Spoke sites connectivity verification

Without the VPRN spoke type configuration in VPRN 1 on PE-2, CE-3 takes the shortest path to CE-7, which violates the hub-and-spoke design approach explained earlier.

The VPRN has to be disabled (**shutdown**) in order to modify the type.

```
*A:PE-2>config>service>vprn# no type
INFO: PIP #1162 Instance must be 'shutdown'
```

```
# on PE-2:
configure
    service
        vprn "VPRN1"
            shutdown
            no type
            no shutdown
```

Note:
In this setup, a VPRN is configured on CE-3, but that is not necessary.

Traffic from CE-3 takes the shortest path to CE-7, because VPRN 1 on PE-2 is not configured with spoke type anymore.

```
*A:CE-3# traceroute router 1 172.31.0.7 no-dns
traceroute to 172.31.0.7, 30 hops max, 40 byte packets
  1  172.16.23.1    2.74 ms  2.60 ms  2.64 ms
  2  172.31.0.7    3.28 ms  3.21 ms  3.07 ms
```

After enabling the **type spoke** feature on PE-2, CE-3 takes the longest path via hub CE-6 to reach CE-7, as it should.

```
# on PE-2:
configure
    service
        vprn "VPRN1"
            shutdown
            type spoke
```

```
*A:CE-3# traceroute router 1 172.31.0.7 no-dns
traceroute to 172.31.0.7, 30 hops max, 40 byte packets
  1  172.16.23.1    2.55 ms  2.80 ms  2.66 ms
```

```
  2  0.0.0.0  * * *
  3  172.16.56.2    4.47 ms  4.36 ms  4.33 ms
  4  172.16.56.1    4.49 ms  4.17 ms  4.20 ms
  5  172.16.27.1    4.10 ms  4.22 ms  3.98 ms
  6  172.31.0.7    6.63 ms  6.42 ms  6.61 ms
```

Similarly, the long path is taken by CE-3 to reach CE-4, as follows. This is unrelated to the VPRN type. It is achieved by policies.

```
*A:CE-3# traceroute router 1 172.31.0.4 no-dns
traceroute to 172.31.0.4, 30 hops max, 40 byte packets
  1  172.16.23.1    2.31 ms  2.47 ms  2.55 ms
  2  0.0.0.0  * * *
  3  172.16.56.2    4.53 ms  4.57 ms  4.35 ms
  4  172.16.56.1    4.66 ms  4.46 ms  4.47 ms
  5  172.16.14.1    6.06 ms  6.21 ms  6.08 ms
  6  172.31.0.4    7.00 ms  6.87 ms  7.30 ms
```

Conclusion

The VPRN type spoke feature completes the CE hub and spoke solution. It brings an additional level of simplicity, scalability, and flexibility to operators using this VPRN architecture for their customers.

NG-MVPN Configuration with MPLS

This chapter provides information about NG-MVPN configuration with MPLS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 9.0.R5, but the CLI in this edition corresponds to Release 15.0.R5. There are no prerequisites for this configuration.

Summary

Multicast VPN (MVPN) or Next Generation IP Multicast in an IP-VPN (NG-MVPNs) architectures describe a set of virtual routing and forwarding (VRFs) or virtual private routed networks (VPRNs) that support the transport of multicast traffic across a provider network. MVPNs are defined in RFC 6513, *Multicast in MPLS/BGP IP VPNs*, and RFC 6514, *BGP Encodings and Procedures for Multicast in MPLS/IP VPNs*.

Initial MVPN deployments were originally based on Rosen MVPN (RFC 6037) which described the protocols and procedures required to support an IP Multicast VPN. There were a number of limitations with the Rosen MVPN implementation including, but not limited to:

- Rosen MVPN requires a set of multicast distribution trees (MDTs) per VPN, which requires a PIM state per MDT. There is no option to aggregate MDTs across multiple VPNs.
- Customer signaling. Initially, PE discovery and Data MDT signaling were all PIM-based because there was no mechanism available to decouple these. Now, PE discovery is supported using a BGP MDT address family identifier/subsequent address family identifier (AFI/SAFI), however, the data MDT still needs PIM.
- There is no mechanism for using MPLS to encapsulate multicast traffic in the VPN. GRE is the only encapsulation method available in Rosen MVPN.
- Rosen MPVN multicast trees are signaled using PIM only. MVPN allows the use of mLDP and RSVP P2MP LSPs.
- PE to PE protocol exchanges for Rosen MVPN is achieved using PIM only. MVPN allows for the use of BGP signaling as per unicast Layer 3 VPNs.

NG-MVPN addresses these limitations by extending the idea of the per-VRF tree by introducing the idea of provider multicast service interfaces (PMSIs). These are equivalent to the default MDTs of Rosen MVPN. NG-MVPN allows the decoupling of the mechanisms required to create a multicast VPN, such as PE auto-discovery (which PEs are members of which VPN), PMSI signaling (creation of tunnels between PEs), and customer multicast signaling (multicast signaling —IGMP/PIM— received from customer edge routers). Two types of PMSI exist:

- Inclusive (I-PMSI) — Contains all the PEs for a given MVPN, I-PMSI is the default multicast data path between all PEs of the same VPN.
- Selective (S-PMSI) — Contains only a subset of PEs of a given MVPN, used to optimize multicast stream distribution to only the PEs with active receivers for those streams.

The NG-MVPN Configuration with PIM chapter contains the VPN configuration required for the provider multicast domain using PIM Any Source Multicast (ASM) with auto-discovery based on PIM or BGP auto-discovery (AD), PIM used for the customer multicast signaling and PIM Source Specific Multicast (SSM) used for the S-PMSI creation. The customer domain configuration covers the following cases:

- PIM ASM with the Rendezvous Point (RP) in the provider PE
- PIM ASM using anycast RP on the provider RPs
- PIM SSM

This chapter introduces some of the features that were not supported at the time of writing of chapter NG-MVPN Configuration with PIM (Release 7.0). It provides configuration details to implement:

- Multicast LDP (mLDP) and RSVP-TE Point to Multipoint (P2MP) for building customer trees (C-trees) which are using MPLS instead of PIM techniques.
- MVPN source redundancy.
- MDT AFI/SAFI (to fully interoperate with Cisco networks).

PIM SSM is the only case addressed in this example, other PIM customer domain configurations are out of the scope, for more information refer to NG-MVPN Configuration with PIM.

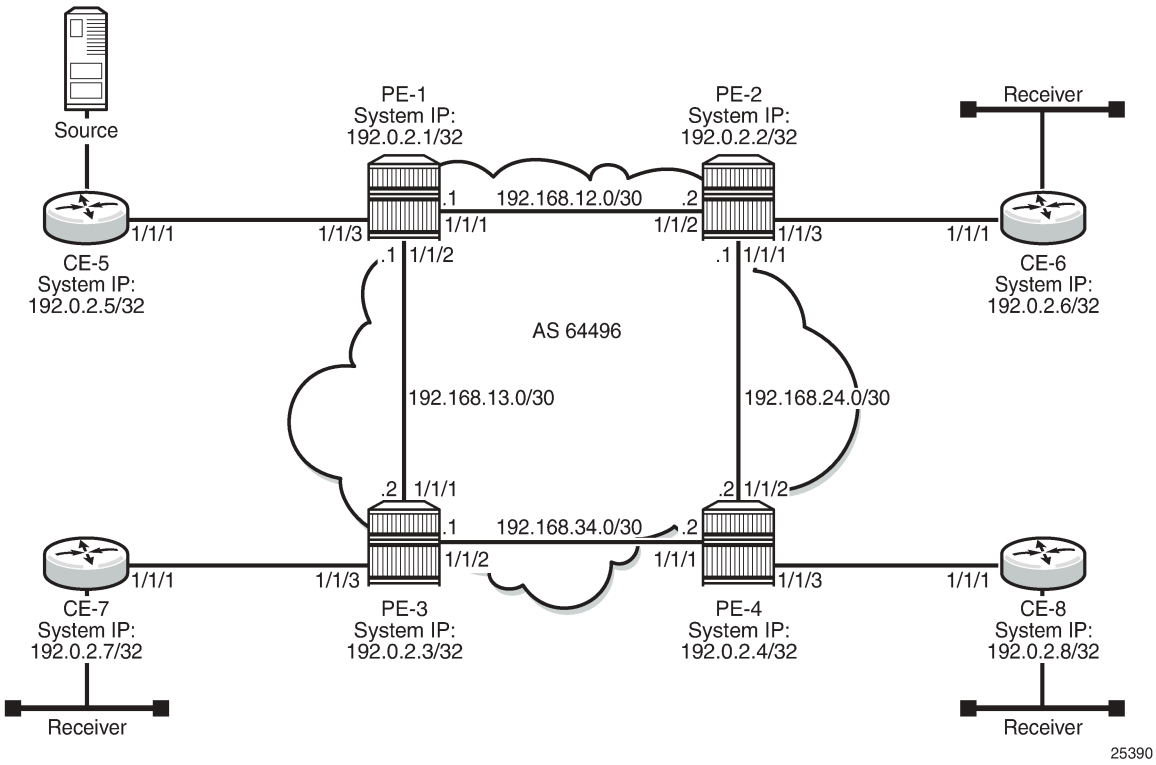
Overview

The network topology is shown in Figure 354: Network Topology. The setup consists of four 7750 SRs acting as provider edge (PE) routers within a single autonomous system (AS).

- Full mesh IS-IS in the AS (OSPF could be used instead)
- LDP on all interfaces in each AS (RSVP could be used instead)
- MP-iBGP sessions between the PE routers in the AS (route reflectors (RRs) could also be used).
- Layer 3 VPN on all PEs with identical route targets.

Connected to each PE is a single 7750 SR acting as a customer edge (CE) router. CE-5 has a multicast source connected, and PE-2, PE-3, and PE-4 each have a single receiver connected which will receive the multicast streams from the source. In this setup, each receiver is IGMPv3 capable. If the receiver is IGMPv3 capable, it will issue IGMPv3 reports that may include a list of required source addresses.

Figure 354: Network Topology



When the receiver wishes to become a member of any group, the source address of the group must be known to the CE. As a result, the source address must be IP reachable by each CE, so it is advertised using BGP by CE-5 to the PEs with attachment circuits in the VPRN. Static routes are then configured on the receiver CEs to achieve IP reachability to the source address of the multicast group.

Multicast traffic from the source is streamed toward router CE-5. Receivers connected to PE-2, PE-3 and PE-4 are interested in joining this multicast group.

CEs 5 to 8 are PIM enabled routers, which form a PIM adjacency with their nearest PE. Between the PEs across the provider network, there are no PIM adjacencies, because BGP auto-discovery and BGP signaling are used. Selective PMSI using mLDP or RSVP P2MP are out of the scope of this chapter. Selective PMSI using PIM SSM is supported too. I-PMSI and S-PMSI must use the same tunneling technology, either PIM/GRE, or mLDP, or RSVP P2MP.

Configuration

The configuration is divided into the following sections:

- Provider common configuration
  - PE global configuration
- PE VPRN configuration and PE VPRN multicast configuration for NG-MVPN
  - PMSI using mLDP
  - PMSI using RSVP-TE

  - UMH (upstream multicast hop)
- PE VPRN configuration and PE VPRN multicast configuration for Rosen MVPN using MDT AFI SAFI
  - Auto discovery using BGP MDT AFI SAFI as per Rosen MVPN version 9 with MDT using PIM SSM

Provider Common Configuration

PE Global Configuration

This section describes the common configuration required for each PE within the provider multicast domain, regardless of the MVPN PE auto-discovery or customer signaling methods. This includes interior gateway protocol (IGP) and VPRN service configuration.

The configuration tasks can be summarized as follows:

- PE global configuration.

  This includes configuration of the IGP (IS-IS will be used); configuration of link layer LDP between PEs (LDP will be used here as the method to interconnect VPRNs); configuration of iBGP between PEs to facilitate VPRN route learning.
- VPRN configuration on the PEs.

  This includes configuration of basic VPRN parameters (route-distinguisher, route target communities), configuration of attachment circuits toward CEs, configuration of VRF routing protocol and any routing policies.
- PIM within the VRF and MVPN parameters — I-PMSI
- CE configuration.

Step 1.

Configure the interfaces, the IGP (IS-IS) in all PE nodes (where IS-IS redistributes route reachability to all routers) and LDP in the interfaces (link layer LDP). To facilitate the IS-IS configuration, all routers are Level2-Level1 capable within the same ISIS area-id, so there is only a single topology area in the network (all routers share the same topology). The configuration for PE-1 is displayed below.

```
# on PE-1
configure
    router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
            no shutdown
        exit
        interface "int-PE-1-PE-3"
            address 192.168.13.1/30
            port 1/1/2
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
            no shutdown
        exit
        autonomous-system 64496
        isis 0
            area-id 49.0001
```

```
            traffic-engineering
            interface "system"
                passive
                no shutdown
            exit
            interface "int-PE-1-PE-2"
                interface-type point-to-point
                no shutdown
            exit
            interface "int-PE-1-PE-3"
                interface-type point-to-point
                no shutdown
            exit
            no shutdown
        exit
        ldp
            interface-parameters
                interface "int-PE-1-PE-2" dual-stack
                exit
                interface "int-PE-1-PE-3" dual-stack
                exit
            exit
        exit
    exit
exit
```

The configuration for the rest of nodes is similar. The IP addresses can be derived from Figure 354: Network Topology.

Step 2.

Verify that IS-IS adjacencies and LDP peer sessions are formed.

```
*A:PE-1# show router isis adjacency

===============================================================================
Rtr Base ISIS Instance 0 Adjacency
===============================================================================
System ID               Usage State Hold Interface                    MT-ID
-------------------------------------------------------------------------------
PE-2                    L1L2  Up    22   int-PE-1-PE-2                0
PE-3                    L1L2  Up    22   int-PE-1-PE-3                0
-------------------------------------------------------------------------------
Adjacencies : 2
===============================================================================
*A:PE-1#
```

```
*A:PE-1# show router ldp session ipv4

===============================================================================
LDP IPv4 Sessions
===============================================================================
Peer LDP Id         Adj Type  State         Msg Sent  Msg Recv  Up Time
-------------------------------------------------------------------------------
192.0.2.2:0         Link      Established   21        22        0d 00:00:33
192.0.2.3:0         Link      Established   19        20        0d 00:00:24
-------------------------------------------------------------------------------
No. of IPv4 Sessions: 2
===============================================================================
*A:PE-1#
```

Step 3.

Configure iBGP full mesh between the PEs for VPRN routing (Route Reflectors could also be an option).

```
# on PE-1
configure
    router
        bgp
            min-route-advertisement 1
            rapid-withdrawal
            rapid-update mvpn-ipv4 mdt-safi
            group "INTERNAL"
                family vpn-ipv4 mvpn-ipv4 mdt-safi
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
```

The families configured under the group "INTERNAL" are vpn-ipv4, mvpn-ipv4, and mdt-safi, since the three families are referenced in this chapter.

The mdt-safi parameter is not needed for NG-MVPN (mLDP/RSVP scenarios) and is only required for Rosen MVPN with MDT AFI SAFI.

Rapid withdrawal (configured on all PEs) disables the minimum route advertisement interval (MRAI) interval on sending BGP withdrawals. Rapid update (configured for MVPN-IPv4 and MDT AFI/SAFI address families) disables the MRAI interval on sending BGP update messages for the address family MVPN-IPv4 and MDT-SAFI).

Step 4.

Verify that BGP peer relationships are established.

```
*A:PE-1# show router bgp summary
===============================================================================

*A:PE-1#
```

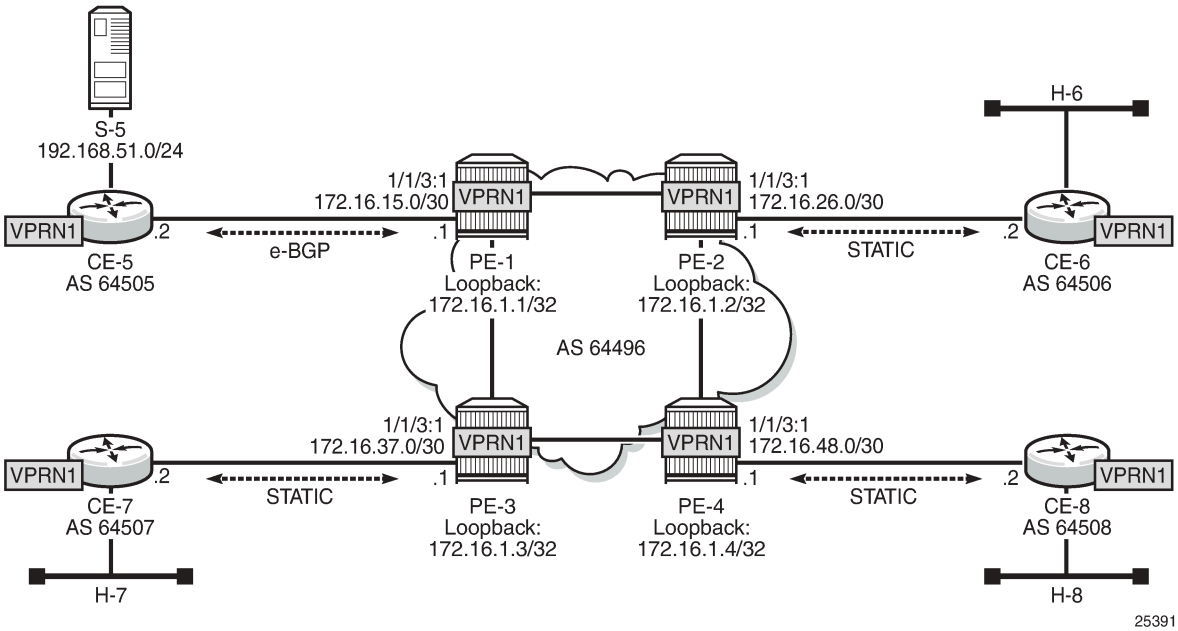
PE VPRN Configuration and PE VPRN Multicast Configuration

A VPRN is created on each PE per service (the different services using mLDP, RSVP-TE, and AFI/SAFI with PIM); these are the multicast VPRNs. PE-1 is the PE containing the attachment circuit toward CE-5. CE-5 is the CE nearest to the source. PE-2, PE-3, and PE-4 contain attachment circuits toward CE-6, CE-7, and CE-8 respectively. Each CE has a receiving host attached.

PMSI using mLDP

Figure 355: VPRN 1 Topology used for mLDP shows the details of the topology for VPRN 1.

Figure 355: VPRN 1 Topology used for mLDP



Unicast

Step 1.

Create VPRN 1 on each PE, containing a route-distinguisher of 64496:10X (where X= number of PE) and vrf-target of 64496:100. The autonomous system number is 64496. For the next hop tunnel route resolution to connect the VPRNs between the PEs, manually configured spoke SDPs are created (other methods such as auto-bind-tunnel resolution-filter LDP resolution filter could also be used). LDP was already enabled.

```
# on PE-1
configure
    service
        sdp 12 mpls create
            far-end 192.0.2.2
            ldp
            no shutdown
        exit
        sdp 13 mpls create
            far-end 192.0.2.3
            ldp
            no shutdown
        exit
        sdp 14 mpls create
            far-end 192.0.2.4
            ldp
            no shutdown
        exit
        vprn 1 customer 1 create
            description "mLDP"
            autonomous-system 64496
            route-distinguisher 64496:101
            vrf-target target:64496:100
            spoke-sdp 12 create
            exit
            spoke-sdp 13 create
            exit
            spoke-sdp 14 create
            exit
```

Step 2.

Create an attachment circuit interface toward the CE and a loopback (the loopback is not mandatory, but it is configured to aid troubleshooting the routers).

```
# on PE-1
configure
    service
        vprn 1
            interface "loopback" create
                address 172.16.1.1/32
                loopback
            exit
            interface "int-PE-1-CE-5" create
                address 172.16.15.1/30
                sap 1/1/3:1 create
                exit
            exit
```

Step 3.

The source address of the multicast stream will need to be reachable by all routers (PEs and CEs) within the VPN. This will be advertised within BGP from CE-5 to PE-1. Create a BGP peering relationship with the CE as follows:

```
# on PE-1
configure
    service
        vprn 1
            bgp
                group "EXTERNAL"
                    type external
                    peer-as 64505
                    neighbor 172.16.15.2
                    exit
                exit
                no shutdown
            exit
```

Step 4.

On CE-5, create a VPRN to support the connection of the source to CE-5 and the connection from CE-5 to PE-1. Two attachment circuits are required as well as a BGP peering relationship with the PE. This uses a default BGP address family of ipv4.

```
# on CE-5
configure
    service
        vprn 1 customer 1 create
            autonomous-system 64505
            route-distinguisher 64505:1
            interface "int-CE-5-PE-1" create
                address 172.16.15.2/30
                sap 1/1/1:1 create
                exit
            exit
            interface "int-CE-5-S-5" create
                address 192.168.51.1/24
                sap 1/1/3 create
                exit
            exit
            bgp
                group "EXTERNAL"
                    type external
                    peer-as 64496
                    neighbor 172.16.15.1
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

Step 5.

In order for the subnet on the CE connecting to the source to be advertised within BGP, a route policy is required. The subnet containing the multicast source is 192.168.51.0/24, so a prefix-list can be used to define a match, and then used within a route policy to inject into BGP.

```
# on CE-5
configure
    router
```

```
        policy-options
            begin
            prefix-list "SOURCE-PREFIX"
                prefix 192.168.51.0/24 exact
            exit
            policy-statement "EXPORT-SOURCE-PREFIX-TO-BGP"
                entry 10
                    from
                        prefix-list "SOURCE-PREFIX"
                    exit
                    to
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

```
configure
    service
        vprn 1
            bgp
                export "EXPORT-SOURCE-PREFIX-TO-BGP"
            exit
        exit
```

Step 6.

Check that the route is seen in PE-1:

```
*A:PE-1# show router 1 route-table 192.168.51.0/24

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.168.51.0/24                               Remote  BGP       00h01m29s  170
       172.16.15.2                                                 0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-1#
```

This prefix will also be automatically advertised within the BGP VPRN to all other PEs, and will be installed in VRF 1.

For example, on PE-4, the source subnet 192.168.51.0/24 is received via BGP VPN with a next-hop of PE-1 (192.0.2.1):

```
*A:PE-4# show router 1 route-table 192.168.51.0/24

===============================================================================
Route Table (Service: 1)
===============================================================================
```

```
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.168.51.0/24                                 Remote  BGP VPN   00h01m40s  170
       192.0.2.1 (tunneled)                                        0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-4#
```

Each CE containing a multicast receiver must be able to reach the source. As an example on CE-6, a static route is configured with next hop 172.16.26.1 of interface int-PE-2-CE-6.

```
# on CE-6
configure
    service
        vprn 1 customer 1 create
            autonomous-system 64506
            route-distinguisher 64506:1
            interface int-CE-6-H-6 create
                address 192.168.61.1/24
                sap 1/1/2:1 create
                exit
            exit
            interface int-CE-6-PE-2 create
                address 172.16.26.2/30
                sap 1/1/1:1 create
                exit
            exit
            static-route-entry 192.168.51.0/24
                next-hop 172.16.26.1
                    no shutdown
                exit
            exit
            no shutdown
        ---snip---
```

After **Steps 1 to 6**, all required unicast routing is provisioned. The following sections show the configuration of the multicast in the VPRN.

Auto-Discovery and mLDP PMSI Establishment

The MP-BGP based auto-discovery is implemented with a dedicated address family defined in RFC 4760 MP_REACH_NLRI/MP_UNREACH_NLRI attributes, with AFI 1 (IPv4) or 2 (IPv6) SAFI 5 (temporary value assigned by IANA). This is the mechanism by which each PE advertises the presence of an MVPN to other PEs. This can be achieved using PIM (like in Rosen MVPN) or using BGP. With the default parameter, BGP is automatically chosen because the PMSIs are mLDP and PIM is not an option in this case. Any PE that is a member of an MVPN will advertise to the other PEs using a BGP multi-protocol network layer reachability information (NLRI) update that is sent to all PEs within the AS. This update will contain an Intra-AS I-PMSI auto-discovery route type, also known as an Intra-AD. These use an address family mvpn-ipv4, so each PE must be configured to originate and accept such updates (this was done earlier when configuring the families).

At this step (auto-discovery), the information about the PMSI is exchanged, but the PMSI is not instantiated.

As each PE contains a CE which will be part of the multicast VRF, it is necessary to enable PIM on each interface containing the attachment circuit toward a CE, and to configure the I-PMSI multicast tunnel for the VRF. In order for the BGP routes to be accepted into the VRF, a route-target community is required (vrf-target). This is configured in the **configure service vprn 1 mvpn** context and, in this case is set to the same value as the unicast vrf-target (the vrf-target community as the **configure service vprn 1 vrf-target** context).

On each PE, the PIM and MVPN context within the VPRN instance are configured as follows:

```
# on PE-4
configure
    service
        vprn 1
            pim
                interface "loopback"
                exit
                interface "int-PE-4-CE-8"
                exit
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
```

When PIM SSM is used, the configuration always shows RP static with no RP entries (this is enabled by default when PIM is provisioned). In order for the BGP routes to be accepted into the VRF, a route-target community is required (vrf-target). Although it is not mandatory for the mvpn target to be equal to the unicast target, Nokia recommends to use **vrf-target unicast** to avoid configuration mistakes and extra complexity.

The status of VPRN 1 on PE-1 is shown with the following output:

```
*A:PE-1# show router 1 mvpn

===============================================================================

*A:PE-1#
```

The following shows a debug of an Intra-AD BGP update message received by PE-1 that was sent by PE-2. The message contains the PMSI tunnel type to be used (LDP P2MP LSP), LSP identification (root node, opaque value) and the type of BGP update (Type: Intra-AD Len: 12 RD: 64496:102 Orig: 192.0.2.2):

```
11 2017/10/07 18:31:59.676 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 91
    Flag: 0x90 Type: 14 Len: 23 Multiprotocol Reachable NLRI:
        Address Family MVPN_IPV4
        NextHop len 4 NextHop 192.0.2.2
        Type: Intra-AD Len: 12 RD: 64496:102 Orig: 192.0.2.2

===============================================================================
*A:PE-1#
```

Because of the receiver-driven nature of mLDP, mLDP P2MP LSPs are set up unsolicited from the leaf PEs toward the head-end PE. The leaf PEs discover the head-end PE via I-PMSI/S-PMSI AD routes. The tunnel identifier carried in the PMSI attribute is used as the P2MP forwarding equivalence class (FEC) Element. The tunnel identifier consists of the address of the head-end PE, along with a generic LSP identifier value. The generic LSP identifier value is automatically generated by the head-end PE. The preceding show command displays the PMSI information with the detail of the root node (192.0.2.2) and the LSP-ID (8193). The PMSI was created after receiving the AD message from PE-2, where the following excerpt from the previous debug shows the same information (0x2001 in HEX is equal to 8193 in decimal).

```
Flag: 0xc0 Type: 22 Len: 22 PMSI:
        Tunnel-type LDP P2MP LSP (2)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label 0
        Root-Node 192.0.2.2, LSP-ID 0x2001
```

Once the mLDP P2MP LSPs are created, the I-PMSI is instantiated in the core:

```

  --                                      --

-------------------------------------------------------------------------------
No. of Generic IPv4 P2MP Active Bindings: 7
===============================================================================
---snip---
*A:PE-1#
```

The two first entries in the output show the P2MP LSP where PE-1 is the root head-end (Push). The other two entries (Swap and Pop) correspond with transit and leaf for the P2MP LSPs originated by the other PEs. The command shows a P2MP-ID (8193) with an interface 73728 (matches with the **show router 1 pim tunnel interface** being the PIM interface created from PE-1) with two egress interfaces pointing to PE-2 and PE-3.

A similar command executed on PE-2 shows:

```
*A:PE-2# show router ldp bindings active p2mp ipv4

---snip---

-------------------------------------------------------------------------------
No. of Generic IPv4 P2MP Active Bindings: 7
===============================================================================
---snip---
*A:PE-2#
```

On PE-2, the first entry shows that PE-2 is a leaf of the P2MP LSP tree created by PE-1 (ingress label is 262138 which was the egress label to reach PE-2 and is popped). However, the second entry shows that PE-2 is transit for the P2MP LSP going to PE-4 (ingress label 262138, egress label 262136 next hop PE-4).

The same command on PE-4 shows:

```
*A:PE-4# show router ldp bindings active p2mp ipv4

===============================================================================

*A:PE-3#
```

As a summary, each root PE has a P2MP LSP with three leaves (the other PEs) and they are also transit points to the P2MP LSPs created in the other PEs. As an additional check, an OAM ping can show the different leaves that a P2MP LSP has:

```
*A:PE-1# oam p2mp-lsp-ping ldp 8193 sender-addr 192.0.2.1 detail
P2MP identifier 8193: | 88 bytes MPLS payload

===============================================================================
Leaf Information
===============================================================================
From            RTT                 Return Code
-------------------------------------------------------------------------------
192.0.2.2       =1.16ms             EgressRtr(3)
192.0.2.3       =1.18ms             EgressRtr(3)
```

```
192.0.2.4        =1.84ms              EgressRtr(3)
===============================================================================

Total Leafs responded = 3
          round-trip min/avg/max  = 1.16 / 1.40 / 1.84 ms
Responses based on return code:
EgressRtr(3)=3
*A:PE-1#
```

An easy way to see the path that the LDP P2MP LSP follows for a specific leaf is the following command (such as LDP trace from PE-1 to PE-4):

```
*A:PE-1# oam ldp-treetrace prefix 192.0.2.4/32

ldp-treetrace for Prefix 192.0.2.4/32:

      192.168.24.2, ttl =   2 dst =      127.1.0.255 rc = EgressRtr status = Done
    Hops:      192.168.12.2

ldp-treetrace discovery state: Done
ldp-treetrace discovery status: ' OK '
Total number of discovered paths: 1
Total number of failed traces: 0

*A:PE-1#
```

The command shows that on PE-4, there is an active leaf of the P2MP LSP, and that there is an intermediate hop on PE-2.

Traffic Flow

The receiver H-8, connected to CE-8, wishes to join the group 232.1.1.1 with source 192.168.51.1 and sends an IGMPv3 report toward CE-8. CE-8 recognizes the report and sends a PIM join toward the source, therefore, it reaches PE-1 where the source is connected to through CE-5. The following output shows the debug seen on PE-4, where the PIM join is received from CE-8 and a BGP update Source Join is sent to all PEs (only the update sent to PE-1 is shown).

```

*A:PE-4#
```

When the receiver is not interested in the channel group any more, the receiver H-8 sends an IGMPv3 leave, PE-4 sends a PIM prune translated to a BGP MP_UNREACH NLRI to all PEs. As mentioned before, rapid withdrawals are sent without waiting for the MRAI (for simplicity, only one BGP update is shown in the output debug).

```

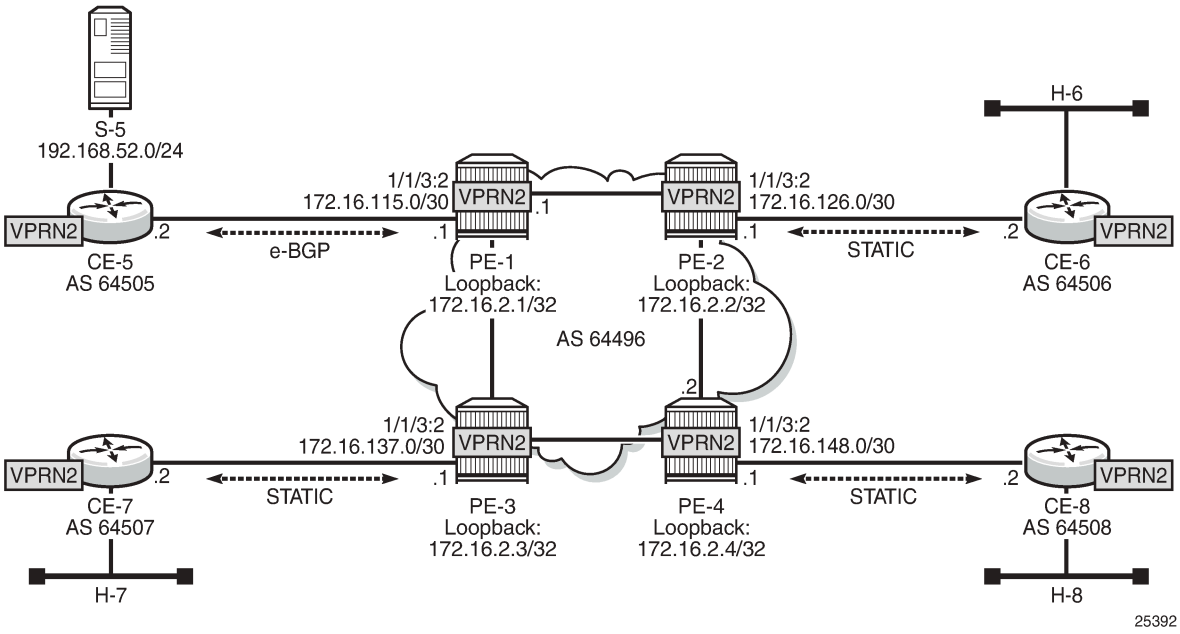
PMSI using RSVP-TE

Figure 356: VPRN 2 Topology used for RSVP-TE P2MP shows the details of the topology for VPRN 2.

Figure 356: VPRN 2 Topology used for RSVP-TE P2MP



Unicast

For the sake of simplicity, check **Steps 1 to 6** in PMSI using mLDP for VPRN 2 creation information. The same steps are repeated for RSVP, check Figure 356: VPRN 2 Topology used for RSVP-TE P2MP for details. The result is the configuration in all the PEs, taking as an example PE-1:

```
# on PE-1
configure
    service
        vprn 2 customer 1 create
            description "P2MP RSVP"
            autonomous-system 64496
            route-distinguisher 64496:201
            vrf-target target:64496:200
            interface "loopback" create
                address 172.16.2.1/30
                loopback
            exit
            interface "int-PE-1-CE-5" create
                address 172.16.115.1/30
                sap 1/1/3:2 create
                exit
            exit

            bgp
                group "EXTERNAL"
```

```
                    type external
                    peer-as 64505
                    neighbor 172.16.115.2
                    exit
                exit
                no shutdown
            exit
            spoke-sdp 12 create
            exit
            spoke-sdp 13 create
            exit
            spoke-sdp 14 create
            exit
            no shutdown
        exit
```

Because RSVP is the signaling protocol to establish the P2MP LSPs, RSVP is configured on the interfaces. In addition, to use P2MP RSVP, an LSP template is needed. The template defines the characteristics of the LSP to be created, for example, make-before-break, bandwidth, administrative groups, CSPF, specific paths, etc. A basic template is used here. TE parameters specified in the template are commonly used in each RSVP PATH message for each of the branches of the P2MP RSVP LSP. The template is used in the mvpn context within the VPRN configuration (see Auto-Discovery and RSVP PMSI Establishment). The resignal timer for P2MP is configured to the minimum value of sixty minutes (60 — 10080 minutes):

```
# on PE-1
configure
    router
        mpls
            p2mp-resignal-timer 60
            interface system
            exit
            interface int-PE-1-PE-2
            exit
            interface int-PE-1-PE-3
            exit
            path EMPTY
                no shutdown
            exit
            lsp-template VRF2 p2mp
                default-path EMPTY
                cspf
                fast-reroute facility
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
```

```
*A:PE-1# configure router rsvp no shutdown
```

Auto-Discovery and RSVP PMSI Establishment

The MP-BGP based auto-discovery is implemented with a new address family defined in RFC 4760 MP_REACH_NLRI/MP_UNREACH_NLRI attributes, with AFI 1 (IPv4) or 2 (IPv6) SAFI 5 (temporary value assigned by IANA). This is the mechanism by which each PE advertises the presence of an MVPN to other

PEs. This can be achieved using PIM (like in Rosen MVPN) or using BGP. With the default parameter, BGP is automatically chosen because the PMSIs are RSVP and PIM is not an option in this case. Any PE that is a member of an MVPN will advertise to the other PEs using a BGP multi-protocol network layer reachability information (NLRI) update that is sent to all PEs within the AS. This update will contain an Intra-AS I-PMSI auto-discovery route type, also known as an Intra-AD. These use an address family mvpn-ipv4, so each PE must be configured to originate and accept such updates (this was done earlier when configuring the families).

At this step (auto-discovery), the information about the PMSI is exchanged, but the PMSI is not instantiated.

As each PE contains a CE which will be part of the multicast VRF, it is necessary to enable PIM on each interface containing the attachment circuit toward a CE, and to configure the I-PMSI multicast tunnel for the VRF. In order for the BGP routes to be accepted into the VRF a route-target community is required (vrf-target). Although it is not mandatory for the MVPN vrf-target to be equal to the unicast target, Nokia recommends to use vrf-target unicast to avoid configuration mistakes and extra complexity.

On each PE, the multicast configuration in the VPRN instance is as follows:

```
# on PE-1
configure service
        vprn 2
            pim
                interface "loopback"
                exit
                interface "int-PE-1-CE-5"
                exit
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        rsvp
                            lsp-template "VRF2"
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
```

The status of VPRN 2 on PE-1 is shown with the following output:

```
*A:PE-1# show router 2 mvpn

For the I-PMSI, the head-end PE firstly discovers all the leaf PEs via I-PMSI A-D routes, it then signals the P2MP LSP to all the leaf PEs using RSVP-TE (subsequently adding or removing S2L (source to leaf) paths as PEs are added or removed from the MVPN).

As in the mLDP case, the demarcation of the domains is in the PE. The PE router participates in both the customer multicast domain and the provider's multicast domain. The customer's CEs are limited to a multicast adjacency with the multicast instance on the PE created to support that specific customer's IP-VPN. This way, customers are isolated from the provider's core multicast domain and other customer multicast domains while the provider's core P routers only participate in the provider's multicast domain and are isolated from all customers's multicast domains. C-trees to P-tunnels bindings are also discovered using BGP routes, instead of PIM join TLVs. MVPN c-multicast routing information is exchanged between PEs by using c-multicast routes that are carried using MCAST-VPN NLRIs.

Once the RSVP-TE P2MP LSPs are created, the I-PMSI is instantiated in the core:

P2MP Cross-connect instances : 2
===============================================================================
*A:PE-2#
```

As transit, PE-2 shows that there is an LSP coming from PE-1 (VRF2-2-73732) and the outgoing interface is 1/1/1 that connects PE-2 with PE-4.

Using the same command with a different filter on PE-4, 3 P2MP LSPs are terminated, one from each remote PE (PE-1, PE-2 and PE-3). On PE-4, an S2L VRF2-2-73732 from 192.0.2.1 and P2MP ID = 2 is traced.

```

*A:PE-1#
```

The last entry, VRF2-2-73732, provides the details of the S2L traced earlier, displaying the different hops (PE-1, PE-2, and PE-4), the fast reroute protection (link protection is supported only) and the labels used (262138 from PE-1 to PE-2, 262131 from PE-2 to PE-4). On PE-1, although only one has been shown, both links PE-1 to PE-3 and PE-1 to PE-2 are fast reroute protected.

If any of the protected links between PE-1 and PE-2 or PE-3 are broken, fast reroute will be initiated. The protected bypass hops are displayed with the following command:

```
*A:PE-1# show router mpls bypass-tunnel protected-lsp p2mp detail

*A:PE-1#
```

Traffic Flow

The receiver H-8, connected to CE-8, wishes to join the group 232.2.2.2 with source 192.168.52.1 and so sends an IGMPv3 report toward CE-8. CE-8 recognizes the report and sends a PIM join toward the source, therefore, it reaches PE-1 where the source is connected to through CE-5. The following output shows the debug seen on PE-4, where the PIM join is received from CE-8 and a BGP update Source Join is sent to all PEs (only the update sent to PE-1 is shown).

```

*A:PE-4#
```

When the receiver is not interested in the channel group anymore, the receiver H-8 sends an IGMPv3 leave, PE-4 sends a PIM prune translated to a BGP MP_UNREACH NLRI to all PEs. As mentioned before, rapid withdrawals are sent without waiting for the MRAI (for simplicity, only one BGP update is shown in the output debug).

```

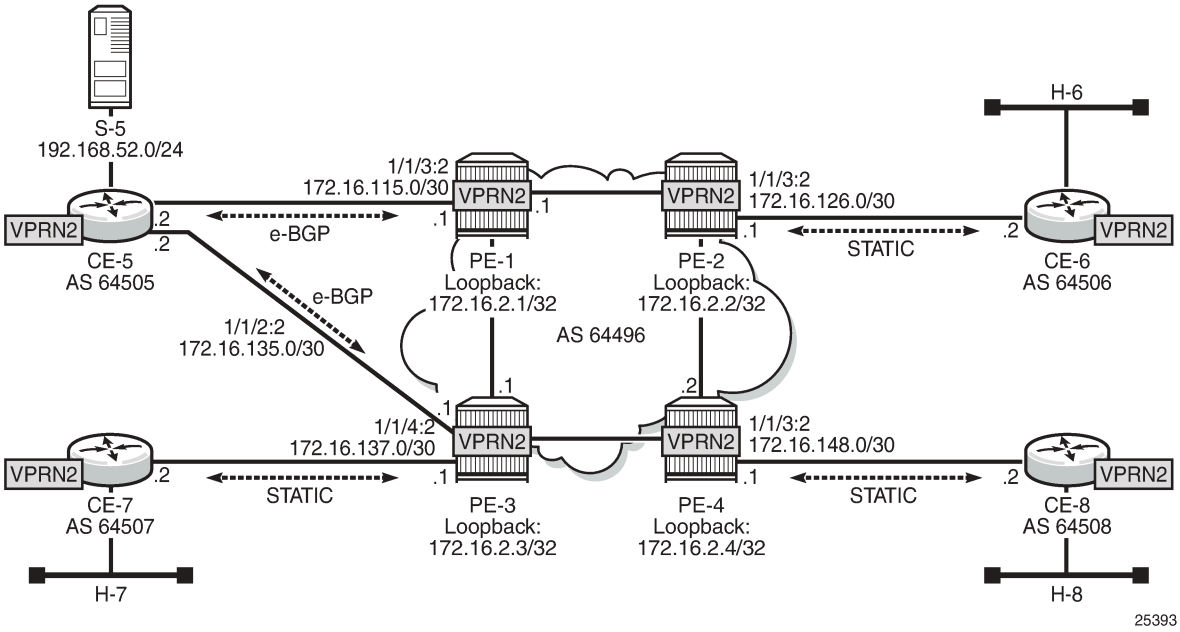
MVPN Source Redundancy

So far, the multicast traffic has been streamed toward router CE-5 from a single source. For security, the source can be redundant (two sources attached to different CEs that connect to a pair of PEs). To simulate the redundancy, CE-5 has been connected to both PE-1 and PE-3, using VPRN 2, and equal

cost multi-path (ECMP) is configured with the value of 2 in all PEs. With this configuration, any PE is able to reach the source through PE-1 and PE-2. The (S,G) is the same as the one used in P2MP RSVP TE (192.168.52.1, 232.2.2.2). Figure 357: VPRN 2 Topology used for MVPN Source Redundancy shows the VPRN 2 topology with the source redundancy.

Figure 357: VPRN 2 Topology used for MVPN Source Redundancy



The configuration change with respect to the previous section (P2MP RSVP-TE PMSIs) is an additional interface created in both CE-5 and PE-3 (int-CE-5-PE-3 on CE-5 and int-PE-3-CE-5 on PE-3), the addition of these interfaces to PIM and also the creation an e-BGP session between the two routers. The following is the additional configuration on PE-3 (CE-5 configuration changes are not displayed for brevity).

```
# on PE-3
configure
    service
        vprn 2
            interface "int-PE-3-CE-5" create
                address 172.16.35.1/30
                sap 1/1/4:2 create
                exit
            exit
            bgp
                group "EXTERNAL"
                    type external
                    peer-as 64505
                    neighbor 172.16.35.2
                    exit
                exit
                no shutdown
            exit
            pim
                interface "int-PE-3-CE-5"
                exit
            exit
        exit
```

Checking the routes on PE-4, the source is reachable through PE-1 and PE-2 as ECMP is set to 2. If the configuration of the VPRN is provisioned with **auto-bind-tunnel resolution-filter rsvp resolution filter,** instead of static spoke-SDPs, the command **ignore-nh-metric** is also needed.

```
*A:PE-4# configure service vprn 2 ecmp 2
```

```
*A:PE-4# show router 2 route-table

===============================================================================

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-4#
```

When PE-4 receives a c-join/prune, PE-4 needs to find the **upstream multicast hop** (UMH) for the (S,G). This is the upstream multihop selection and is configurable. The values are highest-ip, hash-based, tunnel-status, and unicast-rt-pref

```
*A:PE-4# configure service vprn 2 mvpn umh-selection
  - no umh-selection
  - umh-selection {highest-ip|hash-based|tunnel-status|unicast-rt-pref}
```

The default is highest-ip, which is the selection of the highest /32 IP addresses (in this setup, PE-3 is preferred versus PE-1). A BGP c-join is sent with the route target equal to the VRF import extended community distributed by PE-3 for the subnet of the source (see following PE-4 debug).

```

"
```

The second option is hash-based, where the UMH is selected (both PEs are potentially possible UMHs) after hashing the source and group addresses of the stream. For this example, PE-3 is also preferred.

The third option, tunnel-status, is based on the status of the P2MP RSVP tunnel (not available in mLDP or PIM). The roots PE-1 and PE-3 are sending BFD messages to the leaf PE-4 (in fact this is UFD, unidirectional forwarding detection). The c-join from PE-4 for the (S,G) is sent to both PE-1 and PE-3, and in return the traffic is forwarded from both PE-1 and PE-3 for the c-group onto the I-PMSI; therefore PE-4 receives two copies of the c-(S,G) stream. By configuration, the stream from the primary PE-1 is selected by PE-4 to be forwarded to receiver H-8. If BFD messages are no longer received over the primary P2MP LSP, then the stream from the standby PE-3 is selected and forwarded to the receiver.

The configuration on PE-1 and PE-3 is similar and is as follows (only PE-3 is shown):

```
# on PE-3
configure
    service
        vprn 2
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                umh-selection tunnel-status
                provider-tunnel
                    inclusive
                        rsvp
                            lsp-template "VRF2"
                            enable-bfd-root 100
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
```

PE-1 and PE-3 are root. On PE-4, BFD is configured as leaf and the primary PE (PE-1) and backup PE (PE-3) are also provisioned:

```
# on PE-4
configure
    service
        vprn 2
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                umh-selection tunnel-status
                umh-pe-backup
                    umh-pe 192.0.2.1 standby 192.0.2.3
                exit
                provider-tunnel
                    inclusive
                        rsvp
                            lsp-template "VRF2"
                            enable-bfd-leaf
```

```
                        no shutdown
                    exit
                exit
            exit
            vrf-target unicast
            exit
        exit
```

This BFD (UFD) configuration on the root establishes a session with the leaf. The root only transmits BFD packets; it doesn't receive any.

```

*A:PE-4#
```

PE-4 delivers the multicast traffic from the primary configured UMH, PE-1. If, as an example of a failure condition, PE-1 goes down (reboot), PE-4 will switch to the PE-3 P2MP LSP.

MDT AFI SAFI for Rosen MVPN

In Rosen MVPN up to version 6, the default MDT is PIM sparse mode only, and there is no auto-discovery mechanism available. In SR OS Release 7.0, and later, it is possible to configure PIM SSM with auto-discovery, using AFI 1 and SAFI 5. Rosen MVPN version 7 allows use of MDT PIM SM or SSM, and auto-discovery based on AFI 1 and SAFI 66 to distribute the default MDT. Rosen MVPN version 9 adds a new MDT NLRI. SR OS has added the capability and support of MDT SAFI as specified in RFC 6037.

MDT SAFI is used to discover PEs in a specific MVPN, so that PIM SSM can be used for default MDT. The basic idea is the same as MVPN BGP auto-discovery, but it uses a different BGP SAFI. BGP messages in which AFI=1 and SAFI=66 are "MDT-SAFI" messages. The NLRI format is 8-byte-RD:IPv4-address followed by the MDT group address. The IPv4 address identifies the PE that originated this route and the RD identifies a VRF in that PE. The group address must be an IPv4 multicast group address and is used to build the P-tunnels.

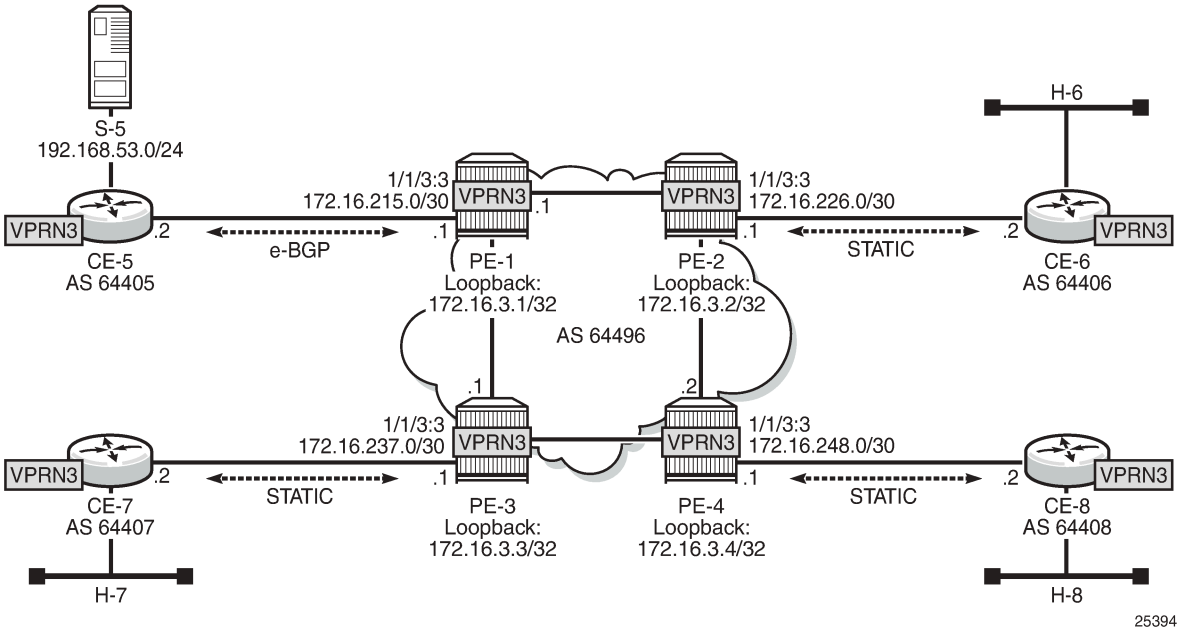
All PEs attached to a given MVPN must specify the same group-address. MDT-SAFI routes do not carry RTs and the group address is used to associate a received MDT-SAFI route with a VRF.

MDT SAFI can only be used when the implicit provider tunnel is PIM GRE based with a specific IPv4 group address.

For additional information on the use of PIM PMSIs, see NG-MVPN Configuration with PIM.

Figure 358: VPRN 3 Topology used for MDT SAFI shows the topology of VPRN 3.

Figure 358: VPRN 3 Topology used for MDT SAFI



In this scenario, there is no MPLS based PMSI, there is PIM in the core for the control plane and the data traffic is GRE encapsulated. PIM needs to be configured in the base router on interface system and on the other interfaces pointing to other PEs. PIM is used for c-signaling. In addition, auto-discovery is

provisioned to use mdt-safi and a PIM SSM inclusive PMSI with address 239.1.1.1 as the default MDT. The configuration is as follows on PE-4:

```
configure
    router
        pim
            interface "system"
            exit
            interface "int-PE-4-PE-2"
            exit
            interface "int-PE-4-PE-3"
            exit
        exit
    exit
    service
        vprn 3 customer 1 create
            description "PIM SSM / MDT SAFI"
            autonomous-system 64496
            route-distinguisher 64496:304
            vrf-target target:64496:300
            interface "loopback" create
                address 172.16.3.4/32
                loopback
            exit
            interface "int-PE-4-CE-8" create
                address 172.16.248.1/30
                sap 1/1/3:3 create
                exit
            exit
            pim
                interface "loopback"
                exit
                interface "int-PE-4-CE-8"
                exit
            exit
            mvpn
                auto-discovery mdt-safi
                provider-tunnel
                    inclusive
                        pim ssm 239.1.1.1
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            spoke-sdp 341 create
            exit
            spoke-sdp 342 create
            exit
            spoke-sdp 343 create
            exit
            no shutdown
```

The following debug output shows a BGP update with MDT AFI SAFI on PE-4:

```

Conclusion

This chapter provides information to configure multicast within a VPRN with next generation multicast VPN techniques. Specifically, the use of MPLS I-PMSIs (mLDP and P2MP RSVP-TE), MVPN source redundancy, and the complete set of features needed to interoperate with Rosen MVPN in live deployments are covered.

NG-MVPN Configuration with PIM

This chapter provides information about multicast in a VPRN service.

Topics in this chapter include:

Applicability

Initially, this chapter was written for SR OS Release 7.0.R5. The configuration in the current edition is based on SR OS Release 15.0.R2. There are no prerequisites for this configuration.

Summary

Multicast VPN (MVPN) architectures describe a set of VRFs that support the transport of multicast traffic across a provider network.

RFC 6037 (herein referred to as Rosen MVPN) describes the use of Multicast Distribution Trees (MDTs) established between PEs within a VRF. Each VRF required its own tree. Customer edge routers form Protocol Independent Multicast (PIM) adjacencies with the PE, and PE-PE PIM adjacencies are formed across the multicast tree. PIM signaling and data streams are transported across the MDT. There were a number of limitations with the Rosen MVPN implementation including, but not limited to:

- Rosen MVPN requires a set of MDTs per VPN, which requires a PIM state per MDT. There is no option to aggregate MDT across multiple VPNs
- Customer signaling, PE discovery and Data MDT signaling are all PIM-based. There is no mechanism available to decouple these. Thus there is an incongruency between unicast and multicast VPNs using Rosen MVPN.
  - There is no mechanism for using MPLS to encapsulate multicast traffic in the VPN. GRE is the only encapsulation method available in Rosen MVPN.
  - Rosen MVPN multicast trees are signaled using PIM only. NG MVPN allows the use of mLDP, RSVP P2MP LSPs.
  - PE to PE protocol exchanges for Rosen MVPN is achieved using PIM only. NG MVPN allows for the use of BGP signaling as per unicast Layer 3 VPNs.

Next Generation MVPN addresses these limitations by extending the idea of the per-VRF tree, by introducing the idea of Provider Multicast Service Interfaces (PMSI). These are equivalent to the default MDTs of Rosen MVPN in that they support control plane traffic (customer multicast signaling), and the data MDTs which carry multicast data traffic streams between PEs within a multicast VRF.

Next Generation MVPN allows the decoupling of the mechanism required to create a multicast VPN, such as PE auto-discovery (which PEs are members of which VPN), PMSI signaling (creation of tunnels

between PEs) and customer multicast signaling (multicast signaling —IGMP/PIM — received from customer edge routers). Two types of PMSI exist:

- Inclusive (I-PMSI): contains all the PEs for an MVPN.
- Selective (S-PMSI): contains only a subset of PEs of an MVPN.

Knowledge of MPLS-VPN RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, architecture and functionality, as well as an understanding of multicast protocols, is assumed throughout.

This chapter provides configuration details required to implement the parts of Next Generation MVPN shown in Table 20: Next Generation MVPN Components.

Table 20: Next Generation MVPN Components

Provider Multicast Domain				Customer Multicast Domain		
I-PMSI	**Auto-discovery**	**C-Mcast**	**S-PMSI Creation**	**PE-based RP**	**Anycast RP on PE**	**PIM SSM**
PIM ASM	PIM	PIM join/leave	PIM SSM with S-PMSI join TLV	X	X	X
PIM ASM	BGP A/D	PIM join/leave	PIM SSM with S-PMSI join TLV			X

The first section of this chapter describes the common configuration required for each PE within the provider multicast domain regardless of the MVPN PE auto-discovery or customer signaling methods. This includes IGP and VPRN service configuration.

Following the common configuration, specific MVPN configuration required for the configuration for the provider multicast domain using PIM Any Source Multicast (ASM) with auto-discovery based on PIM or BGP auto-discovery (A/D), PIM used for the customer multicast signaling and PIM Source Specific Multicast (SSM) used for the S-PMSI creation are described. The customer domain configuration covers the following three cases:

1. PIM ASM with the Rendezvous Point (RP) in the provider PE
2. PIM ASM using anycast RP on the provider RPs
3. PIM SSM

Other possible options, not covered in this section but are described in the 7450 ESS, 7750 SR, 7950 XRS, and VSR Multicast Routing Protocols Guide:

- The use of PIM SSM for the provider multicast I-PMSI.
- The use of BGP for the customer multicast signaling in the provider multicast domain.
- The provider S-PMSI creation through BGP S-PMSI A/D.
- The use of the customer RP based in the customer CE.

The use of mLDP and RSVP p2mp LSPs for the I/S-PMSI was not available in Release 7.0.

The Multicast in a VPRN II example in NG-MVPN Configuration with MPLS introduces features that were not supported in Release 7.0.R5. It provides configuration details to implement:

- Multicast LDP (mLDP) and RSVP-TE Point to Multi-point (P2MP) for building customer trees (C-trees) which are using MPLS instead of PIM techniques.
- MVPN source redundancy

- MDT AFI/SAFI (to fully interoperate with Cisco networks).

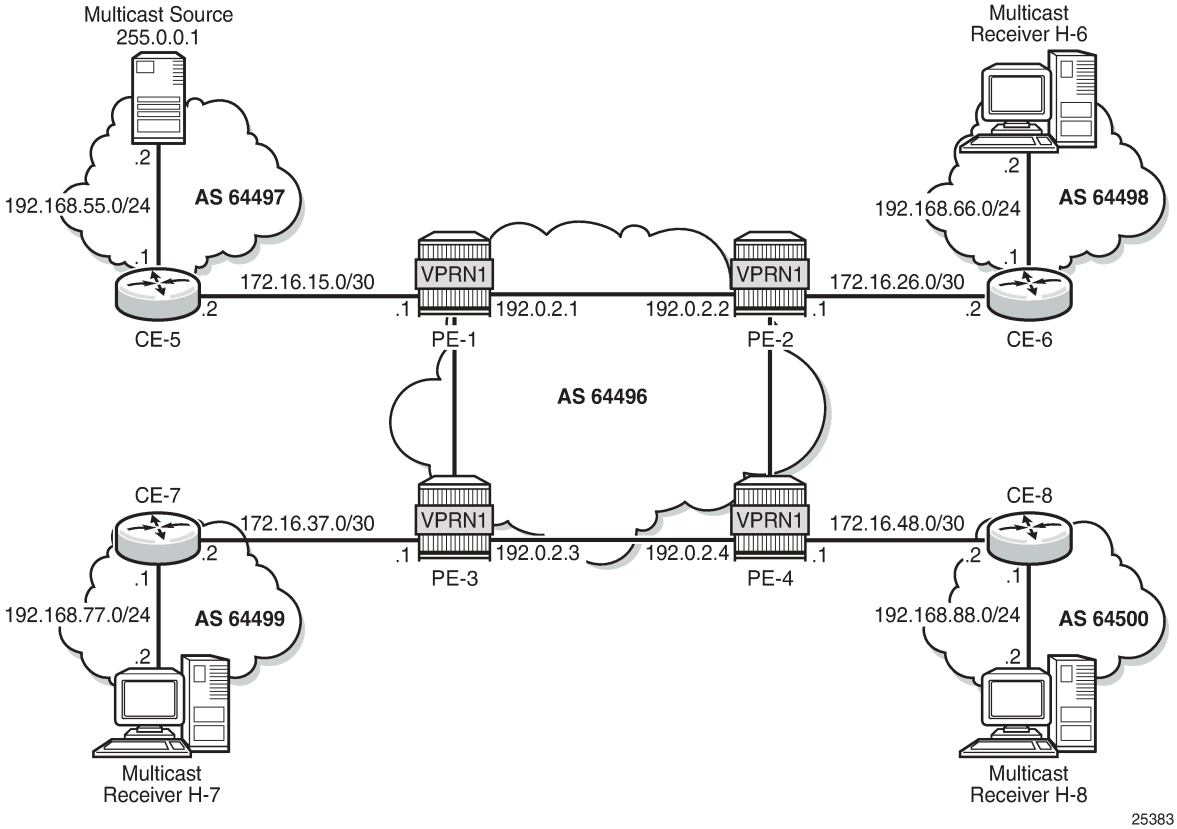
Overview

Figure 359: Network Topology



The network topology is displayed in Figure 359: Network Topology. The setup consists of four SR 7750s acting as Provider Edge (PE) routers within a single Autonomous System (AS).

- Full mesh IS-IS or OSPF in each AS
- LDP on all interfaces in each AS (RSVP could also be used)
- MP-iBGP sessions between the PE routers in each AS (Route Reflectors (RRs) could also be used).
- Layer 3-VPN on all PEs with identical route targets, in the form AS-number: *vprn-service-id*

Connected to each PE is a single SR OS router acting as a Customer Edge (CE) router. CE-5 has a multicast source connected, and PE-6, PE-7, and PE-8 each have a single receiver connected which will receive the multicast streams from the source. In this document, each receiver is both IGMPv2 and IGMPv3 capable. If the customer domain multicast signaling plane uses Source Specific Multicasting (SSM), then an IGMPv3 receiver is configured; if Any Source Multicasting (ASM) is used, the receiver is IGMPv2 capable.

If the receiver is IGMPv3 capable, it will issue IGMPv3 reports that will include a list of required source addresses. The receiver will join the 232.0.0.1 multicast group.

If the receiver is only IGMPv2 capable, then it will issue IGMPv2 reports which do not specify a source of the group. In this case, a Rendezvous Point is required within the PIM control plane of the multicast VRF which is source-aware. In this case, the receiver will join the 225.0.0.1 multicast group.

When the receiver wishes to become a member of any group, the source address of the group must be known to the CE. As a result, the source address must be IP reachable by each CE, so it is advertised by CE-5 to the PEs with attachment circuits in VPRN1 using BGP.

Static routes are then configured on the receiver CEs to achieve IP reachability to the source address of multicast groups. In the case of PIM ASM, any RP that is configured must also be reachable from the CE.

Multicast VPN Overview

Multicast traffic from the source is streamed toward router CE-5. Receivers connected to PE-2, PE-3 and PE-4 are interested in joining this multicast group.

All CEs are PIM enabled routers, which form a PIM adjacency with their nearest PE. The PIM adjacencies between PEs across the Provider network are achieved using I-PMSIs. I-PMSIs carry PIM control messages between PEs. Data plane traffic is transported across the I-PMSI until a configured bandwidth threshold is reached. A Selective PMSI is then signaled that carries data plane traffic. This threshold can be as low as 1kb/second and must be explicitly configured along with the S-PMSI multicast group. An S-PMSI per customer group per VPRN is configured. If no S-PMSI and threshold is configured, data traffic will continue to be forwarded across the provider network within the I-PMSI.

Configuration

The configuration is divided into the following sections:

- Provider Common Configuration
  - PE Global Configuration
  - PE VPRN Configuration
- PE VPRN Multicast Configuration
  - Auto-Discovery within Provider Domain using PIM
  - PIM Autodiscovery: Customer Signaling using PIM
- PIM Any Source Multicasting with RP at the provider PE
- PIM Any Source Multicasting with Anycast RP at the provider PE
- PIM Source Specific Multicasting
  - BGP Autodiscovery: PE VPRN Multicast Configuration
  - Data Path Using Selective-PMSIs

Provider Common Configuration

This section describes the common configuration required for each PE within the Provider multicast domain, regardless of the MVPN PE auto-discovery or customer signaling methods. This includes IGP and VPRN service configuration.

The configuration tasks can be summarized as follows:

- PE global configuration. This includes configuration of the Interior Gateway Protocol (IGP) (IS-IS or OSPF); configuration of link layer LDP between PEs; configuration of iBGP between PEs, to facilitate VPRN route learning; configuration of PIM.
- VPRN configuration on PEs. This includes configuration of basic VPRN parameters (route-distinguisher, route target communities); configuration of attachment circuits toward CEs; configuration of VRF routing protocol and any policies toward CE.
- VRF PIM and MVPN parameters — I-PMSI
- CE configuration.

PE Global Configuration

1. On each of the PE routers, configure the appropriate router interfaces, OSPF (or IS-IS) and link layer LDP. For clarity in the following configuration steps, only the configuration for PE-1 is shown. PE-2, PE-3, and PE-4 are similar.

```
*A:PE-1# configure
    router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-3"
            address 192.168.13.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
        autonomous-system 64496
        ospf
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-PE-3"
                    interface-type point-to-point
                exit
            exit
            no shutdown
        exit
        ldp
            interface-parameters
                interface "int-PE-1-PE-2" dual-stack
                    ipv4
                        no shutdown
                    exit
```

```
                exit
                interface "int-PE-1-PE-3" dual-stack
                    ipv4
                        no shutdown
                    exit
                exit
            exit
        exit
```

2. Verify that OSPF adjacencies are formed and that LDP peer sessions are formed.

```
*A:PE-1# show router ospf neighbor

```

5. Enable PIM on all network interfaces, including the system interface. This allows the signaling of PMSIs that transport PIM signaling within each VRF.
6. Each I-PMSI will be signaled using PIM ASM, so a rendezvous point (RP) is required within the global PIM configuration. A static RP is used and PE-1 is selected. All PEs must be configured with this RP address.

```
*A:PE-1# configure
    router
        pim
            interface "system"
            exit
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-3"
            exit
            rp
                static
                    address 192.0.2.1
                        group-prefix 239.255.0.0/16
                    exit
                exit
            exit
```

7. The following command shows the PIM neighbor relationships.

```
*A:PE-1# show router pim neighbor

*A:PE-1#
```

PE VPRN Configuration

A VPRN (VPRN 1) is created on each PE. This will be the multicast VPRN. PE-1 is the PE containing the attachment circuit toward CE-5. CE-5 is the CE nearest the source. PE-2, PE-3, and PE-4 contain attachment circuits toward CE-6, CE-7, and CE-8 respectively. CE-6 has receiving host H-6 attached; CE-7 has receiving host H-7, and CE-8 receiving host H-8.

1. Create VPRN 1 on each PE, containing a route-distinguisher and vrf-target of 64496:1. The autonomous system number is 64496. Use **auto-bind-tunnel resolution-filter ldp** for next hop tunnel route resolution.

```
*A:PE-1# configure
    service
        vprn 1 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
```

2. Create an attachment circuit interface on PE-1 toward CE-5.

```
*A:PE-1# configure
    service
        vprn 1
            interface "int-PE-1-CE-5" create
                address 172.16.15.1/30
                sap 1/1/3 create
            exit
                exit
```

3. The source address of the multicast stream will need to be reachable by all routers (PEs and CEs) within the VPN. This will be advertised within BGP from the CE to the PE. Create a BGP peering relationship within VPRN 1 on PE-1 with CE-5.

```
*A:PE-1# configure
    service
        vprn 1
            bgp
                group "EXTERNAL"
                    type external
                    peer-as 64497
                    neighbor 172.16.15.2
                    exit
                exit
                no shutdown
```

```
            exit
            no shutdown
```

4. On CE-5, create a VPRN to support the connection of the source to the CE and to connect the CE to the PE. Two attachment circuits are required, as well as a BGP peering relationship with the PE. This uses a default address family of **ipv4**.

   (A pair of IES services could also be used to provide the attachment circuits.)

```
*A:CE-5# configure
    service
        vprn 1 customer 1 create
            autonomous-system 64497
            route-distinguisher 64497:1
            interface "int-CE-5-PE-1" create
                address 172.16.15.2/30
                sap 1/1/1 create
                exit
            exit
            interface "int-CE-5-S-5" create
                address 192.168.55.1/24
                sap 1/1/3 create
                exit
            exit
            bgp
                group "EXTERNAL"
                    type external
                    peer-as 64496
                    neighbor 172.16.15.1
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

5. The following BGP summaries shows that the PE-CE BGP peer relationship between CE-5 and PE-1 is established for address family IPv4:

```
*A:CE-5# show router 1 bgp summary all

-------------------------------------------------------------------------------
*A:PE-1#
```

6. In order for the CE connecting to the source to be advertised within BGP, a route policy is required. The subnet containing the multicast source is 192.168.55.0/24, so a prefix-list can be used to define a match, and then used within a route policy to inject into BGP.

```
*A:CE-5# configure
    router
        policy-options
            begin
            prefix-list "SOURCE-PREFIX"
                prefix 192.168.55.0/24 exact
            exit
            policy-statement "EXPORT-SOURCE-PREFIX-TO-BGP"
                entry 10
                    from
                        prefix-list "SOURCE-PREFIX"
                    exit
                    to
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

7. Apply this policy as an export policy within the **bgp** context.

```
*A:CE-5# configure
    service
        vprn 1
            bgp
                export "EXPORT-SOURCE-PREFIX-TO-BGP"
            exit
```

This results in the 192.168.55.0/24 subnet being seen in the BGP RIB_OUT on CE-5.

```
*A:CE-5# show router 1 bgp routes 192.168.55.0/24 hunt

===============================================================================
*A:PE-2#
```

Each CE containing the multicast receivers must be able to reach the source. The following output shows the VPRN configuration of CE-6 containing an interface toward PE-2 and an interface toward receiving host H-6. A static route will suffice and is configured with next hop of the PE-2 PE-CE interface.

```
*A:CE-6# configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64498:1
            interface "int-CE-6-H-6" create
                address 192.168.66.1/24
                sap 1/1/2 create
                exit
            exit
            interface "int-CE-6-PE-2" create
                address 172.16.26.2/30
                sap 1/1/1 create
                exit
            exit
            static-route-entry 192.168.55.0/24
                next-hop 172.16.26.1
                    no shutdown
                exit
            exit
```

```
            no shutdown
```

PE VPRN Multicast Configuration

This section gives details of the VPRN configuration that allows the support of multicasting.

Sub-sections include:

1. Auto-discovery — This is the mechanism by which each PE advertises the presence of an MVPN to other PEs. This can be achieved using PIM or using BGP. This section covers PIM auto-discovery (auto-discovery using BGP is shown later).
2. Customer domain signaling — This discusses the mechanism of transporting customer signaling.
3. Data plane connectivity — This is the signaling of S-PMSIs within the provider domain to carry each individual customer multicast stream.

This chapter describes the PIM and BGP auto-discovery mechanisms in detail. For each of these, there is an example of customer domain signaling. For completion, a single example of S-PMSI creation is also shown.

Auto-Discovery within Provider Domain Using PIM

Each PE advertises its membership of a multicast VPN using PIM through the configuration of an Inclusive PMSI (I-PMSI). This is a multicast group that is common to each VPRN. The configuration for PE 1 and 2 is as follows:

```
*A:PE-1# configure
    service
        vprn 1
            mvpn
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                exit
            exit

*A:PE-2# configure
    service
        vprn 1
            mvpn
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                exit
            exit
```

The multicast group address used for the PMSI must be the same on all PEs for this VPRN instance.

Verify that PIM in the Global Routing Table (GRT) has signaled the I-PMSIs.

For the PE acting as the RP for global PIM:

```
*A:PE-1# show router pim group
```

```
===============================================================================

PIM Auto-Discovery: Customer Signaling using PIM

Consider now how the signaling plane of the customer domain is dealt with at the provider domain.

The customer domain configuration covers the following three cases:

1. PIM ASM with the RP in the provider PE.
2. PIM ASM using anycast RP on the provider RPs.
3. PIM SSM.

PIM Any Source Multicasting with RP at the Provider PE

Each PE connects to a CE which will be part of the multicast VRF, so it is necessary to enable PIM on each interface containing an attachment circuit toward a CE, and to configure the I-PMSI multicast tunnel for the VRF.

There is a requirement for an RP, because customer multicast signaling will be PIM-ASM.

The RP for the customer multicast will be on PE-2. In order to facilitate this, a loopback interface is created (called RP within the **vprn 1** context of PE-2, and will be advertised to all PEs. It must also be a PIM enabled interface.

The additional configuration for the RP on PE-2 is the following:

```
*A:PE-2# configure
    service
        vprn 1
            interface "RP" create
                address 10.2.3.5/32
                loopback
            exit
            pim
                interface "RP"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
                exit
                no shutdown
            exit
```

The RP must also be configured on each of the PEs and CEs.

On PE-3, the PIM configuration in VPRN 1 is as follows:

```
*A:PE-3# configure
    service
        vprn 1
            pim
                interface "int-PE-3-CE-7"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
                exit
            exit
```

The configuration on the other nodes is similar; only the interfaces are different.

Customer Edge Router Multicast Configuration

Each CE router will have a PIM neighbor peer relationship with its nearest PE.

The CE router (CE-5) containing the source will have PIM enabled on the interface connected to the source. It will also have a static RP entry, as the incoming sources need to be registered with the RP.

```
*A:CE-5# configure
    service
        vprn 1
            pim
                interface "int-CE-5-PE-1"
                exit
                interface "int-CE-5-S-5"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
                exit
            exit
```

The CE containing the receivers will have IGMP enabled on the interface connected to the receivers. Once again, there needs to be an RP configured, because the router needs to issue PIM joins to the RP. The additional configuration in VPRN 1 on CE-6 is as follows:

```
*A:CE-6# configure
    service
        vprn 1
            static-route-entry 10.0.0.0/8
                next-hop 172.16.26.1
                    no shutdown
                exit
            exit
            static-route-entry 192.168.55.0/24
                next-hop 172.16.26.1
                    no shutdown
```

```
            exit
        exit
        igmp
            interface "int-CE-6-H-6"
            exit
        exit
        pim
            interface "int-CE-6-PE-2"
            exit
            rp
                static
                    address 10.2.3.5
                        group-prefix 225.0.0.0/8
                    exit
                exit
            exit
        exit
```

Traffic Flow

The source sends a multicast stream using group address 225.0.0.1 toward CE-5. As the group matches the group address in the static RP configuration, the router sends a register join toward the RP. At this time, no receivers are interested in the group, so there are no entries in the Outgoing Interface List (OIL), and the number of outgoing interfaces (OIFs) is zero.

The PIM status of CE-5 within VPN 1 is as follows:

```
*A:CE-5# show router 1 pim group

===============================================================================
Legend:  A = Active   S = Standby
===============================================================================
PIM Groups ipv4
===============================================================================
Group Address               Type                Spt Bit  Inc Intf       No.Oifs
   Source Address              RP                  State    Inc Intf(S)
-------------------------------------------------------------------------------
225.0.0.1                   (S,G)                       int-CE-5-S-5   0
   192.168.55.2                10.2.3.5
-------------------------------------------------------------------------------
Groups : 1
===============================================================================
*A:CE-5#
```

The receiver H-6 connected to CE-6, wishes to join the group 225.0.0.1, and sends an IGMPv2 report toward CE-6. CE-6 recognizes the report, which contains no source.

```
*A:CE-6# show router 1 igmp group
===============================================================================

===============================================================================
*A:PE-2#
```

The RP can now forward traffic from itself toward CE-6, as the outgoing interface is seen as int-PE-2-CE-6.

CE-6 is now able to determine the source from the traffic stream, so it initiates a Reverse Path Forwarding (RPF) lookup of the source address in the route table, and issues an (S,G) PIM join toward the source.

The join is propagated across the provider network, from PE-2 toward PE-1 which is the resolved RPF next hop for the source.

```

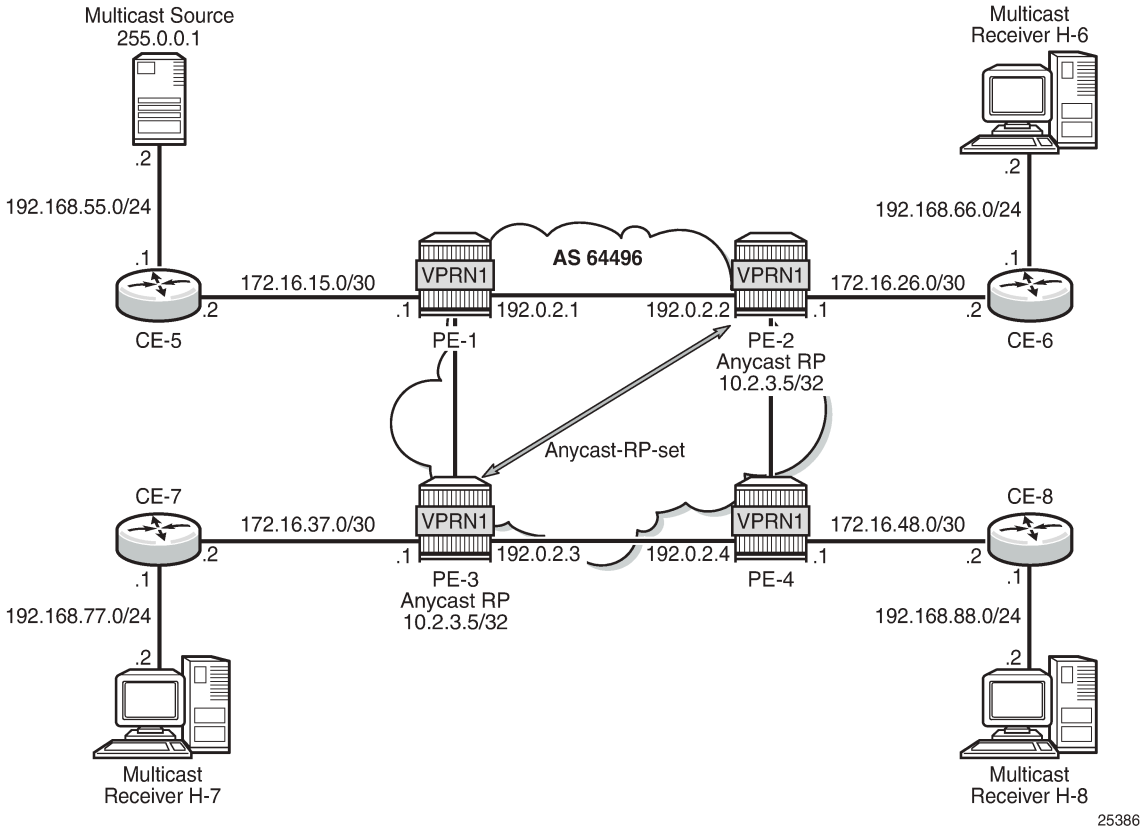
PIM Any Source Multicasting with Anycast RP at the Provider PE

The example topology for anycast RP is shown in Figure 360: Example Topology for Anycast RP. The setup consists of four SR OS routers acting as Provider Edge (PE) routers within a single Autonomous System (AS).

Figure 360: Example Topology for Anycast RP



Connected to each PE is a single SR OS router acting as a Customer Edge (CE) router. CE-5 has a single multicast source connected, and PEs 2 to 4 each have a single receiver connected which will receive the multicast stream from the source. In this section, each receiver is IGMPv2 capable, and will issue IGMPv2 reports. An RP is required by the C-signaling plane to resolve each (*,G) group state into an (S,G) state. In this case, two RPs are chosen to form an Anycast set to resolve each (*,G) group into an (S,G) state.

Multicast traffic from the source group 225.0.0.1 is streamed toward router CE-5. Receivers connected to PE-2, PE-3 and PE-4 are interested in joining this multicast group.

Anycast RP - PE VPRN Configuration

As previously stated, there is a requirement for an RP, as customer multicast signaling will be PIM-ASM and IGMPv2.

In this case, an anycast RP will be used. This is configured on PE-2 and PE-3, and an anycast set is created.

As each PE contains a CE which will be part of the multicast VRF, it is necessary to enable PIM on each interface containing an attachment circuit toward a CE, and to configure the I-PMSI multicast tunnel for the VRF.

The following output shows the VPRN configuration for PE-2 containing the RP and anycast RP configuration. The loopback interface lo1 is used for inter-RP communication:

```
*A:PE-2# configure
    service
        vprn 1
---snip---
            interface "RP" create
                address 10.2.3.5/32
                loopback
            exit
            interface "lo1" create
                address 10.0.0.2/32
                loopback
            exit
            pim
                interface "int-PE-2-CE-6"
                exit
                interface "RP"
                exit
                interface "lo1"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
                    anycast 10.2.3.5
                        rp-set-peer 10.0.0.2
                        rp-set-peer 10.0.0.3
                    exit
                exit
                no shutdown
            exit
```

Similarly, the VPRN configuration for PE-3 is:

```
*A:PE-3# configure
    service
        vprn 1
---snip---
            interface "RP" create
                address 10.2.3.5/32
                loopback
            exit
            interface "lo1" create
                address 10.0.0.3/32
                loopback
            exit
            pim
                interface "int-PE-3-CE-7"
                exit
                interface "RP"
                exit
                interface "lo1"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
```

```
                    anycast 10.2.3.5
                        rp-set-peer 10.0.0.2
                        rp-set-peer 10.0.0.3
                    exit
                exit
                no shutdown
            exit
```

As previously stated, there is a requirement for an RP, as customer multicast signaling will be PIM-ASM and IGMPv2.

In this case, an anycast RP will be used. This is configured on PE-2 and PE-3, and an anycast set is created.

The anycast address will be 10.2.3.5/32 and is created as an interface called *RP* on both PE-2 and PE-3.

An additional loopback interface, called "lo1" is created on each VPRN on PEs containing the anycast address. These are used as source addresses for communication between the routers within the RP set. These addresses will be automatically advertised to all PEs as VPN-IPv4 addresses, and will be installed in the VRF 1 forwarding table of all PEs containing VPRN 1.

Note: All routers containing RP must have their own loopback address included in the RP set as well as all peer routers.

The multicast group address used for the Inclusive PMSI is chosen to be 239.255.255.1 and must be the same on all PEs for this VPRN instance. This is analogous to the MDT within the Rosen MVPN implementation.

```
*A:PE-2# configure
    service
        vprn 1
            mvpn
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                exit
            exit
```

Verify that PIM in the global routing table (GRT) has signaled the I-PMSIs.

For the PE acting as the RP for global PIM:

```
*A:PE-1# show router pim group

Anycast RP — Customer Edge Router Multicast Configuration

Each CE router will have a PIM neighbor peer relationship with its nearest PE.

The CE router (CE-5) containing the source will have PIM enabled on the interface connected to the source.

```
*A:CE-5# configure
    service
        vprn 1
            pim
                interface "int-CE-5-PE-1"
                exit
                interface "int-CE-5-S-5"
                exit
                rp
                    static
                        address 10.2.3.5
                            group-prefix 225.0.0.0/8
                        exit
                    exit
                exit
            exit
```

The CE containing the receivers will have IGMP enabled on the interface connected to the receivers.

```
*A:CE-6# configure
    service
        vprn 1
            igmp
                interface "int-CE-6-H-6"
                exit
            exit
```

Traffic Flow

Figure 361: IGMP and PIM Control Messaging Schematic

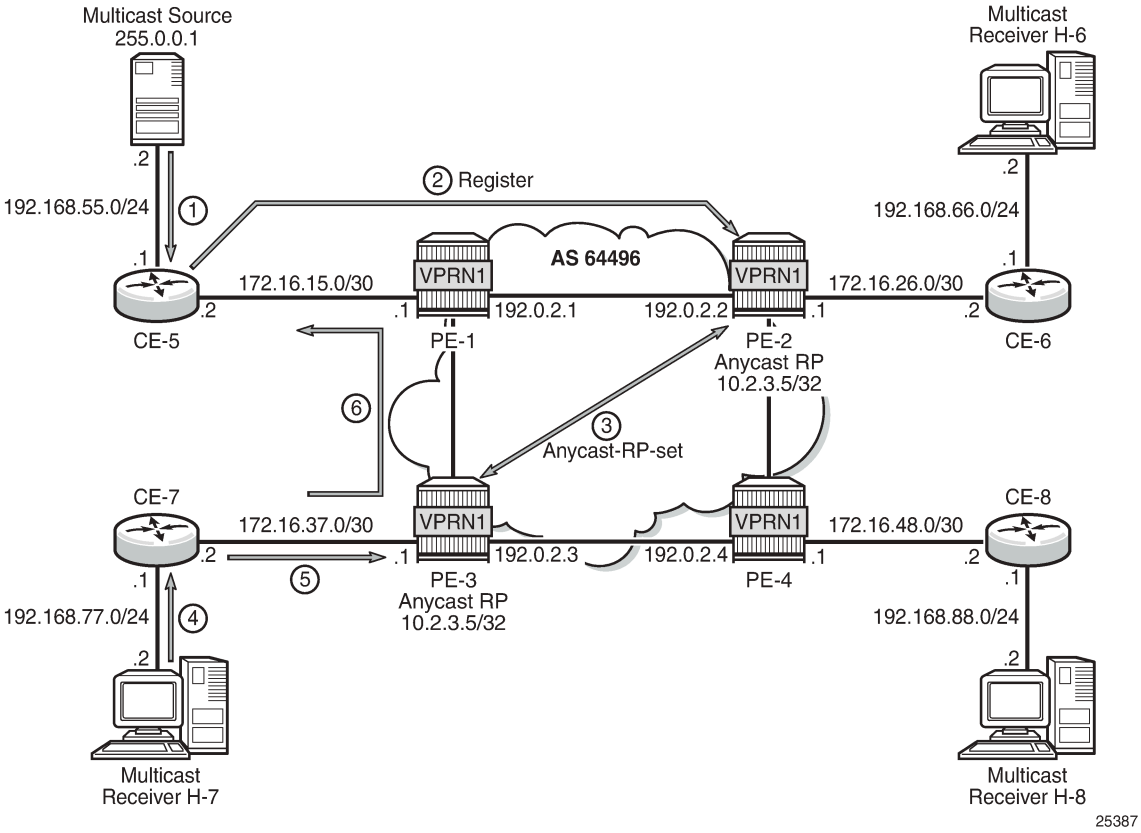

Figure 361: IGMP and PIM Control Messaging Schematic shows the sequence of IGMP and PIM control messaging.

1. The source multicasts a stream with group address 225.0.0.1 toward CE-5.
2. CE-5 matches the group with the group address prefix in the static RP configuration and sends a register message toward the RP.

*A:PE-3#
```

   Now both PEs within the RP set for VPRN have an (S,G) state for 225.0.0.1.

4. The receiver H-7, wishes to join the group 225.0.0.1, and sends in an IGMPv2 report toward CE-7. CE-7 recognizes the report, but has no PIM state for this group.

5. CE-7 sends a PIM join toward the RP, in this case the nearest RP will be PE-3.

   PE-3 already has (S,G) state for this group, so will forward traffic toward receiver H-7.

6. CE-7 does a Reverse Path Forwarding (RPF) lookup of the source address in the route table, and issues a PIM join toward the source.

   The join is propagated across the provider network toward PE-1, which is the resolved RPF next hop for the source.

```

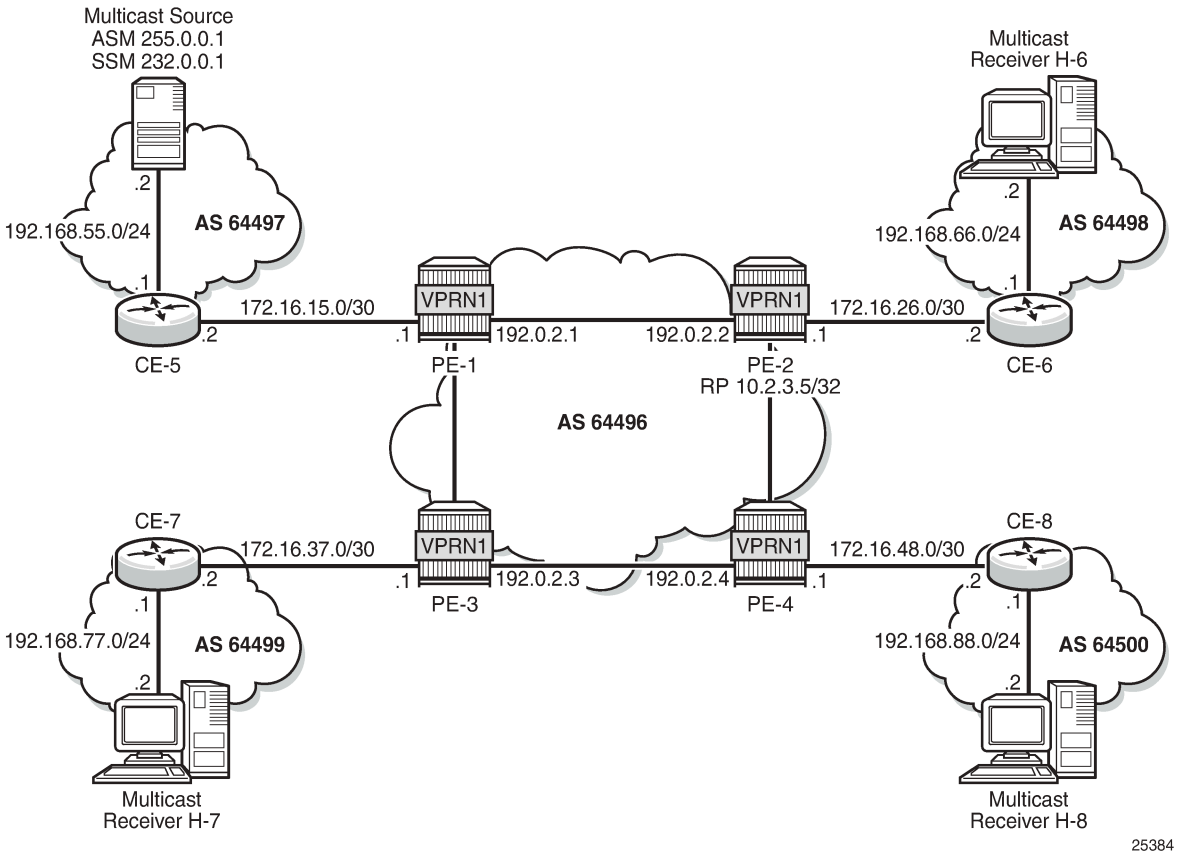
PIM Source-Specific Multicasting

There is no requirement for an RP, because customer multicast signaling will be PIM-SSM. The multicast group address used for the PMSI must be the same on all PEs for this VPRN instance.

Figure 362: PIM SSM in Customer Signaling Plane



The following output shows the VPRN configuration for PIM and MVPN for PE-1.

```
*A:PE-1# configure
    service
        vprn 1
            pim
                interface "int-PE-1-CE-5"
            exit
            mvpn
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                exit
            exit
```

There is a similar configuration required for each of the other PEs. Verify that PIM in the GRT has signaled the I-PMSIs.

For the PE acting as the RP for global PIM:

```
*A:PE-1# show router pim group

```

PIM SSM — Customer Edge Router Multicast Configuration

Each CE router will have a PIM neighbor peer relationship with its nearest PE.

The CE router (CE-5) containing the source will have PIM enabled on the interface connected to the source.

```
*A:CE-5# configure
    service
        vprn 1
            pim
                interface "int-CE-5-PE-1"
                exit
                interface "int-CE-5-S-5"
                exit
            exit
```

The CE containing the receivers will have IGMP enabled on the interface connected to the receivers and PIM on the interface facing the PE.

```
*A:CE-6# configure
    service
        vprn 1
            static-route-entry 192.168.55.0/24
                next-hop 172.16.26.1
                    no shutdown
                exit
            exit
            igmp
                interface "int-CE-6-H-6"
                exit
            exit
            pim
                interface "int-CE-6-PE-2"
                exit
            exit
```

Traffic Flow

The source multicasts a stream with group address 232.0.0.1 toward CE-5. When there is no receiver interested in the group at this time, there are no outgoing interfaces, so the Outgoing Interface List (OIL) is empty.

```
*A:CE-5# show router 1 pim group

PE BGP Auto-Discovery

Discovery of Multicast-enabled Virtual Private Networks (MVPNs) can also be achieved using BGP. To this end, any PE that is a member of a multicast VPN will advertise this using a BGP multi-protocol Network Layer Reachability Information (NLRI) update that is sent to all PEs within the AS. This update will contain an intra-AS I-PMSI Auto-Discovery route type, also known as an Intra-AD. These use a dedicated address family — **mvpn-ipv4** — so each PE must be configured to originate and accept such updates. The following needs to be modified in the **bgp** context for all PE nodes:

```
configure
    router
        bgp
            group "INTERNAL"
                family vpn-ipv4 mvpn-ipv4
                exit all
```

This is achieved in the GRT within the **bgp** context.

This allows each BGP speaker to advertise its capabilities within a BGP Open message.

The following BGP summary on PE-1 shows that BGP sessions are established between the PEs for address families VPN-IPv4 and MVPN-IPv4 in the base routing instance:

```

BGP Auto-Discovery — PE VPRN Multicast Configuration

Each PE contains a CE which will be part of the multicast VRF, so it is necessary to enable PIM on each interface containing an attachment circuit toward a CE, and to configure the I-PMSI multicast tunnel for the VRF.

In order for the BGP routes to be accepted into the VRF, a route-target community is required (vrf-target). This is configured in the **configure service vprn 1 mvpn** context and, in this case, is set to the same value as the unicast vrf-target, the vrf-target community as the **configure service vprn 1 vrf-target** context.

On each PE, the **mvpn** context of the VPRN instance is configured as follows:

```
*A:PE-2# configure
    service
        vprn 1
            mvpn
                auto-discovery default
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
```

The multicast group address used for the PMSI must be the same on all PEs for this VPRN instance.

The presence of auto-discovery will initiate BGP updates between the PEs that contain an MVPN, such as Intra-AD MVPN routes, are generated and advertised to each peer

```

```

This shows that PE-1 has received an Intra-AD route from each of the other PEs, each of which has multicast VPRN 1 configured.

Examining the intra-AD routes received from PE-2 shows that the route-target community matches the unicast VRF-target (64496:1), and also that the PMSI tree has a multicast group address of 239.255.255.1, which matches the I-PMSI group configuration on PE-1.

BGP Auto-Discovery — Customer Signaling Domain

The customer signaling is independent from the provider PE discovery mechanism, therefore, all of the customer signaling techniques described when using PIM for auto-discovery within provider domain are also applicable when using BGP for auto-discovery, namely

- PIM Any Source Multicasting with RP at the provider PE

- PIM Any Source Multicasting with Anycast RP at the provider PE
- PIM Source Specific Multicasting

Data Path Using Selective PMSI

When a configurable data threshold for a multicast group has been exceeded, multicast traffic across the provider network can be switched to a Selective PMSI (S-PMSI).

This has to be configured as a separate group and must contain a threshold which, if exceeded, will see a new PMSI signaled by the PE nearest the source, and traffic switched onto the S-PMSI.

```
*A:PE-1# configure
    service
        vprn
            mvpn
                provider-tunnel
                    inclusive
                        pim asm 239.255.255.1
                        exit
                    exit
                    selective
                        data-threshold 232.0.0.0/8 1
                        pim-ssm 232.255.1.0/24
                    exit
                exit
            exit
```

This shows that when the traffic threshold for multicast groups covered by the range 232.0.0.0/8 exceeds 1 kb/s between a pair of PEs, then an S-PMSI is signaled between the PEs. This is a separate multicast tunnel over which traffic in that group now flows.

```

*A:PE-1#
```

In this example, the (S,G) group is (192.168.55.2, 232.0.0.1). When the data rate has exceeded the configured MDT threshold of 1 kb/s, a new provider tunnel with a group address of 232.255.1.0 has been signaled and now carries the multicast stream.

The TX Joined state indicates that the S-PMSI has been sourced at this PE — PE-1.

Comparing this to PE-3, where a receiver is connected through a CE indicates that it has received a join to connect the S-PMSI.

Conclusion

This chapter provides configuration on how to configure multicast within a VPRN with next generation multicast VPN techniques. Specifically, discovery of multicast VPNs using PIM and BGP auto-discovery mechanisms are described with a number of ASM and SSM signaling techniques within the customer domain.

NG-MVPN Inter-AS Model B Using Non-Segmented mLDP Tunnels

This chapter provides information about NG-MVPN Inter-AS Model B Using Non-Segmented mLDP Tunnels.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 15.0.R6.

There is no specific configuration required to support non-segmented mLDP for inter-AS model B. However, VPN-recursive mLDP Forwarding Equivalence Class (FEC) functionality must be supported.

The configuration of multicast in a VPRN is described in the chapter NG-MVPN Configuration with MPLS.

Overview

Multicast in an inter-AS model B network using Draft-Rosen techniques is described in the chapter Rosen MVPN Inter-AS Option B, where the set of Multicast Distribution Trees (MDTs) are signaled using Protocol Independent Multicast Source-Specific Mode (PIM-SSM).

It is also possible to create MDTs between PEs in different Autonomous Systems (ASs) for Next-Generation MVPN (NG-MVPN) using non-segmented dynamic multicast LDP (mLDP) trees, where the root and leaf PEs are in different ASs. This chapter describes the configuration of MVPN services between PEs in different ASs using NG-MVPN techniques.

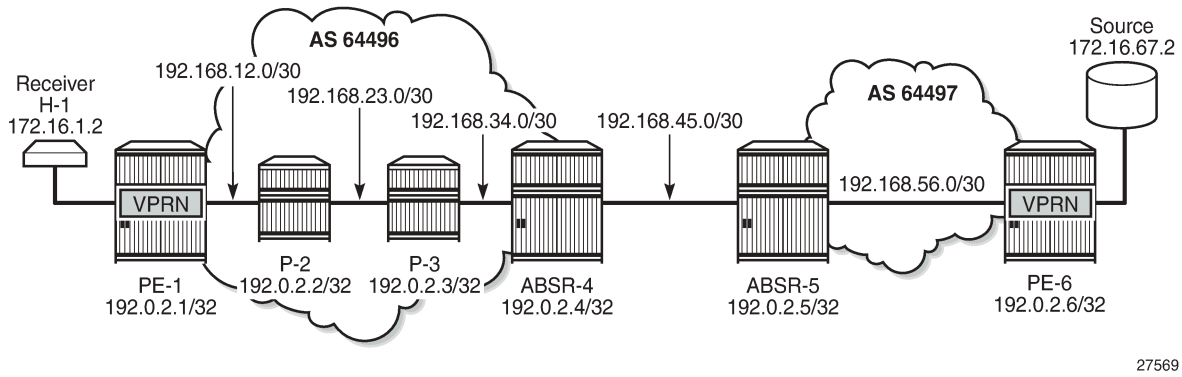
Figure 363: NG-MVPN Inter-AS Model B shows an example of a network comprising routers in two neighboring ASs, modeled as an inter-AS model B network.

A VPRN instance exists on PE-1 and PE-6, with a single source and receiver connected as per Figure 1. PE-1 is connected to its local Autonomous System Border Router (ASBR) via a pair of core routers, P-2 and P-3, neither of which are members of the VPRN instance. P-2 acts as a Route Reflector (RR) for AS 64496.

The source router generates multicast traffic with a group address of 239.255.0.1, and the receiver H-1 in AS 64496 will become a member of the multicast group using IGMPv3 signaling.

No multicast protocols are configured on the ASBRs.

Figure 363: NG-MVPN Inter-AS Model B



In an MVPN, a transport tunnel is signaled that will carry multicast traffic from source PE to any receiver PE that contains attached multicast routers, or hosts that want to become multicast group members. In this case, a multicast LDP (mLDP) tunnel is signaled between source PE and destination PEs to carry multicast traffic across the multi-AS provider network.

The mLDP Provider Multicast Service Interface (PMSI), also known as the provider tunnel, is established between PEs that declare membership of the MVPN, by generating and advertising an MVPN type 1 intra-AD BGP route. This route contains a PMSI Tunnel Attribute (PTA) that describes the tunnel type, the root node, and the LSP ID. Upon receipt of the intra-AD route, the receiving PE checks that the route is valid and can be imported into the VPRN instance. If the route is valid, the receiving router signals a point-to-multipoint (P2MP) LDP label mapping message toward the root address contained within the PTA of the intra-AD route. At the root, MPLS-encapsulated multicast traffic is forwarded to the downstream router by pushing on a label received from the downstream router.

Inter-AS model B unicast has VPN-IPv4 routes advertised from one AS to the other across the AS boundary. No system addresses of the PEs within an AS are advertised across the AS boundary, so the path for inter-AS unicast traffic is resolved using the labeled VPN-IPv4 routes via the ASBR, using MPLS encapsulation. In a unicast environment, traffic from PE-1 to PE-6 would be encapsulated in a tunnel to ASBR-4, de-encapsulated at ASBR-4, forwarded to ASBR-5, and on toward PE-6. The tunnel comprises the MPLS transport label plus the label associated with the VPN-IPv4 route.

For unicast routes, BGP next-hop-self is performed on the ASBR (from a control plane perspective) while service labels are swapped at the ASBR within the data plane side. This results in a segmented approach.

Multicast traffic requires a non-segmented provider tunnel to be routed from the root PE toward the receiver routers. This means that the tunnel must traverse the AS boundary without de-encapsulation, and therefore, must be non-segmented.

If the provider tunnel uses mLDP, the receivers will initiate the signaling by sending an LDP label mapping message along the control path toward the root. This follows the path of the intra-AD route that advertises the root of the I-PMSI. An mLDP label mapping message consists of an allocated label L, with FEC element <X,Y>, where X identifies the root node and Y is the opaque value, so the P2MP label mapping can be denoted as <X,Y,L>.

The FEC element contains the root address of the LSP plus a variable length opaque value. The opaque value contains information meaningful to the root and leaf routers, but not to intermediate routers; for example, a P2MP LSP-ID or a nested opaque value.

The root address is the system address of the router that advertised the intra-AD route. PE-1 has no unicast route to PE-6, but has learned the ASBR-4 address from the BGP next-hop of the intra-AD MVPN route.

However, in an mLDP environment, each router must take part in the signaling of the P2MP LSP, but not every router has an MVPN route, so any mLDP label mapping message received by P-3 to the root address of PE-6 will be dropped.

A solution to this is described in RFC 6512, *Using Multipoint LDP When the Backbone Has No Route to the Root*.

PE-1 will signal an mLDP LSP as if the root is at ASBR-4. P-2 and P-3 have a route to ASBR-4 as they are part of the same IGP instance. The actual root address at PE-6 is encapsulated within the mLDP label mapping message originated by PE-1 as an inner root address. This is a recursive FEC type, where the actual root FEC element is encapsulated within a FEC element as an opaque value that has a root at the ASBR.

ASBR-4 does not have a unicast route toward PE-6, but it has received the intra-AD MVPN route advertised by PE-6. This intra-AD route contains the BGP next-hop of ASBR-5, so a path toward PE-6 exists if the address in this route is used. To distinguish between any number of intra-AD routes at the ASBR, the recursive FEC contains the intra-AD route-distinguisher (RD) as an opaque value, which is used with the root address to match the correct intra-AD route.

This recursive FEC is defined as a VPN-recursive FEC, because the VPN intra-AD route is used as the route lookup to forward the label mapping message.

Table 21: mLDP Message Opaque Value Types in MVPN Model B shows the opaque value types used in MVPN model B.

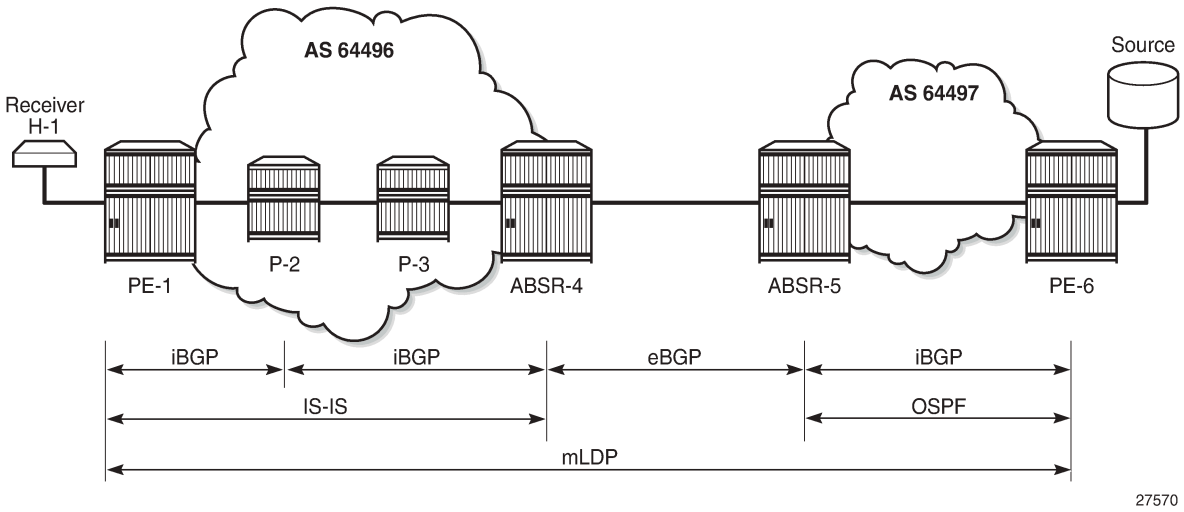
Table 21: mLDP Message Opaque Value Types in MVPN Model B

Opaque Type	Opaque Name	Use	FEC Element Representation
1	Generic	VPRN local AS	Root, Opaque<P2MP ID>
8	VPN Recursive	Inter-AS model B mLDP	<ASBR, Opaque <RD, Root, P2MP ID>>

Configuration

Figure 364: Inter-AS MVPN Protocol Requirements shows the required protocol configuration and peering.

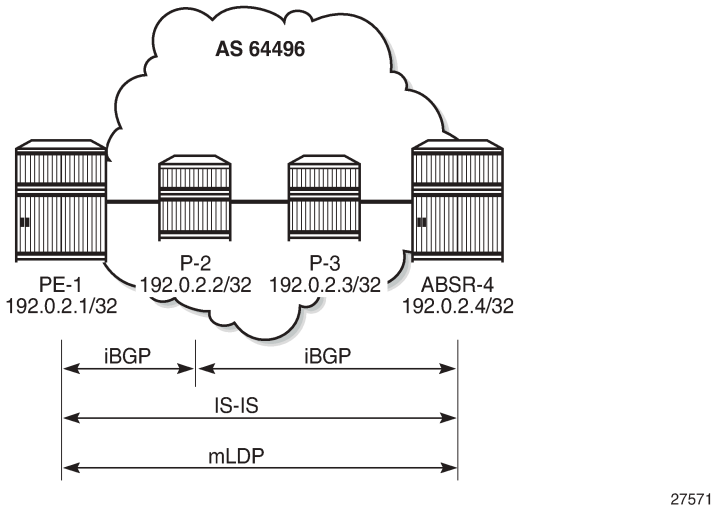
Figure 364: Inter-AS MVPN Protocol Requirements



AS 64496

Figure 365: AS 64496 Protocols shows the protocol requirements for AS 64496.

Figure 365: AS 64496 Protocols



Router Interface and IS-IS Configuration

The first step is to configure the router interfaces and IS-IS as the Interior Gateway Protocol (IGP) in AS 64496.

The router interfaces for PE-1 are configured as per the following output:

```
B:PE-1# configure router
        interface "int-PE-1-P-2"
            address 192.168.12.1/30
            port 1/1/1
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
            no shutdown
        exit
```

Each interface is configured to run IS-IS as the IGP, as per the following output. Each router is configured as a level 2 router.

```
B:PE-1# configure router isis
            level-capability level-2
            area-id 49.0001
            traffic-engineering
            level 2
                wide-metrics-only
            exit
            interface "system"
                level-capability level-2
                no shutdown
            exit
            interface "int-PE-1-P-2"
                level-capability level-2
                interface-type point-to-point
                no shutdown
            exit
```

The configuration for all other nodes in the AS is the same, apart from the IP addresses. The IP addresses can be derived from Figure 1.

LDP Configuration

Label Distribution Protocol (LDP) is used as the MPLS protocol and must be enabled on each router interface, as per the following output.

```
*B:PE-1# configure router ldp
*B:PE-1>config>router>ldp# info
----------------------------------------------
            interface-parameters
                interface "int-PE-1-P-2" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                    no shutdown
                    exit
                    no shutdown
                exit
```

This configuration must be repeated on each of the other routers in the AS. As LDP is used as the provider tunnel interface for multicast traffic, each interface must also support P2MP LDP tunnels. Therefore, the

FEC type capability for IPv4 P2MP tunnels must be enabled. The default value is enable, but is included in the preceding output for clarity.

BGP Configuration

P-2 Route Reflector

P-2 is configured as an RR within AS 64496 and will peer with both PE-1 and PE-4. The address families negotiated are VPN-IPv4 for unicast VPRN routes, and MVPN-IPv4 routes for multicast VPRN routes. The cluster ID is set to ensure that P-2 is an RR.

```
*A:P-2>config>router# info
----------------------------------------------
        autonomous-system 64496
        bgp
            cluster 192.0.2.2
            group "rr-internal"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
```

PE-1

PE-1 will be a BGP peer of RR P-2, as per the following output:

```
*A:PE-1# configure router
        autonomous-system 64496
        bgp
            group "internal"
                family vpn-ipv4 mvpn-ipv4
                type internal
                neighbor 192.0.2.2
                exit
            exit
            no shutdown
        exit
```

ASBR-4

For completeness, the ASBR-4 BGP configuration is as follows.

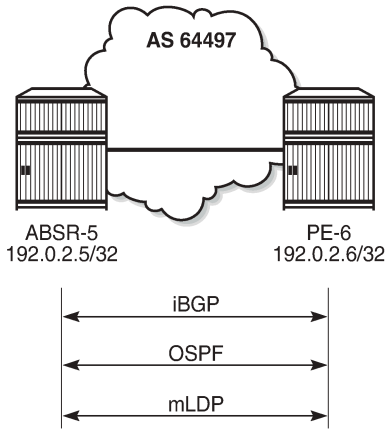
```
*A:ASBR-4# configure router
        autonomous-system 64496
        bgp
            group "internal"
                family vpn-ipv4 mvpn-ipv4
                type internal
```

```
                neighbor 192.0.2.2
                exit
            exit
        exit
```

AS 64497

Figure 366: AS 64497 Protocols shows the protocol requirements for AS 64497.

Figure 366: AS 64497 Protocols



Router Interface and OSPF Configuration

The first step is to configure router interfaces and OSPF on each router shown in Figure 4. All router interfaces are members of a single backbone area: area 0.0.0.0.

The following router interfaces are configured on PE-6:

```
A:PE-6>config>router#
        interface "int-PE-6-ASBR-5"
            address 192.168.56.2/30
            port 1/1/2
            no shutdown
        exit
        interface "system"
            address 192.0.2.6/30
            no shutdown
        exit
```

The configuration for PE-6 to enable OSPF is:

```
A:PE-6>config>router>ospf# info
----------------------------------------------
            area 0.0.0.0
                interface "system"
                    no shutdown
                exit
                interface "int-PE-6-ASBR-5"
```

```
                    interface-type point-to-point
                    metric 1000
                    no shutdown
                exit
            exit
            no shutdown
```

LDP Configuration

LDP is used as the MPLS protocol and must be enabled on each router interface, as per the following output.

```
*A:PE-6# configure router ldp
*A:PE-6>config>router>ldp# info
----------------------------------------------
            interface-parameters
                interface "int-PE-6-ASBR-5" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                    no shutdown
                    exit
                    no shutdown
                exit
```

This configuration must be repeated on each of the other routers in the AS. Again, the default value of FEC type capability for P2MP is enable, but is included for clarity.

BGP Configuration

Within AS 64497, internal BGP peering is required between ASBR-5 and PE-6 for the VPN-IPv4 and MVPN-IPv4 address families.

The following outputs show the BGP configuration for such a peering.

ASBR-5

```
*A:ASBR-5# configure router
        autonomous-system 64497
        bgp
            family vpn-ipv4 mvpn-ipv4
            group "internal"
                type internal
                neighbor 192.0.2.6
                exit
            exit
            no shutdown
```

PE-6

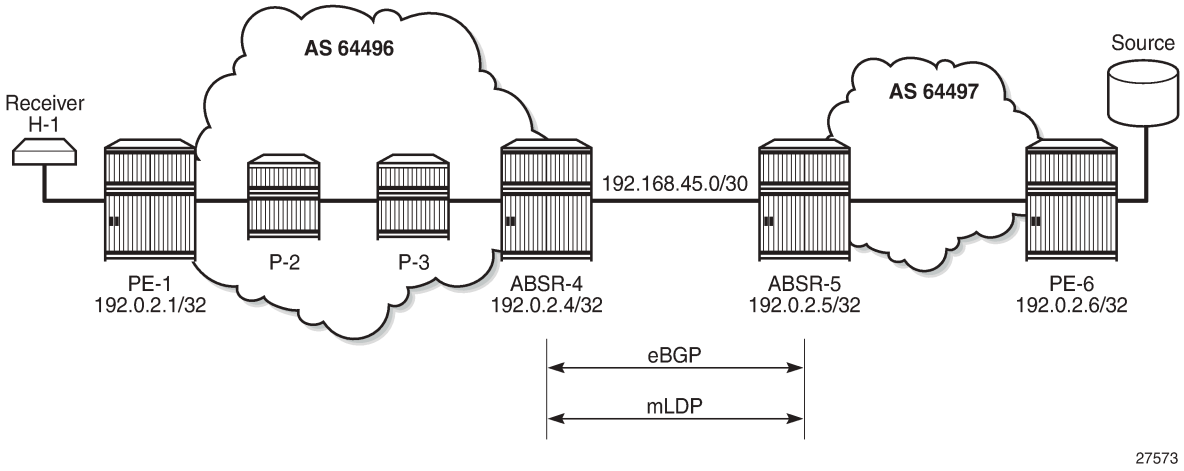
```
*A:PE-6# configure router
        autonomous-system 64497
        bgp
            min-route-advertisement 1
            rapid-withdrawal
            rapid-update mvpn-ipv4 vpn-ipv4
```

```
            group "internal"
                family vpn-ipv4 mvpn-ipv4
                type internal
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

Inter-AS Configuration

Figure 367: Inter-AS Protocols shows the protocols required between ASBR-4 and ASBR-5. The LDP transport address and the BGP speaker peer addresses are the interface addresses.

Figure 367: Inter-AS Protocols



eBGP Peering

The following output shows the eBGP peering configuration for ASBR-4. The peer address is the interface address of ASBR-5.

```
*A:ASBR-4# configure router
        autonomous-system 64496
        bgp
           enable-inter-as-vpn
           group "external"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64497
                neighbor 192.168.45.2
                exit
            exit
            no shutdown
        exit
```

Similarly, the BGP configuration for ASBR-5 peering toward ASBR-4 is as per the following output:

```
*A:ASBR-5# configure router
        autonomous-system 64497
```

```
        bgp
            enable-inter-as-vpn
            group "external"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64496
                neighbor 192.168.45.1
                exit
            exit
            no shutdown
```

Verification of the BGP peering session between ASBR-4 and ASBR-5 is shown in the following output:

```
A:ASBR-4# show router bgp summary group "external"

```

LDP Peering

LDP is configured as the MPLS protocol between ASBR-4 and ASBR-5. On ASBR-4, the interface toward ASBR-5 has LDP enabled, as per the following output:

```
A:ASBR-4# configure router
          ldp
            interface-parameters
                interface "int-ASBR-4-ASBR-5" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                        transport-address interface
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            no shutdown
         exit
```

The P2MP FEC type capability for P2MP LDP is shown. This is the default value.

For completeness, the LDP configuration on ASBR-5 for the interface toward ASBR-4 is as follows:

```
A:ASBR-5# configure router
        ldp
            interface-parameters
                interface "int-ASBR-5-ASBR-4" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                        transport-address interface
                        no shutdown
                    exit
                    no shutdown
                exit
            no shutdown
        exit
```

Verification that the LDP session is successfully established at ASBR-4 is shown in the following output:

```
A:ASBR-4# show router ldp session 192.0.2.5

===============================================================================
LDP IPv4 Sessions
===============================================================================

-------------------------------------------------------------------------------
No. of IPv4 Sessions: 1
---snip---
```

When a label mapping message is received for an LDP FEC prefix, the next-hop for a FEC prefix is resolved in the routing table. The FEC is installed in the Label Information Base (LIB) if the next-hop matches a /32 route table entry.

The local interface configuration will result in a route being installed with a subnet mask matching the interface configuration. In this case, the ASBR-to-ASBR route is 192.168.45.0/30.

For LDP to resolve the LDP FEC egress next-hop on ASBR-4, a /32 route matching the egress next-hop address is required in the FIB.

On ASBR 1, a static route is configured for the /32 address on ASBR-5, as follows.

```
A:ASBR-4>config>router#
        static-route-entry 192.168.45.2/32
            next-hop 192.168.45.2
                no shutdown
            exit
        exit
```

Similarly, a static route on ASBR-5 is configured for the /32 address on ASBR-4, as follows.

```
A:ASBR-5>config>router# info
        static-route-entry 192.168.45.1/32
            next-hop 192.0.2.45.1
                no shutdown
            exit
        exit
```

The following output shows that the static route is installed in the ASBR-4 RIB.

```
A:ASBR-4# show router route-table protocol static

===============================================================================

```

VPRN Configuration

The VPRN service configuration for PE-1 and PE-6 is as follows:

PE-1

```
*B:PE-1# configure service vprn 1
*B:PE-1>config>service>vprn# info
----------------------------------------------
            route-distinguisher 192.0.2.1:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-1-VPRN-1-H-1" create
                address 172.16.1.1/30
                sap 1/1/3:1 create
                exit
            exit
            igmp
                interface "int-PE-1-VPRN-1-H-1"
                    no shutdown
                exit
                no shutdown
            exit

                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            no shutdown
```

PE-6

```
A:PE-6>config# service vprn 1
A:PE-6>config>service>vprn# info
----------------------------------------------
            route-distinguisher 192.0.2.6:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
```

```
            vrf-target target:64496:1
            interface "int-PE-6-VPRN-1-source" create
                address 172.16.67.1/30
                sap 1/1/1 create
                exit
            exit
            igmp
                interface "int-PE-6-VPRN-1-source"
                    no shutdown
                exit
                no shutdown
            exit
            pim
                apply-to all
                no shutdown
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                mdt-type sender-only
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            no shutdown
```

Route Policy for MVPN Routes

The use of non-segmented LDP provider tunnels requires that Intra-AD Auto Discovery routes must be advertised across the AS boundary between PEs. Each intra-AD route generated by a PE that is a member of an MVPN contains the well-known community "No-Export", which prevents a BGP speaker from advertising the route across an AS boundary to another external BGP speaker.

In inter-AS mode B, the ASBR router must support the MVPN address family. If it receives an intra-AD route containing the No-Export community, it will not be advertised to any external peer. A route policy is required to remove the No-Export community before it can be advertised across the AS boundary to a BGP speaker that has negotiated the MVPN address family capability.

In the following example output, the policy will remove the No-Export community at PE-6, the source router from all advertised routes, by configuring the community remove action as a default action.

```
A:PE-6>config>router>policy-options# info
----------------------------------------------
        begin
        community "NoExport" members "no-export"
        policy-statement "RemNoExport"
            default-action accept
                community remove "NoExport"
            exit
        exit
        commit
```

This is applied as an export policy, so that the No-Export community is removed from all intra-AD routes advertised as updates to internal peers. The **vpn-apply-export** command must be included to ensure that the export policy is applied to routes belonging to VPN address families; in this case, MVPN-IPv4 routes.

```
A:PE-6>config>router>bgp# info
----------------------------------------------
            vpn-apply-export
            export "RemNoExport"
```

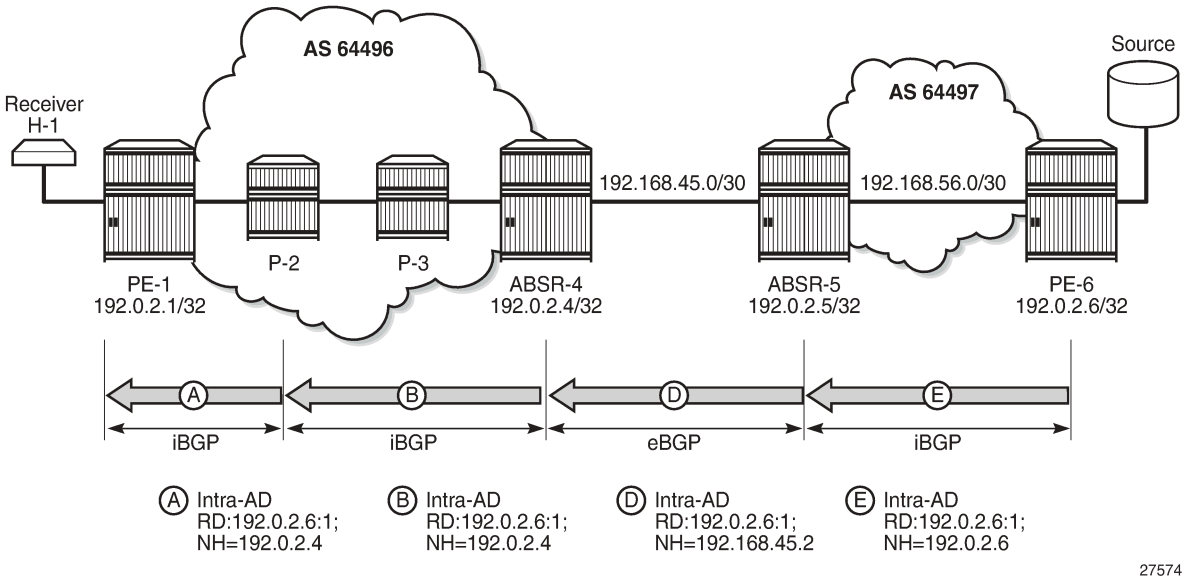
This policy should also be configured and applied on PE-1, so that intra-AD routes can be exported from MVPN PEs in AS 64496 to AS 64497.

Verification

BGP MVPN Intra-AD Route Propagation

Figure 368: BGP MVPN Intra-AD Route Advertisement shows the propagation of the BGP MVPN intra-AD route from PE-6 to PE-1 across the AS boundary. The original route has the No-Export community removed at PE-6 due to the export route policy applied. ASBR-5 receives the route and forwards it to ASBR-4. The BGP next-hop attribute is changed at the AS boundary to the interface address of ASBR-5: 192.168.45.2. ASBR-4 forwards the intra-AD route to the RR at P-2, and changes the BGP next-hop attribute to its system address: 192.0.2.4. P-2 reflects the route to PE-1.

Figure 368: BGP MVPN Intra-AD Route Advertisement



PE-1 receives the route, and will import the route into VPRN 1 as the route target extended community matches the community configured in the MVPN context of the VPRN. PE-1 now uses the PTA contained within the intra-AD route to instantiate the provider tunnel.

The following output shows details of the MVPN intra-AD route received by PE-1, generated by PE-6.

```
B:PE-1# show router bgp routes mvpn-ipv4 type intra-ad originator-ip 192.0.2.6 hunt

P2MP LDP LSP Signaling

The PTA lists the tunnel type as a P2MP LDP LSP. A P2MP label mapping message is originated at PE-1, with LSP-ID 8193, and the root of the mLDP tree is PE-6: 192.0.2.6. However, PE-1 does not have a route

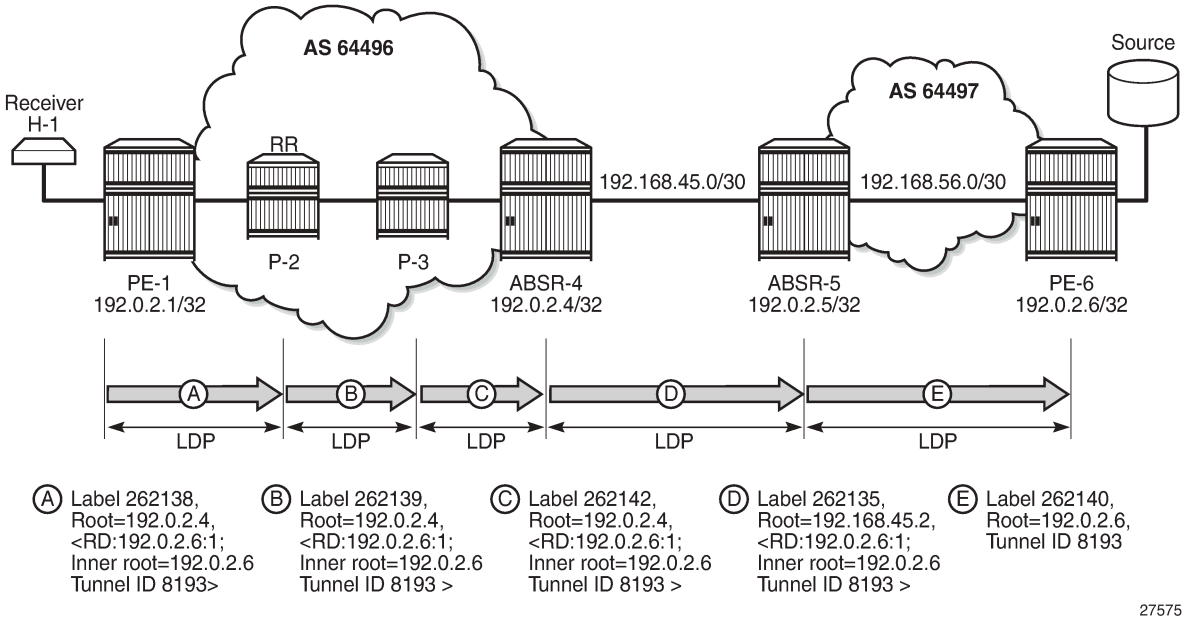
to PE-6, because inter-AS model B VPNs do not require the system addresses of the PEs to be advertised into the neighboring AS.

The intra-AD MVPN route is used to determine the path of the label mapping message from PE-1 toward PE-6. This is comparable to the unicast routing case, where a VPN-IPv4 labeled route is used to determine the path to the source.

The BGP next-hop of the intra-AD route is the system address of ASBR-4, so this can be used as the root address of the mLDP LSP, and the actual root can be contained inside the label mapping message as an inner root. The inner root becomes an opaque value that is known to the originator and receiver of the label mapping message.

Figure 369: P2MP LDP Label Mapping shows the path taken by the label mapping message from PE-1 to PE-6.

Figure 369: P2MP LDP Label Mapping



P-2 and P-3 do not have either a unicast or multicast (intra-AD) route toward PE-6, but have a route to the outer root ASBR-4. The label mapping message is forwarded from PE-1 to ASBR-4 via P-2 and P-3. At each hop, a label is allocated and a label binding entry is created. In the following sections, the debug outputs are achieved using the following debug command:

```
debug
    router "Base"
        ldp
            peer <peer-ip-address>
                packet
                    label detail
                exit
            exit
        exit
    exit
exit
```

where <peer-ip-address> is the system address of the LDP peer.

LDP Hop PE-1 to P-2

The following output shows a debug of the P2MP label mapping message sent from PE-1 to P-2 upon receipt of the BGP MVPN intra-AD route.

```
MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 183725) to 192.0.2.2:0
Protocol version = 1
Label 262138 advertised for the following FECs
P2MP: root = 192.0.2.4, T: 8, L: 25 (RD: 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4,
 TunnelId: 8193)
```

The advertised label is 262138: the ingress label at PE-1. The P2MP root address is that of the BGP next-hop of the intra-AD route, that is, the ASBR-4 system address. T: 8 signifies that the FEC type is 8, VPN-recursive FEC, and L: 25 is the length of the opaque value. The opaque value contains the route distinguisher (RD) of the intra-AD route plus inner root 192.0.2.6 and a second opaque value: a type 1 (T:1) generic of length L = 4 bytes, containing the tunnel ID 8193.

The format of the type 8 opaque value aligns with the representation in Table 21: mLDP Message Opaque Value Types in MVPN Model B:

<ASBR-4, Opaque type 8 <RD, PE-6 Opaque type 1 <Tunnel-ID> > >.

The LDP binding table of PE-1 is shown in the following output:

```
B:PE-1# show router ldp bindings active p2mp ipv4 opaque-type vpn-recursive

-------------------------------------------------------------------------------
No. of VPN Recursive with Generic IPv4 P2MP Active Bindings: 1
===============================================================================
```

This shows the VPN-recursive FEC binding with both root address of ASBR-4 and inner root of PE-6.

LDP Hop P-2 to P-3

At P-2, the label mapping messages received from PE-1 and advertised toward P-3 are shown in the following output.

```
DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 183725) from 192.0.2.1:0
Protocol version = 1
Label 262138 advertised for the following FECs
P2MP: root = 192.0.2.4, T: 8, L: 25 (RD: 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4,
 TunnelId: 8193)
"

DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 77) to 192.0.2.3:0
Protocol version = 1
Label 262139 advertised for the following FECs
P2MP: root = 192.0.2.4, T: 8, L: 25 (RD: 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4,
 TunnelId: 8193)
"
```

The received message matches the advertised label from PE-1, and the label mapping message toward P-3 (192.0.2.3) once again is a VPN-recursive FEC type. P-3 does not have a route to PE-6, but has a route to ASBR-4.

The following output shows the LDP label mapping for the VPN-recursive FEC at P-2.

```
A:P-2# show router ldp bindings active p2mp ipv4 opaque-type vpn-recursive

```

ASBR-4

ASBR-4 is the root of the mLDP tree within AS 64496. Upon receipt of an mLDP label mapping message containing this FEC element, ASBR-4 recognizes that it is the root and that the opaque value is a VPN-recursive opaque value. ASBR-4 parses the VPN-recursive opaque value and extracts the root value: PE-6 plus the RD.

ASBR-4 does not have a unicast route to PE-6, so it must use the multicast VPN intra-AD route. This route contains an NLRI that has the IP address of PE-6, along with the BGP next-hop. As there may be multiple valid MVPN intra-ADs held by ASBR-4, the RD extracted from the mLDP label mapping message will be used as a match to identify the MVPN intra-AD route held in the ASBR FIB.

ASBR-4 will create an mLDP mapping message containing a VPN-recursive FEC whose opaque value has the inner root address of PE-6, and a root address of ASBR-5.

The following output shows the label mapping messages at ASBR-4.

```
12 2018/04/10 13:21:19.266 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 1102) from 192.0.2.3:0
Protocol version = 1
Label 262142 advertised for the following FECs
P2MP: root = 192.0.2.4, T: 8, L: 25 (RD: 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4,
 TunnelId: 8193)
"

13 2018/04/10 13:21:19.266 UTC MINOR: DEBUG #2001 Base LDP
"LDP: Binding
Sending Label mapping label 262135 for P2MP: root = 192.168.45.2, T: 8, L: 25 (RD:
 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4, TunnelId: 8193)
 to peer 192.0.2.5:0."

14 2018/04/10 13:21:19.266 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 1459) to 192.0.2.5:0
Protocol version = 1
Label 262135 advertised for the following FECs
P2MP: root = 192.168.45.2, T: 8, L: 25 (RD: 0x1c00002060001, InnerRoot: 192.0.2.6 T: 1, L: 4,
 TunnelId: 8193)
"
```

The label mapping message uses a format of the opaque type listed in Table 21: mLDP Message Opaque Value Types in MVPN Model B, where the new root is now ASBR-5, and the inner root address remains the PE-6 system address:

<ASBR-5, Opaque type 8 <RD, PE-6 Opaque type 1 <Tunnel-ID>>>.

At ASBR-4, the root changes from ASBR-4 to ASBR-5. ASBR-4 essentially becomes a leaf node with root at ASBR-5.

The following output shows the label binding output at ASBR-4.

```
*A:ASBR-4# show router ldp bindings active p2mp ipv4 opaque-type vpn-recursive

  --                                      --

-------------------------------------------------------------------------------
No. of VPN Recursive with Generic IPv4 P2MP Active Bindings: 2
===============================================================================
```

The label binding message received from the downstream router P-3 is known as the Lower FEC (LF). The label binding message forwarded to ASBR-5 has allocated a label and is stored as the Upper FEC (UF).

To create a non-segmented mLDP LSP, a label swap action must occur at ASBR-4, where the leaf of the P2MP LSP that has a root at ASBR-5 must be stitched to the P2MP LSP that has a root at ASBR-4 and leaf at PE-1. To achieve this, the UF label is swapped to the LF label. They are stitched using the common RD. If there are multiple lower FECs for the same RD at the ASBR, then ASBR-4 will act as a replication point. This stitching action can be seen in the EgrLbl field of the UF entry.

ASBR-5

ASBR-5 receives the label mapping message from ASBR-4. This contains a label mapping plus the opaque value with a VPN-recursive FEC type 8. The root address is a local address, so the recursive FEC is parsed and the root address of PE-6 is extracted.

```
31 2018/04/10 13:00:03.436 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 1459) from 192.0.2.4:0
Protocol version = 1
Label 262135 advertised for the following FECs
P2MP: root = 192.168.45.2, T: 8, L: 25 (RD: 0x1c00002660001, InnerRoot: 192.0.2.6  T: 1, L: 4,
 TunnelId: 8193)
"
```

ASBR-5 has a route to the PE-6 address-192.0.2.6-in the forwarding table.

ASBR-5 will therefore construct an mLDP label mapping message with FEC element containing the address of PE-6 as the root address. This is seen in the following output, where the opaque type is type 1. The opaque value is the tunnel ID contained in the original intra-AD MVPN route.

```
32 2018/04/10 13:00:03.437 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 192313) to 192.0.2.6:0
Protocol version = 1
Label 262140 advertised for the following FECs
P2MP: root = 192.0.2.6, T: 1, L: 4, TunnelId: 8193
```

This compares to the representation for opaque type 1 from Table 21: mLDP Message Opaque Value Types in MVPN Model B:

<PE-6 Opaque type 1 <Tunnel-ID>>.

The following output taken from ASBR-5 shows the stitching of the recursive label mapping received from ASBR-4 to the generic IPv4 label mapping sent to PE-6. The LF label received from ASBR-4 (262135) is stitched to the UF label (262140) via the common root address of 192.0.2.6.

```

```

Conclusion

Inter-AS multicast within a VPRN can be achieved using non-segmented mLDP trees. This chapter provides the configuration for inter-AS model B MVPN. The example also shows the associated commands, debug, and outputs, which can be used for verifying and troubleshooting.

NG-MVPN Inter-AS Model C Using Non-Segmented mLDP Tunnels

This chapter provides information about NG-MVPN Inter-AS Model C Using Non-Segmented mLDP Tunnels.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 15.0.R9.

No specific configuration is required to support non-segmented multicast Label Distribution Protocol (mLDP) for inter-AS model C. However, recursive-opaque mLDP Forwarding Equivalence Class (FEC) functionality must be supported.

The configuration of multicast in a VPRN is described in the NG-MVPN Configuration with MPLS chapter.

Overview

Multicast in an inter-AS model C network can be implemented using Rosen, where the set of Multicast Distribution Trees (MDTs) are signaled using Protocol Independent Multicast Source-Specific Mode (PIM-SSM).

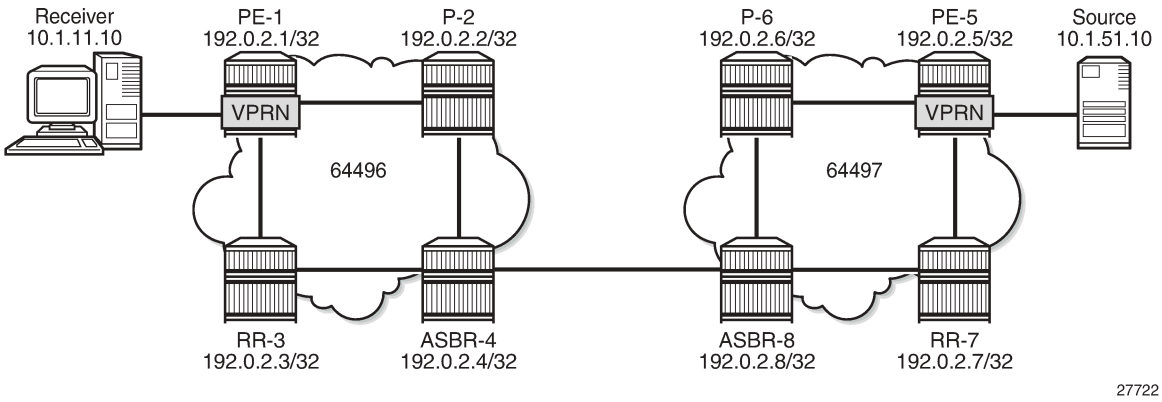
It is also possible to create MDTs between PEs in different Autonomous Systems (ASs) for Next-Generation MVPN (NG-MVPN) using non-segmented dynamic multicast LDP (mLDP) trees, where the root and leaf PEs are in different ASs. This chapter describes the configuration of MVPN services between PEs in different ASs using NG-MVPN techniques.

Figure 370: NG-MVPN Inter-AS Model C shows an example of a network comprising routers in two neighboring ASs, modeled as an inter-AS model C network; see the Inter-AS VPRN Model C chapter.

A VPRN instance exists in PE-1 and PE-5, with a single source and receiver connected as per Figure 1. RR-3 is an off the data path Route Reflector (RR) for the VPN-IPv4 address family, and ASBR-4 is RR for the label IPv4 address family in AS 64496. PE-1 is client to both RRs. The situation in AS 64497 is similar.

The multicast source located at address 10.1.51.10 in AS 64497 generates multicast traffic with group address 239.255.0.1, and the receiver at address 10.1.11.10 in AS 64496 will become a member of the multicast group using IGMPv3 signaling. No multicast protocols are configured on the ASBRs.

Figure 370: NG-MVPN Inter-AS Model C



In an MVPN, a transport tunnel is signaled that will carry multicast traffic from source PE to any receiver PE that has multicast routers attached, or hosts that want to become multicast group members. In this case, an mLDP tunnel is signaled between source PE and destination PEs to carry multicast traffic across the multi-AS provider network.

An mLDP Provider Multicast Service Interface (PMSI), also known as the provider tunnel, is established between PEs that declare membership to the MVPN, by generating and advertising an MVPN type 1 intra-AD (Auto-Discovery) BGP route. This route contains a PMSI Tunnel Attribute (PTA) that provides the tunnel type, the root node, and the LSP ID. Upon receipt of the intra-AD route, the receiving PE checks the route validity so that it can be imported into the VPRN instance. If the route is valid, the receiving router signals a point-to-multipoint (P2MP) LDP label mapping message toward the root address contained within the PTA of the intra-AD route. At the root, MPLS-encapsulated multicast traffic is forwarded to the downstream router by pushing on a label received from the downstream router.

Inter-AS model C unicast requires the RRs in peer ASs to establish a multi-hop EBGP session over which VPN-IPv4 routes can then be exchanged. If RRs are not used, PEs in the peer ASs can exchange the VPN-IPv4 and MVPN-IPv4 routes over a multi-hop eBGP session. Therefore, model C also requires the PE system addresses to be advertised across the AS boundary first.

The path for inter-AS unicast traffic is resolved using VPN-IPv4 routes learnt via the multi-hop eBGP session between RR-3 and RR-7 and label-ipv4 routes learnt via ASBR-4 and ASBR-8. In a unicast environment, traffic from PE-1 to PE-5 takes the following path:

- The tunnel from PE-1 to ASBR-4 comprises of three MPLS labels: the MPLS transport label to reach ASBR-4, followed by the MPLS label to reach PE-5 (bgp label-ipv4 learnt from ASBR-4), followed by the label associated with the VPN-IPv4 route.
- ASBR-4 pops the outer-most MPLS transport label and forwards to ASBR-8.
- ASBR-8 swaps the outer MPLS label (bgp label-ipv4) with the MPLS transport label to reach PE-5.
- PE-5 pops the outer MPLS label and uses the VPRN label to forward traffic to the appropriate VPRN.

Unlike unicast, multicast requires a non-segmented provider tunnel for traffic to be routed from the root PE toward the receiver routers. This means that the tunnel must traverse multiple ASs without decapsulating and encapsulating labels at the AS boundaries, and therefore, must be non-segmented.

If the provider tunnel uses mLDP, the receivers will initiate the signaling by sending an LDP label mapping message along the control path toward the root. This follows the path of the intra-AD route that advertises the root of the ingress PMSI (I-PMSI). An mLDP label mapping message consists of an allocated label L,

with FEC element <X,Y>, where X identifies the root node and Y is the opaque value, so the P2MP label mapping can be denoted as <X,Y,L>.

The FEC element contains the root address of the LSP plus a variable-length opaque value. The opaque value contains information meaningful to the root and leaf routers, but not to intermediate routers; for example, a P2MP LSP ID or a nested opaque value.

The root address is the system address of PE-5 (the router that advertised the intra-AD route) which is reachable via ASBR-4.

However, in an mLDP environment, each router must take part in the signaling of the P2MP LSP, but not every router has an MVPN route, so any mLDP label mapping message received by P-2 to the root address of PE-5 will be dropped. A solution to this is described in RFC 6512, *Using Multipoint LDP When the Backbone Has No Route to the Root*, as follows.

PE-1 signals an mLDP LSP as if the root is at ASBR-4. P-2 has a route to ASBR-4 because it participates in the IGP through the same IGP instance. The actual root address located in PE-5 is encapsulated in the mLDP label mapping message originated by PE-1 as an inner root address. This is a recursive FEC type 7; the root (PE-5) is encapsulated within a FEC element as an opaque value.

ASBR-4 receives the intra-AD MVPN route advertised by PE-5 with BGP next-hop ASBR-8.

Table 22: mLDP Message Opaque Value Types in MVPN inter-AS Model C shows the opaque value types used in MVPN inter-AS model C.

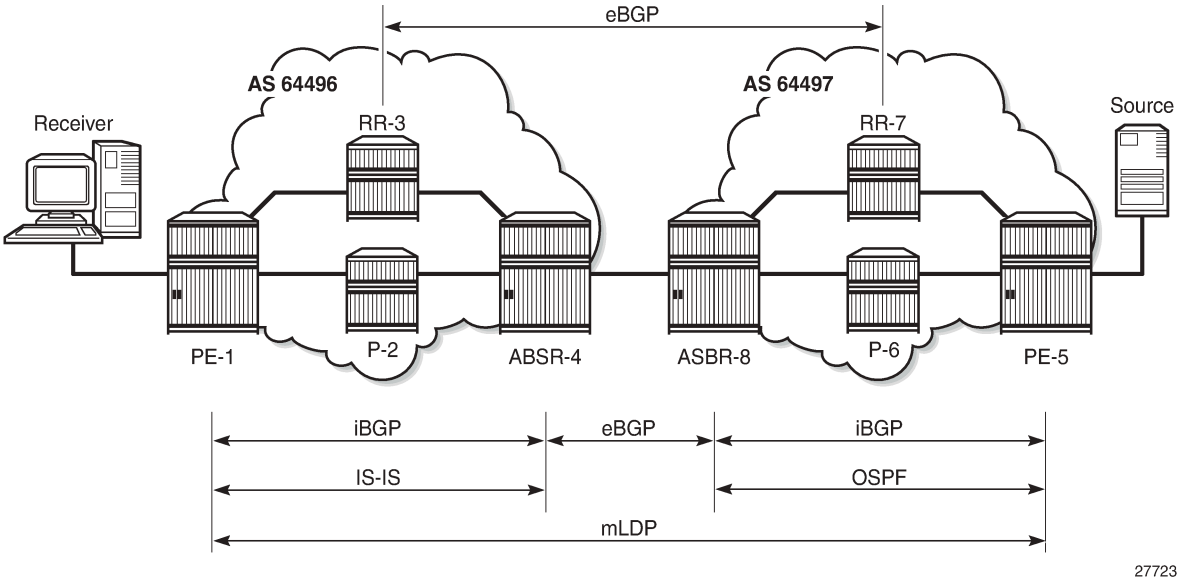
Table 22: mLDP Message Opaque Value Types in MVPN inter-AS Model C

Opaque Type	Opaque Name	Use	FEC Element Representation
1	Generic	VPRN local AS	Root, Opaque<P2MP ID>
7	Recursive FEC	Inter-AS model C mLDP	<ASBR, Opaque < Root, P2MP ID>>

Configuration

Figure 371: Inter-AS MVPN Protocol Requirements shows the required protocol configuration and peering.

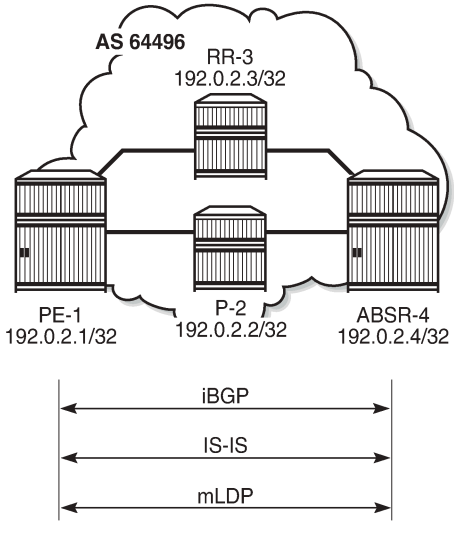
Figure 371: Inter-AS MVPN Protocol Requirements



AS 64496

Figure 372: AS 64496 Protocols shows the protocol requirements for AS 64496.

Figure 372: AS 64496 Protocols



Router Interface and IS-IS Configuration

The first step is to configure the router interfaces and IS-IS as the Interior Gateway Protocol (IGP) in AS 64496.

The router interfaces for PE-1 are configured as follows:

```
# on PE-1
configure
    router
        interface "int-PE-1-P-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-RR-3"
            address 192.168.13.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
    exit
```

Each interface is configured to run IS-IS as the IGP, as follows. Each router is configured as a level 2 router.

```
# on PE-1
configure
    router
        isis
            level-capability level-2
            area-id 49.0001
            advertise-passive-only
            level 2
                wide-metrics-only
            exit
            interface "system"
                passive
                no shutdown
            exit
            interface "int-PE-1-P-2"
                interface-type point-to-point
                no shutdown
            exit
            interface "int-PE-1-RR-3"
                interface-type point-to-point
                no shutdown
            exit
            no shutdown
        exit
```

The configuration for all other nodes in the AS is the same, other than the IP addresses. The IP addresses can be derived from Figure 1.

LDP Configuration

LDP is used as the MPLS protocol and must be enabled on each router interface, except for the VPN RR and the interfaces to the RR, as follows:

```
# on PE-1
configure
    router
        ldp
            interface-parameters
                interface "int-PE-1-P-2" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

This configuration must be repeated on each of the other routers in the AS. Because LDP is used as the provider tunnel interface for multicast traffic, the previously indicated interfaces must also support P2MP LDP tunnels. Therefore, the FEC type capability for IPv4 P2MP tunnels must be enabled. The default value is enable, but is included in the preceding output for clarity.

BGP Configuration

RR-3 Configuration

RR-3 is the route reflector for the VPN-IPv4 and MVPN-IPv4 address families within AS 64496, and peers with PE-1, but not with ASBR-4 and P-2. The cluster ID is set to ensure that RR-3 is an RR. For supporting inter-AS VPRN model C, PE-3 also peers with RR-7 in AS 64497 for the same address families, through a multi-hop eBGP session.

```
configure
    router
        autonomous-system 64496
        bgp
            loop-detect discard-route
            min-route-advertisement 1
            rapid-withdrawal
            split-horizon
            rapid-update vpn-ipv4 mvpn-ipv4
            group "EBGP-vpn-mvpn"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64497
                local-address 192.0.2.3
                neighbor 192.0.2.7
                    multihop 10
                exit
            exit
            group "IBGP-vpn-mvpn"
                cluster 192.0.2.3
                peer-as 64496
```

```
                neighbor 192.0.2.1
                    family vpn-ipv4 mvpn-ipv4
                exit
            exit
            no shutdown
        exit
```

ASBR-4 Configuration

Although ASBR-4 is the AS border router for AS 64496 (so that it peers with ASBR-8 in AS 64497), ASBR-4 is also configured as RR for the labeled IPv4 address family within AS 64496, and peers with PE-1, as follows:

```
configure
    router
        autonomous-system 64496
        bgp
            loop-detect discard-route
            rapid-withdrawal
            split-horizon
            rib-management
                label-ipv4
                    route-table-import "to-AS64497"
                exit
            exit
            group "EBGP-label"
                export "exp-PE-and-RR"
                neighbor 192.168.48.2
                    family label-ipv4
                    peer-as 64497
                    advertise-inactive
                exit
            exit
            group "IBGP-label"
                next-hop-self
                cluster 192.0.2.4
                peer-as 64496
                neighbor 192.0.2.1
                    family label-ipv4
                exit
            exit
            no shutdown
        exit
```

The policies ensure that the system addresses of the PEs and the RRs are exchanged between AS 64496 and AS 64497. In this example, ASBR-4 generates the labeled routes but pops the label associated with RR-3; see the *Pop-Label for /32 Label-IPv4 BGP routes* chapter.

```
configure
    router
        policy-options
            begin
            prefix-list "PE-pfxs"
                prefix 192.0.2.1/32 exact
                prefix 192.0.2.4/32 exact
            exit
            prefix-list "RR-pfxs"
                prefix 192.0.2.3/32 exact
            exit
```

```
            policy-statement "exp-PE-plus-RR"
                entry 10
                    from
                        prefix-list "PE-pfxs" "RR-pfxs"
                    exit
                    action accept
                    exit
                exit
            exit
            policy-statement "to-AS64497"
                entry 10
                    from
                        prefix-list "PE-pfxs"
                    exit
                    action accept
                    exit
                exit
                entry 20
                    from
                        prefix-list "RR-pfxs"
                    exit
                    action accept
                        advertise-label pop
                    exit
                exit
            exit
            commit
        exit
```

PE-1 configuration

PE-1 is a BGP client of RR-3 and ASBR-4, as follows:

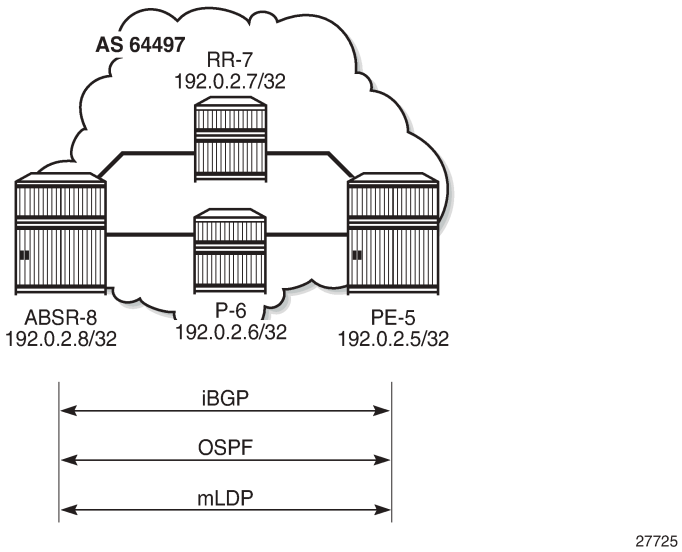
```
configure
    router
        autonomous-system 64496
        bgp
            group "IBGP-lbl"
                peer-as 64496
                neighbor 192.0.2.4
                    family label-ipv4
                exit
            exit
            group "IBGP-vpn-mvpn"
                peer-as 64496
                neighbor 192.0.2.3
                    family vpn-ipv4 mvpn-ipv4
                exit
            exit
            no shutdown
        exit
```

P-2 does not have any BGP configuration; it participates in the MPLS data plane for switching unicast and multicast customer traffic, and does not have any services defined.

AS 64497

Figure 373: AS 64497 Protocols shows the protocol requirements for AS 64497.

Figure 373: AS 64497 Protocols



Router Interface and OSPF Configuration

The first step is to configure router interfaces and OSPF on each router shown in Figure 373: AS 64497 Protocols. All router interfaces are members of a single backbone area: area 0.0.0.0.

The following router interfaces are configured on PE-5:

```
configure
    router
        interface "int-PE-5-P-6"
            address 192.168.56.1/30
            port 1/1/2
        exit
        interface "int-PE-5-RR-7"
            address 192.168.57.1/30
            port 1/1/1
        exit
        interface "system"
            address 192.0.2.5/32
        exit
    exit
exit
```

On PE-5, OSPF is configured as follows:

```
configure
    router
        ospf 0
            area 0.0.0.0
                interface "system"
                    no shutdown
                exit
                interface "int-PE-5-P-6"
                    interface-type point-to-point
                    no shutdown
```

```
                exit
                interface "int-PE-5-RR-7"
                    interface-type point-to-point
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

LDP Configuration

LDP is used as the MPLS protocol and must be enabled on each router interface, except on the RR and the interfaces toward the RR, as follows:

```
configure
    router
        ldp
            interface-parameters
                interface "int-PE-5-P-6"
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

This configuration must be repeated on each of the other routers in the AS, and the FEC type capability for IPv4 P2MP tunnels must again be enabled. The default value is enable, but is included in the preceding output for clarity.

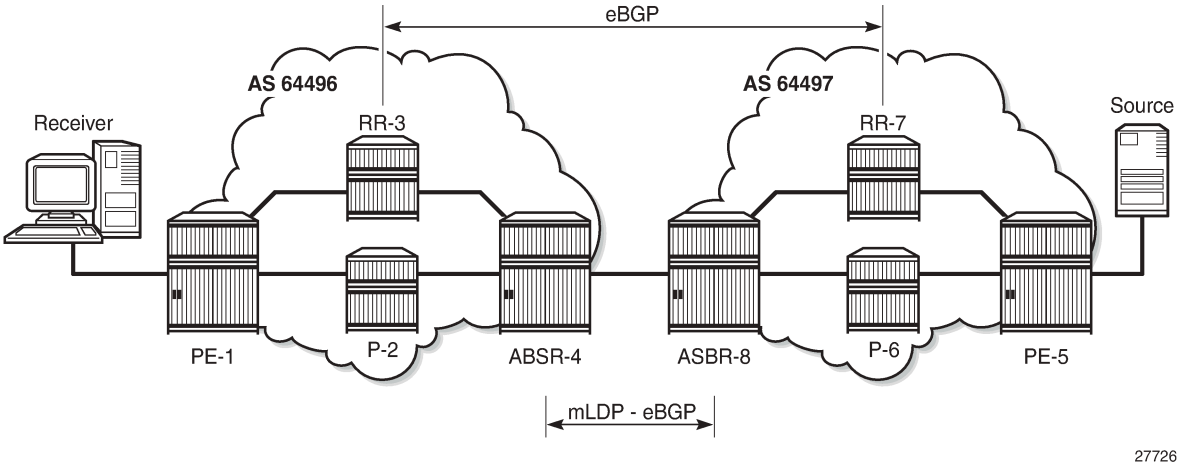
BGP Configuration

The BGP configuration for AS 64497 is mirrored from AS 64497, so the configuration is similar, meaning that RR-7 is RR for VPN and MVPN routes, and ASBR-8 is RR for labeled IPv4 routes, with PE-5 being the client. P-6 is not a BGP client for RR-7 and ASBR-8.

Inter-AS Configuration

Figure 374: Inter-AS Protocols shows the protocols required between ASBR-4 and ASBR-8. The interface addresses are used for the LDP transport and the BGP speaker peer addresses.

Figure 374: Inter-AS Protocols



LDP Peering

LDP is configured as the MPLS protocol between ASBR-4 and ASBR-8. On ASBR-4, the interface toward ASBR-8 has LDP enabled, as follows. The interface address should be used as the LDP transport address because the system address of ASBR-8 is not known to ASBR-4.

```
# on ASBR-4
configure
    router
        ldp
            interface-parameters
                interface "int-ASBR-4-ASBR-8" dual-stack
                    ipv4
                        fec-type-capability
                            p2mp-ipv4 enable
                        exit
                        transport-address interface
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The P2MP FEC type capability for P2MP LDP is shown. This is the default value.

For completeness, the LDP configuration on ASBR-8 for the interface toward ASBR-4 is as follows:

```
configure
    router
        ldp
            interface-parameters
                interface "int-ASBR-8-ASBR-4" dual-stack
                    ipv4
                        fec-type-capability
```

```
                        p2mp-ipv4 enable
                    exit
                    transport-address interface
                exit
            exit
                no shutdown
            exit
        no shutdown
    exit
exit
```

The LDP session is successfully established at ASBR-4, as follows:

```
*A:ASBR-4# show router ldp session 192.0.2.8

===============================================================================
LDP IPv4 Sessions

-------------------------------------------------------------------------------
No Matching Entries Found
===============================================================================
*A:ASBR-8#
```

When a label mapping message is received for an LDP FEC prefix, the next-hop for a FEC prefix is resolved in the routing table. The FEC is installed in the Label Information Base (LIB) if the next-hop matches a /32 route table entry.

The local interface configuration will result in a route being installed with a subnet mask matching the interface configuration. In this case, the ASBR-to-ASBR route is 192.168.45.0/30.

For LDP to resolve the LDP FEC egress next-hop on ASBR-4, a /32 route matching the egress next-hop address is required in the FIB. For that purpose, on ASBR-4, a static route is configured for the /32 address located on ASBR-8, as follows:

```
# on ASBR-4
configure
    router
        static-route-entry 192.168.48.2/32
            next-hop 192.168.48.2
                no shutdown
            exit
        exit
    exit
exit
```

Similarly, a static route on ASBR-8 is configured for the /32 address located on ASBR-4, as follows:

```
# on ASBR-8
configure
    router
        static-route-entry 192.168.48.1/32
            next-hop 192.168.48.1
                no shutdown
            exit
        exit
    exit
exit
```

The following output shows that the static route is installed in the ASBR-4 Routing Information Base (RIB):

```
*A:ASBR-4# show router route-table protocol static
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.168.48.2/32                               Remote  Static    01h39m26s  5
       192.168.48.2                                                 1
-------------------------------------------------------------------------------

===============================================================================
*A:ASBR-4#
```

eBGP Peering - ASBR-4 to ASBR-8

The following shows the eBGP peering configuration for ASBR-4. The peer address is the interface address of ASBR-8.

```
configure
    router
        autonomous-system 64496
        bgp
            group "EBGP-label"
                export "exp-PE-plus-RR"
                neighbor 192.168.48.2
                    family label-ipv4
                    peer-as 64497
                    advertise-inactive
                exit
            exit
```

Similarly, the BGP configuration for ASBR-8 peering toward ASBR-4 is as follows:

```
configure
    router
        autonomous-system 64496
        bgp
            group "EBGP-lbl"
                export "exp-PE-plus-RR"
                neighbor 192.168.48.1
                    family label-ipv4
                    peer-as 64496
                    advertise-inactive
                exit
            exit
```

The BGP peering session between ASBR-4 and ASBR-8 is verified as follows. In this example, only labeled IPv4 routes are exchanged.

```
*A:ASBR-4# show router bgp summary group "EBGP-label"

eBGP Peering - RR-3 to RR-7

The following shows the configuration required for establishing an eBGP multi-hop peering session from RR-3 to RR-7. The peer address is the system address of RR-7.

```
# on RR-3
configure
    router
        static-route-entry 192.0.2.7/32
            indirect 192.0.2.4
                tunnel-next-hop
                    resolution disabled
                exit
                no shutdown
            exit
        exit
        bgp
            loop-detect discard-route
            split-horizon
            rapid-update vpn-ipv4 mvpn-ipv4
            group "EBGP-vpn-mvpn"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64497
                neighbor 192.0.2.7
                    multihop 10
                exit
            exit
            ---snip---
            no shutdown
        exit
    exit
```

Similarly, the BGP configuration for RR-7 multi-hop peering with RR-3 is as follows:

```
# on RR-7
```

```
configure
    router
        static-route-entry 192.0.2.3/32
            indirect 192.0.2.8
                tunnel-next-hop
                    resolution disabled
                exit
                no shutdown
            exit
        exit
        bgp
            loop-detect discard-route
            split-horizon
            rapid-update vpn-ipv4 mvpn-ipv4
            group "EBGP-vpn-mvpn"
                family vpn-ipv4 mvpn-ipv4
                peer-as 64496
                neighbor 192.0.2.3
                    multihop 10
                exit
            exit
            ---snip---
            no shutdown
        exit
    exit
```

This peering session is verified as follows. Only VPN-IPv4 and MVPN-IPv4 routes are exchanged.

```
*A:RR-3# show router bgp summary group "EBGP-vpn-mvpn"

Route Policy for MVPN Routes

The use of non-segmented LDP provider tunnels requires that intra-AD routes must be advertised across the AS boundary between PEs. Each intra-AD route generated by a PE that is a member of an MVPN contains the well-known community "No-Export", which prevents a BGP speaker from advertising the route across an AS boundary to another external BGP speaker.

In inter-AS model C, the RRs must support the MVPN address family. If the RR receives an intra-AD route containing the No-Export community, this route will not be advertised to any external peer. A route policy is required to remove the No-Export community before the route can be advertised across the AS boundary to a BGP speaker that has negotiated the MVPN address family capability.

In the following example, a *RemNoExport* policy is defined, which will remove the No-Export community, using the community remove action as a default action:

```
```

```
# at PE-1 and PE-5
configure
    router
        policy-options
            begin
            community "NoExport" members "no-export"
            policy-statement "RemNoExport"
                default-action accept
                    community remove "NoExport"
                exit
            exit
            commit
        exit
    exit
exit
```

This policy is applied as an export policy, so that the No-Export community is removed from all intra-AD routes advertised as updates to internal peers. The **vpn-apply-export** command must be included to ensure that the export policy is applied to routes belonging to VPN address families; in this case, MVPN-IPv4 routes.

```
# at PE-5
configure
    router
        bgp
            group "IBGP-vpn-mvpn"
                vpn-apply-export
                export "RemNoExport"
                peer-as 64497
                neighbor 192.0.2.7
                    family vpn-ipv4 mvpn-ipv4
                exit
            exit
            no shutdown
        exit
    exit
exit
```

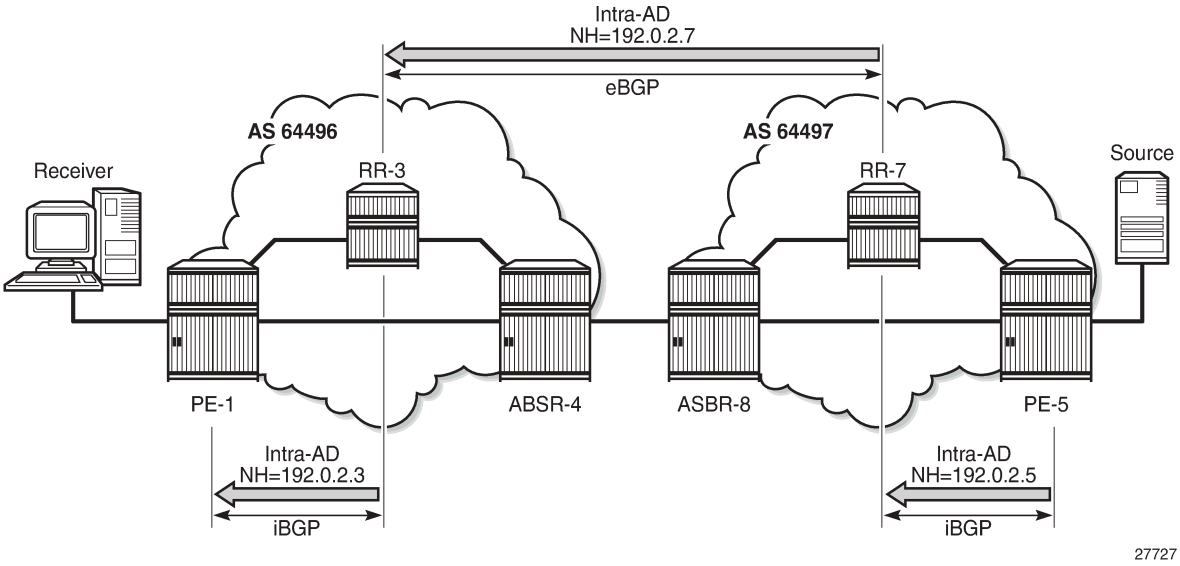
This policy should also be configured and applied on PE-1, so that intra-AD routes can be exported from MVPN PEs in AS 64496 to AS 64497.

Verification

BGP MVPN Intra-AD Route Propagation

Figure 375: BGP MVPN Intra-AD Route Advertisement shows the propagation of the BGP MVPN intra-AD route from PE-5 to PE-1 across the AS boundary. The original route has the No-Export community removed at PE-5, due to the export route policy applied. RR-3 receives the route via RR-7 and reflects it to PE-1. The BGP next-hop attribute is changed by RR-7 to its system address: 192.0.2.7. RR-3 reflects the intra-AD route to PE-1, also changing the BGP next-hop attribute to its system address: 192.0.2.3.

Figure 375: BGP MVPN Intra-AD Route Advertisement



PE-1 receives the route, and will import the route into VPRN 1 because the route target extended community matches the community configured in the MVPN context of the VPRN. PE-1 now uses the PTA contained within the intra-AD route to instantiate the provider tunnel.

The following output shows details of the MVPN intra-AD route received by PE-1, generated by PE-5:

```
*A:PE-1# show router bgp routes mvpn-ipv4 type intra-ad originator-ip 192.0.2.5 hunt

P2MP LDP LSP Signaling

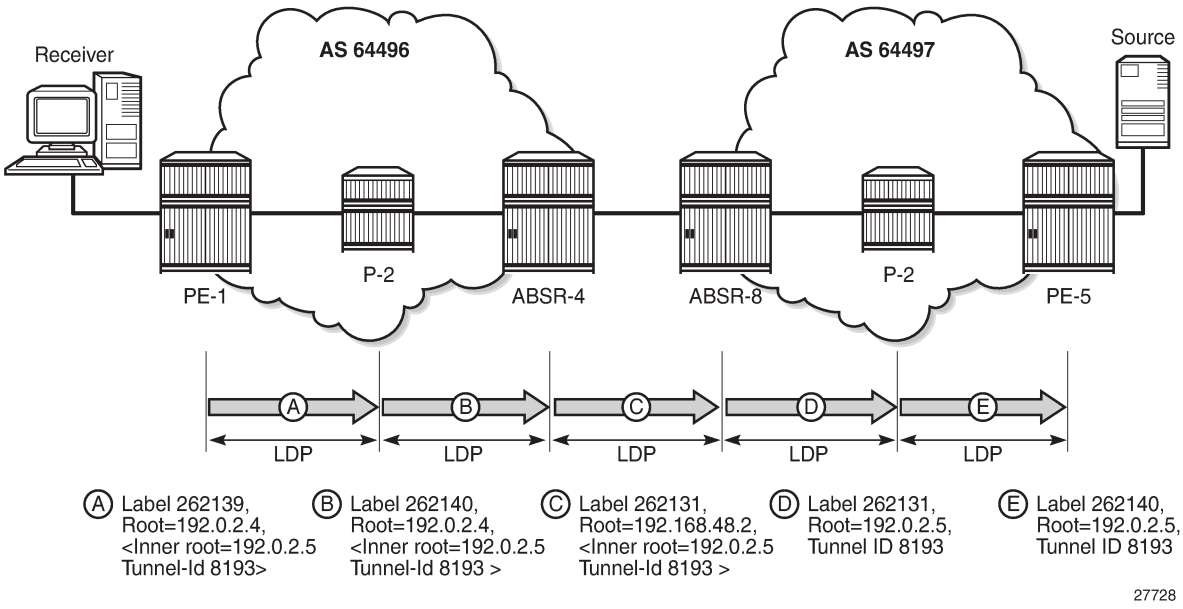
The PTA lists the tunnel type as an LDP P2MP LSP. A P2MP label mapping message is originated at PE-1, with LSP ID 8193, with inner-root PE-5 and outer-root ASBR-4.

The intra-AD MVPN route is used to determine the path of the label mapping message from PE-1 toward PE-5. This is similar to the unicast routing case, where a VPN-IPv4 labeled route is used to determine the path to the source.

The BGP next-hop of the intra-AD route is the system address of ASBR-4, so this can be used as the root address of the mLDP LSP, and the actual root can be contained inside the label mapping message as an inner root. The inner root becomes an opaque value that is known to the originator and receiver of the label mapping message. PE-1 thus generates a recursive-opaque type=7 FEC: <ASBR-4, <PE-5, P2MP-id>>.

Figure 376: P2MP LDP Label Mapping shows the path taken by the label mapping message from PE-1 to PE-5.

Figure 376: P2MP LDP Label Mapping



P-2 does not have a BGP-LBL route to reach PE-5, but has an IGP route to reach the outer root ASBR-4. The label mapping message is forwarded from PE-1 to ASBR-4 via P-2. At each hop, a label is allocated and a label binding entry is created. In the following sections, the debug outputs are achieved using the following debug command:

```
debug
    router "Base"
        ldp
            peer <peer-ip-address>
                packet
                    label detail
                exit
            exit
        exit
    exit
exit
```

where <peer-ip-address> is the system address of the LDP peer.

LDP Hop PE-1 to P-2

The following output shows a debug of the P2MP label mapping message sent from PE-1 to P-2 upon receipt of the BGP MVPN intra-AD route:

```
5 2018/05/25 09:47:20.085 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 125) to 192.0.2.2:0
Protocol version = 1
Label 262139 advertised for the following FECs
P2MP:root = 192.0.2.4, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1, L: 4, TunnelId: 8193)
"
```

The advertised label is 262139: the ingress label at PE-1. The P2MP root address is the next hop for the BGP-LBL route to reach PE-5 (192.0.2.5), namely ASBR-4 (192.0.2.4). T: 7 signifies that the FEC type is 7, GRT-recursive FEC, and L: 17 is the length of the opaque value. The opaque value contains the inner root 192.0.2.5 and a second opaque value: a type 1 (T: 1) generic FEC of length L = 4 bytes, containing the tunnel ID 8193.

The format of the type 7 opaque value aligns with the representation in Table 1:

<ASBR-4, Opaque type 7 <PE-5, Opaque type 1 <Tunnel-ID> > >.

The LDP binding table of PE-1 is shown in the following output:

```
*A:PE-1# show router ldp bindings active p2mp ipv4 opaque-type grt-recursive

-------------------------------------------------------------------------------
8193                                        73728
192.0.2.4                                   Pop             262139      --
192.0.2.5
  --                                          --

-------------------------------------------------------------------------------
No. of GRT Recursive with Generic IPv4 P2MP Active Bindings: 1
===============================================================================
*A:PE-1#
```

The preceding output shows the GRT-recursive FEC binding with both the root address of ASBR-4 and the inner root of PE-5.

LDP Hop P-2 to ASBR-4

At P-2, the label mapping messages received from PE-1 and advertised toward ASBR-4 are shown in the following output:

```
1 2018/05/25 09:47:20.083 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 125) from 192.0.2.1:0
Protocol version = 1
Label 262139 advertised for the following FECs
P2MP:root = 192.0.2.4, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1, L: 4, TunnelId: 8193)
"
```

```
2 2018/05/25 09:47:20.083 UTC MINOR: DEBUG #2001 Base LDP
```

```
"LDP: LDP
Send Label Mapping packet (msgId 124) to 192.0.2.4:0
Protocol version = 1
Label 262140 advertised for the following FECs
P2MP:root = 192.0.2.4, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1, L: 4, TunnelId: 8193)
"
```

The received message matches the advertised label from PE-1, and the label mapping message toward ASBR-4 (192.0.2.4) is again a GRT-recursive FEC type.

The following output shows the LDP label mapping for the GRT-recursive FEC at P-2:

```
*A:P-2# show router ldp bindings active p2mp ipv4 opaque-type grt-recursive

===============================================================================
*A:P-2#
```

LDP Hop ASBR-4 to ASBR-8

ASBR-4 is the root of the mLDP tree in AS 64496. Upon receipt of an mLDP label mapping message containing this FEC element, ASBR-4 recognizes that it is the root and that the opaque value is a GRT-recursive opaque value. ASBR-4 parses the GRT-recursive opaque value and extracts the root value: PE-5.

ASBR-4 checks RTM for a route to reach the inner-root (PE-5), which is a BGP-LBL route with next-hop ASBR-8.

ASBR-4 will create an mLDP mapping message containing a GRT-recursive FEC whose opaque value has the inner root address of PE-5, and a root address of ASBR-8.

The following output shows the label mapping messages at ASBR-4:

```
1 2018/05/25 09:47:20.086 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 124) from 192.0.2.2:0
```

```
Protocol version = 1
Label 262140 advertised for the following FECs
P2MP: root = 192.0.2.4, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1, L: 4, TunnelId: 8193)
"
```

```
2 2018/05/25 09:47:20.086 UTC MINOR: DEBUG #2001 Base LDP
"LDP: Binding
Sending Label mapping label 262131 for P2MP: root = 192.168.48.2, T: 7,
    L: 17 (InnerRoot: 192.0.2.5 T: 1, L: 4, TunnelId: 8193)
    to peer 192.0.2.8:0."
```

```
3 2018/05/25 09:47:20.086 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 82) to 192.0.2.8:0
Protocol version = 1
Label 262131 advertised for the following FECs
P2MP: root = 192.168.48.2, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1,
    L: 4, TunnelId: 8193)
```

The label mapping message uses a format of the opaque type listed in Table 22: mLDP Message Opaque Value Types in MVPN inter-AS Model C , where the new root is now ASBR-8, and the inner root address remains the PE-5 system address:

<ASBR-8, Opaque type 7 <PE-5, Opaque type 1 <Tunnel-ID> > >

At ASBR-4, the root changes from ASBR-4 to ASBR-8. ASBR-4 essentially becomes a leaf node with root at ASBR-8.

The following output shows the label binding output at ASBR-4:

```
*A:ASBR-4# show router ldp bindings active p2mp ipv4 opaque-type grt-recursive

8193                                    Unknw
192.168.48.2 (UF)                       Swap            262131    Stitched
192.0.2.5
  --                                      --
-------------------------------------------------------------------------------
No. of GRT Recursive with Generic IPv4 P2MP Active Bindings: 2
===============================================================================
*A:ASBR-4#
```

The label binding message received from the downstream router P-2 is known as the Lower FEC (LF). The label binding message forwarded to ASBR-8 has allocated a label and is stored as the Upper FEC (UF).

To create a non-segmented mLDP LSP, a label swap action must occur at ASBR-4, where the leaf of the P2MP LSP that has a root at ASBR-8 must be stitched to the P2MP LSP that has a root at ASBR-4 and leaf at PE-1. To achieve this, the UF label is swapped with the LF label. This stitching action is shown in the EgrLbl field of the UF entry.

LDP Hop ASBR-8 to P-6

ASBR-8 receives the label mapping message from ASBR-4. This contains a label mapping plus the opaque value with a GRT-recursive FEC type 7. The root address is a local address, so the recursive FEC is parsed and the root address of PE-5 is extracted.

```
1 2018/05/25 09:47:20.087 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 82) from 192.0.2.4:0
Protocol version = 1
Label 262131 advertised for the following FECs
P2MP: root = 192.168.48.2, T: 7, L: 17 (InnerRoot: 192.0.2.5 T: 1,
                                                    L: 4, TunnelId: 8193)
"
```

ASBR-8 has an IGP route to the PE-5 address (192.0.2.5) in the forwarding table.

Therefore, ASBR-8 will construct an mLDP label mapping message with FEC element containing the address of PE-5 as the root address. This is shown in the following output, where the opaque type is type 1. The opaque value is the tunnel ID contained in the original intra-AD MVPN route, which was contained int the lower FEC received from ASBR-4.

```
2 2018/05/25 09:47:20.087 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 80) to 192.0.2.6:0
Protocol version = 1
Label 262131 advertised for the following FECs
P2MP: root = 192.0.2.5, T: 1, L: 4, TunnelId: 8193
"
```

This aligns with the representation for generic FEC type 1 from Table 1:

<PE-5 Opaque type 1 <Tunnel-ID> >.

The following output taken from ASBR-8 shows the stitching of the recursive label mapping received from ASBR-4 to the generic IPv4 label mapping sent to P-6. The LF label received from ASBR-4 (262131) is stitched to the UF label (262131) via the common root address of 192.0.2.5.

```

LDP Hop P-6 to PE-5

At P-6, the label mapping messages received from ASBR-8 and advertised toward PE-5 are shown in the following output:

```
1 2018/05/25 09:47:20.088 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 12) from 192.0.2.8:0
Protocol version = 1
Label 262131 advertised for the following FECs
P2MP: root = 192.0.2.5, T: 1, L: 4, TunnelId: 8193
"
```

```
2 2018/05/25 09:47:20.089 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 12) to 192.0.2.5:0
Protocol version = 1
Label 262140 advertised for the following FECs
P2MP: root = 192.0.2.5, T: 1, L: 4, TunnelId: 8193
"
```

The following output on P-6 shows the LDP label mapping for this FEC:

```
*A:P-6# show router ldp bindings active p2mp ipv4 opaque-type generic

===============================================================================

*A:P-6#
```

PE-5

Finally, the following debug output on PE-5 shows the receipt of the mLDP label mapping message sent by P-6, which contains the system address of PE-5 as the root address:

```
5 2018/05/25 09:47:20.089 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Mapping packet (msgId 99) from 192.0.2.6:0
Protocol version = 1
Label 262140 advertised for the following FECs
P2MP: root = 192.0.2.5, T: 1, L: 4, TunnelId: 8193
"
```

The label binding output at PE-5 shows that the operation is a push operation. This is expected because PE-5 is the root node of the P2MP LSP.

```
*A:PE-5# show router ldp bindings active p2mp ipv4 opaque-type generic

```

Conclusion

Inter-AS model C multicast within a VPRN can be achieved using non-segmented mLDP trees. This chapter provides the configuration for inter-AS model C MVPN. The example also shows the associated commands, debug, and outputs, which can be used for verifying and troubleshooting.

NG-MVPN Sender-Only, Receiver-Only

This chapter provides information about next generation multicast virtual private network (NG-MVPN) sender-only and receiver-only configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The sender-only/receiver-only feature as described in this chapter is supported in SR OS Release 11.0.R1, and later. The CLI in this edition is based on SR OS Release 15.0.R4.

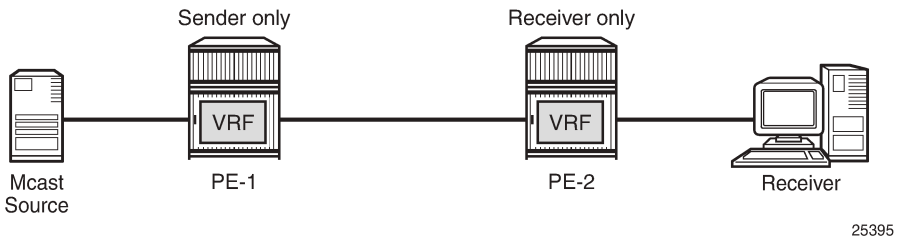
Knowledge of the Nokia multicast and Layer 3 VPNs concepts are assumed throughout this document.

Overview

This example covers a basic technology overview, the network topology, and configuration examples which are used for the Multicast VPN (MVPN) sender-only, receiver-only feature.

By default, if multiple PE nodes form a peering relationship within a common MVPN instance, then each PE node originates a multicast tree locally towards the remaining PE nodes that are members of this MVPN instance. This behavior creates a full mesh of Inclusive-Provider Multicast Service Interfaces (I-PMSIs) across all PE nodes in the MVPN.

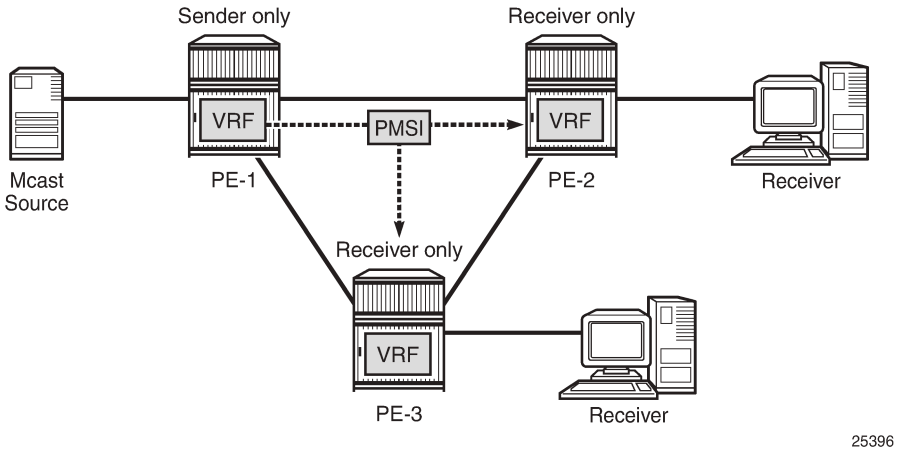
Figure 377: Default PMSI Hierarchy



It is often the case that an MVPN has many sites with multicast receivers, but only a few sites that host either both receivers and sources, or sources only.

The MVPN sender-only/receiver-only feature optimizes control and data plane resources by preventing unnecessary I-PMSI meshing when a PE hosts multicast sources only, or multicast receivers only, for an MVPN. An example of such an optimization is presented in Figure 378: Optimized PMSI Structure.

Figure 378: Optimized PMSI Structure



The general rules to follow are:

- For PE nodes that host only multicast sources for a given MVPN, operators can now block these PEs, through configuration, from joining I-PMSIs from the other PEs in this MVPN.
- For PE nodes that host only multicast receivers for a given MVPN, operators can now block these PEs, through configuration, to set-up a local I-PMSI to the other PEs in this MVPN.

MVPN sender-only/receiver-only is supported with next generation-MVPN for both IPv4 and IPv6 customer multicast using:

- IPv4 RSVP-TE provider tunnels
- IPv4 LDP provider tunnels

Extra attention should be given to the Bootstrap Router/Rendezvous Point (BSR/RP) placement when sender-only/receiver-only is enabled:

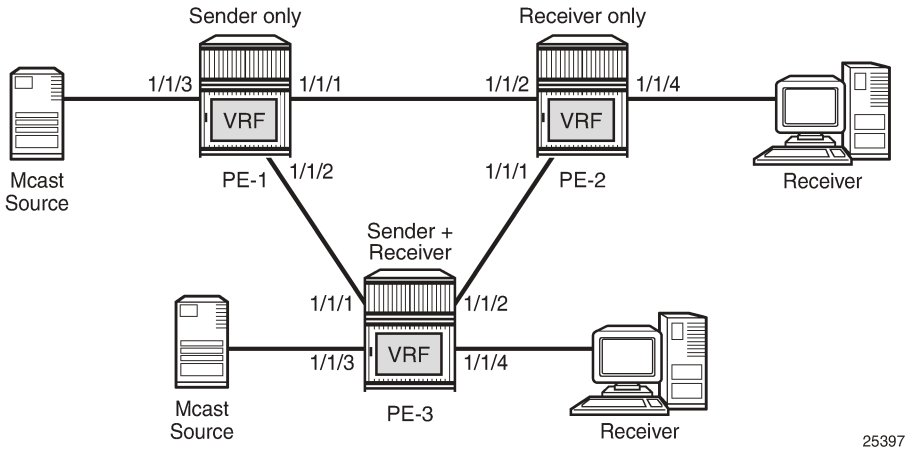
- The RP should be at the sender-receiver or sender-only site so that (*,G) traffic can be sent over the tunnel
- The BSR should be deployed at the sender-receiver site.
- The BSR can be at a sender-only site if the RPs are at the same site.

Note:
(*,G) refers to an individual multicast stream indicating any source (*) and the multicast group (G) used by the stream.

Configuration

The example topology is shown in Figure 379: Example Topology.

Figure 379: Example Topology



To configure the sender-only/receiver-only feature, the following configuration command is used:

```
*A:PE>config>service>vprn>mvpn# mdt-type
  - mdt-type {sender-only|receiver-only|sender-receiver}
  - no mdt-type
```

sender-receiver is the default option and is visible using the **info detail** command.

This command restricts the MVPN instance to a specific role and provides an option to configure either a sender-only or receiver-only mode per PE node per service.

Parameters:

sender-only — MVPN has only senders connected to PE node.

receiver-only — MVPN has only receivers connected to PE node.

sender-receiver — MVPN has both sender and receivers connected to PE node.

Considerations:

- Two general approaches for building MVPNs will be covered in detail in this example:
  - Point-to-multipoint (P2MP) RSVP MVPNs
  - Multicast LDP (mLDP) MVPNs
- IPv4 and IPv6 multicast streaming are used for every MVPN at the same time.
- Basic principles of an MVPN including I-PMSI, S-PMSI, mLDP and P2MP RSVP are covered in the NG-MVPN Configuration with PIM and chapters of this guide.

PIM SSM is used for IPv4/IPv6 Customer (C)-multicast groups.

Initial Configuration

Step 1. The PE routers already have the following configuration:

- Interfaces (IPv4/IPv6)
- IGP (IS-IS or OSPF/OSPFv3)

- LDP (IPv4 only suffices)
- MPLS/RSVP
- BGP

Step 2. The MPLS/RSVP configuration on PE-1 is as follows. An P2MP LSP template is created with an empty path, without explicit hops.

```
# on PE-1
configure
    router
        mpls
            interface system
            exit
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-3"
            exit
            no shutdown
            path EMPTY
                no shutdown
            exit
            lsp-template MVPN-P2MP-LSP p2mp
                default-path EMPTY
                cspf
                no shutdown
            exit
        exit
        rsvp no shutdown
    exit
exit
```

Step 3. The BGP configuration on PE-1 is as follows. No route reflector is used.

```
# on PE-1
configure
    router
        bgp
            min-route-advertisement 1
            enable-peer-tracking
            rapid-withdrawal
            rapid-update mvpn-ipv4 mvpn-ipv6
            group INTERNAL
                family vpn-ipv4 vpn-ipv6 mvpn-ipv4 mvpn-ipv6
                type internal
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
        exit
    exit
exit
```

RSVP-Based MVPN Configuration

Step 1. Configure a basic MVPN using P2MP RSVP as a transport protocol for C-multicast groups.

For this setup, PE-2 and PE-3 are configured to receive the following multicast groups:

- IPv4 group 232.0.0.1 source 172.16.1.1
- IPv6 group FF3E::8000:1 source 2001:DB8:1::1

Step 2. Configure the MDT type for the MVPN.

Based on the example topology, PE-1 is configured as **sender-only** for the MVPN.

```
# on PE-1
configure
    service
        vprn 1 customer 1 create
            description "RSVP-based MVPN"
            ecmp 2
            autonomous-system 64500
            route-distinguisher 64500:101
            auto-bind-tunnel
                resolution-filter
                    ldp
                    rsvp
                exit
                resolution filter
            exit
            vrf-target target:64500:1
            interface "int-PE-1-S-1" create
                description "to multicast source"
                address 172.16.1.2/30
                ipv6
                    address 2001:db8:1::2/126
                exit
                sap 1/1/3 create
                exit
            exit
            pim
                no ipv6-multicast-disable
                apply-to all
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                mdt-type sender-only
                provider-tunnel
                    inclusive
                        rsvp
                            lsp-template "MVPN-P2MP-LSP"
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            service-name "RSVP-based MVPN"
            no shutdown
        exit
```

Based on the example topology, PE-2 is configured as **receiver-only** for the MVPN. PE-2 has static joins for the IPv4 and IPv6 multicast groups:

- group 232.0.0.1,source 172.16.1.1
- group FF3E::8000:1, source 2001:DB8:1::1

```
# on PE-2
```

```
configure
    service
        vprn 1 customer 1 create
            description "RSVP-based MVPN"
            ecmp 2
            autonomous-system 64500
            route-distinguisher 64500:102
            ignore-nh-metric
            auto-bind-tunnel
                resolution-filter
                    ldp
                    rsvp
                exit
                resolution filter
            exit
            vrf-target target:64500:1
            interface "int-PE-2-H-2" create
                description "to receiver Host-2"
                address 172.16.2.2/30
                ipv6
                    address 2001:db8:2::2/126
                exit
                sap 1/1/4 create
                exit
            exit
            igmp
                interface "int-PE-2-H-2"
                    static
                        group 232.0.0.1
                            source 172.16.1.1

            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                mdt-type receiver-only
                provider-tunnel
                    inclusive
                        rsvp
                            lsp-template "MVPN-P2MP-LSP"
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
```

```
            exit
            service-name "RSVP-based MVPN"
            no shutdown
        exit
    exit
exit
```

Based on the example topology, PE-3 is configured as **sender-receiver** (default) for the MVPN. PE-1 has also static joins for the IPv4 and IPv6 multicast groups:

- group 232.0.0.1,source 172.16.1.1
- group FF3E::8000:1, source 2001:DB8:1::1

The interface to the local source for PE-3 is not configured in this example. PE-3 acts as a receiver, not as a sender. Nonetheless, it is configured as sender-receiver and that has its consequences for the I-PMSIs that will be established.

```
# on PE-3

            no shutdown
        exit
    exit
exit
```

The PIM instance must be **shutdown** before the mdt-type is modified; this leads to a multicast service disruption. Trying to change the mdt-type with PIM instance active will result in the following message being displayed.

```
*A:PE-1# configure service vprn 1 mvpn mdt-type receiver-only
MINOR: PIM #1100 PIM instance must be shutdown before changing this configuration
```

RSVP-Based MVPN Verification and Debugging

MDT-Type Verification

The status of the MVPN can be checked using the **show router** <*service-number*> **mvpn** command:

The output for PE-1, PE-2 and PE-3 is as follows:

```
*A:PE-1# show router 1 mvpn

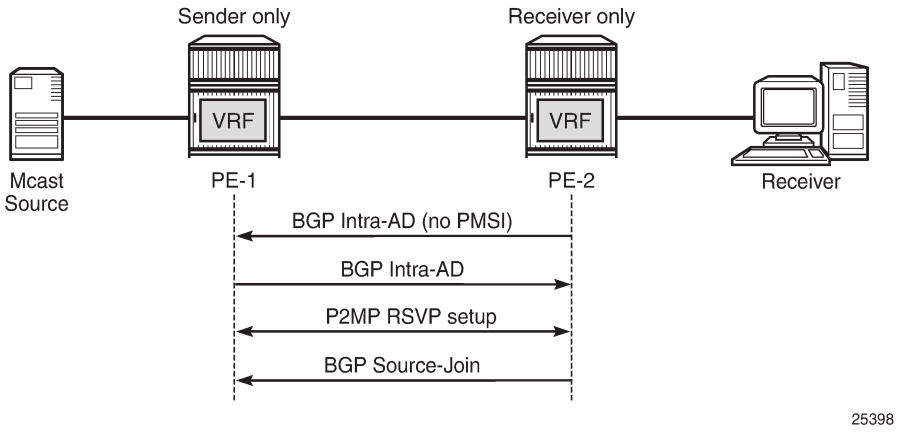
BGP Verification and Debugging

When the MDT type is changed, the BGP signaling is slightly modified in order to achieve the signaling optimization.

The PE router does not include the PMSI part in the Intra-AD BGP messages when the MVPN is configured with mdt-type as **receiver-only**. The message flow is presented in Figure 380: RSVP-Based BGP Message Flow Between PE-1 and PE-2.

Figure 380: RSVP-Based BGP Message Flow Between PE-1 and PE-2



The following BGP debug output is taken from PE-2 and demonstrates the message flow between PE-1 and PE-2 for the MVPN-IPv4 address family.

There is no PMSI part in the BGP Intra-AD message sent by PE-2 (message 7), but the PMSI part is present in the BGP Intra-AD message received from **sender-only** PE-1 (message 1).

```

Similar behavior is observed for IPv6 multicast.

The following BGP debug output is taken from PE-3 and demonstrates the message flow between PE-1 and PE-3 for the MVPN-IPv6 address family.

The PMSI part is present in debug message 4, which is sent by PE-1 (**sender-only**).

```

RSVP Verification and Debugging

When BGP intra-AD messages are exchanged, every PE starts to build multicast tunnels based on the following criteria:

- PE nodes which are configured as **sender-only** for an MVPN do not join P2MP LSPs from other PEs in this MVPN.
- PE nodes which are configured as receiver-only for an MVPN do not originate P2MP LSPs to other PEs in this MVPN.

The RSVP session can be checked with the **show router rsvp session** command:

PE-1 (192.0.2.1) has two originating LSPs: one toward PE-2 (192.0.2.2) and one toward PE-3 (192.0.2.3). PE-1 also has one incoming LSP from PE-3 (**mdt-type sender-receiver**).

```
*A:PE-1# show router rsvp session

===============================================================================
*A:PE-2#
```

PE-3 (192.0.2.3) has two originating LSPs: one toward PE-2 (192.0.2.2) and one toward PE-1 (192.0.2.1). PE-3 also has one incoming LSP from PE-1 (**mdt-type sender-only**).

Theoretically there is no need for the LSP from PE-3 toward PE-1, because PE-1 is a sender-only; this minor limitation should be taken into account during planning phase.

```

Multicast Stream Verification

The status of the multicast groups/streams can be verified using the **show router** <*sid*> **pim group detail [ipv6]** command:

There is an IPv4 sender connected to PE-1. The physical interface where the sender is connected is used as the incoming interface. An I-PMSI is used as the outgoing interface.

```
*A:PE-1# show router 1 pim group detail

*A:PE-3#
```

mLDP-Based MVPN Configuration

Step 1. Reconfigure VPRN 1 to make it mLDP-based. The resolution-filter should only be LDP (no RSVP anymore) for auto-bind-tunnel. The MVPN context also changes: the inclusive provider-tunnel is mLDP-based. The MDT-type remains the same: PE-1 is sender-only, PE-2 is receiver-only and PE-3 is sender-receiver (default).

PE-2 and PE-3 have static joins for the IPv4/IPv6 multicast groups:

- group 232.0.0.1,source 172.16.1.1
- group FF3E::8000:1, source 2001:DB8:1::1

Step 2.The VPRN 1 configuration on PE-1 is as follows:

```
# on PE-1
configure
    service
        vprn 1 customer 1 create
            description "mLDP-based MVPN"
            ecmp 2
            autonomous-system 64500
            route-distinguisher 64500:101
            ignore-nh-metric
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64500:1
            interface "int-PE-1-S-1" create
                description "to multicast source"
                address 172.16.1.2/30
                ipv6
                    address 2001:db8:1::2/126
                exit
                sap 1/1/3 create
                exit
            exit
            pim
                no ipv6-multicast-disable
                apply-to all
            exit
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
```

```
                mdt-type sender-only
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            service-name "mLDP-based MVPN"
            no shutdown
        exit
```

Based on the example topology, PE-2 is configured as receiver-only for the MVPN. PE-2 has also static joins for the IPv4 and IPv6 multicast groups:

- group 232.0.0.1,source 172.16.3.1
- group FF3E::8000:1, source 2001:DB8:3::1

```
# on PE-2
configure
    service
        vprn 1 customer 1 create
            description "mLDP-based MVPN"
            ecmp 2
            autonomous-system 64500
            route-distinguisher 64500:102
            ignore-nh-metric
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64500:1
            interface "int-PE-2-H-2" create
                description "to receiver Host-2"
                address 172.16.2.2/30
                ipv6
                    address 2001:db8:2::2/126
                exit
                sap 1/1/4 create
                exit
            exit
            igmp
                interface "int-PE-2-H-2"
                    static
                        group 232.0.0.1
                            source 172.16.1.1
                        exit
                    exit
                    no shutdown
                exit
                no shutdown
            exit
            mld
                interface "int-PE-2-H-2"
                    static
                        group ff3e::8000:1 source 2001:db8:1::1
                    exit
                    no shutdown
```

```
                exit
                no shutdown
            exit
            pim

```

mLDP-Based MVPN Verification and Debugging

MDT-Type Verification

The status of the MVPN can be checked using the following command:

show router <*service-number*> **mvpn**

The output for PE-1, PE-2 and PE-3 is as follows:

```
*A:PE-1# show router 1 mvpn

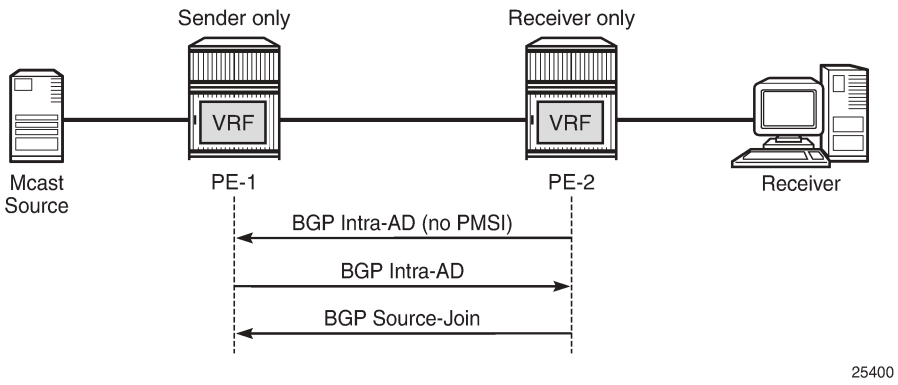
BGP Verification and Debugging

When the MDT type is changed, the BGP signaling is slightly modified in order to achieve the signaling optimization.The PE router does not include the PMSI part in Intra-AD BGP messages when the MVPN is configured with mdt-type as **receiver-only**.

The message flow is presented in Figure 382: mLDP-Based BGP Message Flow Between PE-1 and PE-2.

Figure 382: mLDP-Based BGP Message Flow Between PE-1 and PE-2



In order to demonstrate the BGP message flow sequence the following initialization steps are taken on PE-2:

1. Bring down the VPRN service, PIM protocol in a VPRN and IGMP/MLD protocol. As a result, the state of all signaling protocols is cleared.
2. Bring up the VPRN service. BGP exchanges unicast routing information.
3. Bring up the IPv4 PIM protocol. BGP exchanges IPv4 multicast routing information in order to build the PMSI infrastructure.
4. Bring up IGMP and add a static IGMP join where it is applicable. BGP exchanges IPv4 multicast routing information in order to propagate the multicast traffic to the receiver.
5. Bring up the IPv6 PIM protocol. BGP exchanges IPv6 multicast routing information in order to build the PMSI infrastructure.
6. Bring up MLD and add a static MLD join where it is applicable. BGP exchanges IPv6 multicast routing information in order to propagate the multicast traffic to the receiver.

The following BGP debug is taken from PE-2 and demonstrates the message flow between PE-2 and PE-1. VPN-IPv4 and VPN-IPv6 updates are not present in this output.

Step 1. Bring down the VPRN service and protocols to clear the state of all signaling protocols.

```
# on PE-2
configure
```

```
    service
        vprn 1
            shutdown
            pim shutdown
            pim ipv6-multicast-disable
            igmp shutdown
            mld shutdown
        exit
    exit
```

Step 2. Enable the VPRN service on PE-2.

PE-2 immediately receives Intra-AD messages from PE-1 because the remote VPRN service is already enabled for IPv4 and IPv6 multicast propagation.

```
*A:PE-2# configure service vprn 1 no shutdown
```

```

===============================================================================
*A:PE-2#
```

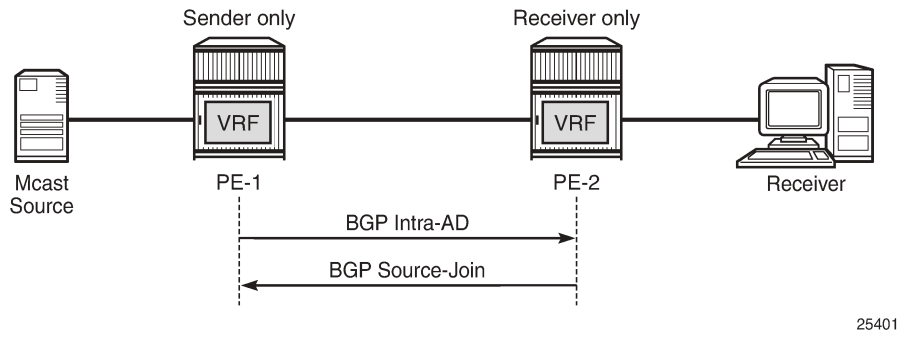
The PE router does not change the BGP behavior when the MVPN is configured with mdt-type as **sender-only**. A schematic of the message flow is presented in Figure 383: mLDP-Based BGP Message Flow Between PE-1 and PE-3.

Figure 383: mLDP-Based BGP Message Flow Between PE-1 and PE-3



In order to demonstrate the BGP message flow sequence, the following initialization steps are taken:

1. Bring down the VPRN service, PIM protocol in the VPRN and IGMP/MLD protocol. As a result, the state of all signaling protocols is cleared.
2. Bring up the VPRN service. BGP exchanges unicast routing information.
3. Bring up the IPv4 PIM protocol. BGP exchanges IPv4 multicast routing information in order to build the PMSI infrastructure.
4. Bring up IGMP and add a static IGMP join where it is applicable. BGP exchanges IPv4 multicast routing information in order to propagate the multicast traffic to the receiver.
5. Bring up the IPv6 PIM protocol. BGP exchanges IPv6 multicast routing information in order to build the PMSI infrastructure.
6. Bring up MLD and add a static MLD join where it is applicable. BGP exchanges IPv6 multicast routing information in order to propagate the multicast traffic to the receiver.

The following BGP debug output is taken from PE-3 and demonstrates the message flow between PE-1 and PE-3.

The PMSI part is present in debug messages sent by PE-1 (**sender-only**).

Step 1. Bring down the VPRN service and protocols to clear the state of all signaling protocols.

```
# on PE-3
configure
    service
        vprn 1
            shutdown
            pim shutdown
```

```
            pim ipv6-multicast-disable
            igmp shutdown
            mld shutdown
        exit
    exit
```

Step 2. Enable the VPRN service on PE-3. PE-3 immediately receives Intra-AD messages from PE-1 because the remote VPRN service is already enabled for IPv4 and IPv6 multicast propagation. The PMSI attribute is present in both messages.

```
*A:PE-3# configure service vprn 1 no shutdown
```

```

LDP Verification and Debugging

When BGP intra-AD messages are exchanged, every PE starts to build a multicast tunnel based on the following criteria:

PE nodes which are configured as **sender-only** do not distribute mLDP forward equivalence classes (FECs) to remote PEs for this MVPN.

PE nodes which are configured as receiver-only do not include the PMSI part for intra-AD messages and remote PEs do not send mLDP FECs for this MVPN.

LDP bindings can be verified using the following command:

show router ldp bindings p2mp

PE-1 (192.0.2.1) has two egress FECs due to the fact that PE-1 has the mdt-type sender-only.

```
*A:PE-1# show router ldp bindings p2mp ipv4

Conclusion

The sender-only/receiver-only feature provides significant signaling optimization in the core network for RSVP and LDP protocols and is recommended to be used when such functionality is required. The following are required before implementing this feature in the network:

- MDT-types **sender-only**, **receiver-only** and **sender-receiver** are enabled per MVPN.

- The default mdt-type is **sender-receiver** mode for backward compatibility.
- This is purely a control plane feature and there are no hardware dependencies.
- Rosen MPVN or MDT-SAFI based MVPNs are not supported.
- IPv4 and IPv6 C-signaling are supported.
- mLDP and RSVP demonstrate slightly different behavior due to the nature of each protocol.
- mLDP provides a better optimization than RSVP in all cases, as mLDP does not initiate LSPs to sender-only routers.

NG-MVPN Source Redundancy

This chapter provides information about MVPN source redundancy.

Topics in this chapter include:

Applicability

The chapter was initially written for Release 12.0.R1, using multicast LDP as the provider tunnel signaling mechanism for IPv4 multi-casting. The customer multicast signaling protocol within the VPN must be BGP. The CLI in the current edition corresponds to 15.0.R5.

Summary

Multicast source redundancy allows operators to provide multiple geo-redundant sources for the same multicast group in a multicast virtual private network (MVPN). For instance, in an IPTV environment where a TV channel maps to a multicast group, the same TV channel can be provided from sources in a geographically diverse manner where a national broadcaster can have multiple sources from two or more regional distribution centers.

Knowledge of Multi-Protocol BGP (MP-BGP) and RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, is assumed throughout this chapter, as well as Protocol Independent Multicast (PIM), RFC 6513, *Multicast in MPLS/BGP IP VPNs*, and RFC 6514, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*.

Overview

Hosts connected to receiver PEs can receive TV channels from a specific source, with a regional backup source available in case of a failure.

Figure 384: Source Redundancy Example.

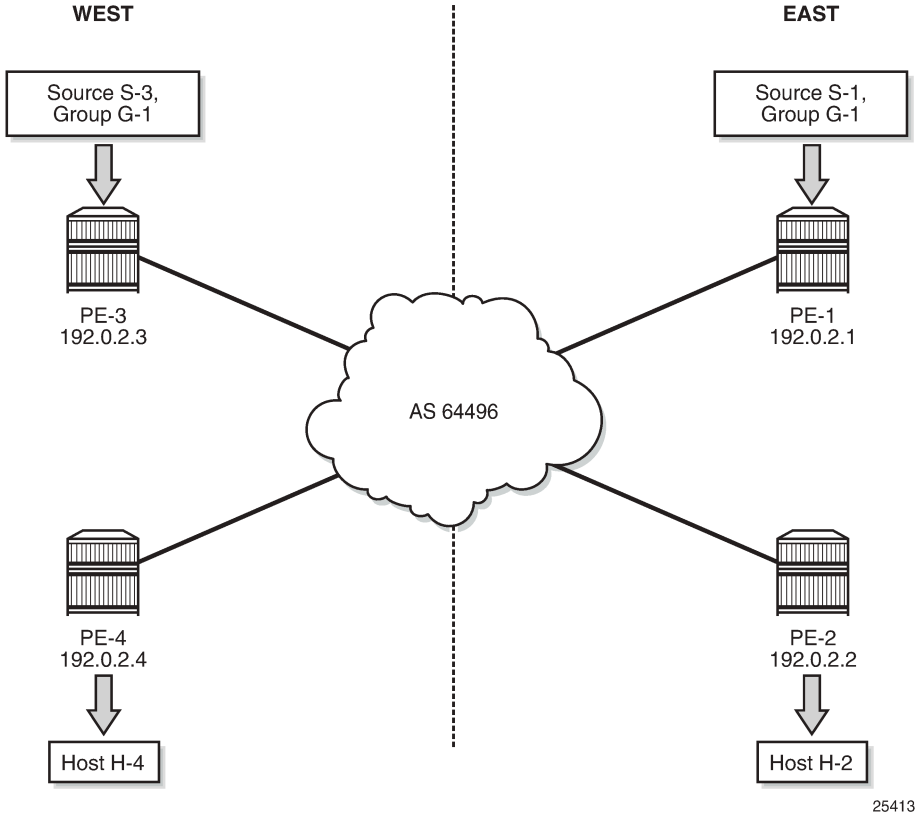

Figure 384: Source Redundancy Example. shows the concept of source redundancy. PE-1 and PE-3 have directly connected multicast sources. For clarity, consider a single multicast group with two separate sources connected at different sites. The content of each group is identical at a given time (allowing for transmission delay), as is expected for an IPTV channel. PE-1 and PE-3 are referred to as sender PEs because they are closer to the source; PE-2 and PE-4 are referred to as receiver PEs because they are closer to hosts H-2 and H-4.

A multicast group, group 1 (G-1) has two sources: Source 1 (S-1) in the east region and Source 3 (S-3) in the west region which are connected to PE-1 and PE-3 respectively. Receivers connected to PE-2 in the east region will join group (S-1,G-1) and receivers connected to PE-4 in the west region will join group (S-3,G-1). The presence of each source is declared within the multicast VPN by the sender PE. When a multicast group becomes active, a BGP Source Active auto-discovery (SA) route is advertised to all PEs within the multicast VPN. This must occur even if no receiver indicates that it wishes to become a member of this group. In other words, the SA must be persistently present in the receiver PEs when the source is available.

Should either source fail or become unavailable, then the sender PE will notify the receiver PEs by sending an NLRI unreachable BGP SA Route that declares the absence of the source. All hosts that are members of this group will then switch to receive traffic from the remaining active source. Only customer multicast joins received as IGMP (*,G) queries or PIM (*,G) joins at the receiver PE are valid, because the source address is not specified.

Source redundancy is achieved by:

- Configuring a list of redundant sources within each receiver PE.
- Configuring the sender PEs to originate a BGP Source Active Auto Discovery for each detected active multicast source, regardless of whether a receiver is joined to the multicast group or not. As a result, a Source Active route is originated on a per (S,G) basis.

  For multiple SAs to be persistently present in the receiver PEs, one of the following two conditions must be configured within the sender PEs:

  – Either disable inter-site shared trees on the sender PEs, such that there is no c-tree with root at the RP. Any active source will announce its presence using a BGP SA to all receiver PEs so no shared joins are sent by receiver PEs to RP, or

  – Leave inter-site shared trees as enabled, but configured so that the SA AD route for each multicast group is persistently present in the receiver PEs, even in the absence of requesting hosts for each group. Shared and Source Joins are sent by the receiver PEs.

  Both of the preceding options are supported. The default behavior has inter-site shared trees enabled without persistency. In this example, inter-site shared trees at the sender PEs are enabled with Source Active routes set to be persistent.
- Ensuring that the preferred source is IP reachable within the VPRN from the receiver PE. This must be a remote source advertised from a remote PE within the VPRN.
- Receiver PEs will accept the Source Active route(s) into the appropriate Multicast VRF.
- Ensuring the preferred active source should have a higher BGP Local Preference. This is achieved using a route policy. Any other sources from the redundant list should exist as suppressed standby sources, but the (S,G) state should exist if the source is active – when a valid BGP MVPN Source Active route for that source has been received.

All of these conditions are achieved by configuration.

In order to allow each receiver PE to choose a preferred source, each SA route advertised by the sender PE will be tagged with a community value. Each receiver PE can then use the community value contained within each SA route update received to set the Local Preference BGP attribute to a value such that the receiver PE can choose the most preferred active source.

The objectives are:

- To configure multicast in a VPRN on PE-1 to PE-4 with inter-site-shared trees enabled on the receiver PEs and Source Active routes persistently present, for reasons previously described.
- To connect redundant sources to the sender PE-1 and PE-3, with each multicast source having the same group address. For ease of configuration, a single redundant source is used.
- To advertise each source to the receiver PEs (PE-2 and PE-4), using appropriate route policies for adding community strings to the BGP Source Active Auto-Discovery routes.
- To configure appropriate route policies that allow each BGP SA route to have the correct Local Preference set, based on the community strings present.
- To allow receivers to connect to the appropriate source, using (*,G) joins.

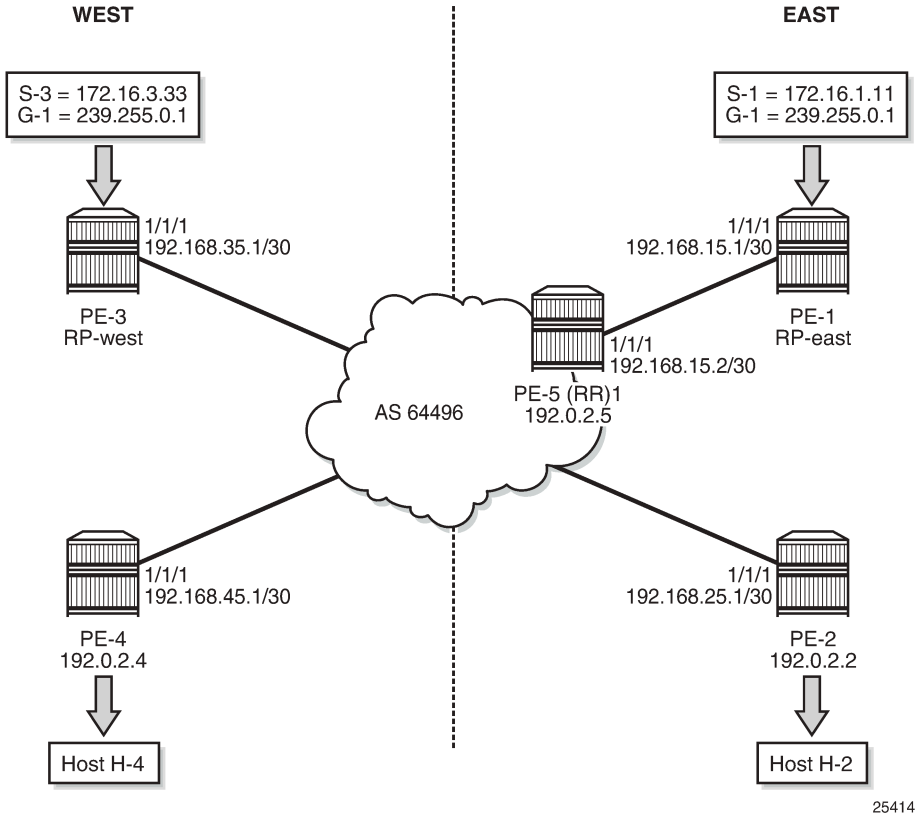
The following configuration tasks should be completed as a pre-requisite:

- Full mesh IS-IS or OSPF between each of the PE routers and the route reflector.
- Link-layer LDP between all PEs. RSVP could also be used.
- Multicast LDP is used as the provider tunnel signaling protocol. This is enabled by default when link layer LDP is enabled. RSVP and PIM SSM are also supported as provider tunnel signaling mechanisms and could be used.

Configuration

The example topology is shown in Figure 385: Schematic Topology, containing the four PEs plus the route reflector at P-5.

Figure 385: Schematic Topology



Global BGP Configuration

The first step is to configure an iBGP session between each of the PEs and the route reflector (RR) seen in Figure 385: Schematic Topology. The address families negotiated between the iBGP peers are vpn-ipv4 (unicast routing) and mvpn-ipv4 (multicast routing).The BGP configuration for all PE nodes is identical:

```
# on PE-1
configure
    router
        bgp
            group "INTERNAL"
                family vpn-ipv4 mvpn-ipv4
                type internal
                neighbor 192.0.2.5
                exit
            exit
            no shutdown
```

```
        exit
```

The configuration for the Route Reflector at P-5 is:

```
# on P-5
configure
    router
        bgp
            group "RRclients"
                family vpn-ipv4 mvpn-ipv4
                type internal
                cluster 1.1.1.1
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
```

On PE-1, verify that the BGP session with RR at P-5 is established with address families "vpn-ipv4" and "mvpn-ipv4" capabilities negotiated:

```

                            3    0           0/0/0 (MvpnIPv4)
-------------------------------------------------------------------------------
*A:PE-1#
```

The same command can be used on the other PEs to verify their BGP sessions to the RR.

Configuring VPRN on PEs

The following outputs show the VPRN configurations for each PE. The specific MVPN configuration is shown later.

PE-1

The VPRN configuration for PE-1 is as follows:

```
# on PE-1
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-1-S-1" create
                address 172.16.1.1/24
                sap 1/1/3 create
                exit
            exit
            interface "RP" create
                address 10.10.10.1/32
                loopback
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.10.10.1
                            group-prefix 239.0.0.0/8
                        exit
                    exit
                exit
                no shutdown
            exit
        exit
```

There is a single interface toward S-1 from which the multicast group is generated.

If the customer signaling uses PIM ASM, then the customer Rendezvous Point (RP) must be positioned on the sender PE because registration of the source with the RP causes the SA to be sent to the remote source PEs.

A loopback interface called *"RP"* acts as the RP for all group prefixes in the 239.0.0.0/8 range. This will be the RP for the East groups.

PE-2

PE-2 has a receiver attached, and a single interface is configured to accommodate this. The RP configured is that of the East region and has a configuration as follows:

```
# on PE-2
configure service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
```

```
                ldp
            exit
            resolution filter
        exit
        vrf-target target:64496:1
        interface "int-PE-2-H-2" create
            address 172.16.2.1/24
            sap 1/1/3 create
            exit
        exit
        igmp
            interface "int-PE-2-H-2"
            exit
        exit
        pim
            apply-to all
            rp
                static
                    address 10.10.10.1
                        group-prefix 239.0.0.0/8
                    exit
                exit
            exit
            no shutdown
        exit
    exit
```

PE-3

PE-3 serves as the RP for the West region and uses a different IP address for the Rendezvous Point interface.

```
# on PE-3
configure service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-3-S-3" create
                address 172.16.3.1/24
                sap 1/1/3 create
                exit
            exit
            interface "RP" create
                address 10.10.10.3/32
                loopback
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.10.10.3
                            group-prefix 239.0.0.0/8
                        exit
                    exit
                exit
                no shutdown
            exit
```

```
        exit
```

PE-4

PE-4 also has a receiver, and uses the West sender PE (PE-3) as the Rendezvous Point.

```
# on PE-4
configure service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-4-H-4" create
                address 172.16.2.1/24
                sap 1/1/3 create
                exit
            exit
            igmp
                interface "int-PE-4-H-4"
                exit
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.10.10.3
                            group-prefix 239.0.0.0/8
                        exit
                    exit
                exit
                no shutdown
            exit
        exit
```

MVPN Configuration for Source PEs

At the PEs closest to the sources (PE-1 and PE-3), Source Active auto-discovery BGP routes are generated when the source is active.

This applies for PIM-ASM (*,G) joins only, or IGMP (*,G) membership queries received by the provider domain. These are received by all PEs.

Inter-site trees must be disabled for this to occur. Alternatively, inter-site trees can be enabled such that when a source is discovered, a Source Active is advertised to each other PE in the MVPN. This occurs regardless of whether any receivers wish to become members of the multicast groups.

As previously stated, the presence of the SA in the receiver PEs means that no shared joins routes are generated toward the C-RPs.

The MVPN configuration enables BGP as both auto-discovery mechanism and the customer multicast signaling protocol across the VPRN. The provider tunnel between PEs within the MVPN is signaled using Multicast LDP.

The MVPN configuration for each PE should be as follows:

```
# on PE-1
configure
    service
        vprn 1
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                    exit
                exit
            exit
```

The VPRN MVPN configuration for PE-2, PE-3, and PE-4 is identical.

Sender PE Route Policies

The choice of active and standby sources by the receiver PEs is determined by the "best route" policy. PE-1 and PE-3 advertise BGP Source Active Auto Discovery routes when a source is active. This is received by all PEs within the MVPN. As two different sources advertise the same group, it is necessary to differentiate between them.

Assuming that receiver PE-2 prefers the source from PE-1, and PE-4 prefers the source active on PE-3, then the export policy for MVPN routes on PE-1 requires the following steps:

1. Set a community value at PE-1 for the (S,G) multicast group – call this "blue" with value 64496:11.
2. Set the route target community for the VPRN – 64496:1.
3. Create a policy statement that becomes the export policy for MVPN routes within PE-1.
4. Create a policy statement entry (entry 10) that adds the community value "blue" along with the route target for Source Active AD BGP routes. Source Active AD routes are MVPN type 5 routes.
5. Create a policy statement entry default-action that adds the route target for all other MVPN AD BGP routes (such as Intra-AD (type 1)) that are exported to the MVPN PEs.

```
# on PE-1
configure
    router
        policy-options
            begin
            community "blue" members "64496:11"
            community "MVPN1_RT" members "target:64496:1"
            policy-statement "MVPN1_export"
                entry 10
                    description "match MVPN routes - type 5 Source AD -
                                 add RT and 'blue' community"
                    from
                        mvpn-type 5
                        family mvpn-ipv4
                    exit
                    action accept
                        community add "blue" "MVPN1_RT"
                    exit
                exit
```

```
                default-action accept
                    community add "MVPN1_RT"
                exit
            exit
            commit
        exit
```

6. Apply as an export policy within the MVPN context.

The import policy requires that all imported MVPN BGP routes have the correct route target extended community value, specifically "target:64496:1".

1. Create a policy statement that becomes the import policy for PE-1.
2. Create a policy statement entry (entry 10) that matches the community of the route target extended community for all MVPN BGP routes. These include the Intra-AD and Source-Join routes.

```
# on PE-1
configure
    router
        policy-options
            begin
                policy-statement "MVPN1_import"
                    entry 10
                        from
                            community "MVPN1_RT"
                        exit
                        action accept
                        exit
                    exit
                exit
            commit
        exit
```

Enable the inter-site-shared type 5 advertisement persistency so that source ADs are advertised when multicast sources are active. Alternatively, inter-site shared trees can be disabled using the **no intersite shared** command. In this example, only inter-site shared MVPN type 5 persistency is shown.

The additional configuration in the MVPN context is as follows, where the PIM instance must be shut down when the intersite-shared configuration is modified.

```
# on PE-1
configure
    service
        vprn 1
            mvpn
                intersite-shared persistent-type5-adv
                vrf-import "MVPN1_import"
                vrf-export "MVPN1_export"
            exit
```

For PE-3 (the other sender PE), similar import and export policies are required. In this case, the community will be called "red" and is added to the Source Active AD route generated when the source is active.

The requirements for the export policy for PE-3 are as follows:

```
# on PE-3
configure
    router
        policy-options
            begin
            community "red" members "64496:33"
```

```
            community "MVPN1_RT" members "target:64496:1"
            policy-statement "MVPN1_export"
                entry 10
                    description "match MVPN routes - type 5 Source AD -
                                 add RT and 'red' community"
                    from
                        mvpn-type 5
                        family mvpn-ipv4
                    exit
                    action accept
                        community add "red" "MVPN1_RT"
                    exit
                exit
                default-action accept
                    community add "MVPN1_RT"
                exit
            exit
            commit
        exit
```

The import policy is exactly the same as for PE-1.

Apply the import and export policies to the MVPN context of the sender PE (PE-3) and enable inter-site-shared type 5 advertisement persistency with the same command as on PE-1.

Receiver PE Configuration

PE-2 and PE-4 are the receiver PEs. These will receive the Source Active AD routes and initiate Joins toward the preferred source.

When a Source-Active AD route is received, the community value is examined and the Local Preference value of the route is set using a Route Policy. The preferred source is determined by the SA AD route with the highest Local Preference value.

In the case of PE-2, the preferred source is that advertised by PE-1, the "blue" source as previously referenced. PE-2 sets the Local Preference to 200. The SA AD tagged with the "red" community has the Local Preference set to 50.

For PE-4, the reverse applies: SA AD routes tagged with the "red" community have the Local Preference set to 200, and "blue" SA AD routes have the Local Preference set to 50.

Once again, assuming that the PE-2 receiver prefers the source from PE-1 and PE-4 prefers the source active on PE-3, the import policy for MVPN routes on PE-2 requires the following steps:

1. Set a community value at PE-2 for the (S,G), call this "blue" with value 64496:11.
2. Set the route target community for the VPRN to 64496:1.
3. Create a prefix list that matches the multicast group address, in this case 239.255.0.0/24.
4. Create a policy statement that becomes the import policy for MVPN routes within PE-1.
5. Create a policy statement entry (entry 10) that matches the following attributes:
   - Source Active AD BGP routes type. Source Active AD routes are classed as MVPN type 5 routes, and
   - Community value "blue" AND Route Target extended community, and
   - Group address prefix 239.255.0.0/24

   If the BGP route matches all three conditions, then set the Local Preference to 200.

6. Create a policy statement default-action that accepts all other MVPN BGP routes, including SA routes tagged with the “red” community value.

   The import policy statement looks like:

```
# on PE-2
configure
    router
        policy-options
            begin
            prefix-list "group_239.255.x.y"
                prefix 239.255.0.0/16 longer
            exit
            community "red" members "64496:33"
            community "blue" members "64496:11"
            community "MVPN1_RT" members "target:64496:1"
            policy-statement "MVPN1_import"
                entry 10
                    description "allow MVPN source-ad - set LP to 200 for 'blue'"
                    from
                        community expression "[blue] AND [MVPN1_RT]"
                        mvpn-type 5
                        group-address "group_239.255.x.y"
                    exit
                    action accept
                        local-preference 200
                    exit
                exit
                entry 20
                    description "allow MVPN source-ad - set LP to 50 for 'red'"
                    from
                        community expression "[red] AND [MVPN1_RT]"
                        mvpn-type 5
                        group-address "group_239.255.x.y"
                    exit
                    action accept
                        local-preference 50
                    exit
                exit
                default-action accept
                exit
            exit
            commit
```

   The export policy for PE-2 MVPN routes requires each MVPN route to be tagged with the route target extended community for VPRN 1. The following policy statement is created:

```
# on PE-2
configure
    router
        policy-options
            begin
            policy-statement "MVPN1_export"
                entry 10
                    from
                        family mvpn-ipv4
                    exit
                    action accept
                        community add "MVPN1_RT"
                    exit
                exit
            exit
```

```
            commit
```

7. Create a list of redundant sources. This is a list of prefixes that match the source addresses of redundant multicast groups. This is an important parameter because the receiver PEs only create active and standby (S,G) states for groups with source address prefixes that are contained in this list.
8. Before any hosts attempt to join the multicast groups, the decision must be made to enable or disable inter-site shared trees at the receiver PEs. In this example, only the Inter-site shared trees disabled option will be considered. In order to make this configuration change, it is necessary to shut the PIM protocol down before and re-enable when completed.

The additional MVPN configuration for PE-2 is shown in the following output, where the redundant source prefix list is included, and inter-site shared trees are disabled.

```
# on PE-2
configure
    service
        vprn 1
            mvpn
                no intersite-shared
                red-source-list
                    src-prefix 172.16.1.0/24
                    src-prefix 172.16.3.0/24
                exit
                vrf-import "MVPN1_import"
                vrf-export "MVPN1_export"
            exit
```

PE-4 requires a similar set of import and export policies. In this case, the "red" sources have the highest Local Preference value, based on the community string added by the export policy of PE-3.

```
# on PE-4
configure
    router
        policy-options
            begin
            prefix-list "group_239.255.x.y"
                prefix 239.255.0.0/16 longer
            exit
            community "red" members "64496:33"
            community "blue" members "64496:11"

The export policy for MVPN routes adds the route target extended community. It is exactly the same export policy as for PE-2.

The additional MVPN configuration for VPRN 1 on PE-4 is identically the same as for PE-2.

Each PE within the MVPN originates an Intra-AD BGP route. This notifies the other PEs within the VPRN. This is used to create a set of Inclusive Provider Multicast Service Interfaces (I-PMSI) between each PE. In this case, I-PMSIs are signaled using mLDP.

Using PE-1 as an example, the set of Intra-AD routes can be seen using the following command:

```
*A:PE-1# show router bgp routes mvpn-ipv4
===============================================================================

Routes : 1
===============================================================================
*A:PE-2#
```

This prefix is advertised with three communities:

- A route target extended community
- An l2-vpn/vrf-import extended community.
- A source-AS extended community (not used in Intra-AS context).

The l2-vpn/vrf-import extended community is significant as it is a unique value. It represents a specific MVPN on a specific PE and is comprised of a 32 bit value that identifies the PE plus an index identifying the VRF. The 32 bit value is the system address. The index (3) can be derived from the command:

```
*A:PE-2# admin display-config index | match vprn1
        virtual-router "vprn1" 2 0
*A:PE-2#
```

Therefore, the l2-vpn/vrf-import community for VPRN 1 on PE-1 is 192.0.2.1:2

This community attribute is included within the source-join BGP route that is sent in a BGP update by a receiver PE as it tries to join a multicast group with a source address that matches the 172.16.1.0/24 prefix. This ensures that the source-join route is only accepted as a valid route and imported by the PE that originated the source address prefix. This is explained in the following section.

Enable Redundant Sources

The redundant sources are now enabled so that multicast traffic flows into both PE-1 and PE-3, using groups (S-1,G-1) and (S-3,G-1), respectively.

On each of these PEs, a source active AD route is generated. By examining each receiver PE, these can be clearly seen.

For PE-2, the source active AD routes can be seen using the following command.

```
*A:PE-2# show router bgp routes mvpn-ipv4 type source-ad

239.255.0.1                 (S,G)                       int-PE-3-S-3   0
   172.16.3.33                10.10.10.3
-------------------------------------------------------------------------------
Groups : 2
===============================================================================
*A:PE-3#
```

By examining the receiver PE-2, it can be seen that the Source AD route for (S,G) (172.16.1.2, 239.255.0.1) from PE-1 has a higher local preference so it is chosen as the preferred (active) source. Examining these routes in more detail shows that each route is tagged with two communities: the route target extended community and the "red" or "blue" community, as seen in the following output.

```
*A:PE-2# show router bgp routes mvpn-ipv4 type source-ad hunt
===============================================================================
 BGP Router ID:192.0.2.2        AS:64496       Local AS:64496

===============================================================================
*A:PE-4#
```

Host Group Membership

If the hosts then send a (*,G) request to join the group, a source-join route is originated by each receiver PE toward the preferred source from the redundant list.

The following output shows a join originated by PE-2:

```
*A:PE-2# show debug
debug
    router "Base"
        bgp
            update neighbor 192.0.2.5
        exit
    exit
exit
```

```
3 2017/10/12 10:08:34.595 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE

        target:192.0.2.1:2
"
```

When an active source AD route is present, there is no shared join sent to the RP. Because the source address is known, only a source-join needs to be sent. The source-join is trying to become a member of group 239.255.0.1 with a source address of 172.16.1.11. As this is sent as a BGP routing update, this must be accepted by the MVPN VRF at the PE that originated the unicast route that represents the c-multicast source. As previously mentioned, there are two extended community values. The second of these is the l2-vpn/vrf-import route target for 192.0.2.1 (PE-1), so only PE-1 will accept this route.

Examining the PIM state table for PE-2 shows the presence of a group with multiple sources.

```
*A:PE-2# show router 1 pim group

===============================================================================
Legend:  A = Active   S = Standby
===============================================================================

Sender PE MVPN Status

The MVPN status of the PE-1 sender PE is as follows:

```
*A:PE-1# show router 1 mvpn

===============================================================================
MVPN 1 configuration data
===============================================================================
signaling          : Bgp                  auto-discovery     : Default
UMH Selection      : Highest-Ip           SA withdrawn       : Disabled
intersite-shared   : Enabled              Persist SA         : Enabled
vrf-import         : MVPN1_import
vrf-export         : MVPN1_export
vrf-target         : N/A
C-Mcast Import RT  : target:192.0.2.1:2

ipmsi              : ldp
i-pmsi P2MP AdmSt  : Up
i-pmsi Tunnel Name : mpls-if-73729
Mdt-type           : sender-receiver

BSR signalling     : none
Wildcard s-pmsi    : Disabled
Multistream-SPMSI  : Disabled
s-pmsi             : none
data-delay-interval: 3 seconds
enable-asm-mdt     : N/A

===============================================================================
*A:PE-1#
```

The C-Mcast Import RT is set to <system-address>:<VPRN index>.

The VPRN index is derived from the following command:

```
*A:PE-1# admin display-config index | match vprn1
        virtual-router "vprn1" 2 0
*A:PE-1#
```

Any Source Join received must include this attribute along with the route target extended community. As previously stated, this is advertised within the VPN-IPv4 routes as a BGP attribute.

A source join received from PE-2 to join (S,G) (172.16.1.2, 239.255.0.1) is as follows:

```
*A:PE-1# show router bgp routes mvpn-ipv4 type source-join hunt
===============================================================================
 BGP Router ID:192.0.2.1        AS:64496       Local AS:64496
===============================================================================

*A:PE-3#
```

The preferred source remains active unless:

- The multicast source ceases to exist, the source PE withdraws the Source Active AD route
- Or a Source Active AD is received with a higher local preference.

Conclusion

MVPN Source Redundancy provides an optimal solution for multicast routing in a VPRN. This protocol provides simple configuration, operation and guaranteed fast protection time. It could be utilized in a regionalized IPTV solution where multiple sources for the same TV channel are used.

NG-MVPN Wildcard S-PMSI

This chapter provides information about next generation multicast virtual private networks (NG-MVPNs): use of wildcard selective PMSI.

Topics in this chapter include:

Applicability

The chapter was initially written based on SR OS Release 13.0.R4, but the CLI in the current edition is based on Release 15.0.R5.

MPLS provider tunnels can be set up using multicast label distribution protocol (mLDP) or point-to-multipoint (P2MP) resource reservation protocol with traffic engineering (RSVP-TE) label switched paths (LSPs). SR OS Release 12.0.R4 or later is required for route reflectors (RRs) peering with multicast virtual private network (MVPN) PEs.

Provider multicast service interfaces (PMSIs) are signaled using mLDP. PE MVPN auto-discovery uses BGP MVPN IPv4 network layer routing.

Knowledge of multi-protocol BGP (MP-BGP), RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, RFC 6513, *Multicast in MPLS/BGP IP VPNs*/RFC 6514, *BGP Encodings and Procedures for Multicast in MPLS/BGP IP VPNs*, and RFC 6625, *Wildcards in Multicast VPN Auto-Discovery Routes*, is assumed throughout this chapter.

Overview

Consider a service provider core network used to deliver multicast services to a number of receiver PEs using Next Generation MVPN techniques, as defined in RFC 6513/6514, where multicast traffic is forwarded between PEs across a mesh of provider tunnels.

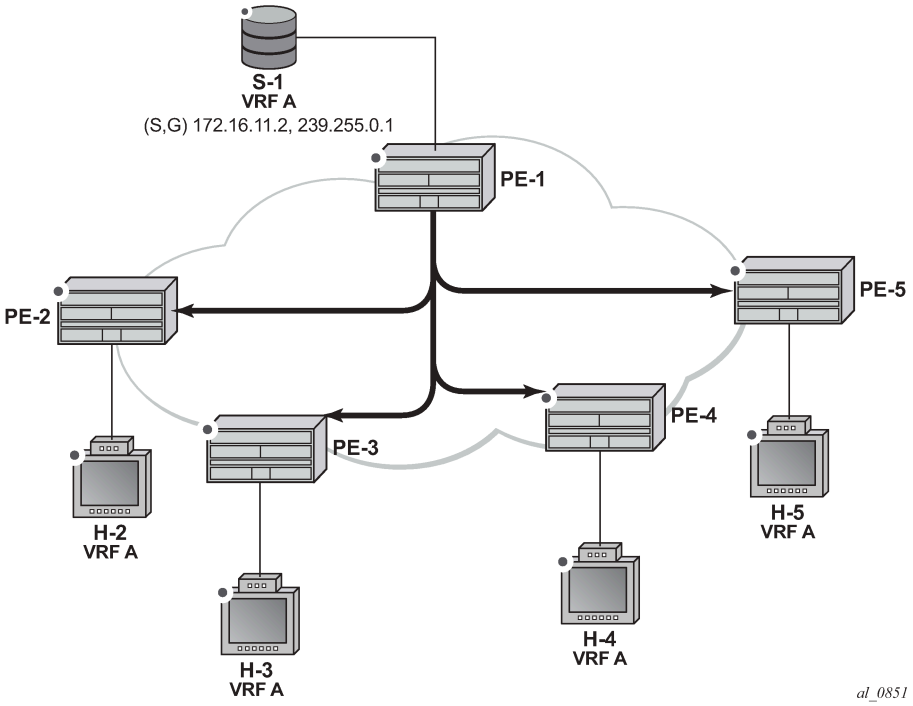
The provider tunnel used is the default Inclusive PMSI (I-PMSI) that is instantiated between all source and receiver PEs. This results in a full mesh of provider tunnels between all PEs in the MVPN. In a large network, this can result in an inefficient use of bandwidth because multicast traffic is forwarded to all PEs regardless of whether the PE has an interested receiver. Some of the mesh scaling issues can be mitigated by using source-only/destination-only configuration on PEs. However, this technique requires additional configuration and is not fully optimal when mLDP is used in the core.

To address the preceding limitation, wildcard Selective PMSI (S-PMSI) has been developed, as per RFC 6625. In the standard customer signaling notation of (C-S,C-G), this becomes (C-*,C-*). Using methods defined in RFC 6625, it is possible to use a (C-*,C-*) S-PMSI as the default tunnel, where the receiver PE can join the S-PMSI by mapping the channel join to a wildcard channel group. Multiple channels can be transported by the wildcard (C-*,C-*) S-PMSI, where an S-PMSI auto-discovery route is advertised with an empty channel group and source address:

1. Bandwidth savings can be achieved by the delivery of multicast channels on S-PMSIs, because traffic is not forwarded to PEs that have no interested receivers.
2. Control plane savings can be achieved by eliminating the need for the full tunnel mesh between all PES. The wildcard S-PMSI is only signaled on PEs containing attached upstream multicast sources, for which the PE is resolved as an upstream multicast hop (UMH) within the MVPN.

Figure 386: Multicast VPN shows the concept of an MVPN.

Figure 386: Multicast VPN



In Figure 386: Multicast VPN, PE-1 has a directly connected multicast source (S-1). For clarity, consider this MVPN as a single multicast group. PE-1 is configured as a sender PE because it is the PE closest to the source. PE-2, PE-3, PE-4, and PE-5 are configured as receiver-only PEs because they have connected receiver hosts H-2, H-3, H-4, and H-5, respectively. Hosts H-2 to H-5 connected to receiver PEs can receive multicast channels from the source, S-1, connected to the source PE, PE-1, within the same virtual private routed network (VPRN).

Within the provider network, multicast traffic is delivered from the source PE to the receiver PE across a PMSI tunnel. This tunnel is, in this case, a P2MP LSP, with its root at PE-1 and with a leaf at each of the receiver PEs. Any traffic that is forwarded into the tunnel interface is replicated so that a single copy of a multicast stream is received at all PEs.

The PMSI tunnel is created after each PE has declared themselves as a member of the MVPN using BGP MVPN auto-discovery techniques.

There are two choices of PMSI:

- An I-PMSI, which is created on each PE within the MVPN, with a root at each PE and a leaf at all other PEs that are members of the MVPN. The I-PMSI is the default tunnel for all multicast traffic carried between sender PE and receiver PEs. When at least one receiver PE has a host interested in becoming

a member of a multicast group, traffic for that group is delivered to all PEs via the I-PMSI, regardless of whether they have an interested host. Receiver PEs with no such interested host then drop the traffic.

- An S-PMSI, which is created to carry multicast traffic to the subset of receiver PEs that have connected hosts interested in receiving multicast traffic. This can be for a specific group, so that one S-PMSI carries traffic for one multicast group, denoted as (C-S,C-G) or (C-*,C-G). The S-PMSI can also be signaled to carry traffic for multiple multicast groups, denoted using a wildcard: (C-*,C-*) or (C-S,C-*). The wildcard S-PMSI can be signaled in place of the I-PMSI, so that all traffic can be carried on the S-PMSI by default. In this case, no I-PMSI is signaled.

In the case of an I-PMSI, the tunnel type is included in the BGP auto-discovery intra-AD route originated and advertised to all other PEs within the VPRN.

If a wildcard S-PMSI is to be used and no I-PMSI tunnel is to be signaled, then an intra-AD route update for I-PMSI is advertised with no tunnel type attribute included. In addition, the source PE will originate an additional S-PMSI auto-discovery route containing no source-encoding wildcard information.

Table 23: S-PMSI Auto-Discovery BGP NLRI shows the S-PMSI MVPN BGP network layer reachability information (NLRI) advertisement.

Table 23: S-PMSI Auto-Discovery BGP NLRI

Route Distinguisher (8 octets)
Multicast Source Length (1 octet)
Multicast Source (variable)
Multicast Group Length (1 octet)
Multicast Group (variable)
Originating Router IP Address

To signal the S-PMSI as wildcard (C-*,C-*) S-PMSI, the multicast source length and multicast group length fields are encoded with the value of zero (0), representing (C-*,C-*) wildcard.

The objectives are to:

- Configure multicast in a VPRN on PE-1 to PE-5 using mLDP as the tunnel signaling method.
- Connect multicast sources to the sender PE-1.
- Create receiver hosts that can receive multicast traffic from the source, and to observe the effect on the provider network.

The following configuration tasks should be completed as a prerequisite:

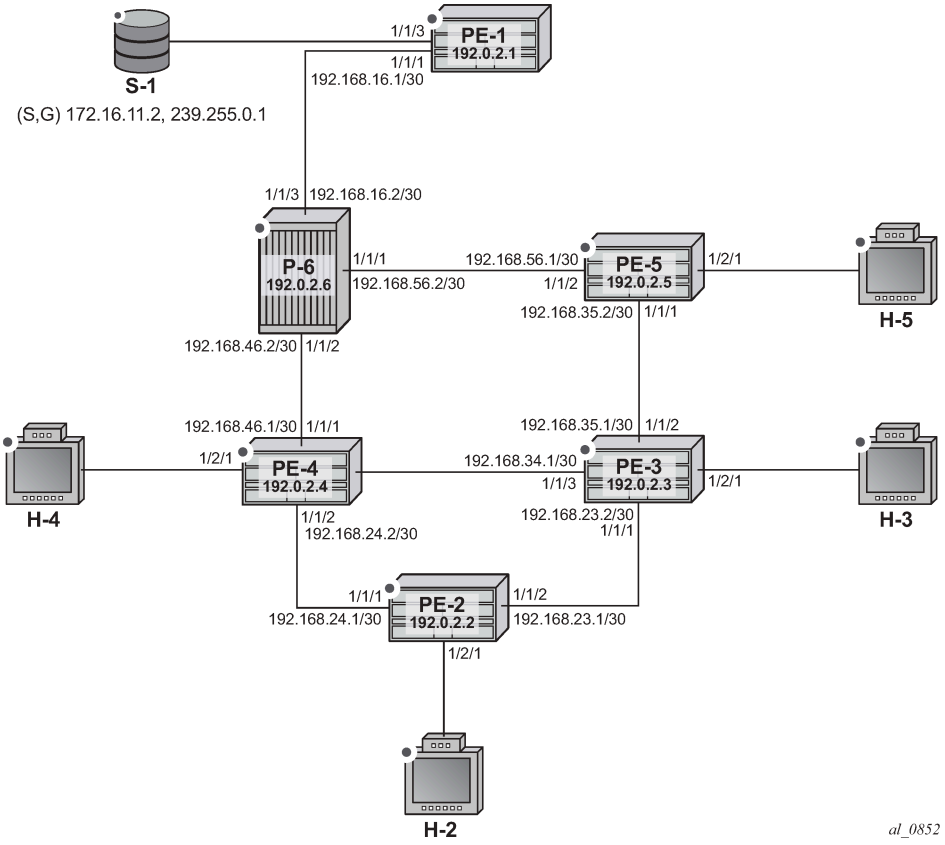
- Full mesh IS-IS or OSPF between each of the PE routers and the RR.
- Link-layer LDP between all PEs.
- mLDP used as the provider tunnel signaling protocol. This is enabled by default when link-layer LDP is enabled.

RSVP-TE is also supported as a provider tunnel signaling mechanism and could be used instead of mLDP.

Configuration

The example topology is shown in Figure 387: Schematic Topology, containing five PE routers. P-6 acts as an RR.

Figure 387: Schematic Topology



Global BGP Configuration

The first step is to configure an IBGP session between each of the PEs and the RR (PE-6) shown in Figure 387: Schematic Topology. The address families negotiated between the IBGP peers are vpn-ipv4 (unicast routing) and mvpn-ipv4 (multicast routing).

The configuration for PE1 is:

```
configure
    router
        bgp
            group INTERNAL
                family vpn-ipv4 mvpn-ipv4
                type internal
                neighbor 192.0.2.6
            exit
        exit
```

The configuration for the other PE nodes is exactly the same.

The configuration for the RR at P-6 is:

```
configure
    router
        bgp
            cluster 0.0.0.1
            group "RR_CLIENTS"
                family vpn-ipv4 mvpn-ipv4
                type internal
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
                neighbor 192.0.2.5
                exit
            exit
```

On PE-1, verify that the BGP session with RR at P-6 is established with address families vpn-ipv4 and mvpn-ipv4 capabilities negotiated:

```

```

The same command can be used on the other PEs to verify their BGP sessions to the RR.

Configuring VPRN on PEs

The following outputs show the VPRN configurations for each PE. The specific MVPN configuration is shown later.

The VPRN configuration for PE-1 is:

```
# on PE-1
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 65545:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:65545:1
            interface "int-PE-1-S-1" create
                address 172.16.11.1/24
                sap 1/1/3 create
                exit
            exit
            interface "rp" create
                address 10.0.0.1/32
                loopback
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.0.0.1
                            group-prefix 239.255.0.0/16
                        exit
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

There is a single interface toward S-1 from which the multicast group is transmitted.

If the customer signaling uses PIM ASM, a customer Rendezvous Point (RP) is required.

A loopback interface called "rp" acts as the RP for all group prefixes in the 239.255.0.0/16 range. This will be the RP for all groups.

MVPN configuration enables BGP as both the auto-discovery mechanism and the customer multicast signaling protocol across the VPRN. The provider tunnel between PEs within the MVPN is signaled using mLDP.

PE-2 contains an attached receiver, therefore a single interface is configured to accommodate this, as follows. The RP is configured as a static RP:

```
# on PE-2
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 65545:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:65545:1
            interface "int-PE-2-H-2" create
```

```
                address 172.16.22.1/24
                sap 1/2/1 create
                exit
            exit
            igmp
                interface "int-PE-2-H-2”
                    no shutdown
                exit
                no shutdown
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.0.0.1
                            group-prefix 239.255.0.0/16
                        exit
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

PE-3 also has an attached receiver, as follows:

```
# on PE-3
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 65545:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:65545:1
            interface "int-PE-3-H-3" create
                address 172.16.33.1/24
                sap 1/2/1 create
                exit
            exit
            igmp
                interface "int-PE-3-H-3"
                    no shutdown
                exit
                no shutdown
            exit
            pim
                apply-to all
                rp
                    static
                        address 10.0.0.1
                            group-prefix 239.255.0.0/16
                        exit
                    exit
                exit
                no shutdown
            exit
            no shutdown
```

The configuration for PE-4 and PE-5 is similar.

MVPN Configuration for PEs

The provider-tunnel inclusive configuration specifies that a wildcard S-PMSI will be used instead of an I-PMSI as the default PMSI. The MVPN configuration for all PEs is:

```
# on all PE's
configure
    service
        vprn 1
            mvpn
                auto-discovery default
                c-mcast-signaling bgp
                provider-tunnel
                    inclusive
                        mldp
                            no shutdown
                        exit
                        wildcard-spmsi
                    exit
                exit
                vrf-target unicast
                exit
            exit
```

The keyword **wildcard-spmsi** reduces the number of PMSIs signaled. If there are no group sources on the receiver PEs, there will be no S-PMSI signaled. This has an effect similar to configuring the receiver PEs as MDT-type receiver-only.

Provider Tunnel Signaling

Each PE originates BGP MVPN intra-AD routes to determine membership of an MVPN.

The provider tunnels constructed between the PEs within the VPRN are signaled on receipt of an intra-AD route update from other PEs. The intra-AD update message contains details of the originator, along with the VRF route-target extended community. If an I-PMSI is to be signaled, a PMSI tunnel attribute is included that determines the tunnel type, such as LDP P2MP LSP. PEs that receive this intra-AD update will import the route into the MVPN, then signal a P2MP LDP label map toward the originator, which is the root of the LDP P2MP LSP.

However, if a wildcard S-PMSI is to be used as the default PMSI, no PMSI tunnel attribute is included within the intra-AD update.

The following output shows a BGP update originated by PE-1, and received by PE-2:

```
*A:PE-2# show router bgp routes mvpn-ipv4 type intra-ad rd 65545:1 detail
                                                        originator-ip 192.0.2.1

===============================================================================
*A:PE-1#
```

Instead of an I-PMSI being signaled, an S-PMSI AD route update is advertised by PE-1 to all receiver PEs within the MVPN. The NLRI encoding has a zero length field for both source and group addresses, so is seen to represent multicast group (C-*,C-*). This is wildcard nomenclature for both source and group addresses.

The BGP route as advertised by PE-1:

```
*A:PE-1# show router bgp routes mvpn-ipv4 type spmsi-ad rd 65545:1 hunt
===============================================================================

===============================================================================
*A:PE-1#
```

At this point, there is no interested host and no customer multicast flow (c-flow), so there is no S-PMSI LDP P2MP LSP signaled.

Data Transmission at Source PE

Multicast traffic for a particular group will be forwarded between the sender and receiver PE over a provider tunnel (PMSI). Because there is no default I-PMSI present, the receiver PE has to choose an S-PMSI to be used for forwarding, based on the NLRI contained within the S-PMSI AD routes.

The provider tunnel is signaled using a P2MP LDP label mapping message toward the root address signaled in the wildcard S-PMSI AD BGP update message. As previously shown, the update message is based on whether traffic is being forwarded on the shared or source-based shortest path tree.

When joining the shared tree, a c-multicast shared-join is sent toward the appropriate PE, which represents the UMH toward the RP. The UMH is chosen from the unicast route that represents the RP address. When joining the shortest path tree, a source-join c-multicast route is sent toward the UMH chosen from the unicast route that represents the actual source address. In both cases, the VPN-IPv4 unicast route advertises a VRF route import community that contains the system address as a next hop. Upon receipt of these updates, the UMH PE will forward traffic along the signaled wildcard S-PMSI.

Each S-PMSI is bound to one or more flows, as determined by the NLRI contained within the S-PMSI BGP update. The use of the wildcard within the BGP update to replace the c-source and c-group allows multiple flows to be bound to a single provider tunnel.

Traffic will only be forwarded upon reception of a BGP MVPN source-join or shared-join BGP route at the sender PE.

Data Reception at Receiver PE

When the sender PE has originated an S-PMSI AD route update, each receiver PE will install the route into its VRF. The S-PMSIs installed are used to select an appropriate upstream multicast router for a c-flow when an attached receiver is interested in receiving traffic from that c-flow.

The receiver PE will receive a flow based on the best match of the incoming (C-S,C-G) or (C-*,C-G) IGMP/MLD or PIM join.

If an IGMP/MLD group membership query or PIM join is received by the receiver PE over an attachment circuit for a group, the contained (C-S,C-G) or (C-*,C-G) must match the (C-S,C-G) contained within any installed S-PMSI AD route. In the case of the wildcard S-PMSI being the only installed NLRI, this will be a match; that is, incoming (C-*,C-G) or (C-S,C-G) will match the S-PMSI (C-*,C-*).

In this example, the c-group flow is 239.255.0.1.

Traffic Flow

A traffic stream representing a c-flow is enabled on PE-1: group address 239.255.0.1 with source address of 172.16.11.2. The RP for this group is found locally on PE-1. The outgoing interface list is empty:

```
*A:PE-1# show router 1 pim group detail

===============================================================================
*A:PE-1#
```

A host connected to PE-2 sends a (C-*,C-G) IGMP v2 group membership query for group 239.255.0.1.

PE-2 sends a BGP MVPN shared-join route update toward PE-1, where the RP address of the group 10.0.0.1 is found.

The following debug output from PE-2 shows the shared-join BGP route update transmitted by PE-2:

```
1 2017/10/11 12:05:18.893 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.6
"Peer 1: 192.0.2.6: UPDATE
Peer 1: 192.0.2.6 - Send BGP UPDATE:
    Withdrawn Length = 0

===============================================================================
*A:PE-1#
```

When traffic is received on the shared tree by PE-2, the source address is learned, so a source-join BGP route update is sent toward the UMH PE, which contains the source address of 172.16.11.2. The UMH is chosen from the unicast route-table using a lookup for the best route matching the source address.

The following debug output from PE-2 shows the BGP source-join route update toward the source of group 239.255.0.1, as transmitted by PE-2:

```
3 2017/10/11 12:05:47.191 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.6
"Peer 1: 192.0.2.6: UPDATE

*A:PE-3#
```

A static IGMPv2 (*,G) group is created on interface int-PE-3-H3 for group 239.255.0.1 toward PE-3. The following debug output shows the process.

```
4 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 vprn1 IGMP[vprn1 inst 2]
"IGMP[vprn1 inst 2]: igmpIfSGStaticAdd
Adding Static SG (0.0.0.0,239.255.0.1) to IGMP interface int-PE-3-H-3 [ifIndex 5]"

5 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 vprn1 IGMP[vprn1 inst 2]
"IGMP[vprn1 inst 2]: igmpIfGroupAdd
Adding 239.255.0.1 to IGMP interface int-PE-3-H-3 [ifIndex 5] database"

6 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 vprn1 IGMP[vprn1 inst 2]
"IGMP[vprn1 inst 2]: igmpProcessGroupRec
Process group rec CHG_TO_EXCL received on interface int-PE-3-H-3 [ifIndex 5]
                           for group 239.255.0.1 in mode INCLUDE. Num srcs 0"

7 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 vprn1 IGMP[vprn1 inst 2]
"IGMP[vprn1 inst 2]: igmpIfSrcAdd
Adding i/f source entry for interface int-PE-3-H-3 [ifIndex 5] (*,239.255.0.1)
                           to IGMP fwdList Database, redir if N/A"
```

A similar process takes place when receiver host H-3 sends an unsolicited IGMP v2 group membership query for this group. The first message would correspond to the IGMP query instead.

After the IGMP interface source entry has been added for interface int-PE-3-H-3, an mLDP P2MP label mapping message is sent from PE-3 toward the root node PE-1, as follows:

```
8 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 Base LDP
"LDP: Binding
Sending Label mapping label 262136 for P2MP: root = 192.0.2.1, T: 1, L: 4,
 TunnelId: 8193 to peer 192.0.2.4:0."

9 2017/10/11 11:32:30.123 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 618) to 192.0.2.4:0
Protocol version = 1
Label 262136 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"
```

BGP shared-join and source-join BGP route updates are sent via the RR toward the RP (source = 10.0.0.1) and the actual source (172.16.11.2), respectively:

```
10 2017/10/11 11:32:30.124 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.6

Conclusion

MVPN wildcard Selective PMSI (S-PMSI), developed as per RFC 6625, provides an optimal solution for multicast routing in a VPRN. This protocol provides simple configuration, operation, and fast protection time in conjunction with MPLS and LDP fast-failover schemes. Wildcard S-PMSI can be used in a multicast network to avoid a large full mesh of an I-PMSI.

Rosen MVPN Core Diversity

This chapter provides information about Rosen multicast virtual private network (MVPN) core diversity.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 13.0.R4, using Rosen MVPN. The CLI in the current edition is based on SR OS Release 15.0.R5.

Default multicast distribution trees (MDTs) for each virtual private routed network (VPRN) are signaled using protocol independent multicasting (PIM) and auto-discovery uses border gateway protocol multicast distribution tree sub-address family indicator (BGP MDT-SAFI) network layer routing.

Overview

This chapter describes a service provider core network used by multiple content providers to deliver multicast services to multiple customers using Rosen MVPN. If the same set of PEs is used to deliver the MVPN, the MDTs will all be routed across the same paths between the set of PEs. Because each MDT is signaled using PIM, and the source of all MDTs is the system address of the PE, the path to this source is the same.

Each remote PE then sends a PIM join toward this PE with its source address set to the system address. For multiple VPNs between the same set of PEs, the MDT will follow the same path.

If there is a requirement to deliver content from each content provider across different MVPNs that use diversely routed MDTs, multiple IGP instances can be used: up to three different instances of IGP, OSPF or ISIS, can exist. In this chapter, two instances of OSPF are used to create incongruent topologies providing isolation between the MDTs of two different MVPNs: a default OSPF instance and OSPF instance 1. A separate /32 loopback address can be used as the MDT source address that is advertised in the non-default IGP, which can also be used as the BGP next hop for labeled IPv4 routes representing the customer source addresses.

Knowledge of multi-protocol BGP (MP-BGP) and RFC 4364, *BGP/MPLS IP VPNs*, is assumed throughout this chapter, as well as the original RFC 6037.

All PEs within an MVPN create a default MDT with their own system address as the source. Auto-discovery of PEs within a Rosen MVPN is achieved using the BGP route type of multicast data tree subsequent address family identifier (MDT-SAFI). Each PE originates an MDT-SAFI route update per MVPN. This route advertises the presence of the MVPN on a specific PE.

Each MDT-SAFI update contains attributes, including the following:

1. Route distinguisher
2. Route target extended community

3. MDT source address (usually the system address)
4. Group address of MDT

Upon receipt of an MDT-SAFI route update, each remote PE accepts or rejects the route based on the route target extended community value. If the route is accepted, a remote PE sends a PIM (S,G) join to this local PE. The (S,G) values are taken from the MDT-SAFI. The set of MDTs extend the c-multicast data tree across the MVPN and form PIM adjacencies between PEs within the MVPN. The neighbor address across the set of PIM-enabled tunnels is the default MDT source address, usually the system address.

When established, the default MDT is used to transport c-multicast PIM signaling between PEs.

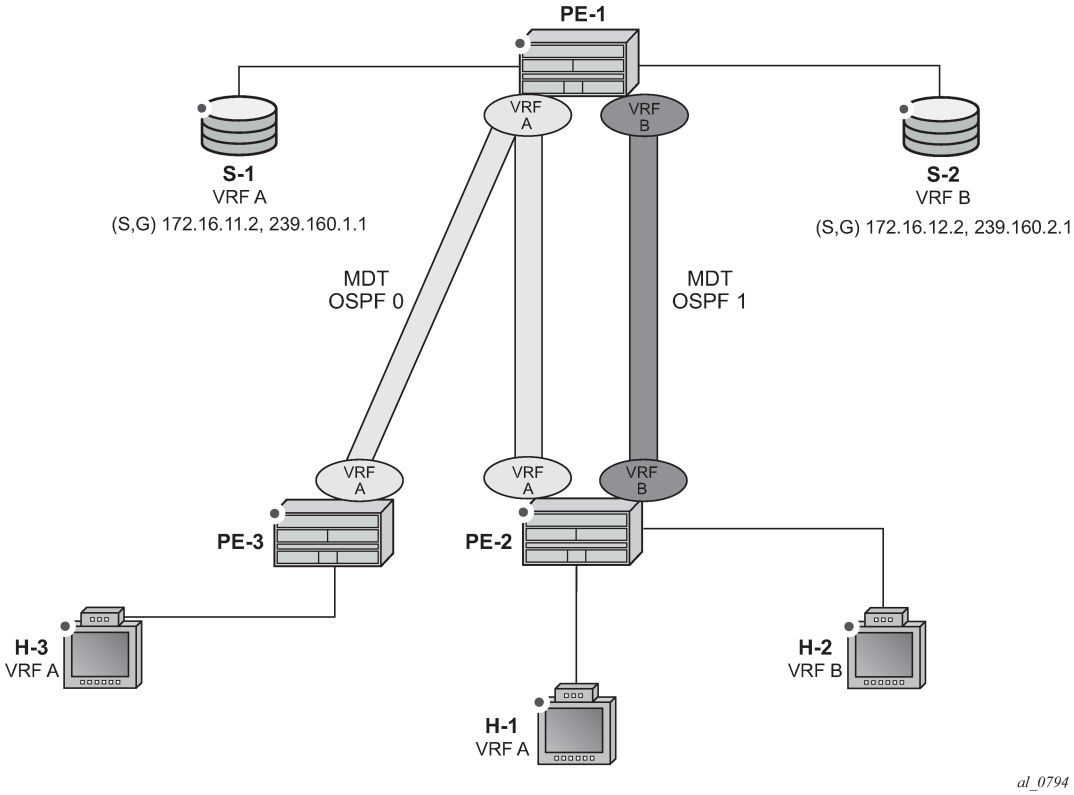
If a source S, of a c-multicast group G, is connected to a sender PE, the route to the source is advertised to remote PEs as a BGP-labeled VPN-IPv4 route.

Therefore, an (S,G) join toward this source at a remote PE will perform a reverse path forwarding (RPF) look-up of the unicast VRF table to find a suitable PIM-enabled interface. The next hop needs be resolved to the MDT source address of the sender PE. A PIM join must now be forwarded toward the sender PE that has a PIM neighbor that matches the next hop for this route, the system address of the sender PE. This is the default MDT.

The system address is a significant address in this process. Any other VPRN that uses the same set of PEs will also signal a set of default MDTs using a different group address, so they will follow the same path between PEs across the provider network.

Figure 389: Core Diversity Schematic shows an example of core diversity; multicast sources provided by two separate content providers are connected to a provider network. There is a requirement to provide topology diversity so that the default MDTs between the same PEs are routed across different paths within the core.

Figure 389: Core Diversity Schematic



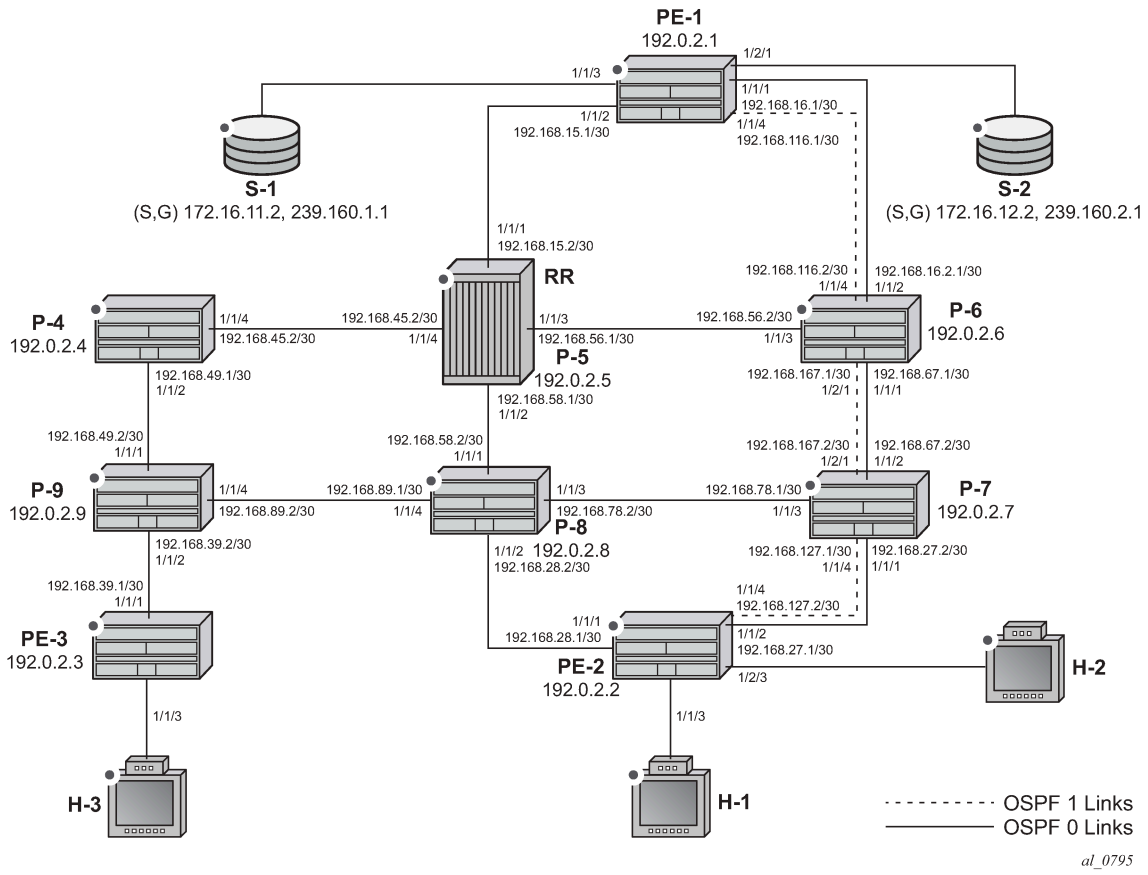
Content servers from two separate content providers are connected to PE-1 with directly connected multicast sources. For simplicity, this example uses only a single multicast group for provider S-1 and S-2.

Source S-1 is reachable via VRF A and source S-2 is reachable via VRF B.

Topology isolation for the multicast data trees of each VPRN can be provided by using two separate IGP instances; in this case, OSPF instances. Multi-instance IS-IS could also be used.

Figure 390: Core Diversity Network shows a schematic of the full network, including the c-multicast groups.

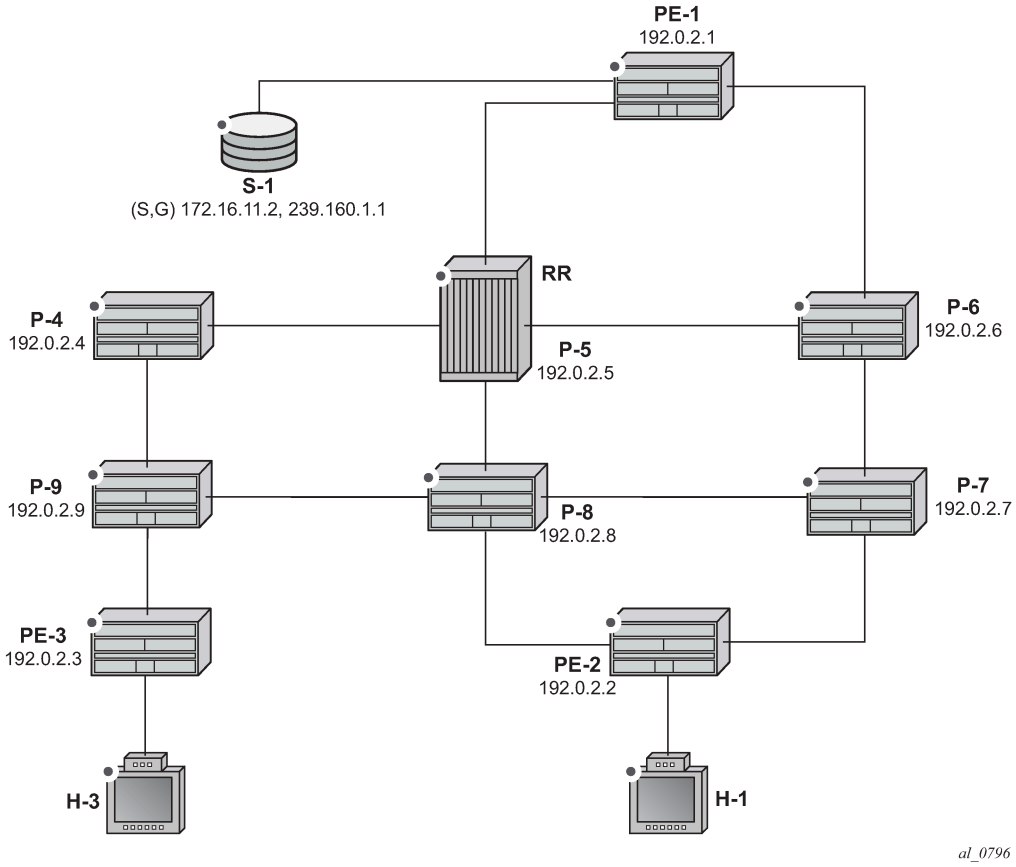
Figure 390: Core Diversity Network



All routers have interfaces in the OSPF base instance (instance 0) and routers interconnected by the dotted lines have interfaces in both the base instance and OSPF 1.

Figure 390: Core Diversity Network shows the extent of the OSFP base instance within the core network.

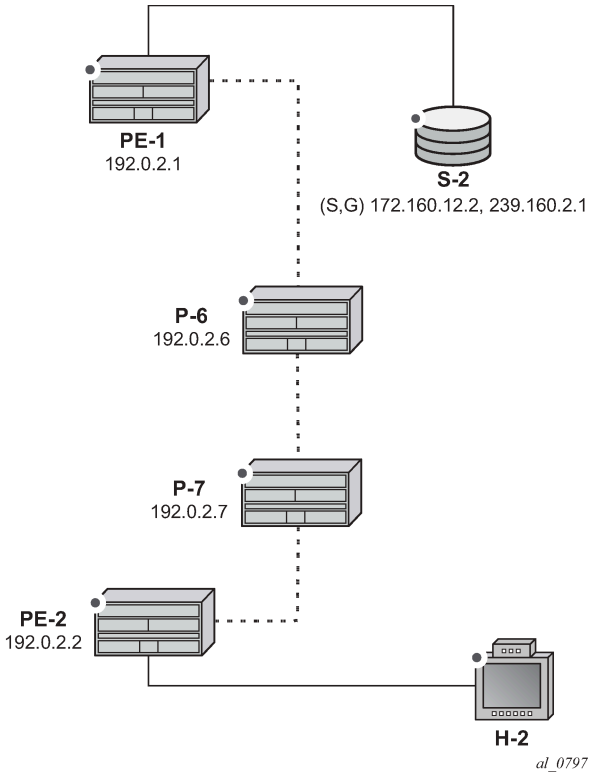
Figure 391: Core Diversity Network — Base OSPF



In this case, assume that the shortest path between PE-1 and PE-2 is the path via P-5 and P-8.

Similarly, Figure 392: Core Diversity Network - OSPF Instance 1 shows the extent of OSPF instance 1.

Figure 392: Core Diversity Network - OSPF Instance 1



The only path available between PE-1 and PE-2 is now completely diverse from the shortest path advertised between the same pair of PEs in the base OSPF instance.

Therefore, for any MDT to be signaled across the OSFP 1 topology, only addresses advertised within OSPF 1 must be used. As previously stated, the system address is used as the default MDT source address. This system address is not advertised within the OSPF 1 topology, so a replacement /32 loopback address is used as the default MDT source address within OSPF 1.

VPN-IPv4 routes that may represent a customer multicast source address should be reachable via the default MDT. In the non-default topology, the c-multicast signaling across the MVPN must resolve the c-multicast route via the MDT, which has its root at the non-default /32 loopback. Therefore, the VPN-IPv4 prefix representing the possible source routes needs to be advertised containing the non-default /32 loopback.

This can be achieved in one of two ways:

1. Use a route policy at the advertising PE that changes the BGP next hop to match the MDT source address for non-default topology MDTs.
2. Use the BGP connector attribute for all VPN-IPv4 route prefixes within a multicast VPRN that has auto-discovery set to MDT-SAFI. The connector attribute contains the MDT source address within the originator field.

This chapter describes the use of the connector attribute.

If the default IGP instance is used, the BGP next hop of the VPN-IPv4 route matches the source address of the default MDT.

Therefore, if a second /32 loopback is used that replaces the system address as MDT source address and also as the next hop for source address RPF look-up, the loopback could be advertised within the non-default IGP instance, and the paths between the PEs would follow this topology.

Core diversity is achieved by configuring the following steps:

1. Configuring multiple OSPF instances, as shown in Figure 391: Core Diversity Network — Base OSPF and Figure 392: Core Diversity Network - OSPF Instance 1, and including the appropriate interfaces. This includes a separate loopback address per instance.
2. Configuring separate VPRNs with their own MDTs using BGP MDT-SAFI auto-discovery and PIM signaling across the appropriate PEs.
3. Configuring the VPRN that uses the base OSPF instance to use the system address as the source addresses for the MDTs (this is default behavior).
4. Configuring a separate loopback (/32) address that is advertised within OSFP instance 1 only.
5. Configuring the VPRN that uses the OSPF instance 1 to use the separate loopback system address as the source addresses for the MDTs.
6. Ensuring the unicast route that represents the c-source address is advertised as a VPN-IPv4 route and has a BGP connector attribute that contains an address that matches the MDT source address of the originating PE.

Configuration

The following configuration tasks must be completed as a prerequisite:

- Full mesh OSPF base instance between each of the nodes. However, IS-IS could also be used for any or all of the IGP instances.
- Link-layer LDP between each P and PE router.
- PIM enabled on each router network interface.

Global BGP Configuration

The first step is to configure an iBGP session between each of the PEs and the route reflector (P-5) shown in Figure 390: Core Diversity Network. The address families negotiated between the iBGP peers are **vpn-ipv4**, for unicast routing, and **mdt-safi** for multicast routing.

The iBGP configuration for PE-1 is the following:

```
# on PE-1
configure router
        bgp
            group "INTERNAL"
                family vpn-ipv4 mdt-safi
                type internal
                neighbor 192.0.2.5
                exit
            exit
```

The configuration for the other PE nodes is the same.

P-5 is the route reflector for PE-1, PE-2, and PE-3, as follows:

```
# on P-5
configure router
        bgp
            cluster 0.0.0.1
            group "RR_CLIENTS"
                family vpn-ipv4 mdt-safi
                type internal
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
            exit
```

On PE-1, verify that the BGP session with the route reflector at P-5 is established with address families **mdt-safi** and **vpn-ipv4** capabilities negotiated:

```

Configuring VPRN on PEs

There are two VPRNs:

- VPRN 1 using the base instance OSPF topology. This is present on PE-1, PE-2, and PE-3.
- VPRN 2 using OSPF instance 1. This is present on PE-1 and PE-2.

The following output displays the configuration for VPRN 1 for the sender PE-1.

```
# on PE-1
configure service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
```

```
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-1-S-1" create
                address 172.16.11.1/24
                sap 1/1/3 create
                exit
            exit
            pim
                apply-to all
                no shutdown
            exit
            mvpn
                auto-discovery mdt-safi
                provider-tunnel
                    inclusive
                        pim ssm 239.160.1.1
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            no shutdown
```

There is a single interface toward S-1, from which the multicast group is received.

PIM is enabled and applied to all interfaces.

The MVPN configuration enables BGP MDT-SAFI as the auto-discovery mechanism. The provider tunnels between the PEs within the MVPN are PIM SSM multicast data trees with a group address of 239.160.1.1.

The configuration for VPRN 1 for the receiver PE-2 is the following.

```
# on PE-2
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-2-H-1" create
                address 172.16.21.1/24
                sap 1/1/3 create
                exit
            exit
            igmp
                interface "int-PE-2-H-1
                    no shutdown
                exit
                no shutdown
            exit
            pim
                apply-to all
                no shutdown
            exit
```

```
            mvpn
                auto-discovery mdt-safi
                provider-tunnel
                    inclusive
                        pim ssm 239.160.1.1
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            no shutdown
```

The configuration for VPRN 1 for receiver PE-3 is as follows.

```
# on PE-3
configure
    service
         vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-3-H-3" create
                address 172.16.33.1/24
                sap 1/1/3 create
                exit
            exit
            igmp
                interface "int-PE-3-H-3"
                    no shutdown
                exit
                no shutdown
            exit
            pim
                apply-to all
                no shutdown
            exit
            mvpn
                auto-discovery mdt-safi
                provider-tunnel
                    inclusive
                        pim ssm 239.160.1.1
                        exit
                    exit
                exit
                vrf-target unicast
                exit
            exit
            no shutdown
```

At PE-2, the MDT SAFI NLRI advertised by PE-1 is as follows:

```

*A:PE-2#
```

The source and group address is used by PE-2 (and PE-3) to join the MDT that has its root at PE-1. The source address used is the system address of PE-1.

Examining the MDTs for this VPRN at PE-1 shows the state, as follows:

```
*A:PE-1# show router pim group 239.160.1.1

*A:PE-1#
```

The source address of the tree is the system address of the router, which is determined from the MDT SAFI NLRI that is advertised to all other PEs via the route reflector. Also, the outgoing interface list contains an interface (int-PE-1-P-5) that is OSPF enabled, and advertised within the base OSPF instance.

From the MDT on PE-2, which has its root on PE-1, the incoming interface is an OSPF interface advertised in the base OSPF instance, as shown.

```

*A:PE-3#
```

VPRN Using Non-Default IGP Instance

A VPRN instance is configured on each of PE-1 and PE-2 that uses an MDT topology governed by the non-default OSPF instance.

Additional interfaces need to be configured.

```
# on PE-1
configure
    router
        interface "int-PE-1-P-6a"
            address 192.168.116.1/30
            port 1/1/4
        exit
        interface "loop-1"
            address 192.0.3.1/32
            loopback
        exit
```

There are parallel links between PE-1 and P-6. The interface name of the second link contains the suffix *a*.

In a Rosen MVPN, each PE constructs a default MDT to all other PEs in the multicast VPN domain, as defined by the MDT SAFI BGP update received. The MDT update contains the source address of the MDT to which each PE should join.

When each of the other PEs receives the MDT SAFI network layer reachability information (NLRI), a PIM join is sent to the source address within the global PIM routing instance to create the MDT.

The MDT source address is usually the system address. Because the system address is advertised in the base instance of OSPF, another /32 address must be used as the source address for the default MDT. Therefore, a second loopback address is configured and used as the source address for the default MDT. For PE-1, this interface is called loop-1, and it is advertised in OSPF 1.

The interface loop-1 will be used as the source address for the MDTs and the next hop for the unicast route representing the source address of the c-multicast group.

The non-default OSPF instance for PE-1 is configured as follows, where 192.0.3.1 is the OSPF 1 router-ID. The router ID need not be equal to the IP address for loop-1, but in this case it is.

```
# on PE-1
configure
    router
        ospf 1 192.0.3.1
            area 0.0.0.0
                interface "int-PE-1-P-6a"
                    interface-type point-to-point
                exit
                interface "loop-1"
                exit
            exit
```

LDP is also required for BGP next-hop resolution and is configured as follows for PE-1.

```
# on PE-1
configure
    router
        ldp
            interface-parameters
                interface int-PE-1-P-6a
                    ipv4
                        transport-address interface
                    exit
                exit
            exit
```

The transport address is set to interface, rather than the default of system address; this is because the system address is not reachable within OSPF instance 1.

For completeness, the configuration of the additional interfaces, OSPF instance 1 and LDP of PE-2 is shown in the following three outputs.

```
# on PE-2
configure
    router
        interface "int-PE-2-P-7a"
            address 192.168.127.1/30
            port 1/1/4
        exit
        interface "loop-1"
            address 192.0.3.2/32
            loopback
        exit
```

The OSPF 1 instance configuration is as follows:

```
# on PE-2
configure
    router
        ospf 1 192.0.3.2
            area 0.0.0.0
                interface "int-PE-2-P-7a"
                    interface-type point-to-point
                exit
                interface "loop-1"
                exit
            exit
            no shutdown
        exit
```

The LDP configuration is as follows:

```
# on PE-2
configure
    router
        ldp
            interface-parameters
                interface "int-PE-2-P-7a"
                    ipv4
                        transport-address interface
                    exit
                exit
            exit
```

PIM needs to be enabled on all interfaces.

The MDT source address for VPRN 2 is the loop-1 address. Each PE within this VPRN has to join the MDT sourced at PE-1, so the MDT SAFI NLRI must advertise the source address of the MDT group as loop-1. This is achieved by specifying the MDT SAFI source address within the MVPN context. The following output displays the VPRN configuration for PE-1.

```
# on PE-1
configure
    service
         vprn 2 customer 1 create
            route-distinguisher 64496:2
```

```
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:2
            interface "int-PE-1-S-2" create
                address 172.16.12.1/24
                sap 1/2/1 create
                exit
            exit
            pim
                apply-to all
                no shutdown
            exit
            mvpn
                auto-discovery mdt-safi source-address 192.0.3.1
                provider-tunnel
                    inclusive
                        pim ssm 239.160.2.1
                        exit
                    exit
                exit
                vrf-target target:64496:2
                exit
            exit
            no shutdown
```

The MDT SAFI source address modification is only required on PEs that use the non-default /32 addresses. The system address must not be explicitly configured as the MDT source address for MVPNs that use the default IGP instance. As previously stated, only three MVPNs can be used to create core diversity, one of which must be the default instance. Configuring the system address as a source address prevents the creation of a third MVPN because only two MVPNs are allowed to use explicitly configured MDT source addresses.

Verification of Core Diversity

The MDT SAFI NLRI advertised by the PE-1 sender router contains the following information.

```
*A:PE-1# show router bgp routes mdt-safi hunt rd 64496:2 | match "RIB Out" post-lines 25 pre-

*A:PE-2#
```

The originator value within the connector attribute is shown to be 192.0.3.1, which is the same as the MDT source address of PE-1. The BGP next hop is still set to the system address of PE-1, so the unicast route can still be resolved via an LDP tunnel.

PIM will now resolve the c-source address RPF using the originator value within the connector attribute.

Similarly, for VPRN 1, the route on PE-1 representing the source address is also advertised as a VPN-IPv4 address that contains a BGP connector attribute.

```

Verification of Multicast Traffic

An IGMPv3 query is initiated from all 3 hosts: H-1, H-2, and H-3 in Figure 1, and the multicast streams from S-1 and S-2 into interfaces on the two VPRNs are enabled.

Consider VPRN 1, which uses the default topology. On PE-1, the group 239.160.1.123 can be shown. The outgoing and incoming interface lists are populated, with the outgoing interface being the MDT interface for the VPRN:

```
*A:PE-1# show router 1 pim group detail

Conclusion

MVPN Core Diversity allows service providers to provide separation in terms of topology between content providers that use a core network to provide transport between source and receivers in a multicast VPN. This chapter provides the configuration for multiple instances of OSPF which, together with the associated commands and outputs, can be used for verifying and troubleshooting.

Rosen MVPN Inter-AS Option B

This chapter provides information about Rosen MVPN: Inter-AS Option B configurations.

Topics in this chapter include:

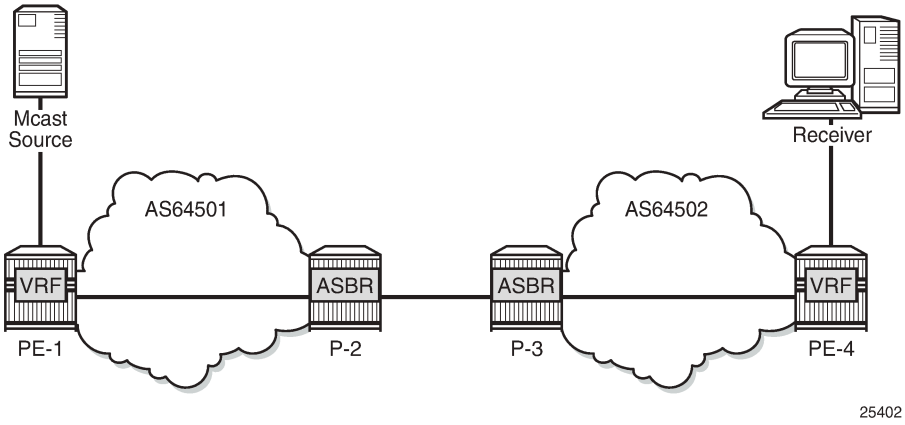
Applicability

This chapter was initially written for SR OS 11.0.R3. The CLI in the current edition is based on SR OS Release 15.0.R5. Knowledge of the Nokia multicast and Layer 3 VPNs concepts are assumed throughout this document.

Overview

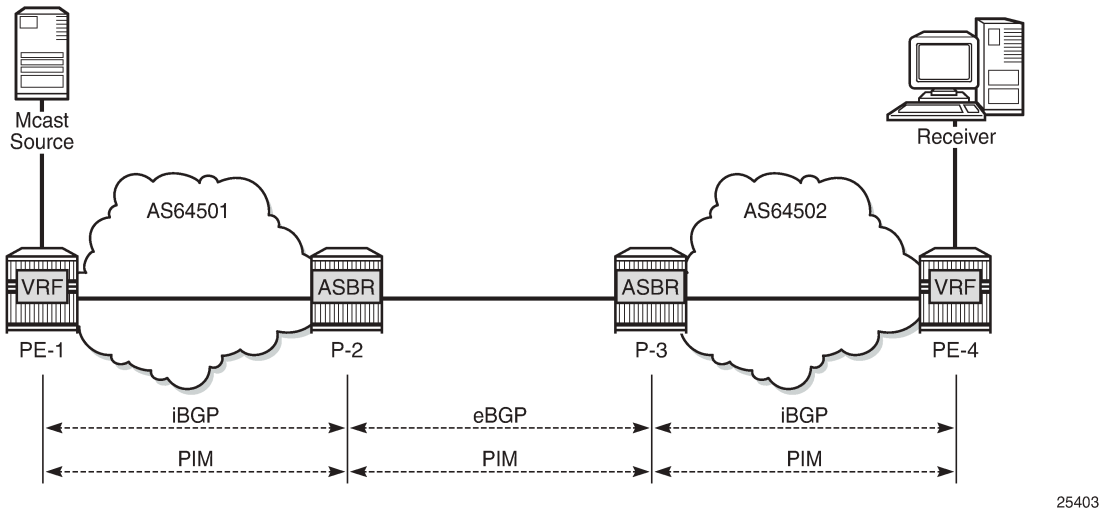
This chapter covers a basic technology overview, the network topology and configuration examples which are used for multicast virtual private network (MVPN) inter-autonomous system (AS) option B.The Inter-AS MVPN feature allows the setup of multicast distribution trees (MDTs) spanning multiple autonomous systems.

Figure 393: General Topology for Inter-AS MVPN



This chapter covers Rosen MVPN Inter-AS support (Option-B). Inter-AS Option B is supported for protocol independent multicast (PIM) source-specific multicast (SSM) with Rosen MVPN using multicast distribution tree (MDT) subsequent address family indicator (SAFI), the border gateway protocol (BGP) connector attribute and PIM reverse path forwarding (RPF) vector.

Figure 394: Protocols Used for Inter-AS MVPN



The following assumptions are made:

- PE-1 is the sender PE because the multicast source is directly connected to this router.
- PE-4 is the receiver PE because the multicast receiver is directly connected to this router.
- P-2 and P-3 are ASBR routers according to the Inter-AS model.

The multicast receiver and source can be indirectly connected to PE routers via CE routers, but for the core multicast distribution, these variations are conceptually the same. For simplicity, the PE and P router configurations will be provided.

There are several challenges which have to be solved in order to make the complete inter-AS solution operational:

Challenge 1:

In case of Inter-AS MVPN Option B, routing information toward the source PE is not available in a remote AS domain because IGP routes are not exchanged between ASs.

As a result, a PIM-P join would never be sent upstream (from the receiver PE to the sender PE in a different AS). However, the PIM-P join has to be propagated from PE-4 to PE-1. Therefore, a solution is required to issue PIM-P join and perform RPF.

Solution:

Use a PIM reverse path forwarding (RPF) vector (RPFV) to propagate PIM-P over multiple segments. In this example there are three segments:

- PE-4 -> ASBR P-3
- ASBR P-3 -> ASBR P-2
- ASBR P-2 -> PE-1

The RPF vector is added to a PIM join by the PE router when the following option is enabled:

```
*A:PE-4# configure router pim rpfv
  - no rpfv [core] [mvpn]
  - rpfv core mvpn
  - rpfv core
```

```
  - rpfv mvpn

 <core>               : Proxy RPF vector for core
 <mvpn>               : Proxy RPF vector for inter-AS rosen mvpn

*A:PE-4#
```

The **mvpn** keyword enables "mvpn RPF vector" processing for Inter-AS Option B MVPN based on RFC 5496 and RFC 6513. If a core RPF vector is received, it will be dropped before a message is processed.

All routers on the multicast traffic transport path must have this option enabled to allow RPF vector processing. If the option is not enabled, the RPF vector is dropped and the PIM join is processed as if the PIM vector is not present.

Details about RPF Vector can be found in the following RFCs: 5496, 5384, 6513.

Challenge 2:

With Inter-AS MVPN Option B, the BGP next-hop is modified by the local and remote ASBRs during re-advertisement of VPN IPv4 routes. When the BGP next-hop is changed, information regarding the originator of the prefix is lost when the advertisement reaches the receiver PE node. Therefore, a solution is required to do a successful RPF check for the VPN source at receiver VPRN.

This challenge does not apply to Model C because in Model C the BGP next-hop for VPN routes is not updated.

Solution:

The transitive BGP connector attribute is added and used to advertise an address of a sender PE node which is carried inside a VPN IPv4 update. The BGP connector attribute allows the sender PE address information to be available to the receiver PE so that a receiver PE is able to associate VPN IPv4 advertisement to the corresponding source PE.

Inter-AS Option B will work when the following criteria are met:

- Rosen MVPN is used with PIM SSM
- BGP MDT-SAFI address family is used
- PIM RPF vector is configured
- BGP connector attribute is used for VPN-IPv4 updates

SR OS inter-AS Option B is designed to be standard compliant based on the following RFCs:

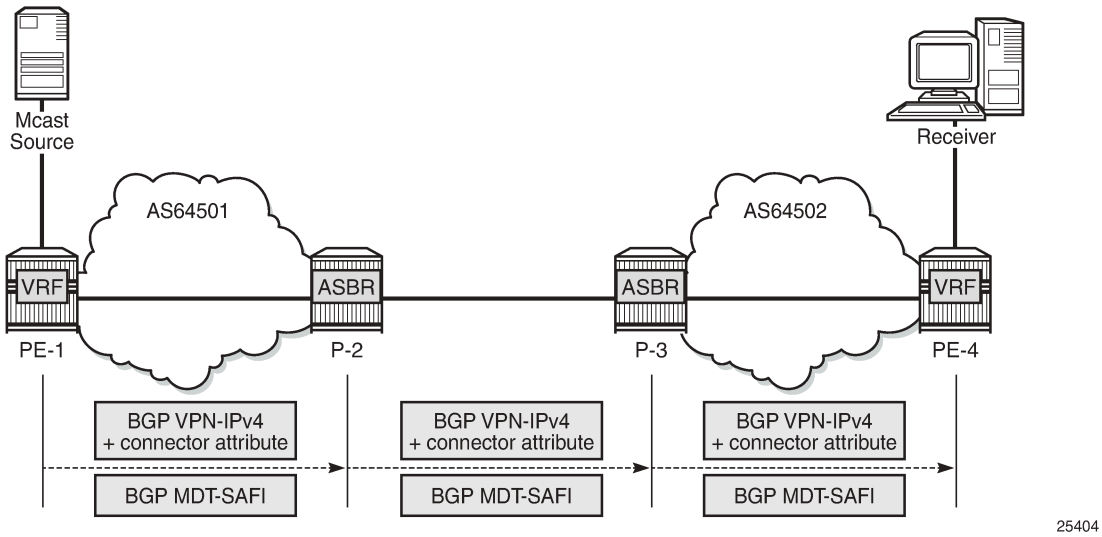
- RFC 5384, *The Protocol Independent Multicast (PIM) Join Attribute Format*
- RFC 5496, *The Reverse Path Forwarding (RPF) Vector TLV*
- RFC 6513, *Multicast in MPLS/BGP IP VPNs*

The following signaling stages can be identified when Inter-AS MVPN is configured:

- Stage 1 - BGP core signaling
- Stage 2 - Core PIM signaling
- Stage 3 - Customer PIM signalling

Stage 1 - BGP core signaling

Figure 395: BGP Signaling Steps



The sender PE sends VPN-IPv4 and MDT-SAFI BGP updates for this particular MVPN:

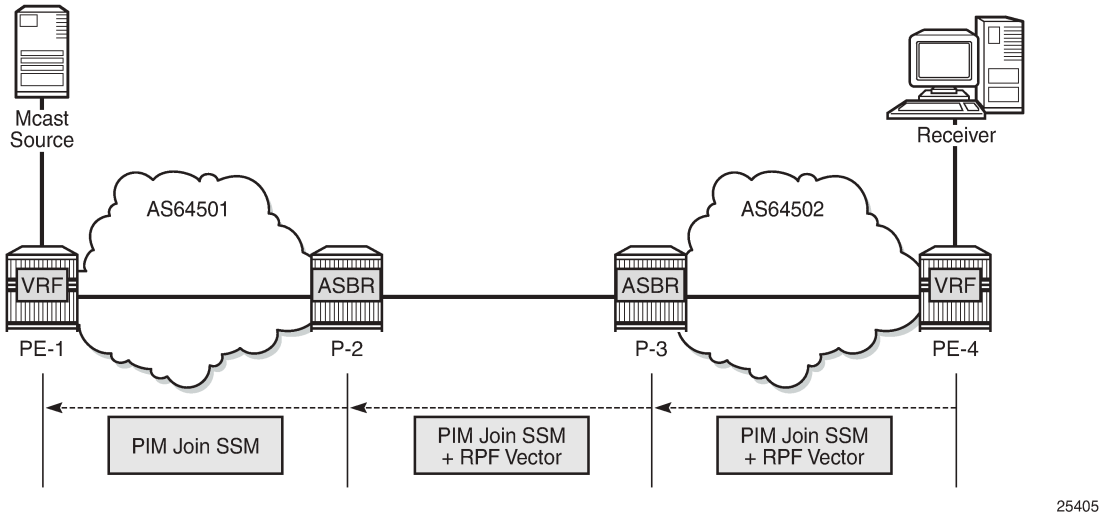
- Every ASBR propagates VPN-IPv4 and MDT-SAFI BGP updates:
  - Next hop (NH) attribute is modified every time
  - Connector attribute stays untouched

When this stage is completed, all routers have information necessary:

- to start PIM signaling in the core network (PIM-P) to prepare the default MDT
- to start PIM signaling of customer multicast streams (PIM-C) inside the VPN

Stage 2 - Core PIM signaling

Figure 396: PIM-P Signaling Steps for Default MDT



PE-4 determines the reverse path to the source based on the RPF vector (ASBR P-3 IP address) and not based on the IP address of the multicast source (PE-1) which is unknown to PE-4.

PE-4 inserts an RPF vector and sends a PIM-P join to the immediate next-hop to reach ASBR P-3. Intermediate P-routers (if present) do not change the RPF vector.

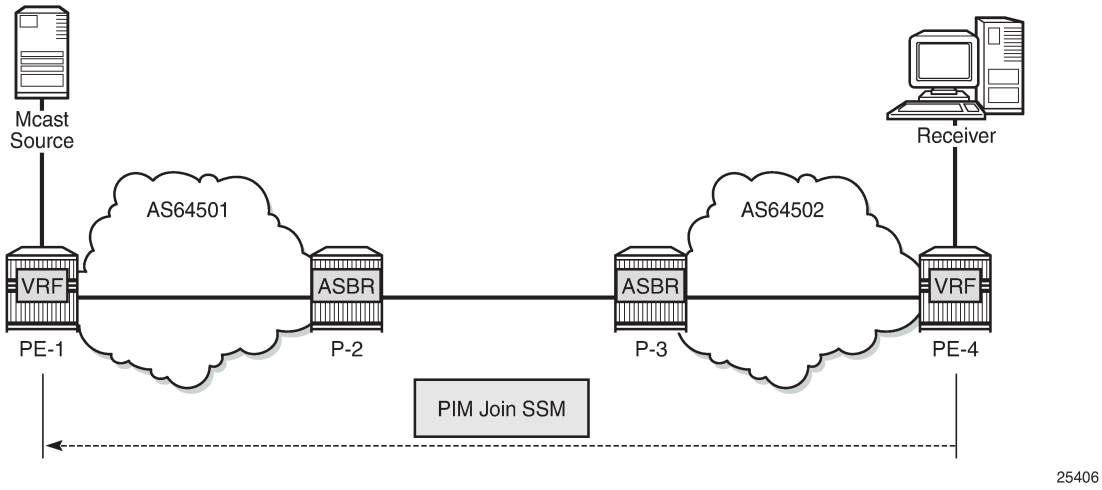
P-3 finds itself in the RPF vector and has to make a decision based on MDT-SAFI BGP table:

- P-3 determines the reverse path to the multicast source based on the RPF vector (ASBR P-2 IP address).
- If the multicast source and the NH do not match, P-3 has to use the RPFV.
- P-3 modifies the PIM-P join received from PE-4 with ASBR P-2's IP address as the upstream (taken from next hop MDT-SAFI network layer reachability information (NLRI)).
- P-2 can match the source IP with the NH in BGP MDT-SAFI. Therefore, there is no need for the RPF vector to be used.
- P-2 removes the RPF vector and sends a normal PIM-P join toward PE-1.

When this stage is completed, the default MDT is established for this MVPN and PE routers have the necessary information to start PIM signaling inside the VPRN (PIM-C).

Stage 3 - Customer PIM signaling

Figure 397: PIM-C Signaling



A PIM-C join is sent to the source PE using the existing tunnel infrastructure to the RPF neighbor PE-1 provided by the BGP connector attribute of the vpn-ipv4 route of the multicast source.

When this stage is completed, the customer multicast flows throughout the network in a default MDT.

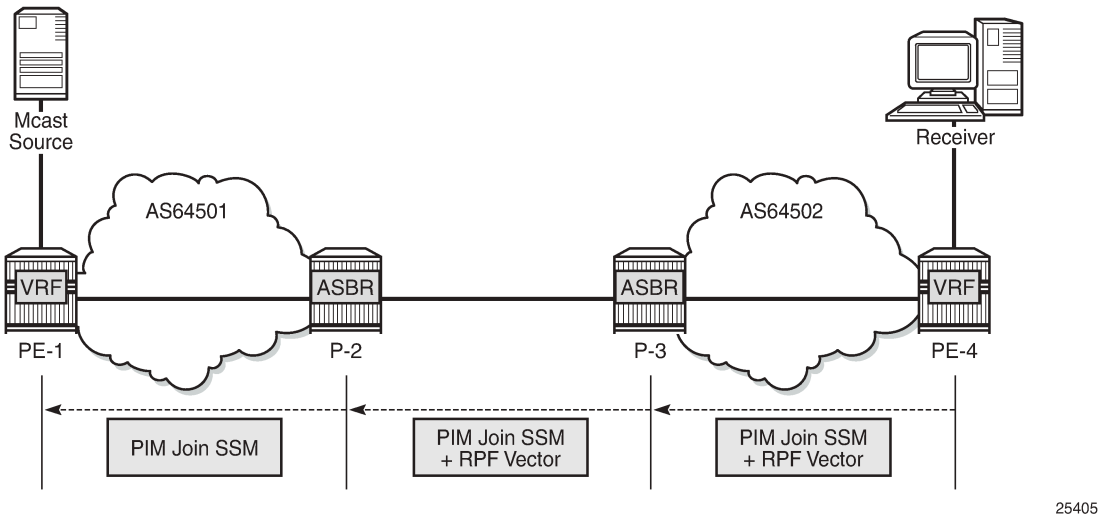
Stage 4 - The multicast stream threshold is reached.

This stage is optional and applicable when S-PMSI instance and S-PMSI threshold are configured.

The process is similar to the default MDT setup:

- PE-4 determines the reverse path to the source based on the RPF vector (ASBR P-3's IP address) and not based on the IP address of the multicast source (PE-1) which is unknown to PE-4.
- PE-4 inserts an RPF vector and sends a PIM-P Join to the immediate next hop to reach ASBR P-3.

Figure 398: PIM-P Signaling Steps for Data MDT



- Intermediate P-routers (if present) do not change the RPF vector.
- P-3 finds itself in the RPF vector and has to make a decision based on the MDT-SAFI BGP table:
  - P-3 determines the reverse path to the multicast source based on the RPF Vector (ASBR P-2's IP address).
  - If the multicast source and the NH do not match, P-3 has to use the RPFV.
  - P-3 modifies the PIM-P join received from PE-4 with ASBR P-2's IP address as upstream (taken from next hop MDT-SAFI NLRI).
- P-2 can match the source IP with the NH in the BGP MDT-SAFI. Therefore, there is no need for the RPF vector to be used.
- P-2 removes the RPF vector and sends a normal PIM-P join toward PE-1.

When this optional stage is completed, the customer multicast traffic flows through a dedicated Data MDT.

The SR OS implementation was also designed to interoperate with Cisco routers' Inter-AS implementations that do not fully comply with the RFC 5384 and RFC 5496.

When the following option is enabled:

```
configure router pim rpfv mvpn
```

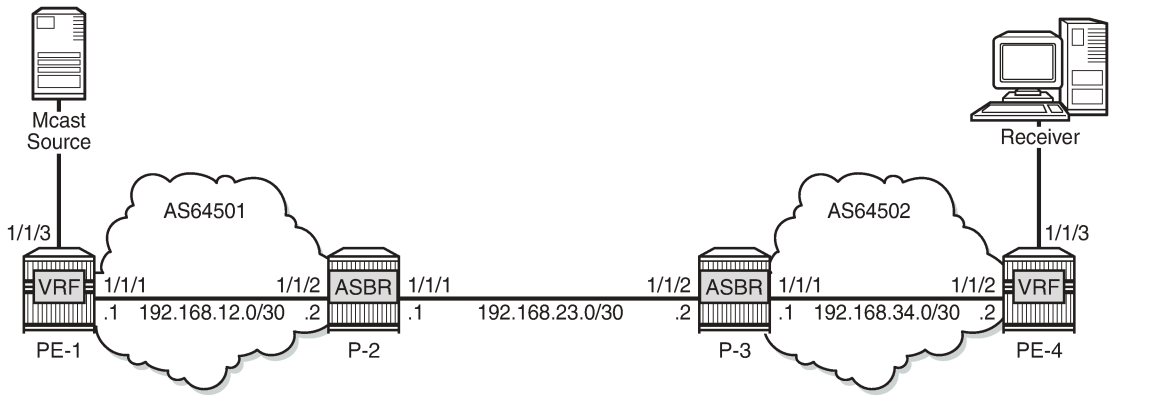
Cisco routers need to be configured to include **rd** in an RPF vector using the following command for interoperability:

```
ip multicast vrf <name> rpf proxy rd vector
```

Configuration

The example topology is shown in Figure 399: Example Topology Details.

Figure 399: Example Topology Details



The following components are used in the example scenario:

- VPRN 1
- Customer multicast group is 232.0.0.0/8
- Default MDT multicast group is 239.255.0.1
- Data MDT multicast group is 239.255.1.0/24
- Multicast source is 172.16.1.1
- PE-x routers have system IP addresses 192.0.2.x
- P-x routers have system IP addresses 192.0.2.x
- Interface between Router A and B has IP address 192.168.AB.x

Global BGP configuration for PE-1 router using the mdt-safi family with an iBGP neighbor to P-2. The system interface IP address is used for the iBGP session.

```
# on PE-1
configure
    router
        bgp
            group "iBGP"
                family vpn-ipv4 mdt-safi
                type internal
                neighbor 192.0.2.2
                    next-hop-self
                exit
            exit
```

The global BGP configuration for P-2 router is using the mdt-safi family with an iBGP neighbor to PE-1 and an eBGP neighbor to P-3. The system interface IP address is used for the iBGP session and the network interface IP address is used for the eBGP session.

```
# on P-2
configure
    router
        bgp
```

```
            enable-inter-as-vpn
            group "eBGP"
                family vpn-ipv4 mdt-safi
                neighbor 192.168.23.2
                    type external
                    peer-as 64502
                exit
            exit
            group "iBGP"
                family vpn-ipv4 mdt-safi
                neighbor 192.0.2.1
                    next-hop-self
                    type internal
                exit
            exit
        exit
```

The global BGP configuration for the router P-3 is using the mdt-safi family with an iBGP neighbor to PE-4 and an eBGP neighbor to P-2. The system interface IP address is used for the iBGP session and the network interface IP address is used for the eBGP session.

```
# on P-3
configure
    router
        bgp
            enable-inter-as-vpn
            group "eBGP"
                family vpn-ipv4 mdt-safi
                neighbor 192.168.23.1
                    type external
                    peer-as 64501
                exit
            exit
            group "iBGP"
                family vpn-ipv4 mdt-safi
                neighbor 192.0.2.4
                    next-hop-self
                    type internal
                exit
            exit
        exit
```

The global BGP configuration for router PE-4 is using the mdt-safi family with an iBGP neighbor to P-3 is as follows. The system interface IP address is used for the iBGP session.

```
# on PE-4
configure
    router
        bgp
            group "iBGP"
                family vpn-ipv4 mdt-safi
                type internal
                neighbor 192.0.2.3
                    next-hop-self
                exit
            exit
        exit
```

The global PIM configuration for all routers is as follows:.

```
# on all routers
```

```
configure
    router
        pim
            rpf-table both
            apply-to non-ies
            rpfv mvpn
        exit
    exit
```

The VPRN configuration for the PE routers is as follows:

```
# on PE-1
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 1:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                    rsvp
                exit
                resolution filter
            exit
            vrf-target target:1:1
            interface "int-PE-1-S-1" create
                address 172.16.1.2/30
                sap 1/1/3 create
                exit
            exit
            pim
                apply-to all
            exit
            mvpn
                auto-discovery mdt-safi
                provider-tunnel
                    inclusive
                        pim ssm 239.255.0.1
                        exit
                    exit
                    selective

                exit
                vrf-target unicast
                exit
            exit
            no shutdown
        exit
```

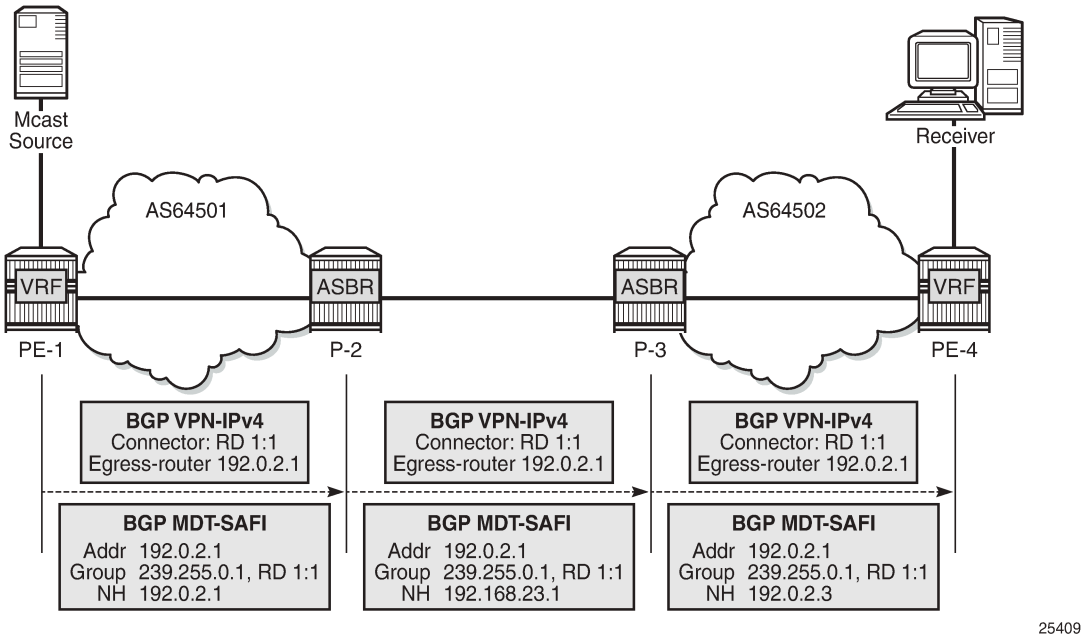
MVPN Verification and Debugging

BGP Core Signaling

Figure 400: BGP Signaling Steps



On PE-1, the **debug router bgp update** output shows the BGP update messages which are sent to P-2. The VPN-IPv4 update contains a connector attribute and the MDT-SAFI update is used for signaling multicast group 239.255.0.1.

```

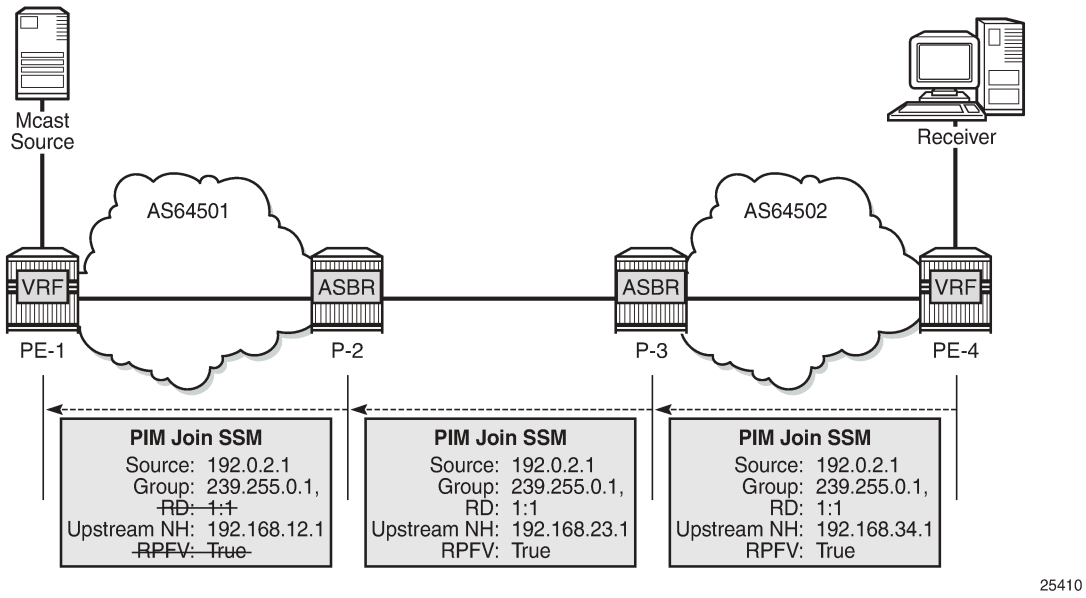
Core PIM Signaling

Figure 401: PIM-P Signaling Steps for Default MDT



On PE-4, the **debug router pim packet jp** output shows the PIM join/prune message which is sent to P-3. This message contains the original source of the multicast traffic (PE-1: 192.0.2.1) and the RPF Vector (P-3: 192.0.2.3).

```
5 2017/10/17 12:03:18.425 UTC MINOR: DEBUG #2001 Base PIM[Instance 1 Base]
"PIM[Instance 1 Base]: Join/Prune
[000 00:27:18.430] PIM-TX ifId 2 ifName int-PE-4-P-3 0.0.0.0 -> 224.0.0.13 Length: 48
PIM Version: 2 Msg Type: Join/Prune Checksum: 0x3d2c
Upstream Nbr IP : 192.168.34.1 Resvd: 0x0, Num Groups 1, HoldTime 210

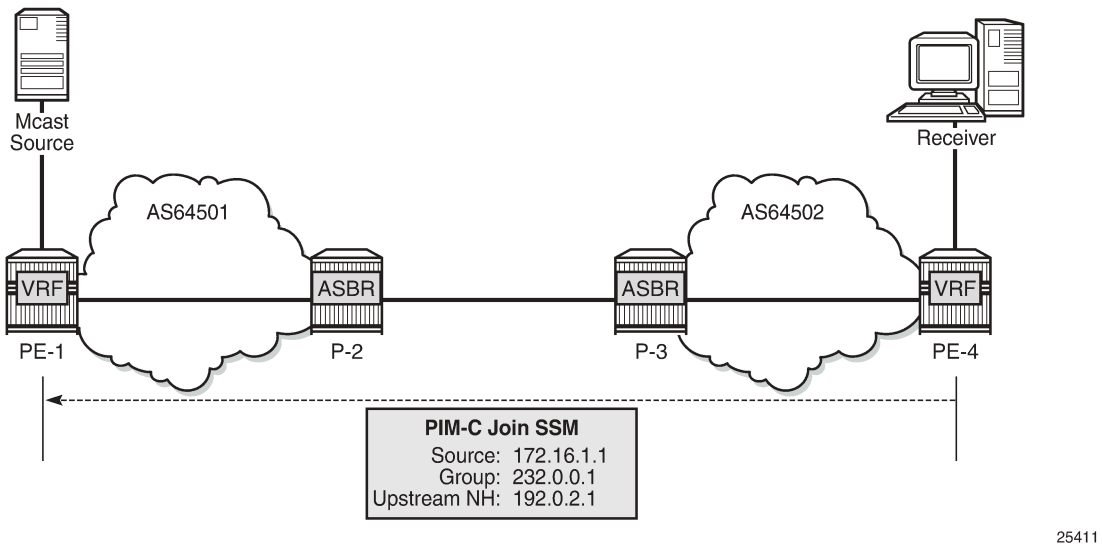
Customer PIM Signaling

Figure 402: PIM-C Signaling



The PIM-C Join is sent to the sender PE using the existing tunnel infrastructure.

On PE-4, the **debug router 1 pim packet jp** output shows the PIM join/prune message which is sent to PE-1 using PMSI interface "1-mt-239.255.0.1" inside VPRN 1. All of this information and more can be found in the output of the **debug** command.

```
29 2017/10/17 12:15:26.477 UTC MINOR: DEBUG #2001 vprn1 PIM[Instance 2 vprn1]
"PIM[Instance 2 vprn1]: Join/Prune
[000 00:39:26.480] PIM-TX ifId 16385 ifName 1-mt-239.255.0.1 0.0.0.0 -> 224.0.0.13

"
```

The detailed information about the PIM-C group for a particular VPRN shows that the default MDT is used to deliver traffic. For this purpose, the **show router 1 pim group detail** command is used. Key parameters such as the correct multicast group, correct incoming/outgoing interfaces and non-zero flow rate allow this conclusion to be made.

PE-1 has the incoming interface "int-PE-1-S-1", and outgoing interface "1-mt-239.255.0.1". If the threshold hasn't been reached to set up a selective provider tunnel, only one outgoing interface is listed.In order to generate this output, the data threshold for the selective provider tunnel was temporarily raised to 100000 kbps in VPRN 1.

```

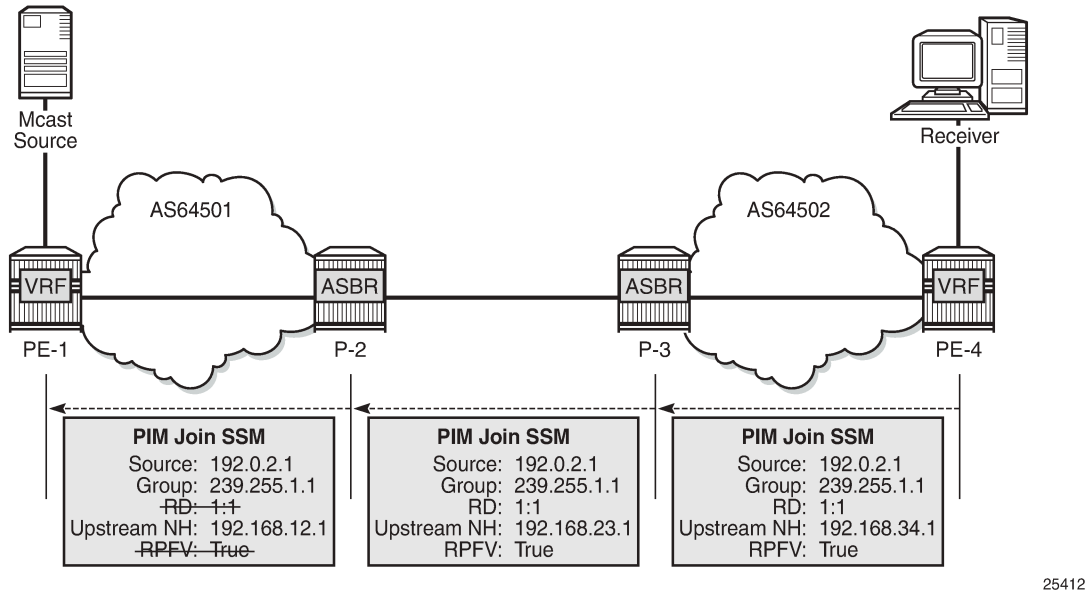
When Multicast Stream Threshold is Reached

Figure 403: PIM-P Signaling Steps for Data MDT



On PE-4, the **debug router pim packet jp** output shows the PIM join/prune message which is sent to P-3. This message contains the original source of the multicast traffic (PE-1: 192.0.2.1) and the RPF Vector (P-3: 192.0.2.3).

A new multicast group (239.255.1.1) is signaled for purposes of establishing the data MDT.

```
19 2017/10/17 12:19:19.174 UTC MINOR: DEBUG #2001 Base PIM[Instance 1 Base]
"PIM[Instance 1 Base]: Join/Prune

===============================================================================
A:PE-4#
```

The detailed information about the PIM group in a VPRN shows that the data MDT is used to receive traffic instead of the default MDT.

The PE-4 output for multicast groups in a VPRN 1 has slightly changed: a new line "Incoming SPMSI Intf" was added. This indicates that the S-PMSI instance and dedicated Data MDT are used for this particular multicast group. The non-zero rate for the multicast flow is also an indication that multicast traffic is forwarded.

```

Conclusion

Inter-AS MVPN offers flexibility for the operators who can use it to provide additional value added services to their customers. Before implementing this feature in the network the following are required:

- The RPF vector must be enabled on every router for inter-AS MVPN.
- Can be used only with Rosen MVPN with PIM SSM and MDT SAFI.

Selective VPRN uRPF Control on Network Interfaces

This chapter provides information about selective VPRN uRPF control on network interfaces.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 15.0.R7. Selective VPRN uRPF control on network interfaces is supported in SR OS Release 15.0.R1, and later.

Overview

Unicast Reverse Path Forwarding (uRPF) can be used to reduce the vulnerability of networks to traffic flows with spoofed source IP addresses. By default, uRPF checking is disabled. In SR OS, uRPF can be enabled in loose mode or in strict mode on the ingress direction of both access and network interfaces.

- uRPF loose mode checking performs a longest-prefix match Forwarding Information Base (FIB) lookup on the IP source address (SA) of every incoming packet. All packets for which there is no matching non-default route are discarded.
- uRPF strict mode checking verifies, in addition to the check executed in loose mode, that the incoming interface matches the next-hop back toward the IP SA. Packets that enter on a different interface are discarded.

Note:
Note: For VPRN traffic that is tunneled between routers, the route in the VPRN FIB has no interface associated with the prefix, so it is impossible to determine whether a packet with a spoofed source IP address enters the router via the correct interface. In that case, uRPF checking is identical for both modes: spoofed source IP address packets with no matching non-default route in the VPRN FIB are discarded.

This chapter focuses on network interfaces. The following command is used to enable uRPF checking on a network interface for IPv4 traffic.

```
*A:PE-1# configure router interface "int-PE-1-PE-2" urpf-check
```

The following command is used to enable uRPF checking on a network interface for IPv6 traffic:

```
*A:PE-1# configure router interface "int-PE-1-PE-2" ipv6 urpf-check
```

The default uRPF mode is strict. The uRPF mode can be changed as follows.

```
*A:PE-1# configure router interface "int-PE-1-PE-2" urpf-check mode ?
```

```
- mode {strict|loose|strict-no-ecmp}
```

When enabled on a base router network interface, uRPF operates as follows.

- For packets arriving on the network interface that require forwarding in the base router, uRPF checking performs a lookup of the IP SA in the base router FIB.
- For packets arriving on the network interface that require forwarding in a VPRN, uRPF checking performs a lookup of the IP SA in the VPRN FIB for locally configured VPRNs.

In some cases, uRPF checking should not be performed for all locally configured VPRNs, for example for VPRNs with asymmetric routing, such as when PE-1 has a route toward PE-2, but PE-2 has no route back to PE-1. Selective VPRN uRPF control on network interfaces offers the possibility to define for which locally configured VPRNs the uRPF should be checked. The following two commands control this selective or per-VPRN uRPF approach:

1. The first command is the following network interface-level command:

```
*A:PE-1# configure router interface "int-PE-1-PE-2" urpf-selected-vprns
```

2. The second command is the following VPRN-specific command that indicates this VPRN should be included in the set of VPRNs covered by the preceding **urpf-selected-vprns** command.

```
*A:PE-1# configure service vprn 1 network ingress urpf-check
```

When a specific VPRN should be excluded from the selective VPRN uRPF check, **no urpf-check** must be configured explicitly within that **vprn** context. Excluding a VPRN from uRPF checking only works for the network interfaces with **urpf-selected-vprns** enabled and **urpf-check mode** *value* configured. When uRPF is configured on a network interface without **urpf-selected-vprns**, uRPF checking is inherited by all locally configured VPRNs, regardless of the presence of the **configure vprn** <*service-id*> **network ingress urpf-check** command.

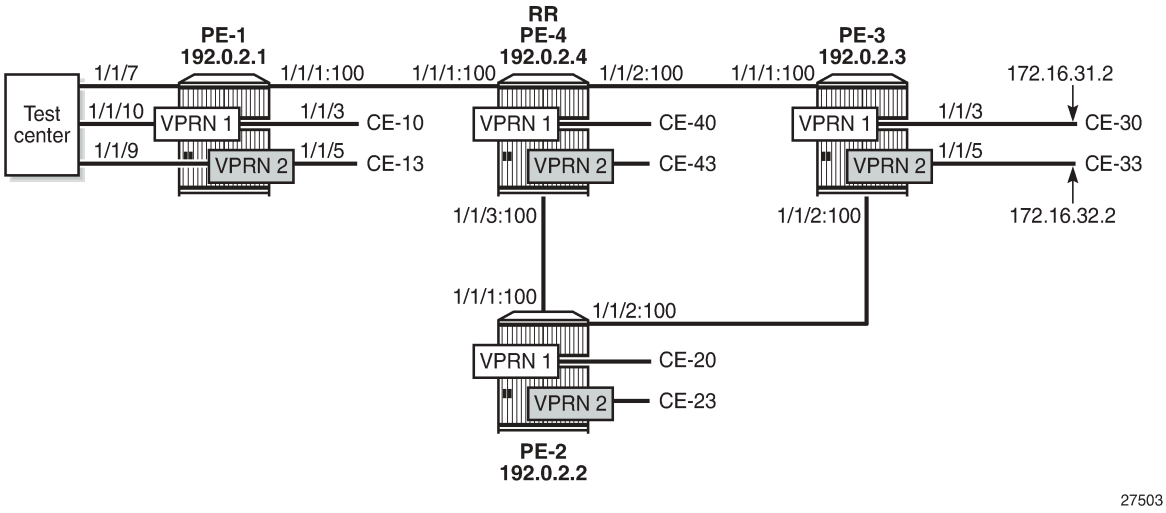
The uRPF checking behavior is as follows.

- If uRPF is enabled on the network interface without **urpf-selected-vprns**, the existing uRPF behavior applies.
- If uRPF is disabled on the network interface, but **urpf-selected-vprns** is enabled, no uRPF lookup is done for any packet arriving on the network interface.
- If uRPF is enabled on the network interface and **urpf-selected-vprns** is enabled, uRPF checking is performed on all packets to be forwarded in the base router. For packets to be forwarded in a VPRN, uRPF checking is only performed for locally configured VPRNs that have **urpf-check** enabled on the network ingress in the VPRN.

Configuration

Figure 404: Example Topology in AS 64496 shows the example topology with four routers and a test center. On each of the routers, VPRN 1 and VPRN 2 are configured. The test center, connected to PE-1, can send IPv4 or IPv6 traffic toward the base router (port 1/1/7) and both VPRNs (port 1/1/10 for VPRN 1 and port 1/1/9 for VPRN 2).

Figure 404: Example Topology in AS 64496



The initial configuration on the four PEs includes the following:

- Cards, MDAs
- Ports:
  - Network ports between the PEs and access ports toward the VPRNs on each PE
  - Port 1/1/7 on PE-1 toward the test center is configured as a network port and is associated with a network interface in the base router. Ports 1/1/9 and 1/1/10 on PE-1 toward the test center are configured as access ports and associated with SAPs in the VPRNs.
- Network interfaces between the PEs and from PE-1 to the test center with a dual-stack IPv4/IPv6
- IS-IS as IGP (alternatively, OSPF can be used) on all network interfaces
- LDP on all network interfaces between the PEs

As an example, the initial configuration on PE-1 is as follows. By default, uRPF is disabled on the network interfaces. The configuration on the other PEs is similar.

```
*A:PE-1# configure
    router
        interface "int-PE-1-PE-4"
            address 192.168.14.1/30
            port 1/1/1:100
            ipv6
                address 2001:db8::14:1/126
            exit
        exit
        interface "int-PE-1-TestCenter"
            address 192.168.11.1/30
            port 1/1/7
            ipv6
                address 2001:db8::11:1/126
            exit
        exit
        interface "system"
            address 192.0.2.1/32
            ipv6
```

```
                address 2001:db8::2:1/128
            exit
        exit
        isis
            area-id 49.0001
            ipv6-routing native
            interface "system"
            exit
            interface "int-PE-1-PE-4"
                interface-type point-to-point
            exit
            no shutdown
        exit
        ldp
            interface-parameters
                interface "int-PE-1-PE-4" dual-stack
                    ipv4
                        no shutdown
                    exit
                exit
            exit
        exit
```

The initial VPRN service configuration on PE-1 is as follows. Auto-bind-tunnel is enabled and LDP tunnels will be used. The service configuration on the other PEs is similar, excluding the interface to the test center.

```
configure
    service
        vprn 1 customer 1 create
            description "PE-1-VPRN-1"
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:1
            interface "int-PE-1-CE-10" create
                address 172.16.11.1/24
                ipv6
                    address 2001:db8::11:1/120
                exit
                sap 1/1/3 create
                exit
            exit
            interface "toTestCenter" create
                address 172.16.110.1/24
                ipv6
                    address 2001:db8::110:1/120
                exit
                sap 1/1/10 create
                exit
            exit
            no shutdown
        exit
        vprn 2 customer 1 create
            description "PE-1-VPRN-2"
            route-distinguisher 64496:2
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:2
            interface "int-PE-1-CE-13" create
                address 172.16.12.1/24
                ipv6
```

```
                    address 2001:db8::12:1/120
                exit
                sap 1/1/5 create
                exit
            exit
            interface "toTestCenter" create
                address 172.16.120.1/24
                ipv6
                    address 2001:db8::120:1/120
                exit
                sap 1/1/9 create
                exit
            exit
            no shutdown
        exit
```

BGP is configured for the VPN-IPv4 and VPN-IPv6 address families with PE-4 as route reflector. The following is the BGP configuration on PE-1:

```
configure
    router
        autonomous-system 64496
        bgp
            split-horizon
            group "iBGP"
                family vpn-ipv4 vpn-ipv6
                peer-as 64496
                neighbor 192.0.2.4
                exit
            exit
        exit
```

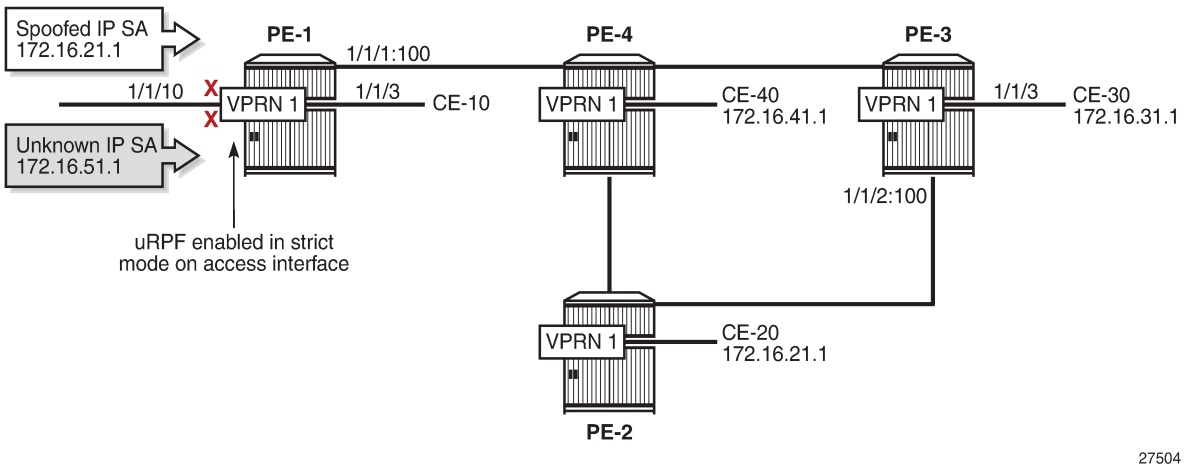
In this example, no uRPF checking will be enabled on the access interfaces of the VPRNs, but obviously, it might be combined with uRPF control on network interfaces.

The following commands to enable uRPF in strict mode (default) on the access interface are only shown for completeness:

```
*A:PE-1# configure service vprn 1 interface "toTestCenter" urpf-check
*A:PE-1# configure service vprn 1 interface "toTestCenter" ipv6 urpf-check
```

With this configuration, packets with spoofed or unknown IP SAs arriving on a VPRN SAP, where uRPF checking is enabled in strict mode, are dropped at the access interface, as shown in Figure 405: uRPF Enabled in Strict Mode on Access Interface in VPRN 1. IP SA 172.16.21.1 has a non-default route in the FIB via a tunnel to PE-2, but packets with this IP SA are not expected on the access interface, so they are dropped in strict mode on interface "toTestCenter" (whereas they would be forwarded in loose mode). All packets with unknown IP SAs—for which there is no non-default route in the FIB of the VPRN—are dropped in strict and in loose mode on interface "toTestCenter".

Figure 405: uRPF Enabled in Strict Mode on Access Interface in VPRN 1



In the remainder of this chapter, uRPF is disabled on the access interfaces, so all packets with spoofed or unknown IP SAs in VPRN 1 will be forwarded by PE-1.

uRPF is enabled on the network interfaces of all PEs. The following commands enable uRPF (in strict mode, by default) for IPv4 and IPv6 on the network interfaces on PE-1. The configuration is similar on the other PEs.

```
*A:PE-1# configure router interface "int-PE-1-PE-4" urpf-check
*A:PE-1# configure router interface "int-PE-1-PE-4" ipv6 urpf-check
*A:PE-1# configure router interface "int-PE-1-TestCenter" urpf-check
*A:PE-1# configure router interface "int-PE-1-TestCenter" ipv6 urpf-check
```

The FIB for the base router on PE-1 is as follows.

```
*A:PE-1# show router fib 1

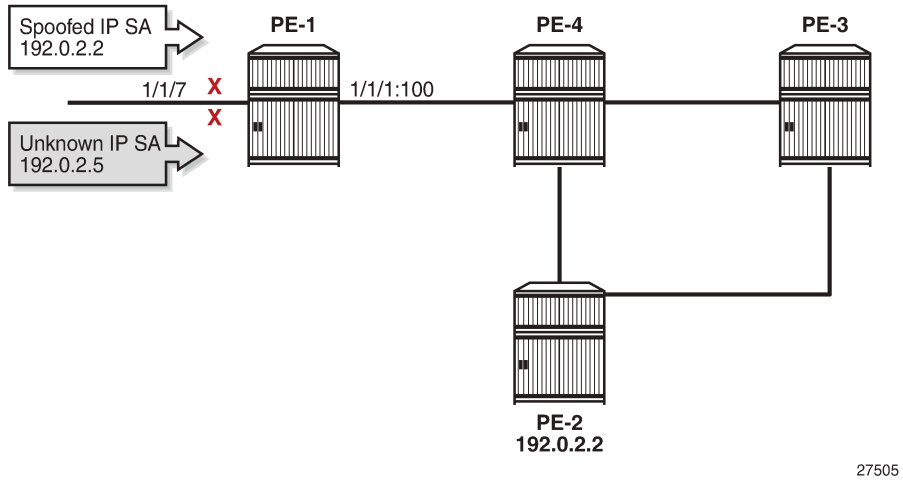
The test center sends two traffic flows with IP destination address (DA) 192.0.2.3 to the base router on PE-1. The first traffic flow has IP SA 192.0.2.2, which is the system address of PE-2 and is expected on another network interface, so it will be dropped by uRPF in strict mode. The second traffic flow has IP SA 192.0.2.5 for which there is no non-default route available in the FIB, so it will be dropped due to uRPF checking. Figure 406: uRPF Checking in Strict Mode in Base Router on PE-1 shows how uRPF drops packets with spoofed or unknown IP SAs at the incoming network interface "int-PE-1-TestCenter" on PE-1.

Figure 406: uRPF Checking in Strict Mode in Base Router on PE-1



The following monitor command output on PE-1 shows that the incoming traffic on network port 1/1/7 toward the test center is dropped. No traffic is forwarded to port 1/1/1 toward PE-4. The packets sent and received on port 1/1/1 are of a different nature, such as IS-IS messages.

uRPF Control on Network Interfaces Inherited by VPRNs

By default, the uRPF control settings of the network interface are inherited by the VPRNs.

The test center sends a first traffic flow with IP DA 172.16.31.2 (CE-30) to SAP 1/1/10 of VPRN 1 on PE-1. The traffic flow has IP SA 172.16.21.1, which has a non-default route in the FIB of VPRN 1 on all PEs. Afterward, the test center sends a second traffic flow with IP DA 172.16.31.2 (CE-30) to SAP 1/1/10 of VPRN 1 on PE-1. These packets have IP SA 172.16.51.1, which is unknown in the VPRN FIB. uRPF is disabled on the access interface, so the packets are not dropped at the SAP, but forwarded in tunnels toward PE-3. No uRPF checking is performed on PE-4, because it is not the endpoint of the tunnel. The tunnel terminates at PE-3 and uRPF is checked on the incoming network interface. The FIB for VPRN 1 on PE-3 is as follows.

```
*A:PE-3# show router 1 fib 1

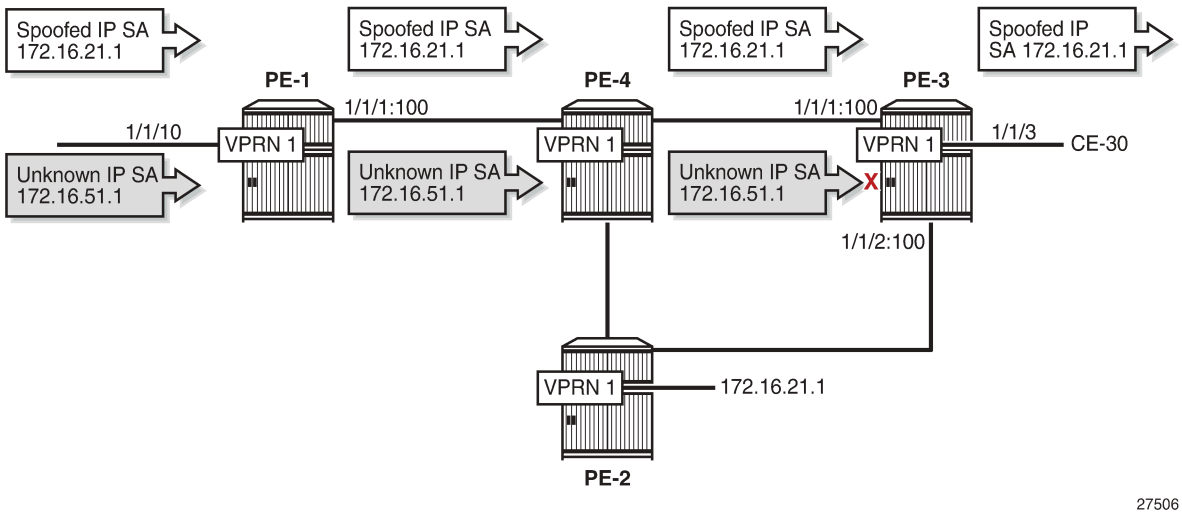
```

All IP packets with IP SA 172.16.21.1 will be forwarded to CE-30, regardless of the interface where they are received, because no network interface is associated with prefix 172.16.21.0/24 in the FIB of VPRN 1. Figure 407: uRPF Checking in VPRN 1 on PE-3 shows that the only packets that will be dropped on PE-3 have an IP SA for which no non-default route is present in the FIB of VPRN 1; in this case, IP SA 172.16.51.1.

Figure 407: uRPF Checking in VPRN 1 on PE-3



The following monitor command output on PE-3 for the traffic flow with IP DA 172.16.31.2 and IP SA 172.16.21.1 shows that the traffic is forwarded to port 1/1/3 toward CE-30.

```

To show selective uRPF for different VPRNs, uRPF checking is needed on the network interfaces for VPRN 1, but not for VPRN 2. To achieve this, additional configuration is required to exclude VPRN 2 from the uRPF check. The following configuration in VPRN 2 is required, but not sufficient to exclude VPRN 2 from the uRPF check.

```
*A:PE-3# configure service vprn 2 network ingress no urpf-check
```

This setting is ignored because no selective VPRN uRPF checking is enabled on the network-interfaces level and the behavior remains unchanged: the uRPF settings are inherited by VPRN 2, even though the configuration in VPRN 2 might be misleading. When the test center generates a traffic flow with IP DA 172.16.32.2 (CE-33) and unknown IP SA 172.16.52.1, the traffic is dropped by PE-3 after uRPF checking. The FIB for VPRN 2 on PE-3 is as follows.

```

Selective VPRN uRPF Control on Network Interfaces

Selective VPRN uRPF control on network interfaces requires the following:

- uRPF configured on the network interfaces (by default disabled): **urpf-check**
- Selective VPRN uRPF control enabled on the network interfaces: **urpf-selected-vprns** (by default disabled)
- **[no] urpf-check** configured on the network ingress of the VPRNs (by default enabled)

In this example, uRPF is already configured on the network interfaces. The configuration on PE-3 is as follows.

```
*A:PE-3# configure router interface "int-PE-3-PE-2" urpf-check
*A:PE-3# configure router interface "int-PE-3-PE-2" ipv6 urpf-check
*A:PE-3# configure router interface "int-PE-3-PE-4" urpf-check
*A:PE-3# configure router interface "int-PE-3-PE-4" ipv6 urpf-check
```

Selective VPRN uRPF control needs to be enabled on all nodes. The configuration on PE-3 is as follows.

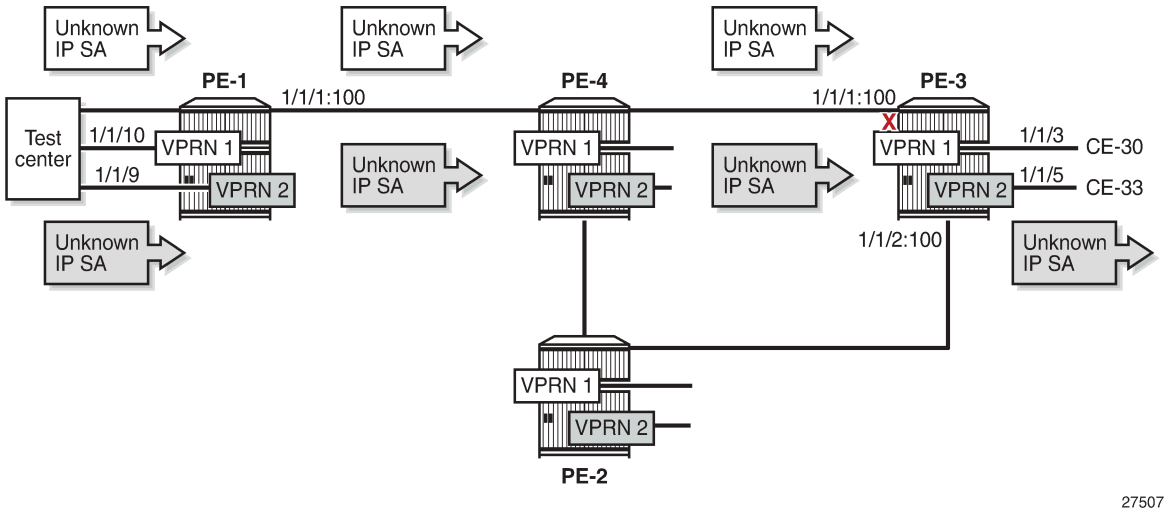
```
*A:PE-3# configure router interface "int-PE-3-PE-2" urpf-selected-vprns
*A:PE-3# configure router interface "int-PE-3-PE-4" urpf-selected-vprns
```

uRPF checking is enabled for VPRN 1 (default) and disabled for VPRN 2, as follows.

```
*A:PE-3# configure service vprn 2 network ingress no urpf-check
```

When the test center generates a traffic flow with IP DA 172.16.31.2 (CE-30) and unknown IP SA 172.16.51.1 in VPRN 1, the packets will be dropped at the incoming network port 1/1/1 on PE-3. For VPRN 2, traffic with IP DA 172.16.32.2 (CE-33) is forwarded, even if the IP SA is unknown (such as 172.16.52.1), because uRPF checking is disabled. Figure 408: Selective VPRN uRPF on Network Interfaces Enabled for VPRN 1 and Disabled for VPRN 2 shows that packets with unknown IP SA in VPRN 1 are dropped by uRPF control on PE-3, while packets with unknown IP SA in VPRN 2 are forwarded on PE-3.

Figure 408: Selective VPRN uRPF on Network Interfaces Enabled for VPRN 1 and Disabled for VPRN 2



The following monitor command output shows that traffic in VPRN 1 with IP DA 172.16.31.2 and IP SA 172.16.51.1 is dropped at incoming port 1/1/1 on PE-3. A similar result occurs for IPv6 addressing.

```

The uRPF control in the base router remains unchanged. In strict mode, PE-1 will drop all packets with spoofed or unknown IP addresses on the incoming network interface, as shown in Figure 406: uRPF Checking in Strict Mode in Base Router on PE-1.

Conclusion

uRPF checking can help service providers to mitigate spoofing attacks. uRPF checking can be executed for all base router traffic and VPRN traffic independently. When the routes held by specific VPRNs are asymmetric, it may be useful to exclude those VPRNs from network ingress uRPF checking.

Spoke Termination for IPv6-6VPE

This chapter provides information about spoke termination for IPv6-6VPE.

Topics in this chapter include:

Applicability

This chapter was originally written for SR OS Release 8.0, where Epipe Virtual Leased Line (VLL) is supported for IPv6 spoke termination within a Virtual Private Routed Network (VPRN). The CLI in the current edition corresponds to SR OS Release 21.10.R2.

Overview

RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*, standardized the use of an IPv6 over IPv4 tunneling scheme. SR OS supports the standardized IPv6 over IPv4 tunneling scheme for VPRN services using Multi-Protocol Border Gateway Protocol (MP-BGP), also known as 6VPE.

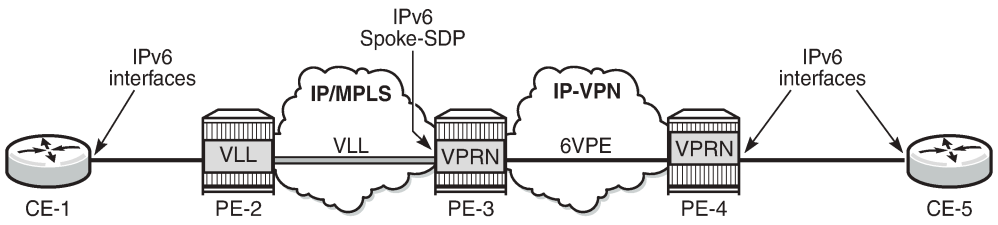
SR OS supports pseudowire termination by a VPRN from an Epipe Virtual Leased Line (VLL) or VPLS spoke Service Distribution Point (spoke SDP) where the pseudowire can be given IPv6 addresses and run IPv6 protocols. In the example used in this chapter, any advertisements across the Multi-Protocol Labeled Switching (MPLS) network between VPRN Provider Edge (PE) devices will use 6VPE. This chapter describes the configuration for IPv6 spoke termination to a VPRN over an Epipe VLL and transporting IPv6 packets over 6VPE tunnels between PE devices.

This solution can be used where a service provider is providing VPRN services built on a transport network whose Interior Gateway Protocol (IGP) is using IPv4 addressing on the network interfaces. The customer's CE and the service provider's PE must support IPv6 pseudowires, IPv6 interfaces and in addition, the service provider also must be able to support the advertisements of IPv6 prefixes between CE-PE peerings and between the transport PE routers using MP-BGP. The advertisement of IPv6 prefixes across the MPLS network and the transport of IPv6 traffic is tunneled using 6VPE.

The VPRN PE supports spoke termination of Epipe VLL services on access with IPv6 addressing between the CE and VPRN PE. The IPv6 spoke termination on VPRN services has the same functionality as VPRN IPv4 spoke termination.

The example in Figure 409: Spoke termination for IPv6 illustrates a CE device that connects to a VPRN PE on an IPv6 interface addressing using spoke termination.

Figure 409: Spoke termination for IPv6



CE-1 is connected to the VPRN service on PE-3, using IPv6 interfaces. CE-1 reaches PE-3 by connecting to PE-2. PE-2 uses an Epipe VLL for transport to the VPRN on the PE-3. The connectivity between the VLL service on the VPRN service on PE-3 is using spoke termination with IPv6 addressing on the spoke SDP interface on PE-3.

Figure 410: IPv6 addressing and IPv6 prefixes

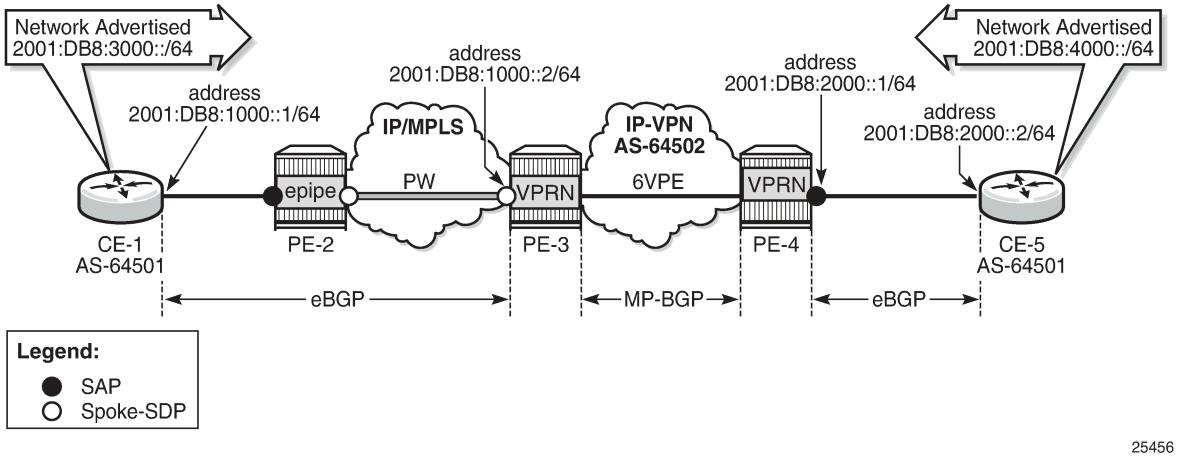


Figure 410: IPv6 addressing and IPv6 prefixes shows the overall IPv6 addressing from interfaces to prefixes advertised from CE-1 and CE-5 across the VPRN network.

- Link between CE-1 and PE-3: 2001:db8:1000::/64
- Link between CE-5 and PE-4: 2001:db8:2000::/64
- Advertised prefix from CE-1: 2001:db8:3000::/64
- Advertised prefix from CE-5: 2001:db8:4000::/64

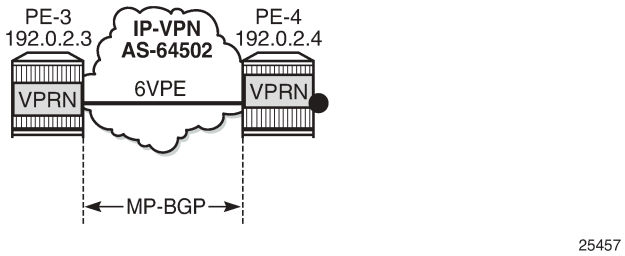
PE-3 has an MP-eBGP session with CE-1 to receive and advertise IPv6 routes. PE-3 also has an MP-iBGP peering session with PE-4 to use 6VPE to tunnel IPv6 routes and traffic to and from PE-4. PE-4 has an IPv6 SAP interface to CE-5 and uses MP-eBGP to advertise to and receive routes from CE-5 (no spoke termination). The configuration of PE-3 is included to provide examples of the end-to-end VPRN service using a 6VPE model.

This network topology illustrates the use of spoke termination using IPv6 interfaces and the tunneling of IPv6 traffic over a 6VPE MPLS network.

Configuration

First an MPLS network is established where the VPRN service can use 6VPE to tunnel traffic across the IPv4 IGP.

Figure 411: MP-BGP VPN IPv6



In Figure 411: MP-BGP VPN IPv6, PE-3 and PE-4 are edge routers running VPRN services on access with IPv6 interfaces. The MPLS network is configured using IPv4 link addressing. Interior Border Gateway Protocol (iBGP) peerings need to be established with MP-BGP for the VPN-IPv6 address family between PE-3 and PE-4.

```
# on PE-3:
configure
    router Base
        bgp
            group "iBGP"
                description "iBGP peering in AS 64502"
                family vpn-ipv6
                type internal
                neighbor 192.0.2.4
                    description "PE-4"
                exit
            exit
            no shutdown
        exit
    exit
```

```
# on PE-4:
configure
    router Base
        bgp
            group "iBGP"
                description "iBGP peering in AS 64502"
                family vpn-ipv6
                type internal
                neighbor 192.0.2.3
                    description "PE-3"
                exit
            exit
            no shutdown
        exit
    exit
```

Configuring address family VPN-IPv6 between VPRN PE edge routers in BGP enables MP-BGP for the Layer 3 VPNs supporting the customer's IPv6 addressing (6VPE).

The following commands verify the BGP sessions for the VPN-IPv6 address family between PE-3 and PE-4:

```
*A:PE-3# show router bgp neighbor 192.0.2.4

===============================================================================

```

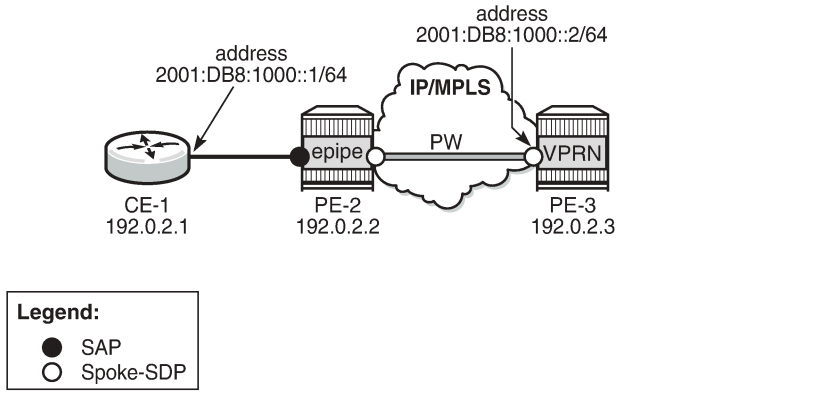
After the MP-BGP sessions are established for the VPN-IPv6 address-family, 6VPE tunnel support is provided between PE-3 and PE-4.

Figure 412: Spoke termination for IPv6 addressing illustrates the model for spoke termination for IPv6 using VPRN services.

Figure 412: Spoke termination for IPv6 addressing



CE-1 is configured with IPv6 addressing on the access interface facing the VPRN service. CE-1's access is backhauled to the VPRN service on PE-3 using Epipe VLL with spoke termination. The configuration of the Epipe VLL on PE-2 is as follows:

```
# on PE-2:
configure
    service
        sdp 231 mpls create
            far-end 192.0.2.3
            ldp
            no shutdown
        exit
        epipe 1 name "Epipe 1" customer 1 create
            sap 1/1/2 create
                no shutdown
            exit
            spoke-sdp 231:1 create
                no shutdown
            exit
            no shutdown
        exit
    exit
```

Epipe 1 on PE-2 is configured with a SAP interface facing the customer and a spoke SDP facing PE-3. The spoke SDP is terminated into the customer's VPRN service on PE-3.

The possible IPv6 options for spoke SDP interfaces on the CLI for VPRN Services are as follows (compliant with RFC 4213, *Basic Transition Mechanisms for IPv6 Hosts and Routers <draft-ietf-v6ops-mech-v2-07.txt>*):

- Interface spoke SDP (IPv6 options only)

```
*A:PE-3>config>service>vprn# interface "int-PE-3-PE-2" ?
---snip---
[no] ipv6            + Enables/Configures IPv6 for a VPRN interface
---snip---
```

```
*A:PE-3>config>service>vprn>if# ipv6 ?
  - ipv6
  - no ipv6
```

```
 [no] address         - Assigns an IPv6 address to the VPRN interface.
 [no] bfd             - Configure BFD parameters
 [no] dad-disable     - Disable Duplicate Address Detection
 [no] dhcp6-relay     + Configure DHCPv6 relay parameters for the VPRN interface
 [no] dhcp6-server    + Configure DHCPv6 server parameters for the VPRN interface
 [no] forward-ipv4-p* - Enable/disable forwarding unencapsulated IPv4 packets
      icmp6           + Configure ICMPv6 parameters for the VPRN interface
 [no] link-local-add* - Configure link-local address
 [no] local-dhcp-ser* - Assign a DHCP server to the interface
 [no] local-proxy-nd  - Enable/disable local proxy Neighbor Discovery on the VPRN
                        interface
      nd-host-route   + Configure ND host route to populate
 [no] nd-learn-unsol* - Configure neighbor discover learn unsolicited
 [no] nd-proactive-r* - Configure neighbor discovery proactive refresh
 [no] neighbor        - Configure IPv6-to-MAC address mapping on the VPRN interface
 [no] neighbor-limit  - Configures the maximum amount of IPv6 neighbor entries
 [no] proxy-nd-policy - Configure a proxy Neighbor Discovery policy for the VPRN
                        interface
 [no] qos-route-look* - Enable/Disable Qos route lookup for the interface
 [no] reachable-time  - Configure neighbor reachability detection timer
 [no] secure-nd       + Configure Secure Neighbor Discovery (SEND) parameters for the
                        interface
 [no] stale-time      - Configure the time a neighbor discovery cache entry can remain
                       stale before being removed
 [no] tcp-mss         - Configure TCP maximum segment size for the interface
 [no] urpf-check      + Enables/Configures unicast RPF check for an interface
 [no] vrrp            + Context to create and configure VRRP virtual router instance
                        on the interface
```

- IPv6 address

```
*A:PE-3>config>service>vprn>if>ipv6# address ?

                                         x:x:x:x:x:x:d.d.d.d
                                         x [0..FFFF]H
                                         d [0..255]D
 <dad-disable>        : keyword
```

- Neighbor: IPv6 to MAC address mapping on the VRPN interface

```
*A:PE-3>config>service>vprn>if>ipv6# neighbor ?
  - neighbor <ipv6-address> <mac-address>
  - no neighbor <ipv6-address>

 <ipv6-address>       : x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                      x:x:x:x:x:x:d.d.d.d
                                      x [0..FFFF]H
                                      d [0..255]D
                        prefix-length [1..128]
 <mac-address>        : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
```

- Enabling local proxy neighbor discovery

```
*A:PE-3>config>service>vprn>if>ipv6# local-proxy-nd ?
  - local-proxy-nd
  - no local-proxy-nd
```

- VRRP

```
*A:PE-3>config>service>vprn>if>ipv6# vrrp ?
  - no vrrp <virtual-router-id>
  - vrrp <virtual-router-id> [owner] [passive]

 <virtual-router-id>  : [1..255]
 <owner>              : keyword

 [no] backup          - Configure virtual router IP addresses for the interface
 [no] bfd-enable      - Configure a BFD interface
 [no] init-delay      - Configure VRRP initialization delay timer
 [no] mac             - Configure a Virtual MAC address to use in Neighbor Discovery
 [no] master-int-inh* - Allow/disallow the master instance to dictate the master down
                        timer (non-owner context only)
 [no] message-interv* - Configure the interval for sending VRRP Advertisement messages
 [no] ntp-reply       - Allow/disallow non-owner master to reply to NTP requests
                       (non-owner context only)
 [no] oper-group      - Associate group-name to VRRP
 [no] ping-reply      - Allow/disallow non-owner master to reply to ICMP Echo requests
                       (non-owner context only)
 [no] policy          - Associate a VRRP Priority Control Policy with the virtual
                        router instance (non-owner context only)
 [no] preempt         - Allow/disallow the virtual router instance to override an
                        existing non-owner master (non-owner context only)
 [no] priority        - Configure the base priority for the virtual router instance
                        (non-owner context only)
 [no] shutdown        - Administratively enable/disable the virtual router instance
                        (non-owner context only)
 [no] standby-forwar* - Allow/disallow the forwarding of packets by a standby router
 [no] telnet-reply    - Allow/disallow non-owner master to reply to Telnet requests
                        (non-owner context only)
 [no] traceroute-rep* - Allow/disallow non-owner master to reply to traceroute requests
                       (non-owner context only)
```

The VPRN on PE-3 exports IPv6 routes (IPv6 route on CE-5) to CE-1 using the following route policy.

```
# on PE-3
configure
    router Base
        policy-options
            begin
            prefix-list "PE-3-CE-1"
                prefix 2001:db8:4000::/64 exact
            exit
            policy-statement "PE-3-BGP-CE-1"
                entry 10
                    from
                        prefix-list "PE-3-CE-1"
                    exit
                    action accept
                       origin igp
                    exit
                exit
                default-action drop
                exit
            exit
            commit
        exit
```

The configuration for the VPRN service on PE-3 with IPv6 interface (spoke SDP) as shown in Figure 412: Spoke termination for IPv6 addressing:

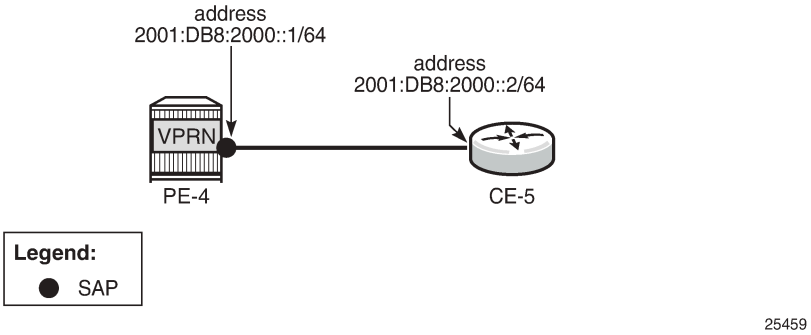
```
# on PE-3
configure
    service
        sdp 321 mpls create
            far-end 192.0.2.2
            ldp
            no shutdown
        exit
        vprn 1 name "VPRN 1" customer 1 create
            router-id 192.0.2.31
            autonomous-system 64502
            interface "loopback" create
                address 192.0.2.31/32
                loopback
            exit
            interface "int-PE-3-PE-2" create
                description "Spoke SDP"
                ipv6
                    address 2001:db8:1000::2/64
                exit
                spoke-sdp 321:1 create
                    no shutdown
                exit
            exit
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    route-distinguisher 64502:1
                    vrf-target target:64502:1
                    no shutdown
                exit
            exit
            bgp
                router-id 192.0.2.31
                group "Spoke-CE-1-PE-3"
                    family ipv6
                    peer-as 64501
                    local-address 2001:db8:1000::2
                    neighbor 2001:db8:1000::1
                        as-override
                        type external
                        export "PE-3-BGP-CE-1"
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
```

In the preceding configuration example, PE-3 has been configured with an IPv6 spoke SDP (spoke termination) with interface int-PE-3-PE-2. The VPRN configuration has also been set up for MP-eBGP peering to CE-1 through the IPv6 spoke interface. The MP-eBGP peering receives and advertises IPv6

prefixes from and to CE-1. The included route policy configuration shows how IPv6 routes are advertised to CE-1 from PE-3 (policy-statement PE-3-BGP-CE-1).

The configuration on PE-4 is similar, but with a SAP interface to CE-5 instead of a spoke-SDP.

Figure 413: PE-4 VPRN with SAP to CE-5



The IPv6 configuration options for the SAP interface (int-PE-4-CE-5) are similar to those in the preceding example for the spoke SDP on PE-3. The PE-4 BGP export policy (PE-4-BGP-CE-5) is also similar to the example for PE-3 in advertising the learned IPv6 route to CE-5.

```
# on PE-4:
configure
    router Base
        policy-options
            begin
            prefix-list "PE-4-CE-5"
                prefix 2001:db8:3000::/64 exact
            exit
            policy-statement "PE-4-BGP-CE-5"
                entry 10
                    from
                        prefix-list "PE-4-CE-5"
                    exit
                    action accept
                        origin igp
                    exit
                exit
                default-action drop
                exit
            exit
            commit
        exit
```

```
configure
    service
        vprn 1 name "VPRN 1" customer 1 create
            router-id 192.0.2.41

                    local-address 2001:db8:2000::1
                    neighbor 2001:db8:2000::2
                        as-override
                        type external
                        export "PE-4-BGP-CE-5"
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

In this setup, the configuration on CE-1 is as follows.

```
# on CE-1:
configure
    router Base
        static-route 2001:db8:3000::/64
            black-hole
                no shutdown
            exit
        exit
        policy-options
            begin
            prefix-list "CE-1-192.0.2.1"
                prefix 2001:db8:3000::/64 exact
            exit
            policy-statement "CE-1-sys-to-eBGP"
                entry 10
                    from
                        prefix-list "CE-1-192.0.2.1"
                    exit
                    action accept
                        origin igp
                    exit
                exit
                default-action drop
                exit
            exit
            commit
        exit
        bgp
```

```
            router-id 192.0.2.1
            group "eBGP_to_64502"
                description "eBGP_to_PE-3_AS64502"
                family ipv6
                type external
                peer-as 64502
                local-address 2001:db8:1000::1
                neighbor 2001:db8:1000::2
                    export "CE-1-sys-to-eBGP"
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
# on CE-1:
configure
    service
        ies 1 name "IES 1" customer 1 create
            interface "int-CE-1-PE-2" create
                description "SAP_toward_VPRN_Service"
                ipv6
                    address 2001:db8:1000::1/64
                exit
                sap 1/1/1 create
                exit
            exit
            no shutdown
        exit
```

The configuration on CE-5 is similar.

The following command on PE-2 shows that the Epipe VLL is established with the SAP facing CE-1 and spoke SDP facing VPRN 1 on PE-3.

```
*A:PE-2# show service id 1 base

===============================================================================
```

MP-iBGP, providing 6VPE is configured and built between PE-3 and PE-4 across the MPLS network. IPv6 prefixes are received on PE-3 from CE-1 (2001:db8:3000::/64) and on PE-4 from CE-5 (2001:db8:4000::/64) across the MPLS network using MP-iBGP (6VPE).

CE-1 advertises IPv6 prefix 2001:db8:3000::/64 and CE-5 advertises IPv6 prefix 2001:db8:4000::/64.

The following command on PE-3 shows whether VPN-IPv6 routes were received from and advertised to its iBGP peer PE-4:

```
*A:PE-3# show router bgp summary

Conclusion

Spoke termination for IPv6-6VPE extends the use of spoke terminated interfaces from an Epipe VLL into a VPRN service using IPv6 interfaces on the access. Supporting the requirement of IPv6 interfaces, routing of IPv6 prefixes and the use of 6VPE for IPv6 tunneling over an IPv4 network allows SR OS to provide capabilities supporting the growth of IPv6 architectures.

Traffic Leaking from VPRN to GRT

This chapter provides information about Traffic Leaking from VPRN to GRT.

Topics in this chapter include:

Applicability

The information and configuration in this chapter were originally based on SR OS Release 14.0 R4. The CLI in the current edition corresponds to SR OS Release 22.2.R2.

Overview

RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, describes a method of distributing routing information using BGP and MPLS forwarding data to provide a Layer 3 VPN service to end users. Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via Multi-Protocol Border Gateway Protocol (MP-BGP) peering. Each route exchanged via the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association and resolves any IP address overlap.

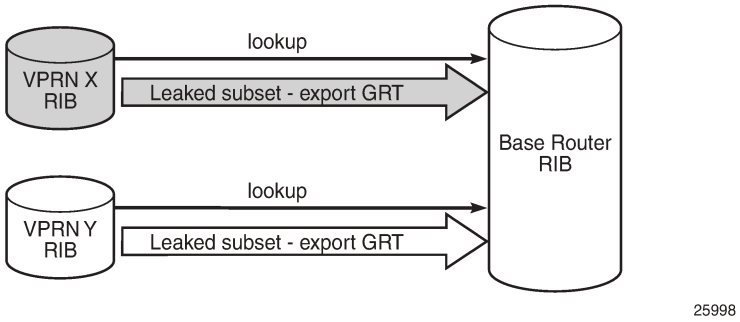
It has always been possible to exchange traffic from one VPRN to another, using scenarios such as "extranet", "hub and spoke" and so on, using the vrf-import and vrf-export policies for BGP VPN-IPv4 route distribution.

Traffic leaking to the Global Route Table (GRT) allows service providers to offer VPRN and Internet services over a single virtual routing and forwarding VRF interface. Packets entering a VRF interface can have route processing results derived from the VRF or the GRT. The leaking and preferred lookup settings are configured on a per-VPRN basis.

To allow data flowing from a VPRN to the base router, routing information from the base router must be made available for lookup by the VPRN. The GRT lookup can be general (for example, any lookup miss in the Virtual Routing and Forwarding (VRF) table can be resolved in the GRT), or specific (for example, specific routes should only be searched for in the GRT and ignored by the VPRN).

To enable the GRT lookup from the VPRN, the **enable-grt** command is used. This only provides part of the solution, because packets can now be forwarded from the VPRN to the GRT, but not in the opposite direction. The GRT needs to learn specific destination prefixes from the VPRN and this is achieved by route leaking from the VPRN to the GRT, using policies (**export-grt** command). The maximum number of routes leaked from a VPRN to the GRT is five by default, but this maximum can be modified or even removed. Prefixes should be globally unique within the service provider network and if these are propagated outside the provider's network, they must be from the public IP space and globally unique.

Figure 414: VPRN to GRT leak process

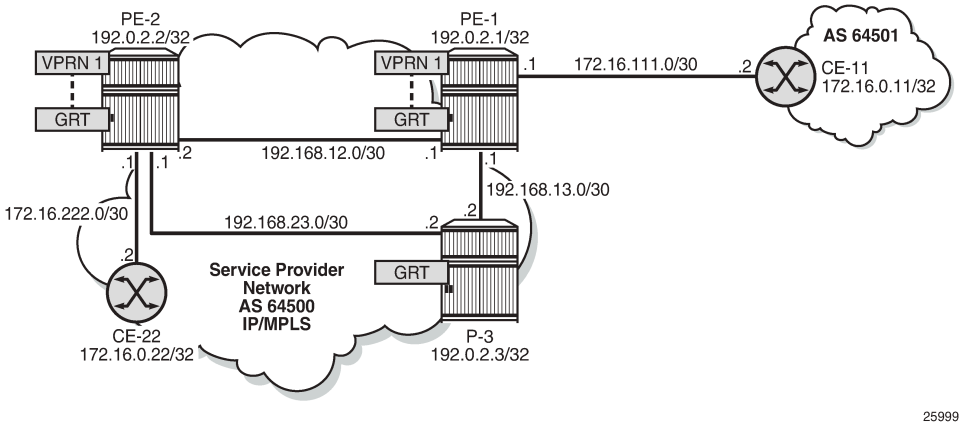


The method described in this chapter allows the network administrator to leak specific or all routes that are inside a VPRN to the GRT. Route leaking from VPRN to GRT is protocol-independent and can be applied for BGP, OSPF(v3), IS-IS, static, local routes, and so on. For BGP routes, there is an improved route leaking mechanism that allows leaking routes preserving all BGP attributes; see chapter *BGP Route Leaking*.

Configuration

Figure 415: Example topology with IPv4 addresses shows the example topology used in this chapter, including the IPv4 addresses. The interfaces also have IPv6 addresses, which will be shown in Figure 417: Example topology with IPv6 addresses.

Figure 415: Example topology with IPv4 addresses



Initial configuration

The nodes in the example topology have the following initial configuration:

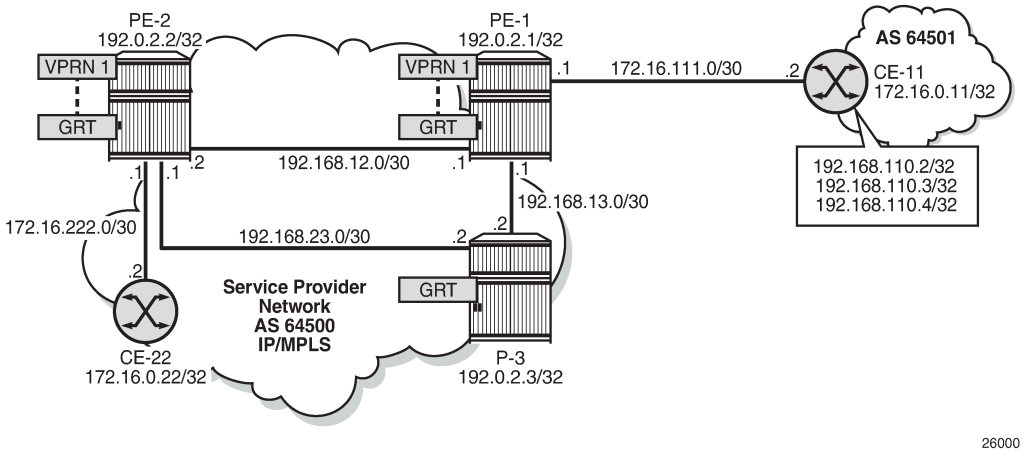
- Cards, MDAs, ports
- Router interfaces
- IGP (IS-IS or OSPF) between the PEs

- LDP between the PEs
- VPRN "VPRN 1" on PE-1
- BGP (IBGP between the PEs; EBGP between PE-1 and CE-11)
  - On PE-1, BGP is configured in the base router and in VPRN 1.
- Loopback addresses on CE-11, such as 192.168.110.2/32.
- Export policies on CE-11 to export routes from direct with certain prefixes.

Protocol-independent IPv4 route leaking from VPRN to GRT

Figure 416: IPv4 VPRN to GRT route leaking for IS-IS shows the topology with the IP addresses for this example. Route leaking from VPRN to GRT is protocol independent and in this example, VPRN "VPRN 1" on PE-1 will leak local routes, static routes, and imported BGP routes to the GRT. IS-IS or OSPF routes can also be leaked, but that is not shown here.

Figure 416: IPv4 VPRN to GRT route leaking for IS-IS



GRT-leak is by default disabled. The routing table for VPRN 1 on PE-1 contains local routes, static routes, and BGP routes that are learned from CE-11, as follows:

```
*A:PE-1# show router 1 route-table

===============================================================================

192.168.23.0/30                                 Remote  ISIS      00h01m03s  15
       192.168.12.2                                                 20
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

To enable VPRN to GRT leaking, the following route policy is configured on PE-1 and applied in VPRN 1:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "LeakVPRNtoGRT_pref8"
                entry 10
                    action accept
                        preference 8
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn "VPRN 1"
            grt-lookup
                enable-grt
                exit
                export-grt "LeakVPRNtoGRT_pref8"
```

```
            exit
        exit
```

This policy allows leaking all routes from a VPRN to the base router, without any match criteria. However, when routes are leaked from VPRNs to the GRT, they need to be unique and only routes that need to be known in the GRT should be leaked. By default, the preference for a leaked route is 180. The preference can be manually configured to a lower value, such as 8, to avoid network inconsistencies between the IGP and the RT on the router where the routes are leaked.

When **enable-grt** is configured, any lookup miss in the VRF table will be resolved in the GRT, if available. This only works from VPRN to GRT and does not require route leaking. However, the base router needs to be able to route packets back to the VPRN and it cannot perform a lookup in the routing table of the VPRN. Therefore, route leaking from VPRN to GRT is required, and **export-grt** is configured. Prefixes in the VPRN must be leaked to the GRT through a policy. Prefixes leaked from any VPRN should never conflict with prefixes leaked from any other VPRN or existing prefixes in the GRT.

This configuration is protocol-independent. Route leaking from VPRN to GRT is applicable for all kinds of learned routes, such as static routes, local routes, IS-IS, OSPF, BGP, and so on.

After routes are leaked from the VPRN to the GRT, the routing table of the base router includes the leaked routes, with protocol "VPN Leak". For PE-1, the routing table contains the following routes:

```
*A:PE-1# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric

192.168.13.0/30                               Local   Local     00h03m06s  0
       int-PE-1-P-3                                                  0
192.168.23.0/30                               Remote  ISIS      00h02m49s  15
       192.168.12.2                                                  20
192.168.110.3/32                              Remote  VPN Leak  00h00m20s  8
       172.16.111.2                                                  0
192.168.110.4/32                              Remote  VPN Leak  00h00m20s  8
       172.16.111.2                                                  0
192.168.120.0/24                              Remote  VPN Leak  00h00m20s  8
       172.16.111.2                                                  0
-------------------------------------------------------------------------------
No. of Routes: 11
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Regardless the preference of the original routes in VPRN 1, all the leaked routes in the GRT have preference 8, as configured. By default, a maximum of five routes are leaked. This export limit can be overruled, as follows:

```
# on PE-1:
configure
    service
        vprn "VPRN 1"
            grt-lookup
                export-limit 10
```

The following command shows only the routes leaked from any VPRN to GRT on PE-1:

```
*A:PE-1# show router route-table protocol vpn-leak all

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref

Export IPv4 VPN-leak routes to routing protocols

Until now, the VPN-leak routes are leaked locally to the GRT, but they are not advertised in IS-IS, OSPF, or BGP. Router P-3 has not learned any of the leaked routes, as follows:

```
*A:P-3# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h03m44s  15
       192.168.13.1                                                 10
192.0.2.2/32                                    Remote  ISIS      00h03m44s  15
       192.168.23.1                                                 10
192.0.2.3/32                                    Local   Local     00h03m51s  0
       system                                                       0
192.168.12.0/30                                 Remote  ISIS      00h03m44s  15
       192.168.13.1                                                 20
192.168.13.0/30                                 Local   Local     00h03m51s  0
       int-P-3-PE-1                                                 0
192.168.23.0/30                                 Local   Local     00h03m51s  0
       int-P-3-PE-2                                                 0
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

To reduce the number of routes to be exported on PE-1, a match criterion is added for the routes to be leaked, as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            prefix-list "192.168.110.0"
                prefix 192.168.110.0/24 longer
            exit
            policy-statement "LeakVPRNtoGRT_pref8_110"
                entry 10
                    from
                        prefix-list "192.168.110.0"
                    exit
                    action accept
                        preference 8
                    exit
                exit
            exit
            commit
```

```
        exit
    exit
    service
        vprn "VPRN 1"
            grt-lookup
                enable-grt
                exit
                export-grt "LeakVPRNtoGRT_pref8_110"
            exit
```

VPN-leak routes can be exported to any routing protocol. Prefix lists can be used to filter routes, but that is not configured in this example. The following export policy is configured on PE-1 to export the VPN-leak routes:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "export-vpn-leak"
                entry 10
                    from
                        protocol vpn-leak
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The same export policy will be used for export to IS-IS, OSPF, and BGP.

Export IPv4 VPN-leak routes to IS-IS

The export policy is applied in the IS-IS context on PE-1, as follows:

```
# on PE-1:
configure
    router Base
        isis 0
            export "export-vpn-leak"
        exit
```

The leaked routes are now advertised via IS-IS and appear as IS-IS routes with default preference for IS-IS routes on PE-2 and P-3. The route table on P-3 looks as follows:

```
*A:P-3# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                  Remote  ISIS      00h04m39s  15
       192.168.13.1                                                10
192.0.2.2/32                                  Remote  ISIS      00h04m39s  15
       192.168.23.1                                                10
192.0.2.3/32                                  Local   Local     00h04m46s  0
```

```
       system                                                          0
192.168.12.0/30                          Remote  ISIS      00h04m39s  15
       192.168.13.1                                                    20
192.168.13.0/30                          Local   Local     00h04m46s  0
       int-P-3-PE-1                                                    0
192.168.23.0/30                          Local   Local     00h04m46s  0
       int-P-3-PE-2                                                    0
192.168.110.2/32                         Remote  ISIS      00h00m21s  15
       192.168.13.1                                                    10
192.168.110.3/32                         Remote  ISIS      00h00m21s  15
       192.168.13.1                                                    10
192.168.110.4/32                         Remote  ISIS      00h00m21s  15
       192.168.13.1                                                    10
-------------------------------------------------------------------------------
No. of Routes: 9
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed from the IS-IS context on PE-1, as follows:

```
# on PE-1:
configure
    router Base
        isis 0
            no export
```

Export IPv4 VPN-leak routes to OSPF

When OSPF is used instead of IS-IS, the behavior is similar. The export policy is applied in the OSPF context on PE-1, as follows:

```
# on PE-1:
configure
    router Base
        ospf 0
            export "export-vpn-leak"
```

To export routes into OSPF using a policy, the router must be configured as ASBR, as follows:

```
# on PE-1:
configure
    router Base
        ospf 0
            asbr
```

The routes with protocol VPN-leak on PE-1 are now exported in OSPF to PE-2 and P-3. The default preference for external OSPF routes is 150. On P-3, the routing table contains the following OSPF routes:

```
*A:P-3# show router route-table protocol ospf

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                       Type    Proto     Age        Pref
      Next Hop[Interface Name]                                 Metric
```

```
-------------------------------------------------------------------------------
192.0.2.1/32                                Remote  OSPF      00h00m44s  10
       192.168.13.1                                             10
192.0.2.2/32                                Remote  OSPF      00h00m44s  10
       192.168.23.1                                             10
192.168.12.0/30                             Remote  OSPF      00h00m44s  10
       192.168.13.1                                             20
192.168.110.2/32                            Remote  OSPF      00h00m14s  150
       192.168.13.1                                             1
192.168.110.3/32                            Remote  OSPF      00h00m14s  150
       192.168.13.1                                             1
192.168.110.4/32                            Remote  OSPF      00h00m14s  150
       192.168.13.1                                             1
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed from the OSPF context on PE-1 as follows:

```
# on PE-1:
configure
    router Base
        ospf
            no export
```

Export IPv4 VPN-leak routes to BGP

The export policy is applied in the general **bgp** context of PE-1, as follows:

```
# on PE-1:
configure
    router Base
        bgp
            export "export-vpn-leak"
```

The VPN-leak routes from PE-1 will be advertised as BGP routes to BGP neighbors PE-2 and P-3, and the routing tables will contain BGP routes with preference 170. P-3 has the following BGP routes:

```
*A:P-3# show router route-table protocol bgp

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                          Type    Proto     Age        Pref
      Next Hop[Interface Name]                                Metric
-------------------------------------------------------------------------------
192.168.110.2/32                            Remote  BGP       00h00m16s  170
       192.168.13.1                                             10
192.168.110.3/32                            Remote  BGP       00h00m16s  170
       192.168.13.1                                             10
192.168.110.4/32                            Remote  BGP       00h00m16s  170
       192.168.13.1                                             10
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
```

```
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Note:
If it is required to preserve the BGP path attributes in the leaking process, you must use the BGP Route Leaking process described in chapter *BGP Route Leaking*. However, with this protocol-independent route leaking mechanism, it is possible to leak non-BGP routes to the GRT that will be advertised as BGP routes.

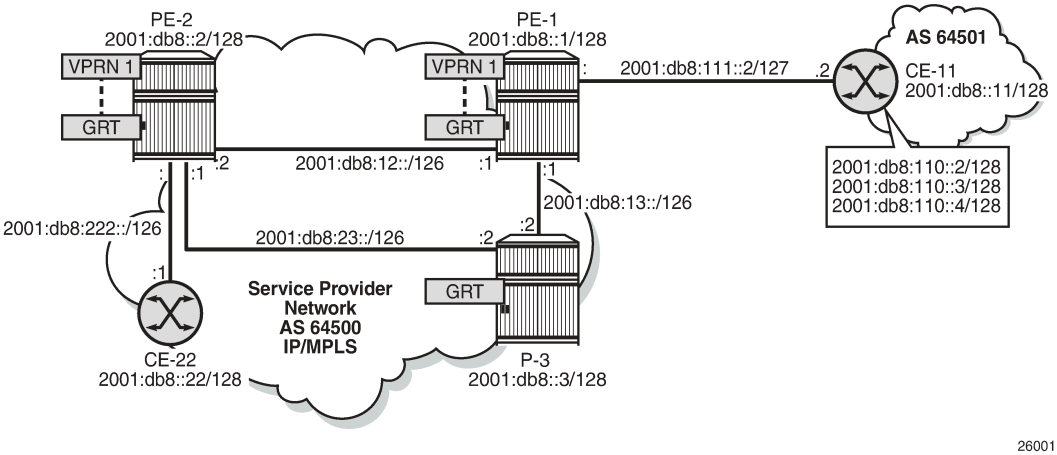
The export policy is removed from the **bgp** context, as follows:

```
# on PE-1:
configure
    router Base
        bgp
            no export
```

Protocol-independent IPv6 route leaking from VPRN to GRT

Figure 417: Example topology with IPv6 addresses shows the topology and the IP addresses used for IPv6. CE-11 exports routes such as 2001:db8:110::2/128 to VPRN 1on PE-1. On PE-1, local routes, static routes, and BGP routes will be leaked to the GRT.

Figure 417: Example topology with IPv6 addresses



The IPv6 routing table for VPRN 1 on PE-1 includes local addresses, a static route, and three BGP routes exported by CE-11, as follows:

```
*A:PE-1# show router 1 route-table ipv6

===============================================================================
IPv6 Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
```

```
2001:db8::1:1/128                               Local   Local     00h08m49s  0
       system                                                         0
2001:db8:110::2/128                             Remote  BGP       00h07m49s  170
       2001:db8:111::1                                                0
2001:db8:110::3/128                             Remote  BGP       00h07m49s  170
       2001:db8:111::1                                                0
2001:db8:110::4/128                             Remote  BGP       00h07m49s  170
       2001:db8:111::1                                                0
2001:db8:111::/127                              Local   Local     00h08m48s  0
       int-PE-1-CE-11                                                 0
2001:db8:120::/120                              Remote  Static    00h08m48s  5
       2001:db8:111::1                                                1
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

By default, route leaking is disabled and the IPv6 GRT on PE-1 does not contain any of the IPv6 routes in VPRN 1, as follows:

```
*A:PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8::1/128                                 Local   Local     00h08m50s  0
       system                                                         0
2001:db8::2/128                                 Remote  OSPF3     00h08m38s  10
       fe80::14:1ff:fe01:1-"int-PE-1-PE-2"                            10
2001:db8::3/128                                 Remote  OSPF3     00h08m26s  10
       fe80::18:1ff:fe01:2-"int-PE-1-P-3"                             10
2001:db8:12::/126                               Local   Local     00h08m49s  0
       int-PE-1-PE-2                                                  0
2001:db8:13::/126                               Local   Local     00h08m49s  0
       int-PE-1-P-3                                                   0
2001:db8:23::/126                               Remote  OSPF3     00h08m22s  10
       fe80::18:1ff:fe01:2-"int-PE-1-P-3"                             20
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The VPN-leak route policy is the same as for IPv4 routes, and is applied in the **vprn** context in the same way as for IPv4 routes, as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "LeakVPRNtoGRT_pref8"
                entry 10
                    action accept
```

```
                    preference 8
                exit
            exit
        exit
        commit
    exit
exit
service
    vprn "VPRN 1"
        grt-lookup
            enable-grt
            exit
            export-grt "LeakVPRNtoGRT_pref8"
        exit
```

On PE-1, the IPv6 routing table for VPRN 1 contains six routes, but by default, a maximum of five routes are leaked, as follows:

```
*A:PE-1# show router route-table ipv6 protocol vpn-leak all

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                           Active     Metric
-------------------------------------------------------------------------------
2001:db8::1:1/128                               Remote  VPN Leak  00h00m12s  8
       system                                             Y            0
2001:db8:110::2/128                             Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                    Y            0
2001:db8:110::4/128                             Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                    Y            0
2001:db8:111::/127                              Remote  VPN Leak  00h00m12s  8
       int-PE-1-CE-11                                     Y            0
2001:db8:120::/120                              Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                    Y            0
-------------------------------------------------------------------------------
No. of Routes: 5
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

The export limit for IPv6 routes is removed, as follows:

```
# on PE-1:
configure
    service
        vprn "VPRN 1"
            grt-lookup
                export-v6-limit 0
```

As a result, there is no limit to the number of leaked IPv6 routes, and all six IPv6 routes are leaked from VPRN 1 to the GRT with the configured preference 8, as follows:

```
*A:PE-1# show router route-table ipv6 protocol vpn-leak all

===============================================================================
IPv6 Route Table (Router: Base)
```

```
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                           Active     Metric
-------------------------------------------------------------------------------
2001:db8::1:1/128                               Remote  VPN Leak  00h00m05s  8
       system                                             Y            0

Export IPv6 VPN-leak routes to routing protocols

Until now, the IPv6 VPN-leak routes are leaked locally to the GRT, but they are not advertised in IS-IS, OSPFv3, or BGP. Router P-3 has not learned any of the leaked IPv6 routes, as follows:

```
*A:P-3# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                     Metric
-------------------------------------------------------------------------------
```

```
2001:db8::1/128                                 Remote  OSPF3     00h10m51s  10
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                             10
2001:db8::2/128                                 Remote  OSPF3     00h10m46s  10
       fe80::14:1ff:fe01:2-"int-P-3-PE-2"                             10
2001:db8::3/128                                 Local   Local     00h10m52s  0
       system                                                         0
2001:db8:12::/126                               Remote  OSPF3     00h10m51s  10
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                             20
2001:db8:13::/126                               Local   Local     00h10m51s  0
       int-P-3-PE-1                                                   0
2001:db8:23::/126                               Local   Local     00h10m51s  0
       int-P-3-PE-2                                                   0
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

To reduce the number of VPN-leak routes, a match criterion is added to the route policy on PE-1, as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            prefix-list "2001:db8:110::"
                prefix 2001:db8:110::/125 longer
            exit
            policy-statement "LeakVPRNtoGRT_pref8_110"
                entry 20
                    from
                        prefix-list "2001:db8:110::"
                    exit
                    action accept
                        preference 8
                    exit
                exit
            exit
            commit
        exit
    exit
    service
        vprn "VPRN 1"
            grt-lookup
                enable-grt
                exit
                export-grt "LeakVPRNtoGRT_pref8_110"
            exit
```

The following IPv6 routes are leaked from VPRN 1 to GRT on PE-1:

```
*A:PE-1# show router route-table ipv6 protocol vpn-leak

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
```

```
2001:db8:110::2/128                             Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                             0
2001:db8:110::3/128                             Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                             0
2001:db8:110::4/128                             Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                             0
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv6 VPN-leak routes can be exported to routing protocols IS-IS, OSPFv3, and BGP.

The export policy on PE-1 is the same as in all the preceding examples for IPv4, as follows:

```
# on PE-1:
configure
    router Base
        policy-options
            begin
            policy-statement "export-vpn-leak"
                entry 10
                    from
                        protocol vpn-leak
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

Export IPv6 VPN-leak routes to IS-IS

The export policy for IPv6 routes of protocol VPN-leak is applied for IS-IS, as follows:

```
# on PE-1:
configure
    router Base
        isis 0
            export "export-vpn-leak"
```

The three IPv6 VPN-leak routes from PE-1 are now advertised by IS-IS to PE-2 and P-3. The routing table on P-3 contains the following IPv6 IS-IS routes:

```
*A:P-3# show router route-table ipv6 protocol isis

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
2001:db8::1/128                                 Remote  ISIS      00h11m54s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           10
2001:db8::2/128                                 Remote  ISIS      00h11m54s  15
       fe80::14:1ff:fe01:2-"int-P-3-PE-2"                           10
2001:db8:12::/126                               Remote  ISIS      00h11m54s  15
```

```
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              20
2001:db8:110::2/128                          Remote  ISIS      00h00m15s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8:110::3/128                          Remote  ISIS      00h00m15s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8:110::4/128                          Remote  ISIS      00h00m15s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed for IS-IS, as follows:

```
# on PE-1:
configure
    router Base
        isis 0
            no export
```

Export IPv6 VPN-leak routes to OSPFv3

The export policy for IPv6 routes of protocol VPN-leak is applied for OSPFv3, as follows:

```
# on PE-1:
configure
    router Base
        ospf3
            export "export-vpn-leak"
```

Routes can only be exported to OSPFv3 if the router is configured as ASBR, as follows:

```
# on PE-1:
configure
    router Base
        ospf3
            asbr
```

The IPv6 VPN-leak routes from PE-1 are now advertised by OSPFv3 to PE-2 and P-3. The preference for remote OSPFv3 routes is by default 150. The routing table on P-3 contains the following IPv6 OSPFv3 routes:

```
*A:P-3# show router route-table ipv6 protocol ospf3

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                           Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8::1/128                              Remote  OSPF3     00h00m48s  10
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8::2/128                              Remote  OSPF3     00h00m48s  10
       fe80::14:1ff:fe01:2-"int-P-3-PE-2"                              10
2001:db8:12::/126                            Remote  OSPF3     00h00m48s  10
```

```
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              20
2001:db8:110::2/128                          Remote  OSPF3     00h00m22s  150
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              1
2001:db8:110::3/128                          Remote  OSPF3     00h00m22s  150
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              1
2001:db8:110::4/128                          Remote  OSPF3     00h00m22s  150
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              1
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed for OSPFv3, as follows:

```
# on PE-1:
configure
    router Base
        ospf3
            no export
```

Export IPv6 VPN-leak routes to BGP

The export policy for IPv6 routes of protocol VPN-leak is applied for BGP, as follows:

```
# on PE-1:
configure
    router Base
        bgp
            export "export-vpn-leak"
```

The three IPv6 VPN-leak routes from PE-1 are now advertised by BGP to PE-2 and P-3. The routing table on P-3 contains the following IPv6 BGP routes:

```
*A:P-3# show router route-table ipv6 protocol bgp

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                           Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8:110::2/128                          Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8:110::3/128                          Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8:110::4/128                          Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed for BGP, as follows:

```
# on PE-1:
configure
    router Base
        bgp
            no export
```

In this example, BGP leaked IPv6 routes are advertised by BGP. For scenarios with only BGP routes, a dedicated BGP route leaking mechanism that preserves all attributes is preferred, as described in chapter *BGP Route Leaking*. However, with the same configuration as in this chapter, it is possible to leak non-BGP routes and advertise them using BGP.

Conclusion

Routes learned in a VPRN can be leaked to the base router and advertised using routing protocols. The mechanism described in this chapter is protocol-independent: all kinds of routes can be leaked from a VRF to the GRT: local, static, IS-IS, OSPF, BGP routes, and so on. In some cases, it might be useful to leak the routes from a VPRN to the entire network using the routing protocol, in order to access the resources defined inside the VRF. Routes that are leaked from VPRNs to the GRT must be unique in the network where they will be advertised.

For BGP routes, the protocol-independent route leaking mechanism described here does not preserve the attributes, unlike the dedicated BGP route leaking feature.

Weighted ECMP for VPRN over RSVP-TE or SR-TE LSPs

This chapter provides information about Weighted Equal Cost Multipath (ECMP) for Virtual Private Routed Network (VPRN) over Resource Reservation Protocol with Traffic Engineering (RSVP-TE) or Segment Routing with Traffic Engineering (SR-TE) Label Switched Paths (LSPs).

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 23.3.R2. Weighted load balancing over Multi Protocol Label Switching (MPLS) LSPs - as described in chapter *BGP Weighted ECMP* in the Unicast Routing Protocols volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*- is supported in SR OS Release 13.0.R1, and later. Weighted load balancing for VPRN with auto-bind-tunnel over RSVP-TE LSPs is supported in SR OS Release 15.0.R2, and later. Weighted load balancing for VPRN with auto-bind-tunnel over SR-TE LSPs is supported inSR OS Release 15.0.R4, and later.

Overview

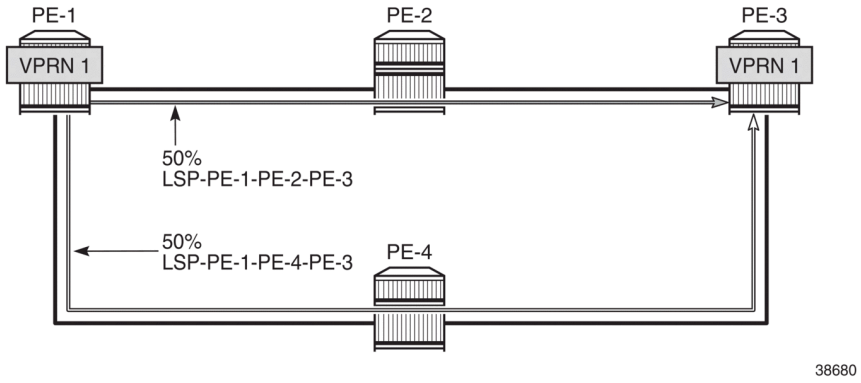
Equal Load Balancing

In this chapter, ECMP refers to spraying traffic flows over multiple RSVP-TE or SR-TE LSPs within an ECMP set. ECMP spraying consists of hashing the relevant fields in the packet header and selecting the tunnel next-hop based on the modulo operation of the output of the hash and the number of LSPs present in the ECMP set. The maximum number of LSPs in the ECMP set is defined by the **ecmp** command.

Only LSPs with the same lowest LSP metric can be part of the ECMP set. If the number of such LSPs exceeds the maximum number of LSPs allowed in the ECMP set as defined by the **ecmp** command, the LSPs with the lowest tunnel IDs are selected first. By default, all LSPs in the ECMP set have the same weight, and traffic flows are spread evenly over all LSPs in the ECMP set, regardless of the bandwidth of the active path in the LSPs. By default, ECMP is enabled and set to 1.

Figure 418: Regular ECMP in AS 64496 shows that PE-1 sprays the traffic flows equally over two LSPs between PE-1 and PE-3. If three or more LSPs with the same lowest LSP metric were available from PE-1 to PE-3, only two of those would be used, because an ECMP value of 2 allows the traffic to be sprayed over two LSPs.

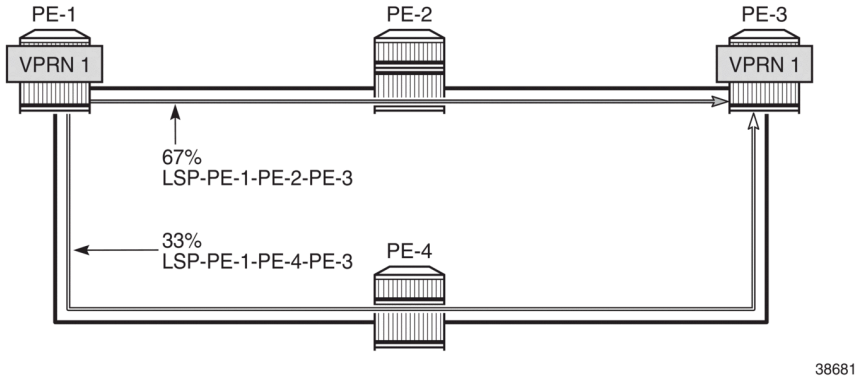
Figure 418: Regular ECMP in AS 64496



Unequal Load Balancing

Weighted ECMP sprays traffic flows over MPLS LSPs proportionally to the **load-balancing-weight** <*weight*> value configured on each MPLS LSP in the ECMP set. Figure 419: Weighted ECMP in AS 64496 shows that PE-1 forwards two thirds of the traffic flows on LSP-PE-1-PE-2-PE-3 with weight 2 and one third on LSP-PE-1-PE-4-PE-3 with weight 1. Each of the links can be link aggregation group (LAG) ports. For instance, when LSP-PE-1-PE-2-PE-3 uses LAG ports, 67% of the traffic is sprayed evenly over all ports belonging to the LAG.

Figure 419: Weighted ECMP in AS 64496



The LSP load balancing weight can be configured in an LSP template or on an LSP. By default, the load balancing weight equals zero, in which case regular ECMP applies.

The following command is used to configure the weight in an LSP template:

```
*A:PE-1# configurerouter Base mpls lsp-template "LSPtemplate1" load-balancing-weight ?
  - no load-balancing-weight
  - load-balancing-weight <weight>

 <weight>             : [0..4294967295] Default - 0
```

The following command is used to configure the weight on an LSP (for example on LSP "LSP-PE-1-PE-2-PE-3"):

```
*A:PE-1# configurerouter Base mpls lsp "LSP-PE-1-PE-2-PE-3" load-balancing-weight ?
  - load-balancing-weight <weight>
  - no load-balancing-weight

 <weight>             : [0..4294967295] Default - 0
```

The LSP load balancing weight on LSP-PE-1-PE-2-PE-3 is configured with a value of 2, as follows:

```
configure
    router Base
        mpls
            path "path-PE-1-PE-2-PE-3"
                hop 10 192.168.12.2 strict
                hop 20 192.168.23.2 strict
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2-PE-3"
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 2
                primary "path-PE-1-PE-2-PE-3"
                exit
                no shutdown
            exit
```

Weighted ECMP is enabled in the **vprn 1 bgp-ipvpn mpls auto-bind-tunnel** context as follows:

```
configure
    service
        vprn 1 name "1" customer 1 create
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        ecmp 2
                        weighted-ecmp
                    exit
```

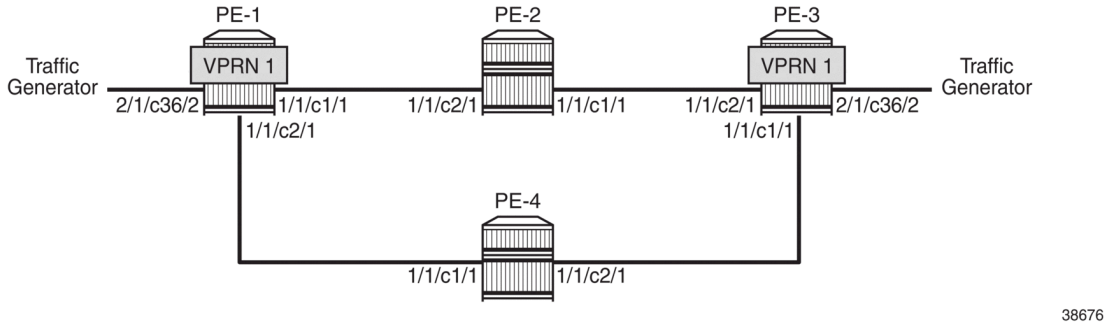
Weighted load balancing within a **vprn** context can be performed only when the next-hops are associated with the same neighbor and all LSPs in the ECMP set are configured with non-zero load balancing weights. If one or more LSPs in the ECMP set toward a specific next-hop do not have a load balancing weight configured, regular ECMP spraying is used. The weighted ECMP support for ECMP routes applies to both IPv4 and IPv6.

Additionally, it is possible to enable ECMP in the **vprn** context, with: **configure service vprn 1 ecmp** *<max-ecmp-routes>*, to control load balancing to a different next-hop. The **weighted-ecmp** option in the **VPN 1 bgp-ipvpn mpls auto-bind-tunnel** context controls load balancing to the same next-hop.

Configuration

Figure 420: Example Topology shows the example topology with four PEs. VPRN 1 is configured on PE-1 and PE-3. A traffic generator is connected to VPRN 1 SAP 2/1/c36/2 on PE-1 and VPRN 1 SAP 2/1/c36/2 on PE-3. The traffic generator generates multiple traffic flows with random IP addresses and TCP/UDP port numbers. As a result, these flows are sprayed over different MPLS LSPs between PE-1 and PE-3.

Figure 420: Example Topology



The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used) with traffic engineering enabled
- MPLS and RSVP enabled on all router interfaces

The initial configuration on PE-1 is as follows:

```
configure
    router Base
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/c1/1
        exit
        interface "int-PE-1-PE-4"
            address 192.168.14.1/30
            port 1/1/c2/1
        exit
        interface "system"
            address 192.0.2.1/32
        exit
        isis 0
            area-id 49.0001
            traffic-engineering
            interface "system"
            exit
            interface "int-PE-1-PE-2"
                interface-type point-to-point
            exit
            interface "int-PE-1-PE-4"
                interface-type point-to-point
            exit
            no shutdown
        exit
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-4"
            exit
            no shutdown
        exit
        rsvp
            no shutdown
```

```
        exit
```

The initial configuration on the other PEs is similar.

With the preceding configuration, MPLS and RSVP are enabled on all interfaces, including the system interface, which is added automatically.

In the next sections, the following use cases are described:

- Weighted ECMP for VPRN with Auto-bind-tunnel RSVP-TE
- Weighted ECMP for an SDP used as a spoke SDP in a VPRN
- Weighted ECMP for VPRN with Auto-bind-tunnel SR-TE

Weighted ECMP for VPRN with Auto-bind-tunnel RSVP-TE

On PE-1, the following paths and LSPs are configured. LSP-PE-1-PE-2-PE-3 is configured with a load balancing weight of 2; LSP-PE-1-PE-4-PE-3 is configured with a load balancing weight of 1.

```
configure
    router Base
        mpls
            path "path-PE-1-PE-2-PE-3"
                hop 10 192.168.12.2 strict
                hop 20 192.168.23.2 strict
                no shutdown
            exit
            path "path-PE-1-PE-4-PE-3"
                hop 10 192.168.14.2 strict
                hop 20 192.168.34.1 strict
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2-PE-3"
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 2
                primary "path-PE-1-PE-2-PE-3"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-4-PE-3"
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 1
                primary "path-PE-1-PE-4-PE-3"
                exit
                no shutdown
            exit
        exit
```

On PE-1, VPRN 1 is configured as follows. ECMP and weighted ECMP can be configured in the **vprn** context, for example, **configure service vprn 1 ecmp 2** and **configure service vprn 1 weighted-ecmp** but it is not required when the next-hop for the MPLS LSPs is the same. In this example, ECMP and weighted ECMP are only configured in the **vprn 1 bgp-ipvpn mpls auto-bind-tunnel** context. The

resolution filter only allows RSVP-TE tunnels, no other MPLS LSPs, such as LDP, BGP, or segment routing (SR) tunnels.

```
configure
    service
        vprn 1 name "1" customer 1 create
            description "CE-1"
            bgp-ipvpn
                mpls
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                        ecmp 2
                        weighted-ecmp
                    exit
                    route-distinguisher 64496:1
                    vrf-target target:64496:1
                    no shutdown
                exit
            exit
            interface "loopback1" create
                address 172.16.0.1/32
                ipv6
                    address 2001:db8::1/128
                exit
                loopback
            exit
            interface "int-CE-1-STC" create
                address 192.168.11.1/24
                ipv6
                    address 2001:db8::11:1/120
                exit
                sap 2/1/c36/2 create
                exit
            exit
            no shutdown
        exit
```

The service configuration on PE-3 is similar.

VPRN 1 is dual stacked. Weighted ECMP applies to both IPv4 and IPv6 traffic streams. BGP is configured for the VPN-IPv4 and VPN-IPv6 address family to exchange the routes used in VPRN 1 between PE-1 and PE-3. The BGP configuration on PE-1 is as follows:

```
configure
    router Base
        autonomous-system 64496
        bgp
            group "iBGP"
                neighbor 192.0.2.3
                    family vpn-ipv4 vpn-ipv6
                    export "export-vpn-ipv4" "export-vpn-ipv6"
                    peer-as 64496
                exit
```

The BGP configuration on PE-3 is similar.

The export policies on PE-1 are defined as follows:

```
configure
```

```
    router Base
        policy-options
            begin
            prefix-list "vpn-ipv4"
                prefix 172.16.0.0/16 longer
                prefix 192.168.11.0/24 exact
            exit
            prefix-list "vpn-ipv6"
                prefix 2001:db8::/120 longer
                prefix 2001:db8::11:0/120 exact
            exit
            policy-statement "export-vpn-ipv4"
                entry 10
                    from
                        prefix-list "vpn-ipv4"
                    exit
                    action accept
                    exit
                exit
            exit
            policy-statement "export-vpn-ipv6"
                entry 10
                    from
                        prefix-list "vpn-ipv6"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The export policies on PE-3 are similar.

With ECMP enabled for MPLS LSPs with the same next-hop and two RSVP-TE LSPs available with equal metric, the route table of VPRN 1 on PE-1 shows two routes for each prefix with the same next-hop 192.0.2.3: one via RSVP LSP 1 and the other via RSVP LSP 2, as follows:

```
*A:PE-1# show router 1 route-table

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
172.16.0.1/32                                 Local   Local     00h01m16s  0
       loopback1                                                     0
172.16.0.3/32 [2]                             Remote  BGP VPN   00h00m29s  170
       192.0.2.3 (tunneled:RSVP:1)                                   100
172.16.0.3/32 [2]                             Remote  BGP VPN   00h00m29s  170
       192.0.2.3 (tunneled:RSVP:2)                                   100
192.168.11.0/24                               Local   Local     00h01m16s  0
       int-CE-1-STC                                                  0
192.168.33.0/24 [2]                           Remote  BGP VPN   00h00m29s  170
       192.0.2.3 (tunneled:RSVP:1)                                   100
192.168.33.0/24 [2]                           Remote  BGP VPN   00h00m29s  170
       192.0.2.3 (tunneled:RSVP:2)                                   100
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
```

```
===============================================================================
```

The flag [2] indicates that next-hop 192.0.2.3 occurs twice for the prefix 172.16.0.3/32; next-hop 192.0.2.3 also occurs twice for the prefix 192.168.33.0/24.

The following IPv6 route table is similar, with next-hop 192.0.2.3 occurring twice for prefix 2001:db8::3/128 and twice for prefix 2001:db8::33:0/120.

```
*A:PE-1# show router 1 route-table ipv6

===============================================================================

===============================================================================
```

To verify the weighted load balancing between the two RSVP-TE LSPs, the traffic generator sends multiple IPv4 and IPv6 traffic flows with random IP addresses and TCP/UDP port numbers via PE-1 to PE-3. The traffic enters PE-1 through port 2/1/c36/2. When LSP-PE-1-PE-2-PE-3 is configured with weight 2 and

LSP-PE-1-PE-4-PE-3 with weight 1, PE-1 forwards two thirds of the traffic via port 1/1/c1/1 toward PE-2 and one third of the traffic via port 1/1/c2/1 toward PE-3, as follows:

```
*A:PE-1# monitor port 1/1/c1/1 1/1/c2/1 2/1/c36/2 rate interval 3 repeat 3

===============================================================================
```

Restrictions

All RSVP-TE LSPs in the ECMP set must have a load balancing weight configured. When at least one RSVP-TE LSP in the ECMP set is configured without weight, regular ECMP is applied.

RSVP-TE LSP without Weight in ECMP Set

If one of the RSVP-TE LSPs in the ECMP set does not have a load balancing weight configured, the traffic flows are sprayed equally between all RSVP-TE LSPs, regardless of the configured weight of the other RSVP-TE LSPs in the ECMP set.

On PE-1, LSP-PE-1-PE-2-PE-3 is configured without a load balancing weight, as follows:

```
configure
    router Base
        mpls
            lsp "LSP-PE-1-PE-2-PE-3"
                no load-balancing-weight
```

LSP-PE-1-PE-4-PE-3 is still configured with a load balancing weight of 1, but it is impossible to calculate its relative weight, because the sum of the weight values is not defined. Therefore, PE-1 reverts to regular ECMP for the load balancing between the two RSVP-TE LSPs to PE-3. When the traffic generator sends multiple traffic flows via PE-1 to PE-3, the load is spread equally over both RSVP-TE LSPs, as shown in the following monitor output. Port 1/1/c1/1 is used for traffic sent via LSP-PE-1-PE-2-PE-3 and port 1/1/c2/1 for traffic sent via LSP-PE-1-PE-4-PE-3.

```

```

The configuration is restored as follows:

```
configure
    router Base
        mpls
            lsp "LSP-PE-1-PE-2-PE-3"
                load-balancing-weight 2
```

Weighted ECMP for an SDP used as a spoke SDP in a VPRN

The following LSPs are configured on PE-1. The LSP load balancing weight values are 4 and 1 and the metric is 101 for both LSPs.

```
configure
    router Base
        mpls
            lsp "LSP-PE-1-PE-2-PE-3-spoke"
                to 192.0.2.3
                path-computation-method local-cspf
                metric 101
                load-balancing-weight 4
                primary "path-PE-1-PE-2-PE-3"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-4-PE-3-spoke"
                to 192.0.2.3
                path-computation-method local-cspf
                metric 101
                load-balancing-weight 1
                primary "path-PE-1-PE-4-PE-3"
                exit
                no shutdown
            exit
            no shutdown
        exit
        rsvp
            no shutdown
        exit
```

Similar LSPs are configured on PE-3.

On PE-1, an SDP is configured, as follows:

```
configure
    service
        sdp 13 mpls create
            far-end 192.0.2.3
            lsp "LSP-PE-1-PE-2-PE-3-spoke"
```

```
            lsp "LSP-PE-1-PE-4-PE-3-spoke"
            no shutdown
        exit
```

A similar SDP is configured on PE-3.

These SDPs are configured as spoke SDPs in a VPRN, as follows:

```
configure
    service
        vprn 1
            spoke-sdp 13 create
        exit

configure
    router Base
        ldp
            no shutdown
        exit
```

On PE-1, weighted ECMP is enabled on an SDP, as follows:

```
configure
    service
        sdp 13
            weighted-ecmp
        exit
```

The ECMP configuration on PE-3 is similar.

With ECMP enabled for MPLS LSPs with the same next-hop and two RSVP-TE LSPs available with equal metric, the route table of VPRN 1 on PE-1 shows one route for each prefix via the SDP tunnel, as follows:

```
*A:PE-1# show router 1 route-table

===============================================================================

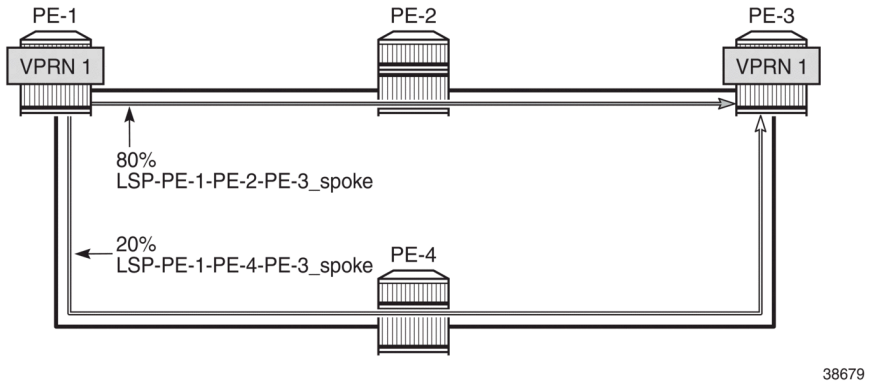
Figure 421: Weighted ECMP over RSVP LSPs used in a spoke SDP shows how the traffic flows are sprayed over the two RSVP LSPs:

Figure 421: Weighted ECMP over RSVP LSPs used in a spoke SDP



Weighted ECMP for VPRN with Auto-bind-tunnel SR-TE

The following configuration is added to enable SR-ISIS on PE-1.

```
configure
    router Base
        mpls-labels
            sr-labels start 20000 end 20099
        exit
        isis 0
            advertise-router-capability as
            interface "system"
                ipv4-node-sid label 20001
            exit
            segment-routing
                prefix-sid-range start-label 20000 max-index 99
                no shutdown
            exit
        exit
```

The configuration on the other PEs is identical, except for the **ipv4-node-sid label** value.

The following SR-TE LSPs are configured on PE-1. For more information about SR-TE LSPs, see the *Segment Routing Traffic Engineered Tunnels* chapter. The load balancing weight values are 75 and 25. The values 3 and 1, which have the same ratio, can be used instead.

```
configure
    router Base
        mpls
            lsp "LSP-PE-1-PE-2-PE-3_SR-TE" sr-te
                to 192.0.2.3
                load-balancing-weight 75
                primary "path-PE-1-PE-2-PE-3"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-4-PE-3_SR-TE" sr-te
```

```
                to 192.0.2.3
                load-balancing-weight 25
                primary "path-PE-1-PE-4-PE-3"
                exit
                no shutdown
            exit
```

The configuration on PE-3 is similar.

The following tunnel table on PE-1 shows two SR-TE tunnels with equal metrics: SR-TE tunnel 655362 has PE-2 as next-hop (192.168.12.2) and SR-TE tunnel 655363 has PE-4 as next-hop (192.168.14.2).

```
*A:PE-1# show router tunnel-table protocol sr-te

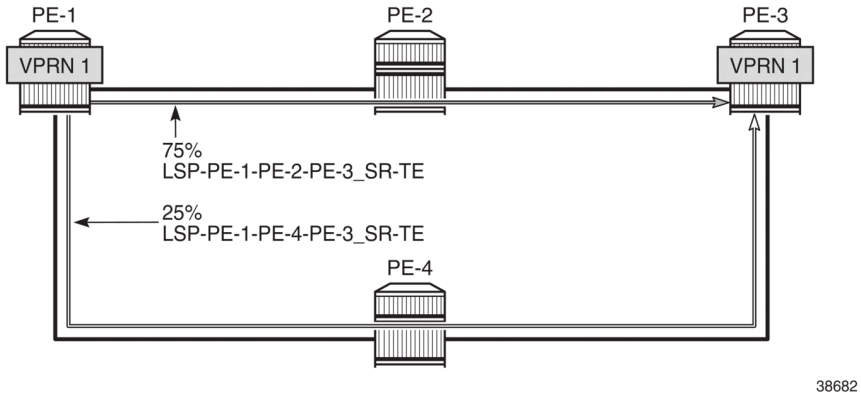
Figure 422: Weighted ECMP over SR-TE LSPs in AS 64496 shows how the traffic flows are sprayed over the two SR-TE LSPs:

Figure 422: Weighted ECMP over SR-TE LSPs in AS 64496



Conclusion

Operators can control how traffic in a VPRN is load balanced unequally over multiple transport tunnels by defining a load balancing weight factor on each LSP and enabling weighted ECMP in the VPRN. In this chapter, weighted ECMP for VPRN over transport LSPs is enabled for RSVP-TE tunnels and for SR-TE tunnels.

Quality of Service

This section provides configuration information for the following topics:

- Class Fair Hierarchical Policing for SAPs
- FP and Port Queue Groups
- High Scale QoS IOM: QoS, Service, and Network Configuration
- Pseudowire QoS
- QoS Architecture and Basic Operation

Class Fair Hierarchical Policing for SAPs

This chapter provides information to configure Class Fair Hierarchical Policing for SAPs.

Topics in this chapter include:

Applicability

This chapter was written based on SR OS Release 9.0.R1. There are no specific pre-requisites for this configuration.

Summary

The Quality of Service (QoS) features of the 7x50 platforms provide traffic control with both shaping and policing.

Shaping is achieved using a queue; packets are placed on the queue and a scheduler removes packets from the queue at a given rate. This provides an upper bound to the traffic rate sent, thereby protecting down stream devices from bursts. However, shaping can introduce latency and jitter as packets are delayed in the queue. Packets can be dropped when the queue is full or statistically when weighted random early discard is applied. Configuration of shaping on the 7x50 is described in QoS Architecture and Basic Operation.

Policing is another mechanism for controlling traffic rates but it does not introduce latency/jitter. This is achieved using a token bucket mechanism which drops certain packets from the traffic. A common disadvantage of policing implementations is that they are usually applicable to a single level of traffic priority and have no way to fairly share capacity between multiple streams at the same priority level. Nokia's Class Fair Hierarchical Policing (CFHP) addresses these problems by implementing a four level prioritized policing hierarchy which also provides weighted fairness for traffic at a given priority.

Regardless of whether shaping or policing is being used, the preceding QoS classification and subsequent packet marking functionality is similar for both and is covered in more detail in QoS Architecture and Basic Operation.

This note describes the configuration and operation of CFHP when applied to Service Access Points (SAPs). It is also possible to use CFHP for subscribers in a Triple Play Service Delivery Architecture (TPSDA) environment but it is beyond the scope of this note.

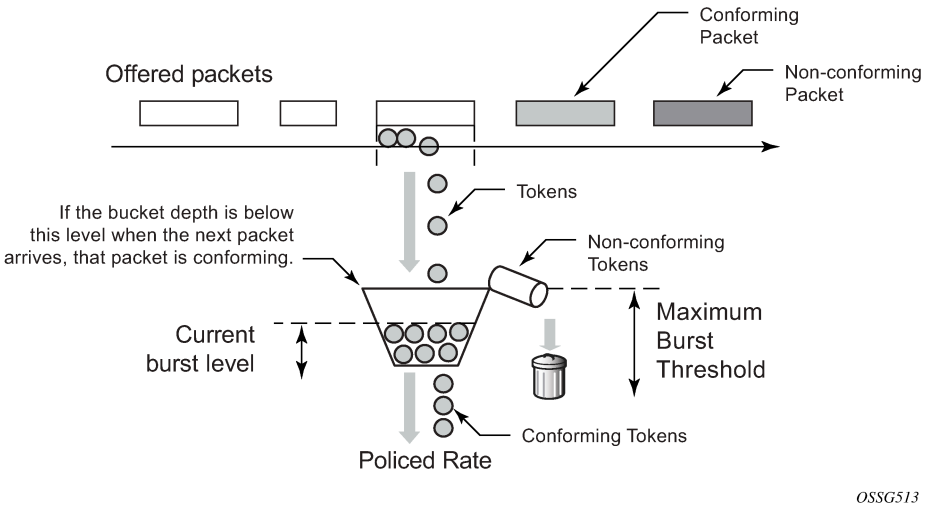
Overview

Policers

CFHP can be used both for ingress and egress QoS. The basic element is a policer which can apply both a committed information rate (CIR) and peak information rate (PIR) to a traffic flow (determined by the ingress classification). Traffic is directed to a policer by assigning a forwarding class (FC) to the policer.

To describe the operation of a policer we will use a token bucket model, this is shown in Figure 423: Policer Token Bucket Model.

Figure 423: Policer Token Bucket Model



The policer is modeled by a bucket being filling with tokens which represent the bytes in the packets passing through the policer. The bucket drains at a given rate (the policed rate) and if the token (byte) arrival rate exceeds the drain rate then the bucket will fill. The bucket has a maximum depth, defined by a maximum burst threshold. If tokens for a packet arrive in the bucket when the current burst level of tokens is below the maximum burst threshold then the packet is considered to be conforming and all of its tokens are accepted into the bucket. If a packet's tokens arrive when the current burst level has exceeded the maximum burst threshold then none its tokens are accepted into the bucket and the packet is considered to be non-conforming (in the representation, these tokens over-flow into a waste bin).

Table 24: Burst Levels shows an example of the two possibilities.

Table 24: Burst Levels

Maximum burst threshold = 2000 tokens (bytes) **Policed rate 2 Mbps = 250000 bytes/sec (250 tokens/ms)**				
Arrival Time	**Packet Size**	**Current Burst Level**	**Conforming Packet**	**New Burst Level**
T0	1024	1500	Yes	1500 + 1024 = 2524
T0 + 1ms	128	2524 - 250 = 2274	No	2274

When the first packet arrives the current burst level is below the maximum burst threshold so it is conforming, however, when the second packet arrives the current burst level is above the maximum burst threshold so it is non-conforming.

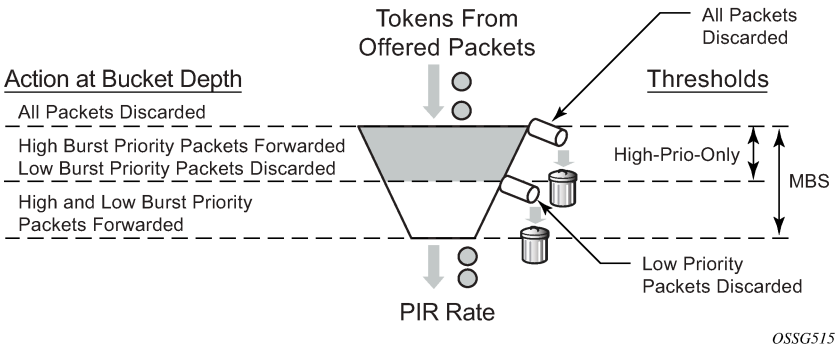
An important aspect of the implementation of hierarchical policing is the ability of a policer bucket to have multiple burst thresholds. The tokens for each arriving packet are only compared against a single threshold relating to the characteristics of packet. These burst thresholds allow specific granular QoS control.

Policer Buckets

A policer uses up to 3 buckets depending on its configuration. A PIR bucket to control the traffic rate which is always used though its rate could be max, there can be an optional CIR bucket if a CIR rate is defined for dynamically profiling (in-profile/out-of-profile) packets, finally there may be a fair information rate (FIR) bucket used to maintain traffic fairness in a hierarchical policing scenario when multiple child policers are configured at the same parent priority level.

The PIR bucket is drained at the PIR rate and has two burst thresholds, one for high burst priority traffic (defined by the maximum burst size (MBS)) and a second for low burst priority traffic (defined by the MBS minus high-prio-only), see Figure 424: Peak Information Rate (PIR) Bucket. The traffic burst priority is determined at ingress by the configured priority of either high or low, and at the egress by the profile state of the packets (in-profile=high, out-of-profile=low). Note that by default all FCs are low burst priority. If a packet conforms at the PIR bucket (its tokens enter the bucket) then the packet is forwarded, otherwise the packet is discarded. Discarding logically results in the packet's tokens not being placed into the CIR, FIR or parent policer buckets.

Figure 424: Peak Information Rate (PIR) Bucket



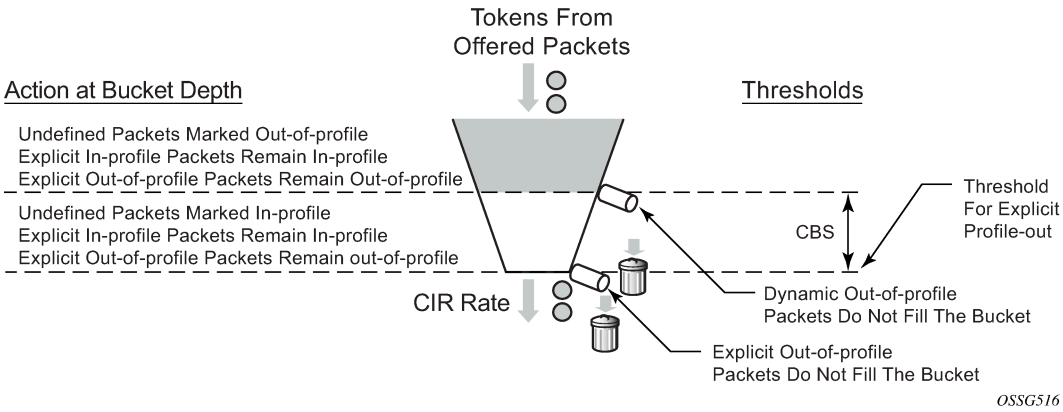
The CIR bucket is drained at the CIR rate and has one configurable burst threshold (defined by the committed burst size (CBS)). At the ingress, if the bucket level is below this threshold traffic is determined to be in-profile so the only action of the CIR bucket is to set the state of dynamically profiled packets to be either in-profile or out-of-profile. At the egress, re-profiling only affects Dot1P and DEI (Layer 2) egress marking (if the frame is double tagged, only the outer VLAN tag is remarked).

The CBS threshold is used when operating in color-blind mode, the profile of incoming packets is undefined and dynamically set based on the current burst level in the CIR bucket compared to the CBS threshold. It is also possible to operate (simultaneously) in color-aware mode, where the classification of incoming packets is used to explicitly determine whether a packet is in-profile or out-of-profile. For color-aware mode, the CIR bucket does not change the packet profile state.

In order to ensure that the overall amount of in-profile traffic takes into account both the explicit and dynamic in-profile packets, tokens from the explicit in-profile packets are allowed to fill the bucket above

the CBS threshold. By doing this, dynamically profiled packets are only marked as in-profile after the token level representing dynamically in-profile and explicit in-profile packets have fallen below the CBS threshold (as the bucket drains). Note that explicitly marked out-of-profile packets remain out-of-profile, so the bottom of the bucket can be considered to be an implicit burst threshold for these packets. This is shown in Figure 425: Committed Information Rate (CIR) Bucket.

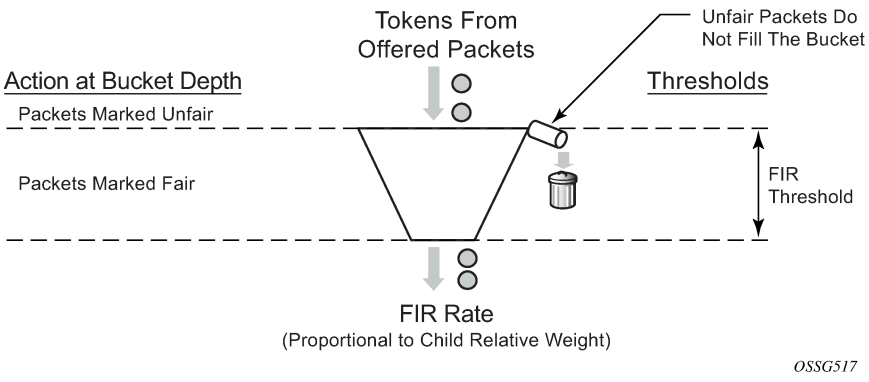
Figure 425: Committed Information Rate (CIR) Bucket



As the depths of the PIR and CIR buckets (MBS and CBS, respectively) are configured independently it is possible to have, for example, the CBS to be larger than the MBS (which is not possible for a queue). This could result in traffic being discarded because it is non-conforming at the PIR bucket but would have been conforming at the CIR bucket. Conversely, if the CBS is smaller than the MBS and the PIR=CIR traffic can be forwarded as out-of-profile, which would not be the case with a queue.

The FIR bucket is controlled by the system and is only used in hierarchical policing scenarios to determine a child's fair access to the available capacity at a parent priority level relative to other children at the same level. This bucket is only used when there is more than one child policer assigned to a given parent policer priority level. The drain rate of the FIR bucket is dynamically set proportionally to the weight configured for the child. This is shown in Figure 426: Fair Information Rate (FIR) Bucket.

Figure 426: Fair Information Rate (FIR) Bucket



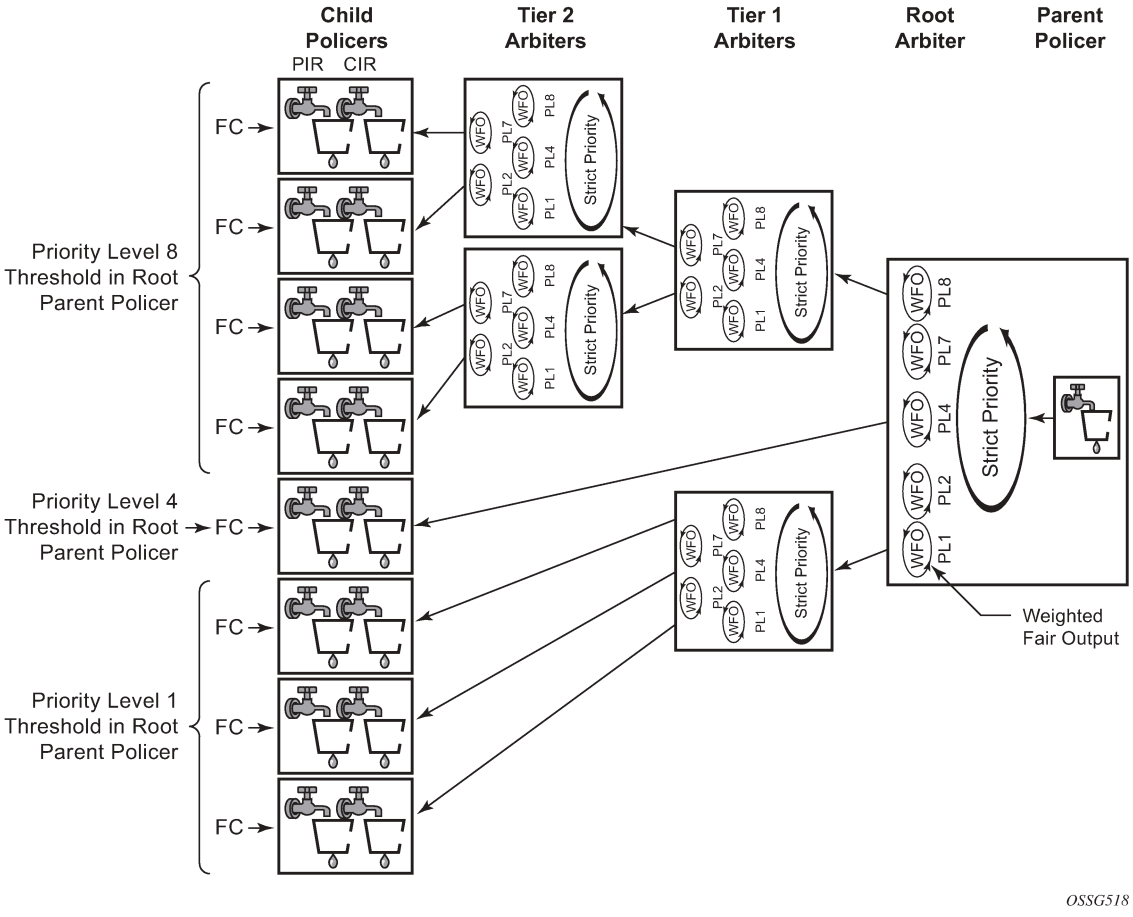
Hierarchical Policing

Policers can be used standalone or with a parent policer to provide hierarchical policing. Up to four stages can be configured in the hierarchy: the child policer, tier 1 and 2 intermediate arbiters, and a root arbiter (which is associated with the parent policer). The arbiters are logical entities that distribute bandwidth at a particular tier to their children in a priority level order, see Figure 427: Policer and Arbiter Hierarchy .

This may result in the drain rates for the child policer buckets being modified, so each child policer PIR and CIR bucket has an administrative rate value (what it is configured to) and an operational rate value (the current operating rate) based on the bandwidth distribution by the parent arbiters.

Each stage in the hierarchy connects to its parent at a priority level and a weight. There are eight available priorities which are serviced in a strict order (8 to 1, highest to lowest, respectively). The weight is used to define relative fairness when multiple children are configured in the same priority level. Note that the child access to parent policer burst capacity is governed by the level at which the child ultimately connects into the root arbiter, not by its connection level at any intermediate arbiters.

Figure 427: Policer and Arbiter Hierarchy



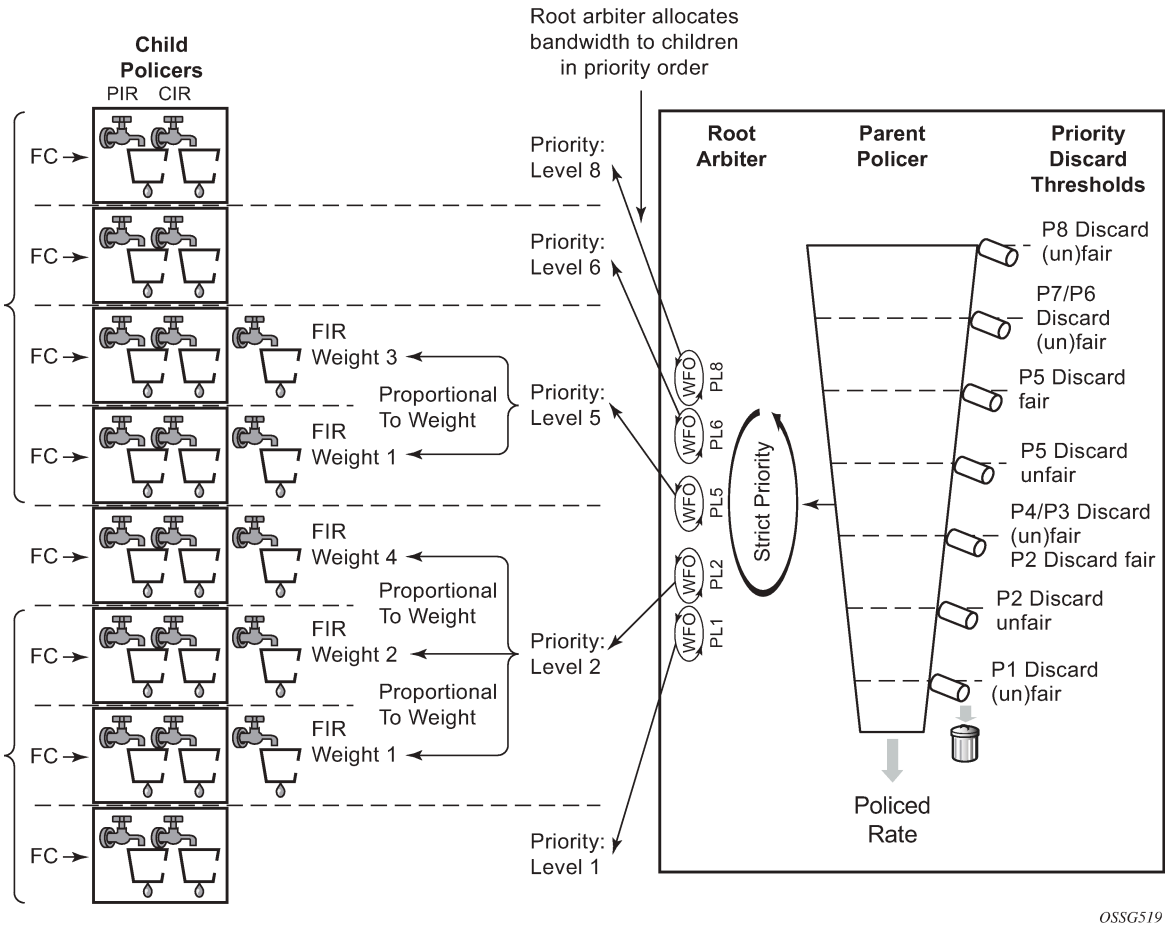
The final configuration aspect to consider is the parent policer, specifically its multiple thresholds and how they relate to the child policers. See Figure 428: Parent Policer and Root Arbiter.

There are 8 priority levels at the parent policer, each having an associated discard-fair and discard-unfair threshold.

The discard-fair threshold is the upper burst limit for all tokens (consequently, all packets) at the given priority, all traffic at a given priority level is discarded when its tokens arrive with this threshold being exceeded. The discard-fair thresholds enable prioritization at the parent policer by having the burst capacity for each priority threshold be larger (or equal) to those of lower priorities. For example, referring to Figure 428: Parent Policer and Root Arbiter, the priority 6 (P6) discard-fair threshold is larger than the priority 5 (P5) discard-fair threshold with the result that even if the priority 5 and below traffic is overloading the parent policer, the priority 6 traffic has burst capacity available in order to allow some of its packets to conform and get forwarded through the parent policer.

Note that if a packet is discarded at the parent policer, the discard needs to be reflected in the associated child policer, this is achieved by also logically removing the related tokens from the child policer buckets.

Figure 428: Parent Policer and Root Arbiter



Each priority also has a discard-unfair threshold which discards only unfair traffic of that priority, remembering that fair and unfair are determined by the FIR bucket based on the relative weights of the children.

By default, if there are no children configured at a given priority level then both its discard-fair and discard-unfair thresholds are set to zero bytes above the previous priority's discard-fair threshold.

If there is only a single child at a priority level, the discard-fair will be greater than the previous priority's discard-fair value (by an amount equal to the maximum of the min-thresh-separation and the mbs-

contribution, see below) but the discard-unfair will be the same as the previous priority's discard-fair threshold (there is no need for a fairness function when there is only a single child at that priority).

If there is more than one child at a priority level, the discard-unfair threshold will be greater than the previous priority's discard-fair threshold by min-thresh-separation (see below) and the discard-fair threshold will be adjusted upwards by an amount equal to mbs-contribution minus min-thresh-separation.

The result can be summarized as follows:

- With no children at a priority level, the discard fair and unfair thresholds match the values of the previous priority.
- If there are at least two children at a priority level, the discard-unfair burst capacity equals min-thresh-separation.
- The burst capacity for a given priority level with at least one child equals the mbs-contribution, unless this is less than min-thresh-separation in which case the min-thresh-separation is used.

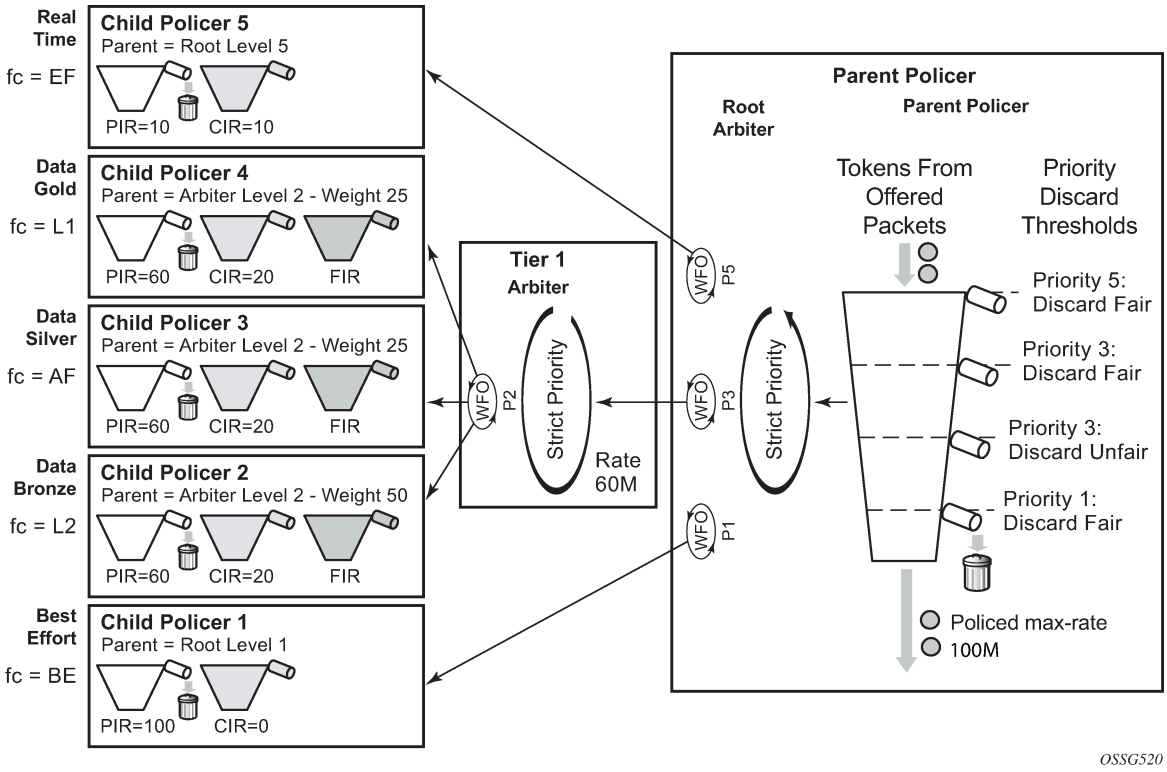
The burst tolerance for each threshold is its own burst capacity plus the sum of the burst capacities of all lower thresholds. Referring to Figure 428: Parent Policer and Root Arbiter, the total burst capacity for priority 6 is the sum of the burst capacities for priorities 1 to 6. Note that the burst for a given FC is normally controlled by the burst allowed at the child PIR threshold, not by the parent policer.

As the burst capacity at the parent policer for a given priority level can change when adding or removing children at lower priority levels, a parameter (fixed) is available per priority threshold which causes the discard-fair and discard-unfair thresholds to be non-zero and so greater than the previous priority's thresholds, calculated as above, even when there are no children at that priority level. An exception to this is when the mbs-contribution is set to zero with the fixed parameter configured, in which case both the discard unfair and fair for that priority level are set to zero bytes above the previous level's thresholds (which results in the corresponding traffic being dropped).

A specific configuration and associated show output is included below to highlight the different threshold options described above.

The QoS example shown in Figure 429: Configuration Example is used to describe the configuration of CFHP.

Figure 429: Configuration Example



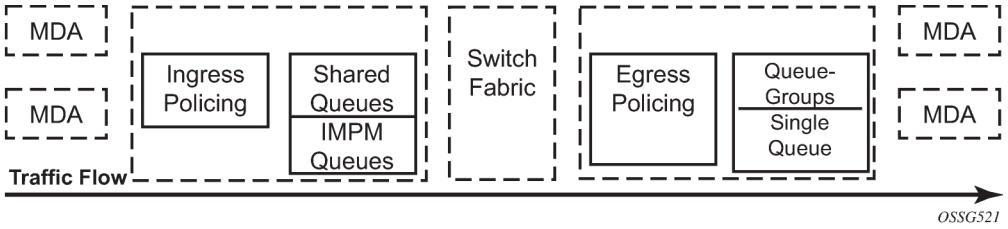
Five classes of services are accepted, each with a specific CIR and PIR. The data classes, bronze, silver and gold (L2/AF/L1), have a relative weighting of 50/25/25 at priority Level 2 of an intermediate arbiter which is constrained to 60Mbps. At the parent policer, the real time traffic (EF) is defined at level 5, with the data classes at Level 3 and a best effort class (BE) at Level 1. The overall traffic is constrained to 100Mbps at the parent policer. Only unicast traffic is policed in this example.

This example focuses on ingress policing, however, the configuration of policers, arbiters and the parent policer at the egress is almost identical to that at the ingress, the only difference being the particular statistics that can be collected.

There is a difference between ingress and egress policing in terms of how the ingress traffic accesses the switch fabric and the egress traffic access the port after it has been policed. In both cases, unicast access is enabled through a set of policer-output-queues, which are shared-queues at the ingress and queue-groups at the egress (at the egress, user defined queue-groups can be used). It is also possible to use a single service queue to access the egress port. Ingress multipoint traffic accesses the switch fabric using the Ingress Multicast Path Management (IMPM) queues.

This is shown in Figure 430: Post Policing Queues on a line card.

Figure 430: Post Policing Queues



The differences between the ingress and egress policing configuration will be high-lighted in the associated sections.

Configuration

To achieve the QoS shown in Figure 429: Configuration Example, configure a SAP-ingress QoS policy to define the child policers and a policer-control-policy to define the intermediate arbiter and the root arbiter/parent policer. As this example is for ingress, the unicast traffic will pass through a set of shared queues called policer-output-queues, which could be modified if required.

Policers

Policers control the CIR and PIR rates for each of the traffic classes and are defined in a SAP-ingress QoS policy. The focus here are parameters related to policing.

The configuration of a child (or standalone) policer is similar to that of a queue.

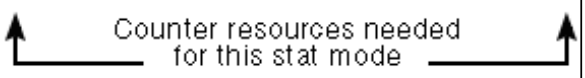
```
config>qos>sap-ingress# policer policer-id [create]
    description "description-string"
    adaptation-rule [pir {max | min | closest}] [cir {max | min | closest}]
    stat-mode {no-stats|minimal|offered-profile-no-cir|
           offered-priority-no-cir|offered-profile-cir|offered-priority-cir|
           offered-total-cir|offered-limited-profile-cir}
    rate {max | kilobits-per-second} [cir {max | kilobits-per-second}]
    percent-rate pir-percent [cir cir-percent]
    mbs size [bytes | kilobytes]
    cbs size [bytes | kilobytes]
    high-prio-only [default | percent-of-mbs]
    parent {root | arbiter-name} [level level] [weight weight-within-level]
    packet-byte-offset {add bytes | subtract bytes}
```

Parameters:

- description — This configures a text string, up to 80 characters, which can be used to describe the use of the policy.
- adaptation-rule — The hardware supports distinct values for the rates. This parameter tells the system how the rate configured should be mapped onto the possible hardware values. min results in the next higher hardware value being used, max results in the next lower hardware value being used and closest results in the closest available hardware value being used. As can be seen, it is possible to set the adaptation-rule independently for the CIR and PIR. Default: closest
- stat-mode — This defines the traffic statistics collected by the policer, summarized in Table 25: Policer stat-mode.

Table 25: Policer stat-mode

stat-mode	Ingress		Egress	
no-stats	0	Neither policer nor parent arbiter account are required.	0	Neither policer nor parent arbiter accounting are required.
minimal (default)	1	Basic policer accounting (default).	1	Basic policer accounting (default).
offered-profile-no-cir	2	All ingress packets are either in-profile or out-of-profile.	2	Accounting for egress offered profile is required. No visibility for CIR profile state output.
offered-priority-no-cir	2	Ingress packet burst priority accounting is the primary requirement.		N/A
offered-limited-profile-cir	3	Ingress color-aware profiling is in use but packets are not being classified as in-profile.		N/A
offered-profile-cir	4	Ingress color-aware profiling is in use and packets are undefined or classified as out-of-profile or in-profile.	4	Egress profile reclassification is performed.
offered-priority-cir	4	Ingress policer is used in color-blind mode and ingress packet priority and CIR state output accounting is needed.		N/A
offered-total-cir	2	Ingress priority and ingress profile accounting is not needed. CIR profiling is in use.	2	Offered profile visibility is not required (such as, all offered packets have the same profile) and CIR profiling is in use.
				



- rate and cir — The rate defines the PIR and the cir defines the CIR, both are in Kbps. The parameters rate and percent-rate are mutually exclusive and will overwrite each other when configured in the same policy. Range: PIR=1 to 20,000,000 Kbps or max ; CIR=0 to 20,000,000 Kbps or max Default: rate(PIR)=max ; cir=0
- percent-rate and cir — The percent-rate defines the PIR and the cir defines the CIR with their values being a percentage of the maximum policer rate of 20Gbps. The parameters rate and percent-rate are mutually exclusive and will overwrite each other when configured in the same policy. Range: pir-percent = [0.01..100.00]; cir-percent = [0.00..100.00] Default: pir-percent = 100; cir-percent = 0.00
- mbs and cbs — The mbs defines the MBS for the PIR bucket and the cbs defines the CBS for the CIR bucket, both can be configured in bytes or kilobytes. Note that the PIR MBS applies to high burst priority packets (these are packets whose classification match criteria is configured with priority high at the ingress and are in-profile packets at the egress). Range: mbs=0 to 4194304 bytes; cbs=0 to 4194304 bytes Note: mbs=0 prevents any traffic from being forwarded. Default: mbs=10ms of traffic or 64KB if PIR=max; cbs=10ms of traffic or 64KB if CIR=max

- high-prio-only — This defines a second burst threshold within the PIR bucket to give a maximum burst size for low burst priority packets (these are packets whose classification match criteria is configured with priority low at the ingress and are out-of-profile packets at the egress). It is configured as a percentage of the MBS. Default: 10%
- parent — This parameter is used when hierarchical policing is being performed and points to the parent arbiter (which could be the root arbiter or an intermediate arbiter), giving the level to which this policer connects to its parent arbiter and its relative weight compared to other children at the same level. Note that for a child policer to be associated with a parent, its stat-mode cannot be no-stats. Range: level=1 to 8; weight=1 to 100 Default: level=1; weight=1
- packet-byte-offset — This changes the packet size used for accounting purposes, both in terms of the CIR and PIR rates and what is reported in the statistics. The change can either add or subtract a number of bytes. For example:
  - To have the policer work on Layer 2 frame size including inter-frame gap and preamble, add 20 bytes.
  - To have the policer work on IP packet size instead of the default layer 2 frame size, subtract the encapsulation overhead:

    14 bytes L2 + 4bytes VLAN ID + 4 bytes FCS = 22 bytes

    Range: add-bytes=0 to 31; sub-bytes=1 to 32 Default: add-bytes=0; sub-bytes=0

A FC must be assigned to the policer in order for the policer to be instantiated (allocating a hardware policer).

By default, any unicast traffic assigned to the FC at the ingress will be processed by the policer, non-unicast traffic would continue to use the multipoint queue. At the egress all traffic assigned to the FC is processed by the policer (as there is no distinction between unicast and non-unicast traffic at the egress).

If required, non-unicast traffic can be policed in IES/VPRN and VPLS services at the ingress (note: all Epipe traffic is treated as unicast). Within an IES/VPRN service, multicast traffic can be assigned to a specific ingress policer on a PIM enabled IP interface. When the service is VPLS, broadcast, unknown unicast and multicast traffic can be individually assigned to ingress policers. In each of these cases, the policers used could be separate from the unicast policer, resulting in the instantiation of additional hardware policers, or a single policer could be used for multiple traffic types (this differs from the queuing implementation where separate queue types are used for unicast and non-unicast traffic).

```
config>qos>sap-ingress>fc#
    broadcast-policer <policer-id>
    unknown-policer <policer-id>
    multicast-policer <policer-id>
```

As mentioned above, the ingress policed unicast traffic passes through a set of shared-queues (policer-output-queues) to access the switch fabric with the multipoint traffic using the IMPM queues.

When policers are required at the egress, a SAP-egress policy is used. The configuration of the policers is almost identical to that used in the SAP-ingress policy, the only difference being the available stat-modes (as shown above).

At the egress, the policed traffic can also be directed to a specific queue-group (instead of the default policer-output-queues) and to a specific queue within that queue-group, as follows:

```
config>qos>sap-egress>fc# policer <policer-id> [group <queue-group-name> [queue <queueid>]]
```

It is also possible to direct the egress policed traffic to a single service queue if specific egress queuing is required, as follows:

```
config>qos>sap-egress>fc# policer <policer-id> queue <queue-id>
```

Multiple egress policers in a SAP-egress policy can use the same local queue and other forwarding classes can directly use the same local queue that is being used by policers.

Parent Policer and Arbiters

The parent policer and its associated root arbiter, together with the tier 1 and 2 arbiters, are configured within a policer-control-policy.

```
config>qos# policer-control-policy policy-name [create]
    description description-string
    root
        max-rate {kilobits-per-second | max}
        priority-mbs-thresholds
            min-thresh-separation size [bytes|kilobytes]
            priority level
                mbs-contribution size [bytes|kilobytes] [fixed]
    tier 1
        arbiter arbiter-name [create]
            description escription-string
            rate {kilobits-per-second|max}
            parent root [level priority-level] [weight weight-within-level]
    tier 2
        arbiter arbiter-name [create]
            description description-string
            rate {kilobits-per-second | max}
            parent {root|arbiter-name} [level priority-level] [weight weight-within-level]
```

Parameters:

- description — This configures a text string, up to 80 characters, which can be used to describe the use of the policy.
- root — This section defines the configuration of the parent policer and the root arbiter.
  - max-rate — This defines the policed rate of the parent policer, the rate at which the bucket is drained. It is defined in Kbps with an option to use max, in which case the maximum possible rate is used. Range: 1 to 20,000,000Kbps or max Default: max
  - priority-mbs-thresholds This section defines the thresholds used for the 8 priorities available in the parent policer.
    - min-thresh-separation — This defines the minimum separation between any two active thresholds in the parent policer in units of bytes or kilobytes.

      It should be set to a value greater than the maximum packet size used for traffic passing through the policer. This ensures that a single packet arriving in the parent policer will not cause the depth of tokens to cross two burst thresholds, if this did happen it would result in the prioritization failing as a given priority level could be starved of burst capacity by a lower priority traffic.

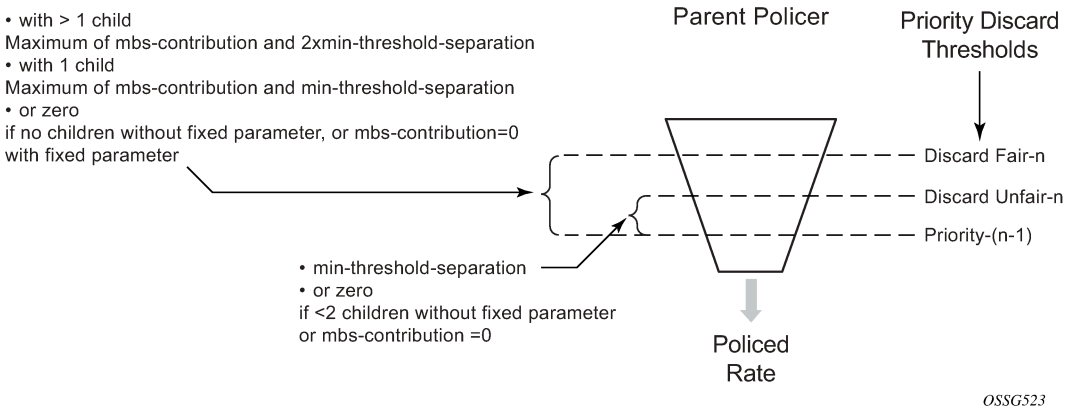
      This parameter is also used as the burst capacity for each priority level's unfair packets. Range: 0 to 4194304 bytes Default: 1536 bytes

- mbs-contribution — This is normally used to define the amount of packet burst capacity required at the parent policer for a particular priority level with at least one child, keeping in mind that the total capacity is the sum of this plus that of all lower thresholds. The actual burst capacity used depends also on the setting of min-thresh-separation, as described earlier. This permits the tuning of the burst capacity at the parent for any children at a given priority level. A conservative setting would ensure that the burst at the parent policer for a given priority is the sum of the bursts of all children at that priority. Less conservative settings could use a lower value and assume some level of oversubscription.

  The use of the fixed parameter causes both the fair and unfair discard thresholds to be non-zero even when there are no children assigned to this priority level (unless the mbs-contribution is set to zero). Range: 0 to 4194304 Default: 8192 bytes

  The relationship between these two parameters is shown in Figure 431: Parent Policer Thresholds.

  Figure 431: Parent Policer Thresholds



- tier

  This section defines the configuration of any intermediate tier 1 or 2 arbiters.

  – arbiter

    This specifies the name of the arbiter.

    - description — This configures a text string, up to 80 characters, which can be used to describe the use of the policy.
    - rate — This defines the rate of the arbiter, it is the maximum rate at which the arbiter will distribute burst capacity to its children. It is defined in Kbps with an option to use max, in which case the maximum possible rate is used. Range: 1 to 20,000,000Kbps or max Default: max
    - parent — This parameter is used when hierarchical policing is being performed and points to the parent arbiter (which could be the root arbiter or a tier 1 arbiter), giving the level to which this arbiter connects to its parent arbiter and its relative weight compared to other children at the same level. Range: level=1 to 8; weight=1 to 100 Default: level=1; weight=1

Access to Switch Fabric and Egress Port

After the traffic has been processed by the policers it must pass through a set of queues in order to access the switch fabric at the ingress or the port at the egress.

For the ingress unicast traffic, there is a set of shared-queues (one queue per FC for each possible switch fabric destination) called policer output queues. Note that only their queue characteristics can be configured, the FC to queue mapping is fixed. Also, the PIR/CIR rates only affect the packet scheduling, they do not alter the packet profile state. The details of shared-queues are beyond the scope of this note.

```
config>qos# shared-queue "policer-output-queues"
    description description-string
    fc <fc-name> [create]
        broadcast-queue <queue-id>
        multicast-queue <queue-id>
        queue <queue-id>
        unknown-queue <queue-id>
    queue queue-id [queue-type] [multipoint] [create]
        cbs percent
        mbs percent
        high-prio-only percent
        pool pool-name
        rate percent [cir percent]
```

Multipoint traffic uses the IMPM queues to access the switch fabric. For the egress to the port, either a queue-group or a single service queue is used. There is a default queue-group called policer-output-queues or a user configured queue-group can also be used.

As mentioned above, when a policer is assigned to a specific queue-group (default or user defined) it is optionally possible to configure explicitly the queue to be used. Within the queue-group it is also possible to redirect a FC for policed traffic to a specific queue, using the FC parameter. The preference of the FC to queue mapping is (in order, highest to lowest):

1. Explicitly configured in SAP-egress FC definition
2. Mapped using FC parameter within queue-group definition
3. Default is to use queue 1

```
config>qos>qgrps>egr# queue-group queue-group-name [create]
    description description-string
    queue queue-id [queue-type] [create]
        adaptation-rule [pir adaptation-rule] [cir adaptation-rule]
        burst-limit size [bytes|kilobytes]
        cbs size-in-kbytes
        high-prio-only percent
        mbs size [bytes|kilobytes]
        parent scheduler-name [weight weight] [level level] [cir-weight cir-weight]
                              [cir-level cir-level]
        percent-rate pir-percent [cir cir-percent]
        pool pool-name
        port-parent [weight weight] [level level] [cir-weight cir-weight]
                    [cir-level cir-level]
        rate pir-rate [cir cir-rate]
        xp-specific
            wred-queue [policy slope-policy-name]
    fc fc-name [create]
        queue queue-id
```

The default policer-output-queues queue-group consists of two queues; queue 1 being best-effort and queue 2 being expedite. The lowest four FCs (BE, L2, AF, L1) are assigned to queue 1 and the highest four queues (H2, EF, H1, NC) are assigned to queue 2. It may be important to change the queue 2 definition in the queue-group to have CIR=PIR when there are other best-effort queues using a non-zero CIR on the same egress port. This ensures that the policed traffic using queue 2 will be scheduled before any other

best-effort within CIR traffic. It also results in the queue CBS being non-zero, allowing the queue 2 traffic access to reserved buffer space.

```
A:PE-1>config>qos# queue-group-templates egress queue-group "policer-output-queues"
A:PE-1>cfg>qos>qgrps>egr>qgrp# info detail

                    exit
                    fc h2 create
                        queue 2
                    exit
                    fc l1 create
                        queue 1
                    exit
                    fc l2 create
                        queue 1
                    exit
                    fc nc create
                        queue 2
                    exit
```

The remaining details of queue-groups are beyond the scope of this section.

Applying the SAP Ingress and Policer Control Policy

The SAP ingress policy and policer control policy are both applied under the associated SAP. After applying these, it is possible to override the configuration of specific policers and/or the policer control policy. This is shown below. The parameter values are the same as detailed for the policies, as above.

```
config>service><service>#
    sap sap-id [create]
        [ingress|egress]
            qos policy-id
            policer-control-policy policy-name
            policer-override
                policer policer-id [create]
cbs size [bytes|kilobytes]
     mbs size [bytes|kilobytes]
packet-byte-offset {add add-bytes | subtract sub-bytes}
rate {rate | max} [cir {max | rate}
percent-rate <pir-percent> [cir <cir-percent>]
stat-mode stat-mode
            policer-control-override [create]
                max-rate {rate | max}
                priority-mbs-thresholds
min-thresh-separation size [bytes | kilobytes]
priority level
                        mbs-contribution size [bytes | kilobytes]
```

The SAP ingress policy and policer control policy required for the configuration example in Figure 429: Configuration Example is shown below.

```
#--------------------------------------------------
echo "QoS Policy Configuration"
#--------------------------------------------------
    qos
        policer-control-policy "cfhp-1" create
            root
                max-rate 100000
            exit
            tier 1
                arbiter "a3" create
                    parent "root" level 3
                    rate 60000
                exit
            exit
        exit
        sap-ingress 10 create
            queue 1 create
            exit
            queue 11 multipoint create
            exit
            policer 1 create
                stat-mode offered-total-cir
                parent "root"
                rate 100000
                high-prio-only 0
            exit
            policer 2 create
                stat-mode offered-total-cir
                parent "a3" level 2 weight 50
                rate 60000 cir 20000
                high-prio-only 0
            exit
```

```
            policer 3 create
                stat-mode offered-total-cir
                parent "a3" level 2 weight 25
                rate 60000 cir 20000
                high-prio-only 0
            exit
            policer 4 create
                stat-mode offered-total-cir
                parent "a3" level 2 weight 25
                rate 60000 cir 20000
                high-prio-only 0
            exit
            policer 5 create
                stat-mode offered-total-cir
                parent "root" level 5
                rate 10000 cir 10000
                high-prio-only 0
            exit
            fc "af" create
                policer 3
            exit
            fc "be" create
                policer 1
            exit
            fc "ef" create
                policer 5
            exit
            fc "l1" create
                policer 4
            exit
            fc "l2" create
                policer 2
            exit
            dot1p 1 fc "be"
            dot1p 2 fc "l2"
            dot1p 3 fc "af"
            dot1p 4 fc "l1"
            dot1p 5 fc "ef"
        exit
```

Traffic is classified based on dot1p values, each of which is assigned to an individual FC which in turn is assigned to a policer. The policer rates are configured as required for the example with an appropriate stat-mode. Default values are used for the policer burst thresholds. As all FCs are low burst priority by default, the high-prio-only has been set to zero in order to allow the traffic to use all of the MBS available at the PIR bucket.

Policers 2, 3 and 4 are parented to the arbiter "a3" with the required weights and at a single level (Level 2). In this example it does not matter which level of "a3" is used to parent these policers, the important aspect is the level at which "a3" is parented to the root. Consequently, these policers use the Level 3 parent policer thresholds (not the level they are parented on a"a3" not Level 2). Arbiter "a3" has a rate of 60Mbps so that its children cannot exceed this rate (except up to the burst tolerances).

Policers 1 and 5 are directly parented to the root arbiter, together with tier 1 arbiter "a3".

The total capacity for the 5 traffic streams is constrained to 100Mbps by the parent policer, again with the default burst tolerances at the root arbiter.

The SAP-ingress and policer-control-policies are applied to a SAP within an Epipe.

```
#--------------------------------------------------
echo "Service Configuration"
#--------------------------------------------------
```

```
    service

            exit
            no shutdown
        exit
```

A policer-control-policy can also be applied under a multi-service site (MSS) so that the hierarchical policing applies to traffic on multiple SAPs, potentially from different services. The MSS can only be assigned to a port, which could be a LAG, but it is not possible to assign an MSS to a card. When MSS are used, policer overrides are not supported.

```
config>service><service>#
    service
        customer customer-id [create]
            multi-service-site customer-site-name [create]
                assignment port port-id
                egress
                    policer-control-policy name
                ingress
                    policer-control-policy name
        service-type
            sap sap-id
                multi-service-site customer-site-name
                ingress
                    qos policy-id
                egress
```

```
                    qos policy-id
```

Show Output

After configuring the example as described in the previous section, steady state traffic was sent through the Epipe to overload each of the policers and the show output below was collected. This output focuses on the policer and arbiter details.

The following shows the policers on the SAP and their current state.

```
A:PE-1# show qos policer sap 1/1/3:1

```

The output above shows the configured values for the policers, e.g. PIR and CIR, together with their operational (current) state, such as PIR, CIR and FIR. The depth of each of the PIR buckets is also shown.

The detailed state of each policer can be seen by adding the parameter detail. The following is the output for policer 3.

```
A:PE-1# show qos policer sap 1/1/3:1 ingress detail
...

```

Notice that the above output shows the depth of the PIR, CIR and FIR buckets together with their operational rates. This can be used to explain the operation of the policers in this example and is discussed later in this section.

The stat-mode of offered-total-cir configured on policer 3 results in these statistics being collected.

```

The following command shows the policer hierarchy, including the child policers and their relationship to the intermediate arbiter (a3) and the root arbiter. It can be used to monitor the status of the child policers in the hierarchy. The output shows the assigned, offered and consumed capacity for each policer.

A:PE-1#
```

The complete information about the policer hierarchy can be seen by adding the detail parameter, as shown below, with alternative parameters to select more specific information.

- root-detail — Rates, depth and thresholds for the root arbiter.
- thresholds — CBS, MBS and high-prio-only thresholds with associated rates of child policers.
- priority-info — Discard-fair and discard-unfair thresholds, with number of associated children, for each of the root priority levels.
- depth — Parent policer and child PIR buckets depth, with PIR and FIR rate information.
- arbiter — Specific information of a given arbiter.
- port — For use with LAGs in different line cards or using adapt-qos link.

The output adds a good representation of the root arbiter thresholds, indicating the priority levels, discard-unfair and discard-fair thresholds, and how many child policers are associated with each level. It also includes the current depth of the child policer PIR buckets and the parent policer bucket.

A:PE-1#
```

From the output above, it can be seen that the offered rate for policers 1-4 is 45800Kbps, in fact it is the same for policer 5 but this is capped at the admin PIR rate, 10000Kbps.

The depth of the parent policer is only 8111 bytes, so this is not causing any discarding of priority 2-5 traffic at the parent policer as their discard thresholds are all above this value. Therefore the drops in policers 2-5 are all occurring in the child policers.

Policer 5 is consuming all of its operational capacity (PIR, CIR and FIR), and it can be seen that the level of the PIR bucket is 12814 bytes, which is slightly above its MBS of 12800 bytes. The level of the PIR bucket will oscillate around the MBS value as tokens are added to exceed the threshold (causing discards) then the draining reduces the level to just below the threshold (allowing forwarding).

Policers 2-4 are functioning in the same way as policer 5, as can be seen from their PIR bucket levels (levels are 77828 bytes with MBS of 77824), resulting in the PIR buckets constraining the rates of the traffic through these policers. This is happening because the arbiter "a3" is distributing its 60000Kbps in the configured ratio to these policers, which changes the operational PIR to 30000Kbps for policer 2 and 15000Kbps for policers 3 and 4, all being below the offered traffic rate. A similar effect can be seen with the CIR rates and bucket depths, as the operational CIR rate of policer 2 has reached its administrative value with those of policer 3 and 4 being constrained by the operational PIR. The CIR bucket depths are just above the CBS, again this will oscillate causing traffic to both in-profile and out-of-profile. As this is steady state traffic, the operational FIR rates for these policers have settled to match their operational PIR rates.

Policer 1 is also discarding traffic at the PIR bucket but it is also discarding traffic at the parent policer. This can be seen by the fact that policer 1 PIR depth is nowhere near its MBS whereas the parent policer level is just below the priority 1 discard-fair threshold. The level of the parent policer bucket will oscillate around this threshold causing policer 1 traffic to be discarded, which in turn is reflected back into the level of tokens in the policer 1 PIR bucket.

As this example is based on ingress unicast policing, the traffic exits the policers and then accesses the switch fabric using a set of shared-queue (policer-output-queues). The parameters for these queues can be seen using the following **show** command.

```
A:PE-1# show qos shared-queue "policer-output-queues" detail
```

```

Where

- Priority Level 1 has no children so both its fair and unfair thresholds are 0.
- Priority Level 2 has one child so its unfair threshold is 0 and its fair threshold is at the configured mbs-contribution [1024 bytes] (given that this is larger than the min-thresh-separation).
- Priority Level 3 has two children so its unfair threshold is equal to the min-thresh-separation plus the fair threshold of priority 2 [256+1024=1280 bytes]. Its fair threshold is effectively the mbs-contribution plus the fair threshold of priority 2 [1024+1024=2048 bytes] (given that the mbs-contribution is larger than 2x min-thresh-separation).
- Priorities 4, 5 and 6 have the fixed parameter configured. Even though priority 4 has no children, priority 5 has only one child and priority 6 has two children, all three priorities have the same incremental values for their unfair and fair discard threshold. This result in
  - Priority 4's unfair threshold being equal to the min-thresh-separation plus the fair threshold of priority 3 [256+2048=2304 bytes]. Its fair threshold is effectively the mbs-contribution plus the fair threshold of priority 3 [1024+2048=3072 bytes] (given that the mbs-contribution is larger than 2x min-thresh-separation).
  - Priority 5's unfair threshold being equal to the min-thresh-separation plus the fair threshold of priority 4 [256+3072=3328 bytes]. Its fair threshold is effectively the mbs-contribution plus the fair threshold of priority 4 [1024+3072=4096 bytes] (given that the mbs-contribution is larger than 2x min-thresh-separation).
  - Priority 6's unfair threshold being equal to the min-thresh-separation plus the fair threshold of priority 5 [256+4096=4352 bytes]. Its fair threshold is effectively the mbs-contribution plus the fair threshold of priority 5 [1024+4096=5120 bytes] (given that the mbs-contribution is larger than 2x min-thresh-separation).

Note that the above parameter values were chosen to exactly match available hardware values to simplify the output.

Conclusion

This note has described the configuration of Class Fair Hierarchical Policing for SAPs. This hardware policing provides low latency ingress and egress prioritized traffic control with the ability to provide fairness between child policers at the same parent policer priority level.

FP and Port Queue Groups

This chapter provides information about FP and port queue groups.

Topics in this chapter include:

Applicability

This chapter is applicable to the 7950 XRS-16c/20, 7750 SR-7/12, 7750 SR-a4/8, 7750 SR-c4/12, and 7450 ESS-6/6v/7/12 platforms and assumes only FP2- and higher-based line cards are used.

Port queue groups can be configured on FP1 line cards but not all functions described in this chapter are supported on FP1 line cards. FP queue groups are not supported on FP1 line cards because FP queue groups rely on hardware policing.

The configuration was tested on Release 13.0.R7. There are no other specific prerequisites for this configuration.

Overview

Queue groups provide flexible QoS control beyond that available by default for SAPs and network interfaces.

Many applications require detailed QoS control for SAPs, with aggregated QoS control across the core on network interfaces. Queue groups allow the reverse, specifically aggregated QoS control for multiple SAPs and per-network interface QoS control. This is summarized in Table 26: Default QoS and Queue Group Comparison .

Table 26: Default QoS and Queue Group Comparison

	Default	Queue group
SAPs	• Per-SAP ingress queues and policers • Per-SAP egress queues and policers	• Policers for a set of SAPs at ingress • Queues for a set of SAPs at egress
Network interfaces	• Per-MDA ingress network queues • Per-port egress network queues	• Policers per network interface at ingress • Policers and queues per network interface at egress

Queue groups were introduced in SR OS Release 7 as a mechanism of grouping a set of queues and enhanced in subsequent Releases. Release 10 added the ability to configure policers within queue groups and introduced a more flexible configuration where the queue group template could be applied multiple times with different instances. The term queue groups was retained even though they can now contain queues, policers, or both. This chapter describes this new configuration.

Queue groups can be used for other applications than those listed in Table 26: Default QoS and Queue Group Comparison ; for example:

- Pseudowire (PW) QoS

  Providing QoS control for spoke SDPs in the various pipe services, different types of VPLS services, and associated IES/VPRN interfaces (see chapter Pseudowire QoS).

- Carrier Supporting Carrier (CSC) services

  Providing QoS control for CSC network interfaces in VPRN services.

- Ingress QoS control on VPRN network interfaces

  Providing for ingress QoS control of unicast traffic into a VPRN over automatically created or manually created bindings in a VPRN service.

- Network egress QoS

  Providing queue rates in kbps instead of the percentage of the port rate, and queue CBS/MBS in kbytes instead of a fractional percentage of the pool size.

When egress queue groups are used for SAPs, the groups provide a similar functionality to multi-service sites in that both can provide an overall rate for a set of SAPs. However, multi-service sites also provide per-SAP QoS control, whereas the queue groups do not.

Queue groups are not applicable to subscriber management except when egress policing is used.

Note:
The queue groups described in this chapter are different from those that are configured when using a high-scale Ethernet MDA (HS-MDAv2).

Configuration

Following the description of the overall configuration of queue groups, their configuration is illustrated using examples on a SAP, a network interface, and with egress subscriber policing.

The steps required to configure a queue group are summarized as follows:

- Create a queue group template:
  - Ingress or egress
- Apply an instance of the queue group template to:
  - FP ingress
    - Access or network
  - Ethernet egress port
    - Access or network
- Redirect traffic to a policer or queue in the FP or port queue group instance per forwarding class (FC) within a:
  - SAP ingress or egress QoS policy

  - Network QoS policy for both ingress and egress
- Consider post-egress policer queuing

Creating Queue Group Templates

Queue group templates are configured separately for ingress and egress; an ingress queue group template with the same name as an egress queue group template is a different object.

Ingress queue group templates can contain policers or queues, but not both.

Egress queue group templates can contain policers or queues, or both; queue 1 is created by default and cannot be deleted. A forwarding class (FC) can also be configured to determine the queue mapping of the FC for forwarded SAP egress post-policer traffic.

To summarize the use of policers with respect to queue groups:

- Ingress FP queue groups can only use policers.
- Port egress access queue groups cannot use policers.
- Network ingress and egress applications can only use policers in a queue group.

The configuration of an ingress and egress queue group template is as follows:

```
configure
    qos
        queue-group-templates
            ingress
                queue-group <queue-group-name> [create]
                    description <description-string>
                    policer <policer-id> [create]
                    queue <queue-id> [multipoint] [<queue-type>]
                                     [<queue-mode>] [create]
            egress
                queue-group <queue-group-name> [create]
                    description <description-string>
                    fc <fc-name> [create]
                        queue <queue-id>
                    policer <policer-id> [create]
                    queue <queue-id> [<queue-type>] [create]
```

The configuration of the policer and queue is similar to the configuration in a SAP ingress and egress QoS policy. However, the SAP ingress QoS policy allows the configuration of a percent-rate and the SAP egress QoS policy allows the configuration of an avg-frame-overhead, neither of which is available in a queue group template. An ingress queue group template supports the creation of up to 32 queues and 32 policers, while an egress queue group template supports the creation of up to 8 queues and 8 policers.

Because an egress queue group template uses kbps for the CIR/PIR rates and bytes/kbytes for the CBS/MBS, unlike a network-queue QoS policy, a network egress interface can use them when an egress queue group template is applied.

The system instantiates the following queue group templates by default. Table 28: Queue Group Templates - Egress shows the ingress queue group templates:

Table 27: Queue Group Templates - Ingress

Group name	Description
_tmnx_nat_ing_q_grp	NAT/LNS Ingress Queue Group Template
_tmnx_nat_ing_q_grp_v2	NAT/LNS Ingress Queue Group Template for ISAv2
_tmnx_lns_esm_ing_q_grp	LNS ESM Ingress Queue Group Template

Table 28: Queue Group Templates - Egress shows the egress queue group templates:

Table 28: Queue Group Templates - Egress

Group name	Description
_tmnx_nat_egr_q_grp	NAT/LNS Egress Queue Group Template
policer-output-queues	Default egress policer output queues
_tmnx_nat_egr_q_grp_v2	NAT/LNS Egress Queue Group Template for ISAv2
_tmnx_lns_esm_egr_q_grp	LNS ESM Egress Queue Group Template

This chapter will only discuss the policer-output-queues queue group from the preceding table, an instance of which is created on all egress access and hybrid ports, to be used for egress policed traffic.

Applying Queue Group Templates

Ingress

An ingress queue group template containing only policers can be applied to an FP ingress. When applied, an instance identifier must be specified, which represents the instantiated instance of the related queue group template.

If an attempt is made to configure a queue group template containing queues for an FP ingress, the following error message appears:

```
*A:PE-1>config#  card 5 fp 1 ingress access queue-group "qg2" instance 1 create
MINOR: CHMGR #1164 Cannot attach a Queue Group containing queues
```

Because 7750 SR-a4/8 platforms do not support SAP or network hardware policers, FP ingress queue groups are not supported on those platforms.

Queue group templates containing only queues can be applied to port ingress. However, only one such queue group can be applied per ingress port.

An ingress template can be applied to an FP ingress as either an ingress access queue group or an ingress network queue group, or both. In each case:

- An accounting policy can be applied.
- Statistics collection can be enabled.
- A description can be configured.

- A policer control policy can be applied, containing parent arbiters for the queue group policers, and its parameters can be overridden.
- Policer parameters configured within the queue group template can also be overridden.

Note:
When the queue group applies to a tunnel object that can move between different network interfaces, and consequently different network ingress FPs (for example, PW QoS), a network ingress queue group instance must be applied to each FP ingress that could be used.

The configuration of ingress queue group templates for ingress FPs is as follows:

```
configure
    card <slot-number>
        fp [<fp-number>]
            ingress
                access
                    queue-group <queue-group-name>
                                instance <[1..65535]> [create]
                        accounting-policy <acct-policy-id>
                        collect-stats
                        description <description-string>
                        policer-control-override [create]
                            max-rate {<rate> | max}
                            priority-mbs-thresholds
                                min-thresh-separation <size> [bytes | kilobytes]
                                priority <level>
                                   mbs-contribution <size> [bytes | kilobytes]
                        policer-control-policy
                                <policer-control-policy-name>
                        policer-override
                            policer <policer-id> [create]
               network
                    queue-group <queue-group-name>
                                instance <[1..65535]> [create]
                        accounting-policy <acct-policy-id>
                        collect-stats
                        description <description-string>
                        policer-control-override [create]
                            max-rate {<rate> | max}
                            priority-mbs-thresholds
                                min-thresh-separation <size> [bytes | kilobytes]
                                priority <level>
                                   mbs-contribution <size> [bytes | kilobytes]
                        policer-control-policy
                                <policer-control-policy-name>
                        policer-override
                            policer <policer-id> [create]
```

Note:
Configure FP ingress access and network queue group instances consistently across FPs relating to a LAG.

A single ingress template containing only queues can also be applied to an Ethernet port ingress, which can be used only for access ingress:

- An accounting policy can be applied.
- Statistics collection can be enabled.
- A description can be configured.

- Queue parameters configured within the queue group template can be overridden.
- A scheduler policy can be applied containing parent schedulers for the queue group queues.

The configuration of an ingress queue group template for an ingress port is as follows:

```
configure
    port <port-id>
        ethernet
            access
                ingress
                    queue-group <queue-group-name> [create]
                        accounting-policy <acct-policy-id>
                        collect-stats
                        description <description-string>
                        queue-overrides
                            queue <queue-id> [create]
                        scheduler-policy <scheduler-policy-name>
```

Egress

An egress queue group template containing policers or queues, or both, can be applied to an Ethernet port network egress. Only queue group templates containing queues (not policers) can be applied to an Ethernet port access egress. When applied, an instance identifier can be specified, which represents the instantiated instance of the related queue group template; the default being 1.

If an attempt is made to configure a queue group template containing policers for an Ethernet port access egress, the following error message appears:

```
*A:PE-1# configure port 5/1/5 ethernet access egress queue-group "qg1" instance 1 create
MINOR: CLI Could not create/change "qg1".
MINOR: PMGR #1324 Cannot attach a Queue Group containing policers
```

An egress template can be applied as either an egress access queue group or an egress network queue group, or both. In each case:

- An accounting policy can be applied.
- Statistics collection can be enabled.
- A description can be configured.
- Queue parameters configured within the queue group template can be overridden.
- A scheduler policy can be applied containing parent schedulers for the queue group queues.

When applied to the Ethernet access egress, a host-match can be configured, which is used to select a queue group for subscriber egress policed traffic; see later in this chapter for details.

When applied to the Ethernet network egress, a policer control policy can be applied, which contains parent arbiters for the queue group policers.

Note:
When the queue group applies to a tunnel object that can move between different network interfaces, and consequently different network egress ports (for example, PW QoS), a network egress queue group instance must be applied to each network egress port that could be used.

The configuration of egress queue group templates for egress ports is as follows:

```
configure
    port <port-id>
        ethernet
            access
                egress
                    queue-group <queue-group-name> [create]
                                [instance <instance-id>]
                        accounting-policy <acct-policy-id>
                        agg-rate
                            limit-unused-bandwidth
                            queue-frame-based-accounting
                            rate <kilobits-per-second>
                        collect-stats
                        description <description-string>
                        host-match dest <destination-string> [create]
                        queue-overrides
                            queue <queue-id> [create]
                        scheduler-policy <scheduler-policy-name>
               network
                    queue-group <queue-group-name> [create]
                                [instance <instance-id>]
                        accounting-policy <acct-policy-id>
                        agg-rate
                            limit-unused-bandwidth
                            queue-frame-based-accounting
                            rate <kilobits-per-second>
                        collect-stats
                        description <description-string>
                        policer-control-policy
                                <policer-control-policy-name>
                        queue-overrides
                            queue <queue-id> [create]
                        scheduler-policy <scheduler-policy-name>
```

Note:
When port egress queue groups are used with a LAG, the system enforces a consistent configuration between the ports (based on only the configuration of the primary LAG port).

Redirecting Traffic to a Queue Group Queue or Policer

There are multiple ways to redirect traffic to a queue group queue or policer. The redirection is always on a per-FC basis so that different FCs within the same policy can use a mix of a local SAP policer, a local SAP or network queue, or a queue group policer or queue (where applicable).

Redirection to a queue group queue or policer is not supported for subscribers; attempting to do so will display the following errors:

```
*A:PE-1>config>qos>sap-ingress# fc "af" policer 1 fp-redirect-group
MINOR: QOS #1489 Cannot assign a queue-group because SLA profile references to this policy
 exist

*A:PE-1>config>qos>sap-egress# fc af policer 1 port-redirect-group-queue
MINOR: QOS #1628 Cannot assign a queue-group because SLA profile references to this policy
 exist

*A:PE-1>config>qos>sap-egress# fc af queue 1 port-redirect-group-queue
```

```
MINOR: QOS #1628 Cannot assign a queue-group because SLA profile references to this policy
 exist

*A:PE-1>config>subscr-mgmt>sla-prof>ingress# qos 40
MINOR: SUBMGR #1110 Cannot assign Qos Policy, QOS Plcy contains queue-group references

*A:PE-1>config>subscr-mgmt>sla-prof>egress# qos 40
MINOR: SUBMGR #1110 Cannot assign Qos Policy, QOS Plcy contains queue-group references
```

SAP Ingress Redirection

Traffic can be redirected per FC to a policer in an FP ingress access queue group, using the fp-redirect-group parameter in the SAP ingress QoS policy, as follows:

```
configure
    qos
        sap-ingress <policy-id> [create]
            fc <fc-name> [create]
                policer <policer-id> fp-redirect-group
```

The policer-id is referencing a policer in the FP ingress queue group.

The queue group name and instance to be used is not yet configured, allowing this QoS policy to be applied to objects using different FP ingress queue group instances, which results in greater flexibility.

Compare this preferred configuration to the original configuration used for ingress port queue groups, as follows, where the queue group name is specified within the SAP ingress QoS policy and the instance is not available:

```
configure
    qos
        sap-ingress <policy-id> [create]
            fc <fc-name> [create]
                queue <queue-id> group <queue-group-name>
```

In the preferred configuration, redirection is completed by applying the SAP ingress QoS policy to the SAP with the queue group name and instance to be used, as follows:

```
configure
    service
        {apipe|cpipe|epipe|fpipe|ipipe} <service-id>
            sap <sap-id>
                ingress
                    qos <policy-id> fp-redirect-group <queue-group-name>
                                                instance <instance-id>
        {ies|vprn} <service-id>
            interface <ip-int-name>
                sap <sap-id>
                    ingress
                        qos <policy-id>
                            fp-redirect-group <queue-group-name>
                                     instance <instance-id>
```

SAP Egress Redirection

Traffic can be redirected per FC to a queue in a port egress access queue group, using the port-redirect-group parameter, as follows:

```
configure
    qos
        sap-egress <policy-id> [create]
            fc <fc-name> [create]
                queue <queue-id> port-redirect-group-queue
```

The queue-id is referencing a queue in the port egress queue group.

The queue group name and instance to be used is not yet configured, allowing this QoS policy to be applied to objects using different port egress queue groups.

Compare this preferred configuration to the original configuration, which allows the queue group name with an instance to be specified:

```
queue <id> {group <grp-name> [instance instance-id]}
```

In the preferred configuration, redirection is completed by applying the SAP egress QoS policy to the SAP with the queue group name and instance to be used, as follows:

```
configure
    service
        {apipe|cpipe|epipe|fpipe|ipipe} <service-id>
            sap <sap-id>
                egress
                    qos <policy-id>
                        port-redirect-group <queue-group-name>
                                        instance <instance-id>
        {ies|vprn} <service-id>
            interface <ip-int-name>
                sap <sap-id>
                    egress
                        qos <policy-id>
                            port-redirect-group <queue-group-name>
                                            instance <instance-id>
```

Network Ingress Redirection

Traffic can be redirected per FC to a policer in an FP ingress network queue group, using the fp-redirect-group parameter, as follows:

```
configure
    qos
        network <network-policy-id> [create]
            ingress
                fc <fc-name>
                    fp-redirect-group <policer-type> <policer-id>
```

The policer-id is referencing a policer in the FP ingress queue group.

The traffic usage for each policer type for the supported services is shown in Table 4.

Table 29: Network Ingress FP Queue Group Policer Usage

Policer Type	Usage
broadcast-policer	Broadcast traffic for PW QoS in a VPLS service
mcast-policer	Multipoint traffic (except for ingress QoS control on VPRN network interfaces and CSC services where the IP multicast traffic uses the ingress network queues or queue group related to the network interface) Multicast traffic for PW QoS in a VPLS service
unknown-policer	Unknown traffic for PW QoS in a VPLS service
policer	Unicast traffic

The queue group name and instance to be used is not yet configured, allowing this QoS policy to be applied to objects using different FP ingress queue group instances.

The redirection is completed by applying the network QoS policy to the required object with the queue group name and instance to be used, as follows (only the network interface redirection is shown):

```
configure
    router
        interface <interface-name>
            qos <network-policy-id>
                        ingress-fp-redirect-group <queue-group-name>
                        ingress-instance <instance-id>
```

Network Egress Redirection

Traffic can be redirected per FC to a policer or a queue in a port egress network queue group, using the port-redirect-group parameter, as follows:

```
configure
    qos
        network <network-policy-id> [create]
            egress
                fc <fc-name>
                    port-redirect-group {queue <queue-id> |
                                policer <plcr-id> [queue <queue-id>]}
```

The queue-id and policer-id are referencing a queue and a policer in the port egress queue group.

The queue group name and instance to be used are not yet configured, allowing this QoS policy to be applied to objects using different port egress queue groups.

The redirection is completed by applying the network QoS policy to the required object with the queue group name and instance to be used, as follows (only the network interface redirection is shown):

```
configure
    router
        interface <interface-name>
            qos <network-policy-id>
```

```
                        egress-fp-redirect-group <queue-group-name>
                        egress-instance <instance-id>
```

Note:
Non-IPv4/non-IPv6/non-MPLS packets are not subject to the redirection to an egress queue group instance and will remain on the regular port network egress queues. When using an egress port scheduler, parent the related regular network port queues to appropriate port scheduler priority levels, to ensure the required operation under port congestion. This is important for protocol traffic, such as LACP, EFMOAM, ETH-CFM, ARP, and IS-IS, which by default use the FC nc regular network port queue.

Post-egress Policer Queuing

The queuing of traffic exiting an egress policer is described as follows for SAP egress and network egress.

SAP egress policed traffic exits a port, using either a local queue or an egress queue group instance queue. If an egress queue group instance queue is to be used, the policed traffic can be mapped to the queue in the following ways, listed in reverse preference order (first is lowest preference):

1. By default, SAP egress policed traffic exits using a queue in the policer-output-queues queue group instance when only a policer is configured:

   ```
   configure
       qos
           sap-egress <policy-id> [create]
               fc <fc-name> [create]
                   policer <policer-id>
   ```

   The system always creates this egress queue group template and applies it to all access and hybrid ports (for use by the access part of the hybrid port) as instance 1. The queue group template contains the mapping for all FCs to one of the two created queues to determine which queue is to be used.

   The default configuration of the policer-output-queues group template is as follows (without the queue details):

   ```
   configure
       qos
           queue-group-templates
               egress
                   queue-group "policer-output-queues" create
                       description "Default egress policer
                                    output queues."
                       queue 1 best-effort create
                       exit
                       queue 2 expedite create
                       exit
                       fc af create
                           queue 1
                       exit
                       fc be create
                           queue 1
                           exit
                       fc ef create
                           queue 2
                       exit
                       fc h1 create
                           queue 2
                       exit
   ```

```
                    fc h2 create
                        queue 2
                    exit
                    fc l1 create
                        queue 1
                    exit
                    fc l2 create
                        queue 1
                    exit
                    fc nc create
                        queue 2
                    exit
                exit
```

This queue group template cannot be deleted, but its configuration can be modified. The configuration commands under a port access egress queue group instance are also available under the policer-output-queues queue group instance.

2. The FC in the SAP egress QoS policy can be mapped to a policer with its traffic redirected to a port access egress queue group, as follows:

```
configure
    qos
        sap-egress <policy-id> [create]
            fc <fc-name> [create]
                policer <policer-id> port-redirect-group-queue
```

The QoS policy must be applied to the SAP with a redirection to a queue group instance. By default, queue 1 in the queue group will be used, but other queues can be created and used by creating an FC-to-queue mapping to them.

3. Similar to step 2, the FC in the SAP egress QoS policy can be mapped to a policer with its traffic redirected to a port access egress queue group instance and the queue within that queue group instance to be used, as follows:

```
configure
    qos
        sap-egress <policy-id> [create]
            fc <fc-name> [create]
                policer <policer-id> port-redirect-group-queue queue <id>
```

The QoS policy must again be applied to the SAP with a redirection to a queue group instance. In this case, the queue specified with the port-redirect-group-queue will be used.

Network egress can only use policers that are created within an egress queue group instance, and this requires the egress FC to have the port-redirect-group parameter configured.

With the following configuration, traffic exits the port on the network egress queue to which its FC is mapped (not on a queue group queue):

```
configure
    qos
        network <network-policy-id> [create]
            egress
                fc <fc-name>
                    port-redirect-group policer <plcr-id>
```

If a queue is specified on the port-redirect-group statement, as follows, the traffic exits on the referenced queue within the port network egress queue group instance:

```
configure
    qos
        network <network-policy-id> [create]
            egress
                fc <fc-name>
                    port-redirect-group policer <plcr-id> queue <queue-id>
```

Configuration Examples

The following configuration examples are for the use of queue groups with a SAP, network interface, and egress policed traffic subscriber traffic. Different queue group templates and instances have been used to highlight the flexibility of the configuration.

SAP Configuration Example

In this example, a SAP is created in an IES service using ingress queue group qg1 instance 1 and egress queue group qg1 instance 1.

First, the queue group templates are configured, as follows:

```
configure
    qos
        queue-group-templates
            ingress
                queue-group "qg1" create
                    policer 1 create
                    exit
                    policer 2 create
                    exit
                exit
            exit
            egress
                queue-group "qg1" create
                    queue 1 best-effort create
                    exit
                    queue 2 expedite create
                    exit
                exit
                queue-group "policer-output-queues" create
                    queue 3 best-effort create
                    exit
                    fc l2 create
                        queue 3
                    exit
                exit
```

The policer-output-queues queue group template has been modified to add an extra queue and map FC l2 to it. This is used by the traffic mapped to policer 1 in the SAP egress QoS policy.

The ingress template is applied to card 5 fp 1 to create an FP access queue group instance, as follows:

```
configure
    card 5
        fp 1
```

```
            ingress
                access
                    queue-group "qg1" instance 1 create
                    exit
                exit
```

The egress template is applied to port 5/1/5 to create a port access queue group instance, as follows:

```
configure
    port 5/1/5
        ethernet
            mode hybrid
            encap-type dot1q
            access
                egress
                    queue-group "qg1" instance 1 create
                    exit
                exit
```

The SAP ingress QoS policy is created to redirect FC af to policer 1 and FC ef to policer 2 in the FP ingress queue group. To emphasize that the redirection is per FC and can coexist with locally mapped queues or policers, FC be is mapped to the local queue 1 and FC l2 to local queue 2, as follows:

```
configure
    qos
        sap-ingress 10 create
            queue 1 create
            exit
            queue 2 create
            exit
            queue 11 multipoint create
            exit
            fc "af" create
                policer 1 fp-redirect-group
            exit
            fc "be" create
                queue 1
            exit
            fc "ef" create
                policer 2 fp-redirect-group
            exit
            fc "l2" create
                queue 2
            exit
            dot1p 0 fc "be"
            dot1p 1 fc "l2"
            dot1p 2 fc "af"
            dot1p 3 fc "ef"
        exit
```

The SAP egress QoS policy is created to redirect FC af to queue 1 in the port egress queue group and FC ef to local policer 2, with its traffic exiting through queue 2 in the port egress queue group. FC be is mapped to the local queue 1 and FC l2 to local policer 1. The policer 1 traffic will exit using queue 3 of the policer-output-queues queue group, because the mapping for FC l2 has been modified in its template, as follows:

```
configure
    qos
        sap-egress 10 create
            queue 1 create
```

```
            exit
            policer 1 create
            exit
            policer 2 create
            exit
            fc af create
                queue 1 port-redirect-group-queue
            exit
            fc be create
                queue 1
            exit
            fc ef create
                policer 2 port-redirect-group-queue queue 2
            exit
            fc l2 create
                policer 1
            exit
        exit
```

The IES service is created with an interface on SAP 5/1/5:1, using the preceding ingress and egress QoS policies and queue group instances. A second interface (not shown) is used to forward the traffic to and from this interface, as follows:

```
configure
    service
        ies 1 customer 1 create
           interface "PE-1-int1-2" create
                address 10.1.2.1/24
                sap 5/1/5:1 create
                    ingress
                        qos 10 fp-redirect-group "qg1" instance 1
                    exit
                    egress
                        qos 10 port-redirect-group "qg1" instance 1
                    exit
                exit
            exit
            no shutdown
        exit
```

The following output shows the configuration and the QoS state after sending traffic through the service.

The traffic statistics are either counted in the SAP queues and policers, or in the queue group instance queues and policers, but not in both. However, summary statistics per SAP are available when using FP ingress queue groups, as shown.

The queue group templates can be shown. The output shows the details related to the ingress queue group template:

```
*A:PE-1# show qos queue-group "qg1" ingress detail

*A:PE-1#
```

For SAP ingress QoS policy 10, the redirection is true for FC af using policer 1 and FC ef using policer 2 to an FP ingress queue group, as follows:

```
*A:PE-1# show qos sap-ingress 10 detail | match post-lines 5 expression "af Unicast|ef Unicast"
FC                  : af Unicast
-------------------------------------------------------------------------------
Policer             : 1                 Queue              : def
Queue-Group         : None
FP Queue-Group      : True
FC                  : ef Unicast
-------------------------------------------------------------------------------
Policer             : 2                 Queue              : def
Queue-Group         : None
FP Queue-Group      : True
```

In the following output for SAP egress QoS policy 10:

- The redirection is true for FC af using queue 1 in the queue group instance, to be specified when the policy is applied to a SAP.
- The redirection is true for FC ef using local policer 2 with its traffic exiting queue 2 in the queue group instance, to be specified when the policy is applied to a SAP.
- FC l2 is using local policer 1 with its traffic exiting using queue 3 in the policer-output-queues port access egress queue group.

```
*A:PE-1# show qos sap-egress 10 detail | match post-lines 6 expression "Queue-Group"

-------------------------------------------------------------------------------
*A:PE-1#
```

The number of valid ingress packets received on a SAP, or subscribers on that SAP, in the sap-stats output, are shown as follows. The received valid counter includes both the local SAP counters and the counters from the related FP ingress queue group instance. This is useful to display SAP-level traffic statistics when forwarding classes in a SAP ingress policy have been redirected to an ingress queue group.

```
*A:PE-1# show service id 1 sap 5/1/5:1 sap-stats | match post-lines 6 "Forwarding Engine Stats"
Forwarding Engine Stats
Dropped               : 0                      0
Received Valid        : 4000                   512000
Off. HiPrio           : 0                      0
Off. LowPrio          : 2000                   256000
Off. Uncolor          : 0                      0
Off. Managed          : 0                      0
```

Traffic forwarded through FP ingress access, port ingress access, and port egress access queue groups can be monitored, as follows:

```
monitor card <slot-number> fp <fp-number>  ingress {access|network} queue-group <queue-
group-name> instance <instance-id> [interval <seconds>][repeat<repeat>] policer <policer-id>
 [absolute | percent-rate [<reference-rate>]]

monitor port queue-group <queue-group-name> ingress <access> ingress-queue <ingress-queue-id>
 [interval <seconds>] [repeat <repeat>] [absolute|rate]

monitor port queue-group <queue-group-name> egress <access> [instance <instance-id>] [egress-
queue <egress-queue-id>] [interval <seconds>] [repeat <repeat>] [absolute|rate]
```

The summary of the queue groups applied to a port is shown as follows:

```
*A:PE-1# show port 5/1/5 queue-group summary
===============================================================================
Port queue-group summary
===============================================================================

1         0             0             0             0             0
2         0             0             0             0             0
3         0             0             0             0             0
4         0             0             0             0             0
5         0             3             0             1             0
-------------------------------------------------------------------------------
Total ingress QG templates per system :  4
Total egress  QG templates per system :  5
===============================================================================
*A:PE-1#
```

The preceding output includes the created ingress template plus the three system-created ingress templates (making four in total), and the created egress template plus the four system-created egress templates (making five in total). There is one applied FP access ingress queue group instance on card 5. There are three port access egress queue group instances (the applied queue group instance and two instances of the policer-output-queues queue group), one on each access port used for IES service interfaces.

Network Interface Configuration Example

A network interface is created using ingress queue group qg2 instance 2 and egress queue group qg2 instance 2. If the goal is to provide per-network interface QoS on a single port, each network interface would be configured on a separate VLAN.

First, the queue group templates are configured, as follows:

```
configure
    qos
        queue-group-templates
            ingress
                queue-group "qg2" create
                    policer 1 create
                    exit
                    policer 2 create
                    exit
                exit
            exit
            egress
                queue-group "qg2" create
                    queue 1 best-effort create
                    exit
                    queue 2 expedite create
                    exit
                    policer 1 create
                    exit
                    policer 2 create
                    exit
                exit
            exit
```

The ingress template is applied to card 5 fp 1 to create an FP network queue group instance, as follows:

```
configure
    card 5
        fp 1
            ingress
                network
                    queue-group "qg2" instance 2 create
                    exit
                exit
```

The egress template is applied to port 5/1/5 to create a port network queue group instance, as follows:

```
configure
    port 5/1/5
        ethernet
            mode hybrid
            encap-type dot1q
            network
                egress
                    queue-group "qg2" instance 2 create
                    exit
                exit
```

The network QoS policy is created to:

- Ingress

  Redirect FC af to policer 1 and FC ef to policer 2 in the FP ingress queue group. FC be and FC l2 continue to use their default mapping to the local network ingress queues 1 and 2, respectively.

- Egress

  Redirect FC af to queue 1 in the port egress queue group and FC ef to policer 2 in the port egress queue group, with its traffic exiting through queue 2 of the port egress queue group. FC l2 is redirected to policer 1 in the port egress queue group, with its traffic exiting through the default network egress queue mapped by FC l2; that is, queue 2. FC be continues to use the default network egress queue 1.

```
configure
    qos
        network 10 create
            ingress
                dot1p 0 fc be profile out
                dot1p 1 fc l2 profile out
                dot1p 2 fc af profile out
                dot1p 3 fc ef profile in
                fc af
                    fp-redirect-group policer 1
                exit
                fc ef
                    fp-redirect-group policer 2
                exit
            exit
            egress
                fc af
                    port-redirect-group queue 1
                exit
                fc ef
                    port-redirect-group policer 2 queue 2
                exit
                fc l2
                    port-redirect-group policer 1
```

```
            exit
        exit
    exit
```

The network interface is created on port 5/1/5:2 using the preceding network QoS policy with the ingress and egress being redirected to created queue group instances. A second interface (not shown) is used to forward the traffic to and from this network interface.

```
configure
    router Base
        interface "PE-1-int2-2"
            address 10.2.2.1/24
            port 5/1/5:2
            qos 10 egress-port-redirect-group "qg2" egress-instance 2
                   ingress-fp-redirect-group "qg2" ingress-instance 2
            no shutdown
        exit
```

The following output shows the details of the configuration and the QoS state after sending traffic through the network interface.

The traffic statistics are either counted in the network interface queues or in the queue group instance queues and policers, but not in both.

The queue group templates can be shown. The output shows the details related to the ingress queue group template:

```
*A:PE-1# show qos queue-group "qg2" ingress detail

*A:PE-1#
```

The preceding output shows that:

- Ingress
  - FC af is redirected to unicast policer 1 in the queue group instance, to be specified when the policy is applied to a network interface.

  - FC ef is redirected to unicast policer 2 in the queue group instance, to be specified when the policy is applied to a network interface.
- Egress
  - FC af is redirected to queue 1 in the queue group instance, to be specified when the policy is applied to a network interface.
  - FC ef is redirected to policer 2 and queue 2 in the queue group instance, to be specified when the policy is applied to a network interface, so that the policer 2 traffic exits using queue 2 in the port network egress queue group instance.

The queue group instances used by the network interface are shown as follows:

```
*A:PE-1# show router interface "PE-1-int2-2" detail | match post-lines 3 "QoS Queue-Group
 Redirection Details"
QoS Queue-Group Redirection Details
-------------------------------------------------------------------------------
Ingress FP QGrp  : qg2                  Egress Port QGrp  : qg2
Ing FP QGrp Inst : 2                    Egr Port QGrp Inst: 2
```

After traffic is sent through the network, it can be shown in the FP ingress network queue group policers, as follows:

```
*A:PE-1# show card 5 fp 1 ingress queue-group "qg2" instance 2 mode network statistics
===============================================================================

Stats mode: minimal
Off. All              : 1000                   128000
Dro. All              : 0                      0
For. All              : 1000                   128000
-------------------------------------------------------------------------------
*A:PE-1#
```

In the preceding output, the traffic on queue 1 is FC af, on policer 1 is FC l2, and on policer 2 is FC ef, with the post-policed traffic on queue 2.

Finally, the FC l2 traffic using the network egress queue group policer 1 can be shown in queue 2 of the default network egress queues, as follows:

```
*A:PE-1# show port 5/1/5 detail | match post-lines 4 "Egress Queue  2"
Egress Queue  2             Packets                 Octets
     In Profile forwarded  :    0                      0
     In Profile dropped    :    0                      0
     Out Profile forwarded :    1000                   128000
     Out Profile dropped   :    0                      0
```

Traffic forwarded through both FP ingress network and port egress network queue groups can be monitored, as follows:

```
monitor card <slot-number> fp <fp-number>  ingress {access|network} queue-group <queue-
group-name> instance <instance-id> [interval <seconds>][repeat<repeat>] policer <policer-id>
 [absolute | percent-rate [<reference-rate>]]

monitor port queue-group <queue-group-name> egress <access> [instance <instance-id>] [egress-
queue <egress-queue-id>] [interval <seconds>] [repeat <repeat>] [absolute|rate]
```

The summary of the queue groups applied to a port is shown as follows:

```
*A:PE-1# show port 5/1/5 queue-group summary

===============================================================================
Port queue-group summary
===============================================================================

-------------------------------------------------------------------------------
Total ingress QG templates per system :  4
Total egress  QG templates per system :  5
===============================================================================
*A:PE-1#
```

The preceding output includes the created ingress template plus the three system-created ingress templates (making four in total), and the created egress template plus the four system-created egress templates (making five in total). There is the one applied FP network ingress queue group instance on card 5. There is the one created port network egress queue group instance. There are also two port access egress queue group instances, which are the policer-output-queues queue group instances associated with the access port used for IES service interface (not discussed) and the access side of the hybrid port 5/1/5.

Egress Policed Subscriber Configuration Example

Queue groups are only applicable to subscribers for egress policed traffic. By default, subscriber egress policed traffic exits the port using a queue in the egress access policer-output-queues queue group instance. The queue used is determined by the FC mapping in the policer-output-queues queue group template. This is the same default operation as in the SAP example.

The subscriber policed traffic can be sent to a different queue group instance using the inter-dest-id and a host-match (described when applying an egress access queue group template to a port), which represent an intermediate destination, such as a downstream DSLAM or GPON OLT. The inter-dest-id can be associated with a subscriber host when it is created; this would usually be received from the DHCP, or RADIUS server, or Diameter Gx (Policy and Rule Charging Function), or the local user database, or configured under a static host.

An alternative to host matching on an inter-dest-id is to match on the top VLAN tag when a QinQ SAP is configured using a default inter-dest-id.

A default inter-dest-id can be configured in IES, VPRN, and VPLS services, and under an MSAP policy, as follows:

```
configure
    service
        {ies|vprn} <service-id>
            subscriber-interface <ip-int-name>
                group-interface <ip-int-name> [create]
                    sap <sap-id>
                        sub-sla-mgmt
                              def-inter-dest-id {<inter-dest-string>|use-top-q}
```

```
configure
```

```
    service
        vpls <service-id>
            sap <sap-id>
                sub-sla-mgmt
                    def-inter-dest-id {<inter-dest-string>|use-top-q}
```

```
configure
    subscriber-mgmt
        msap-policy <msap-policy-name> [create]
                sub-sla-mgmt
                    def-inter-dest-id {<inter-dest-string>|use-top-q}
```

The egress queue group template is configured as follows:

```
configure
    qos
        queue-group-templates
            egress
                queue-group "qg3" create
                    queue 1 best-effort create
                    exit
                    queue 2 expedite create
                    exit
                    fc af create
                        queue 1
                    exit
                    fc ef create
                        queue 2
                    exit
                exit
            exit
```

The egress template is applied to port 5/1/5 to create a port access queue group instance. A host match is configured under the created queue group instance on an egress access port. In the following, the host match dslam-1 is used:

```
configure
    port 5/1/5
        ethernet
            mode hybrid
            encap-type dot1q
            access
                egress
                    queue-group "qg3" instance 1 create
                        host-match dest "dslam-1" create
                    exit
                exit
```

A host-match can only be configured under instance 1 of a port access egress queue group; if its configuration is attempted on a different instance, the following error is displayed:

```
*A:PE-1# configure port 5/1/5 ethernet access egress queue-group "qg3" instance 3 create host-
match dest another-dslam create
MINOR: PMGR #1337 Host match entries only supported on port access egress queue groups with
 system default instance 1
*A:PE-1#
```

The subscriber host uses a SAP egress QoS policy in an egress SLA profile to map FCs to egress queue and policers. The SAP egress QoS policy is created with FC af using policer 1 and FC ef using policer 2, as follows:

```
configure
    qos
        sap-egress 30 create
            queue 1 create
            exit
            queue 2 create
            exit
            policer 1 create
            exit
            policer 2 create
            exit
            fc af create
                policer 1
            exit
            fc be create
                queue 1
            exit
            fc ef create
                policer 2
            exit
            fc l2 create
                queue 2
            exit
        exit
```

To redirect the subscriber egress policed traffic to the access egress queue group qg3 instance 1 on port 5/1/5, which is configured with the host-match, an inter-dest-id is configured for the created subscriber static host, as follows:

```
configure
    service
        vprn 3 customer 1 create
            route-distinguisher 65536:200
            subscriber-interface "sub-int-1" create
                address 10.3.2.1/24
                group-interface "group-int-1" create
                    arp-populate
                    sap 5/1/5:3 create
                        sub-sla-mgmt
                            def-sub-profile "basic-sub"
                            def-sla-profile "basic-sla"
                            multi-sub-sap 200
                            single-sub-parameters
                                profiled-traffic-only
                            exit
                            no shutdown
                        exit
                        static-host ip 10.3.2.2 mac 00:00:10:03:02:02 create
                            inter-dest-id "dslam-1"
                            sla-profile "basic-sla"
                            sub-profile "basic-sub"
                            subscriber "sub1"
                            no shutdown
                        exit
                    exit
```

The host match configured under the egress queue group instance is shown as follows:

```
A:PE-1# show port 5/1/5 queue-group "qg3" instance 1 access | match post-lines 3 Host-Matches
Host-Matches
-------------------------------------------------------------------------------
Dest: dslam-1
-------------------------------------------------------------------------------
```

When the subscriber host is created, the inter-dest-id for the subscriber host is shown as follows:

```
A:PE-1# show service active-subscribers subscriber "sub1" detail | match expression "Subscriber
 sub1 |Sub. Int Dest Id"
Subscriber sub1 (basic-sub)
Sub. Int Dest Id : "dslam-1"
```

The inter-dest-id dslam-1 is matched against the host-match destination configured on the access egress group instances on the port on which the host is being created. If a match is found, the subscriber egress policed traffic will use that egress queue group instance, with the actual queue used being selected by the FC-to-queue mapping in the related queue group template. Otherwise, the default policer-output-queues queue group instance will be used.

The egress queue group instance subscriber host associations are shown as follows:

```
A:PE-1# show port 5/1/5 queue-group egress "qg3" associations | match post-lines 6 Subscriber-
Host
Subscriber-Host Queue-Group Associations
-------------------------------------------------------------------------------
svc-id : 3 (VPRN)
 sap   : 5/1/5:3
 subscr: sub1
 ip    : 10.3.2.2
 mac   : 00:00:10:03:02:02  pppoe-sid: N/A
```

The following output shows that FC ef is using policer 2 and its traffic exits using queue 2 in queue group qg3, while FC af is using policer 1 and its traffic exits using queue 1 in queue group qg3.

```
A:PE-1# show qos policer subscriber "sub1" egress detail | match post-lines 4 "Policer Info"
Policer Info (Sub=1:1 3->5/1/5:3->2), Slot 5
===============================================================================
Policer Name       : Sub=1:1 3->5/1/5:3->2
Direction          : Egress             Fwding Plane       : 1
FC->[QGrp:Inst->]Q : ef->qg3->2
Policer Info (Sub=1:1 3->5/1/5:3->1), Slot 5
===============================================================================
Policer Name       : Sub=1:1 3->5/1/5:3->1
Direction          : Egress             Fwding Plane       : 1
FC->[QGrp:Inst->]Q : af->qg3->1
```

After traffic is sent through the subscriber, the egress policed traffic can be shown in the port egress access queue group instance, as follows:

```
A:PE-1# show port 5/1/5 queue-group "qg3" instance 1 access egress statistics

-------------------------------------------------------------------------------
Ethernet port 5/1/5 Access Egress queue-group
-------------------------------------------------------------------------------
                        Packets                Octets

Egress Queue: 1 Group: qg3 Instance: 1
```

```
In Profile forwarded  : 0                       0
In Profile dropped    : 0                       0
Out Profile forwarded : 1000                    128000
Out Profile dropped   : 0                       0
Egress Queue: 2 Group: qg3 Instance: 1
In Profile forwarded  : 0                       0
In Profile dropped    : 0                       0
Out Profile forwarded : 1000                    128000
Out Profile dropped   : 0                       0
-------------------------------------------------------------------------------
A:PE-1#
```

The traffic statistics are either counted in the subscriber queues or policers, or in the queue group instance queues, but not in both. However, summary statistics per SAP are available when using FP ingress queue groups.

The number of valid ingress packets received on a SAP, or subscribers on that SAP, can be shown in the sap-stats output, as follows. The received valid counter includes both the local SAP counters and the counters from the related FP ingress queue group instance. This is useful to display SAP-level traffic statistics when forwarding classes in a SAP ingress policy have been redirected to an ingress queue group.

```
*A:PE-1# show service id 3 sap 5/1/5:3 sap-stats | match post-lines 6 "Forwarding Engine Stats"
Forwarding Engine Stats
Dropped               : 0                       0
Received Valid        : 4000                    512000
Off. HiPrio           : 0                       0
Off. LowPrio          : 0                       0
Off. Uncolor          : 0                       0
Off. Managed          : 0                       0
```

Traffic forwarded through port egress access queue groups can be monitored, as follows:

```
monitor port queue-group <queue-group-name> egress <access> [instance <instance-id>] [egress-
queue <egress-queue-id>] [interval <seconds>] [repeat <repeat>] [absolute|rate]
```

The summary of the queue groups applied to a port is shown as follows:

```
A:PE-1# show port 5/1/5 queue-group summary

===============================================================================
Port queue-group summary
===============================================================================
Access-egress queue groups:
---------------------------
qg3
policer-output-queues
Total number of access-egress queue groups  : 2

Network-egress queue groups:
---------------------------
Total number of network-egress queue groups : 0

Access-ingress queue groups:
---------------------------
Total number of access-ingress queue groups : 0
===============================================================================
A:PE-1#
```

The total usage of queue groups is shown as follows:

```
A:PE-1# show qos queue-group summary

===============================================================================
Queue-group instances per card

card      port-acc-ing  port-acc-egr  port-nw-egr   fp-acc-ing    fp-nw-ing
-------------------------------------------------------------------------------
1         0             0             0             0             0
2         0             0             0             0             0
3         0             0             0             0             0
4         0             0             0             0             0
5         0             3             0             0             0
-------------------------------------------------------------------------------
Total ingress QG templates per system :  3
Total egress  QG templates per system :  5
===============================================================================
A:PE-1#
```

The preceding output includes the three system-created ingress templates, and the created egress template plus the four system-created egress templates (making five in total). There are three port access egress queue group instances (the applied queue group instance and two instances of the policer-output-queues queue group), one on each access port used for VPRN service interfaces.

Conclusion

This chapter described the use of queue groups as a mechanism to provide an aggregate QoS control for multiple SAPs and per-network interface QoS control. The configuration steps and commands are described, followed by example configurations on a SAP, network interface, and for egress policed traffic subscriber traffic.

High Scale QoS IOM: QoS, Service, and Network Configuration

This chapter provides information about High Scale QoS IOM: QoS, Service, and Network Configuration.

Topics in this chapter include:

Applicability

This chapter is applicable to the 7750 SR-7/12/12e platforms and describes the High Scale QoS (HSQ) IOM. The configuration was tested on Release 15.0.R5.

Overview

This chapter describes the QoS operation and configuration of the HSQ IOM, with a focus on services and network interfaces. For the subscriber management configuration, see chapters *High Scale QoS IOM in ESM Context: Single SLA Mode* and *High Scale QoS IOM in ESM Context: Expanded SLA Mode* in the Triple Play Service Delivery Architecture volume of *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Book III*.

The HSQ IOM is an FP3-based IOM that has a multicore CPU and accepts up to two MDA-e cards. The HSQ IOM supports an enhanced egress QoS architecture to provide scalable network, service, and subscriber QoS. At ingress, the HSQ IOM supports regular FP3 QoS with a high ingress policer scaling. This chapter focuses on the HSQ IOM egress QoS.

The HSQ IOM supports six scheduling classes across multiple hierarchical levels of hardware egress shaping with very stringent egress burst control. The scheduling allows a mix of strict priority and weighted round-robin (WRR). A flexible buffer pool structure permits both buffer isolation and buffer oversubscription for the queue buffer allocation.

The HSQ IOM supports 768k queues, which are grouped into 96k queue groups; each comprises eight queues (referred to as HSQ queue groups). HSQ queue groups are used for SAP egress queues, network egress queues, and both access and network egress queue group instance queues.

The SAP egress, network egress, and access and network egress queue group related commands that are not supported with an HSQ IOM are provided in the associated configuration chapters following. In addition, the following are not applicable to the HSQ:

- QoS related
  - Egress access and network MDA and port pools
  - All HSMDA commands
  - All VPORT related commands
  - PBB egress B-SAP per ISID shaping
  - Port **hybrid-buffer-allocation egr-weight**

- MPLS related
  - Generalized Multiprotocol Label Switching (GMPLS) UNI
- Service related
  - G.8031 protected Ethernet tunnels
- System related
  - Port cross-connects (PXC)
  - Ethernet satellite host ports
  - Soft reset

The operation of the HSQ IOM is described in the following sections:

- Shaping
- Scheduling
- Buffer Management
- LAGs

Shaping

The HSQ egress shaping uses the following objects:

- HSQ queue groups

  An HSQ queue group comprises eight egress queues with two WRR groups. One HS queue group is allocated to each of the following:

  - An egress SAP
  - An egress network port
  - An egress access queue group instance
  - An egress network queue group instance
  - A subscriber egress (single SLA profile instance in single HS SLA mode). Enhanced Subscriber Management (ESM) is beyond the scope of this chapter.
- Primary shapers

  In the context of this chapter, a primary shaper is allocated for each secondary shaper because it is required in the hierarchy, but it does not perform any QoS control. Primary shapers are also allocated for each subscriber egress configured with multiple SLA profile instances in extended HS SLA mode, however, ESM is beyond the scope of this chapter.
- Secondary shapers

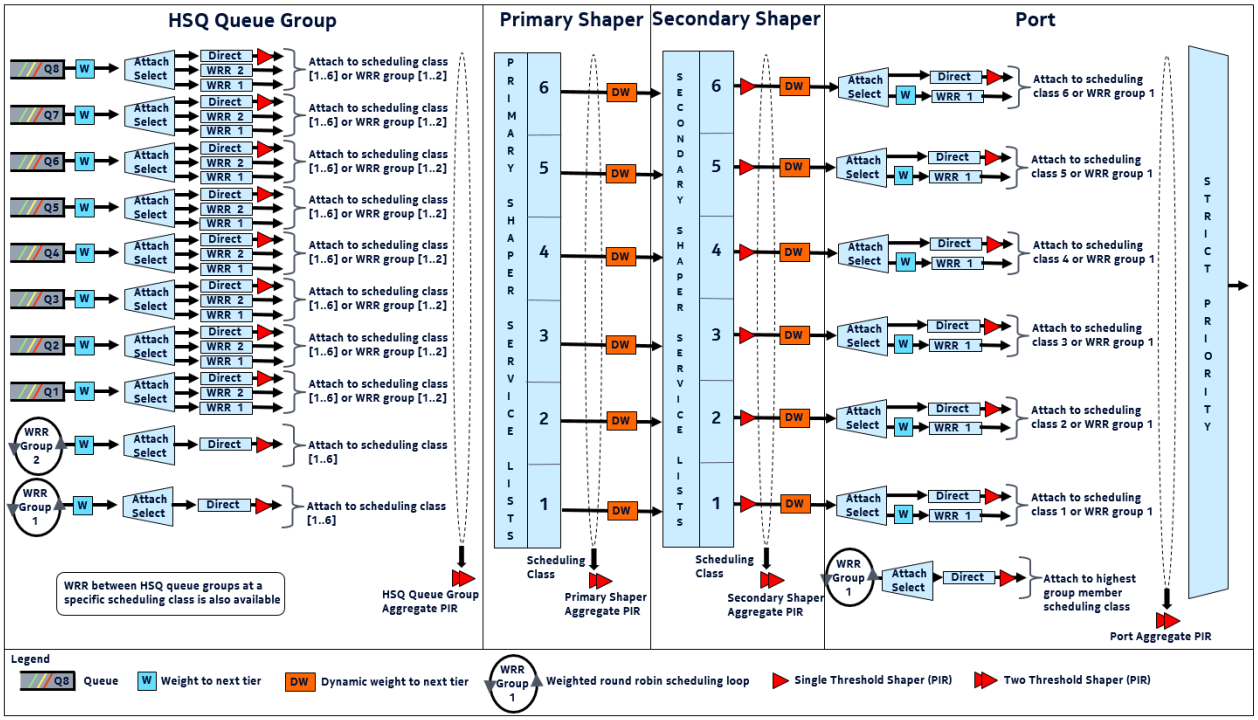
  Secondary shapers provide an abstraction to be used for QoS control of traffic to a downstream device such as an access node. Shaping can be performed on the entire traffic or on each scheduling class within the secondary shaper.
- Ports

  The traffic forwarded to each port can be shaped. In addition, traffic in each scheduling class within a port can be shaped individually or within a single WRR group.

Six scheduling classes are supported across all the preceding objects.

The egress QoS scheduling hierarchy is shown in Figure 432: Egress HSQ IOM Scheduling Hierarchy.

Figure 432: Egress HSQ IOM Scheduling Hierarchy



The available egress shaping is described in detail, as follows:

- Per-queue or per-WRR group of queues
- Per-HSQ queue group aggregate
- Per-primary shaper aggregate
- Per-secondary shaper aggregate
- Per-secondary shaper per scheduling class
- Per-port aggregate
- Per-port per scheduling class

Per-Queue or Per-WRR Group of Queues

Each queue can be independently shaped by configuring its PIR and attaching it to a primary shaper scheduling class. Alternatively, it can be shaped together with other queues in the same HSQ queue group as part of a WRR group. The WRR group can have a configured rate, and also needs to be attached to a primary shaper scheduling class.

There are eight queues and two WRR groups available within an HSQ queue group, which attach to the six primary shaper scheduling classes. Only one object (queue or WRR group) per HSQ queue group can attach to a scheduling class at any time, so to make use of all queues in an HSQ queue group, at least three queues must be attached to a WRR group. Queues and WRR groups can remain unattached from a scheduling class, in which case the related queues discard all received packets.

The queue PIR is configured under the queue within a SAP egress QoS policy for services, in a network queue policy for network interfaces, or in an egress queue group template for both access and network egress queue group instances. The queue CIR is ignored when the policy is applied to an HSQ IOM. The per-WRR group PIR is configured within the same policies under the **hs-wrr-group** context. Queue and WRR group PIR use packet-based accounting (L2 rate), which can be adjusted using the queue **packet-byte-offset** parameter for SAP egress and egress queue group instances.

The attachment of a queue or WRR group to a scheduling class is configured within an **hs-attachment-policy**. A default **hs-attachment-policy** (which is not configurable) is created by the system and is applied to all SAP egress QoS policies, network queue policies, and egress queue group templates. The default policy has queues 1 to 3 attached to WRR group 1, which is attached to scheduling class 1, and queues 4 to 8 attached directly to scheduling classes 2 to 6.

When creating a new **hs-attachment-policy**, the following rules apply to the queue and WRR attachment:

- A queue must be attached to a scheduling class, or a WRR group, which is also attached to a scheduling class, so as to forward packets.
- Only one queue or WRR group can be attached to a scheduling class per HSQ queue group.
- Queues can only be attached to scheduling classes in an ascending order; for example, if queue 2 is attached to scheduling class 2, then queue 1 cannot attach to scheduling classes 3 to 6.
- The queue identifiers must be contiguous when attaching queues to a WRR group.
- Queues attached to WRR group 1 must have lower queue identifiers than those attached to WRR group 2.
- The maximum number of queues attached to a WRR group is six: six to group 1 or six to group 2, or six to a combination of groups 1 and 2.
- WRR group 2 can only be attached to a scheduling class after WRR group 1 has at least one attached queue and has been attached to a scheduling class.
- WRR group 2 must be attached to a higher scheduling class than WRR group 1.

Per-HSQ Queue Group Aggregate

A per-HSQ queue group aggregate shapes traffic forwarded by all the queues in its associated HSQ queue group to an aggregate rate. This is applicable to SAP egress queues, and to both access and network egress queue group instances. It is not applicable to network egress queues.

The per-HSQ queue group aggregate PIR is configurable as an egress aggregate rate limit applied under a SAP or a port access or network egress queue group instance. The HSQ queue group PIR uses packet-based accounting (L2 rate), which can be adjusted using the queue **packet-byte-offset** parameter for SAP egress and egress queue group instances.

When using HSQ queue groups with access or network egress queue group instances on 100G ports, the **hs-turbo** parameter can be configured under the port queue group instance to allow the corresponding HSQ queue group queues to achieve a higher throughput. The **hs-turbo** parameter is not applicable to 10G ports and so is ignored when configured under a queue group instance on a 10G port.

Per-Primary Shaper Aggregate

A primary shaper aggregate shapes the traffic forwarded by all of the HSQ queue groups connected to the primary shaper to an aggregate rate.

User-configured primary shapers are not applicable to SAP egress HSQ queue groups, network egress HSQ queue groups, or both access and network egress queue group instance HSQ queue groups. However, the hierarchy shown in Figure 432: Egress HSQ IOM Scheduling Hierarchy is always conformed to, so by default these HSQ queue groups always connect to a system-created per-port default primary shaper that has its aggregate PIR rate set to the maximum rate, so as not to constrain the traffic rate at this level.

The system also instantiates a primary shaper, again with its aggregate PIR set to the maximum rate, when the first egress SAP or pseudowire SAP (PW-SAP) is associated with a secondary shaper. This primary shaper is then used by all HSQ queue groups associated with that secondary shaper. User-configured primary shaper aggregates are applicable to ESM, which is beyond the scope of this chapter.

Per-Secondary Shaper Aggregate

Secondary shapers are aimed at providing QoS control for traffic forwarded to a specific downstream device, such as an access node.

A secondary shaper aggregate shapes the traffic forwarded by all of its connected primary shapers (and HSQ queue groups). Secondary shapers are applicable to SAP egress queues, but not to network egress or to both access and network egress queue group instance HSQ queue groups. The hierarchy shown in Figure 432: Egress HSQ IOM Scheduling Hierarchy is always conformed to, so by default all primary shapers (and their HSQ queue groups) always connect to a system-created per-port default secondary shaper that has its aggregate PIR rate set to the maximum rate, so as not to constrain the traffic rate at this level. Secondary shaper aggregates are also applicable to ESM, which is beyond the scope of this chapter.

Multiple HS secondary shapers can be created under the **config>port>ethernet>egress** context using the **hs-secondary-shaper** statement. The HS secondary shaper aggregate PIR is configured under the associated secondary shaper. A default hs-secondary-shaper is applied under each HSQ egress port with an aggregate PIR rate **max**, which can be configured if required. The secondary shaper PIR uses frame-based accounting (L1 rate) and is not affected by a queue **packet-byte-offset** parameter.

SAP egress HSQ queue groups are connected to an HS secondary shaper using the **hs-secondary-shaper** parameter under a queue override, which is configured under the SAP egress context. When the first egress SAP or PW-SAP is associated with a user-configured HS secondary shaper, the system instantiates a default primary shaper for that secondary shaper.

Per-Secondary Shaper per Scheduling Class

Each of the six scheduling classes can be individually shaped within an HS secondary shaper. The HS secondary shaper scheduling class PIR is configured under the associated secondary shaper. The default HS secondary shaper scheduling class PIRs are set to **max** and can also be modified. The secondary shaper scheduling class PIR uses frame-based accounting (L1 rate) and is not affected by a queue **packet-byte-offset** parameter.

Per-Port Aggregate

A per-port aggregate shapes the traffic forwarded by its connected secondary shapers, that is, all the traffic egressing out of the physical port. It is applicable to SAP egress, network egress, and both access and network egress queue group instance traffic. A default HS scheduler policy (which is not configurable) is applied to all ports.

A user-defined HS scheduler policy can be created in which the port aggregate PIR (**max-rate**) can be configured and the policy then applied under the **config>port>ethernet>egress** context. Only a single HS scheduler policy is supported on each port. The port aggregate PIR uses frame-based accounting (L1 rate) and is not affected by a queue **packet-byte-offset** parameter.

An alternative to configuring a per-port aggregate is to configure an **egress-rate** on the port. This provides more granular control as it is configured in kb/s (whereas the per-port aggregate is in Mb/s). The HSQ **egress-rate** is based on the Ethernet size of the packet including the IFG (Inter-Frame-Gap) and preamble.

Per-Port per Scheduling Class

Each of the six scheduling classes can also be individually shaped per port by configuring a scheduling class PIR within an HS scheduler policy. The scheduling classes can also be grouped in a single WRR group at each egress port with each class being assigned a weight within the group.

The scheduling class identifiers must be contiguous within the WRR group and the group is scheduled at the scheduling class of its highest member scheduling class. Both the scheduling class PIR and the WRR group PIR are set to **max** in the default HS scheduler policy, with the WRR group being unused. The port scheduling class PIR uses frame-based accounting (L1 rate) and is not affected by a queue **packet-byte-offset** parameter.

Scheduling

The scheduling allows a mix of strict priority and WRR. There are six scheduling classes, which are implemented from the HSQ queue group queues through the primary shaper, secondary shaper, and port. The scheduling classes are serviced in a strict priority order (scheduling class 6 having the highest priority and scheduling class 1 having the lowest priority), with WRR groups at the HSQ queue group and port levels, and a dynamic weight at the primary and secondary shaper levels.

Packet forwarding is achieved using service lists; the objects at each level are on a service list at that level if they are in a state ready to send packets, or are off the service list if they have exceeded their configured PIR together with its related burst. When a port has a scheduling opportunity, it selects the secondary shaper to be serviced next, which selects the primary shaper to be serviced next, which selects the HSQ queue group to be serviced next, which selects a queue to be serviced next, resulting in a packet from that queue being forwarded.

At the HSQ queue group level, queues can be attached to one of two WRR groups, each of which is scheduled at a single scheduling class with packets being taken from the constituent queues based on a configured queue weighting. The weight is configured using the **hs-wrr-weight** under the **queue** statement within a SAP egress QoS policy, a network queue policy, or in an egress queue group template.

Weighting is also supported between queues and WRR groups in different HSQ queue groups per-primary shaper scheduling class. This allows the capacity available at the primary shaper scheduling class to be shared in a WRR manner between the HSQ queue group queues and WRR groups attached to that scheduling class. This is configured within a SAP egress QoS policy, network queue policy, and egress queue group template, using the **hs-class-weight** parameter under the respective **queue** or **hs-wrr-group** statement.

This weighting should not be confused with the **hs-wrr-weight** parameter, which specifies the relative weights of different queues within the same HSQ queue group WRR group. This **hs-class-weight** parameter could be used to give unequal shares of the available capacity to different types of service offerings.

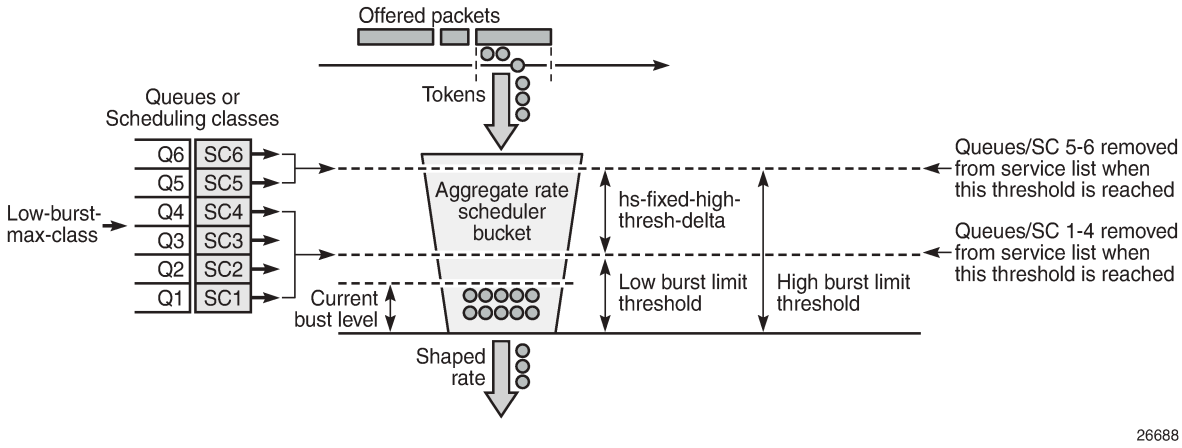
There is a single WRR group at the port level that allows multiple scheduling classes to be collapsed to a single class per port with each class in the group being assigned a weight. The weight of each scheduling class in the group is configured within the applied HS scheduler policy.

The dynamic weights at the primary and secondary shapers are managed by the system, based on the number of pending packets for each of the shapers, not on the number of attached objects in each. The more pending packets a shaper has, the higher the weight it gets. The goal is to ensure a balanced distribution of capacity between each of the primary shapers and each of the secondary shapers. For example, this allows a secondary shaper with 10 000 active HSQ queue groups to receive proportionately more scheduling opportunities than another secondary shaper with only 100 active HSQ queue groups.

The HSQ queue group and secondary shaper aggregate rates are implemented as a set of token buckets to control the aggregate rates. As packets are transmitted from each, the scheduler updates its bucket states based on the number of bytes forwarded. Two thresholds are used within each bucket to provide more granular control over this scheduling behavior: a low burst limit threshold and a high burst limit threshold.

These thresholds control when their respective queues are removed from the scheduler list, thereby allowing the queues using the high threshold to continue to forward packets even after the queues using the low threshold are no longer being serviced. This is shown in Figure 433: HSQ Queue Group and Secondary Shaper Aggregate Scheduler Bucket. The **low-burst-max-class** parameter defines which queues use each of the thresholds, and is described following.

Figure 433: HSQ Queue Group and Secondary Shaper Aggregate Scheduler Bucket



Tokens representing the bytes in the packets are added to the bucket as packets are forwarded. Tokens are drained from the scheduler bucket at the configured aggregate PIR rate. If the rate at which packets are forwarded (tokens are added) exceeds the shaping rate (tokens drained), a depth of tokens builds up in the bucket. If the depth reaches the low burst limit threshold, the queues using the low threshold are removed from the scheduling list. If the depth continues to increase and reaches the high threshold, the remaining queues are removed from the scheduler list.

The low burst threshold depth is determined by the system. It is equivalent to the burst control group visitation time used by the FP egress queue scheduler. The shaping rate tokens are periodically removed from the bucket by the system by decrementing the current burst size. This period must be small enough to ensure that the resulting decrement does not cause the bucket depth to be negative, which is not permitted. Because the bucket depth cannot be negative, any potential negative decrement is lost, which equates to a loss of scheduling opportunities and the queue would underrun.

The high burst limit threshold uses a fixed increment on top of the low burst limit threshold. This fixed increment is configured under **card>fp>egress** using the **hs-fixed-high-thresh-delta** parameter and has a default value of 4000 bytes. It is recommended to set this parameter to a value at least two times the maximum packet size to prevent the classes using the low burst threshold from affecting those using the high burst threshold when forwarding larger packets. An insufficient burst threshold delta defeats the intended purpose of mapping classes to the high burst threshold.

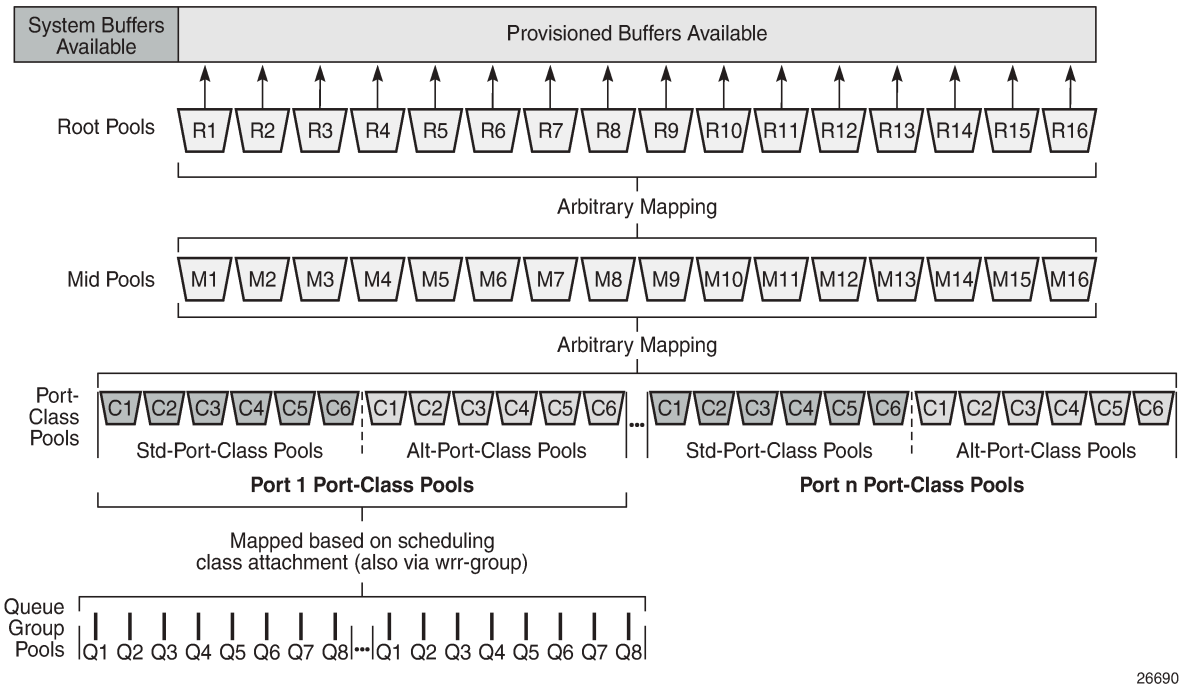
The **low-burst-max-class** parameter in the HS attachment policy (for the HSQ queue group aggregate rate) or under the secondary shaper configuration (for the secondary shaper aggregate rate) configures which queues use the low burst limit threshold and which use the high burst limit threshold. This parameter has a default max class of 6 in both contexts. As the name of the parameter implies, the specified class is the highest class that uses the low burst threshold; classes above the specified class use the high burst threshold.

Buffer Management

The HSQ supports a flexible buffer management configuration that allows both buffer isolation and buffer oversubscription for the queue buffer allocation. There are four levels to the buffer hierarchy, which are shown in Figure 434: HSQ Buffer Pool Hierarchy:

- Root pools
- Mid pools
- Port class pools
- Queue group queues

Figure 434: HSQ Buffer Pool Hierarchy



The total buffer allocation is divided into a system-reserved portion and a user-provisioned portion. The system buffers are allocated 5% of the total buffers in the default **hs-pool-policy**, which is applied to all HSQ IOMs under card>fp>egress. This value can be modified by creating a new **hs-pool-policy**, setting its **system-reserve** parameter, and applying the policy on an HSQ IOM. The user-provisioned portion is allocated the remainder of the available buffers, which can be configured as follows.

Root Pools

The root pools represent the total number of available buffers that can be provisioned. Up to 16 root pools can be configured, each having an allocation weight to determine its allocation of the available buffers. A root pool with an allocation weight of zero is not allocated any buffers. Root pools cannot oversubscribe the real buffers on the IOM. The use of multiple root pools provides buffer isolation between the queues using each root pool. At least one root pool (root pool 1) must be assigned buffers by having a non-zero allocation weight.

A high watermark is maintained for the buffer usage in each root pool. A slope policy is applied to each root pool to handle congestion control, the default being the *_tmnx_hs_default* slope policy. Root pools are configured per FP in an **hs-pool-policy** applied under **card>fp>egress**. Root pools 1 and 2 have an allocation weight of 75 and 25, respectively, in the default **hs-pool-policy**, with the remaining pools having a weight of 0.

Mid Pools

The mid pools are an abstract pool mapping mechanism. Each mid pool can be parented to a single parent root pool using its **parent-root-pool** parameter. Mid pools cannot be parented to a root pool without buffers and mid pools are unused if not parented to a root pool. Up to 16 mid pools are available and at least one mid pool must be parented to a root pool for its queues to buffer packets. The number of buffers in a mid pool is configured as a percentage of its parent root pool size using the **allocation-percent** parameter.

Mid pools can facilitate buffer isolation by being mapped to different root pools. Mapping multiple mid pools to the same root pool allows the buffers of that root pool to be shared by those child mid pools, and if the sum of the child mid pool allocation percent is greater than 100, then the root pool will be oversubscribed accordingly.

An oversubscription factor can also be applied to each mid pool (using the **port-bw-oversub-factor** parameter) to permit its child class pools to oversubscribe it. This does not change the size of the mid pool, but allows the mid pool size to be increased in the calculation of each of its child port class pools.

A high watermark is maintained for the buffer usage in each mid pool. A slope policy is applied to each mid pool to handle congestion control, the default being the *_tmnx_hs_default* slope policy. Mid pools are configured per FP egress in an **hs-pool-policy** applied under **card>fp>egress**. In the default **hs-pool-policy**, mid pools 1 to 4 are parented to root pool 1 with allocation percentages of 40, 35, 30, and 25; mid pools 5 and 6 are parented to root pool 2 with allocation percentages of 80 and 20; and mid pools 7 to 16 are not parented to any root pool. All mid pools have a **port-bw-oversub-factor** of 1.

Port Class Pools

Port class pools, as the name implies, are per-class pools that exist at the port level. There are two sets of port class pools per port: six standard port class pools and six alternative port class pools. The alternative set of port class pools enables additional flexibility for both buffer isolation and oversubscription

by providing a simple mechanism to parent queues to different port class pools and, therefore, to different mid and root pools.

HSQ queue group queues are statically assigned to the port class pool associated with the scheduling class that they have been attached to (via a WRR group, if used): scheduling class 1 to port class pool 1, up to scheduling class 6 to port class pool 6. Port class pools are configured in an **hs-port-pool-policy**, which is applied under **config>port>ethernet>egres**s. A default **hs-port-pool-policy** in which only the standard port class pools are used is applied to all HSQ ports.

Queues can be assigned to an alternative class pool (again based on the associated scheduling class) using the **hs-alt-port-class-pool** parameter under the queue in the SAP egress QoS policy, network queue policy, or egress queue group template.

Each port class pool parents to a single mid pool using its **parent-mid-pool** parameter. Port class pools are unused if not parented to a mid pool. Each port class pool must be parented to a mid pool that is parented to a root pool for queues to buffer packets. Port class pools can facilitate buffer isolation by being parented to different mid pools that are parented to different root pools. The standard port class pools are parented to their respective mid pool (port class pool 1 to mid pool 1, up to port class pool 6 to mid pool 6) in the default **hs-port-pool-policy**, with the alternative port class pools not parented to any mid pool.

The oversubscription of port class pools in a mid pool can be achieved by configuring the **port-bw-oversub-factor** under the parent mid pool (in the **hs-pool-policy**), which is multiplied by the size of the mid pool when calculating the size of each child class pool.

A weight is configurable per port to handle the allocation of buffers to different class pools parented to the same mid pool. This is configured using the **allocation port-bw-weight** under the class pool statement, where the weight configured for a port class pool is divided by the sum of the weights of the port class pools parented to the same mid pool, to determine the proportion of the allocated buffers for that port class pool. It is also possible to configure an **explicit-percent** for a port class pool, in which case that port class pool will be allocated the configured explicit percentage of the mid pool (without any mid pool **port-bw-oversub-factor** being applied).

If there are multiple port class pools parented to the same mid pool, their buffer allocation is determined using the weighting mechanism based on the port class pool **allocation port-bw-weight** parameter. Port class pools configured with an **explicit-percent** have a weight of zero (that is, they do not participate in the weighting buffer allocation). The port class pools in the default **hs-port-pool-policy** are configured with an **allocation port-bw-weight** of 1.

The port class pools are sized dynamically to provide a fair share of a mid pool size to each of its child port class pools, based on the potential bandwidth represented by each port on which the port class pools exist. The first step is to determine the usable bandwidth of each port. The mid pool buffers are then shared between its child port class pools, based on their related port usable bandwidth. An oversubscription factor is then applied to allow the port class pools to oversubscribe their mid pool. Finally, each port mid pool buffer allocation is shared between the child port class pools on that port.

No buffers are allocated to port class pools if there are no SAPs or network interfaces configured on that port and the port is shutdown. The details of the port class pool sizing calculation are as follows (examples of each are shown in the Buffer Pools configuration section):

1. Determine each port bandwidth value.
   a. This is the minimum of the port current line rate, the port **egress-rate** limit, and the **hs-scheduler-policy max-rate** configured on the port.
   b. The port bandwidth may be further modified by the port **modify-buffer-allocation-rate egr-percentage-of-rate** command, which can increase or decrease the port bandwidth by the specified percent. This allows the port to have a higher or lower bandwidth derived weight, based on how the port is being used, instead of bandwidth alone.

2. Determine each port portion of each mid pool.

   The port class pools are configured to map to the mid pools, so it is possible that not every port will have a port class pool associated with a mid pool. This requires that the system perform the relative bandwidth calculations separately per mid pool. A port without any port class pools associated with a mid pool will have a port portion of zero for that mid pool.

   Per mid pool, each port portion of the mid pool size is calculated based on:

   Port_Portion = (Port_Adj_Bw / Sigma_Mid_Pool_Ports_Adj_Bw) * Mid_Pool_Size

   Where:

   - *Port_Adj_Bw* is calculated in (1).
   - *Sigma_Mid_Pool_Ports_Adj_Bw* is the sum of the adjusted bandwidths for all ports, with port class pools mapped to the mid pool that are not sized configured with **explicit-percent** (see (4)).
   - *Mid_Pool_Size* is the mid pool parent root pool size multiplied by the mid pool allocation weight.

3. Modify the mid pool sizes by their **port-bw-oversub-factor**.

   The port bandwidth weighting mechanism allocates 100% of the mid pool size to the associated port class pools. To allow the port class pools to oversubscribe their parent mid pool, the mid pool **port-bw-oversub-factor** parameter can be used to increase the apparent size of the mid pool (this does not change the mid pool size) in the calculation in (2). This potentially provides a more efficient use of the mid pool available buffers since it is not expected that all port class pools will be using their allotted size simultaneously.

4. Determine each port class pool share of the mid pool port share.

   Multiple port class pools on the same port may be mapped to the same mid pool. This requires a mechanism to distribute the portion of the mid pool allocated to each port class pool on that port.

   Each port class pool **allocation port-bw-weight** parameter is used to determine how much of the port mid pool is given to each port class pool associated with the mid pool. A port class pool is allocated the portion of its mid pool size multiplied by its port class pool **port-bw-weight** divided by the sum of the **port-bw-weight** for all port class pools associated with that mid pool on that port.

   Alternatively, port class pools can be sized using an **explicit-percent** of the actual mid pool size (without applying the **port-bw-oversub-factor**). These class pools are assigned a **port-bw-weight** equal to zero, causing them to be excluded from the port portion distribution. It is expected (but not required) that either port bandwidth-based sizing or explicit percent-based sizing will be used, with concurrent use of both mechanisms being transitory in nature.

Whenever one of the inputs to the preceding calculations changes, the bandwidth weighted sizes for the corresponding pool class pools are recalculated.

A high watermark is maintained for the buffer usage in each port class pool. A slope policy is applied to each port class pool to handle congestion control, the default being the *_tmnx_hs_default* slope policy.

Queue Group Queues

HSQ queue group queues always operate in WRED per queue mode, supporting three WRED slopes. The total number of buffers usable by the queue is limited by the queue MBS configuration, and each packet profile type (exceed, out, in) is limited by the respective slope configuration (exceed, low, high) in the applied slope policy, if the slope is not shutdown. For a buffer to be allocated, the applicable WRED

slope processing (if enabled) must accept the packet, the MBS must not be exceeded, and there must be available buffers in its parent port class pool, mid pool, and root pool.

The regular **mbs** queue parameter configuration is used within SAP egress QoS policies and egress queue group templates, using the regular defaults. In the network queue policy, the MBS is configured using the **hs-mbs** parameter, which allows a different default to be used, with its value calculated based on a percentage of one second of the queue PIR converted to bytes (the regular **mbs** parameter is ignored in the network queue policy). The queue CBS and drop tail configuration is ignored on an HSQ queue group queue.

A default slope (named *_tmnx_hs_default*) is applied to each HSQ queue, using the **policy** parameter on the **hs-wred-queue** statement within a SAP egress QoS policy, network queue policy, and egress queue group template. A user-configured regular slope policy can be applied using the same parameter and statement. The **highplus-slope** and **time-average-factor** in the applied slope policy are ignored on HSQ queue group queues.

LAGs

LAGs are supported on HSQ ports. The LAG **port-type** must be set to **hs** to add an HSQ port to a LAG, at which point only HSQ ports can be added to that LAG. When an HSQ queue group is created on a LAG, an HSQ queue group is allocated on each LAG port.

LAG **access adapt-qos** modes **link** and **port-fair** are supported; **distribute** mode is not supported.

LAG **access per-fp-egr-queuing** is supported and, when configured, either **per-link-hash** or **per-service-hashing** (supported service types only) must be enabled under the **LAG access**. LAG **access per-fp-sap-instance** is supported (this requires **per-fp-egr-queuing** to be enabled).

The full configured queue MBS is applied to all the related HSQ queue group queues on the individual LAG ports.

Configuration

This section describes simple configurations using an HSQ IOM for SAP egress, network egress, and access and network egress queue group instances.

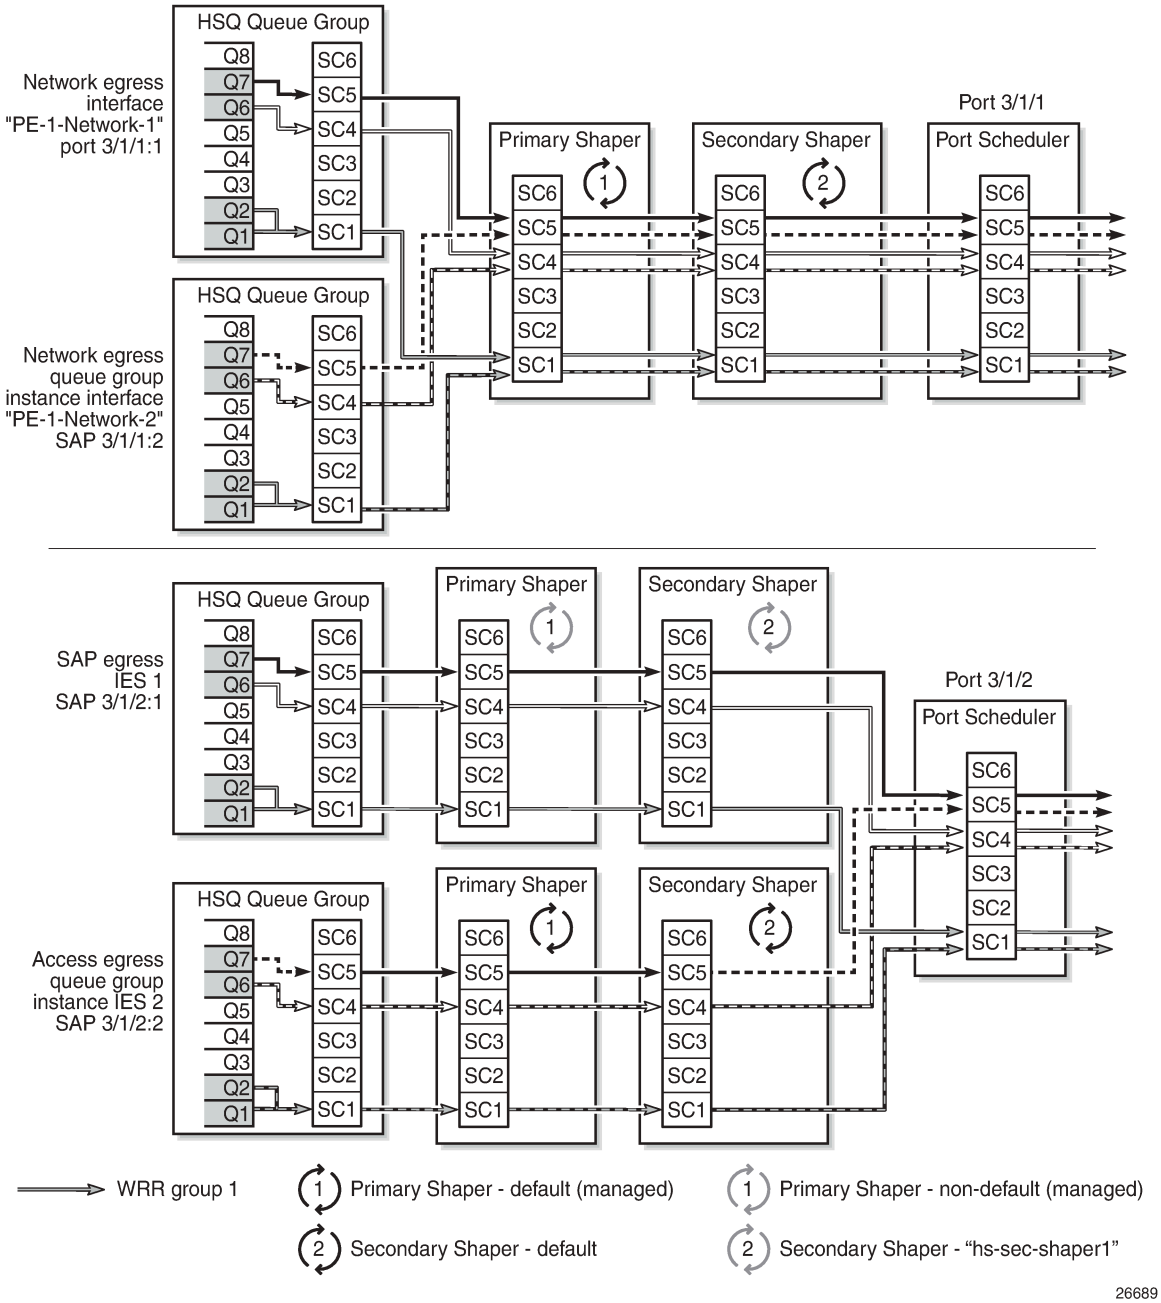
Each configuration uses the same four queues:

- Queue 7 at scheduling class 5
- Queue 6 at scheduling class 4
- Queues 1 and 2 in WRR group 1 using scheduling class 1, with queue 1 having a weight of 2 and queue 2 having a weight of 1

Scheduling class 6 has been reserved for queue 8 to be used for network protocol traffic. Queue 3 is unattached, but could at some point be added to WRR group 1. The configuration provides the future flexibility to either add queues 4 and 5 to WRR group 1, to WRR group 2, or attach them to scheduling classes 2 and 3. Although eight queues are always allocated in an HSQ queue group, only the queues to be used need to be configured.

The QoS path for the configured SAP, network interface, and access and network queue group instances with respect to their HSQ queue group, primary shaper, secondary shaper, and port scheduler, is shown in Figure 435: Configured QoS Paths.

Figure 435: Configured QoS Paths



The configurations start with the generic aspects:

- Card configuration
- Buffer pools
- Shaping and scheduling
  - HSQ queue groups

  - HS secondary shapers
    - These are specific to SAP egress in the context of this chapter; however, as secondary shapers can also be used by subscribers, they are included with the generic aspects.
  - Ports

This is followed by the specific configuration related to:

- SAP egress
- Network egress
- Access and network egress queue groups

Card Configuration

An HSQ IOM is configured with the card type *iom4-e-hs* and the associated supported MDAs:

```
A:PE-1# configure card 3
A:PE-1>config>card# info
----------------------------------------------
        card-type iom4-e-hs
        mda 1
            mda-type me10-10gb-sfp+
            no shutdown
        exit
        no shutdown
----------------------------------------------
A:PE-1>config>card# exit all
A:PE-1# show card

===============================================================================
Card Summary
===============================================================================
Slot      Provisioned Type                        Admin Operational   Comments
              Equipped Type (if different)        State State
-------------------------------------------------------------------------------
2         imm-2pac-fp3                            up    up
3         iom4-e-hs                               up    up
A         cpm5                                    up    up/active
B         cpm5                                    up    up/standby
===============================================================================
A:PE-1#
```

The supported MDA types are displayed by entering a "?" after the **mda-type** parameter:

```
A:PE-1# configure card 3 mda 1 mda-type
  - mda-type <mda-type>
  - no mda-type

 <mda-type>           : me1-100gb-cfp2|me10-10gb-sfp+|me12-10/1gb-sfp+|me2-100gb-cfp4|me2-
100gb-qsfp28|me40-1gb-csfp|me6-10gb-sfp+
```

The **hs-fixed-high-thresh-delta** on card 3 fp 1 is *default*, resulting in the high burst limit threshold (which is used by queues and WRR groups attached to scheduling classes above the **low-burst-max-class**) being 4000 bytes larger than the low burst limit threshold:

```
*A:PE-1# show card 3 detail | match "HS Fixed High Threshold Delta"
    HS Fixed High Threshold Delta : default
```

```
*A:PE-1#
```

The HSQ-specific resource usage is displayed as follows:

```
*A:PE-1# tools dump resource-usage card 3 fp 1

===============================================================================
Resource Usage Information for Card Slot #3 FP #1

                        Egress HS Queue Group |      98240         36      98204
                           HS Primary Shapers +      16384         22      16362
                  HS Explicit Primary Shapers -                    0
                   HS Managed Primary Shapers -                   22
                         HS Secondary Shapers |       4096         22       4074
===============================================================================
*A:PE-1#
```

The preceding output displays the usage information of the egress queues, the ingress policers and their statistics, the HS turbo queue groups, HS queue groups, HS primary shapers (the managed primary shapers are system-created, whereas the explicit primary shapers are used for ESM), and the HS secondary shapers.

The following card commands are ignored on HSQ IOMs:

- All regular **pool** commands
- **ingress-buffer-allocation**
- **reset-on-recoverable-error**
- **virtual-scheduler-adjustment** (egress only)

The following card commands are not configurable on HSQ IOMs:

- **named-pool-mode**
- **stable-pool-sizing**
- **egress wred-queue-control**

Buffer Pools

The buffer pool configuration used in this example provides buffer isolation between traffic in queue 7, queue 6, and WRR group 1, by assigning each to a different root and mid pool. The combined queue 1 and 2 traffic share a root and mid pool.

Root and Mid Pools

The HSQ root and mid pools for an IOM are configured in an HS pool policy, which is applied under **card>fp>egress**.

An HS pool policy is configured as follows:

```
configure
    qos
        hs-pool-policy <policy-name> [create]
            description <description-string>
            mid-tier
                mid-pool <mid-pool-id>
                    allocation-percent <percent-of-parent-pool>
                    parent-root-pool <root-pool-id>
                    port-bw-oversub-factor <oversubscription-factor>
                    slope-policy <policy-name>
            root-tier
                root-pool <root-pool-id>
                    allocation-weight <pool-weight>
                    slope-policy <policy-name>
            system-reserve <percent-of-buffers>
```

Where (in order):

```
<policy-name>        : [32 chars max]
<description-string> : [80 chars max]
<mid-pool-id>        : [1..16]
<percent-of-parent*> : [0.01..100.00]

<policy-name>        : [32 chars max]
<percent-of-buffers> : [1.00..30.00]
```

A default HS pool policy is created by the system with the following configuration:

hs-pool-policy default							
System reserve: 5%							
Root pools			**Mid pools**				
Root Pool ID	**Allocation weight**	**Slope policy**	**Mid Pool ID**	**Parent mid pool**	**Allocation %**	**Port BW oversub factor**	**Slope policy**
1	75	_tmnx_hs_default	1	1	40%	1	_tmnx_hs_default
2	25	_tmnx_hs_default	2	1	35%	1	_tmnx_hs_default
3-16	0		3	1	30%	1	_tmnx_hs_default
			4	1	25%	1	_tmnx_hs_default
			5	2	80%	1	_tmnx_hs_default
			6	2	20%	1	_tmnx_hs_default
			7-16	None			

If a new HS pool policy is created, its initial configuration is as follows:

hs-pool-policy <new>							
System reserve: 5%							
Root pools			Mid pools				
Root Pool ID	Allocation weight	Slope policy	Mid Pool ID	Parent mid pool	Allocation %	Port BW oversub factor	Slope policy
1	100	_tmnx_hs_default	1-16	1	1%	1	_tmnx_hs_default
2-16							

The HS pool policy (*hs-pool-pol-1*) used for this example is shown following. Root pool 1 and mid pool 1 have been reserved for network protocol traffic and are not used. Root pool 2 and mid pool 2 are used for queue 7 traffic, root pool 3 and mid pool 3 are used for queue 6 traffic, and root pool 4 and mid pool 4 are used for queue 1 and queue 2 (WRR group 1) traffic. The buffer allocation for each pool is based on the expected traffic volumes.

Root pool 4 and mid pool 4 have a more aggressive slope policy (*hs-slope-1*) than the default HSQ slope policy (*_tmnx_hs_default*). The default HSQ slope policy is as follows (the HSQ slopes use the instantaneous queue depth so the **time-average-factor** is ignored and the **highplus-slope** is also ignored):

```
*A:PE-1>config>qos# slope-policy "_tmnx_hs_default"
*A:PE-1>config>qos>slope-policy# info detail
----------------------------------------------
            description "Default HS slope policy."
            highplus-slope
                shutdown
                start-avg 100
                max-avg 100
                max-prob 100
            exit
            high-slope
                start-avg 100
                max-avg 100
                max-prob 100
                no shutdown
            exit
            low-slope
                start-avg 90
                max-avg 90
                max-prob 100
                no shutdown
            exit
            exceed-slope
                start-avg 80
                max-avg 80
                max-prob 100
                no shutdown
            exit
            time-average-factor 7
```

The slope policy *hs-slope-1* is configured as follows:

```
A:PE-1>config>qos# slope-policy "hs-slope-1"
```

```
A:PE-1>config>qos>slope-policy# info
----------------------------------------------
            highplus-slope
                shutdown
            exit
            high-slope
                start-avg 85
                max-avg 100
                no shutdown
            exit
            low-slope
                no shutdown
            exit
            exceed-slope
                shutdown
            exit
```

Mid pool 4 has been configured to allow a 4 times oversubscription by its child class pools.

Root pools 5 to 16 and mid pools 5 to 16 are unused.

HS pool policy *hs-pool-pol-1* is summarized as follows:

hs-pool-policy hs-pool-pol-1							
System reserve: 5%							
Root pools			**Mid pools**				
Root Pool ID	**Allocation weight**	**Slope policy**	**Mid Pool ID**	**Parent mid pool**	**Allocation %**	**Port BW oversub factor**	**Slope policy**
1	5	_tmnx_hs_default	1	1	100%	1	_tmnx_hs_default
2	10	_tmnx_hs_default	2	2	100%	1	_tmnx_hs_default
3	20	_tmnx_hs_default	3	3	100%	1	_tmnx_hs_default
4	65	hs-slope-1	4	4	100%	4	hs-slope-1
5-16	0	_	5-16	None			

The HS pool policy hs-pool-pol-1 is configured as follows:

```
A:PE-1>config>qos>hs-pool-policy# info
----------------------------------------------
            root-tier
                root-pool 1
                    allocation-weight 5
                exit
                root-pool 2
                    allocation-weight 10
                exit
                root-pool 3
                    allocation-weight 20
                exit
                root-pool 4
                    allocation-weight 65
                    slope-policy "hs-slope-1"
                exit
            exit
```

```
            mid-tier
                mid-pool 1
                    allocation-percent 100.00
                exit
                mid-pool 2
                    parent-root-pool 2
                    allocation-percent 100.00
                exit
                mid-pool 3
                    parent-root-pool 3
                    allocation-percent 100.00
                exit
                mid-pool 4
                    parent-root-pool 4

Port Class Pools

The HSQ port class pools for a port are configured in an HS port pool policy, which is applied under **config>port>ethernet>egress**.

An HS port pool policy is configured as follows:

```
configure
    qos
        hs-port-pool-policy <policy-name> [create]
            description <description-string>
            std-port-class-pools
                class-pool <std-class-pool-id>
                    allocation explicit-percent <percent-of-parent-pool>
                    allocation port-bw-weight <pool-weight>
                    parent-mid-pool <mid-pool-id>
                    slope-policy <policy-name>
            alt-port-class-pools
                class-pool <alt-class-pool-id>
                    allocation explicit-percent <percent-of-parent-pool>
                    allocation port-bw-weight <pool-weight>
                    parent-mid-pool <mid-pool-id>
                    slope-policy <policy-name>
```

Where (in order):

```
<policy-name>        : [32 chars max]
<description-string> : [80 chars max]
<std-class-pool-id>  : [1..6]
<percent-of-parent*> : [0.01..100.00]
<pool-weight>        : [1..100]
<mid-pool-id>        : [1..16 | none]
<policy-name>        : [32 chars max]
<alt-class-pool-id>  : [1..6]
<percent-of-parent*> : [0.01..100.00]
<pool-weight>        : [1..100]
<mid-pool-id>        : [1..16 | none]
<policy-name>        : [32 chars max]
```

A default HS pool policy is created by the system with the following configuration:

hs-port-pool-policy default							
Standard port class pools				**Alternative port class pools**			
Class Pool ID	**Parent mid pool**	**Allocatior port bw weight**	**Slope policy**	**Class Pool ID**	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**
1	1	1	_tmnx_hs_default	1-6	None		
2	2	1	_tmnx_hs_default				
3	3	1	_tmnx_hs_default				
4	4	1	_tmnx_hs_default				
5	5	1	_tmnx_hs_default				
6	6	1	_tmnx_hs_default				

Newly created HS port pool policies have the following parameters:

hs-port-pool-policy <new>							
Standard port class pools				**Alternative port class pools**			
Class Pool ID	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**	**Class Pool ID**	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**
1-6	1	1	_tmnx_hs_default	1-6	None		

The HS port pool policy used for traffic in this example is shown following. Only port class pools 1, 4, 5, and 6 are used, which are parented to mid pools 4, 3, 2, and 1, respectively. As scheduling classes 2 and 3 are unused, their associated standard port class pools are not parented to a mid pool. The alternative port class pools are also unused, so are not parented to a mid pool. Standard port class pools 4 to 6 use the default HSQ slope policy with standard port class pool 1 using slope policy *hs-slope-1*.

hs-port-pool-policy hs-port-pool-pol-1							
Standard port class pools				**Alternative port class pools**			
Class Pool ID	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**	**Class Pool ID**	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**
1	4	1	hs-slope-1	1-6	None		
2-3	None						
4	3	1	_tmnx_hs_default				
5	2	1	_tmnx_hs_default				
6	1	1	_tmnx_hs_default				

The HS port pool policy is configured as follows:

```
*A:PE-1>config>qos# hs-port-pool-policy "hs-port-pool-pol-1"
*A:PE-1>config>qos>hs-port-pool-policy# info
----------------------------------------------
            std-port-class-pools
                class-pool 1
                    parent-mid-pool 4
                    slope-policy "hs-slope-1"
                exit
                class-pool 2
                    parent-mid-pool none
                exit
                class-pool 3
                    parent-mid-pool none
                exit
                class-pool 4
                    parent-mid-pool 3
                exit
                class-pool 5
                    parent-mid-pool 2
                exit
            exit
```

The HS port pool policy is shown as follows:

```
*A:PE-1# show qos hs-port-pool-policy "hs-port-pool-pol-1"

-------------------------------------------------------------------------------
3/1/1
3/1/2
-------------------------------------------------------------------------------
===============================================================================
*A:PE-1#
```

The remaining ports (3/1/[3..10]) are unused in this example, so their port class pools are not parented, by applying the following HS port pool policy to each:

hs-port-pool-policy no-class-pools						
Standard port class pools				**Alternative port class pools**		
Class Pool ID	**Parent mid pool**	**Allocation port bw weight**	**Slope policy**	**Class Pool ID**	**Parent mid pool**	**Allocatior Slope policy port bw weight**
1-6	None			1-6	None	

```
*A:PE-1>config>qos# hs-port-pool-policy "no-class-pools"
*A:PE-1>config>qos>hs-port-pool-policy# info
----------------------------------------------
            std-port-class-pools
                class-pool 1
                    parent-mid-pool none
                exit
                class-pool 2
                    parent-mid-pool none
                exit
                class-pool 3
                    parent-mid-pool none
                exit
                class-pool 4
                    parent-mid-pool none
                exit
                class-pool 5
                    parent-mid-pool none
                exit
                class-pool 6
                    parent-mid-pool none
                exit
```

```
            exit
```

The HS port pool policies applied to the ports on card 3 are configured as follows:

```
configure
    port 3/1/1
        ethernet
            egress
                hs-port-pool-policy "hs-port-pool-pol-1"
    port 3/1/2
        ethernet
            egress
                hs-port-pool-policy "hs-port-pool-pol-1"
    port 3/1/[3..10]
        ethernet
            egress
                hs-port-pool-policy "no-class-pools"
```

The pools created on port 3/1/1, after applying the preceding HS pool policy and HS port pool policies, are shown following. The root and mid pools in this output are the same as in the **show hs-pools 3 fp 1 egress** output; these pools are configured per FP so are the same for all ports. The additional information shows the details of the port class pools on this port and to which mid pools they are parented:

```
*A:PE-1# show hs-pools port 3/1/1 egress

|     |      Excd-Slope Drop Prob: 0
|     |      Hs Slope Policy     : hs-slope-1
|     |
```

Note:
The maximum size of a port class pool is capped here at 4194302 kbytes, as shown for the port class pool parented to mid/root pool 4.

The following show commands are available to display the pool configuration and queue details:

```
show hs-pools port <port-id> egress
show hs-pools port <port-id> egress network-queues
show hs-pools port <port-id> egress queue-group <queue-group-name>
                             [instance <instance-id>]
show hs-pools port <port-id> egress sap <sap-id>
show hs-pools port <port-id> egress subscriber <sub-ident-string>
```

The root and mid pool information in each command is the same as in the command **show hs-pools <card-slot-number> fp <forwarding-plane> egress** but the commands also show the port class pool information on the specified port, together with the queue information for that port.

Pool Sizing and Oversubscription

The logic to size the root, mid, and port class pools is described in the Buffer Management section.

Root pools are sized using their **allocation-weight** parameter, which is divided by the sum of all root pool **allocation-weight** to give the portion of the total user-provisioned buffers allocated to the root pool.

The mid pools are sized using their **allocation-percent** parameter, which is a percentage of their parent root pool size.

The port class pools size calculation has more factors. The following output shows the effect of the different sizing parameters on the port class pools size. The steps are:

- An HS pool policy and HS port pool policies are applied to an HSQ IOM and its ports to configure one root pool with one child mid pool that has one child standard port class pool on port 3/1/1. Each pool has the same size matching the total available buffers:

```
*A:PE-1# show hs-pools port 3/1/1 egress |
             match "Root Pool : 1" post-lines 26 | match "Pool" post-lines 1
Root Pool : 1
|  Total               : 3978866 KB  Allocated         : 0 KB
|--- Mid Pool : 1
|     | Total               : 3978866 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 3978866 KB  Allocated         : 0 KB
```

- A standard port class pool is added to port 3/1/2, causing the mid pool size to be shared between port class pool 1 on port 3/1/1 and 3/1/2:

```
*A:PE-1# configure port 3/1/2 ethernet egress
                              hs-port-pool-policy "hs-port-pool-policy-test"
*A:PE-1# show hs-pools port 3/1/1 egress |
             match "Root Pool : 1" post-lines 26 | match "Pool" post-lines 1
Root Pool : 1
|  Total               : 3978866 KB  Allocated         : 0 KB
|--- Mid Pool : 1
|     | Total               : 3978866 KB  Allocated         : 0 KB

                              no egr-percentage-of-rate
```

- Standard port class pool 2 is parented to the mid pool with a **port-bw-weight** set to 2. The **port-bw-weight** of port class pool 1 is the default of 1. This causes this port mid pool size to be shared in a 1:2 ratio between port class pool 1 and 2 on both ports 3/1/1 and 3/1/2 (only port 3/1/1 is shown). The total port class pool size is shown in the second step preceding, that is, 1989432 kbytes.

```
*A:PE-1# configure qos hs-port-pool-policy "hs-port-pool-policy-test"
```

```
*A:PE-1>config>qos>hs-port-pool-policy# std-port-class-pools
                                            class-pool 2 parent-mid-pool 1
*A:PE-1>config>qos>hs-port-pool-policy# std-port-class-pools
                                  class-pool 2 allocation port-bw-weight 2
*A:PE-1>config>qos>hs-port-pool-policy# exit all
*A:PE-1# show hs-pools port 3/1/1 egress |

|     |      Total               : 1326288 KB  Allocated         : 0 KB
```

- "The two port class pools 1 and 2 on port 3/1/1 are modified to use an **explicit-percent** of 40% and 60%, respectively:

```
*A:PE-1# configure qos hs-port-pool-policy "hs-port-pool-policy-test"
*A:PE-1>config>qos>hs-port-pool-policy# std-port-class-pools
                                 class-pool 1 allocation explicit-percent 40
*A:PE-1>config>qos>hs-port-pool-policy# std-port-class-pools
                                 class-pool 2 allocation explicit-percent 60
*A:PE-1>config>qos>hs-port-pool-policy# exit all
*A:PE-1# show hs-pools port 3/1/1 egress |
             match "Root Pool : 1" post-lines 47 | match "Pool" post-lines 1
Root Pool : 1
|  Total               : 3978866 KB  Allocated         : 0 KB
|--- Mid Pool : 1
|     | Total               : 3978866 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 1591546 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 2
|     |      Total               : 2387318 KB  Allocated         : 0 KB
```

To assist with sizing the buffer pools, each pool has a high watermark, which can be displayed using the **show hs-pools** command and cleared using the following commands:

```
clear card <slot-number> fp <[1..2]> hs-pool high-water-mark
clear card <slot-number> fp <[1..2]> hs-pool high-water-mark mid-pool <[1..16]>
clear card <slot-number> fp <[1..2]> hs-pool high-water-mark root-pool <[1..16]>
clear card <slot-number> fp <[1..2]> hs-pool high-water-mark system
clear port <port-id> hs-pool high-water-mark
                                   { [standard <1..6>] | [alternate <1..6>] }
```

The HSQ ingress and non-HSQ egress line cards support a **stable-pool-sizing** command under **card>fp**, which avoids pool sizes changing when MDAs and ports are configured.

An equivalent effect can be achieved at the egress of an HSQ by creating two sets of root pools and two sets of mid pools in the **hs-pool-policy** applied to the IOM under **card>fp>egress**. The first set of mid pools parent to the first set of root pools and the second set of mid pools parent to the second set of root pools. Then create two hs-port-pool-policies: one applied to the ports on the first MDA with its port class pools parented to the first set of mid pools and the other applied to the ports on the second MDA with its port class pools parented to the second set of mid pools. This provides deterministic pool sizing independent of MDAs being inserted or removed.

Further control at the port class level can be obtained by using port class pool **explicit-percent** based sizing to eliminate the effect of changing port states, including bandwidth changes.

The root pools cannot oversubscribe the user-provisioned buffers, but the mid pools can oversubscribe their root pool and the port class pools can oversubscribe their mid pool.

The following configuration and output shows the oversubscription possibilities.

The default HS pool policy is applied to the HSQ IOM, so root pools 1 and 2 are allocated 75% and 25% of the user-provisioned buffers:

```
*A:PE-1>config>qos>hs-pool-policy# info detail |
                      match expression " root-pool 1$| root-pool 2$" post-lines 1
                root-pool 1
                    allocation-weight 75
                root-pool 2
                    allocation-weight 25

*A:PE-1# show hs-pools 3 fp 1 egress | match "Root Pool" post-lines 1
Root Pool : 1
|  Total               : 2984148 KB  Allocated         : 0 KB
Root Pool : 2
|  Total               : 994716 KB   Allocated         : 0 KB
```

If a new HS pool policy is applied to this IOM, only one root pool is allocated buffers with an allocation weight of 100:

```
*A:PE-1>config>qos>hs-pool-policy$ info detail |
                      match expression " root-pool 1$" post-lines 1
                root-pool 1
                    allocation-weight 100

*A:PE-1# show hs-pools port 3/1/1 egress | match "Root Pool : 1" post-lines 1
Root Pool : 1
|  Total               : 3978866 KB  Allocated         : 0 KB
```

Root pool 16 is configured with the same allocation weight of 100, causing the two root pools to share the available user-provisioned buffers:

```
*A:PE-1>config>qos>hs-pool-policy# info detail |
                      match expression " root-pool 1$| root-pool 16$" post-lines 1
                root-pool 1
                    allocation-weight 100
                root-pool 16
                    allocation-weight 100

*A:PE-1# show hs-pools port 3/1/1 egress | match "Root Pool : 1" post-lines 1
Root Pool : 1
|  Total               : 1989432 KB  Allocated         : 0 KB
Root Pool : 16
|  Total               : 1989432 KB  Allocated         : 0 KB
```

Mid pool 16 is parented to root pool 16 with an allocation percent of 100, so it has the same number of allocated buffers as root pool 16:

```
*A:PE-1>config>qos>hs-pool-policy# info detail |
      match expression " root-pool 16$| mid-pool 16$" post-lines 2 |
      match invert-match slope
                root-pool 16
                    allocation-weight 100
                mid-pool 16
                    parent-root-pool 16
                    allocation-percent 100.00
```

```
*A:PE-1# show hs-pools port 3/1/1 egress |
              match "Root Pool : 16" post-lines 19 | match "Pool" post-lines 1
Root Pool : 16
|  Total              : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
```

Mid pool 15 is also parented to root pool 16 with an allocation percent of 100, causing both mid pools 15 and 16 to have the same number of allocated buffers as root pool 16; therefore, the root pool is oversubscribed two times:

```
*A:PE-1>config>qos>hs-pool-policy# info detail |
     match expression " root-pool 16$| mid-pool 15$| mid-pool 16$" post lines 2 |
     match invert-match slope
                root-pool 16
                    allocation-weight 100
                mid-pool 15
                    parent-root-pool 16
                    allocation-percent 100.00
                mid-pool 16
                    parent-root-pool 16
                    allocation-percent 100.00

*A:PE-1# show hs-pools port 3/1/1 egress |
              match "Root Pool : 16" post-lines 19 |
              match "Pool" post-lines 1
Root Pool : 16
|  Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 15
|     | Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
```

An HS port pool policy is applied to port 3/1/1 with standard port class pool 1 parented to mid pool 16 with an **allocation port-bw-weight** of 1. This port class pool has the same number of allocated buffers as mid pool 16:

```
*A:PE-1>config>qos>hs-port-pool-policy>std-port-class-pools# info
----------------------------------------------
                class-pool 1
                    parent-mid-pool 16
                exit

*A:PE-1# show hs-pools port 3/1/1 egress |
                match "Root Pool : 16" post-lines 26 | match "Pool" post-lines 1
Root Pool : 16
|  Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 15
|     | Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 1989432 KB  Allocated         : 0 KB
```

The **port-bw-oversub-factor** is set to 2 for mid pool 16 in the HS pool policy, after which the size of mid pool 16 does not change. However, its apparent size for the calculation of its port class pool doubles, which causes the size of port class pool 1 to be twice that of mid pool 16, thereby oversubscribing it:

```
*A:PE-1>config>qos>hs-pool-policy# info
```

```
-----------------------------------------------
            root-tier
                root-pool 16
                    allocation-weight 100
                exit
            exit
            mid-tier
                mid-pool 15
                    parent-root-pool 16
                    allocation-percent 100.00
                exit
                mid-pool 16
                    parent-root-pool 16
                    allocation-percent 100.00
                    port-bw-oversub-factor 2
                exit
            exit

*A:PE-1# show hs-pools port 3/1/1 egress |
             match "Root Pool : 16" post-lines 26 |
             match "Pool" post-lines 1
Root Pool : 16
|  Total              : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 15
|     | Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 3978864 KB  Allocated         : 0 KB
```

A second standard port class pool, pool 2, on port 3/1/1 is parented to mid pool 16. The two port class pools share the buffer allocation equivalent to two times that of mid pool 16:

```
*A:PE-1>config>qos>hs-port-pool-policy>std-port-class-pools# info
-----------------------------------------------
                class-pool 1
                    parent-mid-pool 16
                exit
                class-pool 2
                    parent-mid-pool 16
                exit
*A:PE-1# show hs-pools port 3/1/1 egress |
             match "Root Pool : 16" post-lines 33  |
             match "Pool" post-lines 1
Root Pool : 16
|  Total              : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 15
|     | Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 1989432 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 2
|     |      Total               : 1989432 KB  Allocated         : 0 KB
```

The proportion of buffers available to the port class pools can be modified by configuring their **allocation port-bw-weight**. If the **allocation port-bw-weight** of port class pool 2 is set to 2, the port class pools will be allocated buffers in a 2:1 ratio:

```
*A:PE-1>config>qos>hs-port-pool-policy>std-port-class-pools# info
-----------------------------------------------
                class-pool 1
```

```
                    parent-mid-pool 16
                exit
                class-pool 2
                    parent-mid-pool 16
                    allocation port-bw-weight 2
                exit

*A:PE-1# show hs-pools port 3/1/1 egress |
              match "Root Pool : 16" post-lines 33 |
              match "Pool" post-lines 1
Root Pool : 16
|  Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 15
|     | Total               : 1989432 KB  Allocated         : 0 KB
|--- Mid Pool : 16
|     | Total               : 1989432 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 1
|     |      Total               : 1326288 KB  Allocated         : 0 KB
|     |--- Std Port Class Pool : 2
|     |      Total               : 2652576 KB  Allocated         : 0 KB
```

A third standard port class pool, pool 3, is parented to mid pool 16 with an **allocation port-bw-weight** of 2. Port class pools 1, 2, and 3 share the oversubscribed mid pool 16 size in a ratio of 1:2:2:

```
*A:PE-1>config>qos>hs-port-pool-policy>std-port-class-pools# info
----------------------------------------------
                class-pool 1

```

Standard port class pool 1, 2, and 3 are now configured with an allocation **explicit-percent** of 80%, 60%, and 60% respectively. This allocates these percentages of mid pool 16 real size to port class pools 1, 2, and 3, which oversubscribed the mid pool by 100%. The mid pool 16 oversubscription factor is not applied.

```

Shaping and Scheduling

HSQ Queue Groups

Each configuration uses the same four queues:

- Queue 7 at scheduling class 5
- Queue 6 at scheduling class 4
- Queues 1 and 2 in WRR group at scheduling class 1

The **low-burst-max-class** is configured to be class 1, to match the scheduling class of WRR group 1. This results in queues 1 and 2 being subject to the low burst limit threshold.

HSQ queue group queues can be attached to scheduling classes or to WRR groups, which can then be attached to a scheduling class. The eight queues and two WRR groups in an HSQ queue group can also be unattached (not attached to any scheduling class, or for queues, to any WRR group). This is configured using an **hs-attachment-policy**:

```
configure
    qos
        hs-attachment-policy <policy-name> [create]
            description <description-string>
            low-burst-max-class <class>
            queue <queue-id> sched-class <class-id>
            queue <queue-id> unattached
            queue <queue-id> wrr-group <wrr-group-id>
            wrr-group <group-id> sched-class <class-id>
```

Where (in order):

```
<policy-name>        : [32 chars max]
<description-string> : [80 chars max]
<class>              : [1..6]
<queue-id>           : [1..8]
<class-id>           : [1..6]
<wrr-group-id>       : [1..2]
<group-id>           : [1..2]
<class-id>           : [1..6]
```

When a queue or WRR group is unattached, the related queues discard all received packets.

When a queue is attached to a WRR group, the weight of that queue within the group is configured under the queue in the SAP egress QoS policy, network queue policy, and egress queue group template.

When a queue is attached to a WRR group, the following queue parameters are ignored. The corresponding configuration is applied to the entire WRR group in the SAP egress QoS policy for services, network queue policy for network interfaces, and egress queue group templates for both access and network egress queue group instances:

- **adaptation-rule**
- **hs-class-weight**
- **percent-rate**
- **rate**

A default **hs-attachment-policy** is created by the system and applied by default to all SAP egress QoS policy for services, to all network queue policy for network interfaces, and to all egress queue group templates for both access and network egress queue group instances. The default policy is not configurable.

```
*A:PE-1>config>qos# hs-attachment-policy "default"
*A:PE-1>config>qos>hs-attachment-policy# info detail
----------------------------------------------
            no description
            low-burst-max-class 6
            queue 1 wrr-group 1
            queue 2 wrr-group 1
            queue 3 wrr-group 1
            queue 4 sched-class 2
            queue 5 sched-class 3
            queue 6 sched-class 4
            queue 7 sched-class 5
            queue 8 sched-class 6
            wrr-group 1 sched-class 1
            wrr-group 2 unattached
```

Note:
Queues 1, 2, and 3 are attached by default to WRR group 1, so their configured rates are ignored.

To use a user-defined policy, a new HS attachment policy must be created and applied to the appropriate SAP egress QoS policy, network queue policy, or egress queue group template. A newly created policy has all queues and WRR groups unattached and the **low-burst-max-class** set to 6:

```
*A:PE-1# configure qos hs-attachment-policy hs-att-policy-new create
*A:PE-1>config>qos>hs-attachment-policy$ info detail
```

```
-----------------------------------------------
            no description
            low-burst-max-class 6
            queue 1 unattached
            queue 2 unattached
            queue 3 unattached
            queue 4 unattached
            queue 5 unattached
            queue 6 unattached
            queue 7 unattached
            queue 8 unattached
            wrr-group 1 unattached
            wrr-group 2 unattached
```

The hs-attachment-policy used for this example is as follows (queue 8 is reserved to be attached to scheduling class 6 for network protocol traffic, but is not used in this example):

```
*A:PE-1>config>qos# hs-attachment-policy "hs-att-pol-1"
*A:PE-1>config>qos>hs-attachment-policy# info detail
-----------------------------------------------
            no description
            low-burst-max-class 1
            queue 1 wrr-group 1
            queue 2 wrr-group 1
            queue 3 unattached
            queue 4 unattached
            queue 5 unattached
            queue 6 sched-class 4
            queue 7 sched-class 5
            queue 8 sched-class 6
            wrr-group 1 sched-class 1
            wrr-group 2 unattached
```

An HS attachment policy is shown as follows:

```
*A:PE-1# show qos hs-attachment-policy "hs-att-pol-1"

HS Secondary Shapers

HS secondary shapers are only applicable to SAP egress in the context of this chapter (not to network egress or egress access and network queue group instances). However, because secondary shapers can also be used by subscribers, they are included with the generic configuration aspects.

Secondary shapers are aimed at providing QoS control for traffic forwarded to a specific downstream device, such as an access node. Multiple HS secondary shapers can be configured on an egress port.

An aggregate rate and per-scheduling class rates are configurable for each secondary shaper. A **low-burst-max-class** parameter is also available to provide granular control over the scheduling behavior of which queues (via a WRR group, if used) use the low burst limit threshold and which use the high burst limit threshold.

Secondary shapers are configured on each port under the **config>port>ethernet>egress** context:

```
configure
    port <port-id>
        ethernet
            egress
                hs-secondary-shaper <secondary-shaper-name>
                    description <description-string>
                    aggregate
                        low-burst-max-class <class>
                        rate <rate>
                    class <class-number>
                        rate <rate>
```

Where (in order):

```
<port-id>            : slot/mda/port
<secondary-shaper-*> : [32 chars max]
<description-string> : [80 chars max]
<class>              : [1..6]
<class-number>       : [1..6]
<rate>               : [1..100000000|max] Kbps
<rate>               : [1..100000000|max] Kbps
```

A default HS secondary shaper is applied to all egress HSQ ports with the rates set to **max** and the **low-burst-max-class** set to 6. It is possible to modify the configuration of the default HS secondary shaper.

```
*A:PE-1>config>port>ethernet>egress# hs-secondary-shaper "default"
*A:PE-1>config>port>ethernet>egress>hs-sec-shaper# info detail
----------------------------------------------
                    no description
                    aggregate
                        rate max
                        low-burst-max-class 6
                    exit
                    class 1
                        rate max
                    exit
                    class 2
                        rate max
                    exit
                    class 3
                        rate max
                    exit
                    class 4
                        rate max
                    exit
                    class 5
                        rate max
                    exit
                    class 6
                        rate max
                    exit
```

An HS secondary shaper is configured on port 3/1/2 with a rate of 100 Mb/s for scheduling class 1 and a **low-burst-max-class** set to 1:

```
*A:PE-1>config>port>ethernet>egress# hs-secondary-shaper "hs-sec-shaper-1"
*A:PE-1>config>port>ethernet>egress>hs-sec-shaper# info detail
----------------------------------------------
                    no description
                    aggregate
                        rate max
                        low-burst-max-class 1
                    exit
                    class 1
                        rate 100000
                    exit
                    class 2
                        rate max
                    exit
                    class 3
                        rate max
                    exit
                    class 4
                        rate max
```

```
                    exit
                    class 5
                        rate max
                    exit
                    class 6
                        rate max
                    exit
```

This is shown, in this case with its associations, as follows:

```
*A:PE-1# show port 3/1/2 hs-secondary-shaper "hs-sec-shaper-1" associations

===============================================================================
*A:PE-1#
```

These statistics are cleared using the following command:

```
clear port 3/1/2 hs-secondary-shaper "hs-sec-shaper-1" statistics
```

The SAP egress queues in an HSQ queue group can be associated with a secondary shaper by configuring an egress queue override under the SAP and specifying the name of the secondary shaper. In addition, when using PW-SAPs, an HS secondary shaper can be applied to the egress of a PW port to control the PW-SAP egress traffic over that PW. See the SAP Egress section for configuration details.

If the user configures an HS secondary shaper on a port, the system instantiates a default primary shaper for that secondary shaper (which is used by all HSQ queue groups sending traffic to the secondary shaper) when the first egress SAP or PW-SAP is associated with that HS secondary shaper.

The current traffic rates through the secondary shapers on a port are shown, as follows, where the default interval is 1 second:

```
show qos hs-scheduler-hierarchy port <port-id>
             [hs-secondary-shaper <shaper-name>] [interval <time-in-seconds>]
show qos hs-scheduler-hierarchy port <port-id>
             [interval <time-in-seconds>] hs-secondary-shapers
```

The output shows the current aggregate traffic rate and the current traffic rate for each scheduling class:

```
*A:PE-1# show qos hs-scheduler-hierarchy port 3/1/2
                     hs-secondary-shaper "hs-sec-shaper-1"

```

Ports

A single HS scheduler policy can be applied to an egress HSQ port to configure an aggregate rate (**max-rate**) and per-scheduling class rates on that port. In addition, contiguous scheduling classes can be configured with weights in a WRR group, which can also be configured with a rate. The WRR group is scheduled at the scheduling class of its highest member scheduling class. The **max-rate** caps the scheduling class and group rates if its rate is lower.

The rates configured within an HS scheduler policy are applicable to all types of traffic (SAP egress, network egress, and egress queue group instances) exiting that port.

An HS scheduler policy is configured as follows:

```
configure
    qos
        hs-scheduler-policy <policy-name> [create]
            description <description-string>
            group <group-id> rate <rate>
            max-rate <rate>
            scheduling-class <class-id> group <group-id> [weight <weight-in-group>]
            scheduling-class <class-id> rate <rate>
```

Where (in order):

```
<policy-name>        : [32 chars max]
<description-string> : [80 chars max]
<group-id>           : [1]
<rate>               : [1..100000|max] Mbps
<rate>               : [1..100000|max] Mbps
<class-id>           : [1..6]
<group-id>           : [1]
<weight-in-group>    : [1..127]
```

```
<rate>               : [1..100000|max] Mbps
```

Note:
The rates configured in an HS scheduler policy are in Mb/s (not kb/s).

A default HS scheduler policy is applied to all egress HSQ ports and all its rates are set to **max**. It is not possible to modify the default HS scheduler policy.

```
*A:PE-1>config>qos# hs-scheduler-policy "default"
*A:PE-1>config>qos>hs-scheduler-policy# info detail
----------------------------------------------
            description "Default hs scheduler QoS policy"
            max-rate max
            group 1 rate max
            scheduling-class 1 rate max
            scheduling-class 2 rate max
            scheduling-class 3 rate max
            scheduling-class 4 rate max
            scheduling-class 5 rate max
            scheduling-class 6 rate max
```

A newly created HS scheduler policy has the same configuration as the default policy.

An HS scheduler policy with a rate of 5 Gb/s for scheduling class 1 is applied to port 3/1/1:

```
*A:PE-1# configure qos
*A:PE-1>config>qos# hs-scheduler-policy "hs-sched-pol-1"
*A:PE-1>config>qos>hs-scheduler-policy# info detail
----------------------------------------------
            no description
            max-rate max
            group 1 rate max
            scheduling-class 1 rate 5000
            scheduling-class 2 rate max
            scheduling-class 3 rate max
            scheduling-class 4 rate max
            scheduling-class 5 rate max
            scheduling-class 6 rate max
----------------------------------------------
*A:PE-1>config>qos>hs-scheduler-policy# exit all
*A:PE-1# configure port 3/1/1 ethernet egress hs-scheduler-policy "hs-sched-pol-1"
*A:PE-1#
```

The preceding policy is shown as follows:

```
*A:PE-1# show qos hs-scheduler-policy "hs-sched-pol-1"

===============================================================================
HS Scheduler Policy Information
===============================================================================

*A:PE-1#
```

The current traffic rates through the port aggregate, scheduling class, and WRR group shapers are shown, as follows, where the default interval is 1 second:

```
show qos hs-scheduler-hierarchy port <port-id> [interval <time-in-seconds>]
          queue-group <queue-group-name> instance <instance-id> {access|network}
show qos hs-scheduler-hierarchy sap <sap-id> egress [interval <time-in-seconds>]
show qos hs-scheduler-hierarchy subscriber <sub-ident> egress
                                                    [interval <time-in-seconds>]
```

The output shows the current aggregate traffic rate and the current traffic rates for each scheduling class:

```
*A:PE-1# show qos hs-scheduler-hierarchy port 3/1/1

===============================================================================

```

The HS scheduler policy parameters can be overridden under the port policy configuration:

```
configure
    port <port-id>
        ethernet
            egress
                hs-scheduler-overrides [create]
                    group <group-id> rate <rate>
                    max-rate <rate>
                    scheduling-class <class> rate <rate>
                    scheduling-class <class> weight <weight-in-group>
```

Where (in order):

```
<port-id>            : slot/mda/port
<group-id>           : [1..1]
<rate>               : [1..100000|max] Mbps
<rate>               : [1..100000|max] Mbps
<class>              : [1..6]
<rate>               : [1..100000|max] Mbps
<class>              : [1..6]
<weight-in-group>    : [1..127]
```

SAP Egress

A SAP configured on an HSQ IOM port uses an HSQ queue group for its egress queues. This occurs automatically and dedicates one HSQ queue group, so eight egress queues, to each SAP egress. Only the queues to be used need to be configured within the SAP egress QoS policy.

The operation of classification, policing, and marking within a SAP egress QoS policy when applied to a SAP on an HSQ port is unchanged. For example, it is possible to use egress policers and direct the post-policer traffic to either a local HSQ queue group queue or to an HSQ queue group queue in an access egress queue group instance.

Most of the commands in a SAP egress QoS policy apply to the HSQ egress SAPs, with the following exceptions (including their SAP egress related overrides) being ignored:

- HSMDA commands
- **parent-location sla**
- Policer commands
  - **policers-hqos-manageable**
  - **policer scheduler-parent**
- Queue related
  - **adaptation-rule cir <adaptation-rule>**
  - **adv-config-policy**
  - **avg-frame-overhead**

  - **burst-limit**
  - **cbs**
  - **drop tail**
  - **parent**
  - **percent-rate cir**
  - **percent-rate local-limit**
  - **pool**
  - **port-parent**
  - **rate cir**
  - **wred-queue**
- Subscriber commands
  - **dynamic-policer** commands
  - **sub-insert-shared-pccrule**

The following SAP commands are not configurable on HSQ SAPs:

- **"ingress qos shared-queuing**
- **"ingress qos multipoint-shared**
- **"egress agg-rate limit-unused-bandwidth**
- **"egress agg-rate queue-frame-based-accounting**
- **"multi-service-site**

As mentioned, an HS attachment policy is applied to the SAP egress QoS policy to define the attachment of the queues to scheduling classes or WRR groups, with the WRR group then being attached to a scheduling class:

```
configure
    qos
        sap-egress <policy-id>
            hs-attachment-policy <policy-name>
```

Where:

```
<policy-id>          : [1..65535]|<name:64 char max>
<policy-name>        : [32 chars max]
```

When queues are attached to one of the HSQ queue group WRR groups, the relative weight of each queue within the group is configured under the queue, with the default weight being 1:

```
configure
    qos
        sap-egress <policy-id>
            queue <queue-id>
                hs-wrr-weight <weight>
```

Where:

```
<policy-id>          : [1..65535]|<name:64 char max>
```

```
<queue-id>           : [1..8]
<weight>             : [1..127]
```

The rate-related configuration of the two WRR groups in the HSQ queue group is defined within the SAP egress QoS policy, as follows, with the defaults being **rate max** and **adaptation-rule closest**:

```
configure
    qos
        sap-egress <policy-id>
            hs-wrr-group <group-id>
                adaptation-rule [pir <adaptation-rule>]
                percent-rate <percent>
                rate <rate>
```

Where:

```
<policy-id>          : [1..65535]|<name:64 char max>
<group-id>           : [1..2]
<adaptation-rule>    : max|min|closest
<percent>            : [0.01..100.00]
<rate>               : [1..2000000000|max] Kbps
```

The **percent-rate** configured within the **hs-wrr-group** and under a queue is relative to the port rate, so is equivalent to the queue **port-limit** and includes both the **egress-rate** and HS scheduler policy **max-rate**, if configured.

The SAP egress queue default slope policy is *_tmnx_hs_default*. A user-defined slope policy can be configured on a queue, as follows:

```
configure
    qos
        sap-egress <policy-id>
            queue <queue-id>
                hs-wred-queue [policy <slope-policy-name>]
```

Where:

```
<policy-id>          : [1..65535]|<name:64 char max>
<queue-id>           : [1..8]
<slope-policy-name>  : [32 chars max]
```

The **highplus-slope** and **time-average-factor** in the applied slope policy are ignored on HSQ queue group queues.

By default, SAP egress HSQ queue group queues use buffers from the standard port class pools on their associated port. Each queue can be configured to use the port alternative class pools, as follows:

```
configure
    qos
        sap-egress <policy-id>
            queue <queue-id>
                hs-alt-port-class-pool
```

Where:

```
<policy-id>          : [1..65535]|<name:64 char max>
<queue-id>           : [1..8]
```

WRR group scheduling between queues and WRR groups in different HSQ queue groups is available at a primary shaper scheduling class. This is configured within a SAP egress QoS policy, as follows:

```
configure
    qos
        sap-egress <policy-id>
            hs-wrr-group <group-id>
                hs-class-weight <weight>
            queue <queue-id>
                hs-class-weight <weight>
```

Where (in order):

```
<policy-id>          : [1..65535]|<name:64 char max>
<group-id>           : [1..2]
<weight>             : 1|2|4|8
```

The **hs-class-weight** parameter under the **queue** or **hs-wrr-group** statement specifies the relative weight of the respective **queue** or **hs-wrr-group** for scheduling opportunities when their parent primary shaper scheduling class is serviced. By default, the **hs-class-weight** is 1.

Note:
This parameter should not be confused with the **hs-wrr-weight** parameter, which specifies the relative weights of different queues within the same HSQ queue group WRR group.

The HSQ queue group aggregate rate is applied to a SAP egress using the **agg-rate rate** command:

```
configure
    service
        {ipipe <service-id>|epipe <service-id>|vpls <service-id>|
         ies <service-id> interface <ip-int-name>|
         vprn <service-id> interface <ip-int-name>}
            sap
                egress
                    agg-rate
                        rate <kilobits-per-second>
```

Where:

```
<service-id>         : [1..2147483647]|<svc-name:64 char max>
<ip-int-name>        : [32 chars max]  (must start with a letter)
<kilobits-per-seco*> : [1..3200000000|max] Kbps
```

The following HSQ-specific overrides are available under a SAP egress corresponding to the preceding commands:

```
configure
    service
        {ipipe <service-id>|epipe <service-id>|vpls <service-id>|
         ies <service-id> interface <ip-int-name>|
         vprn <service-id> interface <ip-int-name>}
            sap
                egress
                    queue-override
                        hs-secondary-shaper <policy-name>
                        hs-wrr-group <group-id> [create]
                        hs-wrr-group <group-id> class-weight <weight>
                        hs-wrr-group <group-id> percent-rate <percent>
```

```
                        hs-wrr-group <group-id> rate <rate>
                        queue <queue-id> hs-class-weight <weight>
                        queue <queue-id> hs-wred-queue policy <slope-policy-name>
                        queue <queue-id> hs-wrr-weight <weight>
```

Where (in order):

```
<service-id>         : [1..2147483647]|<svc-name:64 char max>
<ip-int-name>        : [32 chars max]  (must start with a letter)
<policy-name>        : [32 chars max]
<group-id>           : [1..2]
<weight>             : 1|2|4|8
<percent>            : [0.01..100.00]
<rate>               : [1..2000000000|max] Kbps
<queue-id>           : [1..8]
<weight>             : 1|2|4|8
<slope-policy-name>  : [32 chars max]
<weight>             : [1..127]
```

Note:
Queue depth monitoring is supported for SAP egress HSQ queue group queues. This is enabled by configuring the queue override **monitor-depth** command under SAP egress with the associated **show** command output displaying buffer occupancy in ranges of 10% of the queue depth for each configured queue.

An additional SAP egress override is provided to redirect the traffic from an HSQ queue group to a user-configured secondary shaper:

```
configure
    service
        {ipipe <service-id>|epipe <service-id>|vpls <service-id>|
         ies <service-id> interface <ip-int-name>|
         vprn <service-id> interface <ip-int-name>}
            sap
                egress
                    queue-override
                        hs-secondary-shaper <policy-name>
```

Where:

```
<service-id>         : [1..2147483647]|<svc-name:64 char max>
<ip-int-name>        : [32 chars max]  (must start with a letter)
<policy-name>        : [32 chars max]
```

When using pseudowire SAPs (PW-SAPs), an HS secondary shaper can be configured under the SDP binding to apply QoS control to the PW used by the SAPs, as follows:

```
configure
    service
        sdp <sdp-id>
            binding
                pw-port <pw-port-id>
                    egress
                        shaper
                        pw-sap-secondary-shaper <pw-sap-sec-shaper-name>
```

Where:

```
<sdp-id>             : [1..32767]
<pw-port-id>         : [1..32767]
<pw-sap-sec-shaper*> : [32 chars max]
```

When the first egress SAP or PW-SAP is associated with a user-configured HS secondary shaper, the system instantiates a default primary shaper for that secondary shaper, which is used by all HSQ queue groups sending traffic to that secondary shaper.

An IES interface SAP is configured with the HSQ queue group having an aggregate rate of 50 Mb/s (using the **agg-rate rate** command). The SAP egress traffic is directed to an HS secondary shaper, which is applied to port 3/1/2:

```
*A:PE-1>config>service>ies# info
----------------------------------------------
            description "HSQ egress SAP queues"
            interface "PE-1-IES-1" create
                address 192.168.11.1/30
                sap 3/1/2:1 create
                    egress
                        qos 10
                        queue-override
                            hs-secondary-shaper "hs-sec-shaper-1"
                        exit
                        agg-rate
                            rate 50000
                        exit
                    exit
                exit
            exit
            no shutdown
```

The SAP egress QoS policy contains the applied HS attachment policy described for the queue attachment. Queue 1 is configured with a WRR weight of 2. Rates of 20 Mb/s and 10 Mb/s are configured on queues 6 and 7, respectively. WRR group 1 is configured with a rate of 40 Mb/s. DSCP values are used to classify the egress traffic to the forwarding classes mapped to the queues:

```
*A:PE-1>config>qos# sap-egress 10
*A:PE-1>config>qos>sap-egress# info
----------------------------------------------
            hs-attachment-policy "hs-att-pol-1"
            queue 1 create
                hs-wrr-weight 2
            exit
            queue 2 create
            exit
            queue 6 create
                rate 20000
            exit
            queue 7 create
                rate 10000
            exit
            hs-wrr-group 1
                rate 40000
            exit
            fc af create
                queue 2
            exit
            fc ef create
                queue 6
```

```
            exit

```

Network Egress

Each network egress port uses one HSQ queue group for its egress queues. This occurs automatically and dedicates one HSQ queue group, so eight egress queues, to each network egress port, which are used by all network interfaces configured on that port.

The HSQ-specific configuration of network egress queues on an HSQ IOM is similar to that for SAP egress.

The operation of classification, policing, and marking within the network QoS and network queue policies when applied to a network interface and egress HSQ port, respectively, is unchanged. Only the queues to be used need to be configured within the network queue policy.

Most of the commands in a network queue policy apply to the HSQ egress network interfaces, with the following exceptions being ignored:

- Queue commands
  - **adaptation-rule cir** <*adaptation-rule*>
  - **avg-frame-overhead**
  - **mbs**
  - **cbs**
  - **drop tail**
  - **port-parent**

- **pool**
- **rate cir**

The network queue policy **mbs** parameter is ignored, and replaced for HSQ queue group queues with the **hs-mbs** parameter. This is required to allow a more suitable default value to be assigned for the operation of HSQ queues. Both are configured as fractional percentages, with the default for the **mbs** parameter being 50% of the network egress pool, which is not used for HSQ queues, whereas the default for **hs-mbs** is 100% of one second of the queue PIR, converted to bytes. If the queue rate is **max**, the port rate is used (including the HS scheduler policy **max-rate** and the **egress-rate**, if configured on the port).

The network-queue policy has the same HS-specific configuration as in the SAP egress QoS policy, so is not repeated here, but includes:

- The application of an HS attachment policy to define the attachment of the queues to scheduling classes or WRR groups, with the WRR group then being attached to a scheduling class.
- The queue **hs-wrr-weight** to configure the relative weight of each queue within its parented WRR group.
- The rate-related configuration of the two WRR groups in the HSQ queue group.
- The slope policy configured on each HS WRED queue, again with the **highplus-slope** and **time-average-factor** being ignored.
- The use of the port alternative class pools by each queue.
- The HS class weight for WRR group scheduling between queues and WRR groups in different HSQ queue groups at a primary shaper scheduling class.

HS WRR group and queue rates are configured as a percentage of the port rate, which includes both the **egress-rate** and HS scheduler policy **max-rate**, if configured.

Secondary shapers and HSQ queue group aggregate rates are not applicable to network egress HSQ queue group queues.

The related network queue policy configuration is as follows:

```
configure
    qos
        network-queue <policy-name> [create]
            hs-attachment-policy <policy-name>
            hs-wrr-group <group-id>
                adaptation-rule [pir <adaptation-rule>]
                hs-class-weight <weight>
                rate <percent>
            queue <queue-id> [multipoint] [<queue-type>] [create]
                hs-alt-port-class-pool
                hs-class-weight <weight>
                hs-mbs <percent-of-queue-rate>
                hs-wred-queue [policy <slope-policy-name>]
                hs-wrr-weight <weight>
```

See the SAP Egress section for details of the preceding parameters.

A network interface is configured on port 3/1/1:1:

```
*A:PE-1>config>router# info | match "IP Configuration" pre-lines 1 post-lines 10
#------------------------------------------------
echo "IP Configuration"
#------------------------------------------------
        interface "PE-1-Network-1"
```

```
            address 192.168.10.1/30
            description "HSQ network egress queues"
            port 3/1/1:1
            qos 10
            no shutdown
        exit
```

The network QoS policy 10 applied to the interface only contains the necessary egress **dscp** statements to classify the egress traffic to the forwarding classes mapped to the queues.

The network queue policy configured on port 3/1/1 contains the applied HS attachment policy described for the queue attachment. Queue 1 is configured with a WRR weight of 2. Rates of 2% and 1% are configured on queues 6 and 7, respectively. WRR group 1 is configured with a rate of 2%:

```
*A:PE-1>config>qos>network-queue# info
----------------------------------------------
            hs-attachment-policy "hs-att-pol-1"
            queue 1 create
                hs-wrr-weight 2
            exit
            queue 2 create
            exit
            queue 6 create
                rate 2
            exit
            queue 7 create
                rate 1
            exit
            hs-wrr-group 1
                rate 2
            exit
```

The network queue information is shown as follows:

```
*A:PE-1# show hs-pools port 3/1/1 egress network-queues |

Access and Network Egress Queue Groups

Each access and network egress queue group instance configured on an HSQ IOM uses an HSQ queue group for its queues. This occurs automatically and dedicates one HSQ queue group, so eight egress queues, to each egress queue group instance. Only the queues to be used need to be configured within the egress queue group template.

The operation of classification, policing, and marking related to egress queue group instances on an HSQ port is unchanged.

Most of the commands in an egress queue group template apply to the HSQ egress queue group instances, with the following exceptions (including their related overrides) being ignored:

- HSMDA commands
- **queues-hqos-manageable**
- Queue related
  - **adaptation-rule cir <adaptation-rule>**
  - **adv-config-policy**
  - **avg-frame-overhead**
  - **burst-limit**
  - **cbs**
  - **drop tail**
  - **dynamic-mbs**
  - **parent**
  - **percent-rate cir**
  - **pool**
  - **port-parent**

  - **rate cir**
  - **wred-queue**

The following commands are not configurable under port access and network egress queue group instances:

- **egress agg-rate limit-unused-bandwidth**
- **egress agg-rate queue-frame-based-accounting**

The configuration of egress queue groups using HSQ queue groups is unchanged. The egress queue group template is applied under **config>port>ethernet>access>egress** or **config>port>ethernet>network>egr** to create the queue group instances, and traffic is redirected to these instances in either a SAP egress QoS policy or network QoS policy.

The system-created egress queue group instances each use an HSQ queue group; for example, the post-policer access egress *policer-output-queues* queue groups.

The egress queue group template has the same HS-specific configuration as in the SAP egress QoS policy, so is not repeated here, but includes:

- The application of an HS attachment policy to define the attachment of the queues to scheduling classes or WRR groups, with the WRR group then being attached to a scheduling class.
- The queue **hs-wrr-weight** to configure the relative weight of each queue within its parented WRR group.
- The rate-related configuration of the two WRR groups in the HSQ queue group.
- The slope policy configured on each HS WRED queue, again with the **highplus-slope** and **time-average-factor** being ignored.
- The use of the port alternative class pools by each queue.
- The HS class weight for WRR group scheduling between queues and WRR groups in different HSQ queue groups at a primary shaper scheduling class.

Secondary shapers are not applicable to both access and network egress queue group instance HSQ queue groups.

The related egress queue group template configuration syntax is as follows:

```
configure
    qos
        queue-group-templates
            egress
                queue-group <queue-group-name> [create]
                    hs-attachment-policy <policy-name>
                    hs-wrr-group <group-id>
                        adaptation-rule [pir <adaptation-rule>]
                        hs-class-weight <weight>
                        percent-rate <percent>
                        rate <rate>
                    queue <queue-id> [queue-type] [create]
                        hs-alt-port-class-pool
                        hs-class-weight <weight>
                        hs-wred-queue [policy <slope-policy-name>]
                        hs-wrr-weight <weight>
```

See the SAP Egress section for details of the preceding parameters.

The **percent-rate** configured within the **hs-wrr-group** and under a queue is relative to the port rate, and includes both the **egress-rate** and HS scheduler policy **max-rate**, if configured.

The HSQ queue group aggregate rate is applied to an egress queue group instance using the **agg-rate rate** command under the application of the queue group template on the port:

```
configure
    port <port-id>
        ethernet
            access
                egress
                    queue-group <queue-group-name> [instance <instance-id>]
                        agg-rate
                            rate <kilobits-per-second>
            network
                egress
                    queue-group <queue-group-name> [instance <instance-id>]
                        agg-rate
                            rate <kilobits-per-second>
```

Where:

```
<port-id>            : slot/mda/port
<queue-group-name>   : [32 chars max]
<instance-id>        : [1..65535]
<kilobits-per-seco*> : [1..3200000000|max] Kbps
```

When using HSQ queue groups with access or network egress queue group instances on 100G ports, the **hs-turbo** parameter can be configured under the port queue group instance to allow the corresponding HSQ queue group queues to achieve a higher throughput. The default is **no hs-turbo**. The **hs-turbo** parameter is not applicable to 10G ports and is ignored when configured under a queue group instance on a 10G port.

```
configure
    port <port-id>
        ethernet
            access
                egress
                    queue-group <queue-group-name> [instance <instance-id>]
                        hs-turbo
            network
                egress
                    queue-group <queue-group-name> [instance <instance-id>]
                        hs-turbo
```

Where:

```
<port-id>            : slot/mda/port
<queue-group-name>   : [32 chars max]
<instance-id>        : [1..65535]
```

Note:
Queue depth monitoring is supported for access and network egress queue groups HSQ queues. This is enabled by configuring the queue override **monitor-depth** command under the queue group instance with the associated output showing buffer occupancy in ranges of 10% of the queue depth for each configured queue.

An egress queue group template is configured containing the applied HS attachment policy described for the queue attachment. Queue 1 is configured with a WRR weight of 2. Rates of 20 Mb/s and 10 Mb/s are configured on queues 6 and 7, respectively. WRR group 1 is configured with a rate of 40 Mb/s:

```
A:PE-1# configure qos queue-group-templates egress
A:PE-1>cfg>qos>qgrps>egr# info
----------------------------------------------
                queue-group "queue-group-1" create
                    hs-attachment-policy "hs-att-pol-1"
                    queue 1 best-effort create
                        hs-wrr-weight 2
                    exit
                    queue 2 best-effort create
                    exit
                    queue 6 best-effort create
                        rate 20000
                    exit
                    queue 7 best-effort create
                        rate 10000
                    exit
                    hs-wrr-group 1
                        rate 40000
                    exit
                exit
```

The queue group template is applied to the network port 3/1/1 and access port 3/1/2, each with an aggregate rate of 100 Mb/s:

```
A:PE-1# configure port 3/1/1
A:PE-1>config>port# info
----------------------------------------------
        ethernet
            network
                egress
                    queue-group "queue-group-1" instance 1 create
                        agg-rate
                            rate 100000
                        exit
                    exit
                exit
            exit
        exit
        no shutdown
----------------------------------------------
A:PE-1>config>port# exit all
A:PE-1# configure port 3/1/2
A:PE-1>config>port# info
----------------------------------------------
        ethernet
            access
                egress
                    queue-group "queue-group-1" instance 1 create
                        agg-rate
                            rate 100000
                        exit
                    exit
                exit
            exit
        exit
        no shutdown
```

The configured aggregate rates are shown as follows:

```
*A:PE-1# show port 3/1/[1,2] queue-group queue-group-1 instance 1 |
                                match "Ethernet port" pre-lines 1 post-line 7

```

Conclusion

The HSQ IOM provides high scale QoS in terms of the number of ingress policers and egress queues supported. It supports six scheduling classes across multiple hierarchical levels of hardware egress shaping encompassing HSQ queue groups, primary shapers, secondary shapers, and port schedulers. A

flexible buffer allocation mechanism permits both buffer isolation and buffer oversubscription for the queue buffer allocation.

Pseudowire QoS

This chapter describes pseudowire QoS configurations.

Topics in this chapter include:

Applicability

The information and configuration is based on Release 11.0.R4. There are no specific prerequisites for this configuration.

Overview

A pseudowire (PW) provides a virtual connection across an IP or MPLS network between services configured on provider edge (PE) devices. In SR OS Release 10.0.R1, and later, it is possible to provide specific QoS to either a single pseudowire or a multiple pseudowires. This is supported for the following:

- SDP
  - MPLS
  - GRE
- Epipe
  - Including vc-switching and dynamic MS-PW
  - PBB-epipe
  - BGP-VPWS (Release 11.0.R1 and later)
- VPLS
  - Mesh and spoke SDP
  - LDP signaled pseudowires
  - BGP-AD signaled pseudowires
  - I-VPLS, B-VPLS
  - R-VPLS
  - BGP-VPLS
- Spoke termination on IES/VPRN (both Epipe and Ipipe)
- Apipe (from R10.0.R4)
- Cpipe (from R10.0.R4)
- Fpipe (from R10.0.R4)
- Ipipe (from R10.0.R4)

It is supported at ingress on both Ethernet and POS/TDM ports and only on Ethernet ports at egress.

Bandwidth control is achieved using queue-groups which are implemented per flexpath (FP) at the ingress and per port at the egress (these being relative to the data path through the system), as shown in Figure 436: Ingress PW QoS and Figure 437: Egress PW QoS, respectively.

Figure 436: Ingress PW QoS

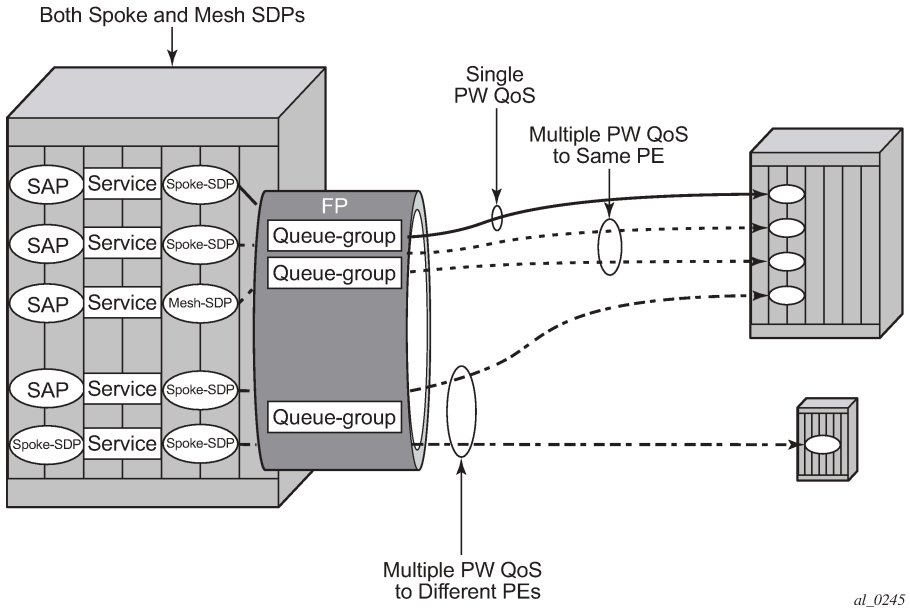

Figure 437: Egress PW QoS

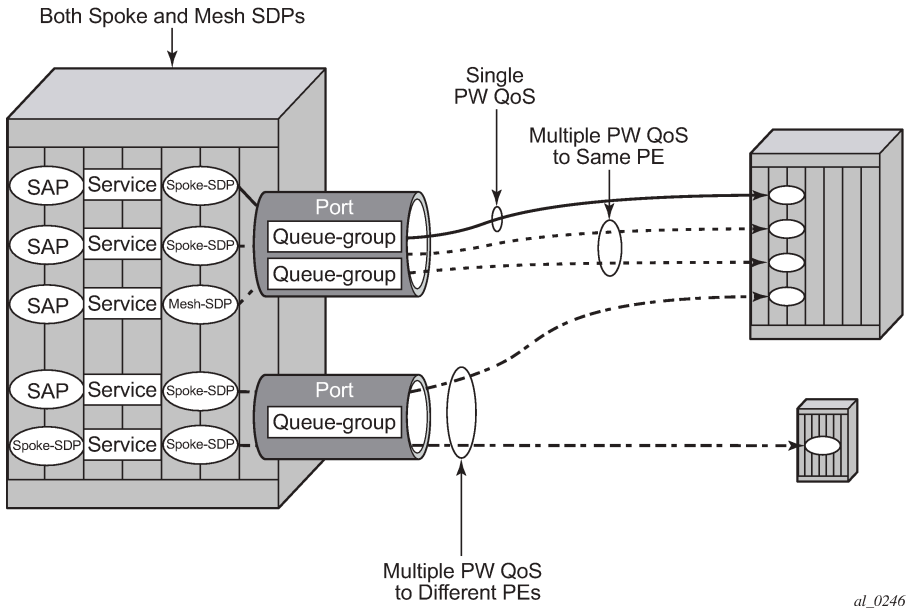


Bandwidth control is applied independently for ingress and egress, and can be set up for a single pseudowire or for multiple pseudowires where the remote services are located on a single PE or on multiple PEs.

It is possible to benefit from Hierarchical QoS which can be configured under the queue-groups, but this is beyond the scope of this chapter.

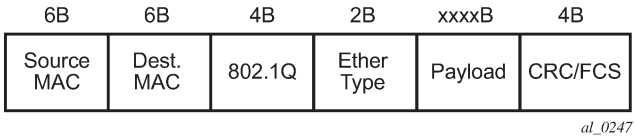
The ingress and egress classification and egress marking is configured by applying a network QoS policy to each pseudowire.

Ingress QoS

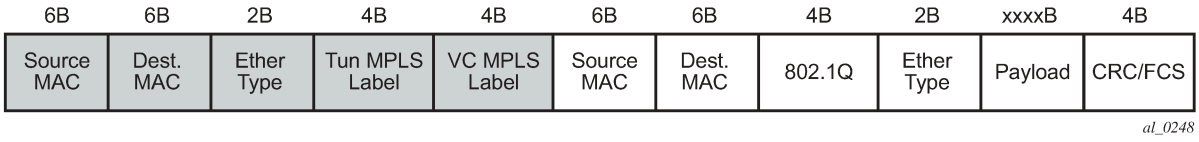
Ingress QoS is achieved using a queue group which is applied to an ingress FP on a card. Queue groups applied to an FP can only contain policers, not queues. The network QoS policy applied to the pseudowire redirects forwarding classes (FCs) to the individual queue group (unicast or multipoint) policers. The actual queue group to be used is defined separately to the network QoS policy, thereby allowing the network QoS policies to be independent from the queue groups used and therefore both are reusable.

Ingress bandwidth control does not take into account the outer Ethernet header, the MPLS labels/control word or GRE headers, or the FCS of the incoming frame. The configuration allows an offset to be added or subtracted from the received frame size in order to change the actual length used for the bandwidth control. For example: if the same ingress rate is configured on a pseudowire (without a control word) and a dot1q SAP, what packet-byte-offset needs to be used on the pseudowire in order to achieve the same throughput as on the SAP?

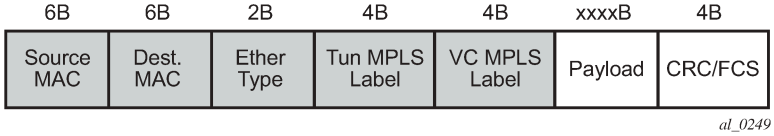
- SAP — The following shows the bytes in the frame that are used by default on a policer for the rate at a SAP ingress.



- VPLS Pseudowire — For a tagged (**vc-type vlan**) pseudowire, it would be necessary to add 4 bytes using the packet-byte-offset applied to the ingress policer in order to achieve the same throughput as on the SAP. This compensates for the omission of the FCS that is included on the SAP and so needs to be added.



- VPRN Pseudowire — For an Ipipe (**vc-type** ipipe) pseudowire, it would be necessary to add 22 bytes using the packet-byte-offset to the ingress policer to achieve the same throughput as on the SAP. This compensates for the omission of the source and destination MAC addresses (12 bytes), Ether type (2 bytes), VLAN tag (4 bytes) and the FCS (4 bytes) that are included on the SAP and so needs to be added.



The ingress classification is configured in the ingress section of the network QoS policy and is based on the outer encapsulation header only, the outer Ethernet header (dot1p/DE), MPLS labels (EXP), or GRE headers (DSCP). At an egress LER, the ler-use-dscp is applicable only to IES and VPRN pseudowires.

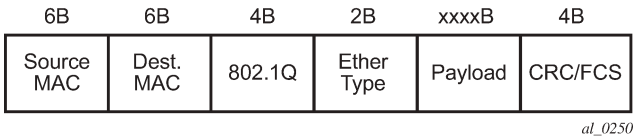
Egress QoS

Egress QoS is achieved using a queue group which is applied to an egress port. Queue groups applied to a port can contain both policers and queues. The network QoS policy applied to the pseudowire redirects forwarding classes (FCs) to the individual queue group policers/queues. The actual queue group to be used is defined separately to the network QoS policy, thereby allowing the network QoS policies to be independent from the queue groups used and therefore both are reusable.

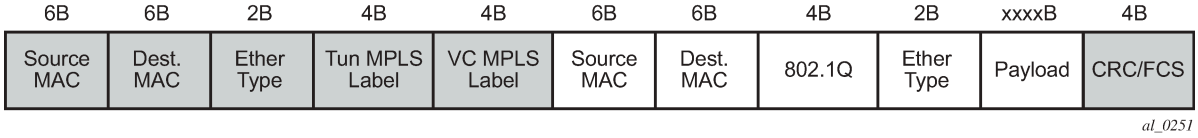
Egress bandwidth control takes into account the outer Ethernet header, MPLS labels/control word, or GRE headers, and the FCS of the outgoing frame. The configuration allows an offset to be added or subtracted from the sent frame size in order to affect the actual length used for the bandwidth control.

For example, if the same egress rate is configured on a pseudowire (without a control word) and a dot1q SAP, what packet-byte-offset needs to be used on the pseudowire in order to achieve the same throughput as on the SAP?

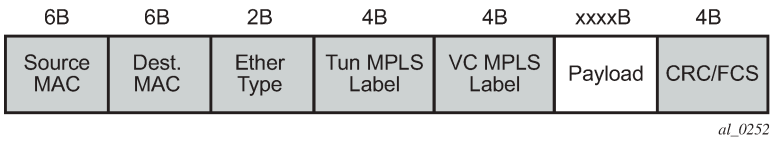
- SAP — The following shows the bytes in the frame that are used by default on a policer/queue at a SAP egress.



- VPLS Pseudowire — For a tagged (**vc-type vlan**) pseudowire, it would be necessary to subtract 22 bytes using the packet-byte-offset applied to the egress policer/queue applied to achieve the same throughput as on the SAP. This compensates for the MPLS header (source and destination MAC addresses (12 bytes), Ether type (2 bytes), two labels (8 bytes)) that is not included on the SAP and needs to be subtracted.



- VPRN Pseudowire — For an Ipipe (**vc-type ipipe**) pseudowire, it would be necessary to subtract 4 bytes using the packet-byte-offset applied to the egress policer/queue applied to achieve the same throughput as on the SAP. This compensates for the MPLS header (source and destination MAC addresses (12 bytes), Ether type (2 bytes), two labels (8 bytes)) that is not included on the SAP so is subtracted, and the source and destination MAC addresses (12 bytes), dot1q header (4 bytes) and Ether type (2 bytes) of the SAP frame which needs to be added. This results in subtracting 4 bytes.



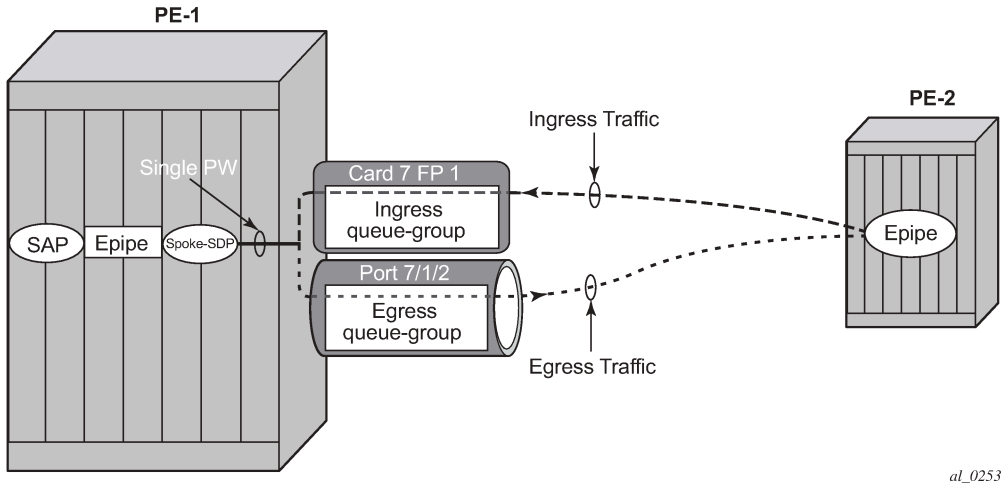
The egress classification and marking is configured in the egress section of the network QoS policy. DSCP/prec egress reclassification is supported in SR OS Release 10.0.R4, and later, for IES and VPRN spoke

SDPs. The egress marking affects the outer encapsulation header, the outer Ethernet header (dot1p/DE), MPLS labels (EXP) or GRE headers (DSCP).

Configuration

The configuration of pseudowire QoS is described using an Epipe pseudowire. The topology is shown in Figure 438: Example Epipe Pseudowire Topology.

Figure 438: Example Epipe Pseudowire Topology



The following prerequisite configuration is assumed to be in place:

- Hardware provisioning
- IP address and routing
- MPLS protocols
- SDP
- Epipe service, including the SAP
- SAP QoS policies

Traffic is sent across a virtual leased line between PE-1 and PE-2 using Epipes with a pseudowire configured as a spoke SDP on each PE. The QoS is applied to the pseudowire at the ingress and egress of PE-1.

The following configuration is required for applying pseudowire QoS:

- Create the ingress and egress queue groups. These contain the ingress policer and egress policer/queue definitions.
- Create an instance of the ingress queue group on the ingress FP and instance of the egress queue group on the port that will be used for the pseudowire traffic.
- Create a network QoS policy to redirect the traffic to the ingress and egress queue groups, and to perform the ingress classification and egress marking.
- Apply the network QoS policy, together with the reference to the ingress and egress queue group instances, to the spoke SDP representing the pseudowire.

The traffic consists of two bidirectional flows, one in FC BE and one in FC EF. At the ingress of the pseudowire, each FC is assigned to its own policer, whereas at the egress of the pseudowire, FC BE is assigned to a queue and FC EF is assigned to a policer.

Although this example makes use of both ingress and egress queue groups, the focus is pseudowire QoS, so the full details of queue group configuration are not covered.

Create the Ingress and Egress Queue Groups

Queue groups are created using templates, which are separate for ingress and egress. The following shows the queue group templates configured.

```
configure qos
        queue-group-templates
            ingress
                queue-group "ingress-queue-group" create
                    policer 1 create
                        rate 6000
                        packet-byte-offset add 4
                    exit
                    policer 2 create
                        rate 4000
                        packet-byte-offset add 4
                    exit
                exit
            exit
            egress
                queue-group "egress-queue-group" create
                    queue 1 best-effort create
                        rate 6000
                        xp-specific
                            packet-byte-offset subtract 22
                        exit
                    exit
                    policer 1 create
                        rate 4000
                        packet-byte-offset subtract 22
                    exit
                exit
            exit
        exit
```

The ingress queue group has two policers associated with it; policer 1 will be used for the FC BE traffic and policer 2 will be used for the FC EF traffic. The configuration of policers in an ingress queue group is the same as that in a sap-ingress QoS policy, with the exception that the percent-rate is not supported within the queue group.

In order to achieve the same ingress throughput as that when applying the same rates to policers on a dot1q tagged SAP, the packet-byte-offset adds 4 bytes to the packet length for both policers.

The egress queue group has one queue (queue 1) that will be used for the FC BE traffic and one policer (policer 1) that will be used for the FC EF traffic. The configuration of policers in an egress queue group is the same as that in a sap-egress QoS policy, with the exception that the percent-rate is not supported within the queue group. The configuration of queues in an egress queue group is the same as in a sap-egress QoS policy, with the exception that the avg-frame-overhead is not supported within the queue group.

In order to achieve the same egress throughput as that when applying the same rates to policers/queues on a dot1q tagged SAP, the packet-byte-offset subtracts 22 bytes from the packet length for both the policer and queue.

Rates have been configured such that the ingress and egress capacity of the BE traffic is 6Mb/s and 4Mb/s for the EF traffic.

Create the Ingress FP and Egress Port Queue Group Instances

The queue group templates are then applied as individual instances to the ingress FP and egress port; using instances allows the reuse of the same template.

Following is the ingress FP configuration. From a QoS perspective, it is also possible to configure a policer-control-policy under the ingress queue group in order to perform hierarchical policing. In Release 11.0.R4, and later, the configuration supports overrides for both the policer-control-policy parameters and some of the queue group policer parameters.

```
configure
    card 7
        card-type imm5-10gb-xfp
        mda 1
            no shutdown
        exit
        fp 1
            ingress
                network
                    queue-group "ingress-queue-group" instance 1 create
                    exit
                exit
            exit
        exit
        no shutdown
    exit
```

Following is the egress port configuration. From a QoS perspective, it is also possible to configure under the egress queue group a policer-control-policy in order to perform hierarchical policing, a scheduler-policy in order to perform hierarchical shaping and overrides for some of the queue group queue parameters.

```
configure
    port 7/1/2
        ethernet
            network
                egress
                    queue-group "egress-queue-group" instance 1 create
                    exit
                exit
            exit
        exit
        no shutdown
    exit
```

If there are redundant network interfaces over which the pseudowire traffic can enter or exit the system, it is necessary to configure any ingress FP and egress port queue groups consistently across all possible interfaces to be used by the pseudowire to ensure the QoS is always applied. If a queue group configuration was omitted, the pseudowire would not be subject to the QoS defined in that queue group.

If a LAG is used, the system only allows the egress port queue group to be added or removed from the LAG primary port, thereby keeping the LAG configuration consistent. However, this is not possible at the

ingress as the queue-group is applied at the FP, so it is necessary to ensure that the ingress queue group is applied consistently on all FPs corresponding to the configured LAG.

Create the Network QoS Policy

A network QoS policy is created to redirect ingress and egress traffic to the respective queue groups, and perform ingress classification (in this example).

The redirection to the queue group policer/queue is performed per FC.

At ingress, traffic can be redirected to policers (being the same or different policers) based on the traffic type. Unicast traffic is redirected to a policer specified by the policer command and will use the ingress shared policer-output-queues to access the switch fabric. All multipoint traffic is redirected to the policer specified by the multicast-policer command (for example, with a pseudowire configured in a VPLS service, all broadcast, unknown, and multicast traffic will use this policer). The multipoint traffic accesses the switch fabric using the Ingress Multicast Path Management queues. It is possible to individually redirect one traffic type (unicast or multipoint) within an FC to a queue group policer while allowing the other traffic type to use default network queues.

At egress, traffic can be redirected to a queue or to a policer. The policed traffic will exit the egress port using one of the default network queues (with the queue chosen by FC assignment) or optionally can use a queue in the egress queue group if configured in the port-redirect-group command following the policer parameter.

Any FC not redirected to a queue-group, will continue to use the regular default network ingress and egress queues.

The syntax for the FC redirection is as follows.

```
config# qos
  network <network-policy-id> [create]
      ingress
          fc <fc-name>
              fp-redirect-group multicast-policer <policer-id>
              fp-redirect-group policer <policer-id>
      egress
          fc <fc-name>
              port-redirect-group {queue <queue-id>|
policer <policer-id> [queue <queue-id>]}
```

The required commands are shown below.

```
configure qos
        network 10 create
            ingress
                lsp-exp 5 fc ef profile in
                fc be
                    fp-redirect-group policer 1
                exit
                fc ef
                    fp-redirect-group policer 2
                exit
            exit
            egress
                fc be
                    port-redirect-group queue 1
                exit
                fc ef
                    port-redirect-group policer 1
```

```
            exit
        exit
    exit
```

At ingress, the FC BE and FC EF traffic are redirected to the two policers in the queue-group applied to the FP. At egress, the two FCs are redirected to the queue and policer in the queue group applied to the egress port.

The ingress classification required here is for the traffic which is received with exp=5 to be in FC EF.

Apply Network QoS Policy with Queue Group Instances to the Spoke SDP

To apply the QoS to the pseudowire, the following commands can be used, dependent on the service type.

```
config# service {apipe|cpipe|epipe|fpipe|ipipe} <service-id>
  spoke-sdp <sdp-id:vc-id>
     ingress
       qos <network-policy-id> fp-redirect-group <queue-group-name>
                               instance <instance-id>
     egress
       qos <network-policy-id> port-redirect-group <queue-group-name>
                               instance <instance-id>
```

```
config# service {ies|vprn} <service-id>
  interface <ip-int-name>
    spoke-sdp <sdp-id:vc-id>
      ingress
        qos <network-policy-id> fp-redirect-group <queue-group-name>
                                instance <instance-id>
      egress
        qos <network-policy-id> port-redirect-group <queue-group-name>
                                instance <instance-id>
```

```
config# service vpls <service-id>
  {spoke-sdp|mesh-sdp} <sdp-id:vc-id>
     ingress
       qos <network-policy-id> fp-redirect-group <queue-group-name>
                               instance <instance-id>
     egress
       qos <network-policy-id> port-redirect-group <queue-group-name>
                               instance <instance-id>
```

For services using BGP auto-discovery to signal the pseudowire, the QoS configuration is included in the pseudowire template.

```
config# service pw-template <policy-id>
     ingress
       qos <network-policy-id> fp-redirect-group <queue-group-name>
                               instance <instance-id>
     egress
       qos <network-policy-id> port-redirect-group <queue-group-name>
                               instance <instance-id>
```

To propagate changes in a pw-template to existing BGP-AD pseudowires, it is necessary to use the following command:

```
tools perform service eval-pw-template policy-id
```

The allow-service-impact parameter is not required for changing the ingress or egress QoS definition as these do not affect the operational state of the pseudowire.

QoS applied directly to a pseudowire, using the preceding commands, takes precedence over any QoS applied to the network interface (using a network QoS policy with or without queue group redirection).

Each time a pseudowire uses a network egress port queue group, an FP resource is allocated. This only requires that the pseudowire egress QoS is configured with a port-redirect-group, and will occur even if there are no FCs redirected using a port-redirect-group within the configured network QoS policy. The resources used can be seen using the **tools dump system-resources** command and is listed under Egr Network Queue Group Mappings which is part of the total for the "Dynamic Service Entries ".

As an Epipe is used in this example, QoS is configured directly under a spoke SDP.

```
configure service
        epipe 1 customer 1 create
            spoke-sdp 1:1 vc-type vlan create
                ingress
                    qos 10 fp-redirect-group "ingress-queue-group" instance 1
                exit
                egress
                    qos 10 port-redirect-group "egress-queue-group" instance 1
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The created network QoS policy is applied at both ingress and egress, with the ingress referencing the ingress queue group instance applied to the FP and the egress referencing the egress queue group instance applied to the port.

Show Output

The configured ingress queue group can be shown, including the details of the configured policers and where it is applied, as follows.

Conclusion

This example has shown the configuration and monitoring of pseudowire QoS, providing a powerful QoS solution for pseudowire applications. QoS can be applied independently to the ingress and/or egress of a single pseudowire or multiple pseudowires.

QoS Architecture and Basic Operation

This chapter provides information about QoS architecture and basic operation.

Topics in this chapter include:

Applicability

The chapter was initially written for SR OS Release 9.0.R3. The CLI in the current edition corresponds to SR OS Release 14.0.R2.

Overview

The 7x50 platforms provide an extensive Quality of Service (QoS) capability for service provider solutions. QoS is a system behavior to provide different traffic with different amounts of resources, including buffer memory and queue serving time.

By allocating system resources with certain degrees of guarantee, the bandwidth can be used more efficiently and more controllably. Lack of buffer memory leads to packet drop, while a smaller amount of queue serving time normally means longer delay for the packet and may cause buffer memory to be completely consumed and eventually also lead to packet drop.

In a system, such as the 7x50 platform, different types of traffic contend for the same resources at several major points, such as the ingress to the switch fabric and the egress out of a physical port. In a multi-node network, QoS is achieved on hop by hop basis. Thus, QoS needs to be configured individually but with the consistency across the whole network.

This chapter is focused on the configuration of the basic QoS, namely the use of queues to shape traffic at the ingress and egress of the system. More sophisticated aspects will be referenced where appropriate but their details are beyond the scope of this chapter. Other topics not included are Hierarchical QoS scheduling, egress port-scheduler, queue-groups, named buffer pools, WRED-per-queue, LAGs, high scale MDA, QoS for ATM/FR and Enhanced Subscriber Management.

QoS Components

QoS consists of four main components:

- Classification
- Buffering (enqueuing)
- Scheduling (dequeuing)
- Remarking

These are also the fundamental building blocks of the QoS implementation in the 7x50. Ingress packets, classified by various rules, belong to one of eight Forwarding Classes (FC). An FC can be viewed a set of packets which are treated in a similar manner within the system (have the same priority level and scheduling behavior). Each FC has a queue associated with it and each queue has a set of parameters controlling how buffer memory is allocated for packets; if a packet is enqueued (placed on the queue) a scheduler will control the way the packet gets dequeued (removed from the queue) relative to other queues. When a packet exits an egress port, a remarking action can be taken to guarantee the next downstream device will properly handle the different types of traffic.

Configuration

Policies

QoS policies are used to control how traffic is handled at distinct points in the service delivery model within the device. There are different types of QoS policies catering to the different QoS needs at each point. QoS policies only take effect when applied to a relevant entity (Service Access Point (SAP) or network port/ interface) so by default can be seen as templates with each application instantiating a new set of related resources.

The following QoS policies are discussed:

- Ingress/egress QoS Policies — For classification, queue attributes and remarking.
- Slope policies — Define the RED slope definitions.
- Scheduler policies — Determine how queues are scheduled (only the default scheduling is included here).

Access, Network, and Hybrid Ports

The system has two different types of interfaces: access and network.

- A network interface will classify packets received from the network core at ingress and remark packets sent to the core at egress. Aggregated differentiated service QoS is performed on network ports, aggregating traffic from multiple services into a set of queues per FC.
- An access interface connects to one or more customer devices; it receives customer packets, classifies them into different FCs at ingress and remarks packets according to FCs at egress. Since an access interface needs application awareness, it has many more rules to classify the ingress packets. Access and network also differ in how buffer memory is handled, as will be made clear when discussing the buffer management. Here the QoS is performed per SAP.

Access interfaces (SAPs) are configured on access ports and network interfaces are configured on network ports. A third type of port is available, the hybrid port, which supports both access and network interfaces on the same port.

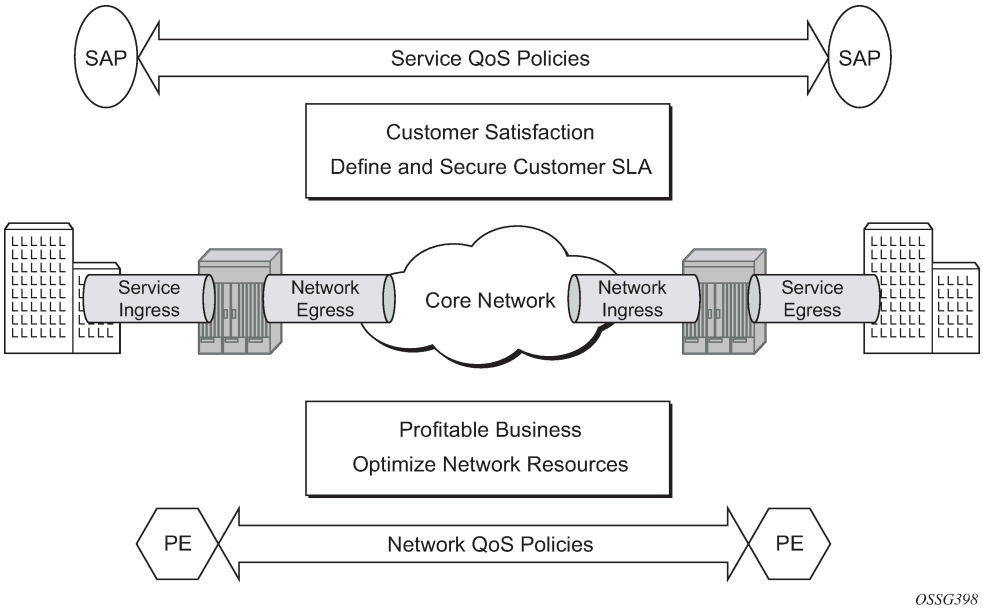
Hybrid ports are only supported on Ethernet ports and optionally with a single-chassis LAG. They must be configured to use VLANs (either single (dot1q encapsulation) or double (QinQ encapsulation) tagging) with each VLAN mapping to either the access or network part of the port. This allows the classification to associate incoming traffic with the correct port type and service. Port based traffic, such as LACP, CCM and EFM, uses a system queue on an access port, but the default network queues on a network or hybrid port.

Customer traffic follows the path shown below:

[service ingress → network egress]	→	[network ingress → network egress]	→	[network ingress → service egress]
ingress PE		transit P		egress PE

The network administrator needs to make sure that QoS is configured correctly at each point using the appropriate QoS policies (Figure 439: Service and Network QoS Policies).

Figure 439: Service and Network QoS Policies



Service Ingress QoS Policy

The SAP ingress policies are created in the **qos** context of the CLI and require a unique identifier (from 1 to 65535). The default **sap-ingress** policy has identifier 1.

Classification

Services can be delineated at the SAP ingress by

- A physical port (null encapsulated) or
- An encapsulation on the physical port, for example a VLAN ID on an Ethernet port or a DLCI on a Frame Relay port.

The following configuration is an example of an IES service created with an IP interface on VLAN 2 of port 3/2/10 (IOM 3, MDA 2, port 10) and has SAP ingress QoS policy 10 applied.

```
configure
    service
        ies 1 customer 1 create
            interface "int-access" create
```

```
                address 192.168.1.1/30
                sap 1/1/1:1 create
                    ingress
                        qos 10
                    exit
                exit
            exit
            no shutdown
        exit
```

As traffic enters the port, the service can be identified by the VLAN tag (and unwanted packets dropped). The ingress service QoS policy applied to the SAP maps traffic to FCs, and thus to queues, and sets the enqueuing priority. Mapping flows to FCs is controlled by comparing each packet to the match criteria in the QoS policy. The match criteria that can be used in ingress QoS policies can be combinations of those listed in Table 30: SAP Ingress Classification Match Criteria. When a packet matches two criteria (802.1p priority and DSCP) it is the lowest precedence value that is used to map the packet to the FC.

Table 30: SAP Ingress Classification Match Criteria

Match Precedence	Match Criteria		
1	IPv4 fields match criteria: • Destination IP address/prefix including prefix list • Destination port/range • DSCP value • IP fragment • Protocol type (TCP, UDP, etc.) • Source port/range • Source IP address/prefix including prefix list	IPv6 fields match criteria: • Destination IP address/prefix • Destination port/range • DSCP value • Next header • Source port/range • Source IP address/prefix	MAC fields match criteria: • Frame type [802dot3|802dot2-llc|802dot2-snap|ethernetII|atm] • ATM VCI value • IEEE 802.1p value/mask • Source MAC address/mask • Destination MAC address/mask • EtherType value • IEEE 802.2 LLC SSAP value/mask • IEEE 802.2 LLC DSAP value/mask • IEEE 802.3 LLC SNAP OUI zero or non-zero value • IEEE 802.3 LLC SNAP PID value
	Note: For an ingress QoS policy, either IP match criteria or MAC match criteria can be defined, not both.		
2	DSCP		
3	IP precedence		
4	LSP EXP		
5	IEEE 802.1p priority and/or Drop Eligibility Indicator (DEI)		

Match Precedence	Match Criteria
6	Default forwarding class for non-matching traffic

It is possible to match MAC criteria on VPLS/Epipe SAPs and IP criteria on IP interface SAPs. However, it is also possible to classify on MAC criteria on an IP interface SAP and conversely to classify on IP criteria on VPLS/Epipe SAPs. When MPLS labeled traffic is received on a VPLS/Epipe SAP, it is possible to match on either of the LSP EXP bits (outer label) or the MAC criteria.

A SAP can be configured to have no VLAN tag (null encapsulated), one VLAN tag (dot1q encapsulated) or two VLAN tags (QinQ encapsulated). The configuration allows the selection of which VLAN tag to match against for the 802.1p bits, using the keyword **match-qinq-dot1p** with the keyword **top** or **bottom**.

The following example configuration shows match QinQ traffic with dot1p value 1 in the top VLAN tag entering the QinQ SAP in Epipe service 1 and assign it to FC *af* using queue 2.

```
configure
    qos
        sap-ingress 10 create
            queue 2 create
            exit
            fc "af" create
                queue 2
            exit
            dot1p 1 fc "af"
        exit
```

```
configure
    service
        epipe 2 customer 1 create
            sap 1/1/2:1.2 create
                ingress
                    qos 10
                exit
                ingress
                    match-qinq-dot1p top
                exit
            exit
            no shutdown
        exit
```

The classification of traffic using the default, **top** and **bottom** keyword parameters is summarized in Table 31: QinQ Dot1p Bit Classification . A TopQ SAP is a QinQ SAP where only the outer (top) VLAN tag is explicitly specified (sap 1/1/1:10.* or sap 1/1/1:10.0).

Table 31: QinQ Dot1p Bit Classification

Port/SAP Type	Existing Packet Tags	Pbits Used for Match		
		Default	Match Top	Match Bottom
Null	None	None	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits	Dot1P PBits	Dot1P PBits

Port/SAP Type	Existing Packet Tags	Pbits Used for Match		
		Default	Match Top	Match Bottom
Null	Dot1Q	Dot1Q PBits	Dot1Q PBits	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits	TopQ PBits	BottomQ PBits
Null	TopQ (No BottomQ)	TopQ PBits	TopQ PBits	TopQ PBits
Dot1Q	None (Default SAP)	None	None	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits	Dot1P PBits	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits	Dot1Q PBits	Dot1Q PBits
QinQ/TopQ	TopQ	TopQ PBits	TopQ PBits	TopQ PBits
QinQ/TopQ	TopQ BottomQ	TopQ PBits	TopQ PBits	BottomQ PBits
QinQ/QinQ	TopQ BottomQ	BottomQ PBits	TopQ PBits	BottomQ Pbits

The Drop Eligibility Indicator (DEI) bit (IEEE 802.1ad-2005 and IEEE 802.1ah (PBB)) can be used to indicate the in/out profile state of the packet, this will be covered later in the discussion on profile mode.

Ingress traffic with a local destination (for example, OSPF hellos) is classified by the system automatically and uses a set of dedicated system queues.

After the traffic has been classified, the next step is to assign it to a given FC. There are 8 pre-defined FCs within the system which are shown in Table 33: Queue Priority vs. Profile Mode (the FC identifiers are keywords and do not have a fixed relationfship with the associated Differentiated Services Code Points (DSCP)).

Table 32: Forwarding Classes

FC Identifier	FC Name	Default Scheduling Priority
NC	Network Control	Expedited
H1	High-1	Expedited
EF	Expedited	Expedited
H2	High-2	Expedited
L1	Low-1	Best Effort
AF	Assured	Best Effort
L2	Low-2	Best Effort
BE	Best Effort	Best Effort

When an FC is configured for a classification, it must first be created in the configuration. One of the FCs can be also configured to be the default in case there is no explicit classification match and by default this FC is *be*.

Normally, once traffic is assigned to an FC at the ingress it remains in that FC throughout its time within the system. Re-classification of IP traffic at a SAP egress is possible, but is beyond the scope of this chapter. The FC used at egress can also be specified to be different than that used at ingress by configuring **egress-fc** under the FC configuration in the SAP ingress policy.

Packets also have a state of being in-profile or out-of-profile which represents their drop precedence within the system, therefore there can be up to 8 distinct per hop behavior (PHB) classes with two drop precedences.

Buffering (Enqueuing)

Once a packet is assigned to a certain forwarding class, it will try to get a buffer in order to be enqueued. Whether the packet can get a buffer is determined by the instantaneous buffer utilization and several attributes of the queue (such as Maximum Burst Size (MBS), Committed Burst Size (CBS) and high-prio-only) that will be discussed in more detail later in this chapter. If a packet cannot get a buffer for whatever reason, the packet will get dropped immediately.

As traffic is classified at the SAP ingress it is also assigned an enqueuing priority, which can be high or low. This governs the likelihood of a packet being accepted into a buffer and so onto a queue, and is managed using the queue's high-prio-only parameter and the buffer pools weighted random early detection (WRED) slope policies. Traffic having a high enqueuing priority has more chance of getting a buffer than traffic with low enqueuing priority. The enqueuing priority is specified with the classification using the parameter **priority**, and a default enqueuing priority can be configured, its default being low.

Enqueuing priority is a property of a packet and should not to be confused with scheduling priority, expedited or best-effort, which is a property of a queue.

The following configuration shows an example where all packets with dot1p value 3 are classified as *ef* and have their enqueuing priority set to high, while all other packets are classified as *af* with a low enqueuing priority.

```
configure
    qos
        sap-ingress 10 create
            fc "af" create
            exit
            fc "ef" create
            exit
            dot1p 3 fc "ef" priority high
            default-fc "af"
            default-priority low # this is the default
        exit
```

Each forwarding class is associated with at most one unicast queue. In the case of a VPLS service, each FC can also be assigned a single multipoint queue at ingress, or for more granular control, separate queues for broadcast, multicast and unknown traffic. Since each queue maintains forward/drop statistics, it allows the network operator to easily track unicast, broadcast, multicast and unknown traffic load per forwarding class. Separate multicast queues can also be assigned for IES/VPRN services which have IP multicast enabled.

This results in an Epipe SAP having up to 8 ingress queues, an IES/VPRN SAP having up to 16 ingress queues and a VPLS SAP having up to 32 ingress queues. Each queue has a locally significant (to the policy) identifier, which can be from 1 to 32.

The default SAP ingress QoS policy (id=1) has two queues; queue 1 for unicast traffic and queue 11 for multipoint traffic, and is assigned to every ingress SAP at service creation time. Equally, when a new (non-default) SAP ingress policy is created, queue 1 and queue 11 are automatically created with all FCs assigned to both by default. Additional queues must be created before being assigned to a FC, with multipoint queues requiring the **multipoint** keyword. When a SAP ingress policy is applied to a SAP, physical hardware queues on the FP are allocated for each queue with a FC assigned (if no QoS policy is explicitly configured, the default policy is applied). Multipoint queues within the SAP ingress policy are ignored when applied to an Epipe SAP or an IES/VPRN SAP which is not configured for IP multicast.

The mechanism described here uses a separate set of queues per SAP. For cases where per-SAP queuing is not required it is possible to use port based queues, known as **queue-groups**, which reduces the number of queues required, as described in chapter *FP and Port Queue Groups*.

Scheduling (Dequeuing)

A queue has a priority which affects the relative scheduling of packets from it compared to other queues. There are two queue priorities: expedited and best-effort, with expedited being the higher. When creating a queue, one of these priorities can be configured, thereby explicitly setting the queue's priority. Alternatively, the default is auto-expedite in which case the queue's priority is governed by the FCs assigned to it, as shown in Table 32: Forwarding Classes. If there is a mix of expedited and best-effort FCs assigned, the queue is deemed to be best-effort.

The following configuration displays an example that ensures that EF traffic is treated as expedited by assigning it to new unicast and multicast queues.

```
configure
    qos
        sap-ingress 10 create
            queue 3 expedite create
            exit
            queue 13 multipoint expedite create
            exit
            fc "ef" create
                queue 3
                multicast-queue 13
            exit
            default-fc "ef"
        exit
```

Once a packet gets a buffer and is queued, it will wait to be served and sent through the switch fabric to its destination port by the hardware scheduler. There are two scheduler priorities: expedited or best-effort, corresponding to the queue's priority. The expedited hardware schedulers are used to enforce priority access to internal switch fabric destinations with expedited queues having a higher preference than best-effort queues. Queues of the same priority get equally serviced in round robin fashion by the associated scheduler.

When a queue gets its turn to be serviced, the scheduler will use the operational Peak Information Rate (PIR) and Committed Information Rate (CIR) attributes of the queue to determine what to do with the packet.

- The scheduler does not allow queues to exceed their configured PIR. If the packet arrival rate for a given queue is higher than the rate at which it is drained, the queue will fill. If the queue size (in bytes or Kbytes) reaches its defined MBS all subsequent packets will be discarded, this is known as tail drop.
- If the dequeue rate is below or equal to the operational CIR, the packet will be forwarded and marked as **in-profile**.
- If the dequeue rate is below or equal to the operational PIR but higher than the CIR, the packet will be forwarded but marked as **out-of-profile**.

Out-of-profile packets have a higher probability of being dropped when there is congestion somewhere in the downstream path. Packets that are marked as out-of-profile will also be treated differently at the network egress and service egress.

These marking actions are known as color marking (green for in-profile and yellow for out-of-profile). Using the default queue setting of **priority-mode**, as described above, the in/out-of-profile state of a packet is determined from the queue scheduling state (within CIR or above CIR, as described later) at the time that the packet is dequeued. An alternative queue mode is **profile-mode**.

Profile Mode

A queue is created with profile mode when the aim is that the in/out-of-profile state of packets is determined by the QoS bits of the incoming packets, this is known as color-aware (as opposed to color-unaware for priority mode).

As part of the classification, the profile state of the packets is explicitly configured. To provide granular control, it is possible to configure FC sub-classes with each having a different profile state, while inheriting the other parameters from their parent FC (for example the queue, in order to avoid out of order packets). The FC subclasses are named *fc.sub-class*, where *sub-class* is a text string up to 29 characters (though normally the words *in* and *out* are used for clarity). Any traffic classified without an explicit profile state is treated as if the queue were in priority mode.

When using the profile mode, the DEI in the Ethernet header can be used to classify a packet as in-profile (DEI=0) or out-of-profile (DEI=1).

The following configuration shows traffic with dot1p 3 is set to in-profile, dot1p 2 to out-of-profile and the profile state of dot1p 0 depends on the scheduling state of the queue.

```
configure
    qos
        sap-ingress 20 create
            queue 2 profile-mode create
            exit
            fc "af" create
                queue 2
            exit
            fc "af.in" create
                profile in
            exit
            fc "af.out" create
                profile out
            exit
            dot1p 0 fc "af"
            dot1p 2 fc "af.out"
            dot1p 3 fc "af.in"
        exit
```

The difference between a queue configured in priority (default) and profile mode is summarized in Table 33: Queue Priority vs. Profile Mode (within/above CIR is described later).

Table 33: Queue Priority vs. Profile Mode

	Priority Mode	**Profile Mode**
Packet In-Profile/ Out-of-Profile state	Determined by state of the queue at scheduling time. Within CIR – In Profile Above CIR – Out Profile	Explicitly stated in FC or subclass classification. If not, then defaults to state of the queue at scheduling time
Packet High/Low Enqueuing Priority	Explicitly stated in FC classification. If not, then defaults to Low priority	Always follows state of in-profile/out-of-profile determined above In-profile = High Priority Out-Profile = Low Priority If not set = High Priority

Remarking

Remarking at the service ingress is possible when using an IES or VPRN service. The DSCP/precedence field can be remarked for in-profile (**in-remark**) and out-of-profile (**out-remark**) traffic as defined above for queues in either priority mode or profile mode. If configured for other services, the remarking is ignored. If remarking is performed at the service ingress, then the traffic is not subject to any egress remarking on the same system.

The following configuration displays an example classifying traffic to 10.0.0.0/8 as FC *ef* in-profile and remark its DSCP to *ef*.

```
configure
    qos
        sap-ingress 30 create
            queue 2 profile-mode create
            exit
            fc "ef" create
                queue 2
                in-remark dscp ef
                profile in
            exit
            ip-criteria
                entry 10 create
                    match
                        dst-ip 10.0.0.0/8
                    exit
                    action fc "ef"
                exit
            exit
        exit
```

Service Egress QoS Policy

The service egress uses a SAP egress QoS policy to define how FCs map to queues and how a packet of an FC is remarked. SAP egress policies are created in the CLI qos context and require a unique identifier (from 1 to 65535). The default SAP egress policy has identifier 1.

Once a service packet is delivered to the egress SAP, it has following attributes:

- Forwarding class, determined from classification at the ingress of the node.
- In/out-of-profile state from the service ingress or network ingress.

Similar to the service ingress enqueuing process, it is possible that a packet cannot get a buffer and thus gets dropped. Once on an egress queue, a packet is scheduled from the queue based on priority of the queue (expedited or best-effort) and the scheduling state with respect to the CIR/PIR rates (the profile state of the packet [in/out] is not modified here). Egress queues do not have a priority/profile mode and have no concept of multipoint.

Only one queue exists in the default SAP egress QoS policy (id=1) and also when a new **sap-egress** policy is created, this being queue 1 which is used for both unicast traffic and multipoint traffic. All FCs are assigned to this queue unless otherwise explicitly configured to a different configured queue. When a SAP egress policy is applied to a SAP, physical hardware queues on the FP are allocated for each queue with FC assigned (if no QoS policy is explicitly configured, the default policy is applied).

As mentioned earlier, re-classification at a SAP egress is possible based on the packet's dot1p, DSCP or precedence values or using IP or IPv6 criteria matching, similar to the functionality at SAP ingress.

SAP egress also supports two additional profiles, inplus-profile and exceed-profile. Both can be assigned to a packet using egress reclassification and the exceed-profile can be assigned to a packet in an egress policer configured with the **enable-exceed-pir** command.

Traffic originated by the system (known as self generated traffic) has its FC and marking configured under router/sgt-qos (for the base routing) or under service/vprn/sgt-qos (for a VPRN service). This is beyond the scope of this chapter.

Remarking

At the service egress, the dot1p/DEI can be remarked for any service per FC with separate marking for in/out/exceed profile if required (inplus-profile packets are marked with the same value as in-profile packets and exceed-profile packets are marked with the same value as out-of-profile packets if not explicitly configured). The DEI bit can also be forced to a specific value (using the **de-mark force** command). When no **dot1p/de-mark** is configured, the ingress dot1p/DEI is preserved; if the ingress was untagged, the dot1p/DEI bit is set to 0.

The following configuration shows a remark example with different FCs with different dot1p values. FC *af* also differentiates between in/out-of-profile and then remarks the DEI bit accordingly based on the packet's profile.

```
configure
    qos
        sap-egress 10 create
            queue 1 create
                rate 20000
            exit
            queue 2 create
                rate 10000 cir 5000
            exit
            queue 3 create
```

```
                rate 2000 cir 2000
            exit
            fc af create
                queue 2
                dot1p in-profile 3 out-profile 2
                de-mark
            exit
            fc be create
                queue 1
                dot1p 0
            exit
            fc ef create
                queue 3
                dot1p 5
            exit
        exit
```

If QinQ encapsulation is used, the default is to remark both tags in the same way. However, it is also possible to remark only the top tag using the **qinq-mark-top-only** parameter configured under the SAP egress.

The following configuration shows a remark example with only the dot1p/DEI bits in top tag of a QinQ SAP.

```
configure
    service
        vpls 3 customer 1 create
            sap 1/1/2:2.2 create
                egress
                    qos 20
                    qinq-mark-top-only
                exit
            exit
            no shutdown
        exit
```

For IES and VPRN services, the DSCP/precedence field can also be remarked based on the in/out/exceed-profile state (with inplus-profile packets marked with the same values as in-profile packets, and exceed-profile packets marked with the same value as out-of-profile packets if not explicitly configured) of the packets (and only if no ingress remarking was performed).

The following configuration shows DSCP values for FC *af* based on in/out-of-profile traffic.

```
configure
    qos
        sap-egress 20 create
            queue 2 create
            exit
            fc af create
                queue 2
                dscp in-profile af41 out-profile af43
            exit
        exit
```

Network Ports

The QoS policies relating to the network ports are divided into a network and a network-queue policy. The network policy covers the ingress and egress classification into FCs and the egress remarking based on FCs, while the network-queue policy covers the queues parameters and the FC to queue mapping. The

logic behind this is that there is only one set of queues provisioned on a network port, whereas the use of these queues is configured per network IP interface. This in turn determines where the two policies can be applied. Network ports are used for IP routing and switching, and for GRE/MPLS tunneling.

Network QoS Policy

The network QoS policy has an ingress section and an egress section. It is created in the **qos** context of the CLI and requires a unique identifier (from 1 to 65535). The default network policy has identifier 1. Network QoS policies are applied to IP interfaces configured on a network port.

The following configuration shows an example to apply different network QoS policies to two network interfaces.

```
configure
    router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/3:1
            qos 28
        exit
        interface "int-PE-1-PE-3"
            address 192.168.13.1/30
            port 1/1/4
            qos 18
        exit
```

Classification

Classification is available at both ingress and egress.

The ingress section defines the classification rules for IP/MPLS packets received on a network IP interface. The rules for classifying traffic are based on the incoming QoS bits (Dot1p, DSCP, EXP [MPLS experimental bits]). The order in which classification occurs relative to these fields is:

1. IPv4 and IPv6 match criteria for IP packets
2. EXP (for MPLS packets) or DSCP (for IP packets) Dot1p/DEI bit (network ports do not support QinQ encapsulation)
3. default action (default = fc be profile out)

The configuration specifies the QoS bits to match against the incoming traffic together with the FC and profile (in/out) to be used (it is analogous to the SAP profile-mode in that the profile of the traffic is determined from the incoming traffic, rather than the CIR configured on the queue). A **default-action** keyword configures a default FC and profile state.

The IPv4 and IPv6 criteria matching only applies to the outer IP header of *non-tunneled* traffic, except for traffic received on an RFC 6037 MVPN tunnel for which classification on the outer IP header only is supported, and is only supported on network interfaces.

For tunneled traffic (GRE or MPLS), the match is based on the outer encapsulation header unless the keyword **ler-use-dscp** is configured. In this case, traffic received on the router terminating the tunnel that is to be routed to the base router or a VPRN destination is classified based on the encapsulated packet DSCP value (assuming it is an IP packet) rather than its EXP bits.

The ability exists for an egress LER to signal an implicit-null label (numeric value 3). This informs the previous hop to send MPLS packets without an outer label and so is known as penultimate hop popping

(PHP). This can result in MPLS traffic being received at the termination of an LSP without any MPLS labels. In general, this would only be the case for IP encapsulated traffic, in which case the egress LER would need to classify the incoming traffic using IP criteria.

The egress section also defines the classification rules based on both the DSCP and precedence values in a packet to re-assign the packet's FC and profile (inplus/in/out/exceed).

Remarking

The egress section of the network policy defines the remarking of the egress packets, there is no remarking possible at the network ingress. The egress remarking is configured per FC and can set the related dot1p/DEI (explicitly or dependent on in/out-of-profile), DSCP (dependent on in/out-of-profile) and EXP (dependent on in/out-of-profile; inplus-profile packets are marked with the same values as in-profile packets and exceed-profile packets are marked with the same value as out-of-profile packets).

The traffic exiting a network port is either tunneled (in GRE or MPLS) or IP routed.

For tunneled traffic exiting a network port, the remarking applies to the DSCP/EXP bits in any tunnel encapsulation headers (GRE/MPLS) pushed onto the packet by this system, together with the associated dot1p/DEI bits if the traffic has an outer VLAN tag. For MPLS tunnels, the EXP bits in the entire label stack are remarked.

Note:
Strictly speaking this is marking (as opposed to remarking) as the action is adding QoS information rather than changing it.

A new outer encapsulation header is pushed onto traffic at each MPLS transit label switched router as part of the label swap operation.

For VPLS/Epipe services no additional remarking is possible. However, for IES/VPRN/base-routing traffic, the remarking capabilities at the network egress are different at the first network egress (egress on the system on which the traffic entered by a SAP ingress) and subsequent network egress in the network (egress on the systems on which the traffic entered through another network interface).

At the first network egress, the DSCP of the routed/tunneled IP packet can be remarked, but this is dependent on two configuration settings:

- The trusted state of the ingress (service/network) interface and
- The **remarking** keyword in the network QoS policy at the network egress. The configuration combinations are summarized in Table 34: Network QoS Policy DSCP Remarking .

This is in addition to the remarking of any encapsulation headers and, as stated earlier, is not performed if the traffic was remarked at the service ingress.

For traffic exiting a subsequent network egress in the network, only the IP routed traffic can be remarked, again this is dependent on the ingress trusted state and egress remarking parameter.

There is one addition to the above to handle the marking for IP-VPN Option-B in order to remark the EXP, DSCP and dot1p/DEI bits at a network egress, this being **remarking force**. Without this, only the EXP and dot1p/DEI bits are remarked. This does not apply to label switched path traffic switched at a label switched router.

Table 34: Network QoS Policy DSCP Remarking

Ingress	Trusted State	Remarking Configuration	Marking Performed
IES	Untrusted (default)	remarking	Yes
		no remarking (default)	Yes
	Trusted	remarking	Yes
		no remarking (default)	No
Network	Untrusted	remarking	Yes
		no remarking (default)	Yes
	Trusted (default)	remarking	Yes
		no remarking (default)	No
VPRN	Untrusted	remarking	Yes
		no remarking (default)	Yes
	Trusted (default)	remarking	No
		no remarking (default)	No

The following configuration shows a ingress network classification for DSCP EF explicitly, with a default action for the remainder of the traffic and use the DSCP from the encapsulated IP packet if terminating a tunnel. Remark the DSCP values for FC *af* and *ef* and remark all traffic (except incoming VPRN traffic) at the egress. Apply this policy to a network interface.

```
configure
    qos
        network 20 create
            ingress
                default-action fc af profile out
                ler-use-dscp
                dscp ef fc ef profile in
            exit
            egress
                remarking
                fc af
                    no dscp-in-profile
                    dscp-out-profile af13
                    lsp-exp-in-profile 6
                    lsp-exp-out-profile 5
                exit
                fc ef
                    dscp-in-profile af41
                exit
            exit
        exit

configure
    router
        interface "int-PE-1-PE-4"
```

```
            address 192.168.14.1/30
            port 1/2/1
            qos 20
        exit
```

The following configuration shows the trusted IES interface.

```
configure
    service
        ies 1 customer 1 create
            interface "int-access" create
                address 192.168.1.1/30
                tos-marking-state trusted
                sap 1/1/1:1 create
                exit
            exit
            no shutdown
        exit
```

The network QoS ingress and egress sections also contain the configuration for the use of FP-based policers and port-based queues by queue-groups which are out of scope of this chapter.

Network Queue Policy

The network queue QoS policy defines the queues and their parameters together with the FC to queue mapping. The policies are named, with the default policy having the name *default*. Network queues policies are applied under **config>card>mda>network>ingress** for the network ingress queues though only one policy is supported per MDA, so when a new policy is applied under one MDA, it is automatically applied under the other MDA on the same FP. At egress, network queue policies are applied under Ethernet: **config>port>ethernet>network**, POS: **config>port>sonet-sdh>path>network**, TDM: **config>port>tdm>e3|ds3>network** for the egress.

The following configuration shows an ingress and egress network-queue policy.

```
configure
    card 1
        card-type iom3-xp
        mda 1
            mda-type m4-10gb-xp-xfp
            network
                ingress
                    queue-policy "network-queue-1"
                exit
            exit
            no shutdown
        exit

configure
    port 1/1/3
        ethernet
            encap-type dot1q
            network
                queue-policy "network-queue-1"
            exit
        exit
        no shutdown
    exit
```

Up to 16 queues can be configured in a network-queue policy, each with a queue-type of best-effort, expedite, or auto-expedite. A new network-queue policy contains two queues, queue 1 for unicast traffic and queue 9 for multipoint traffic and by default all FCs are mapped to these queues. There is no differentiation for broadcast, multicast and unknown traffic. If the policy is applied to the egress, then any multipoint queues are ignored. As there are 8 FCs, there would be up to 8 unicast queues and 8 multipoint queues, resulting in 16 ingress queues and 8 egress queues. Normally, the network queue configuration is symmetric (the same queues/FC-mapping at the ingress and egress).

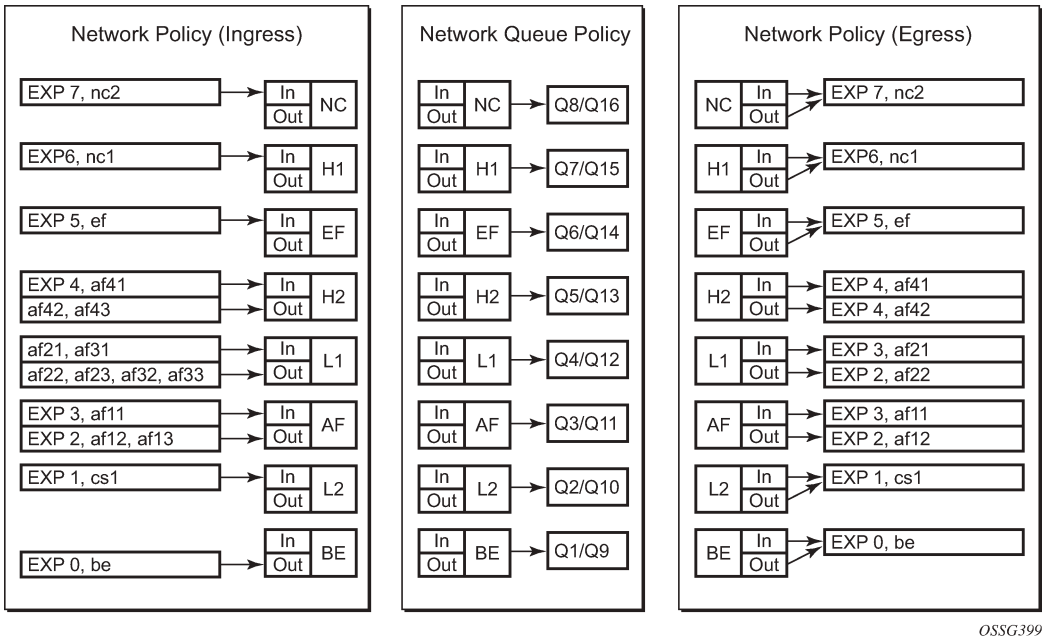
The following configuration defines a network-queue policy with FC *af* and *ef* assigned to queues 2 and 3 for unicast traffic, and queue 9 for multipoint traffic.

```
configure qos
        network-queue "network-queue-1" create
            queue 1 create
                mbs 50
                high-prio-only 10
            exit
            queue 2 create
            exit
            queue 3 create
            exit
            queue 9 multipoint create
                mbs 50
                high-prio-only 10
            exit
            fc af create
                multicast-queue 9
                queue 2
            exit
            fc ef create
                multicast-queue 9
                queue 3
            exit
        exit
```

Summary of Network Policies

Figure 440: Visualization of Default Network Policies displays the default network policies with respect to classification, FC to queue mapping and remarking.

Figure 440: Visualization of Default Network Policies



Queue Management

The policies described so far define queues but not the characteristics of those queues which determine how they behave. This section describes the detailed configuration associated with these queues. There are two aspects:

- Enqueuing packets onto a queue
  - buffer pools
  - queue sizing
  - Weighted Random Early Detection (WRED)
- Dequeuing packets from a queue
  - queue rates
  - scheduling

Enqueuing Packets: Buffer Pools

The packet buffer space is divided equally between ingress and egress. For line cards using a 50G FP2 for both ingress and egress traffic, the proportion of ingress versus egress buffer space can be modified using the following command:

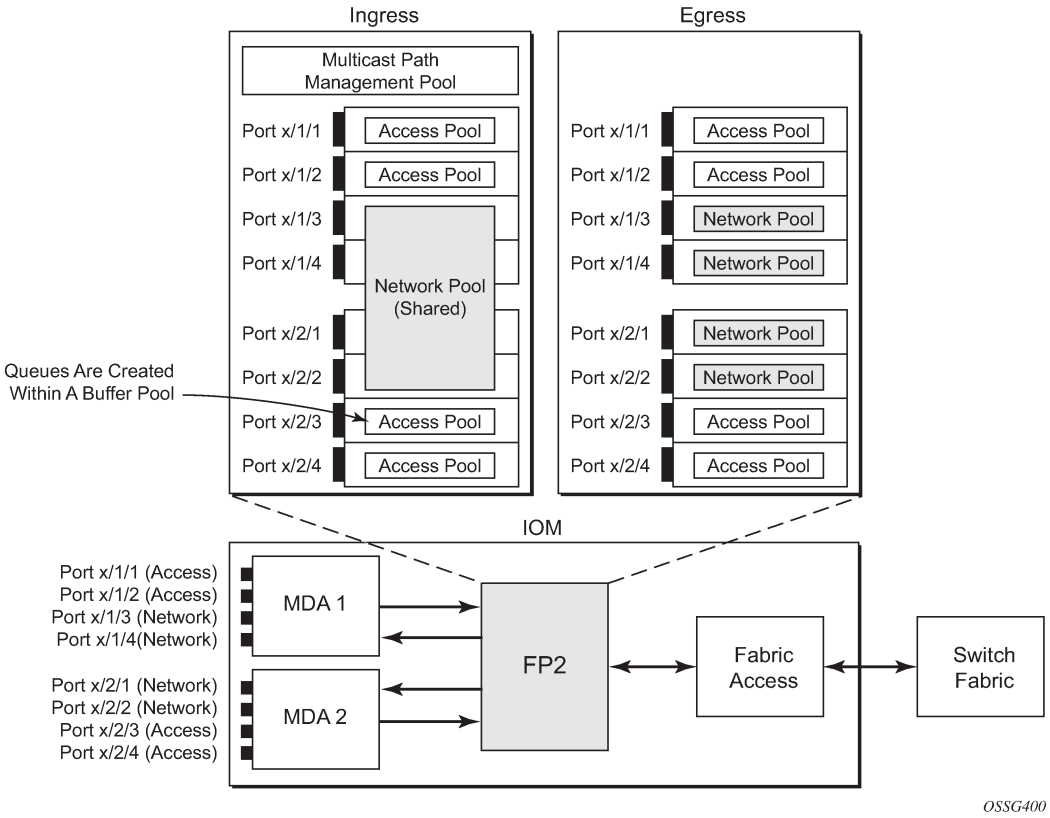
```
configure
    card <slot-number>
        ingress-buffer-allocation <percentage>
```

The ingress buffer allocation percentage can be configured from 20% up to 80%.

Beyond that, by default there is one pool for network ingress per FP2/IOM, with one pool per access ingress port and one pool per access/network egress port. This is shown in Figure 441: Default Buffer Pools. This segregation provides isolation against buffer starvation between the separate pools. An additional ingress pool exists for managed multicast traffic (the multicast path management pool) but this is beyond the scope of this chapter.

The buffer management can be modified using named buffer pools and/or WRED-per-queue pools which are out of scope of this chapter.

Figure 441: Default Buffer Pools



The size of the pools is based on the MDA type and the speed/type (access or network) of each port. Buffer space is allocated in proportion to the active bandwidth of each port, which is dependent on:

- The actual speed of the port
- Bandwidth for configured channels only (on channelized cards)
- Zero for ports without queues configured

This calculation can be tuned separately for ingress and egress, without modifying the actual port speed, using the port/modify-buffer-allocation-rate. Changing the port's ingress-rate or egress-rate will also modify its buffer sizes.

The following configuration changes the relative size for the ingress/egress buffer space on port 1/1/10 to 50% of the default.

```
configure
    port 1/1/3
```

```
        modify-buffer-allocation-rate
            ing-percentage-of-rate 50
            egr-percentage-of-rate 50
        exit
```

Each of the buffer pools created is further divided into a section of reserved buffers and another of shared buffers, see Figure 443: Ingress Buffer Pools and Queue Sizing. The amount of reserved buffers is calculated differently for network and access pools. For network pools, the default is approximately the sum of the CBS (committed burst size) values defined for all of the queues within the pool. The reserved buffer size can also be statically configured to a percentage of the full pool size (ingress: **config>card>mda>network>ingress>pool**; egress: **config>port>network>egress>pool**). For access pools, the default reserved buffer size is 30% of the full pool size and can be set statically to an explicit value (ingress: **config>port>access>ingress>pool**; egress: **config>port>access>egress>pool**).

The following configuration sets the reserved buffer size to 50% of the egress pool space on a network port.

```
configure
    port 1/1/3
        network
            egress
                pool
                    resv-cbs 50
                exit
            exit
        exit
```

On an access port, the reserved buffer size is set to 50% of the egress pool space, as follows:

```
configure
    port 1/1/1
        access
            egress
                pool
                    resv-cbs 50
                exit
            exit
        exit
```

Both the total buffer and the reserved buffer sizes are allocated in blocks (discrete values of Kbytes). The pool sizes can be seen using the **show pools** command.

It is possible to configure alarms to be triggered when the usage of the reserved buffers in the buffer pools reaches a certain percentage. Two alarm percentages are configurable, amber and red, **amber-alarm-threshold** <*percentage*> and **red-alarm-threshold** <*percentage*>. The percentage range is 1 — 1000.

- The percentage for the red must be at least as large as that for the amber.
- The alarms are cleared when the reserved CBS drops below the related threshold.
- When the amber alarm is enabled, dynamic reserved buffer sizing can be used; after the amber alarm is triggered the reserved buffer size is increased or decreased depending on the CBS usage. This requires a non-default resv-cbs to be configured together with a step and max value for the amber-alarm-action parameters. As the reserved CBS usage increases above the amber alarm percentage, the reserved buffer size is increased in increments defined by the step, up to a maximum of the max. If the CBS usage decreases, the reserved buffer size is reduced in steps down to its configured size.

- As the reserved buffer size changes, alarms will continue to be triggered at the same color (amber or red) indicating the new reserved buffer size. The pool sizing is checked at intervals, so it can take up to one minute for the alarms and pool re-sizing to occur.

The following displays a configuration for access ingress and egress pools.

```
configure
    port 1/1/1
        access
            ingress
                pool
                    amber-alarm-threshold 25
                    red-alarm-threshold 50
                    resv-cbs 20 amber-alarm-action step 5 max 50
                exit
            exit
            egress
                pool
                    amber-alarm-threshold 25
                    red-alarm-threshold 25
                    resv-cbs 20 amber-alarm-action step 5 max 50
                exit
            exit
        exit
```

The following is an example alarm that is triggered when the amber percentage has been exceeded and the reserved buffer size has increased from 20% to 25%:

```
82 2016/04/25 14:21:52.42 UTC MINOR: PORT #2050 Base Resv CBS Alarm
"Amber Alarm: CBS over Amber threshold: ObjType=port Owner=1/1/1 Type=accessIngress
 Pool=default NamedPoolPolicy= ResvSize=672 SumOfQ ResvSize=138 Old ResvCBS=20
New ResvCBS=25 Old ResvSize=528"
```

When a port is configured to be a hybrid port, its buffer space is divided into an access portion and a network portion. The split by default is 50:50 but it can be configured on a per port basis.

```
configure port 1/1/1
        ethernet
            mode hybrid
            encap-type dot1q
        exit
        hybrid-buffer-allocation
            ing-weight access 70 network 30
            egr-weight access 70 network 30
        exit
```

Enqueuing Packets: Queue Sizing

Queue sizes change dynamically when packets are added to a queue faster than they are removed, without any traffic the queue depth is zero. When packets arrive for a queue there will be request for buffer memory which will result in buffers being allocated dynamically from the buffer pool that the queue belongs to.

A queue has four buffer size related attributes: MBS, CBS, high-prio-only, and hi-low-prio-only, which affect packets only during the enqueuing process.

- Maximum Burst Size (MBS) defines the maximum buffer size that a queue can use. If the actual queue depth is larger than the MBS, any incoming packet will not be able to get a buffer and the packet will be

dropped. This is defined in bytes or Kbytes for access queues with a configurable non-zero minimum of 1byte or a default (without configuring the MBS) of the maximum between 10ms of the PIR or 64Kbytes. A value of zero will cause all packets to be dropped. MBS is a fractional percentage (xx.xx%) of pool size for network queues with defaults varying dependent on the queue (see default network-queue policy for default values). The MBS setting is the main factor determining the packet latency through a system when packets experience congestion. Queues within an egress queue group can have their MBS configured with as target packet queue delay in milliseconds.

- Committed Burst Size (CBS) defines the maximum guaranteed buffer size for an incoming packet. This buffer space is effectively reserved for this queue as long as the CBS is not oversubscribed (such the sum of the CBS for all queues using this pool does not exceed its reserved buffer pool size). For access queues, the CBS is defined in Kbytes with a configurable non-zero minimum of 6Kbytes or a default (without configuring the CBS) of the maximum between 10ms of the CIR or 6Kbytes. It is a fractional percentage (xx.xx%) of pool size for network queues with defaults varying dependent on the queue (see default network-queue policy for default values). Regardless of what is configured, the CBS attained normally will not be larger than the MBS. One case where CBS could be configured larger than MBS is for queues on LAGs, because in some cases the CBS is shared among the LAG ports (LAG QoS is not covered in this chapter). If the MBS and CBS values are configured to be equal (or nearly equal) this will result in the CBS being slightly higher than the value configured.
- High-prio-only. As a queue can accept both high and low enqueuing priority packets, a high enqueuing priority packet should have a higher probability to get a buffer. High-prio-only is a way to achieve this. Within the MBS, high-prio-only defines that a certain amount of buffer space will be exclusively available for high enqueuing priority packets. At network ingress and all egress buffering, highpriority corresponds to in-profile and low priority to out-of-profile. At service ingress, enqueuing priority is part of the classification. The high-prio-only is defined as a percentage of the MBS, with the default being 10%. A queue being used only for low priority/out-of-profile packets would normally have this set to zero. The high-prio-only could be considered to be an MBS for low enqueuing/out-of-profile packets.
- Hi-low-prio-only. There is an additional threshold, hi-low-prio-only, at egress which is equivalent to an MBS for exceed-profile packet. When the queue depth is beyond the hi-low-prio-only depth, the exceed-profile packets are dropped. The hi-low-prio-only is defined as a percentage of the MBS, with the default being 20%.

As with the buffer pools, the MBS, CBS, high-prio-only, and hi-low-prio-only values attained are based on a number of discrete values (not always an increment of 3Kbytes). The values for these parameters can be seen using the **show pools** command.

The MBS changes dynamically for queues in an egress queue group when H-QoS is used and the queue command **dynamic-mbs** is configured. This results in the MBS being modified in the ratio of the operational PIR to the admin PIR which derives an operational MBS. The ratio also affects the high-prio-only and hi-low-prio-only drop tails, and the WRED slopes if a slope policy is applied ot the queue. The configured CBS is used as the minimum operational MBS and the maximum MBS is capped by the maximum admin MBS (1GB).

As packets are added to a queue they will use the available CBS space, in which case they are placed in the reserved portion in the buffer pool. Once the CBS is exhausted, packets use the shared buffer pool space up to the hi-low-prio-only threshold (for exceed-profile packets), the high-prio-only threshold (for out-of-profile packets), or the maximum MBS size (for inplus-profile and in-profile packets).

The following configuration shows a queue with a specific MBS, CBS and disable high-prio-only.

```
configure
    qos
        sap-ingress 10 create
            queue 1 create
```

```
                mbs 10000
                cbs 100
                high-prio-only 0
            exit
        exit
```

Queue depth monitoring aims to give more visibility to the operator of the queue depths when traffic is bursty. It is a polling mechanism that is by default disabled. Queue depth monitoring can be enabled as a queue override on a service SAP or on a queue group.

The following command enables queue depth monitoring on SAP 1/1/1:11 in VPLS 10:

```
configure service vpls 10 sap 1/1/1:11 ingress queue-override queue 1 create monitor-depth
```

The result of the queue depth monitoring is presented in the form of occupancy ranges of 10% on the queue depth for each configured queue with the percentage of polls seen in each occupancy range, as follows:

```
*A:PE-1# show service id 10 sap 1/1/1:11 queue-depth

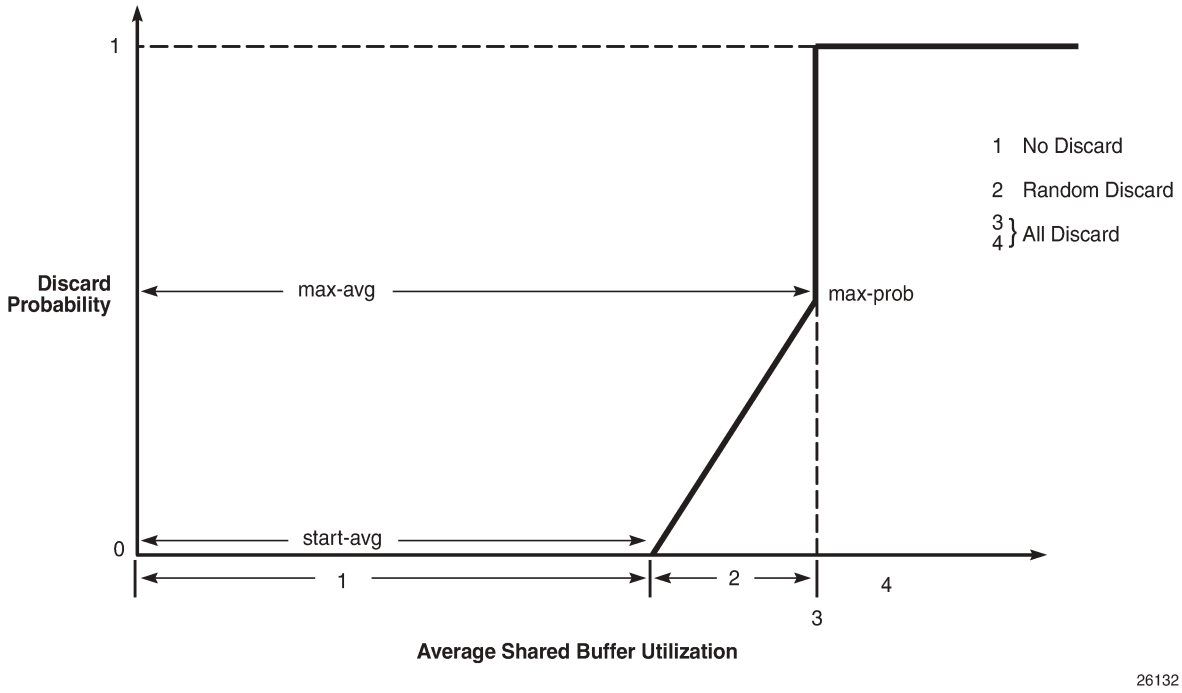
Enqueuing Packets: Weighted Random Early Detection (WRED)

In order to gracefully manage the use of the shared portion of the buffer pool, WRED can be configured on that part of the pool, and therefore applies to all queues in the shared pool as it fills. WRED is a congestion avoidance mechanism designed for TCP traffic. This chapter will only focus on the configuration of WRED. WRED-per-queue is an option to have WRED apply on a per egress queue basis, but is not covered here.

WRED is configured by a slope-policy which contains two WRED slope definitions, a high-slope which applies WRED to high enqueuing priority/in-profile packets and a low-slope which applies WRED to low enqueuing priority/out-of-profile packets. Both have the standard WRED parameters: start average (start-avg), maximum average (max-avg) and maximum probability (max-prob), and can be enabled or disabled individually. WRED slope policies also contain definitions for two slopes which are only applicable to access and network egress; a highplus-slope which applies WRED to inplus-profile packets and an

exceed-slope which applies WRED to exceed-profile packets. The WRED slope characteristics are shown in Figure 442: WRED Slope Characteristics.

Figure 442: WRED Slope Characteristics



A time-average-factor parameter can be configured per slope-policy which determines the sensitivity of the WRED algorithm to shared buffer utilization fluctuations (the smaller the value makes the average buffer utilization more reactive to changes in the instantaneous buffer utilization). The slope-policy is applied on a network port under **config>card>mda>network>ingress>pool** and **config>port>network>egress>pool** and on an access port under **config>port>access>ingress>pool** and **config>port>access>egress>pool**.

WRED is usually configured for assured and best-effort service traffic with premium traffic not typically being subject to WRED as it is always given preferential treatment and should never be dropped.

The following configuration defines a WRED slope policy and applies it to an ingress access port (the highplus and exceed slopes are ignored at ingress).

```
configure
    qos
        slope-policy "slope1" create
            exceed-slope
                shutdown
                start-avg 30
                max-avg 55
                max-prob 80
            exit
            high-slope
                start-avg 80
                max-avg 100
                max-prob 100
                no shutdown
            exit
```

```
            highplus-slope
                shutdown
                start-avg 85
                max-avg 100
                max-prob 80
            exit
            low-slope
                max-avg 100
                start-avg 80
                max-prob 100
                no shutdown
            exit
            time-average-factor 12
        exit
```

```
configure
    port 1/1/1
        access
            ingress
                pool
                    slope-policy "slope1"
                exit
            exit
        exit
```

The queue sizing parameters and buffer pools layout for ingress is shown in Figure 443: Ingress Buffer Pools and Queue Sizing.

Figure 443: Ingress Buffer Pools and Queue Sizing

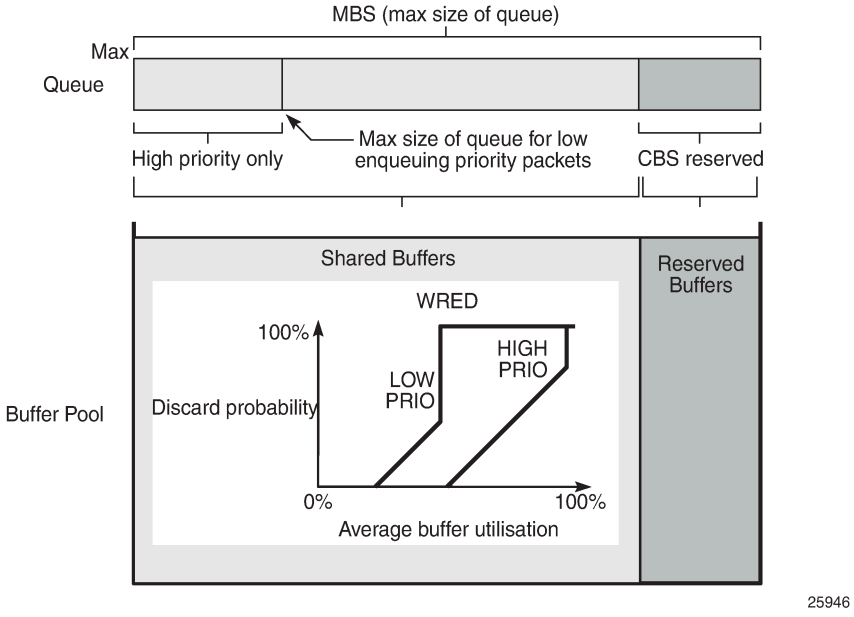


Figure 444: Egress Buffer Pools and Queue Sizing shows the queue sizing parameters and buffer pools layout for egress.

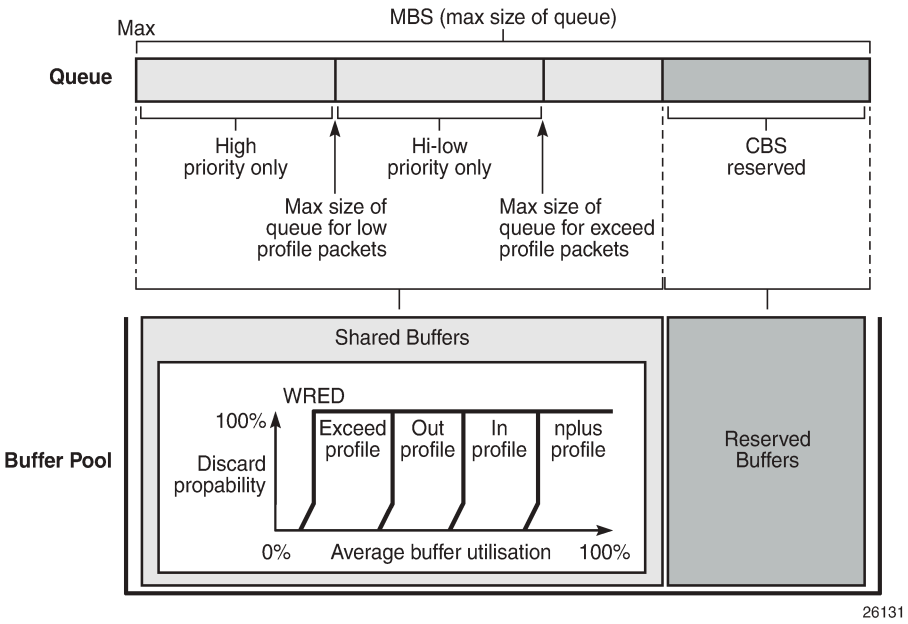
Figure 444: Egress Buffer Pools and Queue Sizing



Dequeuing Packets: Queue Rates

A queue has two rate attributes: PIR and CIR. These affect packets only during the dequeue process.

- PIR — If the instantaneous dequeue rate of a queue reaches this rate, the queue is no longer served. Excess packets will be discarded eventually when the queue reaches its MBS/high-prio-only/hi-low-prio-only sizes. The PIR for access ports can be set in Kb/s with a default of **max** or as a percentage (see below). For network ports, the PIR is set as a percentage of the sum of the capacities of network and hybrid ports on that FP (taking into account any ingress-rate configuration) for ingress queues and of the port speed for egress queues, both with a default of 100%.
- CIR — The CIR is used to determine whether an ingress packet is in-profile or out-of-profile at the SAP ingress. It is also used by the scheduler in that queues operating within their CIRs will be served ahead of queues operating above their CIRs. The CIR for access ports can be set in Kb/s with a default of zero or as a percentage (see below). For network ports, it is set as a percentage of the sum of the capacities of network and hybrid ports on that FP (taking into account any ingress-rate configuration) for ingress queues and of the port speed for egress queues, with defaults varying dependent on the queue.

A percentage rate can be used in the sap-ingress and sap-egress policies, and can be defined relative to the local-limit (the parent scheduler rate) or the port-limit (the rate of the port on which the SAP is configured, including any egress-rate configured). The parameters rate and percent-rate are mutually exclusive and will overwrite each other when configured in the same policy. The following example shows a percent-rate configured as a port-limit.

```
configure
    qos
        sap-egress 10 create
            queue 1 create
                percent-rate 50.00 cir 10.00 port-limit
```

```
            exit
```

The PIR and CIR rates are shown in Figure 445: Scheduling (Dequeuing Packets from the Queue).

The queues operate at discrete rates supported by the hardware. If a configured rate does not match exactly one of the hardware rates an adaptation rule can be configured to control whether the rate is rounded up or down or set to the closest attainable value. The actual rate used can be seen under the operational PIR/CIR (O.PIR/O.CIR) in the **show pools** command output.

The following configuration shows a queue with a PIR, CIR and adaptation rule.

```
configure
    qos
        sap-ingress 20 create
            queue 2 profile-mode create
                adaptation-rule pir max cir min
                rate 10000 cir 5000
            exit
```

By default, the rates apply to packet bytes based on packet accounting, which for Ethernet includes the Layer 2 frame plus the FCS. An alternative is frame accounting which adds the Ethernet inter-frame gap, preamble and start frame delimiter.

Dequeuing Packets: Scheduling

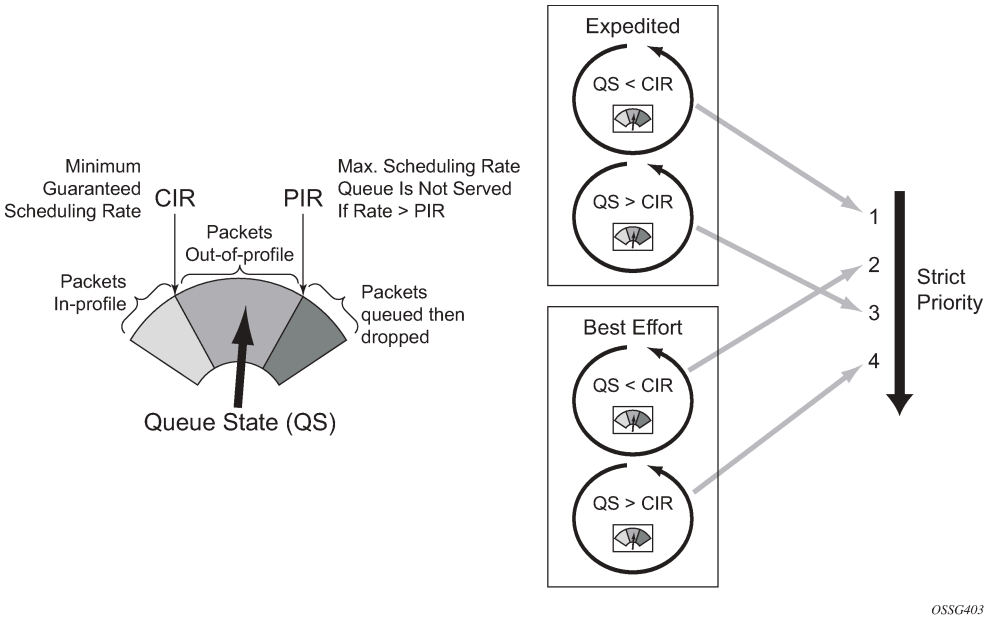
Once a packet is placed on a queue, it is always dequeued from the queue by a scheduler. The scheduling order of the queues dynamically changes depending on whether a queue is currently operating below or above its CIR, with expedited queues being serviced before best-effort queues. This results in a default scheduling order of (in strict priority).

1. Expedited queues operating below CIR
2. Best-effort queues operating below CIR
3. Expedited queues operating above CIR
4. Best-effort queues operating above CIR

This is displayed in Figure 445: Scheduling (Dequeuing Packets from the Queue).

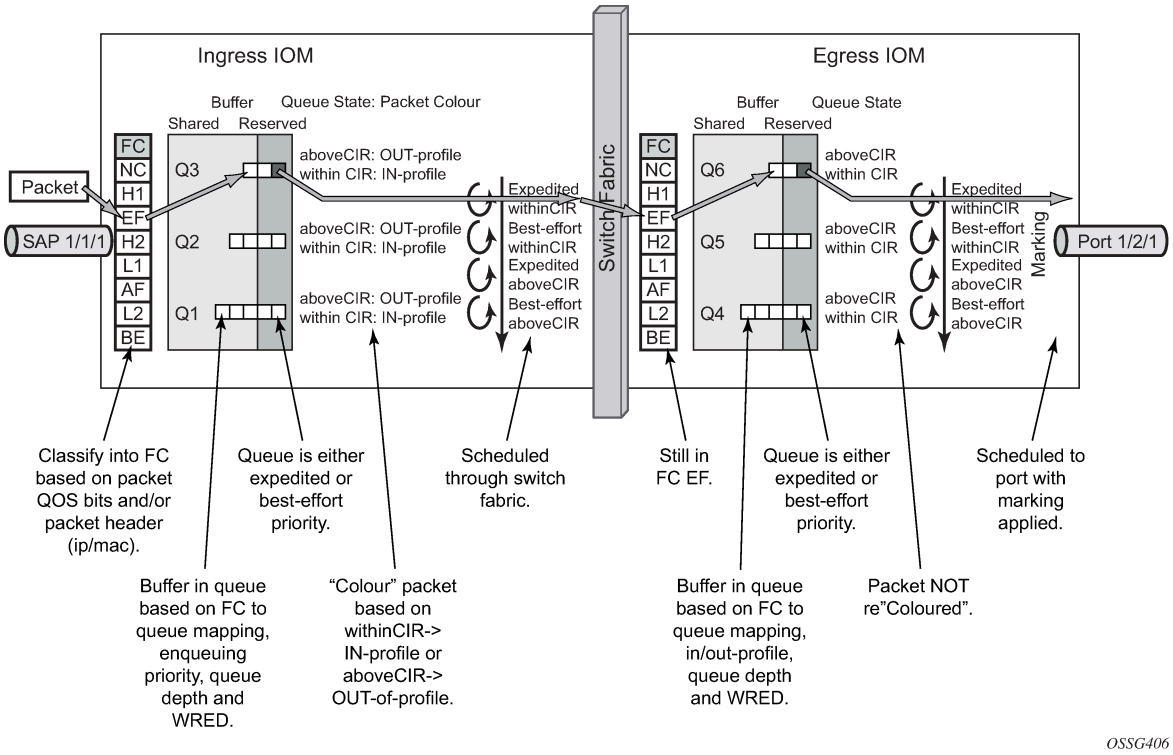
The scheduling operation can be modified using hierarchical QoS (with a scheduler-policy or port-scheduler-policy) which is out of scope of this chapter.

Figure 445: Scheduling (Dequeuing Packets from the Queue)



The overall QoS actions at both the ingress and egress IOMs are shown in Figure 446: IOM QoS Overview.

Figure 446: IOM QoS Overview



Show Output

The following displays **show** command output for:

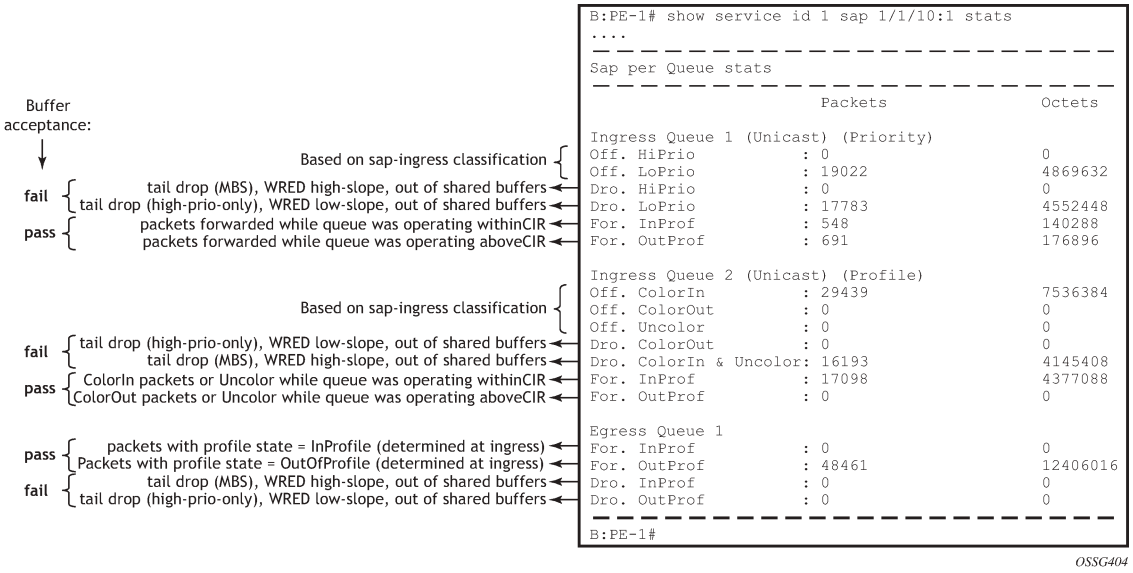
- SAP queue statistics
- port queue statistics
- per-port aggregate egress-queue statistics monitoring
- access-ingress pools

The **show pools** command output for network-ingress and network/access-egress is similar to that of access-ingress and is not included here.

SAP Queue Statistics

The following output shows an example of the ingress and egress statistics on a SAP for an IES service (without multicast enabled, therefore no ingress multicast queue). There are two ingress queues, one being in priority mode and the other in profile mode. An explanation of the statistics is given for each entry.

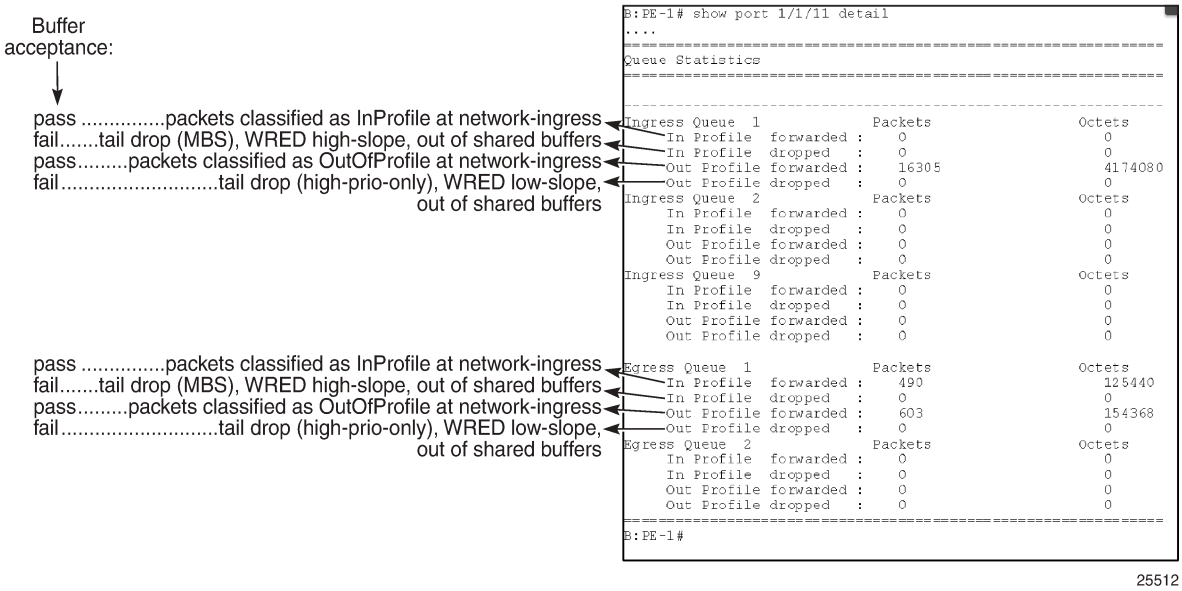
Figure 447: Ingress and Egress SAP Queue Statistics for an IES Service



Port Queue Statistics

This output shows an example of the ingress and egress network port statistics. There are two unicast ingress queues (1 and 2) and one multicast ingress queue (9) with two egress queues. An explanation of the statistics is given for each entry.

Figure 448: Ingress and Egress Network Port Queue Statistics



Per-Port Aggregate Egress-Queue Statistics Monitoring

Per-port aggregate egress-queue statistics show the number of forwarded and the number of dropped packets for in-profile and out-of-profile packets. All egress queues on the port are monitored: SAP egress, network egress, subscriber egress, egress queue group queues, system queues.

Per-port aggregate egress-queue statistics monitoring is enabled with the following command:

```
configure port 1/1/1 monitor-agg-egress-queue-stats
```

The collected statistics can be displayed as follows:

```
*A:PE-1# show port 1/1/1 statistics egress-aggregate

Access-Ingress Pools

This output shows an example of the default pools output for access-ingress. It includes the pools sizes, WRED information and queue parameters for each queue in the pool.

For this particular output, queue 2 on SAP 5/1/1:1 is being over-loaded which is causing its queue depth to be 67087296 bytes, made up of 64509 Kbytes from the shared pool (in use) and 1008 Kbytes from the reserved pool (in use). The output shows the pool total in usage as 65517 Kbytes, which is the sum of the shared and reserved pool in use. Sometimes the sum and total could be different by the size of one buffer, however, this is due to the dynamics of the buffer allocation which uses a 'sliding-window' mechanism and may therefore not always be perfectly aligned.

It can be seen that the high, low, and exceed WRED slopes are enabled and their instantaneous drop probability is shown 100% and their max averages are 64512 Kbytes, 46080 Kbytes, and 27648 Kbytes, respectively – this shows that the reserved portion of the buffer pool on this port is exhausted causing WRED to drop the packets for this queue.

The admin and operational PIR on the overloaded queues is 10Mb/s with CIR values of zero.

Conclusion

This chapter has described the basic QoS functionality available on the Nokia 7x50 platforms, specifically focused on the FP2 chipset. This comprises of the use of queues to shape traffic at the ingress and egress of the system and the classification, buffering, scheduling and remarking of traffic on access, network, and hybrid ports.
