
The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces: level 2 between the core PEs and level 1 in the access networks

No MPLS protocol is configured.

BGP is configured on the core PEs for the EVPN address family with RR PE-2. The BGP configuration on RR PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-update {
                evpn true
            }
            group "iBGP" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "iBGP"
            }
            neighbor "192.0.2.4" {
                group "iBGP"
            }
```

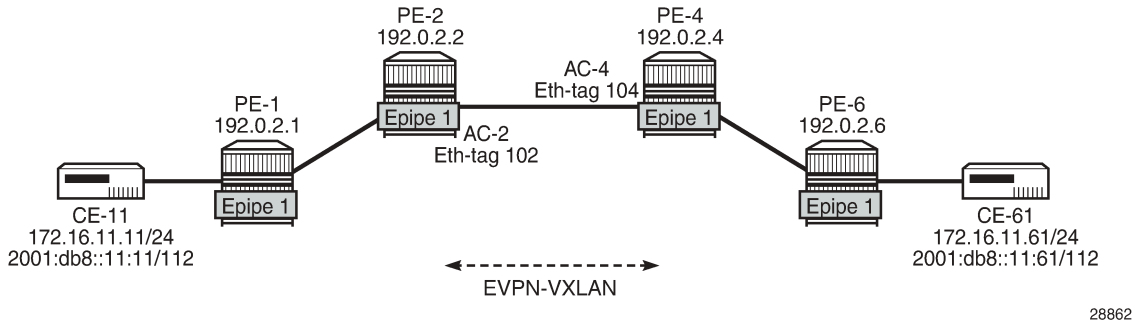
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            neighbor "192.0.2.5" {
                group "iBGP"
            }
```

Single-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 158: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses shows the routers PE-1, PE-2, PE-4, and PE-6 configured with Epipe 1. VXLAN-EVPN is only configured on the core PEs PE-2 and PE-4.

Figure 158: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses



Configuration of Epipe 1

On PE-1, Epipe 1 is configured without EVPN-VXLAN, as follows.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/1:1 {
            }
            sap 1/2/1:1 {
            }
        }
```

On PE-2, Epipe 1 is configured with EVPN-VXLAN. The local AC "AC-2" has Ethernet tag 102 and the remote AC is "AC-4" with Ethernet tag 104, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/2:1 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "AC-2" {
                    eth-tag 102
                }
                remote-attachment-circuit "AC-4" {
                    eth-tag 104
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The Epipe configuration on PE-4 is similar, but the local AC and remote AC are swapped, as follows. Instead of a SAP, a spoke-SDP is configured toward PE-6. The SDP itself is GRE-based.

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            spoke-sdp 46:1 {
            }
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "AC-4" {
                    eth-tag 104
                }
                remote-attachment-circuit "AC-2" {
                    eth-tag 102
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 46 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

On PE-6, Epipe 1 is an ordinary Epipe with spoke-SDP 64:1 toward PE-4 and SAP 1/2/1:1 toward a CE, as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 64:1 {
            }
            sap 1/2/1:1 {
            }
        }
        sdp 64 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.4
            }
        }
```

Verification

VPRN 11 on PE-1 and PE-6 simulates the CEs CE-11 and CE-61. The connectivity between the CEs can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.11.61 router-instance "VPRN 11" interval 0.1
                                                              output-format summary
PING 172.16.11.61 56 data bytes
!!!!!
---- 172.16.11.61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.42ms, avg = 5.89ms, max = 10.9ms, stddev = 2.49ms
```

```
[/]
A:admin@PE-1# ping 2001:db8::11:61 router-instance "VPRN 11" interval 0.1
                                                              output-format summary
PING 2001:db8::11:61 56 data bytes
!!!!!
---- 2001:db8::11:61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.14ms, avg = 5.63ms, max = 11.2ms, stddev = 2.79ms
```

On PE-2, the VXLAN destination for Epipe 1 is the system address of PE-4: 192.0.2.4, as follows. There are no VXLAN ES destinations for Epipe 1, because the service is single-homed.

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

PE-2 has received the following BGP-EVPN AD per-EVI route with RD 192.0.2.4:1 and Ethernet tag 104 from PE-4. Epipe 1 is single-homed, so ESI=0 and there is no primary or backup node (P=B=0). Also, no control word is used, so C=0.

```

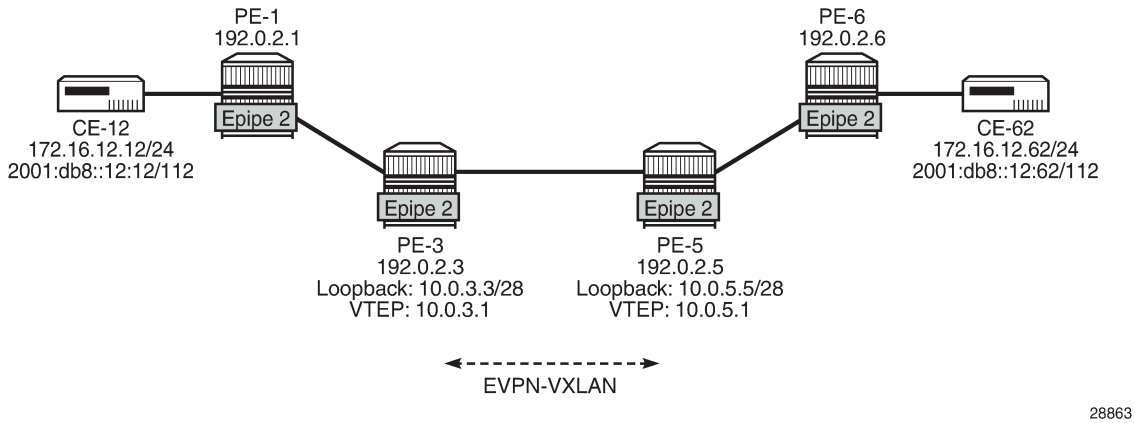
Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 159: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses shows the single-homed service Epipe 2 configured on PE-1, PE-3, PE-5, and PE-6. On PE-3, a loopback interface is created in the base router with IPv4 address 10.0.3.3/28. Epipe 2 uses VXLAN termination 10.0.3.1 from the same subnet.

Figure 159: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses



Configuration of Epipe 2

On PE-1 and PE-6, the configuration of Epipe 2 is similar to the configuration of Epipe 1.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-3, FPE needs to be configured using PXC, as described in chapter Static VXLAN Termination in Epipe Services. The following configuration is included without further explanation about FPE or PXC. The same configuration is required on PE-5.

```
# on PE-3:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            encap-type dot1q
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port-xc {
        pxc 1 {
            admin-state enable
            port 1/2/5
        }
    }
```

On PE-3, the following loopback interface is created and IS-IS is enabled on it. The subnet must allow multiple IP addresses; one other IP address from the subnet will be defined as VXLAN tunnel termination. The IPv6 address is only required in the next use-case, but this configuration will not be repeated in that section.

```
# on PE-3:
configure {
    router "Base" {
        interface "lo1" {
            loopback
            ipv4 {
                primary {
                    address 10.0.3.3
                    prefix-length 28
                }
            }
            ipv6 {
                address 2001::3:3 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    prefix-length 124
                }
            }
        }
        isis 0 {
            interface "lo1" {
                passive true
            }
        }
```

Up to three VXLAN tunnel terminations can be defined per system. On PE-3, the following two VXLAN tunnel terminations are configured. For Epipe 2, only the first VXLAN tunnel termination is required; the second (IPv6) VXLAN tunnel termination is used in Epipe 3. The VXLAN tunnel termination is used as VXLAN source VTEP in Epipe 2. No egress VTEP can be defined when BGP-EVPN is configured in the service; egress VTEPs are configured in static VXLAN tunnels instead.

```
# on PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.3.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::3:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:2 {
            }
            vxlan {
                source-vtep 10.0.3.1
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-3" {
                    eth-tag 103
                }
                remote-attachment-circuit "AC-5" {
                    eth-tag 105
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration on PE-5 is similar. The following is the service configuration on PE-5.

```
# on PE-5:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        system {
            vxlan {
                tunnel-termination 10.0.5.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::5:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            spoke-sdp 56:2 {
            }
            vxlan {
                source-vtep 10.0.5.1
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-5" {
                    eth-tag 105
                }
                remote-attachment-circuit "AC-3" {
                    eth-tag 103
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 56 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

It is possible to use a system IPv4 address as a VXLAN tunnel termination on one of the nodes and a non-system IPv4 address on another, but that is not configured here.

Verification

The connectivity between the CEs that are emulated by VPRN 12 can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.12.62 router-instance "VPRN 12" interval 0.1
                                                        output-format summary
PING 172.16.12.62 56 data bytes
!!!!!

Configuration of Epipe 3

The following single-homed Epipe 3 using non-system IPv6 addresses for the VXLAN tunnel terminations is configured on PE-3.

```
# on PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.3.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::3:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:3 {
            }
            vxlan {
                source-vtep 2001::3:1
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-3_v6" {
                    eth-tag 163
                }
                remote-attachment-circuit "AC-5_v6" {
                    eth-tag 165
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The service configuration on PE-5 is similar, as follows:

```
# on PE-5:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.5.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::5:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-3" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
            }
            spoke-sdp 56:3 {
            }
            vxlan {
                source-vtep 2001::5:1
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-5_v6" {
                    eth-tag 165
                }
                remote-attachment-circuit "AC-3_v6" {
                    eth-tag 163
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 56 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

Verification

The connectivity between the CEs that are emulated by VPRN 13 is verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.13.63 router-instance "VPRN 13" interval 0.1
                                                              output-format summary

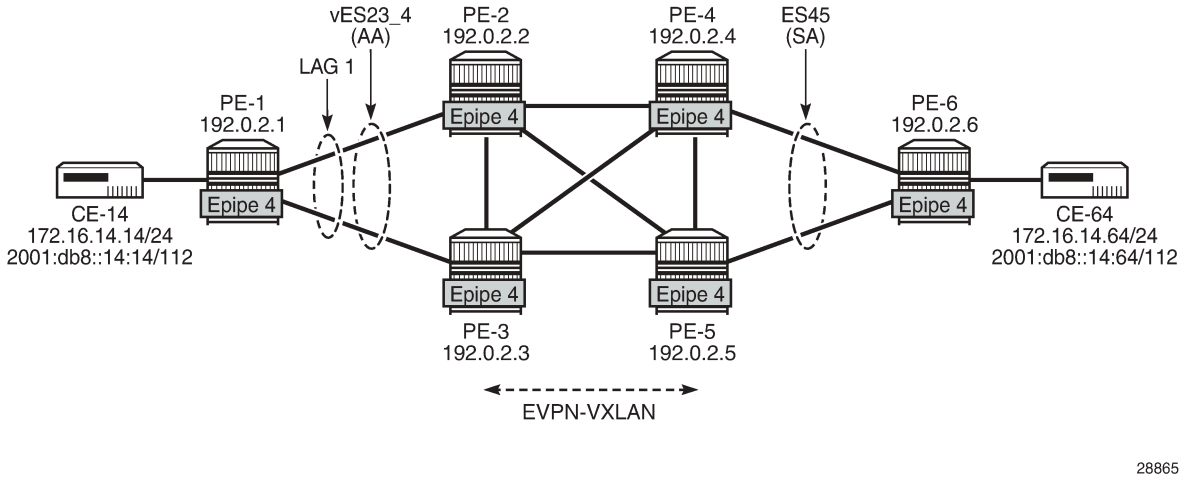
AA and SA multi-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 161: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 4 with AA MH ES "vES23_4" between PE-2 and PE-3 and SA MH ES "ES45" between PE-4 and PE-5.

Figure 161: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses



Configuration of Epipe 4

On PE-1, Epipe 4 is configured as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            sap 1/2/1:4 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap lag-1:4 {
            }
        }
```

On PE-2 and PE-3, the AA MH ES "vES23_4" is configured as a virtual ES for LAG 1 and dot1q-tag 4, so it only affects Epipe 4.

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_4" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:00:00:00:04
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 4 {
                                            end 4
                                        }
                                    }
                                }
                            }
                        }
                    }
```

On PE-2 and PE-3, Epipe 4 is configured as follows. The system IPv4 address is used as VXLAN termination, the local AC Ethernet tag is 123, and the remote AC Ethernet tag is 145.

```
# on PE-2, PE-3:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
            }
            sap lag-1:4 {
            }
            vxlan {
                instance 1 {
                    vni 4
                }
            }
            bgp-evpn {
                evi 4
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-45" {
                    eth-tag 145
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

On PE-4 and PE-5, the SA MH ES "ES45" is configured with a GRE SDP toward PE-6: SDP 460 on PE-4 and SDP 560 on PE-6. The following is the configuration of "ES45" on PE-4:

```
# on PE-4:
configure {
    service {
        sdp 460 {
            admin-state enable
            description "GRE SDP for SA MH"
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ES45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:04
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 460 {
                            }
                        }
                    }
                }
            }
        }
```

On PE-4, Epipe 4 is configured as follows. The configuration on PE-5 is similar, but with spoke-SDP 560:4 instead.

```
# on PE-4:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
            }
            spoke-sdp 460:4 {
            }
            vxlan {
                instance 1 {
                    vni 4
                }
            }
            bgp-evpn {
                evi 4
                local-attachment-circuit "AC-45" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    eth-tag 145
                }
                remote-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

On PE-6, Epipe 4 is configured as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            description "Epipe-4 with active/standby pseudowire"
            service-id 4
            customer "1"
            endpoint "EP" {
            }
            spoke-sdp 640:4 {
                endpoint {
                    name "EP"
                }
            }
            spoke-sdp 650:4 {
                endpoint {
                    name "EP"
                }
            }
            sap 1/2/1:4 {
            }
        }
```

Verification

The connectivity between the CEs emulated by VPRN 14 can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.14.64 router-instance "VPRN 14" interval 0.1
                                                              output-format summary
PING 172.16.14.64 56 data bytes

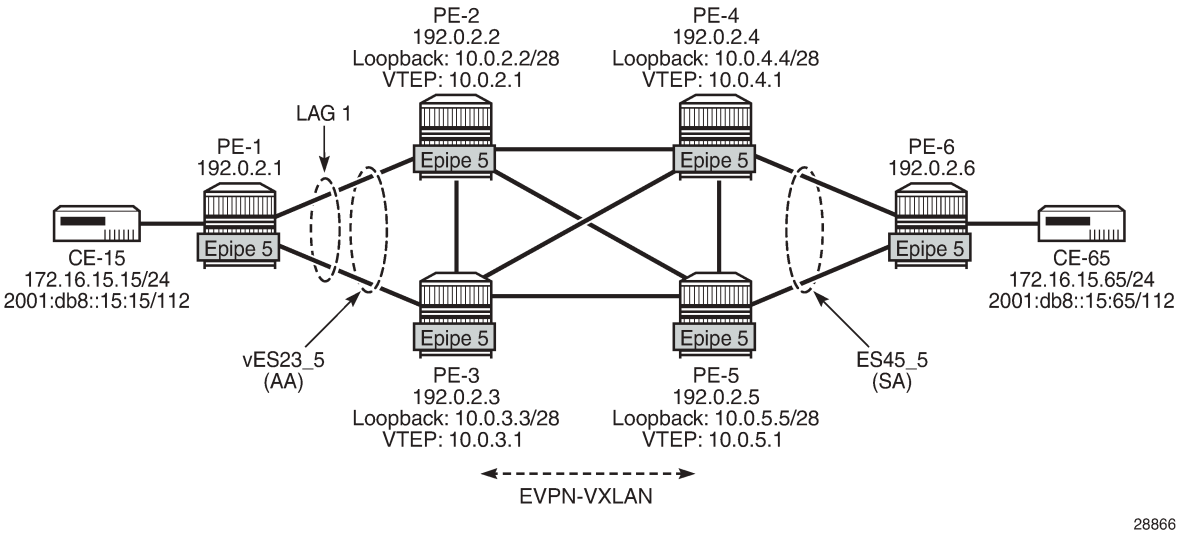
AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 162: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 5 with AA MH ES "vES23_5" between PE-2 and PE-3 and SA MH ES "ES45_5" between PE-4 and PE-5.

Figure 162: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses



The configuration of Epipe 5 on PE-1 is similar to the configuration of Epipe 4 on PE-1, so it is not shown here. The same applies for Epipe 5 on PE-6.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-2, VTEP 10.0.2.1 is used instead of the system IP address. The ES must include two additional parameters for the DF selection: **orig-ip** and **route-next-hop**, which are both equal to the VTEP. Without these parameters, the DF selection will not work. The **orig-ip** command modifies the originator IP address of the ES route and the **route-next-hop** modifies the next-hop of the AD per-ES routes for the ES. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.2.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::2:1 {
                    fpe-id 1
                }
            }
            bgp {
                evpn {
                    ethernet-segment "vES23_5" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:00:00:00:05
                        orig-ip 10.0.2.1
                        route-next-hop 10.0.2.1
                        multi-homing-mode all-active
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 5 {
                                            end 5
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
        epipe "Epipe-5" {
            admin-state enable
            service-id 5
            customer "1"
            bgp 1 {
            }

                instance 1 {
                    vni 5
                }
            }
            bgp-evpn {
                evi 5
                local-attachment-circuit "AC-23_2" {
                    eth-tag 223
                }
                remote-attachment-circuit "AC-45_2" {
                    eth-tag 245
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

The service configuration on PE-3 is similar.

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure {
    service {
        sdp 465 {
            admin-state enable
            description "GRE SDP for SA MH_Epipe5"
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            vxlan {
                tunnel-termination 10.0.4.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::4:1 {

```

Conclusion

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, and can be used in networks without MPLS.

Inter-AS Model C for VLL

This chapter describes advanced inter-AS model C for Virtual Leased Line (VLL) configurations.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 8.0.R4. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports RFC 3107, *Carrying Label Information in BGP-4*, including VLL/VPLS. BGP SDPs can also be used with PBB-VPLS services.

Internet service providers are looking for mechanisms to implement the VLL and VPLS services across Autonomous Systems (ASs). Service providers may have inter-AS operation as a consequence of delivering inter-provider VLL/VPLS or because they use multiple ASs as a result of acquisitions and mergers.

The objective of this chapter is to describe the interconnection of VLL services across multiple ASs, using inter-AS model C. Inter-AS Model C involves eBGP redistribution of internal system addresses to the neighboring AS using labeled IPv4 routes.

Example topology

Figure 164: Example topology – Inter-AS model C for VLL shows the example topology used for Inter-AS Model C VLL.

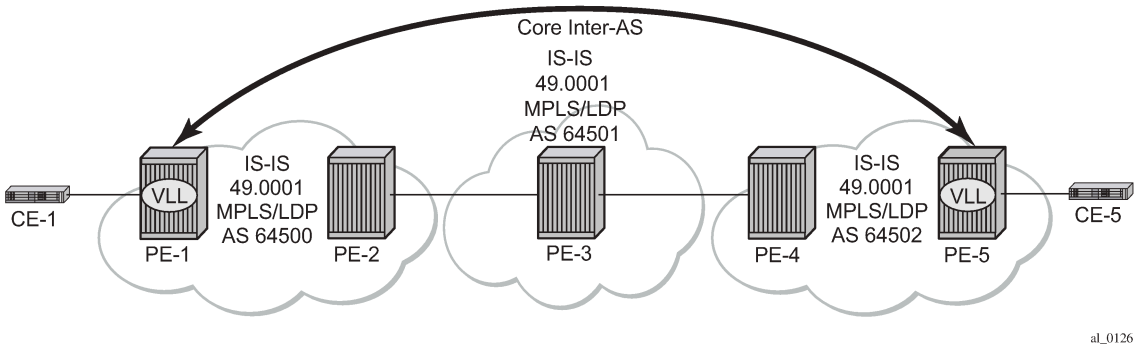
Use subject to Terms available at: www.nokia.com/terms.

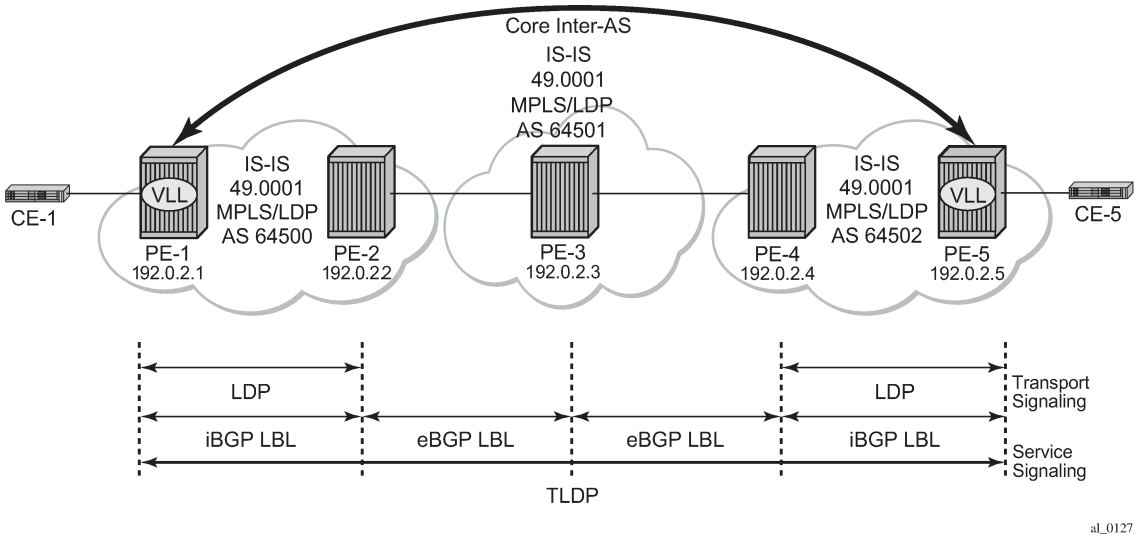
Figure 164: Example topology – Inter-AS model C for VLL



The example topology shown in Figure 164: Example topology – Inter-AS model C for VLL consists of three sites in different ASs with each site using SR OS nodes.

AS 64500 contains PE-1 and PE-2, AS 64501 contains PE-3, and AS 64502 contains PE-4 and PE-5. There is a business customer with two remote locations, Site A and Site B, with Customer Edge (CE) devices CE-1 connected to the AS 64500 via PE-1 and CE-5 connected to the AS 64502 via PE-5. A VLL Epipe service is configured between PE-1 and PE-5 to connect site A and site B.

Figure 165: Inter-AS model C for VLL



Configuration

This section describes all of the relevant configuration tasks for the detailed setup shown in Figure 166: Network setup configuration. In this particular example, the following protocols are assumed to be already configured.

- IS-IS as the IGP with all the nodes being level Level1/Level 2.
- LDP as the MPLS protocol to signal the transport tunnels within AS 64500 and AS 64502.

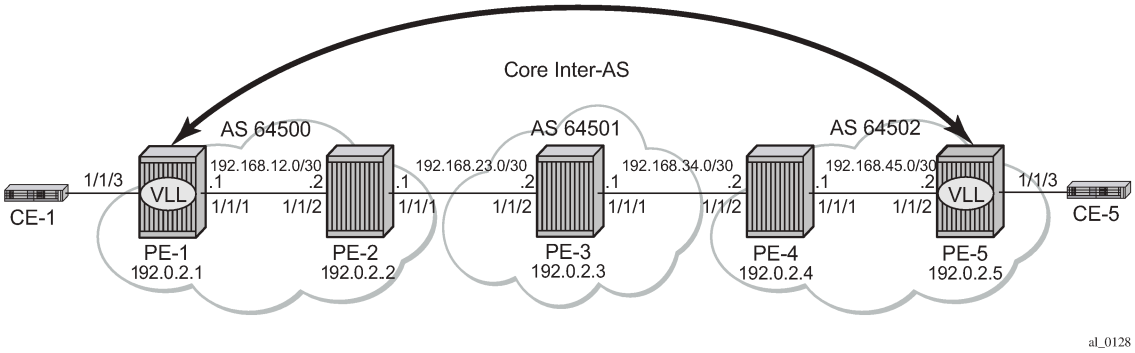
Figure 166: Network setup configuration



BGP configuration

A BGP tunnel must be established between PE-1 and PE-5, therefore, labeled BGP routes must be exchanged for prefixes 192.0.2.1/32 and 192.0.2.5/32 across the ASs. The following shows the BGP configuration — iBGP and eBGP — required for the PE routers to implement an Inter-AS VLL.

The BGP configuration on PE-3 in AS 64501 is as follows:

```
# on PE-3:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64501
                }
            }
            neighbor "192.168.23.1" {
                group "EBGP"
                peer-as 64500
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64500"]
                }
                export {
                    policy ["export-from64502"]
                }
            }
            neighbor "192.168.34.2" {
                group "EBGP"
                peer-as 64502
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64502"]
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                export {
                    policy ["export-from64500"]
                }
            }
        }
```

The address family **label-ipv4** must be configured so that MPLS labels are carried along with MP-BGP Network Layer Reachability Information (NLRIs), see chapter "Separate BGP RIBs for Labeled Routes" in the Unicast Routing Protocols volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*. The setting **split-horizon** is optional and prevents that a received route is sent back to the originator, which may result in multiple routes for a certain prefix.

To export the prefixes of the nodes where the Epipe is configured (PE-1 and PE-5) to another AS, a common scenario is to advertise the prefix to be exported within the AS as labeled BGP. Therefore, an export policy is defined for prefix192.0.2.1/32 on PE-1 and this prefix will be advertised with community "64500:0" to the ASBR in AS 64500, in this case to PE-2.

On PE-2, the labeled BGP route for prefix 192.0.2.1/32 is inactive, because the IGP route for that prefix is preferred. The setting **advertise-inactive** will allow the inactive labeled BGP routes from AS 64500 to be advertised to PE-3 in AS 64501. However, for EBGP sessions on Autonomous System Border Routers (ASBRs) such as PE-2, RFC 8212 is supported, so that routes are neither imported nor exported unless specifically enabled by configuration. Export policy "export-from64500" exports all routes with community "64500:0" and import policy "import-from64502" imports all routes with community "64502:0" which is the community added by the export policy on PE-5.

On PE-5, an export policy is configured to advertise prefix 192.0.2.5/32 with community "64502:0" to ASBR PE-4 in AS 64502.

On PE-4, BGP is configured with **advertise-inactive** to advertise the labeled BGP route to its EBGP peer, PE-3. Export policy "export-64502:0" exports routes with community "64502:0" to PE-3. Import policy "import-64500:0" imports routes with community "64500:0".

On PE-3, import and export policies are configured toward the EBGP peers. PE-3 imports routes with community "64500:0" from PE-2 and exports these routes to PE-4. Simultaneously, PE-3 imports routes with community "64502:0" from PE-4 and exports these routes to PE-2.

Labeled BGP is used end-to-end between PE-1 and PE-5 and no IGP routes are to be redistributed into BGP, which would be the case if no local BGP labeled routes were advertised within AS 64500 or AS 64502 and only IGP routes were defined within these ASs.

The ASBRs PE-2, PE-3, and PE-4 will swap the BGP labels. PE-3 will advertise the labeled BGP routes learned from AS 64500 to AS 64502 and vice versa and the ASBRs will advertise these labeled routes for remote PE prefixes to their BGP peers. Eventually, PE-1 will have learned a labeled BGP route for prefix 192.0.2.5/32 and PE-5 will have learned a labeled BGP route for prefix 192.0.2.1/32 and a VLL Epipe can be established between PE-1 and PE-5.

The following policies are configured on ASBR PE-2:

```
# on PE-2:
configure {
    policy-options {
        community "64500:0" {
            member "64500:0" { }
        }
        community "64502:0" {
            member "64502:0" { }
        }
        policy-statement "export-from64500" {
            entry 10 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                from {
                    community {
                        name "64500:0"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
        policy-statement "import-from64502" {
            entry 10 {
                from {
                    community {
                        name "64502:0"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

The BGP configuration of PE-2 in AS 64500 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64500
                }
            }
            group "IBGP" {
            }
            neighbor "192.0.2.1" {
                group "IBGP"
                next-hop-self true
                peer-as 64500
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.23.2" {
                advertise-inactive true
                group "EBGP"
                peer-as 64501
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64502"]
                }
                export {
                    policy ["export-from64500"]
                }
            }
        }
```

The BGP configuration of ASBR PE-4 in AS 64502 is as follows.The import and export policies are similar to the policies on PE-2.

```
# on PE-4:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64502
                }
            }
            group "IBGP" {
            }
            neighbor "192.0.2.5" {
                group "IBGP"
                next-hop-self true
                peer-as 64502
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.34.1" {
                advertise-inactive true
                group "EBGP"
                peer-as 64501
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64500"]
                }
                export {
                    policy ["export-from64502"]
                }
            }
        }
```

PE-1 and PE-5 are the PEs to which the CEs are connected in AS 64500 and AS 64502. PE-1 and PE-5 advertise their system prefixes as labeled BGP routes to their BGP peers within the AS.

The BGP configuration of PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base"{
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "IBGP" {
                export {
                    policy ["export-PE-1"]
                }
            }
            neighbor "192.0.2.2" {
                group "IBGP"
                next-hop-self true
                peer-as 64500
                family {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    label-ipv4 true
                }
            }
        }
```

The BGP configuration of PE-5 in AS 64502 is as follows:

```
# on PE-5:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "IBGP" {
                export {
                    policy ["export-PEsys"]
                }
            }
            neighbor "192.0.2.4" {
                group "IBGP"
                next-hop-self true
                peer-as 64502
                family {
                    label-ipv4 true
                }
            }
        }
```

Policy configuration

The export policies on PE-1 and PE-5 advertise the system addresses to the remote AS. The added communities are used by the export and import policies on PE-2, PE-3, and PE-4. The export policy on PE-1 has a prefix list that only contains prefix 192.0.2.1/32 as follows:

```
# on PE-1:
configure {
    policy-options {
        community "64500:0" {
            member "64500:0" { }
        }
        prefix-list "PE-1" {
            prefix 192.0.2.1/32 type exact {
            }
        }
        policy-statement "export-PE-1" {
            entry 10 {
                from {
                    prefix-list ["PE-1"]
                }
                action {
                    action-type accept
                    origin igp
                    community {
                        add ["64500:0"]
                    }
                }
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A similar export policy can be configured for prefix 192.0.2.5/32 on PE-5. However, the export policy on PE-5 is slightly different: the policy has a prefix list that can be applied for prefixes on multiple PEs, but in this case, only prefix 192.0.2.5/32 will be exported:

```
# on PE-5:
configure {
    policy-options {
        community "64502:0" {
            member "64502:0" { }
        }
        prefix-list "PEsys" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "export-PEsys" {
            entry 10 {
                from {
                    prefix-list ["PEsys"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                    origin igp
                    community {
                        add ["64502:0"]
                    }
                }
            }
        }
```

The same policy could have been applied on PE-1.

Service configuration

Once BGP is configured, the configuration requires the service to be defined (Epipe 1). The focus here is a VLL service, however, it is also possible to have a similar configuration with VPLS services.

The following shows the service level configuration on PE-1:

```
# on PE-1:
configure {
     service {
        epipe "Epipe 1" {
            admin-state enable
            description "Tunnel-PE-1-PE-5"
            service-id 1
            customer "1"
            spoke-sdp 15:1 {
            }
            sap 1/1/3:1 {
            }
        }
        sdp 15 {
            admin-state enable
            delivery-type mpls
            bgp-tunnel true
            far-end {
                ip-address 192.0.2.5
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
```

The following CLI shows the service level configuration on PE-5:

```
# on PE-5:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            description "Tunnel-PE-5-PE-1"
            service-id 1
            customer "1"
            spoke-sdp 51:1 {
            }
            sap 1/1/3:1 {
            }
        }
        sdp 51 {
            admin-state enable
            delivery-type mpls
            bgp-tunnel true
            far-end {
                ip-address 192.0.2.1
            }
        }
```

Show commands and troubleshooting

On PE-5, BGP tunnels exist to the remote AS system addresses that are using LDP as a transport mechanism and the configuration of end-to-end SDPs over which T-LDP service labels are exchanged.

In the following sections, the same commands are launched on the nodes in the following order: first on PE-1 and PE-5; then on PE-3, and finally, on PE-2 and PE-4.

Show commands and troubleshooting on PE-1

The following shows information about SDP 15 on PE-1:

```
[]
A:admin@PE-1# show service sdp

Conclusion

The BGP tunnel-based SDP binding is allowed for VLL and VPLS services, including PBB-VPLS. Using RFC 3107, it is possible to implement inter-AS Model C VLLs.

The example used in this chapter illustrates the configuration of an Inter-AS VLL providing access to CE sites. Troubleshooting commands also have been shown to verify all the procedures.

L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing

This chapter provides information about L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 23.7.R1.

Overview

IPv4 multicast traffic can be forwarded from an EVPN-MPLS service into an attached R-VPLS service in which the receiving devices are using EVPN all-active multi-homing.

The routed service to which the R-VPLS service attaches can be an IES or a VPRN service. In this way, IPv4 multicast traffic can be transported using native IP for the IES case or NG-MVPN technologies for the VPRN case.

This feature requires:

- IGMP support on the R-VPLS IP interface
- Forwarding IPv4 multicast traffic from the IP interface of a VPRN or IES to its EVPN-MPLS R-VPLS service
- IGMP snooping within the VPLS of the R-VPLS service
- IGMP snooping state synchronization based on the ESI label to synchronize the IGMP snooping state between the all-active (R-)VPLS LAG SAPs

The configuration used in this chapter is the NG-MVPN scenario as shown in Figure 167: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing.

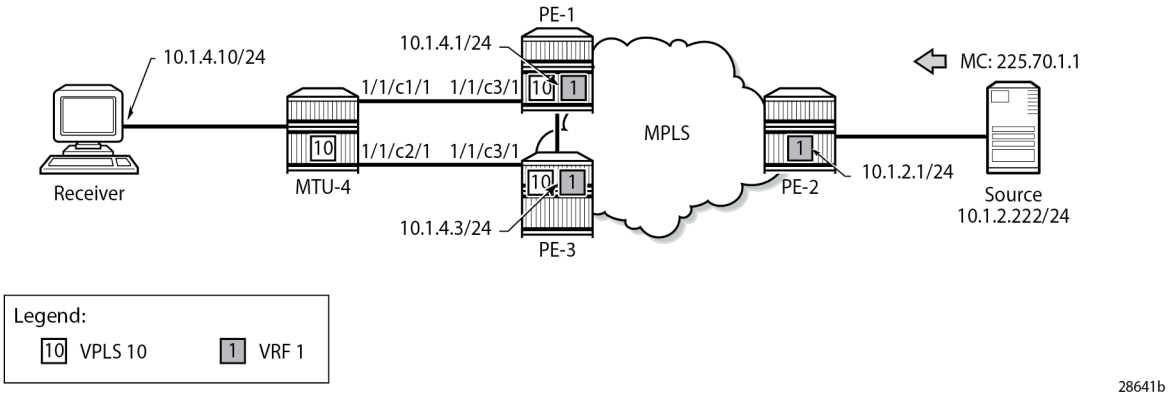
Figure 167: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing



A multicast stream is emitted by the source connected to PE-2 with group address 225.70.1.1. A multicast receiver connected to MTU-4 joins group 225.70.1.1. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. On MTU-4, LAG 1 comprises port 1/1/c1/1 and 1/1/c2/1, and this LAG is used in VPLS 10. On PE-1 and PE-3, VPLS 10 is interconnected with VPRN 1 through an Integrated Routing and Bridging (IRB) interface. VPRN 1 is defined in PE-1, PE-2, and PE-3, and uses NG-MVPN for transporting the multicast traffic through the core of the network. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information about EVPN. See the "NG-MVPN Configuration with MPLS" and "NG-MVPN Configuration with PIM" chapters in the Layer 3 Services volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part II* for more information about NG-MVPN.

Configuration

The initial configuration on the PE nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- MPLS tunnels between the PEs: LDP- or RSVP-based

BGP is required at the core of the network, using the VPN IPv4 and MVPN IPv4 address families between all PEs, for supporting unicast and multicast traffic on VPRN services, and additionally using the EVPN address family between PE-1 and PE-3 to support EVPN services. The BGP configurations for PE-1, PE-2, and PE-3 are as follows:

```
# on PE-1:
configure {
    router {
        autonomous-system 64496
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            family {
                ipv4 false
```

                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "iBGP" { }
            neighbor "192.0.2.1" {
                group "iBGP"
                peer-as 64496
            }
            neighbor "192.0.2.3" {
                group "iBGP"
                peer-as 64496
            }
        }
    }
}
```

```
# on PE-3:
configure {
    router {
        autonomous-system 64496
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            family {
                ipv4 false
                vpn-ipv4 true
                mvpn-ipv4 true
                evpn true
            }
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "iBGP" { }
            neighbor "192.0.2.1" {
                group "iBGP"
                peer-as 64496
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                peer-as 64496
            }
        }
    }
}
```

The receiver connected to MTU-4 joins group 225.70.1.1, and the corresponding multicast stream is emitted by the source that is connected to PE-2. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. The VPLS and the LAG on MTU-4 are defined as follows:

```
# on MTU-4:
configure {
    service {
        vpls "mcast-vpls" {
            admin-state enable
            service-id 10
            customer "1"
            igmp-snooping {
                admin-state enable
            }
            sap 1/2/c1/1 { }
            sap lag-1:10 { }
        }
    }
}

configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        port 1/1/c1/1 { }
        port 1/1/c2/1 { }
    }
}
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The all-active multi-homing Ethernet segment esi-13 is configured identically on PE-1 and PE-3, as follows. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information.

```
# on PE-1 and PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "esi-13" {
                        admin-state enable
                        esi 0x01000000001300000001
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 30
                                }
                            }
                        }
                        association {
                            lag "lag-1" { }
                        }
                    }
                }
            }
        }
    }
}
```

The multi-homed access circuits of esi-13 are located on port 1/1/c3/1 for PE-1 and PE-3, so the LAG is configured identically, as follows:

```
# on PE-1 and PE-3:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        port 1/1/c3/1 { }
    }
}
```

Also, the EVPN VPLS service with ID 10 is configured identically on PE-1 and PE-3, as follows. The *mcast-vpls* name is needed to link VPLS 10 to VPRN 1 at a later stage, without requiring a physical loop or hairpin. The **routed-vpls** command enables the VPLS to become an R-VPLS. The **igmp-snooping** and **mrouter-port true** commands are required for multicast to work correctly in an all-active multi-homed scenario.

```
# on PE-1 and PE-3:
configure {
    service {
        vpls "mcast-vpls" {
            admin-state enable
            service-id 10
            customer "1"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            routed-vpls {
                multicast {
                    ipv4 {
                        igmp-snooping {
                            mrouter-port true
                        }
                    }
                }
            }
            bgp 1 { }
            igmp-snooping {
                admin-state enable
            }
            bgp-evpn {
                evi 111
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:10 { }
        }
    }
}
```

The VPRN service with ID 1 provides the connection toward MTU-4 via VPLS 10, through the *int-MCAST-VPLS* interface with address 10.1.4.1/24 on PE-1, and with address 10.1.4.3/24 on PE-3. This L3 interface is linked to VPLS 10 with the **vpls "mcast-vpls" { }** command. The *int-MCAST-VPLS* interface is also included in the IGMP and PIM configurations of VPRN 1. The full configuration of VPRN 1 on PE-1 is as follows. The configuration of VPRN 1 on PE-3 is similar.

```
# on PE-1:
configure {
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp {
                ssm-translate {
                    group-range start 225.70.1.1 end 225.70.255.255 {
                        source 10.1.2.222 { }
                    }
                }
                interface "int-MCAST-VPLS" { }
                interface "int-PE-1-CE-1" { }
            }
            pim {

The full configuration of VPRN 1 on PE-2 is as follows. The *int-PE-2-CE-2-source* interface provides the connection to the multicast source.

```
# on PE-2:
configure {
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            pim {
                interface "int-PE-2-CE-2-source" { }
                interface "system" { }
            }
            mvpn {
                c-mcast-signaling bgp
                mdt-type sender-only
                auto-discovery {
                    type bgp
                }
                vrf-target {
                    unicast true
                }
                provider-tunnel {
                    inclusive {
                        mldp {

A stream with group address 225.70.1.1 is started by the multicast source and joined by the multicast receiver connected to MTU-4. This stream is forwarded from PE-2 to PE-3; PE-1 is not involved in the forwarding.

PE-1 maintains IGMP state for group 225.70.1.1 in VPRN 1, and so does PE-3. PE-1 and PE-3 synchronize IGMP state using a data-driven mechanism. The forwarding list includes the *int-MCAST-VPLS* interface, as follows:

```
[/]
A:admin@PE-1# show router 1 igmp group 225.70.1.1 interfaces
===============================================================================
IGMP Interface Groups
===============================================================================

(*,225.70.1.1)                                          UpTime: 0d 00:01:41
    Fwd List  : int-MCAST-VPLS
-------------------------------------------------------------------------------
Entries : 1
===============================================================================
```

PE-1 maintains PIM state for group 225.70.1.1, as follows. The outgoing interfaces list is empty and the forwarding rate is zero; both are indications that PE-1 is not forwarding any multicast traffic.

```

PE-3 sends this multicast stream to MTU-4, which in turn sends it to the receiver that sent the join, so the path taken by the multicast stream runs via PE-2, PE-3, and MTU-4.

In the example from Figure 167: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing, and the commands and traces that follow, PE-1 is the active IGMP querier using address 10.1.4.1, sending out the queries across the L2 domain. The group queries are sent by PE-1 to PE-3 across the EVPN-MPLS tunnel because PE-3 is DF for *esi-13*, then forwarded onto MTU-4 to reach the (potential) receiver. MTU-4 relays the IGMP responses from the receiver to one of the links; in this example, the link between MTU-4 and PE-1. When the IGMP response for joining the 225.1.70.1 stream is received on PE-1, this event is signaled across the EVPN-MPLS tunnel because it is received over esi-13. This way, the IGMP state is synchronized between PE-3 and PE-1 in a data-driven way.

The basic IGMP snooping state for VPLS 10 on PE-1 and PE-3 is as follows. The output shows that IGMP snooping is enabled on ports sap:lag-1:10, rvpls, and evpn-mpls.

```

PE-1 sends the IGMP queries on VPRN 1 via the *int-MCAST-VPLS* interface, so the VPLS that is referenced in the *int-MCAST-VPLS* interface registers the ports on which the IGMP queries are received as multicast router ports. EVPN-MPLS tunnels are always multicast router ports. The following output displays the source addresses of the multicast routers:

```
[/]
A:admin@PE-1# show service id 10 igmp-snooping mrouters

Debug

Debugging is useful for troubleshooting purposes, and the debug configuration used on PE-1 and PE-3 for checking IGMP and IGMP snooping functionalities is as follows:

```
debug {
    router "VPRN 1" {
        igmp {
            packet {
                dropped true
                ingress true
                egress true
            }
        }
    }
    service {
        vpls "mcast-vpls" {
            igmp-snooping {
                packet {
                    dropped true
                    ingress true
                    egress true
                    evpn-mpls true
                    sap lag-1:10 { }
                }
            }
        }
    }
}
```

When group 225.70.1.1 is joined, the trace on PE-1 is as follows. Event 4 is the IGMPv3 join message for group 225.70.1.1 received on SAP lag-1:10 in VPLS 10 from the receiver. The reception of this message is synchronized across the EVPN-MPLS tunnel for VPLS 10, as indicated by event 5. Event 6 is the IGMPv3 join message as received on interface *int-MCAST-VPLS* by VPRN 1.

```

Similar events are logged when the multicast receiver leaves the 225.70.1.1 group.

Conclusion

By connecting customers to EVPN-MPLS VPRN/IES routed services via an R-VPLS, service providers can offer IPv4 multicast services to customers in an all-active multi-homing scenario.

L2 Services with Auto-GRE Spoke-SDPs

This chapter provides information about L2 Services with Auto-GRE Spoke-SDPs.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Auto-GRE spoke-SDPs are supported in L2 services in SR OS Release 16.0.R1, and later.

Overview

When the connectivity between nodes is IP-based (not MPLS), VPWS and VPLS services can use manually provisioned or auto-generated GRE transport tunnels. For auto-GRE transport tunnels, the signaling can be BGP or Targeted LDP (T-LDP). BGP signaling is more scalable than T-LDP, because T-LDP requires point-to-point sessions between communicating peers.

Auto-GRE spoke-SDPs can be used in the following services:

- BGP-VPLS with BGP signaling
- LDP VPLS using BGP-AD with T-LDP signaling
- BGP-VPWS with BGP signaling
- Dynamic Multi-segment Pseudowire (MS-PW) spoke-SDP Forwarding Equivalence Class (FEC) 129 with T-LDP signaling (*not* supported in MD-CLI for SR OS Release 21.5.R1)

PW templates for auto-GRE spoke-SDPs are configured with **auto-gre-sdp true**.

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# auto-gre-sdp ?

 auto-gre-sdp <boolean>
 <boolean>  - ([true]|false)
 Default    - false

 'auto-gre-sdp' is: immutable

    Use a GRE tunnel to automatically create an SDP

    Warning: Modifying this element recreates 'configure service pw-template "PW3"'
    automatically for the new value to take effect.

 Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **auto-gre-sdp** parameter can be combined with the parameter **provisioned-sdp prefer**, but not with **provisioned-sdp use** (because that might contradict the use of auto-GRE spoke-SDPs), as follows:

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# commit
MINOR: SVCMGR #5626: configure service pw-template "PW3" auto-gre-sdp - not compatible with
 auto-gre-sdp - auto-gre-sdp is not allowed with used-provisioned-sdp
```

The auto-GRE SDP and SDP binding are created after a matching BGP route has been received. Subsequent requests for an auto-GRE SDP of the same type and to the same destination as an existing auto-GRE SDP will use the existing auto-GRE SDP.

Downstream fragmentation is allowed for auto-GRE SDPs by clearing the Don't Fragment (DF) bit in the GRE IP header. The following command controls fragmentation for a PW template:

```
configure {
    service {
        pw-template "PW40" {
            pw-template-id 40
            allow-fragmentation true
            auto-gre-sdp true
        }
```

The following PW template parameters are not supported with GRE tunnels and will be ignored when a GRE SDP is auto-created:

- Hash label
- Entropy label
- SDP include/exclude (there is no mechanism to configure an SDP admin group for auto-GRE SDPs)

However, these parameters are relevant for provisioned MPLS SDPs when the PW template is configured with **provisioned-sdp prefer**.

The **pw-template-binding** parameter in the **bgp <..>** context of the L2 service allows to configure the PW template to be used. It is possible to define multiple PW template bindings within a service. The mechanism for selecting the PW template is as follows:

- In BGP-VPWS, BGP-VPLS, and BGP-AD services, the PW template binding selection is based on matching the configured import Route Targets (RTs) for a PW template binding with the RTs in the received routes.
- The binding with the first matching RT is chosen. If no import RTs are configured, the lowest PW template binding ID is used.
- It is not possible to add RTs to BGP-VPWS BGP updates using import or export policies, because they are ignored. However, the RT exported to select the destination service can be used on the receiving PE with PW template binding statement to influence the PW template to be selected; see the first use case in the Configuration section.
- If the selected PW template is configured with **provisioned-sdp prefer** and an SDP with a matching far-end address exists, the system chooses the SDP with the lowest metric from the tunnel table. If multiple matching SDPs with the same metric occur, the highest SDP ID that is operationally up is chosen.

The following **tools** command allows for PW template bindings to change:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
[policy-id] <number>
<number>  - <1..2147483647>

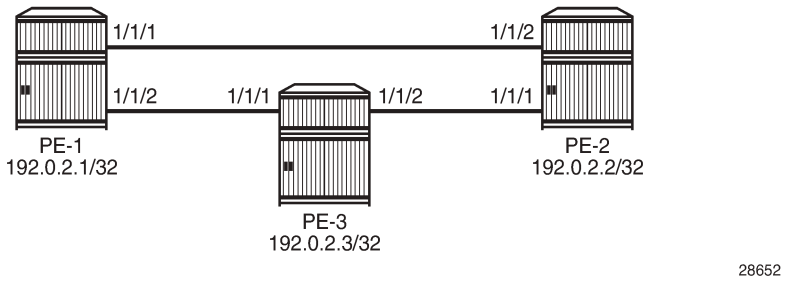
   <number> - <1..2147483647>
```

The policy ID refers to the PW template currently in use. With the **allow-service-impact** option, the current binding will be torn down and re-signaled.

Configuration

Figure 168: Example topology shows the example topology with three PEs in AS 64500. Services will be configured on PE-1 and PE-2, and PE-3 is the route reflector (RR).

Figure 168: Example topology



The initial configuration on the three PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)

Auto-GRE spoke-SDPs are configured in the following use cases:

1. BGP-VPLS with BGP signaling
2. BGP-AD in VPLS with T-LDP signaling
3. BGP-VPWS with BGP signaling

In these three use cases (BGP-VPLS, BGP-AD, BGP-VPWS), BGP is configured for the L2-VPN address family. In each of the use cases, two L2 services will be configured using different PW templates with **auto-gre-sdp**: one with **provisioned-sdp prefer** and one without.

Auto-GRE spoke-SDPs in BGP-VPLS

Figure 169: BGP-VPLS with auto-GRE spoke-SDPs shows the example topology with BGP-VPLSs 1 and 2 configured on PE-1 and PE-2. BGP is configured for the L2-VPN address family with PE-3 as Route Reflector (RR). The CEs are emulated through VPRNs configured on the PEs and connected to the VPLSs via Port Cross-connect (PXC).

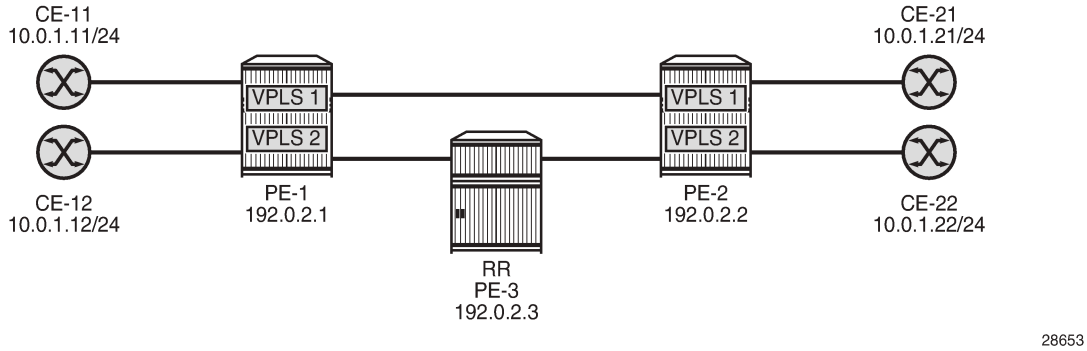
Figure 169: BGP-VPLS with auto-GRE spoke-SDPs



BGP configuration

For the BGP-VPLS, BGP-AD, and BGP-VPWS use cases, BGP is configured with the L2-VPN address family. The BGP configuration on PE-1 and PE-2 is identical, as follows:

```
# on PE-1, PE-2::
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "WAN" {
                type internal
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.3" {
                group "WAN"
            }
```

On RR PE-3, BGP is configured as follows:

```
# on RR PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "WAN" {
                type internal
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 192.0.2.3
                }
            }
            neighbor "192.0.2.1" {
                group "WAN"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            neighbor "192.0.2.2" {
                group "WAN"
            }
```

Service configuration

The configuration of BGP-VPLS services is described in the BGP VPLS chapter.

PW template 10 is configured with **auto-gre-sdp**; PW template 20 is configured with **provisioned-sdp prefer** and **auto-gre-sdp**. Because only IP connectivity is present between the nodes (no MPLS), the provisioned SDP is GRE-based using BGP signaling (no T-LDP). VPLS 1 has PW template bindings with IDs 10 and 20; VPLS 2 is configured with PW template binding 20. The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        sdp 12 {
            admin-state enable
            signaling bgp
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "BGP-VPLS-1" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP"
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "64500:1"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 100
                ve {
                    name "PE-1"
                    id 1
                }
            }
            sap pxc-10.a:1 {        # SAP to connect to CE-11
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        vpls "BGP-VPLS-2" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "64500:2"
                route-target {
                    export "target:64500:2"
                    import "target:64500:2"
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 100
                ve {
                    name "PE-1"
                    id 1
                }
            }
            sap pxc-10.a:2 {        # SAP to connect to CE-12
            }
        }
```

The service configuration on PE-2 is similar, but the VE name is "PE-2" and the VE ID equals 2 instead, as follows:

```
# on PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        sdp 21 {
            admin-state enable
            signaling bgp
            far-end {
                ip-address 192.0.2.1
            }
        }
        vpls "BGP-VPLS-1" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP"
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "64500:1"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
```

===============================================================================
```

VPLS 1 is configured with two PW template bindings without import RT. Because the PW template binding with the lowest ID is preferred, PW template 10 is used and therefore, the following GRE SDP 32767 is auto-created:

```
[/]
A:admin@PE-1# show service id 1 sdp detail

===============================================================================
Services: Service Destination Points Details
===============================================================================
-------------------------------------------------------------------------------
 Sdp Id 32767:4294967295  -(192.0.2.2)

---snip---
```

VPLS 2 is configured with PW template binding 20, which prefers provisioned SDPs, so the provisioned SDP 12 is used, as follows:

```
[/]
A:admin@PE-1# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967294    BgpVpls  192.0.2.2       Up      Up        524273    524272
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In VPLS 1, the PW template binding selection can be changed by configuring a non-matching import RT to PW template 10, as follows:

```
# on PE-1:
configure {
    service {
        vpls "BGP-VPLS-1" {
            bgp 1 {
                pw-template-binding "PW10-auto-GRE" {
                    import-rt ["target:64500:999"]
                }
            }
```

This does not change the selected PW template during service operation and PW template 10 remains in use, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 10
```

The following **tools** command forces the system to re-evaluate the PW template binding:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 10 allow-service-impact
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 10
```

When the PW template binding is re-evaluated, PW template binding 20 is selected and the provisioned SDP 12 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 20
```

```
[/]
A:admin@PE-1# show service id 1 sdp

```

Auto-GRE spoke-SDPs in LDP-VPLS using BGP-AD

Figure 170: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs shows the example topology with VPLSs 3 and 4 configured with BGP-AD on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

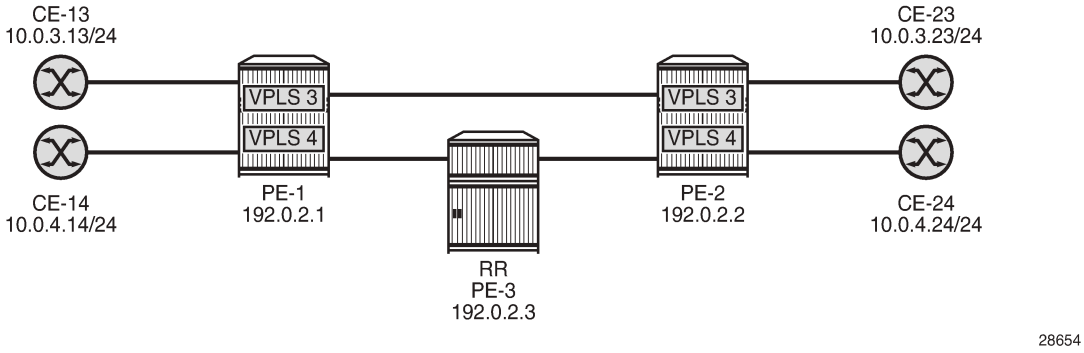
Use subject to Terms available at: www.nokia.com/terms.

Figure 170: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs



The following T-LDP session is configured between PE-1 and PE-2:

```
# on PE-1:
configure {
    router "Base" {
        ldp {
            targeted-session {
                peer 192.0.2.2 {
                }
            }
```

```
# on PE-2:
configure {
    router "Base" {
        ldp {
            targeted-session {
                peer 192.0.2.1 {
                }
            }
```

The following T-LDP signaled SDP is configured on PE-1 and PE-2:

```
# on PE-1:
configure {
    service {
        sdp 120 {
            admin-state enable
            far-end {
                ip-address 192.0.2.2
            }
        }
```

```
# on PE-2:
configure {
    service {
        sdp 210 {
            admin-state enable
            far-end {
                ip-address 192.0.2.1
            }
        }
```

The service configuration on PE-1 and PE-2 is as follows; see chapter LDP VPLS Using BGP Auto-Discovery for a description of BGP-AD in LDP VPLS. PW templates 10 and 20 are the same as in the preceding example.

```
# on PE-1, PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        vpls "BGP-AD VPLS-3" {
            admin-state enable
            description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP"
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "64500:3"
                route-target {
                    export "target:64500:3"
                    import "target:64500:3"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }

Auto-GRE spoke-SDPs in BGP-VPWS

Figure 171: BGP-VPWS with auto-GRE spoke-SDPs shows the example topology with BGP-VPWS Epipes 5 and 6 on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

© 2023 Nokia.

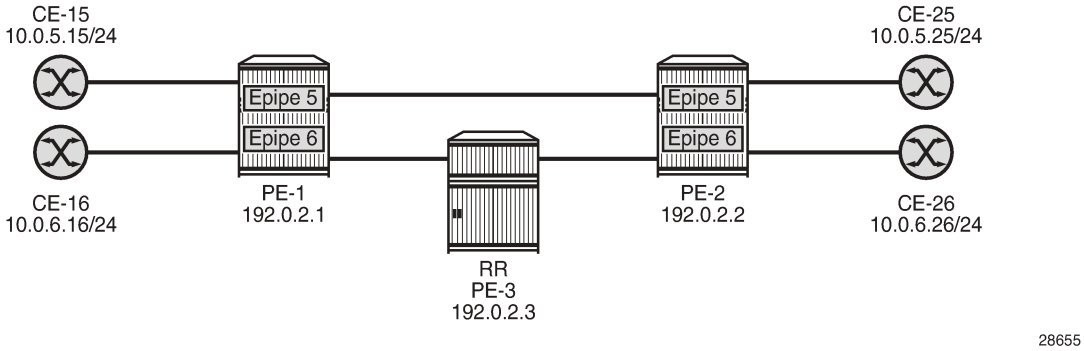
Figure 171: BGP-VPWS with auto-GRE spoke-SDPs



Chapter BGP Virtual Private Wire Services describes the configuration of BGP VPWS. The configuration of Epipes 5 and 6 on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        epipe "BGP-VPWS-5" {
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP"
            service-id 5
            customer "1"
            bgp 1 {
                route-distinguisher "64500:5"
                route-target {
                    export "target:64500:5"
                    import "target:64500:5"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"
                    id 1
                }
                remote-ve "PE-2" {
                    id 2
                }
            }
            sap pxc-10.a:5 {        # SAP to connect to CE-15
            }
        }
        epipe "BGP-VPWS-6" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
            service-id 6
            customer "1"
            bgp 1 {
                route-distinguisher "64500:6"
                route-target {
                    export "target:64500:6"
                    import "target:64500:6"
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"
                    id 1
                }
                remote-ve "PE-2" {
                    id 2
                }
            }
            sap pxc-10.a:6 {        # SAP to connect to CE-16
            }
        }
```

The configuration of the Epipes is similar on PE-2, but the VE names and VE IDs are different, as follows:

```
# on PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        epipe "BGP-VPWS-5" {
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP"
            service-id 5
            customer "1"
            bgp 1 {
                route-distinguisher "64500:5"
                route-target {
                    export "target:64500:5"
                    import "target:64500:5"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-2"

Conclusion

In IP-based networks, auto-GRE spoke-SDPs can be used in VPWS and VPLS services. Manually configured GRE tunnels are not an option in networks — such as LTE networks — where it is common to assign IP addresses dynamically from a pool of addresses, but auto-GRE spoke-SDPs can be applied instead.

Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication

This chapter provides information about Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3. Layer 2 multicast optimization for EVPN-VXLAN - Assisted Replication (AR) is supported in SR OS Release 14.0.R4, and later.

Overview

Typically, EVPN-VXLAN can use either Ingress Replication (IR) or Protocol Independent Multicast (PIM) for Broadcast, Unknown unicast, and Multicast (BUM) traffic (although SR OS does not support PIM along with EVPN-VXLAN). PIM requires keeping multicast state awareness per subnet per tenant in the core routers, which may not scale. Not all core routers support PIM.

IR inefficiency is usually tolerable in EVPN networks for broadcast and unknown unicast traffic; however, it is not tolerable for multicast traffic:

- Broadcast traffic can be reduced by the proxy-ARP and proxy-ND capabilities supported by EVPN.
- Unknown unicast traffic is greatly reduced in virtualized Data Center (DC) networks where all MAC and IP addresses are learned in the control or management planes. In such cases, unknown MAC addresses are always outside the DC. An **unknown-mac-route** can be enabled to ensure that the unknown unicast traffic is sent only to the DC gateway, which minimizes flooding within the DC.
- Multicast traffic may be an issue for the hypervisors holding the multicast sources, because the hypervisors need to replicate the multicast traffic to the remote VXLAN Tunnel Endpoints (VTEPs). The multicast replication at the hypervisors is a software process and the throughput can be heavily impacted. This is also true when VPLS services are used in the Virtual Service Router (VSR) and many replicas must be done from the VSR. Using a dedicated service node to replicate the multicast traffic on behalf of the hypervisors can help, but the replication capabilities of such service nodes are limited too.

SR OS supports the Assisted Replication (AR) feature for IPv4 VXLAN tunnels (both replicator and leaf functions) in compliance with the non-selective mode described in *draft-ietf-bess-evpn-optimized-ir*. AR is a Layer 2 multicast optimization feature that helps software-based PEs and Network Virtualization Edge (NVE) devices with low-performance replication capabilities to deliver Broadcast and Multicast (BM) Layer 2 traffic to remote VTEPs in the VPLS.

SR OS nodes support the AR-Replicator (AR-R) and AR-Leaf (AR-L) functions, although not simultaneously on the same service. Nodes configured as AR-L select an AR-R within a service and send

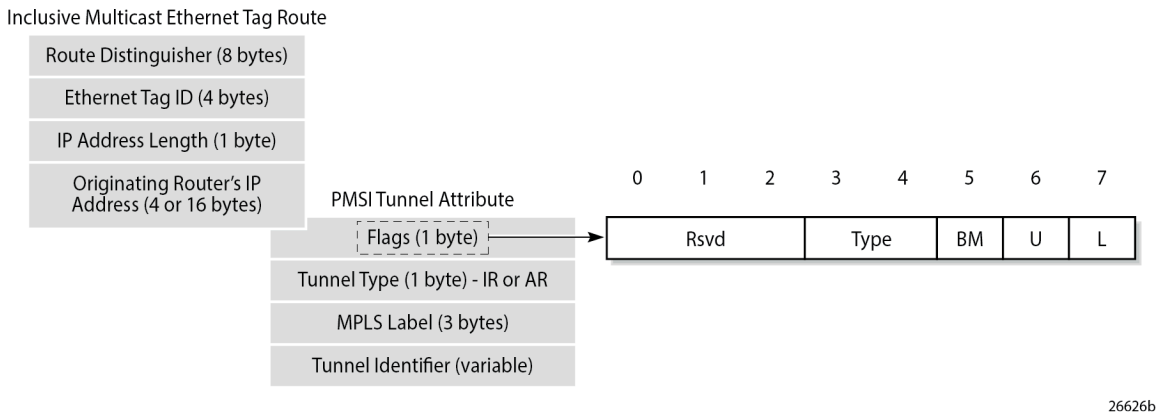
Use subject to Terms available at: www.nokia.com/terms.

all BM packets to this AR-R. AR-Rs replicate traffic to all the VTEPs in the VPLS on behalf of the AR-Ls, so BM traffic is delivered to all VPLS participants without any packet loss caused by performance issues. Unknown unicast packets follow the same path as known unicast packets to avoid packet reordering. Therefore, no AR-R is used for unknown unicast traffic.

When multiple AR-Rs exist in a service, the AR-L performs per-service load-balancing of the BM traffic. The AR-L lists the candidate AR-Rs, ordered by IP address and VXLAN Network Identifier (VNI); candidate 0 having the lowest IP address and VNI. The replicator is selected using a modulo function of the service ID and the number of candidate AR-Rs. For example, assume that VPLS 1 has two candidate AR-Rs: because 1 modulo 2 equals 1, the second AR-R in the list is selected. In case of failure, a new AR-R is selected. If there are no more AR-Rs, the system falls back to IR.

Figure 172: PMSI Tunnel Attribute - Flags shows an EVPN route-type 3, an Inclusive Multicast Ethernet Tag (IMET) route containing a PMSI tunnel attribute with a flags octet. Flag L was already defined in RFC 6514. *Draft-ietf-bess-evpn-optimized-ir* defines additional flags: type, BM, and U. The BM and U flags are used for Pruned Flood Lists (PFL) signaling and they are not supported.

Figure 172: PMSI Tunnel Attribute - Flags



The type field has two bits that define the AR role of the advertising router, as follows:

- Type 00 = Regular Network Virtualization Edge (RNVE) - indicates that AR is not supported and IR is applied instead (for backward compatibility)
- Type 01= AR-R
- Type 10 = AR-L
- Type 11 = reserved

The tunnel type in the PMSI tunnel attribute can be configured with the following options for IR and AR:

- Tunnel type 0x06 = (non-optimized) IR, sent by AR-R and AR-L if **ingress-repl-inc-mcast-advertisement** is enabled, which is the default option
- Tunnel type 0x0A = type AR, originated by AR-R

For regular IR routes, the originating router's IP address equals the system IP address. The MPLS label and tunnel identifier must be used as described in RFC 7432. The tunnel identifier is set to a routable address of the PE.

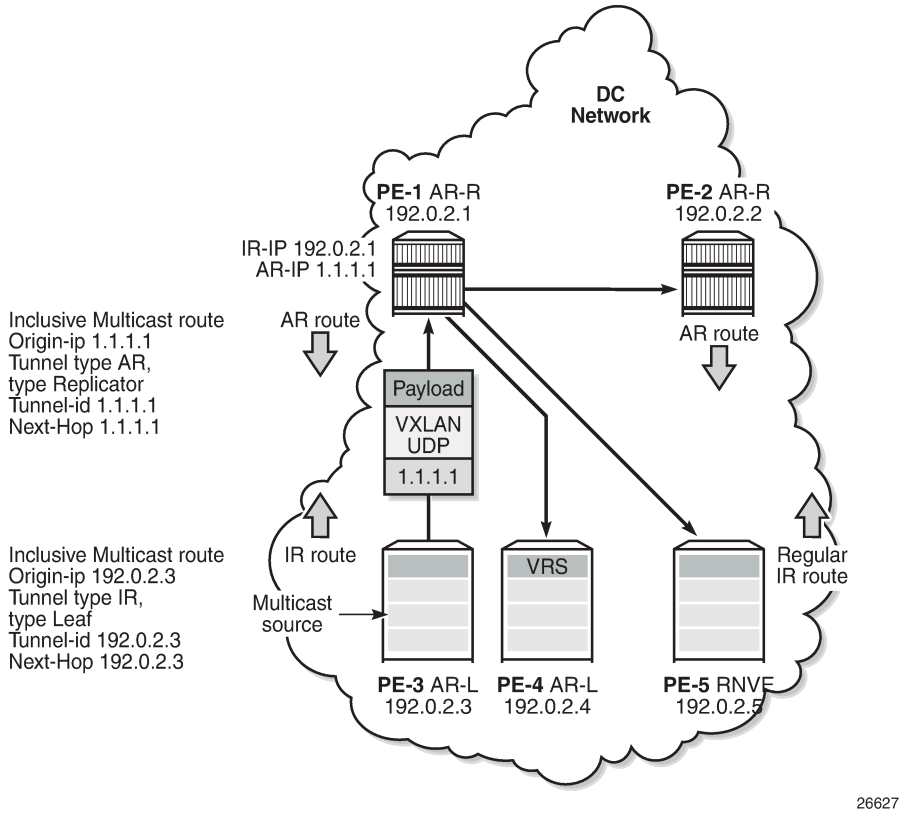
For AR routes, the originating router's IP address and the tunnel identifier are both set to the AR IP address (AR-IP) configured in the **service system vxlan** context. The AR-IP must be previously defined as a loopback interface address in the base router and must be different from the IR IP address (IR-IP).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note:
If the AR-IP loopback interface is down, the router does not withdraw the AR route. However, the remote AR-Ls is not able to resolve the AR route's BGP next-hop if the AR-IP is no longer propagated in the IGP.

Figure 173: EVPN Assisted Replication for VXLAN shows the example topology with the multicast source connected to a hypervisor PE-3 that acts as AR-L, which sends an IR route containing the system address of PE-3. The AR-R PE-1 sends an AR route that uses AR-IPs instead of IR-IPs; for example, PE-1 has AR-IP 1.1.1.1 and IR-IP 192.0.2.1.

Figure 173: EVPN Assisted Replication for VXLAN



Hypervisor PE-3 sends the BM traffic to the AR-R, which replicates it to all the VTEPs in the VPLS, except to PE-3.

Table 10: Inclusive multicast route information sent by different AR roles shows the inclusive multicast route information sent by each role in an AR-capable service.

Table 10: Inclusive multicast route information sent by different AR roles

AR role	function	inclusive multicast route advertised
AR-R	assists AR-Ls	IR inclusive multicast route (tunnel = 0x06 = IR, IR-IP, type = 0 = none)

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

AR role	function	inclusive multicast route advertised
		AR inclusive multicast route (tunnel = 0x0A = AR, AR-IP, type = 1 = AR-R)
AR-L	sends BM only to AR-R	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 2 = AR-L)
RNVE	non-AR support	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 0 = none)

Unicast traffic (known or unknown) is processed as normal. For BM traffic, the AR-R uses AR or IR based on the IP destination address (DA):

- If IP DA equals the AR-IP, the AR-R replicates to the VTEPs in the VXLAN service, except for the VTEP over which the BM traffic was received.
- If IP DA equals the IR-IP, normal IR forwarding is done.

Non-optimized-IR nodes are unaware of the PMSI tunnel attribute flag definition with the additional flags for AR, so they ignore the information in the flags field.

The *draft-ietf-bess-evpn-optimized-ir* describes the following three types of IR optimizations:

- Non-selective AR - the chosen AR-R replicates the BM traffic to all NVEs in the Ethernet VPN Instance (EVI) except for the source NVE.
- Selective AR - AR-Rs replicate BM traffic to only their AR-L set and the rest of the AR-Rs. Selective AR allows a "multi-stage" AR replication, as opposed to a "single-stage" AR replication.
- Pruned Flood Lists - AR-Ls can signal PFL flags to be pruned from the flood lists for BM or for unknown unicast traffic. PFL may be used in combination with AR.

This chapter only describes non-selective AR.

Configure AR-R and AR-L

The AR-IP is configured on the AR-R, as follows:

```
configure {
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address ?

 ip-address <unicast-ipv4-address>
 <unicast-ipv4-address> - <d.d.d.d>

    IP address for assisted replication in the router
```

The AR-IP is the IPv4 address of a loopback interface in the base router instance. When attempting to configure an AR-IP and the loopback address does not exist, the following error message is raised:

```
configure {
    service {
        system {
            vxlan {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                assisted-replication {
                    ip-address 1.1.1.1

MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address
 - loopback interface with address (max prefix) needed for assisted replication
 - configure router "Base"
```

The AR types replicator and leaf are configured in a VPLS with the following command:

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication ?

 assisted-replication

 Choice: role
 leaf                :+ Enter the leaf context
 replicator          :- AR role as replicator
```

When attempting to configure an AR-R before the AR-IP is set, the following error is raised:

```
configure {
    service {
        vpls "VPLS 10" {
            customer "1"
            service-id 10
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        replicator
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 10" vxlan instance 1 assisted-replication
 replicator
 - assisted-replication ip address needed for replication role
 - configure service system vxlan assisted-replication ip-address
```

The assisted-replication-time can only be configured on leaf nodes. The following error is raised after an attempt to configure the assisted-replication-time on an AR-R:

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    assisted-replication {
                        replicator {
                            acttime 5
MINOR: MGMT_CORE #2201: Unknown element - 'acttime'
```

The **acttime** can optionally be activated, and works as follows. When the router creates an AR-R destination for the first time, the assisted replication time must expire before this AR-R destination is eligible as candidate AR-R to forward BM traffic. Upon expiration, the router runs the AR-R selection (service ID modulo the number of AR-Rs provides the selected AR-R in the ordered list of candidate AR-Rs). The AR-R EVPN destination is created as "BM" and the destinations to the remaining nodes is shown as "U".

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **acttime** allows the AR-R some time to program the leaf VTEPs in the following cases:

- Configuration of a new AR-R
- AR-R rebooting
- AR-R going operationally down and up again

If the timer is zero (default value), the AR-R may receive packets from a VTEP that has not been programmed yet, in which case the AR-R drops the packets.

With the AR-Rs and AR-Ls configured, IMET AR routes can be exchanged. IR can be enabled or disabled independently of the AR configuration. The following command is required to enable IR inclusive multicast routes, and is enabled by default:

```
configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-ingress-replication true
```

BGP-EVPN routes

By default, IR is enabled in BGP-EVPN. The following IMET IR route is sent from PE-5 (RNVE) to Route Reflector (RR) PE-1. The flags in the PMSI Tunnel Attribute (PTA) indicate that regular IR is used to forward BUM traffic (tunnel type: 0x06). The AR type is "None", because AR is disabled on PE-5. The IR-IP 192.0.2.5 is used as next-hop, originator IP address, and tunnel endpoint. The MPLS label corresponds to the VNI.

```
A:admin@PE-5# //
A:PE-5# show debug
debug
    router "Base"
        bgp
            update
        exit
    exit
exit
A:PE-5# //
```

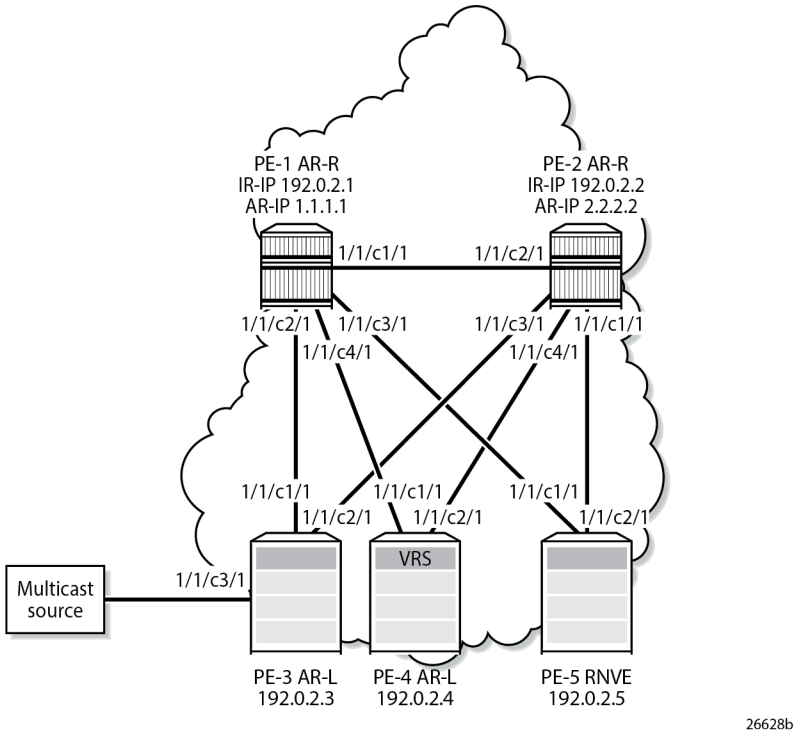
Configuration

Figure 174: Example topology shows the example topology with PE-1 and PE-2 as AR-R nodes, PE-3 and PE-4 as AR-L nodes, and PE-5 as RNVE node. The multicast source is connected to PE-3, which is a low-performance node. PE-1 acts as an RR for all nodes.

Figure 174: Example topology



The initial configuration on the nodes includes:

- Cards, MDAs, ports
- Router interfaces between the nodes
- IS-IS as IGP (alternatively, OSPF can be used)

BGP is configured for address family EVPN with RR PE-1. The BGP configuration on PE-1 is as follows:

```
On PE-1:
configure {
    router "Base" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        autonomous-system 64500
        bgp {

            vpn-apply-import true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "DC" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.1
                }
            }
            neighbor "192.0.2.2" {
                group "DC"
            }
            neighbor "192.0.2.3" {
                group "DC"
            }
            neighbor "192.0.2.4" {
                group "DC"
            }
            neighbor "192.0.2.5" {
                group "DC"
            }
        }
```

The BGP configuration on the other nodes is as follows:

```
On the other PEs:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "DC" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "DC"
            }
```

```
        }
```

VPLS 10 is configured on all nodes. PE-1 is configured as AR-R with AR-IP 1.1.1.1, which must be configured as loopback IPv4 address in the base router and as AR-IP that can be shared between services. When attempting to configure an AR-IP with an IP address that does not exist in the base router, the following error is raised:

```
configure {
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address 1.1.1.1
MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address
 - loopback interface with address (max prefix) needed for assisted replication
 - configure router "Base"
```

First, a loopback interface is configured in the base router. The IP address needs to be routable and, in this example, an export policy exporting this IP address is configured in IS-IS. Alternatively, a static route can be configured or an additional IS-IS passive interface can be configured for the loopback interface. The IP address is then configured as AR-IP in the **service system vxlan** context. PE-1 is configured as AR-R for VPLS 10, as follows:

```
On PE-1:
configure {
    policy-options {
        prefix-list "AR-IP" {
            prefix 1.1.1.1/32 type exact {
            }
        }
        policy-statement "export_AR-IP" {
            entry 10 {
                from {
                    prefix-list ["AR-IP"]
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        interface "AR-IP" {
            loopback
            ipv4 {
                primary {
                    address 1.1.1.1
                    prefix-length 32
                }
            }
        }
        isis 0 {
            export-policy ["export_AR-IP"]
        }
    }
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address 1.1.1.1
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
        vpls "VPLS 10" {
            customer "1"
            service-id 10
            admin-state enable
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        replicator
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
    }
```

The configuration is similar on PE-2, but with AR-IP 2.2.2.2 instead of 1.1.1.1.

PE-3 and PE-4 are configured as AR-L nodes for VPLS 10. No AR-IP needs to be configured. The configuration of VPLS 10 on PE-3 is as follows:

```
On PE-3:
configure {
    service {
        vpls "VPLS 10" {
            admin-state enable
            service-id 10
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        leaf { }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/1/c3/1 {    # sap for ingress traffic from STC
            }
            sap 1/2/c1/1:1 {    # sap for egress traffic to VPLS 10
            }
```

Multicast traffic enters SAP 1/1/c3/1, whereas receiving hosts can be connected to other SAPs, such as SAP 1/2/c1/1:1. The configuration of VPLS 10 on PE-4 is similar, but no multicast source is connected.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When a node is configured as AR-L, optionally the **acttime** can be configured to define the waiting time before the leaf can begin sending multicast traffic to a new replicator or a replicator that was rebooted. The default is zero seconds, in which case the AR-L starts sending packets to the AR-R without delay. Nokia recommends configuring a **acttime** value different from zero.

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        leaf {
                            acttime ?

 acttime <number>
 <number> - <1..255> - seconds

    Time for the leaf to wait before sending traffic to a new replicator
```

PE-5 is configured as an RNVE node for VPLS 10, as follows:

```
On PE-5:
configure {
    service {
        vpls "VPLS 10" {
            admin-state enable
            service-id 10
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/2/c1/1:1 {    # sap for egress traffic to VPLS 10
            }
```

BGP-EVPN IMET routes are exchanged between the nodes. The following IMET routes are used on AR-L PE-3, with two routes from each AR-R: one IR route with BGP next-hop 192.0.2.x and one AR route with BGP next-hop x.x.x.x (with x equal to 1 or 2).

===============================================================================
```

When the AR-R has no local attachment circuits, such as SAPs or SDP-bindings, it should not generate regular IR routes. This can be controlled by disabling **advertise-ingress-replication** on PE-1 and PE-2, as follows:

```
On PE-1 and PE-2:
configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-ingress-replication false
```

When IR is disabled on the AR-Rs, no IR routes are sent to the other nodes and PE-3 only sees the AR routes from PE-1 and PE-2, as follows:

```
[/]
A:admin@PE-3# show router bgp routes evpn incl-mcast

PE-3 is configured as AR-L and no **acttime** is defined (default). Four egress VTEPs are listed: the system IP addresses are used for IR routes and the AR-IPs are used for AR routes. All BM traffic is forwarded to AR-IP 1.1.1.1 on PE-1. The AR-R in use is selected by the modulo operation on the service ID (10). In this example, two AR-Rs are available, and the service ID modulo 2 equals zero: 10 mod 2 = 0. This is the lowest possible outcome, so the first AR-R in the ordered candidate list is used. The AR-Rs are ordered by IP and VNI, with candidate 0 the lowest IP and VNI.

```
[/]
A:admin@PE-3# show service id 10 vxlan assisted-replication replicator

1     2.2.2.2                1        no      yes               0
-------------------------------------------------------------------------------
Number of entries : 2
-------------------------------------------------------------------------------
===============================================================================
```

Within a service, no load-sharing is done between the AR-Rs. However, different AR-Rs can be used for different services.

- If PE-3 were configured as AR-L in VPLS 11, the calculation would be as follows: 11 mod 2 = 1; therefore, the second AR-R in the list would be selected.
- When three AR-Rs were available for VPLS 11, the calculation would be: 11 mod 3 = 2, so the third AR-R in the list would be used.

In case different VNIs are configured for the AR-Rs, the lowest IP address is always higher in the list, even when the VNI is higher. This can be shown when the VPLS VXLAN configuration on PE-1 is modified with VNI 99 instead of VNI 1, as follows:

```
On PE-1:
configure {
    service {
        vpls "VPLS 10" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp-evpn {
                delete vxlan 1
            }
            delete vxlan

configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 99
                    assisted-replication {
                        replicator

configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
```

The list of AR-Rs on PE-3 shows that the first entry is the VTEP with the lowest IP address (1.1.1.1), even though the VNI 99 is higher than 1:

```
[/]
A:admin@PE-3# show service id 10 vxlan assisted-replication replicator

Note:
If the AR-IP loopback interface is down, BGP does not withdraw the AR route. When the route to the AR-IP is signaled using IGP, the route is removed from the routing table and the AR-L selects another AR-R. However, when a static route is defined for the AR-IP, a black-hole exists when the AR-IP interface is down.

PE-5 is configured as an RNVE node that signals regular IMET IR routes and is unaware of the AR-R and AR-L roles in the EVI. RNVE nodes ignore IMET AR routes. In the example, only PE-3, PE-4, and PE-5 send IMET IR updates, so the list of VTEP addresses on PE-5 only contains PE-3 and PE-4, as follows:

```
[/]
A:admin@PE-5# show service id 10 vxlan destinations

Verification of multicast traffic

The multicast source connected to PE-3 generates multicast traffic. PE-3 acts as AR-L and forwards the multicast packets to AR-R PE-1. In this example topology, multicast traffic enters port 1/1/c3/1 on PE-3 and is forwarded to egress port 1/1/c1/1 toward PE-1. Port statistics are cleared and traffic is generated, then the port statistics are verified.

===============================================================================
```

Besides the multicast traffic, IGP signaling is sent and received on the network interfaces. This explains why the counters on the network interface 1/1/c1/1 toward PE-1 show a slightly higher value than on the interface 1/1/c3/1 toward the multicast source. No multicast traffic is forwarded to PE-2, which is an AR-R candidate, but not used. AR-L PE-3 selected PE-1 for VPLS 10.

When the AR-R PE-1 receives the multicast traffic from PE-3, it forwards the traffic to PE-4 and PE-5 within the VXLAN service. The VXLAN information for VPLS 10 on PE-1 shows that PE-2 is not in the list of egress VTEPs. The reason is that PE-2 does not have any SAPs or SDP-bindings and no IMET IR route is sent by PE-2 because **advertise-ingress-replication** is disabled.

AR-R PE-1 receives the multicast traffic from PE-3 on port 1/1/c2/1 and forwards it to the egress ports 1/1/c3/1 toward PE-5 and 1/1/c4/1 toward PE-4, as follows. No multicast traffic needs to be forwarded to egress port 1/1/c1/1 toward PE-2. Source squelching ensures that the traffic is not sent back to the originator AR-L PE-3. PE-1 has no local SAPs or SDP-bindings.

An egress AR-L or RNVE node performs regular egress BUM forwarding procedures. Packets are replicated to local SAPs or SDP-bindings, but not to VXLAN-bindings.

AR-R failure scenarios

When the AR-IP interface on the used AR-R is down for any kind of reason, the route to this AR-IP is removed from the routing table on AR-L PE-3, and PE-3 selects AR-R PE-2. To simulate an AR-R failure, the AR-IP interface on PE-1 is disabled, as follows:

```
On PE-1:
configure {
    router "Base" {
        interface "AR-IP" {
            admin-state disable
```

After a while, the routing table on PE-3 does not contain an entry for prefix 1.1.1.1/32 anymore, as follows:

```
[/]
A:admin@PE-3# show router route-table 1.1.1.1/32

In this case, IR is done for all BUM traffic toward PE-4 and PE-5.

Conclusion

AR uses replicators to forward broadcast and multicast traffic on behalf of less-performing nodes that are configured as AR-Ls. AR is primarily used for L2 multicast optimization in data centers, but may also be used in any network using overlay EVPN-VXLAN tunnels.

LDP VPLS Using BGP Auto-Discovery

This chapter provides information about LDP VPLS using BGP Auto-Discovery.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The MD-CLI in this edition is based on SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Knowledge of BGP-auto-discovery RFC 6074 architecture and functionality, RFC 4447 Pseudo-wire set-up using label distribution protocol is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

Overview

MPLS-based Virtual Private LAN Services (VPLS) may have many different provisioning models to allow the signaling of pseudowires between Provider Edge (PE) routers containing VPLS instances.

Network Management System (NMS) provisioning using Label Distribution Protocol (LDP) signaling is a well understood method of provisioning of Layer 2 VPLS services as described in RFC 4762. This relies on the provisioning of pseudowires between VPLS instances using LDP signaling with a common Virtual Circuit (VC) identifier within the label mapping message to instantiate pseudowires.

Border Gateway Protocol Auto-Discovery (BGP-AD), as specified in RFC 6074, is an alternative method of provisioning of Layer 2 PE routers containing VPLS service instances to those described above where PEs in a common VPLS instance are automatically discovered using BGP-AD techniques.

Each PE router advertises the presence of VPLS instances to other PE routers using defined parameters within a BGP update message.

LDP is used as the pseudowire signaling protocol and relies on the auto-discovery of VPLS endpoints to instantiate pseudowires instead of manually provisioning virtual circuits. Locally configured parameters, along with BGP learned parameters, are used to determine local and remote VPLS endpoints, which are used by LDP to signal service labels to peer routers.

Figure 175: Example topology shows the example topology with six SR OS nodes located in the same autonomous system (AS).There are three PEs and RR-6 acts as a route reflector for the AS. The PE routers are all VPLS-aware. The provider (P) routers are VPLS-unaware and do not take part in the BGP process. A full mesh VPLS between PE-1, PE-2, and PE-3 is described.

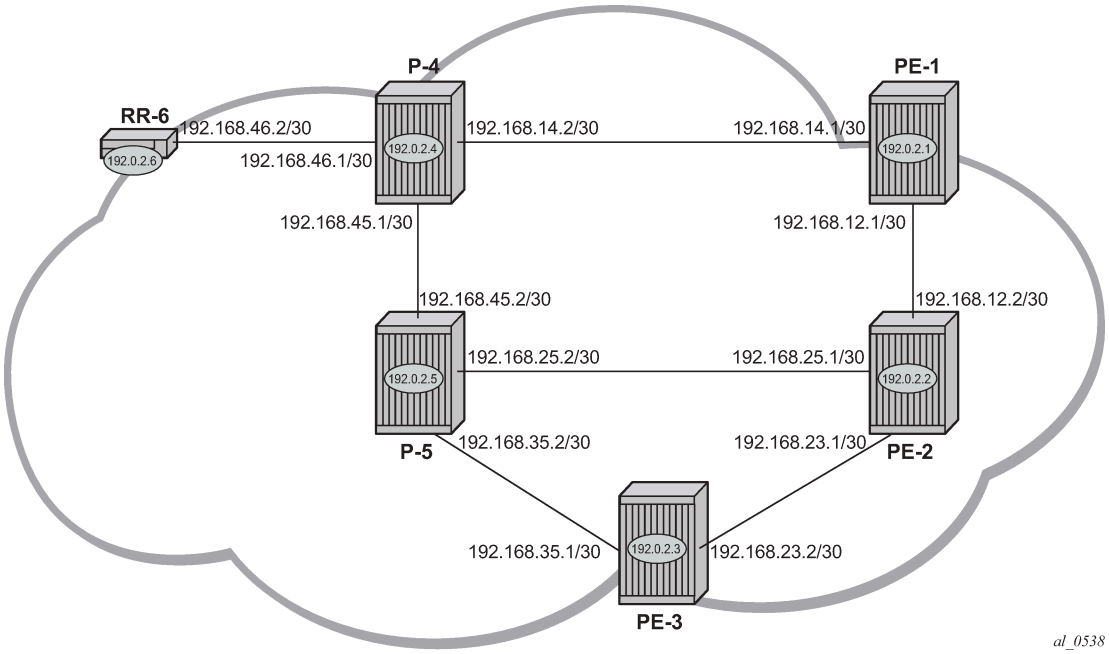
Figure 175: Example topology



The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is enabled on all network interfaces between each of the PE/P routers and route reflector RR-6.
- MPLS is configured on all interfaces between PE and P routers; MPLS is not required between P-4 and RR-6.
- LDP is configured on interfaces between PE and P routers; LDP is not required between P-4 and RR-6.
- The RSVP protocol must be enabled.

BGP-AD

In this architecture, a VPLS service is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, VPLS-aware devices are PE routers. Each VPLS instance has a unique identifier known as the VPLS identifier (VPLS-ID). All PEs that have this VPLS instance present will have a common VPLS-ID configured.

Each VPLS instance within a PE contains a Virtual Switching Instance (VSI). The VPLS attachment circuits and pseudowires are associated with the VSI. Each VSI within a VPLS has a unique identifier called the VSI identifier (VSI-ID) and is a concatenation of the VPLS-ID plus an IP address, usually the system IP address.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP Layer 2 Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs. In turn, this allows peer PE routers to set up pseudowire connectivity using LDP signaling for data flow between peers containing a local VPLS within the same VPLS instances.

Each update contains parameters usually associated with Multi-Protocol BGP updates:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- NLRI encoded as route target (RT)—usually the VPLS-ID—and PE system address.
- Next-Hop — The system IP address of the sending PE router.
- Extended communities — Contains the RT extended community and the VPLS-ID as community values.

Each VPLS instance is configured with import and export RT extended communities to create the required pseudowire topology by controlling the distribution of each NLRI.

This chapter describes the provisioning of a VPLS instance across three PE routers. A full mesh of pseudowires interconnects the VSI of each PE within the VPLS instance. A single attachment circuit is also configured on each VSI.

Configuration

The first step is to configure an MP-iBGP session using the L2-VPN address family between each of the PEs and the RR.

The configuration on the PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure {
    router "Base"
        autonomous-system 65536
        bgp {
            group "internal" {
                peer-as 65536
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
```

The IP addresses can be derived from Figure 175: Example topology.

The configuration for RR-6 is as follows:

```
# on RR-6:
configure {
    router "Base"
        autonomous-system 65536
        bgp {
            group "rr-internal" {
                peer-as 65536
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "rr-internal"
            }
            neighbor "192.0.2.2" {
                group "rr-internal"
            }
            neighbor "192.0.2.3" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                group "rr-internal"
            }
```

On PE-1, the BGP session with RR-6 is established with address family L2-VPN capability negotiated, as follows:

```
[]
A:admin@PE-1# show router bgp neighbor 192.0.2.6

===============================================================================

-------------------------------------------------------------------------------
```

A full mesh of RSVP Label Switched Paths (LSPs) is configured between the PE routers. For reference, the MPLS interface configuration and LSPs for PE-1 to PE-2 and PE-3 is as follows:

```
# on PE-1:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    router "Base"
        mpls {
            admin-state enable
            interface "int-PE-1-P-4" {
            }
            interface "int-PE-1-PE-2" {
            }
            path "loose" {
                admin-state enable
            }
            lsp "LSP-PE-1-PE-2" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.2
                primary "loose" {
                }
            }
            lsp "LSP-PE-1-PE-3" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                primary "loose" {
                }
            }
```

VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate Service Distribution Point (SDP) bindings. For a given service, pseudowire templates signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, plus other usage characteristics such as Split Horizon Groups (SHGs), MAC-pinning, filters, and so on.

The MPLS transport tunnel between PE routers can be signaled using either LDP or RSVP.

LDP-based pseudowires can be automatically instantiated; RSVP-based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, it is necessary for link layer LDP to be configured between all PEs/Ps so that a transport label for each PE system interface address is available. Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required which may contain an SHG. Each SDP created with this template is contained within the configured SHG so that traffic cannot be forwarded between them.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
            split-horizon-group {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                name "vpls-shg"
            }
        }
```

A pseudowire template can also be created that does not contain a split horizon group. The split horizon group can then be specified when the pw-template is included within the service.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW2" {
            pw-template-id 2
        }
```

Pseudowire templates for provisioned SDPs using RSVP

To use an RSVP tunnel as transport between PEs, it is necessary to bind the RSVP LSPs to the SDPs between each PE.

On PE-1, SDP 12 from PE-1 to PE-2 is configured as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
```

To create an SDP within a service that uses an RSVP transport tunnel, a pseudowire template is required that has the **provisioned-sdp use** parameter.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
provisioned-sdp use
        }
```

Alternatively, the **provisioned-sdp prefer** parameter can be used, see chapter LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP.

VPLS BGP-AD using auto-provisioned SDPs

Figure 176: VPLS instance with auto-provisioned SDPs

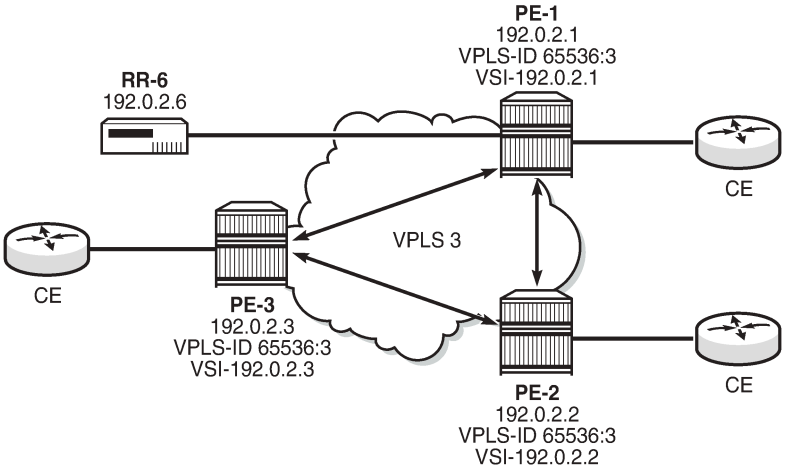

Figure 176: VPLS instance with auto-provisioned SDPs shows a schematic of a VPLS instance where the SDPs are auto-provisioned. SDPs are instantiated by a PE router using LDP signaling upon receipt of BGP Auto-Discovery (BGP-AD) updates from peer PE routers.

PE-1 configuration:

The following output shows the configuration required for a VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure {
    service {
         vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.1
            }
            sap 1/1/4:3.0 {
            }
```

Within the **bgp** context, the pseudowire template is referenced which can be linked to an SHG and an import RT, if required.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Within the **bgp-ad** context, the signaling parameters are configured. These are two parameters used by each PE to determine the presence of a VPLS instance on a PE router. In turn, these are translated into endpoint identifiers for LDP signaling of pseudowires. As previously discussed, these parameters are:

- VPLS-ID — a unique identifier of the VPLS instance. Each PE that is a member of a VPLS must share the same VPLS-ID. This is inserted as an extended community value in the format AS:n. In this case, the VPLS-ID for VPLS 3 is 65536:3. This is a mandatory parameter and if it is not configured, it is not possible to enable BGP-AD (admin-state enable).
- Virtual Switching Instance (VSI) prefix — This identifies a specific instance of the VPLS. This must be unique within the VPLS instance, and is encoded using the 4 byte dotted-decimal notation. Generally, the system address is used as the VSI prefix. If this parameter is not configured, then the system address is used automatically.

The VPLS-ID and VSI prefix for VPLS 3 on each PE is shown in Figure 176: VPLS instance with auto-provisioned SDPs.

The VPLS-ID and VSI prefix are concatenated to form a unique VSI-ID. In this case, PE-1 has a VSI-ID of 65536:3:192.0.2.1. This uniquely identifies the VPLS instance on each individual PE and is advertised as an L2-VPN BGP update.

A BGP-AD update is transmitted to all other PEs via the RR, as follows:

```

```
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

The preceding BGP update is transmitted by PE-1 and has route type auto-discovery.

In this L2-VPN update, the VPLS-ID is encoded as the L2-VPN extended community 65536:3.

The VSI is seen as the prefix 192.0.2.1. The combination of the VPLS-ID and the VSI forms the VSI-ID and uniquely identifies the VPLS instance within this PE router.

The next-hop is also encoded as the local system IP address 192.0.2.1, which allows remote PEs to identify a suitable transport tunnel to PE-1 and for the targeted-LDP peer for instantiating the SDP.

As can be seen within the update, the VPLS-ID 65536:3 is also used to determine the RT extended community and the route distinguisher (RD).

PE-2 configuration

On PE-2, VPLS 3 is created using pseudowire template 1, with VPLS-ID 65536:3 and VSI-ID prefix 192.0.2.2 (system IP address), as follows”

```
# on PE-2:
configure {
    service {
        vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.2
            }
            sap 1/1/4:3.0 {
            }
```

PE-3 configuration

On PE-3, VPLS 3 is created using pseudowire template 2, with VPLS-ID 65536:3—identical to the VPLS-ID of PE-1 and PE-2—and VSI-ID 192.0.2.3 (system IP address), as follows:

```
# on PE-3:
configure {
    service {
         vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.3
            }
            sap 1/1/4:3.0 {
            }
```

PE-1 service operation verification

The following output on PE-1 shows that the VPLS and its objects (SAP and auto-discovered spoke SDPs) are operationally up on PE-1:

```
[]

===============================================================================
* indicates that the corresponding row element may have been truncated.
```

The **SB** flag indicates that the SDP is of type spoke-SDP (S flag) BGP (B flag).

BGP is used to discover the VPLS endpoints and exchange network reachability information. LDP is used to signal the pseudowires between the PEs.

LDP signaling occurs when each PE has discovered the endpoints of the VPLS instance. This compares with the use of the provisioned virtual circuit IDs used in an NMS provisioned VPLS instances as per RFC 4762.

The ability of PE-1 to reach the other PE routers with VSIs within the VPLS instance is verified from the following L2-route table:

```
[]
A:admin@PE-1# show service l2-route-table bgp-ad
```

© 2023 Nokia.

```

This output shows the presence of the signaled pseudowire SDPs. SDPs from PE-1 to PE-2 and PE-3 are signaled using LDP Forwarding Equivalence Class (FEC) Element 129.

Each PE router uses targeted LDP to signal the local and remote endpoints. If there is an endpoint match, then SDPs are instantiated. This compares with the use of LDP for NMS provisioned SDPs, which uses virtual circuit IDs to signal pseudowires using LDP FEC Element 128.

In order to signal the SDPs, the following parameters are required:

1. Attachment Group Identifier (AGI): this is used to carry the VPLS-ID of the local PE router VPLS instance. The VPLS-ID must be identical for all PEs in the same VPLS instance.
2. Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII): these use AII type 1 (RFC 4446) and are used to carry the NLRI (VSI-ID minus the RD) of the remote PE router VPLS instance.

The AGI for each PE must be identical. SAII and TAII must be different.

The following shows the service LDP bindings for VPLS 3 on PE-1:

```

32767:4294967295 BgpAd    192.0.2.2       Up      Up        524280    524277
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

The SDP ID for the auto-provisioned SDP toward PE-2 is 32767, the SDP ID toward PE-3 is 32766.

The actual AGI, SAII, and TAII values are seen in the following detailed SDP output.

- AGI — 65536:3
- SAII — Local system IP address 192.0.2.1
- TAII — Remote system IP address 192.0.2.2 or 192.0.2.3

```

BGP AD using pre-provisioned SDPs

It is possible to configure BGP-AD instances that use RSVP transport tunnels. In this case, the LSPs and SDPs must be manually created.

Figure 177: VPLS instance using pre-provisioned SDPs

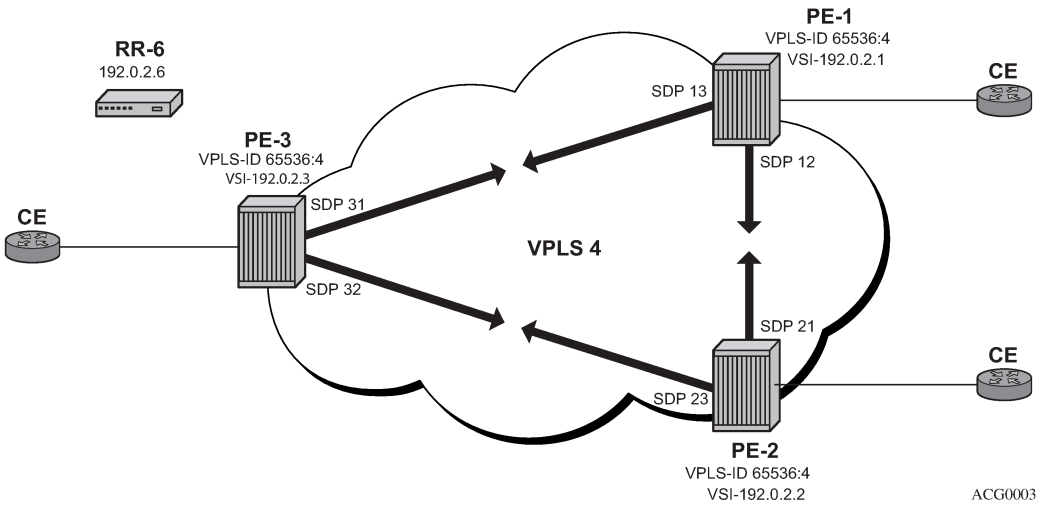

Figure 177: VPLS instance using pre-provisioned SDPs shows a VPLS instance configured across three PE routers as before.

The following SDPs are configured on the three PEs:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
        sdp 13 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-3"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.3
            }
            lsp "LSP-PE-1-PE-3" { }
        }
```

```
# on PE-2:
configure {
    service {
        sdp 21 {
            admin-state enable
            description "RSVP-based SDP from PE-2 to PE-1"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-PE-2-PE-1" { }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        sdp 23 {
            admin-state enable
            description "RSVP-based SDP from PE-2 to PE-3"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.3
            }
            lsp "LSP-PE-2-PE-3" { }
        }
```

```
# on PE-3:
configure {
    service {
        sdp 31 {
            admin-state enable
            description "RSVP-based SDP from PE-3 to PE-1"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-PE-3-PE-1" { }
        }
        sdp 32 {
            admin-state enable
            description "RSVP-based SDP from PE-3 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-3-PE-2" { }
        }
```

The PW template to be used within each VPLS instance must be provisioned on all PEs and must use the keyword provisioned-sdp use, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
            provisioned-sdp use
        }
```

The following output shows the configuration required for a VPLS service using a pseudowire template configured for pre-provisioned RSVP SDPs.

```
# on PE-1:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
                vsi-id-prefix 192.0.2.1
            }
            sap 1/1/4:4.0 {
            }
```

Similarly, on PE-2 the configuration is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
                vsi-id-prefix 192.0.2.2
            }
            sap 1/1/4:4.0 {
            }
```

On PE-3, VPLS 4 is configured as follows:

```
# on PE-3:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vsi-id-prefix 192.0.2.3
            }
            sap 1/1/4:4.0 {
            }
```

The following output shows that the service and its objects are operationally up on PE-1.

```
[]
A:admin@PE-1# show service id 4 base

```

Conclusion

BGP-AD coupled with LDP pseudowire signaling allows the delivery of L2-VPN services to customers where BGP is commonly used. This example shows the configuration of BGP-AD together with the associated show outputs which can be used for verification and troubleshooting.

LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP

This chapter provides information about LDP VPLS using BGP auto-discovery — prefer provisioned SDP.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. BGP Auto-Discovery (BGP-AD) based on RFC 6074 is supported in SR OS Release 6.0, and later. The **provisioned-sdp prefer** option is supported in SR OS Release 14.0.R1, and later.

Overview

As described in chapter LDP VPLS Using BGP Auto-Discovery, BGP-AD based on RFC 6074 can auto-create SDP bindings, but an operator can force the system to use a provisioned SDP by specifying the **provisioned-sdp use** option. This chapter compares the **provisioned-sdp use** option with the **provisioned-sdp prefer** option. The chapter describes a migration scenario for a VPLS service with a pseudowire (PW) template binding, restricted to using provisioned SDPs toward a PW template binding preferring to use provisioned SDPs, but auto-creating SDPs in case there is no suitable manually created SDP available.

PW templates

PW templates can be configured with the following command:

```
[ex:/configure service]
A:admin@PE-1# pw-template "PW 1" ?

 pw-template

 Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

When provisioned SDPs are to be used, the **provisioned-sdp** context must be configured:

```
*[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# provisioned-sdp ?

 provisioned-sdp <keyword>
 <keyword>  - (use|prefer)

 'provisioned-sdp' is: immutable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

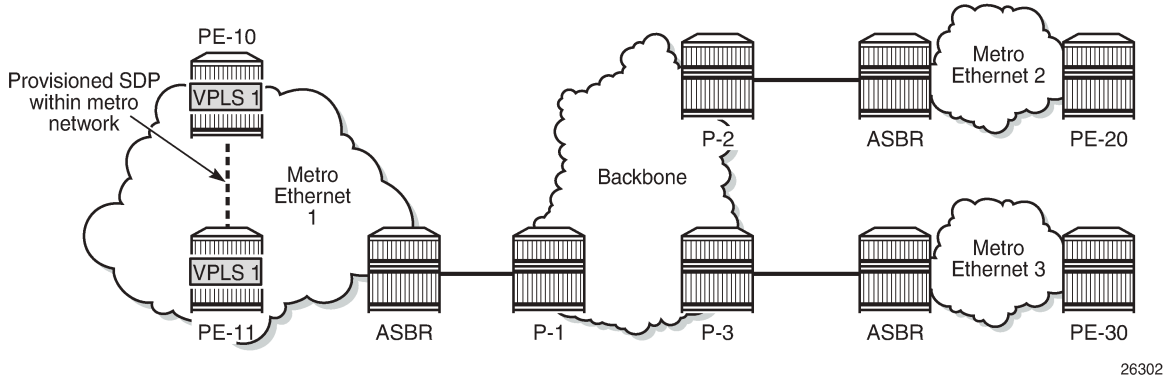
```
Provisioned SDP type

Warning: Modifying this element recreates 'configure service pw-template "PW 1"'
automatically for the new value to take effect.
```

- When the **provisioned-sdp use** option is configured, the tunnel manager is forced to look for a provisioned and active SDP to the far-end PE. The far-end PE is auto-discovered from the BGP next hop. If multiple SDPs are active to this far-end PE, the tunnel manager chooses the SDP template with the best metric. If there is a tie, the SDP ID is used as a tie-breaker and the highest SDP ID wins. However, if no provisioned SDP exists, the SDP binding will not be instantiated.
- When the **provisioned-sdp prefer** option is configured, the behavior is the same when a provisioned SDP exists. When the tunnel manager finds an existing matching SDP, it will use it even if it is operationally down. Only when no provisioned SDP exists, will the SDP binding be auto-created.
- When a PW template is configured without the **provisioned-sdp use** or **provisioned-sdp prefer** option, the SDP bindings will be auto-created.

Figure 178: LDP VPLS using BGP-AD with provisioned-sdp use option shows the following use case: the metro Ethernet networks were initially built with provisioned SDPs. Intra-metro services are provisioned using provisioned SDPs; for example, customer X has a VPLS service defined in the metro Ethernet networks, using BGP-AD with a PW template to use the provisioned SDPs in the metro Ethernet networks.

Figure 178: LDP VPLS using BGP-AD with provisioned-sdp use option



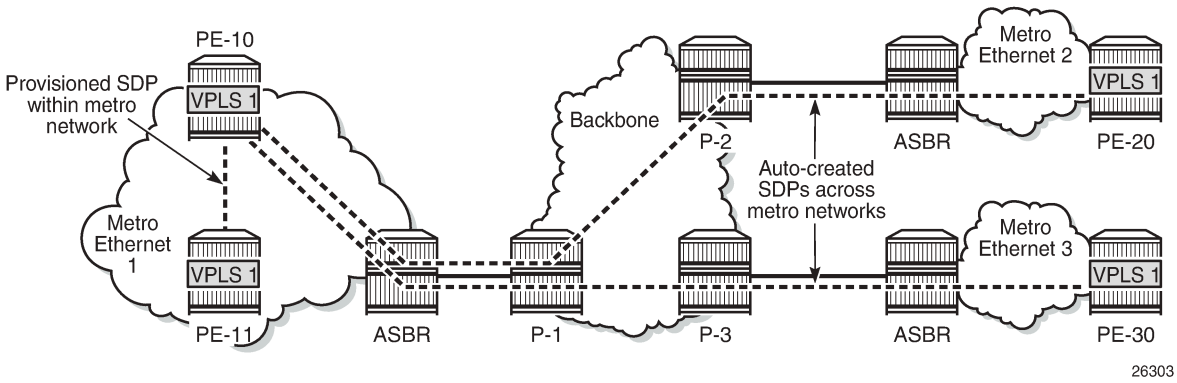
The service provider initially started with PE-10 and PE-11 in metro Ethernet 1, but now wants to add PE-20 and PE-30 as new sites to the VPLS service. Therefore, the BGP-AD routes should propagate beyond the boundaries of the metro Ethernet network. The backbone network may be in a different AS, but in this example, all networks are in the same AS. VPLS 1 of customer X can have sites added to the service on PEs in different metro Ethernet networks. A new PW template is configured with the **provisioned-sdp prefer** option and applied to the VPLS service.

- When a new site within the metro Ethernet network is added, an SDP is already provisioned to this site and this SDP is used for the SDP binding in the VPLS.
- When a new site in a different metro Ethernet network is added, no SDP is available to the site in the remote metro Ethernet network and the SDP binding is auto-created.

Figure 179: LDP VPLS using BGP-AD with provisioned-sdp prefer option shows the SDP bindings in VPLS 1 between PE-10 and the other PEs. For simplicity, the SDP bindings between the other PEs are not shown.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 179: LDP VPLS using BGP-AD with provisioned-sdp prefer option

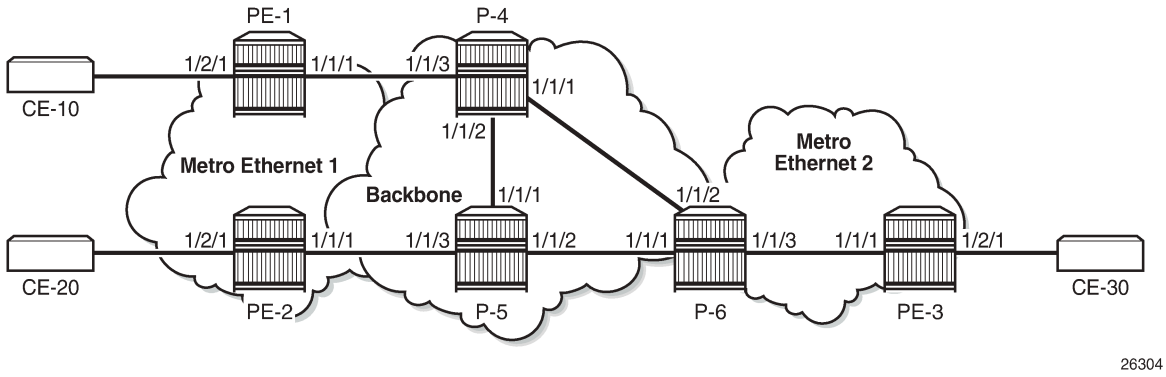


When PW templates are in use, it is not possible to modify the **provisioned-sdp prefer** option to **provisioned-sdp use** and vice versa. To support migration from one PW template to another with minimal service impact, two PW templates can be applied in parallel, as shown in the Configuration section.

Configuration

Figure 180: Example topology shows the example topology. For simplicity, all nodes are in the same AS.

Figure 180: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (or OSPF) on all interfaces
- MPLS and RSVP on all interfaces, except "int-P-4-P-6" and "int-P-5-P-6".
- LDP on all interfaces

BGP is configured on all PE routers for address family l2-vpn, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    router "Base" {
        autonomous-system 64496
        bgp {
            group "internal" {
                peer-as 64496
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
        }
```

The BGP configuration on the route reflector (RR) P-6 is as follows:

```
# on P-6:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "rr-internal" {
                peer-as 64496
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "rr-internal"
            }
            neighbor "192.0.2.2" {
                group "rr-internal"
            }
            neighbor "192.0.2.3" {
                group "rr-internal"
            }
        }
```

On PE-1 and PE-2 in metro Ethernet network 1, an RSVP LSP is created that is used in a manually created SDP. The LSP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        mpls {
            admin-state enable
            path "loose" {
                admin-state enable
            }
            lsp "LSP-PE-1-PE-2" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.2
                primary "loose" {
                }
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-1, SDP 12 is configured as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "SDP12 to 192.0.2.2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
```

The configuration on PE-2 is similar.

LDP VPLS using AD without provisioned-sdp prefer option

Initially, the following two PW templates are configured on all PEs: PW template 1 has the **provisioned-sdp use** option and PW template 2 is configured without any option; therefore, SDP bindings will be auto-created.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW 1" {
            pw-template-id 1
            provisioned-sdp use
        }
        pw-template "PW 2" {
            pw-template-id 2
        }
```

The following lists the PW templates configured on PE-1:

```
[/]
A:admin@PE-1# show service pw-template

1                   Use-provisioned               04/01/2021 16:35:27
2                   Auto-mpls                     04/01/2021 15:33:56
===============================================================================
```

On all PEs, two VPLS services are configured: VPLS 1 with BGP-AD PW template 1 and VPLS 2 with PW template 2, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
                route-distinguisher "64496:1"
                route-target {
                    export "target:64496:1"
                    import "target:64496:1"
                }
                pw-template-binding "PW 1" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "64496:1"
            }
            sap 1/2/1:1 {
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "64496:2"
                route-target {
                    export "target:64496:2"
                    import "target:64496:2"
                }
                pw-template-binding "PW 2" {
                    import-rt ["target:64496:2"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "64496:2"
            }
            sap 1/2/1:2 {
            }
        }
```

On PE-1, the following SDP bindings have been created:

```
[/]
A:admin@PE-1# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
1          12:4294967295      BgpAd  192.0.2.2           Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3           Up    524278  524280
2          32767:4294967294   BgpAd  192.0.2.2           Up    524279  524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

The first SDP binding is created by BGP-AD in VPLS 1 and uses the configured SDP 12 with far-end PE-2; the other two SDP bindings have been auto-created by BGP-AD in VPLS 2 and have far-end PE-2 and PE-3.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The list of SDP bindings on PE-2 looks similar:

```
[/]
A:admin@PE-2# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
1          21:4294967295      BgpAd  192.0.2.1           Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3           Up    524278  524281
2          32767:4294967294   BgpAd  192.0.2.1           Up    524279  524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

On PE-3, there are only two SDP bindings, both in VPLS 2:

```
[/]
A:admin@PE-3# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End             Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
2          32766:4294967294   BgpAd  192.0.2.2           Up    524281  524278
2          32767:4294967295   BgpAd  192.0.2.1           Up    524280  524278
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

Log "99" on PE-3 shows that the system failed to create a dynamic BGP-L2VPN SDP binding because no provisioned SDP was found, as follows:

```
69 2021/04/01 16:36:44.405 CEST MAJOR: SVCMGR #2322 Base
"The system failed to create a dynamic bgp-l2vpn SDP Bind  in service 1 with SDP pw-template
 policy 1 for the following reason: suitable manual SDP not found."
```

Figure 181: SDP bindings in VPLS 1 with provisioned-sdp use option shows the SDPs used in VPLS 1. PE-1 and PE-2 both used the provisioned SDP. PE-3 has no SDP bindings in VPLS 1.

Figure 181: SDP bindings in VPLS 1 with provisioned-sdp use option

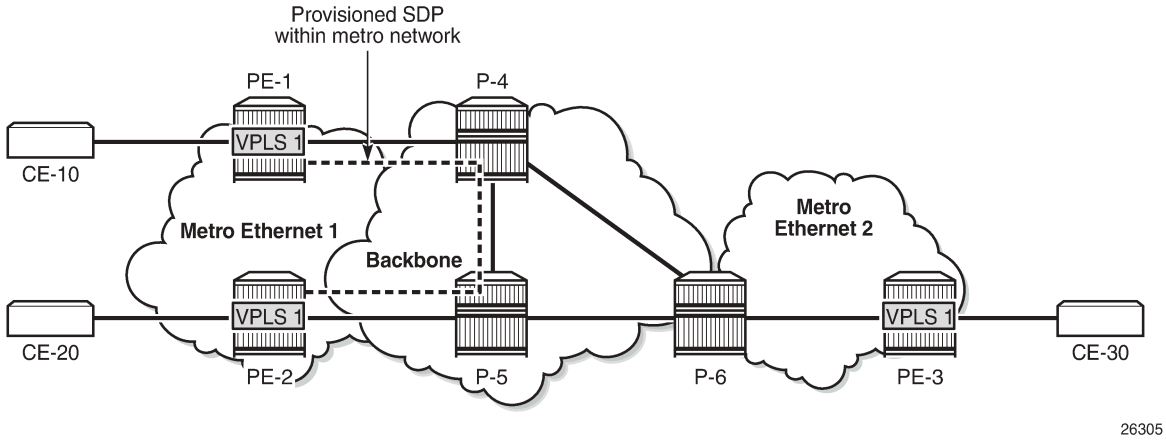

Figure 182: Auto-created SDP bindings in VPLS 2 shows the auto-created SDP bindings in VPLS 2. Each PE has two auto-created SDP bindings to each other PE.

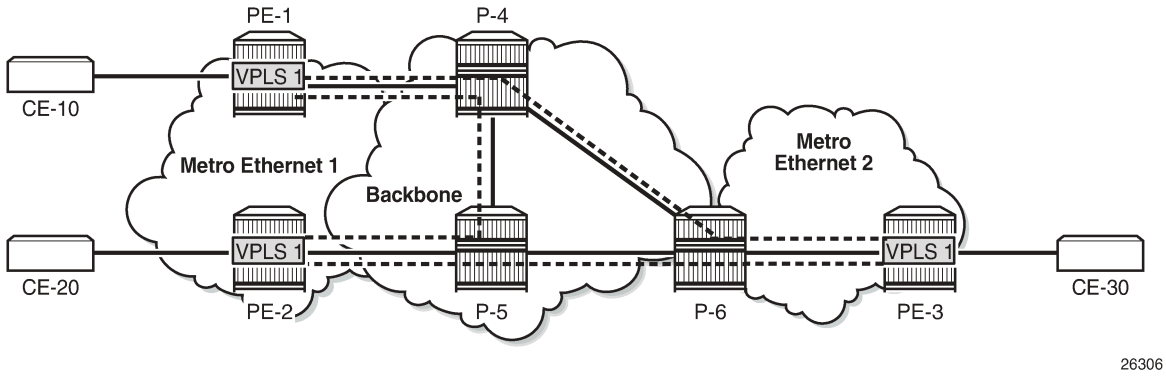
Figure 182: Auto-created SDP bindings in VPLS 2



Migrate VPLS 1 to provisioned-sdp prefer option

VPLS 1 uses PW template 1 with the **provisioned-sdp use** option. This option cannot be modified when the PW template is in use, as follows:

```
[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# provisioned-sdp prefer

*[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# commit
MINOR: SVCMGR #5609: configure service vpls "VPLS 1" bgp 1 pw-template-binding "PW 1" - PW
 Template is in use
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following steps are needed to migrate to another PW template with the **provisioned-sdp prefer** option without service outage:

1. Configure new PW template with **provisioned-sdp prefer** option.
2. Add new PW template binding to VPLS and verify which PW template is used.
3. Modify old PW template binding to make it not usable.
4. Launch tools command to re-evaluate old PW template in the VPLS.
5. When the old PW template is not used anymore, remove PW template binding from the VPLS configuration.

A new PW template with the provisioned-sdp prefer option is configured on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW 10" {
            pw-template-id 10
            provisioned-sdp prefer
        }
```

An additional PW template binding is configured in VPLS 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                pw-template-binding "PW 10" {
                }
            }
        }
```

The configuration of VPLS 1 includes two PW template bindings, as follows:

```
[ex:/configure service vpls "VPLS 1"]
A:admin@PE-1# info
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
        route-distinguisher "64496:1"
        route-target {
            export "target:64496:1"
            import "target:64496:1"
        }
        pw-template-binding "PW 1" {
        }
        pw-template-binding "PW 10" {
        }
    }
    bgp-ad {
        admin-state enable
        vpls-id "64496:1"
    }
    sap 1/2/1:1 {
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following shows that no additional SDP bindings have been created. The only SDP binding in VPLS 1 on PE-1 uses the provisioned SDP 12.

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The following shows that PW template 1 was used for the creation of the SDP binding:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967295            Type              : BgpAd
PW-Template Id     : 1
```

The PW template 10 has a higher ID than PW template 1 and is not used. Re-evaluating the PW template binding for PW template 1 in VPLS 1 will make no difference if both PW templates are usable. However, PW template 1 can be made unusable by adding a dummy **import-rt** not matching any route in the VPLS, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                pw-template-binding "PW 1" {
                    import-rt "target:111:111"
                }
```

As a result, PW template 10 with the **provisioned-sdp prefer** option is used for the automatic creation of SDP bindings where no provisioned SDP is available, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
32766:4294967292 BgpAd    192.0.2.3       Up      Up        524277    524279
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

For the first SDP binding, PW template 1 is used, and for the second SDP binding, PW template 10 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967295           Type              : BgpAd
PW-Template Id     : 1
SDP Id             : 32766:4294967292        Type              : BgpAd
PW-Template Id     : 10
```

The following command forces the system to re-evaluate PW template 1 in VPLS 1:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1 12:4294967295 Policy 1
```

As a result, only PW template 10 is used for the creation of SDP bindings in VPLS 1, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967291           Type              : BgpAd
PW-Template Id     : 10
SDP Id             : 32766:4294967292        Type              : BgpAd
PW-Template Id     : 10
```

PW template 1 is not used anymore and can be removed from the VPLS configuration, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                delete pw-template-binding "PW 1" {
                }
```

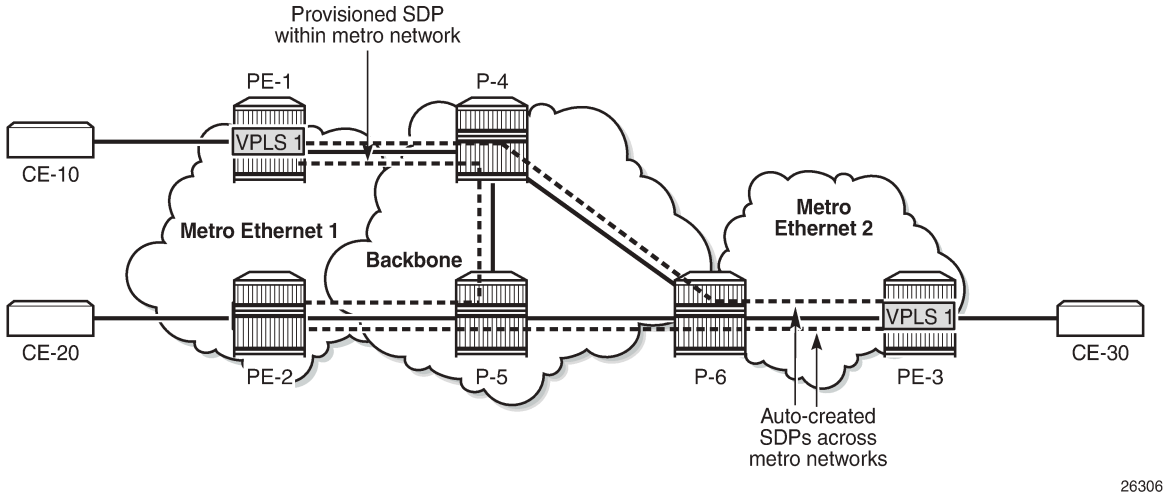
The configuration of VPLS 1 on PE-1 contains only a PW template binding for PW template 10, as follows:

```
[ex:/configure service vpls "VPLS 1" bgp 1]
A:admin@PE-1# info
    route-distinguisher "64496:1"
    route-target {
        export "target:64496:1"
        import "target:64496:1"
    }
    pw-template-binding "PW 10" {
    }
```

Figure 183: SDP bindings in VPLS 1 with provisioned-sdp prefer option shows the SDP bindings in VPLS 1 with the **provisioned-sdp prefer** option. Within metro Ethernet network 1, the provisioned SDP is used, and between metro Ethernet networks, auto-created SDP bindings are used.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 183: SDP bindings in VPLS 1 with provisioned-sdp prefer option



Conclusion

LDP VPLS using BGP-AD allows the creation of SDP bindings that are either auto-created or that use provisioned SDPs. When the **provisioned-sdp prefer** option is used, the tunnel manager will look for a provisioned and active SDP to the far end and use it, if available, even if it is down. When no provisioned SDP is available, the system will auto-create an SDP binding.

Mobility for EVPN Hosts Within an R-VPLS

This chapter provides information about Mobility for EVPN Hosts Within an R-VPLS.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R2. Efficient EVPN host mobility without tromboning or hairpinning in an R-VPLS is supported for IPv4 in SR OS Release 19.10.R3 and later and is supported for IPv6 in SR OS Release 20.5.R1 and later.

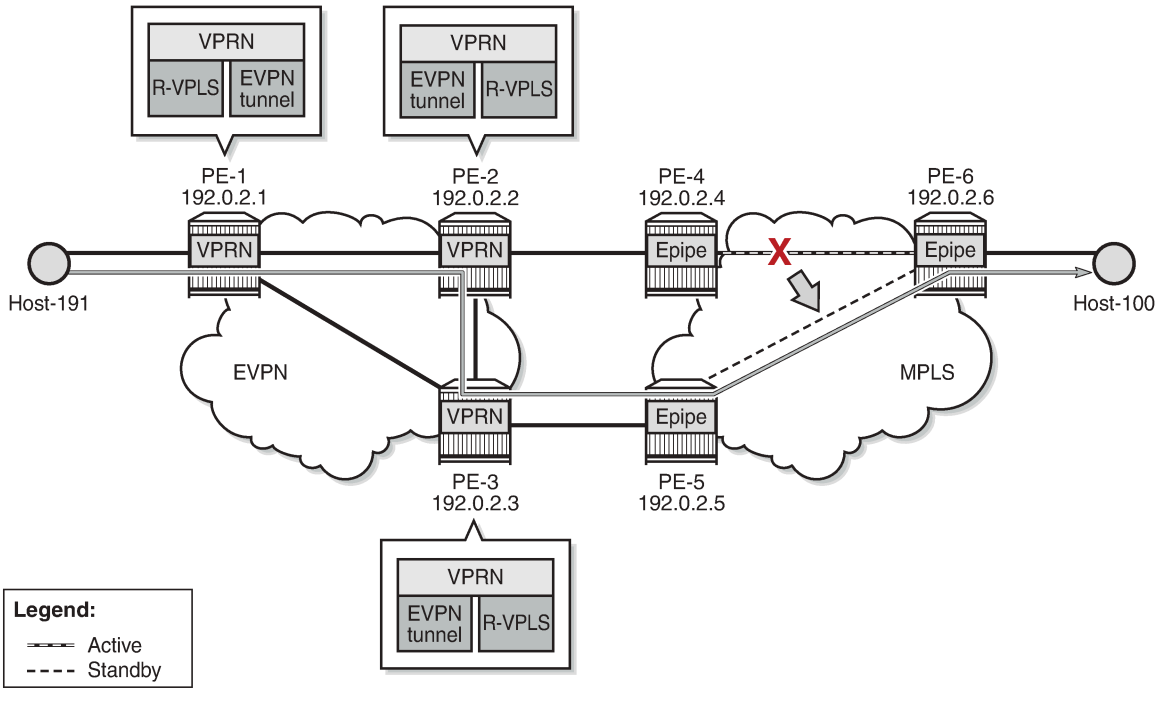
Overview

SR OS can populate a VPRN route table with host routes learned from the IPv4 Address Resolution Protocol (ARP) messages or IPv6 Neighbor Discovery (ND) protocol messages. The host routes can be advertised in the VPRN context as IP-VPN or EVPN route type 5 (RT5), to be used by an IP-VPN or EVPN core network for inter-subnet forwarding. SR OS supports *draft-ietf-bess-evpn-inter-subnet-forwarding* for a dynamic and efficient routing between remote hosts, avoiding hairpinning.

In SR OS releases earlier than Release 19.10.R3, inefficient hairpinning situations may occur when the VPRN is configured to advertise IPv4 host routes as IP-VPN or EVPN RT5 routes. Figure 184: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3 shows hairpinning in an EVPN broadcast domain with PE-1, PE-2, and PE-3.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 184: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3

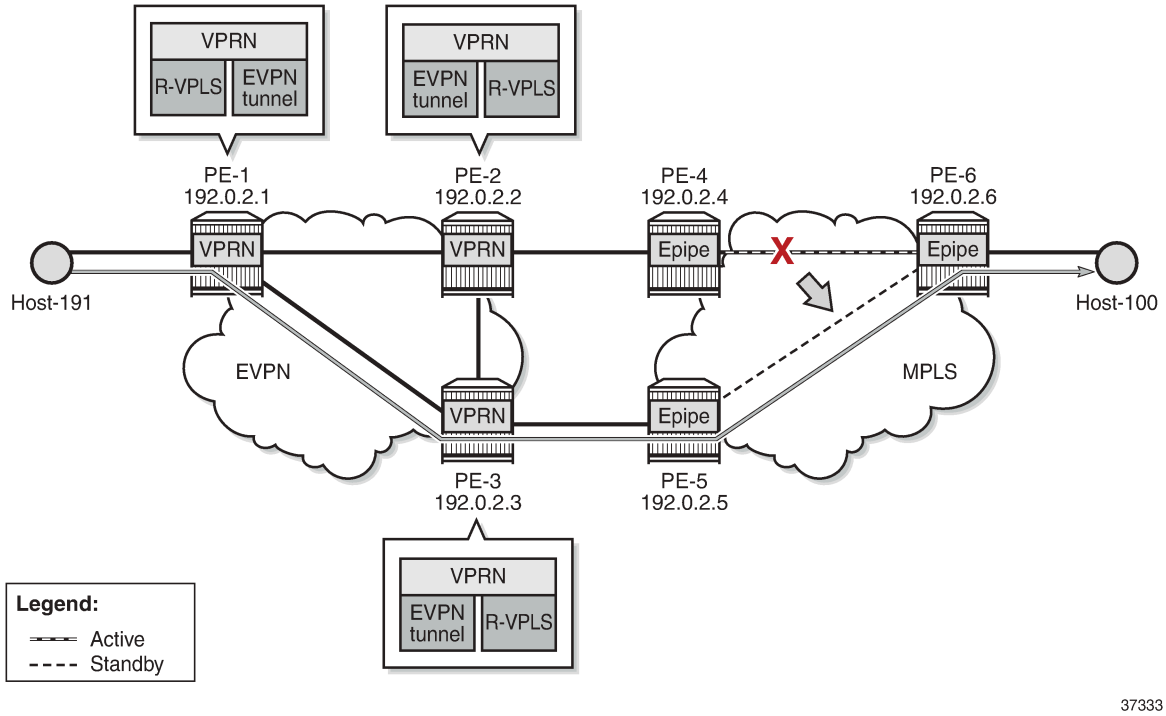


When host-100 comes up, it sends a Gratuitous Address Resolution Protocol (GARP) message that is then learned on PE-2 and PE-3. PE-2 and PE-3 are configured to advertise host routes, so they generate an RT5 host route for prefix 10.0.0.100/32 of host-100. PE-3 selects its best RT5 for 10.0.0.100/32 and traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-4, and PE-6. However, when the active path between PE-4 and PE-6 fails, the standby path between PE-5 and PE-6 takes over and hairpinning occurs when PE-1 continues selecting PE-2 as the next hop, while a more efficient path is possible via next-hop PE-3. Traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-3, PE-5, and PE-6.

In SR OS Release 19.10.R3 and later, the more efficient path from host-191 via PE-1, PE-3, PE-5, and PE-6 to host-100 is used, as shown in Figure 185: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 185: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later



In SR OS Release 19.10.R3 and later, EVPN host mobility is supported for IPv4 as described in section "Symmetric and Asymmetric IRB" of *draft-ietf-bess-evpn-inter-subnet-forwarding*. When a host moves from a source PE to a target PE in the same broadcast domain, the behavior for IPv4 hosts is one of the following.

1. The host initiates an ARP request or GARP.
2. The host sends a data packet without first initiating an ARP request or GARP.
3. The host does not send any traffic and the source PE generates an ARP request when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-100 from source PE-2 to target PE-3 is simulated.

For the first of these scenarios, the VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            interface "evi-17" {
                mac 00:00:00:00:2f:17
                ipv4 {
                    primary {
                        address 10.0.0.2
                        prefix-length 24
                    }
                    neighbor-discovery {
                        timeout 300
                        learn-unsolicited true
                        proactive-refresh true
                        local-proxy-arp true
                        host-route {
                            populate dynamic {
                            }
                        }
                    }
                    vrrp 1 {
                        backup [10.0.0.254]
                        passive true
                        ping-reply true
                        traceroute-reply true
                    }
                }
                vpls "evi-17" {
                    evpn {
                        arp {
                            learn-dynamic false
                            flood-garp-and-unknown-req false
                            advertise dynamic {
                            }
                        }
                    }
                }
            }
        }
```

For IPv4, the behavior is controlled by the following commands.

- **ipv4>neighbor-discovery>host-route>populate [dynamic | evpn | static]** configures PE-2 to advertise host routes. The type of ARP entry that can create a host route can be dynamic, EVPN, static, or a combination of these.
- **ipv4>neighbor-discovery>learn-unsolicited** triggers the learning of an ARP entry upon receiving an ARP or GARP message that was not requested by the router.
- **ipv4>neighbor-discovery>proactive-refresh** triggers the refresh of the ARP entry 30 seconds before aging out.
- **ipv4>neighbor-discovery>local-proxy-arp** ensures that PE-2 replies to any received ARP request on behalf of the other hosts in the R-VPLS broadcast domain.
- **vpls>evpn>arp>learn-dynamic** controls whether data path ARP messages received on EVPN connections can populate the ARP tables.
- **vpls>evpn>arp>flood-garp-and-unknown-req** controls the flooding of Control Processing Module (CPM)-generated ARP requests to EVPN destinations.
- **vpls>evpn>arp>advertise [dynamic | static]** enables PE-2 to advertise MAC and IP in EVPN-MAC routes for ARP entries of the dynamic or static type.

For IPv6, the corresponding commands are as follows:

- **ipv6>neighbor-discovery>host-route>populate [dynamic | evpn | static]**

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **ipv6>neighbor-discovery>learn-unsolicited [global | link-local | both]**
- **ipv6>neighbor-discovery>proactive-refresh [global | link-local | both]** triggers the refresh of the ND entry upon aging out.
- **ipv6>neighbor-discovery>local-proxy-nd**
- **vpls>evpn>nd>learn-dynamic**
- **vpls>evpn>nd>advertise [dynamic | static]**

For IPv6, CPM-generated Neighbor Solicitation (NS) messages are always flooded to EVPN destinations. This is not configurable in the **vpls>evpn>nd** context of the VPRN service, in contrast to the **flood-garp-and-unknown-req** command in the **vpls>evpn>arp** context for IPv4.

The behavior for IPv6 hosts when moving from a source PE to a target PE is one of the following.

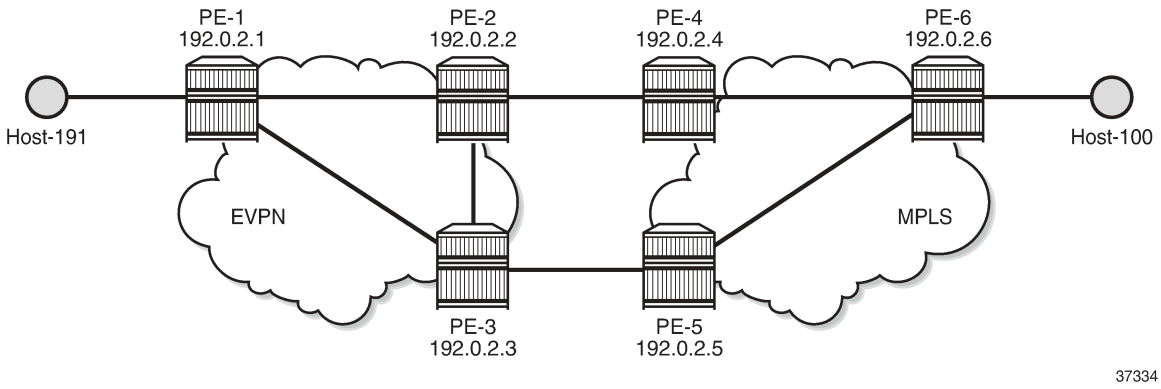
1. The host initiates an unsolicited Neighbor Advertisement (NA).
2. The host sends traffic, without first initiating NA or NS messages.
3. The host does not send any traffic, and the source PE generates an NS message when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-66 from source PE-2 to target PE-3 is simulated.

Configuration

Figure 186: Example topology with system IP addresses shows the example topology with PE-1, PE-2, and PE-3 in an EVPN-MPLS network and PE-4, PE-5, and PE-6 in an MPLS network.

Figure 186: Example topology with system IP addresses



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- LDP between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- BGP configured for the EVPN address family on PE-1, PE-2, and PE-3

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-1, BGP is configured as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "dc" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "dc"
            }
            neighbor "192.0.2.3" {
                group "dc"
            }
        }
```

The BGP configuration is similar on PE-2 and PE-3.

IPv4 host mobility

The following use cases for IPv4 host mobility are described:

1. Host initiates ARP request or GARP after moving
2. Host initiates non-ARP traffic after moving
3. Host does not send any traffic after moving

IPv4 host mobility case 1: host initiates ARP request or GARP after moving

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        vpls "sbd-15" {
            admin-state enable
            description "R-VPLS 15"
            service-id 15
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.1:15"
            }
            bgp-evpn {
                evi 15
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                routes {
                    ip-prefix {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:01
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
            interface "evi-20" {
                mac 00:00:00:00:1e:20
                ipv4 {
                    primary {
                        address 10.0.20.1
                        prefix-length 24
                    }
                }
                vpls "evi-20" {
                }
            }
        }
        vpls "evi-20" {
            admin-state enable
            description "R-VPLS 20"
            service-id 20
            customer "1"
            routed-vpls {
            }
            sap pxc-10.a:20 {
            }
        }
```

VPRN "ip-vrf-16" has two interfaces: interface "evi-15" toward R-VPLS "sbd-15" and interface "evi-20" toward R-VPLS "evi-20". Host-191 is connected to interface "evi-20" of R-VPLS "evi-20".

PE-2 and PE-3 are configured with an anycast gateway, that is, a VRRP passive instance with the same backup IP address 10.0.0.254 on interface "evi-17" in VPRN "ip-vrf-16". The MAC address under VRRP is by default derived from the Virtual Router ID (VRID), so both PE-2 and PE-3 get MAC address 00:00:5E:00:01:01. The service configuration on PE-2 and PE-3 is similar.

```
# on PE-2:
configure {
    service {
        vpls "evi-17" {
            admin-state enable
            description "R-VPLS 17"
            service-id 17
            customer "1"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:17"        # on PE-3: 192.0.2.3:17
            }
            bgp-evpn {
                evi 17
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:17 {                                # on PE-3: sap 1/1/2:17
            }
        }
        vpls "sbd-15" {
            admin-state enable
            description "R-VPLS 15"
            service-id 15
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:15"         # on PE-3: 192.0.2.3:15
            }
            bgp-evpn {
                evi 15
                routes {
                    ip-prefix {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02              # on PE-3: 00:00:00:00:00:03
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
            interface "evi-17" {
                mac 00:00:00:00:2f:17              # on PE-3: 00:00:00:00:3f:17
                ipv4 {
                    primary {
                        address 10.0.0.2           # on PE-3: 10.0.0.3
                        prefix-length 24
                    }
                    neighbor-discovery {
                        timeout 300
                        learn-unsolicited true
                        proactive-refresh true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        local-proxy-arp true
                        host-route {
                            populate dynamic {
                            }
                        }
                    }
                    vrrp 1 {
                        backup [10.0.0.254]      # anycast IP address on PE-2, PE-3
                        passive true
                        ping-reply true
                        traceroute-reply true
                    }
                }
                vpls "evi-17" {
                    evpn {
                        arp {
                            learn-dynamic false
                            flood-garp-and-unknown-req false
                            advertise dynamic {
                            }
                        }
                    }
                }
            }
        }
```

The **ipv4>neighbor-discovery>host-route>populate dynamic** ensures that route-table ARP-ND host routes are created for dynamic entries, not for static or EVPN entries. The **learn-dynamic false** command prevents PE-2 and PE-3 from learning ARP entries from ARP messages received on an EVPN destination. The **flood-garp-and-unknown-req false** command suppresses CPM-generated ARP to reduce unnecessary ARP flooding.

In this sample topology, an Epipe is used where a failover from the primary to the secondary path simulates a move of host-100 from PE-2 to PE-3. SAP 1/1/1:17 in R-VPLS "evi-17" on PE-2 is connected to a SAP of Epipe 17 on PE-4; SAP 1/1/2:17 in R-VPLS "evi-17" on PE-3 to a SAP of Epipe 17 on PE-5. The service configuration on PE-4 is as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 17" {
            admin-state enable
            service-id 17
            customer "1"
            spoke-sdp 46:17 {
                oper-group "op-grp-1"
            }
            sap 1/1/2:17 {
                description "SAP connected to SAP 1/1/1:17 on PE-2"
                monitor-oper-group "op-grp-1"
            }
        }
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

On PE-6, the service configuration is as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe 17" {
            admin-state enable
            service-id 17
            customer "1"
            endpoint "EP17" {
            }
            spoke-sdp 64:17 {
                endpoint {
                    name "EP17"
                    precedence primary
                }
            }
            spoke-sdp 65:17 {
                endpoint {
                    name "EP17"
                }
            }
            sap 1/2/1:17 {
            }
        }
        sdp 64 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.4
            }
        }
        sdp 65 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.5
            }
        }
```

Host-100 is connected to SAP 1/2/1:17 in Epipe 17.

On PE-2 and PE-3, debugging is enabled (in classic CLI):

```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-16"
        ip
            arp
            route-table
        exit
    exit
exit
```

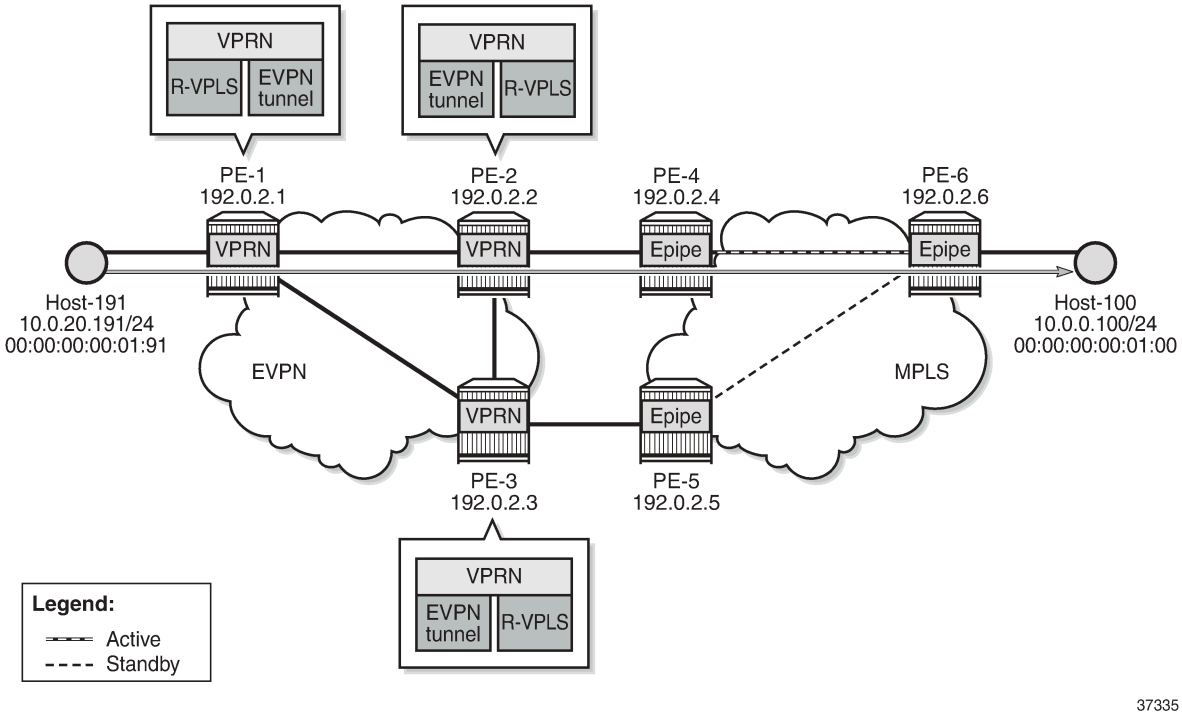
Initial phase

Figure 187: Initial situation with forwarding path via PE-2 shows that traffic from host-191 to host-100 is forwarded via PE-1, PE-2, PE-4, and PE-6.

Figure 187: Initial situation with forwarding path via PE-2



Host-191 sends a traceroute to host-100 via PE-2 (10.0.0.2):

```
[/]
A:admin@PE-1# traceroute 10.0.0.100 router-instance "H-191" source-address 10.0.20.191
traceroute to 10.0.0.100 from 10.0.20.191, 30 hops max, 40 byte packets
  1  10.0.20.1 (10.0.20.1)    3.96 ms  2.27 ms  2.07 ms
  2  10.0.0.2 (10.0.0.2)    2.96 ms  2.95 ms  2.82 ms
  3  10.0.0.100 (10.0.0.100)    10.9 ms  5.54 ms  5.07 ms
```

The ARP table for VPRN "ip-vrf-16" on PE-2 shows that IP address 10.0.0.100 corresponds to MAC address 00:00:00:00:01:00 and is learned dynamically:

```
[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h04m49s Dyn[I] evi-17
===============================================================================
```

© 2023 Nokia.

```

PE-3 receives the IP and MAC addresses of host-100 as EVPN type. PE-3 must not learn these IP and MAC addresses as dynamic because PE-3 must be prevented from advertising an RT5 route. If PE-3 advertised prefix 10.0.0.100, then PE-1 could select PE-3 as next hop to reach host-100, causing an undesired hairpinning forwarding behavior.

Host-100 sends an ARP request or GARP after moving

Figure 188: Host-100 sends an ARP request or GARP after switchover shows a switchover from the active to the standby path where host-100 sends an ARP request or GARP and its IP and MAC addresses are learned on PE-3 instead of PE-2. The failure is simulated by disabling the SDP from PE-4 to PE-6.

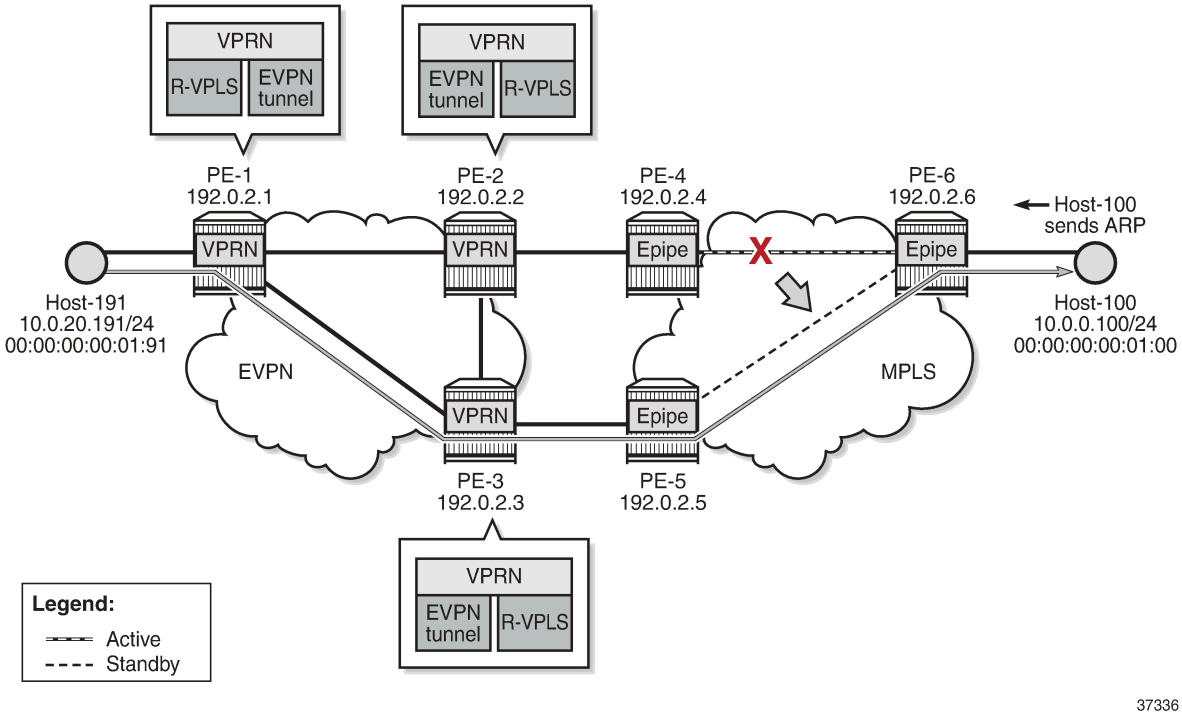
Figure 188: Host-100 sends an ARP request or GARP after switchover



Due to the SDP failure on PE-4, the initial path can no longer be used. Host-100 sends an ARP request or GARP with its IP and MAC addresses. In the following example, PE-3 receives the following ARP request and replies to it:

```
1 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP ingressing on evi-17
   Who has 10.0.0.254 ? Tell 10.0.0.100
"
2 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP egressing on evi-17
   10.0.0.254 is at 00:00:5e:00:01:01
"
```

The Route Table Manager (RTM) for prefix 10.0.0.100 in VPRN "ip-vrf-16" is modified with preference 1 and owner ARP-ND. This behavior is due to the **ipv4>neighbor-discovery>host-route>populate dynamic** command.

```
3 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP

===============================================================================
```

On PE-3, the ARP table for VPRN "ip-vrf-16" shows that IP address 10.0.0.100 is learned dynamically on interface "evi-17":

```
[/]
A:admin@PE-3# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h04m40s Dyn[I] evi-17
===============================================================================
```

On PE-2, the ARP table for VPRN "ip-vrf-16" shows that the entry for IP address 10.0.0.100 is updated from dynamic to type EVPN:

```
[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h00m00s Evp[I] evi-17
===============================================================================
```

An ARP entry's change from dynamic to EVPN triggers a CPM-generated ARP request from PE-2, but the configured **flood-garp-and-unknown-req false** command prevents PE-2 from flooding the ARP request to EVPN destinations such as PE-3.

On PE-3, the route table for VPRN "ip-vrf-16" shows an ARP-ND host route for prefix 10.0.0.100:

```
[/]
```

IPv4 host mobility case 2: host sends traffic without first initiating an ARP request or GARP after moving

In use cases 2 and 3, the configuration of VPRN "ip-vrf-16" is modified on PE-2 and PE-3. The only difference from case 1 is that the **flood-garp-and-unknown-req** is configured, which is the default setting. The VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
```

Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
        interface "evi-17" {
            mac 00:00:00:00:2f:17
            ipv4 {
                primary {
                    address 10.0.0.2
                    prefix-length 24
                }
                neighbor-discovery {
                    timeout 300
                    learn-unsolicited true
                    proactive-refresh true
                    local-proxy-arp true
                    host-route {
                        populate dynamic {
                        }
                    }
                }
                vrrp 1 {
                    backup [10.0.0.254]
                    passive true
                    ping-reply true
                    traceroute-reply true
                }
            }
            vpls "evi-17" {
                evpn {
                    arp {
                        learn-dynamic false
                        flood-garp-and-unknown-req true  # default behavior
                        advertise dynamic {
                        }
                    }
                }
            }
        }
```

Initial forwarding path

The initial forwarding path via PE-2 is restored by enabling the SDP from PE-4 to PE-6. The route table for VPRN "ip-vrf-16" on PE-2 shows the following ARP-ND host route for prefix 10.0.0.100/32:

```
[/]
A:admin@PE-2# show router 16 route-table 10.0.0.100

===============================================================================

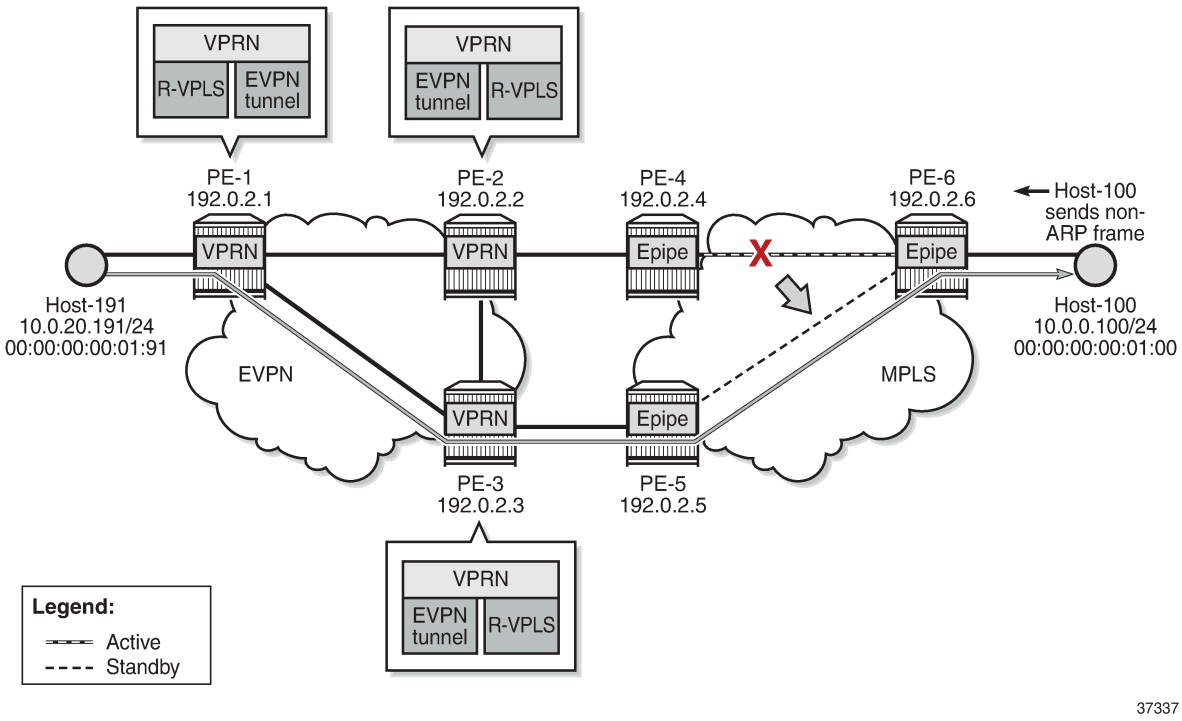
Host-100 generates non-ARP traffic after moving

On PE-4, the SDP from PE-4 to PE-6 is disabled, causing a switchover to the standby path. Figure 189: Host sends non-ARP frame after switchover shows the path after switchover. Host-100 generates non-ARP traffic after moving.

Figure 189: Host sends non-ARP frame after switchover



Host-100 sends a non-ARP frame with MAC source address 00:00:00:00:01:00 to host-191. The following steps occur:

1. PE-3 receives this frame with MAC 00:00:00:00:01:00 and updates its FDB.
2. PE-3 advertises an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address) with a higher sequence number.
3. PE-2 receives this EVPN MAC route, updates its FDB and withdraws its EVPN-MAC routes for MAC 00:00:00:00:01:00.
4. The FDB update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for MAC 00:00:00:00:01:00.
5. PE-2 is configured with **flood-garp-and-unknown-req**, so the ARP request is flooded to the EVPN destinations PE-1 and PE-3. PE-3 floods this ARP request to its SAPs and SDP-bindings; in this case, to SAP 1/1/2:17.
6. When the ARP request reaches host-100, it sends an ARP reply to the anycast IP address 10.0.0.254. This ARP reply is received by PE-3.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

7. When PE-3 receives the ARP reply, it updates the ARP entry for 10.0.0.100 to type dynamic instead of type EVPN.
8. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. Also, MAC 00:00:00:00:01:00 is now learned in ARP as local, so PE-3 sends an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100.
9. PE-2 receives the EVPN routes and updates the ARP entry for prefix 10.0.0.100 from type dynamic to type EVPN. PE-2 also removes its ARP-ND host route from the route table and withdraws its RT5 for prefix 10.0.0.100/32.

On PE-3, the route for prefix 10.0.0.100/32 is an ARP-ND host route:

```

IPv4 host mobility case 3: host does not send any traffic after moving

The service configuration on PE-2 and PE-3 remains the same as in use case 2.

The forwarding path is restored by enabling the SDP from PE-4 to PE-6, so the initial situation is the same as in the preceding cases. PE-2 learns MAC address 00:00:00:00:01:00 on its local SAP 1/1/1:17, as follows:

```
[/]
A:admin@PE-2# show service id 17 fdb detail

===============================================================================
```

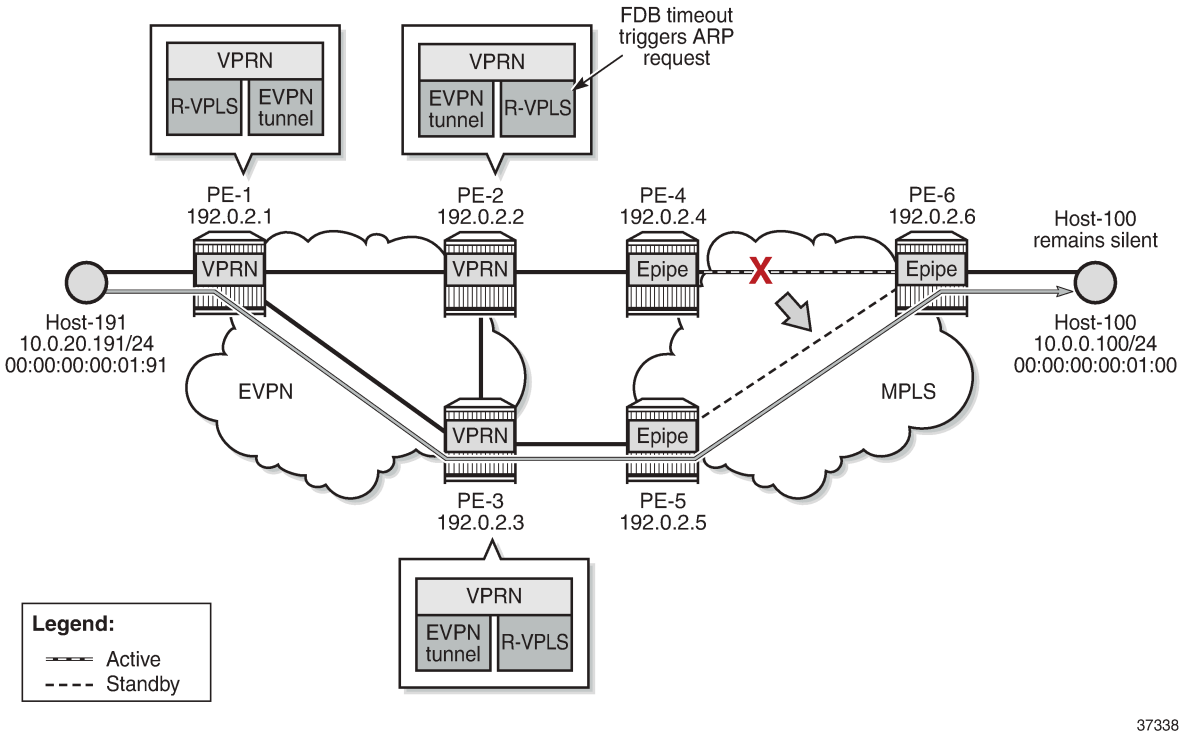
The SDP from PE-4 to PE-6 is disabled and host-100 does not send any traffic, as shown in Figure 190: Host does not send any traffic after switchover.

Figure 190: Host does not send any traffic after switchover



The following steps occur:

1. When MAC 00:00:00:00:01:00 ages out in the FDB of R-VPLS 17 on PE-2, PE-2 withdraws the EVPN-MAC routes for MAC 00:00:00:00:01:00. The update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for 10.0.0.100.

```
# on PE-2:
99 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP egressing on evi-17
   Who has 10.0.0.100 ? Tell 10.0.0.254
"
```

```
101 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 42
    Flag: 0x90 Type: 15 Len: 38 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-MAC Len: 33 RD: 192.0.2.2:17 ESI: ESI-0, tag: 0, mac len: 48
                       mac: 00:00:00:00:01:00, IP len: 0, IP: NULL, label1: 0
```

```
"
```

2. PE-2 is configured with **flood-garp-and-unknown-req true**. PE-2 floods the CPM-generated ARP request to PE-3. PE-3 forwards the ARP request to host-100.
3. Host-100 sends an ARP reply that is received by PE-3. PE-3 updates its FDB and ARP tables.
4. The FDB update on PE-3 makes PE-3 advertise an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address). The ARP update makes PE-3 advertise an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100. PE-2 receives two EVPN-MAC routes from PE-3:

```
103 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 128
    Flag: 0x90 Type: 14 Len: 83 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-MAC Len: 37 RD: 192.0.2.3:17 ESI: ESI-0, tag: 0, mac len: 48
                  mac: 00:00:00:00:01:00, IP len: 4, IP: 10.0.0.100, label1: 8388528
        Type: EVPN-MAC Len: 33 RD: 192.0.2.3:17 ESI: ESI-0, tag: 0, mac len: 48
                  mac: 00:00:00:00:01:00, IP len: 0, IP: NULL, label1: 8388528

    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:17
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:5
"
```

5. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. In the route table for VPRN "ip-vrf-16", the route for IP prefix 10.0.0.100/32 is ARP-ND host route. PE-2 receives the following RT5 route from PE-3:

```
102 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 90
    Flag: 0x90 Type: 14 Len: 45 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-IP-PREFIX Len: 34 RD: 192.0.2.3:15, tag: 0,
         ip_prefix: 10.0.0.100/32 gw_ip 0.0.0.0 Label: 8388544 (Raw Label: 0x7fffc0)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:15
        mac-nh:00:00:00:00:00:03
        bgp-tunnel-encap:MPLS
"
```

6. PE-2 receives the EVPN routes and updates its FDB and ARP tables. When the ARP entry changes its type from dynamic to EVPN, PE-2 withdraws its RT5 route.

On PE-2, the FDB for R-VPLS 17 shows an EVPN route for MAC 00:00:00:00:01:00:

IPv6 host mobility

The following use cases for IPv6 host mobility are described:

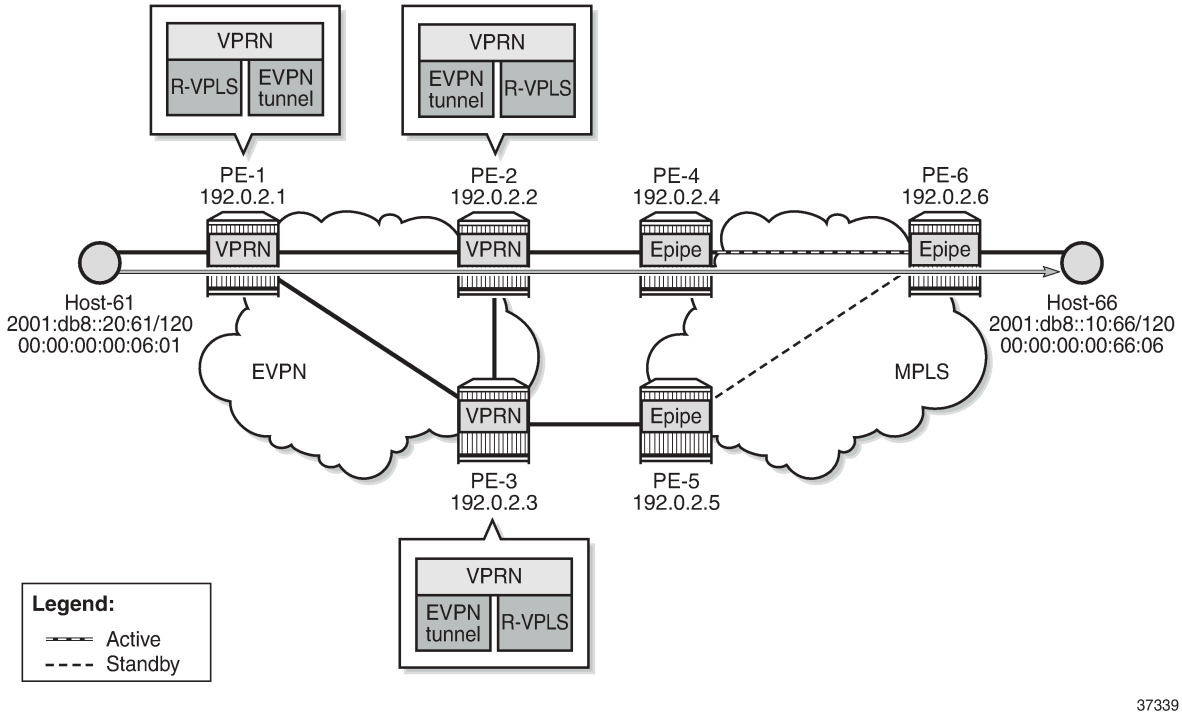
1. Host initiates an unsolicited NA message after moving
2. Host sends non-ND traffic after moving
3. Host does not send any traffic after moving

The configuration is identical in these use cases.

Figure 191: Example topology for initial forwarding path via PE-2 with IPv6 addresses shows the topology with IPv6 addresses for host-61 and host-66.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 191: Example topology for initial forwarding path via PE-2 with IPv6 addresses



The services are the following:

- R-VPLS "sbd-5" on PE-1, PE-2, and PE-3
- VPRN "ip-vrf-6" on PE-1, PE-2, and PE-3
- R-VPLS "evi-10" on PE-1; R-VPLS "evi-7" on PE-2 and PE-3
- Epipe "Epipe 7" on PE-4, PE-5, and PE-6
- Host-61 is connected to R-VPLS "evi-10" on PE-1
- Host-66 is connected to Epipe "Epipe 7" on PE-6

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        vpls "evi-10" {
            admin-state enable
            description "R-VPLS 10"
            service-id 10
            customer "1"
            routed-vpls {
            }
            sap pxc-10.a:10 {
            }
        }
        vpls "sbd-5" {
            admin-state enable
            description "R-VPLS 5"
            service-id 5
```

© 2023 Nokia.

```
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.1:5"
            }
            bgp-evpn {
                evi 5
                routes {
                    ip-prefix {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vprn "ip-vrf-6" {
            admin-state enable
            service-id 6
            customer "1"
            interface "evi-10" {
                mac 00:00:00:06:1e:20
                vpls "evi-10" {
                }
                ipv6 {
                    address 2001:db8::20:1 {
                        prefix-length 120
                    }
                }
            }
            interface "evi-5" {
                mac 00:00:00:00:06:01
                vpls "sbd-5" {
                    evpn-tunnel {
                    }
                }
                ipv6 {
                }
            }
        }
```

The service configuration on PE-2 is as follows. The service configuration on PE-3 is similar.

```
# on PE-2:
configure {
    service {
        vpls "sbd-5" {
            admin-state enable
            description "R-VPLS 5"
            service-id 5
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:5"         # on PE-3: 192.0.2.3:5
            }
            bgp-evpn {

            bgp-evpn {
                evi 7
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:7 {                                # on PE-3: sap 1/1/2:7
            }
        }
```

Debugging is enabled on PE-2 and PE-3 (in classic CLI):

```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-6"
        ip
            route-table
            icmp6 "evi-7"
            neighbor "evi-7"
        exit
    exit
exit
```

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    1034 ms  2.80 ms  4.17 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.1 ms  5.59 ms  4.95 ms
```

The following route table on PE-2 shows an ARP-ND host route for prefix 2001:db8::10:66/128:

```
[/]
A:admin@PE-2# show router 6 route-table 2001:db8::10:66

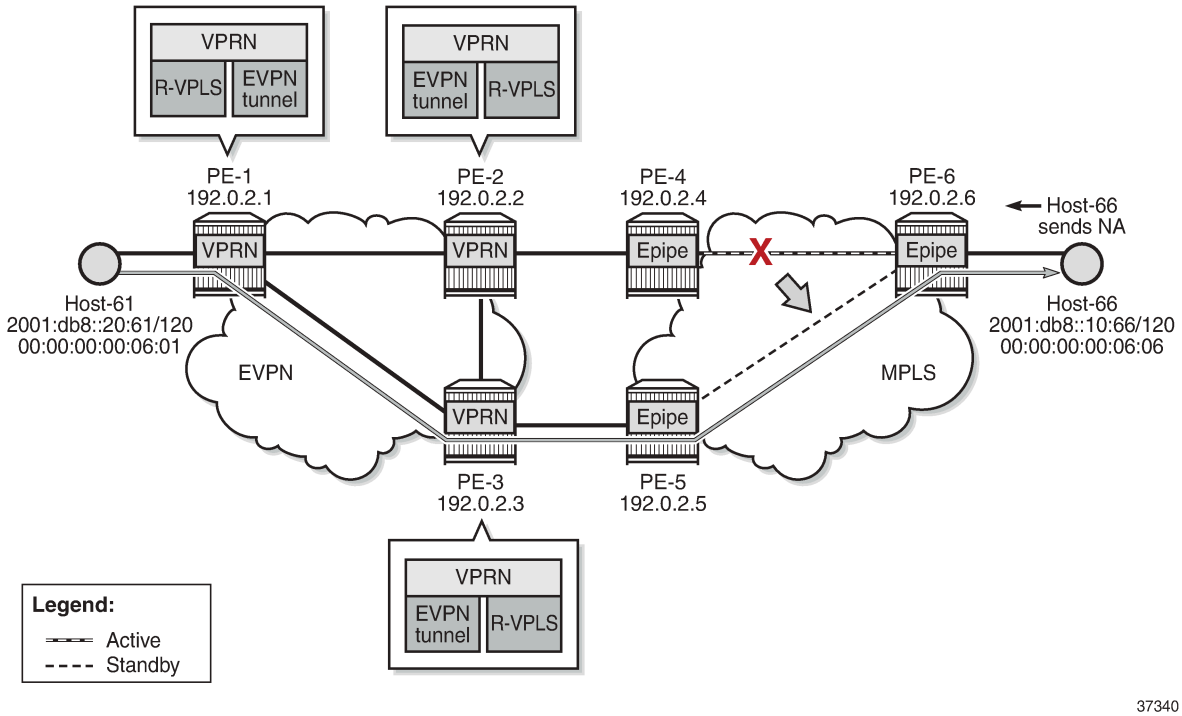
IPv6 host mobility case 1: host initiates an unsolicited NA message after moving

On PE-2 and PE-3, the **learn-unsolicited** command is configured on interface "evi-7" in VPRN "ip-vrf-6". When an unsolicited NA message is received, a stale neighbor is created. If **host-route>populate dynamic** is enabled, a confirmation message is sent for all the neighbor entries created as stale, and if confirmed, the corresponding ARP-ND routes are added to the route table.

Disabling SDP 46 on PE-4 causes a failover from the primary path via PE-4 to the secondary path via PE-5, simulating host-66 moving from PE-2 to PE-3. To trigger an unsolicited NA message from host-66, its MAC address 00:00:00:00:66:06 is replaced by MAC address 00:00:00:00:06:06. Figure 192: Host-66 sends unsolicited NA message after switchover shows that host-66 sends an unsolicited NA message.

Figure 192: Host-66 sends unsolicited NA message after switchover



Host-66 advertises its new MAC address in unsolicited NA messages. PE-3 receives the following NA messages from host-66. PE-2 also receives the NA messages, but it rejects NA messages received on interface "evi-7" when **learn-dynamic false** is configured:

```
# on PE-3:

-------------------------------------------------------------------------------
7          00:00:00:00:06:06 sap:1/1/2:7             L/90     01/28/22 13:19:56
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

PE-3 sends CPM-generated NS messages that are also flooded to the EVPN destinations. The **learn-dynamic false** command prevents PE-2 from learning MAC addresses dynamically on an EVPN connection.

PE-3 sends an EVPN-MAC update to PE-2 and MAC address 00:00:00:00:06:06 appears in the FDB on PE-2 as an EVPN entry:

```
[/]
A:admin@PE-2# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================
Forwarding Database, Service 7

```

IPv6 host mobility case 2: host sends non-ND traffic after moving,

The service configuration is the same as in the use case 1. The only difference from use case 1 is the type of message that is sent by host-66 after moving.

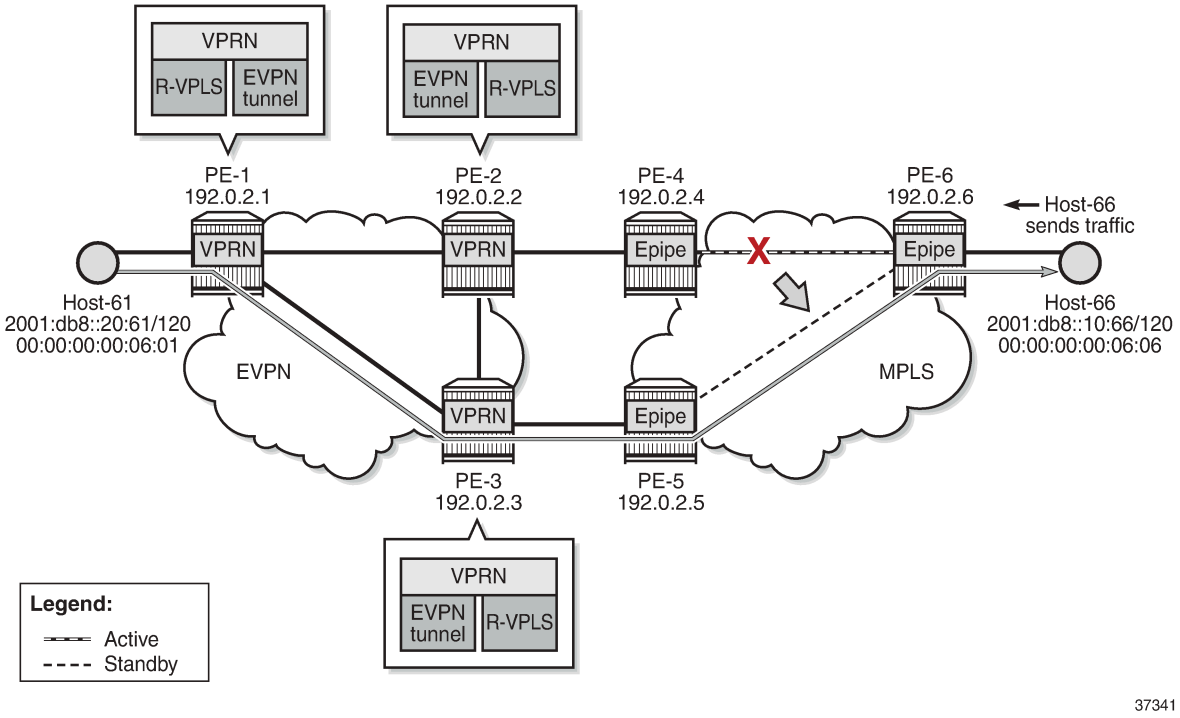
Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    7.88 ms  3.85 ms  3.67 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.0 ms  5.19 ms  5.30 ms
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A switchover from the primary path to the secondary path takes place, so host-66 moves from PE-2 to PE-3. Figure 193: Host generates non-ND traffic after switchover shows that host-66 sends non-ND traffic after moving.

Figure 193: Host generates non-ND traffic after switchover



The traceroute from host-66 to host-61 is via PE-3 (2001:db8::10:3) instead of PE-2, as follows:

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:3 (2001:db8::10:3)    7.68 ms  3.84 ms  3.65 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    5.54 ms  5.55 ms  5.64 ms
```

On PE-3, MAC address 00:00:00:00:06:06 from host-66 is learned on the local SAP 1/1/2:17:

```
[/]
A:admin@PE-3# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================

===============================================================================
```

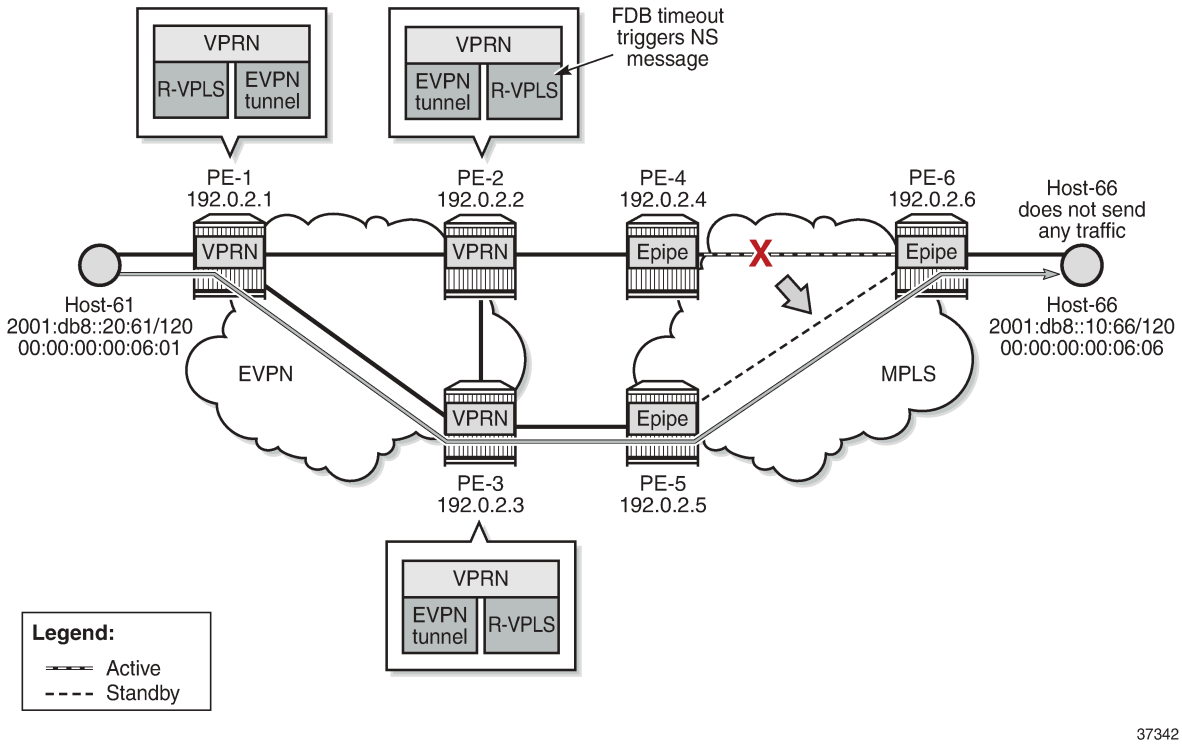
A failure is simulated, causing a failover from the primary path via PE-4 to the secondary path via PE-5. Host-66 does not send any traffic after switchover. Figure 194: Host does not send any traffic after switchover shows that PE-2 sends an NS message when the FDB entry for host-66 ages out.

Figure 194: Host does not send any traffic after switchover



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-2, MAC address 00:00:00:00:06:06 expires in the FDB for R-VPLS "evi-7", which triggers PE-2 to send an NS message for 2001:db8::10:66. This CPM-generated NS message is flooded to the EVPN destinations PE-1 and PE-3.

```
# on PE-2:
202 2022/01/28 13:37:34.634 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Sending NS for nbr addr 2001:db8::10:66 nbr type dynamic"
```

The NS message reaches host-66, which replies with an NA message. PE-3 receives the NA message and updates its FDB and ND tables. PE-2 also receives the NA message, but it rejects NA messages received on interface "evi-7" when no learn-dynamic is configured:

```
225 2022/01/28 13:37:34.638 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Ignore NA for target address 2001:db8::10:66 on evpn endpoint evi-7 because learn-dynamic is
 disabled."
```

PE-2 receives the following EVPN-MAC routes from PE-3:

```
237 2022/01/28 13:43:03.001 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

Conclusion

EVPN host mobility is supported in SR OS as described in draft-ietf-bess-evpn-inter-subnet-forwarding. This chapter describes several cases when a host moves from a source PE to a target PE within the same broadcast domain.

Operational Groups for EVPN-VXLAN VPWS Services

This chapter describes the Operational Groups for EVPN-VXLAN VPWS Services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 16.0.R5, but the MD-CLI in the current edition corresponds to SR OS Release 21.7.R1. EVPN-VXLAN VPWS and service-level operational groups for VPWS services are supported in SR OS Release 16.0.R1, or later.

Overview

Operational groups on Epipe services are used for fault propagation to other services, such as I-VPLS or R-VPLS services. Epipes with VXLAN destinations are used in some edge PE applications along with port cross-connect (PXC) so that VXLAN networks can be terminated in other VPLS or VPRN services. In such cases, the operational status of the Epipe services terminating VXLAN must override the operational status of the SAPs of the VPLS or VPRN where the Epipe is stitched to.

Operational group on egress VTEP in Epipes with static VXLAN bindings

The Static VXLAN Termination in Epipe Services chapter describes how Epipes with static VXLAN termination are stitched to I-VPLS services. In Epipes with static VXLAN bindings, operational groups can be configured in the egress VTEP context. Figure 195: Epipe with static VXLAN termination shows the example topology with a static VXLAN tunnel between PE-1 and an anycast address on PE-2 and PE-3. The All-Active Multi-Homing Ethernet Segments (AA MH ESs) "vES23_1.101" and "vES23_1.102" are used by the I-VPLSs 101 and 102, which are both stitched to Epipe 1 in PE-2 and PE-3. The SAPs in these I-VPLSs monitor the operational group configured in the egress VTEP context of the Epipe service, so the SAPs will go operationally down when the operational group of the VTEP goes operationally down.

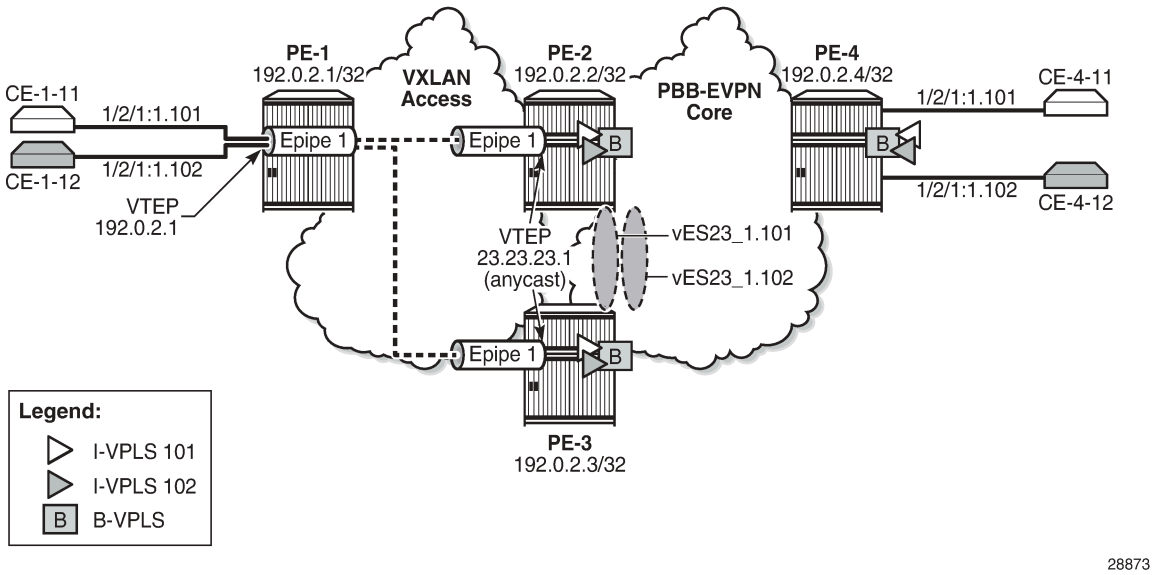
Figure 195: Epipe with static VXLAN termination



On PE-2 and PE-3, Epipe 1 is configured with static VXLAN bindings, as follows. The egress VTEP is 192.0.2.1, which is the system IP address of PE-1. Operational group "op-grp-1" in configured for this egress VTEP. LAG 2 combines PXC ports and is used to stitch Epipe 1 to the I-VPLS services 101 and 102. For a detailed description of the configuration, see the Static VXLAN Termination in Epipe Services chapter.

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap lag-2:1.* {
            }
            vxlan {
                source-vtep 23.23.23.1
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.1
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

For failure propagation to the stitched I-VPLSs, the SAPs in the I-VPLSs can monitor the operational group "op-grp-1", for I-VPLS 101 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap lag-1:1.101 {
                monitor-oper-group "op-grp-1"
            }
        }
```

When the egress VTEP prefix 192.0.2.1 disappears from the global route-table on PE-2, the VXLAN binding goes down, as follows:

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================

===============================================================================

-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

When the egress VTEP 192.0.2.1 goes down, the operational group "op-grp-1" goes down too, as follows:

```
[/]
A:admin@PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

When the operational group "op-grp-1" goes down, the monitoring SAP in I-VPLS 101 goes operationally down with flag OperGroupDown, as follows:

```
[/]
A:admin@PE-2# show service id 101 sap lag-1:1.101 detail | match 'Flags | Oper State'
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Admin State        : Up                        Oper State        : Down
Flags              : OperGroupDown
Stp Admin State    : Up                        Stp Oper State    : Down
```

When this SAP goes down, the entire I-VPLS 101 service goes down on PE-2, as follows:

```
[/]
A:admin@PE-2# show service id 101 base | match 'State'
Admin State       : Up                  Oper State        : Down
```

Epipes with static VXLAN bindings impose the following restrictions, which cannot be overcome unless a control plane protocol such as BGP-EVPN is used for the VXLAN bindings.

- When anycast VTEPs on the PEs are used, a change in the vES preference on the DF PE triggers a DF switchover for the I-VPLS service. However, the access PE (PE-1 in Figure 1) is unaware and keeps sending the VXLAN traffic to the same PE, unless a change in DF comes with an automatic change in the underlay IGP metrics, which cannot be easily accomplished.
- Without a control plane, Eth-CFM must be used between PEs and access PEs to detect end-to-end service-level failures.
- Traffic from the access PE is forwarded to the anycast VTEP, based on underlay IGP metrics. There is no control on a per-service basis.
- The architecture does not support AA MH for the Epipe service, so the access PEs always send the traffic to one single PE.

The preceding challenges can be addressed by using different VTEPs on the PEs and adding a BGP-EVPN control plane on the Epipe, as described in the next section.

Operational groups in EVPN-VXLAN Epipes

Figure 196: Epipe 2 with EVPN-VXLAN and all-active multi-homing shows EVPN-VXLAN Epipe 2 stitched to I-VPLSs 201 and 202. AA MH ESs "vES23_2.201" and "vES23_2.202" are used by the I-VPLSs 201 and 202 respectively.

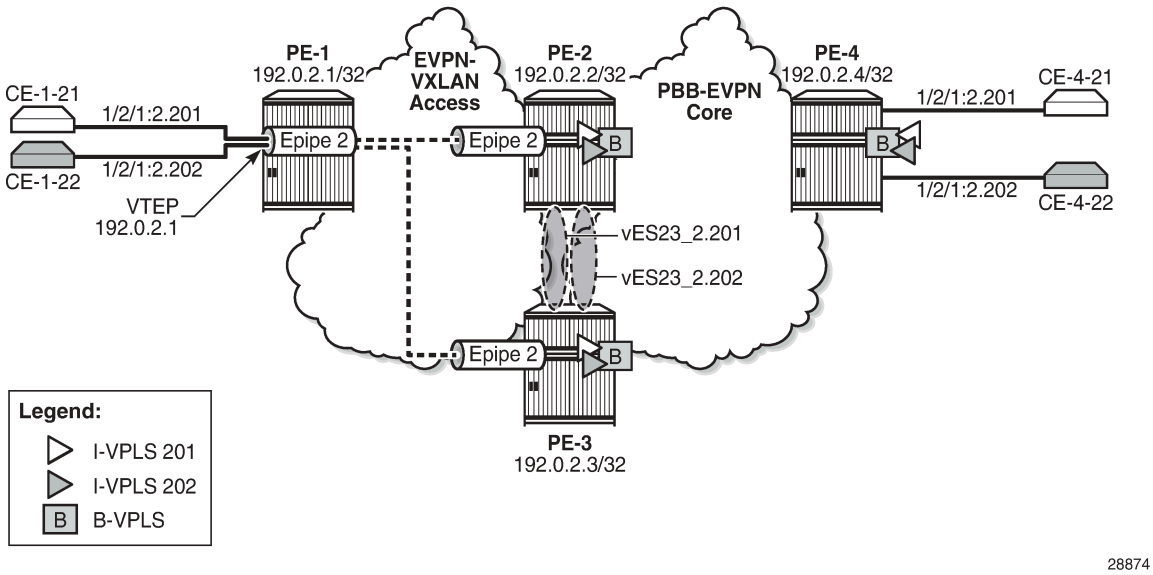
Use subject to Terms available at: www.nokia.com/terms.

Figure 196: Epipe 2 with EVPN-VXLAN and all-active multi-homing



The EVPN-VXLAN VPWS chapter describes the configuration of Epipes with EVPN-VXLAN bindings instead of static VXLAN bindings. The egress VTEP is not configured manually, but dynamically learned through BGP-EVPN. Therefore, the operational group cannot be configured in the egress VTEP context. However, it is possible to configure an operational group in an Epipe at the service level, as follows:

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-2" {
        }
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            oper-group "op-grp-2"
            bgp 1 {
            }
            sap lag-2:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

The following shows the error messages raised when attempting to configure the egress VTEP manually in an Epipe service with BGP-EVPN enabled:

```
[ex:/configure service epipe "Epipe 2" vxlan instance 1 egress-vtep]
A:admin@PE-2# ip-address 192.0.2.1

*[ex:/configure service epipe "Epipe 2" vxlan instance 1 egress-vtep]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 2" vxlan instance 1 egress-vtep ip-address -
 Inconsistent Value error - configuration incompatible with bgp-evpn - configure service epipe
 "Epipe 2" bgp-evpn
MINOR: MGMT_CORE #4001: configure service epipe "Epipe 2" vxlan instance 1 egress-vtep ip-
address - egress vtep not supported with bgp-evpn - configure service epipe "Epipe 2" bgp-evpn
```

An operational group can be associated with the entire Epipe or with specific objects, such as SAPs or spoke-SDPs, but not simultaneously. The following error is raised when attempting to associate the operational group "op-grp-2"—that is already associated with the Epipe with the SAP on PE-2:

```
[ex:/configure service epipe "Epipe 2" sap lag-2:2.*]
A:admin@PE-2# oper-group "op-grp-2"

*[ex:/configure service epipe "Epipe 2" sap lag-2:2.*]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 2" sap lag-2:2.* oper-group - Inconsistent
 Value error - cannot monitor or belong to a service oper-group within the same service -
 configure service epipe "Epipe 2" oper-group
```

The service-level operational group status is derived from the service operational status: when Epipe 2 is operationally down, the operational group "op-grp-2" will be down.

For fault propagation to the stitched I-VPLSs 201 and 202, the SAPs in the I-VPLSs monitor the operational group "op-grp-2", for I-VPLS 201 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 201" {
            admin-state enable
            service-id 201
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 201
                }
            }
            sap lag-1:2.201 {
                 monitor-oper-group "op-grp-2"
            }
        }
```

Configuration

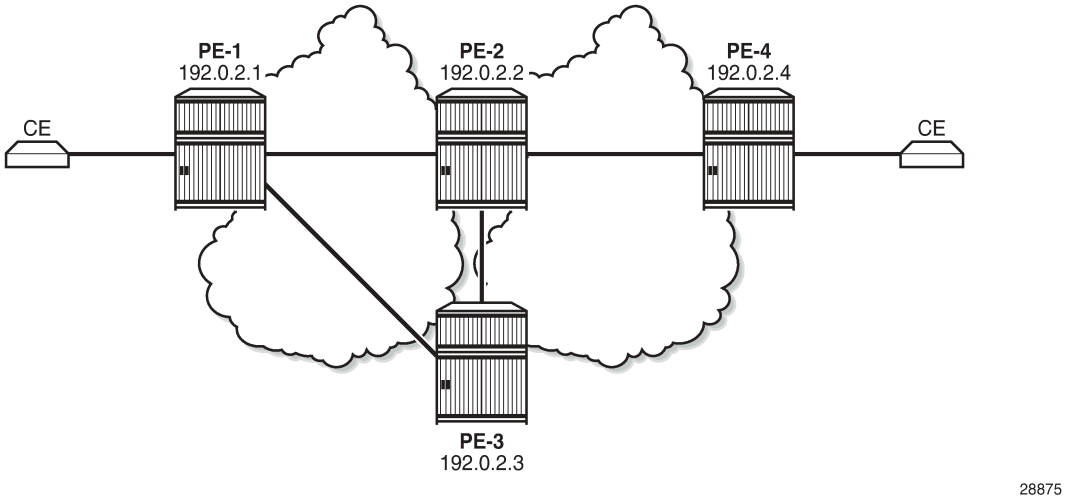
In this section, the following use cases are described:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- operational group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using Single-Active (SA) MH ESs

Figure 197: Example topology shows the example topology with four PEs in an autonomous system.

Figure 197: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (level capability 2 in the core between PE-2, PE-3, and PE-4; level capability 1 in the access toward PE-1)
- LDP between the core routers PE-2, PE-3, and PE-4

Oper group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs

When static VXLAN bindings are used, no BGP-EVPN is required in the access network to and from PE-1; BGP is only configured in the core network. When PE-2 acts as the route reflector, its BGP configuration is as follows:

```
# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-update {
                evpn true
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "CORE" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "CORE"
            }
            neighbor "192.0.2.4" {
                group "CORE"
            }
```

Figure 195: Epipe with static VXLAN termination shows that Epipe 1 is configured in the access network: on PE-1, the VTEP is the system address 192.0.2.1 (default), and on PE-2 and PE-3, the VTEP is a unicast address 23.23.23.1.

On PE-1, Epipe 1 is configured with egress VTEP 23.23.23.1, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 23.23.23.1
                    }
                }
            }
        }
```

On PE-2 and PE-3, the following unicast address is configured:

```
# on PE-2, PE-3:
configure {
    router "Base" {
        interface "lo23" {
            loopback
            ipv4 {
                primary {
                    address 23.23.23.0
                    prefix-length 31
                }
            }
```

On PE-2 and PE-3, three ports are configured as PXC. PXC 1 is used as Forwarding Path Extension (FPE) and the VXLAN tunnel termination 23.23.23.1 is configured with this FPE, as follows:

```
# on PE-2, PE-3:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        system {
            vxlan {
                tunnel-termination 23.23.23.1 {
                    fpe-id 1
                }
            }
```

PXCs 2 and 3 are used in the internal LAGs that are used to stitch Epipe 1 to I-VPLSs 101 and 102, as follows. LAG "lag-1" will be used in the I-VPLS services; LAG "lag-2" in the Epipe services.

```
# on PE-2, PE-3:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-2.a {
        }
        port pxc-3.a {
        }
    }
    lag "lag-2" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-2.b {
        }
        port pxc-3.b {
        }
    }
```

On PE-2 and PE-3, Epipe 1 is configured with source VTEP 23.23.23.1 and egress VTEP 192.0.2.1, as follows. The operational group "op-grp-1" is associated with the egress VTEP. The SAP stitches Epipe 1 to the I-VPLSs 101 and 102.

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap lag-2:1.* {
            }
            vxlan {
                source-vtep 23.23.23.1
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.1
                        oper-group "op-grp-1"
                    }
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

On PE-2, B-VPLS 100 is configured as follows. The configuration is similar on PE-3 and PE-4.

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS-100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 1532
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:02
                    use-es-bmac-lsb true
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

On PE-2, I-VPLS 101 is configured as follows. The SAP monitors the operational group "op-grp-1" that is configured in Epipe 1. The AA MH ES "vES23_1.101" is used. The configuration of I-VPLS 102 is similar, but it uses AA MH ES "vES23_1.102" with preference value 50 instead. On PE-3, the preference values are reversed: preference value 50 for "vES23_1.101" and 100 for "vES23_1.102".

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_1.101" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000111
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 100
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                                    s-tag-c-tag 1 c-tag-start 101 {
                                        c-tag-end 101
                                    }
                                }
                            }
                        }
                    }
                    pbb {
                        source-bmac-lsb 0x2311
                    }
                }
            }
        }
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap lag-1:1.101 {
                monitor-oper-group "op-grp-1"
            }
        }
```

On PE-4, I-VPLS 101 is configured as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap 1/2/1:1.101 {
            }
        }
```

To emulate a failure that affects the operational state of the egress VTEP (and also of the Epipe service), the SAP of Epipe 1 on PE-2 is disabled, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 1" {
            sap lag-2:1.* {
                admin-state disable
```

When the SAP is operationally down, Epipe 1 goes down, as follows:

```
[/]
A:admin@PE-2# show service id 1 base | match 'State'
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Admin State       : Up                  Oper State        : Down
```

The egress VTEP 192.0.2.1 is operationally down, as follows:

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================

===============================================================================
BGP EVPN VXLAN ES Dest
===============================================================================
I Eth Seg Id                    TEP Address       VNI       Last Changed
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

The operational group "op-grp-1" is associated with the egress VTEP, so it goes operationally down, as follows:

```
[/]
A:admin@PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

This operational group is monitored by the SAPs in I-VPLSs 101 and 102, so these SAPs go down with flag OperGroupDown; for example, for I-VPLS 101 on PE-2:

```
[/]
A:admin@PE-2# show service id 101 sap lag-1:1.101 detail | match 'Flags'
Flags              : OperGroupDown
```

When the SAP goes down, the I-VPLS service goes down, as follows:

```
[/]
A:admin@PE-2# show service id 101 base | match 'State'
Admin State       : Up                  Oper State        : Down
```

Even though Epipe 1 on PE-2 is operationally down while Epipe 1 on PE-3 is up, PE-1 is unaware because the VXLAN destination in Epipe 1 remains up, as follows:

```
[/]
```

```

Traffic from the CEs attached to PE-1 is forwarded by PE-1 to PE-2, where it is dropped.

Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using AA MH ESs

BGP must be enabled on all nodes for the EVPN address family, also in the access to and from PE-1. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            vpn-apply-export true
            rapid-update {
                evpn true
            }
            group "ACCESS" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
            }
            neighbor 192.0.2.2 {
                group "ACCESS"
            }
            neighbor 192.0.2.3 {
                group "ACCESS"
            }
```

On PE-1, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 101 and remote Ethernet tag 123.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/2/1:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                remote-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

On PE-2, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 123 and remote Ethernet tag 101. The operational group "op-grp-2" is associated with Epipe 2. The configuration on PE-3 is identical.

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-2" {
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            oper-group "op-grp-2"
            bgp 1 {
            }
            sap lag-2:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration of B-VPLS 100 remains unchanged and the configuration of the I-VPLSs 201 and 202 resembles the configuration of VPLSs 101.

When there is no failure, the egress VTEP for Epipe 2 on PE-1 is 192.0.2.2, which is the system IP address of PE-2, as follows:

```
[/]
A:admin@PE-1# show service id 2 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------

To emulate a failure that affects the operational state of the Epipe service, the SAP in Epipe 2 is disabled, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 2" {
            sap lag-2:2.* {
                admin-state disable
```

When the SAP goes down, the Epipe goes down, as follows:

```
[/]
A:admin@PE-2# show service id 2 base | match 'State'
Admin State       : Up                 Oper State        : Down
```

On PE-1, the egress VTEP for Epipe 2 is 192.0.2.3, which is the system IP address of PE-3, as follows:

```
[/]
A:admin@PE-1# show service id 2 vxlan destinations

===============================================================================

```

The SAPs in I-VPLSs 201 and 202 go down with the OperGroupDown flag, as follows:

```
[/]
A:admin@PE-2# show service id 201 sap lag-1:2.201 detail | match 'Flags'
Flags              : OperGroupDown

[/]
A:admin@PE-2# show service id 202 sap lag-1:2.202 detail | match 'Flags'
Flags              : OperGroupDown
```

When the SAPs go down, the I-VPLSs 201 and 202 also go down, as follows:

```
[/]
A:admin@PE-2# show service id 201 base | match 'State'
Admin State       : Up                 Oper State        : Down

[/]
A:admin@PE-2# show service id 202 base | match 'State'
Admin State       : Up                 Oper State        : Down
```

Even with this failure on PE-2, traffic can still flow between the CEs, as follows:

```
[/]
A:admin@PE-4# ping 172.16.21.11 router-instance "VPRN 21" interval 0.1 output-format summary
PING 172.16.21.11 56 data bytes
!!!!!
---- 172.16.21.11 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 3.40ms, avg = 4.02ms, max = 4.57ms, stddev = 0.388ms
```

The following FDB for I-VPLS 201 on PE-4 shows that MAC address 00:ca:fe:00:21:11 of CE-1-21 is reachable via AA MH ES with ES-BMAC 00:00:00:00:23:21:

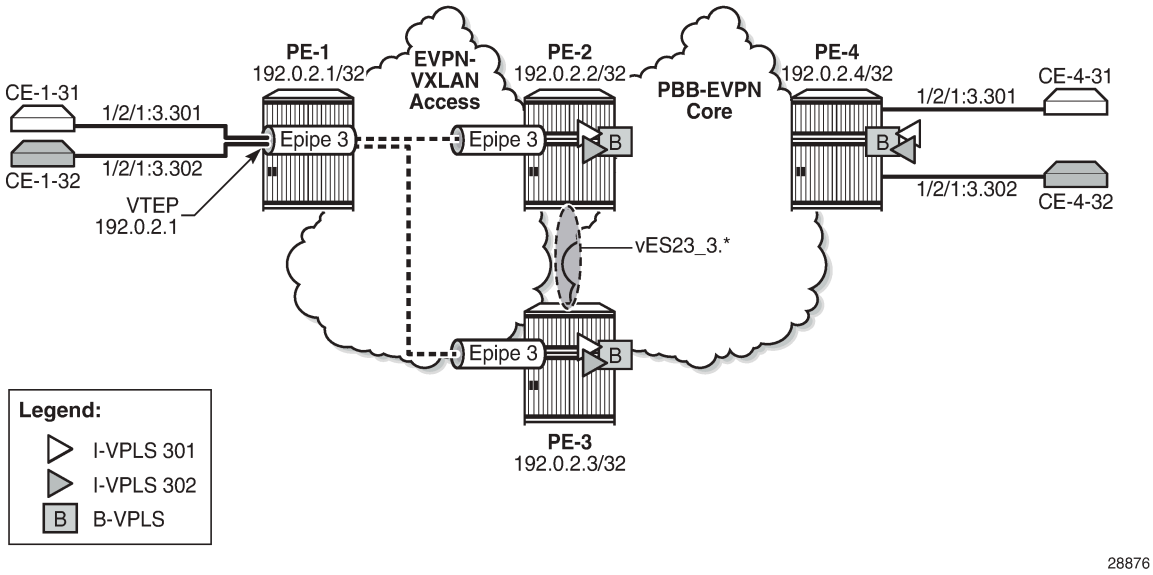
Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using SA MH ESs

Figure 198: Epipe 3 with EVPN-VXLAN and SA MH ES shows the example topology with an SA MH ES used by the I-VPLSs.

Figure 198: Epipe 3 with EVPN-VXLAN and SA MH ES



The configuration of Epipe 3 resembles the configuration of Epipe 2: the same Ethernet tags are used, only the VNI, EVI, and SAPs are different.

On PE-2 and PE-3, PXC 4 is configured to stitch Epipe 3 to I-VPLSs 301 and 302. The PXC port will be used in the SA MH ES.

On PE-2 and PE-3, Epipe 3 is configured as follows:

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-3" {
        }
        epipe "Epipe 3" {
            admin-state enable
            description "EVPN-VXLAN Epipe 3"
            service-id 3
            customer "1"
            oper-group "op-grp-3"
            sap pxc-4.b:3.* {
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            vxlan {
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

On PE-2, I-VPLS 301 uses SA MH ES "vES23_3.*", and is configured as follows.

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-3" {
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_3.*" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000301
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 100
                                }
                            }
                        }
                        association {
                            port pxc-4.a {
                                virtual-ranges {
                                    qinq {
                                        s-tag 3 {
                                            end 3
                                        }
                                    }
                                }
                            }
                        }
                        pbb {
                            source-bmac-lsb 0x2334
                        }
                    }
                }
            }
        }
        vpls "I-VPLS 301" {
```

Conclusion

Some service providers use VXLAN as a next-generation access technology used between the MSANs (or access PEs) and core PE routers. EVPN-VXLAN Epipes can be stitched using PXC to other services, such as I-VPLS. Operational groups can be defined in the Epipe for fault propagation to the SAPs of the services where the Epipe is stitched to.

Operational Groups in EVPN Services

This chapter provides information about Operational Groups in EVPN Services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R1. EVPN operational groups are supported in EVPN-VXLAN and EVPN-MPLS VPLS and R-VPLS services in SR OS Release 19.10.R2 and later; in EVPN-MPLS Epipes in SR OS Release 19.5.R1 and later.

Overview

An operational group includes objects and drives the status of service endpoints (such as pseudowires, SAPs, IP interfaces) located in the same or in different service instances. The operational group status is derived from the status of the individual components. Other service objects can monitor the operational group status. The status of the operational group influences the status of the monitoring objects.

If the operational group goes down, the monitoring objects are also brought operationally down. When one of the objects included in the operational group comes up, the entire operational group comes up, as well as the monitoring objects.

Operational groups for EVPN destinations

Figure 199: EVPN mesh going down triggers DF switchover from PE-5 to PE-4 shows a sample topology with VPLS 1 configured on all nodes. PE-4 and PE-5 share a single-active Ethernet Segment (ES) "ESI-45_1" where PE-5 is the Designated Forwarder (DF).

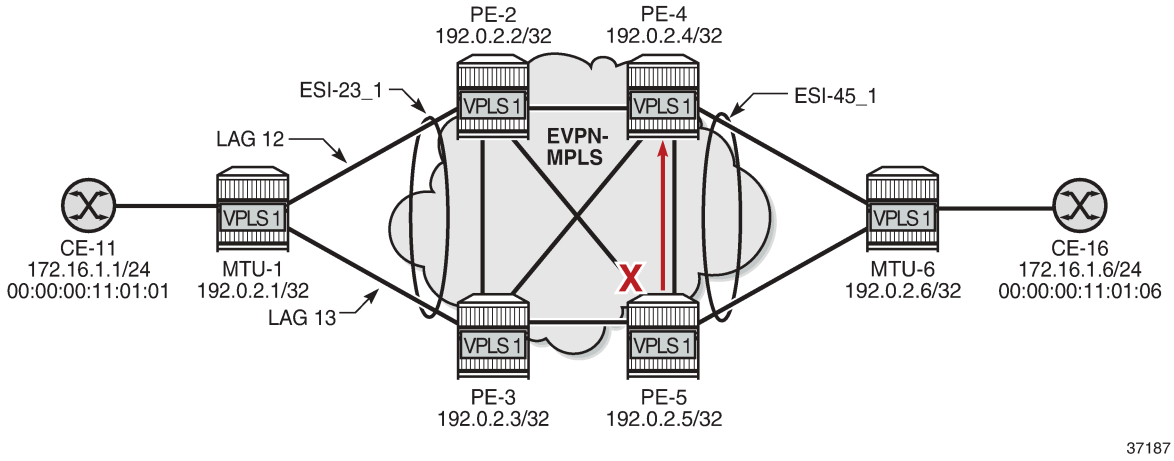
Use subject to Terms available at: www.nokia.com/terms.

Figure 199: EVPN mesh going down triggers DF switchover from PE-5 to PE-4



When the EVPN-VPLS service becomes isolated from the rest of the EVPN network (for example, all EVPN destinations are removed on DF PE-5), an operational group for EVPN destinations is required to trigger a DF switchover and bring the monitoring access SAP (or spoke SDP) down. EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. Ethernet Connectivity Fault Management (ETH-CFM) is enabled on a down Maintenance Endpoint (MEP) configured on the SAP to detect SAP failure. After the remote MEP on MTU-6 detects the failure, MTU-6 redirects its traffic to PE-4. This avoids blackholes when PE-5 is disconnected from the EVPN core.

On PE-5, VPLS 1 is configured with operational group "vpls-1_45" in EVPN-MPLS and SAP 1/1/2:1 monitoring this operational group. The operational group configured under a BGP-EVPN instance cannot be configured under any other object, such as SAPs or SDP-bindings.

```
# on PE-5:
configure {
    service {
        oper-group "vpls-1_45" {
            hold-time {
                down 0
                up 0
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                routes {
                    mac-ip {
                        cfm-mac true
                    }
                }
                mpls 1 {
                    admin-state enable
                    oper-group "vpls-1_45"
                    auto-bind-tunnel {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        resolution any
                    }
                }
            }
            sap 1/1/2:1 {
                description "to MTU-6"
                monitor-oper-group "vpls-1_45"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-11" mep-id 56 {
                        admin-state enable
                        mac-address 00:00:00:00:56:05
                        fault-propagation suspend-ccm
                        ccm true
                    }
                }
            }
        }
```

Using operational groups in the EVPN service, it is possible to monitor if the PE is isolated and, if it is, trigger a Designated Forwarder switchover. The operational group associated with the EVPN-MPLS instance goes down in the following cases:

- bgp-evpn mpls is disabled
- VPLS is disabled
- all EVPN destinations associated with the instance are removed, for example, when:
  - no tunnels are available for auto-bind-tunnel resolution
  - the network ports facing the EVPN ports are down
  - the BGP sessions to the route reflector or PEs are down

Operational groups for Ethernet Segments (Port-active multi-homing)

Operational groups can be configured on single-active ESs that need to function as port-active multi-homing Ethernet Segments. 'Port-active' refers to a special single-active mode where the PE is DF or non-DF for all the services attached to the ES. The configuration of a port-active ES is as follows:

```
# on PE-2:
configure {
    service {
        oper-group "vpls-1_23" {
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23_1" {
                        admin-state enable
                        esi 01:23:00:00:00:00:01:00:00:00
                        multi-homing-mode single-active
                        oper-group "vpls-1_23"
                        ac-df-capability exclude
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                                preference {
                                    value 150              # on PE-3: value 100
                                }
                            }
                        }
                        association {
                            lag "lag-12" {                 # on PE-3: lag 13
                            }
                        }
                    }
                }
            }
        }
```

This ES operational group "vpls-1_23" can be monitored on the LAG:

```
# on PE-2:
configure {
    lag "lag-12" {
        admin-state enable
        description "to MTU-1"
        encap-type dot1q
        mode access
        standby-signaling lacp                      # default value
        monitor-oper-group "vpls-1_23"
        max-ports 64
        lacp {
            mode active
            system-id 00:00:00:01:02:01
            system-priority 1
            administrative-key 1
        }
        port 1/1/2 {
        }
    }
```

When the operational group is configured on the ES and monitored on the associated LAG:

- The status of the ES operational group is driven by the ES DF status.
  - When a node becomes NDF, the ES operational group goes down and all the SAPs in the ES go down.
- The ES operational group goes down when all the SAPs in the ES go down.
  - When all SAPs in the ES go down, the operational group goes down and the node becomes NDF.

The monitoring LAG goes down when the ES operational group is down. The LAG signals the LAG standby state to the access node. The LAG standby signaling can be configured as **lacp** or **power-off.**

```
*[ex:/configure lag "lag-12"]
A:admin@PE-2# standby-signaling ?

 standby-signaling <keyword>
 <keyword>  - (lacp|power-off)
Default    - lacp

    Way of signaling a member port to the remote side
```

- **standby-signaling lacp** signals LACP out-of-sync to the CE when the application layer instructs the LAG to become standby
- **standby-signaling power-off** brings the LAG members down, and hence the access SAPs down

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The ES and AD routes for the ES are not withdrawn because the router recognizes that the LAG becomes standby due to the ES operational group.

Some restrictions:

- Multi-chassis LAG and ES are mutually exclusive:

```
*[ex:/configure redundancy multi-chassis peer 192.0.2.2 mc-lag lag "lag-13"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure lag "lag-13" - invalid combination mc-lag <-> monitor-
oper-group
```

- LAG sub-groups are blocked:

```
*[ex:/configure lag "lag-13" port 1/1/1]
A:admin@PE-3# sub-group 2

*[ex:/configure lag "lag-13" port 1/1/1]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure lag "lag-13" port 1/1/1 - invalid combination port sub-
group <-> monitor-oper-group - configure lag "lag-13" monitor-oper-group
```

- Only LAGs in access mode can monitor operational groups:

```
*[ex:/configure lag "lag-3"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #3001: configure lag "lag-3" mode - monitor-oper-group not allowed when lag
 is not access
```

- Operational groups cannot be assigned to virtual ESs:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" association lag "lag-5"
 virtual-ranges dot1q q-tag 1]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "vESI-23_1" oper-
group - Inconsistent Value error - ethernet-segment oper-group not supported with virtual
 ethernet-segment
```

- Operational groups cannot be assigned to all-active ESs:

```
*[ex:/configure service system bgp evpn]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "AA_ESI-23_1" oper-
group - Inconsistent Value error - all-active multi-homing not supported with ethernet-
segment oper-group
```

- Operational groups cannot be assigned to ESs with service-carving auto:

```
*[ex:/configure service system bgp evpn]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "ESI-23_auto" oper-
group - Inconsistent Value error - ethernet-segment oper-group not supported with service-
carving-mode auto
```

Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM. However, not all access nodes support ETH-CFM and, in that case, LAG **standby-signaling lacp** or **power-off** can be used instead.

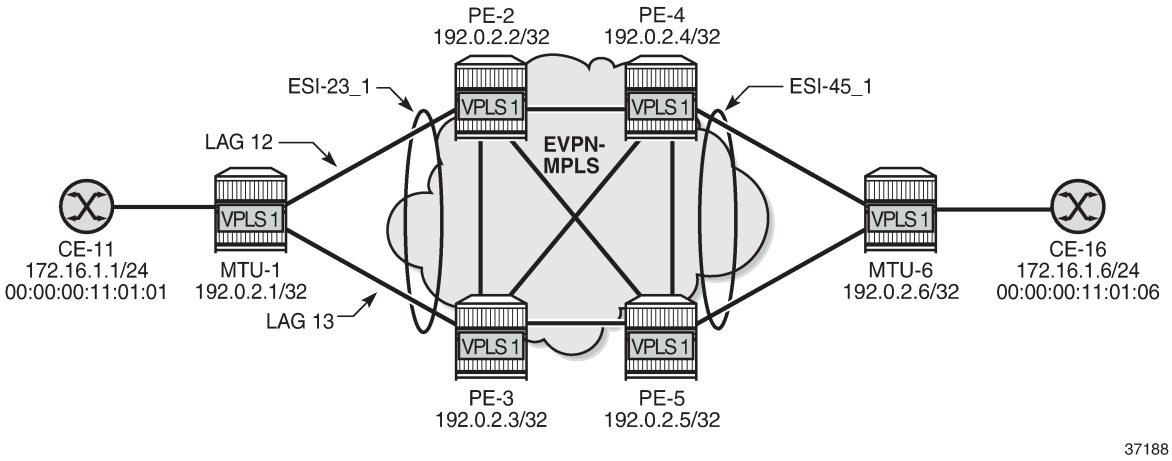
Configuration

Figure 200: Sample topology with VPLS 1 shows the sample topology with VPLS 1 configured on all nodes.

Figure 200: Sample topology with VPLS 1



The initial configuration includes:

- Cards, MDAs, ports
- LAG 12 between PE-1 and PE-2; LAG 13 between PE-1 and PE-3
- Router interfaces between PE-2, PE-3, PE-4, and PE-5
- IS-IS on all router interfaces
- LDP between PE-2, PE-3, PE-4, and PE-5
- BGP between PE-2, PE-3, PE-4, and PE-5

For BGP, PE-2 acts as route reflector and the configuration is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

Operational groups for EVPN destinations

On PE-4, single-active ES "ESI-45_1" is configured with service carving auto. Operational group "vpls-1_45" is associated with EVPN-MPLS in VPLS 1 and SAP 1/1/1:1 is monitoring that operational group. ETH-CFM is enabled on a down MEP configured on the SAP to detect SAP failures. The service configuration is as follows:

```
# on PE-4:
configure {
    service {
        oper-group "vpls-1_45" {
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45_1" {
                        admin-state enable
                        esi 01:45:00:00:00:00:01:00:00:00
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            port 1/1/1 {
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                routes {
                    mac-ip {
                        cfm-mac true
                    }
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                mpls 1 {
                    admin-state enable
                    oper-group "vpls-1_45"
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:1 {
                description "to MTU-6"
                monitor-oper-group "vpls-1_45"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-10" mep-id 46 {
                        admin-state enable
                        mac-address 00:00:00:00:46:04
                        ccm true
                    }
                }
            }
        }
```

The configuration on PE-5 is similar.

On MTU-6, VPLS 1 is configured with three SAPs: SAP 1/1/2:1 toward PE-4, SAP 1/1/1:1 toward PE-5, and SAP 1/2/1:1 toward CE-16. ETH-CFM MEPs are configured on SAP 1/1/1:1 and SAP 1/1/2:1. The service configuration is as follows:

```
# on MTU-6:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/1:1 {
                description "to PE-5"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-11" mep-id 65 {
                        admin-state enable
                        mac-address 00:00:00:00:65:06
                        ccm true
                    }
                }
            }
            sap 1/1/2:1 {
                description "to PE-4"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-10" mep-id 64 {
                        admin-state enable
                        mac-address 00:00:00:00:64:06
                        ccm true
                    }
                }
            }
            sap 1/2/1:1 {
                description "to CE-16"
            }
        }
```

Initial situation without failure

On MTU-6, ETH-CFM MEP 65 receives Continuity Check (CC) messages from its remote peer 56 on PE-5:

```
[/]
A:admin@MTU-6# show eth-cfm mep 65 domain 1 association 11 all-remote-mepids

================================================================================
Eth-CFM Remote-Mep Table
================================================================================
R-mepId AD Rx CC RxRdi Port-Tlv If-Tlv Peer Mac Addr     CCM status since
--------------------------------------------------------------------------------
56         True  False Absent   Absent 00:00:00:00:56:05 12/23/2021 16:59:01
================================================================================
Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

The following command shows that PE-5 is DF for VPLS 1:

```
[/]
A:admin@PE-5# show service id 1 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
1/1/2:1               ESI-45_1                        DF
===============================================================================
No sdp entries
No vxlan instance entries
```

PE-5 has full mesh with all EVPN destinations in VPLS 1:

```
[/]
A:admin@PE-5# show service id 1 evpn-mpls

Avoiding blackholes when EVPN destinations are removed

On PE-5, a failure is simulated by disabling LDP:

```
# on PE-5:
configure exclusive
    router "Base" {
        ldp {
            admin-state disable
            commit
```

With LDP disabled, PE-5 has no tunnels available for auto-bind-tunnel in VPLS 1 and all EVPN destinations are removed, as follows:

```
[/]
A:admin@PE-5# show service id 1 evpn-mpls

```

Finally, the failure is restored by re-enabling LDP on PE-5:

```
# on PE-5:
configure exclusive
    router "Base" {
        ldp {
            admin-state enable
            commit
```

Operational groups for ES (Port-Active Multi-Homing)

On PE-2 and PE-3, operational group vpls-1_23 is configured and associated with ES " ESI-23_1", but not configured or monitored in VPLS 1. The service configuration on PE-3 is as follows:

```
# on PE-3:
configure {
    service {
        oper-group "vpls-1_23" {
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
```

                            manual {
                                preference {
                                    value 100           # on PE-2: value 150
                                }
                            }
                        }
                        association {
                            lag "lag-13" {
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-13:1 {                          # on PE-2: sap lag-12:1
                description "to MTU-1"
            }
        }
```

LAG 12 on PE-2 and LAG 13 on PE-3 monitor operational group "vpls-1_23". The **monitor-oper-group** command can be added to the LAG:

```
# on PE-3:
configure {
    lag "lag-13" {
        admin-state enable
        description "to MTU-1"
        encap-type dot1q
        mode access
        standby-signaling lacp      # default value
        monitor-oper-group "vpls-1_23"
        max-ports 64
        lacp {
            mode active
            system-id 00:00:00:01:03:01
            system-priority 1
            administrative-key 1
        }
        port 1/1/1 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

Note:
In this example, MTU-1 is connected to PE-2 and PE-3 through two different LAGs, however, this port-active multi-homing mode also supports the use of a single LAG on MTU-1. If a single LAG was used on MTU-1, the LAG ports on PE-2 and PE-3 must be configured with the same LACP parameters (administrative-key, system-id and system-priority) to ensure that PE-2 and PE-3 show themselves as a single system to MTU-1.

EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. In this port-active multi-homing mode, ETH-CFM is not used, and other notification mechanisms are needed, such as LAG standby signaling (**lacp** or **power-off**). When the EVPN application layer instructs the LAG to become standby as a result of the NDF status, the behavior is as follows:

- the **lacp** option signals LACP out-of-sync to MTU-1
- the **power-off** option brings down the LAG ports connected to MTU-1

MTU-1 is connected to PE-2 and PE-3 using two different access LAGs with encapsulation dot1q and at least one port in each LAG. Any encapsulation type is supported in the LAGs. The LAG configuration is as follows:

```
# on MTU-1:
configure {
    lag "lag-12" {
        admin-state enable
        description "to PE-2"
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32768
        }
        port 1/1/1 {
        }
    }
    lag "lag-13" {
        admin-state enable
        description "to PE-3"
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32769
        }
        port 1/1/2 {
        }
    }
```

On MTU-1, VPLS 1 is configured as follows:

```
# on MTU-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
```

© 2023 Nokia.

```
            customer "1"
            sap 1/2/1:1 {
                description "to CE-11"
            }
            sap lag-12:1 {
                description "to PE-2"
            }
            sap lag-13:1 {
                description "to PE-3"
            }
        }
```

Initial situation without failures

PE-2 is DF for VPLS 1:

```

DF switchover

To trigger a DF switchover, the preference value is modified on PE-2, as follows:

```
# on PE-2:
configure exclusive
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23_1" {
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 50
                                }
                            }
                        }
```

Figure 201: DF switchover in single-active ESI-23_1 shows a DF switchover from PE-2 to PE-3. PE-2 becomes the NDF and LAG 12 is in standby.

Figure 201: DF switchover in single-active ESI-23_1

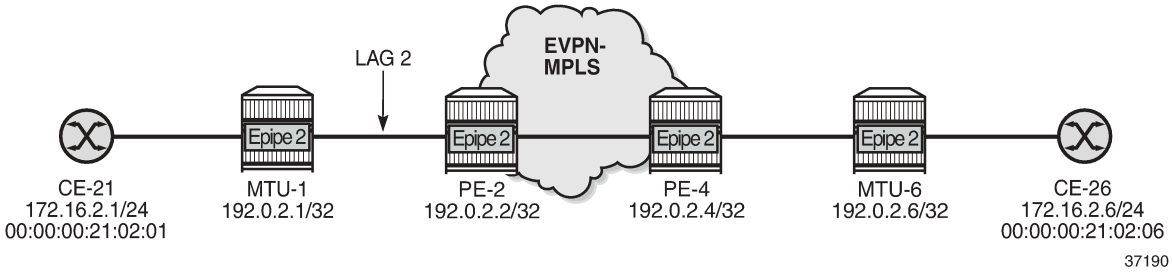
Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM, but also using LAG **standby-signaling lacp** or **power-off**.

Figure 202: Sample topology with Epipe 2 shows the sample topology with Epipe 2.

Figure 202: Sample topology with Epipe 2



The configuration on MTU-1 is as follows:

```
# on MTU-1:
configure {
    lag "lag-2" {
        admin-state enable
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            administrative-key 32770
        }
        port 1/1/5 {
        }
    }
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap 1/2/1:2 {
            }
            sap lag-2:2 {
            }
        }
```

On PE-2, operational group "llf-1" is configured and associated to EVPN-MPLS. LAG 2 monitors this operational group.

```
# on PE-2:
configure {
    lag "lag-2" {
        admin-state enable
        encap-type dot1q
        mode access
        standby-signaling lacp
        monitor-oper-group "llf-1"
        max-ports 64
        lacp {
            mode active
```

```
            system-id 00:00:00:00:12:01
            system-priority 1
            administrative-key 2
        }
        port 1/1/5 {
        }
    }
    service {
        oper-group "llf-1" {
            hold-time {
                down 0
                up 0
            }
        }
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap lag-2:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-1_2" {
                    eth-tag 12
                }
                remote-attachment-circuit "ac-6_2" {
                    eth-tag 62
                }
                mpls 1 {
                    admin-state enable
                    oper-group "llf-1"
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The configuration on PE-4 is as follows:

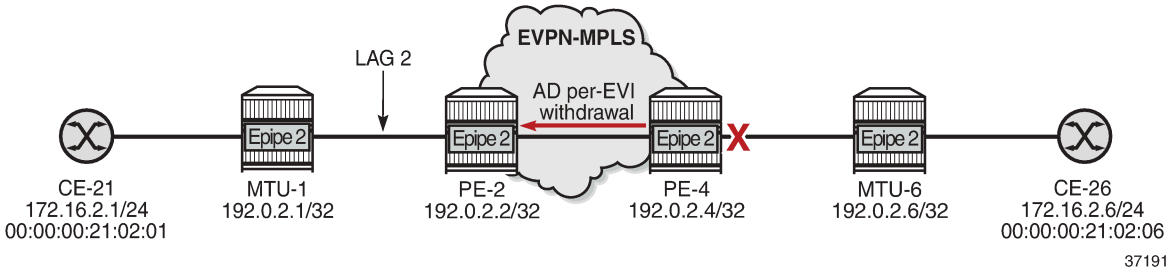
```
# on PE-4:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/5:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-6_2" {
                    eth-tag 62
                }
                remote-attachment-circuit "ac-1_2" {
                    eth-tag 12
                }
                mpls 1 {
                    admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

Figure 203: LLF in Epipe 2 - PE-4 failure shows when a failure occurs on PE-4.

Figure 203: LLF in Epipe 2 - PE-4 failure



The failure is simulated on PE-4 by disabling port 1/1/5 toward MTU-6.

```
# on PE-4:
configure exclusive
    port 1/1/5 {
        admin-state disable
        commit
```

When the link between PE-4 and MTU-6 fails, PE-4 withdraws the AD per-EVI route for Epipe 2. PE-2 receives the following AD per-EVI withdrawal from PE-4:

```
155 2021/12/23 17:18:37.217 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 34
    Flag: 0x90 Type: 15 Len: 30 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:2 ESI: ESI-0, tag: 62
              Label: 0 (Raw Label: 0x0) PathId:
"
```

Upon receiving this AD per-EVI route, Epipe 2 goes operationally down on PE-2:

```
[/]
A:admin@PE-2# show service id 2 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

Operational group "llf-1" goes down when the Epipe is operationally down:

```
[/]
A:admin@PE-2# show lag 2 detail | match "per group"
Monitor oper group  : llf-1
Oper group status   : down
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-2, the detailed information for operational group "llf-1" shows that the operational group and the monitoring LAG are down.

```
[/]
A:admin@PE-2# show service oper-group "llf-1" detail

```

PE-2 signals the fault based on the configuration of the LAG standby signaling:

- If the LAG standby signaling is power-off, PE-2 brings down the ports in the LAG.
- If the LACP standby signaling is configured, PE-2 signals an LACP out-of-sync on the LAG ports.

In either case, MTU-1 stops forwarding traffic to PE-2.

The following debug message in log 99 on MTU-1 shows that MTU-1 received an LACP out-of-sync message for port 1/1/5 of LAG 2:

```
154 2021/12/23 17:18:37.216 CET WARNING: LAG #2007 Base LAG
"LAG lag-2 : partner oper state bits changed on member 1/1/5 : [sync TRUE -> FALSE] [collecting
 TRUE -> FALSE]"
```

The following debug messages in log 99 on MTU-1 show that LAG 2 and interface 1/1/5 are not operational:

```
156 2021/12/23 17:18:37.217 CET WARNING: SNMP #2004 Base lag-2
"Interface lag-2 is not operational"

155 2021/12/23 17:18:37.216 CET WARNING: SNMP #2004 Base 1/1/5
"Interface 1/1/5 is not operational"
```

    lag-2
===============================================================================
```

Conclusion

Operational groups can be useful in EVPN services to avoid blackholes when a PE is disconnected from the EVPN core. Failures can be propagated by the PEs to access nodes, either by ETH-CFM or LAG standby signaling.

P2MP mLDP FEC Resolution for BGP-LU in EVPN

This chapter provides information about P2MP mLDP FEC Resolution for BGP-LU in EVPN.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 16.0.R3, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Recursive and non-recursive multicast Label Distribution Protocol (mLDP) Forwarding Equivalence Class (FEC) resolution for BGP Labeled Unicast (BGP-LU) is supported in SR OS Release 15.0.R1 or later; see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

In SR OS Release 15.0.R4, and later, a leaf node in an MVPN can generate non-recursive mLDP mapping messages even if the root IP address is resolved using BGP-LU, without the need to leak BGP routes to IGP and LDP. In SR OS Release 16.0.R1, this is also supported for EVPN-MPLS services.

Overview

In inter-AS and intra-AS scenarios, recursive and non-recursive FEC label mapping messages can be used to set up the mLDP tree. In the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter, recursive and non-recursive mLDP FEC resolution is documented for inter-AS model C.

This chapter describes the following use cases for recursive and non-recursive mLDP FEC resolution for BGP-LU:

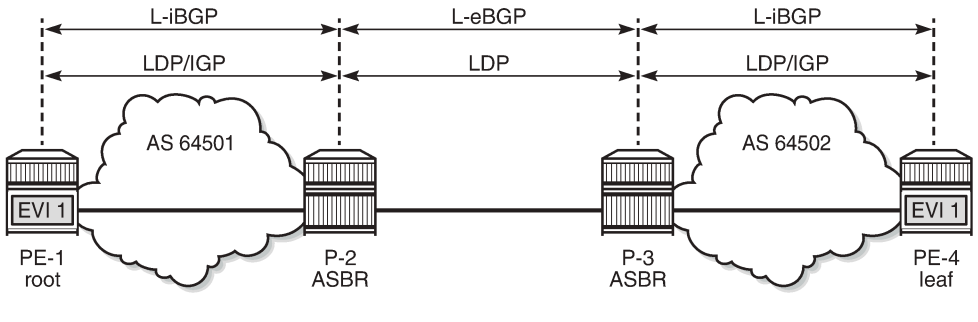
- P2MP mLDP FEC resolution for inter-AS model C
- P2MP mLDP FEC resolution for seamless MPLS

Some routers do not support recursive mLDP FEC, so basic non-recursive mLDP FEC is used instead. The non-recursive mLDP FEC resolution does not require the root IP address to be leaked from BGP to IGP and LDP. This is different from the configuration in the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

Figure 204: Example topology for inter-AS model C shows the example topology for inter-AS model C with the configured protocols (IGP, LDP, BGP). Root node PE-1 is situated in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are AS Border Routers (ASBRs) that are configured with next-hop-self (NHS). VPLS 1 is configured on root node PE-1 and leaf node PE-4, and is EVPN-MPLS enabled. The example topology for seamless MPLS is similar, but P-2 and P-3 will then act as Area Border Routers (ABRs) and IGP instance 0 is configured between them.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 204: Example topology for inter-AS model C

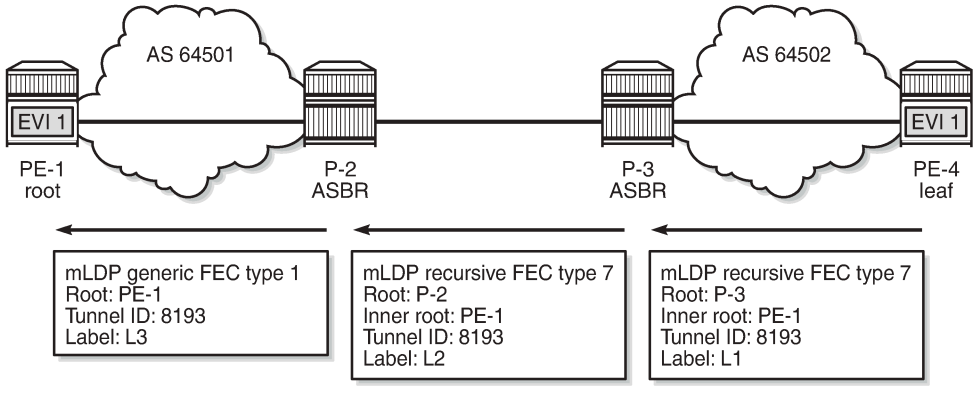


Recursive mLDP FEC resolution requires the nodes in a remote AS (or remote area in case of seamless MPLS) to support GRT recursive FEC type 7 to join the root node.

- PE-4 has a labeled BGP route to root PE-1 with next-hop P-3 in its route table. If PE-4 supports it, it sends a GRT recursive FEC type 7 label mapping message with inner root PE-1 and root P-3.
- P-3 has a labeled BGP route to PE-1 with next-hop P-2. When P-3 receives the mLDP label mapping message from PE-4, it generates its own GRT recursive FEC type 7 message with inner root PE-1 and root P-2.
- P-2 has an IGP route to root PE-1. When P-2 receives the mLDP label mapping message from P-3, it generates a non-recursive FEC type 1 message with root PE-1.

Figure 205: mLDP FEC label mapping messages for inter-AS model C shows the mLDP label mapping messages for inter-AS model C.

Figure 205: mLDP FEC label mapping messages for inter-AS model C



However, if the leaf node PE-4 does not support GRT recursive FEC type 7, it is possible to generate a non-recursive FEC type 1 label mapping message with root PE-1 to the local ASBR that supports GRT recursive FEC type 7. The following command generates only generic FEC type 1 label mapping messages with PE-1 as the root, on the leaf node PE-4:

```
# on PE-4:
configure {
    router "Base" {
        ldp {
```

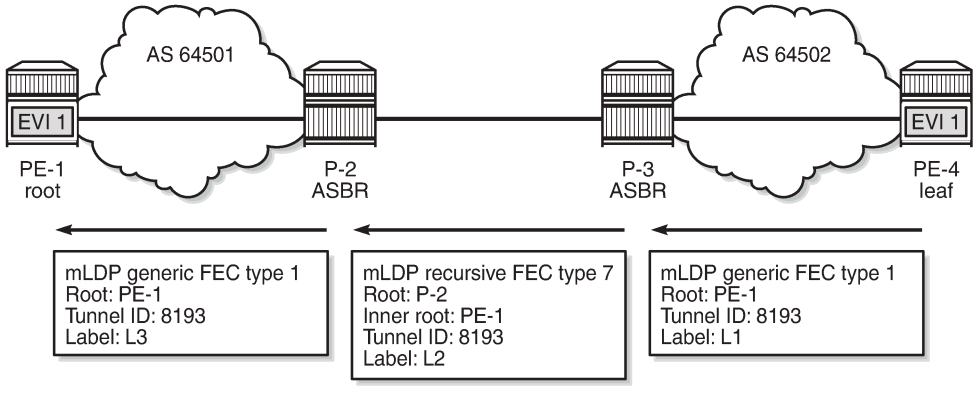
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            generate-basic-fec-only true
```

Note:
SR OS always generates a recursive FEC if the root node is resolved via BGP; if the root node is resolved via IGP, basic FEC is generated instead. The only way to not generate a recursive FEC when the root is resolved via BGP is by configuring the **generate-basic-fec-only** command.

Figure 206: Non-recursive mLDP FEC for inter-AS model C shows the non-recursive mLDP label mapping messages for inter-AS model C.

Figure 206: Non-recursive mLDP FEC for inter-AS model C

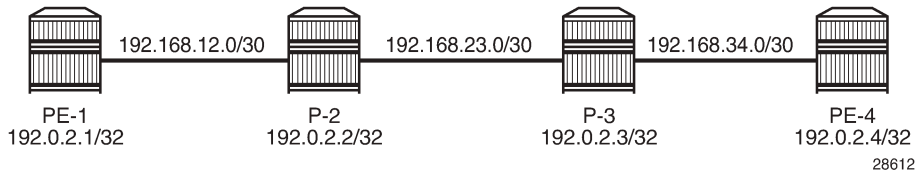


It is also possible that the ASBR routers do not support GRT recursive FEC either. The same **generate-basic-fec-only** command can be configured on all these nodes, which will then generate basic FEC type 1 label mapping messages with root address 192.0.2.1 to the next-hop.

Configuration

Figure 207: Example topology shows the example topology with four nodes.

Figure 207: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Inter-AS model C

Figure 204: Example topology for inter-AS model C showed the example topology for inter-AS model C. The following is configured for that topology. For a detailed explanation of the configuration, see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

- Within each AS, OSPF is configured as IGP (alternatively, IS-IS can be used).
- LDP is enabled within each AS.
- LDP is enabled between the ASBRs using the interface IP addresses 192.168.23.x.
- On the ASBRs, a static route 192.168.23.y/32 for the interface IP address on the ASBR peer is configured (with mask /32 instead of /30). When a label mapping message is received for an LDP FEC prefix, the next-hop for a FEC prefix is resolved using the routing table. The FEC is installed in the Label Information Base (LIB) if the next-hop matches a /32 route entry.
- BGP is configured on all nodes for the labeled IPv4 address family. An export policy exports the system IP addresses of the root and leaf nodes PE-1 and PE-4.
- A multi-hop BGP session is established between PE-1 and PE-4 for the EVPN address family, allowing inclusive multicast EVPN routes to be exchanged.
- EVPN-MPLS VPLS 1 is configured on PE-1 and PE-4 with mLDP enabled. PE-1 is configured as root node.

The BGP configuration on PE-1 is as follows. The BGP configuration on PE-4 is similar, but with different neighbors and AS numbers. The export policy is identical.

```
# on PE-1:
configure {
    policy-options {
        prefix-list "sysPE" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "PE-sys-to-labeled-BGP" {
            entry 10 {
                from {
                    prefix-list ["sysPE"]
                    protocol {
                        name [direct]
                    }
                }
                to {
                    protocol {
                        name [bgp-label]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true

            }
```

On PE-1, VPLS 1 is configured as follows. The service configuration on PE-4 is similar, but with different RT values and without the **root-and-leaf** parameter.

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer 1
            bgp 1 {
                route-target {
                    export target:64501:1
                    import target:64502:1
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Recursive mLDP FEC resolution for inter-AS model C

With the preceding configuration, leaf node PE-4 sends a recursive mLDP FEC label mapping message with PE-1 as inner root and P-3 as root. On PE-4, the number of GRT recursive mLDP bindings is 1, as follows:

```
[/]
A:admin@PE-4# show router ldp bindings active p2mp summary ipv4
 No. of Generic IPv4 P2MP Active Bindings: 0
 No. of In-Band-SSM IPv4 P2MP Active Bindings: 0
```

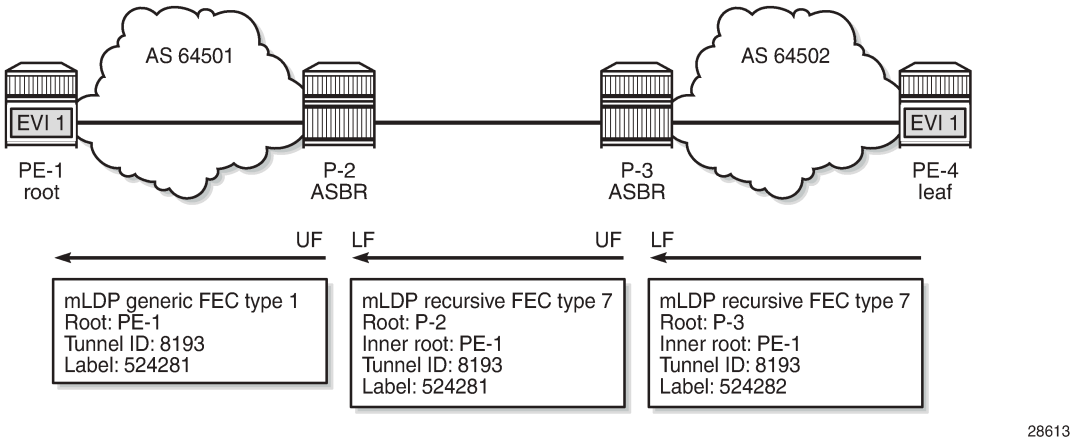
Figure 208: Recursive mLDP FEC for inter-AS model C



Non-recursive mLDP FEC resolution for inter-AS model C

Some routers may not support GRT recursive FEC type 7. In that case, the router generates a non-recursive FEC type 1 with root PE-1 to the next-hop P-3. In this example, leaf node PE-4 does not support GRT recursive FEC type 7 and is configured to only send basic FEC type 1 messages. ASBR P-3 supports GRT recursive type 7 and sends similar messages as in the preceding scenario. However, it is possible that none of the routers supports GRT recursive FEC type 7. In that case, the **generate-basic-fec-only** command is configured on all nodes.

The following command is configured on leaf node PE-4 to make the system send only basic FEC type 1 messages:

```
# on PE-4:
configure {
    router "Base" {
        ldp {
            generate-basic-fec-only true
```

When PE-4 is configured to only generate basic FEC type 1, PE-4 withdraws the GRT recursive type 7 (T:7) label mapping message with PE-1 as inner root and P-3 as root and sends a non-recursive generic type 1 (T:1) label mapping message with PE-1 as root instead. When debugging is enabled on PE-4 for LDP label mapping messages between P-3 and PE-4, the following messages are logged:

```
# on PE-4:
1 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Withdraw packet (msgId 96) to 192.0.2.3:0
Protocol version = 1
Label 524282 withdrawn for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"

2 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 97) to 192.0.2.3:0
Protocol version = 1
Label 524281 advertised for the following FECs
```

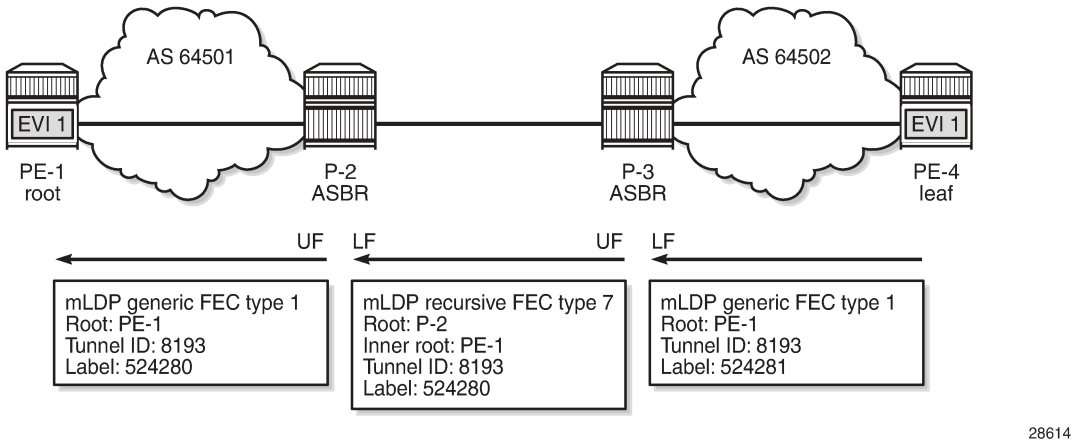
On P-2 and PE-1, the mLDP bindings are similar to the preceding scenario, but the labels are different. Figure 209: Non-recursive mLDP FEC for inter-AS model C shows the label mapping messages with label 524280 between PE-1 and P-2 and label 524280 between P-2 and P-3; label 524281 is used between P-3 and PE-4.

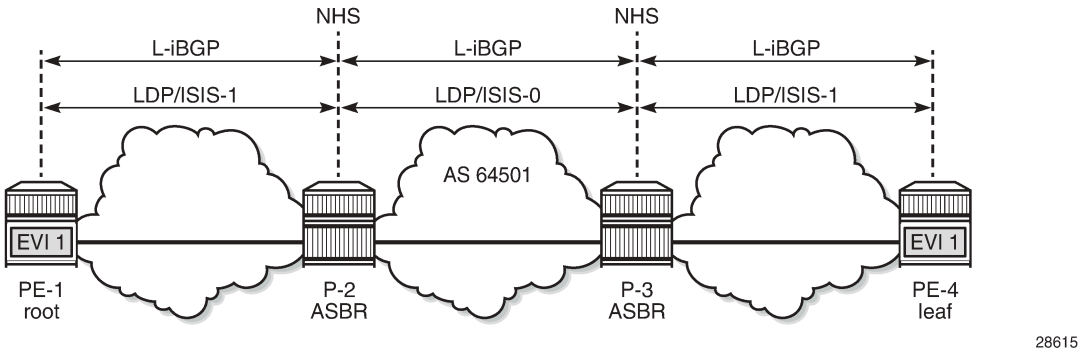
Figure 209: Non-recursive mLDP FEC for inter-AS model C



Seamless MPLS

Figure 210: Example topology for seamless MPLS shows the example topology for seamless MPLS.

Figure 210: Example topology for seamless MPLS



The configuration is according to the *Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP* chapter in the MPLS volume of *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Part I*.

IS-IS is configured as IGP. IS-IS instance 0 is configured between P-2 and P-3, whereas IS-IS instance 1 is configured between P-2 and PE-1 and between P-3 and PE-4. On P-2, IS-IS is configured as follows:

```
# on P-2:
configure {
    router "Base" {
        isis 0 {
            admin-state enable
            level-capability 2
            area-address [49.0001]
            interface "int-P-2-P-3" {
                interface-type point-to-point
            }
            interface "system" {
            }
        }
        isis 1 {
            admin-state enable
            level-capability 2
            area-address [49.0001]
            interface "int-P-2-PE-1" {
                interface-type point-to-point
            }
            interface "system" {
            }
        }
```

Other characteristics of this example are as follows:

- Unlike the preceding use case for inter-AS model C, no static route is required between P-2 and P-3.
- LDP is configured on all interfaces.
- VPLS 1 is configured as before, but the route target is identical for import and export, and equal to 64501:1.
- All nodes are in AS 64501, so only iBGP is configured.

On PE-1, BGP is configured as follows, using the same policy as for inter-AS model C. The BGP configuration on PE-4 is similar, but the neighbors are different.

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
                export {
                    policy ["PE-sys-to-labeled-BGP"]
                }
            }
            neighbor "192.0.2.4" {
                group "iBGP"
                family {
                    evpn true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

On P-2, the BGP configuration is as follows. The ABRs are configured with **next-hop-self** in both directions. The BGP configuration is similar on P-3.

```
# on P-2:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "iBGP"
                next-hop-self true
                family {
                    label-ipv4 true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                advertise-inactive true
                group "iBGP"
                next-hop-self true
                family {
                    label-ipv4 true
                }
            }
        }
```

The following route table on PE-4 shows a labeled BGP route to root node PE-1 with P-3 as the next-hop:

```
[/]
A:admin@PE-4# show router route-table 192.0.2.1

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                  Remote  BGP_LABEL 00h00m47s  170
       192.0.2.3 (tunneled)                                       10

===============================================================================
```

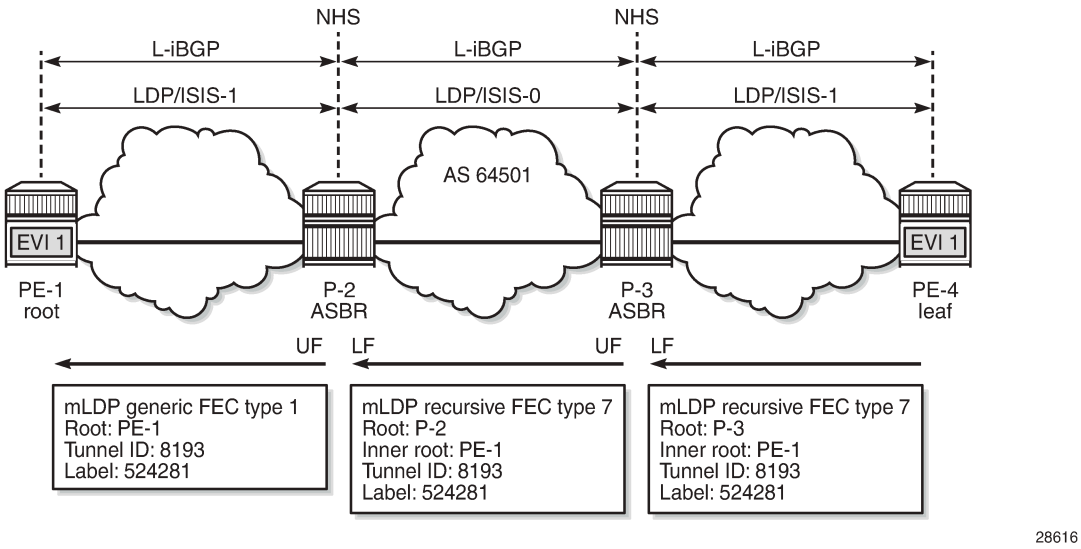
P-2 has one GRT recursive FEC binding with inner root PE-1 and root P-2 (LF). P-2 also has one non-recursive FEC binding with root PE-1 (UF). PE-1 only has a non-recursive FEC binding with root PE-1. Figure 211: Recursive mLDP FEC for seamless MPLS shows the mLDP label mapping messages that all have label 524281 in this example.

Figure 211: Recursive mLDP FEC for seamless MPLS



Non-recursive mLDP FEC resolution for seamless MPLS

For nodes that do not support GRT recursive mLDP FEC type 7, the following command ensures that only non-recursive mLDP type 1 label mapping messages will be sent. In this example, it is assumed that only PE-4 does not support GRT recursive mLDP FEC type 7.

```
# on PE-4:
configure {
    router "Base" {
        ldp {
            generate-basic-fec-only true
```

PE-4 sends a non-recursive mLDP label mapping message with PE-1 as the root to its peer P-3, as follows:

```
[/]
A:admin@PE-4# show router ldp bindings p2mp opaque-type generic detail ipv4

===============================================================================
```

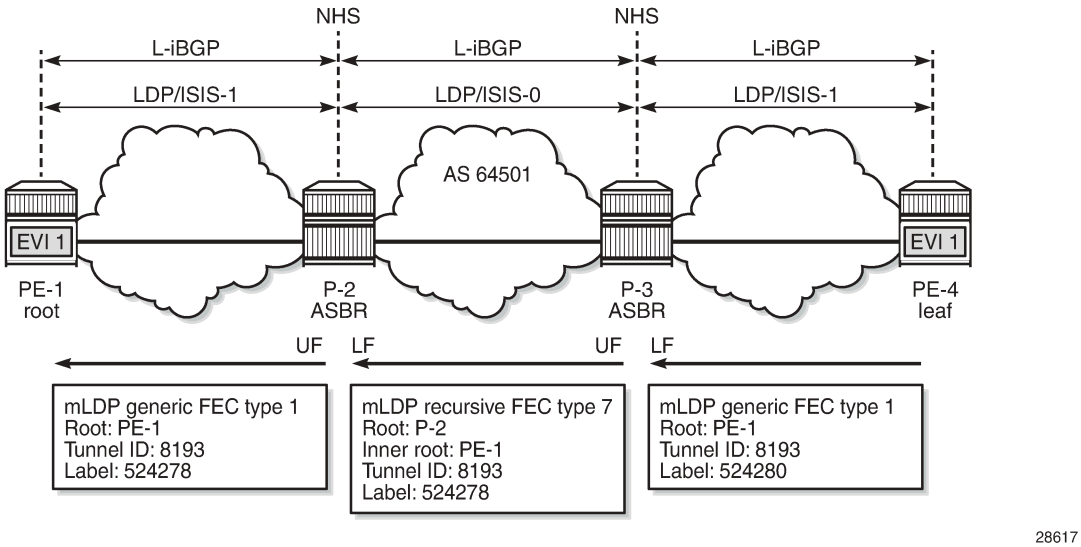
Figure 212: Leaf node sends basic FEC in seamless MPLS shows the label mapping messages when leaf node PE-4 only generates basic FEC type 1 messages.

Figure 212: Leaf node sends basic FEC in seamless MPLS



It is possible that ABR routers do not support GRT recursive either. The same command is configured on P-2 and P-3, as follows:

```
# on P-2, P-3:
configure {
    router "Base" {
        ldp {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            generate-basic-fec-only true
```

When **generate-basic-fec-only** is enabled in the ABRs, P-2 and P-3 will only generate basic FEC messages. On P-3, there are no GRT recursive mLDP bindings anymore, as follows:

```
[/]
A:admin@P-3# show router ldp bindings p2mp summary ipv4
 No. of Generic IPv4 P2MP Bindings: 2
 No. of In-Band-SSM IPv4 P2MP Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Bindings: 0
 No. of Recursive with In-Band-SSM IPv4 P2MP Bindings: 0
 No. of VPN Recursive with Generic IPv4 P2MP Bindings: 0
 No. of GRT Recursive with Generic IPv4 P2MP Bindings: 0
```

The two generic mLDP bindings on P-3 have root address 192.0.2.1, as follows. There is no UF or LF.

```

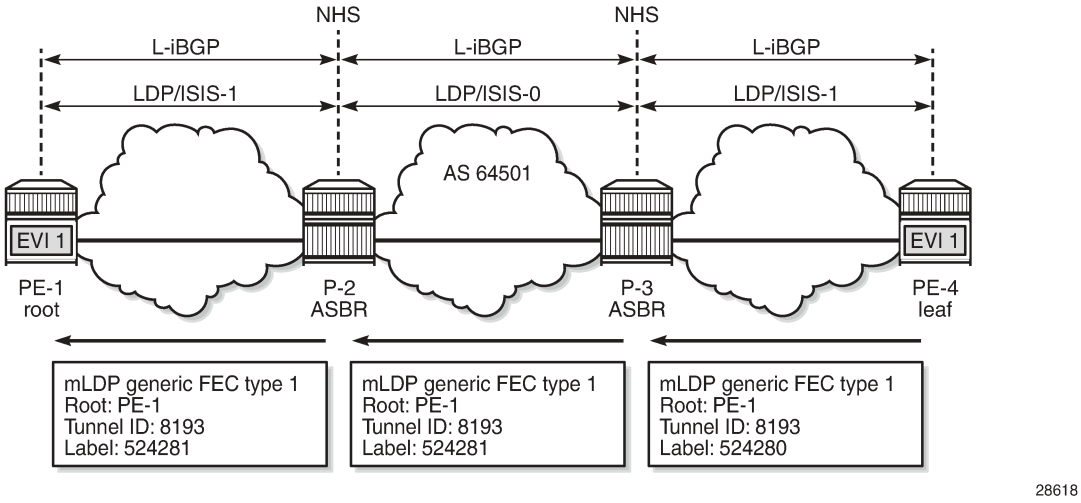
Figure 213: ABRs and leaf node send basic FEC in seamless MPLS



Conclusion

In inter-AS and intra-AS scenarios, mLDP trees can be set up using recursive or non-recursive label mapping messages. Routers not supporting recursive FEC can generate only non-recursive FEC, even if the system address of the root node is resolved via BGP. This feature is supported in MVPN and in EVPN.

P2MP mLDP Inter-AS Model C for EVPN-MPLS Services

This chapter provides information about P2MP mLDP Inter-AS Model C for EVPN-MPLS Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R5, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1.

Point-to-Multipoint Multicast Label Distribution Protocol (P2MP mLDP) for Broadcast, Unknown Unicast, and Multicast (BUM) traffic in EVPN-MPLS networks is supported in SR OS Release 14.0.R1, and later. EVPN with P2MP mLDP LSPs is supported in a seamless MPLS or inter-AS model C scenario in SR OS Release 15.0.R1, and later. This chapter describes the inter-AS model C scenario, but the configuration for seamless MPLS is similar.

Overview

Chapter "P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services" in the Layer 2 Services and EVPN volume in the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Part II* describes P2MP mLDP within an Autonomous System (AS). PEs configured with **root-and-leaf true** can send BUM traffic over P2MP mLDP tunnels; PEs configured with root-and-leaf false (that is, leaf-only) can only send BUM traffic over Ingress Replication (IR) tunnels. Both types of PEs (root-and-leaf and leaf-only) can receive BUM traffic over either P2MP mLDP tunnels or IR tunnels.

When **provider-tunnel inclusive mldp** is enabled in an EVPN-MPLS service in combination with **root-and-leaf true** and **bgp-evpn>mpls>ingress-replication-bum-label true**, the system will send an Inclusive Multicast Ethernet Tag (IMET) route with a composite tunnel type (IMET-P2MP-IR) in the provider tunnel attributed.

Inter-AS VPN model C is described in chapters Inter-AS VPRN Model C and Inter-AS Model C for VLL. Labeled IPv4 unicast BGP is used to provide inter-AS connectivity. The system IP addresses within each AS are exported by the Autonomous System Border Routers (ASBRs) and a multi-hop BGP session is established between root node and leaf node for address family EVPN. The root node advertises a composite IMET-P2MP-IR route to the leaf nodes and the leaf nodes advertise an IMET-IR route to the root node. Figure 214: Inter-AS Model C for P2MP mLDP shows an example topology with root node PE-1 in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are ASBRs.

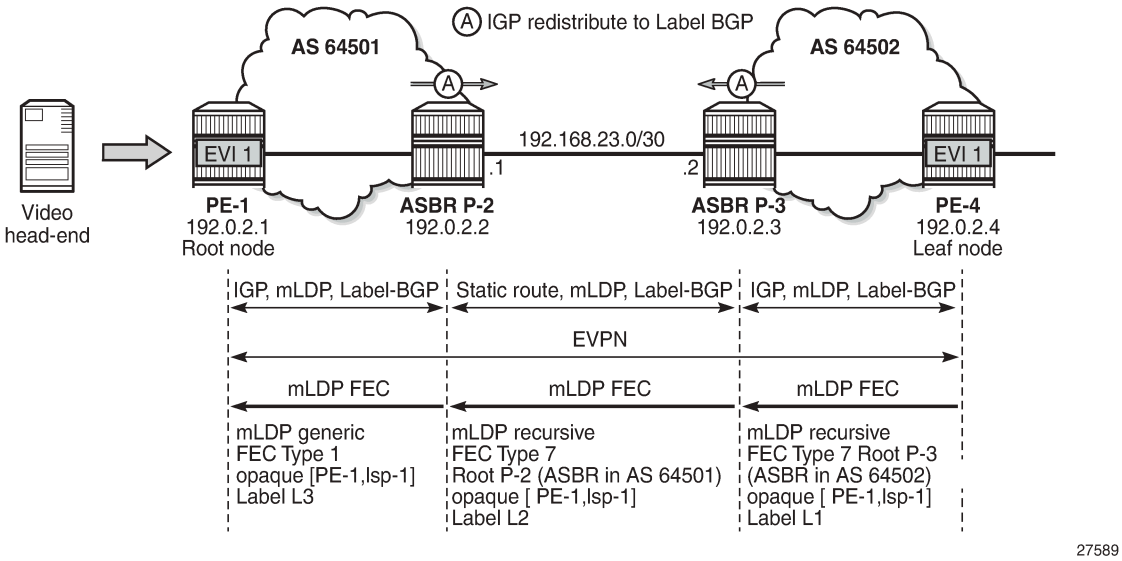
Figure 214: Inter-AS Model C for P2MP mLDP



The composite IMET-P2MP-IR route received by leaf node PE-4 contains the root node (192.0.2.1) and the LSP ID (0x2001) that will be used by the nodes to set up a P2MP mLDP tree toward the root.

"
```

The Provider Multicast Service Interface (PMSI) tunnel attribute for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 always equals zero in SR OS Release 21.5.R1, because SR OS does not support aggregated P2MP tunnels. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388544 needs to be divided by 16 to get the MPLS label value: 8388544/16 = 524284. This is due to the debug message being shown before the router can parse the label field and see whether it corresponds to an

© 2023 Nokia.

---snip---
```

The use of mLDP with recursive opaque values is specified in RFC 6512.

When the leaf node PE-4 receives the composite IMET-P2MP-IR route from the root node PE-1, a P2MP mLDP tree needs to be established from the leaf node to the root node. Leaf node PE-4 resolves the IP address of PE-1 to a labeled BGP route with next-hop ASBR P-3. PE-4 then sends an mLDP FEC with root node ASBR P-3 and an opaque value containing the root PE-1 and an LSP ID that was advertised in the IMET-P2MP-IR route, as follows:

```
# on PE-4:
4 2021/06/02 08:31:13.915 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 40) to 192.0.2.3:0
Protocol version = 1
Label 524283 advertised for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

T: 7 indicates the MLDP recursive FEC type 7. The tunnel ID 8193 corresponds to the hexadecimal value 0x2001 sent by the root node PE-1, which is the inner root 192.0.2.1 in the recursive opaque value.

When ASBR P-3 receives this mLDP FEC, it identifies itself as root node and resolves the recursive opaque value (PE-1, LSP ID) and creates a new mLDP FEC element with root node ASBR P-2 and an identical opaque value (PE-1, LSP ID). The following mLDP FEC is sent to ASBR P-2:

```
# on P-3:
4 2021/06/02 08:32:36.794 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 34) to 192.168.23.1:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.168.23.1, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

ASBR P-2 receives the mLDP FEC and finds that it is the root node. P-2 creates a new mLDP FEC, but no recursion is required because P-2 knows the IP address of PE-1 through the IGP. P-2 sends the following mLDP FEC with root node PE-1, LSP ID 8193, and mLDP FEC type 1.

```
# on P-2:
6 2021/06/02 08:32:36.814 UTC MINOR: DEBUG #2001 Base LDP
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
"LDP: LDP
Send Label Mapping packet (msgId 50) to 192.0.2.1:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"
```

Configuration

The example topology was already shown in Figure 214: Inter-AS Model C for P2MP mLDP. The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- OSPF as IGP within each AS (alternatively, IS-IS can be used)
- LDP enabled within each AS

The following two scenarios are configured:

- Inter-AS model C for mLDP
- Optimized inter-AS model C for mLDP

Inter-AS Model C for mLDP

The initial BGP configuration on the PEs only includes a label-IPv4 peering with the ASBRs. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
            }
```

On the ASBRs, BGP is configured for address family label-IPv4, both internal to PE-1 and external to the peer ASBR. A policy exports the system prefixes as label-IPv4 routes to the eBGP peer. The BGP configuration on P-2 is as follows:

```
# on P-2:
configure {
    policy-options {
        prefix-list "sysPE" {
            prefix 192.0.2.0/24 type longer {
            }
        }
        policy-statement "PE-sys-to-labeled-BGP" {
            entry 10 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                from {
                    prefix-list ["sysPE"]
                }
                to {
                    protocol {
                        name [bgp-label]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        bgp {
            ebgp-default-reject-policy {
                import false
            }
            group "eBGP" {
                type external
            }
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.23.2" {
                split-horizon true
                group "eBGP"
                peer-as 64502
                family {
                    label-ipv4 true
                }
                local-as {
                    as-number 64501
                }
                export {
                    policy ["PE-sys-to-labeled-BGP"]
                }
            }
```

The BGP configuration on ASBR P-3 is similar, but the IP addresses are different and the local AS and peer AS are swapped. The export policy is identical on both ASBRs P-2 and P-3.

When a P2MP mLDP tree must be established across ASs, LDP needs to be enabled on the interface between the ASBRs with **local-lsr-id>interface-name <..>** instead of the default value "system". The LDP configuration on P-2 is as follows:

```
# on P-2:
configure {
    router "Base" {
        ldp {
            interface-parameters {
                interface "int-P-2-P-3" {
                    ipv4 {
                        local-lsr-id {
                            interface-name "int-P-2-P-3"
                        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
```

With this LDP configuration, a link adjacency will be established toward the interface IP address instead of the system address, as follows:

```
[/]
A:admin@P-2# show router ldp session ipv4

===============================================================================
LDP IPv4 Sessions
===============================================================================
Peer LDP Id         Adj Type  State         Msg Sent  Msg Recv  Up Time
-------------------------------------------------------------------------------
192.0.2.1:0         Link      Established   100       101       0d 00:04:05
192.168.23.2:0      Link      Established   16        18        0d 00:00:20
-------------------------------------------------------------------------------
No. of IPv4 Sessions: 2
===============================================================================
```

However, this LDP configuration is insufficient for the resolution of mLDP FEC as link LSR ID. LDP needs a /32 route instead of a /30 route, so the following /32 static route is configured on P-2:

```
# on P-2:
configure {
    router "Base" {
        static-routes {
            route 192.168.23.2/32 route-type unicast {
                next-hop "192.168.23.2" {
                    admin-state enable
                }
            }
```

The configuration on ASBR P-3 is similar for static route 192.168.23.1/32. When this static route is not configured, no mLDP label mapping message will be sent from P-3 to P-2, so the mLDP P2MP tree cannot be established.

On PE-1, VPLS 1 is configured with mLDP root-and-leaf, as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-target {
                    export "target:64501:1"
                    import "target:64502:1"
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
        }
```

On PE-4, VPLS 1 is configured with mLDP leaf-only (no root-and-leaf, which is default), as follows:

```
# on PE-4:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-target {
                    export "target:64502:1"
                    import "target:64501:1"
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
        }
```

The Route Distinguisher (RD) is auto-derived from EVI 1, but the route target (RT) should not be auto-derived, because the export RT on PE-1 must match the import RT on PE-4, and vice versa. It is an option to configure an identical RT on all PEs, such as 1:1, but in this example, the export RT on PE-1 is 64501:1, which equals the import RT on PE-4. When the RTs do not match, the BGP routes will be received at the PE in the peer AS, but they will not become active and no mLDP P2MP tree can be established.

Multi-hop BGP peering is configured between PE-1 and PE-4 for address family EVPN. The external BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            group "eBGP" {
                multihop 10
                peer-as 64502
                family {
                    evpn true
                }
                local-as {
                    as-number 64501
                }
            }
            neighbor "192.0.2.4" {
                group "eBGP"
            }
```

The external BGP configuration on PE-4 is similar, but the local AS and peer AS are swapped, and the neighbor IP address is different.

Inter-AS Model C for mLDP - Verification

The following BGP summary shows that P-2 has sent and received two prefixes with its eBGP peer P-3 and has advertised two prefixes to its iBGP peer PE-1:

```
[/]
A:admin@P-2# show router bgp summary all

-------------------------------------------------------------------------------
```

Optimized Inter-AS Model C for mLDP

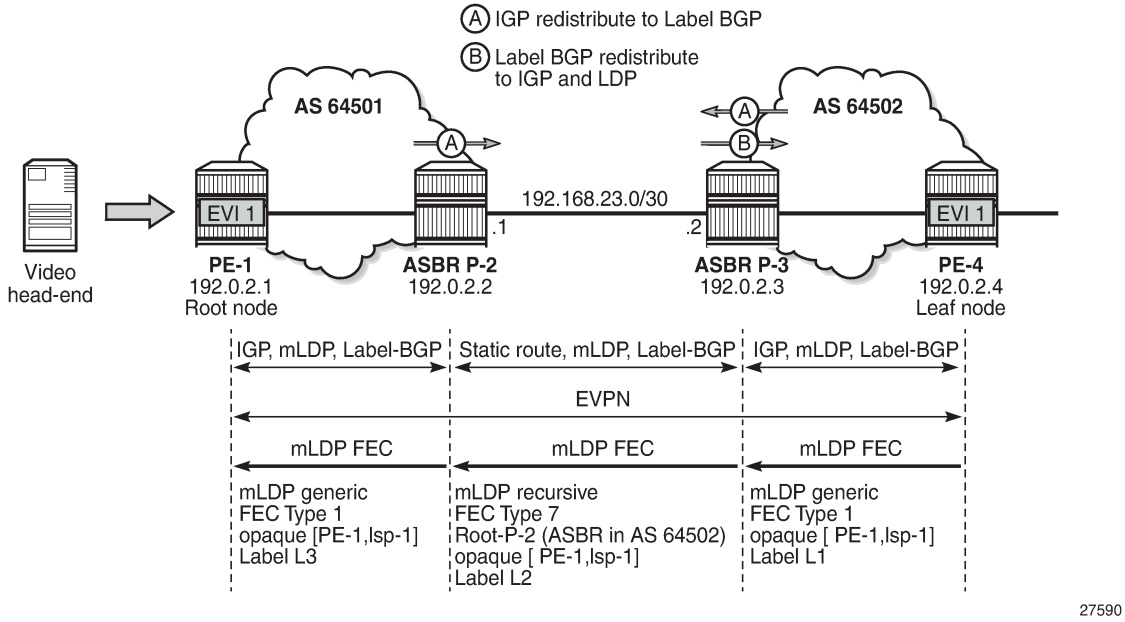
When some leaf nodes do not support labeled BGP routes or recursive opaque mLDP label mapping, the ASBR in the AS where the leaf nodes are situated needs to leak the root IP address into the leaf PE

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

IGP, which allows the leaf node PE-4 to send a generic FEC type 1 to join the root. The recursive opaque functionality is pushed to the local ASBR P-3.

Figure 215: Example topology for optimized Inter-AS Model C for mLDP shows the example topology for the optimized inter-AS model C for mLDP.

Figure 215: Example topology for optimized Inter-AS Model C for mLDP



The configuration starts with the configuration in the preceding section Inter-AS Model C for mLDP. The policy to export system prefixes from the ASs to labeled BGP is already configured and applied on both ASBRs. The following additional policies are defined on ASBR P-3 in the AS of the leaf node to export labeled BGP routes to OSPF and to LDP.

```
# on ASBR P-3:
configure {
    policy-options {
        policy-statement "bgpToLdp" {
            entry 10 {
                from {
                    protocol {
                        name [bgp-label]
                    }
                }
                to {
                    protocol {
                        name [ldp]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
        policy-statement "bgpToOspf" {
            entry 10 {
                from {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    protocol {
                        name [bgp-label]
                    }
                }
                to {
                    protocol {
                        name [ospf]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

Policy "bgpToOspf" is configured in the OSPF context and policy "bgpToLdp" in the **ldp** context, as follows:

```
# on ASBR P-3:
configure {
    router "Base" {
        ldp {
            export-tunnel-table ["bgpToLdp"]
        }
        ospf 0 {
            export-policy ["bgpToOspf"]
        }
```

Optimized Inter-AS Model C for mLDP - Verification

The prefixes from AS 64501 are now exported to OSPF and LDP in AS 64502; therefore, leaf node PE-4 will no longer use the labeled BGP routes to a node in AS 64501.

```

===============================================================================
```

The P2MP mLDP bindings on P-2 and PE-1 are the same as in the previous non-optimized inter-AS model C for mLDP scenario. P-2 has one GRT recursive mLDP binding to P-3 and one generic mLDP binding to root node PE-1, whereas PE-1 only has a generic mLDP binding to P-2.

The following command on root node PE-1 shows that an EVPN-MPLS destination is created to the leaf node PE-4. This EVPN destination runs over a BGP tunnel and can transport multicast (BUM) traffic. However, as discussed in the preceding section, the EVPN destination is used for BUM traffic only in the case where the provider tunnel goes operationally down.

```
[/]
A:admin@PE-1# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address     Egr Label     Num. MACs   Mcast           Last Change
                Transport:Tnl                             Sup BCast Domain
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
-------------------------------------------------------------------------------
192.0.2.4       524284        0           bum             06/02/2021 08:31:14
                bgp:262146                                No
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The same command on the leaf node PE-4 shows an EVPN destination running on an LDP tunnel instead of a BGP tunnel. This destination is used whenever PE-4 needs to send BUM traffic to PE-1:

```
[/]
A:admin@PE-4# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address     Egr Label     Num. MACs   Mcast           Last Change

-------------------------------------------------------------------------------
192.0.2.1       524284        0           bum             06/02/2021 08:31:14
                ldp:65538                                 No
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The other **show** commands in the Inter-AS Model C for mLDP section have an identical output for both scenarios.

Conclusion

P2MP mLDP is supported in inter-AS model C for EVPN-MPLS services with or without optimization. Optimization in this chapter refers to the ability to set up an end-to-end mLDP tunnel without the need for recursive opaque mLDP FECs on the leaf nodes. A similar configuration is applied in the case of seamless MPLS across different areas.

P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services

This chapter provides information about P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3.

Point-to-Multipoint (P2MP) multicast Label Distribution Protocol (mLDP) tunnels for Broadcast, Unknown unicast, and Multicast (BUM) traffic in Ethernet Virtual Private Network Multiprotocol Label Switching (EVPN-MPLS) networks are supported in SR OS Release 14.0.R1, and later. Internet Group Management Protocol (IGMP) snooping support for EVPN-MPLS services is supported in SR OS Release 14.0.R4, and later.

Overview

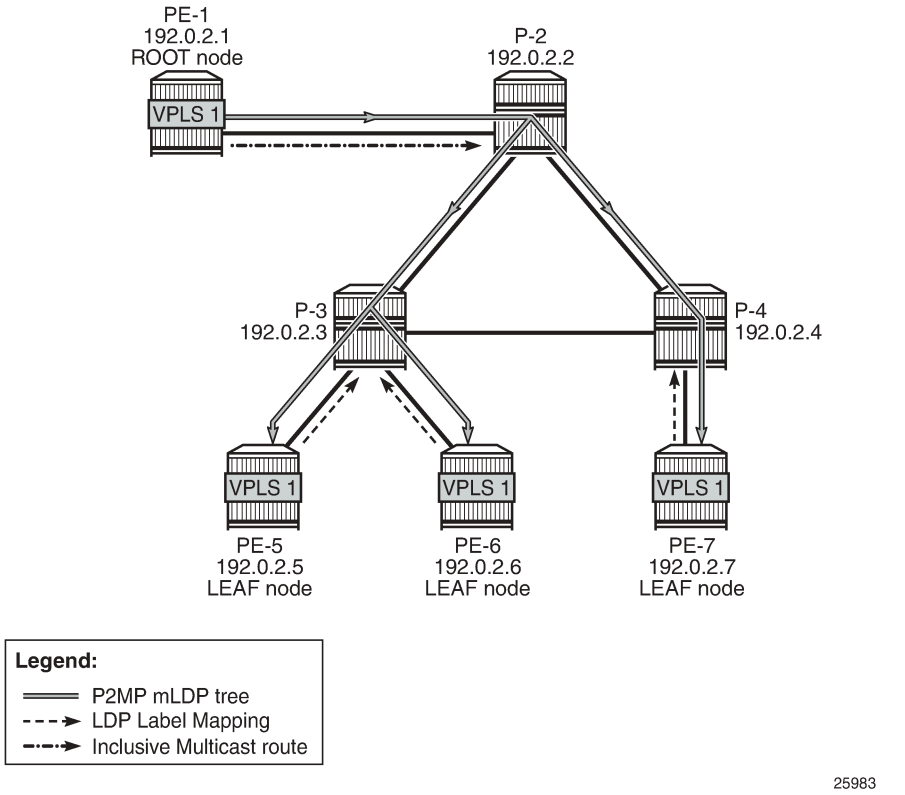
Service providers are moving their existing VPN services to EVPN. Providers using P2MP LSPs for VPLS services expect the same capabilities in EVPN. Before SR OS Release 14.0.R1, only Ingress Replication (IR) was supported. This works well for broadcast and unknown unicast traffic, but it is inefficient for multicast. Ingress replication does not use a multicast mechanism. Instead, the parent node makes n individual copies and unicasts each copy through an MPLS or IP tunnel to each child node.

BUM traffic is sent from a root node to a number of leaf nodes, but leaf nodes are also allowed to send BUM traffic to root nodes. If most BUM traffic is flowing from a few root nodes to leaf nodes, it would be inefficient to promote all leaf nodes to root-and-leaf nodes because of the amount of P2MP tunnels that would need to be set up. Another solution is to use a combination of P2MP mLDP and ingress replication (IR) tunnels in the service. The root nodes send BUM traffic using P2MP tunnels while the leaf nodes use IR tunnels to send BUM traffic to the root nodes. This avoids the need to set up a P2MP tree from each leaf, while it still allows leaf nodes to send BUM traffic to the root nodes.

Figure 216: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a multicast mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 216: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7



The Inclusive Multicast Ethernet Tag (IMET) route (EVPN route type 3) sent by root node PE-1 contains the required information to set up an mLDP tree, such as the root node IP address and an opaque value. As described in chapter "Multicast Label Distribution Protocol" in the MPLS volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide - Part I*, the mLDP tree is set up from the leaf nodes toward the root.

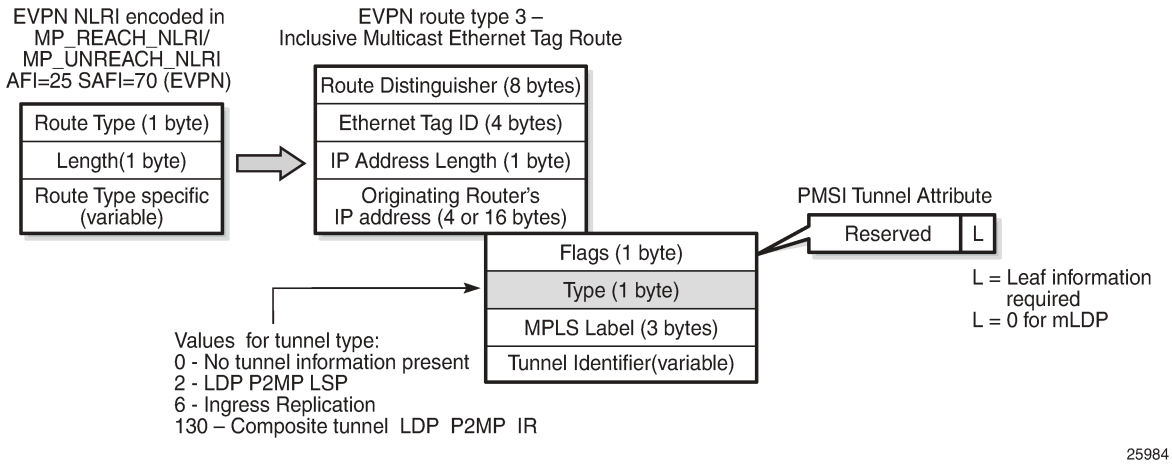
The LDP label mapping message contains the root node address, an opaque value, and an MPLS label. The leaf nodes send an LDP label mapping message to their upstream next hop toward the root node of the tree. Each transit node that has received such LDP label mapping message generates a new LDP label mapping message to its upstream next hop toward the root. This is repeated until the root node receives an LDP label mapping message and the multicast tree is completed.

Figure 216: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a P2MP mLDP tree rooted in PE-1, which is optimal for multicast traffic. However, no P2MP mLDP tree needs to be rooted in PE-5, PE-6, and PE-7 for the reverse direction. These three PEs can use IR to send traffic to the root (and to the other leaf nodes if needed).

EVPN route type 3 is used for setting up the flooding tree for a specified VPLS service. EVPN route type 3 includes the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PMSI Tunnel Attribute = PTA), which can have different formats depending on the tunnel type; see Figure 217: BGP-EVPN route type 3 with PTA.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 217: BGP-EVPN route type 3 with PTA



The following route values are used for EVPN-MPLS services:

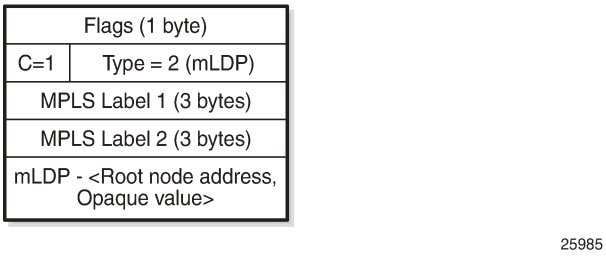
- The route distinguisher (RD) is taken from the RD of the VPLS service, which can be configured in the BGP context or auto-derived from the BGP-EVPN EVPN Instance (EVI) value. In this case, the RD is auto-derived from the EVI, resulting in a value of 192.0.2.1:1 for VPLS 1 on PE-1.
- The Ethernet tag ID equals 0.
- The IP address length equals 32.
- The originating router's IP address carries the IPv4 system address.
- The PTA can have different formats depending on the tunnel type enabled in the service. The SR OS EVPN-MPLS implementation supports the following tunnel types (SR OS supports different tunnel types for EVPN-VXLAN):
  - Tunnel type 2 - P2MP mLDP
    - The route is referred to as an Inclusive Multicast Ethernet Tag Point-to-Multipoint (IMET-P2MP).
    - Flags: leaf not required.
    - The MPLS label is zero.
    - The tunnel identifier includes the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join to the mLDP P2MP tree.
  - Tunnel type 6 - Ingress Replication (IR)
    - The route is referred to as an Inclusive Multicast Ethernet Tag Ingress Replication (IMET-IR).
    - Flags: leaf not required.
    - The MPLS label is a non-zero, downstream allocated label. This MPLS label is allocated to the service and is the same for unicast MAC/IP routes for the same service, unless **ingress-replication-bum-label** is configured in the service.
    - The tunnel identifier is the tunnel endpoint and is equal to the originating IP address.
  - Tunnel type 130 - Composite tunnel: Type: C-bit (composite) + type 2 (mLDP)
    - The route is referred to as an IMET-P2MP-IR.
    - Flags: leaf not required.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MPLS label 1 equals zero.
- MPLS label 2 is a non-zero, downstream allocated label (as any other IR label). The leaf nodes use the label to set up an EVPN-MPLS binding to the root and add it to the default multicast list.
- The mLDP tunnel identifier is the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join the mLDP P2MP tree.

Figure 218: PTA for composite tunnel IMET-P2MP-IR shows the PTA for tunnel type 130.

Figure 218: PTA for composite tunnel IMET-P2MP-IR



The composite bit C is set, indicating that the PTA identifies two tunnels: the transmit tunnel is a P2MP mLDP tunnel and the receive tunnel is an IR tunnel.

IMET-P2MP-IR routes

The composite tunnel type is an optimized solution that combines mLDP and IR within the same EVPN service so that each root node sends BUM traffic using the P2MP tunnel whereas each leaf-only node sends BUM traffic to the root node using IR.

- PEs configured with **root-and-leaf** can send all BUM traffic over P2MP mLDP tunnels while they receive BUM traffic either over P2MP mLDP tunnels (from other root-and-leaf nodes) or over ingress-replication tunnels (from leaf-only nodes).
- PEs configured without **root-and-leaf** (default setting) can use IR to send BUM traffic to root nodes and other leaf-only nodes, while receiving BUM traffic over either P2MP mLDP tunnels (from root nodes) or ingress-replication tunnels (from leaf-only nodes).

The root PEs signal an IMET-P2MP-IR route, indicating that they intend to transmit BUM traffic using an mLDP P2MP tunnel, while they can receive traffic over an IR EVPN-MPLS binding. Composite tunnels reduce the number of P2MP mLDP tunnels that the PE/P routers in the EVI need to handle, because no full mesh of P2MP tunnels among all the PEs in the EVI is required. This is important (in terms of scaling) in services where there are just a pair of root nodes sending BUM in P2MP tunnels and hundreds of leaf nodes that only need to send BUM traffic to the root nodes using IR tunnels.

Configuration

Initial configuration

The PE and P nodes have the following initial configuration:

- The ports between the routers are configured as network ports and have router interfaces configured.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- IS-IS is enabled on all the router interfaces.
- LDP is enabled on all the router interfaces.
- BGP is enabled on all PEs with route reflector (RR) P-2. The BGP configuration on RR P-2 is as follows:

```
# On P-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
            vpn-apply-export true
            peer-ip-tracking true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
            neighbor "192.0.2.7" {
                group "internal"
            }
        }
    }
```

Configure EVPN P2MP mLDP in VPLS Service

On the root node PE-1, VPLS 1 is configured as follows:

```
# On PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
            sap 1/2/c3/1 {    # sap for ingress traffic from STC
            }
        }
    }
```

The configuration options in the **bgp-evpn** context of the VPLS are as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            bgp-evpn ?
*[ex:/configure service vpls "VPLS 1"]
A:admin@PE-1#             bgp-evpn ?

 bgp-evpn

 accept-ivpls-evpn-    - Accept and process non-zero ethernet-tag MAC routes
  flush
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 evi                   - EVPN ID
 ignore-mtu-mismatch   - Ignore MTU mismatch
 incl-mcast-orig-ip    - Originating IP address
 isid-route-target     + Enter the isid-route-target context
 mac-duplication       + Enter the mac-duplication context
 mpls                  + Enter the mpls list instance
 routes                + Enter the routes context
 segment-routing-v6    + Enter the segment-routing-v6 list instance
 vxlan                 + Enter the vxlan list instance
```

By default, the advertisement of the inclusive multicast route with IR is enabled (**ingress-repl-inc-mcast-advertisement**). However, if it is disabled, the router does not send the IMET-IR or IMET-P2MP-IR routes, regardless of the service being enabled for BGP EVPN-MPLS or BGP EVPN-VXLAN.

For information about the other parameters in the **bgp-evpn** context of the VPLS, see chapters EVPN for VXLAN Tunnels (Layer 2) and EVPN for MPLS Tunnels.

The configuration options in the **provider-tunnel inclusive** context are as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            provider-tunnel {
                inclusive ?
*[ex:/configure service vpls "VPLS 1" provider-tunnel]
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
A:admin@PE-1#                 inclusive ?

 inclusive

 admin-state           - Administrative state of P2MP LSP as the I-PMSI
 data-delay-interval   - I-PMSI data delay timer
 owner                 - Configure provider-tunnel owner
 root-and-leaf         - Configure whether the provider tunnel acts as a leaf or both a root
 and leaf

 Choice: ipmsi
 mldp                 :- Enable/Disable MLDP
 rsvp                 :+ Enter the rsvp context
```

- The **data-delay-interval** is configured in seconds in the range from 3 to 180 seconds. A node configured with **root-and-leaf** sends all BUM packets (data plane and control plane: ARP, CCMs, and so on) to its provider tunnel after the delay-data-interval has expired. This timer keeps the provider tunnel operationally down until its expiration, and, during that time, the router can use the EVPN-MPLS destinations typically used for IR.
- mLDP is enabled by adding the keyword **mldp** and enabling the provider tunnel (**admin-state enable**).
- The owner must be **bgp-evpn-mpls** if MPLS is enabled in the EVPN.

```
configure {
    service {
        vpls "VPLS 1" {
            provider-tunnel {
                inclusive {
                    owner ?
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
A:admin@PE-1#                     owner ?

 owner <keyword>
 <keyword> - (bgp-ad|bgp-vpls|bgp-evpn-mpls)
```

Only one of the three possible owner protocols supports the provider tunnel in the service and needs to be set before the provider tunnel can be enabled. By default, no owner is configured. The following error is raised when a user wants to enable the provider tunnel without an owner:

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
MINOR: SVCMGR #12: configure service vpls "VPLS 1" provider-tunnel inclusive admin-state
 - Inconsistent Value error
 - no owner configured for the provider tunnel
```

After the provider tunnel has an owner and is enabled, the owner can only be changed when the provider tunnel is disabled.

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" provider-tunnel inclusive owner
 - the enabled provider-tunnel cannot have owner set to bgp-vpls when evpn-mpls is enabled
 - configure service vpls "VPLS 1" bgp-evpn mpls 1 admin-state
```

After the owner is set, the corresponding protocol is checked to see if it is enabled in the service configuration.

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
MINOR: SVCMGR #12: configure service vpls "VPLS 1" provider-tunnel inclusive admin-state
 - Inconsistent Value error
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
  - bgp-vpls must be configured when the provider tunnel with owner bgp-vpls is enabled
  - configure service vpls "VPLS 1"
```

- If **ingress-repl-inc-mcast-advertisement** is enabled and the PE is configured with **root-and-leaf**, the router sends an IMET-P2MP-IR route; if the PE is configured without **root-and-leaf** (default), the router sends an IMET-IR route. However, if **ingress-repl-inc-mcast-advertisement** is disabled and the PE is configured with **root-and-leaf**, the router only sends IMET-P2MP routes. Leaf-only nodes do not send any IMET routes at all in case no IR multicast advertisement is allowed.

  Root-and-leaf nodes only send BUM traffic to the P2MP tunnel as long as it is active. If the P2MP tunnel goes operationally down, it starts sending BUM traffic to IR tunnels (EVPN-MPLS destinations shown in the **show service id 1 evpn-mpls** command).
- If a provider tunnel is configured on a node, the router can join P2MP trees as a leaf, by generating an LDP label mapping message including the corresponding P2MP mLDP FEC. If no provider tunnel is configured, the node does not join P2MP mLDP trees, and can only use IR for BUM.
- If one node is configured as root, all other nodes must be configured with provider tunnels; otherwise, they do not receive BUM traffic sent on P2MP tunnels. The configuration of leaf-only node PE-5 is as follows, the main difference with the configuration for the root being the absence of **root-and-leaf** (default setting):

```
# On PE-5:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
            sap 1/2/c1/1:1 {    # sap for egress traffic to VPLS 1
            }
        }
    }
```

As described, the tunnel types for BUM traffic are controlled by **ingress-repl-inc-mcast-advertisement** and the **provider-tunnel** context (**root-and-leaf**). The IMET route sending behavior is summarized in Table 11: IMET routes and Tunnel Types advertised based on the configuration .

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Table 11: IMET routes and Tunnel Types advertised based on the configuration

IMET route set	Root + Leaf PE	Leaf-only	No provider-tunnel
IR-mcast advertisement	Composite P2MP + IR	IR	IR
No IR-mcast advertisement	P2MP	-	-

Information about the provider tunnel can be retrieved as follows:

```
[/]
A:admin@PE-1# show service id 1 provider-tunnel

```

Note:
The same IMET-P2MP route cannot be imported by two services at the same time. If two VPLS services (where a provider tunnel is enabled) have the same import route-target, only one service joins the mLDP tree (whichever comes first).

EVPN P2MP mLDP operation

After the root node and leaf nodes are configured as shown, the root node sends BGP EVPN composite IMET-P2MP-IR routes, as follows:

```
# On PE-1:
2 2023/07/03 22:26:27.189 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

```
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 25 PMSI:
        Tunnel-type Composite LDP P2MP IR (130)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label1 Ag  0
        MPLS Label2 IR 8388480
        Root-Node 192.0.2.1, LSP-ID 0x2001
"
```

The PTA for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 equals zero. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388480 needs to be divided by 16 to have the MPLS label: 8388480/16 = 524280. This is because the debug message is shown before the router can parse the label field and see whether it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits).

The tunnel identifier field contains the root node address 192.0.2.1 and the opaque value 0x2001, which corresponds to decimal value 8193. With this tunnel identifier, the leaf nodes can join the mLDP multicast tree toward the root node by sending LDP label mapping messages that contain the root node IP address and the opaque value.

Note:
When static P2MP mLDP tunnels and dynamic P2MP mLDP tunnels used by BGP-EVPN coexist on the same router,Nokia recommends that the static tunnels use a tunnel ID less than 8193. If a tunnel ID is statically configured with a value equal to or greater than 8193, BGP-EVPN may attempt to use the same tunnel ID for services with an enabled provider tunnel and fail to set up an mLDP tunnel.

The root node PE-1 receives IMET-IR routes from all leaf nodes, as shown for the BGP update sent by leaf node PE-5 (via RR P-2):

```
# On PE-1:
3 2023/07/03 22:28:45.189 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The PTA tunnel type 6 for IR has only one MPLS label, which corresponds to the MPLS label 524280 allocated for the service. The tunnel identifier is the tunnel endpoint 192.0.2.5, which is the system address of the originating leaf node.

On leaf node PE-5, three BGP EVPN inclusive multicast routes have been learned and are used, as follows:

```
[/]
A:admin@PE-5# show router bgp routes evpn incl-mcast

```

The MPLS label is 524280, as described. The LSP ID equals 8193, which corresponds to the hexadecimal value 0x2001 in the preceding BGP update message sent by the root node PE-1.

To set up the mLDP tree, leaf node PE-5 has generated an LDP label mapping message to the next hop router toward the root, P-3. The label mapping message includes the root address 192.0.2.1, the opaque value 8193, and MPLS label 524279, as follows:

```

```

When the LDP label reaches the root node PE-1, the mLDP tree is complete and it can be used for BUM traffic.

The following **tools** command shows the provider tunnels for VPLS 1 on root node and leaf nodes. On root node PE-1, there is one originating inclusive provider tunnel and there are no terminating inclusive provider tunnels, as follows:

```
[/]
A:admin@PE-1# tools dump service id 1 provider-tunnels

===============================================================================
VPLS 1 Inclusive Provider Tunnels Originating
===============================================================================
ipmsi (LDP)                                 P2MP-ID  Root-Addr
-------------------------------------------------------------------------------
8193                                        8193    192.0.2.1

-------------------------------------------------------------------------------

===============================================================================

-------------------------------------------------------------------------------
                                                8193    192.0.2.1

-------------------------------------------------------------------------------
---snip---
```

The inclusive provider tunnels are identified by the combination of the P2MP ID (opaque value) and the root address. These parameters are in every label mapping message and they are included in the PTA tunnel identifier for tunnel type 130 (IMET-P2MP-IR) and for tunnel type 2 (IMET-P2MP).

In VPLS 1 on root node PE-1, an SDP of type VplsPmsi is auto-created, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl

IGMP snooping

When IGMP snooping is disabled and a multicast stream enters VPLS 1 on the root node, this stream is sent to all the leaf nodes, even if no receivers join the multicast group on the leaf nodes. In this example, a receiver connected to PE-5 joins a multicast group, but there are no receivers for any multicast group on PE-6 and PE-7. By default, IGMP is disabled and the multicast stream is flooded to all leaf PEs, as can be verified with the following monitor command on PE-6 where no receivers have joined any multicast stream:

```
[/]
A:admin@PE-6# monitor port all-ethernet-rates repeat 15 interval 4

=======================================================================

This implies that bandwidth is wasted, which can be prevented by enabling IGMP snooping. IGMP snooping ensures that multicast traffic is only sent to the receivers that joined a multicast group. IGMP snooping can be enabled in VPLS 1 on all PEs, as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            igmp-snooping {
                admin-state enable
            }
```

A receiver connected to PE-5 has sent an IGMP report whereas PE-6 has no receivers that joined a multicast group. The traffic counters are monitored on the outgoing port to the (potential) receivers. On PE-5, traffic is sent to the receiver, as follows:

```
[/]
A:admin@PE-5# monitor port all-ethernet-rates repeat 15 interval 4

=============================================================================

IGMP snooping can be enabled in EVPN-MPLS services with IR or provider-tunnel mLDP trees. When IGMP snooping is enabled on the VPLS, all the EVPN-MPLS destinations are added to the MFIB as a single router interface. IGMP queries and reports are properly forwarded to and from EVPN-MPLS destinations.

The following shows the EVPN-MPLS destinations as part of the MFIB when IGMP snooping is enabled:

```
[/]
A:admin@PE-5# show service id 1 mfib

Connected to SAP 1/2/c1/1:1, PE-5 has a receiver that joined the multicast stream. EVPN-MPLS is added as a single logical IGMP snooping interface and treated as an mrouter, also on the other leaf nodes, as follows:

```
[/]
A:admin@PE-5# show service id 1 igmp-snooping base

===============================================================================

```

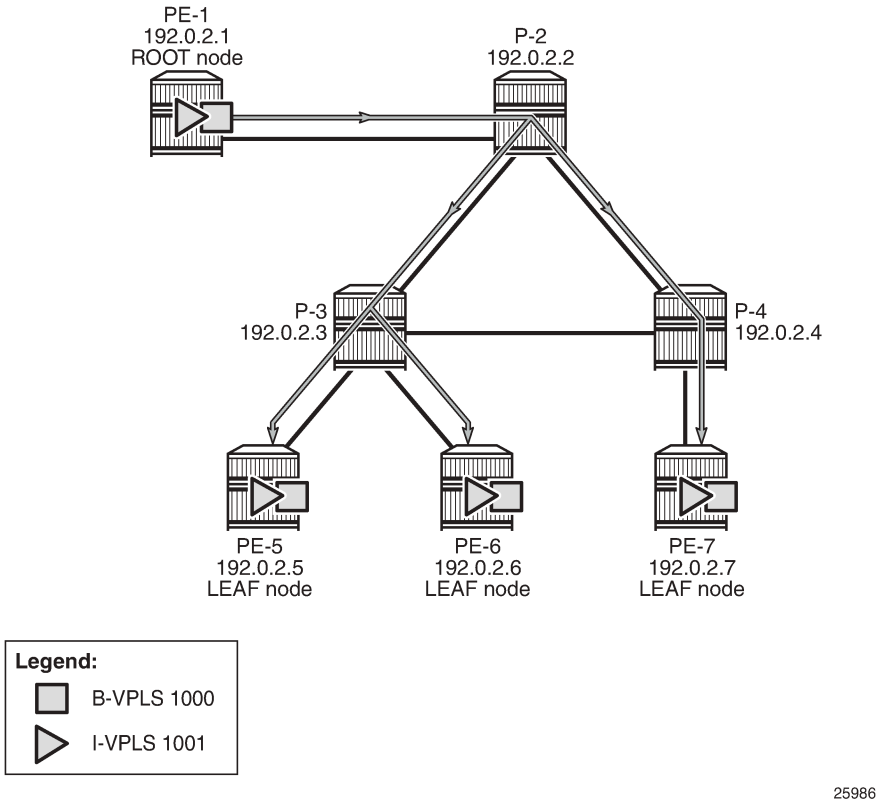
PBB-EVPN and P2MP mLDP

Provider Backbone Bridging (PBB) EVPN is described in chapter EVPN for PBB over MPLS (PBB-EVPN).

Figure 219: P2MP mLDP in PBB-EVPN shows the setup for P2MP mLDP in PBB-EVPN.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 219: P2MP mLDP in PBB-EVPN



P2MP mLDP tunnels can also be used in PBB-EVPN services. In Release 14.0, the use of **provider-tunnel inclusive mldp** is only for the default multicast list; no per-ISID IMET-P2MP routes are supported.

The Backbone (B) -VPLS still uses Multicast Forwarding Information Bases (MFIBs) for ISIDs using IR.

If an ISID policy is configured in the B-VPLS, a range of ISIDs configured with **use-def-mcast** use the P2MP tree, and a range of ISIDs configured with **advertise-local** make the router advertise IMET-IR routes for the local ISIDs in the range.

PE-1 is configured with **root-and-leaf**. The configuration for B-VPLS and I-VPLS is as follows:

```
# On PE-1:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                }
            }
            bgp 1 {
            }
            bgp-evpn {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
            isid-policy {
                entry 10 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 1001
                        end 2000
                    }
                }
            }
        }
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            sap 1/2/c3/1 {    # sap for ingress traffic from STC
            }
        }
    }
```

In this example, ISIDs in the range from 1001 to 2000 use the P2MP tree (**use-def-mcast**) and the router does not advertise the IMET-IR routes for the local ISIDs included in that range (**no advertise-local**). Any other local ISID advertises an IMET-IR and uses the MFIB to forward BUM packets to the remote EVPN-MPLS bindings created by IMET-IR routes.

The configuration on the leaf nodes PE-5, PE-6, and PE-7 is similar to the one for the root node, except for the absence of the **root-and-leaf** setting (which is default), as follows:

```
# On PE-5:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:05
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
            isid-policy {
                entry 10 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 1001
                        end 2000
                    }
                }
            }
        }
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            sap 1/2/c1/1:1001 {    # sap for egress traffic to VPLS 1001
            }
        }
    }
```

A VPLS-PMSI SDP is auto-created in the B-VPLS at the root node, as follows:

```
[/]
A:admin@PE-1# show service id 1000 sdp

===============================================================================
Services: Service Destination Points
===============================================================================

Use subject to Terms available at: www.nokia.com/terms.

The default multicast list for the B-VPLS 1000 can be retrieved on root node and leaf nodes, for instance for leaf node PE-5, as follows:

```
[/]
A:admin@PE-5# tools dump service id 1000 evpn-mpls default-multicast-list
-------------------------------------------------------------------------
TEP Address                           Egr Label
                                      Transport
-------------------------------------------------------------------------
192.0.2.1                             524283
                                      ldp
192.0.2.6                             524286
                                      ldp
192.0.2.7                             524281
                                      ldp
-------------------------------------------------------------------------
```

IGMP snooping can be enabled in the I-VPLS 1001 on all PEs, as follows:

```
configure {
    service {
        vpls "I-VPLS 1001" {
            igmp-snooping {
                admin-state enable
            }
```

After IGMP snooping is enabled, the multicast stream is not flooded anymore to any receivers until they send an IGMP report for the multicast stream.

On each PE, the logical interface B-EVPN-MPLS is added as a single IGMP snooping interface and treated as an mrouter, as follows:

```
[/]
A:admin@PE-5# show service id 1001 igmp-snooping base

===============================================================================
IGMP Snooping Base info for service 1001
===============================================================================

-------------------------------------------------------------------------------
Number of mrouters: 1
===============================================================================
```

Conclusion

Service providers are migrating their existing VPN services to EVPN and expect at least the same capabilities in EVPN, including the forwarding of BUM traffic. Ingress replication is a good mechanism for broadcast and unknown unicast traffic in EVPN networks, but not efficient for multicast applications. EVPN P2MP mLDP offers efficiency for multicast, using composite tunnels combining the benefits of P2MP mLDP and IR.

PBB-Epipe

This chapter provides information about Provider Backbone Bridging (PBB) — Ethernet Virtual Leased Line in an MPLS-based network which is applicable to SR OS.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 7.0.R5. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2. There are no specific prerequisites.

Overview

RFC 7041, *Extensions to VPLS PE model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

The PBB model is organized around a B-component (backbone instance) and an I-component (customer instance). In Nokia's implementation of the PBB model, the use of an Epipe as I-component is allowed for point-to-point services. Multiple I-VPLS and Epipe services can be all mapped to the same B-VPLS (backbone VPLS instance).

The use of Epipe scales the E-Line services because no MAC switching, learning, or replication is required in order to deliver the point-to-point service. All packets ingressing the customer SAP are PBB-encapsulated and unicasted through the B-VPLS tunnel using the backbone destination MAC of the remote PBB PE. All the packets egressing the B-VPLS destined for the Epipe are PBB de-encapsulated and forwarded to the customer SAP.

Some use cases for PBB-Epipe are:

- Get a more efficient and scalable solution for point-to-point services:
  - Up to 8K VPLS services per box are supported (including I-VPLS or B-VPLS) and using I-VPLS for point-to-point services takes VPLS resources as well as unnecessary customer MAC learning. A better solution is to connect a PBB-Epipe to a B-VPLS instance, where there is no customer MAC switching/learning.
- Take advantage of the pseudowire aggregation in the M:1 model:
  - Many Epipe services may use only a single service and set of pseudowires over the backbone.
- Have a uniform provisioning model for both point-to-point (Epipe) and multipoint (VPLS) services.
  - Using the PBB-Epipe, the core MPLS/pseudowire infrastructure does not need to be modified: the new Epipe inherits the existing pseudowire and MPLS structure already configured on the B-VPLS and there is no need for configuring new tunnels or pseudowire switching instances at the core.

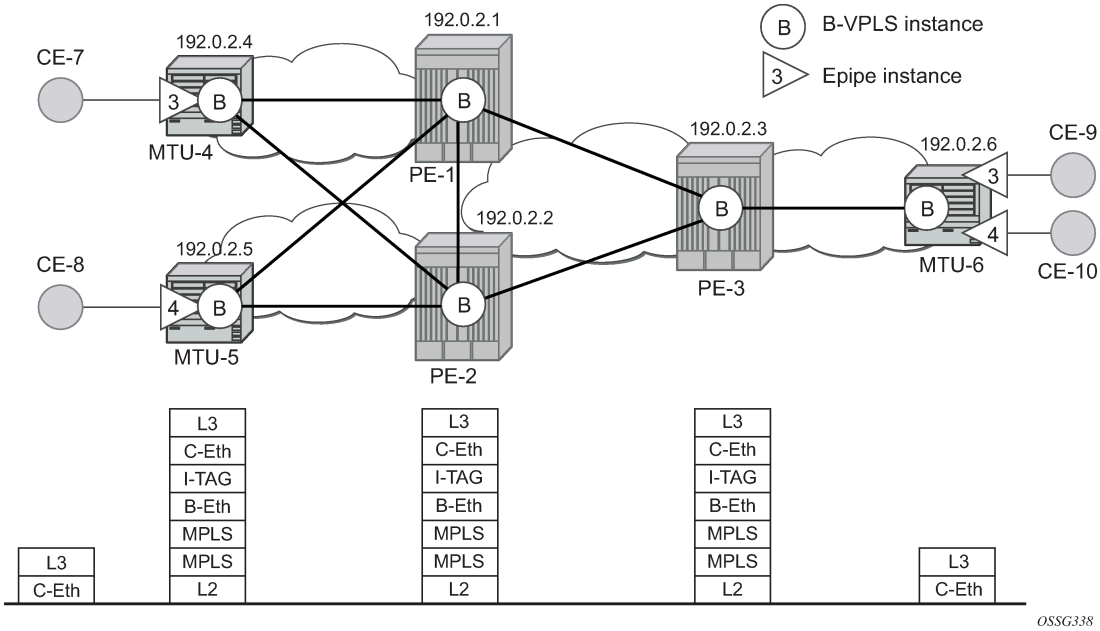
Knowledge of the PBB-VPLS architecture and functionality on the service router family is assumed throughout this section. For additional information, see the relevant Nokia user documentation.

The following network setup will be used throughout the rest of the chapter.

Figure 220: Network topology



The setup consists of a three SR OS routers in the core (PE-1, PE-2, and PE-3) core and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 101) will be defined in all the six nodes, whereas two Epipe services will be defined as illustrated in Figure 220: Network topology (Epipe 3 in nodes MTU-4 and MTU-6, Epipe 4 in nodes MTU-5 and MTU-6). Those Epipe services will be multiplexed into the common B-VPLS 101, using the I-Service ID (ISID) field within the I-TAG as the demultiplexer field required at the egress MTU to differentiate each specific customer. I-VPLS and Epipe services can be mapped to the same B-VPLS.

The B-VPLS domain constitutes a H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby (A/S) spoke-SDPs can be used from the MTUs to the PEs (like in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (like MTU-6).

The protocol stack being used along the path between the CEs is represented in Figure 220: Network topology.

Configuration

This section describes all the relevant PBB-Epipe configuration tasks for the setup shown in Figure 220: Network topology. The appropriate B-VPLS and associated IP/MPLS configuration is out of the scope of this document. In this particular example, the following protocols will be configured beforehand in the core:

- ISIS-TE as IGP with all the interfaces being level-2. Alternatively, OSPF could have been used.
- RSVP-TE as the MPLS protocol to signal the transport tunnels.
- LSPs between core PEs will be fast re-route protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

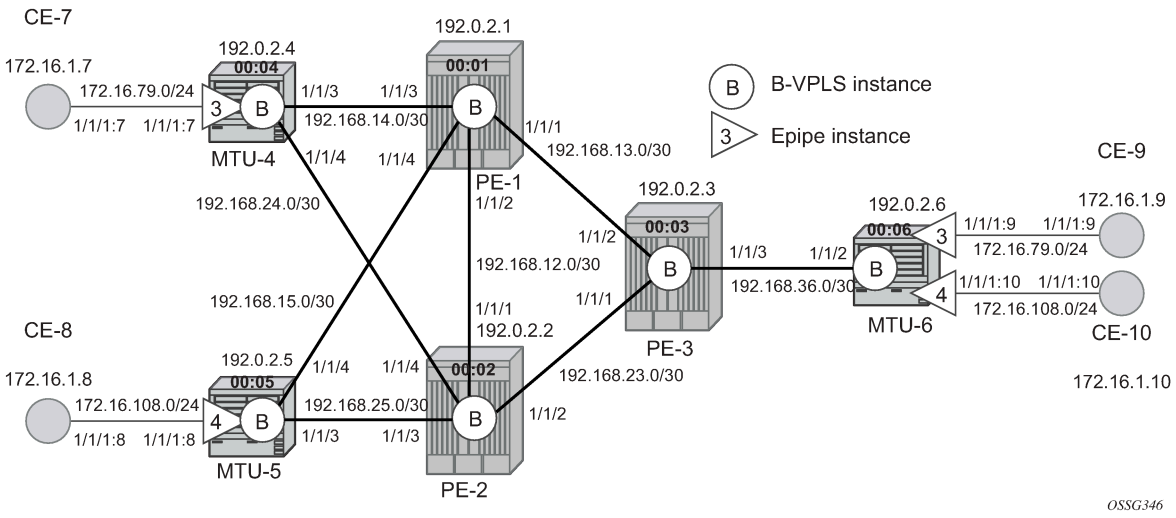
- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the A/S pseudowire protection configured in the B-VPLS.
- BGP is configured for auto-discovery—BGP-AD (Layer 2 VPN family), because FEC 129 will be used to establish the pseudowires between PEs in the core (FEC 128 between MTU and PE nodes).

Once the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB Epipe service configuration

In this particular example, the Epipes 3 and 4 are using the B-VPLS 101 in the core. The same B-VPLS which is multiplexing the Epipe services into a common service provider infrastructure can also be used to connect the I-VPLS instances existing in the network for multipoint services.

Figure 221: Setup detailed view



B-VPLS and PBB configuration

First, configure the B-VPLS instance that will carry the PBB traffic. There is no specific requirement on the B-VPLS to support Epipes. The following shows the B-VPLS configuration on MTU-4 and PE-1.

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:04:04:04:04:04
                }
            }
            endpoint "core" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                suppress-standby-signaling false
            }
            spoke-sdp 41:101 {
                endpoint {
                    name "core"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 42:101 {
                endpoint {
                    name "core"
                }
                stp {
                    admin-state disable
                }
            }
        }
```

```
# on PE-1:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
            provisioned-sdp use
            split-horizon-group {
                name "CORE"
            }
        }
        vpls "B-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:01:01:01:01:01
                }
            }
            bgp 1 {
                route-target {
                    export "target:65000:101"
                    import "target:65000:101"
                }
                pw-template-binding "PW1" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65000:101"
            }
            spoke-sdp 14:101 {
            }
            spoke-sdp 15:101 {
            }
        }
```

- The B-VPLS service MTU must be at least 18 bytes greater than the Epipe MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1514 bytes),

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

therefore, any MTU equal or greater than 1532 bytes must be configured. In this particular example, an MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.

- The source B-MAC is the MAC that will be used as a source when the PBB traffic is originated from that node. It is possible to configure a source B-MAC per B-VPLS instance (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. A common B-MAC is configured as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
        }
```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported.
  - Default SAP types are blocked in the CLI for the B-VPLS SAP.
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowire, the outgoing PBB frame on an SDP (for example, Bpseudowire) contains a BVID q-tag only if the pseudowire type is Ethernet VLAN (vc-type=vlan). If the pseudowire type is Ethernet (vc-type=ether), the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS, therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group has been configured to emulate the behavior of mesh SDPs in the core.
- While Multiple MAC Registration Protocol (MMRP) is useful to optimize the flooding in the B-VPLS domain and build a flooding tree on a per I-VPLS basis, it does not have any effect for Epipes because the destination B-MAC used for Epipes is always the destination B-MAC configured in the Epipe and never the group B-MAC corresponding to the ISID.
- If a local Epipe instance is associated with the B-VPLS, local frames originated or terminated on local Epipe(s) are PBB encapsulated or de-encapsulated using the PBB Etype provisioned under the related port or SDP component.

By default, the PBB Etype is 0x88e7 (which is the standard one defined in the 802.1ah, indicating that there is an I-TAG in the payload) but this PBB Etype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
[ex:configure port 1/1/3 ethernet]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 35047

    Ethertype for PBB encapsulation on the Ethernet port
```

```
[ex:configure service sdp 41]
A:admin@MTU-4# pbb-etype ?
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 0x88E7

    Ethertype used in frames sent out on this SDP when VC type is 'vlan' for
    Provider Backbone Bridging frames
    as 0xXXYY with range 0x0600-0xFFFF.
```

The following commands are useful to check the actual PBB Etype.

```
[]
A:admin@MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                   PBB Etype          : 0x88e7
```

```
[]
A:admin@MTU-4# show port 1/1/3 | match PBB
PBB Ethertype      : 0x88e7
```

Before configuring the Epipe itself, the operator can optionally configure MAC names under the PBB context. MAC names will simplify the Epipe provisioning later on and in case of any change on the remote node MAC address, only one configuration modification is required as opposed as one change per affected Epipe (potentially thousands of Epipes which are terminated onto the same remote node). The MAC names are configured in the service PBB CLI context:

```
[ex:configure service pbb]
A:admin@MTU-4# mac ?

 [name] <string>
 <string> - <1..32 characters>

    MAC address name
```

The MAC names of the MTUs are configured on all nodes, as follows:

```
# on all nodes:
configure {
    service {
        pbb {
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
```

It is not required to configure a node with its own MAC address, so on MTU-4, the line defining the mac-name MTU-4 can be omitted.

Epipe configuration

Once the common B-VPLS is configured, the next step is the provisioning of the customer Epipe instances. For PBB-Epipes, the I-component or Epipe is composed of an I-SAP and a PBB tunnel endpoint which points to the backbone destination MAC address (B-DA).

The following outputs show the relevant CLI configuration for the two Epipe instances represented in Figure 221: Setup detailed view. The Epipe instances are configured on the MTU devices, whereas the core PEs are kept as customer-unaware nodes.

Epipes 3 and 4 are configured on MTU-6 as follows:

```
# on MTU-6:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-4"
                }
            }
            sap 1/1/1:9 {
            }
        }
        epipe "Epipe 4" {
            admin-state enable
            description "pbb epipe number 4"
            service-id 4
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 4
                    backbone-dest-mac-name "MTU-5"
                }
            }
            sap 1/1/1:10 {
            }
        }
```

The following shows the Epipe configuration on MTU-4 and MTU-5.

```
# on MTU-4:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-6"
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap 1/1/1:7 {
            }
        }
```

```
# on MTU-5:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            description "pbb epipe number 4"
            service-id 4
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 4
                    backbone-dest-mac-name "MTU-6"
                }
            }
            sap 1/1/1:8 {
            }
        }
```

All Ethernet SAPs supported by a regular Epipe are also supported in the PBB Epipe. spoke-SDPs are not supported in PBB-Epipes, for example, no spoke-SDP is allowed when PBB tunnels are configured on the Epipe.

The PBB tunnel links the SAP configured to the B-VPLS 101 existing in the core. The following parameters are accepted in the PBB tunnel configuration:

```
[ex:configure service epipe "Epipe 4" pbb]
A:admin@MTU-5# tunnel ?

 tunnel

 Immutable fields     - backbone-vpls-service-name, isid

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 backbone-vpls-        ^ Backbone VPLS service
  service-name
 isid                  ^ Service instance ID

 Mandatory choice: backbone-mac
 backbone-dest-mac    :- Backbone Destination MAC address
 backbone-dest-mac-   :- Name for backbone Destination MAC address
  name
```

Where:

- The backbone VPLS service name matches the B-VPLS name, in this case, "B-VPLS 101".
- The backbone destination can be configured by a MAC name (as in the configuration example, with MAC name "MTU-6") or the MAC address itself. It is recommended to use MAC names, as explained in the previous section.
- The ISID corresponds to the Epipe service ID and must be specified.

Use subject to Terms available at: www.nokia.com/terms.

Flood avoidance in PBB-Epipes

As already discussed in the previous section, when provisioning a PBB Epipe, the remote backbone destination MAC (MAC name or MAC address) must be explicitly configured on the PBB tunnel so that the ingress PBB node can build the 802.1ah encapsulation.

If the configured remote backbone destination MAC address is not known in the local FDB, the Epipe customer frames will be 802.1ah encapsulated and flooded into the B-VPLS until the MAC address is learned. As previously stated, MMRP does not help to minimize the flooding because the PBB Epipes always use the configured backbone destination MAC for flooding traffic as opposed to the group B-MAC derived from the ISID.

Flooding could be indefinably prolonged in the following cases:

- Configuration mistake of the backbone destination MAC (either MAC name or MAC address). The service will not work, but the operator will not detect the mistake, because the customer traffic is not dropped at the source node. Every single frame is turned into an unknown unicast PBB frame and therefore flooded into the B-VPLS domain.
- Change the backbone source MAC in the remote PE B-VPLS instance.
- There is only unidirectional traffic in the Epipe service. In this case, the backbone destination MAC address will never be learned in the local FIB and the frames will always be flooded into the B-VPLS domain.
- The remote node owning the backbone destination MAC simply goes down.

In any of those cases, the operator can easily check whether the PBB Epipe is flooding into the B-VPLS domain, just by looking at the flood flag in the following command output:

```
[]
A:admin@MTU-4# show service id 3 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 3                   Vpn Id            : 0

===============================================================================
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In this particular example, the PBB Epipe 3 is flooding into the B-VPLS 101, as the flood flag indicates. The operator can also confirm that the operational destination B-MAC for the PBB tunnel, MTU-6, has not been learned in the B-VPLS FDB:

```
[]
A:admin@MTU-4# show service id 101 fdb pbb

===============================================================================
Forwarding Database, b-Vpls Service 101
===============================================================================
MAC               Source-Identifier     iVplsMACs  Epipes     Type/Age
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

In small B-VPLS environments (up to 20 B-VPLSs, each with 10 MC-LAGs), it is possible to configure the PBB V-VPLS MAC notification mechanism to send notification messages at regular intervals (using the renotify parameter), rather than being only event-driven. This can avoid flooding into the B-VPLS.

Flooding cases 1 and 2 — Wrong backbone destination MAC

Flooding cases 1 and 2 should be fixed after detecting the flooding (see previous commands) and checking the FDBs and PBB tunnel configurations.

Flooding case 3 — Unidirectional traffic: virtual MEP and CCM configuration

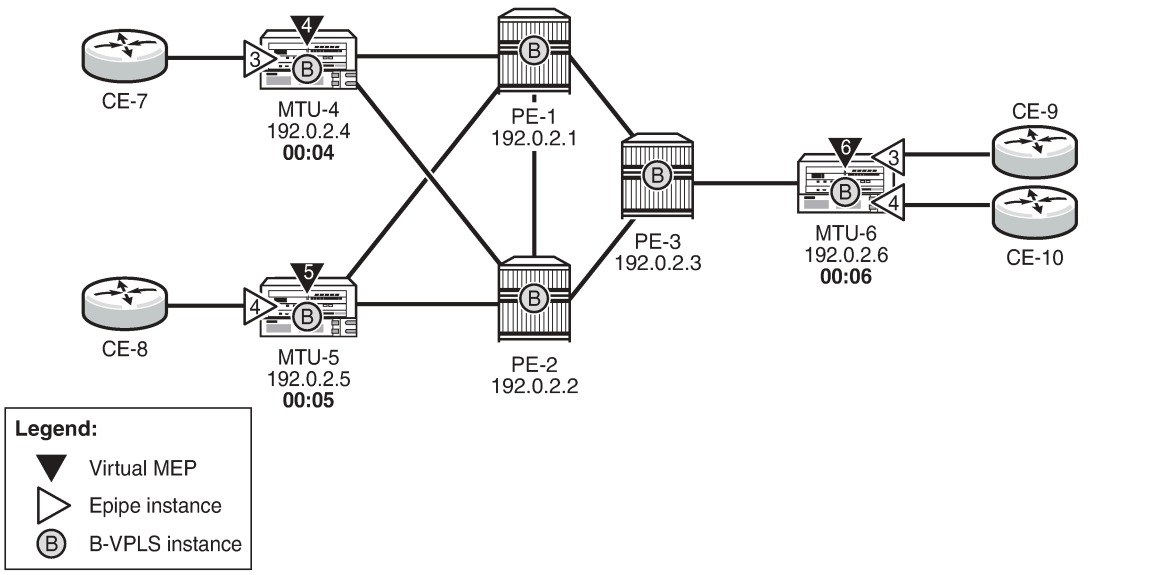
For flooding case 3 (unidirectional traffic), Nokia recommends the use of ETH-CFM (802.1ag/Y.1731 Connectivity Fault Management) virtual Maintenance End Points (MEPs). By defining a virtual MEP per node terminating a PBB Epipe, configuring the MEP MAC address to be the source BMAC value and activating continuity check messages (CCM), a twofold effect is achieved:

- The PBB tunnel backbone destination MAC address will always be learned at the local FDB, as long as the remote virtual MEP is active and sending CC messages. As a result, there will not be flooding even if we have unidirectional traffic.
- An automatic proactive OAM mechanism exists to detect failures on remote nodes, which ultimately cause unnecessary flooding in the B-VPLS domain.

In the following network example, the virtual MEPs in B-VPLS 101: MEP4, MEP5, and MEP6 are configured.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 222: Virtual MEPs for flooding avoidance



The following configuration example uses MTU-4. First, the general ETH-CFM configuration is made, as follows:

```
# on MTU-4:
configure {
    eth-cfm {
        domain "domain-1" {
            level 3
            name "domain-1"
            md-index 1
            association "assoc-1" {
                icc-based "B-VPLS-000101"
                ma-index 1
                bridge-identifier "B-VPLS 101" {
                }
                remote-mep 5 {
                }
                remote-mep 6 {
                }
            }
```

Then the actual virtual MEP configuration is made:

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 101" {
            eth-cfm {
                mep md-admin-name "domain-1" ma-admin-name "assoc-1" mep-id 4 {
                    admin-state enable
                    mac-address 00:04:04:04:04:04
                    ccm true
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

The MAC address configured for the MEP4 matches the MAC address configured as the **source-bmac** on MTU-4, which is the **backbone-destination-mac** configured on the Epipe 3 PBB tunnel on MTU-6. The source-BMAC address on MTU-4 is 00:04:04:04:04:04, as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
```

In Epipe 3 on MTU-6, the configured backbone destination MAC name is MAC name "MTU-4", which corresponds to MAC address 00:04:04:04:04:04, as follows:

```
# on MTU-6:
configure {
    service {
        pbb {
            source-bmac {
                address 00:06:06:06:06:06
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-4"
                }
            }
            sap 1/1/1:9 {
            }
        }
```

Once MEP4 has been configured, check that MTU-6 is receiving CC messages from MEP4 with the following command:

```
[]
A:admin@MTU-6# show eth-cfm mep 6 domain 1 association 1 all-remote-mepids

================================================================================
Eth-CFM Remote-Mep Table
================================================================================
R-mepId AD Rx CC RxRdi Port-Tlv If-Tlv Peer Mac Addr     CCM status since
--------------------------------------------------------------------------------
4          True  False Absent   Absent 00:04:04:04:04:04 01/11/2021 16:26:59
5          True  False Absent   Absent 00:05:05:05:05:05 01/11/2021 16:26:59
================================================================================
Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

As a result of the CC messages coming from MEP4, the MTU-4 MAC is permanently learned in the B-VPLS 101 FDB on node MTU-6 and no flooding takes place. The following output shows that the flooding flag is not set.

```
[]
A:admin@MTU-6# show service id 3 base

```

Flooding case 4 — Remote node failure

If the node owner of the backbone destination MAC fails or gets isolated, the node where the PBB Epipe is initiated will not detect the failure; that is, if MTU-4 fails, the Epipe 3 remote end will also fail, but MTU-6 will not detect the failure and, as a result of that, MTU-6 will flood the traffic to the network (flooding will occur after MTU-4 MAC is removed from the B-VPLS FDBs, due to either the B-VPLS flushing mechanisms or aging).

In order to avoid/reduce flooding in this case, the following mechanisms are recommended:

- Provision virtual MEPs in the B-VPLS instances terminating PBB Epipes, as already explained. This will guarantee there is no unknown B-MAC unicast being flooded under normal operation.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- CCM timers should be provisioned based on how long the service provider is willing to accept flooding.

```
[ex:configure eth-cfm domain "domain-1" association "assoc-1"]
A:admin@MTU-6# ccm-interval ?

 ccm-interval <keyword>
 <keyword> - (10ms|100ms|1s|10s|60s|600s)
 Default   - 10s

    CCM transmission interval for all MEPs in the association
```

- It is possible to provision **discard-unknown** in the B-VPLS, so that flooded traffic due to the destination MAC being unknown in the B-VPLS is discarded immediately. This can be configured on the PEs and the MTUs. On the MTUs, it is important to configure this in conjunction with the CC messages from the virtual MEPs to ensure that the remote B-MACs are learned in both directions. If, for any reason, the remote B-MACs are not in the MTU B-VPLS, no traffic will be forwarded at all on the PBB-Epipe.

```
configure {
    service {
        vpls "B-VPLS 101" {
            fdb {
                discard-unknown true
            }
```

  As soon as the MTU node recovers, it will start sending CC messages and the backbone MAC address will be learned on the backbone nodes and MTU nodes again.

With the recommended configuration in place, in case MTU-4 fails, the backbone destination MAC configured on the PBB tunnel for Epipe 3 on MTU-6 will be removed from the B-VPLS 101 on all the nodes (either by MAC flush mechanisms on the B-VPLS or by aging). From that point on, traffic originated from CE-9 will be discarded at MTU-6 and won't be flooded further.

As soon as MTU-4 comes back up, MEP4 will start sending CCM and as such the MTU-4 MAC will be learned throughout the B-VPLS 101 domain and in particular in PE-1, PE-3, and MTU-6 (CCM PDUs use a multicast address). From the moment MTU-4 MAC is known on the backbone nodes and MTU-6, the traffic will not be discarded any more, but forwarded to MTU-4.

PBB-Epipe show commands

The following commands can help to check the PBB Epipe configuration and their related parameters.

For the B-VPLS service:

```
[]
A:admin@MTU-4# show service id 101 base

The bDefRemoteCCMdefect flag clearly shows that there is a remote MEP in the association which has stopped sending CCMs. In order to find out which node is affected, see the following output:

```
[]
A:admin@MTU-4# show eth-cfm mep 4 domain 1 association 1 all-remote-mepids

===============================================================================
Eth-CFM Remote-Mep Table

Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

CCMs are no longer received from virtual MEP 6 (the one defined in MTU-6) since 01/11/2021 16:43:56. This conveys which node has failed and when it failed.

Conclusion

Point-to-Point Ethernet services can use the same operational model followed by PBB VPLS for multipoint services. In other words, Epipes can be linked to the same B-VPLS domain being used by I-VPLS instances and use the existing H-VPLS network infrastructure in the core. The use of PBB Epipes reduces dramatically the number of services and pseudowires in the core and therefore allows the service provider to scale the number of E-Line services in the network.

The example used in this document shows the configuration of the PBB Epipes as well as all the related features which are required for this environment. Show commands have also been suggested so that the operator can verify and troubleshoot the service.

PBB-EVPN ISID-based CMAC Flush

This chapter provides information about PBB-EVPN ISID-based CMAC Flush.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. PBB-EVPN ISID-based CMAC flush is supported on the following objects in an I-VPLS:

- SAPs in a BGP multi-homing site (no Ethernet Segment (ES))-supported in SR OS Release 14.0.R4, and later
- SAPs in ESs or virtual ESs (vESs)-SR OS Release 15.0.R1, and later
- Spoke-SDPs (that may be part of an ES/vES or not)-SR OS Release 15.0.R4, and later.

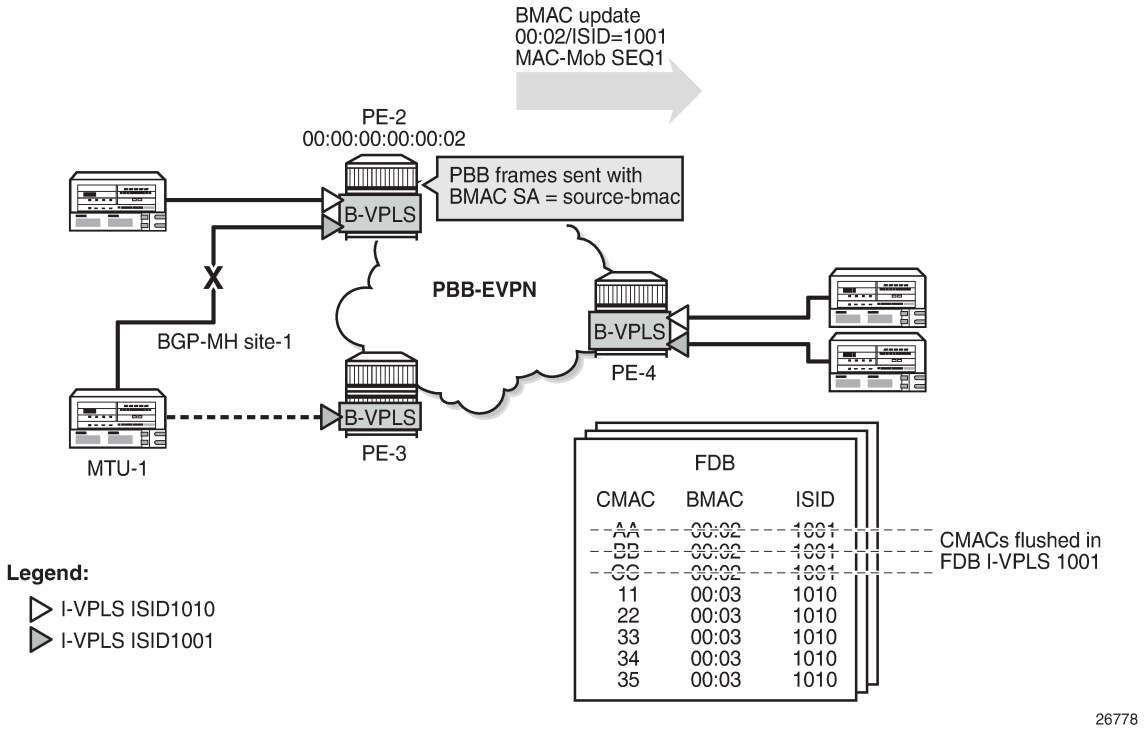
Chapter EVPN for PBB over MPLS (PBB-EVPN) is prerequisite reading.

Overview

Figure 223: CMAC flush when SAP in BGP multi-homing site fails shows an example topology with PBB-EVPN where a CMAC flush is triggered after a SAP in a BGP multi-homing site fails.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 223: CMAC flush when SAP in BGP multi-homing site fails



I-VPLS 1001 is configured in PE-2 and PE-3 with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** and connected to MTU-1. In the example, the SAP goes operationally down in I-VPLS 1001 on PE-2. To speed up convergence without flushing CMAC addresses in other I-VPLS services, PE-2 sends a BGP-EVPN BMAC route for ISID 1001 with increased sequence number to trigger a MAC-flush for I-VPLS 1001 on the remote PEs. All CMAC addresses in the FDB for other I-VPLS services, such as I-VPLS 1010 in this example, will be preserved. When PE-4 needs to send traffic to one of the flushed CMAC addresses in I-VPLS 1001, it will flood the frames until the CMAC address is learned again (via PE-3).

When SAPs or SDP-bindings-associated with ESs, vESs, or BGP-MH sites-in an I-VPLS service fail, a BGP-EVPN BMAC route (route type 2) can trigger an ISID-based CMAC flush on the remote PEs. For the CMAC addresses to be flushed from the FDB of the I-VPLS, the existing EVPN BMAC routes will be used with the Ethernet tag equal to the ISID. Figure 224: EVPN BMAC route with ISID indication shows the EVPN BMAC route with ISID indication (BMAC/ISID). A BMAC/ISID update may trigger a selective MAC-flush for a specific I-VPLS, whereas a BMAC/0 update (BMAC/ISID route where ISID=0) may trigger a MAC-flush for all I-VPLS services. This procedure is based on *draft-snr-bess-pbb-evpn-isid-cmacflush*.

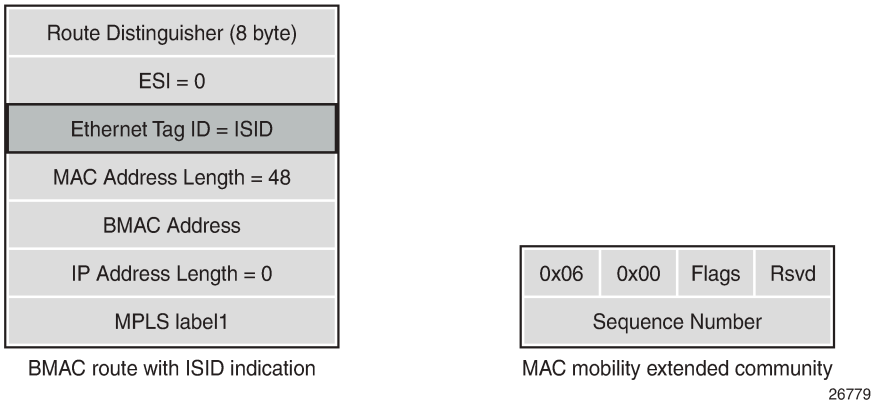
Figure 224: EVPN BMAC route with ISID indication



By default, ISID-based CMAC flush is disabled: no I-VPLS will send a B-VPLS EVPN flush message and no B-VPLS will accept any I-VPLS EVPN flush messages. The router only installs CMAC entries corresponding to a zero Ethernet tag and ignores non-zero Ethernet tag MAC routes. However, when the B-VPLS is configured to accept BMAC/ISID routes, non-zero Ethernet tag BMAC routes can be processed for CMAC flush. The CMAC flush trigger will be an EVPN BMAC/ISID route with a sequence number that is higher than before. The receiving PE will then flush all CMACs associated with this BMAC address in the I-VPLS.

The first time that a BMAC/ISID route is received, it is added to the database as a baseline. It does not cause a CMAC flush. Only subsequent BMAC/ISID updates with increased sequence number or withdrawals will cause CMAC flush.

The following command shows that B-VPLS 1000 does not accept any I-VPLS EVPN flush messages. This is the default behavior.

```
[/]
A:admin@PE-2# show service id 1000 bgp-evpn | match "Accept IVPLS Flush"
Accept IVPLS Flush : Disabled
```

At the receiving node, B-VPLS 1000 will accept BMAC/ISID routes when the following command is configured:

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS 1000" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
```

By default, I-VPLS 1001 will not send any B-VPLS EVPN flush messages, as follows:

```
[/]
A:admin@PE-2# show service id 1001 base | match SendBvplsEvpnFlush
SendBvplsEvpnFlush: Disabled
```

The following configuration allows I-VPLS 1001 to send B-VPLS EVPN flush messages when a SAP or SDP-binding fails:

```
# on PE-2:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        vpls "I-VPLS 1001" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
```

When enabled, the I-VPLS will send a BMAC/ISID route and subsequent updates with a higher sequence number whenever a SAP fails in the I-VPLS on the node. The default setting for a SAP allows a B-VPLS EVPN flush message to be sent (when enabled in the I-VPLS itself):

```
[/]
A:admin@PE-2# show service id 1001 sap 1/2/1:1001 detail | match SendBvplsEvpnFlush
SendBvplsEvpnFlush : Enabled
```

When no alternative route via another node is available for specific SAPs (single-homed SAPs), no CMAC flush should be triggered. When no B-VPLS EVPN flush messages need to be sent from PE-4 when SAP 1/2/1:1001 goes down, the configuration is as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1001" {
            sap 1/2/1:1001 {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls false
```

The router only installs the BMACs received in MAC routes that have Ethernet tag zero. When CMAC flush is enabled, MAC routes with Ethernet tag equal to the ISID (always non-zero) are for CMAC flush, but not for installing the conveyed BMACs.

BMAC/ISID routes have the following characteristics:

- BMAC/ISID routes are sent with the static bit flag set as for any other BMAC route. The static bit is ignored at reception because this route is never used to install a BMAC in the FDB.
- BMAC/ISID routes received with non-zero ESI and non-zero Ethernet tag are treated as withdraw by the router at application level. Route Reflectors (RRs) treat such BMAC/ISID routes as valid routes that can be forwarded.
- BMAC/ISID routes are shown as valid in the **show router bgp routes evpn mac** commands, as in the following output, even though they are not used to populate the FDB. This shows that BGP is sending the routes to the application layer for CMAC flush processing. The BMAC/0 route should be sent before the BMAC/ISID routes for the same BMAC. Also, when the B-VPLS goes operationally down, the BMAC/0 should be withdrawn before the BMAC/ISID routes.

When **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** is configured in an I-VPLS that is associated with a B-VPLS, BGP-EVPN BMAC/ISID updates will be sent when certain events take place in the I-VPLS or B-VPLS. Table 12: CMAC flush transmission behavior shows the CMAC flush transmission behavior at the egress PE.

Table 12: CMAC flush transmission behavior

Local Event	pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	sap>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	Action
Reconfigure I-VPLS: enable or disable send-to-bvpls	true or false	N/A	Send update/withdraw source BMAC/ISID with Seq=0
Associate/disassociate I-VPLS to/from B-VPLS	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
I-VPLS oper-up/oper-down	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
B-VPLS oper-up/oper-down	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0 Note: All BMACs are also advertised/withdrawn.
B-VPLS bgp-evpn mpls enabled/disabled	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Local Event	pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	sap>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	Action
B-VPLS operational source BMAC change	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
SAP oper-up	true	N/A	No operation
SAP oper-down	true	true	Send update source BMAC/ ISID Seq=Seq+1
	true	false	No operation

Table 13: CMAC flush reception behavior shows the reception behavior at the ingress PE. For the CMAC flush triggered by a BMAC/ISID update with increased sequence number, the B-VPLS in the receiving PE must be configured with **accept-ivpls-evpn-flush true**. BMAC/0 refers to a BMAC route where the Ethernet Tag is 0.

Table 13: CMAC flush reception behavior

Received route	Action
BMAC/0 withdraw	Flush all CMACs for that BMAC
BMAC/ISID withdraw	Flush all CMACs for that BMAC and ISID
BMAC/0 update + Seq change	Flush all CMACs for that BMAC
BMAC/ISID update + Seq change	Flush all CMACs for that BMAC and ISID
BMAC/0 update + PE (NHop) change	No CMAC-flush
BMAC/ISID update + PE (NHop) change	Flush all CMACs for that BMAC and ISID

BMAC/ISID updates will trigger CMAC flush procedures regardless of the Termination Endpoint (TEP) or Route Distinguisher (RD) with which the update is received. CMAC flush will be processed even if the BMAC-ISID comes from a TEP or RD different from the BMAC/0 route. Even when the sequence number is the same as in the previous BMAC/ISID update, CMAC flush will happen when the TEP is different. When the same BMAC/ISID is received from two PEs, both are accepted and any change in sequence number causes a MAC flush. However, when the same BMAC/ISID route is received from two PEs with the same RD, BGP will select only one, so the router only sees one.

CMAC flush for ES/vES

RFC 7623 (PBB-EVPN) defines the following CMAC Flush notification mechanisms for single-active multi-homing. These notifications do not include the local ISIDs:

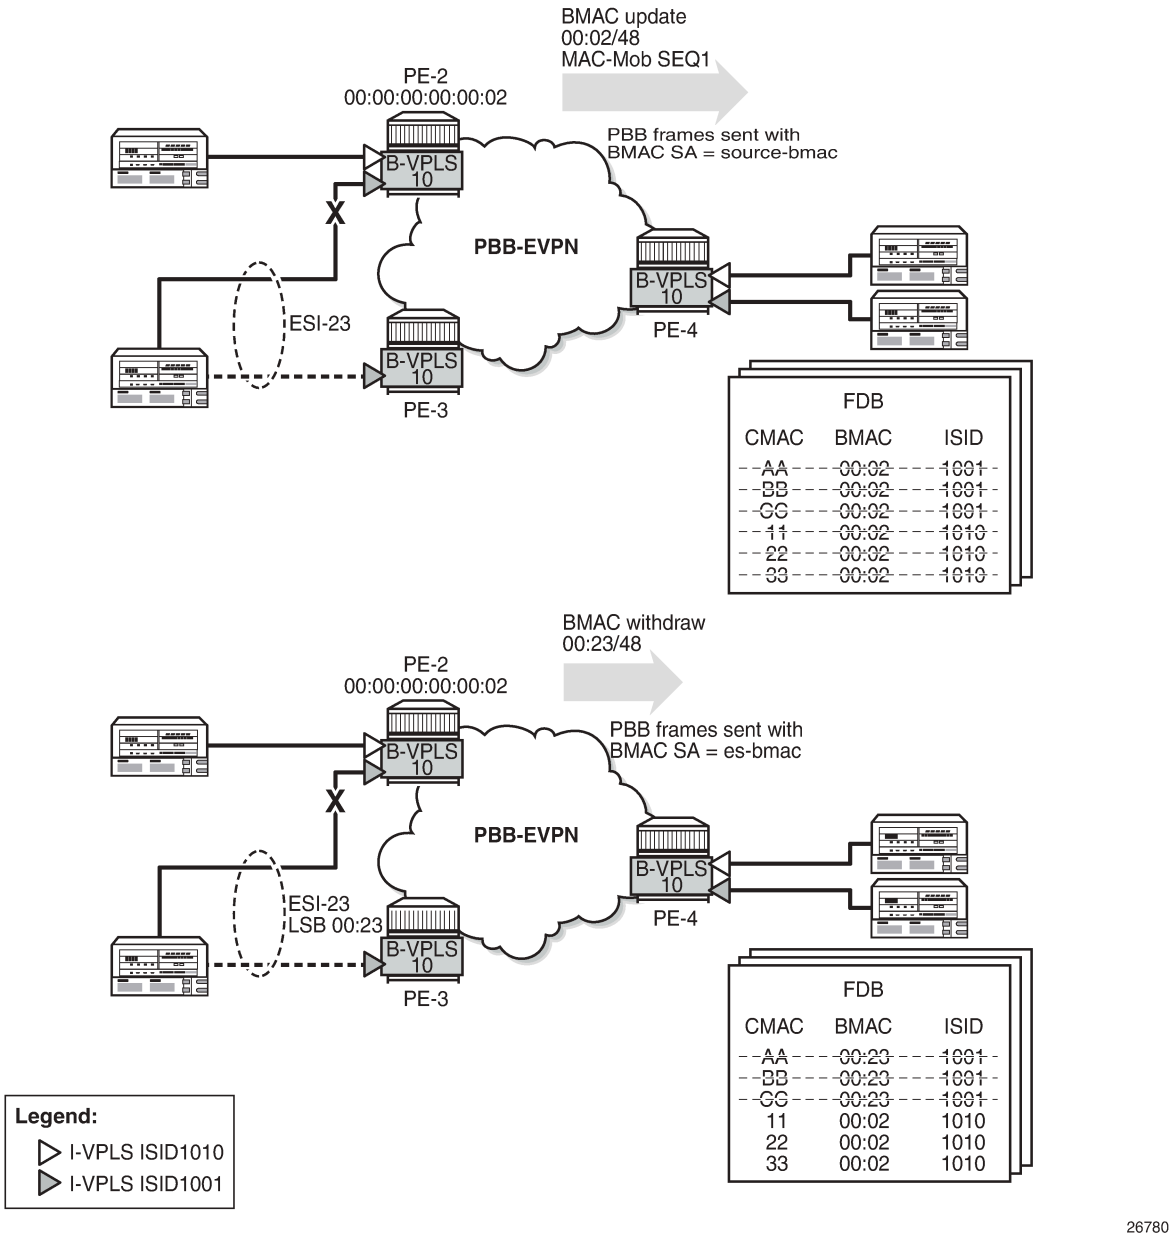
- When ES-BMACs are used and the ES goes operationally down, the ES-BMAC will be withdrawn.
- When source-BMACs are used and the ES goes operationally down, a BGP-EVPN BMAC/0 is sent with a higher sequence number.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 225: ISID-independent CMAC flush when ES fails shows the following two scenarios for ISID-independent CMAC flush that are supported in SR OS Release 13.0.R4, and later:

- PBB frames are sent with the source-BMAC. When the ES goes operationally down, a BMAC update is sent with an increased sequence number, triggering a CMAC flush for all CMAC addresses associated with the BMAC address in I-VPLS, regardless of the ISID.
- PBB frames are sent with the ES-BMAC address. When the ES goes operationally down, a BMAC withdraw message is sent, triggering the remote PEs to flush all CMAC addresses associated to the ES-BMAC address, regardless of the ISID.

Figure 225: ISID-independent CMAC flush when ES fails



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In addition to the preceding ISID-independent CMAC flush mechanisms, ISID-based CMAC flush is also supported in I-VPLS services with SAP or spoke-SDPs that are part of an ES or vES. ISID-based CMAC flush is enabled in the I-VPLS with the **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** command. An I-VPLS that is configured with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** requires one of the following conditions to be met:

- The SAP or spoke-SDP has **i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** configured.
- The SAP or spoke-SDP has **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured (default) and one of the following conditions is met:
  - The SAP or spoke-SDP is not on an ES.
  - The SAP or spoke-SDP is on an ES or vES with no **src-bmac-lsb** configured.
  - The B-VPLS has **pbb>source-bmac>use-es-bmac-lsb false** configured.

For ES SAPs with **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** in I-VPLS services that have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured, the ISID-based CMAC flush replaces the RFC 7623-based CMAC flush mechanism.

For each ES/vES and B-VPLS, the system will check whether all I-VPLS services in the ES/B-VPLS have ISID-based MAC-flush enabled.

- If all I-VPLSs have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured:
  - No BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Only BMAC/ISID updates with increased sequence number will be sent when the I-VPLS attachment circuit goes operationally down.
- If at least one I-VPLS has **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** configured:
  - BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Also, BMAC/ISID updates with increased sequence number will be generated for those I-VPLS services that have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured.

The number of CMAC addresses that may be flushed at the remote nodes can be reduced by enabling ISID-based MAC-flush for all the I-VPLS services in the ES/vES.

When attempting to set **use-es-bmac-lsb true** in B-VPLS 1000 on PE-4 when the SAP/SDP-binding has default settings (and **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** in the I-VPLS), the following error is raised:

```
[ex:/configure service vpls "B-VPLS 1000" pbb source-bmac]
A:admin@PE-4# use-es-bmac-lsb true

*[ex:/configure service vpls "B-VPLS 1000" pbb source-bmac]

```

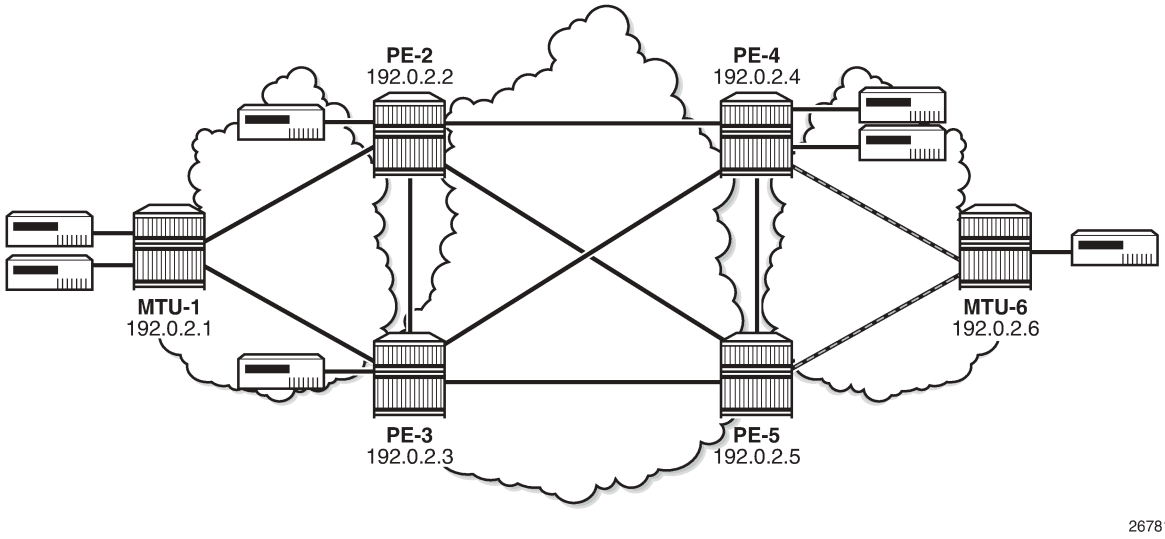
Configuration

Figure 226: Example topology shows the example topology.

Figure 226: Example topology



The initial configuration includes the following:

- Cards, MDAs
- Ports: the ports between the MTUs and the PEs are hybrid or access ports with dot1q encapsulation; the ports between the PEs are network ports with null encapsulation
- Router interfaces
- IS-IS on all router interfaces (alternatively, OSPF could be used)
- LDP on all router interfaces

The following use cases are described in this section:

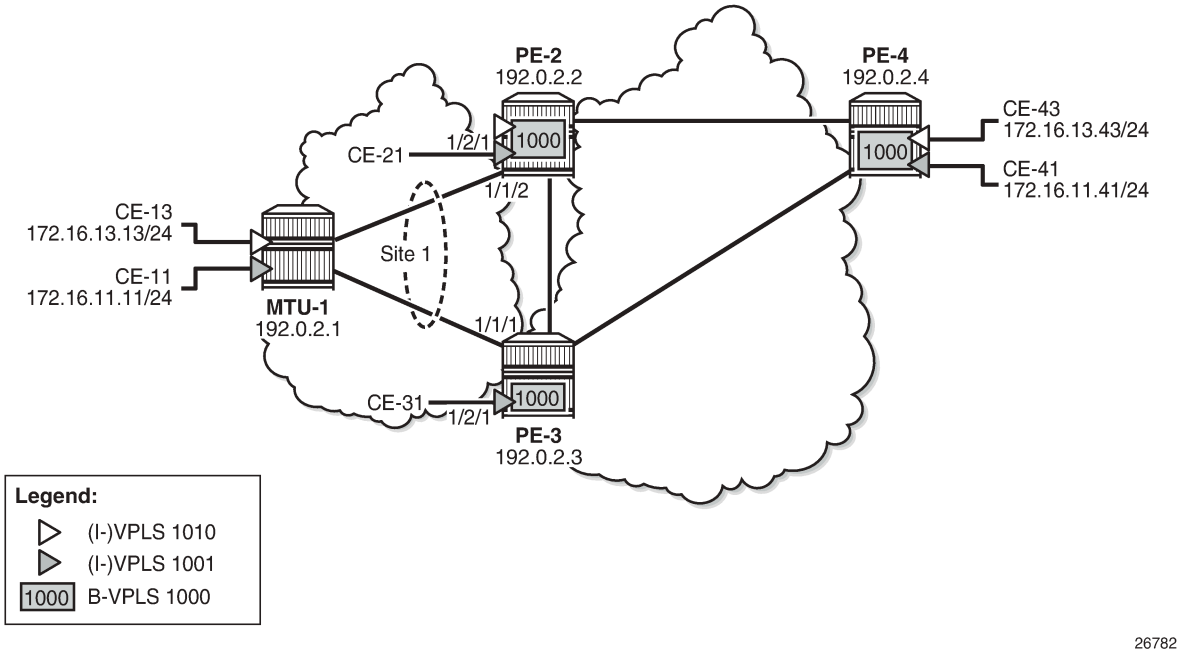
- ISID-based CMAC flush for BGP non-EVPN multi-homing (no ES)
- ISID-based CMAC flush for BGP-EVPN in a single-active ES

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

ISID-based CMAC flush for BGP multi-homing

Figure 227: Example topology with BGP multi-homing shows the example topology with BGP multi-homing site 1 between PE-2 and PE-3. B-VPLS 1000 is configured on all the core nodes (PEs) and I-VPLS 1001 and I-VPLS 1010 are associated with this B-VPLS in the PEs. On MTU-1, regular VPLSs are configured. For more information about BGP non-EVPN multi-homing, see chapter BGP Multi-Homing for VPLS Networks.

Figure 227: Example topology with BGP multi-homing



BGP is configured for address family EVPN on all PEs with PE-2 as RR. For BGP multi-homing, address family L2-VPN is enabled between PE-2 and PE-3. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base"
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                l2-vpn true
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
                family {
                    l2-vpn true
                    evpn true
                }
            }
            neighbor "192.0.2.4" {
                group "internal"
                family {
                    evpn true
                }
            }
        }
```

The BGP configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    router "Base"
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
        }
```

The configuration of B-VPLS 1000 and I-VPLS 1001 on PE-2 is as follows. ISID-based CMAC flush is disabled by default. BGP multi-homing site "MH-site-1" is configured on PE-2 with SAP 1/1/2:1001 associated with it, whereas SAP 1/2/1:1001 is not associated to the MH site. CE-21 is attached to I-VPLS 1001 with SAP 1/2/1:1001.

```
# on PE-2:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2
                community-value {
                    start 1
                    end 999
                }
            }
        }
        vpls "B-VPLS 1000" {
```

```
                }
            }
            sap 1/1/2:1010 {
            }
        }
```

I-VPLS 1010 is configured without multi-homing. The configuration of VPLS 1001 on PE-3 is similar, but without I-VPLS 1010.

ISID-based CMAC flush is not enabled yet. The PEs exchange BGP-EVPN MAC routes with Ethernet tag zero. PE-3 has received BMAC/0 routes from PE-2 and PE-4, as follows:

```
[/]
A:admin@PE-3# show router bgp routes evpn mac

===============================================================================
```

PE-2 and PE-4 have also received BMAC/0 routes from the other PEs.

ISID-based CMAC flush is enabled in I-VPLS 1001 on PE-2 and PE-3. PE-4 has no multi-homing in I-VPLS 1001, so it should not send any CMAC flush. I-VPLS 1010 has no multi-homing in any PE, so ISID-based MAC-flush should not be enabled in I-VPLS 1010.

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 1001" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-2 and PE-3 will send BMAC/1001 updates with sequence number 0 to the other two PEs. As an example, the following EVPN-MAC route for BMAC 00:00:00:00:00:03 with tag 1001 is sent by PE-3:

```
22 2021/04/15 08:07:57.818 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

```
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

When a failure occurs on PE-2, PE-3 and PE-4 should accept the BMAC/ISID with increased sequence number; for a failure on PE-3, PE-2 and PE-4 should accept the BMAC/ISID update. Therefore, the B-VPLS on all PEs should accept the CMAC flush message for ISID 1001, and this is configured as follows:

```
# on PE-2, PE-3, PE-4:
configure {
    service {
        vpls "B-VPLS 1000" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
```

The FDB for VPLS 1001 on PE-4 includes MAC address 00:00:11:11:11:11 with source-identifier 192.0.2.2:524282, so PE-4 will forward traffic toward that MAC address to PE-2.

```
[/]
A:admin@PE-4# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================

-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

A failure is simulated on SAP 1/1/2:1001 in multi-homing site 1 on PE-2 as follows:

```
# on PE-2:
configure {
    service {
        vpls "I-VPLS 1001" {
            sap 1/1/2:1001 {
                admin-state disable
```

SAP 1/1/2:1001 has the default **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** and I-VPLS 1001 is configured with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true**, so PE-2 will send BMAC/ISID updates for BMAC 00:00:00:00:00:02, ISID 1001, and sequence number 1 to its BGP peers. The following BGP update is sent by PE-2 to PE-4:

```
# on PE-2:
64 2021/04/15 08:12:55.058 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

        target:64500:1000
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:1/Static
"
```

This BMAC/ISID with sequence number 1 triggers a CMAC flush in the FDB for VPLS 1001, so the entry for 00:00:11:11:11:11 will be flushed, along with all other MAC addresses associated with BMAC 00:00:00:00:00:02. The FDB on PE-4 does not contain any entries with source-identifier BMAC 00:00:00:00:00:02, as follows:

```
[/]
A:admin@PE-4# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1001       00:00:41:41:41:41 sap:1/2/1:1001          L/150    04/15/21 08:11:36

No. of MAC Entries: 1
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

When the MAC address 00:00:11:11:11:11 is learned via PE-3, the FDB is as follows:

```
[/]
A:admin@PE-4# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
1001       00:00:11:11:11:11 b-mpls:                 L/0      04/15/21 08:15:16
                             192.0.2.3:524282
           ldp:65538
1001       00:00:41:41:41:41 sap:1/2/1:1001          L/0      04/15/21 08:11:36
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

The CMAC flush is only applied for VPLS 1001, so the FDB for VPLS 1010 on PE-4 will keep entries learned from PE-2, as follows:

```
[/]
A:admin@PE-4# show service id 1010 fdb detail
```

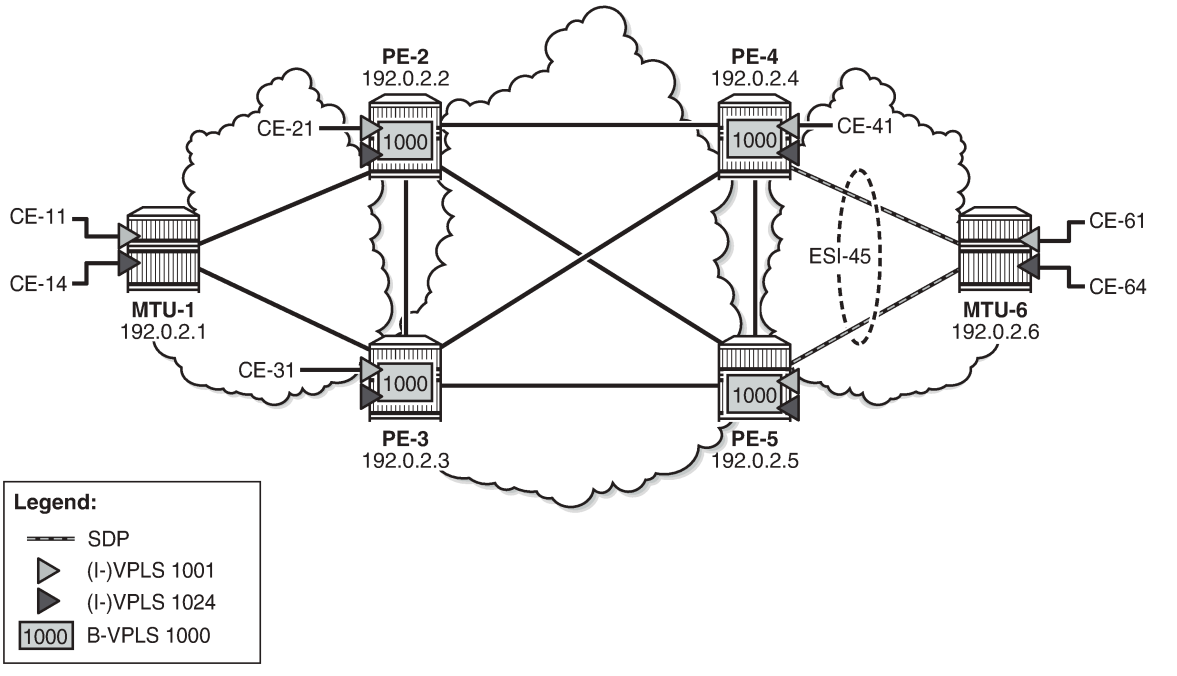
ISID-based CMAC flush in single-active ES

CMAC flush only makes sense for single-active multi-homing. Also, CMAC flush only works for single-active multi-homing; not for all-active multi-homing, because ES-BMAC is required in all-active multi-homing. Figure 228: Example topology with single-active ES shows the example topology with a single-active ES "ESI-45" configured in PE-4 and PE-5.

Figure 228: Example topology with single-active ES



The multi-homing configuration has been removed from PE-2 and PE-3, so no CMAC flush should be sent by PE-2 or PE-3. VPLS 1001 is configured as follows on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1001"
                    import "target:64500:1001"
                }
            }
            sap 1/2/1:1001 {
            }
            sap lag-1:1001 {
            }
        }
```

SDPs are configured between PE-4 and MTU-6, and between PE-5 and MTU-6. These SDPs are associated with the single-active ES "ESI-45".

The configuration of B-VPLS 1000 on PE-4 is as follows. The B-VPLS configuration on the other PEs is similar, but with a different source BMAC.

```
# on PE-4:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:04
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                accept-ivpls-evpn-flush true
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The service configuration on PE-4 includes an SDP toward PE-6 and a single-active multi-homing ES, as follows:

```
# on PE-4:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 46 {
                            }
                        }
                        pbb {
                            source-bmac-lsb 45-04
                        }
                    }
                }
            }
        }
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
```

The configuration on PE-5 is similar. The configuration of B-VPLS 1000 is similar to the one for PE-2, with only a different BMAC. The configuration of I-VPLS 1001 on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1001"
                    import "target:64500:1001"
                }
            }
            spoke-sdp 46:1001 {
            }
            sap 1/2/1:1001 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
```

ISID-based MAC-flush is enabled in B-VPLS 1000 and I-VPLS 1001 on all PEs.

I-VPLS 1024 is also associated with B-VPLS 1000 and contains one object (SAP or spoke-SDP) in each PE. The configuration of I-VPLS 1024 is identical on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 1024" {
            admin-state enable
            service-id 1024
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1024
                }
            }
            sap lag-1:1024 {
            }
        }
```

The configuration of I-VPLS 1024 on PE-4 has **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured and contains a spoke-SDP instead of a SAP, as follows. The configuration on PE-5 is similar, but with a different SDP.

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1024" {
            admin-state enable
            service-id 1024
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1024
                }
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
            spoke-sdp 46:1024 {
            }
        }
```

ISID-based MAC-flush is enabled on PE-4 and PE-5 for both I-VPLS 1001 and I-VPLS 1024, and BMAC/ISID updates are sent for ISID 1001 and ISID 1024, as follows:

```

```

PE-5 is the DF for VPLS 1001 in "ESI-45". A failure is simulated by disabling the SDP toward PE-5 on MTU-6, as follows:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state disable
```

PE-5 sends the following BMAC/ISID with increased sequence number for ISID 1001 to the RR PE-2:

```
50 2021/04/15 08:24:35.567 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:

```
"
```

When PE-3 receives this BMAC/ISID, all MAC routes with next-hop PE-5 are flushed and the FDB will contain the following MAC entries:

```
[/]
A:admin@PE-3# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1001       00:00:11:11:11:11 sap:lag-1:1001          L/0      04/15/21 08:19:47
1001       00:00:41:41:41:41 b-mpls:                 L/0      04/15/21 08:19:47
                             192.0.2.4:524282
           ldp:65538
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

If MAC address 00:00:61:61:61:61 is learned again, the next hop will be PE-4 instead of PE-5.

The configuration is restored as follows:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state enable
```

No CMAC/ISID update will be sent when the last SAP/SDP-binding in a service goes operationally down. VPLS 1024 only has one SAP/SDP-binding in DF PE-4: spoke-SDP 46:1024. A failure of the spoke-SDP is simulated as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state disable
```

When the last SAP/SDP-binding is down, the service will be operationally down, as follows:

```
[/]
A:admin@PE-4# show service id 1024 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

PE-4 sends the following withdrawal message instead of a CMAC/ISID:

```
56 2021/04/15 08:26:10.691 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 61
    Flag: 0x90 Type: 15 Len: 57 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-INCL-MCAST Len: 17 RD: 192.0.2.4:1000, tag: 1024,
```

© 2023 Nokia.

```
                              orig_addr len: 32, orig_addr: 192.0.2.4
        Type: EVPN-MAC Len: 33 RD: 192.0.2.4:1000 ESI: ESI-0, tag: 1024, mac len: 48
                       mac: 00:00:00:00:00:04, IP len: 0, IP: NULL, label1: 0
"
```

The configuration is restored as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state enable
```

ISID-based and regular CMAC flush in ES

When ISID-based CMAC flush is not enabled in all I-VPLS services using the ES, a failure in the ES will trigger BMAC/0 updates and BMAC/ISID updates with increased sequence number. An additional I-VPLS is configured on the nodes with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** (default). The configuration of I-VPLS 1021 on PE-5 is as follows:

```
# on PE-5:
configure {
    service {
        vpls "I-VPLS 1021" {
            admin-state enable
            service-id 1021
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1021
                }
            }
            spoke-sdp 56:1021 {
            }
            sap 1/2/1:1021 {
            }
        }
```

The configuration on PE-4 is similar; PE-2 and PE-3 have SAP lag-1:1021 instead of the spoke-SDP.

On MTU-6, SDP 65 is disabled, which will cause an ES failure on PE-5:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state disable
```

The following BMAC updates are sent by PE-5:

- BMAC/0 with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for all I-VPLS services (ISID-independent)
- BMAC/ISID with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for VPLS 1001

```

Conclusion

ISID-based MAC-flush speeds up convergence after a SAP or spoke-SDP failure, triggering a selective CMAC flush on the receiving nodes, which flushes all CMAC entries associated with that ISID and BMAC. The feature can be enabled per I-VPLS and disabled for those SAPs or spoke-SDPs for which no alternative route is available, or for those SAPs that are contained in an all-active Ethernet Segment. The BMAC/ISID update always contains the source-BMAC, not the ES-BMAC. CMAC flush based on ES-BMAC is not performed per ISID.

PBB-EVPN ISID-based Route Targets

This chapter provides information about PBB-EVPN ISID-based Route Targets.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.5.R1. PBB-EVPN ISID-based route targets are supported in SR OS Release 15.0.R1, and later.

Overview

The following BGP-EVPN routes are used in PBB-EVPN according to RFC 7623:

- B-MAC routes—based on BGP-EVPN route type 2—are sent with the B-VPLS Route Target (RT), so they are sent to all the PEs where the B-VPLS is defined.
- Ethernet Segment (ES) routes—route type 4—are used for multi-homing. ES routes are sent with an RT auto-derived from the ES Identifier (ESI). If the RT-constraint is enabled, the routes are sent to only those PEs that are part of the ES.
- Inclusive Multicast Ethernet Tag (IMET) routes—route type 3—are used for the setup of per-ISID flooding domains and can be sent with a B-VPLS RT or with an ISID-based RT.
  - IMET routes are, by default, sent with a B-VPLS RT (referred to as IMET/0 routes), so they are imported by all the PEs where the B-VPLS is defined, as per RFC 7623, and supported in SR OS Release 13.0.R4, and later.
  - IMET routes with an ISID-based RT (referred to as IMET/ISID routes) are imported by only the PEs where the ISID is defined. RFC 7623 recommends these routes for deployments where the ISIDs are sparsely distributed in the network. This is supported in SR OS Release 15.0.R1, and later. The service ISID is encoded in the Ethernet tag field.

Figure 229: PBB-EVPN B-VPLS-based RT shows how the B-MAC and IMET routes with a B-VPLS RT sent by PE-1 are advertised to all other PEs (via the Route Reflector (RR)), regardless of the ISID.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 229: PBB-EVPN B-VPLS-based RT

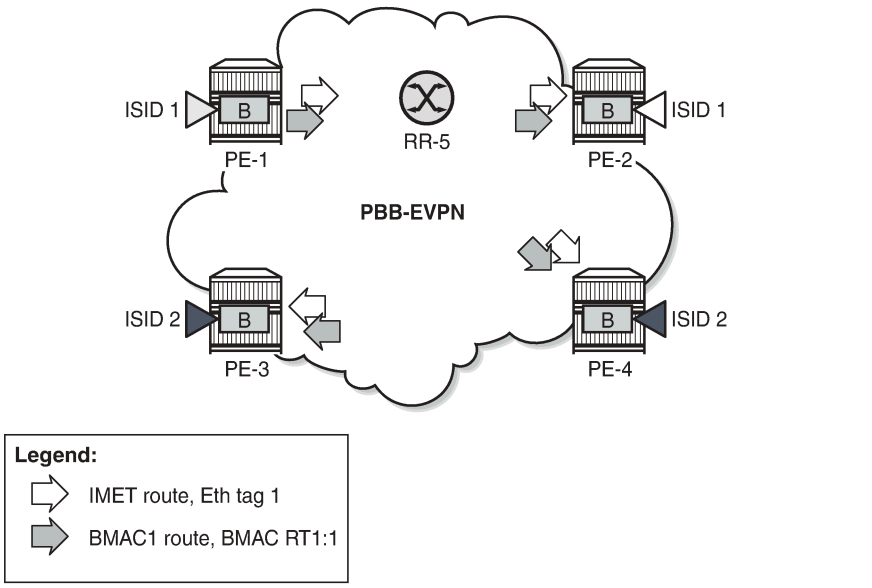

Figure 230: PBB-EVPN ISID-based RT shows how the B-MAC routes are sent to all PEs within the B-VPLS, whereas the IMET routes sent by PE-1 are selectively reflected by the RR (due to RT-constraints) and only sent to PE-2, which is the only PE with the same ISID.

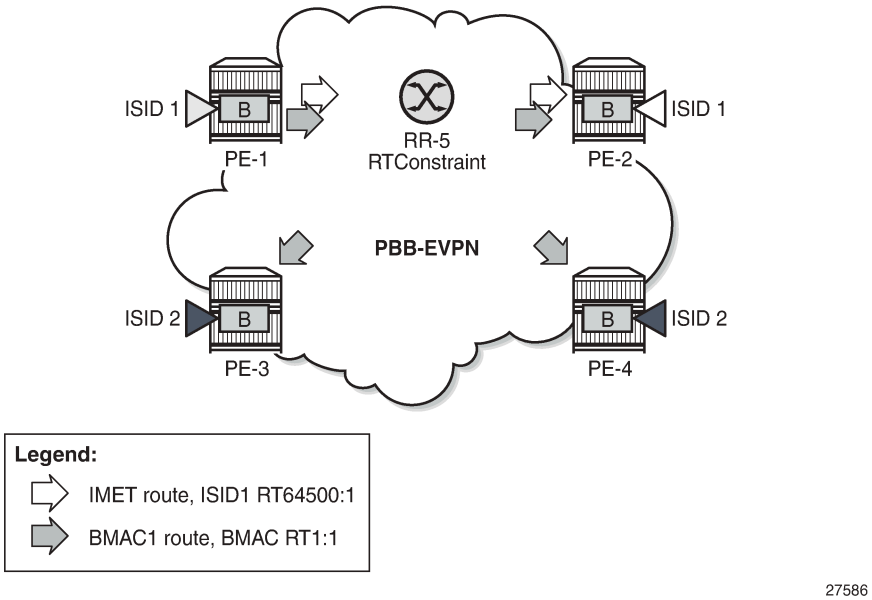
Figure 230: PBB-EVPN ISID-based RT



IMET routes with ISID-based RTs (IMET/ISID) can significantly reduce the number of IMET/ISID routes distributed by the RRs. The RT for the IMET/ISID route can be auto-derived from the corresponding Ethernet tag (ISID).

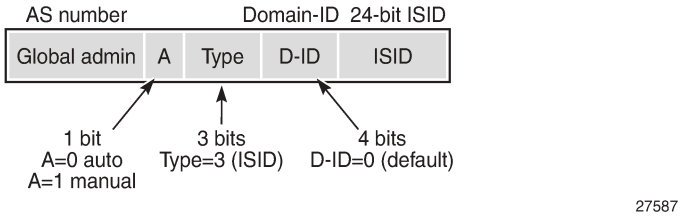
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In addition to RFC 7623, the ISID-derived RTs can be used for BMAC/ISID routes if ISID-based CMAC flush is enabled, as per *draft-snr-bess-pbb-evpn-isid-cmacflush*. The service ISID is encoded in the Ethernet tag field.

PBB-EVPN ISID-based RT format

Figure 231: PBB-EVPN ISID-based RT format shows the ISID-based RT format:

Figure 231: PBB-EVPN ISID-based RT format



For an auto-derived ISID-based RT, the values are as follows:

- The Autonomous System (AS) number is obtained from the **config>router>autonomous-system** command:
  - Value = 2-byte AS number
  - For AS numbers with more than 2 bytes, the low-order 16-bit value is used.
- A = 0 for auto-derivation
- Type = 011 = 3 for ISID-based RT
- Domain ID = 0000 (default)
- ISID value

The auto-derived RT will be AS:00110000+ISID = AS:0x30+ISID Hex.

The type and sub-type of the BGP extended community is 0x00 and 0x02.

Enabling ISID-based RT

The following command is used to enable ISID-based RT for specific ISID ranges for IMET/ISID and BMAC/ISID routes.

```
*[ex:/configure service vpls "B-VPLS 100" bgp-evpn]
A:admin@PE-1# isid-route-target ?

 isid-route-target

 range                 + Enter the range list instance
```

The ISID range is configured as follows:

```
[ex:/configure service vpls "B-VPLS 100" bgp-evpn isid-route-target]
A:admin@PE-1# range ?

 [start] <number>
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 <number>  - <1..16777215>

    Starting value of the isid-range entry
```

```
[ex:/configure service vpls "B-VPLS 100" bgp-evpn isid-route-target range 1]
A:admin@PE-1# end ?

 end <number>
 <number>  - <1..16777215>

 'end' is: mandatory

    Ending value of the isid-range entry
```

The RT to be used for the I-VPLS can be auto-derived (default) or explicitly configured. The following configures an ISID range from 20 to 29 with auto-derived RT (default: type auto), whereas ISID 30 has a manually configured RT of 64500:30.

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 20 {
                        end 29
                        # type auto   # default
                    }
                    range 30 {
                        end 30
                        type configured
                        route-target "target:64500:30"
                    }
                }
```

If **isid-route-target** is enabled, the IMET/ISID and BMAC/ISID route processing is modified in the export and import directions:

- "Exported IMET/ISID and BMAC/ISID routes:
  - IMET/ISID routes are sent with an ISID-based RT for the local I-VPLS ISIDs and static ISIDs, unless the ISID is contained in an ISID policy for which **advertise-local false** is configured.
  - When **isid-route-target** and **ivpls-mac-flush>bgp-evpn>send-to-bvpls** are both enabled for an I-VPLS, the BMAC/ISID route will also be sent with the ISID-based RT instead of the B-VPLS-based RT.
  - The **isid-route-target** command has impact only on IMET/ISID and BMAC/ISID, not on IMET/0, BMAC/0, or ES routes.
  - When a new ISID-based RT is added for an I-VPLS, a BGP update is sent for the existing IMET/ISID and BMAC/ISID routes. The new RT will be added when the routes are advertised.
- Imported IMET/ISID and BMAC/ISID routes:
  - When **isid-route-target** is enabled for an I-VPLS, BGP will start importing IMET/ISID routes and—if **ivpls-mac-flush>bgp-evpn>send-to-bvpls** is enabled—BMAC/ISID routes with ISID-based RTs.
  - ISID-based RTs are added for import operations when the I-VPLS is associated with the B-VPLS (regardless of the operational state of the I-VPLS) and/or when the static ISID has been added.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - Ensure that the ISID-based RTs are configured consistently in the network. The system does not keep a mapping of RTs and ISIDs for imported routes.
  - The system will not check the format of the received auto-derived RTs. Routes will be imported when the RT is on the list of RTs for the B-VPLS.
- When **isid-route-target** is configured for an I-VPLS, VSI import/export policies are blocked in the B-VPLS, whereas BGP import/export policies are allowed and matching on the export ISID-based RT is supported.

Some other considerations:

- ISID ranges cannot overlap within a B-VPLS, but they can overlap across different B-VPLSs.
- The explicitly configured RT is meant to be used in two cases:
  - ISID aggregation - when multiple ISIDs are using the same ISID RT
  - Interoperability - in case the peer sends an RT in a different format

ISID-based RTs and RT-constraint

The use of the RT-constraint feature (BGP family route-target) maximizes the benefits of using different RTs per ISID; therefore, service providers are expected to enable both ISID-based RTs and RT-constraint. RT-constraint is enabled by adding the BGP address family route-target in the general BGP settings, per group, or per neighbor, as follows:

```
configure {
    router "Base" {
        bgp {
            family {
                route-target true
                ---snip---

            group "internal" {
                family {
                    route-target true
                    ---snip---

            neighbor 192.0.2.4 {
                family {
                    route-target true
                    ---snip---
```

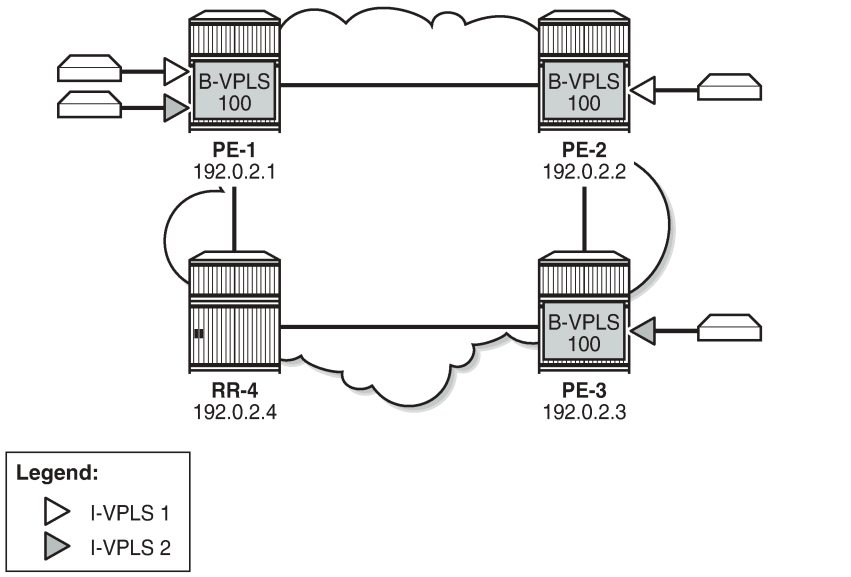
The system will advertise the RT-constraint route when the I-VPLS is associated with the B-VPLS, regardless of the operational state of the I-VPLS. However, the IMET/ISID and the BMAC/ISID routes are sent based on the I-VPLS operational state.

Configuration

Figure 232: Example topology shows the example topology with three PEs and an RR.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 232: Example topology



Initial configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on all router interfaces (alternatively, OSPF could be used)
- SR-ISIS enabled on the PEs (but disabled on the RR)

BGP is configured on all PEs for address family EVPN, as follows.

```
# on PE-1, PE-2, PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

On RR-4, BGP is configured as follows:

```
# on RR-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
        }
```

For the RT-constraint feature, the route-target address family can be configured in combination with the EVPN address family; see section ISID-based RTs and RT-constraint.

The initial service configuration on PE-1 without ISID-based RTs is as follows:

```
# on PE-1:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.1
                community-value {
                    start 10
                    end 99
                }
            }
        }
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
            }
            sap 1/2/1:1 {
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:2"
                    import "target:64500:2"
                }
            }
            sap 1/2/1:2 {
            }
        }
```

The service configuration on PE-2 is similar, but only I-VPLS 1 is configured. On PE-3, only I-VPLS 2 is configured.

PE-1 sends the following default BGP-EVPN IMET/0 update to the RR:

```
# on PE-1:
2 2021/05/28 08:55:18.406 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

```
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
```

In the preceding output, each of the four inclusive multicast routes occurs twice: the first time with the original attributes, the second time with the modified attributes, but in this example, the attribute did not change.

For the EVPN MAC routes, the output is similar. ISID-based CMAC flush is not enabled yet, so there are only BMAC/0 routes, no BMAC/ISID routes, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn mac

ISID-based RTs

On the PEs, B-VPLS 100 is configured with ISID-based RTs, but initially without ISID-based CMAC flush, as follows:

```
# on PE-1, PE-2:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 1 {
                        end 2
                    }
                    range 10 {
                        end 11
                        type configured
                        route-target "target:64500:10"
                    }
                }
            }
```

B-VPLS 100 has two ISID-ranges configured:

- For ISIDs 1 and 2, the RT is auto-derived. The hexadecimal value for ISID 1 is 0x30000001, which corresponds to decimal value 805306369. The hexadecimal value for ISID 2 is 0x30000002 (decimal value 805306370). For ISID 1, the RT is 64500: 805306369; for ISID 2, the RT is 64500: 805306370.
- For ISIDs 10 and 11, the RT is manually configured as 64500:10.

The configuration is identical on PE-2. On PE-3, only ISID range 2 is configured, as follows:

```
# on PE-3:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 2 {
                        end 2
                    }
                }
            }
```

On PE-1, the same four BGP-EVPN IMET routes are shown, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn incl-mcast
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

      0                   192.0.2.3

u*>i  192.0.2.3:100       192.0.2.3
      2                   192.0.2.3

-------------------------------------------------------------------------------
Routes : 4
```

The IMET route with Ethernet tag 1 now has RT 64500:805306369 (ISID 1) and the IMET route with Ethernet tag 2 has RT 64500:805306370 (ISID 2), as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn incl-mcast detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
```

Again, each route has two identical entries in the preceding command: one with the original attributes and another with the modified attributes.

The following BGP-EVPN IMET/ISID route is sent by PE-1 for ISID 1. The Ethernet tag is 1 and the RT is 64500:805306369.

```

"
```

When a SAP (or SDP binding) is added with static ISID 11, RT 64500:10 will be added. The service configuration on PE-1 is modified as follows:

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 1 {
                        end 2
                    }
                    range 10 {
                        end 11
                        type configured
                        route-target "target:64500:10"
                    }
                }
            }
            sap 1/1/1:100 {
                static-isid {
                    range 1 {
                        start 11
                        end 11
                    }
                }
            }
            isid-policy {
                entry 10 {
                    range {
                        start 11
                        end 11
                    }
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The configuration is similar on PE-2. Only on PE-1 and PE-2, SAPs are configured, with static ISID 11. The following IMET/ISID route with RT 64500:10 is sent by PE-1:

```
# on PE-1:
13 2021/05/28 08:59:47.251 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 77
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.1
        Type: EVPN-INCL-MCAST Len: 17 RD: 192.0.2.1:100, tag: 11, orig_addr len: 32,
                              orig_addr: 192.0.2.1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:64500:10
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 9 PMSI:
        Tunnel-type Ingress Replication (6)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label 8388560
        Tunnel-Endpoint 192.0.2.1
"
```

This RT 64500:10 is not auto-derived, but configured manually for ISID range 10 to 11.

ISID-based CMAC flush

ISID-based CMAC flush is described in chapter PBB-EVPN ISID-based CMAC Flush and requires the following configuration on PE-1:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
        }
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
        }
        vpls "B-VPLS 100" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The configuration on PE-2 and PE-3 is similar, but only needs to be applied for I-VPLS 1 on PE-2 (I-VPLS 2 is not configured on PE-2) and for I-VPLS 2 on PE-3. The configuration for B-VPLS 100 is the same on all PEs.

When ISID-based CMAC flush is enabled on the PEs, additional BGP-EVPN MAC routes are sent by PE-1 for ISIDs 1 and 2:

```
# on PE-1:
27 2021/05/28 09:02:38.769 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
```

ISID-based RTs and RT-constraint

To show that RT BGP updates are sent when the I-VPLS is associated with the B-VPLS, the I-VPLSs are initially disassociated from B-VPLS 100 on PE-1, as follows:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                delete backbone-vpls "B-VPLS 100"
            }
        }
        vpls "I-VPLS 2" {
            pbb {
                delete backbone-vpls "B-VPLS 100"
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The BGP configuration is modified on all nodes to include address families route-target and EVPN, as follows:

```
# on PE-1, PE-2, PE-3, RR-4:
configure {
    router "Base" {
        bgp {
            family {
                route-target true
                evpn true
            }
```

The following RT-constraint route is sent by PE-1 after I-VPLS 1 is associated with B-VPLS 100. The RT is auto-derived from the ISID 1:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
        }
        vpls "I-VPLS 2"
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
        }
```

```
# on PE-1:
73 2021/05/28 09:09:34.587 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

    Total Path Attr Length = 20
    Flag: 0x90 Type: 15 Len: 16 Multiprotocol Unreachable NLRI:
        Address Family RTC_V4
        [RT-Const-V4] origin-as 64500, Target target:64500:805306369
"
```

Conclusion

PBB-EVPN ISID-based RTs, in combination with RT-constraint, reduce the number of advertised IMET routes to only those nodes where the ISID is configured. The ISID-based RT can be auto-derived from the ISID or configured manually. When ISID-based CMAC flush is also enabled, the BMAC/ISID routes will contain the same auto-derived RT.

PBB-VPLS

This chapter provides information about Provider Backbone Bridging (PBB) in a Multi-Protocol Label Switching (MPLS) based network.

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 7.0.R6. The MD-CLI in the current edition is based on SR OS Release 20.10.R2.

Note:
Although it can be used in an MPLS-based PBB network as described in this document, the MAC notification feature for dual-homed access is normally used in native PBB networks.

Overview

RFC 7041, *Extensions to the Virtual Private LAN Service (VPLS) Provider Edge (PE) Model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

PBB-VPLS combines the best of the PBB and VPLS technologies to deliver the most scalable multi-point Layer 2 VPN in the market. PBB-VPLS inherits all the benefits derived from MPLS (for example, sub-50ms Fast Reroute (FRR) protection, Traffic Engineering (TE), no need for Multiple Spanning Tree Protocol (MSTP) in the backbone) while greatly increasing the scalability of the network by providing MAC hiding, service multiplexing, and pseudowire aggregation.

The SR OS PBB-VPLS implementation also includes support for:

- Multiple MAC Registration Protocol (MMRP), application within IEEE 802.1ak for flood containment in the backbone instances, as specified in Section 6 of RFC 7041.
- Extensions to LDP signaling for PBB-VPLS, according to *draft-balus-l2vpn-pbb-ldp-ext-00*. These extensions avoid network black-hole issues, as described in the Section 3 of the mentioned draft.

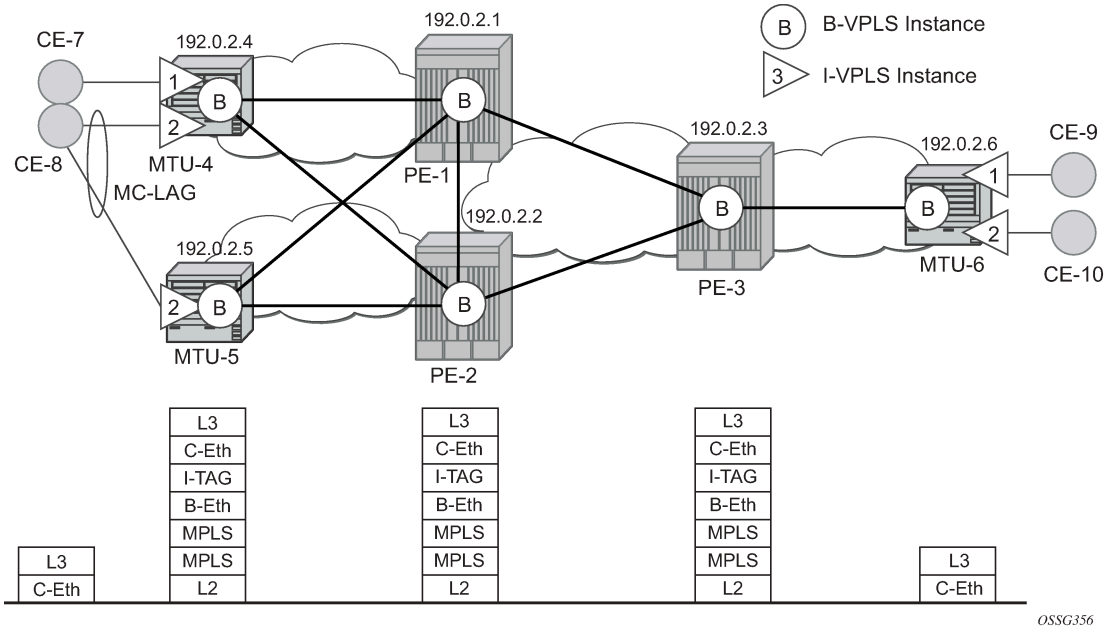
This chapter describes how to configure and troubleshoot a PBB-VPLS network.

Knowledge of the VPLS and H-VPLS (RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*) architecture and functionality is assumed throughout this chapter. The most relevant concepts are briefly described in this chapter. For further information, see the relevant Nokia documentation.

Figure 233: Example topology including B-VPLS, I-VPLSs, and protocol stacks shows the example topology that are used throughout the rest of the chapter.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 233: Example topology including B-VPLS, I-VPLSs, and protocol stacks



The topology consists of three core nodes (PE-1, PE-2, and PE-3) and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 100) will be defined in all the six nodes, whereas a few customer I-VPLS instances will be defined on the three MTU nodes.

Those I-VPLS instances will be multiplexed into the common B-VPLS, using the ISID field within the I-TAG as the demultiplexer field at the egress MTU to differentiate each specific customer.

The B-VPLS domain constitutes an H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby spoke-SDPs can be used from the MTUs to the PEs (for example, in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (for example, MTU-6). CE-8 is dual-connected to the service provider network through MC-LAG.

The protocol stack being used along the path between the CEs is shown in Figure 233: Example topology including B-VPLS, I-VPLSs, and protocol stacks.

Configuration

This section describes all the relevant PBB-VPLS configuration tasks for the setup shown in Figure 233: Example topology including B-VPLS, I-VPLSs, and protocol stacks. The appropriate associated IP/MPLS configuration is out of the scope of this example. In this particular example, the following protocols will be configured beforehand:

- ISIS-TE as IGP with all the interfaces being Level-2 (OSPF-TE could have been used instead).
- RSVP-TE as the MPLS protocol to signal the transport tunnels (LDP could have been used instead).
- LSPs between core PEs will be fast reroute protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.
- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the active/standby pseudowire protection configured in the B-VPLS.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

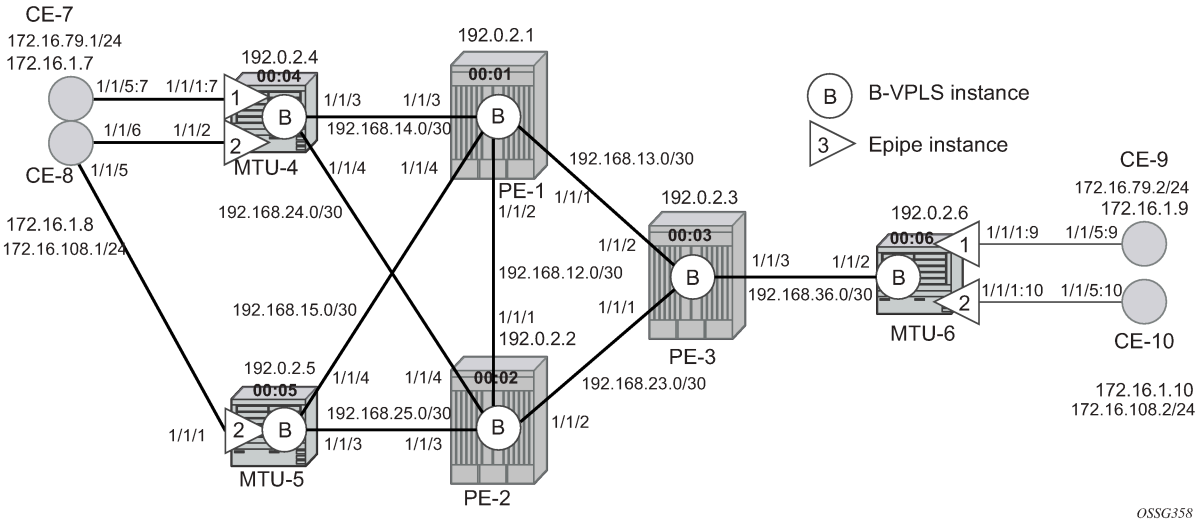
- BGP is configured for auto-discovery (Layer 2-VPN family), because FEC 129 will be used for the pseudowires between PEs in the core.

When the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB-VPLS M:1 service configuration

This section describes the process to configure PBB-VPLS services in a M:1 fashion, M being the number of customer I-VPLS services multiplexed into the same B-VPLS instance (instance 100). An alternative configuration is 1:1, where each customer I-VPLS has its own B-VPLS. MTU-4 and PE-1 will be picked to show the relevant CLI configuration commands. The bold digits separated by colons **00:xx** are abbreviations for the backbone MAC addresses.

Figure 234: Example topology with port numbers and IP addresses



B-VPLS configuration

The first step is to configure the B-VPLS instance that will carry the PBB traffic. The following shows the B-VPLS configuration on MTU-4 and PE-1. The configuration on MTU-5 and MTU-6 resembles the configuration on MTU-4; the configuration on PE-2 and PE-3 resembles the configuration on PE-1.

The configuration for B-VPLS 100 on MTU-4 is as follows:

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:04:04:04:04:04
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            endpoint "core" {
                suppress-standby-signaling false
            }
            spoke-sdp 41:100 {
                endpoint {
                    name "core"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 42:100 {
                endpoint {
                    name "core"
                }
                stp {
                    admin-state disable
                }
            }
        }
```

On PE-1, B-VPLS 100 is configured as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
            provisioned-sdp use
            split-horizon-group {
                name "CORE"
            }
        }
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:01:01:01:01:01
                }
            }
            bgp 1 {
                route-target {
                    export "target:65000:100"
                    import "target:65000:100"
                }
                pw-template-binding "PW1" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65000:100"
            }
            spoke-sdp 14:100 {
            }
            spoke-sdp 15:100 {
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The B-VPLS is a regular VPLS instance in terms of configuration, with the following exceptions:

- The B-VPLS service MTU must be at least 18 bytes greater than the I-VPLS MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1500 bytes); therefore, any MTU equal to or greater than 1518 bytes must be configured. In this particular example, a MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.
- The source B-MAC is the MAC address that will be sourced when the PBB traffic is originated from that node. A source B-MAC per B-VPLS instance can be configured (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. If no specific source B-MAC is provisioned, the system MAC address is used as the source B-MAC. When using the access multi-homing feature for native PBB, the source B-MAC must be a configured one and never the chassis MAC address. The way to configure a common B-MAC for all the B-VPLS instances on MTU-4 is as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported
  - Default SAP (:*) types are blocked in the CLI for the B-VPLS SAP
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowires, the outgoing PBB frame on an SDP (for example, B-pseudowire) contains a BVID qtag only if the pseudowire type is Ethernet VLAN. If the pseudowire type is **Ethernet**, the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS; therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group (SHG) has been configured to emulate the behavior of mesh-SDPs in the core.
- If a local I-VPLS instance is associated with the B-VPLS, local frames originated/terminated on local I-VPLS(s) are PBB encapsulated/de-encapsulated using the PBB Ethertype provisioned under the related port or SDP component.

By default, the PBB Ethertype is 0x88e7 (which is the standard one defined in 802.1ah for the I-TAG) but this PBB Ethertype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
[ex:configure port 1/1/3 ethernet]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 35047
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    Ethertype for PBB encapsulation on the Ethernet port
```

```
[ex:configure service sdp 41]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 0x88E7

    Ethertype used in frames sent out on this SDP when VC type is 'vlan' for
    Provider Backbone Bridging frames as 0xXXYY with range 0x0600-0xFFFF.
```

The following commands are useful to check the actual PBB Ethertype:

```
[]
A:admin@MTU-4# show port 1/1/3 | match PBB
PBB Ethertype      : 0x88e7
```

```
[]
A:admin@MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                   PBB Etype          : 0x88e7
```

I-VPLS configuration

When the common B-VPLS is configured, the next step is to provision the customer I-VPLS instances. The following shows the relevant configuration on MTU-4 for the two I-VPLS instances represented in Figure 234: Example topology with port numbers and IP addresses. The I-VPLS instances are configured on the MTU devices, whereas the core PEs are customer-unaware nodes.

```
# on MTU-4:
configure {
    service {
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            sap 1/1/1:7 {
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            sap lag-1 {
            }
```

```
        }
```

The I-VPLS instance has to be linked to its corresponding transport B-VPLS instance. That link is specified by the **backbone-vpls <b-vpls> isid <isid>** command. The ISID is mandatory when configuring the backbone VPLS.

The following considerations will be taken into account when configuring the I-VPLS:

- I-VPLS SAPs:
  - SAPs can be defined on ports with any Ethernet encapsulation type (null, dot1q, and qinq)
  - The I-VPLS SAPs can coexist on the same port with SAPs for other business services, for example, VLL and VPLS SAPs.
- I-VPLS SDPs:
  - GRE and MPLS SDPs are supported.
  - No mesh-SDPs are supported, only spoke-SDP. Mesh-SDPs can be emulated by using SHGs.

Existing SAP processing rules still apply for the I-VPLS case; the SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service that the packet belongs to:

- Null encapsulation defined on ingress — Any VLAN tags are ignored and the packet goes to a default service for the SAP.
- Dot1q encapsulation defined on ingress — only first VLAN tag is considered.
- QinQ encapsulation defined on ingress — both VLAN tags are considered; wildcard for the inner VLAN tag is supported.
- For dot1q/qinq encapsulations, traffic encapsulated with VLAN tags for which there is no definition is discarded.
- Any VLAN tag used for service selection on the I-SAP is stripped before the PBB encapsulation is added. Appropriate VLAN tags are added at the remote PBB PE when sending the packet out on the egress SAP.

MMRP for flooding optimization

When the M:1 model is used (as in this example), any I-VPLS broadcast, unknown unicast, or multicast (BUM) frame is flooded throughout the B-VPLS domain regardless of the nodes where the originating I-VPLS is defined. In other words, in our example in Figure 233: Example topology including B-VPLS, I-VPLSs, and protocol stacks, any BUM frame coming from CE-7 would be flooded in the B domain and would reach PE-2 and MTU-5, even though that traffic only needs to go to PE-3 and MTU-6. To build customer-based flooding trees and optimize the flooding, Multiple MAC Registration Protocol (MMRP) must be configured on the B-VPLS.

MMRP can be enabled with its default settings just by executing the following command on all nodes:

```
# on all nodes:
configure {
    service {
        vpls "B-VPLS 100" {
            mrp {
                admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

There are specific B-VPLS MRP settings that can be modified. These are the default values:

```
[ex:configure service vpls "B-VPLS 100" mrp]
A:admin@MTU-4# info detail
    admin-state enable
    mmrp {
        admin-state enable
        end-station-only false
     ## flood-time
        attribute-table {
            high-wmark 95
            low-wmark 90
            size 2048
        }
    }
```

These attributes can be changed to control the number of MMRP attributes per B-VPLS and optimize the convergence time in case of failures in the B-VPLS:

- Controlling the number of attributes per B-VPLS

  The MMRP exchanges create one entry per attribute (group B-MAC) in the B-VPLS where MMRP protocol is running. PBB uses a group B-MAC address—built using a specific OUI (00:1e:83) with the multicast bit set, and the ISID value for the last 24 bits—as a destination MAC address for flooding any BUM frame into the B-domain.

  When the first registration is received for an attribute, an MFIB entry is created for it. The **attribute-table size** allows the user to control the number of MMRP attributes (group B-MACs) created on a per B-VPLS basis, between 1 and 2048. Based on the configured size, high and low watermarks can be set (in percentage) so that alarms can be triggered upon exceeding the watermarks. This ensures that no B-VPLS will take up all the resources from the total pool. The maximum number of attributes per B-VPLS is 2048 and 4000 can be configured globally on the system.

- Optimizing the convergence time

  Assuming that MMRP is used in a certain B-VPLS, under failure conditions, the time it takes for the B-VPLS forwarding to resume may depend on the data plane and control plane convergence plus the time it takes for MMRP exchanges to stabilize the flooding trees on a per ISID basis. In order to minimize the convergence time, the PBB SR OS implementation offers the selection of a mode where B-VPLS forwarding reverts for a short time to flooding so that MMRP has enough time to converge. This mode can be selected through configuration using the **flood-time <value>** command where value represents the amount of time in seconds (between 3 and 600) that flooding will be enabled. If this behavior is selected, the forwarding plane starts with B-VPLS flooding for a configurable time period, then it reverts back to the MFIB entries installed by MMRP. The following B-VPLS events initiate the switch from per I-VPLS (MMRP) MFIB entries to B-VPLS flooding:

  – Reception or local triggering of a Spanning Tree Topology Change Notification (TCN)

  – B-SAP failure

  – Failure of a B-SDP binding

  – Pseudowire activation in a primary/standby H-VPLS resiliency solution

  – SF/CPM switchover due to STP reconvergence

The IEEE 802.1ak standard, which defines MRP, requires the implementation of different state machines with associated timers that can be tuned. A full MRP participant maintains the following state machines:

- Registrar state machine

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Applicant state machine
- LeaveAll state machine
- PeriodicTransmission state machine

The two first state machines are maintained for each attribute in which the participant is interested, whereas the two latter are global to all the attributes.

The job of the registrar function is to record declarations of the attribute made by other participants on the LAN. A registrar does not send any protocol messages, because the applicant looks after the interests of all would-be participants.

The job of the applicant is twofold: first, to ensure that this participant's declaration is correctly registered by other participants' registrars, and next, to prompt other participants to register again after one withdraws a declaration.

The associated timers can be tuned on a per SAP/SDP basis:

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 41:100]
A:admin@MTU-4# mrp ?

 mrp

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 join-time             - Set the maximum rate for attribute join messages to be sent
                         on the SDP.
 leave-all-time        - Set the frequency where all attribute declarations on the
                         SDP are refreshed.
 leave-time            - Set the time an attribute is held in leave state before
                         registration is removed.
 periodic-time         - Set the freqeuency of retransmission of attribute
                         declarations.
 periodic-timer        - Enable/Disable retransmission of attribute declarations.
 policy                - Specify they MRP policy to control which Group BMAC
                         attributes will advertise on the egress SDP Bind.
```

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 41:100 mrp]

 ## apply-groups
 ## apply-groups-exclude
    join-time 2
    leave-time 30
    leave-all-time 100
    periodic-time 10
    periodic-timer false
 ## policy
```

A brief description of the MRP SAP/SDP attributes follows:

- **Join-time** — This command controls the interval between transmit opportunities that are applied to the applicant state machine. An instance of this join period timer is required on a per-port, per-MRP participant basis. For more information, see IEEE 802.1ak-2007 section 10.7.4.1.
- **Leave-time** — This command controls the period of time that the registrar state machine will wait in the leave state before transitioning to the MT state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The leave period timer is set to the value leave-time when it is started. A registration is normally in "in" state where there is an MFIB entry and traffic being forwarded. When a "leave all" is performed (periodically around every 10-15 seconds per SAP/SDP binding – see leave-all-time below), a node sends a message to its peer indicating a leave

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

all is occurring and puts all of its registrations in leave state. The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations. See IEEE 802.1ak-2007 section 10.7.4.2.

- **Leave-all-time** — This command controls the frequency with which the leaveall state machine generates leaveall PDUs. The timer is required on a per-port, per-MRP participant basis. The leaveall period timer is set to a random value, T, in the range leavealltime<T<1.5*leave-all-time when it is started. See IEEE 802.1ak-2007, section 10.7.4.3.
- **Periodic-time** — This command controls the frequency the periodic transmission state machine generates periodic events if the periodic transmission timer is enabled. The timer is required on a per-port basis. The periodic transmission timer is set to one second when it is started.
- **Periodic-timer** — This command enables or disables the periodic transmission timer.

The following command shows the MRP configuration and statistics on a per SAP/SDP basis within the B-VPLS:

In the example throughout the chapter, as soon as MMRP is enabled, an optimized flooding tree will be built for ISID 1, because the I-VPLS 1 is only defined in MTU-4 and MTU-6, but not in MTU-5. A good way to track the flooding tree for a particular ISID is the following command:

```
[]
A:admin@MTU-4# show service id 100 mmrp mac
-------------------------------------------------------------------------------
SAP/SDP                               MAC Address       Registered  Declared

sdp:52:100                            01:1e:83:00:00:02 Yes         No
-------------------------------------------------------------------------------
Number of Entries=2 SAPs=0 SDPs=2
-------------------------------------------------------------------------------
```

The group B-MAC ending in **01** corresponds to the I-VPLS 1 whereas the one ending in **02** to the I-VPLS 2. MMRP PDUs for the two attributes are sent throughout the loop-tree topology (not over STP blocked ports or standby spoke-SDPs and observing the split-horizon rules). The two attributes are registered on every B-VPLS virtual port; however, the tree is only built on those ports where the attribute is also declared, and not only registered. For instance, the spoke-SDP 52:100 in MTU-5 will not be part of the ISID 1 or ISID 2 flooding trees. Neither attribute is declared because I-VPLS 1 does not exist on MTU-5 and I-VPLS 2 is operationally down on MTU-5 (MC-LAG SAP is in standby state, so the I-VPLS is down).

As soon as a group B-MAC attribute is registered on a particular port, an MFIB entry is added for that B-MAC on that port, regardless of the declaration state for that attribute on the port. For instance, neither

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

B-MAC is declared on MTU-5, however, the two MFIB entries are created as soon as the attributes are registered:

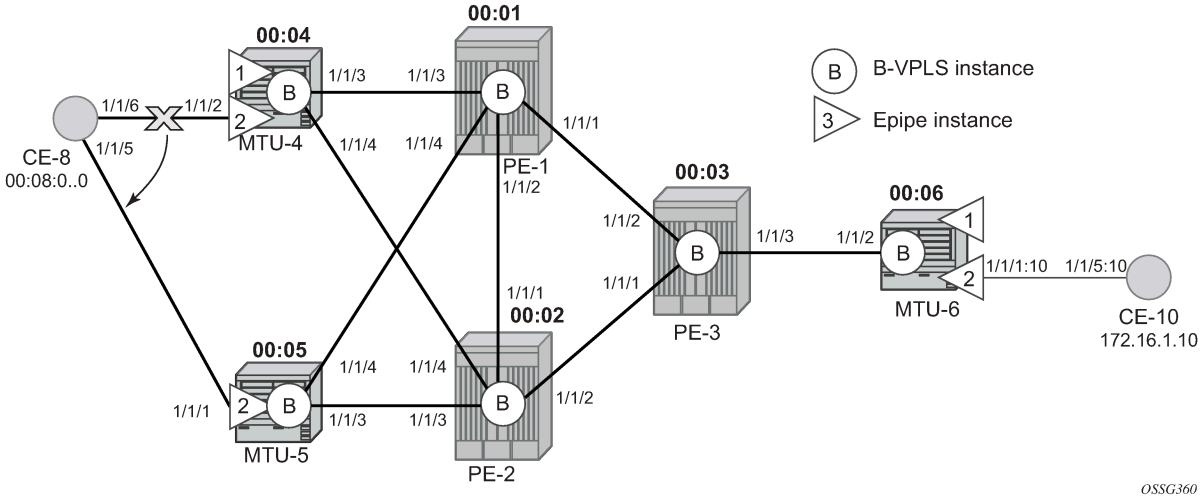
MAC flush: avoiding black-holes

Both the I-VPLS and B-VPLS components inherit the MAC flush capabilities of a regular VPLS clearing the related C-MAC and respectively B-MAC FIBs. All types of MAC flush—all-but-mine and all-from-me—are supported together with the related CLI. In addition to these features, some extensions have been added so that MAC flush can be triggered on the B-VPLS based on some events happening on the I-VPLS. The following diagram shows a potential scenario where black-holes can occur if the correct configuration is not added.

Figure 235: Black-hole



Under normal conditions, the I-VPLS 2 FIB on MTU-6 shows that CE-8 MAC address is learned through B-MAC 00:04 of MTU-4:

```
[]
A:admin@MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2
===============================================================================
```

Use subject to Terms available at: www.nokia.com/terms.

```
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:04:04:04:04:04 L/60
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/60
===============================================================================
```

When a failure happens in the CE-8 MC-LAG active link, the link to MTU-5 takes over. However, the FIB on MTU-6 still points at the BMAC of MTU-4 and that will still be the B-MAC used in the PBB encapsulation. Therefore, a black-hole occurs until either bidirectional traffic is sent or the FIB aging timer expires.

The configuration in the I-VPLS can be modified to trigger a MAC flush in the B-VPLS with the following command:

```
[ex:configure service vpls "I-VPLS 2" pbb i-vpls-mac-flush tldp]
A:admin@MTU-4# send-to-bvpls ?

 send-to-bvpls

 all-but-mine          - Generate LDP MAC withdraw message to b-VPLS
 all-from-me           - Generate LDP MAC withdraw all from me message to b-VPLS
```

The following command is executed on all MTUs to solve the black-hole:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    tldp {
                        send-to-bvpls {
                            all-from-me true
                        }
                    }
                }
            }
```

By configuring **send-to-bvpls all-from-me true** on I-VPLS 2, a failure on the MC-LAG active link on I-VPLS 2 will trigger an LDP MAC **flush-all-from-me** into the B-VPLS that will flush the FIB in MTU-6 for I-VPLS 2, avoiding the black-hole. A MC-LAG failure is emulated by disabling the LAG on MTU-4, as follows:

```
# on MTU-4:
configure {
    lag 1 {
        admin-state disable
    }
```

MTU-4 sends the following LDP MAC flush for all MAC addresses learned from MTU-4:

```
1 2021/01/12 17:02:25.211 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Address Withdraw packet (msgId 263) to 192.0.2.1:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
ISID 1 = 2
Number of Path Vectors : 1
Path Vector(  1) = 192.0.2.4
"
```

On MTU-6:

```
1 2021/01/12 17:02:25.227 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Address Withdraw packet (msgId 206) from 192.0.2.3:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
ISID 1 = 2
Number of Path Vectors : 3
Path Vector(  1) = 192.0.2.4
Path Vector(  2) = 192.0.2.1
Path Vector(  3) = 192.0.2.3
```

Immediately after receiving the MAC flush, the CE-8 MAC is flushed. The CE-8 MAC is learned again, but this time linked to the B-MAC 00:05, which is the B-MAC of MTU-5:

```
[]
A:admin@MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2

===============================================================================
```

The following I-VPLS events are propagated into the B-VPLS depending on the all-but-mine or all-from-me keywords used in the configuration:

If the all-but-mine keyword is configured (positive flush), the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. TCN event in one or more of the related I-VPLS/M-VPLS.
2. Pseudowire/SDP binding activation with active/standby pseudowire (standby to active or down to up).
3. Reception of an LDP MAC withdraw flush-all-but-mine in the related I-VPLS.

If the all-from-me keyword is configured (negative flush) the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. MC-LAG active link failure (in our example).
2. Failure of a local SAP – requires **mac-flush>tldp>send-on-failure true** to be enabled in I-VPLS.
3. Failure of a local pseudowire/SDP binding – requires **mac-flush>tldp>send-on-failure true** to be enabled in I-VPLS.
4. Reception of an LDP MAC withdraws flush-all-from-me in the related I-VPLS.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In addition to this and regardless of what type, MAC flush has been optimized to avoid flushing in the core PEs, flushing only the C-MACs mapped to a specific B-MAC (belonging to a specific ISID FIB) and the ability to indicate to core PEs which messages should always be forwarded endpoint-to-endpoint toward all PBB PEs regardless of the propagate-mac-flush setting in B-VPLS. All of this is implemented without the need of any additional CLI commands and it is part of **draft-balus-l2vpn-pbb-ldp-ext-00**.

Another extension supported to avoid black-holes within this mix of I- and B-VPLS environments is the **block-on-mesh-failure** feature in PBB. When the VPLS mesh exists only in I-VPLS or in B-VPLS, and the **block-on-mesh-failure** feature is enabled, the regular VPLS behavior will apply (when all the mesh-SDPs go down an LDP notification with pseudowire status bits = 0x01—Pseudo Wire Not Forwarding—is sent over the spoke-SDPs). When the active/standby pseudowire resiliency is implemented in I-VPLS such that the PBB PE performs the role of a PE-rs, the B-VPLS core replaces the pseudowire (SDP binding) mesh. The block-on-mesh notification (LDP notification indicating pseudowire not forwarding) will be sent to the MTUs only when the related B-VPLS is operationally down. The B-VPLS core is operationally down only when all of its SAPs and SDPs are down.

The final feature that can be enabled in an I-VPLS with CLI is the **send-on-bvpls-failure** feature, as follows:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    tldp {
                        send-on-bvpls-failure true
                        }
                    }
```

This feature is required to avoid black-holes when there is a full mesh of pseudowires in the I-VPLS domain and the B-VPLS instance can go operationally down. Figure 236: Send flush on B-VPLS failure example shows a typical scenario where this feature is needed (normally when PBB-VPLS and multi-chassis end point are combined together).

Figure 236: Send flush on B-VPLS failure example

Access dual-homing and MAC notification

Although this section is focused on PBB in a MPLS based network, the Nokia PBB implementation also allows the operator to use a native Ethernet infrastructure in the PBB core. Native Ethernet tunneling can be emulated using Ethernet SAPs to interconnect the related B-VPLS instances. In those cases, there is no LDP signaling available; therefore, there is no MAC flush sent when the active link in a multi-homed access device fails.

The SR OS supports a mechanism to avoid potential black-holes in native Ethernet PBB networks. In addition to the source B-MAC associated with each B-VPLS, an additional B-MAC is associated with each MC-LAG supporting Multi-homed I-VPLS SAPs. The nodes that are in a multi-homed MC-LAG configuration share a common B-MAC on the related MC-LAG interfaces. When the MAC notification is enabled, an Ethernet CFM notification message is sent from the node holding the active link. That message will be flooded in the B-VPLS domain using the MC-LAG SAP B-MAC as the source MAC address. The remote nodes will learn the customer MAC addresses behind the MC-LAG and will link them to this new SAP B-MAC. MC-LAG will keep track of the active link for each particular LAG associated with a SAP B-MAC. Should MC-LAG detect any new active link in a node, a new CFM notification message will be flooded from the new active node.

The following restrictions and considerations must be taken into account:

- Only MC-LAG is supported as dual-home mechanism.
- This mechanism is supported for native PBB and/or MPLS-based PBB-VPLS. Although it is mostly beneficial when native PBB is used in the core, it can also help to optimize the re-learning process in a MPLS-based core in case of MC-LAG failures, in addition to the existing LDP MAC flush procedures.

The example of this configuration shows the setup being used in this configuration example. MAC-notification will be configured in MTU-4 and MTU-5 for the dual-homed CE-8.

The first step is to configure the SAP B-MAC that will be used for the MAC notification messages. The **source-bmac-lsb** (source backbone MAC least significant bits) command has been added to the MC-LAG branch so that the operator can decide the two last octets to be used in the SAP B-MAC. Those two last octets can be derived from the LACP key (if the **use-lacp-key** statement is used) or can be specifically defined.

```
[ex:configure redundancy multi-chassis peer 192.0.2.5 mc-lag]
A:admin@MTU-4# lag 1 ?

 lag

 Immutable fields      - lacp-key, system-id, system-priority
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 lacp-key              - Key based on the remote MC-LAG
 remote-lag            - Lag ID of the remote MC-LAG
 source-bmac-lsb       - MAC address value to apply to all ingress traffic
 system-id             - ID based on the remote MC-LAG
 system-priority       - Priority based on the remote MC-LAG
```

There must be a different SAP B-MAC per MC-LAG. The use of the LACP key as a default for two least significant octets makes the operations simpler. In this example, the last two octets of the SAP BMAC will come from the lacp-key. The configuration on MTU-4 is as follows:

```
# on MTU-4:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.5 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                admin-state enable
                mc-lag {
                    admin-state enable
                    lag 1 {
                        lacp-key 15
                        system-id 00:00:00:00:00:01
                        system-priority 65535
                        source-bmac-lsb use-lacp-key
                    }
                }
            }
        }
```

Therefore, the SAP B-MAC will be formed in the following way:

[SAP BMAC = 4 first bytes of the source BMAC + 2 bytes from source-bmac-lsb]

MAC notification in B-VPLS 100 is enabled on all MTUs, as follows:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "B-VPLS 100"
            pbb {
                mac-notification {
                    admin-state enable
                }
```

The **mac-notification** command activates the described mechanism and has the following parameters:

```
[ex:configure service vpls "B-VPLS 100" pbb]
A:admin@MTU-4# mac-notification ?

 mac-notification

 admin-state          - Administrative state of MAC notification
 count                - MAC notification messages count
 interval             - Interval for MAC notification messages
 renotify             - Re-notify interval for MAC-notification messages
```

Where:

- interval <value> controls how often the subsequent MAC notification messages are sent. Default = 100 ms. Required values: 100 ms – 10 sec, in increments of 100 ms.
- count <value> controls how often the MAC notification messages are sent. Default: 3. Range: 1–10.

The "count" and "interval" parameters can also be configured at the service context. The settings configured at the B-VPLS service context take precedence though.

```
[ex:configure service pbb]
A:admin@MTU-4# mac-notification ?

 mac-notification

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 count                 - MAC notification messages count
 interval              - Interval for MAC-notification messages
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Finally, the B-VPLS is instructed to use the SAP B-MAC. The **use-mclag-bmac-lsb** statement enables the use of the source B-MAC allocated to the multi-homed SAPs (assigned to the MC-LAG) in the related I-VPLS service (could be Epipe service as well). The command will fail if the value of the source B-MAC assigned to the B-VPLS is the hardware (chassis) B-MAC. In other words, the source B-MAC must be a configured one. The **use-mclag-bmac-lsb** statement is by default false.

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 100"
            pbb {
                source-bmac {
                    address 00:aa:aa:aa:aa:04
                    use-mclag-bmac-lsb true
                }
```

```
# on MTU-5:
configure {
    service {
        vpls "B-VPLS 100"
            pbb {
                source-bmac {
                    address 00:aa:aa:aa:aa:05
                    use-mclag-bmac-lsb true
                }
```

```
[]
A:admin@MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2
===============================================================================
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:aa:aa:aa:00:0f L/0
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/0
===============================================================================
```

As soon as MAC notification is enabled, an Ethernet CFM notification message is sent from MTU-4, which is the node where the active MC-LAG link resides. The CFM message will have the source MAC address "00:aa:aa:aa:00:0f" (4 first bytes of the configured source BMAC + 2 bytes from the configured source-bmac-lsb, which is 15 in hex) and will be flooded throughout the B-VPLS domain. Should the link between CE-8 and MTU-4 fail, the MC-LAG protocol will activate the redundant link and MTU-5 will immediately issue a CFM message with the shared sourced SAP B-MAC that will be flooded in the B-VPLS domain.

PBB and IGMP snooping

IGMP snooping can be enabled on I-VPLS SAPs and SDPs (it cannot be enabled on B-VPLS). SR OS can keep track of IGMP joins received over individual B-SDPs or B-SAPs, and it starts flooding the multicast group (and only the multicast group) to all B-components (using the group B-MAC for I-SID) as soon as the first IGMP join for that multicast group is received in one of the B-SAP/SDP components.

The first IGMP join message received over the local B-VPLS will add all the B-VPLS SAP/SDP components into the related multicast table associated with the I-VPLS context. When the querier is connected to a remote I-VPLS instance, over the B-VPLS infrastructure, its location is identified by the B-

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VPLS SDP/SAP on which the query was received and also by the source B-MAC address used in the PBB header for the query message, the B-MAC associated with the B-VPLS instance on the remote PBB PE.

The following configuration on MTU-4 enables IGMP snooping in I-VPLS 1 and adds some static groups on a SAP. The location of the querier is configured by adding the B-MAC where the querier is connected to (in this example, MTU-6) and adding the two B-VPLS spoke-SDPs as mrouter ports (B-VPLS mrouter ports are added in the I-VPLS backbone-vpls context).

The **mac** command translates MAC address into strings so that the names can be used instead of typing the entire MAC address every time we need to.

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                    igmp-snooping {
                        mrouter-destination "MTU-6" { }
                    }
                    spoke-sdp 41:100 {
                        igmp-snooping
                            mrouter-port true
                        }
                    }
                    spoke-sdp 42:100 {
                        igmp-snooping
                            mrouter-port true
                        }
                    }
                }
            }
            igmp-snooping
                admin-state enable
            }
            sap 1/1/1:7 {
                igmp-snooping {
                    static {
                        group 228.0.0.1 {
                            starg
                        }
                        group 228.0.0.2 {
                            starg
                        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        group 239.0.0.1 {
                            source 172.16.99.99 { }
                        }
                    }
                }
            }
```

As in regular VPLS instances, mrouter ports are added to all the multicast groups:

```

MMRP policies and ISID-based filtering for PBB inter-domain expansion

As described in the MMRP for flooding optimization section, MMRP is used in the backbone VPLS instances to build per I-VPLS flooding trees. Each I-VPLS has an associated group B-MAC in the B-

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VPLS, which is derived from the ISID, and is advertised by MMRP throughout the whole B-VPLS context, regardless of whether a specific I-VPLS is present in one or all the B-VPLS PEs.

In an inter-domain environment, the same B-VPLS can be defined in different domains and therefore MMRP will advertise all the group B-MACs in every domain. The group B-MACs are consuming resources in all the PEs no matter if a particular ISID—and therefore its group B-MAC—is required in one of the domains or not. When MMRP is enabled in a particular PE, data plane and control plane resources are consumed and they must be taken into consideration when designing PBB-VPLS networks:

- Control plane – MRRP processing takes CPU cycles and the number of attributes that can be advertised is not unlimited
- Data plane – each group B-MAC registration takes one MFIB entry (the MFIB is shared between MMRP and IGMP/PIM snooping)

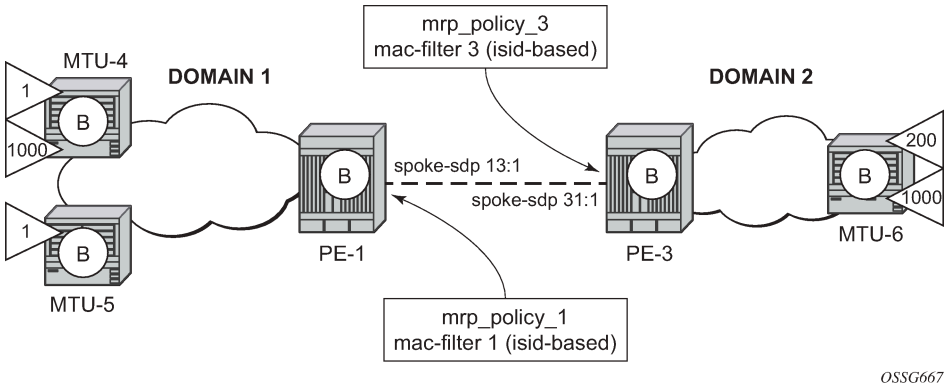
SR OS routers support MMRP policies and ISID-based filters so that control plane and data plane resources can be saved when I-VPLS instances are not defined in all the domains.

Figure 237: Inter-domain B-VPLS and MMRP policies/ISID-based filters example illustrates an example of usage for MMRP policies and ISID-based filters that will be configured in this section. "Domain 1" and "domain 2" will have a range of local ISIDs each and a range of "inter-domain" ISIDs:

- Domain 1 local ISIDs: from 1 to 100
- Domain 2 local ISIDs: from 101 to 200
- Inter-domain ISIDs: from 1000 to 2000

By applying the MMRP policies indicated in Figure 237: Inter-domain B-VPLS and MMRP policies/ISID-based filters example, domain 1 attributes will be prevented from being declared and registered in domain 2 and the other way around, domain 2 attributes from being declared and registered in domain 1. The egress MAC filters will drop any traffic sourced from a local ISID preventing it to be transmitted to the remote domain.

Figure 237: Inter-domain B-VPLS and MMRP policies/ISID-based filters example



MMRP policies

The following shows the MMRP policy configuration on node PE-1. This policy will block any registration/declaration except those for ISIDs 1000-2000. Packets will be compared against the configured matching ISIDs as long as the PBB Etype matches the one configured on the port or SDP.

```
# on PE-1:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        mrp {
            policy "mrp_policy_1" {
                description "allow-inter-domain-isids"
                default-action block
                entry 10 {
                    action allow
                    match {
                        isid 1000 {
                            higher-value 2000
                        }
                    }
                }
            }
```

After the MMRP policy is configured, it must be applied on the corresponding SAP or SDP-binding. An MRP policy can be applied to a B-VPLS SAP, B-VPLS spoke-SDP or B-VPLS mesh-SDP:

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            spoke-sdp 14:100 {
                mrp {
                    policy "mrp_policy_1"
                }
            }
            spoke-sdp 15:100 {
                mrp {
                    policy "mrp_policy_1"
                }
            }
```

In the same way, mrp_policy_3 will be configured in PE-3.

Some additional considerations about the MMRP policies:

- Different entries within the same MRP policy can have overlapping ISID ranges. The entries will be evaluated in the order of their IDs and the first match will cause the implementation to execute the associated action for that entry and then to exit the MRP policy.
- If no ISID is specified in the match condition then:
  - If the action is "end-station", no entry is added and the action is block.
  - If the action is different from "end-station", every ISID is considered for that action.
- The MRP policy specifies either a forward or a drop action for the group B-MAC attributes associated with the ISIDs specified in the match criteria.

```
[ex:configure service mrp policy "mrp_policy_1" entry 10]
A:admin@PE-1# action ?

 action <keyword>
 <keyword>  - (block|allow|end-station)

    Specify the action to take for packets that match this mrp-policy entry
```

- There is an additional action called end-station. This action specifies that an end-station emulation is present on the SAP/SDP-binding where the policy has been applied. The matching ISIDs will not get declared/registered in the SAP/SDP-binding (just like the block action). However, those attributes will

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

get mapped as static MMRP entries on the SAP/SDP-binding, which implicitly get instantiated in the data plane as MFIB entries associated with that SAP/SDP-binding for the related group B-MAC. When the action is "end-station", the default action must be block:

```
*[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# default-action allow

*[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service mrp policy "mrp_policy_3" entry 10 action -
Mrp-policy default-action must be block when end-station action exists - configure
 service mrp policy "mrp_policy_3" default-action
```

- The end-station action can be used in the inter-domain gateways when, for instance, we do not want MMRP control plane exchanges between domains. The following output shows how to define the static MMRP entries 1000-2000 in PE-3 without receiving any declaration for any of those attributes or having any of those locally configured.

```
# on PE-3:
configure {
    service {
        mrp {
             policy "mrp_policy_3" {
                default-action block
                entry 10 {
                    action end-station
                    match {
                        isid 1000 {
                            higher-value 2000
                        }
                    }
                }
            }
```

```

```

- The MRP policy can be applied to multiple B-VPLS services as long as the scope of the policy is template (the scope can also be exclusive).
- Any changes made to the existing policy will be applied immediately to all services where this policy is applied. For this reason, when many changes are required on a MRP policy, Nokia recommends copying the policy to a work-in-progress policy. That work-in-progress policy can be modified until

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

complete and then written over the original MRP policy. You can use the **configure service mrp copy** command to work with the policies in this manner.

```
[ex:configure service mrp]
A:admin@PE-1# copy policy "mrp_policy_3" to policy ?

 [policy-name] <string>
 <string>  - <1..32 characters>

    Specify the policy name associated with the MRP
```

The **rename** command can help to change the entries sequence order.

```
[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# rename entry 10 to ?

 [entry-id] <number>
 <number>  - <1..65535>

    Sepcify an id for the MRP policy entry
```

An MRP policy cannot be deleted until it is removed from all the SAPs/SDP-bindings where it is applied.

ISID-based filters

The MMRP policies help to control the exchange of group B-MAC attributes across domains. Based on the registration state of a specific group B-MAC on a SAP/SDP-binding, the BUM traffic for a particular I-VPLS will be allowed or dropped. However, to avoid that any local ISID packet is flooded to the remote B-VPLS domain, all the packets tagged with the local ISIDs at the gateway PEs need to be filtered at the data plane. ISID-based filters will prevent the local ISIDs from sending any packet with unicast B-MAC to the remote domain. This is particularly useful for PBB-Epipe services across domains, where all the frames use unicast B-MACs and MMRP policies cannot help because they only act on group B-MAC packets.

The following CLI output shows how to configure an ISID-based filter that drops all the traffic sourced from the local ISIDs on PE-1 (the default action is drop and it does not show up in the configuration).

```
# on PE-1:
configure {
    filter {
        mac-filter "MAC 1" {
            description "drop_local_isids"
            type isid
            filter-id 1
            entry 10 {
                log 101
                match {
                    frame-type 802dot3
                    isid {
                        range {
                            start 1000
                            end 2000
                        }
                    }
                }
                action {
                    accept
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Once the filter is configured, it must be applied on a B-VPLS SAP or SDP-binding and always at egress.

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            spoke-sdp 14:100 {
                egress {
                    filter {
                        mac "MAC 1"
                    }
                }
            }
            spoke-sdp 15:100 {
                egress {
                    filter {
                        mac "MAC 1"
                    }
                }
            }
```

Some additional comments about ISID-based filters:

- The **type isid** statement must be added when ISIDs are defined in the match command, otherwise the system will show an error, as follows:

```
*[ex:configure filter mac-filter "MAC 2"]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure filter mac-filter "MAC 2" entry 10 match isid value
 - The match criteria entered are not compatible with the Mac filter type - Allowed
only with mac-filter type ISID - configure filter mac-filter "MAC 2" type
```

- When the operator sets the "type isid", the filter cannot be applied at ingress. Only egress ISID-based filters are allowed:

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress filter]
A:admin@PE-1# mac "MAC 1"

*[ex:configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress filter]
A:admin@PE-1# commit
MINOR: SVCMGR #2050: configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress
 filter mac - Can not apply filter of type 'isid' on ingress - configure filter
 mac-filter "MAC 1" type
```

- Like any filter or MMRP policy, the filter can be applied to multiple B-VPLS services as long as the scope of the policy is "template" (the scope can also be "exclusive").
- The following command shows the filter configuration and packets that have matched the filter (field "Egr. Matches"):

```
[]
A:admin@PE-1# show filter mac 1

[no] sdp             - Enable/disable MRP debugging for a particular SDP
```

Conclusion

PBB-VPLS allows the service providers to scale VPLS services by multiplexing customer I-VPLS instances into one or more B-VPLS instances. This multiplexing dramatically reduces the number of services, pseudowires, and MAC addresses in the core and therefore allows the service provider to scale Layer 2 multi-point networks and provide services across international backbones.

The example used in this chapter shows the configuration of the customer and backbone VPLS instances as well as all the related features which are required for this environment. Show and debug commands have also been suggested so that the operator can verify and troubleshoot the service.

PIM Snooping for IPv4 in EVPN-MPLS Services

This chapter provides information about PIM snooping for IPv4 in EVPN-MPLS services.

Topics in this chapter include:

Applicability

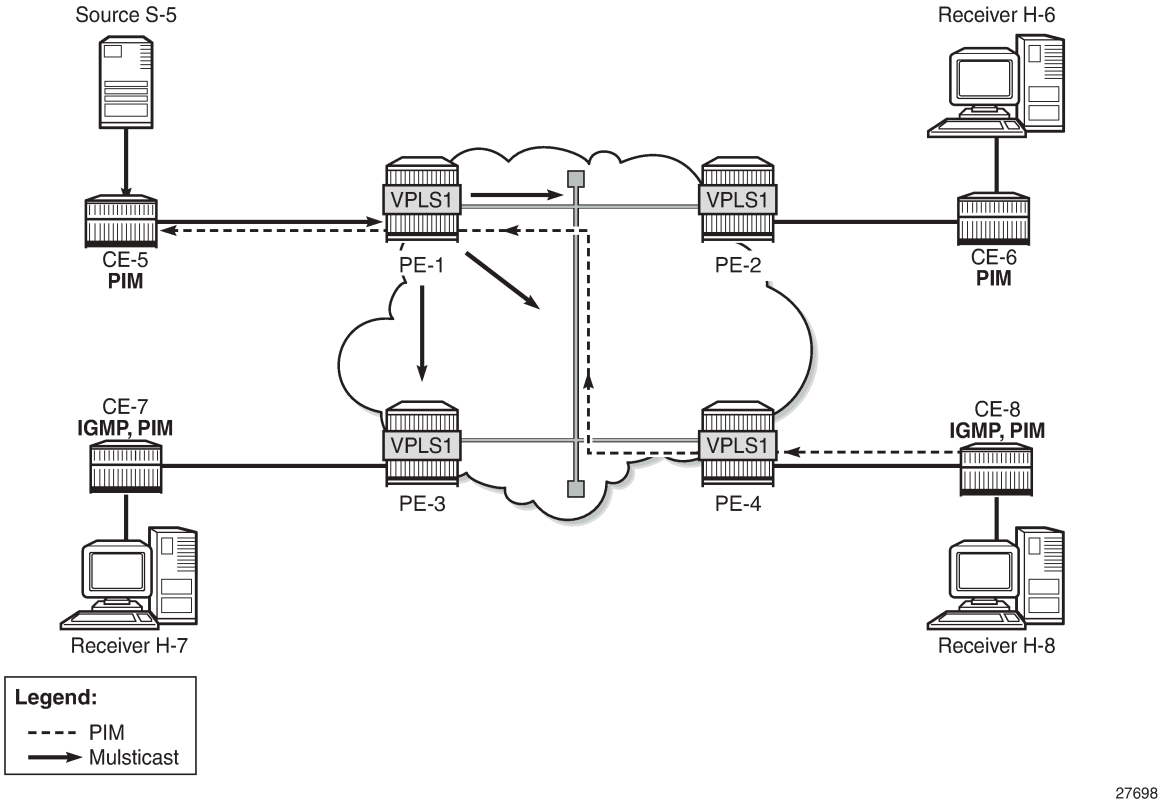
This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. PIM snooping for IPv4 is supported in EVPN-MPLS services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing mode without ESI label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active multi-homing mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping in all-active multi-homing mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

Figure 238: Multicast in VPLS without PIM Snooping shows the example topology with four CEs that have IGMP and PIM enabled (L3) and four PEs configured with VPLS 1 (L2). Source-specific multicast is used in this example. The following description applies to all VPLSs, with or without EVPN.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 238: Multicast in VPLS without PIM Snooping



The VPLS emulates a LAN interconnecting sites with L3-capable devices that use PIM to join or leave multicast groups. When receiver H-8 sends an IGMP report message to join a multicast group, CE-8 sends a PIM join message to CE-5. The PEs forward the PIM message without learning any PIM-related information, such as which CE sent the PIM join and for which multicast group.

The source S-5 is sending the multicast stream to CE-5. When CE-5 receives a PIM join message for this multicast group from CE-8, it forwards the multicast stream to CE-8. By default, all PEs flood the multicast stream on all their connections in the VPLS domain, regardless of whether a PIM join was received from that connection. L2 flooding is not aware of the PIM join/prune messages from the L3 edge routers, resulting in an inefficient use of network resources. To avoid this L2 flooding, PIM snooping can be enabled in the VPLS by the following command:

```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping ?

 pim-snooping

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 group-policy          - Group policy name
 hold-time             - Duration that allows the PIM-snooping switch to snoop all the PIM
 states in the VPLS
 ipv4                  + Enter the ipv4 context
 ipv6                  + Enter the ipv6 context
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping {
            ipv4 ?

 ipv4

 admin-state           - Administrative state of snooping for multicast traffic
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
```

The default mode is proxy, but PIM snooping can also use snooping mode, depending on the information in the received PIM hello messages. In snooping mode, the PE does not modify the PIM messages; in proxy mode, the PE terminates incoming PIM messages and generates its own PIM messages.

PIM snooping is used for router multicast registration, whereas IGMP snooping is used for host/client multicast registration. IGMP snooping in EVPN-MPLS services is described in chapter P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services. Optionally, PIM snooping and IGMP snooping can be enabled simultaneously.

With PIM enabled, the CEs send PIM hello messages to the well-known multicast address for PIM, 224.0.0.13. PIM hello messages are used to form PIM neighbors and can be used to form the Forwarding Database (FDB). With PIM snooping enabled in the VPLS in the PEs, the PEs snoop PIM messages. The PEs only forward multicast traffic downstream when required, as determined from the received PIM messages. This provides a more efficient use of network resources.

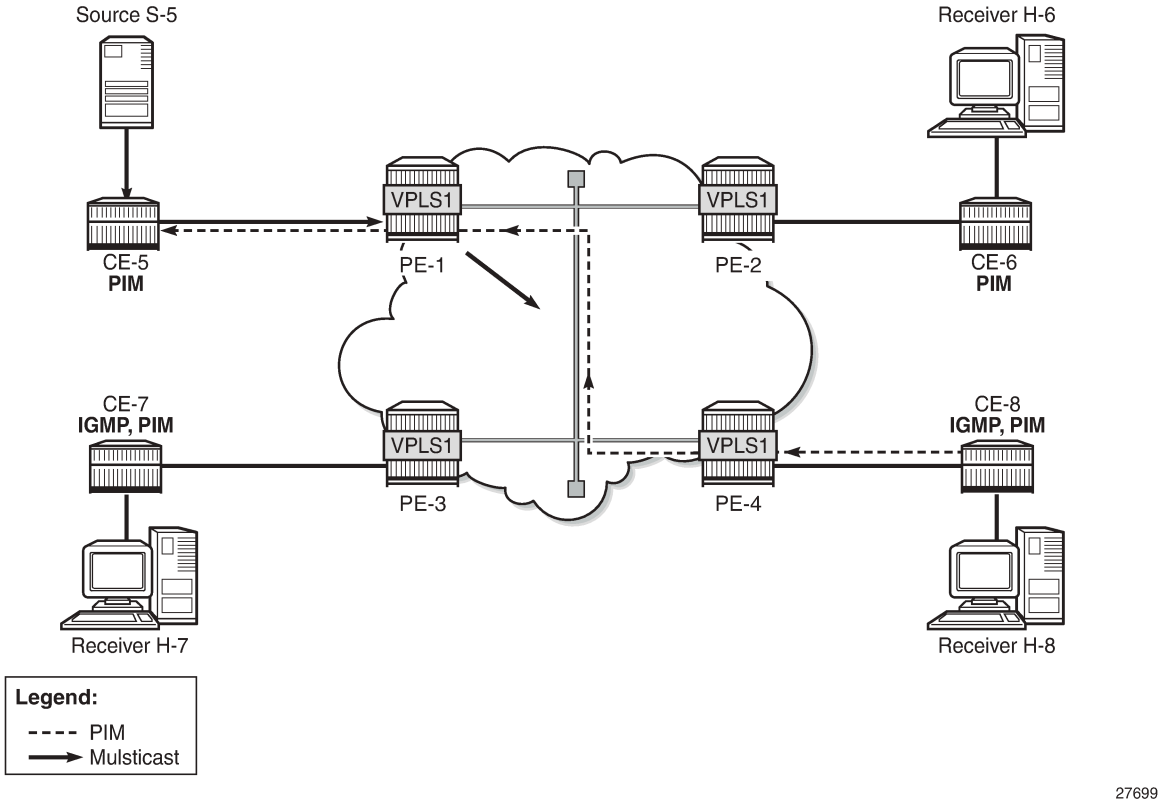
PIM snooping states in a PE are maintained per VPLS instance. When PIM snooping is enabled, IP multicast traffic to a multicast group that is not learned via snooping is dropped by default, unless it is received from a directly connected source.

PIM Snooping in Snooping Mode

Figure 239: Multicast in VPLS with PIM Snooping in Snooping Mode shows that the multicast stream is not flooded in PE-1 when PIM snooping is enabled and operating in snooping mode.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 239: Multicast in VPLS with PIM Snooping in Snooping Mode



When H-8 sends an IGMP report message to join the multicast stream from source S-5 to CE-8, CE-8 sends a PIM join message to CE-5. PE-4 snoops the PIM join message and builds the FDB. PE-4 forwards the PIM join message to PE-1 by matching the upstream neighbor address in the join with the neighbor database. PE-1 snoops the PIM join message, builds its Multicast Forwarding Information Base (MFIB), and performs a similar lookup in its FDB. PE-1 forwards the PIM join to CE-5. The Source Path Tree (SPT) between receiver CE-8 and sender CE-5 is now built and CE-5 forwards multicast data frames to CE-8. PE-1 does not flood multicast frames, but forwards them to CE-8 only, based on the MFIB.

Figure 240: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs shows how the number of PIM messages in the control plane increases when multiple client CEs are connected to PE-4.

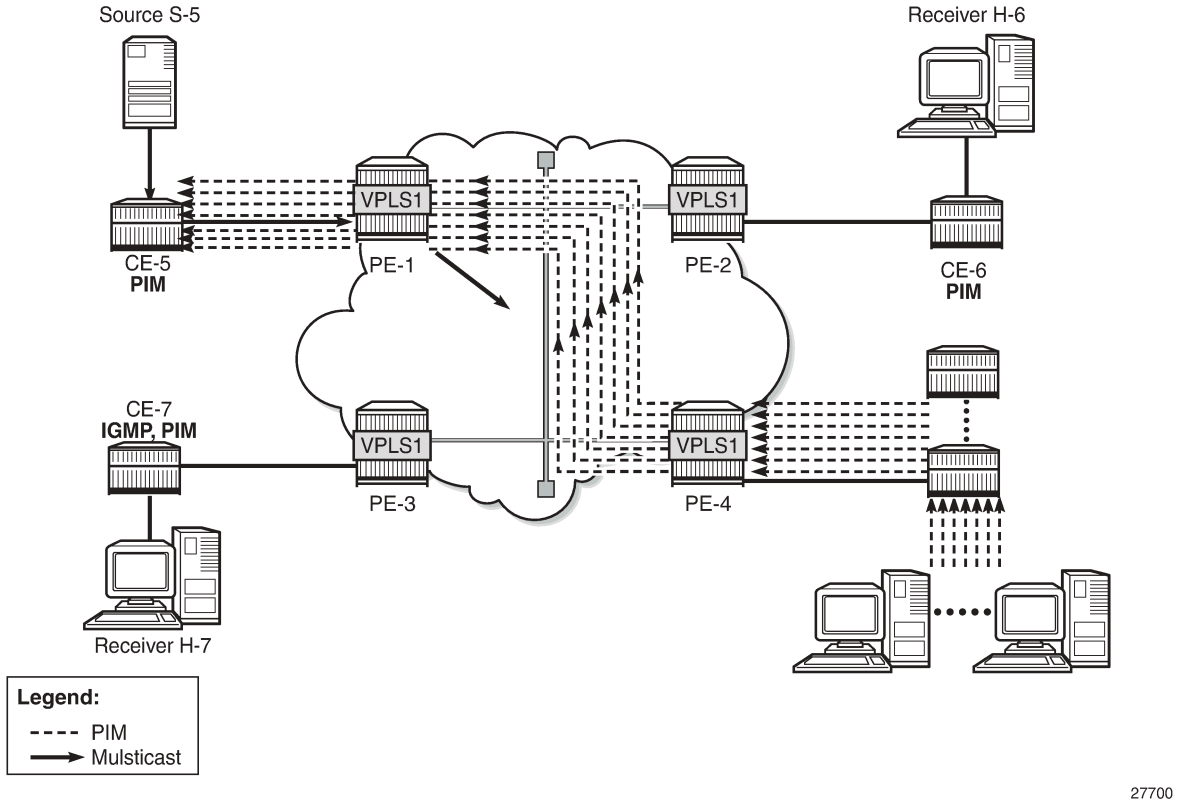
Use subject to Terms available at: www.nokia.com/terms.

Figure 240: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs



PIM Snooping in Proxy Mode

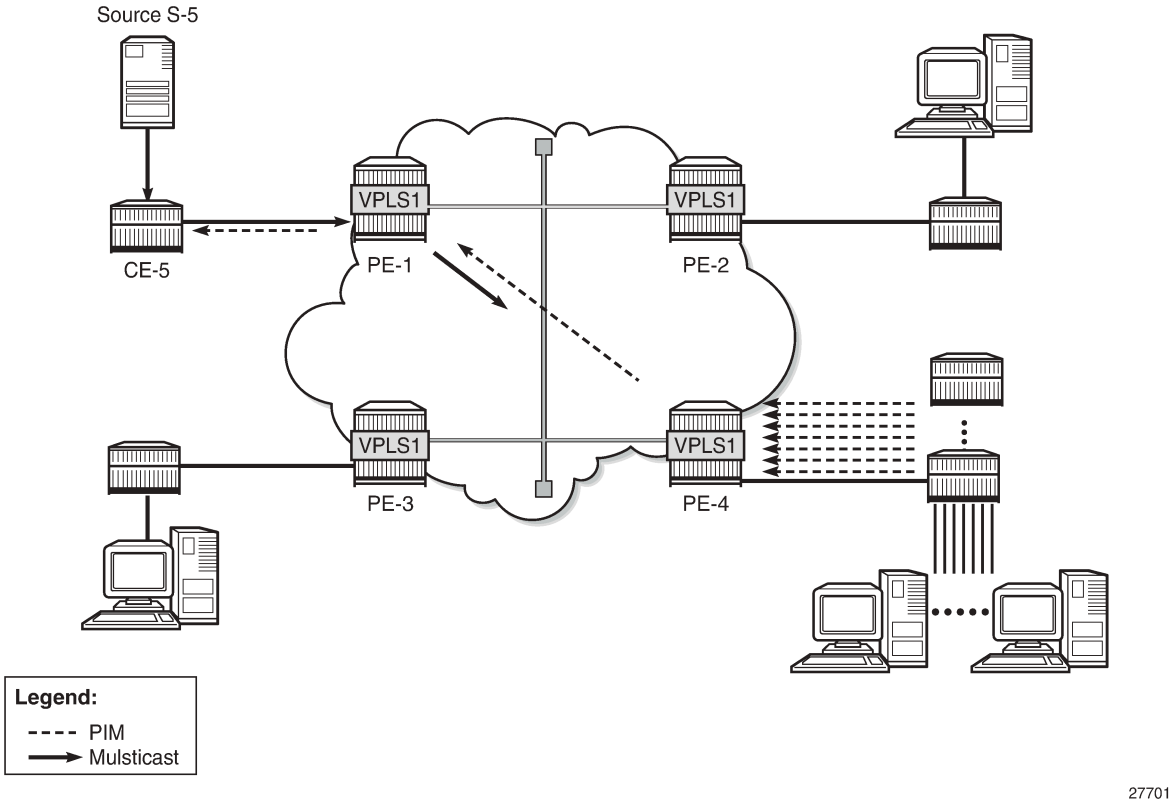
When H-8 sends an IGMP report message to join a multicast stream, CE-8 again sends a PIM join message to CE-5. PE-4 terminates the incoming PIM join message and generates its own PIM join message using CE-5 as the source address, learned from the PIM hello messages. PE-4 builds its MFIB and sends a new PIM join message to S-5. PE-1 terminates the incoming PIM join message and builds its MFIB. PE-1 generates its own PIM join message using CE-5 as the source address. PE-1 forwards the PIM join to CE-5. The SPT between CE-8 and CE-5 is now built and the multicast stream flows from source S-5 to receiver H-8. No multicast traffic is sent to CE-6 and CE-7, because they do not have receivers attached that joined the multicast stream.

The default mode for PIM snooping is proxy mode.

Figure 241: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs shows that the number of PIM messages in the control plane does not increase when multiple client CEs are connected to PE-4, compared to snooping mode.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 241: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs



PIM snooping in proxy mode can be configured with a delay to avoid existing traffic interruption. PIM snooping in proxy mode does not program the MFIB until a hold timer has expired. This hold time is useful in the following cases:

- PIM snooping being enabled on the VPLS
- PIM snooping states being manually cleared by an operator

When the hold timer is started, but not expired yet, multicast traffic is flooded in the VPLS as if PIM snooping was not enabled. VPLS flooding ensures flow delivery during the hold time.

PIM Snooping in VPLS with EVPN-MPLS

PIM snooping in an EVPN-MPLS service supports the following:

- Regular PIM snooping on SAPs/SDP-bindings
  - PIM messages received on EVPN-MPLS endpoints are forwarded to SAPs/SDP-bindings.
  - IP multicast traffic received on an EVPN-MPLS binding is forwarded to SAPs/SDP-bindings from which a PIM join was received, or to ports configured as mrouter ports.
- The EVPN-MPLS endpoints are treated as a single PIM interface:
  - IP multicast traffic and PIM messages received on an EVPN-MPLS endpoint are not forwarded to other EVPN-MPLS endpoints (split-horizon).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - Hello and join/prune messages from SAPs/SDP-bindings are forwarded to all EVPN-MPLS destinations.
  - When a hello message is received from one PIM neighbor on an EVPN-MPLS destination, the single interface representing all EVPN-MPLS destinations has that neighbor.
    - Individual destinations appear in the MFIB, but the information for each EVPN-MPLS destination entry is identical.
- If a Point-to-Multipoint (P2MP) mLDP provider tunnel is configured:
  - If the PE is the root node of a P2MP LSP that is up, PIM messages and IP multicast traffic are only forwarded over the P2MP Label Switched Path (LSP) instead of being sent to the EVPN-MPLS endpoints. Therefore, the P2MP leaves must match the EVPN-MPLS endpoints, in this case, PE-2, PE-3, and PE-4.
  - If the PE is a leaf node of a P2MP LSP, it sends PIM messages and IP multicast traffic over its EVPN-MPLS endpoints.
  - The PEs can expect to receive IP multicast traffic and PIM messages from leaf nodes over their EVPN-MPLS endpoints, or over the P2MP LSPs for traffic from root nodes.
- PIM snooping is supported in inter-AS model B and inter-AS model C, as for IGMP snooping.
- All-active and single-active EVPN multi-homing are supported.
- Multi-chassis Synchronization (MCS) of PIM snooping state is supported on SAPs and spoke-SDPs in dual-homing.
  - The active (Designated Forwarder (DF)) PE sends the PIM states to the backup non-DF (NDF) PE.
  - In case of failure, the backup PE has the PIM states already, and the multicast traffic path can be re-established fast without any need to wait for PIM states to be snooped.
  - A sync-tag is configured on the ports or SDPs that need to be synchronized on both PEs.
  - MCS PIM snooping is restricted to two peers, even though MCS supports more peers for other types of information. An error is raised when attempting to configure a sync-tag on the same port or SDP to more than one peer.
- PIM snooping is supported for both IPv4 and IPv6 multicast. PIM snooping for IPv6 uses MAC-based forwarding by default, and can be configured to use (S,G)-based forwarding.
- PIM snooping is transparent to the underlying tunnel. PIM snooping works with RSVP, LDP, SR-ISIS, SR-OSPF, SR-TE, BGP, and MPLSoUDP.
- PIM snooping is not supported with routed VPLS with EVPN-MPLS, and its configuration is blocked.

Configuration

Figure 242: Example Topology shows the example topology. Source S-5 sends multicast streams to CE-5, which forwards those only after a PIM join message has been received. An mLDP P2MP LSP is used to distribute the multicast from the root node PE-1 to the other PEs. All CEs have PIM enabled and the receiving CEs (CE-6, CE-7, and CE-8) have IGMP configured on the interface toward the receivers (H-6, H-7, and H-8). EVPN-MPLS VPLS 1 is configured on the PEs. Initially, PIM snooping is disabled in the VPLS. Receiver H-8 joins multicast group 232.1.1.1 from source S-5.

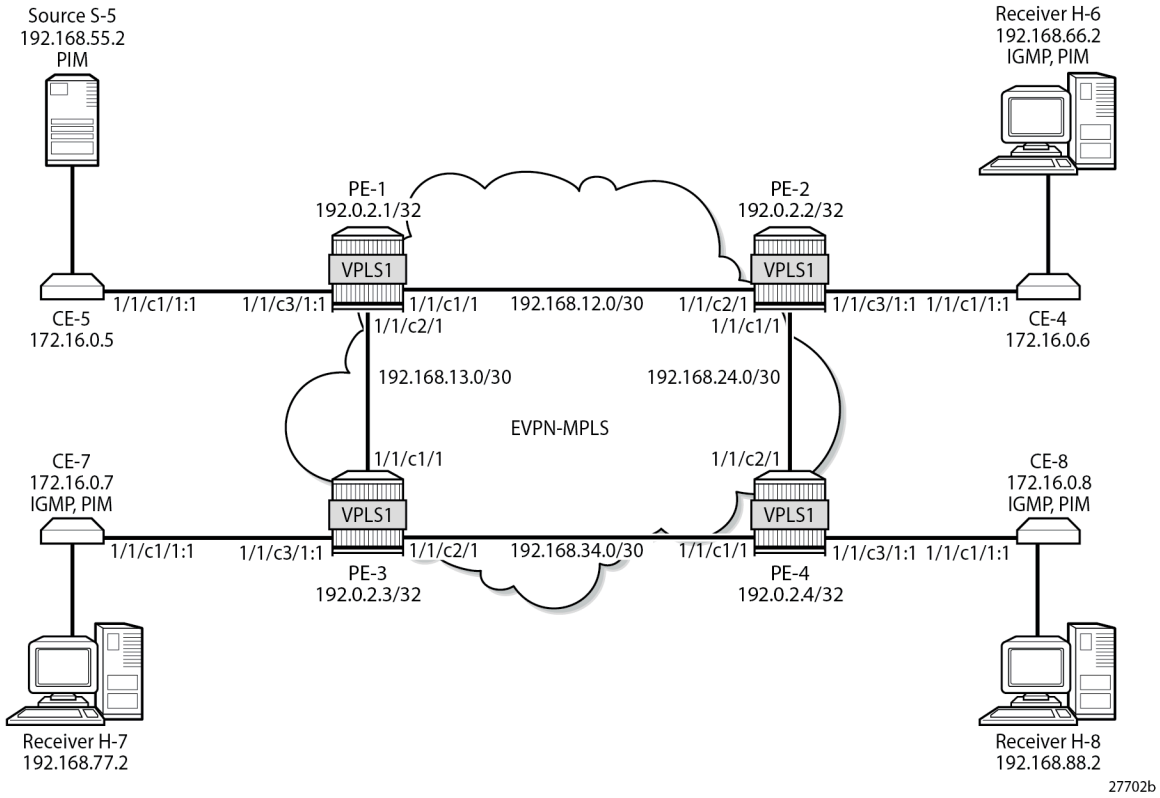
Figure 242: Example Topology



The initial configuration includes the following:

- Cards, MDAs
- Ports
  - Ports between PEs are network ports with null encapsulation
  - Ports between CEs and PEs are hybrid ports with dot1q encapsulation
- IS-IS as IGP between the PEs (alternatively, OSPF can be used)
- LDP between the PEs
- BGP with address family EVPN between the PEs. PE-2 is the route reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
On PE-2:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            rapid-withdrawal true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            group "INTERNAL" {
                type internal
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.1" {
                group "INTERNAL"
            }
            neighbor "192.0.2.3" {
                group "INTERNAL"
            }
            neighbor "192.0.2.4" {
                group "INTERNAL"
            }
        }
    }
}
```

EVPN-MPLS VPLS without PIM Snooping

VPLS 1 is configured with EVPN-MPLS in the PEs. By default, PIM snooping is disabled. PE-1 is configured as **root-and-leaf** node for the P2MP mLDP multicast tree, while the other three PEs have the default **no root-and-leaf** configured, so they are leaf-only nodes. The configuration of VPLS 1 on PE-1 is as follows:

```
On PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 { }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/c3/1:1 { }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
        }
    }
}
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A P2MP mLDP multicast tree is created from root node PE-1 to the leaf nodes. On the root node PE-1, an SDP of type **VplsPmsi** is auto-created:

```
[/]

```

When a P2MP mLDP provider tunnel is configured, the root node forwards PIM messages and IP multicast traffic over the provider tunnel instead of over the EVPN-MPLS endpoints. However, the leaf nodes of a P2MP mLDP provider tunnel send PIM messages and IP multicast traffic over the EVPN-MPLS endpoints.

The following P2MP mLDP bindings are active on root node PE-1: one toward PE-2 via port 1/1/c1/1 and one toward PE-3 via port 1/1/c2/1.

```

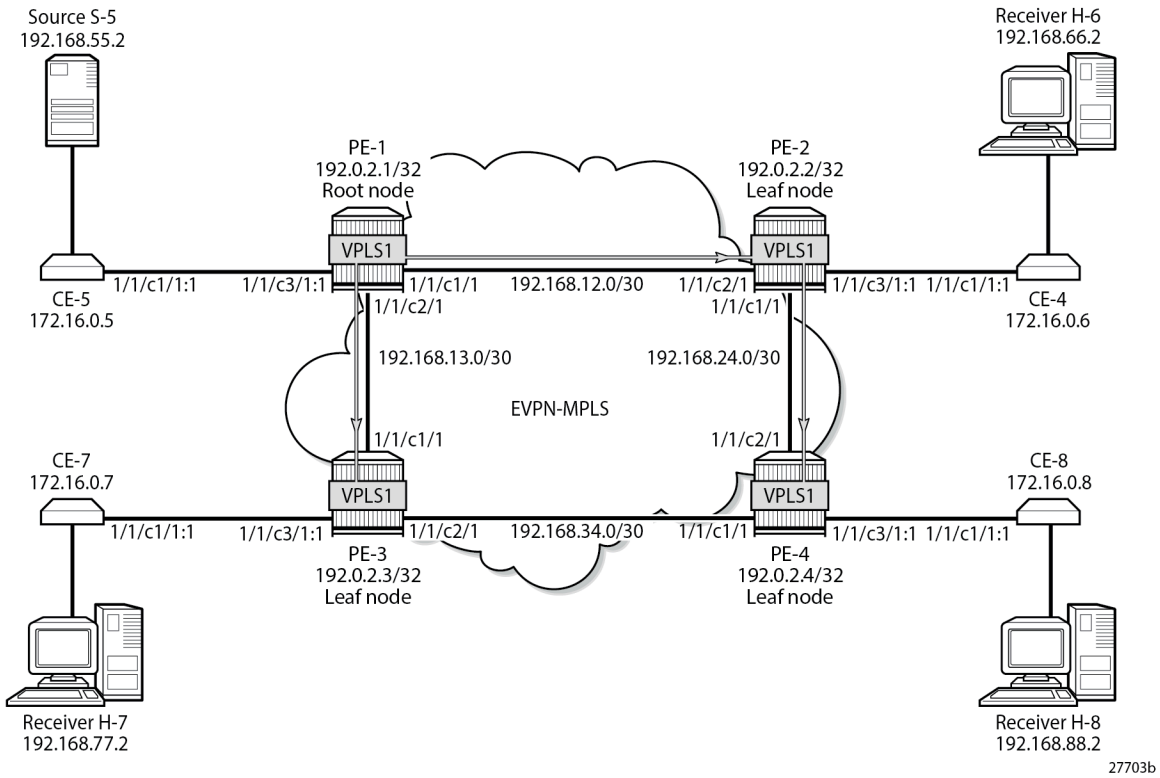
Figure 243: P2MP mLDP Multicast Tree shows the mLDP multicast tree. Multicast traffic from source S-5 uses the mLDP multicast tree from PE-1 to both PE-2 and PE-3. PE-2 is a transit node for multicast traffic to PE-4, and also a leaf node. PE-3 and PE-4 are leaf nodes.

Figure 243: P2MP mLDP Multicast Tree



CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. The configuration on CE-8 is as follows:

```
On CE-8:
configure {
    router "Base" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        interface "int-CE-8-H-8" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.88.1
                    prefix-length 24
                }
            }
        }
        interface "int-CE-8-PE-4" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.8
                    prefix-length 16
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.8
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.55.0/30 route-type unicast {
                next-hop "172.16.0.5" {
                    admin-state enable
                }
            }
        }
        pim {
            apply-to all
        }
        igmp {
            interface "int-CE-8-H-8" { }
        }
    }
}
```

The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure {
    router "Base" {
        interface "int-CE-5-PE-1" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.5
                    prefix-length 16
                }
            }
        }
        interface "int-CE-5-S-5" {
            port 1/1/c3/1
            ipv4 {
                primary {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    address 192.168.55.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.5
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.66.0/24 route-type unicast {
                next-hop "172.16.0.6" {
                    admin-state enable
                }
            }
            route 192.168.77.0/24 route-type unicast {
                next-hop "172.16.0.7" {
                    admin-state enable
                }
            }
            route 192.168.88.0/24 route-type unicast {
                next-hop "172.16.0.8" {
                    admin-state enable
                }
            }
        }
        pim {
            apply-to all
        }
    }
}
```

The PIM neighbors of CE-5 are the receiving CEs: CE-6, CE-7, and CE-8, as follows:

```
[/]

Figure 244: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled shows that receiver H-8 sends an IGMP report to CE-8 and CE-8 sends a PIM join message to CE-5 via PE-4. PE-4 floods the PIM join message to all PEs, and the message is not snooped by any intermediate PE.

© 2023 Nokia.

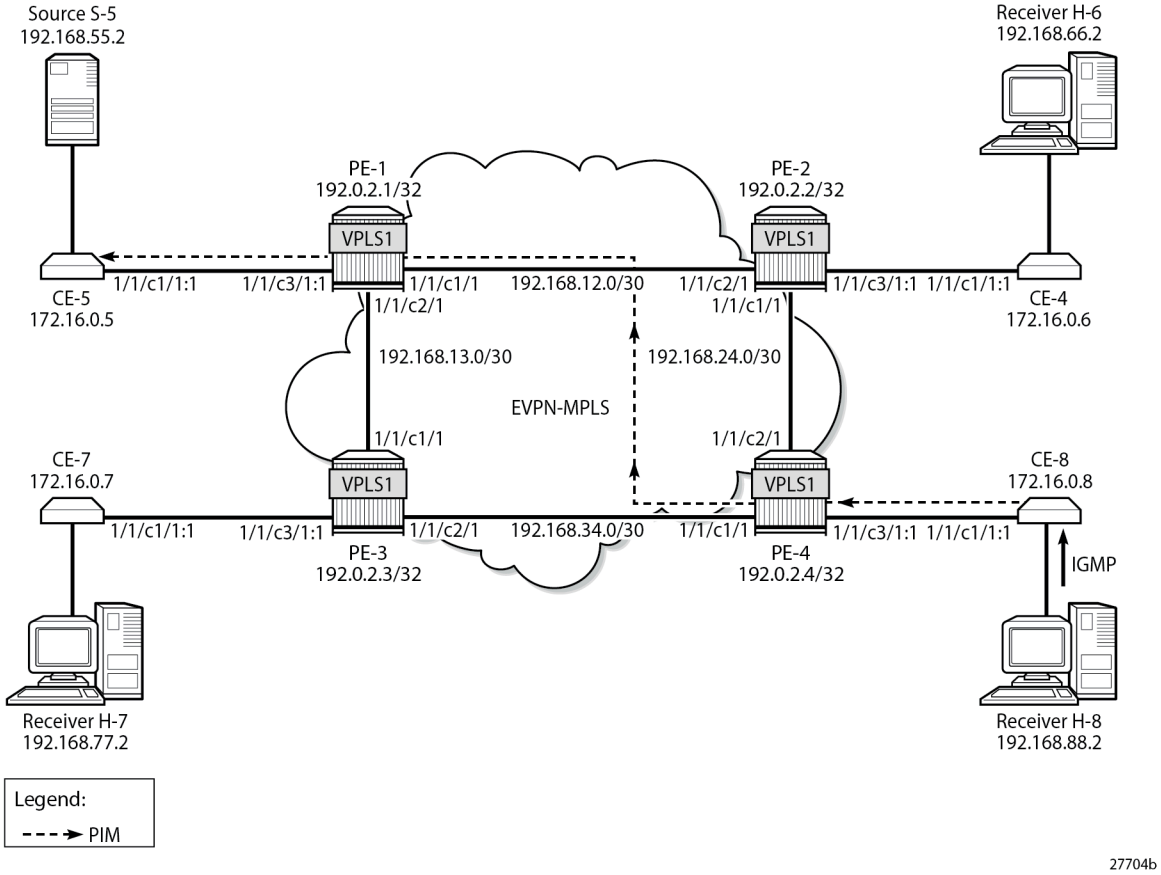
Figure 244: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled



Alternatively, a static multicast group can be configured on IGMP interface int-CE-8-H-8 for multicast group (192.168.55.2, 232.1.1.1), as follows:

```
On CE-8:
configure {
    router "Base" {
        igmp {
            interface "int-CE-8-H-8" {
                ssm-translate {
                    group-range start 232.0.0.0 end 232.255.255.255 {
                        source 192.168.55.2 { }
                    }
                }
                static {
                    group 232.1.1.1 {
                        source 192.168.55.2 { }
                    }
                }
            }
        }
    }
}
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

CE-8 sends the following PIM join message for multicast group (192.168.55.2, 232.1.1.1) to upstream IP address 172.16.0.5 on CE-5:

```
1 2023/08/10 22:51:38.087 CEST MINOR: DEBUG #2001 Base PIM[Instance 1 Base]
"PIM[Instance 1 Base]: Join/Prune
[000 00:17:08.130] PIM-TX ifId 3 ifName int-CE-8-PE-4 0.0.0.0 -> 224.0.0.13 Length: 34
PIM Version: 2 Msg Type: Join/Prune Checksum: 0x4828
Upstream Nbr IP : 172.16.0.5 Resvd: 0x0, Num Groups 1, HoldTime 210

Joined Srcs:
192.168.55.2/32 Flag S  <S,G>

"
```

Multicast stream 232.1.1.1 is sent from source S-5 to CE-5. When CE-5 has received the PIM join message, it floods the multicast stream to PE-1. Root node PE-1 sends the multicast stream to both PE-2 and PE-3. PE-2 forwards the multicast stream to PE-4 and to CE-6; PE-3 forwards the stream to CE-7, and PE-4 forwards to CE-8. The following PIM group for group address 232.1.1.1 is joined on CE-8:

```
[/]

===============================================================================
```

Besides the multicast traffic, signaling messages (such as IS-IS or BGP) are sent, which explains the other counters on the ports being different from zero.

A similar result occurs on PE-2, where incoming traffic from PE-1 is forwarded to PE-4 and to CE-6.

The following port statistics on CE-6 show that the incoming traffic on port 1/1/c1/1 from PE-2 is not forwarded to port 1/1/c2/1 to H-6:

```

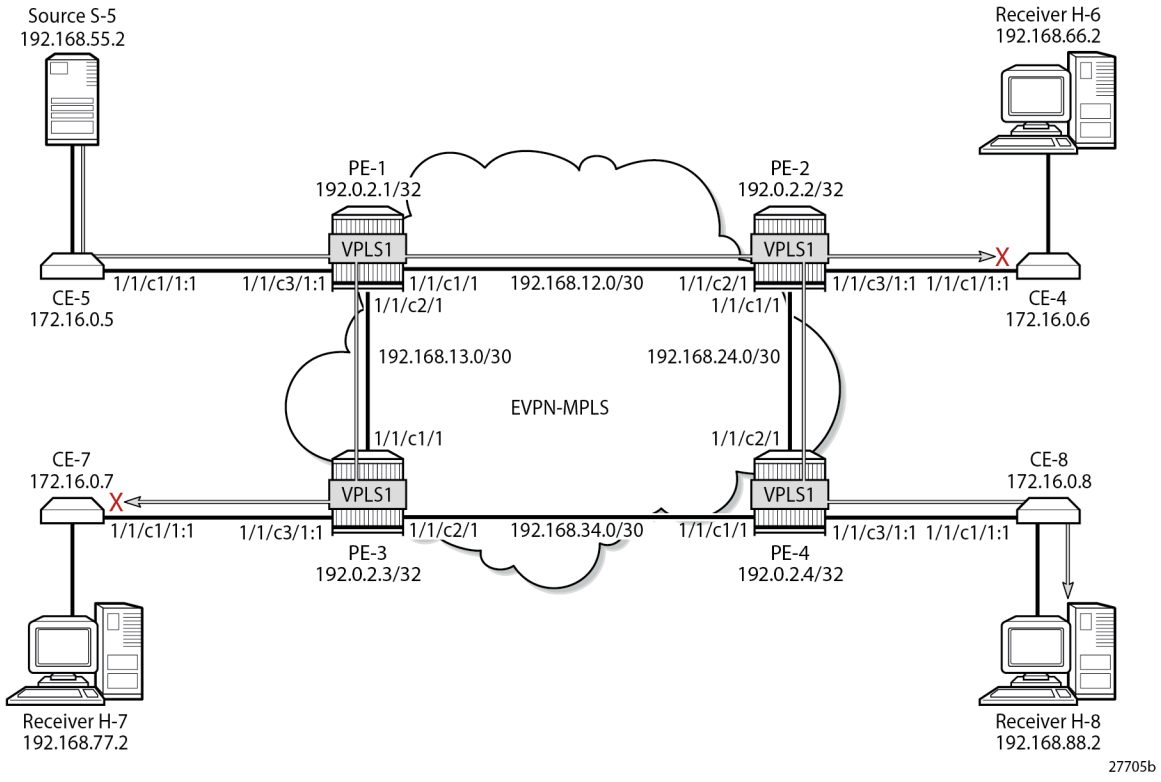
Without PIM snooping, multicast streams are forwarded to CEs that drop them, which wastes resources. Figure 245: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled shows the multicast data streams with receiver H-8 joined and PIM snooping disabled.

Figure 245: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled



EVPN-MPLS VPLS with PIM Snooping Enabled

PIM snooping is enabled on all PEs as follows:

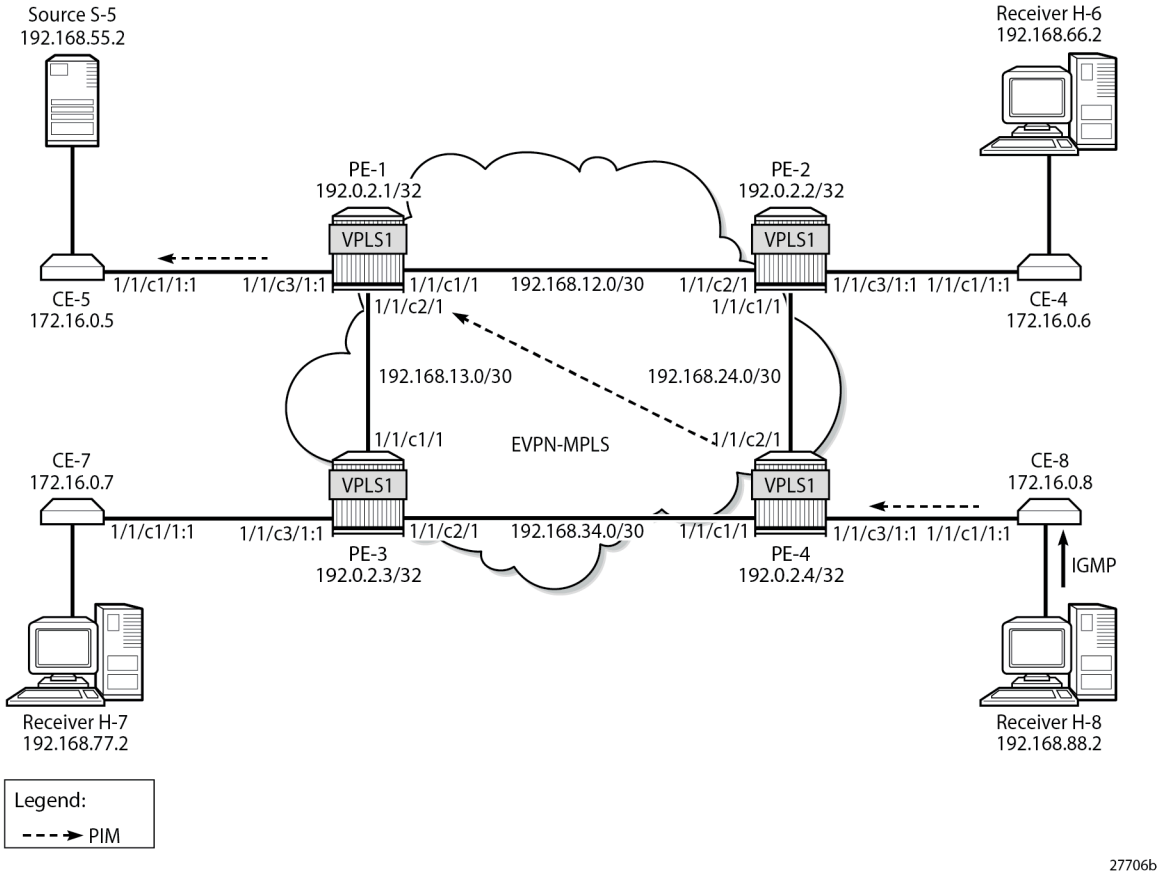
```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping { }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
}
```

The default mode for PIM snooping is proxy mode, which allows the intermediate PEs to terminate the incoming PIM join or prune messages and create their own PIM join or prune message to be sent toward CE-5, as shown in Figure 246: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode:

Figure 246: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode



PE-4 receives the following PIM join message for multicast group (192.168.55.2, 232.1.1.1) from CE-8 to CE-5 on SAP 1/1/c3/1:1:

```
17 2023/08/10 22:59:27.162 CEST MINOR: DEBUG #2001 Base PIM[vpls 1 ]
"PIM[vpls 1 ]: Join/Prune

The following identical **show** command of the PIM group snooped on PE-4 shows the EVPN-MPLS interface as incoming interface. Even though the EVPN-MPLS interface is also listed as outgoing interface, traffic coming from that interface is not forwarded on that interface (all EVPN-MPLS destinations are treated as one single EVPN-MPLS interface), so the traffic is forwarded to the SAP toward the receiving CE only.

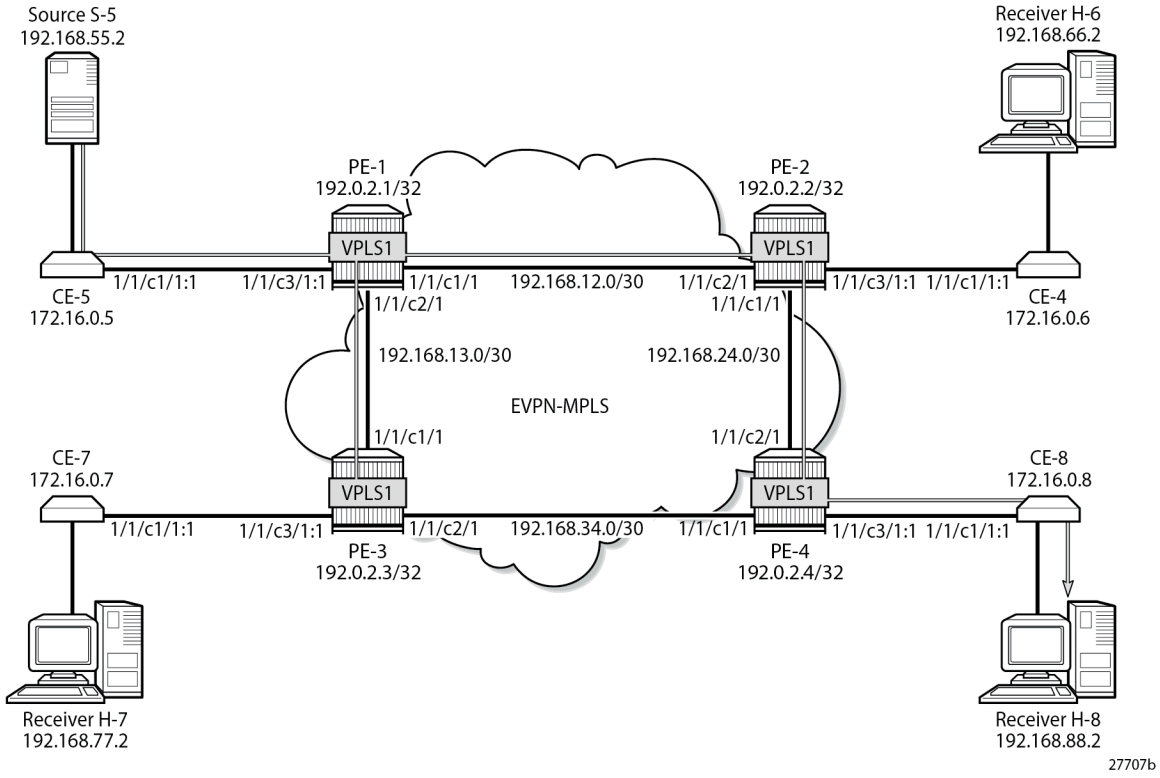
Figure 247: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled shows that the multicast stream still flows from the source S-5 to the receiver H-8, but is not forwarded to CE-6 and CE-7 when PIM snooping is enabled. The root node PE-1 sends the multicast traffic received on the SAP to all EVPN-MPLS destinations over the P2MP mLDP provider tunnel. The EVPN-MPLS interface is treated as a single interface.

Figure 247: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled



Multi-homed EVPN-MPLS VPLS without PIM Snooping

When CE-5 receives a PIM join message, it forwards the multicast stream to PE-1. All multicast traffic in VPLS 2 is sent to all receiving CEs, regardless of the received PIM join messages.

Figure 248: Example Topology with Multi-homing ESs shows the example topology with an all-active multi-homing virtual Ethernet Segment (ES) "ESI-34_2" between PE-3 and PE-4 using a LAG, and a single-active multi-homing ES "ESI-24" between PE-2 and PE-4 using SDPs.

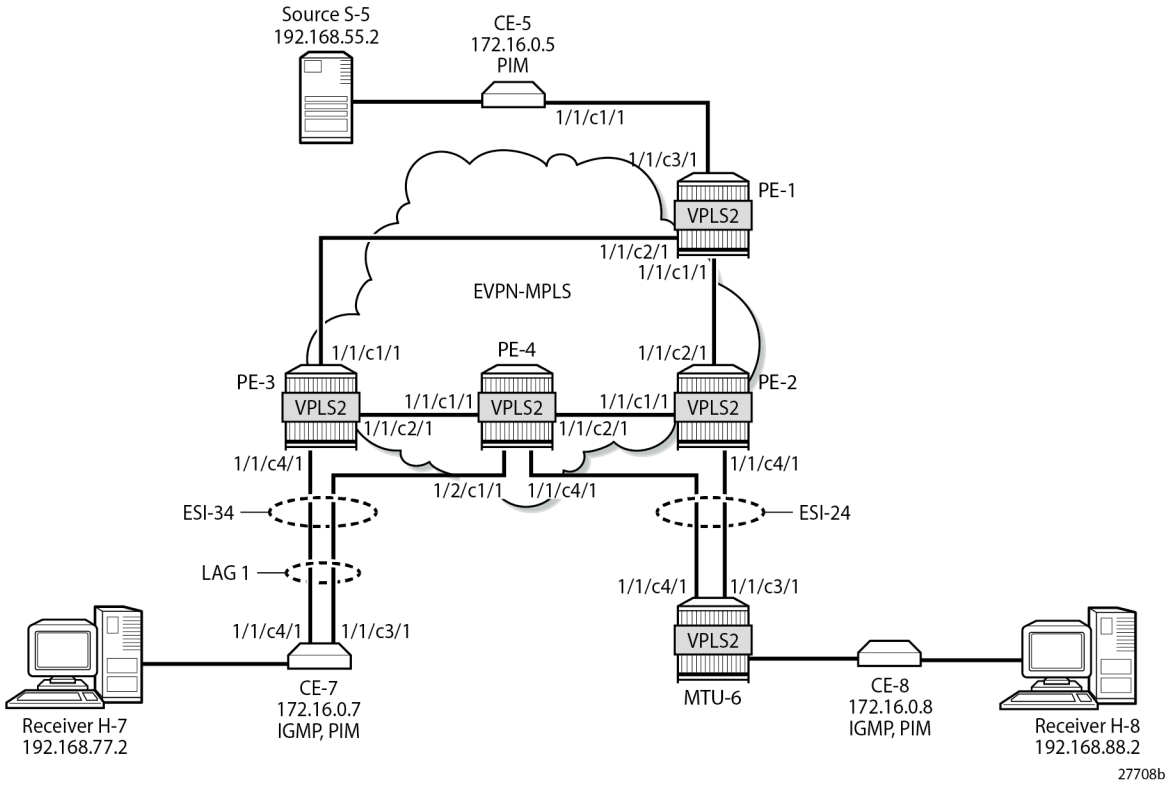
Figure 248: Example Topology with Multi-homing ESs



The configuration of VPLS 2 is similar to the configuration of VPLS 1 on all PEs. An identical P2MP mLDP provider tunnel is established on the PEs for VPLS 2: PE-1 is the root node, PE-2 is a leaf node and a transit node, PE-3 is a leaf node, and PE-4 is also a leaf node.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active multi-homing ES "ESI-24". Spoke-SDP 26:2 is associated with VPLS 2.

```
On PE-2:
configure {
    service {
        sdp 26 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 { }
            bgp-evpn {
                evi 2
                mpls 1 {
                    admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            spoke-sdp 26:2 { }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 10000
                                }
                            }
                        }
                        association {
                            sdp 26 { }
                        }
                    }
                }
            }
        }
    }
}
```

The same ES is configured on PE-4, together with another ES-an all-active multi-homing virtual ES that applies to VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 5000 (which is lower than the preference 10000 on PE-3); see chapter Preference-based and Non-revertive EVPN DF Election. VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure exclusive
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
```

For VPLS 2, PE-2 is the DF in ES "ESI-24", as follows:

```
[/]
A:admin@PE-2# show service id 2 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
26:2                 ESI-24                           DF
===============================================================================
No vxlan instance entries
```

PE-3 is the DF in ES "ESI-34_2", as follows:

```
[/]
A:admin@PE-3# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
lag-1:2              ESI-34_2                         DF
===============================================================================
No sdp entries
No vxlan instance entries
```

PE-4 is NDF for both ESI-24 and ESI-34_2, as follows:

```
[/]
A:admin@PE-4# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
lag-1:2              ESI-34_2                         NDF
===============================================================================

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
46:2                 ESI-24                           NDF
===============================================================================
No vxlan instance entries
```

When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tree to PE-2, PE-3, and PE-4. The DF PE-2 forwards the traffic to MTU-6, and DF PE-3 forwards it to CE-7, even though a PIM join for this group has not been received from CE-7. PE-4 is NDF, so it does not forward the traffic to MTU-6 or CE-7. MTU-6 forwards the traffic to CE-8, which sends it to H-8. CE-7 drops the multicast traffic because no attached receiver has joined the multicast group. Figure 249: EVPN-MPLS with Multi-homing – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

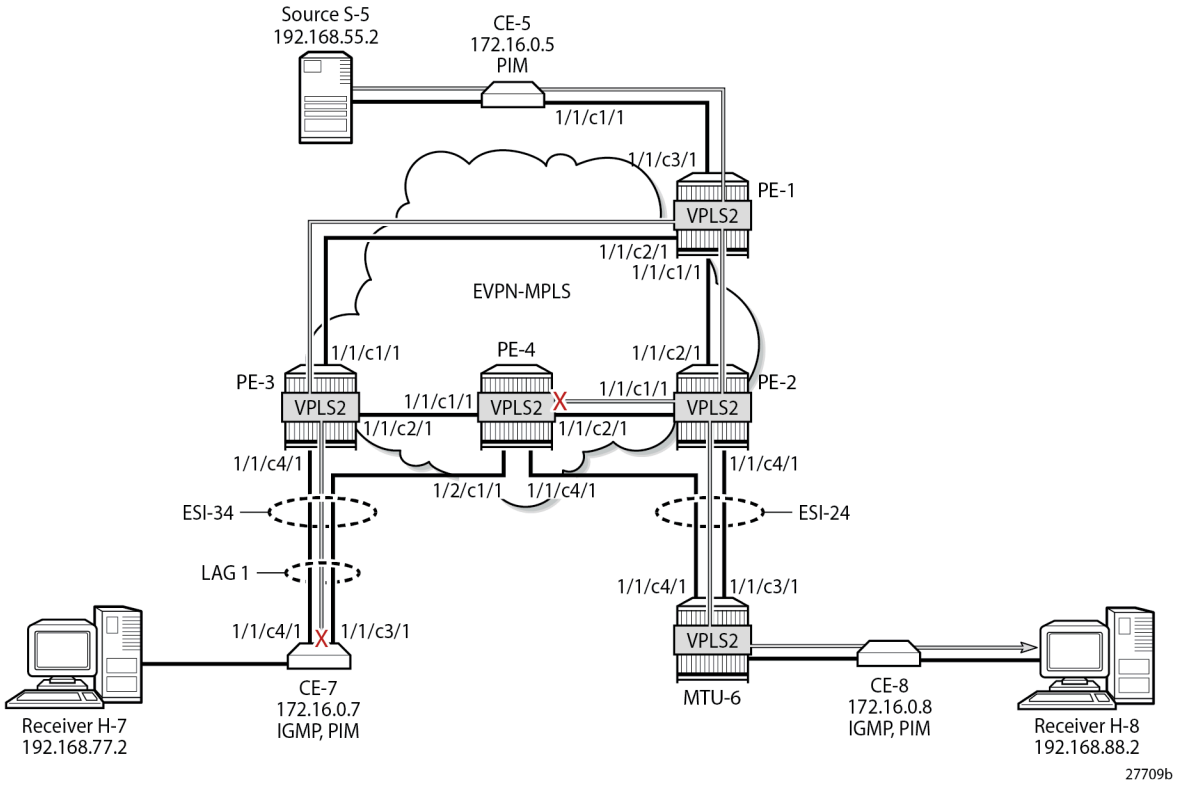
Figure 249: EVPN-MPLS with Multi-homing – Receiver H-8 Joined



The static IGMP multicast is removed to emulate an IGMPv3 report from receiver H-8 to exclude multicast group 232.1.1.1 from source 192.168.55.2, as follows:

```
On CE-8:
configure {
    router "Base" {
        igmp {
            interface "int-CE-8-H-8" {
                static {
                    delete group 232.1.1.1
                }
            }
        }
    }
}
```

Multi-homed EVPN-MPLS VPLS with PIM Snooping

PIM snooping is enabled in VPLS 2 on all PEs, including PE-1, which is not part of an ES-with the following command:

```
configure {
    service {
        vpls "VPLS 2" {
            pim-snooping { }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
}
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
[/]
A:admin@PE-1# show service id 2 pim-snooping neighbor

===============================================================================
PIM Snooping Neighbors ipv4
===============================================================================
Port Id                 Nbr DR Prty     Up Time       Expiry Time     Hold Time

  172.16.0.5
EVPN-MPLS               1               0d 00:01:17   0d 00:01:27     105
  172.16.0.7
-------------------------------------------------------------------------------
Neighbors : 3
===============================================================================
```

PE-3 and PE-4 also have these three CEs as PIM snooping neighbors.

All-active MH EVPN-MPLS VPLS with PIM Snooping

On CE-7, the following static IGMP membership is configured on interface int-CE-7-H-7:

```
On CE-7:
configure {
    router "Base" {
        igmp {
            interface "int-CE-7-H-7" {
                ssm-translate {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    group-range start 232.0.0.0 end 232.255.255.255 {
                        source 192.168.55.2 { }
                    }
                }
                static {
                    group 232.1.1.1 {
                        source 192.168.55.2 { }
                    }
                }
            }
        }
    }
}
```

When H-7 joins the multicast group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2, with four port IDs: the local SAP to CE-5 and the EVPN-MPLS destinations, as follows:

```
[/]
A:admin@PE-1# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------

===============================================================================
```

When debugging is enabled on the PEs as follows, the synchronization between peers in ES "ESI-34_2" is logged:

```
debug {
    service {
        vpls "VPLS 2" {
            pim-snooping {
                events {
                    port {
                        evpn-mpls
                    }
                    jp { }
                }
                packet {
                    packet-types {
                        jp true
                    }
                }
            }
        }
    }
}
```

For example, PE-4 sends the following PIM message to its remote peer PE-3 in ESI-34_2:

```
82 2023/08/10 23:13:20.784 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimVplsFwdJPToEvpn
Forwarding to remote peer on bgp-evpn ethernet-segment ESI-34_2"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-3 receives the following PIM message from its remote peer PE-4 in ESI-34_2:

```
74 2023/08/10 23:13:20.786 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimProcessPdu
Received from remote peer on bgp-evpn ethernet-segment ESI-34_2, will be applied on lag-1:2
"
```

On PE-1, the PIM snooping group (192.168.55.2, 232.1.1.1) has incoming interface SAP 1/1/c3/1:2 toward CE-5 and the EVPN-MPLS interface as outgoing interface, as follows:

```
[/]
A:admin@PE-1# show service id 2 pim-snooping group detail

===============================================================================

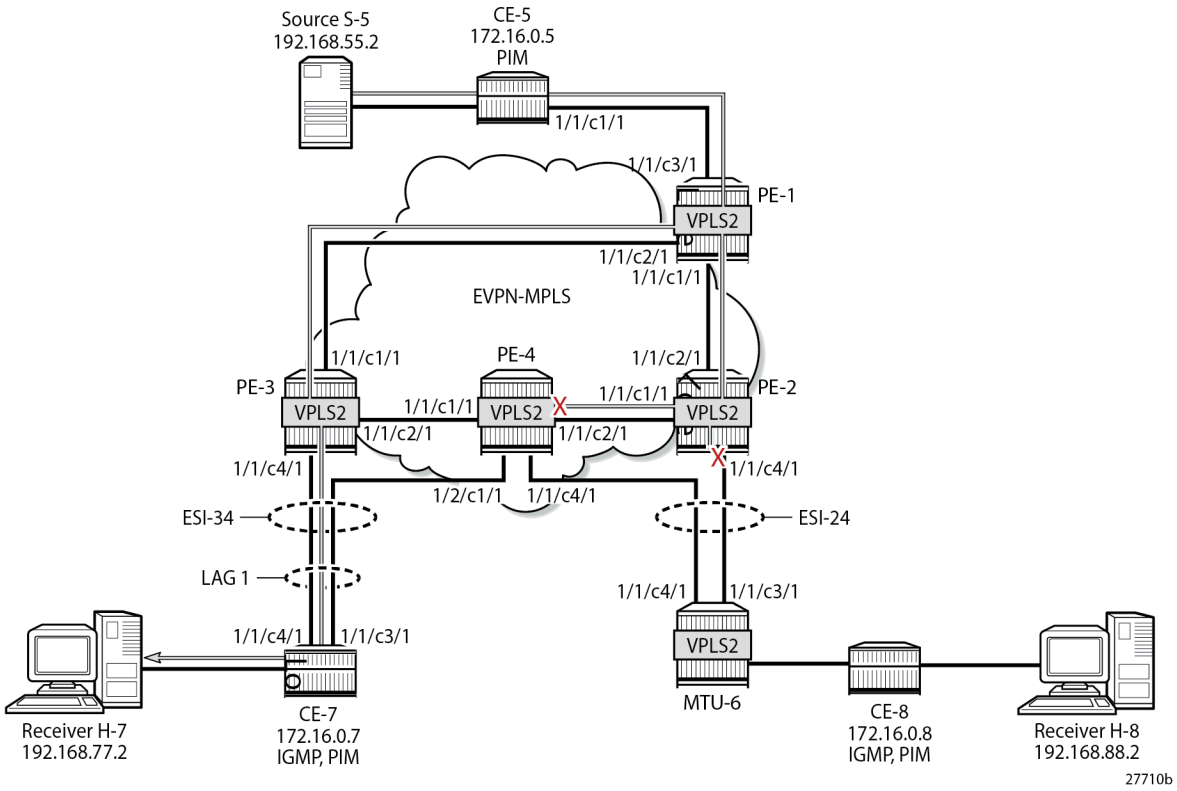
Figure 250: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined shows how the multicast traffic is forwarded when H-7 joins the multicast group and PIM snooping is enabled. DF PE-3 forwards the traffic toward CE-7. The multicast stream also reaches PE-2 and PE-4, where it is dropped.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 250: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined



H-7 leaves the multicast group and H-8 joins it instead.

Single-active MH EVPN-MPLS VPLS with PIM Snooping

When H-8 joins the multicast group and PIM snooping is enabled, only DF PE-2 forwards traffic from the EVPN-MPLS toward a receiver. PE-3 does not forward traffic to CE-7 because no PIM join message was received from CE-7. Figure 251: EVPN-MPLS with Single-active Multi-homing and PIM Snooping Enabled – Receiver H-8 Joined shows how the multicast traffic is forwarded when H-8 joins the multicast group and PIM snooping is enabled.

The MFIB on PE-3 is empty, because multicast traffic toward H-8 is not sent via PE-3, as follows:

```
[/]
A:admin@PE-3# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Number of entries: 0
===============================================================================
```

The data-driven PIM state synchronization ensures that DF PE-2 sends updates to NDF PE-4. With debugging enabled, the following debug message is displayed at PE-2:

```
205 2023/08/10 23:15:21.053 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimVplsFwdJPToEvpn
Forwarding to remote peer on bgp-evpn ethernet-segment ESI-24"
```

The following debug message is displayed at PE-4:

```
122 2023/08/10 23:15:21.053 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimProcessPdu
Received from remote peer on bgp-evpn ethernet-segment ESI-24, will be applied on 46:2
"
```

As a result, the MFIB on PE-4 is not empty, as follows:

```
[/]
A:admin@PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================

On PE-2, the same PIM snooping group has the EVPN-MPLS as incoming interface and the spoke-SDP 26:2 as outgoing interface. Again, the split-horizon mechanism ensures that the multicast traffic that enters through the EVPN-MPLS interface is not forwarded on the EVPN-MPLS interface, which is regarded as a single interface.

```

PIM state synchronization is data-driven, so the PIM states are not stored in a database. Therefore, the ESs must be configured as **non-revertive** to avoid reverting back to the preferred PE while this PE is unaware of the PIM states.

PIM Snooping with Multi-chassis Synchronization

Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later. The ES must be configured as non-revertive, so that after a failover, the new DF remains the DF even when the original DF is operational again. When data-driven PIM state synchronization cannot be used, for example, when the service carving is configured in auto mode, or when the SR OS Release is an earlier release of 15.0, Multi-chassis synchronization (MCS) can be configured for a faster failover. MCS of the PIM snooping state on SAPs and spoke-SDPs is supported between an active and a standby PE and the PIM states are stored in a synchronization database. This can be configured in case of single-active multi-homing (MH), for example on PE-2 for peer PE-4, with PIM snooping on spoke-SDPs, as follows:

```
On PE-2:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 26 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                            }
                        }
                    }
                }
            }
        }
    }
}
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.2 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 46 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
        }
    }
}
```

When H-8 joins the multicast group, the following entries are in the MCS synchronization database of the PEs. The MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
[/]
A:admin@PE-2# tools dump redundancy multi-chassis sync-database detail

If no entries are present for an application, no detail will be displayed.

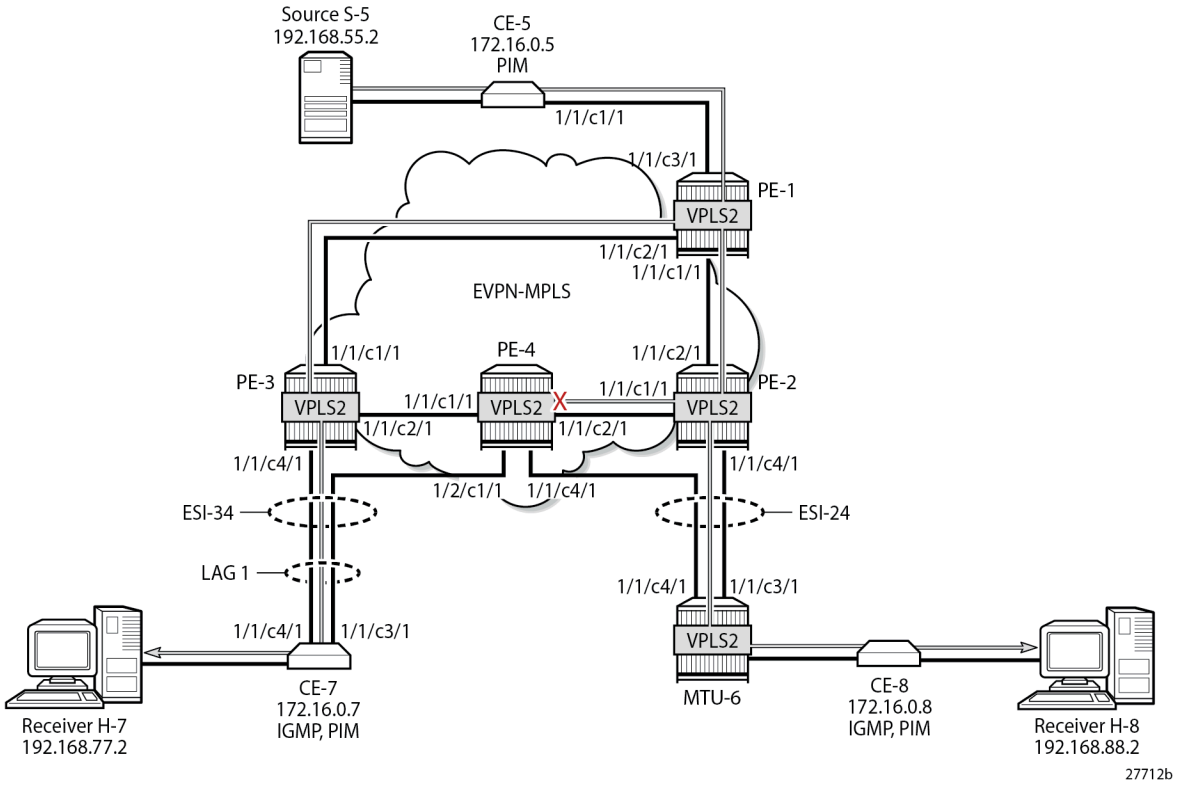
Failover

Figure 252: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined shows the multicast traffic flow in the case where both receivers H-7 and H-8 joined multicast group 232.1.1.1 from source 192.168.55.2 and no failures have occurred. For SR OS Release 15.0.R4, and later, MCS need not be configured for faster failover in single-active MH when the ES is non-revertive.

Figure 252: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined



NDF PE-4 has an MFIB table with the required information for a fast failover, as follows:

```
[/]
A:admin@PE-4# show service id 2 mfib

===============================================================================

```

The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. On MTU-6, SDP 62 is disabled, as follows:

```
configure {
    service {
        sdp 62 {
            admin-state disable
        }
    }
}
```

On CE-7, port 1/1/c4/1 toward PE-3 is disabled, as follows:

```
configure {
    port 1/1/c4/1 {
        admin-state disable
    }
}
```

Log 99 on PE-3 shows that the DF state in ESI-34_2 changed to false:

```
172 2023/08/10 23:18:51.662 CEST MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-34_2, EVI:2, Designated Forwarding state changed to:false"
```

PE-4 becomes the DF for both ESs, as follows:

```

```

PE-4 receives the multicast traffic on port 1/1/c2/1 and forwards it on port 1/1/c4/1 toward MTU-6, and on port 1/2/c1/1 to CE-7, as follows:

```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. CE-7 forwards the traffic to H-7. PE-3 drops the multicast traffic because LAG-1 is down because of the failure that was introduced at CE-7 (port disabled).

Conclusion

PIM snooping in EVPN-MPLS services results in a more efficient use of network resources because multicast traffic no longer needs to be flooded. PIM snooping can be used in EVPN-MPLS services with all-active and single-active multi-homing with data-driven PIM state synchronization. Alternatively, MCS synchronization of the PIM snooping state on SAPs and spoke-SDPs is supported with single-active MH.

PIM Snooping for IPv4 in PBB-EVPN Services

This chapter describes PIM Snooping for IPv4 in PBB-EVPN Services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. Protocol Independent Multicast (PIM) snooping for IPv4 is supported in Provider Backbone Bridging - Ethernet Virtual Private Network (PBB-EVPN) services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing (MH) mode without Ethernet Segment Identifier (ESI) label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active MH mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping for IPv4 in all-active MH mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

PBB-EVPN services have EVPN-MPLS enabled in the B-VPLS. PIM snooping in PBB-EVPN I-VPLS provides the following:

- PIM snooping in SAPs and SDP-bindings: PIM messages received from SAPs, SDP-bindings, or the B-VPLS are forwarded to SAPs or SDP-bindings according to the PIM snooping.
- Multicast flooding between I-VPLS and B-VPLS is the same for a PBB-EVPN B-VPLS as for a B-VPLS without EVPN. The first PIM join message received over the local B-VPLS from a B-VPLS SAP/SDP-binding or EVPN endpoint results in adding the B-VPLS SAP/SDP-binding or EVPN interface into the Multicast Forwarding Information Base (MFIB) associated with the I-VPLS context. Multicast traffic is flooded throughout the B-VPLS on a per-ISID single tree.
- When the PIM router is connected to a remote I-VPLS instance over the B-VPLS infrastructure, its location is identified by the B-VPLS SAP/SDP-binding or by the set of all EVPN endpoints on which PIM hellos are received. The location is also identified by the source BMAC address in the PBB header for the PIM hello message, which is the BMAC address associated with the B-VPLS instance on the remote PBB PE.
- The set of all EVPN endpoints in the B-VPLS is treated as a single PIM interface.
  - Hello and join/prune messages from I-VPLS SAPs/SDP-bindings are always sent to all B-VPLS PBB-EVPN destinations.
  - When a hello message is received from one B-VPLS PBB-EVPN destination PIM neighbor, the single interface representing all B-VPLS PBB-EVPN destinations will have that PIM neighbor.
  - All individual B-VPLS PBB-EVPN destinations appear in the MFIB, but the information for each B-VPLS PBB-EVPN destination entry is identical.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - The EVPN split-horizon logic ensures that IP multicast traffic and PIM messages received on a PBB-EVPN endpoint are not forwarded back to other PBB-EVPN endpoints.

- When a point-to-multipoint (P2MP) mLDP provider tunnel is configured in the B-VPLS, the provider tunnel only works for the default multicast list. Ingress Replication (IR) is used for the per-ISID MFIB trees. ISID policies can be configured to specify ISID ranges that will use the default multicast list. ISID policies can help reduce the per-ISID MFIB resources used.
- PIM snooping for IPv4 within a PBB-EVPN I-VPLS is supported with single-active MH and with all-active MH in the associated I-VPLS.
- Data-driven PIM state synchronization between remote peers in an all-active MH Ethernet Segment (ES) is supported.
- Multi-Chassis Synchronization (MCS) of PIM snooping state on SAPs and spoke-SDPs is supported in active/standby scenarios.

The following command enables PIM snooping in an I-VPLS:

```
configure {
    service {
        vpls "I-VPLS 1" {
            pim-snooping { }
        }
```

The default PIM snooping mode is proxy mode, which implies that the PE will terminate the PIM join/prune messages and generate its own PIM join/prune messages with the same (S,G). The advantage is that the number of PIM messages to be sent can be reduced: regardless of the number of PIM join messages received for a certain (S,G), the node only needs to send one PIM join message toward the source. PIM snooping can also use snooping mode based on the information in the received PIM hello messages; in snooping mode, the PE does not modify the PIM messages.

Configuration

Figure 254: Example Topology for PBB-EVPN without MH shows the example topology with source S-5 and receivers H-6, H-7, and H-8 attached to CEs that are connected to PEs. On the PEs, B-VPLS 100 is configured and I-VPLS 1 is associated with it. B-VPLS 100 has EVPN-MPLS enabled. An mLDP P2MP provider tunnel is used to distribute multicast traffic from PE-1 to the other PEs.

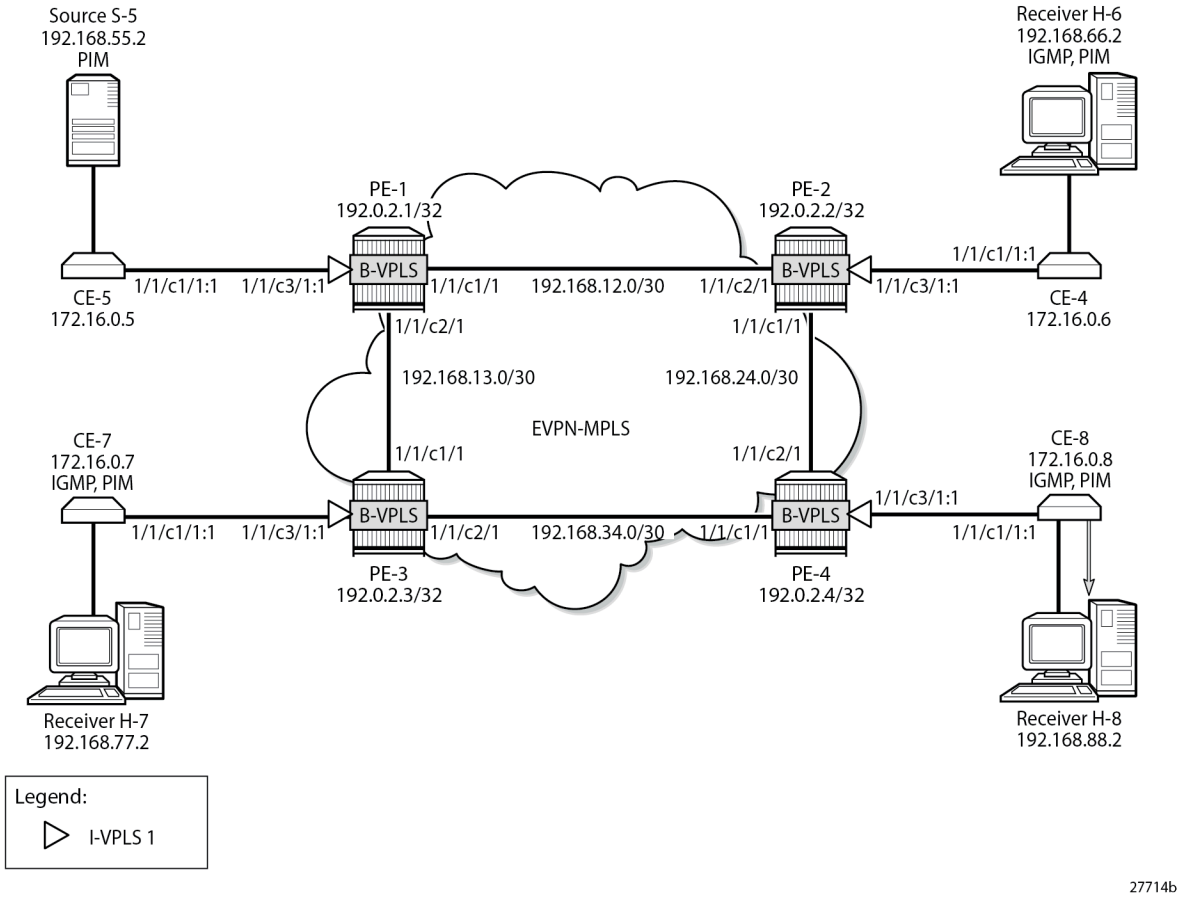
Figure 254: Example Topology for PBB-EVPN without MH



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on the PEs (alternatively, OSPF can be used)
- LDP enabled on the PEs

BGP is configured on the PEs with address family EVPN, and PE-2 is configured as route reflector (RR). The BGP configuration on PE-2 is as follows:

```
On PE-2:
configure {
    router "Base" {
        bgp {
            rapid-withdrawal true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "INTERNAL" {
                type internal
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.1" {
                group "INTERNAL"
            }
            neighbor "192.0.2.3" {
                group "INTERNAL"
            }
            neighbor "192.0.2.4" {
                group "INTERNAL"
            }
        }
```

PBB-EVPN without MH – No PIM Snooping

B-VPLS 100 is configured with EVPN-MPLS enabled on all PEs. Multicast LDP is configured in B-VPLS 100 with PE-1 as the P2MP tunnel root node (**root-and-leaf**) and the other PEs as leaf nodes (**no root-and-leaf** is default). An (optional) ISID policy defines that the default multicast tree -which is used by the P2MP mLDP tunnel- is used for ISIDs 1 and 2 (range 1 to 2). The configuration of B-VPLS 100 on PE-1 is as follows:

```
On PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            description "B-VPLS 100"
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                    use-es-bmac-lsb true
                }
            }
            bgp 1 { }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    split-horizon-group "CORE"
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            split-horizon-group "CORE" { }
            provider-tunnel {
                inclusive {
                    admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
            isid-policy {
                entry 1 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 1
                        end 2
                    }
                }
            }
        }
```

The configuration of B-VPLS on the other PEs is similar, but without the root-and-leaf option.

In B-VPLS 100 on root node PE-1, the following mLDP provider tunnel is created with Provider Multicast Service Interface (PMSI) owner bgpEvpnMpls. PE-1 is configured as root-and-leaf node.

```
[/]
A:admin@PE-1# show service id 100 provider-tunnel

```

When the B-VPLS is created, I-VPLS 1 can be associated with it, as follows:

```
On PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            sap 1/1/c3/1:1 { }
        }
}
```

The configuration of I-VPLS 1 on the other PEs is identical.

© 2023 Nokia.

CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. Source-specific multicast is used in this example. The configuration on CE-8 is as follows:

```
On CE-8:
configure {
    router "Base" {
        interface "int-CE-8-PE-4" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.8
                    prefix-length 16
                }
            }
        }
        interface "int-CE-8-H-8" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.88.1
                    prefix-length 24
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.8
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.55.0/30 route-type unicast {
                next-hop "172.16.0.5" {
                    admin-state enable
                }
            }
        }
        igmp {
            interface "int-CE-8-H-8" { }
        }
        pim
            apply-to all
        }
    }
```

The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure {
    router "Base" {
        interface "int-CE-5-PE-1" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.5
                    prefix-length 16
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        interface "int-CE-5-S-5" {
            port 1/1/c3/1
            ipv4 {
                primary {
                    address 192.168.55.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.5
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.66.0/24 route-type unicast {
                next-hop "172.16.0.6" {
                    admin-state enable
                }
            }
            route 192.168.77.0/24 route-type unicast {
                next-hop "172.16.0.7" {
                    admin-state enable
                }
            }
            route 192.168.88.0/24 route-type unicast {
                next-hop "172.16.0.8" {
                    admin-state enable
                }
            }
        }
        pim {
            apply-to all
        }
    }
```

When receiver H-8 sends an IGMP report to join multicast group (S,G), CE-8 sends a PIM join message to CE-5. This PIM join message is flooded by the PEs. When CE-5 receives the PIM join message, it forwards the multicast stream to receiver H-8. PIM snooping is disabled by default and the MFIB on each of the PEs remains empty, so the multicast stream is not only sent to CE-8, but also to CE-6 and CE-7. CE-6 and CE-7 drop this stream when no receiver is active, while CE-8 forwards the multicast stream to receiver H-8, as shown in Figure 255: Multicast Stream to Receiver H-8 with PIM Snooping Disabled.

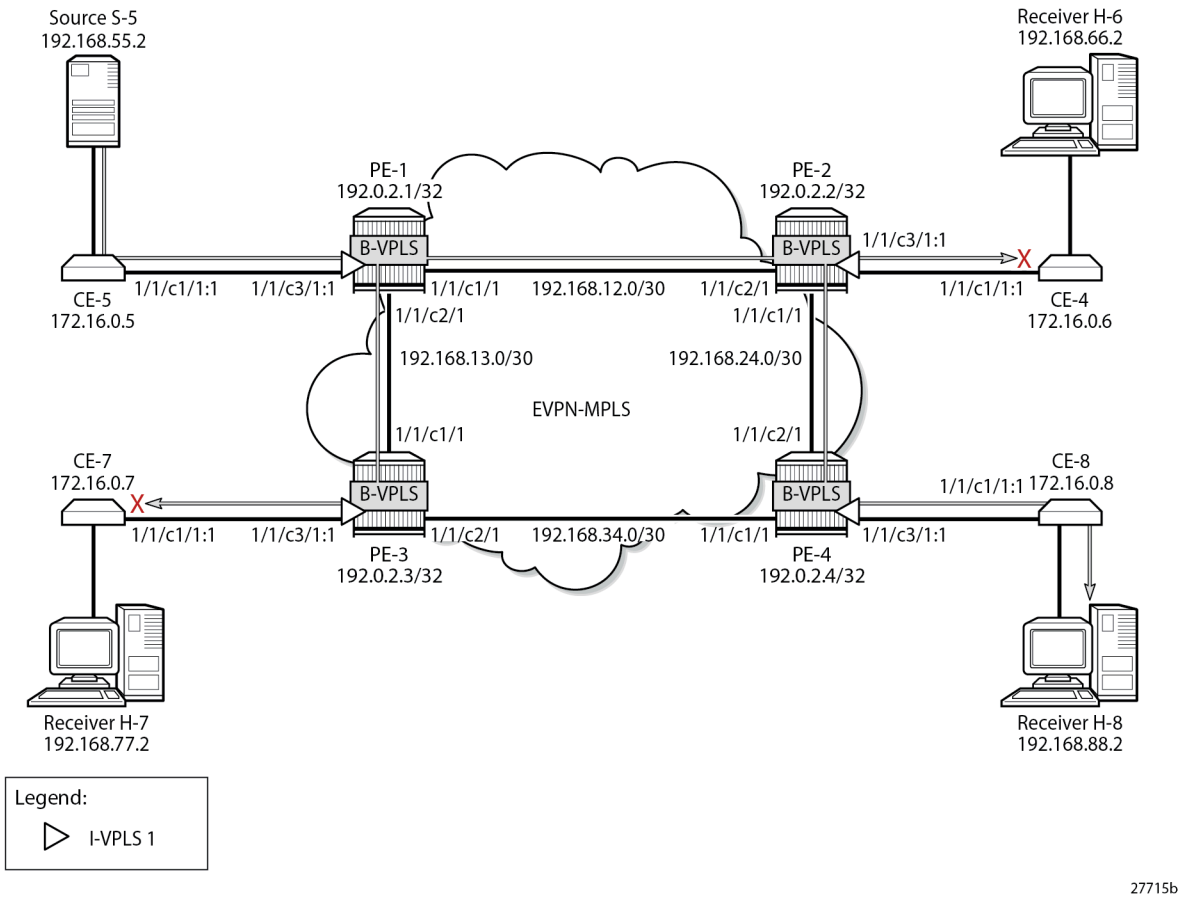
Figure 255: Multicast Stream to Receiver H-8 with PIM Snooping Disabled



PBB-EVPN without MH – PIM Snooping for IPv4 Enabled

PIM snooping for IPv4 is enabled in I-VPLS 1 on all PEs as follows:

```
On all PEs:
configure {
    service {
        vpls "I-VPLS 1" {
            pim-snooping { }
        }
```

When PIM snooping for IPv4 is enabled, the PEs only forward the multicast traffic to those CEs that have sent PIM join messages for that multicast group. This implies that PE-2 and PE-3 do not forward traffic to the CEs; only PE-4 forwards traffic toward CE-8 and CE-8 forwards to receiver H-8, as shown in Figure 256: Multicast Stream to Receiver H-8 with PIM Snooping Enabled.

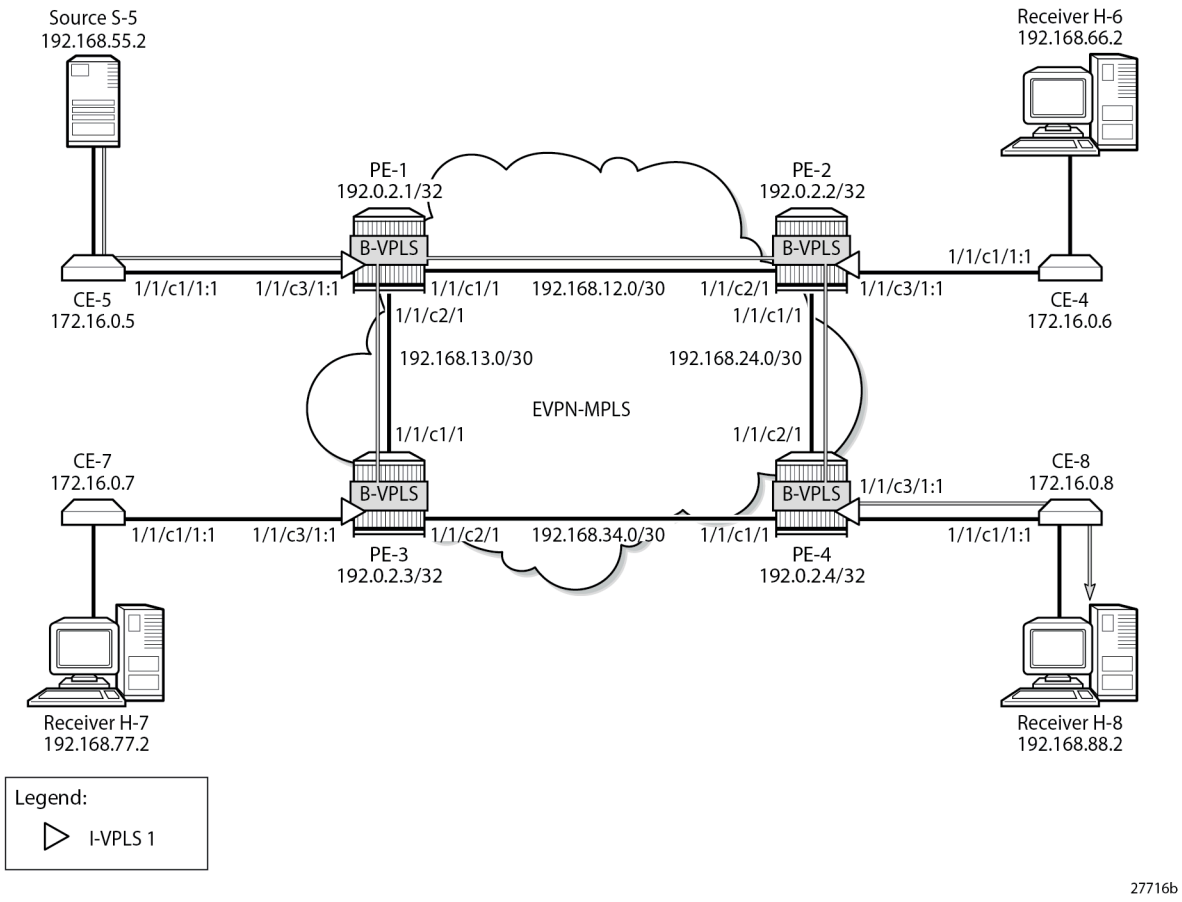
Figure 256: Multicast Stream to Receiver H-8 with PIM Snooping Enabled



When PIM snooping for IPv4 is enabled, PE-1 has the following two PIM snooping ports: the SAP toward the source and the backbone b-EVPN-MPLS interface, which is treated as one entity for all PBB-EVPN destinations.

```
[/]

With PIM snooping for IPv4 enabled, and after receiving a PIM join message for multicast (192.168.55.2, 232.1.1.1), the MFIB on PE-1 has an entry for group address 232.1.1.1 and source address 192.168.55.2, as follows. The local SAP connects to CE-5; the other port IDs correspond to the b-EVPN-MPLS interface.

```

The following shows that PE-2 receives the multicast packets on port 1/1/c2/1 and forwards them to PE-4 on port 1/1/c1/1. With PIM snooping for IPv4 enabled, PE-2 does not forward the traffic to CE-6 on port 1/1/c3/1 because no PIM join message was received from CE-6. Besides the multicast traffic, some signaling

The following PIM snooping group with group address 232.1.1.1 and source address 192.168.55.2 is shown on PE-1. The incoming interface is the SAP toward CE-5 and the outgoing interface is the b-EVPN-MPLS interface. A single b-EVPN-MPLS interface is shown in the outgoing interface list, regardless of the B-VPLS PBB-EVPN destination. The split-horizon mechanism ensures that all traffic from the incoming interface SAP 1/1/c3/1:1 is only forwarded on the b-EVPN-MPLS interface, not sent back on the SAP.

```

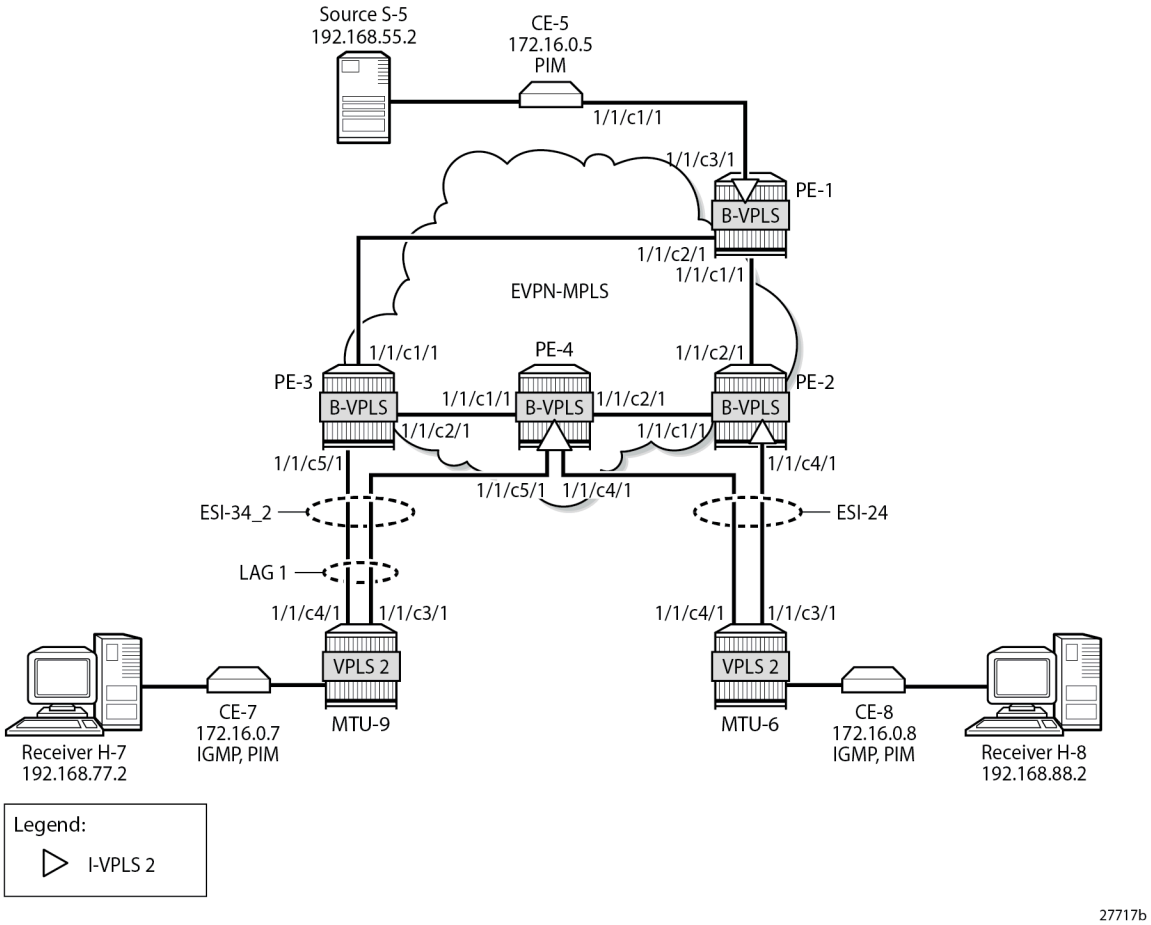
PBB-EVPN with MH – No PIM Snooping

Figure 257: Example Topology for PBB-EVPN with MH shows the example topology with CE-7 attached to MTU-9, which is connected to both PE-3 and PE-4 via LAG lag-1. Virtual ES (vES) ESI-34_2 is configured in all-active MH mode using lag-1 for dot1q value 2. MTU-6 is connected to PE-2 and PE-4 with SDPs. These SDPs are associated with a single-active MH ES ESI-24.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 257: Example Topology for PBB-EVPN with MH



The configuration of I-VPLS 2 is similar to the preceding configuration of I-VPLS 1 on all PEs.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active MH ES ESI-24, that is non-restrictive -after failover, it does not restore to the initial designated forwarder (DF) if available again; see chapter Preference-based and Non-revertive EVPN DF Election. The manually configured preference is 200 on PE-2, which is higher than preference 50 at PE-3, so PE-2 is the DF when no failover has occurred. Spoke-SDP 26:2 is associated with I-VPLS 2. The B-VPLS 100 remains unchanged and is not repeated here.

```
On PE-2:
configure {
    service {
        sdp 26 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 200
                                }
                            }
                        }
                        association {
                            sdp 26 { }
                        }
                        pbb {
                            source-bmac-lsb 0x2402
                        }
                    }
                }
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            spoke-sdp 26:2 { }
        }
        vpls "B-VPLS 100" {
            pbb {
                source-bmac {
                    use-es-bmac-lsb true
                }
            }
        }
    }
```

On PE-4, lag-1 is configured in access mode with dot1q encapsulation on the port to MTU-9, as follows. The LAG configuration is similar on PE-3.

```
On PE-4:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        lacp {
            mode active
            system-id 00:00:00:00:01:34
            administrative-key 1
        }
        port 1/1/c5/1 { }
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Single-active ES ESI-24 is configured on PE-4, together with a virtual ES ESI-34_2, which is an all-active MH virtual ES that applies to lag-1 for I-VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 50 (which is lower than preference 200 on the remote peer in the ES). I-VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure {
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 50
                                }

            }
        }
    }
```

On PE-4, the source BMAC in the all-active MH ESI-34_2 is identical to the source BMAC on remote peer PE-3, but in the single-active MH ESI-24, the source BMAC must be different. Remote PEs might send traffic to the NDF PE based on the shared source BMAC, which is fine for all-active MH ESs, but not for single-active MH ESs.

The following service configuration on PE-3 includes an all-active virtual ES ESI-34_2 with preference 200, which makes PE-3 the DF for ESI-34_2 when no failover has occurred. After failover, PE-4 becomes DF, and it does not revert to PE-3 when available.

```
On PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-34_2" {
                        admin-state enable
                        type virtual
                        esi 0x01000000003402000001
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 200
                                }
                            }

                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 64:2 {
                endpoint {
                    name "x"
                }
                stp {
                    admin-state disable
                }
            }
            sap 1/2/c1/1:2 { }
        }
    }
```

The following is the LAG configuration on MTU-9:

```
On MTU-9:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        lacp {
            mode active
            administrative-key 32768
        }
        port 1/1/c3/1 { }
        port 1/1/c4/1 { }
    }
```

The configuration of VPLS 2 on MTU-9 is as follows:

```
On MTU-9:
configure {
    service {
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap 1/1/c1/1:2 { }
            sap lag-1:2 { }
        }
```

For I-VPLS 2, PE-2 is the DF in ES ESI-24, as follows:

```
[/]
A:admin@PE-2# show service id 2 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information

```

When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tunnel to all EVPN-MPLS destinations: PE-2, PE-3, and PE-4. PE-2 is the DF for ESI-24 and forwards the traffic to MTU-6, which forwards it to CE-8, where it is sent to the attached receiver H-8 that joined the multicast group. PE-3 is the DF for ESI-34_2 and sends the multicast stream to MTU-9, which forwards it to CE-7, where it is dropped because no attached receiver has joined the multicast group. PE-4 is the NDF for both ESs, so it does not forward the traffic to MTU-6 or MTU-9. Figure 258: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

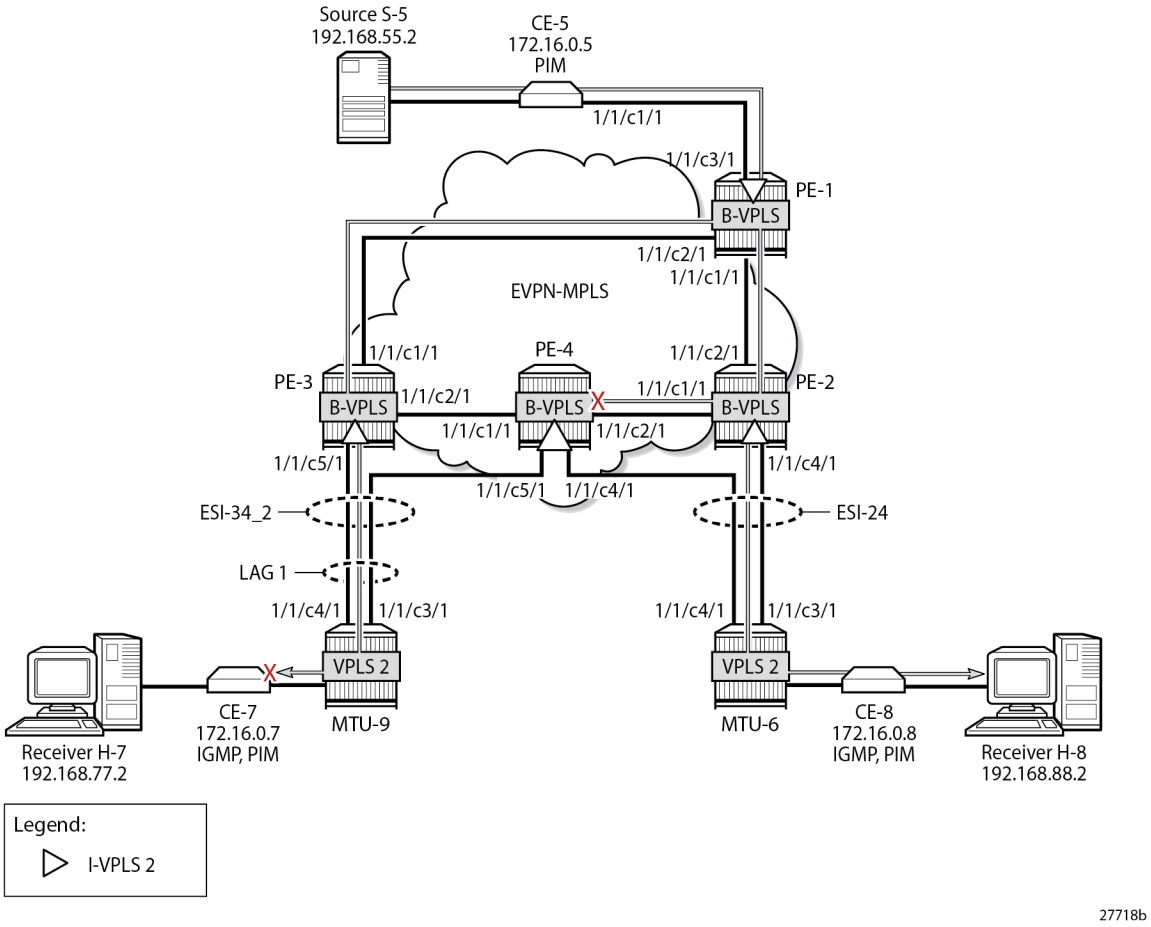
Figure 258: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 Enabled

PIM snooping for IPv4 is enabled in I-VPLS 2 on all PEs with the following command:

```
On all PEs:
configure {
    service {
        vpls "I-VPLS 2" {
            pim-snooping { }
        }
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
[/]
A:admin@PE-1# show service id 2 pim-snooping neighbor

===============================================================================
PIM Snooping Neighbors ipv4
===============================================================================

```

When H-7 and H-8 join the group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2 with four port IDs: the local SAP to CE-5 and the B-VPLS PBB-EVPN destinations, as follows:

```
[/]
A:admin@PE-1# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------

===============================================================================
```

Furthermore, data-driven PIM state synchronization between PEs in an all-active MH ES allows the NDF PE-4 to build its MFIB, even when the NDF does not forward multicast traffic to the receivers. When the NDF has the MFIB information, the failover is faster and the loss of traffic is limited. For data-driven PIM state synchronization, the source BMAC must be identical within the ES, so it only works for all-active MH in PBB-EVPN, not for single-active MH. The MFIB on PE-4 contains the SAP from the all-active MH ESI-34_2, but not the spoke-SDP from the single-active MH ESI-24, as follows:

```
[/]
A:admin@PE-4# show service id 2 mfib

In case of all-active MH ES ESI-34_2, one of the PE -DF or NDF- in the ES forwards the PIM states to its remote peer and therefore, PE-4 has the same PIM snooping group information as PE-3, as follows:

```

With the PIM snooping group information available on the NDF, the traffic loss is limited when the NDF PE-4 becomes the DF after failover. Data-driven PIM state synchronization does not store PIM states in a database, so the DF election in the ES should be configured as non-revertive, to prevent that when the preferred DF is restored after a failover, the system would revert to a DF that is unaware of the PIM state.

PE-4 is also NDF in the single-active MH ES ESI-24, but it received no PIM state synchronization information from DF PE-2. Data-driven PIM state synchronization is not supported for single-active MH in PBB-EVPN services, because it is not allowed to have two PEs in a single-active MH ES using the same source BMAC, with the potential risk of traffic sent by remote PEs to the NDF PE (based on it sending to the shared source BMAC) being dropped. However, for a faster failover in single-active MH, multi-chassis synchronization (MCS) can be configured, as described in the next section.

Figure 259: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined shows the multicast traffic flow when PIM snooping is enabled and both receivers H-7 and H-8 have joined the multicast group. All PEs receive the multicast traffic on the P2MP tunnel, but only DF PE-2 and DF PE-3 forward the multicast traffic to the MTUs, which forward the traffic to the CEs, where it is forwarded to the receivers.

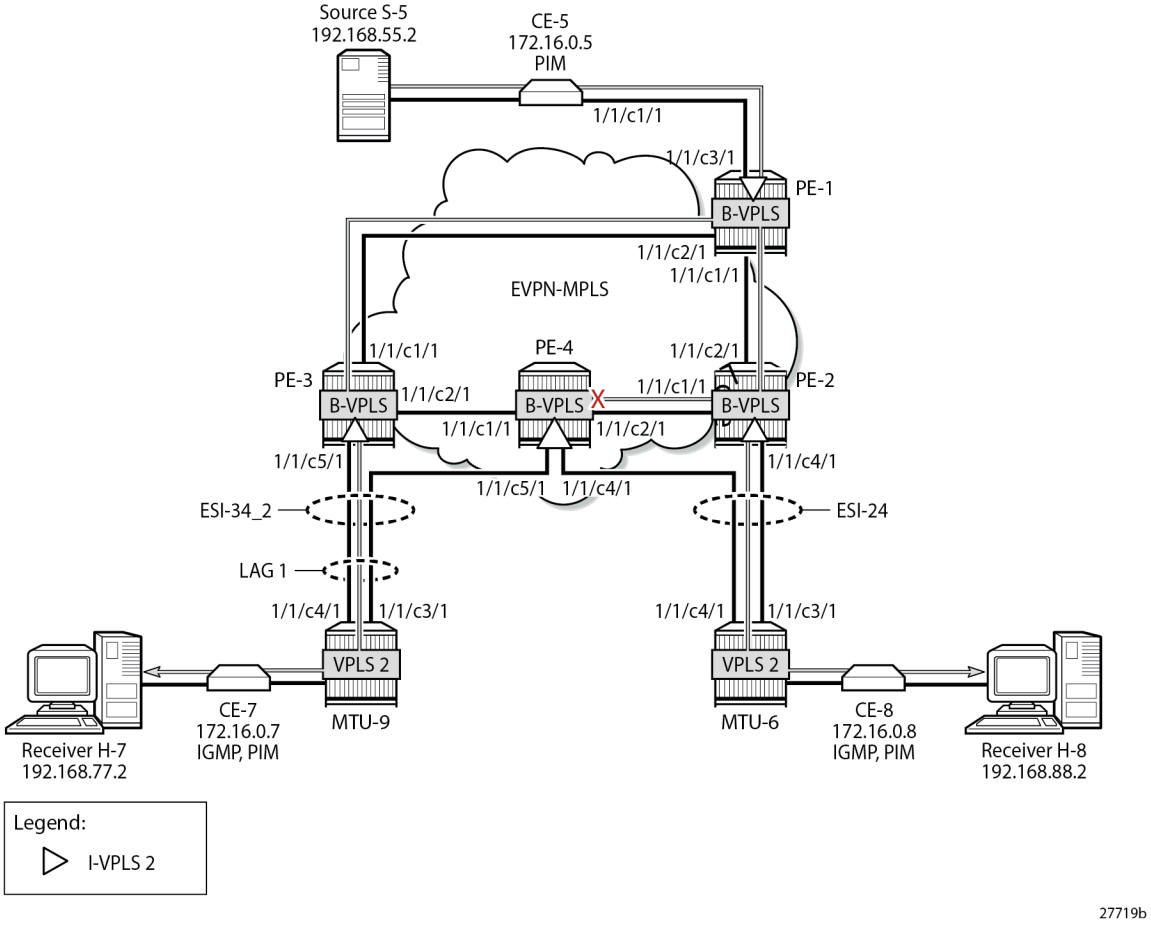
Figure 259: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 with MCS

MCS of the IPv4 PIM snooping state for SAPs and spoke-SDPs can optionally be configured in the case of MH. MCS reduces the failover time when data-driven PIM state synchronization is not supported; for example, for single-active MH in PBB-EVPN services. The synchronization information is stored in an MCS synchronization DB. MCS is configured on PE-2, identifying the peer (PE-4), with PIM snooping for spoke-SDPs as MCS client application and the list of spoke-SDPs, as follows:

```
On PE-2:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        sdp 26 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure exclusive
    redundancy {
        multi-chassis {
            peer 192.0.2.2 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 46 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
```

When H-8 has joined the multicast group, the MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
[/]
A:admin@PE-2# tools dump redundancy multi-chassis sync-database detail

If no entries are present for an application, no detail will be displayed.

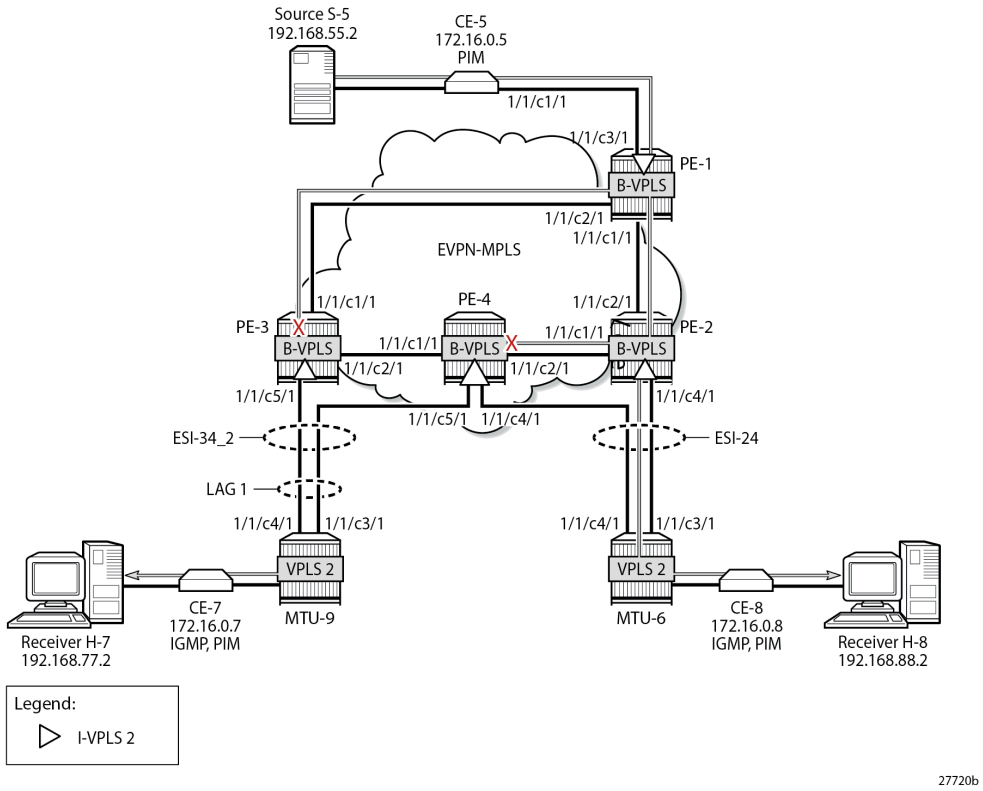
Figure 260: PBB-EVPN with MH and PIM Snooping – Receiver H-8 Joined



Failover

Figure 259: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined showed the multicast traffic flow when both H-7 and H-8 have joined the multicast group. PE-2 is the DF for ESI-24 and PE-4 is the DF for ESI-34_2. The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. Data-driven PIM state synchronization is used for all-active MH; MCS is configured for fast failover in the single-active MH ES ESI-24.

On MTU-6, SDP 62 is disabled, as follows:

```
On MTU-6:
configure {
    service {
        sdp 62 {
            admin-state disable
        }
```

On MTU-9, port 1/1/c3/1 toward PE-3 is disabled, as follows:

```
On MTU-9:
configure {
    port 1/1/c3/1 {
        admin-state disable
    }
```

```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. MTU-9 forwards the traffic to CE-7, which sends it to H-7. PE-3 drops the multicast traffic because lag-1 is down because of the failure that was introduced at MTU-9 (port disabled).

Conclusion

PIM snooping reduces flooding of multicast traffic in L2 services and can be used in PBB-EVPN I-VPLSs in the same way as in I-VPLSs using B-VPLS without EVPN. PIM snooping can be used in all-active and single-active MH scenarios with data-driven state synchronization and MCS, respectively.

Preference-based and Non-revertive EVPN DF Election

This chapter provides information about Preference-based and Non-revertive EVPN DF Election.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R3, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2. Preference-based and non-revertive EVPN Designated Forwarder (DF) election is supported in SR OS Release 15.0.R1, and later. This mechanism works for Ethernet Segments (ESs) and virtual ESs (vESs).

Overview

RFC 7432 defines the Designated Forwarder (DF) in (PBB-)EVPN networks as the PE that will forward the following packets to a multi-homed node:

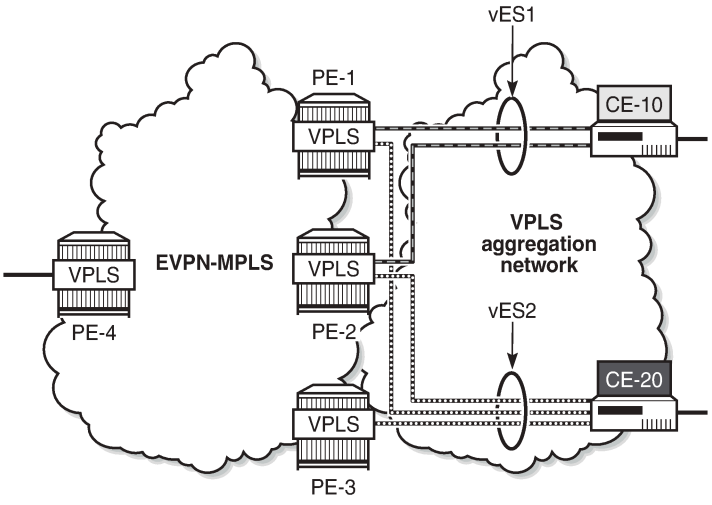
- Broadcast, Unknown unicast, and Multicast (BUM) traffic in an all-active multi-homing Ethernet Segment (ES)
- BUM and unicast in a single-active multi-homing ES

For more information about vESs, see chapter Virtual Ethernet Segments.

Figure 262: Virtual Ethernet Segments shows a topology with two vESs.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 262: Virtual Ethernet Segments

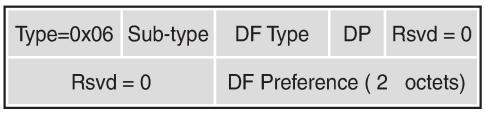


Taking the Ethernet VPN Identifier (EVI) or ISID and the number of PEs in the ES as input, the RFC 7432 service-carving algorithm elects the DF from the list of candidate PEs that advertise the ES identifier (ESI). While this algorithm provides an automated and fair DF distribution across services in the ES, it does not allow the operator to control what PE is the DF for which service. In addition, in case of a DF failure, when the former DF comes back up, a new DF switchover will cause unnecessary packet loss (this mode of operation is called revertive). SR OS implements *draft-ietf-bess-evpn-pref-df* to give more control to the operator on the DF election and avoid the revertive mode.

In SR OS, in addition to the automated service-carving, the DF election can also be controlled by configuring a preference manually. Also, it is possible to force an on-demand DF switchover without reconfiguring the PEs in the ES. Furthermore, the non-revertive option prevents an automatic switchover when a new active PE can preempt the existing DF PE. The non-revertive option avoids service impact when an ES comes back up.

Figure 263: BGP-EVPN extended community for DF election shows the BGP-EVPN extended community defined for DF election and the different values described in draft-ietf-bess-evpn-pref-df.

Figure 263: BGP-EVPN extended community for DF election



Type=0x06	Sub-type	DF Type	DP	Rsvd = 0
Rsvd = 0		DF Preference (2 octets)		

DP = Do not preempt (non-revertive)
DF = Designated forwarder
- Type 0 – Default, modulo-based DF election (RFC7432)
- Type 1 – Highest Random Weight (HRW) algorithm
- Type 2 – Preference algorithm

26787

The "Do not preempt" (DP) bit is set to enable the non-revertive option. When preference-based service carving is configured in the ES, DF type 2 is advertised along with a 2-byte preference value, which is 32767 by default.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Service carving can be configured in auto mode or manual mode. The preference can only be configured in manual mode.

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election]
A:admin@PE-2# service-carving-mode ?

 service-carving-mode <keyword>
 <keyword>  - (auto|manual|off)
 Default    - auto

    Mode of service carving enabled per EVPN associated with this Ethernet segment entry
```

When manual mode is enabled, the following parameters can be configured to control which PE will be elected as DF:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election]
A:admin@PE-2# manual ?

 manual

 evi                   + Enter the evi list instance
 isid                  + Enter the isid list instance
 preference            + Enable the preference context
```

The EVI and ISID ranges configured in the service-carving context do not need to be consistent with any ranges configured for virtual ESs.

When preference is configured manually, the mode can be configured as revertive (default) or non-revertive:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election manual
 preference]
A:admin@PE-2# mode ?

 mode <keyword>
 <keyword>  - (revertive|non-revertive)
 Default    - revertive

 'mode' is: immutable

    Method used to elect the DF

    Warning: Modifying this element recreates 'configure service system bgp evpn
    ethernet-segment "vESI-23_1" df-election manual preference' automatically for the
    new value to take effect.
```

The preference-based EVPN DF election is as follows:

- By default, all SAPs and spoke-SDPs on the configured ES select the highest-preference PE as DF; however, when the EVI or ISID ranges are configured in the ES, the lowest-preference PE is selected.
- When the preference is equal, the DP bit is the tiebreaker: DP=1 wins over DP=0.
- For equal preference and DP, the PE IP address is the tiebreaker: the lowest IP address wins.

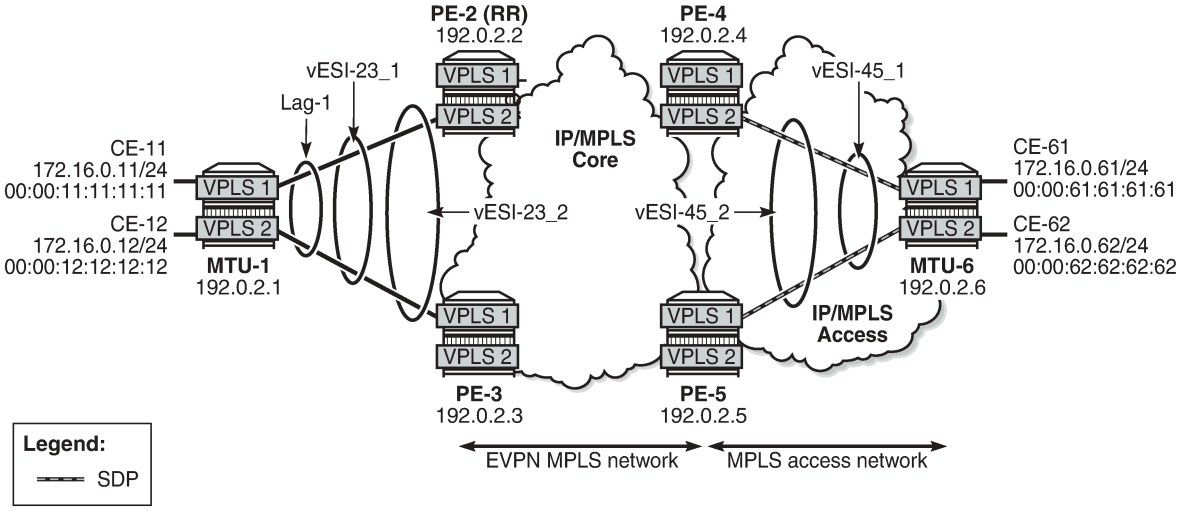
Configuration

Figure 264: Example topology with all-active and single-active vESs shows the example topology with six nodes. EVPN-MPLS is configured between the core PE nodes. All-active vESs are configured between PE-2 and PE-3 and single-active vESs are configured between PE-4 and PE-5.

Figure 264: Example topology with all-active and single-active vESs



The initial configuration includes:

- Cards, MDAs, ports
- LAG 1 between MTU-1, PE-2, PE-3
- Router interfaces
- IS-IS (alternatively, OSPF could be used)
- LDP

BGP is configured on the four core PEs with PE-2 as Route Reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
```

© 2023 Nokia.

```
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

VPLS 1 and VPLS 2 are configured on each node. The PEs have EVPN-MPLS enabled. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:1.1 {
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:2.1 {
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The configuration on the other PEs is similar; PE-4 and PE-5 have a spoke-SDP configured instead of a SAP. For an explanation of the configuration, see chapter EVPN for MPLS Tunnels.

Service carving: auto mode

On PE-2 and PE-3, the following all-active multi-homing vESs are configured:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:01:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode auto
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 1 {
                                            end 1
                                        }
                                    }
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_2" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:02:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode auto
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 2 {
                                            end 2
                                        }
                                    }
                                }
                            }
                        }
                    }
```

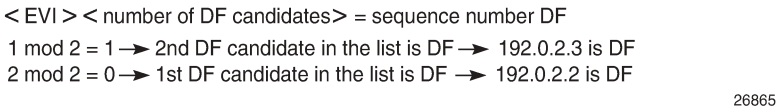
The service carving mode is set to **auto**, so the DF election is based on a modulo function of the EVI and the number of DF candidates. In the vES "vESI-23_1", there are two DF candidates, PE-2 and PE-3, listed in that order because PE-2 has the lower system IP address, as follows:

```
[/]
A:admin@PE-3# show service system bgp-evpn ethernet-segment name "vESI-23_1" all
                                          | match "EVI Information" post-lines 19
EVI Information
===============================================================================
EVI                 SvcId               Actv Timer Rem      DF
-------------------------------------------------------------------------------
1                   1                   0                   yes
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
-------------------------------------------------------------------------------
DF Candidate list
-------------------------------------------------------------------------------
EVI                                     DF Address
-------------------------------------------------------------------------------
1                                       192.0.2.2
1                                       192.0.2.3
-------------------------------------------------------------------------------
Number of entries: 2
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
===============================================================================
```

The first DF candidate from the list will be selected when the result of the modulo function equals 0; the second DF candidate when the result equals 1. The calculation is as follows:



The following shows that PE-2 is not the DF for VPLS 1, but it is the DF for VPLS 2:

```
[/]
A:admin@PE-2# show service id 1 ethernet-segment

```

Instead of the preceding show commands, the following tools commands can be used:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_1"  evi 1 df

[04/26/2021 09:19:25] Computed DF: 192.0.2.3 (Remote) (Boot Timer Expired: Yes)

[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_2"  evi 2 df

[04/26/2021 09:19:25] Computed DF: 192.0.2.2 (This Node) (Boot Timer Expired: Yes)
```

Service carving: preference-based manual mode

To have more control, the vES can be configured in manual mode. The following reconfigures the vES "vESI-23_1" in manual mode, preference-based and revertive with preference value 32767 (default) on PE-2 and 5000 on PE-3, whereas vES "vESI-23_2" is preference-based and non-revertive with preference value 15000 on PE-2 and 20000 on PE-3.

An EVI range is configured for ES "vESI-23_2", but not for ES "vESI-23_1". When no EVI range is configured, the highest preference wins; for configured EVI ranges, the lowest preference wins. When there are no failures, PE-2 will be the DF for "vESI-23_1" (highest preference) and for "vESI-23_2" (lowest preference for configured EVI 2).

On PE-2, the ESs are reconfigured as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_2" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 15000
                                }
                            }
                        }
                    }
```

```
                }
```

The **non-revertive** mode is configured for vES "vESI-23_2", but not for vES "vESI-23_1".

On PE-3, the ES configuration is modified as follows:

```
# on PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 5000
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_2" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 20000
                                }
                            }
                        }
                    }
                }
```

For the single-active multi-homing vESs on PE-4 and PE-5, the same preferences are configured manually. The ES configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:01:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                }
                            }
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
```

                        }
                    }
```

The preference configuration must be consistent across the PEs in the ES (manual or auto), otherwise the system reverts to the modulo-based DF election.

With preference-based DF election configured with default preference value 32767 and revertive, PE-4 sends the following BGP-EVPN update to the RR PE-2. The **df-election** extended community shows the DP=0 (revertive) and DF preference 32767.

```
# on PE-4:

It is important to note that a router will prune a remote PE from the DF candidate list for an ES if it does not receive the corresponding Auto Discovery (AD) per-EVI and AD per-ES routes for that PE. A remote PE will not be shown in the DF Candidate list if its AD per-ES route is withdrawn. This is only true for EVPN. In PBB-EVPN, there are no AD routes, therefore the DF Candidate list is built out of the ES routes only.

DF election: higher preference prevails for non-configured EVI ranges

The PEs run the DF election per PE per EVI, and the elected DF for a service will activate the SAP/Spoke-SDP when the es-activation-timer expires. PE-4 is the DF in "vESI-45_1" used in VPLS 1, as follows. The EVI is not configured in ES "vESI-45_1", so the higher preference prevails. The ES "vESI-45_1" has (default) preference 32767 on PE-4 (DF) and preference 5000 on PE-5 (Non-Designated Forwarder (NDF)).

```

The preference value can be modified on the fly on an active ES. This allows the user to force a new DF for the ES for maintenance operations on the former DF or other reasons.

DF election: lowest preference prevails for configured EVI ranges

ES "vESI-45_2" is configured with EVI 2, so the lowest preference prevails. The admin preference value is 15000 on PE-4 and 20000 on PE-5. Both PE-4 and PE-5 are DF candidates, but PE-4 has the lowest preference, so it will be the DF, as follows:

```

DF election: DP prevails when preferences are equal

The service carving in the ES is configured with default preference and non-revertive option, as follows:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    delete value    # default value: 32767
                                }
                            }
                        }
```

The ES configuration on PE-4 remains unchanged, so the behavior is revertive. PE-4 and PE-5 have the same preference (default 32767), but PE-5 is non-revertive and becomes the DF, as follows:

```
[/]
A:admin@PE-5# show service id 1 ethernet-segment
No sap entries
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
===============================================================================

```

DF election: lowest IP address prevails when preferences and DP are equal

The vES configuration on PE-4 is modified by enabling the non-revertive option, as follows:

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            manual {
                                preference {
                                    mode non-revertive
                                }
                            }
                        }
```

PE-4 and PE-5 have an equal preference (default value = 32767) and non-revertive behavior. The tiebreaker for the DF selection is the IP address. PE-4 has the lower IP address and becomes the DF, as follows:

```
[/]
A:admin@PE-4# show service id 1 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================

-------------------------------------------------------------------------------
46:1                 vESI-45_1                        DF
===============================================================================
No vxlan instance entries
```

Service-carving configuration must be consistent

When the service carving on one of the PEs in the ES is configured in auto mode while one of the other PEs in the ES is configured in manual mode, the system reverts to modulo-based auto mode. The configuration of ES "vESI-45_1" remains unchanged on PE-4, but is modified on PE-5, as follows:

```
# on PE-5#
configure {
    service {
        system {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode auto
                            delete manual
                        }
```

ES "vESI-45_1" will operate in auto mode on PE-4 and on PE-5. The following **show** command on PE-4 shows that the ES is configured in manual mode, but operates in auto mode:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"

```
===============================================================================
```

For the remainder of the chapter, the vES configuration for "vESI-45_1" on PE-4 and PE-5 is restored to the initial settings. On PE-4, vESI-45_1" is configured with manual service-carving mode, reversive, and with default preference value (32767):

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    delete mode     # default mode: revertive
                                }
                            }
```

On PE-5, "vESI-45_1" is configured with manual service-carving mode, reversive, and with preference value 5000:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 5000
                                }
                            }
```

When there are no failures, PE-4 is the DF, because it has a higher preference.

Revertive behavior

When SDP 64 fails on MTU-6, PE-4 becomes the NDF for ES "vESI-45_1" and PE-5 will be the DF instead, as follows. The failure is emulated by disabling the SDP on MTU-6.

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state disable
```

When the PE is not a candidate DF because it cannot be used, the operational preference value equals 0, as follows:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"
                                            | match "DF Pref Election" post-lines 6
```

```

When the SDP is restored, the DF does not revert even though the list of DF candidates contains both PE-4 and PE-5. The preference mode is non-revertive; therefore, the DP bit has been set. PE-4 will not become the DF, as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state enable
```

```

The operational preference value on NDF PE-4 equals the preference value on DF PE-5, as follows. In this example, EVI 2 is included in the configured EVI range, so the lowest preference wins. To avoid the system reverting to the lower preference of 15000, the operational preference is raised to the value of 20000, which equals the preference of the current DF PE-5.

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2"
                                            | match "DF Pref Election" post-lines 6

-------------------------------------------------------------------------------
non-revertive  15000          04/26/2021 09:21:41      20000          Disabled
-------------------------------------------------------------------------------
```

PE-4 checks its own administrative preference and compares it with the one of the Highest-PE and Lowest-PE that have DP=1 in their ES routes.

- The Highest-PE is the PE with higher preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.
- The Lowest-PE is the PE with lower preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.

Depending on this comparison, PE-4 will send the ES route with a preference and DP that may be different from its administrative values.

- If PE-4's preference value is higher than the Highest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Highest-PE's and DP=0.
- If PE-4's preference value is lower than the Lowest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Lowest-PE's and DP=0.
- If PE-4's preference value is neither higher nor lower than the Highest-PE's or the Lowest-PE's respectively, PE-4 will send the ES route with its administrative [preference,DP]=[15000,1].

In this example, NDF PE-4 sends operational preference 20000 and DP=0, because its admin preference value was lower than the Lowest-PE's (PE-5), as follows:

```
# on PE-4:
148 2021/04/26 09:43:17.492 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

With equal operational preference, the current DF PE-5 sends DP=1, which is preferred over DP=0. The following output shows the BGP extended community of the ES routes for "vESI-45_2" in the RIB-In (received ES route from PE-5) and RIB-Out (sent ES route) on PE-4:

```
[/]
A:admin@PE-4# show router bgp routes evpn eth-seg hunt
                                    | match "target:00:00:00:00:45:02" pre-lines 2
Community      :                                  # in RIB-In
                  df-election::DF-Type:Preference/DP:1/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
Community      :                                  # in RIB-Out
                  df-election::DF-Type:Preference/DP:0/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
```

Either of the following events cause PE-4 to re-advertise its admin preference 15000 and DP=1:

- DF PE-5 withdraws its ES route.
- The admin preference for ES "vESI-45_2" on DF PE-5 is modified by configuration to a value preferred over PE-4's admin preference; in this case, to a value lower than 15000.

The admin preference value can be modified on ES "vESI-45_2" on DF PE-5, as follows:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_2" {
                        df-election {
                            manual {
                                preference {
                                    mode non-revertive
                                    value 10000
                                }
                            }
```

The preference value 10000 is lower than 15000 and, therefore, preferred when the lowest preference wins. PE-5 remains DF, but now there is no need to modify the preference of PE-4, because the system does not need to revert. Therefore, PE-4 can send the admin preference 15000 and configured DP=1, as follows:

```
# on PE-4:
151 2021/04/26 09:47:45.433 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 71

Conclusion

Preference-based DF election offers more control over the DF Election and applies to regular ESs and vESs, either in single-active or in all-active multi-homing mode, in VPLS, I-VPLS, or Epipe services. The DF election is by default revertive, but when preference mode is chosen, it can be configured as non-revertive to reduce service impact.

Proxy-ARP/ND MAC List for Dynamic Entries

This chapter provides information about Proxy-ARP/ND MAC List for Dynamic Entries.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. Proxy-Address Resolution Protocol/Neighbor Discovery (proxy-ARP/ND) MAC list for dynamic entries is supported in SR OS Release 15.0.R1, and later.

Overview

In some EVPN networks, the use of static proxy-ARP/ND entries is preferred to dynamically learned entries. For example, this is the case with some Internet eXchange Points (IXPs) that use EVPN and proxy-ARP/ND technologies. The MAC address in the static entry can be a MAC address from a list of n preregistered MAC addresses. The advantage is that—in case of a router or card failure—the hardware can be replaced, and no reconfiguration is required if the new MAC address is within a list of allowed MAC addresses.

In SR OS, these allow lists are called MAC lists. The associated proxy-ARP/ND entries will not be added upon configuration, but dynamically through a resolve procedure. This follows *draft-ietf-bess-evpn-proxy-arp-nd*.

- When the dynamic proxy-ARP/ND IP address with its associated MAC list is configured, the system sends a resolve message to all its non-EVPN peers.
- The resolve message is an ARP request for IPv4, or a Neighbor Solicitation (NS) message for IPv6.
- The resolve message is sent at a configurable interval between 1 and 60 minutes; the default is 5 minutes.
- The system keeps sending resolve messages until a dynamic entry is created for the proxy-ARP/ND IP address. This entry is only created when two conditions are met:
  - An ARP/Gratuitous Address Resolution Protocol (GARP) or Neighbor Advertisement (NA) is received for the configured IP address.
  - The associated MAC address belongs to the MAC list configured for the IP address. If the MAC list is empty or not configured, the system will never create an entry for the IP address.

When the dynamic proxy-ARP/ND IP entry is created, the system advertises an EVPN-MAC update to its EVPN peers. The sticky bit will be set depending on how the corresponding MAC address is learned. If the MAC address is learned on a SAP/SDP-binding with Auto-Learn MAC Protect (ALMP) enabled, the EVPN-MAC route will be advertised as static.

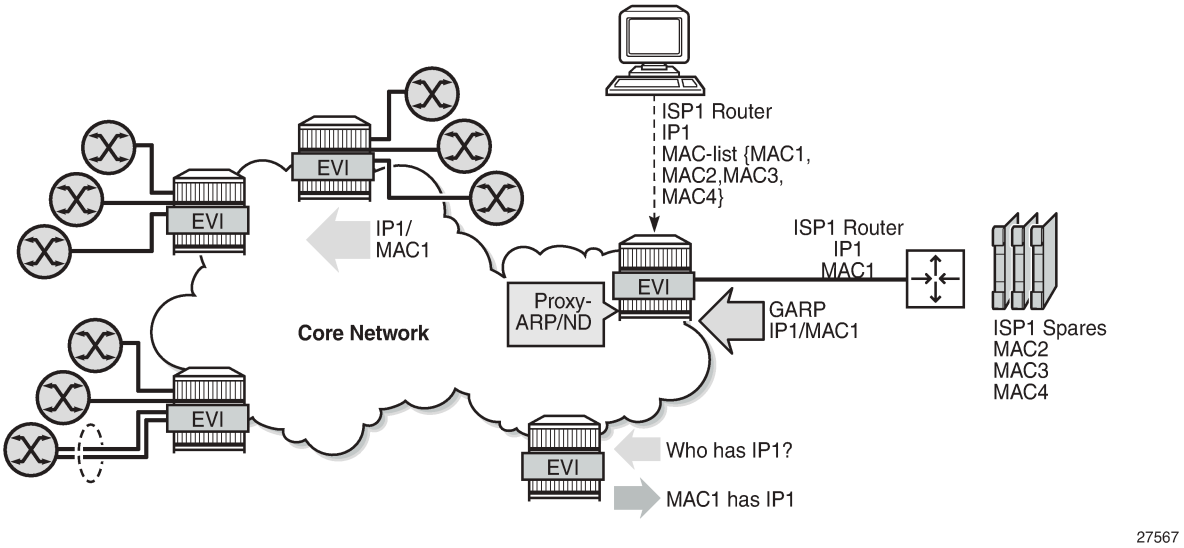
Figure 265: IXP with proxy-ARP/ND MAC list for dynamic entries shows an example of an IXP network that uses proxy-ARP/ND and a MAC list.

Figure 265: IXP with proxy-ARP/ND MAC list for dynamic entries



The ISP1 router with IP1 and MAC1 is connected to a PE in the core network that has proxy-ARP/ND enabled and a list of allowed MAC addresses. This MAC list contains four MAC addresses: MAC1 (for the hardware that is currently in use) and three MAC addresses for spares: MAC2, MAC3, and MAC4. The proxy-ARP/ND table will be populated as follows:

- The PE floods a resolve message for the configured IP address for proxy-ARP/ND to its non-EVPN peers.
- The ISP1 router that is connected to the network sends a GARP or ARP Reply message with IP1 and MAC1 that will be snooped by the PE.
- The PE checks whether IP1 is configured as a dynamic proxy-ARP/ND entry and MAC1 is in the MAC list assigned to proxy-ARP/ND entry IP1.
  - If true, the IP1/MAC1 entry is created in the proxy-ARP/ND table and advertised in EVPN.
  - If the GARP message contains MAC5, which is not in the MAC allow list, no proxy-ARP/ND entry is created, and IP/MAC is not advertised. If **proxy-arp>evpn>flood>gratuitous-arp false** is configured, the GARP containing MAC5 will be discarded.

If after the proxy-ARP/ND creation, the corresponding MAC address is flushed from the Forwarding Database (FDB), the entry goes inactive. After the age-time, the inactive entry will age out and the resolve process will restart.

MAC lists are configured with the following command:

```
[ex:/configure service proxy-arp-nd mac-list]
A:admin@PE-2# list "ISP1" ?

 list

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 mac                   - Add a list entry for mac
```

The MAC list contains the allowed MAC addresses and can be associated in one or more services with a proxy-ARP/ND IP address. A MAC list is associated with dynamic proxy-ARP IP 1.1.1.1 with the following command:

```
[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp]
A:admin@PE-2# ip-address 1.1.1.1 ?

 ip-address

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 mac-list              - MAC list for the dynamic entry
 resolve-retry-time    - Frequency at which the resolve messages are sent
```

The configuration for proxy-ND is similar:

```
[ex:/configure service vpls "EVI-1" proxy-nd dynamic-neighbor]
A:admin@PE-2# ip-address 2001:db8::99 ?

 ip-address

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 mac-list              - MAC list for the dynamic entry
 resolve-retry-time    - Frequency at which the resolve messages are sent
```

- The MAC list can be associated with multiple configured dynamic IP addresses:
  - In different services
  - In the same service, for proxy-ARP and proxy-ND
- An empty MAC list can be configured and applied, but no proxy-ARP/ND entries will be created when the PE receives a GARP message containing a MAC address that is not in the allow list.
- MAC lists can be modified at any time: MAC addresses can be added or removed even when the MAC lists are associated with configured dynamic IP addresses. If the MAC list changes, all the IP addresses associated with that MAC list will delete the proxy entries and restart the resolve process.

An existing dynamic proxy-ARP/ND entry IP1/MAC1 can be overridden when the system receives a GARP/ARP/NA for IP1 with another MAC address from the MAC list (IP1/MAC2). The system will first send a confirm message to check whether the old IP1/MAC1 is still reachable. Only when there is no answer, the entry IP1/MAC1 is replaced by IP1/MAC2. The existing duplicate-detect and confirm procedures are only applied for MAC address changes within the MAC list.

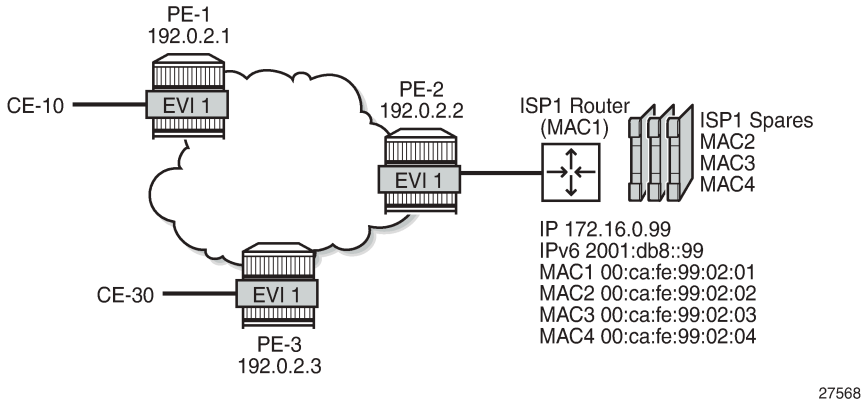
An existing dynamic proxy-ARP/ND entry IP1/MAC1 will be deleted when the system receives a GARP/ARP/NA IP1/MAC5 with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message will be discarded and the resolve procedure is restarted.

Configuration

Figure 266: Example topology shows the example topology with three PEs. ISP router 1 is connected to PE-2. MAC1 is used; MAC2, MAC3, and MAC4 correspond to spares.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 266: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between the PEs (alternatively, OSPF can be used)
- LDP between the PEs

BGP is enabled between the PEs for address family EVPN. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
        }
```

VPLS 1 is configured on PE-2 as follows. The configuration on the other PEs is similar.

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            sap 1/2/1:3 {
            }
        }
```

MAC list

The following MAC lists are configured on PE-2: ISP1 is an empty list; ISP2 is a MAC list containing four MAC addresses.

```
# on PE-2:
configure {
    service {
        proxy-arp-nd {
            mac-list {
                list "ISP1" {
                }
                list "ISP2" {
                    mac 00:ca:fe:99:02:01 { }
                    mac 00:ca:fe:99:02:02 { }
                    mac 00:ca:fe:99:02:03 { }
                    mac 00:ca:fe:99:02:04 { }
                }
            }
```

The following command shows the configured MAC lists on PE-2, with the number of MAC addresses and the number of associations. None of the MAC lists has been associated with a proxy-ARP/ND IP entry, so the number of associations is zero.

```
[/]
A:admin@PE-2# show service proxy-arp-nd mac-list

MAC list associated with proxy-ARP/ND in VPLS

MAC lists can be associated with one or more services. An empty MAC list—such as ISP1—can be associated, but it is impossible to associate a non-existing MAC list with a service. The following error is raised when attempting to associate the non-existing MAC list ISP3 with proxy-ARP IP 1.1.1.1 in VPLS 1 on PE-2:

```
*[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1]
A:admin@PE-2# mac-list "ISP3"

*[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #224: configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1
 mac-list - Entry does not exist - configure service proxy-arp-nd mac-list list "ISP3"
```

MAC list ISP2 is associated with proxy-ARP IP 172.16.0.99 and with proxy-ND IP 2001:db8::99 in VPLS 1 on PE-2, as follows:

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            proxy-arp {
                admin-state enable
                dynamic-populate true
                dynamic-arp {
                    ip-address 172.16.0.99 {
                        mac-list "ISP2"
                        resolve-retry-time 1
                    }
                }
            }
            proxy-nd {
                admin-state enable
                dynamic-populate true
                dynamic-neighbor {
                    ip-address 2001:db8::99 {
                        mac-list "ISP2"
```

```
                    }
                }
            }
```

For proxy-ARP IP 172.16.0.99, the resolve interval is 1 minute, which is the minimum; for proxy-ND IP 2001:db::99, the resolve interval is the default of 5 minutes. In scaled environments, Nokia recommends using the default interval, or even configuring a longer interval. The proxy-ARP and proxy-ND tables can be populated with dynamic entries (**dynamic-populate true**).

The following command shows all associations for MAC list ISP2: two associations are defined in VPLS 1: one for IP address 172.16.0.99 and another for IP address 2001:db8::99.

```
[/]
A:admin@PE-2# show service proxy-arp-nd mac-list name "ISP2" associations

===============================================================================

===============================================================================
```

Different dynamic proxy-ARP/ND entries

A distinction is made between regular dynamic entries and configured dynamic entries:

- No IP address needs to be configured for regular dynamic proxy-ARP/ND entries. What only needs to be configured, is the option **dynamic-populate true**.
- IP address and MAC list need to be defined for configured proxy-ARP/ND entries.

Configured dynamic entries can override static and regular dynamic entries.

Regular dynamic proxy-ARP/ND entries can override configured dynamic entries.

EVPN entries cannot override configured dynamic entries, even though they can override regular dynamic entries.

Likewise, static entries can override regular dynamic entries, but they cannot override dynamic configured entries. The following error is raised when attempting to configure a static proxy-ARP entry for IP 172.16.0.99, which has already been configured as dynamic and associated with a MAC list.

```
*[ex:/configure service vpls "EVI-1" proxy-arp static-arp ip-address 172.16.0.99]A:admin@PE-2#
 commit
MINOR: MGMT_CORE #258: configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address
 172.16.0.99 - Unique values required - configure service vpls "EVI-1" proxy-arp static-arp ip-
address 172.16.0.99
```

Debugging

Debugging for both proxy-ARP/ND IP entries is enabled—in classic CLI—on PE-2 as follows:

```
# on PE-2:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
debug
    service
        id 1
            proxy-arp ip 172.16.0.99
            proxy-nd ip 2001:db8::99
        exit
    exit
exit
```

When the dynamic proxy-ARP IP 172.16.0.99 is configured with MAC list "ISP2", PE-2 floods a resolve message—in this case, an ARP request—to all its EVPN peers. Router ISP1 replies. PE-2 advertises an EVPN-MAC update to its EVPN peers PE-1 and PE-3. PE-2 adds a dynamic proxy-ARP entry for 172.16.0.99 with MAC address 00:ca:fe:99:02:01. Router ISP1 sends a GARP message. The following messages are logged:

```
29 2021/05/11 14:11:39.920 CEST MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 flood resolve"

Tools command to trigger resolve procedure

The following tools command can be used to force the system to send a resolve message to its non-EVPN peers. The **force** option will trigger the resolve process even for existing entries in the proxy-ARP/ND table.

```
[/]
A:admin@PE-2# tools perform service id 1 proxy-arp dynamic-resolve ?

 dynamic-resolve all [force]
 dynamic-resolve <IP address> [force]

 [ip-address] (<ipv4-address> | <ipv6-address>)
 <ipv4-address>  - <d.d.d.d>
 <ipv6-address>  - (<x:x:x:x:x:x:x:x>|<x:x:x:x:x:x:d.d.d.d>)

 [ip-address]          - ipv4 address '<d.d.d.d>' or ipv6 address
 '(<x:x:x:x:x:x:x:x>|<x:x:x:x:x:x:d.d.d.d>)'
 all                   - <keyword>
 force                 - <keyword>
```

```
[/]
A:admin@PE-2# tools perform service id 1 proxy-nd dynamic-resolve ?

 dynamic-resolve all [force]
 dynamic-resolve <ipv6 address> [force]

 [ipv6-address] <ipv6-address>
 x:x:x:x:x:x:x:x   (eight 16-bit pieces)
 x:x:x:x:x:x:d.d.d.d
 x - [0..FFFF]H
 d - [0..255]D

    Attribute ipv6-address for dynamic-resolve

 [ipv6-address]        - Attribute ipv6-address for dynamic-resolve
 all                   - <keyword>
 force                 - <keyword>
```

By default, aging is disabled, and the entries remain in the inactive status until the MAC address is learned again. However, if aging is enabled, the inactive proxy-ARP/ND entry will age out. After the entry is

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

deleted, the system sends a resolve message. When the ISP1 router replies, the entry is created again in the proxy-ARP/ND table. The age time is configured in seconds with the following command:

```
[ex:/configure service vpls "EVI-1" proxy-arp]
A:admin@PE-2# age-time ?

 age-time (<number> | <keyword>)
 <number>   - <60..86400>  - seconds
 <keyword>  - never        - seconds
 Default    - never

    Aging timer for proxy entries, where entries are flushed upon timer expiry
```

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            proxy-arp {
                age-time 60
            }
            proxy-nd {
                age-time 60
            }
```

The following debug messages for proxy ARP IP 172.16.0.99 show that an EVPN-MAC withdraw message is sent (when the MAC address is flushed from the FDB) and—after time-out—the proxy-ARP entry is deleted. PE-2 sends a resolve message to all its non-EVPN peers. Router ISP1 replies and the proxy-ARP entry is created again; an EVPN-MAC update is sent to the EVPN peers. Similar debug messages occur for proxy-ND.

```

MAC address replacement

When the system receives a GARP/ARP/NA for the same IP address, but with another MAC address from the MAC list, it will first send a confirm message to ensure that the old MAC address is not used anymore for the IP address. If the existing proxy-ARP/ND entry is IP1/MAC1 and a GARP/ARP/NA message is received for IP1/MAC4, the system sends an EVPN-MAC withdraw message for MAC1 and changes MAC1 to MAC4 for proxy-ARP/ND IP1, but the status is pending (pendng), as follows:

```
[/]A:admin@PE-2# show service id 1 proxy-arp detail | match 172.16.0.99 pre-lines 6
                                                                      post-lines 3

```

The system sends a confirm message (unicast ARP request) for the old entry IP1/MAC1 to ensure that there is no duplication. When there is no reply from MAC1, there is no duplication. An EVPN-MAC route is advertised for MAC4. The status of the proxy-ARP entry IP1/MAC4 changes to active. The following debug messages are logged for proxy-ARP 172.16.0.99:

```
151 2021/05/11 14:23:29.394 CEST MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 mac: 00:ca:fe:99:02:01 evpn withdraw"

152 2021/05/11 14:23:29.394 CEST MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 Mac Change: 00:ca:fe:99:02:01->00:ca:fe:99:02:04 "
```

===============================================================================
```

The mechanism is similar for proxy-ND.

The behavior is different when the system receives a GARP/ARP/NA for the IP address with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message is discarded and the proxy-ARP/ND entry deleted. The resolve procedure gets restarted.

Modified MAC list

MAC lists can be modified at any time, as follows:

```
# on PE-2:
configure {
    service {
        proxy-arp-nd {
            mac-list {
                list "ISP2" {
                    mac 00:ca:fe:99:02:05 { }
```

```
[/]A:admin@PE-2# show service proxy-arp-nd mac-list name "ISP2"

190 2021/05/11 14:25:23.322 CEST MINOR: DEBUG #2001 Base proxy nd
"proxy nd:
svc: 1 ip: 2001:db8::99 mac: 00:ca:fe:99:02:04 evpn advertise"

191 2021/05/11 14:25:23.322 CEST MINOR: DEBUG #2001 Base proxy nd
"proxy nd:
svc: 1 ip: 2001:db8::99 type: Dyn mac: 00:ca:fe:99:02:04 Added"

195 2021/05/11 14:25:23.420 CEST MINOR: DEBUG #2001 Base proxy nd
"proxy nd:
svc: 1 ip: 2001:db8::99 type: Dyn mac: 00:ca:fe:99:02:04 Gratuitous Update"
```

Conclusion

MAC lists can be associated with configured dynamic proxy-ARP/ND IP addresses. The actual proxy entries will only be created after a GARP/ARP/NA message is received for the IP address and one of the MAC addresses from the MAC list.

This tool complements the SR OS EVPN proxy-ARP/ND solution for providers present at IXPs.

Static VXLAN Termination in Epipe Services

This chapter provides information about Static VXLAN Termination in Epipe Services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Static VXLAN termination for Epipe services is supported in SR OS Release 15.0.R1, and later.

Overview

Static Virtual eXtensible Local Area Network (VXLAN) termination on non-system IP addresses of the PEs is supported in VPLS services, as described in chapter VXLAN Forwarding Path Extension, and in Epipe services, as described in this chapter. Whereas VPLSs using VXLAN require BGP-EVPN control plane in the current release, Epipe services using VXLAN do not. This implies that only the configured values are used because no auto-discovery of the remote Termination Endpoints (TEPs) can be done without BGP-EVPN.

This chapter describes the configuration and use of static VXLAN as an access tunneling mechanism to a PBB-EVPN network. This is a design deployed in some service provider networks where the aggregation network is a non-MPLS IP network.

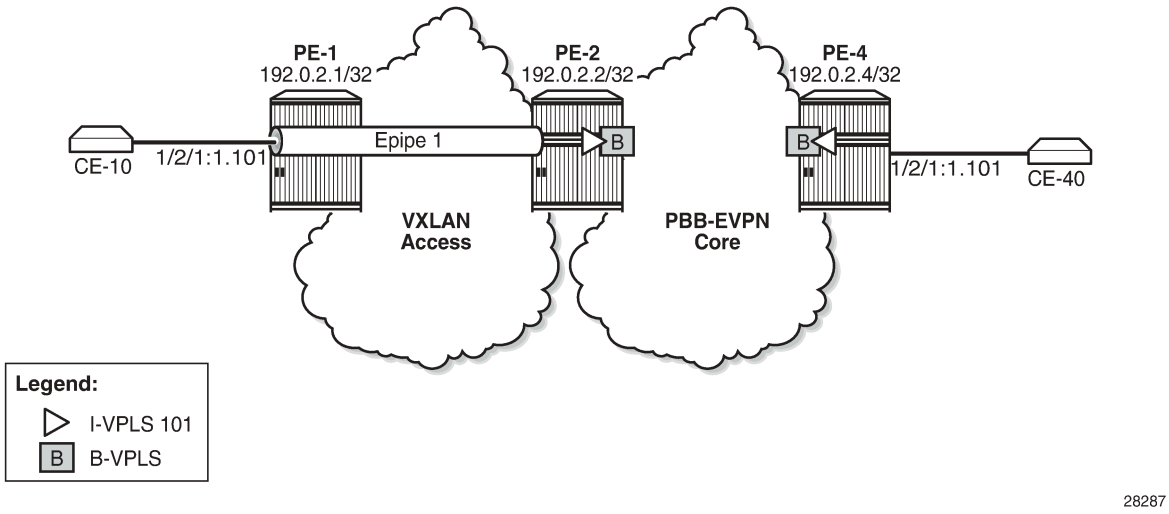
Static VXLAN termination for Epipe services can be applied on system IP addresses or non-system IP addresses.

Static VXLAN termination on system IP addresses

Figure 267: Static VXLAN termination on system IP addresses shows an example topology with three PEs and two CEs. Epipe 1 is configured on PE-1 and PE-2. PE-2 and PE-4 are part of a PBB-EVPN network. On PE-2, a port cross-connect (PXC) is configured to connect the SAP in Epipe 1 and the SAP in I-VPLS 101. CE-10 and CE-40 can send traffic to each other.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 267: Static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VXLAN Termination Endpoint (VTEP) 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows:

```
# on PE-1:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.2
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

where:

- The configured VXLAN Virtual Network Identifier (VNI) is used by the system as follows:
  - As the egress VNI when sending VXLAN packets for the Epipe service
  - As the source VNI that identifies the VXLAN packet to be part of the Epipe
  - Unique in the system, so it can only be configured in one service, either VPLS or Epipe

  The configuration of the VXLAN VNI in an Epipe is similar to the configuration of the VXLAN VNI in a VPLS, except that in a VPLS, the VNI is only used as the source VNI, because the egress VNI is learned from BGP-EVPN. However, in Epipe services with static VXLAN, the egress VNI is also the configured VNI.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The egress VTEP is the system IP address of the remote PE. The system will add the configured egress VTEP IP address as the remote VTEP when encapsulating the frames into VXLAN packets. Only the egress VTEP is configured, not the source VTEP. The PE receiving VXLAN packets will not check the source VTEP.
- The egress VTEP IP address must be in the Routing Table Manager (RTM). An oper-group is associated with the egress VTEP IP address, so that when the egress VTEP disappears from the base route table, the oper-group is brought operationally down, which propagates the failure to other objects that have this oper-group associated. The status of the oper-group and the service will be as follows:
  - When the egress VTEP disappears from the RTM, the VXLAN binding goes operationally down and the oper-group associated with the egress VTEP goes operationally down.
  - When the Epipe SAP goes down, the service goes down too.
  - When the VXLAN binding goes down, the service remains up as long as the access SAP is up.
  - When the service is disabled, the VXLAN binding and the oper-group associated with the egress VTEP are both brought operationally down.
- Only SAPs can be associated with the Epipe; no spoke-SDPs are supported in SR OS Release 21.5.R1, as follows. Regular SAPs and PXC SAPs are supported.

```
*[ex:/configure service epipe "Epipe 1" spoke-sdp 11:1]
A:admin@PE-1# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 1" vxlan instance 1 egress-vtep ip-address -
 Inconsistent Value error - vxlan-egr-vtep not supported with spoke-sdps in service - configure
 service epipe "Epipe 1" spoke-sdp 11:1
```

Frame encapsulation and forwarding

Incoming traffic in the PEs is treated as follows:

- For frames received from the SAPs, a SAP lookup identifies all frames matching the configured SAP (on PE-1, SAP 1/2/1:1.*). The matching frames will be encapsulated into VXLAN IPv4 packets with the following fields:
  - Source VTEP = system IP address
  - Destination VTEP = configured address in **egress-vtep**
  - VNI = configured VXLAN VNI
  - Source and destination UDP ports will be populated as per the existing VXLAN implementation VPLS services, with the source UDP port populated with the result of a hash on the ingress packets.
- For VXLAN frames received from the VXLAN network, a VNI lookup is done for packets with IP DA = system IP address. Frames with the configured VNI 1 are assigned to Epipe 1. The VXLAN encapsulation is removed and the frames are forwarded to the SAP.

Per-service hashing is not supported in Epipe-VXLAN services; only regular hashing and spraying in LAG/ECMP is supported as in any Epipe.

Static VXLAN termination on IPv6 or non-system IPv4 addresses

The non-system IPv4 or IPv6 VXLAN termination on Epipe services is configured in the same way as for VPLS services and described in the VXLAN Forwarding Path Extension chapter, using the FPE function for additional processing. The following steps are required for configuring the FPE for VXLAN termination:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

1. Create FPE.
2. Associate FPE with VXLAN termination.
3. Configure the loopback router interface subnet for VXLAN termination and its advertisement into the routing protocol. The subnet can be IPv4 or IPv6.
4. Configure the loopback address for VXLAN termination.
5. Add the service configuration.

Configuration

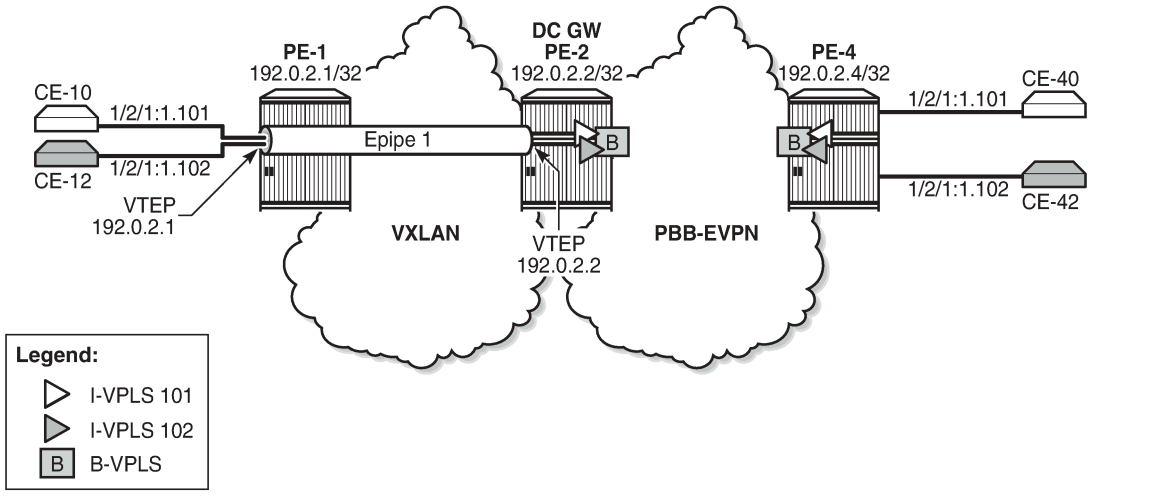
In this section, static VXLAN termination for Epipe services is configured for the following cases:

- VXLAN termination on system IP addresses
- VXLAN termination on non-system IPv4 addresses
- VXLAN termination on IPv6 addresses
- Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing

Static VXLAN termination on system IP addresses

Figure 268: Example topology for static VXLAN termination on system IP addresses shows the example topology for static VXLAN termination on system IP addresses. The initial configuration of the PEs includes the cards, MDAs, ports, router interfaces, and IGP. BGP is not required on PE-1; on PE-2 and PE-4, BGP is configured for address family EVPN.

Figure 268: Example topology for static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VTEP 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows. This configuration was explained in the text under Figure 267: Static VXLAN termination on system IP addresses.

```
# on PE-1:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.2
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

On PE-2, BGP is configured for address family EVPN, as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
        }
```

There is a PXC configured on port 1/2/1 that will connect SAP pxc-21.a:1.* in Epipe 1, SAP pxc-21.b:1.101 in I-VPLS 101, and SAP pxc-21.b:1.102 in I-VPLS 102. The PXC is configured on PE-2 as follows. See the "Port Cross-Connect (PCX)" chapter in the Interface Configuration volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I* for more information.

```
# on PE-2:
configure {
    port-xc {
        pxc 21 {
            admin-state enable
            port-id 1/2/1
        }
    }
    port pxc-21.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    }
    port pxc-21.b {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port 1/2/1 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
```

The service configuration on PE-2 includes Epipe 1, B-VPLS 100, and I-VPLSs 101-102, as follows:

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap pxc-21.a:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.1
                        oper-group "op-grp-1"
                    }
                }
            }
        }
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:02
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

© 2023 Nokia.

```
        }
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 101
                }
            }
            sap pxc-21.b:1.101 {
            }
        }
        vpls "I-VPLS 102" {
            admin-state enable
            service-id 102
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 102
                }
            }
            sap pxc-21.b:1.102 {
            }
        }
```

The service configuration on PE-4 is similar for the B-VPLS and the I-VPLSs, but Epipe 1 is not configured on PE-4.

The following command shows the VXLAN information for Epipe 1 on PE-1. By default, the source VTEP is the system IP address 192.0.2.1.

```

-------------------------------------------------------------------------------
1                   1                   192.0.2.2
-------------------------------------------------------------------------------
Egr-Vtep Entries found: 1
===============================================================================
```

The oper-group with member egress VTEP 192.0.2.2 cannot be monitored on a SAP in the same Epipe. The following error is raised when attempting to configure the same oper-group for the SAP in Epipe 1 on PE-1:

```
[ex:/configure service epipe "Epipe 1" sap 1/2/1:1.*]
A:admin@PE-1# oper-group "op-grp-1"

*[ex:/configure service epipe "Epipe 1" sap 1/2/1:1.*]
A:admin@PE-1# commit
MINOR: MGMT_CORE #5001: configure service epipe "Epipe 1" sap 1/2/1:1.* - Oper-group has an Egr
Vtep member, no other members allowed
```

The following ports on PE-2 are disabled to make the destination VTEP unreachable from PE-1:

```
# on PE-2:
configure {
    port 1/1/1 {
        admin-state disable
    }
    port 1/1/2 {
        admin-state disable
    }
```

When the destination VTEP disappears from the RTM, the oper-group op-grp-1 goes down and the VXLAN binding in Epipe 1 goes down, while the Epipe service remains up, as follows:

```
[/]
A:admin@PE-1# show service oper-group "op-grp-1"

===============================================================================
```

The output is similar on PE-2. The ports are re-enabled on PE-2, which will cause the VXLAN binding and the oper-group to be operationally up again:

```
# on PE-2:
configure {
    port 1/1/1 {
        admin-state enable
    }
    port 1/1/2 {
        admin-state enable
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The preceding example proved that the Epipe service remains up when the VXLAN binding goes down. The following example shows that the Epipe service goes down when the SAP goes down. On PE-1, port 1/2/1 is disabled, as follows:

```
# on PE-1:
configure {
    port 1/2/1
        admin-state disable
```

The following command shows that SAP 1/2/1:1.* and Epipe 1 are down on PE-1:

```
[/]
A:admin@PE-1# show service id 1 base

===============================================================================
Service Basic Information
===============================================================================
Service Id        : 1                   Vpn Id            : 0

===============================================================================
```

The port is re-enabled and SAP 1/2/1:1 and service Epipe 1 will be up again.

```
# on PE-1:
configure {
    port 1/2/1 {
        admin-state enable
```

When the service is disabled (**admin-state disable**), the SAP goes down, the VXLAN binding goes down, and the oper-group goes down, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state disable
```

```

Static VXLAN termination on non-system IPv4 addresses

Non-system IP VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 269: Example topology for static VXLAN termination on non-system IPv4 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The non-system loopback address on PE-2 will be used for VXLAN termination, whereas the system IP address will be used on PE-1.

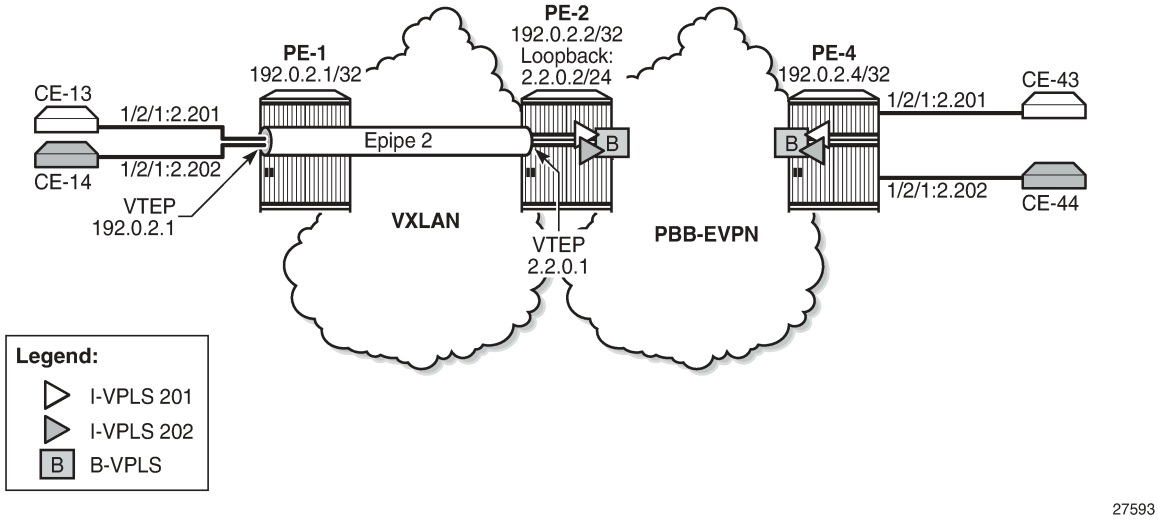
Use subject to Terms available at: www.nokia.com/terms.

Figure 269: Example topology for static VXLAN termination on non-system IPv4 addresses



Create FPE

FPE uses the back-to-back PXC, either a PXC port or a LAG-based PXC. PXC 1 is created on PE-2:

```
# on PE-2:
configure {
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/5
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
```

```
[/]
A:admin@PE-2# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
```

© 2023 Nokia.

```
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPE uses the PXC:

```
# on PE-2:
configure {
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
```

The following shows that FPE 1 uses PXC 1 and has no VXLAN termination associated:

```
[/]
A:admin@PE-2# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description        : (Not Specified)
Path               : pxc 1
Pw Port            : Disabled                          Oper     : down
Sub Mgmt Extension : Disabled                          Oper     : N/A
Vxlan Termination  : Disabled                          Oper     : down
Segment-Routing V6 : Disabled
===============================================================================
```

Associate FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-2:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
```

When attempting to associate the FPE with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*[ex:/configure fwd-path-ext fpe 1 application vxlan-termination]
A:admin@PE-2# commit
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
MINOR: FPE #1021: configure fwd-path-ext fpe 1 - sdp-id-range is not configured - configure
 fwd-path-ext sdp-id-range
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs; see the VXLAN Forwarding Path Extension chapter for more information about the use of SDP IDs. The application for FPE 1 is VXLAN termination.

```
[/]
A:admin@PE-2# show fwd-path-ext

After the FPEs are associated with VXLAN termination, the system creates two internal router interfaces per FPE, one per PXC sub-port, as follows:

```
[/]
A:admin@PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
---snip---
```

Configure router loopback interface

The following loopback interface is configured in PE-2 and added to the IS-IS context. The IPv6 address is not required yet.

```
# on PE-2:
configure {
    router "Base" {
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 2.2.0.2
                    prefix-length 24
                }
            }
            ipv6 {
                address 220::2 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    prefix-length 120
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
        }
```

A subnet must be assigned to the loopback interface, but not a /32 or /128 subnet mask, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 2.2.0.0/24 can be used for VXLAN tunnel termination, except for 2.2.0.2. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127.

Configure non-system VTEP addresses

On PE-2, non-system IP address 2.2.0.1 in the subnet of the loopback address 2.2.0.2/24 is configured as VTEP, as follows. Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs.

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 2.2.0.1 {
                    fpe-id 1
                }
            }
```

No non-system VTEP addresses need to be configured on PE-1.

When the non-system VTEP address is configured, an internal loopback interface _tmnx_vli_vxlan_1_131075 with VTEP address 2.2.0.1/32 is auto-created that can respond to ICMP requests.

```
[/]
A:admin@PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                PREFERRED
_tmnx_vli_vxlan_1_131075         Up        Up/Up       Network loopback
   2.2.0.1/32                                                  n/a
   fe80::13:ffff:fe00:0/64                                     PREFERRED
---snip---
```

The system does not verify if there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding ICMP for that address, regardless of the presence of a loopback

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the services

Epipe 2 is configured on PE-1 as follows. By default, the system IP address will be used as source VTEP of the VXLAN-encapsulated frames. The non-system IP address 2.2.0.1 is used as egress VTEP.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap 1/2/1:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                    egress-vtep {
                        ip-address 2.2.0.1
                    }
                }
            }
        }
```

The configuration of Epipe 2 on PE-2 defines the non-system IP address 2.2.0.1 as source VTEP, as follows. The egress VTEP is 192.0.2.1, the system IP address of PE-1. The configuration of the B-VPLS is the same as in the preceding example; the configuration of the I-VPLSs 201 and 202 is similar to the configuration of I-VPLS 101 in the preceding example.

```
# on PE-2:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap pxc-21.a:2.* {
            }
            vxlan {
                source-vtep 2.2.0.1
                instance 1 {
                    vni 2
                    egress-vtep {
                        ip-address 192.0.2.1
                    }
                }
            }
        }
```

The following **show** command on PE-1 shows that no VXLAN source VTEP IP address is configured:

```
[/]
A:admin@PE-1# show service id 2 vxlan
===============================================================================
Vxlan Src Vtep IP: N/A
===============================================================================
```

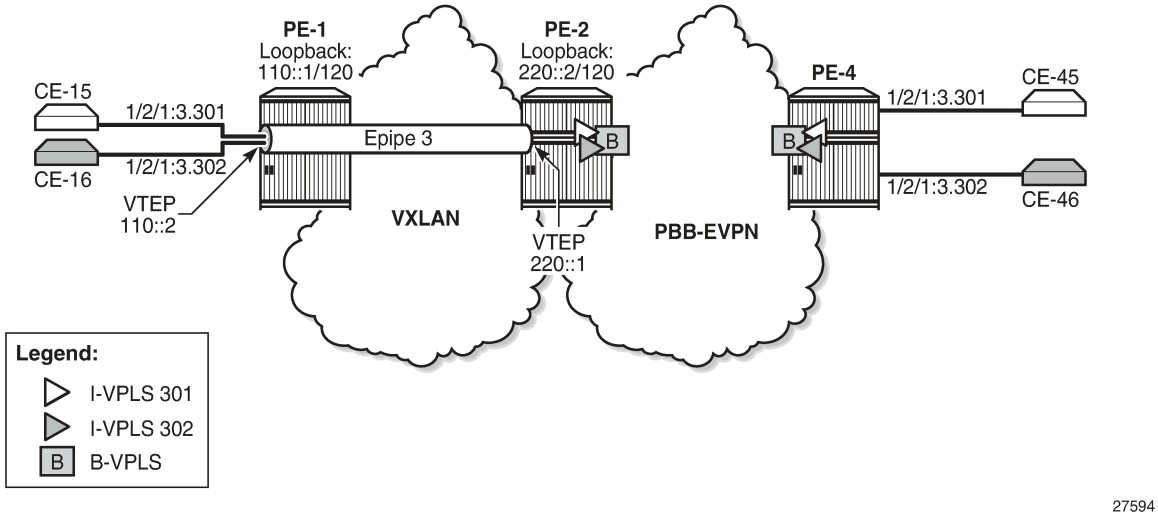
Static VXLAN termination on IPv6 addresses

IPv6 VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 270: Example topology for static VXLAN termination on IPv6 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The loopback addresses on PE-1 and PE-2 will be used for IPv6 VXLAN termination. The existing PXC 1 on PE-2 is reused for FPE; only an IPv6 VTEP address needs to be added.

Figure 270: Example topology for static VXLAN termination on IPv6 addresses



For IPv6 routing, the following option is configured for IS-IS on all nodes:

```
# on all PEsL
configure {
    router "Base" {
        isis 0 {
            ipv6-routing native
```

Use subject to Terms available at: www.nokia.com/terms.

Create FPE

The following PXC is created on PE-1; PXC 1 will be used for FPE:

```
# on PE-1:
configure {
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/5
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
```

```
[/]
A:admin@PE-1# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

Configure FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-1:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs. The application for FPE 1 is VXLAN termination.

```
[/]
A:admin@PE-1# show fwd-path-ext

===============================================================================
FPE Info
===============================================================================
FPE Id                  Path                          Application
                        pxc/xc-a, xc-b
-------------------------------------------------------------------------------
1                       pxc 1                         vxlan-term
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
SDP-Id Range: 10000 - 10127
===============================================================================
```

The following shows that FPE 1 has a VXLAN termination that is oper up:

```
[/]
A:admin@PE-1# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description        : (Not Specified)
Path               : pxc 1
Pw Port            : Disabled                        Oper     : down
Sub Mgmt Extension : Disabled                        Oper     : N/A
Vxlan Termination  : Router: Base                    Oper     : up
Segment-Routing V6 : Disabled
===============================================================================
```

After the FPEs are associated with VXLAN termination, the system creates two internal router interfaces per FPE, one per PXC sub-port, as follows:

```
[/]
A:admin@PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
---snip---
```

Configure router loopback interface

The following loopback interface is configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure {
    router "Base" {
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 1.1.0.1
                    prefix-length 24
                }
            }
            ipv6 {
                address 110::1 {
                    prefix-length 120
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
        }
```

All IPv6 addresses in the 110::/120 subnet can be used for VXLAN tunnel termination, except for 110::1.

Configure non-system VTEP addresses

On PE-1, IPv6 address 110::2 in the subnet of the loopback address 110::1/120 is configured as VTEP, as follows:

```
# on PE-1:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 110::2 {
                    fpe-id 1
                }
            }
```

On PE-2, IPv6 address 220::1 in the subnet of the loopback address 220::2/120 is configured as VTEP, as follows:

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 220::1 {
                    fpe-id 1
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When the IPv6 VTEP address is configured on PE-1, an internal loopback interface _tmnx_vli_vxlan_1_131075 is created, as follows.

```
[/]
A:admin@PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
_tmnx_vli_vxlan_1_131075         Up        Down/Up     Network loopback
   110::2/128                                                   PREFERRED
   fe80::f:ffff:fe00:0/64                                       PREFERRED
---snip---
```

The following IPv6 route table on PE-1 contains an internal static route for source VTEP 110::2/128 using the FPE internal interface _tmnx_fpe_1.a:

```
[/]
A:admin@PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
110::/120                                     Local   Local     01h34m32s  0
       loopback1                                                    0
110::2/128                                    Remote  Static    00h33m20s  5
       fe80::101-"_tmnx_fpe_1.a"                                    1
220::/120                                     Remote  ISIS      00h15m03s  15
       fe80::616:1ff:fe01:2-"int-PE-1-PE-2"                         10
---snip---
```

The following IPv6 route table on PE-2 shows that an internal static route is configured for the source VTEP 220::1/128 using the FPE internal interface _tmnx_fpe_1.a:

```
[/]
A:admin@PE-2# show router route-table ipv6

===============================================================================

Configure the services

Epipe 3 is configured on PE-1 with **source-vtep** 110::2, which is the VTEP address configured in the preceding step (VXLAN tunnel termination). The egress VTEP is 220::1, which is the VXLAN termination configured on PE-2.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            service-id 3
            customer "1"
            sap 1/2/1:3.* {
            }
            vxlan {
                source-vtep 110::2
                instance 1 {
                    vni 3
                    egress-vtep {
                        ip-address 220::1
                    }
                }
            }
        }
```

Epipe 3 on PE-2 has VXLAN source VTEP 220::1 and egress VTEP 110::2.

```
# on PE-2:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            service-id 3
            customer "1"
            sap pxc-21.a:3.* {
            }
            vxlan {
                source-vtep 220::1
                instance 1 {
                    vni 3
                    egress-vtep {
                        ip-address 110::2
                    }
                }
            }
        }
```

The configuration of the B-VPLS is the same as in the preceding example. The configuration of I-VPLS 302 is similar.

```
# on PE-2:
configure {
    service {
        vpls "I-VPLS 301" {
            admin-state enable
            service-id 301
            customer "1"
            pbb-type i-vpls
            pbb {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                backbone-vpls "B-VPLS 100" {
                    isid 301
                }
            }
            sap pxc-21.b:3.301 {
            }
        }
```

The following **show** commands on PE-1 show that the VXLAN source VTEP IP address is 110::2 and the egress VTEP is 220::1. The VXLAN tunnel is operationally up.

```
[/]

Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing and anycast VTEPs

Figure 271: Example topology for static VXLAN termination using anycast shows the example topology with PE-1, PE-2, and PE-3 in the VXLAN access network. Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, the system IP address 192.0.2.1 is used as source VTEP, while (anycast) IP address 23.23.23.4 is used as source VTEP on PE-2 and PE-3.

In the PBB-EVPN core network, all-active multi-homing virtual Ethernet segments vES-23_401 and vES-23_402 are configured on PE-2 and PE-3.

VXLAN access network

On PE-2 and PE-3, PXC ports are configured: PXC 2 will be used as FPE, whereas PXC-3 and PXC-4 will be used to make a LAG for the PXC between Epipe and I-VPLS services. The PXC sub-ports for FPE have dot1q encapsulation whereas the PXC sub-ports for port cross-connect have qinq encapsulation. The configuration of the PXC ports and sub-ports is as follows:

```
# on PE-2, PE-3:
configure {
    port 1/2/6 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/7 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/8 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port pxc-3.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-3.b {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-4.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-4.b {
        admin-state enable
        ethernet {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            encap-type qinq
        }
    }
    port-xc {
        pxc 2 {
            admin-state enable
            port-id 1/2/6
        }
        pxc 3 {
            admin-state enable
            port-id 1/2/7
        }
        pxc 4 {
            admin-state enable
            port-id 1/2/8
        }
    }
```

On PE-2 and PE-3, FPE 2 is configured. FPE 2 is associated with VXLAN termination and two internal interfaces will be auto-created: _tmnx_fpe_2.a and _tmnx_fpe_2.b.

```
# on PE-2, PE-3:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                vxlan-termination {
                }
            }
        }
```

```
[/]
A:admin@PE-2# show router interface

   fe80::200/64                                                PREFERRED
_tmnx_fpe_2.b                    Up        Up/Up       Network pxc-2.b:1
   fe80::201/64                                                PREFERRED
---snip---
```

A router loopback interface with IP address 23.23.23.2/24 is created on PE-2, and on PE-3 with IP address 23.23.23.3/24:

```
# on PE-2:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    router "Base" {
        interface "loopback2" {
            loopback
            ipv4 {
                primary {
                    address 23.23.23.2
                    prefix-length 24
                }
            }
        }
        isis 0 {
            interface "loopback2" {
            }
        }
```

On PE-2 and PE-3, the VTEP 23.23.23.4 is configured for FPE 2, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 23.23.23.4 {
                    fpe-id 2
                }
            }
        }
```

The following command shows an additional VTEP 23.23.23.4 to the existing router interface _tmnx_vli_vxlan_1_131075 on PE-2:

```
[/]
A:admin@PE-2# show router interface "_tmnx_vli_vxlan_1_131075"

===============================================================================
```

On PE-2 and PE-3, the VXLAN Epipe 4 uses LAG 4 (composed of pxc-3.b and pxc-4.b) to extend the VXLAN toward the I-VPLSs 401 and 402. The I-VPLS SAPs use LAG 3 (composed of pxc-3.a and pxc-4.a). The PXC LAGs provide higher bandwidth and better resiliency. The LAGs are configured as follows on both PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
    lag "lag-3" {
        admin-state enable
        encap-type qinq
        mode hybrid
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        max-ports 64
        port pxc-3.a {
        }
        port pxc-4.a {
        }
    }
    lag "lag-4" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-3.b {
        }
        port pxc-4.b {
        }
    }
```

Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, no FPE is required because the system IP address is used as VTEP. Epipe 4 is configured on PE-1 with egress VTEP 23.23.23.4, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            service-id 4
            customer "1"
            sap 1/2/1:4.* {
            }
            vxlan {
                instance 1 {
                    vni 4
                    egress-vtep {
                        ip-address 23.23.23.4
                    }
                }
            }
        }
```

Epipe 4 is configured on PE-2 and PE-3 with source VTEP 23.23.23.4 and egress VTEP 192.0.2.1, as follows. The SAP uses LAG 4, which is composed of PXC sub-ports pxc-3.b and pxc-4.b.

```
# on PE-2, PE-3:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            service-id 4
            customer "1"
            sap lag-4:4.* {
            }
            vxlan {
                source-vtep 23.23.23.4
                instance 1 {
                    vni 4
                    egress-vtep {
                        ip-address 192.0.2.1
                    }
                }
            }
```

```

PBB-EVPN core network

Two all-active multi-homing virtual ESs are configured on PE-2 and PE-3. The preference for the DF election is configured manually, with opposite preference values for the vESs so that DF load balancing is achieved. While vES-23_401 has preference 5000 on PE-2 and preference 10000 on PE-3, vES-23_402 has preference 10000 on PE-2 and preference 5000 on PE-3. When no event has occurred that caused a DF switchover, PE-2 is DF for vES-23_402 and PE-3 is DF for vES-23_401. Both vESs use LAG 3, which is composed of pxc-3.a and pxc-4.a. For vES-23_401, the qinq encapsulation must match S-tag 4 and C-tag 401; for vES-23_402, the S-tag must be 4 and the C-tag 402. On PE-2, the vESs are configured as follows.

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES-23_401" {
                        admin-state enable
                        type virtual
                        esi 0x01000000230401000001
                        multi-homing-mode all-active
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 5000
                                }
                            }
                        }
                        association {
                            lag "lag-3" {

                                value 10000
                            }
                        }
                    }
                    association {
                        lag "lag-3" {
                            virtual-ranges {
                                qinq {
                                    s-tag-c-tag 4 c-tag-start 402 {
                                        c-tag-end 402
                                    }
                                }
                            }
                        }
                    }
                    pbb {
                        source-bmac-lsb 0x2342
                    }
                }
            }
        }
    }
```

The B-VPLS 100 is configured to use the ES-BMAC. On PE-2, the B-VPLS is configured as follows.

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:02
                    use-es-bmac-lsb true
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

On PE-4, the following configuration sets ECMP to a value of 2 in the **bgp-evpn mpls** context of the B-VPLS, so that aliasing is possible.

```
# on PE-4:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                mpls 1 {
                    ecmp 2
                }
            }
```

On PE-2 and PE-3, the I-VPLSs are configured with SAP LAG 3, which is composed of pxc-3.a and pxc-4.a, as follows. The qinq encapsulation 4.401 in I-VPLS 401 matches the condition in vES-23_401, whereas qinq 4.402 in I-VPLS 402 matches vES-23_402.

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 401" {
            admin-state enable
            service-id 401
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 401
                }
            }
            sap lag-3:4.401 {
            }
        }
        vpls "I-VPLS 402" {
            admin-state enable
            service-id 402
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 402
                }
            }
            sap lag-3:4.402 {
            }
        }
```

With the preceding configuration, PBB-EVPN all-active multi-homing and the anycast VTEP at the access VXLAN network can be combined for an efficient and fully redundant network. PE-4 can alias the known unicast traffic to PE-2 and PE-3 on a per-flow basis, whereas if ECMP (and shared queuing) is enabled on PE-1, traffic can also be load-balanced to PE-2 and PE-3. BUM traffic sent from PE-4 will be forwarded by the corresponding DF for the ES.

See chapter EVPN for PBB over MPLS (PBB-EVPN) for more information about PBB-EVPN and all-active multi-homing.

Verification

The following command shows that PE-2 is NDF in vES-23_401 in I-VPLS 401:

```
[/]
A:admin@PE-2# show service id 401 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-3:4.401           vES-23_401                      NDF
===============================================================================
No sdp entries
No vxlan instance entries
```

For I-VPLS 402, PE-2 is DF, as follows:

```
[/]
A:admin@PE-2# show service id 402 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-3:4.402           vES-23_402                      DF
===============================================================================
No sdp entries
No vxlan instance entries
```

For PE-3, the reverse is true: PE-3 is DF in vES-23_401 for I-VPLS 401 and NDF in vES-23_402 for I-VPLS 402.

Within B-VPLS 100, the BMAC addresses are advertised via BGP-EVPN. On PE-2, the following FDB for B-VPLS 100 contains the BMAC addresses of PE-3 and PE-4, which are advertised via BGP-EVPN:

```
[/]
A:admin@PE-2# show service id 100 fdb detail

===============================================================================
```

When a ping is initiated from CE-17 to CE-47, the ICMP packets are forwarded from PE-1 to PE-2, because the best route to 23.23.23.4 is via PE-2. PE-2 learns MAC address ca:fe:01:17:17:17 of CE-17 on the local I-VPLS SAP. PE-2 forwards the ICMP packets through I-VPLS 401 and B-VPLS 100 toward PE-4.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-4 learns MAC ca:fe:01:17:17:17 of CE-17 via the ES-BMAC. When the reply is sent, PE-4 learns MAC address ca:fe:04:47:47:47 of CE-47 on the local SAP.

The FDB for I-VPLS 401 on PE-2 shows that MAC ca:fe:04:47:47:47 is learned on the local SAP and MAC ca:fe:04:47:47:47 can be reached via the B-VPLS to PE-4.

Conclusion

VXLAN FPE is required to terminate non-system IPv4/IPv6 VXLAN tunnels. The examples in this chapter show how VXLAN FPE can be applied in Epipe services, to stitch static VXLAN to other services, such as I-VPLS services.

Three-byte EVI in EVPN Services

This chapter provides information about the three-byte EVI in EVPN services.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. The three-byte EVI is supported in EVPN services in SR OS Release 21.10.R1 and later. Three-byte EVI values can be configured in VPLS, R-VPLS, B-VPLS, and Epipe services for MPLS, VXLAN, and SRv6 instances.

Overview

In SR OS implementations earlier than SR OS Release 21.10.R1, the EVPN instance (EVI) is defined as a two-byte integer value, providing up to 65535 unique identifiers. The EVI is a unique value per service that can be used for three purposes:

- service route target (RT) auto-derivation – autonomous system number (ASN):EVI; for example, 64496:10
- service route distinguisher (RD) auto-derivation – system IP address:EVI; for example, 192.0.2.1:10
- designated forwarder (DF) election, as described in the Preference-based and Non-revertive EVPN DF Election chapter

However, in large networks, more than 65535 EVI values are required if the EVI is desired to be unique network-wide. The three-byte EVI provides up to 16777215 values and is supported in SR OS Release 21.10.R1 and later.

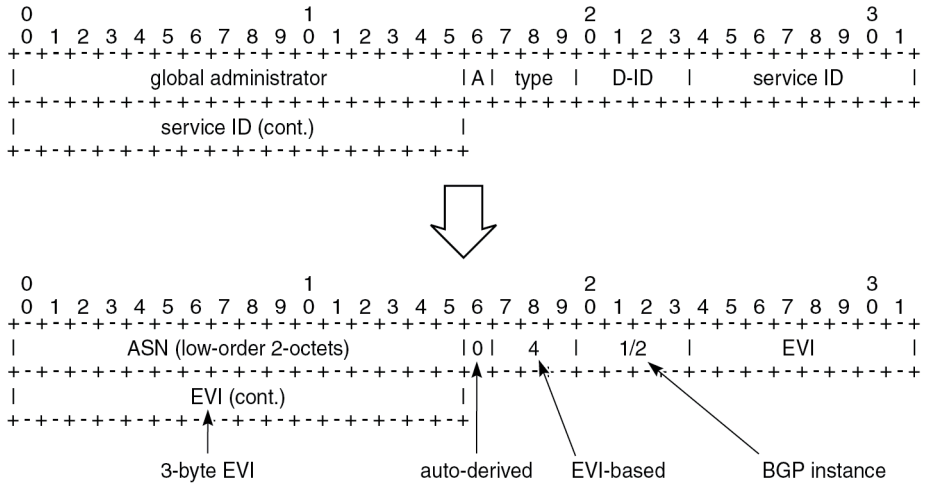
All DF election procedures support the extended EVI range. The RD auto-derivation is only possible for the two-byte EVI; the RT auto-derivation for the three-byte EVI can be enabled with the **evi-three-byte-auto-rd** command.

Auto-derived RT

The figure Figure 272: Auto-derived RT in RFC 8365shows the RT auto-derivation for configured EVI values in the range up to 16777215.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 272: Auto-derived RT in RFC 8365



For three-octet EVI values, the fields in the RT format are:

- the global administrator field, which contains (the lower two octets of) the autonomous system number (ASN)
- the single-bit field A, which indicates if the RT is auto-derived: A=0 for auto-derivation
- the three-bit type field, which indicates the space in which the three-byte service ID is defined:
  - 0: VID (802.1Q VLAN ID)
  - 1: VXLAN
  - 2: NVGRE
  - 3: I-SID
  - **4: EVI**
  - 5: dual-VID (QinQ VLAN ID)
- the four-bit D-ID field, which encodes the domain ID. For type 4 (EVI), the D-ID corresponds to the BGP instance ID in the EVPN service.
- the three-octet service ID, which is set to the EVI (for type 4)

As an example, in a dual-instance EVPN-VPLS service with the following characteristics:

- ASN 64496
- EVI 100002 (0x186A2)
- BGP 1 for EVPN-VXLAN; BGP 2 for EVPN-MPLS
- **evi-three-byte-auto-rt** enabled

The two auto-derived RTs are:

- 64496:1090619042 (0x4**1**0186A2) for BGP 1
- 64496:1107396258 (0x4**2**0186A2) for BGP 2

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The RT can also be configured manually, for example, 64496:100002. A manually configured RT has precedence over an auto-derived RT.

Auto-derived RD

Each BGP instance in an EVPN service has an RD. Only for EVI values smaller than or equal to 65535, the RD for BGP instance 1 can be auto-derived out of the system IP address and the EVI, for example, 192.0.2.2:10. EVI values greater than 65535 do not generate RDs automatically.

The VPLS RD is selected based on the following precedence order:

- manually configured RD or auto-RD take precedence when configured,
- if there is no manual RD or auto-RD configuration, the RD is derived from the **bgp-ad>vpls-id**,
- if there is no manual RD, auto-RD, or VPLS ID configuration, the RD is derived from the EVI for EVI values up to 65535 and except for **bgp-mh** which does not support EVI-derived RD,

The Epipe RD is determined in a similar way, but there is no VPLS ID in Epipes.

The following error messages are raised when attempting to enable **bgp-evpn** with an EVI value greater than 65535 without having configured a manual RD, auto-RD, or BGP-AD VPLS ID:

```
*[ex:/configure service vpls "VPLS-99"]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS-99" bgp-evpn vxlan 1 admin-state - No

MINOR: MGMT_CORE #4001: configure service vpls "VPLS-99" bgp-evpn vxlan 1 admin-state - No bgp-
ad vpls-id configured to derive RD or RT - configure service
MINOR: MGMT_CORE #4001: configure service vpls "VPLS-99" bgp-evpn vxlan 1 admin-state - No bgp-
evpn evi to derive RD or RT - configure service vpls "VPLS-99" bgp-evpn evi
```

The RD configuration can be changed dynamically. When the RD changes, the active routes for the service are withdrawn and readvertised with the new RD.

EVI RT set for AD per-ES routes

As described in the EVPN for MPLS Tunnels chapter, Auto-discovery per Ethernet Segment (AD per-ES) routes carry the ESI label and the multi-homing mode. When multiple EVIs are defined in an ES, the AD per-ES routes can be aggregated.

EVI RT set for AD per-ES routes with two-byte EVI

The following command enables the aggregation of AD per-ES routes for two-byte EVI values:

```
configure {
    service {
        system {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp {
                evpn {
                    ad-per-es-route {
                        route-target-type evi-route-target-set
                        route-distinguisher-ip-address <ip-address>
                    }
```

The RD is specific for this EVI RT set feature. If enabled, a single AD per-ES route with the associated RD and a set of maximum 128 EVI RTs can be advertised. The EVI RTs are distributed in routes with the RD configured in the preceding command and one of the following *comm-val* values (the *comm-val* range is not configurable):

- EVIs from 1 to 128 – *comm-val* = 1
- EVIs from 129 to 256 – *comm-val* = 2
- ...
- EVIs from 65409 to 65535 – *comm-val* = 512

EVI RT set for AD per-ES routes with three-byte EVI

The command to enable AD per-ES route aggregation with extended EVI range is:

```
configure {
    service {
        system {
            bgp {
                evpn {
                    ad-per-es-route {
                        route-target-type evi-route-target-set
                        route-distinguisher-ip-address <ip-address>
                        extended-evi-range true
                    }
```

For three-byte EVIs, the *comm-val* range is extended from 512 to 65535 and the maximum number of AD per-ES routes that can be aggregated is increased from 128 to 257. The 257 RTs per route packing is done for any configured EVI, regardless of the value being greater than 65535 or not.

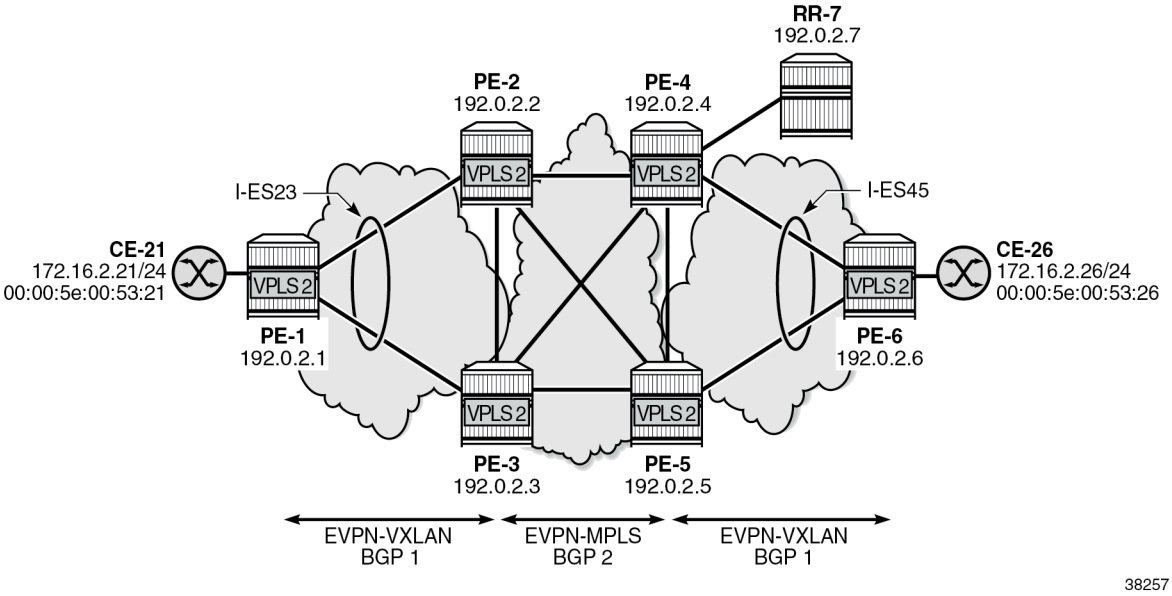
- EVIs from 1 to 257 – *comm-val* = 1
- EVIs from 258 to 514 – *comm-val* = 2
- ...
- EVIs from 16776961 to 16777215 – *comm-val* = 65281

Configuration

The figure Figure 273: Example topology with dual-instance VPLS shows the example topology with dual-instance VPLS 2: VXLAN is used between PE-1, PE-2, PE-3 and also between PE-4, PE-5, and PE-6. MPLS is used between the core PEs PE-2, PE-3, PE-4, and PE-5.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 273: Example topology with dual-instance VPLS



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 2 between core PEs PE-2, PE-3, PE-4, PE-5, and RR-7
- IS-IS level 1 between PE-1, PE-2, and PE-3
- IS-IS level 1 between PE-6, PE-4, and PE-5
- SR-ISIS between core PEs PE-2, PE-3, PE-4, and PE-5

The BGP configuration and the used policies for dual-instance VPLSs in ESs are described in the EVPN Interconnect Ethernet Segmentschapter. Policies are required to prevent loops. RR-7 acts as route reflector for the core PEs PE-2, PE-3, PE-4, and PE-5. The policy and BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    policy-options {
        community "SOO-DCGW-23" {
            member "origin:64500:23" { }
        }
        community "vxlan" {
            member "bgp-tunnel-encap:VXLAN" { }
        }
        policy-statement "add SOO to vxlan routes" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "vxlan"
                    }
                }
                action {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    action-type accept
                    community {
                        add ["SOO-DCGW-23"]
                    }
                }
            }
            default-action {
                action-type accept
            }
        }
        policy-statement "allow only mpls" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "vxlan"
                    }
                }
                action {
                    action-type reject
                }
            }
        }
        policy-statement "allow only vxlan" {
            entry 10 {
                from {

```
            group "WAN" {
                peer-as 64496
                family {
                    evpn true
                }
                export {
                    policy ["allow only mpls"]
                }
            }
            group "access1" {
                peer-as 64496
                family {
                    evpn true
                }
                export {
                    policy ["allow only vxlan"]
                }
            }
            neighbor "192.0.2.1" {
                group "access1"
            }
            neighbor "192.0.2.3" {
                group "access1"
                import {
                    policy ["drop SOO-DCGW-23"]
                }
                export {
                    policy ["add SOO to vxlan routes"]
                }
            }
            neighbor "192.0.2.7" {
                group "WAN"
            }
```

The all-active interconnect ES "I-ES23" is configured on PE-2 and PE-3; the single-active interconnect ES "I-ES45" is configured on PE-4 and PE-5. VPLS 1 with EVI 1 (0x1) and VPLS 2 with EVI 100002 (0x186A2) are configured on all PEs. Both VPLSs have BGP 1 for VXLAN and BGP 2 for MPLS (SR-ISIS) in the core. For VPLS 1, no extended EVI range is required. The RD can be auto-derived for BGP instance 1, but not for BGP instance 2. For VPLS 2, the EVI is greater than 65535, so the RD must always be configured (manual configuration or auto-RD). The RT is auto-derived in VPLS 1 and VPLS 2. For VPLS 2, the **evi-three-byte-auto-rt** command is configured to enable auto-derivation of RTs for EVI values up to 16777215. On all core PEs, **evi-route-target-set** is enabled for the aggregation of AD per-ES routes. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure exclusive
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2
                community-value {
                    start 2000
                    end 2999
                }
            }
            bgp {
                evpn {
                    ethernet-segment "I-ES23" {
                        admin-state enable
                        type virtual
                        esi 00:00:00:00:00:23:23:00:00:01
```

```
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp 1 {
                route-distinguisher auto-rd    # RD cannot be auto-derived from EVI
            }
            bgp 2 {
                route-distinguisher auto-rd
            }
            bgp-evpn {
                evi 100002
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    evi-three-byte-auto-rt true
                }
                mpls 2 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    evi-three-byte-auto-rt true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

When configuring the **evi-route-target-set** command, the RD must be different from the RD in the auto-rd range. If not, the following error message is raised:

```
*[ex:/configure service system bgp evpn ad-per-es-route]
A:admin@PE-2# route-distinguisher-ip-address 192.0.2.2

*[ex:/configure service system bgp evpn ad-per-es-route]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service system bgp-auto-rd-range ip-address - Inconsistent Value
 error - cannot be the same as ad-per-es-route/route-distinguisher-ip-address - configure
 service system bgp evpn ad-per-es-route route-distinguisher-ip-address
```

The following command shows the RD and RT values for both BGP instances in VPLS 1 on PE-2:

```
[/]
A:admin@PE-2# show service id 1 bgp

-------------------------------------------------------------------------------
===============================================================================
```

RD 192.0.2.2:1 for BGP instance 1 is auto-derived whereas RD 192.0.2.2:2000 for BGP instance 2 is the result of auto-RD. RT 64496:1 is auto-derived based on the system IP address and the EVI. It is possible to configure **evi-three-byte-auto-rt true** in VPLS 1, even though the EVI value is smaller than 65535.

```
# on PE-2:
configure {
    service {
        vpls "VPLS-1" {
            bgp-evpn {
                vxlan 1 {
                    evi-three-byte-auto-rt true
                }
                mpls 2 {
                    evi-three-byte-auto-rt true
                }
            }
```

In this case, the auto-derivation is based on RFC 8365 and the value is 64496:1090519041 (0x41000001) for BGP 1 and 64496:1107296257 (0x42000001) for BGP 2.

```

The auto-derived RTs on the other nodes are the same as on PE-2 when the BGP instance is the same. On PE-2, PE-3, PE-4, and PE-5, BGP 1 is for VXLAN and BGP 2 is for MPLS in the core. That way, EVPN messages can be exchanged in BGP instance 2 between the core PEs.

AD per-ES aggregation is enabled on the core nodes. The following command on PE-2 shows one AD per-ES with RD 10.0.2.4:390 (10.0.2.4 is the RD configured for **evi-route-target-set** and 390 is the *comm-val* value for the EVI range from 99974 to 100230) and one AD per-EVI with RD 192.0.2.4:2002 (auto-RD).

Instead of VXLAN or MPLS, SRv6 can be used too. As an example,VPLS 6 with EVI 100006 (0x186A6) is configured on PE-1, PE-2, PE-4, and PE-6. SRv6 is configured between PE-4 and PE-6, as described in the *Segment Routing over IPv6* chapter. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS-6" {
            admin-state enable
            service-id 6
            customer "1"
            vxlan {
                instance 1 {
                    vni 6
                }
            }
            segment-routing-v6 1 {
                locator "PE-2_loc" {
                    function {
                        end-dt2u {
                        }
                        end-dt2m {
                        }
                    }
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
            }
            bgp 2 {
                route-distinguisher auto-rd
            }

```

Conclusion

In large networks, a three-byte EVI can be required as a unique identifier for services. RTs can be auto-derived based on a three-byte EVI, but RDs cannot be auto-derived that way.

VCCV BFD for Epipe Services

This chapter describes the VCCV BFD for Epipe services.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R7. The MD-CLI in the current edition corresponds to SR OS Release 23.7.R1.

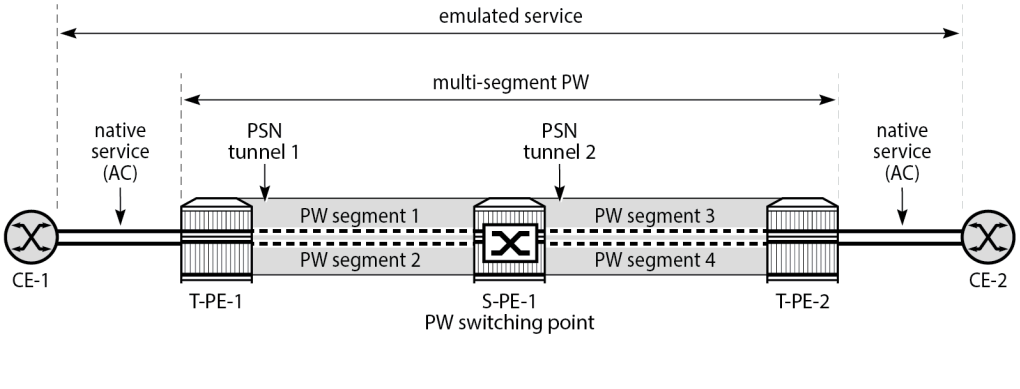
Overview

Virtual circuit connectivity verification (VCCV) is defined by RFC 5085. Bidirectional forwarding detection (BFD) is defined by RFC 5880.

VCCV is an end-to-end fault-detection tool for testing pseudowires (PWs), and typically requires an operator to take manual actions. The PWs can be used for virtual leased line (VLL), virtual private LAN service (VPLS), and Internet enhanced service (IES)/virtual private routed network (VPRN) services with Epipe or Ipipe spoke-SDPs.

SR OS supports RFC 5885 which specifies a method for carrying BFD messages in a PW-associated channel and is referred to as VCCV BFD in SR OS. Because the associated channel shares fate with the data plane, VCCV BFD monitors the PW between two terminating PEs (T-PEs), regardless of the number of provider routers or switching PEs (S-PEs) the PW may traverse; see Figure 275: PW reference model. When enabled, faults in individual PWs can be detected quickly, whether or not other provider routers or S-PEs also carry other PWs. VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in a minimum amount of time is critical.

Figure 275: PW reference model



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VCCV BFD avoids manual hop-by-hop troubleshooting of each element along the path of the PW, which minimizes the probability of not detecting silent failures on intermediate routers.

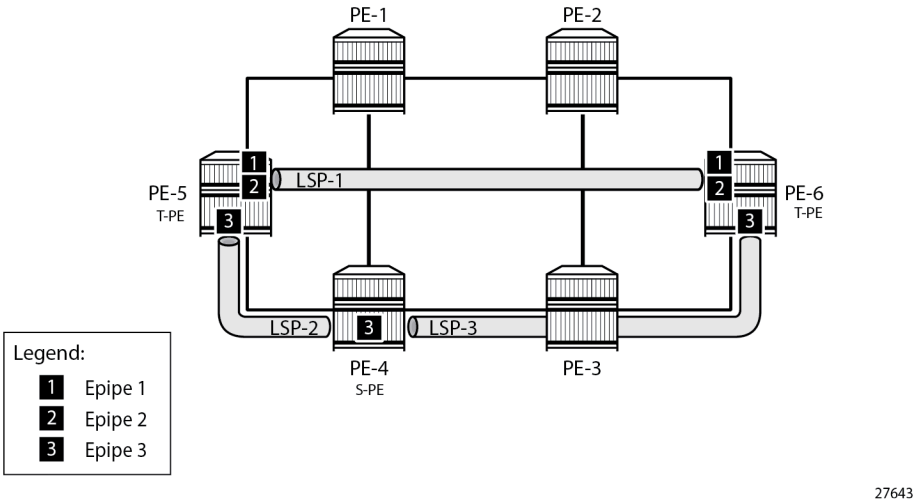
VCCV BFD sessions run end-to-end on a switched or single-hop PW, from T-PE to T-PE. They do not terminate on an intermediate S-PE; therefore, the TTL of the PW label on VCCV BFD packets is always set to 255, to ensure that the packets reach the far-end T-PE of a multi-segment PW.

BFD is only used for fault detection. While RFC 5885 provides a mode in which VCCV BFD can be used to signal PW status, this mode is only applicable for PWs that have no other status signaling mechanism in use. LDP status and static PW status signaling always take precedence over BFD-signaled PW status, and BFD-signaled PW status is not used on PWs that use LDP status or static PW status signaling mechanisms.

Configuration

Figure 276: Example topology shows the example topology with Epipes "Epipe-1" and "Epipe-2" using LSP "lsp-1" between PE-5 and PE-6 and Epipe "Epipe-3" using LSP "lsp-2" between PE-5 and S-PE PE-4 and LSP "lsp-3" between PE-4 and PE-6.

Figure 276: Example topology



The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled
- MPLS paths and LSPs:
  - LSP "lsp-1" configured on PE-5 with primary path "path-5-1-2-6" and on PE-6 with primary path "path-6-2-1-5"
  - LSP "lsp-2" configured on PE-5 with primary path "path-5-4" and on PE-4 with primary path "path-4-5"
  - LSP "lsp-3" configured on PE-4 with primary path "path-4-3-6" and on PE-6 with primary path "path-6-3-4"

VCCV BFD configuration

Three steps are needed when configuring VCCV BFD:

1. Configure the BFD template
2. Apply the BFD template
3. Enable BFD

Step 1: configure BFD template

The **bfd-template** command provides the control packet timer values for the BFD.

The general command to define a BFD template is as follows:

```
configure {
    bfd {
        bfd-template <name> {
            echo-receive <echo-interval>
            multiplier <multiplier>
            receive-interval <receive-interval>
            transmit-interval <transmit-interval>
            type {cpm-np}
```

However, network processor BFD (cpm-np) is not supported for VCCV, and the minimum supported receive or transmit timer interval is 100 ms. An error is generated if a user tries to apply a BFD template with the **type cpm-np** command or any unsupported transmit or receive interval value. An error is also generated when the user attempts to commit changes to a BFD template that is already bound to a spoke-SDP.

Steps 2 and 3: apply BFD template and enable BFD

To apply and enable the BFD template to a spoke-SDP where LDP is used as the SDP signaling protocol for a service, the following command can be used, depending on the service:

```
configure {
    service {
        [epipe|cpipe|ipipe|vpls|ies|vprn] <name> {
            spoke-sdp <sdp-binding-id> {
                bfd {
                    bfd-template <name>
                    bfd-liveness {
                    }
```

If BGP is used as the SDP signaling protocol, the following command is used:

```
configure {
    service {
        [epipe|vpls] <name> {
            bgp 1 {
                pw-template-binding <reference> {
                    bfd 1 {
                        bfd-template <name>
                        bfd-liveness true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In this example, the following BFD templates are configured on PE-5 and PE-6:

```
# on PE-5, PE-6:
configure {
    bfd {
        bfd-template "bfdt-1" {
            multiplier 5
            receive-interval 2000
            transmit-interval 2000
        }
        bfd-template "bfdt-2" {
            receive-interval 1000
            transmit-interval 1000
        }
```

These BFD templates are used in the Epipe services configured in the next section.

Service configuration

LDP VLL "Epipe-1"

The service "Epipe-1" is an LDP VLL running between PE-5 and PE-6, and uses manually configured SDP 56 on PE-5 and SDP 65 on PE-6, respectively, so the signaling is set to T-LDP. On PE-5, the spoke-SDP 56:1 has BFD template *bfdt-2* applied, and BFD is enabled. The configuration on PE-6 is similar.

```
# on PE-5:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 56:1 {
                bfd {
                    bfd-template "bfdt-2"
                    bfd-liveness {
                    }
                }
            }
            sap 1/1/c4/1:1 {
            }
        }
        sdp 56 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            lsp "lsp-1" { }
        }
```

Log 99 indicates the local discriminator value used for the VCCV BFD session, as follows:

```
95 2023/08/21 08:23:10.590 CEST MINOR: VRTR #2070 Base 127.0.0.1
"The vccv BFD session with Local Discriminator 1 on Svc 1 SdpBind 56:1 is up"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Configuring the spoke-SDP with a template with an invalid type (for example, type "cpm-np") or with invalid transmit or receive intervals leads to errors, as follows:

```
[ex:/configure service epipe "Epipe-1" spoke-sdp 56:1 bfd]
A:admin@PE-5# bfd-template "bfdt-cpm-np-50ms"

*[ex:/configure service epipe "Epipe-1" spoke-sdp 56:1 bfd]
A:admin@PE-5# commit
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
- bfd-template transmit-interval must be minimum 100 for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" transmit-interval
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
- bfd-template receive-interval must be minimum 100 for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" receive-interval
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
- bfd-template type is not valid for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" type
```

BGP VPWS "Epipe-2"

The service "Epipe-2" is a BGP VPWS, also running between PE-5 and PE-6, using the manually configured SDPs 561 and 651 with the signaling set to BGP, as follows. Again, BFD template *bfdt-2* is used, but now the BFD template is referred to from the **pw-template-binding** context. See the BGP Virtual Private Wire Services chapter for more information.

```
# PE-5:
configure {
    service {
        pw-template "1" {
            provisioned-sdp prefer
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "65545:2"
                route-target {
                    export "target:65545:2"
                    import "target:65545:2"
                }
                pw-template-binding "1" {
                    bfd-template "bfdt-2"
                    bfd-liveness true
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-5"
                    id 5
                }
                remote-ve "PE-6" {
                    id 6
                }
            }
            sap 1/1/c4/1:2 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
        sdp 561 {
            admin-state enable
            delivery-type mpls
            signaling bgp
            far-end {
                ip-address 192.0.2.6
            }
            lsp "lsp-1" { }
        }
```

LDP VLL "Epipe-3" with switching node PE-4

The service "Epipe-3" is another LDP VLL running between PE-5 and PE-6, but switched at PE-4. It uses the manually configured SDPs 54 and 45 between PE-5 and PE-4, and SDPs 46 and 64 between PE-4 and PE-6. All these SDPs are using T-LDP for the signaling. On PE-5, the spoke-SDP 54:3 has BFD template "bfdt-1" applied, and **control-word** is active. This ensures that BFD packets get into the PW mapping to that spoke-SDP and that these packets are forwarded between the VC-switched spoke-SDPs at PE-4. The configuration on PE-6 is similar.

```
# on PE-5:
configure {
    bfd {
        bfd-template "bfdt-1" {
            multiplier 5
            receive-interval 2000
            transmit-interval 2000
        }
    }
    service {
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            spoke-sdp 54:3 {
                control-word true
                bfd {
                    bfd-template "bfdt-1"
                    bfd-liveness {
                    }
                }
            }
            sap 1/1/c4/1:3 {
            }
        }
        sdp 54 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.4
            }
            lsp "lsp-2" { }
        }
```

For PE-4 to switch traffic from one VC to another, **vc-switching true** is configured in the Epipe, as follows:

```
# on PE-4:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            vc-switching true      # S-PE
            spoke-sdp 45:3 {
            }
            spoke-sdp 46:3 {
            }
        }
        sdp 45 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.5
            }
            lsp "lsp-2" { }
        }
        sdp 46 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            lsp "lsp-3" { }
        }
```

VCCV BFD verification

The following command shows that BFD template "bfdt-2" is applied to SDP 56:1 in the "Epipe-1" service and to SDP 561:4294967295 in the "Epipe-2" service:

```
[/]

```
1                   56:1                            yes            ipv4
2                   561:4294967295                  yes            ipv4
===============================================================================
```

The BFD configuration for SDP 56:1 on the "Epipe-1" service is listed in the detailed output for the SDP, as follows. The BFD template used is *bfdt-2*, BFD is enabled, and the BFD encapsulation used is IPv4. The peer VCCV CV bits indicate that the remote end supports LSP ping as well as BFD fault detection.

Similar output can be obtained on PE-6.

Disconnecting the link between PE-1 and PE-2 affects the traffic taking the upper path; the VCCV BFD sessions for the services "Epipe-1" and "Epipe-2" go down, and so do the SDPs and the services. This is reflected in log 99, as follows:

```
# on PE-5:
132 2023/08/21 08:29:40.782 CEST WARNING: MPLS #2012 Base VR 1:

```

Conclusion

VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in the minimal amount of time is critical. VCCV BFD complements other on-demand tools such as VCCV ping and VCCV trace by providing proactive detection of faults. VCCV ping and VCCV trace can later be used to localize and diagnose the root cause of the fault.

Virtual Ethernet Segments

This chapter provides information about Virtual Ethernet Segments.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

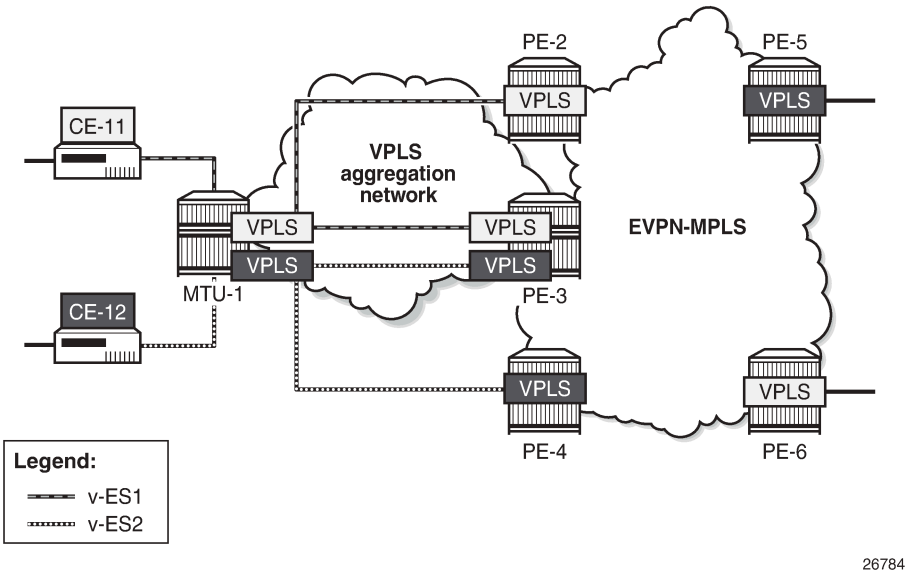
Applicability

This chapter was initially written based on SR OS Release 15.0.R3, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. Virtual Ethernet segments are supported in SR OS Release 15.0.R1, and later.

Overview

RFC 7432 describes the use and procedures for Ethernet segments (ESs) that can be associated with physical Ethernet ports and LAGs. The SR OS implementation also allows an ES to be associated with SDPs. ESs meet the redundancy requirements of directly connected CEs. However, ESs will not work when an aggregation network exists between CEs and ES PEs, which requires different ESs to be defined for the port, LAG, or SDP. *Draft-ietf-bess-evpn-virtual-eth-segment* describes how virtual ESs (vESs) can be defined with an Attachment Circuit (AC) level granularity. Figure 277: vESs for PWs shows an example where vES definition at the pseudowire (PW) granularity level is required:

Figure 277: vESs for PWs



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When a Layer 2 aggregation network is used to get access to EVPN, the association of ACs that belong to the same ES and physical ports or SDPs can be arbitrary. For example, the SDP between MTU-1 and PE-3 (Figure 277: vESs for PWs) cannot be associated with only one ES, because it is being used by two different CEs that require different ESs. The association must be at spoke-SDP level. The RFC 7432 port/lag-based ES definition is not sufficient, so vESs need to be defined. Virtual ESs can be configured with up to eight ranges of one or more:

- VC-IDs (spoke-SDPs)
- Q-tags (dot1q)
- S-tags (qinq)
- C-tags for a fixed S-tag (qinq)

Mesh-SDPs are not allowed for an SDP used by a vES.

Virtual ESs are configured as Ethernet segments of type virtual:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-1"]
A:admin@PE-2# type ?

 type <keyword>
 <keyword>  - (none|virtual)
 Default    - none

 'type' is: immutable

    Type of the ethernet segment.

    Warning: Modifying this element recreates
    'configure service system bgp evpn ethernet-segment "ESI-1"' automatically for the
 new value to take effect.
```

Virtual ES "vESI-23_600" is associated with LAG 1 and one service-delimiting VLAN range is defined for the S-tag, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_600" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:06:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                            virtual-ranges {
                                qinq {
                                    s-tag 600 {
                                        end 602
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
```

The configured ES will match all the SAPs for which the top (outer) service-delimiting tag is within the 600 to 602 range.

When the ES is created as virtual, a port, LAG, or SDP needs to be created before any VLAN or VC-ID can be associated.

- For VC-ID, only spoke-SDPs are allowed, no mesh-SDPs. Manual spoke-SDP VC-IDs and BGP-AD VC-IDs can be included in the range.
- For dot1q, only those SAPs that match the service-delimiting VLAN range will be associated with the vES
- For qinq, the following two commands can be configured, with a mutually exclusive S-tag:
  - **s-tag <qtag1> end <qtag1>** - associates all qinq SAPs with outer tag between the configured qtags.
  - **s-tag-c-tag <qtag1> c-tag-start <qtag2> c-tag-end <qtag2>** - associates all qinq SAPs with outer qtag1 and inner qtag between the configured qtag2 values to the vES

  A mutually exclusive S-tag means that a value for the S-tag can be configured in either of the two commands, but not in both.

Table 14: Supported examples for Q-tag values between 1 and 4094 shows the supported examples for qtag values between 1 and 4094; Table 15: Supported examples for Q-tag values 0, *, and null shows the supported examples for qtag values 0, *, and null:

Table 14: Supported examples for Q-tag values between 1 and 4094

vES configuration for port 1/1/1	SAP association
dot1q qtag 100	1/1/1:100
dot1q qtag-range 100 to 102	1/1/1:100, 1/1/1:101, 1/1/1:102
qinq s-tag 100 c-tag 200	1/1/1:100.200
qinq s-tag 100 c-tag-range 200 to 202	1/1/1:100.200, 1/1/1:100.201, 1/1/1:100.202
qinq s-tag 100	All SAPs 1/1/1:100.x (x being 1 to 4094, 0, or *)
qinq s-tag-range 100 to 102	All SAPs 1/1/1:100.x, 1/1/1:101.x, 1/1/1:102.x (x being 1 to 4094, 0, or *)

*Table 15: Supported examples for Q-tag values 0, *, and null*

vES configuration for port 1/1/1	SAP association
dot1q qtag 0	1/1/1:0

vES configuration for port 1/1/1	SAP association
dot1q qtag *	1/1/1:*
qinq s-tag 0 c-tag *	1/1/1:0.*
qinq s-tag * c-tag *	1/1/1:*.*
qinq s-tag * c-tag null	1/1/1:*.null

Considerations:

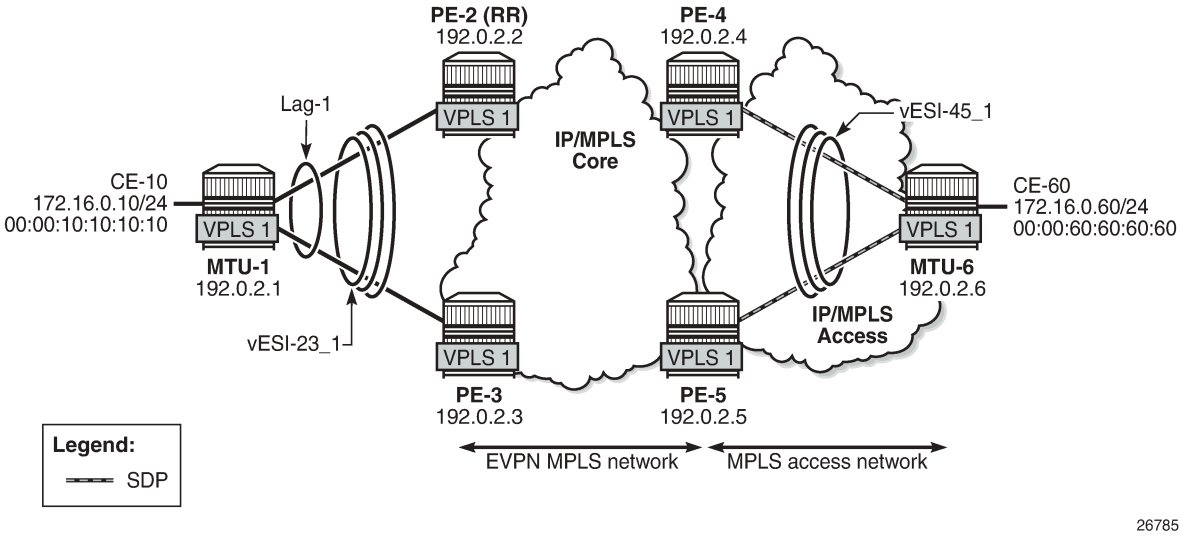
- The ranges can be modified on the fly for qtag, s-tag/c-tag, or vc-id.
- For port-based vESs, PXC sub-ports are supported. For more information about PXC, see the "Port Cross-Connect (PCX)" chapter in the Interface Configuration volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.
- Virtual ESs are supported in EVPN-MPLS, PBB-EVPN, and EVPN-VPWS
- Virtual ESs are supported in single-active and all-active EVPN multi-homing
  - Two all-active vESs must use different ES-BMAC addresses, even if they are defined in the same LAG.
- Virtual ESs implement CMAC flush procedures described in RFC 7623. Optionally, ISID-based CMAC-flush can be used where the single-active vES does not use ES-BMAC allocation. See chapter PBB-EVPN ISID-based CMAC Flush.
- Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. For more information about CP-SAPs, see chapter VLAN Range SAPs for VPLS and Epipe Services.

Configuration

Figure 278: Example topology shows the example topology with four core PEs in an EVPN-MPLS network and two MTUs. VPLS 1 is configured in all the nodes. EVPN is configured on the core PEs, not on the MTUs. LAG 1 is configured on MTU-1, PE-2, and PE-3 and associated with an all-active vES "ESI-23_1" on PE-2 and PE-3. A single-active vES "ESI-45_1" is configured on PE-4 and PE-5, associated with SDPs.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 278: Example topology



The configuration is similar to the one in chapter EVPN for MPLS Tunnels, where the parameters are described in detail.

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be configured)
- LDP in the IP/MPLS core and IP/MPLS access network

LAG 1 is configured with qinq encapsulation. The LAG configuration on MTU-1 is as follows:

```
# on MTU-1:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type qinq
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32768
        }
        port 1/1/1 {
        }
        port 1/1/2 {
        }
    }
```

BGP is configured on all PEs for address family EVPN. PE-2 is the Route Reflector (RR) and is configured as follows.

```
# on RR PE-2:
configure {
    router "Base" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

VPLS 1 is configured on all nodes. On the PEs, BGP-EVPN is enabled for MPLS. The following is configured on PE-2:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:1.1 {
            }
        }
```

The configuration on the other PEs is similar, but on PE-4 and PE-5, a spoke-SDP is configured instead of a SAP. The service configuration on PE-4 is as follows:

```
# on PE-4:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            spoke-sdp 46:1 {
            }
        }
```

Virtual ESs must be configured with type **virtual**; if not, the following error is raised after an attempt to define virtual ranges:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-3" association lag "lag-1"]
A:admin@PE-2# virtual-ranges {
MINOR: MGMT_CORE #2203: configure service system bgp evpn ethernet-segment "ESI-3" association
 lag "lag-1" virtual-ranges - Invalid element - virtual-ranges allowed only on virtual
 ethernet-segments
```

On PE-2 and PE-3, the two following two all-active multi-homing vESs are created, each with a unique ESI:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:01:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag-c-tag 495 c-tag-start 100 {
                                            c-tag-end 102
                                        }
```

© 2023 Nokia.

```
                                    s-tag 1 {
                                        end 1
                                    }
                                    s-tag 500 {
                                        end 501
                                    }
                                }
                            }
                        }
                    }
                ethernet-segment "vESI-23_600" {
                    admin-state enable
                    type virtual
                    esi 01:00:00:00:00:23:06:00:00:01
                    multi-homing-mode all-active
                    df-election {
                        es-activation-timer 3
                        service-carving-mode manual
                        manual {
                            evi 2 {
                                end 2
                            }
                        }
                    }
                    association {
                        lag "lag-1" {
                            virtual-ranges {
                                qinq {
                                    s-tag 600 {
                                        end 602
                                    }
                                }
                            }
                        }
                    }
                }
            }
```

When attempting to configure another vES with the ESI of an existing ES/vES, the following error is raised:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_610"]
A:admin@PE-2# esi 01:00:00:00:00:23:06:00:00:01

*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_610"]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_610" -
 Inconsistent value - esi 01:00:00:00:00:23:06:00:00:01 in use by ethernet segment vESI-23_600
```

Multiple vESs can be defined on the same LAG. However, the ranges should not overlap. The following error is raised after attempting to configure an additional range in vES "ESI-23_600" that uses S-tag 600 in combination with a range of C-tags. S-tag 600 is already included in the first range: **s-tag 600 end 602**. The error message points out that this range is of a different type: the existing range defines only S-tags, whereas the new range defines a range of C-tags for S-tag 600.

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_600" association lag "lag-1"
 virtual-ranges qinq s-tag-c-tag 600 c-tag-start 100]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_600"
 association lag "lag-1" virtual-ranges qinq s-tag-c-tag 600 c-tag-start 100 - Inconsistent
 value - range overlaps with range of a different type in this ethernet-segment
```

When attempting to define **s-tag 1** in "vESI-23_2", when S-tag 1 is already defined in "vESI-23_1", the following error is raised:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_600" association lag "lag-1"
 virtual-ranges qinq s-tag 1]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_600"
 association lag "lag-1" virtual-ranges qinq s-tag 1 - Inconsistent value - range overlaps with
 range in ethernet-segment vESI-23_1
```

On PE-4, the following single-active multi-homing vESs are configured. The configuration on PE-5 contains a different SDP.

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:01:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
                                    vc-id 1 {
                                        end 1
                                    }
                                    vc-id 500 {
                                        end 501
                                    }
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-45_2" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:02:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                            }
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
                                    vc-id 2 {
                                        end 2
                                    }
                                }
                            }
```

The ranges in the vES can be modified while the vES is operationally up, for example, an S-tag range can be added as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-23_1" {
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 10 {
                                            end 10
                                        }
                                    }
                                }
```

The S-tag ranges can be verified with the following command. Compared with the preceding output, the S-tag 10 has been added:

```
[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "vESI-23_1" virtual-ranges |
 match S-Tag post-lines 8
S-Tag Ranges

Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. CP-SAP 10 is created on PE-3, as follows:

```
# on PE-3:
configure {
    connection-profile vlan 10 {
        qtag-range 5 {
            end 100
        }
        qtag-range 495 {
            end 495
        }
```

The following vES is configured on PE-3:

```
# on PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_10" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:10:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            port 1/2/3 {
                                virtual-ranges {
                                    qinq {
                                        s-tag 100 {
                                            end 100
                                        }
                                    }
                                }
                            }
                        }
                    }
```

This vES can only be configured when no CP-SAPs are defined on port 1/2/3. The following error message is raised when a CP-SAP is configured on port 1/2/3 already and the vES is configured afterward:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_10" association port 1/2/3
 virtual-ranges qinq s-tag 100]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/3:100.cp-10 - connection
 profile saps not allowed on port/lags associated with evpn ethernet-segments - configure
 service system bgp evpn ethernet-segment "vESI-23_10" association
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When attempting to configure CP-SAP 1/2/3:cp-10 in VPLS 1 with port 1/2/3 associated with a vES, the following error message is raised.

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/3:100.cp-10]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/3:100.cp-10 - connection
 profile saps not allowed on port/lags associated with evpn ethernet-segments - configure
 service system bgp evpn ethernet-segment "vESI-23_10" association
```

Conclusion

Regular ESs and vESs can be associated with ports, LAGs, and SDPs; in case of vES, ranges of Q-tags, S-tags, C-tags, or VC-IDs can be defined. The granularity for vES is per AC. Multiple vESs with different ESIs can be defined on the same port, LAG, or SDP.

VLAN Range SAPs for VPLS and Epipe Services

This chapter provides information about VLAN range SAPs for VPLS and Epipe services.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. Connection-Profile VLAN SAPs (CP SAPs) are supported in SR OS Release 14.0.R1, and later.

Overview

Backhaul services through metro Ethernet networks require bundled interface support. In SR OS terminology, bundling refers to Connection-Profile VLAN SAPs (CP SAPs)—special SAPs that capture the traffic of a range of CE VLAN IDs (VIDs) entering an Ethernet port. CP SAPs are fully compatible with Metro Ethernet Forum (MEF) 10.3 bundling service attributes and RFC 7432 EVPN VLAN bundle service interfaces. CP SAPs are supported in Layer 2 services only, and can be configured together with other SAPs and/or SDP-bindings.

For frames with an ingress VID contained in the range configured in the SAP's CP, the behavior is similar to default SAPs, such as 1/1/1:*, where "*" spans the entire VID range from 0 to 4095 and serves as a wildcard. However, unlike a default SAP, a CP SAP cannot co-exist with a VLAN SAP that is in the same range and on the same port or LAG. For example, 1/1/1:* and 1/1/1:100 can co-exist whereas 1/1/2:cp-1 (where cp-1 corresponds to the VLAN range from 1 to 200) and 1/1/2:100 cannot co-exist.

The VLAN manipulation between VLAN SAPs, default SAPs, and CP SAPs is compared in Table 16: VLAN manipulation in SAPs .

Table 16: VLAN manipulation in SAPs

	VLAN SAP	Default SAP	CP SAP
Service-delimiting VLAN	Yes For example: VLAN 100 in 1/1/1:100	No	No
Push/pop VLAN tags in egress/ ingress frames	Yes	No	No
VLAN translation	Yes	No	No

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 279: Customer VID is popped and pushed by VLAN SAPs - VLAN translation shows how dot1q VLAN SAPs pop the customer VLAN tag in ingress frames and push the VLAN tag in egress frames. Therefore, frames are untagged between PE-1 and PE-2. VLAN translation is possible when the VIDs in the VLAN tags that are popped or pushed at the SAPs are different at ingress and egress, as follows.

Figure 279: Customer VID is popped and pushed by VLAN SAPs - VLAN translation

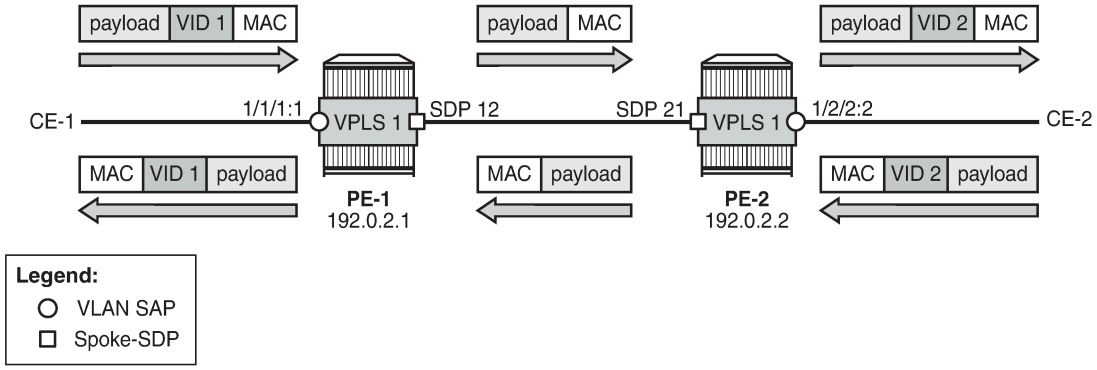

Figure 280: Customer VID is preserved between dot1q CP SAPs - no VLAN translation shows that dot1q CP SAPs do not pop or push the CE VID. Frames keep the same tag end-to-end; therefore, VLAN translation is not possible.

Figure 280: Customer VID is preserved between dot1q CP SAPs - no VLAN translation

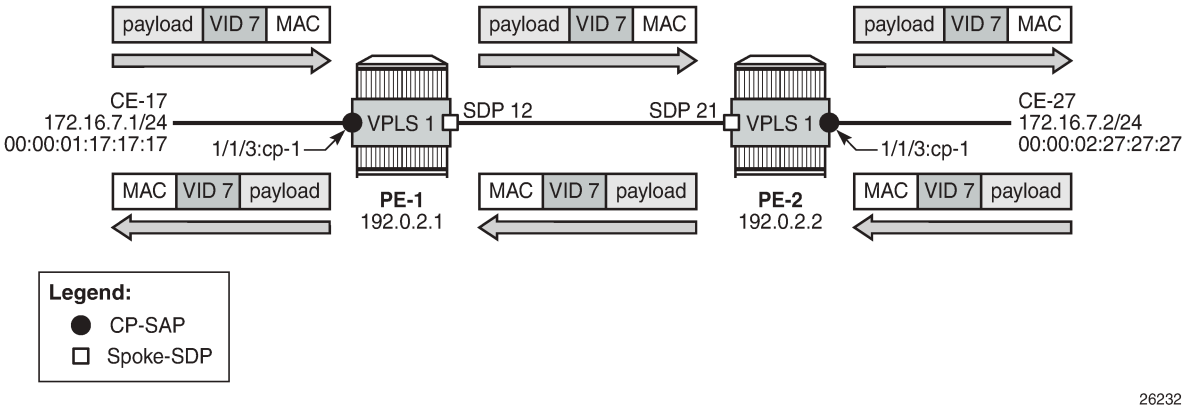

Figure 281: Customer VID is preserved between QinQ CP SAPs - no VLAN translation shows that QinQ CP SAPs only pop or push the service delimiting VID (VID 100), but not the customer VID in the CP range, as follows:

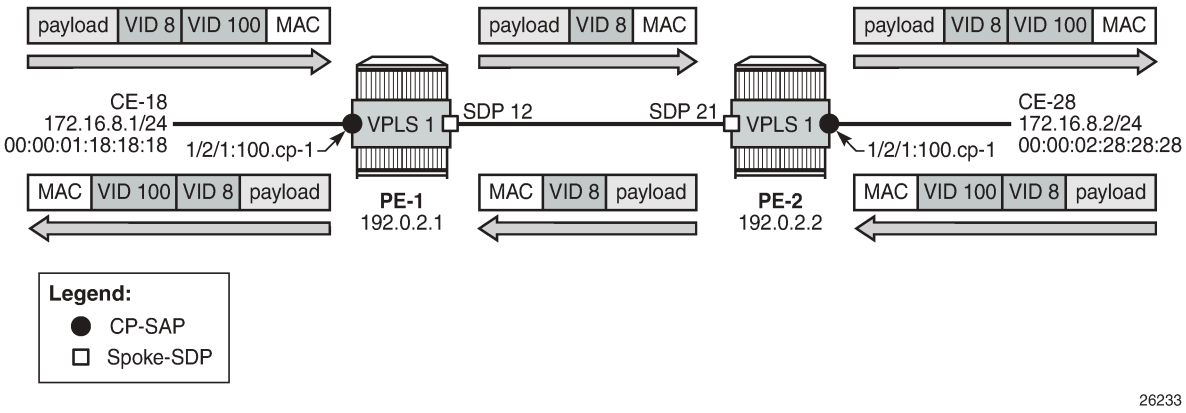
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 281: Customer VID is preserved between QinQ CP SAPs - no VLAN translation



VID 100 is service delimiting and can be different in both SAPs, but the customer VID in the VLAN range of the CP is not.

Connection profile VLAN

Note:
The **connection-profile>vlan** context is different from the connection-profile used for ATM connectivity.

CP SAPs refer to connection profiles that can contain up to 32 ranges of customer VIDs. Connection profiles are configured with the following command:

```
[ex:/configure connection-profile]
A:admin@PE-1# vlan ?

 [connection-profile-id] <number>
 <number>  - <1..8000>

    Identifier of this connection profile
```

VLAN ranges in a CP contain one or more consecutive VIDs, as follows:

```
*[ex:/configure connection-profile vlan 10]
A:admin@PE-1# qtag-range ?

 [start] <number>
 <number>  - <1..4094>

    Lower bound of VLAN range for connection profile
```

```
*[ex:/configure connection-profile vlan 10]
A:admin@PE-1# qtag-range 150 ?

 qtag-range

 Immutable fields      - end

 apply-groups          - Apply a configuration group at this level
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 apply-groups-exclude  - Exclude a configuration group at this level
 end                   - Upper bound of VLAN range for connection profile
```

Following is an example of a CP configuration containing three non-overlapping VLAN ranges:

```
configure {
    connection-profile {
        vlan 10 {
            qtag-range 5 {
                end 100
            }
            qtag-range 150 {
                end 300
            }
            qtag-range 350 {
                end 350
            }
        }
```

Overlapping ranges are not allowed within the same CP. The following error is raised when attempting to add a VLAN range from 7 to 9 to the preceding CP.

```
*[ex:/configure connection-profile vlan 10 qtag-range 7]
A:admin@PE-1# commit
MINOR: SVCMGR #9012: configure connection-profile vlan 10 - Overlapping range - configure
 connection-profile vlan 10 qtag-range 7 end
```

Additional VLAN ranges can be configured to the CP defined in an existing and operationally up SAP. The CP's VLAN ranges can also be removed on the fly. When a user wants to extend a VLAN range, for example, VLAN range 350 becoming a range from 350 to 400, the existing VLAN range is overwritten, as follows:

```
[ex:configure connection-profile vlan 10]
A:admin@PE-1# qtag-range 350 {

[ex:configure connection-profile vlan 10 qtag-range 350]
A:admin@PE-1# end 400

*[ex:configure connection-profile vlan 10 qtag-range 350]
A:admin@PE-1# }

*[ex:configure connection-profile vlan 10]
A:admin@PE-1# commit

[ex:configure connection-profile vlan 10]
A:admin@PE-1# info
    qtag-range 5 {
        end 100
    }
    qtag-range 150 {
        end 300
    }
    qtag-range 350 {
        end 400
    }
```

The following example shows three VLAN ranges in CP 10, with a timestamp of the last change for each VLAN range:

```

```

If a VLAN tag combination matches different SAPs, the highest priority SAP will be picked regardless of the operational status. For completeness, the following two tables show the SAP lookup matching order for dot1q and QinQ ports.

Table 17: SAP lookup order for dot1q ports

Incoming frame qtag VID value	**SAP lookup precedence order (:0 and :* are mutually exclusive on the same port)**			
	:X	**:CP**	**:0**	**:***
X (belongs to the CP range)	1st	1st		2nd
0			1st	1st
<untagged>			1st	1st

Table 18: SAP lookup order for QinQ ports

Incoming frame qtag1.qtag2	**System/port settings = new-qinq-untagged-sap SAP lookup precedence order (assumption: X and Y are defined in CP ranges)**							
	:X.Y	**:X.0**	**:X.CP**	**:CP.***	**:X.***	**:0.***	**:*.null**	**:*.***
X.Y	1st		1st	2nd	2nd			3rd
X.0		1st		2nd	2nd			3rd
0.Y						1st		2nd
0.0						1st		2nd
X		1st		2nd	2nd		3rd	4th
0						1st	2nd	3rd

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Incoming frame qtag1.qtag2	System/port settings = new-qinq-untagged-sap SAP lookup precedence order (assumption: X and Y are defined in CP ranges)							
	:X.Y	:X.0	:X.CP	:CP.*	:X.*	:0.*	:*.null	:*.*
<untagged>						1st	2nd	3rd

For example, ingress frames with VIDs 100.20 are classified as part of CP SAP 1/2/1:100.cp-10, not of CP SAP 1/2/3:cp-10.*. Only when SAP 1/2/1:100.cp-10 is removed from the configuration, frames with VIDs 100.20 will go to SAP 1/2/3:cp-10.*.

Assign CP SAPs to VPLS or Epipe services

Like ordinary SAPs, CP SAPs can be assigned to VPLS or Epipe services, as follows. The VPLS and Epipe can be EVPN services or not. In the following example, VPLS 1 has BGP-EVPN enabled, whereas Epipe 2 does not:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            spoke-sdp 12:2 {
            }
            sap 1/2/1:200.cp-10 {
            }
        }
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/3:cp-10 {
            }
            sap 1/2/1:1.11 {
            }
            sap 1/2/1:100.cp-10 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap 1/2/3:cp-10.* {
            }
        }
```

CP SAPs are configured in the same way as VLAN SAPs and default SAPs, with the following restrictions:

- A CP can be defined for inner or outer tags as shown in the preceding configuration, but not both at the same time, as follows:

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:cp-3.cp-10]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/1:cp-3.cp-10 - SAP and port
 encapsulation values are incompatible - configure port 1/2/1 ethernet encap-type
```

- If a CP is defined for the outer VID, the inner VID cannot be a specific VID, as follows. The inner VID can only be a "*" (where the inner tag can have any value) or a "0" (where the inner tag can be 0 or null).

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:cp-3.4]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/1:cp-3.4 - SAP and port
 encapsulation values are incompatible - configure port 1/2/1 ethernet encap-type
```

- No VLAN SAP can be added on a port in dot1q (or a combination of port and service-delimiting VLAN in case of QinQ) when the VLAN is included in the VLAN range in a CP SAP on the same port. One of the VLAN ranges in CP 10 contains all VIDs from 5 to 100. Therefore, it is not allowed to configure a VLAN SAP with VID 100 on port 1/1/3, where a CP SAP is configured with CP 10, as follows:

```
*[ex:/configure service vpls "VPLS 1" sap 1/1/3:100]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:100 - Configuration change
 failed validation - sap conflicts with connection-profile-vlan 10
```

- No CP SAPs can be added with overlapping VLAN ranges on the same port for dot1q (or on the same port- and service-delimiting tag for QinQ), as follows. CP 1 contains VLAN range from 7 to 9, which overlaps with VLAN range from 5 to 100 in CP 10.

```
# on PE-1:
configure {
    connection-profile {
        vlan 1 {
            qtag-range 7 {
                end 9
            }
```

```
*[ex:/configure service vpls "VPLS 1" sap 1/1/3:cp-1]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:7 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:8 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:9 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
```

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:100.cp-1]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.7 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.8 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.9 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
```

However, the CP can be referred to by SAPs on other ports for dot1q or for QinQ on other combinations of port and service-delimiting VLAN.

- CP SAPs can be added when they contain non-overlapping VLAN ranges on the same port, as follows. CP 3 contains one VLAN range with only one VID: 3. This VLAN range (3) does not overlap with any VLAN range in the CP SAPs assigned to VPLS 1.

```
# on PE-1:
configure {
    connection-profile {
        vlan 3 {
            qtag-range 3 {
                end 3
            }
        }
    }
    service {
        vpls "VPLS 1" {
            sap 1/1/3:cp-3 {
            }
            sap 1/2/1:100.cp-3 {
            }
```

VPLS 1 contains the following SAPs. There is no overlap between the VLAN ranges on a port (or port and service-delimiting tag for QinQ).

```
[/]
A:admin@PE-1# show service id 1 sap

```

Constraints to be considered when applying CP SAPs in Layer 2 services are described in the Release Notes, section "Known Limitations" - "Services General".

Consumed resources for CP SAPs

The following SAPs are used on PE-1: nine SAPs are used in VPLS 1 and one SAP is used in Epipe 2:

```
[/]
A:admin@PE-1# show service sap-using

-------------------------------------------------------------------------------
Number of SAPs : 10
-------------------------------------------------------------------------------
===============================================================================
```

Regular and default SAPs consume one SAP instance each, whereas CP SAPs consume a number of SAP instances equal to the number of VLANs in the range. The following shows that there are ten SAP entries (in this example, nine SAPs in VPLS 1 and one SAP in Epipe 2), which can be regular, default, or CP SAP entries:

```

===============================================================================
```

However, the number of SAP instances consumed for card 1 FP 1 exceeds the number of SAP entries in the system, as follows:

```
[/]
A:admin@PE-1# tools dump resource-usage card 1 fp 1

===============================================================================
Resource Usage Information for Card Slot #1 FP #1
===============================================================================
                                                 Total   Allocated        Free
-------------------------------------------------------------------------------
---snip---
                              SAP Instances |      63999       1497      62502
---snip---
===============================================================================
```

The calculation of the number of SAP instances is as follows. In this example, CP 10 is used in five SAPs (four in VPLS 1 and one in Epipe 2) and contains the following VLAN ranges:

```
[/]
A:admin@PE-1# show connection-profile-vlan 10

150                 300                           03/31/2021 09:11:59
350                 400                           03/31/2021 09:12:08
===============================================================================
===============================================================================
```

The number of VLANs in the VLAN ranges of CP 10 equals 298. For each of the five SAP entries with CP 10, 298 SAP instances are used, for a total of 1490. As well, there is one CP SAP using CP 1 with three VLANs in the VLAN range from 7 to 9 (for three more SAP instances). Three CP SAPs use CP 3 with only VID 3 in the VLAN range (for three more SAP instances), and one SAP is a regular SAP that consumes one SAP instance. Therefore, the total number of SAP instances is 1497.

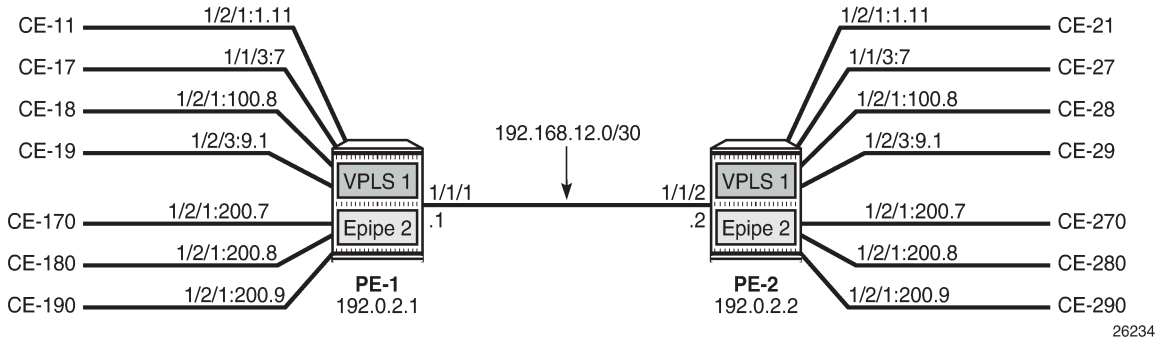
Configuration

Figure 282: Example topology shows the example topology used in this chapter.

Figure 282: Example topology



The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (or OSPF) between the PEs
- LDP between the PEs

In this example, no BGP is configured and no BGP-EVPN will be configured in the VPLS and Epipe services. However, VLAN ranges can be applied in EVPN VPLS and EVPN Epipe services.

VLAN ranges in VPLS services

Figure 283: Example topology for VLAN ranges in VPLS 1 shows the example topology for VPLS 1 with a combination on VLAN SAPs and CP SAPs. The port:VID represents the port to which the CE is connected and the VID sent by the CE; for example, CE-17 is connected to port 1/1/3 on PE-1 and sends frames with VID 7. When VLAN ranges are used, the port:VID 1/1/3:7 does not represent the configured SAP, which is 1/1/3:cp-1.

Figure 283: Example topology for VLAN ranges in VPLS 1

The service configuration for VPLS 1 on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 12:1 {
            }
            sap 1/1/3:cp-1 {
            }
            sap 1/2/1:1.11 {
            }
            sap 1/2/1:100.cp-1 {
            }
            sap 1/2/3:cp-1.* {
            }
        }
```

The configuration of VPLS 1 on PE-2 is as follows:

```
‘# on PE-2:
configure {
    service {
        sdp 21 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.1
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 21:1 {
            }
            sap 1/1/3:cp-1 {
            }
            sap 1/2/1:1.21 {
            }
            sap 1/2/1:100.cp-1 {
            }
            sap 1/2/3:cp-1.* {
            }
        }
```

When the CEs send traffic to each other, such as ICMP echo requests, the MAC addresses are learned in the SAPs, and the forwarding database (FDB) on PE-1 is as follows:

```
[/]
```

```

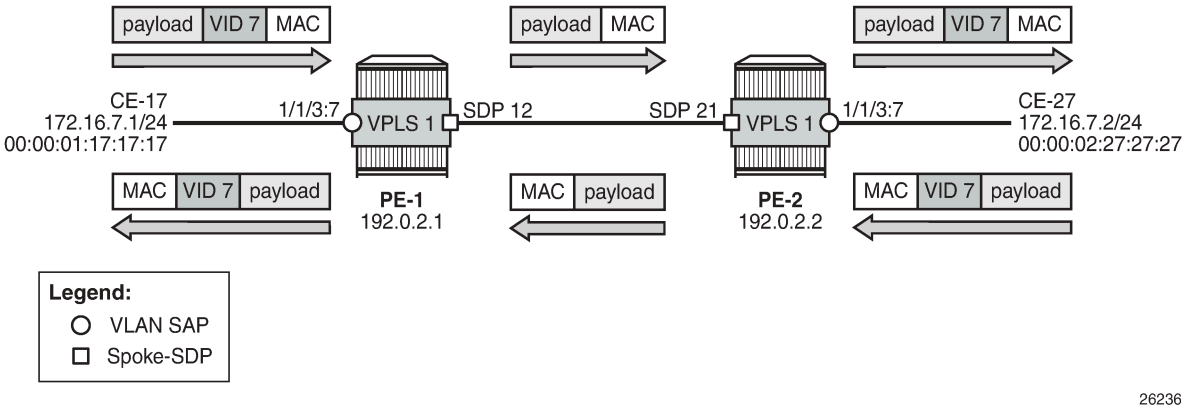
VLAN manipulation in dot1q SAPs

Figure 284: Customer VIDs are popped and pushed by dot1q VLAN SAPs shows the VLAN manipulation for VLAN SAPs. CE-17 and CE-18 are connected to VLAN SAPs, where the VLAN tag with VID 7 will be popped or pushed. VLAN translation is possible, but does not apply. The configuration of the SAPs in VPLS 1 on PE-1 and PE-2 is modified as follows:

```
# on PE-1, PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:cp-1
            sap 1/1/3:7 {
            }
```

Figure 284: Customer VIDs are popped and pushed by dot1q VLAN SAPs



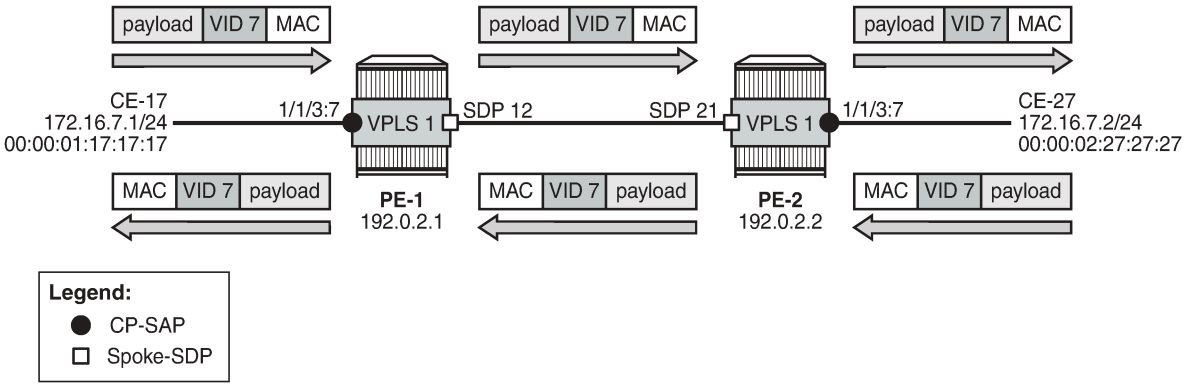
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 285: Customer VID is preserved between two dot1q CP SAPs shows how the customer VID 7 is preserved between CE-17 and CE-27 when CP SAPs are used instead of VLAN SAPs. The configuration for the SAPs is modified as follows:

```
# on PE-1, PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:7
            sap 1/1/3:cp-1 {
            }
```

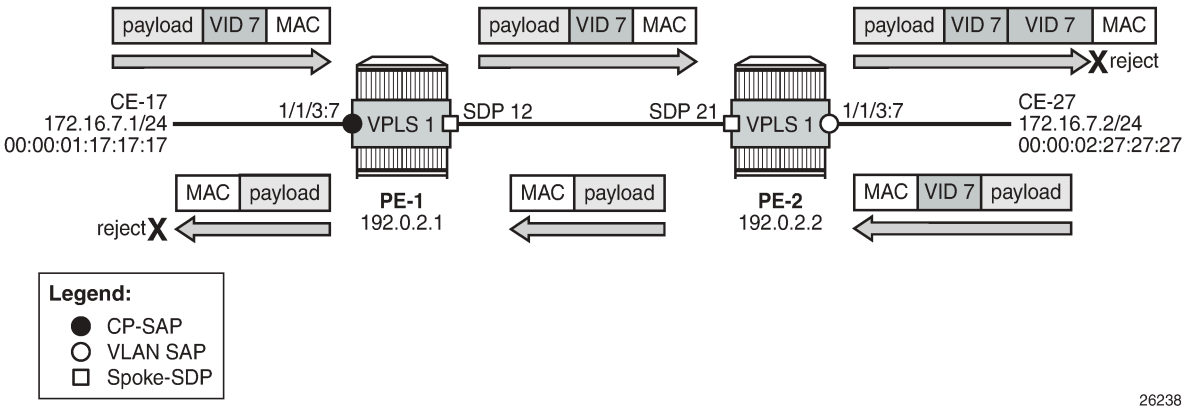
CE-17 sends frames with VID 7 to dot1q CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1, and this CP SAP preserves the VLAN tag. When the frames with VID 7 reach the egress CP SAP 1/1/3:cp-1 of VPLS 1 on PE-2, the egress CP SAP preserves the VID, and the frames are forwarded to CE-27. Traffic in the opposite direction is treated in the same way: the customer VID is preserved between the CEs.

Figure 285: Customer VID is preserved between two dot1q CP SAPs



No traffic is possible between a CP SAP in VPLS 1 on PE-1 and a VLAN SAP in VPLS 1 on PE-2, as shown in Figure 286: No traffic between dot1q CP SAP and dot1q VLAN SAP.

Figure 286: No traffic between dot1q CP SAP and dot1q VLAN SAP



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 remains unchanged, whereas the SAP in VPLS 1 on PE-2 is reconfigured as VLAN SAP 1/1/3:7 for VLAN 7, as follows:

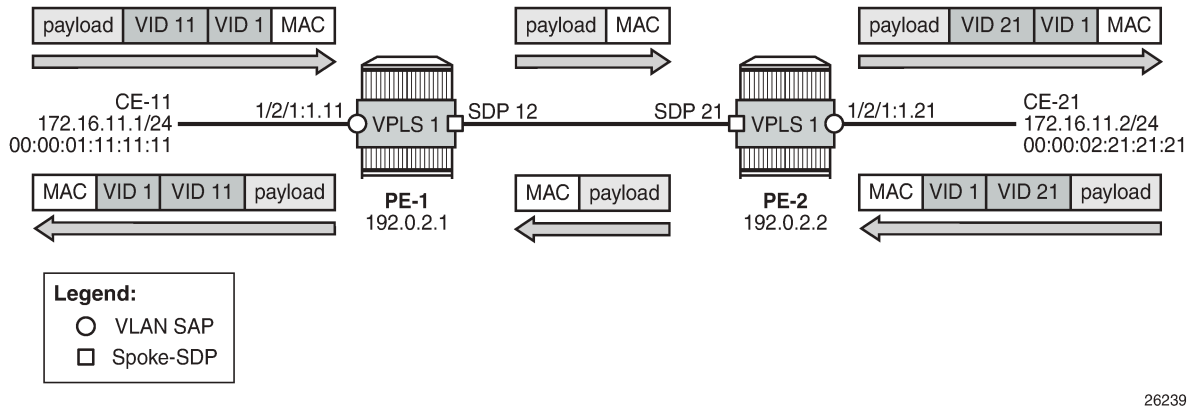
```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:cp-1
            sap 1/1/3:7 {
            }
```

Frames from CE-17 are forwarded by CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 without any changes to the VLAN tag. The tagged frames reach the VLAN SAP 1/1/3:7, where another VLAN tag with VID 7 is pushed onto the frame. The receiver CE-27 rejects the double-tagged frame. When CE-27 sends traffic to CE-17, the VLAN SAP 1/1/3:7 in VPLS 1 on PE-2 pops the VLAN tag and the frame is forwarded untagged to PE-1. The CP SAP 1/1/3:cp-1 on PE-1 does not push any VLAN tag and the frame is forwarded untagged to CE-17, where it is rejected.

VLAN manipulation in QinQ SAPs

Figure 287: Traffic between two QinQ VLAN SAPs - VLAN translation shows the VLAN manipulation in QinQ VLAN SAPs that pop and push the VLAN labels. In the example, the customer VID is translated.

Figure 287: Traffic between two QinQ VLAN SAPs - VLAN translation



CE-11 sends double-tagged traffic to QinQ VLAN SAP 1/2/1:1.11 in VPLS 1 on PE-1. This VLAN SAP pops both labels and forwards the frame untagged to PE-2. The egress VLAN SAP 1/2/1:1.21 in VPLS 1 on PE-2 pushes a label stack with two labels: the inner label with VID 21 and the outer label with VID 1. Both VIDs can be translated, but in this example, only the inner label gets another VID.

Figure 288: No traffic between two QinQ CP SAPs - VLAN translation not supported shows that VLAN translation is not possible between two QinQ CP SAPs. In the example, the outer tag with VID 1 is popped by the CP SAPs (VLAN translation is possible for this VLAN tag, but not done here) and the inner tag with VID 11 or 21 is preserved by the CP SAPs, which implies that the received frames will be rejected.

In this example, CP 2 is configured on both PE-1 and PE-2 with one VLAN range with one VID (11 or 21), as follows:

```
# on PE-1:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    connection-profile {
        vlan 2 {
            qtag-range 11 {
                end 11
            }
```

```
# on PE-2:
configure {
    connection-profile {
        vlan 2 {
            qtag-range 21 {
                end 21
            }
```

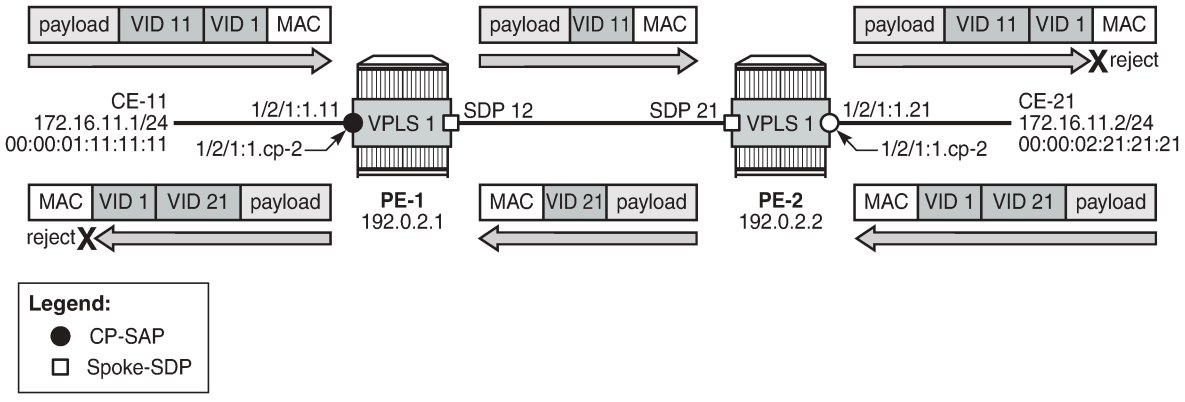
The VLAN SAP 1/2/1:1.11 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

```
# on PE-1:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/2/1:1.11
            sap sap 1/2/1:1.cp-2 {
            }
```

Likewise, the VLAN 1/2/1:1.21 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/2/1:1.21
            sap sap 1/2/1:1.cp-2 {
            }
```

Figure 288: No traffic between two QinQ CP SAPs - VLAN translation not supported



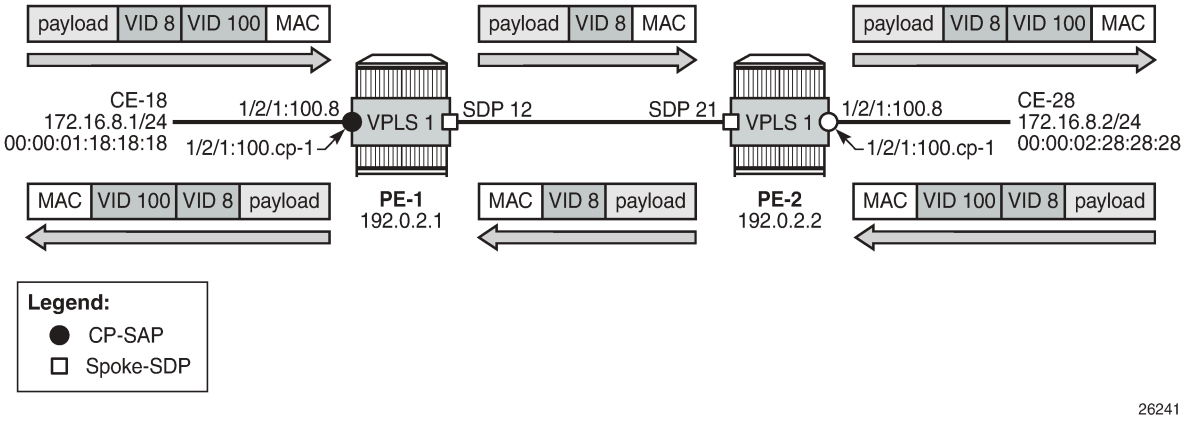
CE-11 sends double-tagged frames to SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1. This CP SAP pops the outer tag with VID 1, but preserves the VLAN tag with VID 11. The single-tagged frame is sent to PE-2 where CP SAP 1/2/1:1.cp-2 pushes an outer tag with VID 1 onto the frame. This double-tagged frame is sent to CE-12 where it is rejected, because an inner label with VID 21 is expected.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When CE-21 sends frames to CE-11, the frames will be double-tagged with inner tag VID 21 and outer tag 1. The outer tag is popped by the ingress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-2, but the inner tag is preserved. The egress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1 preserves the inner tag with VID 21 and pushes an outer tag with VID 1. This double-tagged frame is rejected by CE-11, because another inner tag is expected, with VID 11 instead of VID 21.

Figure 289: Traffic between two QinQ CP SAPs - no VLAN translation shows how traffic is sent between two QinQ CP SAPs without VLAN translation. Both CE-18 and CE-28 send double-tagged frames with inner tag VID 8 and outer tag VID 100. The tag with VID 100 need not be the same on both CEs, because it is popped and pushed by the CP SAPs; only the tag with VID 8 from the VLAN range must be unchanged.

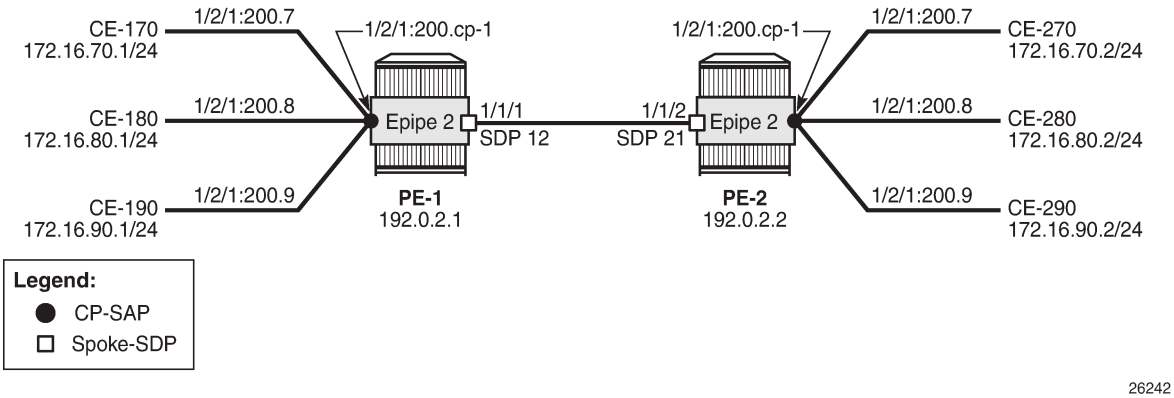
Figure 289: Traffic between two QinQ CP SAPs - no VLAN translation



VLAN ranges in Epipe services

Figure 290: Example topology for VLAN ranges in Epipe 2 shows the example topology for VLAN ranges in Epipe 2.

Figure 290: Example topology for VLAN ranges in Epipe 2



© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Epipe 2 is configured with one CP SAP and a spoke-SDP, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            spoke-sdp 12:2 {
            }
            sap 1/2/1:200.cp-1 {
            }
        }
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
```

CE-170 and CE-270 send double-tagged frames with inner VID 7 and outer VID 200. The inner VID 7 is preserved by the CP SAPs; therefore, CE-170 can only communicate with CE-270, not with any other CE at the other end, because they have different customer VIDs.

Conclusion

CP SAPs can be used to build services that can be bundled as per MEF 10.3 and RFC 7432. Multiple customer VIDs can be mapped to one CP-SAP.

VXLAN Forwarding Path Extension

This chapter provides information about VXLAN Forwarding Path Extension.

Topics in this chapter include:

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2. Virtual eXtensible Local Area Network (VXLAN) Forwarding Path Extension (FPE) is supported in SR OS Release 14.0.R4, and later. IPv6 addresses are supported for EVPN-VXLAN BGP peering in SR OS release 15.0.R1, and later.

Overview

Use cases

VXLAN Forwarding Path Extension (FPE) is an SR OS feature that enables VXLAN tunnels to terminate on non-system IPv4 and IPv6 Destination Addresses (DAs). The non-system IPv4/IPv6 VXLAN termination feature can be applied in the following use cases:

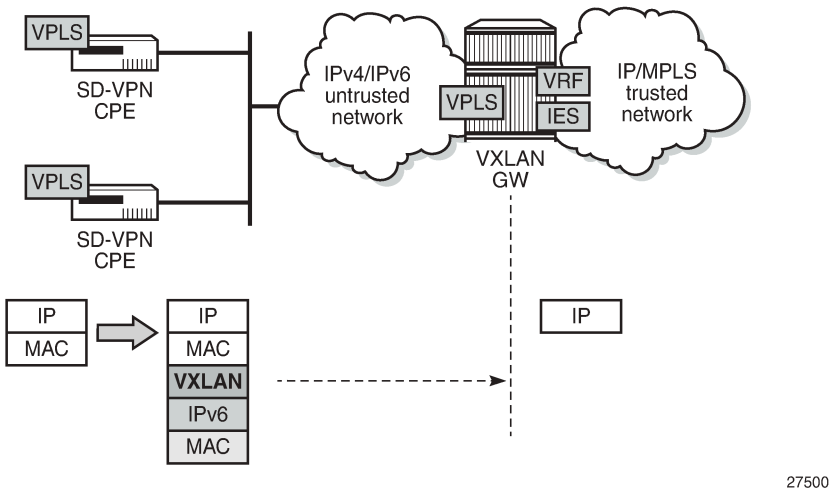
- VXLAN Gateway (GW) in Software-Defined VPNs (SD-VPNs)
- VXLAN IPv6 underlay for Data Centers (DCs)

VXLAN GW in SD-VPNs

Traffic transported on a VXLAN is usually connected to a trusted environment through a VPRN running in a private IP/MPLS network. The VXLAN GW system IP address is used for all internal management and MPLS termination in the trusted network. However, in this use case, SR OS routers are expected to be used as a VXLAN GW in SD-VPNs where the VXLAN GW terminates untrusted VXLAN tunnels initiated on the SD-VPN CPEs and forwards packets to a trusted IP/MPLS network, as shown in Figure 291: VXLAN GW in an SD-VPN.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 291: VXLAN GW in an SD-VPN



For security reasons, service providers will not expose system IP addresses to the untrusted IP network. Therefore, an IPv4 or IPv6 loopback address will be defined and used for VXLAN termination. The VXLAN tunnel can be terminated in a VPLS, an Epipe, or an R-VPLS service connected to a VPRN.

VXLAN IPv6 underlay for DCs

Some service providers migrate their entire network infrastructure to IPv6, including the DC network, so the DC GW must be able to terminate a VXLAN over an IPv6 infrastructure. Layer 2 (VPLS termination) and Layer 3 (R-VPLS termination) DC interconnect are both supported. Figure 292: VXLAN IPv6 underlay for DC shows the VXLAN IPv6 underlay for DC.

Figure 292: VXLAN IPv6 underlay for DC

VXLAN FPE function

The following applies to VXLAN FPE:

- In an SR OS node, VXLAN tunnels can be terminated in four different VXLAN Tunnel Endpoints (VTEPs):
  - System IPv4 address
  - Up to three non-system IPv4/IPv6 addresses

  This limit is based on the number of supported source IP addresses that can be used for VXLAN encapsulation.
- The preceding four terminating IP addresses can be used in addition to the Assisted Replication IP address (AR IP). The AR IP does not count against this limit of four VTEPs. See chapter "Layer 2 Multicast Optimization for EVPN-VXLAN - Assisted Replication" in the Layer 2 Services and EVPN volume of the *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Part II* for more information about AR.
- VXLAN FPE requires PXC ports; see the "Port Cross-Connect (PCX)" chapter in the Interface Configuration volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.
  - Ingress traffic from a VXLAN with an IP DA equal to a loopback address will be redirected to the PXC port where the IP header will get additional processing.
  - Usually, only the ingress traffic from the VXLAN is redirected to the PXC port. The egress traffic to the VXLAN tunnel can go straight out of the egress network port, except for R-VPLS traffic toward an IPv6 VXLAN that is redirected to the PXC port.
- The VPLS/R-VPLS functionality is not impacted by the choice of VTEP termination (system IP address or not).

Provisioning model

Non-system IP VXLAN termination and VXLAN IPv6 underlay are both provisioned as per the following steps:

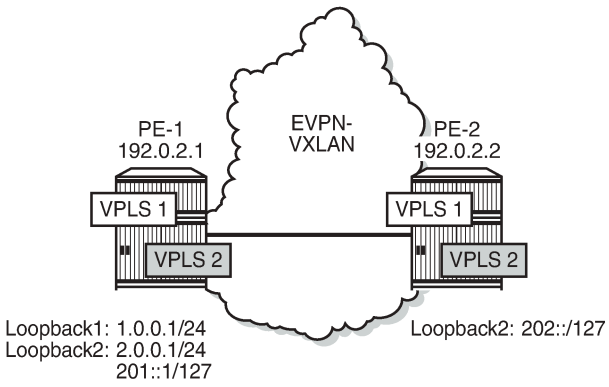
1. Create an FPE
2. Associate the FPE with VXLAN termination
3. Configure a router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Configuration

Figure 293: Example topology for VXLAN FPE shows the example topology with two PEs in an EVPN-VXLAN network. The loopback addresses in the base router will be used for non-system IP VXLAN termination.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 293: Example topology for VXLAN FPE



The initial configuration includes the cards, MDAs, ports, router interfaces and IGP. BGP is configured for address family EVPN, for example on PE-1 as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
        }
```

In this example, the BGP peering is IPv4-based, but EVPN-VXLAN routes can also be exchanged between IPv6 BGP peers.

Non-system IP VXLAN termination

Create FPEs

PXC is used as a simple back-to-back cross-connect. An FPE uses the PXC ports assigned in the FPE path, either a PXC port or a LAG-based PXC. For non-system IP VXLAN terminations between VPLSs, the PXC is only required on the ingress (from VXLAN, or from PE-1 to GW PE-2). PXC 1 and PXC 2 are created on PE-1, as follows:

```
# on PE-1:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    port 1/2/1 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/2 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/1
        }
        pxc 2 {
            admin-state enable
            port-id 1/2/2
        }
    }
```

The sub-ports of PXC 1 are operationally up, as follows.

```
[/]
A:admin@PE-1# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPEs use the PXCs.

```
# on PE-1, PE-2:
configure {
    fwd-path-ext {
        fpe 1 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            path {
                pxc 1
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
        }
```

These FPEs are created without defining a range of SDP IDs. SDP IDs are required in case of R-VPLS services terminating IPv6 VXLAN tunnels, where the FPE is also used at the egress and an internal static SDP is created to allow for the required extra processing.

When the FPE has no VXLAN termination associated, no internal router interfaces are created, so the only router interfaces are the system interface and the interface between PE-1 and PE-2, as follows.

```
[/]
A:admin@PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
int-PE-1-PE-2                    Up        Up/Down     Network 1/1/1
   192.168.12.1/30                                             n/a
system                           Up        Up/Down     Network system
   192.0.2.1/32                                                n/a
-------------------------------------------------------------------------------
Interfaces : 2
===============================================================================
```

Associate the FPEs with VXLAN termination

The following command associates the FPEs with VXLAN termination.

```
# on PE-1, PE-2:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                vxlan-termination {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

When attempting to associate the FPEs with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*[ex:/configure fwd-path-ext fpe 1 application vxlan-termination]
A:admin@PE-1# commit
MINOR: FPE #1021: configure fwd-path-ext fpe 1 - sdp-id-range is not configured - configure
 fwd-path-ext sdp-id-range
```

After the FPEs are associated with VXLAN terminations, the system creates two internal router interfaces per FPE, one per PXC sub-port:

```
[/]
A:admin@PE-1# show router interface

===============================================================================

```

Configure router loopback interfaces

The following loopback interfaces are configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure {
    router "Base"
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 1.0.0.1
                    prefix-length 24
                }
            }
        }
        interface "loopback2" {
            loopback
            ipv4 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                primary {
                    address 2.0.0.1
                    prefix-length 31
                }
            }
            ipv6 {
                address 201:: {
                    prefix-length 127
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
            interface "loopback2" {
            }
        }
```

A non /32 or /128 subnet must be assigned to the loopback interface, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 1.0.0.0/24 can be used for VXLAN tunnel termination, except for 1.0.0.1. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127, as for example for interface "loopback2".

In this scenario, only one loopback interface with an IPv4 address is sufficient: interface "loopback1" with IPv4 address 1.0.0.1/24. There is no need to configure loopback interfaces in the GW PE-2, because VXLAN FPE is only required in the ingress (from VXLAN to GW).

Configure non-system VTEP addresses

Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs; on PE-1 as follows:

```
# on PE-1:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 1.0.0.2 {
                    fpe-id 1
                }
                tunnel-termination 2.0.0.2 {
                    fpe-id 2
                }
                tunnel-termination 201::1 {
                    fpe-id 2
                }
```

No non-system VTEP addresses need to be configured on PE-2.

When attempting to configure the IP address of the loopback interface as a VXLAN tunnel termination, the following error is raised:

```
*[ex:/configure service system vxlan tunnel-termination 1.0.0.1]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service system vxlan tunnel-termination 1.0.0.1 - IP address
 matches a local interface IP address
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When attempting to configure more than three non-system VTEP addresses, the following error is raised:

```
*[ex:/configure service system vxlan tunnel-termination 1.0.0.100]A:admin@PE-1# commit
MINOR: MGMT_CORE #232: configure service system vxlan tunnel-termination 1.0.0.100 - Reached
 maximum number of entries - maximum is 3 but has 4
```

When the non-system VTEP addresses are configured, an internal loopback interface "_tmnx_vli_vxlan_1_131077" is created that can respond to ICMP requests.

```

```

The system does not verify whether there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding using ICMP for that address, regardless of the presence of a loopback interface in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the VPLS

A VPLS will be configured with EVPN-VXLAN enabled. By default, the system IP address will be used as the source VTEP of the VXLAN-encapsulated frames. This default behavior can be overruled by the

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

source-vtep command in the VPLS. The IP address corresponds to the non-system VTEP address configured in the preceding step (VXLAN tunnel termination). VPLS 1 is configured on PE-1 as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                source-vtep 1.0.0.2
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/1/2:1 {
            }
```

When attempting to configure an IP address different from the VTEP addresses, the following error is raised:

```
[ex:/configure service vpls "EVI-1" vxlan]
A:admin@PE-1# source-vtep 1.0.0.99

*[ex:/configure service vpls "EVI-1" vxlan]
A:admin@PE-1# commit
MINOR: MGMT_CORE #224: configure service vpls "EVI-1" vxlan source-vtep - Entry does not
 exist - configure service system vxlan tunnel-termination 1.0.0.99
```

A different VTEP address can be configured as **source-vtep** in different services on the same PE, as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 201::1
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration of VPLS 1 on PE-2 does not include any VTEP address, because it is not required in the egress, as follows:

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

When a source VTEP is configured in VPLS 1 on PE-1, this VTEP address will be used as the IP source VTEP for VPLS 1 and BGP will use this VTEP to the BGP NLRI next-hop, as shown in the following BGP route update messages.

The following BGP EVPN inclusive multicast route sent by PE-1 shows the configured source VTEP address 1.0.0.2 as NLRI next-hop, as originator address, and as tunnel endpoint.

```
# on PE-1:
1 2021/05/06 09:40:06.914 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:

```
"
```

The following BGP EVPN-MAC route sent by PE-1 shows the configured VTEP for VPLS 1 as NLRI next-hop:

```
# on PE-1:
8 2021/05/06 09:41:43.212 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 81
    Flag: 0x90 Type: 14 Len: 44 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 1.0.0.2
        Type: EVPN-MAC Len: 33 RD: 192.0.2.1:1 ESI: ESI-0, tag: 0, mac len: 48
                       mac: ca:fe:01:10:10:10, IP len: 0, IP: NULL, label1: 1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:64500:1
        bgp-tunnel-encap:VXLAN
"
```

A BGP peer policy might override the NLRI next-hop created due to the **source-vtep** configuration.

The following shows that the source VTEP address on PE-1 is 1.0.0.2:

```
[/]
A:admin@PE-1# show service id 1 vxlan
===============================================================================
VPLS VXLAN
===============================================================================
Vxlan Src Vtep IP: 1.0.0.2

Underlay IPv6 VXLAN termination

The configuration for underlay IPv6 VXLAN termination is similar to the non-system IP VXLAN termination. In the following example, R-VPLS 2 is configured; therefore, non-system VTEP addresses are configured in PE-2 as well as in PE-1. The changes required in PE-1 are as follows.

- IPv6 must be enabled on the router interfaces
- IPv6 native routing is configured in IS-IS
- IPv6 addresses are loopback address 201::/127 and VTEP address 201::1

```
# on PE-1:
configure {
    port-xc {
        pxc 2 {
            admin-state enable
            port-id 1/2/2
        }
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port 1/2/2 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                vxlan-termination {
                }
            }
        }
    }
    router "Base" {
        interface "int-PE-1-PE-2" {
            port 1/1/1
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
            ipv6 {
            }
        }
        interface "loopback2" {
            loopback
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            ipv4 {
                primary {
                    address 2.0.0.1
                    prefix-length 31
                }
            }
            ipv6 {
                address 201:: {
                    prefix-length 127
                }
            }
        }
        isis 0 {
            ipv6-routing native
            interface "loopback2" {
            }
        }
    }
    service {
        system {
            vxlan {
                tunnel-termination 201::1 {
                    fpe-id 2
                }
            }
        }
        vpls "EVI-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 201::1
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The service configuration on PE-2 is as follows.

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 202:: {
                    fpe-id 2
                }
            }
        }
        vpls "EVI-2" {
            admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            service-id 2
            customer "1"
            vxlan {
                source-vtep 202::
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The routing table for IPv6 on PE-1 shows that an internal static route is configured for the source VTEP 201::1 using the FPE internal interface "_tmnx_fpe_2.a". The route to egress VTEP 202:: is an IS-IS route.

```
[/]
A:admin@PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
201::/127                                       Local   Local     00h16m34s  0
       loopback2                                                       0
201::1/128                                      Remote  Static    00h11m53s  5
       fe80::201-"_tmnx_fpe_2.a"                                       1
202::/127                                       Remote  ISIS      00h00m06s  15
       fe80::14:1ff:fe01:1-"int-PE-1-PE-2"                             10
-------------------------------------------------------------------------------
No. of Routes: 3
```

Likewise, the routing table for IPv6 on PE-2 shows an internal static route for source VTEP 202:: using the FPE internal interface "_tmnx_fpe_2.a":

```
[/]
A:admin@PE-2# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
201::/127                                       Remote  ISIS      00h00m06s  15
       fe80::10:1ff:fe01:1-"int-PE-2-PE-1"                             10
202::/127                                       Local   Local     00h00m12s  0
       loopback2                                                       0
202::/128                                       Remote  Static    00h00m13s  5
       fe80::201-"_tmnx_fpe_2.a"                                       1
-------------------------------------------------------------------------------
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
No. of Routes: 3
```

When non-system IPv6 VTEP addresses are used in an R-VPLS, VTEP addresses need to be configured on ingress and egress VXLAN. The system creates an internal SDP binding for the egress processing. A range of SDP IDs has been configured from 10000 to 10127. The following command lists all SDP bindings for FPE:

```
[/]
A:admin@PE-2# show service sdp-using | match "Fpe"

Conclusion

VXLAN FPE is required to terminate VXLAN tunnels on non-system IPv4/IPv6 addresses and to configure IPv6 underlay.

Layer 3 Services

This section provides configuration information for the following topics:

- BGP Best External in a VPRN
- Carrier Supporting Carrier IP VPNs
- Flexible Algorithms for SRv6-based VPRNs
- Inter-AS VPRN Model B
- Inter-AS VPRN Model B Using MPLS over UDP
- Inter-AS VPRN Model C
- Layer 3 VPN: VPRN Type Spoke
- Spoke Termination for IPv6-6VPE
- Traffic Leaking from VPRN to GRT
- Weighted ECMP for VPRN over RSVP-TE or SR-TE LSPs

BGP Best External in a VPRN

This chapter provides information about BGP Best External in a VPRN.

Topics in this chapter include:

Applicability

The information and configuration in this chapter was originally written for SR OS Release 14.0.R7. In the current edition, the MD-CLI is updated to SR OS Release 22.2.R2.

Overview

By default, BGP speakers only advertise their best route for a destination. The BGP best external feature allows BGP speakers to advertise their best external route for a prefix Network Layer Reachability Information (NLRI) to their IBGP peers when their best overall route for this prefix NLRI is an internal route. This feature provides additional path visibility to the IBGP mesh. When two paths are available to reach a destination, and one is preferred, the availability of an alternate path in the RIB means that only a FIB update is required if the preferred next-hop fails. Also, the presence of two paths can reduce route oscillation.

BGP best external can be enabled in the base router with the following command:

```
[ex:/configure router "Base" bgp]
A:admin@PE-2# advertise-external ?

 advertise-external

 ipv4                  - Enable support for unlabeled unicast IPv4 routes
 ipv6                  - Enable support for unlabeled unicast IPv6 routes
 label-ipv4            - Enable support for labeled-unicast IPv4 routes
 label-ipv6            - Enable support for labeled-unicast IPv6 routes
---snip---
```

```
# on PE-2:
configure {
    router "Base" {
        bgp {
            advertise-external {
                ipv4 true
            }
```

Chapter "BGP Add-Path" in the Unicast Routing Protocols volume of *7450 ESS, 7750 SR, and 7950 XRS Advanced Configuration Guide — Book I* describes the use of the add-paths parameter for different address families. Chapter "BGP Fast Reroute" in the Unicast Routing Protocols volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I* includes a configuration example

Use subject to Terms available at: www.nokia.com/terms.

with BGP best external enabled in the base router, whereas this chapter focuses on BGP best external in a VPRN context.

VPRN BGP best external can be configured with the following command:

```
[ex:/configure service]
A:admin@PE-2# vprn "VPRN 1" ?
---snip---

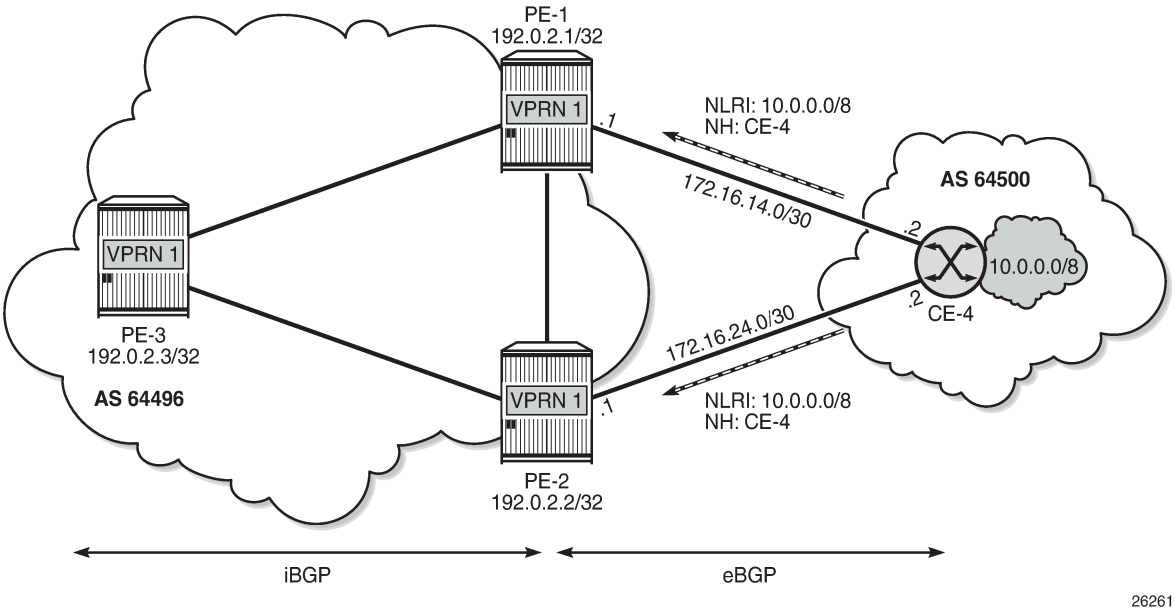
 export-inactive-bgp   - Export preferred BGP route even if inactive
---snip---
```

```
# on PE-2:
configure {
    service {
        vprn "VPRN 1" {
            export-inactive-bgp true
```

VPRN BGP best external allows the best EBGP IPv4/IPv6 route learned by a VPRN to be exported as a BGP VPN-IPv4/IPv6 route, even when that EBGP IPv4/IPv6 route is inactive due to the presence of a preferred BGP VPN-IPv4/IPv6 route from another PE. This best external route advertisement is useful in active/standby multi-homing scenarios because it can ensure that all PEs have knowledge of the backup path provided by the standby PE, thus reducing convergence times. VPRN BGP best external can also be applied in combination with Equal Cost Multi-Path (ECMP).

Figure 294: CE-4 advertises prefix 10.0.0.0/8 to its EBGP peers PE-1 and PE-2 shows the example topology with CE-4 in Autonomous System (AS) 64500 advertising prefix 10.0.0.0/8 to VPRN 1 in PE-1 and PE-2 in AS 64496.

Figure 294: CE-4 advertises prefix 10.0.0.0/8 to its EBGP peers PE-1 and PE-2

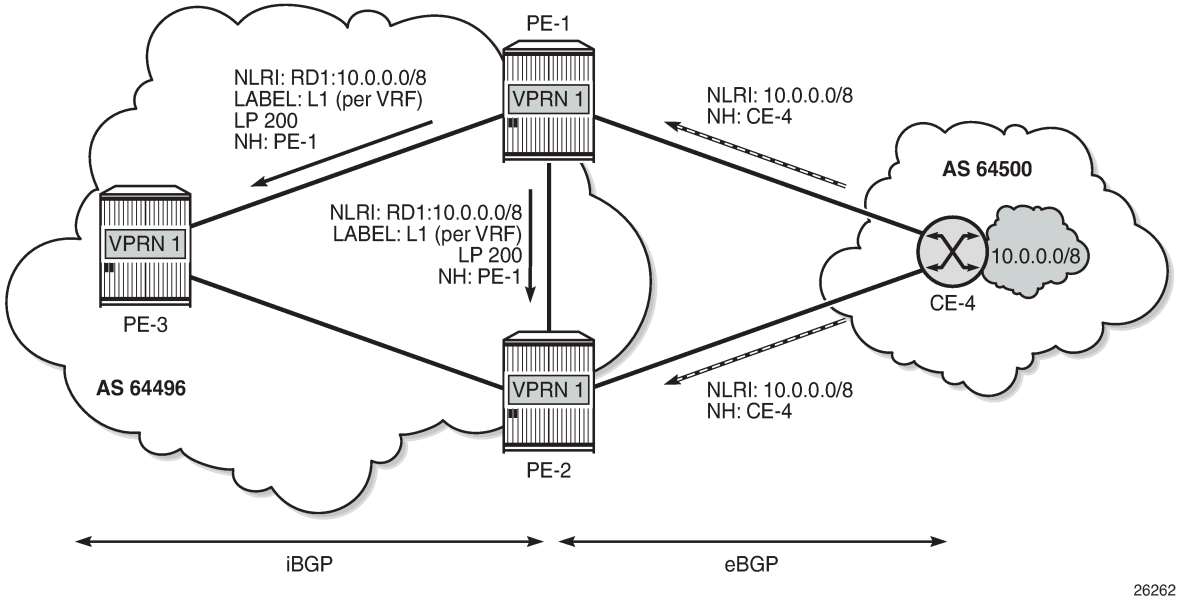


PE-1 is the primary PE for this prefix and it creates a corresponding BGP VPN-IPv4 route with a higher local preference (LP) value (for example, 200) compared to the default LP (100). PE-1 advertises this BGP VPN-IPv4 route to its IBGP peers PE-2 and PE-3. PE-2 imports this BGP VPN-IPv4 route into its

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VRF, which deactivates the EBGP route received from CE-4, because it has the default LP of 100 (by BGP selection rules, the highest LP wins). By default, BGP prevents PE-2 from exporting its inactive BGP IPv4 route from CE-4 and, therefore, PE-1 and PE-3 cannot learn a BGP VPN-IPv4 backup route for prefix 10.0.0.0/8, as shown in Figure 295: Default BGP behavior: BGP advertises best route only.

Figure 295: Default BGP behavior: BGP advertises best route only



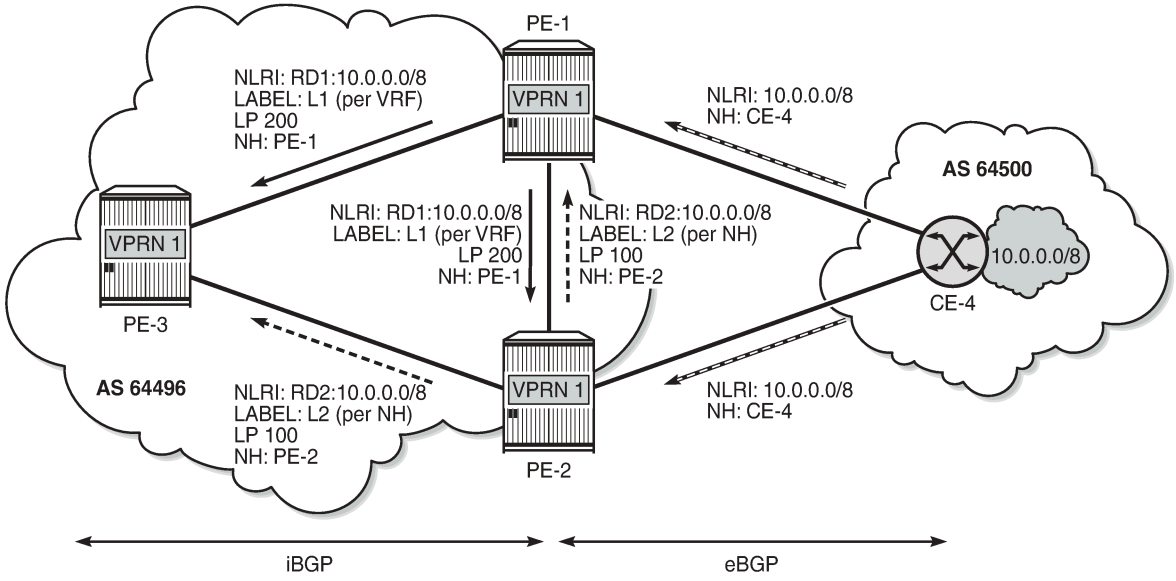
VPRN BGP best external allows PE-2 to advertise its best external route as backup on the following conditions:

- The option **export-inactive-bgp true** is configured in VPRN 1 on PE-2 (or on all PEs in the multi-homed site).
- The BGP route from CE-4 must match the VRF export policy in PE-2.
- The BGP VPN-IPv4 route exported by PE-2 must have a unique NLRI (RD:IP prefix combination) that does not overlap with a BGP VPN-IPv4 route from another PE for the same prefix. Therefore, a different RD can be allocated to the VRF in each PE connected to the multi-homed site. For example, VPRN 1 in PE-1 has RD 64496:11 and VPRN 1 in PE-2 has RD 64496:12.

Figure 296: VPRN BGP best external enabled: BGP advertises active and standby routes shows the BGP route advertisements when VPRN BGP best external is enabled. The BGP VPN-IPv4 route from PE-2 carries a per-next-hop label (meaning pop and forward to CE-4) regardless of the configured label mode of the VPRN service in PE-2.

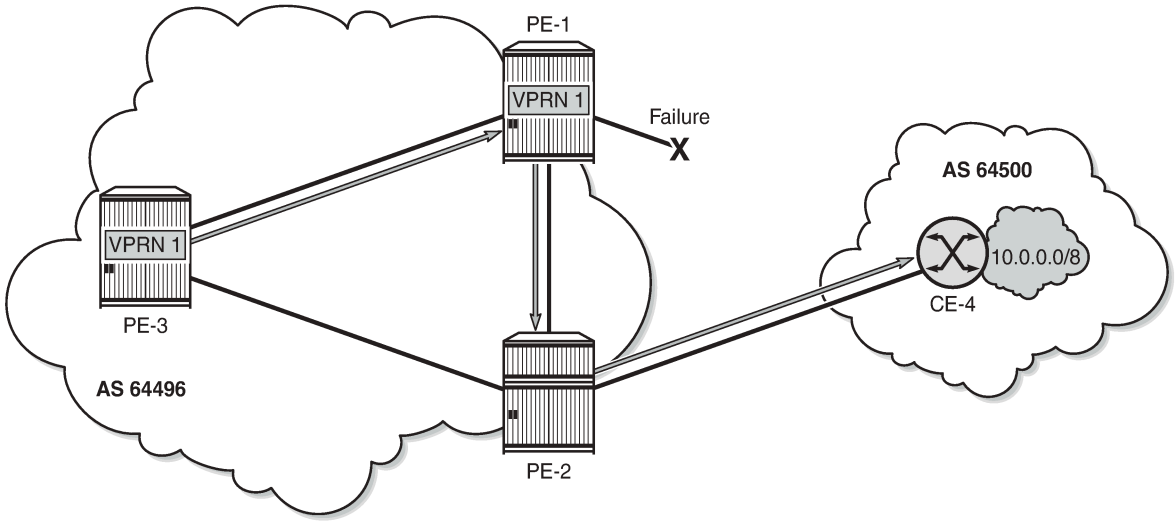
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 296: VPRN BGP best external enabled: BGP advertises active and standby routes



The PEs support BGP Fast Reroute (BGP FRR) using BGP VPN-IPv4 routes; therefore, PE-1 and PE-3 can install the route advertised by PE-2 as a backup path for prefix 10.0.0.0/8 and use that path immediately after detecting that the primary path has failed. When the link between PE-1 and CE-4 fails, PE-1 will detect this link failure typically seconds before the other PEs do. Therefore, PE-3 keeps sending traffic toward the network 10.0.0.0/8 to PE-1 and PE-1 uses the repair path via PE-2, as shown in Figure 297: BGP FRR on PE-1 after failure of active link to CE.

Figure 297: BGP FRR on PE-1 after failure of active link to CE

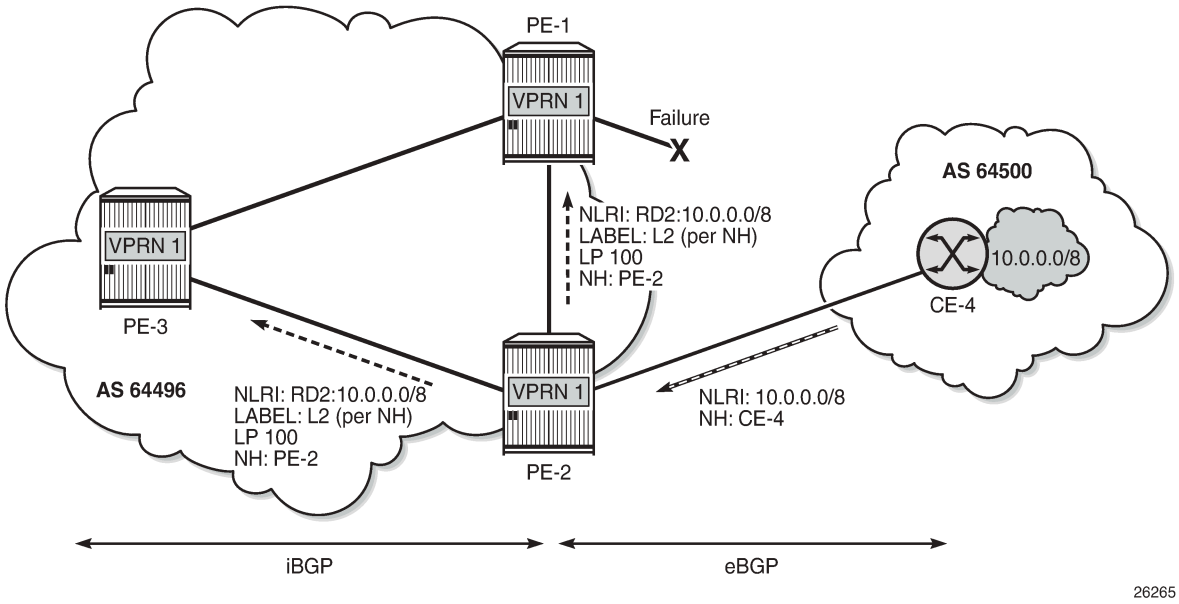


© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Even when PE-2 is still unaware of the link failure between PE-1 and CE-4, PE-2 will not loop traffic back to PE-1. The reason is that PE-1 sends traffic to PE-2 with a per-next-hop label so that no FIB lookup occurs in PE-2. Traffic is forwarded correctly to CE-4.

When PE-2 receives the BGP VPN-IPv4 route withdrawal from PE-1 for prefix 10.0.0.0/8, it removes the route from its RIB-IN and reruns the decision process. In this example, the EBGP route to CE-4 becomes the new primary/best path. PE-2 will re-advertise its BGP VPN-IPv4 route for prefix 10.0.0.0/8. The difference is that the BGP VPN-IPv4 route is based on the export of an active/used route and, therefore, the advertised label value is based on the configured label mode of the VPRN service, as shown in Figure 298: PE-2 re-advertises VPN-IPv4 route with label based on VRF for label mode VRF (default).

Figure 298: PE-2 re-advertises VPN-IPv4 route with label based on VRF



It takes time for this route to reach all ingress routers and for these routers to update their forwarding tables to use the per-VRF label value. For a while, there may still be traffic destined for prefix 10.0.0.0/8 that is received by PE-2 with the per-next-hop label L2. Traffic will be dropped if the per-next-hop label is deleted by the IOM as soon as PE-2 determines there are no more inactive/standby paths with CE-4 as next hop. Traffic loss can be avoided by delaying the deletion of per-next-hop labels in the IOM by configuring label retention for BGP labels with the following command:

```
*[ex:/configure router "Base" mpls-labels]
A:admin@PE-2# bgp-labels-hold-timer ?

 bgp-labels-hold-timer <number>
 <number>  - <0..255>
 Default   - 0

    BGP labels hold timer for the ingress router
```

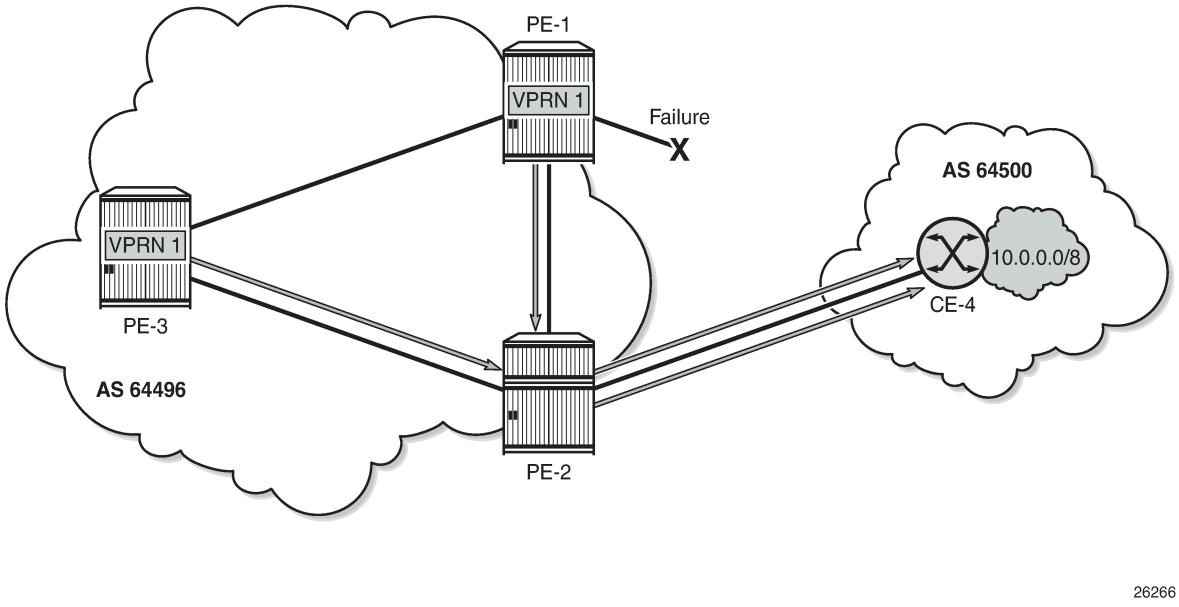
```
# on PE-2:
configure {
    router "Base" {
        mpls-labels {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp-labels-hold-timer 60
```

Finally, all ingress routers have updated their forwarding tables based on the BGP update sent by PE-2, and PE-3 sends traffic for prefix 10.0.0.0/8 directly toward PE-2, as shown in Figure 299: Traffic destined for prefix 10.0.0.0/8 after control plane convergence.

Figure 299: Traffic destined for prefix 10.0.0.0/8 after control plane convergence

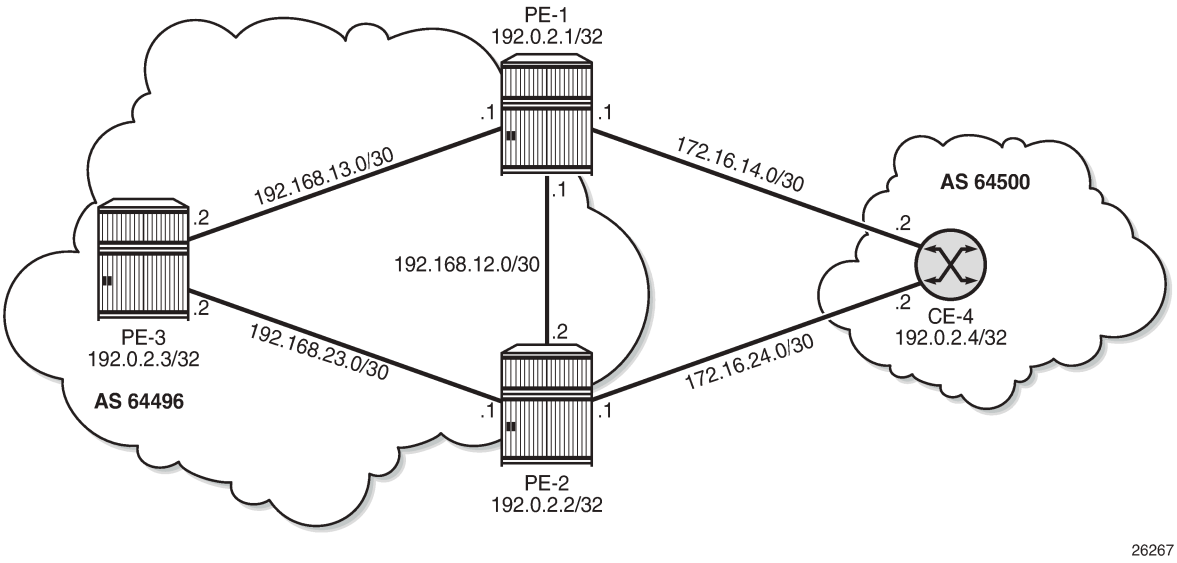


Configuration

Figure 300: Example topology shows the example topology with the used IP addresses.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 300: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (or OSPF) as IGP within AS 64496
- LDP on all interfaces within AS 64496

BGP is configured in the base router context of all PEs for address family VPN-IPv4; for example, for PE-1 as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            rapid-withdrawal true
            group "IBGP" {
                peer-as 64496
                family {
                    vpn-ipv4 true
                }
            }
            neighbor "192.0.2.2" {
                group "IBGP"
            }
            neighbor "192.0.2.3" {
                group "IBGP"
            }
```

The BGP configuration for the base router on the other two PEs is similar and a full mesh is established in AS 64496.

Configure VPRN without BGP best external

VPRN 1 is created on all PEs with the following settings:

- Default label mode: **label-mode vrf**
- Ready for BGP FRR: **bgp-vpn-backup>ipv4 true**
- Different RDs in VPRN 1 for each PE: 64496:11 on PE-1, 64496:12 on PE-2, and 64496:13 on PE-3
- **Auto-bind-tunnel** with **resolution any**. In this example, LDP will be used.
- Loopback interface "lo0" with IP address 172.31.2.1/32 on PE-1, which is also defined as the router ID in VPRN 1. The same approach is used on PE-2 and PE-3: 172.31.2.2/32 and 172.31.2.3/32.
- IBGP between all PEs (full mesh) for address family IPv4
- EBGP between PE-1 and CE-4 and between PE-2 and CE-4
- BGP best external is disabled, by default.

The configuration of VPRN 1 on PE-3 is as follows:

```
# on PE-3:
configure {
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64496
            router-id 172.31.2.3
            # label-mode vrf    # default
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:13"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
                rapid-withdrawal true
                group "IBGP" {
                    peer-as 64496
                }
                neighbor "172.31.2.1" {
                    group "IBGP"
                }
                neighbor "172.31.2.2" {
                    group "IBGP"
                }
            }
            interface "lo0" {
                loopback true
                ipv4 {
                    primary {
                        address 172.31.2.3
                        prefix-length 32
                    }
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            bgp-vpn-backup {        # enable BGP FRR
                ipv4 true
            }
```

On PE-1 and PE-2, the VPRN configuration includes an external interface toward CE-4, and EBGP is defined toward peer CE-4. The VPRN 1 configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    policy-options {
        policy-statement "import-bgp-LP100" {
            default-action {
                action-type accept
                local-preference 100
            }
        }
    }
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64496
            router-id 172.31.2.2
            # label-mode vrf    # default
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:12"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
                rapid-withdrawal true
                split-horizon true
                group "EBGP" {
                    peer-as 64500
                    import {
                        policy ["import-bgp-LP100"]
                    }
                }
                group "IBGP" {
                    peer-as 64496
                }
                neighbor "172.16.24.2" {
                    group "EBGP"
                }
                neighbor "172.31.2.1" {
                    group "IBGP"
                }
                neighbor "172.31.2.3" {
                    group "IBGP"
                }
            }
            interface "int-PE-2-CE-4_VPRN1" {
                ipv4 {
                    primary {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        address 172.16.24.1
                        prefix-length 30
                    }
                }
                sap 1/1/3:1 {
                }
            }
            interface "lo0" {

                ipv4 {
                    primary {
                        address 172.31.2.2
                        prefix-length 32
                    }
                }
            }
            bgp-vpn-backup {        # enable BGP FRR
                ipv4 true
            }
```

PE-2 has an import policy that sets the LP to 100, which is the default LP, but without import policy, no EBGP routes are accepted by default.

The VPRN 1 configuration on PE-1 looks similar to the configuration on PE-2, but includes an import policy that assigns an LP of 200 to each prefix that is received from CE-4, as follows:

```
# on PE-1:
configure {
    policy-options {
        policy-statement "import-bgp-LP200" {
            default-action {
                action-type accept
                local-preference 200
            }
        }
    }
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64496
            router-id 172.31.2.1
            # label-mode vrf    # default
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:11"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
                rapid-withdrawal true
                split-horizon true
                group "EBGP" {
                    peer-as 64500
                    import {
                        policy ["import-bgp-LP200"]
```

        }
        interface "lo0" {
            loopback true
            ipv4 {
                primary {
                    address 172.31.2.1
                    prefix-length 32
                }
            }
        }
        bgp-vpn-backup {        # enable BGP FRR
            ipv4 true
        }
    }
```

CE-4 has EBGP configured toward PE-1 and PE-2. CE-4 exports the prefix 10.0.0.0/8, as defined in export policy "export-bgp" that is applied in the **bgp** context:

```
# on CE-4:
configure {
    policy-options {
        prefix-list "10.0.0.0/8" {
            prefix 10.0.0.0/8 type longer {
            }
        }
        policy-statement "export-bgp" {
            entry 10 {
                from {
                    prefix-list ["10.0.0.0/8"]
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64500
        interface "int-CE-4-PE-1_VPRN1" {
```

© 2023 Nokia.

                }
            }
        }
        interface "test_connectedNW" {
            loopback
            ipv4 {
                primary {
                    address 10.0.0.1
                    prefix-length 8
                }
            }
        }
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                peer-as 64496
                export {
                    policy ["export-bgp"]
                }
            }
            neighbor "172.16.14.1" {
                group "EBGP"
            }
            neighbor "172.16.24.1" {
                group "EBGP"
            }
        }
```

Initially, VPRN BGP best external is disabled and, so only the best BGP route will be advertised and IBGP peers will not learn backup paths. The following section shows which routes are exchanged. Afterward, VPRN BGP best external will be enabled and the same show commands will be used.

Verification - VPRN without BGP best external

PE-1 imports prefix 10.0.0.0/8, assigns LP 200 to it, and advertises a corresponding VPN-IPv4 route to its IBGP peers (PE-2 and PE-3). Toward PE-2, this is as follows:

```
# on PE-1:
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
15 2022/05/02 11:24:40.478 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 65
    Flag: 0x90 Type: 14 Len: 30 Multiprotocol Reachable NLRI:
        Address Family VPN_IPV4
        NextHop len 12 NextHop 192.0.2.1
        10.0.0.0/8 RD 64496:11 Label 524283 (Raw label 0x7fffb1)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 6 AS Path:
        Type: 2 Len: 1 < 64500 >
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 200
    Flag: 0xc0 Type: 16 Len: 8 Extended Community:
        target:64496:1
"
```

The NLRI includes the prefix 10.0.0.0/8 and the RD 64496:11, and the label is 524283. BGP prevents PE-2 from sending a similar BGP update for prefix 10.0.0.0/8 because that route is not active on PE-2. PE-3 receives a BGP VPN-IPv4 route for network 64496:11:10.0.0.0/8, and this route has PE-1 as next hop and LP 200. No route is received from PE-2 for network 64496:12:10.0.0.0/8; as follows:

```

10.0.0.0/8                                    Remote  BGP VPN   00h02m00s  170
       192.0.2.1 (tunneled)                                        10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Instead of using an external route to CE-4, the route for prefix 10.0.0.0/8 is internal (BGP VPN), using an LDP transport tunnel to PE-1. There are no non-active routes, as can be shown by adding the keyword all to the preceding show command, as follows:

```
[/]
A:admin@PE-2# show router 1 route-table 10.0.0.0/8 all

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                           Active     Metric
-------------------------------------------------------------------------------
10.0.0.0/8                                    Remote  BGP VPN   00h02m23s  170
       192.0.2.1 (tunneled)                                Y           10
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

There are no standby routes, because BGP only advertises the best used route.

On PE-1, the following BGP IPv4 route with next hop CE-4 is used for prefix 10.0.0.0/8 in VPRN 1:

```
[/]
A:admin@PE-1# show router 1 bgp routes
===============================================================================
 BGP Router ID:172.31.2.1       AS:64496       Local AS:64496
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP IPv4 Routes
```

       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

There is no backup route because BGP prevents PE-2 from sending a standby route for prefix 10.0.0.0/8 to its IBGP peers.

PE-2 has advertised two VPN-IPv4 routes in the base router (the last number in Rcv/Act/Sent = Received/Active/Sent), as follows:

```
*A:PE-2# show router bgp summary family vpn-ipv4
===============================================================================
 BGP Router ID:192.0.2.2        AS:64496       Local AS:64496
===============================================================================
BGP Admin State         : Up          BGP Oper State              : Up
---snip---

Enable BGP best external in VPRN

VPRN BGP best external is configured on PE-2 (or on all PEs in the multi-homing site) as follows:

```
# on PE-2:
configure {
    service {
        vprn "VPRN 1" {
            export-inactive-bgp true
```

When configured, this command causes all IPv4 and IPv6 VPRN BGP best external routes to be exported in the multi-protocol BGP (MP-BGP) domain. Best external routes are BGP routes for which all the following conditions are met:

- The BGP route is matched by the VRF export policy.
- The BGP route is inactive because a more preferred BGP VPN route for the same prefix is present in the route table manager (RTM).
- This BGP route is best and valid considering only VPRN BGP routes.

PE-2 is advertising a best external route and is called the standby PE for prefix 10.0.0.0/8. PEs can be active for some IP prefixes and standby for other IP prefixes.

Best external routes are advertised to the BGP VPN-IPv4 neighbors. In this example, the BGP VPN-IPv4 neighbors are IBGP neighbors, but they can also be EBGP neighbors. The RD must be unique across the PEs exporting a BGP VPN-IP route for the same prefix; otherwise, the best external route may not be advertised. The advertised VPRN label is based on the next hop IP of the best external route, regardless of the label mode of the VPRN in the standby PE.

Verification - VPRN with BGP best external - BGP FRR

VPRN with BGP best external BGP FRR results in the following. VPRN BGP best external is enabled (BGP Export Inactv) in VPRN 1 on PE-2:

```
[/]
A:admin@PE-2# show service id 1 base

===============================================================================

===============================================================================
```

After VPRN BGP best external is enabled, PE-2 advertises its standby route for prefix 10.0.0.0/8 to its IBGP peers, as follows:

```
# on PE-2:
15 2022/05/02 11:28:51.976 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 65
    Flag: 0x90 Type: 14 Len: 30 Multiprotocol Reachable NLRI:
        Address Family VPN_IPV4
        NextHop len 12 NextHop 192.0.2.2
        10.0.0.0/8 RD 64496:12 Label 524284 (Raw label 0x7fffc1)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 6 AS Path:
        Type: 2 Len: 1 < 64500 >
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 8 Extended Community:
        target:64496:1
"
```

The RD is 64496:12, the LP is 100, and the label is 524284. The BGP update shown is sent by PE-2 toward PE-3; the BGP update sent by PE-2 toward PE-1 is similar.

The number of BGP VPN-IPv4 routes sent by PE-2 to each IBGP peer increased from 2 to 3, as follows:

```
[/]
A:admin@PE-2# show router bgp summary all

Configure ECMP

Because BGP best external allows advertising of an alternative path, it can also be used for load-sharing. ECMP is configured with value 2 in VPRN 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vprn "VPRN 1" {
            ecmp 2
```

Other than the ECMP configuration, the VPRN configuration is the same as in the previous example. If ECMP is configured, BGP FRR is not needed anymore:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vprn "VPRN 1" {
            delete bgp-vpn-backup
```

On PE-3, the BGP decision process will prefer the route with the highest LP and, therefore, only the route via PE-1 with LP 200 will be used and there will be no load-sharing. To ensure that the routes via PE-1 and PE-2 have the same cost, the import policy in VPRN 1 on PE-1 that sets the LP to 200 is replaced by an import policy that sets the LP to 100, as follows:

```
# on PE-1:
configure {
    policy-options {
        policy-statement "import-bgp-LP100" {
            default-action {
                action-type accept
                local-preference 100
            }
        }
    }
    service {
        vprn "VPRN 1" {
            bgp {
                group "EBGP"
                    delete import
                    import {
                        policy ["import-bgp-LP100"]
                    }
                }
```

BGP best external is enabled (on PE-1 and) PE-2, as follows:

```
# on PE-2:
configure {
    service {
        vprn "VPRN 1" {
            export-inactive-bgp true
```

===============================================================================
```

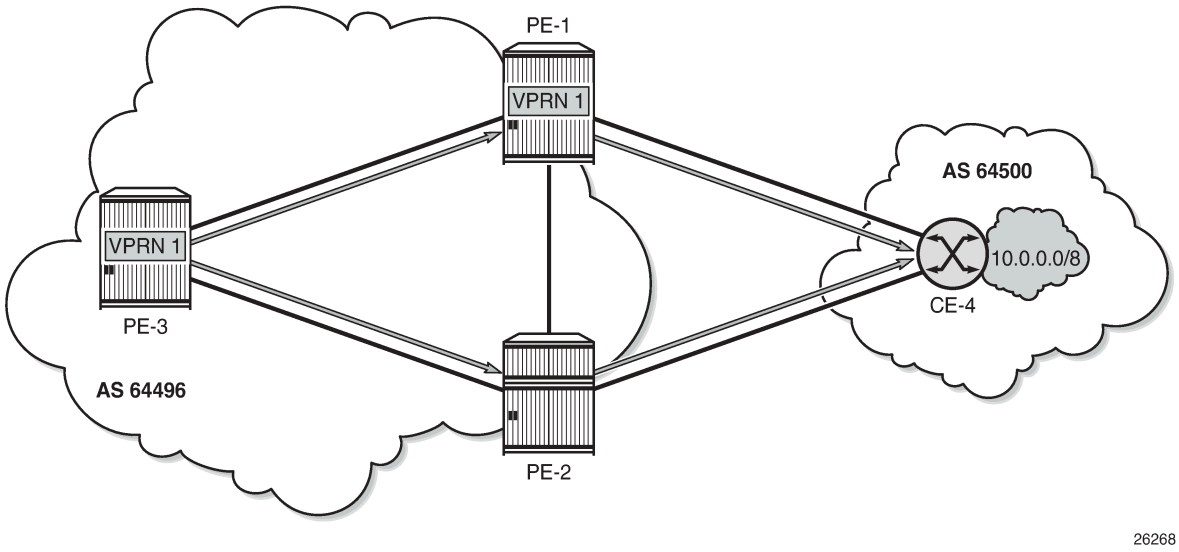
Figure 301: Loadsharing for traffic from PE-3 destined to 10.0.0.0/8 shows that traffic from VPRN 1 on PE-3 destined to prefix 10.0.0.0/8 is sprayed over two paths: one via PE-1 and one via PE-2.

Figure 301: Loadsharing for traffic from PE-3 destined to 10.0.0.0/8



Conclusion

VPRNs can be configured with the option **export-inactive-bgp true**, which allows a BGP speaker to advertise its best external BGP route to its BGP peers even if that route is inactive due to the presence of a more preferred BGP VPN route from another PE. BGP best external in VPRN is useful in active/standby multi-homing scenarios because it allows the standby PE to advertise a backup path. The traffic failover

Use subject to Terms available at: www.nokia.com/terms.

time can be reduced when all PE routers have advance knowledge of the potential backup paths and do not have to wait for BGP route advertisements and/or withdrawals to reprogram their forwarding tables. VPRN BGP best external can also be used in combination with ECMP.

Carrier Supporting Carrier IP VPNs

This chapter provides information about carrier supporting carrier IP VPN configurations.

Topics in this chapter include:

Applicability

This chapter was initially written for on SR OS Release 11.0.R1. The MD-CLI in the current edition corresponds to SR OS Release 22.2.R1. Carrier Supporting Carrier is supported on the 7750 SR and 7950 XRS.

Overview

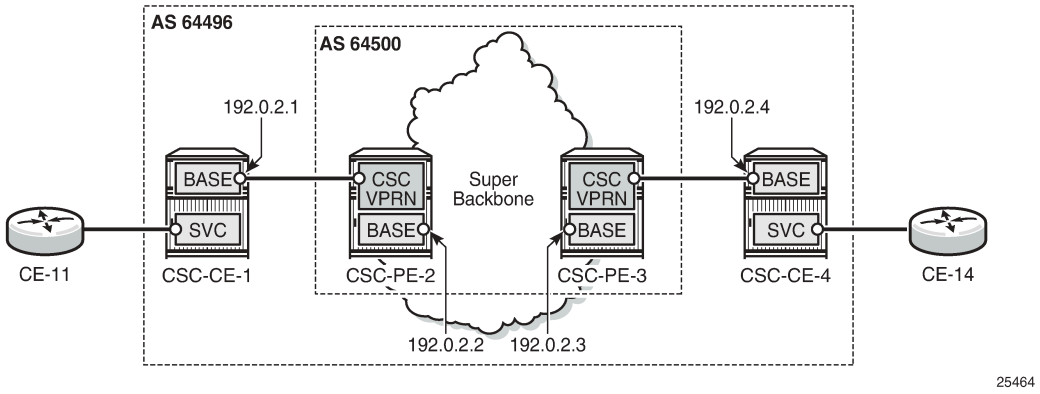
Carrier Supporting Carrier (CSC) is a solution that allows one service provider (the Customer Carrier) to use the IP VPN service of another service provider (the Super Carrier) for some or all of its backbone transport. RFC 4364 defines a Carrier Supporting Carrier solution for BGP/MPLS IP VPNs that uses MPLS at the interconnection points between the two service providers to provide a scalable and secure solution.

A simplified CSC network topology is shown in Figure 302: CSC network topology. A CSC deployment involves the following types of devices:

- CE — Customer premises equipment dedicated to one enterprise.
- PE — Edge router managed and operated by the Customer Carrier that connects to CEs to provide business VPN or Internet services.
- CSC-CE — Peering router managed and operated by the Customer Carrier that is connected to CSC-PEs for purposes of using the associated CSC IP VPN services for backbone transport. The CSC-CE may attach directly to CEs if it is also configured to be a PE for business VPN services.
- CSC-PE — A PE router managed and operated by the Super Carrier that supports one or more CSC IP VPN services possibly in addition to other traditional PE services.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 302: CSC network topology



In the CSC solution, the CSC-CE and CSC-PE are directly connected by a link that supports MPLS. The CSC-CE distributes an MPLS label for every /32 IPv4 prefix it and any downstream PE uses as a BGP next-hop in routes associated with services offered by the Customer Carrier. BGP must be used as the label distribution protocol between CSC-CE and CSC-PE if the latter device is an SR OS node. Typically, the Customer Carrier and Super Carrier operate as two different Autonomous Systems (ASs) and therefore BGP, more specifically EBGP, is the best label distribution protocol, even if other options are available. The BGP session between CSC-CE and CSC-PE must be single-hop EBGP (or IBGP) if either device is an SR OS node.

In an SR OS CSC-PE, the interface to a CSC-CE is a special type of IP/MPLS interface that belongs to a VPRN configured for CSC mode. This special type of interface is called a CSC VPRN interface throughout the remainder of this chapter. The CSC VPRN interface has many of the same characteristics as a network interface of the base router but its association with a Virtual Routing and Forwarding (VRF) ensures that the traffic and control plane routes of the Customer Carrier are kept separate from other services.

When an SR OS CSC-PE receives a labeled-IPv4 route (with label L1, next-hop N1) from a CSC-CE BGP peer, the following actions take place in the CSC-PE:

1. The BGP route is installed into the routing table of the CSC VPRN (assuming the BGP route is the best route to the destination).
2. If the BGP route matches the VRF export policy, it is advertised to the core Multi-Protocol Border Gateway Protocol (MP-BGP) peers as a VPN-IPv4 route. The advertised label value is changed to label value L2.
3. BGP programs the line cards with an MPLS forwarding entry that swaps label value L2 for L1 and sends the MPLS packet over the CSC VPRN interface associated with next-hop N1.

When an SR OS CSC-PE receives a VPN-IPv4 route (with label L2, next-hop N2) the following actions take place in the CSC-PE:

1. If the VPN-IPv4 route matches the VRF import policy of a CSC VPRN, it is installed into the routing table of that CSC VPRN.
2. If the imported BGP-VPN route matches the BGP export policy associated with a CSC-CE BGP peer, it is advertised to that peer as a labeled-IPv4 route. The advertised label value is changed to label value L3.
3. BGP programs the line cards with an MPLS forwarding entry that swaps label value L3 for L2 and sends the packet inside the MPLS tunnel to next-hop N2.

Once a CSC-CE has learned a labeled-IPv4 route for a remote CSC-CE and vice versa, the two CSC-CEs can set up a BGP session between themselves and exchange VPN routes over this session if they are both PEs with services. Typically, this BGP session will be an IBGP session because the local and remote CSC-CEs belong to the same AS. The Layer 2 VPN and Layer 3 VPN routes exchanged by the CSC-CEs are resolved by the labeled-IPv4 routes they have for each other's /32 IPv4 address.

Configuration

This section will walk through the steps to configure the CSC solution shown in Figure 302: CSC network topology. The IPv4 addresses in Figure 302: CSC network topology are the system IP addresses of the routers. The steps are the following:

- Configure CSC-CE-1
- Configure CSC service on CSC-PE-2
- Verify exchange of labeled IPv4 routes between CSC-CE-1 and CSC-PE-2
- Configure core connectivity for CSC-PE-2
- Configure core connectivity for CSC-PE-3
- Configure CSC service on CSC-PE-3
- Verify exchange of VPN-IPv4 routes between CSC-PE-2 and CSC-PE-3
- Configure CSC-CE-4
- Verify exchange of labeled IPv4 routes between CSC-PE-3 and CSC-CE-4
- Configure BGP session between CSC-CE-1 and CSC-CE-4
- Verify exchange of VPN-IPv4 routes between CSC-CE-1 and CSC-CE-4

Step 1. Configure CSC-CE-1

This example assumes that CSC-CE-1 is a PE router with Layer 2 and Layer 3 VPN services that must extend across the CSC VPN service; assume that there are no further downstream PEs in AS 64496. The configuration of one such Layer 3 VPN service in CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:11"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "loopback-1" {
                loopback true
                ipv4 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    primary {
                        address 10.11.30.2
                        prefix-length 24
                    }
                }
            }
        }
```

For brevity, the preceding configuration sample omits commands related to SAP IP interfaces, spoke-SDP IP interfaces, PE-CE routing protocols, QoS, IP filters, and so on. The loopback interface is used to test whether this prefix is learned at the remote CSC-CE-4.

The base routing instance of the CSC-CE is configured with the appropriate router ID and autonomous system number and the system interface is configured with an IPv4 address (usually the same as the router ID). If the router ID is not configured, by default, the system IP address is used as the router ID. The interface to CSC-PE-2 is created and configured. The base router configuration of CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure {
    router "Base" {
        autonomous-system 64496
        interface "int-CSC-CE-1-CSC-PE-2" {
            port 1/1/1:1        # connected to VPRN1 network interface on CSC-PE-2
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.1
                    prefix-length 32
                }
            }
        }
```

On CSC-CE-1, BGP is configured as the control plane protocol running on the interface to CSC-PE-2. The export policy exports the system IP address of CSC-CE-1 as a labeled-IPv4 route to CSC-PE-2; the import policy imports other system IP addresses, in this case, the system IP address of CSC-CE-4.

```
# on CSC-CE-1:
configure {
    policy-options {
        prefix-list "system-IP" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "export-systemIP" {
            entry 10 {
                from {
                    prefix-list ["system-IP"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            default-action {
                action-type reject
            }
        }
        policy-statement "import-systemIP" {
            entry 10 {
                from {
                    prefix-list ["system-IP"]
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
    }
    router "Base" {
        autonomous-system 64496
        bgp {
            group "CSC-PE" {
                peer-as 64500
            }
            neighbor "192.168.12.2" {
                split-horizon true
                group "CSC-PE"
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-systemIP"]
                }
                export {
                    policy ["export-systemIP"]
                }
            }
```

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**)

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Family label-IPv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels), as can be observed from the following debug message (in this example, debugging is enabled on CSC-CE-1 for BGP OPEN messages using the command **debug router bgp open**).This BGP OPEN message can obviously only be seen when the BGP peer is up. The configuration for CSC-PE-2 will be shown later, but in order to have the debug message, it must be configured already.

```
# on CSC-CE-1:
1 2022/04/06 15:54:53.648 CEST MINOR: DEBUG #2001 Base BGP

The **split-horizon true** command is optional. It prevents a best BGP route from the CSC-PE peer from being re-advertised back to that peer.

Step 2. Configure CSC service on SCS-PE-2

CSC-PE-2 must be configured with a VPRN in **carrier-carrier-vpn** mode to provide CSC service to CSC-CE-1. VPRN 1 is configured on CSC-PE-2, as follows:

```
# on CSC-PE-2:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64500
            router-id 192.0.2.2
            carrier-carrier-vpn true
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64500:12"
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
                group "CSC-CE" {
                    as-override true
                    peer-as 64496
                    ebgp-default-reject-policy {
                        import false
                    }
                    export {
                        policy ["BGP-VPN-routes"]
                    }
                }
                neighbor "192.168.12.1" {
                    split-horizon true
                    group "CSC-CE"
                    family {
                        label-ipv4 true
                    }
                }
            }
            network-interface "int-CSC-PE-2-CSC-CE-1" {
                port 1/1/2:1
                ipv4 {
                    primary {
                        address 192.168.12.2
                        prefix-length 30
                    }
                }
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **carrier-carrier-vpn true** command is mandatory. It cannot be configured if the VPRN has any SAP or spoke-SDP access interfaces configured; they must first be deleted.

```
*[ex:/configure service vprn "VPRN1"]
A:admin@CSC-PE-2# carrier-carrier-vpn true

*[ex:/configure service vprn "VPRN1"]
A:admin@CSC-PE-2# commit
MINOR: COMMON #238: configure service vprn "VPRN1" carrier-carrier-vpn - Configuration change
 failed validation - combination of carrier-carrier-vpn and service interfaces present. -
 configure service vprn "VPRN1"
```

The **auto-bind-tunnel** command must be set appropriately for the type of transport desired to other CSC-PEs, but note that GRE is not supported.

```
*[ex:/configure service vprn "VPRN1" bgp-ipvpn mpls auto-bind-tunnel resolution-filter]
A:admin@CSC-PE-2# gre true

*[ex:/configure service vprn "VPRN1" bgp-ipvpn mpls auto-bind-tunnel resolution-filter]
A:admin@CSC-PE-2# commit
INFO: PIP #1195: configure service vprn "VPRN1" carrier-carrier-vpn - Cannot toggle carrier-
carrier-vpn - GRE auto-bind enabled - configure service vprn "VPRN1" bgp-ipvpn mpls auto-bind-
tunnel resolution-filter gre
```

The interface to CSC-CE-1 must be a network interface. A network interface can be associated with an entire Ethernet port, a VLAN sub-interface of an Ethernet port, an entire LAG or a VLAN sub-interface of a LAG. In all cases, the associated Ethernet ports must be configured in network or hybrid mode.

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon true** command is optional. It prevents a best BGP route from the CSC-CE peer from being re-advertised back to that peer.

The **as-override** command replaces CSC-CE-1's AS number 64496 with CSC-PE-2's AS number 64500 in the AS_PATH attribute of routes advertised to CSC-CE-1. Without this configuration, CSC-CE-1 may reject routes originated by CSC-CE-4 as invalid due to an AS-path loop.

The **export** command applies a BGP export policy to the session. The configuration of the policy is as follows:

```
# on CSC-PE-2:
configure {
    policy-options {
        policy-statement "BGP-VPN-routes" {
            entry 10 {
                from {
                    protocol {
                        name [bgp-vpn]
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The effect of the BGP export policy is to re-advertise VPN-IPv4 routes imported into the CSC VPRN (and used for forwarding) to CSC-CE-4.

Step 3. Verify exchange of labeled IPv4 routes

When steps 1 and 2 have been completed, CSC-CE-1 advertises the labeled-IPv4 route for its system IP address 192.0.2.1/32 to CSC-PE-2. This can be checked in the RIB Out of CSC-CE-1, as follows:

```
[/]
A:admin@CSC-CE-1# show router bgp routes 192.0.2.1/32 label-ipv4 hunt
===============================================================================

```

Step 4. Configure core connectivity for CSC-PE-2

The next step is to configure the base router instance of CSC-PE-2 so that it can exchange VPN-IPv4 routes with CSC-PE-3 (and potentially other CSC-PEs). This requires:

- Router ID and autonomous system configuration.
- Network interface creation and configuration, including assignment of an IPv4 address to the system interface.
- Configuration of the IGP protocol; in this example, IS-IS is used.
- Configuration of the LDP protocol (optional).
- Configuration of RSVP LSPs used to reach remote CSC-PE devices (optional).
- Configuration of the BGP protocol.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The base router configuration of CSC-PE-2 is as follows:

```
# on CSC-PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        interface "int-CSC-PE-2-CSC-PE-3" {
            port 1/1/1:1000
            ipv4 {
                primary {
                    address 192.168.23.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.2
                    prefix-length 32
                }
            }
        }
        bgp {
            group "core" {
                type internal
            }
            neighbor "192.0.2.3" {
                group "core"
                family {
                    vpn-ipv4 true
                }
            }
        }
        isis 0 {
            admin-state enable
            level-capability 2
            area-address [49.01]
            interface "int-CSC-PE-2-CSC-PE-3" {
                interface-type point-to-point
            }
            interface "system" {
                passive true
            }
            level 2 {
                wide-metrics-only true
            }
        }
        ldp {
            interface-parameters {
                interface "int-CSC-PE-2-CSC-PE-3" {
                    ipv4 {
                    }
                }
            }
        }
```

The peer type is IBGP (**type internal**. It is also possible to configure this in a similar way as for EBGP, with the same value for **peer-as** as the locally configured **autonomous-system**).

The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128 (=0x80), as can be observed from the following debug trace of the BGP OPEN message from CSC-PE-2 to CSC-PE-3.

```
1 2022/04/06 16:01:45.985 CEST MINOR: DEBUG #2001 Base BGP
"BGP: OPEN
Peer 1: 192.0.2.3 - Send (Active) BGP OPEN: Version 4
   AS Num 64500: Holdtime 90: BGP_ID 192.0.2.2: Opt Length 20 (ExtOpt F)
   Opt Para: Type CAPABILITY: Length = 18: Data:
     Cap_Code GRACEFUL-RESTART: Length 2
       Bytes: 0x0 0x78
     Cap_Code MP-BGP: Length 4
       Bytes: 0x0 0x1 0x0 0x80
     Cap_Code ROUTE-REFRESH: Length 0
     Cap_Code 4-OCTET-ASN: Length 4
       Bytes: 0x0 0x0 0xfb 0xf4
"
```

Step 5. Configure core connectivity for CSC-PE-3

The next step is to configure the base router instance of CSC-PE-3 so that it can exchange VPN-IPv4 routes with CSC-PE-2 and potentially other CSC-PEs. This requires:

- Router ID and AS configuration.
- Network interface creation and configuration, including assignment of an IPv4 address to the system interface.
- Configuration of the IGP protocol; in this example IS-IS is used.
- Configuration of the LDP protocol (optional).
- Configuration of RSVP LSPs used to reach remote CSC-PE devices (optional).
- Configuration of the BGP protocol.

The base router configuration of CSC-PE-3 is as follows:

```
# on CSC-PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        interface "int-CSC-PE-3-CSC-PE-2" {
            port 1/1/2:1000
            ipv4 {
                primary {
                    address 192.168.23.2
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.3
                    prefix-length 32
                }
            }
        }
        bgp {
            group "core" {
                type internal
                cluster {
                    cluster-id 192.0.2.3
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            neighbor "192.0.2.2" {
                split-horizon true
                group "core"
                family {
                    vpn-ipv4 true
                }
            }
        }
        isis 0 {
            admin-state enable
            level-capability 2
            area-address [49.01]
            interface "int-CSC-PE-3-CSC-PE-2" {
                interface-type point-to-point
            }
            interface "system" {
                passive true
            }
            level 2 {
                wide-metrics-only true
            }
        }
        ldp {
            interface-parameters {
                interface "int-CSC-PE-3-CSC-PE-2" {
                    ipv4 {
                    }
                }
            }
        }
```

The peer type is IBGP (**type internal**. Can also be configured with **peer-as** equal to the locally configured **autonomous-system**).

The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).

The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128.

The **cluster** command configures CSC-PE-2 as a route reflector for clients in the BGP group "core". This is not required and in a more typical deployment, the route reflector would be a separate router from any CSC-PE.

Step 6. Configure CSC service on CSC-PE-3

CSC-PE-3 must be configured with a VPRN in **carrier-carrier-vpn** mode to provide CSC service to CSC-CE-4. The configuration of the VPRN is as follows:

```
# on CSC-PE-3:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64500
            router-id 192.0.2.3
            carrier-carrier-vpn true
            bgp-ipvpn {
                mpls {
                    admin-state enable
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    route-distinguisher "64500:13"
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
                group "CSC-CE" {
                    as-override true
                    peer-as 64496
                    ebgp-default-reject-policy {
                        import false
                    }
                    export {
                        policy ["BGP-VPN-routes"]
                    }
                }
                neighbor "192.168.34.2" {
                    split-horizon true
                    group "CSC-CE"
                    family {
                        label-ipv4 true
                    }
                }
            }
            network-interface "int-CSC-PE-3-CSC-CE-4" {
                port 1/1/1:1
                ipv4 {
                    primary {
                        address 192.168.34.1
                        prefix-length 30
                    }
                }
            }
        }
```

The **carrier-carrier-vpn true** command is mandatory. It cannot be configured if the VPRN has any SAP or spoke-SDP access interfaces configured; they must first be removed.

The **auto-bind-tunnel** command must be set appropriately for the type of transport desired to other CSC-PEs, but GRE is not supported.

The interface to CSC-CE-4 must be a network interface. A network interface can be associated with an entire Ethernet port, a VLAN sub-interface of an Ethernet port, an entire LAG or a VLAN sub-interface of a LAG. In all cases, the associated Ethernet ports must be configured in network or hybrid mode.

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon true** command is optional. It prevents a best BGP route from the CSC-CE peer from being re-advertised back to that peer.

The **as-override** command replaces CSC-CE-4's AS number 64496 with CSC-PE-3's AS number 64500 in the AS_PATH attribute of routes advertised to CSC-CE-4. Without this configuration, CSC-CE-4 may reject routes originated by CSC-CE-1 as invalid due to an AS-path loop.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **export** command applies a BGP export policy to the session. The configuration of the policy is as follows:

```
# on CSC-PE-3:
configure {
    policy-options {
        policy-statement "BGP-VPN-routes" {
            entry 10 {
                from {
                    protocol {
                        name [bgp-vpn]
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
```

The effect of the BGP export policy is to re-advertise VPN-IPv4 routes imported into the CSC VPRN (and used for forwarding) to CSC-CE-4.

Step 7. Verify exchange of VPN-IPv4 routes between CSC-PE-2 and CSC-PE-3.

When the preceding steps have been completed, CSC-PE-2 advertises the labeled-IPv4 route for 192.0.2.1/32 (the system IP address of CSC-CE-1) to CSC-PE-3. This can be checked in the RIB Out of CSC-PE-2, as follows:

```
[/]

===============================================================================
```

Step 8. Configure CSC-CE-4

In this example, CSC-CE-4 is a PE router with Layer 2 and Layer 3 VPN services that must extend across the CSC VPN service. The configuration of one such Layer 3 VPN service in CSC-CE-4 is as follows:

```
# on CSC-CE-4:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:14"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "loopback-1" {
                loopback true
                ipv4 {
                    primary {
                        address 10.14.30.2
                        prefix-length 24
                    }
                }
            }
        }
```

For brevity, the preceding configuration sample omits commands related to SAP IP interfaces, spoke-SDP IP interfaces, PE-CE routing protocols, QoS, IP filters, and so on.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The base routing instance of CSC-CE-4 is configured with the appropriate router ID and AS number and the system interface has an IPv4 address (usually the same as the router ID). The interface to CSC-PE-3 is configured. The base router configuration of CSC-CE-4 is as follows:

```
# on CSC-CE-4:
configure {
    router "Base" {
        interface "int-CSC-CE-4-CSC-PE-3" {
            port 1/1/2:1        # connected to VPRN1 network interface on CSC-PE-3
            ipv4 {
                primary {
                    address 192.168.34.2
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.4
                    prefix-length 32
                }
            }
        }
```

BGP is configured as the control plane protocol running on the interface to CSC-PE-3, as follows:

```
# on CSC-CE-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "CSC-PE" {
                peer-as 64500
            }
            neighbor "192.168.34.1" {
                split-horizon true
                group "CSC-PE"
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-systemIP"]
                }
                export {
                    policy ["export-systemIP"]
                }
            }
```

The peer type is EBGP (**peer-as** is different from the locally configured **autonomous-system**).

The address family for the EBGP session is **label-ipv4** (the **neighbor** address is an IPv4 address). Address family label-ipv4 causes MP-BGP negotiation of the address family for AFI=1 and SAFI=4 (IPv4 NLRI with MPLS labels).

The **split-horizon true** command is optional. It prevents a best BGP route from the CSC-PE peer from being re-advertised back to that peer.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **export** and **import** commands apply BGP export and import policies to the session. The configuration of the policies is as follows:

```
# on CSC-CE-4:
configure {
    policy-options {
        prefix-list "system-IP" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "export-systemIP" {
            entry 10 {
                from {
                    prefix-list ["system-IP"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
        policy-statement "import-systemIP" {
            entry 10 {
                from {
                    prefix-list ["system-IP"]
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
```

The purpose of the BGP export policy is to advertise the system IP address of CSC-CE-4 as a labeled-IPv4 BGP route toward CSC-PE-3. The import policy imports the system IP address of CSC-CE-1.

Step 9. Verify exchange of labeled IPv4 routes between CSC-PE-3 and CSC-CE-4

When the preceding steps are completed, CSC-PE-3 advertises the labeled-IPv4 route for 192.0.2.1/32 to CSC-CE-4. This can be checked in the RIB Out for CSC VPRN 1 on CSC-PE-3, as follows:

```
[/]
A:admin@CSC-PE-3# show router 1 bgp routes 192.0.2.1/32 label-ipv4 hunt

NextHop                       Received       Advertised     Label
                              Label          Label          Origin
-------------------------------------------------------------------------------
192.0.2.2                     524284         524283         Internal
192.0.2.2                     524285         524285         Internal
-------------------------------------------------------------------------------
Total Labels allocated:   2
===============================================================================
```

In the preceding output, the second entry for NextHop 192.0.2.2 corresponds to the prefix 192.0.2.1/32; recall from Step 7 that CSC-PE-3 received the VPN-IPv4 route with label value 524285 and it can be seen from this step that it re-advertised the route to CSC-CE-4 with the same label value 524285.

Step 10. Configure BGP session between CSC-CE-1 and CSC-CE-4

The final step in the setup of the CSC solution shown in Figure 302: CSC network topology is the creation of a BGP session between CSC-CE-1 and CSC-CE-4 so that they can exchange routes belonging to VPN services they support. The configuration of this BGP session on CSC-CE-1 is as follows:

```
# on CSC-CE-1:
configure {
    router "Base" {
        bgp {
            group "CSC-CE" {
                type internal
            }
            neighbor "192.0.2.4" {
                group "CSC-CE"
                family {
                    vpn-ipv4 true
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

The configuration of the BGP session on CSC-CE-4 is similar, as follows:

```
# on CSC-CE-4:
configure {
    router "Base" {
        bgp {
            group "CSC-CE" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "CSC-CE"
                family {
                    vpn-ipv4 true
                }
            }
```

The configuration of the BGP session between CSC-CE-1 and CSC-CE-4 has the following properties:

- The peer type is IBGP (**type internal**. Alternatively, **peer-as** can be configured with the same value as the locally configured **autonomous-system**).
- The transport for the IBGP session is IPv4 (the **neighbor** address is an IPv4 address).
- The **family vpn-ipv4** command causes MP-BGP negotiation of the address family for AFI=1 and SAFI=128.

Step 11. Verify exchange of VPN-IPv4 routes

When the preceding steps have been completed, CSC-PE-3 can advertise a VPN-IPv4 route for some IP prefix (for example, 10.11.30.0/24) to CSC-CE-4. This can be checked in the RIB In of CSC-CE-4 as follows:

```
[/]
A:admin@CSC-CE-4# show router bgp routes 10.11.30.0/24 vpn-ipv4 hunt

```

Conclusion

Carrier Supporting Carrier is a scalable and secure solution for using an infrastructure IP VPN to transport traffic between dispersed CSC-CE devices belonging to an ISP or other service provider. Many different topology models are supported by SR OS. This chapter has explored one simplified configuration that can serve as the basis for more complicated setups.

Flexible Algorithms for SRv6-based VPRNs

This chapter provides information about flexible algorithms (Flex-Algorithm) for VPRNs that are based on segment routing over IPv6 (SRv6).

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. The Flex-Algorithm for SRv6-based VPRNs feature is supported on FP-based platforms with FP4-based network ports in SR OS Release 21.5.R2 and later.

Overview

The Flex-Algorithm for SRv6-based VPRNs feature allows the computation of constraint-based paths across an SRv6-enabled network, based on metrics other than the default interior gateway protocol (IGP) metrics. The supported metrics are:

- IGP metrics
- link delay metrics
- traffic engineering (TE) metrics

Based on the metrics that are specifically configured for it, each Flex-Algorithm instance computes optimum paths across routers that participate in the Flex-Algorithm instance. For these paths, the IGP protocol automatically creates SRv6 tunnels between every pair of routers participating in the Flex-Algorithm instance. Two or more routers participate in a single Flex-Algorithm instance; a single router may participate in multiple Flex-Algorithm instances.

At least one router advertises (via extensions to the IGP protocol) the flexible algorithm definition (FAD). The **metric-type** command in the **routing-options flexible-algorithm-definitions flex-algo <flex-algo-name>** context configures the metric type that the Flex-Algorithm instance uses: *igp*, *delay*, or *te-metric*. The router that advertises the FAD typically also participates in the Flex-Algorithm instance. The other routers participate in the advertised Flex-Algorithm instance, without also advertising it. For reasons of redundancy, multiple routers may advertise the same FAD. In that case, the configuration of that FAD should be identical on all these routers. If not, all routers that participate in the Flex-Algorithm instance install from conflicting FADs only the FAD that has the highest priority value. If conflicting FADs have the same priority value, all routers that participate in the Flex-Algorithm instance install only the FAD that is advertised by the IS-IS-enabled router with the highest IS-IS system ID (or by the OSPF-enabled router with the highest OSPF router ID).

The **algorithm** command in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context, associates each Flex-Algorithm instance (algorithm 128 to algorithm 255) with one specific SRv6 locator, which must be different from the base algorithm (algorithm 0) SRv6 locator. This algorithm

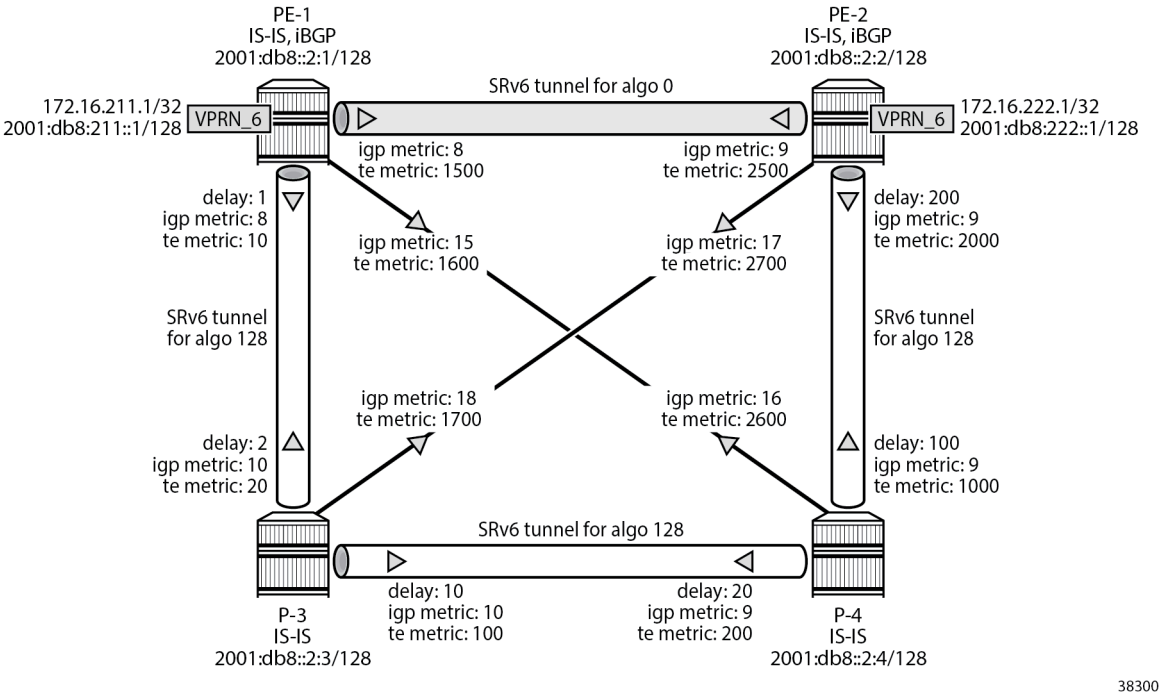
identifier is included in the SRv6 locator TLV when advertising the locator into IS-IS. The same FAD may be used in multiple Flex-Algorithm instances. Each Flex-Algorithm instance is associated with, at most, one SRv6 locator. Each SRv6 locator has, at most, one associated Flex-Algorithm instance. The **default-locator** command in the **service vprn <service-name> bgp-ipvpn segment-routing-v6 <bgp-instance> srv6** context configures the SRv6 locator that the VPRN data traffic across SRv6-enabled networks uses.

The further processing of the Flex-Algorithm-based VPRN data traffic across SRv6-enabled networks follows that of the base algorithm-based VPRN data traffic across SRv6-enabled networks, as described in the "Segment Routing over IPv6 for VPRN" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

Configuration

Figure 303: Example topology shows the example topology with four routers. The SRv6-enabled network that it represents comprises PE-1 and PE-2 in the control and data plane, and P-3 and P-4 in the data plane only. The SRv6-enabled network has only IPv6 addresses and interfaces. IS-IS is configured on all routers. BGP is configured only on PE-1 and PE-2.

Figure 303: Example topology



PE-1 and PE-2 are SRv6-enabled routers that each contain a VPRN instance. In this example, bidirectional IPv4 and IPv6 VPRN traffic flows are enabled between PE-1 and PE-2.

To illustrate what IS-IS interface metrics are used and how, the IS-IS interface metrics are configured explicitly (that is, differently from their default values), using the **metric** <*metric*> command (for IPv4 unicast traffic) and the **ipv6-unicast-metric** <*ipv6-unicast-metric*> command (for IPv6 unicast traffic) in the **router Base isis 0 interface <interface-name> level <level-number>** context. Different values can be applied for IS-IS level 1 and IS-IS level 2; for each IS-IS level, a distinction can be made between

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

IPv4 unicast traffic and IPv6 unicast traffic. For each IS-IS level and traffic type, different values can be configured in the two directions between two routers.

As a first example, the link delay metric is chosen for the Flex-Algorithm operation. The link delay metrics are configured explicitly, using the **static** <*value*> command (value in microseconds) in the **router Base interface <interface-name> if-attribute delay** context, only on the links between PE-1 and P-3, P-3 and P-4, and P-4 and PE-2. These metrics are configured differently in the two directions on each link (shown in the example topology as: "delay: <value in microseconds>"). The link delay metric can be configured on links between any pair of routers participating in the Flex-Algorithm instance. Any link that does not have the link delay metric configured is excluded from the Flex-Algorithm instance computation, which may result in no valid path between the ingress and egress routers. The link delay metric values are used for both IPv4 unicast traffic and IPv6 unicast traffic.

As a second example, the TE metric is chosen for the Flex-Algorithm operation. The TE metrics are configured explicitly, using the **te-metric** <*value*> command in the **router Base mpls interface <interface-name>** context, on all links. These metrics are configured differently in the two directions on each link, such that the direct link between the two routers PE-1 and PE-2 is always preferred.

The **ping** and **traceroute** commands between IPv4 and IPv6 loopback addresses in the VPRNs, as described in following sections, are used to simulate data traffic.

SRv6 requires wide metrics to match the 32-bit metric field in SRv6 locator TLV. The example configuration has wide metrics configured only for level 2. So, only the explicitly configured IS-IS level 2 interface metric values are used. Also, multi-topology and multi-protocol are not enabled in the example configuration. So, the explicitly configured IS-IS level 2 interface metric values are used for both IPv4 unicast traffic and IPv6 unicast traffic.

Configure the router

This configuration includes:

- ports and IPv6-only interfaces on PE-1, PE-2, P-3, and P-4, with link delay metrics configured where needed
- port cross-connect (PXC) on PE-1 and PE-2, using internal loopbacks on an FP4 MAC chip, as described in the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*
- IS-IS on PE-1, PE-2, P-3, and P-4, which includes:
  - level 2 capability with wide metrics, and IPv4 metrics on all IS-IS level 2 interfaces
  - native IPv6 routing
  - the **traffic-engineering** and **traffic-engineering-options** commands, as a best practice to advertise the router capability within the autonomous system (AS)
- BGP on PE-1 and PE-2, with internal group "gr_v6_internal", which includes:
  - the IPv4 and IPv6 families
  - **extended-nh-encoding** for IPv4
  - **advertise-ipv6-next-hops** for IPv4
  - BGP neighbor **system** IPv6 addresses
  - **next-hop-self**

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

As the core network topology uses IPv6 for BGP peering (with IPv6 next hop addresses), the commands **advertise-ipv6-next-hops** and **extended-nh-encoding** need to be applied at the BGP, group, or neighbor level, so as to advertise and receive IPv4 routes with IPv6 next hop addresses. The **advertise-ipv6-next-hops** command instructs the system to advertise IPv4 routes with IPv6 next hop addresses. The **extended-nh-encoding** command configures BGP to advertise the capability to receive IPv4 routes with IPv6 next hop addresses.

The following example configuration applies for PE-1. A similar configuration applies for PE-2. P-3 and P-4 have no BGP configuration.

```
A:admin@PE-1# configure {
    router "Base" {
        autonomous-system 64500
        interface "int-PE-1-PE-2" {
            description "interface between PE-1 and PE-2"
            port 1/1/c1/1:1000
            ipv6 {
                address 2001:db8::168:12:1 {
                    prefix-length 126
                }
            }
            admin-state enable
        }
        interface "int-PE-1-P-3" {
            description "interface between PE-1 and P-3"
            port 1/1/c2/1:1000
            ipv6 {
                address 2001:db8::168:13:1 {
                    prefix-length 126
                }
            }
            if-attribute {
                delay {
                    static 1    # microseconds
                }
            }
            admin-state enable
        }
        interface "int-PE-1-P-4" {
            description "interface between PE-1 and P-4"
            port 1/1/c3/1:1000
            ipv6 {
                address 2001:db8::168:14:1 {
                    prefix-length 126
                }
            }
            admin-state enable
        }
        interface "system" {
            description "system interface of PE-1"
            ipv6 {
                address 2001:db8::2:1 {
                    prefix-length 128
                }
            }
            admin-state enable
        }
        isis 0 {
            level-capability 2
            area-address [49.0001]
            traffic-engineering true
            traffic-engineering-options {

    }
}
```

Configure the VPRN services on PE-1 and on PE-2

This configuration includes:

- an IPv4 address and an IPv6 address for a loopback interface "lb_itf_vprn"
- BGP, with external group "gr_v6_vprn", which includes:
  - IPv4 and IPv6 families
  - **extended-nh-encoding** for IPv4
  - **advertise-ipv6-next-hops** for IPv4
  - BGP neighbor **interface** IPv6 addresses, with BGP neighbors in a different external AS

The following example configuration applies for the VPRN on PE-1. A similar configuration applies for the VPRN on PE-2.

```
A:admin@PE-1# configure {
    service {
        vprn "VPRN_6" {
            service-id 6
            customer "1"
            description "VPRN_6 on PE-1"
            autonomous-system 64500
            interface "lb_itf_vprn" {
                ipv4 {
                    primary {
                        address 172.16.211.1
                        prefix-length 32
                    }
                }
                description "VPRN_6 interface on PE-1 for external subnet"
                ipv6 {
                    address 2001:db8:211::1 {
                        prefix-length 128
                    }
                }
                loopback true
            }
            bgp {
                ebgp-default-reject-policy {
                    import false
                    export false
                }
                group "gr_v6_vprn" {

    }
}
```

Configure SRv6 in the router Base context on PE-1 and PE-2

Configure the SRv6 **locator** in the **router Base segment-routing segment-routing-v6** context on PE-2. Perform a similar configuration on PE-1, with **ip-prefix** *2001:db8:aaaa:101::/64* for SRv6 **locator** *"PE-1_loc"*.

```
A:admin@PE-2# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                locator "PE-2_loc" {
                    block-length 48
                    function-length 20
                    prefix {
                        ip-prefix 2001:db8:aaaa:102::/64
                    }
                    admin-state enable
                }
            }
        }
    }
}
```

Configure the FPEs on PE-1 and PE-2.

```
A:admin@PE-2# configure {
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
            application {
                srv6 {
                    type origination
                }
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                srv6 {
                    type termination
                }
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    }
}
```

Use FPE 1 as the SRv6 origination FPE in the **router Base segment-routing segment-routing-v6** context and FPE 2 as the SRv6 termination FPE in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*. For more information, see the "Segment Routing over IPv6" chapter in the Segment Routing and PCE volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

```
*A:PE-2# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                origination-fpe [1]
                locator "PE-2_loc" {
                    termination-fpe [2]
                    admin-state enable
                }
            }
        }
    }
}
```

Configure the SRv6 End function (equivalent to an IPv4 node SID) in the **router Base segment-routing segment-routing-v6 base-routing-instance locator <locator-name>** context on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*.

```
A:admin@PE-2# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                base-routing-instance {
                    locator "PE-2_loc" {
                        function {
                            end 1 {
                                srh-mode usp
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Advertise the SRv6 locator in IS-IS while ensuring level 2 capability on PE-2. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc"*.

```
A:admin@PE-2# configure {
    router "Base" {
        isis 0 {
            segment-routing-v6 {
                locator "PE-2_loc" {
                    level-capability 2
                }
                admin-state enable
            }
        }
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
}
```

Configure SRv6 for the VPRNs on PE-1 and PE-2

On PE-1 and PE-2, extend the BGP advertisements to include the VPN-IPv4 and VPN-IPv6 families.

```
A:admin@PE-1#/A:admin@PE-2# configure {
    router "Base" {
        bgp {
            rapid-update {
                vpn-ipv4 true
                vpn-ipv6 true
            }
            group "gr_v6_internal" {
                family {
                    ipv4 true
                    ipv6 true
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
                extended-nh-encoding {
                    ipv4 true
                    vpn-ipv4 true
                }
                advertise-ipv6-next-hops {
                    ipv4 true
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
            admin-state enable
        }
    }
}
```

On PE-2, create an SRv6 instance for the VPRN service. Use the SRv6 locator from the **router Base segment-routing segment-routing-v6** context and configure End.DT4 and End.DT6 functions for it.

Use the created SRv6 instance in the **service vprn <service-name> bgp-ipvpn segment-routing-v6 <bgp-instance>** context, with the configured SRv6 locator as the default locator. Ensure a unique route distinguisher. Use the unique PE-2 system IPv6 address as the source address. Perform a similar configuration on PE-1, with the PE-1 SRv6 locator as the default locator, the PE-1 system IPv6 address as the source address, and a different route distinguisher.

```
A:admin@PE-2# configure {
    service {
        vprn "VPRN_6" {
            segment-routing-v6 1 {
                locator "PE-2_loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                    }
                }
            }
            bgp-ipvpn {
                segment-routing-v6 1 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    route-distinguisher "192.0.2.2:6"
                    srv6 {
                        instance 1
                        default-locator "PE-2_loc"
                    }
                    source-address 2001:db8::2:2
                    vrf-target {
                        community "target:64506:6"
                    }
                    admin-state enable
                }
            }
            admin-state enable
        }
    }
}
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that IPv4 data traffic is possible between the local VPRN on PE-1 and the remote VPRN on PE-2:

```
A:admin@PE-1# ping 172.16.222.1 router-instance "VPRN_6"
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=1.72ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.51ms, avg = 1.65ms, max = 1.75ms, stddev = 0.085ms

A:admin@PE-1# traceroute 172.16.222.1 router-instance "VPRN_6"
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    1.64 ms  1.57 ms  1.61 ms
```

This data traffic uses the SRv6 tunnels over the direct link between PE-1 and PE-2.

For IPv4 data traffic, the VPRN routing table shows the next hop and the applicable IGP metric for the route to 172.16.222.1.

```
A:admin@PE-1# show router 6 route-table 172.16.222.1

The **show router isis 0 topology** command lists the IS-IS nodes, and for each IS-IS node, the outgoing interface and the next hop. There are only IS-IS nodes at IS-IS level 2. The output of this command shows that data traffic from PE-1 to PE-2 uses interface "int-PE-1-PE-2" to PE-2, while, for example, data traffic from PE-1 to P-3 uses interface "int-PE-1-P-3" to P-3.

```

===============================================================================
```

Verify the IS-IS data base on PE-1 with **show router isis 0 database detail**. The output of this command (shortened here for PE-1 and PE-2, and omitted for P-3 and P-4) provides information about each IS-IS-enabled router. For each uniquely identified IS-IS-enabled router, the SRv6 information indicates:

- the IS-IS-advertised router capabilities
- the IS-IS topology details
- the IPv4 and IPv6 reachability details
- the advertised SRv6 locator TLV
- the advertised configured SRv6 End SID

There is only IS-IS information at IS-IS level 2. On each IS-IS interface, the IS-IS level 2 metrics for IPv4 and IPv6 are identical.

Only the default metric-based SPF algorithm instance 0 is in use, as listed in the SR Alg sub-TLV of the Router Cap TLVs.

On PE-1 and PE-2, the SRv6 locator prefix for algorithm 0, with their End SRv6 SID are present.

```

PE-2 advertises to PE-1 the information for network prefix 172.16.222.1/32, as listed in the RIB In Entries section in the following example. PE-1 acts in a similar way as PE-2 for network prefix 172.16.211.1/32, as listed in the RIB Out Entries section.

The following output shows the corresponding VPN-IPv4 BGP routes on PE-1:

```
A:admin@PE-1# show router bgp routes vpn-ipv4 hunt

Verify the IPv6 route table on PE-1. The IPv6 route table has routes to the local and remote SRv6 locators and to the local SRv6 End function SID. The SRv6 locator prefix of PE-2 is reached via an SRv6 tunnel using IS-IS. The routes with protocol **"SRV6"** correspond with the locally configured SRv6 locator prefix of PE-1 and the locally configured SRv6 End function.

```
A:admin@PE-1# show router route-table ipv6

===============================================================================
```

The next hop is the End.DT6 SRv6 SID of the SRv6 **locator** *"PE-2_loc"* for the VPRN on PE-2, which PE-1 learns from a BGP update from PE-2. The SRv6 tunnel to this next hop has label 524287.

The applicable IGP metric is also 8, which again corresponds with the IS-IS level 2 "int-PE-1-PE-2" interface metric value.

PE-2 advertises to PE-1 the information for network prefix 2001:db8:222::1/128, as listed in the RIB In Entries section in the following example. PE-1 acts in a similar way as PE-2 for network prefix 2001:db8:211::1/128, as listed in the RIB Out Entries section.

The following output shows the corresponding VPN-IPv6 BGP routes on PE-1:

```
A:admin@PE-1# show router bgp routes vpn-ipv6 hunt

```

Configure a delay-based flexible algorithm

Define a Flex-Algorithm definition "FAD_delay" that takes delay as its metric. The FAD can reside on any IS-IS-enabled router. In this example, it resides on PE-1.

```
A:admin@PE-1# configure {
    routing-options {
        flexible-algorithm-definitions {
            flex-algo "FAD_delay" {
                description "FAD_delay_based"
                metric-type delay
                admin-state enable
            }
        }
    }
}
```

Configure PE-1 so as to advertise the FAD "FAD_delay" in Flex-Algorithm instance 128 (possible values between 128 and 255) and to participate in the Flex-Algorithm instance 128.

```
A:admin@PE-1# configure {
    router "Base" {
        isis 0 {
            flexible-algorithms {
                flex-algo 128 {
                    advertise "FAD_delay"
                    participate true
                    loopfree-alternate {
                    }
                }
                admin-state enable
            }
        }
    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
}
```

Ensure that the other IS-IS-enabled routers that must support the Flex-Algorithm instance participate in this Flex-Algorithm instance.

```
A:admin@PE-2#/A:admin@P-3#/A:admin@P-4# configure {
    router "Base" {
        isis 0 {
            flexible-algorithms {
                flex-algo 128 {
                    participate true
                    loopfree-alternate {
                    }
                }
                admin-state enable
            }
        }
    }
}
```

Define a new and unique SRv6 locator prefix to this new Flex-Algorithm instance. A separate SRv6 locator is needed for each Flex-Algorithm instance. So, for the Flex-Algorithm instance 128, configure SRv6 **locator** *"PE-2_loc_FAD128"* on PE-2. Perform a similar configuration for SRv6 **locator** *"PE-1_loc_FAD128"* with **ip-prefix** *2001:db8:a128:101::/64* on PE-1.

```
A:admin@PE-2# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                locator "PE-2_loc_FAD128" {
                    block-length 48
                    function-length 20
                    algorithm 128
                    prefix {
                        ip-prefix 2001:db8:a128:102::/64
                    }
                    admin-state enable
                }
            }
        }
    }
}
```

For SRv6 **locator** *"PE-2_loc_FAD128"* on PE-2, use FPE 2 as the SRv6 termination FPE in the **router Base segment-routing segment-routing-v6 locator <locator-name>** context and configure the SRv6 End function (equivalent to an IPv4 node SID) in the **router Base segment-routing segment-routing-v6 base-routing-instance locator <locator-name>** context. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
A:admin@PE-2# configure {
    router "Base" {
        segment-routing {
            segment-routing-v6 {
                locator "PE-2_loc_FAD128" {
                    termination-fpe [2]
                    admin-state enable
                }
                base-routing-instance {
                    locator "PE-2_loc_FAD128" {
                        function {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                            end 1 {
                                srh-mode usp
                            }
                        }
                    }
                }
            }
        }
    }
}
```

In the **router Base isis 0 segment-routing-v6 locator <locator-name>** context on PE-2, configure the IS-IS level capability for SRv6 **locator** *"PE-2_loc_FAD128"* and enable SRv6 in the IS-IS context. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
A:admin@PE-2# configure {
    router "Base" {
        isis 0 {
            segment-routing-v6 {
                locator "PE-2_loc_FAD128" {
                    level-capability 2
                }
                admin-state enable
            }
        }
    }
}
```

The **show router isis 0 segment-routing-v6 locator** command lists the local and remote SRv6 locator prefixes for all applied algorithms (0 and 128).

```
A:admin@PE-2# show router isis 0 segment-routing-v6 locator

```

On PE-2, in the **service vprn <service-name> segment-routing-v6 <bgp-instance> locator <locator-name>** context, configure End.DT4 and End.DT6 functions for SRv6 **locator** *"PE-2_loc_FAD128"*.

On PE-2, in the **service vprn <service-name> bgp-ipvpn segment-routing-v6 <bgp-instance> srv6** context, use the SRv6 **locator** *"PE-2_loc_FAD128"* as the default locator, instead of the earlier SRv6 **locator** *"PE-2_loc"*. Perform a similar configuration on PE-1, for SRv6 **locator** *"PE-1_loc_FAD128"*.

```
A:admin@PE-2# configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        vprn "VPRN_6" {
            segment-routing-v6 1 {
                locator "PE-2_loc_FAD128" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                    }
                }
            }
            bgp-ipvpn {
                segment-routing-v6 1 {
                    srv6 {
                        instance 1
                        default-locator "PE-2_loc_FAD128"
                    }
                    admin-state enable
                }
            }
            admin-state enable
        }
    }
}
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that data traffic between the local VPRN on PE-1 and the remote VPRN on PE-2 uses the Flex-Algorithm.

For IPv4 data traffic:

```
A:admin@PE-1# ping 172.16.222.1 router-instance "VPRN_6"
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=2.84ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.49ms, avg = 2.68ms, max = 2.84ms, stddev = 0.136ms

A:admin@PE-1# traceroute 172.16.222.1 router-instance "VPRN_6"
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    3.04 ms  2.60 ms  2.54 ms
```

For IPv6 data traffic:

```
A:admin@PE-1# ping 2001:db8:222::1 router-instance "VPRN_6"
PING 2001:db8:222::1 56 data bytes
64 bytes from 2001:db8:222::1 icmp_seq=1 hlim=64 time=2.11ms.
---snip---
---- 2001:db8:222::1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 1.87ms, avg = 2.07ms, max = 2.43ms, stddev = 0.194ms

A:admin@PE-1# traceroute 2001:db8:222::1 router-instance "VPRN_6"
traceroute to 2001:db8:222::1, 30 hops max, 60 byte packets
  1  2001:db8:222::1 (2001:db8:222::1)    2.89 ms  2.70 ms  2.55 ms
```

This data traffic uses the SRv6 tunnels over the links between PE-1 and P-3, P-3 and P-4, and P-4 and PE-2.

For IPv4 data traffic, the VPRN routing table shows the next hop and the applicable metric for the route to 172.16.222.1. In this example, the End.DT4 SID is copied into the IPv6 DA field of the tunneled packet.

```
A:admin@PE-1# show router 6 route-table 172.16.222.1

===============================================================================
Route Table (Service: 6)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric

The **show router isis 0 topology flex-algo 128** command lists the IS-IS nodes in the topology, and for each IS-IS node, the outgoing interface and the next hop. There are only IS-IS nodes at IS-IS level 2. The output of this command shows that data traffic from PE-1 to all IS-IS-enabled routers that participate in the Flex-Algorithm instance 128 (PE-2, P-3, and P-4) uses interface "int-PE-1-P-3" to P-3.

```
A:admin@PE-1# show router isis 0 topology flex-algo flex-algo-id 128

```

The IS-IS database on PE-1 contains more information, which relates to the use of the Flex-Algorithm.

There are additional link delay metrics (identical for IPv4 and IPv6) for each IS-IS-enabled router, as listed in the TE APP LINK ATTR sub-TLVs. The non-legacy Standard Application Bit Mask (SABM) flag value X indicates that they are associated with the Flex-Algorithm. Only the End SRv6 SIDs of the SRv6 locators are present.

Next to the default metric-based SPF, the Flex-Algorithm instance 128 is also in use, as listed in the SR Alg sub-TLV of the Router Cap TLVs.

The FAD sub-TLV of the PE-1 Router Cap TLV contains the delay-based definition for the Flex-Algorithm instance 128, which only router PE-1 advertises. The FAD flag value M indicates that the delay is a prefix metric.

On PE-1 and PE-2, next to the base SRv6 locator (for algorithm 0), with its End SRv6 SID, there is an additional SRv6 locator for the Flex-Algorithm instance 128, with its End SRv6 SID. This additional SRv6 locator indicates the prefix.

The **show router isis 0 database detail** command output on PE-1 is shown below, with separate entries for each IS-IS-enabled router.

For PE-1:

```
A:admin@PE-1# show router isis 0 database detail

PE-2 advertises to PE-1 payload prefix 172.16.222.1/32, as listed in the RIB In Entries section in the following example. PE-1 computes the applicable metric 111, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2". PE-1 advertises to PE-2 payload prefix 172.16.211.1/32, as listed in the RIB Out Entries section in the following example. PE-2 computes the applicable metric 222, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-2-P-4", "int-P-4-P-3", and "int-P-3-PE-1".

The following output shows the corresponding VPN-IPv4 BGP routes on PE-1:

```
A:admin@PE-1# show router bgp routes vpn-ipv4 hunt

```

The next hop is the End.DT6 SRv6 SID of the SRv6 **locator** *"PE-2_loc_FAD128"* for the VPRN on PE-2, which PE-1 learns from a BGP update from PE-2. The SRv6 tunnel to this next hop has label 524285.

The applicable metric is also 111, which again corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2".

PE-2 advertises to PE-1 the information for network prefix 2001:db8:222::1/128, as listed in the RIB In Entries section in the following example. PE-1 computes the applicable metric 111, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-1-P-3", "int-P-3-P-4", and "int-P-4-PE-2". PE-1 advertises to PE-2 payload prefix 2001:db8:211::1/128, as listed in the RIB Out Entries section in the following example. PE-2 computes the applicable metric 222, which corresponds with the sum of the link delays that are configured on the router interfaces "int-PE-2-P-4", "int-P-4-P-3", and "int-P-3-PE-1".

The following output shows the corresponding VPN-IPv6 BGP routes on PE-1:

```
A:admin@PE-1# show router bgp routes vpn-ipv6 hunt

Configure TE metrics on the router interfaces

For example for PE-1. A similar configuration applies for the other routers.

```
A:admin@PE-1# configure {
    router "Base" {
        mpls {
            interface "int-PE-1-PE-2" {
                te-metric 1500
                admin-state enable
            }
            interface "int-PE-1-P-3" {
                te-metric 10
                admin-state enable
            }
            interface "int-PE-1-P-4" {
                te-metric 1600
                admin-state enable
            }
            admin-state enable
        }
        rsvp {
            admin-state enable
            interface "int-PE-1-P-3" {
            }
            interface "int-PE-1-P-4" {
            }
            interface "int-PE-1-PE-2" {
            }
        }
    }
}
```

Configure a TE-metric-based flexible algorithm

Define a Flex-algorithm definition "FAD_te_metric" that uses TE metric metric type. The FAD can reside on any IS-IS-enabled router. In this example, it resides on PE-1.

```
A:admin@PE-1# configure {
    routing-options {
        flexible-algorithm-definitions {
            flex-algo "FAD_te_metric" {
                description "FAD_te_metric_based"
                metric-type te-metric
                admin-state enable
            }
        }
    }
}
```

Configure PE-1 so as to advertise the FAD "FAD_te_metric" in Flex-Algorithm instance 128 and to participate in the Flex-Algorithm instance 128.

Note: SR OS 22.10 supports multiple concurrent Flex-Algorithm instances, with different instance values between 128 and 255. While "FAD_te_metric" would be associated with a new Flex-Algorithm instance 129 in a deployment scenario, "FAD_te_metric" in the example setup replaces "FAD_delay" for Flex-Algorithm instance 128, so that, for the sake of brevity, the SRv6 locators

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

and labels that were in use earlier for the delay-based flexible algorithm scenario remain in use for the TE-metric-based flexible algorithm scenario.

```
A:admin@PE-1# configure {
    router "Base" {
        isis 0 {
            flexible-algorithms {
                admin-state enable
                flex-algo 128 {
                    advertise "FAD_te_metric"
                    participate true
                }
            }
        }
    }
}
```

Ensure that the IS-IS-enabled routers that must support the Flex-Algorithm instance participate in this Flex-Algorithm instance.

```
A:admin@PE-2#/A:admin@P-3#/A:admin@P-4# configure {
    router "Base" {
        isis 0 {
            flexible-algorithms {
                flex-algo 128 {
                    participate true
                    loopfree-alternate {
                    }
                }
                admin-state enable
            }
        }
    }
}
```

Verify data traffic

At this point, using **ping** and **traceroute** commands, verify that data traffic between the local VPRN on PE-1 and the remote VPRN on PE-2 uses the modified Flex-Algorithm.

For IPv4 data traffic:

```
A:admin@PE-1# ping 172.16.222.1 router-instance "VPRN_6"
PING 172.16.222.1 56 data bytes
64 bytes from 172.16.222.1: icmp_seq=1 ttl=64 time=2.67ms.
---snip---
---- 172.16.222.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.51ms, avg = 2.60ms, max = 2.72ms, stddev = 0.083ms

A:admin@PE-1# traceroute 172.16.222.1 router-instance "VPRN_6"
traceroute to 172.16.222.1, 30 hops max, 40 byte packets
  1  172.16.222.1 (172.16.222.1)    2.66 ms  2.87 ms  2.81 ms
```

For IPv6 data traffic:

```
A:admin@PE-1# ping 2001:db8:222::1 router-instance "VPRN_6"
PING 2001:db8:222::1 56 data bytes
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
64 bytes from 2001:db8:222::1 icmp_seq=1 hlim=64 time=2.05ms.
---snip---
---- 2001:db8:222::1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 2.05ms, avg = 2.46ms, max = 2.70ms, stddev = 0.242ms

A:admin@PE-1# traceroute 2001:db8:222::1 router-instance "VPRN_6"
traceroute to 2001:db8:222::1, 30 hops max, 60 byte packets
  1  2001:db8:222::1 (2001:db8:222::1)    3.05 ms  2.90 ms  2.64 ms
```

For the example with the TE-metric-based flexible algorithm, the same set of **show** commands as for the example with the delay-based flexible algorithm shows that:

- the metric type changes to *te-metric* (from *delay*)
- the TE APP LINK ATTR sub-TLVs contain a **TE Metric** value
- the applicable metric for the route between the local VPRN on PE-1 and the remote VPRN on PE-2 changes to 1110 (from 111 microseconds), corresponding with the sum of the metric values along the path PE-1, P-3, P-4, PE-2, as shown in the following **show router isis 0 topology flex-algo 128 detail** command output examples.
  On PE-1:

```
A:admin@PE-1# show router isis 0 topology flex-algo flex-algo-id 128 detail

Conclusion

The Flex-Algorithm for SRv6-based VPRNs feature allows the computation of constraint-based paths across an SRv6-enabled network, based on metrics other than the default IGP metrics. This allows carrying data traffic over an end-to-end path that is optimized using the best suited metric IGP, delay, or TE).

Inter-AS VPRN Model B

This chapter describes the Inter-AS VPRN Model B.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 15.0.R8, but the MD-CLI in the current edition is based on SR OS Release 22.2.R1.

Overview

An inter-AS Virtual Private Routed Network (VPRN) contains sites that are connected to different Autonomous Systems (ASs). Inter-AS is typically used either to provide extended reach through a partnership/trust agreement, as an interim means to interconnect ASs following acquisition, or because of the internal organization of a single Service Provider (SP). Three models for interconnecting ASs are defined in RFC 4364, labeled model A, B, and C. This chapter describes model B.

Inter-AS VPRN model B encompasses EBGP redistributing VPN-IPv4 and VPN-IPv6 routes between neighboring ASs. An Autonomous System Border Router (ASBR) learns VPN routes from within its AS using IBGP, potentially as a client of a Route Reflector (RR), then uses EBGP to redistribute those labeled VPN routes to its adjacent ASBR.

When redistributing the routes into EBGP, the ASBR imposes next-hop-self on the VPN-IPv4 and VPN-IPv6 update messages and generates its own label value when it advertises the update message upstream. Therefore, the ASBR programs a label-swap entry in its FIB and forwards traffic to the neighboring ASBR using a single-level label stack (the VPN label).

A key property of model B is that it eliminates the need for per-VPRN configuration on the ASBRs. However, both ASBRs must have a mechanism to implicitly learn all VPN prefixes within their local AS and selectively advertise some of those prefixes to the neighboring ASBR.

Figure 304: Inter-AS VPRN Model B control and data plane example shows an example of the control plane and corresponding data plane used in model B, where MPLS is used for transport in both ASs. CE-1 is attached to PE-1 in AS 64496 and advertises prefix 172.31.100.0/24, which is propagated between neighboring ASBRs to PE-2 in AS 64510 and upstream to CE-2.

The IP traffic originating from CE-2 and received by PE-2 is received on the VRF interface of VPRN 100 and encapsulated using a two-level label stack; the inner label is the VPN label (300) and the outer label is the LDP transport label used for reaching the local ASBR-2.

ASBR-2 passes the traffic to ASBR-1, removing the LDP transport label and swapping the VPN label (300) with its VPN label (200), resulting in a single-level label stack.

In turn, ASBR-1 swaps the received VPN label (200) with another VPN label (100) and adds an LDP transport label to reach PE-1.

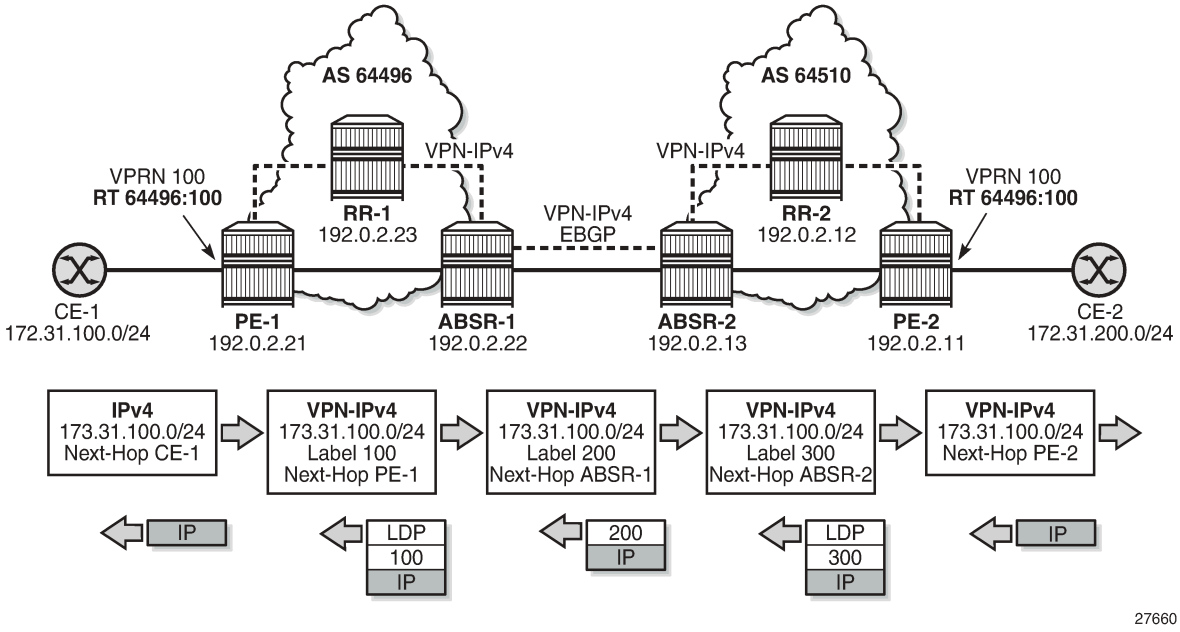
Use subject to Terms available at: www.nokia.com/terms.

Finally, PE-1 removes the VPN label and delivers the unlabeled IP traffic to CE-1.

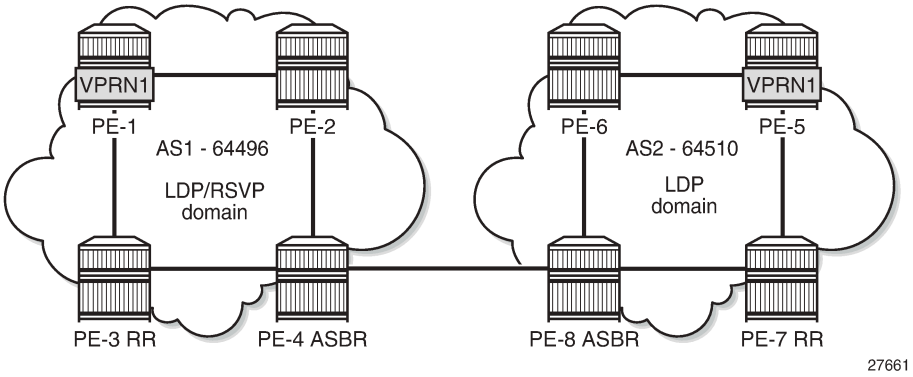
Figure 304: Inter-AS VPRN Model B control and data plane example



Configuration

In the example shown in Figure 305: Inter-AS VPRN Model B topology, IS-IS is configured in each AS, and MP-IBGP sessions are established between the PEs and the RRs in AS 64496 and 64510, PE-3 and PE-7, respectively. LDP and RSVP-TE is used for transport in AS 64496, whereas AS 64510 uses LDP for its transport. An MP-EBGP session is established between ASBR PE-4 and ASBR PE-8.

Figure 305: Inter-AS VPRN Model B topology



The initial configuration includes:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Cards, MDAs, and ports
- Router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled
- LDP and RSVP-TE configured in AS 64496, LDP configured in AS 64510
- IBGP configured in AS 64496, with PE-3 as RR for clients PE-1, PE-2, and PE-4
- IBGP configured in AS 64510, with PE-7 as RR for clients PE-5, PE-6, and PE-8

Model B configuration

There are no specific requirements on PE routers or RRs for enabling inter-AS VPRN model B; only specific configurations are required on the ASBRs.

First, an ASBR must learn the VPN-IPv4 and VPN-IPv6 routes from the local AS and export these routes to the neighbor AS over an MP-EBGP session. This is achieved on each ASBR by declaring an IBGP group for peering with the local RR, and declaring an EBGP group for peering with the neighboring AS. The IBGP and EBGP groups have included the address family **vpn-ipv4**, **vpn-ipv6**, or both.

Additionally, import and export policies can be used to control the VPN-IPv4 and VPN-IPv6 routes exchanged. The latter requires the **vpn-apply-import** and **vpn-apply-export** commands for SR OS to match the prefixes of the VPN-IPv4 and VPN-IPv6 address families.

The use of the **next-hop-resolution** command is described in the Service configuration section. The BGP configuration on ASBR PE-4 is as follows:

```
# on ASBR PE-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            loop-detect discard-route
            inter-as-vpn true                   # required for inter-as VPRN model B
            split-horizon true
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution filter
                            resolution-filter
                                ldp true        # by default enabled for VPN routes
                                rsvp true
                            }
                        }
                    }
                }
            }
            group "vpn-eBGP" {
            }
            group "vpn-iBGP" {
                peer-as 64496
            }
            neighbor "192.0.2.3" {
                group "vpn-iBGP"
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            neighbor "192.168.48.2" {
                group "vpn-eBGP"
                peer-as 64510
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
                ebgp-default-reject-policy {
                    import false
                    export false
                }
            }
```

The configuration on ASBR PE-8 is similar.

Second, the **inter-as-vpn true** command enables the inter-AS functionality and causes the ASBR to store the received VPN-IPv4 routes in its RIB-In, even though it has no VRF that imports these routes. For a route to be considered valid, the ASBR still needs to resolve the next-hop of this route to a tunnel. The **inter-as-vpn true** command will also change the BGP next-hop of advertised and received VPN-IPv4/ VPN-IPv6 routes. When a route is advertised to an EBGP peer, the BGP next-hop is changed to the local-address used for communicating with the EBGP peer. When a route is received from an EBGP peer and advertised to an IBGP peer, the BGP next-hop is changed to the local-address used for communicating with the IBGP peer.

The configuration of the MP-EBGP session between the ASBRs in the EBGP group allows the ASBR to forward labeled packets over its connection with its peer ASBR.

MPLS LSP configuration

Two LSPs are needed between the end-to-end PEs (PE-1 and PE-5) to exchange service traffic bidirectionally, because LSPs are unidirectional. In AS 64496, this is achieved by configuring a first LSP from the service PE (PE-1) to the local ASBR (PE-4), and a second LSP back from the local ASBR (PE-4) toward the service PE (PE-1). In AS 64510, LDP is enabled on all interfaces; no RSVP LSPs are used.

In AS 64496, both LDP and RSVP are enabled. The LSP (and path) from PE-1 to PE-4 runs via PE-3, as follows:

```
# on PE-1:
configure {
    router "Base" {
        ldp {
            interface-parameters {
                interface "int-PE-1-PE-2" {
                    ipv4 {
                    }
                }
                interface "int-PE-1-PE-3" {
                    ipv4 {
                    }
                }
            }
        }
        mpls {
            admin-state enable
            interface "int-PE-1-PE-2" {
            }
            interface "int-PE-1-PE-3" {
            }
            interface "system" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            path "path-PE-1-PE-3-PE-4" {
                admin-state enable
                hop 10 {
                    ip-address 192.168.13.2
                    type strict
                }
                hop 20 {
                    ip-address 192.168.34.2
                    type strict
                }
            }
            lsp "lsp-PE-1-PE-4" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.4
                primary "path-PE-1-PE-3-PE-4" {
                }
            }
        }
        rsvp {
            admin-state enable
            interface "int-PE-1-PE-2" {
            }
            interface "int-PE-1-PE-3" {
            }
        }
```

The LSP (and path) from PE-4 to PE-3 also runs via PE-3, as follows:

```
# on ASBR PE-4:
configure {
    router "Base" {
        ldp {
            interface-parameters {
                interface "int-PE-4-PE-2" {
                    ipv4 {
                    }
                }
                interface "int-PE-4-PE-3" {
                    ipv4 {
                    }
                }
            }
        }
        mpls {
            admin-state enable
            interface "int-PE-4-PE-2" {
            }
            interface "int-PE-4-PE-3" {
            }
            interface "system" {
            }
            path "path-PE-4-PE-3-PE-1" {
                admin-state enable
                hop 10 {
                    ip-address 192.168.34.1
                    type strict
                }
                hop 20 {
                    ip-address 192.168.13.1
                    type strict
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            lsp "lsp-PE-4-PE-1" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.1
                primary "path-PE-4-PE-3-PE-1" {
                }
            }
        }
        rsvp {
            admin-state enable
            interface "int-PE-4-PE-2" {
            }
            interface "int-PE-4-PE-3" {
            }
        }
```

Service configuration

VPRN 1 is configured on PE-1 and PE-5. Although the VPRN service IDs used in both ASs do not need to match, in an inter-AS VPRN model B context, the route targets (RTs) used in both ASs must be coordinated. The RT exported by the PE-1 VPRN 1 must be imported by the PE-5 VPRN 1, and vice versa. In this example, specific **import-community** and **export-community** values are used for VPRN 1; the simplified method using a single **vrf-target community** is used for VPRN 33.

To carry the customer data across AS 64496, tunnels must bind to a VPRN service with the **auto-bind-tunnel** command. Resolution is set to filter, indicating that SR OS must select a tunnel using the information defined in the **resolution-filter** context. The keywords **ldp true** and **rsvp true** in the resolution-filter context indicate that LDP or RSVP tunnels can be used, but SR OS prefers the RSVP tunnels because the preference for RSVP (7) is lower than the preference for LDP (9).

In AS 64496, the VPRN service on PE-1 is defined as follows:

```
# on PE-1:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:1"
                    vrf-target {
                        import-community "target:64510:1"
                        export-community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            ldp true
                            rsvp true
                        }
                    }
                }
            }
            interface "int-S1-1" {
                ipv4 {
                    primary {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        address 10.1.10.1
                        prefix-length 24
                    }
                }
                sap 1/2/1:1 {
                }
                ipv6 {
                    primary {
                        address 2001:db8:1::1:1
                        prefix-length 120
                    }
                }
            }
            interface "int-S1-2" {
                loopback true
                ipv4 {
                    primary {
                        address 10.1.11.1
                        prefix-length 24
                    }
                }
            }
        }
```

In AS 64510, the transport technology is LDP only, so the VPRN service in PE-5 auto-binds using LDP LSPs in the tunnel table to resolve VPN-IPv4 and VPN-IPv6 routes for which the **vrf-target import-community** matches the **vrf-target export-community** value configured in PE-1 and vice versa, as follows:

```
# on PE-5 in AS 64510:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64510:1"
                    vrf-target {
                        import-community "target:64496:1"
                        export-community "target:64510:1"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            ldp true
                        }
                    }
                }
            }
            interface "int-S1-1" {
                ipv4 {
                    primary {
                        address 10.1.50.1
                        prefix-length 24
                    }
                }
                sap 1/2/1:1 {
                }
                ipv6 {
                    primary {
```

```
                        address 2001:db8:1::5:1
                        prefix-length 120
                    }
                }
            }
            interface "int-S1-2" {
                loopback true
                ipv4 {
                    primary {
                        address 10.1.51.1
                        prefix-length 24
                    }
                }
            }
        }
```

A second service is defined on PE-1 and PE-2 (VPRN 33), using loopback addresses 10.33.1.1/32 and 10.33.2.1/32 in PE-1 and PE-2, respectively. These addresses might appear in traces and commands later, but are of no concern because these are used for transporting intra-AS traffic. On PE-1, VPRN 33 is configured as follows:

```
# on PE-1:
configure {
    service {
        vprn "VPRN33" {
            admin-state enable
            service-id 33
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:33"
                    vrf-target {
                        community "target:64496:33"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            ldp true
                        }
                    }
                }
            }
            interface "int-S1-1" {
                loopback true
                ipv4 {
                    primary {
                        address 10.33.1.1
                        prefix-length 24
                    }
                }
            }
        }
```

For VPRN 1 service traffic to flow in the direction from PE-5 to PE-1, ASBR PE-4 in AS 64496 must offer the possibility to use RSVP-TE tunnels when resolving a BGP next-hop for VPN services. Therefore, ASBR PE-4 must be explicitly configured, as follows:

```
# on ASBR PE-4:
configure {
    router "Base" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        autonomous-system 64496
        bgp {
            next-hop-resolution
                labeled-routes
                    transport-tunnel
                        family vpn
                            resolution filter
                            resolution-filter
                                # ldp true    # LDP by default enabled
                                rsvp true
                            }
                        }
                    }
                }
            }
```

On ASBR PE-8 in AS 64510, no explicit configuration is required because resolving a BGP next-hop for VPN service to LDP tunnels is the default behavior.

Verification

With the configurations from previous sections applied, PE-1 receives three VPN-IPv4 routes and one VPN-IPv6 route, as follows:

```
[/]
A:admin@PE-1# show router bgp summary all

===============================================================================
```

The IPv4 addresses for VPRN 1 on PE-8 are 10.1.50.0/24 and 10.1.51.0/24, and are reachable through RSVP-TE tunnel 1 (tunneled:RSVP:1). The VPN label value for these prefixes is assigned and advertised by ASBR PE-4 and gets to PE-1 via the RR PE-3 in an MP-BGP update message. The 10.33.2.0/24 prefix belongs to a different service and is not relevant for model B because it is used for intra-AS traffic. The VPN-IPv4 routes received on PE-1 are as follows:

```
[/]
A:admin@PE-1# show router bgp neighbor 192.0.2.3 received-routes vpn-ipv4
===============================================================================

SR OS uses a label-per-VRF mode of label distribution, meaning that the same label is used for different VPN-IPv4 and different VPN-IPv6 prefixes from the same VRF, which saves on MPLS label resources. In this example, the VPRN service label is 524279 for the VPN-IPv4 prefixes 10.1.50.0/24 and 10.1.51.0/24, and 524278 for VPN-IPv6 prefix 2001:db8:1::5:0/120.

The forwarding plane is also programmed with the outer label to be used for transport purposes. Two labels are present: 524282 assigned through RSVP, and 524284 assigned through LDP. Because RSVP takes precedence over LDP, the RSVP label is actively used, as follows:

```
[/]
A:admin@PE-1# show router fp-tunnel-table 1 192.0.2.4/32

Traffic over VPRN 1 is generated using a ping command on PE-1 to the remote loopback address, as follows:

```
[/]
A:admin@PE-1# ping 10.1.50.1 router-instance "VPRN1"
PING 10.1.50.1 56 data bytes
64 bytes from 10.1.50.1: icmp_seq=1 ttl=64 time=5.55ms.

64 bytes from 10.1.50.1: icmp_seq=3 ttl=64 time=5.91ms.
64 bytes from 10.1.50.1: icmp_seq=4 ttl=64 time=5.75ms.
64 bytes from 10.1.50.1: icmp_seq=5 ttl=64 time=5.43ms.

---- 10.1.50.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 5.43ms, avg = 5.80ms, max = 6.38ms, stddev = 0.331ms
```

On PE-1, the IPv4 VPRN 1 traffic is pushed with VPN label 524279, followed by RSVP-TE transport label 524282. ASBR PE-4 removes the RSVP-TE transport label and swaps the internal (advertised) VPN label 524279 with the external VPN label 524280 received from ASBR PE-8. For IPv6 VPRN 1 traffic, VPN label 524278 is swapped by VPN label 524279. The inter-AS BGP labels stored by ASBR PE-4 are as follows:

```
[/]
A:admin@PE-4# show router bgp inter-as-label

===============================================================================

-------------------------------------------------------------------------------
Total Labels allocated:   6
===============================================================================
```

The forward data flow (from AS 64496 to AS 64510) for VPRN 1 uses the labels for which the label origin is external. The VPN labels used for the backward data flow (from AS 64510 to 64496) uses the labels for which the label origin is internal.

For brevity, the commands to display and check VPN prefixes and labels used in AS 64510 are omitted.

By disabling (**admin-state disable**) both RSVP LSPs between PE-1 and ASBR PE-4 in AS 64496, both PE-1 and PE-4 will select LDP tunnels for resolving VPN BGP next-hops. Then, the route table for VPRN 1 is as follows, where **tunneled** indicates an LDP tunnel is used to reach the next hop:

```
[/]
A:admin@PE-1# show router 1 route-table

```

On PE-1, the IPv4 traffic in VPRN 1 is pushed with VPN label 524279, followed by LDP transport label 524284. ASBR PE-4 removes the LDP transport label and swaps the internal (advertised) VPN label 524279 with the external VPN label 524280 received from ASBR PE-8. The inter-AS label mapping between the ASBRs remains unchanged.

On the directly connected interface between the ASBRs, nothing has changed; only a single MPLS label is used to carry the VPN data, as shown in the following capture:

With this configuration, all the VPN-IPv4 and VPN-IPv6 routes known to AS 64496 are advertised by ASBR PE-4 to AS 64510, even the VPN-IPv4 and VPN-IPv6 routes from other AS 64496 VPRN services that do not need to be distributed:

```

```
-------------------------------------------------------------------------------
i     64496:1:10.1.10.0/24
i     64496:1:10.1.11.0/24
i     64496:33:10.33.1.0/24
i     64496:33:10.33.2.0/24
-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

As already indicated, the 10.33.1.0/24 and 10.33.2.0/24 prefixes belong to VPRN 33. This service exists on PE-1 and PE-2 only, and the corresponding customer traffic must be kept within AS 64496, so there is no need to advertise these prefixes to the peer AS. The "exp-SVC-1" policy is defined at ASBR PE-4 to achieve this, as follows:

```
# on ASBR PE-4:
configure {
    policy-options {
        prefix-list "pfx-SVC-1" {
            prefix 10.1.10.0/24 type longer {
            }
            prefix 10.1.11.0/24 type longer {
            }
            prefix 2001:db8:1::/96 type longer {
            }
        }
        policy-statement "exp-SVC-1" {
            entry 10 {
                from {
                    prefix-list "pfx-SVC-1"
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
```

The "exp-SVC-1" policy is applied to ASBR PE-4 as an export policy, but also import policies can be used to control which prefixes are exchanged. This additionally requires the **vpn-apply-export true** (and the **vpn-apply-import true**) command, and the change required at ASBR PE-4 is as follows:

```
# on ASBR PE-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "vpn-eBGP" {
                vpn-apply-export true
                export {
                    policy ["exp-SVC-1"]
                }
            }
            neighbor "192.168.48.2" {
                group "vpn-eBGP"
                peer-as 64510
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                ebgp-default-reject-policy {
                    import false
                    delete export
                }
            }
```

Therefore, the PE-4 ASBR will only advertise the VPN-IPv4 and VPN-IPv6 prefixes for VRPN 1, as follows:

```

Conclusion

Inter-AS VPRN model B offers service providers a way to interconnect IPv4 and IPv6 VPN sites across different ASs, avoiding the need for dedicated services in the ASBR, which would otherwise consume valuable resources in the ASBR. Model B is useful for scenarios where model C does not apply; for example, when there is no trust agreement with the peer AS, so that exchanging PE system addresses with that peer is not permitted or does not make sense.

Inter-AS VPRN Model B Using MPLS over UDP

This chapter describes Inter-AS VPRN Model B using MPLS over UDP.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

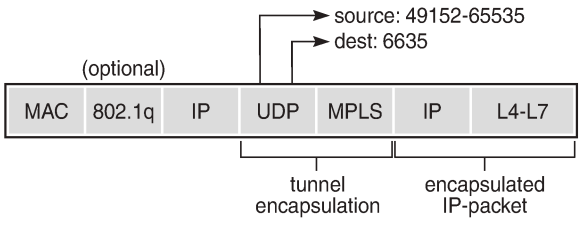
This chapter was initially written based on SR OS Release 15.0.R8, but the MD-CLI in the current edition corresponds to SR OS Release 23.3.R3.

Overview

MPLS over UDP encapsulates MPLS packets into a UDP tunnel that can be transported by any IP network, and is defined in RFC 7510.

With MPLS over UDP, an outer IPv4/UDP or IPv6/UDP header encapsulates the inner MPLS label stack and message body; see Figure 306: IP over MPLS over UDP packet format. In the UDP header, the destination UDP port 6635 identifies the MPLS over UDP format to the egress PE and the source port number in the range from 49152 to 65535 is a source of entropy, because it is based on an ECMP hash calculation by the ingress PE. The entropy in the IP/UDP header ensures that ECMP uses all the available parallel paths between the tunnel endpoints.

Figure 306: IP over MPLS over UDP packet format



The MPLS over UDP implementation in SR OS has the following characteristics:

- The UDP checksum is set to 0 on transmission and ignored on reception.
- MPLS over UDP packets are processed only if they arrive with an IP destination address matching the system IP address.
- MPLS over UDP packets are originated with the Don't Fragment (DF) bit set in the outer IP header.
- Reassembly of received MPLS over UDP packets is not supported.

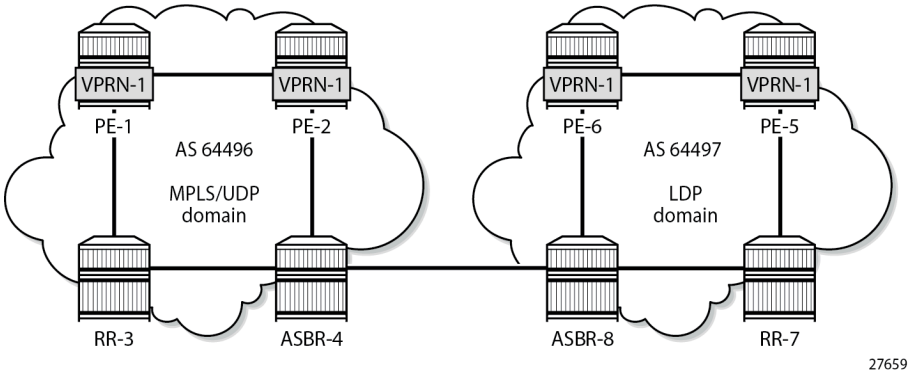
BGP next-hops can be resolved to UDP-based tunnels for L3 VPN and EVPN services, which is useful, for example, in data center (DC) environments where IP is prevalent. This chapter describes the use and configuration of MPLS over UDP in an inter-AS VPRN model B environment. See the Inter-AS VPRN Model B chapter for more information.

Configuration

Figure 307: Inter-AS VPRN model B topology using MPLS over UDP in AS 64496 shows the topology used in this chapter, with two autonomous systems (ASs) and using inter-AS VPRN model B. VPRN "VPRN-1" carries customer traffic between PE-1 and PE-2 in AS 64496, and PE-5 and PE-6 in AS 64497. IS-IS is configured in AS 64496 and AS 64497, and MP-IBGP sessions are established between the PEs of each AS. An MP-EBGP session is established between autonomous system border routers (ASBRs) ASBR-4 and ASBR-8. RR-3 and RR-7 are the route reflectors (RRs) in AS 64496 and 64497, respectively, for the VPN-IPv4 and VPN-IPv6 address families. AS 64496 uses MPLS over UDP for its transport, whereas AS 64497 uses LDP.

Figure 307: Inter-AS VPRN model B topology using MPLS over UDP in AS 64496



An inter-AS VPRN model B requires configuration of an MP-EBGP session with support for the VPN-IPv4 and VPN-IPv6 address families and enabling the inter-AS functionality on the ASBRs by the **inter-as-vpn** command. No configuration is required to support inter-AS VPRN model B on the PEs and the RRs. See the Inter-AS VPRN Model B chapter for more information.

The initial configuration includes:

- cards, MDAs, and ports
- router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled.
- LDP configured in AS 64497, but not in AS 64496
- IBGP configured in both ASs
- EBGP configured between ASBR-4 and ASBR-8
- RR-3 and RR-7 configured as RR for VPN-IPv4 and VPN-IPv6 in AS 64496 and AS 64497

MPLS over UDP configuration

MPLS over UDP tunnels are UDP-based LSP tunnels that are created dynamically through a BGP import policy, where the action is **create-udp-tunnel true**. This import policy is configured and used on PE-1, PE-2, and ASBR-4. MPLS over UDP tunnels are created when BGP receives an update message where the incoming route has a next hop which matches the import policy. This import policy *create-UDP-tunnel* is defined as follows:

```
# on PE-1, PE-2, ASBR-4:
configure {
    policy-options {
        prefix-list "system-pfxs" {
            prefix 192.0.2.0/24 type range {
                start-length 32
                end-length 32
            }
        }
        policy-statement "create-UDP-tunnel" {
            entry 10 {
                from {
                    family [vpn-ipv4 vpn-ipv6]
                    next-hop {
                        prefix-list "system-pfxs"
                    }
                }
                action {
                    action-type accept
                    create-udp-tunnel true
                }
            }
```

This policy is applied to the IBGP sessions on which the VPN routes are exchanged; on PE-1 and PE-2, this is in the *IBGP-vpn* group, as follows:

```
# on PE-1, PE-2:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            loop-detect discard-route
            split-horizon true
            next-hop-resolution {
                labeled-routes {
                    transport-tunnel {
                        family vpn {
                            resolution-filter {
                                bgp false
                                ldp false
                                udp true
                            }
                        }
                    }
                }
            }
            group "IBGP-vpn" {
                vpn-apply-import true
                peer-as 64496
                import {
                    policy ["create-UDP-tunnel"]
                }
            }
            neighbor "192.0.2.3" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                group "IBGP-vpn"
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
```

On RR-3, BGP is configured as follows:

```
# on RR-3:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            loop-detect discard-route
            split-horizon true
            group "IBGP-vpn" {
                peer-as 64496
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
                cluster {
                    cluster-id 192.0.2.3
                }
            }
            neighbor "192.0.2.1" {
                group "IBGP-vpn"
            }
            neighbor "192.0.2.2" {
                group "IBGP-vpn"
            }
            neighbor "192.0.2.4" {
                group "IBGP-vpn"
            }
```

For ASBR-4 to advertise VPRN routes to the peer AS, ASBR-4 must know the VPRN routes used within the AS, so it peers with RR-3 through IBGP, using the *IBGP-vpn* group. Although the **inter-as-vpn true** command enables inter-AS VPN model B, the VPN-IPv4 and VPN-IPv6 address family must also resolve to MPLS over UDP tunnels, so the BGP configuration on ASBR-4 is as follows:

```
# on ASBR-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            loop-detect discard-route
            inter-as-vpn true                       # inter-AS VPRN model B
            split-horizon true
            next-hop-resolution {
                labeled-routes {
                    transport-tunnel {
                        family vpn {
                            # resolution filter     # default
                            resolution-filter {
                                bgp false           # default: bgp true
                                ldp false           # default: ldp true
                                udp true            # default: udp false
                            }
                        }
                    }
                }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            group "EBGP-vpn" {
                peer-as 64497
            }
            group "IBGP-vpn" {
                vpn-apply-import true
                peer-as 64496
                import {
                    policy ["create-UDP-tunnel"]
                }
            }
            neighbor "192.0.2.3" {
                group "IBGP-vpn"
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
            neighbor "192.168.48.2" {
                group "EBGP-vpn"
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
                ebgp-default-reject-policy {
                    import false
                    export false
                }
            }
```

Service configuration

VPRN "VPRN-1" is configured on PE-1, PE-2, PE-5, and PE-6. Although the VPRN service names and IDs used in both ASs do not have to match, when inter-AS VPRN model B applies, the route targets (RTs) used in both ASs must be coordinated. The RT exported by the PE-1 VPRN must be imported by PE-2, PE-5, and PE-6, and vice versa. In this example, no specific VRF import and VRF export policies are used; the **vrf-target** command is used instead.

To carry the customer data across AS 64496, the MPLS over UDP tunnels must bind to a VPRN service with the **auto-bind-tunnel** command. The resolution is set to **filter**, indicating that SR OS must select a tunnel using the information defined in the **resolution-filter** context. The **udp** keyword in the **resolution-filter** context indicates that MPLS over UDP tunnels can be used. If **resolution** is set to **any**, the resolution filter is ignored, and a tunnel from the tunnel table manager (TTM) is selected, based on availability and preference.

In AS 64496, the service "VPRN-1" on PE-1 is defined as follows. The configuration of service "VPRN-1" on PE-2 is similar.

```
# on PE-1:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:1"
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            bgp false
                            udp true
                        }
                    }
                }
            }
            interface "int-S1-1" {
                ipv4 {
                    primary {
                        address 10.1.10.1
                        prefix-length 24
                    }
                }
                sap 1/1/c4/1:1 {
                }
                ipv6 {
                    address 2001:db8:1::1:1 {
                        prefix-length 120
                    }
                }
            }
```

The transport technology in AS 64497 is LDP, so service "VPRN-1" in PE-5 and PE-6 auto-binds to LDP LSPs in the tunnel table, to resolve VPN-IPv4 routes for which the VRF target matches the VRF target community value configured in PE-1 and PE-2, as follows. The configuration of "VPRN-1" on PE-6 is similar.

```
# on PE-5:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64497:1"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            bgp false
                            ldp true
                        }
                    }
                }
            }
            interface "int-S1-1" {
                ipv4 {
                    primary {
                        address 10.1.50.1
                        prefix-length 24
                    }
                }
```

```
                sap 1/1/c4/1:1 {
                }
                ipv6 {
                    address 2001:db8:1::5:1 {
                        prefix-length 120
                    }
                }
            }
```

Verification

With the configurations from previous subsections applied, so that PE-1, PE-2, PE-5, and PE-6 have a service instance of "VPRN-1" running, PE-1 receives three VPN-IPv4 and three VPN-IPv6 prefixes, as follows:

```
[/]
A:admin@PE-1# show router bgp summary all

===============================================================================
BGP Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================
Neighbor
Description
ServiceId          AS PktRcvd InQ  Up/Down   State|Rcv/Act/Sent (Addr Family)
                      PktSent OutQ
-------------------------------------------------------------------------------
192.0.2.3
Def. Inst       64496      18    0 00h04m56s 3/3/1 (VpnIPv4)
                           18    0           3/3/1 (VpnIPv6)

-------------------------------------------------------------------------------
```

PE-1 creates two UDP tunnels, and its tunnel table is as follows. The UDP tunnel to 192.0.2.2 is used for intra-AS customer traffic; the UDP tunnel to 192.0.2.4 is used for inter-AS customer traffic.

```
[/]
A:admin@PE-1# show router tunnel-table

===============================================================================

Traffic over the VPRN is generated using a **ping** command on PE-1 to the remote address, as follows:

```
[/]
A:admin@PE-1# ping 10.1.50.1 router-instance "VPRN-1"
PING 10.1.50.1 56 data bytes
64 bytes from 10.1.50.1: icmp_seq=1 ttl=64 time=6.21ms.
64 bytes from 10.1.50.1: icmp_seq=2 ttl=64 time=5.93ms.
64 bytes from 10.1.50.1: icmp_seq=3 ttl=64 time=5.88ms.
64 bytes from 10.1.50.1: icmp_seq=4 ttl=64 time=5.98ms.
64 bytes from 10.1.50.1: icmp_seq=5 ttl=64 time=4.92ms.

---- 10.1.50.1 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.92ms, avg = 5.78ms, max = 6.21ms, stddev = 0.445ms
```

In contrast with the traditional inter-AS VPRN model B, where customer traffic is pushed with a VPN label followed by a transport label, now customer traffic to destination 10.1.50.1 is pushed with VPN label 524287, followed by an IP/UDP header with IP SA 192.0.2.1 and IP DA 192.0.2.4 and with UDP source and destination port.

The interconnection between the ASBRs carries the VPN data with a single MPLS label, so ASBR-4 removes the IP/UDP header and swaps the VPN label 524287 with the VPN label 524283 received from ASBR-8. The inter-AS label mapping on ASBR-4 is as follows:

```
[/]
A:admin@ASBR-4# show router bgp inter-as-label

Total Labels allocated:   8
===============================================================================
```

The forward data flow from PE-1 to PE-5 for VPRN 1 uses the labels for which the label origin is external. The VPN labels used for the backward data flow use the labels for which the label origin is internal.

For brevity, the commands to display and check VPN prefixes and labels in AS 64497 are omitted.

Customer traffic destined to the VPN routes received by ASBR-4 can be sent to the correct destination because ASBR-4 has the relevant BGP next-hops resolved to UDP tunnels, as follows:

Conclusion

VPRN services support the resolution of VPN-IPv4 and VPN-IPv6 BGP next-hops to MPLS over UDP tunnels. MPLS over UDP tunnels are useful in IP-based fabric networks, such as DCs. SR OS supports inter-AS model B for any type of MPLS-based tunnels, including MPLS over UDP.

Inter-AS VPRN Model C

This chapter provides information about virtual private routed network (VPRN) inter-autonomous system (AS) virtual private network (VPN) model C.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 7.0. The MD-CLI in the current edition corresponds to SR OS Release 22.2.R1. There are no prerequisites for this configuration.

Overview

Introduction

Section 10 of RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, describes three potential methods for service providers to interconnect their IP-VPN (Internet Protocol — Virtual Private Network) backbones to provide an end-to-end MPLS-VPN where one or more sites of the VPN are connected to different service provider autonomous systems (ASs). The purpose of this chapter is to describe the configuration and troubleshooting for inter-AS VPN model C.

In this architecture, VPN prefixes are neither held, nor re-advertised by the Autonomous System Border Router – Provider Edge (ASBR-PE) routers, which makes Model C more scalable than Model B (where the only prefixes exchanged between ASs are VPN-IPv4). In Model C, the only MPLS data plane resources consumed in the ASBRs are for infrastructure addresses of PEs and RRs rather than VPN prefixes.

In this example, an export policy is configured to ensure that the nodes advertise their system IP addresses (IPv4 /32 addresses) in labeled BGP to all their BGP peers within the AS. Therefore, the ASBR-PE maintains labeled IPv4 /32 BGP routes to other PE routers within its own AS. These BGP routes are inactive, because for each destination within the AS, an IGP route exists which is preferred to BGP routes. The ASBR redistributes these inactive /32 IPv4 prefixes in external Border Gateway Protocol (EBGP) to the ASBR-PE in other service providers ASs, because **advertise-inactive** is configured in EBGP. No export policy is required in EBGP.

At the same time, the ASBR programs a label switch for the received and advertised BGP labels. The receiving ASBR advertises the received IP system prefixes to its IBGP peers (in this case, a Route Reflector (RR)) within their AS, and eventually, all PEs in the AS learn the system IP prefixes of the peer AS. However, there is no need to learn the system IP address of the ASBRs in peer ASs, because they do not exchange customer VPN prefixes.

After the system IP addresses have been learned in the peer AS, it is possible for PE routers in different ASs to establish multi-hop Multi Protocol – external Border Gateway Protocol (MP-EBGP) sessions for address family VPN-IPv4 to each other to exchange customer VPN prefixes over those connections. The

Use subject to Terms available at: www.nokia.com/terms.

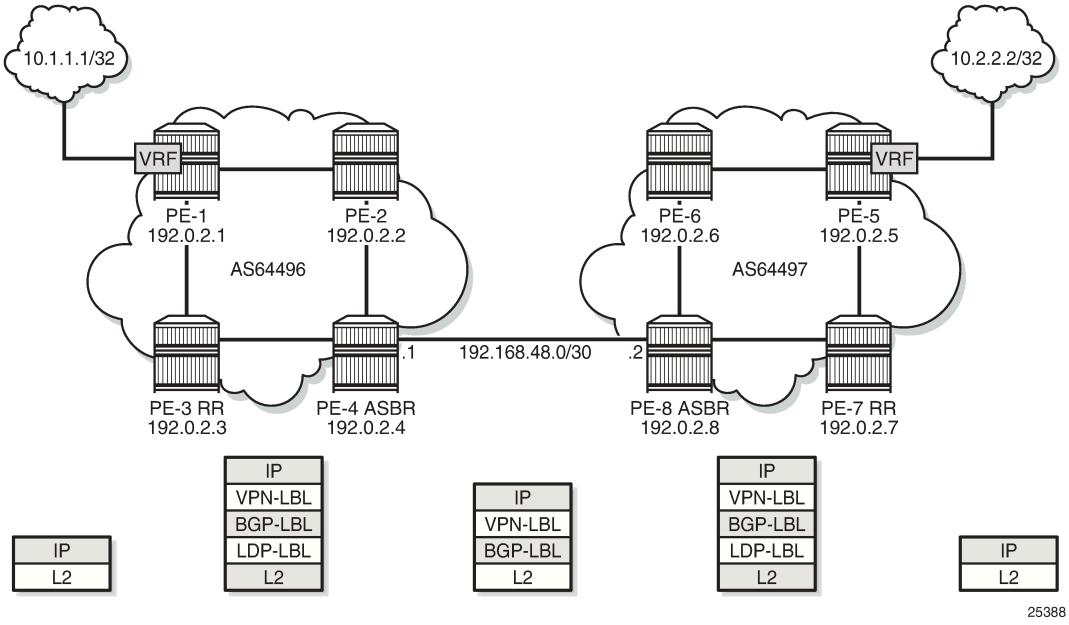
multihop sessions can be established between the RR in the ASs, but these RRs should not modify the next-hop attribute of the BGP update across the EBGP session.

A three-level label stack is imposed on the ingress PE. The bottom-level label is assigned by the egress PE (advertised in multi-hop MP-EBGP without next-hop override) and is commonly referred to as the VPN-label. The middle label is assigned by the local ASBR-PE and corresponds to the /32 route of the egress PE (in a different AS) using BGP-LBL (RFC 3107, *Carrying Label Information in BGP-4*). The top level label is the label assigned by the local ASBR-PE /32 loopback address, which is assigned by the IGP next-hop of the ingress PE. This label is referred to as the LDP-LBL.

Figure 308: Inter-AS VPN Model C illustrates this mechanism. The VPN-LBL is assigned by PE-5, the BGP-LBL is assigned by PE-4 and the LDP-LBL is also assigned by PE-4. The BGP-LBL is swapped in both ASBRs. The label stack contains three labels in each AS: VPN-LBL, BGP-LBL, and LDP-LBL) and two labels on the EBGP link between the ASs: VPN-LBL and BGP-LBL.

Note:
This configuration that uses **advertise-inactive** is preferred to a configuration where the BGP routes are not exchanged within their AS and the ASBRs use an export policy with a prefix list for all local system prefixes to be advertised to the peer ASs. The routes for those prefixes are taken from the RTM, where these routes are not known via BGP, but via IS-IS. In that case, IS-IS routes are effectively redistributed into labeled BGP (which most operators do not want) and as a result, the ASBR is not programming a label switch for the BGP label. Furthermore, the label stack is asymmetrical: three labels in the originating AS (VPN-LBL, BGP-LBL, and LDP-LBL) and only two labels in the target AS (VPN-LBL, LDP-LBL), because the local routes are not known via labeled BGP in this scenario. This scenario is not described in this chapter; only the preferred scenario with local labeled BGP routes in each AS is described.

Figure 308: Inter-AS VPN Model C



The VPN connectivity is established using Labeled VPN route exchange using MP-EBGP without next-hop override. The PE connectivity is established as follows.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

EBGP PE /32 loopback leaking routing exchange using EBGP LBL (RFC 3107) at the ASBR-PE. The /32 PE routes learned from the other AS through the ASBR-PE are further distributed into the local AS using IBGP and optionally through Route Reflectors (RRs). This model uses a three label stack and is referred to as Model C. Resilience for ASBR-PE failures depends on BGP.

Figure 309: Protocol overview

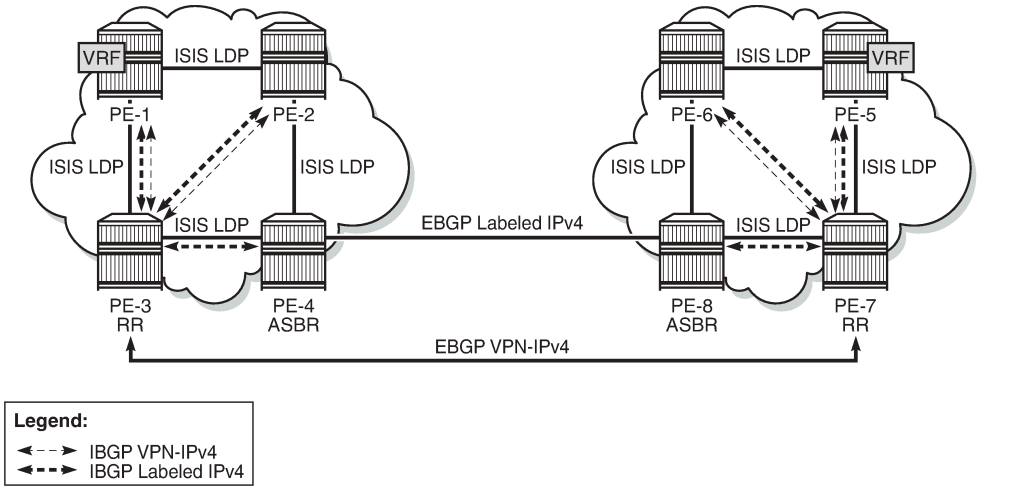


Figure 309: Protocol overview shows the protocols used when implementing Inter-AS Model C. Inside each AS, there is an IS-IS adjacency and a link LDP session between each pair of adjacent nodes. As an alternative, OSPF can be used as IGP. There is also an IBGP session between each PE and the RR. The address family is both VPN-IPv4 for the exchange of customer VPN prefixes and Labeled IPv4 for the exchange of labeled IPv4 prefixes. Between the RR and the ASBR, only Labeled IPv4 is required, because the ASBR does not exchange any customer VPN prefixes. When no RR is used, a full mesh of IBGP sessions can be established in each AS.

Between the ASBRs, there is an EBGP session for the exchange of labeled IPv4 prefixes. The ASBRs override the next-hop for those prefixes. Between the RRs in the different ASs, there is a multihop EBGP session for the exchange of VPN-IPv4 customer prefixes. The RRs do not override the next-hop for those prefixes.

The main advantage of this model is that no VPN routes need to be held on the ASBR-PEs and therefore, it scales the best among all the three Inter-AS IP-VPN models. However, leaking /32 PE addresses between service providers raises some security concerns. Therefore, we see Model C typically deployed within a service provider network.

Figure 308: Inter-AS VPN Model C shows the example topology which consists of four SR OS nodes in AS 64496 and four SR OS nodes in AS 64497. There is an AS interconnection between ASBR PE-4 to ASBR PE-8. PE-3 and PE-7 act as RRs for their AS. An IP-VPN is configured in each AS. The initial configuration includes the following:

- IS-IS or OSPF on all interfaces within each of the ASs.
- LDP on all interfaces within each of the ASs.
- MP-IBGP sessions between the PE routers and the RRs in each of the ASs, as shown in the following section.
- IP-VPN on PE-1 and on PE-5 with identical route targets.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- A loopback interface in the VRF on PE-1 and PE-5.

Configuration

The first step is to configure an MP-IBGP session between the PEs in both ASs. An export policy is configured to export the system prefixes from the PEs in labeled BGP.

PE-3 and PE-7 act as RR in the ASs. In AS 64496, PE-1 and PE-2 are peered with RR PE-3 for the labeled IPv4 and VPN-IPv4 address families; ASBR PE-4 is peered with RR PE-3 for the labeled IPv4 address family only. In AS 64497, PE-5 and PE-6 are peered with RR PE-7 for the labeled IPv4 and VPN-IPv4 address families; ASBR PE-8 is peered with RR PE-7 for the labeled IPv4 address family only.

Address family **label-ipv4** is required to advertise labeled IPv4 routes toward each neighbor PE. Address family **vpn-ipv4** is required to advertise IPv4 customer VPN routes within the AS.

The initial BGP configuration for RR PE-3 is as follows:

```
# on RR PE-3:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            split-horizon true
            group "IBGP" {
                peer-as 64496
                cluster {
                    cluster-id 192.0.2.3
                }
                export {
                    policy ["export-bgp"]
                }
            }
            neighbor "192.0.2.1" {
                advertise-inactive true
                group "IBGP"
                family {
                    vpn-ipv4 true
                    label-ipv4 true
                }
            }
            neighbor "192.0.2.2" {
                advertise-inactive true
                group "IBGP"
                family {
                    vpn-ipv4 true
                    label-ipv4 true
                }
            }
            neighbor "192.0.2.4" {
                advertise-inactive true
                group "IBGP"
                family {
                    label-ipv4 true
                }
            }
```

The export policy exports the system IP address and is defined as follows:

```
# on PE-1, PE-2, PE-3, PE-5, PE-6, PE-7:
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    policy-options {
        prefix-list "PE-sys" {
            prefix 192.0.2.0/28 type longer {
            }
        }
        policy-statement "export-bgp" {
            entry 10 {
                from {
                    prefix-list ["PE-sys"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

On the ASBRs in both ASs, EBGP and IBGP need to be configured. The EBGP session is configured with **advertise-inactive** and is used to redistribute labeled IPv4 routes for the /32 system IP addresses between the ASs, even if those routes are not the most preferred routes within the system for a specific destination.

The configuration for ASBR PE-4 is as follows. The address family **label-ipv4** is required to enable the advertising of labeled IPv4 routes. This address family is also required on the RR neighbor to propagate the labeled IPv4 routes toward the other PEs in the AS.

```
# on ASBR PE-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            split-horizon true
            group "EBGP" {
            }
            group "IBGP" {
                peer-as 64496
            }
            neighbor "192.0.2.3" {
                group "IBGP"
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.48.2" {
                advertise-inactive true
                group "EBGP"
                peer-as 64497
                family {
                    label-ipv4 true
                }
                ebgp-default-reject-policy {
                    import false
                    export false
                }
            }
        }
```

On the remaining PE nodes in AS 64496, PE-1 and PE-2, the address families **label-ipv4** and **vpn-ipv4** must be enabled, as follows:

```
# on PE-1, PE-2:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            split-horizon true
            group "IBGP" {
                peer-as 64496
                export {
                    policy ["export-bgp"]
                }
            }
            neighbor "192.0.2.3" {
                group "IBGP"
                family {
                    vpn-ipv4 true
                    label-ipv4 true
                }
            }
        }
```

The configuration for the nodes in AS 64497 is similar. The IP addresses can be derived from Figure 308: Inter-AS VPN Model C.

The following command on ASBR PE-4 verifies that the EBGP and IBGP sessions for the labeled IPv4 address family are up:

```
[/]

In this example, the IP prefix for PE-8 itself is not included. The prefix of the ASBR need not be advertised in labeled BGP to the remote AS, because ASBRs do not advertise VPN-IPv4 prefixes.

More detailed information about the advertised route from PE-5 can be seen with following command on PE-4:

```
[/]
A:admin@PE-4# show router bgp routes 192.0.2.5/32 label-ipv4 hunt

192.168.48.2                 524283         524283         External
-------------------------------------------------------------------------------
Total Labels allocated:   6
===============================================================================
```

The route from PE-1 toward PE-5 uses received label 524283 and advertised label 524283, as indicated on the sixth row in the table. The BGP label in the label stack sent by PE-1 contains BGP label 524283 toward ASBR PE-4, where it is swapped to BGP label 524283 toward ASBR PE-8.

ASBR PE-8 swaps BGP label 524283 to BGP label 524283 toward PE-5, as follows:

```
[/]
A:admin@PE-8# show router bgp inter-as-label

       int-PE-4-PE-8                                                0
-------------------------------------------------------------------------------
No. of Routes: 10
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The BGP labeled routes for the remote PE system prefixes are further advertised toward all the PEs in the AS (through the RR) and are installed in the routing table on all PEs.

At this point, all PEs in one AS have the /32 system IPs of the remote PEs in their routing table, for example for PE-1:

```
[/]
A:admin@PE-1# show router route-table

===============================================================================

       192.0.2.4 (tunneled)                                            20
192.168.12.0/30                                 Local   Local     00h07m25s  0
       int-PE-1-PE-2                                                   0
192.168.13.0/30                                 Local   Local     00h07m25s  0
       int-PE-1-PE-3                                                   0
-------------------------------------------------------------------------------
No. of Routes: 9
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

All PEs in one AS have also received labels for all /32 system IP addresses of the remote PEs. Therefore, an MP-EBGP session can be created between the RRs in the different ASs to exchange VPN-IPv4 routes.

The additional BGP configuration for RR PE-3 is as follows. The configuration for RR PE-7 is similar. The IP addresses can be derived from Figure 309: Protocol overview.

```
# on RR PE-3:
configure {
    router "Base" {
        bgp {
            group "peer-AS-RR" {
                peer-as 64497
                local-address 192.0.2.3
                family {
                    vpn-ipv4 true
                }
            }
            neighbor "192.0.2.7" {
                group "peer-AS-RR"
                multihop 10
                vpn-apply-export true
                vpn-apply-import true
                import {
                    policy ["import-ebgp-vpn"]
                }
                export {
                    policy ["export-ebgp-vpn"]
                }
            }
        }
```

Policies can be applied on the peering session using the **export** or **import** command followed by a policy name, together with the **vpn-apply-export** or **vpn-apply-import** command necessary to enforce base BGP instance policy on VPN-IPv4 prefixes.

On the RRs, the MP-EBGP session is up, as follows:

```
[/]
```

Conclusion

Inter-AS option C allows the delivery of Layer 3 VPN services to customers who have sites connected in different ASs. This example shows the configuration of inter-AS option C (specific to this feature) together with the associated show output which can be used for verification and troubleshooting.

Layer 3 VPN: VPRN Type Spoke

This chapter provides information about Layer 3 VPRN CE hub and spoke architecture.

Topics in this chapter include:

Applicability

This chapter was initially written for SR OS Release 12.0. However, the MD-CLI in the current edition is based on SR OS Release 22.2.R1.

Knowledge of Nokia's Layer 3 VPN concepts is assumed throughout this document.

Overview

This chapter provides a basic technology overview and configuration examples of a network topology used for a Layer 3 VPRN CE hub and spoke architecture.

VPRN type hub

In SR OS releases earlier than 12.0, a CE hub and spoke architecture was partially supported. Internal optimization was available for the hub sites connected to the same PE router only. This feature is known as VPRN type hub. If, on the other hand, multiple spoke sites were connected to the same PE router, separate VPRN instances had to be created to maintain the split horizon forwarding behavior. This approach was complex, hard to maintain and consumed extra VPRN instances.

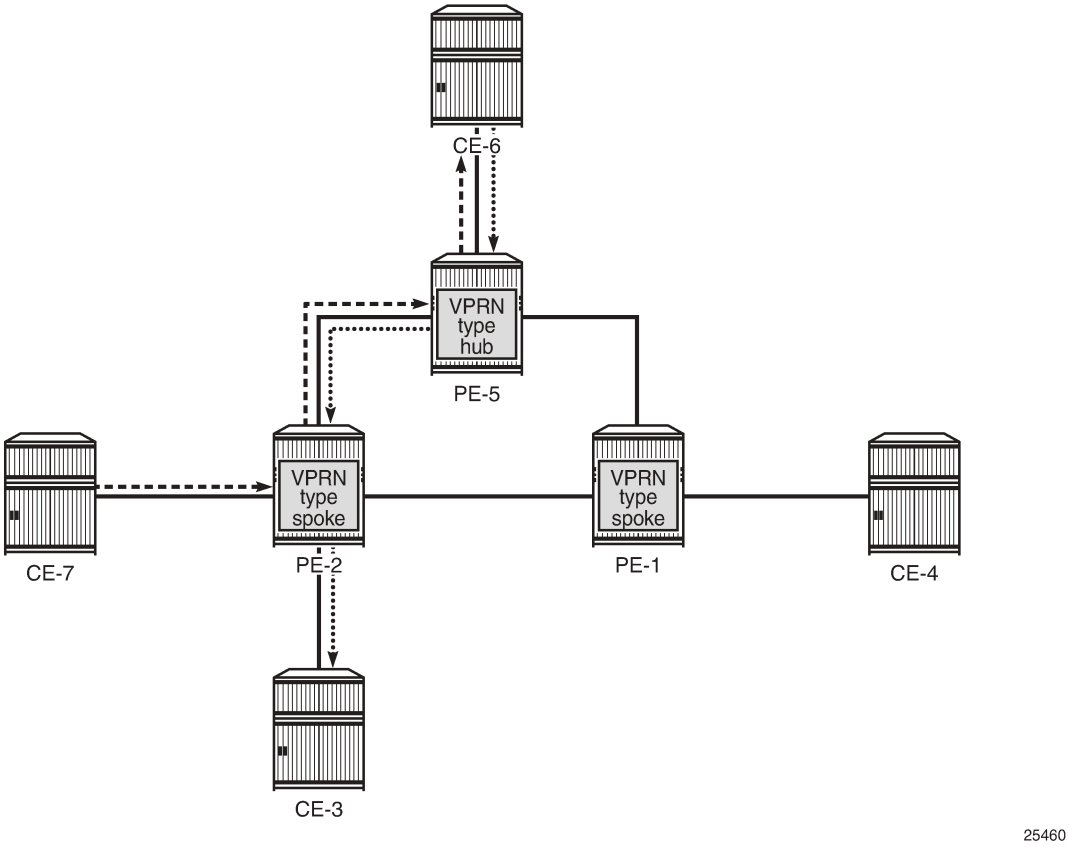
VPRN type spoke

Release 12.0.R1 added new functionality to overcome these limitations. Introducing the VPRN type spoke feature allows multiple spoke sites to be kept within the same VPRN instance while at the same time maintaining the split horizon approach such that spoke sites cannot send traffic directly to each other.

The primary goal of the feature is to allow multiple spoke sites to be part of a single VPRN instance without allowing direct communication between the spoke CE sites which are part of that VPRN (of type spoke). The packet flow is demonstrated in Figure 310: CE hub and spoke data path.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 310: CE hub and spoke data path



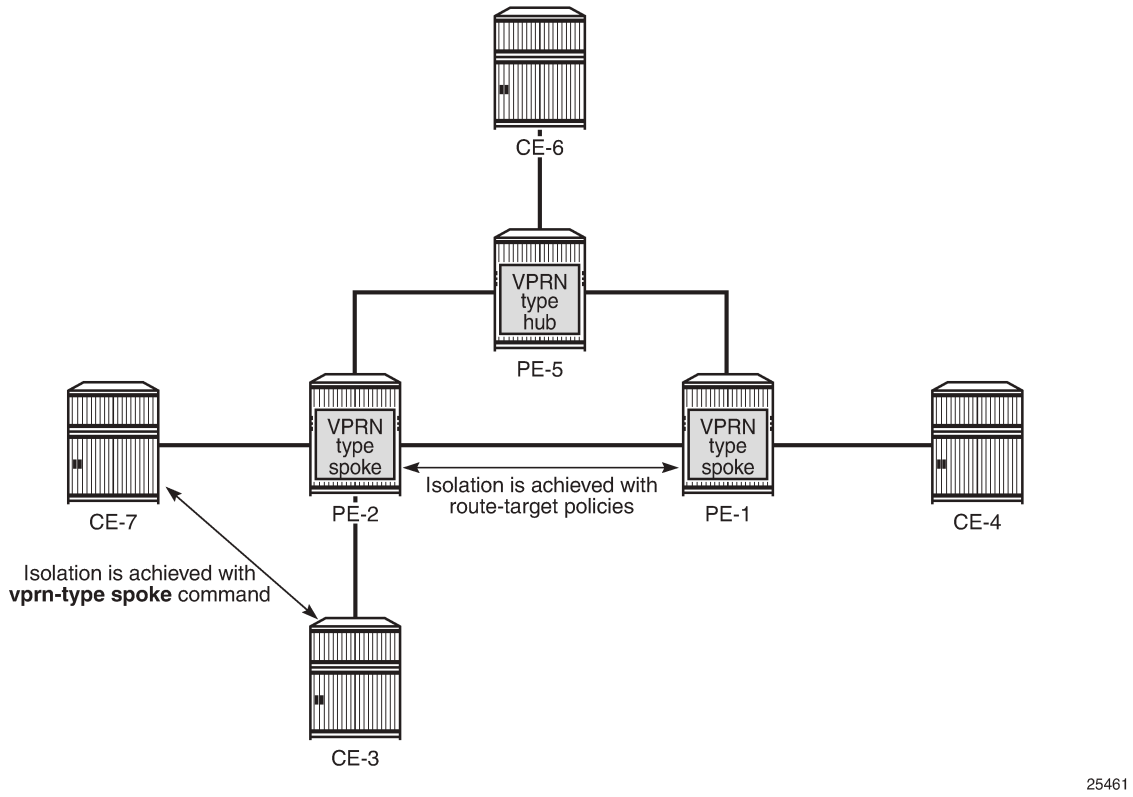
The only way for CE-7 to communicate with CE-3 is via hub site CE-6. The same applies to the communication between CE-7 and CE-4. The VPRN on PE-2 is configured as **vprn-type spoke** and has IP interfaces using SAPs or spoke SDPs that are considered spoke sites only. No direct communication between any of the spoke CE sites in the network is allowed.

Direct communication between the spoke CE sites is blocked using two techniques, as illustrated in Figure 311: CE hub and spoke control plane isolation.

- Using the **vprn-type spoke** command under the **vprn** context as explained later.
- The extended community configuration using route-target policies (this is not covered in detail in this chapter).

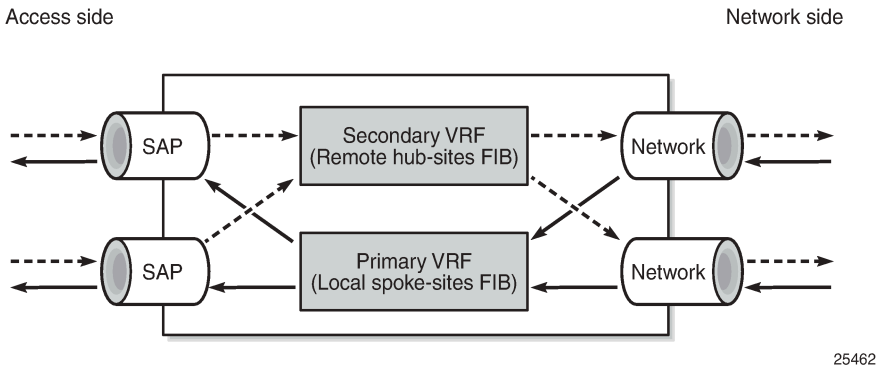
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 311: CE hub and spoke control plane isolation



When a VPRN on a PE router is configured as **vprn-type spoke**, then the internal forwarding logic changes as demonstrated in Figure 312: Internal VPRN logic on a PE router.

Figure 312: Internal VPRN logic on a PE router



- VPRNs of type spoke create a primary and a secondary VRF internally to the VPRN:
  - The primary VRF is used for forwarding traffic from the network interfaces toward the IP interfaces using SAPs or spoke SDPs. This VRF is populated with routes learned from the spoke CE sites connected to the local PE through IP interfaces using SAPs or spoke SDPs.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - The secondary VRF is used for forwarding traffic from the IP interfaces using SAPs or spoke SDPs toward the network interfaces or other VPRN instances. This VRF is populated with routes learned via MP-BGP from hub sites.
- VPRNs of type spoke export routes using a specific extended community (for instance, spoke-ext-comm) via an export policy to identify them as spoke site originated routes.
  - This community is not hard-coded and has to be configured manually (see configuration example later).
- VPRNs of type spoke import routes (using an import policy) received from other PEs or VPRN instances with a hub specific community only (for example, hub-ext-comm). Routes with spoke-ext-comm community are ignored.
  - This community is not hard-coded and has to be configured manually (see configuration example later).
- Multiple VPRNs of type spoke and hub can coexist on the same PE if they use different VPRN instances.
- The configuration of type hub and type spoke is mutually exclusive within one VPRN instance.

Configuration

The physical topology and addressing scheme are presented in Figure 313: CE hub and spoke topology and addressing scheme.

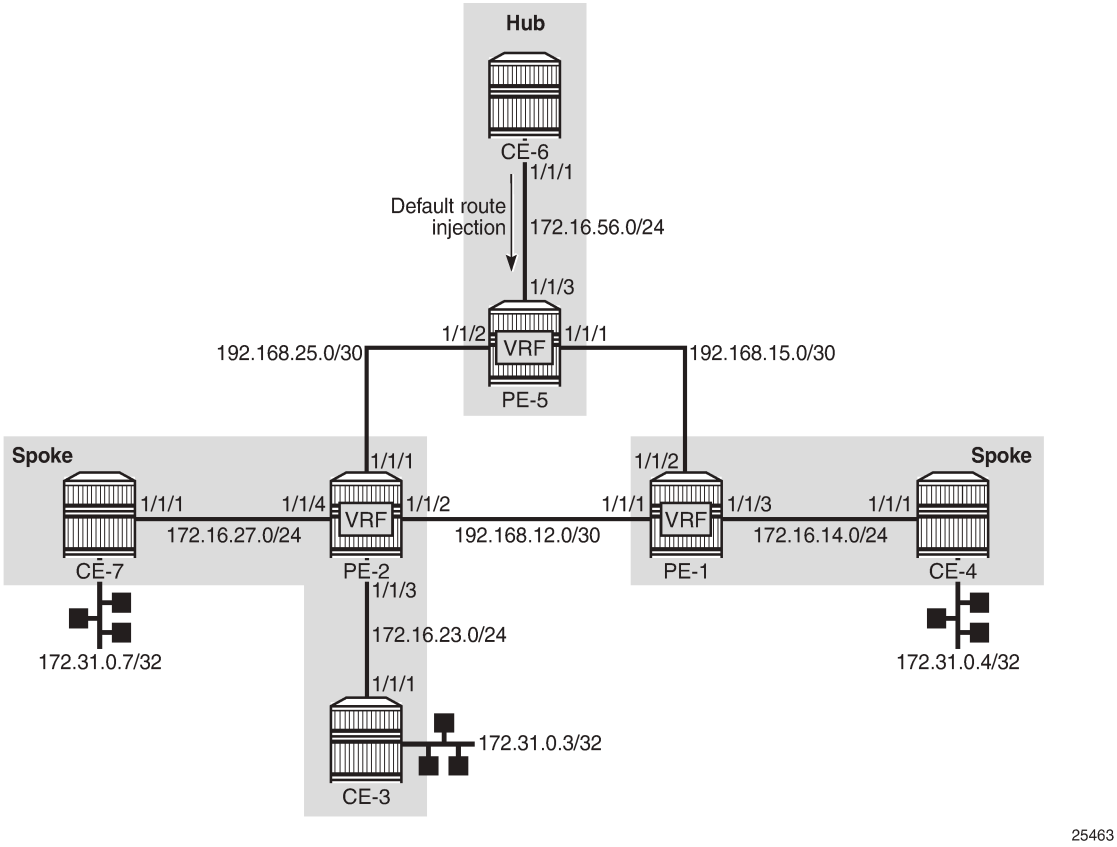
Figure 313: CE hub and spoke topology and addressing scheme



The configuration of PE-2 and PE-5 are the main focus of this example. The configuration of PE-1 is similar to that of PE-2.

Hub site configuration

Only the essential part of the configuration is provided for the hub site.

Vrf-import and vrf-export policies are used to manipulate the vrf-target in order to achieve logical isolation between the spoke sites in the network.

```
# on PE-5:
configure {
    policy-options {
        community "hub-ext-comm" {
            member "target:64500:11" { }
        }
        community "spoke-ext-comm" {
            member "target:64500:12" { }
        }
        policy-statement "export-ospf" {
            entry 10 {
                from {
                    protocol {
                        name [direct]
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type accept
            }
        }
        policy-statement "vrf-export" {
            default-action {
                action-type accept
                community {
                    add ["hub-ext-comm"]
                }
            }
        }
        policy-statement "vrf-import" {
            entry 10 {
                from {
                    community {
                        name "spoke-ext-comm"
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
```

PE-5 is configured with VPRN "VPRN1" providing OSPF connectivity to customer CE-6.

```
# on PE-5:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            description "VPRN type hub"
            service-id 1
            customer "1"
            vprn-type hub
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64500:15"
                    vrf-import {
                        policy ["vrf-import"]
                    }
                    vrf-export {
                        policy ["vrf-export"]
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "int-PE-5-CE-6" {
                ipv4 {
                    primary {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        address 172.16.56.1
                        prefix-length 24
                    }
                }
                sap 1/1/3:1 {
                }
            }
            ospf 0 {
                admin-state enable
                export-policy ["export-ospf"]
                area 0.0.0.0 {
                    interface "int-PE-5-CE-6" {
                        interface-type point-to-point
                        mtu 1500
                    }
                }
            }
```

At the same time, CE-6 is configured to advertise a default route which is used by all remote spoke CE sites to forward traffic via CE-6.

```
# on CE-6:
configure {
    policy-options {
        policy-statement "export-ospf-default" {
            entry 10 {
                from {
                    protocol {
                        name [static]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-CE-6-PE-5" {
                ipv4 {
                    primary {
                        address 172.16.56.2
                        prefix-length 24
                    }
                }
                sap 1/1/1:1 {
                }
            }
            static-routes {
                route 0.0.0.0/0 route-type unicast {
                    blackhole {
                        admin-state enable
                    }
                }
            }
            ospf 0 {
                admin-state enable
                router-id 192.0.2.6
                export-policy ["export-ospf-default"]
```

```
                ignore-dn-bit true
                suppress-dn-bit true
                area 0.0.0.0 {
                    interface "int-CE-6-PE-5" {
                        interface-type point-to-point
                        mtu 1500
                    }
                }
            }
        }
```

Spoke site configuration

According to the example topology, two spoke VPRNs are present: one VPRN with two CE spoke sites connected is located on PE-2, and another VPRN with one spoke CE site on PE-1. The service configuration for PE-2 is as follows with the one for PE-1 being similar.

Vrf-import and vrf-export policies are used to build a hub-and-spoke topology in order to achieve a logical isolation between spoke sites connected to different PE routers.

```
# on PE-2:
configure {
    policy-options {
        community "hub-ext-comm" {
            member "target:64500:11" { }
        }
        community "spoke-ext-comm" {
            member "target:64500:12" { }
        }
        policy-statement "export-ospf" {
            default-action {
                action-type accept
            }
        }
        policy-statement "vrf-export" {
            default-action {
                action-type accept
                community {
                    add ["spoke-ext-comm"]
                }
            }
        }
        policy-statement "vrf-import" {
            entry 10 {
                from {
                    community {
                        name "hub-ext-comm"
                    }
                }
                action {
                    action-type accept
                }
            }
            default-action {
                action-type reject
            }
        }
```

PE-2 is configured with VPRN 1, which has OSPF connectivity to the customer CE-3 and CE-7. The **vprn-type spoke** command is used to prevent direct CE spoke to CE spoke communications for this VPRN.

```
# on PE-2:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            description "VPRN type spoke"
            service-id 1
            customer "1"
            vprn-type spoke
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64500:12"
                    vrf-import {
                        policy ["vrf-import"]
                    }
                    vrf-export {
                        policy ["vrf-export"]
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "int-PE-2-CE-3" {
                ipv4 {
                    primary {
                        address 172.16.23.1
                        prefix-length 24
                    }
                }
                sap 1/1/3:1 {
                }
            }
            interface "int-PE-2-CE-7" {
                ipv4 {
                    primary {
                        address 172.16.27.1
                        prefix-length 24
                    }
                }
                sap 1/1/4:1 {
                }
            }
            ospf 0 {
                admin-state enable
                export-policy ["export-ospf"]
                area 0.0.0.0 {
                    interface "int-PE-2-CE-3" {
                        interface-type point-to-point
                        mtu 1500
                    }
                    interface "int-PE-2-CE-7" {
                        interface-type point-to-point
                        mtu 1500
                    }
                }
            }
        }
```

For connectivity verification purposes, CE-3, CE-4, and CE-7 are configured to advertise their internal loopback interfaces via OSPF:

- CE-3 advertises 172.31.0.3/32
- CE-4 advertises 172.31.0.4/32
- CE-7 advertises 172.31.0.7/32

```
# on CE-3:
configure {
    service {
        vprn "VPRN1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-CE-3-PE-2" {
                ipv4 {
                    primary {
                        address 172.16.23.2
                        prefix-length 24
                    }
                }
                sap 1/1/1:1 {
                }
            }
            interface "lo0" {
                loopback true
                ipv4 {
                    primary {
                        address 172.31.0.3
                        prefix-length 32
                    }
                }
            }
            ospf 0 {
                admin-state enable
                router-id 192.0.2.3
                ignore-dn-bit true
                suppress-dn-bit true
                area 0.0.0.0 {
                    interface "int-CE-3-PE-2" {
                        interface-type point-to-point
                        mtu 1500
                    }
                    interface "lo0" {
                    }
                }
            }
        }
```

Hub site verification

The Routing Information Base (RIB) for VPRN 1 on hub site PE-5 lists all reachable networks:

```

Spoke site verification

The RIB for VPRN 1 on PE-2 (spoke VPRN) lists all reachable networks.

The other spoke sites connected to the remote PEs are not present in the routing table, in this example, CE-4 with prefixes such as 172.31.0.4/32 and 172.16.14.0/24.

The local interface addresses of PE-2 (172.16.23.1/32 and 172.16.27.1/32) are present in the routing table of VPRN 1, as follows. From a FIB point of view, these are reachable from any spoke VPRN, but the spoke CE's router host addresses are not. This fact does not influence the data plane isolation for the customer networks.

```

Spoke sites connectivity verification

Without the VPRN spoke type configuration in VPRN 1 on PE-2, CE-3 takes the shortest path to CE-7, which violates the hub-and-spoke design approach explained earlier.

```
# on PE-2:
configure exclusive
    service {
        vprn "VPRN1" {
            delete vprn-type
            commit
```

Note:
In this setup, a VPRN is configured on CE-3, but that is not necessary.

Traffic from CE-3 takes the shortest path to CE-7, because VPRN 1 on PE-2 is not configured with spoke type anymore.

```
[/]
A:admin@CE-3# traceroute 172.31.0.7 router-instance "VPRN1" numeric
traceroute to 172.31.0.7, 30 hops max, 40 byte packets
  1  172.16.23.1    2.54 ms  2.80 ms  2.93 ms
  2  172.31.0.7    3.28 ms  3.23 ms  3.05 ms
```

After enabling the **vprn-type spoke** feature on PE-2, CE-3 takes the longest path via hub CE-6 to reach CE-7, as it should.

```
# on PE-2:
configure exclusive
    service {
        vprn "VPRN1" {
            vprn-type spoke
            commit
```

```
[/]
A:admin@CE-3# traceroute 172.31.0.7 router-instance "VPRN1" numeric
traceroute to 172.31.0.7, 30 hops max, 40 byte packets
  1  172.16.23.1    2.34 ms  2.71 ms  2.58 ms
  2  0.0.0.0  * * *
  3  172.16.56.2    4.64 ms  4.62 ms  3.95 ms
  4  172.16.56.1    4.24 ms  4.44 ms  4.76 ms
  5  172.16.27.1    4.31 ms  4.30 ms  4.20 ms
  6  172.31.0.7    6.32 ms  6.39 ms  6.36 ms
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Similarly, the long path is taken by CE-3 to reach CE-4, as follows. This is unrelated to the VPRN type. It is achieved by policies.

```
[/]
A:admin@CE-3# traceroute 172.31.0.4 router-instance "VPRN1" numeric
traceroute to 172.31.0.4, 30 hops max, 40 byte packets
  1  172.16.23.1    2.39 ms  2.80 ms  2.58 ms
  2  0.0.0.0  * * *
  3  172.16.56.2    4.69 ms  4.46 ms  4.23 ms
  4  172.16.56.1    4.53 ms  4.61 ms  4.12 ms
  5  172.16.14.1    5.83 ms  6.02 ms  6.24 ms
  6  172.31.0.4    7.00 ms  6.54 ms  6.99 ms
```

Conclusion

The VPRN type spoke feature completes the CE hub and spoke solution. It brings an additional level of simplicity, scalability, and flexibility to operators using this VPRN architecture for their customers.

Spoke Termination for IPv6-6VPE

This chapter provides information about spoke termination for IPv6-6VPE.

Topics in this chapter include:

Applicability

This chapter was originally written for SR OS Release 8.0, where Epipe Virtual Leased Line (VLL) is supported for IPv6 spoke termination within a Virtual Private Routed Network (VPRN). The MD-CLI in the current edition corresponds to SR OS Release 21.10.R2.

Overview

RFC 4659, *BGP-MPLS IP Virtual Private Network (VPN) Extension for IPv6 VPN*, standardized the use of an IPv6 over IPv4 tunneling scheme. SR OS supports the standardized IPv6 over IPv4 tunneling scheme for VPRN services using Multi-Protocol Border Gateway Protocol (MP-BGP), also known as 6VPE.

SR OS supports pseudowire termination by a VPRN from an Epipe Virtual Leased Line (VLL) or VPLS spoke Service Distribution Point (spoke SDP) where the pseudowire can be given IPv6 addresses and run IPv6 protocols. In the example used in this chapter, any advertisements across the Multi-Protocol Labeled Switching (MPLS) network between VPRN Provider Edge (PE) devices will use 6VPE. This chapter describes the configuration for IPv6 spoke termination to a VPRN over an Epipe VLL and transporting IPv6 packets over 6VPE tunnels between PE devices.

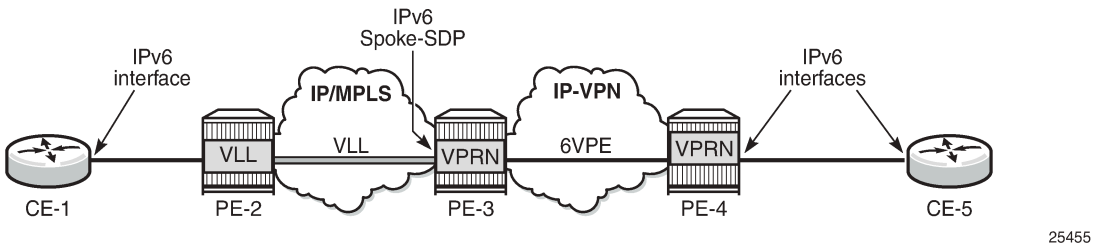
This solution can be used where a service provider is providing VPRN services built on a transport network whose Interior Gateway Protocol (IGP) is using IPv4 addressing on the network interfaces. The customer's CE and the service provider's PE must support IPv6 pseudowires, IPv6 interfaces and in addition, the service provider also must be able to support the advertisements of IPv6 prefixes between CE-PE peerings and between the transport PE routers using MP-BGP. The advertisement of IPv6 prefixes across the MPLS network and the transport of IPv6 traffic is tunneled using 6VPE.

The VPRN PE supports spoke termination of Epipe VLL services on access with IPv6 addressing between the CE and VPRN PE. The IPv6 spoke termination on VPRN services has the same functionality as VPRN IPv4 spoke termination.

The example in Figure 314: Spoke termination for IPv6 illustrates a CE device that connects to a VPRN PE on an IPv6 interface addressing using spoke termination.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 314: Spoke termination for IPv6



CE-1 is connected to the VPRN service on PE-3, using IPv6 interfaces. CE-1 reaches PE-3 by connecting to PE-2. PE-2 uses an Epipe VLL for transport to the VPRN on the PE-3. The connectivity between the VLL service on the VPRN service on PE-3 is using spoke termination with IPv6 addressing on the spoke SDP interface on PE-3.

Figure 315: IPv6 addressing and IPv6 prefixes

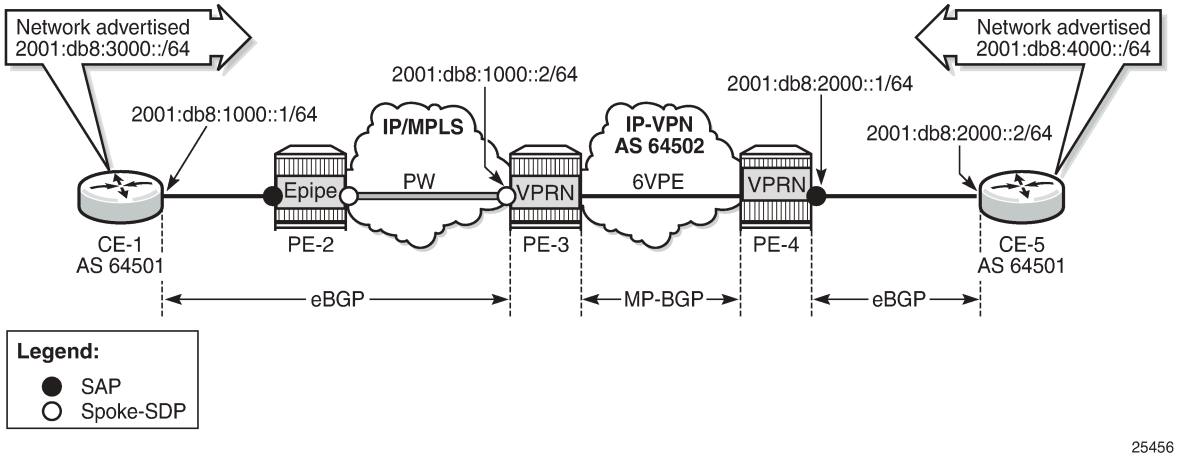


Figure 315: IPv6 addressing and IPv6 prefixes shows the overall IPv6 addressing from interfaces to prefixes advertised from CE-1 and CE-5 across the VPRN network.

- Link between CE-1 and PE-3: 2001:db8:1000::/64
- Link between CE-5 and PE-4: 2001:db8:2000::/64
- Advertised prefix from CE-1: 2001:db8:3000::/64
- Advertised prefix from CE-5: 2001:db8:4000::/64

PE-3 has an MP-eBGP session with CE-1 to receive and advertise IPv6 routes. PE-3 also has an MP-iBGP peering session with PE-4 to use 6VPE to tunnel IPv6 routes and traffic to and from PE-4. PE-4 has an IPv6 SAP interface to CE-5 and uses MP-eBGP to advertise to and receive routes from CE-5 (no spoke termination). The configuration of PE-3 is included to provide examples of the end-to-end VPRN service using a 6VPE model.

This network topology illustrates the use of spoke termination using IPv6 interfaces and the tunneling of IPv6 traffic over a 6VPE MPLS network.

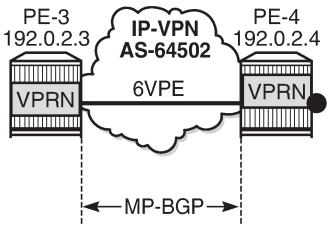
Configuration

First an MPLS network is established where the VPRN service can use 6VPE to tunnel traffic across the IPv4 IGP.

Figure 316: MP-BGP VPN IPv6



In Figure 316: MP-BGP VPN IPv6, PE-3 and PE-4 are edge routers running VPRN services on access with IPv6 interfaces. The MPLS network is configured using IPv4 link addressing. Interior Border Gateway Protocol (iBGP) peerings need to be established with MP-BGP for the VPN-IPv6 address family between PE-3 and PE-4.

```
# on PE-3:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            group "iBGP" {
                description "iBGP peering in AS 64502"
                peer-as 64502
                family {
                    vpn-ipv6 true
                }
            }
            neighbor "192.0.2.4" {
                description "PE-4"
                group "iBGP"
            }
        }
```

```
# on PE-4:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            group "iBGP" {
                description "iBGP peering in AS 64502"
                peer-as 64502
                family {
                    vpn-ipv6 true
                }
            }
            neighbor "192.0.2.3" {
                description "PE-3"
                group "iBGP"
            }
        }
```

Configuring address family VPN-IPv6 between VPRN PE edge routers in BGP enables MP-BGP for the Layer 3 VPNs supporting the customer's IPv6 addressing (6VPE).

The following commands verify the BGP sessions for the VPN-IPv6 address family between PE-3 and PE-4:

```
[/]
A:admin@PE-3# show router bgp neighbor 192.0.2.4

===============================================================================
BGP Neighbor
===============================================================================
-------------------------------------------------------------------------------
Peer                 : 192.0.2.4
Description          : PE-4
Group                : iBGP
-------------------------------------------------------------------------------

```

After the MP-BGP sessions are established for the VPN-IPv6 address-family, 6VPE tunnel support is provided between PE-3 and PE-4.

Figure 317: Spoke termination for IPv6 addressing illustrates the model for spoke termination for IPv6 using VPRN services.

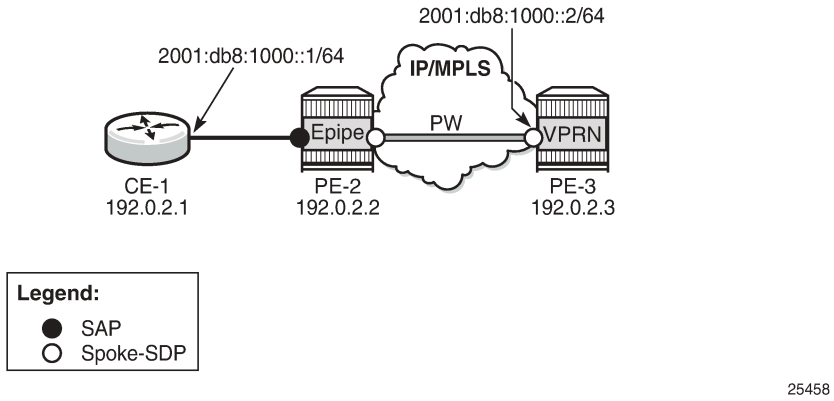
Use subject to Terms available at: www.nokia.com/terms.

Figure 317: Spoke termination for IPv6 addressing



CE-1 is configured with IPv6 addressing on the access interface facing the VPRN service. CE-1's access is backhauled to the VPRN service on PE-3 using Epipe VLL with spoke termination. The configuration of the Epipe VLL on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            service-mtu 9190
            spoke-sdp 231:1 {
            }
            sap 1/1/2 {
            }
        }
        sdp 231 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.3
            }
        }
```

Epipe 1 on PE-2 is configured with a SAP interface facing the customer and a spoke SDP facing PE-3. The spoke SDP is terminated into the customer's VPRN service on PE-3.

The possible IPv6 options for spoke SDP interfaces on the CLI for VPRN services are as follows (compliant with RFC 4213, *Basic Transition Mechanisms for IPv6 Hosts and Routers <draft-ietf-v6ops-mech-v2-07.txt>*):

- Interface spoke SDP (IPv6 options only)

```
[ex:/configure service vprn "VPRN 1" interface "int-PE-3-PE-2"]

```
  mac                   - MAC address used by virtual router instance overriding the
                          VRRP default derived from the VRID
  master-int-inherit    - Allow the master instance to dictate the master down timer
  message-interval      - Interval for sending VRRP Advertisement messages
  ntp-reply             - Allow processing of NTP Requests
  oper-group            - Operational group name associated with VRRP
  owner                 - Designate virtual router instance as owning the virtual
                          router IP addresses
  passive               - Suppress the transmission and reception of VRRP
                          advertisement messages
  ping-reply            - Allow non-owner master to reply to ICMP echo requests
  policy                - VRRP priority control policy associated with the virtual
                          router instance
  preempt               - Allow the VRRP to override an existing non-owner master
  priority              - Base priority for the VRRP
  standby-forwarding    - Allow the forwarding of packets by a standby router
  telnet-reply          - Allow non-owner master to reply to Telnet requests
  traceroute-reply      - Allow non-owner master to reply to traceroute requests
```

The VPRN on PE-3 exports IPv6 routes (IPv6 route on CE-5) to CE-1 using the following route policy.

```
# on PE-3
configure {
    policy-options {
        prefix-list "PE-3-CE-1" {
            prefix 2001:db8:4000::/64 type exact {
            }
        }
        policy-statement "PE-3-BGP-CE-1" {
            entry 10 {
                from {
                    prefix-list ["PE-3-CE-1"]
                }
                action {
                    action-type accept
                    origin igp
                }
            }
            default-action {
                action-type reject
            }
        }
```

EBGP routes are discarded by default, so an import policy is required:

```
# on PE-3, PE-4, CE-1, CE-5:
configure {
    policy-options {
        prefix-list "2001:db8::/32" {
            prefix 2001:db8::/32 type longer {
            }
        }
        policy-statement "import-2001:db8::/32" {
            entry 10 {
                from {
                    prefix-list ["2001:db8::/32"]
                }
                action {
                    action-type accept
                    origin igp
                }
            }
            default-action {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                action-type reject
            }
        }
```

The configuration for the VPRN service on PE-3 with IPv6 interface (spoke SDP) as shown in Figure 317: Spoke termination for IPv6 addressing:

```
# on PE-3:
configure {
    service {
        sdp 321 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64502
            router-id 192.0.2.31
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64502:1"
                    vrf-target {
                        community "target:64502:1"
                    }
                    auto-bind-tunnel {
                        resolution filter
                        resolution-filter {
                            ldp true
                        }
                    }
                }
            }
            bgp {
                router-id 192.0.2.31
                group "Spoke-CE-1-PE-3" {
                    peer-as 64501
                    local-address 2001:db8:1000::2
                    family {
                        ipv6 true
                    }
                }
                neighbor "2001:db8:1000::1" {
                    group "Spoke-CE-1-PE-3"
                    as-override true
                    type external
                    import {
                        policy ["import-2001:db8::/32"]
                    }
                    export {
                        policy ["PE-3-BGP-CE-1"]
                    }
                }
            }
            interface "int-PE-3-PE-2" {
                description "Spoke SDP"
                spoke-sdp 321:1 {
```

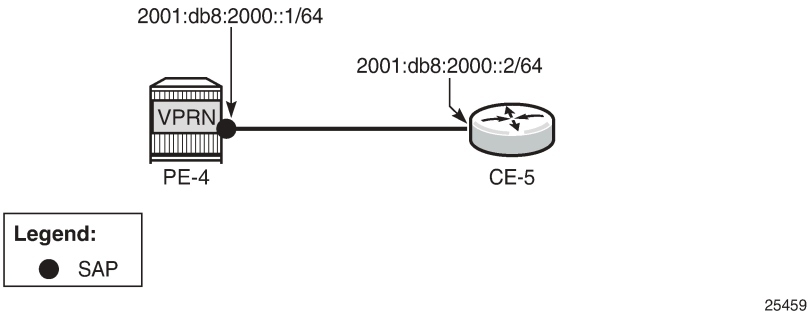
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
                ipv6 {
                    address 2001:db8:1000::2 {
                        prefix-length 64
                    }
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 192.0.2.31
                        prefix-length 32
                    }
                }
            }
        }
```

In the preceding configuration example, PE-3 has been configured with an IPv6 spoke SDP (spoke termination) with interface int-PE-3-PE-2. The VPRN configuration has also been set up for MP-eBGP peering to CE-1 through the IPv6 spoke interface. The MP-eBGP peering receives and advertises IPv6 prefixes from and to CE-1. The included route policy configuration shows how IPv6 routes are advertised to CE-1 from PE-3 (policy-statement PE-3-BGP-CE-1).

The configuration on PE-4 is similar, but with a SAP interface to CE-5 instead of a spoke-SDP.

Figure 318: PE-4 VPRN with SAP to CE-5



The IPv6 configuration options for the SAP interface (int-PE-4-CE-5) are similar to those in the preceding example for the spoke SDP on PE-3. The PE-4 BGP export policy (PE-4-BGP-CE-5) is also similar to the example for PE-3 in advertising the learned IPv6 route to CE-5.

```
# on PE-4:
configure {
    policy-options {
        prefix-list "PE-4-CE-5" {
            prefix 2001:db8:3000::/64 type exact {
            }
        }
        policy-statement "PE-4-BGP-CE-5" {
            entry 10 {
                from {
                    prefix-list ["PE-4-CE-5"]
                }
                action {
                    action-type accept
                    origin igp
```

                group "eBGP_to_64502"
                import {
                    policy ["import-2001:db8::/32"]
                }
                export {
                    policy ["CE-1-sys-to-eBGP"]
                }
            }
        }
        static-routes {
            route 2001:db8:3000::/64 route-type unicast {
                blackhole {
                    admin-state enable
                }
            }
        }
    }
    service
        ies "IES 1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-CE-1-PE-2" {
                description "SAP_toward_VPRN_Service"
                sap 1/1/1 {
                }
                ipv6 {
                    address 2001:db8:1000::1 {
                        prefix-length 64
                    }
                }
            }
        }
```

The configuration on CE-5 is similar.

The following command on PE-2 shows that the Epipe VLL is established with the SAP facing CE-1 and spoke SDP facing VPRN 1 on PE-3.

```
[/]
A:admin@PE-2# show service id 1 base

```

With the **show service id 1 all** command, an extensive list of parameters is displayed, including IPv6-related fields that can be checked if configured: DHCP6-relay, DHCP6-server, and so on. It is possible to use filters to reduce the output.

After verification of the services (Epipe, VPRN), the MP-eBGP peering connectivity (through IPv6 interfaces) on the VPRN between PE-3 and CE-1 can be verified as follows:

```
[/]
A:admin@PE-3# show router 1 bgp neighbor

===============================================================================
```

MP-iBGP, providing 6VPE is configured and built between PE-3 and PE-4 across the MPLS network. IPv6 prefixes are received on PE-3 from CE-1 (2001:db8:3000::/64) and on PE-4 from CE-5 (2001:db8:4000::/64) across the MPLS network using MP-iBGP (6VPE).

CE-1 advertises IPv6 prefix 2001:db8:3000::/64 and CE-5 advertises IPv6 prefix 2001:db8:4000::/64.

The following command on PE-3 shows whether VPN-IPv6 routes were received from and advertised to its iBGP peer PE-4:

```

Conclusion

Spoke termination for IPv6-6VPE extends the use of spoke terminated interfaces from an Epipe VLL into a VPRN service using IPv6 interfaces on the access. Supporting the requirement of IPv6 interfaces, routing of IPv6 prefixes and the use of 6VPE for IPv6 tunneling over an IPv4 network allows SR OS to provide capabilities supporting the growth of IPv6 architectures.

Traffic Leaking from VPRN to GRT

This chapter provides information about Traffic Leaking from VPRN to GRT.

Topics in this chapter include:

Applicability

The information and configuration in this chapter were originally based on SR OS Release 14.0 R4. The MD-CLI in the current edition corresponds to SR OS Release 22.2.R2.

Overview

RFC 4364 *BGP/MPLS IP Virtual Private Networks (VPNs)* describes a method of distributing routing information using BGP and MPLS forwarding data to provide a Layer 3 VPN service to end users. Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via Multi-Protocol Border Gateway Protocol (MP-BGP) peering. Each route exchanged via the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association and resolves any IP address overlap.

It has always been possible to exchange traffic from one VPRN to another, using scenarios such as "extranet", "hub and spoke" and so on, using the vrf-import and vrf-export policies for BGP VPN-IPv4 route distribution.

Traffic leaking to the Global Route Table (GRT) allows service providers to offer VPRN and Internet services over a single virtual routing and forwarding VRF interface. Packets entering a VRF interface can have route processing results derived from the VRF or the GRT. The leaking and preferred lookup settings are configured on a per-VPRN basis.

To allow data flowing from a VPRN to the base router, routing information from the base router must be made available for lookup by the VPRN. The GRT lookup can be general (for example, any lookup miss in the Virtual Routing and Forwarding (VRF) table can be resolved in the GRT), or specific (for example, specific routes should only be searched for in the GRT and ignored by the VPRN).

To enable the GRT lookup from the VPRN, the **grt-leaking>grt-lookup true** command is used. This only provides part of the solution, because packets can now be forwarded from the VPRN to the GRT, but not in the opposite direction. The GRT needs to learn specific destination prefixes from the VPRN and this is achieved by route leaking from the VPRN to the GRT, using policies (**grt-leaking>export-grt** command). The maximum number of routes leaked from a VPRN to the GRT is five by default, but this maximum can be modified or even removed. Prefixes should be globally unique within the service provider network and if these are propagated outside the provider's network, they must be from the public IP space and globally unique.

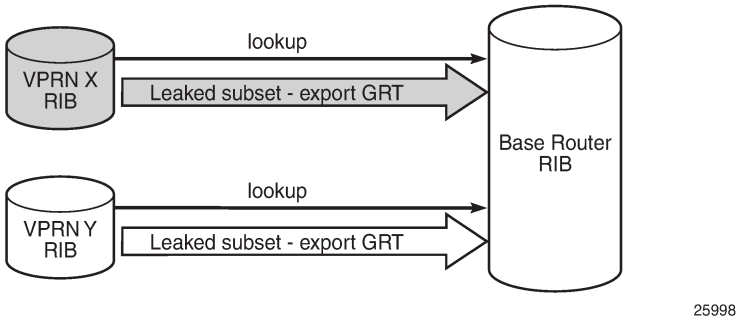
Figure 319: VPRN to GRT leak process

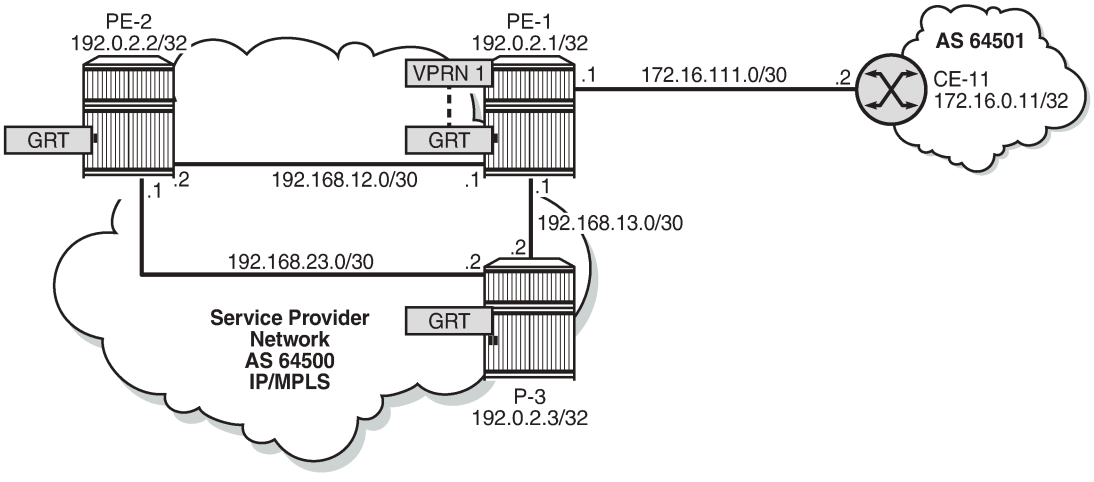


The method described in this chapter allows the network administrator to leak specific or all routes that are inside a VPRN to the GRT. Route leaking from VPRN to GRT is protocol-independent and can be applied for BGP, OSPF(v3), IS-IS, static, local routes, and so on. For BGP routes, there is an improved route leaking mechanism that allows leaking routes preserving all BGP attributes; see chapter the "BGP Route Leaking" in the Unicast Routing Protocols volume in the *7450 ESS, 7750 SR, and 7950 XRS MD-CLI Advanced Configuration Guide - Part I*.

Configuration

Figure 320: Example topology with IPv4 addresses shows the example topology used in this chapter, including the IPv4 addresses. The interfaces also have IPv6 addresses, which will be shown in Figure 322: Example topology with IPv6 addresses.

Figure 320: Example topology with IPv4 addresses



Initial configuration

The nodes in the example topology have the following initial configuration:

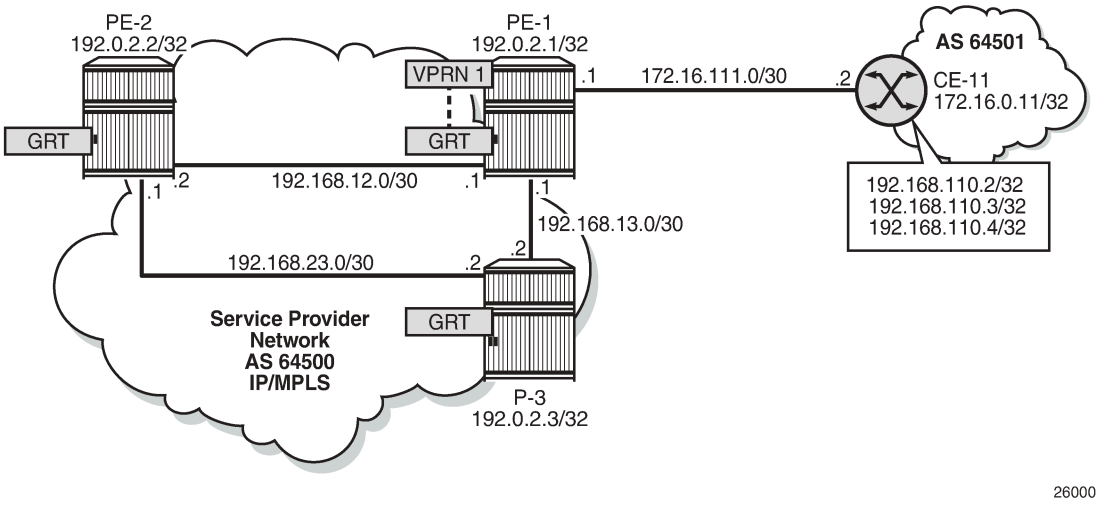
© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Cards, MDAs, ports
- Router interfaces
- IGP (IS-IS or OSPF) between the PEs
- LDP between the PEs
- VPRN "VPRN 1" on PE-1
- BGP (IBGP between the PEs; EBGP between PE-1 and CE-11)
  - On PE-1, BGP is configured in the base router and in VPRN 1.
- Loopback addresses on CE-11, such as 192.168.110.2/32.
- Export policies on CE-11 to export routes from direct with certain prefixes.

Protocol-independent IPv4 route leaking from VPRN to GRT

Figure 321: IPv4 VPRN to GRT route leaking for IS-IS shows the topology with the IP addresses for this example. Route leaking from VPRN to GRT is protocol independent and in this example, VPRN "VPRN 1" on PE-1 will leak local routes, static routes, and imported BGP routes to the GRT. IS-IS or OSPF routes can also be leaked, but that is not shown here.

Figure 321: IPv4 VPRN to GRT route leaking for IS-IS



GRT-leak is by default disabled. The routing table for VPRN 1 on PE-1 contains local routes, static routes, and BGP routes that are learned from CE-11, as follows:

```
[/]

192.168.23.0/30                          Remote  ISIS      00h01m03s  15
       192.168.12.2                                                 20
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

To enable VPRN to GRT leaking, the following route policy is configured on PE-1 and applied in VPRN 1:

```
# on PE-1:
configure {
    policy-options {
        policy-statement "LeakVPRNtoGRT_pref8" {
            entry 10 {
                action {
                    action-type accept
                    preference 8
                }
            }
        }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    }
    service {
        vprn "VPRN 1" {
            grt-leaking {
                grt-lookup true
                export-grt {
                    policy-name ["LeakVPRNtoGRT_pref8"]
                }
            }
```

This policy allows leaking all routes from a VPRN to the base router, without any match criteria. However, when routes are leaked from VPRNs to the GRT, they need to be unique and only routes that need to be known in the GRT should be leaked. By default, the preference for a leaked route is 180. The preference can be manually configured to a lower value, such as 8, to avoid network inconsistencies between the IGP and the RT on the router where the routes are leaked.

When **grt-leaking>grt-lookup true** is configured, any lookup miss in the VRF table will be resolved in the GRT, if available. This only works from VPRN to GRT and does not require route leaking. However, the base router needs to be able to route packets back to the VPRN and it cannot perform a lookup in the routing table of the VPRN. Therefore, route leaking from VPRN to GRT is required, and **grt-leaking>export-grt** is configured. Prefixes in the VPRN must be leaked to the GRT through a policy. Prefixes leaked from any VPRN should never conflict with prefixes leaked from any other VPRN or existing prefixes in the GRT.

This configuration is protocol-independent. Route leaking from VPRN to GRT is applicable for all kinds of learned routes, such as static routes, local routes, IS-IS, OSPF, BGP, and so on.

After routes are leaked from the VPRN to the GRT, the routing table of the base router includes the leaked routes, with protocol "VPN Leak". For PE-1, the routing table contains the following routes:

```
[/]
A:admin@PE-1# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref

===============================================================================
```

Regardless the preference of the original routes in VPRN 1, all the leaked routes in the GRT have preference 8, as configured. By default, a maximum of five routes are leaked. This export limit can be overruled, as follows:

```
# on PE-1:
configure {
    service {
        vprn "VPRN 1" {
            grt-leaking {
                export-limit 10
                grt-lookup true
                export-grt {
                    policy-name ["LeakVPRNtoGRT_pref8"]
                }
            }
```

The following command shows only the routes leaked from any VPRN to GRT on PE-1:

```
[/]
A:admin@PE-1# show router route-table protocol vpn-leak all

Export IPv4 VPN-leak routes to routing protocols

Until now, the VPN-leak routes are leaked locally to the GRT, but they are not advertised in IS-IS, OSPF, or BGP. Router P-3 has not learned any of the leaked routes, as follows:

```
[/]
A:admin@P-3# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h03m44s  15
       192.168.13.1                                                 10
192.0.2.2/32                                    Remote  ISIS      00h03m44s  15
       192.168.23.1                                                 10
192.0.2.3/32                                    Local   Local     00h03m51s  0
       system                                                       0
192.168.12.0/30                                 Remote  ISIS      00h03m44s  15
       192.168.13.1                                                 20
192.168.13.0/30                                 Local   Local     00h03m51s  0
       int-P-3-PE-1                                                 0
192.168.23.0/30                                 Local   Local     00h03m51s  0
       int-P-3-PE-2                                                 0
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

To reduce the number of routes to be exported on PE-1, a match criterion is added for the routes to be leaked, as follows:

```
# on PE-1:
configure {
    policy-options {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        prefix-list "192.168.110.0" {
            prefix 192.168.110.0/24 type longer {
            }
        }
        policy-statement "LeakVPRNtoGRT_pref8_110" {
            entry 10 {
                from {
                    prefix-list ["192.168.110.0"]
                }
                action {
                    action-type accept
                    preference 8
                }
            }
        }
    }
    service {
        vprn "VPRN 1" {
            grt-leaking {
                export-limit 10
                grt-lookup true
                export-grt {
                    delete policy-name ["LeakVPRNtoGRT_pref8"]
                    policy-name ["LeakVPRNtoGRT_pref8_110"]
                }
```

VPN-leak routes can be exported to any routing protocol. Prefix lists can be used to filter routes, but that is not configured in this example. The following export policy is configured on PE-1 to export the VPN-leak routes:

```
# on PE-1:
configure {
    policy-options
        policy-statement "export-vpn-leak" {
            entry 10 {
                from {
                    protocol {
                        name [vpn-leak]
                    }
                }
                action {
                    action-type accept
                }
            }
```

The same export policy will be used for export to IS-IS, OSPF, and BGP.

Export IPv4 VPN-leak routes to IS-IS

The export policy is applied in the IS-IS context on PE-1, as follows:

```
# on PE-1:
configure {
    router "Base" {
        isis 0 {
            export-policy ["export-vpn-leak"]
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The leaked routes are now advertised via IS-IS and appear as IS-IS routes with default preference for IS-IS routes on PE-2 and P-3. The route table on P-3 looks as follows:

```
[/]
A:admin@P-3# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h04m39s  15
       192.168.13.1                                               10
192.0.2.2/32                                    Remote  ISIS      00h04m39s  15
       192.168.23.1                                               10
192.0.2.3/32                                    Local   Local     00h04m46s  0
       system                                                     0
192.168.12.0/30                                 Remote  ISIS      00h04m39s  15
       192.168.13.1                                               20
192.168.13.0/30                                 Local   Local     00h04m46s  0
       int-P-3-PE-1                                               0
192.168.23.0/30                                 Local   Local     00h04m46s  0
       int-P-3-PE-2                                               0
192.168.110.2/32                                Remote  ISIS      00h00m21s  15
       192.168.13.1                                               10
192.168.110.3/32                                Remote  ISIS      00h00m21s  15
       192.168.13.1                                               10
192.168.110.4/32                                Remote  ISIS      00h00m21s  15
       192.168.13.1                                               10
-------------------------------------------------------------------------------
No. of Routes: 9
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed from the IS-IS context on PE-1, as follows:

```
# on PE-1:
configure {
    router "Base" {
        isis 0 {
            delete export-policy ["export-vpn-leak"]
```

Export IPv4 VPN-leak routes to OSPF

When OSPF is used instead of IS-IS, the behavior is similar. The export policy is applied in the OSPF context on PE-1, as follows:

```
# on PE-1:
configure {
    router "Base"
        ospf 0 {
            export-policy ["export-vpn-leak"]
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

To export routes into OSPF using a policy, the router must be configured as ASBR, as follows:

```
# on PE-1:
configure {
    router "Base"
        ospf 0 {
            asbr {
            }
```

The routes with protocol VPN-leak on PE-1 are now exported in OSPF to PE-2 and P-3. The default preference for external OSPF routes is 150. On P-3, the routing table contains the following OSPF routes:

```
[/]
A:admin@P-3# show router route-table protocol ospf

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  OSPF      00h00m44s  10
       192.168.13.1                                                 10
192.0.2.2/32                                    Remote  OSPF      00h00m44s  10
       192.168.23.1                                                 10
192.168.12.0/30                                 Remote  OSPF      00h00m44s  10
       192.168.13.1                                                 20
192.168.110.2/32                                Remote  OSPF      00h00m14s  150
       192.168.13.1                                                 1
192.168.110.3/32                                Remote  OSPF      00h00m14s  150
       192.168.13.1                                                 1
192.168.110.4/32                                Remote  OSPF      00h00m14s  150
       192.168.13.1                                                 1
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed from the OSPF context on PE-1 as follows:

```
# on PE-1:
configure {
    router "Base" {
        ospf 0 {
            delete export-policy ["export-vpn-leak"]
```

Export IPv4 VPN-leak routes to BGP

The export policy is applied in the general **bgp** context of PE-1, as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
            export {
                policy ["export-vpn-leak"]
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

The VPN-leak routes from PE-1 will be advertised as BGP routes to BGP neighbors PE-2 and P-3, and the routing tables will contain BGP routes with preference 170. P-3 has the following BGP routes:

```
[/]
A:admin@P-3# show router route-table protocol bgp

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                     Metric
-------------------------------------------------------------------------------
192.168.110.2/32                                Remote  BGP       00h00m16s  170
       192.168.13.1                                                 10
192.168.110.3/32                                Remote  BGP       00h00m16s  170
       192.168.13.1                                                 10
192.168.110.4/32                                Remote  BGP       00h00m16s  170
       192.168.13.1                                                 10
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

Note:
If it is required to preserve the BGP path attributes in the leaking process, you must use the BGP Route Leaking process described in chapter *BGP Route Leaking*. However, with this protocol-independent route leaking mechanism, it is possible to leak non-BGP routes to the GRT that will be advertised as BGP routes.

The export policy is removed from the **bgp** context, as follows:

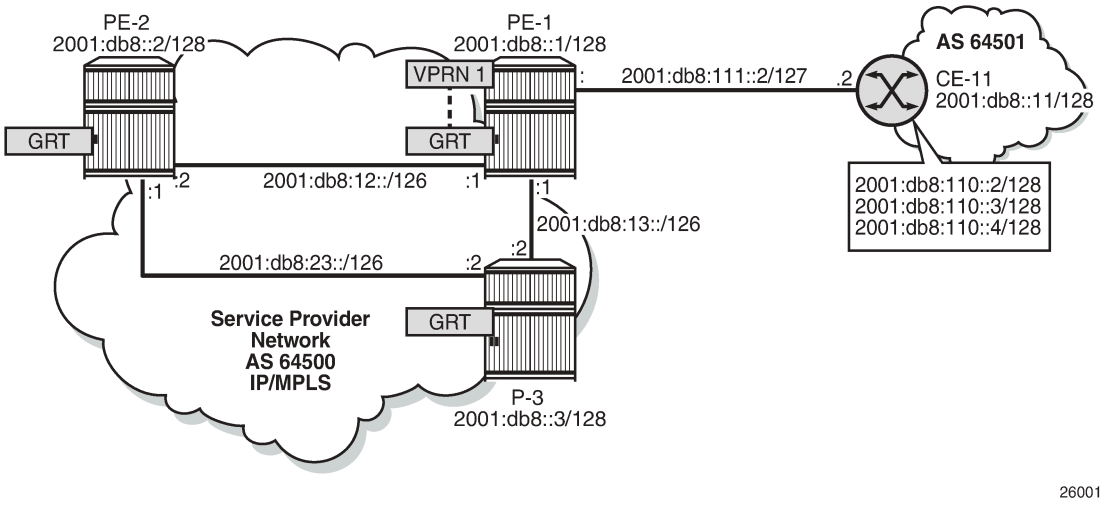
```
# on PE-1:
configure {
    router "Base" {
        bgp {
            delete export
```

Protocol-independent IPv6 route leaking from VPRN to GRT

Figure 322: Example topology with IPv6 addresses shows the topology and the IP addresses used for IPv6. CE-11 exports routes such as 2001:db8:110::2/128 to VPRN 1on PE-1. On PE-1, local routes, static routes, and BGP routes will be leaked to the GRT.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 322: Example topology with IPv6 addresses



The IPv6 routing table for VPRN 1 on PE-1 includes local addresses, a static route, and three BGP routes exported by CE-11, as follows:

```
[/]
A:admin@PE-1# show router 1 route-table ipv6

===============================================================================
IPv6 Route Table (Service: 1)
===============================================================================

       fe80::18:1ff:fe01:2-"int-PE-1-P-3"                             20
-------------------------------------------------------------------------------
No. of Routes: 6
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The VPN-leak route policy is the same as for IPv4 routes, and is applied in the **vprn** context in the same way as for IPv4 routes, as follows:

```
# on PE-1:
configure {
    policy-options
        policy-statement "LeakVPRNtoGRT_pref8" {
            entry 10 {
                action {
                    action-type accept
                    preference 8
                }
            }
        }
    }
    service {
        vprn "VPRN 1" {
            grt-leaking {
                grt-lookup true
                export-grt {
                    policy-name ["LeakVPRNtoGRT_pref8"]
                }
            }
```

On PE-1, the IPv6 routing table for VPRN 1 contains six routes, but by default, a maximum of five routes are leaked, as follows:

```
[/]
A:admin@PE-1# show router route-table ipv6 protocol vpn-leak all

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                           Active     Metric
-------------------------------------------------------------------------------
```

```
2001:db8::1:1/128                               Remote  VPN Leak  00h00m12s  8
       system                                            Y           0
2001:db8:110::2/128                             Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                   Y           0
2001:db8:110::4/128                             Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                   Y           0
2001:db8:111::/127                              Remote  VPN Leak  00h00m12s  8
       int-PE-1-CE-11                                    Y           0
2001:db8:120::/120                              Remote  VPN Leak  00h00m12s  8
       2001:db8:111::1                                   Y           0
-------------------------------------------------------------------------------
No. of Routes: 5
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
       E = Inactive best-external BGP route
===============================================================================
```

The export limit for IPv6 routes is removed, as follows:

```
# on PE-1:
configure {
    service {
        vprn "VPRN 1" {
            grt-leaking {
                export-v6-limit 0
                grt-lookup true
                export-grt {
                    policy-name ["LeakVPRNtoGRT_pref8"]
                }
            }
```

As a result, there is no limit to the number of leaked IPv6 routes, and all six IPv6 routes are leaked from VPRN 1 to the GRT with the configured preference 8, as follows:

```
[/]
A:admin@PE-1# show router route-table ipv6 protocol vpn-leak all

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref

Export IPv6 VPN-leak routes to routing protocols

Until now, the IPv6 VPN-leak routes are leaked locally to the GRT, but they are not advertised in IS-IS, OSPFv3, or BGP. Router P-3 has not learned any of the leaked IPv6 routes, as follows:

```
[/]
A:admin@P-3# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
2001:db8::1/128                                 Remote  OSPF3     00h10m51s  10
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              10
2001:db8::2/128                                 Remote  OSPF3     00h10m46s  10
       fe80::14:1ff:fe01:2-"int-P-3-PE-2"                              10
2001:db8::3/128                                 Local   Local     00h10m52s  0
       system                                                          0
2001:db8:12::/126                               Remote  OSPF3     00h10m51s  10
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                              20
2001:db8:13::/126                               Local   Local     00h10m51s  0
       int-P-3-PE-1                                                    0
2001:db8:23::/126                               Local   Local     00h10m51s  0
       int-P-3-PE-2                                                    0
-------------------------------------------------------------------------------

To reduce the number of VPN-leak routes, a match criterion is added to the **export-grt** policy on PE-1, as follows:

```
# on PE-1:
configure {
    policy-options {
        prefix-list "2001:db8:110::" {
            prefix 2001:db8:110::/125 type longer {
            }
        }
        policy-statement "LeakVPRNtoGRT_pref8_110" {
            entry 20 {
                from {
                    prefix-list ["2001:db8:110::"]
                }
                action {
                    action-type accept
                    preference 8
                }
            }
        }
    }
    service {
        vprn "VPRN 1" {
            grt-leaking {
                export-v6-limit 0
                grt-lookup true
                export-grt {
                    delete policy-name ["LeakVPRNtoGRT_pref8"]
                    policy-name ["LeakVPRNtoGRT_pref8_110"]
                }
            }
```

The following IPv6 routes are leaked from VPRN 1 to GRT on PE-1:

```
[/]
A:admin@PE-1# show router route-table ipv6 protocol vpn-leak

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8:110::2/128                           Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                            0
2001:db8:110::3/128                           Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                            0
2001:db8:110::4/128                           Remote  VPN Leak  00h00m21s  8
       2001:db8:111::1                                            0
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv6 VPN-leak routes can be exported to routing protocols IS-IS, OSPFv3, and BGP.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The export policy on PE-1 is the same as in all the preceding examples for IPv4, as follows:

```
# on PE-1:
configure {
    policy-options {
        policy-statement "export-vpn-leak" {
            entry 10 {
                from {
                    protocol {
                        name [vpn-leak]
                    }
                }
                action {
                    action-type accept
                }
            }
```

Export IPv6 VPN-leak routes to IS-IS

The export policy for IPv6 routes of protocol VPN-leak is applied for IS-IS, as follows:

```
# on PE-1:
configure {
    router "Base" {
        isis 0 {
            export-policy ["export-vpn-leak"]
```

The three IPv6 VPN-leak routes from PE-1 are now advertised by IS-IS to PE-2 and P-3. The routing table on P-3 contains the following IPv6 IS-IS routes:

```
[/]
A:admin@P-3# show router route-table ipv6 protocol isis

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8::1/128                               Remote  ISIS      00h11m54s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           10
2001:db8::2/128                               Remote  ISIS      00h11m54s  15
       fe80::14:1ff:fe01:2-"int-P-3-PE-2"                           10
2001:db8:12::/126                             Remote  ISIS      00h11m54s  15
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           20

The export policy is removed for IS-IS, as follows:

```
# on PE-1:
configure {
    router "Base" {
        isis 0 {
            delete export-policy ["export-vpn-leak"]
```

Export IPv6 VPN-leak routes to OSPFv3

The export policy for IPv6 routes of protocol VPN-leak is applied for OSPFv3, as follows:

```
# on PE-1:
configure {
    router "Base" {
        ospf3 0 {
            export-policy ["export-vpn-leak"]
```

Routes can only be exported to OSPFv3 if the router is configured as ASBR, as follows:

```
# on PE-1:
configure {
    router "Base" {
        ospf3 0 {
            asbr { }
```

The IPv6 VPN-leak routes from PE-1 are now advertised by OSPFv3 to PE-2 and P-3. The preference for remote OSPFv3 routes is by default 150. The routing table on P-3 contains the following IPv6 OSPFv3 routes:

```
[/]
A:admin@P-3# show router route-table ipv6 protocol ospf3

===============================================================================

The export policy is removed for OSPFv3, as follows:

```
# on PE-1:
configure {
    router "Base" {
        ospf3 0 {
            delete export-policy ["export-vpn-leak"]
```

Export IPv6 VPN-leak routes to BGP

The export policy for IPv6 routes of protocol VPN-leak is applied for BGP, as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
            export {
                policy ["export-vpn-leak"]
```

The three IPv6 VPN-leak routes from PE-1 are now advertised by BGP to PE-2 and P-3. The routing table on P-3 contains the following IPv6 BGP routes:

```
[/]
A:admin@P-3# show router route-table ipv6 protocol bgp

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8:110::2/128                           Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           10
2001:db8:110::3/128                           Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           10
2001:db8:110::4/128                           Remote  BGP       00h00m15s  170
       fe80::10:1ff:fe01:1-"int-P-3-PE-1"                           10
-------------------------------------------------------------------------------
No. of Routes: 3
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The export policy is removed for BGP, as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
            delete export
```

In this example, BGP leaked IPv6 routes are advertised by BGP. For scenarios with only BGP routes, a dedicated BGP route leaking mechanism that preserves all attributes is preferred, as described in chapter "BGP Route Leaking" in the Unicast Routing Protocols volume in the *7450 ESS, 7750 SR, and 7950 XRS*

MD-CLI Advanced Configuration Guide - Part I. However, with the same configuration as in this chapter, it is possible to leak non-BGP routes and advertise them using BGP.

Conclusion

Routes learned in a VPRN can be leaked to the base router and advertised using routing protocols. The mechanism described in this chapter is protocol-independent: all kinds of routes can be leaked from a VRF to the GRT: local, static, IS-IS, OSPF, BGP routes, and so on. In some cases, it might be useful to leak the routes from a VPRN to the entire network using the routing protocol, in order to access the resources defined inside the VRF. Routes that are leaked from VPRNs to the GRT must be unique in the network where they will be advertised.

For BGP routes, the protocol-independent route leaking mechanism described here does not preserve the attributes, unlike the dedicated BGP route leaking feature.

Weighted ECMP for VPRN over RSVP-TE or SR-TE LSPs

This chapter provides information about Weighted Equal Cost Multipath (ECMP) for Virtual Private Routed Network (VPRN) over Resource Reservation Protocol with Traffic Engineering (RSVP-TE) or Segment Routing with Traffic Engineering (SR-TE) Label Switched Paths (LSPs).

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 23.3.R2. Weighted load balancing over Multi Protocol Label Switching (MPLS) LSPs -as described in chapter *BGP Weighted ECMP*- is supported in SR OS Release 13.0.R1, and later. Weighted load balancing for VPRN with auto-bind-tunnel over RSVP-TE LSPs is supported in SR OS Release 15.0.R2, and later. Weighted load balancing for VPRN with auto-bind-tunnel over SR-TE LSPs is supported in SR OS Release 15.0.R4, and later.

Overview

Equal Load Balancing

In this chapter, ECMP refers to spraying traffic flows over multiple RSVP-TE or SR-TE LSPs within an ECMP set. ECMP spraying consists of hashing the relevant fields in the packet header and selecting the tunnel next-hop based on the modulo operation of the output of the hash and the number of LSPs present in the ECMP set. The maximum number of LSPs in the ECMP set is defined by the **ecmp** command.

Only LSPs with the same lowest LSP metric can be part of the ECMP set. If the number of such LSPs exceeds the maximum number of LSPs allowed in the ECMP set as defined by the **ecmp** command, the LSPs with the lowest tunnel IDs are selected first. By default, all LSPs in the ECMP set have the same weight, and traffic flows are spread evenly over all LSPs in the ECMP set, regardless of the bandwidth of the active path in the LSPs. By default, ECMP is enabled and set to 1.

Figure 323: Regular ECMP in AS 64496 shows that PE-1 sprays the traffic flows equally over two LSPs between PE-1 and PE-3. If three or more LSPs with the same lowest LSP metric were available from PE-1 to PE-3, only two of those would be used, because an ECMP value of 2 allows the traffic to be sprayed over two LSPs.

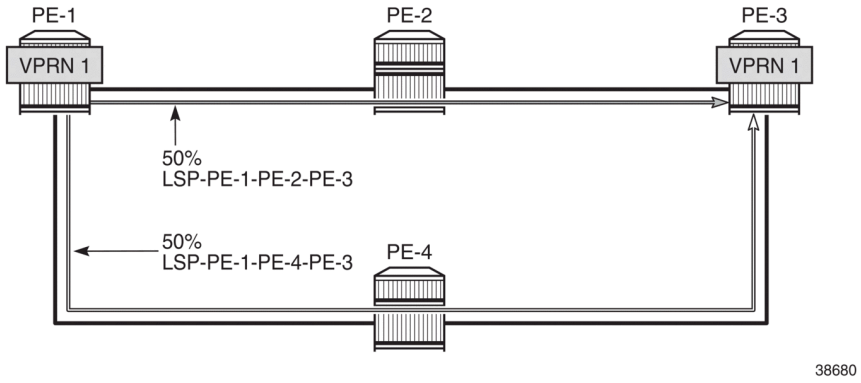
Use subject to Terms available at: www.nokia.com/terms.

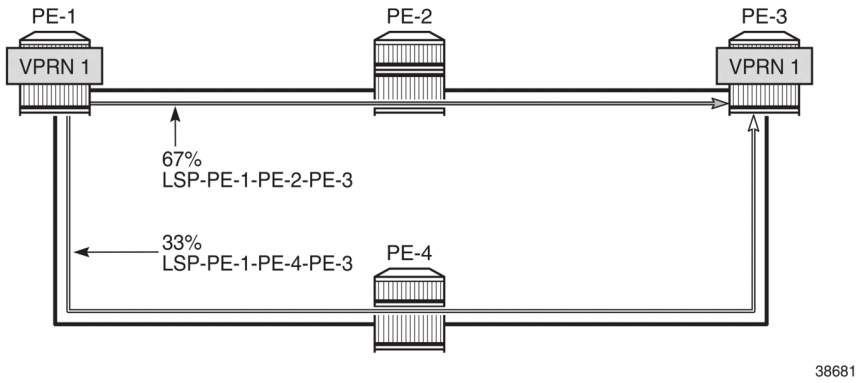
Figure 323: Regular ECMP in AS 64496



Unequal Load Balancing

Weighted ECMP sprays traffic flows over MPLS LSPs proportionally to the **load-balancing-weight** <*weight*> value configured on each MPLS LSP in the ECMP set. Figure 324: Weighted ECMP in AS 64496 shows that PE-1 forwards two thirds of the traffic flows on LSP-PE-1-PE-2-PE-3 with weight 2 and one third on LSP-PE-1-PE-4-PE-3 with weight 1. Each of the links can be link aggregation group (LAG) ports. For instance, when LSP-PE-1-PE-2-PE-3 uses LAG ports, 67% of the traffic is sprayed evenly over all ports belonging to the LAG.

Figure 324: Weighted ECMP in AS 64496



The LSP load balancing weight can be configured in an LSP template or on an LSP. By default, the load balancing weight equals zero, in which case regular ECMP applies.

The following command is used to configure the weight in an LSP template:

```
A:admin@PE-1# configure {
    router "Base" {
        mpls {
            lsp-template "LSPtemplate1" {
                load-balancing-weight ?

 load-balancing-weight <number>
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 <number> - <1..4294967295>

    Load balancing weight for an MPLS LSP template

    Warning: Modifying this element toggles
    'configure router "Base" mpls lsp-template "LSPtemplate1" admin-state'
    automatically for the new value to take effect.
```

The following command is used to configure the weight on an LSP (for example on LSP "LSP-PE-1-PE-2-PE-3"):

```
A:admin@PE-1# configure {
   router "Base" {
        mpls {
            lsp "LSP-PE-1-PE-2-PE-3" {
                load-balancing-weight ?

 load-balancing-weight <number>
 <number> - <1..4294967295>

    Load balancing weight for an MPLS LSP
```

The LSP load balancing weight on LSP-PE-1-PE-2-PE-3 is configured with a value of 2, as follows:

```
configure {
   router "Base" {
        mpls {
            path "path-PE-1-PE-2-PE-3" {
                admin-state enable
                hop 10 {
                    ip-address 192.168.12.2
                    type strict
                }
                hop 20 {
                    ip-address 192.168.23.2
                    type strict
                }
            }
            lsp "LSP-PE-1-PE-2-PE-3" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 2
                primary "path-PE-1-PE-2-PE-3" {
                }
            }
        }
```

Weighted ECMP is enabled in the **vprn "1" bgp-ipvpn mpls auto-bind-tunnel** context as follows:

```
configure {
    service {
        vprn "1" {
            customer "1"
            bgp-ipvpn {
                mpls {
                    auto-bind-tunnel {
                        ecmp 2
                        weighted-ecmp true
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
```

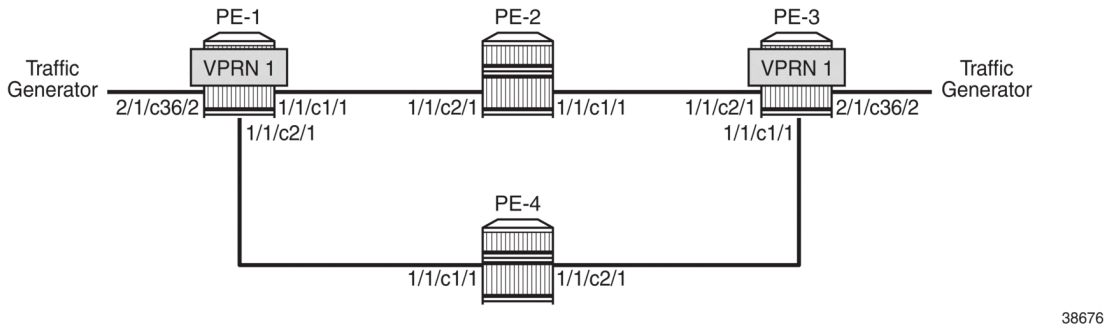
Weighted load balancing within a **vprn** context can be performed only when the next-hops are associated with the same neighbor and all LSPs in the ECMP set are configured with non-zero load balancing weights. If one or more LSPs in the ECMP set toward a specific next-hop do not have a load balancing weight configured, regular ECMP spraying is used. The weighted ECMP support for ECMP routes applies to both IPv4 and IPv6.

Additionally, it is possible to enable ECMP in the **vprn** context, with: **configure service vprn "1" ecmp** *<max-ecmp-routes>*, to control load balancing to a different next-hop. The **weighted-ecmp true** option in the **vprn "1" bgp-ipvpn mpls auto-bind-tunnel** context controls load balancing to the same next-hop.

Configuration

Figure 325: Example Topology shows the example topology with four PEs. VPRN 1 is configured on PE-1 and PE-3. A traffic generator is connected to VPRN 1 SAP 2/1/c36/2 on PE-1 and VPRN 1 SAP 2/1/c36/2 on PE-3. The traffic generator generates multiple traffic flows with random IP addresses and TCP/UDP port numbers. As a result, these flows are sprayed over different MPLS LSPs between PE-1 and PE-3.

Figure 325: Example Topology



The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used) with traffic engineering enabled
- MPLS and RSVP enabled on all router interfaces

The initial configuration on PE-1 is as follows:

```
configure {
   router "Base" {
        interface "int-PE-1-PE-2" {
            port 1/1/c1/1
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-4" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.14.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.1
                    prefix-length 32
                }
            }
        }
        isis 0 {
            admin-state enable
            area-address [49.0001]
            traffic-engineering true
            interface "system" {
            }
            interface "int-PE-1-PE-2" {
                interface-type point-to-point
            }
            interface "int-PE-1-PE-4" {
                interface-type point-to-point
            }
        }
        mpls {
            admin-state enable
            interface "int-PE-1-PE-2" {
            }
            interface "int-PE-1-PE-4" {
            }
        }
        rsvp {
            admin-state enable
            interface "int-PE-1-PE-2" {
            }
            interface "int-PE-1-PE-4" {
            }
        }
    }
```

The initial configuration on the other PEs is similar.

With the preceding configuration, MPLS and RSVP are enabled on all interfaces, including the system interface, which is added automatically.

In the next sections, the following use cases are described:

- Weighted ECMP for VPRN with Auto-bind-tunnel RSVP-TE
- Weighted ECMP for an SDP used as a spoke SDP in a VPRN
- Weighted ECMP for VPRN with Auto-bind-tunnel SR-TE

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Weighted ECMP for VPRN with Auto-bind-tunnel RSVP-TE

On PE-1, the following paths and LSPs are configured. LSP-PE-1-PE-2-PE-3 is configured with a load balancing weight of 2; LSP-PE-1-PE-4-PE-3 is configured with a load balancing weight of 1.

```
configure {
   router "Base" {
        mpls {
            path "path-PE-1-PE-2-PE-3" {
                admin-state enable
                hop 10 {
                    ip-address 192.168.12.2
                    type strict
                }
                hop 20 {
                    ip-address 192.168.23.2
                    type strict
                }
            }
            path "path-PE-1-PE-4-PE-3" {
                admin-state enable
                hop 10 {
                    ip-address 192.168.14.2
                    type strict
                }
                hop 20 {
                    ip-address 192.168.34.1
                    type strict
                }
            }
            lsp "LSP-PE-1-PE-2-PE-3" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 2
                primary "path-PE-1-PE-2-PE-3" {
                }
            }
            lsp "LSP-PE-1-PE-4-PE-3" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                path-computation-method local-cspf
                metric 100
                load-balancing-weight 1
                primary "path-PE-1-PE-4-PE-3" {
                }
            }
        }
```

On PE-1, VPRN 1 is configured as follows. ECMP and weighted ECMP can be configured in the **vprn** context, for example, **configure service vprn "1" ecmp 2** and **configure service vprn "1" weighted-ecmp true** but it is not required when the next-hop for the MPLS LSPs is the same. In this example, ECMP and weighted ECMP are only configured in the **vprn "1" bgp-ipvpn mpls auto-bind-tunnel** context. The resolution filter only allows RSVP-TE tunnels, no other MPLS LSPs, such as LDP, BGP, or segment routing (SR) tunnels.

```
configure {
    service {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        vprn "1" {
            admin-state enable
            customer "1"
            description "CE-1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:1"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        ecmp 2
                        weighted-ecmp true
                        resolution filter
                        resolution-filter {

                    }
                }
                sap 2/1/c36/2 {
                }
            }
        }
```

The service configuration on PE-3 is similar.

VPRN 1 is dual stacked. Weighted ECMP applies to both IPv4 and IPv6 traffic streams. BGP is configured for the VPN-IPv4 and VPN-IPv6 address family to exchange the routes used in VPRN 1 between PE-1 and PE-3. The BGP configuration on PE-1 is as follows:

```
configure {
   router "Base" {
        autonomous-system 64496
        bgp {
            group "iBGP" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            neighbor 192.0.2.3 {
                group "iBGP"
                peer-as 64496
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
                export {
                    policy ["export-vpn-ipv4" "export-vpn-ipv6"]
                }
            }
        }
```

The BGP configuration on PE-3 is similar.

The export policies on PE-1 are defined as follows:

```
configure {
    policy-options {
        prefix-list "vpn-ipv4" {
            prefix 172.16.0.0/16 type longer {
            }
            prefix 192.168.11.0/24 type exact {
            }
        }
        prefix-list "vpn-ipv6" {
            prefix 2001:db8::/120 type longer {
            }
            prefix 2001:db8::11:0/120 type exact {
            }
        }
        policy-statement "export-vpn-ipv4" {
            entry 10 {
                from {
                    prefix-list ["vpn-ipv4"]
                }
                action {
                    action-type accept
                }
            }
        }
        policy-statement "export-vpn-ipv6" {
            entry 10 {
                from {
                    prefix-list ["vpn-ipv6"]
                }
                action {
                    action-type accept
                }
            }
        }
    }
```

The export policies on PE-3 are similar.

With ECMP enabled for MPLS LSPs with the same next-hop and two RSVP-TE LSPs available with equal metric, the route table of VPRN 1 on PE-1 shows two routes for each prefix with the same next-hop 192.0.2.3: one via RSVP LSP 1 and the other via RSVP LSP 3, as follows:

```
[/]
A:admin@PE-1# show router 1 route-table
```

===============================================================================
```

To verify the weighted load balancing between the two RSVP-TE LSPs, the traffic generator sends multiple IPv4 and IPv6 traffic flows with random IP addresses and TCP/UDP port numbers via PE-1 to PE-3. The traffic enters PE-1 through port 2/1/c36/2. When LSP-PE-1-PE-2-PE-3 is configured with weight 2 and LSP-PE-1-PE-4-PE-3 with weight 1, PE-1 forwards two thirds of the traffic via port 1/1/c1/1 toward PE-2 and one third of the traffic via port 1/1/c2/1 toward PE-3, as follows:

```
[/]
A:admin@PE-1# monitor port 1/1/c1/1 rate interval 3 repeat 3

Restrictions

All RSVP-TE LSPs in the ECMP set must have a load balancing weight configured. When at least one RSVP-TE LSP in the ECMP set is configured without weight, regular ECMP is applied.

RSVP-TE LSP without Weight in ECMP Set

If one of the RSVP-TE LSPs in the ECMP set does not have a load balancing weight configured, the traffic flows are sprayed equally between all RSVP-TE LSPs, regardless of the configured weight of the other RSVP-TE LSPs in the ECMP set.

On PE-1, LSP-PE-1-PE-2-PE-3 is configured without a load balancing weight, as follows:

```
configure {
   router "Base" {
        mpls {
            lsp "LSP-PE-1-PE-2-PE-3" {
                delete load-balancing-weight
            }
```

LSP-PE-1-PE-4-PE-3 is still configured with a load balancing weight of 1, but it is impossible to calculate its relative weight, because the sum of the weight values is not defined. Therefore, PE-1 reverts to regular ECMP for the load balancing between the two RSVP-TE LSPs to PE-3. When the traffic generator sends multiple traffic flows via PE-1 to PE-3, the load is spread equally over both RSVP-TE LSPs, as shown in the following monitor output. Port 1/1/c1/1 is used for traffic sent via LSP-PE-1-PE-2-PE-3 and port 1/1/c2/1 for traffic sent via LSP-PE-1-PE-4-PE-3.

```

```

The configuration is restored as follows:

```
configure {
   router "Base" {
        mpls {
            lsp "LSP-PE-1-PE-2-PE-3" {
                load-balancing-weight 2
            }
```

Weighted ECMP for an SDP used as a spoke SDP in a VPRN

The following LSPs are configured on PE-1. The LSP load balancing weight values are 4 and 1 and the metric is 101 for both LSPs.

```
configure {
   router "Base" {
        mpls {
            admin-state enable
            lsp "LSP-PE-1-PE-2-PE-3-spoke" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                path-computation-method local-cspf
                metric 101
                load-balancing-weight 4
                primary "path-PE-1-PE-2-PE-3" {
                }
            }
            lsp "LSP-PE-1-PE-4-PE-3-spoke" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                path-computation-method local-cspf
                metric 101
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                load-balancing-weight 1
                primary "path-PE-1-PE-4-PE-3" {
                }
            }
        }
        rsvp {
            admin-state enable
            interface "int-PE-1-PE-2" {
            }
            interface "int-PE-1-PE-4" {
            }
        }
    }
```

Similar LSPs are configured on PE-3.

On PE-1, an SDP is configured, as follows:

```
configure {
    service {
        sdp 13 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.3
            }
            lsp "LSP-PE-1-PE-2-PE-3-spoke" { }
            lsp "LSP-PE-1-PE-4-PE-3-spoke" { }
        }
```

A similar SDP is configured on PE-3.

These SDPs are configured as spoke SDPs in a VPRN, as follows:

```
configure {
    service {
        vprn "1" {
            spoke-sdp 13:2 {
            }

configure {
    router "Base" {
        ldp {
            admin-state enable
        }
```

On PE-1, weighted ECMP is enabled on an SDP, as follows:

```
configure {
    service {
        sdp 13 {
            weighted-ecmp true
        }
```

The ECMP configuration on PE-3 is similar.

With ECMP enabled for MPLS LSPs with the same next-hop and two RSVP-TE LSPs available with equal metric, the route table of VPRN 1 on PE-1 shows one route for each prefix via the SDP tunnel, as follows:

```
[/]
```

       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

To verify the weighted load balancing between the two RSVP-TE LSPs, the traffic generator sends multiple IPv4 traffic flows with random IP addresses and TCP/UDP port numbers via PE-1 to PE-3. The traffic enters PE-1 through port 2/1/c36/2. When LSP-PE-1-PE-2-PE-3-spoke is configured with weight 4 and LSP-PE-1-PE-4-PE-3-spoke with weight 1, PE-1 forwards four fifths of the traffic via port 1/1/c1/1 toward PE-2 and one fifth of the traffic via port 1/1/c2/1 toward PE-3, as follows:

```
[/]
A:admin@PE-1# monitor port 1/1/c1/1 rate interval 3 repeat 3

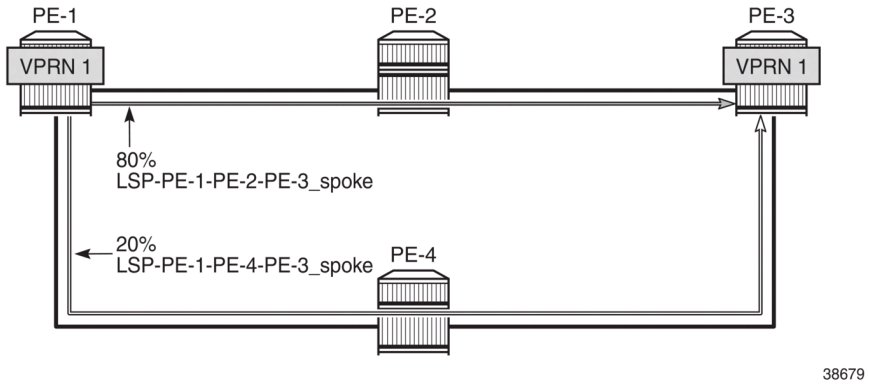
Figure 326: Weighted ECMP over RSVP LSPs used in a spoke SDP



Weighted ECMP for VPRN with Auto-bind-tunnel SR-TE

The following configuration is added to enable SR-ISIS on PE-1.

```
configure {
   router "Base" {
        mpls-labels {
            sr-labels {
                start 20000
                end 20099
            }
        }
        isis 0 {
            advertise-router-capability as
            interface "system" {
                ipv4-node-sid {
                    label 20001
                }
            }
            segment-routing {
                admin-state enable
                prefix-sid-range {
                    start-label 20000
                    max-index 99
                }
            }
        }
    }
```

The configuration on the other PEs is identical, except for the **ipv4-node-sid label** value.

The following SR-TE LSPs are configured on PE-1. For more information about SR-TE LSPs, see the *Segment Routing Traffic Engineered Tunnels* chapter. The load balancing weight values are 75 and 25. The values 3 and 1, which have the same ratio, can be used instead.

```
configure {
   router "Base" {
        mpls {
            lsp "LSP-PE-1-PE-2-PE-3_SR-TE" {
                admin-state enable
                type p2p-sr-te
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                to 192.0.2.3
                load-balancing-weight 75
                primary "path-PE-1-PE-2-PE-3" {
                }
            }
            lsp "LSP-PE-1-PE-4-PE-3_SR-TE" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.3
                load-balancing-weight 25
                primary "path-PE-1-PE-4-PE-3" {
                }
            }
        }
```

The configuration on PE-3 is similar.

The following tunnel table on PE-1 shows two SR-TE tunnels with equal metrics: SR-TE tunnel 655362 has PE-2 as next-hop (192.168.12.2) and SR-TE tunnel 655363 has PE-4 as next-hop (192.168.14.2).

```
[/]
A:admin@PE-1# show router tunnel-table protocol sr-te

===============================================================================
```

The resolution filter for VPRN 1 is configured on PE-1 and PE-3 to only allow SR-TE tunnels. ECMP and weighted ECMP are enabled in the **vprn bgp-ipvpn mpls auto-bind-tunnel** context.

```
configure {
    service {
        vprn "1" {
            admin-state enable
            customer "1"
            description "CE-1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:1"
                    vrf-target {
                        community "target:64496:1"
                    }
                    auto-bind-tunnel {
                        ecmp 2
                        weighted-ecmp true
                        resolution filter
                        resolution-filter {
                            sr-te true
                        }
                    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
        interface "loopback1" {
            loopback true
            ipv4 {
                primary {
                    address 172.16.0.1
                    prefix-length 32
                }
            }
            ipv6 {
                address 2001:db8::1 {
                    prefix-length 128
                }
            }
        }
        interface "int-CE-1-STC" {
            ipv4 {
                primary {
                    address 192.168.11.1
                    prefix-length 24
                }
            }
            ipv6 {
                address 2001:db8::11:1 {
                    prefix-length 120
                }
            }
            sap 2/1/c36/2 {
            }
        }
    }
```

The following route table for VPRN 1 on PE-1 shows two entries for each remote prefix with the same next-hop 192.0.2.3 and a different SR-TE LSP: SR-TE tunnel 655362 and SR-TE tunnel 655363.

```

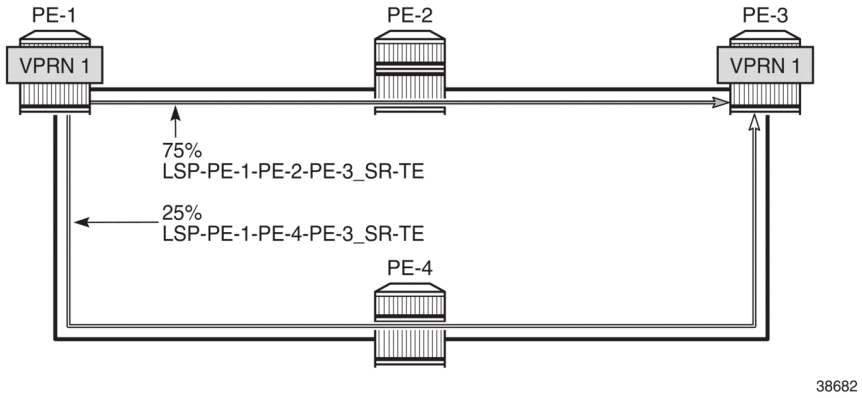
Figure 327: Weighted ECMP over SR-TE LSPs in AS 64496 shows how the traffic flows are sprayed over the two SR-TE LSPs:

Figure 327: Weighted ECMP over SR-TE LSPs in AS 64496



Conclusion

Operators can control how traffic in a VPRN is load balanced unequally over multiple transport tunnels by defining a load balancing weight factor on each LSP and enabling weighted ECMP in the VPRN. In this chapter, weighted ECMP for VPRN over transport LSPs is enabled for RSVP-TE tunnels and for SR-TE tunnels.

Multi-Service Integrated Service Adapter and Extended Services Appliance

This section provides MS-ISA and ESA configuration information for the following topics:

- Multi-Chassis IPSec Redundancy
- N:M MC-IPsec Redundancy

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Multi-Chassis IPSec Redundancy

This chapter provides information about multi-chassis IPSec redundancy configurations.

Topics in this chapter include:

Applicability

This initial version of this chapter was based on SR OS Release 10.0.R8, but the MD-CLI in the current edition corresponds to SR OS Release 22.10.R2.

Overview

Multi-Chassis IPSec redundancy (MC-IPSec) is a stateful inter-chassis IPSec failover mechanism. IPSec tunnel states are synchronized between the primary and standby chassis. A tunnel group failure on the primary chassis or a primary chassis failure could trigger MC-IPSec failover to the standby chassis.

The following are some highlights of this feature:

- Internet Key Exchange version 2 (IKEv2) only
- Multi-active tunnel group only
- The granularity of failover is tunnel group, which means a specific tunnel group could failover to the standby chassis independent of other tunnel groups on the primary chassis
- Both static and dynamic LAN-to-LAN tunnels are supported

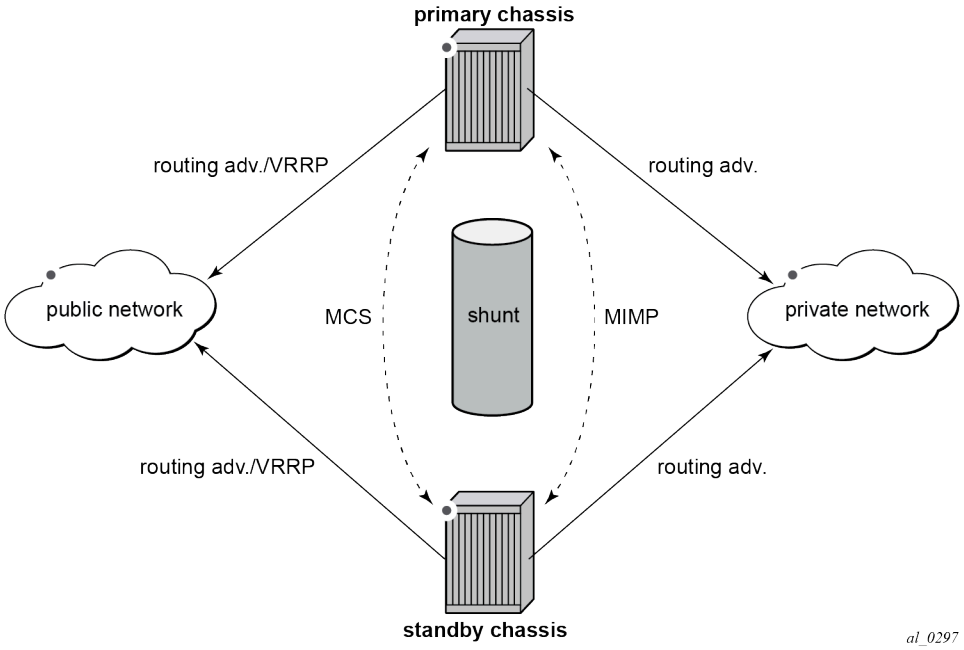
This feature has the following building blocks:

- Primary chassis election: MC-IPSec mastership protocol (MIMP) runs between the chassis to elect a primary chassis with independent MIMP runs for each tunnel group
- Synchronization: multi-chassis synchronization (MCS) synchronizes the IPSec states between chassis
- Routing:
  - MC-IPSec-aware routing attracts traffic to the primary chassis
  - Shunting support
  - MC-IPSec-aware virtual router redundancy protocol (VRRP)

The figure Figure 328: MC-IPSec architecture shows two redundant IPSec chassis in the middle: a primary chassis and a standby chassis.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 328: MC-IPSec architecture



The fundamentals of MC-IPSec are:

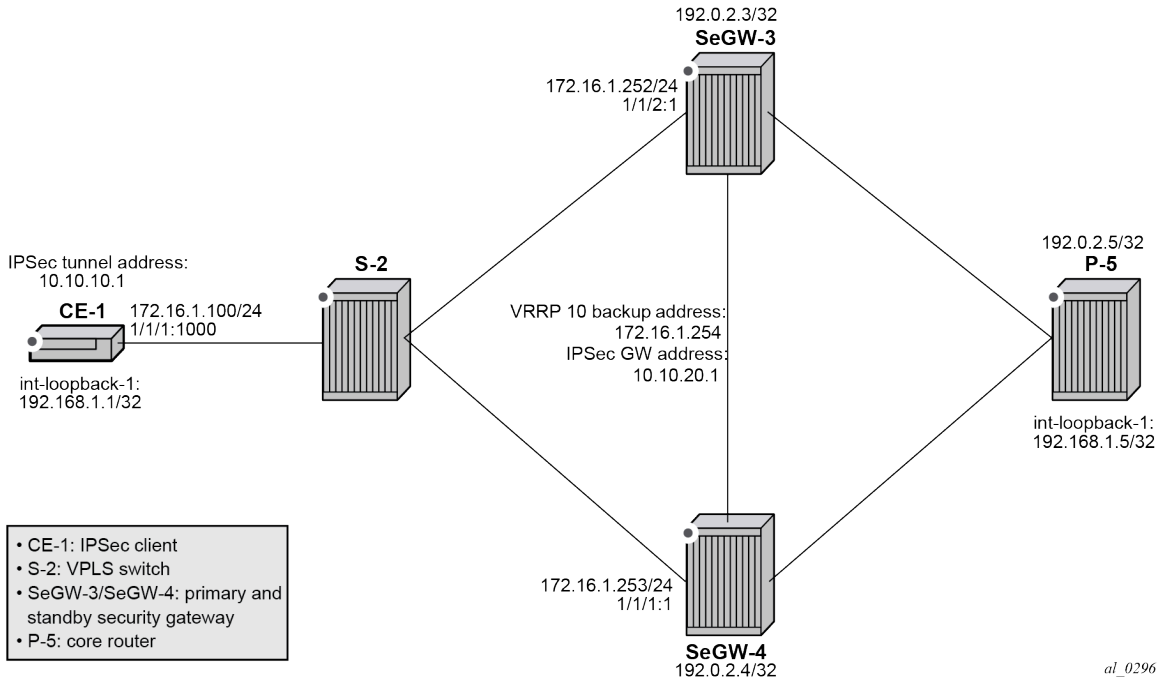
- Only the primary chassis processes encapsulating security payload (ESP) and IKE traffic. If the standby chassis receives traffic, it shunts it to the primary chassis, if possible. The traffic is discarded if the standby chassis fails to shunt the traffic.
- The same local gateway address must be provisioned on both chassis.
- MC-IPSec does not synchronize configurations.
- MC-IPSec-aware routing attracts traffic to the primary chassis for both public and private services, which is achieved by exporting the corresponding IPSec routes to the routing protocol using a route policy and setting a different routing metric according to the MC-IPSec state.
- In case of a Layer 2 public network, MC-IPSec-aware VRRP can be used to trigger VRRP switchover upon MC-IPSec switchover.
- MCS synchronizes IPSec states between chassis so that existing IPSec tunnels do not need to be re-established upon switchover.
- MIMP elects mastership between two chassis, and it can also detect chassis failure and tunnel group failure; a central BFD session can be associated with MIMP to achieve fast chassis failure detection.

Configuration

The example topology is shown in the figure Figure 329: Example topology.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 329: Example topology



The example setup includes:

- an IPSec tunnel initiated by CE-1 and terminated on the primary chassis of the two SeGWs.
- a public IES service "IES-1" and a private VPRN service "VPRN-2" configured on CE-1, SeGW-3, and SeGW-4.
- VPRN "VPRN-2" (also) configured on P-5.
- a static LAN-to-LAN tunnel with pre-shared key.
- a local VPLS service "VPLS-3" on S-2 to simulate a Layer 2 switch.
- VRRP 10 between SeGW-3 and SeGW-4 to provide a backup address 192.168.1.254, which is the default next hop for CE-1.
- VRRP policy 1 bound to VRRP 10 on the primary chassis SeGW-3 to change the in-use priority upon MC-IPSec switchover.
- OSPF as IGP running in the base routing instance between SeGW-3, SeGW-4, and P-5.
- MP-BGP running between SeGW-3, SeGW-4, and P-5 for the VPN-IPv4 address family.

A ping in VPRN "VPRN-2" between loopback interface address 192.168.1.1 on CE-1 and 192.168.1.5 on P-5 is used to verify the connectivity over the IPSec tunnel.

The MC-IPSec configuration commands are shown below.

```
configure
    redundancy
        multi-chassis
            peer <ip-address>
                sync
                    ipsec
                    tunnel-group <1..64>
```

                    priority
                        priority-level <1..254>
                        event-type (delta|explicit)
```

The parameters are the following:

- in the **configure redundancy multi-chassis** context:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **peer** <*ip-address*> — This command creates or enters a multi-chassis peer. The peer address is by default the system address. This can be changed on the peer using the **configure redundancy multi-chassis peer source-address** command.
  - **sync** — This command enters the sync configuration context.
    - **ipsec** <*boolean*> — This command enables MCS to synchronize IPSec states.
    - **tunnel-group** <*tunnel-group-id*> **sync-tag** <*tag-name*> — This command enables MCS to synchronize the IPSec states of the specified tunnel group. The **sync-tag** parameter is used to match the tunnel group of the peer. The tunnel group states with the same **sync-tag** on both chassis will be synchronized.
  - **mc-ipsec** — This command enters the multi-chassis IPSec configuration context.
    - **bfd-liveness** <*boolean*> — The command **bfd-liveness** *true* enables tracking a central BFD session; if the BFD session goes down, then the system considers the peer as down and changes the MC-IPSec status of the configured tunnel group accordingly.

      The BFD session uses the source address of MCS as its source address and the MCS peer address as the destination address. Other BFD parameters are configured in the **bfd** context on the interface that the MCS source address resides on.

      The configuration of BFD is optional for MC-IPSec.
    - **discovery-interval interval-secs** <*interval-1*> **[boot** <*interval-2*>**]** — This command specifies the time interval that the tunnel group stays in **discovery** state. Interval 1 is used as discovery interval when a new tunnel group is added to multi-chassis redundancy (**mp-ipsec**); interval 2 is used as discovery interval after system boot-up. Interval 2 is optional, and when it is not specified, the value for interval 1 is used. Both intervals have a default value of 300 seconds.
    - **hold-on-neighbor-failure** <*2..25*> — This command specifies the number of keep-alive failures before considering the peer to be down. The default value is 3.
    - **keep-alive-interval** <*5..500*> — This command specifies the time interval of the mastership election protocol keep-alive packets in deciseconds. The default value is 10 deciseconds (1 s).
    - **tunnel-group** <*tunnel-group-id*> — This command enables multi-chassis redundancy for the specified tunnel group, or enters an already configured tunnel group context. The configured tunnel groups can failover independently.

      — **peer-group** <*tunnel-group-id*> — This command specifies the corresponding tunnel group ID on the peer node. The peer tunnel group ID is not necessarily equal to local tunnel group ID.

      — **priority** <*priority*> — This command specifies the local priority of the tunnel group, this is used to elect a primary chassis, where the higher number prevails. If the priorities are the same, then the peer which has more active ISAs wins; if the priority and the number of active ISAs are same, then the peer with higher IP address wins. The range is from 0 to 255 and the default value is 100.

- in a **from** statement of a route policy entry:
  - **state ipsec-master-with-peer | ipsec-non-master | ipsec-master-without-peer** — These commands specify the MC-IPSec state in a **from** statement of a route policy entry:
    - **ipsec-master-with-peer**: The tunnel group is the primary chassis with a peer reachable.
    - **ipsec-master-without-peer**: The tunnel group is the primary chassis with peer unreachable.

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

    - **ipsec-non-master**: The tunnel group is not the primary chassis.
  - **protocol name ipsec** — This command specifies IPSec as protocol in a **from** statement of a route policy entry. **protocol name ipsec** refers to the /32 local gateway routes (of both static and dynamic tunnels) and reverse route of dynamic tunnel.
- on a public or private IPSec interface in an IES or VPRN service:
  - **static-tunnel-redundant-nexthop** <*ip-address*> and **dynamic-tunnel-redundant-nexthop** <*ip-address*> — These commands specify the redundant next hop address on a public or private IPSec interface (with public or private tunnel SAP) for a static and dynamic IPSec tunnel respectively. The specified next hop address is used by the standby chassis to shunt traffic to the primary chassis in case it receives any traffic. The next hop address is resolved in the routing table of the corresponding service.

    Note:
    - Shunting is supported over:
      - directly connected SAPs
      - spoke SDP terminated IP interfaces
    - Shunting over auto-bind tunnel is not supported.
    - Shunting does not work if the tunnel group is down.

- in the **isa tunnel-group <id>** context:
  - **ipsec-responder-only** <*boolean*> — With the command **ipsec-responder-only** *true* , the system only acts as IKE responder except for the automatic CHILD_SA rekey upon MC-IPSec switchover.

    This command is required for MC-IPSec support of static LAN-to-LAN tunnels.
- in the **vrrp policy <id> priority-event** context:
  - **mc-ipsec-non-forwarding** <*tunnel-grp-id*> — This command creates a VRRP policy priority event: *mc-ipsec-non-forwarding*, which is triggered whenever the specified tunnel group enters the non-forwarding state.
    - **hold-clear** <*seconds*> — This command configures the hold time before clearing the event. The range is from 0 to 86400 seconds and the default value is 0 s.
    - **hold-set** <*seconds*> — This command configures the hold time before setting the event. The range is from 0 to 86400 seconds and the default value is 0 s.
    - **priority** <*priority-level*> **explicit** — This command sets the VRRP in-use priority to the configured value upon the event. The range is from 0 to 254 and the default value is 0.

The initial configuration must include the following:

- The system time of SeGW-3 and SeGW-4 must be the same for the feature to work. Nokia recommends to use a time synchronization protocol such as NTP or SNTP.
- SeGW-3 and SeGW-4 must be IP reachable in the base routing instance because both MCS and MIMP run in the base routing instance.

Configuration of MC-IPSec

In this section, the following steps are described:

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- configure CE-1
- configure S-2
- configure P-5
- configure IPSec tunnel on SeGW-3
- enable MC-IPSec for tunnel group on SeGW-3
- configure MC-IPSec-aware routing on SeGW-3
- configure MC-IPSec-aware VRRP on SeGW-3
- configure SeGW-4

Configure CE-1

On CE-1, the following is configured:

- a public IES service "IES-1" and a private VPRN service "VPRN-2".
- a static default route pointing to the VRRP backup address 172.16.1.254.
- a static IPSec tunnel "tunnel-1" with local address 10.10.10.1 and remote address 10.10.20.1.
- a loopback interface in VPRN "VPRN-2" with address 192.168.1.1/32 to be used as source address for the ping command to verify the connectivity between CE-1 and P-5 over the IPSec tunnel.

The following base router configuration on CE-1 includes a static route with next hop 172.16.1.254, which is the VRRP backup address.

```
# on CE-1:
configure {
    router "Base" {
        interface "int-CE-1-S-2" {
            port 1/1/1:1000
            ipv4 {
                primary {
                    address 172.16.1.100
                    prefix-length 24
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 172.31.2.1
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 0.0.0.0/0 route-type unicast {
                next-hop "172.16.1.254" {       # VRRP backup address
                    admin-state enable
                }
            }
        }
```

IPSec is configured as follows:

```
configure {
    ipsec {
        ike-policy 1 {
            ike-transform [1]
            ike-version-2 {
            }
            dpd {    # dead peer detection (on peer side; not on MC-IPSec chassis)
            }
        }
        ike-transform 1 {
        }
        ipsec-transform 1 {
        }
```

Tunnel group 1 is configured as follows:

```
configure {
    isa {
        tunnel-group 1 {
            admin-state enable
            isa-scale-mode tunnel-limit-2k
            primary 1/2
        }
```

The public IES service is configured as follows:

```
configure {
    service {
        ies "IES-1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-IPsec-Public-1" {
                sap tunnel-1.public:1 {
                }
                ipv4 {
                    primary {
                        address 10.10.10.254
                        prefix-length 24
                    }
                }
            }
        }
```

The private VPRN service on CE-1 is configured as follows:

```
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            ipsec {
                security-policy 1 {
                    entry 10 {
                        local-ip {
                            address 192.168.1.1/32
                        }
                        remote-ip {
```

```
                        address 192.168.1.5/32
                    }
                }
            }
        }
        interface "int-IPsec-private-1" {
            tunnel true
            sap tunnel-1.private:1 {
                ipsec-tunnel "tunnel-1" {
                    admin-state enable
                    key-exchange {
                        dynamic {
                            ike-policy 1
                            ipsec-transform [1]
                            pre-shared-key "pass"
                        }
                    }
                    tunnel-endpoint {
                        local-gateway-address 10.10.10.1
                        remote-ip-address 10.10.20.1
                        delivery-service "IES-1"
                    }
                    security-policy {
                        id 1
                    }
                }
            }
        }
        interface "int-loopback-1" {
            loopback true
            ipv4 {
                primary {
                    address 192.168.1.1
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.1.5/32 route-type unicast {
                ipsec-tunnel "tunnel-1" {
                    admin-state enable
                }
            }
        }
```

Configure S-2

On S-2, a local VPLS service 3 simulates a Layer 2 switch between CE-1, SeGW-3, and SeGW-4:

```
# on S-2:
configure {
    service {
        vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            sap 1/1/c1/1:1 {
                description "to SAP in IES 1 on SeGW-3"
            }
            sap 1/1/c1/2:1000 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                description "to router interface in CE-1"
            }
            sap 1/1/c1/3:1 {
                description "to SAP in IES 1 on SeGW-4"
            }
        }
```

Configure P-5

P-5 simulates the core network router, connecting to SeGW-3 and SeGW-4. The configuration on P-5 includes the following:

- a loopback interface with address 192.168.1.5/32 in VPRN "VPRN-2", which is the destination address of the ping traffic from CE-1.
- an MP-BGP session for the VPN-IPv4 address family between P-5, SeGW-3, and SeGW-4.
- GRE spoke SDPs to connect to SeGW-3 and SeGW-4.

On P-5, the following router interfaces are configured in the base router. OSPF is used as IGP.

```
# on P-5:
configure {
    router "Base" {
        interface "int-P-5-SeGW-3" {
            port 1/1/c1/2:1000
            ipv4 {
                primary {
                    address 192.168.35.2
                    prefix-length 30
                }
            }
        }
        interface "int-P-5-SeGW-4" {
            port 1/1/c1/1:1000
            ipv4 {
                primary {
                    address 192.168.45.2
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.5
                    prefix-length 32
                }
            }
        }
        ospf 0 {
            admin-state enable
            area 0.0.0.0 {
                interface "int-P-5-SeGW-3" {
                }
                interface "int-P-5-SeGW-4" {
                }
                interface "system" {
                }
            }
        }
```

On P-5, the following GRE SDPs are configured toward SeGW-3 and SeGW-4:

```
configure {
    service {
        sdp 53 {
            admin-state enable
            description "GRE SDP toward SeGW-3"
            signaling off
            far-end {
                ip-address 192.0.2.3
            }
        }
        sdp 54 {
            admin-state enable
            description "GRE SDP toward SeGW-4"
            signaling off
            far-end {
                ip-address 192.0.2.4
            }
        }
```

VPRN "VPRN-2" is configured on P-5, as follows:

```
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:2"
                    vrf-target {
                        community "target:64496:2"
                    }
                }
            }
            interface "int-loopback-1" {
                loopback true
                ipv4 {
                    primary {
                        address 192.168.1.5
                        prefix-length 32
                    }
                }
            }
            spoke-sdp 53:2 {
            }
            spoke-sdp 54:2 {
            }
        }
```

The BGP configuration on P-5 is as follows:

```
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "MPBGP" {
                type internal
                family {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    vpn-ipv4 true
                }
            }
            neighbor "192.0.2.3" {
                group "MPBGP"
            }
            neighbor "192.0.2.4" {
                group "MPBGP"
            }
        }
```

Configure IPSec tunnel on SeGW-3

The configuration on SeGW-3 is described in four consecutive sections. In this first section, the following is configured:

- the tunnel group, which must be in multi-active mode before MC-IPSec can be enabled.
- an interface "int-Redundant-1", which is a spoke-SDP terminated interface used for shunting.
- GRE SDP 34 toward SeGW-4 and GRE SDP 35 toward P-5.
- IPSec tunnel "tunnel-1" is the tunnel to CE-1; both SeGW-3 and SeGW-4 use the same local gateway address: 10.10.20.1.

The following configures tunnel group 1 on SeGW-3:

```
# on SeGW-3
configure {
    isa {
        tunnel-group 1 {
            admin-state enable
            isa-scale-mode tunnel-limit-2k
            ipsec-responder-only true
            multi-active {
                isa 1/2 { }
            }
        }
```

On SeGW-3, the following router interfaces are configured in the base router. A static route is configured toward CE-1. OSPF is the IGP used between SeGW-3, SeGW-4, and P-5.

```
configure {
    router "Base" {
        interface "int-SeGW-3-P-5" {
            port 1/1/1:1000
            ipv4 {
                primary {
                    address 192.168.35.1
                    prefix-length 30
                }
            }
        }
        interface "int-SeGW-3-SeGW-4" {
            port 1/1/3:1000
            ipv4 {
                primary {
                    address 192.168.34.1
                    prefix-length 30
                }
            }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        interface "system" {
            ipv4 {
                bfd {
                    admin-state enable
                }
                primary {
                    address 192.0.2.3
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 10.10.10.0/24 route-type unicast {
                next-hop "172.16.1.100" {
                    admin-state enable
                }
            }
        }
        ospf 0 {
            admin-state enable
            area 0.0.0.0 {
                interface "int-SeGW-3-P-5" {
                }
                interface "int-SeGW-3-SeGW-4" {
                }
                interface "system" {
                }
            }
        }
```

The IPSec settings are as follows:

```
configure {
    ipsec {
        ike-policy 1 {
            ipsec-lifetime 7200
            ike-transform [1]
            ike-version-2 {
            }
        }
        ike-transform 1 {
            isakmp-lifetime 172800
        }
        ipsec-transform 1 {
        }
```

The GRE SDPs are configured as follows:

```
configure {
    service {
        sdp 34 {
            admin-state enable
            description "GRE SDP toward SeGW-4"
            signaling off
            far-end {
                ip-address 192.0.2.4
            }
        }
        sdp 35 {
            admin-state enable
            description "GRE SDP toward P-5"
            signaling off
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            far-end {
                ip-address 192.0.2.5
            }
        }
```

The public IES service is configured as follows. In a later step, a VRRP policy will be configured and applied.

```
configure {
    service {
        ies "IES-1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-IPsec-Public-1" {
                static-tunnel-redundant-nexthop 192.168.34.2
                sap tunnel-1.public:1 {
                }
                ipv4 {
                    primary {
                        address 10.10.20.254
                        prefix-length 24
                    }
                }
            }
            interface "int-SeGW-3-S-2" {
                sap 1/1/2:1 {
                    description "SAP to switch S-2"
                }
                ipv4 {
                    primary {
                        address 172.16.1.252
                        prefix-length 24
                    }
                    vrrp 10 {
                        backup [172.16.1.254]
                        priority 200
                        ping-reply true
                    }
                }
            }
```

The private VPRN service "VPRN-2" is configured as follows:

```
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            ipsec {
                security-policy 1 {
                    entry 10 {
                        local-ip {
                            address 192.168.1.5/32
                        }
                        remote-ip {
                            address 192.168.1.1/32
                        }
                    }
                }
            }
```

Enable MC-IPSec for tunnel group 1 on SeGW-3

In this section, the following steps are described:

- Create a multi-chassis peer using the system address of SeGW-4.
- Enable MCS for IPSec and tunnel group 1.
- Enable MC-IPSec for the tunnel group with a configured priority 200.
- Bind a central BFD session to MC-IPSec from the system interface.

Multi-chassis peer 192.0.2.4 is configured and MCS and MC-IPSec are enabled for tunnel group 1:

```
# on SeGW-3:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                sync {
                    admin-state enable
                    ipsec true
                    tunnel-group 1 {
                        sync-tag "tag-1"
                    }
                }
                mc-ipsec {
                    bfd-liveness true
                    tunnel-group 1 {
                        admin-state enable
                        peer-group 1
                        priority 200
                    }
                }
            }
```

BFD is enabled for MC-IPSec in the preceding configuration. BFD is configured on the system interface 192.0.2.3:

```
configure {
    router "Base" {
        interface "system" {
            ipv4 {
                bfd {
                    admin-state enable
                }
                primary {
                    address 192.0.2.3
                    prefix-length 32
                }
            }
        }
```

Configure MC-IPSec-aware routing on SeGW-3

In this step, a route policy is defined and applied to VPRN "VPRN-2".

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Route policy "IPsec-to-MPBGP" exports static route 192.168.1.1/32 in VPRN "VPRN-2" to P-5. This policy sets the local preference of the prefix 192.168.1.1/32 according to the MC-IPSec state:

- for the **ipsec-master-with-peer** state: local preference 200
- for the **ipsec-non-master** state: local preference 100
- for the **ipsec-master-without-peer** state: local preference 200

The state **ipsec-master-without-peer** can be used to attract traffic to the designated primary chassis in case of "dual master" (meaning two chassis lose the MIMP connection in the base routing instance). In this example, SeGW-3 has local preference 200 and SeGW-4 has local preference 100 for **ipsec-master-without-peer**.

The route policy is configured as follows:

```
# on SeGW-3:
configure {
    policy-options {
        community "vprn2" {
            member "target:64496:2" { }
        }
        prefix-list "CE-1-Internal" {
            prefix 192.168.1.1/32 type exact {
            }
        }
        policy-statement "IPsec-to-MPBGP" {
            entry 10 {
                from {
                    prefix-list ["CE-1-Internal"]
                    state ipsec-master-with-peer
                }
                action {
                    action-type accept
                    local-preference 200
                    community {
                        add ["vprn2"]
                    }
                }
            }
            entry 20 {
                from {
                    prefix-list ["CE-1-Internal"]
                    state ipsec-non-master
                }
                action {
                    action-type accept
                    local-preference 100
                    community {
                        add ["vprn2"]
                    }
                }
            }
            entry 30 {
                from {
                    prefix-list ["CE-1-Internal"]
                    state ipsec-master-without-peer
                }
                action {
                    action-type accept
                    local-preference 200
                    community {
                        add ["vprn2"]
                    }
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            default-action {
                action-type accept
                community {
                    add ["vprn2"]
                }
            }
        }
```

The BGP configuration on SeGW-3 is as follows:

```
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "MPBGP" {
                type internal
                family {
                    vpn-ipv4 true
                }
            }
            neighbor "192.0.2.4" {
                group "MPBGP"
            }
            neighbor "192.0.2.5" {
                group "MPBGP"
            }
```

The route policy is applied as **vrf-export** in VPRN "VPRN-2":

```
configure {
    service {
        vprn "VPRN-2" {
            bgp-ipvpn {
                mpls {
                    vrf-export {
                        policy ["IPsec-to-MPBGP"]
                    }
```

Configure MC-IPSec-aware VRRP on SeGW-3

In this section, a VRRP policy is defined that uses the **mc-ipsec-non-forwarding** priority event to lower the in-use VRRP priority upon MC-IPSec switchover, which ensures VRRP and MC-IPSec have the same primary chassis. The VRRP instance needs to be in preempt mode.

This VRRP policy is only configured on the designated VRRP primary chassis SeGW-3, not on the standby chassis. The VRRP policy is applied to the interface "int-SeGW3-S-2" of IES "IES-1".

VRRP policy 1 is configured as follows:

```
# on SeGW-3:
configure {
    vrrp {
        policy 1 {
            priority-event {
                mc-ipsec-non-forwarding 1 {
                    priority {
                        priority-level 50
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        event-type explicit
                    }
                }
            }
        }
```

VRRP policy 1 is applied in VRRP instance 10 in the IES service:

```
configure {
    service {
        ies "IES-1" {
            interface "int-SeGW-3-S-2" {
                sap 1/1/2:1 {
                    description "SAP to switch S-2"
                }
                ipv4 {
                    primary {
                        address 172.16.1.252
                        prefix-length 24
                    }
                    vrrp 10 {
                        backup [172.16.1.254]
                        priority 200
                        ping-reply true
                        policy 1
                    }
                }
            }
---snip---
```

Configure SeGW-4

The configuration on the standby chassis SeGW-4 is similar, but with different priorities and without the VRRP policy.

The tunnel group is configured in multi-active mode:

```
# on SeGW-4:
configure {
    isa {
        tunnel-group 1 {
            admin-state enable
            isa-scale-mode tunnel-limit-2k
            ipsec-responder-only true
            multi-active {
                isa 1/2 { }
            }
        }
```

The MCS and MC-IPSec configuration is as follows:

```
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.3 {
                admin-state enable
                sync {
                    admin-state enable
                    ipsec true
                    tunnel-group 1 {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        sync-tag "tag-1"
                    }
                }
                mc-ipsec {
                    bfd-liveness true
                    tunnel-group 1 {
                        admin-state enable
                        peer-group 1
                        priority 150
                    }
                }
            }
        }
```

The base router configuration on SeGW-4 includes the following router interfaces and a static route to CE-1. OSPF is used as IGP between SeGW-3, SeGW-4, and P-5.

```
configure {
    router "Base" {
        interface "int-SeGW-4-P-5" {
            port 1/1/2:1000
            ipv4 {
                primary {
                    address 192.168.45.1
                    prefix-length 30
                }
            }
        }
        interface "int-SeGW-4-SeGW-3" {
            port 1/1/3:1000
            ipv4 {
                primary {
                    address 192.168.34.2
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                bfd {
                    admin-state enable
                }
                primary {
                    address 192.0.2.4
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 10.10.10.0/24 route-type unicast {
                next-hop "172.16.1.100" {
                    admin-state enable
                }
            }
        }
        ospf 0 {
            admin-state enable
            area 0.0.0.0 {
                interface "int-SeGW-4-P-5" {
                }
                interface "int-SeGW-4-SeGW-3" {
                }
                interface "system" {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

The IPSec configuration is as follows:

```
configure {
    ipsec {
        ike-policy 1 {
            ipsec-lifetime 7200
            ike-transform [1]
            ike-version-2 {
            }
        }
        ike-transform 1 {
            isakmp-lifetime 172800
        }
        ipsec-transform 1 {
        }
```

The following route policy is configured on SeGW-4, The local preference is lower for the **ipsec-master-without-peer** state.

```
configure {
    policy-options {
        community "vprn2" {
            member "target:64496:2" { }
        }
        prefix-list "CE-1-Internal" {
            prefix 192.168.1.1/32 type exact {
            }
        }
        policy-statement "IPsec-to-MPBGP" {
            entry 10 {
                from {
                    prefix-list ["CE-1-Internal"]
                    state ipsec-master-with-peer
                }
                action {
                    action-type accept
                    local-preference 200

                }
            }
        }
```

The BGP configuration on SeGW-4 is as follows:

```
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "MPBGP" {
                type internal
                family {
                    vpn-ipv4 true
                }
            }
            neighbor "192.0.2.3" {
                group "MPBGP"
            }
            neighbor "192.0.2.5" {
                group "MPBGP"
            }
        }
```

The following GRE SDPs are configured:

```
configure {
    service {
        sdp 43 {
            admin-state enable
            description "GRE SDP toward SeGW-3"
            signaling off
            far-end {
                ip-address 192.0.2.3
            }
        }
        sdp 45 {
            admin-state enable
            description "GRE SDP toward P-5"
            signaling off
            far-end {
                ip-address 192.0.2.5
            }
        }
```

The public IES service is configured as follows:

```
configure {
```

© 2023 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        ies "IES-1" {
            admin-state enable
            service-id 1
            customer "1"
            interface "int-IPsec-Public-1" {
                static-tunnel-redundant-nexthop 192.168.34.1
                sap tunnel-1.public:1 {
                }
                ipv4 {
                    primary {
                        address 10.10.20.254
                        prefix-length 24
                    }
                }
            }
            interface "int-SeGW-4-S-2" {
                sap 1/1/1:1 {
                }
                ipv4 {
                    primary {
                        address 172.16.1.253
                        prefix-length 24
                    }
                    vrrp 10 {
                        backup [172.16.1.254]
                        ping-reply true
                    }
                }
            }
        }
```

The private VPRN service is configured as follows:

```
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            ipsec {
                security-policy 1 {
                    entry 10 {
                        local-ip {
                            address 192.168.1.5/32
                        }
                        remote-ip {
                            address 192.168.1.1/32
                        }
                    }
                }
            }
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "64496:2"
                    vrf-target {
                        community "target:64496:2"
                    }
                    vrf-export {
                        policy ["IPsec-to-MPBGP"]
                    }
                }
```
