCS of the IPv4 PIM snooping state for SAPs and spoke-SDPs can optionally be configured in the case of MH. MCS reduces the failover time when data-driven PIM state synchronization is not supported; for example, for single-active MH in PBB-EVPN services. The synchronization information is stored in an MCS synchronization DB. MCS is configured on PE-2, identifying the peer (PE-4), with PIM snooping for spoke-SDPs as MCS client application and the list of spoke-SDPs, as follows:

```
On PE-2:
configure
    redundancy
        multi-chassis
            peer 192.0.2.4 create
                sync
                    pim-snooping spoke-sdps
                    sdp 26 create
                        range 2-2 sync-tag "syncSA"
                    exit
                    no shutdown
                exit
                no shutdown
            exit all
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure
    redundancy
        multi-chassis
            peer 192.0.2.2 create
                sync
                    pim-snooping spoke-sdps
                    sdp 46 create
                        range 2-2 sync-tag "syncSA"
                    exit
                    no shutdown
                exit
                no shutdown
            exit all
```

When H-8 has joined the multicast group, the MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
*A:PE-2# tools dump redundancy multi-chassis sync-database detail

If no entries are present for an application, no detail will be displayed.

```

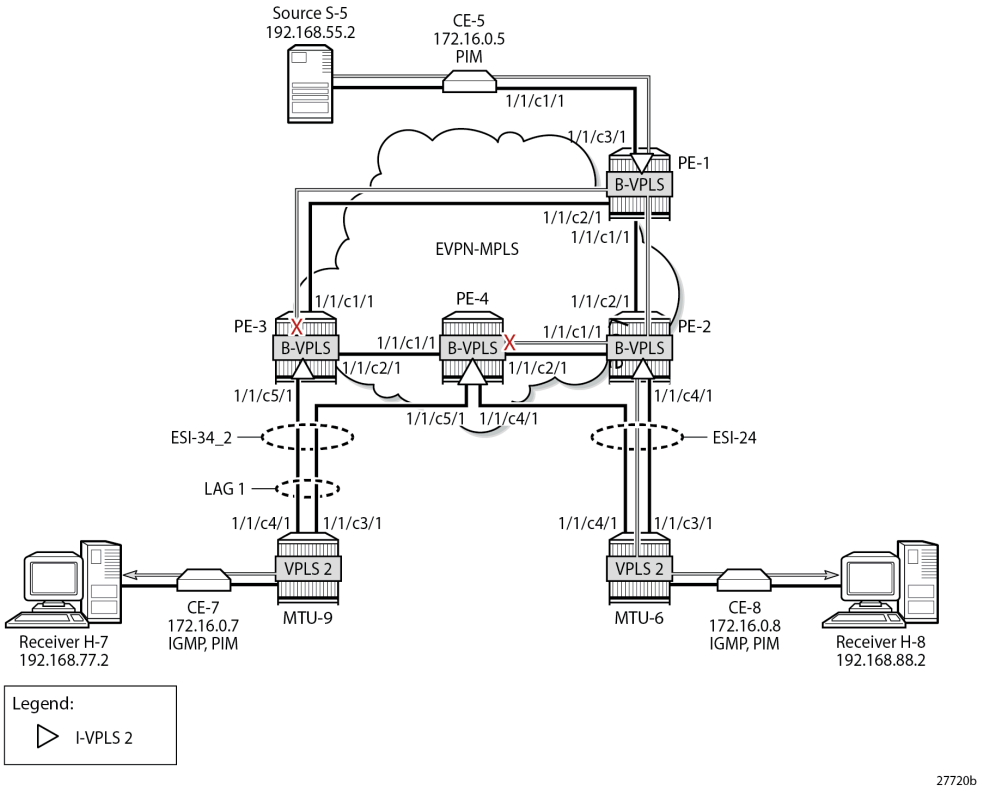
However, PE-4 remains the NDF for both ESs and does not forward any traffic from the B-VPLS EVPN-MPLS interface to the spoke-SDP. Figure 287: PBB-EVPN with MH and PIM Snooping – Receiver H-8 Joined shows the multicast traffic flow when PIM snooping is enabled and receiver H-8 has joined.

Figure 287: PBB-EVPN with MH and PIM Snooping – Receiver H-8 Joined



Failover

Figure 286: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined showed the multicast traffic flow when both H-7 and H-8 have joined the multicast group. PE-2 is the DF for ESI-24 and PE-4 is the DF for ESI-34_2. The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. Data-driven PIM state synchronization is used for all-active MH; MCS is configured for fast failover in the single-active MH ES ESI-24.

On MTU-6, SDP 62 is disabled, as follows:

```
On MTU-6:
configure service sdp 62 shutdown
```

On MTU-9, port 1/1/c3/1 toward PE-3 is disabled, as follows:

```
On MTU-9:
configure port 1/1/c3/1 shutdown
```

Log 99 on PE-3 shows that the DF state in ESI-34_2 changed to false:

```
184 2023/08/24 14:29:36.634 UTC MINOR: SVCMGR #2095 Base
"Ethernet Segment:ESI-34_2, ISID:2, Designated Forwarding state changed to:false"
```

PE-4 becomes the DF for both ESs, as follows:

```
*A:PE-4# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status

===============================================================================
```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. MTU-9 forwards the traffic to CE-7, which sends it to H-7. PE-3 drops the multicast traffic because LAG 1 is down because of the failure that was introduced at MTU-9 (port disabled).

Conclusion

PIM snooping reduces flooding of multicast traffic in L2 services and can be used in PBB-EVPN I-VPLSs in the same way as in I-VPLSs using B-VPLS without EVPN. PIM snooping can be used in all-active and single-active MH scenarios with data-driven state synchronization and MCS, respectively.

Preference-based and Non-revertive EVPN DF Election

This chapter provides information about Preference-based and Non-revertive EVPN DF Election.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R3, but the CLI in the current edition corresponds to SR OS Release 21.2.R2. Preference-based and non-revertive EVPN Designated Forwarder (DF) election is supported in SR OS Release 15.0.R1, and later. This mechanism works for Ethernet Segments (ESs) and virtual ESs (vESs).

Overview

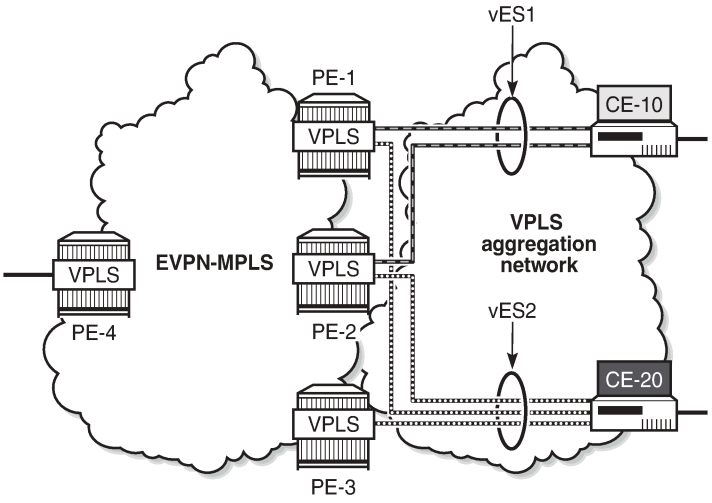
RFC 7432 defines the Designated Forwarder (DF) in (PBB-)EVPN networks as the PE that will forward the following packets to a multi-homed node:

- Broadcast, Unknown unicast, and Multicast (BUM) traffic in an all-active multi-homing Ethernet Segment (ES)
- BUM and unicast in a single-active multi-homing ES

For more information about vESs, see chapter Virtual Ethernet Segments.

Figure 289: Virtual Ethernet Segments shows a topology with two vESs.

Figure 289: Virtual Ethernet Segments

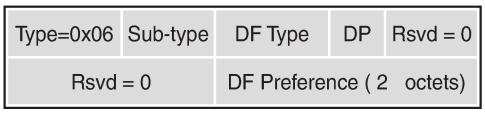


Taking the Ethernet VPN Identifier (EVI) or ISID and the number of PEs in the ES as input, the RFC 7432 service-carving algorithm elects the DF from the list of candidate PEs that advertise the ES identifier (ESI). While this algorithm provides an automated and fair DF distribution across services in the ES, it does not allow the operator to control what PE is the DF for which service. In addition, in case of a DF failure, when the former DF comes back up, a new DF switchover will cause unnecessary packet loss (this mode of operation is called revertive). SR OS implements *draft-ietf-bess-evpn-pref-df* to give more control to the operator on the DF election and avoid the revertive mode.

In SR OS, in addition to the automated service-carving, the DF election can also be controlled by configuring a preference manually. Also, it is possible to force an on-demand DF switchover without reconfiguring the PEs in the ES. Furthermore, the non-revertive option prevents an automatic switchover when a new active PE can preempt the existing DF PE. The non-revertive option avoids service impact when an ES comes back up.

Figure 290: BGP-EVPN extended community for DF election shows the BGP-EVPN extended community defined for DF election and the different values described in draft-ietf-bess-evpn-pref-df.

Figure 290: BGP-EVPN extended community for DF election



Type=0x06	Sub-type	DF Type	DP	Rsvd = 0
Rsvd = 0		DF Preference (2 octets)		

DP = Do not preempt (non-revertive)
DF = Designated forwarder
- Type 0 – Default, modulo-based DF election (RFC7432)
- Type 1 – Highest Random Weight (HRW) algorithm
- Type 2 – Preference algorithm

26787

The "Do not preempt" (DP) bit is set to enable the non-revertive option. When preference-based service carving is configured in the ES, DF type 2 is advertised along with a 2-byte preference value, which is 32767 by default.

Service carving can be configured in auto mode or manual mode. The preference can only be configured in manual mode.

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>service-carving# mode ?
  - mode {auto|manual|off}

 <auto|manual|off>    : auto|manual|off
```

When manual mode is enabled, the following parameters can be configured to control which PE will be elected as DF:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>service-carving# manual ?
  - manual

 [no] evi              - Configure EVI range (primary for non-preference based DF
                     election and lowest-preference for preference based DF election)
 [no] isid             - Configure ISID range (primary for non-preference based DF
                     election and lowest-preference for preference based DF election)
 [no] preference       + Configure DF preference election information
```

The EVI and ISID ranges configured in the service-carving context do not need to be consistent with any ranges configured for virtual ESs.

When preference is configured manually, a preference value can be provided along with the non-revertive option:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>service-carving>manual# preference ?
  - no preference
  - preference [create] [non-revertive]

 <create>              : keyword
 <non-revertive>       : keyword

      value            - Configure DF preference value
```

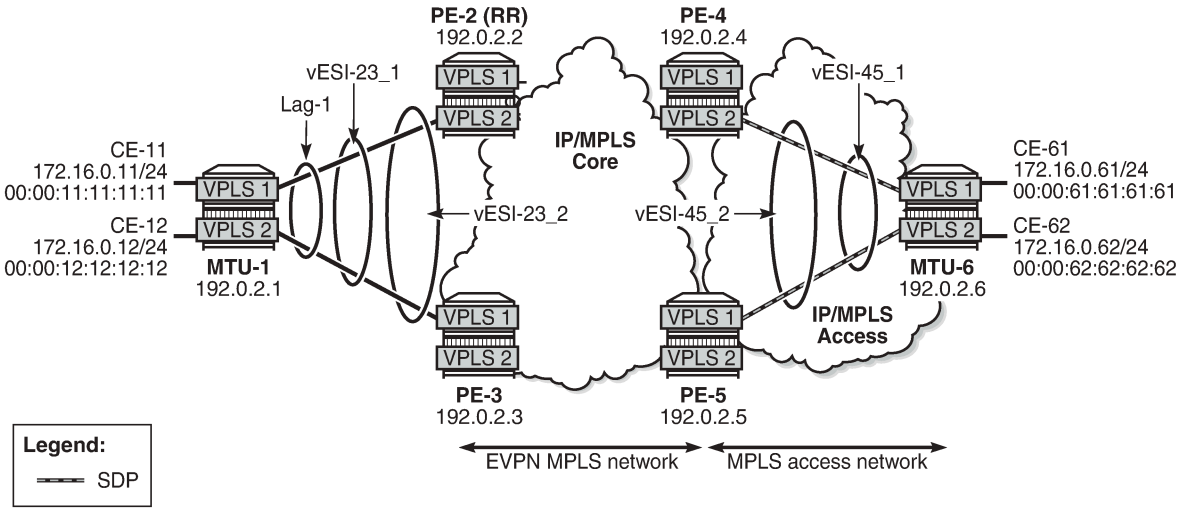
The preference-based EVPN DF election is as follows:

- By default, all SAPs and spoke-SDPs on the configured ES select the highest-preference PE as DF; however, when the EVI or ISID ranges are configured in the ES, the lowest-preference PE is selected.
- When the preference is equal, the DP bit is the tiebreaker: DP=1 wins over DP=0.
- For equal preference and DP, the PE IP address is the tiebreaker: the lowest IP address wins.

Configuration

Figure 291: Example topology with all-active and single-active vESs shows the example topology with six nodes. EVPN-MPLS is configured between the core PE nodes. All-active vESs are configured between PE-2 and PE-3 and single-active vESs are configured between PE-4 and PE-5.

Figure 291: Example topology with all-active and single-active vESs



The initial configuration includes:

- Cards, MDAs, ports
- LAG 1 between MTU-1, PE-2, PE-3
- Router interfaces
- IS-IS (alternatively, OSPF could be used)
- LDP

BGP is configured on the four core PEs with PE-2 as Route Reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
# on RR PE-2:
configure
    router
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

VPLS 1 and VPLS 2 are configured on each node. The PEs have EVPN-MPLS enabled. The configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:1.1 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 2 name "VPLS 2" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 2
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:2.1 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on the other PEs is similar; PE-4 and PE-5 have a spoke-SDP configured instead of a SAP. For an explanation of the configuration, see chapter EVPN for MPLS Tunnels.

Service carving: auto mode

On PE-2 and PE-3, the following all-active multi-homing vESs are configured:

```
# on PE-2, PE-3:
configure
```

```
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_1" virtual create
                    esi 01:00:00:00:00:23:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    qinq
                        s-tag-range 1
                    exit
                    no shutdown
                exit
                ethernet-segment "vESI-23_2" virtual create
                    esi 01:00:00:00:00:23:02:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    qinq
                        s-tag-range 2
                    exit
                    no shutdown
                exit
```

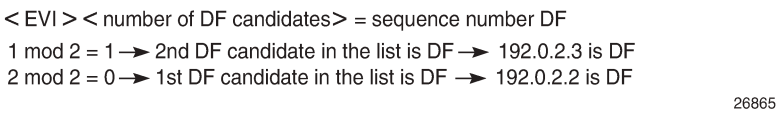
The service carving mode is set to **auto**, so the DF election is based on a modulo function of the EVI and the number of DF candidates. In the vES "vESI-23_1", there are two DF candidates, PE-2 and PE-3, listed in that order because PE-2 has the lower system IP address, as follows:

```
*A:PE-3# show service system bgp-evpn ethernet-segment name "vESI-23_1" all
| match "EVI Information" post-lines 20
EVI Information
===============================================================================
EVI                 SvcId               Actv Timer Rem      DF
-------------------------------------------------------------------------------
1                   1                   0                   yes
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================

-------------------------------------------------------------------------------
DF Candidate list
-------------------------------------------------------------------------------
EVI                                     DF Address
-------------------------------------------------------------------------------
1                                       192.0.2.2
1                                       192.0.2.3
-------------------------------------------------------------------------------
Number of entries: 2
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
```

The first DF candidate from the list will be selected when the result of the modulo function equals 0; the second DF candidate when the result equals 1. The calculation is as follows:

Figure 292: Calculation



The following shows that PE-2 is not the DF for VPLS 1, but it is the DF for VPLS 2:

```
*A:PE-2# show service id 1 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-1:1.1             vESI-23_1                       NDF
===============================================================================
No sdp entries
No vxlan instance entries
```

```
*A:PE-2# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-1:2.1             vESI-23_2                       DF
===============================================================================
No sdp entries
No vxlan instance entries
```

Instead of the preceding show commands, the following tools commands can be used:

```
*A:PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_1"  evi 1 df

[04/22/2021 15:20:08] Computed DF: 192.0.2.3 (Remote) (Boot Timer Expired: Yes)

*A:PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_2"  evi 2 df

[04/22/2021 15:20:08] Computed DF: 192.0.2.2 (This Node) (Boot Timer Expired: Yes)
```

Service carving: preference-based manual mode

To have more control, the vES can be configured in manual mode. The following reconfigures the vES "vESI-23_1" in manual mode, preference-based and revertive with preference 32767 (default) on PE-2 and 5000 on PE-3, whereas vES "vESI-23_2" is preference-based and non-revertive with preference 15000 on PE-2 and 20000 on PE-3.

An EVI range is configured for ES "vESI-23_2", but not for ES "vESI-23_1". When no EVI range is configured, the highest preference wins; for configured EVI ranges, the lowest preference wins. When there are no failures, PE-2 will be the DF for "vESI-23_1" (highest preference) and for "vESI-23_2" (lowest preference for configured EVI 2).

To modify the service-carving mode from auto to manual, the ES must be disabled first (shutdown). The following is configured on PE-2:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_1" virtual create
                    shutdown
                    service-carving
                        mode manual
                        manual
                            preference create
                            exit
                        exit
                    exit
                    no shutdown
                exit
                ethernet-segment "vESI-23_2" virtual create
                    shutdown
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 15000
                            exit
                            evi 2
                        exit
                    exit
                    no shutdown
                exit
```

The keyword **non-revertive** is added for vES "vESI-23_2", but not for vES "vESI-23_1".

The following is configured on PE-3:

```
# on PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_1" virtual create
                    shutdown
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 5000
                            exit
                        exit
                    exit
                    no shutdown
                exit
                ethernet-segment "vESI-23_2" virtual create
                    shutdown
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 20000
                            exit
                            evi 2
```

```
                    exit
                exit
                no shutdown
            exit
```

For the single-active multi-homing vESs on PE-4 and PE-5, the same preferences are configured manually. The ES configuration on PE-4 is as follows:

```
# on PE-4:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    esi 01:00:00:00:00:45:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                            exit
                        exit
                    exit
                    multi-homing single-active
                    sdp 46
                    vc-id-range 1
                    vc-id-range 500 to 501
                    no shutdown
                exit
                ethernet-segment "vESI-45_2" virtual create
                    esi 01:00:00:00:00:45:02:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference non-revertive create
                                value 15000
                            exit
                            evi 2
                        exit
                    exit
                    multi-homing single-active
                    sdp 46
                    vc-id-range 2
                    no shutdown
                exit
```

The ES configuration on PE-5 is as follows:

```
# on PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    esi 01:00:00:00:00:45:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            preference create
                                value 5000
```

```
                        exit
                    exit
                exit
                multi-homing single-active
                sdp 56
                vc-id-range 1
                vc-id-range 500 to 501
                no shutdown
            exit
            ethernet-segment "vESI-45_2" virtual create
                esi 01:00:00:00:00:45:02:00:00:01
                es-activation-timer 3
                service-carving
                    mode manual
                    manual
                        preference non-revertive create
                            value 20000
                        exit
                        evi 2
                    exit
                exit
                multi-homing single-active
                sdp 56
                vc-id-range 2
                no shutdown
            exit
```

The preference configuration must be consistent across the PEs in the ES (manual or auto), otherwise the system reverts to the modulo-based DF election.

With preference-based DF election configured with default preference value 32767 and revertive, PE-4 sends the following BGP-EVPN update to the RR PE-2. The **df-election** extended community shows the DP=0 (revertive) and DF preference 32767.

```
# on PE-4:

```

It is important to note that a router will prune a remote PE from the DF candidate list for an ES if it does not receive the corresponding Auto Discovery (AD) per-EVI and AD per-ES routes for that PE. A remote PE will not be shown in the DF Candidate list if its AD per-ES route is withdrawn. This is only true for EVPN. In PBB-EVPN, there are no AD routes, therefore the DF Candidate list is built out of the ES routes only.

DF election: higher preference prevails for non-configured EVI ranges

The PEs run the DF election per PE per EVI, and the elected DF for a service will activate the SAP/Spoke-SDP when the es-activation-timer expires. PE-4 is the DF in "vESI-45_1" used in VPLS 1, as follows.

The EVI is not configured in ES "vESI-45_1", so the higher preference prevails. The ES "vESI-45_1" has (default) preference 32767 on PE-4 (DF) and preference 5000 on PE-5 (Non-Designated Forwarder (NDF)).

```
*A:PE-4# show service id 1 ethernet-segment

===============================================================================
No vxlan instance entries
```

The preference value can be modified on the fly on an active ES without the need to disable the ES (shutdown). This allows the user to force a new DF for the ES for maintenance operations on the former DF or other reasons.

DF election: lowest preference prevails for configured EVI ranges

ES "vESI-45_2" is configured with EVI 2, so the lowest preference prevails. The admin preference value is 15000 on PE-4 and 20000 on PE-5. Both PE-4 and PE-5 are DF candidates, but PE-4 has the lowest preference, so it will be the DF, as follows:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2" all
| match "EVI Ranges" post-lines 30
EVI Ranges
-------------------------------------------------------------------------------
From                                  To

-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
```

DF election: DP prevails when preferences are equal

In the preceding example, PE-4 was the DF in ES "vESI-45_1" because of the higher preference. The ES configuration is modified on PE-5 as follows: the preference is set to the default, which is equal to the preference on PE-4, and the non-revertive (do not preempt - DP) option enabled. The **non-revertive** keyword can only be configured at creation time. An attempt to modify this behavior afterward results in the following error message:

```
*A:PE-5>config>service>system>bgp-evpn>eth-seg>service-carving>manual#
preference non-revertive create
MINOR: CLI revertive mode can be specified only at creation time.
```

The existing preference first needs to be removed, which can only be done when the ES is disabled (shutdown); if not, the following error is raised:

```
*A:PE-5>config>service>system>bgp-evpn>eth-seg>service-carving>manual#
 no preference
MINOR: SVCMGR #8074 Cannot delete preference - ethernet-segment not shut
```

The service carving in the ES is configured with default preference and non-revertive option, as follows:

```
# on PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    ahutdown
                    service-carving
                        mode manual
                        manual
                            no preference
                            preference non-revertive create
                            exit
                        exit
                    exit
                    no shutdown
```

The ES configuration on PE-4 remains unchanged, so the behavior is revertive. PE-4 and PE-5 have the same preference (default 32767), but PE-5 is non-revertive and becomes the DF, as follows:

```
*A:PE-5# show service id 1 ethernet-segment
No sap entries
```

```
===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
56:1                 vESI-45_1                        DF
===============================================================================
No vxlan instance entries
```

DF election: lowest IP address prevails when preferences and DP are equal

The vES configuration on PE-4 is modified by enabling the non-revertive option (after deleting the existing preference configuration), as follows:

```
# on PE-4:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    shutdown
                    service-carving
                        mode manual
                        manual
                            no preference
                            preference non-revertive create
                            exit
                        exit
                    exit
                    no shutdown
```

PE-4 and PE-5 have an equal preference (32767) and non-revertive behavior. The tiebreaker for the DF selection is the IP address. PE-4 has the lower IP address and becomes the DF, as follows:

```
*A:PE-4# show service id 1 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
46:1                 vESI-45_1                        DF
===============================================================================
No vxlan instance entries
```

Service-carving configuration must be consistent

When the service carving on one of the PEs in the ES is configured in auto mode while one of the other PEs in the ES is configured in manual mode, the system reverts to modulo-based auto mode. The configuration of ES "vESI-45_1" remains unchanged on PE-4, but is modified on PE-5, as follows:

```
*A:PE-5#
configure
    service
        system
```

```
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    shutdown
                    service-carving
                        manual no preference
                        mode auto
                    exit
                    no shutdown
```

ES "vESI-45_1" will operate in auto mode on PE-4 and on PE-5. The following **show** command on PE-4 shows that the ES is configured in manual mode, but operates in auto mode:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"

===============================================================================
```

For the remainder of the chapter, the vES configuration for "vESI-45_1" on PE-4 and PE-5 is restored to the initial settings: the behavior is revertive; PE-4 has the default preference, and PE-5 has preference 5000. When there are no failures, PE-4 is the DF, because it has a higher preference.

Revertive behavior

When SDP 64 fails on MTU-6, PE-4 becomes the NDF for ES "vESI-45_1" and PE-5 will be the DF instead, as follows. The failure is emulated by disabling the SDP on MTU-6.

```
# on MTU-6:
configure
    service
        sdp 64
            shutdown
```

When the PE is not a candidate DF because it cannot be used, the operational preference value equals 0, as follows:

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"
                                          | match "DF Pref Election" post-lines 6
DF Pref Election Information
-------------------------------------------------------------------------------

-------------------------------------------------------------------------------
Preference     Preference     Last Admin Change        Oper Pref      Do No
Mode           Value                                   Value          Preempt
-------------------------------------------------------------------------------
revertive      5000           04/22/2021 15:43:19      5000           Disabled
-------------------------------------------------------------------------------
```

When the failure is restored, the system reverts and PE-4 will again be the DF for "vESI-45_1" in VPLS 1.

```
# on MTU-6:
configure
    service
        sdp 64
            no shutdown
```

```
*A:PE-4# show service id 1 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                   Eth-Seg                         Status
-------------------------------------------------------------------------------

===============================================================================
No vxlan instance entries
```

Non-revertive behavior

When no failures have occurred, PE-4 is the DF for "vESI-45_2" because the lowest preference prevails for the configured EVI 2. The preference of PE-4 is 15000, which is lower than PE-5's preference of 20000.

```
*A:PE-4# show service id 2 ethernet-segment

No sap entries
===============================================================================
SDP Ethernet-Segment Information
===============================================================================

===============================================================================
No vxlan instance entries
```

A failure is simulated as follows:

```
# on MTU-6:
configure
    service
```

```
        sdp 64
            shutdown
```

When SDP 64 on MTU-6 goes down, SDP 46 on PE-4 goes down which brings the vESs down on PE-4. PE-4 is no longer the DF for "vESI-45_2" and not even a DF candidate anymore. The operational preference value is 0.

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2"
                                    | match "DF Pref Election" post-lines 6

-------------------------------------------------------------------------------
```

When the SDP is restored, the DF does not revert even though the list of DF candidates contains both PE-4 and PE-5. The preference mode is non-revertive; therefore, the DP bit has been set. PE-4 will not become the DF, as follows:

```
# on MTU-6:
configure
    service
        sdp 64
            no shutdown
```

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2" evi 2

```

The operational preference value on NDF PE-4 equals the preference value on DF PE-5, as follows. In this example, EVI 2 is included in the configured EVI range, so the lowest preference wins. To avoid the system reverting to the lower preference of 15000, the operational preference is raised to the value of 20000, which equals the preference of the current DF PE-5.

```
*A:PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2"
                                      | match "DF Pref Election" post-lines 6

-------------------------------------------------------------------------------
non-revertive  15000          04/22/2021 15:21:19      20000          Disabled
-------------------------------------------------------------------------------
```

PE-4 checks its own administrative preference and compares it with the one of the Highest-PE and Lowest-PE that have DP=1 in their ES routes.

- The Highest-PE is the PE with higher preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.
- The Lowest-PE is the PE with lower preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.

Depending on this comparison, PE-4 will send the ES route with a preference and DP that may be different from its administrative values.

- If PE-4's preference value is higher than the Highest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Highest-PE's and DP=0.
- If PE-4's preference value is lower than the Lowest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Lowest-PE's and DP=0.
- If PE-4's preference value is neither higher nor lower than the Highest-PE's or the Lowest-PE's respectively, PE-4 will send the ES route with its administrative [preference,DP]=[15000,1].

In this example, NDF PE-4 sends operational preference 20000 and DP=0, because its admin preference value was lower than the Lowest-PE's (PE-5), as follows:

```
# on PE-4:
195 2021/04/22 15:47:32.487 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 71
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:

               ESI: 01:00:00:00:00:45:02:00:00:01, IP-Len: 4 Orig-IP-Addr: 192.0.2.4
```

```
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        df-election::DF-Type:Preference/DP:0/DF-Preference:20000/AC:1
        target:00:00:00:00:45:02
"
```

With equal operational preference, the current DF PE-5 sends DP=1, which is preferred over DP=0. The following output shows the BGP extended community of the ES routes for "vESI-45_2" in the RIB-In (received ES route from PE-5) and RIB-Out (sent ES route) on PE-4:

```
*A:PE-4# show router bgp routes evpn eth-seg hunt | match "target:00:00:00:00:45:02" pre-lines
 2
Community      :                                      # in RIB-In
                  df-election::DF-Type:Preference/DP:1/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
Community      :                                      # in RIB-Out
                  df-election::DF-Type:Preference/DP:0/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
```

Either of the following events cause PE-4 to re-advertise its admin preference 15000 and DP=1:

- DF PE-5 withdraws its ES route.
- The admin preference for ES "vESI-45_2" on DF PE-5 is modified by configuration to a value preferred over PE-4's admin preference; in this case, to a value lower than 15000.

The admin preference value can be modified on ES "vESI-45_2" on DF PE-5 on the fly, as follows:

```
# on PE-5:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_2" virtual create
                    service-carving
                        manual
                            preference non-revertive create
                                value 10000
                            exit
```

The preference value 10000 is lower than 15000 and, therefore, preferred when the lowest preference wins. PE-5 remains DF, but now there is no need to modify the preference of PE-4, because the system does not need to revert. Therefore, PE-4 can send the admin preference 15000 and configured DP=1, as follows:

```
# on PE-4:
198 2021/04/22 15:55:30.795 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 71
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0
              ESI: 01:00:00:00:00:45:02:00:00:01, IP-Len: 4 Orig-IP-Addr: 192.0.2.4
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
```

```
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        df-election::DF-Type:Preference/DP:1/DF-Preference:15000/AC:1
        target:00:00:00:00:45:02
"
```

Conclusion

Preference-based DF election offers more control over the DF Election and applies to regular ESs and vESs, either in single-active or in all-active multi-homing mode, in VPLS, I-VPLS, or Epipe services. The DF election is by default revertive, but when preference mode is chosen, it can be configured as non-revertive to reduce service impact.

Proxy-ARP/ND MAC List for Dynamic Entries

This chapter provides information about Proxy-ARP/ND MAC List for Dynamic Entries.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the CLI in the current edition is based on SR OS Release 21.2.R2. Proxy-Address Resolution Protocol/Neighbor Discovery (proxy-ARP/ND) MAC list for dynamic entries is supported in SR OS Release 15.0.R1, and later.

Overview

In some EVPN networks, the use of static proxy-ARP/ND entries is preferred to dynamically learned entries. For example, this is the case with some Internet eXchange Points (IXPs) that use EVPN and proxy-ARP/ND technologies. The MAC address in the static entry can be a MAC address from a list of n preregistered MAC addresses. The advantage is that—in case of a router or card failure—the hardware can be replaced, and no reconfiguration is required if the new MAC address is within a list of allowed MAC addresses.

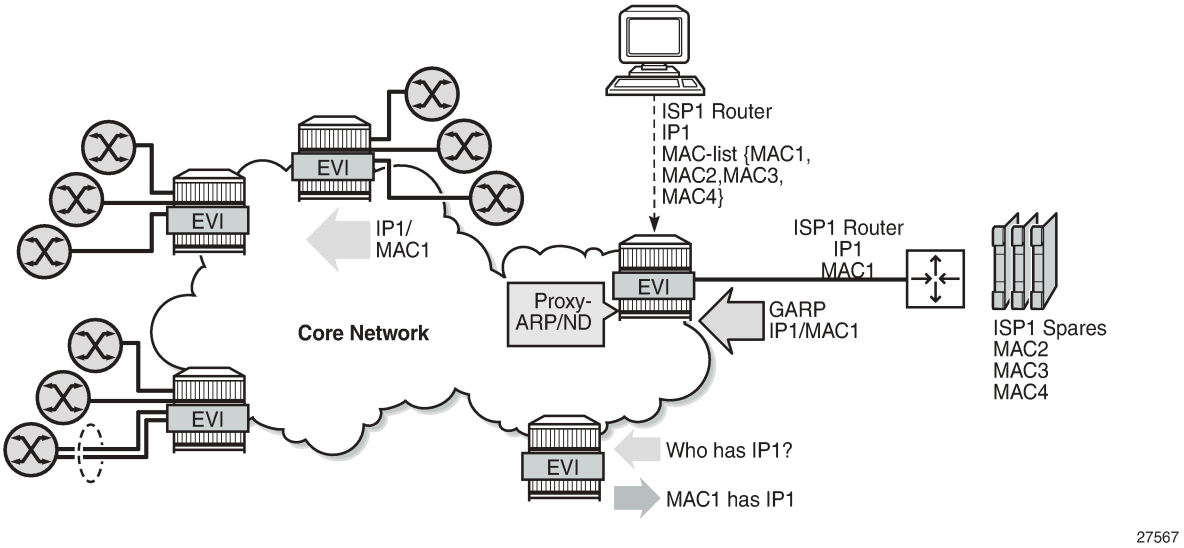
In SR OS, these allow lists are called MAC lists. The associated proxy-ARP/ND entries will not be added upon configuration, but dynamically through a resolve procedure. This follows *draft-ietf-bess-evpn-proxy-arp-nd*.

- When the dynamic proxy-ARP/ND IP address with its associated MAC list is configured, the system sends a resolve message to all its non-EVPN peers.
- The resolve message is an ARP request for IPv4, or a Neighbor Solicitation (NS) message for IPv6.
- The resolve message is sent at a configurable interval between 1 and 60 minutes; the default is 5 minutes.
- The system keeps sending resolve messages until a dynamic entry is created for the proxy-ARP/ND IP address. This entry is only created when two conditions are met:
  - An ARP/Gratuitous Address Resolution Protocol (GARP) or Neighbor Advertisement (NA) is received for the configured IP address.
  - The associated MAC address belongs to the MAC list configured for the IP address. If the MAC list is empty or not configured, the system will never create an entry for the IP address.

When the dynamic proxy-ARP/ND IP entry is created, the system advertises an EVPN-MAC update to its EVPN peers. The sticky bit will be set depending on how the corresponding MAC address is learned. If the MAC address is learned on a SAP/SDP-binding with Auto-Learn MAC Protect (ALMP) enabled, the EVPN-MAC route will be advertised as static.

Figure 293: IXP with proxy-ARP/ND MAC list for dynamic entries shows an example of an IXP network that uses proxy-ARP/ND and a MAC list.

Figure 293: IXP with proxy-ARP/ND MAC list for dynamic entries



The ISP1 router with IP1 and MAC1 is connected to a PE in the core network that has proxy-ARP/ND enabled and a list of allowed MAC addresses. This MAC list contains four MAC addresses: MAC1 (for the hardware that is currently in use) and three MAC addresses for spares: MAC2, MAC3, and MAC4. The proxy-ARP/ND table will be populated as follows:

- The PE floods a resolve message for the configured IP address for proxy-ARP/ND to its non-EVPN peers.
- The ISP1 router that is connected to the network sends a GARP or ARP Reply message with IP1 and MAC1 that will be snooped by the PE.
- The PE checks whether IP1 is configured as a dynamic proxy-ARP/ND entry and MAC1 is in the MAC list assigned to proxy-ARP/ND entry IP1.
  - If true, the IP1/MAC1 entry is created in the proxy-ARP/ND table and advertised in EVPN.
  - If the GARP message contains MAC5, which is not in the MAC allow list, no proxy-ARP/ND entry is created, and IP/MAC is not advertised. If **no garp-flood-evpn** is configured, the GARP containing MAC5 will be discarded.

If after the proxy-ARP/ND creation, the corresponding MAC address is flushed from the Forwarding Database (FDB), the entry goes inactive. After the age-time, the inactive entry will age out and the resolve process will restart.

MAC lists are configured with the following command:

```
*A:PE-2>config>service>proxy-arp-nd# mac-list ?
  - mac-list <name> [create]
  - no mac-list <name>

 <name>                : [32 chars max]
 <create>              : keyword
```

```
 [no] mac             - Configure proxy ARP/ND MAC address information
```

The MAC list contains the allowed MAC addresses and can be associated in one or more services with a proxy-ARP/ND IP address. A MAC list is associated with dynamic proxy-ARP IP 1.1.1.1 with the following command:

```
*A:PE-2>config>service>vpls>proxy-arp# dynamic 1.1.1.1 create ?
  - dynamic <ip-address> [create]
  - no dynamic <ip-address>

 <ip-address>         : a.b.c.d
 <create>             : keyword

 [no] mac-list        - Configure MAC list
      resolve         - Configure address resolve time in minutes
```

The configuration for proxy-ND is similar:

```
*A:PE-2>config>service>vpls>proxy-nd# dynamic 2001:db8::99 create ?
  - dynamic <ipv6-address> [create]
  - no dynamic <ipv6-address>

 <ipv6-address>       : x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                        x:x:x:x:x:x:d.d.d.d
                        x - [0..FFFF]H
                        d - [0..255]D
 <create>             : keyword

 [no] mac-list        - Configure MAC list
      resolve         - Configure address resolve time in minutes
```

- The MAC list can be associated with multiple configured dynamic IP addresses:
  - In different services
  - In the same service, for proxy-ARP and proxy-ND
- An empty MAC list can be configured and applied, but no proxy-ARP/ND entries will be created when the PE receives a GARP message containing a MAC address that is not in the allow list.
- MAC lists can be modified at any time: MAC addresses can be added or removed even when the MAC lists are associated with configured dynamic IP addresses. If the MAC list changes, all the IP addresses associated with that MAC list will delete the proxy entries and restart the resolve process.

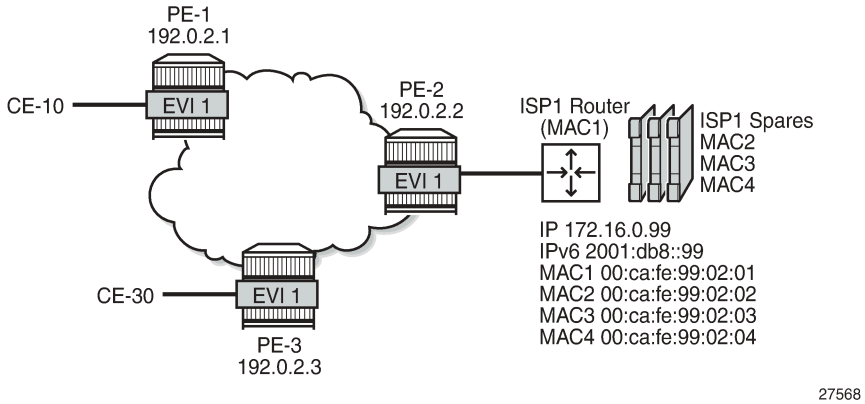
An existing dynamic proxy-ARP/ND entry IP1/MAC1 can be overridden when the system receives a GARP/ARP/NA for IP1 with another MAC address from the MAC list (IP1/MAC2). The system will first send a confirm message to check whether the old IP1/MAC1 is still reachable. Only when there is no answer, the entry IP1/MAC1 is replaced by IP1/MAC2. The existing dup-detect and confirm procedures are only applied for MAC address changes within the MAC list.

An existing dynamic proxy-ARP/ND entry IP1/MAC1 will be deleted when the system receives a GARP/ARP/NA IP1/MAC5 with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message will be discarded and the resolve procedure is restarted.

Configuration

Figure 294: Example topology shows the example topology with three PEs. ISP router 1 is connected to PE-2. MAC1 is used; MAC2, MAC3, and MAC4 correspond to spares.

Figure 294: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between the PEs (alternatively, OSPF can be used)
- LDP between the PEs

BGP is enabled between the PEs for address family EVPN. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
            exit
        exit
```

VPLS 1 is configured on PE-2 as follows. The configuration on the other PEs is similar.

```
# on PE-2:
configure
    service
        vpls 1 name "EVI-1" customer 1 create
            bgp
            exit
```

```
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/2/1:1 create
                no shutdown
            exit
            sap 1/2/1:3 create
                no shutdown
            exit
            no shutdown
        exit
```

MAC list

The following MAC lists are configured on PE-2: ISP1 is an empty list; ISP2 is a MAC list containing four MAC addresses.

```
# on PE-2:
configure
    service
        proxy-arp-nd
            mac-list "ISP1" create
            exit
            mac-list "ISP2" create
                mac 00:ca:fe:99:02:01
                mac 00:ca:fe:99:02:02
                mac 00:ca:fe:99:02:03
                mac 00:ca:fe:99:02:04
            exit
```

The following command shows the configured MAC lists on PE-2, with the number of MAC addresses and the number of associations. None of the MAC lists has been associated with a proxy-ARP/ND IP entry, so the number of associations is zero.

```
*A:PE-2# show service proxy-arp-nd mac-list

===============================================================================

```

MAC list associated with proxy-ARP/ND in VPLS

MAC lists can be associated with one or more services. An empty MAC list—such as ISP1—can be associated, but it is impossible to associate a non-existing MAC list with a service. The following error is raised when attempting to associate the non-existing MAC list ISP3 with proxy-ARP IP 1.1.1.1 in VPLS 1 on PE-2:

```
*A:PE-2>config>service>vpls>proxy-arp>dynamic$ mac-list "ISP3"
MINOR: SVCMGR #8372 Cannot modify dynamic configured proxy arp entry - invalid mac-list
```

MAC list ISP2 is associated with proxy-ARP IP 172.16.0.99 and with proxy-ND IP 2001:db8::99 in VPLS 1 on PE-2, as follows:

```
# on PE-2:
configure
    service
        vpls "EVI-1"
            proxy-arp
                dynamic-arp-populate
                dynamic 172.16.0.99 create
                    mac-list ISP2
                    resolve 1
                exit
                no shutdown
            exit
            proxy-nd
                dynamic-nd-populate
                evpn-nd-advertise router
                dynamic 2001:db8::99 create
                    mac-list ISP2
                exit
                no shutdown
            exit
```

For proxy-ARP IP 172.16.0.99, the resolve interval is 1 minute, which is the minimum; for proxy-ND IP 2001:db::99, the resolve interval is the default of 5 minutes. In scaled environments, Nokia recommends using the default interval, or even configuring a longer interval. The proxy-ARP and proxy-ND tables can be populated with dynamic entries (**dynamic-arp-populate**/**dynamic-nd-populate**).

The following command shows all associations for MAC list ISP2: two associations are defined in VPLS 1: one for IP address 172.16.0.99 and another for IP address 2001:db8::99.

```
*A:PE-2# show service proxy-arp-nd mac-list "ISP2" associations

===============================================================================
MAC List Associations
===============================================================================
Service Id                    IP Addr
-------------------------------------------------------------------------------
1                             172.16.0.99
1                             2001:db8::99
-------------------------------------------------------------------------------
Number of Entries: 2
===============================================================================
```

Different dynamic proxy-ARP/ND entries

A distinction is made between regular dynamic entries and configured dynamic entries:

- No IP address needs to be configured for regular dynamic proxy-ARP/ND entries. What only needs to be configured, is the option **dynamic-arp-populate**/**dynamic-nd-populate**.
- IP address and MAC list need to be defined for configured proxy-ARP/ND entries.

Configured dynamic entries can override static and regular dynamic entries.

Regular dynamic proxy-ARP/ND entries can override configured dynamic entries.

EVPN entries cannot override configured dynamic entries, even though they can override regular dynamic entries.

Likewise, static entries can override regular dynamic entries, but they cannot override dynamic configured entries. The following error is raised when attempting to configure a static proxy-ARP entry for IP 172.16.0.99, which has already been configured as dynamic and associated with a MAC list.

```
*A:PE-2>config>service>vpls>proxy-arp# static 172.16.0.99 aa:bb:cc:99:02:02
MINOR: SVCMGR #8011 Cannot create static proxy arp entry - Dynamic configured entry exists
```

Debugging

Debugging for both proxy-ARP/ND IP entries is enabled on PE-2 as follows:

```
# on PE-2:
debug
    service
        id 1
            proxy-arp ip 172.16.0.99
            proxy-nd ip 2001:db8::99
        exit
    exit
exit
```

When the dynamic proxy-ARP IP 172.16.0.99 is configured with MAC list "ISP2", PE-2 floods a resolve message—in this case, an ARP request—to all its EVPN peers. Router ISP1 replies. PE-2 advertises an EVPN-MAC update to its EVPN peers PE-1 and PE-3. PE-2 adds a dynamic proxy-ARP entry for

172.16.0.99 with MAC address 00:ca:fe:99:02:01. Router ISP1 sends a GARP message. The following messages are logged:

```
49 2021/05/10 14:32:18.859 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 flood resolve"

Tools command to trigger resolve procedure

The following tools command can be used to force the system to send a resolve message to its non-EVPN peers. The **force** option will trigger the resolve process even for existing entries in the proxy-ARP/ND table.

```
*A:PE-2# tools perform service id 1 proxy-arp dynamic-resolve ?
```

```
  - dynamic-resolve all [force]
  - dynamic-resolve <ip-address> [force]

 <ip-address>         : a.b.c.d
 <all>                : keyword
 <force>              : keyword
```

```
*A:PE-2# tools perform service id 1 proxy-nd dynamic-resolve ?
  - dynamic-resolve all [force]
  - dynamic-resolve <ipv6-address> [force]

 <ipv6-address>       : x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                        x:x:x:x:x:x:d.d.d.d
                        x - [0..FFFF]H
                        d - [0..255]D
 <all>                : keyword
 <force>              : keyword
```

Some examples:

```
*A:PE-2# tools perform service id 1 proxy-arp dynamic-resolve 172.16.0.99
*A:PE-2# tools perform service id 1 proxy-arp dynamic-resolve 172.16.0.99 force
*A:PE-2# tools perform service id 1 proxy-arp dynamic-resolve all

By default, aging is disabled, and the entries remain in the inactive status until the MAC address is learned again. However, if aging is enabled, the inactive proxy-ARP/ND entry will age out. After the entry is deleted, the system sends a resolve message. When the ISP1 router replies, the entry is created again in the proxy-ARP/ND table. The age time is configured in seconds with the following command:

```
*A:PE-2>config>service>vpls>proxy-arp# age-time ?
  - age-time <seconds>
  - no age-time

 <seconds>            : [60..86400]
```

```
# on PE-2:
configure
    service
        vpls "EVI-1"
            proxy-arp
                age-time 60
```

The following debug messages for proxy ARP IP 172.16.0.99 show that an EVPN-MAC withdraw message is sent (when the MAC address is flushed from the FDB) and—after time-out—the proxy-ARP entry is deleted. PE-2 sends a resolve message to all its non-EVPN peers. Router ISP1 replies and the proxy-ARP entry is created again; an EVPN-MAC update is sent to the EVPN peers. Similar debug messages occur for proxy-ND.

```

MAC address replacement

When the system receives a GARP/ARP/NA for the same IP address, but with another MAC address from the MAC list, it will first send a confirm message to ensure that the old MAC address is not used anymore for the IP address. If the existing proxy-ARP/ND entry is IP1/MAC1 and a GARP/ARP/NA message is received for IP1/MAC4, the system sends an EVPN-MAC withdraw message for MAC1 and changes MAC1 to MAC4 for proxy-ARP/ND IP1, but the status is pending (pendng), as follows:

```
*A:PE-2# show service id 1 proxy-arp detail | match 172.16.0.99 pre-lines 6
                                                                post-lines 3

```

The system sends a confirm message (unicast ARP request) for the old entry IP1/MAC1 to ensure that there is no duplication. When there is no reply from MAC1, there is no duplication. An EVPN-MAC route is advertised for MAC4. The status of the proxy-ARP entry IP1/MAC4 changes to active. The following debug messages are logged for proxy-ARP 172.16.0.99:

```
113 2021/05/10 14:37:34.570 UTC MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 mac: 00:ca:fe:99:02:01 evpn withdraw"

-------------------------------------------------------------------------------
172.16.0.99         00:ca:fe:99:02:04   dyn       active    05/10/2021 14:37:37
-------------------------------------------------------------------------------
Number of entries : 1
===============================================================================
```

The mechanism is similar for proxy-ND.

The behavior is different when the system receives a GARP/ARP/NA for the IP address with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message is discarded and the proxy-ARP/ND entry deleted. The resolve procedure gets restarted.

Modified MAC list

MAC lists can be modified at any time, as follows:

```
# on PE-2:
configure
    service
        proxy-arp-nd
            mac-list "ISP2" create
                mac 00:ca:fe:99:02:05
```

```
*A:PE-2# show service proxy-arp-nd mac-list "ISP2"

===============================================================================
MAC List MAC Addr Information
===============================================================================

```

Conclusion

MAC lists can be associated with configured dynamic proxy-ARP/ND IP addresses. The actual proxy entries will only be created after a GARP/ARP/NA message is received for the IP address and one of the MAC addresses from the MAC list.

This tool complements the SR OS EVPN proxy-ARP/ND solution for providers present at IXPs.

Shortest Path Bridging for MAC

This chapter describes advanced shortest path bridging for MAC configurations.

Topics in this chapter include:

Applicability

Shortest Path Bridging for MAC (SPBM) is supported in SR OS Release 10.0.R4, or later. SPB Static MAC, static backbone-service instance identifiers (ISIDs) and ISID policies for SPB are supported in SR OS Release 11.0.R4, or later. This chapter was initially written for SR OS Release 11.0.R4, but the CLI in the current edition is based on SR OS Release 21.2.R1.

Overview

SPB enables a next generation control plane for Provider Backbone Bridges (PBB) and PBB-VPLS that adds the stability and efficiency of link state to unicast and multicast services (Epipes and I-VPLSs). In addition, SPBM provides resiliency, load balancing and multicast optimization without the need for any other control plane in the B-VPLS (for example, there is no need for spanning tree, or G.8032, or Multiple MAC Registration Protocol (MMRP)).

SPBM exploits the complete knowledge of backbone addressing, which is a key consequence of the PBB hierarchy, by advertising and distributing the backbone MAC addresses (BMACs) through a link-state protocol, namely IS-IS. An immediate effect of this is that the old "flood-and-learn" can at last be turned off in the backbone and every B-VPLS node in the network will know what destination BMAC addresses are expected and valid. As a result of that, receiving an unknown unicast BMAC on a B-VPLS SAP/PW is indicative of an error, whereupon the frame is discarded (due to the Reverse Path Forwarding Check (RPFC) performed in SPBM) instead of flooded. Furthermore, SPBM allows condensing all the relevant information distribution (unicast and multicast) into a single control protocol: IS-IS.

SPBM can be easily enabled on the existing B-VPLS instances being used for multiplexing I-VPLS/Epipe services, providing the following benefits:

- Per-service flood containment (for I-VPLS services) without the need for an additional protocol such as MMRP.
- Loop avoidance in the B-VPLS domain without the need for MSTP or other technologies.
- No unknown BMAC flooding in the B-VPLS domain.
- No need for MAC notification mechanisms or vMEPs in the B-VPLS to update the B-VPLS forwarding databases (FDBs) (vMEPs can still be configured though for OAM purposes).

Some other characteristics of the SPB implementation in the SR OS are:

- The SR OS SPB implementation always uses Multi-Topology (MT) topology instance zero. However, up to four logical instances (that is, SPB instances in different B-VPLS services) are supported if different topologies are required for different services.
- Area addresses are not used and SPB is assumed to be a single area. SPB must be consistently configured on nodes in the system. SPB regions information and IS-IS hello logic that detect mismatched configuration are not supported. IS-IS area is always zero.
- SPB uses all-intermediate systems 09-00-2B-00-00-05 destination MAC to communicate.
- SPB Source ID is always zero.
- SPB uses a separate instance of IS-IS from the base IP IS-IS. IS-IS for SPB is configured in the SPB context under the B-VPLS component. Up to four ISIS-SPB instances are supported, where the instance identifier can be any number between 1024 and 2047. The instance number is not in TLVs.
- Two Equal Cost Tree (ECT) algorithms (IEEE 802.1aq) per SPB instance are supported: low-path-id and high-path-id algorithms.
- SPB link state protocol data units (link state packets) contain BMACs, ISIDs (for multicast services) and link and metric information for an IS-IS database.
  - Epipe ISIDs are not distributed in SR OS SPB allowing high scalability of PBB Epipes.
  - I-VPLS ISIDs are distributed in SR OS SPB and the respective multicast group addresses (composed of PBB-OUI plus ISID) are automatically populated in a manner that provides automatic pruning of multicast to the subset of the multicast tree that supports an I-VPLS with a common ISID. This replaces the function of MMRP and is more efficient than MMRP.
- Multiple ISIS-SPB adjacencies between two nodes are not supported as per the IEEE 802.1aq standard specification. If multiple links between two nodes exist, LAG must be used.

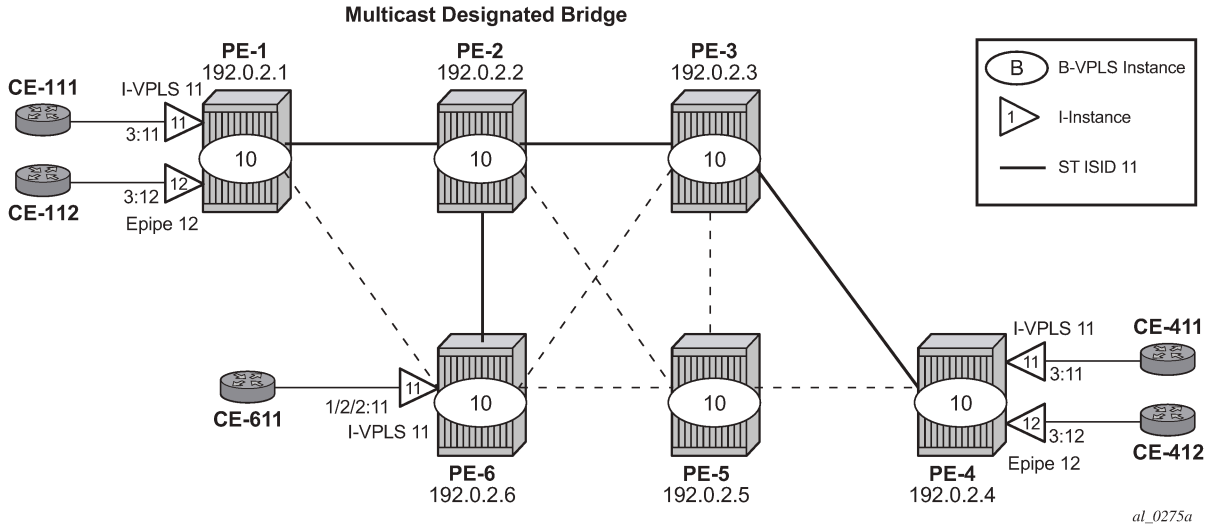
Configuration

This section describes the configuration of SPBM on SR OS as well as the available troubleshooting commands.

Basic SPBM configuration

Figure 295: Basic SPBM topology shows the topology used as an example of a basic SPBM configuration.

Figure 295: Basic SPBM topology



Assume the following protocols and objects are configured beforehand:

- The six PEs shown in Figure 295: Basic SPBM topology are running IS-IS for the global routing table with all the interfaces being Level-2.
- LDP is used as the MPLS protocol to signal transport tunnel labels.
- LDP SDPs are configured among the six PEs, as shown in Figure 295: Basic SPBM topology (dashed lines and bold lines among PEs).

Once the network infrastructure is properly running, the actual service configuration can be carried out. In the example, B-VPLS 10 will provide backbone connectivity for the services I-VPLS 11 and Epipe 12.

The SPBM configuration is only relevant to the B-VPLS instance and can be added to an existing B-VPLS, assuming that such a B-VPLS does not contain any non-SPB-compatible configuration parameters. The following parameters are not supported in SPB-enabled B-VPLS instances:

- Mesh SDPs (only SAPs or spoke-SDPs are supported in SPB-enabled B-VPLS)
- Spanning Tree Protocol (STP)
- Split-Horizon Groups
- Non-conditional Static-MACs (configured under SAP/spoke-SDPs, see the Static BMACs and static ISIDs configuration section)
- G.8032
- Propagate-mac-flush and send-flush-on-failure
- Maximum number of MACs (max-nbr-mac-addr)
- Bridge Protocol Data Unit (BPDU) translation
- Layer 2 Protocol Termination (L2PT)
- MAC-pinning
- Oper-groups
- MAC-move

- Any BGP, BGP auto-discovery (BGP-AD), or BGP virtual private LAN services (BGP-VPLS) parameters
- Endpoints
- Local/remote age
- MAC notification
- MAC protect
- Multiple MAC Registration Protocol (MMRP)
- Provider tunnel
- Temporary flooding

Assuming all the parameters mentioned are not configured in the B-VPLS (B-VPLS 10 in the example), SPBM can be enabled. The SPBM parameters are all configured in the **config>service>vpls(b-vpls)>spb** and **config>service>vpls(b-vpls)>spoke-sdp/sap>spb** contexts:

```
*A:PE-1# configure service vpls 10 spb ?
  - no spb
  - spb [<isis-instance>] [fid <fid>] [create]

 <isis-instance>      : [1024..2047]
 <fid>                : [1..4095]

      level           + Configure SPB level information
 [no] lsp-lifetime    - Configure LSP lifetime
 [no] lsp-refresh-in* - Configure LSP refresh interval
 [no] overload        - Configure the local router so that it appears to be overloaded
 [no] overload-on-bo* - Configure the local router so that it appears to be overloaded
                        at boot up
 [no] shutdown        - Administratively enable or disable the operation of ISIS
      timers          + Configure ISIS timers
```

```
*A:PE-1# configure service vpls 10 spb timers ?
  - timers

 [no] lsp-wait        -  [no] spf-wait        -
```

```
*A:PE-1# configure service vpls 10 spoke-sdp 12:10 spb ?
  - no spb
  - spb [create]

 <create>             : keyword

      level           + Configure SPB level information
 [no] lsp-pacing-int* - Configure the interval for sending LSPs from the interface
 [no] retransmit-int* - Configure the minimum interval between LSP packets
                        retransmission for the given interface
 [no] shutdown        - Administratively Enable/disable the interface
```

```
*A:PE-1# configure service vpls 10 spoke-sdp 12:10 spb level 1 ?
  - level <[1..1]>

 [no] hello-interval  - Configure hello-interval for this interface
 [no] hello-multipli* - Configure hello-multiplier for this level
 [no] metric          - Configure IS-IS interface metric for IPv4 unicast
```

The parameters configured in the **spb** context refer to the SPB IS-IS and they should be configured following the same considerations as for the IS-IS base instance:

- spb [<isis-instance>] [fid <fid>] [create]
  - <isis-instance> identifies the SPB IS-IS process. Up to four different IS-IS SPB processes can be run in a system (range 1024 to 2047).
  - forwarding identifier <fid> identifies the standard SPBM B-VID which is signaled in IS-IS with each advertised BMAC. Each B-VPLS has a single configurable FID.
- spb>lsp-lifetime <seconds> : [350..65535]
- spb>lsp-refresh-interval <seconds> : [150..65535]
- spb>overload [timeout <seconds>] : [60..1800]
- spb>overload-on-boot [timeout <seconds>] : [60..1800]
- spb>timers>lsp-wait <lsp-wait> [<lsp-initial-wait> [<lsp-second-wait>]]
  - <lsp-wait> : [10..120000] in milliseconds
  - <lsp-initial-wait> : [10..100000] in milliseconds
  - <lsp-second-wait> : [10..100000] in milliseconds
- spb>timers>spf-wait <spf-wait> [<spf-initial-wait> [<second-wait>]]
  - <spf-wait> : [10..120000] in milliseconds
  - <spf-initial-wait> : [10..100000] in milliseconds
  - <second-wait> : [10..100000] in milliseconds
- spoke-sdp/sap>spb>lsp-pacing-interval <milli-seconds> : [0..65535]
  - spoke-sdp/sap>spb>retransmit-interval <seconds> : [1..65535]
  - spoke-sdp/sap>spb>level 1>hello-interval <seconds> : [1..20000]
  - spoke-sdp/sap>spb>level 1>hello-multiplier <multiplier> : [2..100]

In the same way, lsp-wait (initial-wait) and spf-wait (initial-wait) can be tuned in the base router IS-IS instance to minimize the convergence time (to 0 and 10 respectively), the equivalent SPB IS-IS parameters should also be adjusted so that failover time is minimized at the service level.

The following parameters are specific to SPBM (note that only IS-IS level 1 is supported for SPB):

- spb>level 1>bridge-priority <bridge-priority> : [0..15]
  - This parameter will influence the election of the multicast designated bridge through which all the Single Trees (STs) for the multicast traffic will be established. The default value will be lowered on that node where the multicast designated bridge function is desired, normally because that node is the best connected node. In the example, PE-2 is the multicast designated bridge for B-VPLS 10 and therefore, PE-2 will be the root of the STs for the I-VPLS instances in that B-VPLS. Default value = 8.
- spb>level 1>ect-algorithm fid-range <fid-range> {low-path-id|high-path-id}
  - This command defines the ECT algorithm used and the FIDs assigned. Two algorithms are supported: low-path-id and high-path-id. They can provide the required path diversity for an efficient load balancing in the B-VPLS. Default = fid-range 1-4095 low-path-id
- spb>level 1>forwarding-tree-topology unicast {spf|st}

  - This command configures the type of tree that will be used for unicast traffic: shortest path tree or single tree. The multicast traffic (that encapsulated I-VPLS Broadcast, Unknown unicast, and Multicast (BUM) traffic always uses the ST path. Using SPF for unicast traffic can produce some packet re-ordering for unicast traffic compared to BUM traffic because different trees are used, therefore, when the B-VPLS transports I-VPLS traffic and the unicast and multicast trees do not follow the same path, it is recommended to use ST paths for unicast and multicast. Default value = spf.

- spoke-sdp/sap>spb>level 1>metric <ipv4-metric> : [1..16777215]
  - This command configures the metric for each SPB interface (spoke-SDP or SAP). This value helps influence the SPF calculation in order to pick a certain path for the traffic to a remote system BMAC.When the SPB link metric advertised by two peers is different, the maximum value is chosen according to the RFC 6329. Default metric = 10.

As an example, the following CLI output shows the relevant configuration of PE-1 and PE-2 (the multicast designated bridge). SPB has to be created and enabled at B-VPLS service level first and then created and enabled under each and every SAP/spoke-SDP in the B-VPLS. Non-SPB-enabled SAPs/spoke-SDPs can exist in the SPB B-VPLS only if conditional static-MACs are configured for them (see the Static BMACs and static ISIDs configuration section). As for regular B-VPLS services, the service MTU has to be changed from the default value (1500) to a number 18 bytes greater than the I-VPLS service MTU in order to allow for the PBB encapsulation.

```

```

As discussed, the **bridge-priority** will influence the election of the multicast designated bridge. By making PE-2's bridge-priority zero, it ensures that PE-2 becomes the root of all the STs for B-VPLS 10 as long as the priority for the rest of the PEs is larger than zero. In case of a tie, the PE owning the lowest system BMAC will be elected as multicast designated bridge. Figure 295: Basic SPBM topology shows the ST for I-VPLS 11 (see a thicker continuous line representing the ST). PE-2 is the root of the ST tree.

```
# on PE-2:
configure

            no shutdown
        exit
        no shutdown
    exit
```

The rest of the nodes will be configured accordingly. SPB instance 1024 will set up Shortest Path First (SPF) trees for unicast traffic and a Single Tree (ST) per ISID with PE-2 as the root bridge (because it has the lowest bridge priority 0 configured) for BUM traffic. The ECT algorithm chosen for the B-VPLS FID (10) is the low-path-id (default one).

Once SPBM is configured on all the six nodes, the six system BMACs and the ISID 11 will be advertised by SPB IS-IS.

The following show commands can help understand the IS-IS configuration for SPB 1024 and the BMACs populated by IS-IS:

- **show service id 10 spb base**: provides the SPB configuration and parameters for a particular SPB B-VPLS.

```
*A:PE-1# show service id 10 spb base

It can be seen that the unicast (SPF) tree and the multicast (ST) tree differ with respect to PE-6.

The following commands help check the unicast and multicast topology for B-VPLS 10:

- **show service id 10 spb routes** provides a detailed view of the unicast and multicast routes computed by SPF. As shown in the following command, the SPB unicast and multicast routes match on PE-2 because this node is the multicast designated bridge. Unicast and multicast routes will differ on most other nodes.

```
*A:PE-2# show service id 10 spb routes

SPB multicast trees (STs) are pruned for each particular I-VPLS ISID, based on the advertisement of I-VPLS ISIDs in SPB IS-IS by each individual PE. Multicast B-VPLS traffic not belonging to any particular I-VPLS follows the default tree. The default tree is an ST for the B-VPLS which is not pruned and therefore reaches all the PE nodes in the B-VPLS. For instance, Ethernet-CFM CCM messages sent from vMEPs

configured on the SPB B-VPLS will use the default tree. The default tree does not consume MFIB entries and can be checked in each node through the use of the following command:

```
*A:PE-5# tools dump service id 10 spb default-multicast-list
saps : { }
spoke-sdps : { 52:10 }
```

PE-5 is not part of the tree for I-VPLS 11. However, as with any SPB node part of B-VPLS 10, PE-5 is part of the default tree. Refer to Configuration of ISID policies in SPB B-VPLS to see more use cases for the default tree.

The following tools commands allow the operator to easily see the forwarding path (unicast and multicast) followed by the traffic to a remote node, with the aggregate metric from the source.

```
*A:PE-1# tools dump service id 10 spb fid 10 forwarding-path destination PE-4 forwarding-tree
 unicast

Hop  BridgeId                Metric From Src
0    PE-1                    0
1    PE-2                    10
2    PE-3                    20
3    PE-4                    30
```

```
*A:PE-1# tools dump service id 10 spb fid 10 forwarding-path destination PE-4 forwarding-tree
 multicast

Hop  BridgeId                Metric From Src
0    PE-1                    0
1    PE-2                    10
2    PE-3                    20
3    PE-4                    30
```

In large networks or networks where IP multicast, PBB, and PBB-SPB services coexist, the data plane MFIB entries is a hardware resource that should be periodically checked. The **tools dump service vpls-mfib-stats** command shows the total number of hardware MFIB entries (in this case, 40959 entries) and the entries being used by IP multicast or PBB (MMRP or SPB) (in this case, 16383 entries). The **tools dump service vpls-pbb-mfib-stats** shows the breakdown between MFIB entries populated by MMRP, SPB, or by EVPN, and the individual limits, system-wide, and per service:

```
*A:PE-2# tools dump service vpls-mfib-stats

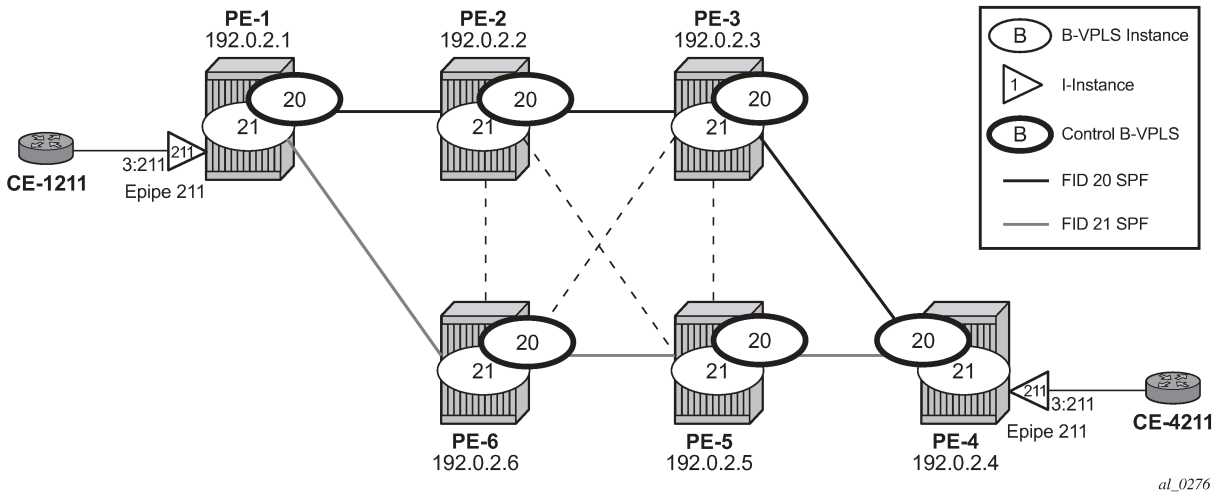
Control and user B-VPLS configuration

The SR OS implementation of SPB allows a single SPB IS-IS instance to control the paths and FDBs of many B-VPLS instances. This is done by using the control B-VPLS, user B-VPLS, and fate-sharing concepts.

The control B-VPLS will be SPB-enabled and configured with all the related SPB IS-IS parameters. Although the control B-VPLS might or might not have I-VPLS/Epipes directly attached, it must be configured on all the nodes where SPB forwarding is expected to be active. SPB uses the logical instance and a Forwarding ID (FID) to identify SPB locally on the node. That FID must be consistently configured on all the nodes where the B-VPLS exists. User B-VPLS are other instances of B-VPLS that are usually configured to separate the traffic for manageability reasons, QoS, or ECT different treatment.

Figure 296: Control and user B-VPLS example topology illustrates the control B-VPLS (B-VPLS 20) and user B-VPLS (B-VPLS 21) concept. In this example, there is only one user B-VPLS, but there might be many B-VPLSs sharing fate with the same control B-VPLS. The control B-VPLS and the user B-VPLS must share the same topology and both B-VPLSs must share exactly the same interfaces. The user B-VPLS, which is linked to the control B-VPLS by its FID, follows—that is, inherits the state of—the control B-VPLS, but may use a different ECT path in case of equal metric paths, like in this example: FID 20, that is, the control B-VPLS, follows the low-path-id ECT, whereas FID 21, for example, the user B-VPLS, follows the high-path-id ECT.

Figure 296: Control and user B-VPLS example topology



The configurations of B-VPLSs 20 and 21, on PE-1 and PE-2, are as follows. The **spbm-control-vpls 20 fid 21** command in B-VPLS 21 associates FID 21 to the user B-VPLS and links the B-VPLS to its control B-VPLS 20.

```
# on PE-1:
configure

            no shutdown
        exit
```

If there is a mismatch between the topology of a user B-VPLS and its control B-VPLS, only the user B-VPLS links and nodes that are in common with the control B-VPLS will function.

User B-VPLS instances supporting only unicast services (PBB-Epipes) may share the FID with the other B-VPLS (control or user). This is a configuration shortcut that reduces the LSP advertisement size for B-VPLS services but results in the same separation for forwarding between the B-VPLS services. In the case of PBB-Epipes, only BMACs are advertised per FID, but BMACs are populated per B-VPLS in the FIB. If I-VPLS services are to be supported on a B-VPLS, that B-VPLS must have an independent FID.

Although user B-VPLS 21 does not have any SPB setting (other than the **spbm-control-vpls**), the spoke-SDPs use the same SDPs as the parent control B-VPLS 20. The **show service id <user b-vpls> spb fate-sharing** command shows the control spoke-SDP/SAPs that control the user spoke-SDP/SAPs.

```

SPBM access resiliency configuration

The following example shows how to configure an I-VPLS or Epipe attached to an SPB-enabled B-VPLS when access resiliency is used.

Multi-Chassis LAG (MC-LAG) is the only resiliency mechanism supported for PBB-Epipes. The MC-LAG active node will advertise the MC-LAG BMAC (or SAP BMAC) in SPB IS-IS. In case of failure, when the standby node takes over, it will advertise the MC-LAG SAP BMAC. Without SPB, the MC-LAG solution for PBB-Epipe required the use of MAC notification and periodic MAC notification. SPB provides a faster and more efficient solution without the need for any extra MAC notification mechanism. In the example described in this section, Epipe 31 uses MC-LAG access resiliency to get connected to the B-VPLS 30 on nodes PE-2 and PE-6.

As far as I-VPLS access resiliency is concerned, the same mechanisms supported for regular B-VPLS are supported for SPB-enabled B-VPLS, except for G.8032. A very important aspect of the I-VPLS resiliency is a proper MAC flush propagation when there is a failure at the I-VPLS access links.

If the SPB-enabled B-VPLS uses B-SAPs for its connectivity to the backbone, there is no MAC flush propagation (because there is no TLDP). In this case, if MC-LAG is used and there is an MC-LAG

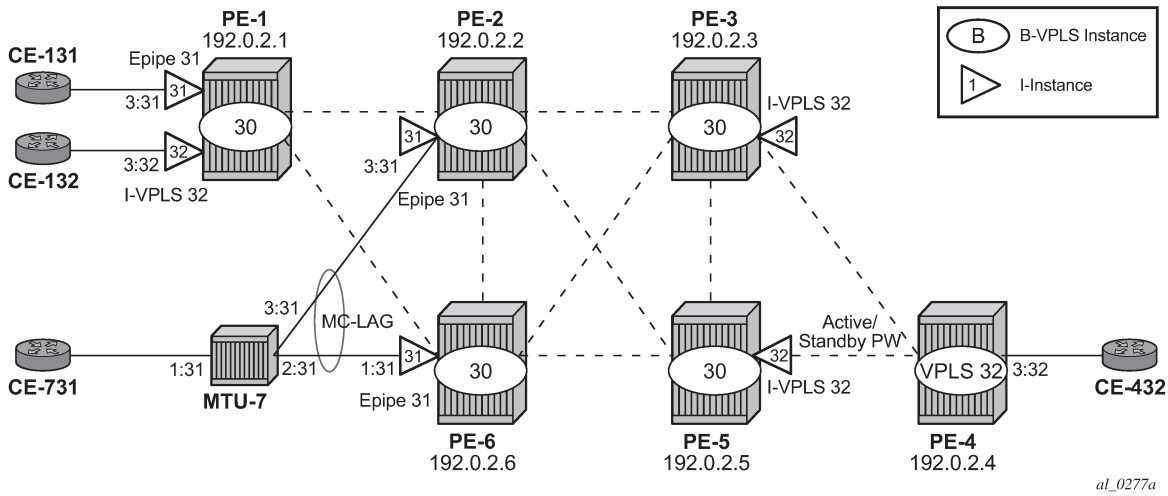
switchover, the new active chassis will keep using the same source BMAC, such as the SAP BMAC, and it will advertise it in the B-VPLS domain so that the remote FDBs can be properly updated. No MAC flush is required in this case.

When the B-VPLS uses spoke-SDPs for its backbone connectivity, the traditional LDP MAC flush propagation mechanisms and commands can be used as follows:

- **send-flush-on-failure** works as expected when SPB is used at the B-VPLS. When configured, a flush-all-from-me event is triggered upon a SAP or spoke-SDP failure in the I-VPLS.
- **send-bvpls-flush** works as expected when SPB is used at the B-VPLS. Two variants are configurable: all-from-me/all-but-mine. Any I-VPLS SAP/spoke-SDP failure is propagated to the I-VPLS on the peers to flush their respective customer MACs (CMACs). It works only in conjunction with send-flush-on-failure configuration on I-VPLS. The associated ISID list is passed along with the LDP MAC flush message, which is flushed/retained according to the **all-from-me**/**all-but-me** flag.
- **send-flush-on-bvpls-failure** works as expected when SPB is used at the B-VPLS. A local B-VPLS failure is propagated to the I-VPLS, which then triggers a LDP MAC flush if it has any spoke SDP on it.
- **propagate-mac-flush-from-bvpls** does not work when SPB is used at the B-VPLS (because failures within the B-VPLS are handled by SPB) and its configuration is blocked.

In the example described later in this section, I-VPLS 32 uses active/standby spoke-SDP resiliency to get connected to the B-VPLS 30 on nodes PE-3 and PE-5.

Figure 297: Access resiliency example topology



As an example of MC-LAG connectivity, the Epipe 31 configuration is shown. Just like for regular PBB-VPLS, a SAP BMAC is used as source BMAC for the Epipe traffic from PE-2/PE-6 to PE-1. A SAP BMAC is a virtual BMAC formed from the configured source BMAC plus the MC-LAG LACP-key (if configured this way) and owned by the MC-LAG active chassis.

The following CLI output shows the configuration of MC-LAG as well as the generation of the SAP BMAC. Once it is properly configured and the MC-LAG and Epipe are up and running, SPB IS-IS will distribute the SAP BMAC throughout the B-VPLS, as it does for the system BMACs and OAM vMEP MACs. In this example, PE-2 is the MC-LAG active node, therefore the SAP BMAC for Epipe 31 is generated from PE-2.

                no shutdown
            exit
            no shutdown
        exit
        vpls 32 name "IVPLS32" customer 1 i-vpls create
            send-flush-on-failure
            pbb
                backbone-vpls 30
                exit
                send-flush-on-bvpls-failure
                send-bvpls-flush all-from-me
            exit
            spoke-sdp 34:32 create
                no shutdown
            exit
            no shutdown
        exit
```

As discussed, **send-flush-on-failure** and **send-bvpls-flush all-from-me** are configured in the I-VPLS. When the active spoke-SDP goes down on PE-3, a flush-all-from-me message will be propagated through the backbone and will flush the corresponding CMACs associated to the I-VPLS 32 in node PE-1. MAC flush-all-from-me messages are automatically propagated in the core up to the remote I-VPLS 32 on node PE-1 (there is no need for any propagate-mac-flush in the intermediate nodes). The **send-flush-on-bvpls-failure** command works as expected. The command **propagate-mac-flush-from-bvpls** is never used when the B-VPLS is SPB-enabled (the command is not allowed).

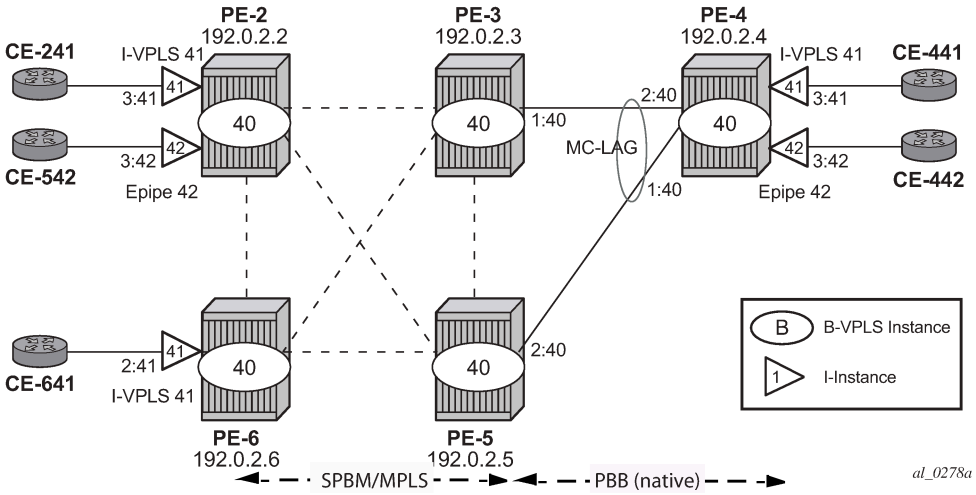
Static BMACs and static ISIDs configuration

SR OS supports the interworking between SPB-enabled B-VPLS and non-SPB B-VPLS instances. SPB networks can be connected to non-SPB capable nodes, for example third party vendor PBB switches or 7210 SAS nodes. This is possible through the use of conditional static BMACs and static ISIDs on the nodes doing the interworking function. Conditional static BMACs and static ISIDs can be associated to non-SPB B-VPLS SAPs or spoke-SDPs.

The following example shows an SPB-enabled B-VPLS (40) on nodes PE-2, PE-6, PE-3, and PE-5. Node PE-4 supports PBB, but not SPB and it is connected by a MC-LAG to nodes PE-3 and PE-5. Services I-VPLS 41 and Epipe 42 have endpoints on node PE-4. In this example, nodes PE-3 and PE-5 are acting

as interworking nodes. They will be configured with the BMAC of PE-4 so that the MC-LAG active node advertises the non-SPB capable node BMAC into SPB IS-IS. The BMAC will be configured as a conditional static BMAC so that an SPB node, such as PE-3 or PE-5, will only advertise PE-4's BMAC if its connection to PE-4 is active. Besides the conditional static BMAC, nodes PE-3/PE-5 should advertise the I-VPLS ISIDs defined in PE-4. Epipe ISIDs are not advertised in SPB IS-IS, therefore, it is not necessary to create a static ISID for Epipe 42.

Figure 298: Access resiliency example topology



The commands to configure conditional static BMACs and static ISIDs are as follows.

```
*A:PE-3# configure service vpls 40 name "BVPLS40" static-mac mac ?
  - mac <ieee-address> [create] black-hole
  - mac <ieee-address> [create] sap <sap-id> monitor {fwd-status}
  - no mac <ieee-address>
  - mac <ieee-address> [create] spoke-sdp <sdp-id:vc-id> monitor {fwd-status}
---snip---
```

```
*A:PE-3# configure service vpls 40 name "BVPLS40" sap lag-1:40 static-isid range ?
  - no range <range-id>
  - range <range-id> isid <isid-value> [to <isid-value>] [create]

 <range-id>           : [1..8191]
 <isid-value>         : [1..16777215]
 <create>             : keyword
```

The **monitor fwd-status** attribute identifies this to be a conditional MAC and is mandatory for static BMACs. This parameter instructs SR OS to advertise the BMAC only if the corresponding SAP/spoke-SDP is in forwarding state.

The configuration of the conditional static BMAC and static ISID is as follows. The values for **spf-wait** are the default ones.

```
# on PE-3:
configure
    service
        vpls 40 name "BVPLS40" customer 1 b-vpls create
            service-mtu 2000
            stp
```

```
                shutdown
            exit
            spb 1027 fid 40 create
                timers
                    spf-wait 10000 spf-initial-wait 10 spf-second-wait 1000
                exit
                no shutdown
            exit
            sap lag-1:40 create
                static-isid
                    range 1 create isid 41
                exit
            exit
            spoke-sdp 32:40 create
                spb create
                    no shutdown
                exit
                no shutdown
            exit
            spoke-sdp 35:40 create
                spb create
                    no shutdown
                exit
                no shutdown
            exit
            spoke-sdp 36:40 create
                spb create
                    no shutdown
                exit
                no shutdown
            exit
            static-mac
                mac 00:00:00:04:04:04 create sap lag-1:40 monitor fwd-status
            exit
            no shutdown
        exit
```

```
# on PE-5:
configure
    service
        vpls 40 name "BVPLS40" customer 1 b-vpls create
            service-mtu 2000
            stp
                shutdown
            exit
            spb 1027 fid 40 create
                no shutdown
            exit
            sap lag-1:40 create
                static-isid
                    range 1 create isid 41
                exit
            exit
            spoke-sdp 52:40 create
                spb create
                    no shutdown
                exit
                no shutdown
            exit
            spoke-sdp 53:40 create
                spb create
                    no shutdown
                exit
```

```
                no shutdown
            exit
            spoke-sdp 56:40 create
                spb create
                    no shutdown
                exit
                no shutdown
            exit
            static-mac
                mac 00:00:00:04:04:04 create sap lag-1:40 monitor fwd-status
            exit
            no shutdown
        exit
```

The configuration of the conditional static BMAC is different from the legacy **static-mac** command, configured within the SAP/SDP-binding context. The latter static-MAC is not conditional and it is always added to the FDB. The conditional static BMAC is added to the FDB based on the SAP/SDP-binding state (the conditional static BMAC is tagged in the FDB as *CStatic*, for Conditional Static).

```
*A:PE-3# show lag 1

00:00:00:06:06:06 sdp:56:40             0          0          Spb
===============================================================================
```

The **static-isid** command identifies a set of ISIDs for I-VPLS services that are external to SPBM. These ISIDs are advertised as supported locally on this node unless altered by an ISID-policy. Although the preceding example shows the use of the static ISID associated to a MC-LAG SAP, regular SAPs or spoke-SDPs are also supported. ISIDs declared in this way become part of the ISID multicast and consume MFIBs. Multiple SPBM static-ISID ranges are allowed under a SAP/spoke-SDP. ISIDs are advertised as if they were attached to the local BMAC. Only remote I-VPLS ISIDs need to be defined. In the MFIB, the backbone group MACs are then associated with the active SAP or spoke-SDP.

Once the conditional static BMAC for PE-4 and the static ISID 41 (for I-VPLS 41) are configured as described, the advertised BMAC and ISID can be checked in the remote SPB nodes:

```
*A:PE-6# show service id 40 spb fdb

Configuration of ISID policies in SPB B-VPLS

ISID policies are an optional aspect of SPBM which allow additional control of the advertisement of ISIDs and creation of MFIB entries for I-VPLS (Epipe services do not trigger ISID advertisements or the creation of MFIB entries). By default, if no ISID policies are used, SPBM automatically advertises and populates MFIB entries for I-VPLS and static ISIDs. ISID policies can be used on any SPB-enabled node with locally defined I-VPLS instances or static ISIDs. The ISID policy parameters are as follows:

```
*A:PE-3# configure service vpls 40 isid-policy entry ?
  - entry <range-entry-id> [create]
  - no entry <range-entry-id>

 <range-entry-id>     : [1..8191]
 <create>             : keyword

 [no] advertise-local - Configure local advertisement of the range
 [no] range           - Configure ISID range for the entry
 [no] use-def-mcast   - Use default multicast tree to propogate ISID range
```

Where:

- **advertise-local** defines whether the local ISIDs (I-VPLS ISIDs linked to the B-VPLS) or static ISIDs contained in the configured range are advertised in SPBM.
- **use-def-mcast** controls whether the ISIDs contained in the range use MFIB entries (if **no use-def-mcast** is used) or just the default tree which does not use any MFIB entry.

The ISID policy becomes active as soon as it is defined, as opposed to other policies in SR OS, which require the policy itself to be applied within the configuration.

The typical use of ISID policies is to reduce the number of ISIDs being advertised and to save MFIB space (in deployments where MFIB space is shared with MMRP and IP Multicast). The use of ISID policies is recommended for I-VPLS where most of the traffic is unicast or for I-VPLS where the ISID endpoints are present in all the backbone edge bridges (BEBs) of the SPB network. In both cases, advertising ISIDs or consuming MFIB entries for those I-VPLSs has little value because no multicast (first case) or the default tree (second case) are as efficient as using MFIB entries.

The following configuration example will use the example topology in Figure 298: Access resiliency example topology. In this case, the objective of the ISID policy will be to use the default tree for all the I-VPLS services with ISIDs between 41 and 100, excluding the range 80-90. The following example shows the policy configuration in the SPB nodes PE-2, PE-3, PE-5, and PE-6:

```
# on PE-2, PE-3, PE-5, PE-6:
configure
    service
        vpls "BVPLS40"
            isid-policy
                entry 10 create
                    range 80 to 90
                exit
                entry 20 create
                    use-def-mcast
                    no advertise-local
                    range 41 to 79
                exit
                entry 30 create
                    use-def-mcast
                    no advertise-local
                    range 91 to 100
                exit
            exit
```

The **no advertise-local** option can only be configured if the **use-def-mcast** option is also configured.

```
*A:PE-3>config>service>vpls>isid-policy# entry 40 create
*A:PE-3>config>service>vpls>isid-policy>entry# no advertise-local
MINOR: SVCMGR #7855 Cannot set AdvLocal for entry - advertise-local or use-def-mcast option
 must be specified
```

Overlapping ISID values can be configured as long as the actions are consistent for the same ISID. Conflicting actions are shown in the CLI.

```
*A:PE-3>config>service>vpls>isid-policy# entry 40 create
*A:PE-3>config>service>vpls>isid-policy>entry# range 82 to 85
*A:PE-3>config>service>vpls>isid-policy>entry# use-def-mcast
MINOR: SVCMGR #7854 Cannot set UseDefMctree for entry - Conflicting Actions with Entry-10
```

The ISID policy configured for B-VPLS 40 in all the four nodes makes the SPB network to use the default tree for ISIDs 41-79 and 91-100 and not advertise those ISIDs in SPB ISIS even if the ISID is locally defined (as in the case for ISIDs 41-100 in PE-3). As discussed in Basic SPBM configuration , the default

tree path can be checked from each node by using the **tools dump service id 40 spb default-multicast-list** command.

Due to entry 10 in the policy, ISIDs 80-90 will be advertised by PE-3 (active MC-LAG node). However, nodes PE-2 and PE-6 will not create any MFIB entry for those ISIDs until the corresponding I-VPLS ISIDs are locally created (or configured through static-ISIDs). The following command executed on PE-2 proves that ISIDs 80-90 are indeed being advertised by PE-3:

```
*A:PE-2# show service id 40 spb database detail

```

The **mfib** parameter in the **show service id 40 sap static-isids mfib** command can help understand the state of the MFIB entries added (or not) by the configured static ISID. The following possible states can be shown:

- If the static ISID is configured and programmed in the MFIB, the status is shown as:
  - ok
- If the static ISID is not configured and not programmed in the MFIB, the reasons can be (order of priority):
  - useDefMCTree - ISID policy is applied on the service for the ISID.
  - sysMFibLimit - system MFIB limit has been exceeded
  - addPending - adding pending due to processing delays
- If the static ISID is not configured, but present in the MFIB:

– delPending - cleanup pending due to processing delays.

The following output shows the status of the static ISIDs:

```
*A:PE-5# show service id 40 sap lag-1:40 static-isids mfib

==================================

```

Conclusion

SR OS supports an efficient SPBM implementation in the context of a B-VPLS, where system BMACs, vMEP OAM BMACs, and SAP BMACs are advertised in SPB IS-IS. SPBM provides a simple solution where no other control plane protocol is required in the B-VPLS to take care of the resiliency, load-balancing, and multicast optimization. The SPBM implementation in the SR OS provides scale optimization through the use of control and user B-VPLSs, allows the interworking between SPB networks and PBB networks, as well as the optimization of the MFIB resources and advertisement of ISIDs through the use of ISID policies.

Static VXLAN Termination in Epipe Services

This chapter provides information about Static VXLAN Termination in Epipe Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the CLI in the current edition is based on SR OS Release 21.5.R1. Static VXLAN termination for Epipe services is supported in SR OS Release 15.0.R1, and later.

Overview

Static Virtual eXtensible Local Area Network (VXLAN) termination on non-system IP addresses of the PEs is supported in VPLS services, as described in chapter VXLAN Forwarding Path Extension, and in Epipe services, as described in this chapter. Whereas VPLSs using VXLAN require BGP-EVPN control plane in the current release, Epipe services using VXLAN do not. This implies that only the configured values are used because no auto-discovery of the remote Termination Endpoints (TEPs) can be done without BGP-EVPN.

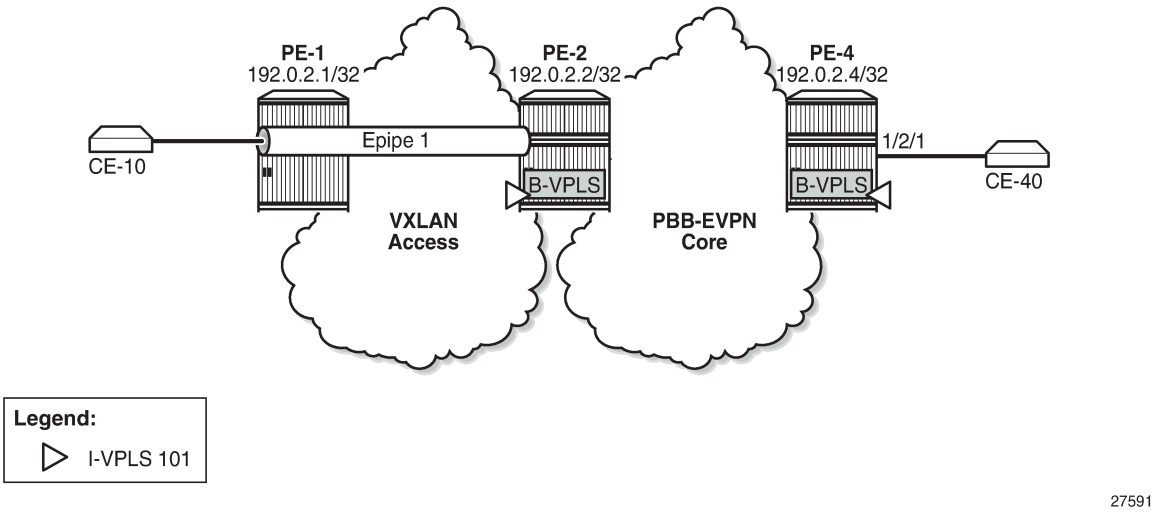
This chapter describes the configuration and use of static VXLAN as an access tunneling mechanism to a PBB-EVPN network. This is a design deployed in some service provider networks where the aggregation network is a non-MPLS IP network.

Static VXLAN termination for Epipe services can be applied on system IP addresses or non-system IP addresses.

Static VXLAN termination on system IP addresses

Figure 299: Static VXLAN termination on system IP addresses shows an example topology with three PEs and two CEs. Epipe 1 is configured on PE-1 and PE-2. PE-2 and PE-4 are part of a PBB-EVPN network. On PE-2, a port cross-connect (PXC) is configured to connect the SAP in Epipe 1 and the SAP in I-VPLS 101. CE-10 and CE-40 can send traffic to each other.

Figure 299: Static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VXLAN Termination Endpoint (VTEP) 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows:

```
# on PE-1:
configure
    service
        oper-group "op-grp-1" create
        exit
        epipe 1 name "Epipe 1" customer 1 create
            vxlan instance 1 vni 1 create
                egr-vtep 192.0.2.2
                    oper-group "op-grp-1"
                exit
            exit
            sap 1/2/1:1.* create
                no shutdown
            exit
            no shutdown
        exit
```

where:

- The configured VXLAN Virtual Network Identifier (VNI) is used by the system as follows:
  - As the egress VNI when sending VXLAN packets for the Epipe service
  - As the source VNI that identifies the VXLAN packet to be part of the Epipe
  - Unique in the system, so it can only be configured in one service, either VPLS or Epipe

  The configuration of the VXLAN VNI in an Epipe is similar to the configuration of the VXLAN VNI in a VPLS, except that in a VPLS, the VNI is only used as the source VNI, because the egress VNI is learned from BGP-EVPN. However, in Epipe services with static VXLAN, the egress VNI is also the configured VNI.
- The egress VTEP is the system IP address of the remote PE. The system will add the configured egress VTEP IP address as the remote VTEP when encapsulating the frames into VXLAN packets.

Only the egress VTEP is configured, not the source VTEP. The PE receiving VXLAN packets will not check the source VTEP.

- The egress VTEP IP address must be in the Routing Table Manager (RTM). An oper-group is associated with the egress VTEP IP address, so that when the egress VTEP disappears from the base route table, the oper-group is brought operationally down, which propagates the failure to other objects that have this oper-group associated. The status of the oper-group and the service will be as follows:
  - When the egress VTEP disappears from the RTM, the VXLAN binding goes operationally down and the oper-group associated with the egress VTEP goes operationally down.
  - When the Epipe SAP goes down, the service goes down too.
  - When the VXLAN binding goes down, the service remains up as long as the access SAP is up.
  - When the service is admin shutdown, the VXLAN binding and the oper-group associated with the egress VTEP are both brought operationally down.
- Only SAPs can be associated with the Epipe; no spoke-SDPs are supported in SR OS Release 21.5.R1, as follows. Regular SAPs and PXC SAPs are supported.

```
*A:PE-1>config>service>epipe# spoke-sdp 11:1 create
MINOR: SVCMGR #1957 SDP binding not supported - service has vxlan vtep configured
```

Frame encapsulation and forwarding

Incoming traffic in the PEs is treated as follows:

- For frames received from the SAPs, a SAP lookup identifies all frames matching the configured SAP (on PE-1, SAP 1/2/1:1.*). The matching frames will be encapsulated into VXLAN IPv4 packets with the following fields:
  - Source VTEP = system IP address
  - Destination VTEP = configured address in **egr-vtep**
  - VNI = configured VXLAN VNI
  - Source and destination UDP ports will be populated as per the existing VXLAN implementation VPLS services, with the source UDP port populated with the result of a hash on the ingress packets.
- For VXLAN frames received from the VXLAN network, a VNI lookup is done for packets with IP DA = system IP address. Frames with the configured VNI 1 are assigned to Epipe 1. The VXLAN encapsulation is removed and the frames are forwarded to the SAP.

Per-service hashing is not supported in Epipe-VXLAN services; only regular hashing and spraying in LAG/ECMP is supported as in any Epipe.

Static VXLAN termination on IPv6 or non-system IPv4 addresses

The non-system IPv4 or IPv6 VXLAN termination on Epipe services is configured in the same way as for VPLS services and described in the VXLAN Forwarding Path Extension chapter, using the FPE function for additional processing. The following steps are required for configuring the FPE for VXLAN termination:

1. Create FPE.
2. Associate FPE with VXLAN termination.

3. Configure the loopback router interface subnet for VXLAN termination and its advertisement into the routing protocol. The subnet can be IPv4 or IPv6.
4. Configure the loopback address for VXLAN termination.
5. Add the service configuration.

Configuration

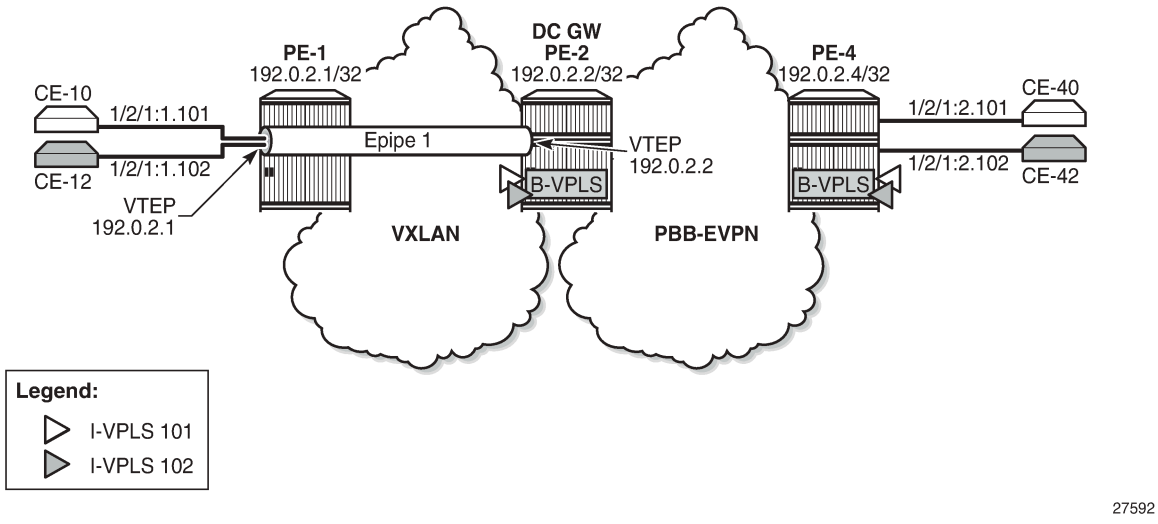
In this section, static VXLAN termination for Epipe services is configured for the following cases:

- VXLAN termination on system IP addresses
- VXLAN termination on non-system IPv4 addresses
- VXLAN termination on IPv6 addresses
- Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing

Static VXLAN termination on system IP addresses

Figure 300: Example topology for static VXLAN termination on system IP addresses shows the example topology for static VXLAN termination on system IP addresses. The initial configuration of the PEs includes the cards, MDAs, ports, router interfaces, and IGP. BGP is not required on PE-1; on PE-2 and PE-4, BGP is configured for address family EVPN.

Figure 300: Example topology for static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VTEP 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows. This configuration was explained in the text under Figure 299: Static VXLAN termination on system IP addresses.

```
# on PE-1:
configure
    service
        oper-group "op-grp-1" create
        exit
```

```
        epipe 1 name "Epipe 1" customer 1 create
            vxlan instance 1 vni 1 create
                egr-vtep 192.0.2.2
                    oper-group "op-grp-1"
                exit
            exit
            sap 1/2/1:1.* create
                no shutdown
            exit
            no shutdown
        exit
```

On PE-2, BGP is configured for address family EVPN, as follows:

```
# on PE-2:
configure
    router
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.4
                exit
            exit
```

There is a PXC configured on port 1/2/1 that will connect SAP pxc-21.a:1.* in Epipe 1, SAP pxc-21.b:1.101 in I-VPLS 101, and SAP pxc-21.b:1.102 in I-VPLS 102. The PXC is configured on PE-2 as follows. See chapter *Port Cross-Connect (PXC)* for more information.

```
# on PE-2:
configure
    port-xc
        pxc 21 create
            port 1/2/1
            no shutdown
        exit
    exit
    port pxc-21.a
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit
    port pxc-21.b
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit
    port 1/2/1
        no shutdown
    exit
```

The service configuration on PE-2 includes Epipe 1, B-VPLS 100, and I-VPLSs 101-102, as follows:

```
# on PE-2:
configure
```

```
    service
        oper-group "op-grp-1" create
        exit
        epipe 1 name "Epipe 1" customer 1 create
            vxlan instance 1 vni 1 create
                egr-vtep 192.0.2.1
                    oper-group "op-grp-1"
                exit
            exit
            sap pxc-21.a:1.* create
                no shutdown
            exit
            no shutdown
        exit
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:02
            exit
            bgp
            exit
            bgp-evpn
                evi 100
                mpls bgp 1
                    ingress-replication-bum-label
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
        vpls 101 name "I-VPLS 101" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap pxc-21.b:1.101 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 102 name "I-VPLS 102" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap pxc-21.b:1.102 create
                no shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-4 is similar for the B-VPLS and the I-VPLSs, but Epipe 1 is not configured on PE-4.

The following command shows the VXLAN information for Epipe 1 on PE-1. By default, the source VTEP is the system IP address 192.0.2.1.

```
*A:PE-1# show service id 1 vxlan

-------------------------------------------------------------------------------
1                   1                  192.0.2.2
-------------------------------------------------------------------------------
Egr-Vtep Entries found: 1
===============================================================================
```

The oper-group with member egress VTEP 192.0.2.2 cannot be monitored on a SAP in the same Epipe. The following error is raised when attempting to configure the same oper-group for the SAP in Epipe 1 on PE-1:

```
*A:PE-1>config>service>epipe>sap# oper-group "op-grp-1"
MINOR: SVCMGR #6221 Oper-group can not have monitor and member in the same service
```

The following ports on PE-2 are disabled to make the destination VTEP unreachable from PE-1:

```
# on PE-2:
configure
    port 1/1/1
        shutdown
    exit
    port 1/1/2
        shutdown
    exit
```

When the destination VTEP disappears from the RTM, the oper-group op-grp-1 goes down and the VXLAN binding in Epipe 1 goes down, while the Epipe service remains up, as follows:

```
*A:PE-1# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 0
===============================================================================
```

```
*A:PE-1# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                        Egress VNI          Oper      Vxlan
                                                        State     Type
-------------------------------------------------------------------------------
192.0.2.2                           1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

```
*A:PE-1#*A:PE-1# show service id 1 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 1                   Vpn Id            : 0
Service Type      : Epipe
---snip---

Admin State       : Up                  Oper State        : Up
---snip---
```

```
-------------------------------------------------------------------------------
Service Access & Destination Points
-------------------------------------------------------------------------------
Identifier                              Type         AdmMTU  OprMTU  Adm  Opr
-------------------------------------------------------------------------------
sap:1/2/1:1.*                           qinq         1578    1578    Up   Up
===============================================================================
```

The output is similar on PE-2. The ports are re-enabled on PE-2, which will cause the VXLAN binding and the oper-group to be operationally up again:

```
# on PE-2:
configure
    port 1/1/1
        no shutdown
    exit
    port 1/1/2
        no shutdown
    exit
```

The preceding example proved that the Epipe service remains up when the VXLAN binding goes down. The following example shows that the Epipe service goes down when the SAP goes down. On PE-1, port 1/2/1 is disabled, as follows:

```
# on PE-1:
configure
    port 1/2/1
        shutdown
```

The following command shows that SAP 1/2/1:1.* and Epipe 1 are down on PE-1:

```
*A:PE-1# show service id 1 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 1                   Vpn Id            : 0
Service Type      : Epipe
---snip---

Admin State       : Up                  Oper State        : Down
---snip---

-------------------------------------------------------------------------------
Service Access & Destination Points

sap:1/2/1:1.*                           qinq         1578    1578    Up   Down
===============================================================================
```

The port is re-enabled and SAP 1/2/1:1 and service Epipe 1 will be up again.

```
# on PE-1:
configure
    port 1/2/1
        no shutdown
```

When the service is disabled (admin shutdown), the SAP goes down, the VXLAN binding goes down, and the oper-group goes down, as follows:

```
# on PE-1:
configure
    service
        epipe "Epipe 1"
            shutdown
```

```
*A:PE-1# show service id 1 base

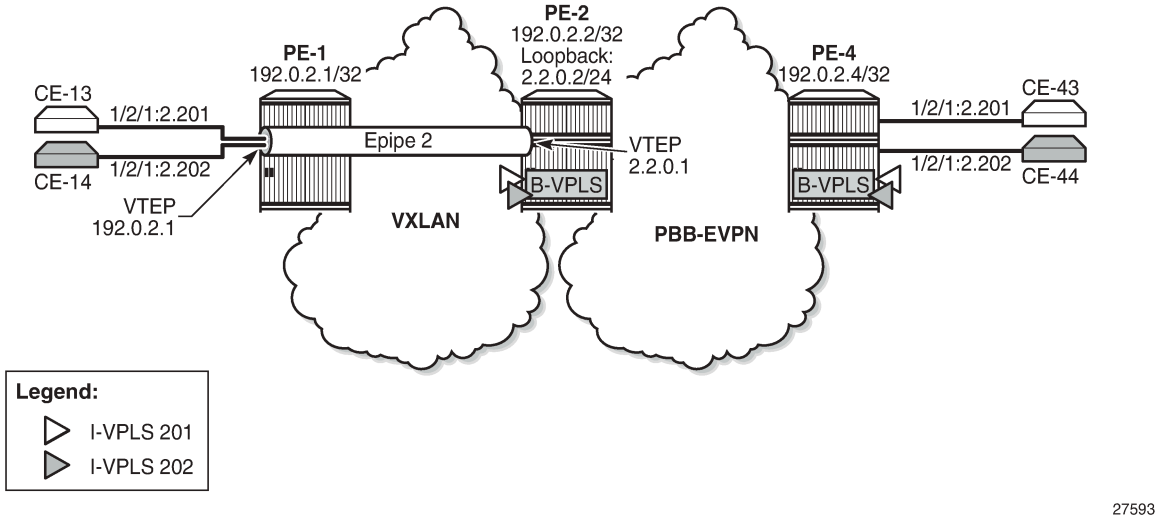
Static VXLAN termination on non-system IPv4 addresses

Non-system IP VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 301: Example topology for static VXLAN termination on non-system IPv4 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The non-system loopback address on PE-2 will be used for VXLAN termination, whereas the system IP address will be used on PE-1.

Figure 301: Example topology for static VXLAN termination on non-system IPv4 addresses



Create FPE

FPE uses the back-to-back PXC, either a PXC port or a LAG-based PXC. The following PXC is created on PE-2:

```
# on PE-2:
configure
    port-xc
        pxc 1 create
            port 1/2/5
            no shutdown
        exit
```

The PXC sub-ports and ports are enabled as follows:

```
# on PE-2:
configure
    port pxc-1.a
        ethernet
```

```
            encap-type dot1q
        exit
        no shutdown
    exit
    port pxc-1.b
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port 1/2/5
        no shutdown
    exit
```

```
*A:PE-2# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPE uses the PXC:

```
# on PE-2:
configure
    fwd-path-ext
        fpe 1 create
            path pxc 1
        exit
```

The following shows that FPE 1 uses PXC 1 and has no VXLAN termination associated:

```
*A:PE-2# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description        : (Not Specified)
Path               : pxc 1
Pw Port            : Disabled                          Oper     : down
Sub Mgmt Extension : Disabled                          Oper     : N/A
Vxlan Termination  : Disabled                          Oper     : down
Segment-Routing V6 : Disabled
===============================================================================
```

Associate FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-2:
configure
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 1 create
```

```
            path pxc 1
            vxlan-termination
        exit
```

When attempting to associate the FPE with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*A:PE-2>config>fwd-path-ext>fpe# vxlan-termination
MINOR: FPE #1021 sdp-id-range is not configured
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs; see the VXLAN Forwarding Path Extension chapter for more information about the use of SDP IDs. The application for FPE 1 is VXLAN termination.

```
*A:PE-2# show fwd-path-ext

===============================================================================
FPE Info
===============================================================================
FPE Id                  Path                          Application
                        pxc/xc-a, xc-b
-------------------------------------------------------------------------------
1                       pxc 1                         vxlan-term
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
SDP-Id Range: 10000 - 10127
===============================================================================
```

After the FPEs are associated with VXLAN termination, the system creates two internal router interfaces per FPE, one per PXC sub-port, as follows:

```
*A:PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                  Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                   Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                   Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
---snip---
```

The configuration of the internal interfaces can be verified as follows:

```
*A:PE-2>config>router# interface "_tmnx_fpe_1.a"
*A:PE-2>config>router>if# info
----------------------------------------------
            port pxc-1.a:1
            mac 00:00:00:00:00:01
            ipv6
                link-local-address fe80::100 dad-disable
                neighbor fe80::101 00:00:00:00:00:02
            exit
            no shutdown
```

```
-------------------------------------------
```

```
*A:PE-2>config>router# interface "_tmnx_fpe_1.b"
*A:PE-2>config>router>if# info
-------------------------------------------
            port pxc-1.b:1
            mac 00:00:00:00:00:02
            ipv6
                link-local-address fe80::101 dad-disable
                neighbor fe80::100 00:00:00:00:00:01
            exit
            no shutdown
-------------------------------------------
```

Configure router loopback interface

The following loopback interface is configured in PE-2 and added to the IS-IS context. The IPv6 address is not required yet.

```
# on PE-2:
configure
    router Base
        interface "loopback1"
            address 2.2.0.2/24
            loopback
            ipv6
                address 220::2/120
            exit
        exit
        isis 0
            interface "loopback1"
                no shutdown
            exit
        exit
```

A subnet must be assigned to the loopback interface, but not a /32 or /128 subnet mask, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 2.2.0.0/24 can be used for VXLAN tunnel termination, except for 2.2.0.2. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127.

Configure non-system VTEP addresses

On PE-2, non-system IP address 2.2.0.1 in the subnet of the loopback address 2.2.0.2/24 is configured as VTEP, as follows. Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs.

```
# on PE-2:
configure
    service
        system
            vxlan
                tunnel-termination 2.2.0.1 fpe 1 create
            exit
        exit
```

No non-system VTEP addresses need to be configured on PE-1.

When the non-system VTEP address is configured, an internal loopback interface _tmnx_vli_vxlan_1_131075 with VTEP address 2.2.0.1/32 is auto-created that can respond to ICMP requests.

```
*A:PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                PREFERRED
_tmnx_vli_vxlan_1_131075         Up        Up/Up       Network loopback
   2.2.0.1/32                                                  n/a
   fe80::13:ffff:fe00:0/64                                     PREFERRED
---snip---
```

The system does not verify if there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding ICMP for that address, regardless of the presence of a loopback in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the services

Epipe 2 is configured on PE-1 as follows. By default, the system IP address will be used as source VTEP of the VXLAN-encapsulated frames. The non-system IP address 2.2.0.1 is used as egress VTEP.

```
# on PE-1:
configure
    service
        epipe 2 name "Epipe 2" customer 1 create
            vxlan instance 1 vni 2 create
                egr-vtep 2.2.0.1
                exit
            exit
            sap 1/2/1:2.* create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of Epipe 2 on PE-2 defines the non-system IP address 2.2.0.1 as source VTEP, as follows. The egress VTEP is 192.0.2.1, the system IP address of PE-1. The configuration of the B-VPLS is the same as in the preceding example; the configuration of the I-VPLSs 201 and 202 is similar to the configuration of I-VPLS 101 in the preceding example.

```
# on PE-2:
configure
    service
        epipe 2 name "Epipe 2" customer 1 create
            vxlan-src-vtep 2.2.0.1
```

```
            vxlan instance 1 vni 2 create
                egr-vtep 192.0.2.1
                exit
            exit
            sap pxc-21.a:2.* create
                no shutdown
            exit
            no shutdown
        exit
```

The following **show** command on PE-1 shows that no VXLAN source VTEP IP address is configured:

```
*A:PE-1# show service id 2 vxlan
===============================================================================
Vxlan Src Vtep IP: N/A
===============================================================================

===============================================================================
Vxlan Instance
===============================================================================
VXLAN Instance               VNI                     Oper-flags
-------------------------------------------------------------------------------
1                            2                       none
-------------------------------------------------------------------------------
Number of Entries : 1
-------------------------------------------------------------------------------
===============================================================================
```

The following shows that the egress VTEP is 2.2.0.1, which is a non-system VTEP on PE-2. The VXLAN tunnel is operationally up.

```
*A:PE-1# show service id 2 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
2.2.0.1                               2                   Up        static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The same commands on PE-2 show that source VTEP IP address 2.2.0.1 is configured and the egress VTEP is 192.0.2.1, which is the system IP address of PE-1, as follows:

```
*A:PE-2# show service id 2 vxlan
===============================================================================
Vxlan Src Vtep IP: 2.2.0.1
===============================================================================

===============================================================================
Vxlan Instance
===============================================================================

-------------------------------------------------------------------------------
1                            2                       none
-------------------------------------------------------------------------------
```

```
Number of Entries : 1
-------------------------------------------------------------------------------
===============================================================================
```

```
*A:PE-2# show service id 2 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI         Oper      Vxlan
                                                         State     Type
-------------------------------------------------------------------------------
192.0.2.1                             2                  Up        static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

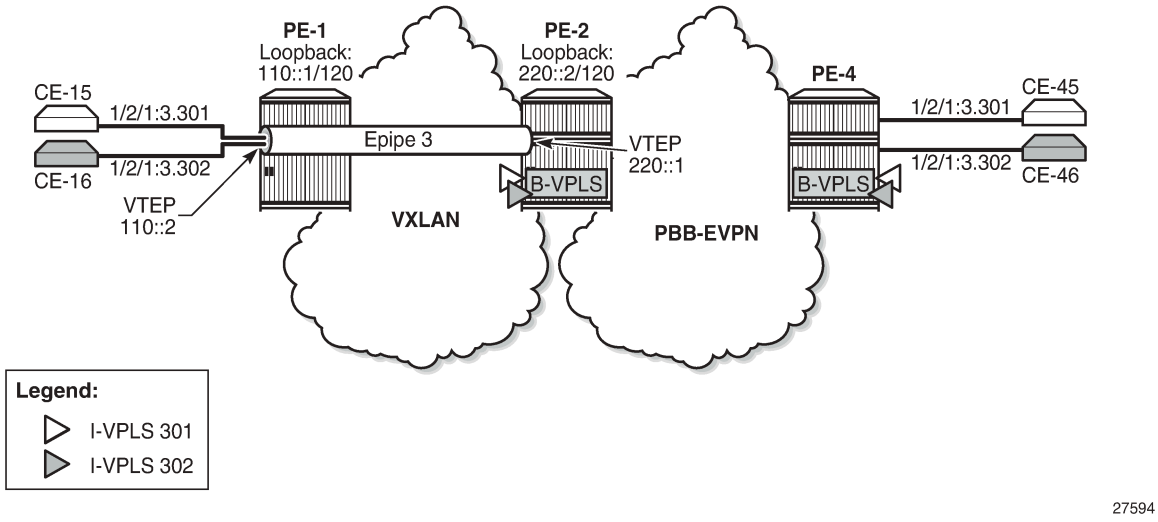
Static VXLAN termination on IPv6 addresses

IPv6 VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 302: Example topology for static VXLAN termination on IPv6 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The loopback addresses on PE-1 and PE-2 will be used for IPv6 VXLAN termination. The existing PXC 1 on PE-2 is reused for FPE; only an IPv6 VTEP address needs to be added.

Figure 302: Example topology for static VXLAN termination on IPv6 addresses



For IPv6 routing, the following option is configured for IS-IS on all nodes:

```
# on all PEsL
configure
    router Base
        isis 0
            ipv6-routing native
```

Create FPE

The following PXC is created on PE-1; PXC 1 will be used for FPE:

```
# on PE-1:
configure
    port-xc
        pxc 1 create
            port 1/2/5
            no shutdown
        exit
```

The PXC sub-ports and ports are enabled as follows:

```
# on PE-1:
configure
    port pxc-1.a
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port pxc-1.b
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port 1/2/5
        no shutdown
    exit
```

```
*A:PE-1# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

FPE 1 uses PXC 1:

```
# on PE-1:
configure
    fwd-path-ext
        fpe 1 create
```

```
            path pxc 1
        exit
```

The following shows that FPE 1 uses PXC 1 and has no VXLAN termination associated:

```
*A:PE-1# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description        : (Not Specified)
Path               : pxc 1
Pw Port            : Disabled                          Oper     : down
Sub Mgmt Extension : Disabled                          Oper     : N/A
Vxlan Termination  : Disabled                          Oper     : down
Segment-Routing V6 : Disabled
===============================================================================
```

Associate FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-1:
configure
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 1 create
            path pxc 1
            vxlan-termination
        exit
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs. The application for FPE 1 is VXLAN termination.

```
*A:PE-1# show fwd-path-ext

===============================================================================
FPE Info
===============================================================================
FPE Id                  Path                          Application
                        pxc/xc-a, xc-b
-------------------------------------------------------------------------------
1                       pxc 1                         vxlan-term
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
SDP-Id Range: 10000 - 10127
===============================================================================
```

After the FPEs are associated with VXLAN termination, the system creates two internal router interfaces per FPE, one per PXC sub-port, as follows:

```
*A:PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
```

```
   IP-Address                                                    PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                  PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                  PREFERRED
---snip---
```

Configure router loopback interface

The following loopback interface is configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure
    router Base
        interface "loopback1"
            address 1.1.0.1/24
            loopback
            ipv6
                address 110::1/120
            exit
        exit
        isis 0
            interface "loopback1"
                no shutdown
            exit
        exit
```

All IPv6 addresses in the 110::/120 subnet can be used for VXLAN tunnel termination, except for 110::1.

Configure non-system VTEP addresses

On PE-1, IPv6 address 110::2 in the subnet of the loopback address 110::1/120 is configured as VTEP, as follows:

```
# on PE-1:
configure
    service
        system
            vxlan
                tunnel-termination 110::2 fpe 1 create
            exit
        exit
```

On PE-2, IPv6 address 220::1 in the subnet of the loopback address 220::2/120 is configured as VTEP, as follows:

```
# on PE-2:
configure
    service
        system
            vxlan
                tunnel-termination 220::1 fpe 1 create
            exit
        exit
```

When the IPv6 VTEP address is configured on PE-1, an internal loopback interface _tmnx_vli_vxlan_1_131075 is created, as follows.

```
*A:PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
_tmnx_vli_vxlan_1_131075         Up        Down/Up     Network loopback
   110::2/128                                                   PREFERRED
   fe80::f:ffff:fe00:0/64                                       PREFERRED
---snip---
```

The following IPv6 route table on PE-1 contains an internal static route for source VTEP 110::2/128 using the FPE internal interface _tmnx_fpe_1.a:

```
*A:PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)

       fe80::101-"_tmnx_fpe_1.a"                                   1
---snip---
```

Configure the services

Epipe 3 is configured on PE-1 with **vxlan-src-vtep 110::2**, which is the VTEP address configured in the preceding step (VXLAN tunnel termination). The egress VTEP is 220::1, which is the VXLAN termination configured on PE-2.

```
# on PE-1:
configure
    service
        epipe 3 name "Epipe 3" customer 1 create
            vxlan-src-vtep 110::2
            vxlan instance 1 vni 3 create
                egr-vtep 220::1
                exit
            exit
            sap 1/2/1:3.* create
                no shutdown
            exit
            no shutdown
        exit
```

Epipe 3 on PE-2 has VXLAN source VTEP 220::1 and egress VTEP 110::2.

```
# on PE-2:
configure
    service
        epipe 3 name "Epipe 3" customer 1 create
            vxlan-src-vtep 220::1
            vxlan instance 1 vni 3 create
                egr-vtep 110::2
                exit
            exit
            sap pxc-21.a:3.* create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of the B-VPLS is the same as in the preceding example. The configuration of I-VPLS 302 is similar.

```
# on PE-2:
configure
    service
        vpls 301 name "I-VPLS 301" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap pxc-21.b:3.301 create
                no shutdown
            exit
            no shutdown
        exit
```

The following **show** commands on PE-1 show that the VXLAN source VTEP IP address is 110::2 and the egress VTEP is 220::1. The VXLAN tunnel is operationally up.

```
*A:PE-1# show service id 3 vxlan

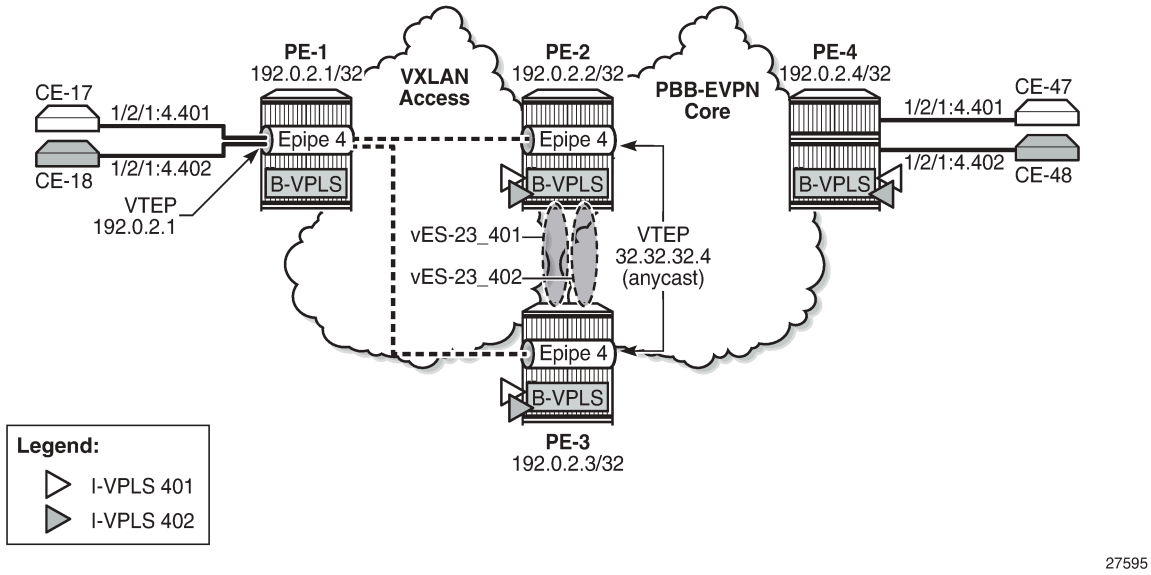
Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing and anycast VTEPs

Figure 303: Example topology for static VXLAN termination using anycast shows the example topology with PE-1, PE-2, and PE-3 in the VXLAN access network. Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, the system IP address 192.0.2.1 is used as source VTEP, while (anycast) IP address 23.23.23.4 is used as source VTEP on PE-2 and PE-3.

In the PBB-EVPN core network, all-active multi-homing virtual Ethernet segments vES-23_401 and vES-23_402 are configured on PE-2 and PE-3.

Figure 303: Example topology for static VXLAN termination using anycast



VXLAN access network

On PE-2 and PE-3, PXC ports are configured: PXC 2 will be used as FPE, whereas PXC-3 and PXC-4 will be used to make a LAG for the PXC between Epipe and I-VPLS services. The configuration of the PXC ports is as follows:

```
# on PE-2, PE-3:
configure
    port-xc
        pxc 2 create
            port 1/2/6
            no shutdown
        exit
        pxc 3 create
            port 1/2/7
            no shutdown
        exit
        pxc 4 create
            port 1/2/8
            no shutdown
```

```
        exit
```

The PXC sub-ports for FPE have dot1q encapsulation whereas the PXC sub-ports for port cross-connect have qinq encapsulation. The sub-ports and ports are enabled, as follows:

```
# on PE-2, PE-3:
configure
    port pxc-2.a
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port pxc-2.b
        ethernet
            encap-type dot1q
        exit
        no shutdown
    exit
    port pxc-3.a
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit
    port pxc-3.b
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit
    port pxc-4.a
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit
    port pxc-4.b
        ethernet
            encap-type qinq
        exit
        no shutdown
    exit all
    port 1/2/6
        no shutdown
    exit
    port 1/2/7
        no shutdown
    exit
    port 1/2/8
        no shutdown
    exit
```

On PE-2 and PE-3, FPE 2 is configured as follows:

```
# on PE-2, PE-3:
configure
    fwd-path-ext
        fpe 2 create
            path pxc 2
        exit
```

FPE 2 is associated with VXLAN termination and two internal interfaces will be auto-created: _tmnx_fpe_2.a and _tmnx_fpe_2.b.

```
# on PE-2, PE-3:
configure
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 2 create
            path pxc 2
            vxlan-termination
        exit
```

```
*A:PE-2# show router interface

===============================================================================
Interface Table (Router: Base)

   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                PREFERRED
_tmnx_fpe_2.a                    Up        Up/Up       Network pxc-2.a:1
   fe80::200/64                                                PREFERRED
_tmnx_fpe_2.b                    Up        Up/Up       Network pxc-2.b:1
   fe80::201/64                                                PREFERRED
---snip---
```

A router loopback interface with IP address 23.23.23.2/24 is created on PE-2, and on PE-3 with IP address 23.23.23.3/24:

```
# on PE-2:
configure
    router Base
        interface "loopback2"
            address 23.23.23.2/24
            loopback
            no shutdown
        exit
        isis 0
            interface "loopback2"
                no shutdown
            exit
        exit
```

On PE-2 and PE-3, the VTEP 23.23.23.4 is configured for FPE 2, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            vxlan
                tunnel-termination 23.23.23.4 fpe 2 create
            exit
```

The following command shows an additional VTEP 23.23.23.4 to the existing router interface _tmnx_vli_vxlan_1_131075 on PE-2:

```
*A:PE-2# show router interface "_tmnx_vli_vxlan_1_131075"

===============================================================================
Interface Table (Router: Base)
===============================================================================

===============================================================================
```

On PE-2 and PE-3, the VXLAN Epipe 4 uses LAG 4 (composed of pxc-3.b and pxc-4.b) to extend the VXLAN toward the I-VPLSs 401 and 402. The I-VPLS SAPs use LAG 3 (composed of pxc-3.a and pxc-4.a). The PXC LAGs provide higher bandwidth and better resiliency. The LAGs are configured as follows on both PE-2 and PE-3:

```
# on PE-2, PE-3:
configure
    lag 3
        mode hybrid
        encap-type qinq
        port pxc-3.a
        port pxc-4.a
        no shutdown
    exit
    lag 4
        mode hybrid
        encap-type qinq
        port pxc-3.b
        port pxc-4.b
        no shutdown
    exit
```

Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, no FPE is required because the system IP address is used as VTEP. Epipe 4 is configured on PE-1 with egress VTEP 23.23.23.4, as follows:

```
# on PE-1:
configure
    service
        epipe 4 name "Epipe 4" customer 1 create
            vxlan instance 1 vni 4 create
                egr-vtep 23.23.23.4
                exit
            exit
            sap 1/2/1:4.* create
                no shutdown
            exit
            no shutdown
        exit
```

Epipe 4 is configured on PE-2 and PE-3 with source VTEP 23.23.23.4 and egress VTEP 192.0.2.1, as follows. The SAP uses LAG 4, which is composed of PXC sub-ports pxc-3.b and pxc-4.b.

```
# on PE-2, PE-3:
configure
    service
        epipe 4 name "Epipe 4" customer 1 create
            vxlan-src-vtep 23.23.23.4
            vxlan instance 1 vni 4 create
                egr-vtep 192.0.2.1
                exit
            exit
            sap lag-4:4.* create
                no shutdown
            exit
            no shutdown
        exit
```

The following command on PE-1 shows that the egress VTEP in Epipe 4 equals 23.23.23.4.

```
*A:PE-1# show service id 4 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
23.23.23.4                            4                   Up        static
-------------------------------------------------------------------------------

```

PBB-EVPN core network

Two all-active multi-homing virtual ESs are configured on PE-2 and PE-3. The preference for the DF election is configured manually, with opposite preference values for the vESs so that DF load balancing is achieved. While vES-23_401 has preference 5000 on PE-2 and preference 10000 on PE-3, vES-23_402 has preference 10000 on PE-2 and preference 5000 on PE-3. When no event has occurred that caused a DF switchover, PE-2 is DF for vES-23_402 and PE-3 is DF for vES-23_401. Both vESs use LAG 3, which is composed of pxc-3.a and pxc-4.a. For vES-23_401, the qinq encapsulation must match S-tag 4 and C-tag 401; for vES-23_402, the S-tag must be 4 and the C-tag 402. On PE-2, the vESs are configured as follows.

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vES-23_401" virtual create
                    esi 01:00:00:00:23:04:01:00:00:01

                        exit
                    exit
                    multi-homing all-active
                    lag 3
                    qinq
                        s-tag 4 c-tag-range 402
                    exit
                    no shutdown
                exit
```

The B-VPLS 100 is configured to use the ES-BMAC. On PE-2, the B-VPLS is configured as follows.

```
# on PE-2:
configure
    service
        vpls 100 name "B-VPLS 100" customer 1 b-vpls create
            service-mtu 2000
            pbb
                source-bmac 00:00:00:00:00:02
                use-es-bmac
            exit
            bgp
            exit
            bgp-evpn
                evi 100
                mpls bgp 1
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            no shutdown
```

On PE-4, the following configuration sets ECMP to a value of 2 in the **bgp-evpn mpls** context of the B-VPLS, so that aliasing is possible.

```
# on PE-4:
configure
    service
        vpls "B-VPLS 100"
            bgp-evpn
                mpls
                    ecmp 2
```

On PE-2 and PE-3, the I-VPLSs are configured with SAP LAG 3, which is composed of pxc-3.a and pxc-4.a, as follows. The qinq encapsulation 4.401 in I-VPLS 401 matches the condition in vES-23_401, whereas qinq 4.402 in I-VPLS 402 matches vES-23_402.

```
# on PE-2, PE-3:
configure
    service
        vpls 401 name "I-VPLS 401" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-3:4.401 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 402 name "I-VPLS 402" customer 1 i-vpls create
            pbb
                backbone-vpls 100
                exit
            exit
            sap lag-3:4.402 create
                no shutdown
            exit
            no shutdown
        exit
```

With the preceding configuration, PBB-EVPN all-active multi-homing and the anycast VTEP at the access VXLAN network can be combined for an efficient and fully redundant network. PE-4 can alias the known unicast traffic to PE-2 and PE-3 on a per-flow basis, whereas if ECMP (and shared queuing) is enabled on PE-1, traffic can also be load-balanced to PE-2 and PE-3. BUM traffic sent from PE-4 will be forwarded by the corresponding DF for the ES.

See chapter EVPN for PBB over MPLS (PBB-EVPN) for more information about PBB-EVPN and all-active multi-homing.

Verification

The following command shows that PE-2 is NDF in vES-23_401 in I-VPLS 401:

```
*A:PE-2# show service id 401 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                  Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-3:4.401          vES-23_401                      NDF
===============================================================================
No sdp entries
No vxlan instance entries
```

For I-VPLS 402, PE-2 is DF, as follows:

```
*A:PE-2# show service id 402 ethernet-segment

===============================================================================
```

```
SAP Ethernet-Segment Information
===============================================================================
SAP                  Eth-Seg                        Status
-------------------------------------------------------------------------------
lag-3:4.402          vES-23_402                     DF
===============================================================================
No sdp entries
No vxlan instance entries
```

For PE-3, the reverse is true: PE-3 is DF in vES-23_401 for I-VPLS 401 and NDF in vES-23_402 for I-VPLS 402.

Within B-VPLS 100, the BMAC addresses are advertised via BGP-EVPN. On PE-2, the following FDB for B-VPLS 100 contains the BMAC addresses of PE-3 and PE-4, which are advertised via BGP-EVPN:

```
*A:PE-2# show service id 100 fdb detail

===============================================================================
Forwarding Database, Service 100
===============================================================================

===============================================================================
```

When a ping is initiated from CE-17 to CE-47, the ICMP packets are forwarded from PE-1 to PE-2, because the best route to 23.23.23.4 is via PE-2. PE-2 learns MAC address ca:fe:01:17:17:17 of CE-17 on the local I-VPLS SAP. PE-2 forwards the ICMP packets through I-VPLS 401 and B-VPLS 100 toward PE-4. PE-4 learns MAC ca:fe:01:17:17:17 of CE-17 via the ES-BMAC. When the reply is sent, PE-4 learns MAC address ca:fe:04:47:47:47 of CE-47 on the local SAP.

The FDB for I-VPLS 401 on PE-2 shows that MAC ca:fe:04:47:47:47 is learned on the local SAP and MAC ca:fe:04:47:47:47 can be reached via the B-VPLS to PE-4.

Conclusion

VXLAN FPE is required to terminate non-system IPv4/IPv6 VXLAN tunnels. The examples in this chapter show how VXLAN FPE can be applied in Epipe services, to stitch static VXLAN to other services, such as I-VPLS services.

Three-byte EVI in EVPN Services

This chapter provides information about the three-byte EVI in EVPN services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. The three-byte EVI is supported in EVPN services in SR OS Release 21.10.R1 and later. Three-byte EVI values can be configured in VPLS, R-VPLS, B-VPLS, and Epipe services for MPLS, VXLAN, and SRv6 instances.

Overview

In SR OS implementations earlier than SR OS Release 21.10.R1, the EVPN instance (EVI) is defined as a two-byte integer value, providing up to 65535 unique identifiers. The EVI is a unique value per service that can be used for three purposes:

- service route target (RT) auto-derivation – autonomous system number (ASN):EVI; for example, 64496:10
- service route distinguisher (RD) auto-derivation – system IP address:EVI; for example, 192.0.2.1:10
- designated forwarder (DF) election, as described in the Preference-based and Non-revertive EVPN DF Election chapter

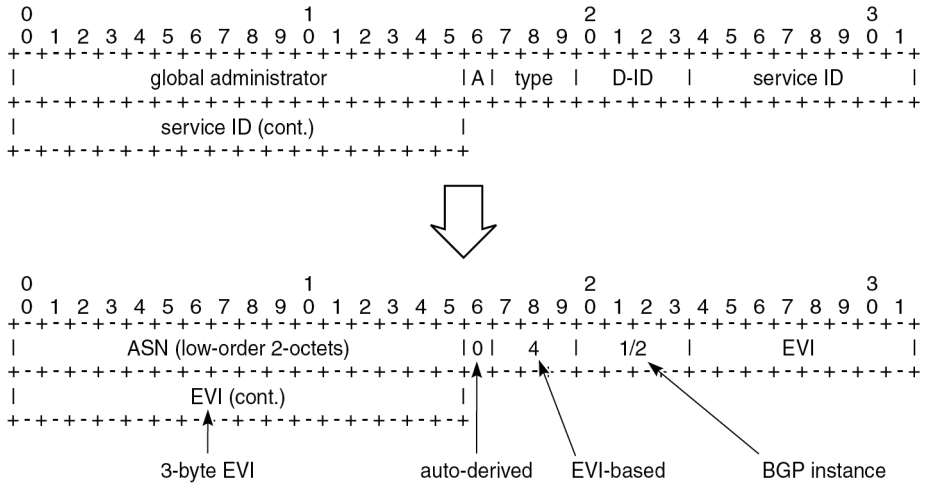
However, in large networks, more than 65535 EVI values are required if the EVI is desired to be unique network-wide. The three-byte EVI provides up to 16777215 values and is supported in SR OS Release 21.10.R1 and later.

All DF election procedures support the extended EVI range. The RD auto-derivation is only possible for the two-byte EVI; the RT auto-derivation for the three-byte EVI can be enabled with the **evi-three-byte-auto-rd** command.

Auto-derived RT

Figure 304: Auto-derived RT in RFC 8365 shows the RT auto-derivation for configured EVI values in the range up to 16777215.

Figure 304: Auto-derived RT in RFC 8365



For three-octet EVI values, the fields in the RT format are:

- the global administrator field, which contains (the lower two octets of) the autonomous system number (ASN)
- the single-bit field A, which indicates if the RT is auto-derived: A=0 for auto-derivation
- the three-bit type field, which indicates the space in which the three-byte service ID is defined:
  - 0: VID (802.1Q VLAN ID)
  - 1: VXLAN
  - 2: NVGRE
  - 3: I-SID
  - **4: EVI**
  - 5: dual-VID (QinQ VLAN ID)
- the four-bit D-ID field, which encodes the domain ID. For type 4 (EVI), the D-ID corresponds to the BGP instance ID in the EVPN service.
- the three-octet service ID, which is set to the EVI (for type 4)

As an example, in a dual-instance EVPN-VPLS service with the following characteristics:

- ASN 64496
- EVI 100002 (0x186A2)
- BGP 1 for EVPN-VXLAN; BGP 2 for EVPN-MPLS
- **evi-three-byte-auto-rt** enabled

The two auto-derived RTs are:

- 64496:1090619042 (0x4**1**0186A2) for BGP 1
- 64496:1107396258 (0x4**2**0186A2) for BGP 2

The RT can also be configured manually, for example, 64496:100002. A manually configured RT has precedence over an auto-derived RT.

Auto-derived RD

Each BGP instance in an EVPN service has an RD. Only for EVI values smaller than or equal to 65535, the RD for BGP instance 1 can be auto-derived out of the system IP address and the EVI, for example, 192.0.2.2:10. EVI values greater than 65535 do not generate RDs automatically.

The VPLS RD is selected based on the following precedence order:

- manually configured RD or auto-RD take precedence when configured,
- if there is no manual RD or auto-RD configuration, the RD is derived from the **bgp-ad>vpls-id**,
- if there is no manual RD, auto-RD, or VPLS ID configuration, the RD is derived from the EVI for EVI values up to 65535 and except for **bgp-mh** which does not support EVI-derived RD,

The Epipe RD is determined in a similar way, but there is no VPLS ID in Epipes.

The following error message is raised when attempting to enable **bgp-evpn** with an EVI value greater than 65535 without having configured a manual RD, auto-RD, or BGP-AD VPLS ID:

```
*A:PE-1>config>service>vpls>bgp-evpn>vxlan$ no shutdown
MINOR: SVCMGR #6554 no route-distinguisher configured - missing route-distinguisher or vpls-id
 or evi or evi is 3-byte
```

The RD configuration can be changed dynamically. When the RD changes, the active routes for the service are withdrawn and readvertised with the new RD.

EVI RT set for AD per-ES routes

As described in the EVPN for MPLS Tunnels chapter, Auto-discovery per Ethernet segment (AD per-ES) routes carry the ESI label and the multi-homing mode. When multiple EVIs are defined in an ES, the AD per-ES routes can be aggregated.

EVI RT set for AD per-ES routes with two-byte EVI

The following command enables the aggregation of AD per-ES routes for two-byte EVI values: **configure service system bgp-evpn ad-per-es-route-target evi-rt-set route-distinguisher <ip-address>**. The RD is specific for this EVI RT set feature. If enabled, a single AD per-ES route with the associated RD and a set of maximum 128 EVI RTs can be advertised. The EVI RTs are distributed in routes with the RD configured in the preceding command and one of the following *comm-val* values (the *comm-val* range is not configurable):

- EVIs from 1 to 128 – *comm-val* = 1
- EVIs from 129 to 256 – *comm-val* = 2
- ...
- EVIs from 65409 to 65535 – *comm-val* = 512

EVI RT set for AD per-ES routes with three-byte EVI

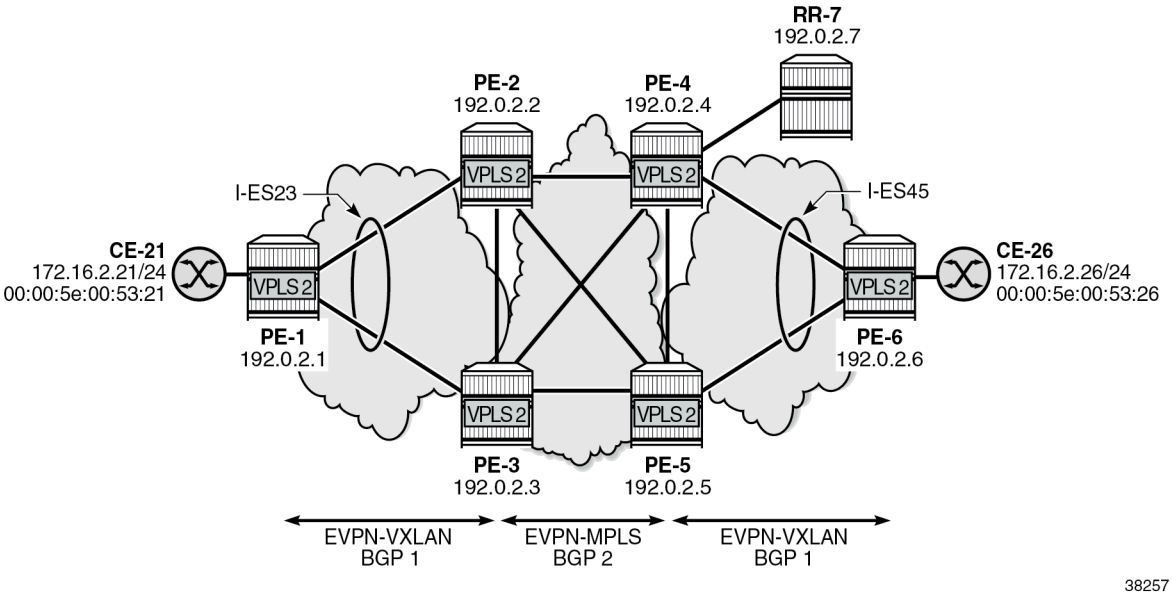
The command to enable AD per-ES route aggregation with extended EVI range is: **configure service system bgp-evpn ad-per-es-route-target evi-rt-set route-distinguisher <ip-address> extended-evi-range**. For three-byte EVIs, the *comm-val* range is extended from 512 to 65535 and the maximum number of AD per-ES routes that can be aggregated is increased from 128 to 257. The 257 RTs per route packing is done for any configured EVI, regardless of the value being greater than 65535 or not.

- EVIs from 1 to 257 – *comm-val* = 1
- EVIs from 258 to 514 – *comm-val* = 2
- ...
- EVIs from 16776961 to 16777215 – *comm-val* = 65281

Configuration

Figure 305: Example topology with dual-instance VPLS shows the example topology with dual-instance VPLS 2: VXLAN is used between PE-1, PE-2, PE-3 and also between PE-4, PE-5, and PE-6. MPLS is used between the core PEs PE-2, PE-3, PE-4, and PE-5.

Figure 305: Example topology with dual-instance VPLS



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 2 between core PEs PE-2, PE-3, PE-4, PE-5, and RR-7
- IS-IS level 1 between PE-1, PE-2, and PE-3
- IS-IS level 1 between PE-6, PE-4, and PE-5
- SR-ISIS between core PEs PE-2, PE-3, PE-4, and PE-5

The BGP configuration and the used policies for dual-instance VPLSs in ESs are described in the EVPN Interconnect Ethernet Segmentschapter. Policies are required to prevent loops. RR-7 acts as route reflector for the core PEs PE-2, PE-3, PE-4, and PE-5. The policy and BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            community "vxlan"
                members "bgp-tunnel-encap:VXLAN"
            exit
            community "SOO-DCGW-23"
                members "origin:64500:23"
            exit
            policy-statement "allow only mpls"
                entry 10
                    from
                        community "vxlan"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
            policy-statement "allow only vxlan"
                entry 10
                    from
                        community "vxlan"
                        family evpn
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            policy-statement "drop SOO-DCGW-23"
                entry 10
                    from
                        community "SOO-DCGW-23"
                        family evpn
                    exit
                    action drop
                    exit
                exit
            exit
            policy-statement "add SOO to vxlan routes"
                entry 10

                exit
                neighbor 192.0.2.3
                    import "drop SOO-DCGW-23"
                    export "add SOO to vxlan routes"
                exit
            exit
        exit
```

The all-active interconnect ES "I-ES23" is configured on PE-2 and PE-3; the single-active interconnect ES "I-ES45" is configured on PE-4 and PE-5. VPLS 1 with EVI 1 (0x1) and VPLS 2 with EVI 100002 (0x186A2) are configured on all PEs. Both VPLSs have BGP 1 for VXLAN and BGP 2 for MPLS (SR-ISIS) in the core. For VPLS 1, no extended EVI range is required. The RD can be auto-derived for BGP instance 1, but not for BGP instance 2. For VPLS 2, the EVI is greater than 65535, so the RD must always be configured (manual configuration or auto-RD). The RT is auto-derived in VPLS 1 and VPLS 2. For VPLS 2, the **evi-three-byte-auto-rt** command is configured to enable auto-derivation of RTs for EVI values up to 16777215. On all core PEs, **evi-rt-set** is enabled for the aggregation of AD per-ES routes. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        system
            bgp-auto-rd-range 192.0.2.2 comm-val 2000 to 2999

                    resolution any
                exit
                evi-three-byte-auto-rt
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
```

```
            no shutdown
        exit
```

When configuring the **evi-rt-set** command, the RD must be different from the RD in the auto-rd range. If not, the following error message is raised:

```
*A:PE-2>config>service>system>bgp-evpn# ad-per-es-route-target evi-rt-set route-distinguisher
 192.0.2.2 extended-evi-range
MINOR: SVCMGR #7905 Range is in use - auto-rd range exists with same ip-address
```

The following command shows the RD and RT values for both BGP instances in VPLS 1 on PE-2:

```
*A:PE-2# show service id 1 bgp

-------------------------------------------------------------------------------
===============================================================================
```

RD 192.0.2.2:1 for BGP instance 1 is auto-derived whereas RD 192.0.2.2:2000 for BGP instance 2 is the result of auto-RD. RT 64496:1 is auto-derived based on the system IP address and the EVI. It is possible to configure **evi-three-byte-auto-rt** in VPLS 1, even though the EVI value is smaller than 65535. To reconfigure VPLS 1 with evi-three-byte-auto-rd in both BGP instances, EVPN-VXLAN and EVPN-MPLS must be disabled, as follows:

```
# on PE-2:
configure
    service
        vpls "VPLS-1"
            bgp-evpn
                vxlan bgp 1
                    shutdown
                    evi-three-byte-auto-rt
                    no shutdown
                exit
                mpls bgp 2
                    shutdown
```

```
                    evi-three-byte-auto-rt
                    no shutdown
                exit
            exit
```

In this case, the auto-derivation is based on RFC 8365 and the value is 64496:1090519041 (0x41000001) for BGP 1 and 64496:1107296257 (0x42000001) for BGP 2.

```
*A:PE-2# show service id 1 bgp

```

The auto-derived RTs on the other nodes are the same as on PE-2 when the BGP instance is the same. On PE-2, PE-3, PE-4, and PE-5, BGP 1 is for VXLAN and BGP 2 is for MPLS in the core. That way, EVPN messages can be exchanged in BGP instance 2 between the core PEs.

AD per-ES aggregation is enabled on the core nodes. The following command on PE-2 shows one AD per-ES with RD 10.0.2.4:390 (10.0.2.4 is the RD configured for **evi-rt-set** and 390 is the *comm-val* value for the EVI range from 99974 to 100230) and one AD per-EVI with RD 192.0.2.4:2002 (auto-RD).

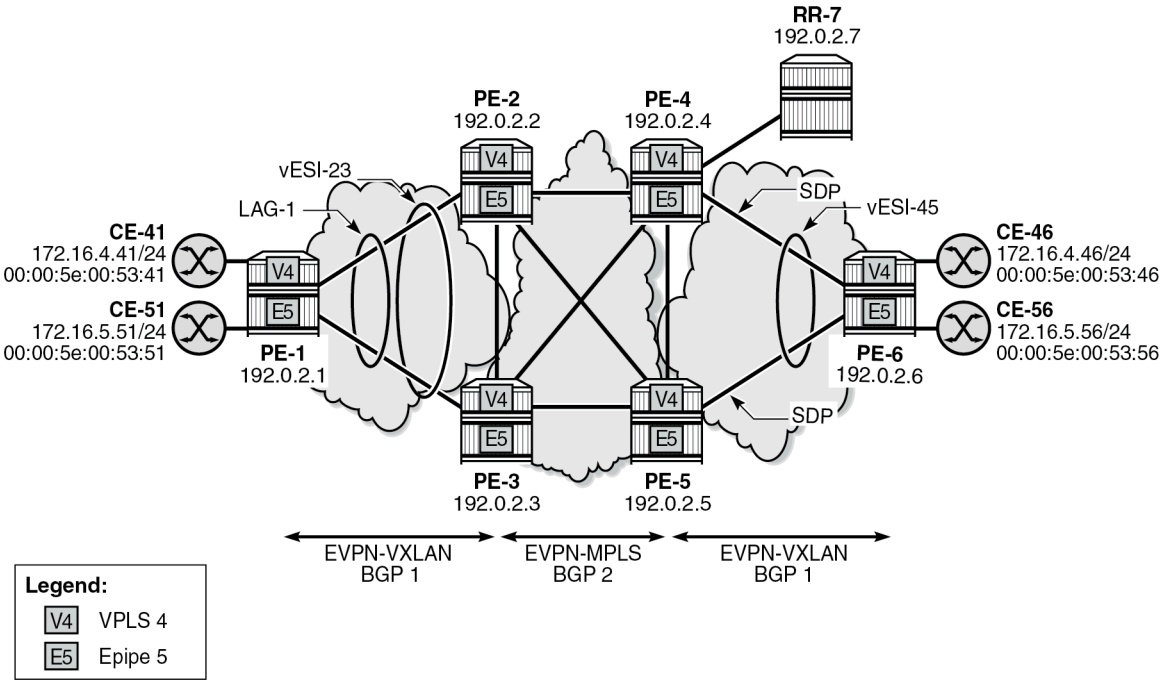
Figure 306: Example topology with VPLS 4 and Epipe 5 shows an example topology with EVPN-MPLS in the core, all-active ES "vESI-23" on PE-2 and PE-3, and single-active ES "vESI-45" on PE-4 and PE-5. VPLS 4 with EVI 100004 is configured on all PEs with manually configured RD and RT.

Figure 306: Example topology with VPLS 4 and Epipe 5



The configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23" virtual create
                    esi 01:00:00:00:00:23:03:04:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    dot1q
                        q-tag-range 3 to 10
                    exit
                    no shutdown
                exit
            exit
        exit
        vpls 4 name "VPLS-4" customer 1 create
            bgp
                route-distinguisher 192.0.2.2:4
                route-target export target:64496:100004 import target:64496:100004
            exit
            bgp-evpn
                evi 100004
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
```

```
                    auto-bind-tunnel
                        resolution any
                    exit
                    # evi-three-byte-auto-rt     # not required - manual RT
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:4 create
                no shutdown
            exit
            no shutdown
        exit
```

With the configured RD 192.0.2.2:4 and RT 64496:100004, the following BGP information is retrieved on PE-2 for VPLS 4:

```
*A:PE-2# show service id 4 bgp

```

Instead of VXLAN or MPLS, SRv6 can be used too. As an example,VPLS 6 with EVI 100006 (0x186A6) is configured on PE-1, PE-2, PE-4, and PE-6. SRv6 is configured between PE-4 and PE-6, as described in the *Segment Routing over IPv6* chapter in the Segment Routing and PCE volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*. The configuration on PE-2 is as follows:

```
# on PE-2
configure
    service
        vpls 6 name "VPLS-6" customer 1 create
            vxlan instance 1 vni 6 create
            exit
            segment-routing-v6 1 create
                locator "PE-2_loc"
                    function
                        end-dt2u
                        end-dt2m
                    exit
                exit
            exit
            bgp
                route-distinguisher auto-rd
            exit
            bgp 2
                route-distinguisher auto-rd
            exit
            bgp-evpn
                evi 100006
                vxlan bgp 1 vxlan-instance 1
                    evi-three-byte-auto-rt
                    no shutdown
                exit
                segment-routing-v6 bgp 2 srv6-instance 1 default-locator "PE-2_loc" create
                    ecmp 2
```

```
                    evi-three-byte-auto-rt
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

On PE-2, RT 64496:1090619046 (0x410186A6) is auto-derived for BGP 1 and RT 64496:1107396262 (0x420186A6) for BGP 2:

```
*A:PE-2# show service id 6 bgp

```

Conclusion

In large networks, a three-byte EVI can be required as a unique identifier for services. RTs can be auto-derived based on a three-byte EVI, but RDs cannot be auto-derived that way.

VCCV BFD for Epipe Services

This chapter describes the VCCV BFD for Epipe services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R7. The CLI in the current edition corresponds to SR OS Release 23.7.R1.

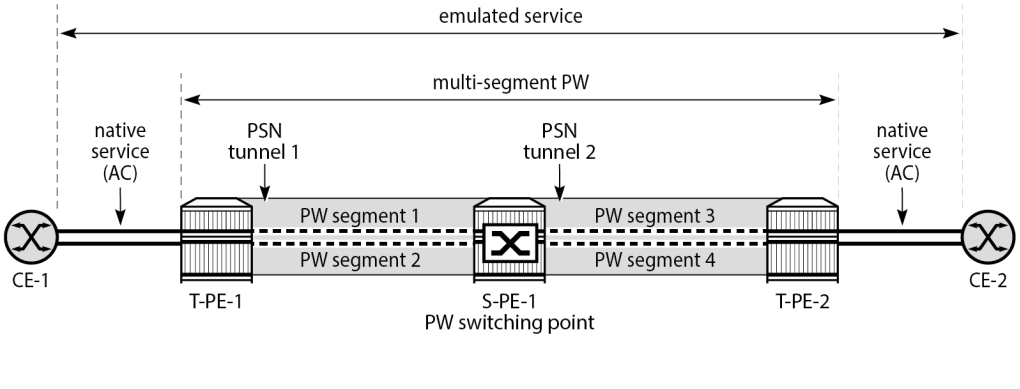
Overview

Virtual circuit connectivity verification (VCCV) is defined by RFC 5085. Bidirectional forwarding detection (BFD) is defined by RFC 5880.

VCCV is an end-to-end fault-detection tool for testing pseudowires (PWs), and typically requires an operator to take manual actions. The PWs can be used for virtual leased line (VLL), virtual private LAN service (VPLS), and Internet enhanced service (IES)/virtual private routed network (VPRN) services with Epipe or Ipipe spoke-SDPs.

SR OS supports RFC 5885 which specifies a method for carrying BFD messages in a PW-associated channel and is referred to as VCCV BFD in SR OS. Because the associated channel shares fate with the data plane, VCCV BFD monitors the PW between two terminating PEs (T-PEs), regardless of the number of provider routers or switching PEs (S-PEs) the PW may traverse; see Figure 307: PW reference model. When enabled, faults in individual PWs can be detected quickly, whether or not other provider routers or S-PEs also carry other PWs. VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in a minimum amount of time is critical.

Figure 307: PW reference model



VCCV BFD avoids manual hop-by-hop troubleshooting of each element along the path of the PW, which minimizes the probability of not detecting silent failures on intermediate routers.

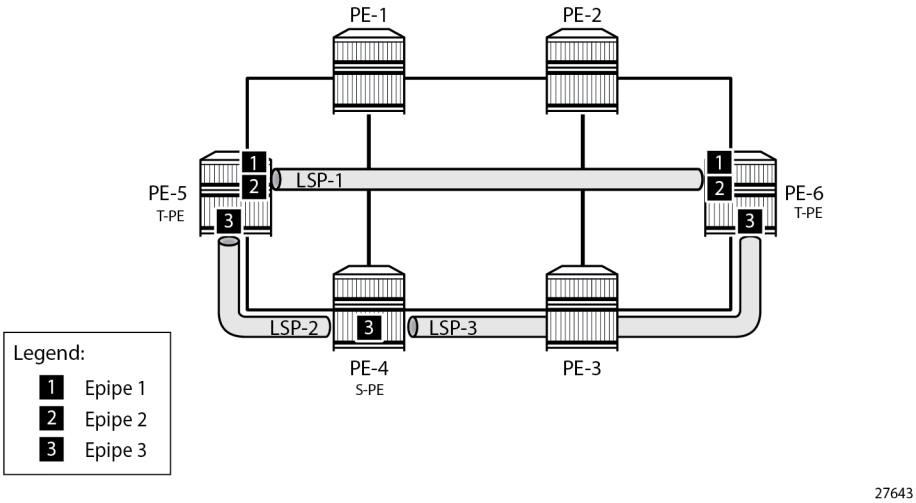
VCCV BFD sessions run end-to-end on a switched or single-hop PW, from T-PE to T-PE. They do not terminate on an intermediate S-PE; therefore, the TTL of the PW label on VCCV BFD packets is always set to 255, to ensure that the packets reach the far-end T-PE of a multi-segment PW.

BFD is only used for fault detection. While RFC 5885 provides a mode in which VCCV BFD can be used to signal PW status, this mode is only applicable for PWs that have no other status signaling mechanism in use. LDP status and static PW status signaling always take precedence over BFD-signaled PW status, and BFD-signaled PW status is not used on PWs that use LDP status or static PW status signaling mechanisms.

Configuration

Figure 308: Example topology shows the example topology with Epipes "Epipe-1" and "Epipe-2" using LSP "lsp-1" between PE-5 and PE-6 and Epipe "Epipe-3" using LSP "lsp-2" between PE-5 and S-PE PE-4 and LSP "lsp-3" between PE-4 and PE-6.

Figure 308: Example topology



The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled
- MPLS paths and LSPs:
  - LSP "lsp-1" configured on PE-5 with primary path "path-5-1-2-6" and on PE-6 with primary path "path-6-2-1-5"
  - LSP "lsp-2" configured on PE-5 with primary path "path-5-4" and on PE-4 with primary path "path-4-5"
  - LSP "lsp-3" configured on PE-4 with primary path "path-4-3-6" and on PE-6 with primary path "path-6-3-4"

VCCV BFD configuration

Three steps are needed when configuring VCCV BFD:

1. Configure the BFD template
2. Apply the BFD template
3. Enable BFD

Step 1: configure BFD template

The **bfd-template** command provides the control packet timer values for the BFD.

The general command to define a BFD template is as follows:

```
configure
    router Base
        bfd
            bfd-template <name>
                transmit-interval <transmit-interval>
                receive-interval <receive-interval>
                echo-receive <echo-interval>
                multiplier <multiplier>
                type {cpm-np}
            exit
```

However, network processor BFD (cpm-np) is not supported for VCCV, and the minimum supported receive or transmit timer interval is 100 ms. An error is generated if a user tries to apply a BFD template with the **type cpm-np** command or any unsupported transmit or receive interval value. An error is also generated when the user attempts to commit changes to a BFD template that is already bound to a spoke-SDP.

Steps 2 and 3: apply BFD template and enable BFD

To apply and enable the BFD template to a spoke-SDP where LDP is used as the SDP signaling protocol for a service, the following command can be used, depending on the service:

```
configure
    service
        [epipe|cpipe|ipipe|vpls|ies|vprn] <service-id>
            spoke-sdp <sdp-binding-id>
                bfd
                    bfd-template <name>
                    bfd-enable
```

If BGP is used as the SDP signaling protocol, the following command is used:

```
configure
    service
        [epipe|vpls] <service-id>
            pw-template-binding <reference>
                bfd-template <name>
                bfd-enable
```

In this example, the following BFD templates are configured on PE-5 and PE-6:

```
# on PE-5, PE-6:
configure
    router Base
        bfd
            begin
            bfd-template "bfdt-1"
                transmit-interval 2000
                receive-interval 2000
                multiplier 5
            exit
            bfd-template "bfdt-2"
                transmit-interval 1000
                receive-interval 1000
            exit
            commit
        exit
```

These BFD templates are used in the Epipe services configured in the next section.

Service configuration

LDP VLL "Epipe-1"

The service "Epipe-1" is an LDP VLL running between PE-5 and PE-6, and uses manually configured SDP 56 on PE-5 and SDP 65 on PE-6, respectively, so the signaling is set to T-LDP. On PE-5, the spoke-SDP 56:1 has BFD template *bfdt-2* applied, and BFD is enabled. The configuration on PE-6 is similar.

```
# on PE-5
configure
    service
        sdp 56 mpls create
            signaling tldp    # default
            far-end 192.0.2.6
            lsp "lsp-1"
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 1 name "Epipe-1" customer 1 create
            sap 1/1/c4/1:1 create
                no shutdown
            exit
            spoke-sdp 56:1 create
                bfd
                    bfd-template "bfdt-2"
                    bfd-enable
                exit
                no shutdown
            exit
            no shutdown
        exit
```

Log 99 indicates the local discriminator value used for the VCCV BFD session, as follows:

```
88 2023/08/17 11:47:44.610 UTC MINOR: VRTR #2070 Base 127.0.0.1
"The vccv BFD session with Local Discriminator 1 on Svc 1 SdpBind 56:1 is up"
```

Configuring the spoke-SDP with a template with an invalid type (for example, type "cpm-np") leads to an error, as follows:

```
*A:PE-5>config>service>epipe>spoke-sdp>bfd# bfd-template "bfdt-cpm-np-100ms"
MINOR: SVCMGR #6260 Invalid bfd-template - incompatible bfd-template param
with VCCV: invalid type (oper)
```

Configuring the spoke-SDP with a template with an invalid transmit timer value also leads to an error, as follows:

```
*A:PE-5>config>service>epipe>spoke-sdp>bfd# bfd-template "bfdt-cpm-np-50ms"
MINOR: SVCMGR #6260 Invalid bfd-template - incompatible bfd-template param
with VCCV: invalid tx interval (oper)
```

BGP VPWS "Epipe-2"

The service "Epipe-2" is a BGP VPWS, also running between PE-5 and PE-6, using the manually configured SDPs 561 and 651 with the signaling set to BGP, as follows. Again, BFD template *bfdt-2* is used, but now the BFD template is referred to from the **pw-template-binding** context. See the BGP Virtual Private Wire Services chapter for more information.

```
# PE-5:
configure
    service
        sdp 561 mls create
            signaling bgp
            far-end 192.0.2.6
            lsp "lsp-1"
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        pw-template 1 prefer-provisioned-sdp create
        exit
        epipe 2 name "Epipe-2" customer 1 create
            bgp
                route-distinguisher 65545:2
                route-target export target:65545:2 import target:65545:2
                pw-template-binding 1
                    bfd-template "bfdt-2"
                    bfd-enable
                exit
            exit
            bgp-vpws
                ve-name "PE-5"
                    ve-id 5
                exit
                remote-ve-name "PE-6"
                    ve-id 6
                exit
                no shutdown
            exit
```

```
            sap 1/1/c4/1:2 create
                no shutdown
            exit
            no shutdown
        exit
```

LDP VLL "Epipe-3" with switching node PE-4

The service "Epipe-3" is another LDP VLL running between PE-5 and PE-6, but switched at PE-4. It uses the manually configured SDPs 54 and 45 between PE-5 and PE-4, and SDPs 46 and 64 between PE-4 and PE-6. All these SDPs are using T-LDP for the signaling. On PE-5, the spoke-SDP 54:3 has BFD template "bfdt-1" applied, and **control-word** is active. This ensures that BFD packets get into the PW mapping to that spoke-SDP and that these packets are forwarded between the VC-switched spoke-SDPs at PE-4. The configuration on PE-6 is similar.

```
# on PE-5:
configure
    service
        sdp 54 mpls create
            signaling tldp        # default
            far-end 192.0.2.4
            lsp "lsp-2"
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 3 name "Epipe-3" customer 1 create
            sap 1/1/c4/1:3 create
                no shutdown
            exit
            spoke-sdp 54:3 create
                control-word
                bfd
                    bfd-template "bfdt-1"
                    bfd-enable
                exit
                no shutdown
            exit
            no shutdown
        exit
```

For PE-4 to switch traffic from one VC to another, the creation time keyword **vc-switching** is required, as follows:

```
# on PE-4:
configure
    service
        sdp 45 mpls create
            signaling tldp        # default
            far-end 192.0.2.5
            lsp "lsp-2"
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        sdp 46 mpls create
            signaling tldp        # default
```

```
            far-end 192.0.2.6
            lsp "lsp-3"
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        epipe 3 name "Epipe-3" customer 1 vc-switching create
            spoke-sdp 45:3 create
                no shutdown
            exit
            spoke-sdp 46:3 create
                no shutdown
            exit
            no shutdown
        exit
```

VCCV BFD verification

The following command shows that BFD template "bfdt-2" is applied to SDP 56:1 in the "Epipe-1" service and to SDP 561:4294967295 in the "Epipe-2" service:

```
*A:PE-5# show router bfd bfd-template "bfdt-2"

===============================================================================

Service Associations
-------------------------------------------------------------------------------
SvcId               Sdp Bind                      BFD Enable     BFD Encap
-------------------------------------------------------------------------------
1                   56:1                          yes            ipv4
2                   561:4294967295                yes            ipv4
===============================================================================
```

The BFD configuration for SDP 56:1 on the "Epipe-1" service is listed in the detailed output for the SDP, as follows. The BFD template used is *bfdt-2*, BFD is enabled, and the BFD encapsulation used is IPv4. The peer VCCV CV bits indicate that the remote end supports LSP ping as well as BFD fault detection.

```
*A:PE-5# show service id 1 sdp 56:1 detail

-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
```

Similar output can be obtained on PE-6.

Disconnecting the link between PE-1 and PE-2 affects the traffic taking the upper path; the VCCV BFD sessions for the services "Epipe-1" and "Epipe-2" go down, and so do the SDPs and the services. This is reflected in log 99, as follows:

```
142 2023/08/17 12:00:42.764 UTC WARNING: MPLS #2012 Base VR 1:
"LSP path lsp-1::path-5-1-2-6 is operationally disabled ('shutdown') because
resvTear"

143 2023/08/17 12:00:42.764 UTC WARNING: MPLS #2010 Base VR 1:
"LSP lsp-1 is operationally disabled ('shutdown') because noPathIsOperational"

144 2023/08/17 12:00:42.765 UTC MINOR: SVCMGR #2303 Base

2            Epipe     Up   Down 1          Epipe-2
3            Epipe     Up   Up   1          Epipe-3
-------------------------------------------------------------------------------
Matching Services : 3
-------------------------------------------------------------------------------
===============================================================================
```

Conclusion

VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in the minimal amount of time is critical. VCCV BFD complements other on-demand tools such as VCCV ping and VCCV trace by providing proactive detection of faults. VCCV ping and VCCV trace can later be used to localize and diagnose the root cause of the fault.

Virtual Ethernet Segments

This chapter provides information about Virtual Ethernet Segments.

- Overview
- Configuration
- Conclusion

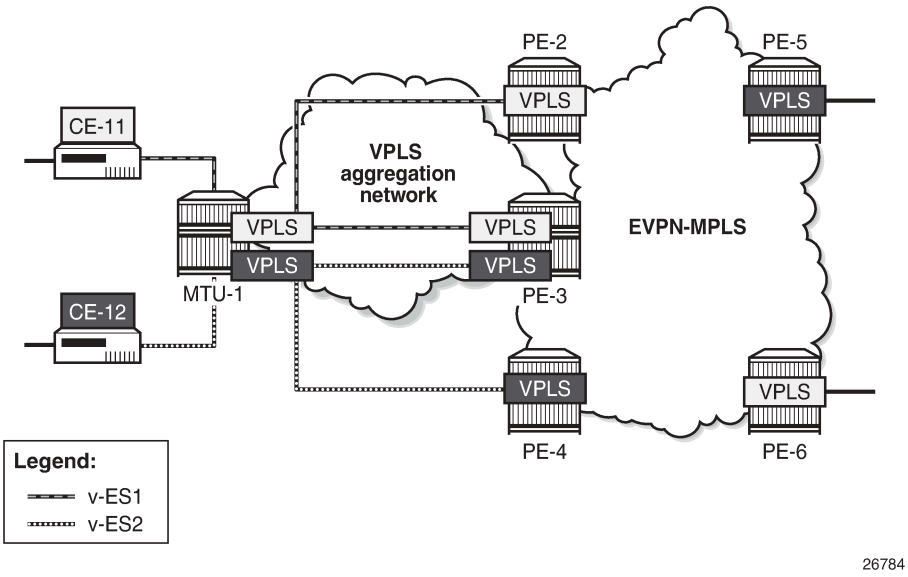
Applicability

This chapter was initially written based on SR OS Release 15.0.R3, but the CLI in the current edition is based on SR OS Release 21.2.R2. Virtual Ethernet segments are supported in SR OSRelease 15.0.R1, and later.

Overview

RFC 7432 describes the use and procedures for Ethernet segments (ESs) that can be associated with physical Ethernet ports and LAGs. The SR OS implementation also allows an ES to be associated with SDPs. ESs meet the redundancy requirements of directly connected CEs. However, ESs will not work when an aggregation network exists between CEs and ES PEs, which requires different ESs to be defined for the port, LAG, or SDP. *Draft-ietf-bess-evpn-virtual-eth-segment* describes how virtual ESs (vESs) can be defined with an Attachment Circuit (AC) level granularity. Figure 309: vESs for PWs shows an example where vES definition at the pseudowire (PW) granularity level is required:

Figure 309: vESs for PWs



When a Layer 2 aggregation network is used to get access to EVPN, the association of ACs that belong to the same ES and physical ports or SDPs can be arbitrary. For example, the SDP between MTU-1 and PE-3 (Figure 309: vESs for PWs) cannot be associated with only one ES, because it is being used by two different CEs that require different ESs. The association must be at spoke-SDP level. The RFC 7432 port/lag-based ES definition is not sufficient, so vESs need to be defined. Virtual ESs can be configured with up to eight ranges of one or more:

- VC-IDs (spoke-SDPs)
- Q-tags (dot1q)
- S-tags (qinq)
- C-tags for a fixed S-tag (qinq)

Mesh-SDPs are not allowed for an SDP used by a vES.

Virtual ESs are configured as Ethernet segments with the creation-time keyword **virtual**:

```
*A:PE-2>config>service>system>bgp-evpn# ethernet-segment ?
  - ethernet-segment <name> [create] [virtual]
  - no ethernet-segment <name>

 <name>               : [32 chars max]
 <virtual>            : keyword

      dot1q           + Configure dot1q port or lag information
 [no] es-activation-* - Configure ethernet segment activation timer
 [no] es-orig-ip      - Configure ES route's originating IP address.
 [no] esi             - Configure ethernet segment identifier
 [no] lag             - Configure lag for service BGP EVPN ethernet segment
 [no] multi-homing    - Configure multi-homing for service BGP EVPN ethernet segment
 [no] network-interc* - Configure network interconnect vxlan information
 [no] oper-group      - Configure operational-group for the ethernet-segment
 [no] port            - Configure port for service BGP EVPN ethernet segment
 [no] pw-port         - Configure pw-port for service BGP EVPN ethernet segment
      qinq            + Configure qinq port or lag information
 [no] route-next-hop  - Configure next hop IP for ES and AD per-ES routes.
 [no] sdp             - Configure sdp for service BGP EVPN ethernet segment
      service-carving + Configure service carving mode for BGP EVPN ethernet segment
      service-id      + Configure service id vxlan information under ethernet segment
 [no] shutdown        - Enable/disable administrative state of the ethernet segment
 [no] source-bmac-lsb - Configure source  BMAC address LSB information
 [no] vc-id-range     - Configure VC ID range
```

Virtual ES "vESI-23_600" is associated with LAG 1 and one service-delimiting VLAN range is defined for the S-tag, as follows:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_600" virtual create
                    esi 01:00:00:00:00:23:06:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            evi 2
                        exit
                    exit
                    multi-homing all-active
```

```
                    lag 1
                    qinq
                        s-tag-range 600 to 602
                    exit
                    no shutdown
                exit
```

The configured ES will match all the SAPs for which the top (outer) service-delimiting tag is within the 600 to 602 range.

When the ES is created as virtual, a port, LAG, or SDP needs to be created before any VLAN or VC-ID can be associated.

- For VC-ID, only spoke-SDPs are allowed, no mesh-SDPs. Manual spoke-SDP VC-IDs and BGP-AD VC-IDs can be included in the range.
- For dot1q, only those SAPs that match the service-delimiting VLAN range will be associated with the vES
- For qinq, the following two commands can be configured, with a mutually exclusive S-tag:
  - **s-tag-range** <*qtag1*> **to** <*qtag1*> - associates all qinq SAPs with outer tag between the configured qtags.
  - **s-tag** <*qtag1*> **c-tag-range** <*qtag2*> **to** <*qtag2*> - associates all qinq SAPs with outer qtag1 and inner qtag between the configured qtag2 values to the vES

  A mutually exclusive S-tag means that a value for the S-tag can be configured in either of the two commands, but not in both.

Table 15: Supported examples for Q-tag values between 1 and 4094 shows the supported examples for qtag values between 1 and 4094; Table 16: Supported examples for Q-tag values 0, *, and null shows the supported examples for qtag values 0, *, and null:

Table 15: Supported examples for Q-tag values between 1 and 4094

vES configuration for port 1/1/1	SAP association
dot1q qtag-range 100	1/1/1:100
dot1q qtag-range 100 to 102	1/1/1:100, 1/1/1:101, 1/1/1:102
qinq s-tag 100 c-tag-range 200	1/1/1:100.200
qinq s-tag 100 c-tag-range 200 to 202	1/1/1:100.200, 1/1/1:100.201, 1/1/1:100.202
qinq s-tag-range 100	All SAPs 1/1/1:100.x (x being 1 to 4094, 0, or *)
qinq s-tag-range 100 to 102	All SAPs 1/1/1:100.x, 1/1/1:101.x, 1/1/1:102.x (x being 1 to 4094, 0, or *)

*Table 16: Supported examples for Q-tag values 0, *, and null*

vES configuration for port 1/1/1	SAP association
dot1q qtag-range 0	1/1/1:0

vES configuration for port 1/1/1	SAP association
dot1q qtag-range *	1/1/1:*
qinq s-tag 0 c-tag-range *	1/1/1:0.*
qinq s-tag * c-tag-range *	1/1/1:*.*
qinq s-tag * c-tag-range null	1/1/1:*.null

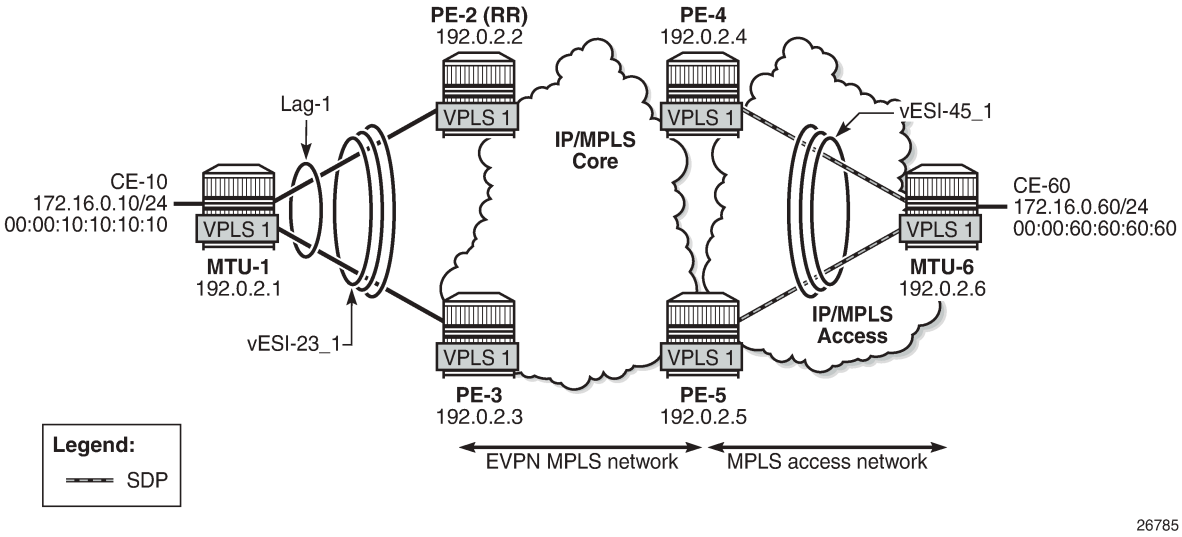
Considerations:

- The ranges can be modified on the fly: qtag-range, s-tag/c-tag-range, vc-id-range.
- For port-based vESs, PXC sub-ports are supported. For more information about PXC, see chapter *Port Cross-Connect (PXC)* in the Interface Configuration volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*.
- Virtual ESs are supported in EVPN-MPLS, PBB-EVPN, and EVPN-VPWS
- Virtual ESs are supported in single-active and all-active EVPN multi-homing
  - Two all-active vESs must use different ES-BMAC addresses, even if they are defined in the same LAG.
- Virtual ESs implement CMAC flush procedures described in RFC 7623. Optionally, ISID-based CMAC-flush can be used where the single-active vES does not use ES-BMAC allocation. See chapter PBB-EVPN ISID-based CMAC Flush.
- Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. For more information about CP-SAPs, see chapter VLAN Range SAPs for VPLS and Epipe Services.

Configuration

Figure 310: Example topology shows the example topology with four core PEs in an EVPN-MPLS network and two MTUs. VPLS 1 is configured in all the nodes. EVPN is configured on the core PEs, not on the MTUs. LAG 1 is configured on MTU-1, PE-2, and PE-3 and associated with an all-active vES "ESI-23_1" on PE-2 and PE-3. A single-active vES "ESI-45_1" is configured on PE-4 and PE-5, associated with SDPs.

Figure 310: Example topology



The configuration is similar to the one in chapter EVPN for MPLS Tunnels, where the parameters are described in detail.

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be configured)
- LDP in the IP/MPLS core and IP/MPLS access network

LAG 1 is configured with qinq encapsulation. The LAG configuration on MTU-1 is as follows:

```
# on MTU-1:
configure
    lag 1 name "lag-1"
        mode access
        encap-type qinq
        port 1/1/1
        port 1/1/2
        lacp active administrative-key 32768
        no shutdown
```

BGP is configured on all PEs for address family EVPN. PE-2 is the Route Reflector (RR) and is configured as follows.

```
# on RR PE-2:
configure
    router Base
        autonomous-system 64500
        bgp
            vpn-apply-import
            vpn-apply-export
            enable-peer-tracking
            rapid-withdrawal
            split-horizon
```

```
            rapid-update evpn
            group "internal"
                family evpn
                cluster 1.1.1.1
                peer-as 64500
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

VPLS 1 is configured on all nodes. On the PEs, BGP-EVPN is enabled for MPLS. The following is configured on PE-2:

```
# on PE-2:
configure
    service
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap lag-1:1.1 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration on the other PEs is similar, but on PE-4 and PE-5, a spoke-SDP is configured instead of a SAP. The service configuration on PE-4 is as follows:

```
# on PE-4:
configure
    service
        sdp 46 mpls create
            far-end 192.0.2.6
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        vpls 1 name "VPLS 1" customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls bgp 1
```

```
                    ingress-replication-bum-label
                    ecmp 2
                    auto-bind-tunnel
                        resolution any
                    exit
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            spoke-sdp 46:1 create
                no shutdown
            exit
            no shutdown
        exit
```

Virtual ESs must be created with the **virtual** keyword; if not, the following error is raised after an attempt to define a range:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>qinq# s-tag-range 1
MINOR: SVCMGR #8070 Cannot create range - ethernet-segment is not virtual
```

On PE-2 and PE-3, the two following two all-active multi-homing vESs are created, each with a unique ESI:

```
# on PE-2, PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_1" virtual create
                    esi 01:00:00:00:00:23:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing all-active
                    lag 1
                    qinq
                        s-tag-range 1
                        s-tag-range 500 to 501
                        s-tag 495 c-tag-range 100 to 102
                    exit
                    no shutdown
                exit
                ethernet-segment "vESI-23_600" virtual create
                    esi 01:00:00:00:00:23:06:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            evi 2
                        exit
                    exit
                    multi-homing all-active
                    lag 1
                    qinq
                        s-tag-range 600 to 602
                    exit
                    no shutdown
                exit
```

When attempting to configure another vES with the ESI of an existing ES/vES, the following error is raised:

```
*A:PE-2>config>service>system>bgp-evpn# ethernet-segment "vESI-23_610" virtual create
*A:PE-2>config>service>system>bgp-evpn>eth-seg# esi 01:00:00:00:00:23:06:00:00:01
MINOR: SVCMGR #8047 Ethernet segment id is not valid - ESI already in use by another ethernet
 segment
```

Multiple vESs can be defined on the same LAG. However, the ranges should not overlap. The following error is raised after attempting to configure an additional range in vES "ESI-23_600" that uses S-tag 600 in combination with a range of C-tags. S-tag 600 is already included in the first range: **s-tag-range 600 to 602**. The error message points out that this range is of a different type: the existing range defines only S-tags, whereas the new range defines a range of C-tags for S-tag 600.

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>qinq# s-tag 600 c-tag-range 100 to 111
MINOR: SVCMGR #8070 Cannot create range - range overlaps with existing range of a different
 type
```

When attempting to define **s-tag-range 1** in "vESI-23_2", when S-tag 1 is already defined in "vESI-23_1", the following error is raised:

```
*A:PE-2>config>service>system>bgp-evpn>eth-seg>qinq# s-tag-range 1
MINOR: SVCMGR #8070 Cannot create range - range overlaps with existing range in ethernet-
segment vESI-23_1
```

On PE-4, the following single-active multi-homing vESs are configured. The configuration on PE-5 contains a different SDP.

```
# on PE-4:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-45_1" virtual create
                    esi 01:00:00:00:00:45:01:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    sdp 46
                    vc-id-range 1
                    vc-id-range 500 to 501
                    no shutdown
                exit
                ethernet-segment "vESI-45_2" virtual create
                    esi 01:00:00:00:00:45:02:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode manual
                        manual
                            evi 2
                        exit
                    exit
                    multi-homing single-active
                    sdp 46
                    vc-id-range 2
                    no shutdown
                exit
```

The configured ESs and vESs can be retrieved as follows:

```
*A:PE-2# show service system bgp-evpn ethernet-segment

===============================================================================
Service Ethernet Segment
===============================================================================
Name                            ESI                           Admin     Oper
-------------------------------------------------------------------------------
vESI-23_1                       01:00:00:00:00:23:01:00:00:01 Enabled   Up
vESI-23_600                     01:00:00:00:00:23:06:00:00:01 Enabled   Up
-------------------------------------------------------------------------------
Entries found: 2
===============================================================================
```

The following information for the first entry in the list shows that it is a virtual ES.

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "vESI-23_1"

```

The ranges in the vES can be modified while the vES is operationally up, for example, an S-tag range can be added as follows:

```
# on PE-2:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_1"
                    qinq
                        s-tag-range 10
```

The S-tag ranges can be verified with the following command. Compared with the preceding output, the S-tag 10 has been added:

```
*A:PE-2# show service system bgp-evpn ethernet-segment name "vESI-23_1" virtual-ranges | match
 S-Tag post-lines 9
S-Tag Ranges

```

Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. CP-SAP 10 is created on PE-3, as follows:

```
# on PE-3:
configure
```

```
    connection-profile-vlan 10 create
        vlan-range 5 to 100
        vlan-range 495
    exit
```

The following vES is configured on PE-3:

```
# on PE-3:
configure
    service
        system
            bgp-evpn
                ethernet-segment "vESI-23_10" virtual create
                    esi 01:00:00:00:00:23:10:00:00:01
                    es-activation-timer 3
                    service-carving
                        mode auto
                    exit
                    multi-homing single-active
                    port 1/2/3
                    qinq
                        s-tag-range 100
                    exit
                    no shutdown
                exit
```

This vES can only be configured when no CP-SAPs are defined on port 1/2/3. The following error message is raised when a CP-SAP is configured on port 1/2/3 already and the vES is configured afterward:

```
*A:PE-3>config>service>system>bgp-evpn>eth-seg# port 1/2/3
MINOR: SVCMGR #8048 Ethernet segment access port/lag/sdp/vxlan-instance/pw-port is not valid -
 not allowed when connection profile saps configured on port/lag
```

When attempting to configure CP-SAP 1/2/3:cp-10 in VPLS 1 with port 1/2/3 associated with a vES, the following error message is raised.

```
*A:PE-3>config>service>vpls# sap 1/2/3:100.cp-10 create
MINOR: SVCMGR #6044 Cannot create sap - sap type not allowed when port is associated with
 virtual ethernet-segment
```

Conclusion

Regular ESs and vESs can be associated with ports, LAGs, and SDPs; in case of vES, ranges of Q-tags, S-tags, C-tags, or VC-IDs can be defined. The granularity for vES is per AC. Multiple vESs with different ESIs can be defined on the same port, LAG, or SDP.

VLAN Range SAPs for VPLS and Epipe Services

This chapter provides information about VLAN range SAPs for VPLS and Epipe services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the CLI in the current edition is based on SR OS Release 21.2.R1. Connection-Profile VLAN SAPs (CP SAPs) are supported in SR OS Release 14.0.R1, and later.

Overview

Backhaul services through metro Ethernet networks require bundled interface support. In SR OS terminology, bundling refers to Connection-Profile VLAN SAPs (CP SAPs)—special SAPs that capture the traffic of a range of CE VLAN IDs (VIDs) entering an Ethernet port. CP SAPs are fully compatible with Metro Ethernet Forum (MEF) 10.3 bundling service attributes and RFC 7432 EVPN VLAN bundle service interfaces. CP SAPs are supported in Layer 2 services only, and can be configured together with other SAPs and/or SDP-bindings.

For frames with an ingress VID contained in the range configured in the SAP's CP, the behavior is similar to default SAPs, such as 1/1/1:*, where "*" spans the entire VID range from 0 to 4095 and serves as a wildcard. However, unlike a default SAP, a CP SAP cannot co-exist with a VLAN SAP that is in the same range and on the same port or LAG. For example, 1/1/1:* and 1/1/1:100 can co-exist whereas 1/1/2:cp-1 (where cp-1 corresponds to the VLAN range from 1 to 200) and 1/1/2:100 cannot co-exist.

The VLAN manipulation between VLAN SAPs, default SAPs, and CP SAPs is compared in Table 17: VLAN manipulation in SAPs .

Table 17: VLAN manipulation in SAPs

	VLAN SAP	Default SAP	CP SAP
Service-delimiting VLAN	Yes For example: VLAN 100 in 1/1/1:100	No	No
Push/pop VLAN tags in egress/ ingress frames	Yes	No	No
VLAN translation	Yes	No	No

Figure 311: Customer VID is popped and pushed by VLAN SAPs - VLAN translation shows how dot1q VLAN SAPs pop the customer VLAN tag in ingress frames and push the VLAN tag in egress frames. Therefore, frames are untagged between PE-1 and PE-2. VLAN translation is possible when the VIDs in the VLAN tags that are popped or pushed at the SAPs are different at ingress and egress, as follows.

Figure 311: Customer VID is popped and pushed by VLAN SAPs - VLAN translation

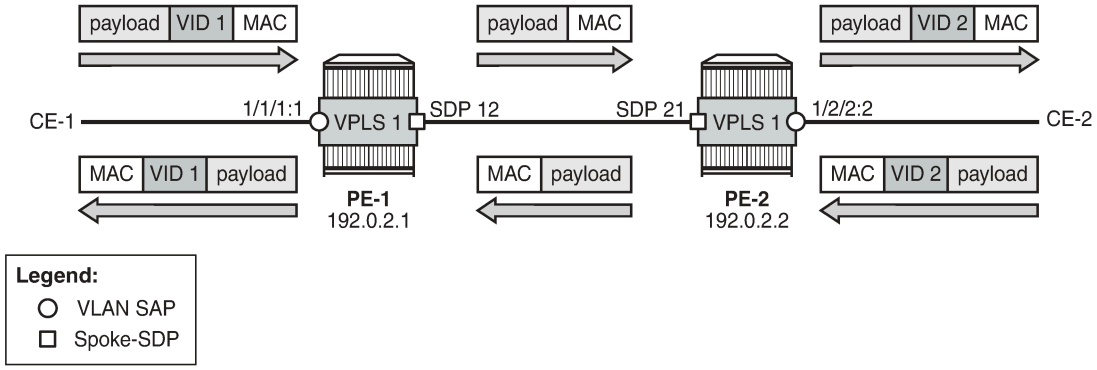

Figure 312: Customer VID is preserved between dot1q CP SAPs - no VLAN translation shows that dot1q CP SAPs do not pop or push the CE VID. Frames keep the same tag end-to-end; therefore, VLAN translation is not possible.

Figure 312: Customer VID is preserved between dot1q CP SAPs - no VLAN translation

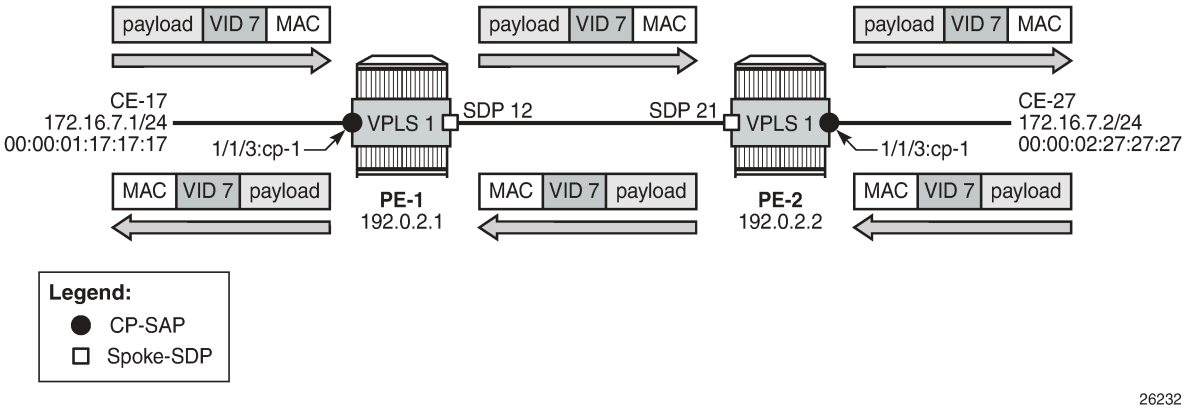

Figure 313: Customer VID is preserved between QinQ CP SAPs - no VLAN translation shows that QinQ CP SAPs only pop or push the service delimiting VID (VID 100), but not the customer VID in the CP range, as follows:

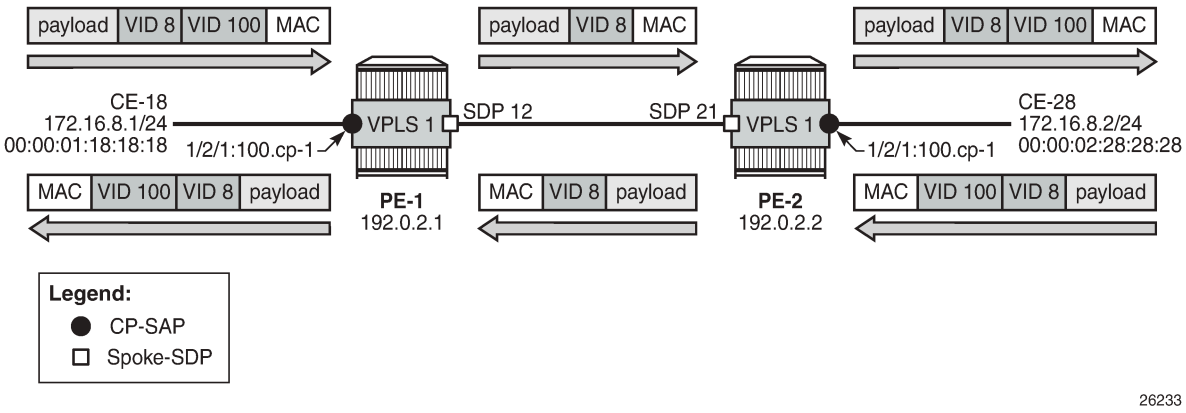
Figure 313: Customer VID is preserved between QinQ CP SAPs - no VLAN translation



VID 100 is service delimiting and can be different in both SAPs, but the customer VID in the VLAN range of the CP is not.

Connection profile VLAN

Note:
The **connection-profile-vlan** context is different from the connection-profile used for ATM connectivity.

CP SAPs refer to connection profiles (connection-profile-vlan) that can contain up to 32 ranges of customer VIDs. Connection profiles are configured with the following command:

```
*A:PE-1>config# connection-profile-vlan ?
  - connection-profile-vlan <conn-prof-id> [create]
  - no connection-profile-vlan <conn-prof-id>

 <conn-prof-id>       : [1..8000]

 [no] description     - Configure a connection profile VLAN description
 [no] vlan-range      - Configure a connection profile vlan range
```

VLAN ranges in a CP contain one or more consecutive VIDs, as follows:

```
*A:PE-1>config>connprofvlan$ vlan-range ?
  - no vlan-range <from>
  - vlan-range <from> [to <to>]

 <from>               : [1..4094]
 <to>                 : [1..4094]
```

Following is an example of a CP configuration containing three non-overlapping VLAN ranges:

```
# on PE-1:
configure
    connection-profile-vlan 10 create
        vlan-range 5 to 100
        vlan-range 150 to 300
```

```
        vlan-range 350
    exit
```

Overlapping ranges are not allowed within the same CP. An error message indicates that the VLAN range from 7 to 9 overlaps with the previously configured ranges (in this example, the VLAN range from 5 to 100), as follows:

```
*A:PE-1>config>connprofvlan# vlan-range 7 to 9
MINOR: SVCMGR #9012 Overlapping range
```

New non-overlapping VLAN ranges can be added to the CP defined in an existing and operationally up SAP. The CP's VLAN ranges can also be removed on the fly. When a user wants to extend a VLAN range, for example, VLAN range 350 becoming a range from 350 to 400, the existing VLAN range is not overwritten and a message is raised indicating that the VLAN ranges overlap, as follows:

```
*A:PE-1>config>connprofvlan# vlan-range 350 to 400
MINOR: SVCMGR #9012 Overlapping range
```

The existing VLAN range of 350 can be preserved when the CP SAP is operational and a new VLAN range from 351 to 400 can be added, as follows:

```
*A:PE-1>config>connprofvlan# vlan-range 351 to 400
```

The following example shows four VLAN ranges in CP 10, with a timestamp of the last change for each VLAN range:

```
*A:PE-1# show connection-profile-vlan 10

===============================================================================

351                 400                           03/30/2021 07:59:58
===============================================================================
===============================================================================
```

If a VLAN tag combination matches different SAPs, the highest priority SAP will be picked regardless of the operational status. For completeness, the following two tables show the SAP lookup matching order for dot1q and QinQ ports.

Table 18: SAP lookup order for dot1q ports

Incoming frame qtag VID value	SAP lookup precedence order (:0 and :* are mutually exclusive on the same port)			
	:X	:CP	:0	:*
X (belongs to the CP range)	1st	1st		2nd
0			1st	1st
<untagged>			1st	1st

Table 19: SAP lookup order for QinQ ports

Incoming frame qtag1.qtag2	System/port settings = new-qinq-untagged-sap SAP lookup precedence order (assumption: X and Y are defined in CP ranges)							
	:X.Y	:X.0	:X.CP	:CP.*	:X.*	:0.*	:*.null	:*.*
X.Y	1st		1st	2nd	2nd			3rd
X.0		1st		2nd	2nd			3rd
0.Y						1st		2nd
0.0						1st		2nd
X		1st		2nd	2nd		3rd	4th
0						1st	2nd	3rd
<untagged>						1st	2nd	3rd

For example, ingress frames with VIDs 100.20 are classified as part of CP SAP 1/2/1:100.cp-10, not of CP SAP 1/2/3:cp-10.*. Only when SAP 1/2/1:100.cp-10 is removed from the configuration, frames with VIDs 100.20 will go to SAP 1/2/3:cp-10.*.

Assign CP SAPs to VPLS or Epipe services

Like ordinary SAPs, CP SAPs can be assigned to VPLS or Epipe services, as follows. The VPLS and Epipe can be EVPN services or not. In the following example, VPLS 1 has BGP-EVPN enabled, whereas Epipe 2 does not:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            far-end 192.0.2.2
            ldp
            keep-alive
```

```
            shutdown
        exit
        no shutdown
    exit
    vpls 1 name "VPLS 1" customer 1 create
        bgp
        exit
        bgp-evpn
            evi 1
            mpls bgp 1
                ingress-replication-bum-label
                auto-bind-tunnel
                    resolution any
                exit
                no shutdown
            exit
        exit
        stp
            shutdown
        exit
        sap 1/1/3:cp-10 create
            no shutdown
        exit
        sap 1/2/1:1.11 create
            no shutdown
        exit
        sap 1/2/1:100.cp-10 create
            no shutdown
        exit
        sap 1/2/3:cp-10.* create
            no shutdown
        exit
        no shutdown
    exit
    epipe 2 name "Epipe 2" customer 1 create
        sap 1/2/1:200.cp-10 create
            no shutdown
        exit
        spoke-sdp 12:2 create
            no shutdown
        exit
        no shutdown
    exit
```

CP SAPs are configured in the same way as VLAN SAPs and default SAPs, with the following restrictions:

- A CP can be defined for inner or outer tags as shown in the preceding configuration, but not both at the same time, as follows:

```
*A:PE-1>config>service>vpls# sap 1/2/1:cp-3.cp-10 create
MINOR: CLI SAP-id has an invalid port number or encapsulation value.
```

- If a CP is defined for the outer VID, the inner VID cannot be a specific VID. The inner VID can only be a "*" (where the inner tag can have any value) or a "0" (where the inner tag can be 0 or null), as follows:

```
*A:PE-1>config>service>vpls# sap 1/2/1:cp-3.4 create
MINOR: CLI SAP-id has an invalid port number or encapsulation value.
```

```
*A:PE-1>config>service>vpls# sap 1/2/1:cp-10.* create
```

```
*A:PE-1>config>service>vpls>sap# exit
```

```
*A:PE-1>config>service>vpls# sap 1/2/1:cp-3.0 create
*A:PE-1>config>service>vpls>sap$ exit
```

- No VLAN SAP can be added on a port in dot1q (or a combination of port and service-delimiting VLAN in case of QinQ) when the VLAN is included in the VLAN range in a CP SAP on the same port. One of the VLAN ranges in CP 10 contains all VIDs from 5 to 100. Therefore, it is not allowed to configure a VLAN SAP with VID 100 on port 1/1/3, where a CP SAP is configured with CP 10, as follows:

```
*A:PE-1>config>service>vpls# sap 1/1/3:100 create
MINOR: SVCMGR #1602 The SAP-id is already in use - 1/1/3:100 is already configured
```

- No CP SAPs can be added with overlapping VLAN ranges on the same port for dot1q (or on the same port- and service-delimiting tag for QinQ), as follows. CP 1 contains VLAN range from 7 to 9, which overlaps with VLAN range from 5 to 100 in CP 10.

```
# on PE-1:
configure
    connection-profile-vlan 1 create
        vlan-range 7 to 9
    exit
```

```
*A:PE-1>config>service>vpls# sap 1/1/3:cp-1 create
MINOR: SVCMGR #1602 The SAP-id is already in use - 1/1/3:cp-10 is already configured
```

```
*A:PE-1>config>service>vpls# sap 1/2/1:100.cp-1 create
MINOR: SVCMGR #1602 The SAP-id is already in use - 1/2/1:100.cp-10 is already configured
```

  However, the CP can be referred to by SAPs on other ports for dot1q or for QinQ on other combinations of port and service-delimiting VLAN, as follows:

```
*A:PE-1>config>service>vpls# sap 1/2/1:101.cp-1 create
*A:PE-1>config>service>vpls>sap$ exit
```

- CP SAPs can be added when they contain non-overlapping VLAN ranges on the same port, as follows. CP 3 contains one VLAN range with only one VID: 3. This VLAN range (3) does not overlap with any VLAN range in the CP SAPs assigned to VPLS 1.

```
# on PE-1:
configure
    connection-profile-vlan 3 create
        vlan-range 3
    exit
```

```
*A:PE-1>config>service>vpls# sap 1/1/3:cp-3 create
*A:PE-1>config>service>vpls>sap# exit
```

```
*A:PE-1>config>service>vpls# sap 1/2/1:100.cp-3 create
*A:PE-1>config>service>vpls>sap# exit
```

VPLS 1 contains the following SAPs. There is no overlap between the VLAN ranges on a port (or port and service-delimiting tag for QinQ).

```
*A:PE-1# show service id 1 sap

-------------------------------------------------------------------------------
Number of SAPs : 10
-------------------------------------------------------------------------------
===============================================================================
```

Regular and default SAPs consume one SAP instance each, whereas CP SAPs consume a number of SAP instances equal to the number of VLANs in the range. The following shows that there are ten SAP

entries (nine in use by VPLS 1 and one in use by Epipe 2), which can be regular, default, or CP SAP entries:

```
*A:PE-1# tools dump resource-usage system

            Subscriber Next-Hop Entries -      500000           0      500000
                            SAP Entries +      262143          10      262133
                   (in use by:   Apipe) -                      0
                   (in use by:   Cpipe) -                      0
                   (in use by:   Epipe) -                      1
                   (in use by:   Fpipe) -                      0
                   (in use by:   Ipipe) -                      0
                   (in use by:     Ies) -                      0
                   (in use by:  Mirror) -                      0
                   (in use by:    Vpls) -                      9
                   (in use by:    Vprn) -                      0
===============================================================================
```

However, the number of SAP instances consumed for card 1 FP 1 exceeds the number of SAP entries in the system, as follows:

```
*A:PE-1# tools dump resource-usage card 1 fp 1

===============================================================================
Resource Usage Information for Card Slot #1 FP #1
===============================================================================
                                                 Total   Allocated        Free
-------------------------------------------------------------------------------
---snip---
                              SAP Instances |      63999       1497      62502
---snip---
===============================================================================
```

The calculation of the number of SAP instances is as follows. In this example, CP 10 is used in five SAPs (four in VPLS 1 and one in Epipe 2) and contains the following VLAN ranges:

```
*A:PE-1# show connection-profile-vlan 10
===============================================================================
Connection Profile 10 Information
===============================================================================

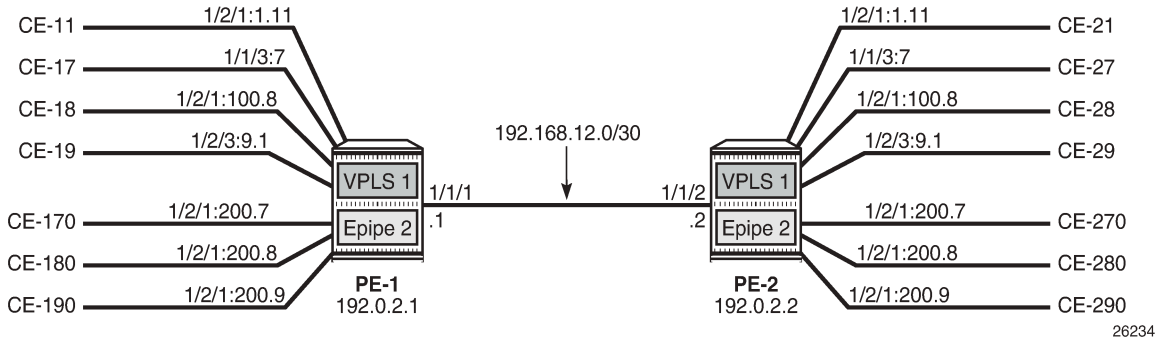
5                   100                           03/30/2021 07:58:07
150                 300                           03/30/2021 07:58:07
350                 350                           03/30/2021 07:58:07
351                 400                           03/30/2021 07:59:58
===============================================================================
===============================================================================
```

The number of VLANs in the VLAN ranges of CP 10 equals 298. For each of the five SAP entries with CP 10, 298 SAP instances are used, for a total of 1490. As well, there is one CP SAP using CP 1 with three VLANs in the VLAN range from 7 to 9 (for three more SAP instances). Three CP SAPs use CP 3 with only VID 3 in the VLAN range (for three more SAP instances), and one SAP is a regular SAP that consumes one SAP instance. Therefore, the total number of SAP instances is 1497.

Configuration

Figure 314: Example topology shows the example topology used in this chapter.

Figure 314: Example topology



The initial configuration on the PEs includes the following:

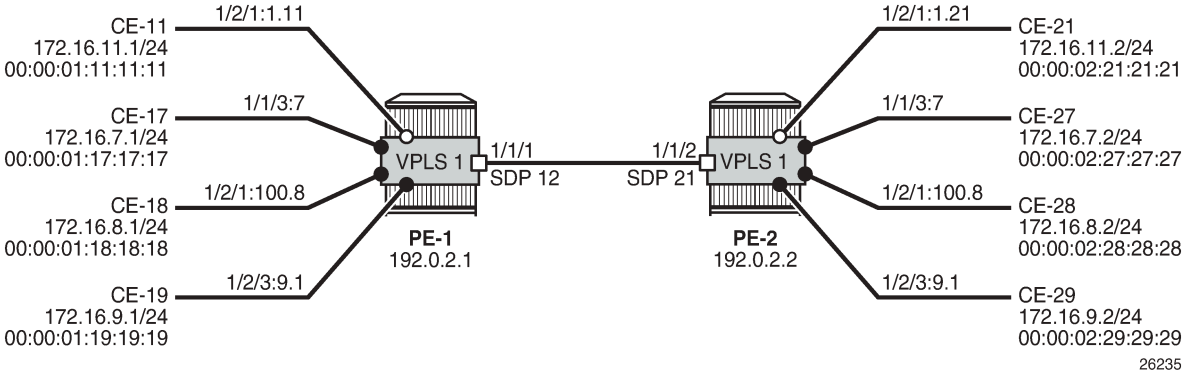
- Cards, MDAs, ports
- Router interfaces
- IS-IS (or OSPF) between the PEs
- LDP between the PEs

In this example, no BGP is configured and no BGP-EVPN will be configured in the VPLS and Epipe services. However, VLAN ranges can be applied in EVPN VPLS and EVPN Epipe services.

VLAN ranges in VPLS services

Figure 315: Example topology for VLAN ranges in VPLS 1 shows the example topology for VPLS 1 with a combination on VLAN SAPs and CP SAPs. The port:VID represents the port to which the CE is connected and the VID sent by the CE; for example, CE-17 is connected to port 1/1/3 on PE-1 and sends frames with VID 7. When VLAN ranges are used, the port:VID 1/1/3:7 does not represent the configured SAP, which is 1/1/3:cp-1.

Figure 315: Example topology for VLAN ranges in VPLS 1



The service configuration for VPLS 1 on PE-1 is as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            far-end 192.0.2.2
            ldp
            keep-alive
                shutdown
            exit
            no shutdown
        exit
        vpls 1 name "VPLS 1" customer 1 create
            stp
                shutdown
            exit
            sap 1/1/3:cp-1 create
                no shutdown
            exit
            sap 1/2/1:1.11 create
                no shutdown
            exit
            sap 1/2/1:100.cp-1 create
                no shutdown
            exit
            sap 1/2/3:cp-1.* create
                no shutdown
            exit
            spoke-sdp 12:1 create
                no shutdown
            exit
            no shutdown
        exit
```

The configuration of VPLS 1 on PE-2 is as follows:

```
# on PE-2:
configure
    service
        sdp 21 mpls create
            far-end 192.0.2.1
            ldp
            keep-alive
```

```
                shutdown
            exit
            no shutdown
        exit
        vpls 1 name "VPLS 1" customer 1 create
            stp
                shutdown
            exit
            sap 1/1/3:cp-1 create
                no shutdown
            exit
            sap 1/2/1:1.21 create
                no shutdown
            exit
            sap 1/2/1:100.cp-1 create
                no shutdown
            exit
            sap 1/2/3:cp-1.* create
                no shutdown
            exit
            spoke-sdp 21:1 create
                no shutdown
            exit
            no shutdown
        exit
```

When the CEs send traffic to each other, such as ICMP echo requests, the MAC addresses are learned in the SAPs, and the forwarding database (FDB) on PE-1 is as follows:

```
*A:PE-1# show service id 1 fdb detail

===============================================================================
Forwarding Database, Service 1
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

VLAN manipulation in dot1q SAPs

Figure 316: Customer VIDs are popped and pushed by dot1q VLAN SAPs shows the VLAN manipulation for VLAN SAPs. CE-17 and CE-18 are connected to VLAN SAPs, where the VLAN tag with VID 7 will be popped or pushed. VLAN translation is possible, but does not apply. The configuration of the SAPs in VPLS 1 on PE-1 and PE-2 is modified as follows:

```
# on PE-1, PE-2:
```

```
configure
    service
        vpls "VPLS 1"
            sap 1/1/3:cp-1
                shutdown
            exit
            no sap 1/1/3:cp-1
            sap 1/1/3:7 create
                no shutdown
            exit
```

Figure 316: Customer VIDs are popped and pushed by dot1q VLAN SAPs

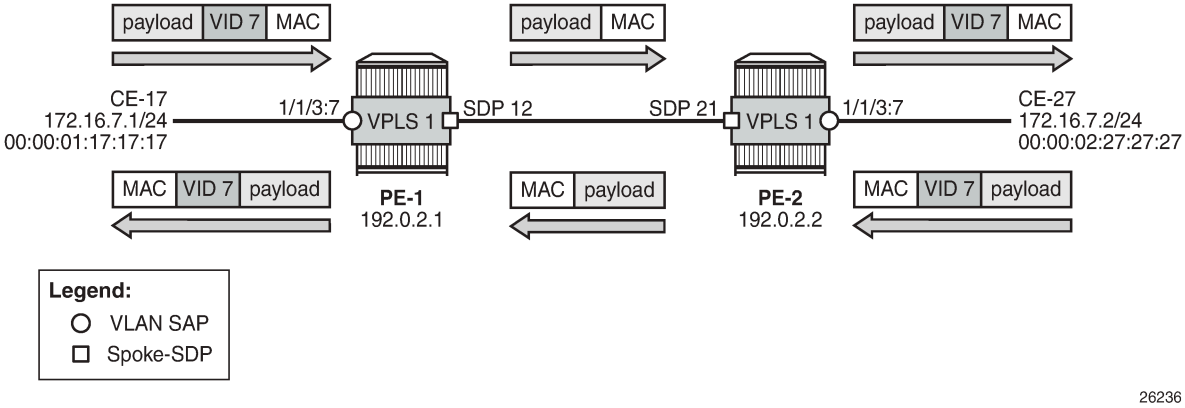

Figure 317: Customer VID is preserved between two dot1q CP SAPs shows how the customer VID 7 is preserved between CE-17 and CE-27 when CP SAPs are used instead of VLAN SAPs. The configuration for the SAPs is modified as follows:

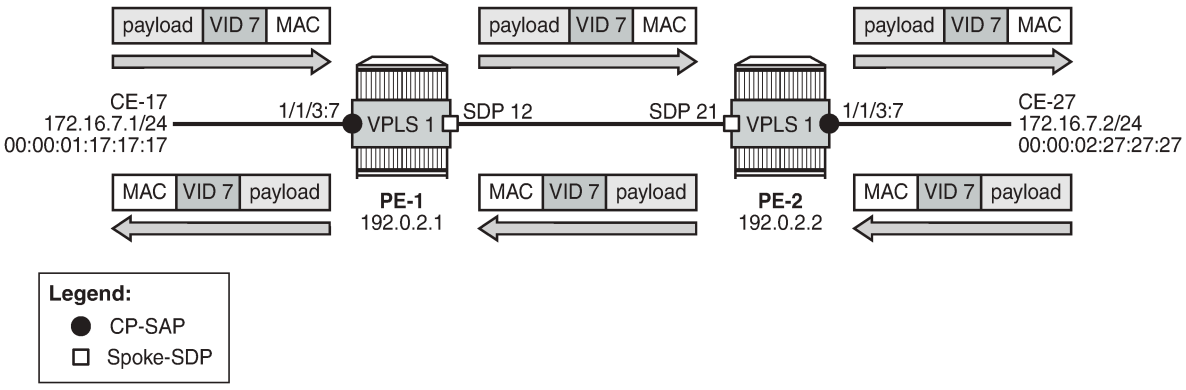
```
# on PE-1, PE-2:
configure
    service
        vpls "VPLS 1"
            sap 1/1/3:7
                shutdown
            exit
            no sap 1/1/3:7
            sap 1/1/3:cp-1 create
                no shutdown
            exit
```

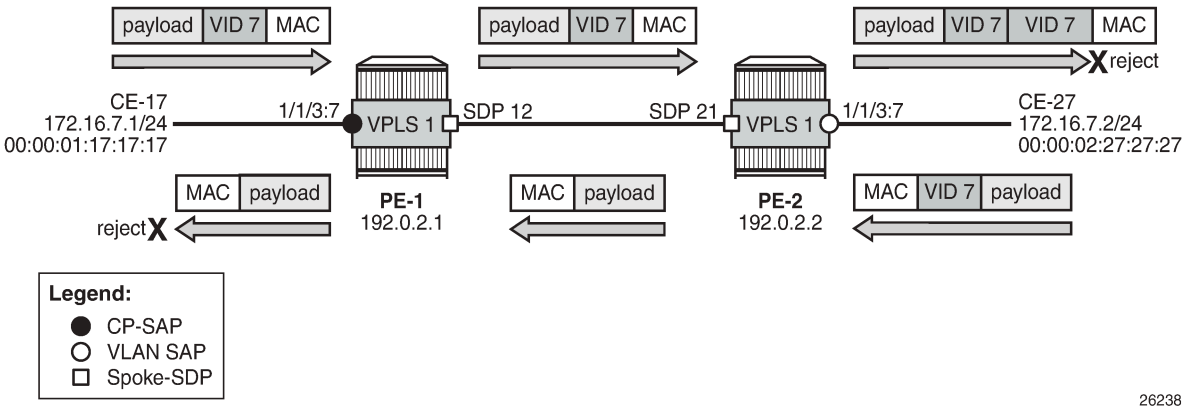
CE-17 sends frames with VID 7 to dot1q CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1, and this CP SAP preserves the VLAN tag. When the frames with VID 7 reach the egress CP SAP 1/1/3:cp-1 of VPLS 1 on PE-2, the egress CP SAP preserves the VID, and the frames are forwarded to CE-27. Traffic in the opposite direction is treated in the same way: the customer VID is preserved between the CEs.

Figure 317: Customer VID is preserved between two dot1q CP SAPs



No traffic is possible between a CP SAP in VPLS 1 on PE-1 and a VLAN SAP in VPLS 1 on PE-2, as shown in Figure 318: No traffic between dot1q CP SAP and dot1q VLAN SAP.

Figure 318: No traffic between dot1q CP SAP and dot1q VLAN SAP



The CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 remains unchanged, whereas the SAP in VPLS 1 on PE-2 is reconfigured as VLAN SAP 1/1/3:7 for VLAN 7, as follows:

```
# on PE-2:
configure
    service
        vpls "VPLS 1"
            sap 1/1/3:cp-1
                shutdown
            exit
            no sap 1/1/3:cp-1
            sap 1/1/3:7 create
                no shutdown
            exit
```

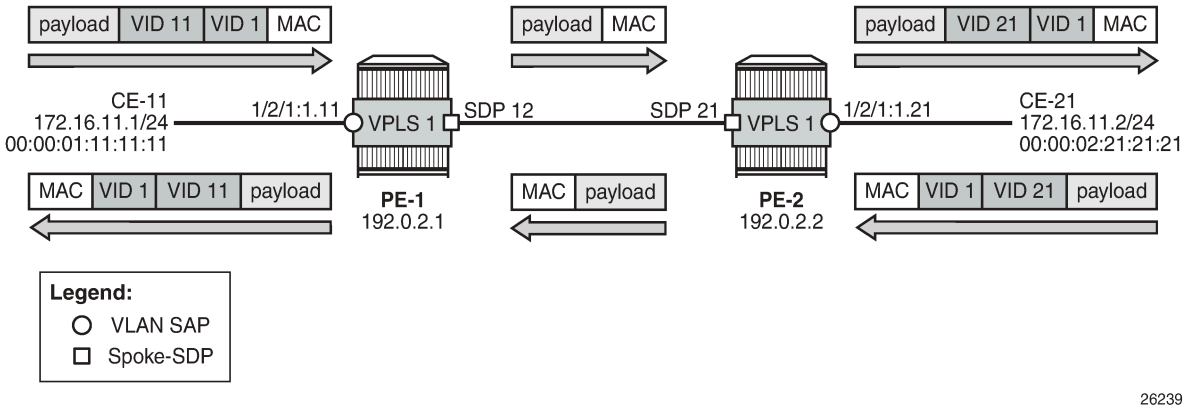
Frames from CE-17 are forwarded by CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 without any changes to the VLAN tag. The tagged frames reach the VLAN SAP 1/1/3:7, where another VLAN tag with VID 7 is pushed onto the frame. The receiver CE-27 rejects the double-tagged frame. When CE-27 sends traffic to CE-17,

the VLAN SAP 1/1/3:7 in VPLS 1 on PE-2 pops the VLAN tag and the frame is forwarded untagged to PE-1. The CP SAP 1/1/3:cp-1 on PE-1 does not push any VLAN tag and the frame is forwarded untagged to CE-17, where it is rejected.

VLAN manipulation in QinQ SAPs

Figure 319: Traffic between two QinQ VLAN SAPs - VLAN translation shows the VLAN manipulation in QinQ VLAN SAPs that pop and push the VLAN labels. In the example, the customer VID is translated.

Figure 319: Traffic between two QinQ VLAN SAPs - VLAN translation



CE-11 sends double-tagged traffic to QinQ VLAN SAP 1/2/1:1.11 in VPLS 1 on PE-1. This VLAN SAP pops both labels and forwards the frame untagged to PE-2. The egress VLAN SAP 1/2/1:1.21 in VPLS 1 on PE-2 pushes a label stack with two labels: the inner label with VID 21 and the outer label with VID 1. Both VIDs can be translated, but in this example, only the inner label gets another VID.

Figure 320: No traffic between two QinQ CP SAPs - VLAN translation not supported shows that VLAN translation is not possible between two QinQ CP SAPs. In the example, the outer tag with VID 1 is popped by the CP SAPs (VLAN translation is possible for this VLAN tag, but not done here) and the inner tag with VID 11 or 21 is preserved by the CP SAPs, which implies that the received frames will be rejected.

In this example, CP 2 is configured on both PE-1 and PE-2 with one VLAN range with one VID (11 or 21), as follows:

```
# on PE-1:
configure
    connection-profile-vlan 2 create
        vlan-range 11
    exit
```

```
# on PE-2:
configure
    connection-profile-vlan 2 create
        vlan-range 21
    exit
```

The VLAN SAP 1/2/1:1.11 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

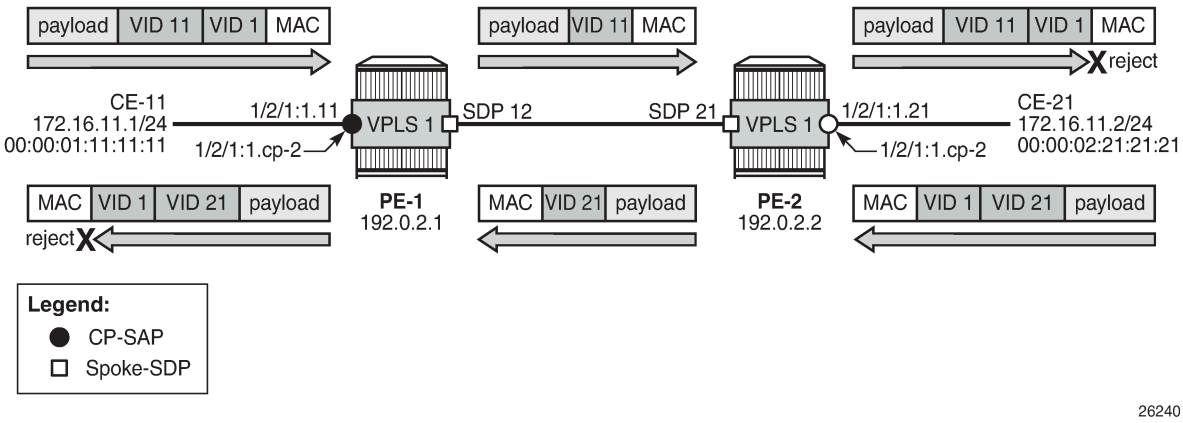
```
# on PE-1:
```

```
configure
    service
        vpls "VPLS 1"
            sap 1/2/1:1.11
                shutdown
            exit
            no sap 1/2/1:1.11
            sap 1/2/1:1.cp-2 create
        exit
```

Likewise, the VLAN 1/2/1:1.21 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

```
# on PE-2:
configure
    service
        vpls "VPLS 1"
            sap 1/2/1:1.21
                shutdown
            exit
            no sap 1/2/1:1.21
            sap 1/2/1:1.cp-2 create
        exit
```

Figure 320: No traffic between two QinQ CP SAPs - VLAN translation not supported

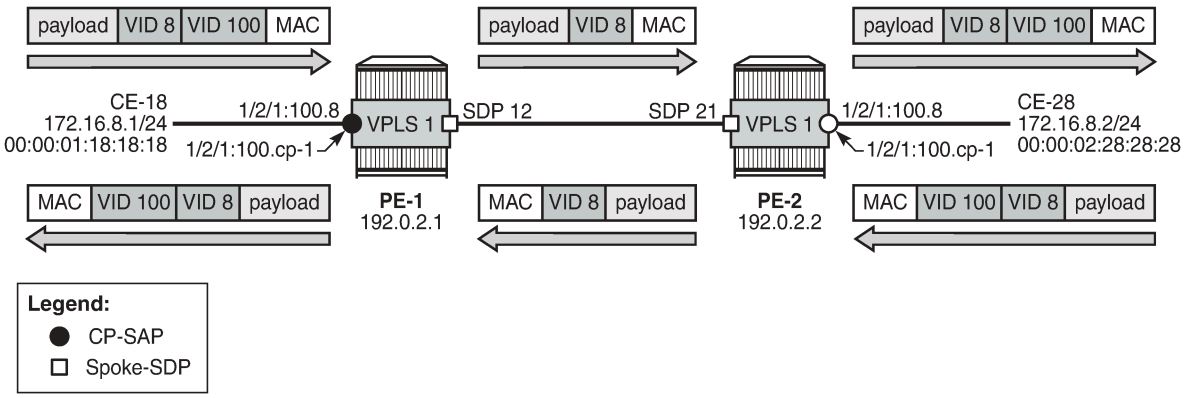


CE-11 sends double-tagged frames to SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1. This CP SAP pops the outer tag with VID 1, but preserves the VLAN tag with VID 11. The single-tagged frame is sent to PE-2 where CP SAP 1/2/1:1.cp-2 pushes an outer tag with VID 1 onto the frame. This double-tagged frame is sent to CE-12 where it is rejected, because an inner label with VID 21 is expected.

When CE-21 sends frames to CE-11, the frames will be double-tagged with inner tag VID 21 and outer tag 1. The outer tag is popped by the ingress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-2, but the inner tag is preserved. The egress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1 preserves the inner tag with VID 21 and pushes an outer tag with VID 1. This double-tagged frame is rejected by CE-11, because another inner tag is expected, with VID 11 instead of VID 21.

Figure 321: Traffic between two QinQ CP SAPs - no VLAN translation shows how traffic is sent between two QinQ CP SAPs without VLAN translation. Both CE-18 and CE-28 send double-tagged frames with inner tag VID 8 and outer tag VID 100. The tag with VID 100 need not be the same on both CEs, because it is popped and pushed by the CP SAPs; only the tag with VID 8 from the VLAN range must be unchanged.

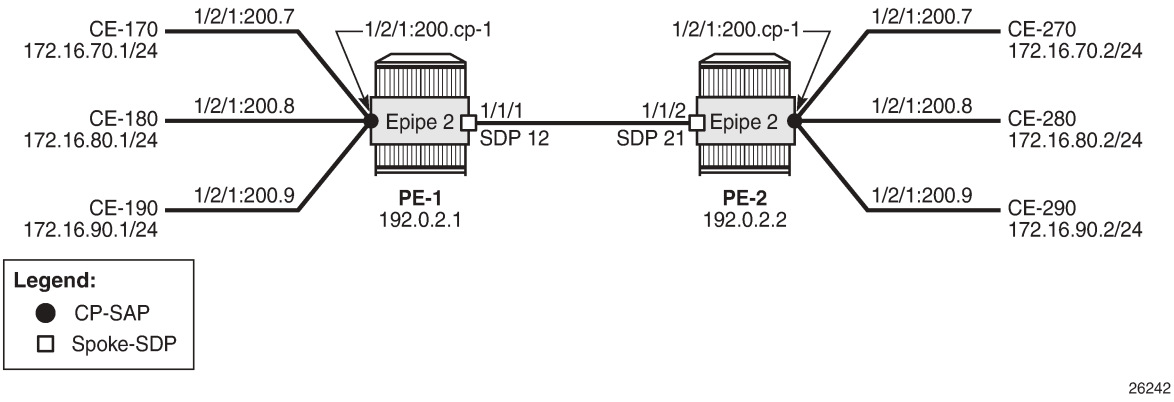
Figure 321: Traffic between two QinQ CP SAPs - no VLAN translation



VLAN ranges in Epipe services

Figure 322: Example topology for VLAN ranges in Epipe 2 shows the example topology for VLAN ranges in Epipe 2.

Figure 322: Example topology for VLAN ranges in Epipe 2



Epipe 2 is configured with one CP SAP and a spoke-SDP, as follows:

```
# on PE-1:
configure
    service
        sdp 12 mpls create
            far-end 192.0.2.2
            ldp
            keep-alive
                shutdown
            exit
        no shutdown
        exit
        epipe 2 name "Epipe 2" customer 1 create
```

```
            sap 1/2/1:200.cp-1 create
                no shutdown
            exit
            spoke-sdp 12:2 create
                no shutdown
            exit
            no shutdown
        exit
```

CE-170 and CE-270 send double-tagged frames with inner VID 7 and outer VID 200. The inner VID 7 is preserved by the CP SAPs; therefore, CE-170 can only communicate with CE-270, not with any other CE at the other end, because they have different customer VIDs.

Conclusion

CP SAPs can be used to build services that can be bundled as per MEF 10.3 and RFC 7432. Multiple customer VIDs can be mapped to one CP-SAP.

VXLAN Forwarding Path Extension

This chapter provides information about VXLAN Forwarding Path Extension.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the CLI in the current edition corresponds to SR OS Release 21.2.R2. Virtual eXtensible Local Area Network (VXLAN) Forwarding Path Extension (FPE) is supported in SR OS Release 14.0.R4, and later. IPv6 addresses are supported for EVPN-VXLAN BGP peering in SR OS Release 15.0.R1, and later.

Overview

Use cases

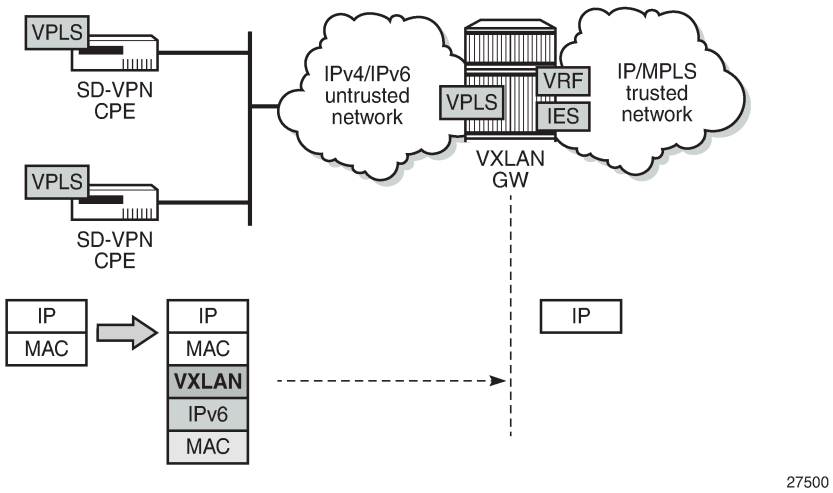
VXLAN Forwarding Path Extension (FPE) is an SR OS feature that enables VXLAN tunnels to terminate on non-system IPv4 and IPv6 Destination Addresses (DAs). The non-system IPv4/IPv6 VXLAN termination feature can be applied in the following use cases:

- VXLAN Gateway (GW) in Software-Defined VPNs (SD-VPNs)
- VXLAN IPv6 underlay for Data Centers (DCs)

VXLAN GW in SD-VPNs

Traffic transported on a VXLAN is usually connected to a trusted environment through a VPRN running in a private IP/MPLS network. The VXLAN GW system IP address is used for all internal management and MPLS termination in the trusted network. However, in this use case, SR OS routers are expected to be used as a VXLAN GW in SD-VPNs where the VXLAN GW terminates untrusted VXLAN tunnels initiated on the SD-VPN CPEs and forwards packets to a trusted IP/MPLS network, as shown in Figure 323: VXLAN GW in an SD-VPN.

Figure 323: VXLAN GW in an SD-VPN

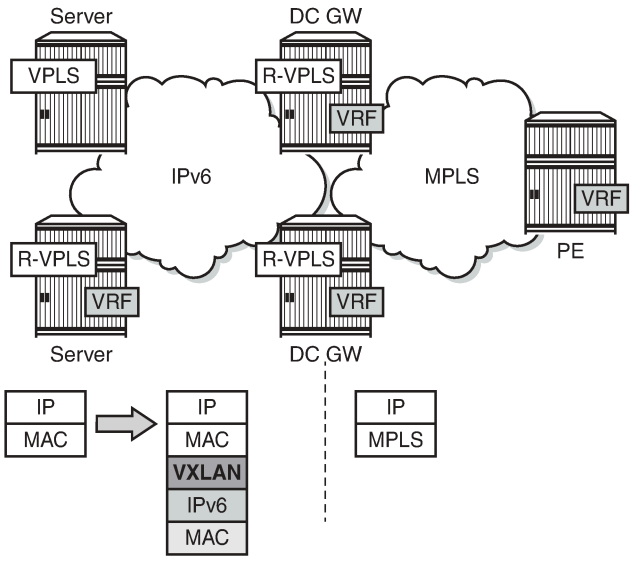


For security reasons, service providers will not expose system IP addresses to the untrusted IP network. Therefore, an IPv4 or IPv6 loopback address will be defined and used for VXLAN termination. The VXLAN tunnel can be terminated in a VPLS, an Epipe, or an R-VPLS service connected to a VPRN.

VXLAN IPv6 underlay for DCs

Some service providers migrate their entire network infrastructure to IPv6, including the DC network, so the DC GW must be able to terminate a VXLAN over an IPv6 infrastructure. Layer 2 (VPLS termination) and Layer 3 (R-VPLS termination) DC interconnect are both supported. Figure 324: VXLAN IPv6 underlay for DC shows the VXLAN IPv6 underlay for DC.

Figure 324: VXLAN IPv6 underlay for DC



VXLAN FPE function

The following applies to VXLAN FPE:

- In an SR OS node, VXLAN tunnels can be terminated in four different VXLAN Tunnel Endpoints (VTEPs):
  - System IPv4 address
  - Up to three non-system IPv4/IPv6 addresses

  This limit is based on the number of supported source IP addresses that can be used for VXLAN encapsulation.
- The preceding four terminating IP addresses can be used in addition to the Assisted Replication IP address (AR IP). The AR IP does not count against this limit of four VTEPs. See chapter Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication for more information about AR.
- VXLAN FPE requires PXC ports; see chapter *Port Cross-connect (PXC)*.
  - Ingress traffic from a VXLAN with an IP DA equal to a loopback address will be redirected to the PXC port where the IP header will get additional processing.
  - Usually, only the ingress traffic from the VXLAN is redirected to the PXC port. The egress traffic to the VXLAN tunnel can go straight out of the egress network port, except for R-VPLS traffic toward an IPv6 VXLAN that is redirected to the PXC port.
- The VPLS/R-VPLS functionality is not impacted by the choice of VTEP termination (system IP address or not).

Provisioning model

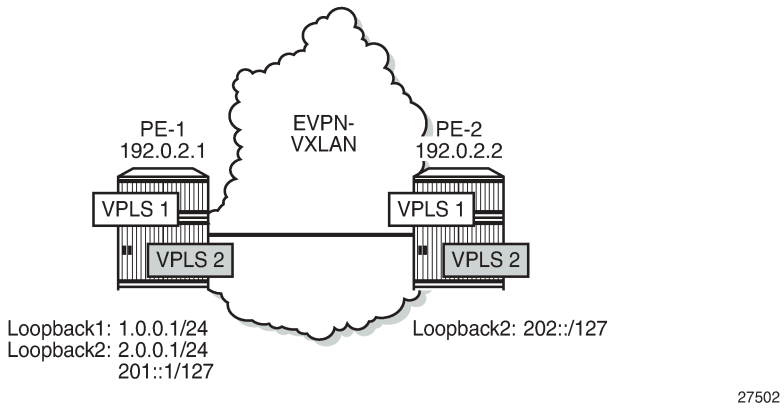
Non-system IP VXLAN termination and VXLAN IPv6 underlay are both provisioned as per the following steps:

1. Create an FPE
2. Associate the FPE with VXLAN termination
3. Configure a router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Configuration

Figure 325: Example topology for VXLAN FPE shows the example topology with two PEs in an EVPN-VXLAN network. The loopback addresses in the base router will be used for non-system IP VXLAN termination.

Figure 325: Example topology for VXLAN FPE



The initial configuration includes the cards, MDAs, ports, router interfaces and IGP. BGP is configured for address family EVPN, for example on PE-1 as follows:

```
# on PE-1:
configure
    router
        autonomous-system 64500
        bgp
            rapid-withdrawal
            split-horizon
            rapid-update evpn
            group "internal"
                family evpn
                peer-as 64500
                neighbor 192.0.2.2
                exit
            exit
        exit
```

In this example, the BGP peering is IPv4-based, but EVPN-VXLAN routes can also be exchanged between IPv6 BGP peers.

Non-system IP VXLAN termination

Create FPEs

PXC is used as a simple back-to-back cross-connect. An FPE uses the PXC ports assigned in the FPE path, either a PXC port or a LAG-based PXC. For non-system IP VXLAN terminations between VPLSs, the PXC is only required on the ingress (from VXLAN, or from PE-1 to GW PE-2). The following PXCs are created on PE-1:

```
# on PE-1:
configure
    port-xc
        pxc 1 create
            port 1/2/1
            no shutdown
```

```
        exit
        pxc 2 create
            port 1/2/2
            no shutdown
        exit
```

The PXC auto-created sub-ports and ports are enabled as follows.

```
# on PE-1:
configure
    port pxc-1.a
        no shutdown
    exit
    port pxc-1.b
        no shutdown
    exit
    port 1/2/1
        no shutdown
    exit
```

```
*A:PE-1# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPEs use the PXCs.

```
# on PE-1, PE-2:
configure
    fwd-path-ext
        fpe 1 create
            path pxc 1
        exit
        fpe 2 create
            path pxc 2
        exit
```

These FPEs are created without defining a range of SDP IDs. SDP IDs are required in case of R-VPLS services terminating IPv6 VXLAN tunnels, where the FPE is also used at the egress and an internal static SDP is created to allow for the required extra processing.

When the FPE has no VXLAN termination associated, no internal router interfaces are created, so the only router interfaces are the system interface and the interface between PE-1 and PE-2, as follows.

```
*A:PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
int-PE-1-PE-2                    Up        Up/Down     Network 1/1/1
```

```
   192.168.12.1/30                                                 n/a
system                          Up        Up/Down     Network system
   192.0.2.1/32                                                    n/a
-------------------------------------------------------------------------------
Interfaces : 2
===============================================================================
```

Associate the FPEs with VXLAN termination

The following command associates the FPEs with VXLAN termination.

```
# on PE-1, PE-2:
configure
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 1 create
            path pxc 1
            vxlan-termination
        exit
        fpe 2 create
            path pxc 2
            vxlan-termination
        exit
```

When attempting to associate the FPEs with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*A:PE-1>config>fwd-path-ext>fpe# vxlan-termination
MINOR: FPE #1021 sdp-id-range is not configured
```

After the FPEs are associated with VXLAN terminations, the system creates two internal router interfaces per FPE, one per PXC sub-port:

```
*A:PE-1# show router interface

===============================================================================
Interface Table (Router: Base)

===============================================================================
```

Configure router loopback interfaces

The following loopback interfaces are configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure
    router Base
        interface "loopback1"
            address 1.0.0.1/24
            loopback
        exit
        interface "loopback2"
            address 2.0.0.1/31
            loopback
            ipv6
                address 201::/127
            exit
        exit
        isis
            interface "loopback1"
            exit
            interface "loopback2"
            exit
        exit
```

A non /32 or /128 subnet must be assigned to the loopback interface, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 1.0.0.0/24 can be used for VXLAN tunnel termination, except for 1.0.0.1. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127, as for example for interface "loopback2".

In this scenario, only one loopback interface with an IPv4 address is sufficient: interface "loopback1" with IPv4 address 1.0.0.1/24. There is no need to configure loopback interfaces in the GW PE-2, because VXLAN FPE is only required in the ingress (from VXLAN to GW).

Configure non-system VTEP addresses

Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs; on PE-1 as follows:

```
# on PE-1:
configure
    service
        system
            vxlan
                tunnel-termination 1.0.0.2 fpe 1 create
                tunnel-termination 2.0.0.2 fpe 2 create
                tunnel-termination 201::1 fpe 2 create
            exit
        exit
```

No non-system VTEP addresses need to be configured on PE-2.

When attempting to configure the IP address of the loopback interface as a VXLAN tunnel termination, the following error is raised:

```
*A:PE-1>config>service>system>vxlan# tunnel-termination 1.0.0.1 fpe 1 create
MINOR: SVCMGR #8353 VXLAN Tunnel termination IP address cannot be configured - IP address in
 use by another application or matches a local interface IP address
```

When attempting to configure more than three non-system VTEP addresses, the following error is raised:

```
*A:PE-1>config>service>system>vxlan# tunnel-termination 1.0.0.100 fpe 1 create
MINOR: SVCMGR #8353 VXLAN Tunnel termination IP address cannot be configured - Reached system
 limit of VXLAN tunnel-termination addresses
```

When the non-system VTEP addresses are configured, an internal loopback interface "_tmnx_vli_vxlan_1_131077" is created that can respond to ICMP requests.

```
*A:PE-1# show router interface

===============================================================================

-------------------------------------------------------------------------------
Interfaces : 9
===============================================================================
```

The system does not verify whether there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding using ICMP for that address, regardless of the presence of a loopback interface in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the VPLS

A VPLS will be configured with EVPN-VXLAN enabled. By default, the system IP address will be used as the source VTEP of the VXLAN-encapsulated frames. This default behavior can be overruled by the **vxlan-src-vtep** command in the VPLS. The IP address corresponds to the non-system VTEP address configured in the preceding step (VXLAN tunnel termination). VPLS 1 is configured on PE-1 as follows:

```
# on PE-1:
```

```
configure
    service
        vpls 1 name "EVI-1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            vxlan-src-vtep 1.0.0.2
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            sap 1/1/2:1 create
                no shutdown
            exit
            no shutdown
        exit
```

When attempting to configure an IP address different from the VTEP addresses, the following error is raised:

```
*A:PE-1# configure service vpls 1 vxlan-src-vtep 1.0.0.99
MINOR: SVCMGR #8351 VXLAN Tunnel termination IP address does not exist
```

A different VTEP address can be configured as **vxlan-src-vtep** in different services on the same PE, as follows:

```
# on PE-1:
configure
    service
        vpls 2 name "EVI-2" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 2 create
            exit
            vxlan-src-vtep 201::1
            bgp
            exit
            bgp-evpn
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

The configuration of VPLS 1 on PE-2 does not include any VTEP address, because it is not required in the egress, as follows:

```
# on PE-2:
configure
    service
```

```
        vpls 1 name "VPLS 1" customer 1 create
            vxlan instance 1 vni 1 create
            exit
            bgp
            exit
            bgp-evpn
                evi 1
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

When a vxlan-src-vtep is configured in VPLS 1 on PE-1, this VTEP address will be used as the IP source VTEP for VPLS 1 and BGP will use this VTEP to the BGP NLRI next-hop, as shown in the following BGP route update messages.

The following BGP EVPN inclusive multicast route sent by PE-1 shows the configured source VTEP address 1.0.0.2 as NLRI next-hop, as originator address, and as tunnel endpoint.

```
# on PE-1:
1 2021/05/06 09:40:06.914 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:

Underlay IPv6 VXLAN termination

The configuration for underlay IPv6 VXLAN termination is similar to the non-system IP VXLAN termination. In the following example, R-VPLS 2 is configured; therefore, non-system VTEP addresses are configured in PE-2 as well as in PE-1. The changes required in PE-1 are as follows.

- IPv6 must be enabled on the router interfaces
- IPv6 native routing is configured in IS-IS
- IPv6 addresses are loopback address 201::/127 and VTEP address 201::1

```
# on PE-1:
configure
    port-xc
        pxc 2 create
            port 1/2/2
            no shutdown
        exit
    exit
    port pxc-2.a
        no shutdown
    exit
```

```
    port pxc-2.b
        no shutdown
    exit
    port 1/2/2
        no shutdown
    exit
    fwd-path-ext
        sdp-id-range from 10000 to 10127
        fpe 2 create
            path pxc 2
            vxlan-termination
        exit
    exit
    router Base
        interface "int-PE-1-PE-2
            address 192.168.12.1/30
            port 1/1/1
            ipv6
            exit
        exit
        interface "loopback2"
            address 2.0.0.1/31
            loopback
            ipv6
                address 201::/127
            exit
        exit
        isis 0
            ipv6-routing native
            interface "loopback2"
            exit
        exit
    exit
    service
        system
            vxlan
                tunnel-termination 201::1 fpe 2 create
            exit
        exit
        vpls 2 name "EVI-2" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 2 create
            exit
            vxlan-src-vtep 201::1
            bgp
            exit
            bgp-evpn
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

The service configuration on PE-2 is as follows.

```
# on PE-2:
configure
```

```
    service
        system
            vxlan
                tunnel-termination 202:: fpe 2 create
            exit
        exit
        vpls 2 name "EVI-2" customer 1 create
            allow-ip-int-bind
            exit
            vxlan instance 1 vni 2 create
            exit
            vxlan-src-vtep 202::
            bgp
            exit
            bgp-evpn
                evi 2
                vxlan bgp 1 vxlan-instance 1
                    no shutdown
                exit
            exit
            stp
                shutdown
            exit
            no shutdown
        exit
```

The routing table for IPv6 on PE-1 shows that an internal static route is configured for the source VTEP 201::1 using the FPE internal interface "_tmnx_fpe_2.a". The route to egress VTEP 202:: is an IS-IS route.

```
*A:PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
201::/127                                     Local   Local     00h16m34s  0
       loopback2                                                    0
201::1/128                                    Remote  Static    00h11m53s  5
       fe80::201-"_tmnx_fpe_2.a"                                    1
202::/127                                     Remote  ISIS      00h00m06s  15
       fe80::14:1ff:fe01:1-"int-PE-1-PE-2"                          10
-------------------------------------------------------------------------------
No. of Routes: 3
```

Likewise, the routing table for IPv6 on PE-2 shows an internal static route for source VTEP 202:: using the FPE internal interface "_tmnx_fpe_2.a":

```
*A:PE-2# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
201::/127                                     Remote  ISIS      00h00m06s  15
       fe80::10:1ff:fe01:1-"int-PE-2-PE-1"                          10
202::/127                                     Local   Local     00h00m12s  0
       loopback2                                                    0
202::/128                                     Remote  Static    00h00m13s  5
```

```
       fe80::201-"_tmnx_fpe_2.a"                                    1
-------------------------------------------------------------------------------
No. of Routes: 3
```

When non-system IPv6 VTEP addresses are used in an R-VPLS, VTEP addresses need to be configured on ingress and egress VXLAN. The system creates an internal SDP binding for the egress processing. A range of SDP IDs has been configured from 10000 to 10127. The following command lists all SDP bindings for FPE:

```
*A:PE-2# show service sdp-using | match "Fpe"
2          10002:2            Fpe    fpe_2.b             Up    524286  524286
```

The internal SDP has ID 10002 and the far-end is fpe_2.b. The following command shows that the SDP source is FPE.

```
*A:PE-2# show service sdp 10002 detail | match "Sdp" pre-lines 4 post-lines 10

===============================================================================
Service Destination Point (Sdp Id : 10002) Details
===============================================================================
-------------------------------------------------------------------------------
 Sdp Id 10002  -fpe_2.b
-------------------------------------------------------------------------------
Description           : (Not Specified)
SDP Id               : 10002                 SDP Source         : fpe
Admin Path MTU       : 0                     Oper Path MTU      : 1552
Delivery             : MPLS
Far End              : fpe_2.b               Tunnel Far End     : n/a
Oper Tunnel Far End  : n/a

Conclusion

VXLAN FPE is required to terminate VXLAN tunnels on non-system IPv4/IPv6 addresses and to configure IPv6 underlay.

Layer 3 Services

This section provides configuration information for the following topics:

- BGP Best External in a VPRN
- Carrier Supporting Carrier IP VPNs
- Flexible Algorithms for SRv6-based VPRNs
- Inter-AS VPRN Model B
- Inter-AS VPRN Model B Using MPLS over UDP
- Inter-AS VPRN Model C
- Intra-AS NG-MVPN over BIER
- Layer 3 VPN: VPRN Type Spoke
- NG-MVPN Configuration with MPLS
- NG-MVPN Configuration with PIM
- NG-MVPN Inter-AS Model B Using Non-Segmented mLDP Tunnels
- NG-MVPN Inter-AS Model C Using Non-Segmented mLDP Tunnels
- NG-MVPN Sender-Only, Receiver-Only
- NG-MVPN Source Redundancy
- NG-MVPN Wildcard S-PMSI
- Rosen MVPN Core Diversity
- Rosen MVPN Inter-AS Option B
- Selective VPRN uRPF Control on Network Interfaces
- Spoke Termination for IPv6-6VPE
- Traffic Leaking from VPRN to GRT
- Weighted ECMP for VPRN over RSVP-TE or SR-TE LSPs

BGP Best External in a VPRN

This chapter provides information about BGP Best External in a VPRN.

Topics in this chapter include:

Applicability

The information and configuration in this chapter was originally written for SR OS Release 14.0.R7. In the current edition, the CLI is updated to SR OS Release 22.2.R2.

Overview

By default, BGP speakers only advertise their best route for a destination. The BGP best external feature allows BGP speakers to advertise their best external route for a prefix/Network Layer Reachability Information (NLRI) to their IBGP peers when their best overall route for this prefix/NLRI is an internal route. This feature provides additional path visibility to the IBGP mesh. When two paths are available to reach a destination, and one is preferred, the availability of an alternate path in the RIB means that only a FIB update is required if the preferred next-hop fails. Also, the presence of two paths can reduce route oscillation.

BGP best external can be enabled in the base router with the following command:

```
*A:PE-2>config>router# bgp ?
  - bgp
  - no bgp

 [no] add-paths       + Enable/Disable BGP ADD-PATHS
 [no] advertise-exte* - Enable/Disable Advertise Best External for the bgp family
 [no] advertise-inac* - Enable/disable advertising of inactive BGP routes to other BGP
 peers
---snip---
```

```
# on PE-2:
configure
    router Base
        bgp
            advertise-external ipv4
```

Chapter *BGP Add-Path* in the Unicast Routing Protocols volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I* describes the use of the add-paths parameter for different address families. Chapter *BGP Fast Reroute* in the Unicast Routing Protocols volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I* includes a configuration example with BGP best external enabled in the base router, whereas this chapter focuses on BGP best external in a **vprn** context.

VPRN BGP best external can be configured with the following command:

```
*A:PE-2>config>service# vprn "VPRN 1" ?
  - vprn <service-id> [name <name>] [customer <customer-id>] [create]
  - no vprn <service-id>
---snip---

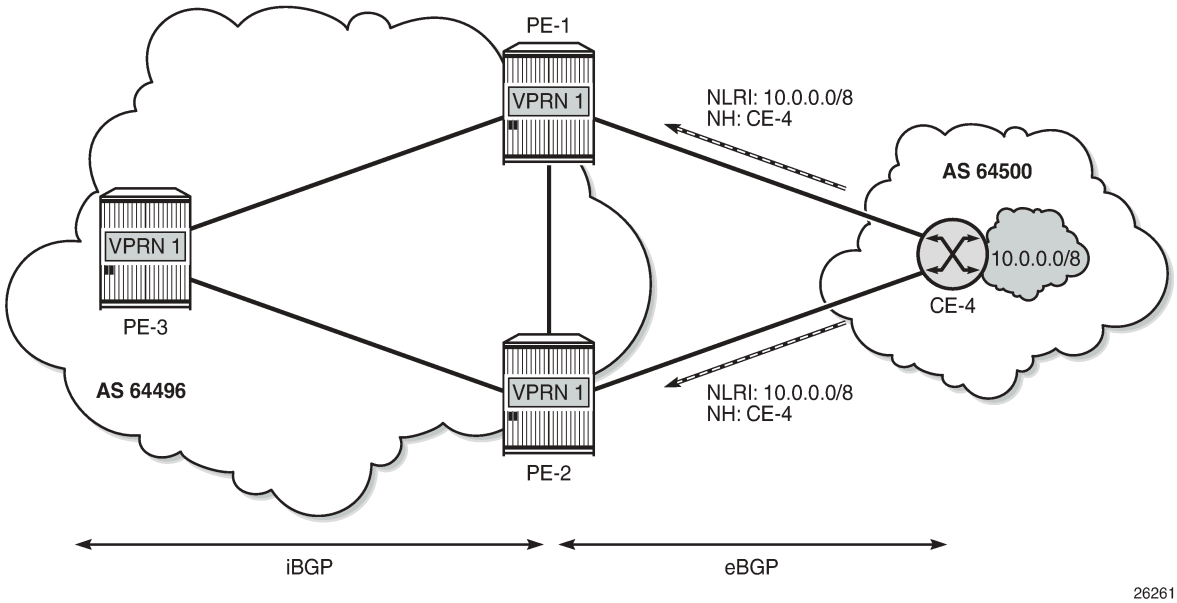
 [no] export-inactiv* - Allow/Disallow exporting inactive BGP routes
---snip---
```

```
# on PE-2:
configure
    service
        vprn 1 name "VPRN 1" customer "1" create
            export-inactive-bgp
```

VPRN BGP best external allows the best EBGP IPv4/IPv6 route learned by a VPRN to be exported as a BGP VPN-IPv4/IPv6 route, even when that EBGP IPv4/IPv6 route is inactive due to the presence of a preferred BGP VPN-IPv4/IPv6 route from another PE. This best external route advertisement is useful in active/standby multi-homing scenarios because it can ensure that all PEs have knowledge of the backup path provided by the standby PE, thus reducing convergence times. VPRN BGP best external can also be applied in combination with Equal Cost Multi-Path (ECMP).

Figure 326: CE-4 advertises prefix 10.0.0.0/8 to its EBGP peers PE-1 and PE-2 shows the example topology with CE-4 in Autonomous System (AS) 64500 advertising prefix 10.0.0.0/8 to VPRN 1 in PE-1 and PE-2 in AS 64496.

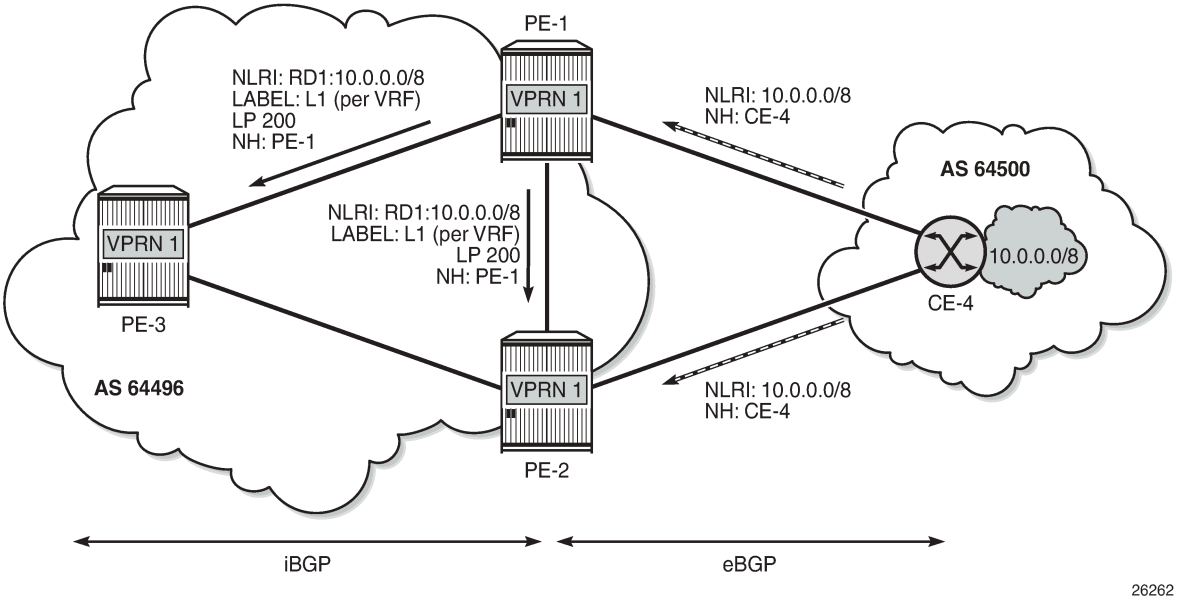
Figure 326: CE-4 advertises prefix 10.0.0.0/8 to its EBGP peers PE-1 and PE-2



PE-1 is the primary PE for this prefix and it creates a corresponding BGP VPN-IPv4 route with a higher local preference (LP) value (for example, 200) compared to the default LP (100). PE-1 advertises this BGP VPN-IPv4 route to its IBGP peers PE-2 and PE-3. PE-2 imports this BGP VPN-IPv4 route into its VRF, which deactivates the EBGP route received from CE-4, because it has the default LP of 100 (by BGP selection rules, the highest LP wins). By default, BGP prevents PE-2 from exporting its inactive BGP IPv4

route from CE-4 and, therefore, PE-1 and PE-3 cannot learn a BGP VPN-IPv4 backup route for prefix 10.0.0.0/8, as shown in Figure 327: Default BGP behavior: BGP advertises best route only.

Figure 327: Default BGP behavior: BGP advertises best route only

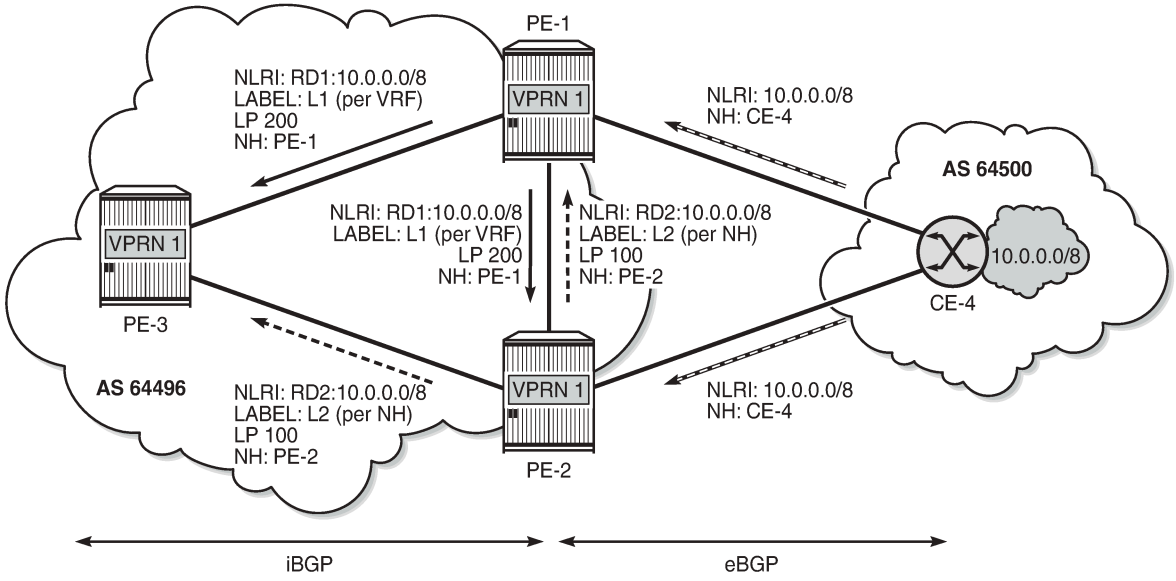


VPRN BGP best external allows PE-2 to advertise its best external route as backup on the following conditions:

- The option **export-inactive-bgp** is configured in VPRN 1 on PE-2 (or on all PEs in the multi-homed site).
- The BGP route from CE-4 must match the VRF export policy in PE-2.
- The BGP VPN-IPv4 route exported by PE-2 must have a unique NLRI (RD:IP prefix combination) that does not overlap with a BGP VPN-IPv4 route from another PE for the same prefix. Therefore, a different RD can be allocated to the VRF in each PE connected to the multi-homed site. For example, VPRN 1 in PE-1 has RD 64496:11 and VPRN 1 in PE-2 has RD 64496:12.

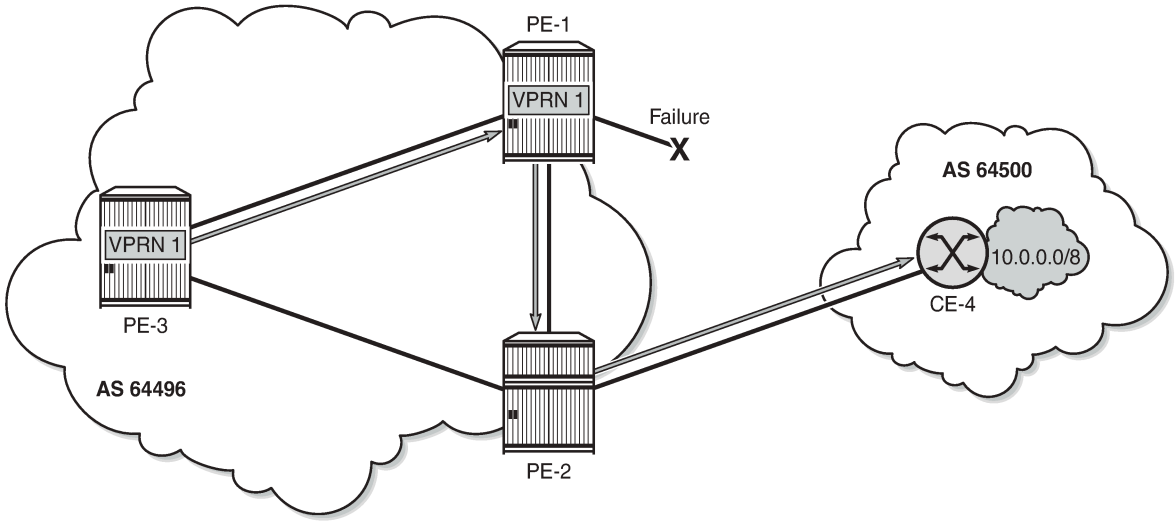
Figure 328: VPRN BGP best external enabled: BGP advertises active and standby routes shows the BGP route advertisements when VPRN BGP best external is enabled. The BGP VPN-IPv4 route from PE-2 carries a per-next-hop label (meaning pop and forward to CE-4) regardless of the configured label mode of the VPRN service in PE-2.

Figure 328: VPRN BGP best external enabled: BGP advertises active and standby routes



The PEs support BGP Fast Reroute (BGP FRR) using BGP VPN-IPv4 routes; therefore, PE-1 and PE-3 can install the route advertised by PE-2 as a backup path for prefix 10.0.0.0/8 and use that path immediately after detecting that the primary path has failed. When the link between PE-1 and CE-4 fails, PE-1 will detect this link failure typically seconds before the other PEs do. Therefore, PE-3 keeps sending traffic toward the network 10.0.0.0/8 to PE-1 and PE-1 uses the repair path via PE-2, as shown in Figure 329: BGP FRR on PE-1 after failure of active link to CE.

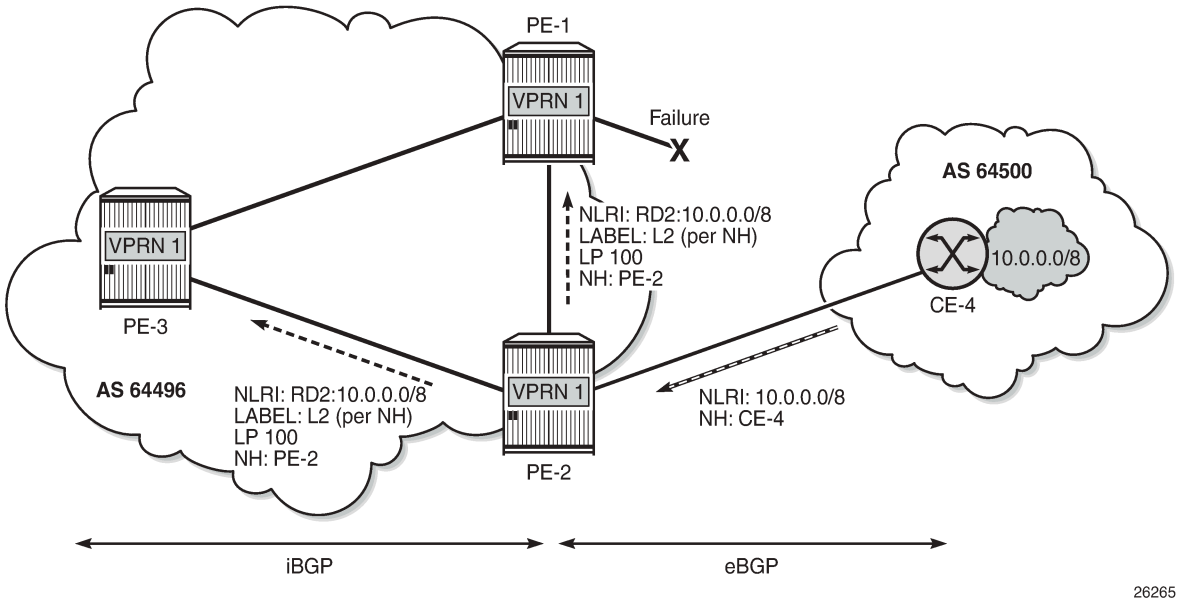
Figure 329: BGP FRR on PE-1 after failure of active link to CE



Even when PE-2 is still unaware of the link failure between PE-1 and CE-4, PE-2 will not loop traffic back to PE-1. The reason is that PE-1 sends traffic to PE-2 with a per-next-hop label so that no FIB lookup occurs in PE-2. Traffic is forwarded correctly to CE-4.

When PE-2 receives the BGP VPN-IPv4 route withdrawal from PE-1 for prefix 10.0.0.0/8, it removes the route from its RIB-IN and reruns the decision process. In this example, the EBGP route to CE-4 becomes the new primary/best path. PE-2 will re-advertise its BGP VPN-IPv4 route for prefix 10.0.0.0/8. The difference is that the BGP VPN-IPv4 route is based on the export of an active/used route and, therefore, the advertised label value is based on the configured label mode of the VPRN service, as shown in Figure 330: PE-2 re-advertises VPN-IPv4 route with label based on VRF for label mode VRF (default).

Figure 330: PE-2 re-advertises VPN-IPv4 route with label based on VRF



It takes time for this route to reach all ingress routers and for these routers to update their forwarding tables to use the per-VRF label value. For a while, there may still be traffic destined for prefix 10.0.0.0/8 that is received by PE-2 with the per-next-hop label L2. Traffic will be dropped if the per-next-hop label is deleted by the IOM as soon as PE-2 determines there are no more inactive/standby paths with CE-4 as next hop. Traffic loss can be avoided by delaying the deletion of per-next-hop labels in the IOM by configuring label retention for BGP labels with the following command:

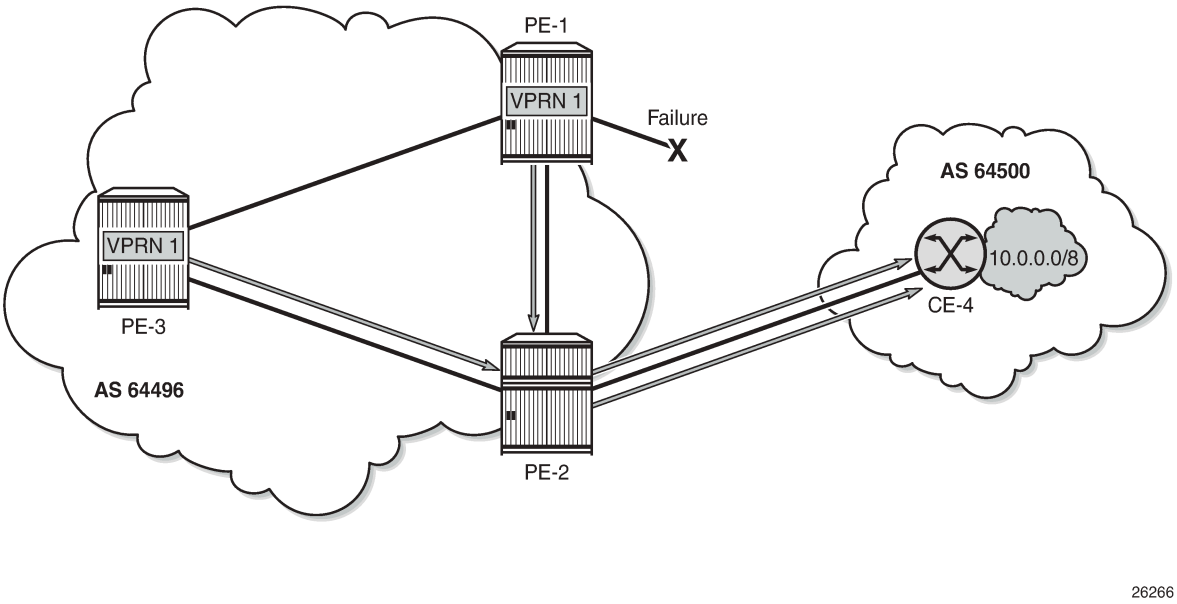
```
*A:PE-2>config>router>mpls-labels# bgp-labels-hold-timer ?
  - bgp-labels-hold-timer <seconds>
  - no bgp-labels-hold-timer

 <seconds>            : [0..255]
```

```
# on PE-2:
configure
    router Base
        mpls-labels
            bgp-labels-hold-timer 60
```

Finally, all ingress routers have updated their forwarding tables based on the BGP update sent by PE-2, and PE-3 sends traffic for prefix 10.0.0.0/8 directly toward PE-2, as shown in Figure 331: Traffic destined for prefix 10.0.0.0/8 after control plane convergence.

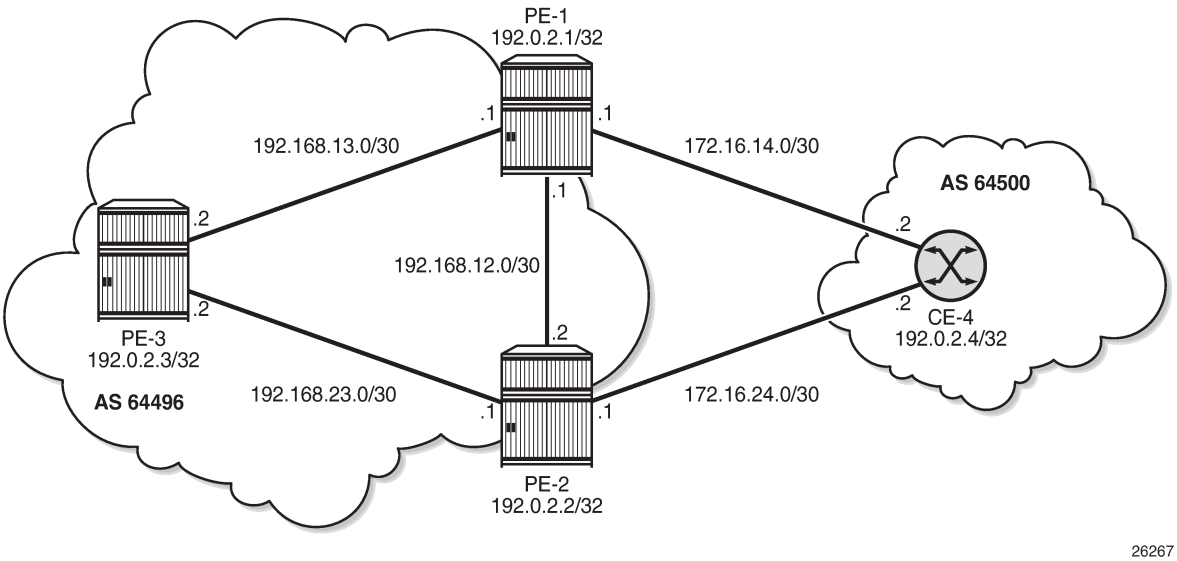
Figure 331: Traffic destined for prefix 10.0.0.0/8 after control plane convergence



Configuration

Figure 332: Example topology shows the example topology with the used IP addresses.

Figure 332: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (or OSPF) as IGP within AS 64496
- LDP on all interfaces within AS 64496

BGP is configured in the base router context of all PEs for address family VPN-IPv4; for example, for PE-1 as follows:

```
# on PE-1:
configure
    router Base
        autonomous-system 64496
        bgp
            rapid-withdrawal
            group "IBGP"
                family vpn-ipv4
                peer-as 64496
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

The BGP configuration for the base router on the other two PEs is similar and a full mesh is established in AS 64496.

Configure VPRN without BGP best external

VPRN 1 is created on all PEs with the following settings:

- Default label mode: label-mode vrf
- Ready for BGP FRR: **enable-bgp-vpn-backup ipv4**
- Different RDs in VPRN 1 for each PE: 64496:11 on PE-1, 64496:12 on PE-2, and 64496:13 on PE-3
- Auto-bind-tunnel with resolution any. In this example, LDP will be used.
- Loopback interface "lo0" with IP address 172.31.2.1/32 on PE-1, which is also defined as the router ID in VPRN 1. The same approach is used on PE-2 and PE-3: 172.31.2.2/32 and 172.31.2.3/32.
- IBGP between all PEs (full mesh) for address family IPv4
- EBGP between PE-1 and CE-4 and between PE-2 and CE-4
- BGP best external is disabled, by default.

The configuration of VPRN 1 on PE-3 is as follows:

```
# on PE-3:
configure
    service
        vprn 1 name "VPRN 1" customer 1 create
            router-id 172.31.2.3
            autonomous-system 64496
            label-mode vrf                  # default
            enable-bgp-vpn-backup ipv4
            interface "lo0" create
```

```
                address 172.31.2.3/32
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:13
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            bgp
                rapid-withdrawal
                group "IBGP"
                    peer-as 64496
                    neighbor 172.31.2.1
                    exit
                    neighbor 172.31.2.2
                    exit
                exit
            exit
            no shutdown
```

On PE-1 and PE-2, the VPRN configuration includes an external interface toward CE-4, and EBGP is defined toward peer CE-4. The VPRN 1 configuration on PE-2 is as follows:

```
# on PE-2:
configure
    service
        vprn 1 name "VPRN 1" customer 1 create
            router-id 172.31.2.2
            autonomous-system 64496
            label-mode vrf                  # default
            enable-bgp-vpn-backup ipv4
            interface "lo0" create
                address 172.31.2.2/32
                loopback
            exit
            interface "int-PE-2-CE-4_VPRN1" create
                address 172.16.24.1/30
                sap 1/1/3:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:12
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            bgp
                rapid-withdrawal
                split-horizon
                group "EBGP"
                    peer-as 64500
                    neighbor 172.16.24.2
                    exit
                exit
```

```
                group "IBGP"
                    peer-as 64496
                    neighbor 172.31.2.1
                    exit
                    neighbor 172.31.2.3
                    exit
                exit
            exit
            no shutdown
```

PE-2 does not have an import policy that sets the LP and, therefore, the default LP of 100 is used for routes imported from EBGP peer CE-4.

The VPRN 1 configuration on PE-1 looks similar to the configuration on PE-2, but includes an import policy that assigns an LP of 200 to each prefix that is received from CE-4, as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "import-bgp-LP200"
                default-action accept
                    local-preference 200
                exit
            exit
            commit
        exit
    exit
    service
        vprn 1 name "VPRN 1" customer 1 create
            router-id 172.31.2.1
            autonomous-system 64496
            label-mode vrf                  # default
            enable-bgp-vpn-backup ipv4
            interface "lo0" create
                address 172.31.2.1/32
                loopback
            exit
            interface "int-PE-1-CE-4_VPRN1" create
                address 172.16.14.1/30
                sap 1/1/3:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:11
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            bgp
                rapid-withdrawal
                split-horizon
                group "EBGP"
                    import "import-bgp-LP200"
                    peer-as 64500
                    neighbor 172.16.14.2
                    exit
                exit
```

```
                group "IBGP"
                    peer-as 64496
                    neighbor 172.31.2.2
                    exit
                    neighbor 172.31.2.3
                    exit
                exit
            exit
            no shutdown
```

CE-4 has EBGP configured toward PE-1 and PE-2. CE-4 exports the prefix 10.0.0.0/8, as defined in export policy "export-bgp" that is applied in the **bgp** context:

```
# on CE-4:
configure
    router Base
        interface "int-CE-4-PE-1_VPRN1"
            address 172.16.14.2/30
            port 1/1/1:1
        exit
        interface "int-CE-4-PE-2_VPRN1"
            address 172.16.24.2/30
            port 1/1/2:1
        exit
        interface "system"
            address 192.0.2.4/32
        exit
        interface "test_connectedNW"
            address 10.0.0.1/8
            loopback
        exit
        autonomous-system 64500
        policy-options
            begin
            prefix-list "10.0.0.0/8"
                prefix 10.0.0.0/8 longer
            exit
            policy-statement "export-bgp"
                entry 10
                    from
                        prefix-list "10.0.0.0/8"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
        bgp
            rapid-withdrawal
            split-horizon
            group "EBGP"
                export "export-bgp"
                peer-as 64496
                neighbor 172.16.14.1
                exit
                neighbor 172.16.24.1
                exit
            exit
        exit
```

Initially, VPRN BGP best external is disabled and, so only the best BGP route will be advertised and IBGP peers will not learn backup paths. The following section shows which routes are exchanged. Afterward, VPRN BGP best external will be enabled and the same show commands will be used.

Verification - VPRN without BGP best external

PE-1 imports prefix 10.0.0.0/8, assigns LP 200 to it, and advertises a corresponding VPN-IPv4 route to its IBGP peers (PE-2 and PE-3). Toward PE-2, this is as follows:

```
# on PE-1:
9 2022/04/29 09:56:15.585 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 65
    Flag: 0x90 Type: 14 Len: 30 Multiprotocol Reachable NLRI:
        Address Family VPN_IPV4
        NextHop len 12 NextHop 192.0.2.1
        10.0.0.0/8 RD 64496:11 Label 524284 (Raw label 0x7fffc1)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 6 AS Path:
        Type: 2 Len: 1 < 64500 >
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 200
    Flag: 0xc0 Type: 16 Len: 8 Extended Community:
        target:64496:1
"
```

The NLRI includes the prefix 10.0.0.0/8 and the RD 64496:11, and the label is 524284. BGP prevents PE-2 from sending a similar BGP update for prefix 10.0.0.0/8 because that route is not active on PE-2. PE-3 receives a BGP VPN-IPv4 route for network 64496:11:10.0.0.0/8, and this route has PE-1 as next hop and LP 200. No route is received from PE-2 for network 64496:12:10.0.0.0/8; as follows:

```
*A:PE-3# show router bgp routes vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.3        AS:64496       Local AS:64496
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge

      172.16.24.2                                         None        0
      64500                                                           -
i     10.0.0.0/8                                          200         None
      172.16.14.2                                         None        0
      64500                                                           -
-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

The routing table for VPRN 1 on PE-2 and PE-3 for prefix 10.0.0.0/8 shows that the next hop is PE-1 and the protocol is BGP VPN, as follows:

```
*A:PE-2# show router 1 route-table 10.0.0.0/8

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP VPN   00h01m53s  170
       192.0.2.1 (tunneled)                                        10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Instead of using an external route to CE-4, the route for prefix 10.0.0.0/8 is internal (BGP VPN), using an LDP transport tunnel to PE-1. There are no non-active routes, as can be shown by adding the keyword **all** to the preceding show command, as follows:

```
*A:PE-2# show router 1 route-table 10.0.0.0/8 all

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                           Active     Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP VPN   00h02m11s  170
       192.0.2.1 (tunneled)                                Y           10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

There are no standby routes, because BGP only advertises the best used route.

On PE-1, the following BGP IPv4 route with next hop CE-4 is used for prefix 10.0.0.0/8 in VPRN 1:

```
*A:PE-1# show router 1 bgp routes
===============================================================================
 BGP Router ID:172.31.2.1       AS:64496       Local AS:64496
```

```
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP IPv4 Routes
===============================================================================
Flag  Network                                          LocalPref   MED
      Nexthop (Router)                                 Path-Id     IGP Cost
      As-Path                                                      Label
-------------------------------------------------------------------------------
u*>i  10.0.0.0/8                                       200         None
      172.16.14.2                                      None        0
      64500                                                        -
-------------------------------------------------------------------------------
Routes : 1
===============================================================================
```

The route for prefix 10.0.0.0/8 in the routing table of VPRN 1 has next hop 172.16.14.2 on CE-4, as follows:

```
*A:PE-1# show router 1 route-table 10.0.0.0/8 all

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                         Active     Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP       00h03m06s  170
       172.16.14.2                                      Y            0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

There is no backup route because BGP prevents PE-2 from sending a standby route for prefix 10.0.0.0/8 to its IBGP peers.

PE-2 has advertised two VPN-IPv4 routes in the base router (the last number in Rcv/Act/Sent = Received/Active/Sent), as follows:

```
*A:PE-2# show router bgp summary family vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.2        AS:64496       Local AS:64496
===============================================================================
BGP Admin State         : Up          BGP Oper State              : Up
---snip---

===============================================================================
BGP VPN-IPv4 Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================

                   AS PktRcvd PktSent  InQ OutQ Up/Down   State|Recv/Actv/Sent
```

```
-------------------------------------------------------------------------------
192.0.2.1
          64496           18      17    0    0 00h06m02s 3/3/2
192.0.2.3
          64496           16      17    0    0 00h05m55s 1/1/2
-------------------------------------------------------------------------------
```

Enable BGP best external in VPRN

VPRN BGP best external is configured on PE-2 (or on all PEs in the multi-homing site) as follows:

```
# on PE-2:
configure
    service
        vprn "VPRN 1"
            export-inactive-bgp
```

When configured, this command causes all IPv4 and IPv6 VPRN BGP best external routes to be exported in the multi-protocol BGP (MP-BGP) domain. Best external routes are BGP routes for which all the following conditions are met:

- The BGP route is matched by the VRF export policy.
- The BGP route is inactive because a more preferred BGP VPN route for the same prefix is present in the route table manager (RTM).
- This BGP route is best and valid considering only VPRN BGP routes.

PE-2 is advertising a best external route and is called the standby PE for prefix 10.0.0.0/8. PEs can be active for some IP prefixes and standby for other IP prefixes.

Best external routes are advertised to the BGP VPN-IPv4 neighbors. In this example, the BGP VPN-IPv4 neighbors are IBGP neighbors, but they can also be EBGP neighbors. The RD must be unique across the PEs exporting a BGP VPN-IP route for the same prefix; otherwise, the best external route may not be advertised. The advertised VPRN label is based on the next hop IP of the best external route, regardless of the label mode of the VPRN in the standby PE.

Verification - VPRN with BGP best external - BGP FRR

VPRN with BGP best external BGP FRR results in the following. VPRN BGP best external is enabled (BGP Export Inactv) in VPRN 1 on PE-2:

```
*A:PE-2# show service id 1 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 1                   Vpn Id            : 0

===============================================================================
```

After VPRN BGP best external is enabled, PE-2 advertises its standby route for prefix 10.0.0.0/8 to its IBGP peers, as follows:

```
# on PE-2:
16 2022/04/29 10:00:35.266 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 65
    Flag: 0x90 Type: 14 Len: 30 Multiprotocol Reachable NLRI:
        Address Family VPN_IPV4
        NextHop len 12 NextHop 192.0.2.2
        10.0.0.0/8 RD 64496:12 Label 524283 (Raw label 0x7fffb1)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 6 AS Path:
        Type: 2 Len: 1 < 64500 >

-------------------------------------------------------------------------------
u*>i  64496:11:10.0.0.0/8                              200         None
      192.0.2.1                                        None        10
      64500                                                        524284
u*>i  64496:12:10.0.0.0/8                              100         None
      192.0.2.2                                        None        10
      64500                                                        524283
-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

PE-1 has one BGP VPN-IPv4 route for network 64496:12:10.0.0.0/8 with LP 100 and next hop PE-2; PE-2 has one BGP VPN-IPv4 route for network 64496:11:10.0.0.0/8 with LP 200 and next hop PE-1.

All PEs are ready for BGP FRR and the "B" flag indicates that a BGP VPN-IPv4 backup route is available. This flag is present when the VPRN is configured for BGP FRR (**enable-bgp-vpn-backup**) and a standby route has been received, as follows. The B flag was not present in the output for the routing table when VPRN BGP best external was disabled, as shown earlier.

```
*A:PE-1# show router 1 route-table 10.0.0.0/8

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.0/8 [B]                                Remote  BGP       00h03m17s  170
       172.16.14.2                                                 0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The active route on PE-1 has next hop 172.16.14.2 on CE-4.

On PE-3, the active BGP VPN-IPv4 route for prefix 10.0.0.0/8 uses an LDP transport tunnel to PE-1; a BGP VPN-IPv4 backup route is also available, as follows:

```
*A:PE-3# show router 1 route-table 10.0.0.0/8

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.0/8 [B]                                Remote  BGP VPN   00h06m47s  170
       192.0.2.1 (tunneled)                                         10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The active BGP VPN-IPv4 route on PE-2 uses an LDP transport tunnel to PE-1, but no BGP backup route is available:

```
*A:PE-2# show router 1 route-table 10.0.0.0/8

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP VPN   00h07m10s  170
       192.0.2.1 (tunneled)                                         10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

PE-2 has a standby BGP IPv4 route that is displayed with the following show command:

```
*A:PE-2# show router 1 route-table 10.0.0.0/8 all

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                          Active     Metric
-------------------------------------------------------------------------------
10.0.0.0/8 [E]                                Remote  BGP       00h04m12s  170
       172.16.24.2                                       N           0
10.0.0.0/8                                    Remote  BGP VPN   00h08m04s  170
       192.0.2.1 (tunneled)                              Y           10
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
```

```
       E = Inactive best-external BGP route
===============================================================================
```

The "E" flag indicates that this route is an inactive best external BGP route.

VPRN 1 on PE-1 and PE-3 is ready for BGP FRR (**enable-bgp-vpn-backup**) and PE-2 advertised a standby BGP VPN-IPv4 route for prefix 10.0.0.0/8; therefore, PE-1 and PE-3 can add an alternative route to the routing table of VPRN 1, as follows:

```
*A:PE-1# show router 1 route-table 10.0.0.0/8 alternative

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref

                                                                  Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP VPN   00h08m04s  170
       192.0.2.1 (tunneled)                                         10
10.0.0.0/8 (Backup)                           Remote  BGP VPN   00h08m04s  170
       192.0.2.2 (tunneled)                                         10
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       Backup = BGP backup route
       LFA = Loop-Free Alternate nexthop
       S = Sticky ECMP requested
===============================================================================
```

The alternative BGP VPN-IPv4 route for prefix 10.0.0.0/8 in VPRN 1 uses an LDP transport tunnel toward PE-2.

Configure ECMP

Because BGP best external allows advertising of an alternative path, it can also be used for load-sharing. ECMP is configured with value 2 in VPRN 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vprn "VPRN 1"
            ecmp 2
```

Other than the ECMP configuration, the VPRN configuration is the same as in the previous example. If ECMP is configured, BGP FRR is not needed anymore:

```
# on PE-1, PE-2, PE-3:
configure
    service
        vprn "VPRN 1"
            no enable-bgp-vpn-backup
```

On PE-3, the BGP decision process will prefer the route with the highest LP and, therefore, only the route via PE-1 with LP 200 will be used and there will be no load-sharing. To ensure that the routes via PE-1 and PE-2 have the same cost, the import policy in VPRN 1 on PE-1 that sets the LP to 200 is removed, as follows:

```
# on PE-1:
configure
    service
        vprn "VPRN 1"
            bgp
                group "EBGP"
                    no import
```

BGP best external is enabled (on PE-1 and) PE-2, as follows:

```
# on PE-2:
configure
    service
        vprn "VPRN 1"
            export-inactive-bgp
```

Verification - VPRN with BGP best external - ECMP

VPRN with BGP best external ECMP results in the following. With BGP best external enabled on the PEs in the multi-homing site (PE-2 and PE-3), the following two BGP VPN-IPv4 routes are used on PE-3:

```
*A:PE-3# show router bgp routes 10.0.0.0/8 vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.3        AS:64496       Local AS:64496

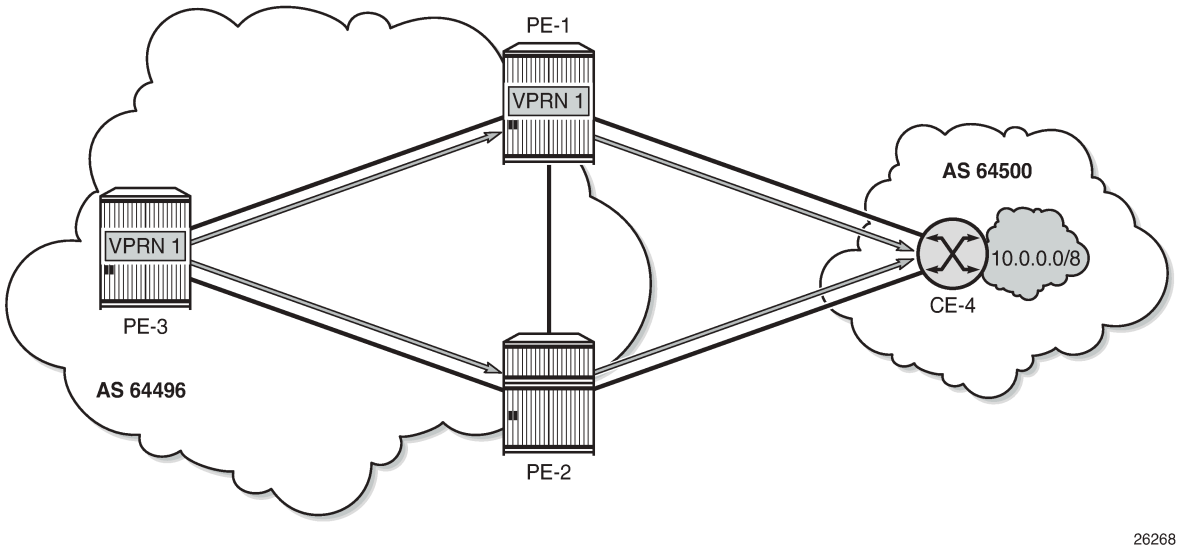
       192.0.2.1 (tunneled)                                          10
10.0.0.0/8                                    Remote  BGP VPN   00h01m50s  170
       192.0.2.2 (tunneled)                                          10
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
```

```
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Figure 333: Loadsharing for traffic from PE-3 destined to 10.0.0.0/8 shows that traffic from VPRN 1 on PE-3 destined to prefix 10.0.0.0/8 is sprayed over two paths: one via PE-1 and one via PE-2.

Figure 333: Loadsharing for traffic from PE-3 destined to 10.0.0.0/8



Conclusion

VPRNs can be configured with the option **export-inactive-bgp**, which allows a BGP speaker to advertise its best external BGP route to its BGP peers even if that route is inactive due to the presence of a more preferred BGP VPN route from another PE. BGP best external in VPRN is useful in active/standby multi-homing scenarios because it allows the standby PE to advertise a backup path. The traffic failover time can be reduced when all PE routers have advance knowledge of the potential backup paths and do not have to wait for BGP route advertisements and/or withdrawals to reprogram their forwarding tables. VPRN BGP best external can also be used in combination with ECMP.

Carrier Supporting Carrier IP VPNs

This chapter provides information about carrier supporting carrier IP VPN configurations.

Topics in this chapter include:

Applicability

This chapter was initially written for on SR OS Release 11.0.R1. The CLI in the current edition corresponds to SR OS Release 22.2.R1. Carrier Supporting Carrier is supported on the 7750 SR and 7950 XRS.

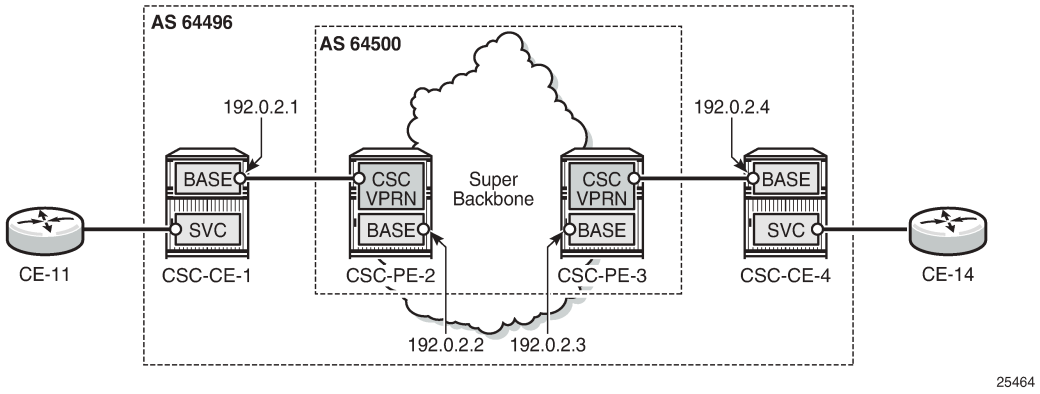
Overview

Carrier Supporting Carrier (CSC) is a solution that allows one service provider (the Customer Carrier) to use the IP VPN service of another service provider (the Super Carrier) for some or all of its backbone transport. RFC 4364 defines a Carrier Supporting Carrier solution for BGP/MPLS IP VPNs that uses MPLS at the interconnection points between the two service providers to provide a scalable and secure solution.

A simplified CSC network topology is shown in Figure 334: CSC network topology. A CSC deployment involves the following types of devices:

- CE — Customer premises equipment dedicated to one enterprise.
- PE — Edge router managed and operated by the Customer Carrier that connects to CEs to provide business VPN or Internet services.
- CSC-CE — Peering router managed and operated by the Customer Carrier that is connected to CSC-PEs for purposes of using the associated CSC IP VPN services for backbone transport. The CSC-CE may attach directly to CEs if it is also configured to be a PE for business VPN services.
- CSC-PE — A PE router managed and operated by the Super Carrier that supports one or more CSC IP VPN services possibly in addition to other traditional PE services.

Figure 334: CSC network topology



In the CSC solution, the CSC-CE and CSC-PE are directly connected by a link that supports MPLS. The CSC-CE distributes an MPLS label for every /32 IPv4 prefix it and any downstream PE uses as a BGP next-hop in routes associated with services offered by the Customer Carrier. BGP must be used as the label distribution protocol between CSC-CE and CSC-PE if the latter device is an SR OS node. Typically, the Customer Carrier and Super Carrier operate as two different Autonomous Systems (ASs) and therefore BGP, more specifically EBGP, is the best label distribution protocol, even if other options are available. The BGP session between CSC-CE and CSC-PE must be single-hop EBGP (or IBGP) if either device is an SR OS node.

In an SR OS CSC-PE, the interface to a CSC-CE is a special type of IP/MPLS interface that belongs to a VPRN configured for CSC mode. This special type of interface is called a CSC VPRN interface throughout the remainder of this chapter. The CSC VPRN interface has many of the same characteristics as a network interface of the base router but its association with a Virtual Routing and Forwarding (VRF) ensures that the traffic and control plane routes of the Customer Carrier are kept separate from other services.

When an SR OS CSC-PE receives a labeled-IPv4 route (with label L1, next-hop N1) from a CSC-CE BGP peer, the following actions take place in the CSC-PE:

1. The BGP route is installed into the routing table of the CSC VPRN (assuming the BGP route is the best route to the destination).
2. If the BGP route matches the VRF export policy, it is advertised to the core Multi-Protocol Border Gateway Protocol (MP-BGP) peers as a VPN-IPv4 route. The advertised label value is changed to label value L2.
3. BGP programs the line cards with an MPLS forwarding entry that swaps label value L2 for L1 and sends the MPLS packet over the CSC VPRN interface associated with next-hop N1.

When an SR OS CSC-PE receives a VPN-IPv4 route (with label L2, next-hop N2) the following actions take place in the CSC-PE:

1. If the VPN-IPv4 route matches the VRF import policy of a CSC VPRN, it is installed into the routing table of that CSC VPRN.
2. If the imported BGP-VPN route matches the BGP export policy associated with a CSC-CE BGP peer, it is advertised to that peer as a labeled-IPv4 route. The advertised label value is changed to label value L3.
3. BGP programs the line cards with an MPLS forwarding entry that swaps label value L3 for L2 and sends the packet inside the MPLS tunnel to next-hop N2.

Once a CSC-CE has learned a labeled-IPv4 route for a remote CSC-CE and vice versa, the two CSC-CEs can set up a BGP session between themselves and exchange VPN routes over this session if they are both PEs with services. Typically, this BGP session will be an IBGP session because the local and remote CSC-CEs belong to the same AS. The Layer 2 VPN and Layer 3 VPN routes exchanged by the CSC-CEs are resolved by the labeled-IPv4 routes they have for each other's /32 IPv4 address.

Configuration

This section will walk through the steps to configure the CSC solution shown in Figure 334: CSC network topology. The IPv4 addresses in Figure 334: CSC network topology are the system IP addresses of the routers. The steps are the following:

- Configure CSC-CE-1
- Configure CSC service on CSC-PE-2
- Verify exchange of labeled IPv4 routes between CSC-CE-1 and CSC-PE-2
- Configure core connectivity for CSC-PE-2
- Configure core connectivity for CSC-PE-3
- Configure CSC service on CSC-PE-3
- Verify exchange of VPN-IPv4 routes between CSC-PE-2 and CSC-PE-3
- Configure CSC-CE-4
- Verify exchange of labeled IPv4 routes between CSC-PE-3 and CSC-CE-4
- Configure BGP session between CSC-CE-1 and CSC-CE-4
- Verify exchange of VPN-IPv4 routes between CSC-CE-1 and CSC-CE-4

Step 1. Configure CSC-CE-1

This example assumes that CSC-CE-1 is a PE router with Layer 2 and Layer 3 VPN services that must extend across the CSC VPN service; assume that there are no further downstream PEs in AS 64496. The configuration of one such Layer 3 VPN service in CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            interface "loopback-1" create
                address 10.11.30.2/24
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:11
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

For brevity, the preceding configuration sample omits commands related to SAP IP interfaces, spoke-SDP IP interfaces, PE-CE routing protocols, QoS, IP filters, and so on. The loopback interface is used to test whether this prefix is learned at the remote CSC-CE-4.

The base routing instance of the CSC-CE is configured with the appropriate router ID and autonomous system number and the system interface is configured with an IPv4 address (usually the same as the router ID). If the router ID is not configured, by default, the system IP address is used as the router ID. The interface to CSC-PE-2 is created and configured. The base router configuration of CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure
    router Base
        interface "int-CSC-CE-1-CSC-PE-2"
            address 192.168.12.1/30
            port 1/1/1:1
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
            no shutdown
        exit
        autonomous-system 64496
    exit
```

On CSC-CE-1, BGP is configured as the control plane protocol running on the interface to CSC-PE-2, as follows:

```
# on CSC-CE-1:
configure
    router Base
        bgp
            group "CSC-PE"
                peer-as 64500
                neighbor 192.168.12.2
                    family label-ipv4
                    export "static-to-BGP"
                    split-horizon
                exit
            exit
            no shutdown
        exit
```

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**)

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Family label-IPv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels), as can be observed from the following debug message of the BGP OPEN message (in this example, debugging is enabled on CSC-CE-1 for BGP OPEN messages using the command **debug router bgp open**).This BGP OPEN message can obviously only be seen when the BGP peer is up. The configuration for CSC-PE-2 will be shown later, but in order to have the trace message, it must be configured already.

```
# on CSC-CE-1:
2 2019/05/09 07:38:09.783 UTC MINOR: DEBUG #2001 Base BGP
"BGP: OPEN
Peer 1: 192.168.12.2 - Received BGP OPEN: Version 4
   AS Num 64500: Holdtime 90: BGP_ID 192.0.2.2: Opt Length 16 (ExtOpt F)
   Opt Para: Type CAPABILITY: Length = 14: Data:
     Cap_Code MP-BGP: Length 4
       Bytes: 0x0 0x1 0x0 0x4
```

```
     Cap_Code ROUTE-REFRESH: Length 0
     Cap_Code 4-OCTET-ASN: Length 4
       Bytes: 0x0 0x0 0xfb 0xf4
"
```

The **split-horizon** command is optional. It prevents a best BGP route from the CSC-PE peer from being re-advertised back to that peer.

The **export** command applies a BGP export policy to the session. The configuration of the export policy on CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure
    router Base
        policy-options
            begin
            prefix-list "system-IP"
                prefix 192.0.2.1/32 exact
            exit
            policy-statement "static-to-BGP"
                entry 10
                    from
                        protocol direct
                        prefix-list "system-IP"
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            commit
```

The purpose of the BGP export policy is to advertise the system IP address of CSC-CE-1 as a labeled-IPv4 BGP route toward CSC-PE-2.

Step 2. Configure CSC service on SCS-PE-2

CSC-PE-2 must be configured with a VPRN in **carrier-carrier-vpn** mode to provide CSC service to CSC-CE-1. VPRN 1 is configured on CSC-PE-2, as follows:

```
# on CSC-PE-2:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            carrier-carrier-vpn
            router-id 192.0.2.2
            autonomous-system 64500
            network-interface "int-CSC-PE-2-CSC-CE-1" create
                address 192.168.12.2/30
                port 1/1/2:1
                no shutdown
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64500:12
                    vrf-target target:64500:1
                    no shutdown
                exit
```

```
            exit
            bgp
                group "CSC-CE"
                    as-override
                    export "BGP-VPN-routes"
                    peer-as 64496
                    neighbor 192.168.12.1
                        family label-ipv4
                        split-horizon
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The **carrier-carrier-vpn** command is mandatory. It cannot be configured if the VPRN currently has any SAP or spoke-SDP access interfaces configured; they must first be disabled if necessary and then deleted.

```
*A:CSC-PE-2>config>service>vprn# carrier-carrier-vpn
INFO: PIP #1195 Cannot toggle carrier-carrier-vpn - service interfaces present
```

The **auto-bind-tunnel** command must be set appropriately for the type of transport desired to other CSC-PEs, but note that GRE is not supported.

```
*A:CSC-PE-2>config>service>vprn>auto-bind-tunnel# resolution-filter gre
MINOR: SVCMGR #1538 auto-bind config not supported - Autobind gre not supported for carrier-
carrier vprn
```

The interface to CSC-CE-1 must be a network interface. A network interface can be associated with an entire Ethernet port, a VLAN sub-interface of an Ethernet port, an entire LAG or a VLAN sub-interface of a LAG. In all cases, the associated Ethernet ports must be configured in network or hybrid mode.

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon** command is optional. It prevents a best BGP route from the CSC-CE peer from being re-advertised back to that peer.

The **as-override** command replaces CSC-CE-1's AS number (64496) with CSC-PE-2's AS number (64500) in the AS_PATH attribute of routes advertised to CSC-CE-1. Without this configuration, CSC-CE-1 may reject routes originated by CSC-CE-4 as invalid due to an AS-path loop.

The **export** command applies a BGP export policy to the session. The configuration of the policy is as follows:

```
# on CSC-PE-2:
configure
    router Base
        policy-options
            begin
            policy-statement "BGP-VPN-routes"
                entry 10
                    from
                        protocol bgp-vpn
                    exit
                    action accept
```

```
                exit
            exit
            default-action drop
            exit
        exit
        commit
    exit
```

The effect of the BGP export policy is to re-advertise VPN-IPv4 routes imported into the CSC VPRN (and used for forwarding) to CSC-CE-4.

Step 3. Verify exchange of labeled IPv4 routes

When steps 1 and 2 have been completed, CSC-CE-1 advertises the labeled-IPv4 route for its system IP address 192.0.2.1/32 to CSC-PE-2. This can be checked in the RIB Out of CSC-CE-1, as follows:

```
*A:CSC-CE-1# show router bgp routes 192.0.2.1/32 label-ipv4 hunt
===============================================================================
 BGP Router ID:192.0.2.1        AS:64496       Local AS:64496

```

Step 4. Configure core connectivity for CSC-PE-2

The next step is to configure the base router instance of CSC-PE-2 so that it can exchange VPN-IPv4 routes with CSC-PE-3 (and potentially other CSC-PEs). This requires:

- Router ID and autonomous system configuration.
- Network interface creation and configuration, including assignment of an IPv4 address to the system interface.
- Configuration of the IGP protocol; in this example, IS-IS is used.
- Configuration of the LDP protocol (optional).

- Configuration of RSVP LSPs used to reach remote CSC-PE devices (optional).
- Configuration of the BGP protocol.

The base router configuration of CSC-PE-2 is as follows:

```
# on CSC-PE-2
configure
    router Base
        interface "int-CSC-PE-2-CSC-PE-3"
            address 192.168.23.1/30
            port 1/1/1:1000
            no shutdown
        exit
        interface "system"
            address 192.0.2.2/32
            no shutdown
        exit
        autonomous-system 64500
        isis 0
            level-capability level-2
            area-id 49.01
            level 2
                wide-metrics-only
            exit
            interface "system"
                passive
                no shutdown
            exit
            interface "int-CSC-PE-2-CSC-PE-3"
                interface-type point-to-point
                no shutdown
            exit
            no shutdown
        exit
        ldp
            interface-parameters
                interface "int-CSC-PE-2-CSC-PE-3" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            targeted-session
            exit
            no shutdown
        exit
        bgp
            group "core"
                type internal
                neighbor 192.0.2.3
                    family vpn-ipv4
                exit
            exit
            no shutdown
        exit
```

The peer type is IBGP (**type internal**. It is also possible to configure this in a similar way as for eBGP, with the same value for **peer-as** as the locally configured **autonomous-system**).

The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).

The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128 (=0x80), as can be observed from the following debug trace of the OPEN message from CSC-PE-2 to CSC-PE-3.

```
1 2022/04/05 07:59:07.576 UTC MINOR: DEBUG #2001 Base BGP
"BGP: OPEN
Peer 1: 192.0.2.3 - Send (Passive) BGP OPEN: Version 4
   AS Num 64500: Holdtime 90: BGP_ID 192.0.2.2: Opt Length 20 (ExtOpt F)
   Opt Para: Type CAPABILITY: Length = 18: Data:
     Cap_Code GRACEFUL-RESTART: Length 2
       Bytes: 0x0 0x78
     Cap_Code MP-BGP: Length 4
       Bytes: 0x0 0x1 0x0 0x80
     Cap_Code ROUTE-REFRESH: Length 0
     Cap_Code 4-OCTET-ASN: Length 4
       Bytes: 0x0 0x0 0xfb 0xf4
"
```

Step 5. Configure core connectivity for CSC-PE-3

The next step is to configure the base router instance of CSC-PE-3 so that it can exchange VPN-IPv4 routes with CSC-PE-2 and potentially other CSC-PEs. This requires:

- Router ID and AS configuration.
- Network interface creation and configuration, including assignment of an IPv4 address to the system interface.
- Configuration of the IGP protocol; in this example IS-IS is used.
- Configuration of the LDP protocol (optional).
- Configuration of RSVP LSPs used to reach remote CSC-PE devices (optional).
- Configuration of the BGP protocol.

The base router configuration of CSC-PE-3 is as follows:

```
# on CSC-PE-3
configure
    router Base
        interface "int-CSC-PE-3-CSC-PE-2"
            address 192.168.23.2/30
            port 1/1/2:1000
            no shutdown
        exit
        interface "system"
            address 192.0.2.3/32
            no shutdown
        exit
        autonomous-system 64500
        isis 0
            level-capability level-2
            area-id 49.01
            level 2
                wide-metrics-only
            exit
            interface "system"
                passive
                no shutdown
            exit
            interface "int-CSC-PE-3-CSC-PE-2"
                interface-type point-to-point
                no shutdown
```

```
            exit
            no shutdown
        exit
        ldp
            interface-parameters
                interface "int-CSC-PE-3-CSC-PE-2" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            targeted-session
            exit
            no shutdown
        exit
        bgp
            group "core"
                type internal
                cluster 192.0.2.3
                neighbor 192.0.2.2
                    family vpn-ipv4
                    split-horizon
                exit
            exit
            no shutdown
        exit
```

The peer type is IBGP (**type internal**. Can also be configured with **peer-as** equal to the locally configured **autonomous-system**).

The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).

The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128.

The **cluster** command configures CSC-PE-2 as a route reflector for clients in the BGP group "core". This is not required and in a more typical deployment, the route reflector would be a separate router from any CSC-PE.

Step 6. Configure CSC service on CSC-PE-3

CSC-PE-3 must be configured with a VPRN in **carrier-carrier-vpn** mode to provide CSC service to CSC-CE-4. The configuration of the VPRN is as follows:

```
# on CSC-PE-3:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            carrier-carrier-vpn
            router-id 192.0.2.3
            autonomous-system 64500
            network-interface "int-CSC-PE-3-CSC-CE-4" create
                address 192.168.34.1/30
                port 1/1/1:1
                no shutdown
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64500:13
```

```
                    vrf-target target:64500:1
                    no shutdown
                exit
            exit
            bgp
                group "CSC-CE"
                    as-override
                    export "BGP-VPN-routes"
                    peer-as 64496
                    neighbor 192.168.34.2
                        family label-ipv4
                        split-horizon
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The **carrier-carrier-vpn** command is mandatory. It cannot be configured if the VPRN has any SAP or spoke-SDP access interfaces configured; they must first be disabled if necessary and removed.

The **auto-bind-tunnel** command must be set appropriately for the type of transport desired to other CSC-PEs, but GRE is not supported.

The interface to CSC-CE-4 must be a network interface. A network interface can be associated with an entire Ethernet port, a VLAN sub-interface of an Ethernet port, an entire LAG or a VLAN sub-interface of a LAG. In all cases, the associated Ethernet ports must be configured in network or hybrid mode.

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon** command is optional. It prevents a best BGP route from the CSC-CE peer from being re-advertised back to that peer.

The **as-override** command replaces CSC-CE-4's AS number 64496 with CSC-PE-3's AS number 64500 in the AS_PATH attribute of routes advertised to CSC-CE-4. Without this configuration, CSC-CE-4 may reject routes originated by CSC-CE-1 as invalid due to an AS-path loop.

The **export** command applies a BGP export policy to the session. The configuration of the policy is as follows:

```
# on CSC-PE-3:
configure
    router Base
        policy-options
            begin
            policy-statement "BGP-VPN-routes"
                entry 10
                    from
                        protocol bgp-vpn
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            commit
```

```
        exit
```

The effect of the BGP export policy is to re-advertise VPN-IPv4 routes imported into the CSC VPRN (and used for forwarding) to CSC-CE-4.

Step 7. Verify exchange of VPN-IPv4 routes between CSC-PE-2 and CSC-PE-3.

When the preceding steps have been completed, CSC-PE-2 advertises the labeled-IPv4 route for 192.0.2.1/32 (the system IP address of CSC-CE-1) to CSC-PE-3. This can be checked in the RIB Out of CSC-PE-2, as follows:

```
*A:CSC-PE-2# show router bgp routes 192.0.2.1/32 vpn-ipv4 hunt
===============================================================================

-------------------------------------------------------------------------------
Total Labels allocated:   1
===============================================================================
```

Step 8. Configure CSC-CE-4

In this example, CSC-CE-4 is a PE router with Layer 2 and Layer 3 VPN services that must extend across the CSC VPN service. The configuration of one such Layer 3 VPN service in CSC-CE-4 is as follows:

```
# on CSC-CE-4
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            interface loopback-1 create
                address 10.14.30.2/24
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64496:14
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

For brevity, the preceding configuration sample omits commands related to SAP IP interfaces, spoke-SDP IP interfaces, PE-CE routing protocols, QoS, IP filters, and so on.

The base routing instance of CSC-CE-4 is configured with the appropriate router ID and AS number and the system interface has an IPv4 address (usually the same as the router ID). The interface to CSC-PE-3 is configured. The base router configuration of CSC-CE-4 is as follows:

```
# on CSC-CE-4
configure
    router Base
        interface "int-CSC-CE-4-CSC-PE-3"
            address 192.168.34.2/30
            port 1/1/2:1
            no shutdown
        exit
        interface "system"
            address 192.0.2.4/32
            no shutdown
        exit
        autonomous-system 64496
    exit
```

BGP is configured as the control plane protocol running on the interface to CSC-PE-3, as follows:

```
# on CSC-CE-4
configure
    router Base
        bgp
            group "CSC-PE"
                peer-as 64500
                neighbor 192.168.34.1
                    family label-ipv4
                    export "static-to-BGP"
                    split-horizon
                exit
            exit
```

```
            no shutdown
        exit
```

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon** command is optional. It prevents a best BGP route from the CSC-PE peer from being re-advertised back to that peer.

The **export** command applies a BGP export policy to the session. The configuration of the policy is as follows:

```
# on CSC-CE-4
configure
    router Base
        policy-options
            begin
            prefix-list "system-IP"
                prefix 192.0.2.4/32 exact
            exit
            policy-statement "static-to-BGP"
                entry 10
                    from
                        protocol direct
                        prefix-list "system-IP"
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            commit
        exit
```

The purpose of the BGP export policy is to advertise the system IP address of CSC-CE-4 as a labeled-IPv4 BGP route toward CSC-PE-3.

Step 9. Verify exchange of labeled IPv4 routes between CSC-PE-3 and CSC-CE-4

When the preceding steps are completed, CSC-PE-3 advertises the labeled-IPv4 route for 192.0.2.1/32 to CSC-CE-4. This can be checked in the RIB Out for VPRN 1 on CSC-PE-3, as follows:

```
*A:CSC-PE-3# show router 1 bgp routes 192.0.2.1/32 label-ipv4 hunt
===============================================================================
 BGP Router ID:192.0.2.3        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

```

The BGP distributed labels are programmed in the line cards of CSC-PE-3 based on the received VPN-IPv4 routes from CSC-PE-2 (Label Origin = Internal) and the advertised labeled-IPv4 routes to CSC-CE-4:

```
*A:CSC-PE-3# show router 1 bgp inter-as-label

===============================================================================
BGP Inter-AS labels
Flags: B - entry has backup, P - entry is promoted
===============================================================================
NextHop                       Received       Advertised     Label
                              Label          Label          Origin
-------------------------------------------------------------------------------
192.0.2.2                     524284         524284         Internal
192.0.2.2                     524285         524286         Internal
-------------------------------------------------------------------------------
Total Labels allocated:   2
===============================================================================
```

In the preceding output, the first entry for NextHop 192.0.2.2 corresponds to the prefix 192.0.2.1/32; recall from Step 7 that CSC-PE-3 received the VPN-IPv4 route with label value 524284 and it can be seen from this step that it re-advertised the route to CSC-CE-4 with the same label value 524284.

Step 10. Configure BGP session between CSC-CE-1 and CSC-CE-4

The final step in the setup of the CSC solution shown in Figure 334: CSC network topology is the creation of a BGP session between CSC-CE-1 and CSC-CE-4 so that they can exchange routes belonging to VPN services they support. The configuration of this BGP session on CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure
    router Base
        bgp
            group "CSC-CE"
                type internal
                neighbor 192.0.2.4
                    family vpn-ipv4
                exit
            exit
            no shutdown
        exit
```

The configuration of the BGP session on CSC-CE-4 is similar, as follows:

```
# on CSC-CE-4:
configure
```

```
    router Base
        bgp
            group "CSC-CE"
                type internal
                neighbor 192.0.2.1
                    family vpn-ipv4
                exit
            exit
            no shutdown
        exit
```

The configuration of the BGP session between CSC-CE-1 and CSC-CE-4 has the following properties:

- The peer type is IBGP (**type internal**. Alternatively, **peer-as** can be configured with the same value as the locally configured **autonomous-system**).
- The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).
- The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128.

Step 11. Verify exchange of VPN-IPv4 routes

When the preceding steps have been completed, CSC-PE-3 can advertise a VPN-IPv4 route for some IP prefix (for example, 10.11.30.0/24) to CSC-CE-4. This can be checked in the RIB In of CSC-CE-4 as follows:

```
*A:CSC-CE-4# show router bgp routes 10.11.30.0/24 vpn-ipv4 hunt
===============================================================================

```

Conclusion

Carrier Supporting Carrier is a scalable and secure solution for using an infrastructure IP VPN to transport traffic between dispersed CSC-CE devices belonging to an ISP or other service provider. Many different topology models are supported by SR OS. This chapter has explored one simplified configuration that can serve as the basis for more complicated setups.

Flexible Algorithms for SRv6-based VPRNs

This chapter provides information about flexible algorithms (Flex-Algorithm) for VPRNs that are based on segment routing over IPv6 (SRv6).

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. The Flex-Algorithm for SRv6-based VPRNs feature is supported on FP-based platforms with FP4-based network ports in SR OS Release 21.5.R2 and later.

Overview

The Flex-Algorithm for SRv6-based VPRNs feature allows the computation of constraint-based paths across an SRv6-enabled network, based on metrics other than the default interior gateway protocol (IGP) metrics. The supported metrics are:

- IGP metrics
- link delay metrics
- traffic engineering (TE) metrics

Based on the metrics that are specifically configured for it, each Flex-Algorithm instance computes optimum paths across routers that participate in the Flex-Algorithm instance. For these paths, the IGP protocol automatically creates SRv6 tunnels between every pair of routers participating in the Flex-Algorithm instance. Two or more routers participate in a single Flex-Algorithm instance; a single router may participate in multiple Flex-Algorithm instances.

At least one router advertises (via extensions to the IGP protocol) the flexible algorithm definition (FAD). The **metric-type** *{igp|te-metric|delay}* command in the **router Base flexible-algorithm-definitions flex-algo <fad-name>** context configures the metric type that the Flex-Algorithm instance uses: *igp*, *delay*, or *te-metric*. The router that advertises the FAD typically also participates in the Flex-Algorithm instance. The other routers participate in the advertised Flex-Algorithm instance, without also advertising it. For reasons of redundancy, multiple routers may advertise the same FAD. In that case, the configuration of that FAD should be identical on all these routers. If not, all routers that participate in the Flex-Algorithm instance install from conflicting FADs only the FAD that has the highest priority value. If conflicting FADs have the same priority value, all routers that participate in the Flex-Algorithm instance install only the FAD that is advertised by the IS-IS-enabled router with the highest IS-IS system ID (or by the OSPF-enabled router with the highest OSPF router ID).

The **algorithm** <*flex-algo-id*> command in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context, associates each Flex-Algorithm instance (algorithm 128 to algorithm 255) with one specific SRv6 locator, which must be different from the base algorithm (algorithm 0) SRv6

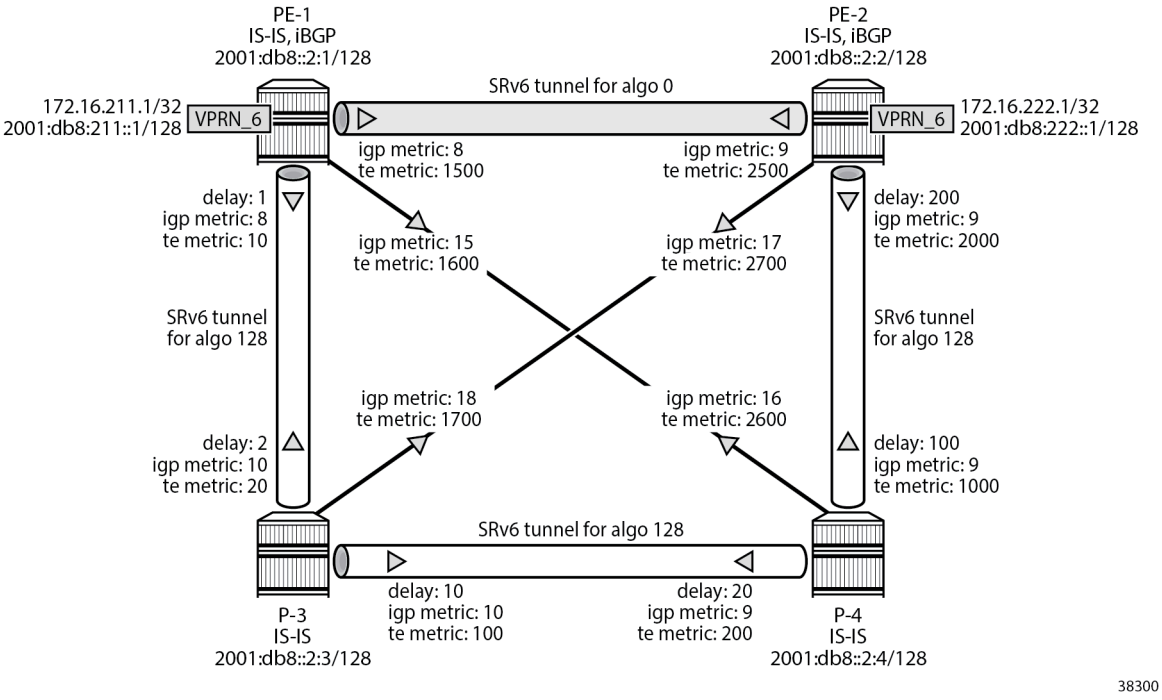
locator. This algorithm identifier is included in the SRv6 locator TLV when advertising the locator into IS-IS. The same FAD may be used in multiple Flex-Algorithm instances. Each Flex-Algorithm instance is associated with, at most, one SRv6 locator. Each SRv6 locator has, at most, one associated Flex-Algorithm instance. The **default-locator** <*name*> command in the **service vprn <service-id> bgp-ipvpn segment-routing-v6 srv6-instance <[1..2]>** context configures the SRv6 locator that the VPRN data traffic across SRv6-enabled networks uses.

The further processing of the Flex-Algorithm-based VPRN data traffic across SRv6-enabled networks follows that of the base algorithm-based VPRN data traffic across SRv6-enabled networks, as described in the Segment Routing over IPv6 for VPRN chapter.

Configuration

Figure 335: Example topology shows the example topology with four routers. The SRv6-enabled network that it represents comprises PE-1 and PE-2 in the control and data plane, and P-3 and P-4 in the data plane only. The SRv6-enabled network has only IPv6 addresses and interfaces. IS-IS is configured on all routers. BGP is configured only on PE-1 and PE-2.

Figure 335: Example topology



PE-1 and PE-2 are SRv6-enabled routers that each contain a VPRN instance. In this example, bidirectional IPv4 and IPv6 VPRN traffic flows are enabled between PE-1 and PE-2.

To illustrate what IS-IS interface metrics are used and how, the IS-IS interface metrics are configured explicitly (that is, differently from their default values), using the **metric** <*ipv4-metric*> command (for IPv4 unicast traffic) and the **ipv6-unicast-metric** <*ipv6-metric*> command (for IPv6 unicast traffic) in the **router Base isis 0 interface <ip-int-name> level {1|2}** context. Different values can be applied for IS-IS level 1 and IS-IS level 2; for each IS-IS level, a distinction can be made between IPv4 unicast traffic and IPv6

unicast traffic. For each IS-IS level and traffic type, different values can be configured in the two directions between two routers.

As a first example, the link delay metric is chosen for the Flex-Algorithm operation. The link delay metrics are configured explicitly, using the **static** <*value*> command (value in microseconds) in the **router Base interface <interface-name> if-attribute delay** context, only on the links between PE-1 and P-3, P-3 and P-4, and P-4 and PE-2. These metrics are configured differently in the two directions on each link (shown in the example topology as: "delay: <value in microseconds>"). The link delay metric can be configured on links between any pair of routers participating in the Flex-Algorithm instance. Any link that does not have the link delay metric configured is excluded from the Flex-Algorithm instance computation, which may result in no valid path between the ingress and egress routers. The link delay metric values are used for both IPv4 unicast traffic and IPv6 unicast traffic.

As a second example, the TE metric is chosen for the Flex-Algorithm operation. The TE metrics are configured explicitly, using the **te-metric** <*value*> command in the **router Base mpls interface <interface-name>** context, on all links. These metrics are configured differently in the two directions on each link, such that the direct link between the two routers PE-1 and PE-2 is always preferred.

The **ping** and **traceroute** commands between IPv4 and IPv6 loopback addresses in the VPRNs, as described in following sections, are used to simulate data traffic.

SRv6 requires wide metrics to match the 32-bit metric field in SRv6 locator TLV. The example configuration has wide metrics configured only for level 2. So, only the explicitly configured IS-IS level 2 interface metric values are used. Also, multi-topology and multi-protocol are not enabled in the example configuration. So, the explicitly configured IS-IS level 2 interface metric values are used for both IPv4 unicast traffic and IPv6 unicast traffic.

Configure the router

This configuration includes:

- ports and IPv6-only interfaces on PE-1, PE-2, P-3, and P-4, with link delay metrics configured where needed
- port cross-connect (PXC) on PE-1 and PE-2, using internal loopbacks on an FP4 MAC chip, as described in the Segment Routing over IPv6 chapter
- IS-IS on PE-1, PE-2, P-3, and P-4, which includes:
  - level 2 capability with wide metrics, and IPv4 metrics on all level 2 IS-IS interfaces
  - native IPv6 routing
  - the **traffic-engineering** and **traffic-engineering-options** commands, as a best practice to advertise the router capability within the autonomous system (AS)
- BGP on PE-1 and PE-2, with internal group "gr_v6_internal", which includes:
  - the IPv4 and IPv6 families
  - **extended-nh-encoding** for IPv4
  - **advertise-ipv6-next-hops** for IPv4
  - BGP neighbor **system** IPv6 addresses
  - **next-hop-self**

As the core network topology uses IPv6 for BGP peering (with IPv6 next hop addresses), the commands **advertise-ipv6-next-hops** and **extended-nh-encoding** need to be applied at the BGP, group, or neighbor

level, so as to advertise and receive IPv4 routes with IPv6 next hop addresses. The **advertise-ipv6-next-hops** command instructs the system to advertise IPv4 routes with IPv6 next hop addresses. The **extended-nh-encoding** command configures BGP to advertise the capability to receive IPv4 routes with IPv6 next hop addresses.

The following example configuration applies for PE-1. A similar configuration applies for PE-2. P-3 and P-4 have no BGP configuration.

```
*A:PE-1# configure
    router Base
        autonomous-system 64500
        interface "int-PE-1-PE-2"
            description "interface between PE-1 and PE-2"
            port 1/1/c1/1:1000
            ipv6
                address 2001:db8::168:12:1/126
            exit
            no shutdown
        exit
        interface "int-PE-1-P-3"
            description "interface between PE-1 and P-3"
            port 1/1/c2/1:1000
            ipv6
                address 2001:db8::168:13:1/126
            exit
            if-attribute
                delay
                    static 1    # microseconds
                exit
            exit
            no shutdown
        exit
        interface "int-PE-1-P-4"
            description "interface between PE-1 and P-4"
            port 1/1/c3/1:1000
            ipv6
                address 2001:db8::168:14:1/126
            exit
            no shutdown
        exit
        interface "system"
            description "system interface of PE-1"
            ipv6
                address 2001:db8::2:1/128
            exit
            no shutdown
        exit
        isis 0

            level-capability level-2
            area-id 49.0001
            traffic-engineering
            traffic-engineering-options
                ipv6
                application-link-attributes
                exit
            exit
            advertise-router-capability as
            ipv6-routing native
            level 2
                wide-metrics-only    # required for SRv6
            exit
            interface "system"
```

```
                passive
                no shutdown
            exit
            interface "int-PE-1-PE-2"
                interface-type point-to-point
                level 2
                    metric 8
                exit
                no shutdown
            exit
            interface "int-PE-1-P-3"
                interface-type point-to-point
                level 2
                    metric 8
                exit
                no shutdown
            exit
            interface "int-PE-1-P-4"
                interface-type point-to-point
                level 2
                    metric 15
                exit
                no shutdown
            exit
            no shutdown
        exit
        bgp
            min-route-advertisement 1
            router-id 1.1.1.10
            rapid-withdrawal
            split-horizon
            group "gr_v6_internal"
                description "internal bgp group on PE-1"
                family ipv4 ipv6
                next-hop-self
                type internal
                extended-nh-encoding ipv4
                advertise-ipv6-next-hops ipv4
                neighbor 2001:db8::2:2
                exit
            exit
            no shutdown
        exit
    exit all
```

Configure the VPRN services on PE-1 and on PE-2

This configuration includes:

- an IPv4 address and an IPv6 address for a loopback interface "lb_itf_vprn"
- BGP, with external group "gr_v6_vprn", which includes:
  - IPv4 and IPv6 families
  - **extended-nh-encoding** for IPv4
  - **advertise-ipv6-next-hops** for IPv4
  - BGP neighbor **interface** IPv6 addresses, with BGP neighbors in a different external AS

The following example configuration applies for the VPRN on PE-1. A similar configuration applies for the VPRN on PE-2.

```
*A:PE-1# configure service
        vprn 6 name "VPRN_6" customer 1 create
            description "VPRN_6 on PE-1"
            autonomous-system 64500
            interface "lb_itf_vprn" create
                address 172.16.211.1/32
                description "VPRN_6 interface on PE-1 for external subnet"
                ipv6
                    address 2001:db8:211::1/128
                exit
                loopback
            exit
            bgp
                group "gr_v6_vprn"
                    description "external bgp group for VPRN_6 on PE-1"
                    family ipv4 ipv6
                    extended-nh-encoding ipv4
                    advertise-ipv6-next-hops ipv4
                    neighbor 2001:db8:101::1
                        type external
                        peer-as 64501
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit all
```

Configure SRv6 in the router Base context on PE-1 and PE-2

Configure the SRv6 **locator** in the **router Base segment-routing segment-routing-v6** context on PE-2. Perform a similar configuration on PE-1, with **ip-prefix** *2001:db8:aaaa:101::/64* for SRv6 **locator** *"PE-1_loc"*.

```
*A:PE-2# configure router Base segment-routing segment-routing-v6
                locator "PE-2_loc"
                    block-length 48
                    function-length 20
                    no algorithm    # algo 0
                    prefix
                        ip-prefix 2001:db8:aaaa:102::/64
                    exit
                    no shutdown
                exit all
```

Configure the FPEs on PE-1 and PE-2.

```
*A:PE-2# configure
    fwd-path-ext
        fpe 1 create
            path pxc 1
            srv6 origination
                interface-a
                exit
                interface-b
                exit
```

```
            exit
        exit
        fpe 2 create
            path pxc 2
            srv6 termination
                interface-a
                exit
                interface-b
                exit
            exit
        exit
    exit all
```

Use FPE 1 as the SRv6 origination FPE in the **router Base segment-routing segment-routing-v6** context and FPE 2 as the SRv6 termination FPE in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*. For more information, see the Segment Routing over IPv6 chapter.

```
*A:PE-2# configure router Base segment-routing
            segment-routing-v6
                origination-fpe 1
                locator "PE-2_loc"
                    termination-fpe 2
                    no shutdown
                exit
            exit all
```

Configure the SRv6 End function (equivalent to an IPv4 node SID) in the **router Base segment-routing segment-routing-v6 base-routing-instance locator <locator-name>** context on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*.

```
*A:PE-2# configure router Base segment-routing segment-routing-v6 base-routing-instance
                    locator "PE-2_loc"
                        function
                            end 1
                                srh-mode usp
                            exit
                        exit
                    exit all
```

Advertise the SRv6 locator in IS-IS while ensuring level 2 capability on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*.

```
*A:PE-2# configure router Base isis 0
            segment-routing-v6
                locator "PE-2_loc"
                    level-capability level-2
                    level 2
                    exit
                exit
                no shutdown
            exit all
```

Configure SRv6 for the VPRNs on PE-1 and PE-2

On PE-1 and PE-2, extend the BGP advertisements to include the VPN-IPv4 and VPN-IPv6 families.

```
*A:PE-1#/*A:PE-2# configure router Base
        bgp
            rapid-update vpn-ipv4 vpn-ipv6
            group "gr_v6_internal"
                family ipv4 ipv6 vpn-ipv4 vpn-ipv6
                extended-nh-encoding ipv4 vpn-ipv4
                advertise-ipv6-next-hops ipv4 vpn-ipv4 vpn-ipv6
            exit
            no shutdown
        exit all
```

On PE-2, create an SRv6 instance for the VPRN service. Use the SRv6 locator from the **router Base segment-routing segment-routing-v6 <instance>** context and configure End.DT4 and End.DT6 functions for it.

Use the created SRv6 instance in the **service vprn <service-id> bgp-ipvpn segment-routing-v6** context, with the configured SRv6 locator as the default locator. Ensure a unique route distinguisher. Use the unique PE-2 system IPv6 address as the source address. Perform a similar configuration on PE-1, with the PE-1 SRv6 locator as the default locator, the PE-1 system IPv6 address as the source address, and a different route distinguisher.

```
*A:PE-2# configure service
        vprn 6
            segment-routing-v6 1 create
                locator "PE-2_loc"
                    function
                        end-dt4
                        end-dt6
                    exit
                exit
            exit
            bgp-ipvpn
                segment-routing-v6
                    route-distinguisher 192.0.2.2:6
                    srv6-instance 1 default-locator "PE-2_loc"
                    source-address 2001:db8::2:2
                    vrf-target target:64506:6
                    no shutdown
                exit
            exit
            no shutdown
        exit all
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that IPv4 data traffic is possible between the local VPRN on PE-1 and the remote VPRN on PE-2:

```
*A:PE-1# ping router 6 172.16.222.1
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=1.49ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
```

```
round-trip min = 1.29ms, avg = 1.47ms, max = 1.65ms, stddev = 0.116ms

*A:PE-1# traceroute router 6 172.16.222.1
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    1.64 ms  1.71 ms  1.63 ms
```

This data traffic uses the SRv6 tunnels over the direct link between PE-1 and PE-2.

For IPv4 data traffic, the VPRN routing table shows the next hop and the applicable IGP metric for the route to 172.16.222.1.

```
*A:PE-1# show router 6 route-table 172.16.222.1

===============================================================================

The **show router isis 0 topology** command lists the IS-IS nodes, and for each IS-IS node, the outgoing interface and the next hop. There are only IS-IS nodes at IS-IS level 2. The output of this command shows that data traffic from PE-1 to PE-2 uses interface "int-PE-1-PE-2" to PE-2, while, for example, data traffic from PE-1 to P-3 uses interface "int-PE-1-P-3" to P-3.

```

===============================================================================
```

Verify the IS-IS data base on PE-1 with **show router isis 0 database detail**. The output of this command (shortened here for PE-1 and PE-2, and omitted for P-3 and P-4) provides information about each IS-IS-enabled router. For each uniquely identified IS-IS-enabled router, the SRv6 information indicates:

- the IS-IS-advertised router capabilities
- the IS-IS topology details
- the IPv4 and IPv6 reachability details
- the advertised SRv6 locator TLV
- the advertised configured SRv6 End SID

There is only IS-IS information at IS-IS level 2. On each IS-IS interface, the IS-IS level 2 metrics for IPv4 and IPv6 are identical.

Only the default metric-based SPF algorithm instance 0 is in use, as listed in the SR Alg sub-TLV of the Router Cap TLVs.

On PE-1 and PE-2, the SRv6 locator prefix for algorithm 0, with their End SRv6 SID are present.

```

Verify also that IPv6 data traffic is possible between the local VPRN on PE-1 and the remote VPRN on PE-2:

```
*A:PE-1# ping router 6 2001:db8:222::1
PING 2001:db8:222::1 56 data bytes
64 bytes from 2001:db8:222::1 icmp_seq=1 hlim=64 time=1.84ms.
---snip---
---- 2001:db8:222::1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.54ms, avg = 1.72ms, max = 1.84ms, stddev = 0.104ms

*A:PE-1# traceroute router 6 2001:db8:222::1
traceroute to 2001:db8:222::1, 30 hops max, 60 byte packets
  1  2001:db8:222::1 (2001:db8:222::1)    1.68 ms  1.84 ms  1.65 ms
```

For IPv6 data traffic, the VPRN routing table shows the next hop and the applicable IGP metric for the route to 2001:db8:222::1.

```
*A:PE-1# show router 6 route-table 2001:db8:222::1

===============================================================================
IPv6 Route Table (Service: 6)
===============================================================================

-------------------------------------------------------------------------------
No. of Routes: 1
---snip---
===============================================================================
```

The next hop is the End.DT6 SRv6 SID of the SRv6 **locator** *"PE-2_loc"* for the VPRN on PE-2, which PE-1 learns from a BGP update from PE-2. The SRv6 tunnel to this next hop has label 524287.

The applicable IGP metric is also 8, which again corresponds with the IS-IS level 2 "int-PE-1-PE-2" interface metric value.

PE-2 advertises to PE-1 the information for network prefix 2001:db8:222::1/128, as listed in the RIB In Entries section in the following example. PE-1 acts in a similar way as PE-2 for network prefix 2001:db8:211::1/128, as listed in the RIB Out Entries section.

The following output shows the corresponding VPN-IPv6 BGP routes on PE-1:

```
*A:PE-1# show router bgp routes vpn-ipv6 hunt

===============================================================================
```

Configure a delay-based flexible algorithm

Define a Flex-algorithm definition "FAD_delay" that takes delay as its metric. The FAD can reside on any IS-IS-enabled router. In this example, it resides on PE-1.

```
*A:PE-1# configure router Base
        flexible-algorithm-definitions
            flex-algo "FAD_delay" create
                description "FAD_delay_based"
                metric-type delay
                no shutdown
            exit
        exit all
```

Configure PE-1 so as to advertise the FAD "FAD_delay" in Flex-Algorithm instance 128 (possible values between 128 and 255) and to participate in the Flex-Algorithm instance 128.

```
*A:PE-1# configure router Base isis 0
            flexible-algorithms
                flex-algo 128
                    advertise "FAD_delay"
                    participate
                    exit
                exit
                no shutdown
            exit all
```

Ensure that the other IS-IS-enabled routers that must support the Flex-Algorithm instance participate in this Flex-Algorithm instance.

```
*A:PE-2#/*A:P-3#/*A:P-4# configure router Base isis 0
            flexible-algorithms
                flex-algo 128
                    participate
                    exit
                exit
                no shutdown
            exit all
```

Define a new and unique SRv6 locator prefix to this new Flex-Algorithm instance. A separate SRv6 locator is needed for each Flex-Algorithm instance. So, for the Flex-Algorithm instance 128, configure SRv6 **locator** *"PE-2_loc_FAD128"* on PE-2. Perform a similar configuration for SRv6 **locator** *"PE-1_loc_FAD128"* with **ip-prefix** *2001:db8:a128:101::/64* on PE-1.

```
*A:PE-2# configure router Base segment-routing segment-routing-v6
                locator "PE-2_loc_FAD128"
                    block-length 48
                    function-length 20
                    algorithm 128
                    prefix
                        ip-prefix 2001:db8:a128:102::/64
                    exit
                    no shutdown
                exit all
```

For SRv6 **locator** *"PE-2_loc_FAD128"* on PE-2, use FPE 2 as the SRv6 termination FPE in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context and configure the SRv6 End function (equivalent to an IPv4 node SID) in the **router Base segment-routing segment-routing-**

v6 base-routing-instance locator <locator-name> context. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
*A:PE-2# configure router Base segment-routing
            segment-routing-v6
                locator "PE-2_loc_FAD128"
                    termination-fpe 2
                    no shutdown
                exit
                base-routing-instance
                    locator "PE-2_loc_FAD128"
                        function
                            end 1
                                srh-mode usp
                            exit
                        exit
                    exit
                exit
            exit all
```

In the **router Base isis 0 segment-routing-v6 locator <locator-name>** context on PE-2, configure the IS-IS level capability for SRv6 **locator** *"PE-2_loc_FAD128"* and enable SRv6 in the IS-IS context. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
*A:PE-2# configure router Base isis 0
            segment-routing-v6
                locator "PE-2_loc_FAD128"
                    level-capability level-2
                    level 2
                    exit
                exit
                no shutdown
            exit all
```

The **show router isis 0 segment-routing-v6 locator** command lists the local and remote SRv6 locator prefixes for all applied algorithms (0 and 128).

```
*A:PE-2# show router isis 0 segment-routing-v6 locator

===============================================================================

2001:db8:aaaa:102::/64            PE-2                          0      2/Int.
  -                                 0                             -      0
-------------------------------------------------------------------------------
No. of Locators: 4
-------------------------------------------------------------------------------
---snip---
===============================================================================
```

On PE-2, in the **service vprn segment-routing-v6 locator** context, configure End.DT4 and End.DT6 functions for SRv6 **locator** *"PE-2_loc_FAD128"*.

On PE-2, in the **service vprn <service-id> bgp-ipvpn segment-routing-v6** context, use the SRv6 **locator** *"PE-2_loc_FAD128"* as the default locator, instead of the earlier SRv6 **locator** *"PE-2_loc"*. The BGP IPVPN SRv6 instance for the VPRN must be shut down to allow this replacement. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
*A:PE-2# configure service
        vprn 6
            segment-routing-v6 1
                locator "PE-2_loc_FAD128"
                    function
                        end-dt4
                        end-dt6
                    exit
                exit
            exit
            bgp-ipvpn
                segment-routing-v6
                    shutdown
                    srv6-instance 1 default-locator "PE-2_loc_FAD128"
                    no shutdown
                exit
            exit
            no shutdown
        exit all
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that data traffic between the local VPRN on PE-1 and the remote VPRN on PE-2 uses the Flex-Algorithm.

For IPv4 data traffic:

```
*A:PE-1# ping router 6 172.16.222.1
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=2.47ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.93ms, avg = 2.35ms, max = 2.51ms, stddev = 0.210ms

*A:PE-1# traceroute router 6 172.16.222.1
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    2.79 ms  2.43 ms  2.41 ms
```

For IPv6 data traffic:

```
*A:PE-1# ping router 6 2001:db8:222::1
PING 2001:db8:222::1 56 data bytes
64 bytes from 2001:db8:222::1 icmp_seq=1 hlim=64 time=2.31ms.
---snip---
---- 2001:db8:222::1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.31ms, avg = 2.50ms, max = 2.71ms, stddev = 0.150ms

*A:PE-1# traceroute router 6 2001:db8:222::1
traceroute to 2001:db8:222::1, 30 hops max, 60 byte packets
```

```
  1  2001:db8:222::1 (2001:db8:222::1)    2.50 ms  2.48 ms  2.40 ms
```

This data traffic uses the SRv6 tunnels over the links between PE-1 and P-3, P-3 and P-4, and P-4 and PE-2.

For IPv4 data traffic, the VPRN routing table shows the next hop and the applicable metric for the route to 172.16.222.1. In this example, the End.DT4 SID is copied into the IPv6 DA field of the tunneled packet.

```
*A:PE-1# show router 6 route-table 172.16.222.1

IS-IS IP paths (MT-ID 0),   Level 2
-------------------------------------------------------------------------------
PE-2.00                           int-PE-1-P-3              P-3
P-3.00                            int-PE-1-P-3              P-3
P-4.00                            int-PE-1-P-3              P-3
===============================================================================
```

The applicable metric is 111, which corresponds with the sum of the static link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2".

The **show router isis 0 topology flex-algo 128 detail** command lists the IS-IS nodes in the topology, and for each IS-IS node, the next hop, the outgoing interface, and the metric (in this case, link delay) that applies.

```
*A:PE-1# show router isis 0 topology flex-algo 128 detail

```

The IS-IS database on PE-1 contains more information, which relates to the use of the Flex-Algorithm.

There are additional link delay metrics (identical for IPv4 and IPv6) for each IS-IS-enabled router, as listed in the TE APP LINK ATTR sub-TLVs. The non-legacy Standard Application Bit Mask (SABM) flag value X indicates that they are associated with the Flex-Algorithm. Only the End SRv6 SIDs of the SRv6 locators are present.

Next to the default metric-based SPF, the Flex-Algorithm instance 128 is also in use, as listed in the SR Alg sub-TLV of the Router Cap TLVs.

The FAD sub-TLV of the PE-1 Router Cap TLV contains the delay-based definition for the Flex-Algorithm instance 128, which only router PE-1 advertises. The FAD flag value M indicates that the delay is a prefix metric.

On PE-1 and PE-2, next to the base SRv6 locator (for algorithm 0), with its End SRv6 SID, there is an additional SRv6 locator for the Flex-Algorithm instance 128, with its End SRv6 SID. This additional SRv6 locator indicates the prefix.

The **show router isis 0 database detail** command output on PE-1 is shown below, with separate entries for each IS-IS-enabled router.

For PE-1:

```
*A:PE-1# show router isis 0 database detail

PE-2 advertises to PE-1 payload prefix 172.16.222.1/32, as listed in the RIB In Entries section in the following example. PE-1 computes the applicable metric 111, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2". PE-1 advertises to PE-2 payload prefix 172.16.211.1/32, as listed in the RIB Out Entries section in the following example. PE-2 computes the applicable metric 222, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-2-P-4", "int-P-4-P-3", and "int-P-3-PE-1".

The following output shows the corresponding VPN-IPv4 BGP routes on PE-1:

```
*A:PE-1# show router bgp routes vpn-ipv4 hunt

For IPv6 data traffic, the VPRN routing table shows the next hop and the applicable metric for the route to 2001:db8:222::1.

```
*A:PE-1# show router 6 route-table 2001:db8:222::1

===============================================================================
IPv6 Route Table (Service: 6)
===============================================================================
Dest Prefix[Flags]                          Type    Proto     Age        Pref
      Next Hop[Interface Name]                                  Metric
-------------------------------------------------------------------------------
2001:db8:222::1/128                         Remote  BGP VPN   00h02m07s  170
       2001:db8:a128:102:7fff:d000:: (tunneled:SRV6)                111
-------------------------------------------------------------------------------
No. of Routes: 1
---snip---
===============================================================================
```

The next hop is the End.DT6 SRv6 SID of the SRv6 **locator** *"PE-2_loc_FAD128"* for the VPRN on PE-2, which PE-1 learns from a BGP update from PE-2. The SRv6 tunnel to this next hop has label 524285.

The applicable metric is also 111, which again corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2".

PE-2 advertises to PE-1 the information for network prefix 2001:db8:222::1/128, as listed in the RIB In Entries section in the following example. PE-1 computes the applicable metric 111, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2". PE-1 advertises to PE-2 payload prefix 2001:db8:211::1/128, as listed in the RIB Out Entries section in the following example. PE-2 computes the applicable metric 222, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-2-P-4", "int-P-4-P-3", and "int-P-3-PE-1".

The following output shows the corresponding VPN-IPv6 BGP routes on PE-1:

```
*A:PE-1# show router bgp routes vpn-ipv6 hunt

Configure TE metrics on the router interfaces

For example for PE-1. A similar configuration applies for the other routers.

```
*A:PE-1# configure
    router Base
        mpls
            interface "int-PE-1-PE-2"
                te-metric 1500
                no shutdown
            exit
            interface "int-PE-1-P-3"
                te-metric 10
                no shutdown
            exit
            interface "int-PE-1-P-4"
                te-metric 1600
                no shutdown
            exit
            no shutdown
        exit
        rsvp
            no shutdown
        exit
    exit all
```

Configure a TE-metric-based flexible algorithm

Define a Flex-Algorithm definition "FAD_te_metric" that uses TE metric metric type. The FAD can reside on any IS-IS-enabled router. In this example, it resides on PE-1.

```
*A:PE-1# configure router Base flexible-algorithm-definitions # strictly needed on only 1
 router in ISIS level
            flex-algo "FAD_te_metric" create
                description "FAD_te_metric_based"
                metric-type te-metric
            exit all
```

Configure PE-1 so as to advertise the FAD "FAD_te_metric" in Flex-Algorithm instance 128 and to participate in the Flex-Algorithm instance 128.

Note: SR OS 22.10 supports multiple concurrent Flex-Algorithm instances, with different instance values between 128 and 255. While "FAD_te_metric" would be associated with a new Flex-Algorithm instance 129 in a deployment scenario, "FAD_te_metric" in the example setup replaces "FAD_delay" for Flex-Algorithm instance 128, so that, for the sake of brevity, the SRv6 locators and labels that were in use earlier for the delay-based flexible algorithm scenario remain in use for the TE-metric-based flexible algorithm scenario.

```
*A:PE-1# configure router Base isis 0
            flexible-algorithms
```

```
                flex-algo 128
                    advertise "FAD_te_metric"
                    participate
                    exit
                exit
                no shutdown
            exit all
```

Ensure that the other IS-IS-enabled routers that must support the Flex-Algorithm instance participate in this Flex-Algorithm instance.

```
*A:PE-2#/*A:P-3#/*A:P-4# configure router Base isis 0
            flexible-algorithms
                flex-algo 128
                    participate
                    exit
                exit
                no shutdown
            exit all
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that data traffic between the local VPRN on PE-1 and the remote VPRN on PE-2 uses the modified Flex-Algorithm.

For IPv4 data traffic:

```
*A:PE-1# ping router 6 172.16.222.1
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=2.77ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.86ms, avg = 2.44ms, max = 2.77ms, stddev = 0.329ms

*A:PE-1# traceroute router 6 172.16.222.1
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    3.09 ms  3.08 ms  2.33 ms
```

For IPv6 data traffic:

```
*A:PE-1# ping router 6 2001:db8:222::1
PING 2001:db8:222::1 56 data bytes
64 bytes from 2001:db8:222::1 icmp_seq=1 hlim=64 time=2.53ms.
---snip---
---- 2001:db8:222::1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.88ms, avg = 2.31ms, max = 2.86ms, stddev = 0.356ms

*A:PE-1# traceroute router 6 2001:db8:222::1
traceroute to 2001:db8:222::1, 30 hops max, 60 byte packets
  1  2001:db8:222::1 (2001:db8:222::1)    2.74 ms  2.40 ms  2.64 ms
```

For the example with the TE-metric-based flexible algorithm, the same set of **show** commands as for the example with the delay-based flexible algorithm shows that:

- the metric type changes to *te-metric* (from *delay*)
- the TE APP LINK ATTR sub-TLVs contain a **TE Metric** value

- the applicable metric for the route between the local VPRN on PE-1 and the remote VPRN on PE-2 changes to 1110 (from 111 microseconds), corresponding with the sum of the metric values along the path PE-1, P-3, P-4, PE-2, as shown in the following **show router isis 0 topology flex-algo 128 detail** command output examples.
  On PE-1:

```
*A:PE-1# show router isis 0 topology flex-algo 128 detail

Conclusion

The Flex-Algorithm for SRv6-based VPRNs feature allows the computation of constraint-based paths across an SRv6-enabled network, based on metrics other than the default IGP metrics. This allows carrying data traffic over an end-to-end path that is optimized using the best suited metric IGP, delay, or TE).

Inter-AS VPRN Model B

This chapter describes the Inter-AS VPRN Model B.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R8, but the CLI in the current edition is based on SR OS Release 22.2.R1.

Overview

An inter-AS Virtual Private Routed Network (VPRN) contains sites that are connected to different Autonomous Systems (ASs). Inter-AS is typically used either to provide extended reach through a partnership/trust agreement, as an interim means to interconnect ASs following acquisition, or because of the internal organization of a single Service Provider (SP). Three models for interconnecting ASs are defined in RFC 4364, labeled model A, B, and C. This chapter describes model B.

Inter-AS VPRN model B encompasses EBGP redistributing VPN-IPv4 and VPN-IPv6 routes between neighboring ASs. An Autonomous System Border Router (ASBR) learns VPN routes from within its AS using IBGP, potentially as a client of a Route Reflector (RR), then uses EBGP to redistribute those labeled VPN routes to its adjacent ASBR.

When redistributing the routes into EBGP, the ASBR imposes next-hop-self on the VPN-IPv4 and VPN-IPv6 update messages and generates its own label value when it advertises the update message upstream. Therefore, the ASBR programs a label-swap entry in its FIB and forwards traffic to the neighboring ASBR using a single-level label stack (the VPN label).

A key property of model B is that it eliminates the need for per-VPRN configuration on the ASBRs. However, both ASBRs must have a mechanism to implicitly learn all VPN prefixes within their local AS and selectively advertise some of those prefixes to the neighboring ASBR.

Figure 336: Inter-AS VPRN Model B control and data plane example shows an example of the control plane and corresponding data plane used in model B, where MPLS is used for transport in both ASs. CE-1 is attached to PE-1 in AS 64496 and advertises prefix 172.31.100.0/24, which is propagated between neighboring ASBRs to PE-2 in AS 64510 and upstream to CE-2.

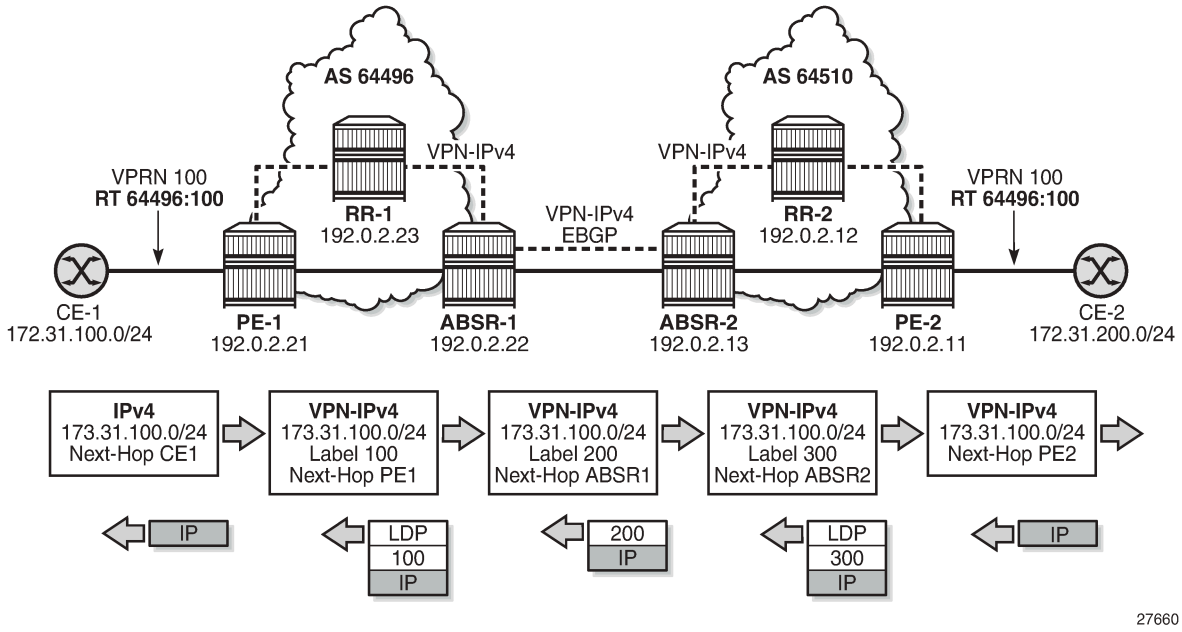
The IP traffic originating from CE-2 and received by PE-2 is received on the VRF interface of VPRN 100 and encapsulated using a two-level label stack; the inner label is the VPN label (300) and the outer label is the LDP transport label used for reaching the local ASBR-2.

ASBR-2 passes the traffic to ASBR-1, removing the LDP transport label and swapping the VPN label (300) with its VPN label (200), resulting in a single-level label stack.

In turn, ASBR-1 swaps the received VPN label (200) with another VPN label (100) and adds an LDP transport label to reach PE-1.

Finally, PE-1 removes the VPN label and delivers the unlabeled IP traffic to CE-1.

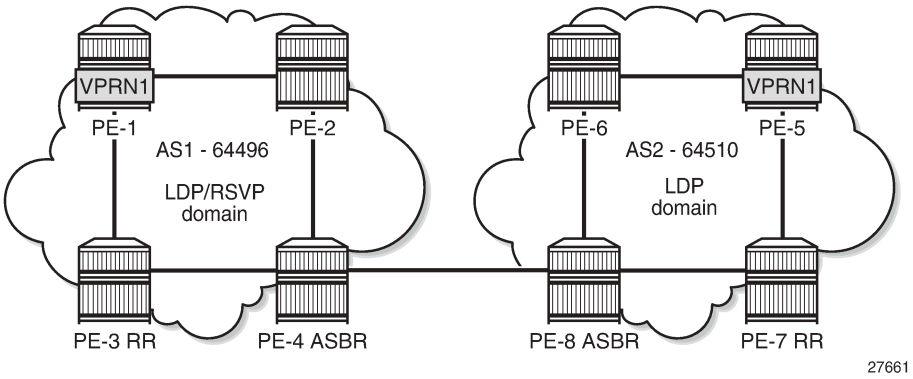
Figure 336: Inter-AS VPRN Model B control and data plane example



Configuration

In the example shown in Figure 337: Inter-AS VPRN Model B topology, IS-IS is configured in each AS, and MP-IBGP sessions are established between the PEs and the RRs in AS 64496 and 64510, PE-3 and PE-7, respectively. LDP and RSVP-TE is used for transport in AS 64496, whereas AS 64510 uses LDP for its transport. An MP-EBGP session is established between ASBR PE-4 and ASBR PE-8.

Figure 337: Inter-AS VPRN Model B topology



The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled
- LDP and RSVP-TE configured in AS 64496, LDP configured in AS 64510
- IBGP configured in AS 64496, with PE-3 as RR for clients PE-1, PE-2, and PE-4
- IBGP configured in AS 64510, with PE-7 as RR for clients PE-5, PE-6, and PE-8

Model B configuration

There are no specific requirements on PE routers or RRs for enabling inter-AS VPRN model B; only specific configurations are required on the ASBRs.

First, an ASBR must learn the VPN-IPv4 and VPN-IPv6 routes from the local AS and export these routes to the neighbor AS over an MP-EBGP session. This is achieved on each ASBR by declaring an IBGP group for peering with the local RR, and declaring an EBGP group for peering with the neighboring AS. The IBGP and EBGP groups have included the address family **vpn-ipv4**, **vpn-ipv6**, or both.

Additionally, import and export policies can be used to control the VPN-IPv4 and VPN-IPv6 routes exchanged. The latter requires the **vpn-apply-import** and **vpn-apply-export** commands for SR OS to match the prefixes of the VPN-IPv4 and VPN-IPv6 address families.

The use of the **next-hop-resolution** command is explained in the Service configuration section. The BGP configuration on ASBR PE-4 is as follows:

```
# on ASBR PE-4:
configure
    router Base
        bgp
            loop-detect discard-route
            enable-inter-as-vpn
            split-horizon
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution-filter
                                ldp            # by default enabled for VPN routes
                                rsvp
                            exit
                            resolution filter
                        exit
                    exit
                exit
            exit
            group "vpn-eBGP"
                neighbor 192.168.48.2
                    family vpn-ipv4 vpn-ipv6
                    peer-as 64510
                exit
            exit
            group "vpn-iBGP"
                peer-as 64496
                neighbor 192.0.2.3
                    family vpn-ipv4 vpn-ipv6
                exit
            exit
            no shutdown
```

```
        exit
    exit
exit
```

The configuration on ASBR PE-8 is similar.

Second, the **enable-inter-as-vpn** command enables the inter-AS functionality and causes the ASBR to store the received VPN-IPv4 routes in its RIB-In, even though it has no VRF that imports these routes. For a route to be considered valid, the ASBR still needs to resolve the next-hop of this route to a tunnel. The **enable-inter-as-vpn** command will also change the BGP next-hop of advertised and received VPN-IPv4/ VPN-IPv6 routes. When a route is advertised to an EBGP peer, the BGP next-hop is changed to the local-address used for communicating with the EBGP peer. When a route is received from an EBGP peer and advertised to an IBGP peer, the BGP next-hop is changed to the local-address used for communicating with the IBGP peer.

The configuration of the MP-EBGP session between the ASBRs in the EBGP group allows the ASBR to forward labeled packets over its connection with its peer ASBR.

MPLS LSP configuration

Two LSPs are needed between the end-to-end PEs (PE-1 and PE-5) to exchange service traffic bidirectionally, because LSPs are unidirectional. In AS 64496, this is achieved by configuring a first LSP from the service PE (PE-1) to the local ASBR (PE-4), and a second LSP back from the local ASBR (PE-4) toward the service PE (PE-1). In AS 64510, LDP is enabled on all interfaces; no RSVP LSPs are used.

In AS 64496, LDP and RSVP are enabled. The LSP (and path) from PE-1 to PE-4 runs via PE-3, as follows:

```
# on PE-1
configure
    router Base
        mpls
            path "path-PE-1-PE-3-PE-4"
                hop 10 192.168.13.2 strict
                hop 20 192.168.34.2 strict
                no shutdown
            exit
            lsp "lsp-PE-1-PE-4"
                to 192.0.2.4
                primary "path-PE-1-PE-3-PE-4"
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

The LSP (and path) from PE-4 to PE-3 also runs via PE-3, as follows:

```
# on ASBR PE-4:
configure
    router Base
        mpls
            path "path-PE-4-PE-3-PE-1"
                hop 10 192.168.34.1 strict
                hop 20 192.168.13.1 strict
                no shutdown
```

```
            exit
            lsp "lsp-PE-4-PE-1"
                to 192.0.2.1
                primary "path-PE-4-PE-3-PE-1"
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

Service configuration

VPRN 1 is configured on PE-1 and PE-5. Although the VPRN service IDs used in both ASs do not need to match, in an inter-AS VPRN model B context, the route targets (RTs) used in both ASs must be coordinated. The RT exported by the PE-1 VPRN 1 must be imported by the PE-5 VPRN 1, and vice versa. In this example, no specific **vrf-import** and **vrf-export** communities are used; the simplified method using a single **vrf-target** community is used instead.

To carry the customer data across AS 64496, tunnels must bind to a VPRN service with the **auto-bind-tunnel** command. Resolution is set to filter, indicating that SR OS must select a tunnel using the information defined in the **resolution-filter** context. The keywords **ldp** and **rsvp** in the resolution-filter context indicate that LDP or RSVP tunnels can be used, but SR OS prefers the RSVP tunnels because the preference for RSVP (7) is lower than the preference for LDP (9).

In AS 64496, the VPRN service on PE-1 is defined as follows:

```
# on PE-1:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            interface "int-S1-1" create
                address 10.1.10.1/24
                ipv6
                    address 2001:db8:1::1:1/120
                exit
                sap 1/2/1:1 create
                exit
            exit
            interface "int-S1-2" create
                address 10.1.11.1/24
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                            rsvp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64496:1
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            no shutdown
```

```
        exit
```

In AS 64510, the transport technology is LDP only, so the VPRN service in PE-5 auto-binds using LDP LSPs in the tunnel table to resolve VPN-IPv4 and VPN-IPv6 routes for which the vrf-target matches the vrf-target community value configured in PE-1, as follows:

```
# on PE-5 in AS 64510:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            description "VPN-1, counterpart is on PE-1"
            interface "int-S1-1" create
                address 10.1.50.1/24
                ipv6
                    address 2001:db8:1::5:1/120
                exit
                sap 1/2/1:1 create
                exit
            exit
            interface "int-S1-2" create
                address 10.1.51.1/24
                loopback
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64510:1
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

A second service is defined on PE-1 and PE-2 (VPRN 33), using loopback addresses 10.33.1.1/32 and 10.33.2.1/32 in PE-1 and PE-2, respectively. These addresses might appear in traces and commands later, but are of no concern because these are used for transporting intra-AS traffic.

For service traffic to flow in the PE-5 to PE-1 direction, ASBR PE-4 in AS 64496 must offer the possibility to use RSVP-TE tunnels when resolving a BGP next-hop for VPN services. Therefore, ASBR PE-4 must be explicitly configured, as follows:

```
# on ASBR PE-4:
configure
    router Base
        bgp
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution-filter
                                rsvp
                            exit
                            resolution filter
                        exit
                    exit
```

```
            exit
         exit
      exit
```

On ASBR PE-8 in AS 64510, no explicit configuration is required because resolving a BGP next-hop for VPN service to LDP tunnels is the default behavior.

Verification

With the configurations from previous sections applied, PE-1 receives three VPN-IPv4 routes and one VPN-IPv6 route, as follows:

```
*A:PE-1# show router bgp summary all

===============================================================================
BGP Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================
Neighbor

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The IPv4 addresses for VPRN 1 on PE-8 are 10.1.50.0/24 and 10.1.51.0/24, and are reachable through RSVP-TE tunnel 1 (*tunneled:RSVP:1*). The VPN label value for these prefixes is assigned and advertised by ASBR PE-4 and gets to PE-1 via the RR PE-3 in an MP-BGP update message. The 10.33.2.0/24 prefix belongs to a different service and is not relevant for model B because it is used for intra-AS traffic. The VPN-IPv4 routes received on PE-1 are as follows:

```
*A:PE-1# show router bgp neighbor 192.0.2.3 received-routes vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64496       Local AS:64496

SR OS uses a label-per-VRF mode of label distribution, meaning that the same label is used for different VPN-IPv4 and different VPN-IPv6 prefixes from the same VRF, which saves on MPLS label resources. In this example, the VPRN service label is 524279 for the VPN-IPv4 prefixes 10.1.50.0/24 and 10.1.51.0/24, and 524278 for VPN-IPv6 prefix 2001:db8:1::5:0/120.

The forwarding plane is also programmed with the outer label to be used for transport purposes. Two labels are present: 524282 assigned through RSVP, and 524284 assigned through LDP. Because RSVP takes precedence over LDP, the RSVP label is actively used, as follows:

```
*A:PE-1# show router fp-tunnel-table 1 192.0.2.4/32

===============================================================================
IPv4 Tunnel Table Display

Legend:
label stack is ordered from bottom-most to top-most

---- 10.1.50.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 6.00ms, avg = 6.18ms, max = 6.61ms, stddev = 0.220ms
```

On PE-1, the IPv4 VPRN 1 service traffic is pushed with VPN label 524279, followed by RSVP-TE transport label 524282. ASBR PE-4 removes the RSVP-TE transport label and swaps the internal (advertised) VPN label 524279 with the external VPN label 524280 received from ASBR PE-8. For IPv6 VPRN 1 traffic, VPN label 524278 is swapped by VPN label 524279. The inter-AS BGP labels stored by ASBR PE-4 are as follows:

```
*A:PE-4# show router bgp inter-as-label
```

```
===============================================================================

-------------------------------------------------------------------------------
Total Labels allocated:   6
===============================================================================
```

The forward data flow (from AS 64496 to AS 64510) for VPRN 1 uses the labels for which the label origin is external. The VPN labels used for the backward data flow (from AS 64510 to 64496) uses the labels for which the label origin is internal.

For brevity, the commands to display and check VPN prefixes and labels used in AS 64510 are omitted.

By disabling (**shutdown**) both RSVP LSPs between PE-1 and ASBR PE-4 in AS 64496, both PE-1 and PE-4 will select LDP tunnels for resolving VPN BGP next-hops. Then, the route table for VPRN 1 is as follows, where *tunneled* indicates an LDP tunnel is used to reach the next hop:

```
*A:PE-1# show router 1 route-table

===============================================================================

```

On PE-1, the IPv4 traffic in VPRN 1 is pushed with VPN label 524279, followed by LDP transport label 524284. ASBR PE-4 removes the LDP transport label and swaps the internal (advertised) VPN label 524279 with the external VPN label 524280 received from ASBR PE-8. The inter-AS label mapping between the ASBRs remains unchanged.

On the directly connected interface between the ASBRs, nothing has changed; only a single MPLS label is used to carry the VPN data, as shown in the following capture:

With this configuration, all the VPN-IPv4 and VPN-IPv6 routes known to AS 64496 are advertised by ASBR PE-4 to AS 64510, even the VPN-IPv4 and VPN-IPv6 routes from other AS 64496 VPRN services that do not need to be distributed:

```
*A:PE-4# show router bgp neighbor 192.168.48.2 advertised-routes vpn-ipv4 brief
===============================================================================
 BGP Router ID:192.0.2.4        AS:64496       Local AS:64496
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP VPN-IPv4 Routes
===============================================================================
Flag  Network
-------------------------------------------------------------------------------
i     64496:1:10.1.10.0/24
i     64496:1:10.1.11.0/24
i     64496:33:10.33.1.0/24
i     64496:33:10.33.2.0/24
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

As already indicated, the 10.33.1.0/24 and 10.33.2.0/24 prefixes belong to VPRN 33. This service exists on PE-1 and PE-2 only, and the corresponding customer traffic must be kept within AS 64496, so there is no need to advertise these prefixes to the peer AS. The "exp-SVC-1" policy is defined at ASBR PE-4 to achieve this, as follows:

```
# on ASBR PE-4:
configure
    router Base
        policy-options
            begin
            prefix-list "pfx-SVC-1"
                prefix 10.1.10.0/24 longer
                prefix 10.1.11.0/24 longer
                prefix 2001:db8:1::/96 longer
            exit
            policy-statement "exp-SVC-1"
                entry 10
                    from
                        prefix-list "pfx-SVC-1"
                    exit
                    action accept
                    exit
                exit
```

```
                default-action drop
                exit
            exit
            commit
        exit
    exit
exit
```

The "exp-SVC-1" policy is applied to ASBR PE-4 as an export policy, but also import policies can be used to control which prefixes are exchanged. This additionally requires the **vpn-apply-export** (and the **vpn-apply-import**) command, and the change required at ASBR PE-4 is as follows:

```
# on ASBR PE-4:
configure
    router Base
        autonomous-system 64496
        bgp
            group "vpn-eBGP"
                vpn-apply-export
                export "exp-SVC-1"
                neighbor 192.168.48.2
                    family vpn-ipv4 vpn-ipv6
                    peer-as 64510
                exit
            exit
        exit
    exit
exit
```

Therefore, the PE-4 ASBR will only advertise the VPN-IPv4 and VPN-IPv6 prefixes for VRPN 1, as follows:

```
*A:PE-4# show router bgp neighbor 192.168.48.2 advertised-routes vpn-ipv4 brief
===============================================================================

```

Conclusion

Inter-AS VPRN model B offers service providers a way to interconnect IPv4 and IPv6 VPN sites across different ASs, avoiding the need for dedicated services in the ASBR, which would otherwise consume valuable resources in the ASBR. Model B is useful for scenarios where model C does not apply; for example, when there is no trust agreement with the peer AS, so that exchanging PE system addresses with that peer is not permitted or does not make sense.

Inter-AS VPRN Model B Using MPLS over UDP

This chapter describes Inter-AS VPRN Model B using MPLS over UDP.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

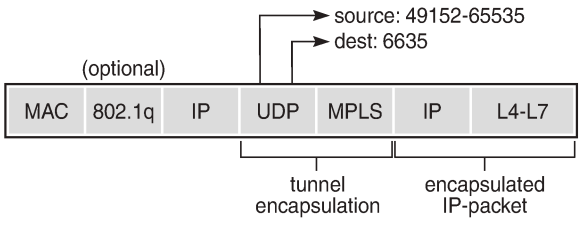
This chapter was initially written based on SR OS Release 15.0.R8, but the CLI in the current edition corresponds to SR OS Release 23.3.R3.

Overview

MPLS over UDP encapsulates MPLS packets into a UDP tunnel that can be transported by any IP network, and is defined in RFC 7510.

With MPLS over UDP, an outer IPv4/UDP or IPv6/UDP header encapsulates the inner MPLS label stack and message body; see Figure 338: IP over MPLS over UDP packet format. In the UDP header, the destination UDP port 6635 identifies the MPLS over UDP format to the egress PE and the source port number in the range from 49152 to 65535 is a source of entropy, because it is based on an ECMP hash calculation by the ingress PE. The entropy in the IP/UDP header ensures that ECMP uses all the available parallel paths between the tunnel endpoints.

Figure 338: IP over MPLS over UDP packet format



The MPLS over UDP implementation in SR OS has the following characteristics:

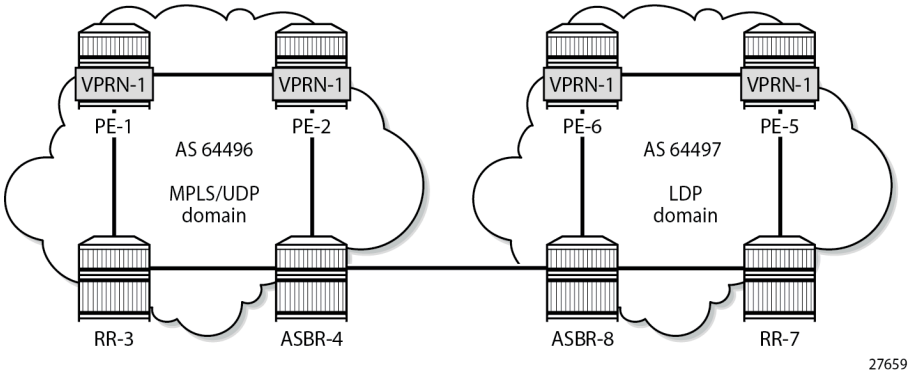
- The UDP checksum is set to 0 on transmission and ignored on reception.
- MPLS over UDP packets are processed only if they arrive with an IP destination address matching the system IP address.
- MPLS over UDP packets are originated with the Don't Fragment (DF) bit set in the outer IP header.
- Reassembly of received MPLS over UDP packets is not supported.

BGP next-hops can be resolved to UDP-based tunnels for L3 VPN and EVPN services, which is useful, for example, in data center (DC) environments where IP is prevalent. This chapter describes the use and configuration of MPLS over UDP in an inter-AS VPRN model B environment. See the Inter-AS VPRN Model B chapter for more information.

Configuration

Figure 339: Inter-AS VPRN model B topology using MPLS over UDP in AS 64496 shows the topology used in this chapter, with two autonomous systems (ASs) and using inter-AS VPRN model B. VPRN 1 carries customer traffic between PE-1 and PE-2 in AS 64496, and PE-5 and PE-6 in AS 64497. IS-IS is configured in AS 64496 and 64497, and MP-IBGP sessions are established between the PEs of each AS. An MP-EBGP session is established between autonomous system border routers (ASBRs) ASBR-4 and ASBR-8. RR-3 and RR-7 are the route reflectors (RRs) in AS 64496 and 64497, respectively, for the VPN-IPv4 and VPN-IPv6 address families. AS 64496 uses MPLS over UDP for its transport, whereas AS 64497 uses LDP.

Figure 339: Inter-AS VPRN model B topology using MPLS over UDP in AS 64496



An inter-AS VPRN model B requires configuration of an MP-EBGP session with support for the VPN-IPv4 and VPN-IPv6 address families and enabling the inter-AS functionality on the ASBRs by the **enable-inter-as-vpn** command. No configuration is required to support inter-AS VPRN model B on the PEs and the RRs. See the Inter-AS VPRN Model B chapter for more information.

The initial configuration includes:

- cards, MDAs, and ports
- router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled.
- LDP configured in AS 64497, but not in AS 64496
- IBGP configured in both ASs
- EBGP configured between ASBR-4 and ASBR-8
- RR-3 and RR-7 configured as RR for VPN-IPv4 and VPN-IPv6 in AS 64496 and AS 64497

MPLS over UDP configuration

MPLS over UDP tunnels are UDP-based LSP tunnels that are created dynamically through a BGP import policy, where the action is **create-udp-tunnel**. This import policy is configured and used on PE-1, PE-2, and ASBR-4. MPLS over UDP tunnels are created when BGP receives an update message where the incoming route has a next hop which matches the import policy. This import policy **create-UDP-tunnel** is defined as follows:

```
# on PE-1, PE-2, ASBR-4:
configure
    router Base
        policy-options
            begin
            prefix-list "system-pfxs"
                prefix 192.0.2.0/24 prefix-length-range 32-32
            exit
            policy-statement "create-UDP-tunnel"
                entry 10
                    from
                        next-hop prefix-list "system-pfxs"
                        family vpn-ipv4 vpn-ipv6
                    exit
                    action accept
                        create-udp-tunnel
                    exit
                exit
            exit
            commit
```

This policy is applied to the IBGP sessions on which the VPN routes are exchanged; on PE-1 and PE-2, this is in the *IBGP-vpn* group, as follows:

```
# on PE-1, PE-2:
configure
    router Base
        autonomous-system 64496
        bgp
            loop-detect discard-route
            split-horizon
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution-filter
                                no ldp
                                no bgp
                                udp
                            exit
                            resolution filter
                        exit
                    exit
                exit
            exit
            group "IBGP-vpn"
                vpn-apply-import
                import "create-UDP-tunnel"
                peer-as 64496
                neighbor 192.0.2.3
                    family vpn-ipv4 vpn-ipv6
                exit
            exit
```

On RR-3, BGP is configured as follows:

```
# on RR-3:
configure
    router Base
        autonomous-system 64496
        bgp
            loop-detect discard-route
            split-horizon
            group "IBGP-vpn"
                family vpn-ipv4 vpn-ipv6
                cluster 192.0.2.3
                peer-as 64496
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.4
                exit
            exit
```

For ASBR-4 to advertise VPRN routes to the peer AS, ASBR-4 must know the VPRN routes used within the AS, so it peers with RR-3 through IBGP, using the *IBGP-vpn* group. Although the **enable-inter-as-vpn** command enables inter-AS VPN model B, the VPN-IPv4 and VPN-IPv6 address family must also resolve to MPLS over UDP tunnels, so the BGP configuration on ASBR-4 is as follows:

```
# on ASBR-4:
configure
    router Base
        autonomous-system 64496
        bgp
            loop-detect discard-route
            enable-inter-as-vpn     # inter-AS VPRN model B
            split-horizon
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution-filter
                                no ldp
                                no bgp
                                udp
                            exit
                            resolution filter
                        exit
                    exit
                exit
            exit
            group "EBGP-vpn"
                neighbor 192.168.48.2
                    family vpn-ipv4 vpn-ipv6
                    peer-as 64497
                exit
            exit
            group "IBGP-vpn"
                vpn-apply-import
                import "create-UDP-tunnel"
                peer-as 64496
                neighbor 192.0.2.3
                    family vpn-ipv4 vpn-ipv6
                exit
            exit
```

Service configuration

VPRN "VPRN-1" is configured on PE-1, PE-2, PE-5, and PE-6. Although the VPRN service names and IDs used in both ASs do not have to match, when inter-AS VPRN model B applies, the route targets (RTs) used in both ASs must be coordinated. The RT exported by the PE-1 VPRN must be imported by PE-2, PE-5, and PE-6, and vice versa. In this example, no specific VRF import and VRF export policies are used; the **vrf-target** command is used instead.

To carry the customer data across AS 64496, the MPLS over UDP tunnels must bind to a VPRN service with the **auto-bind-tunnel** command. The resolution is set to **filter**, indicating that SR OS must select a tunnel using the information defined in the **resolution-filter** context. The **udp** keyword in the **resolution-filter** context indicates that MPLS over UDP tunnels can be used. If **resolution** is set to **any**, the resolution filter is ignored, and a tunnel from the tunnel table manager (TTM) is selected, based on availability and preference.

In AS 64496, the service "VPRN-1" on PE-1 is defined as follows. The configuration of service "VPRN-1" on PE-2 is similar.

```
# on PE-1:
configure
    service
        vprn 1 name "VPRN-1" customer 1 create
            interface "int-S1-1" create
                address 10.1.10.1/24
                ipv6
                    address 2001:db8:1::1:1/120
                exit
                sap 1/1/c4/1:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            no ldp
                            no bgp
                            udp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64496:1
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            no shutdown
```

The transport technology in AS 64497 is LDP, so service "VPRN-1" in PE-5 and PE-6 auto-binds to LDP LSPs in the tunnel table, to resolve VPN-IPv4 routes for which the VRF target matches the VRF target community value configured in PE-1 and PE-2, as follows. The configuration of "VPRN-1" on PE-6 is similar.

```
# on PE-5:
configure
    service
        vprn 1 name "VPRN-1" customer 1 create
            interface "int-S1-1" create
                address 10.1.50.1/24
```

```
                ipv6
                    address 2001:db8:1::5:1/120
                exit
                sap 1/1/c4/1:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                            no bgp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64497:1
                    vrf-target target:64496:1    # same value as on PE-1, PE-2
                    no shutdown
                exit
            exit
            no shutdown
```

Verification

With the configurations from previous subsections applied, so that PE-1, PE-2, PE-5, and PE-6 have a service instance of "VPRN-1" running, PE-1 receives three VPN-IPv4 and three VPN-IPv6 prefixes, as follows:

```
*A:PE-1# show router bgp summary all

===============================================================================
BGP Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================
Neighbor
Description
ServiceId          AS PktRcvd InQ  Up/Down   State|Rcv/Act/Sent (Addr Family)
                      PktSent OutQ
-------------------------------------------------------------------------------
192.0.2.3
Def. Inst       64496      19    0 00h04m24s 3/3/1 (VpnIPv4)
                           17    0           3/3/1 (VpnIPv6)

-------------------------------------------------------------------------------
```

PE-1 creates two UDP tunnels, and its tunnel table is as follows. The UDP tunnel to 192.0.2.2 is used for intra-AS customer traffic; the UDP tunnel to 192.0.2.4 is used for inter-AS customer traffic.

```
*A:PE-1# show router tunnel-table

===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination           Owner     Encap TunnelId  Pref   Nexthop        Metric
   Color
-------------------------------------------------------------------------------
192.0.2.2/32          udp       MPLS  786434    254    192.168.12.2   10
192.0.2.4/32          udp       MPLS  786435    254    192.168.12.2   20
-------------------------------------------------------------------------------
```

```
Flags: B = BGP or MPLS backup hop available
       L = Loop-Free Alternate (LFA) hop available
       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

These tunnels are used as BGP next-hops for the VPN-IPv4 (and VPN-IPv6) routes, as follows:

```
*A:PE-1# show router bgp next-hop vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.1        AS:64496       Local AS:64496
===============================================================================

```

Traffic over the VPRN is generated using a **ping** command on PE-1 to the remote address, as follows:

```
*A:PE-1# ping router 1 10.1.50.1 source 10.1.10.1
PING 10.1.50.1 56 data bytes
64 bytes from 10.1.50.1: icmp_seq=1 ttl=64 time=6.06ms.
64 bytes from 10.1.50.1: icmp_seq=2 ttl=64 time=6.16ms.
64 bytes from 10.1.50.1: icmp_seq=3 ttl=64 time=6.12ms.
64 bytes from 10.1.50.1: icmp_seq=4 ttl=64 time=5.89ms.
64 bytes from 10.1.50.1: icmp_seq=5 ttl=64 time=6.00ms.

---- 10.1.50.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 5.89ms, avg = 6.05ms, max = 6.16ms, stddev = 0.094ms
```

In contrast with the traditional inter-AS VPRN model B, where customer traffic is pushed with a VPN label followed by a transport label, now customer traffic to destination 10.1.50.1 is pushed with VPN label 524286, followed by an IP/UDP header with IP SA 192.0.2.1 and IP DA 192.0.2.4 and with UDP source and destination port.

The interconnection between the ASBRs carries the VPN data with a single MPLS label, so ASBR-4 removes the IP/UDP header and swaps the VPN label 524286 with the VPN label 524282 received from ASBR-8. The inter-AS label mapping on ASBR-4 is as follows:

```
*A:ASBR-4# show router bgp inter-as-label

===============================================================================
BGP Inter-AS labels
Flags: B - entry has backup, P - entry is promoted

-------------------------------------------------------------------------------
Total Labels allocated:   8
===============================================================================
```

The forward data flow from PE-1 to PE-5 for VPRN 1 uses the labels for which the label origin is external. The VPN labels used for the backward data flow use the labels for which the label origin is internal.

For brevity, the commands to display and check VPN prefixes and labels in AS 64497 are omitted.

Customer traffic destined to the VPN routes received by ASBR-4 can be sent to the correct destination because ASBR-4 has the relevant BGP next-hops resolved to UDP tunnels, as follows:

```
*A:ASBR-4# show router bgp next-hop vpn-ipv4
```

```

Changing the BGP next-hop resolution for auto-binding the BGP next-hop on PE-1, and for VPN next-hop resolution on ASBR-4 from **resolution filter** to **resolution any**, does not lead to the tunnel being changed, but to a change of the allowed tunnel types for auto-bind. On PE-1 and PE-2, SR OS selects UDP as the

only viable tunnel type, because no tunnels of type LDP, RSVP, SR-ISIS, SR-OSPF, GRE and so on are available:

Conclusion

VPRN services support the resolution of VPN-IPv4 and VPN-IPv6 BGP next-hops to MPLS over UDP tunnels. MPLS over UDP tunnels are useful in IP-based fabric networks, such as DCs. SR OS supports inter-AS model B for any type of MPLS-based tunnels, including MPLS over UDP.

Inter-AS VPRN Model C

This chapter provides information about virtual private routed network (VPRN) inter-autonomous system (AS) virtual private network (VPN) model C.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 7.0. The CLI in the current edition corresponds to SR OS Release 22.2.R1. There are no prerequisites for this configuration.

Overview

Introduction

Section 10 of RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, describes three potential methods for service providers to interconnect their IP-VPN (Internet Protocol — Virtual Private Network) backbones in order to provide an end-to-end MPLS-VPN where one or more sites of the VPN are connected to different service provider autonomous systems (ASs). The purpose of this chapter is to describe the configuration and troubleshooting for inter-AS VPN model C.

In this architecture, VPN prefixes are neither held, nor re-advertised by the Autonomous System Border Router — Provider Edge (ASBR-PE) routers, which makes Model C more scalable than Model B (where the only prefixes exchanged between ASs are VPN-IPv4). In Model C, the only MPLS data plane resources consumed in the ASBRs are for infrastructure addresses of PEs and RRs rather than VPN prefixes.

In this example, an export policy is configured to ensure that the nodes advertise their system IP addresses (IPv4 /32 addresses) in labeled BGP to all their BGP peers within the AS. Therefore, the ASBR-PE maintains labeled IPv4 /32 BGP routes to other PE routers within its own AS. These BGP routes are inactive, because for each destination within the AS, an IGP route exists which is preferred to BGP routes. The ASBR redistributes these inactive /32 IPv4 prefixes in external Border Gateway Protocol (EBGP) to the ASBR-PE in other service providers ASs, because **advertise-inactive** is configured in EBGP. No export policy is required in EBGP.

At the same time, the ASBR programs a label switch for the received and advertised BGP labels. The receiving ASBR advertises the received IP system prefixes to its IBGP peers (in this case, a Route Reflector (RR)) within their AS, and eventually, all PEs in the AS learn the system IP prefixes of the peer AS. However, there is no need to learn the system IP address of the ASBRs in peer ASs, because they do not exchange customer VPN prefixes.

After the system IP addresses have been learned in the peer AS, it is possible for PE routers in different ASs to establish multi-hop Multi Protocol — external Border Gateway Protocol (MP-EBGP) sessions

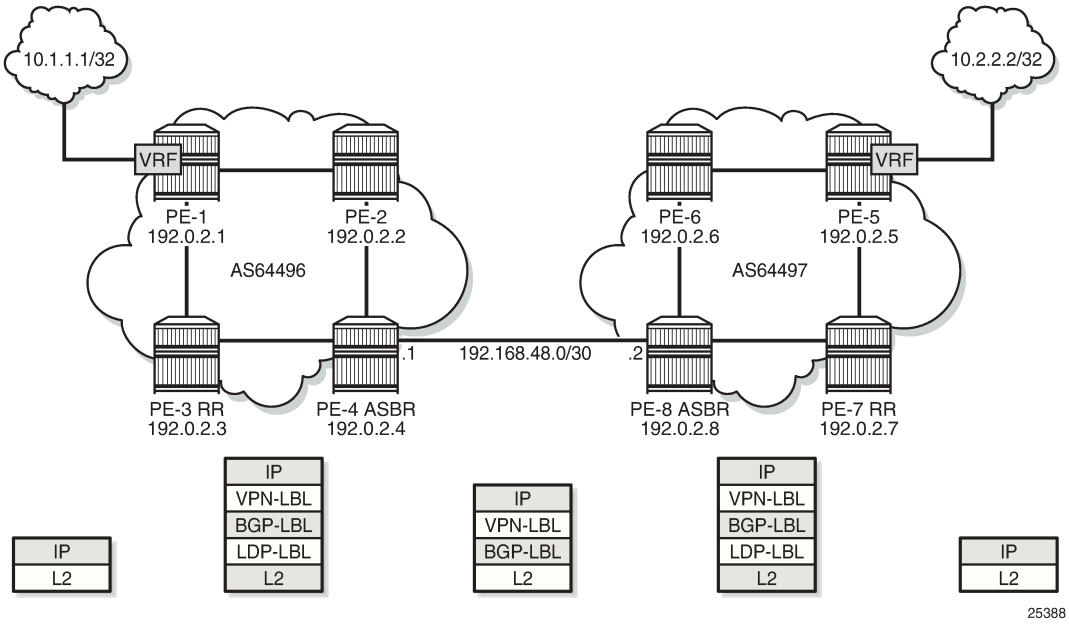
for address family VPN-IPv4 to each other in order to exchange customer VPN prefixes over those connections. The multihop sessions can be established between the RR in the ASs, but these RRs should not modify the next-hop attribute of the BGP update across the EBGP session.

A three-level label stack is imposed on the ingress PE. The bottom-level label is assigned by the egress PE (advertised in multi-hop MP-EBGP without next-hop override) and is commonly referred to as the VPN-label. The middle label is assigned by the local ASBR-PE and corresponds to the /32 route of the egress PE (in a different AS) using BGP-LBL (RFC 3107, *Carrying Label Information in BGP-4*). The top level label is the label assigned by the local ASBR-PE /32 loopback address, which is assigned by the IGP next-hop of the ingress PE. This label is referred to as the LDP-LBL.

Figure 340: Inter-AS VPN Model C illustrates this mechanism. The VPN-LBL is assigned by PE-5, the BGP-LBL is assigned by PE-4 and the LDP-LBL is also assigned by PE-4. The BGP-LBL is swapped in both ASBRs. The label stack contains three labels in each AS: VPN-LBL, BGP-LBL, and LDP-LBL) and two labels on the EBGP link between the ASs: VPN-LBL and BGP-LBL.

Note: This configuration that uses **advertise-inactive** is preferred to a configuration where the BGP routes are not exchanged within their AS and the ASBRs use an export policy with a prefix list for all local system prefixes to be advertised to the peer ASs. The routes for those prefixes are taken from the RTM, where these routes are not known via BGP, but via IS-IS. In that case, IS-IS routes are effectively redistributed into labeled BGP (which most operators do not want) and as a result, the ASBR is not programming a label switch for the BGP label. Furthermore, the label stack is asymmetrical: three labels in the originating AS (VPN-LBL, BGP-LBL, and LDP-LBL) and only two labels in the target AS (VPN-LBL, LDP-LBL), because the local routes are not known via labeled BGP in this scenario. This scenario is not explained in this chapter; only the preferred scenario with local labeled BGP routes in each AS is explained.

Figure 340: Inter-AS VPN Model C



The VPN connectivity is established using Labeled VPN route exchange using MP-EBGP without next-hop override. The PE connectivity is established as follows.

EBGP PE /32 loopback leaking routing exchange using EBGP LBL (RFC 3107) at the ASBR-PE. The /32 PE routes learned from the other AS through the ASBR-PE are further distributed into the local AS using

IBGP and optionally through Route Reflectors (RRs). This model uses a three label stack and is referred to as Model C. Resilience for ASBR-PE failures depends on BGP.

Figure 341: Protocol overview

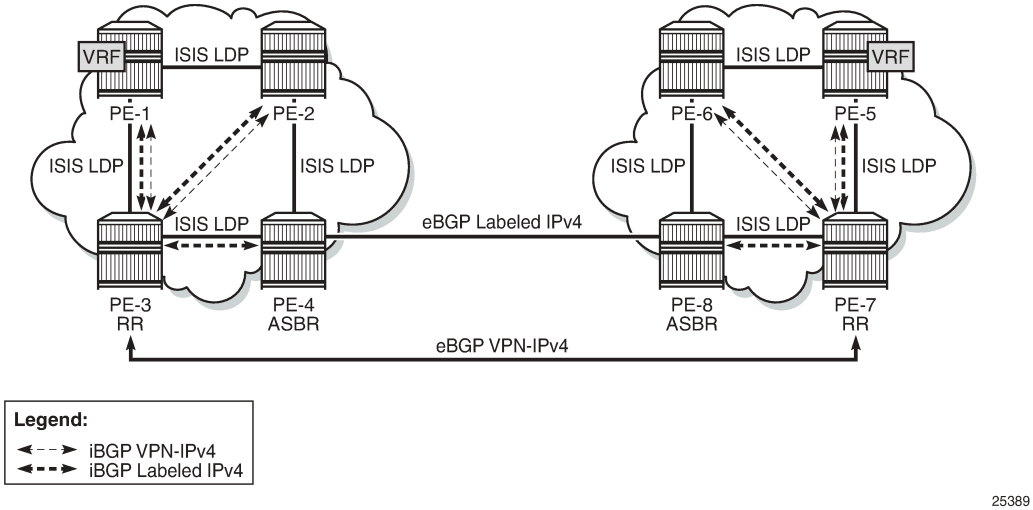


Figure 341: Protocol overview shows the protocols used when implementing Inter-AS Model C. Inside each AS, there is an IS-IS adjacency and a link LDP session between each pair of adjacent nodes. As an alternative, OSPF can be used as IGP. There is also an IBGP session between each PE and the RR. The address family is both VPN-IPv4 for the exchange of customer VPN prefixes and Labeled IPv4 for the exchange of labeled IPv4 prefixes. Between the RR and the ASBR, only Labeled IPv4 is required, because the ASBR does not exchange any customer VPN prefixes. When no RR is used, a full mesh of IBGP sessions can be established in each AS.

Between the ASBRs, there is an EBGP session for the exchange of labeled IPv4 prefixes. The ASBRs override the next-hop for those prefixes. Between the RRs in the different ASs, there is a multihop EBGP session for the exchange of VPN-IPv4 customer prefixes. The RRs do not override the next-hop for those prefixes.

The main advantage of this model is that no VPN routes need to be held on the ASBR-PEs and therefore, it scales the best among all the three Inter-AS IP-VPN models. However, leaking /32 PE addresses between service providers raises some security concerns. Therefore, we see Model C typically deployed within a service provider network.

Figure 340: Inter-AS VPN Model C shows the example topology which consists of four SR OS nodes in AS 64496 and four SR OS nodes in AS 64497. There is an AS interconnection between ASBR PE-4 to ASBR PE-8. PE-3 and PE-7 act as RRs for their AS. An IP-VPN is configured in each AS. The initial configuration includes the following:

- IS-IS or OSPF on all interfaces within each of the ASs.
- LDP on all interfaces within each of the ASs.
- MP-IBGP sessions between the PE routers and the RRs in each of the ASs, as shown in the following section.
- IP-VPN on PE-1 and on PE-5 with identical route targets.
- A loopback interface in the VRF on PE-1 and PE-5.

Configuration

The first step is to configure an MP-IBGP session between the PEs in both ASs. An export policy is configured to export the system prefixes from the PEs in labeled BGP.

PE-3 and PE-7 act as RR in the ASs. In AS 64496, PE-1 and PE-2 are peered with RR PE-3 for the labeled IPv4 and VPN-IPv4 address families; ASBR PE-4 is peered with RR PE-3 for the labeled IPv4 address family only. In AS 64497, PE-5 and PE-6 are peered with RR PE-7 for the labeled IPv4 and VPN-IPv4 address families; ASBR PE-8 is peered with RR PE-7 for the labeled IPv4 address family only.

Address family **label-ipv4** is required to advertise labeled IPv4 routes toward each neighbor PE. Address family **vpn-ipv4** is required to advertise IPv4 customer VPN routes within the AS.

The initial BGP configuration for RR PE-3 is as follows:

```
# on RR PE-3:
configure
    router Base
        autonomous-system 64496
        bgp
            split-horizon
            group "IBGP"
                cluster 192.0.2.3
                export "export-bgp"
                peer-as 64496
                neighbor 192.0.2.1
                    family vpn-ipv4 label-ipv4
                    advertise-inactive
                exit
                neighbor 192.0.2.2
                    family vpn-ipv4 label-ipv4
                    advertise-inactive
                exit
                neighbor 192.0.2.4
                    family label-ipv4
                    advertise-inactive
                exit
            exit
```

The export policy is defined as follows:

```
# on PE-1, PE-2, PE-3, PE-5, PE-6, PE-7:
configure
    router Base
        policy-options
            begin
            prefix-list "PE-sys"
                prefix 192.0.2.0/28 longer
            exit
            policy-statement "export-bgp"
                entry 10
                    from
                        protocol direct
                        prefix-list "PE-sys"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

On the ASBRs in both ASs, EBGP and IBGP need to be configured. The EBGP session is configured with **advertise-inactive** and is used to redistribute labeled IPv4 routes for the /32 system IP addresses between the ASs, even if those routes are not the most preferred routes within the system for a certain destination.

The configuration for ASBR PE-4 is as follows. The address family **label-ipv4** is required to enable the advertising of labeled IPv4 routes. This address family is also required on the RR neighbor in order to propagate the labeled IPv4 routes toward the other PEs in the AS.

```
# on ASBR PE-4:
configure
    router Base
        autonomous-system 64496
        bgp
            split-horizon
            group "EBGP"
                neighbor 192.168.48.2
                    family label-ipv4
                    peer-as 64497
                    advertise-inactive
                exit
            exit
            group "IBGP"
                peer-as 64496
                neighbor 192.0.2.3
                    family label-ipv4
                exit
            exit
       exit
    exit
exit
```

On the remaining PE nodes in AS 64496, PE-1 and PE-2, the address families **label-ipv4** and **vpn-ipv4** must be enabled, as follows:

```
# on PE-1, PE-2:
configure
    router Base
        autonomous-system 64496
        bgp
            split-horizon
            group "IBGP"
                export "export-bgp"
                peer-as 64496
                neighbor 192.0.2.3
                    family vpn-ipv4 label-ipv4
                exit
            exit
        exit
    exit
exit
```

The configuration for the nodes in AS 64497 is similar. The IP addresses can be derived from Figure 340: Inter-AS VPN Model C.

The following command on ASBR PE-4 verifies that the EBGP and IBGP sessions for the labeled IPv4 address family are up:

```
*A:PE-4# show router bgp summary all

===============================================================================
```

```
BGP Summary

In this example, the IP prefix for PE-8 itself is not included. The prefix of the ASBR need not be advertised in labeled BGP to the remote AS, because ASBRs do not advertise VPN-IPv4 prefixes.

More detailed information about the advertised route from PE-5 can be seen with following command on PE-4:

```
*A:PE-4# show router bgp routes 192.0.2.5/32 label-ipv4 hunt
===============================================================================

In the RIB In entries, the received label from PE-8 can be seen (524283). In the RIB Out entries, the locally assigned (Advertised) label for this prefix can be seen (524283). These labels need not match. The ASBR PE-4 swaps BGP labels, according to the following label mapping:

```
*A:PE-4# show router bgp inter-as-label

===============================================================================
BGP Inter-AS labels
Flags: B - entry has backup, P - entry is promoted
===============================================================================
NextHop                       Received       Advertised     Label
                              Label          Label          Origin
-------------------------------------------------------------------------------
192.0.2.1                     524283         524280         Internal
192.0.2.2                     524283         524279         Internal
192.0.2.3                     524283         524278         Internal
192.168.48.2                  524281         524281         External
```

```
192.168.48.2                  524282         524282         External
192.168.48.2                  524283         524283         External
-------------------------------------------------------------------------------
Total Labels allocated:   6
===============================================================================
```

The route from PE-1 toward PE-5 uses received label 524283 and advertised label 524283, as indicated on the sixth row in the table. The BGP label in the label stack sent by PE-1 contains BGP label 524283 toward ASBR PE-4, where it is swapped to BGP label 524283 toward ASBR PE-8.

ASBR PE-8 swaps BGP label 524283 to BGP label 524283 toward PE-5, as follows:

```
*A:PE-8# show router bgp inter-as-label

===============================================================================
BGP Inter-AS labels
Flags: B - entry has backup, P - entry is promoted
===============================================================================
NextHop                       Received       Advertised     Label
                              Label          Label          Origin
-------------------------------------------------------------------------------

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

All PEs in one AS have also received labels for all /32 system IP addresses of the remote PEs. Therefore, an MP-EBGP session can be created between the RRs in the different ASs to exchange VPN-IPv4 routes.

The additional BGP configuration for RR PE-3 is as follows. The configuration for RR PE-7 is similar. The IP addresses can be derived from Figure 341: Protocol overview.

```
# on RR PE-3:
configure
    router Base
        bgp
            group "peer-AS-RR"
                family vpn-ipv4
                peer-as 64497
                local-address 192.0.2.3
```

```
                neighbor 192.0.2.7
                    multihop 10
                    vpn-apply-export
                    export "EBGP-VPN-IPv4"
                exit
            exit
        exit
```

Policies can be applied on the peering session using the **export** command followed by a policy name, together with the **vpn-apply-export** command necessary to enforce base BGP instance policy on VPN-IPv4 prefixes.

On the RRs, the MP-EBGP session is up, as follows:

```
*A:PE-3# show router bgp neighbor 192.0.2.7

===============================================================================

---snip---
```

The EBGP session between the two RRs is established.

The VPRNs on PE-1 in AS 64496 and PE-5 in AS 64497 are now interconnected. The route table for VPRN 1 shows that the remote PE can be reached via a BGP tunnel, as follows:

```
*A:PE-1# show router 1 route-table

===============================================================================
Route Table (Service: 1)
===============================================================================

Conclusion

Inter-AS option C allows the delivery of Layer 3 VPN services to customers who have sites connected in different ASs. This example shows the configuration of inter-AS option C (specific to this feature) together with the associated show output which can be used for verification and troubleshooting.

Intra-AS NG-MVPN over BIER

This chapter provides information about Intra-AS NG-MVPN over BIER.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 16.0.R7.

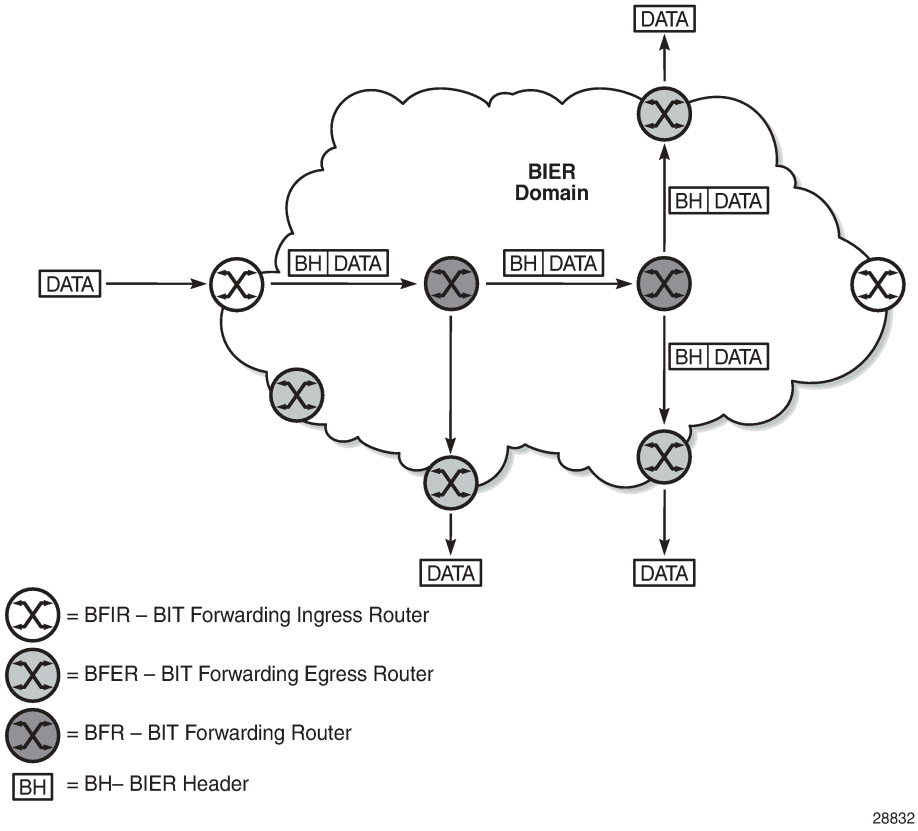
Overview

RFC 8279, *Multicast Using Bit Index Explicit Replication (BIER)*, defines an architecture for the forwarding of multicast data packets through a multicast domain, without requiring any explicit tree-building protocol nor any intermediate nodes to maintain any per-flow state, thereby offering significant operational simplification.

BIER concepts

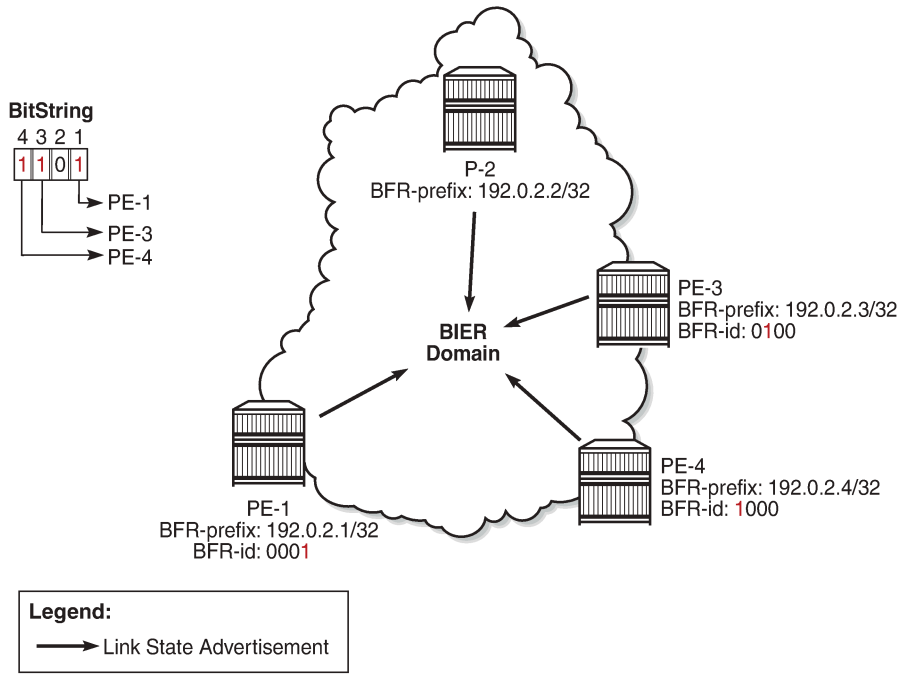
BIER-enabled routers are known as Bit Forwarding Routers (BFRs). A BIER domain contains Bit Forwarding Ingress Routers (BFIRs), Bit Forwarding Egress Routers (BFERs), and transit BFRs; see Figure 342: Bit Forwarding Router types. A router can be a BFIR for one flow, and at the same time be a BFER or a transit BFR for other flows. A BFIR adds a BIER header holding the information used by the BIER forwarding procedures to the multicast packets entering the BIER domain. A BFER removes the BIER header when forwarding the packets out of the BIER domain. The BIER encapsulated data can be further encapsulated in MPLS, where a BIER forwarding table is identified through an MPLS label on the adjacent node. BIER tunnels can build a fully meshed multicast network, thereby providing multicast interconnections between all the PEs in the network.

Figure 342: Bit Forwarding Router types



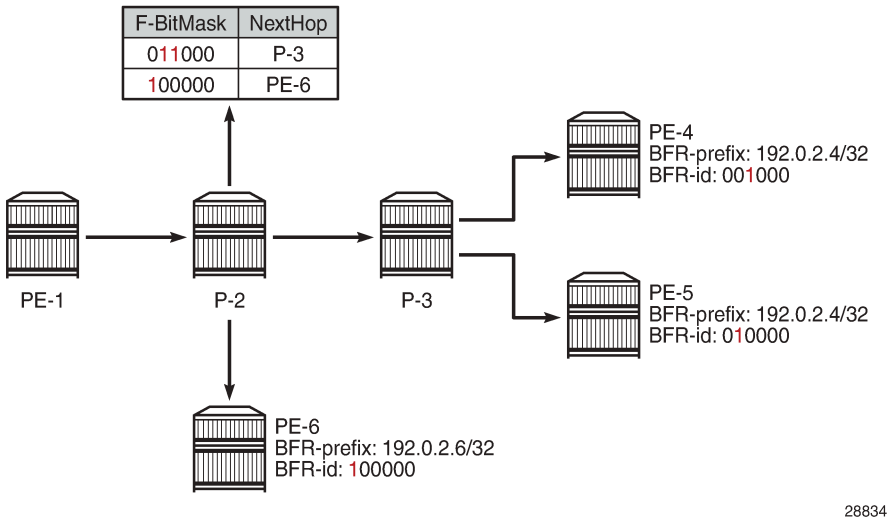
Every BIER receiver has a BFR-prefix and a BFR-id. The BFR-id identifies a unique bit position in a bit string assigned to that BFR; by convention, the rightmost bit is bit number 1. The mapping between the BFR-id and the BFR-prefix must be known to all BFRs in the domain; therefore, this information is distributed by the underlying Interior Gateway Protocol (IGP) in new TLVs and sub-TLVs defined in IGP extensions. In the example in Figure 343: BIER control plane: example bit position assignment and advertisement, PE-1 has BFR-prefix 192.0.2.1/32 and BFR-id 1, PE-3 has BFR-prefix 192.0.2.3/32 and BFR-id 3, and so on. Routers in the core of the network are transit BFRs and, as such, they are not BIER receivers; they require a BFR-prefix but not a BFR-id, so their BFR-id is zero.

Figure 343: BIER control plane: example bit position assignment and advertisement



Every BFR in the domain constructs a Bit Indexed Forwarding Table (BIFT) using the shortest unicast path route (SPF). In the construction of a BIFT, every BFR computes the unicast SPF path to each BFR-prefix. BFR-ids sharing the same next hop are combined using a logical OR operation, thereby saving memory resources by occupying a single entry in the BIFT; see Figure 344: BIER data plane: example BIER forwarding table for P-2 for an example. On P-2, PE-4 and PE-5 are reachable via P-3, so the forwarding bitmask is 011000 with next hop P-3.

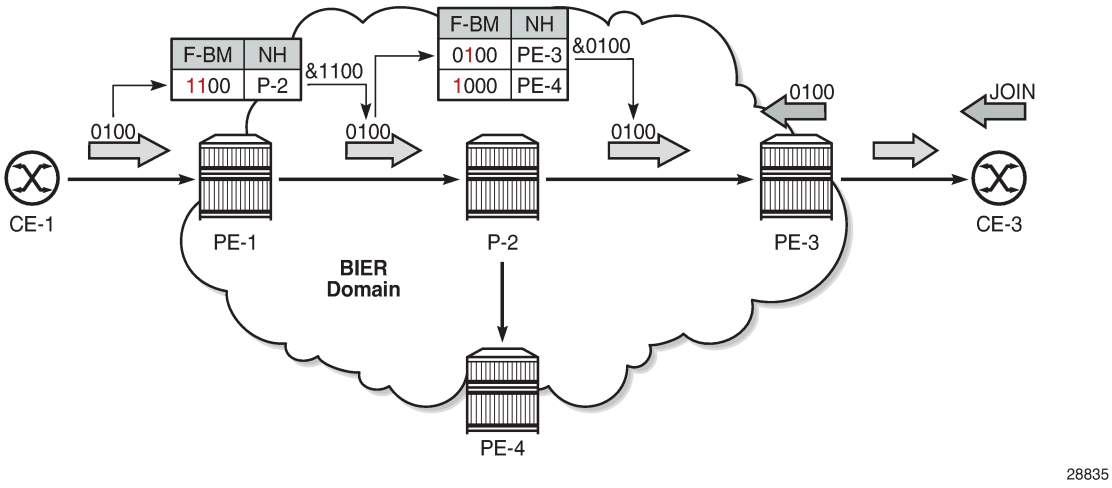
Figure 344: BIER data plane: example BIER forwarding table for P-2



The set of receivers a multicast data packet must be sent to is encoded in a bit string that is embedded in the BIER header. A BFR receiving a multicast data packet uses its BIFT to replicate these packets. When replicating a packet, the bit string in the BIER header is rewritten by the BFRs to avoid loops. Packets are forwarded and replicated hop by hop, following the unicast path from the BFIR to the BFERs.

The example in Figure 345: BIER data plane: example BIER packet forwarding assumes that CE-3 sends an IGMP join to PE-3, which in turn signals the join in MP-BGP to PE-1. PE-1 searches and finds BFR-id 3 in its BIFT with P-2 as the next hop, and logically ANDs (&1100) its bitmap when forwarding the packet to P-2. The AND operation explicitly clears bits for destinations that do not need the packet, thereby preventing potential duplication, and avoiding multicast routing loops. P-2 performs a similar set of steps to forward the packet to PE-3, which delivers the packet to CE-3. The overall result is that only nodes that requested the multicast stream will get that stream, leading to better, more optimal network usage.

Figure 345: BIER data plane: example BIER packet forwarding

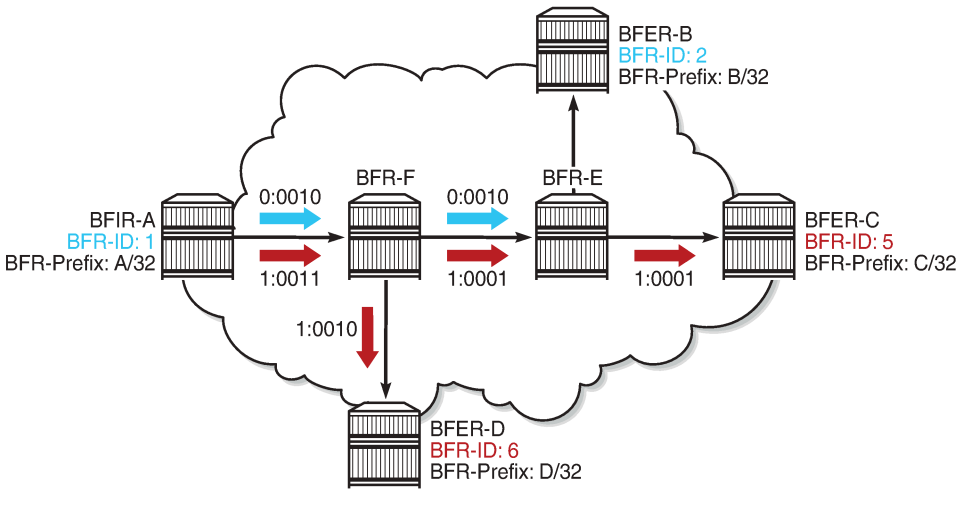


A BIER domain contains one or more sub-domains (SDs), where each SD is associated with a single IS-IS or OSPF topology. Each SD is identified by a number in the range 0 to 255, and each BIER domain must contain at least one SD, where SD 0 is the default. If a BIER domain contains more than one SD, each BFR in the domain must be provisioned with the set of SDs it belongs to. The BFR-id of a BFR is a number in the range 1 to 65535, and must be unique within an SD. If a BFR belongs to more than one SD, it may have different BFR-ids in each SD. Nokia recommends using a loopback interface for the BFR-prefix. The BFR-prefix to BFR-id mapping is flooded within the SD.

For scalability, a BIER domain contains one or more BIER sets, where each BIER set is identified by a Set Identifier [SI]. The Bit String Length (BSL) dictates how many BFRs can be represented in a BIER set. The BSL, the SI, and the Bit Position (BP) are encoded in the BIER header, where the SI and the BP are derived from the BFR-id. Assuming a BSL of 256, BPs can range from 1 to 256 in BIER set 0. If more than 256 BFIRs and BFERs are required, a second BIER set is required with SI 1, where the BP can again range from 1 to 256. However, if a multicast flow has multiple receivers in different BIER sets on the same outgoing interface, the packet must be replicated to every BIER set.

Figure 346: BIER sets provides an example where BSL is 4 bits, and BFER B, C, and D are interested in the same stream entering the BIER domain at BFIR A. Because BFER C and D have BFR-id 5 and 6, respectively, they are part of SI 1, and BFIR A has to make two copies of the stream; a first (blue) copy to reach BFER-B, and a second (red) copy to reach BFER C and BFER D. Therefore, Nokia recommends assigning BFR-ids as dense as possible; for example, in consecutive order starting from 1.

Figure 346: BIER sets



BIER is encapsulated in MPLS and the MPLS label for each forwarding table (identified through BSL, SI, and SD) is distributed through IS-IS; the BSL is 256 and the maximum number of BIER sets is 16. RFC 8401, *Bit Index Explicit Replication Support via IS-IS*, defines the extensions needed for distributing BIER information in IS-IS.

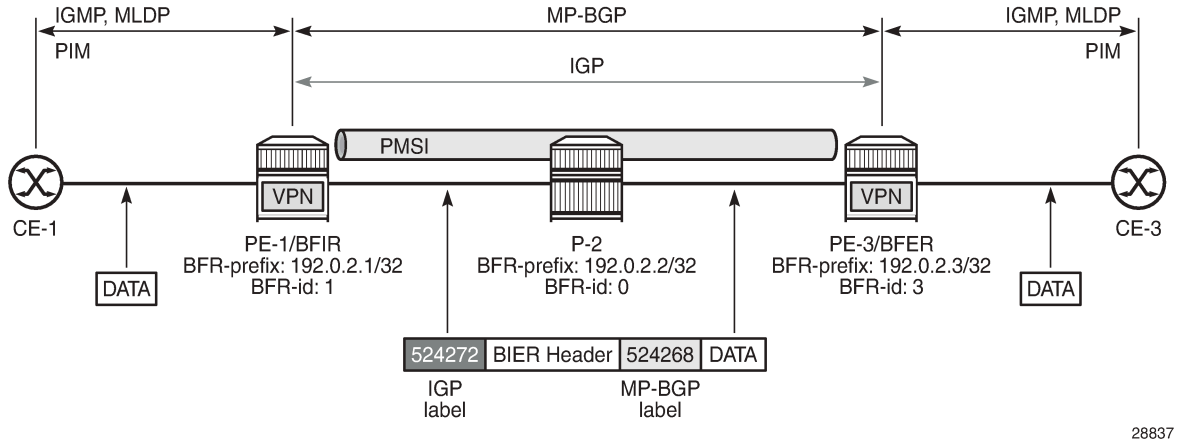
Multicast VPN over BIER

Multicast VPN (MVPN) or Next Generation IP Multicast in an IP-VPN (NG-MVPN) architectures describe a set of virtual routing and forwarding (VRF) or virtual private routed networks (VPRNs) that support the transport of multicast traffic across a provider network. MVPNs are defined in RFC 6513, *Multicast in MPLS/BGP IP VPNs*, and RFC 6514, *BGP Encodings and Procedures for Multicast in MPLS/IP VPNs*.

The *NG-MVPN Configuration with MPLS* and *NG-MVPN Configuration with PIM* chapters provide examples where the provider tunnels are signaled through either mLDP or PIM.

In this chapter, MVPN is used as the overlay to BIER in a single Autonomous System (AS). The MP-BGP control plane is used for the Auto-Discovery (A-D) of the MVPN memberships, the provider tunnel (P-tunnel) signaling, and the customer route (C-route) signaling; see Figure 347: MVPN over BIER.

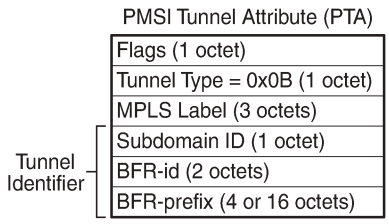
Figure 347: MVPN over BIER



BIER supports the use of Inclusive PMSIs (I-PMSIs) and Selective PMSIs (S-PMSIs). In the case of I-PMSI, the A-D route signaling, P-tunnel instantiation, and C-multicast routing information are restricted to the I-PMSI, where every BFIR and BFER participating in the MVPN receives every packet forwarded onto the I-PMSI. This way BFIRs and BFERs are interconnected in full mesh. Bandwidth utilization can be optimized by using S-PMSIs, where the C-flow is sent only to BFERs that have interested receivers, and where explicit tracking is used to create the list of interested receivers. The C-flow will be moved from I-PMSI to S-PMSI by the BFIR when a configured data threshold is reached.

The MP-BGP UPDATE messages used to establish the I-PMSI and the S-PMSI tunnels include the PMSI Tunnel Attribute (PTA), where the tunnel type is set to BIER, and where the MPLS label value is the upstream assigned MPLS label that identifies the VRF; see Figure 348: PTA: PMSI tunnel attribute. By using BIER, multicast provisioning in the core can be simplified; the core routers must be provisioned for BIER, but not for PIM, mLDP, or RSVP-TE. A PIM-free core can be created where no multicast state needs to be maintained.

Figure 348: PTA: PMSI tunnel attribute



Field	Purpose
Flags	LIR-bit. Leaf-Information Required. Used for Explicit Tracking
Tunnel Type	PMSI Tunnel Type; 0x0B for BIER
MPLS Label	Upstream-assigned non-zero MPLS Label
Subdomain ID	BIER subdomain ID
BFR-id	BFR-id of the BFIR constructing the PMSI Tunnel Attribute (PTA)
BFR-prefix	BFR-prefix of the BFIR that is constructing the PTA

28838

A multicast client joining a group through IGMP, MLD, or PIM results in the VRF sending an MP-BGP Source-Join message to the BFIR. The BFIR responds with a Source-AD message and establishes an S-PMSI tunnel if S-PMSI is enabled for the VPRN. Next, the S-PMSI tunnel is used to transport the C-flow from the BFIR to the BFER. Otherwise, the I-PMSI tunnel is used for transporting the C-flow.

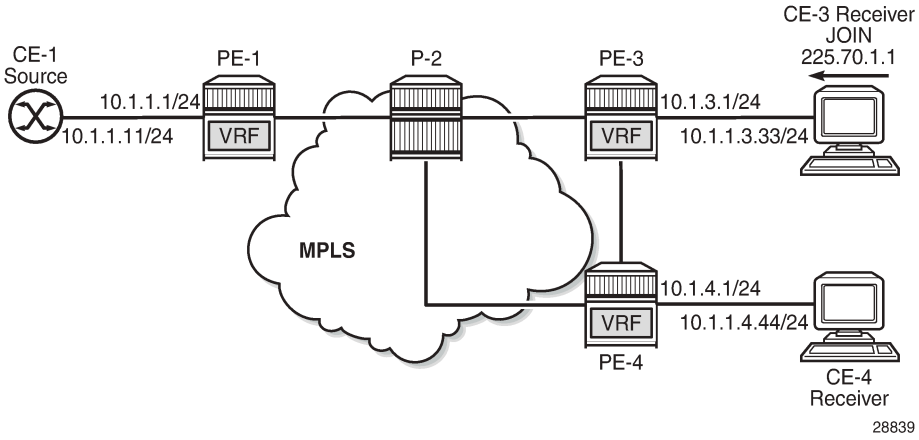
On CE to PE links, PIM Hello messages are used to establish C-PIM adjacencies. Also between the PEs, across the I-PMSIs, adjacencies are established, not using PIM but using MP-BGP instead. The announcement of MP-REACH-NLRI Intra-AS I-PMSI A-D routes in the discovery process serves as the

means to establish the PE-PE adjacencies. A response of the corresponding MP-UNREACH-NLRI results in the adjacency being dropped.

Configuration

The configuration used in this chapter is shown in Figure 349: Intra-AS NG-MVPN over BIER. IS-IS is the interior gateway protocol (IGP) used in AS 64496, and all nodes are at IS-IS level 2. These nodes share the same BIER domain and sub-domain (0). A multicast stream with group address 225.70.1.1 is transmitted by source 10.1.1.11 connected to PE-1. CE-3 and CE-4 are multicast receivers connected to PE-3 and PE-4, respectively. VPRN 1 is defined in PE-1, PE-3, and PE-4, and uses NG-MVPN for transporting the multicast traffic through the core of the network. See the *NG-MVPN with MPLS* and the *NG-MVPN with PIM* chapters for more information about NG-MVPN. The BFR-ids used by PE-1, PE-3, and PE-4 are 1, 3, and 4, respectively, so they are part of a single set with SI 0.

Figure 349: Intra-AS NG-MVPN over BIER



The initial configuration on the PE nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS

BGP configuration

BGP is required at the core of the network, using the VPN IPv4 and MVPN IPv4 address families in support of unicast and multicast for VPRN services. PE-1, PE-3, and PE-4 are clients of the route reflector located in P-2. The BGP configuration on PE-1, PE-3, and PE-4 is as follows:

```
# on PE-1, PE-3, and PE-4
configure
    router
        autonomous-system 64496
        bgp
            family vpn-ipv4 mvpn-ipv4
            vpn-apply-import
            vpn-apply-export
```

```
            rapid-withdrawal
            rapid-update vpn-ipv4 mvpn-ipv4
            group "iBGP"
                neighbor 192.0.2.2
                    peer-as 64496
                exit
            exit
            no shutdown
        exit
    exit
exit
```

P-2 is the route reflector and configured as follows:

```
# on P-2
configure
    router
        autonomous-system 64496
        bgp
            family vpn-ipv4 mvpn-ipv4
            vpn-apply-import
            vpn-apply-export
            cluster 0.0.0.1
            rapid-withdrawal
            rapid-update vpn-ipv4 mvpn-ipv4
            group "iBGP"
                peer-as 64496
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
    exit
exit
```

BIER configuration

All the nodes in the topology have a BIER template named *bier-tmpl0*; however, the content for that template is different on each node. Although multiple sub-domains can be defined through the range command, in this example all nodes in the topology are in the single sub-domain 0 of the BIER domain.

PE-1, PE-3, and PE-4 are the termination points for the BIER tunnels; therefore, they require a BFR-id. For PE-1, PE-3, and PE-4, the system addresses are used as the prefix, and the BFR-ids are set to 1, 3, and 4, respectively. For brevity, only the BIER template on PE-1 is shown:

```
# on PE-1
configure
    router
        bier
            template "bier-tmpl0"
                sub-domain 0
                    prefix 192.0.2.1
                    bfr-id 1
                exit
                no shutdown
            exit
```

```
            no shutdown
        exit
    exit
exit
```

P-2 is a transit BFR, so P-2 does not require a BFR-id. This is made explicit in the BIER template for P-2, as follows:

```
# on P-2
configure
    router
        bier
            template "bier-tmpl0"
                sub-domain 0
                    prefix 192.0.2.2
                    no bfr-id
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

The BIER template must be applied to the IGP, so that the MPLS labels required for the BIER tunnels are distributed through the IGP, which is IS-IS.

In the example topology shown in Figure 8, the IS-IS configuration is similar on all nodes, with **level-capability** set to **level-2**, and *bier-templ0* applied and enabled (no shutdown) at level 2, as follows. For brevity, only the IS-IS configuration for PE-1 is shown.

```
# on PE-1
configure
    router
        isis
            level-capability level-2
            area-id 49.0001
            traffic-engineering
            level 2
                bier
                    template "bier-tmpl0"
                    no shutdown
                exit
            exit
            interface "system"
                no shutdown
            exit
            interface "int-PE-1-P-2"
                interface-type point-to-point
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

The status of IS-IS shows that BIER is active at L2 using template bier-tmpl0, but not at L1. BIER must be active on all nodes in the topology, but for brevity only the IS-IS status on P-1 is shown, as follows:

```
*A:PE-1# show router isis status
```

```
===============================================================================

BIER allocates an MPLS label per BIER set, and 16 consecutive labels are allocated to accommodate the 16 BIER sets supported by SR OS. This label range is shown together with the BFR-id and BFR-prefix from the BIER template in the BIER database. For PE-1, the BIER database is as follows:

```
*A:PE-1# show router bier database

===============================================================================
BIER Database
===============================================================================
Template                        MT             Sub-domain     BSL

IS-IS distributes the BIER information across all the BFRs in the network using link state packets (shown as "LSP" in the output); consequently, this information is the same on all BFRs. As an example, the details for LSP PE-3.00-00 show that for PE-3 at level 2, the BFR-id is 3, and the MPLS label value is 524271:

```
*A:PE-1# show router isis database PE-3.00-00 detail

```

Based on the link state packets distributed across the network, every BFR generates a BIER routing table and a BIER forwarding table. The BIER routing table defines the interface, next-hop, and neighbor to use for all BFRs. On P-1, the BIER routing table is as follows:

```
*A:PE-1# show router bier routing

===============================================================================
Destination Prefix                          Bfr-ID          Age

*A:PE-1#
```

The BIER forwarding table has one entry per BIER neighbor, defining the next hop, interface, and forwarding bit mask. On PE-1, the BIER forwarding table is as follows. For neighbor 192.0.2.2, the forwarding bit mask is 0xC in hexadecimal, or 0b1100 in binary. Using the convention that the rightmost bit is bit 1, this means bits 3 and 4 are set, and these bits correspond to BFRs with system addresses 192.0.2.3 and 192.0.2.4, according their BFR-id.

```

```

No multicast configuration is required in the base routers of the BFERs, BFIRs, and the transit BFR, resulting in a simplified configuration. Only the BFIRs and BFERs must be configured with MVPN-enabled VPRN services.

Service configuration

The full configuration of VPRN 1 on PE-1 is as follows. The *int-PE-1-CE-1* interface provides the connection to the multicast source. PIM is enabled for all interfaces in the service through the **apply-to all** command. To support BIER, MVPN must be enabled with **auto-discovery** set to **default** and **c-mcast-signaling** set to **bgp**. BIER is enabled (no shutdown) for inclusive and selective provider tunnels for sub-domain 0.

```
# on PE-1
configure
    service
        vprn 1 name "svc-1" customer 1 create
            description "runs between PE-1, PE-3 and PE-4"
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:1
            interface "int-PE-1-CE-1" create
                address 10.1.1.1/24
                sap 1/1/c5/1:10 create
                exit
            exit
            pim
                apply-to all
                no shutdown
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        bier
                            sub-domain 0
                            no shutdown
                        exit
                    exit
                    selective
                        bier
                            sub-domain 0
                            no shutdown
                        exit
                        data-threshold 224.0.0.0/4 10
                    exit
                exit
```

```
                vrf-target unicast
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The MVPN configuration for VRF 1 on PE-3 and PE-4 is the same. However, PE-3 and PE-4 provide connections to multicast clients CE-3 and CE4, and they have IGMP configured. Because the configurations for PE-3 and PE-4 are similar, only the configuration of PE-3 is provided.

```
# on PE-3
configure
    service
        vprn 1
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:1
            interface "int-PE-3-CE-3" create
                address 10.1.3.1/24
                sap 1/1/c5/1:10 create
                exit
            exit
            igmp
                ssm-translate
                    grp-range 225.70.1.1 225.70.255.255
                        source 10.1.1.11
                    exit
                exit
                interface "int-PE-3-CE-3"
                    no shutdown
                exit
                no shutdown
            exit
            pim
                no shutdown
            exit
            ---snip---
         exit
    exit
exit
```

With VRF 1 on PE-1, PE-3, and PE-4 configured as previously described, VPN and MVPN routes are exchanged, as follows:

```
*A:PE-1# show router bgp summary all

===============================================================================

The receiver located at address 10.1.3.33/24 and connected to PE-3 then joins group 225.70.1.1, so VRF 1 creates an IGMP state, and (*,255.70.1.1) is forwarded to interface *int-PE-3-CE-3*, as follows:

```
*A:PE-3# show router 1 igmp group interfaces
===============================================================================
IGMP Interface Groups
===============================================================================

(*,225.70.1.1)                                          UpTime: 0d 00:10:59
    Fwd List  : int-PE-3-CE-3
-------------------------------------------------------------------------------
Entries : 1
===============================================================================
*A:PE-3#
```

VRF 1 on PE-3 also creates a PIM state for group 225.70.1.1, where the incoming S-PMSI interface is *mpls-if-73734*, and the outgoing interface is *int-PE-3-CE-3*, as follows:

```
*A:PE-3# show router 1 pim group detail

===============================================================================
```

```

*A:PE-1#
```

In summary, for the multicast traffic originated by CE-1 to VPRN 1, PE-1 passes the core network through a BIER tunnel and leaves VPRN 1, PE-3 to terminate in CE-3. A transit node in the core network (P-2 in the example of Figure 1) does not maintain any multicast state for the multicast stream.

With MVPN-enabled VPRN 1 instances defined on PE-1, PE-3, and PE-4, and group 225.70.1.1 active, an entry is added to the MVPN list. On PE-1, this list is as follows:

```
*A:PE-1# show router mvpn-list type bier

Legend: Sig = Signal  Pim-a = pim-asm  Pim-s = pim-ssm  A-D = Auto-Discovery
SR = Sender-Receiver  SO = Sender-Only  RO = Receiver-Only

===============================================================================
*A:PE-1#
```

As opposed to Rosen MVPNs, at no place in the network must multicast be configured in the base router. The status of PIM can be verified as follows, but for brevity the command is executed on P-2 only.

```
*A:P-2# show router pim status
MINOR: CLI PIM is not configured.
*A:P-2#
```

Debug

The following debug configuration can be used for troubleshooting BIER:

```
debug
    router "Base"
        bier
            management
            template
            tunnel
        exit
    exit
exit
```

The log shows the trace when CE-4 joins group 225.70.1.1 on PE-4, VPRN 1. To see the interactions with IGMP, PIM, and BGP, these protocols should be debugged too, but these are omitted here. The message sequence indicates what happens when a new BIER tunnel is created on PE-4. The new BIER tunnel ID 73735 is highlighted.

```
*A:PE-4# show log log-id 1 ascending

Conclusion

Using BIER as multicast transport technology provides operators an alternative to Rosen MVPN scenarios that optimizes network resources. Multicast provisioning is simplified because the use of PIM, mLDP, or RSVP-TE as tunneling technologies can be avoided. Because no multicast control protocol is required in the core, no multicast state must be maintained; consequently, there is no need to reconverge state and resignal multicast state in the case of a network failure.

Layer 3 VPN: VPRN Type Spoke

This chapter provides information about Layer 3 VPRN CE hub and spoke architecture.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 12.0. However, the CLI in the current edition is based on SR OS Release 22.2.R1.

Knowledge of Nokia's Layer 3 VPN concepts is assumed throughout this document.

Overview

This chapter provides a basic technology overview and configuration examples of a network topology used for a Layer 3 VPRN CE hub and spoke architecture.

VPRN type hub

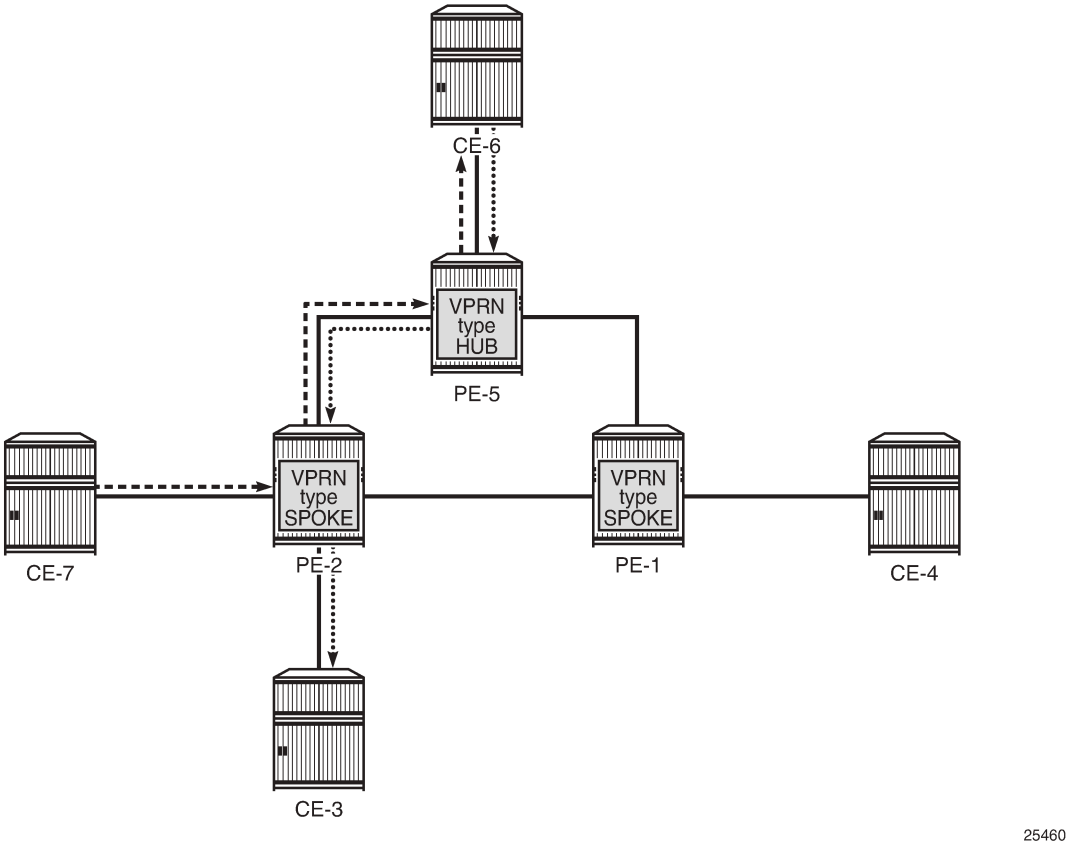
In SR OS Releases earlier than 12.0, a CE hub and spoke architecture was partially supported. Internal optimization was available for the hub sites connected to the same PE router only. This feature is known as VPRN type hub. If, on the other hand, multiple spoke sites were connected to the same PE router, separate VPRN instances had to be created to maintain the split horizon forwarding behavior. This approach was complex, hard to maintain and consumed extra VPRN instances.

VPRN type spoke

Release 12.0.R1 added new functionality to overcome these limitations. Introducing the VPRN type spoke feature allows multiple spoke sites to be kept within the same VPRN instance while at the same time maintaining the split horizon approach such that spoke sites cannot send traffic directly to each other.

The primary goal of the feature is to allow multiple spoke sites to be part of a single VPRN instance without allowing direct communication between the spoke CE sites which are part of that VPRN (of type spoke). The packet flow is demonstrated in Figure 350: CE hub and spoke data path.

Figure 350: CE hub and spoke data path

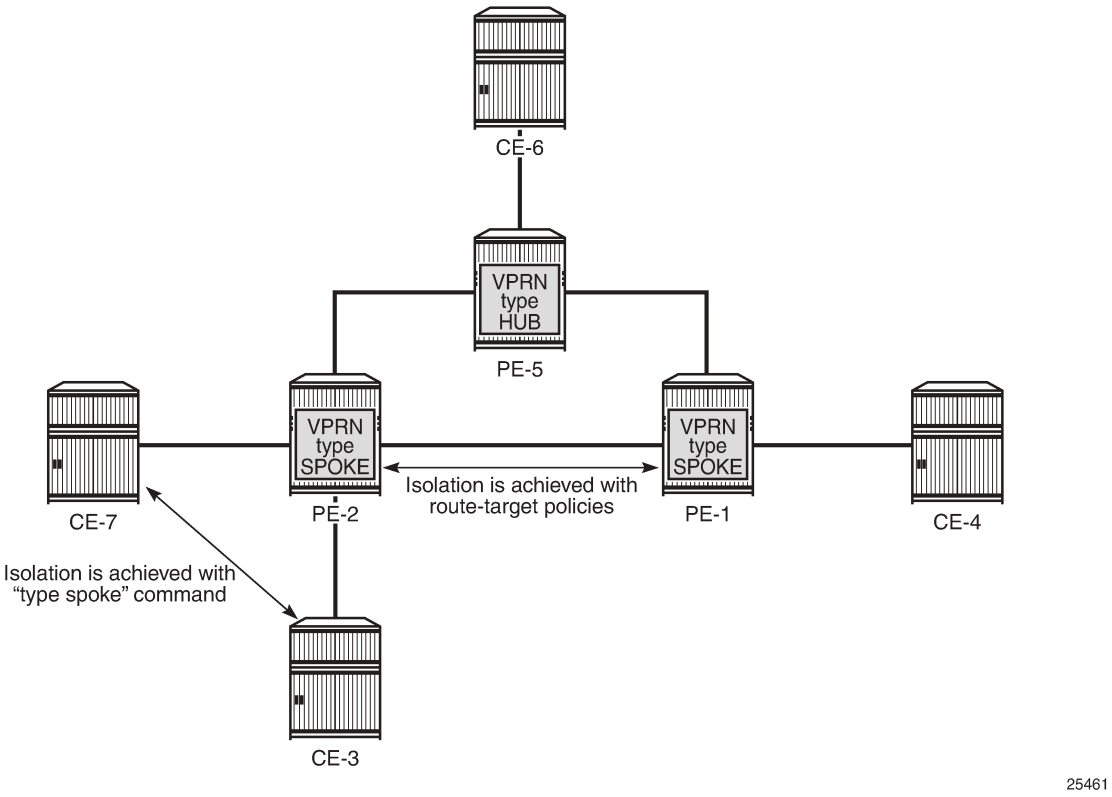


The only way for CE-7 to communicate with CE-3 is via hub site CE-6. The same applies to the communication between CE-7 and CE-4. The VPRN on PE-2 is configured as **type spoke** and has IP interfaces using SAPs or spoke SDPs that are considered spoke sites only. No direct communication between any of the spoke CE sites in the network is allowed.

Direct communication between the spoke CE sites is blocked using two techniques, as illustrated in Figure 351: CE hub and spoke control plane isolation.

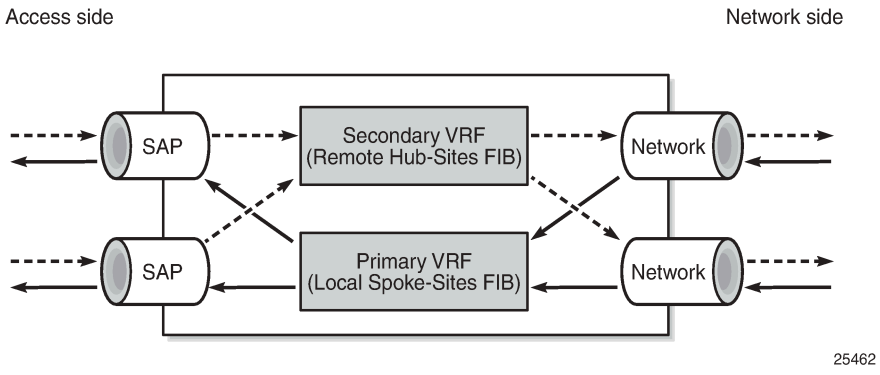
- Using the **type spoke** command under the **vprn** context as explained later.
- The extended community configuration using route-target policies (this is not covered in detail in this chapter).

Figure 351: CE hub and spoke control plane isolation



When a VPRN on a PE router is configured as **type spoke**, then the internal forwarding logic changes as demonstrated in Figure 352: Internal VPRN logic on a PE router.

Figure 352: Internal VPRN logic on a PE router



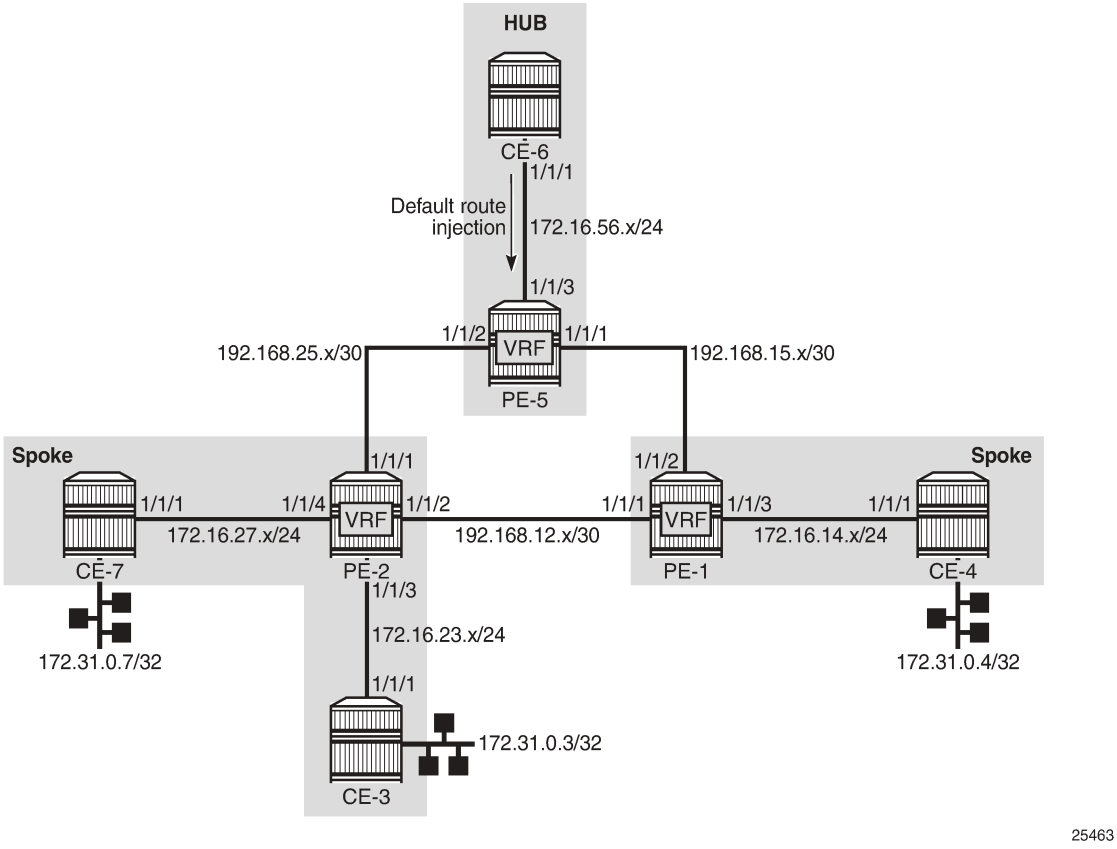
- VPRNs of type spoke create a primary and a secondary VRF internally to the VPRN:
  - The primary VRF is used for forwarding traffic from the network interfaces toward the IP interfaces using SAPs or spoke SDPs. This VRF is populated with routes learned from the spoke CE sites connected to the local PE through IP interfaces using SAPs or spoke SDPs.

  - The secondary VRF is used for forwarding traffic from the IP interfaces using SAPs or spoke SDPs toward the network interfaces or other VPRN instances. This VRF is populated with routes learned via MP-BGP from hub sites.
- VPRNs of type spoke export routes using a specific extended community (for instance, spoke-ext-comm) via an export policy to identify them as spoke site originated routes.
  - This community is not hard-coded and has to be configured manually (see configuration example later).
- VPRNs of type spoke import routes (using an import policy) received from other PEs or VPRN instances with a hub specific community only (for example, hub-ext-comm). Routes with spoke-ext-comm community are ignored.
  - This community is not hard-coded and has to be configured manually (see configuration example later).
- Multiple VPRNs of type spoke and hub can coexist on the same PE if they use different VPRN instances.
- The configuration of type hub and type spoke is mutually exclusive within one VPRN instance.

Configuration

The physical topology and addressing scheme are presented in Figure 353: CE hub and spoke topology and addressing scheme.

Figure 353: CE hub and spoke topology and addressing scheme



The configuration of PE-2 and PE-5 are the main focus of this example. The configuration of PE-1 is similar to that of PE-2.

Hub site configuration

Only the essential part of the configuration is provided for the hub site.

Vrf-import and vrf-export policies are used to manipulate the vrf-target in order to achieve logical isolation between the spoke sites in the network.

```
# on PE-5:
configure
    router Base
        policy-options
            begin
            community "hub-ext-comm"
                members "target:64500:11"
            exit
            community "spoke-ext-comm"
                members "target:64500:12"
            exit
            policy-statement "vrf-export"
                default-action accept
                    community add "hub-ext-comm"
```

```
            exit
        exit
        policy-statement "vrf-import"
            entry 10
                from
                    community "spoke-ext-comm"
                exit
                action accept
                exit
            exit
            default-action drop
            exit
        exit
        policy-statement "export-ospf"
            entry 10
                from
                    protocol direct
                exit
                action accept
                exit
            exit
            default-action accept
            exit
        exit
        commit
    exit
```

PE-5 is configured with VPRN 1 providing OSPF connectivity to customer CE-6.

```
# on PE-5:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            description "VPRN type hub"
            type hub
            interface "int-PE-5-CE-6" create
                address 172.16.56.1/24
                sap 1/1/3:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64500:15
                    vrf-import "vrf-import"
                    vrf-export "vrf-export"
                    no shutdown
                exit
            exit
            ospf
                export "export-ospf"
                area 0.0.0.0
                    interface "int-PE-5-CE-6"
                        interface-type point-to-point
                        mtu 1500
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

```
        exit
```

At the same time, CE-6 is configured to advertise a default route which is used by all remote spoke CE sites to forward traffic via CE-6.

```
# on CE-6:
configure
    router Base
        policy-options
            begin
            policy-statement "export-ospf-default"
                entry 10
                    from
                        protocol static
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

```
# on CE-6:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            interface "int-CE-6-PE-5" create
                address 172.16.56.2/24
                sap 1/1/1:1 create
                exit
            exit
            static-route-entry 0.0.0.0/0
                black-hole
                    no shutdown
                exit
            exit
            ospf 192.0.2.6
                export "export-ospf-default"
                ignore-dn-bit
                suppress-dn-bit
                area 0.0.0.0
                    interface "int-CE-6-PE-5"
                        interface-type point-to-point
                        mtu 1500
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

Spoke site configuration

According to the example topology, two spoke VPRNs are present: one VPRN with two CE spoke sites connected is located on PE-2, and another VPRN with one spoke CE site on PE-1. The service configuration for PE-2 is as follows with the one for PE-1 being similar.

Vrf-import and vrf-export policies are used to build a hub-and-spoke topology in order to achieve a logical isolation between spoke sites connected to different PE routers.

```
# on PE-2:
configure
    router Base
        policy-options
            begin
            community "hub-ext-comm"
                members "target:64500:11"
            exit
            community "spoke-ext-comm"
                members "target:64500:12"
            exit
            policy-statement "vrf-export"
                default-action accept
                    community add "spoke-ext-comm"
                exit
            exit
            policy-statement "vrf-import"
                entry 10
                    from
                        community "hub-ext-comm"
                    exit
                    action accept
                    exit
                exit
                default-action drop
                exit
            exit
            policy-statement "export-ospf"
                default-action accept
                exit
            exit
            commit
        exit
```

PE-2 is configured with VPRN 1, which has OSPF connectivity to the customer CE-3 and CE-7. The **type spoke** command is used to prevent direct CE spoke to CE spoke communications for this VPRN.

```
# on PE-2:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            description "VPRN type spoke"
            type spoke
            interface "int-PE-2-CE-3" create
                address 172.16.23.1/24
                sap 1/1/3:1 create
                exit
            exit
            interface "int-PE-2-CE-7" create
                address 172.16.27.1/24
                sap 1/1/4:1 create
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution any
                    exit
                    route-distinguisher 64500:12
```

```
                    vrf-import "vrf-import"
                    vrf-export "vrf-export"
                    no shutdown
                exit
            exit
            ospf
                export "export-ospf"
                area 0.0.0.0
                    interface "int-PE-2-CE-3"
                        interface-type point-to-point
                        mtu 1500
                        no shutdown
                    exit
                    interface "int-PE-2-CE-7"
                        interface-type point-to-point
                        mtu 1500
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

For connectivity verification purposes, CE-3, CE-4, and CE-7 are configured to advertise their internal loopback interfaces via OSPF:

- CE-3 advertises 172.31.0.3/32
- CE-4 advertises 172.31.0.4/32
- CE-7 advertises 172.31.0.7/32

```
# on CE-3:
configure
    service
        vprn 1 name "VPRN1" customer 1 create
            interface "int-CE-3-PE-2" create
                address 172.16.23.2/24
                sap 1/1/1:1 create
                exit
            exit
            interface "lo0" create
                address 172.31.0.3/32
                loopback
            exit
            ospf 192.0.2.3
                ignore-dn-bit
                suppress-dn-bit
                area 0.0.0.0
                    interface "int-CE-3-PE-2"
                        interface-type point-to-point
                        mtu 1500
                    exit
                    interface "lo0"
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

Hub site verification

The Routing Information Base (RIB) for VPRN 1 on hub site PE-5 lists all reachable networks:

```

The forwarding table for the secondary VRF of VPRN 1 is displayed using following command, including the **secondary** keyword. All local hub CE sites are reachable via this VRF.

```
*A:PE-5# show router 1 fib 1 secondary

Spoke site verification

The RIB for VPRN 1 on PE-2 (spoke VPRN) lists all reachable networks.

The other spoke sites connected to the remote PEs are not present in the routing table, in this example, CE-4 with prefixes such as 172.31.0.4/32 and 172.16.14.0/24.

The local interface addresses of PE-2 (172.16.23.1/32 and 172.16.27.1/32) are present in the routing table of VPRN 1, as follows. From a FIB point of view, these are reachable from any spoke VPRN, but the spoke CE's router host addresses are not. This fact does not influence the data plane isolation for the customer networks.

```
*A:PE-2# show router 1 route-table
