```

Verification

The following will be verified in this section:

- the MC-IPSec status and VRRP status on SeGW-3 and SeGW-4

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- the status of the IPSec tunnel on CE-1
- the status of the IPSec tunnel on the SeGWs

Verify the MC-IPSec status on SeGW-3 and SeGW-4

The following is verified:

- SeGW-3 is the primary chassis (**master**) and SeGW-4 is the standby for tunnel group 1 because SeGW-3 has the higher priority 200.
- SeGW-3 is the primary node for VRRP instance 10 and SeGW-4 is the backup.

SeGW-3 is the primary chassis in tunnel group 1 with priority 200:

```

```

Verify the IPSec tunnel on the SeGWs

In this section, the following is verified:

- the MCS database is in-sync, so the tunnel status is up on both chassis.
- P-5 receives two VPN-IPv4 routes for prefix 192.168.1.1/32: the route from SeGW-3 has local preference 200; the route from SeGW-4 has local preference 100.

On both SeGWs, the IPSec tunnel with local address 10.10.20.1 and remote address 10.10.10.1 is up:

```
[/]
A:admin@SeGW-3# show ipsec tunnel

================================================================================
IPsec Tunnels
================================================================================
TunnelName                       LocalAddress      SvcId        Admn   Keying

MC-IPSec failover scenarios

Two MC-IPSec failover scenarios are described in this section:

- MC-IPSec failover when MS-ISA is disabled
- MC-IPSec failover when the primary chassis SeGW-3 reboots

Failover when MS-ISA is disabled

Initially, MS-ISA is enabled, so SeGW-3 is the primary chassis and SeGW-4 is the standby:

```

The following command disables the MS-ISA on the primary chassis SeGW-3, which will trigger an MC-IPSec failover.

```
configure {
    card 1 {
        mda 2 {
            admin-state disable
```

With MS-ISA disabled, the MC-IPSec state of tunnel group 1 on SeGW-3 becomes **notEligible**, which means that the tunnel group is down, see the *7450 ESS, 7750 SR, and VSR Multiservice ISA and ESA Guide* for details description of MIMP states.:

Configuration guidelines

The following is a list of guidelines for configuring MC-IPSec:

- To avoid high CPU load and issues in some complex cases, the following are suggestions for configuring the IKEv2 lifetime:
  - Both IKE_SA and CHILD_SA lifetime on MC-IPSec chassis (SeGW-3 and SeGW-4) should be around three times larger than on the IPSec peer CE-1.
  - With the first rule, the lifetime of the side with smaller lifetime (IPSec peer CE-1) should not be too small (these being the default values):
    - IKE_SA: >= 86400 seconds
    - CHILD_SA: >= 3600 seconds

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - With the first rule, on the side with smaller lifetime (IPSec peer CE-1), the IKE_SA lifetime must be at least 3 times larger than CHILD_SA lifetime.
- The IKE protocol is the control plane of IPSec, so IKE packets must be treated as high QoS priority in the end-to-end path of the public service. On the public interface, a SAP ingress QoS policy must be configured to ensure that IKE packets get high QoS priority.
- Configure **ipsec-responder-only true** under **tunnel-group** for static LAN-to-LAN tunnels.
- Enable dead peer detection (DPD) on the IPSec peer side (CE-1); disable DPD (default) on the MC-IPSec chassis side.
- The direct and redundant physical link between MC-IPSec chassis must be configured with sufficient bandwidth for MCS and shunting traffic, and proper QoS configuration to make sure the MIMP and MCS packets are treated as high priority traffic.
- The system time must be same on both MC-IPSec chassis.
- Make sure the protection status is **nominal** on both chassis before provoking a controlled switchover. The protection status can be displayed with the **show redundancy multi-chassis mc-ipsec peer ip-address <addr>** command.
- Wait at least five minutes between two consecutive switchovers if possible, to prevent a second switchover happening before the standby is ready to become the primary chassis.

Conclusion

MC-IPSec provides a stateful multi-chassis IPSec redundancy solution. This is very important in a carrier grade network, especially in applications such as mobile backhaul where high value mobile services run over IPSec tunnels.

N:M MC-IPsec Redundancy

This chapter describes N:M MC-IPsec redundancy.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and MD-CLI configuration in this chapter are based on SR OS Release 22.10.R1.

The IPsec tunnel termination configuration described in this chapter requires an MS-ISA2 or an ESA server configured with a virtual machine. Configuration and setup for ISA2 or ESA are beyond the scope of this chapter; see the Multi-Chassis IPSec Redundancy chapter.

Overview

The N:M MC-IPsec redundancy model is a feature of the multi-chassis (MC) capabilities of SR OS when the router is deployed as Security Gateway (SeGW). N:M aims at enhancing the existing 1:1 redundancy model for IPsec tunnels. For the definition of N:M terminology and a description of its benefits, see the *7450 ESS, 7750 SR, and VSR Multiservice ISA and ESA Guide*.

The figure Figure 330: Three-node redundancy domain with a 2 DA + 1 DS model shows a three-node redundancy domain (RD) with the SeGWs SEG1, SEG2, and SEG3. SEG 1 and SEG 2 are designated active (DA) SeGWs and SEG 3 is designated standby (DS) SeGW.

Figure 330: Three-node redundancy domain with a 2 DA + 1 DS model

Radio access network (RAN) elements are opening IPsec tunnels toward SeGW cluster tunnel endpoint IP addresses. The RAN, aggregation network, and core network are emulated with standard routing nodes. For this deployment, assume that connectivity between elements is established using routing protocols and, as for a classic SeGW router, the public side where traffic is encrypted is built on top of a public-side VPRN, while private side (clear-text traffic) is associated with another VPRN. ISA2 or ESA resources manage encryption and decryption operations across the VPRN boundary.

This chapter describes configuration of SeGW elements, as well as MD-CLI commands for tracking the functionality of N:M nodes in the same redundancy domain (RD).

Configuration

Assume that IP connectivity is established across the IP network elements in the architecture. It is beyond the scope of this chapter to describe how traffic is carried from the RAN to the SeGW or from SeGW to the mobile packet core. Among the protocols and techniques that are required to speed up convergence of routing, the bidirectional forwarding detection (BFD) protocol is especially useful to keep network convergence time in a range compatible with mobile traffic use case.

ISA2 or ESA setup for N:M

The nodes participating in the IPsec domain have a standard setup for ISA2 or ESA resources.

SEG1 and SEG 2 can each be configured like a classic SeGW, as follows:

```
[gl:/configure isa]
A:admin@SEG1# info
    tunnel-group 1 {
        admin-state enable
        isa-scale-mode tunnel-limit-2k
        ipsec-responder-only true
        multi-active {
            isa 1/2 { }
            active-isa-number 1
        }
        reassembly {
            max-wait-time 1200
        }
        stats-collection {
            isa-dp-cpu-usage true
        }
    }
```

The **active-isa-number** command specifies the number of active encryption and decryption elements. Nokia recommends implementing the same number of ISA2 and ESA resources among the nodes participating in the RD, which allows for the DS node to activate the same number of ISA2 or ESA resources when failover occurs. However, a failover can occur even if the DS node has a lower number of ISA2 or ESA resources available in its local pool. This allows operators to save costs, but if the ISA2 ore ESA resources on the initial DA nodes were fully loaded, the DS node cannot host all tunnels and the protection is only partial.

N:M redundancy allows DS nodes to cover multiple TGs, and therefore, multiple RDs. DS nodes may have more ISA2 or ESA resources than the DA nodes, because the DS nodes should be able to cover one or more DA node failures, with a maximum of 16.

The output from SEG2 is the same as for SEG1.

SEG3 is configured as the DS node of the domain, where the configuration contains the **tunnel-member-pool** command:

```
[gl:/configure isa]
A:admin@SEG3# info
    tunnel-group 1 {
        admin-state enable
        isa-scale-mode tunnel-limit-2k
        ipsec-responder-only true
        multi-active {
            member-pool "MP1"
        }
        reassembly {
            max-wait-time 1200
        }
    }
    tunnel-member-pool "MP1" {
        isa 1/2 { }
    }
```

The **tunnel-member-pool** option defines the set of ISA2 or ESA resources used by the DS node during failures on active nodes. It is referenced in the tunnel group (TG) configuration, because multiple TGs can use the same tunnel member pool using the same set of ISA2 or ESA resources.

The output of the **show isa tunnel-member-pool** command lists ISA (ISA2 or ESA) members and their states. Under normal conditions, the ISA2 or ESA resource is not active on SEG3.

```
[gl:/configure isa]
A:admin@SEG3# /show isa tunnel-member-pool "MP1" detail

```

Redundancy domain configuration

The configuration of MC-IPsec as N:M starts by defining node roles and behavior. The configuration on SEG1 (with system IP address 192.0.2.1) is as follows:

```
[gl:/configure redundancy]
A:admin@SEG1# info
    multi-chassis {
        ipsec-domain 1 {
            admin-state enable
            designated-role active
            priority 250
            tunnel-group 1
        }
        peer 192.0.2.2  {
            admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            sync {
                admin-state enable
                ipsec true
            }
            mc-ipsec {
                bfd-liveness true
                domain 1 {
                    admin-state enable
                }
            }
        }
        peer 192.0.2.3 {
            admin-state enable
            sync {
                admin-state enable
                ipsec true
            }
            mc-ipsec {
                bfd-liveness true
                domain 1 {
                    admin-state enable
                }
            }
        }
    }
```

The preceding configuration example shows a multi-chassis IPsec domain, where the following domain characteristics have been specified:

- domain number – must be shared across all the nodes joining the redundancy domain (RD)
- designated role – DA or DS
- priority – required by the multi-chassis IPsec mastership protocol (MIMPv2) when an operationally active (OA) node must be elected. Setting a higher priority for an SeGW increases the likelihood of it being elected as the OA. In this case, SEG1 has the highest priority and DA role, so it is elected OA for RD 1.
- tunnel group – must be defined as per the ISA2 or ESA setup. The TG is always mapped to the RD in a 1:1 relationship
- peers – up to three peers can be added. While full-mesh peering between them is required, Nokia also recommends deploying highly redundant network paths between these peers.

  Each peer has its own CLI tree where the following characteristics must be defined:

  – the domain or domains the peer belongs to

  – the synchronization state for IPsec

  – whether BFD is applied to check peer liveliness.
- (optional) other parameters for keepalives, hold-time, and discovery-interval are configured with default values. Do not change these values unless a different setup is required under specific network conditions.

The configuration for the redundancy domain on SEG2 is the same as on SEG1, but with different IP addresses for peers and different priority:

```
A:admin@SEG2# info
    multi-chassis {
        ipsec-domain 1 {
            admin-state enable
            designated-role active
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            priority 240
            tunnel-group 1
        }
        peer 192.0.2.1 {
            admin-state enable
            sync {
                admin-state enable
                ipsec true
            }
            mc-ipsec {
                bfd-liveness true
                domain 1 {
                    admin-state enable
                }
            }
        }
        peer 192.0.2.3 {
            admin-state enable
            sync {
                admin-state enable
                ipsec true
            }
            mc-ipsec {
                bfd-liveness true
                domain 1 {
                    admin-state enable
                }
            }
        }
    }
```

The designated role of SEG2 is **active**, which means SEG2 behaves similarly to the 1:1 model where tunnel states are synchronized with SEG1 and immediately pushed to ISA2 or ESA resources. This behavior allows for a very quick failover when SEG1 experiences a failure.

The priority is 240, which is lower than for SEG1. As a result, SEG1 receives node role DA and is operationally active (OA) while SEG2 receives node role DA and is operationally standby (OS).

The RD configuration for DS SEG3 is as follows:

```
[gl:/configure redundancy multi-chassis]
A:admin@SEG3# info
    ipsec-domain 1 {
        admin-state enable
        designated-role standby
        priority 230
        tunnel-group 1
    }
    peer 192.0.2.1 {
        admin-state enable
        sync {
            admin-state enable
            ipsec true
        }
        mc-ipsec {
            bfd-liveness true
            domain 1 {
                admin-state enable
            }
        }
    }
    peer 192.0.2.2 {
        admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        sync {
            admin-state enable
            ipsec true
        }
        mc-ipsec {
            bfd-liveness true
            domain 1 {
                admin-state enable
            }
        }
    }
```

The peer configuration is similar to those of other nodes where BFD liveliness is enabled.

The designated role is standby (DS). The default value in the configuration is not shown from the **info** command.

The priority is 230 but the node role is DS. The DS node will not become OA because the DA role of SEG1 and SEG2 always prevails when electing the OA, regardless of priority value. Therefore, a DS node can become OA only if there are no DA nodes available in the domain.

After the setup of MC IPsec RD is completed across all the nodes, **show** commands can be used to track RD behavior and state:

```
A:admin@SEG1# show redundancy multi-chassis ipsec-domain 1

===============================================================================
Multi-Chassis IPsec Domain: 1
===============================================================================
Designated Role    : active            Priority          : 250

Installing                   0                   0
Standby Dormant              0                   0
Awaiting Config              0                   0
Failed                       0                   0
===============================================================================
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The output shows important information about the redundancy domain:

- the designated role of the node – active or standby
- the activity state based on fault conditions – active or standby
- the protection status – "nominal" means that the nodes are synchronized.
- the domain adjacencies – list of peers and their activity state and designated role
- the tunnel statistics – in this case, seven dynamic tunnels are established

The same **show** command executed on SEG2 provides similar output, with differences for the priority and the designated role. The seven tunnels are shown in the "Installed" state because SEG2 is a DA node.

The same **show** command on DS SEG3 shows the following:

```
A:admin@SEG3# show redundancy multi-chassis ipsec-domain 1

===============================================================================
Multi-Chassis IPsec Domain: 1

===============================================================================
```

Relevant information from the SEG3 CLI output, apart from the activity state, the designated role, and the peer’s state, is the tunnel state, which is now marked as "Standby Dormant".

Tunnels on SEG3 are not installed on the ISA2 or ESA; rather, they are stored in the router CPM and are kept ready to be offloaded on the ISA2 or ESA resources connected to the router. These tunnels are offloaded as soon as SEG3 becomes OA, following a node reboot, failure, or manual switchover.

Services configuration

The tunnels opened by RAN elements are terminated in a public-side VPRN IP address called TEIP (the public side can also be made on a IES service). Assume that the RAN nodes are using a single tunnel setup with a single IKE_SA, whereas the Child_SA's number is specific to the deployment. The configuration of this public side VPRN is the same for all three nodes and follows the standard SeGW setup:

```
[gl:/configure service vprn "100"]
A:admin@SEG1# info
    vprn "100" {
        admin-state enable
        description "public side"
        customer "1"
        ipsec {
            multi-chassis-shunt-interface "to_SEG2_Shunt" {
                next-hop {
                    address 10.1.12.2
                }
            }
            multi-chassis-shunt-interface "to_SEG3_Shunt" {
                next-hop {
                    address 10.1.13.2
                }
            }
            multi-chassis-shunting-profile "MCSPROF1" {
                peer 192.0.2.2 {
                    multi-chassis-shunt-interface "to_SEG2_Shunt"
                }
                peer 192.0.2.3 {
                    multi-chassis-shunt-interface "to_SEG3_Shunt"
                }
            }
        }
        interface "PUBLIC1" {
            multi-chassis-shunting-profile "MCSPROF1"
            sap tunnel-1.public:100 {
                ipsec-gateway "IPSECGW1" {
                    admin-state enable
                    default-tunnel-template 1
                    ike-policy 1
                    pre-shared-key "uCLxzS3PxoW0foPjmAKJ/Wv41hy6O3H76tg=" hash2
                    default-secure-service {
                        service-name "200"
                        interface "PRIVATE1"
                    }
                    local {
                        gateway-address 10.51.100.1
                    }
                }
            }
            ipv4 {
                primary {
                    address 198.51.100.2
                    prefix-length 24
                }
            }
        }
        interface "to_SEG2_Shunt" {
            spoke-sdp 2000:1 {
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            ipv4 {
                primary {
                    address 10.1.12.1
                    prefix-length 30
                }
            }
        }
        interface "to_SEG3_Shunt" {
            spoke-sdp 3000:1 {
            }
            ipv4 {
                primary {
                    address 10.1.13.1
                    prefix-length 30
                }
            }
        }
        ospf 0 {
            export-policy ["EXPORT_OSPF"]
        }
```

The parts of the configuration that are exclusive of N:M are those related to shunt-link setup.

The **multi-chassis-shunting-profile** command can be found under the **ipsec** configuration for the IES or VPRN service, where the multi-chassis shunting (MCS) profile is required to map each peer to a dedicated shunt interface. The MCS profile is referenced under the interface where the IPsec gateway is configured. In this scenario, peer 192.0.2.2 is reached through the to_SEG2_Shunt interface, which is defined under the same VPRN as an interface built on top of sdp:2000:1.

A full mesh of shunt interfaces is made across the RD, for both public and private side services.

```
A:admin@SEG1# show ipsec multi-chassis-shunt-interface service "100"

===============================================================================
IPsec Multi-Chassis Shunt Interfaces
===============================================================================
Service Id  MC Shunt Interface Name          Next Hop                Resolved
-------------------------------------------------------------------------------
100         to_SEG2_Shunt                    10.1.12.2               Yes
100         to_SEG3_Shunt                    10.1.13.2               Yes
-------------------------------------------------------------------------------
No. of IPsec MC Shunt Interfaces: 2
===============================================================================
```

The **show ipsec multi-chassis-shunt-interface service** command shows the liveliness of shunt interfaces and information on the next-hop resolution, whereas the **show ipsec multi-chassis-shunting-profile service** command provides a summary of the MCS profile and associated peers:

```
A:admin@SEG1# show ipsec multi-chassis-shunting-profile service "100"

===============================================================================
Multi-Chassis Shunting Profile Params Entries
===============================================================================
Service Id  MC Shunting Profile Name                MC Shunt Interface Name
            Peer
-------------------------------------------------------------------------------
100         MCSPROF1                                to_SEG2_Shunt
            192.0.2.2
100         MCSPROF1                                to_SEG3_Shunt
            192.0.2.3
-------------------------------------------------------------------------------
No. of IPsec MC Shunting Profile Params Entries: 2

```
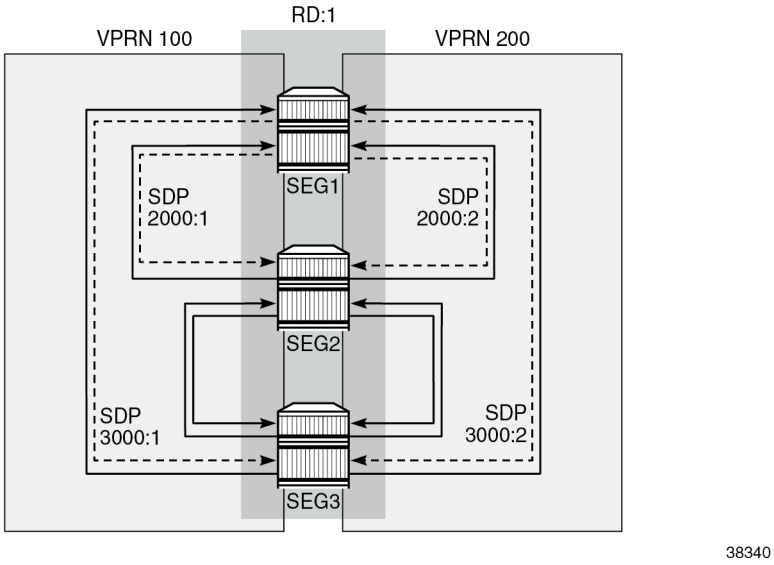
===============================================================================
```

The SDP full mesh must be configured on both sides, as shown in the figure Figure 331: SDP full mesh.

Figure 331: SDP full mesh



Note: Only the SDPs from SEG1 are shown with IDs.

The shunt link can be built from a standard spoke SDP or from a port-based interface. In this example, the following spoke SDPs are used in the public-side VPRN 100:

```
A:admin@SEG1# show service id "100" sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
2000:1           Spok     192.0.2.2       Up      Up        524285    524285
3000:1           Spok     192.0.2.3       Up      Up        524283    524285
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

The **show** output for the private-side VPRN 200 looks similar to that for the public-side VPRN, except for the SDP IDs and label values:

```
A:admin@SEG1# show service id "200" sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
2000:2           Spok     192.0.2.2       Up      Up        524284    524284
```

Use subject to Terms available at: www.nokia.com/terms.

```
3000:2           Spok     192.0.2.3       Up      Up        524282    524284
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

There are no routing policy changes from the 1:1 MC-IPsec cluster, although this example could have a more complex routing setup, considering that the number of routers in a domain is higher than in the 1:1 model. The following configuration shows the SEG1-2-3 export policy used on the public side where the OSPF protocol is used under VPRN 100:

```
[gl:/configure policy-options policy-statement "EXPORT_OSPF"]
A:admin@SEG1# info
    description "EXPORT TEIP OSPF - PUBLIC SIDE"
    entry 10 {
        from {
            state ipsec-master-with-peer
            protocol {
                name [ipsec]
            }
        }
        action {
            action-type accept
            tag 100
            metric {
                set 30
            }
        }
    }
    entry 20 {
        from {
            state ipsec-non-master
            protocol {
                name [ipsec]
            }
        }
        action {
            action-type accept
            tag 100
            metric {
                set 190
            }
        }
    }
    entry 30 {
        from {
            state ipsec-master-without-peer
            protocol {
                name [ipsec]
            }
        }
        action {
            action-type accept
            tag 100
            metric {
                set 40
            }
        }
    }
    default-action {
        action-type reject
    }
```

On SEG2, only the metrics are different and are aligned with DA priorities:

```
[gl:/configure policy-options policy-statement "EXPORT_OSPF"]
A:admin@SEG2# info
    policy-statement "EXPORT_OSPF" {
        description "EXPORT TEIP OSPF - PUBLIC SIDE"
        entry 10 {
            from {
                state ipsec-master-with-peer
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 200
                metric {
                    set 60
                }
            }
        }
        entry 20 {
            from {
                state ipsec-non-master
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 200
                metric {
                    set 190
                }
            }
        }
        entry 30 {
            from {
                state ipsec-master-without-peer
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 200
                metric {
                    set 50
                }
            }
        }
        default-action {
            action-type reject
        }
    }
```

On SEG3, the export policy is as follows:

```
[gl:/configure policy-options policy-statement "EXPORT_OSPF"]
A:admin@SEG3# info
    policy-statement "EXPORT_OSPF" {
        description "EXPORT TEIP OSPF - PUBLIC SIDE"
        entry 10 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            from {
                state ipsec-master-with-peer
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 300
                metric {
                    set 90
                }
            }
        }
        entry 20 {
            from {
                state ipsec-non-master
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 300
                metric {
                    set 195
                }
            }
        }
        entry 30 {
            from {
                state ipsec-master-without-peer
                protocol {
                    name [ipsec]
                }
            }
            action {
                action-type accept
                tag 300
                metric {
                    set 60
                }
            }
        }
        default-action {
            action-type reject
        }
    }
```

The export policy on the private-side VPRN is made with the same concept as the public side, but is not shown here.

Note: Parts of the configuration where the parameters remain the same as those in classic SeGW deployments (either stand-alone or 1:1) have not been added to this chapter. This information is described in the Multi-Chassis IPSec Redundancy chapter.

On the private side of SeGWs, a different VPRN is required, as per standard IPsec configuration. The private-side VPRN configuration on SEG1 is as follows:

```
[gl:/configure service vprn "200"]
A:admin@SEG1# info
    admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    description "private segw testing"
    customer "1"
    ipsec {
        multi-chassis-shunt-interface "to_SEG2_Shunt" {
            next-hop {
                address 10.2.12.2
            }
        }
        multi-chassis-shunt-interface "to_SEG3_Shunt" {
            next-hop {
                address 10.2.13.2
            }
        }
        multi-chassis-shunting-profile "MCSPROF1" {
            peer 192.0.2.2 {
                multi-chassis-shunt-interface "to_SEG2_Shunt"
            }
            peer 192.0.2.3 {
                multi-chassis-shunt-interface "to_SEG3_Shunt"
            }
        }
    }
    bgp-ipvpn {
        mpls {
            admin-state enable
            route-distinguisher "300:4"
        }
    }
    interface "PRIVATE1" {
        tunnel true
        multi-chassis-shunting-profile "MCSPROF1"
        sap tunnel-1.private:100 {
        }
    }
    interface "to_SEG2_Shunt" {
        ipv4 {
            primary {
                address 10.2.12.1
                prefix-length 30
            }
        }
        spoke-sdp 2000:2 {
        }
    }
    interface "to_SEG3_Shunt" {
        ipv4 {
            primary {
                address 10.2.13.1
                prefix-length 30
            }
        }
        spoke-sdp 3000:2 {
        }
    }
```

As the configuration shows, the same setup of shunt links is required on the private side to allow path resiliency in case of faults for the traffic going downstream from core toward the RAN.

Failure scenario – active node experiences a power failure

N:M can be triggered by different fault conditions, such as a complete node failure, an ISA2 or ESA failure, or a manual switchover executed with the **tools** command. In this scenario, complete node failures are simulated. When SEG1 experiences a node failure, SEG2 takes over. When SEG2 fails too, SEG3 takes over and remains the only node with active tunnels.

The initial scenario has SEG1 and SEG2 configured as DA nodes, while SEG3 is the DS node for the domain configured as **ipsec-domain 1**. The state can be verified with the **show redundancy multi-chassis ipsec-domain 1** command (as shown above in the Redundancy domain configurationsection).

As soon as SEG1 experiences a node failure, SEG2 takes over:

```
A:admin@SEG2# show redundancy multi-chassis ipsec-domain 1

===============================================================================
Multi-Chassis IPsec Domain: 1

===============================================================================
```

Although the protection status, as seen from SEG2 and SEG3, is initially "notReady", it changes to "nominal" after few minutes. From the SEG2 and SEG3 point of view, SEG1 is unreachable, and its activity state remains unknown. Log 99 also records the failure event:

```
A:admin@SEG2# show log log-id 99

===============================================================================
Event Log 99 log-name 99
===============================================================================

```

Both SEG1 and SEG2 are seen as operationally down with an unknown activity state. On SEG3, the tunnel states have been copied from the CPM to the ISA2 or ESA entities and are now shown as "Installed", rather than "Standby Dormant". As soon as SEG1 or SEG2 are back up, the **revertive** flag configured

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

under the **ipsec-domain** command determines if the tunnels are kept on the current active DS node or if they are moved back to SEG1 ownership.

Failure scenario – using the tools command line

A planned failure condition is commonly seen when executing software upgrades or hardware maintenance on SeGW nodes, which leverages the **tools** command line utility to move tunnels toward other peering nodes.

The initial state is the same as for the previous example where SEG1 is initially the operationally active DA.

The following tools command triggers a switchover and therefore causes all the tunnels installed on the operationally active DA node to move on another node in the domain, selected by the **auto** flag in this case.

```
A:admin@SEG1# tools perform redundancy multi-chassis mc-ipsec force-switchover domain 1 auto
 now
```

To specify a peer IP address among those available in the domain, the **to <peer_ip>** option could be used instead of **auto**.

The following output shows the domain state as seen from SEG1 after the execution of the tools command:

```
A:admin@SEG1# show redundancy multi-chassis ipsec-domain 1

===============================================================================
Multi-Chassis IPsec Domain: 1

After maintenance operations on SEG1 have been completed and the node is operational (which can be verified using the **show** commands described in this chapter), the operator reverts services and traffic back to SEG1. For this purpose and in this specific example, the same **tools** command can be used. The **auto** flag selects SEG1, according to its highest priority in the domain. If more predictability is required in the selection choice, the **to <peer_ip>** flag can be used, as in this example:

```
A:admin@SEG2# tools perform redundancy multi-chassis mc-ipsec force-switchover domain 1 to
 192.0.2.1 now
```

Conclusion

N:M adds a level of redundancy to an already efficient redundancy model; it ensures that RAN elements stay connected to the core network under a wide range of failure conditions. SR OS uses a full set of commands to implement this feature, available for both classic and MD-CLI. N:M also gives network engineers and architects the capability to deploy SeGW services with greater flexibility; for example, to deploy super-resilient SeGW clusters to serve high-density RAN areas, or to introduce cost-optimized solutions with an acceptable level of automated fault recovery.

BNG Dual-Homing with EVPN VPWS in the Access Network and SRv6 Transport

This chapter describes BNG dual-homing with EVPN VPWS in the access network and SRv6 transport.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion
- Appendix with configuration files

Applicability

The information and configuration in this chapter is based on SR OS Release 22.10.R1. The feature described in this chapter applies to all FP4 and above based SR systems; it is not supported on VSR.

Enhanced subscriber management (ESM) is prerequisite knowledge. This chapter can serve as an SRv6 primer for subscriber management users who are less familiar with this technology.

Overview

Segment routing over IPv6 dataplane (SRv6) is a technology that supports overlay network designs over a single dataplane protocol (IPv6). The size of an IPv6 address (128 bits) is large enough to carry more information than only the addressing of interfaces on a network device. SRv6 allows for additional information so that an IPv6 address can encode functions that extend beyond simple node reachability information. Mature routing protocols (IGP and BGP) with proven fast rerouting mechanisms continue to be used to disseminate SRv6 information across the networks. The mix of those fast-rerouting mechanisms, SRv6, and synchronized subscribers in dual-homed environment enhanced subscriber management with multi-chassis synchronization (ESM MCS) results in simplified and robust access networks that benefit service providers and their customers.

This chapter describes an example topology with:

- redundant BNGs
- synchronized subscribers
- an SRv6-based network providing access to the subscribers
- routing on the core side where the cost of advertised subscriber routes depends on the forwarding state —specifically, the subscriber routed redundancy protocol (SRRP) state—in the access network

Note: Although SRv6 is the transport technology described in this chapter, SRv6 is not a prerequisite for active/standby BNG with EVPN VPWS in the access network. Multi-chassis BNG redundancy can be realized with a variety of other transport technologies in the access network.

This chapter provides integrated configuration content for BNG and SRv6.

The figure Figure 332: Example topology shows the example topology used throughout this chapter. The terminology is as follows:

- The access network refers to all nodes downstream of the BNGs, including the interfaces and SAPs on the BNGs connected to that part of the network.
- The core part of the network refers to all nodes upstream of the BNGs, including the interfaces and SAPs on the BNGs connecting them to that part of the network.
- The term "EVPN VPWS" is used interchangeably with "Epipe" because the EVPN VPWS deployed in the access network is configured in SR OS nodes as an Epipe.

Note: Although terms such as "active or standby subscriber" or "active or standby node" are commonly used in redundant BNG topologies and may occasionally be used within this document, it is important to state that subscribers and nodes do not have redundancy states, such as "active" or "standby". Only SRRP has states that are here referred to as "active" and "standby".

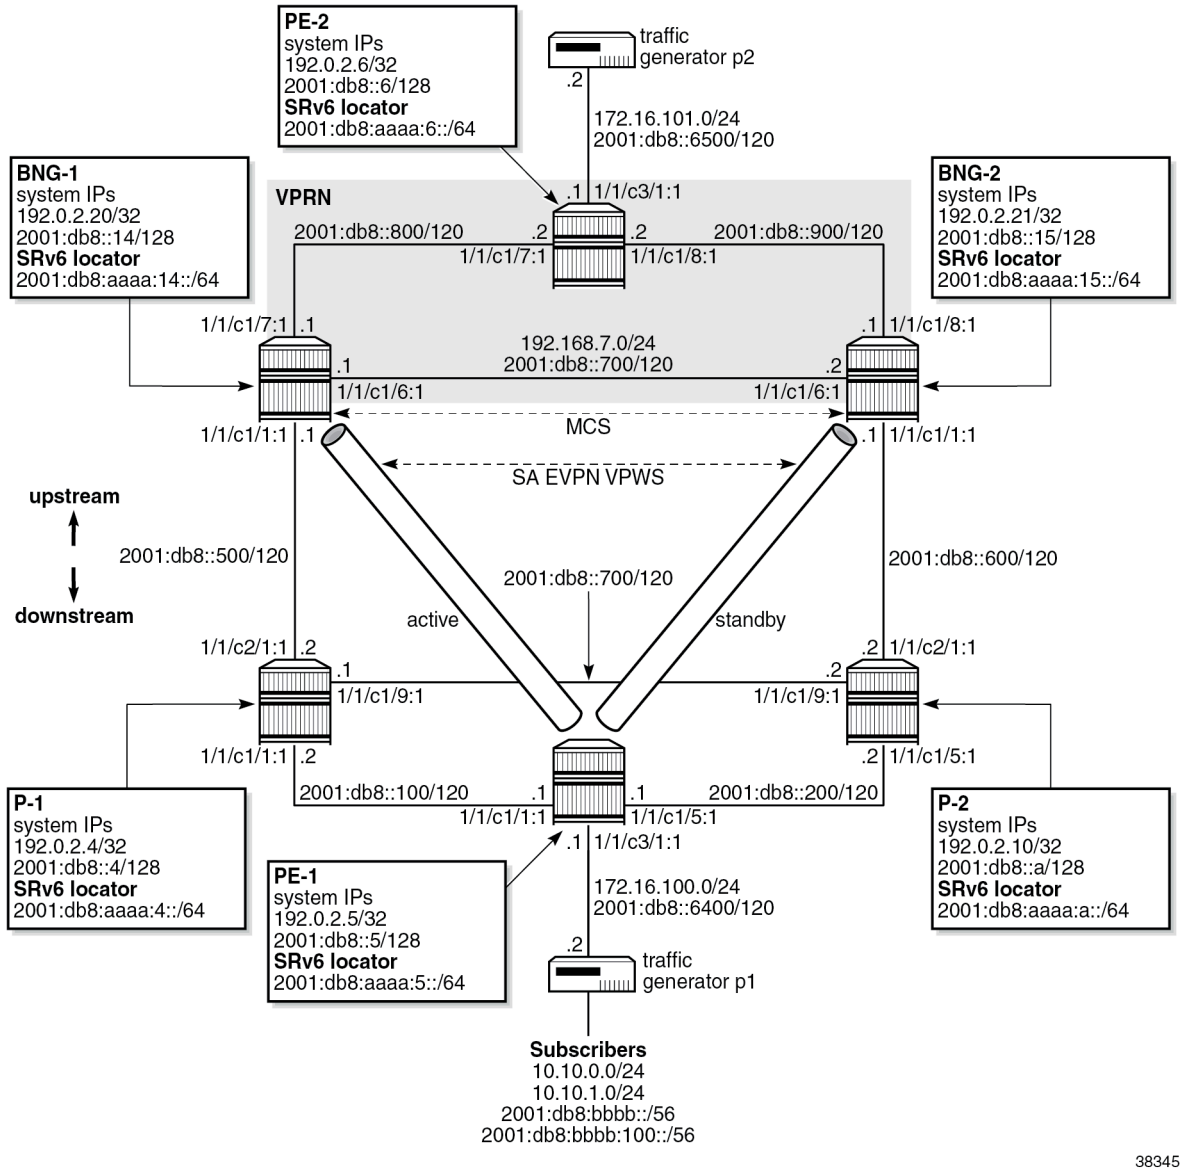
Use subject to Terms available at: www.nokia.com/terms.

Figure 332: Example topology



At a high level, the topology in the figure Figure 332: Example topology can be described in terms of access-related configuration, subscriber-related configuration, and core-related configuration.

Access-related configuration

- Subscribers are connected to the first-mile access node (PE-1), which is dual-homed to the two BNGs (BNG-1 and BNG-2).
- Pseudowire (PW) ports on the two BNGs are part of an Ethernet segment (ES) configured in single-active (SA) mode in the EVPN VPWS multihoming (MH) environment.
- The EVPN transport technology in the access network is SRv6.

Subscriber-related configuration

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- There are 10 IPoE and 10 PPPoE dual-stack sessions terminated on a PW-SAP in a VPRN on both BNGs.
- Each IPoE and PPPoE session has an IPv4 address, a DHCPv6 identity association for non-temporary addresses (IA-NA), and a DHCPv4 identity association for prefix delegation (IA-PD) addresses. IA-PD addresses are modeled as managed routes with IPv6 next hops.
- Each session is mapped to a separate subscriber.
- Subscriber sessions are synchronized between the two BNGs. A fully synchronized model offers redundancy protection with minimal loss during network outages.
- DHCPv4/v6 servers are instantiated on the BNGs and their pools are synchronized, except for DHCPv4 pools used for internal address assignment to PPPoEv4 sessions. IPv4 addresses for PPPoEv4 sessions are synchronized in DHCPv4 pools through PPPoE session synchronization and not directly through DHCP pools.
- The SRRP state is indirectly derived from the state of the dual-homed EVPN ES in the access network and does not rely on exchange of SRRP keepalive messages between the two BNGs.
- A redundant interface between the two BNGs provides a temporary path for subscriber traffic while the network is converging during switchovers.

Core-related configuration

- A VPRN with SRv6 transport is deployed in the core.
- SRRP-aware routing on the core side ensures that the core traffic follows the BNG with the active SRRP instance. In other words, traffic in both directions (upstream and downstream) is attracted to one BNG or the other based on the SRRP state.

The example topology provides protection against failures of network elements in the access and core networks, including the BNGs themselves.

Subscriber traffic is run between two ports of a traffic generator. For topology verification purposes, network failures are purposefully introduced and their effect on the subscriber traffic is examined.

Subscriber synchronization

The subscriber state is synchronized between the two BNGs, including DHCPv4/v6 lease state and PPPoEv4/v6 states.

DHCPv4/v6 pools on the local DHCP servers in both BNGs are synchronized in access-driven mode (except for the pools used for internal IP address allocation to PPPoEv4, which are synchronized indirectly through PPPoE session synchronization). In access driven mode, the DHCPv4/v6 servers in each BNG are configured identically and are attached to an interface with the same IP address. Both servers can allocate IP addresses at any time; however, to prevent duplication of IP addresses, access to only one server is allowed at any given time. This restriction is achieved through the redundancy model, which relies on the SA mode of operation on the ES coupled with SRRP.

The figure Figure 333: DHCP pool synchronization in access-driven mode shows a topology using the redundancy model, where subscribers have access only to BNG-1 via EVPN VPWS multihoming. The path of the EVPN VPWS on the left side is active while the path on the right side is standby.

SRv6

This section provides a brief introduction to SRv6. For more information about SRv6, refer to the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I* and EVPN VPWS Services with SRv6 Transport chapter and to the *7750 SR and 7950 XRS Segment Routing and PCE User Guide*.

SRv6 allows for more flexible network management over a single IPv6 dataplane protocol, using the following concepts:

- traffic engineering, where traffic is securely steered through pre-selected network nodes on its way to the destination
- network programmability, which includes encoding higher-level functions (such as service identification) into the IPv6 address

At the dataplane level, SRv6-based traffic steering is implemented with the help of a routing extension header, called a segment routing header (SRH). Each application typically provides its own type of the routing header, as is the case here, with inherent support for security.

The SRH contains a list of segments, each of which has a unique segment identifier (SID), through which a packet is steered as it transits the network on its way to the destination. These segments may be nodes, adjacencies, bindings to downstream tunnels, and so on. Each node that owns a SID in the SRH needs to intercept the SRv6 packet for inspection and consequently update the IPv6 header. Transit nodes that are not in the SRH list do not intercept SRv6 packets because the packet is not addressed to them. Such transit nodes forward the packet to the destination based on a lookup of the destination address (DA) in the outer IPv6 header.

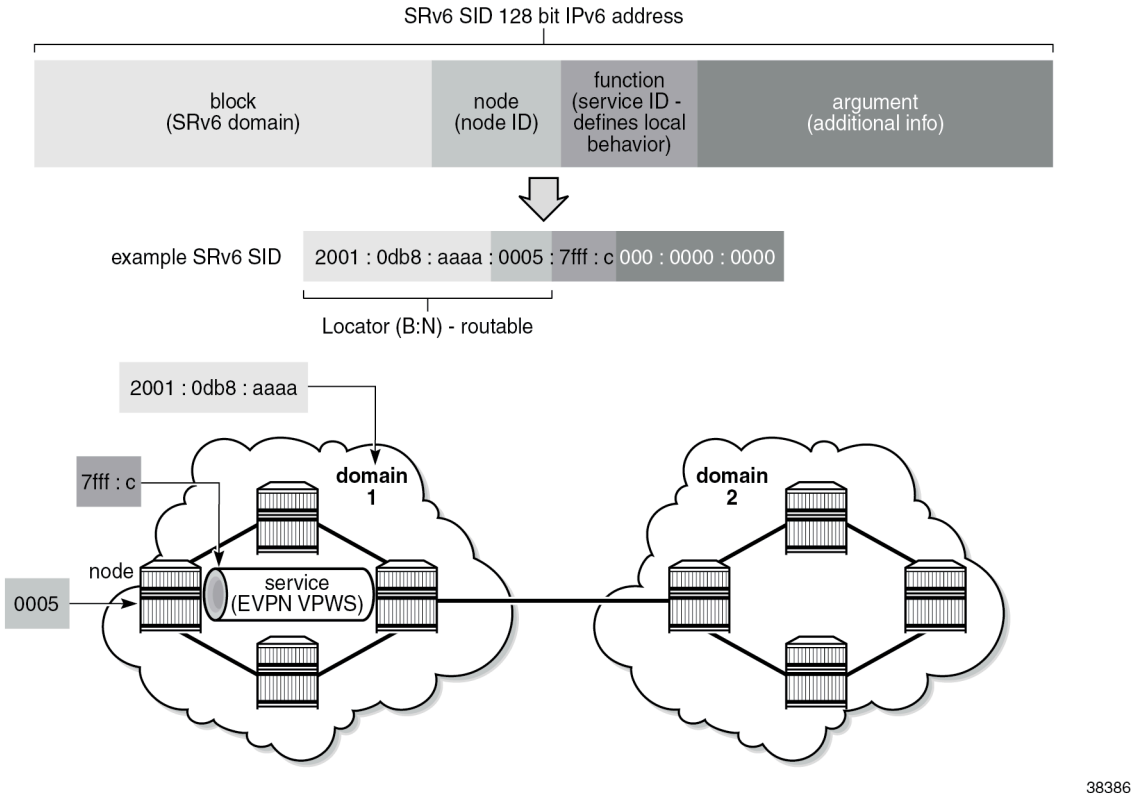
As well as identifying specific segments via IPv6 addresses in SRv6, SIDs carry additional information beyond node reachability. This additional information instructs the target node how to map arriving

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

IPv6 packets to a service. For example, a SID can be an IPv6 address that, in addition to carrying the address of the target node (SRv6 prefix or a locator), also carries specific EVPN VPWS information. This additional information is interpreted at the target node as “extract the payload of this packet and process it in the context of EVPN Epipe ID=10”. In this way, an arriving IPv6 packet is directly mapped into the corresponding service based on the IPv6 address, without the need for additional transport protocols such as MPLS with its VC labels.

The figure Figure 334: SRv6 SID shows the SID structure, where the length of the fields is configurable.

Figure 334: SRv6 SID



To differentiate between SIDs used in plain routing and the higher level SIDs that are used with services (such as EVPN and VPRN), the SIDs are sometimes referred to as transport SIDs and service SIDs. SIDs are advertised in routing protocols through segment routing extensions. Nokia SR OS supports such extensions in IS-IS for transport-related SIDs and in BGP for Layer 2 and Layer 3 service-related SIDs.

SIDs are an integral part of routing in SRv6, but SIDs are not interface addresses; SIDs are configured and allocated in respective **segment-routing-v6** contexts (outside of the interface configuration) to the Base router and service to which they pertain.

As the figure Figure 334: SRv6 SID shows, the block and the node form a locator field in the SID. The locator field is used for node reachability in basic destination-based routing. Typically, a node advertises IPv6 prefixes matching the locator function of its SIDs. In SR OS, when the locator prefix is advertised in IS-IS, it is encoded in an SRv6 Locator Sub-TLV, which is an SRv6 extension in IS-IS. A node can advertise multiple locators simultaneously (for example, one locator per Flexible-Algorithm).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The block part of the locator defines an SRv6 domain. In an SRv6 domain, nodes share the same block prefix. SRv6 domains can be considered as administrative units that can be formed based on geography or some other logical entity, such as enterprise VPN. The node part of the locator is unique to each node.

The function part of the locator defines a local behavior on the node that owns the SID. Specific functions that can be associated with SIDs are described in RFC 8986 and RFC 8402. The End and End.X functions are used by IS-IS to create repair tunnels and backup paths (topology-independent loop-free-alternate (TI-LFA) and remote LFA). The combination of TI-LFA and remote LFA provides full coverage of any access network. The End function represents the node prefix which is reachable based on the shortest path. The End.X function represents links between the nodes (these links are router adjacencies which can be local or remote) and is used to specify the router adjacency (for example, for strict mode routing) out of which the frame is forwarded. Together, the End and End.X functions are used to install optimal and loop-free backup paths in the forwarding plane with achievable failover times of less than 50 ms.

The table Table 19: SRv6 endpoint behaviors shows the functions used in this chapter:

Table 19: SRv6 endpoint behaviors

Function	Description	Advertised in
End	SRv6 instantiation of a node SID	IS-IS SRv6 End SID sub-TLV
End.X	SRv6 instantiation of an adjacency SID	IS-IS SRv6 End.X SID sub-TLV
End.DX2	decapsulation and L2 cross-connect (L2VPN)	EVPN VPWS AD per-EVI route
End.DT4	decapsulation and specific IPv4 table lookup (IPv4-L3VPN)	BGP
End.DT6	decapsulation and specific IPv6 table lookup (IPv6-L3VPN)	BGP
End.B6.Encap.Red	function bound to an SRv6-policy with reduced encapsulation	N/A

The argument field is optional, and it can carry additional information related to the local function. It is set to 0 inSR OS.

Routing

IS-IS is used as IGP to disseminate node reachability information (the node's interface routes, BGP next hops, SRv6 locators, and node and adjacency SIDs), while BGP is used to disseminate SRv6 service SIDs and VPN and EVPN routes.

As shown in the figure Figure 335: Separation of routing domains, IS-IS is segmented into two instances:

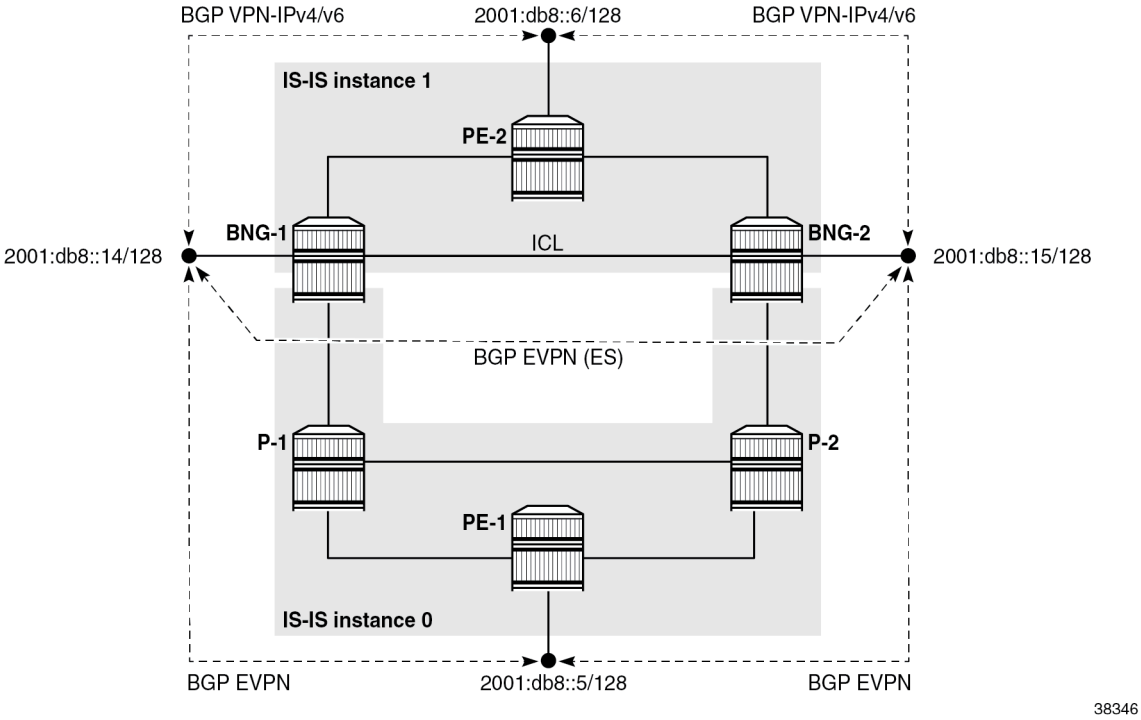
- IS-IS instance 0 runs in the access network
- IS-IS instance 1 runs in the core part of the network, including the inter-chassis link (ICL) between the two BNGs

The system IPv6 addresses are included in both instances. There is no route exchange between the two IS-IS instances.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

IPv6 BGP peering is established directly (with no route reflector) between the service endpoints with respective BGP address families, as shown in the figure Figure 335: Separation of routing domains. IPv6 BGP peering is not a prerequisite and IPv4 BGP peering would work just as well.

Figure 335: Separation of routing domains

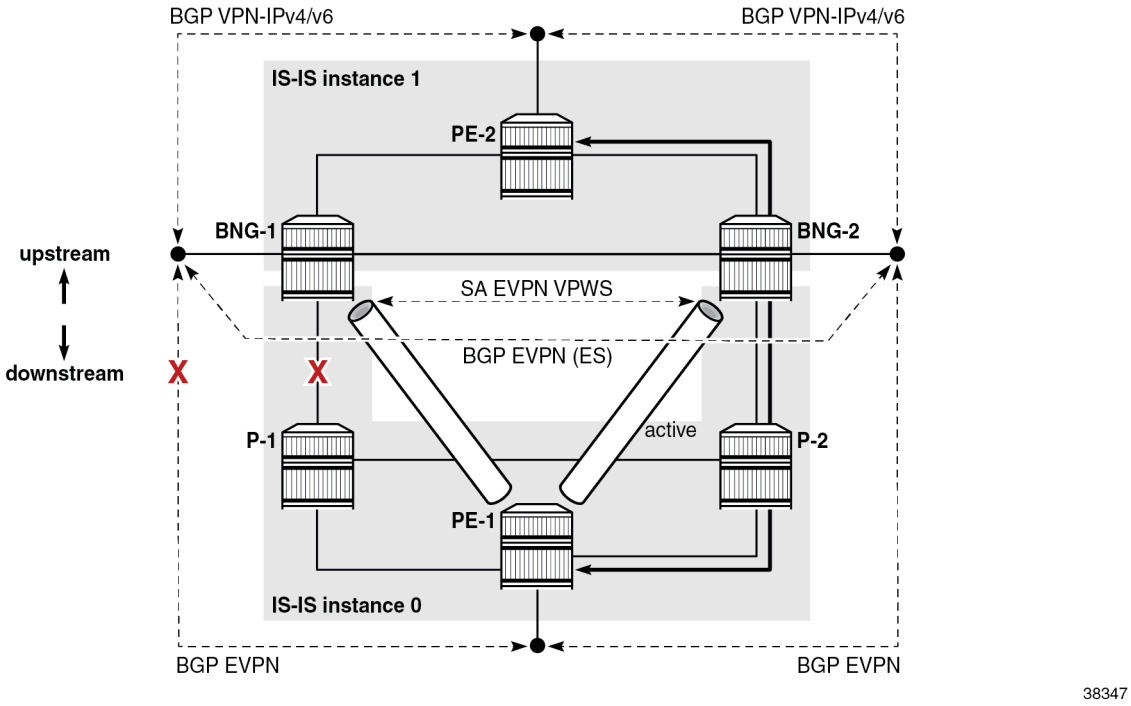


The ICL must be highly redundant but does not need to support high bandwidth. Its use is typically limited to subscriber synchronization and to shunt data traffic between BNGs during transient network conditions while the network reconverges during switchovers. For cost reductions, it may not be desirable to dimension this ICL to carry all subscriber traffic during prolonged periods of network failures. To minimize the use of ICL for data traffic, the topology shown in the figure Figure 335: Separation of routing domains relies on the separation of IS-IS routing domains between the access network and the core network, as described in the Examining failovers section. The hard separation of IS-IS routing domains is not a prerequisite or the only design option, but rather an arbitrary choice used in this chapter.

When the link between the nodes BNG-1 (with the active SRRP) and P-1 fails, the PE-1 BGP next hop becomes unreachable on BNG-1 because of the separation of IS-IS routing domains, which causes the active EVPN VPWS between BNG-1 and PE-1 to switch over to BNG-2. The switch to BNG-2, combined with SRRP-aware routing on the core side, ensures that the use of ICL is limited to transient conditions while routing is converging during the failure. The figure Figure 336: Optimal traffic flow during network failures shows the steady state traffic path after the network has converged: the path from PE-1 to PE-2 via P-2 and BNG-2.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 336: Optimal traffic flow during network failures



In an alternative design where all nodes are in the same IS-IS routing instance 0, the PE-1 node continues to be reachable from BNG-1 (via BNG-2 or PE-2) even after the access link on BNG-1 fails. As a result, BNG-1 remains the designated forwarder (DF) for the ES and SRRP on BNG-1 remains in the active state. This causes traffic in both directions to take a path over the ICL link or even to cross some of the core links twice, as shown in Figure 337: Suboptimal traffic flow during network failure . Traffic from PE-1 goes via P-2 to BNG-2, which sends the traffic to DF BNG-1 via PE-2 (the ICL is not used). BNG-1 forwards the traffic (back to) PE-2.

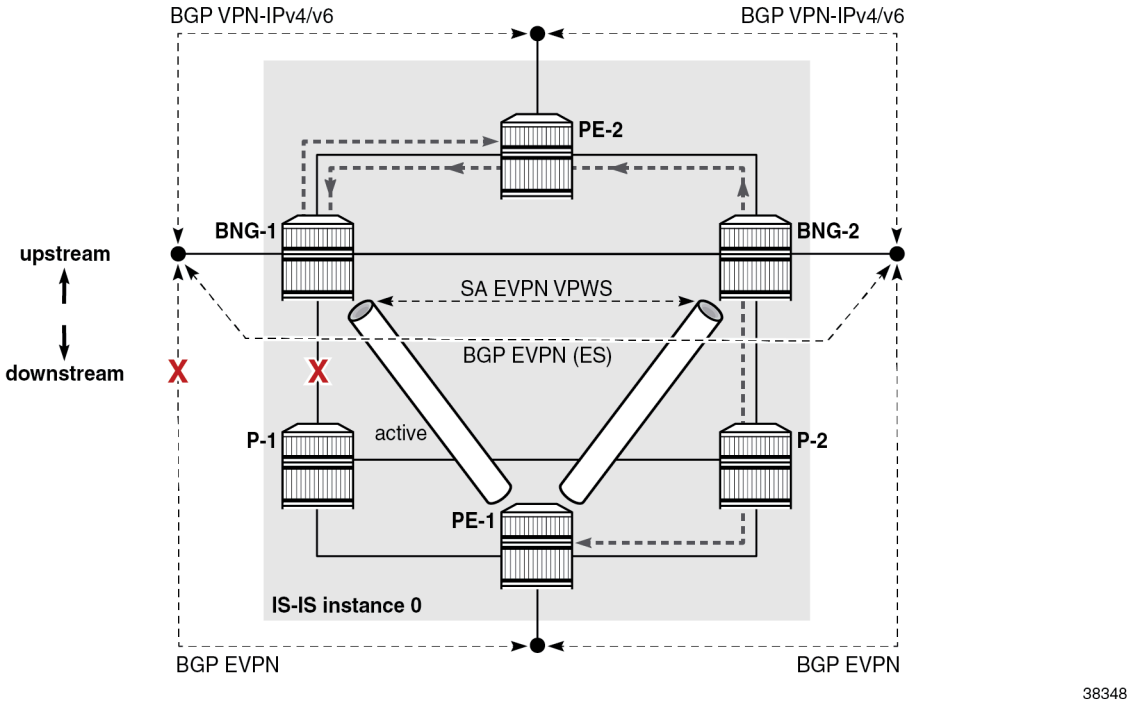
Figure 337: Suboptimal traffic flow during network failure



IPv4 addressing

Subscriber traffic in the overlay network utilizes both IPv4 and IPv6 address families, as part of dual-stack configuration. Comparatively, the underlay network is based on SRv6, with the advantage that IPv4 addressing is no longer needed.

Therefore, in the example topology, IPv4 addresses in the underlay network are removed from most interfaces. There are a few exceptions where local IPv4 addresses are kept, but without advertising them into the network, which means that routing protocols in the underlay network remain free of IPv4 addresses.

The following are exceptions where IPv4 addresses in the underlay network are still used:

- System IPv4 addresses are still used locally on each node for legacy reasons where some functionalities may still require it. For example, in EVPN VPWS multihoming, an IPv4 system address is required to derive the route distinguisher (RD) for the ES route (even if static RD for the EVPN VPWS is configured).
- Multi-chassis synchronization (MCS) peering between the two nodes is supported only over IPv4 addresses. For the MCS peering, the system IP addresses of the BNGs are used, with static routes over the IPv4 next hops configured on the direct link between the two BNG nodes. Because this link directly connects the two BNGs, no advertisement of the IPv4 prefix is required.
- The **redundant-Interface** command under the BNG **group-interface** context also requires IPv4 addressing. Those IPv4 addresses are also not advertised into the network.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

SRv6 policy

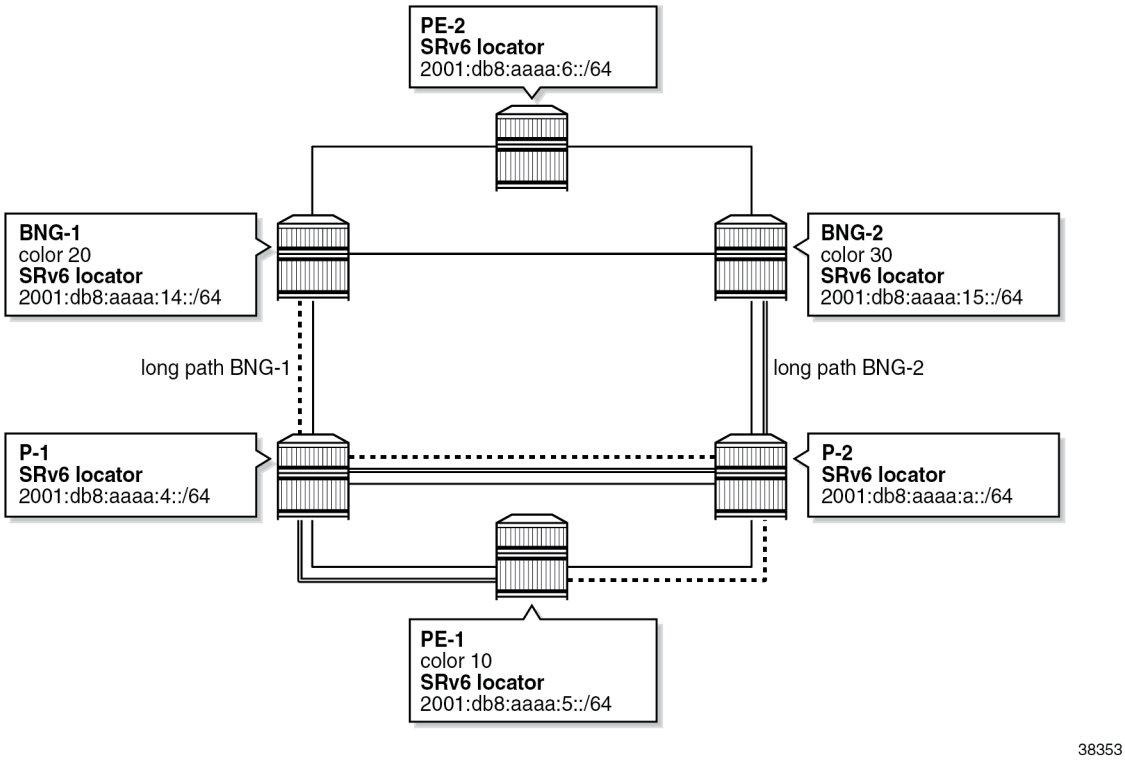
For illustrative purposes, the example uses a static SR policy of type SRv6 in the access network. This SR policy is configured with segment list entries, which are node SIDs that are to be visited on the way to the final destination.

The SR policy is treated as a routing entity whose configured endpoint is installed as an entry in the tunnel table. The SR policy becomes the protocol owner of such an entry in the routing or tunnel table. The tunnel entry can be used for BGP next-hop resolution.

Configuring hops in the SR policy triggers the generation of an SRH, which is further described in the Configuration section.

The SR policy in the example steers traffic onto a longer path, despite a shorter path with lower cost being available. This behavior is shown in the figure Figure 338: Static SRv6 policy paths where traffic from the BNGs to PE-1, and vice versa, always flows through both P-1 and P-2.

Figure 338: Static SRv6 policy paths



Examining failovers

The configuration used in this chapter has been tested by running traffic and incurring network failures at various points. Traffic was monitored after the failures to ensure the traffic was flowing through a predicted path.

Traffic is run bidirectionally between two ports on a traffic generator, representing the subscribers on the 10.10.*x*.*x* networks and the Internet on the 172.16.101.*x* network.

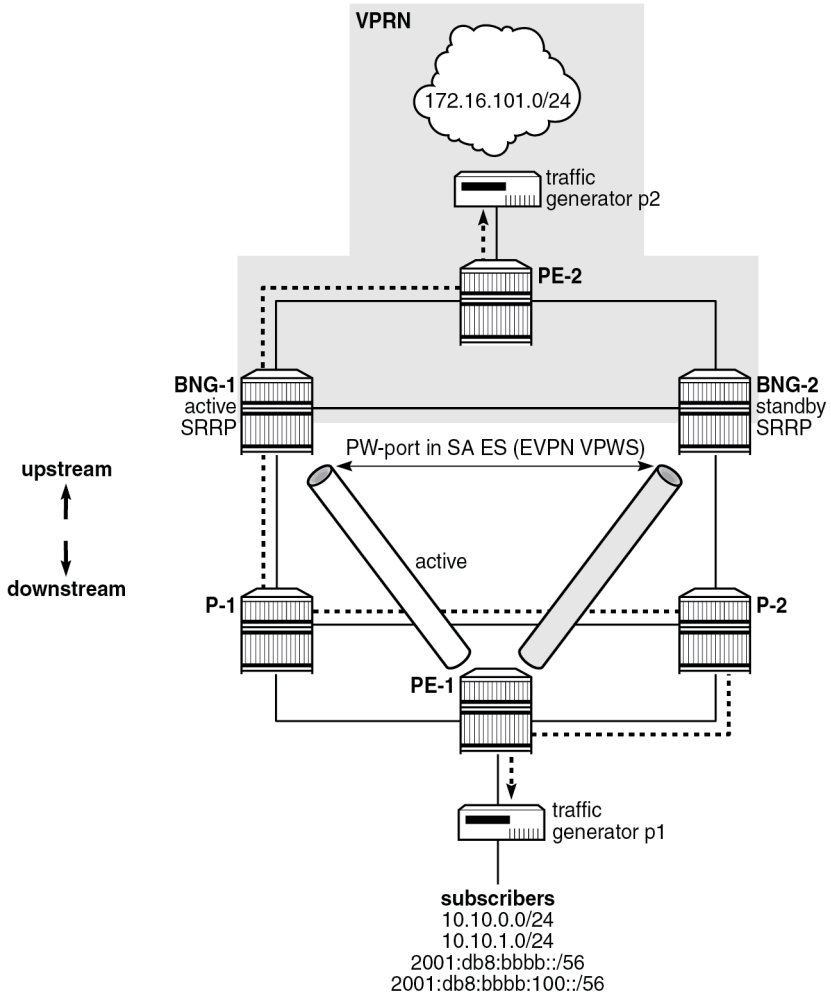
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

BNG-1 advertises subscriber IPv4 and IPv6 subnets into the core network (VPRN) with lower cost than BNG-2, because SRRP is active on BNG-1 and standby on BNG-2.

In the access network, the ES in EVPN VPWS on BNG-1 is selected as DF due to a higher preference.

Traffic through the access network is steered by the SRH, which is inserted by the static SR policy configured on both BNGs and PE-1. In the upstream direction, traffic follows the path depicted in 8: from traffic generator port 1 via PE-1, P-2, P-1, BNG-1, and PE-2 to traffic generator port 2. Downstream traffic follows the same path in reverse direction.

Figure 339: Baseline traffic flow



Three switchovers are examined:

- switchover due to failure of the link between BNG-1 and P-1
- switchover due to failure of the network link connecting BNG-1 to PE-2
- switchover due to failure of the entire BNG-1 node

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

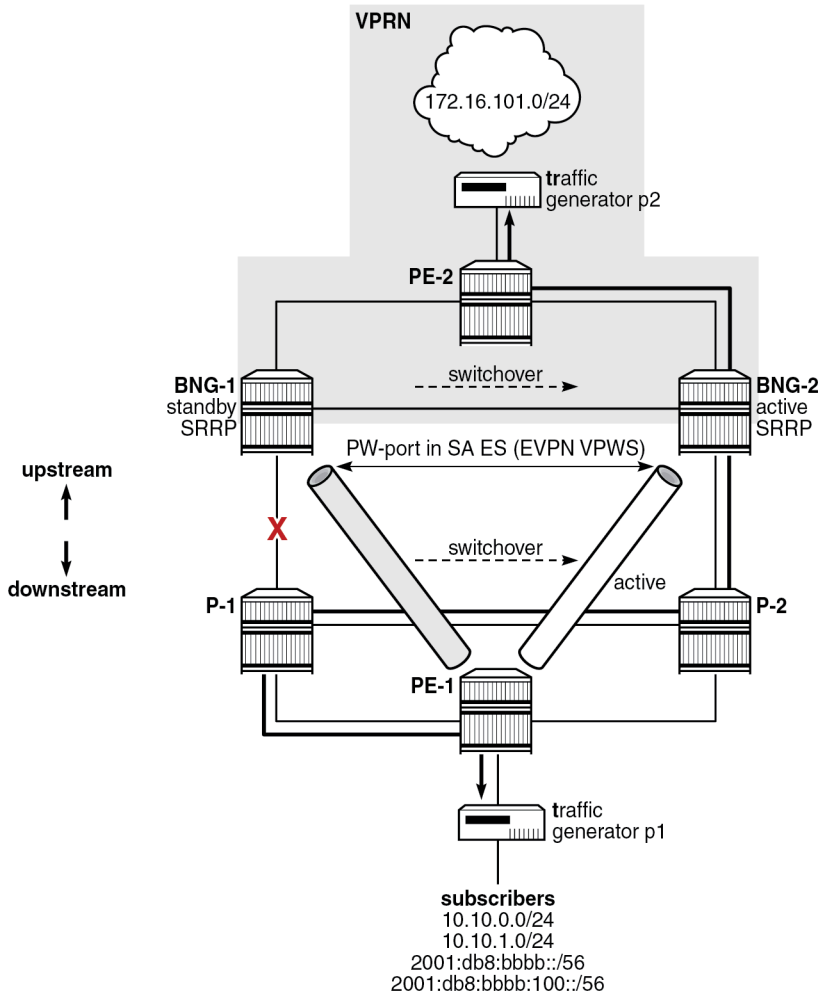
In all three cases, the failover time depends on the failure detection speed and convergence of the routing protocols. Nokia encourages operators to run performance-related tests, which includes measuring failover times, in their own test environment on service routers with Nokia native hardware (non-server based service routers).

Failure detection speed can, in some cases, be improved by bi-directional forwarding detection (BFD). In the example topology, BFD is configured for detection of BGP peer failures.

Switchover caused by the failure of the access link on BNG-1

The figure Figure 340: Access port failure shows a switchover scenario where the access port on BNG-1 toward P-1 is disabled and all traffic is diverted to BNG-2 as indicated. The traffic detour over the link between P-1 and P-2 is taken because the static SR policies favor longer paths over shorter.

Figure 340: Access port failure



The following events trigger the traffic switchover from BNG-1 to BNG-2:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

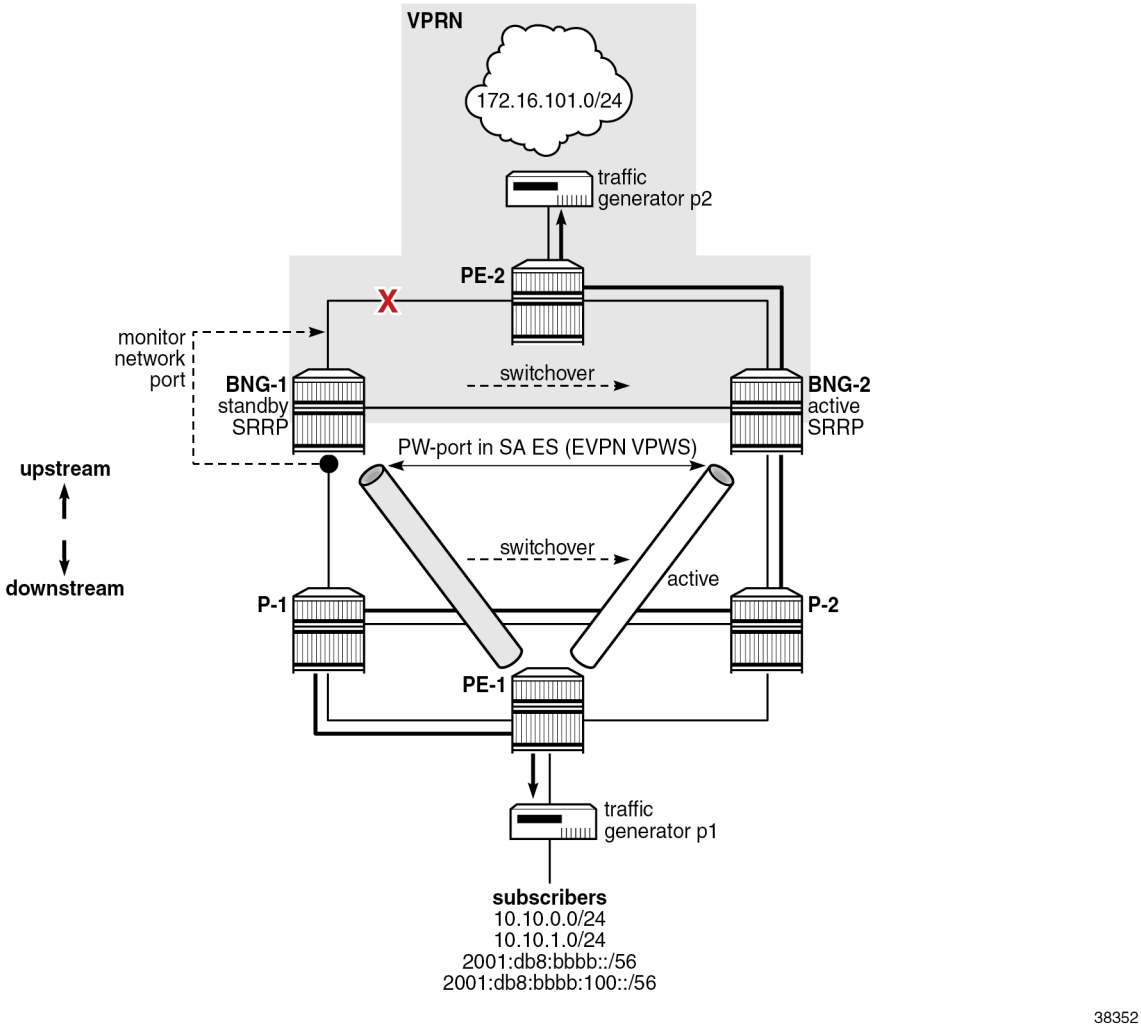
- When the access port on BNG-1 is disabled, the BGP peering connection between BNG-1 and PE-1 is lost because of the separation of IS-IS routing domains. The BGP connection is required for the advertisement of the overlay EVPN routes.
- On BNG-1, the speed of detecting the BGP connection failure is locally driven by the speeds of the link loss detection and the consequent IS-IS algorithm that is run to determine that an alternate path to the BGP peer (PE-1) does not exist.
- On PE-1, the speed of detecting the BGP connection failure is driven by the speed of IS-IS link state advertisement (LSA) propagation.
- The severed BGP connection between BNG-1 and PE-1 triggers the DF election process on the ES between the two BNGs, which is driven by BGP. BNG-2 is selected as the DF and BNG-1 as the non-DF.
- The newly elected DF on BNG-2 performs the following actions:
  - It activates EVPN VPWS toward PE-1 so that traffic can be sent to it and be received from it. (More explicitly, it advertises an Auto-Discovery route with the Primary flag (P-bit) set to 1 to indicate that it is active, and the Backup flag (B-bit) set to zero.)
  - It triggers activation of SRRP on BNG-2 (but does not activate it). SRRP continues to run through its own state machine, which involves waiting for three times the SRRP transmit interval (SRRP keepalive messages) before it becomes active. Due to this delay in becoming active, it is still important to have a short SRRP transmit interval configured under SRRP, even if SRRP keepalive messages are not exchanged between the two BNGs, as in this example. In other words, SRRP activation is driven by the DF outcome of the EVPN ES election process, which then triggers the SRRP activation process with its own state machine.
- PE-1 does not wait for the BGP update from BNG-2 that contains the new DF decision. PE-1 activates the stored backup route from BNG-2 as soon as it realizes, via IS-IS, that the BGP connection to BNG-1 is lost.
- Lastly, the activation of SRRP on BNG-2 triggers the advertisement of subscriber routes into the core with a lower cost than that advertised by BNG-1. After the core network converges, traffic in the downstream direction is diverted from the link between PE-2 and BNG-1 to the link between PE-2 and BNG-2. While the routing is converging, traffic in the downstream direction might be flowing from BNG-1 to BNG-2 through the redundant interface (over the ICL) between the two BNGs.

Switchover caused by the network link failure between BNG-1 and PE-2

In the figure Figure 341: Network port failure, the port on BNG-1 toward PE-2 is disabled, which results in a switchover due to the network link failure between BNG-1 and PE-2. All traffic is diverted to BNG-2. The traffic detour over the link between P-1 and P-2 is taken because of the static SR policies on BNGs and PE-1.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 341: Network port failure



A failure of the core link on BNG-1 diverts downstream traffic to BNG-2 in the core network, which uses VPRN. But in the access network, which uses EVPN, traffic still flows through BNG-1, which remains the DF on EVPN ES and where SRRP is active. To prevent a scenario where the inter-chassis link is used to carry traffic between the two BNGs during the failure, a feedback loop from the core port to the access port is required. In this way, the state change of the core port is reflected in the access port and, as result, traffic is completely diverted from BNG-1 to BNG-2. This feedback loop is implemented through an operational group associated with a core port and monitored by the access port.

The remainder of the switchover mechanics are the same as those in the Switchover caused by the failure of the access link on BNG-1 section.

Switchover caused by the BNG-1 node failure

After the loss of the BGP peering connection to BNG-1, BNG-2 becomes the DF for the EVPN ES. The BGP peering connection loss can be detected by a loss of link on BNG-2, by BFD, or by IS-IS LSA propagation.

BNG-2 becoming DF has the same effects as already described in the previous two cases.

Recovery

To restore the network to its state from before the failure, the operators have the option to revert traffic automatically to the primary paths that were available before the failure. The revertive behavior involves another switchover, which is associated with possible traffic loss. Whether to enable revertive behavior is a choice between the cost of another switchover measured by affected user experience due to a small traffic loss and the cost of keeping the traffic on backup paths which may not be optimized for such traffic.

To ensure minimal traffic loss when revertive behavior is enabled, the network must have fully converged after the recovery, before the switchover to the previous state occurs. For example, upon reboot, the recovered BNG must be fully integrated into the network; that is, all subscribers must be synchronized between the two BNGs, the BGP peering sessions must be reestablished, and routes exchanged. The synchronization between the BNGs is independent of the exchange of BGP routes and these events may occur in any sequence. For this reason, bootup timers must be configured properly to make sure that all relevant processes are completed before the switchover occurs. Bootup timers are described in the Configuration section.

Configuration

The complete configuration files for all six nodes in this example topology are provided in the Appendix.

The examples in this section focus on the Forwarding Path Extension (FPE)-based PW port in multihomed EVPN environments with SRv6 transport.

The configuration shown in this section is mainly for the two nodes that represent the two endpoints of the EVPN VPWS: BNG-1 and PE-1.

The configuration blocks, together with the output of the **show** commands, cover the following topics:

- FPE
- SRv6
- IS-IS routing related to SRv6
- BGP routing related to SRv6
- EVPN VPWS (including ES and PW port) and service-related SRv6 configuration
- VPRN-related SRv6 configuration
- multi-chassis redundancy configuration
- DHCP server configuration
- subscriber management configuration

While many of these topics are described in other chapters, the purpose of this chapter is to show how they interact together.

© 2023 Nokia.

The less important parts in the configuration blocks or the output from the **show** commands are removed for brevity.

FPE

In SR OS Release 22.10, the example setup requires three FPE-based port cross-connects (PXCs) on each BNG, one for each of:

- the SRv6 origin
- the SRv6 termination
- the PW port

All three PXCs are port-based and they are set up on the same port. Selecting port-based PXCs in this example versus MAC- or internal-based PXCs is an arbitrary choice. Either type of PXC can be used.

The PXC configuration on BNG-1 is as follows. The configuration on BNG-2 is identical. Other nodes do not have a PW port and require only two PXCs for SRv6.

```
[pr:/configure port-xc]
A:admin@bng-1#
    pxc 1 {
        admin-state enable
        description "fpe srv6 origin"
        port-id 1/1/c4/1
    }
    pxc 2 {
        admin-state enable
        description "fpe srv6 termination"
        port-id 1/1/c4/1
    }
    pxc 3 {
        admin-state enable
        description "fpe pw-port"
        port-id 1/1/c4/1
    }
```

The logical PXC ports are configured as follows:

```
[pr:/configure]
A:admin@bng-1#
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port pxc-3.a {
        admin-state enable
    }
    port pxc-3.b {
        admin-state enable
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
}
```

The following FPE configuration is required for PW port and SRv6 configuration:

```
[pr:/configure]
A:admin@bng-1#
    fwd-path-ext {
        sdp-id-range {
            start 17500
            end 17600
        }
        fpe 1 {
            description "srv6 origination"
            path {
                pxc 1
            }
            application {
                srv6 {
                    type origination
                }
            }
        }
        fpe 2 {
            description "srv6 termination"
            path {
                pxc 2
            }
            application {
                srv6 {
                    type termination
                }
            }
        }
        fpe 3 {
            description "pw-port on a single port"
            path {
                pxc 3
            }
            application {
                pw-port-extension { }
            }
        }
```

SRv6

SRv6 is configured on several levels:

- the base routing context level (which is the focus of this section)
- the IS-IS routing protocol level
- the services level

The static SRv6 policy is configured in the base routing context and is examined in the context of the Epipe to which it is applied.

Relevant to the example setup, the global SRv6 configuration under the base router provides:

- an SRv6 association with an FPE
- an SRv6 locator

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- the source address
- the allocation and behavior of End and End.X SIDs

Note: Nokia encourages that the source address is configured at the Base routing context level. Although some entities, such as EVPN or VPRN services, provide the configuration option for the source address, other entities, such as the static SR policy, do not. In these cases, the entities inherit the source address from the global configuration provided here. Without the configured source address, SRv6 is not operational.

```
[pr:/configure router "Base" segment-routing segment-routing-v6]
A:admin@bng-1#
    origination-fpe [1]
    source-address 2001:db8::14
    locator "bng-1-loc" {
        admin-state enable
        block-length 48
        termination-fpe [2]
        prefix {
            ip-prefix 2001:db8:aaaa:14::/64
        }
    }
    base-routing-instance {
        locator "bng-1-loc" {
            function {
                end 1 {
                    srh-mode usp
                }
                end-x-auto-allocate usp protection protected { }
            }
        }
    }
```

The following **show** command displays a summary of SRv6 on a global level:

```
A:admin@bng-1# /show router segment-routing-v6 summary

```

The InstId field for End.X SIDs shows the IS-IS instance in which they are configured.

SRv6 locators are used for node reachability and are, through route advertisements, installed in the route tables of other nodes. For example, the following output shows the SRv6 locator of BNG-1 is installed in the IPv6 routing table of BNG-2:

```
A:admin@bng-2# /show  router route-table ipv6

===============================================================================

---snip---
```

IS-IS routing related to SRv6

As described in the Routing section, IS-IS is split into two instances. Instance 0, as indicated by its configured interfaces, is active on the access side. Instance 1 is active on the core side, including the link between the two BNGs.

The **segment-routing-v6** section in the IS-IS configuration block references the SRv6 locator that IS-IS, together with its basic functions (node and adjacency SIDs), advertises into the network.

Some of the IS-IS configuration outside of the **isis segment-routing-v6** context is directly pertinent to SRv6. For example, the SRv6 locator is only advertised when the **wide-metrics** command is configured.

BNG-2 is configured similarly to BNG-1. P-1, P-2, and PE-1 have only IS-IS instance 0 configured, while PE-2 has only IS-IS instance 1 configured. Although only a portion of the configuration on BNG-1 is provided, the IS-IS configuration on other nodes in respective IS-IS instances is similar with different naming for interfaces and for the SRv6 locator.

Between the two IS-IS instances in BNG-1, the only configuration difference is that they reference different interfaces. In the following example, only one repeated part of the IS-IS instance 1 configuration is shown:

```
[pr:/configure router "Base"]
    isis 0 {
        admin-state enable
        advertise-passive-only false
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        advertise-router-capability area
        ipv6-routing native
        level-capability 2
        traffic-engineering true
        area-address [49.0001]
        loopfree-alternate {
            remote-lfa {
            }
            ti-lfa {
            }
        }
        traffic-engineering-options {
            ipv6 true
            application-link-attributes {
            }
        }
        segment-routing-v6 {
            admin-state enable
            locator "bng-2-loc" {
                level-capability 2
                level 2 {
                    metric 10
                }
            }
        }
        interface "int-1-bng-2-p-2" {
        }
        interface "system" {
        }
        level 2 {
            wide-metrics-only true
        }
    }
    isis 1 {
        ---snip---
        interface "int-1-bng-2-bng-1" {
        }
        interface "int-1-bng-2-pe-2" {
        }
        interface "system" {
        }
        ---snip---
```

The following **show** command confirms that IS-IS adjacencies in instance 1 are up. A similar command can be used for IS-IS instance 0.

```
A:admin@bng-1# /show  router isis 1 adjacency

===============================================================================
Rtr Base ISIS Instance 1 Adjacency
===============================================================================
System ID               Usage State Hold Interface                    MT-ID
-------------------------------------------------------------------------------
bng-2                   L2    Up    24   int-1-bng-1-bng-2            0
pe-2                    L2    Up    9    int-1-bng-1-pe-2             0
-------------------------------------------------------------------------------
Adjacencies : 2
```

Further SRv6-related information in IS-IS, such as exchanged locators or node SIDs, can be explored by using commands under the following hierarchy:

```
A:admin@bng-1# /show  router isis 1 segment-routing-v6
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following **show** command lists the locators that are present in IS-IS instance 1 on BNG-1. These locators can be local or learned through IS-IS. For BNG-1, locator 2001:db8:aaaa:14::/64 is local.

```
A:admin@bng-1# /show  router isis 1 segment-routing-v6 locator

===============================================================================
Rtr Base ISIS Instance 1 SRv6 Locator Table

  -                                   0                             -      0
2001:db8:aaaa:14::/64               bng-1                         0      2/Int.
  -                                   0                             -      0
2001:db8:aaaa:15::/64               bng-2                         0      2/Int.
  -                                   0                             -      0
-------------------------------------------------------------------------------
```

BGP peering

IBGP is used to exchange EVPN and VPRN routes between the BNGs and the edge nodes (PE-1 and PE-2). IBGP peering sessions with corresponding address families are shown in the figure Figure 335: Separation of routing domains.

In the EVPN part of the network, BGP is used between the two BNGs to elect the DF on the ES, and between the BNGs and PE-1 to exchange the reachability EVPN routes. PE-1 uses the advertised EVPN route from the BNGs to set up and activate an EVPN VPWS connection toward the active (DF) BNG.

In the VPRN, the two BNGs exchange VPN-IPv4 and VPN-IPv6 routes (subscriber and Internet routes from the traffic generator) with PE-2.

BGP is not configured on nodes P-1 and P-2.

Consider the following when configuring BGP:

- All BGP peers are IPv6 peers.
- The **advertise-ipv6-next-hops** command for the VPN IPv4 and VPN IPv6 address families must be explicitly enabled. By default, only IPv4 next hops are advertised, which in this case do not exist. The counterpart command for EVPN address family is enabled under the **bgp-evpn** configuration for the corresponding Epipe: the **route-next-hop system-ipv6** command is configured in the **configure service epipe <..> bgp-evpn segment-routing-v6** context.
- The **extended-nh-encoding** command must be enabled to allow IPv6 next hops for the VPN IPv4 address family.
- The SR policy used for traffic steering is deployed in the access network.
- BFD is enabled for faster failure detection of all BGP neighbors.

For the SR policy to take effect, the target node referenced in the **endpoint** command must advertise its routes with a color extended community, in the format community:color, that matches the one configured in the policy. The configured color extended community advertised by BNG-1 is color-20. Rather than exporting this color extended community through a VSI-export policy at the service level, for simplicity reasons, it is exported at the global BGP level. This way, the color extended community can be easily added to the existing communities, such as the route target (RT) community in the Epipe.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note: With the alternative approach relying on the VSI export policy, the RT community would need to be explicitly readvertised along with the color extended community.

The routing policy name used to export the color extended community is "pol-color-20". It is applied only toward the BGP peer PE-1 (neighbor 2001:db8::5). To activate the export policy, the **vpn-apply-export** command must be specifically enabled in MD-CLI.

The BGP configuration on BNG-1 is as follows:

```
[pr:/configure router "Base"]
A:admin@bng-1#
    bgp {
        admin-state enable
        vpn-apply-export true
        vpn-apply-import true
        rapid-withdrawal true
        rapid-update {
            vpn-ipv4 true
            vpn-ipv6 true
            evpn true
        }
        extended-nh-encoding {
            vpn-ipv4 true
        }
        advertise-ipv6-next-hops {
            vpn-ipv6 true
            vpn-ipv4 true
        }
        group "evpn" {
            peer-as 64500
            local-address 2001:db8::14
            bfd-liveness true
            family {
                evpn true
            }
        }
        group "ipvpn" {
            peer-as 64500
            local-address 2001:db8::14
            bfd-liveness true
            family {
                vpn-ipv4 true
                vpn-ipv6 true
            }
        }
        neighbor "2001:db8::5" {
            group "evpn"
            export {
                policy ["pol-color-20"]
            }
        }
        neighbor "2001:db8::6" {
            group "ipvpn"
        }
        neighbor "2001:db8::15" {
            group "evpn"
        }
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following shows the export policy "pol-color-20", which adds the community "color-20" to all BGP route advertisements with the family type EVPN originating from the service with the tag 11. For this purpose, the EVPN VPWS (Epipe) is explicitly tagged with tag 11, as shown in the Epipe configuration section.

```
[pr:/configure policy-options]
A:admin@bng-1#
    community "color-20" {
        member "color:00:20" { }
    }
    policy-statement "pol-color-20" {
            entry 10 {
            from {
                family [evpn]
                tag 11
            }
            action {
                action-type accept
                community {
                    add ["color-20"]
                }
            }
        }
    }
```

BFD is enabled on the interface advertised as the next hop in BGP updates:

```
[pr:/configure router "Base"]
A:admin@bng-1#

```

The BGP configurations on nodes BNG-2, PE-1, and PE-2 are similar in that both PE-1 and PE-2 nodes only interact with the two BNGs within their respective address families.

The following command shows a summary of the BGP status. The output of this command has been shortened to show only that the peers are communicating and exchanging routes. The advertised routes are examined in the service configuration sections.

```

EVPN VPWS (including ES and PW port) and related SRv6 configuration

EVPN VPWS is configured as an Epipe. The three instances to be configured are:

- SRv6
- BGP
- BGP-EVPN

The SRv6 instance is configured at the top level of the Epipe and represents the dataplane instantiation of SRv6. In Release 22.10, SRv6 can be used only with the EVPN control plane (BGP-EVPN). Under this hierarchy:

- The SRv6 locator is referenced.
- The function part (End.DX2) required for creating the service SID is defined. The function value can be allocated statically or automatically; in this case, it is allocated automatically.

The BGP instance is configured at the top level of the Epipe (**bgp 1** in the example), where RT and RD can be optionally configured (otherwise they are auto-derived) and where VSI policies are applied.

The BGP-EVPN instance is configured at the top level of the Epipe, with information related to EVPN control plane signaling. The number 1 in the **segment-routing-v6 1** configuration under the **bgp-evpn** context refers to the **bgp 1** instance. Consider the following aspects of this configuration:

- The source IPv6 address of the SRv6 tunnel is, in this case, the system IP address (2001:db8::14). If the source address is not defined in the configuration, the one from the global SRv6 configuration is used. Without the source address defined in one of those two places, the SRv6 transport for the service is non-operational.
- The Epipe is tagged with a tag 11 (0xb), which is used to identify the Epipe in the BGP export policy for the color extended community, as described in the BGP peering section.
- The **resolution fallback-tunnel-to-route-table** command forces the system to first check if the next hops for the received EVPN routes are present (or resolved) in the tunnel table, before falling back to the routing table for the resolution. This is required because the endpoint in the SR policy, along with the color, is installed in the tunnel table. A valid next-hop resolution via SR policy is a trigger for the addition of the SRH to the packet header. Without the SR policy, the SRH is not added, and the packet takes the shortest path to the final destination based on plain destination-based routing.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The **route-next-hop** command identifies the next hop that is used in EVPN route advertisements. In this case, it is the system IPv6 address, but it can be any reachable locally configured IPv6 address.

The benefit of using the multi-instance provisioning model via three provisioning instances (SRv6, BGP, and BGP-EVPN) within the Epipe is that it offers more configuration flexibility when it comes to provisioning multiple data and control planes in the same service.

The Epipes on the two BNGs are configured with the same Ethernet tags. When the AD per-EVI routes with those tags are advertised, the AD per-EVI route advertised from BNG-1 has the P-bit set to 1 and the B-bit set to 0, making it the active route on PE-1. BNG-2 advertises the same AD per-EVI route (but with a different next-hop) with the value of the P-bit set to 0 and the B-bit to 1, making it the standby route on the PE-1.

```
[pr:/configure service epipe "evpn-dual-homing"]
A:admin@bng-1#
    admin-state enable
    service-id 11
    customer "1"
    segment-routing-v6 1 {
        locator "bng-1-loc" {
            function {
                end-dx2 {
                }
            }
        }
    }
    bgp 1 {
    }
    bgp-evpn {
        evi 11
        local-attachment-circuit "bng" {
            eth-tag 2
        }
        remote-attachment-circuit "access" {
            eth-tag 1
        }
        segment-routing-v6 1 {
            admin-state enable
            default-route-tag 0xb
            source-address 2001:db8::14
            resolution fallback-tunnel-to-route-table
            srv6 {
                instance 1
                default-locator "bng-1-loc"
            }
            route-next-hop {
                system-ipv6
            }
        }
    }
```

The preceding configuration defines the remote EVPN destination (or connection to the remote node over SRv6) in the Epipe. The local termination point in the Epipe is a PW port. The PW port is FPE-based and associated with the Epipe, as follows:

```
[pr:/configure pw-port 1]
A:admin@bng-1#
    encap-type qinq
    epipe "evpn-dual-homing" {
        admin-state enable
        fpe-id 3
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        oper-up-on-mh-standby true
    }
```

The **oper-up-on-mh-standby** command is related to an optimization of the ES in EVPN VPWS multihoming. The effect of this command is that the PW port and its SAPs remain operationally up when the associated ES is non-DF. This effect results in faster recovery during switchovers when the PW port has a large number of PW SAPs in the subscriber-management environment. In other words, during a non-DF to DF transition (standby to active), the system does not have to wait additional time to bring up thousands of PW SAPs from a down to an up state before it starts forwarding traffic.

The geo-redundant BNG setup in this chapter relies on two superimposed redundancy mechanisms:

- EVPN multihoming deployed in the access network-based DF election on the ES
- SRRP-based redundancy in ESM

These two redundancy mechanisms are, by themselves, independent of each other. However, to provide predictable results, they must be made co-dependent where one mechanism drives the other. In this context, EVPN MH as a technology deployed in the access network is used to detect the failures and to drive the state of SRRP. SRRP follows the states of the EVPN MH through operational groups.

ESM geo-redundancy based on SRRP does not support active-active mode of operation for a set of paired SRRP instances. As a result, the EVPN MH must be configured in the single-active (SA) mode of operation. The load-balancing between the two BNGs is achieved by distributing the activity of multiple SRRP instances across the two BNGs, some of them being active on one side and some of them on the other. In other words, the granularity of load balancing in ESM is per SRRP instance.

The configuration for coupling EVPN MH and SRRP through operational groups is shown in the following three configuration snippets, involving the definition of the operational group, the SA ES, and the SRRP messaging SAP.

The following configures the operational group "ES-1" with hold times of 0 s to prevent any reaction time delays during switchovers. Only the up time is set explicitly to 0 (from a default value of 4 s). The default value for a hold down time is already set to 0.

```
[pr:/configure service oper-group "ES-1"]
A:admin@bng-1#
    hold-time {
        up 0
    }
```

The following configures SA ES "ES-1" as part of the operational group "ES-1" and associated with PW-port 1. The state of the operational group "ES-1" depends on the state of the ES. If the ES is elected as the DF, then the operational group is up. Otherwise, it is down.

```
[pr:/configure service system]
A:admin@bng-1#
    bgp {
        evpn {
            ethernet-segment "ES-1" {
                admin-state enable
                esi 0x01010101010101010101
                orig-ip 2001:db8::14
                route-next-hop 2001:db8::14
                multi-homing-mode single-active
                oper-group "ES-1"
                df-election {
                    es-activation-timer 0
                    service-carving-mode manual
                    manual {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        preference {
                            mode revertive
                            value 150
                        }
                    }
                }
                association {
                    pw-port 1 {
                        pw-port-headend true
                    }
                }
            }
        }
    }
```

In the preceding ES configuration, the **orig-ip** command and the **route-next-hop** command must be explicitly configured in pure IPv6 environments. By default, the ES route is advertised with an IPv4 address as the next hop, which is not reachable in this example.

Under the **df-election** context, the configuration of the preference value influences which side becomes active and which becomes standby and the configuration of the preference mode indicates whether to enable revertive behavior, as explained in the Recovery section. In this example, the **es-activation-timer** command is set to 0 s, which means that the DF election occurs immediately after the failure is detected. Configuring this timer to a value greater than 0 allows some time for the peer routes to be received and collected before DF election is run. This configuration is applicable to environments with multiple routes and nodes in the same ES, but can be ignored in this example topology with only two BNGs.

The following configures the SRRP messaging SAP that tracks the state of the ES (active/standby) by monitoring the operational group "ES-1". The state of the SRRP messaging SAP is up if the ES is a DF, and down if it is a non-DF. An SRRP instance with a messaging SAP in a down state assumes the INIT state, rendering its side as standby. The pairing SRRP instance on the other BNG becomes active.

```
[pr:/configure service vprn "dual-homing" subscriber-interface "sub-int-1" group-interface
 "group-int-1"]
A:admin@bng-1#
    srrp 1 {
        admin-state enable
        keep-alive-interval 2
        message-path pw-1:2.4094
    }
    sap pw-1:2.4094 {
        monitor-oper-group "ES-1"
    }
```

The boot timer, whose purpose is to wait for routing to converge after a node reboots, is also important when revertive mode is enabled in the ES. The boot timer accounts for completion of subscriber synchronization between the two BNGs upon reboot. In this example, there is a wait time of 2 minutes after the node reboot for the network to converge before the ES is considered stable and ready for DF election.

```
*[pr:/configure redundancy]
A:admin@bng-1#
    bgp-evpn {
        ethernet-segment {
            boot-timer 120
        }
    }
```

The multihomed Epipe configuration on PE-1 (the subscriber-connecting access node) is as follows:

```
[pr:/configure service epipe "dual-homing"]
A:admin@pe-1# info
    admin-state enable
    service-id 11
    customer "1"
    segment-routing-v6 1 {
        locator "pe-1-loc" {
            function {
                end-dx2 {
                }
            }
        }
    }
    sap 1/1/c3/1:*.* {
    }
    bgp-evpn {
        evi 11
        local-attachment-circuit "access" {
            eth-tag 1
        }
        remote-attachment-circuit "bng" {
            eth-tag 2
        }
        segment-routing-v6 1 {
            admin-state enable
            default-route-tag 0xb
            source-address 2001:db8::5
            resolution fallback-tunnel-to-route-table
            srv6 {
                instance 1
                default-locator "pe-1-loc"
            }
            route-next-hop {
                system-ipv6
            }
        }
    }
```

SR policy

An SR policy is identified by the tuple <`headend, color, endpoint`>, and its origin can be derived from the path computation element protocol (PCEP), BGP, or may be static via configuration.

In this example, a static SR policy is used in the access network as a traffic-engineering tool to guide traffic through a predetermined network path. This path is configured in the SR policy **segment-list** command as a list of next hop SIDs that are programmed into the SRH.

The SR policy is not explicitly applied to an object in a classical sense, such as routing policies, which are applied in routing and service contexts. Instead, the `end-node` and the `color` parameters configured in the SR policy are programmed (or activated) in the tunnel table. As such, the SR policy is used for the BNG advertised next-hop resolution in the tunnel table. Forcing the next-hop resolution through the tunnel-table is configured via the **resolution route-table | tunnel-table | fallback-tunnel-to-route-table** command under the Epipe configuration.

The **segment-list** command references the node-SIDs, while the **endpoint** configured in the SR policy is not a SID but instead a regular IPv6 address of the destination node. When multiple routing policies with

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

the same endpoint and color are defined, the one with the highest `preference` prevails and is installed in the tunnel-table.

The **head-end local** command signifies that the SR policy is locally defined and activated, as opposed to advertised to BGP peers.

The binding SID is a mandatory local SID associated with the SR policy. Its function value is `end-b6-encaps-red`.

The reachability of the first SID in the SR policy must be validated before the SR policy is activated.

Multiple segment lists can be defined in the SR policy. Traffic between these segment lists can be distributed according to the configured weight (not shown in the following configuration).

The SR policy does not have the configuration option for the **source-address**. Instead, it uses the one configured for the segment-routing configuration in the global routing context. Without the **source-address** configured in the global SRv6 context, the SR policy is not activated.

```
[pr:/configure router "Base" segment-routing sr-policies]
A:admin@bng-1#
    admin-state enable
    static-policy "to-pe-1-long-path" {
        admin-state enable
        color 20
        endpoint 2001:db8::5
        preference 150
        head-end local
        type srv6
        segment-routing-v6 {
            binding-sid 1 {
                locator {
                    locator-name "bng-1-loc"
                    function end-b6-encaps-red
                }
            }
        }
        segment-list 1 {
            admin-state enable
            segment 1 {
                srv6-sid 2001:db8:aaaa:4:0:1000::
            }
            segment 2 {
                srv6-sid 2001:db8:aaaa:a:0:1000::
            }
        }
    }
```

To verify that the SR policy has been activated:

```
A:admin@pe-1# show router segment-routing sr-policies static

Verify routes

In this section, **show** commands are used to verify forwarding and show routing-related information. The outputs from the following **show** commands focus primarily (but not exclusively) on nodes BNG-1 and PE-1, which are the endpoints of the active leg of EVPN VPWS multihoming.

The following command shows the SRv6 information on BNG-1. The locator SID is advertised to other nodes via IS-IS. The locator SID is installed in the routing table of all other nodes and is used for reachability information.

```
A:admin@bng-1# show router segment-routing-v6 locator
===============================================================================
Locator bng-1-loc
===============================================================================
Admin State                 : Up

---snip---
```

The following command lists different SIDs allocated to BNG-1:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- one node SID (End), advertised in IS-IS
- three adjacency SIDs (End.X), representing the BNG-1 connections to adjacent nodes BNG-2, PE-2, and P-1 (these SIDs are used to build fast failover alternate paths and are also advertised in IS-IS)
- one EVPN SID (End.DX2), advertised via BGP-EVPN for EVPN routes
- two VPN SIDs (End.DT4 and End.DT6), advertised via BGP-IPVPN for VPN-IPv4 and VPN-IPv6 routes
- one binding SID (End.b6.encaps.red), for the SRv6 static segment-policy (this SID is not advertised in this case)

```
A:admin@bng-1# show router segment-routing-v6 local-sid

```

The following route table on BNG-1 shows:

- system IPv6 interfaces from all other nodes learned through IS-IS
- IPv6 prefixes on links between all nodes learned through IS-IS
- SRv6 locators from all nodes learned through IS-IS
- all local SIDs except for service SIDs, which are part of services and not global routing

BNGs are connected to both the core network (VPRN) and the access network (EVPN), so network addresses from all nodes are visible on a BNG. By contrast, the PE-1 node in the EVPN part of the network sees only routes in the EVPN part of the network, but not the routes in the VPRN part of the network (Figure 332: Example topology).

```
A:admin@bng-1# show router route-table ipv6

When an IPv4 packet from the traffic generator enters the SAP of the Epipe on PE-1, the packet goes through the Epipe toward the Epipe's other endpoint, which is the EVPN destination on BNG-1. BNG-1 is the primary EVPN destination because PE-1 receives an active (P=1, B=0) AD-per EVI route with the tag 2 from BNG-1. This route has:

- color 20
- next-hop 2001:db8::14 (BNG-1)
- service SID 2001:db8:aaaa:14:7fff:e000:: (End.DX2 on BNG-1)

The service SID is the final destination of the packet and it is inserted in the SRH as the first segment. The received next-hop in the route must be resolved before the route is validated and installed in the routing table. The first attempt to resolve the next-hop for this route is performed through the tunnel table, as indicated by the **resolution fallback-tunnel-to-route-table** command. The following command shows the IPv6 tunnel table with an entry for the next-hop address 2001:db8::14 and color 20, as received in the AD per-EVI route. The owner of this entry is SRv6-policy and the encapsulation is SRv6.

```
A:admin@pe-1# show router tunnel-table ipv6

---snip---
```

The presence of the two node SIDs for P-2 and P-1 implies that the nodes P-2 and P-1 must be visited, in that order, on the path from PE-1 to BNG-1. This path is accomplished by inserting the SRH header into the packet. The trigger for the SRH creation and insertion into the packet is the next-hop resolution via SR policy.

Because the **End.B6.Encap.Red** function for the binding SID in the SR policy reduces the encapsulation, as defined in RFC 8986, the node SID for P-2 is not part of the SRH, even though it is listed as the first node to be visited in the segment list of the SR policy. As the first node to be visited, its SID is directly included in the DA in the SRv6 header of the packet without repeating itself in the SRH. The SRH contains two SIDs: the node SID for P-1 (2001:db8:aaaa:4:0:1000::) and the service SID (2001:db8:aaaa:14:7fff:e000:) which represents the Epipe on BNG-1, retrieved from the received EVPN AD-per-EVI route. These two SIDs are, in turn, copied to the IPv6 DA field of the packet by the visited nodes, as described in the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

The longest match lookup for the DA 2001:db8:aaaa:a:0:1000:: (P-2 node-SID) reveals the next hop leading to its SRv6 locator (P-2 locator):

```
A:admin@pe-1#  show router route-table ipv6 2001:db8:aaaa:a:0:1000:: extensive
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix             : 2001:db8:aaaa:a::/64
  Protocol              : ISIS
  Age                   : 03d02h40m
  Preference            : 18
  Next-Hop              : 2001:db8:aaaa:a::/64 (SRV6-ISIS tunnel)
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    ---snip---
```

The tunnel table for next hop 2001:db8:aaaa:a::/64 (P-2 SRv6 locator) points to the link-local IPv6 address of the adjacent node that advertised this next hop (P-2 SRv6 locator) in IS-IS:

```
A:admin@pe-1# show router tunnel-table ipv6 2001:db8:aaaa:a::/64 detail
===============================================================================
Tunnel Table (Router: Base)
Destination      : 2001:db8:aaaa:a::/64 [L]
NextHop          : fe80::b6a1:ffff:fe00:0-"int-1-pe-1-p-2"
Tunnel Flags     : has-lfa
Age              : 03d02h42m
CBF Classes      : (Not Specified)
Owner            : srv6-isis (0)        Encap            : SRV6
Tunnel ID        : 524293               Preference       : 0
Tunnel SRV6 SID  :  -                   Tunnel Metric    : 20
Tunnel MTU       : 8894                 Max Label Stack  : 0
-------------------------------------------------------------------------------
```

The neighbor cache on PE-1 shows the mapping between the link local IPv6 of the adjacent next hop and its MAC address, which is the destination MAC address in the packet:

```
A:admin@pe-1# show router neighbor
===============================================================================
Neighbor Table (Router: Base)
===============================================================================
IPv6 Address                                Interface
   MAC Address               State         Expiry          Type         RTR
-------------------------------------------------------------------------------
---snip---
fe80::b6a1:ffff:fe00:0                      int-1-pe-1-p-2
   b4:a1:01:01:00:05         REACHABLE     00h00m25s       Dynamic      Yes
---snip---
```

In summary:

- PE-1 receives an AD per-EVI from BNG-1 with the address of the final destination (service SID), the route color, and the next-hop of the advertised route.
- The next-hop resolution in the tunnel table points to the SR policy with SRv6 encapsulation.
- The SR policy is configured with a list of node SIDs that need to be visited, with the first SID in the list copied to the destination IPv6 address of the packet.
- The remaining SID in the SR policy along with the service SID advertised in the route are populated in the SRH.
- The destination MAC address is resolved through a series of lookups that lead to the directly connected IS-IS node that advertised the SRv6 locator for the first node to be visited.

Without the SR policy, the SRH would not be inserted into the packet. As a result, the final destination (the service SID on BNG-1 for EVPN, 2001:db8:aaaa:14:7fff:e000::) would immediately be populated in the DA field of the packet. The destination-based lookup for this DA gives us a different next hop for the packet (P-1 instead of P-2):

```
A:admin@pe-1# show router route-table ipv6 2001:db8:aaaa:14:7fff:e000:: extensive
Route Table (Router: Base)
Dest Prefix             : 2001:db8:aaaa:14::/64
  Protocol              : ISIS
  Age                   : 04d07h47m
```

VPRN related SRv6 configuration

The SRv6 locator and functions in a VPRN are configured in a similar way as in the EVPN.

The export VRF policy advertises the subscriber subnets on the active SRRP node with a better metric than the same routes on the node with standby SRRP. The result is that traffic in the downstream direction is attracted to the node with the active SRRP instance.

```
[pr:/configure service vprn "dual-homing"]

Multi-chassis redundancy configuration

The full configuration under the **configure redundancy multi-chassis peer <IP address>** context is provided in the configuration files in the Appendix.

This section emphasizes on the time synchronization of each node to the same clock, which is an aspect of the subscriber synchronization that is easily overlooked. Without times that match on both BNGs, the subscribers are not synchronized. In the example, simple network timing protocol (SNTP) is used.

```
[pr:/configure system time]
A:admin@bng-1#
    prefer-local-time true
    zone {
        standard {
            name cst
        }
    }
    dst-zone "CDT" {
        end {
            day sunday
            month november
            hours-minutes "02:00"
        }
        start {
            day sunday
            month march
            hours-minutes "02:00"
        }
    }
    sntp {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        admin-state enable
        server 135.227.160.253 {
        }
    }
```

DHCP server configuration

DHCP configuration shows that all pools are synchronized via the **peer** command, except for the pool for PPPoEv4 sessions. The IP addresses in the pool for PPPoE sessions are synchronized indirectly as part of the PPPoE session synchronization.

The second important aspect of the DHCP redundancy in access driven mode is that the DHCP servers are associated with interfaces configured with the same IP address on both BNGs (see the Appendix).

```
[pr:/configure service vprn "dual-homing"]
A:admin@bng-1#
    dhcp-server {
        dhcpv4 "dhcpv4" {
            admin-state enable
            pool-selection {
                use-gi-address {
                    scope pool
                }
                use-pool-from-client {
                }
            }
            pool "dhcpv4-1" {
                max-lease-time 1200
                failover {
                    admin-state enable
                    peer 192.0.2.21 {
                        sync-tag "dhcp4"
                    }
                }
                subnet 10.10.0.0/24 {
                    address-range 10.10.0.10 end 10.10.0.100 {
                        failover-control-type access-driven
                    }
                }
            }
            pool "pppoev4-1" {
                max-lease-time 1200
                subnet 10.10.1.0/24 {
                    address-range 10.10.1.10 end 10.10.1.100 {
                        failover-control-type access-driven
                    }
                }
            }
        }
        dhcpv6 "dhcpv6" {
            admin-state enable
            pool-selection {

Summary of show commands

Show commands are powerful tools when building and troubleshooting networks. An extensive set of **show** command outputs relevant to the example topology described in this chapter are provided in separate files for BNG-1, P-1, and PE-1. The following is the list of these commands. Not all commands are applicable to all nodes; for example, commands related to subscriber management do not apply to P and PE nodes.

The following commands show ports and router interfaces:

```
show port
show router <id> interface
```

The following command shows FPE information:

```
show fwd-path-ext fpe <id>
```

The following commands show EVPN VPWS information:

```
show service id <name> base
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
show service id <name> bgp-evpn
show service system bgp-evpn ethernet-segment name <name>
show service system bgp-evpn ethernet-segment name <name> evi evi-1 <id>
show router bgp routes evpn eth-seg detail
show router bgp routes evpn auto-disc tag <id> detail
show service id <name> ethernet-segment <name>
show service id <name> segment-routing-v6 detail
show service id <name> segment-routing-v6 instance 1 destinations
show service id <name> segment-routing-v6 instance 1 end-dx2
show service id <name> segment-routing-v6 instance 1 locator <name>
```

The following commands show VPRN information:

```
show service id <name> base
show service id <name> bgp-ipvpn segment-routing-v6
show service id <name> segment-routing-v6 instance 1 locator <name>
show router <id> route-table
show router <id> route-table ipv6
show router bgp routes vpn-ipv4 hunt
show router bgp routes vpn-ipv6 hunt
```

The following commands show SRv6-related information:

```
show router segment-routing-v6 base-routing-instance all
show router segment-routing-v6 local-sid context  "Base"
show router segment-routing-v6 local-sid context <id>
```

The following commands show routing and forwarding information:

```
show router route-table ipv6
show router tunnel-table ipv6
show router fp-tunnel-table 1 ipv6
```

The following commands show BGP and IS-IS information:

```
show router bgp  summary
show router isis  adjacency
show router isis database
show router isis 1 adjacency
show router isis 1 database
show router isis <instance-id> adjacency
show router isis <instance-id> database
```

The following commands show redundancy-related information:

```
show redundancy multi-chassis sync peer <ip-address> detail
tools dump redundancy multi-chassis sync-database
```

The following commands show subscriber-related information:

```
show service active-subscribers summary
show service active-subscribers hierarchy
show service id <id> subscriber-hosts detail
show service id <id> ipoe session
show service id <id> pppoe session
show service id <id> dhcp lease-state
show service id <id> dhcp6 lease-state
show srrp <id> detail
```

The following commands show DHCP information:

```
show router <id> dhcp local-dhcp-server <name> summary
show router <id> dhcp6 local-dhcp-server <name> summary
show router <id> dhcp local-dhcp-server <name> leases
show router <id> dhcp6 local-dhcp-server <name> leases
```

Conclusion

Resilient overlay networks that support traffic engineering can be built with the simplicity of a single dataplane protocol (IPv6) using SRv6. When SRv6 is deployed in the access network in combination with BNG dual-homing, subscribers are protected against network failures with minimal recovery times. This chapter shows one example of such network.

Appendix

The following configurations are included.

- bng-1-config
- bng-2-config
- p-1-config
- p-2-config
- pe-1-config
- pe-2-config
- users.radius

bng-1-config

#
#    Configuration file for the rlm_files module.
#    Please see rlm_files(5) manpage for more information.
#
#    This file contains authentication security and configuration
#    information for each user.  Accounting requests are NOT processed
#    through this file.  Instead, see 'accounting', in this directory.
#
#    The first field is the user's name and can be up to
#    253 characters in length.  This is followed (on the same line) with
#    the list of authentication requirements for that user.  This can
#    include password, comm server name, comm server port number, protocol
#    type (perhaps set by the "hints" file), and huntgroup name (set by
#    the "huntgroups" file).
#
#    If you are not sure why a particular reply is being sent by the
#    server, then run the server in debugging mode (radiusd -X), and
#    you will see which entries in this file are matched.
#
#    When an authentication request is received from the comm server,
#    these values are tested. Only the first match is used unless the
#    "Fall-Through" variable is set to "Yes".
#
#    A special user named "DEFAULT" matches on all usernames.
#    You can have several DEFAULT entries. All entries are processed
#    in the order they appear in this file. The first entry that
#    matches the login-request will stop processing unless you use
#    the Fall-Through variable.
#
#    Indented (with the tab character) lines following the first
#    line indicate the configuration values to be passed back to
#    the comm server to allow the initiation of a user session.
#    This can include things like the PPP configuration values
#    or the host to log the user onto.
#
#    You can include another `users' file with `$INCLUDE users.other'

#
#    For a list of RADIUS attributes, and links to their definitions,
#    see: http://www.freeradius.org/rfc/attributes.html
#
#    Entries below this point are examples included in the server for
#    educational purposes. They may be deleted from the deployed
#    configuration without impacting the operation of the server.
#

############################################################
# You should add test accounts to the TOP of this file! #
# See the example user "bob" above.                     #

Diameter Base Protocol: Establishing a Diameter Peer Connection

This chapter provides information about configuring and troubleshooting the Diameter Base protocol to establish a Diameter peer connection.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This information and configuration in this chapter are based on SR OS Release 19.10.R1.

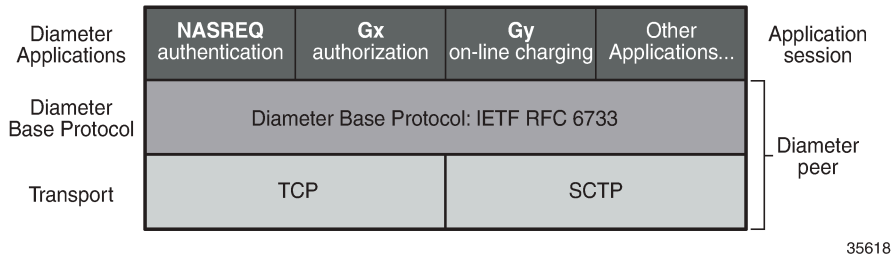
Note:
This chapter covers the Diameter base protocol implementation that is available from SR OS Release 16.0.R4 onward (configured in **aaa** CLI context as **diameter node**). The legacy Diameter base implementation (configured in the **aaa** CLI context as **diameter-peer-policy**) is supported in maintenance mode only, without any further feature enhancement planned. Nokia recommends using or transitioning to the new Diameter base protocol implementation.

Overview

Diameter is an Authentication, Authorization and Accounting (AAA) protocol defined by the IETF in RFC 6733, *Diameter Base Protocol*. While historically wireline access networks were largely based on RADIUS for subscriber authentication, authorization, and accounting, it was decided by 3rd Generation Partnership Project (3GPP) that wireless access networks will be largely based on Diameter. Over time, operators are looking to converge both types of networks, and one of the aspects of this is to replace RADIUS in wireline access networks by Diameter.

Diameter is based on three layers: the transport layer, the Diameter base protocol layer and the Diameter applications as shown in Figure 342: Diameter protocol stack.

Figure 342: Diameter protocol stack



The bottom layer is the transport layer and can be either TCP or SCTP. SR OS supports TCP. The Diameter base protocol implementation in SR OS is based on RFC 6733. The top layer contains

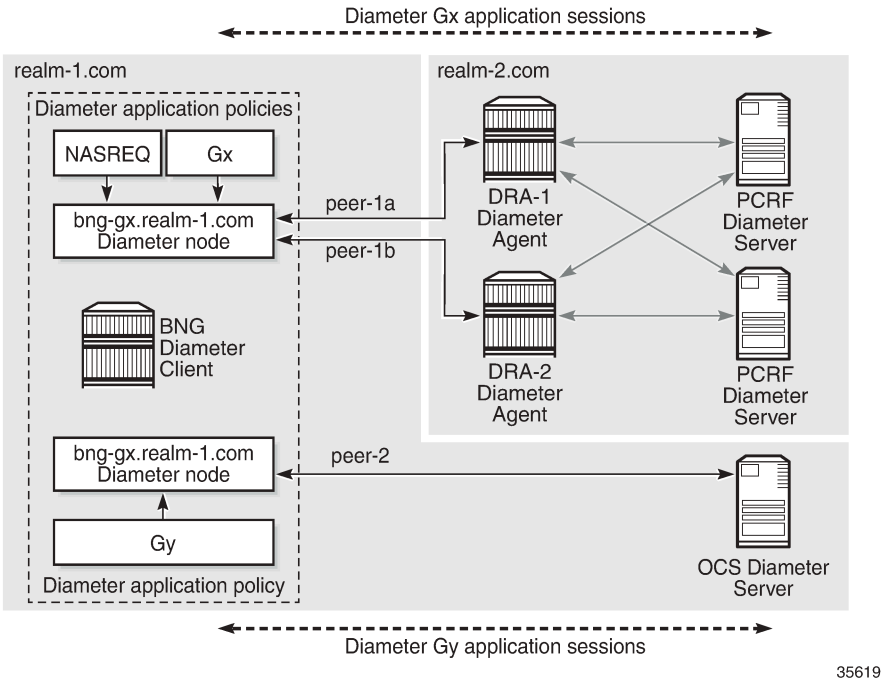
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

the Diameter applications. SR OS supports NASREQ for authentication, Gx for authorization, policy management and usage monitoring and Gy or Diameter Credit Control Application (DCCA) for online charging.

Figure 343: Diameter network topology shows a Diameter network topology that will be used in the configuration examples in this chapter.

A Diameter Client (BNG) is connected via peer-1a and peer-1b to two Diameter Agents (DRA-1 and DRA-2) that provide connectivity to the Diameter Application Servers (PCRF). Via these peers, the BNG can authenticate and perform policy control of subscriber sessions using the NASREQ and Gx applications. The same Diameter Client (BNG) is also directly connected to another Diameter Application Server (OCS) via peer-2. Via this peer, on-line charging can be done for the subscriber sessions using the Gy application.

Figure 343: Diameter network topology



Configuration

The Diameter base protocol and the Diameter applications are configured separately, where the Diameter base protocol must be configured first, and the Diameter applications next. The transport layer configuration is part of the Diameter base protocol layer. This example describes the Diameter base protocol configuration.

The Diameter base protocol and the corresponding transport layer configuration is based on Diameter Nodes. Each Diameter Node represents a Diameter routing instance and contains a list of peers in the routing domain that provide direct or indirect connectivity to application servers.

An example Diameter node configuration that corresponds with the topology in Figure 343: Diameter network topology is shown below.

```
configure {
    aaa {
        diameter {
            node "bng-gx.realm-1.com" {
                description "Authentication and Policy Management"
                connection {
                    ipv4 {
                        local-address 192.0.2.2
                    }
                    ipv6 {
                        local-address 2001:db8::2
                    }
                }
                peer index 1 {
                    admin-state enable
                    address 2001:db8:2:6::1
                    destination-host "dra-1.realm-2.com"
                    preference 10
                }
                peer index 2 {
                    admin-state enable
                    address 172.16.7.2
                    destination-host "dra-2.realm-2.com"
                    preference 20
                }
            }
            node "bng-gy.realm-1.com" {
                description "Credit Control"
                origin-realm "realm-1.com"
                router-instance "management"
                peer index 1 {
                    admin-state enable
                    address 192.99.3.0
                    destination-host "ocs.realm-1.com"
                }
            }
        }
```

A Diameter node configuration requires a unique origin host as key. The origin host is used in Diameter application policies to associate the application with the node. All Diameter base and application messages forwarded via the peers of that node use the configured origin host in the Origin-Host AVP. The value for the Origin-Realm AVP is by default derived from the configured origin host: the realm is the part of the origin host after the first dot (".") as delimiter or equal to the origin host when it does not contain a delimiter. For example, for **node** "*bng-gx.realm-1.com*": Origin-Host = "bng-gx.realm-1.com", Origin-Realm = "realm-1.com". It is also possible to explicitly configure an origin realm as shown in the example for the **node** "*bng-gy.realm-1.com*".

A node configuration can include a routing context, and an IPv4 and/or IPv6 source address. These parameters are used to establish the TCP transport connection for all peers in the node. The specified **local-address** must be a reachable local interface address in the specified or in the default router instance. For **node** "*bng-gx.realm-1.com*" in the example, no router instance is specified. By default, the TCP connections are established in the Base router using the specified local addresses. For **node** "*bng-gy.realm-1.com*" in the example, the out of band router instance "*management*" is used to establish the TCP connection of its peer. As no local address is specified, the system will automatically select an interface address, in this case an out of band IP address configured in the Boot Options File (BOF).

Use subject to Terms available at: www.nokia.com/terms.

Within a Diameter node, up to 5 peers can be configured with an index value between 1 and 5 as key, an IPv4 or IPv6 destination address for the TCP connection, and a mandatory destination host that is used as Destination-Host AVP value for all Diameter base messages on the peer. In a Diameter node, one peer is selected to forward application messages for a specific application session. The other peers provide redundancy when supported by the Diameter application, such as Gy session failover. A Diameter peer for application messages is selected based on following criteria:

1. Forwarding:

   If the application message contains a Destination-Host AVP, select the peer in the peer table with a matching configured destination host. This is the forwarding phase.

2. Routing:

   When the lookup in the peer table fails, perform a lookup in the realm routing table and select the peer with realm name equal to the Destination-Realm AVP in the application message, and with matching application ID. When multiple peers are matched, select in order or priority until a single peer is found:

   a. the peer with the lowest configured preference (default preference is 50)

   b. the peer with the lowest index

3. Default peer:

   When both forwarding lookup in the peer table and routing lookup in the realm routing table were unsuccessful, use the peer configured as **default-peer**. Only a single peer in a node can be configured as a default-peer. Multiple peers in a node configured as default-peer results in a validation error:

```
MINOR: MGMT_CORE #5001: configure aaa diameter node "bng-gx.realm-1.com" peer index 2 -
 Multiple default peer is not allowed
```

For **node** "*bng-gx.realm-1.com*" in the example, peer-1a with index 1 has a configured preference of 10 and peer-2 with index 2 has a configured preference of 20. Diameter Gx application messages will fail the peer table lookup as the destination host of the PCRF will not be present (no direct connection between Diameter client and Diameter application server):

```
# /show aaa diameter-node "bng-gx.realm-1.com" peers

===============================================================================
Peers
===============================================================================
Host identity                       Status        Default Preference Active
-------------------------------------------------------------------------------
dra-1.realm-2.com                   I-Open        No      10         Yes
dra-2.realm-2.com                   I-Open        No      20         Yes
-------------------------------------------------------------------------------
No. of peers: 2
===============================================================================
```

Instead a realm routing table lookup is performed to find the peer for forwarding the application messages. In this case peer-1a (dra-1.realm-2.com) is selected based on the matching destination realm (realm-2.com), application ID (Gx) and the lower preference value:

```
# /show aaa diameter-node "bng-gx.realm-1.com" routing-table

===============================================================================
Routes
===============================================================================
Realm-Name
           Application   Pref. Id  Server-Identifier
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
-------------------------------------------------------------------------------
realm-2.com
          nasreq gx     10    1   dra-1.realm-2.com
realm-2.com
          nasreq gx     20    2   dra-2.realm-2.com
-------------------------------------------------------------------------------
No. of routes: 2
===============================================================================
```

The realm routing table is populated based on the Origin-Realm AVP and Application-Id AVP received in the Capability Exchange Answer message together with the configured index and preference values.

Note that Diameter answer messages do not rely on peer or realm routing table lookups. Answers are forwarded over the same route in the reverse direction of the matching requests. This is achieved with a transactional cache in each traversed Diameter node, using the Hop-by-Hop AVP to match requests with answers.

When enabling the peer (**admin-state enable**), the system tries to establish the transport TCP connection. Once the TCP session is up, the system starts a Diameter Capability Exchange using the configured Diameter identity (Origin-Host and Origin-Realm AVPs) and advertising support for all SR OS Diameter applications in Application-Id AVP's (NASREQ, Gx, and Gy). When the Origin-Host AVP in the received CEA message corresponds with the destination host configured for the peer (case insensitive) and at least one application in the CEA is common with the SR OS advertised applications, then the peer moves to the I-Open state (I from Initiator). An example of a Capability Exchange is illustrated in detail in the troubleshooting section.

Optionally, a connection and a watchdog timer can be configured in the Diameter node:

```
configure {
    aaa {
        diameter {
            node "bng-gx.realm-1.com" {
                connection {
                    timer 30
                    ---snip---
                }
                peer index 1 {
                    connection-timer 30
                    watchdog-timer 30
                    ---snip---
```

- **connection-timer**

  The connection timer or Tc timer controls the frequency at which a transport connection is attempted to be established. The default value is 30 seconds. This timer can be configured per node to be used by all peers or overridden per peer.

- **watchdog-timer**

  The watchdog timer controls the frequency at which Device-Watchdog-Request messages are transmitted to the peer, and is called the Tw timer in RFC 3539, *Authentication, Authorization and Accounting (AAA) Transport Profile*. A small timer results in a faster detection of a peer failure at the expense of generating more messages. The timer is configured per peer and its default value is 30 seconds.

A Python policy can be configured in the Diameter node to manipulate Diameter messages transmitted to and/or received on its peers.

```
configure {
    aaa {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        diameter {
            node "bng-gy.realm-1.com" {
                python-policy "py-diameter-1"
                ---snip---
```

Manipulating Diameter messages, such as changing the content or format of AVPs using Python is out of the scope of this chapter.

By default, Diameter messages are sent with a DSCP set to AF41. The DSCP value can be changed with the sgt-qos configuration:

```
# /configure router sgt-qos dscp application diameter dscp nc1
```

SR OS uses TCP as transport and the TCP destination port number is fixed to the standard Diameter base protocol port 3868. The source port is randomly chosen from the ephemeral port range.

Troubleshooting

The status and statistics of the Diameter peers can be verified with following show commands:

```
# /show aaa diameter-node "bng-gx.realm-1.com" peers

===============================================================================
Peers
===============================================================================
Host identity                       Status        Default Preference Active
-------------------------------------------------------------------------------
dra-1.realm-2.com                   I-Open        No      10         Yes
dra-2.realm-2.com                   I-Open        No      20         Yes
-------------------------------------------------------------------------------
No. of peers: 2
===============================================================================
```

```
# /show aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com"

===============================================================================
Peer "dra-1.realm-2.com"

Disconnect-Peer-Request              1                    4
Disconnect-Peer-Answer               4                    1
Device-Watchdog-Request              1217                 778
Device-Watchdog-Answer               778                  1217
Application message request          0                    0
Application message answer           0                    0

Last cleared time: N/A
===============================================================================
```

To clear the peer statistics, use following command:

```
# /clear aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com" statistics
```

Diameter debugging is split between node and application level:

```
debug
    diameter
        application
            policy "diam-nasreq-1"
                session-messages
            exit
        exit
        node "bng-gx.realm-1.com"
            peer "dra-1.realm-2.com"
                peer-to-peer
            exit
        exit
    exit
exit
```

In this chapter, the Diameter base protocol debugging for peer messages is explained, configured at the node level debug. When a Python script is active for the node, the debug messages are logged after Python processing.

To debug the Diameter base protocol messages for **peer** "*dra-1.realm-2.com*", use the following debug commands:

```
debug
    diameter
        node "bng-gx.realm-1.com"
            peer "dra-1.realm-2.com"
                peer-to-peer
            exit
        exit
    exit
exit
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **peer-to-peer** option enables debug output for all Diameter base messages of the specified peer: Capabilities Exchange, Device Watchdog and Disconnect Peer messages. By default, error conditions are also logged in the debug output. Debug for error conditions can be disabled per Diameter node or per peer with the debug option **no on-error**. Errors reported at the node level include Diameter base errors that are unrelated to a peer, such as a routing problem for a Diameter application message. Errors reported at the peer level include all errors that occur after peer selection and peer connection errors.

Let's start with the peer connection in Closed state (remote end rebooting):

```
# /show aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com"

===============================================================================
Peer "dra-1.realm-2.com"
===============================================================================
Index                       : 1
Status                      : Closed
Administrative state        : enabled
Active                      : No
Active applications         :
Last disconnect cause       : rebooting

Events

Following events are defined for the Diameter base protocol:

```
===============================================================================
Application
 ID#    Event Name                       P   g/s     Logged     Dropped
-------------------------------------------------------------------------------
   2007 tmnxDiamMessageDropped           MI  thr          0           0
   2008 tmnxDiamNdPeerStatActiveChanged  MI  thr         46           0
===============================================================================
```

The **tmnxDiamNdPeerStatActiveChanged** event is generated when the state of a Diameter peer toggles between active / not active:

```
38080 2019/11/22 14:52:02.269 UTC MINOR: DIAMETER #2008 management peer state change
"DIAMETER node bng-gy.realm-1.com, peer ocs.realm-1.com is active"
```

The **tmnxDiamMessageDropped** event is generated when Diameter base drops a malformed message.

Conclusion

As a result of fixed mobile network convergence, Diameter is used in fixed access networks as an alternative for Radius based AAA. Diameter peering provides reliable and secure transport with peer

redundancy. Its functionality is defined in a base Diameter protocol specified in RFC 6733. Various applications can be layered on top of base Diameter and they can utilize the robust transport capabilities that Diameter provides.

L2TP for Subscriber Access — LAC

This chapter provides information about L2TP for subscriber access.

Topics in this chapter include:

Applicability

This chapter describes L2TP Access Concentrator (LAC) support for the L2TP Access Aggregation (LAA) architecture model and was initially written for SR OS Release 11.0.R4. The MD-CLI in the current edition is based on Release 19.5.R1. PPP hosts are supported in a Routed CO model (with IES or VPRN services) using ATM, Ethernet or Ethernet over Pseudowire SAPs. A description of the L2TP Tunnel Switch (LTS) and L2TP Network Server (LNS) functions are out of the scope of this chapter.

Overview

PPP access architectures

The Broadband Forum proposes two architectures for Point-to-Point Protocol (PPP) access.

- The PPP Terminated Aggregation architecture (PTA)
- The L2TP Access Aggregation architecture (LAA)

The PTA architecture (local-access model) uses the Broadband Network Gateway (BNG) to terminate user PPP sessions (see scenario PPPoE-5 in Figure 344: PPP access architectures).

The LAA architecture (which is a tunneled access model) uses a LAC and an LNS to transport PPP sessions from the LAC to the LNS which performs tunnel termination (see scenario PPPoE-1 and PPPoE -2 in Figure 344: PPP access architectures).

Optionally, an LTS can be used in the transport network to perform the grooming of traffic between tunnels (see scenarios PPPoE-3 and PPPoE-4 in Figure 344: PPP access architectures).

The LNS is the logical termination point of the PPP sessions originated by the remote clients and tunneled by the LAC/LTS.

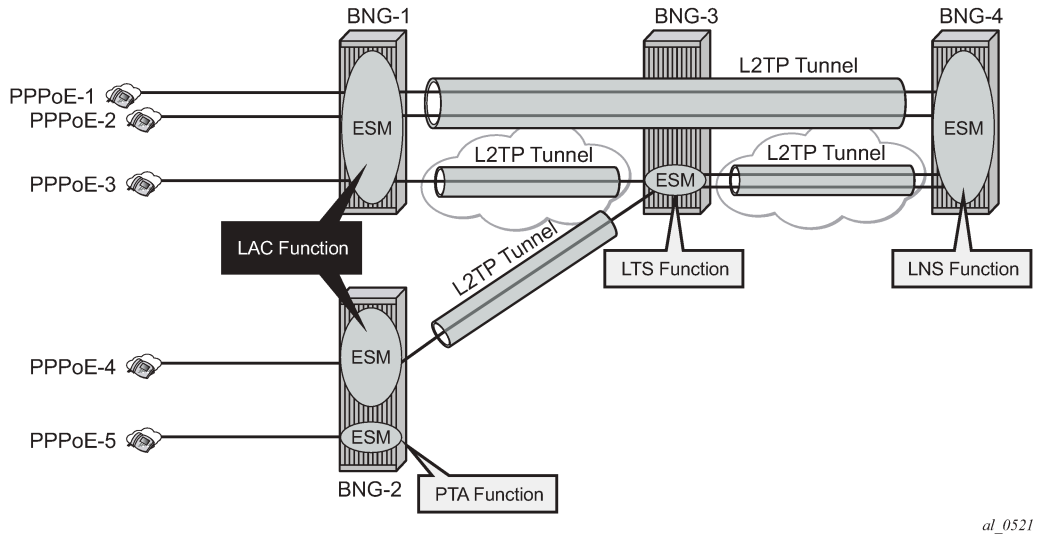
Figure 344: PPP access architectures



L2TP tunnels - LAC and LNS reachability options

The router instance where the L2TP tunnel starts and where ESM is handled can be one and the same, but does not need to be the same. The LNS peer address can be reachable via IP, BGP/IGP shortcuts, over a spoke SDP (GRE/MPLS), RFC 4364 VPRNs (*BGP/MPLS IP Virtual Private Networks*), but cannot be an address belonging to a directly connected interface. See Figure 345: Supported LT2P reachability options.

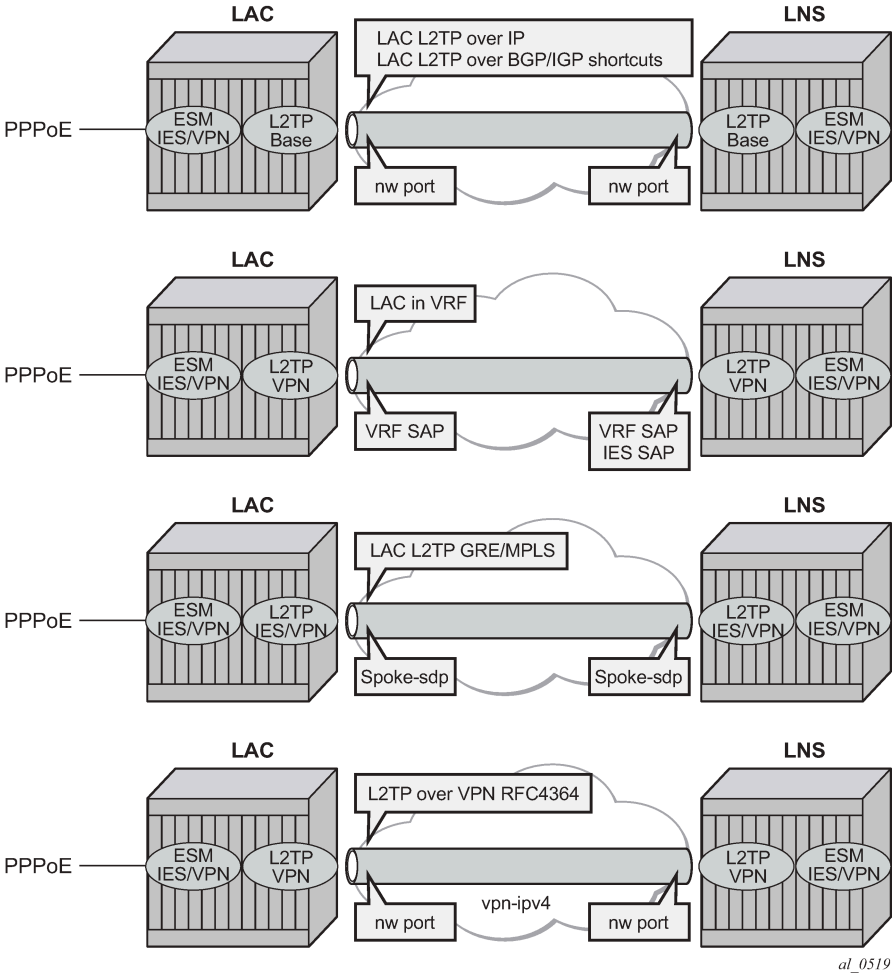
Figure 345: Supported LT2P reachability options



Recap of the L2TPv2 protocol

L2TPv2 is a client-server protocol relying on UDP and encapsulates Layer 2 packets such as PPP for transmission across a network. L2TPv2 passes control and data messages over separate control and data channels, thus defines following message types:

- Control messages—The in-band control channel passes sequenced control messages, supporting connection management, call management, error reporting, and session control. Optionally, a shared-secret challenge authentication method can be used between the tunnel endpoints.

  The following messages are used for L2TP tunnel management:

  – Tunnel setup (Control Connection Management)

    - Start-Control-Connection-Request (SCCRQ)
    - Start-Control-Connection-Reply (SCCRP)
    - Start-Control-Connection-Connected (SCCCN)
    - Stop-Control-Connection-Notification (StopCCN)

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - Tunnel keepalive
    - Hello (HELLO)

  The following messages are used for L2TP session (call) management:

  - Session setup over an existing tunnel
    - Incoming-Call-Request (ICRQ)
    - Incoming-Call-Reply (ICRP)
    - Incoming-Call-Connected (ICCN)
    - Call-Disconnect-Notify (CDN)

  Zero-Length Body (ZLB) messages are control packets with an L2TP header only and are used to explicitly acknowledge packets, making the control channel reliable.

  L2TP message encoding is done through Attribute Value Pairs (AVP).

- Data messages — Data messages encapsulate the PPP frames that are sent into the L2TP tunnel.

L2TPv2 sessions run over an L2TP tunnel and are referenced by an L2TP session-id. An L2TP tunnel can carry none, one, or multiple L2TP sessions. An L2TP session corresponds to a PPPoE session. L2TPv3 for LAC-LNS dynamic tunnel setup is not supported.

L2TP header and AVP layout

The L2TPv2 header consists of following fields (RFC 2611, *URN Namespace Definition Mechanisms*):

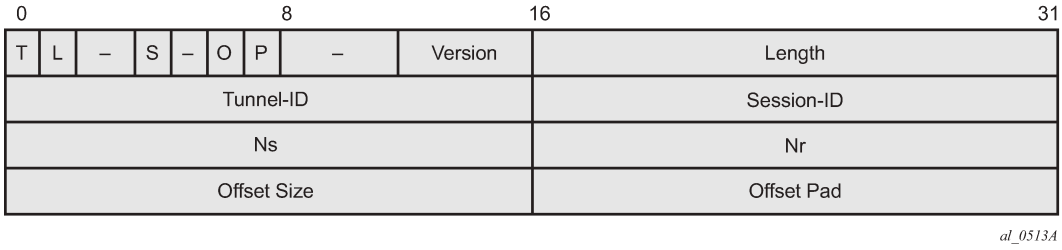


Table 20: L2TPv2 header fields and descriptions

Field	Description
T	Type of L2TP message (1 bit): 0—data message 1—control message
L	Indicates if the optional Length field is present in the message (1 bit): 0—the field is left out of the message entirely 1—the field is included (must be included in control messages)
-	Reserved for future use, must be set to zero.
S	Indicates if the Ns and Nr fields are present (1 bit): 0 — the fields are left out of the message; entirely 1 — the fields are included (must be included in control messages)
O	Indicates if the Offset field is present (1 bit): 0 — the field is left out of the message entirely (must be left out of control messages); 1 — the field is included

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Field	Description
P	Used with data messages only. Indicates priority of the data message (1 bit): 0 — no (this value is used for all control messages); 1 — yes
Version	The version of the message (4 bits): 2 — this is the latest version of the L2TP data message header; 1 — indicates an L2F packet as described in RFC 2341 Packets with an unknown version number are discarded.
Length	The total length (in bytes) of the L2TP message (16 bits).
Tunnel-ID	Identifies the L2TP tunnel (that is, the control connection).This number has local significance — each end gives the same tunnel different tunnel IDs. The ID refers to the receiver, not the sender, and is assigned during tunnel creation (16 bits).
Session-ID	Identifies the PPP session within a tunnel. This number has local significance — each end gives the same session different session IDs. The ID refers to the receiver, not the sender, and is assigned during session creation (16 bits).
Ns	The sequence number of the message. This is mandatory for control messages (to enable re-transmission of lost messages) but optional for data messages (to re-order data messages that were mis-sequenced during forwarding). The number, which starts at 0 and increments by 1, is assigned by an L2TP peer for each session in a tunnel (16 bits).
Nr	The sequence number of the next control message expected to be received. This is equal to the sequence number of last received control message plus 1. Used by the receiving peer to ensure that control messages are sent in order without duplication. In data messages, the field (if present as indicated by the S bit) is ignored (16 bits).
Offset Size	The location of the L2TP payload, expressed as the number of octets from the start of the message header (16 bits).
Offset pad	User-defined bytes used to pad the message header so that the payload starts at the location indicated by the Offset Size field (16 bits).

The AVP header consists of following fields (RFC 2611):

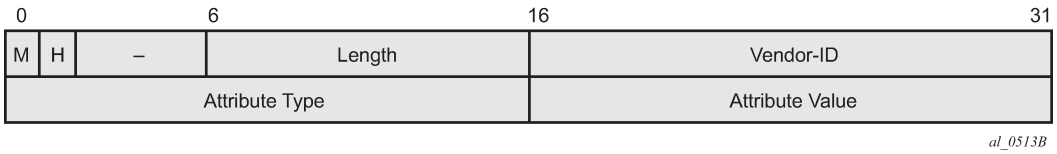

Table 21: AVP header fields and descriptions

Field	Description
M	Mandatory bit — If the M bit is set on an unrecognized AVP within a message associated with a particular session, the session associated with this message MUST be terminated (1 bit).
H	Hidden bit — Identifies the hiding of data in the Attribute-Value field of an AVP. This capability can be used to avoid the passing of sensitive data, such as user passwords, as clear text in an AVP. The H-bit MUST only be set if a shared secret exists between the LAC and LNS. The shared secret is the same secret that is used for tunnel authentication. If the H-bit is set in any

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Field	Description
	AVP(s) in a given control message, a Random Vector AVP must also be present in the message and MUST precede the first AVP having an H bit of 1 (1 bit).
-	Reserved for future use, must be set to zero (4 bits).
Length	Indicates the total number of bytes (including the overall length and bitmask fields) contained in this AVP (10 bits).
Vendor-id	Any vendor wishing to implement their own L2TP extensions can use their own Vendor ID along with private Attribute values. Vendor-ID=0 means that the standard AVPs are used (2 bytes).
Attribute Type	A value with a unique interpretation across all AVPs defined under a given Vendor (2 bytes).
Attribute Value	This is the actual value as indicated by the Vendor ID and Attribute Type (2 bytes).

RADIUS-triggered tunnel/session setup without LNS renegotiation

Figure 346: RADIUS triggered tunnel/session setup without LNS renegotiation depicts the complete PPP session setup, using RADIUS authentication on both LAC and LNS. After the discovery phase (PADI/PADO/PADR/PADS) and LCP negotiation phase (LCP config_request/Ack), the LAC initiates the L2TP tunnel setup based on RADIUS authentication information (RADIUS Request/Accept) and includes the negotiated PPP user-LAC information (called LCP proxy information). The LNS replies directly with a successful CHAP authentication if it agrees with the received proxy information. IP negotiation (IPCP config_request/Ack) is handled between the user and the LNS, and the LAC has no IP knowledge of this PPP session.

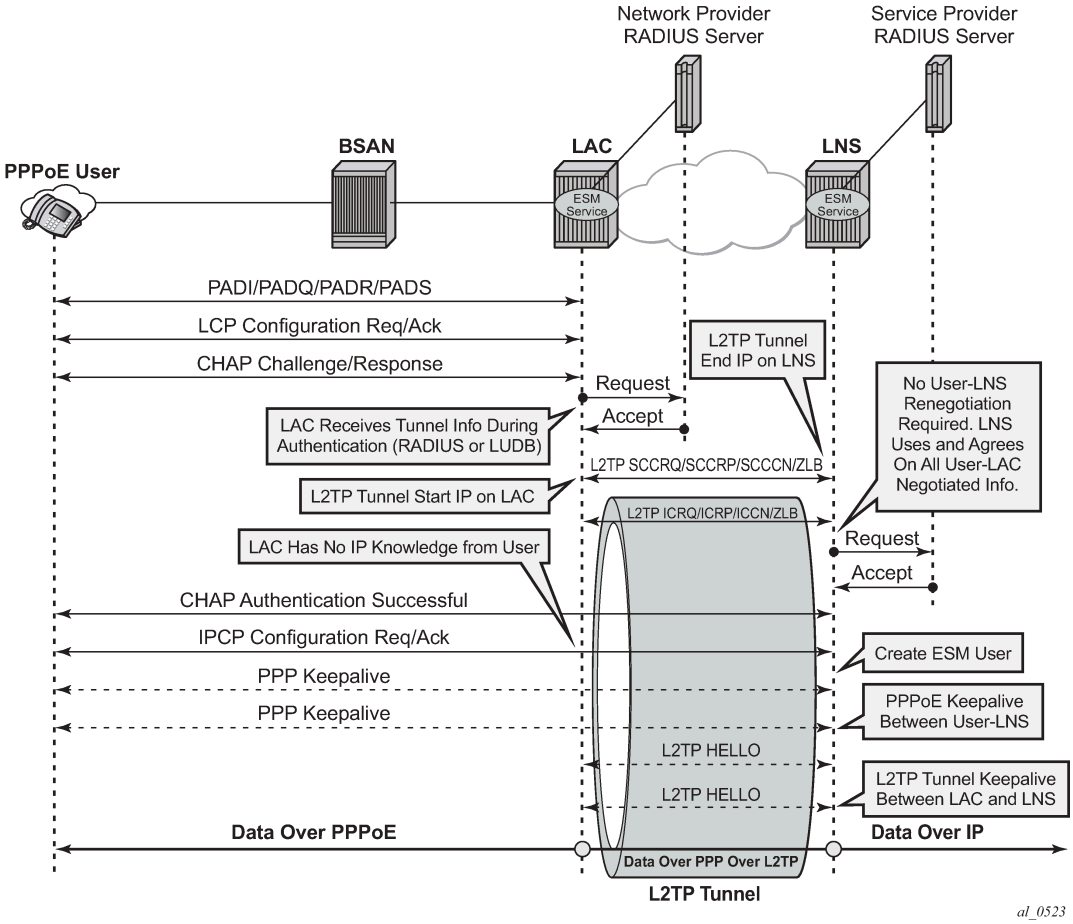
Figure 346: RADIUS triggered tunnel/session setup without LNS renegotiation



RADIUS-triggered tunnel/session setup with LNS renegotiation

Figure 347: RADIUS triggered tunnel/session setup with LNS renegotiation shows the scenario where the LNS does not agree with the received LCP proxy information and (re)starts the LCP phase (LCP config_request/Ack) directly with the PPP user. The rest of this scenario is the same as shown in Figure 346: RADIUS triggered tunnel/session setup without LNS renegotiation.

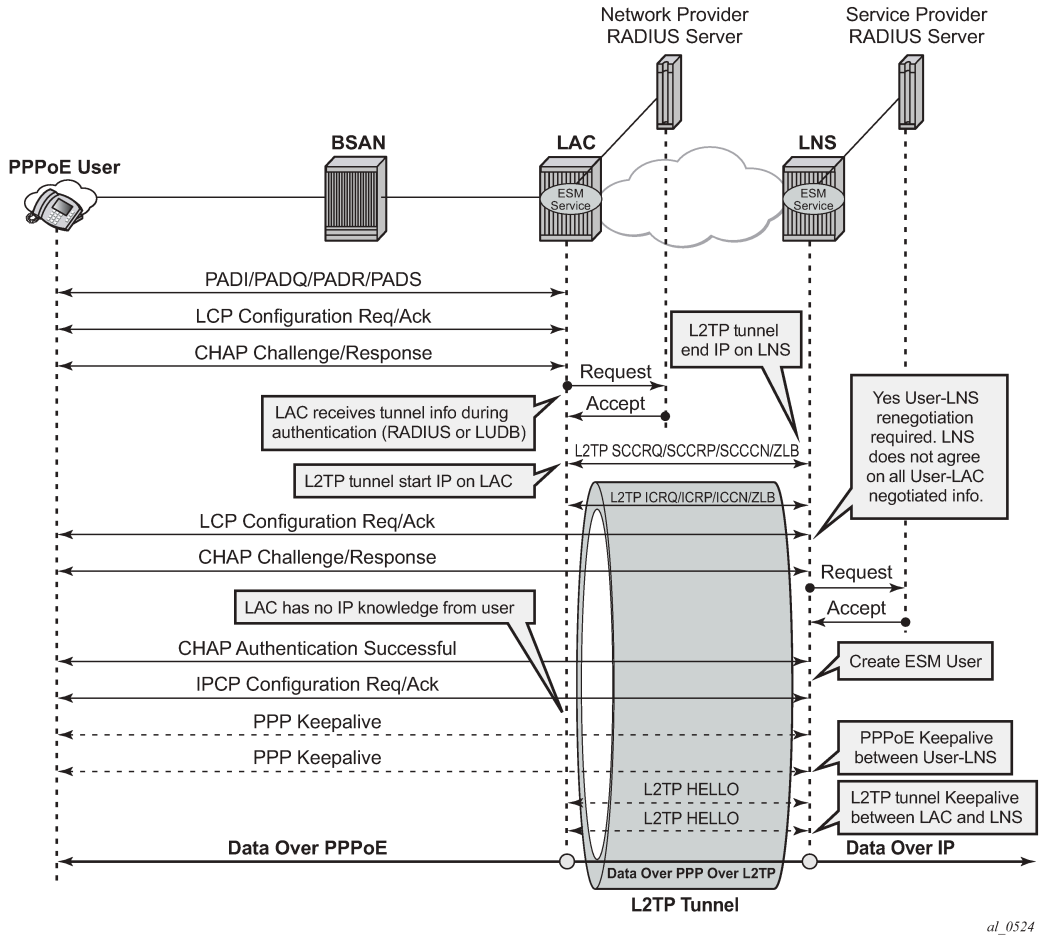
Figure 347: RADIUS triggered tunnel/session setup with LNS renegotiation

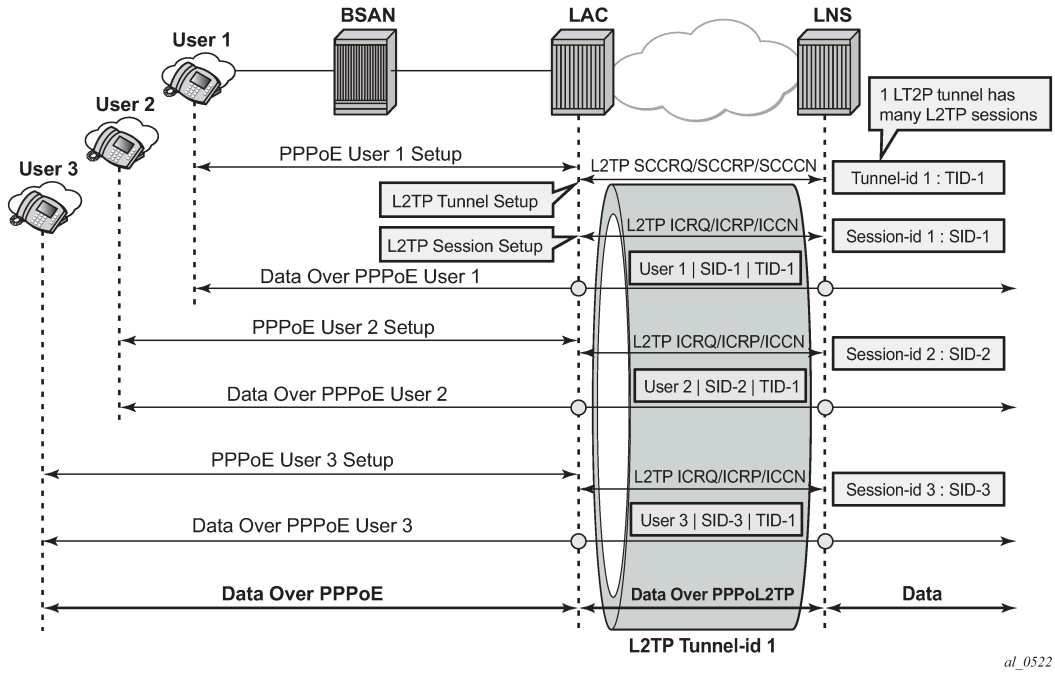


Running multiple PPP sessions over a single L2TP tunnel

Figure 348: Running multiple PPP sessions over a single L2TP tunnel shows multiple PPP sessions tunneled over a single L2TP Tunnel. The LAC encapsulates each PPP session with a different L2TP session-id (SID) but with the same L2TP tunnel-id (TID).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

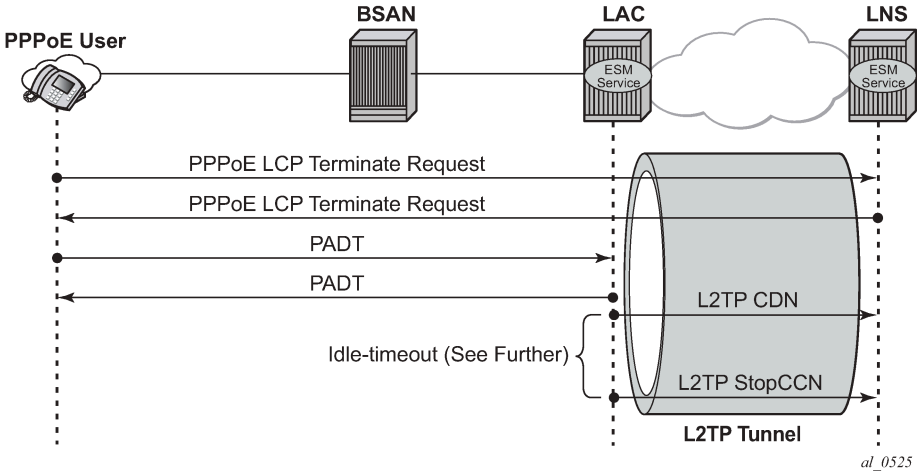
Figure 348: Running multiple PPP sessions over a single L2TP tunnel



PPP user-initiated release/terminate

Figure 349: PPP user-initiated release/terminate shows the user initiated terminate_request tunneled by the LAC followed by the user initiated PADT terminated on the LAC. The LAC informs the LNS about the termination of the session via the L2TP CDN message. The L2TP tunnel can be optionally (idle-timeout) terminated via the L2TP StopCCN message.

Figure 349: PPP user-initiated release/terminate



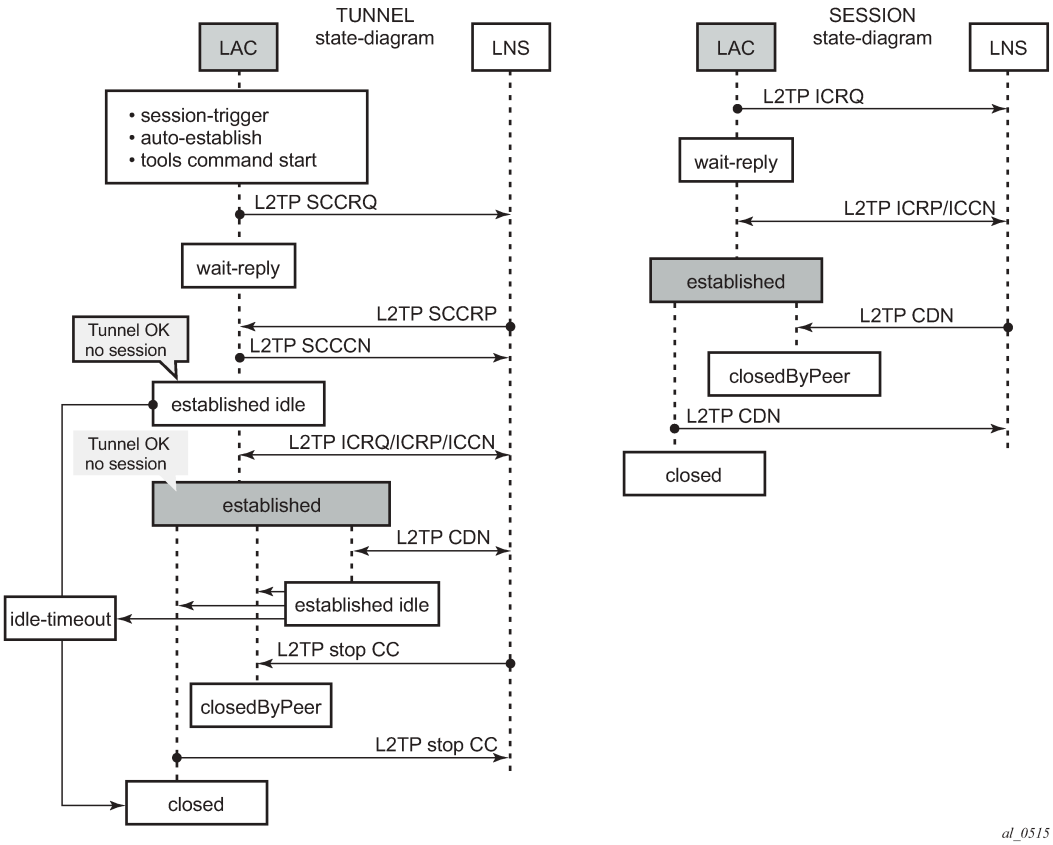
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

L2TP tunnel/session state diagram

Figure 350: L2TP tunnel and session state diagram gives an overview of the main L2TP tunnel and session states. An L2TP tunnel in the establishedIdle state is a tunnel without sessions. A **tools** command (see Advanced topics) can put an L2TP tunnel in a draining state (this prevents adding new sessions to the tunnel but leaves the current sessions intact) or in a drained state (moved from draining to drained when all sessions are terminated). The draining and drained state are not shown in the state diagram.

The L2TP tunnel setup occurs first with the triggers being: session activation, auto-establish, and a **tools start** command (see the Advanced topics section). An L2TP session setup trigger is always session based.

Figure 350: L2TP tunnel and session state diagram



Configuration

Scenario 1: RADIUS-derived L2TP parameters

In the first scenario, the LAC receives an incoming connection and contacts the LAC RADIUS server. The RADIUS server retrieves the attributes for the user's domain (for example @wholesale.com) and passes the tunnel attributes to the LAC. Based on these RADIUS provided tunnel attributes, the LAC selects or initiates a new tunnel to the LTS or directly to the LNS. Once the tunnel is established, the LNS

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

authenticates the end user using its own RADIUS server. Configuring the LNS and the LTS are out of the scope of this example.

In a RADIUS driven L2TP setup, either all or some of the required L2TP attributes are returned via RADIUS. If the RADIUS server only returns the L2TP [67] Tunnel-Server-Endpoint attributes, then the L2TP tunnel/session is established using the 'l2tp node parameter values' for the other required L2TP parameters. The 'l2tp node parameters' are defined under the configure router/service l2tp hierarchy. If the RADIUS server does not return all of the L2TP attributes and the node values are not configured, then the system falls back to default settings for these L2TP parameters.

The standard and vendor specific [26-6572] L2TP RADIUS attributes are listed in the tables below, together with the corresponding l2tp node parameters and defaults.

Table 22: Generic L2TP RADIUS attributes

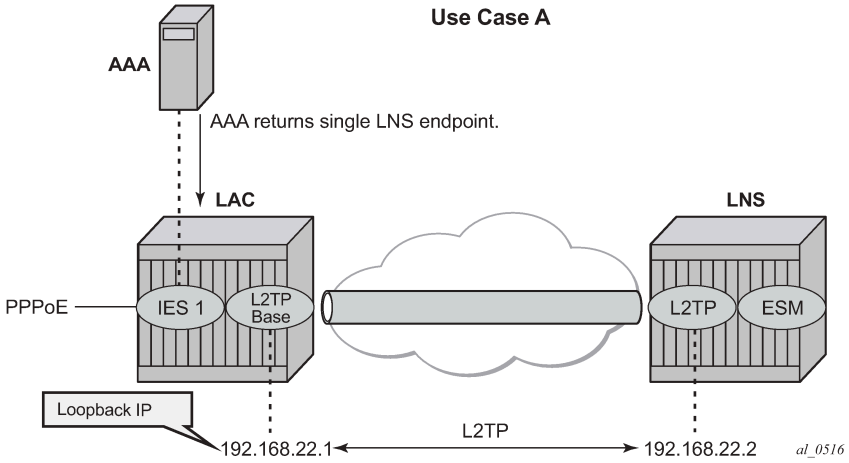
Base router hosted LAC with single endpoint/single tunnel

Using the mandatory L2TP RADIUS attributes (see the following RADIUS user file) the LAC initiates an L2TP tunnel. The source address for the tunnel is the IPv4 address of a loopback interface in the Base router system (LAC tunnel endpoint).The destination for the tunnel is defined by the Tunnel-Server-Endpoint RADIUS attribute [67], and is also known as the peer tunnel LNS endpoint address.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 351: Base router hosted LAC with single endpoint/single tunnel



The PPPoE user terminates on IES service 1, sap 1/1/3:100, and is authenticated via RADIUS **authentication-policy** *radius-1* which provides wholesale/retail (L2TP) information.

```

The excerpt from the FreeRADIUS users file below shows the attributes to be returned.

```
user1@wholesale.com     Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                        Alc-Subsc-ID-Str = "%{User-name}",
                        Alc-Subsc-Prof-Str = "sub-profile-1",
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        Alc-SLA-Prof-Str = "sla-profile-1",
                        Tunnel-Type:1 += L2TP,
                        Tunnel-Medium-Type:1 +=IP,
                        Tunnel-Server-Endpoint:1 += 192.168.22.2,
```

L2TP is enabled (no shutdown) in the related service instance.

The L2TP tunnel is set up in the base instance and not in a VRF because the attribute Alc-Tunnel-Serv-Id is not returned from RADIUS.

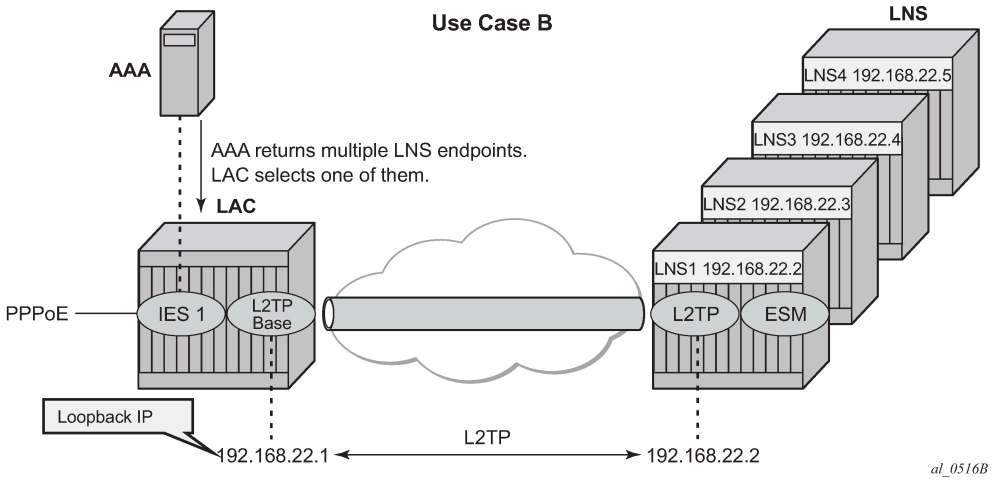
Missing L2TP parameters are taken from defaults defined in the router l2tp context.

```
configure router l2tp
       calling-number-format "%S %s"  # L2TP AVP 22 format
                                      # Default format 'system-name sap-id'
       ---snip---
       no local-name                  # default name equals system-name
       no max-retries-estab           # default value equals 5
       ---snip---
       no shutdown                    # enable L2TP
```

This scenario shows the PPPoE session termination (base IES service 1) and the L2TP tunnel setup in the base router instance.

Base router hosted LAC with multiple endpoints

Figure 352: Base router hosted LAC with multiple endpoints



The following excerpt from the FreeRADIUS users file shows that user *user1@wholesale.com* has 4 possible endpoints (LNS), each with its own tunnel preference. The LAC selects one L2TP endpoint out of these 4 tunnel specifications according to the configured L2TP selection process. This use case uses weighted load balancing between RADIUS-tunnel-1 and RADIUS-tunnel-2. The L2TP tunnel selection process is out of the scope of this chapter.

```
user1@wholesale.com     Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                        Alc-Subsc-ID-Str = "%{User-name}",
                        Alc-Subsc-Prof-Str = "sub-profile-1",
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        Alc-SLA-Prof-Str = "sla-profile-1",
# group related info
                        Tunnel-Client-Endpoint:0 = 192.168.22.1,
                        Alc-Tunnel-Algorithm:0 = weighted-access,
                        Tunnel-Client-Auth-Id:0 = "lac-pe1",
                        Tunnel-Assignment-Id:0 = "RADIUS-group",
                        Alc-Tunnel-Max-Retries-Estab:0 = 2,
# tunnel-1 related info
                        Tunnel-Type:1 += L2TP,
                        Tunnel-Medium-Type:1 +=IP,
                        Tunnel-Server-Endpoint:1 += 192.168.22.2,
                        Tunnel-Assignment-Id:1 += "RADIUS-tunnel-1",
                        Tunnel-Preference:1 += 100,
# tunnel-2 related info
                        Tunnel-Type:2 += L2TP,
                        Tunnel-Medium-Type:2 +=IP,
                        Tunnel-Server-Endpoint:2 += 192.168.22.3,
                        Tunnel-Assignment-Id:2 += "RADIUS-tunnel-2",
                        Tunnel-Preference:2 += 100,
# tunnel-3 related info
                        Tunnel-Type:3 += L2TP,
                        Tunnel-Medium-Type:3 +=IP,
                        Tunnel-Server-Endpoint:3 += 192.168.22.4,
                        Tunnel-Assignment-Id:3 += "RADIUS-tunnel-3",

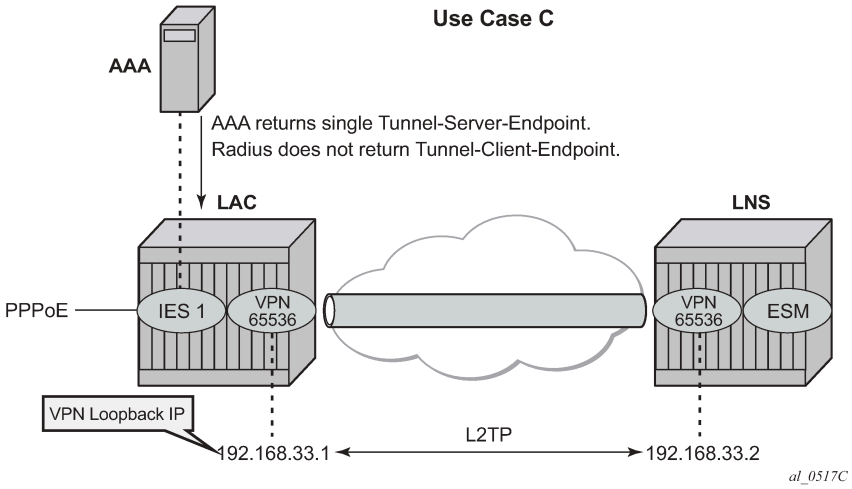
---snip---
```

This scenario shows the PPPoE session termination (base IES service 1) and the L2TP tunnel setup in the base router instance.

VRF hosted LAC

Figure 353: VRF hosted LAC shows the PPPoE session termination (base IES service 1) and the L2TP tunnel setup in a different router instance (VPRN 65536).

Figure 353: VRF hosted LAC



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Using the following L2TP RADIUS attributes, the LAC initiates an L2TP tunnel in VPRN 65536. The PPPoE session is still handled by IES service 1, which proves that both router instances can be different. (See use-case A for configuration details of IES service 1).

```
user1@wholesale.com     Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                        Alc-Subsc-ID-Str = "%{User-name}",
                        Alc-Subsc-Prof-Str = "sub-profile-1",
                        Alc-SLA-Prof-Str = "sla-profile-1",
                        Alc-Tunnel-Serv-Id = 65536,
                        Tunnel-Client-Auth-Id:0 = "lac-pe1",
                        Tunnel-Assignment-Id:0 = "RADIUS-returned-TG",
                        Tunnel-Type:1 += L2TP,
                        Tunnel-Medium-Type:1 +=IP,
                        Tunnel-Server-Endpoint:1 += 192.168.33.2,
                        Tunnel-Assignment-Id:1 += "RADIUS-returned-TN",
```

If RADIUS does not return the L2TP source IP address (Tunnel-Client-Endpoint), then the IP address from the VPRN 65536 interface named 'system' is used as the L2TP source address. The tunnel setup fails if this system interface does not exist.

```
configure {
    service {
        vprn "vprn-65536" {
            admin-state enable
            customer "1"
            service-id 65536
            route-distinguisher "64496:65536"
            l2tp {
                admin-state enable
            }
            vrf-target {
                community "target:64496:65536"
            }
            interface "system" {
                loopback true
                ipv4 {
                    primary {
                        address 192.168.33.1
                        prefix-length 32
                    }
                }
            }
```

Scenario 2: Node-derived L2TP parameters

In the second scenario, the LAC receives the incoming connection and an 'L2TP tunnel-group-name' is assigned during LUDB or RADIUS authentication. This tunnel-group-name refers to the CLI preconfigured tunnel-group name context (**configure router** <*router-name*> **l2tp group** <*tunnel-group-name*>), which provides the context for all relevant tunnel attributes.

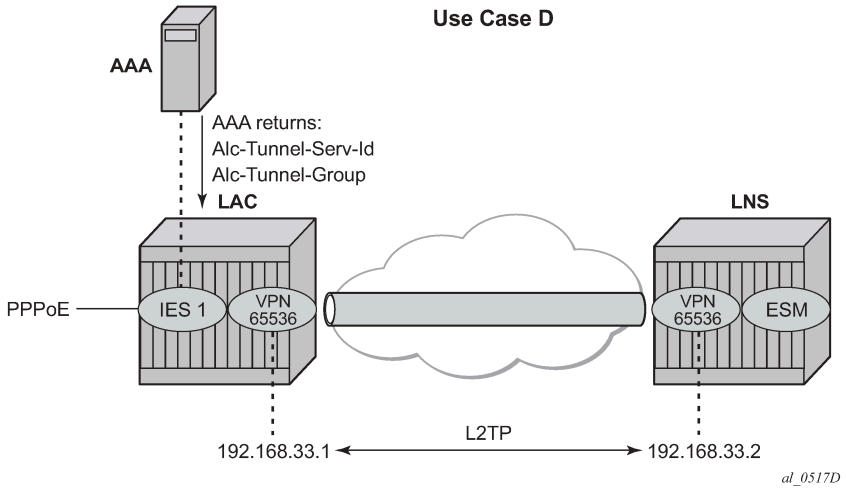
Based on these attributes, the LAC selects and initiates a tunnel to the LTS or directly to the LNS as in Scenario 1: RADIUS-derived L2TP parameters.

RADIUS returns L2TP tunnel group

In use case D, the L2TP tunnel-group-name is assigned during RADIUS authentication.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 354: RADIUS returns L2TP tunnel group



```
user1@wholesale.com     Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                        Alc-Subsc-ID-Str = "%{User-name}",
                        Alc-Subsc-Prof-Str = "sub-profile-1",
                        Alc-SLA-Prof-Str = "sla-profile-1",
                        Alc-Tunnel-Serv-Id = 65536,
                        Alc-Tunnel-Group = "wholesale.com",
```

The L2TP tunnel is initiated from VPRN 65536 (Alc-Tunnel-Serv-Id) and all L2TP tunnel information is taken from the l2tp group wholesale.com hierarchy (Alc-Tunnel-Group) as defined on the node.

```
configure {
    service {
        vprn "vprn-65536" {
            admin-state enable
            customer "1"
            service-id 65536
            route-distinguisher "64496:65536"
            ---snip---
            l2tp {
                admin-state enable
                group "wholesale.com" {
                    admin-state enable
                    tunnel "wholesale.com" {
                        admin-state enable
                        auto-establish false
                        peer 192.168.33.2
                        local-address 192.168.33.1
                        local-name "lac-pe1"
                    }
                }
            }
            interface "system" {
                loopback true
                ipv4 {
                    primary {
                        address 192.168.33.1
                        prefix-length 32
                    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

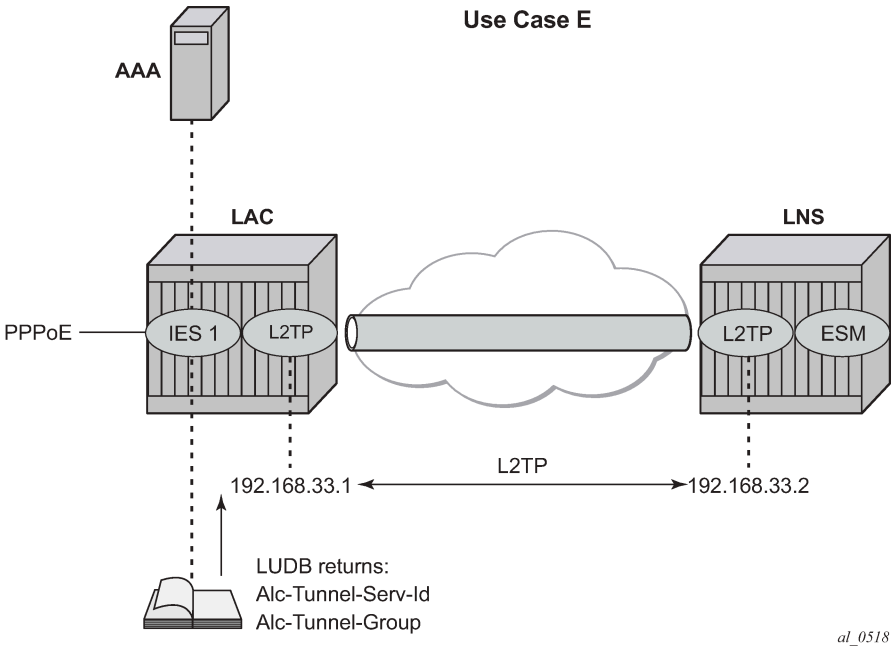
```
                }
            }
        }
    }
```

An L2TP tunnel is set up by either a PPP session-trigger, a **tools** command or by the l2tp group tunnel auto-establish parameter configuration. See the Advanced topics section for the non-session-triggered tunnel setup.

LUDB returns L2TP tunnel group

In use case E, the L2TP tunnel-group-name is assigned during LUDB authentication, so this essentially is a RADIUS-less scenario.

Figure 355: LUDB returns L2TP tunnel group



The PPPoE user enters on an IES service 1, sap 1/1/3:100, and is authenticated via the LUDB which provides L2TP wholesale/retail and ESM information. The PPPoE context refers to a local-user database *l2tp* to provide the subscriber authentication and the tunnel setup parameters, so no RADIUS is needed.

```
configure {
    service {
        ies "ies-1" {
            admin-state enable
            service-id 1
            customer "1"
            subscriber-interface "sub-l2tp" {
                ipv4 {
                    unnumbered {
                        ip-int-name "system"
                    }
                }
                group-interface "grp-l2tp" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    pppoe {
                        admin-state enable
                        session-limit 3
                        sap-session-limit 10
                        user-db "l2tp"
                    }
                    sap 1/1/3:100 {
                        sub-sla-mgmt {
                            admin-state enable
                            sub-ident-policy "all-subscribers"
                            subscriber-limit 1000
                        }
                    }
                }
            }
        }
    }
```

The referenced local user database *l2tp* configuration provides all of the required L2TP and ESM information.

```
configure {
    subscriber-mgmt {
        local-user-db "l2tp" {
            admin-state enable
            ppp {
                match-list [user-name]
                host "wholesale.com" {
                    admin-state enable
                    host-identification {
                        user-name {
                            name "wholesale.com"
                            format domain-only
                        }
                    }
                    identification {
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                        subscriber-id "user@wholesale.com"
                    }
                    l2tp {
                        group {
                            name "wholesale.com"
                            service-id 65536
                        }
                    }
                    password {
                        ignore
                    }
                }
            }
        }
    }
```

Operation and troubleshooting

The subsequent sections explain how the use cases A to E described in the configuration section are verified using show, debug, and tools commands.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The standard router debugging tools can be used to monitor and troubleshoot the L2TP tunnel and session setup.

Useful show commands are:

```
show service id <service-id> ppp session [detail]
show router l2tp tunnel [detail]
show router l2tp session [detail]
show router l2tp peer [ip-address]
```

To debug and show PPPoE packets:

```
debug service id <service-id> ppp packet mode egr-ingr-and-dropped
debug service id <service-id> ppp packet detail-level medium
```

To debug and show RADIUS authentication:

```
debug router radius packet-type authentication
```

To debug and show LUDB authentication:

```
debug subscriber-mgmt local-user-db <local-user-db-name> detail all
```

To debug and show the LAC tunnel selection process and L2TP state machine:

```
debug router l2tp event lac-session-setup
debug router l2tp event finite-state-machine
```

To debug and show the L2TP tunnel and session setup:

```
debug router l2tp packet direction both
debug router l2tp packet detail-level high
```

Understanding the L2TP debug output

The following L2TP ICRQ message (**debug router l2tp packet**) is used to explain how the displayed debug output should be interpreted. See Recap of the L2TPv2 protocol -L2TP header and AVP layout for more details.

```

```
14 2019/05/28 11:15:51.763 CEST MINOR: DEBUG #2001 Base PPPoE 255217->L2TP
"PPPoE 255217->L2TP: UDP 192.0.2.1:1701 -> 192.168.22.2:1701
preference 50 tunnel default_radius_group:unnamed
    create session 791813970"
```

The **debug router l2tp packet detail-level** command shows the L2TP tunnel and session setup for this example.

For the tunnel setup, the LAC sends a Start-Control-Connection-Request (SCCRQ) containing the assigned tunnel-id (no tunnel authentication in the example). The tunnel is now in a wait-reply state.

```
15 2019/05/28 11:15:51.763 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701
tunnel 0 session 0, ns 0 nr 0, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0

```
    AVP FirmwareRevision(0,6), flags:, reserved=0
        4869
    AVP VendorName(0,8), flags:, reserved=0
        "Nokia"
    AVP AssignedTunnelId(0,9), flags: mandatory, reserved=0
        12082"
```

The LNS can bring up the tunnel, so the LNS replies with a Start-Control-Connection-Reply (SCCRP) including the assigned tunnel-id.

```
16 2019/05/28 11:15:51.765 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, ingress)
"L2TP(v2, ctrl, ingress): UDP 192.168.22.2:1701 -> 192.0.2.1:1701
tunnel 12082 session 0, ns 0 nr 1, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        StartControlConnectionReply(2)
    AVP ProtocolVersion(0,2), flags: mandatory, reserved=0
        version=1, revision=0
    AVP HostName(0,7), flags: mandatory, reserved=0
        "lns-pe2"
    AVP WindowSize(0,10), flags: mandatory, reserved=0
        64
    AVP FramingCapabilities(0,3), flags: mandatory, reserved=0
        sync=no, async=no
    AVP BearerCapabilities(0,4), flags: mandatory, reserved=0
        digital=yes, analogue=no
    AVP FirmwareRevision(0,6), flags:, reserved=0
        4869
    AVP VendorName(0,8), flags:, reserved=0
        "Nokia"
    AVP AssignedTunnelId(0,9), flags: mandatory, reserved=0
        4734"
```

As the last step in the tunnel setup phase, the LAC responds with a Start-Control-Connection-Connected (SCCCN) message. After an LNS ZLB acknowledgment, the tunnel is in the establishedIdle state.

```
17 2019/05/28 11:15:51.765 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701
tunnel 4734 session 0, ns 1 nr 1, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        StartControlConnectionConnected(3)"
```

Once the tunnel exists the session setup starts, a three-way exchange for session establishment within the tunnel is performed. The LAC sends an Incoming-Call-Request (ICRQ) with the parameter information for the session. The session is now in the wait-reply state.

```
19 2019/05/28 11:15:51.766 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701

```
        2000000
    AVP ActDataRateDown(3561,130), flags:, reserved=0
        4000000"
```

The LNS then sends an Incoming-Call-Reply (ICRP) that contains the assigned session-id. The session is now in the connect state.

```
21 2019/05/28 11:15:51.768 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, ingress)
"L2TP(v2, ctrl, ingress): UDP 192.168.22.2:1701 -> 192.0.2.1:1701
tunnel 12082 session 8018, ns 1 nr 3, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        IncomingCallReply(11)
    AVP AssignedSessionId(0,14), flags: mandatory, reserved=0
        24477"
```

Finally the LAC sends an Incoming Call Connected (ICCN) and provides the LNS with additional information from the user initiated session. This information includes the LCP information from the negotiation that the LAC and remote user performed. This information is used by the LNS to decide whether to start LCP re-negotiation and/or Authentication re-negotiation with the PPP user or not. After an LNS ZLB acknowledgment, the session is in the established state.

```

Base router hosted LAC with multiple endpoints

The **debug router radius packet-type authentication** command shows the actual RADIUS authentication parameters returned. This example returns multiple tunnel endpoints from which the LAC selects one. This example uses weighted load balancing. (The L2TP tunnel selection process is out of the scope of this example).

```

VRF hosted LAC

This example returns VPRN 65536 as the L2TP service instance [26-6527-104 Alc-Tunnel-Serv-Id]. The VPRN 65536 interface system address is used as the L2TP source address since the attribute Tunnel-Client-Endpoint is not returned.

The IP address 192.168.33.1 (Tunnel-Server-Endpoint) needs to be routable in VRF 65536 over a SAP or to a remote PE. This example uses BGP/MPLS IP Virtual Private Networks (VPNs) (RFC 4364) to access the remote PE.

Advanced topics

Non-session-triggered L2TP tunnel setup

In addition to the ppp-session-triggered setup, an L2TP tunnel can also be set up via a tools command or an auto-establish command.

These non-session-triggers are useful, for example, during the initial configuration phase where the LAC-LNS tunnel setup can be tested without the need for a user to attempt and establish a PPPoE connection.

The PPPoE user still triggers the L2TP session-setup over this L2TP tunnel and RADIUS needs to return an l2tp group-name with the relevant name during authentication.

Auto-establish

Every minute, a check is performed to determine if tunnels need to be established (a process referred to as scan auto-establish). The tunnel state is establishedIdle when the tunnel is setup, and becomes established when user triggered sessions are set up over this tunnel.

```
service
    vprn 65536
        l2tp {
            admin-state enable
            group "wholesale.com" {
                admin-state enable
                tunnel "wholesale.com" {
                    admin-state enable
                    auto-establish true
                    peer 192.168.33.2
                    local-address 192.168.33.1
                    local-name "lac-pe1"
                }
            }
        }
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

There is no difference in operational behavior for a tunnel set up via a session-trigger or an auto-establish command. Removing the auto-establish parameter has no impact on active tunnels (establishedIdle or established).

```
[]
A:admin@LAC# show router 65536 l2tp tunnel

Tools tunnel start

First revert to the original situation, without auto-establish, as follows:

```
configure exclusive
service vprn 65536 l2tp group "wholesale.com" tunnel "wholesale.com"
                                                      delete auto-establish
commit
```

Verify the tunnel does not exist anymore, as follows:

```
[]
A:admin@LAC# show router 65536 l2tp tunnel
No entries found.
```

Issue the tools command to manually establish the L2TP tunnel, as follows:

```
[]
A:admin@LAC# tools perform router 65536 l2tp group "wholesale.com" tunnel
                                                        "wholesale.com" start
```

Verify a new tunnel has been created, as follows:

```
[]
A:admin@LAC# show router 65536 l2tp tunnel
===============================================================================

How long remains a tunnel idle before torn down?

An L2TP tunnel can be torn down automatically, after the expiration of an idle-timer, or manually through a tools command.

Idle-timeout

A persistent tunnel is a tunnel that remains available after the last session over that tunnel is closed. To create a persistent tunnel, the idle-timeout parameter must be set to infinite.

A non-persistent tunnel is torn down immediately (idle-timeout zero) after the last session over that tunnel is closed or after a configurable delay. The idle-timeout parameter is set via the RADIUS [26-6527-49] Alc-Tunnel-Idle-Timeout attribute or the corresponding node parameter. The default value for this parameter is infinite (persistent).

```
configure router l2tp | configure service vprn l2tp
       idle-timeout [0..3600] s
       ---snip---
       group <tunnel-group-name>
           idle-timeout [0..3600] s | infinite
           ---snip---
           tunnel  <tunnel-name>
              idle-timeout [0..3600] s | infinite
              ---snip---
```

The following shows an example of a non-persistent tunnel (idle-timeout 30 seconds). The tunnel changes state from established to establishedIdle when the last session is terminated. Idle-timeout seconds later, the session changes to the closed state. For the purpose of troubleshooting, the operational data stays available for destruct-timeout seconds (see later).

Tools tunnel stop

In addition to the idle-timeout used for tunnel termination, a tools stop command is also available that can be used to terminate persistent and non-persistent tunnels at any moment in time. Be aware that this command is very destructive and destroys all sessions carried over the closed tunnel.

Following command shows the tunnel is in the establishedIdle state.

```
[]
A:admin@LAC# show router 65536 l2tp tunnel
===============================================================================
Conn ID    Loc-Tu-ID Rem-Tu-ID State              Blacklist-state   Ses Active
  Group                                                            Ses Total
    Assignment

===============================================================================
```

The following command terminates the l2tp tunnel. The tunnel is aborted (the LAC sends StopCCN) using the <connection-id> or <tunnel-group-name>+<tunnel-name> as input. This StopCCN indicates "operator request" as the error reason.

```
[]
A:admin@LAC# tools perform router 65536 l2tp group wholesale.com
                                                        tunnel wholesale.com stop
INFO: CLI #2007: Info while processing command - INFO: CLI stopped 1 tunnels,
                                                            destructed 0 tunnels.
```

The following debug output shows the tunnel being aborted.

```
5 2019/05/28 16:01:14.824 CEST MINOR: DEBUG #2001 vprn65536 L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.168.33.1:1701 -> 192.168.33.2:1701
tunnel 9053 session 0, ns 2 nr 1, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        StopControlConnectionNotification(4)
    AVP ResultCode(0,1), flags: mandatory, reserved=0
        result-code: "generalRequestToClearControlConnection"(1),
                                error-code: "noGeneralError"(0)
        error-msg: "operator request"
    AVP AssignedTunnelId(0,9), flags: mandatory, reserved=0
        5051"
```

Alternatively, the tunnel can also be stopped with the following command. The effect would be the same.

```
[]
A:admin@LAC# tools perform router 65536 l2tp tunnel 964886528 stop
```

Keepalive - L2TP Hello

A keepalive mechanism is employed by L2TP in order to differentiate between tunnel outages and no control or data activity on a tunnel for an extended period. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message (ZLB not included) was received on a tunnel. As for any other L2TP control message, if the Hello message is not reliably delivered, then the tunnel is declared down and reset, as defined in RFC 2661, *Layer Two Tunneling Protocol "L2TP"*. This means that SR OS does not send Hello packets if session control traffic is handled over this tunnel. The hello timer is reset if the system transmits any control packet over this tunnel (ZLB packets and data traffic are not taken into account).

The keepalive function is disabled (not recommended) using RADIUS [26-6527-50] Alc-Tunnel-Hello-Interval -1 or hello-interval infinite (default 300). The number of retries for unsuccessful Hello packet delivery equals RADIUS [26-6527-52] Alc-Tunnel-Max-Retries-Estab or node parameter max-retries-estab (default 5). The retry interval is initially set to 1 second and doubles on each retry with a maximum interval of 8 seconds. Using a max-retries-estab 7 results in a retry of [1,2,4,8,8,8,8 seconds].

```
configure router l2tp | configure service vprn l2tp]
    hello-interval [60..3600] s | infinite  # default 300 s
    max-retries-estab [2..7]                # default 5
    ---snip---
    group <tunnel-group-name>
```

Use subject to Terms available at: www.nokia.com/terms.

```
        hello-interval [60..3600] s | infinite
        max-retries-estab [2..7]
        ---snip---
        tunnel  <tunnel-name>
            hello-interval [60..3600] s | infinite
            max-retries-estab [2..7]
            ---snip---
```

For example, the LAC can be configured with an hello-timer of 1 minute and the LNS with an hello-timer of 2 minutes. The hello-timer interval for LAC and LNS do not have to be same because the keepalive mechanism works asynchronous. See Figure 356: L2TP keepalive mechanism.

Keeping closed tunnel and session information

The destruct-timeout parameter (expressed in seconds) controls the period of time that the tunnel, or session data related to a closed (disconnected) tunnel, or session persists before being removed. The destruct_timeout is a debugging aid by keeping underlying memory structures after the tunnel or session is terminated. It is configured via the RADIUS [26-6527-51] Alc-Tunnel-Destruct-Timeout attribute or the corresponding node parameter. Default value for this parameter is 60 seconds.

```
configure router l2tp | configure service vprn l2tp
    destruct-timeout [60..86400]
    ---snip---
    group <tunnel-group-name>
        destruct-timeout [60..86400]
        ---snip---
        tunnel  <tunnel-name>
            destruct-timeout [60..86400]
```

The following output shows a session that is closed and the reason for it being terminated.

Floating peers

A floating peer exists if the peer LNS address indicated in the source address of the SCCRP is different from the peer address known on the LAC. Floating peer allowance is configuration driven and is rejected by default.

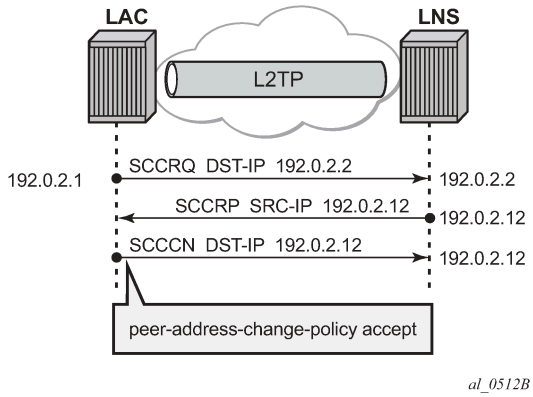
The parameter peer-address-change-policy specifies whether the LAC accepts, ignores or rejects requests from a peer to change the destination IP address or UDP port.

```
configure router l2tp | configure service vprn l2tp
       peer-address-change-policy accept | ignore | reject
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

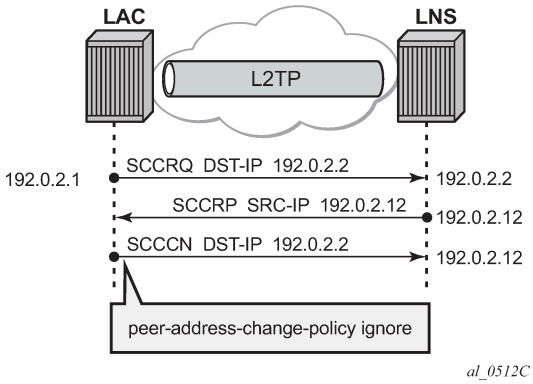
- accept — Specifies that this system accepts any source IP address change for received L2TP control messages related to a locally originated tunnel in the state wait-reply and rejects any peer address change for other tunnels. In case the new peer IP address is accepted, it is learned and used as destination address in subsequent L2TP messages.

  Figure 357: Floating peers accept



- Ignore — Specifies that this system ignores any source IP address change for received L2TP control messages, does not learn any new peer IP address and does not change the destination address in subsequent L2TP messages.

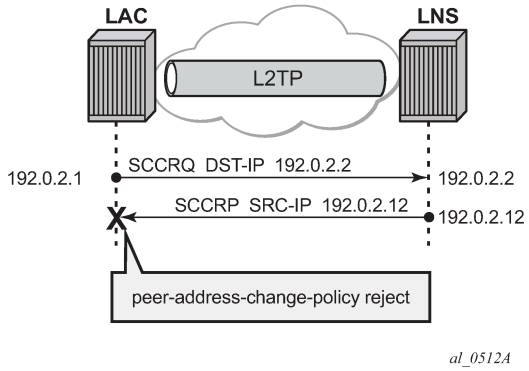
  Figure 358: Floating peers ignore



- Reject — Specifies that this system rejects any source IP address change for received L2TP control messages and drops those messages.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 359: Floating peers reject



The values Peer IP, Tx dst-IP and Rx src-IP in the **show router l2tp tunnel detail** command indicates if floating peers are used or not.

An example of a floating peer (peer-address-change-policy accept) is as follows.

```
[]
A:admin@:LAC# show router l2tp tunnel detail
=======================================

```

Tx/Rx connect speed - AVP 24/38

The connect speed (TX AVP 24 and RX AVP 38) is passed in the ICCN messages sent from the LAC to the LNS. The L2TP AVP 24 defines the (Tx) connect speed in bps from the perspective of traffic flowing from the LAC towards the subscriber (BNG downstream rate).The L2TP AVP 38 defines the (Rx) connect speed in bps from the perspective of traffic flowing from the subscriber towards the LAC (BNG upstream rate).

The report-rate configuration option indicates what rate is reported to the LNS when creating an L2TP session.

```
configure subscriber-mgmt sla-profile <sla-profile-name> ingress | egress
    report-rate agg-rate-limit|scheduler|pppoe-actual-rate|
                                    policer|rfc5515-actual-rate
```

- agg-rate-limit — Take the aggregate rate as received from the RADIUS Access-Accept message in VSA Alc-Subscriber-QoS-Override. When this RADIUS VSA is not present in the Access-Accept, or

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

when RADIUS is not used, then take the configured aggregate rate limit. In the case where this is not configured, then take the port rate.

- scheduler <scheduler-name> — Take the rate of the specified scheduler. In case the scheduler is not linked with the scheduler-policy from the subscriber-profile, then take the port rate.
- pppoe-actual-rate — Take the rate from the DSL-Forum Vendor-Specific PPPoE Tag when available, otherwise take the port rate.
- rfc5515-actual-rate — Put the same value as the transmitted Actual-Data-Rate-Upstream AVP in the Rx-Connect-Speed AVP, and the same value as the transmitted Actual-Data-Rate-Downstream AVP in the Tx-Connect-Speed AVP.

Calling number AVP 22 format

The format of AVP 22 Calling Number in the ICRQ message is configurable via the parameter calling-number-format. The default format is "%S<space>%s" and corresponds to the concatenation of system-name<space>sap-id. Available parameters are %S (system-name), %c (Agent Circuit Id), %r Agent Remote Id, %s (sap-id), %l (Logical Line ID) and fixed strings. A combination can be configured from any of these parameters, but the total configured format cannot exceed 255 characters.

Example 1: Default configuration.

```
configure exclusive
service vprn 65536 l2tp lac calling-number-format "%S %s"
```

```
18 2019/05/28 16:26:20.903 CEST MINOR: DEBUG #2001 vprn65536 L2TP(v2, ctrl, egress)

```

Prevent LAC from transmitting calling number AVP 22 to LNS

By default, the LAC includes the Calling Number AVP 22 in the L2TP incoming-call-request (ICRQ) packets transmitted to LNS. This AVP identifies the interface that is connected to the customer in the access network. Network access interface information can be hidden by configuring the LAC not to send the Calling Number AVP to the LNS.

Use the following command to disable the sending of L2TP Calling Number AVP 22.

```
configure exclusive
router l2tp exclude-avps calling-number
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

AVP 100 - Cisco-Nas-Port

Interoperation with a Cisco LNS requires that the LAC communicates a NAS port type to the LNS via the L2TP ICRQ 'Cisco Nas Port Info AVP (100)'. This AVP (100) includes information that identifies the NAS port and indicates whether the port type is Ethernet or ATM and is configured via the cisco-nas-port parameter.

The Cisco AVP 100 format is as follows:

- First 5 bytes are NAS-Port-Type:
  - 0f10090203 (Ethernet)
  - 0f10090201 (ATM)
- Remaining 4 bytes corresponds with the configured cisco-nas-port value

Example:

- Ethernet 12b s-vlan-id; 10b c-vlan-id; 3b slot number; 2b MDA nbr; 5b port
- ATM 12b VPI; 10b VCI; 3b slot number; 2b MDA nbr; 5b port

```
configure exclusive
service vprn 65536 l2tp lac cisco-nas-port ethernet "*12o*10i*3s*2m*5p"
```

nas-port 1/1/3:100 corresponds to 102563 (000000000000 0001100100 001 01 00011).

```

        4000000"
```

L2TP group/peer/tunnel draining

When the LAC has established sessions, the LAC can avoid the creation of new sessions for a specific group, peer, or tunnel, via the **drain** command.

No new sessions are created for a group, peer or tunnel that is being drained (draining state) but the current sessions are left intact.

After the **drain** command is issued, the group, peer, or tunnel moves from a draining to drained state when the last session is closed. A drained group, peer, or tunnel can then be managed (reconfigured, deleted) without any user impact.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Be aware that a group, peer, or tunnel in a draining or drained state is skipped in the tunnel selection process. The next example shows a tunnel draining; group and peer draining works according in the same way.

A tunnel has 1 session and is in established state.

```

Vport-Based Load Balancing on a LAG

This chapter describes Vport-based load balancing on a LAG.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion
- Appendix with configuration files

Applicability

The information and MD-CLI configuration in this chapter is based on SR OS Release 22.10.R1.

Vport-based load balancing on a LAG applies to all service router (SR) systems based on FP4 and higher. This functionality is not supported on Virtualized Service Router (VSR) because VSR does not support Vports.

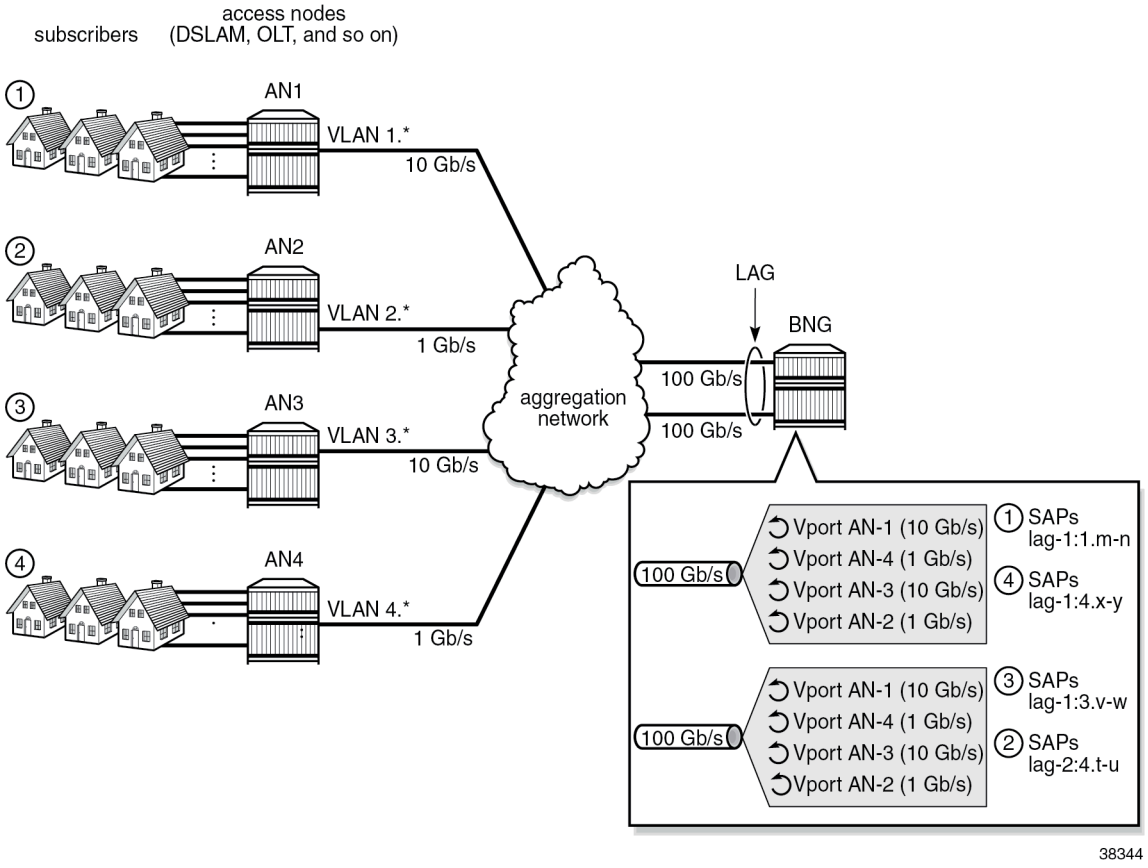
The target audience for this chapter is subscriber management users who are already familiar with subscriber management and EVPN VPWS. In this chapter, the emphasis is on the LAG configuration.

Overview

In enhanced subscriber management (ESM), a Vport is a representation of a downstream access node that hosts subscribers. A Vport is used to control bandwidth toward the access node. When deployed on a link aggregation group (LAG), Vports must be configured on every LAG member port, as shown in the figure Figure 360: Vport concept.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 360: Vport concept



The Vport bandwidth in a LAG can be configured in two ways:

- The configured Vport bandwidth is assigned to every LAG member port.
- The Vport on each link gets only a fraction of the total bandwidth of the access node that it represents.

In both cases, the configured Vport bandwidth corresponds to the full capacity of the access node that it controls (a bandwidth cap or ceiling per access node). The difference is in how this bandwidth is assigned by the system to each LAG member port, which is controlled by the **lag access adapt-qos mode link | port-fair** command.

When the configured Vport bandwidth is assigned to every LAG member port, oversubscription of the access node must be avoided by directing all traffic associated with a Vport to a single LAG member link. This configuration requires load balancing per Vport and is the focus of this chapter. Per-Vport load balancing is suitable in environments with a large variation in bandwidth consumption between subscribers within a Vport.

When the Vport on each link gets only a fraction of the total bandwidth of the access node, the configured Vport bandwidth is automatically distributed over the LAG member links: the Vport bandwidth per LAG member port is the Vport bandwidth divided by the number of LAG member ports.

In other words, each LAG member port gets an equal share of the configured bandwidth. This scenario calls for load balancing per subscriber, where traffic toward the same access node is distributed over the member links. This scenario is suitable for environments with subscribers with similar bandwidth

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

requirements. Otherwise, a few high-bandwidth-consuming subscribers within a Vport can use the same link, causing the aggregate bandwidth to exceed the Vport cap per LAG member port. This issue can cause unnecessary congestion and packet drops, while the instance of the same Vport on the other links remain underutilized.

In Releases earlier than Release 22.10, the implementation of load balancing per Vport, where the configured Vport bandwidth is assigned to every member, implies the following:

- The subscriber SAPs must be instantiated on all LAG member ports, which has a negative effect on the subscriber scalability that is driven by the finite number of SAPs per forwarding complex.
- All Vports are accounted with equal weight in the hashing algorithm, regardless of the configured bandwidth of the Vports, which could lead to suboptimal load balancing when Vports with different bandwidths are present on the LAG.

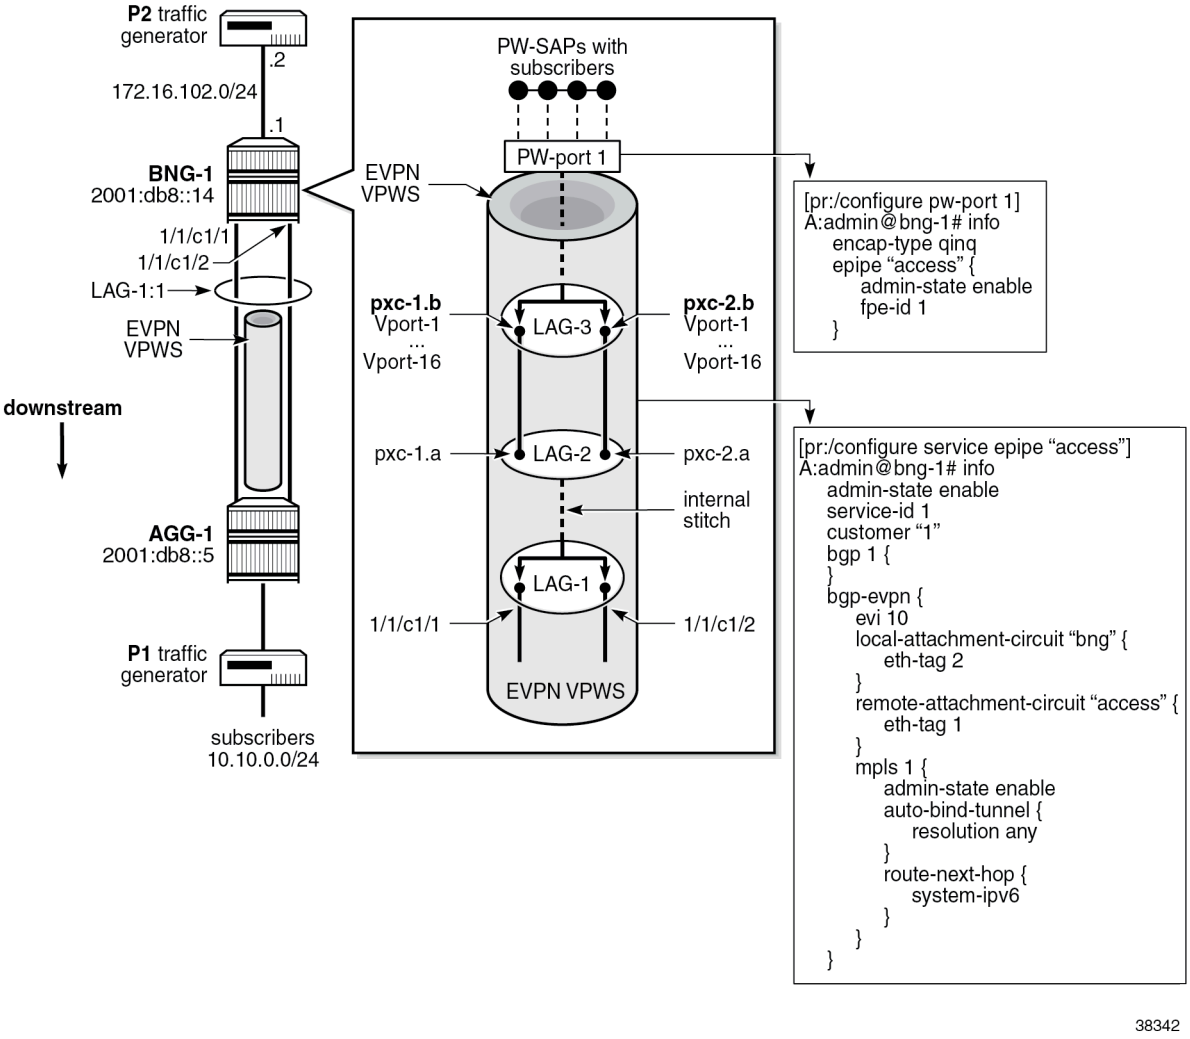
Release 22.10 expands load balancing per Vport to include the class and weight per Vport and the support for a single subscriber SAP instance per forwarding complex.

The focus of this chapter is on the class- and weight-based Vport load balancing where a single copy of a SAP is created per forwarding complex for each subscriber.

The figure Figure 361: Example topology shows the example topology used in this chapter.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 361: Example topology



In this setup:

- The subscribers are instantiated in 1:1 mode of operation (one subscriber per SAP) on a pseudowire (PW) port in the Broadband Network Gateway (BNG) "BNG-1".
- The PW-port is the termination point for the EVPN VPWS, which connects the BNG to an aggregation node "AGG-1" in the access network.
- The PW-port is based on the Forwarding Path Extension (FPE), with the LAG "lag-3" containing two PXC member ports, pxc-1.b and pxc-2.b.
- There are 16 Vports configured on each of the PXC ports in the LAG "lag-3".
- 32 IPv4 subscribers are associated with these Vports. The individual subscriber association with Vports is shown in Table 1.
- The EVPN VPWS connecting the BNG to "AGG-1" is configured over the LAG "lag-1" with two member ports on the BNG (ports 1/1/c1/1 and 1/1/c1/2).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Traffic is sent in the downstream direction, from traffic generator port "p2" toward the simulated subscribers on traffic generator port "p1".
- The traffic flow and traffic load balancing in the BNG is examined at two points:
  - on the "lag-3" underlaying the PW-port, where traffic is load-balanced per Vport in the ESM context
  - on the "lag-1" where traffic is load-balanced in the service context, outside of the ESM
- Bandwidth utilization on the LAG links is examined via **show** and **monitor** commands at the BNG.

Traffic load balancing on the LAGs "lag-1" and "lag-3" are independent of each other. Traffic on the LAG "lag-3" is load-balanced in the subscriber context and is Vport-aware, while traffic on the LAG "lag-1" is disjoined from the subscriber context. On the LAG "lag-1", service hashing mechanisms apply; on the LAG "lag-3", subscriber management hashing mechanisms apply.

Note: An example topology with FPE-based PW ports might give the impression that load balancing on the external links connecting the BNG to the AGG node is performed in the subscriber context, based on subscriber ID or Vport. This is not the case.

To demonstrate the two-stage load balancing, first on "lag-3" and then on "lag-1", an example topology with subscribers instantiated on a FPE based PW-port is chosen.

Although the focus of this chapter is class- and weight-based Vport load balancing, using the same traffic patterns, in addition, the following two other types of load balancing are evaluated:

- load balancing based on Vports without class and weights
- load balancing based on subscribers (subscriber IDs that are internally assigned identifiers for each subscriber)

Comparing the three types of load balancing helps to form a better overall picture about load balancing traffic options in a subscriber management context.

Association between subscribers and Vports

Subscribers are associated with Vports during the subscriber authentication phase. In this example, RADIUS is used for authentication.

The table Table 24: Subscriber association with Vports shows the mapping between subscribers and Vport names, Vport configured rates (bandwidth), classes, weights, and transmission (Tx) rates in frames per second (FPS) of generated traffic (offered traffic).

Table 24: Subscriber association with Vports

Class	Vport	Weight	Vport rate in kb/s	Tx rate FPS	Subscriber
1	vport-1	15	9 000 000	900	1
1	vport-2	5	3 000 000	300	2, 3
1	vport-3	5	3 000 000	300	4, 5
1	vport-4	5	3 000 000	300	6, 7
2	vport-5	15	3 000 000	300	8
2	vport-6	5	1 000 000	100	9, 10

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Class	Vport	Weight	Vport rate in kb/s	Tx rate FPS	Subscriber
2	vport-7	5	1 000 000	100	11, 12
2	vport-8	5	1 000 000	100	13, 14
3	vport-9	7	1 400 000	140	15
3	vport-10	1	200 000	20	16, 17
3	vport-11	1	200 000	20	18, 19
3	vport-12	1	200 000	20	20, 21
3	vport-13	1	200 000	20	22, 23
3	vport-14	1	200 000	20	24, 25
3	vport-15	1	200 000	20	26, 27
3	vport-16	1	200 000	20	28, 29, 30, 31, 32

The Vports in SR have names from "vport-1" to "vport-16".

The class represents a bandwidth tier. Vports with similarly configured bandwidth values can be grouped into classes and can be load-balanced independently of Vports in other classes. For example, Vports in class 1 are distributed over the LAG member ports independently of the Vports in classes 2 and 3.

The weight is configured for each Vport. Within each class, the hashing algorithm tries to equalize the sum of weights across the LAG member ports.

The traffic generator sends a traffic stream for each subscriber. For example, the traffic generator sends 900 fps toward subscriber 1 associated with Vport "vport-1", while toward the subscribers 28, 29, 30, 31, and 32 associated with "vport-16", the traffic generator sends an aggregated rate of 20 fps, or 4 fps toward each subscriber. The packet size is uniform (200 bytes) across the subscribers.

The selected traffic rates represent the Vport bandwidth. In other words, the ratio of the traffic rates within each Vport is the same as the ratio between the configured Vport bandwidths, which allows for a more intuitive interpretation of the results.

Because this setup is run on PC-based sims, the selected offered rates are low (tens of fps rather than millions of fps). However, the rates are high enough for the purpose of this chapter.

For brevity, the subscribers in this table are represented by numerical values. In SR, the subscriber numbers are prepended with the string "ipoe -", for example, subscriber 1 in the table represents subscriber "ipoe-1" in the SR.

The table Table 24: Subscriber association with Vports shows that the configured Vport bandwidth and, consequently, the transmission rates are selected in a very unbalanced way. These unbalanced values are used to allow for a clearer interpretation of the results that are presented later in this chapter.

For example, traffic for "vport-9" is seven times higher than traffic in each of the Vports from 10 to 16. If the eight Vports from 9 to 16 were distributed without regarding their configured Vport bandwidth, then the most likely outcome would be that four Vports would be hashed to one link and four to the other. This outcome would result in a very uneven load balancing with traffic utilization on one link being more than twice the utilization on the other link.

Vport classes and weights ensure that uneven load balancing does not happen and that traffic is more evenly split across the two LAG member ports.

Use subject to Terms available at: www.nokia.com/terms.

The figure Figure 362: Vport bandwidth distribution is a graphical representation of the Vport bandwidth in the table Table 24: Subscriber association with Vports, where the size of each rectangle represents the Vport bandwidth configured rate. Vports in different classes are represented in different colors. Vports are divided into smaller areas, where each area represents the bandwidth of subscribers associated with the Vport. For example, the size of Vport 1 (9 Gb/s) is three times the size of each of the Vports 2, 3, 4, and 5 (3 Gb/s), or 45 times the size of any of the Vports from 10 to 16 (200 Mb/s). The SR independently attempts to equalize traffic in class 1, class 2, and class 3.

Configuration

Complete configuration files for the AGG-1 and the BNG-1 node in this topology are provided in the appendix.

This section describes key configuration blocks and **show** output on the BNG.

The configuration section is split into the three following sections:

- FPE
- Vports
- LAG

FPE

The setup on the BNG requires FPE-based PXCs for the PW-port. An arbitrary choice is made to select a port-based PXC instead of the MAC- or internal-based PXC. The following two PXCs will become part of the PXC-based LAG on which the subscribers are instantiated.

```
[pr:/configure port-xc]
A:admin@bng-1#

    pxc 1 {
        admin-state enable
        description "pw-port lag 2,3"
        port-id 1/1/c4/2
    }
    pxc 2 {
        admin-state enable
        description "pw-port lag 2,3"
        port-id 1/1/c4/3
    }

A:admin@bng-1# /show port-xc

===============================================================================
Port Cross-Connect Information
===============================================================================
PXC    Admin     Oper      Port          Description
Id     State     State     Id
-------------------------------------------------------------------------------
1      Up        Up        1/1/c4/2      pw-port lag 2,3
2      Up        Up        1/1/c4/3      pw-port lag 2,3
-------------------------------------------------------------------------------
No. of PXCs: 2
===============================================================================
```

The logical PXC ports must be explicitly configured and enabled by the operator:

```
[pr:/configure]
A:admin@bng-1#
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
```

The FPE configuration that is required for the PW-port is as follows:

```
[pr:/configure]
A:admin@bng-1#
    fwd-path-ext {
        sdp-id-range {
            start 17500
            end 17600
        }
        fpe 1 {
            description "pw-port on a lag"
            path {
                xc-lag-a "lag-2"
                xc-lag-b "lag-3"
            }
            application {
                pw-port-extension {
                }
            }
        }
    }

A:admin@bng-1#/show  fwd-path-ext fpe 1

Vports

The egress QoS hierarchy for the subscriber is the following:

- subscriber queues with their own rates and buffering capabilities
- the aggregate rate of the subscriber – the total traffic from all the queues of a subscriber cannot exceed this rate
- the aggregate rate of a group of subscribers connected to the same access node or a PON – this aggregate rate is controlled by a Vport
- the aggregate rate of subscribers connected to the same local port – this aggregate rate is controlled by a port-scheduler-policy

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Vports are configured on every member port of "lag-3". The LAG underlies the PW-port on which the subscribers are terminated. The member ports of "lag-3" are pxc-1.b and pxc-2.b.

The Vports are attached to the port scheduler via a port scheduler policy named "lag-3-pxc", which is shown in the following configuration.

Only the configuration of the pxc-1.b is shown. The configuration of port-2.b is identical to that for port pxc-1.b.

Each Vport is configured with an aggregate rate, the class, and the weight as described in the table Table 24: Subscriber association with Vports.

The mapping between the Vport and the subscriber is based on the `int-dest-id` string returned by RADIUS during subscriber authentication. For example, the RADIUS-returned string for subscriber "ipoe-1" is carried in the Nokia VSA `Alc-Int-Dest-Id-Str` with value "`vport-1`".

The Vport configuration and port-scheduler policy reference under pxc-1.b (a member port of "lag-3") is as follows:

```
pr:/configure port pxc-1.b]
A:admin@bng-1#
    admin-state enable
    description "PXC lag-3, pw-port termination"
    ethernet {
        access {
            egress {
                virtual-port "vport-1" {
                    aggregate-rate {
                        rate 9000000
                    }
                    host-match {
                        int-dest-id "vport-1" { }
                    }
                    lag-per-link-hash {
                        class 1
                        weight 15
                    }
                }
                virtual-port "vport-2" {
                    aggregate-rate {
                        rate 3000000
                    }
                    host-match {
                        int-dest-id "vport-2" { }
                    }
                    lag-per-link-hash {
                        class 1
                        weight 5
                    }
                }
                virtual-port "vport-3" {
                    aggregate-rate {
                        rate 3000000
                    }
                    host-match {
                        int-dest-id "vport-3" { }
                    }
                    lag-per-link-hash {
                        class 1
                        weight 5
                    }
                }
                virtual-port "vport-4" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    aggregate-rate {
                        rate 3000000
                    }
                    host-match {
                        int-dest-id "vport-4" { }
                    }
                    lag-per-link-hash {
                        class 1
                        weight 5
                    }
                }
                virtual-port "vport-5" {
                    aggregate-rate {

```

The following configuration shows that each subscriber has only one egress queue, which is port-parented. This queue is configured in the egress SAP policy, which is then referenced in the SLA profile assigned to the subscriber during the authentication phase.

Port-schedule policy "lag-3-pxc" is also configured under the QoS hierarchy, using default values in this case (which is why there is nothing explicitly configured under **port-scheduler-policy**).

```
[pr:/configure qos]
A:admin@bng-1#
    sap-egress "sap-egess-1" {
        policy-id 2
        queue 1 {
            port-parent {
            }
        }
    }
    port-scheduler-policy "lag-3-pxc" {
    }
```

The SLA profile for the subscriber must include **vport** as the port-parent location, otherwise the subscriber would not be associated with the Vport:

```
[pr:/configure subscriber-mgmt sla-profile "sla-profile-1"]
A:admin@bng-1#
    egress {
        qos {
            sap-egress {
                policy-name "sap-egess-1"
                port-parent-location vport

            }
        }
    }
```

There are 32 subscribers instantiated in the BNG:

```
A:admin@bng-1# show service active-subscribers summary

===============================================================================
Active Subscriber table summary
===============================================================================
Total Count       : 32
===============================================================================
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following **show** command displays the subscriber hierarchy:

```
A:admin@bng-1# show service  active-subscribers hierarchy

===============================================================================
Active Subscribers Hierarchy
===============================================================================
-- ipoe-1
   (sub-profile-1)
   |
   +-- sap:[pw-1:1.1] - sla:sla-profile-1
       |
       +-- IPOE-session - mac:00:14:01:00:00:01 - svc:10
           |

           |
           +-- 10.10.0.27 - DHCP

---snip---

-------------------------------------------------------------------------------
Number of active subscribers : 32
Flags: (N) = the host or the managed route is in non-forwarding state
===============================================================================
---snip---
```

Some of the additional **show** commands that can be used to display subscriber states are:

```
show service active-subscribers detail
show service id "vport-hashing" subscriber-hosts detail
show service id "vport-hashing" ipoe session detail
show service id "vport-hashing" dhcp lease-state detail
```

The following **show** commands display information related to the QoS hierarchy:

```
show qos scheduler-hierarchy port pxc-1.b detail
show qos agg-rate port pxc-1.b vport "vport-1" detail
```

LAG

The two LAGs examined in this chapter are:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- PXC LAG "lag-3", which underlies the PW-port where the subscribers are terminated. This LAG is implicitly applied to the ESM context(directly via FPE, indirectly via PW-port and PW capture SAP) where load balancing is performed based on Vports.
- LAG "lag-1" connects the BNG to the aggregation node "AGG-1". This LAG is applied in the service context. Load balancing on this LAG is performed based on the service context.

This chapter examines load balancing over member links for both LAGs.

PXC LAG "lag-3" (ESM)

The configuration for "lag-3" is the following:

```
[pr:/configure lag "lag-3"]
A:admin@bng-1#
    admin-state enable
    description "fpe pw-port pxc lag - termination side"
    mode hybrid
    max-ports 64
    access {
        per-fp-ing-queuing true
        per-fp-egr-queuing true
        per-fp-sap-instance true
        adapt-qos {
            mode link
        }
    }
    per-link-hash {
        weighted {
            subscriber-hash-mode vport
        }
    }
    port pxc-1.b {
    }
    port pxc-2.b {
    }
```

The **per-link-hash** command enables weighted Vport hashing in the subscriber context.

If classes and weights for Vports are not configured, hashing is still performed per Vport, in which case all Vports are treated equally, regardless of the bandwidth.

With the **per-fp-sap-instance** command enabled, the system allocates only one SAP instance per subscriber per forwarding complex.

For example, if a LAG has two member ports on the same forwarding complex, then for each subscriber, only one SAP instance is allocated (as opposed to one SAP instance on each member port). The result of this allocation is improved scaling because the number of SAPs per forwarding complex is finite. The scaling improvement can be verified with the following commands.

Before any subscriber is instantiated, the number of subscriber hosts and SLA profile instances is 0. A number of SAPs are already allocated (three in this case), related to non-subscriber interfaces (EVPN VPWS, regular interfaces, and so on).

Note: The setup runs on PC-based simulators where total scaling figures are reduced.

```
A:admin@bng-1# tools dump resource-usage card "1" fp 1
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
===============================================================================
Resource Usage Information for Card Slot #1 FP #1
===============================================================================
                                                  Total  Allocated       Free
-------------------------------------------------------------------------------

                            Subscriber Hosts -     262143          0     262143

            Subscriber SLA Profile Instances |     131071          0     131071
                               SAP Instances |      98303          3      98300
===============================================================================
```

After 32 subscribers are instantiated on the PW-port and on "lag-3", only 32 SAP instances are allocated:

35 allocated SAP instances − 3 residual SAP instances = 32 SAP instances (for 32 subscriber hosts)

The following command shows that 32 subscriber hosts and 35 SAP instances are allocated:

```
A:admin@bng-1#  /tools dump resource-usage card 1 fp 1

===============================================================================
Resource Usage Information for Card Slot #1 FP #1
===============================================================================
                                                  Total  Allocated       Free
-------------------------------------------------------------------------------
                            Subscriber Hosts -     262143         32     262111

            Subscriber SLA Profile Instances |     131071         32     131039
                               SAP Instances |      98303         35      98268

===============================================================================
```

The **per-fp-ing-queuing** and **per-fp-egr-queuing** commands have similar effect for queues, although the **per-fp-egr-queuing true** command is the only mode of operation in subscriber management on a LAG.

The **access adapt-qos mode link** command instructs the system to apply the configured Vport bandwidth to every member port of a LAG. This command is required in per-Vport load balancing.

The alternative mode is **port-fair**, where the configured Vport bandwidth is divided across the member ports in the LAG (each member port gets a share of the configured bandwidths). Per-Vport load balancing is not recommended in this case due to likely overshoot of the Vport assigned bandwidth to each member port, which would result in unnecessary packet drops.

Examining Vport load balancing effects

For a better understanding of what per-Vport load balancing means, the results for three cases are compared:

- traffic utilization on LAG member links with weighted (for class and weight) per-Vport load balancing
- traffic utilization on LAG member links with Vport load balancing but without classes and weights configured
- traffic utilization on LAG member links with per-subscriber load balancing (Vport load balancing is disabled)

The expectation is that there is a higher degree of load balancing in the first case than in the next two cases. This different degree for load balancing is because of the unequal nature of the generated traffic,

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

where some subscribers send significantly more traffic than others, and the inability of the latter two cases to deal with this lack of balance.

Load balancing per Vport with classes and weights

The configuration file for BNG-1 can be found here.

In this setup, classes and weights configured under Vports are considered in the hashing algorithm. The following command shows how Vports are distributed over the LAG member ports. Although all Vports are instantiated on both member ports of "lag-3", this command shows how the actual traffic for each Vport is distributed over the member links of "lag-3":

```
A:admin@bng-1# show lag "lag-3" associations per-link-hash vport

=====================================================
VPort Associations
=====================================================
Vport Name                        Active Link
-----------------------------------------------------
vport-1                           pxc-1.b
vport-2                           pxc-2.b
vport-3                           pxc-2.b
vport-4                           pxc-2.b
vport-5                           pxc-1.b
vport-6                           pxc-2.b
vport-7                           pxc-2.b
vport-8                           pxc-2.b
vport-9                           pxc-2.b
vport-10                          pxc-1.b
vport-11                          pxc-1.b
vport-12                          pxc-1.b
vport-13                          pxc-1.b
vport-14                          pxc-1.b
vport-15                          pxc-1.b
vport-16                          pxc-1.b
=====================================================
Number of VPort associations: 16
=====================================================
```

The following command shows how subscriber traffic is distributed over the member ports, based on each subscriber's association with a Vport. For example, the subscriber "ipoe-1" is associated with "vport-1". The output of the previous command shows that "vport-1" is hashed to port pxc-1.b and, therefore, the LAG active link (as shown below) for the subscriber "ipoe-1" is pxc-1.b.

```
A:admin@bng-1# show service  id "vport-hashing" subscriber-hosts detail

The table Table 25: Vport distribution over member ports repeats the Vport distribution shown in the table Table 24: Subscriber association with Vports, but adds a column with the active member link for each Vport:

Table 25: Vport distribution over member ports

Class	Vport	Weight	Vport rate in kb/s	Tx rate FPS	Subscriber	Member link
1	vport-1	15	9 000 000	900	1	**pxc-1.b**
1	vport-2	5	3 000 000	300	2, 3	**pxc-2.b**
1	vport-3	5	3 000 000	300	4, 5	**pxc-2.b**
1	vport-4	5	3 000 000	300	6, 7	**pxc-2.b**
2	vport-5	15	3 000 000	300	8	**pxc-1.b**

Class	Vport	Weight	Vport rate in kb/s	Tx rate FPS	Subscriber	Member link
2	vport-6	5	1 000 000	100	9, 10	**pxc-2.b**
2	vport-7	5	1 000 000	100	11, 12	**pxc-2.b**
2	vport-8	5	1 000 000	100	13, 14	**pxc-2.b**
3	vport-9	7	1 400 000	140	15	**pxc-2.b**
3	vport-10	1	200 000	20	16, 17	**pxc-1.b**
3	vport-11	1	200 000	20	18, 19	**pxc-1.b**
3	vport-12	1	200 000	20	20, 21	**pxc-1.b**
3	vport-13	1	200 000	20	22, 23	**pxc-1.b**
3	vport-14	1	200 000	20	24, 25	**pxc-1.b**
3	vport-15	1	200 000	20	26, 27	**pxc-1.b**
3	vport-16	1	200 000	20	28, 29, 30, 31, 32	**pxc-1.b**

To verify the Vport distribution over member ports, the traffic on the member ports of "lag-3" can be monitored.

An efficient way to observe utilization on ports in an SR is to run a **monitor port** command that periodically collects the port data (forwarded octets and packets) and displays them in various forms (raw counts or as rates). This **monitor port** command is used on regular ports on "lag-1" in the next section. However, the **monitor port** command cannot be used on PXC ports.

Because the **monitor port** command is not supported on PXC ports, a dedicated **monitor-lag** command is developed via pysros. The output of this command shows the distribution of traffic per LAG member port, per Vport, and per subscriber. Rates are displayed in percentages of the total downstream traffic sent toward all subscribers. During each command execution, the data is, by default, collected three times in 10 second intervals (this frequency is configurable).

This example demonstrates that bandwidth is evenly distributed over the two LAG member ports (approximately 50% on pxc-1.b port and 50% on pxc-2.b port). Subscriber rates and subscriber to Vport mappings are also consistent with the expectations according to the table Table 25: Vport distribution over member ports .

The output shows that in each class, the high-bandwidth Vports ("vport-1" in class 1, "vport-5" in class 2, and "vport-9" in class 3) are counterbalanced with lower-bandwidth Vports from the same class that are hashed to the opposite link. In this way, load balancing is distributed in 50/50 ratio over the two member ports on the "lag-3": both member ports pxc-1.b and pxc-2.b get approximately 50% of the load.

```
 A:admin@bng-1# monitor-lag -l lag-3 -i 10 -r 3

-------------------------------------------------------------------------
                                  Run 1

```

Another way to verify the Vport distribution over member ports is to run the following command:

```
show port "pxc-1.b" vport statistics
```

The output of this command shows the number of forwarded octets and packets. By running this command periodically, and with the help of some arithmetic, it can be deduced how much traffic is forwarded by each port.

Load balancing per Vport without classes and weights

In this example, Vport classes and weights are all set to the same value. This scenario is the same as one where classes and weight are not used at all. Traffic is still load-balanced per Vport but with no regard to the bandwidth of each Vport. In other words, all Vports are treated equally, contrary to the fact that their configured bandwidth is very different.

The configuration file for BNG-1 can be found here .

The same commands are used as in the previous example. The output of the following command shows that the ports are hashed very differently than before, with Vports evenly distributed between the two member ports (eight Vports hashed to pxc-1.b and eight Vports hashed to pxc-2.b).

```
A:admin@bng-1# show lag "lag-3" associations per-link-hash vport

=====================================================
VPort Associations
=====================================================
Vport Name                      Active Link
-----------------------------------------------------
vport-1                         pxc-1.b
```

```

Per-subscriber load balancing

In this example, Vports are not considered in hashing, due to the removal of the **subscriber-hash-mode vport** command:

```
    per-link-hash {
        weighted {
            delete subscriber-hash-mode
```

The configuration file for BNG-1 can be found here .

The "lag-3" configuration is now as follows:

```
    lag "lag-3" {
        admin-state enable
```

        }
        port pxc-1.b {
        }
        port pxc-2.b {
        }
    }
```

Because Vports are not used, a simpler **monitor** command is used to collect the data that is going through the port scheduler without visibility into subscribers. The output of this command is:

```
A:admin@bng-1# monitor-scheduler -l lag-3 -i 10 -r 3

-------------------------------------------------------------------------
                    Run 1 (interval = 10 seconds)
-------------------------------------------------------------------------
         Lag Member Port           |           BW % of Total
-------------------------------------------------------------------------
             pxc-1.b               |               36.27
             pxc-2.b               |               63.73

-------------------------------------------------------------------------
                    Run 2 (interval = 10 seconds)
-------------------------------------------------------------------------
         Lag Member Port           |           BW % of Total
-------------------------------------------------------------------------
             pxc-1.b               |               36.27
             pxc-2.b               |               63.73

-------------------------------------------------------------------------
                    Run 3 (interval = 10 seconds)
-------------------------------------------------------------------------
         Lag Member Port           |           BW % of Total
-------------------------------------------------------------------------
             pxc-1.b               |               36.27
             pxc-2.b               |               63.73
```

The output shows that the per-subscriber hashing also produces unequal load balancing due to the significant difference in rates between the subscribers.

This unequal load balancing can be corrected by configuring classes and weights per subscriber (defined in the sub-profile), but this configuration is beyond the scope of this chapter.

LAG "lag-1"

This section describes the load balancing on the LAG that connects the BNG to the aggregation node "AGG-1". LAG "lag-1" contains regular ports (no PXCs) and is referenced under the L3 interfaces that connect the BNG to the aggregation node.

```
[pr:/configure router "Base"]
A:admin@bng-1#
    autonomous-system 64500
    router-id 192.0.2.20
    interface "int-1-bng-1-p-1" {
        port lag-1:1
        ipv6 {
            address 2001:db8::501 {
                prefix-length 120
            }
        }
    }
```

Although not explicitly referenced in the Epipe (EVPN VPWS), this LAG is used to reach the network destination in EVPN, which is the BGP neighbor in the following configuration:

```
[pr:/configure service epipe "access"]
A:admin@bng-1#
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
    }
    bgp-evpn {
        evi 10
        local-attachment-circuit "bng" {
            eth-tag 2
        }
        remote-attachment-circuit "access" {
            eth-tag 1
        }
        mpls 1 {
            admin-state enable
            send-tunnel-encap {
                mpls-over-udp false
            }
            auto-bind-tunnel {
                resolution any
            }
            route-next-hop {
                system-ipv6
            }
        }
    }

[pr:/configure router "Base" bgp]
A:admin@bng-1#
    admin-state enable
    vpn-apply-export true
    vpn-apply-import true
    rapid-withdrawal true
    rapid-update {
        evpn true
    }
    group "evpn" {
        peer-as 64500
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        local-address 2001:db8::14
        family {
            evpn true
        }
    }
    neighbor "2001:db8::5" {
        group "evpn"
    }
```

LAG "lag-1" is configured as follows with the member ports shown in the figure Figure 361: Example topology:

```
[pr:/configure lag "lag-1"]
A:admin@bng-1#
    admin-state enable
    description "lag to p-1"
    mode hybrid
    max-ports 64
    port 1/1/c1/1 {
    }
    port 1/1/c1/2 {
    }
```

This section describes two ways of traffic load balancing toward the network destination (in this case, the system IPv6 address, 2001:db8::5, on the aggregation node) in the Epipe (EVPN VPWS).

By default, traffic is load-balanced per source and destination IP address pair. Traffic is sent from the same source IP address on the traffic generator toward each individual subscriber, each subscriber with its own IP address. Because every <source, destination> IP address pair in the setup represents a unique subscriber, one could conclude that this would be equivalent to per-subscriber load balancing. However, the hashing keys here are the source and destination IP address, while in per-subscriber hashing, the hashing key is the subscriber ID (and internal SR number). As a result, the outcome of traffic distribution is different in "lag-1" and "lag-3" in the preceding **monitor-scheduler** command with load-balancing per subscriber.

Optimally, L4 ports can be added to the source and destination IP address as the hashing input.

The output of the **monitor lag** command when load balancing per source and destination IP address is enabled is shown below.

Note: The **monitor lag** command is a native SR command, not to be confused with the **monitor-lag** command using pysros.

The distribution of this traffic is 30/70 (811 output packet on port 1/1/c1/1 versus 1864 output packets on port 1/1/c1/2; all packets are the same size of 200 bytes).

This is a very different distribution from the output in the preceding **monitor-scheduler** command with load balancing per subscriber where the traffic distribution over the two ports was approximately 36/63.

```
A:admin@bng-1# monitor lag 1 interval 3 repeat 999 rate packets

===============================================================================
Monitor statistics for LAG ID 1
===============================================================================
Port-id         Input packets                   Output packets
-------------------------------------------------------------------------------

-------------------------------------------------------------------------------
At time t = 3 sec (Mode: Rate)
-------------------------------------------------------------------------------
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
1/1/c1/1        0                                   811
1/1/c1/2        0                                   1864
-------------------------------------------------------------------------------
Totals          0                                   2675

-------------------------------------------------------------------------------
At time t = 6 sec (Mode: Rate)
-------------------------------------------------------------------------------
1/1/c1/1        0                                   812
1/1/c1/2        0                                   1868
-------------------------------------------------------------------------------
Totals          0                                   2680

-------------------------------------------------------------------------------
At time t = 9 sec (Mode: Rate)
-------------------------------------------------------------------------------
1/1/c1/1        2                                   813
1/1/c1/2        1                                   1869
-------------------------------------------------------------------------------
Totals          3                                   2682
---snip---
```

A more even distribution is achieved by enabling additional fields for hashing purposes. In the following example, in addition to the source and destination IP addresses, the hashing algorithm also considers L4 ports, which in this example, are randomly changing in each packet.

```
[pr:/configure system load-balancing]
A:admin@bng-1#
    l4-load-balancing true
```

The result of such hashing is more even load balancing (approximately 50/50), as follows:

```
A:admin@bng-1# monitor lag 1 interval 3 repeat 5 rate packets

===============================================================================
Monitor statistics for LAG ID 1
===============================================================================
Port-id         Input packets                   Output packets

Conclusion

This chapter provides fundamentals for understanding and configuring the class- and weight-based Vport traffic load balancing on a LAG in ESM. This is used in deployments where not only the bandwidth service offerings for subscribers vary greatly, but also where there is a significant variation in configured bandwidth between the Vports.

The configuration setup relies on FPE-based PW-ports, with two stage LAGs. The first stage LAG contains PXC based member ports as the subscriber termination points. This stage is the focus of this chapter. The second stage LAG is applied in the EVPN VPWS service context with the regular faceplate ports connecting the BNG to the access nodes. The distinct role of each LAG is explained, and the outcome of the load balancing techniques is each stage is explored.

Traffic utilization on the LAG member links is analyzed and compared between different hashing algorithms (per Vport with classes and weights, per Vport without classes and weighs, and per subscriber).

Appendix

The following files are used in this chapter:

- configuration of AGG-1
- configuration of BNG-1 with per-Vport load balancing with classes and weights
- configuration of BNG-1 with per-Vport load balancing without classes and weights
- configuration of BNG-1 with per-subscriber load balancing
- RADIUS users
