Preface

About This Guide

Each Advanced Configuration Guide is organized alphabetically and provides feature and configuration explanations, CLI descriptions, and overall solutions. The Advanced Configuration Guide chapters are written for and based on several Releases, up to 24.7.R2. The Applicability section in each chapter specifies on which release the configuration is based.

The Advanced Configuration Guides supplement the user configuration guides listed in the 7450 ESS, 7750 SR, and 7950 XRS Guide to Documentation.

Audience

This manual is intended for network administrators who are responsible for configuring the routers. It is assumed that the network administrators have a detailed understanding of networking principles and configurations.

ARP Hosts

This chapter describes advanced ARP host configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This section describes ARP hosts and is applicable to the 7450 ESS and 7750 SR series and was tested on SR OS 13.0 R3.

Overview

In business access areas, CPEs typically get their IP address information through DHCP and PPPoE. However, CPE network facing interfaces can be configured statically. In such cases, the first packet the network receives from the user is an ARP to the Broadband Service Aggregator (BSA) or Broadband Service Router (BSR) interface. In order to accommodate such configurations, Enhanced Subscriber Management (ESM) feature set supports RP hosts.

In practice, this means that authentication, self-provisioning and Service Level Agreement (SLA) enforcement can be triggered by reception of ARP packets.

The BRAS node will learn the IP-MAC association based on the received ARP request packet and will instanciate subscriber hosts based on results from RADIUS authentication, the same way as this would happen through DHCP or PPPoE.

This chapter provides configuration and troubleshooting commands for ARP hosts. Features common with other host types and not unique to ARP hosts are not described in this chapter. (Not exhaustive list: RADIUS managed routes, routed subscriber with dynamic BGP peering, Wholesale/Retail, Managed SAPs configurations, ESM related host limitation mechanisms, host High-Availability, multi-chassis peer synchronization).

Knowledge of the Triple Play Service Delivery Architecture (TPSDA) concepts is assumed throughout this chapter.

⚠️ **WARNING:**
Enhanced Subscriber Management and RADIUS authentication are mandatory for the use of ARP hosts.

ARP host is supported in the bridged CO (VPLS) and the routed CO (Subscriber Interface) model. It is triggered by the first ARP packet received from the host. ARP host is also supported in a wholesale/retail context and on managed SAPs (MSAP).

The IP and MAC addresses are extracted from the ARP request. They are copied in the access-request message sent to the RADIUS server:

- RADIUS attribute [1] Username = IP address
- VSA [26][27] Client Hardware Address = MAC address

On successful authentication RADIUS will reply with an access-accept message, and ESM will create the ARP host. ESM string assignment options are out of the scope for this scenario.

Figure 1: Bridged CO and Routed CO Example
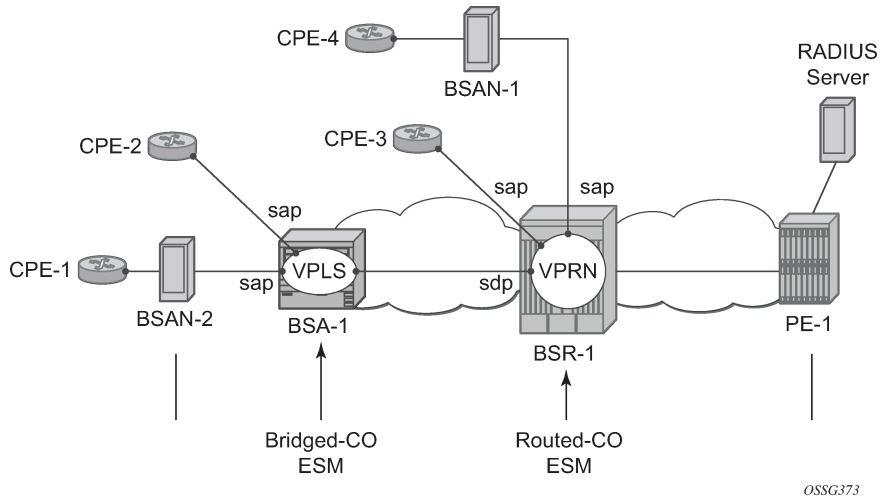

OSSG373

Configuration

ARP Hosts in a Bridged CO Environment

Figure 2: ARP Hosts in a Bridged CO Environment Example
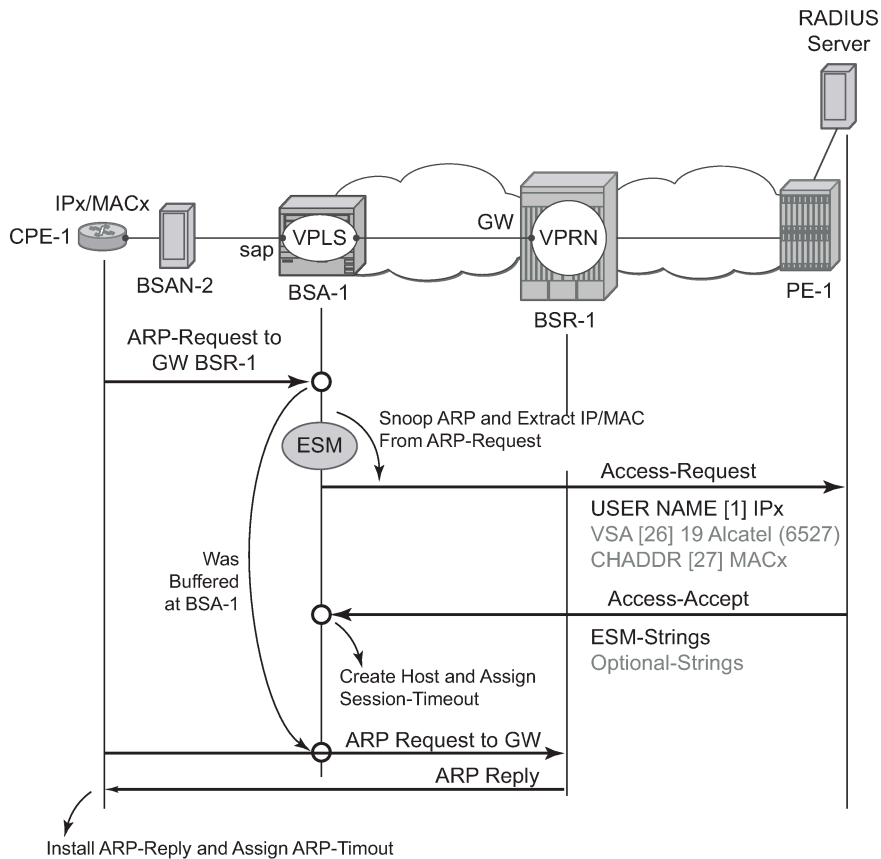

Enabling ARP-host for the Bridged CO model requires a composite service; a VPLS on the BSA node and a VPRN/IES on the BSR node. RADIUS authentication and subscriber management, which mandates IP-MAC or NH-MAC type anti-spoofing, are mandatory for ARP hosts.

```
# on BSA-1
configure
    service
        vpls 2 customer 1 create
            description "ARP host - Bridged CO"
            stp
                shutdown
            exit
            sap 1/1/1:1 create
                authentication-policy "authentication-1"
                anti-spoof ip-mac
                sub-sla-mgmt
                    sub-ident-policy "sub-id-default"
```

```
                    multi-sub-sap 10
                    no shutdown
                exit
                arp-host
                    no shutdown
                exit
            exit
            spoke-sdp 12:2 create
            exit
            no shutdown
        exit
    exit
exit
```

The RADIUS authentication policy does not require any specific parameter settings. The RADIUS username attribute will always contain the host IP address, meaning that the authentication policy parameter user-name-format is irrelevant for ARP hosts.

```
configure
    subscriber-mgmt
        authentication-policy "authentication-1" create
        password ALU
        radius-authentication-server
            server 1 address 172.16.1.1 secret ALU
        exit
        # re-authentication is optional
        re-authentication
        # only required when RADIUS Disconnect is needed (optional)
        accept-authorization-change
    exit
exit
```

The CPE ARPs are snooped and the first CPE ARP triggers a RADIUS accept-request. Any subsequent ARPs will trigger RADIUS re-authentication only if the ARP host configurable min-auth-interval is expired and if the previously defined re-authentication parameter is set. The initial ARP is only forwarded to the BSR-1 upon successful RADIUS authentication by means of a RADIUS access-accept message. The same RADIUS access-accept message and passing the several session limit checks, triggers the instanciation of the host.

The BSR-1 node requires a VPRN/IES as part of the composite service. No ARP-host-specific parameters are required on the BSR-1 for the bridged CO model.

```
# on BSR-1
configure service
    vprn 1 customer 1 create
        route-distinguisher 64496:1
        auto-bind-tunnel
            resolution-filter
                ldp
            exit
            resolution filter
        exit
        vrf-target target:64496
        interface "int-BSA1-p2mp-1" create
            description "ARP host - Bridged CO" address 10.2.0.6/29
            ip-mtu 1500
            spoke-sdp 21:2 create
            exit
        exit
    exit
```

```
exit
```

ARP Hosts in a Routed CO Environment

Figure 3: ARP Hosts in a Routed CO Environment Example
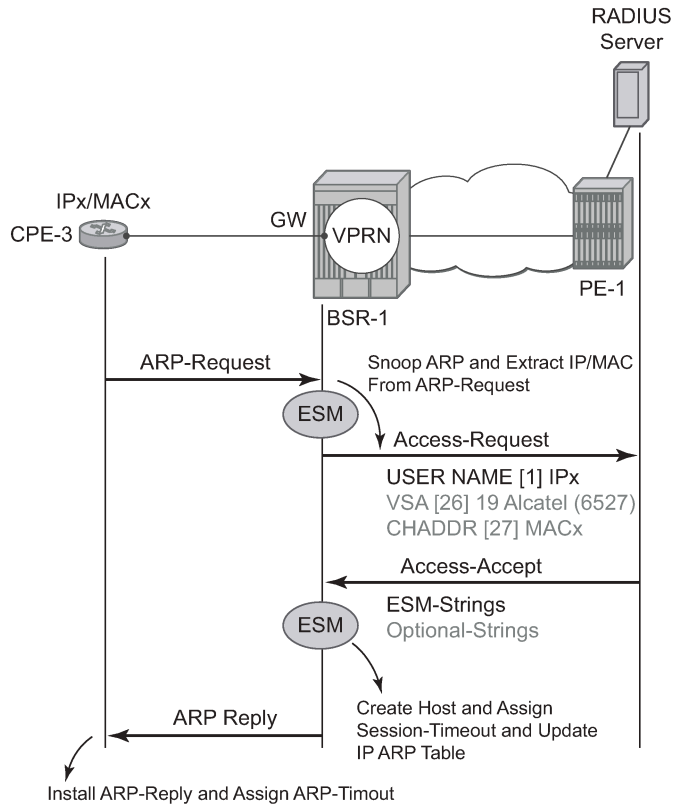

Enabling ARP-host for the routed CO model is identical for VPRN and IES services. RADIUS authentication and subscriber management, which mandates IP-MAC or NH-MAC type anti-spoofing, are mandatory for ARP hosts.

The initial ARP will, only upon successful RADIUS authentication and passing the several sessions limit checks, create the ARP host. The ARP reply or update of the IP ARP table is not performed on any unsuccessful RADIUS authentication.

```
# on BSR-1
configure service
    vprn 1 customer 1 create
        route-distinguisher 64496:1
        auto-bind-tunnel
            resolution-filter
                ldp
            exit
            resolution filter
        exit

        vrf-target target:64496:1
```

```
        subscriber-interface "sub-int-1" create
            description "ARP host - Routed CO" address 10.1.0.6/29
            group-interface "group-int-1" create
                authentication-policy "authentication-1"
                sap 1/1/1:1 create
                    anti-spoof ip-mac
                    sub-sla-mgmt
                        sub-ident-policy "sub-id-default"
                        no shutdown
                    exit
                exit
                arp-host
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

RADIUS User Configuration Bridged/Routed CO

The username in the RADIUS access request is always the statically configured IP address from the CPE and configured as key in the RADIUS users file. The RADIUS Framed-Route attribute is not required and is silently ignored (if returned to BSA/BSR node).

```
"10.1.0.1"        Auth-Type := Local, User-Password == ALU
                  Alc-Subsc-ID-Str = "arp-host-routed-%{User-name}",
                  Alc-Subsc-Prof-Str = "sub-profile-1",
                  Alc-SLA-Prof-Str = "sla-profile-1"

"10.2.0.1"        Auth-Type := Local, User-Password == ALU
                  Alc-Subsc-ID-Str = "arp-host-bridged-%{User-name}",
                  Alc-Subsc-Prof-Str = "sub-profile-1",
                  Alc-SLA-Prof-Str = "sla-profile-1"
```

Setup and Debugging of ARP Host

Identical methodologies are used to debug/setup and troubleshoot ARP hosts for the bridged or the Routed CO model. The Routed CO model is used as an example through the rest of this section on ARP hosts.

There are two modes of ARP host debugging: all and dropped-only. The dropped-only mode shows all cases where the creation of the ARP host will be unsuccessful.

By default, all enabled ARP hosts on a service will be monitored. More specific filtering on a particular IP, MAC or SAP is optional.

All main traps are by default cyclically logged in log-id 99 and can be viewed anytime.

```
debug service id 1 arp-host mode all
```

ARP host mandate RADIUS authentication and a separate debug option is available for RADIUS interaction.

```
debug radius detail
```

CPE-3 with statically configured IP1 10.1.0.1 sends an ARP to the BSR-1 gateway.

```

=========================================================
A:BSR-1#
```

An ARP host can be manually deleted from the system using one of the two following methods:

*   clear service id 1 arp-host

*   RADIUS disconnect message

Using the first method, **clear service id 1 arp-host** and omitting any more specific parameter results in the removal of all ARP hosts in this service. Extra filters such as **ip-address**, **mac** or **sap-id** are required to remove a specific ARP host.

```
*A:BSR-1# clear service id 1 arp-host
  - arp-host {all | mac <ieee-address> | sap <sap-id> | ip-address <ip-address[/mask]> }
  - arp-host {port <port-id> | {inter-dest-id <intermediate-destination-id> | no-inter-dest-id}
 [port <port-id>] }
  - arp-host statistics [sap <sap-id> | interface <interface-name>]

A:BSR-1# clear service id 1 arp-host ip-address 10.1.0.1
```

Using the second method, RADIUS disconnect always result in the removal of a unique host because **nas-port-id** and **framed-ip-address** are mandatory parameters in the RADIUS disconnect message. This RADIUS disconnect message is used also for other host-types.

```
nas-port-id = 1/1/1:1
framed-ip-address=10.1.0.1
```

RADIUS disconnect messages are, for security reasons, rejected by default. The RADIUS disconnect messages can be accepted by enabling the **accept-authorization-change** parameter in the authentication

policy. The **debug radius detail** command and **show subscriber-mgmt authentication coa-statistics** can be used during troubleshooting.

```
10 2015/06/22 15:51:08.43 CEST MINOR: DEBUG #2001 Base RADIUS

    IP: 10.1.0.1
    MAC: 00:00:0a:01:00:01
"
```

In both cases the ARP host with an IP address is removed from the system together with all related state information (such as an anti-spoof filter and an IP ARP entry).

ARP Host Session Timeout

The remaining time is initialized at the ARP host session timeout value (300s to 14400s) and starts counting down when an ARP host is instanciated. Ultimately the host is removed from the system when the remaining time becomes zero. Any subsequent arp-request or arp-reply for this host results in the remaining value to be reset to the host session timeout value defined.

The default assigned session timeout at ARP host creation time is 14400 seconds, a value which can be overruled by the optional RADIUS attribute session-Timeout but not by the node group-interface arp-timeout parameter.

RADIUS values lower than 300 seconds will be silently adjusted to 300 seconds and values above 14400 seconds are topped silently to 14400 seconds.

```
"10.1.0.1"     Auth-Type := Local, User-Password == ALU
               Alc-Subsc-ID-Str = "arp-host-routed-%{User-name}",

Typical time related parameters of the ARP host are:

Table 1: ARP Host Time-Related Parameters

Parameter	Comment
Session Timeout	Time value in seconds and retrieved by default or by the RADIUS Accept message and pasted into the remaining time at the moment of ARP host creation or RADIUS re-authentication.
Remaining Time	The remaining time before the ARP host is deleted from the system (updated each time an ARP request/reply is seen for this host).
Start Time	Time and date when this host was created (first ARP received).
Last Auth	Time and date when this host was last RADIUS authenticated.
Last Refresh	Time and date when last ARP was received for this host.

ARP hosts do not have an expiry timer in the ARP table and have type **managed**.

```

An automatic mechanism is implemented to handle the possible asynchronicity between the ARP session timeout values installed on the BSR and the ARP timeouts installed on the CPE. This mechanism is mostly effective in case the timeout on the CPE exceeds the timeout on the BSR. In this case, the BSR session would expire, resulting in a host removal with a deletion of the corresponding anti-spoof entry because the CPE ARP request arrives too late. This CPE ARP request will however recreate the session but requires the complete setup of the host RADIUS authentication included. This mechanism causes unwanted service interruption for this ARP host.

A better approach, which is implemented in an automatic way, and illustrated in Figure 4: ARP Host Session Timeout Example is an ARP request triggered by the BSR towards the CPE prior to the session timeout. The ARP reply sent by the CPE then will reset the remaining lifetime for the ARP host to the session timeout. If the ARP reply is received outside the **min-auth-interval** window and the parameter re-authentication in the authentication policy is set, then RADIUS re-authentication is executed. This re-authentication mechanism is described later in theThrottling Toward RADIUSThrottling Toward RADIUS section.

Figure 4: ARP Host Session Timeout Example
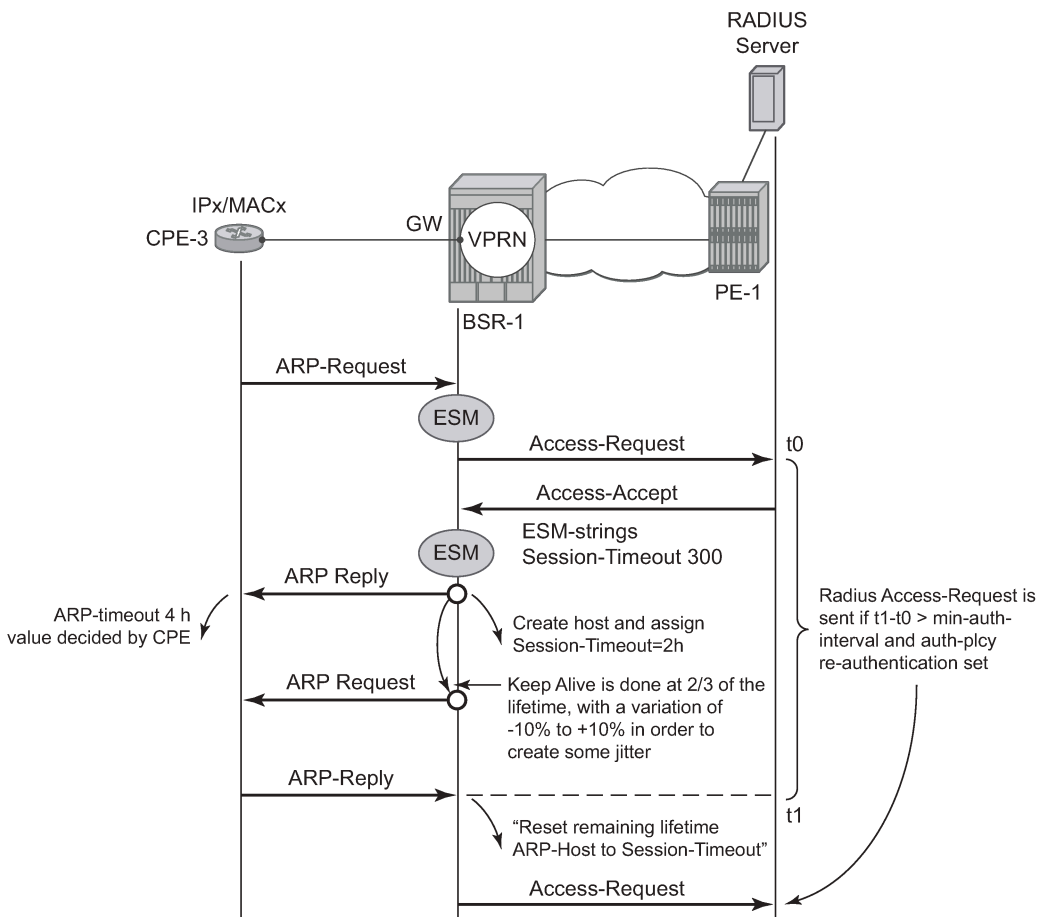

This mechanism, also known as automatic Subscriber Host Connectivity Verification (SHCV), will prevent that the host will be deleted and re-created, resulting in undesired service interruptions, in case asynchronous CPE-BSR ARP session values would be used.

The **debug service id 1 host-connectivity-verify** command shows the sequence of events and can be used for troubleshooting. Debugging and ARP host counters show the automatic SHCV mechanism with an active CPE.

```

CPEs that are not active and which therefore do not respond to ARP requests as part of the automatic SHCV check will be rechecked three times with 10 second intervals.

The number of retries and the interval cannot be changed. A trap is generated, but the ARP host is not removed and will remain until the session-timeout expires or until the host revives. This mechanism is displayed in Figure 5: Trap Generation Example.

```

Throttling Toward RADIUS

A new ARP request from the ARP host will trigger RADIUS re-authentication only when the min-auth-interval has expired. The minimum RADIUS authentication interval between two consecutive authentication attempts for the same ARP host is by default 15 minutes but can range between 1 and 6000 minutes.

```
configure
    service
        vprn 1 customer 1 create
            ---snip---
                arp-host
                    min-auth-interval 60   # value in minutes
                    no shutdown
                exit
            exit
        exit
```

ARP Host Mobility

In order for ARP host mobility to function, host-connectivity-verification must **not** be enabled. This is different when compared with DHCP host mobility.

The implementation for routed CO is displayed in Figure 7: ARP Host Mobility Example and works the same for bridged CO. The **mac-pinning** command in routed CO context has no influence on this behavior.

Figure 7: ARP Host Mobility Example
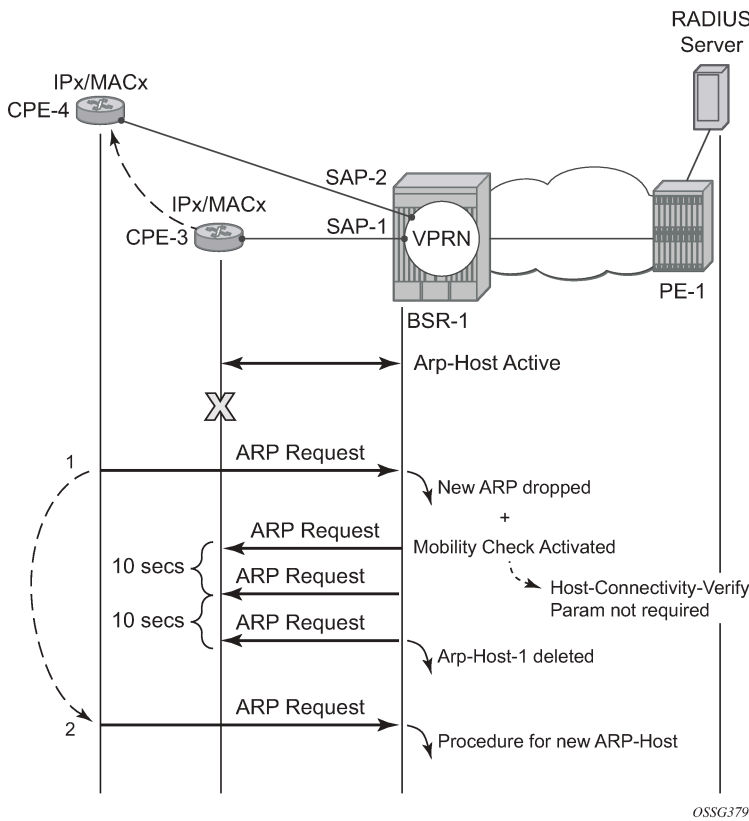

ARP Host Persistency

ARP hosts can be made persistent across reboots and do not differ with other host types such as DHCP hosts.

```
configure
    system
```

```
            persistence
                subscriber-mgmt
                    location cf3:
                exit
        exit
```

The persistence key and the index into the persistency file are linked to the ARP host at host creation time.

```

Session Limitation Options

The maximum number of allowed arp-hosts in a bridged CO model can be configured with the per SAP parameter **host-limit** in the range of 1 to 32767.

```
configure
    service
        vpls 2
            ---snip---
            sap 1/1/3:1
                arp-host
                    # default value for host-limit is 1
                    host-limit 1
                    no shutdown
                exit
            exit
        exit
```

The maximum number of allowed arp-hosts in a routed CO model can be configured with the per group interface parameter **host-limit** in the range of 1 to 32767 and/or by the **sap-host-limit** parameter.

```
configure
    service
        vprn 1
            ---snip---
                arp-host
                    # default value for host-limie is 1
                    host-limit 1
                    # default value for sap-host-limit is 1
                    sap-host-limit 1
                    no shutdown
                exit
            exit
```

⚠️ **WARNING:**
Specific ESM-related host limit mechanisms such as **sla-profile host-limit** and **sub-sla-mgmt multi-sub-sap** also apply to ARP hosts but are not further elaborated in this section.

Debugging **arp-host mode dropped-only** indicates the dropped reason and a logging trap is included in the standard log 99.

```
56 2015/06/22 16:08:35.37 CEST MINOR: DEBUG #2001 vprn1 ARP Host

```

Conclusion

This chapter provides configuration and troubleshooting commands for dynamic ARP hosts. ARP hosts can be instantiated in a Layer 2 bridged CO (VPLS) environment as well as in a Layer 3 Routed CO (IES/ VPRN subscriber interface) context.

Bridged CO

This chapter provides information about bridged CO model of Triple Play Service Delivery Architecture (TPSDA).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 7.0.R4. This chapter is related only to the use of IPv4 DHCP hosts.

Knowledge of the Triple Play Service Delivery Architecture (TPSDA) concepts is assumed throughout this chapter.

Overview

This chapter provides information about basic technology, network topology and configuration examples which are used in Bridged CO model of Triple Play Service Delivery Architecture (TPSDA). Regardless of aggregation technologies which are used by customers, Nokia offers flexible and easy to use methodology to manage DHCP subscribers in Layer 2 domain and distribute subscriber management intelligence across multiple nodes.

Bridged CO is a basic TPSDA model and implies that access nodes are united in one Layer 2 aggregation network and VPLS is used as a primary technology for these purposes. This fact allows the use of subscriber management functionality on BSA nodes. Bridged CO network topology is shown in Figure 8: Bridged CO Network Topology.

Figure 8: Bridged CO Network Topology

© 2024 Nokia.

Use subject to Terms available at: www.nokia.com/terms.
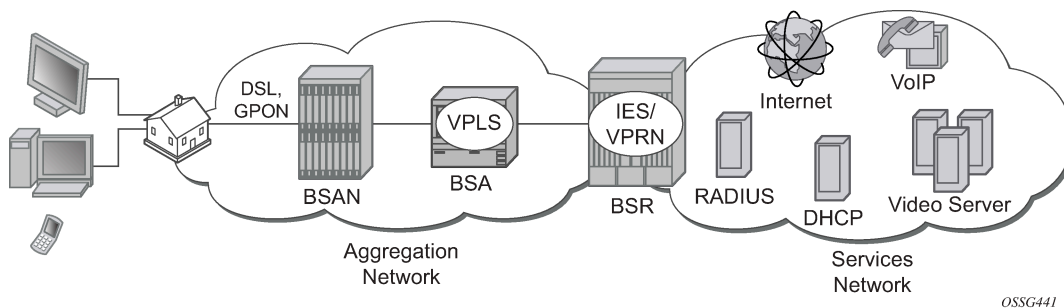

Following types of nodes are defined in Bridged CO model:

- Broadband Service Access Node (BSAN) — Access node connected to Layer 2 domain to aggregate all traffic from subscribers (IP DSLAM, ethernet switch).
- Broadband Services Aggregator (BSA) — Layer 2 node, which is capable for subscriber management in VPLS service (7450 ESS).
- Broadband Service Router (BSR) — Layer 3 node, which is capable for routing and service allocation (7750 SR).

As any model, Bridged CO introduces several key concepts that must be determined in advance. Major ones are presented in Figure 9: Key Concepts of Bridged CO Model and include:

- Subscriber— A set of hosts belonging to a single connection line (switch port, DSL line)
- Subscriber host — Unique customer device (could be PC, IP phone, STB, routed CPE).
- Subscriber-profile — Configured entity which defines the aggregate QoS for all hosts within a subscriber context.
- SLA-profile — Configured entity which defines QoS policies and filters for a subset of hosts within a subscriber context.
- Subscriber identification policy — Configured entity which defines the python script for dynamic subscriber host identification
- Authentication policy — Configured entity which defines the RADIUS servers to use for dynamic subscriber host identification
- Subscriber identification string — 32 characters identification string which uniquely identifies a subscriber on a node.

Figure 9: Key Concepts of Bridged CO Model
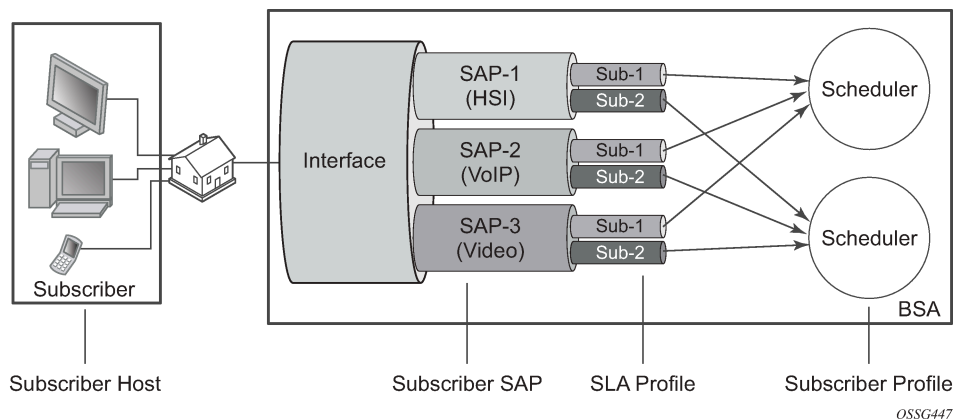

For normal operation each subscriber has to get several parameters / attributes:

- Subscriber-ID — Attribute, which uniquely identifies subscriber on the node and used as index key in subscriber database
- IP parameters — Attributes, which allows host to get access to services
- Subscriber profile and SLA profile for subscriber host — a set of filters and QoS policies.
- Lease time — Period when subscriber parameters are kept in subscriber database on the node.

There are several methods how to get each of these parameters:

- Static

- Python scripts

- RADIUS

- DHCP

Each of the subscriber parameters could be defined in several ways simultaneously. In this case use the following algorithm for selecting:

1. For subscriber profile

   a. A lookup in the **subscriber-explicit-map** is performed with the *sub-ident* string returned by the Python script, RADIUS or statically configured. If a matching entry is found, the sub-profile-name (if defined) is taken. If no entry was found go to 1.b.

   ```
   A:BSA>config>subscr-mgmt# info
           explicit-subscriber-map
               entry key "Sub-1" sub-profile "sub-profile-1" sla-profile "sla-profile-1"
   ```

   b. If a sub-ident-policy is defined on the SAP, a lookup is done on its sub-profile-map with the sub-profile string from the script. The sub-profile-name is taken from the entry. If no entry was found go to 1.c.

   ```
   A:BSA>config>service>vpls>sap# info
                   sub-sla-mgmt
                       sub-ident-policy "sub-ident-policy-1"

   A:BSA>config>subscr-mgmt# info
           sub-ident-policy "sub-ident-policy-1" create
               sub-profile-map
                   entry key "sub-1" sub-profile "sub-profile-1"
   ```

   c. If provisioned, the sub-profile-name is taken from the def-sub-profile attribute on the SAP. If no entry was found go to 1.d.

   ```
   A:BSA>config>service>vpls>sap# info
                   sub-sla-mgmt
                       def-sub-profile "sub-profile-1"
   ```

   d. If a sub-profile with the name *default* is provisioned. If no entry was found DHCP Ack is dropped.

   ```
   A:BSA>config>subscr-mgmt# info
           sub-profile "default" create
   ```

Figure 10: Flow Chart for Subscriber-Profile Identification Algorithm
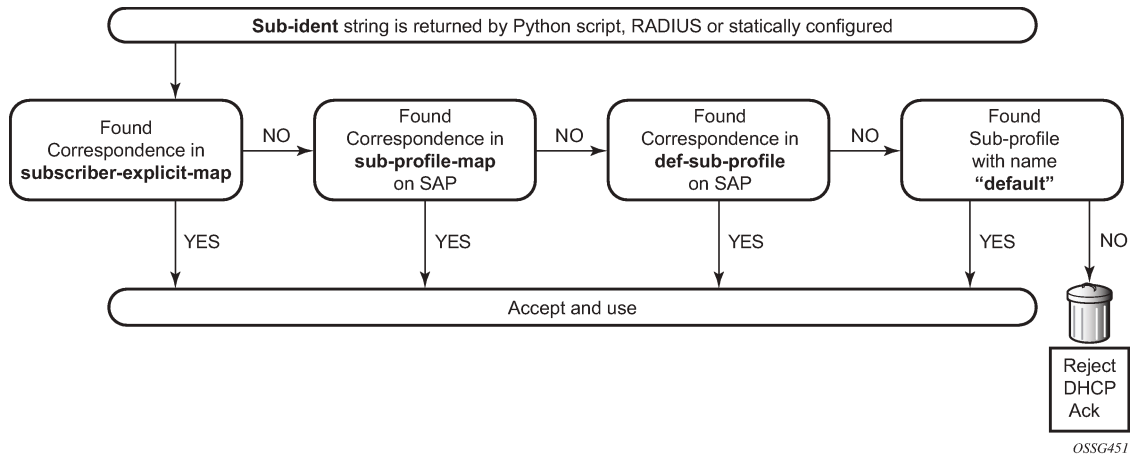

2. **For SLA profile**

   a. The sla-profile-name is taken from the sub-ident string (returned by the Python script, RADIUS or statically configured) in the subscriber-explicit-map. If no entry was found go to 2.b2.a.

   ```
   A:BSA>config>subscr-mgmt# info
           explicit-subscriber-map
               entry key "Sub-1" sub-profile "sub-profile-1" sla-profile "sla-profile-1"
   ```

   b. A lookup with the sla-profile string from the script is done in the sla-profile-map of the sub-profile found earlier. The corresponding sla-profile-name is used. If no entry was found go to 2.c:

   ```
   A:BSA>config>subscr-mgmt# info
           sub-profile "sub-profile-1" create
               sla-profile-map
                   entry key "sla-1" sla-profile "sla-profile-1"
   ```

   c. The sla-profile-name is taken from sla-profile-map of the sub-ident-policy configured on the SAP. The corresponding sla-profile-name is used. If no entry was found go to 2.d.

   ```
   A:BSA>config>service>vpls>sap# info
                   sub-sla-mgmt
                       sub-ident-policy "sub-ident-policy-1"

   A:BSA>config>subscr-mgmt# info
           sub-ident-policy "sub-ident-policy-1" create
               sla-profile-map
                   entry key "sla-1" sla-profile "sla-profile-1"
   ```

   d. The *sla-profile-name* is taken from the **def-sla-profile** attribute on the SAP. If no entry was found DHCP Ack is dropped.

   ```
   A:BSA>config>service>vpls>sap# info
                   sub-sla-mgmt
   ```

```
                         def-sla-profile "sla-profile-1"
```

Figure 11: Flowchart for SLA-Profile Identification Algorithm

OSSG452
> ✏️ **Note:**
> Static configuration has priority over RADIUS configuration and RADIUS has priority over DHCP/
> Python scripts.

> ✏️ **Note:**
> Each host can have different SLA-profile, while sub-profile applies to whole subscriber. The last
> definition of sub-profile will force all previously defined hosts to change their sub-profile.

Bridged CO supports typical access node connection models, such as:

- One VLAN per service (ESM for subscriber differentiation and SAP for service)
- One VLAN per subscriber (SAP for subscriber differentiation and QoS flag for service)
- One VLAN per access node (ESM for subscriber differentiation and QoS flag for service)

Each of these modes has its pros and cons, but this is out of scope of this document.

This configuration guide focuses on configuration of one subscriber with three different hosts. VLAN
per service is used as mode of subscriber aggregation and mixed RADIUS and DHCP as subscriber
identification method. IP termination is done in IES service of BSR.

Correlation of BSA/BSR services and subscriber hosts is presented in Table 2: Correlation of Hosts and
BSA/BSR Services .

Table 2: Correlation of Hosts and BSA/BSR Services

	BSA (Service/Features)	BSR (Service/Features)
Host-1 ca:00:0c:54:00:08	VPLS-100 • DHCP proxy server • SAP/SDP DHCP snoop • Sub-Ident origin via RADIUS • Sla/Sub-profiles via RADIUS	IES-100

	BSA (Service/Features)	BSR (Service/Features)
	• IP options via RADIUS	
Host-2 ca:01:08:10:00:08	VPLS-200 • SAP/SDP DHCP snoop • Sub-Ident origin through RADIUS • Sla/Sub-profiles through RADIUS • IP options through DHCP	IES-200 • DHCP relay
Host-3 ca:02:02:d0:00:08	VPLS-300 • SAP/SDP DHCP snoop • Sub-Ident origin through DHCP • Sla/Sub-profiles through DHCP • IP options through DHCP	IES-300 • DHCP relay

Different methods of authentication and address allocation were chosen for demonstration purposes. The customer is not limited to one method and can use a combination of methods as presented in this guide.

The following entities should be configured in advance. Refer to the appropriate platform user guide for specific information.

• Basic router configuration (interfaces, routing protocols, MPLS)

• External RADIUS server

• External/Local DHCP server

Configuration

A sample topology is presented in Figure 12: Sample Topology.

Figure 12: Sample Topology
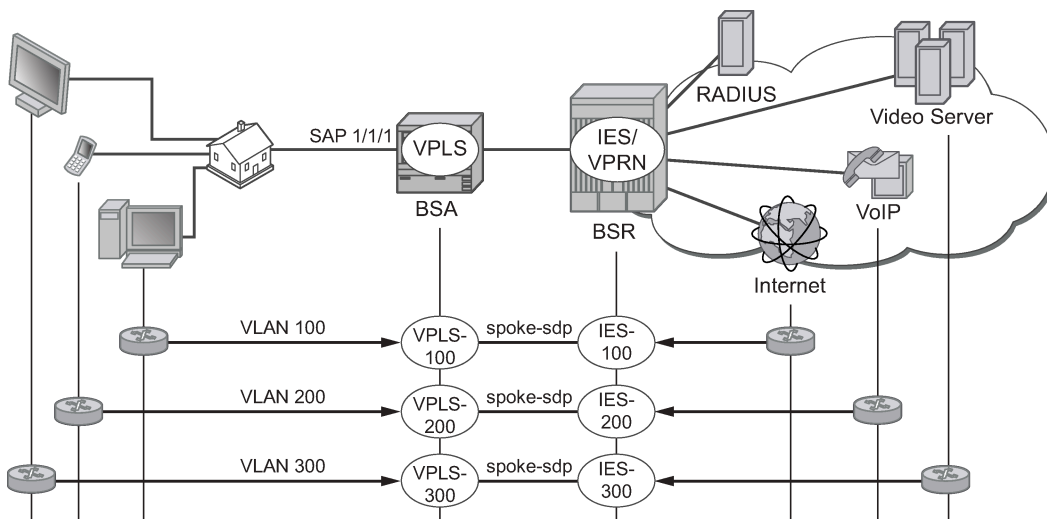

Bridged CO model requires certain techniques and features to be used on different nodes. Major methods are presented in Figure 13: Functionality of Each Node.

Figure 13: Functionality of Each Node
The following configuration steps are required:

1. On BSA

    a. Configure subscriber management profiles

        i. Configure sla profiles

        ii. Configure subscriber profiles

        iii. Configure subscriber identification policies

        iv. Configure authentication and accounting policies if required

    b. Configure VPLS service

        i. Configure split horizon group

        ii. Configure SAP

            2.1 Configure anti-spoofing filters

            2.2 Configure DHCP snooping

2.3 Configure optional parameters (lease split, L2 DHCP relay agent, etc.)

2.4 In case of RADIUS authentication apply authentication policy

2.5 Configure ESM

iii. Configure SDP

3.1 Configure DHCP snooping

2. On BSR

a. Configure IES service

i. Configure IP interface

1.1 Configure DHCP relay agent if required

Basic ESM Configuration on BSA

Subscriber management is enabled on BSA in Bridged CO model. A relevant configuration is presented below. SLA and subscriber profiles show the default configurations. The authentication policy appeals to RADIUS server 192.0.2.5. The subscriber identification policy is configured to use DHCP Option 254 to transfer custom attributes (subscriber-id, sla-profile, sub-profile, etc.)

```
A:BSA>config>subscr-mgmt# info
        authentication-policy "auth-policy-1" create
            password password-1
            radius-authentication-server
                router "management"
                server 1 address 192.0.2.5 secret ALU
            exit
            include-radius-attribute
                circuit-id
                remote-id
                nas-port-id
                nas-identifier
            exit
        exit
        sla-profile "sla-profile-1" create
        exit
        sla-profile "sla-profile-2" create
        exit
        sla-profile "sla-profile-3" create
        exit
        sla-profile "sla-profile-default" create
        exit
        sub-profile "sub-profile-1" create
        exit
        sub-profile "sub-profile-default" create
        exit
        sub-ident-policy "sub-ident-policy-1" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
            strings-from-option 254
        exit
```

The **strings-from-option 254** command is shared in-built dhcp-server of BSR. Using this option, the DHCP server could transmit subscriber identification options such the subscriber-id, sla-profile-string, and sub-profile-string.

BSA/BSR Configuration for Host-1 Operation

The test subscriber has three hosts. Host-1 gets all necessary information from RADIUS server.

Table 3: BSA/BSR Configuration for Host-1 Operation

	BSA (Service/Features)	BSR (Service/Features)
Host-1 ca:00:0c:54:00:08	VPLS-100 • DHCP proxy server • SAP/SDP DHCP snoop • Sub-Ident origin through RADIUS • Sla/Sub-profiles through RADIUS • IP options through RADIUS	IES-100

In this case BSA takes role of DHCP proxy with DHCP server emulation. DHCP snooping on the SAP must be enabled. Anti-spoofing filters on the SAP must be enabled. An authentication policy must be applied on the SAP.

```
        vpls 100 customer 1 create
            split-horizon-group "RSHG-1" residential-group create
            exit
---snip---
            sap 1/1/4:100 split-horizon-group "RSHG-1" create
                dhcp
                    snoop
                    lease-populate 400
                    proxy-server
                        emulated-server 10.0.1.253
                        no shutdown
                    exit
                    no shutdown
                exit
                authentication-policy "auth-policy-1"
                anti-spoof ip-mac
                sub-sla-mgmt
                    def-sub-id string "default-subscriber"
                    def-sub-profile "sub-profile-default"
                    def-sla-profile "sla-profile-default"
                    sub-ident-policy "sub-ident-policy-1"
                    no shutdown
                exit
            exit
            spoke-sdp 12:100 create
            exit
            no shutdown
        exit
```

On BSR IES-100, the service is configured with a pure IP interface, which plays role of DG for host-1.

```
ies 100 customer 1 create
    interface "int-host-1" create
        address 10.0.1.254/24
        spoke-sdp 21:100 create
        exit
    exit
    no shutdown
exit
```

BSA/BSR Configuration for Host-2 Operation

The test subscriber has three hosts. Host-2 gets subscriber-id and sla/sub-profiles information from RADIUS server and IP options from DHCP server.

Table 4: BSA/BSR Configuration for Host-2 Operation

	BSA (Service/Features)	BSR (Service/Features)
Host-2 ca:01:08:10:00:08	VPLS-200 • SAP/SDP DHCP snoop • Sub-Ident origin through RADIUS • Sla/Sub-profiles through RADIUS • IP options through DHCP	IES-200 • DHCP relay

DHCP snooping on the SAP and SDP must be enabled. Anti-spoofing filters on the SAP must be enabled.

```
vpls 200 customer 1 create
    split-horizon-group "RSHG-1" residential-group create
    exit
---snip---
    sap 1/1/4:200 split-horizon-group "RSHG-1" create
        dhcp
            snoop
            lease-populate 400
            no shutdown
        exit
        authentication-policy "auth-policy-1"
        anti-spoof ip-mac
        sub-sla-mgmt
            def-sub-id string "default-subscriber"
            def-sub-profile "sub-profile-default"
            def-sla-profile "sla-profile-default"
            sub-ident-policy "sub-ident-policy-1"
            no shutdown
        exit
    exit
    spoke-sdp 12:200 create
        dhcp
            snoop
        exit
    exit
```

```
                no shutdown
            exit
```

On BSR IES-200, the service is configured with an IP interface which as the DG for Host-2. DHCP relay
must be configured to transform broadcast DHCP discover message into unicast and send it to DHCP
server for processing.

```
        ies 200 customer 1 create
            interface "int-host-2" create
                address 10.0.2.254/24
                dhcp
                    server 192.0.2.4
                    trusted
                    no shutdown
                exit
                spoke-sdp 21:200 create
                exit
            exit
            no shutdown
        exit
```

BSA/BSR Configuration for Host-3 Operation

The test subscriber has three hosts. Host-3 receives all necessary information from the DHCP server.

Table 5: BSA/BSR Configuration for Host-3 Operation

	BSA (Service/Features)	BSR (Service/Features)
Host-3 ca:02:02:d0:00:08	VPLS-300 * SAP/SDP DHCP snoop * Sub-Ident origin through DHCP * Sla/Sub-profiles through DHCP * IP options through DHCP	IES-300 * DHCP relay

DHCP snooping on the SAP and SDP must be enabled. Anti-spoofing filters on the SAP must be enabled.

```
        vpls 300 customer 1 create
            split-horizon-group "RSHG-1" residential-group create
            exit
---snip---
            sap 1/1/4:300 split-horizon-group "RSHG-1" create
                dhcp
                    snoop
                    lease-populate 400
                    no shutdown
                exit
                anti-spoof ip-mac
                sub-sla-mgmt
                    def-sub-id string "default-subscriber"
                    def-sub-profile "sub-profile-default"
                    def-sla-profile "sla-profile-default"
                    sub-ident-policy "sub-ident-policy-1"
```

```
                no shutdown
            exit
        exit
        spoke-sdp 12:300 create
            dhcp
                snoop
            exit
        exit
        no shutdown
    exit
```

On BSR IES-300, the service is configured with IP interface, which plays role of DG for host-3. DHCP relay must be configured to transform broadcast DHCP discover message into unicast and send it to DHCP server for processing.

```
    ies 300 customer 1 create
        interface "int-host-3" create
            address 10.0.3.254/24
            dhcp
                server 192.0.2.4
                trusted
                no shutdown
            exit
            spoke-sdp 21:300 create
            exit
        exit
        no shutdown
    exit
```

RADIUS Configuration Bridged CO

The username in the RADIUS access request is configurable and could be one of the following formats:

- mac — MAC Source Address of the DHCP DISCOVER message

- circuit-id — Taken from option 82 in the received DHCP message. If no circuit-id can be found, the DHCP-msg is rejected.

- tuple — Concatenation of MAC source address and circuit-ID

- ascii-converted-circuit-id — Identical to circuit-id, but the user name will be sent to the RADIUS server as a string of hex digits

- ascii-converted-tuple — Identical to tuple, but the circuit-id part of the user name will be sent to the RADIUS server as a string of hex digits

> **Note:**
> Refer to IPv4 DHCP Hosts for detailed information about how to use different options.

```
A:BSA>config>subscr-mgmt>auth-plcy# user-name-format
 - user-name-format <format> [append domain-name]
 - no user-name-format

 <format>             : mac|circuit-id|tuple|ascii-converted-circuit-id|
                        ascii-converted-tuple
```

For simplicity, MAC format is used in this guide.

There are two hosts configured in the users file on RADIUS server:

- a:00:0c:54:00:08 — The mac address of host-1 host [VPLS/IES 100]. For host-1 all necessary parameters are returned: subscriber-id, sla/sub-profiles, IP parameters and lease time.

- a:01:08:10:00:08 — The mac address of host-2 host [VPLS/IES 200]. For host-2 only subscriber-id, sla/sub-profiles are returned, while ip parameters and lease time are returned from DHCP server.

```
ca:00:0c:54:00:08 Auth-Type := Local, User-Password == "password-1"
                  Alc-Subsc-ID-Str = "sub-id-1",
                  Alc-Subsc-Prof-Str == "sub-profile-1",
                  Alc-SLA-Prof-Str == "sla-profile-1",
                  Framed-IP-Address = 10.0.1.1,
                  Framed-IP-Netmask = 255.255.255.0,
                  Alc-Default-Router = 10.0.1.254,
                  Session-Timeout = 6000

ca:01:08:10:00:08 Auth-Type := Local, User-Password == "password-1"
                  Alc-Subsc-ID-Str = "sub-id-1",
                  Alc-Subsc-Prof-Str == "sub-profile-1",
                  Alc-SLA-Prof-Str == "sla-profile-2"
```

Local DHCP Server Configuration Bridged CO

In the setup local DHCP server is used with reference to local user database.

```
A:BSR>config>router>dhcp# info
            local-dhcp-server "dhcp-server-1" create
                user-db "user-db-1"
                pool "pool-1" create
                    subnet 10.0.2.0/24 create
                    exit
                    subnet 10.0.3.0/24 create
                    exit
                exit
                no shutdown
            exit
```

Note:
Subnets must be configured, even if all IP parameters are returned from local user DB. Without this option, DHCP server do not return IP parameters.

The local user database is configured on BSR. Identification is done via MAC address of a host, which is taken from DHCP-Discover message. There are several possibilities to identify DHCP host. **match-list** command is used for this purpose.

```
*A:BSR>config>subscr-mgmt>loc-user-db>dhcp#              match-list
  - no match-list
  - match-list <dhcp-match-type-1> [<dhcpmatch-type-2>...(up to 4 max)]

 <dhcp-match-type>    : circuit-id|mac|option60|remote-id|sap-id|service-id|
                        string|system-id
```

There are two hosts configured:

- a:01:08:10:00:08 — mac address of host-2 [VPLS/IES 200]. DHCP returns ip address, subnet mask and default route.

- a:02:02:d0:00:08 — mac address of host-3 [VPLS/IES 300]. DHCP returns all necessary parameters: subscriber-id, sla/sub-profiles and all ip options.

```
A:BSR>config>subscr-mgmt# info
        local-user-db "user-db-1" create
            dhcp
                match-list mac
                host "host-2" create
                    host-identification
                        mac ca:01:08:10:00:08
                    exit
                    address 10.0.2.1
                    options
                        subnet-mask 255.255.255.0
                        default-router 10.0.2.254
                    exit
                    no shutdown
                exit
                host "host-3" create
                    host-identification
                        mac ca:02:02:d0:00:08
                    exit
                    address 10.0.3.1
                    identification-strings 254 create
                        subscriber-id "sub-id-1"
                        sla-profile-string "sla-profile-3"
                        sub-profile-string "sub-profile-1"
                    exit
                    options
                        subnet-mask 255.255.255.0
                        default-router 10.0.3.254
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

Setup Procedures and Debugging

Subscriber/Host Verification

The initialization of all active subscribers and hosts can be shown using the **show service active-subscribers** command. Different options can be used to filter the output of the command.

```
A:BSA# show service active-subscribers
===============================================================================

   |    |-- 10.0.2.1 - ca:01:08:10:00:08 - N/A (DHCP)
   |    |
   |
   |-- sap:1/1/4:300 - sla:sla-profile-3
   |    |
   |    |-- 10.0.3.1 - ca:02:02:d0:00:08 - N/A (DHCP)
   |    |
```

Host-1 Setup Debug

The Host-1 setup process is shown in .

Figure 14: Host-1 Setup Process
Host-1 sends DHCP discover message in VLAN 100 to BSA. BSA plays role of DHCP proxy server and transforms DHCP discover into RADIUS access-request message. After receiving RADIUS access-accept BSA transforms it to DHCP Ack message. Session setup process could be represented using debug commands:

```
A:BSA# debug service id 100 dhcp mode egr-ingr-and-dropped
A:BSA# debug service id 100 dhcp detail-level medium
A:BSA# debug radius detail

Host-2 Setup Debug

Host-1 setup process is displayed in .

Figure 15: Host-2 Setup Process
OSSG444

Host-2 sends DHCP discover message in VLAN 200 to BSA. Host-2 is authenticated through RADIUS and gets subscriber-id, sla/sub-profiles. DHCP Discover message is flooded in VPLS service and reaches IP interface on BSA, where DHCP relay is configured. Session setup process could be represented using debug commands:

```

Conclusion

This note provides configuration and troubleshooting commands for Bridged CO model.

DHCP Server Failover States

This chapter describes DHCP server failover states.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and is based on SR OS Release 14.0.R7.

Overview

A common way to maintain DHCP service during a partial power loss or partial network outage is to provide DHCP server redundancy, where two DHCP servers in the network serve a common set of subnets. Failover is a mechanism where the second server takes the role of the first server in case of a failure or a planned network outage, thereby providing a backup.

Failover requires a pair of redundant servers, and IP address assignment continuity is ensured in case of a failure of one of the servers, while at same time preventing address duplication. This contributes to a higher availability of service in the network.

Failover can be performed by an operator taking manual actions, but in most networks failover is usually performed automatically, relying on failure detection mechanisms that can trigger the activation of the second server.

For the peers of a redundant pair to take over the role of each other, they must have the same view of the network and subnets they need to serve, in terms of:

- the definition of the common subnets
- the leases already assigned in these subnets

The definitions of the subnets to be shared are synchronized through configuration, whereas the leases assigned by both DHCP peers are synchronized with each other through Multi Chassis Synchronization (MCS). MCS is also used to detect communication failures between the DHCP servers, but MCS cannot detect whether the cause is a link failure or a server failure.

Figure 17: General Redundancy Model shows the general redundancy model, where clients connected to the Layer 2 access nodes AN1, AN2, and AN3 get their addresses from the DHCP servers located in BNG1 and BNG2, via relay agents that are also located in BNG1 and BNG2. Access network redundancy can be supported through the Subscriber Routed Redundancy protocol (SRRP) or through Multi Chassis Link Aggregation (MC-LAG) in combination with SRRP.

Figure 17: General Redundancy Model
26352

Figure 18: DHCP Relay Agent and Server Redundancy Model shows the DHCP relay agent and server redundancy model, where the DHCP relay agents R1 and R2 and the DHCP servers S1 and S2 are situated in different nodes in the network. DHCP requests received from the access network are relayed onto S1 and S2 via R1 and R2. MCS is used for synchronizing the lease database between servers S1 and S2. MCS can also be used for synchronizing the subscriber management information between R1 and R2, but that is out of the scope of this chapter.

MCS typically runs over a direct link connecting the two peers of a pair (scenario 1 in Figure 17: General Redundancy Model), but can also run over backbone links if no direct link is present (scenario 2 in Figure 17: General Redundancy Model). Regardless of the scenario, this link is referred to as the intercommunication link (ICL), and it should be well protected with multiple underlying physical paths.

DHCP server failover relies on the detection of a failure of the ICL. This link should be disjoint from the access links toward the DHCP clients.

Figure 18: DHCP Relay Agent and Server Redundancy Model
DHCP server failover requires the nodes of a failover pair to have their date and time synchronized. This is commonly implemented using the network time protocol (NTP).

In the configuration section of this chapter, the local-remote deployment model is used, using a single relay agent and two DHCPv4 servers.

For basic DHCPv4 server configuration, see the DHCPv4 Server Basics chapter.

DHCP Server Failover and Address Management

For DHCP servers to support failover, the redundant servers need to share a set of subnets and address ranges so that one can take the role of the other in case of a failure, at the same time avoiding double allocations.

Following models are supported to achieve these requirements; see Figure 19: Access-Driven and Local-Remote Model:

- access-driven model
- local-remote model

Note:
An unsupported local-local model is similar to the access-driven model. They behave the same in terms of their failover, but different in terms of error handling; the local-local model can emit erroneous traps, whereas the access-driven model does not.

Figure 19: Access-Driven and Local-Remote Model
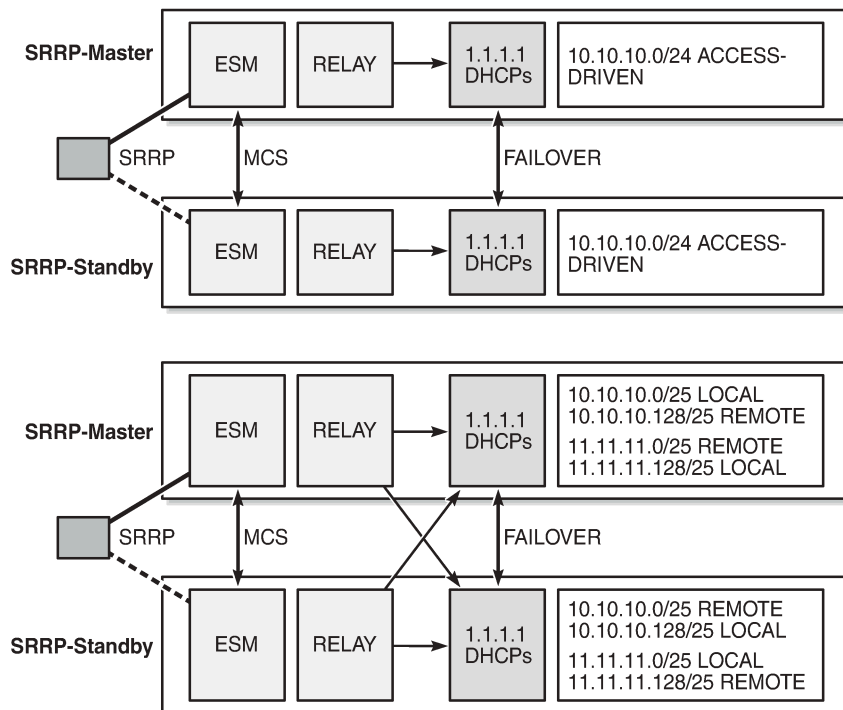

In the access-driven model, the address ranges on both DHCP servers are defined as access-driven. As for the topology, the relay agents are configured to relay the messages to and from one server only, and Nokia recommends that both DHCP servers use the same interface address. This can be achieved by hosting the ESM, relay, and DHCP server functionalities in the same router.

In the local-remote model, address ranges declared as local on one peer must be declared as remote on the other peer, and vice versa. As for the topology, the relay agents are configured to relay the messages to and from both servers, and do not need to be hosted by the same routers as the DHCP servers.

Avoiding Double Allocations

To avoid double allocations in the access-driven model, only one path should be active out of the access network toward the relay agent and the accompanying DHCP server. This is achieved through SRRP or MC-LAG in combination with SRRP in the access network. The relay agent must relay the messages to and from one server only, so this model is effectively an active-standby model.

To avoid double allocations in the local-remote model, where two paths from the access network to the DCHP servers exist and where two DHCP servers work in parallel, the following rules apply:

- Addresses from the local (and access-driven) ranges can always be allocated, even when there is a communication failure between the peer servers, or when the peer server is down.

- Addresses from remote ranges should only be allocated when the peer server is down.

When the ICL between the peers fails, so that the DHCP servers become isolated from each other, new clients connecting are allocated addresses from local (or access-driven) address ranges only. Because the

ranges are declared as local on one peer, and remote on the other, without any overlap, there is no risk of double allocations. Because of the ICL failure, lease synchronization between the peers is not possible.

However, if the ICL failure lasts for an extended time, while both servers are up and running, then both peers consider their partner to be down. Both servers can start allocating addresses from their remote ranges, and there is a risk of assigning the same address to different clients. This situation **must be avoided** by ensuring that, when both peers are up, the ICL is also up.

Double allocations in a network is an indication of either two DHCP servers being isolated for too long or a misconfiguration in the network, and **must never happen**.

The DHCP Server Failover States and State Transitions section in this chapter provides a more extensive explanation.

Local-Remote Model – Active-Standby Configuration

The first example of the local-remote model is an active-standby configuration; see Figure 20: Local-Remote Model – Active-Standby. All the ranges in all pools are declared local on DHCP server A (the active server), and remote on DHCP server B (the standby server).

Usually, leases are allocated by the active DHCP server. The standby DHCP server synchronizes with the active server through MCS, so it can take over all ranges of all subnets in case of a failure.

Even though server B also receives DHCP requests from clients, it will not allocate addresses from its subnets (because they are all declared remote) unless server A is down. Only when server A goes down does server B become active, and connects, rebinds, and renews clients.

Caution must be taken when deploying this model, because fast switchover requires ignoring the maximum client lead time (MCLT) on takeover and a low value for the partner down delay, as described later in this chapter.

Figure 20: Local-Remote Model – Active-Standby
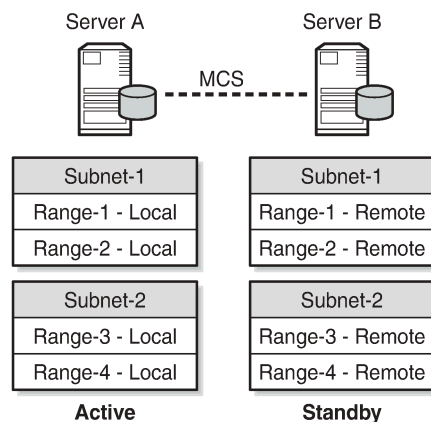

Local-Remote Model – Load Sharing Configuration

The second example of the local-remote model is a load sharing configuration; see Figure 21: Local-Remote Model – Subnet-Based Load Sharing. All subnet-1 ranges are declared local on server A, and remote on server B. For subnet-2, this is the opposite.

Usually, leases are allocated by both server A and server B. Server A is responsible for subnet-1, and thus manages addresses from subnet-1 (allocation, rebind, renew). At the same time, server B is responsible for subnet-2.

The standby DHCP server synchronizes with the active server through MCS, so it can take over all ranges of all subnets in case of a failure. Addresses from the remote ranges are managed only in case the server is in the partner down state.

Figure 21: Local-Remote Model – Subnet-Based Load Sharing
A variant of this model is shown in Figure 22: Local-Remote Model – Range-Based Load Sharing, where a subnet is split into two ranges with the first range declared as local and the second range declared as a remote. The local/remote ratio can be chosen arbitrarily. For example, the ratio for subnet-1 can be defined as 80/20, meaning that for a range of 100 addresses, 80 addresses are available in the local range and 20 in the remote range. At the same time, a 50/50 ratio can be defined for subnet-2.

Figure 22: Local-Remote Model – Range-Based Load Sharing
Note:
All these deployment models are supported for both IPv4 and IPv6, except for the model shown in Figure 22: Local-Remote Model – Range-Based Load Sharing, because IPv6 prefixes cannot be organized in ranges.

DHCP Server Failover States and State Transitions

When a DHCP server is configured and enabled for failover, SR OS maintains a failover state, see Figure 23: Failover State Transition Diagram. The failover state can have one of the following values:

- INIT – the DHCP server is initializing and possibly recovering its leases from the persistency database (if persistency is enabled). In this state, the DHCP server does not respond to any unicast or broadcast messages.

- STARTUP – the DHCP server recovers leases through MCS, and does not respond to any unicast or broadcast messages.

- PRE-NORMAL – the DHCP server responds to unicast and broadcast messages for addresses in the local range, and to unicast messages for addresses in the remote range.

- NORMAL – the DHCP server responds to local addresses only.

- COMMUNICATIONS-INTERRUPTED – the DHCP server responds to local (and access-driven) addresses only, and operator intervention is required. In the remainder of this chapter, this state is abbreviated as COMM-INT.

- PARTNER-DOWN – the DHCP server responds to local and remote ranges.

Figure 23: Failover State Transition Diagram
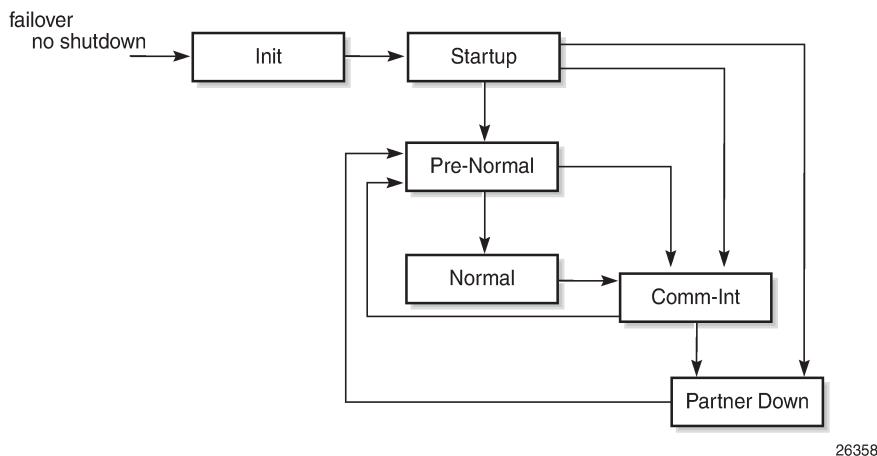

Enabling failover (no shutdown) triggers the change to the INIT failover state.

The INIT state is used while the DHCP server is recovering its lease database from persistency files when persistency applies. When recovery is completed, the failover state transitions to STARTUP. When persistency does not apply, the failover state transitions immediately to STARTUP.

When entering the STARTUP state, the startup-wait-timer is started to supervise the TCP connection setup to the MCS peer. If this timer expires and the connection is still not established, MCS communication has failed, and the failover state changes to COMM-INT. MCS recovery starts automatically if the TCP connection is established. When MCS recovery finishes, the failover state is changed to PRE-NORMAL.

However, if an MCS state-record indicates that the failover state was PARTNER-DOWN before a reboot, the failover state is set to PARTNER-DOWN immediately.

The DHCP server will not respond to any DHCP messages while in the INIT or STARTUP state.

When the PRE-NORMAL state is reached at power on or reboot (so the previous failover state was STARTUP), the system immediately changes the failover state to NORMAL.

In the NORMAL state, the DHCP server manages the addresses from the local (and access-driven) address ranges. In parallel, MCS keeps the DHCP lease states between the peers synchronized. If an MCS no-sync event is received, the failover state changes to COMM-INT.

Because MCS cannot determine whether a server is down or a server is not reachable because of an ICL failure, an operator must intervene when the COMM-INT state is reached. If no operator intervenes for an extended period of time (defined by the partner-down-delay, default 23h 59m 59s), the failover state changes to PARTNER-DOWN.

This is not a problem if the DHCP peer is down; for example, because of a power failure. The active DHCP server starts managing the addresses from the local and the remote address ranges. When the failing DHCP peer is up and running again, it gets to the NORMAL state through the process previously described.

The situation where two DHCP peers are isolated and running independent of each other, so that both are in the PARTNER-DOWN state, **must be avoided**. It would lead to double allocations, where both servers assign the same addresses to different clients, which is service disrupting to the users involved. Potential duplicates are resolved when the MCLT timer expires, and both peers are synchronized again.

Getting into the COMM-INT status is not service affecting, but should be avoided because DHCP lease synchronization fails. Operators must prevent both DHCP servers getting into the PARTNER-DOWN state, and the time to take corrective actions is bound by the partner-down-delay. If the partner-down-delay is not sufficiently large, ensure that one of the peer DHCP servers is not reachable by any of the clients anymore; for example, by shutting down or removing power from that server.

When in either the COMM-INT or PARTNER-DOWN state, and an MCS sync-event is received because the ICL becomes active again, the DHCP server moves to the PRE-NORMAL state, and starts the pre-normal-timer, which is initialized to the MCLT value, described in the next section.

In the PRE-NORMAL state, the DHCP server recovers the remote leases through MCS. While in this state, the DHCP server will respond to unicast and broadcast DHCP messages from the local ranges, and to unicast DHCP messages from the remote range. Recovery will be finished before the pre-normal timer expires, after which the failover state returns to NORMAL.

Maximum Client Lead Time

When failover does not apply, the DHCP server provides lease durations as defined in the pool or subnet definitions. When a client explicitly requests a lease duration, the server checks and validates the requested lease duration, potentially changing the requested lease duration to match the boundaries.

Regardless of the failover deployment model, it is important that DHCP servers can only allocate or extend a lease for a limited amount of time beyond the lease time known by its peer. The maximum client lead time (MCLT) defines the maximum time that one server can extend the lease for a client's binding, beyond the time known by the partner server, and is a safeguard against potential double allocations.

Nokia recommends using the same value for the MCLT on both partners of a failover pair. If they are different, the larger value is used. The default MCLT value is 10 min.

In the NORMAL state, clients initially get a lease time equal to the MCLT time. Over time, when renewing and rebinding, the allocated lease times are gradually increased to:

- the requested lease times if they are within the configured bounds
- the configured lease timer value

See the *Lease Time Synchronization* chapter in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* for examples.

In the COMM-INT state, lease durations for existing leases are gradually decreased on renewal and rebinding, down to a minimum value defined by the MCLT. New clients are provided lease times equal to the MCLT.

When the DHCP server returns to the NORMAL state, lease durations start increasing again if clients renew and rebind.

Commands Controlling Failover and Failover State

Commands controlling failover are available at the DHCP server level, or at the pool level, in the base router and in a VPRN context.

These commands are grouped in the failover context:

- peer <ip-address> tag <sync-tag>
- ignore-mclt-on-takeover
- maximum-client-lead-time
- partner-down-delay
- startup-wait-time

The peer address is the IPv4 or IPv6 address of the DHCP failover peer, and is accompanied by a string of up to 32 characters, which serves as the sync-tag. This sync-tag must be the same on both peers.

The use of the other parameters is explained in the DHCP Server Failover States and State Transitions and Maximum Client Lead Time sections of this chapter.

A tools command is available, forcing the failover state to PARTNER-DOWN, and should be used with caution:

```
*A:P-2# tree flat | match tools | match force-partner
tools perform router dhcp local-dhcp-server failover force-partner-down
tools perform router dhcp local-dhcp-server pool failover force-partner-down
tools perform router dhcp6 local-dhcp-server failover force-partner-down
tools perform router dhcp6 local-dhcp-server pool failover force-partner-down
*A:P-2#
```

Configuration

Starting a DHCP server in an SR OS environment requires following steps:

1. Configure the DHCP server.
2. Configure the interfaces for the DHCP server to listen on.
3. Configure one or more relay agents.

The baseline configuration used in this chapter is shown in Figure 24: VPRN-1 Service Configuration, and relies on the relay agent to relay DHCP messages to and from both DHCP servers.

The example scenario uses DHCP clients only.

Figure 24: VPRN-1 Service Configuration
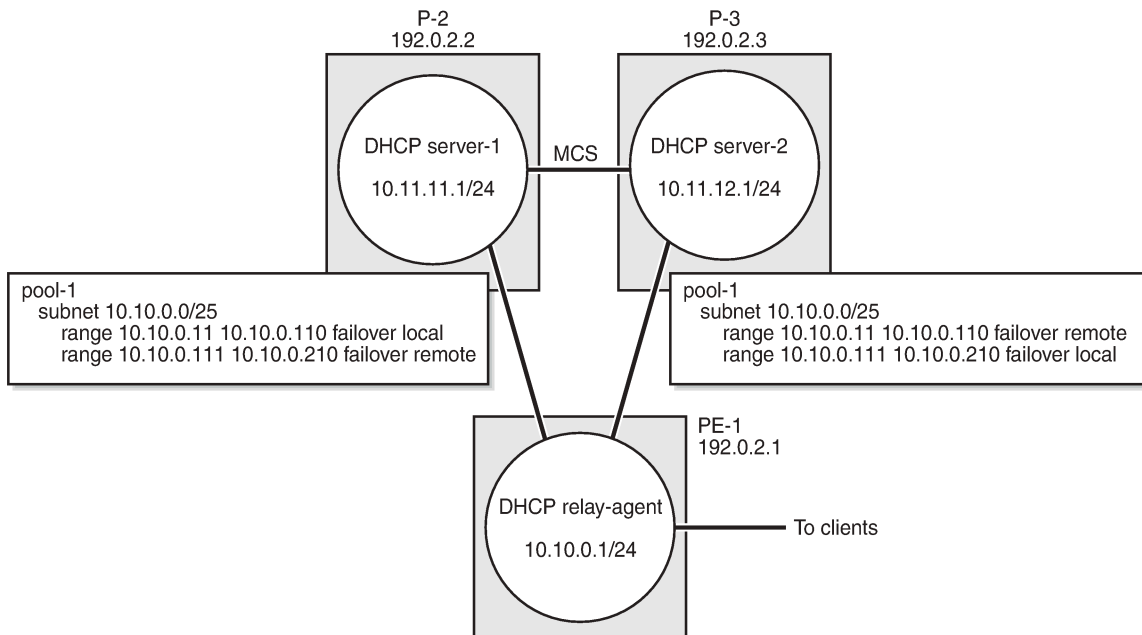

Configure Multi-Chassis Synchronization

MCS must be configured before configuring failover, because the DHCP lease state database is to be synchronized between the failover peers. Therefore, P-2 points to P-3, and vice-versa, as follows:

```
# P-2
configure
    redundancy
        multi-chassis
            peer 192.0.2.3 create
                sync
                    local-dhcp-server
                    no shutdown
                exit
                no shutdown
            exit
        exit
    exit
exit
```

```
# P-3
configure
    redundancy
        multi-chassis
```

```
                    peer 192.0.2.2 create
                        sync
                            local-dhcp-server
                                no shutdown
                        exit
                        no shutdown
                exit
            exit
        exit
exit
```

For MCS and failover to work, the clocks of the servers must be aligned, which is achieved through NTP. Configuration of NTP is beyond the scope of this chapter.

Configure common DHCP subnets

The 10.10.0.0/24 subnet is shared by P-2 and P-3. The [11-110] range is declared local to P-2 and remote to P-3. The [111-210] range is declared remote to P-2 and local to P-3, as follows:

```
# P-2
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "dhcp-1" create
                    use-gi-address scope pool
                    pool "pool-1" create
                        options
                            dns-server 1.1.1.1 1.1.2.2
                            lease-time min 20
                        exit
                        subnet 10.10.0.0/24 create
                            options
                                subnet-mask 255.255.255.0
                                default-router 10.10.0.1
                            exit
                            address-range 10.10.0.11 10.10.0.110 failover local
                            address-range 10.10.0.111 10.10.0.210 failover remote
                        exit
                    exit
```

The subnet and pool definitions on P-3 are as follows:

```
# P-3
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "dhcp-2" create
                    use-gi-address scope pool
                    pool "pool-1" create
                        options
                            dns-server 1.1.1.1 1.1.2.2
                            lease-time min 20
                        exit
                        subnet 10.10.0.0/24 create
                            options
                                subnet-mask 255.255.255.0
                                default-router 10.10.0.1
                            exit
```

```
                            address-range 10.10.0.11 10.10.0.110 failover remote
                            address-range 10.10.0.111 10.10.0.210 failover local
                        exit
                    exit
```

Configure Failover

P-2's failover configuration for this example is as follows:

```
# P-2
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "dhcp-1" create
                    failover
                        peer 192.0.2.3 tag "mytag"
                        maximum-client-lead-time min 12
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
```

P-3's failover configuration for this example is as follows:

```
# P-3
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "dhcp-2" create
                    failover
                        peer 192.0.2.2 tag "mytag"
                        maximum-client-lead-time min 12
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
```

Configure the Relay Agent

The DHCP relay agent for service VPRN 1 on PE-1 relays the DHCP messages to and from servers
10.11.11.1 and 10.11.12.1, as follows:

```
# PE-1
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
```

```
                    vrf-target target:64496:1
                    subscriber-interface "int-SUB1" create
                        address 10.10.0.1/24
                        group-interface "int-GRP1" create
                            arp-populate
                            dhcp
                                option
                                    action replace
                                    circuit-id
                                    no remote-id
                                exit
                                server 10.11.11.1 10.11.12.1
                                lease-populate 100
                                client-applications dhcp ppp
                                gi-address 10.10.0.1
                                no shutdown
                            exit
                            sap 1/1/1:1 create
                                sub-sla-mgmt
                                    ---snip---
                                exit
                        exit
                    exit
                exit
```

Debug and Troubleshooting

The following configuration enables debugging for DHCP server *dhcp-1* on VPRN 1 on both P-2 and P-3:

```
debug
    router "1"
        local-dhcp-server "dhcp-1"
            detail-level medium
            mode egr-ingr-and-dropped
        exit
    exit
exit
```

To ensure that the debug output is sent to a session, the following additional configuration is needed:

```
configure
    log
        log-id 1
            from debug-trace
            to session
            no shutdown
        exit
    exit
exit
```

Operation and Verification

The following command shows all DHCP servers for VPRN 1. The DHCP server names are listed together with their administrative state.

```
*A:P-2# show router 1 dhcp servers all
===============================================================
```

```
Overview of DHCP Servers
===============================================================
Active Leases:        2
Maximum Leases:       159744
Router                Server                          Admin State

"DHCP server:  dhcp-1
dropped: Client didn't accept our offer, deleting lease 10.10.0.112
"

7 2017/02/02 15:18:23.70 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
lease added for 10.10.0.12 state=stable
"
```

With one user connected, check the leases on P-2 and P-3, as follows:

```
*A:P-2# show router 1 dhcp local-dhcp-server "dhcp-1" leases

===============================================================================
Leases for DHCP server dhcp-1 router 1
===============================================================================
IP Address      Lease State      Mac Address        Remaining  Clnt Fail
  PPP user name/Opt82 Circuit Id                     LifeTime   Type Ctrl
  User-db/Sticky-lease Hostname
-------------------------------------------------------------------------------
10.10.0.12      stable           00:00:00:01:01:01 0h33m31s    dhcp local
  PE-1|1|int-GRP1|1/1/1:1
-------------------------------------------------------------------------------
1 leases found
===============================================================================
```

```
*A:P-2#
```

```
*A:P-3# show router 1 dhcp local-dhcp-server "dhcp-1" leases

===============================================================================
Leases for DHCP server dhcp-1 router 1
===============================================================================
IP Address      Lease State    Mac Address        Remaining  Clnt  Fail
  PPP user name/Opt82 Circuit Id                   LifeTime   Type  Ctrl
  User-db/Sticky-lease Hostname
-------------------------------------------------------------------------------
10.10.0.12      stable          00:00:00:01:01:01 0h33m5s     dhcp  remote
  PE-1|1|int-GRP1|1/1/1:1
-------------------------------------------------------------------------------
1 leases found
===============================================================================
*A:P-3#
```

For lease 10.10.0.12, failover control is local on P-2 and remote on P-3, and this matches the pool
definitions from the beginning of the configuration section.

The details for the 10.10.0.12 lease can be shown with the following command. The remaining potential
expiration time is ahead of the remaining lifetime, as follows:

```
*A:P-2# show router 1 dhcp local-dhcp-server "dhcp-1" leases 10.10.0.12 detail

```

New clients connecting are allocated addresses from the local address ranges on either P-2 or P-3, even when the server is in the COMM-INT failover state. In this example, both clients are allocated and acknowledged addresses by P-2, as follows:

```
*A:P-2# show router 1 dhcp local-dhcp-server "dhcp-1" leases

===============================================================================
Leases for DHCP server dhcp-1 router 1
===============================================================================
IP Address      Lease State      Mac Address      Remaining  Clnt  Fail
  PPP user name/Opt82 Circuit Id                  LifeTime   Type  Ctrl
  User-db/Sticky-lease Hostname
-------------------------------------------------------------------------------
10.10.0.12      stable           00:00:00:01:01:01 0h19m2s    dhcp  local
  PE-1|1|int-GRP1|1/1/1:1
10.10.0.14      stable           00:00:00:01:01:02 0h10m51s   dhcp  local
  PE-1|1|int-GRP1|1/1/1:1
-------------------------------------------------------------------------------
2 leases found
===============================================================================
*A:P-2#
```

Solving the communications issue is emulated by enabling failover for VPRN-1 on P-3 again:

```
*A:P-3# configure service vprn 1 dhcp local-dhcp-server "dhcp-1" failover no shutdown
```

The debug log on P-2 shows as follows:

```
49 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
RX failover peer state NORMAL
"

50 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
Failover oper state change from COMMUNICATION-INTERRUPTED to PRE-NORMAL
"
```

The debug log on P-3 shows as follows:

```
37 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
```

```
"DHCP server:  dhcp-1
Failover oper state change from SHUTDOWN to STARTUP
"

38 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
Failover oper state change from STARTUP to PRE-NORMAL
"

39 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
Failover oper state change from PRE-NORMAL to NORMAL
"

40 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
lease added for 10.10.0.12 state=stable
"

41 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1

"

42 2017/02/02 16:41:17.60 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
RX failover peer state NORMAL
"
```

The leases allocated by P-2 are synchronized with peer P-3, so they are marked as remote leases, as follows:

```
*A:P-3# show router 1 dhcp local-dhcp-server "dhcp-1" leases

===============================================================================
Leases for DHCP server dhcp-1 router 1
===============================================================================
IP Address      Lease State      Mac Address         Remaining  Clnt  Fail
  PPP user name/Opt82 Circuit Id                      LifeTime   Type  Ctrl
  User-db/Sticky-lease Hostname
-------------------------------------------------------------------------------
10.10.0.12      stable           00:00:00:01:01:01 0h38m37s     dhcp  remote
  PE-1|1|int-GRP1|1/1/1:1
10.10.0.14      stable           00:00:00:01:01:02 0h31m57s     dhcp  remote
  PE-1|1|int-GRP1|1/1/1:1
-------------------------------------------------------------------------------
2 leases found
===============================================================================
*A:P-3#
```

Eventually, P-2's failover state changes to NORMAL again, as follows:

```
57 2017/02/02 16:53:17.85 CET MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp-1
Failover oper state change from PRE-NORMAL to NORMAL
"
```

Conclusion

SR OS supports DHCP server redundancy with failover, providing ISPs the capabilities to offer DHCP
service during a partial power loss or partial network outage.

DHCPv4 Server Basics

This chapter describes DHCPv4 server basics.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and is based on SR OS Release 14.0.R4.

Overview

The Dynamic Host Configuration Protocol for IPv4 (DHCPv4) provides a method for assigning addresses to hosts, and conveys additional configuration data to these hosts.

DHCPv4 allows for a flexible mapping of addresses to devices; for example, identified through their MAC address. While the DHCPv4 server owns and manages addresses organized in one or more pools, a DHCPv4 client obtains an address from the DHCPv4 server, which creates a lease for that client. This provides the client the right to use the address, and the server ensures that the address will not be assigned to other clients.

The DHCPv4 server implemented in SR OS has the following features:

- Address management. The DHCPv4 server keeps track of the used and unused addresses. For the used addresses, lease durations are maintained.
- Configuration parameter management. The DHCPv4 server stores parameters that are to be used by clients when they connect.
- Persistency. When enabled, the DHCPv4 server stores the leases on non-volatile storage so that the leases remain across potential node reboots.
- Failover capability. In dual-homed DHCPv4 server scenarios, a primary DHCPv4 server can take over the responsibility of a failing peer.

The DHCPv4 server failover capability is beyond the scope of this chapter.

In this chapter, when DHCP is mentioned, it implies DHCPv4.

Characteristics

IPv4 addresses and parameters are provided by the DHCP server through the Discover – Offer – Request – Acknowledge (DORA) message sequence as explained in the IPv4 DHCP Hosts chapter.

IPoE clients use DORA messages to communicate with the DHCP server via a relay agent. PPP clients use Link Control Protocol (LCP) and Internet Protocol Control Protocol (IPCP) to communicate with the router, and a local (DHCP) client manages the communication with the DHCP server. IPoE clients and PPP clients are also referred to as native clients and simulated clients, respectively.

When the DHCP server and the relay agent are physically located in the same SR OS node, the server is referred to as a local DHCP server; when they are in different nodes, the server is considered remote. Clients can obtain an address from a local, remote, or (external) third-party DHCP server.

A DHCP server can be used for IPoE users and PPP users simultaneously. A DHCP server must be hosted by a VPRN service or the base router. It can be accessed in either of the following ways; see Figure 25: Accessing a DHCP server:

- When a DHCP user connects, the DORA message sequence running between the DHCP client and the DHCP server also passes through a relay agent, adding and removing user-defined options along the way. The relay agent and the DHCP server can be located in the same or in a different (remote) node.

- When a PPP user connects through LCP and IPCP on a service with an internal DHCP client (local client) configured, the local client manages the DORA communication toward the DHCP server, if the relay agent also has relaying enabled for PPP applications. The local client and the DHCP server can be located in the same or in a different (remote) node.

- When a PPP user connects through LCP and IPCP on a service with local address assignment configured, the DHCP server is accessed through an API-call. See the ESM SLAAC Prefix Assignment via Local Address Server chapter for an explanation of the local address assignment concept, which also applies to PPP.

Figure 25: Accessing a DHCP server
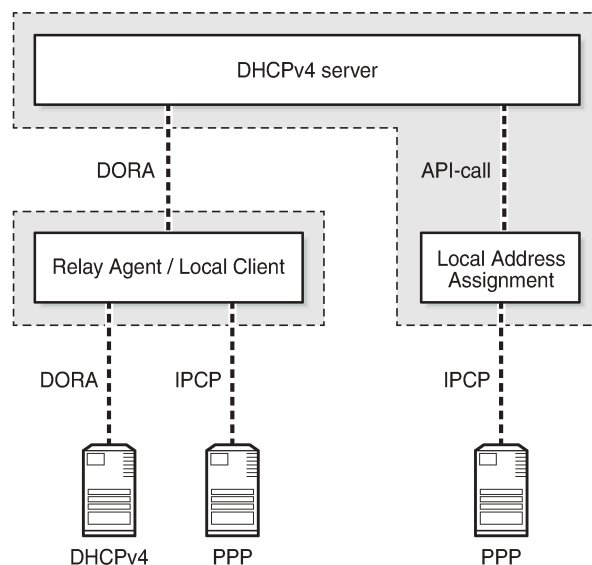

A DHCP server is supported for the routed CO model as well as for the bridged CO model.

A DHCP server can be hosted by the base router or a VPRN service, for public or private use. Because multiple VPRN services can coexist in a single node, each having its own DHCP server, overlapping address ranges are supported.

DHCP Lease

The DHCP server maintains the following data for every allocation request in a lease:

1. client-type (PPP or DHCP)

2. IP address

3. MAC address

4. lease state

5. option 82, if relevant

6. option 60 (vendor class identifier), if relevant

7. lease timer related data

8. persistence key, if applicable

A lease for a single client is in one of the following states:

1. offered: The IP address was offered to the client. The client still has to acknowledge the offer by sending a DHCP request.

2. stable: The IP address is now in use by the client.

3. force-renew-pending: The IP address is in use by the client, but the server sends a DHCP force-renew message to the client, because an option has changed at pool, subnet, or client (via LUDB) level.

4. remove-pending: The IP address is in use by the client, but the corresponding subnet range is deleted. The server sends a force-renew message to the client to force the client to reinitialize in order to get a new IP address.

5. held: The IP address has been used by the client but the lease has expired. The lease is now in the hold list so that the client can get the same IP address upon the next request for a lease.

6. internal: The IP address has been leased via local address assignment and is in use.

7. internal-orphan: The IP address has been leased via local address assignment and is in use. However, there is no configured subnet to which this lease belongs, because it has been removed or because this lease was installed through dual-homing.

8. internal-offered: The IP address has been offered via local address assignment, but the client has not acknowledged the offer yet.

9. internal-held: The IP address has been offered via local address assignment, but the lease is currently not active. The address is now in the hold list so that the same IP address can be offered to the same client upon request of a lease.

10. sticky: The IP address is reserved for the client and will remain reserved until the reservation for it is cleared. The client will get the same IP address upon the next request for a lease.

User Identification

The key to the leases managed by the DHCP server is configured at server level, and can be set to one of the following values (the default value being **mac-circuit-id**):

```
configure (router | service vprn <service-id>) dhcp local-dhcp-server <server-name>
    user-ident {client-id|circuit-id|mac|mac-circuit-id|remote-id}
```

The client ID is DHCP option 61; the circuit ID and the remote ID are sub-options 1 and 2 of DHCP option 82, respectively.

Setting **user-ident** to, for example, **circuit-id** can provide a CPE the same IP address regardless of its MAC address; thereby facilitating CPE replacement scenarios.

Lease Hold Time

The usual way for a DHCP client to indicate to the DHCP server it does not need its lease anymore is by sending a release message to the server; this is referred to as a solicited release.

However, when a client gets disconnected, or loses power, no release message is received by the server and the lease ultimately expires; this is referred to as an unsolicited release.

Without a lease hold timer, a lease is immediately deleted when the client sends the release message, or when the lease expires. The corresponding address is returned back to the pool of free addresses, and can be assigned to different clients. There is no guarantee that a client gets the same address again.

With a lease hold timer defined, a lease (entry) is not immediately deleted when the lease timer expires. Instead, the lease is put in the *held* or *internal-held* state. The lease is deleted when the hold timer expires, and the address is returned back to the pool. When the client connects, renews, or rebinds its lease before the hold timer expires, the client gets its previous lease again. There is no guarantee that the client gets the same address.

A lease hold timer can optionally be defined at the DHCP server level using the following command:

```
configure (router | service vprn <service-id>) dhcp local-dhcp-server <server-name>
    lease-hold-time [days <days>] [hrs <hours>] [min <minutes>] [sec <seconds>]

 <days>              : [0..7305]
 <hours>             : [0..23]
 <minutes>           : [0..59]
 <seconds>           : [0..59]
```

If delayed deletion is also required on reception of a release message (solicited release), use the following command:

```
configure (router | service vprn <service-id>) dhcp local-dhcp-server <server-name>
    lease-hold-time-for solicited-release
```

The same behavior can be applied to IPSec, but that is beyond the scope of this chapter.

Fixed address allocation using DHCP server

Devices using DHCPv4 but still require the same IPv4 (fixed) can be populated in a LUDB associated with a DHCPv4 server. Sometimes these devices are called static devices because they get a fixed IP addressed assigned each time they request a DHCP lease. See the Local User Database for DHCPv4 Server chapter.

The DHCPv4 server also supports lease reservation based on client identifiers provisioned at the time of reservation. After a lease is reserved, it is referred to as a sticky lease in the server.

This sticky lease will subsequently only be assigned to a DHCP client using the same identifiers, though it is not required for such a client to ever exist. Sticky leases are not removed via timeout or DHCP releases but can only be removed via the management interface (SNMP/CLI). Sticky leases are typically not used for devices using DHCPv4 but for applications like vRGW through SNMP.

A sticky lease requires a host name. Identification of the host can be through a MAC address, a circuit ID, a remote ID, or a combination of these. The IP address must be in the range of the parenting pool.

```
tools perform router <router-id> dhcp local-dhcp-server <server-name> pool <pool-name> create-
sticky-lease <hostname>
   [mac <ieee-address>]
   [circuit-id <circuit-id>]
  [client-id <client-id>]
   [requested-ip-address <ip-address>]
   [circuit-id-hex <circuit-id-hex-string>]
   [client-id-hex <client-id-hex-string>]
<hostname> : [32 chars max]
<ieee-address> : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
<circuit-id> : [253 chars max]
<client-id> : [255 chars max]
<ip-address> : a.b.c.d
<circuit-id-hex-st*> : [0x0..0xFFFFFFFF...(max 506 hex nibbles)]
<client-id-hex-str*> : [0x0..0xFFFFFFFF...(max 510 hex nibbles)]
```

Address Allocation for Sticky Leases

Sticky leases provide a static mapping between a hardware address and an IP address. This means that a particular device always gets the same IP address.

A sticky lease requires a host name. Identification of the host can be through a MAC address, a circuit ID, a remote ID, or a combination of these. The IP address must be in the range of the parenting pool.

```
tools perform router <router-id> dhcp local-dhcp-server <server-name>
    pool <pool-name> create-sticky-lease <hostname>
                                [mac <ieee-address>]
                                [circuit-id <circuit-id>]
                                [client-id <client-id>]
                                [requested-ip-address <ip-address>]
                                [circuit-id-hex <circuit-id-hex-string>]
                                [client-id-hex <client-id-hex-string>]
 <hostname>          : [32 chars max]
 <ieee-address>      : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
 <circuit-id>        : [253 chars max]
 <client-id>         : [255 chars max]
 <ip-address>        : a.b.c.d
 <circuit-id-hex-st*> : [0x0..0xFFFFFFFF...(max 506 hex nibbles)]
```

```
<client-id-hex-str*> : [0x0..0xFFFFFFFF...(max 510 hex nibbles)]
```

As an alternative to sticky leases, an LUDB can also be used to provide a static mapping between a hardware address and an IP address. See the Local User Database for DHCPv4 Server chapter. However, hosts added to a local user database can only survive a reboot by saving the configuration through the **admin save** command.

Pool and Subnet Management

The DHCPv4 servers manage IPv4 addresses, subnets, and pools. These are hierarchically related to one another; see Figure 26: Addresses, Subnets, and Pools in a DHCPv4 Server.

Figure 26: Addresses, Subnets, and Pools in a DHCPv4 Server
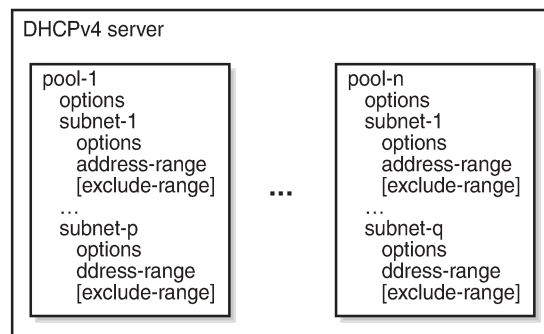

A subnet is identified by an IP address and a netmask, and defines:

- One or more address ranges – The ranges in the subnet that the server can allocate addresses from. Multiple address ranges cannot overlap.

- One or more exclude address ranges (optional) – A sub-range of the preceding range that the server will not allocate addresses from.

- Minimum-free – A notification is generated when the amount of free leases reaches this value (trap and log 99).

- Maximum-declined – Security counter measure, to prevent rogue clients from depleting the subnet. When this maximum value is reached, the oldest declined address will be returned to the pool.

- DHCP options:

    – default-router – up to four addresses can be defined

    – subnet-mask – subnet mask to be used by the clients

    – custom-options – additional options, when required

A pool is identified by name (maximum 32 characters), and defines:

- One or more subnets

- Min-lease-time – requests for a shorter lease time are set to this value; default is 10 min

- Max-lease-time – requests for a longer lease time are set to this value; default is 10 days

- Offer-time – a timer indicating how long an offer remains valid before the address offered is returned to the pool when no Request message is received (default 1 min)

- Minimum-free – a notification is generated when the amount of free leases reaches this value (trap and log 99), with an optional trap when all leases are used

- DHCP options:

  – dns-server – up to four DNS servers can be specified

  – domain-name – the domain to use for DNS resolution when clients provide unqualified host names.

  – lease-renew-time – defines when the client transitions to the renew state (T1)

  – lease-rebind-time – defines when the client transitions to the rebinding state (T2)

  – lease-time – the duration of time that the DHCP server grants to the DHCP client

  – netbios-name-server – defines up to four NetBIOS name servers

  – netbios-node-type – defines the NetBIOS node type (B, P, M, or H)

  – custom-option – additional options, when required

The options added by the DHCP server in response to an allocation request is a combination of the options provided by an LUDB (if applicable), subnet options, and pool options, in this sequence.

Lease Time

A DHCP client can request a specific lease time. The DHCP server checks for this value to be within the bounds as defined at pool level. If the requested lease time is out of bounds, it is set to either the minimum or the maximum value.

If a DHCP client does not request a specific lease time, the DHCP server takes the value from a matching LUDB entry, if available, or from the lease-time parameter defined at pool level, in this sequence. If the pool level lease time is not defined, the maximum lease time is used.

The best practice is to apply the following rule when defining values for the various timers:

```
lease-time > lease-rebind-time > lease-renew-time
```

However, the server does not check consistency of these timers, because the final values offered to the DHCP clients can come from various sources, which are out of the control of the DHCP server.

The local DHCP client always requests a lease time of 1 h to the server for PPP users connecting via the local client.

Address Allocation

When a request arrives at the DHCPv4 server, the server accesses the lease state database using the user ID as a key, checking for an existing lease. If a lease is already available, that lease is used.

Assuming that no lease is present in the lease state database yet, and that the server has a local user database attached, a matching entry is searched for in that local user database; see the Local User Database for DHCPv4 Server chapter.

In terms of address assignment, an LUDB attached to a DHCP server can return:

- an IP address – This (fixed) address is offered to the requester, where this address must not overlap with the address ranges configured in the local DHCP server.

- a Gi address – This address overrules any Gi address received from the requester.

- a pool name – A free address in one of the subnets in that pool is offered. Optionally, a secondary pool can be defined, which is used in case the primary pool is exhausted.

- **use-gi-address [scope <subnet | pool>]** – When the scope is set to subnet, the server offers an address from the subnet that includes the Gi address. When the scope is set to pool, the server offers an address from the subnet that includes the Gi address, or from the other subnets belonging to the same pool.

- use-pool-from-client [delimiter <delimiter>] – The pool name specified in the DHCP client message options and added by the relay agent is used. A free address in one of the subnets in that pool is offered. If two pools are available, the configured delimiting character identifies the splitting-point to find the names of both pools.

If a unique address is found in the LUDB, that address is offered by the server to the requester.

For the general address allocation flow, see Figure 27: General Address Allocation for DHCP. The Local User Database for DHCPv4 Server chapter applies when an LUDB is attached to the DHCP server.

Figure 27: General Address Allocation for DHCP
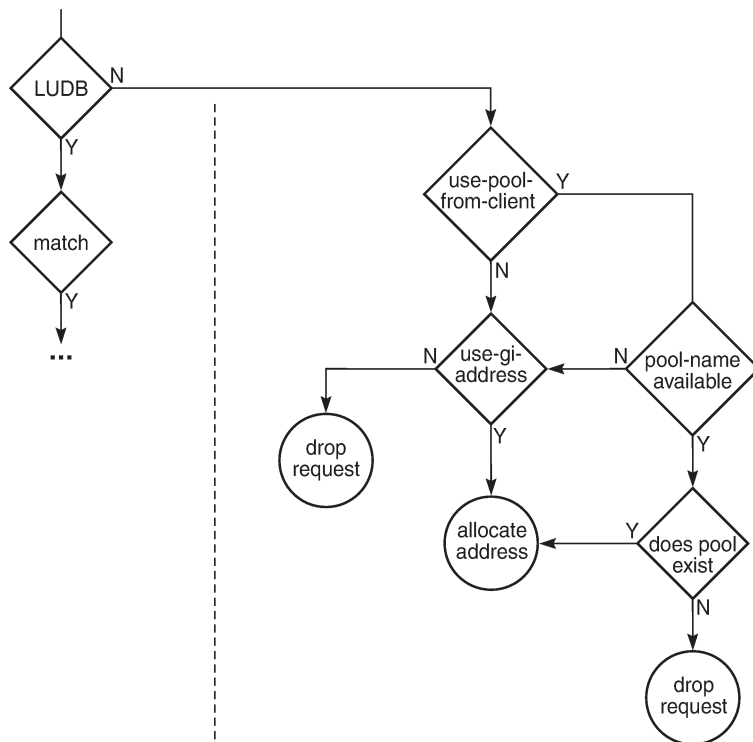

Two additional parameters are available at the server level, controlling which pool and subnet an address is taken from, as follows:

```
[no] use-pool-from-client [delimiter <delimiter>]
     <delimiter>          : [1 chars max]

[no] use-gi-address [scope <scope>]
     <scope>              : subnet|pool
```

With a requester-provided pool name and **use-pool-from-client** active, the server checks for that pool to exist before selecting a free address from one of the subnets in that pool.

With a requester-provided Gi address and **use-gi-address scope subnet** active, a free address is taken from the subnet that includes the Gi address. With **use-gi-address scope pool**, another subnet in the pool is used if the original subnet is exhausted.

The following rules apply to the DHCP server address allocation flow:

- Assume a DHCP server with an LUDB applied, and **use-gi-address** active:
  - A host lookup failure will not result in the request being dropped. The server sends an offer using an address selected based on the Gi address.
  - A successful host lookup, but returning a non-existent pool name, results in the server dropping the request, so no offer is sent.
- Assume a DHCP server without an LUDB applied, but with **use-pool-from-client** and **use-gi-address** active:
  - A requester not providing a pool name results in the server sending an offer using an address selected based on the Gi address.
  - A requester providing a non-existent pool name results in the server dropping the request, so no offer is sent.

Therefore, **use-pool-from-client** takes precedence over **use-gi-address**. The DHCP server selects an address from a pool if that pool exists. If no pool name is provided to the DHCP server, address selection is based on the Gi address, when allowed through the **use-gi-address** directive.

The pool name provided by a relay agent can be a concatenation of two pool names, where the delimiter character is used to split the string apart in the original pool names.

Subnet Draining

When a subnet is put in the drained state through the drain command, no new leases can be assigned from that subnet. Existing leases are cleaned up upon renewal or rebinding of the client. This is useful in renumbering scenarios; see the Configuration section for an example.

Force Renew

Parameter force-renews enables DHCP servers to issue DHCP force-renew messages to stable clients, informing them about a configuration change.

With **force-renews** enabled, the server does not need to wait for a client to pass through its renew or rebind sequence to provide the reconfigured options, speeding up the configuration change.

Changes can be applied at the LUDB-level, subnet level, or pool-level.

DHCP Server Persistency

The DHCP protocol does not have a keep-alive mechanism to detect unavailability. Without precaution, a node reboot causes the loss of the DHCP lease state. Because DHCP clients only attempt a reinitialization sequence after expiration of the lease timer, service outages could become unacceptably long.

The DHCP server lease state can be made persistent across reboots. The lease state is then restored from a persistency file stored on the compact flash. Therefore, DHCP clients will only lose connectivity for the duration of the reboot, and no renew or rebind is needed.

Configuration

Starting a DHCP server up in an SR OS environment requires following steps:

- Configure the DHCP server.
- Configure the interfaces for the DHCP server to listen on.
- Configure one or more relay agents.

The baseline configuration used in this chapter is shown in Figure 28: Baseline Service Configuration.

Figure 28: Baseline Service Configuration
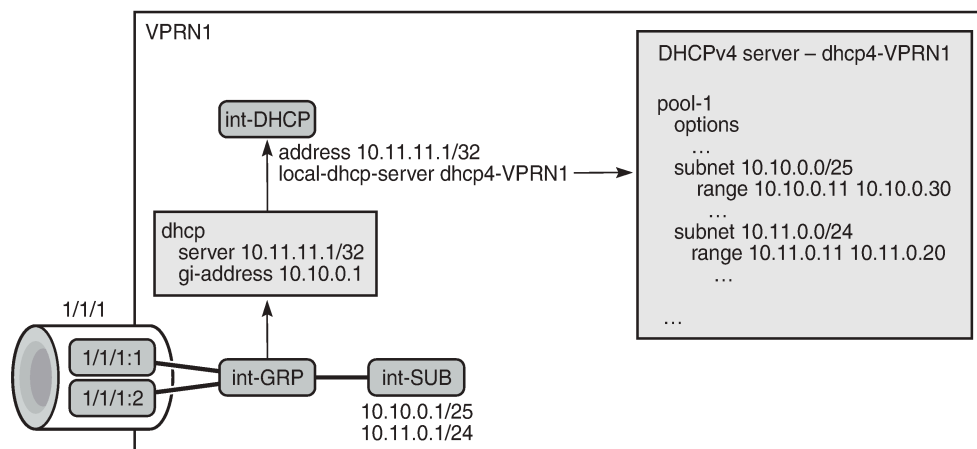

Configure the DHCP Server

One or more DHCP servers can be configured in the base router or in any routed service. VPRN 1 from Figure 28: Baseline Service Configuration has a single DHCP server named *dhcp4-VPRN1*, with two pools: *pool-1* and *pool-2*. The first pool contains two subnets; the second pool contains a single subnet.

Address selection is primarily based on a pool name (**use-pool-from-client**), and secondarily on the Gi address with the scope set to pool (**use-gi-address scope pool**). This means that address selection will be Gi address-based, if no pool name is provided to the server. Having the scope set to **pool** enables the server to allocate addresses from other subnets within the same pool.

Different options and custom options are defined at different levels. All subnets include an address range. Subnet 10.10.0.0/25 also has an exclusion range, as follows:

```
configure
    service
        vprn 1 customer 1 create
            dhcp
```

© 2024 Nokia.

```
                        local-dhcp-server dhcp4-VPRN1 create
                            use-gi-address scope pool
                            use-pool-from-client
                            pool "pool-1" create
                                options
                                    dns-server 1.1.1.1 1.1.2.2
                                    lease-time hrs 2
                                    custom-option 150 address 1.1.1.1
                                exit
                                subnet 10.10.0.0/25 create
                                    options
                                        subnet-mask 255.255.255.128
                                        default-router 10.10.0.1 10.10.0.2
                                        custom-option 130 string "MyOption1"
                                    exit
                                    exclude-addresses 10.10.0.61 10.10.0.70
                                    address-range 10.10.0.11 10.10.0.126
                                exit
                                subnet 10.11.0.0/24 create
                                    options
                                        subnet-mask 255.255.255.0
                                        default-router 10.11.0.1
                                        custom-option 130 string "MyOption2"
                                    exit
                                    address-range 10.11.0.11 10.11.0.20
                                exit
                            exit
                            pool "pool-2" create
                                subnet 10.20.0.0/16 create
                                    options
                                        subnet-mask 255.255.0.0
                                        default-router 10.20.0.1
                                    exit
                                    address-range 10.20.0.21 10.20.0.120
                                exit
                            exit
                            no shutdown
                        exit
                    exit
                exit
            exit
    exit
```

Configure the DHCP Interface

The DHCP server needs to be listening on one or more interfaces. In the example from Figure 27: General Address Allocation for DHCP, the DHCP server is associated with interface *int-DHCP*, with loopback address 10.11.11.1, as follows. The DHCP server cannot be applied to a group interface.

```
configure
    service
        vprn 1 create
            interface "int-DHCP" create
                address 10.11.11.1/24
                local-dhcp-server "dhcp4-VPRN1"
                loopback
            exit
        exit
    exit
exit
```

Configure Relay Agents

The configuration of the DHCP server must align with the configuration of the relay agents for the server to assign addresses correctly. For example, defining the server to allocate addresses based on a pool name, but not providing a pool name toward the server, might not provide the expected result, because this will not necessarily lead to addresses being assigned and offered to clients.

The DHCP relay agent is configured in the dhcp context, as follows:

- **gi-address** – the gateway IPv4 address used by the relay agent

- **server** – up to 8 DHCP servers can be defined by their IPv4 address; only 10.11.11.11 is used in this example

- **client-applications dhcp ppp** – the DHCP server will allocate addresses for DHCP and PPP clients

- **option** – the options added/removed to/from messages toward the server. In the example, the circuit-id, the remote-id, and the pool-name are added.

- **trusted** – this parameter ensures that DHCP messages with option 82 included and the gi-address set to zero are being processed instead of being dropped

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "int-SUB" create
                group-interface "int-GRP" create
                    dhcp
                        option
                            action replace
                            circuit-id
                            remote-id
                            vendor-specific-option
                                pool-name
                            exit
                        exit
                        server 10.11.11.1
                        lease-populate 100
                        client-applications dhcp ppp
                        gi-address 10.10.0.1
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

Configure DHCP Server Persistency

The following configuration stores the DHCP server lease-state persistency file on cf1:

```
configure
    system
        persistence
            dhcp-server
                location cf1:
            exit
        exit
```

```
    exit
exit
```

The persistency file is pre-allocated, providing space for the maximum number of allowed leases, which
avoids file system space issues during normal operation, as follows:

```
*A:PE1>file cf1:\ # dir

Volume in drive cf1 on slot A has no label.

Volume in drive cf1 on slot A is formatted as FAT32

Directory of cf1:\

            2 File(s)             254338048 bytes.
            1 Dir(s)            7759888384 bytes free.

*A:PE1>file cf1:\ #
```

A message is issued to log-id 99 to indicate that the persistence file is ready for use, as follows:

```
*A:PE1# show log log-id 99

===============================================================================
Event Log 99
===============================================================================
Description : Default System Log
Memory Log contents  [size=500    next event=10722  (wrapped)]
10721 2016/09/21 12:44:58.24 CEST WARNING: SYSTEM #2037 Base dhcp-server Persistence Report
"Persistency event: dhcp-server persistence file ready for use"
```

The **tools dump persistence summary** command provides persistency information. The following
example shows that the file cf1:\dhcp_serv.006 is used for storing persistency records for the DHCP server:

```
*A:PE1# tools dump persistence summary
===============================================================================
Persistence Summary on Slot A (active)
===============================================================================
Client          Location             #Registrations   File State
                Avg Nr Fragments     #Entries         Subsystem State
                File Fill Level      #Entries Queued
-------------------------------------------------------------------------------
dhcp-server     cf1:\dhcp_serv.006   5                ACTIVE
                1.0                  5                OK
                0%                   0
-------------------------------------------------------------------------------
Total for cf1:    3% in use

*A:PE1#
```

Persistency records are identified using the persistence key. This key is part of the lease state. The
following command shows the persistence key for lease 10.11.0.14:

```
*A:PE1# show router 1 dhcp local-dhcp-server "dhcp4-VPRN1" leases 10.11.0.14 detail

===============================================================================
```

```
Lease for DHCP server dhcp4-VPRN1 router 1
===============================================================================
IP-address                   : 10.11.0.14
Lease-state                  : stable
Lease started                : 2016/10/17 15:28:36

---snip---

User-db Address Type         : N/A
Persistence Key              : 0x00000004

===============================================================================
*A:PE1#
```

The DHCP server lease state records can be shown using the following command. This example shows
the record for key 0x00000004:

```
*A:PE1# tools dump persistence dhcp-server record 0x00000004
---------------------------------------
Persistence Record

 sticky name:
*A:PE1#
```

DHCP server lease state persistency is typically used together with subscriber management persistency if
the DHCP server and subscriber management functions are managed by the same network node; see the
IPv4 DHCP Hosts chapter.

Configure a Sticky Lease

The following command creates a sticky lease with name me-010101, using MAC address
00:00:00:01:02:02 and IP address 10.11.0.20:

```
*A:PE1# tools perform router 1 dhcp local-dhcp-server "dhcp4-VPRN1" pool "pool-1" create-
sticky-lease me-010202 mac 00:00:00:01:02:02 requested-ip-address 10.11.0.20
```

```
======================================================================
Sticky lease creation result
======================================================================
Result                   : Success
IP-address               : 10.11.0.20
Lease-state              : sticky
Lease started            : 2016/10/17 17:07:00
Remaining LifeTime       : N/A
Sticky-lease Host Name   : me-010202
MAC address              : 00:00:00:01:02:02
Persistence Key          : N/A
======================================================================
*A:PE1#
```

No user database may be assigned to the DHCP server to create sticky leases.

A **clear** command can be used to delete a sticky lease, as follows:

```
clear router 1 dhcp local-dhcp-server "dhcp4-VPRN1" sticky-leases hostname "me-010202"
```

Operation and Verification

The following command shows all DHCP servers defined in the system. The maximum and active number of leases are shown. The router and services where the DHCP servers are hosted are listed, together with the server name and an indication whether this server is in- or out-of-service.

```
*A:PE1# show router dhcp servers all

===============================================================
Overview of DHCP Servers
===============================================================
Active Leases:     5
Maximum Leases:    159744

Router            Server                    Admin State
---------------------------------------------------------------
Service: 1        dhcp4-VPRN1               inService
===============================================================
*A:PE1#
```

The following command shows all leases currently allocated by DHCP server dhcp4-VPRN1 in VPRN-1. In this example, the leases for the DHCP and PPP clients are all "stable". Sticky leases are always shown, even when they are not online.

```
*A:PE1# show router 1 dhcp local-dhcp-server "dhcp4-VPRN1" leases

======================================================================

-------------------------------------------------------------------------------
===============================================================================
*A:PE1#
```

The following configuration enables debugging for DHCP server *dhcp4-VPRN1* on VPRN 1:

```
debug
    router "1"
        local-dhcp-server "dhcp4-VPRN1"
            detail-level high
            mode egr-ingr-and-dropped
        exit
    exit
exit
```

To ensure that the debug output is sent to a session, the following additional configuration is needed:

```
configure
    log
        log-id 1
            description "Send debug log to the current telnet/ssh session"
            from debug-trace
            to session
            no shutdown
        exit
    exit
exit
```

With this configuration, the following output is shown when the IPoE host with MAC address 00:00:00:01:01:01 connects:

```
13 2016/10/17 18:51:12.30 CEST MINOR: DEBUG #2001 vprn1 DHCP server

"
```

Renumbering – Subnet Mask Change

The baseline configuration has the subnet 10.10.0.0/25 defined, providing address space for up to 126 addresses. The range that the server can take free addresses from starts at 10.10.0.11, and ends at 10.10.0.126, excluding the 10.10.0.61 to 10.10.70 sub-range.

Assume that subnet 10.10.0.128/25 was removed from a different BNG, and now can be used in this BNG. This subnet can be aggregated with the 10.10.0.0/25 network to become subnet 10.10.0.0/24. At the same time, the requirement is to not disrupt services for already connected users.

The following steps are required at the DHCP server:

- ensure that **no force-renews** is active
- delete the original subnet
- create the new subnet

Preventing the DHCP server from sending force-renew messages is important so that already connected users do not lose their connection, as follows:

```
*A:PE1# configure service vprn 1 dhcp local-dhcp-server dhcp4-VPRN1 no force-renews
```

The following command deletes the original subnet:

```
*A:PE1# configure service vprn 1 dhcp local-dhcp-server "dhcp4-VPRN1"
                                   pool "pool-1" no subnet 10.10.0.0/25
```

Leases are not deleted when the subnet is deleted; their status changes from *stable* to *removePending*, as follows:

```
*A:PE1# show router 1 dhcp local-dhcp-server "dhcp4-VPRN1" leases

===============================================================================
Leases for DHCP server dhcp4-VPRN1 router 1
===============================================================================
IP Address      Lease State       Mac Address        Remaining  Clnt  Fail
  PPP user name/Opt82 Circuit Id                      LifeTime   Type  Ctrl
  User-db/Sticky-lease Hostname
-------------------------------------------------------------------------------
10.10.0.11      removePending     00:00:00:01:01:01 1h57m25s    dhcp  local

10.10.0.12      removePending     00:00:00:03:01:01 0h57m30s    ppp   local
  PE1|1|int-GRP|1/1/1:1
-------------------------------------------------------------------------------
2 leases found
===============================================================================
*A:PE1#
```

This status change is also shown in the debug log, as follows:

```
132 2016/10/14 14:10:57.66 CEST MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp4-VPRN1

"

135 2016/10/14 14:10:57.66 CEST MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  dhcp4-VPRN1
lease 10.10.0.12 scheduled for removal
"
```

Users trying to renew or connect will not get an address as long as no new subnet is defined.

Create the new 10.10.0.0/24 subnet, with the new address range starting at 10.10.0.11 and ending at 10.10.0.254, as follows. The original exclusion range still applies, but a new exclusion address 10.10.0.129 is added, to be described later:

```
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server dhcp4-VPRN1 create
                    use-gi-address scope pool
                    no force-renews
                    pool "pool-1" create
                        options
                            dns-server 1.1.1.1 1.1.2.2
                            lease-time hrs 2
                            custom-option 150 address 1.1.1.1
                        exit
                        subnet 10.10.0.0/24 create
                            options
                                subnet-mask 255.255.255.0
                                default-router 10.10.0.1
                            exit
                            exclude-addresses 10.10.0.61 10.10.0.70
                            exclude-addresses 10.10.0.129 10.10.0.129
                            address-range 10.10.0.11 10.10.0.254
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

Leases that were in use before return to the *stable* state, if they are not in the exclusion range, as follows:

```
*A:PE1# show router 1 dhcp local-dhcp-server "dhcp4-VPRN1" leases

===============================================================================
Leases for DHCP server dhcp4-VPRN1 router 1
===============================================================================

10.10.0.12      stable           00:00:00:03:01:01 0h49m48s    ppp   local
  PE1|1|int-GRP|1/1/1:1
```

```
-----------------------------------------------------------------------
2 leases found
=======================================================================
*A:PE1#
```

The following command adds the 10.10.0.129/25 address to the *int-SUB* subscriber interface, so that offers in the 10.10.0.128/25 range will not get dropped by the relay agent. Any address in the 10.10.0.128/25 subnet could be used; the lowest one is used in this example. Because this address is in use by the subscriber interface, it must be added to the exclusion list in the DHCP server, as follows:

```
*A:PE1# configure service vprn 1 subscriber-interface int-SUB address 10.10.0.129/25
```

This configuration ensures service continuity for already connected subscribers. They will get their new /24 subnet when they renew or rebind their lease. No change is needed at the relay agent.

Merging the two subnets at the subscriber interface is only possible with a service interruption, because the subscriber interface addresses cannot be deleted when leases are in use. Also the Gi address configured in the dhcp context must be deleted.

```
*A:PE1>config>service>vprn>sub-if# no address 10.10.0.1/25
INFO: PIP #1398 Cannot delete/change address when managed ARPs or leases defined for this
 subnet exist - 1 managed-arps or leases exist
*A:PE1>config>service>vprn>sub-if#
```

To also merge the subnets at the subscriber interface, all the leases in these subnets must be deleted. When the address defined at the subscriber interface is also used as the Gi address by the relay agent, the Gi address must be removed first. Then, the subscriber interface address can be deleted and recreated with the correct netmask. Also, the Gi address can be redefined after that. The changes at the DHCP server are similar to the ones defined previously.

Renumbering – Subnet Migration

The following changes to the baseline configuration have to be made to support the migration of DHCP clients from the 10.10.0.0/25 and 10.11.0.0/24 subnets to the 10.12.0.0/20 subnet. For that purpose, the 10.10.0.0/25 and the 10.11.0.0/24 subnets have the keyword **drain** added, so that leases in the corresponding address ranges will not be extended.

This new 10.12.0.0/20 subnet has a new subnet mask, a new default router, and three address ranges. New clients connecting will automatically get addresses from this new subnet. To ensure existing clients will not lose their connection, the **use-gi-address scope** is set to **pool**, so that they get a new lease from the new subnet when renewing or rebinding.

In scenarios where lease times are long (an order of magnitude of months or even years), it can take a considerable time before all clients have a lease in the new subnet. Having DHCP clients supporting force-renew can help speed up the migration process. The following configuration has force-renews enabled.

Address 10.12.0.1 is used as the default router for this subnet, so this address is added to the *int-SUB* subscriber-interface. This address will later be used as the Gi address.

```
configure
    service
        vprn 1
            dhcp
                local-dhcp-server "dhcp4-VPRN1" create
                    use-gi-address scope pool
                    force-renews
```

```
                        pool "pool-1" create
                            options
                                dns-server 1.1.1.1 1.1.2.2
                                lease-time hrs 2
                            exit
                            subnet 10.10.0.0/25 create
                                drain
                                options
                                    subnet-mask 255.255.255.0
                                    default-router 10.10.0.1
                                exit
                                address-range 10.10.0.11 10.10.0.12
                            exit
                            subnet 10.11.0.0/24 create
                                drain
                                options
                                    subnet-mask 255.255.255.0
                                    default-router 10.10.0.1
                                exit
                                address-range 10.11.0.11 10.11.0.254
                            exit
                            subnet 10.12.0.0/20 create
                                options
                                    subnet-mask 255.255.240.0
                                    default-router 10.12.0.1
                                exit
                                address-range 10.12.0.10 10.12.12.255
                                address-range 10.12.13.1 10.12.14.255
                                address-range 10.12.15.10 10.12.15.254
                            exit
                        exit
                        no shutdown
                    exit
                exit
                subscriber-interface "int-SUB"
                    address 10.12.0.1/20
                exit
            exit
        exit
exit
```

The following command shows that the original subnets are in the drained state:

```

*A:PE1#
```

Because the DHCP server is configured with force-renew, connected clients are sent a force-renew message. In response, the client tries to extend its lease by sending a request message using the current address. The DHCP server sends a negative-acknowledgement (NAK) to the requesting client, because the subnet is in the draining state. This forces the client to go through the DHCP initialization process; a new DORA message sequence is initiated. Therefore, the client gets a free address in the new subnet, with a new netmask, and a new default router, as follows. The same DNS servers are offered, because these pool options were not changed.

```

```

This lease will be deleted when the lease expires.

The relay agent can then have the Gi address updated (10.12.0.1) and the old subnets can be removed from the group interface.

Conclusion

SR OS supports DHCPv4 servers on any routing instance (VPRN or base router), offering pool, subnet, and address management, combined with configuration parameter management and persistency.

Diameter Application NASREQ

This chapter provides information about Diameter Application NASREQ.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 19.10.R1.

> **Note:**
> This chapter covers the Diameter NASREQ application in combination with the Diameter base protocol implementation that is available from SR OS Release 16.0.R4 onward (configured in the aaa CLI context as diameter node). The legacy Diameter base implementation (configured in the aaa CLI context as diameter-peer-policy) is supported in maintenance mode only, without any further feature enhancement planned. Nokia recommends using or transitioning to the new Diameter base protocol implementation. See also the Diameter Base Protocol: Establishing a Diameter Peer Connection chapter of this Advanced Configuration Guide

Overview

NASREQ is defined in RFC 7155, *Diameter Network Access Server Application*, and uses the Diameter base protocol defined in RFC 6733, *Diameter Base Protocol*. The purpose of NASREQ in SR OS is to provide subscriber authentication and authorization. NASREQ provides functionality that is also available via RADIUS but uses the Diameter protocol instead.

NASREQ complements the other Diameter applications supported in SR OS:

- Gx provides advanced authorization capabilities for subscribers and usage monitoring, and interfaces with a Policy and Charging Rules Function (PCRF).
- Gy or Diameter Credit Control Application (DCCA) provides on-line charging functionality, and interfaces with an On-line Charging Server (OCS).
- NASREQ provides subscriber authentication and authorization, and interfaces with a AAA server.

These three Diameter applications use the Diameter base protocol, which is described in the Diameter Base Protocol: Establishing a Diameter Peer Connection chapter of this Advanced Configuration Guide. That chapter also describes the configuration of the Diameter base protocol, which is very similar for all supported Diameter applications, and is not repeated in this chapter.

When a subscriber connects to the BNG, NASREQ is triggered, as would have been the case with RADIUS authentication. Figure 29: NASREQ trigger shows a sample call flow for NASREQ and Gx

applications when an IPoE IPv4 subscriber session connects. The supported NASREQ messages are Authentication and Authorization Request (AAR) and Authentication and Authorization Answer (AAA), and the BNG assumes that the AAA server does not maintain session state. Therefore, there is no need for the BNG to send a message to the AAA server to indicate when the subscriber has ended the session. The BNG negotiates with the AAA server that it expects a stateless behavior by sending the Auth-Session-State AVP with value NO_STATE_MAINTAINED (1) as defined in RFC 6733, and the AAA server must confirm that by sending back the AVP with the same value.

Figure 29: NASREQ trigger

al_0804
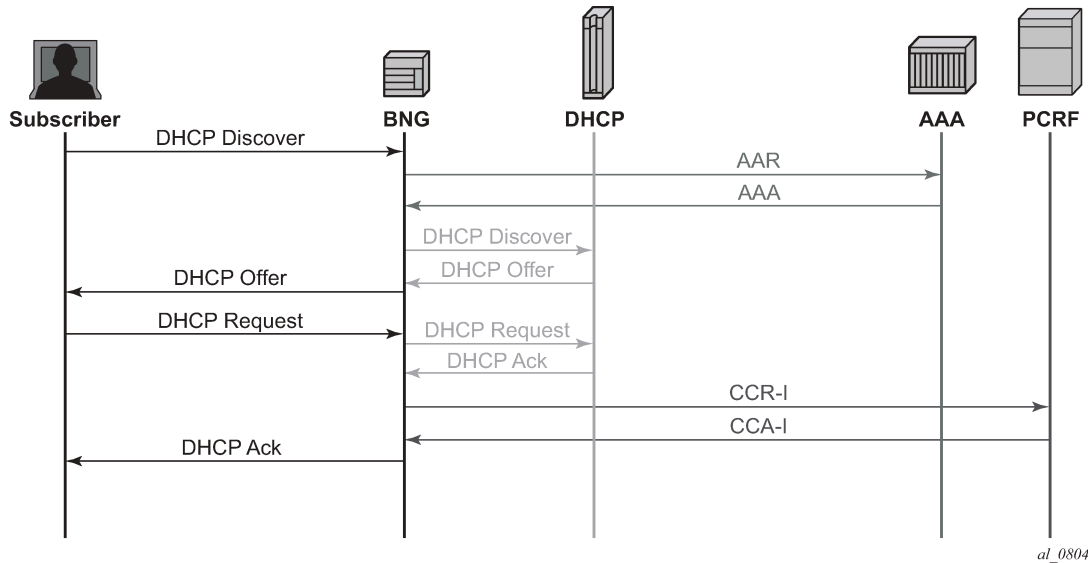

As shown in Figure 29: NASREQ trigger, NASREQ is triggered when the DHCP discover is received, while Gx, using the Credit Control Request (CCR-I) and Credit Control Answer (CCA-I) messages, is triggered at the end, after the IP address allocation.

Supported NASREQ AVPs in AAA are listed in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide*, and include AVPs for subscriber identification, profiles, service selection, address allocation, and so on.

All the NASREQ AVPs are also supported by RADIUS, and their meaning is described in the *7450 ESS, 7750 SR, and VSR RADIUS Attributes Reference Guide*.

Some AVPs, such as SLA profile and subscriber profile strings can be obtained from both NASREQ in the authentication phase and from Gx in the authorization phase. In this case, the last received value from Gx is used for the subscriber session creation.

The AAA server authenticates a subscriber based on a password. For IPoE subscribers, the password is configured in the BNG because DHCP cannot provide a subscriber password, and for PPP, the authentication is performed through PAP or CHAP. PPPoE PADI authentication via NASREQ is not supported in SR OS.

Configuration

The configuration of NASREQ authentication is performed in four steps:

1. Configure a Diameter node

2. Configure a Diameter application policy.

3. Assign the Diameter application policy.

4. Apply a Python policy (optional).

In the first step, the Diameter node configures the Diameter base protocol and is described in the Diameter Base Protocol: Establishing a Diameter Peer Connection chapter. As explained in this chapter, a Diameter peer can support multiple applications, such as NASREQ and Gx:

```
# show aaa diameter-node "bng-gx.realm-1.com" routing-table

===============================================================================
Routes
===============================================================================
Realm-Name
          Application    Pref. Id  Server-Identifier
-------------------------------------------------------------------------------
realm-2.com
          nasreq gx     10    1   dra-1.realm-2.com
realm-2.com
          nasreq gx     20    2   dra-2.realm-2.com
-------------------------------------------------------------------------------
No. of routes: 2
===============================================================================
```

For the example in this chapter, a direct connection exists between the Diameter NASREQ client (BNG) and two NASREQ servers (aaa-1 and aaa-2):

```
configure
    aaa
        diameter
            node "bng-nasreq.nokia.com" create
                peer index 1 "aaa-1.nokia.com" create
                    address 2001:db8:2:6::1
                    preference 10
                    no shutdown
                exit
                peer index 2 "aaa-2.nokia.com" create
                    address 172.16.7.2
                    preference 20
                    no shutdown
                exit
            exit
        exit
    exit
```

```
# show aaa diameter-node "bng-nasreq.nokia.com" peers

===============================================================================
Peers
===============================================================================
Host identity                     Status       Default Preference Active
-------------------------------------------------------------------------------
aaa-1.nokia.com                   I-Open       No      10         Yes
aaa-2.nokia.com                   I-Open       No      20         Yes
-------------------------------------------------------------------------------
No. of peers: 2
===============================================================================
```

```
# show aaa diameter-node "bng-nasreq.nokia.com" routing-table

===============================================================================
Routes
===============================================================================
Realm-Name
          Application   Pref. Id  Server-Identifier
-------------------------------------------------------------------------------
nokia.com
          nasreq        10    1   aaa-1.nokia.com
nokia.com
          nasreq        20    2   aaa-2.nokia.com
-------------------------------------------------------------------------------
No. of routes: 2
===============================================================================
```

When the transport connection for one of the peers is down, the remaining peer is used for authentication. When multiple peers are available, the peer selection is based on the lowest preference value or in case of equal preference, based on the lowest index number. In the example peer aaa-1.nokia.com is used when both peers are up.

In the second step, the Diameter application policy configures the NASREQ application. For example (info detail):

```
configure
    subscriber-mgmt
        diameter-application-policy "diam-nasreq-1"
            description "Diameter application policy - NASREQ"
            application nasreq
            diameter-node "bng-nasreq.nokia.com" destination-realm "nokia.com"
            on-failure failover enabled handling retry-and-terminate
            tx-timer 10
            nasreq
                mac-format "aa:"
                password "YqXTV45qof/gOY1WFhJbKjjkhg==" hash2
                user-name-format mac
                no user-name-operation
                include-avp
                    no called-station-id
                    no calling-station-id
                    circuit-id
                    no imei
                    no nas-port
                    nas-port-id prefix-type none suffix-type none
                    no nas-port-type
                    no rat-type
                    remote-id
                    no user-location-info
                exit
            exit
        exit
    exit
```

A Diameter application policy handles exact one application: NASREQ, Gx, or Gy. In this example, we use **application nasreq** and configure application specific parameters in the **nasreq** context.

A Diameter node is configured in the application policy to select the diameter routing context in which the NASREQ messages should be forwarded to the AAA server: **diameter-node "bng-nasreq.nokia.com" destination-realm "nokia.com"**. The node is identified with its origin host *"bng-nasreq.nokia.com"* and must be configured in the **aaa** context. The destination realm specifies the realm of the NASREQ server

and is used in the Destination-Realm AVP of the application messages. In the example, client and server are in the same realm.

The **on-failure** session failure handling specifies the Diameter application behavior when no answer is received on a request or an answer is received with a protocol error in the result code (except for DIAMETER_UNABLE_TO_DELIVER (3002) and DIAMETER_TOO_BUSY (3004) that are handled in the Diameter node). Possible configuration options are:

- The subscriber sessions must be authenticated (that is, accepted) in case of failure. NASREQ should not retransmit the AA-Request message.

```
on-failure failover disabled handling continue
```

- The subscriber sessions must be rejected in case of failure. NASREQ should not retransmit the AA-Request message.

```
on-failure failover disabled handling terminate
```

- NASREQ should retransmit the AA-Request and reject the subscriber session when the second attempt also fails (this is the configuration used in the example):

```
on-failure failover enabled handling retry-and-terminate
```

The **tx-timer** is the time that the Diameter application waits to get an answer from the AAA server before applying the configured failure handling. In the example, no **tx-timer** is configured, so the default of 10 seconds applies.

The application specific parameters are configured in the **nasreq** context:

- The format of the MAC address to be used in all NASREQ AVPs with a MAC is configured with the **mac-format** command. The default format is ab:cd:ef:01:02:03

- **password** configures the authentication password to be used for IPoE subscriber sessions. For PPP subscribers sessions, the credentials are provided in the PAP or CHAP authentication.

- the AAA server checks the identity of the subscriber based on the User-Name AVP. For PPPoE subscriber sessions, the PAP/CHAP username is copied in the User-Name AVP. For IPoE subscriber sessions, the username can be configured with the command **user-name-format**. Options for the username format are, for example:

  - MAC address (with or without giaddr)

  - circuit-id from the relay agent information (for example, DHCP Option 82 for IPv4)

  - information from DHCP option 60 and 61 (which contain the Client-id and Vendor-Class information)

  - and NAS port Id.

- For both IPoE and PPPoE subscriber sessions, the username format can optionally be manipulated with the **user-name-operation** command to add, remove, or replace a domain name.

- Several optional AVPs can be included in the NASREQ AA-Request message and are configured in the **include-avp** context. In the example, **circuit-id**, **remote-id**, and **nas-port-id** are added.

In the third and last mandatory step, the Diameter application policy must be applied using the **diameter-auth-policy** *name* command to any of the following:

- a VPRN or IES group interface

- a local user database (LUDB) IPoE or PPP host

- a VPLS capture SAP

- a gtp apn policy

A diameter authentication policy is mutually exclusive with a radius authentication policy:

```
>config>subscr-mgmt>loc-user-db>ipoe>host# auth-policy "auth-policy-1"
MINOR: SVCMGR #1558 cannot configure a nasreq and a radius policy together
```

The fourth optional configuration step enables the manipulation of AA-Request and AA-Answer NASREQ messages with a Python script. A sample script that copies the User-Name AVP into the Subscription-Id AVP (which is not defined for NASREQ) in AA-Request messages is as follows:

```
# show python python-script "nasreq-1" source-in-use

===============================================================================
Python script "nasreq-1"
===============================================================================
Admin state    : inService
Oper state     : inService
Primary URL    : ftp://*:*@10.1.1.1/./python/diameter/nasreq-1.py
Secondary URL  : (Not Specified)
Tertiary URL   : (Not Specified)
Active URL     : primary

-------------------------------------------------------------------------------
Source (dumped from memory)
-------------------------------------------------------------------------------
     1 from binascii import *
     2 from alc import diameter
     3
     4 def getint_b2a_hex(val):
     5     return  int(b2a_hex(val),16)
     6
     7 def byte_to_binary(n):
     8     return ''.join(str((n & (1 << i)) and 1) for i in reversed(range(8)))
     9
    10 def hex_to_binary(h):
    11     return ''.join(byte_to_binary(ord(b)) for b in unhexlify(h))
    12
    13 def checkbitset(byte,index):
    14     return ((byte&(1<<index))!=0)
    15
    16 def checkRequestOrReply():
    17     if checkbitset(int(hex_to_binary(b2a_hex(diameter.flags))),7) is True:
    18         return 'R'
    19     else :
    20         return 'A'
    21
    22 if getint_b2a_hex(diameter.code) == 265 and checkRequestOrReply() == 'R':
    23     try:
    24         username = diameter.get_avps(1,0)[0][1]
    25         if username != "":
    26           diameter.set_grouped_avps(443,0,[('@', {(450,0): [('@','\x00\x00\x00\x04')]},
 (444,0): [('@',str(username))]})])
    27     except Exception, err: print "Python FAILED to fetch username"
===============================================================================
```

Configuration to activate the Python script for the example:

```
configure
    python
```

```
            python-script "nasreq-1" create
                description "Diameter NASREQ - AAR: copy User-Name in Subscription-Id"
                primary-url "ftp://*:*@10.1.1.1/./python/diameter/nasreq-1.py"
                no shutdown
            exit
            python-policy "py-nasreq-1" create
                description "Diameter NASREQ - Python"
                diameter aar direction egress script "nasreq-1"
            exit
        exit
        aaa
            diamater
                node "bng-nasreq.nokia.com" create
                    python-policy "py-nasreq-1"
                    ---snip---
                exit
            exit
        exit
```

The Python policy must be configured in the Diameter node and can act on all Diameter base and application messages forwarded or received on any of the peers in the node. The Python policy defines on which messages a script should be activated. In the example, the script "nasreq-1" operates on the AAR messages in the egress direction. In a similar way, Python scripts can also be applied to AAA messages in the ingress direction.

Troubleshooting

The operational state of the Diameter application policy can be shown with the following show command:

```
# show subscriber-mgmt diameter-application-policy "diam-nasreq-1"

===============================================================================
DIAMETER application policy "diam-nasreq-1"
===============================================================================
Description                 : Diameter application policy - NASREQ

===============================================================================
* indicates that the corresponding row element may have been truncated.
```

Diameter debugging is split between node and application level:

```
debug
    diameter
        application
            policy "diam-nasreq-1"
                session-messages
            exit
        exit
        node "bng-nasreq.nokia.com"
            peer "aaa-1.nokia.com"
            exit
            peer "aaa-2.nokia.com"
            exit
        exit
```

```
        exit
```

In this chapter, the Diameter application level debugging for application messages is explained as well as application message routing errors that are reported in the node level debug. When a Python script is active for the node, the debug messages are logged after Python processing.

The **session-messages** option configured in the diameter application policy debug enables debug output for all Diameter application messages for the specified application policy. For a NASREQ application policy, this includes AA-Request and AA-Answer messages. By default, application error conditions are also logged in the debug output. Debug for application error conditions can be disabled with the debug option **no on-error** at the application or at the policy debug context.

To enable debug for the Python script that manipulates the NASREQ messages, use this debug configuration:

```
debug
    python
        python-script "nasreq-1"
            script-all-info
        exit
    exit
exit
```

Following is a debug output example of a new IPoE subscriber setup: a DHCP Discover is received on a capture SAP, followed by the Diameter NASREQ AAR and AAA authentication messages. The Python script debug output shows that AVP 443 (Subscription ID) is added which is also visible in the AAR message debug (logged after the Python script is executed):

```

```

Let's consider a failure scenario, for example a configuration error in the diameter application policy where the destination realm for the NASREQ server is incorrect: the *realm realm-1.com* cannot be routed in the node *bng-nasreq.nokia.com*:

```
configure
    subscriber-mgmt
        diameter-application-policy "diam-nasreq-1"
            description "Diameter application policy - NASREQ"
            application nasreq
            diameter-node "bng-nasreq.nokia.com" destination-realm "realm-1.com"
            ---snip---

# show aaa diameter-node "bng-nasreq.nokia.com" routing-table

===============================================================================
Routes
===============================================================================
Realm-Name
        Application   Pref. Id  Server-Identifier
-------------------------------------------------------------------------------
nokia.com
        nasreq        10    1   aaa-1.nokia.com
nokia.com
        nasreq        20    2   aaa-2.nokia.com
-------------------------------------------------------------------------------
No. of routes: 2
===============================================================================
```

In this case, the diameter node level debug displays the routing failure:

```
244903 2019/11/27 14:26:48.705 UTC minor: DEBUG #2001 Base SVCMGR

Conclusion

In this chapter the configuration and troubleshooting of the Diameter NASREQ application is described. The NASREQ application provides subscriber authentication and authorization.

Diameter Base Protocol: Establishing a Diameter Peer Connection

This chapter provides information about configuring and troubleshooting the Diameter Base protocol to establish a Diameter peer connection.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This information and configuration in this chapter are based on SR OS Release 19.10.R1.

> **Note:**
> This chapter covers the Diameter base protocol implementation that is available from SR OS Release 16.0.R4 onward (configured in the **aaa** CLI context as **diameter node**). The legacy Diameter base implementation (configured in the **aaa** CLI context as **diameter-peer-policy**) is supported in maintenance mode only, without any further feature enhancement planned. Nokia recommends using or transitioning to the new Diameter base protocol implementation.

Overview

Diameter is an Authentication, Authorization and Accounting (AAA) protocol defined by the IETF in RFC 6733, *Diameter Base Protocol*. While historically wireline access networks were largely based on RADIUS for subscriber authentication, authorization, and accounting, it was decided by 3rd Generation Partnership Project (3GPP) that wireless access networks will be largely based on Diameter. Over time, operators are looking to converge both types of networks, and one of the aspects of this is to replace RADIUS in wireline access networks by Diameter.

Diameter is based on three layers: the transport layer, the Diameter base protocol layer and the Diameter applications as shown in Figure 30: Diameter protocol stack.

Figure 30: Diameter protocol stack
The bottom layer is the transport layer and can be either TCP or SCTP. SR OS supports TCP. The Diameter base protocol implementation in SR OS is based on RFC 6733. The top layer contains the Diameter applications. SR OS supports NASREQ for authentication, Gx for authorization, policy management and usage monitoring and Gy or Diameter Credit Control Application (DCCA) for online charging.

Figure 31: Diameter network topology shows a Diameter network topology that will be used in the configuration examples in this chapter.

A Diameter Client (BNG) is connected via peer-1a and peer-1b to two Diameter Agents (DRA-1 and DRA-2) that provide connectivity to the Diameter Application Servers (PCRF). Via these peers, the BNG can authenticate and perform policy control of subscriber sessions using the NASREQ and Gx applications. The same Diameter Client (BNG) is also directly connected to another Diameter Application Server (OCS) via peer-2. Via this peer, on-line charging can be done for the subscriber sessions using the Gy application.

Figure 31: Diameter network topology
Configuration

The Diameter base protocol and the Diameter applications are configured separately, where the Diameter base protocol must be configured first, and the Diameter applications next. The transport layer configuration is part of the Diameter base protocol layer. This example describes the Diameter base protocol configuration.

The Diameter base protocol and the corresponding transport layer configuration is based on Diameter Nodes. Each Diameter Node represents a Diameter routing instance and contains a list of peers in the routing domain that provide direct or indirect connectivity to application servers.

An example Diameter node configuration that corresponds with the topology in Figure 31: Diameter network topology is shown below.

```
configure
    aaa
        diameter
            node "bng-gx.realm-1.com" create
                description "Authentication and Policy Management"
                ipv6-source-address 2001:db8::2
                source-address 192.0.2.2
                peer index 1 "dra-1.realm-2.com" create
                    address 2001:db8:2:6::1
                    preference 10
                    no shutdown
                exit
                peer index 2 "dra-2.realm-2.com" create
                    address 172.16.7.2
                    preference 20
                    no shutdown
                exit
            exit
            node "bng-gy.realm-1.com" origin-realm "realm-1.com" create
                description "Credit Control"
                router "management"
                peer index 1 "ocs.realm-1.com" create
                    address 192.99.3.0
                    no shutdown
                exit
            exit
        exit
    exit
```

A Diameter node configuration requires a unique origin host as key. The origin host is used in Diameter application policies to associate the application with the node. All Diameter base and application messages forwarded via the peers of that node use the configured origin host in the Origin-Host AVP. The value for the Origin-Realm AVP is by default derived from the configured origin host: the realm is the part of the origin host after the first dot (".") as delimiter or equal to the origin host when it does not contain a delimiter. For example, for **node** "*bng-gx.realm-1.com*": Origin-Host = "bng-gx.realm-1.com", Origin-Realm = "realm-1.com". It is also possible to explicitly configure an origin realm as shown in the example for the **node** "*bng-gy.realm-1.com*".

A node configuration can include a routing context, and an IPv4 and/or IPv6 source address. These parameters are used to establish the TCP transport connection for all peers in the node. The specified source address must be a reachable local interface address in the specified or in the default routing instance. For **node** "*bng-gx.realm-1.com*" in the example, no routing instance is specified. By default, the TCP connections are established in the Base router using the specified source addresses. For **node** "*bng-*

gy.realm-1.com" in the example, the out of band routing instance **router** "*management*" is used to establish the TCP connection of its peer. As no source address is specified, the system will automatically select an interface address, in this case an out of band IP address configured in the Boot Options File (BOF).

Within a Diameter node, up to 5 peers can be configured with an index value between 1 and 5 as key, an IPv4 or IPv6 destination address for the TCP connection, and a mandatory destination host that is used as Destination-Host AVP value for all Diameter base messages on the peer. In a Diameter node, one peer is selected to forward application messages for a specific application session. The other peers provide redundancy when supported by the Diameter application, such as Gy session failover. A Diameter peer for application messages is selected based on following criteria:

1. Forwarding:

   If the application message contains a Destination-Host AVP, select the peer in the peer table with a matching configured destination host. This is the forwarding phase.

2. Routing:

   When the lookup in the peer table fails, perform a lookup in the realm routing table and select the peer with realm name equal to the Destination-Realm AVP in the application message, and with matching application ID. When multiple peers are matched, select in order of priority until a single peer is found:

   a. the peer with the lowest configured preference (default preference is 50)

   b. the peer with the lowest index

3. Default peer:

   When both forwarding lookup in the peer table and routing lookup in the realm routing table were unsuccessful, use the peer configured as **default-peer**. Only a single peer in a node can be configured as a default-peer:

   ```
   >config>aaa>diam>node>peer# default-peer
   MINOR: DIAM #2001 Multiple default peer is not allowed
   ```

For **node** "*bng-gx.realm-1.com*" in the example, peer-1a with index 1 has a configured preference of 10 and peer-2 with index 2 has a configured preference of 20. Diameter Gx application messages will fail the peer table lookup as the destination host of the PCRF will not be present (no direct connection between Diameter client and Diameter application server):

```
# show aaa diameter-node "bng-gx.realm-1.com" peers

===============================================================================
Peers
===============================================================================
Host identity                      Status       Default Preference Active
-------------------------------------------------------------------------------
dra-1.realm-2.com                  I-Open       No      10         Yes
dra-2.realm-2.com                  I-Open       No      20         Yes
-------------------------------------------------------------------------------
No. of peers: 2
===============================================================================
```

Instead a realm routing table lookup is performed to find the peer for forwarding the application messages. In this case peer-1a (dra-1.realm-2.com) is selected based on the matching destination realm (realm-2.com), application ID (Gx) and the lower preference value:

```
# show aaa diameter-node "bng-gx.realm-1.com" routing-table

===============================================================================
```

```
Routes
==============================================================================
Realm-Name
        Application    Pref. Id  Server-Identifier
------------------------------------------------------------------------------
realm-2.com
        nasreq gx      10    1    dra-1.realm-2.com
realm-2.com
        nasreq gx      20    2    dra-2.realm-2.com
------------------------------------------------------------------------------
No. of routes: 2
==============================================================================
```

The realm routing table is populated based on the Origin-Realm AVP and Application-Id AVP received in
the Capability Exchange Answer message together with the configured index and preference values.

Note that Diameter answer messages do not rely on peer or realm routing table lookups. Answers are
forwarded over the same route in the reverse direction of the matching requests. This is achieved with a
transactional cache in each traversed Diameter node, using the Hop-by-Hop AVP to match requests with
answers.

When enabling the peer (no shutdown), the system tries to establish the transport TCP connection. Once
the TCP session is up, the system starts a Diameter Capability Exchange using the configured Diameter
identity (Origin-Host and Origin-Realm AVPs) and advertising support for all SR OS Diameter applications
in Application-Id AVP's (NASREQ, Gx, and Gy). When the Origin-Host AVP in the received CEA message
corresponds with the destination host configured for the peer (case insensitive) and at least one application
in the CEA is common with the SR OS advertised applications, then the peer moves to the I-Open state (I
from Initiator). An example of a Capability Exchange is illustrated in detail in the troubleshooting section.

Optionally, a connection and a watchdog timer can be configured in the Diameter node:

```
configure
    aaa
        diameter
            node "bng-gx.realm-1.com" create
        connection-timer 30
        ---snip---
        peer index 1 "dra-1.realm-2.com" create
            connection-timer 30
            watchdog-timer 30
            ---snip---
```

- **connection-timer**

  The connection timer or Tc timer controls the frequency at which a transport connection is attempted to
  be established. The default value is 30 seconds. This timer can be configured per node to be used by
  all peers or overridden per peer.

- **watchdog-timer**

  The watchdog timer controls the frequency at which Device-Watchdog-Request messages are
  transmitted to the peer, and is called the Tw timer in RFC 3539, *Authentication, Authorization and
  Accounting (AAA) Transport Profile*. A small timer results in a faster detection of a peer failure at the
  expense of generating more messages. The timer is configured per peer and its default value is 30
  seconds.

A Python policy can be configured in the Diameter node to manipulate Diameter messages transmitted to
and/or received on its peers.

```
configure
```

```
        aaa
            diameter
                node "bng-gy.realm-1.com" origin-realm "realm-1.com" create
                    python-policy "py-diameter-1"
                        ---snip---
                    exit
            exit
        exit
```

Manipulating Diameter messages, such as changing the content or format of AVPs using Python is out of the scope of this chapter.

By default, Diameter messages are sent with a DSCP set to AF41. The DSCP value can be changed with the sgt-qos configuration:

```
# configure router sgt-qos application diameter dscp "nc1"
```

SR OS uses TCP as transport and the TCP destination port number is fixed to the standard Diameter base protocol port 3868. The source port is randomly chosen from the ephemeral port range.

Troubleshooting

The status and statistics of the Diameter peers can be verified with following show commands:

```
# show aaa diameter-node "bng-gx.realm-1.com" peers

===============================================================================
Peers
===============================================================================
Host identity                        Status      Default Preference Active
-------------------------------------------------------------------------------
dra-1.realm-2.com                    I-Open      No      10         Yes
dra-2.realm-2.com                    I-Open      No      20         Yes
-------------------------------------------------------------------------------
No. of peers: 2
===============================================================================
```

```
# show aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com"

===============================================================================

Application message request      0                    0
Application message answer       0                    0

Last cleared time: N/A
===============================================================================
```

To clear the peer statistics, use following command:

```
# clear aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com" statistics
```

Diameter debugging is split between node and application level:

```
debug
    diameter
        application
            policy "diam-nasreq-1"
                session-messages
            exit
        exit
        node "bng-gx.realm-1.com"
            peer "dra-1.realm-2.com"
                peer-to-peer
            exit
        exit
    exit
exit
```

In this chapter, the Diameter base protocol debugging for peer messages is explained, configured at the node level debug. When a Python script is active for the node, the debug messages are logged after Python processing.

To debug the Diameter base protocol messages for **peer** "*dra-1.realm-2.com*", use the following debug commands:

```
debug
    diameter
        node "bng-gx.realm-1.com"
            peer "dra-1.realm-2.com"
                peer-to-peer
            exit
        exit
    exit
```

```
exit
```

The **peer-to-peer** option enables debug output for all Diameter base messages of the specified peer: Capabilities Exchange, Device Watchdog and Disconnect Peer messages. By default, error conditions are also logged in the debug output. Debug for error conditions can be disabled per Diameter node or per peer with the debug option **no on-error**. Errors reported at the node level include Diameter base errors that are unrelated to a peer, such as a routing problem for a Diameter application message. Errors reported at the peer level include all errors that occur after peer selection and peer connection errors.

Let's start with the peer connection in Closed state (remote end rebooting):

```
*A:pe2# show aaa diameter-node "bng-gx.realm-1.com" peer "dra-1.realm-2.com"

===============================================================================
Peer "dra-1.realm-2.com"
===============================================================================
Index                      : 1
Status                     : Closed

===============================================================================
```

The **Connection timer (s)** field in above peer details output show that in 18 seconds, a new connection attempt will be made, followed by a Capabilities Exchange when successful. The transmitted Capabilities-Exchange-Request (CER) and received Capabilities-Exchange-Answer (CEA) are shown in the debug output:

```

Now let's try to bring up the peer in the **node** *bng-gy.realm-1.com*:

```
# show aaa diameter-node "bng-gy.realm-1.com" peers

===============================================================================
Peers
===============================================================================
Host identity                      Status      Default Preference Active
-------------------------------------------------------------------------------
ocs.realm-1.com                    Closed      No      50         No
-------------------------------------------------------------------------------
No. of peers: 1
===============================================================================
```

Debug is enabled at the peer level for error conditions without the **peer-to-peer** option. Failures are reported, but not all transmitted and received peer messages.

```
debug
    diameter
        node "bng-gy.realm-1.com"
            peer "ocs.realm-1.com"
            exit
        exit
    exit
exit
```

The Diameter server is provisioned with an origin host different from the configured destination host for the peer, resulting in a failure and peer reset:

```
234330 2019/11/22 14:57:32.272 UTC minor: DEBUG #2001 management DIAMETER

```

Events

Following events are defined for the Diameter base protocol:

```
===========================================================================
Application
 ID#    Event Name                    P   g/s    Logged     Dropped
---------------------------------------------------------------------------
  2007 tmnxDiamMessageDropped          MI  thr        0           0
  2008 tmnxDiamNdPeerStatActiveChanged MI  thr       46           0
===========================================================================
```

The *tmnxDiamNdPeerStatActiveChanged* event is generated when the state of a Diameter peer toggles
between active / not active:

```
38080 2019/11/22 14:52:02.269 UTC MINOR: DIAMETER #2008 management peer state change
"DIAMETER node bng-gy.realm-1.com, peer ocs.realm-1.com is active"
```

The *tmnxDiamMessageDropped* event is generated when Diameter base drops a malformed message.

Conclusion

As a result of fixed mobile network convergence, Diameter is used in fixed access networks as an alternative for Radius based AAA. Diameter peering provides reliable and secure transport with peer redundancy. Its functionality is defined in a base Diameter protocol specified in RFC 6733. Various applications can be layered on top of base Diameter and they can utilize the robust transport capabilities that Diameter provides.

ESM Basics

This chapter provides information about Enhanced Subscriber Management.

Topics in this chapter include:

* Applicability
* Overview
* Configuration
* Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 11.0.R4.

Overview

Subscriber management in general includes the following functions:

* subscriber host authentication, identification, addressing, authorization and accounting:
  * authentication – Check whether the subscriber host is allowed access via a Local User Data Base (LUDB) or via a RADIUS server.
  * identification – Fetch the data to use for the subscriber host, including the definition of the subscriber-ID.
  * addressing – Fetch the address information to use, IPv4 and/or IPv6.
  * authorization – Check what the subscriber host is allowed to do.
  * accounting – Both off-line charging (RADIUS and XML) and on-line charging (RADIUS credit control and Diameter credit control application) are supported.
* subscriber host instantiation, based on:
  * a protocol (DHCP, PPPoE/oA/oEoA or ARP) for dynamic hosts, and started through a trigger packet.
  * a static configuration for static hosts.
* subscriber QoS - Ensure per service and per application SLAs, based on:
  * the overall subscriber rate
  * subscriber profiles
  * service level agreement profiles
* subscriber security:
  * Avoid malicious access through anti-spoofing and based on access control lists (ACLs) / IP-filters.
  * DDOS mitigation.

- subscriber persistency – The subscriber state is written to flash-disk (a.k.a. persistent data) and automatically restored on node reboot.

- subscriber resiliency – The subscriber state is retained in case of a node failure in redundant environments, through Multi Chassis Synchronization (MCS).

- subscriber troubleshooting, using:

  - OAM test.

  - mirroring.

  - debugging and event logging.

Enhanced Subscriber Management (ESM) implies subscriber management functions are applied at subscriber level. Subscriber hosts are created, and all of the features listed above apply.

Basic Subscriber Management (BSM) implies subscriber management functions are applied at SAP level. Only a subset of the functions listed above apply.

This example gives an overview of the ESM data required to perform subscriber management functions, and how the ESM data is organized.

The following terminology is used extensively in Triple Play Service Delivery Architecture (TPSDA) and is key to understanding ESM:

- device

- subscriber host

- subscriber

A device is equipment located at the customer premises. Example devices are computers, smartphones, set-top boxes, etc including the Residential Gateway (RGW) providing the connection towards the Internet. The RGW is connected to the access network using an XDSL-connection, a PON-connection, and so on.

A subscriber is a collection of subscriber hosts connected to a single RGW. The subscriber is identified by its subscriber ID, a character string of 32 characters maximum which is used for administrative purposes.

Unlike devices, which are physical entities, subscribers and subscriber hosts are logical entities. These are created dynamically and resources are allocated when a device connects to the network and becomes active.

The following host types are recognized by the Broadband Network Gateway (BNG):

- DHCP hosts

- PPPoE hosts

- ARP hosts

The BNG uses the combination of following parameters to uniquely identify a single subscriber host:

- SAP ID

- IP address

- MAC address

- session ID (PPPoE only)

Multiple subscriber hosts can be associated with a single device.

Figure 32: Bridged RGW Scenario shows a bridged RGW scenario. Subscriber-1has two devices, device-1 and device-2. Device-1 is a dual stack PPPoE device and is assigned an IPv4 address for host-1 and an

IPv6 SLAAC prefix for host-2, both running over a single PPPoE session. Device-2 is a single stack IPoE device and is assigned an IPv4 address for host-3.

Figure 32: Bridged RGW Scenario
Figure 33: Routed RGW Scenario shows a routed dual stack RGW scenario. Subscriber-2 has two devices but they are hidden behind the RGW. The IP-addresses used by these devices are not known by the BNG. The RGW contains three hosts:

- Host-1 is assigned an outside IPv4 address, which the RGW uses for Network Address Translation (NAT).

- Host-2 is assigned an IPv6 wan host address or SLAAC prefix, which the RGW uses towards the outside network.

- Host-3 is assigned an IPv6 prefix for prefix delegation, which the RGW uses for allocating IPv6 addresses to IPv6 capable devices in the home network.

Figure 33: Routed RGW Scenario
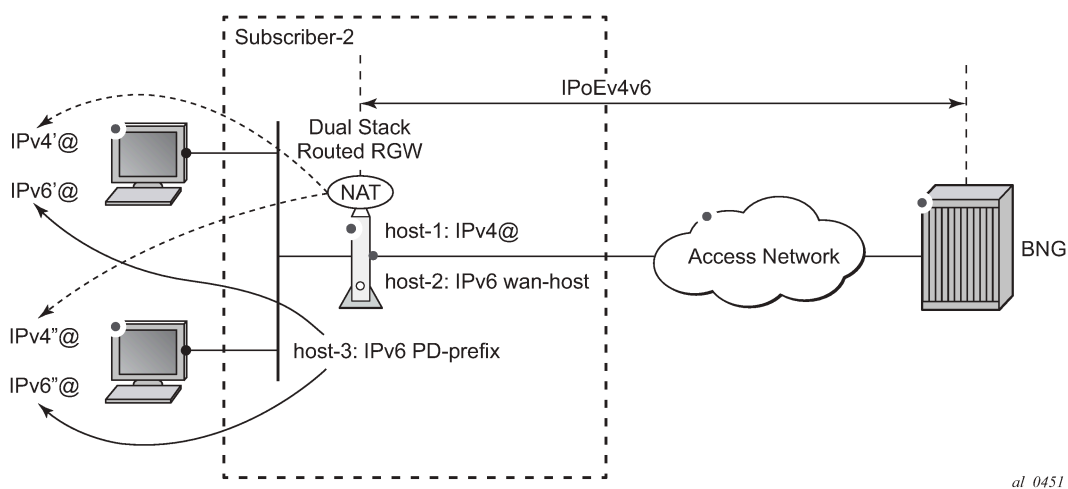

Detailed information on both scenarios can be found in ESMv6: IPoE Dual Stack Hosts and the ESMv6: PPPoE Dual Stack Hosts respectively.

Configuration

Figure 34: SLA-Profile and Sub-Profile shows two objects closely related to subscribers and subscriber hosts:

- SLA profile

- Subscriber profile

Figure 34: SLA-Profile and Sub-Profile
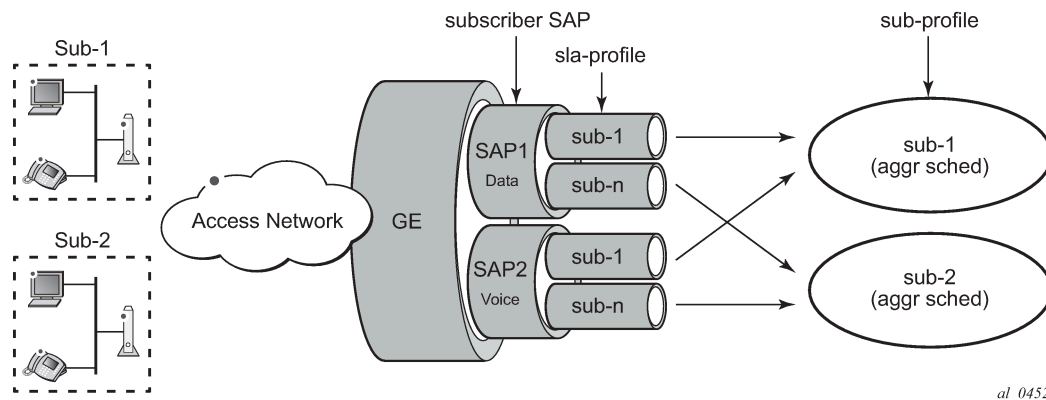

SLA Profile

A Service Level Agreement profile (SLA profile) is a template identified by name (maximum 32 chars) which defines:

- per service QoS settings as part of the QoS policy (ingress and egress):

    – queue/policer

    – scheduling/priority levels

    – bandwidth limits (CIR/PIR) and queue/policer depths (MBS/CBS)

    – classification

    – (re-)marking

- IP-filters for IPv4 and/or IPv6 (ingress and egress):

    – Access Control Lists (ACL)/Filters

- host-limit

- credit-control

An example SLA profile is shown below.

```
configure
    subscriber-mgmt
        sla-profile "sla-prof-1" create
            ingress
                qos 100
                exit
```

```
                    exit
                    egress
                        qos 100
                        exit
                    exit
                exit
```

An instance of the sla-profile is created at host instantiation time.

The SLA profile enforces traffic control on a per service per subscriber basis. When multiple hosts for the same subscriber use the same SLA profile they share the same set of queues/policers as long as they are on the same SAP. The combined traffic for these hosts is controlled by the settings defined in the SLA profile.

Subscriber Profile

The subscriber profile (sub-profile) is a template identified by name (maximum 32 chars) which defines:

- per subscriber QoS settings:
  - aggregate rate (egress only)
  - scheduler policy (ingress and egress)
  - policer control policy (ingress and egress)
- the accounting profile (RADIUS or XML)
- multicast parameters (igmp-policy, etc.)
- Network Address Translation (NAT) parameters
- the ANCP (Access Node Control Protocol) parameters
- the default sla-profile mappings
- etc.

An example subscriber profile is shown below.

```
configure
    subscriber-mgmt
        sub-profile "sub-prof-1" create
            ingress
                policer-control-policy "pol-ctrl-1"
                exit
            exit
            egress
                scheduler-policy "down-1"
                exit
            exit
        exit
```

An instance of the sub-profile is created at host instantiation time.

The sub-profile enforces traffic control on a per subscriber basis. he aggregate traffic of all hosts of a particular subscriber is controlled by the settings defined in the sub-profile, as long as the subscriber hosts are terminated on the same card.

QoS details are out of the scope of this example.

Subscriber SAP

A subscriber SAP is a SAP in a VPLS (Bridged CO model, which is not covered), VPRN or IES service (both in the Routed CO model) on which the queues/policers and other resources are allocated and de-allocated on a per subscriber basis.

A static SAP is a subscriber SAP when sub-sla-mgmt is enabled and becomes operational when in the no shutdown state. Multiple subscribers can connect through this SAP simultaneously when multi-sub-sap is enabled.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    sap 1/1/1:101 create
                        description "data SAP for DLSAM-1"
                        sub-sla-mgmt
                            multi-sub-sap 400
                            ---snip---
                            no shutdown
                        exit
                    exit
```

Single SAP parameters (profiled-traffic-only and non-sub-traffic) are taken into account only when multi-sub-sap is left at its default of 1.

Subscriber Host Identification and Instantiation

The general subscriber host identification (authentication) process is depicted in Figure 35: Subscriber Host Identification and Instantiation Process and encompasses fetching the ESM data for a connecting device.

Figure 35: Subscriber Host Identification and Instantiation Process
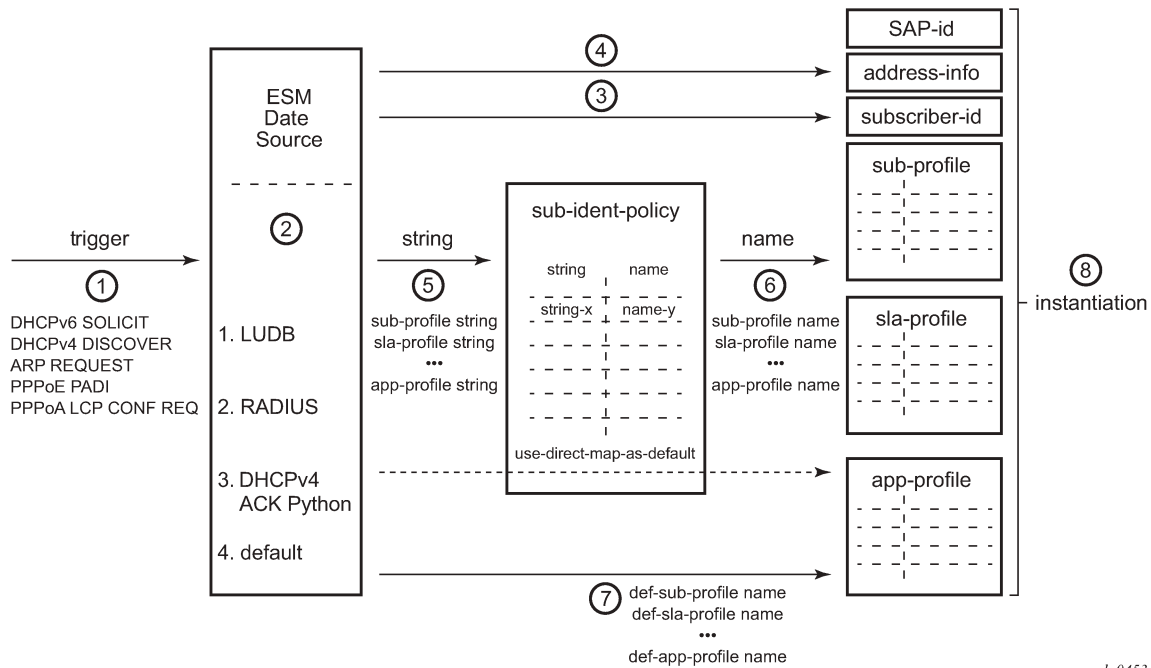

al_0453

ESM data is organized as a set of profiles which control the behavior of individual subscribers and subscriber hosts.

Static hosts are instantiated using the manually provisioned ESM data.

For dynamic hosts, the host identification and instantiation process is started by a trigger message (1 in Figure 35: Subscriber Host Identification and Instantiation Process) which can be one of the following:

- DHCPv4 DISCOVER
- DHPCv6 SOLICIT
- PPPoE PADI
- PPPoA LCP Configuration Request
- ARP REQUEST

The following types of ESM data are distinguished as mandatory or optional ESM data.

Mandatory ESM data is:

- address information (IPv4 and/or IPv6)
- subscriber ID
- sub-profile data
- sla-profile data

Optional ESM data includes:

- app-profile data
- inter-dest-id
- Access Node Control Protocol (ANCP) data

A host is instantiated only when all mandatory ESM data is available for that host.

The ESM data sources (2) are consulted in following predefined sequence:

1. LUDB

2. RADIUS

3. DHCPv4 ACK python

4. Default

The ESM data sources provide:

- the subscriber-id (3)

- the profile strings (5)

Address information (IPv4 and/or IPv6) (4) can be provided by:

- the LUDB or RADIUS ESM data sources

- a DHCP server

The LUDB, RADIUS or DHCPv4 ACK python ESM data sources provide profile strings (5) which have a maximum length of 16 characters. They must be translated into profile names (6) which have a maximum length of 32 characters. The profile name is the key to access the actual profile data. The ESM data source *default* directly returns profile names (7), which do not need any translation.

The ESM string to profile name translation is defined in configurable mapping tables which are part of the subscriber identification policy (sub-ident-policy). Mapping tables can be defined for:

- the sub-profile

- the sla-profile

- the app-profile

In case no mapping is needed because the strings and names are set to the same set of values, then a subscriber identification policy is needed with the attribute **use-direct-map-as-default**. (See section Subscriber Identification Policy.)

Note the subscriber-id does not need to be translated.

The instantiation process (8) ensures the subscriber host is created:

- The subscriber host is added to the active subscriber list.

- Resources (queues, policers, filters, etc) are allocated for SLA enforcement.

- Status information is updated.

As a result the system starts forwarding user data to and from that subscriber host.

A subscriber is instantiated as soon as the first subscriber host for this subscriber is instantiated, and deleted when the last subscriber host for this subscriber is deleted.

Subscriber Identification Policy

The subscriber identification policy is identified by name and defines:

- a description (optional)

- the sub-profile map

- the sla-profile map

- the app-profile map (optional)
- the location of a DHCPv4 ACK python script (optional):
  - primary, secondary and tertiary locations are possible
- the DHCP option used to get the identification strings from (optional)

A subscriber identification policy is needed for dynamic hosts only. In that case one of the ESM data sources from Figure 35: Subscriber Host Identification and Instantiation Process is used.

Using a python script for subscriber host identification and instantiation is restricted to IPv4 hosts when triggered by the DHCPv4 ACK message.

The first example has no explicit mappings.

```
configure
    subscriber-mgmt
        sub-ident-policy "sub-id-pol-1" create
            description "direct mapping policy"
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
            app-profile-map
                use-direct-map-as-default
            exit
        exit
```

The second example contains explicit mappings.

```
configure
    subscriber-mgmt
        sub-ident-policy "sub-id-pol-2" create
            description "explicit mapping policy"
            sub-profile-map
                entry key "sub-string-1" sub-profile "sub-prof-1"
                entry key "sub-string-2" sub-profile "sub-prof-2"
                entry key "sub-string-3" sub-profile "sub-prof-3"
            exit
            sla-profile-map
                entry key "sla-string-1" sla-profile "sla-prof-1"
                entry key "sla-string-2" sla-profile "sla-prof-2"
                entry key "sla-string-21" sla-profile "sla-prof-20"
                entry key "sla-string-22" sla-profile "sla-prof-20"
            exit
        exit
```

Note that multiple strings can be mapped to the same profile, as the example above shows.

The subscriber identification policy is applied at SAP level in the sub-sla-mgmt context, as shown below.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                ---snip---
                group-interface "grp-int-1-1" create
                    ---snip---
                    sap 1/1/1:111 create
                        sub-sla-mgmt
```

```
                                def-sub-profile "sub-prof-1"
                                def-sla-profile "sla-prof-1"
                                sub-ident-policy "sub-id-pol-1"
                                multi-sub-sap 400
                                no shutdown
                            exit
                        exit
                    exit
                exit
```

Combining Multiple ESM Data Sources

Multiple ESM data sources from Figure 35: Subscriber Host Identification and Instantiation Process can be consulted for instantiating a subscriber host. When multiple ESM data sources are used, they are accessed in following sequence:

1. LUDB

2. RADIUS

3. DHCPv4 ACK python

4. Default

The outputs from the different data sources are merged. Data is appended as explained in the Flexible Authentication Model in ESM section of this guide.

Default ESM Data Profiles

Default ESM data profiles are used when the other ESM data sources (LUDB, RADIUS, DHCPv4 ACK python) only provide partial data, or no data at all. The default data complements the data provided by the data sources in order to get the full set of ESM data needed for host instantiation.

Default ESM data profiles are defined per SAP in the sub-sla-mgmt context, as shown in the following example.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1-1"
                group-interface "grp-int-1-1"
                    sap 1/1/1:111 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            sub-ident-policy "sub-id-pol-1"
                            multi-sub-sap 400
                            no shutdown
                        exit
```

Address Information

Address information for both IPv4 as well as IPv6 is provided to subscriber hosts using a DHCPv4/v6 server, an LUDB or a RADIUS server.

The IPv4 and IPv6 address information encompasses:

© 2024 Nokia.

Use subject to Terms available at: www.nokia.com/terms.

- IPv4 and/or IPv6 address/mask and prefix

- default gateway (in IPv6 announced through RA messages)

- DNS server(s)

- etc

The following cases can be distinguished to obtain an IPv4 or IPv6 address/prefix upon LUDB/RADIUS authentication:

- LUDB/RADIUS returns a unique IPv4/IPv6 address/prefix, directly.

- LUDB/RADIUS returns a pool name, which then is resolved to a unique IP address/prefix through:

  – a DHCP server

  – or Local Address Assignment (LAA)

- LUDB/RADIUS does not return a unique IPv4/IPv6 address/prefix, nor a pool-name. In that case a DHCP server is contacted using a gi-address or link-address to obtain an address/prefix.

Configuring a DHCP server is out of the scope of this example.

Direct Address Assignment using LUDB/RADIUS

In the example shown in Figure 36: Direct Address Assignment using LUDB/RADIUS, a unique IP address is retrieved from LUDB/RADIUS. No interaction with a DHCP server is needed at all.

This scenario applies to IPoE (DHCPv4, DHCPv6 and SLAAC) as well as to PPPoE (IPCP, DHCPv6, and SLAAC).

Figure 36: Direct Address Assignment using LUDB/RADIUS
DHCP clients require a DHCP server address in the DHCP messages, and as such a **server-id** (IPv6) and/or an **emulated-server** (IPv4) must be configured, see the example below. IPCP and SLAAC do not require a DHCP server so these commands can be omitted.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                ---snip---
                group-interface "grp-int-1-1" create
                    ipv6
```

```
            dhcp6
                ---snip---
                proxy-server
                    server-id duid-ll
                    client-applications dhcp ppp
                    no shutdown
                exit
        exit
    exit
    arp-populate
    dhcp
        proxy-server
            emulated-server 10.1.1.254
            no shutdown
        exit
        ---snip---
    exit
```

The emulated-server address must be a unique address in one of the subnets allowed on this subscriber
interface.

Indirect Address Assignment using a DHCP server

In the example shown in Figure 37: Indirect Address Assignment using a DHCP Server, the IPv4/IPv6
address/prefix is obtained from a DHCP server, using a pool-name as returned by LUDB/RADIUS.

The DHCP server (DHCPv4/DHCPv6) can be co-located with the BNG node (internal DHCP server) or can
be external to the BNG node.

This scenario applies to both DHCPv4/DHCPv6 as well as to PPP. PPP relies on an internal DHCP client
and communicates with the PPP client through IPCP.

Figure 37: Indirect Address Assignment using a DHCP Server
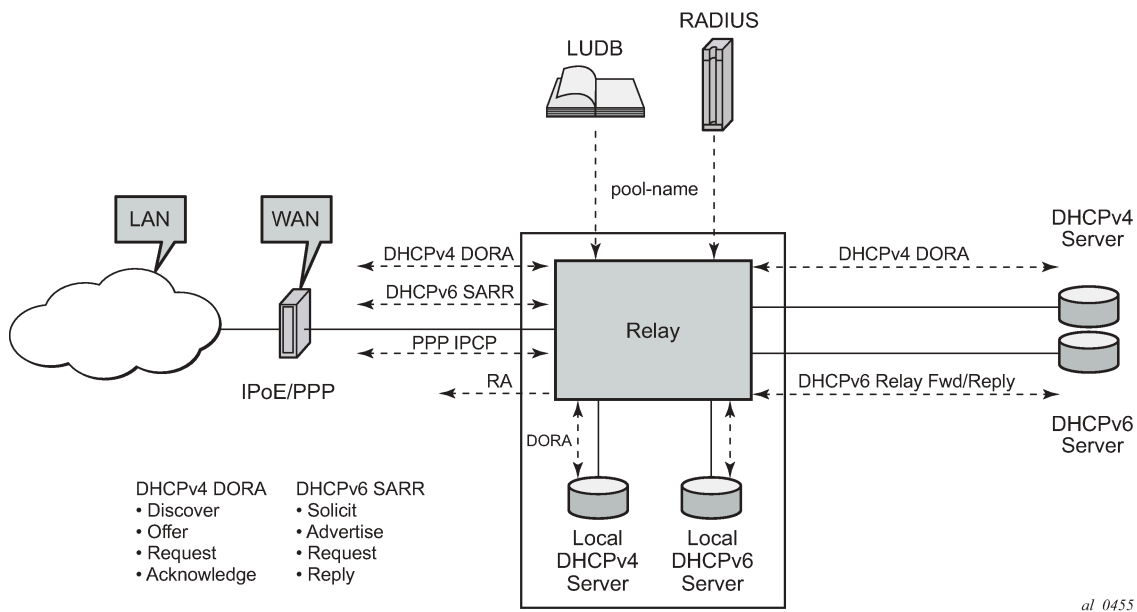

Relaying is configured for IPv4 and for IPv6 separately, at group-interface level.

The DHCPv4 relay agent is configured in the dhcp context:

- **gi-address** – The gateway IPv4-address used by the relay-agent.

- **server** - The DHCP server IPv4-address, 10.11.11.11 in the example.

- **client-applications dhcp ppp**

    – The DHCP server accepts requests for DHCP and for PPP.

- **option** – The options added/removed to/from messages towards the server. In the example the circuit-id, the remote-id and the pool-name are added.

- **trusted** – This parameter ensures that DHCP messages with option 82 included and the gi-address set to zero are being processed instead of being dropped.

The DHCPv6 relay agent is configured in the ipv6 dhcp6 relay context:

- **server** - The DHCP server IPv6 address, 2001:DB8::11 in the example.

- **client-applications dhcp ppp**

The DHCP server accepts requests for DHCP and for PPP.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                ---snip---
                group-interface "grp-int-1-1"
                    ipv6
                        ---snip---
                        dhcp6
                            relay
                                server 2001:DB8::11
                                client-applications dhcp ppp
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        option
                            action replace
                            circuit-id
                            remote-id
                            vendor-specific-option
                                pool-name
                            exit
                        exit
                        server 10.11.11.1
                        trusted
                        lease-populate 100
                        client-applications dhcp ppp
                        gi-address 10.1.1.254
                        no shutdown
                    exit
```

Indirect Address Assignment using LAA

In the example shown in Figure 38: Indirect Address Assignment using LAA LUDB/RADIUS returns a pool-name which is resolved into an IP address using Local Address Assignment (LAA). LAA is implemented

using a procedure call to an internal DHCP server, and not through the typical DHCPv4 DORA or DHCPv6
SARR sequence.

Figure 38: Indirect Address Assignment using LAA
This scenario applies to PPPv4 hosts as well as to IPv6 SLAAC hosts. LAA can also be used to provide
the IA-NA address in DHCPv6 proxy scenarios where an LUDB or a RADIUS server provides an IPv6
Delegated Prefix (Delegated-IPv6-Prefix) and an IPv6 WAN Address Pool (Framed-IPv6-Pool).

LAA is configured at group-interface level and overrules the relay scenario for the IPCP DHCP client (PPP)
when both are configured.

The IPv4 parameters are configured in the local-address-assignment context:

- **server** – The internal DHCPv4 server to contact, identified by name.

- **default-pool** – Defines the pool name to use in case neither the LUDB nor the RADIUS server provides
  a pool-name.

- **client-application** – ppp-v4.

The IPv6 parameters are configured in the local-address-assignment ipv6 context:

- **server** – the DHCPv6 server to contact, identified by name.

- **client-application** – ppp-slaac and/or ipoe-wan.

An example is show below.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                ---snip---
                group-interface "grp-int-1-1" create
                    local-address-assignment
                        server "int-dhcp-v4"
                        client-application ppp-v4
```

```
                                default-pool "pool4-2"
                                ipv6
                                    server "int-dhcp-v6"
                                    client-application ppp-slaac ipoe-wan
                                exit
                                no shutdown
                        exit
```

LAA details are out of the scope of this example.

ESM Data Retrieval Examples

The following ESM data source scenarios are examined below:

- static host ESM data retrieval
- dynamic host ESM data retrieval:
    - RADIUS
    - LUDB + RADIUS access

DHCPv4 ACK python details are out of the scope of this example.

ESM Data Retrieval for Static Hosts

The example below shows the creation of a static host. The IP address is mandatory, a MAC address is optional.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    sap 1/1/1:111
                        description "sap for customer 1"
                        static-host ip 10.1.1.101 create
                            sla-profile "sla-prof-2"
                            sub-profile "sub-prof-2"
                            subscriber 03-7654321
                            no shutdown
                        exit
                    exit
```

Identification is not needed for static hosts: the subscriber-id, sub-profile and sla-profile used, are configured explicitly. Instantiation takes place at host creation time (**no shutdown**).

The following command shows the details for a single static host. The forwarding state is *Not Fwding*, meaning that no traffic can be forwarded to and from that host in this state.

```
 *A:BNG# show service id 1 static-host ip-address 10.1.1.101 detail

ESM Data Retrieval through RADIUS

A RADIUS server can provide ESM data, including:

- subscriber-id

- address information

- sub-profile-string

- sla-profile-string

- etc.

The BNG sends a RADIUS Access-Request including the User-Name attribute identifying the host for authentication purposes. The User-Name format is configurable on the BNG:

- MAC-address

- circuit-ID, remote-ID

- user@domain

- etc.

An excerpt from the Free-RADIUS user file used for this example is shown below. The first line of a block contains the User-Name with the credentials.

```
00:00:00:22:22:22    Auth-Type := Local, Cleartext-Password := ""
      Alc-Subsc-ID-Str = "sub-22",
      Alc-Subsc-Prof-Str = "sub-string-1",
      Alc-SLA-Prof-Str = "sla-string-1"

BSAN64|40|1/1/2:300 Auth-Type := Local, User-Password == "LetMeIn"
```

```
        Alc-Subsc-ID-Str = "subscriber-300",
        Alc-Subsc-Prof-Str = "subpro1-string",
        Alc-SLA-Prof-Str = "slapro1-string",
        Session-Timeout = 600

sub202@provider  Cleartext-Password := "sub202"
        Alc-Subsc-ID-Str = "sub-44",
        Alc-Subsc-Prof-Str = "sub-string-3",
        Alc-SLA-Prof-Str = "sla-string-22",
        Framed-IP-Address = 10.2.1.202,
        Framed-IP-Netmask = 255.255.255.0
```

The lines following the User-Name with the credentials lists the attributes the RADIUS server returns after successfully authenticating the user, and include:

- Alc-Subsc-ID-Str

- Alc-Subsc-Prof-Str

- Alc-SLA-Prof-Str

- Framed-IP-Address

- Framed-IP-Netmask

- etc.

Authentication Policy

An authentication policy is needed for retrieval of the data from a RADIUS server, indirectly indicating the RADIUS server(s) to contact.

The following steps are needed to create an authentication policy:

1. Define one or more RADIUS servers.

2. Define a RADIUS server policy.

3. Define an authentication policy.

1. The example defines a single RADIUS server, indicating the name, the address and the secret to use.

```
configure
    router
        radius-server
            server "server-1" address 192.168.202.84 secret secret-1 create
        exit
```

2. The radius-server-policy refers to the server defined above. In this example the Base router is used to reach the RADIUS server.

```
configure
    aaa
        radius-server-policy "rad-serv-pol-1" create
            description "Radius AAA server policy"
            servers
                router "Base"
                server 1 name "server-1"
            exit
        exit
```

3. The authentication policy specifies to include the circuit-id and the remote-id attributes towards the RADIUS server as well as the radius-server-policy to use. Multiple authentication policies can be defined.

```
configure
    subscriber-mgmt
        authentication-policy "auth-pol-1" create
            pppoe-access-method pap-chap
            include-radius-attribute
                circuit-id
                remote-id
            exit
            radius-server-policy "rad-serv-pol-1"
```

The authentication policy is applied at a group-interface. The example below shows both group interfaces using the same authentication policy.

```
configure
 service
    ies 1
        subscriber-interface "sub-int-1"
            group-interface "grp-int-1-1"
                ---snip---
                authentication-policy "auth-pol-1"
                ---snip---
            exit
            group-interface "grp-int-1-2"
                ---snip---
                authentication-policy "auth-pol-1"
                ---snip---
            exit
```

DHCP Host

The following command shows the strings returned by the RADIUS server for the DHCPv4 host with MAC-address 00:00:00:22:22:22.

```
A:BNG# show service id 1 dhcp lease-state mac 00:00:00:22:22:22 detail

For both the DHCPv4 host as well as the PPPv4 host, the output aligns with the data provided by the RADIUS server and the defined profile maps.

ESM Data Retrieval through a Local User Database

A Local User Database (LUDB) can provide ESM data for DHCP and PPP hosts, including:

- subscriber-id

- address information

- sub-profile string

- sla-profile string

- MSAP service-id

- retail service-id

- etc.

Retrieval of data in an LUDB requires matching criteria, which can be one of the following items, or a combination of the following items, including:

- MAC-address

- circuit-id/remote-id

- username

- SAP-id

- etc.

The example below defines an LUDB named *ludb-1* which matches DHCP hosts by means of MAC address, and PPP hosts by means of username.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            dhcp
                match-list mac
                host "host-121" create
                    host-identification
                        mac 00:00:00:aa:aa:aa
                    exit
                    address 10.1.1.121
                    identification-strings 254 create
                        subscriber-id "sub-121"
                        sla-profile-string "sla-string-3"
                        sub-profile-string "sub-string-2"
                    exit
                    options
                        subnet-mask 255.255.255.0
                        default-router 10.1.1.254
                    exit
                    ipv6-wan-address-pool "pool6-2"
                    ipv6-delegated-prefix-pool "pool6-2"
                    no shutdown
                exit
                host "host-122" create
                    host-identification
                        mac 00:00:00:bb:bb:bb
                    exit
                    auth-policy "auth-pol-1"
                    no shutdown
                exit
            exit
            ppp
                match-list username
                host "host-123" create
                    host-identification
                        username "user@domain"
                    exit
                    address 10.1.1.123/32
                    password pap user
                    identification-strings 254 create
```

```
                        subscriber-id "sub-123"
                        sla-profile-string "sla-string-3"
                        sub-profile-string "sub-string-1"
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

> **Note:**
>
> • The entire LUDB can be disabled.
>
> • Individual host entries can be disabled.

An LUDB can be applied at group interface level in different contexts:

• dhcp

• ipv6 dhcp6

• ppp

• pppoe

For the LUDB to provide ESM data, no authentication policy may be applied at group interface level, and the LUDB itself must be in the no shutdown state.

The following example shows the LUDB named *ludb-1* applied to group-interface *grp-int-1-2* in the dhcp and the pppoe context.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                address 10.1.1.254/24
                address 10.1.2.254/24
                group-interface "grp-int-1-2"
                    dhcp
                        ---snip---
                        gi-address 10.1.1.254
                        user-db "ludb-1"
                        no shutdown
                    exit
                    no authentication-policy
                    sap 1/1/1:121 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            sub-ident-policy "sub-id-pol-1"
                            multi-sub-sap
                            no shutdown
                        exit
                    exit
                    sap 1/1/1:122 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            sub-ident-policy "sub-id-pol-1"
                            multi-sub-sap
                            no shutdown
                        exit
                    exit
```

```
                                    pppoe
                                        session-limit 100
                                        user-db "ludb-1"
                                        no shutdown
                                    exit
                            exit
```

For *host-121*, with MAC-address 00:00:00:aa:aa:aa, all ESM data is provided by the LUDB. The detailed
DHCP lease state shows the actual profile strings, the subscriber-ID and the IP address used. The Lease
Info origin is set to UserDb.

```

LUDB details are out of the scope of this example.

Optional ESM Data

Limits

The maximum number of hosts, subscribers, sessions and leases are checked during the host instantiation process, and can be defined at following levels:

- sla-profile level: host-limit

- sap-level: multi-sub-sap

- group-interface level: lease-populate, session-limit, sap-session-limit

The sla-profile optionally defines a maximum number of hosts allowed by this profile. An example is shown below.

```
configure
   subscriber-mgmt
        sla-profile "sla-prof-3" create
            host-limit 4
            ingress
                qos 100
                exit
            exit
            egress
                qos 100
                exit
            exit
        exit
```

By default only hosts from a single subscriber can connect through a SAP. This condition can be lifted as follows.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"sub-sla-mgmt
                    sap 1/1/1:112 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            sub-ident-policy "sub-id-pol-2"
                            multi-sub-sap
                            no shutdown
                        exit
                    exit
```

The maximum number of leases assigned to subscriber hosts by the DHCP server can be defined at group interface level as follows.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                address 10.1.1.254/24
                group-interface "grp-int-1-1"
                    dhcp
                        proxy-server
                            emulated-server 10.1.1.254
                            no shutdown
                        exit
                        server 10.11.11.1
                        trusted
                        lease-populate 100
                        client-applications dhcp ppp
                        gi-address 10.1.1.254
                        no shutdown
                    exit
```

The maximum number of sessions for PPP as well as for PPPoE, including the sap-session-limit, is also defined at group interface level, as the example below shows.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    ppp
                        session-limit 50
                    exit
                    pppoe
                        session-limit 40
                        sap-session-limit 30
                        no shutdown
                    exit
```

Filtering

Filter policies allow for selectively dropping, forwarding or redirecting ingress/egress traffic. They are also known as access control lists (ACLs) and can optionally be included in the SLA-profile.

An example sla-profile with IP-filters is show below.

```
configure
    subscriber-mgmt
        sla-profile "sla-prof-3" create
            host-limit 4
            ingress
                qos 100
                exit
                ip-filter 1
                ipv6-filter 1
            exit
            egress
                qos 100
                exit
                ip-filter 2
                ipv6-filter 2
            exit
```

Filter policies must be defined before they can be used in an SLA profile.

Accounting

Accounting policies define how to count the traffic for billing purposes on a per service basis. Two types of accounting are available:

• RADIUS accounting

• XML accounting

For RADIUS accounting, the accounting data is stored on the RADIUS accounting server. For XML accounting, the accounting data is stored locally on a flash-disk on the node.

The example below shows the definition of a radius-accounting-policy and reuses the radius-server-policy defined before.

```
configure
    subscriber-mgmt
        radius-accounting-policy "rad-acct-pol-1" create
            host-accounting interim-update
            update-interval 5
            include-radius-attribute
                framed-ip-addr
                sla-profile
                sub-profile
            exit
            radius-accounting-server
                router "Base"
                server 1 address 192.168.202.84 secret secret-1
            exit
            radius-server-policy "rad-serv-pol-1"
        exit
```

The radius-accounting policy is referred to from the SUB profile as shown in the example below.

```
configure
    subscriber-mgmt
        sub-profile "sub-prof-1" create
            radius-accounting-policy "rad-acct-pol-1"
            ingress
                policer-control-policy "pol-ctrl-1"
                exit
            exit
            egress
                scheduler-policy "down-1"
                exit
            exit
        exit
```

For XML accounting, an accounting policy is referred to from the SUB profile.

```
configure
    subscriber-mgmt
        sub-profile "sub-prof-2" create
            accounting-policy 10
            collect-stats
            ingress
                scheduler-policy "sched-up-1"
                exit
            egress
                scheduler-policy "sched-down-1"
                exit
            exit
        exit
```

The **collect-stats** command activates the generation of accounting files.

Accounting policies must be defined before they can be used in a SUB profile.

RADIUS accounting and XML accounting details are out of the scope of this example.

Application Profile

An application profile is needed for supporting Application Assurance.

Traffic is diverted to an MS-ISA MDA which processes the traffic according the application profile, which for that purpose is assigned to:

- an ESM subscriber, or an group of ESM subscribers

- a SAP

- a spoke SDP

ESM subscribers are assigned an application profile either statically or dynamically.

The example below shows the assignment of an application profile to a static host.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    sap 1/1/1:111
                        description "sap for customer 1"
                        static-host ip 10.1.1.101 create
                            app-profile "app-prof-3"
                            sla-profile "sla-prof-2"
                            sub-profile "sub-prof-1"
                            subscriber 03-7654321
                            no shutdown
                        exit
                exit
```

For dynamic hosts, the same rules apply as for the sub-profile scriber and the sla-profile, meaning that the app-profile can be found through:

1. LUDB

2. RADIUS

3. DHCPv4 ACK python

4. Default

The example below shows the assignment of a default application profile at the SAP level.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"sub-sla-mgmt
                    sap 1/1/1:112 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            def-app-profile "app-prof-1"
                            sub-ident-policy "sub-id-pol-2"
                            multi-sub-sap
                            no shutdown
                        exit
                exit
```

Application profiles must be defined before they can be referenced.

Application Assurance and Application Assurance subscribers details are out of the scope of this example.

Intermediate Destinations

An intermediate destination is an aggregation point in the network and identified through the intermediate destination identity (inter-dest-id).

Most typically Access Nodes (ANs) are considered intermediate destinations.

The inter-dest-id is an optional per subscriber attribute.

The intermediate destination is used in the BNG for supporting QoS, as an example:

- By shaping the aggregate rate of all egress traffic of subscribers connected to an AN to prevent congestion of the link towards that AN.

- To ensure fairness amongst the subscriber hosts connected to that AN. For that purpose the inter-dest-id is linked to an hierarchical scheduler via a virtual port (Vport).

The example below shows the assignment of the inter-dest-id to a static host.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    sap 1/1/1:111
                        description "sap for customer 1"
                        static-host ip 10.1.1.101 create
                            inter-dest-id "bsan-1"
                            sla-profile "sla-prof-2"
                            sub-profile "sub-prof-1"
                            subscriber 03-7654321
                            no shutdown
                        exit
                    exit
```

The inter-dest-id does not to be translated.

Intermediate destination details are is out of the scope of this example.

Conclusion

This chapter explains basic ESM concepts including the definition of subscribers and subscriber hosts. The host identification and instantiation process was explained, indicating the mandatory and optional ESM data fetched during the process (address information, sub-profile, sla-profile, app-profile, inter-dest-id, etc.). The address information retrieval process was explained. The different sources from where the ESM data can originate were mentioned, including some examples. Also the sub-ident-policy and the authentication-policy, needed during the identification and instantiation process, are explained in detail.

ESM 128-bit Mode for DHCPv6 IA_NA WAN Hosts

This chapter describes ESM 128-bit Mode for DHCPv6 IA_NA WAN Hosts.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 16.0.R4 and cover both IPoE and PPPoE subscribers.

Basic knowledge of ESM is a prerequisite.

Overview

Nokia Triple Play Service Delivery Architecture (TPSDA) supports both 64-bit and 128-bit WAN mode. This chapter describes 64-bit and 128-bit WAN mode for DHCPv6 IA_NA WAN hosts and provides an example 128-bit WAN mode subscriber interface configuration for IPoE IPv6 hosts.

The 64-bit and 128-bit WAN mode is a creation time configurable parameter on the subscriber interface. The parameter specifies the host addressing schema for a DHCPv6 WAN host (DHCPv6 IA_NA). By default, all subscriber interfaces use the 64-bit WAN mode. This means that each WAN host created on the system would consume an entire /64 prefix. More specifically, the WAN host would construct only one 128-bit address out of the entire /64 prefix. By comparison, the 128-bit WAN mode allows a single 128-bit address for each DHCPv6 WAN host. Therefore, when using DHCPv6 IA_NA, the 128-bit WAN mode reduces IPv6 address consumption. All ESM features are supported regardless of the configured WAN mode.

In 64-bit mode, the subscriber interface expects all WAN hosts to have /64 unique prefixes. The system will only distinguish individual IPv6 subscribers by the first 64 bits of an IPv6 address. When IPv6 WAN addresses are /64 unique, a WAN host consumes an entire /64 prefix (with the exception of IPoE-bridged mode, described later). For example, if the first IPv6 WAN host is assigned an DHCPv6 IA_NA address of 2001::1, the next address must be a 64-bit increment. Therefore, the second IPv6 WAN host must be assigned a DHCPv6 IA_NA address of 2001:0:0:1::1. In this mode, all WAN hosts are assigned a /64 prefix regardless of whether the host is using SLAAC or DHCPv6. This provides the flexibility for allowing the subscriber to choose between using SLAAC or DHCPv6 when assigned a /64 prefix.

The 128-bit mode allows the system to distinguish individual IPv6 WAN hosts using the full 128-bit address. For example, if the first IPv6 WAN host is assigned an address of 2001::1, the next host address can be a 128-bit increment, which is 2001::2. Compared to 64-bit mode, a single WAN host no longer consumes an entire /64 prefix. When the system is operating in 128-bit mode, a /96 prefix is automatically

created in the FIB to assist in subscriber host lookup. Therefore, in 128-bit mode, subnets using a prefix length of 96 or longer are recommended. Within a /96 subnet, about 4 billion IPv6 addresses (WAN hosts) can be supported.

Extra considerations are required for subscriber interfaces operating in 128-bit mode.

- All subscribers within a subscriber interface should use a single /96 prefix (or longer; for example, /97).

- In the case where multiple prefixes are required (for example, service differentiation), Nokia recommends keeping the number of /96 prefixes to a minimum.

- The 128-bit WAN mode can support SLAAC hosts. The system will not derive a /96 prefix from the SLAAC host. However, the system does not allow a SLAAC host and a DHCPv6 IA_NA host to share the same subscriber interface prefix. SLAAC hosts must use a different prefix than a DHCPv6 IA_NA host.

- The routing instance (VPRN or IES) supports a mixture of 64-bit and 128-bit WAN mode subscriber interfaces.

The local DHCPv6 server supports assigning both incremental DHCP IA_NA /64 and /128 addresses. The local DHCP server will determine which subscriber interface the DHCP IA_NA request is from. With this information, the server will automatically determine whether the next incremental /64 or /128 address should be assigned. There is no configuration required on the local DHCP server; this is performed automatically by the server.

In addition, it is possible to use the local DHCP server for DHCPv6 IA_NA address assignment while using AAA for DHCPv6 IA_PD prefix assignment. For this, the local address assignment feature is required (configured under group-interface). The client application is IPoE WAN and the DHCPv6 IA_NA address is assigned via a pool name retrieved from AAA or LUDB. The local address assignment also supports incremental /64 and /128 address assignment. This is also determined automatically by the local DHCP server without requiring any additional configuration.

For IPoE-bridged mode, Nokia recommends using only the 64-bit WAN mode. IPoE-bridged mode allows a single subscriber up to 128 bridge hosts sharing the same /64 prefix. Nokia does not recommend using 128-bit WAN mode when IPoE bridging is required. This is due to the 128-bit WAN mode generating at least one /96 prefix per subscriber. There is a limit of prefixes supported per subscriber interface. In 64-bit WAN mode, the subscriber is assigned an entire /64 prefix, but the mode allows each host to have an incremental 128-bit address.

> **Note:**
> In 64-bit mode, all bridge hosts must use the same SLA profile, while in 128-bit mode, each DHCPv6 IA_NA host can have a unique SLA profile.

Table 1 compares the 64-bit WAN mode with the 128-bit WAN mode.

Table 6: 64-bit WAN Mode Versus 128-bit WAN Mode

	64-bit WAN mode	128-bit WAN mode	Comments
IPv6 WAN hosts	IPv6 WAN hosts must be assigned 64-bit incremental addresses.	IPv6 WAN hosts can be assigned 128-bit incremental addresses.	
DHCPv6 local-dhcp-server	Automatically assigns incremental /64	Automatically assigns incremental /128 addresses to DHCP IA_NA requests.	Requires no configuration.

	64-bit WAN mode	128-bit WAN mode	Comments
	addresses to DHCP IA_NA requests.		
Local-address-assignment for DHCPv6 IA_NA	Automatically assigns incremental /64 addresses to DHCP IA_NA requests.	Automatically assigns incremental /128 addresses to DHCP IA_NA requests.	Local address assignment is used when the local DHCP server is used to assign the DHCPv6 IA_NA addresses while AAA assigns the DHCPv6 IA_PD addresses.
IPoE-bridged-mode	Supported. Recommended mode.

Up to 128 bridge hosts can share the same /64 prefix.

All bridge hosts must share the same SLA profile. | Supported. Not recommended mode.

Up to 128 bridge hosts can share the same /64 prefix.

DHCPv6 IA_NA hosts can have unique SLA profiles

SLAAC hosts must share the same SLA profile. | |
| FIB | No FIB impact. | A host creation will automatically install a /96 FIB entry.

Hosts that share the same /96 will not create new FIB entries.

If all hosts within the same /96 entry are removed from the system, the /96 FIB entry will automatically be removed. | 128-bit WAN mode can impact FIB scaling if used incorrectly.

128-bit WAN mode is intended for deployments where all WAN hosts under a single subscriber interface share a /96 prefix (or smaller). A /96 prefix can serve up to 4 billion WAN subscribers. |

Configuration

Create a 128-bit WAN mode subscriber interface for IPoE IPv6 hosts.

As already indicated, the WAN mode is a creation-time parameter. It is not possible to toggle between 64-bit and 128-bit mode once the subscriber interface is created.

1. Create a subscriber interface as a 128-bit WAN mode interface, as follows:

```
*A:BNG-1>config>service>ies# info
----------------------------------------------
            description "BNG-1"
            subscriber-interface "sub-int-1" wan-mode mode128 create
```

2. Following is the rest of a subscriber management configuration on the BNG. For 128-bit WAN mode, the prefix length for the WAN host is 96. Nokia recommends using prefix length 96 or longer when using 128-bit WAN mode.

```
*A:BNG-1>config>service>ies# info
----------------------------------------------
            description "BNG-1"
            subscriber-interface "sub-int-1" wan-mode mode128 create
                address 10.255.255.253/8
                ipv6
                    subscriber-prefixes
                        prefix 2001:db8::/96 wan-host
                    exit
                exit
                group-interface "group-int-1" create
                    dhcp
                        server 192.168.0.1
                        lease-populate 10
                        client-applications dhcp
                        gi-address 10.255.255.253
                        no shutdown
                    exit
                    ipv6
                        dhcp6
                            proxy-server
                                no shutdown
                            exit
                            relay
                                link-address 2001:db8::
                                server 2001:db9::1
                                client-applications dhcp
                                no shutdown
                            exit
                        exit
                    exit
                    sap 1/1/5:4 create
                        sub-sla-mgmt
                            def-sub-id use-sap-id
                            def-sub-profile "sub-profile-1"
                            def-sla-profile "sla-profile-1"
                            sub-ident-policy "sub-ident-policy-1"
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                exit
            exit
```

With the preceding configuration, the subscriber interface is ready to support 128-bit incremental IPv6 address assignment, as follows:

```
*A:BNG-1> show  service active-subscribers hierarchy

===============================================================================
Active Subscribers Hierarchy
===============================================================================
-- sub_1 (sub-profile-1)
   |
   +-- sap:1/1/5:4 - sla:sla-profile-1
        |
```

```
          +-- IPOE-session - mac:00:00:10:10:13:13 - svc:1
                |
                +-- 2001:db8::1/128 - DHCP6

-- sub_2 (sub-profile-1)
     |
   +-- sap:1/1/5:4 - sla:sla-profile-1
        |
          +-- IPOE-session - mac:00:00:10:10:13:14 - svc:1
                |
                +-- 2001:db8::2/128 - DHCP6

-------------------------------------------------------------------------------
Number of active subscribers : 2
Flags: (N) = the host or the managed route is in non-forwarding state
===============================================================================
```

If the subscriber interface is in 64-bit WAN mode, the system will reject a subsequent subscriber host that requests addresses that overlap with the /64 prefix of existing hosts, as follows:

```
*A:eng-BNG-2>config>service>vprn>sub-if>grp-if>ipv6# show log log-id 99

===============================================================================
Event Log 99
===============================================================================
Description : Default System Log
Memory Log contents  [size=500   next event=367512  (wrapped)]

367507 2018/09/19 20:18:37.656 UTC WARNING: DHCP #2005 IES1 Lease State Population Error
"Lease state table population error on SAP 1/1/5:4 in service 1 - Host with IP 2001:db8::2/
128 and MAC 00:00:10:10:13:14 conflicts with existing host in service 1"
===============================================================================
```

Conclusion

Different operators have unique IPv6 WAN addressing requirements. The 64-bit WAN mode is most suitable for assigning a /64 prefix to a subscriber (WAN host). This mode gives the subscriber flexibility to either use the /64 prefix for SLAAC or one address out of the /64 prefix for a DHCPv6 IA_NA address. The 128-bit WAN mode is for operators who prefer to use DHCPv6 IA_NA addressing. With 128-bit mode, each subscriber is assigned a single 128-bit address, minimizing IPv6 WAN address consumption. By using different WAN modes, addressing scaling and efficiency can be improved.

ESM IPv4: Multicast in a Wholesale/Retail Scenario

This chapter describes ESM IPv4 multicast configurations in a wholesale/retail scenario.

Topics in this chapter include:

* Applicability

* Overview

* Configuration

* Conclusion

Applicability

This chapter applies to SR OS routers, covers multicast in a wholesale and retail scenario for both IPoE and PPPoE subscribers, and was originally written for SR OS Release 11.0.R1. The CLI is updated to Release 15.0.R3.

Overview

Triple Play Service Delivery Architecture (TPSDA) allows operators to integrate High Speed Internet (HSI), voice and video services within a single network. The goal of this configuration example is to provide a walkthrough of a wholesale/retail multicast setup.

There are two wholesale/retail models in TPSDA. In the first model, a retail service instance is co-located with the wholesale service on the wholesale router whereas in the second model, for PPP services only, the retail service is on a separate BNG. Figure 39: Wholesale/Retail Model 1 shows the first model, and consists of two 7750s. The first is a wholesaler Broadband Network Gateway (BNG) with a co-located retail service and the second is a retailer router. Figure 40: Wholesale/Retail Model 2 shows the second model where the retail service is hosted by a separate router and the connection between the wholesale and retail utilizes Layer 2 Tunneling Protocol (L2TP).

Figure 39: Wholesale/Retail Model 1
Figure 40: Wholesale/Retail Model 2
In both models, the 7450 is used as an aggregation switch to aggregate the traffic of the PPPoE and IPoE subscribers. The wholesale router and the retail router are 7750s. The wholesale router is connected to the aggregation switch and to the retail router. The retail router is connected directly to the multicast source. The 7450 can only be an L2TP Access Concentrator (LAC), whereas the 7750 can be a LAC or an L2TP Network Server (LNS).

There are two basic requirements for a subscriber to receive multicast streams. First, the group interface for the subscribers must have IGMP enabled. Second, the Enhanced Subscriber Management (ESM) subscriber must be allowed to receive multicast streams by having IGMP enabled. When both requirements are met, the BNG will process the subscribers' IGMP messages, otherwise, IGMP messages are dropped. All customer premise equipment (CPE) originated IGMP messages are aggregated via the 7450 and passed onto the wholesale BNG. It is always the retail VPRN that processes the IGMP messages. The wholesale VPRN SAPs forward the actual multicast streams.

Configuration

Note that basic knowledge of multicast and ESM is assumed.

ESM Wholesale-Retail Multicast

There are various ways to provide wholesale and retail multicast function.

- For the IPoE and PPPoE Layer 3 wholesale/retail model, the wholesale and the retail services reside on separate VPRNs.
- For the PPPoE Layer 2 wholesale/retail model, L2TP is used.

ESM Layer 3 Wholesale-Retail Multicast

#unique_137/unique_137_Connect_42_d2e4Figure 41: Layer 3 Wholesale/Retail depicts a Layer 3 wholesale/retail scenario for both IPoE and PPPoE. The first BNG contains both the wholesale and retail configuration. There are two options for the retail BNG to deliver the multicast streams to the wholesale BNG:

1. MVPN between the BNGs

or

2. If using a routed interface between the BNGs, multicast routing is required.

This example uses the second option for delivery of the multicast streams in order to keep the configuration simple.

Figure 41: Layer 3 Wholesale/Retail

al_0551
Step 1 - Configure wholesale service on BNG-1

The configuration for the wholesale service on BNG-1 with the group interface added to IGMP is as follows. This configuration applies to both IPoE and PPPoE.

```
# on BNG-1
configure
    service
        vprn 1 customer 1 create
            description "wholesale"
            route-distinguisher 65536:1
            interface "system" create
                address 192.0.2.20/32
                loopback
            exit
            subscriber-interface "sub-vprn-1-ws" create
                unnumbered "system"
                group-interface "grp-vprn-1-ws" create
                    arp-populate
                    dhcp
                        client-applications dhcp ppp
                        no shutdown
                    exit
                    authentication-policy "auth-radius-1"
                    sap 1/1/2:1 create
                        sub-sla-mgmt
                            def-sub-id use-sap-id
                            def-sub-profile "sub-profile-1"
                            def-sla-profile "sla-profile-1"
                            sub-ident-policy "sub-ident-1"
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                    pppoe
                        session-limit 10
                        sap-session-limit 10
                        no shutdown
                    exit
                exit
            exit
            igmp
```

```
                    group-interface "grp-vprn-1-ws"
                        no shutdown
                    exit
                    no shutdown
                exit
                no shutdown
            exit
        exit
 exit
```

Step 2 - Configure retail service on BNG-1

Also on BNG-1, a separate VPRN is configured for the retail provider. The retail configuration is a little
different from the wholesale configuration. The configuration for the retail VPRN with IGMP and PIM
enabled is as follows. This configuration is applicable to both IPoE and PPPoE. The multicast streams
received in the retail VPRN are forwarded to the wholesale VPRN. Other retail VPRNs can offer multicast
streams as well, and the same multicast addresses can be re-used as long as the address is assigned to a
different retail VPRN.

```
# on BNG-1
configure
    service
        vprn 2 customer 2 create
            description "retail"
            route-distinguisher 65536:2
            interface "system" create
                address 172.16.1.1/32
                loopback
            exit
            interface "int-BNG-1-BNG-2" create
                address 192.168.12.1/30
                sap 1/1/1 create
                exit
            exit
            subscriber-interface "sub-vprn-2-rt" \
                        fwd-service 1 fwd-subscriber-interface "sub-vprn-1-ws" create
                address 10.255.255.254/8
                dhcp
                    server 172.16.1.2
                    lease-populate 200
                    client-applications dhcp ppp
                    gi-address 10.255.255.254
                    no shutdown
                exit
            exit
            igmp
                group-interface fwd-service 1 "grp-vprn-1-ws"
                    no shutdown
                exit
                no shutdown
            exit
            pim
                interface "int-BNG-1-BNG-2"
                exit
                no shutdown
            exit
            ospf
                area 0.0.0.0
                    interface "sub-vprn-2-rt"
                        interface-type point-to-point
                        no shutdown
```

```
                            exit
                            interface "system"
                                no shutdown
                            exit

                            interface "int-BNG-1-BNG-2"
                                interface-type point-to-point
                                no shutdown
                            exit
                    exit
                    no shutdown
                exit
                no shutdown
            exit
        exit
exit
```

Step 3 - Configure an IGMP policy

Per host replication is mandatory in a wholesale/retail scenario. A single SAP in a wholesale service might be shared among different retailers. A wholesale host that has requested a multicast group will always have the multicast delivered directly. Other hosts on the SAPs might belong to a different retailer and therefore 1) retailers might not have the same multicast group and sources and 2) their bandwidth should not be impacted by other hosts' multicast. Per-host replication is configured in the **igmp-policy igmp-policy-1**. This is mandatory for both IPoE and PPPoE subscribers.

```
# on BNG-1
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1" create
            per-host-replication
        exit
        sla-profile "sla-profile-1" create
        exit
        sub-profile "sub-profile-1" create
            igmp-policy "igmp-policy-1"
        exit
    exit
exit
```

Step 4 - Configure retail service on BNG-2

The interfaces are added to OSPF and to PIM on the retail BNG that is connected to the multicast source.

```
# on BNG-2
configure
    service
        vprn 2 customer 2 create
            dhcp
                local-dhcp-server "dhcp-RETAIL" create
                    use-gi-address
                    pool "pool-RETAIL-1" create
                        subnet 10.0.0.0/8 create
                            options
                                default-router 10.255.255.254
                            exit
                            address-range 10.0.0.1 10.0.0.100
                        exit
                    exit
                    no shutdown
                exit
            exit
```

```
                route-distinguisher 65536:2
                interface "system" create
                    address 172.16.1.2/32
                    local-dhcp-server "dhcp-RETAIL"
                    loopback
                exit
                interface "int-BNG-2-BNG-1" create
                    address 192.168.12.2/30
                    sap 2/1/1 create
                    exit
                exit
                interface "int-BNG-2-MCAST" create
                    address 192.168.4.1/30
                    sap 1/1/6 create
                    exit
                exit
                pim
                    interface "int-BNG-2-BNG-1"
                    exit
                    interface "int-BNG-2-MCAST"
                    exit
                    no shutdown
                exit
                ospf
                    area 0.0.0.0
                        interface "system"
                            no shutdown
                        exit
                        interface "int-BNG-2-BNG-1"
                            interface-type point-to-point
                            no shutdown
                        exit
                        interface "int-BNG-2-MCAST"
                            passive
                            no shutdown
                        exit
                    exit
                    no shutdown
                exit
                no shutdown
            exit
        exit
exit
```

With the configuration from all previous steps, the wholesale/retail setup is ready to process IGMP
messages. Now an IGMPv3 request is sent to the wholesale SAP. The (S,G) is (192.168.4.2, 239.255.1.1)
and the subscriber IP address is 10.0.0.1. The following output shows that the (S,G) is not registered in the
wholesale VPRN, but in the retail VPRN.

```

```

Only the retail VPRN is responsible for processing the IGMP messages. Therefore to troubleshoot a wholesale/retail setup, debug is only relevant on the retail router instance.

```
debug
    router "2"
        igmp
            group-interface fwd-service "1" "grp-vprn-1-ws"
            host "10.0.0.1"
            packet mode egr-ingr-and-dropped
        exit
    exit
exit
```

```

ESM L2TP Wholesale/Retail Multicast

As previously mentioned, the other option for PPPoE wholesale/retail is to use an L2TP connection as shown in Figure 42: L2TP Wholesale-Retail Multicast . LAC-1 contains the wholesale configuration while LNS-1 contains the retail configuration.

Figure 42: L2TP Wholesale-Retail Multicast
A partial configuration for the wholesale LAC service is as follows. It is using the local database named *ppp-retail*, defined with the **pppoe user-db** command, to authenticate subscribers. The wholesale LAC does not process any IGMP messages so it passes all messages to the retailer LNS.

```
# on LAC-1
configure
    service
        vprn 1 customer 2 create
            route-distinguisher 65536:1
            ---snip---
            interface "system" create
                address 192.168.1.1/32
                loopback
            exit
            subscriber-interface "int-SUB-LAC-1" create
                unnumbered "system"
                group-interface "int-GRP-LAC-1" create
                    sap 1/1/2:1 create
                        sub-sla-mgmt
                            def-sub-id use-sap-id
                            def-sub-profile "sub-profile-1"
                            def-sla-profile "sla-profile-1"
                            sub-ident-policy "sub-ident-1"
                            multi-sub-sap 1000
                            no shutdown
                        exit
                    exit
                    pppoe
                        session-limit 10
                        sap-session-limit 10
                        user-db "ppp-retail"
                        no shutdown
                    exit
                exit
            exit
            ---snip---
            l2tp
                group "grp-retail-1" create
                    tunnel "tnl-retail-1" create
                        local-address 192.168.1.1
                        local-name "lac-1"
                        peer 192.168.1.2
                        no shutdown
                    exit
                    no shutdown
                exit
```

```
                    no shutdown
                exit
                no shutdown
            exit
        exit
    exit
exit
```

The local user database *ppp-retail* is defined as follows:

```
# on LAC-1
configure
    subscriber-mgmt
        local-user-db "ppp-retail" create
            ppp
                match-list username
                host "retail1.com" create
                    host-identification
                        username "retail1.com" domain-only
                    exit
                    identification-strings 254 create
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    l2tp
                        group "grp-LAC-RETAIL-1" service-id 1
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The retailer BNG hosts the L2TP Network Server (LNS). The following is a configuration extract for the LNS. To support multicast, IGMP is enabled on the ESM group-interface in the retail service, and PIM is enabled on the interface to the multicast source.

```
# on LNS-1
configure
    service
        vprn 1 customer 2 create
            route-distinguisher 65536:1
            ---snip---
            interface "system" create
                address 192.168.1.2/32
                loopback
            exit
            interface "int-VPRN-1-MCAST" create
                address 192.168.4.1/30
                sap 1/1/6 create
                exit
            exit
            subscriber-interface "int-SUB-LNS-1" create
                address 10.1.1.254/24
                group-interface "int-GRP-LNS-1" lns create
                    sap-parameters
                        sub-sla-mgmt
                            def-sla-profile "sla-profile-1"
                            def-sub-profile "sub-profile-1"
                            sub-ident-policy "sub-ident-1"
                        exit
```

```
                        exit
                    exit
                exit
                igmp
                    group-interface "int-GRP-LNS-1"
                        no shutdown
                    exit
                    no shutdown
                exit

                            no shutdown
                        exit
                        no shutdown
                    exit
                    no shutdown
                exit
                pim
                    interface "int-VPRN-1-MCAST"
                    exit
                    no shutdown
                exit
                no shutdown
            exit
        exit
exit
```

With the previous configuration applied, the wholesale/retail multicast setup can be verified. Firstly, send an IGMP message from the subscriber; the following example uses IGMPv3. The (S,G) sent is (192.168.4.2, 239.255.1.1) from the subscriber with IP address 10.1.1.1.

```
*A:LNS-1# show service active-subscribers igmp detail

```

Only the retail BNG (LNS-1) is responsible for processing the IGMP messages. Therefore, to troubleshoot
ESM multicast for an L2TP service, the following debug commands are used on the LNS.

```
debug
    router "1"
        igmp
            group-interface "int-GRP-1"
            host "10.1.1.1"
            packet mode egr-ingr-and-dropped
        exit
    exit
exit
```

```
56 2017/07/05 15:21:09.51 CEST MINOR: DEBUG #2001 vprn1 IGMP[2]

Conclusion

Multicast is an essential part of Triple Play Services. The SR/ESS TPSDA solution is much more than
a baseline multicast delivery. It includes individual subscriber awareness and provides each retailer a
separate routing context for managing their own multicast content. Subscriber awareness allows for the
fine-tuning of each subscriber multicast experience and also for troubleshooting on a per subscriber basis.
This example provides a complete configuration walkthrough for multicast delivery for both IPoE and
PPPoE in a wholesale/retail model.

ESM IPv4: Multicast with Redirection

This chapter describes ESM IPv4 multicast with redirection configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The configuration in this chapter was initially based on SR OS Release 11.0.R1 and covers both IPoE and PPPoE subscribers. The CLI is updated to Release 15.0.R3.

Overview

Triple Play Service Delivery Architecture (TPSDA) allows operators to integrate High Speed Internet (HSI), voice, and video services within a single network. The goal of this chapter is to walk through a TPSDA multicast architecture with redirection. The topics are divided into the following sections:

- Single BNG with redirection
- SRRP BNG configuration with Multi Chassis Link Aggregation (MC-LAG) and redirection
- IPoE ESM multicast walkthrough
- PPPoE ESM multicast walkthrough
- Subscriber Routed Redundancy Protocol (SRRP)
  - Multi-Chassis Synchronization (MCS) walkthrough
- IGMP Debugging

In ESM IPv4: Multicast with SRRP, multicast is directly distributed to a subscriber through a subscriber SAP. This chapter walks through another popular model which redirects all multicast streams to a common routed interface for all subscribers. When multicast is put on the common routed interface, one single copy of a multicast stream is delivered to multiple subscribers. In this model, per-subscriber replication of multicast streams is done on an access node or on the aggregation network in order to minimize the bandwidth consumed by the multicast traffic in access/aggregation.

Figure 43: Network Topology Overview shows two BNGs configured with SRRP to provide redundancy. The P router is connected to the multicast source and is connected to both BNGs. The connections between the BNGs and the P router, and the multicast source and the P router, are running PIM to provide multicast delivery. On the access side, the two BNGs are connected to an aggregation switch via MC-LAG aggregating the traffic for both PPPoE and IPoE subscribers. The BNGs facing the subscriber side are IGMP aware and will respond to any subscribers' IGMP requests.

Figure 43: Network Topology Overview
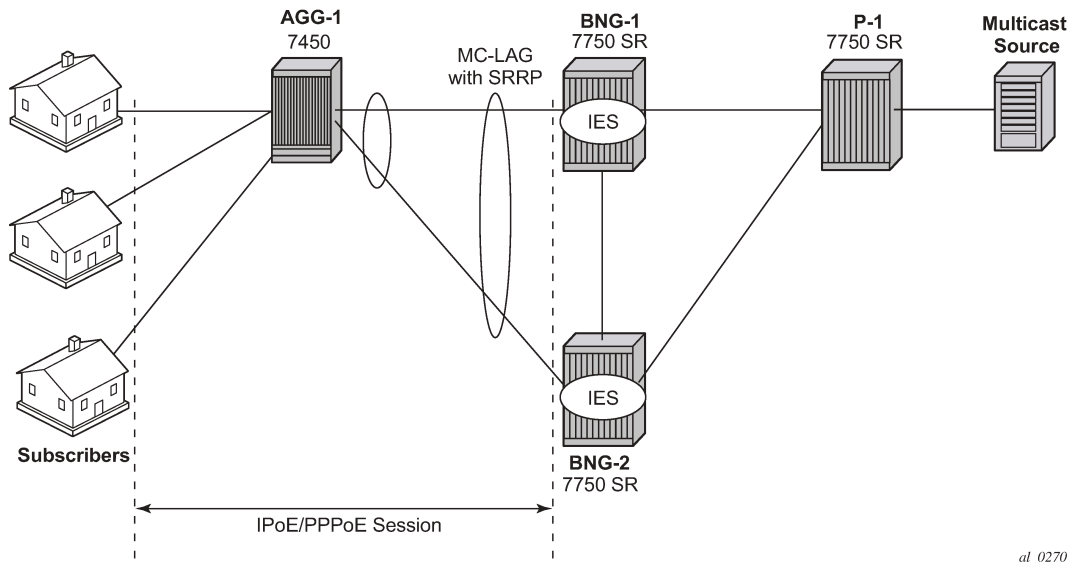

There are two requirements for a subscriber to receive multicast streams. First, the ESM group-interface must have IGMP enabled. Second, each subscriber's subscriber profile must be customized to allow them to receive multicast streams. When both requirements are met, the BNG will process the subscribers' IGMP messages, otherwise, IGMP messages are dropped. All customer premise equipment (CPE) IGMP messages are aggregated via the 7450 and passed onto the BNGs. Because the BNGs are running SRRP, the SRRP master is the only BNG processing and answering the IGMP messages. Protocol Independent Multicast (PIM) is used between the BNG and the P router to request the multicast streams. If PIM is successful in retrieving the multicast group, the multicast stream is forwarded toward the individual subscribers. This is the typical multicast delivery for TPSDA.

Configuration

This example builds on the ESM multicast foundation described in chapter ESM IPv4: Multicast with SRRP. It starts with a single BNG setup with redirection.

ESM Multicast Interface Redirection

Figure 44: Single BNG Setup with Multicast Redirection shows a popular ESM multicast model that redirects all multicast streams to a dedicated router interface. When configuring a redirected interface be aware that:

1. Redirection between Global Routing Table (GRT) interfaces and VPRN interfaces is not supported

2. GRT interfaces are interfaces that reside in the base router or in an IES.

3. Redirection can be performed between interfaces in the GRT or between the interfaces in any VPRN (even different VPRNs).

The following scenario start with a simple ESM multicast configuration for BNG, without redirection.

Figure 44: Single BNG Setup with Multicast Redirection
The BNG-1 baseline configuration excluding multicast redirection is as follows. The local DHCP server is hosted on BNG-1, and is bound to interface *int-DHCP-lb1*.

```
configure
    router Base
        dhcp
            local-dhcp-server "dhcp-local-server" create
                use-gi-address scope pool
                pool "pool-1" create
                    subnet 10.0.0.0/8 create
                        options
                            subnet-mask 255.0.0.0
                            default-router 10.255.255.254
                        exit
                        address-range 10.0.0.10 10.0.0.254
                    exit
                exit
                no shutdown
            exit
        exit
        interface "int-DHCP-lb1"
            address 192.168.0.1/32
            loopback
            local-dhcp-server "dhcp-local-server"
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
            no shutdown
        exit
    exit
exit
```

Subscribers are located in the 10.0.0.0/8 subnet. The multicast stream (S,G) is (192.168.4.2, 239.255.1.1).

```
configure
    service
        ies 1 customer 1 create
            description "BNG-1"
            interface "int-BNG-1-MCAST-S1" create
                address 192.168.4.1/30
                sap 1/1/5 create
                exit
            exit
            subscriber-interface "sub-int-1" create
```

```
                    address 10.255.255.254/8
                    group-interface "grp-int-1" create
                        srrp-enabled-routing
                        dhcp
                            server 192.168.0.1
                            trusted
                            lease-populate 10
                            client-applications dhcp ppp
                            gi-address 10.255.255.254
                            no shutdown
                        exit
                        authentication-policy "auth-1"
                        sap 1/1/4:1 create
                            sub-sla-mgmt
                                def-sub-profile "sub-profile-1"
                                def-sla-profile "sla-profile-1"
                                sub-ident-policy "sub-ident-1"
                                multi-sub-sap 10
                                no shutdown
                            exit
                        exit
                        pppoe
                            no shutdown
                        exit
                    exit
                exit
                no shutdown
            exit
        exit
exit
```

To support multicast, group-interface *grp-int-1* is IGMP enabled, and interface *int-BNG-1-MCAST-S1* is PIM
enabled.

```
configure
    router Base
        igmp
            group-interface "grp-int-1"
                no shutdown
            exit
            no shutdown
        exit
        pim
            interface "int-BNG-1-MCAST-S1"
            exit
            no shutdown
        exit
    exit
exit
```

The subscriber management profiles enabling multicast for ESM subsribers are defined as follows:

```
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1" create
        exit
        sub-profile "sub-profile-1" create
            igmp-policy "igmp-policy-1"
        exit
    exit
exit
```

A router interface is defined to redirect all multicast streams to, and added to the igmp context, as follows.

```
configure
    service
        ies 1
            interface "int-REDIRECT" create
                address 192.168.10.1/30
                sap 1/1/2:1 create
                exit
            exit
        exit
    exit
exit
```

```
configure
    router
        igmp
            interface "int-REDIRECT"
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

A router redirection policy is defined, redirecting every (S,G) toward the redirected interface, as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "mcast-REDIR-IF"
                default-action accept
                    multicast-redirection fwd-service 1 "int-REDIRECT"
                exit
            exit
            commit
        exit
    exit
exit
```

The redirection policy then is applied to the igmp policy, which in turn is applied to the subscriber profile, as follows:

```
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1"
            redirection-policy "mcast-REDIR-IF"
        exit
        sub-profile "sub-profile-1" create
            igmp-policy "igmp-policy-1"
        exit
    exit
exit
```

From this point on all multicast streams will be redirected to the *int-REDIRECT* interface.

Now send an IGMPv3 join message and then use the **show router igmp group** command to verify that all multicast streams are redirected. In this example, IGMPv3 is used with an (S,G) of (192.168.4.2, 239.255.1.1).

For PPPoE subscribers, the multicast (S,G) shows up on both the redirected interface and the host, as follows:

```
*A:BNG-1# show router igmp group
===============================================================================
IGMP Interface Groups
===============================================================================

(192.168.4.2,239.255.1.1)                               UpTime: 0d 00:00:30
    Fwd List  : int-REDIRECT

ESM Multicast Redirection with SRRP and MC-LAG

Figure 45: Network Topology with MC-LAG shows a numbered SRRP setup with MC-LAG SAPs serving
both IPoE and PPPoE subscribers. ESM IPv4: Multicast with SRRP covers the configuration of regular
SRRP SAPs, consequently this example provides configuration guidelines to use a different type of SAP:
SRRP MC-LAG SAPs. Note that redirection on SRRP SAPs without MC-LAG is also supported. The
configuration of the RADIUS server is out of the scope of this example.

Figure 45: Network Topology with MC-LAG
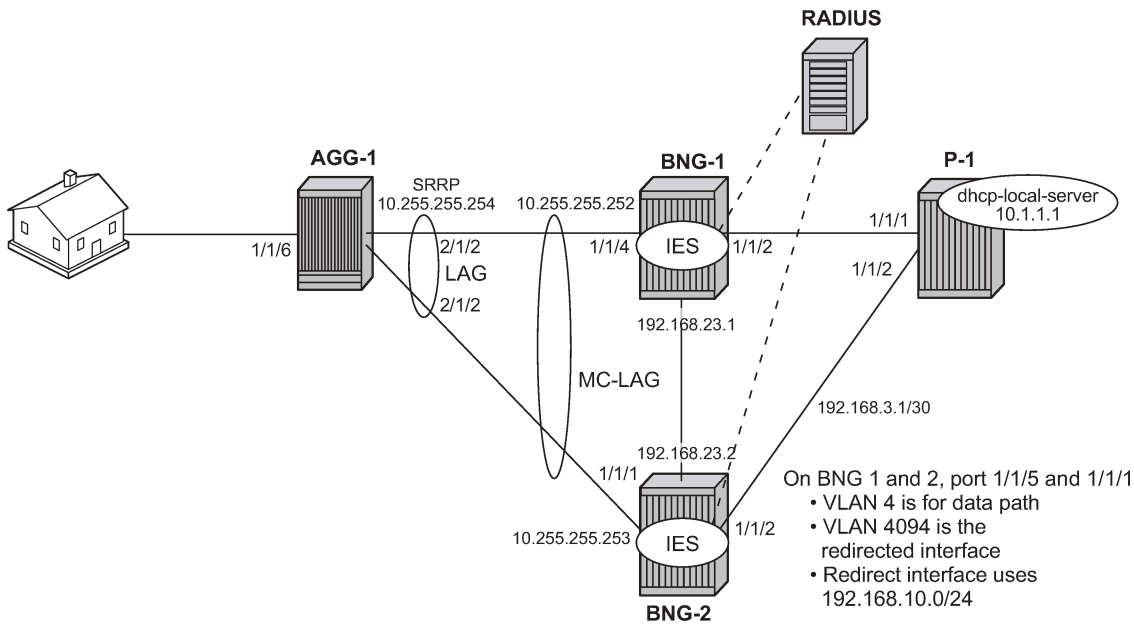

The baseline configuration for BNG-1 excluding the IGMP configuration is as follows. The configuration begins with the MC-LAG configuration. ESM is configured in an IES service, but it is also possible to configure ESM in a VPRN. The redirection interface must be in the same routing instance as the group-interface, this applies to both regular SRRP SAPs and MC-LAG SAPs. In the following example, the MC-LAG is **lag-1**, customer data traffic is using VLAN 4, MC-LAG control traffic is using VLAN 5, and the redirected multicast streams are using VLAN 4094.

```
# Baseline for BNG-1
configure
    lag 1

                no shutdown
            exit
        exit
 exit
```

The baseline configuration for the P router is as follows. It is now responsible for DHCP address
assignment (moved from BNG-1 in the previous configuration to allow for redundant operations in case of
failure of either BNG-1 or BNG-2) and is also attached to the multicast source.

```
# Baseline for P-1
configure
    router
        dhcp
            local-dhcp-server "dhcp-local-server" create
                use-gi-address scope pool
                pool "pool-1" create
                    subnet 10.0.0.0/8 create
                        options
                            subnet-mask 255.0.0.0
                            default-router 10.255.255.254
                        exit
                        address-range 10.0.0.10 10.0.0.254
                    exit
                exit

                interface "int-P-1-mcast-source"
                exit
                ---snip---
                no shutdown
            exit
        exit
    exit
```

Enable IGMP on Group Interface and Redirect Interface

The following configuration shows how to add the group-interface and redirect interface to IGMP. If ESM is configured in a VPRN, each VPRN will have its own IGMP instance. Remember to apply the following configuration to both BNG-1 and BNG-2.

```
# on BNG-1 and BNG-2
configure
    router
        igmp
            group-interface "grp-int-1"
                no shutdown
            exit
            interface "int-LAG-REDIRECTED"
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

Next, the IGMP policy is configured to redirect all multicast streams to a dedicated interface. The following configuration outlines the steps necessary to enable multicast redirection.

Define a router redirection policy. This will redirect every (S,G) toward the redirected interface.

```
configure
    router
        policy-options
```

```
            begin
            policy-statement "mcast-REDIR-IF"
                default-action accept
                    multicast-redirection fwd-service 1 "int-LAG-REDIRECTED"
                exit
            exit
            commit
        exit
    exit
exit
```

Apply the redirection policy to the IGMP policy, as follows:

```
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1" create
            redirection-policy "mcast-REDIR-IF""
        exit
    exit
exit
```

Add multi-chassis synchronization for the redirected interface on BNG-1. This will synchronize the IGMP state on this MC-LAG interface. A similar configuration is required on BNG-2.

```
# on BNG-1
configure
    redundancy
        multi-chassis
            peer 192.0.2.3 create
                sync
                    igmp
                    srrp
                    sub-mgmt ipoe pppoe
                    port lag-1 create
                        range 4-4 sync-tag "mclagdata"
                        range 5-5 sync-tag "mclagcontrol"
                        range 4094-4094 sync-tag "mclagmulticast"
                    exit
                    no shutdown
                exit
                no shutdown
            exit
        exit
    exit
exit
```

ESM IGMP IPoE walkthrough

With the baseline configuration applied, the BNG is ready to process IGMP messages and deliver multicast streams to the subscribers through the redirected interface. Figure 4 shows the message flow for IPoE subscribers requesting and receiving multicast traffic.

• The group-interface and redirect interface must have IGMP enabled.

• The subscriber must be associated with an IGMP-policy via a sub-profile.

Figure 46: IPoE Multicast Message Flow

al_0274
To verify the (ESM enabled) group-interface and the redirect interface are ready for multicast, use the following show commands. Remember the IES service ID is 1, the group-interface name is *grp-int-1* and the interface name is *int-LAG-REDIRECTED*.

Verify if the group interface and redirected interface have IGMP enabled.

```
*A:BNG-1# show router igmp group-interface

```

After the verification, the BNGs are ready to deliver multicast streams. Next, initiate an IGMP report from a subscriber requesting a multicast channel. In this example, IGMPv3 with SSM is used. If the IPoE subscriber is receiving multicast through the subscriber SAP then the IGMP group will be associated with the SAP. Because redirection is used, the IGMP group is associated with the redirected interface instead. The following output shows that when an IGMP message is received and processed, an (S,G) binding

is associated with the redirected interface. The example uses an IGMPv3 SSM message requesting (192.168.4.2, 239.255.1.1). The subscriber IP address is 10.0.0.11.

```

ESM IGMP PPPoE Walkthrough

The same baseline configuration is used for PPPoE subscriber. Figure 47: PPPoE Multicast Flow shows the message flow for delivery of multicast streams to PPPoE subscribers.

Figure 47: PPPoE Multicast Flow

al_0275
By default, PPPoE subscribers receive multicast streams via Ethernet unicast over subscriber SAPs. PPPoE does not have a multicast mechanism and requires all data traffic to be unicasted. However, because multicast streams are redirected, the streams are sent as multicast at both Layers 2 and 3 (the Layer 2 header will have a multicast destination MAC address and the Layer 3 header will have a multicast destination IP address).

Verify the IGMP on the group-interface. It shows very little difference from the IPoE group interface. No multicast streams are delivered directly over the subscriber SAP group interface.

```
*A:BNG-1# show router igmp group-interface detail

ESM IGMP MCS

The BNGs are configured with SRRP for both IPoE and PPPoE subscribers. This provides stateful redundancy when the master BNG fails. The SRRP master BNG will be the only BNG processing and answering IGMP messages, while the standby BNG synchronizes the state information of all subscribers via MCS in real time. In the event of a failure, the standby takes over and starts processing all IGMP messages. As the standby BNG has the full state information of all subscribers, including the (S,G)s they have joined, PIM starts sending joins for those (S,G)s immediately after failover. Restoration of all multicast streams happens quickly and relies on the PIM configuration and the underlying routing infrastructure. Note that the PIM command **non-dr-attract-traffic** can be used to reduce the failover outage by attracting multicast to the non designated PIM router.

The following output shows the items that are synchronized between the BNGs. To reduce the ESM multicast restoration time, it is important that all subscriber related data (IPoE, PPPoE, SRRP and IGMP) are kept in sync. BNG-1 has system IP address 192.0.2.2 and BNG-2 has system IP address 192.0.2.3.

ESM IGMP Debug

Debug facilities allow for real-time monitoring of events happening on the system. This includes tools for debugging ESM multicast streams.

First enable the required debug on the system, then send an IGMP message to join a multicast group (S,G). The message used in this example is an IGMPv3 message with SSM.

The following is the debug information for an ESM IGMP report message at packet level.

```
debug
    router
        igmp
            packet mode egr-ingr-and-dropped
        exit
    exit
exit
```

```
13 2017/06/28 10:09:32.86 CEST MINOR: DEBUG #2001 Base IGMP[1]
"IGMP[1]: RX-PKT
[000 22:17:54.700] IGMP host 10.0.0.15 V3 PDU: 10.0.0.15 -> 224.0.0.22 pduLen 20
    Type: V3 REPORT maxrespCode 0x0 checkSum 0x2352
    Num Group Records: 1
        Group Record 0

Data Type: Group, Len: 20, Ver: 0, RecType: 1, Compat Mode: 3,
Num Fwd Srcs: 1, Num Blk Srcs: 0
Fwd Sources:
    192.168.4.2
"

47 2017/06/28 10:19:11.05 CEST MINOR: DEBUG #2001 Base IGMP MCS[1]
"IGMP MCS[1]: TX-MCS Data
interface int-LAG-REDIRECTED [ifIndex 7]
Key Type: Group, Len: 9, Grp Addr: 239.255.1.1
Data Type: Group, Len: 20, Ver: 0, RecType: 1, Compat Mode: 3,
Num Fwd Srcs: 1, Num Blk Srcs: 0
Fwd Sources:
    192.168.4.2
"
```

The corresponding debug information for ESM IGMP MCS sync on BNG-2 looks as follows:

```
1 2017/06/28 10:19:06.24 CEST MINOR: DEBUG #2001 Base IGMP MCS[1]
"IGMP MCS[1]: RX-MCS Data
interface int-LAG-REDIRECTED [ifIndex 8]
Key Type: Group, Len: 9, Grp Addr: 239.255.1.1
Data Type: Group, Len: 20, Ver: 0, RecType: 1, Compat Mode: 3,
Num Fwd Srcs: 1, Num Blk Srcs: 0
Fwd Sources:
    192.168.4.2
"
```

The same debug commands can be used for viewing IGMP leave messages. The following debug information is received for an ESM IGMP leave at the packet level. The leave report message received over the subscriber SAP results in the multicast stream being stopped on the redirected interface, after ensuring no other CPE devices still require the multicast streams (by means of a query).

```
debug
    router
        igmp
            packet mode egr-ingr-and-dropped
        exit
    exit
exit
```

```

Conclusion

Multicast is an essential part of Triple Play Services. The SR OS TPSDA solution is much more than a baseline multicast delivery, it includes individual subscriber awareness and offers a full state redundancy option. Subscriber awareness allows for fine tuning of subscriber multicast settings and for troubleshooting on a per subscriber basis. Full state redundancy reduces failover time and ensures high availability of multicast services. This example provided a complete configuration walkthrough of both the IPoE and PPPoE SRRP model with redirection. All multicast streams can be redirected to a dedicated interface for all subscribers to receive.

ESM IPv4: Multicast with SRRP

This chapter describes ESM IPv4 multicast with SRRP configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter applies to SR OS routers, and was originally written for Release 11.0.R1. The CLI is updated to Release 15.0.R3. It covers multicast with Subscriber Routed Redundancy Protocol (SRRP) for IPoE and PPPoE subscribers.

Overview

Triple Play Service Delivery Architecture (TPSDA) has allowed operators to integrate High Speed Internet (HSI), voice, and video services within a single network. The goal of this chapter is to walk through the configuration of a redundant TPSDA multicast architecture and the configuration of multicast filters. The topics are divided into the following sections:

- Enhanced Subscriber Management (ESM) multicast baseline configuration
    - IGMP configuration on ESM group interface
    - ESM IGMP-policy configuration
- IPoE ESM multicast walkthrough
- PPPoE ESM multicast walkthrough
- IGMP Subscriber Router Redundancy Protocol (SRRP)
    - Multi-Chassis Synchronization (MCS) walkthrough
- IGMP Debugging
- IGMP Control Plane Filters
- IGMP Data Plane Filters

The network topology displayed in Figure 48: Network Topology Overview shows a typical TPSDA setup. It consists of three 7750s and a single 7450. Two 7750s are configured as Broadband Network Gateways (BNGs) and the third 7750 is configured as a P router. The 7450 is used as an aggregation switch to aggregate all subscribers.

Figure 48: Network Topology Overview
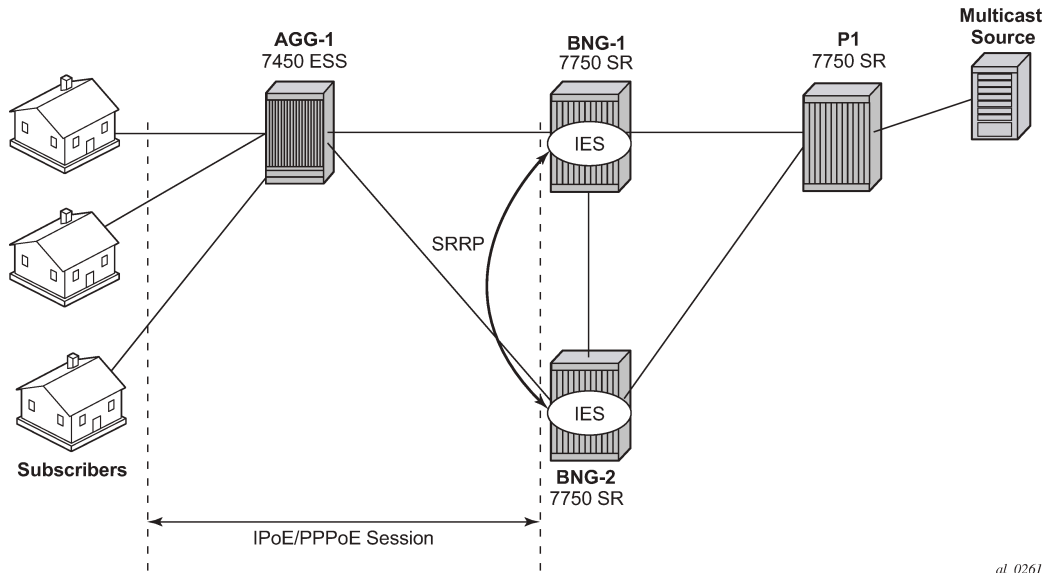

Both BNGs are configured with SRRP to provide redundancy. SRRP is only used for redundancy purposes. SRRP is not required for supporting multicast. The P router is connected to the multicast source and to the network side of both BNGs. The connections between the BNGs and the P router are also running PIM to provide multicast delivery. On the access side, the two BNGs are connected to an aggregation switch which aggregates the traffic originating from both PPPoE and IPoE subscribers. The BNGs are IGMP capable and will respond to subscribers' IGMP requests.

There are two requirements to enable multicast delivery using ESM. First, the ESM group interface must have IGMP enabled. Second, the ESM subscribers must be configured with an IGMP-policy to receive multicast. When both requirements are met, the BNG will process the subscribers' IGMP messages, otherwise, IGMP messages are simply ignored and dropped. All customer premise equipment (CPE) IGMP messages are aggregated via the 7450 and passed to the BNGs. Because the BNGs are running SRRP, the SRRP master is the only BNG processing and answering the IGMP messages. Protocol Independent Multicasting (PIM) is then used between the BNG and the P router to request the multicast stream. If PIM is successful in retrieving the multicast group, the multicast stream is forwarded toward the subscribers. This is the typical multicast delivery model for TPSDA.

Configuration

This section expects a basic knowledge of ESM.

ESM SRRP Baseline Configuration

Figure 49: Example Topology shows the addressing scheme used in the setup. The example uses numbered SRRP subscriber interfaces with static SAPs serving both IPoE and PPPoE subscribers. The configuration of the RADIUS server is out of the scope of this example.

Figure 49: Example Topology

al_0262
The baseline configuration for BNG-1 follows, excluding the IGMP configuration. In this example, the subscriber-interface is configured in an IES, although it is possible to configure the subscriber-interface in a VPRN. OSPF and PIM are provisioned to provide routing and multicast capabilities. The SRRP configuration with priority 200 ensures BNG-1 is the master when both BNGs are active because the SRRP priority for BNG-2 is lower.

```
# BNG-1
configure
    service
        ies 1 customer 1 create
            redundant-interface "mclink-BNG-1-BNG-2" create

                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
configure
    router
        ospf
            area 0.0.0.0
                interface "system"
                    no shutdown
                exit
                interface "int-BNG-1-BNG-2"
                    interface-type point-to-point
                    metric 10000
                    no shutdown
                exit
                interface "int-BNG-1-P-1"
                    interface-type point-to-point
                    no shutdown
                exit
                interface "sub-int-1"
                    no shutdown
                exit
            exit
            no shutdown
        exit
        pim
            interface "int-BNG-1-P-1"
            exit
            no shutdown
        exit
    exit
exit
```

The baseline configuration for BNG-2 follows, excluding the IGMP configuration. The SRRP priority for BNG-2 is lower than the SRRP priority for BNG-1, thus BNG-2 will be in standby mode.

```
# BNG-2
configure
    service
        ies 1 customer 1 create
            no shutdown

            exit
        exit
exit
```

The baseline configuration for the aggregation switch AGG-1 follows. Two VPLS services are configured.
VPLS 5 is responsible for passing SRRP control traffic over VLAN 5. VPLS 4 is responsible for passing all
subscriber data traffic over VLAN 4.

```
# AGG-1
configure
    service
        vpls 4 customer 1 create
            description "for user traffic"
            stp
                shutdown
            exit
            sap 1/1/6:4 create
                no shutdown
            exit
            sap 2/1/1:4 create
                no shutdown
            exit
            sap 2/1/2:4 create
                no shutdown
            exit
            no shutdown
        exit
        vpls 5 customer 1 create
            description "for SRRP/redundancy"
            stp
                shutdown
            exit
            sap 2/1/1:5 create
                no shutdown
            exit
            sap 2/1/2:5 create
                no shutdown
            exit
            no shutdown
```

```
            exit
        exit
    exit
```

The baseline configuration on the P router is as follows. The P router has a local DHCP server configured
and performs the DHCP address assignment. The P router also is attached to the multicast source and
uses PIM to deliver multicast streams.

```
# P-1
configure
    router Base
        dhcp
            local-dhcp-server "dhcp-local-server" create
                use-gi-address scope pool
                pool "pool-1" create
                    subnet 10.0.0.0/8 create
                        options
                            subnet-mask 255.0.0.0
                            default-router 10.255.255.254
                        exit
                        address-range 10.0.0.10 10.0.0.254
                    exit
                exit
                no shutdown
            exit
        exit
        interface "int-DHCP-lb1"
            address 192.168.0.1/32
            loopback
            local-dhcp-server "dhcp-local-server"
            no shutdown
        exit
        interface "int-P-1-BNG-1"
            address 192.168.24.2/30
            port 1/1/1:4094
            no shutdown
        exit
        interface "int-P-1-BNG-2"
            address 192.168.34.2/30
            port 1/1/2:4094
            no shutdown
        exit
        interface "int-P-1-mcast-source"
            address 192.168.4.1/30
            port 1/1/5:4092
            no shutdown
        exit
        interface "system"
            address 192.0.2.4/32
            no shutdown
        exit
        ospf 0
            traffic-engineering
            area 0.0.0.0
                interface "system"
                    no shutdown
                exit
                interface "int-DHCP-lb1"
                    no shutdown
                exit
                interface "int-P-1-BNG-1"
                    interface-type point-to-point
                    no shutdown
```

```
                    exit
                    interface "int-P-1-BNG-2"
                        interface-type point-to-point
                        no shutdown
                    exit
                    interface "int-P-1-mcast-source"
                        passive
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            pim
                interface "int-P-1-BNG-1"
                exit
                interface "int-P-1-BNG-2"
                exit
                interface "int-P-1-mcast-source"
                exit
                ---snip---
                no shutdown
            exit
        exit
exit
```

Enable IGMP on Group Interfaces

The configuration below adds the group interface to IGMP. If the subscriber-interface is configured in a VPRN, each VPRN will have its individual IGMP instance. Add the group-interface to the IGMP instance.

```
# on BNG-1 and BNG-2
configure
    router
        igmp
            group-interface "grp-int-1"
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

Placing the group-interface into IGMP is the first step required to deliver multicast streams. The options available in this IGMP context can be classified into two categories:

1. Bandwidth and multicast group management

2. Interoperability

```
 [no] disable-router* - Enable/disable the IGMP router alert check option
 [no] import         - Import a policy to filter IGMP packets
 [no] max-groups     - Configure the maximum number of groups for this group-interface
 [no] max-grp-sources - Configure the maximum number of group sources for this
                        group-interface
 [no] max-sources    - Configure the maximum number of sources for this group-interface
      mcac           + Configure multicast CAC policy and constraints for this interface
 [no] query-interval - Configure the frequency at which Host-Query packets are
                        transmitted
 [no] query-last-mem* - Configure the frequency at which Group-Specific-Query packets
                        are transmitted
```

```
     [no] query-response* - Configure the time to wait to receive a response to the
                            Host-Query message from the host
     [no] query-src-ip    - Configure the IP source address used in IGMP queries for this
                            group interface
     [no] shutdown        - Administratively enable/disable the interface
     [no] sub-hosts-only  - Enable/disable the IGMP traffic from known hosts only
     [no] subnet-check    - Enable/disable local subnet checking for IGMP
     [no] version         - Configure the version of IGMP
```

The bandwidth and multicast group management options are:

- Import — Used for white-listing or black-listing multicast groups in the IGMP control plane. More configuration detail is offered in a later section.

- Max-groups — Controls the maximum number of groups (channels) allowed on the group interface.

- Max-sources — Controls the maximum number of sources of the multicast streams on a group interface.

- Max-grp-sources — Specifies the maximum number of multicast group and source pairs for a group-interface.

- MCAC — Multicast Connection Admission Control (MCAC) is a bandwidth management feature to control the amount of multicast streams a group interface is allowed to receive. It can also be applied at subscriber level to offer a hierarchical control. Multicast bandwidth can be controlled on a per subscriber basis.

- query-interval — defines the frequency at which general host-query messages are sent out by the querier.

- query-last-member-interval — defines the frequency at which the querier sends group-specific queries including messages sent in response to leave-group messages.

- query-response-interval — defines how long the querier waits to receive a response to a host-query message from a host.

- query-src-ip — defines the query source IP address for the group interface.

The interoperability options available are:

- Router alert — enable or disable router alert processing.

- Sub-hosts-only — Only subscriber originated IGMP messages are accepted and anything else is ignored. Sometimes, IGMP message might not arrive directly from the subscriber. For example, an aggregation switch or DSLAM residing between the CPE and the BNG might perform IGMP proxy. The switch/DSLAM will insert its own source IP-address in place of the subscriber.

  It should be noted that, when an IGMP proxy is used, the identity of the subscriber is lost (because the original source IP of the IGMP message is replaced).

- Subnet-check — IGMP messages will be checked against the group interface subnet. All IGMP messages with a source address that is not in the local subnet are dropped.

- Version — The RFCs define three versions of IGMP, all of them are supported by SR OS.

  It must be noted that when subscribers are sending IGMPv1 or v2 in a bridged LAN, suppression of IGMP messages can occur. If an IGMP host detects the presence of another host reporting for the same multicast group, it will suppress its own IGMP report message and silently receive the multicast stream. When IGMP messages are suppressed, the BNG might not be able to account for the real multicast bandwidth consumption of each subscriber. IGMPv3, on the other hand, forces all hosts to send IGMP reports. This guarantees that the BNG identifies each subscriber's IGMP request.

ESM IGMP Policy

In addition to enabling IGMP on the group interface, the subscriber must be allowed to receive multicast streams through an IGMP policy. For this purpose, the IGMP-policy is associated with the subscriber's subscriber-profile. Therefore during authentication, either RADIUS, the local user database (LUDB), or the default-sub-profile should return a sub-profile with an IGMP policy. The provisioning requires two steps:

First create the IGMP policy, as follows:

```
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1" create
        exit
    exit
exit
```

Then add the IGMP policy to a subscriber-profile, as follows:

```
configure
    subscriber-mgmt
        sub-profile "sub-profile-1" create
            igmp-policy "igmp-policy-1"
        exit
    exit
exit
```

The above configuration is the minimum requirement for a subscriber to receive multicast streams. The different options inside an IGMP policy are:

```
[no] description     - Description for the policy
[no] disable-router* - Enable/disable the router alert check option
[no] egress-rate-mo* - Configure the egress rate modification
[no] fast-leave      - Enable/disable fast-leave processing
[no] import          - Specify the import policy to filter packets
[no] max-num-groups  - Configure the max number of multicast groups
[no] max-num-grp-so* - Configure the max number of multicast group sources
[no] max-num-sources - Configure the max number of multicast sources
[no] mcast-reporting + Configure the mcast reporting
[no] per-host-repli* - Enable/disable per-host-replication processing
[no] query-interval  - Configure the frequency at which Host-Query packets are
                       transmitted
[no] query-last-mem* - Configure the frequency at which Group-Specific-Query packets
                       are transmitted
[no] query-response* - Configure the time to wait to receive a response to the
                       Host-Query message from the host
[no] redirection-po* - Specify the redirection policy
     static          + Add/remove static group membership
[no] version         - Configure the version
```

Again, two groups of options are available: the bandwidth and multicast group management options, and the interoperability options.

Bandwidth and multicast group management options:

- Import — Used for white-listing and black-listing multicast groups. This allows the import policy to be defined per subscriber.

- Max-num-group — Limits the maximum multicast groups for the group interface. This limits the groups per subscriber.

- Max-num-sources — Limits the maximum multicast sources for the group interface. This limits the sources per subscriber.

- Max-num-grp-sources — Limits the maximum multicast group and source pairs for the group interface.

- Egress-rate-modify — This feature adjusts the subscriber queue bandwidth according to multicast consumption. It is used in conjunction with MCAC. An MCAC policy defines the bandwidth consumption per multicast group. As a subscriber joins a multicast group, the bandwidth of the multicast channel is subtracted from the subscriber queue bandwidth. The remaining bandwidth is what the subscriber can use for all other services.

- query-interval — defines the frequency at which general host-query messages are sent out by the querier.

- query-last-member-interval — defines the frequency at which the querier sends group-specific queries including messages sent in response to leave-group messages.

- query-response-interval — defines how long the querier waits to receive a response to a host-query message from a host.

Interoperability options:

- Fast-leave — Enables the router to withdraw the multicast group quickly when receiving an IGMP leave message without any last query. This should be used in a subscriber per SAP (dot1q or qinq) model.

- Static — This allows the provisioning of static multicast groups that the subscriber will receive regardless of any IGMP report. The static multicast group can be Source Specific Multicast (SSM) based.

- Per-host-replication — SR OS has the capability to replicate a multicast source per subscriber. For example, if 10 subscribers are requesting the same multicast group, then 10 multicast streams are replicated and delivered individually to each subscriber. PPPoE requires service delivery to be point to point. To achieve this, the Ethernet header destination address for the multicast stream is the subscriber's source MAC. The IP layer destination is the same as the multicast group that the subscriber requested. For IPoE, without per-host replication, the standard multicast MAC representing the multicast group is used as the destination MAC address when delivering the multicast streams to the subscribers. When per-host replication is used for IPoE subscribers, the destination MAC address will be the host's own MAC address and the IP destination will be the same as the multicast group that the subscriber is interested in. The multicast stream is then delivered to the subscriber via MAC learning as a unicast stream.

  When per-host-replication is enabled, all multicast streams will be using the subscriber queues. It is no longer necessary to use egress-rate-modify as mentioned before.

- Redirection-policy — Another popular model for multicast deployment is to redirect all multicast streams to another interface instead of sending the content directly to the subscriber. All subscribers use a common VLAN to receive the multicast streams.

ESM IGMP IPoE Walkthrough

With the baseline configuration applied, the BNG is ready to process IGMP messages and deliver multicast. Figure 50: IPoE Subscriber Multicast Flow shows a flow for IPoE subscribers requesting and receiving multicast traffic. The key items are highlighted in dotted box:

1. The ESM group-interface must have IGMP enabled

2. The subscriber must be associated with an IGMP-policy via sub-profile.

The subscriber sends an IGMPv3 report using (192.168.4.2, 239.255.1.1).

Figure 50: IPoE Subscriber Multicast Flow
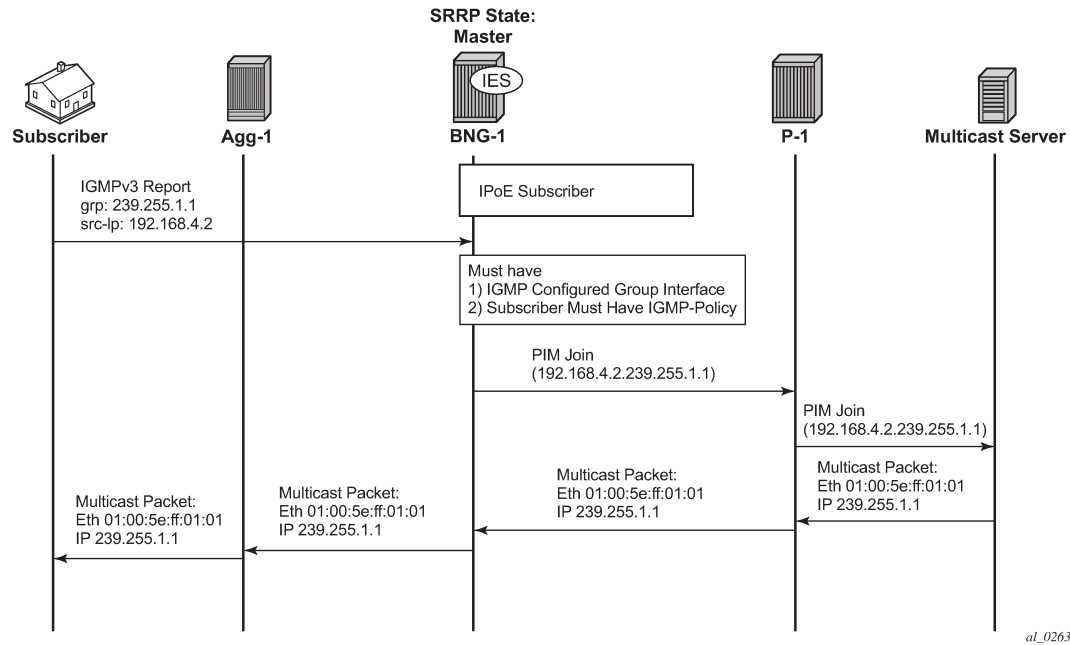

To verify that the group interface is ready for multicast, use the following **show** command. Remember that the IES service id is 1 and the group-interface name is *grp-int-1*.

```
*A:BNG-1# show router igmp group-interface

===============================================================================
IGMP Group-Interfaces

```

After the verification, the BNGs are ready to deliver multicast streams.

First, initiate an IGMP report from a subscriber requesting a multicast channel. In this example, IGMPv3 SSM is used. IPoE by default replicates per-SAP. If the IGMP message was successfully received and processed, an (S,G) binding will be associated with the subscriber SAP.

In this case, the IGMPv3 SSM message requests (192.168.4.2, 239.255.1.1). The subscriber host is assigned an IP address of 10.0.0.11. To verify the IGMP message was successfully processed, check that the (S,G) is learned on the IGMP instance. The following example shows a successful IGMP message processed by the BNG, the (S,G) is registered against the subscriber SAP and the host.

```

ESM IGMP PPPoE Walkthrough

IGMP message processing and delivery of multicast streams to PPPoE subscribers is considered next.
Figure 51: PPPoE Multicast Flow shows the message flow for multicast stream delivery to PPPoE
subscribers.

Figure 51: PPPoE Multicast Flow

al_0264
As stated earlier, the important configuration aspects are highlighted in the dotted box. The main difference between IPoE subscribers and PPPoE subscribers is the encapsulation on the last stretch of the multicast data path. PPPoE subscribers receive multicast streams via Ethernet unicast while IPoE subscribers receive multicast streams via Ethernet multicast. PPPoE natively does not have a multicast mechanism and requires all data traffic to be unicasted. Even if the subscribers are on the same SAP, multicast streams are replicated per subscriber. To achieve this, the IP header indicates a multicast address while the Ethernet header destination MAC address is changed to the subscriber's MAC address.

Verify the group interface. It is very similar to the output for the IPoE group interface.

```

* indicates that the corresponding row element may have been truncated.
*A:BNG-1#
```

Next an IGMPv3 message is sent toward the BNG. The (S,G) is (192.168.4.2, 239.255.1.1). The PPPoE subscriber is assigned an IP address of 10.0.0.15.

The following output shows the key difference between a PPPoE subscriber and an IPoE subscriber. A PPPoE multicast stream is replicated per host and not per SAP. This output shows this clearly because the multicast group is associated with the host and not with the SAP.

```
*A:BNG-1# show router igmp group
=========================================================================

ESM IGMP MCS

The BNGs are configured with SRRP for both IPoE and PPPoE subscribers. This provides stateful redundancy when the master BNG fails. The master BNG will be the only one processing and answering IGMP messages. The standby BNG does not perform any IGMP processing and receives updates through MCS for all subscribers in real time. In the event of a failure, the standby will become active and starts processing all IGMP messages. The standby will also immediately trigger PIM joins for all of the subscribers's (S,G)s. This is all possible because the standby is always synchronized with the master BNG prior to the failover. Restoration of all multicast channels should happen quickly after the failover and depends on both the PIM configuration and the underlying routing infrastructure.

The key parameters for MCS for ESM multicast are: syncing of subscribers (ipoe, pppoe), SRRP and IGMP. The redundancy configuration for BNG-1 is as follows. The configuration for BNG-2 is similar.

```
configure
    redundancy
        multi-chassis
            peer 192.0.2.3 create
                sync
                    igmp
                    srrp
```

```
                        sub-mgmt ipoe pppoe
                        port 1/1/4 create
                            range 4-4 sync-tag "sub"
                            range 5-5 sync-tag "srrp"
                        exit
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
        exit
exit
```

The following command displays the number of entries being synced across the BNGs.

```

ESM IGMP Debug

There are many debug features for ESM multicast. Debug allows real-time monitoring of all events happening on the system and can assist operators with troubleshooting. First enable debug on the system, then send an IGMP message to join a multicast group (S,G). Again the IGMP message used in this case is IGMPv3 with SSM. The following is the debug information for ESM IGMP at packet level.

```
debug
    router
        igmp
            packet mode egr-ingr-and-dropped
        exit
    exit
exit
```

```
1050 2017/06/22 15:58:25.90 CEST MINOR: DEBUG #2001 Base IGMP[1]

```

IGMP Control Plane Filters

IGMP control plane filtering can be applied at the router level and/or subscriber level (IGMP-policy). The filter list contains multicast groups (S,G) and is provisioned at the router level in the policy-options context. The filter can be applied either as a black-list or a white-list.

Provision a prefix list for the multicast group (G). The following configuration is an example showing the various options possible for the prefix list. The only one used in this configuration is the prefix 239.255.1.1/32.

```
configure
    router
        policy-options
            begin
            prefix-list "igmp-prefix-list-1"
                prefix 239.255.1.1/32 exact
                prefix 239.255.2.0/24 longer
                prefix 239.255.3.0/24 prefix-length-range 24-25
                prefix 239.255.4.0/24 through 25
            exit
```

```
            commit
        exit
    exit
exit
```

A white-list router policy is configured as follows, allowing only the prefix list specified and rejecting everything else. Source-address configuration is also possible for IGMP v3 (S,G). The white-list is used for the demonstration later in this chapter.

```
configure
    router
        policy-options
            begin
            policy-statement "igmp-white-list-1"
                entry 10
                    from
                        group-address "igmp-prefix-list-1"
                        source-address 192.168.4.2
                    exit
                    action accept
                    exit
                exit
                default-action reject
            exit
            commit
        exit
    exit
exit
```

An example black-list router policy is configured as follows, denying the prefix list and accepting everything else. Again, source-address configuration is possible for IGMP v3 (S,G). The use of this black-list is not demonstrated.

```
configure
    router
        policy-options
            begin
            policy-statement "igmp-black-list-1"
                entry 10
                    from
                        group-address "igmp-prefix-list-1"
                        source-address 192.168.4.2
                    exit
                    action reject
                exit
                default-action accept
                exit
            exit
            commit
        exit
    exit
exit
```

Hierarchical filter

The filter can be applied in two places. First, at router/group-interface level, this will apply to all subscribers connected to the group interface.

```
configure
    router
        igmp
```

```
            group-interface "grp-int-1"
                import "igmp-white-list-1"
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

The group-interface filter takes precedence over the subscriber level filter. After the group-interface applies its filter against the incoming IGMP messages, the individual subscriber defined IGMP filters will be applied to the remaining IGMP messages.

```
configure
    subscriber-mgmt
        igmp-policy "igmp-policy-1" create
            import "igmp-white-list-1"
        exit
    exit
exit
```

Use the **debug** command to verify that the policy is working correctly for the host. Group 239.255.1.2 is not in the white-list and so is dropped.

```
debug

```

IGMP Data Plane Filters

IGMP data plane filter utilize the ip-filter defined in the sla-profile. Again the filter can be used as a black-list or a white-list.

Configure an ip-filter. The following is an example of a black-list filter.

```
configure
    filter
        ip-filter 1 create
            default-action forward
            entry 1 create
                match
                    dst-ip 239.255.1.1/32
                exit
                action
                    drop
                exit
            exit
        exit
    exit
exit
```

Apply the configured ip filter into an sla-profile. Because multicast content is sent toward the subscriber, it is applied to the sla-profile egress.

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-1" create
            egress
                ip-filter 1
            exit
        exit
    exit
exit
```

To view the statistics of the filter applied to the subscribers, use the following command.

```
*A:BNG-1# show filter ip 1 counters

Conclusion

Multicast is an essential part of Triple Play Services. The TPSDA solution offers much more than a baseline multicast delivery, it includes individual subscriber awareness and a full state redundancy option. Subscriber awareness allows for the fine tuning of each subscriber's multicast experience and also for troubleshooting on a per subscriber basis. Full state redundancy reduces failover time and ensures high availability of the services offered. This example provides a complete configuration walkthrough of both the IPoE and PPPoE SRRP models.

For operators wanting to further control and restrict individual subscriber's multicast content, ESM has a comprehensive set of both control path filtering and data path filtering.

ESM SLAAC Prefix Assignment via Local Address Server

This chapter provides information about ESM SLAAC prefix assignment via local address server.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter was based on SR OS Release 13.0.R1. The CLI in the current edition is SR OS Release 16.0.R7 based. Both Internet Protocol over Ethernet (IPoE) and Point-to-Point Protocol over Ethernet (PPPoE) are supported.

Overview

Triple Play Service Delivery Architecture (TPSDA) supports IPv6 address/prefix assignment through Dynamic Host Configuration Protocol (DHCP), Point-to-Point Protocol (PPP), and Stateless Address Auto-Configuration (SLAAC). This chapter provides configuration examples of SLAAC prefix assignment via the local address server.

The network topology shown in Figure 52: TPSDA Network Topology shows a TPSDA setup. The setup consists of a 7750 SR serving as a Broadband Network Gateway (BNG). The 7450 is used as a Layer 2 switch aggregating all subscriber traffic.

Figure 52: TPSDA Network Topology
There are two methods available for subscriber SLAAC prefix assignment. The first method, not covered in this chapter, is to pre-define a static SLAAC prefix for each subscriber on the BNG, in a Local User Database (LUDB) or via a RADIUS AAA server. With such a configuration, the database would contain hundreds of thousands of /64 SLAAC prefixes, each with their associated host. Every time a subscriber moved to a new location (a new subnet), the allocation of a new prefix within the new subnet would be required, along with a manual update of the database.

The second method, covered in this chapter, is to simplify SLAAC prefix assignment. A local address server is configured to dynamically assign SLAAC prefixes to hosts. Only a SLAAC pool name is obtained from RADIUS or LUDB after a successful subscriber authentication. This pool name is then used to assign a SLAAC prefix to the subscriber, out of the named address pool.

Using a local pool for SLAAC prefix assignment provides the following advantages:

- Reduces the configuration required on the RADIUS server, the local user database (LUDB), and the BNG to a few lines;

- Removes the complexity of managing actual prefixes in a database;

- Reduces configuration errors; for example, accidentally assigning the same prefix to two different subscribers.

The local address server already has tools, logs, and monitoring features for prefix management, such as prefix depletion and subnet migration. Service providers can rely on the local address server to assist in SLAAC prefix assignment.

Configuration

This guide assumes a basic knowledge of ESM.

Different Types of SLAAC Hosts

SLAAC is supported for both PPP and IP over Ethernet hosts. The local address server can be enabled for either or both host types on a group interface level.

PPP SLAAC Hosts

PPP IPv4 hosts rely on IPCP to retrieve an IPv4 address. However, IPv6CP does not assign IPv6 addresses or prefixes to the host. PPP hosts rely on router solicitations (RSs) or DHCPv6 to obtain IPv6 addresses/prefixes.

PPP SLAAC hosts creation requires three configuration steps.

Step 1. Following is a baseline PPP subscriber management configuration on the BNG.

```
# on BNG-1
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                ipv6
                    subscriber-prefixes
                        prefix 2001:db8::/32 wan-host
                exit
```

```
                    exit
                    group-interface "group-int-1" create
                        ipv6
                            router-advertisements
                                prefix-options
                                    autonomous
                                exit
                                no shutdown
                            exit
                        exit
                        sap 1/1/1:1 create
                            sub-sla-mgmt
                                def-sub-id use-sap-id
                                def-sub-profile "sub-profile-1"
                                def-sla-profile "sla-profile-1"
                                sub-ident-policy "sub-ident-policy-1"
                                multi-sub-sap 10
                                no shutdown
                            exit
                        exit
                        pppoe
                            no shutdown
                        exit
                    exit
                exit
        exit
```

Step 2. A DHCPv6 server is used as the local address server to assign SLAAC prefixes. It is possible to reuse the same pool for both DHCPv6 and SLAAC address/prefix assignment. For SLAAC hosts, the keyword **wan-host** is required.

```
# on BNG-1
configure
    router
        dhcp6
            local-dhcp-server "dhcp6-server-1" create
                use-pool-from-client
                pool "pool-v6-1" create
                    prefix 2001:db8::/32 wan-host create
                    exit
                exit
                no shutdown
            exit
        exit
```

Step 3. On the PPP group interface, configure the local address server. Specify that the local address server is to be used for client application ppp-slaac. The server name must match the name configured for the DHCPv6 server (step 2). The DHCPv6 server is reused as the local address server.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    local-address-assignment
                        ipv6
                            client-application ppp-slaac ipoe-slaac
                            server "dhcp6-server-1"
                        exit
                        no shutdown
                    exit
```

```
                    exit
                exit
            exit
```

There are two options for supplying a SLAAC pool name for a PPP host: RADIUS and LUDB.

Option 1: During PPP authentication, RADIUS can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the user-db configuration from pppoe when using RADIUS authentication. Add an authentication policy to the group interface to enable RADIUS authentication.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    authentication-policy "auth-policy-1"
                exit
            exit
        exit
```

Then, add the attribute Alc-SLAAC-IPv6-Pool to the RADIUS user database. The following is an example from a freeradius clients file.

```
user_ppp_01  Auth-Type := CHAP,    Cleartext-Password := password
        Alc-SLA-Prof-Str = "sla-profile-1",
        Alc-Subsc-ID-Str = "home-ppp-1",
        Alc-Subsc-Prof-Str = "sub-profile-1",
        Alc-SLAAC-IPv6-Pool = pool-v6-1,
        Alc-PPP-Force-IPv6CP = 1
```

Option 2: During PPP authentication, an LUDB can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the authentication policy from the group interface when using LUDB.

First, create an LUDB and add a user to the LUDB. This LUDB is configured with a default host for all PPPoE hosts and returns a default SLAAC pool name.

```
# on a/BNG1
configure
    subscriber-mgmt
        local-user-db "pppoe-ludb-lookup" create
            ppp
                match-list username
                host "default" create
                    ipv6-slaac-prefix-pool "pool-v6-1"
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Then, refer to this LUDB from the group interface.

```
# on a/BNG1
configure
    service
```

```
            ies 1
                subscriber-interface "sub-int-1" create
                    group-interface "group-int-1" create
                        pppoe
                            user-db "pppoe-ludb-lookup"
                            no shutdown
                        exit
                    exit
                exit
            exit
```

With the preceding configuration, this group interface supports SLAAC prefix assignment through the local
address pool. The following is the result of a PPP host being assigned a SLAAC prefix by the local address
server.

```

```

IPoE SLAAC Hosts

IPoE offers two methods to create an SLAAC host:

1. Triggered by a successful IPv4 host creation

2. Triggered by an RS request

SLAAC Host Creation via IPv4 Host

A successful IPv4 host creation can subsequently trigger the creation of a SLAAC host; this is known as IPoE-linking. The SLAAC prefix for the host must be provided through either RADIUS or LUDB during the IPv4 host authentication.

IPoE SLAAC host creation through IPoE linking requires four steps.

Step 1. Following is a baseline IPoE subscriber management configuration on the BNG.

```
# on BNG-1
configure
    service
        ies 1 customer 1 create
            description "BNG-1"
            subscriber-interface "sub-int-1" create
                address 10.255.255.253/8
                ipv6
                    subscriber-prefixes
                        prefix 2001:db8::/32 wan-host
                    exit
                exit
                group-interface "group-int-1" create
                    dhcp
                        server 192.168.0.1
                        lease-populate 10
                        client-applications dhcp
                        gi-address 10.255.255.253
                        no shutdown
                    exit
                    ipv6
                        router-advertisements
                            prefix-options
                                autonomous
                            exit
                            no shutdown
                    exit
                exit
                sap 1/1/1:1 create
```

```
                        sub-sla-mgmt
                            def-sub-id use-sap-id
                            ---snip---
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                exit
            exit
```

Step 2. Enable IPoE-linking to allow SLAAC host creation after a successful IPv4 host creation. Several options should be enabled for the SLAAC host to function. Gratuitous router advertisement will send unsolicited router advertisements with a SLAAC prefix for the host to use. The BNG uses the gratuitous router advertisement to let the subscriber know the assigned prefix to auto-configure. In this case, where prefixes are dynamically assigned, the subscriber will not know the prefix ahead of time, so the gratuitous router advertisement must be enabled. Shared-circuit-id will allow the SLAAC host to use the same circuit ID as the IPv4 host.

```
# on BNG-1
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "group-int-1"
                    ipoe-linking
                        shared-circuit-id
                        gratuitous-rtr-adv
                        no shutdown
                    exit
```

Step 3. As with PPP hosts, the DHCPv6 server is reused as the local address server for SLAAC prefix assignment. It is possible to reuse the same pool for both DHCPv6 and SLAAC subscribers. For SLAAC hosts, the keyword wan-host is required. In this case, an IPv4 host must be created first to trigger the creation of the IPv6 SLAAC host. The following example uses the local DHCPv4 server for IPv4 address assignment, but it is possible to use other methods for IPv4 address assignment, such as through LUDB and RADIUS proxy.

```
configure
    router
        dhcp
            local-dhcp-server "dhcp-server-1" create
                use-gi-address scope pool
                pool "pool-v4-1" create
                    subnet 10.0.0.0/8 create
                        options
                            subnet-mask 255.0.0.0
                            default-router 10.255.255.253
                        exit
                        address-range 10.0.0.10 10.0.0.254
                    exit
                exit
                no shutdown
            exit
        exit
        dhcp6
            local-dhcp-server "dhcp6-server-1" create
                use-pool-from-client
                pool "pool-v6-1" create
                    prefix 2001:db8::/32 wan-host create
                    exit
```

```
                        exit
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
```

Step 4. On the group interface, configure the local address server. Specify that the local address-server is to be used for client application ipoe-slaac. The server name must match the name configured for the DHCPv6 server (Step 3). The local address server reuses the local DHCPv6 server.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    local-address-assignment
                        ipv6
                            client-application ipoe-slaac
                            server "dhcp6-server-1"
                        exit
                        no shutdown
                    exit
```

There are two options for supplying a SLAAC pool name for the DHCPv4 host: RADIUS and LUDB.

Option 1: During authentication, RADIUS can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the user-db configuration from the DHCP and IPOE-session context when using RADIUS authentication. First, add an authentication policy to the group interface to allow RADIUS authentication.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    authentication-policy "auth-policy-1"
                exit
            exit
        exit
```

Then, add the attribute Alc-SLAAC-IPv6-Pool to the subscriber host RADIUS user database. The following is an example using the client file on freeradius.

```
00:00:10:10:12:13  Cleartext-Password := password
        Alc-SLA-Prof-Str = "sla-profile-1",
        Alc-Subsc-ID-Str = "home-ipoe-1",
        Alc-Subsc-Prof-Str = "sub-profile-1",
        Alc-SLAAC-IPv6-Pool = pool-v6-1
```

Option 2: During authentication, LUDB can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the authentication policy from the group interface when using LUDB.

First, create an LUDB and add a user in the LUDB. This LUDB is configured with a default host for all DHCPv4 hosts and returns a default SLAAC pool name.

```
# on a/BNG1
configure
```

```
        subscriber-mgmt
            local-user-db "ipoe-ludb-lookup" create
                ipoe
                    match-list sap-id
                    host "default" create
                        ipv6-slaac-prefix-pool "pool-v6-1"
                        no shutdown
                    exit
                exit
                no shutdown
            exit
        exit
    exit
```

Then, refer to this LUDB from the group interface. The LUDB can be referred to in two places.

Nokia recommends that IPoE subscribers use an IPoE session. In this case, the LUDB is referenced from the group interface ipoe-session context.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipoe-session
                        user-db "ipoe-ludb-lookup"
                        no shutdown
                    exit
                exit
            exit
        exit
```

For operators that do not use IPoE sessions (not recommended), the LUDB is referenced from the group interface dhcp context.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    dhcp
                        user-db "ipoe-ludb-lookup"
                        no shutdown
                    exit
                exit
            exit
        exit
```

With the preceding configuration, the local address server on the group interface is ready to assign SLAAC prefixes. Start a DHCPv4 session to the group interface SAP.

```

```

SLAAC Host Creation via RS Trigger

An IPv6 SLAAC host can be created through a host router originated solicit message, which removes the dependency of a SLAAC host on successful DHCPv4 host creation.

SLAAC hosts creation via RS trigger requires four configuration steps.

Step 1. The following is a baseline IPoE subscriber management configuration on the BNG.

```
# on BNG-1
configure
```

```
        service
            ies 1
                description "BNG-1"
                subscriber-interface "sub-int-1" create
                    ipv6
                        subscriber-prefixes
                            prefix 2001:db8::/32 pd wan-host
                    exit
                exit
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            prefix-options
                                autonomous
                            exit
                            no shutdown
                        exit
                    exit
                    sap 1/1/1:1 create
                        sub-sla-mgmt
                            def-sub-id use-sap-id
                            def-sub-profile "sub-profile-1"
                            def-sla-profile "sla-profile-1"
                            sub-ident-policy "sub-ident-policy-1"
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
```

Step 2. Enable the group interface to process router solicit messages. There are a few options available for router solicit triggered hosts. The inactivity timer will remove the host if the global unique address of the host is not learned through Neighbor Solicitation (NS), Router Solicitation (RS), or Duplicate Address Detection (DAD) messages within the time specified. The min-auth-interval is the interval that a subscriber must wait before the next router-solicit messages is used for re-authentication. Re-authentication can occur if the first RS was lost, or the BNG/RADIUS system was queued up with requests.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-solicit
                            inactivity-timer min 5
                            min-auth-interval min 5
                            user-db "ipoe-ludb-lookup"
                            no shutdown
                        exit
```

Step 3. A DHCPv6 server is used as the local address server for SLAAC prefix assignment. It is possible to reuse the same pool for both DHCPv6 and SLAAC subscribers. For SLAAC hosts, the keyword **wan-host** is required.

```
# on BNG-1
configure
    router
        dhcp6
```

```
        local-dhcp-server "dhcp6-server-1" create
            use-pool-from-client
            pool "pool-v6-1" create
                prefix 2001:db8::/32 wan-host create
                exit
            exit
            no shutdown
        exit
    exit
```

Step 4. On the group interface, configure the local address server. Specify that the local address server is to be used for client application ipoe-slaac. The server name must match the name configured for the DHCPv6 server. The local address server reuses the local DHCPv6 server.

```
# on BNG-1
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    local-address-assignment
                        ipv6
                            client-application ppp-slaac ipoe-slaac
                            server "dhcp6-server-1"
                        exit
                        no shutdown
                    exit
                exit
```

There are two options for supplying the SLAAC pool name for the DHCPv4 host: RADIUS and LUDB.

Option 1: During authentication, RADIUS can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the user-db configuration from the router-solicit and ipoe-session when using RADIUS authentication. First, add an authentication policy to the group interface to allow RADIUS authentication.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    authentication-policy "auth-policy-1"
                exit
```

Then, add the attribute Alc-SLAAC-IPv6-Pool to the subscriber host RADIUS user database.

```
00:00:10:10:12:13  Cleartext-Password := password
        Alc-SLA-Prof-Str = "sla-profile-1",
        Alc-Subsc-ID-Str = "home-ipoe-1",
        Alc-Subsc-Prof-Str = "sub-profile-1",
        Alc-SLAAC-IPv6-Pool = pool-v6-1,
```

Option 2: During authentication, LUDB can return the SLAAC pool name attribute along with other subscriber attributes. Note: Remove the authentication policy from the group interface when using LUDB.

First, create an LUDB and add a user in the LUDB. The LUDB configures a default host for all SLAAC hosts and returns a default SLAAC pool name.

```
# on BNG-1
```

© 2024 Nokia.

Use subject to Terms available at: www.nokia.com/terms.

```
configure
    subscriber-mgmt
        local-user-db "ipoe-ludb-lookup" create
            ipoe
                match-list sap-id
                host "default" create
                    ipv6-slaac-prefix-pool "pool-v6-1"
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Then, refer to this LUDB from the group interface. The LUDB can be referred to in two places.

Nokia recommends that IPoE subscribers use an IPoE session. In this case, the LUDB is referenced from the group interface ipoe-session context.

```
# on BNG-1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipoe-session
                        user-db "ipoe-ludb-lookup"
                        no shutdown
                    exit
                exit
            exit
        exit
```

For operators that do not enable IPoE sessions on the BNG (not recommended), the LUDB can be referred to from the group interface in the router-solicit context.

```
# on a/BNG1
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-solicit
                            user-db "ipoe-ludb-lookup"
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
```

With the preceding configuration, the group interface is ready to assign SLAAC prefixes from the local address pool. Let the host trigger a router solicit packet.

```
*A:BNG-1# show service active-subscribers hierarchy

Conclusion

7750 SR TPSDA offers a variety of address assignment options such as PPP, DHCPv4, DHCPv6, and
SLAAC. These options allow service providers to pick the address assignment scheme that best fits their
networks. SLAAC address assignment is an essential IPv6 address assignment protocol. Having to assign
a static prefix per subscriber host in advance could be a challenge for operators. This chapter provides a
complete configuration example of using the local address server to assign prefixes dynamically to IPoE

and PPPoE subscriber hosts. This efficient way to assign SLAAC prefixes to subscribers enables operators to achieve a faster time to market for new IPv6 services.

ESMv4: PPPoE Hosts

This chapter describes advanced IPv4 Enhanced Subscriber Management (ESM) PPPoE host configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter applies to SR OS routers and was written for Release 8.0.R4. The CLI is updated to Release 15.0.R2.

This chapter describes support of PPP termination and aggregation (PTA) hosts. L2TP-hosts are out of the scope of this chapter. Only IPv4 PPPoE hosts are handled in this chapter.

PPPoE hosts are only supported in a Routed CO model (IES or VPRN) using Ethernet SAPs with null, dot1q, or QinQ encapsulation.

Overview

The delivery of services to residential customers encompassing voice, video, and data is covered by Triple Play Service Delivery Architecture (TPSDA).

In the TPSDA, a subscriber is defined as a collection of hosts pertaining to a single access connection (for example, DSL line) and identified by a subscriber identifier. A subscriber host is an end user terminal within the subscriber home (PC, set-top box, home gateway) that is identified in the network with a unique (IP address/MAC address) tuple for IPoE or (PPPoE session ID; MAC address) tuple for PPPoE.

The following host types are distinguished:

Static hosts

- IP-MAC
- IP only

Dynamic hosts

- ARP host
- DHCP host
- PPPoE host

This chapter provides configuration and troubleshooting commands for PPPoE-hosts and will use a local user database (LUDB) for host authentication and ESM (Enhanced Subscriber Management) string assignments.

The IP information in this chapter is retrieved from a Local DHCP server.

The authentication, IP information, and ESM strings can come all from an LUDB, a RADIUS server, a (local) DHCP server, or any combination of them. These combinations are out of the scope of this chapter.

Knowledge of the TPSDA concept is assumed throughout this document.

PPPoE hosts in a routed CO environment

The network topology for a Routed CO environment is displayed in Figure 53: Routed CO network topology.

Figure 53: Routed CO network topology
The following configuration tasks should already be configured and are not detailed or explained in this chapter. See the appropriate user guide.

- Basic service router configuration (system interface, IGP, MPLS, BGP)
- Routed CO service topology: VPRN or IES service with subscriber- and group-interface on BSR-1
- ESM
- Local User Data Base (LUDB)
- Local Dynamic Host Configuration Protocol (DHCP) server

In the Routed CO model, PPPoE hosts can be instantiated in routed services, such as the base router, IES, and VPRN. The configuration section of this chapter focuses on PPPoE hosts instantiated in a VPRN servicelocated in BSR-1 (Routed CO).

Review of the PPPoE protocol

PPPoE, Point-to-Point Protocol over Ethernet, is a network protocol for encapsulating PPP frames inside Ethernet frames. The protocol is described in RFC 2516, *A Method for Transmitting PPP Over Ethernet (PPPoE)*, and is based on RFC 1661, *The Point-to-Point Protocol (PPP)*, which provides a standard method for transporting multi-protocol datagrams over point-to-point links.

PPP has three main components:

- A method for encapsulating multi-protocol datagrams.

- A link control protocol (LCP) for establishing, configuring, and testing the data-link connection.
- A family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

Ethernet networks are packet-based and have no concept of a connection or circuit. By using PPPoE, users can virtually dial from one machine to another over an Ethernet network; establish a point to point connection between them and then transport data packets over the connection.

In a typical wire-line solution with broadband access, PPPoE is used between a client (PC or modem) and a Network Access Server (NAS) (also called Broadband Network Gateway (BNG) or Broadband Service Router (BSR)) through an access node, like a Broadband Service Access Node (BSAN).

PPPoE consists of two phases, the Discovery Stage and the Session Stage.

Discovery stage

The discovery phase offers a stateless client-server model. When the Discovery Stage completes, both peers know the PPPoE SESSION_ID and the peer's Ethernet address, which together uniquely define the PPPoE session. There are four steps in the Discovery Stage:

1. PPPoE Active Discovery Initiation (PADI)

   Initiation (Host broadcast) — This broadcast packet is used by the client to search for an active server (BNG/BSR/NAS) providing access to a service.

   Additional attributes on the PADI message could be added if a BSAN is situated between the client and the BRAS.

2. PPPoE Active Discovery Offer (PADO)

   Access concentrator unicast — If the access server can provide the service it will respond with a unicast PADO to signal the client it may request connectivity.

   Multiple servers may respond and the client may choose a server to connect.

3. PPPoE Active Discovery Request (PADR):

   Host unicast — After the client receives a PADO it will send a PADR unicast packet to connect to a server.

4. PPPoE Active Discovery Session-Confirmation (PADS)

   Access concentrator unicast — A server will respond to the client with this unicast packet to establish the session and provide the session-id. Once the PADS was provided, the Session Stage begins.

   Discovery PPPoE Ethernet frames have the ETHER_TYPE field set to the value 0x8863.

PPPoE tags

IANA has set up a registry of PPPoE tag values (16-bit values). PPPoE tag values already in use are specified as reserved values as shown in Table 7: Reserved PPPoE tags. All other tag values between 0 and 65535 are to be assigned by IANA.

Table 7: Reserved PPPoE tags

Tag Value	Tag Name
0 0x0000	End-Of-List
257 0x0101	Service-Name
258 0x0102	AC-Name
259 0x0103	Host-Uniq
260 0x0104	AC-Cookie
261 0x0105	Vendor-Specific
262 0x0106	Credits
263 0x0107	Metrics
264 0x0108	Sequence Number
272 0x0110	Relay-Session-Id
273 0x0111	HURL
274 0x0112	MOTM
288 0x0120	PPP-Max-Payload
289 0x0121	IP_Route_Add
513 0x0201	Service-Name-Error
514 0x0202	AC-System-Error
515 0x0203	Generic-Error

Explanations for some PPPoE tags (RFC 2516) are shown in the PPPoE discovery debug messages:

(0x0101) Service-Name — This tag indicates that a service name follows. The tag_value is an UTF-8 string that is not null terminated. When the tag_length is zero, this tag is used to indicate that any service is acceptable. Examples of the use of the **service-name** tag are to indicate an ISP name or a class or quality of service.

(0x0102) AC-Name — This tag indicates that a string follows which uniquely identifies this particular Access Concentrator unit from all others. It may be a combination of trademark, model, and serial id information, or simply an UTF-8 rendition of the MAC address of the box. It is not null terminated.

(0x0103) Host-Uniq — This tag is used by a host to uniquely associate an access concentrator response (PADO or PADS) to a particular host request (PADI or PADR). The tag_value is binary data of any value and length that the host chooses. It is not interpreted by the Access Concentrator. The host may include a host-uniq tag in a PADI or PADR. If the access concentrator receives this tag, it must include the tag unmodified in the associated PADO or PADS response.

(0x0104) AC-Cookie — This tag is used by the access concentrator to aid in protecting against denial of service attacks. The access concentrator may include this tag in a PADO packet. If a host receives this tag, it must return the tag unmodified in the following PADR. The tag_value is binary data of any value and length and is not interpreted by the host.

Figure 54: Discovery stage messages

OSSG449-2a
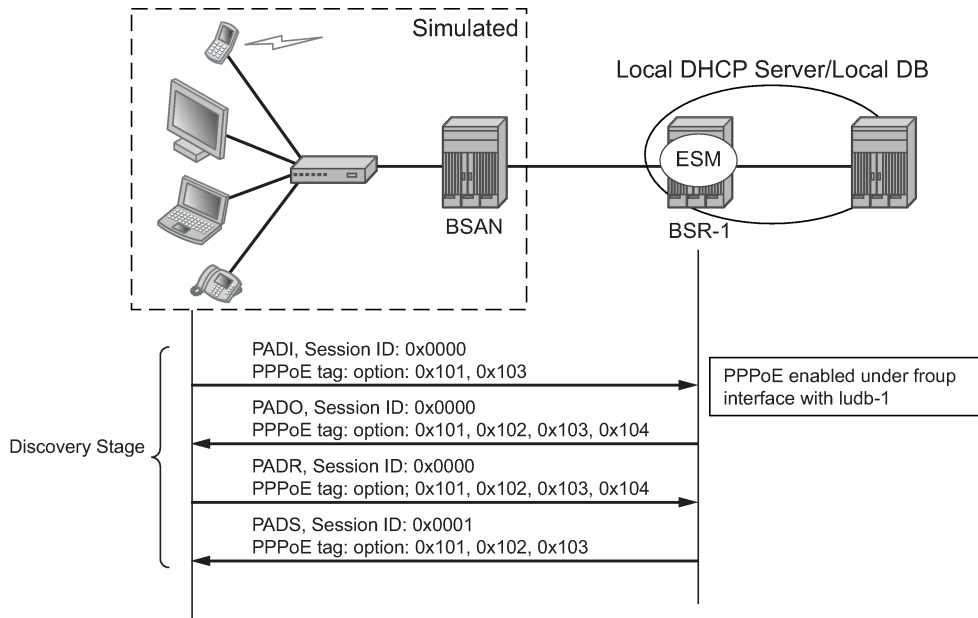

Session stage

This next stage after Discovery is called the Session Stage. Once the MAC address of the peer is known and a session-id is exchanged, the two end points have all the information needed to start building a point-to-point connection over Ethernet and exchange packets over the connection.

This stage can be divided into to the following sections:

- Setup
- Maintenance
- Termination

Setup

PPP Link Control Protocol (LCP)

Both the NAS and the user open the PPP session based on LCP packets. All post-discovery PPPoE Ethernet frames have the ETHER_TYPE field set to the value 0x8864.

The authentication method and the MRU are negotiated during this phase.

RFC 2516 mandates a maximum negotiated Maximum Receive Unit (MRU) of 1492.

RFC 4638, *Accommodating a Maximum Transit Unit/Maximum Receive Unit (MTU/MRU) Greater Than 1492 in the Point-to-Point Protocol over Ethernet (PPPoE)*, relaxes this restriction and allows a maximum negotiated MRU greater than 1492 to minimize fragmentation in next-generation broadband networks.

The SR OS implementation follows RFC 4638 when the client implements these extensions.

LCP uses config_request and config_ack/nack to negotiate parameters:

- LCP goes to final state opened when configure-ack is sent & received.

- The own options are proposed in configure request.

There are three cases for the LCP negations parameters:

- Peer supports the option and its content.

  - Peer will agree and send config-ack.

- Peer does not support an option

  - Peer will send configure-reject with the option that is not supported.

  - Resend of configure-request without that option.

  - Peer agrees and sends config-ack.

- Peer does support the option, but not the content.

  - Peer will send config-nack with the option and its new content.

  - Resend of configure-request with same options but new content.

  - Peer agrees and sends config-ack.

Table 8: LCP and IPCP code

Code	Packet type
1	Configure-Request
2	Configure-Ack
3	Configure-Nak
4	Configure-Reject
5	Terminate-Request
6	Terminate-Ack
7	Code-Reject
8	Protocol-Reject
9	Echo-Request
10	Echo-Reply
11	Discard-Request
12	Identification

Code	Packet type
13	Time-Remaining
14	Reset-request CCP
15	Reset-Ack CCP

Figure 55: LCP phase messages
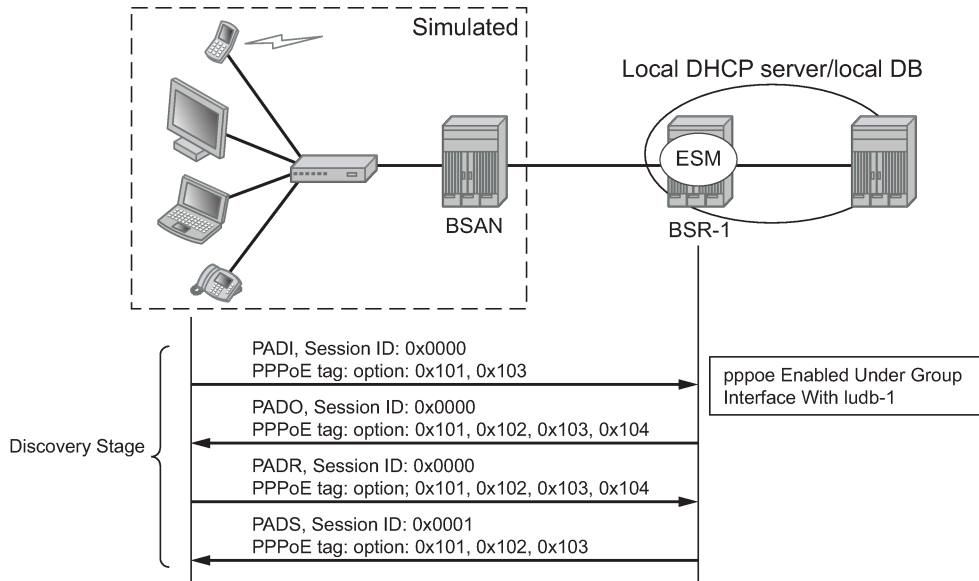

Authentication phase

The client authenticates itself through PAP (PPP Password Authentication Protocol) or CHAP (Challenge Handshake Authentication Protocol) to check for access permission. For the CHAP authentication, the BSR initiates the authentication as shown in Figure 56: CHAP handshaking overview process. The password is hashed on the link and plain text in the RADIUS Access-Request message.

Figure 56: CHAP handshaking overview process
For PAP, the client initiates the authentication as shown in Figure 57: PAP overview process. The password is sent as plain text on the link and hashed in a RADIUS Access-Request message.

Figure 57: PAP overview process
Network layer protocol phase (PPP IPCP opening phase)

At this stage, the user requests an IP address to be used for data transmission. During this negotiation, the client will also receive a Domain Name Server (DNS), NBNS (Netbios Name Server) address, etc. if they are requested.

Figure 58: IPCP phase messages
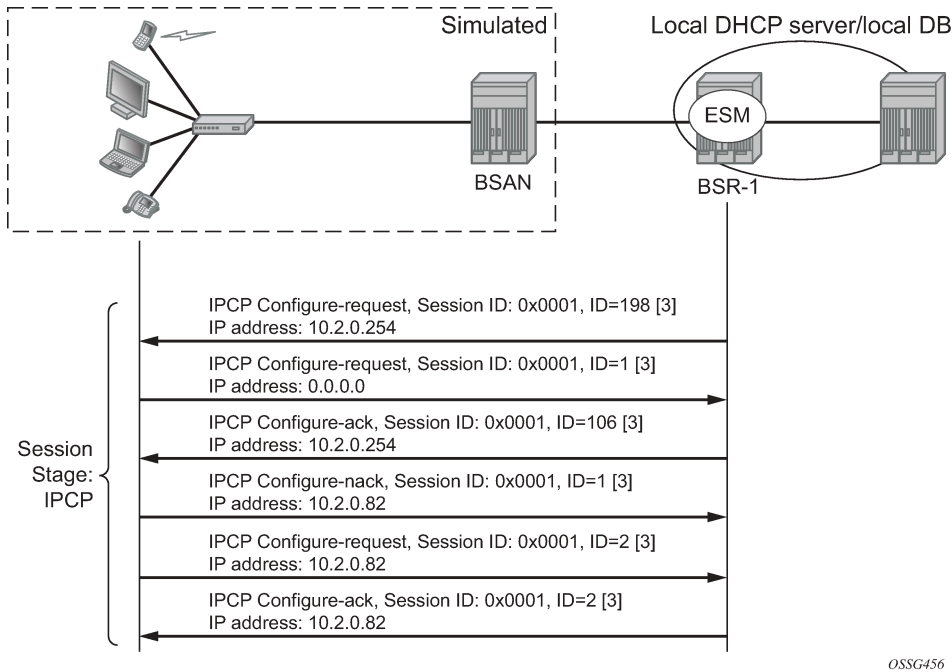

Maintenance

PPP uses keepalives in order to maintain the integrity of the connection. This keepalive mechanism uses an echo-request that is sent to remote PPP peer, following which the remote PPP peer should respond with an echo-reply. The connection is considered down if a number of echo replies are missed. Both sides can initiate keepalives which run independently.

Figure 59: Keepalive messages
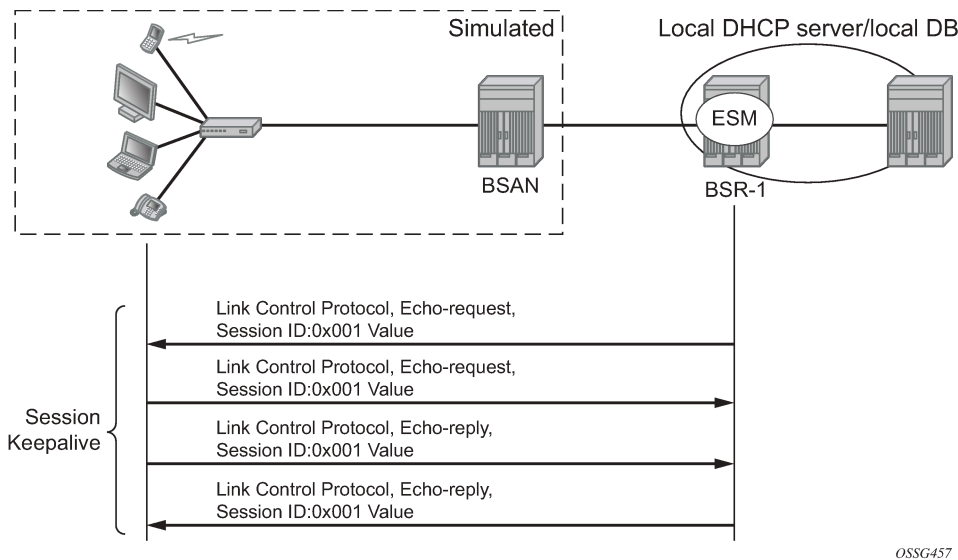

Termination

Link termination phase

A PPPoE session can be terminated by either the client or the BRAS and consists of a Terminate-request followed by a PADT.

Figure 60: Link termination phase

OSSG458
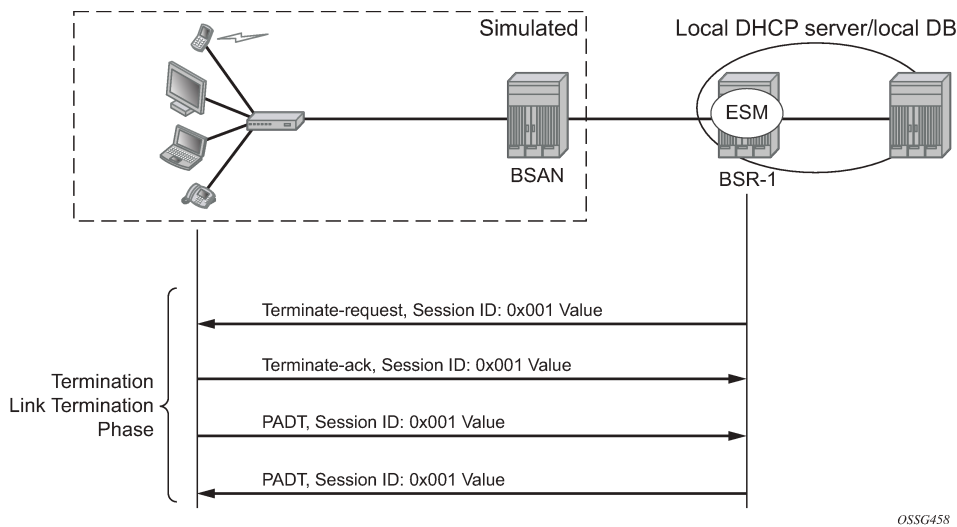

Configuration

Session setup, operation, and release

Enable PPPoE termination under the group-interface context.

Enable the local user database under the PPPoE node of the group-interface.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.2.0.254/16
                group-interface "grp-int-1" create
                    sap 1/1/1:1 create
                        sub-sla-mgmt
                            sub-ident-policy "sub-id-default"
                            no shutdown
                        exit
                    exit
                    pppoe
                        policy "ppp-policy-1"
                        user-db "ludb-1"
                        no shutdown
```

```
                exit
            exit
        exit
    exit
```

The local user database is configured with the following parameters.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            ppp
                match-list username
                host "user1" create
                    host-identification
                        username "user1@domain1"
                    exit
                    address pool "pool-1"
                    password chap letmein
                    identification-strings 254 create
                        subscriber-id "PPPoE-host-user1@domain1"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    no shutdown
                exit
                ---snip---
            exit
        exit
```

The PPPoE policy *ppp-policy-1* is defined as follows:

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1"
*A:BSR-1>config>subscr-mgmt>ppp-policy# info detail
----------------------------------------------
            no description
            no default-pap-password
            no default-user-name
            disable-cookies
            no force-ppp-mtu-gt-1492
            no ipcp-subnet-negotiation
            keepalive 30 hold-up-multiplier 3
            no pado-ac-name
            pado-delay 30
            no ppp-initial-delay
            no ppp-mtu
            no lcp-ignore-magic-numbers
            max-sessions-per-mac  63
            mlppp
                no accept-mrru
                no endpoint
                no short-sequence-numbers
            exit
            reply-on-padt
            ppp-authentication pref-chap
            ppp-chap-challenge-length min 32 max 64
            no unique-sid-per-sap
            no re-establish-session
            no reject-disabled-ncp
            no session-timeout
            ppp-options
            exit
----------------------------------------------
```

```
*A:BSR-1>config>subscr-mgmt>ppp-policy#
```

The PPPoE policy defines the parameters which are used when establishing the PPPoE session, and includes:

- Disable-cookies — This parameter disables the use of cookies.
- Keepalive — This command defines the keepalive interval and the number of keepalives that can be missed before the session is declared down for this PPPoE policy.
  - [10 — 300] seconds: Specifies the keepalive interval in seconds.
  - hold-up-multiplier [1 — 5]: Specifies the number of keepalives that can be missed.
- PADO-delay — This parameter configures the delay timeout before sending a PPPoE Active Discovery Offer (PADO) packet.
  - [1 — 30] deciseconds
- PPP-mtu — This parameter configures the maximum PPP MTU size.
  - [512 — 9212]: possible values for MTU size.
- Max-sessions-per-mac — This parameter sets the maximum PPPoE sessions that can be opened for the MAC address.
  - [1 — 63]: possible PPPoE sessions per MAC address.
- Reply-on-PADT — Some of the PPPoE clients expect reply on PPPoE Active Discovery Terminate (PADT) message before the context of the session is cleared up. To support such client, a command enabling reply to PADT is provided.
  - [Default] **no reply-on-padt**
- PPP-options — This parameter enables the context to configure PPP options which is not supported by default

These parameters will be explained later in details according to their existence in the respective PPPoE phase.

Multiple PPPoE policies may be configured, but the default policy cannot be modified or deleted.

The PPPoE policy is applied within the PPPoE context under the group interface.

Troubleshooting the PPPoE discovery messages (PADI, PADO, PADR, PADS, and PADT) is done through PPPoE debugging:

```
*A:BSR-1# debug service id 1 ppp packet discovery
  - discovery [padi] [pado] [padr] [pads] [padt]
  - no discovery

 <padi>                 : keyword - debug PADI packets
 <pado>                 : keyword - debug PADO packets
 <padr>                 : keyword - debug PADR packets
 <pads>                 : keyword - debug PADS packets
 <padt>                 : keyword - debug PADT packets

 *A:BSR-1#
```

```
*A:BSR-1# show debug
debug
    service
        id 1
            ppp
```

```
                    packet
                        mode egr-ingr-and-dropped
                        discovery
                        ppp
                        dhcp-client
                    exit
            exit
        exit
    exit
exit
*A:BSR-1#
```

To display the debugging information, a dedicated log should be created:

```
configure
    log
        log-id 1
            from debug-trace
            to session
            no shutdown
        exit
    exit
exit
```

Discovery stage

The following is an example of PPPoE (PADI discovery packet) debug log output:

```
1 2017/05/16 12:07:16.94 CEST MINOR: DEBUG #2001 vprn1 PPPoE

When **disable-cookies** is configured, the use of cookies will be disabled, when omitted the **no-disable-cookies** will be used.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" disable-cookies
```

The cookies are encoded back by the client in the next PADR message.

AC-Name — The string that uniquely identifies the access concentrator (AC).

```
2 2017/05/16 12:07:19.97 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: TX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 00:00:67:14:01:02
   SMAC: 14:f2:01:01:00:01
   Ether Type: 0x8863 (Discovery)

   PPPoE Header:
   Version: 1              Type      : 1
   Code   : 0x07 (PADO)    Session-Id: 0x0000 (0)
   Length : 48

   PPPoE Tags:
   ---snip---
   [0x0102] AC-Name: "BSR-1"
   ---snip---
"
```

PADO-delay — SR OS has the possibility to delay the sending of the PADO message to the client. This feature could be used if the client is dual homed to two BSRs and is explained later in the chapter.

When PADO-delay is configured, the configured value equals the delay timeout before sending PADO, when omitted the PADO-delay value of 0 msec will be used.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" pado-delay ?
  - no pado-delay
  - pado-delay <deci-seconds>

 <deci-seconds>       : [1..30]

*A:BSR-1#
```

Authentication — PPPoE hosts are authenticated based on username-password information (PAP/CHAP authentication) or on information embedded in the PADI message in case of PADI authentication.

For CHAP authentication, the **min** and **max** values for the **ppp-chap-challenge-length** are defined when enabling **ppp-chap-challenge-length**. When omitted, a **min** of 32 and **max** of 64 are used.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" ppp-chap-challenge-length
  - ppp-chap-challenge-length min <minimum-length> max <maximum-length>
  - no ppp-chap-challenge-length

 <minimum-length>     : [8..64]
 <maximum-length>     : [8..64]

*A:BSR-1#
```

To complete the discovery phase, the server must provide a session-id to the client and SR OS allocates session-id 1 when the MACs are different.

```
*A:BSR-1# show service id 1 pppoe session
===============================================================================
PPPoE sessions for svc-id 1
===============================================================================
Sap Id              Mac Address     Sid    Up Time         Type
    IP/L2TP-Id/Interface-Id                                MC-Stdby
-------------------------------------------------------------------------------
1/1/1:1             00:00:67:14:01:02 1     0d 00:01:32     local
    10.2.0.1
-------------------------------------------------------------------------------
Number of sessions   : 1
===============================================================================
*A:BSR-1#
```

> **Note:**
> In the VLAN per service model (N: 1 VLAN), the MACs are the same and the PPPoE interworking is done at the BSAN.

Session stage

LCP

During the link establishment phase, client and server negotiate options and need to come to an agreement on these options. Options that are unknown by the peer are rejected whereas known options with unknown content are nack'd. In the latter case, the peer needs to resend the same option, but with another content. In case of a reject, the peer should remove that option. An Ack will be sent if there is a full agreement.

One of the more important options that is exchanged is the maximum receive unit (MRU) and the authentication protocol that will be used later in the authentication phase. The first option, the MRU value (minus overhead) is sent from the BSR toward the client and is the lowest value between the port MTU and the optional configured ppp-mtu in the ppp-policy.

RFC 2516 mandates a maximum negotiated Maximum Receive Unit (MRU) of 1492, but RFC 4638 relaxes this restriction and allows a maximum negotiated MRU greater than 1492 to minimize fragmentation in next-generation broadband networks. The SR OS implementation follows RFC 4638 when the client implements these extensions.

If a PPPoE client wants to use MRU>1492 in the LCP-config request, it should include the **ppp-max-payload** tag with the higher MTU value in the initial PADI message.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" ppp-mtu ?
  - no ppp-mtu
  - ppp-mtu <mtu-bytes>

 <mtu-bytes>         : [512..9212]

*A:BSR-1#
```

For LCP, the PPPoE debug output is as follows:

```
5 2017/05/16 12:07:20.12 CEST MINOR: DEBUG #2001 vprn1 PPPoE
```

```
"PPPoE: TX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 00:00:67:14:01:02
   SMAC: 14:f2:01:01:00:01
   Ether Type: 0x8864 (Session)

   PPPoE Header:
   Version: 1                 Type       : 1
   Code   : 0x00              Session-Id: 0x0001 (1)
   Length : 21

   PPP:
   Protocol  : 0xc021 (LCP)
   Code      : 1 (Configure-Request)
   Identifier: 239            Length     : 19

   Options:
   [1] MRU: 1492
   ---snip---
 "
```

The second important option, the authentication method used in the authentication phase is exchanged between client and server and can be PAP or CHAP authentication. The authentication method is not exchanged when PADI authentication is done. PADI authentication means that the BSR will authenticate the user based on parameters in the PADI message. Authentication based on PADI and PAP/CHAP is possible.

The debug output for CHAP authentication protocol is as follows:

```
8 2017/05/16 12:07:20.89 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: RX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 14:f2:01:01:00:01
   SMAC: 00:00:67:14:01:02
   Ether Type: 0x8864 (Session)

   PPPoE Header:
   Version: 1                 Type       : 1
   Code   : 0x00              Session-Id: 0x0001 (1)
   Length : 21

   PPP:
   Protocol  : 0xc021 (LCP)
   Code      : 2 (Configure-Ack)
   Identifier: 239            Length     : 19

   Options:
   [1] MRU: 1492
   [3] Authentication-Protocol: 0xc223 (CHAP), Algorithm = 5 (MD5)
   [5] Magic-Number: 0x772a29d2
 "
```

The debug output for PAP authentication is as follows:

```
72 2017/05/16 14:46:50.68 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: RX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 14:f2:01:01:00:01
```

```
    SMAC: 00:00:67:13:01:02
    Ether Type: 0x8864 (Session)
    PPPoE Header:
    Version: 1                Type       : 1
    Code   : 0x00             Session-Id: 0x0001 (1)
    Length : 20

    PPP:
    Protocol  : 0xc021 (LCP)
    Code      : 2 (Configure-Ack)
    Identifier: 134           Length     : 18

    Options:
    [1] MRU: 1492
    [3] Authentication-Protocol: 0xc023 (PAP)
    [5] Magic-Number: 0x0538a9d5
"
```

CHAP to PAP fallback case

For user authentication, with pap-chap-access, always try CHAP first; if that doesn't succeed, try PAP.

The option to be used first (CHAP/PAP) is defined when enabling the ppp-authentication. When omitted, CHAP is always preferred.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" ppp-authentication ?
  - no ppp-authentication
  - ppp-authentication {pap|chap|pref-chap|pref-pap}

*A:BSR-1#
```

PPPoE clients that implement undocumented options also require an agreement on those unknown options. By default, the 7750 SR will reject unknown options, but the **ppp-options** feature in the **pppoe-policy** allows for support of undocumented client LCP or IPCP/IPv6CP options. If the received LCP or IPCP/IPv6CP option matches the configured options in the pppoe-policy, an ack will be sent instead of a reject.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1"
                                        ppp-options custom-option ?
  - custom-option <protocol> <option-number> address <ip-address>
  - custom-option <protocol> <option-number> hex <hex-string>
  - custom-option <protocol> <option-number> string <ascii-string>
  - no custom-option <protocol> <option-number>

 <protocol>           : lcp|ipcp|ipv6cp
 <option-number>      : [0..255]
 <ip-address>         : a.b.c.d
 <ascii-string>       : [127 chars max]
 <hex-string>         : [0x0..0xFFFFFF...(max 254 hex nibbles)]

 *A:BSR-1#
```

Troubleshooting the PPPoE LCP session messages is done with PPPoE debugging:

```
A:BSR-1# debug service id 1 ppp packet ppp ?
  - no ppp
  - ppp [lcp] [pap] [chap] [ipcp] [ipv6cp]

 <lcp>                : keyword - debug LCP packets
 <pap>                : keyword - debug PAP packets
 <chap>               : keyword - debug CHAP packets
```

```
<ipcp>              : keyword - debug IPCP packets
<ipv6cp>            : keyword - debug IPv6CP packets

A:BSR-1#
```

At the end of the LCP phase, authentication is started.

SR OS supports three main methods for PPPoE authentication.

- PADI or PAP/CHAP authentication through RADIUS
- PADI or PAP/CHAP authentication through a LUDB
- PADI authentication via LUDB then PAP/CHAP pre-authentication through RADIUS

DHCP server authentication will not be explained in this section because this is more authorization than authentication.

The flow chart of the PPPoE host authentication process is shown in Figure 61: Authentication flow chart and starts with the request to the middle left.

Figure 61: Authentication flow chart
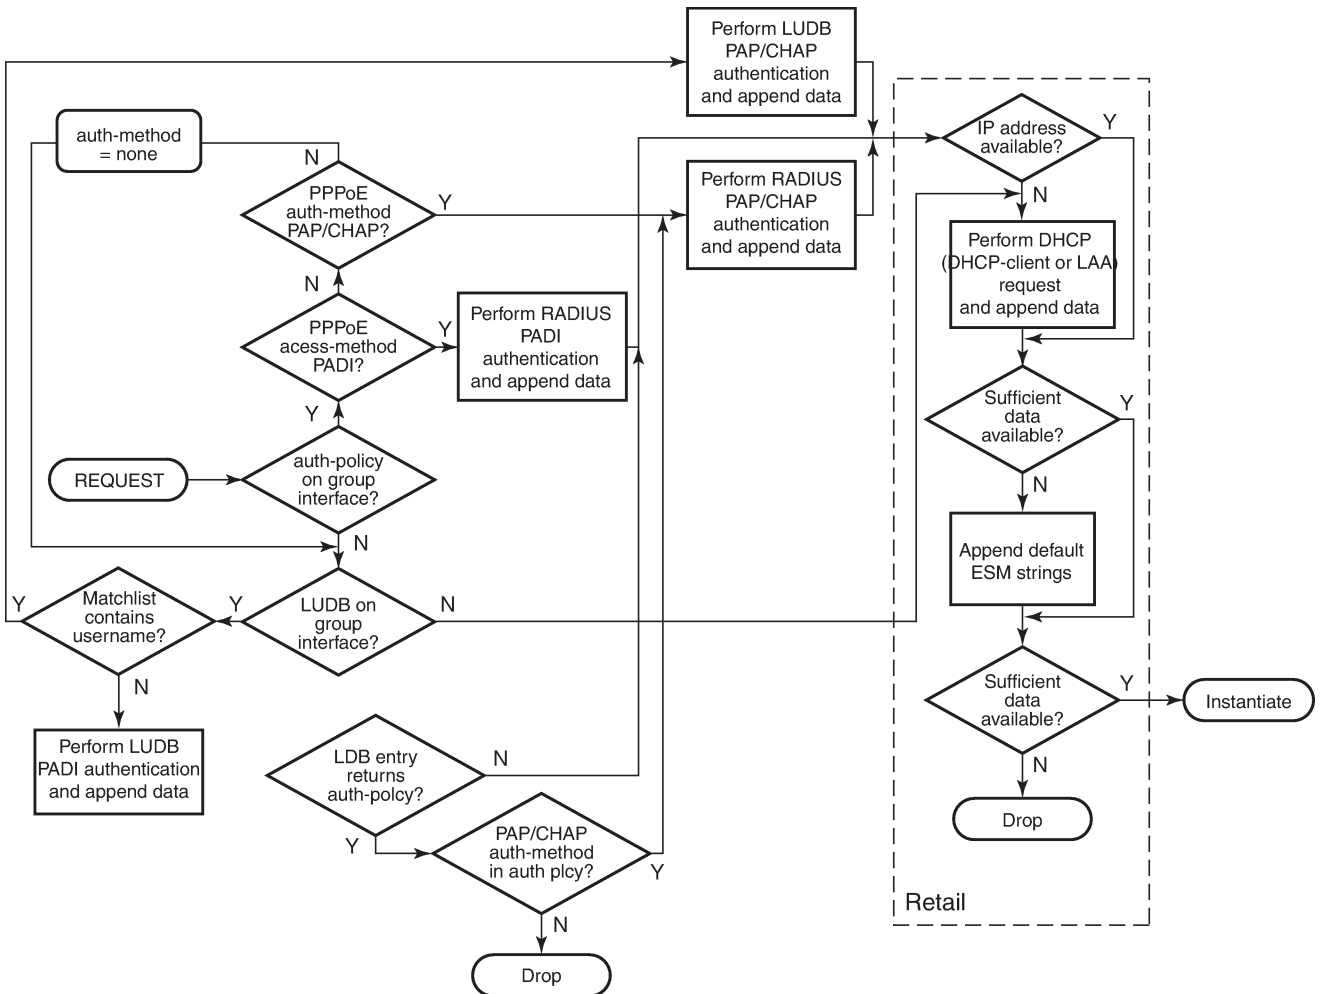

OSSG460

PPPoE users get authenticated via the LUDB if this LUDB is configured under the group-interface, as follows:

```
configure
    service
        vprn 1
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    pppoe
                        user-db "ludb-1"
```

Users get authenticated via RADIUS if an authentication-policy is configured under the same group-interface. RADIUS has precedence if both are configured, as follows:

```
configure
    service
        vprn 1
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    authentication-policy "auth-1"
                    pppoe
                        user-db "ludb-1"
                        no shutdown
                    exit
                exit
```

Users that get authenticated via the LUDB can still go to RADIUS if the authentication-policy is moved from the group-interface to the LUDB.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            ppp
                match-list username
                ---snip---
                host "user2" create
                    host-identification
                        username "user2@domain1"
                    exit
                    auth-policy "auth-1"
                    address pool "pool-1"
                    password pap letmein
                    identification-strings 254 create
                        subscriber-id "PPPoE-host-user2@domain1"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    no shutdown
                exit
                ---snip---
            exit
        exit
    exit
exit
```

This last mechanism could be used to pick up parameters like **pado-delay** or to check some variables such as **circuit-id**, **remote-id** from the LUDB during discovery phase and subsequently to use RADIUS for PAP/CHAP authentication.

```
*A:BSR-1# configure subscriber-mgmt local-user-db "ludb-1" ppp host "user2"
```

```
                                                    host-identification ?
  - host-identification

 [no] circuit-id       - Configure the circuit id of this host
 [no] derived-id       - Configure the host ID to be derived by a python script from
                         DHCP packets during a DHCP transaction
 [no] encap-tag-range  - Configure the SAP encap range tags for this host
 [no] mac              - Configure the MAC address of this host
 [no] remote-id        - Configure the remote id of this host
 [no] sap-id           - Configure the SAP identifier of this host
 [no] service-name     - Configure the service name of this host
 [no] username         - Configure the user name of this host

 *A:BSR-1#
```

Both RADIUS and LUDB support PADI or PAP/CHAP authentication.

PPPoE users that are authenticated through the LUDB and have in the LUDB a match-list other than
username will get authenticated based on PADI parameters like mac, circuit-id, remote-id.

```
*A:BSR-1# configure subscriber-mgmt local-user-db "ludb-1" ppp match-list ?
  - no match-list
  - match-list <ppp-match-type-1> [<ppp-match-type-2>...(up to 3 max)]

 <ppp-match-type>     : circuit-id|derived-id|mac|remote-id|sap-id|
                                     encap-tag-range|service-name|username

 *A:BSR-1#
```

PPPoE users that have in the LUDB a match-list equal to **username** will use the PAP/CHAP authentication
method.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            ppp
                match-list username
                host "user1" create
                    host-identification
                        username "user1@domain1"
                    exit
                    address pool "pool-1"
                    password chap letmein
                    identification-strings 254 create
                        subscriber-id "PPPoE-host-user1@domain1"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    no shutdown
                exit
                ---snip---
            exit
        exit
    exit
exit
```

PPPoE users that are authenticated through RADIUS and have in the authentication policy, a pppoe-
access-method equal to PADI will use the **mac** or **circuit-id** information from the PADI in their request to
RADIUS.

```
 *A:BSR-1# configure subscriber-mgmt authentication-policy "auth-1"
```

```
                                                        pppoe-access-method ?
  - no pppoe-access-method
  - pppoe-access-method {none|padi|pap-chap}

 *A:BSR-1#
```

The selection for mac or circuit-id can be altered via the parameter user-name-format.

```
 *A:BSR-1# configure subscriber-mgmt authentication-policy "auth-1"
                                                 user-name-format ?
  - no user-name-format
  - user-name-format <format> [mac-format <mac-format>]
  - user-name-format <format> append [<domain-name>]
                                      [mac-format <mac-format>]
  - user-name-format <format> append domain-name
  - user-name-format <format> default-domain <domain-name>
                                      [mac-format <mac-format>]
  - user-name-format <format> replace <domain-name>
                                      [mac-format <mac-format>]
  - user-name-format <format> strip [mac-format <mac-format>]

 <format>                : ascii-converted-circuit-id|ascii-converted-tuple|
                             circuit-id|dhcp-client-vendor-opts|mac|
                             mac-giaddr|ppp-user-name|tuple
 <domain-name>           : max 128 chars, no @ needed
 <mac-format>            : (only when format is dhcp-client-vendor-opts)
                            like ab:   for 00:0c:f1:99:85:b8
                            or   XY-   for 00-0C-F1-99-85-B8

 *A:BSR-1#
```

PPPoE users that are authenticated through RADIUS and having a pppoe-access-method equal to pap-chap in the authentication policy use the username from the authentication phase in their request to RADIUS. The parameter user-name-format is irrelevant in this last case.

RADIUS authentication

When authentication is provided through RADIUS, two methods can be used to authenticate the PPPoE session.

• PADI authentication

• PAP/CHAP authentication

The RADIUS policy specifies which parameters are provided in the RADIUS access-request message.

The following parameters can be configured:

• Circuit-id: Provided through the PADI/PADR PPPoE relay vendor specific tag as specified in TR-101 of the DSL Forum.

• Remote-id: Provided through the PADI/PADR PPPoE relay vendor specific tag as specified in TR-101 of the DSL Forum.

• NAS-port-id: SAP ID on which the PPPoE session terminates (e.g. 1/1/3:1).

• NAS-identifier: System name of the NAS or BNG.

• PPPoE-service-name: Provided through the PPPoE PADI packet.

- access-loop-options: Provided through the PAD/PADR PPPoE extensions as specified in TR-101 of the DSL Forum.

The option to use PADI authentication or PAP/CHAP authentication is selected with the following configuration in the RADIUS policy:

```
*A:BSR-1# configure subscriber-mgmt authentication-policy "auth-1" pppoe-access-method ?
  - no pppoe-access-method
  - pppoe-access-method {none|padi|pap-chap}

*A:BSR-1#
```

When PADI authentication is used the MAC address or the PPPoE relay tag (Circuit-ID) or a combination of MAC address and circuit ID can be used to identify the subscriber in the RADIUS server.

The attributes included in the RADIUS Access-Request message is configured in the RADIUS policy using the following command:

```
*A:BSR-1# configure subscriber-mgmt authentication-policy "auth-" include-radius-attribute ?
  - include-radius-attribute
  - no include-radius-attribute

 [no] access-loop-op* - Enable/disable generation of the DSL Forum access loop
 characteristics RADIUS attributes
 [no] acct-session-id - Enable/disable generation of the Acct-Session-Id RADIUS
 attribute

 attribute
 [no] wifi-ssid-vlan  - Enable/disable including the per-SSID VLAN ID in Alc-Wlan
 -SSID-VLAN

*A:BSR-1#
```

Local User Database authentication

A second authentication option for PPPoE termination is to use the local user database of the BSR 7750 for PAP/CHAP authentication (this option will be used in this example). With this authentication method, the client's PPPoE session is authenticated locally on the BSR without any constraint of an external radius server.

The local user database is configured with the following parameters:

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            ppp
                match-list username
                host "user1" create
                    host-identification
                        username "user1@domain1"
                    exit
                    address pool "pool-1"
                    password chap letmein
                    identification-strings 254 create
                        subscriber-id "PPPoE-host-user1@domain1"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    no shutdown
                exit
                ---snip---
```

With the LUDB authentication method, authentication can be provided by the username/password combination.

To enable the local authentication method, the local user database is configured under the PPPoE node of the group-interface as follows.

```
configure
    service
        vprn 1
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    pppoe
                        policy "ppp-policy-1"
                        user-db "ludb-1"
                        no shutdown
                    exit
                exit
            exit
```

The properties of LUDB user user-1 are as follows:

```
*A:BSR-1# show subscriber-mgmt local-user-db "ludb-1" ppp-host "user1"

*A:BSR-1#
```

To debug the LUDB, use the command as follows:

```
*A:BSR-1# debug subscriber-mgmt local-user-db "ludb-1" detail ?
  - detail {all|failed}
  - no detail

*A:BSR-1#
```

See the LUBD Basics chapter for further information.

DHCP client authentication

A third authentication method for PPPoE termination is to perform PPPoE to DHCP transformation (where the router acts as a DHCP client on behalf of the PPP session) and to use a DHCP server for session authentication. This method is useful when a similar authentication is used for DHCP based clients.

The PPPoE to DHCP authentication method can provide authentication on the basis of MAC address, circuit ID or remote ID.

IPCP

IP and DNS information can be obtained from different sources like LUDB and RADIUS for fixed IP addressing or (local) DHCP for dynamic IP pool management.

If IP information is returned from a DHCP server, then the PPPoE options such as the DNS name are retrieved from the DHCP ACK and provided to the PPPoE client.

Local DHCP server

This chapter uses a local DHCP server as a source for the IP address information of the PPPoE host.

```
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "server-1" create
                    use-pool-from-client
                    pool "pool-1" create
                        subnet 10.2.0.0/16 create
                            exclude-addresses 10.2.0.254 10.2.0.255
                            address-range 10.2.0.1 10.2.0.253
                        exit
                    exit
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

To check the DHCP server summary:

```
*A:BSR-1# show router 1 dhcp local-dhcp-server "server-1" summary

===============================================================================
*A:BSR-1#
```

To debug the DHCP server:

```
debug
    router "1"
        local-dhcp-server "server-1"
            detail-level high
            mode egr-ingr-and-dropped
        exit
    exit
exit
```

Keepalive

The keepalive timer (defined in seconds) and the hold-up-multiplier are defined when enabling keepalives. When omitted, a 30 second keepalive timer and three hold-up-multipliers are used.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1"  keepalive ?
  - keepalive <seconds> [hold-up-multiplier <multiplier>]
  - no keepalive

 <seconds>            : [4..300]
 <multiplier>         : [1..5]

*A:BSR-1#
```

The keepalive defines the interval between LCP Echo Requests in seconds. The hold-up-multiplier defines the number of missed replies before the PPPoE session is considered dead.

To check the keepalive statistics:

```
*A:BSR-1# show service id 1 pppoe session session-id 1 mac 00:00:67:14:01:02
                                                      statistics

=========================================================================
*A:BSR-1#
```

The BSR supports an optimized implementation of keepalive mechanism; this is a mechanism where client
and/or server can check the aliveness of the peer. This LCP echo-request is sent on expiration of a timer,
derived from the configured **pppoe-policy keepalive** value.

An LCP echo reply is returned to the client after a LCP echo request is received and the preceding timer on
the BSR is reset to the initial keepalive value.

The preceding mechanism results in an optimized mechanism if the keepalive timers from the client are
smaller than the configured values on the BSR.

The client or BSR will terminate the session with a PADT if no LCP echo-reply is received within the time
specified by the hold-up-multiplier.

An example for Echo Request from BSR and Echo Reply from the PPPoE host is as follows:

```
15:36:27.907363 00:00:67:14:01:02 > 14:f2:01:01:00:01, ethertype 802.1Q (0x8100),
length 64: vlan 1, p 7, ethertype PPPoE S, PPPoE  [ses 0x1] LCP (0xc021),
length 10: LCP, Echo-Request (0x09), id 249, length 10
        encoded length 8 (=Option(s) length 4)
        0x0000:  c021 09f9 0008
         Magic-Num 0x00000000
15:36:27.907844 14:f2:01:01:00:01 > 00:00:67:14:01:02, ethertype 802.1Q (0x8100),
```

```
length 60: vlan 1, p 5, ethertype PPPoE S, PPPoE  [ses 0x1] LCP (0xc021),
length 10: LCP, Echo-Reply (0x0a), id 249, length 10
        encoded length 8 (=Option(s) length 4)
        0x0000:  c021 0af9 0008
          Magic-Num 0x3298fadc
```

To check the PPPoE session for a particular service, use the **show service id** *<service-id>* **pppoe session** command. Detailed output as well as additional output filtering is available:

```
*A:BSR-1# show service id 1 pppoe session ?
  - session [interface <ip-int-name|ip-address> | sap <sap-id>]
    [type <pppoe-session-type>] [session-id <session-id>] [mac <ieee-address>]
    [ip-address <ip-prefix[/prefix-length]>] [port <port-id>]
    [no-inter-dest-id | inter-dest-id <intermediate-destination-id>]
    [steering-profile <steering-profile>] [router-advertisement-policy
    <router-adv-policy>] [detail|statistics]
  - session l2tp-connection-id <connection-id> [detail|statistics]
```

The details of the PPPoE session for MAC address 00:00:67:14:01:02 are as follows:

```
*A:BSR-1# show service id 1 pppoe session mac 00:00:67:14:01:02 detail

===============================================================================
*A:BSR-1#
```

To advertise the PPPoE host subnets to other protocol/network, a policy statement should be defined with using **from protocol direct**.

```
configure
    router
        policy-options
            begin
                policy-statement "policy-1"
                    entry 10
                        from
                            protocol direct
                        exit
                        ---snip---
                    exit
                exit
            commit
        exit
    exit
exit
```

Terminate

Some PPPoE clients expect a reply on PADT message before the context of the session is cleared up. To support such clients, a command enabling reply to PADT is configured.

When reply-on-padt is configured, the BSR will reply with PADT message, when omitted, no PADT will be sent from the BSR as a reply on the client's PADT.

```
*A:BSR-1# configure subscriber-mgmt ppp-policy "ppp-policy-1" reply-on-padt
```

The PPPoE debug output:

```
116 2017/05/16 15:47:16.67 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: RX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 14:f2:01:01:00:01
   SMAC: 00:00:67:14:01:02
   Ether Type: 0x8863 (Discovery)

   PPPoE Header:
   Version: 1               Type      : 1
   Code   : 0xa7 (PADT)     Session-Id: 0x0001 (1)
   Length : 0
"

117 2017/05/16 15:47:16.68 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: TX Packet
   VPRN 1, SAP 1/1/1:1

   DMAC: 00:00:67:14:01:02
   SMAC: 14:f2:01:01:00:01
   Ether Type: 0x8863 (Discovery)

   PPPoE Header:
   Version: 1               Type      : 1
   Code   : 0xa7 (PADT)     Session-Id: 0x0001 (1)
   Length : 0
"
```

A PPPoE host can be manually deleted from the system using following clear command:

```
*A:BSR-1# clear service id 1 ppp session ?
  - session [sap-id <sap-id>] [interface <ip-int-name|ip-address>]
            [mac <ieee-address>] [session-id <session-id>]
            [type <pppoe-session-type>] [ip-address <ip-prefix[/prefix-length]>]
            [port <port-id>] [inter-dest-id <intermediate-destination-id>]
            [no-inter-dest-id] [user-name <user-name>]
            [sub-ppp-type {oa|oe|oeoa|ol2tp}] [no-padt]
  - session all [no-padt]

---snip---

*A:BSR-1#
```

The logs indicate a cause for terminating the PPP session:

- **Admin Reset** — Use the **clear** command or a RADIUS Disconnect Request.

  TERMINATE CAUSE [49] 4 Admin Reset(6)

- **User Request** — User disconnects the session.

  TERMINATE CAUSE [49] 4 User Request(1)

- **Accounting OFF**

  – When accounting policy has been removed from sap/interface/sub-profile.

–   The VPRN service which is transporting accounting information has been shutdown.

–   The last RADIUS accounting server has been removed from an already applied accounting policy.

```
TERMINATE CAUSE [49] 4 NAS Request(10)
```

- **PPPoE keepalive timeout**

```
TERMINATE CAUSE [49] 4 Lost Carrier(2)
```

- **RADIUS session timeout**

PPPoE hosts advanced topics

QoS Aspects

VLAN encapsulated downstream PPPoE control traffic is generated by default with dot1p value 7. This value can be overruled with the following commands:

In case of the PPPoE hosts instantiated in the Base routing instance using an IES service.

```
*A:BSR-1# configure router sgt-qos application pppoe dot1p 5
```

In case of the PPPoE hosts instantiated in a VPRN service subscriber-interface.

```
*A:BSR-1# configure service vprn 1 sgt-qos application pppoe dot1p 5
```

The **show router sgt-qos** command displays the configured and default DSCP and default dot1p values per application. Because PPPoE is a Layer 2 protocol we will see only the dot1p settings. The default dot1p value **none** corresponds with value 7.

```
*A:BSR-1# show router 1 sgt-qos application pppoe

===============================================================================
Dot1p Application Values
===============================================================================
Application          Configured Dot1p Value      Default Dot1p Value
-------------------------------------------------------------------------------
pppoe                5                           7
===============================================================================
*A:BSR-1#
```

Limiting the number of PPPoE hosts

The maximum number of PPPoE sessions can be controlled by the parameters session-limit, sap-session-limit, host-limit, multi-sub-sap limit and max-sessions-per mac.

session-limit — The maximum number of PPPoE sessions for an IES/VPRN group-interface is defined when enabling session-limit. When omitted, a single PPPoE session is allowed.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
```

```
                group-interface "grp-int-1" create
                    pppoe
                        policy "ppp-policy-1"
                        session-limit 1
                        user-db "ludb-1"
                        no shutdown
                    exit
                exit
```

Note:
The discovery phase is completed before the session-limit check is executed.

The debug log shows a message when the session-limit is reached, as follows:

```
199 2017/05/16 16:03:22.14 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: Dropped Packet
   VPRN 1, SAP 1/1/1:1

   Problem: Reached the interface session limit (1) for "grp-int-1"

   DMAC: ff:ff:ff:ff:ff:ff
   SMAC: 00:00:67:13:01:02
   Ether Type: 0x8863 (Discovery)

   PPPoE Header:
   Version: 1              Type      : 1
   Code   : 0x09 (PADI)    Session-Id: 0x0000 (0)
   Length : 37

   PPPoE Tags:

---snip---

*A:BSR-1#
```

Sap-session-limit

The maximum number of PPPoE sessions per SAP for an IES/VPRN group-interface is defined when
enabling sap-session-limit. When omitted, a single PPPoE session per SAP is allowed:

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    pppoe
                        policy "ppp-policy-1"
                        session-limit 10
                        sap-session-limit 1
                        user-db "ludb-1"
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

The debug log shows a message when the session-limit is reached, as follows:

```
201 2017/05/16 16:10:34.00 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: Dropped Packet
    VPRN 1, SAP 1/1/1:1

    Problem: Reached the per-SAP session limit (1) for "grp-int-1"

    [0x0105] Vendor-Specific: vendor-id = 0x0de9 (ADSL Forum)
        [0x01] Agent-Circuit-Id: "cicuit11"
        [0x02] Agent-Remote-Id: "remote11"
"
```

A trap is generated when trying to instantiate a new PPPoE session while the configured number of the
sessions per sap is reached.

```
*A:BSR-1# show log log-id 99

===============================================================================
Event Log 99
===============================================================================
Description : Default System Log
Memory Log contents  [size=500   next event=89  (not wrapped)]

88 2017/05/16 16:10:34.00 CEST WARNING: PPPOE #2001 vprn1 PPPoE session failure
```

```
"PPPoE session failure on SAP 1/1/1:1 in service 1 - Reached the per-SAP session limit
 (1) for "grp-int-1""

---snip---

*A:BSR-1#
```

Max-sessions-per-mac

The BSR 7750 implementation defines a unique PPPoE session based on the PPPoE SESSION_ID and the client's MAC address.

The maximum number of PPPoE sessions per mac is defined when enabling max-sessions-per-mac. When omitted, a single PPPoE session per mac is allowed.

```
configure
    subscriber-mgmt
        ppp-policy "ppp-policy-1"
            disable-cookies
            max-sessions-per-mac 256
            reply-on-padt
        exit
    exit
exit
```

Although the command is max-session-per-mac, actually it means the maximum number of supported sessions-per-MAC-per-SAP especially in N: 1 VLAN model.

The debug log shows a message when the max-sessions-per-mac limit is reached, as follows:

```
226 2017/05/16 16:30:38.82 CEST MINOR: DEBUG #2001 vprn1 PPPoE
"PPPoE: Dropped Packet
   VPRN 1, SAP 1/1/1:1

   Problem: Reached the maximum number (1) of PPPoE sessions for MAC

```

Redundancy

Redundancy for PPPoE sessions can be used for load balancing sessions between the two BSRs. PADO-delays (which can come from RADIUS, LUDB, and policy) are used to achieve that.

The redundant BSRs need different IP subnets, and upon failure the PPP sessions will need to be re-established.

Because PADI messages are broadcast on a multi-access network, all BSRs on that network will reply with a PADO to the initiator.

The PADR and PADS are sent in unicast to the MAC address from the first received PADO message.

In order to allow control over the NAS/BSR selection for a PPPoE session, SR OS offers the ability to delay the PADO message. Due to the fact that PPPoE clients select the NAS/BSR for further communication based on the first PADO message that arrives, this functionality provides control over the NAS/BSR that gets selected for a PPPoE session.

On top if for some reason a NAS/BSR, without PADO delay configured in the PPPoE policy, does not reply on PADI messages to the client, another NAS/BSR with a PADO delay configured will reply based on the time configured and ultimately the PPPoE session will be established with the PADO delayed NAS/BSR.

Figure 62: Pado-Delay Scenario
Check the PADO delay value, as follows:

```
*A:BSR-1# show subscriber-mgmt ppp-policy "ppp-policy-1"

```

```
*A:BSR-1#
```

Another option to achieve redundancy is through Multi Chassis Synchronization (MCS), but that is beyond the scope of this chapter.

High availability

The PPPoE session state is HA: the session state is synchronized to the standby CPM. When the active CPM fails, all PPPoE hosts stay active without service interruption.

Conclusion

This chapter provides configuration and troubleshooting commands for PPPoE hosts in a Layer 3 Routed CO (IES/VPRN subscriber interface) context.

ESMv6: IPoE Dual Stack Hosts

This chapter describes IPoE dual stack hosts for ESMv6 configurations.

Topics in this chapter include:

- Applicability
- Summary
- Overview
- Configuration
- Conclusion

Applicability

This chapter describes ESMv6: IPoE dual stack hosts and is based on SR OS 8.0.R4.The CLI is updated to Release 15.0.R1.

This chapter focuses on IPoE IPv6. IPv4 configuration is shown for completeness and is described in more detail in IPv4 DHCP Hosts.

Prerequisites

Configuring IPoE dual stack hosts for ESMv6 are dependent on the following.

- Routed CO (IES/VPRN service) with Enhanced Subscriber Management (ESM)
- Routed Gateway (RG) in the home

Summary

In this chapter, the configuration, operation, and troubleshooting of IPoE dual stack hosts in a routed home gateway environment is described. Focus is on the Enhanced Subscriber Management for IPv6 (ESMv6) part where DHCPv6 is used for IPv6 address assignment. In the Broadband Network Gateway (BNG), authentication, authorization, and IPv6 prefix configuration for an IPoE IPv6 host can be done by a local user database (LUDB) or RADIUS.

Overview

IPoE Dual Stack Hosts

An IPoE dual stack subscriber may support both IPv4 and IPv6 simultaneously. The dual stack hosts share a common subscriber identification policy and have a common SLA- and Subscriber-profile.

IPoE IPv4 and IPv6 hosts operate independently because they are set up through different protocols, DHCPv4 and DHCPv6 respectively.

For a stateful IPoE dual stack subscriber, up to three different types of subscriber hosts can be instantiated.

Figure 63: Stateful IPoE Dual Stack Subscriber Hosts
Dual Stack IPoE Routed Gateway

In services supporting dual stack IPoE Routed Gateways, the RG in the home network obtains an IPv4 address through the DHCPv4 protocol and an IPv6 Prefix Delegation (PD) prefix and/or wan-host IPv6 address through the DHCPv6 protocol. The Broadband Network Gateway (BNG) authenticates and authorizes both sessions independently.

In the home network, the dual stack RG performs Network Address Translation (NAT) for IPv4, using the assigned IPv4 address as outside address. A globally unique IPv6 prefix per subscriber is assigned and delegated by the BNG to the RG for use in the home network. The RG can use Stateless Address Auto Configuration (SLAAC) or DHCPv6 to allocate IPv6 addresses from this so called Prefix Delegation (PD) prefix to the devices in the home network. The wan-host IPv6 address is used by the RG on the WAN side (network facing). In case of an unnumbered RG, no wan-host address is obtained.

Figure 64: Dual Stack IPoE Routed Gateway Service
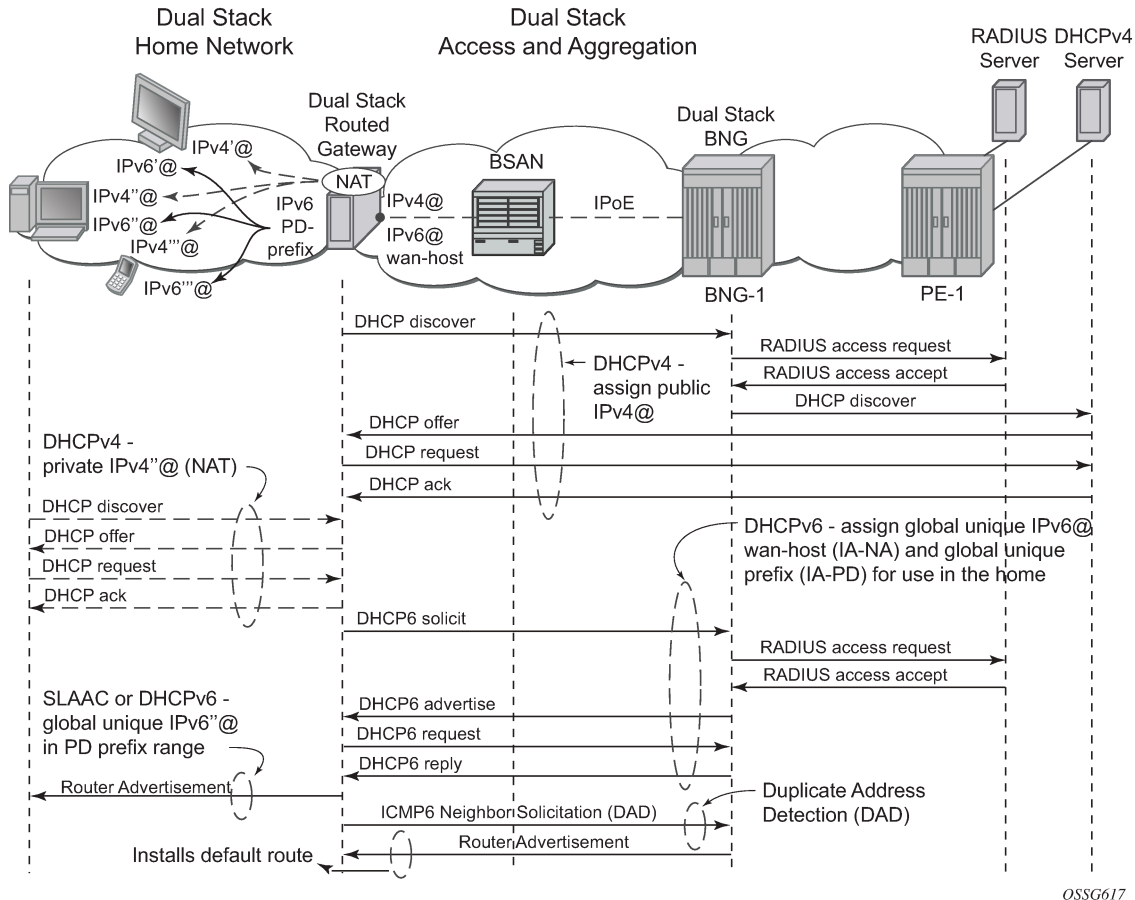

Recap of the DHCPv6 Protocol

The Dynamic Host Configuration Protocol for IPv6 (DHCPv6) is defined in RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. The protocol enables DHCPv6 servers to pass configuration parameters such as IPv6 network addresses to IPv6 nodes.

DHCPv6 uses the Identity Association (IA) option to assign IPv6 addresses or prefixes. Two different IA types will be used in this section:

- Identity Association for Non-temporary Address (IA-NA) defined in RFC 3315. Used for wan-host IPv6 address assignment.

```
Option : IA_NA (3), Length : 40
  IAID : 1
  Time1: 1800 seconds
  Time2: 2880 seconds
  Option : IAADDR (5), Length : 24
    Address : 2001:db8:b001:101::1
    Preferred Lifetime : 3600 seconds
    Valid Lifetime    : 86400 seconds
```

- Identity Association for Prefix Delegation (IA-PD), defined in RFC 3633. Used for prefix delegation assignment (for an explanation on prefix delegation, see Prefix Delegation)

```
Option : IA_PD (25), Length : 41
  IAID : 1
  Time1: 1800 seconds
  Time2: 2880 seconds
  Option : IAPREFIX (26), Length : 25
    Prefix : 2001:db8:a001:103::/56
    Preferred Lifetime : 3600 seconds
    Valid Lifetime    : 86400 seconds
```

The DHCPv6 lease process is outlined in Figure 65: DHCPv6 Lease Process (Part A) and Figure 66: DHCPv6 Lease Process (Part B).

Figure 65: DHCPv6 Lease Process (Part A)
A DHCPv6 client, sends a Solicit message to locate servers to the All DHCPv6 Relay Agents and Servers link-scoped multicast address (FF02::1:2), using its link-local address as source address. The DHCPv6 client includes in the Solicit message its ClientID, Identity Associations (IA) to request IPv6 address or prefix allocation and optionally an Option Request option.

Any on-link DHCPv6 server responds with a unicasted Advertise message using the link local addresses. The server includes in the Advertise message the ClientID, its ServerID, IPv6 addresses and/or prefixes in Identity Associations (IA) and options containing the requested configuration parameters.

The DHCPv6 client selects an Advertise message and sends a Request message to the All DHCPv6 Relay Agents and Servers link-scoped multicast address. It includes its ClientID, the ServerID of the corresponding DHCPv6 server, Identity Associations (IA) to request IPv6 address or prefix allocation and optionally an Option Request option.

Upon receipt of a valid Request message, the DHCPv6 server with corresponding ServerID, sends a unicast Reply message using the link local addresses. The Reply contains the ClientID and ServerID, IPv6 addresses and/or prefixes in Identity Associations (IA) and options containing the requested configuration options.

The DHCPv6 client should perform Duplicate Address Detection (DAD) on the addresses in any IA it received in the REPLY before using that address for traffic.

Figure 66: DHCPv6 Lease Process (Part B)
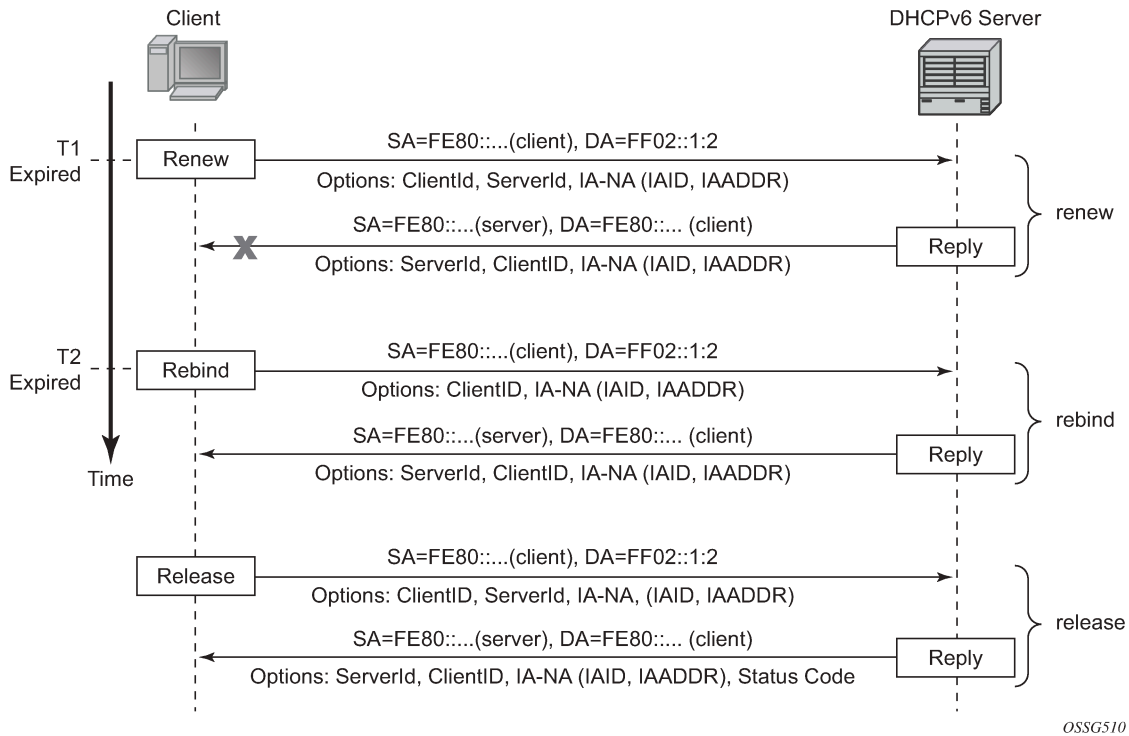

Upon expiration of the renew timer T1 associated with the Identity Association option, the DHCPv6 client sends a Renew to the All DHCPv6 Relay Agents and Servers link-scoped multicast address to request an extension of the lifetime of an address. It includes its ClientID, the ServerID of the DHCPv6 server that originally provided the address, and Identity Associations (IA) containing the IPv6 address or prefix for which an extension of the lifetime is requested.

Upon expiration of the rebind timer T2 associated with the Identity Association option (no response received to the Renew), the DHCPv6 client sends a Rebind to the All DHCPv6 Relay Agents and Servers link-scoped multicast address to request an extension of the lifetime of an address. It includes its ClientID and Identity Associations (IA) containing the IPv6 address or prefix for which an extension of the lifetime is requested.

If a DHCPv6 client no longer uses one or more of the assigned addresses or prefixes, it sends a Release message to the server that assigned the address or prefix. The server acknowledges with a Reply message and includes a status code (for example, success).

If the DHCPv6 server sends a Server Unicast Option, then the DHCPv6 client should unicast the Request, Renew Release, and Decline messages to the server using the IPv6 address specified in the option. The 7750 SR DHCPv6 proxy server does not include the Server Unicast Option.

The DHCPv6 client should perform Duplicate Address Detection (DAD) on each of the addresses assigned through DHCPv6, before using that address for traffic. The DHCPv6 client uses Neighbor Solicitation for this purpose as described in RFC 4862, *IPv6 Stateless Address AutoConfiguration*.

Unlike DHCPv4, DHCPv6 does not provide a default route. In IPv6, default routes are learned via Router Advertisements (see Enable Router Advertisements).

Prefix Delegation

Prefix Delegation (PD) is a mechanism for automated delegation of IPv6 prefixes using DHCPv6. A delegating router delegates a long-lived IPv6 prefix to a requesting router. The delegating router does not require knowledge about the topology of the links in the network to which the prefixes will be assigned.

Figure 67: Prefix Delegation
In the context of ESM IPv6, the BNG is the delegating router (DHCPv6 server) and the Routed Gateway in the home is the requesting router (DHCPv6 client). The DHCPv6 option Identity Association for Prefix Delegation (IA-PD) (Figure 67: Prefix Delegation) is used to assign the IPv6 prefix.

Note that the mechanism through which a requesting router (routed gateway) assigns IPv6 addresses on its interfaces (home network) is arbitrary and can be based upon SLAAC (as shown in Figure 67: Prefix Delegation) or DHCPv6.

Configuration

ESMv6 for IPoE is applicable in a Routed CO environment. The two following scenarios show a minimal configuration to enable dual stack subscribers in a VPRN service context where the ESM IPv6 specific parts are highlighted. No subscriber QoS policies are defined because this is out of the scope for this chapter.

Scenario 1 - RADIUS

RADIUS is used for authentication and authorization (later referenced as RADIUS), and is configured as follows:

```
configure
    router
        radius-server
            server "radius-172.16.1.2" address 172.16.1.2 secret vsecret1 create
                accept-coa
            exit
        exit
    exit
exit

configure
```

```
        aaa
            radius-server-policy "rsp-1" create
                servers
                    router "Base"
                    source-address 192.0.2.1
                    server 1 name "radius-172.16.1.2"
                exit
            exit
        exit
exit

configure
    subscriber-mgmt
        authentication-policy "auth-1" create
            description "RADIUS authentication policy"
            pppoe-access-method pap-chap
            radius-server-policy "rsp-1"
            password letmein
        exit
    exit
exit
```

The subscriber management profiles used in this chapter are defined as follows:

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-1" create
        exit
        sub-profile "sub-profile-1" create
        exit
        sub-ident-policy "sub-ident-1" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
            strings-from-option 254
        exit
    exit
exit
```

Service VPRN-1 is defined as follows:

```
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "dhcp-s1" create
                    use-gi-address
                    pool "pool-1" create
                        subnet 10.1.0.0/16 create
                            options
                                subnet-mask 255.255.0.0
                                default-router 10.1.255.254
                            exit
                            address-range 10.1.0.1 10.1.0.255
                        exit
                    exit
                    no shutdown
                exit
            exit
            ---snip---
```

```
            interface "system" create
                address 192.0.2.1/32
                local-dhcp-server "dhcp-s1"
                loopback
            exit
            subscriber-interface "sub-int-1" create
                address 10.1.255.254/16
                dhcp
                    gi-address 10.1.255.254
                exit
                ipv6
                    delegated-prefix-len 56
                    subscriber-prefixes
                        prefix 2001:db8:a001::/48 pd
                        prefix 2001:db8:b001:100::/56 wan-host
                    exit
                exit
                group-interface "grp-int-1" create
                    description "radius authentication and authorization"
                    ipv6
                        router-advertisements
                            managed-configuration
                            no shutdown
                        exit
                        dhcp6
                            proxy-server
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        proxy-server
                            emulated-server 10.1.255.254
                            no shutdown
                        exit
                        server 192.0.2.1
                        trusted
                        lease-populate 10
                        no shutdown
                    exit
                    authentication-policy "auth-1"
                    sap 1/1/1:1 create
                        sub-sla-mgmt
                            sub-ident-policy "sub-ident-1"
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                exit
                ---snip---
            exit
            service-name "dual-stack-service"
            no shutdown
        exit
    exit
exit
```

Scenario 2 - LUDB

The Local User Database used for authentication and authorization (later referenced as LUDB) is defined as follows:

```
configure
    subscriber-mgmt
        local-user-db ludb-1 create
            ipoe
                match-list mac
                host "host-3" create
                    host-identification
                        mac 00:0c:29:00:00:23
                    exit
                    address gi-address
                    identification-strings 254 create
                        subscriber-id "sub-3"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    options
                        subnet-mask 255.255.0.0
                        default-router 10.1.255.254
                    exit
                    ipv6-address 2001:db8:b001:103::3
                    ipv6-delegated-prefix 2001:db8:a001:300::/56
                    ipv6-delegated-prefix-len 56
                    options6
                        dns-server 2001:db8:dddd:1::1 2001:db8:dddd:2::1
                    exit
                    no shutdown
                exit
                ---snip---
            exit
            no shutdown
        exit
    exit
exit
```

Service VPRN-1 is extended as follows:

```
configure
    service
        vprn 1 customer 1 create
            ---snip---
            subscriber-interface "sub-int-1" create
                address 10.1.255.254/16
                dhcp
                    gi-address 10.1.255.254
                exit
                ipv6
                    delegated-prefix-len 56
                    subscriber-prefixes
                        prefix 2001:db8:a001::/48 pd
                        prefix 2001:db8:b001:100::/56 wan-host
                    exit
                exit
                group-interface "grp-int-2" create
                    description "ludb authentication and authorization"
                    ipv6
                        router-advertisements
```

```
                               prefix-options
                                   autonomous
                               exit
                               no shutdown
                           exit
                           dhcp6
                               user-db "ludb-1"
                               proxy-server
                                   client-applications ipoe
                                   no shutdown
                               exit
                           exit
                       exit
                       dhcp
                           proxy-server
                               emulated-server 10.1.255.254
                               no shutdown
                           exit
                           server 192.0.2.1
                           trusted
                           lease-populate 10
                           user-db "ludb-1"
                           no shutdown
                       exit
                       sap 1/1/1:2 create
                           sub-sla-mgmt
                               def-sub-profile "sub-profile-1"
                               def-sla-profile "sla-profile-1"
                               sub-ident-policy "sub-ident-1"
                               multi-sub-sap 10
                               no shutdown
                           exit
                       exit
                   exit
               exit
               service-name "dual-stack-service"
               no shutdown
           exit
       exit
 exit
```

Configuring IPv6 Subscriber Prefixes

Applies to both scenarios RADIUS and LUDB.

IPv6 subscriber prefixes must be defined at the **subscriber-interface>ipv6>subscriber-prefixes** context. Three types of prefixes can be configured:

- **wan-host** — Prefix from which the IPv6 addresses are assigned that are to be used on the Routed Gateway WAN interface (network facing).

- **pd** — Prefix from which the IPv6 Prefix Delegation prefixes are assigned that are to be used by the Routed Gateway for allocation in the home network (LAN interfaces).

- **pd wan-host** (both) — Prefix from which both IPv6 addresses (wan-host) and IPv6 Prefix Delegation prefixes (pd) can be assigned. This requires that the delegated prefix length is set to 64 bits.

A subscriber prefix length must be between /32 and /63.

Subscriber prefixes are subnetted in fixed length subnets that are assigned to subscriber hosts:

- /64 for **wan-host** subscriber prefixes

A /128 IPv6 address is assigned to the subscriber host. Broadband Forum standards require a /64 prefix per subscriber even when used for WAN interfaces and thus the full /64 subnet gets associated with the subscriber host [ref. WT-177 - IPv6 in the context of TR-101]. Two subscriber hosts cannot get an IPv6 address from the same /64 subnet.

- /delegated-prefix-len (/48..64) for **pd** subscriber prefixes

The delegated prefix length is configured in the **subscriber-interface>ipv6** context. The recommended value by Broadband Forum standards is /56 (default = /64) [ref. WT-177 - IPv6 in the context of TR-101]. The configured length applies to all **pd** subscriber prefixes on a subscriber-interface.

Table 9: Applicable Subscriber-Prefix Parameters provides an overview of the subscriber-prefix parameters that apply:

Table 9: Applicable Subscriber-Prefix Parameters

Subscriber prefix type	Subscriber prefix length	DHCPv6 option	Must be subnetted as
wan-host	/32..63	IA-NA	/64 (assigned as /128)
pd	/32..63 (*)	IA-PD	/delegated-prefix-len

(*) must be smaller than configured delegated prefix length

Enable DHCPv6 Proxy Server

Applies to RADIUS and LUDB scenarios.

An IPv6 IPoE subscriber host initiates a DHCPv6 session to request its configuration data (IPv6 addresses and/or IPv6 PD prefixes, DNS servers). Upon receipt of a DHCPv6 Solicit message, the BNG authenticates the IPv6 subscriber host and obtains its configuration information from a RADIUS server or local user database. A DHCPv6 proxy server in the BNG maintains the DHCPv6 session with the IPv6 IPoE subscriber host.

The DHCPv6 proxy server must be enabled in the **subscriber-interface>group-interface>ipv6>dhcp6>proxy-server** context. The default is **shutdown**.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1"
                    ipv6
                        dhcp6
                            proxy-server
                                server-id duid-ll
                                renew-timer min 30
                                rebind-timer min 48
                                valid-lifetime days 1
                                preferred-lifetime hrs 1
                                client-applications dhcp
                                no shutdown
                            exit
                        exit
                    exit
                exit
```

```
            exit
        exit
    exit
exit
```

When enabled, the DHCPv6 proxy server by default allows IPv6 IPoE hosts to authenticate (configured with client-applications dhcp). Additionally, you can enable support for IPv6 PPPoE hosts. See ESMv6: PPPoE Dual Stack Hosts.

A number of timers associated with IPv6 addresses and IPv6 prefixes within DHCPv6 Identity Associations can be configured in the DHCPv6 proxy server.

RFC 4862 defines two timers associated with graceful degradation of address bindings:

- Preferred lifetime — The length of time that a valid address is preferred (the time until deprecation). When the preferred lifetime expires, the address becomes deprecated and its use should be discouraged for new sessions.

- Valid lifetime — The length of time an address remains in the valid state (the time until invalidation). The valid lifetime must be greater than or equal to the preferred lifetime. When the valid lifetime expires, the address becomes invalid.

RFC 3315, *DHCPv6*, defines two timers associated with an Identity Association (IA) option that give the servers explicit control over when a client recontacts the server about a specific IA:

- T1 (renew) — The time at which the client contacts the server from which the addresses/prefix in the IA were obtained to extend the lifetimes of the addresses/prefix assigned to the IA

- T2 (rebind) — The time at which the client contacts any available server to extend the lifetimes of the addresses/prefixes assigned to the IA;

These timers are common for all DHCPv6 sessions in a group-interface and cannot be configured from RADIUS or local user database.

Figure 68: IPv6 Address/Prefix Timers
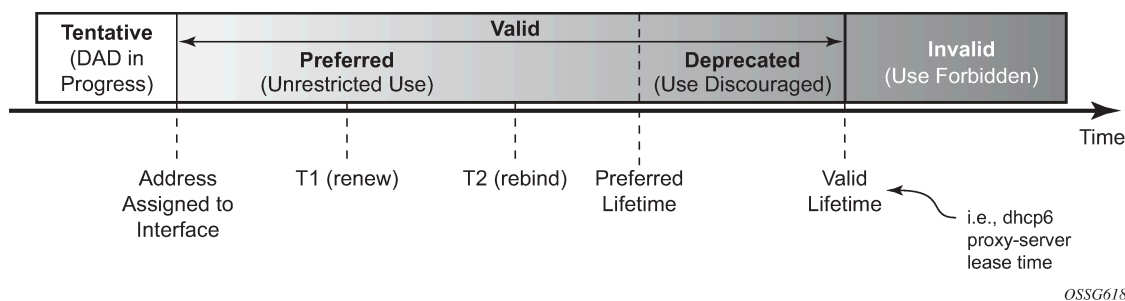

When violating the following rule, the default timers will be used:

Table 10: Timer Parameters

Timer	Use	Default	Range
T1	Renew timer	1800s (30 min)	0..604800s (7 days)
T2	Rebind timer	2880s (48 min)	0..1209600s (14 days)
preferred-lifetime		3600s (1hr)	300..4294967295s

Timer	Use	Default	Range
valid-lifetime	DHCPv6 lease time	86400s (24 hrs)	300..4294967295s

If the DHCPv6 lease is not renewed by the client before the DHCPv6 lease timer expires, then the subscriber host is deleted from the system. In other words, beyond the valid lifetime, subscriber traffic from/ to the associated IPv6 addresses is dropped.

Enable Router Advertisements

Applies to both scenarios RADIUS and LUDB.

In IPv6, default routes are automatically installed via the router discovery mechanism. Unsolicited Router Advertisements (RA) must explicitly be enabled on a group interface. The default is **shutdown**.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1"
                    ipv6
                        router-advertisements
                            managed-configuration
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
exit
```

The managed-configuration flag is set for consistency only. It tells the hosts that addresses can be requested using DHCPv6. However, as described in the Security section later (see Security), the host cannot rely on this flag because DHCPv6 must be initiated by the host before the BNG sends RAs.

Additional parameters that can be configured with respect to the router advertisements (defaults are shown):

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1"
                    ipv6
                        router-advertisements
                            shutdown
                            current-hop-limit 64
                            dns-options
                                no include-dns
                                rdnss-lifetime 3600
                            exit
                            no force-mcast
                            no managed-configuration
                            max-advertisement 1800
                            min-advertisement 900
                            no mtu
                            no other-stateful-configuration
```

```
                                    prefix-options
                                        no autonomous
                                        on-link
                                        preferred-lifetime 3600
                                        valid-lifetime 86400
                                    exit
                                    reachable-time 0
                                    retransmit-time 0
                                    router-lifetime 4500
                            exit
                        exit
                    exit
                exit
            exit
        exit
    exit
```

Table 11: Router Advertisements Parameters

Parameter	Description (RFC 4861, *Neighbor Discovery for IP version 6 (IPv6)*)	Value Range (default)
current-hop-limit	The default value that should be placed in the Hop Count field of the IP header for outgoing IP packets. A value of zero means unspecified (by this router); the RG picks its own value.	0..255 (64)
dns-options: include-dns	Indication to include the Recursive DNS Server (RDNSS) option as defined in RFC 6106 in IPv6 RAs for DNS name resolution of IPv6 SLAAC hosts	(no)
dns-options: rdnss-lifetime	Indicates the maximum time that the RDNSS address may be used for name resolution	3600 (s)
force-mcast	Configures multicast router advertisements on this interface, either IP or MAC	(no)
managed-configuration	Managed address configuration flag. When set, it indicates that addresses are available through DHCPv6	(no)
max-advertisement	Unsolicited Router Advertisements are not strictly periodic: the interval between subsequent transmissions is randomized to reduce the probability of synchronization with the advertisements from other routers on the same link. Whenever a multicast advertisement is sent from an interface, the timer is reset to a uniformly distributed random value between the interface's configured MinRtrAdvInterval and MaxRtrAdv Interval.	900..1800 s (1800)
min-advertisement		900..1350 s (900)
mtu	Routers can advertise an MTU for hosts to use on the link.	1280..9212 bytes (no)
other-stateful-configuration (not applicable for IPoE)	Other configuration flag. When set, it indicates that other configuration information is available through DHCPv6. (DNS). Can be ignored if managed address configuration flag is enabled	(no)

Parameter	Description (RFC 4861, *Neighbor Discovery for IP version 6 (IPv6)*)	Value Range (default)
prefix-options: autonomous (not applicable for IPoE)	Autonomous address-configuration flag. When set indicates that this prefix can be used for stateless address autoconfiguration (SLAAC)	(no)
prefix-options: on-link	Indicates whether the prefix will be assigned to an interface on the specified link	(no)
prefix-options: preferred-lifetime (not applicable for IPoE)	The length of time in seconds that addresses generated from the prefix via stateless address autoconfiguration (SLAAC) remain preferred	0..4294967295 (3600)
prefix-options: valid-lifetime (not applicable for IPoE)	The length of time in seconds that the prefix is valid for the purpose of on-link determination. (also used by SLAAC)	0..4294967295 (86400)
reachable-time	The time that a node assumes a neighbor is reachable after having received a reachability confirmation. Used by the Neighbor Unreachability Detection algorithm. A value of zero means unspecified (by this router); the RG picks its own value.	0..3600000 ms (0)
retransmit-time	The time between retransmitted Neighbor Solicitation messages. Used by address resolution and the Neighbor Unreachability Detection algorithm. A value of zero means unspecified (by this router); the RG picks its own value.	0..1800000 ms (0)
router-lifetime	The lifetime associated with the default router in units of seconds.	2700..9000 s (4500)

RADIUS Authentication and Authorization

Applies to the RADIUS scenario only.

The RADIUS authentication and authorization configuration for IPoE IPv6 subscriber host is no different from an IPv4 subscriber host:

```
configure
    router
        radius-server
            server "radius-172.16.1.2" address 172.16.1.2 secret vsecret1 create
                accept-coa
            exit
        exit
    exit
exit

configure
    aaa
        radius-server-policy "rsp-1" create
            servers
                router "Base"
                source-address 192.0.2.1
```

```
                    server 1 name "radius-172.16.1.2"
                exit
            exit
        exit
    exit

    configure
        subscriber-mgmt
            authentication-policy "auth-1" create
                description "RADIUS authentication policy"
                pppoe-access-method pap-chap
                radius-server-policy "rsp-1"
                password letmein
            exit
        exit
    exit
```

Additional RADIUS AVPs that are applicable to IPoE IPv6 subscriber hosts are listed in Table 12: RADIUS AVPs.

Table 12: RADIUS AVPs

RADIUS AVP	Type	Purpose
Alc-IPv6-Address [26-6527-99]	ipv6addr	maps to IA_NA of DHCPv6 (RG WAN interface address)
Alc-Ipv6-Primary-Dns [26-6527-105]	ipv6addr	maps to DNS Recursive Name Server option (RFC 3646, *DNS Configuration options for Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*) in DHCPv6
Alc-Ipv6-Secondary-Dns [26-6527-106]	ipv6addr	maps to DNS Recursive Name Server option (RFC 3646) in DHCPv6
Delegated-IPv6-Prefix [123]	ipv6prefix	maps to IA_PD for prefix delegation (RFC 3633, *IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6*) in DHCPv6

A sample FreeRADIUS users record to authenticate a dual stack IPoE subscriber:

```
00:0c:20:00:00:21 Cleartext-Password := "letmein"
        Alc-Subsc-ID-Str = "sub-1",
        Alc-Subsc-Prof-Str = "sub-profile-1",
        Alc-SLA-Prof-Str = "sla-profile-1",
        Framed-IP-Address = 10.1.0.1,
        Framed-IP-Netmask = 255.255.0.0,
        Framed-Route = "172.16.11.0/24 0.0.0.0",
        Alc-Ipv6-Address = 2001:db8:b001:101::1,
        Delegated-IPv6-Prefix = 2001:db8:a001:100::/56,
        Alc-Ipv6-Primary-Dns = 2001:db8:dddd:1::1,
        Alc-Ipv6-Secondary-Dns = 2001:db8:dddd:2::1,
```

The FreeRADIUS Server 2.0.0 and greater has full support for both IPv6 attributes and IPv6 network packets.

The IPv6 address/prefix related timers can be configured in the **dhcp6>proxy-server** context (see Enable DHCPv6 Proxy Server).

Local User Database Authentication and Authorization

Applies to the LUDB scenario only.

The configuration example below focuses on the IPv6 host configuration. The details for local user database host matching and IPv4 host specific parameters are out of scope for this section.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            dhcp
                match-list mac
                host "host-1" create
                    host-identification
                        mac 00:0c:29:00:00:23
                    exit
                    address gi-address                      # IPv4 host
                    identification-strings 254 create
                        subscriber-id "sub-3"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    options
                        subnet-mask 255.255.0.0             # IPv4 host
                        default-router 10.1.255.254         # IPv4 host
                    exit
                    ipv6-address 2001:db8:b001:103::3          # IPv6 host
                    ipv6-delegated-prefix 2001:db8:a001:300::/56  # IPv6 host
                    options6
                        dns-server 2001:db8:dddd:1::1 2001:db8:dddd:2::1
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-2" create
                    description "ludb authentication and authorization"
                    ipv6
                        ---snip---
                        dhcp6
                            user-db "ludb-1"
                            proxy-server
                                client-applications dhcp
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        ---snip---
```

```
                                 server 192.0.2.1
                                 trusted
                                 lease-populate 10
                                 user-db "ludb-1"
                                 no shutdown
                             exit
                         exit
                     exit
                 exit
             exit
     exit
```

Besides the identification strings that are common to theIPv4 and IPv6 hosts, specific IPv6 host related parameters can be configured:

Table 13: Local User Database Parameters

local-user-db CLI parameter	Purpose
ipv6-address	Maps to IA_NA of DHCPv6 (RG WAN interface address)
ipv6-prefix	Maps to IA_PD for prefix delegation (RFC 3633) in DHCPv6
options6: dns-server	Defines the IPv6 DNS server address to be used for name resolution

The IPv6 address/prefix related timers can be configured in the **dhcp6>proxy-server** context (see Enable DHCPv6 Proxy Server).

DHCP and DHCP6 Lease State

Applies to both scenarios RADIUS and LUDB.

The DHCP lease state is an internal database structure that keeps track of the DHCP host states. The DHCP lease state enables subscriber management functions (for example, per subscriber QoS and accounting) and security functions (for example, dynamic anti-spoof filtering) on the DHCP host.

The DHCP lease information for a specific host is extracted from the DHCPv4 ack message in case of DHCPv4 and from the DHCPv6 reply message in case of DHCPv6

Typical information stored in the DHCP lease state includes (partial table; additional data can be stored for managed SAPs, wholesale-retail).

Table 14: DHCP Lease State Information

Parameter	Comment
Service ID	Service where the DHCP host is connected.
IP Address	IPv4 or IPv6 address of the DHCP host.
Client HW Address	Ethernet MAC address of the DHCP host.

Parameter	Comment
Subscriber-interface (Routed CO only)	Subscriber interface name where the DHCP host is instantiated.
Group-interface (Routed CO only)	Group interface name where the DHCP host is instantiated.
SAP	SAP where the DHCP hosts is connected.
Remaining Lifetime	The remaining time before the DHCP host is deleted from the system (updated each time a DHCP renew/rebind occurs).
Persistence Key	Lookup key for this host in the persistency file.
Sub-Ident	ESM: Subscriber ID of the DHCP host.
Sub-Profile-String	ESM: Subscriber profile string of the DHCP host.
SLA-Profile-String	ESM: SLA profile string of the DHCP host.
App-Profile-String	ESM: Application profile string of the DHCP host.
Lease ANCP-String	ESM: ANCP string for this DHCP host.
Lease Int Dest Id	ESM: Internal destination ID for this DHCP host.
Category-Map-Name	ESM: Volume and Time based accounting.
Dhcp6 ClientId (DUID)	DHCPv6 client unique identifier.
Dhcp6 IAID	Identity Association ID chosen by the client.
Dhcp6 IAID Type	Identity Association type: prefix (PD) or non-temporary (wan-host).
Dhcp6 Client Ip	Link local IPv6 address of the host.
Sub-Ident origin	ESM: Origin for the Subscriber ID for this host (None, DHCP, RADIUS).
Strings origin	ESM: Origin for the ESM strings for this host (None, DHCP, RADIUS).
Lease Info origin	ESM: Origin for the IP configuration for this host (None, DHCP, RADIUS).
Ip-Netmask	The IP netmask for this DHCP host.
Broadcast-Ip-Addr	The broadcast IP address for this host.
Default-Router	The default gateway for this host.
Primary-Dns	The primary DNS server for this host.
Secondary-Dns	The secondary DNS server for this host.

Parameter	Comment
Primary-Nbns	The primary NetBIOS name server for this host.
Secondary-Nbns	The secondary NetBIOS name server for this host.
ServerLeaseStart	Time and date that the lease for this host started (first DHCP ack received).
ServerLastRenew	Time and date that the lease for this host was last renewed.
ServerLeaseEnd	Time and date that the lease for this host will expire.
Session-Timeout	Lease time specified by the DHCP server.
DHCP Server Addr	IP address of the DHCP server that allocated the lease for this host.
Circuit Id	DHCP Relay Agent information option 82 Circuit ID content.
Remote Id	DHCP Relay Agent information option 82 Remote ID content.
RADIUS User-Name	ESM: Username used in the RADIUS authentication access request.

DHCPv4 lease state population is enabled by default on a group-interface with DHCP configured as **no shutdown**. The number of DHCPv4 leases allowed on each SAP of the group-interface must be configured with the **lease-populate** option (by default a single DHCPv4 host is allowed on each SAP of the group-interface).

DCHPv6 lease state population is enabled by default on a group-interface with DHCP6 proxy-server configured as **no shutdown**. The number of DHCPv6 leases (hosts) cannot be limited per group-interface.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    description "radius authentication and authorization"
                    ipv6
                        dhcp6
                            proxy-server
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        proxy-server
                            emulated-server 10.1.255.254
                            no shutdown
                        exit
                        server 192.0.2.1
                        trusted
                        lease-populate 10
                        no shutdown
                    exit
                exit
            exit
        exit
```

```
    exit
exit
```

To check the DHCPv4 or DHCPv6 lease state for a particular service, use the following commands (detailed output as well as additional output filtering is available):

```
*A:BNG# show service id 1 dhcp | dhcp6 lease-state ?

  - lease-state [wholesaler <service-id>] [sap <sap-id>|sdp <sdp-id:vc-id>|
    interface <interface-name>|ip-address <ip-address[/mask]>|chaddr
    <ieee-address>|mac <ieee-address>|{[port <port-id>][no-inter-dest-id |
     inter-dest-id <inter-dest-id>]}] [session {none|ipoe}] [detail]
```

```
*A:BNG# show service id 1 dhcp lease-state detail

```

Operation

An IPoE dual stack subscriber in a numbered Routed Gateway scenario consumes three subscriber host entries:

- IPv4 host — DHCPv4 session based

- IPv6 wan-host — DHCPv6 session based

- IPv6 Prefix Delegation host — DHCPv6 session based

```
*A:BNG# show service active-subscribers

Number of active subscribers : 2
===============================================================================
*A:BNG#
```

The optional **hierarchy** parameter for the active-subscribers display provides a top-down level overview for
this subscriber:

```
*A:BNG# show service active-subscribers hierarchy

===============================================================================
Active Subscribers Hierarchy
===============================================================================
-- sub-1 (sub-profile-1)
   |
   +-- sap:1/1/1:1 - sla:sla-profile-1
        |
        |-- 10.1.0.1 - mac:00:0c:29:00:00:21 - DHCP - svc:1
        |
        |-- 2001:db8:a001:100::/56 - mac:00:0c:29:00:00:21 - DHCP6 - svc:1
        |
        +-- 2001:db8:b001:101::1/128 - mac:00:0c:29:00:00:21 - DHCP6 - svc:1

-- sub-3 (sub-profile-1)
   |
   +-- sap:1/1/1:2 - sla:sla-profile-1
        |
        |-- 10.1.0.8 - mac:00:0c:29:00:00:23 - DHCP - svc:1
        |
        |-- 2001:db8:a001:300::/56 - mac:00:0c:29:00:00:23 - DHCP6 - svc:1
        |
        +-- 2001:db8:b001:103::3/128 - mac:00:0c:29:00:00:23 - DHCP6 - svc:1

-------------------------------------------------------------------------------
Number of active subscribers : 2
Flags: (N) = the host or the managed route is in non-forwarding state
===============================================================================
*A:BNG#
```

The total number (sum) of IPv4 and IPv6 hosts per subscriber can be limited in the corresponding sla-profile with the **host-limits** parameter:

```
configure
    subscr-mgmt
        sla-profile "sla-profile-1" create
            host-limits
                overall 3
            exit
        exit
    exit
exit
```

To display the IPv4/IPv6 routing table for dual stack hosts:

```
*A:BNG# show router 1 route-table ipv4 protocol sub-mgmt

===============================================================================
Route Table (Service: 1)
===============================================================================

===============================================================================
*A:BNG#
```

Troubleshooting

Apart from the show commands in this chapter, the following additional commands can be used for troubleshooting:

- Default system log

- Debug

- Statistics

The default system log can be shown as follows:

```
A:BNG-1# show log log-id 99
```

Use appropriate filtering to reduce the output if needed.

Debugging can be done with the definitions as follows:

```
debug
    router "Base"
        radius
            packet-type authentication accounting coa
            detail-level high
        exit
    exit
    router "1"
        ip
            dhcp
                detail-level high
                mode egr-ingr-and-dropped
            exit
            dhcp6
                mode egr-ingr-and-dropped
                detail-level high
            exit
            icmp6
        exit
        local-dhcp-server "dhcp-s1"
            detail-level medium
            mode egr-ingr-and-dropped
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-1"
            detail all
        exit
    exit
exit
```

Additional filtering (such as only DHCPv6 debug for a particular interface) may be needed to prevent a flood of debug messages.

DHCPv4 statistics can be shown as follows:

```
*A:BNG# show router 1 dhcp statistics

===============================================================

Advanced Topics

Security

Downstream Router Advertisements

When a SAP is bound to a subscriber/group-interface which has IPv6 enabled, there will be no initial downstream Router Advertisement (RA) message sent. If a SAP is shared by multiple subscribers, it would be possible for an unauthenticated host to receive the RA.

Instead the RAs are sent in unicast to allow per-host IPv6 link configuration. This requires the host information (MAC address and link-local IPv6 address) to be known. Therefore, for IPoE, until a DHCPv6 session is bound, no unsolicited or solicited RAs are sent.

Processing Neighbor Discovery Messages

Processing Neighbor Discovery messages: Neighbor Advertisements (NA), Neighbor Solicitations (NS) and Router Solicitations (RS).

Neighbor discovery messages are not processed prior to IPoE IPv6 host authentication to avoid DoS attacks consuming CPU resources. This implies that an IPoE host should initiate the DHCPv6 session without link information and knowledge of routers on the link as required by the Broadband Forum standards (ref. TR-124 issue 2 — Functional Requirements for Broadband Residential Gateway Devices). This is not a problem as the DHCPv6 solicit/request messages are sent to a well-known multicast address with direct link-layer mapping.

After DHCP host authentication, Neighbor Discovery messages will not result in a neighbor cache entry. Instead a managed neighbor cache entry is created based on the DHCPv6 lease state. This managed neighbor cache entry cannot be displayed. The above mechanism prevents DoS attacks from poisoning the neighbor cache with bogus entries.

Router advertisements in response to a router solicitation are internally throttled so that they are not sent more often than once every three seconds.

Anti-spoof Filters

For each authenticated IPoE IPv6 host, an anti-spoof filter entry is created that allows upstream traffic with exact match on the tuple {masked source IP, source MAC} to pass. Traffic from unauthenticated hosts is silently dropped.

Managed SAPs

To allow the creation of managed SAPs in a dual stack environment, both DHCPv4 discover and DHCPv6 solicit messages received on a capture SAP should trigger RADIUS authentication:

```
configure
    service
        vpls 2 customer 1 create
            sap 1/1/2:* capture-sap create
                trigger-packet dhcp dhcp6
                authentication-policy "radius-1"
            exit
            no shutdown
        exit
    exit
exit
```

A full description of the managed SAP functionality is out of the scope of this chapter.

RADIUS Change of Authorization (CoA)

The only CoA action that is allowed for IPoE IPv6 hosts is a change of ESM strings (SLA-profile, subscriber-profile, application-profile, etc). Creation of a new IPv6 host or forcing a DHCPv6 renew is not supported.

Only a single address attribute (Framed-IP-Address, Delegated-IPv6-Prefix or Alc-IPv6-Address) may be given in a single request. When host-accounting is enabled, only the host specific accounting session IDs (Acct-Session-Id) can be used. This means that to change for example the sla-profile for all three hosts of a dual stack subscriber, three CoA messages should be sent.

A full description of the RADIUS CoA functionality is out of the scope of this section.

Accounting

There are no separate accounting statistics available for IPv4 and IPv6 traffic unless they are mapped in a different Forwarding Class/queue.

In RADIUS accounting, host-accounting could be enabled to see the IPv4 and IPv6 host instantiations separately: an accounting start/stop is generated for each individual subscriber host. The actual accounting data is included in the interim updates and accounting stop message for the sla-profile instance.

A full description of the accounting functionality is out of the scope of this section.

Lease State Persistency

A DHCPv4/DHCPv6 (hereafter referred to as DHCP) session does not have a keep-alive mechanism to detect unavailability. A new DHCP session set-up is only attempted after expiration of the DHCP lease time. A node reboot causing the loss of DHCP lease state and the corresponding anti-spoof filters could therefore result in unacceptable long service outages.

The DHCP lease state can be made persistent across node reboots: DHCP lease state is restored from a persistency file stored on the compact flash file system. As a result, DHCP sessions will only lose connectivity during the time of reboot without being completely disconnected.

To activate the DHCP lease state persistency:

```
configure
    system
        persistence
            subscriber-mgmt
                description "DHCP lease state persistency"
                location cf1:
            exit
        exit
    exit
exit
```

A dedicated persistency file will be created on the specified compact flash file system. The file is initialized to store the maximum number of allowed hosts; its size is fixed to avoid file system space problems during operations.

```
*A:BNG# file dir cf1:

Volume in drive cf1 on slot A has no label.

Volume in drive cf1 on slot A is formatted as FAT32

Directory of cf1:\

09/19/2016  04:29p    <DIR>           .ssh/
04/20/2017  03:02p         536871424 submgmt.012
04/20/2017  02:59p          12583424 submgmt.i12
              2 File(s)          549454848 bytes.
              1 Dir(s)          7464747008 bytes free.

*A:BNG#
```

Each time the DHCP lease is renewed, the persistency file is updated together with the lease state. If the file update fails, an event is generated to indicate that persistency cannot be guaranteed.

The format of the persistency file may vary between different SR OS software releases. When upgrading, the persistency file is automatically upgraded to the new format. To downgrade the persistency file to a lower SR OS Release version, use the following command:

```
*A:BNG# tools perform persistence downgrade target-version ?
  - downgrade target-version <target> [reboot]

 <target>               : the version you want to downgrade to
                          submgt
                            14.0 (current) - cf1:\submgmt.012
                            13.0           - cf1:\submgmt.011
                            12.0           - cf1:\submgmt.010
```

```
                         11.0             - cf1:\submgmt.009
                         10.0             - cf1:\submgmt.008
                         9.0              - cf1:\submgmt.007
                         8.0              - cf1:\submgmt.006
                         7.0              - cf1:\submgmt.005
                         6.0              - cf1:\submgmt.004
                         5.0              - cf1:\submgmt.003
                         4.0              - cf1:\submgmt.pst
 <reboot>                : reboot system after successful conversion

 *A:BNG#
```

The content of the persistency file can be looked at using the following commands:

```
*A:BNG# show service id 1 dhcp6 lease-state detail

Conclusion

This chapter provides configuration, operation, and troubleshooting commands for dual stack IPoE subscribers on Routed Gateways. Focus is on the ESMv6 part where DHCPv6 is used for IPv6 address assignment on the RG network interface (wan host) and for allocation of an IPv6 prefix delegation prefix for use in the home network (pd host). In the BNG, authentication, authorization and IPv6 prefix configuration for an IPoE IPv6 host is done by a local user database or RADIUS.

ESMv6: PPPoE Dual Stack Hosts

This chapter describes ESMv6 PPPoE dual stack host configurations.

Topics in this chapter include:

- Applicability

- Overview

- Configuration

- Conclusion

Applicability

This chapter is applicable to SR OS routers and was initially based on Release 8.0.R4. The CLI is updated to Release 15.0.R1.

Prerequisites:

- Routed CO (IES/VPRN service) with Enhanced Subscriber Management (ESM)

- Bridged or routed home gateway

> **Note:**
> The focus of this chapter is on PPPoE IPv6. IPv4 configuration is shown for completeness.

Overview

PPPoE Dual Stack

A PPPoE dual stack subscriber may support both IPv4 and IPv6 simultaneously. The dual stack hosts share a common subscriber identification policy and have a common sla-profile and subscriber-profile and are linked together through one PPPoE session.

For PPPoE dual stack hosts, one subscriber host is created for IPv4 and another one for the IPv6 address family.

Figure 69: PPPoE Dual Stack Hosts
ESM for IPv6 is supported through RADIUS and local user database (LUDB) for authentication, address assignment and authorization.

PPPoE dual stack subscriber-hosts are supported for bridged and routed home gateways.

Dual Stack PPPoE Bridged Gateway Service

In the dual stack PPPoE host service, the PPPoE session is initiated directly from a dual stack device in the home network. PPPoE is used to carry IPv6 and (optionally) IPv4 traffic from the device to the broadband remote access server (BRAS), also called broadband network gateway (BNG).

Unlike the routed gateway application examples (see later), no IPv6 prefix delegation occurs in the bridged gateway service. Instead, a global unicast address prefix (/64) is advertised using Router Advertisements (RAs) directly to the PPPoE interface on the host.

The device addresses are self-assigned through stateless auto configuration (SLAAC). where SLAAC makes use of ICMPv6 router-advertisements to announce these IPv6 prefixes. The SLAAC prefixes have a mandatory length of /64.

This application is targeted at operators who currently use a bridging modem in the customer premises and who want to incrementally add IPv6 capability without a change of the modem on the customer site.

Figure 70: Dual Stack PPPoE Bridged Gateway Service Example
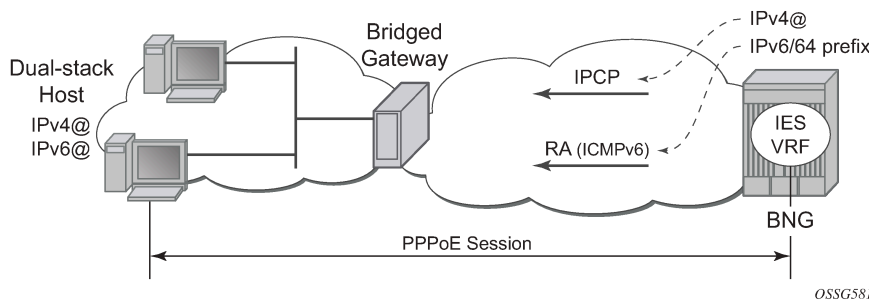

Dual Stack PPPoE Routed Gateway Service

The dual stack PPPoE routed gateway service runs over a dual stack PPPoE session between a dual stack router and BNG. It allows operators using PPPoE in their networks (with either PPPoE to the RG or PPPoA with translation to PPPoE in the DSLAM) to deploy IPv6 services in conjunction with existing IPv4 services.

Because a routed RG is used, a unique subscriber IPv6 prefix is delegated to the dual stack router for use within the home network. DHCPv6 is used to provide prefix delegation (PD). No WAN IPv6 address assignment is supported in this model. The dual stack router does not perform any NAT for IPv6 traffic.

Figure 71: Dual Stack PPPoE Routed Gateway Service Example
SLAAC

The IPv6 stateless auto configuration (SLAAC) mechanism requires no manual configuration of hosts, minimal configuration of routers, and no additional servers (such as DHCP). The stateless mechanism allows a host to generate its own address using a combination of locally available information and information advertised by routers. Routers advertise /64 prefixes, by an ICMPv6 router advertisement, that identify the subnet(s) associated with a link, while hosts generate a 64-bit "interface identifier" that uniquely identifies an interface on a subnet. An address is formed by combining the two.

DHCPv6

The Dynamic Host Configuration Protocol for IPv6 (DHCPv6) is defined in RFC 3315. The protocol enables DHCPv6 servers to pass configuration parameters such as IPv6 network addresses or DNSv6 addresses to IPv6 nodes.

For further information on DHCPv6, see ESMv6: IPoE Dual Stack Hosts.

Prefix Delegation

Prefix Delegation (PD) is a mechanism for automated delegation of IPv6 prefixes using DHCPv6. A delegating router delegates a long-lived IPv6 prefix to a requesting router. The delegating router does not require knowledge about the topology of the links in the network to which the prefixes will be assigned.

For further information on Prefix Delegation, see ESMv6: IPoE Dual Stack Hosts.

Configuration

ESMv6 for PPPoE is applicable in a routed CO environment. Details of non-specific dual stack configurations like authentication-policies, sla-profile, subscriber-profile, accounting-policies and QoS policies are out of scope for this chapter.

The minimal RADIUS authentication configuration and ESM string configuration is added for completeness.

```
configure
    router
        radius-server
            server "radius-172.16.1.2" address 172.16.1.2 secret vsecret1 create
                accept-coa
            exit
        exit
    exit
```

```
configure
    aaa
        radius-server-policy "rsp-1" create
            servers
                router "Base"
                source-address 192.0.2.1
                server 1 name "radius-172.16.1.2"
            exit
        exit
    exit
```

```
configure
    subscriber-mgmt
        authentication-policy "auth-1" create
            description "RADIUS authentication policy"
            pppoe-access-method pap-chap
            radius-server-policy "rsp-1"
        exit
    exit
```

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-1" create
        exit
        sub-profile "sub-profile-1" create
        exit
        sub-ident-policy "sub-ident-1" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
    exit
```

Service

Dual Stack PPPoE for Bridged Gateway

Figure 72: Message Flow for a Dual Stack PPPoE Host shows the message flow for a dual stack PPPoE host behind a bridged gateway corresponding with the configured service.

Figure 72: Message Flow for a Dual Stack PPPoE Host
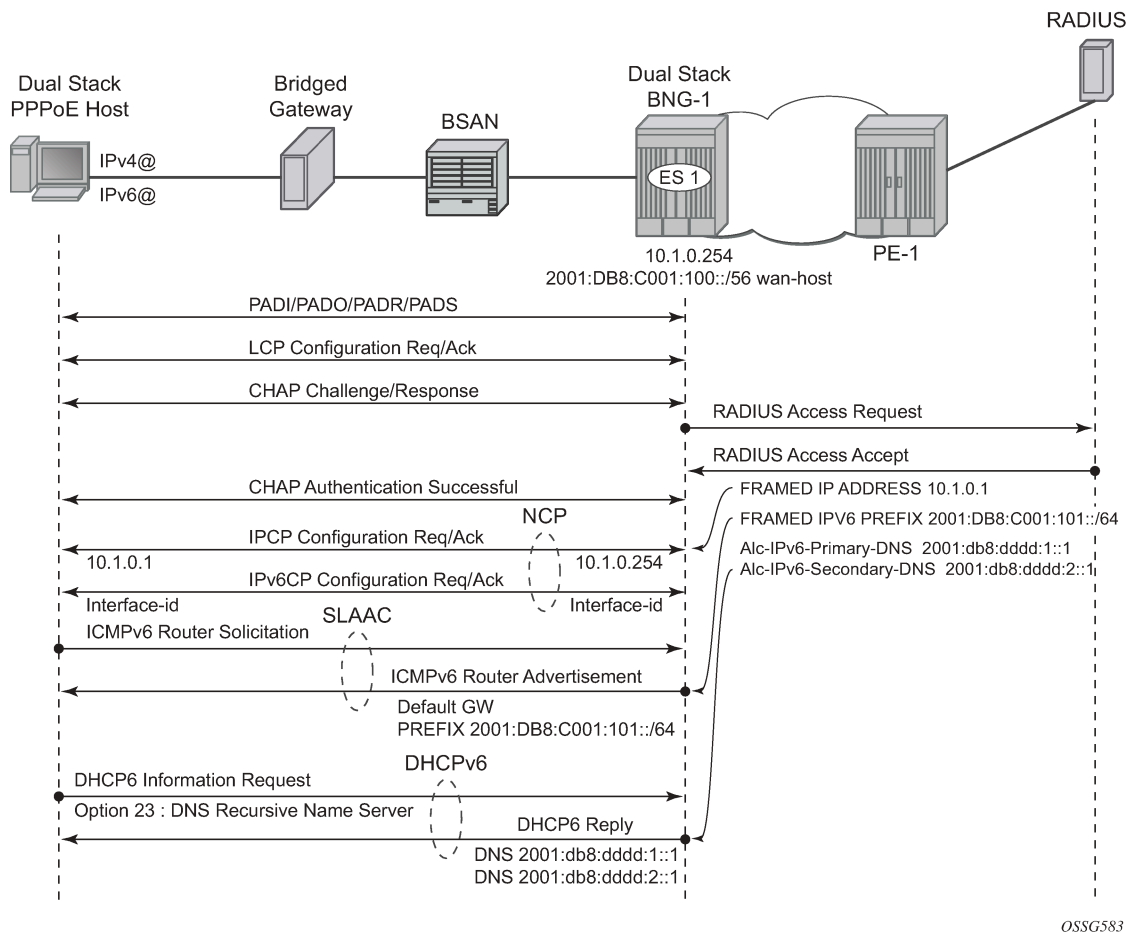

For dual stack PPPoE, the BNG initiates the IPv6 control protocol (IPv6CP) protocol to the client during the session setup phase if the appropriate attributes have been returned by the RADIUS server on authentication. The RADIUS attribute that triggers the setup of a dual stack PPPoE host in bridged mode is **framed-ipv6-prefix** which should contain a /64 prefix for the client. When a PPPoE host has successfully completed the IPv6CP negotiation, the BNG will transmit an RA to the PPPoE host containing the prefix and any other option that is configured. The host can request optional IPv6 DNS server information from the BNG by sending a DHCPv6 information-request.

The following example shows a minimal configuration to enable dual stack subscribers in an IES service context with the ESM IPv6-specific parts in bold.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.1.0.254/16
                ipv6
                    subscriber-prefixes
                        prefix 2001:db8:c001:100::/56 wan-host
                    exit
                exit
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            prefix-options
                                autonomous
                            exit
                            no shutdown
                        exit
                        dhcp6
                            proxy-server
                                client-applications ppp
                                no shutdown
                            exit
                        exit
                    exit
                    authentication-policy "auth-1"
                    sap 1/1/1:1 create
                        sub-sla-mgmt
                            sub-ident-policy "sub-ident-1"
                            multi-sub-sap 10
                            no shutdown
                        exit
                    exit
                    pppoe
                        session-limit 10
                        sap-session-limit 10
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
```

IPv6 subscriber prefixes must be defined in the **subscriber-interface>ipv6>subscriber-prefixes** context.

Three types of prefixes can be configured where **wan-host** is required for the bridged gateway scenario and **pd** is used for the dual stack PPPoE routed gateway scenario.

- wan-host — Prefix from which the IPv6 addresses are assigned (by DHCPv6 IA_NA) for the IPoEv6 routed gateway WAN interface (network facing) or a prefix from which /64 prefixes are assigned for the PPPoE (by RA SLAAC) hosts in the bridged gateway model.

- pd — Prefix from which the IPv6 prefix delegation prefixes are assigned that are to be used by the IPoEv6 or PPPoEv6 routed gateway for allocation in the home network (LAN interfaces).

- pd wan-host (both) — Prefix from which both IPv6 addresses (wan-host) and IPv6 prefix delegation prefixes (pd) can be assigned. This requires that the delegated prefix length is set to 64 bits.

Table 15: Subscriber Prefix Parameters and Table 16: Subscriber Prefix Subnetting for SLAAC provide an overview of the subscriber-prefix parameters that apply and an example of subscriber prefix subnetting for SLAAC.

Table 15: Subscriber Prefix Parameters

Subscriber Prefix Type	Prefix Length	DHCPv6 Option	SLAAC	RADIUS AVP	Must be subnetted as
wan-host	/32..63	N/A	yes	[97]Framed-IPv6-Prefix	/64

Table 16: Subscriber Prefix Subnetting for SLAAC

Dual Stack PPPoE for Routed Gateway

Figure 73: Dual Stack PPPoE for Routed Gateway shows the message flow for a dual stack PPPoE host located behind a routed gateway corresponding with the configured service.

Figure 73: Dual Stack PPPoE for Routed Gateway
Initially, a PPPoE routed gateway follows the same steps as a dual stack PPPoE host. The BNG receives a prefix from RADIUS (in this case through a **delegated-ipv6-prefix** attribute), which is used as a trigger to initiate the IPv6CP protocol to the client. The prefix that is offered to the client should have the same prefix length as the one configured under the subscriber interface ipv6 context (delegated-prefix length).This length should be between 48 and 64 bits, inclusive.

After the IPv6CP protocol has completed, the client must run the DHCPv6 protocol over its PPPoE tunnel to receive a delegated prefix (IA_PD) and optionally IPv6 DNS server information.

This delegated prefix can then be subdivided by the client and distributed over its own downstream interfaces. During the DHCPv6 message exchange, no extra RADIUS request will be made; the information is stored during the initial PPPoE authentication until the client starts DHCPv6. Only after DHCPv6 has completed, the IPv6 subscriber host will be instantiated, and the BNG will start sending RAs if configured. (It is a mandatory requirement for the BNG to send RAs which makes enabling router-advertisements under the group-level mandatory). The router advertisements do not contain any prefix information, which has already been provided by DHCPv6, but it is used as an indication to the client that its default gateway should be the BNG.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.1.0.254/16
```

```
                        ipv6
                            delegated-prefix-len 56
                            subscriber-prefixes
                                prefix 2001:db8:d001::/48 pd
                            exit
                        exit
                        group-interface "group-int-1" create
                            ipv6
                                router-advertisements
                                    prefix-options
                                        autonomous
                                    exit
                                    no shutdown
                                exit
                                dhcp6
                                    proxy-server
                                        client-applications ppp
                                        no shutdown
                                    exit
                                exit
                            exit
                            authentication-policy "auth-1"
                            sap 1/1/1:1 create
                                sub-sla-mgmt
                                    sub-ident-policy "sub-ident-1"
                                    multi-sub-sap 10
                                    no shutdown
                                exit
                            exit
                            pppoe
                                session-limit 10
                                sap-session-limit 10
                                no shutdown
                            exit
                        exit
                    exit
                    no shutdown
                exit
            exit
 exit
```

IPv6 subscriber prefixes must be defined at the **subscriber-interface>ipv6>subscriber-prefixes** context, see Dual Stack PPPoE Bridged Gateway Service.

Subscriber prefixes are subnetted in fixed length subnets that are assigned to subscriber hosts:

• /delegated-prefix-len (/48..64) for p subscriber prefixes

The delegated prefix length is configured in the **subscriber-interface>ipv6** context. The recommended value is /56 (default = /64). The configured length applies to all pd subscriber prefixes on a subscriber-interface.

Table 17: Subscriber-Prefix Parameters and Table 18: Prefix Subnetting for delegated-prefix-length /56 provide an overview of the subscriber-prefix parameters that apply and an example of prefix subnetting for delegated-prefix-length /56.

Table 17: Subscriber-Prefix Parameters

Subscriber Prefix Type	Prefix Length	DHCPv6 Option	SLAAC	RADIUS AVP	Must be sub netted as
pd	/48..64 *	IA-PD	N/A	[123] Delegated-IPv6-Prefix	/delegated-prefix-len

*Must be smaller than configured delegated prefix length.

Table 18: Prefix Subnetting for delegated-prefix-length /56

Subscriber Prefix and /56 delegated-prefix-len	Framed-IPv6-Prefix	Hosts
2001:db8:d001::/48	2001:db8:d001:100::/56	Responsibility Home Gateway (HGW)
		Responsibility HGW

		Responsibility HGW
		Responsibility HGW

RADIUS

The RADIUS authentication policy shown at the beginning of the Configuration section must be applied to the group-interface, and is used for both IPv4 and IPv6.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    authentication-policy "auth-1"
                exit
            exit
        exit
    exit
exit
```

IPv4 and IPv6 configuration information can come from LUDB or AAA/RADIUS.

Commonly used RADIUS Attribute Value pairs (AVPs) that are applicable for PPPoE IPv6 subscriber hosts are listed in Table 19: RADIUS AVPs.

Table 19: RADIUS AVPs

RADIUS AVP	Type	Purpose
Framed-IPv6-Prefix [97]	ipv6prefix	Maps to SLAAC (RFC 4862) /64 Prefix-information in ICMPv6 RA.
Delegated-IPv6-Prefix [123]	ipv6prefix	Maps to IA_PD for prefix delegation (RFC 3633) in DHCPv6
Alc-Ipv6-Primary-Dns [26-6527-105]	ipv6addr	Maps to DNS recursive name server option (RFC 3646) in DHCPv6
Alc-Ipv6-Secondary-Dns [26-6527-106]	ipv6addr	Maps to DNS recursive name server option (RFC 3646) in DHCPv6

Dual Stack PPPoE for Bridged Gateway

The following shows a sample of a FreeRADIUS user record to authenticate a dual stack PPPoE subscriber for a bridged gateway:

```
bridged@domain1 Cleartext-Password := "letmein"
    Framed-IP-Address = 10.1.0.1,
    Framed-IP-Netmask = 255.255.255.0,
```

```
    Alc-Subsc-ID-Str = "%{User-name}",
    Alc-Subsc-Prof-Str = "sub-profile-1",
    Alc-SLA-Prof-Str = "sla-profile-1",
    Framed-IPv6-Prefix = "2001:db8:c001:0101::/64",
    Alc-IPv6-Primary-DNS = "2001:db8:dddd:1::1",
    Alc-IPv6-Secondary-DNS = "2001:db8:dddd:2::1",
```

Dual Stack PPPoE for Routed Gateway

The following shows a sample of a FreeRADIUS user record to authenticate a dual stack PPPoE subscriber for a routed gateway:

```
routed@domain1 Cleartext-Password := "letmein"
    Framed-IP-Address = 10.1.0.2,
    Framed-IP-Netmask = 255.255.255.0,
    Alc-Subsc-ID-Str = "%{User-name}",
    Alc-Subsc-Prof-Str = "sub-profile-1",
    Alc-SLA-Prof-Str = "sla-profile-1",
    Delegated-IPv6-Prefix = "2001:db8:d001:0100::/56",
    Alc-IPv6-Primary-DNS = "2001:db8:dddd:1::1",
    Alc-IPv6-Secondary-DNS = "2001:db8:dddd:2::1",
```

A RADIUS user's configuration with multiple delegated-ipv6-prefixes for the same dual stack PPPoE host will result in a single DHCPv6 advertise message sent by the BNG with a single IA_PD option and single IA-Prefix. The other RADIUS configured delegated-IPv6-prefixes are silently dropped by the BNG.

Router Advertisements

ICMPv6 router advertisements have two major functions.

- Default router function for hosts

- Address auto-configuration for hosts aka SLAAC

Unsolicited RA must explicitly be enabled on a group interface (default shutdown) and are refreshed with a pseudo random timer. The boundaries of this random timer are configurable with the min-advertisement parameter (minimum with default set to 900s) and max-advertisement (maximum with default set to 1800s).

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            max-advertisement 1800  # default 30 min
                            min-advertisement 900   # default 15 min
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
    exit
```

The **router-advertisements router-lifetime** parameter (default 4500 sec) specifies how long the host is allowed to use the originator of the RA as default gateway. This timer is configurable between 2700 and 9000 seconds.

Configuring a **router-advertisements router-lifetime** timer smaller than the **router-advertisements min-advertisement** timer results in a dual stack PPPoE host without a default gateway.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            router-lifetime 4500
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
    exit
```

The following **prefix-options autonomous** parameter specifies whether or not offered RADIUS IPv6 prefix can be used for stateless address configuration (SLAAC). The **prefix-options lifetime** parameter defines how long the host is allowed to use this prefix. Configuring a **prefix-option valid-lifetime** smaller than the **router-advertisements min-advertisement** timer results in host traffic being sourced with the link-local address instead of global unique IPv6 address.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            prefix-options
                                autonomous                 # required for SLAAC
                                on-link
                                preferred-lifetime 3600    # default 1 hour
                                valid-lifetime 86400       # default 24 hours
                            exit
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

The following is a snapshot from an ICMPv6 RA message with default timer settings with a focus on the SLAAC function.

```
Internet Control Message Protocol v6
    Type: 134 (Router advertisement)

    ---snip---

    ICMPv6 Option (Prefix information)
```

```
        Type: Prefix information (3)
        Length: 32
        Prefix length: 64
        Flags: 0x40
            1... .... = on link
            .1.. .... = Auto                  # Auto-Configuration flag
            ..0. .... = Not router address
            ...0 .... = Not site prefix
        Valid lifetime: 86400                 # Default value 24 hour
        Preferred lifetime: 3600              # Default value  1 hour
        Prefix: 2001:DB8:C001:101::           # SLAAC prefix
```

SLAAC-related parameters are listed in Table 20: SLAAC-Related Parameters .

Table 20: SLAAC-Related Parameters

Parameter	Description (RFC-4861)	Value Range (Default)
prefix-options: autonomous	Autonomous address-configuration flag. When set indicates that this prefix can be used for stateless address auto configuration (SLAAC)	(no)
prefix-options: preferred-lifetime	The length of time in seconds that the addresses generated from the prefix through stateless address auto configuration (SLAAC) remains preferred.	0..4294967295 s (3600s) 1hour
prefix-options: valid-lifetime	The length of time in seconds that the prefix is valid for the purpose of on-link determination.	0..4294967295 s (86400s) 24hours

Router advertisements parameters common to PPPoEv6 and IPoEv6 are listed and explained in ESMv6: IPoE Dual Stack Hosts.

For dual stack PPPoE hosts, the default values, as shown in the following output, can be used. Timer values equal to zero (reachable-time and retransmit-time) causes the host to use its own timers for that function. The reachable-time is used by the host for Neighbor_Unreachable_Detection (NUD) whereas the retransmit-time is used by the host for Duplicate_Address_Detection (DAD). DAD is normally only performed by dual stack IPoE hosts and not by dual stack PPPoE hosts.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        router-advertisements
                            current-hop-limit 64
                            dns-options
                                no include-dns
                                rdnss-lifetime 3600
                            exit
                            no force-mcast
                            no managed-configuration
                            no mtu
                            no other-stateful-configuration
                            reachable-time 0
                            retransmit-time 0
```

```
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
```

DHCPv6 Proxy Server

Dual Stack PPPoE for Bridged Gateway

Dual stack PPPoE hosts using SLAAC for address assignment do not require DHCPv6. SR OS supports DNSv6 information through the RA DNS Option (RFC 5006, *IPv6 Router Advertisement Option for DNS Configuration*), and can also be configured to use DHCPv6 information requests and replies to retrieve the DNSv6 information. This requires the DHCPv6 proxy server to be enabled (the default is **shutdown**) and PPPoE defined as client-application (default=dhcp only). No lease state is kept for this DNSv6 information and therefore it is known as stateless DHCPv6.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ipv6
                        dhcp6
                            proxy-server
                                client-applications ppp
                                no shutdown
                            exit
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

Dual Stack PPPoE for Routed Gateway

An IPv6 PPPoE routed gateway initiates, after successful IPv6CP negotiation, a DHCPv6 session to request its configuration data (IPv6 PD prefixes, DNS servers). A DHCPv6 proxy server in the BNG maintains the DHCPv6 session with the IPv6 PPPoE subscriber host. The DHCPv6 proxy server must be enabled (the default is **shutdown**) and PPPoE defined as client-application (default=dhcp only).

```
configure
    service

                                    exit
                                exit
```

A number of timers associated with IPv6 addresses and IPv6 prefixes within DHCPv6 identity associations can be configured in the DHCPv6 proxy server context. These timers are valid for IPoEv6 and PPPoEv6 sessions and are listed and further explained in ESMv6: IPoE Dual Stack Hosts.

There is never RADIUS re-authentication for dual stack PPPoE routed gateways on DHCPv6 renewals as indicated in Figure 74: DHCPv6 Renewals.

Figure 74: DHCPv6 Renewals
DHCPv6 Lease State

The DHCPv6 lease state table keeps track of the DHCPv6 host states. The DHCP lease information for a specific host is extracted from the DHCPv6 reply message in case of DHCPv6. Stateful (with lease state) DHCPv6 is applicable for dual stack PPPoE on routed gateway where Stateless (without lease state) DHCPv6 is optional and applicable for dual stack PPPoE on bridged gateways.

For more information on DHCPV6 lease states, see ESMv6: IPoE Dual Stack Hosts.

Operation

Dual Stack PPPoE for Bridged Gateway

A PPPoEv6 dual stack subscriber scenario for a bridged home gateway consumes two subscriber host entries shared by a common subscriber.

- IPv4 host-addressing by IPCP
- IPv6 wan-host addressing by SLAAC

```

Use the following command to clear the DHCPv6 statistics.

```
A:BNG-1# clear router dhcp6 statistics
```

Troubleshooting

Following tools are available for troubleshooting PPPoE dual stack scenarios.

- system log (log-id 99)
- debugging aids
- protocol statistics

Log-id 99 is the default system log. Use appropriate filtering to reduce the output if needed.

```
*A:BNG# show log log-id 99
```

Following debug configuration is useful for troobleshooting PPPoE, RADIUS, DHCPv6 and ICMPv6.

```
debug
    service
        id 1
            ppp
                packet
                    mode egr-ingr-and-dropped
                    detail-level high
                    discovery
                    ppp
                    dhcp-client
                exit
            exit
        exit
    exit
exit
```

```
debug
    router
        radius
            packet-type authentication accounting coa
            detail-level high
        exit
    exit
exit
```

```
debug
    router "Base"
```

```
        ip
            dhcp6
                mode egr-ingr-and-dropped
                detail-level high
            exit
            icmp6
        exit
    exit
exit
```

Use the following commands for showing protocol related statistics.

```
show router dhcp6 statistics
show service id 1 pppoe session statistics
```

Advanced Topics

RADIUS COA

For dual stack PPPoE subscriber hosts, RADIUS-triggered mid-session change or/and session terminations identify the subscriber host to be changed by the same prefix that was originally returned from RADIUS or by the host-session-id (If RADIUS accounting host-accounting is enabled and the accounting session-id format equals number). Changing either the IPv4 or IPv6 information will result in both the v4 and v6 subscriber hosts being modified. Further elaboration on accounting is out of scope in this document.

IPv6CP Interface ID

IPv6CP negotiates, unlike ipv4-addresses in IPv4CP, only interface-ids (interface-id: the last 64 bits of an IPv6 address is the interface identifier that is unique to the 64-bit prefix of the IPv6 address and is usually derived from the link-layer or MAC address).

Dual stack PPPoE subscribers and the BNG exchange their interface-ids during the NCP phase. For ESM subscriber-interfaces on the BNG the interface-id is derived from the chassis-mac address.

- The BNG will nack the PPPoE host's IPv6CP configuration request if the dual stack PPPoE host negotiates an interface-id equal zero or an interface-id equal to the BNG interface ID. In that scenario, the BNG offers in the IPv6CP nack message a suitable interface ID, see Table 21: IPv6CP Nack Message Format.

- The BNG terminates the session if the dual stack PPPoE hosts nacks its IPv6CP configuration request and offers something else to the BNG.

Table 21: IPv6CP Nack Message Format

1	2	3	4	5	6	7	8
SAP ID				Last 2 bytes MAC host		Session ID	

Conclusion

This chapter provides configuration and troubleshooting commands for dual stack PPPoE subscribers on bridged or routed gateways. SLAAC is used as IPv6 address assignment for bridged gateway scenarios and stateful DHCPv6 prefix-delegation is used for address assignment for routed gateway scenarios. No RG WAN IPv6 address assignment is supported in this latter model.

DNSv6 addressing on a bridged gateway is retrieved by stateless DHCPv6 (information request and reply).

Flexible Authentication Model in ESM

This chapter provides information about Flexible Authentication Models in ESM.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers in the Routed Central Office (RCO) model and was initially written for SR OS Release 11.0.R2, but the CLI in the current edition is based on SR OS Release 15.0.R2.

Overview

The flexible authentication model for IPoE and PPPoE subscribers allows for mixing of configuration parameters obtained during the authentication phase from different sources: Local User Database (LUDB), RADIUS, or DHCP options that can be populated via a custom Python script. In case the same parameter is available from multiple sources, a priority mechanism is enforced whereby the parameter received from a higher priority source overrides the parameters received from the lower priority source in the following priority: LUDB to RADIUS to Python.

In this chapter we will configure a dual-stack IPoE and a dual stack PPPoE host using four different methods to obtain their configuration parameters. The setup will utilize a single BNG node with a locally configured DHCP server and LUDB as well as an external RADIUS server. Subscriber hosts are instantiated on managed (dynamic) SAPs.

The subscriber configuration parameters are in general divided into two categories:

- IP addressing parameters of the host — IPv4/v6 address/prefix, DNS servers, IPv4 default-gateway, IPv4 subnet-mask, IPv4/v6 address pool name, DHCPv4/v6 lease times, etc.
- Non IP addressing parameters of the host — Subscriber hosts strings are used to associate the subscriber-host with the desired level of service (sub/sla-profiles, inter-dest-id string, etc); managed routes are used for routing purposes to/from the host; etc.

The following four scenarios will be examined:

1. DHCP relay case (IP address is assigned via local DHCP server) with NO authentication. See DHCP Relay Case with No Authentication.

2. DHCP relay case (IP address is assigned via local DHCP server) with LUDB + RADIUS authentication. See DHCP Relay Case with LUDB + RADIUS Authentication.

   RADIUS provides: sub/sla-profile strings and a framed IPv4 route.

LUDB provides: IP address pool, inter-dest-id string for Vport assignment, msap-defaults (routing context parameters and msap-policy).

3. IP proxy case (IP address is assigned via RADIUS) with LUDB + RADIUS authentication. IP Proxy Case with LUDB + RADIUS Authentication

RADIUS provides: IP addresses and related parameters (DNS server, IPv4 default-gateway, etc), inter-dest-id string for Vport assignment and a framed route.

IPv6 lease-times are provided under the group-interface.

LUDB provides: sub/sla-profile strings and msap-defaults (routing context parameters and msap-policy).

4. IP proxy case (IP address is assigned via LUDB) with LUDB + RADIUS authentication. IP Proxy Case with LUDB + RADIUS Authentication

RADIUS provides: sub/sla-profile strings and a framed IPv4 route.

LUDB provides IP addresses and related parameters (DNS server, IPv4 default-gateway, etc), inter-dest-id string for Vport assignment and msap-defaults (routing context parameters and msap-policy).

In cases 2-4, the domain-name *domain1* is appended to the IPoE and PPPoE username in LUDB, before RADIUS authentication takes place.

Configuration

The topology is shown in Figure 75: Topology.

Figure 75: Topology
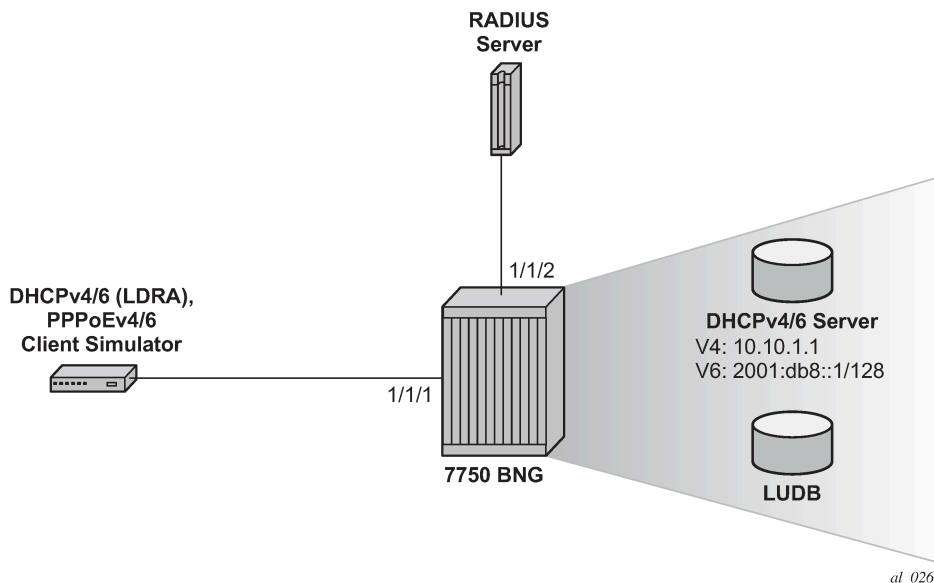

There is a common part of the configuration that applies uniformly across all four examined scenarios. This common part is outlined below and will not be repeated again when we describe more specific cases. It is assumed that the more specific cases also contain this common part of the configuration.

Common Configuration Part

Access Ethernet Port with QinQ Encapsulation

The following output displays a configuration example.

```
configure
    port 1/1/1
        ethernet
            mode access
            encap-type dot1q
        exit
    exit
exit
```

Capture SAP

A capture SAP is used to dynamically detect the VLAN id(s) in incoming DHCP/PPPoE packets (triggering packets) and conditionally instantiate the managed (dynamic) SAP. LUDB must be configured under the capture SAP to authorize the user accessing the capture SAP. The LUDB may contain additional parameters needed to set up the subscriber, it can point the subscriber to the RADIUS server for additional parameters or it may contain a default subscriber-host entry without any configuration parameters.

In this case, the **msap-defaults** under the capture SAP is used to select the routing context where the msap is created. **msap-defaults** can be also configured in the LUDB or be supplied via RADIUS.

PPPoE policy and *msap policy* are used to define PPPoE and SAP level parameters. Because the (dynamic) SAP does not exist at the time when the initial DHCP/PPPoE packets are received, the PPPoE/ SAP level parameters are taken from the PPPoE/msap policy under the capture SAP. For example, those parameters are used in the PPP PADx/LCP/Authentication setup phase, they define default subscriber host strings, maximum number of subscriber hosts per SAP, the anti-spoofing mode, etc.

The X in the LUDB name (ludb-X) has to be replaced by a number depending on the scenario.

```
configure
    service
        vpls 2 customer 1 create
            stp
                shutdown
            exit
            sap 1/1/1:* capture-sap create
                description "open DHCP model testing"
                trigger-packet dhcp dhcp6 pppoe
                dhcp-user-db "ludb-X"
                dhcp6-user-db "ludb-X"
                pppoe-policy "pppoe-pol-1"
                pppoe-user-db "ludb-X"
                msap-defaults
                    group-interface "grp-int-1"
                    policy "msap-pol-1"
                    service 1
                exit
            exit
            no shutdown
        exit
```

auto-sub-id

The **auto-sub-id-key** command can be used in situations where the more specific **subscriber-id** string is not returned from LUDB or RADIUS. In this case, the auto subscriber-id for IPoE hosts is set to the circuit-id while for PPPoE hosts the auto subscriber-id is set to the circuit-id plus session-id separated by the "|" delimiter which is inserted by default.

```
configure
    subscriber-mgmt
        auto-sub-id-key
            ipoe-sub-id-key circuit-id
            ppp-sub-id-key circuit-id session-id
        exit
    exit
exit
```

PPPoE Policy

There is a maximum of PPPoE sessions per MAC on a managed SAP. The default is 1 but is increased here to 10.

```
configure
    subscriber-mgmt
        ppp-policy "pppoe-pol-1" create
            ppp-mtu 1400
            max-sessions-per-mac  10
        exit
    exit
exit
```

MSAP Policy

The MSAP policy defines the anti-spoofing mode which is in this particular example set to next-hop MAC (nh-mac). It also defines the default subscriber management parameters in case they are not supplied via LUDB or RADIUS.

```
configure
    subscriber-mgmt
        msap-policy "msap-pol-1" create
            sub-sla-mgmt
                def-sub-id use-auto-id
                def-sub-profile "sub-profile-1"
                def-sla-profile "sla-profile-1"
                sub-ident-policy "sub-ident-1"
                multi-sub-sap limit 500
            exit
            ies-vprn-only-sap-parameters
                anti-spoof nh-mac
            exit
        exit
    exit
```

```
exit
```

subscriber-interface Configuration

The following output displays a subscriber interface configuration.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                # support for un-numbered IPv4 clients
                allow-unmatching-subnets
                # default gateway for IPv4 numbered clients
                address 10.12.0.1/24
                ipv6
                    # fixed delegated prefix length for IA-PD
                    delegated-prefix-len 56
                    # support for un-numbered IPv6 clients
                    allow-unmatching-prefixes
                exit
                group-interface "grp-int-1" create
                    ipv6
                        router-advertisements
                            # hint to the client to use DHCPv6
                            managed-configuration
                            # enabling router-advertisements
                            no shutdown
                        exit
                        dhcp6
                            # must be the same as under the capture-SAP
                            user-db "ludb-1"
                        exit
                    exit
                    # ARP table is populated based on the lease state table
                    arp-populate
                    dhcp
                        server 10.10.1.1
                        # accept DHCP packets on this group interface
                        trusted
                        # max number of DHCPv4 clients on each
                        # SAP of this group-interface
                        lease-populate 100
                        # must be the same as under the capture-SAP
                        user-db "ludb-1"
                        no shutdown
                    exit
                    pppoe
                        policy "pppoe-pol-1"
                        session-limit 1000
                        sap-session-limit 1000
                        # must be the same as under the capture-SAP
                        user-db "ludb-1"
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

For numbered/unnumbered subscriber-hosts also take a look at the DHCP/PPPoE clients whose assigned IP address is outside of any IP subnet/prefix configured under the subscriber-interface.

Specific Configuration Parts

DHCP Relay Case with No Authentication

The IP address is assigned via local DHCP server. The LUDB is accessed even in the scenario without authentication. There must be a default host LUDB entry present that will match on any value specified in the match-list criteria. The LUDB is accessed from the capture SAP (part of the common configuration).

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            description "for CASE-1"
            ipoe
                # host matching is based on circuit-ID in DHCP packets
                match-list circuit-id
                host "default" create
                    no shutdown
                exit
            exit
            ppp
                # host matching is base on PPPoE username
                match-list username
                host "default" create
                    # explicitly enable IPCPv6
                    force-ipv6cp
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Once the routing context (service id and group-interface) is determined as defined under the capture SAP defaults (part of the common configuration), the DHCP/PPPoE requests are served according to the group-interface configuration. The IP address request is relayed to the DHCPv4/v6 server. Since the LUDB does not provide a pool name, the **gi-address** and the **link-address** is used by the DHCP relay/server to select the pool from which the IP address will be assigned.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    ipv6
                        dhcp6
                            # DHCPv6 relay configuration
                            relay
                                link-address 2001:DB8:30::
                                # DHCPv6 server IPv6 address
                                server 2001:DB8::1
                                client-applications dhcp ppp
                                no shutdown
                            exit
```

```
                        exit
                    exit
                    arp-populate
                    dhcp
                        # DHCPv4 server IP address
                        server 10.10.1.1
                        client-applications dhcp ppp
                        gi-address 10.12.0.1
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

DHCPv4/v6 servers are locally configured in the node and attached to a loopback interface.

```
configure
    service
        vprn 1 customer 1 create
            interface "int-DHCP" create
                # IPv4 address which the DHCPv4 is listening on
                address 10.10.1.1/24
                ipv6
                    # IPv6 address which the DHCPv6 server is listening on
                    address 2001:DB8::1/128
                    local-dhcp-server "svc-1-dhcp6"
                exit

                loopback
            exit
        exit
    exit
exit
```

In the local DHCP servers two pools are defined:

- LUDB — To be used for IP address assignment when LUDB returns the pool name.

- Gi-addr — To be used when gi-address/link-address are used to select the pool for IP address assignment.

Lease times for IPv4 and IPv6 are configured in the local DHCP server which is used only in the relay case (when the IP address is supplied via DHCP server and not through RADIUS or the LUDB).

```
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "svc-1-dhcp4" create
                    # the gi-address can be used to select the pool
                    use-gi-address
                    # the pool name can be explicitly provided
                    use-pool-from-client
                    # the pool used when the LUDB provides the pool name
                    pool "ludb" create

```

Default sub/sla-profiles, from the msap-policy, are used (part of the common configuration).

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-1" create
            description "default SLA profile"
            host-limits
                overall 3
            exit
        exit
        sub-profile "sub-profile-1" create
            description "default SUB profile"
            egress
                agg-rate-limit 1000
            exit
        exit
    exit
exit
```

Show Commands

The following command shows that the default sub/sla-profiles are in use, that the IP addresses are selected from the gi-addr pool in local DHCP server and that the subscriber-id is set to circuit-id for the IPoE subscriber-host and to **username|session-id** combination for the PPPoE subscriber-host.

```

*A:BNG-1#
```

The following command shows more details about the subscriber-host, such as the group-interface,
address origin, acct-session-id, etc. Even though there are only two dual-stack hosts (one IPoE and one
PPPoE), each of them has three IP addresses that show up as different hosts.

For the purpose of brevity, the output for only two IP hosts are shown, one with an IPv4 address and one
with an IPv6 address. The remaining IP addresses/prefixes are not shown because the output follows the
same logic.

```

*A:BNG-1#
```

DHCP Relay Case with LUDB + RADIUS Authentication

IP address is assigned via local DHCP server.

*   RADIUS provides sub/sla-profile strings and a framed IPv4 route.

*   LUDB provides IP address pool, inter-dest-id string for Vport assignment, msap-defaults (routing context parameters and msap-policy).

Vport aggregate rate limit and the port scheduler are now added to the physical port. The Vport is associated with the subscriber through the inter-dest-id string obtained via LUDB.

```
configure
    port 1/1/1
        ethernet
            mode access

        exit
        no shutdown
    exit
exit
```

The LUDB is used to assign the IP pool name (pool-name = ludb) and the inter-dest-id string (inter-dest-id = open-auth-vport) to the subscriber. The pool name is carried to the DHCP server via custom DHCP options [(82,9,13) in DHCPv4 and (17,1->wan_pool and 2->pfx_pool) in DHCPv6].

The domain name *domain1* is appended to the username (circuit-id = open-dhcp-2 or username = open-pppoe-2) before an Access-Request message is sent to the RADIUS server which is configured in the authentication policy *auth-pol-1*.

The inter-dest-id string taken from the LUDB is passed to the subscriber management module in the node via DHCP option 254 in DHCP ACK/Reply.

```
configure
    subscriber-mgmt
        local-user-db "ludb-2" create
            description "for CASE-2"
            ipoe
                match-list circuit-id
                host "open-dhcp-2" create
                    host-identification
                        circuit-id string "open-dhcp-2"
                    exit
                    address pool "ludb"
                    auth-policy "auth-pol-1"
                    auth-domain-name "domain1"
                    identification-strings 254 create
                        inter-dest-id "open-auth-vport"
                    exit
                    msap-defaults
                        group-interface "grp-int-1"
                        policy "msap-pol-1"
                        service 1
                    exit
                    ipv6-wan-address-pool "ludb"
                    ipv6-delegated-prefix-pool "ludb"
                    no shutdown
                exit
            exit
            ppp
                match-list circuit-id mac username
                host "open-ppp-2" create
                    host-identification
                        username "open-pppoe-2"
                    exit
                    auth-policy "auth-pol-1"
                    address pool "ludb"
                    password chap "letmein"
                    identification-strings 254 create
                        inter-dest-id "open-auth-vport"
                    exit
                    msap-defaults
                        group-interface "grp-int-1"
                        policy "msap-pol-1"
                        service 1
                    exit
                    ipv6-delegated-prefix-pool "ludb"
                    ipv6-wan-address-pool "ludb"
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The **inter-dest-id** string taken from the LUDB is passed to the subscriber management module in the node via DHCPv4/v6 option 254 that is specified in the subscriber identification policy.

```
configure
    subscriber-mgmt
        sub-ident-policy "sub-ident-1" create
            strings-from-option 254
        exit
    exit
exit
```

The RADIUS server is defined via the authentication policy. The domain name can be appended to the PPPoE subscriber host directly via the authentication-policy while for IPoE subscribers, the domain name is appended via the authentication-policy in conjunction with the LUDB. This can be verified in the output (shown later) of the **show service id 1 dhcp lease-state detail** and **show service id 1 dhcp6 lease-state detail** commands (on the "radius user-name" line).

```
configure
    subscriber-mgmt
        authentication-policy "auth-pol-1" create
            description "RADIUS authentication policy"
            password "letmein"
            ppp-user-name append "domain1"
            user-name-format circuit-id append
            accept-authorization-change
            pppoe-access-method pap-chap
            radius-server-policy "rad-serv-pol-1"
        exit
    exit
exit
```

The RADIUS user configuration file uses the domain-name extension, as inserted by the BNG, to authenticate the user:

```
open-dhcp-2@domain1   Cleartext-Password := "letmein"
            Alc-Subsc-Prof-Str = rad-sub,
            Alc-SLA-Prof-Str = rad-sla,
            Framed-Route = "192.168.1.0/24 0.0.0.0",

open-pppoe-2@domain1  Cleartext-Password := "letmein"
            Alc-Subsc-Prof-Str = rad-sub,
            Alc-SLA-Prof-Str = rad-sla,
            Framed-Route = "192.168.2.0/24 0.0.0.0",
```

DHCPv4/v6 servers are locally configured in the SR OS and attached to a loopback interface:

```
configure
    service
        vprn 1 customer 1 create
            interface "int-DHCP" create
                # IPv4 address which the DHCPv4 server is listening on
                address 10.10.1.1/24
                ipv6
                    # IPv6 address which the DHCPv6 server is listening on
                    address 2001:DB8::1/128
                    # attach the DHCPv6 server to this loopback interface
                    local-dhcp-server "svc-1-dhcp6"
                exit
                # attach the DHCPv4 server to this loopback interface
                local-dhcp-server "svc-1-dhcp4"
```

```
                    loopback
            exit
        exit
    exit
exit
```

Group-interface configuration. Note that common parts of the configuration as defined earlier, still apply:

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    ipv6
                        dhcp6
                            user-db "ludb-2"
                            # DHCPv6 relay configuration
                            relay
                                link-address 2001:DB8:30::
                                server 2001:DB8::1
                                client-applications dhcp ppp
                                no shutdown
                            exit
                        exit
                    exit
                    arp-populate
                    # DHCPv6 relay configuration
                    dhcp
                        proxy-server
                            emulated-server 10.12.0.1
                            no shutdown
                        exit
                        option
                            # SR OS will not insert its own circuit-ID
                            no circuit-id
                            # SR OS will not insert its own remote-ID
                            no remote-id
                            vendor-specific-option
                                pool-name
                        exit
                        server 10.10.1.1
                        client-applications dhcp ppp
                        user-db "ludb-2"
                        no shutdown
                    exit

                        policy "pppoe-pol-1"
                        session-limit 1000
                        sap-session-limit 1000
                        user-db "ludb-2"
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Lease times for IPv4 and IPv6 are configured in the local DHCP server. Lease times under the local DHCP server are used only in the relay case (when IP address is supplied via DHCP server and **not** RADIUS or LUDB). In the proxy case, the lease times can be obtained via LUDB, RADIUS, or group-interface.

```
configure
    service
        vprn 1 customer 1 create
            dhcp
                local-dhcp-server "svc-1-dhcp4" create
                    # gi-address can be used to select the pool
                    use-gi-address
                    # pool name can be explicitly provided
                    use-pool-from-client
                    # pool used when LUDB provides the pool name
                    pool "ludb" create
                        options
                            dns-server 172.16.16.16 172.16.16.17
                            lease-time hrs 1

            exit
        exit
exit
```

RADIUS sub/sla-profiles supplied via RADIUS are used:

```
configure
    subscriber-mgmt
        sla-profile "rad-sla" create
            description "sla-profile obtained from RADIUS"
            host-limits
                overall 100
            exit
            egress
                qos 1 vport-scheduler
                exit
                ip-filter 1
            exit
        exit
        sub-profile "rad-sub" create
            description "sub-profile obtained from RADIUS"
            egress
                agg-rate-limit 15000
            exit
        exit
    exit
exit
```

Show Commands

The following command shows that the rad-sub/sla-profiles, as supplied via RADIUS, are in use.

The IP addresses are selected from the pool-name LUDB in the local DHCP server. The subscriber-id is **circuit-id** for IPoE subscriber-host and the **username|session-id** combination for PPPoE subscriber host.

```

*A:BNG-1#
```

The following command shows more details about the subscriber-host, such as the group-interface, vport, address origin, acct-session-id, etc. Vport is selected based on the **inter-dest-id** string supplied via the LUDB.

For the purpose of brevity, the output for only two IP addresses *hosts* is shown, one with an IPv4 address and one with an IPv6 address. The remaining IP addresses/prefixes are not shown because the output follows the same logic.

```
*A:BNG-1# show service id 1 subscriber-hosts detail

*A:BNG-1#
```

The following command shows that the subscriber identity is set to **circuit-id** (plus session-id) as instructed by **auto-sub-id-key** command (subscriber-id string is not returned via the LUDB or RADIUS). The lease

times are set to 1h as defined in the DHCP server. The username passed to RADIUS is a **circuit-id** or a **username** appended with the *domain1* domain name.

```

*A:BNG-1#
```

IP Proxy Case with LUDB + RADIUS Authentication

IP address is assigned via RADIUS.

- RADIUS provides IP addresses (IPv6 lease-times are provided under the group-interface) and related parameters (DNS server, IPv4 default-gateway, etc), inter-dest-id string for Vport assignment and a framed route.

- LUDB provides sub/sla-profile strings and msap-defaults (routing context parameters and msap-policy).

Vport aggregate rate limit and the port scheduler are now added to the physical port. The Vport is associated with the subscriber through the inter-dest-id string obtained via the LUDB.

```
configure
    port 1/1/1
```

```
        ethernet
            mode access
            encap-type dot1q
            egress-scheduler-policy "port"
            access
                egress
                    vport "open-dhcp" create
                        agg-rate
                            rate 500
                        exit
                        host-match dest "open-auth-vport" create
                    exit
                exit
            exit
        exit
        no shutdown
    exit
exit
```

The LUDB is used to assign the sub/sla-profile strings.

The domain name *domain1* is appended to the username (circuit-id = open-dhcp-3 or username = open-pppoe-3) before an Access-Request is sent to the RADIUS server that is configured in the authentication policy *auth-pol-1*.

```
configure
    subscriber-mgmt
        local-user-db "ludb-3" create
            description "for CASE-3"
            ipoe
                match-list circuit-id
                host "open-dhcp-3" create
                    host-identification
                        circuit-id string "open-dhcp-3"
                    exit
                    auth-policy "auth-pol-1"
                    auth-domain-name "domain1"
                    identification-strings 254 create
                        sla-profile-string "ludb-sla"
                        sub-profile-string "ludb-sub"
                    exit
                    msap-defaults
                        group-interface "grp-int-1"
                        policy "msap-pol-1"
                        service 1
                    exit
                    no shutdown
                exit
            exit
            ppp
                match-list circuit-id mac username
                host "open-ppp-3" create
                    host-identification
                        username "open-pppoe-3"
                    exit
                    auth-policy "auth-pol-1"
                    password chap "letmein"
                    identification-strings 254 create
                        sla-profile-string "ludb-sla"
                        sub-profile-string "ludb-sub"
                    exit
                    msap-defaults
                        group-interface "grp-int-1"
```

```
                    policy "msap-pol-1"
                    service 1
                exit
                no shutdown
            exit
        exit
        no shutdown
    exit
    exit
exit
```

RADIUS is defined via the **authentication-policy**. The domain name can be appended to the PPPoE
subscriber host directly via authentication-policy, while for IPoE subscribers the domain name is appended
via authentication-policy in conjunction with LUDB.

```
configure
    subscriber-mgmt
        authentication-policy "auth-pol-1" create
            description "RADIUS authentication policy"
            password "letmein"
            ppp-user-name append "domain1"
            user-name-format circuit-id append
            accept-authorization-change
            pppoe-access-method pap-chap
            radius-server-policy "rad-serv-pol-1"
        exit
    exit
exit
```

The RADIUS user configuration file uses the domain extension as inserted by the BNG node to
authenticate the user. The **inter-dest-id** string and the host IP address are provided by the RADIUS server
(proxy case) along with other IP addressing parameters.

The IPv4 lease time (30 minutes) for IPv4 addresses are provided by the RADIUS server, while the lease
time (30 minutes) for IPv6 addresses/prefixes are configured under the **group-interface**.

```
open-dhcp-3@domain1   Cleartext-Password := "letmein"
        Alc-Int-Dest-Id-Str = open-auth-vport,
        Framed-IP-Address = 10.10.0.230,
        Framed-IP-Netmask = 255.255.255.0,
        Alc-Default-Router = 10.10.0.1,
        Alc-Lease-Time = 1800,

        Client-DNS-Sec = 172.16.20.21,
        Alc-IPv6-Address = 2001:db8::100,
        Delegated-IPv6-Prefix = 2001:DB8:40:100::/56,
        Alc-IPv6-Primary-Dns = 2001:DB8::2000,
        Alc-Ipv6-Secondary-Dns = 2001:DB8::2001,
        Framed-Route = "192.168.1.0/24 0.0.0.0",

open-pppoe-3@domain1  Cleartext-Password := "letmein"
        Alc-Int-Dest-Id-Str = open-auth-vport,
        Framed-IP-Address = 10.10.0.231,
        Framed-IP-Netmask = 255.255.255.255,
        Client-DNS-Pri = 172.16.20.20,
        Client-DNS-Sec = 172.16.20.21,
        Alc-IPv6-Address = 2001:db8:0:1::100,
        Delegated-IPv6-Prefix = 2001:DB8:40:200::/56,
        Alc-IPv6-Primary-Dns = 2001:DB8::2000,
        Alc-Ipv6-Secondary-Dns = 2001:DB8::2001,
        Framed-Route = "192.168.2.0/24 0.0.0.0",
```

The group-interface configuration is as follows. Note that common parts of the configuration as defined earlier still apply.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    ipv6
                        dhcp6
                            proxy-server
                                renew-timer min 7
                                rebind-timer min 10
                                valid-lifetime min 30
                                preferred-lifetime min 15
                                client-applications dhcp ppp
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        proxy-server
                            emulated-server 10.12.0.1
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

RADIUS sub/sla-profiles supplied via the LUDB are used:

```
configure
    subscriber-mgmt
        sla-profile "ludb-sla" create
            description "sla-profile obtained via LUDB"
            host-limits
                overall 100
            exit
            egress
                qos 1 vport-scheduler
                exit
                ip-filter 1
            exit
        exit
        sub-profile "ludb-sub" create
            description "sub-profile obtained via LUDB"
            egress
                agg-rate-limit 15000
            exit
        exit
    exit
exit
```

Show Commands

The following command shows that the LUDB-sub/sla-profiles, as supplied via LUDB, are in use. The IP addresses are supplied via the RADIUS server. The subscriber-id is auto-generated (not returned via

LUDB or RADIUS) and it is set to circuit-id for the IPoE subscriber-host, and to the **username|session-id** combination for PPPoE subscriber host.

```

*A:BNG-1#
```

The following command shows more details about the subscriber-host, such as the group-interface, vport, address origin, acct-session-id, etc. Vport is selected based on the **inter-dest-id** string supplied via RADIUS.

For the purpose of brevity, the output for only two hosts is shown, one with IPv4 address and one with IPv6 prefix. The remaining IP addresses/prefixes are not shown because the output follows the same logic.

```
*A:BNG-1# show service id 1 subscriber-hosts detail

*A:BNG-1#
```

The following command shows that the subscriber identity is set to **circuit-id** (plus **session-id**) as instructed by the **auto-sub-id-key** command (the **subscriber-id** string is not returned via LUDB or RADIUS). The lease times are set to 30 minutes as defined by RADIUS for IPv4 addresses and by the group-interface for IPv6 addresses/prefixes (proxy-case). The username passed to RADIUS is the circuit-id or username appended with the *domain1* domain name. The origin of the lease is RADIUS.

```

IP Proxy Case with LUDB + RADIUS Authentication

The IP address is assigned via LUDB.

- RADIUS provides sub/sla-profile strings and a framed IPv4 route.

- LUDB provides IP addresses (IPv6 lease-times are provided under the group-interface) and related parameters (DNS server, IPv4 default-gateway, etc), inter-dest-id string for Vport assignment and msap-defaults (routing context parameters and msap-policy).

Vport aggregate rate limit and the port scheduler are now added to the physical port. The Vport is associated with the subscriber through the inter-dest-id string obtained via the LUDB.

```
configure
    port 1/1/1
        ethernet
            mode access
            encap-type dot1q
            egress-scheduler-policy "port"
            access
                egress
                    vport "open-dhcp" create
                        agg-rate
                            rate 500
                        exit
                        host-match dest "open-auth-vport" create
                    exit
                exit
            exit
        exit
        no shutdown
    exit
exit
```

The LUDB is used to assign the inter-dest-id string, host IP addresses and IP addressing parameters. The DHCP lease time for IPv4 addresses is set to 15 minutes in the LUDB while lease times for IPv6 addresses/prefixes is set under the group-interface (set to 30 minutes).

The domain name *domain1* is appended to the username (circuit-id = open-dhcp-4 or username = open-pppoe-4) before an Access-Request is sent to the RADIUS server that is configured in the authentication-policy *auth-pol-1*.

```
configure
    subscriber-mgmt
        local-user-db "ludb-4" create
            description "for CASE-4"
            ipoe

```

RADIUS is defined via the authentication-policy. The domain name can be appended to the PPPoE
subscriber host directly via authentication-policy while for IPoE subscribers, the domain name is appended
via authentication policy in conjunction with LUDB.

```
configure
    subscriber-mgmt
```

```
            authentication-policy "auth-pol-1" create
                description "RADIUS authentication policy"
                password "letmein"
                ppp-user-name append "domain1"
                user-name-format circuit-id append
                accept-authorization-change
                pppoe-access-method pap-chap
                radius-server-policy "rad-serv-pol-1"
            exit
        exit
 exit
```

The RADIUS user configuration file uses the domain extension as inserted by the SR OS to authenticate the user.

```
open-dhcp-4@domain1   Cleartext-Password := "letmein"
            Alc-Subsc-Prof-Str = rad-sub,
            Alc-SLA-Prof-Str = rad-sla,
            Framed-Route = "192.168.1.0/24 0.0.0.0",

open-pppoe-4@domain1  Cleartext-Password := "letmein"
            Alc-Subsc-Prof-Str = rad-sub,
            Alc-SLA-Prof-Str = rad-sla,
            Framed-Route = "192.168.2.0/24 0.0.0.0",
```

The group interface configuration is as follows. Common parts of the configuration as defined earlier still apply.

```
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1" create
                    ipv6
                        user-db "ludb-4"
                        dhcp6
                            proxy-server
                                renew-timer min 7
                                rebind-timer min 10
                                valid-lifetime min 30
                                preferred-lifetime min 15
                                client-applications dhcp ppp
                                no shutdown
                            exit
                        exit
                    exit
                    dhcp
                        proxy-server
                            emulated-server 10.12.0.1
                            no shutdown
                        exit
                        user-db "ludb-4
                    exit
                exit
            exit
        exit
    exit
exit
```

RADIUS sub/sla-profiles supplied by RADIUS are defined as:

```
configure
    subscriber-mgmt
        sla-profile "ludb-sla" create
            description "sla-profile obtained via LUDB"
            host-limits
                overall 3
            exit
            egress
                qos 1 vport-scheduler
                exit
                ip-filter 1
            exit
        exit
        sub-profile "ludb-sub" create
            description "sub-profile obtained via LUDB"
            egress
                agg-rate-limit 15000
            exit
        exit
    exit
exit
```

Show Commands

The following command shows that the rad-sub/sla-profiles, as provided by RADIUS, are in use. The IP addresses are provided by LUDB. The **subscriber-id** is auto-generated (not returned via the LUDB or RADIUS) and it is set to **circuit-id** for IPoE subscriber-host(s) and to **username|session-id** combination for PPPoE subscriber host(s).

```

*A:BNG-1#
```

The following command shows more details about the subscriber-host, such as the group-interface, vport, address origin, acct-session-id, etc. Vport is selected based on the **inter-dest-id** string as supplied via RADIUS.

For the purpose of brevity, the details for only two hosts is shown, one with IPv4 address and one with IPv6 prefix. The remaining IP addresses/prefixes are not shown because the output follows the same logic.

```

*A:BNG-1#
```

The following command shows that the subscriber identity is set to circuit-id (plus session-id) as instructed by the **auto-sub-id-key** command (the **subscriber-id** string is not returned via the LUDB or RADIUS). The DHCPv4 lease time is set to set to 15 minutes as defined by the LUDB. The DHCPv6 lease times are set to 30 minutes as configured under the group-interface. The username passed to RADIUS is the circuit-id or username appended with the *domain1* domain name. The origin of the lease is RADIUS.

```

                detail all
            exit
            local-user-db "ludb-4"
                detail all
            exit
        exit
exit
```

```
configure
    log
        log-id 1
            from debug-trace
            to session
            no shutdown
        exit
    exit
exit
```

Conclusion

The flexible authentication model allows access to various sources (LUDB, RADIUS, and Python) of subscriber parameters during the subscriber establishment phase. This model can be utilized for IPoE, PPPoE or L2TP subscribers in IES or VPRN services (including a wholesale/retail VRF model). A typical use case would be in a wholesale/retail environment where the wholesaler enforces its own rules via the LUDB before it passes the authentication request to the retailer's RADIUS server.

GTP Access

This chapter provides information about GTP access.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 16.0.R3.

Overview

The GPRS Tunneling Protocol (GTP) is defined by 3GPP for carrying data through mobile backhaul networks. GTP-U (User plane) is used to forward User Equipment (UE) traffic between the Radio Access Network (RAN) and the core network. GTPv2-C (Control plane) is used within the 4G Evolved Packet Core (EPC) to establish and maintain these GTP-U tunnels. Basic Evolved Packet System (EPS) knowledge is assumed throughout this chapter.

Nokia provides Enhanced Subscriber Management (ESM) features to stationary wireless subscribers over GTP. This offers service providers the means to provide broadband services to areas that cannot be easily or sufficiently covered using traditional fixed access technologies. GTP is another type of access to the BNG, and the set of concepts applying to this context are generally referred to as fixed wireless access. In the Nokia GTP solution, the Serving Gateway (S-GW) and the Packet Data Network (PDN) Gateway (P-GW) functions are integrated with the BNG, as shown in Figure 76: GTP Access to the BNG.

Figure 76: GTP Access to the BNG
27982

In 3GPP architectures, specific communication channels between two entities are called interfaces. These 3GPP-defined interfaces are logical interfaces and unrelated to physical router interfaces. For example, the S11 interface covers the communication between the Mobility Management Entity (MME) and the S-GW, the S1-U interface the data path communication between the eNodeB and the S-GW, and the S5 interface the communication between the S-GW and the P-GW. The S1-MME interface covers the communication between the eNB and the MME. S11 and S1-U use GTP as their encapsulation protocol.

When a UE is activated, the UE attachment process is started, where the initial signaling passes via the eNB, the MME, and the S-GW to the P-GW to establish an EPS bearer. The EPS bearer runs from the UE via the eNB and the S-GW to the P-GW; the MME is not on the data path. Some subsequent signaling can run on the straight path from the UE to the P-GW.

The EPS bearer is a transmission path running end-to-end between a UE and a P-GW, which carries the user data; see Figure 77: EPS Bearer Across the Different Interfaces. The EPS bearer is the concatenation of a radio bearer on the air interface, a GTP tunnel on the S1-U interface between the eNB and the S-GW, and a GTP tunnel on the S5 interface between the S-GW and the P-GW.

Figure 77: EPS Bearer Across the Different Interfaces
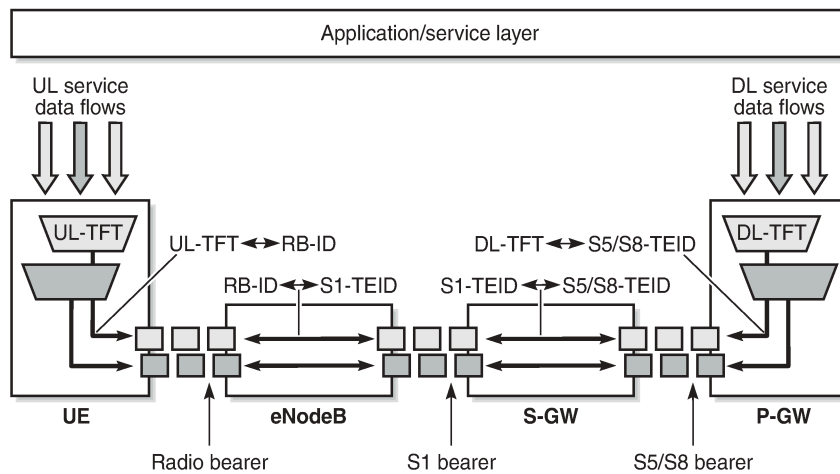

GTP-C signaling procedures are used to establish an S1 and an S5 bearer, during which Tunneling End ID (TEID) values are assigned and exchanged. These TEIDs are locally significant, and the upstream and downstream channels can have different TEIDs. With an S1 and S5 bearer established, user data can pass through using GTP-U encapsulation; see Figure 78: GTP-C and GTP-U Encapsulation. UDP ports 2123 and 2152 are used for GTP-C and GTP-U, respectively.

Figure 78: GTP-C and GTP-U Encapsulation
As part of the UE attachment procedure, the UE is assigned an IPv4/IPv6 address by the P-GW and a default bearer is established. The default bearer remains established throughout the lifetime of the PDN connection to provide the UE with always-on IP connectivity to that PDN. The default bearer QoS parameters can be provided by either the MME, Policy Control and Charging Rules Function (PCRF), RADIUS server, or locally.

The GTP-U tunnel encapsulation used in the network is shown in Figure 79: GTP-U in Up and Downstream. The IPv4/IPv6 address assigned to the UE during the attachment process is used end-to-end. For the outer header of the S1 GTP tunnel, the eNB and the S-GW IPv4 addresses are used. Similarly, for the S5 GTP tunnel, the S-GW and P-GW IPv4 addresses are used.

Figure 79: GTP-U in Up and Downstream

(a) from the UE to the Internet

(b) from the Internet to the UE
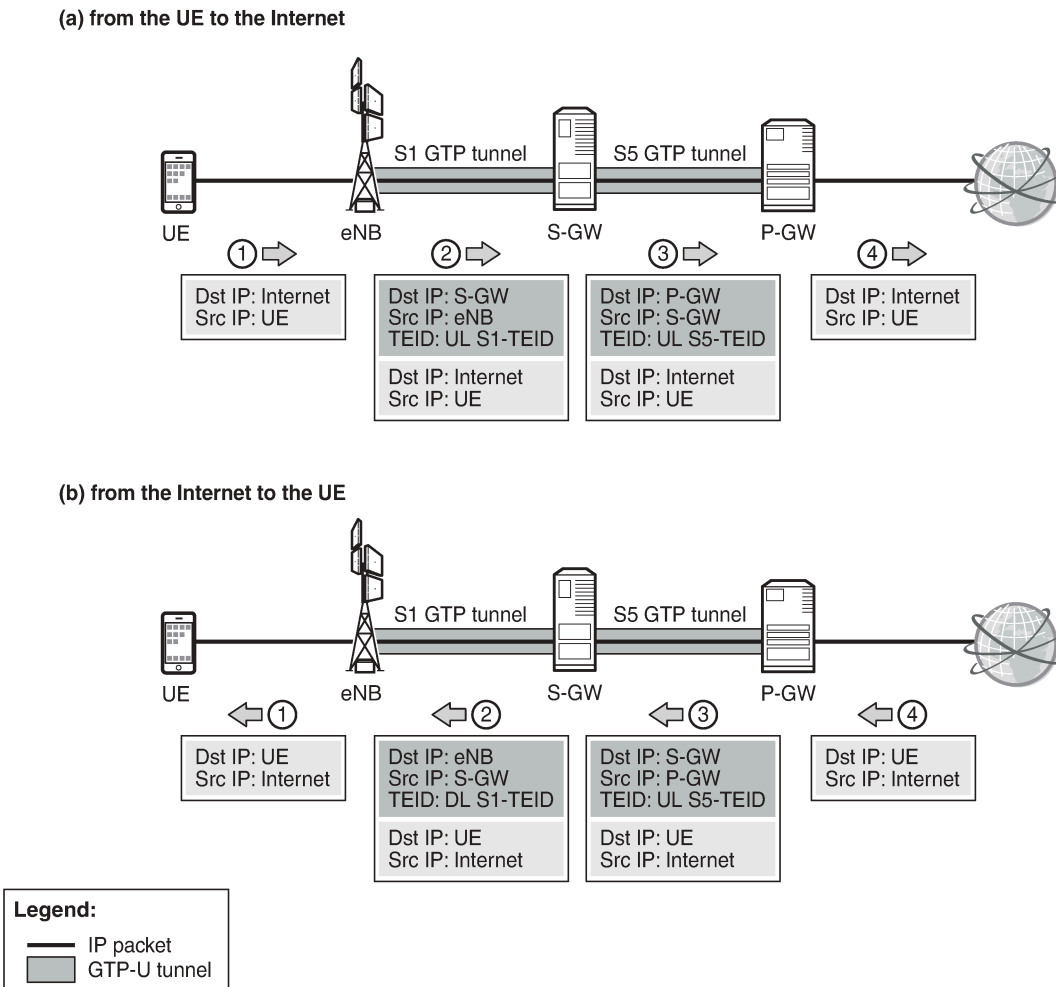

Because the S-GW and P-GW functionalities are integrated with the BNG, the S5 logical interface is internal to the system. SR OS supports TPSDA over GTP access tunnels initiated over the S11 (GTPv2-C) interface, where the UE data traffic is on the S1-U (GTP-U) interface. This is sometimes referred to as ESM over GTP (ESMoGTP).

Both IPv4 and IPv6 connectivity over GTP is supported. GTP session authentication can be performed using LUDB, RADIUS, or NASREQ.

ESMoGTP requires PXC FPE in order to support L3 re-routing in the access network and in-line encapsulation/decapsulation of the GTP protocol.

GTP-C Control - GTP Host Creation and Host Deletion

Figure 80: GTP-C Control - GTP Host Creation shows the steps used for creating a GTP host.

1. A GTP S11 interface must be created and enabled for the BNG to accept and process the Create Session Request message emitted by the MME. This message includes IMSI, IMEI, MS-ISDN, APN, QCI, and so on.

2. The APN received is mapped via the APN policy to an authentication method (RADIUS, LUDB, or NASREQ), and to an optional default service and group interface. Also, a peer profile can be applied to that interface, defining keepalive timer (KA), default GTP Information Elements (IEs), Python-derived policies, and so on.

3. By default, the IMSI is used for authentication toward AAA.

4. The Access Accept message sent by AAA returns the standard set of ESM parameters, such as the IP address, QoS overrides, service ID, and group interface where the GTP host must be created.

5. The Create Session response includes the locally assigned TEID, IPv4/IPv6 information, AMBR, QCI, and the S1-U TEID and the S1-U endpoint. The GTP host is created.

6. The MME sends a Modify Bearer Request Message to update the default bearer information with the eNB final information (IP, TEID, and so on).

7. The BNG starts a keep-alive timer per S11 peer, using the timer values defined by the peer profile. Also, the MME can start a keep-alive timer, independent from the BNG.

Figure 80: GTP-C Control - GTP Host Creation
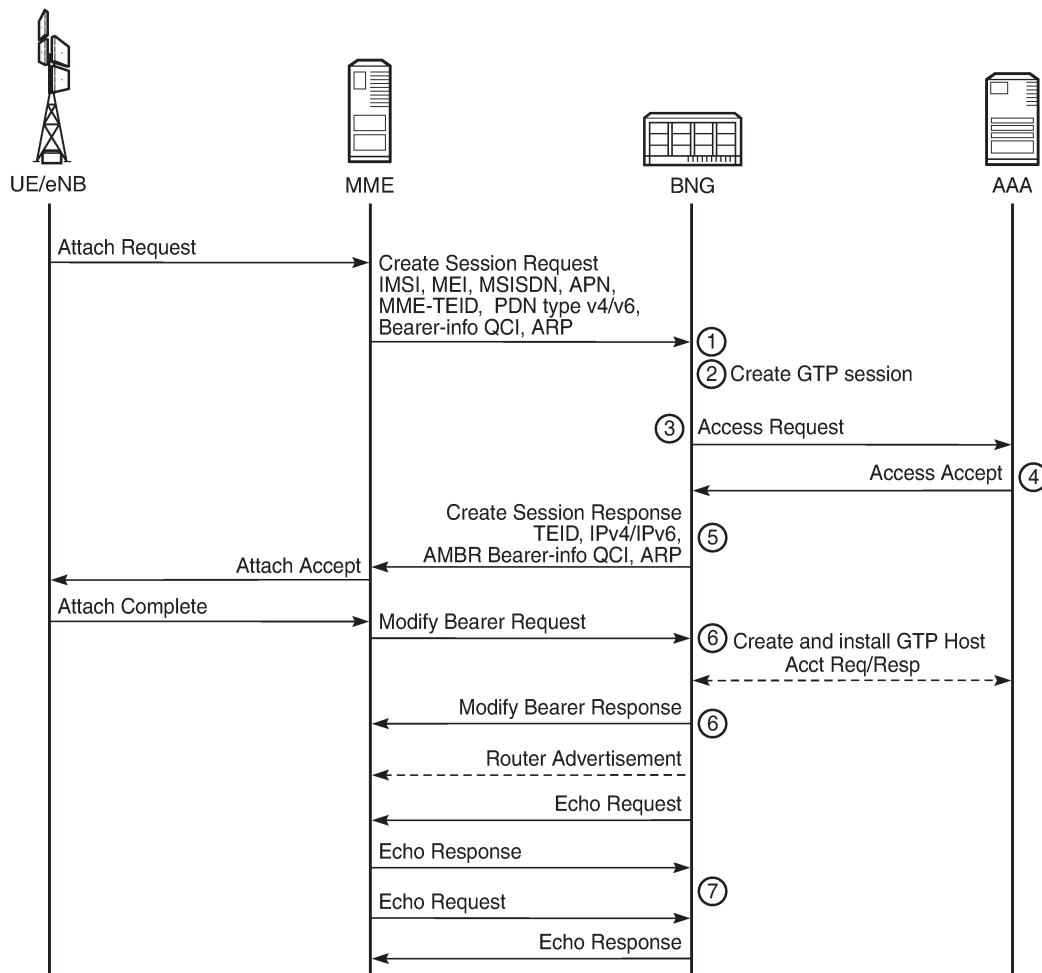

Figure 81: GTP-C Control - GTP Host Deletion shows the actions taken for deleting a GTP host when triggered by a Delete Session Request message sent by the MME: on an incoming Delete Session Request message, the ESM host termination process is executed, and a Delete Session Response message is sent to the MME. This is marked as event 1 in Figure 81: GTP-C Control - GTP Host Deletion.

However, the BNG can also delete GTP hosts because of the echo timers expiring.

The BNG can autonomously start the GTP host deletion process, including the deletion of the GTP session; for example, when idle timers expire. The MME is notified through the Delete Bearer Request message so that it can delete the default bearer for the UE specified.

Figure 81: GTP-C Control - GTP Host Deletion
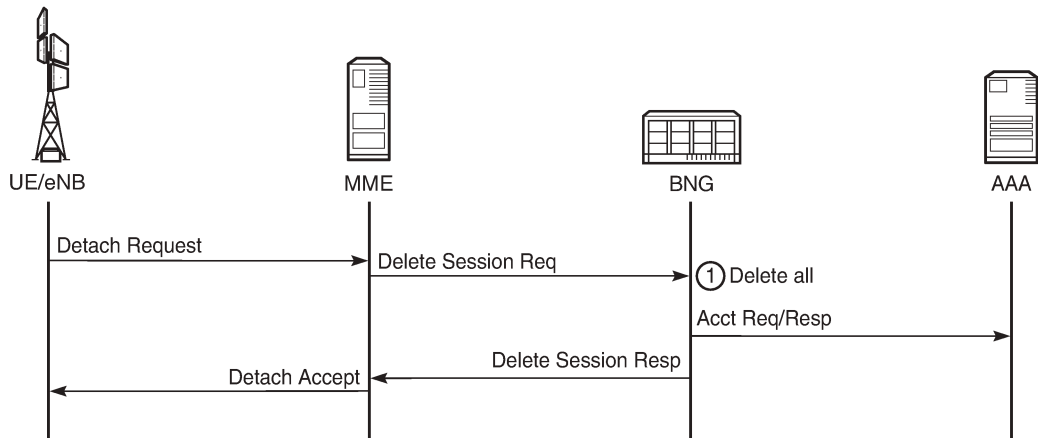

Configuration

Figure 82: GTP Access Topology shows the topology used for demonstrating GTP Access.

Figure 82: GTP Access Topology
On the BNG, the traffic entering on port 1/2/1 is internally routed to port 1/2/4, which is configured as a PXC port; see the *Port Cross-Connect (PXC)* chapter in the *7450 ESS, 7750 SR, and 7950 XRS Interface Configuration Advanced Configuration Guide for Classic CLI* for more information. The PXC port 1/2/4 additionally requires subscriber management extensions to be enabled in the forwarding plane (FPE), see the *VXLAN Forwarding Path Extension* chapter in the *7450 ESS, 7750 SR, and 7950 XRS Layer 2 Services and EVPN Advanced Configuration Guide for Classic CLI*, and the **encap-type** is set to **qinq**:

```
# on BNG-1
configure
    port 1/2/1
        ethernet
```

```
                mode access
                encap-type dot1q
            exit
            no shutdown
        exit
        port 1/2/4
            ethernet
                mode hybrid
                encap-type dot1q
            exit
            no shutdown
        exit
        port-xc
            pxc 1 create
                port 1/2/4
                no shutdown
            exit
        exit
        port-xc
            pxc 1 create
                port 1/2/4
                no shutdown
            exit
        exit
        port pxc-1.a
            ethernet
                encap-type qinq
            exit
            no shutdown
        exit
        port pxc-1.b
            ethernet
                encap-type qinq
            exit
            no shutdown
        exit
exit
```

```
configure
    fwd-path-ext
        fpe 1 create
            path pxc 1
            sub-mgmt-extensions
        exit
    exit
exit
```

The status of the PXC port can be verified as follows:

```
*A:BNG-1# show port-xc

===============================================================================
Port Cross-Connect Information
===============================================================================
PXC     Admin    Oper     Port        Description
Id      State    State    Id
-------------------------------------------------------------------------------
1       Up       Up       1/2/4       (Not Specified)
-------------------------------------------------------------------------------
No. of PXCs: 1
===============================================================================
*A:BNG-1#
```

With subscriber management extensions enabled, SR OS can dynamically create SAPs on which GTP subscribers can be terminated at a later stage. The status for FPE 1 shows that the subscriber management extensions are enabled, as follows. The operational state indicated as N/A at the end of the same line is not relevant.

```
*A:BNG-1# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description         : (Not Specified)
Path                : pxc 1
Pw Port             : Disabled                       Oper     : down
Sub Mgmt Extension : Enabled                         Oper     : N/A
Vxlan Termination  : Disabled                        Oper     : down
===============================================================================
*A:BNG-1#
```

The APN policy *pol-APN-ACG* is defined in the subscriber management **gtp** context, as follows. The other profiles are required for ESM host and subscriber setup.

```
configure
    subscriber-mgmt
        gtp
            apn-policy "pol-APN-ACG" create
                apn acg.mnc001.mcc001.gprs create
                    user-db "ludb-GTP"
                exit
            exit
        exit
        sla-profile "sla-prof-1" create
        exit
        sub-profile "sub-prof-1" create
        exit
        sub-ident-policy "sub-id-pol-direct" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
    exit
exit
```

Two services are used to provide GTP access to the BNG, as shown in Figure 83: GTP Tunnel and Subscriber Termination Configuration Logic. The first routed service provides the GTP tunnel termination, and the second provides the infrastructure to terminate the GTP subscribers.

Figure 83: GTP Tunnel and Subscriber Termination Configuration Logic
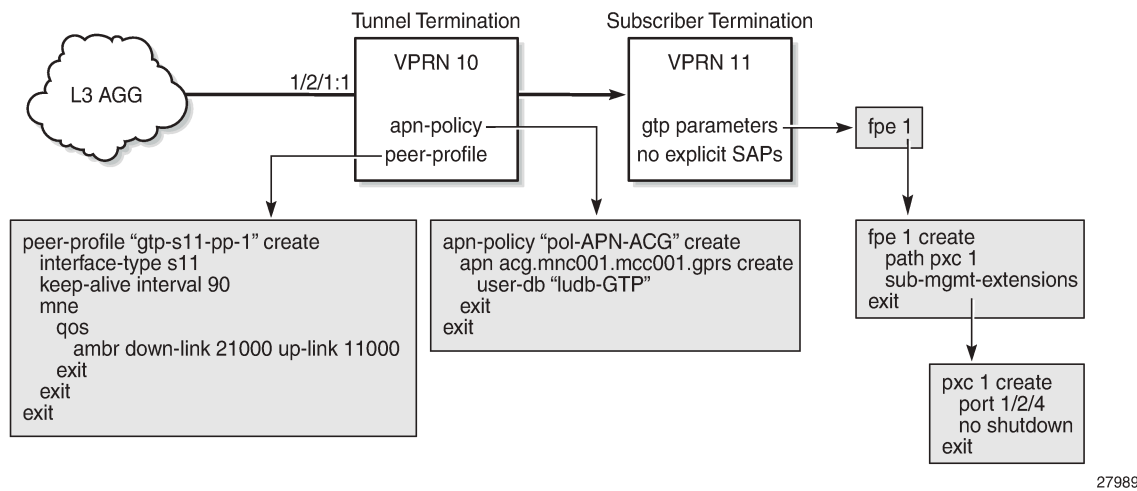

GTP Tunnel Terminating VPRN

In Figure 83: GTP Tunnel and Subscriber Termination Configuration Logic, VPRN 10 implements the
GTP tunnel termination. The GTP traffic enters VPRN 10 on interface *int-BNG-L3AGG* with MAC address
00:00:5e:00:53:01 on SAP 1/2/1:1. The interface *int-GTP-endpoint* is defined as a loopback interface,
potentially providing redundancy to the L3 aggregation network. Static routes and a static ARP entry are
defined in VPRN 10 for reaching the MME and the eNB through the L3 aggregation network, providing
control over the L3 aggregation test environment. The APN policy provides the link between the tunnel
termination VPRN (10) and the subscriber terminating VPRN (11). The peer-profile map defines which peer
profile is used for which MME. In this example, the APN policy is *pol-APN-ACG*, and the peer profile is *gtp-
s11-pp-1*. VPRN 10 is configured as follows:

```
configure
    service
        vprn 10 name "GTP-tunnel-termination" customer 1 create
            description "GTP Tunnel termination"
            route-distinguisher 64496:10
            interface "int-GTP-endpoint" create
                description "Tunnel endpoint IP"
                address 192.0.2.10/32
                loopback
            exit
            interface "int-BNG-L3AGG" create
                address 192.168.0.1/24
                mac 00:00:5e:00:53:01
                static-arp 192.168.0.2 00:00:5e:00:53:00
                sap 1/2/1:1 create
                exit
            exit
            static-route-entry 192.168.100.0/24
                next-hop 192.168.0.2
                    no shutdown
                exit
            exit
            static-route-entry 192.168.101.0/24
                next-hop 192.168.0.2
```

```
                    no shutdown
                exit
            exit
            gtp
                s11
                    interface "int-GTP-endpoint" create
                        apn-policy "pol-APN-ACG"
                    exit
                    peer-profile-map
                        address 192.168.100.1/32 peer-profile "gtp-s11-pp-1"
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Peer Profile

A peer-profile policy controls the keep-alive interval, and the QoS configuration to be used for MMEs (AMBR, ARP, QCI, …). The peer profile *gtp-s11-pp-1* used for the example shown in Figure 8 is defined as follows. AMBR downlink and uplink are set to 21000 kb/s and 11000 kb/s, respectively, and QCI is set to 8.

```
configure
    subscriber-mgmt
        gtp
            peer-profile "gtp-s11-pp-1" create
                interface-type s11
                keep-alive interval 90
                mme
                    qos
                        ambr down-link 21000 up-link 11000
                        arp 1
                        down-link gbr 0 mbr 0
                        qci 8
                        up-link gbr 0 mbr 0
                    exit
                exit
            exit
        exit
    exit
exit
```

APN Policy

An APN policy controls the authentication method per APN (LUDB, RADIUS, or Diameter). The APN policy *pol-APN-ACG* used for the example shown in Figure 83: GTP Tunnel and Subscriber Termination Configuration Logic is defined as follows. Only one APN is defined (*acg.mnc001.mcc001.gprs*), and the UEs using this APN are authenticated through the *ludb-GTP* LUDB.

```
configure
    subscriber-mgmt
        gtp
            apn-policy "pol-APN-ACG" create
                apn acg.mnc001.mcc001.gprs create
                    user-db "ludb-GTP"
```

```
            exit
        exit
     exit
  exit
exit
```

For authenticating GTP users using an LUDB, the LUDB must define hosts in the IPoE section of the
LUDB. In this example, host matching is based on the IMSI, which is automatically populated in the IPoE
string match criterion. Therefore, the **match-list string** command is used, but matching can also be based
on a Derived ID provided by a Python script. Individual hosts can be matched using the **string** command
for host-identification. To avoid the definition of many hosts, a *default* host can be used. In both cases, the
output provides the service and the interface where the GTP subscriber must be implemented, as well as
the IPv4/IPv6 address information required for the Local Address Assignment (LAA), as follows:

```
configure
    subscriber-mgmt
        local-user-db "ludb-GTP" create
            ipoe
                match-list string
                host "host-1" create
                    host-identification
                        string "001020000000111"
                    exit
                    address pool "pool4-1"
                    identification-strings 254 create
                        subscriber-id "GTP-subscriber-111"
                        sla-profile-string "sla-prof-1"
                        sub-profile-string "sub-prof-1"
                    exit
                    interface "int-GRP" service-id 11
                    ipv6-slaac-prefix-pool "pool6-1"
                    no shutdown
                exit
                host "default" create
                    address pool "pool4-1"
                    interface "int-GRP" service-id 11
                    ipv6-slaac-prefix-pool "pool6-1"
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

GTP Subscriber Terminating VPRN

In , VPRN 11 implements the GTP subscriber termination. Because GTP
subscribers are ESM subscribers, the regular ESM concepts apply, meaning that subscriber management
profiles are required; however, no explicit SAP definitions are required. LAA is used, where server *lcl-
DHCPs-ip4* is used for IPv4, and *lcl-DHCPs-ip6* is used for IPv6. To support SLAAC, the IPv6 router-
advertisements context has **prefix-options autonomous** enabled. The **gtp-parameters** context in the
group interface defines the FPE to be used and must be enabled (no shutdown), as follows:

```
configure
    service
        vprn 11 name "GTP-subsc-termination" customer 1 create
            description "GTP subscriber termination"
```

```
                ---snip---

                route-distinguisher 64496:11
                subscriber-interface "int-SUSBC" create
                    address 192.168.50.1/24
                    ipv6
                        delegated-prefix-len 56
                        subscriber-prefixes
                            prefix 2001:db8:101::/48 wan-host
                        exit
                    exit
                    group-interface "int-GRP" gtp create
                        gtp-parameters
                            fpe 1
                            no shutdown
                        exit
                        ipv6
                            router-advertisements
                                prefix-options
                                    autonomous
                                exit
                                no shutdown
                            exit
                        exit
                        local-address-assignment
                            server "lcl-DHCPs-ip4"
                            client-application ipoe-v4
                            ipv6
                                client-application ipoe-slaac
                                server "lcl-DHCPs-ip6"
                            exit
                            no shutdown
                        exit
                        sap-parameters
                            sub-sla-mgmt
                                def-sla-profile "sla-prof-1"
                                def-sub-profile "sub-prof-1"
                                sub-ident-policy "sub-id-pol-direct"
                            exit
                        exit
                    exit
                exit
                no shutdown
            exit
        exit
 exit
```

Enabling the **gtp-parameters** context (**no shutdown**) results in SR OS creating SAP pxc-1.b:1.8,
as follows. The square brackets indicate that the SAP is created automatically, without any explicit
configuration.

```
*A:BNG-1# show service id 11 sap

```

When the UE with IMSI 001020000000111 connects, an S11 session is created, as follows. The 00:03:ff:f0:01:20 MAC address and pxc-1.b:1.8 SAP are internally generated to link the GTP session with an ESM IPoE session. The remote S1-U address is 192.168.101.1 for Bearer 6. The locally and remotely assigned TEID values are also shown.

```
*A:BNG-1# show subscriber-mgmt gtp s11 session imsi 001020000000111

No. of GTP S11 sessions: 1
================================================================================
*A:BNG-1#
```

Additionally, an ESM subscriber and an IPoE session is created on SAP pxc-1.b:1.8, as follows. The subscriber identifier is taken from the LUDB (GTP-subscriber-111). The IPoE session is created on service 11 and uses the internally generated MAC address. The IPv4 and the IPv6 addresses are combined in the same IPoE session, with MAC address 00:03:ff:e0:01:20.

```
*A:BNG-1# show service active-subscribers hierarchy

Debug

Debugging is useful when troubleshooting GTP scenarios. The debug configuration used is as follows:

```
debug
    router service-name "GTP-subsc-termination"
        ip
            dhcp
                detail-level high
                mode egr-ingr-and-dropped
            exit
        exit
        local-dhcp-server "lcl-DHCPs-ip4"
            detail-level high
            mode egr-ingr-and-dropped
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-GTP"
            detail all
        exit
    exit
    gtp
        event
        packet
            detail-level high
            mode all
        exit
    exit
exit
```

The trace for the UE with IMSI 001020000000111 initiating a connection to APN *acg.mnc001.mcc001.gprs* is as follows; also see Figure 80: GTP-C Control - GTP Host Creation. Step 1 is the Create Session request, with the parameters supplied by the test-tool (IMSI, APN, RAT TYPE, PDN TYPE, and so on). Step 9 indicates that a GTP downlink is created. Step 12 indicates that the LUDB is accessed successfully. Steps 13, 14, and 15 indicate that LAA is used for address assignment. Step 28 indicates that an S1-U session is successfully established.

```

Conclusion

Using GTP access technology, service providers can offer broadband services to areas that cannot be easily and sufficiently covered using traditional fixed access technologies. By offering LTE users GTP access to the BNG, the service providers can leverage the potential of wireless access with traditional BNG service offerings, including HQoS and multicast.

High Scale QoS IOM in ESM Context: Expanded SLA Mode

This chapter describes the High Scale QoS (HSQ) IOM in the Enhanced Subscriber Management (ESM) context

Topics in this chapter include:

Applicability

This chapter is applicable to the 7750 SR-7/12/12e platforms and describes the High Scale QoS (HSQ) IOM in the Enhanced Subscriber Management (ESM) context. The information and configuration in this chapter are based on SR OS Release 15.0.R4.

Overview

This chapter describes the QoS operation and configuration of the High Scale QoS IOM (HSQ), with a focus on the expanded SLA mode in the Enhanced Subscriber Management (ESM) context.

This chapter can be considered as an extension of the High Scale QoS IOM in ESM Context: Single SLA Mode chapter and it is recommended that the High Scale QoS IOM in ESM Context: Single SLA Mode chapter be read first. Generic concepts and configuration that is common to both chapters will not be repeated in this chapter. For example, high-level HSQ description or generic ESM configuration (as in Appendix A in the High Scale QoS IOM in ESM Context: Single SLA Mode chapter) will not be repeated here. However, since QoS is a centerpiece of this chapter, the QoS-specific configuration will be provided, even for the parts that may overlap between the two chapters (for example, HS attachment policy configuration is the same in both chapters and it will be repeated here).

Expanded SLA mode on HSQ is the default mode of operation in the ESM context and in contrast to single SLA mode, it allows multiple SLA profile instances (SPIs) per subscriber. That is, expanded SLA mode allows multiple HSQ queue groups per subscriber. Multiple subscriber **hosts\sessions** are supported per each SPI and HSQ queue group.

While expanded SLA mode provides better QoS flexibility at the subscriber level than single SLA mode, its scale becomes restricted by the number of HS primary shapers on the HSQ IOM. In Expanded SLA Mode, one HS primary shaper is allocated per subscriber to limit the subscriber aggregate rate (which can now consist of multiple HSQ queue groups). Since the HSQ IOM supports 16k HS primary shapers, the scale of the subscribers on HSQ IOM becomes limited by the same number. These two factors (greater QoS flexibility at the subscriber level and reduced subscriber scale) are the two main differences between the two SLA modes of operation.

> **Note:**
> Some small number of HS primary shapers are used internally by the system, so are not available to subscribers.

The SLA mode of operation is enabled per subscriber and it cannot be changed online (while the subscriber is established). The reason why expanded SLA mode is the default mode, even though it reduces the subscriber scale, is that this mode adheres to the existing ESM principles in SR OS where the number of SPIs per subscriber is not restricted.

Like the Single SLA Mode chapter, this chapter is also conceptually divided into two parts:

- The focus of the first part is on the (egress) QoS configuration for two subscribers, named "sub-1" and "sub-2". Each subscriber has two hosts and consequently two SPIs and HSQ queue groups. Subscriber hosts will be referred to as:

  - Host 1-1: first host of sub-1

  - Host 1-2: second host of sub-1

  - Host 2-1: first host of sub-2

  - Host 2-2: second host of sub-2

> **Note:**
> Subscriber sessions are also supported. This example is, however, based on subscriber hosts while the subscriber session concept is left disabled.

- The second part focuses on examining HSQ traffic management capabilities in the ESM context by observing output traffic patterns in a congested system.

Topics related to the generic operation of HSQ IOM and ESM that are not directly described in this chapter are included in the following:

- Configuring single SLA mode in ESM is in the chapter High Scale QoS IOM in ESM Context: Single SLA Mode.

- Configuring HSQ in the service context is in the chapter *High Scale QoS IOM: QoS, Service, and Network Configuration*.

- Generic ESM concepts are described in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* and in numerous chapters in ACG part III – TPSDA.

Test Environment

Figure 84: Test Environment Example shows the test environment example with two subscribers in expanded SLA mode, each with two DHCPv4 hosts set up in the BNG. DHCPv4 control traffic (simulated subscriber hosts) is initiated from port 103/1 on a traffic generator. Subscribers are authenticated via local user database (LUDB) and instantiated on managed service access points (MSAPs) in the IES 3 service. Subscriber IP addresses are assigned statically via LUDB.

To explore traffic management capabilities under congestion, a number of traffic streams are generated in the downstream direction, from port 203/1 on the traffic generator toward the subscriber hosts on port 103/1.

Figure 84: Test Environment Example
The QoS hierarchy associated with the subscribers is shown in Figure 85: QoS Hierarchy in Expanded SLA Mode. At a high level, this hierarchy can be described as follows:

- Each of the two subscribers (sub-1 and "sub-2") has two hosts, each of which is associated with an SPI and HSQ queue group. HSQ queue group is always comprised of eight queues. However, not all the queues are required to be used by the subscriber. In this example, only six queues are used by each subscriber while the two remaining queues, although allocated to the subscriber, remain unused.

> **Note:**
> Subscriber sessions are also supported. This example is, however, based on subscriber hosts while the subscriber session concept is left disabled.

- All four hosts use the same HS attachment policy template. This means that the mapping between the queues, scheduling classes (SC), and WRR groups is the same for all four hosts.

- Queues 1 and 2 are attached to WRR group 1 at the local HSQ queue group level and served in 4:1 ratio. WRR group 1 is attached to the lowest scheduling class 1, whereas queues 3, 4, 5, and 6 are directly attached to scheduling classes 3, 4, 5, and 6, respectively.

- Each HSQ queue group is rate limited at the aggregate level. In this example, there is only one host associated with each HSQ queue group. However, multiple hosts per SPI and HSQ queue group can be configured.

- Each subscriber is rate limited at the aggregate level.

- Subscribers are mapped to the same HS secondary shapers.

- Mapping between the subscribers and their HS secondary shapers is achieved via outer VLANs. Sub-1 and sub-2 on SAPs with the outer VLAN 1 are mapped to the HS secondary shaper 1.

- The HS secondary shaper is associated with the HS port scheduler that has its own aggregate rate limit set. Because there is only one HS secondary shaper configured per port in this example, the smaller configured aggregate rate limit of the two (HS secondary shaper and the port shaper) will affect traffic going out this port.

- At the port level, the scheduling class 6 is rate limited while scheduling classes 4 and 5 are collapsed into a WRR group, which is rate limited.

Figure 85: QoS Hierarchy in Expanded SLA Mode
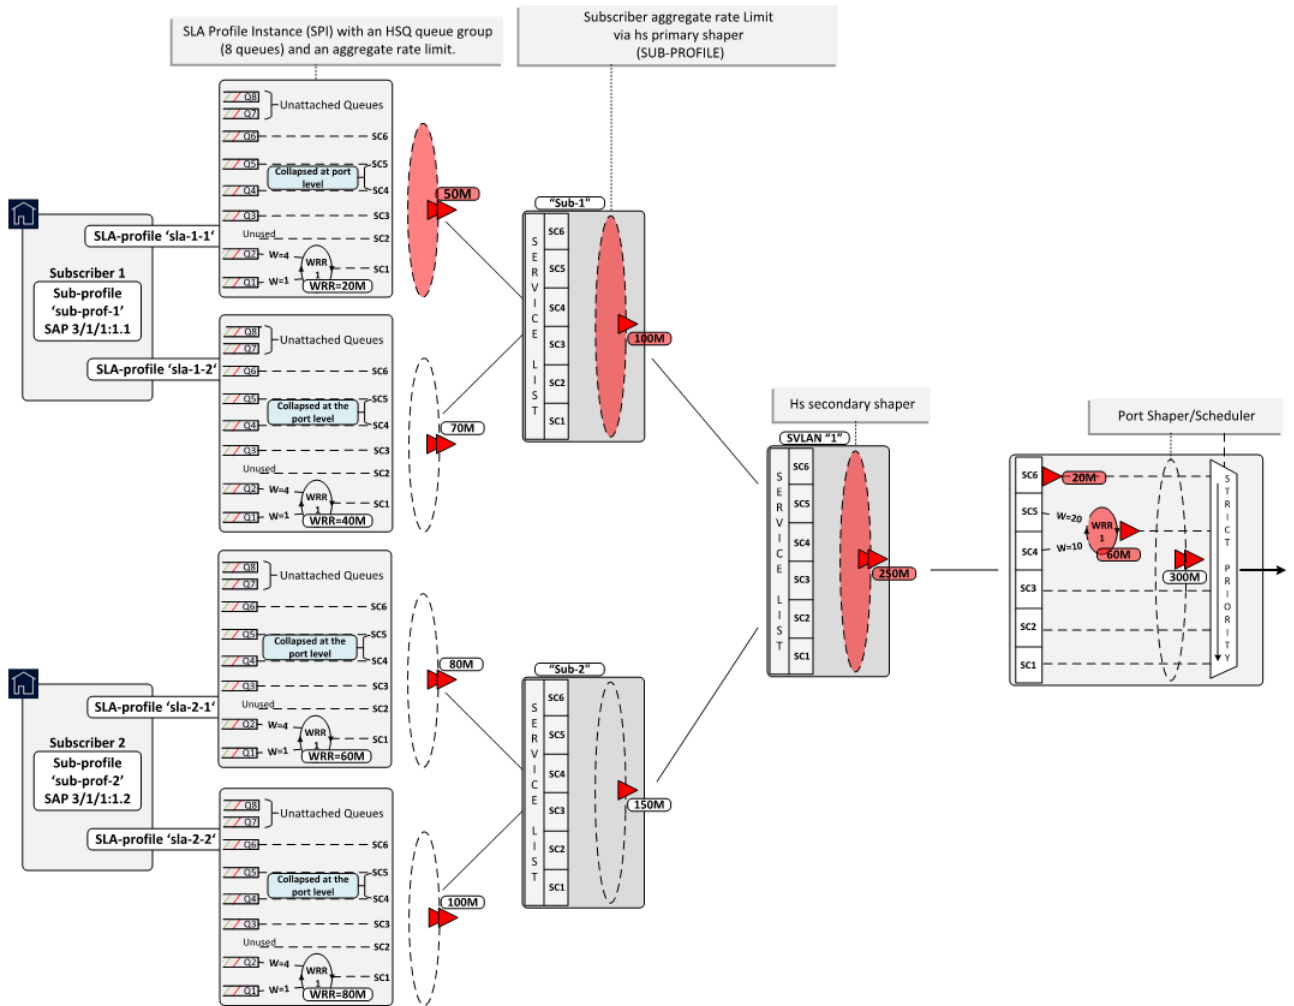

Configuration

The configuration section is split into two parts:

- ESM-specific configuration as it relates to HSQ

- QoS-specific configuration as it relates to HSQ

ESM-specific Configuration

For repeating parts of common ESM configuration, see the High Scale QoS IOM in ESM Context: Single SLA Mode chapter.

Each of the two subscribers (sub-1 and sub-2) have their own **sub-profile**, which will determine the HS SLA mode in which the subscriber operates, as well as the aggregate rate limit in kb/s for each subscriber. The aggregate rate of the subscriber is configured via its HS primary shaper. The **hs-agg-rate-limit** command in sub-profile is the only command that is applicable to HS primary shaper. Since the Expanded SLA Mode is the default mode, its configuration is not shown in the CLI unless requested by the **detail** keyword:

```
configure
   subscriber-mgmt
      sub-profile "sub-prof-1" create
         egress
            hs-agg-rate-limit 100000
         exit
      exit
      sub-profile "sub-prof-2" create
         egress
            hs-agg-rate-limit 150000
         exit
      exit
```

With **info detail** or **admin display-config detail** commands, the Expanded SLA Mode configuration is shown (irrelevant parts are removed from the output):

```
subscriber-mgmt
   sub-profile "sub-prof-1" create
      hs-sla-mode expanded
      egress
         hs-agg-rate-limit 100000
       exit
```

Each subscriber host has its own SPI that references the QoS SAP policy on egress (in this case, QoS SAP egress policies 10, 20, 30, and 40). Each SLA profile defines the aggregate rate in kb/s that will be applied to the corresponding HSQ queue group, and in this case to each subscriber host.

The egress QoS SAP policy defines the QoS characteristics at the subscriber host level (or HSQ queue group level), such as:

- traffic classification

- queue/WRR rates and weights

- mapping between the queues, WRR groups, and scheduling classes by referencing the HS attachment policy.

```
configure
   subscriber-mgmt
      sla-profile "sla-1-1" create
         egress
            qos 10
            exit
            hs-agg-rate-limit 50000
```

```
                exit
            exit
        sla-profile "sla-1-2" create
            egress
                qos 20
                exit
                hs-agg-rate-limit 70000
            exit
        exit
        sla-profile "sla-2-1" create
            egress
            qos 30
            exit
            hs-agg-rate-limit 80000
            exit
        exit
        sla-profile "sla-2-2" create
            egress
                qos 40
                exit
                hs-agg-rate-limit 100000
            exit
        exit
    exit
```

For detailed descriptions of the configuration options in MSAP policy, see the High Scale QoS IOM in ESM Context: Single SLA Mode chapter, because this configuration is shared:

```
configure
    subscriber-mgmt
        msap-policy "msaps" create
            sub-sla-mgmt
                def-inter-dest-id use-top-q
                sub-ident-policy "sub_ident_pol"
                no multi-sub-sap
                single-sub-parameters
                    profiled-traffic-only
                exit
            exit
        ies-vprn-only-sap-parameters
            ingress
                qos 1 service-queuing
                exit
            exit
        exit
    exit
```

QoS-specific configuration

At the subscriber level (or HSQ queue group level), the HS attachment policy defines mapping between the queues, WRR groups, and scheduling classes. In this example, queues 1 and 2 are mapped to a WRR group 1, which is mapped into scheduling class 1. Queues 3 to 6 are mapped to respective scheduling classes (SC 3 to 6). Queues 7 and 8, although allocated, are unattached, so will drop any traffic that they receive. A maximum of two WRR groups are supported at the HSQ queue group level and in this example, only WRR 1 is used.

The low burst max class parameter is set to 3, which ensures that the three lower scheduling classes (1 to 3) are stopped being served first if HSQ queue group aggregate congestion occurs. The HSQ queue group aggregate shaper has two burst tolerance thresholds: when the first threshold is reached, scheduling

classes 1 to 3 will be removed from the service list, followed by the higher-level scheduling classes (4 to 6) being removed when the second burst tolerance threshold is reached. This designation of scheduling classes in two tiers ensures lower latency for traffic associated with higher scheduling classes during short-lived congestion periods.

The following defined HS attachment policy is applied to the subscriber hosts through the SAP egress policy referenced in the SLA profile. In this example, all four subscriber hosts use the same HS attachment policy:

```
configure
   qos
      hs-attachment-policy "hs-attach-1-1" create
         low-burst-max-class 3
         queue 1 wrr-group 1
         queue 2 wrr-group 1
         queue 3 sched-class 3
         queue 4 sched-class 4
         queue 5 sched-class 5
         queue 6 sched-class 6
         queue 7 unattached
         queue 8 unattached
         wrr-group 1 sched-class 1
         wrr-group 2 unattached
      exit
   exit
```

Besides referencing the HS attachment policy, the SAP egress policy defines traffic classification, as well as characteristics of queues and WRR groups at the subscriber level. In this example, the SAP egress policy 10 is associated with the host 1 of subscriber sub-1. The queues 1 and 4 are in the context of WRR group 1 serviced in the ratio 1:4.

> **Note:**
> Although the SAP egress policy syntax implies that such policy is applied per SAP, in the ESM context, this policy is instantiated via the SLA profile; therefore. the queue/policer instantiations are performed per SPI and not per SAP.

The aggregate rate of WRR 1 is set to 20Mb/s. Mapping of forwarding classes to queues is self-explanatory. Separate SAP egress policies (20, 30, and 40) are applied to the remaining hosts (host 1-2, host 2-1, and host 2-2). The only difference between the QoS SAP egress policies for the subscriber hosts is the rate of the WRR group 1, which is 40Mb/s for host 1-2, 60Mb/s for host 2-1, and 80Mb/s for host 2-2.

The SAP egress policy is applied in the SLA profile for the subscriber. The WRR group rate (along with other QoS parameters) can be dynamically overridden via RADIUS/Diameter during authentication or while the host/session is online. This functionality would allow having one SAP egress policy configured where parameters can be dynamically overridden, when the policy is applied to the subscriber host or session.

```
configure
   qos
      sap-egress 10 create
         hs-attachment-policy "hs-attach-1-1"
         queue 1 create
            hs-wrr-weight 1
         exit
         queue 2 create
            hs-wrr-weight 4
         exit
         queue 3 create
         exit
         queue 4 create
```

```
                exit
                queue 5 create
                exit
                queue 6 create
                exit
                hs-wrr-group 1
                    rate 20000
                exit
                fc af create
                    queue 3
                exit
                fc be create
                    queue 1
                exit
                fc h1 create
                    queue 5
                exit
                fc h2 create
                    queue 6
                exit
                fc l1 create
                    queue 4
                exit
                fc l2 create
                    queue 2
                exit
                dscp af12 fc "af"
                dscp be fc "be"
                dscp af22 fc "h1"
                dscp ef fc "h2"
                dscp af21 fc "l1"
                dscp af11 fc "l2"
            exit
```

It was already shown in the ESM-specific Configuration section that the HSQ queue group aggregate
rate limit is configured in the SLA profile while the aggregate rate of the subscriber is managed by the HS
primary shaper and is configured in the sub-profile.

The next hierarchy level in the chain (up from the subscriber level) is performed by the HS secondary
shapers that are directly configured in the egress context of the port. In this example, there is only one
configured HS secondary shaper that corresponds to the outer VLAN on the subscriber SAPs. The network
representation of the HS secondary shaper is an access node downstream from the BNG.

The HS secondary shaper "1" is configured with the aggregate rate of 250Mb/s. The rates are configured
in kb/s. Similarly, as at the subscriber level, the **low-burst-max-class 3** command maps all scheduling
classes at or below level 3 to the low burst tolerance threshold, while all scheduling classes above level 3
are mapped to the high burst tolerance threshold at the HS secondary shaper level. Therefore, in case of
short congestion periods, objects associated with scheduling classes 3 and below will be removed from the
service list before the objects associated with scheduling classes 4 and above.

```
configure
  port 3/1/1
    ethernet
        mode access
        encap-type qinq
        egress
            hs-scheduler-policy "hs1"
            hs-secondary-shaper "1" create
                aggregate
                    rate 250000
                    low-burst-max-class 3
```

```
                    exit
                exit
            exit
        exit
        no shutdown
    exit
```

The last configuration block in the scheduling hierarchy is an HS port scheduler, which is associated with the port via the command **hs-scheduler-policy** "hs1" in the preceding CLI code.

The HS port scheduler characteristics in this example are defined as follows:

- The maximum rate is set to 300Mb/s. However, in this example, this rate limit has no effect on traffic because it is higher than the 250Mb/s rate configured on HS secondary shaper 1. Because HS secondary shaper 1 is the only one configured under the port, the lower rate of this HS secondary shaper will limit traffic before it reaches the 300Mb/s limit configured on the port. More realistic deployment scenarios would contain multiple secondary shapers per port.

- Scheduling classes 4 and 5 are collapsed into a single scheduling priority (5) and they are served in a 1:2 ratio. This is performed via WRR group 1.

  This collapsing of scheduling classes 4 and 5 occurs at the port level, whereas scheduling classes 1 and 2 are collapsed at the subscriber level (HSQ queue group level).

- The WRR 1 at the port level is rate limited to 60Mb/s.

- The highest priority (6) scheduling class is rate limited to 20Mb/s at the port level.

> **Note:**
> All the rates under the HS port scheduler are configured in Mb/s.

```
configure
   qos
      hs-scheduler-policy "hs1" create
        max-rate 200
          group 1 rate 60
          scheduling-class 4 group 1 weight 10
          scheduling-class 5 group 1 weight 20
          scheduling-class 6 rate 20
      exit
   exit
```

The delta between the low and high burst tolerance thresholds at the subscriber and HS secondary shaper levels can be adjusted with the **hs-fixed-high-thresh-delta** command that is configured at the card level. In this example, the difference between the thresholds is set to 12kbytes.

```
configure
   card 3
      card-type iom4-e-hs
         mda 1
            mda-type me10-10gb-sfp+
            no shutdown
         exit
         fp 1
           egress
              hs-fixed-high-thresh-delta 12000
           exit
         exit
         no shutdown
```

Operational Commands

Operational commands are used to troubleshoot the system and monitor its operational state. The focus of this section will be on **show**, **clear**, and **tools dump** commands. The **debug** commands are omitted because there are no debug commands related to QoS on HSQ IOM and the **debug** commands related to ESM are described in other chapters. Also, there are no log events related to QoS on HSQ IOM.

Show Commands

show commands in this section are divided into two groups:

- **show** commands that display association between ESM and QoS objects where all displayed information is static and it does not change autonomously over time.

- **show** commands that display QoS hierarchy with the running rates (where the state is changing autonomously).

show commands have filters (or CLI parameters) that can be used to control the amount of the output information. This section will provide a few **show** commands; it is left to the user to explore all the options available for a particular **show** command.

Subscriber Management Related Show Commands

Examining subscriber associations with QoS objects should begin with the **show service active-subscribers** command. The output of this command provides information about the subscriber context and the output can vary in detail depending on the options with which this command is run. Besides the subscriber name, underlying subscriber SAPs, and SLA/sub-profile names, the following information is provided:

- SLA mode in which the subscriber operates on HSQ (single versus expanded SLA mode)

- Aggregate rate of the subscriber

- Ingress and egress QoS policies

- Subscriber association with an HS secondary shaper and the **inter dest id** string that is used to make this association

- Ingress queue/policer statistics

- Egress queues statistics

For brevity, only the information for subscriber sub-1 (both hosts) is shown in the following output.

```
*A:PE-1# show service  active-subscribers subscriber "sub-1" detail

To reveal the subscriber hierarchy in a terse form with respect to the sub/SLA-profiles and the SAP, the
following command can be run:

```
*A:PE-1# show service  active-subscribers hierarchy

===============================================================================
Active Subscribers Hierarchy
===============================================================================
-- sub-1 (sub-prof-1)
   |
   |-- sap:[3/1/1:1.1] - sla:sla-1-1
   |   |
   |   +-- 10.10.1.1 - mac:00:00:64:01:01:01 - DHCP - svc:3
   |
   +-- sap:[3/1/1:1.1] - sla:sla-1-2
       |
       +-- 10.10.1.2 - mac:00:00:64:01:01:02 - DHCP - svc:3
```

```
-- sub-2 (sub-prof-2)
   |
   |-- sap:[3/1/1:1.2] - sla:sla-2-1
   |   |
   |   +-- 10.10.1.3 - mac:00:00:64:01:01:03 - DHCP - svc:3
   |
   +-- sap:[3/1/1:1.2] - sla:sla-2-2
       |
       +-- 10.10.1.4 - mac:00:00:64:01:01:04 - DHCP - svc:3

-------------------------------------------------------------------------------
Number of active subscribers : 2
Flags: (N) = the host or the managed route is in non-forwarding state
===============================================================================
```

The following SAP related **show** command confirms that the SAP queues are removed from the underlying subscriber SAP (under the **stats** section at the end of the output). This was ensured by configuring the **profiled-traffic-only** command in the MSAP policy, with the purpose of reducing the queue consumption on ingress and egress.

```

QoS-related Show Commands in ESM Context

Examination of the subscriber QoS hierarchy on HSQ can start at the subscriber (HS queue group and
SAP) level and gradually move through the HS secondary shaper, and finally the port level. The output of
the **show** commands should confirm that the subscriber is associated with the QoS object as intended by
the configuration.

For example, the following output shows that HS attachment policy "hs-attach-1-1" is associated with the
QoS SAP egress policy 10. It was determined previously that QoS SAP egress policy 10 is associated
with host 1 of the subscriber 1 ("sub-1-1"). In this case, a two-step process was necessary to track the
association between the subscriber and the HS attachment policy.

```
*A:PE-1# show qos sap-egress 10 association

The output from the HS attachment policy reflects the QoS configuration state at the subscriber level that is shown in Figure 2:

- Queues 1 and 2 are attached to WRR 1.

- Queues 3 to 6 are directly attached to the corresponding scheduling classes (3 to 6).

- Queues 7 and 8 are unattached.

- WRR 2 is unattached.

- HS attachment policy "hs-attach-1" is associated with QoS SAP egress policies 10, 20, 30, and 40 that correspond to subscriber hosts "sub-1-1", "sub-1-2", "sub-2-1", and "sub-2-2".

Association between the HS secondary shaper and the subscribers can be verified with the following
command. HS secondary shaper is allocated per port (or LAG). The two subscribers sub-1 and sub-2 are
instantiated on SAPs with the outer VLAN tag "1" and consequently they are both associated with the HS
secondary shaper 1. The HS secondary shaper 1 is rate limited to 120Mb/s while its scheduling classes
are left open (max rate).

```

The port scheduler information can be obtained with the following command. This command is run in
the QoS context (as opposed to being run in the port context, which was the case for HS secondary
schedulers). The reason for this is that the HS secondary scheduler is configured directly under the port,
while the HS port scheduler is configured in an HS scheduler policy (in QoS context), which is then applied
to a port.

```

Show Commands with Dynamically Changing Information

The following commands show the QoS hierarchy with the running rates of the objects (queues, WRR groups, scheduling classes, secondary shapers, and port shapers) and the queue buffer depths in the QoS hierarchy. The command output in this section is based on the scenario described in the Traffic Management on HSQ section.

> **Note:**
> Running rates are the dynamically calculated rates while traffic is running.

The following subscriber hierarchy (for sub-1) shows the rates per subscriber host, per scheduling priority (and consequently, scheduling class), starting at the queue level and moving up toward the port level. For example, scheduling priority 1 starts with the rates of two subscriber host queues (1 and 2) that are mapped to the WRR group and then it moves up to the rate at the HS secondary shaper level (the summed rate of all the entities at scheduling priority 1 at the HS secondary shaper level), ending with the rate of the scheduling class 1 at the port level. The aggregate rate of the HS secondary shaper and the port in the subscriber hierarchy are also provided.

In this case, the rates between the two HSQ queue groups (or subscriber hosts) are evenly spread. This distribution will be explained in the Traffic Management on HSQ section. The subscriber hosts can be differentiated by the two different SLA profiles with which they are associated.

```
*A:PE-1# show qos hs-scheduler-hierarchy subscriber "sub-1" egress

        Class 1     Rate : 0 Kbps

-------------------------------------------------------------------------------
```

Another important parameter to monitor is the depth of the queues. This provides information about the congestion at the queue level. The buffer space per queue is allocated automatically by the system and, in the following case, the buffers are rather large. Deep buffering causes longer delays. To avoid this, the queue buffers can be adjusted by the **mbs** command under the queue definition in the QoS SAP egress policy. For example, 15kbytes would accommodate roughly fifteen 1000byte packets in a buffer queue.

```
*A:PE-1>config>qos>sap-egress# info
---------------------------------------------
          queue 1 create
              mbs 15 kilobytes
```

The following output shows that, except for queues 3, all queues have their buffers fully used. Because there is no congestion on queues 3, their buffer depth is low.

```
*A:PE-1# show hs-pools port 3/1/1 egress subscriber "sub-1"
| match "Queue Information" pre-lines 1 post-lines 200

Clear Commands

Clear commands in the HSQ context are used to clear statistics associated with the HS secondary shaper:

```
clear port <port-id> hs-secondary-shaper <name> statistics
```

Resources Monitoring

The **tools dump system-resources** command is used to monitor resource on an HSQ IOM.

Some of the resources (HSQ queue groups, HS primary shapers, HS secondary shapers, HS turbo queue groups, and so on) are allocated for internal use, thereby reducing the number of resources in the **Free** column. Such internally consumed resources are not available to be part of the user configuration.

> **Note:**
> 100G ports support port-based (access or network) HS queue groups on egress that can be configured to support higher throughput rates. Such port-based high-rate HS queue groups on egress are referred to as egress HS turbo queue groups.

The number of internally consumed resources depends on the configuration and MDA types. In the following example, the number of allocated HS queue groups is 40. Each of the four subscriber hosts consume one HS queue group, which means that 36 HS queue groups are internally allocated.

Out of 23 allocated HS primary shapers, two are allocated for the two subscribers and one is allocated to fulfill the HSQ hierarchy chain in conjunction with the default HS secondary shaper. This leaves 20 HS primary shapers consumed internally by the HSQ IOM.

Similarly, out of 22 allocated HS secondary shapers in total, only two are user related (and visible via **show** commands): a default HS secondary shaper and the HS secondary shaper 1. This means that 20 HS secondary shapers are internally consumed. The same logic can be followed for turbo HS queue groups, which are out of the scope in this chapter.

> **Note:**
> On HSQ IOM, a complete scheduling hierarchy must be maintained between each attached queue at the SPI level and its port priority. That is, the HSQ has no provision for bypassing the primary and secondary shaping/scheduling levels.

Traffic Management on HSQ

This section examines traffic output on HSQ IOM during congestion. Figure 86: Managing Congestion on HSQ in Expanded SLA Mode is a graphic representation of the configuration described previously, but with traffic streams running through the HSQ IOM.

Six traffic streams are sent in the downstream direction toward each of the four subscriber hosts (host 1-1, host 1-2, host 2-1, and host 2-2): in total, there are 24 traffic streams. The traffic streams are shown on the left side of Figure 86: Managing Congestion on HSQ in Expanded SLA Mode, with their names, offered rates (IN column) and measured output rates (OUT column). The traffic streams are sent and analyzed by the traffic generator.

The four shaded squares in the center of Figure 86: Managing Congestion on HSQ in Expanded SLA Mode represent the four subscriber hosts and their scheduling classes. The QoS hierarchy is shown on the right side. Red shaded areas (shapers) represent points of congestion on HSQ IOM caused by the 24 traffic streams.

Each of the six traffic streams per subscriber host is fed into the six queues of each subscriber host (or HSQ queue groups). The first digit in the traffic stream name represents the subscriber, the second digit

represents the subscriber host, and the third digit represents the queue to which this stream is sent. For example, STRM 1-2-3 represents a traffic stream sent to queue 3 of the second host for subscriber 1.

To summarize the scenario shown in Figure 86: Managing Congestion on HSQ in Expanded SLA Mode:

- Traffic streams 1 and 2 of each subscriber host are mapped to subscriber queues 1 and 2, which are in turn associated with WRR group 1 at the subscriber host (HSQ queue group) level.

- WRR group 1 is, depending on the subscriber host, rate limited to 20Mb/s, 40Mb/s, 60Mb/s, and 80 Mb/s. Weight ratio between queues 2 and 1 is 4:1. WRR group 1 is then attached to scheduling class 1.

- Traffic stream 3 is via queue 3 directly mapped to scheduling class 3.

- Scheduling class 2 is unused in this example.

- Traffic streams 4 and 5 are via queues 4 and 5 mapped to scheduling classes 4 and 5, which are at the port level collapsed into WRR group 1 with an aggregate rate limit of 60Mb/s.

- Traffic stream 6 is the highest priority stream that is via queue 6 mapped to scheduling class 6. At the port level, scheduling class 6 is rate limited to 20Mb/s.

- Subscriber host (HSQ queue group) aggregate rates are set to 50Mb/s, 70Mpbs, 80 Mb/s, and 100Mb/s, respectively.

- Subscribers (sub-1 and sub-2) aggregate rates (HS primary shapers) are set to 100Mb/s and 150 Mb/s, respectively.

- Subscribers sub-1 and sub-2 are mapped to HS secondary shaper "1" (via outer VLAN on their SAPs) with the aggregate rate of 250 Mb/s.

- HS port scheduler is rate limited to 300Mb/s.

The configured rate limits at the subscriber level are L2 rates, while configured rate limits at the HS secondary shaper level and the HS port level include L1 overhead and are, therefore, on-the-wire rates. On-the-wire rates account for 20 additional bytes in each Ethernet frame (8 bytes preamble and 12 bytes IFG).

All traffic streams are sent with constant rates (no added burstiness) and fixed packet size (1000 bytes). Therefore, the difference between the L2 rates and the on-the-wire rates for the 1000byte packets is 1000/1020 = 0.98 or 2%. That is, on-the-wire rates are 2% higher than the L2 rates. The name for this 2% delta factor in this chapter will be the Rate Conversion Factor (RCF).

Figure 86: Managing Congestion on HSQ in Expanded SLA Mode
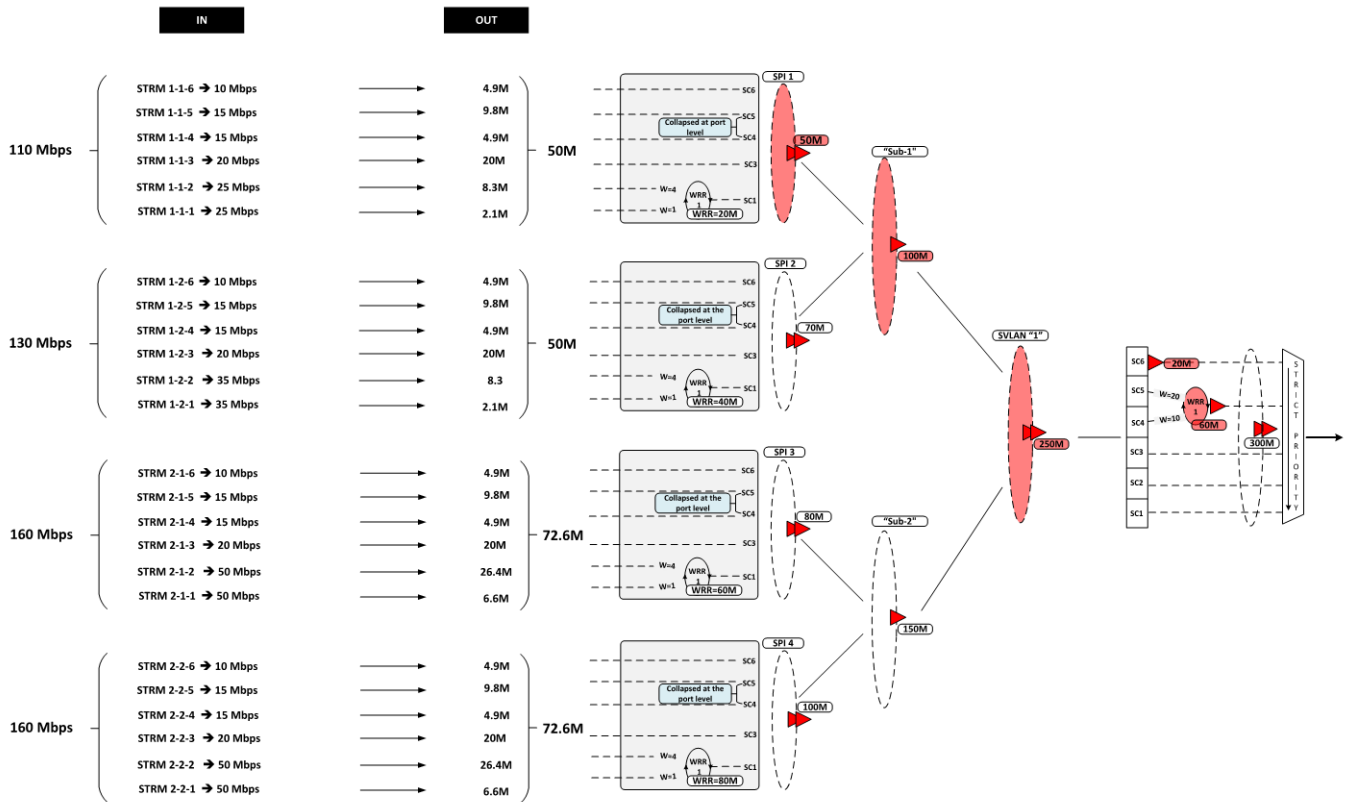

Table 22: Input/Output Rates lists the input/output rates throughout the subscriber QoS hierarchy. Red shaded table cells represent congested objects. The numbers in blue represent the L2 output rates measured on the traffic generator. The numbers in red (in parentheses) are configured aggregate rates for the object in the hierarchy. The numbers above them are either the operational rates measured by SR OS and observed via the show **qos hs-scheduler-hierarchy** command, or the manually summed rates under the hierarchy.

> **Note:**
> Running aggregate rates per HSQ queue group or subscriber (HS primary shaper) are now available via **show** commands.

Some of the output columns in this table require additional explanation:

- Per stream output rates (first column under the Output Rate section) are L2 rates as measured by the traffic generator. The analysis of the results will be based on these rates.

  However, those rates can also be displayed within the system via the **show qos hs-scheduler-hierarchy subscriber** *<sub-name>* **egress** command. RCF must be used to correctly interpret the results in respective rate domains (L1 versus L2).

- WRR rates at the subscriber level (second column under the Output Rate section) are populated by manually adding rates measured by the traffic generator for traffic streams 1 and 2. The 4:1 notation in parentheses represents the weight ratio between the two streams. There are no means to observe the WRR group rates at the subscriber level directly within the system (via **show** commands).

- Aggregate rates per host (third column under the Output Rate section) are populated by manually adding the rates measured by the traffic generator from all six traffic streams for each subscriber. There are no means to observe the aggregate subscriber rate directly within the system (via show commands). Those rates also represent the HSQ queue group aggregate rate because each host in this example is associated with an HSQ queue group.

- Aggregate rates per subscriber (fourth column under the Output Rate section) are populated by manually adding the rates measured by the traffic generator from all six traffic streams for each subscriber. There are no means to observe the aggregate subscriber rate directly within the system (via show commands).

- Aggregate rates per HS secondary shaper (fifth column under the Output Rate section) are on-the-wire rates displayed via the **show qos hs-scheduler-hierarchy port 3/1/1 hs-secondary-shapers** command. The displayed rates are rounded to the nearest Mb/s.

- Per scheduling class rates at the port level (sixth column under the Output Rate section) are displayed via the **show qos hs-scheduler-hierarchy port 3/1/1** command. The displayed rates are rounded by the system to the nearest Mb/s. The discrepancy between the actual rates for scheduling class 3 (80Mb/s) and the displayed rate (81Mb/s) is due to the measuring and rounding inaccuracy at display time. The actual rate at scheduling class 3 at the port level can be calculated by summing the rates measured (by the traffic generator) of each traffic stream 3 for each subscriber and adjusting the sum for the on-the-wire rate (RCF).

  The same logic applies to scheduling class 1 (actual rate 86.8Mb/s vs 88Mb/s measured rate).

- The WRR-1 rate at the port level (seventh column under the Output Rate section) is manually calculated by adding the rates measured by the traffic generator of all streams mapped to scheduling classes 5 and 4 (8 traffic streams in total, two per each subscriber host), then converting this rate into the on-the-wire rate. At the port level, traffic on scheduling classes 5 and 4 is weighted in a 2:1 ratio (this is noted in parentheses).

- The port rate (last column under the Output Rate section) is collected from two places:

  – The top number in obtained via the **show qos hs-scheduler-hierarchy** command and represents the on-the-wire rate.

  – The bottom number in blue is the number measured by the traffic generator, which only measures L2 rates. On-the-wire rates can be converted to L2 rates by multiplying the on-the-wire rates by the RCF.

Table 22: Input/Output Rates

Strm	Input rate in [mbps]		Output rate in [mbps]							
	Per strm	Agg per host	Per strm (L2)	WRR on subscr level	Agg per host (L2)	Agg per subscr (L2)	Agg per secondary shaper (wire)	Per sch class on port level (wire)	WRR-1 on port level (wire)	Port
1-1-6	10	110	4.9	-	50 (50)	100 (100)	250 (250)	SC 6 20 (20)	-	250 (300) 245.1 (L2)
1-1-5	15		9.8	-					-

2-2-6	10	160	4.9	-	72.6 (100)				-	
2-2-5	15		9.8	-					-	
2-2-4	15		4.9	-				SC 1 88	-	
2-2-3	20		20	-					-	
2-2-2	50		26.4	33 (4:1)					-	
2-2-1	50		6.6						-	

Analysis of Results

The analysis of results begins with the rates per stream measured by the traffic generator. The expected behavior is that those rates agree with the theoretical rate calculations based on our understanding of QoS on HSQ IOM.

Considering the six strict priority classes in the HSQ scheduling mechanism, the expectation is that the traffic is serviced in the order of priority, from the highest scheduling class 6 to the lowest scheduling class 1. Consequently, the traffic analysis starts with the streams that are mapped to the highest priority scheduling class 6 (streams 1-1-6, 1-2-6, 2-1-6, 2-2-6, that is, stream 6 of each subscriber host).

Scheduling class 6 (streams 1-1-6, 1-2-6, 2-1-6, and 2-2-6) – the highest priority scheduling class

Due to the aggregate rate limit of 20Mb/s for scheduling class 6 at the port level, it is expected that each subscriber host receives an equal amount of traffic on scheduling class 6:

(*20 Mb/s (aggregate rate of SC 6)*)÷(*4 streams (one per subscriber host)*) =5 *Mb/s*

The measured results on the traffic generator for traffic streams 6 in Table 1 show that each subscriber host receives 4.9Mb/s out of an offered 10Mb/s. The slight difference between the expected (5Mb/s) and the measured (4.9Mb/s) rate is caused by the discrepancy between the L2 rates at the subscriber level (as measured by the traffic generator), and on-the-wire rates enforcement (20Mb/s) at the scheduling class 6 at the port level. Multiplying 5Mb/s by the RCF ($^{1000}/_{1020}$) will align the results.

This slight discrepancy between the L2 and on-the-wire rates is common throughout the remaining analysis. Because this is well understood and expected, it will not be mentioned again.

Scheduling classes 5 and 4 (streams 1-1-5, 1-1-4, 1-2-5, 1-2-4, 2-1-5, 2-1-4, 2-2-5, and 2-2-4)

Scheduling classes 5 and 4 are collapsed at the port level into WRR group 1, which is at the next scheduling priority to be served. These two scheduling classes are served by WRR group 1 in a 2:1 ratio. The aggregate rate limit for WRR 1 at the port level is set to 60Mb/s.

Expected rates for combined scheduling classes 5 and 4 of each host are

60Mb/s÷4=15Mb/s

When 15Mb/s is distributed between the two scheduling classes in the 2:1 ratio, each host should receive 10Mb/s on scheduling class 5 and 5Mb/s on scheduling class 4, for the total of 15Mb/s (out of an offered 30Mb/s).

The measured results in Table 22: Input/Output Rates are 9.8Mb/s on scheduling class 5 and 4.9Mb/s on scheduling class 4 for traffic streams 4 and 5 of each individual host. This is in line with the expected results (the slight difference is due to L2 rates measured by the traffic generator and enforced on-the-wire rates at the port level).

Scheduling class 3 (streams 1-1-3, 1-2-3, 2-1-3, and 2-2-3)

Traffic streams mapped to scheduling class 3 do not have any rate restriction at the scheduling class level. Those streams can be only limited by the congestion at the HSQ queue group aggregate level, the subscriber aggregate level, the HS secondary shaper aggregate level, or the port aggregate level. Because the total amount of traffic so far is below congestion level at each point in the hierarchy, it is expected that traffic stream 3 flows unimpeded. Consequently, each subscriber host should receive the full input rate of 20Mb/s on scheduling class 3. The actual results in Table 22: Input/Output Rates are aligned with the expected results.

To confirm that there is no congestion at the aggregate level so far for the subscriber hosts, the subscribers, the HS secondary shapers, and the port, a calculation shows that each subscriber host has received an equal amount of bandwidth so far: 39.6Mb/s. This is below the configured aggregate rate limits at the host, the subscriber, the HS secondary scheduler and the port levels:

- 39.6Mb/s is below the configured limit of 50Mb/s for host 1-1.
- 39.6Mb/s is below the configured limit of 70Mb/s for host 1-2.
- 39.6Mb/s is below the configured limit of 80Mb/s for host 2-1.
- 39.6Mb/s is below the configured limit of 100Mb/s for host 2-2.
- 79.2Mb/s (39.6Mb/s x 2) is below the configured limit of 100Mb/s for sub-1.
- 79.2Mb/s (39.6Mb/s x 2) is below the configured limit of 150Mb/s for sub-2.
- Sub-1 and sub-2 compete for the bandwidth at HS secondary shaper "1", and their combined rate of 158.4 Mb/s (39.6Mb/s x 4) is below the configured aggregate rate of the HS secondary shaper "1" (250Mb/s) or the port shaper (300Mb/s).

Scheduling classes 2 and 1 (streams 1-1-2, 1-1-1, 1-2-2, 1-2-1, 2-1-2, 2-1-1, 2-2-2, 2-2-1) – the lowest priority scheduling classes

The total amount of offered (input) traffic for lowest priority scheduling classes 1 and 2 across all four subscriber hosts is 560Mb/s (110Mb/s for host 1-1, 130Mb/s for host 1-2, 160Mb/s for host 2-1, and 160Mb/s for host 2-2). This additional amount of traffic will cause congestion on the aggregate level for host 1-1, subscriber sub-1, and HS secondary shaper 1.

Up to this point, the spare capacity on the HS secondary shaper 1 is:

250 Mb/s (HS secondary shaper 1 aggregate on-the-wire rate limit)

- 40.3 Mb/s (on-the-wire traffic from host 1-1 up to this point)

- 40.3 Mb/s (on-the-wire traffic from host 1-2 up to this point)

- 40.3 Mb/s (on-the-wire traffic from host 2-1 up to this point)

- 40.3 Mb/s (on-the-wire traffic from host 2-2 up to this point)

_____

= 88.8 Mb/s (capacity left on the HS secondary shaper 1 up to this point)

Note:

1. 40.3Mb/s corresponds to 39.6Mb/s converted to L2 rate.

2. Spare capacity for HS secondary shaper "1" is calculated based on on-the-wire rates while the subscriber aggregate capacity is calculated in L2 rates because the aggregate rate limit in HS secondary shaper in SR OS is configured in on-the-wire rates while the subscriber aggregate rates are configured in L2 rates.

Considering that each host has so far received 40.3Mb/s (on-the-wire rate), the 88.8Mb/s left on the HS secondary shaper will be distributed between scheduling classes 2 and 1 for each of the hosts (1-1, 1-2, 2-1, and 2-2) in the following manner:

- Host 1-1, limited by its configured aggregate rate limit of 50Mb/s (L2 rate) will receive (50Mb/s – 39.6Mb/s =) 10.4Mb/s.

- The amount of bandwidth that host 1-2 receives is limited by the sub-1 configured aggregate rate limit (100Mb/s). Because host 1-1 and host 1-2 belong to the same subscriber (sub-1) and host 1-1 is limited by its own configured limit of 50Mb/s, this will leave 50Mb/s of aggregate bandwidth for host 2-1. That is, host 1-2 is not limited by its own configured aggregate rate (70Mb/s) but by that of the sub-1, which is now congested. Therefore, host 1-2 will receive (50Mb/s – 39.6Mb/s =) 10.4Mb/s of bandwidth on scheduling classes 2 and 1.

- The remaining 66.2Mb/s (L2 rate) is delegated to sub-2, and this will not be enough to congest any aggregate rate at the sub-2 level. Therefore, this bandwidth will be equally divided over host 2-1 and 2-2, each receiving 33.1Mb/s (L2 rate) on scheduling classes 2 and 1.

Considering the preceding bandwidth distribution for scheduling classes 2 and 1 for all four hosts and the 4:1 weight ratio between scheduling classes 2 and 1, the following conclusion can be reached:

- Host 1-1 → 10.4Mb/s in 4:1 ratio:
  - scheduling class 2 will receive 8.32Mb/s
  - scheduling class 1 will receive 2.08Mb/s
- Host 1-2 → 10.4Mb/s in 4:1 ratio:
  - scheduling class 2 will receive 8.32Mb/s
  - scheduling class 1 will receive 2.08Mb/s
- Host 2-1 → 33.1Mb/s in 4:1 ratio:
  - scheduling class 2 will receive 26.5Mb/s
  - scheduling class 1 will receive 6.62Mb/s
- Host 2-2 → 33.1Mb/s in 4:1 ratio:
  - scheduling class 2 will receive 26.5Mb/s
  - scheduling class 1 will receive 6.62Mb/s

These numbers match the rates measured by the traffic generator for streams <1-1-2>, <1-1-1>, <1-2-2>, <1-2-1>, <2-1-2>, <2-1-1>, <2-2-2>, <2-2-1> in Table 22: Input/Output Rates.

Conclusion

This chapter described traffic management capabilities and configuration of HSQ IOM with ESM in expanded SLA mode. This chapter is an extension of the chapter High Scale QoS IOM in ESM Context: Single SLA Mode. Both single and expanded SLA modes rely on the unique properties of HSQ IOM, while each mode has a unique set of characteristics:

- Single SLA mode provides higher subscriber scale per HSQ IOM, but allows only one SLA profile instance (SPI) per subscriber. This means that only a single SAP per subscriber (or residence) is supported (service per SAP model is not supported).

- In contrast, expanded SLA mode supports multiple SPIs per subscriber (and SAPs), but with the reduced subscriber scale. The reduction in subscriber scale is caused by the tie-in between the subscribers and HS primary shapers. That is, the aggregate subscriber rate is enforced through HS primary shapers, which means that the mapping between a subscriber and an HS primary shaper is 1:1 Therefore, 16k HS primary shapers on HSQ will determine the subscriber scale in expanded SLA mode.

> **Note:**
> On HSQ, a subscriber cannot be dissociated from an HS primary shaper, or from the QoS hierarchy.

Expanded SLA Mode can be used in service per SAP deployments where each subscriber is assigned to multiple SAPs, or it can be used on a single SAP where various services require that each of them is assigned its own HSQ queue group (or SPI).

HSQ IOM is a module of choice in an environment that demands high performance (200Gb/s per IOM) in combination with QoS functionality and a high number of egress queues.

High Scale QoS IOM in ESM Context: Single SLA Mode

This chapter describes the High Scale QoS (HSQ) IOM in the Enhanced Subscriber Management (ESM) context.

Topics in this chapter include:

Applicability

This chapter describes the High Scale QoS (HSQ) IOM in the Enhanced Subscriber Management (ESM) context. The information and configuration in this chapter are based on SR OS Release 15.0.R4.

Overview

This chapter describes the QoS operation and configuration of the High Scale QoS (HSQ) IOM, with a focus on single SLA mode in the Enhanced Subscriber Management ESM context.

Single SLA mode on HSQ is characterized by a single SLA profile instance (SPI) per subscriber. The subscriber can have multiple hosts or sessions, which are all sharing this single SPI. Single SLA mode can be enabled per subscriber and, while enabled, any attempt to establish more than one SPI per subscriber will be rejected by the system.

The default SLA mode on HSQ IOM is expanded SLA mode, which supports multiple SPIs per subscriber. This topic is covered in chapter High Scale QoS IOM in ESM Context: Expanded SLA Mode.

HSQ IOM in the context of ESM provides the following benefits:

- Traffic management functionality on egress with seven tiers of shaping hierarchy, six strict priority scheduling levels, and weighted round-robin (WRR) groups at the subscriber and port level.

- Increased scale with 786k egress queues.

- Aggregate throughput in the range of 200 Gb/s full-duplex per HSQ IOM.

- ~96k subscribers per HSQ IOM in 1:1 (sub/SAP) scenario, each with 8 egress queues in single SLA mode.

With HSQ IOM, the ESM continues to support existing SAP deployment models in the following way:

- Subscriber per SAP (1:1) – single SLA mode and expanded SLA mode

- Multiple subscribers per SAP (N:1) – single SLA mode and expanded SLA mode

- Multiple SAPs per subscriber (service per SAP) – only expanded SLA mode

> **Note:**
>
> 1. The example in this chapter is based on subscriber hosts and the subscriber session concept is disabled.
>
> 2. A few tens of egress queues are allocated for internal use, so are unavailable for subscribers.
>
> 3. The number of subscribers per HSQ IOM in expanded SLA mode depends on the number of available HS primary shapers (16k in total). Because some of the HS primary shapers may be used internally, it is recommended that the exact number of free resources on an HSQ card is periodically checked with the tools dump system-resources command.
>
> 4. Because each SAP under the same subscriber requires its own SPI, this model is not supported in single SLA mode.

HSQ IOM supports an enhanced egress QoS architecture to provide scalable network, service, and subscriber QoS. At ingress, the HSQ supports regular FP3 QoS with a high ingress policer scaling.

The emphasis in this chapter is on egress shaping and scheduling in the ESM context. Buffer pool management on HSQ is not described in this chapter. Generic ESM concepts are described in other chapters, but for the sake of completeness, a basic ESM configuration as it applies to the example in this chapter is outlined in Appendix A — Generic ESM configuration.

This chapter is conceptually divided into two parts:

- The focus of the first part is on the (egress) QoS configuration for three subscribers, named "sub-1", "sub-2", and "sub-3".

- The second part focuses on examining HSQ traffic management capabilities in the ESM context by observing output traffic patterns in a congested system.

Topics related to the generic operation of HSQ IOM and ESM that are not directly described in this chapter are included in the following:

- Configuring expanded SLA mode in ESM is in the chapter High Scale QoS IOM in ESM Context: Expanded SLA Mode.

- Configuring HSQ in the service context is in the chapter High Scale QoS IOM: QoS, Service and Network Configuration.

- Generic ESM concepts are described in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* and in numerous TPSDA chapters in the ACG.

Test environment

Figure 87: Test environment example shows the test environment example with three subscribers in single SLA mode, each with a single DHCPv4 host setup in the BNG.

DHCPv4 traffic (simulated subscriber hosts) is initiated from port 103/1 on a traffic generator. Subscribers are authenticated via local user database (LUDB) and instantiated on managed SAPs (MSAPs) in the IES 3 service. Subscriber IP addresses are assigned statically via LUDB.

To explore traffic management capabilities under congestion, a number of traffic streams are generated in the downstream direction, from port 203/1 on the same traffic generator toward the subscribers on port 103/1.

Figure 87: Test environment example
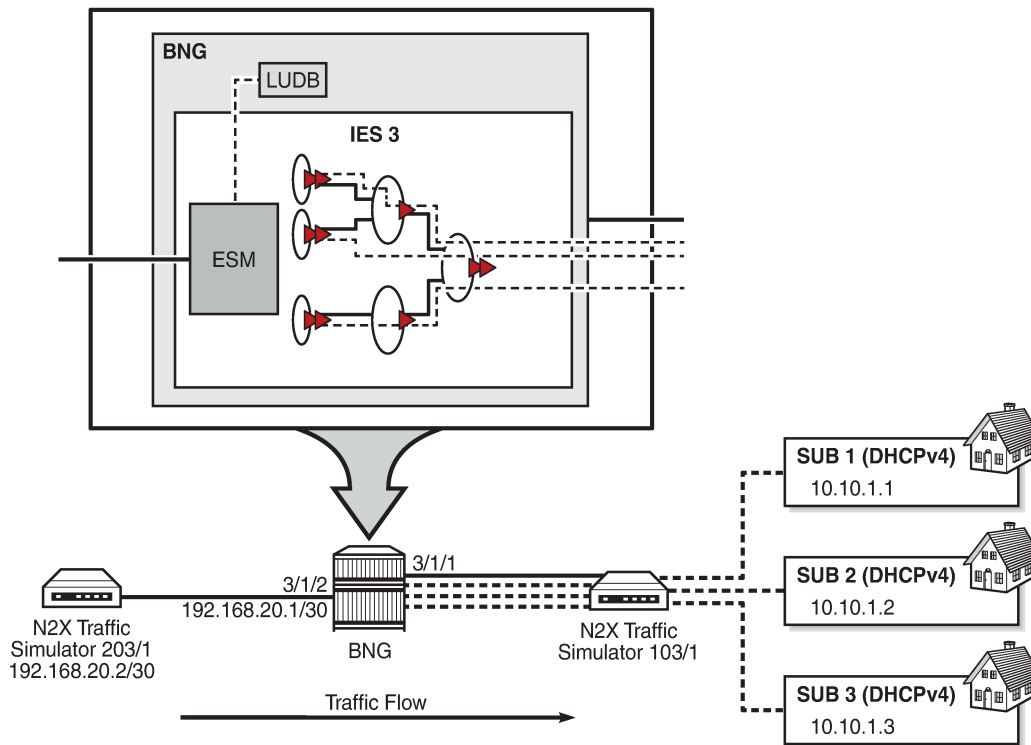

The QoS hierarchy associated with the subscribers is shown in Figure 88: QoS hierarchy in single SLA mode. At a high level, this hierarchy can be described as follows:

- Each of the three subscribers (sub-1, sub-2, and sub-3) is associated with an HSQ queue group. The HSQ queue group always comprises eight queues. However, not all the queues are required to be used by the subscriber. In this example, only six queues are used by each subscriber, while the two remaining queues, although allocated to the subscriber, remain unused.

- All three subscribers share the same HS attachment policy. This means that the mapping between the queues, scheduling classes (SC), and WRR groups is the same for all three subscribers.

- Queues 1 and 2 are attached to WRR group 1 at the local HSQ queue group level and served in 4:1 ratio. WRR group 1 is attached to the lowest scheduling class 1, whereas queues 3, 4, 5, and 6 are directly attached to scheduling classes 3, 4, 5, and 6, respectively.

- Each subscriber is rate limited at the aggregate level.

- Subscribers are mapped to two HS secondary shapers. Limiting the aggregate rates of these shapers will ensure that the bandwidth capacity of the corresponding access nodes in the network is not overrun.

- Mapping between the subscribers and their HS secondary shapers is achieved via outer VLANs. Sub-1 and sub-2 on SAPs with the outer VLAN 1 are mapped to HS secondary shaper 1 while sub-3 on outer VLAN 3 is mapped to HS secondary shaper 2.

- The two HS secondary shapers are associated with the HS port scheduler that has its own aggregate rate limit set.

- At the port level, scheduling class 6 is rate limited while scheduling classes 4 and 5 are collapsed into a WRR group, which is rate limited.

Figure 88: QoS hierarchy in single SLA mode
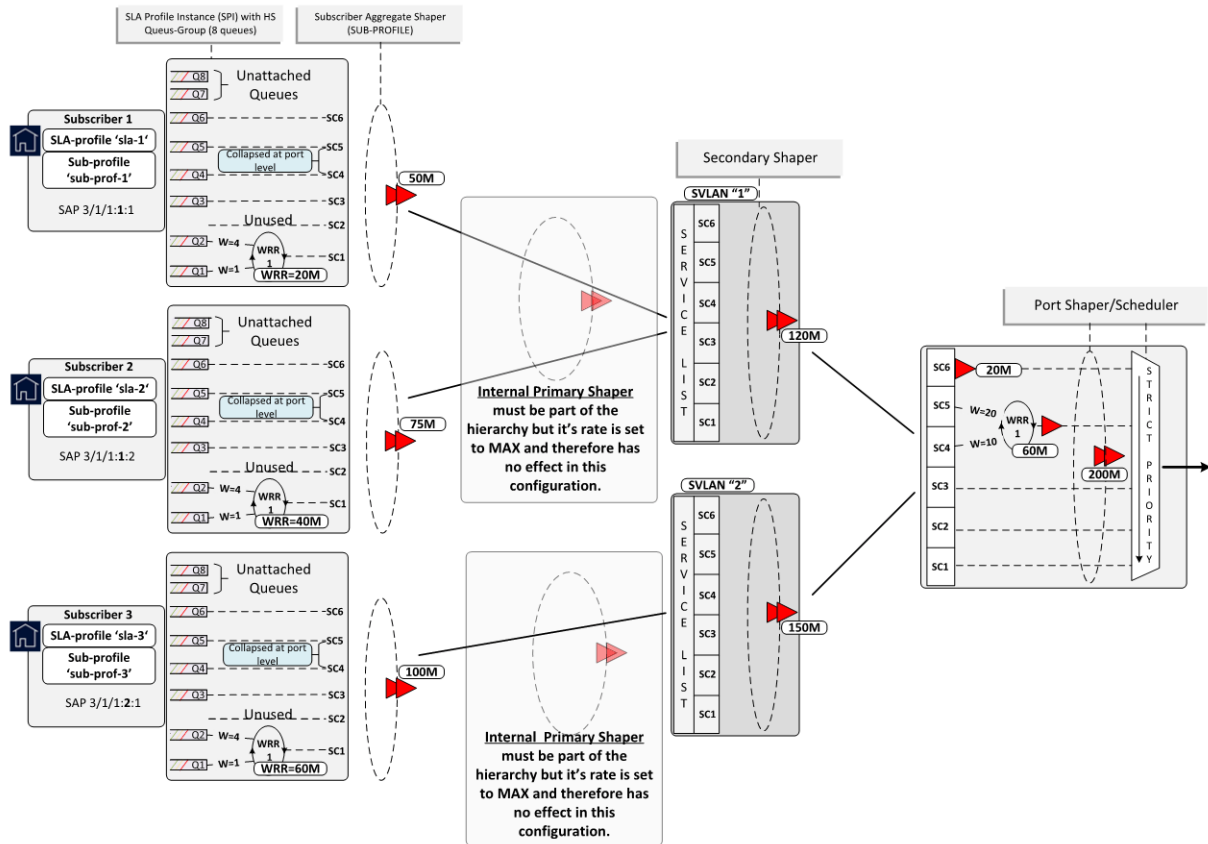

Configuration

The configuration section is split into two parts:

- HSQ-specific ESM configuration
- HSQ-specific QoS configuration

HSQ-specific ESM configuration

The generic ESM configuration used in this example is provided in Appendix A — Generic ESM configuration, for the sake of completeness. This section focuses only on HSQ-specific ESM configuration.

Each of the three subscribers have their own **sub-profile**, which will determine the HS SLA mode in which the subscriber operates, as well as the aggregate rate limit (in kb/s) for each subscriber:

```
configure
```

```
subscriber-mgmt
    sub-profile "sub-prof-1" create
        hs-sla-mode single
        egress
            hs-agg-rate-limit 50000
        exit
    exit
    sub-profile "sub-prof-2" create
        hs-sla-mode single
        egress
            hs-agg-rate-limit 75000
        exit
    exit
    sub-profile "sub-prof-3" create
    hs-sla-mode single
        egress
            hs-agg-rate-limit 100000
        exit
    exit
```

Each subscriber has its own SPI that references the QoS SAP policy on egress (in this case, QoS SAP egress policies 10, 20, and 30). The egress QoS SAP policy defines the QoS characteristics at the local subscriber level (or HSQ queue group level), such as:

- traffic classification

- queue/WRR rates and weights

- mapping between the queues, WRR groups, and scheduling classes by referencing the HS attachment policy

Note: The subscriber, and all the hosts within the subscriber, will share this SPI.

```
configure
    subscriber-mgmt
        sla-profile "sla-1" create
            egress
                qos 10
                exit
            exit
        exit
        sla-profile "sla-2" create
            egress
                qos 20
                exit
            exit
        exit
        sla-profile "sla-3" create
            egress
                qos 30
                exit
            exit
        exit
```

MSAP policy is a mandatory configuration for dynamically created SAPs (Managed SAP or MSAPs) where, in the context of HSQ, a few key parameters are provisioned:

- The **def-inter-dest-id use-top-q** command associates subscribers with the HS secondary shaper by matching the outer VLAN ID of the subscriber SAP to the HS secondary shaper name. For example, a subscriber on SAP 3/1/1:*1.2* will be mapped to HS secondary shaper 1:

```
configure
    port 3/1/1
        ethernet
            mode access
            encap-type qinq
            egress
                hs-scheduler-policy "hs1"
                hs-secondary-shaper "1" create
                    aggregate
                        rate 150000
                    exit
                exit
            exit
        exit
    exit
```

- The **qos 1 service-queuing** command disables shared queueing on ingress because ingress shared queuing is not supported on HSQ. With shared queuing disabled and service queuing enabled, every configured subscriber or SAP queue on ingress is potentially allocated multiple times, which leads to inefficient use of resources. Every configured queue on ingress is multiplied by the number of possible destination forwarding complexes. For this reason, Nokia recommends that policers are used on ingress.

- The **profiled-traffic-only** command provides a resource optimization that removes queues from the subscriber SAP. By default, one ingress and one egress queue is instantiated per subscriber SAP due to a default QoS SAP policy "1" that is applied to a SAP. In most cases, these SAP queues remain unused because each subscriber uses its own sets of separate subscriber queues that are allocated per SPI. Therefore, the SAP queues can be safely removed.

> **Note:**
>
> 1. The default SAP egress policy can be replaced with another, non-default SAP egress policy. However, the SAP egress policy cannot be removed from a SAP.
>
> 2. A SAP queue in the ESM context on HSQ is used when multicast per SAP replication mode for the subscriber is enabled. In multicast per SAP replication mode, a single copy of each multicast stream is sent for all hosts of the subscriber via a SAP queue. If the SAP queue is removed, multicast traffic will flow via failover queues or via a queue group that must be explicitly configured.

For example, if there are 50k subscribers on an HSQ IOM, with each subscriber on its own SAP, then removing the default SAP queues:

– preserves 50k queues on ingress. These ingress queues are allocated from the 128k ingress queue pool and are now available for ingress subscriber queuing.

Removing the SAP queues on ingress becomes even more relevant on HSQ, which does not support shared queuing on ingress. Non-shared queuing on ingress means that the number of ingress queues allocated per each SAP would increase proportionally with the number of destination forwarding complexes in the system.

– preserves 50k queues on egress from the 768k egress queue pool. Because each subscriber requires 8 queues on egress, these 50k egress queues can be used for an additional ~6k subscribers.

SAP queue removal works only for subscribers in 1:1 model (subscriber per SAP) and where the number of subscribers per SAP is limited to 1. This requires one additional command: **no multi-sub-sap** (or alternatively **multi-sub-sap limit 1**).

The following command can be used to verify that the SAP queues have been removed:

```
show service id <srvc-id> sap <sap-id> stats
```

The resulting **msap-policy** configuration is as follows:

```
configure
    subscriber-mgmt
        msap-policy "msaps" create
            sub-sla-mgmt
                def-inter-dest-id use-top-q
                sub-ident-policy "sub_ident_pol"
                no multi-sub-sap
                single-sub-parameters
                    profiled-traffic-only
            exit
        exit
        ies-vprn-only-sap-parameters
            ingress
                qos 1 service-queuing
            exit
        exit
    exit
```

HSQ-specific QoS configuration

At the subscriber level (or HSQ queue group level), the HS attachment policy defines mapping between the queues, WRR groups, and scheduling classes. In this example, queues 1 and 2 are mapped to a WRR group 1, which is mapped into scheduling class 1. Queues 3 to 6 are mapped to respective scheduling classes (SC 3 to 6). Queues 7 and 8, although allocated, are unattached, so will drop any traffic that they receive. A maximum of two WRR groups are supported at the HSQ queue group level and in this example, only WRR 1 is used.

The **low-burst-max-class** parameter is set to 3, which ensures that the 3 lower scheduling classes (1 to 3) are stopped being served first if HSQ queue group aggregate congestion occurs. The HSQ queue group aggregate shaper has two burst tolerance thresholds: when the first threshold is reached, scheduling classes 1 to 3 will be removed from the service list, followed by the higher level scheduling classes (4 to 6) being removed when the second threshold is reached. This designation of scheduling classes in two tiers ensures lower latency for traffic associated with higher scheduling classes during short-lived congestion periods.

The following defined HS attachment policy is applied to the subscriber through the SAP egress policy referenced in the SLA profile. In this example, all three subscribers use the same HS attachment policy:

```
configure
   qos
      hs-attachment-policy "hs-attach-1-1" create
         low-burst-max-class 3
         queue 1 wrr-group 1
         queue 2 wrr-group 1
         queue 3 sched-class 3
```

```
            queue 4 sched-class 4
            queue 5 sched-class 5
            queue 6 sched-class 6
            queue 7 unattached
            queue 8 unattached
            wrr-group 1 sched-class 1
            wrr-group 2 unattached
        exit
    exit
```

Besides referencing the HS attachment policy, the SAP egress policy defines traffic classification, as well as characteristics of queues and WRR groups at the subscriber level. In this example, the SAP egress policy 10 is associated with sub-1. The queues 1 and 4 are in the context of WRR group 1 serviced in the ratio 1:4.

> **Note:**
> Although the SAP egress policy syntax implies that such policy is applied per SAP, in the ESM context this policy is instantiated via the SLA profile; therefore, the queue/policer instantiations are performed per SPI and not per SAP.

The aggregate rate of WRR 1 is set to 20 Mb/s. Mapping of forwarding classes to queues is self-explanatory. Similarly, SAP egress policies are applied to sub-2 (policy 20) and sub-3 (policy 30). The only difference between the QoS SAP egress policies for the subscribers is the rate of the WRR group 1, which is 40 Mb/s for sub-2 and 60 Mb/s for sub-3.

The SAP egress policy is applied in the SLA profile for the subscriber. The WRR group rate (along with other QoS parameters) can be dynamically overridden via RADIUS/Diameter during authentication or while the host/session is online. This functionality would allow having only one SAP egress policy configured where parameters can be dynamically overridden, when the policy is applied to the subscriber host or session.

```
configure
    qos
        sap-egress 10 create
            hs-attachment-policy "hs-attach-1-1"
            queue 1 create
                hs-wrr-weight 1
            exit
            queue 2 create
                hs-wrr-weight 4
            exit
            queue 3 create
            exit
            queue 4 create
            exit
            queue 5 create
            exit
            queue 6 create
            exit
            hs-wrr-group 1
                rate 20000
            exit
            fc af create
                queue 3
            exit
            fc be create
                queue 1
            exit
            fc h1 create
                queue 5
```

```
                exit
                fc h2 create
                    queue 6
                exit
                fc l1 create
                    queue 4
                exit
                fc l2 create
                    queue 2
                exit
                dscp af12 fc "af"
                dscp be fc "be"
                dscp af22 fc "h1"
                dscp ef fc "h2"
                dscp af21 fc "l1"
                dscp af11 fc "l2"
            exit
```

The next hierarchy level in the chain (up from the subscriber level) is performed by the two HS secondary shapers that are directly configured in the egress context of the port. The names of the two HS secondary shapers correspond to the outer VLANs on the subscriber SAPs. The network represents the HS secondary shapers as the access nodes downstream from BNG.

The HS secondary shapers "1" and "2" are configured with the aggregate rates of 120 Mb/s and 150 Mb/s, respectively. The rates are configured in kb/s. Similarly, as at the subscriber level, the **low-burst-max-class 3** command maps all scheduling classes at or below level 3 to the low burst tolerance threshold, while all scheduling classes above level 3 are mapped to the high burst tolerance threshold at the HS secondary shaper level. Therefore, in case of congestion, objects associated with scheduling classes 3 and below will be removed from the service list before the objects associated with scheduling classes 4 and above.

```
configure
    port 3/1/1
        ethernet
            mode access
            encap-type qinq
            egress
                hs-scheduler-policy "hs1"
                hs-secondary-shaper "1" create
                    aggregate
                        rate 120000
                        low-burst-max-class 3
                    exit
                exit
                hs-secondary-shaper "2" create
                    aggregate
                        rate 150000
                        low-burst-max-class 3
                    exit
                exit
            exit
        exit
        no shutdown
    exit
```

The last configuration block in the scheduling hierarchy is an HS port scheduler, which is associated with the port via the command **hs-scheduler-policy** "hs1" in the preceding CLI code.

The HS port scheduler characteristics in this example are defined as follows:

• The maximum rate is set to 200 Mb/s.

- Scheduling classes 4 and 5 are collapsed into a single scheduling priority (5) and they are served in a 1:2 ratio. This is performed via WRR group 1.

  This collapsing of scheduling classes 4 and 5 occurs at the port level, whereas scheduling classes 1 and 2 are collapsed at the subscriber level (HSQ queue group level).

- The WRR 1 at the port level is rate limited to 60 Mb/s.

- The highest priority (6) scheduling class is rate limited to 20 Mb/s at the port level.

> **Note:** All the rates under the HS port scheduler are in Mb/s.

```
configure
   qos
      hs-scheduler-policy "hs1" create
         max-rate 200
            group 1 rate 60
            scheduling-class 4 group 1 weight 10
            scheduling-class 5 group 1 weight 20
            scheduling-class 6 rate 20
      exit
   exit
```

The delta between the low and high burst tolerance thresholds at the subscriber and HS secondary shaper levels can be adjusted with the **hs-fixed-high-thresh-delta** command that is configured at the card level. In this example, the difference between the thresholds is set to 12 kbytes. The default value is 4000 bytes.

The lower threshold for the buckets is calculated automatically by the system, based on many internal inputs (clock frequency of rate timer, shaper type, heuristics, MDA type, and so on).

```
configure
   card 3
      card-type iom4-e-hs
         mda 1
            mda-type me10-10gb-sfp+
            no shutdown
         exit
         fp 1
            egress
               hs-fixed-high-thresh-delta 12000
            exit
         exit
      no shutdown
```

Operational commands

Operational commands are used to troubleshoot the system and monitor its operational state. The focus of this section will be on **show**, **clear**, and **tools dump** commands. The **debug** commands are omitted because there are no **debug** commands related to QoS on HSQ IOM and the **debug** commands related to ESM are described in other chapters. Also, there are no log events related to QoS on HSQ IOM.

Show commands

show commands in this section are divided into two groups:

- **show** commands that display association between ESM and QoS objects where all displayed information is static and does not change autonomously over time.

- **show** commands that display QoS hierarchy with the running rates (where the state is changing autonomously).

show commands have filters (or CLI parameters) that can be used to control the amount of the output information. This section will provide a few **show** command examples; it is left to the user to explore all the options available for a particular **show** command.

Subscriber management related show commands

Examining subscriber associations with QoS objects should begin with the **show service active-subscribers** command. The output of this command provides information about the subscriber context and the output can vary in detail depending on the options with which this command is run. Besides the subscriber name, underlying subscriber SAPs, and SLA/sub-profile names, the following information is provided:

- SLA mode in which the subscriber operates on HSQ (single versus expanded SLA mode)

- Aggregate rate of the subscriber

- Ingress and egress QoS policies

- Subscriber association with an HS secondary shaper and the **inter dest id** string that is used to make this association

- Ingress queue/policer statistics

- Egress queues statistics

For brevity, only the information for subscriber sub-1 is shown in the following output:

```
A:PE-1# show service active-subscribers subscriber "sub-1" detail

To reveal the subscriber hierarchy in a terse form with respect to the sub/SLA-profiles and the SAP, the following command can be run:

```
A:PE-1# show service active-subscribers hierarchy
```

```
================================================================================
Active Subscribers Hierarchy
================================================================================
-- sub-1 (sub-prof-1)
    |
   +-- sap:[3/1/1:1.1] - sla:sla-1
       |
       +-- 10.10.1.1 - mac:00:00:64:01:01:01 - DHCP - svc:3

-- sub-2 (sub-prof-2)
    |
   +-- sap:[3/1/1:1.2] - sla:sla-2
       |
       +-- 10.10.1.2 - mac:00:00:64:01:01:02 - DHCP - svc:3

-- sub-3 (sub-prof-3)
    |
   +-- sap:[3/1/1:2.1] - sla:sla-3
       |
       +-- 10.10.1.3 - mac:00:00:64:01:01:03 - DHCP - svc:3

--------------------------------------------------------------------------------
Number of active subscribers : 3
Flags: (N) = the host or the managed route is in non-forwarding state
================================================================================
```

The following SAP related **show** command confirms that the SAP queues are removed from the underlying subscriber SAP (under the **stats** section at the end of the output). This was ensured by configuring the **profiled-traffic-only** command in the MSAP policy, with the purpose of reducing the queue consumption on ingress and egress.

```
A:PE-1# show service  id 3 sap 3/1/1:1.1 detail

QoS-related show commands in ESM context

Examination of the subscriber QoS hierarchy on HSQ can start at the subscriber (HSQ queue group and SAP) level and gradually move through the HS secondary shaper, and finally the port level. The output of the **show** commands should confirm that the subscriber is associated with the QoS object as intended by the configuration.

For example, the following output shows that HS attachment policy "hs-attach-1-1" is associated with QoS SAP egress policy 10. It was determined previously that QoS SAP egress policy 10 is associated with subscribersub-1. In this case, a two-step process was necessary to track the association between the subscriber and the HS attachment policy.

```
A:PE-1# show qos sap-egress 10 association

The output from the HS attachment policy reflects the QoS configuration state at the subscriber level that is shown in Figure 88: QoS hierarchy in single SLA mode:

- Queues 1 and 2 are attached to WRR 1.

- Queues 3 to 6 are directly attached to the corresponding scheduling classes (3 to 6).

- Queues 7 and 8 are unattached.

- WRR 2 is unattached.

- HS attachment policy "hs-attach-1" is associated with QoS SAP egress policies 10, 20, and 30 that correspond to sub-1, sub-2, and sub-3.

```

Association between the HS secondary shaper and the subscribers can be verified with the following command. The HS secondary shaper is allocated per port (or LAG). The two subscribers (sub-1 and sub-2) are instantiated on SAPs with the outer VLAN tag 1; consequently, they are both associated with HS secondary shaper 1. The HS secondary shaper 1 is rate limited to 120 Mb/s while its scheduling classes are left open (max rate).

```

The port scheduler information can be obtained with the following command. This command is run in the QoS context (as opposed to being run in the port context, which was the case for HS secondary schedulers). The reason for this is that the HS secondary scheduler is configured directly under the port, while the HS port scheduler is configured in an HS scheduler policy (in QoS context), which is then applied to a port.

```

Show commands with dynamically changing information

The following commands show the QoS hierarchy with the measured rates of the objects (queues, WRR groups, scheduling classes, secondary shapers, and port shapers) and the queue buffer depths in the QoS hierarchy. The command output in this section is based on the scenario described in the Traffic management on HSQ section.

The following subscriber hierarchy shows the rates per scheduling priority (and consequently, scheduling class), starting at the queue level and moving up toward the port level. For example, scheduling priority 1 starts with the rates of two subscriber queues (1 and 2) that are mapped to the WRR group. Scheduling priority 1 then moves to the rate at the HS secondary shaper level (the summed rate of all the entities at scheduling priority 1 at the HS secondary shaper level), ending with the rate of the scheduling class 1 at the port level. The aggregate rate of the HS secondary shaper and the port in the subscriber hierarchy are also provided.

Note: Running rates are the dynamically calculated rates while traffic is running.

```
A:PE-1# show qos hs-scheduler-hierarchy subscriber "sub-1" egress
```

```

-------------------------------------------------------------------------
```

Another important parameter to monitor is the depth of the queues. This provides information about the degree of congestion at the queue level. The buffer space per queue is allocated automatically by the system and, in the following case, the buffers are rather large. Deep buffering causes longer delays. To avoid this, the queue buffers can be adjusted by the **mbs** command under the queue definition in the QoS SAP egress policy. For example, 15 kbytes would accommodate roughly fifteen 1000 byte packets in a buffer queue.

```
*A:PE-1>config>qos>sap-egress# info
----------------------------------------------
            queue 1 create
                mbs 15 kilobytes
```

The following output shows that, except for queue 3, all queues have their buffers fully used. Because there is no congestion on queue 3, its buffer is unused.

```
A:PE-1# show hs-pools port 3/1/1 egress subscriber "sub-1" | match "Queue Information" pre-
lines 1 post-lines 100

Clear commands

Clear commands in the HSQ context are used to clear statistics associated with the HS secondary shaper:

```
clear port <port-id> hs-secondary-shaper <name> statistics
```

Resources monitoring

The following command is used to monitor resource on an HSQ IOM. Some of the resources (HSQ queue groups, HS primary shapers, HS secondary shapers, HS turbo queue groups, and so on) are allocated for internal use, thereby reducing the number of resources in the **Free** column. Such internally consumed resources are not available to be part of the user configuration.

The number of internally consumed resources depends on the configuration and MDA types.

In the following example, the number of allocated HS queue groups is 39. Each of the three subscribers consumes one HS queue group, which means that 36 HS queue groups are internally allocated. Similarly, out of 23 allocated HS secondary shapers, only 3 are user related (and visible via **show** commands): a "default" HS secondary shaper, HS secondary shaper 1, and HS secondary shaper 2. This means that 20 HS secondary shapers are internally consumed.

The same logic can be used for turbo HS queue groups and HS primary shapers. In addition, one managed HS primary shaper is always allocated per each HS secondary shaper. Both turbo HS queue groups and HS primary shapers are out of the scope of this chapter.

> **Note:**
> 100G ports support port-based (access or network) HSQ queue groups on egress that can be configured to support higher throughput rates. Such port-based high rate HSQ queue groups on egress are referred to as egress HS turbo queue groups.

Traffic management on HSQ

This section examines traffic output on HSQ IOM during congestion. Figure 89: Managing Congestion on HSQ in Single SLA Mode is a graphic representation of the configuration described previously, but with traffic streams running through the IOM.

Six traffic streams are sent in the downstream direction toward each of the three subscribers-in total there are 18 traffic streams. The traffic streams are shown on the left side of the figure, with their names, offered rates (IN column) and measured output rates (OUT column). The traffic streams are sent and analyzed by the traffic generator.

The three gray shaded squares in the center of the figure represent the three subscribers and their scheduling classes. The QoS hierarchy is shown on the right side. Red shaded areas (shapers) represent points of congestion on HSQ IOM caused by the 18 traffic streams.

Each of the six traffic streams per subscriber is fed into different subscriber queues. The first digit in the traffic stream name represents the subscriber, whereas the second digit represents the queue to which this stream is sent. For example, STRM 2-3 represents a traffic stream sent to sub-2, queue 3.

To summarize the scenario shown in Figure 89: Managing Congestion on HSQ in Single SLA Mode:

- Traffic streams 1 and 2 of each subscriber are mapped to subscriber queues 1 and 2, which are in turn associated with WRR group 1 at the subscriber level.

- WRR group 1 is, depending on the subscriber, rate limited to 20 Mb/s, 40 Mb/s, or 60 Mb/s. Weight ratio between queues 2 and 1 is 4:1. WRR group 1 is then attached to scheduling class 1.

- Traffic stream 3 is via queue 3 directly mapped to scheduling class 3. Scheduling class 2 is unused in this example.

- Traffic streams 4 and 5 are via queues 4 and 5 mapped to scheduling classes 4 and 5, which are at the port level collapsed into WRR group 1 with an aggregate rate limit of 60 Mb/s.

- Traffic stream 6 is the highest priority stream that is via queue 6 mapped to scheduling class 6. At the port level, scheduling class 6 is rate limited to 20 Mb/s.

- Subscriber (sub-1, sub-2, and sub-3) aggregate rates are set to 50 Mb/s, 75 Mb/s, and 100 Mb/s, respectively.

- Subscribers sub-1 and sub-2 are mapped to HS secondary shaper 1 (via the outer VLANs on their SAPs) while sub-3 is mapped to HS secondary shaper 2.

- HS port scheduler is rate limited to 200 Mb/s.

The configured rate limits at the subscriber level are L2 rates, whereas the configured rate limits at the HS secondary shaper level and the HS port level include L1 overhead and are, therefore, on-the-wire rates. On-the-wire rates account for 20 additional bytes in each Ethernet frame (8 bytes preamble and 12 bytes IFG).

All traffic streams are sent with constant rates (no added burstiness) and fixed packet size (1000 bytes). Therefore, the difference between the L2 rates and the on-the-wire rates for the 1000 byte packets is 1000/1020 = 0.98 or 2%. That is, on-the-wire rates are 2% higher than the L2 rates. The name for this 2% delta factor in this chapter will be the Rate Conversion Factor (RCF).

Figure 89: Managing Congestion on HSQ in Single SLA Mode
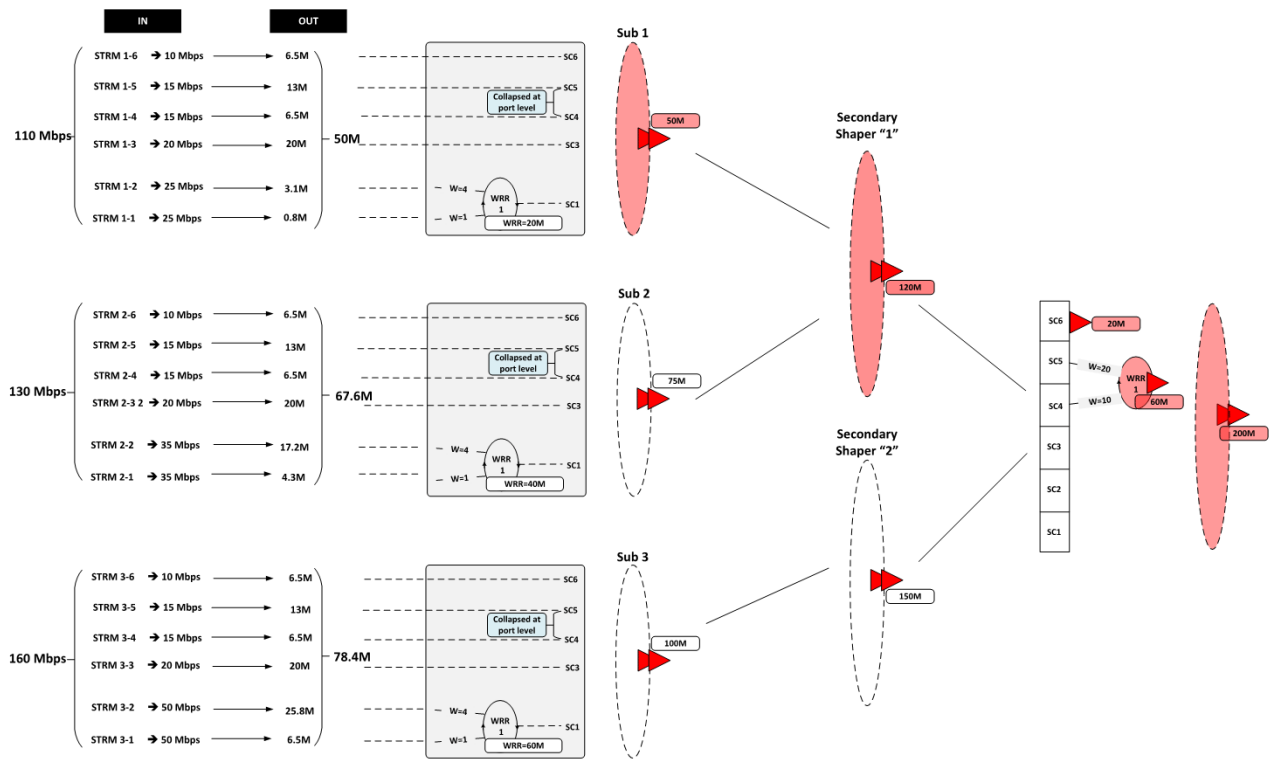

Table 23: Input and output rates throughout the subscriber QoS hierarchy lists the input/output rates throughout the subscriber QoS hierarchy. Red shaded table cells represent congested objects. The numbers on the blue background represent the output rates measured on the traffic generator. The numbers in red (in parentheses) are configured aggregate rates for the object in the hierarchy. The numbers above them are operational rates measured by SR OS and observed via the **show qos hs-scheduler-hierarchy** command.

Some of the **output** columns in this table require additional explanation:

- Per stream output rates are L2 rates as measured by the traffic generator. The resulting analysis will be based on these rates.

- However, those rates can also be displayed via the **show qos hs-scheduler-hierarchy subscriber** *<sub-name>* **egress** command. RCF must be used to correctly interpret the results in respective rate domains (L1 versus L2).

- WRR rates at the subscriber level (second column under the Output Rate section) are populated by manually adding rates measured by the traffic generator for traffic streams 1 and 2. The 4:1 indication in

parentheses represents the weight ratio between the two streams. There are no means to observe the WRR group rates at the subscriber level directly within the system (via **show** commands).

- Aggregate rates per subscriber (third column under the Output Rate section) are populated by manually adding the rates measured by the traffic generator from all six traffic streams for each subscriber. There are no means to observe the aggregate subscriber rate directly within the system (via **show** commands).

- Aggregate rates per HS secondary shaper (fourth column under the Output Rate section) are on-the-wire rates displayed via the **show qos hs-scheduler-hierarchy port 3/1/1 hs-secondary-shapers** command. The displayed rates are rounded to the nearest Mb/s.

- Per scheduling class rates at the port level (fifth column under the Output Rate section) are displayed via the **show qos hs-scheduler-hierarchy port 3/1/1** command. The displayed rates are rounded by the system to the nearest Mb/s. The discrepancy between the actual rates for scheduling class 3 (60 Mb/s) and the displayed rate (61 Mb/s) is due to the measuring and rounding inaccuracy at display time. The actual rate at scheduling class 3 at the port level can be calculated by summing the measured rate of each traffic stream 3 for each subscriber and adjusting the sum for the on-the-wire rate (RCF).

- The same logic applies to scheduling class 1 (actual rate 60 Mb/s versus 59 Mb/s measured rate).

- The WRR 1 rate at the port level (sixth column under the Output Rate section) is manually calculated by adding the rates measured by the traffic generator of all streams mapped to scheduling classes 5 and 4 (6 traffic streams in total, two per each subscriber). At the port level, traffic on scheduling classes 5 and 4 is weighted in a 2:1 ratio (this is noted in parentheses).

- The port rate (last column under the Output Rate section) is collected from two places:

  - The top number in obtained via the **show qos hs-scheduler-hierarchy** command and represents the on-the-wire rate.

  - The bottom number with blue background is the number measured by the traffic generator, which only measures L2 rates. On-the-wire rates can be converted to L2 rates by multiplying the on-the-wire rates by the RCF.

Table 23: Input and output rates throughout the subscriber QoS hierarchy

Subscr	Strm	Input rate in [Mb/s]		Output rate in [Mb/s]						
		Per strm	Agg per subscr	Per strm (L2)	WRR on subscr level	Agg per subscr (L2)	Agg per secondary shaper (wire)	Per sch class on port level (wire)	WRR-1 on port level (wire)	Port

	3-1	50		6.5					-	

Analysis of results

The analysis of results begins with the rates per stream measured by the traffic generator. The expected behavior is that those rates are in line with the theoretical rate calculations based on our understanding of QoS on HSQ IOM.

Considering the six strict priority classes in the HSQ scheduling mechanism, the expectation is that the traffic is serviced in the order of priority, from the highest scheduling class 6 to the lowest scheduling class 1. Consequently, the traffic analysis starts with the streams that are mapped to the highest priority scheduling class 6 (streams 1-6, 2-6, and 3-6), that is, stream 6 of sub-1, sub-2, and sub-3, respectively.

Scheduling class 6 (streams 1-6, 2-6, and 3-6) - the highest priority scheduling class

Due to the aggregate rate limit of 20 Mb/s for scheduling class 6 at the port level, it is expected that each subscriber receives an equal amount of traffic on scheduling class 6:

$$\frac{20 \text{ Mb/s (aggregate of SC 6)}}{3 \text{ streams (one per subscriber)}} = 6.6 \text{ Mb/s}$$

26900

The measured results on the traffic generator for traffic streams 6 in Table 23: Input and output rates throughout the subscriber QoS hierarchy show that each subscriber receives 6.54 Mb/s out of an offered 10 Mb/s. The slight difference between the expected (6.6 Mb/s) and the measured (6.54 Mb/s) rate is caused by the discrepancy between the L2 rates at the subscriber level (as measured by the traffic generator), and on-the-wire rate enforcement (20 Mb/s) at the scheduling class 6 at the port level. Multiplying 6.6 Mb/s by the RCF

$$\left(\frac{1000}{1020} \right)$$

will align the results.

This slight discrepancy between the L2 and on-the-wire rates is common throughout the remaining analysis, and will not be repeated.

Scheduling classes 5 and 4 (streams 1-5, 1-4, 2-5, 2-4, 3-5, and 3-4)

Scheduling classes 5 and 4 are collapsed at the port level into WRR group 1, which is at the next scheduling priority to be served. These two scheduling classes are served by WRR group 1 in a 2:1 ratio. The aggregate rate limit for WRR 1 at the port level is set to 60 Mb/s.

Expected rates for combined scheduling classes 5 and 4 of each subscriber are:

$$\frac{60 \text{ Mb/s}}{3} = 20 \text{ Mb/s}$$

When 20 Mb/s is distributed between the two scheduling classes in the 2:1 ratio, each subscriber should receive 13.34 Mb/s on scheduling class 5 and 6.66 Mb/s on scheduling class 4, for the total of 20 Mb/s (out of offered 30 Mb/s).

The measured results in Table 23: Input and output rates throughout the subscriber QoS hierarchy are 13 Mb/s on scheduling class 5 and 6.5 Mb/s on scheduling class 4 for traffic streams 4 and 5 of each individual subscriber. This is in line with the expected results (the slight difference is due to the measured L2 rates by the traffic generator and enforced on-the-wire rates at the port level).

Scheduling class 3 (streams 1-3, 2-3, and 3-3)

Traffic streams mapped to scheduling class 3 do not have any rate restriction at the scheduling class level. Those streams can be only limited by the congestion at the subscriber aggregate level, the HS secondary shaper aggregate level, or the port aggregate level. Because the total amount of traffic so far is below the congestion level at each point in the hierarchy, it is expected that traffic stream 3 flows unimpeded. Consequently, each subscriber should receive the full input rate of 20 Mb/s on scheduling class 3. The actual results in Table 23: Input and output rates throughout the subscriber QoS hierarchy are aligned with the expected results.

To confirm that there is no congestion at the aggregate level so far for subscribers, HS secondary shapers, and the port, a calculation shows that each subscriber has received an equal amount of bandwidth so far:

46 Mb/s. This is below the configured aggregate rate limits at the subscriber, HS secondary scheduler, and port levels:

- 46 Mb/s is below the configured limit of 50 Mb/s for sub-1.
- 46 Mb/s is below the configured limit of 75 Mb/s for sub-2.
- 46 Mb/s is below the configured limit of 100 Mb/s for sub-3.
- Sub-1 and sub-2 compete for the bandwidth at HS secondary shaper 1, and their combined rate of 92 Mb/s is below the configured aggregate rate of HS secondary shaper 1 (120 Mb/s).
- Sub-3 with its 46 Mb/s is below its configured aggregate subscriber rate limit (100 Mb/s) and that of the HS secondary shaper 2 (150 Mb/s).
- The total subscriber bandwidth of 3 x 46 Mb/s = 138 Mb/s is below the 200 Mb/s aggregate rate limit at the port level.

Scheduling classes 2 and 1 (streams 1-2, 1-1, 2-2, 2-1, 3-2, 3-1) - the lowest priority scheduling classes

The total amount of offered (input) traffic for lowest priority scheduling classes 1 and 2 across all three subscribers is 230 Mb/s (50 Mb/s for sub-1, 70 Mb/s for sub-2, and 100 Mb/s for sub-3). This amount of traffic will cause congestion at the aggregate level for sub-1, at the aggregate level of HS secondary shaper 1, and at the aggregate port level. The amount of traffic that each subscriber will receive for those two scheduling classes will now differ (up to this point, each subscriber received an equal amount of traffic).

Sub-1 will become limited by 50 Mb/s (the L2 rate limit) of its configured aggregate rate limit, which has only ~4 Mb/s left (with ~46 Mb/s received for sub-1). Considering that the scheduling classes 2 and 1 are serviced in 4:1 fashion, the ~4 Mb/s should be split between the two scheduling classes. Scheduling class 2 should receive ~3.2 Mb/s while scheduling class 1 should receive ~0.8 Mb/s. The measured data in Table 23: Input and output rates throughout the subscriber QoS hierarchy shows that the expected and measured results on the traffic generator are aligned.

Up to this point, the spare capacity on the HS secondary shaper 1 is:

```
    120 Mb/s (HS secondary shaper 1 aggregate on-the-wire rate limit)
-    51 Mb/s (on-the-wire traffic from sub-1 up to this point)
-  ~47 Mb/s (on-the-wire traffic from sub-2 up to this point)
─────────────────
=   22 Mb/s¹² (capacity left on the HS secondary shaper 1 up to this point)
```

26901

while the spare capacity at the sub-2 aggregate level is:

```
     75 Mb/s (sub-2 L2 aggregate rate limit)
-  ~46 Mb/s (L2 traffic from sub-2 up to this point)
─────────────────
=   29 Mb/s (L2 capacity left on the HS secondary shaper 1 up to this point)
```

26902

This means that the 70 Mb/s that sub-2 is sending on scheduling classes 2 and 1 will congest the HS secondary shaper 1 (~22 Mb/s left) before it congests the subscriber itself (~29 Mb/s left). The 22 Mb/s of on-the-wire bandwidth capacity left on the HS secondary shaper will be divided in 4:1 ratio between scheduling classes 2 and 1. Therefore, the scheduling class 2 should receive 17.6 Mb/s and the scheduling class 1 should receive 4.4 Mb/s. When converted to L2 rates, these expected results match the measured

rates by the traffic generator in Table 23: Input and output rates throughout the subscriber QoS hierarchy for sub-2.

> **Note:**
>
> 1. At the subscriber level, rate enforcement is based on L2 packet size.
>
> 2. Spare capacity for HS secondary shaper 1 is calculated based on on-the-wire rates while the subscriber aggregate capacity is calculated in L2 rates, because the aggregate rate limit in the HS secondary shaper is configured in on-the-wire rates while the subscriber aggregate rates are configured in L2 rates.

Similar logic can be used for traffic on scheduling classes 2 and 1 for sub-3. The difference from the previous case is that this traffic will be limited by port congestion and not the HS secondary shaper congestion (or subscriber aggregate congestion).

The available bandwidth at the port level up to this point is:

```
    200 Mb/s (on-the-wire port aggregate rate cap)
  - 120 Mb/s (on-the-wire traffic from the HS secondary shaper 1 to sub-1 and sub-2)
  - ~47 Mb/s (on-the-wire traffic from sub-3)
  =  33 Mb/s (on-the-wire capacity left on the port)
```

26903

The 100 Mb/s sent to sub-3 on scheduling classes 2 and 1 will be reduced to 33 Mb/s on the output in 4:1 ratio between scheduling classes 2 and 1. Scheduling class 2 should receive 26.3 Mb/s and scheduling class 1 should receive 6.6 Mb/s. Converted to L2 rates, these numbers match the measured rates by the traffic generator for streams 3-2 and 3-1 in Table 23: Input and output rates throughout the subscriber QoS hierarchy .

Conclusion

This chapter described traffic management capabilities and configuration of HSQ IOM with ESM in single SLA mode. Because HSQ performs egress traffic management functions, the focus in this chapter was on egress QoS. The ingress QoS remains the same as on other non-HSQ IOMs where a combination of queues and policers can be deployed. Ingress and egress queues on HSQ are allocated from different queue pools that are separated at the hardware level (by different chips).

Some configuration practices are summarized here:

- SAP queues in the ESM context should be removed in most subscriber/SAP (1:1) deployment scenarios (**profiled-only-traffic** command). This maximizes the number of ingress queues available for ESM, which is important because HSQ does not support shared queueing on ingress. The alternative to queueing is to use policers on ingress.

- Queue depth (buffer size) can be statically configured (**mbs** command). By default, this parameter (MBS) is set dynamically and is somewhat high. To reduce the amount of buffering and delay, a smaller buffer size can be provisioned per queue.

- The **low-burst-max-class** should be configured at the subscriber level and at the HS secondary scheduler level to ensure smaller buffering delays for higher priority traffic.

- The delta between the high and low thresholds (**hs-fixed-high-thresh-delta** command) should be configured to accommodate a reasonable number of packets on higher priority classes that are serviced after the packets on lower priority classes have stopped due to crossing of the lower burst threshold. In

this example, the value of 12 kbytes means that about 12 packets (each of 1000 byte size) on higher scheduling classes will be serviced unimpeded before the higher burst threshold is reached, which stops the service.

HSQ IOM provides scalable traffic management functions on egress. A high number of egress queues can be serviced in strict priority fashion and extensive shaping hierarchy provides protection against overrunning the link capacities at an access node level or at a subscriber level. HSQ IOM is a card for a scaled ESM (in single SLA mode) environment that requires a higher number of queues per subscriber with throughput demands in the range of 200 Gb/s per HSQ IOM.

Appendix A — Generic ESM configuration

Sub-profile, SLA-profile, and MSAP-policy configuration is omitted because it is already described in the Configuration section.

ESM configuration in this example starts with a **subscriber-interface** configured in an IES context. Subscriber hosts are instantiated in IES 3 service, under the **group-interface "group-int-1"**, which is created under the **subscriber-interface "sub-int-1"**. Authentication and address assignment of the subscriber hosts is performed via LUDB user-db "user-db-1". The IP addresses that are assigned to the hosts are statically configured in LUDB (DHCP server is not used in this setup).

```
configure
   service
      ies 3 name "3" customer 1 create
         subscriber-interface "sub-int-1" create
            address 10.10.1.254/24
            group-interface "group-int-1" create
               dhcp
                  proxy-server
                     emulated-server 10.10.1.254
                     no shutdown
                  exit
                  option
                     action keep
                     circuit-id
                     remote-id
                  exit
                  trusted
                  lease-populate 100
                  gi-address 10.10.1.254
                  user-db "user-db-1"
               no shutdown
               exit
            exit
            no shutdown
         exit
      exit
```

Subscriber SAPs are automatically created based on the VLAN tags carried in the initial control packets of the subscriber hosts. This VLAN auto-detection and SAP auto-creation is configured under the capture SAP hierarchy. The capture SAP is configured to support LUDB authentication for dynamic DHCPv4 host instantiation:

```
configure
   service
      vpls 10 name "10" customer 1 create
      sap 3/1/1:*.* capture-sap create
```

```
            trigger-packet dhcp
            dhcp-user-db "user-db-1"
        exit
    exit
```

Sub-ident-policy is a mandatory configuration in ESM. It determines the mapping method between the
sub/SLA profiles and the corresponding strings obtained during the authentication phase for the subscriber.
Subscribers strings obtained during the authentication phase point, in some form (determined by **sub-
ident-policy**), to the configured sub/SLA profiles (in the SR OS node) that will be associated with the
subscriber.

```
configure
    subscriber-mgmt
        sub-ident-policy "sub_ident_pol" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
```

In this example, authentication of the subscriber hosts and IP address assignment is performed through
LUDB. The hosts are identified based on the **circuit-id** and **remote-id** fields in DHCP control packets. Sub/
SLA -profile strings in LUDB are directly mapped to the configured sub/SLA-profiles in the SR OS node.
This direct mapping is implied by the **use-direct-map-as-default** command within the **sub-ident-policy**.

Service ID, group-interface name, and MSAP policy name for the subscriber is also determined during the
authentication phase via LUDB. LUDB carries only ESM-specific configuration. There is no HSQ relevant
configuration present in LUDB.

```
configure
    subscriber-mgmt
        local-user-db "user-db-1" create
            ipoe
                match-list circuit-id remote-id
                host "sub-1-host-1" create
                    host-identification
                        circuit-id string "sub-1"
                        remote-id string "host-1"
                    exit
                    address 10.10.1.1
                    identification-strings 254 create
                        subscriber-id "sub-1"
                        sla-profile-string "sla-1"
                        sub-profile-string "sub-prof-1"
                    exit
                    msap-defaults
                        group-interface "group-int-1"
                        policy "msaps"
                        service 3
                    exit
                    options
                        subnet-mask 255.255.255.0
                    exit
                    no shutdown
                exit
                host "sub-2-host-1" create
                    host-identification
                        circuit-id string "sub-2"
                        remote-id string "host-1"
```

```
                exit
                address 10.10.1.2
                identification-strings 254 create
                    subscriber-id "sub-2"
                    sla-profile-string "sla-2"
                    sub-profile-string "sub-prof-2"
                exit
                msap-defaults
                    group-interface "group-int-1"
                    policy "msaps"
                    service 3
                exit
                options
                    subnet-mask 255.255.255.0
                exit
                no shutdown
            exit
            host "sub-3-host-1" create
                host-identification
                    circuit-id string "sub-3"
                    remote-id string "host-1"
                exit
                address 10.10.1.3
                identification-strings 254 create
                    subscriber-id "sub-3"
                    sla-profile-string "sla-3"
                    sub-profile-string "sub-prof-3"

Ingress Multicast Path Management

This chapter provides information about Ingress Multicast Path Management (IMPM).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 9.0.R6. There are no prerequisites for this configuration.

Overview

Ingress Multicast Path Management (IMPM) optimizes the IPv4 and IPv6 multicast capacity on the applicable systems with the goal of achieving the maximum system-wide IP multicast throughput. It controls the delivery of IPv4/IPv6 routed multicast groups and of VPLS (IGMP and PIM) snooped IPv4 multicast groups, which usually relate to the distribution of IP TV channels.

A description is also included of the use of IMPM resources by point-to-multipoint LSP IP multicast traffic, and policed ingress routed IP multicast or VPLS broadcast, unknown or multicast traffic. The system capacity for these traffic types can be increased even with IMPM disabled.

IMPM introduces the concept of paths on a line card (IOM/IMM) which connect to planes on the chassis switch fabric (Figure 90: IOM/IMM Paths Connecting to Switch Fabric Planes).

IMPM monitors the ingress rate of IP multicast channels (S,G multicast streams) on line card paths and optimizes the use of the capacity of each switch fabric plane. Its goal is to forward as many channels as possible through the system in order to make maximum use of the switch fabric planes without incurring multicast packet loss. IMPM achieves this by moving entire multicast channels between the line card paths, and therefore between switch fabric planes, to achieve an optimal packing of channels onto path/planes. These actions take into consideration the total ingress multicast traffic being received by all line cards with IMPM enabled and a configured preference of each channel.

> **Note:**
> S,G refers to an individual multicast stream by referencing the source (S) and multicast group (G) used by the steam.

Figure 90: IOM/IMM Paths Connecting to Switch Fabric Planes
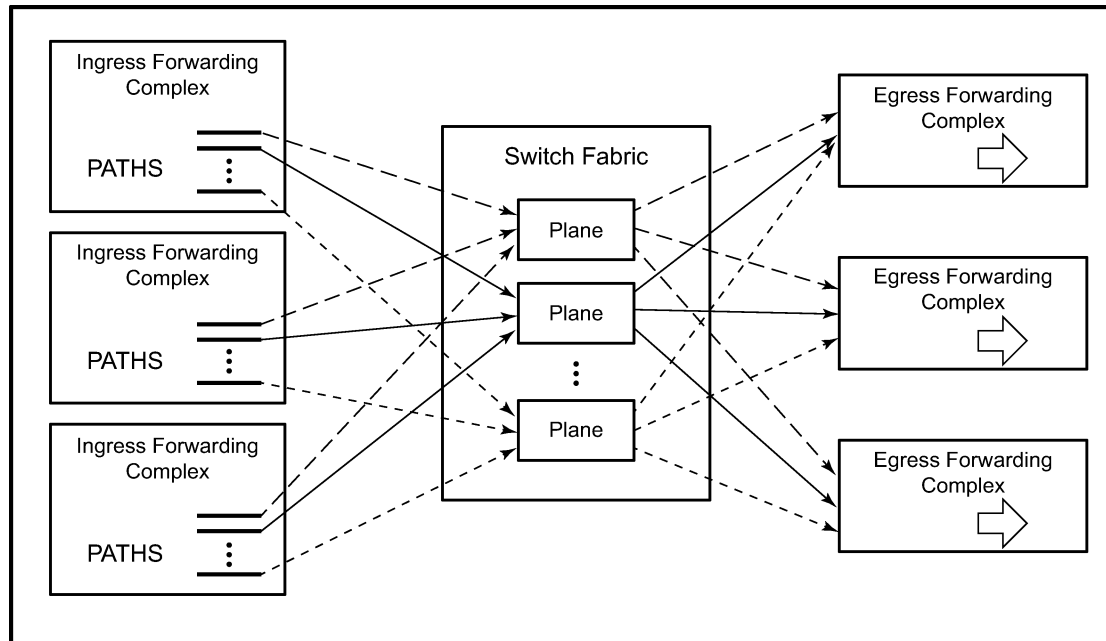

There are three types of path: primary, secondary and ancillary paths (the ancillary path is specific to the IOM1/2 and is discussed in Ancillary Path).

When a new channel is received on a line card for which there is an egress join, its traffic is initially placed on to a secondary path by default. IMPM monitors the channel's traffic rate and, after an initial monitoring period, can move the channel to another path (usually a primary path) on which sufficient capacity exists for the channel. IMPM constantly monitors all of the ingress channels and therefore keeps a picture of the current usage of all the line card paths and switch fabric planes. As new channels arrive, IMPM assigns them onto available capacity, which may involve moving existing channels between paths (and planes). If a channel stops, IMPM will be aware that more capacity is now available. If the traffic rate of any channel(s) changes, IMPM will continue to optimize the use of the path/planes.

In the case where there is insufficient plane capacity available for all ingress channels, entire channel(s) are blackholed (dropped) rather than allowing a random degradation across all channels. This action is based on a configurable channel preference with the lowest preference channel being dropped first. If path/plane capacity becomes available, then the blackholed channel(s) can be re-instated.

Paths and Planes

Each path connects to one plane on the switch fabric which is then used to replicate multicast traffic to the egress line cards. Further replication can occur on the egress line card but this is not related to IMPM so is not discussed.

Each plane has a physical connection to every line card and operates in full duplex mode allowing the possibility for traffic received on a plane from one line card path to be sent to every other line card, and back to the ingress line card (note that traffic is actually only sent to the line cards where it may exit). Therefore a given plane interconnects all line cards which allow ingress multipoint traffic from a line card with a path connected to this plane to be sent to multiple egress line cards.

Traffic could be sent by only one line card, or by multiple line cards simultaneously, on to a given plane. The total amount of traffic on a path or plane cannot exceed the capacity of that path or plane, respectively.

There could be more planes available on the switch fabrics than paths on the line cards. Conversely, there could be more total line card paths than planes available on the switch fabrics. In the latter case, the system distributes the paths as equally as possible over the available planes and multiple paths would be assigned to a given0 plane. Note that multiple paths of either type (primary or secondary) can terminate on a given plane.

The number of paths available per line card depends on the type of line card used whereas the number of planes on a system depends on the chassis type, the chassis mode (**a**, **b**, **c**, **d**) and the number of installed switch fabrics.

To clarify these concepts, consider a system with the following hardware installed.

```
A:PE-1# show card

Output 1: Paths and Planes in Chassis Mode d

This system has two SF/CPM4s and is using chassis mode **d**, this creates 24 planes per SF/CPM4 to give a total of 48 planes which are numbered 0-47. The IOM3-XP/IMMs have 16 paths each which are connected to different planes. The SF/CPM4s together use a single plane and an additional plane (18, which is not in the output above) is used by the system itself. As there are more paths (3x16=48) in this configuration than available planes (48-2[system planes 2,18]=46), some planes are shared by multiple paths, namely planes 0 and 1. Note that the path to plane mapping can change after a reboot or after changing hardware.

The following output shows the equivalent information if an IOM2 is added to this configuration in slot 5. In order for the IOM2 to be recognized, the system must be changed to use chassis mode **a**, **b** or **c**.

```

A:PE-1#
```

Output 2: Paths and Planes in Chassis Mode a/b/c

Now that the system is not in chassis mode **d**, in fact it is in mode a (but the output would be the same in modes **b** or **c**) the SF/CPM4s each create 8 planes giving a total of 16, numbered 0-15. One plane (2) is used by the SF/CPM4s, leaving 15 (0-1,3-15) planes for connectivity to the line card paths. Each IOM2 forwarding complex has 2 paths, so the paths of the IOM2 in slot 5 are using planes 0 and 1, and 3 and 4. Note that there are now fewer planes available and more paths, so there is more sharing of planes between paths than when chassis mode **d** was used.

IMPM Managed Traffic

IMPM manages IPv4/IPv6 routed multicast traffic and VPLS (IGMP and PIM) snooped IPv4 multicast traffic, traffic that matches a <*,G> or a <S,G> multicast record in the ingress forwarding table. It manages IP multicast traffic on a bud LSR when using point-to-multipoint (P2MP) LSPs but it does not manage IP protocol control traffic or traffic using multipoint-shared queuing. Traffic being managed by IMPM involves IMPM monitoring and potentially moving the related channels between paths/planes. The unmanaged traffic rates are also monitored and taken into account in the IMPM algorithm.

Care should be taken when using the mrouter-port configuration in a VPLS service. This creates a (*,*) multicast record and consequently all multicast channels that are not delivered locally to a non-mrouter port will be treated by IMPM as a single channel.

Configuration

This section covers:

- IMPM on an IOM3-XP/IMM
- IMPM on an IOM1/2
- IMPM Not Enabled

Prerequisites

As IMPM operates on IPv4/IPv6 routed or VPLS IGMP/PIM snooped IPv4 multicast traffic, some basic multicast configuration must be enabled. This section uses routed IP multicast in the global routing table which requires IP interfaces to be configured with PIM and IGMP. The configuration uses a PIM rendezvous point and static IGMP joins. The following is an example of the complete configuration of one interface.

```
configure
    router
        interface "int-IOM3-1"
            address 172.16.6.254/24
            port 6/2/1
        exit
        igmp
            interface "int-IOM3-1"
                static
                    group 239.255.0.1
                        starg
                    exit
                exit
            exit
            no shutdown
        exit
        pim
            interface "int-IOM3-1"
            exit
            rp
                static
                    address 192.0.2.1
                        group-prefix 239.255.0.0/16
                    exit
                exit
            exit
            no shutdown
        exit
    exit
```

One interface is configured on each line card configured in the system, as shown in the following output, but omitting their IGMP and PIM configuration.

```
configure
```

```
    router
        interface "int-IMM8"
            address 172.16.3.254/24
            port 7/2/1
        exit
        interface "int-IOM2"
            address 172.16.1.254/24
            port 5/2/1
        exit
        interface "int-IOM3-1"
            address 172.16.2.254/24
            port 6/2/1
        exit
        interface "int-IOM3-2"
            address 172.16.4.254/24
            port 8/2/1
        exit
    exit
```

Configuring IMPM

The majority of the IMPM configuration is performed under the **mcast-management** CLI nodes and
consists of:

1. The bandwidth-policy for characteristics relating to the IOM/IMM paths. This is applied on an IOM3-
   XP/IMM fp (fp is the system term for a forwarding complex on an IOM3-XP/IMM.), or an IOM1/2 MDA,
   under ingress mcast-path-management, with a bandwidth-policy named default being applied by
   default.

   • IOM1/2

```
config# card slot-number mda mda-slot
    ingress
        mcast-path-management
            bandwidth-policy policy-name
```

   • IOM3-XP/IMM

```
config# card slot-number fp [1]
    ingress
        mcast-path-management
            bandwidth-policy policy-name
```

2. The multicast-info policy for information related to the channels and how they are handled by the
   system. To facilitate provisioning, parameters can be configured under a three level hierarchy with each
   level overriding the configuration of its predecessor:

   • Bundle: a group of channels

   • Channel: a single channel or a non-overlapping range of channels

   • Source-override: channels from a specific sender

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        channel ip-address [ip-address] [create]
            source-override ip-address [create]
```

This policy is applied where the channel enters the system, so under router or service (vpls or vprn); the latter allows the handling of channels to be specific to a service, even if multiple services use overlapping channel addresses.

```
config# router multicast-info-policy policy-name

config# service vpls service-id multicast-info-policy policy-name

config# service vprn service-id multicast-info-policy policy-name
```

A default multicast-info-policy is applied to the above when IMPM is enabled.

3. The chassis-level node configures the information relating to the switch fabric planes.

```
config# mcast-management chassis-level
```

In addition, the command hi-bw-mcast-src (under an IOM3-XP/IMM fp or an IOM1/2 MDA) can be used to control the path to plane mapping among forwarding complexes.

IMPM on an IOM3-XP/IMM

IMPM is enabled on IOM3-XP/IMMs on under the card/fp CLI node as follows

```
config# card slot-number fp 1 ingress mcast-path-management no shutdown
```

IOM3-XP/IMM Paths

16 paths are available on an IOM3-XP/IMM when IMPM is enabled which can be either primary paths or secondary paths. By default the 16 paths are divided into 15 primary paths and 1 secondary path, as can be seen using the following command with IMPM enabled only on slot 6 (this corresponds to the plane assignment in Output 1):

```
*A:PE-1# tools dump mcast-path-mgr cpm
McPathMgr[6][0]: 0xf33b0a00
PATH:                                  PLANE:
Type SGs    InUseBW   AvailBW   TotalBw  ID   SGs   InUseBW   AvailBW   TotalBw
P     1        0         -         -      1    1        0      2000000   2000000
P     1        0         -         -      0    1        0      2000000   2000000
P     1        0         -         -      3    1        0      2000000   2000000
P     1        0         -         -      4    1        0      2000000   2000000
P     1        0         -         -      5    1        0      2000000   2000000
P     1        0         -         -      6    1        0      2000000   2000000
P     1        0         -         -      7    1        0      2000000   2000000
P     1        0         -         -      8    1        0      2000000   2000000
P     1        0         -         -      9    1        0      2000000   2000000
P     1        0         -         -      10   1        0      2000000   2000000
P     1        0         -         -      11   1        0      2000000   2000000
P     1        0         -         -      12   1        0      2000000   2000000
P     1        0         -         -      13   1        0      2000000   2000000
P     1        0         -         -      14   1        0      2000000   2000000
P     1        0         -         -      15   1        0      2000000   2000000
S     1        0         -         -      16   1        0      1800000   1800000
B     0        0         -         -      -    -        -         -         -
*A:PE-1#
```

Output 3: Paths/Planes on IOM3-XP/IMM

The left side of the output displays information about the paths (type {P=primary, s=secondary or B=blackholed}, number of "S,G"s and bandwidth in use (the path bandwidth cannot be set on an IOM3-XP/IMM, so the path available and total bandwidth always shows "-")) and the right side displays similar information about the associated planes (this will be a combination of the information for all paths connected to this plane). Note that one SG is always present on each path; this is used by the system and relates to the unmanaged traffic.

The primary/secondary paths are also highlighted in the planes section of Output 1, the primary paths being connected to the planes on the left of the "|" and the secondary paths to its right. There is a default primary path and a default secondary path; these correspond to the left-most plane and right-most plane for each line card, respectively.

Primary paths are used by:

- Expedited IES, VPLS and VPRN service ingress non-managed multipoint traffic (using the SAP based queues). This uses the default primary path.

- Expedited network ingress non-managed multipoint traffic (using the network interface queues). This uses the default primary path.

- Managed multicast explicit path primary channels (using the primary paths managed multipoint queue)

- All managed multicast dynamic path channels when the primary paths or multicast planes are not at their limit (using the primary paths managed multipoint queue)

- Highest preference managed multicast dynamic path channels when the primary paths or multicast planes are at their limit (using the primary paths managed multipoint queue)

- Non-managed P2MP LSP IP multicast traffic. This does not require IMPM to be enabled, so is discussed later in IMPM Not Enabled.

- Non-managed expedited ingress policed multipoint traffic. This does not require IMPM to be enabled, so is discussed in IMPM Not Enabled.

Secondary paths are used by:

- Best-Effort IES, VPLS and VPRN service ingress non-managed multipoint traffic (using the SAP based queues). This uses the default secondary path.

- Best-Effort network ingress non-managed traffic (using the network interface multipoint queues). This uses the default secondary path.

- Managed multicast explicit path secondary channels (using the secondary paths managed multipoint queue)

- Lower preference managed multicast dynamic path channels when the primary paths or multicast planes are at their limit (using the secondary paths managed multipoint queue)

- Non-managed best-effort ingress policed multipoint traffic. This does not require IMPM to be enabled, so is discussed in IMPM Not Enabled.

When IMPM is enabled, the managed traffic does not use the standard multipoint queues but instead is placed onto a separate set of shared queues which are associated with the 16 paths. These queues are instantiated in an access ingress pool (called MC Path Mgmt, see "show output" section) which exists by default (this pool can be used even when IMPM is not enabled – see section "IMPM not enabled"). Statistics relating to traffic on these queues are reflected back to the standard ingress multipoint queues for accounting and troubleshooting purposes. Note that non-managed traffic continues to use the standard ingress multipoint queues, with the exception of P2MP LSP IP multicast traffic and policed multipoint traffic.

The size of the pool by default is 10% of the total ingress pool size, the reserved CBS is 50% of the pool and the default slope policy is applied. Care should be taken when changing the size of this pool as this would affect the size of other ingress pools on the line card.

```
config# mcast-management bandwidth-policy policy-name [create]
    mcast-pool percent-of-total percent-of-buffers
            resv-cbs percent-of-pool
            slope-policy policy-name
```

It is possible to configure the parameters for the queues associated with both the primary and secondary paths, and also the number of secondary paths available, within the bandwidth-policy.

```
config# mcast-management bandwidth-policy policy-name create
    t2-paths
        primary-path
            queue-parameters
                cbs percentage
                hi-priority-only percent-of-mbs
                mbs percentage
        secondary-path
            number-paths number-of-paths [dual-sfm number-of-paths]
            queue-parameters
                cbs percentage
                hi-priority-only percent-of-mbs
                mbs percentage
```

The number of primary paths is 16 minus the number of secondary paths (at least one of each type must exist). The number-paths parameter specifies the number of secondary paths when only one switch fabric is active, while the dual-sfm parameter specifies the same value when two switch fabrics are active.

Packets are scheduled out of the path/multicast queue as follows:

- Traffic sent on primary paths is scheduled at multicast high priority while that on secondary paths is scheduled at multicast low priority.

- For managed traffic, the standard ingress forwarding class/prioritization is not used, instead IMPM managed traffic prioritization is based on a channel's preference (described in Channel Prioritization and Blackholing Control). Egress scheduling is unchanged.

Congestion handling (packet acceptance into the path/multicast queue):

- For non-managed traffic, this is based on the standard mechanism, namely the packet's enqueuing priority is used to determine whether the packet is accepted into the path multipoint queue depending on the queue mbs/cbs and the pool shared-buffers/reserved-buffers/WRED.

For managed traffic, the congestion handling is based upon the channel's preference (described later) and the channel's cong-priority-threshold which is configured in the multicast-info-policy (here under a bundle).

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        cong-priority-threshold preference-level
```

When the preference of a channel is lower than the cong-priority-threshold setting, the traffic is treated as low enqueuing priority, when it is equal to or higher than the cong-priority-threshold it is treated as high enqueuing priority. The default cong-priority-threshold is 4.

IOM3-XP/IMM Planes

The capacity per plane for managed traffic is by default 2Gbps for a primary path and 1.8Gbps for a secondary path. The logic behind a reduced default on the secondary is to leave capacity for new streams in case the default secondary is fully used by managed streams.

The plane capacities can be configured as follows, note that this command configures the plane bandwidth associated with primary/secondary paths as seen by each line card, the TotalBw on the right side of Output 3:

```
config# mcast-management chassis-level
    per-mcast-plane-limit megabits-per-second [secondary megabits-per-second]
                  [dual-sfm megabits-per-second [secondary-dual-sfm megabits-per-second]]
```

The first parameter defines the capacity for a primary path, the second a secondary path and the dual-sfm configures these capacities when two switch fabrics are active. The maximum plane capacity is 4Gbps but for the release used here it should only be configured on 7750 SR-12 or 7450 ESS-12 systems populated with SF/CPM4(s) and 100G FP IMMs; for all other hardware combinations the maximum should be 2Gbps. Note that secondary plane capacity cannot be higher than that of the primary plane.

These values can be tuned to constrain the amount of managed multicast traffic in favour of non-managed multicast and unicast traffic.

On the IOM3-XP/IMM line cards there is no separate control of the line card path capacity, the capacity is only constrained by the plane.

IOM3-XP/IMM Path to Plane Mapping

By default all fps (line cards for IOM3-XP/IMM) are configured into the default (zero) group as seen in Output 1 and the system distributes the paths as equally as possible over the available planes. This default works well if there is a low volume of multicast traffic (compared to the plane capacity), or if there is a higher volume multicast entering only one line card where the ingress capacity does not exceed that provided by the planes the line card is connected to.

If there are more paths than planes and, for example, there is a high bandwidth multicast channel entering two different line cards it could happen that both line cards select the same plane for two paths that are used. This would result in one of the channels being blackholed if the plane capacity is exceeded, effectively reducing the available multicast capacity from that line card. In order to avoid this situation, it is possible to configure the paths in to different groups and the system will attempt to use different planes for each group.

Output 1 and Output 2 show examples of how the paths are mapped to planes.

In both cases there are more paths than planes so some planes are shared by multiple paths. The following command provides control of this mapping.

```
config# card slot-number fp [1] hi-bw-mcast-src [alarm] [group group-id] [default-paths-only]
```

If an fp is configured into a non-zero group (range: 1 to 32), the system will attempt to assign dedicate planes to its paths compared to other line cards in different non-zero groups. This action is dependent on there being sufficient planes available. If two line cards are assigned to the same group, they will be assigned the same planes. The **default-paths-only** parameter performs the assignment optimization only for the default primary and secondary paths and is only applicable to IOM3-XP/IMMs. The **alarm** keyword causes an alarm to be generated if some planes are still shared with fps in a different group.

An example of the use of this command is shown later.

Note: When VPLS IGMP and PIM snooped traffic is forwarded to a spoke or mesh SDP, by default it is sent by the switch fabric to all line card forwarding complexes on which there is a network IP interface. This is due to the dynamic nature of the way that a spoke or mesh SDP is associated with one or more egress network IP interfaces. If there is an active spoke/mesh SDP for the VPLS service on the egress forwarding complex, the traffic will be flooded on that spoke/mesh SDP, otherwise it will be dropped on the egress forwarding complex. This can be optimized by configuring an inclusion list under the spoke or mesh SDP defining which MDAs this traffic should be flooded to.

```
config>service>vpls# [spoke-sdp|mesh-sdp] sdp-id:vc-id egress
    mfib-allowed-mda-destinations
        [no] mda mda-id
```

The switch fabric flooding domain for this spoke or mesh SDP is made up only of the MDAs that have been added to the list. An empty list implies the default behavior.

It is important to ensure that the spoke or mesh SDP can only be established across the MDAs listed, for example by using RSVP with an explicit path.

IMPM Operation on IOM3-XP/IMM

This section covers:

- Principle of Operation
- Monitoring Traffic Rates
- Channel Prioritization and Blackholing Control

Principle of Operation

Where IMPM is enabled, it constantly monitors the line cards for ingress managed traffic.

When a new channel arrives it will be placed by default on to the default secondary path. IMPM determines the ingress point for the channel and then monitors the traffic of the channel within its monitoring period in order to calculate the rate of the channel. The system then searches the multicast paths/planes attached to the line card for available bandwidth. If there is sufficient capacity on such a path/plane, the channel is moved to that plane. Planes corresponding to primary paths are used first, when there is no capacity available on any primary path/plane a secondary path/plane is used (unless the channel is explicitly configured onto a specific path type – see the following description).

If the required bandwidth is unavailable, the system will then look for any channels that ingress this or other line cards that could be moved to a different multicast plane in order to free up capacity for the new channel. Any channel that is currently mapped to a multicast plane available to the ingress line card is eligible to be moved to a different multicast plane.

If an eligible existing channel is found, whether on this or another line card, that existing channel is moved without packet loss to a new multicast plane. If necessary, this process can be repeated resulting in multiple channels being moved. The new multicast channel is then mapped to the multicast plane previously occupied by the moved channels, again this normally is using a primary path.

If no movable channel is found, then lower preference channel(s) on any ingress line card that share multicast planes with the ingress line card of the new channel can be blackholed to free up capacity for the new channel. It is also possible to both blackhole some channels and move other channels in order to

free up the required capacity. If no lower preference channel is found and no suitable channel moves are possible, the new channel will be blackholed.

If required, channels can be explicitly configured to be on either a primary or secondary path. This can be done for a bundle of channels, for example

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        explicit-sf-path {primary|secondary|ancillary}
```

Note that the ancillary path is not applicable to the IOM3-XP/IMM line cards, however, it is discussed in the section relating to the IOM1/2. If a channel on an IOM3-XP/IMM is configured onto the ancillary path it will use a primary path instead.

One secondary path on an IOM3-XP/IMM is used as a default startup path for new incoming channels. If a large amount of new channel traffic could be received within the monitoring period, it is possible that the plane associated with the default secondary path is over loaded before IMPM has time to monitor the channels' traffic rate and move the channels to a primary path (and a plane with available capacity). This can be alleviated by configuring the following command:

```
config# mcast-management chassis-level
    round-robin-inactive-records
```

When round-robin-inactive-records is enabled, the system redistributes new channels (which are referenced by inactive S,G records) among all available line card multicast (primary, secondary) paths and their switch fabric planes.

Monitoring Traffic Rates

The monitored traffic rate is the averaged traffic rate measured over a monitoring period. The monitoring period used depends on the total number of channels seen by IMPM, the minimum is a 1 second interval and the maximum a 10 seconds interval.

The way in which the system reacts to the measured rate can be tuned using the following command:

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        bw-activity {use-admin-bw|dynamic [falling-delay seconds]}
                    [black-hole-rate kbps]
```

The default is to use the dynamic bandwidth rate, in which case a channel's active traffic rate is determined based on the measured monitored rates. IMPM then makes a decision of how to process the channel as follows.

If the channel was un-managed, IMPM will attempt to place the channel on a path/plane with sufficient available bandwidth.

If the channel was already managed, IMPM determines the highest monitored traffic rate (within a given monitoring period) in a sliding window defined by the falling-delay. This highest chosen monitored rate is then used to re-assess the placement of the channel on the path/planes; this may cause IMPM to move the channel. This mechanism prevents the active rate for a channel being reduced due to a momentarily drop in traffic rate. The default value for falling-delay is 30 seconds, with a range of 10-3600 seconds.

The above logic is shown in Figure 91: Dynamic Bandwidth Rate Management (for simplicity, the falling-delay is exactly twice the monitoring period). It can be seen that the active rate used when the traffic rate decreases follows the highest monitored rate in any falling-delay period.

Figure 91: Dynamic Bandwidth Rate Management
By using the sliding window of monitored rate measurements in the dynamic bandwidth measurement mode, IMPM delays releasing capacity for a channel in its calculations when the channel's rate has been reduced. This allows IMPM to ignore temporary fluctuations in a channel's rate. It is possible to tune this for cases where the reduction in a channel's rate is large by using the falling-percent-reset parameter. The default for the falling-percent-reset is 50%. Setting this to 100% effectively disables it.

```
config# mcast-management bandwidth-policy policy-name create
    falling-percent-reset percent-of-highest
```

When the monitored rate falls by a percentage which is greater or equal to falling-percent-reset, the rate used by IMPM is immediately set to this new monitored rate. This allows IMPM to react faster to significant reductions in a channel's rate while at the same time avoiding too frequent reallocations due to normal rate fluctuations. An example of the falling-percent-reset is shown in Figure 92: Falling-Percent-Reset. In the last two monitoring periods, it can be seen that the active rate used is equal to the monitored rate in the previous periods, and not the higher rate in the previous falling-delay window.

Figure 92: Falling-Percent-Reset
The rate management can be further tuned based on the expectation that the channel bandwidth will fluctuate around a given rate. When the bw-activity is set to use-admin-bw within the multicast-info-policy, the following parameters come into play.

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        admin-bw kbps

config# mcast-management bandwidth-policy policy-name create
    admin-bw-threshold kilo-bits-per-second
```

IMPM will use the rate configured for the admin-bw if the monitored rate is above the admin-bw-threshold but below or equal to the admin-bw in the sliding window of the falling-delay. Whenever the monitored rate is below the admin-bw-threshold or above the admin-bw, IMPM uses the dynamic rate management mechanism. The admin-bw-threshold needs to be smaller than the admin-bw, with the latter being non-zero. This is shown in Figure 93: Admin-Bw Rate Management (for simplicity, the falling-delay is exactly twice the monitoring period). It can be seen that while the monitored rate stays between the admin-bw-threshold and the admin-bw, the active rate used is set to the admin-bw.

Figure 93: Admin-Bw Rate Management
Finally, IMPM also takes into consideration the unmanaged traffic rate on the primary and secondary paths associated with SAP/network interface queues when determining the available capacity on these paths/ planes. This is achieved by constantly monitoring the rate of this traffic on these queues and including this rate in the path/plane capacity usage. IMPM must be enabled on the ingress card of the unmanaged traffic otherwise it will not be monitored.

Channel Prioritization and Blackholing Control

IMPM decides which channels will be forwarded and which will be dropped based on a configured channel preference. The preference value can be in the range 0-7, with 7 being the most preferred and the default value being 0.

When there is insufficient capacity on the paths/planes to support all ingress multipoint traffic, IMPM uses the channel preferences to determine which channels should be forwarded and which should be blackholed (dropped).

This is an important distinction compared to the standard forwarding class packet prioritization; by using a channel preference, an entire channel is either forwarded or blackholed, this allows IMPM to avoid congestion having a small impact on multiple channels at the cost of entire channels being lost.

The channel preference is set within the multicast-info-policy, for example at the bundle level, with the settable values being 1-7:

```
config# mcast-management multicast-info-policy policy-name [create]
    bundle bundle-name [create]
        preference preference-level
```

The channel preference is also used for congestion control in the line card path queues – see "congestion handling" in the section on "IOM3-XP/IMM Paths" above.

Blackhole protection can also be enabled using the bw-activity command, shown above in the "Monitoring traffic rates" section. Regardless of which rate monitoring mechanism is used, a channel can be blackholed if the monitored rate exceeds the black-hole-rate, in which case the channel will be put immediately on the blackhole list and its packets dropped at ingress. This channel will no longer consume line card path or switch fabric capacity. The intention of this parameter is to provide a protection mechanism in case channels consume more bandwidth than expected which could adversely affect other channels.

The black-hole-rate can range from 0 to 40000000kbps, with no black-hole-rate by default. This protection is shown in the last monitoring period of both Figure 2 and Figure 4. Note that it will take a falling-delay period in which the channel's rate is always below the black-hole-rate in order for the channel to be re-instated unless the reduction in the rate is above the falling-percent-reset.

IMPM on an IOM1/2

As most of the principles when using IMPM on an IOM1/2 compared to on an IOM3-XP/IMM are the same and are described above, this section focuses only on the difference between the two.

Note that an IOM1 and IOM2 have two independent 10G forwarding complexes; in both cases there is a single MDA per forwarding complex, consequently some aspects of IMPM are configured under the mda CLI node.

IMPM is enabled on an IOM1/2 under the MDA CLI node as follows:

```
config# card slot-number mda mda-slot ingress mcast-path-management no shutdown
```

IOM1/2 Paths

Each forwarding complex has three paths: one primary and one secondary path, and another type called the ancillary path which is IOM1/2 specific. The paths can be seen using the following command with IMPM enabled only on slot 5 MDA 1 and MDA 2 (referenced as [0] and [1] respectively):

```
A:PE-1# tools dump mcast-path-mgr cpm
McPathMgr[5][0]: 0xf33b0a00
PATH:                              PLANE:

A:PE-1#
```

Output 4: Paths/Planes on IOM1/2

The primary and secondary paths function as on the IOM3-XP/IMM, specifically for:

- Traffic usage.

- Associated queues instantiated in the ingress "MC Path Mgmt" ingress pool.

- Packet scheduling.

- Congestion handling.

The queue parameters can be configured within the bandwidth-policy in a similar way to the IOM3-XP/IMM (note that the IOM3-XP/IMM equivalent for this is under the t2-paths CLI node). The bandwidth-policy is then applied under the respective MDA.

```
config# mcast-management bandwidth-policy policy-name create
    primary-path
        queue-parameters
            cbs percentage
            hi-priority-only percent-of-mbs
            mbs percentage
    secondary-path
        queue-parameters
            cbs percentage
            hi-priority-only percent-of-mbs
            mbs percentage
```

The IOM1/2 allows capacity control on the paths themselves, which is not possible on the IOM3-XP/IMM. This is achieved using the following commands.

```
config# mcast-management bandwidth-policy policy-name create
    primary-path
        path-limit megabits-per-second
    secondary-path
        path-limit megabits-per-second
```

The maximum path-limit for both the primary and secondary path is 2Gbps with a default of 2Gbps for the primary path and 1.5Gbps for the secondary path. The capability to set a path limit for the IOM1/2 can be seen when comparing Output 3 with Output 4; in the latter the "AvailBW" and "TotalBw" for the "PATH" shows the path limit.

In addition to setting the path limits in the bandwidth-policy, they can also be overridden on a given MDA.

```
config# card slot-number mda mda-slot
    ingress
        mcast-path-management
            primary-override
                path-limit megabits-per-second
            secondary-override
                path-limit megabits-per-second
```

The achievable capacity will be the minimum of the path's path-limit and the plane's per-mcast-plane-limit.

Ancillary Path

The ancillary path

The ancillary path allows managed multicast traffic to be forwarded through the switch fabric as unicast and so is not constrained to the path or plane capacities. This is achieved using ingress replication, in order to send a channel to multiple destination forwarding complexes (DFCs), the ingress forwarding complex creates and forwards one copy of each packet to each DFC connected to the switch fabric.

However, the total replication capacity available for the ancillary path is constrained to 5G to prevent it impacting the unicast or primary/secondary path capacities. This means that the total amount of ancillary

capacity usable can be calculated from (note that the first copy sent is not included in this capacity, hence the "-1"):

5Gbps/(number_of_switch_fabric_DFCs – 1)

Taking an example shown later, if some channels ingress an IOM2 and egress 2 IOM3-XP (1 DFC each) and 1 IMM8 (1 DFC) to give a total of 3 egress DFCs, then total ancillary capacity available is

5Gbps/(3-1) = 2.5Gbps.

This would allow, for example, approximately 250 channels at 10Mbps each to use the ancillary path.

Due to the relationship between ancillary capacity and number of DFCs, the system will prefer the ancillary path as default whenever a channel enters an IOM1/2 and egresses on up to 3 DFCs. If there are 4 or more egress DFCs for the channel, then the primary path is preferred. The determination is performed on a per channel basis.

The configuration parameters relating to the primary and secondary paths are also available for the ancillary path.

```
config# mcast-management bandwidth-policy policy-name create
    ancillary-path
        queue-parameters
            cbs percentage
            hi-priority-only percent-of-mbs
            mbs percentage

config# mcast-management bandwidth-policy policy-name create
    ancillary-path
        path-limit megabits-per-second

config# card slot-number mda mda-slot
    ingress
        mcast-path-management
            ancillary-override
                path-limit megabits-per-second
```

IOM1/2 Planes

The capacity per plane for managed traffic is by default 2Gbps for a primary path and 1.8Gbps for a secondary path. Note that the default IOM1/2 secondary path limit is 1.5Gbps. A maximum of 2Gbps should be configured for either path type using the per-mcast-plane-limit (as shown for the IOM3-XP/IMM) when an IOM1/2 is being used with IMPM.

As the ancillary path does not use the switch fabric planes, there is no associated plane limit.

IOM1/2 Path to Plane Mapping

The hi-bw-mcast-src command function is the same for IOM1/2 line cards as for IOM3-XP/IMM line cards, as described above.

IMPM Operation on IOM1/2

This is exactly the same as the operation as for the IOM3-XP/IMM, see above.

IMPM Not Enabled

When IMPM is not enabled most multipoint traffic on an IOM1/2 and IOM3-XP/IMM can use only one primary path and one secondary path per forwarding complex. When ingress multipoint arrives it is placed on a multipoint queue and these queues are connected either to a primary path (if the queue is expedited) or a secondary path (if the queue is best-effort) depending on the ingress QOS classification applied. Standard ingress forwarding class/scheduling prioritization is used.

The capacity of the primary and secondary paths is 2Gbps, unless the system is a 7750 SR-12 or 7450 ESS-12 populated with SF/CPM4(s) and 100G FP IMMs in which case the capacity is 4Gbps.

In Output 1 and Output 2, the primary path is associated with the left-most plane and the secondary path is associated with the right-most plane for each line card.

There are exceptions to the above on the IOM3-XP/IMM line cards for

- Point-to-multipoint LSP IP multicast traffic
- Policed ingress routed IP multicast or VPLS broadcast, unknown or multicast traffic

Point-to-Multipoint (P2MP) LSP IP Multicast Traffic

IMPM will manage traffic on a P2MP LSP for any IP multicast channel that is delivered locally, for example, the system is a bud LSR. However, non-managed P2MP LSP IP multicast traffic will also make use of the primary paths, regardless of whether IMPM is enabled or not.

For each primary queue created in the MC IMPM Path pool, an additional queue is created to carry non-managed P2MP LSP IP multicast traffic. The non-managed P2MP LSP IP multicast traffic is automatically distributed across all primary paths based on a modulo N function of the 10 least significant bits of channel destination group address, where N is the number of primary paths. Note that the number of primary paths can be changed with IMPM enabled or disabled by applying a bandwidth-policy which sets the number of secondary paths.

Policed Ingress Routed IP Multicast or VPLS Broadcast, Unknown Or Multicast Traffic

Routed IP multicast or VPLS broadcast, unknown or multicast traffic passing through ingress hardware policers on the IOM3-XP/IMM can also use the IMPM managed queues, with IMPM enabled or disabled. If this traffic is best-effort (forwarding classes BE, L2, AF, L1) it will use the secondary paths, if it is expedited (forwarding classes H2, EF, H1, NC) it will use the primary paths. Note that this traffic uses the shared ingress policer-output-queues which have a fixed forwarding class to queue mapping).

When IMPM is not enabled, this traffic is non-managed and 1 secondary path plus 15 primary paths are available (the default). Consequently, extra capacity is only available for the expedited traffic, which could use up to 15 planes worth of switch fabric capacity. If extra capacity is required for best-effort traffic, a bandwidth-policy allocating more secondary paths can applied to the line card even without IMPM being enabled.

The policed ingress routed IP or VPLS broadcast, unknown or multicast traffic is distributed across the paths using a standard LAG hash algorithm (as described in the Traffic Load Balancing Options section in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Guide*).

For both of these exceptions, it is recommended to reduce the managed traffic primary/secondary plane limits (using per-mcast-plane-limit) in order to allow for the non-managed traffic.

Show Output

This section includes the show output related to IMPM. The first part covers generic output and uses IOM3-XP/IMMs and chassis mode **d**. The second part includes an IOM2 and so uses chassis mode **a**.

IOM3-XP/IMM and Generic Output

The system has an IOM3-XP in slots 6 and 8, with an IMM8 is slot 7.

===============================================================================
*A:PE-1#
```

The channel is using the dynamic bandwidth activity measurement and the current bandwidth, last highest and second last highest rates are shown (which are the same as this traffic is from a traffic generator).

The Time remaining is the time remaining in the current falling-delay period. This is reset to the falling-delay every time the last highest bandwidth gets updated, when it reaches zero the value of last highest bandwidth will be replaced with second highest bandwidth and the second highest bandwidth will be set to the value of current bandwidth.

The Oper Admin Bw displays the value used for the admin-bw for this channel.

A subset of this information can be seen using this tools command.

```

*A:PE-1#
```

Now the system treats the channel as though it is using 12Mbps capacity even though its current rate has not changed.

If the rate is increased above the blackhole rate, the channel is blackholed and an alarm is generated.

```

*A:PE-1#
```

The output displayed above shows an alarm generated for a channel being blackholed due to the channel rate reaching the configured black-hole-rate. The example output below is an alarm for a channel being blackholed due to insufficient bandwidth being available to it.

```
7 2011/10/22 21:53:43.54 UTC MINOR: MCPATH #2001 Base No bandwidth available
"Channel (172.16.2.1,239.255.0.2) for vRtr instance 1 slot/cplx 6/1 has been blackholed."
```

Note that the following alarm relates to a dummy channel used to account for the unmanaged traffic. However, this traffic is never actually blackholed.

```
6 2011/10/21 00:27:58.00 UTC MINOR: MCPATH #2002 Base
"Channel (0.0.0.0,0.6.0.0) for unknown value (2) instance 0 slot/cplx 6/1 is no longer being
 blackholed."
```

Alarms are also generated when all paths of a given type reach certain thresholds.

For primary and secondary paths, the two path range limit thresholds are

- Full: less than 5% capacity is available

```
9 2011/10/24 22:53:27.02 UTC MINOR: MCPATH #2003 Base
"The available bandwidth on secondary path on slot/cplx 6/1 has reached its maximum limit."
```

- Not full: more than 10% of the path capacity is available.

```
10 2011/10/24 22:53:48.02 UTC MINOR: MCPATH #2004 Base
"The available bandwidth on secondary path on slot/cplx 6/1 is within range limits."
```

A maximum of one alarm is generated for each event (blackhole start/stop, path full/not full) within a 3 second period. So, for example, if multiple channels are blackholed within the same 3 second period only one alarm will be generated (for the first event).

The effect of using the hi-bw-mcast-src command is illustrated below. Firstly, line card 6 is configured into group 1.

```
*A:PE-1# configure card 6 fp hi-bw-mcast-src group 1 alarm
*A:PE-1# show system switch-fabric high-bandwidth-multicast

```

The plane assignment has not changed (though it is possible that the system could re-arrange the planes used by card 6) and there are still planes (0,1) shared between card 6 and card 8.

Now card 8 is configured into group 2 (note that IMPM is only enabled on card 6 here).

```
*A:PE-1# configure card 8 fp hi-bw-mcast-src group 2 alarm
*A:PE-1# show system switch-fabric high-bandwidth-multicast

*A:PE-1#
```

There are insufficient planes to allow each card/group to have dedicated planes. Planes 0 and 1 are still shared between cards 6 and 7, generating the associated alarms.

A common example of the use of the **hi-bw-mcast-src** command would be when cards 6 and 8 have uplink ports on which high bandwidth multicast channels could be received. It would be desired to have these cards use different planes. To achieve this, card 7 could be configured into group 1, as follows.

```
*A:PE-1# configure card 7 fp hi-bw-mcast-src group 1 alarm
*A:PE-1# show system switch-fabric high-bandwidth-multicast

*A:PE-1#
```

Now it can be seen that card 7 shares the same planes as card 6, but more importantly card 6 has no planes in common with card 8.

Note that when traffic is received on card 6, it will also be seen on the same plane (not path) on card 7. In the example below, traffic can be seen on plane 4 which is used by both cards 6 and 7, but only card 6 has non-zero InUseBW path capacity.

```
*A:PE-1# tools dump mcast-path-mgr cpm

Conclusion

This chapter has described the configuration of Ingress Multicast Path Management which optimizes IPv4 and IPv6 multicast capacity to achieve the maximum system-wide IP multicast throughput. It can be used for both routed IPv4/IPv6 and VPLS (IGMP and PIM) snooped IPv4 multicast groups, which usually relate to the distribution of IP TV channels.

IPoE Sessions

This chapter describes IPoE Sessions.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 13.0.R7.

IPoE sessions require a Routed CO environment with Enhanced Subscriber Management (ESM) enabled.

Overview

Definitions

Grouping a number of subscriber hosts with different IP stacks belonging to the same end user device in a single IPoE session simplifies operations; see Figure 94: IPoE Session.

In this way, IPoE sessions provide behavior similar to PPPoE sessions for authentication, mid-session changes, and accounting.

Figure 94: IPoE Session
The hosts (IP stacks) associated with a single IPoE session share ESM data, such as the subscriber ID, the sub-profile, the SLA profile, and so on. The shared ESM data is fetched and cached when the first host for that session connects: only a single authentication is needed. This requires ESM to be enabled; see the ESM basics chapter for more information.

An IPoE session can have one IPoEv4 host, up to two IPoEv6 wan hosts (one DHCPv6 host and a SLAAC host), and one IPoEv6 pd host. Hosts with the same SAP, MAC address, and optionally the same circuit ID (CID) or remote ID (RID), are grouped in a single IPoE session, using that combination as a key to the IPoE session data.

Authentication occurs when the first host for that IPoE session is created. Subsequent hosts belonging to the same IPoE session do not require additional authentication. For instantiating these subsequent hosts, SR OS uses the cached ESM data that was fetched while authenticating and instantiating the first host.

Mid-session changes are typically triggered by RADIUS CoA or Diameter Gx RAR messages, and automatically apply to all hosts associated with the IPoE session. A re-authentication could also lead to policy changes, but the changes are triggered through host renewal messages.

As well as queue instance and host accounting, RADIUS session accounting can be enabled for IPoE sessions. An accounting session identity (ASID) is created when an IPoE session is started.

An IPoE session is created when the first host is created, and the IPoE session is deleted when the last host is deleted. IPoE session creation is always protocol triggered. IPoE session deletion is triggered through protocol (DHCPv4, DHCPv6 release, or expiration of a lease) or through policy (idle-timeout, session-timeout, clear command, and so on).

IPoE sessions require the Routed CO model, and are supported on regular as well as on capture and managed SAPs.

Trigger Packets

Unlike PPP, where PPP sessions have clear and unique triggers that start (PADS) and stop (PADT) a PPP session, IPoE does not have unique triggers that start and stop an IPoE session.

IPoE sessions are created when the following trigger packets on ESM-enabled SAPs are received:

- DHCPv4 discover/request
- DHCPv6 solicit/request (native)
- DHCPv6 solicit/request (single relay)
- DHCPv6 solicit/request (double relay)
- Router Solicitation

No IPoE sessions are created on reception of ARP requests or CoA messages.

IPoE Session Key

The key to the IPoE session data is a combination of the SAP ID, the MAC address, and optionally the CID or the RID, as defined by the ipoe-session-policy:

```
configure
    subscriber-mgmt
        ipoe-session-policy <pol-name>
            session-key sap mac [cid] [rid]
```

The ipoe-session-policy name *default* is reserved for future use.

The CID and RID are mutually exclusive; see Figure 95: IPoE Session Key:

- The CID corresponds to DHCPv4 option 82, sub-option 1 (Circuit-ID) and to DHCPv6 option 18 (Interface-ID).

- The RID corresponds to DHCPv4 option 82, sub-option 2 (Remote-ID) and to DHCPv6 option 37 (the remote-id field of the Relay Agent Remote-ID, excluding the enterprise-number field).

Figure 95: IPoE Session Key
When an IPoE session trigger packet is received, the IPoE session key is validated, ensuring that no field is missing. For example, if the key requires the CID or RID, and a device connects without CID or RID, the IPoE session setup and the host setup fail. Therefore, the CID or RID should only be part of the key when all devices include this parameter in the trigger packets.

If no IPoE session exists for a session key derived from a trigger packet, an IPoE session is created. If an IPoE session exists, a new host is created and added to the existing IPoE session, on condition that the host type is compatible with the already associated host types.

IPoE Session Authentication

Authenticating IPoE sessions requires generic identification parameters, which must be supported in both IPv4 and IPv6, so some restrictions apply.

LUDB Authentication

When using an LUDB for IPoE session authentication, all of the host-identification criteria can be used, except for the following:

- Option 60 - DHCPv4 only

LUDB entries containing option 60 are ignored while scanning the LUDB for a matching entry.

AAA/RADIUS Authentication

When using AAA/RADIUS for IPoE session authentication, all username formats can be used, except for the following:

- dhcp-client-vendor-opts - DHCPv4 only

- mac-giaddr - DHCPv4 only

- ppp-user-name - PPP only

IPoE Session Creation

To ensure successful creation of an IPoE session, the following conditions must be met:

- the IPoE session key must be valid

- the session limits should not be exceeded

- an Accounting Session Identity (ASID) must be allocated

- the first ESM host must be successfully authenticated

Figure 96: IPoE Session Creation Flow shows the high-level flow of the IPoE session creation process. When a new trigger is received for an existing IPoE session, a new host is created and added to the session, on condition that the new host is compatible with the already associated hosts.

Figure 96: IPoE Session Creation Flow

- Trigger packet
- All fields available to build session-key? — N → Setup fail
- Y
- IPoE-session exists? — N → Init new IPoE session-state → Authenticate
- Y → Are we allowed to associate this host-type with this existing IPoE session — N → Setup fail
- Y → Min-auth-interval expired?
- Y → Authenticate
- N → Use session authentication data → Complete the subscriber setup
- Auth ok? — Y → Complete the subscriber setup
- N → Setup fail
- Session limits ok? — N → Associate host with IPoE session-state
- N → Setup fail

25643

Figure 97: IPoE Session Creation via AAA/RADIUS shows an example where a device initiates DHCPv6 first. The data fetched while authenticating this device through AAA/RADIUS is cached. When the same device (leading to the same key) later initiates DHCPv4, the cached IPoE session data can be used, so no further AAA/RADIUS access is needed. The sequence could also first initiate DHCPv4, then DHCPv6. The result would be the same.

Figure 97: IPoE Session Creation via AAA/RADIUS
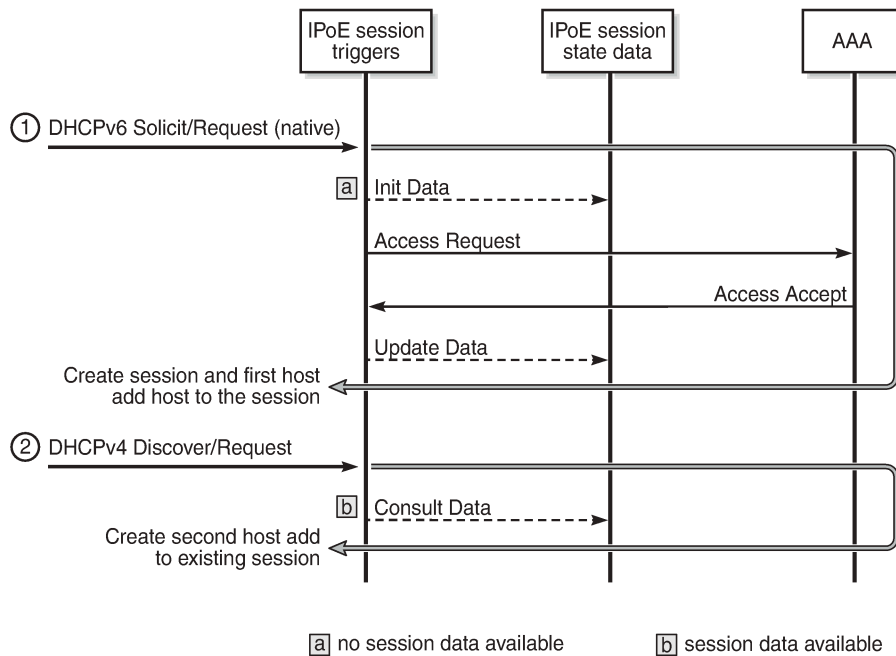

An Access-Request message is sent to the AAA/RADIUS server for authentication. On successful authentication, the AAA/RADIUS returns the ESM data (subscriber ID, sub-profile, SLA profile, and so on) in an Access-Accept message.

The Access-Request message optionally includes the host ID or ASID.

The behavior when authenticating through LUDB is similar.

IPoE Session Re-Authentication

IPoE sessions can be re-authenticated, meaning that the ESM data is fetched again from the ESM data source (LUDB, RADIUS, and so on), and controlled through the min-auth-interval timer.

If a host renewal packet is received while the min-auth-interval timer is running for the corresponding IPoE session, the cached ESM data is used (with one exception: see forced authentication). If a host renewal packet is received when this timer has expired, re-authentication is performed. If re-authentication fails, the host renewal packet is dropped; see Figure 96: IPoE Session Creation Flow.

IPoE session re-authentication is configured in the ipoe-session context using following command:

```
min-auth-interval ?
  - min-auth-interval [days <days>] [hrs <hours>] [min <minutes>] [sec <seconds>]
  - min-auth-interval infinite
  - no min-auth-interval
<days>             : [0..365]
<hours>            : [0..23]
<minutes>          : [0..59]
<seconds>          : [0..59]
<infinite>         : keyword
```

By default, re-authentication is disabled by having the min-auth-interval set to infinite. Setting the min-auth-interval to zero will lead to every single message (DORA, SARR) triggering re-authentication, but that is not recommended.

IPoE session re-authentication can be used to implement dynamic policy changes. For alternatives also implementing dynamic changes, see the Mid-Session Changes section.

For IPoE sessions, the re-authentication option in the RADIUS authentication-policy context is ignored.

IPoE Session Forced Authentication

Forced authentication means that the ESM data is fetched again from the ESM data source, regardless of the value of the re-authentication timer.

By default, forced authentication occurs when the CID or RID in the trigger packet has changed value, but this behavior can be disabled.

An absent or empty CID or RID is not considered as a change.

Forced authentication is configured in the ipoe-session context using following command:

```
force-auth ?
  - force-auth [cid-change] [rid-change]
  - force-auth disabled
  - no force-auth
<cid-change>          : keyword - ignore min-auth-interval when cid changed
<rid_change>          : keyword - ignore min-auth-interval when rid changed
<disabled>            : keyword - never ignore min-auth-interval
```

IPoE Session Deletion

When the last host associated with an IPoE session is deleted, the IPoE session is deleted.

IPoE sessions are forcibly deleted in following situations:

- group-interface ipoe-session shutdown

- clear service <id> ipoe-session

- session timeout

- RADIUS disconnect or Diameter Gx RAR

- Credit Control (out-of-credit)

In all these cases, all hosts belonging to that session are deleted, with one exception. When the SLAAC inactivity-timer expires, only the corresponding SLAAC host is deleted, not the remaining hosts. When this SLAAC host is the last host of the IPoE session, the IPoE session is deleted.

The IPoE session-timeout is configured in the ipoe-session-policy:

```
configure
    subscriber-mgmt
        ipoe-session-policy <pol-name>
            session-timeout <timeout>
```

The timeout value ranges from 1 to 31104000 seconds (360 days). By default, no session-timeout is specified.

When RADIUS or Diameter Gx returns the Session-Timeout [27] or the Alc-Relative-Session-Timeout [26-6527-160] attributes, these values are used and the behavior is the same as for PPP sessions.

When no Session-Timeout or Alc-Relative-Session-Timeout attribute is returned by RADIUS, the session-timeout as configured in the ipoe-session-policy is used.

A RADIUS disconnect message, even when targeted at a single host, will also lead to the deletion of the entire IPoE session including all associated hosts.

A shutdown in the ipoe-session context of the group interface results in the deletion of all its IPoE sessions and associated hosts.

Session and Host limits

The number of IPoE sessions on a group interface and on a SAP can be limited:

```
configure service ies|vprn <service-id>
  subscriber-interface <ip-int-name>
    group-interface <ip-int-name>
      ipoe-session
        session-limit     [1..max*]
        sap-session-limit [1..max*]
```

The default values for the session-limit and the sap-session-limit are unlimited (no session-limit) and 1, respectively.

For retail services, the IPoE session-limit is configured at the linked subscriber interface level:

```
configure service vprn <retail-service-id>
    subscriber-interface <RT-ip-int-name> fwd-service <WS-service-id>
                          fwd-subscriber-interface <WS-ip-int-name>
        session-limit     [1..max*]
```

The default session-limit is unlimited.

Additionally, host limits can be imposed through the SLA profile:

```
configure subscriber-mgmt
  sla-profile <subscriber-profile-name>
    host-limits
      ipv4-arp            - Maximum number of IPv4 ARP hosts
      ipv4-dhcp           - Maximum number of IPv4 DHCP hosts
      ipv4-overall        - Maximum number of IPv4 hosts
      ipv4-ppp            - Maximum number of IPv4 PPP hosts
      ipv6-overall        - Maximum number of IPv6 hosts
      ipv6-pd-ipoe-dhcp   - Maximum number of IPv6-PD IPOE DHCP hosts
      ipv6-pd-overall     - Maximum number of IPv6-PD hosts
      ipv6-pd-ppp-dhcp    - Maximum number of IPv6-PD PPP DHCP hosts
      ipv6-wan-ipoe-dhcp  - Maximum number of IPv6-Wan IPOE DHCP hosts
      ipv6-wan-ipoe-slaac - Maximum number of IPv6-Wan IPOE SLAAC hosts
      ipv6-wan-overall    - Maximum number of IPv6-Wan hosts
      ipv6-wan-ppp-dhcp   - Maximum number of IPv6-Wan PPP DHCP hosts
      ipv6-wan-ppp-slaac  - Maximum number of IPv6-Wan PPP SLAAC hosts
      lac-overall         - Maximum number of L2TP LAC hosts
      overall             - Maximum number of hosts
      remove-oldest       - Remove oldest
    exit
```

See the Wholesale/Retail section for more information about limits in a wholesale/retail configuration.

RADIUS Session Accounting

As well as queue instance and host accounting, RADIUS session accounting can be enabled for IPoE sessions.

Usually, a RADIUS Accounting-Start message is sent when the first host is associated with an IPoE session. Regular and triggered accounting Interim-Update messages are sent during the IPoE session. An Accounting-Stop message is sent when the last host is deleted from the session.

Session accounting is configured in the RADIUS accounting policy, and can be set to the following values:

- session-accounting
- session-accounting interim-update
- session-accounting host-update
- session-accounting interim-update host-update

Plain session accounting sends start and stop messages. The RADIUS accounting server is informed about the start and the stop time of the session, but no counters are maintained. This implements time-based accounting.

The interim-update option additionally sends interim-update messages, so that the RADIUS accounting server maintains counters. This implements volume accounting.

The host-update option additionally sends host up/down event messages, so that the RADIUS accounting server keeps track of host creation and deletion events.

The combination of the interim-update and host-update options allows the RADIUS accounting server to track all changes.

Mid-Session Changes

Mid-session changes, such as those initiated via RADIUS CoA or Diameter Gx RAR messages, are applied to all hosts associated with the IPoE session. There is no way to update a single host of an IPoE session.

A RADIUS CoA message targeting any host of an IPoE session has the same effect as a RADIUS CoA message targeting the IPoE session using the IPoE session Acct-Session-Id as key. All hosts of the session are targeted and the session state data is updated.

Mid-session changes also can be applied manually, using the following command:

```
# tools perform subscriber-mgmt edit-ipoe-session sap <sap-id> mac <mac-address> [subscriber
 <sub-ident-string>] [sub-profile-string <sub-profile-string>] [sla-profile-string <sla-
profile-string>] [inter-dest-id <intermediate-destination-id>] [ancp-string <ancp-string>]
 [app-profile-string <app-profile-string>] [circuit-id <circuit-id>] [remote-id <remote-id>]

# tools perform subscriber-mgmt eval-ipoe-session [svc-id <service-id>] [sap <sap-id>] [mac
 <mac-address>] [circuit-id <circuit-id>] [remote-id <remote-id>] [subscriber <sub-ident-
string>]
```

The tools commands eval-lease-state and eval-slaac-host are blocked when the host is part of a session.

IPoE session re-authentication can also lead to dynamic policy changes.

Subscriber Host Connectivity Verification

Subscriber host connectivity verification (SHCV) can be enabled for hosts associated with an IPoE session.

When a single host fails and stops responding to the SHCV messages, that host is deleted without affecting the other hosts that are part of the session. When the last host fails, the session is deleted.

IA-PD managed routes are not subject to SHCV, and cannot be removed because of SHCV.

Dual Homing

IPoE sessions are supported in a dual-homed environment, where Multichassis Synchronization (MCS) and Subscriber Routed Redundancy Protocol (SRRP) are active.

MCS ensures that the IPoE session data is synchronized between the BNG pair.

Wholesale/Retail

IPoE sessions are supported in single-homed and dual-homed wholesale/retail environments.

The wholesale IPoE session limit is configured at the group interface level, and the retail IPoE session limit is configured at the linked subscriber interface level:

```
configure service vprn <retail-service-id>
    subscriber-interface <RT-ip-int-name> fwd-service <WS-service-id>
                                fwd-subscriber-interface <WS-ip-int-name>
        ipoe-session
            session-limit    [1..max*]  #default unlimited
```

In IPoE, private-retail-subnets only apply to IPoEv6 in single-homed scenarios (no MCS). Therefore, the use cases for private-retail-subnets in combination with IPoE sessions are limited.

Practical Considerations

The rules for configuring authentication for regular, capture, and managed SAPs, also apply to IPoE sessions; see Figure 98: Configuring IPoE session authentication:

- If an authentication policy is applied at capture-SAP or group-interface level, this policy has priority, regardless of whether, or in which other sub-contexts, an LUDB is assigned. Therefore, for an LUDB to provide ESM data, no authentication policy may be applied at capture-SAP or group interface level.

- If an LUDB is applied in the ipoe-session context of a group interface or capture SAP, the LUDBs assigned in the dhcp, dhcp6, and router-solicit related contexts of the same group interface or capture SAP are ignored.

Figure 98: Configuring IPoE session authentication
When the AAA/RADIUS server referenced from the authentication policy is not available, SR OS can rely on a fallback LUDB, if configured; see the LUDB for ESM chapter for more information.

Be aware of the following:

- Static hosts can be configured on a group interface with IPoE sessions enabled. A static host will not be associated with an IPoE session.

- ARP hosts are not supported in an IPoE session and cannot be instantiated on a group interface with IPoE sessions enabled.

- Up to sixteen framed-routes and sixteen framed-IPv6-routes can be associated with an IPoE session.

- Python-based subscriber identification based on the DHCPv4 Ack message is ignored when IPoE sessions are enabled.

Configuration

Baseline configuration

Figure 99: Baseline configuration shows the baseline configuration used for the examples in this chapter, excluding the ipoe-session configurations. These will be added later in this chapter.

The first example uses LUDB authentication, and the second example uses AAA/RADIUS authentication. As alternatives, AAA/NASREQ authentication or AAA/Gx authentication can be used.

Figure 99: Baseline configuration
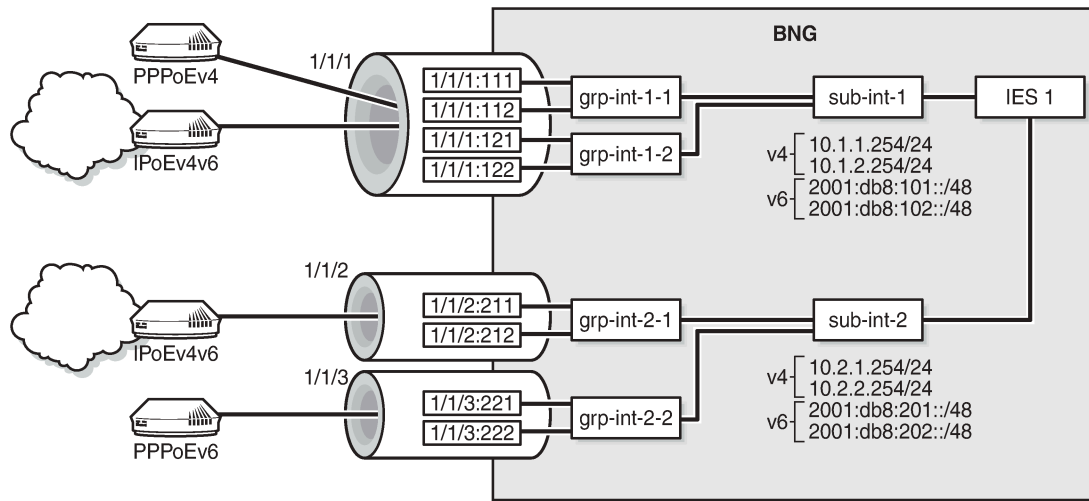

25645

The following partial configuration applies to IES-1. This service is provisioned with ESM on all of its
SAPs, and supports proxy and relay scenarios on all group interfaces for both IPv4 and IPv6. Only the part
relevant to subscriber interface *sub-int-1* and group interface *grp-int-1-1* is shown. The configurations for
the other subscriber and group interfaces are similar. See the ESM Basics and Routed CO chapters for
more information.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.1.1.254/24

                ipv6
                    client-application ipoe-slaac
                    server "dhcp6-srv"
                exit
                no shutdown
            exit
            arp-populate
            dhcp
                proxy-server
                    emulated-server 10.1.1.254
                    no shutdown
                exit
                server 10.11.11.1
                trusted
                lease-populate 1000
                client-applications dhcp ppp
                gi-address 10.1.1.254
                no shutdown
            exit
            ---snip---
            sap 1/1/1:111 create
                sub-sla-mgmt
                    def-sub-profile "sub-prof-1"
                    def-sla-profile "sla-prof-1"
                    sub-ident-policy "sub-id-pol-1"
                    multi-sub-sap
                    no shutdown
                exit
            exit
            ---snip---
```

No DHCPv4 or DHCPv6 relay options are defined.

Troubleshooting

The syntax to show the active IPoE sessions is as follows:

```
show service id <service-id> ipoe session ?
  - session [sap <sap-id>] [mac <ieee-address>] [circuit-id <circuit-id>] [remote-id <remote-
id>] [interface <ip-int-name|ip-address>] [inter-dest-id <intermediate-destination-id>] [no-
inter-dest-id] [ip-address <ip-prefix[/prefix-length]>] [port <port-id>] [subscriber <sub-
ident-string>] [sap-session-id <sap-session-index>] [wholesaler <service-id>]
  - session [sap <sap-id>] [mac <ieee-address>] [circuit-id <circuit-id>] [remote-id <remote-
id>] [interface <ip-int-name|ip-address>] [inter-dest-id <intermediate-destination-id>] [no-
inter-dest-id] [ip-address <ip-prefix[/prefix-length]>] [port <port-id>] [subscriber <sub-
ident-string>] [sap-session-id <sap-session-index>] detail [wholesaler <service-id>]
```

The following show commands have been extended, so that session filtering is available:

```
show service id <svc-id> dhcp lease-state ?
```

```
    - lease-state [wholesaler <service-id>] [sap <sap-id>|sdp <sdp-id:vc-id>|interface
   <interface-name>|ip-address <ip-address[/mask]>|chaddr <ieee-address>|mac <ieee-address>|
  {[port <port-id>] [no-inter-dest-id | inter-dest-id <inter-dest-id>]}] [session {none|ipoe}]
   [detail]

  show service id <svc-id> dhcp6 lease-state ?
    - lease-state [detail] [wholesaler <service-id>] [session {none|ipoe|ppp}]
    - lease-state [detail] interface <interface-name> [wholesaler <service-id>] [session {none|
  ipoe|ppp}]
    - lease-state [detail] ipv6-address <ipv6-prefix[/prefix-length]> [wholesaler <service-id>]
   [session {none|ipoe|ppp}]
    - lease-state [detail] mac <ieee-address> [wholesaler <service-id>] [session {none|ipoe|ppp}]

  show service id <svc-id> slaac host ?
    - host [detail] [wholesaler <service-id>] [session {none|ipoe|ppp}]
    - host interface <interface-name> [detail] [wholesaler <service-id>] [session {none|ipoe|
  ppp}]
    - host mac <ieee-address> [detail] [wholesaler <service-id>] [session {none|ipoe|ppp}]
    - host ipv6-address <ipv6-prefix> [detail] [wholesaler <service-id>] [session {none|ipoe|
  ppp}]
    - host sap <sap-id> [detail] [wholesaler <service-id>] [session {none|ipoe|ppp}]
```

The following debug configuration is used for demonstration and troubleshooting purposes:

```
debug
    router "Base"
        ip
            dhcp
                detail-level medium
                mode egr-ingr-and-dropped
            exit
            dhcp6
                mode egr-ingr-and-dropped
                detail-level medium
            exit
        exit
        radius
            packet-type authentication accounting coa
            detail-level medium
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-1"
            detail all
        exit
    exit
exit
```

IPoE session failure events are also issued to log-id 99:

```
*A:BNG-1# show log event-control "svcmgr"
=======================================================================

    ======================================================================
    *A:BNG-1#
```

IPoE Session Authentication through LUDB

The LUDB *ludb-1* uses the MAC address for host matching, and is defined as follows:

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            description "example user-db"
            ipoe
                match-list mac
                host "entry-01" create
                    host-identification
                        mac 00:00:00:00:00:01
                    exit
                    address pool "pool4-1"
                    identification-strings 254 create
                        subscriber-id "sub-11"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    ipv6-slaac-prefix-pool "pool6-1"
                    ipv6-wan-address-pool "pool6-1"
                    no shutdown
                exit
                ---snip---
```

This LUDB is then applied to the group interface in the ipoe-session context:

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    ipoe-session
                        description "ipoe-sessions with LUDB"
                        ipoe-session-policy "sespol-sap-mac"
                        sap-session-limit 100
                        session-limit 500
                        user-db "ludb-1"
                        no shutdown
                    exit
```

The LUDB applied in the ipoe-session context takes priority over LUDBs applied in the **dhcp router-solicit**, **ipv6 dhcpv6 router-solicit**, and **ipv6 router-solicit** contexts for a Layer 3 service.

The IPoE session policy sespol-sap-mac used in this example is defined as follows:

```
configure
    subscriber-mgmt
        ipoe-session-policy "sespol-sap-mac" create
            description "plain ipoe session policy, sap-mac key"
            session-key sap mac
            no session-timeout
        exit
```

Debug

The following debug trace appears when the user with MAC address 00:00:00:00:00:01 first connects using DHCPv4 and subsequently connects using SLAAC and DHCPv6 (IANA), without disconnecting DHCPv4.

Messages 1 through 9 show the message sequence for DHCPv4 (DORA). Messages 11 through 22 show the message sequence for DHCPv6 (SARR). Message 10 and 23 are the router solicitation and advertisement messages. Therefore, three hosts are created.

The LUDB is accessed just once; immediately after the DHCPv4 Discover message:

```

        [CircuitID] | [RemoteID]
-------------------------------------------------------------------------------
1/1/1:111                       00:00:00:00:00:01   0d 00:10:18
    sub-11
-------------------------------------------------------------------------------
CID | RID displayed when included in session-key
Number of sessions : 1
===============================================================================
*A:BNG-1#
```

The IPoE session details for MAC address 00:00:00:00:00:01 are shown using the following command.
The session time left is undefined (N/A), because no IPoE session-timeout is defined in the IPoE session
policy. Re-authentication does not apply, so the minimum authentication interval is infinite (N/A).

```
*A:BNG-1# show service id 1 ipoe session mac 00:00:00:00:00:01 detail
===============================================================================

```

IPoE Session Authentication through AAA/RADIUS

The FreeRADIUS server users file contains following data for the connecting device:

```
00:00:00:00:00:01    Cleartext-Password := "spasswd"
                     Alc-Subsc-ID-Str = "ipoe-%{User-name}",
                     Alc-Subsc-Prof-Str = "sub-prof-1",
                     Alc-SLA-Prof-Str = "sla-prof-1",
                     Framed-Pool = "pool4-1",
                     Framed-Ipv6-Pool = "pool6-1",
                     Alc-Delegated-IPv6-Pool = "pool6-1",
                     Alc-Relative-Session-Timeout = "300"
```

The authentication policy *radius-pol* used in this example is defined as follows:

```
configure
    subscriber-mgmt
        authentication-policy "radius-pol"
            password letmein
            include-radius-attribute
                acct-session-id
                circuit-id
                sap-session-index
            exit
            radius-server-policy "rsp-1"
        exit
```

The IPoE session policy used in this example is defined as follows. The key now also includes the circuit ID.

```
configure
    subscriber-mgmt
        ipoe-session-policy "sespol-sap-mac-cid" create
            description "key also including cid now"
            session-key sap mac cid
            no session-timeout
        exit
```

The authentication and IPoE session policies are then applied to the group interface *grp-int-1-1*:

```
configure
   service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    authentication-policy "radius-pol"
                    ipoe-session
                        ipoe-session-policy "sespol-sap-mac-cid"
                        sap-session-limit 100
                        session-limit 100
                        no shutdown
                    exit
```

The authentication policy takes precedence over any LUDB applied in one of the subcontexts of that group interface.

Debug

The following debug trace appears when the user with MAC address 00:00:00:00:00:01 first connects using DHCPv6 (IA_NA and IA_PD) and subsequently connects using DHCPv4.

The ESM data source is accessed just once, immediately after the DHCPv6 Solicit message. Because LDRA is active, the Solicit message is embedded in the Relay Forward message. The RADIUS server is sent an Access-Request message including the circuit ID, and returns an Access-Accept message including the Alc-Relative-Session-Timeout attribute (message 3). Message 14 is the final IPv6 Reply message containing both the IA_NA address and the IA_PD prefix used by the CPE. Messages 15 through 22 are the DHCPv4 DORA messages.

The initial DHCPv6 Solicit message and the initial DHCPv4 Discover message contain the same interface ID/CID (11), which is why no re-authentication is triggered. The IPoE session is deleted when the RADIUS-provided session timer expires, so the BNG releases both the IPv4 and the IPv6 address (messages 23 through 31).

```
*A:BNG-1# show service id 1 ipoe session detail
No entries found.
*A:BNG-1#
```

Conclusion

IPoE sessions offer ISPs a simplified way to manage dual-stack IPoE devices. IPoE sessions have features similar to PPP sessions, in terms of authentication, mid-session changes, and accounting. IPoE sessions can be used on regular, capture, and managed SAPs, and are supported in single- and dual-homed scenarios, including wholesale and retail configurations.

IPv4 DHCP Hosts

This chapter provides information about IPv4 DHCP host configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is related to the use of IPv4 only, and was originally written for and tested on Release 7.0.R6. The CLI now corresponds to Release 16.0.R6.

Configuration and troubleshooting commands are given for Bridged CO and Routed CO scenarios.

In the Triple Play Service Delivery Architecture (TPSDA), a subscriber is defined as a collection of hosts pertaining to a single access connection (such as a DSL line) and identified by a subscriber identifier. A subscriber host is an end user terminal within the subscriber home (for example, a PC, set-top box, home gateway) that is identified in the network with a unique (IP address; MAC address) tuple for IPoE or (PPPoE session ID; MAC address) tuple for PPPoE.

Following IPv4 host types are distinguished:

- Static hosts
  - ip-mac
  - ip-only
- Dynamic hosts
  - ARP-host
  - DHCP-host
  - PPPoE-host

This chapter provides configuration and troubleshooting commands for DHCP-hosts.

Overview

Knowledge of the Triple Play Service Delivery Architecture (TPSDA) concepts is assumed throughout this document.

The network topology for a Bridged CO environment is displayed in Figure 100: Bridged CO Network Topology and for a Routed CO environment in Figure 101: Routed CO Network Topology.

Figure 100: Bridged CO Network Topology
Figure 101: Routed CO Network Topology
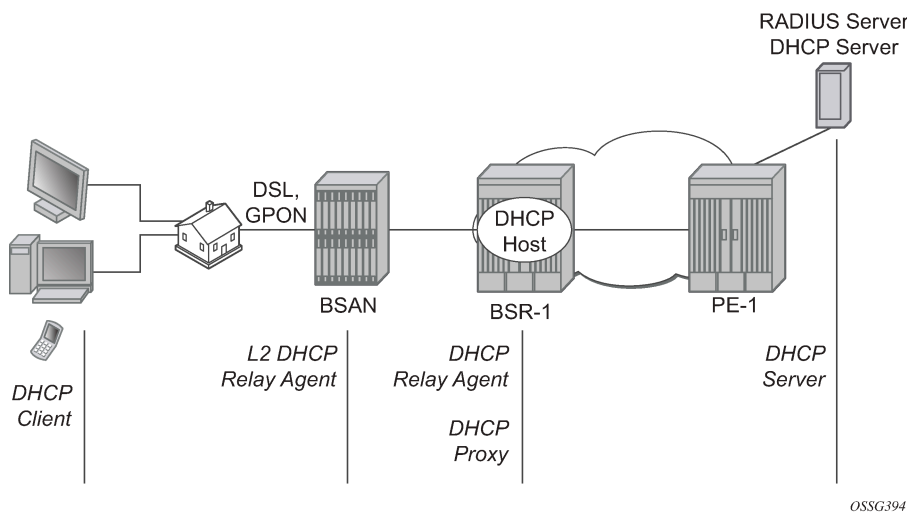

Following configuration tasks should be done first and are not detailed in this configuration note:

- Basic service router configurations such as system interface, IGP (ISIS or OSPF), MPLS, BGP.
- Bridged CO service topology: VPLS on BSA-1, terminated in a VPRN or IES service on BSR-1.
- Routed CO service topology: VPRN or IES service with subscriber and group interface on BSR-1.
- External DHCP server: server configuration and connectivity in the VPRN or base router instance.
- External RADIUS server: server configuration and connectivity in the VPRN or base router instance (Enhanced Subscriber Management (ESM) only).

This chapter focuses on DHCP hosts instantiated in a VPLS service on BSA-1 (Bridged CO) or in a VPRN service subscriber interface on BSR-1 (Routed CO). Note that in case of Routed CO, it is also possible to instantiate the DHCP hosts in the base routing instance using an IES service.

Most of the DHCP host functionality is available with Basic Subscriber Management (BSM). When ESM is required, it is explicitly stated.

Review of the DHCP Protocol

The DHCP protocol is used by a DHCP server to dynamically assign IP addresses and other optional configuration parameters on request of DHCP clients. These parameters are leased by the DHCP server for a duration specified by the lease time.

The DHCP lease process is outlined in Figure 102: DHCP Lease Process.

When a DHCP client boots, a DHCP discover message is broadcast on the local subnet (dest-ip = 255.255.255.255).

A DHCP server in the local subnet responds with a unicast DHCP offer message containing the *your ip address* field as well as other configuration parameters in the option fields (such as subnet mask, default gateway, DNS server IP addresses, lease time, etc.).

The DHCP client responds with a DHCP request message to accept the parameters specified in the DHCP offer. The DHCP request is also broadcast on the local subnet.

The DHCP server acknowledges the DHCP request with a unicast DHCP ack message.

Figure 102: DHCP Lease Process
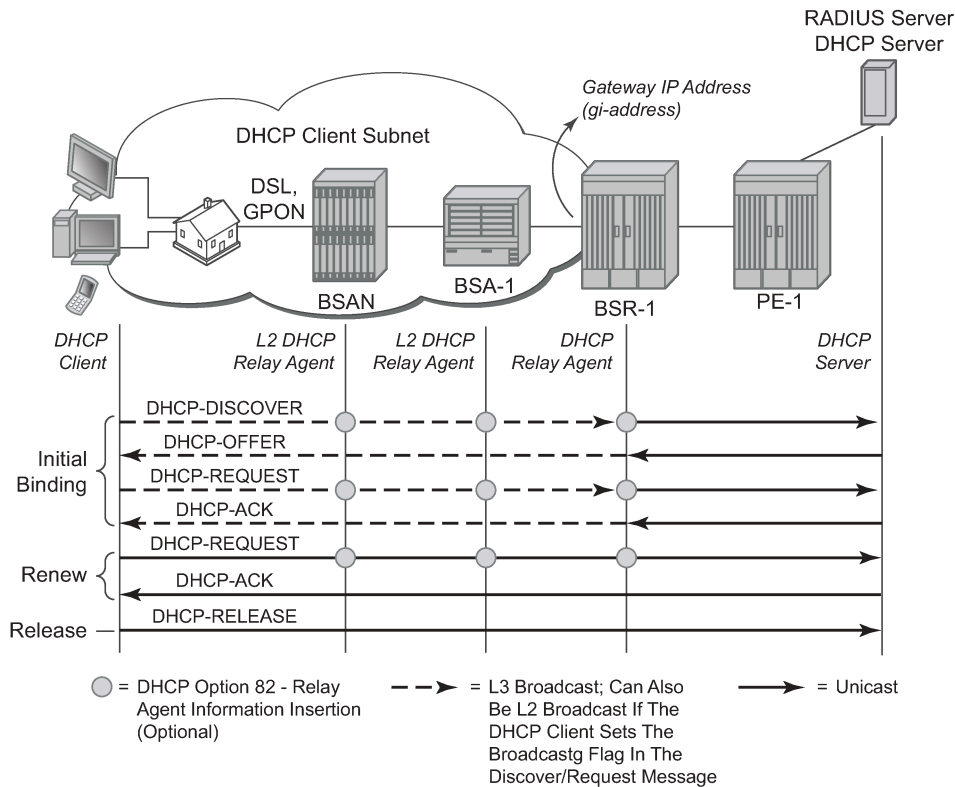

When the DHCP client receives a DHCP ack from the server, it is said to be in the bound state.

When half of the lease time has expired, the DHCP client tries to renew the lease. It will send a unicast DHCP request message to the DHCP server. The DHCP server will reply to the request with a unicast DHCP ack to the client.

If the renew failed, a rebind is attempted by default at 7/8 of the lease time. It will send a broadcast DHCP request message.

Before disconnecting from the local subnet, a DHCP client may return its lease by sending a DHCP release message to the DHCP server.

In case no DHCP server is present in the subnet of the DHCP client, a DHCP relay agent is needed to forward the broadcast DHCP discover/request messages on behalf of the DHCP client to a DHCP server located on a different subnet. The DHCP relay agent will add the gateway IP address field to the messages and send them as unicast to the DHCP server IP address. The DHCP server in this case will respond to the DHCP relay agent using a unicast frame. The DHCP relay agent forwards the DHCP server messages in broadcast frames on the DHCP client subnet.

Configuration

DHCP Snooping

DHCP client originated messages (discover, request, release) must be snooped (intercepted and sent to the control plane for further processing) to enable DHCP Option 82 insertion, authentication through local user database (LUDB), AAA/RADIUS or AAA/Diameter, and releasing the DHCP host session state.

For Bridged CO, DHCP snooping must be enabled explicitly on the subscriber SAP:

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            ---snip---
            sap 1/1/3:1 split-horizon-group "rshg-1" create
                description "sub-1"
                dhcp
                    snoop
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

DHCP server originated messages (offer, ack, nak, etc.) must be snooped to enable DHCP Option 82 removal, lease state population and/or ESM functions.

For Bridged CO, DHCP snooping must be enabled explicitly on all SDPs and/or SAPs that should provide connectivity to the DHCP server:

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            ---snip---
            spoke-sdp 1:1 create
                dhcp
                    snoop
                exit
                no shutdown
            exit
        exit
    exit
exit
```

For Routed CO, DHCP snooping is implicitly enabled by configuring a DHCP relay agent (DHCP Relay Agent): All DHCP messages received on a routed network interface will be snooped, that is, they are intercepted and sent to the control plane for further processing.

DHCP Relay Agent

For Bridged CO, the DHCP relay agent function is configured in the IP edge (BSR), at the regular interface level:

```
# Bridged CO @ BSR-1
configure
    service
        vprn 1
            ---snip---
            interface "int-BSA1-p2mp-1" create
                description "Bridged CO"
                address 10.1.0.254/16
                dhcp
                    server 172.16.0.1
                    trusted
                    gi-address 10.1.0.254
                    no shutdown
                exit
                ---snip---
                ip-mtu 1500
                spoke-sdp 1:1 create
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

For Routed CO, the DHCP relay agent function must be configured at BSR-1 group-interface level where the DHCP host will be instantiated:

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            ---snip---
            subscriber-interface "sub-int-1" create
                description "Routed CO"
                address 10.2.0.254/16
                group-interface "group-int-1" create
                    ---snip---
                    dhcp
                        server 172.16.0.1
                        trusted
                        ---snip---
                        gi-address 10.2.0.254
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

The **server** command defines the IP address of the DHCP server and must be reachable in the same routing instance as where the (subscriber-)interface is defined.

The **trusted** command makes the interface a trusted interface and enables Option 82 insertion by a Layer 2 DHCP relay agent (see DHCP Options (Relay Agent Information)).

The **gi-address** must be a locally configured IP address on the (subscriber-) interface. By default the DHCP messages relayed to the DHCP server use the outgoing interface IP address as source IP address. By specifying the optional **src-ip-addr** flag, the configured gi-address is used as the source IP address:

CLI Syntax:

```
— gi-address 10.2.0.254 src-ip-addr
```

A Layer 2 DHCP relay agent (such as BSAN or BSA) can add DHCP Option 82 information and leave the gi-address field to 0.0.0.0. The gi-address is the gateway IP address, filled in by the DHCP relay agent. An incoming DHCP discover with Option 82 present and gi-address field = 0.0.0.0 will be dropped by the DHCP relay agent according the RFC. The Rx Untrusted Packets and client Packets Discarded counters are increased in the DHCP statistics.

Output from DHCP debug log on BSR-1:

```
158 2019/04/09 14:44:32.78 CET MINOR: DEBUG #2001 vprn1 PIP
"PIP: DHCP
instance 2 (1), interface index 4 (group-int-1),
   DROPPED DHCP Boot Request on Interface group-int-1 (1/1/3:1) Port 67
   Problem: message is received from an untrusted client
```

Therefore, the DHCP relay agent should be configured as trusted to allow DHCP Option 82 insertion by a Layer 2 DHCP relay agent.

DHCP Options (Relay Agent Information)

In Bridged CO, when DHCP snooping is enabled on a VPLS SAP, DHCP Option 82 relay agent information can be altered or added on an incoming DHCP discover/request. This is referred to as a Layer 2 DHCP relay agent function.

In Routed CO, a DHCP relay agent can alter or add the DHCP Option 82 relay agent information on an incoming DHCP discover/request.

Supported DHCP Option 82 sub-options and their format are listed in Table 24: Supported DHCP Option 82 Sub-Options:

Table 24: Supported DHCP Option 82 Sub-Options

Option 82 Sub-Option	Format	Example
Opt82 [1] Circuit ID (Routed CO)	ifindex — 32 bit virtual router ID followed by a 32 bit ifindex in hex	00 00 00 02 00 00 00 04
	sap-id [sap id in ascii]	1/1/3:1
	ascii-tuple [system-name|service-id|group-interface|sap-id]	
	vlan-ascii-tuple [system-name|service-id|group-interface|dot1p|vlan-id]	"BSR-1|1|group-int-1|0|1"
Opt82 [1] Circuit ID (Bridged CO)	ascii-tuple [system-name|service-id|sap-id]	"BSA-1|1|1/1/2:1"

Option 82 Sub-Option	Format	Example
	vlan-ascii-tuple [system-name|service-id|sap-id |dot1p|vlan-id]	"BSA-1|1|1/1/2:1|0|1"
Opt82 [2] Remote ID (Bridged and Routed CO)	MAC [client hw address in hex]	fe fd 00 02 45 00
	string (max. 32 chars)	"Opt-82 [2] – Remote ID"
Opt82 [9] Vendor Specific (Bridged and Routed CO)	[1] system-id [hostname in ascii]	"BSA-1" or "BSR-1"
	[2] client-mac-address [client hw address in hex]	fe fd 00 02 45 00
	[3] service-id	1
	[4] sap-id [sap id in ascii]	"1/1/2:1"
	[5] string (max. 32 chars)	"Opt-82 [9] [5] – string"
Opt82 [9] Vendor Specific (Routed CO)	[13] pool-name [dhcp pool name from Radius/ Local User DB in ascii	"dhcp-pool-1"

> **Note:**
> The application for the Option 82 Circuit-ID vlan-ascii-tuple format is to preserve the Dot1p marking of DHCP packets in the downstream direction (DHCP server to client). The dot1p value of the incoming DHCP discover/request is recorded as part of the Option 82 Circuit ID. The outgoing DHCP offer/ack packets are then marked with the Dot1p value found as part of the Circuit ID echoed by the DHCP server.

Following actions can be taken on incoming DHCP discover/request:

- replace
- drop
- keep (default)

Replace

At ingress:

If present, remove all the Option 82 information from the incoming DHCP discover/request. Insert the configured DHCP options before forwarding to the DHCP relay agent or DHCP server.

At egress:

Remove all Option 82 information from the incoming DHCP offer/ack before forwarding to the client.

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            ---snip---
            sap 1/1/3:1 split-horizon-group "rshg-1" create
                description "sub-1"
                dhcp
                    snoop
                    option
                        action replace
```

```
                              remote-id string "Opt-82 [2] - Remote ID"
                              vendor-specific-option
                                  system-id
                                  client-mac-address
                                  service-id

                        option
                            action replace
                            circuit-id
                            remote-id string "Opt-82 [2] Remote-ID"
                            vendor-specific-option
                                system-id
                                client-mac-address
                                pool-name
                                service-id
                                sap-id
                                string "Opt-82 [9][5] string"
                            exit
                        exit
                        server 172.16.0.1
                        trusted
                        ---snip---
                        gi-address 10.2.0.254
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

Drop

Drop all incoming DHCP discover/request with Option 82 information present.

Incoming DHCP discover/request without Option 82 information will be forwarded to (Bridged CO) or processed by (Routed CO) the DHCP relay agent as is, ignoring the configured options.

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
```

```
                ---snip---
                    sap 1/1/3:1 split-horizon-group "rshg-1" create
                    description "sub-1"
                    dhcp
                        snoop
                        option
                            action drop
                        exit
                    exit
                exit
            exit
        exit
exit
```

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            ---snip---
            subscriber-interface "sub-int-1" create
                description "Routed CO"
                address 10.2.0.254/16
                group-interface "group-int-1" create
                    ---snip---
                    dhcp
                        option
                            action drop
                        exit
                        server 172.16.0.1
                        trusted
                        gi-address 10.2.0.254
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

The output from the DHCP debug log on BSA-1 and BSR-1 is as follows:

```
# Bridged CO @ BSA-1

343 2019/04/10 10:39:28.811 CEST MINOR: DEBUG #2001 Base SVCMGR
"SVCMGR: Dropped DHCP Packet
   VPLS 1, SAP 1/1/3:1

   Problem: port config doesn't allow BOOTP/DHCP packets with option 82
```

```
# Routed CO @ BSR-1

730 2019/04/10 10:42:58.978 CEST MINOR: DEBUG #2001 vprn1 PIP
"PIP: DHCP
instance 2 (1), interface index 6 (group-int-1),
   DROPPED DHCP Boot Request on Interface group-int-1 (1/1/3:1) Port 67
   Problem: action drop is configured and packet contains option 82
```

The Clients Packets Dropped counter is increased in the DHCP statistics:

```
*A:BSA-1# show service id 1 dhcp statistics
```

```

Keep (Default)

At ingress: Incoming DHCP discover/request without Option 82 information will be forwarded to (Bridged CO) or processed by (Routed CO) the DHCP relay agent as is, ignoring any configured option.

At ingress for incoming DHCP discover/request with Option 82 information present. Configured vendor specific options will be merged with the existing Option 82 information before sending to (Routed CO) or processing by (Routed CO) the DHCP relay agent. Configured Circuit ID and Remote ID options will be ignored.

At egress: Remove Option 82 vendor specific information from the incoming DHCP offer/ack before forwarding to the client. Other existing DHCP Option 82 information is retained.

DHCP Lease State

The DHCP lease state table keeps track of the DHCP host states. The DHCP lease state table enables subscriber management functions (per-subscriber QoS and accounting) and security functions (dynamic anti-spoof filtering) on the DHCP host.

The DHCP lease information for a specific host is extracted from the DHCP ack message.

Table 25: Information in DHCP Lease State displays some information stored in the DHCP lease state. The table does not display all information: additional data is added for managed SAPs, DHCPv6, etc.

Table 25: Information in DHCP Lease State

Parameter	Comment
Service ID	Service where the DHCP host is connected
IP Address	IP address of the DHCP host
Client HW Address	Ethernet MAC address of the DHCP host
Subscriber-interface	Subscriber interface name where the DHCP host is instantiated

Parameter	Comment
(Routed CO only)	
Group-interface (Routed CO only)	Group interface name where the DHCP host is instantiated
SAP	SAP where the DHCP hosts is connected
Up Time	The DHCPv4 host uptime
Remaining Lease Time	The time remaining before the lease expires
Remaining SessionTime	The time remaining before the DHCPv4 host is deleted from the system (updated each time a DHCP renew/rebind occurs)
Persistence Key	Lookup key for this host in the persistency file (see further)
Sub-Ident	ESM: Subscriber ID of the DHCP host
Sub-Profile-String	ESM: Subscriber profile string of the DHCP host
SLA-Profile-String	ESM: SLA profile string of the DHCP host
App-Profile-String	ESM: Application profile string of the DHCP host
Lease ANCP-String	ESM: ANCP string for this DHCP host
Lease Int Dest Id	ESM: Internal destination ID for this DHCP host
Category-Map-Name	ESM: Volume and Time based accounting
Lease Info origin	ESM: Origin for the IP configuration for this host (None, DHCP, RADIUS, etc.)
Ip-Netmask	The IP netmask for this DHCP host
Broadcast-Ip-Addr	The broadcast IP address for this host
Default-Router	The default gateway for this host
Primary-Dns	The primary DNS server for this host
Secondary-Dns	The secondary DNS server for this host
Primary-Nbns	The primary NetBIOS name server for this host
Secondary-Nbns	The secondary NetBIOS name server for this host
ServerLeaseStart	Time and date that the lease for this host started (first DHCP ack received)
ServerLastRenew	Time and date that the lease for this host was last renewed
ServerLeaseEnd	Time and date that the lease for this host will expire
Session-Timeout	The DHCPv4 is deleted when its uptime reaches this value

Parameter	Comment
IPoE|PPP session	Indication if this lease belongs to an IPoE or PPP session, or to no session
Lease-Time	The lease time specified by the DHCPv4 server
DHCP Server Addr	IP address of the DHCP server that allocated the lease for this host
Circuit Id	DHCP Relay Agent information Option 82 Circuit ID content
Remote Id	DHCP Relay Agent information Option 82 Remote ID content
RADIUS User-Name	ESM: Username used in the RADIUS authentication access request

For Bridged CO, the DHCP lease state table can only be populated through explicit configuration with the **lease-populate** command. The number of leases allowed on the VPLS SAP must be specified. When omitted, a single DHCP host is allowed per SAP.

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            ---snip---
            sap 1/1/3:1 split-horizon-group "rshg-1" create
                description "sub-1"
                dhcp
                    snoop
                    lease-populate 10
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

For Routed CO, DHCP lease state table population is enabled by default on a group interface with DHCP configured as **no shutdown**. The number of leases allowed on each SAP of the group-interface must be configured (by default a single DHCP host is allowed on each SAP):

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            ---snip---
            subscriber-interface "sub-int-1" create
                description "Routed CO"
                address 10.2.0.254/16
                group-interface "group-int-1" create
                    dhcp
                        server 172.16.0.1
                        trusted
                        lease-populate 10
                        gi-address 10.2.0.254
                        no shutdown
                    exit
                exit
            exit
        exit
```

```
     exit
exit
```

To check the DHCP lease state for a particular service, use the **show service id** *<service-id>* **dhcp lease-state** command. Detailed output as well as additional output filtering is available:

```
*A:BSA-1# show service id 1 dhcp lease-state ?
  - lease-state [wholesaler <service-id>] [sap <sap-id>|sdp <sdp-id:vc-id>|interface
 <interface-name>|ip-address <ip-address[/mask]>|chaddr <ieee-address>|mac <ieee-address>|
{[port <port-id>] [no-inter-dest-id | inter-dest-id <inter-dest-id>]}] [session {none|ipoe}]
 [detail]
```

```
A:BSR-1# show service id 1 dhcp lease-state ?

```

DHCP Host Session: Set-up, Operation and Release

Snooping the DHCP communication between a DHCP client and a DHCP relay agent/server facilitates the DHCP host instantiation: Upon the reception of a DHCP ack message from the server, the DHCP lease state table is populated. With ESM enabled, a DHCP host is also instantiated. The DHCP host will appear in the subscriber-host table for the service with origin set to DHCP.

```
*A:BSA-1# show service id 1 subscriber-hosts
```

```
==========================================================
Subscriber Host table
==========================================================
Sap                    Subscriber

---------------------------------------------------------------------------------

---------------------------------------------------------------------------------
Number of active subscribers : 1
=================================================================================
*A:BSR-1#
```

Troubleshooting the DHCP session set-up is done with DHCP debugging:

```
*A:BSA-1# debug service id 1 dhcp ?
  - dhcp
  - no dhcp
```

```
  [no] detail-level   - Configure the DHCP tracing detail level
  [no] mac            - Show DHCP packets for a particular MAC address
  [no] mode           - Configure the DHCP tracing mode
  [no] sap            - Show DHCP packets for a particular SAP
  [no] sdp            - Show DHCP packets for a particular SDP

 *A:BSA-1#
```

```
 *A:BSR-1# debug router 1 ip dhcp ?
  - dhcp [interface <ip-int-name>]
  - dhcp mac <ieee-address>
  - dhcp sap <sap-id>
  - no dhcp [interface <ip-int-name>]
  - no dhcp mac <ieee-address>
  - no dhcp sap <sap-id>

  ---snip---

 *A:BSR-1#
```

For example:

```
 *A:BSA-1# show debug
 debug
     service
         id 1
             dhcp
                 mode egr-ingr-and-dropped
                 detail-level medium
             exit
         exit
     exit
 exit
 *A:BSA-1#
```

```
 *A:BSR-1# show debug
 debug
     router "1"
         ip
             dhcp
                 detail-level medium
                 mode egr-ingr-and-dropped
             exit
         exit
     exit
 exit
 *A:BSR-1#
```

The example above will log all DHCP packets on the service. When thousands of DHCP hosts are active, fine grained filtering is required: for example look only to dropped packets or look only to packets from a particular MAC address.

To display the debugging information, a dedicated log should be created:

```
 configure
     log
         log-id 1
             description "Send debug log to a buffer in memory"
             from debug-trace
             to memory
```

```
            no shutdown
        exit
    exit
exit
```

The following shows a sample DHCP debug log output (detail-level medium) on BSA-1:

```
77 2019/04/09 13:58:20.022 CEST MINOR: DEBUG #2001 Base SVCMGR
"SVCMGR: RX DHCP Packet
   VPLS 1, spoke-sdp 1:1

   BootReply to UDP port 68
   ciaddr: 0.0.0.0             yiaddr: 10.1.0.102
   siaddr: 172.16.0.1         giaddr: 10.1.0.254
   chaddr: 00:00:00:22:22:22    xid: 0x7

   DHCP options:
   [53] Message type: Ack
   [54] DHCP server addr: 172.16.0.1
   [51] Lease time: 43200
   [1] Subnet mask: 255.255.0.0
   [3] Router: 10.1.0.254
   [58] Renew timeout: 21600
   [59] Rebind timeout: 37800
   [28] Broadcast addr: 10.1.255.255
   [255] End
"
```

During the lifespan of a DHCP host, the DHCP lease state is updated in the system: for example, the remaining lifetime changes after a DHCP renew. To check the lease details from the DHCP host during its lifespan, consult the DHCP lease state details:

```
*A:BSA-1# show service id 1 dhcp lease-state detail

===============================================================================
DHCP lease states for service 1
===============================================================================
Service ID          : 1

-------------------------------------------------------------------------------
Number of lease states : 1
===============================================================================
*A:BSA-1#
```

If the remaining lifetime timer expires before the DHCP session is renewed or rebound, the DHCP lease state is cleared. If ESM is enabled, the DHCP host is removed from the system.

A DHCP host can be manually deleted from the system using following clear command:

```
*A:BSA-1# clear service id 1 dhcp lease-state ?
  - lease-state all [no-dhcp-release]
  - lease-state [port <port-id>] inter-dest-id <intermediate-destination-id>
                                              [no-dhcp-release]
  - lease-state [port <port-id>] no-inter-dest-id [no-dhcp-release]
  - lease-state ip-address <ip-address[/mask]> [no-dhcp-release]
  - lease-state mac <ieee-address> [no-dhcp-release]
  - lease-state port <port-id> [no-dhcp-release]
  - lease-state sap <sap-id> [no-dhcp-release]
  - lease-state sdp <sdp-id:vc-id> [no-dhcp-release]

---snip---

*A:BSA-1# clear service id 1 dhcp lease-state ip-address 10.1.0.100
```

The DHCP lease state is deleted with all related state (such as, anti-spoof filter, ARP table entry). If ESM is enabled, the DHCP host is removed from the system. Optionally, a DHCP release is sent to the DHCP server to notify that the IP address can be released. This is reflected in the DHCP statistics in the DHCP RELEASEs Spoofed counter. Use the **no-dhcp-release** flag in the clear command if no DHCP release is to be sent when issuing the **clear** command.

To display a summary overview of the DHCP configuration on a particular service:

```
*A:BSA-1# show service id 1 dhcp summary

=======================================================================
DHCP Summary, service 1

```

DHCP Hosts Advanced Topics

High Availability

The DHCP lease state supports High Availability (HA): the lease state table is synchronized to the standby CPM. When the active CPM fails, all DHCP hosts stay active without service interruption.

DHCP Lease State Persistency

A DHCP session does not have a keep-alive mechanism to detect unavailability. A new DHCP session set up is only attempted after expiration of the DHCP lease time. A node reboot causing the loss of DHCP lease state and the corresponding anti-spoof filters could therefore result in unacceptable long service outages.

The DHCP lease state can be made persistent across node reboots: DHCP lease state is restored from a persistency file stored on the compact flash file system. As a result, DHCP sessions will only loose connectivity during the time of reboot without being completely disconnected.

To activate the DHCP lease state persistency:

```
configure
    system
        persistence
            subscriber-mgmt
                description "DCHP lease state persistency"
                location cf3:
            exit
        exit
    exit
exit
```

A dedicated persistency file will be created on the specified compact flash file system. The file is initialized to store the maximum number of allowed hosts; its size is constant to avoid file system space problems during operations.

```
*A:BSA-1# file dir cf3:\sub*
Volume in drive cf3 on slot A is SROS VM.
Volume in drive cf3 on slot A is formatted as FAT32
Directory of cf3:
04/10/2019  08:25a             536871424 submgmt.012
04/10/2019  08:25a              12583424 submgmt.i12
               2 File(s)             549454848 bytes.
               0 Dir(s)              330903552 bytes free.
```

```
*A:BSA-1#
```

Each time a DHCP ack is received from the DHCP server, the persistency file is updated together with
the lease state. If the file update fails, an event is generated to indicate that persistency can not be
guaranteed.

The content of the persistency file may vary between different SR OS software releases. When upgrading,
the persistency file is automatically upgraded to the new format. To downgrade the persistency file to a
lower SR OS release version, use the following command:

```
*A:BSA-1# tools perform persistence downgrade ?
  - downgrade target-version <target> [reboot]
 <target>             : the version you want to downgrade to
                         submgt
                          14.0 (current) - cf3:\submgmt.012
                          13.0            - cf3:\submgmt.011
                          12.0            - cf3:\submgmt.010
                          11.0            - cf3:\submgmt.009
                          10.0            - cf3:\submgmt.008
                          9.0             - cf3:\submgmt.007
                          8.0             - cf3:\submgmt.006
                          7.0             - cf3:\submgmt.005
                          6.0             - cf3:\submgmt.004
                          5.0             - cf3:\submgmt.003
                          4.0             - cf3:\submgmt.pst
 <reboot>             : reboot system after successful conversion
```

The content of the persistency file can be looked at using the following command:

```
*A:BSA-1# show service id 1 dhcp lease-state mac 00:00:00:11:11:11 detail

Limiting the Number of DHCP Hosts

Lease populate limit

The maximum number of DHCP lease state entries for a VPLS SAP, for an IES/VPRN interface or for each SAP on an IES/VPRN group-interface is defined when enabling the lease-populate. When omitted, a single DHCP host is allowed:

```
configure
    service
        vpls 1
            ---snip---
            sap 1/1/3:2 split-horizon-group "rshg-1" create
                description "sub-1"
                dhcp
                    snoop
                    lease-populate 1
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

When trying to instantiate a new DHCP host while the configured number of leases is reached, the DHCP ack is dropped (DHCP debug log output):

```
110 2019/04/09 16:25:03.030 CEST MINOR: DEBUG #2001 Base SVCMGR
```

```
"SVCMGR: Dropped DHCP Packet
   VPLS 1, spoke-sdp 1:1

   Problem: lease-populate limit (1) exceeded on SAP 1/1/3:2
```

The following event is generated (log-id 99):

```
95 2019/04/09 16:26:33.871 CEST WARNING: DHCP #2002 Base Maximum number of lease states
"Lease state for (CiAddr = 10.1.0.102, ChAddr = 00:00:00:22:22:22, leaseTime = 43200)
was notstored because the number of DHCP lease states on SAP 1/1/3:2 in service 1 has
reached its upper limit"
```

With ESM enabled, the following additional limits apply:

- sla-profile host-limits

- multi-sub-sap limit

SLA-profile host limits

TheSLA-profile contains host limits defining the maximum number of dynamic subscriber hosts per
subscriber for this sla-profile. Static hosts are not counted in the host-limits.

```
*A:BSA-1>config>subscr-mgmt>sla-prof# host-limits ?
  - host-limits
  - no host-limits

 [no] ipv4-arp       - Maximum number of IPv4 ARP hosts
 [no] ipv4-dhcp      - Maximum number of IPv4 DHCP hosts
 [no] ipv4-overall   - Maximum number of IPv4 hosts
 [no] ipv4-ppp       - Maximum number of IPv4 PPP hosts
 [no] ipv6-overall   - Maximum number of IPv6 hosts
 [no] ipv6-pd-ipoe-d* - Maximum number of IPv6-PD IPOE DHCP hosts
 [no] ipv6-pd-overall - Maximum number of IPv6-PD hosts
 [no] ipv6-pd-ppp-dh* - Maximum number of IPv6-PD PPP DHCP hosts
 [no] ipv6-wan-ipoe-* - Maximum number of IPv6-Wan IPOE DHCP hosts
 [no] ipv6-wan-ipoe-* - Maximum number of IPv6-Wan IPOE SLAAC hosts
 [no] ipv6-wan-overa* - Maximum number of IPv6-Wan hosts
 [no] ipv6-wan-ppp-d* - Maximum number of IPv6-Wan PPP DHCP hosts
 [no] ipv6-wan-ppp-s* - Maximum number of IPv6-Wan PPP SLAAC hosts
 [no] lac-overall    - Maximum number of L2TP LAC hosts
 [no] overall        - Maximum number of hosts
 [no] remove-oldest  - Remove oldest
```

Optionally the remove-oldest command can be used. In that case, the new host is accepted and the DHCP
lease state for the oldest host (with the least remaining lease time) is cleared. A DHCP release message is
sent to the DHCP server.

The following example limits the amount of ipv4-dhcp hosts.

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-2" create
            host-limits
                ipv4-dhcp 1
            exit
        exit
    exit
exit
```

If the configured host-limit is reached for a subscriber, access is denied for a new host, an event is generated (log-id 99) and the corresponding DHCP ack message is dropped:

```
113 2019/04/09 16:34:05.002 CEST WARNING: DHCP #2005 Base Lease State Population Error
"Lease state table population error on SAP 1/1/3:2 in service 1 - subscriber sub-21,
sla-profile sla-profile-2 : host-limit ipv4-dhcp (1) exceeded "
```

Multi-sub-sap limit

The multi-sub-sap parameter defines the maximum number of subscribers (dynamic and static) that can be simultaneously active on this SAP. By default only a single subscriber is allowed (no multi-sub-sap).

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            sap 1/1/3:2
                sub-sla-mgmt
                    multi-sub-sap 2
                exit
            exit
        exit
    exit
exit
```

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            subscriber-interface "sub-int-1"
                group-interface "group-int-1"
                    sap 1/1/3:2
                        sub-sla-mgmt
                            multi-sub-sap 2
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

If the limit is reached, a new subscriber will be denied access, an event is generated (log-id 99) and the corresponding DHCP ack message is dropped:

```
112 2019/04/09 16:38:22.027 CET WARNING: DHCP #2005 vprn1 Lease State Population Error
"Lease state table population error on SAP 1/1/3:2 in service 1 - Number of
subscribers exceeds the configured multi-sub-sap limit (2)"
```

DHCP Host Connectivity Verification

Because the DHCP protocol does not have a keep-alive mechanism and IP address renewal is not frequent enough, alternative mechanisms are needed to track reachability of DHCP hosts.

The first alternative is called Subscriber Host Connectivity Verification (SHCV). An ARP unicast message is periodically sent to the DHCP host. The connectivity test fails:

- If for X consecutive unicast ARP requests no ARP reply is received within the specified retry-timeout ([10 — 60] seconds, default 10). The number of retries (X-1) is specified by the retry-count ([2 — 29], default 2). Hence, at minimum 3 unicast ARP requests are send before connectivity is lost.

- If the ARP reply contains an inconsistent IP/MAC compared with the local DHCP lease state

    For a failed connectivity test, an event is raised and optionally the DHCP lease state is removed from the system by cleaning up all related resources (e.g. anti-spoof table) and sending a DHCP release to the DHCP server. When ESM is enabled, the DHCP host also is removed.

The interval for the periodic checks can be configured between 1 and 6000 minutes. If not specified, the default value of 10 minutes will be used.

The maximum time for DHCP host connectivity loss detection in this case is:

```
( (host-connectivity-verify interval) + ( (retry-count) * (retry-timeout) ) )
```

The parameters for the **host-connectivity-verify** command are:

```
*A:BSA-1>config>service>vpls>sap# host-connectivity-verify ?
  - host-connectivity-verify source-ip <ip-address> [source-mac <ieee-address>] [interval
 <interval>] [action {remove|alarm}] [timeout <retry-timeout>]
    [retry-count <count>]
<ip-address>          : a.b.c.d
<ieee-address>        : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
<interval>            : [1..6000] minutes
<{remove|alarm}>      : keywords
<retry-timeout>       : [10..60] seconds
<count>               : [2..29]
```

Figure 103: Subscriber Host Connectivity Verification
The configuration for Bridged CO is as follows, where the configured source IP should be an unused unique IP address in the DHCP client subnet or alternatively use source-ip 0.0.0.0. As the host-connectivity-verify application is sending a unicast ARP to the DHCP host, its ARP table is updated with the configured source-ip and source-mac (chassis MAC if not configured). If an existing IP address is used, the DHCP host ARP table gets poisoned, breaking the connectivity to that host.

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            sap 1/1/3:2
                host-connectivity-verify source-ip 0.0.0.0 interval 1 action alarm
            exit
```

The configuration for Routed CO is as follows, where the source IP is not configurable. The source-ip used in the unicast ARP is set to the local subscriber interface address in the subnet of the DHCP hosts that is checked for connectivity.

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            subscriber-interface "sub-int-1"
                group-interface "group-int-1"
                    host-connectivity-verify interval 1 action remove
                exit
            exit
```

To verify the result of the connectivity check:

```
*A:BSA-1# show service id 1 host-connectivity-verify statistics

===============================================================================
Host connectivity check statistics
===============================================================================
SvcId   SapId/SdpId          HostIp
  DestIp                                          MAC
    Oper      Last-reply/Conn-lost
-------------------------------------------------------------------------------
1       1/1/3:2               10.1.0.101
  10.1.0.101                                      00:00:00:22:22:21
    Up        04/09/2019 16:53:20  (elapsed: 0d 00:01:05)
-------------------------------------------------------------------------------
1 host-connectivity states : 1 Up / 0 Down / 0 Retry pending
===============================================================================
*A:BSA-1#
```

With action alarm, the lease-state is not removed in case the connectivity with the host is lost. An event is generated (log-id 99) and the statistics show:

```
*A:BSA-1# show service id 1 host-connectivity-verify statistics

===============================================================================
Host connectivity check statistics
===============================================================================
SvcId   SapId/SdpId          HostIp

-------------------------------------------------------------------------------
1 host-connectivity states : 0 Up / 1 Down / 0 Retry pending
===============================================================================
*A:BSA-1#
```

In case the connectivity with the host is lost, following event is generated:

```
229 2019/04/10 09:20:57.933 CEST WARNING: SVCMGR #2206 Base Host connectivity lost
"host connectivity lost on 1/1/3:2 in service 1 for inetAddr = 10.1.0.101,
                            chAddr=00:00:00:22:22:21, verify-addr=10.1.0.101."
```

When connectivity is restored, following event (log-id 99) is generated:

```
231 2019/04/10 09:27:22.933 CEST WARNING: SVCMGR #2207 Base Host connectivity restored
"host connectivity restored on 1/1/3:2 in service 1, for inetAddr = 10.1.0.101,
                                  chAddr=00:00:00:22:22:21, verify-addr=10.1.0.101."
```

Connectivity to a DHCP host can also be checked using an OAM command:

```
*A:BSA-1# oam host-connectivity-verify service 1 sap 1/1/3:2
===============================================================================
Triggering host connectivity verify for service 1 sap 1/1/3:2 ...
Waiting 3 seconds ...

===============================================================================
Host connectivity check statistics
===============================================================================
SvcId   SapId/SdpId          HostIp
  DestIp                                          MAC
    Oper      Last-reply/Conn-lost
-------------------------------------------------------------------------------
1       1/1/3:2              10.1.0.101
  10.1.0.101                                      00:00:00:22:22:21
    Up        04/10/2019 09:33:09  (elapsed: 0d 00:00:02)
-------------------------------------------------------------------------------
1 host-connectivity states : 1 Up / 0 Down / 0 Retry pending
===============================================================================
*A:BSA-1#
```

Note that in this case, no action is triggered. If the connectivity test is successful, the host-connectivity-verify statistics are updated with the new timestamp last-reply. If the connectivity test fails, the host-connectivity state becomes Retry Pending (oper state unknown) until an automatic test is scheduled again in the next interval.

To troubleshoot host-connectivity-verify, enable following debug log (additional filtering is possible on ip address, mac address and/or SAP):

```
debug
    service
        id 1
            host-connectivity-verify
            exit
        exit
    exit
exit
```

DHCP Lease Split

The second alternative to the DHCP protocol not having a keep-alive mechanism to verify connectivity is to use a DHCP proxy server with the lease-split option.

A finer granularity of DHCP lease time is used between the DHCP client and the DHCP proxy server than between the DHCP proxy server and the DHCP server.

The maximum time for DHCP host connectivity loss detection in this case is the configured DHCP lease-split lease time.

DHCP communication between the DHCP client and DHCP server is snooped. In the DHCP ack message, the offered lease-time from the DHCP server is replaced with the configured DHCP proxy server lease-split

lease time. Note that the lease time is only updated if the configured lease-split lease time is less than half of the original lease time value. The minimum value for the proxy server lease-split lease time is 5 minutes. When the DHCP client renews the DHCP session, the DHCP proxy server sends a DHCP ack on behalf of the DHCP server as long as the next renew time is earlier than half of the DHCP server expiry time for this session. With ESM enabled, RADIUS re-authentication will occur only when the DHCP request must be sent to the DHCP server. In other words, configuring a DHCP proxy with lease-split does not put extra load on the RADIUS server.

In the example in Figure 104: DHCP Proxy Server: Lease Split Operation, the DHCP server offers a lease time of 960 seconds. The lease time in the offer sent to DHCP client will be updated with the lease time of 300 seconds as configured in the DHCP proxy server lease-split on BSA-1.

```
# Bridged CO @ BSA-1
configure
    service
        vpls 1
            sap 1/1/3:2
                dhcp
                    proxy-server
                        lease-time min 5
                        no shutdown
                    exit
                exit
```

```
# Routed CO @ BSR-1
configure
    service
        vprn 1
            subscriber-interface "sub-int-1"
                group-interface "group-int-1"
                    dhcp
                        proxy-server
                            lease-time min 5
                            no shutdown
                        exit
                    exit
```

> **Note:**
> The emulated server address in the DHCP proxy-server configuration does not have to be configured for lease-split operation. This parameter is needed for an alternative use of the DHCP proxy server: RADIUS based IP configuration of a subscriber host. This is out of the scope of this configuration note.

If DHCP lease split is operational for a DHCP host, it will be shown in the Remaining Lifetime field of the detailed lease-state output. Note that the Session Timeout field is the original offered lease time from the DHCP server.

```

```

Figure 104: DHCP Proxy Server: Lease Split Operation
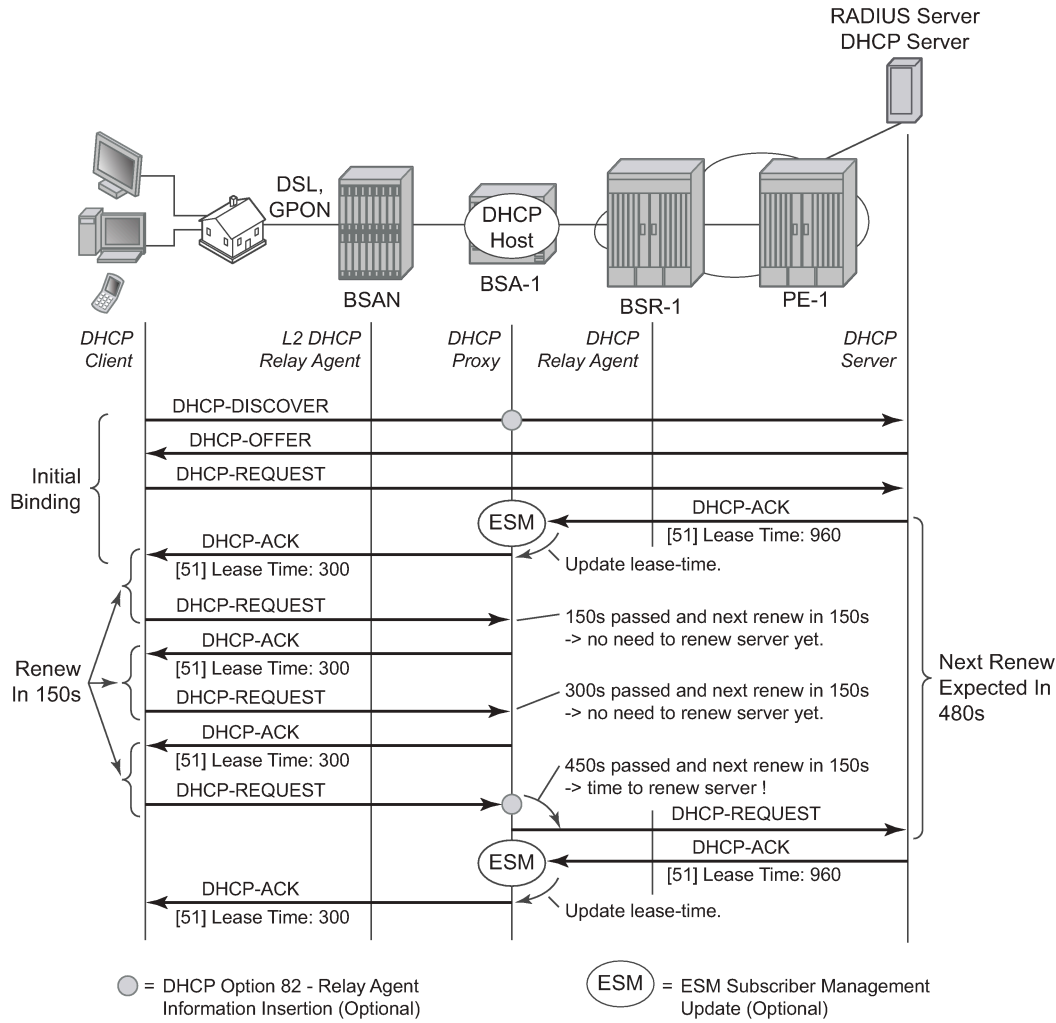

When the DHCP client disconnects without sending a DHCP release, the DHCP lease state in the BSA/ BSR will be removed only when the DHCP lease time expires. With DHCP proxy server lease-split, the DHCP client disconnection can be sped up. In the example below, the DHCP client disconnection is detected in less than 5 minutes (lease-split lease time) while it would have taken up to 16 minutes without the lease-split. Note that the values are illustrative; in reality the DHCP lease times will be higher.

Figure 105: DHCP Proxy Server: Lease Split Operation, DHCP Client Disconnected
DHCP Host Mobility

A field technician verifying DSLAM operation often connects and disconnects from different ports rapidly. This will require the node to clear its own DHCP host state, the DHCP server state as well as flush MAC addresses learned within the VPLS network or clear ARP entries from the routing instance.

A DHCP request enters on SAP2. On SAP1 there exists a lease state with the same Client Hardware address. The packet is dropped and a forced SHCV check verifies the existing lease state on SAP1. Three consecutive checks are launched with a timeout of 10 seconds. If the host indeed moved form SAP1 to SAP2, the connectivity check will fail on SAP1. The existing lease state is deleted and a DHCP release message is sent to the DHCP server. Any subsequent DHCP session setup will proceed as normal.

Figure 106: DHCP Host Mobility
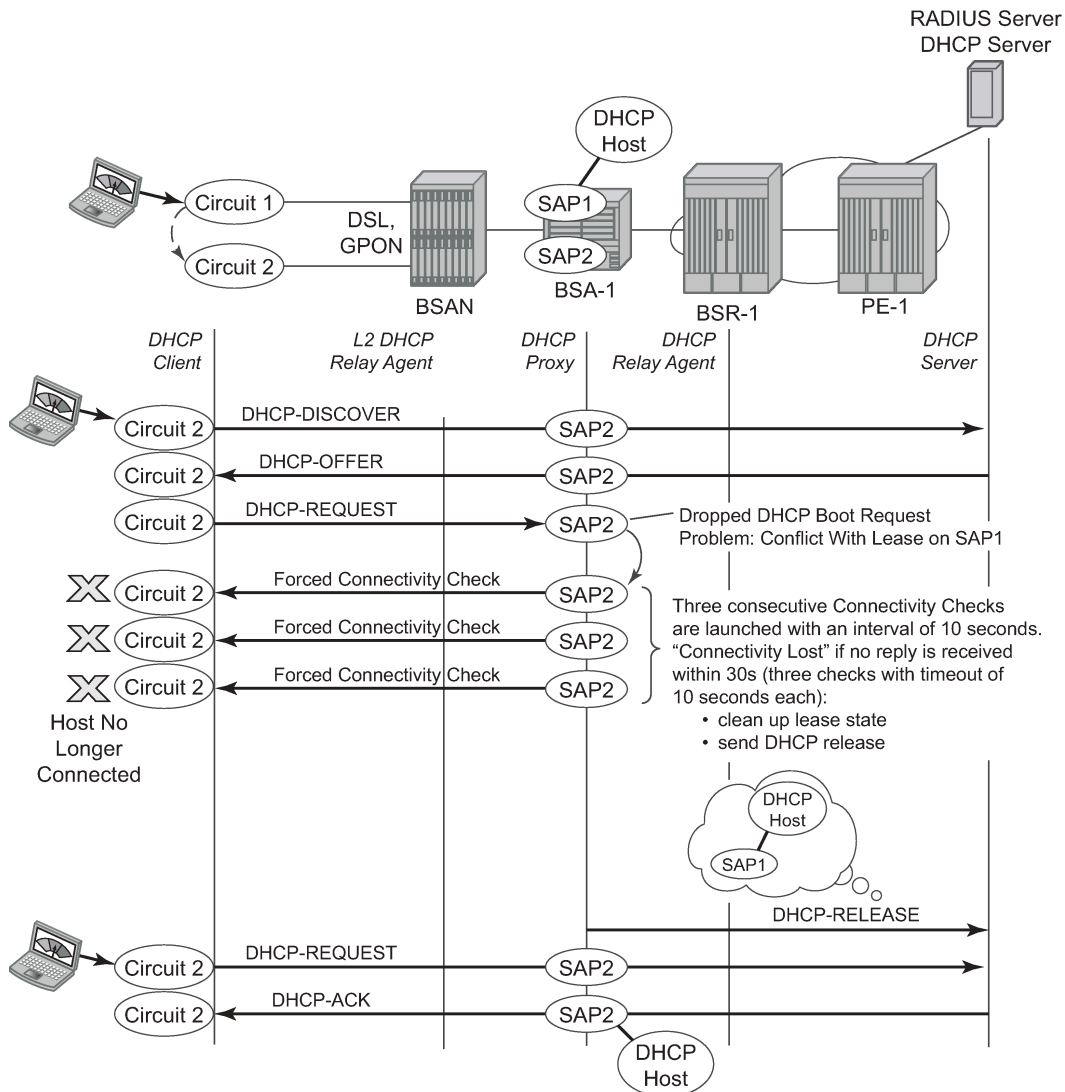

OSSG393

Note that for host mobility to function, host-connectivity-verification must be enabled. Next to periodic connectivity checks, it also enables forced checks triggered by moving hosts.

For Bridged CO, host-connectivity-verify must be enabled on the SAPs. When no interval is specified, it will default to 10 minutes for the periodic connectivity checks.

```
# Brigded CO
configure
    service
        vpls 1
            sap 1/1/3:1
                host-connectivity-verify source-ip 10.1.0.253
            exit
            sap 1/1/3:2
                host-connectivity-verify source-ip 10.1.0.253
            exit
        exit
```

```
    exit
exit
```

The configured source-ip should be an unused unique ip address in the DHCP client subnet or alternatively use source-ip 0.0.0.0. As the host-connectivity-verify application is sending a unicast ARP to the DHCP host, its ARP table is updated with the configured source-ip and source-mac (chassis MAC if not configured). If you would use an existing IP address, the DHCP host ARP table gets poisoned, breaking the connectivity to that host.

For Routed CO, host-connectivity-verify must be enabled on the group-interface. When no interval is specified, it will default to 10 minutes for the periodic connectivity checks.

```
# Routed CO
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    host-connectivity-verify
                exit
            exit
        exit
    exit
exit
```

The source IP address is not configurable. The source-ip used in the unicast ARP is fixed to the local subscriber interface address in the subnet of the DHCP hosts that is checked for connectivity.

Conclusion

This chapter provides configuration and troubleshooting commands for dynamic DHCP hosts. DHCP hosts can be instantiated in a Layer 2 bridged CO (VPLS) environment as well as in a Layer 3 Routed CO (IES/ VPRN subscriber interface) context.

L2TP for Subscriber Access — LAC

This chapter provides information about L2TP for subscriber access.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter describes L2TP Access Concentrator (LAC) support for the L2TP Access Aggregation (LAA) architecture model and was initially written for SR OS Release 11.0.R4. The CLI in the current edition is based on Release 16.0.R7. PPP hosts are supported in a Routed CO model (with IES or VPRN services) using ATM, Ethernet or Ethernet over Pseudowire SAPs. A description of the L2TP Tunnel Switch (LTS) and L2TP Network Server (LNS) functions are out of the scope of this chapter.

Overview

PPP access architectures

The Broadband Forum proposes two architectures for point-to-point protocol (PPP) access.

- The PPP terminated aggregation architecture (PTA)
- The L2TP access aggregation architecture (LAA)

The PTA architecture (local-access model) uses the Broadband Network Gateway (BNG) to terminate user PPP sessions (see scenario PPPoE-5 in Figure 107: PPP access architectures).

The LAA architecture (which is a tunneled access model) uses a LAC and an LNS to transport PPP sessions from the LAC to the LNS which performs tunnel termination (see scenario PPPoE-1 and PPPoE-2 in Figure 107: PPP access architectures).

Optionally, an LTS can be used in the transport network to perform the grooming of traffic between tunnels (see scenarios PPPoE-3 and PPPoE-4 in Figure 107: PPP access architectures).

The LNS is the logical termination point of the PPP sessions originated by the remote clients and tunneled by the LAC/LTS.

Figure 107: PPP access architectures
L2TP tunnels - LAC and LNS reachability options

The router instance where the L2TP tunnel starts and where ESM is handled can be one and the same, but does not need to be the same. The LNS peer address can be reachable via IP, BGP/IGP shortcuts, over a spoke SDP (GRE/MPLS), RFC 4364 VPRNs, but cannot be an address belonging to a directly connected interface. See Figure 108: Supported LT2P reachability options.

Figure 108: Supported LT2P reachability options
Recapitulation of the L2TPv2 protocol

L2TPv2 is a client-server protocol relying on UDP and encapsulates Layer 2 packets such as PPP for transmission across a network. L2TPv2 passes control and data messages over separate control and data channels, thus defines following message types:

- Control messages—The in-band control channel passes sequenced control messages, supporting connection management, call management, error reporting, and session control. Optionally, a shared-secret challenge authentication method can be used between the tunnel endpoints.

  The following messages are used for L2TP tunnel management:

  – Tunnel setup (control connection management)

    - Start-control-connection-request (SCCRQ)
    - Start-control-connection-reply (SCCRP)
    - Start-control-connection-connected (SCCCN)

- Stop-control-connection-notification (StopCCN)
  – Tunnel keepalive
    - Hello

The following messages are used for L2TP session (call) management:

  – Session setup over an existing tunnel
    - Incoming-call-request (ICRQ)
    - Incoming-call-reply (ICRP)
    - Incoming-call-connected (ICCN)
    - Call-disconnect-notify (CDN)

Zero-length body (ZLB) messages are control packets with an L2TP header only and are used to explicitly acknowledge packets, making the control channel reliable.

L2TP message encoding is done through attribute value pairs (AVP).

- Data messages — Data messages encapsulate the PPP frames that are sent into the L2TP tunnel.

L2TPv2 sessions run over an L2TP tunnel and are referenced by an L2TP session-id. An L2TP tunnel can carry none, one, or multiple L2TP sessions. An L2TP session corresponds to a PPPoE session. L2TPv3 for LAC-LNS dynamic tunnel setup is not supported.

L2TP header and AVP layout

The L2TPv2 header consists of following fields (RFC 2611):

0								8		16		31
T	L	–	S	–	O	P	–		Version		Length	
Tunnel-ID										Session-ID		
Ns										Nr		
Offset Size										Offset Pad		
al_0513A

Table 26: L2TPv2 header fields and descriptions

Field	Description
T	Type of L2TP message (1 bit): 0—data message 1—control message
L	Indicates if the optional Length field is present in the message (1 bit): 0—the field is left out of the message entirely 1—the field is included (must be included in control messages)
-	Reserved for future use, must be set to zero.
S	Indicates if the Ns and Nr fields are present (1 bit): 0 — the fields are left out of the message; entirely 1 — the fields are included (must be included in control messages)
O	Indicates if the Offset field is present (1 bit): 0 — the field is left out of the message entirely (must be left out of control messages); 1 — the field is included

Field	Description
P	Used with data messages only. Indicates priority of the data message (1 bit): 0 — no (this value is used for all control messages); 1 — yes
Version	The version of the message (4 bits): 2 — this is the latest version of the L2TP data message header; 1 — indicates an L2F packet as described in RFC 2341. Packets with an unknown version number are discarded.
Length	The total length (in bytes) of the L2TP message (16 bits).
Tunnel-ID	Identifies the L2TP tunnel (that is, the control connection).This number has local significance — each end gives the same tunnel different tunnel IDs. The ID refers to the receiver, not the sender, and is assigned during tunnel creation (16 bits).
Session-ID	Identifies the PPP session within a tunnel. This number has local significance — each end gives the same session different session IDs. The ID refers to the receiver, not the sender, and is assigned during session creation (16 bits).
Ns	The sequence number of the message. This is mandatory for control messages (to enable re-transmission of lost messages) but optional for data messages (to re-order data messages that were mis-sequenced during forwarding). The number, which starts at 0 and increments by 1, is assigned by an L2TP peer for each session in a tunnel (16 bits).
Nr	The sequence number of the next control message expected to be received. This is equal to the sequence number of last received control message plus 1. Used by the receiving peer to ensure that control messages are sent in order without duplication. In data messages, the field (if present as indicated by the S bit) is ignored (16 bits).
Offset Size	The location of the L2TP payload, expressed as the number of octets from the start of the message header (16 bits).
Offset pad	User-defined bytes used to pad the message header so that the payload starts at the location indicated by the Offset Size field (16 bits).

The AVP header consists of following fields (RFC 2611):

0	6		16	31
M	H	−	Length	Vendor-ID
	Attribute Type			Attribute Value
al_0513B

Table 27: AVP header fields and descriptions

Field	Description
M	Mandatory bit — If the M bit is set on an unrecognized AVP within a message associated with a particular session, the session associated with this message MUST be terminated (1 bit).
H	Hidden bit — Identifies the hiding of data in the Attribute-Value field of an AVP. This capability can be used to avoid the passing of sensitive data, such as user passwords, as clear text in an AVP. The H-bit MUST only be set if a shared secret exists between the LAC and LNS. The shared secret is the same secret that is used for tunnel authentication. If the H-bit is set in any

Field	Description
	AVP(s) in a given control message, a Random Vector AVP must also be present in the message and MUST precede the first AVP having an H bit of 1 (1 bit).
-	Reserved for future use, must be set to zero (4 bits).
Length	Indicates the total number of bytes (including the overall length and bitmask fields) contained in this AVP (10 bits).
Vendor-id	Any vendor wishing to implement their own L2TP extensions can use their own Vendor ID along with private Attribute values. Vendor-ID=0 means that the standard AVPs are used (2 bytes).
Attribute type	A value with a unique interpretation across all AVPs defined under a given Vendor (2 bytes).
Attribute value	This is the actual value as indicated by the Vendor ID and Attribute Type (2 bytes).

RADIUS-triggered tunnel/session setup without LNS renegotiation

Figure 109: RADIUS-triggered tunnel/session setup without LNS renegotiation depicts the complete PPP session setup, using RADIUS authentication on both LAC and LNS. After the discovery phase (PADI/ PADO/PADR/PADS) and LCP negotiation phase (LCP config_request/ack), the LAC initiates the L2TP tunnel setup based on RADIUS authentication information (RADIUS request/accept) and includes the negotiated PPP user-LAC information (called LCP proxy information). The LNS replies directly with a successful CHAP authentication if it agrees with the received proxy information. IP negotiation (IPCP config_request/ack) is handled between the user and the LNS, and the LAC has no IP knowledge of this PPP session.

Figure 109: RADIUS-triggered tunnel/session setup without LNS renegotiation
al_0523

RADIUS-triggered tunnel/session setup with LNS renegotiation

Figure 110: RADIUS-triggered tunnel/session setup with LNS renegotiation shows the scenario where the LNS does not agree with the received LCP proxy information and (re)starts the LCP phase (LCP config_request/ack) directly with the PPP user. The rest of this scenario is the same as shown in Figure 109: RADIUS-triggered tunnel/session setup without LNS renegotiation.

Figure 110: RADIUS-triggered tunnel/session setup with LNS renegotiation
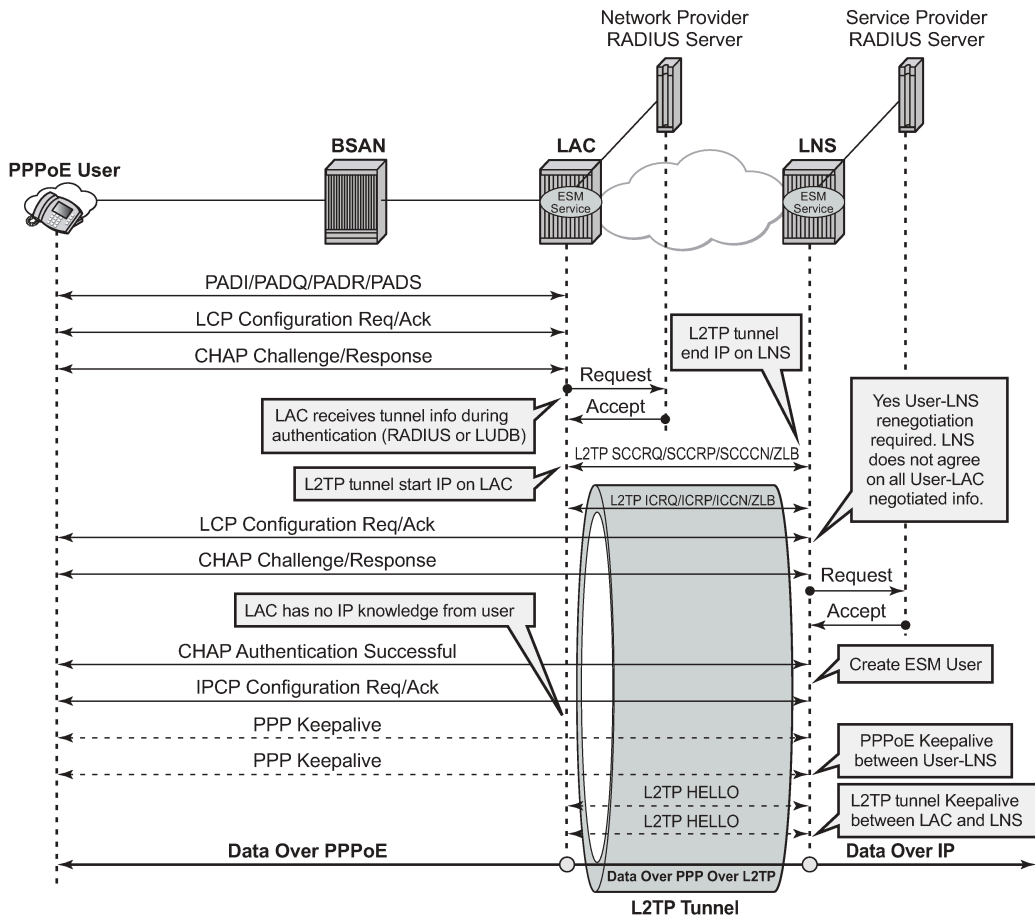

al_0524

Running multiple PPP sessions over a single L2TP tunnel

Figure 111: Running multiple PPP sessions over a single L2TP tunnel shows multiple PPP sessions tunneled over a single L2TP Tunnel. The LAC encapsulates each PPP session with a different L2TP session-id (SID) but with the same L2TP Tunnel-id (TID).

Figure 111: Running multiple PPP sessions over a single L2TP tunnel
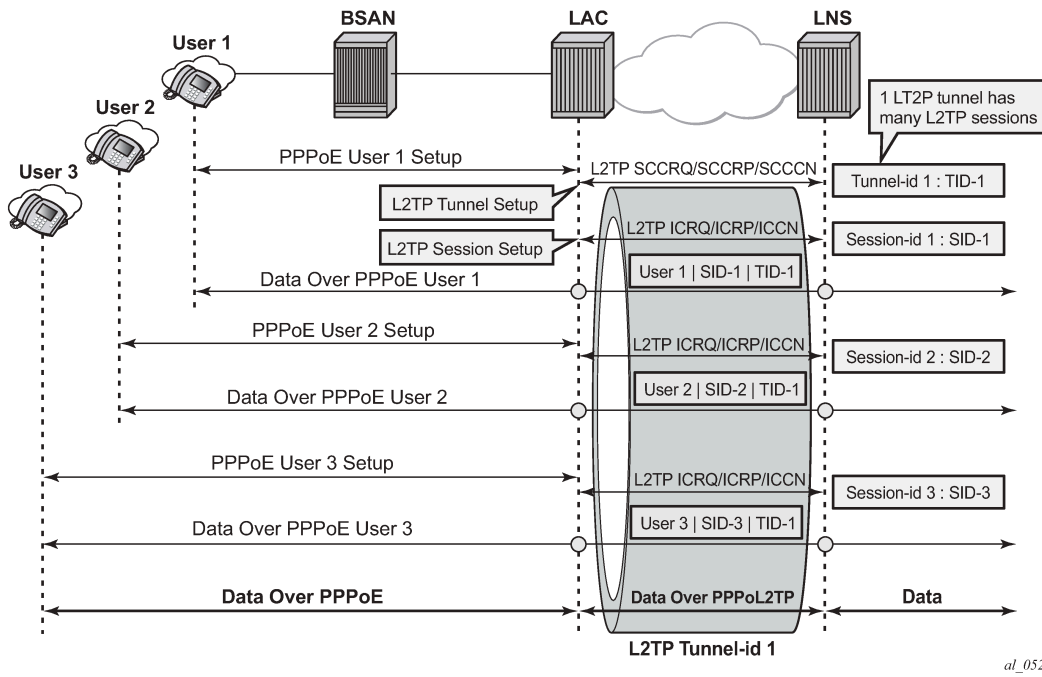

PPP user-initiated release/terminate

Figure 112: PPP user-initiated release/terminate shows the user initiated terminate_request tunneled by the LAC followed by the user initiated PADT terminated on the LAC. The LAC informs the LNS about the termination of the session via the L2TP CDN message. The L2TP tunnel can be optionally (idle-timeout) terminated via the L2TP StopCCN message.

Figure 112: PPP user-initiated release/terminate
L2TP tunnel/session state diagram

Figure 113: L2TP tunnel and session state diagram gives an overview of the main L2TP tunnel and session states. An L2TP tunnel in the establishedIdle state is a tunnel without sessions. A **tools** command (see Advanced topics) can put an L2TP tunnel in a draining state (this prevents adding new sessions on tunnel but leaves the current sessions intact) or in a drained state (moved from draining to drained when all sessions terminated). The draining and drained state are not shown in the state diagram.

The L2TP tunnel setup occurs first with the triggers being: session activation, auto-establish, and a **tools start** command (see the Advanced topics section). An L2TP session setup trigger is always session based.

Figure 113: L2TP tunnel and session state diagram
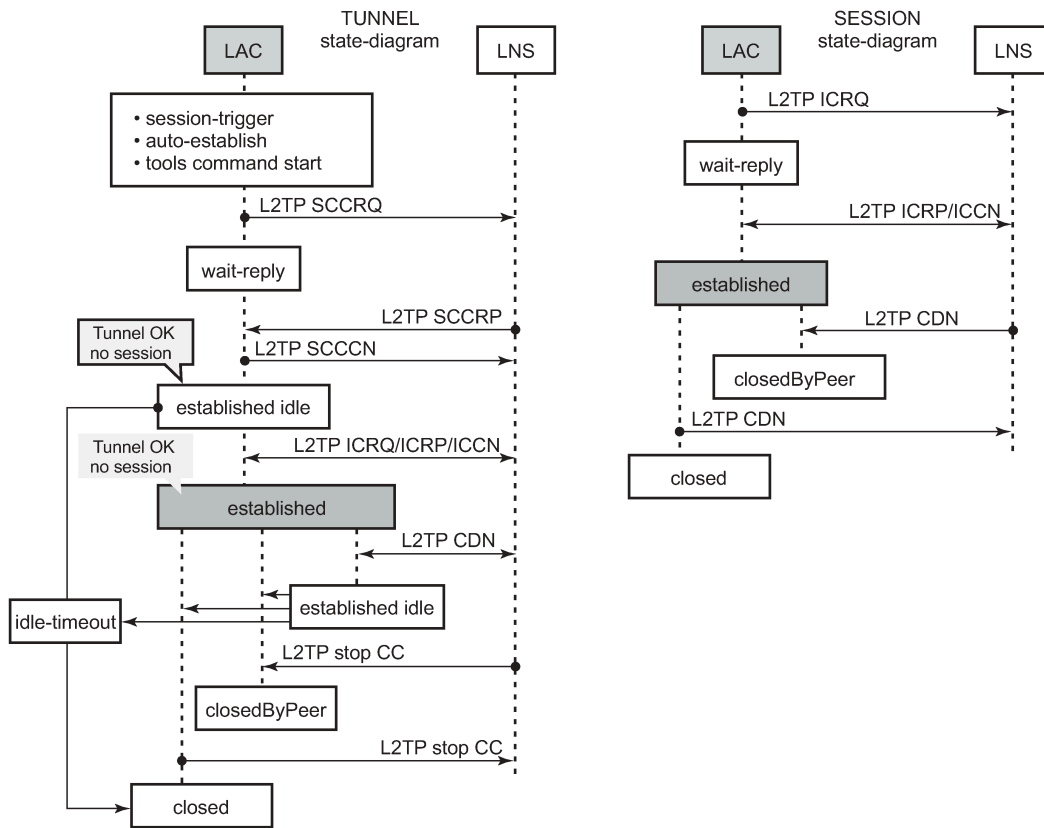

al_0515

Configuration

The following scenarios are configured:

- Scenario 1: RADIUS-derived L2TP parameters
- Scenario 2: node-derived L2TP parameters

Scenario 1: RADIUS-derived L2TP parameters

In the first scenario, the LAC receives an incoming connection and contacts the LAC RADIUS server. The RADIUS server retrieves the attributes for the user's domain (for example @wholesale.com) and passes the tunnel attributes to the LAC. Based on these RADIUS provided tunnel attributes, the LAC selects or initiates a new tunnel to the LTS or directly to the LNS. Once the tunnel is established, the LNS authenticates the end user using its own RADIUS server. Configuring the LNS and the LTS are out of the scope of this example.

In a RADIUS driven L2TP setup, either all or some of the required L2TP attributes are returned via RADIUS. If the RADIUS server only returns the L2TP [67] Tunnel-Server-Endpoint attributes, then the L2TP tunnel/session is established using the 'l2tp node parameter values' for the other required L2TP parameters. The 'l2tp node parameters' are defined under the configure router/service l2tp hierarchy. If the RADIUS server does not return all of the L2TP attributes and the node values are not configured, then the system falls back to default settings for these L2TP parameters.

The standard and vendor specific [26-6572] L2TP RADIUS attributes are listed in the tables below, together with the corresponding l2tp node parameters and defaults.

Table 28: Generic L2TP RADIUS attributes

Attribute ID	Attribute Name	Mandatory	CLI Node Parameter	Corresponding Defaults

Base router hosted LAC with single endpoint/single tunnel

Using the mandatory L2TP RADIUS attributes (see the following RADIUS user file) the LAC initiates an L2TP tunnel, as shown in Figure 114: Base router hosted LAC with single endpoint/single tunnel. The source address for the tunnel is the IPv4 address of a loopback interface in the base router system (LAC tunnel endpoint).The destination for the tunnel is defined by the Tunnel-Server-Endpoint RADIUS attribute [67], and is also known as the peer tunnel LNS endpoint address.

Figure 114: Base router hosted LAC with single endpoint/single tunnel
The PPPoE user terminates on IES service 1, sap 1/1/3:100, and is authenticated via RADIUS
authentication-policy authentication-1 which provides wholesale/retail (L2TP) information.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-l2tp" create
                unnumbered "system"
                group-interface "grp-l2tp" create
                    authentication-policy "radius-1"
                    sap 1/1/3:100 create
                        sub-sla-mgmt
                            sub-ident-policy "all-subscribers"
                            multi-sub-sap 1000
                            no shutdown
                        exit
                    exit
                    pppoe
                        sap-session-limit 10
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The excerpt from the FreeRADIUS users file below shows the attributes to be returned.

```
user1@wholesale.com        Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                           Alc-Subsc-ID-Str = "%{User-name}",
                           Alc-Subsc-Prof-Str = "sub-profile-1",
                           Alc-SLA-Prof-Str = "sla-profile-1",
                           Tunnel-Type:1 += L2TP,
                           Tunnel-Medium-Type:1 +=IP,
                           Tunnel-Server-Endpoint:1 += 192.168.22.2,
```

L2TP is enabled (**no shutdown**) in the related service instance.

The L2TP tunnel is set up in the base instance and not in a VRF because the attribute Alc-Tunnel-Serv-Id is not returned from RADIUS.

Missing L2TP parameters are taken from defaults defined in the router l2tp context.

```
configure router l2tp
      calling-number-format "%S %s"  # L2TP AVP 22 format
                                     # Default format 'system-name sap-id'
      ---snip---
      no local-name                  # default name equals system-name
      no max-retries-estab           # default value equals 5
      ---snip---
      no shutdown                    # enable L2TP
```

This scenario shows the PPPoE session termination (base IES service 1) and the L2TP tunnel setup in the base router instance.

Base router hosted LAC with multiple endpoints

Figure 115: Base router hosted LAC with multiple endpoints shows a scenario with the PPPoE session termination (base IES service 1) and the L2TP tunnel setup in the base router instance.

Figure 115: Base router hosted LAC with multiple endpoints
The following excerpt from the FreeRADIUS users file shows that user *user1@wholesale.com* has four possible endpoints (LNS), each with its own tunnel preference. The LAC selects one L2TP endpoint out of these four tunnel specifications according to the configured L2TP selection process. This use case uses weighted load balancing between RADIUS-tunnel-1 and RADIUS-tunnel-2. The L2TP tunnel selection process is out of the scope of this chapter.

```
user1@wholesale.com    Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                       Alc-Subsc-ID-Str = "%{User-name}",
                       Alc-Subsc-Prof-Str = "sub-profile-1",
                       Alc-SLA-Prof-Str = "sla-profile-1",
# group related info
                       Tunnel-Client-Endpoint:0 = 192.168.22.1,
                       Alc-Tunnel-Algorithm:0 = weighted-access,
```

```
                        Tunnel-Client-Auth-Id:0 = "lac-pe1",
                        Tunnel-Assignment-Id:0 = "RADIUS-group",
                        Alc-Tunnel-Max-Retries-Estab:0 = 2,
# tunnel-1 related info
                        Tunnel-Type:1 += L2TP,
                        Tunnel-Medium-Type:1 +=IP,
                        Tunnel-Server-Endpoint:1 += 192.168.22.2,
                        Tunnel-Assignment-Id:1 += "RADIUS-tunnel-1",
                        Tunnel-Preference:1 += 100,
# tunnel-2 related info
                        Tunnel-Type:2 += L2TP,
                        Tunnel-Medium-Type:2 +=IP,
                        Tunnel-Server-Endpoint:2 += 192.168.22.3,
                        Tunnel-Assignment-Id:2 += "RADIUS-tunnel-2",
                        Tunnel-Preference:2 += 80,
# tunnel-3 related info
                        Tunnel-Type:3 += L2TP,
                        Tunnel-Medium-Type:3 +=IP,
                        Tunnel-Server-Endpoint:3 += 192.168.22.4,
                        Tunnel-Assignment-Id:3 += "RADIUS-tunnel-3",

---snip---
```

VRF hosted LAC

Figure 116: VRF hosted LAC shows the PPPoE session termination (base IES service 1) and the L2TP
tunnel setup in a different router instance (VPRN 65536).

Figure 116: VRF hosted LAC
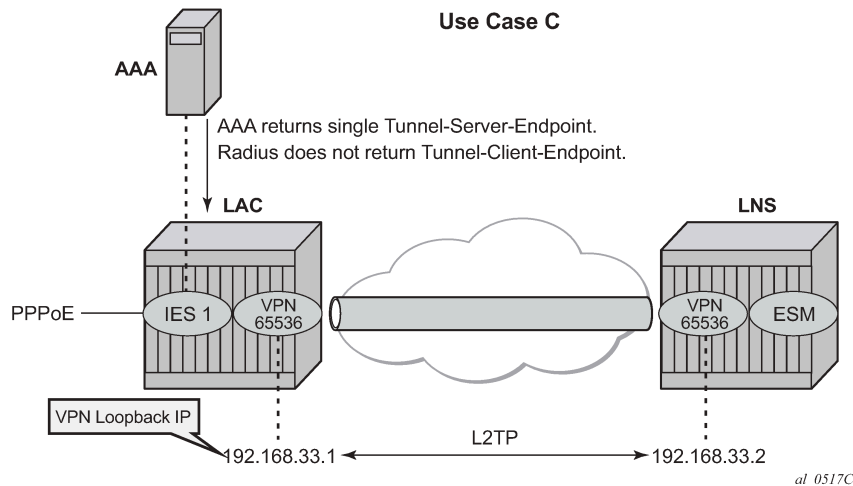

Using the following L2TP RADIUS attributes, the LAC initiates an L2TP tunnel in VPRN 65536. The PPPoE
session is still handled by IES service 1, which proves that both router instances can be different. (See
use-case A for configuration details of IES service 1).

```
user1@wholesale.com     Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                        Alc-Subsc-ID-Str = "%{User-name}",
                        Alc-Subsc-Prof-Str = "sub-profile-1",
                        Alc-SLA-Prof-Str = "sla-profile-1",
                        Alc-Tunnel-Serv-Id = 65536,
```

```
                                Tunnel-Client-Auth-Id:0 = "lac-pe1",
                                Tunnel-Assignment-Id:0 = "RADIUS-returned-TG",
                                Tunnel-Type:1 += L2TP,
                                Tunnel-Medium-Type:1 +=IP,
                                Tunnel-Server-Endpoint:1 += 192.168.33.2,
                                Tunnel-Assignment-Id:1 += "RADIUS-returned-TN",
```

If RADIUS does not return the L2TP source IP address (Tunnel-Client-Endpoint), then the IP address from the VPRN 65536 interface named 'system' is used as the L2TP source address. The tunnel setup fails if this system interface does not exist.

```
configure
    service
        vprn 65536
            interface "system" create
                address 192.168.33.1/32
                loopback
            exit
            l2tp
                no shutdown
            exit
```

Scenario 2: node-derived L2TP parameters

In the second scenario, the LAC receives the incoming connection and an L2TP tunnel-group-name is assigned during LUDB or RADIUS authentication. This tunnel-group-name refers to the CLI preconfigured tunnel-group name context (**configure router** *<router-name>* **l2tp group** *<tunnel-group-name>*), which provides the context for all relevant tunnel attributes.

Based on these attributes, the LAC selects and initiates a tunnel to the LTS or directly to the LNS as in Scenario 1: RADIUS-derived L2TP parameters.

RADIUS returns L2TP tunnel group

Figure 117: RADIUS returns L2TP tunnel group shows use case D, where the L2TP tunnel-group-name is assigned during RADIUS authentication.

Figure 117: RADIUS returns L2TP tunnel group

```
user1@wholesale.com        Cleartext-Password := "letmein", NAS-Identifier == "LAC"
                           Alc-Subsc-ID-Str = "%{User-name}",
                           Alc-Subsc-Prof-Str = "sub-profile-1",
                           Alc-SLA-Prof-Str = "sla-profile-1",
                           Alc-Tunnel-Serv-Id = 65536,
                           Alc-Tunnel-Group = "wholesale.com",
```

The L2TP tunnel is initiated from VPRN 65536 (Alc-Tunnel-Serv-Id) and all L2TP tunnel information is taken from the l2tp group wholesale.com hierarchy (Alc-Tunnel-Group) as defined on the node.

```
configure
    service
        vprn 65536
            ---snip---
            interface "system" create
                address 192.168.33.1/32
                loopback
            exit
            l2tp
                group "wholesale.com" create
                    tunnel "wholesale.com" create
                        local-address 192.168.33.1
                        local-name "lac-pe1"
                        peer 192.168.33.2
                        no auto-establish
                        no shutdown
                    exit
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

An L2TP tunnel is set up by either a PPP session-trigger, a **tools** command or by the l2tp group tunnel auto-establish parameter configuration. See the Advanced topics section for the non-session-triggered tunnel setup.

LUDB returns L2TP tunnel group

Figure 118: LUDB returns L2TP tunnel group shows use case E, where the L2TP tunnel-group-name is assigned during LUDB authentication, so this essentially is a RADIUS-less scenario.

Figure 118: LUDB returns L2TP tunnel group
The PPPoE user enters on an IES service 1, sap 1/1/3:100, and is authenticated via the LUDB which provides L2TP wholesale/retail and ESM information. The PPPoE context refers to a local-user database *l2tp* to provide the subscriber authentication and the tunnel setup parameters, so no RADIUS is needed.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-l2tp" create
                unnumbered "system"
                group-interface "grp-l2tp" create
                    sap 1/1/3:100 create
                        sub-sla-mgmt
                            sub-ident-policy "all-subscribers"
                            multi-sub-sap 1000
                            no shutdown
                        exit
                    exit
                    pppoe
                        sap-session-limit 10
                        user-db "l2tp"
                        no shutdown
                    exit
                exit
```

```
            exit
            no shutdown
        exit
    exit
exit
```

The referenced local user database *l2tp* configuration provides all of the required L2TP and ESM
information.

```
configure
    subscriber-mgmt
        local-user-db "l2tp" create
            ppp
                match-list username
                host "wholesale.com" create
                    host-identification
                        username "wholesale.com" domain-only
                    exit
                    password ignore
                    identification-strings 254 create
                        subscriber-id "user@wholesale.com"
                        sla-profile-string "sla-profile-1"
                        sub-profile-string "sub-profile-1"
                    exit
                    l2tp
                        group "wholesale.com" service-id 65536
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Operation and troubleshooting

The subsequent sections explain how the use cases A to E described in the configuration section are
verified using show, debug, and tools commands.

The standard router debugging tools can be used to monitor and troubleshoot the L2TP tunnel and session
setup.

Useful **show** commands are:

```
show service id <service-id> ppp session [detail]
show router l2tp tunnel [detail]
show router l2tp session [detail]
show router l2tp peer [ip-address]
```

To debug and show PPPoE packets:

```
debug service id <service-id> ppp packet mode egr-ingr-and-dropped
debug service id <service-id> ppp packet detail-level medium
```

To debug and show RADIUS authentication:

```
debug router radius packet-type authentication
```

To debug and show LUDB authentication:

```
debug subscriber-mgmt local-user-db <local-user-db-name> detail all
```

To debug and show the LAC tunnel selection process and L2TP state machine:

```
debug router l2tp event lac-session-setup
debug router l2tp event finite-state-machine
```

To debug and show the L2TP tunnel and session setup:

```
debug router l2tp packet direction both
debug router l2tp packet detail-level high
```

Understanding the L2TP debug output

The following L2TP ICRQ message (**debug router l2tp packet**) is used to explain how the displayed debug output should be interpreted. See Recapitulation of the L2TPv2 protocol -L2TP header and AVP layout for more details.

```
19 2019/05/21 14:02:10.811 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)

      [0x81] Actual-Upstream: 2000
      [0x82] Actual-Downstream: 4000
"
```

The **debug router radius packet-type authentication** command shows the actual authentication parameters returned by RADIUS. This example returns the minimum set of L2TP related RADIUS attributes.

```
12 2019/05/21 14:02:10.806 CEST MINOR: DEBUG #2001 Base RADIUS
"RADIUS: Receive
  Access-Accept(2) id 16 len 89 from 172.16.1.11:1812 vrid 1 pol rsp-radius-1
    VSA [26] 15 Nokia(6527)
      SUBSC PROF STR [12] 13 sub-profile-1
    VSA [26] 15 Nokia(6527)
```

```
      SLA PROF STR [13] 13 sla-profile-1
    TUNNEL TYPE [64] 4 1 L2TP(3)
    TUNNEL MEDIUM TYPE [65] 4 1 IPv4(1)
    TUNNEL SERVER ENDPOINT [67] 13 1 192.168.22.2
"
```

The **debug router l2tp event lac-session-setup** command shows the LAC tunnel selection for this example. An L2TP group-name *default_radius_group* with tunnel-name *unnamed* is created in this case, because RADIUS did not return an explicit group and tunnel name.

```
13 2019/05/21 14:02:10.808 CEST MINOR: DEBUG #2001 Base PPPoE 13->L2TP
"PPPoE 13->L2TP: UDP 192.0.2.1:1701 -> 192.168.22.2:1701
preference 50 tunnel default_radius_group:unnamed
    request to open new tunnel 1640"
```

```
14 2019/05/21 14:02:10.808 CEST MINOR: DEBUG #2001 Base PPPoE 13->L2TP
"PPPoE 13->L2TP: UDP 192.0.2.1:1701 -> 192.168.22.2:1701
preference 50 tunnel default_radius_group:unnamed
    create session 107505580"
```

The **debug router l2tp packet detail-level** command shows the L2TP tunnel and session setup for this example.

For the tunnel setup, the LAC sends a start-control-connection-request (SCCRQ) containing the assigned tunnel ID (no tunnel authentication in the example). The tunnel is now in a wait-reply state.

```
15 2019/05/21 14:02:10.808 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701
tunnel 0 session 0, ns 0 nr 0, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0

        "Nokia"
    AVP AssignedTunnelId(0,9), flags: mandatory, reserved=0
        13008"
```

As the last step in the tunnel setup phase, the LAC responds with a start-control-connection-connected (SCCCN) message. After an LNS ZLB acknowledgment, the tunnel is in the establishedIdle state.

```
17 2019/05/21 14:02:10.810 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701
tunnel 13008 session 0, ns 1 nr 1, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        StartControlConnectionConnected(3)"
```

Once the tunnel exists the session setup starts, a three-way exchange for session establishment within the tunnel is performed. The LAC sends an incoming-call-request (ICRQ) with the parameter information for the session. The session is now in the wait-reply state.

```
19 2019/05/21 14:02:10.811 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701
tunnel 13008 session 0, ns 2 nr 1, flags:, reserved=0

        2000000
    AVP ActDataRateDown(3561,130), flags:, reserved=0
        4000000"
```

The LNS then sends an incoming-call-reply (ICRP) that contains the assigned session ID. The session is now in the connect state.

```
21 2019/05/21 14:02:10.813 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, ingress)
"L2TP(v2, ctrl, ingress): UDP 192.168.22.2:1701 -> 192.0.2.1:1701
tunnel 1640 session 26540, ns 1 nr 3, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        IncomingCallReply(11)
    AVP AssignedSessionId(0,14), flags: mandatory, reserved=0
        2466"
```

Finally, the LAC sends an incoming call connected (ICCN) and provides the LNS with additional information from the user initiated session. This information includes the LCP information from the negotiation that the LAC and remote user performed. This information is used by the LNS to decide

whether to start LCP re-negotiation and/or authentication re-negotiation with the PPP user or not. After an LNS ZLB acknowledgment, the session is in the established state.

```

Base router hosted LAC with multiple endpoints

The **debug router radius packet-type authentication** command shows the actual RADIUS authentication
parameters returned. This example returns multiple tunnel endpoints from which the LAC selects one.
This example uses weighted load balancing. (The L2TP tunnel selection process is out of the scope of this
example).

*A:LAC#
```

VRF hosted LAC

This example returns VPRN 65536 as the L2TP service instance [26-6527-104 Alc-Tunnel-Serv-Id]. The VPRN 65536 interface system address is used as the L2TP source address because the attribute Tunnel-Client-Endpoint is not returned.

The IP address 192.168.33.1 (Tunnel-Server-Endpoint) needs to be routable in VRF 65536 over a SAP or to a remote PE. This example uses BGP/MPLS IP virtual private networks (VPNs) (RFC 4364) to access the remote PE.

```

Advanced topics

Non-session-triggered L2TP tunnel setup

In addition to the PPP-session-triggered setup, an L2TP tunnel can also be set up via a **tools** command or an **auto-establish** command.

These non-session triggers are useful, for example, during the initial configuration phase where the LAC-LNS tunnel setup can be tested without the need for a user to attempt and establish a PPPoE connection.

The PPPoE user still triggers the L2TP session-setup over this L2TP tunnel and RADIUS needs to return an L2TP group name with the relevant name during authentication.

Auto-establish

Every minute, a check is performed to determine if tunnels need to be established (a process referred to as scan auto-establish). The tunnel state is establishedIdle when the tunnel is setup, and becomes established when user triggered sessions are set up over this tunnel.

```
configure
    service
        vprn 65536 customer 1 create
            l2tp
                group "wholesale.com" create
                    tunnel "wholesale.com" create
                        local-address 192.168.33.1
                        local-name "lac-pe1"
                        peer 192.168.33.2
                        auto-establish
                        no shutdown
                    exit
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

There is no difference in operational behavior for a tunnel set up via a session-trigger or an auto-establish command. Removing the auto-establish parameter has no impact on active tunnels (establishedIdle or established).

```

Tools tunnel start

First revert to the original situation, without auto-establish, as follows:

```
*A:LAC# configure service vprn 65536 l2tp group "wholesale.com"
                              tunnel "wholesale.com" no auto-establish
*A:LAC#
```

Verify the tunnel does not exist anymore, as follows:

```
*A:LAC# show router 65536 l2tp tunnel
No entries found.
*A:LAC#
```

Issue the tools command to manually establish the L2TP tunnel, as follows:

```
*A:LAC# tools perform router 65536 l2tp group "wholesale.com"
                                  tunnel "wholesale.com" start
*A:LAC#
```

Verify a new tunnel has been created, as follows:

```
*A:LAC# show router 65536 l2tp tunnel
===================================================================
Conn ID    Loc-Tu-ID Rem-Tu-ID State           Blacklist-state  Ses Active

```

How long remains a tunnel idle before being torn down?

An L2TP tunnel can be torn down automatically, after the expiration of an idle timer, or manually through a tools command.

Idle timeout

A persistent tunnel is a tunnel that remains available after the last session over that tunnel is closed. To create a persistent tunnel, the **idle-timeout** parameter must be set to *infinite*.

A non-persistent tunnel is torn down immediately (idle-timeout zero) after the last session over that tunnel is closed or after a configurable delay. The idle-timeout parameter is set via the RADIUS [26-6527-49] Alc-Tunnel-Idle-Timeout attribute or the corresponding node parameter. The default value for this parameter is infinite (persistent).

```
configure router l2tp | configure service vprn l2tp
        idle-timeout [0..3600] s
        ---snip---
        group <tunnel-group-name>
            idle-timeout [0..3600] s | infinite
            ---snip---
            tunnel  <tunnel-name>
                idle-timeout [0..3600] s | infinite
                ---snip---
```

The following shows an example of a non-persistent tunnel (idle-timeout 30 seconds). The tunnel changes state from established to establishedIdle when the last session is terminated. Idle-timeout seconds later, the session changes to the closed state. For the purpose of troubleshooting, the operational data stays available for destruct-timeout seconds (see later).

```

```

Tools tunnel stop

In addition to the idle timeout used for tunnel termination, a tools stop command is also available that can be used to terminate persistent and non-persistent tunnels at any moment in time. Be aware that this command is very destructive and destroys all sessions carried over the closed tunnel.

Following command shows the tunnel is in the establishedIdle state.

```
*A:LAC# show router 65536 l2tp tunnel
===============================================================================
Conn ID     Loc-Tu-ID Rem-Tu-ID State            Blacklist-state   Ses Active
  Group                                                            Ses Total
    Assignment
-------------------------------------------------------------------------------
60293120    920       7499      establishedIdle   not-blacklisted   0
  wholesale.com                                                     0
    wholesale.com
-------------------------------------------------------------------------------
No. of tunnels: 1
===============================================================================
*A:LAC#
```

The following command terminates the L2TP tunnel. The tunnel is aborted (the LAC sends StopCCN) using the <connection-id> or <tunnel-group-name>+<tunnel-name> as input. This StopCCN indicates "operator request" as the error reason.

```
*A:LAC# tools perform router 65536 l2tp group "wholesale.com"
                                    tunnel "wholesale.com" stop
INFO: CLI stopped 1 tunnels, destructed 0 tunnels.
```

```
*A:LAC#
```

The following debug output shows the tunnel being aborted.

```
13 2019/05/22 12:12:28.377 CEST MINOR: DEBUG #2001 vprn65536 L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.168.33.1:1701 -> 192.168.33.2:1701
tunnel 12828 session 0, ns 2 nr 1, flags:, reserved=0
    AVP MessageType(0,0), flags: mandatory, reserved=0
        StopControlConnectionNotification(4)
    AVP ResultCode(0,1), flags: mandatory, reserved=0
        result-code: "generalRequestToClearControlConnection"(1),
                             error-code: "noGeneralError"(0)
        error-msg: "operator request"
    AVP AssignedTunnelId(0,9), flags: mandatory, reserved=0
        3695"
```

Alternatively, the tunnel can also be stopped with the following command. The effect would be the same.

```
*A:LAC# tools perform router 65536 l2tp tunnel 964886528 stop
```

Keepalive - L2TP hello

A keepalive mechanism is employed by L2TP in order to differentiate between tunnel outages and no control or data activity on a tunnel for an extended period. This is accomplished by injecting hello control messages after a specified period of time has elapsed since the last data or control message (ZLB not included) was received on a tunnel. As for any other L2TP control message, if the hello message is not reliably delivered, then the tunnel is declared down and reset, as defined in RFC 2661. This means that SR OS does not send hello packets if session control traffic is handled over this tunnel. The hello timer is reset if the system transmits any control packet over this tunnel (ZLB packets and data traffic are not taken into account).

The keepalive function is disabled (not recommended) using RADIUS [26-6527-50] Alc-Tunnel-Hello-Interval -1 or hello-interval infinite (default 300). The number of retries for unsuccessful hello packet delivery equals RADIUS [26-6527-52] Alc-Tunnel-Max-Retries-Estab or node parameter max-retries-estab (default 5). The retry interval is initially set to 1 second and doubles on each retry with a maximum interval of 8 seconds. Using a max-retries-estab 7 results in a retry of [1,2,4,8,8,8,8 seconds].

```
configure router l2tp | configure service vprn l2tp]
    hello-interval [60..3600] s | infinite  # default 300 s
    max-retries-estab [2..7]                # default 5
    ---snip---
    group <tunnel-group-name>
        hello-interval [60..3600] s | infinite
        max-retries-estab [2..7]
        ---snip---
        tunnel  <tunnel-name>
            hello-interval [60..3600] s | infinite
            max-retries-estab [2..7]
            ---snip---
```

For example, the LAC can be configured with an hello timer of 1 minute and the LNS with an hello timer of 2 minutes. The hello timer interval for LAC and LNS do not have to be same because the keepalive mechanism works asynchronous. See Figure 119: L2TP keepalive mechanism.

Keeping closed tunnel and session information

The destruct-timeout parameter (expressed in seconds) controls the period of time that the tunnel, or session data related to a closed (disconnected) tunnel, or session persists before being removed. The destruct timeout is a debugging aid by keeping underlying memory structures after the tunnel or session is terminated. It is configured via the RADIUS [26-6527-51] Alc-Tunnel-Destruct-Timeout attribute or the corresponding node parameter. Default value for this parameter is 60 seconds.

```
configure router l2tp | configure service vprn l2tp
    destruct-timeout [60..86400]
    ---snip---
    group <tunnel-group-name>
        destruct-timeout [60..86400]
        ---snip---
        tunnel  <tunnel-name>
            destruct-timeout [60..86400]
```

The following output shows a session that is closed and the reason for it being terminated.

```

Floating peers

A floating peer exists if the peer LNS address indicated in the source address of the SCCRP is different from the peer address known on the LAC. Floating peer allowance is configuration driven and is rejected by default.

The parameter peer-address-change-policy specifies whether the LAC accepts, ignores or rejects requests from a peer to change the destination IP address or UDP port.

```
configure router l2tp | configure service vprn l2tp
      peer-address-change-policy accept | ignore | reject
```

- accept — Specifies that this system accepts any source IP address change for received L2TP control messages related to a locally originated tunnel in the state wait-reply and rejects any peer address change for other tunnels. In case the new peer IP address is accepted, it is learned and used as destination address in subsequent L2TP messages, as shown in Figure 120: Floating peers accept.

Figure 120: Floating peers accept
al_0512B

- ignore — Specifies that this system ignores any source IP address change for received L2TP control messages, does not learn any new peer IP address and does not change the destination address in subsequent L2TP messages, as shown in Figure 121: Floating peers ignore.

Figure 121: Floating peers ignore
al_0512C

- reject — Specifies that this system rejects any source IP address change for received L2TP control messages and drops those messages, as shown in Figure 122: Floating peers reject.

Figure 122: Floating peers reject

al_0512A
The values Peer IP, Tx dst-IP and Rx src-IP in the **show router l2tp tunnel detail** command indicates if floating peers are used or not.

An example of a floating peer (peer-address-change-policy accept) is as follows.

```
*A:LAC# show router l2tp tunnel detail

```

Tx/Rx connect speed - AVP 24/38

The connect speed (TX AVP 24 and RX AVP 38) is passed in the ICCN messages sent from the LAC to the LNS. The L2TP AVP 24 defines the (Tx) connect speed in bps from the perspective of traffic flowing from the LAC towards the subscriber (BNG downstream rate).The L2TP AVP 38 defines the (Rx) connect speed in bps from the perspective of traffic flowing from the subscriber toward the LAC (BNG upstream rate).

The report-rate configuration option indicates what rate is reported to the LNS when creating an L2TP session.

```
configure subscriber-mgmt sla-profile <sla-profile-name> ingress | egress
    report-rate agg-rate-limit|scheduler|pppoe-actual-rate|policer|rfc5515-actual-rate
```

- agg-rate-limit — Take the aggregate rate as received from the RADIUS Access-Accept message in VSA Alc-Subscriber-QoS-Override. When this RADIUS VSA is not present in the Access-Accept, or when RADIUS is not used, then take the configured aggregate rate limit. In the case where this is not configured, then take the port rate.

- scheduler <scheduler-name> — Take the rate of the specified scheduler. In case the scheduler is not linked with the scheduler-policy from the subscriber-profile, then take the port rate.

- pppoe-actual-rate — Take the rate from the DSL-Forum Vendor-Specific PPPoE Tag when available, otherwise take the port rate.

- rfc5515-actual-rate — Put the same value as the transmitted Actual-Data-Rate-Upstream AVP in the Rx-Connect-Speed AVP, and the same value as the transmitted Actual-Data-Rate-Downstream AVP in the Tx-Connect-Speed AVP.

Calling number AVP 22 format

The format of AVP 22 calling number in the ICRQ message is configurable via the parameter calling-number-format. The default format is "%S<space>%s" and corresponds to the concatenation of system-name<space>sap-id. Available parameters are %S (system-name), %c (Agent Circuit Id), %r Agent Remote Id, %s (sap-id), %l (Logical Line ID) and fixed strings. A combination can be configured from any of these parameters, but the total configured format cannot exceed 255 characters.

Example 1: Default configuration.

```
configure router l2tp calling-number-format "%S %s"
```

```
19 2019/05/22 14:01:04.885 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)

Prevent LAC from transmitting calling number AVP 22 to LNS

By default, the LAC includes the calling number AVP 22 in the L2TP incoming-call-request (ICRQ) packets
transmitted to LNS. This AVP identifies the interface that is connected to the customer in the access
network. Network access interface information can be hidden by configuring the LAC not to send the
calling number AVP to the LNS.

Use the following command to disable the sending of L2TP calling number AVP 22.

```
configure router l2tp
      exclude-avps calling-number
```

AVP 100 - Cisco-Nas-Port

Interoperation with a Cisco LNS requires that the LAC communicates a NAS port type to the LNS via
the L2TP ICRQ 'Cisco Nas Port Info AVP (100)'. This AVP (100) includes information that identifies the
NAS port and indicates whether the port type is Ethernet or ATM and is configured via the cisco-nas-port
parameter.

The Cisco AVP 100 format is as follows:

- First 5 bytes are NAS-Port-Type:
    - 0f10090203 (Ethernet)
    - 0f10090201 (ATM)
- Remaining four bytes correspond with the configured cisco-nas-port value

Example:

- Ethernet 12b s-vlan-id; 10b c-vlan-id; 3b slot number; 2b MDA nbr; 5b port
- ATM 12b VPI; 10b VCI; 3b slot number; 2b MDA nbr; 5b port

```
configure router l2tp
        cisco-nas-port ethernet "*12o*10i*3s*2m*5p" atm "*12v*10c*3s*2m*5p"
```

nas-port 1/1/3:100 corresponds to 102563 (000000000000 0001100100 001 01 00011).

```
19 2019/05/22 14:11:49.431 CEST MINOR: DEBUG #2001 Base L2TP(v2, ctrl, egress)
"L2TP(v2, ctrl, egress): UDP 192.0.2.1:1701 -> 192.168.22.2:1701

```

L2TP group/peer/tunnel draining

When the LAC has established sessions, the LAC can avoid the creation of new sessions for a specific group, peer, or tunnel, via the **drain** command.

No new sessions are created for a group, peer or tunnel that is being drained (draining state) but the current sessions are left intact.

After the **drain** command is issued, the group, peer, or tunnel moves from a draining to drained state when the last session is closed. A drained group, peer, or tunnel can then be managed (reconfigured, deleted) without any user impact.

Be aware that a group, peer, or tunnel in a draining or drained state is skipped in the tunnel selection process. The next example shows a tunnel draining; group and peer draining works according in the same way.

A tunnel has 1 session and is in established state.

For draining and undraining for example a group, following commands can be used.

```
tools perform router 65536 l2tp group "wholesale.com" drain
tools perform router 65536 l2tp group "wholesale.com" no drain
```

Conclusion

This example provides the LAC L2TP access server configuration and troubleshooting commands for the
LAA architecture (tunneled-access) model.

Local User Database Basics

This chapter provides information about Local User Database (LUBD) Basics.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 13.0.R1, but the information and configuration in the current edition are based on SR OS Release 16.0.R4.

Overview

A local user database (LUDB) is a data source containing a set of host entries, providing full or partial enhanced subscriber management (ESM) data so that subscribers and subscriber hosts can be instantiated when end-users connect their devices.

An LUDB can be accessed for the following applications; see Figure 123: LUDB applications.

1. To support ESM for retrieval of data to instantiate hosts and subscribers. This applies to the routed central office [CO] model only.

2. To support a local DHCPv4 server; for example for assigning fixed IP addresses to dedicated end-user devices.

3. To allow the system to provide the ESM data in case the RADIUS server referenced from the authentication policy is not available. The LUDB serves as a fallback for RADIUS authentication.

Figure 123: LUDB applications
al_0806

The LUDB lookup process is common to the applications shown in Figure 123: LUDB applications, and performs the following steps:

- Applying match criteria, to select the input parameters that will be used for the lookup.

- Optionally, applying a mask to one or more of the remaining input parameters.

- Performing the lookup.

The LUDB lookup process translates a set of input parameters (the host identification fields) into a set of output parameters; see Figure 124: Processing an LUDB lookup request for the following example:

- An LUDB lookup is requested for a client with MAC address and SAP as input parameters (1).

- The match criteria indicate to consider the SAP only, so the MAC address is ignored (2).

- The masking defines the stripping of the VLAN-tag from the SAP (3).

- The lookup then uses SAP 1/1/1 and finds entry1 to be the matching entry, so the LUDB returns the SLA-profile string and the SUB-profile string together with the Gi address.

Optionally, an LUDB defines a **default** host entry, which is used in case none of the other entries matches the lookup request, so it serves as a wildcard (*).

Not finding any matching host entry in an LUDB results in a setup failure.

Figure 124: Processing an LUDB lookup request
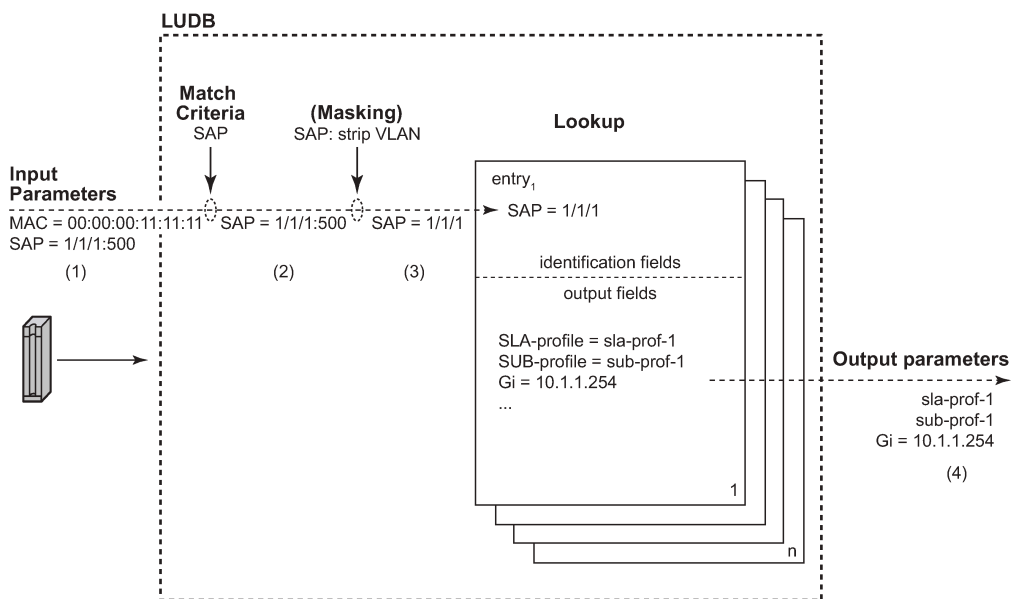

Configuration

Creating LUDBs

An LUDB is identified by a name of 32 characters maximum (Figure 125: Creating LUDBs and LUDB entries).

```
*A:BNG-1>config>subscr-mgmt# local-user-db
  - local-user-db <local-user-db-name> [create]
```

Multiple LUDBs can be defined, and their respective names must be unique.

An LUDB can provide the data for IPoE (DHCPv4, DHCPv6, and SLAAC) as well as for PPP users.

```
*A:BNG-1>config>subscr-mgmt>loc-user-db$
 [no] description    - Description for this local user database
      ipoe           + Configure IPOE hosts
      ppp            + Configure PPP hosts
 [no] shutdown       - Administratively enable/disable this local user database
```

For an LUDB to be active, the LUDB must be in the **no shutdown** state.

Individual host entries in an LUDB can match single or multiple hosts.

Figure 125: Creating LUDBs and LUDB entries

al_0808
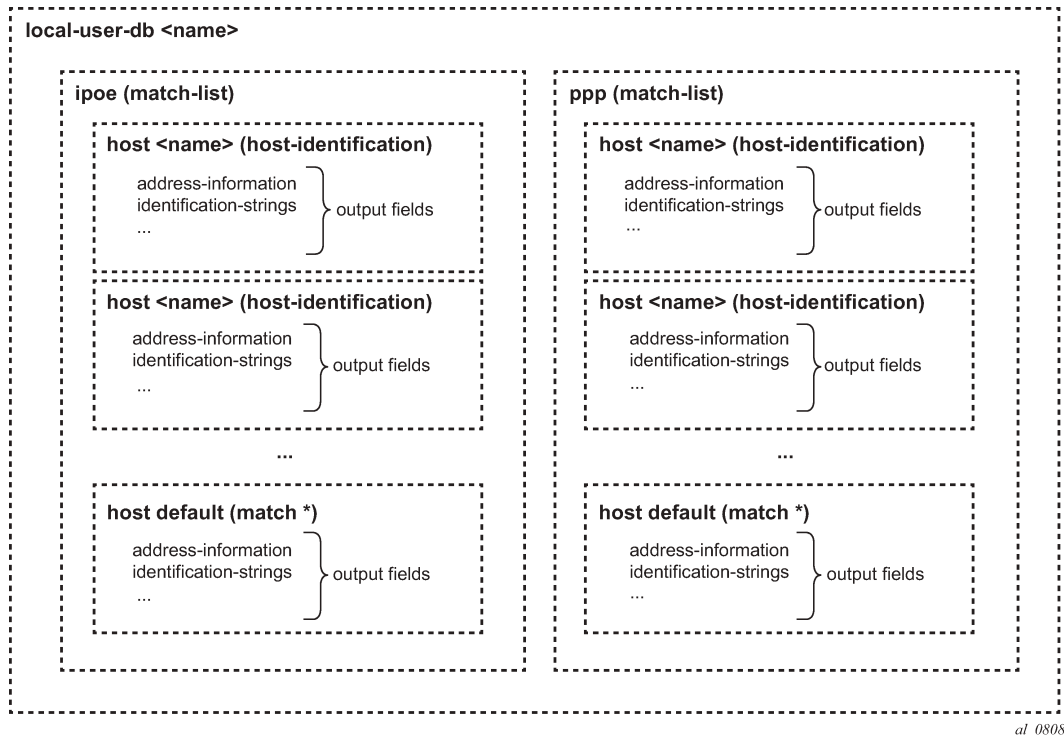

Creating host entries

A host entry is identified by name of 32 characters maximum (Figure 125: Creating LUDBs and LUDB entries).

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe$ host
  - host <host-name> [create]
```

The name **default** can optionally be used as a wildcard for situations where otherwise the lookup fails to find a matching entry. A host entry belongs to either the IPoE or the PPP section of an LUDB. The name of a host entry must be unique within the section. A host entry contains two sets of fields. The first set of fields are the host-identification fields and are used for the lookup, the second set of fields are output to the lookup process.

The host-identification fields available for IPoE are, in alphabetical order:

- circuit-id
- derived-id, which must be defined using a Python script, which derives the value from DHCP messages
- encap-tag-range
- ip-prefix
- mac-address
- option 60
- remote-id

- sap-id

- service-id

- string

- system-id

The host-identification fields available for PPP are, in alphabetical order:

- circuit-id: taken from the PPPoE tags

- derived-id, which must be defined using a Python script, which derives the value from PPP messages

- encap-tag-range

- mac

- remote-id: taken from the PPPoE tags

- sap-id

- service-name

- username

The output fields of the lookup process include the identification strings, DHCP options, IP address information, MSAP information, and so on.

Entry validation

For a host entry to be active, it must be put in the **no shutdown** state.

Before adding the host entry to the lookup database, the system validates the host entry:

- A **default** host entry can be added, preferably without host identification fields.

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe# host default create
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host$ no shutdown
  INFO: DHCPS #1138 This host will be considered as the default host
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host$
```

Defining a **default** host entry with identification fields is not recommended, because it would turn the default host entry into a regular entry, instead of a match all entry, when the match-list is changed.

- A **non default** host entry without host identification fields cannot be added to the lookup database.

```
MINOR: DHCPS #1126 Host-identification must have at least 1 item defined
```

- A **non default** host entry with none of its host identification fields in common with the match-list is added to the unmatched host list.

```
INFO: DHCPS #1107 Host could not be inserted in lookup database - no
                                      match values
```

- A **non default host** entry is added to the lookup database when at least one of the defined host identification fields is in common with the match-list, even when some of the host identification fields are not on the match-list.

- Two or more **non default** host entries with the same host-identification definitions are considered as duplicates. The second entry with the same host-identification definitions is not added to the lookup database; it is considered as a configuration mistake.

```
INFO: DHCPS #1107 Host could not be inserted in lookup database — duplicate
```

LUDB informational and error messages appear to be originating from the DHCPS application (DHCPS #nnn in the preceding outputs), even though the LUDB is not associated with a DHCPv4 server.

Creating a match list

Retrieving data from an LUDB requires one or more criteria to be put on a **match-list**. A match-list is a sequential list of parameters considered for the lookup; other parameters provided on LUDB access are ignored.

For IPoE, up to four criteria can be defined; for PPP, the maximum is three. The criteria on a match-list are processed in the order specified.

For IPoE users, the following match criteria are allowed, in alphabetical order:

- circuit-id
- derived-id (defined by a Python script)
- dual-stack-remote-id (IPv4 and IPv6, with IPv6 enterprise-id stripped off)
- encap-tag-range
- ip
- mac-address
- option 60
- remote-id (IPv4 and IPv6, including the IPv6 enterprise-id)
- sap-id
- service-id
- string
- system-id

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe# match-list
 - no match-list
 - match-list <ipoe-match-type-1> [<ipoe-match-type-2>...(up to 4 max)]
 <ipoe-match-type>   : circuit-id|derived-id|dual-stack-remote-id|
                       encap-tag-range|ip|mac|option60|remote-id|sap-id|
                       service-id|string|system-id

*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe#
```

For PPP users, the following match criteria are allowed, in alphabetical order:

- circuit-id
- derived-id (defined by a Python script)
- encap-tag-range
- mac-address

- remote-id (IPv4 and IPv6, including the IPv6 enterprise-id)

- sap-id

- service-name

- username (complete username, domain part only, host part only)

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ppp# match-list
  - no match-list
  - match-list <ppp-match-type-1> [<ppp-match-type-2>...(up to 3 max)]

 <ppp-match-type>      : circuit-id|derived-id|mac|remote-id|sap-id|
                          encap-tag-range|service-name|username

*A:BNG-1>config>subscr-mgmt>loc-user-db>ppp#
```

Masking

Optionally, the parameters considered for the lookup can be masked.

Masking is prefix- or suffix- based, or a combination of both. A prefix or suffix string, or a prefix or suffix length, can be specified.

For PPP users, masks can be applied to the circuit-id, remote-id, sap-id, service-name, and username. For IPoE users, masks can be applied to the circuit-id, option 60, remote-id, sap-id, string, and system-id.

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ppp# mask ?
  - mask type <ppp-match-type>
   {[prefix-string <prefix-string> | prefix-length <prefix-length>]
    [suffix-string <suffix-string> | suffix-length <suffix-length>]}
  - no mask type <ppp-match-type>

 <ppp-match-type>      : circuit-id|remote-id|sap-id|service-name|username
 <prefix-string>       : [127 chars max] ('*' is wildcard)
 <prefix-length>       : [1..127]
 <suffix-string>       : [127 chars max] ('*' is wildcard)
 <suffix-length>       : [1..127]
```

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe# mask ?
  - mask type <ipoe-match-type>
   {[prefix-string <prefix-string> | prefix-length <prefix-length>]
    [suffix-string <suffix-string> | suffix-length <suffix-length>]}
  - no mask type <ipoe-match-type>

 <ipoe-match-type>     : circuit-id|option60|remote-id|sap-id|string|system-id
 <prefix-string>       : [127 chars max] ('*' is wildcard)
 <prefix-length>       : [1..127]
 <suffix-string>       : [127 chars max] ('*' is wildcard)
 <suffix-length>       : [1..127]
```

The lookup occurs after applying the optional masks.

The examples in Table 30: Masking examples illustrate masking. For the third example, a combination of both prefix and suffix matching is used.

Table 30: Masking examples

Mask Type			prefix-length	suffix-length	prefix-string	suffix-string	result
username	**circuit-id**	**remote-id**					
-	-	87654321-BSAN-1	9	-	-	-	BSAN-1
-	BSAN-2|1|100|1/2/1	-	-	11	-	-	BSAN-2
all@domain-1.com	-	-	-	-	*@	.com	domain-1

Lookup

The following rules apply while scanning through an LUDB in search of a single matching entry:

1. Only criteria on the match-list are considered.

   Assume a client with MAC-address, a circuit-id, and a remote-id. If the match-list only defines the MAC-address to be used as criterion, then the circuit-id and the remote-id are ignored. Only the MAC-address is used for selecting the proper host entry.

2. The order of the criteria on the match-list is important.

   The match-list is a sequential list, and the criteria are processed left to right.

3. As many of the host-identification fields as possible must be matched, while still obeying rule 1.

   Only the (optionally masked) parameters from the match list are verified.

4. A **default host** is excluded from the scan, if defined.

   A **default host** is used as a fallback when scanning through an LUDB does not provide any result.

Figure 126: Host matching examples
The examples in Figure 126: Host matching examples and Figure 127: Host matching examples (continued) illustrate these rules:

1. Matching is based on the MAC-address only. When *client-a* with *mac-1* connects, host *ipoe-x* is matched.

2. Matching is based on the MAC-address, circuit-id, and remote-id, in this sequence. As client-b enters with mac-1, cid-1 and rid-1, the match-list is scanned and matched left to right, so host ipoe-z is matched.

3. Matching is based on the MAC-address only. Even though client-c connects with mac-1, cid-1, and rid-1, the system ignores the circuit-id and the remote-id, so the matching host is ipoe-x. Note that host ipoe-y can never be matched using the match-list defined; it is on the unmatched host list.

4. Matching is based on the MAC-address and the circuit-id, in this sequence. Client-d connects with mac-1 and cid-2, but because the system scans the match-list left through right, the MAC-address takes priority over the circuit-id. The matching host is ipoe-x.

Figure 127: Host matching examples (continued)
5. For the top part, matching is based on MAC-address and the circuit-id, in this sequence. When client-e connects (mac-1, cid-1, and rid-1), the system scans ludb-5-1 and matches host ipoe-x.

   For the bottom part, matching is based on the circuit-id first, then the MAC-address. When client-e connects (mac-1, cid-1, and rid-1), the system scans ludb-5-2 and matches host ipoe-y.

6. Matching is based on MAC-address and the circuit-id, in this sequence. When client-f-1 (mac-1) connects, the matching host is ipoe-x because only the MAC-address is provided and checked. When client-f-2 (cid-1) connects, the matching host is ipoe-y because only the client-id is provided and checked. When client-f-3 (mac-1, cid-1) connects, the matching host is ipoe-z.

7. Matching is based on the MAC-address only. When client-g with mac-2 connects, host default is matched because there is no explicit entry matching mac-2.

As shown is these examples, the system only checks the parameters provided by the client in the sequence as defined by the match-list. Parameters not provided by a client will not be searched for.

Tools commands

The following **tools** command manually triggers the lookup of an IPoE host in an LUDB and is useful during commissioning, troubleshooting, and verification of the configured database, without the need for an external client.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-1" ipoe host-lookup ?
  - host-lookup [mac <ieee-address>] [remote-id <remote-id-ascii>]
    [sap-id <sap-id>] [service-id  <service-id>] [string <vso-string>]
    [system-id <system-id>] [option60 <option-60-ascii>]
    [circuit-id <circuit-id-ascii>] [circuit-id-hex <circuit-id-hex>]
    [option60-hex <option60-hex>] [remote-id-hex <remote-id-hex>]
```

```
        [derived-id <derived-id>] [ip-prefix <ip-prefix/ip-prefix-length>]

 <ieee-address>        : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
 <remote-id-ascii>    : [255 chars max]
 <sap-id>             : [255 chars max]
 <service-id>         : [1..2148278317]|<svc-name:64 char max>
 <vso-string>         : [255 chars max]
 <system-id>          : [255 chars max]
 <option-60-ascii>    : [32 chars max]
 <circuit-id-ascii>   : [127 chars max]
 <circuit-id-hex>     : [0x0..0xFFFFFFFF...(max 254 hex nibbles)]
 <option60-hex>       : [0x0..0xFFFFFFFF...(max 64 hex nibbles)]
 <remote-id-hex>      : [0x0..0xFFFFFFFF...(max 510 hex nibbles)]
 <derived-id>         : [255 chars max]
 <ip-prefix/ip-pref*> : ipv4-prefix    - a.b.c.d (host bits must be 0)
                        ipv4-prefix-le - [0..32]
                        ipv6-prefix    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
                        ipv6-prefix-le - [0..128]
```

A similar command exists for the lookup of a PPP host in an LUDB.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-1" ppp host-lookup ?
 - host-lookup [circuit-id <circuit-id>] [circuit-id-hex <circuit-id-hex>]
   [derived-id <derived-id>] [mac <ieee-address>] [remote-id <remote-id>]
   [remote-id-hex <remote-id-hex>] [sap-id <sap-id>]
   [service-name <service-name>] [user-name <user-name>]

 <circuit-id>          : [127 chars max]
 <circuit-id-hex>      : [0x0..0xFFFFFFFF...(max 254 hex nibbles)]
 <derived-id>          : [255 chars max]
 <ieee-address>        : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx
 <remote-id>           : [255 chars max]
 <remote-id-hex>       : [0x0..0xFFFFFFFF...(max 510 hex nibbles)]
 <sap-id>              : [255 chars max]
 <service-name>        : [255 chars max]
 <user-name>           : [253 chars max]
```

Example 1: Single match criterion

The following shows an excerpt from ludb-1. Host entry-11 defines the parameters for an IPoE host, and host entry-55 defines the parameters for a PPPoE host. Host matching IPoE hosts is MAC-address based, whereas host matching PPP hosts is username based.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            description "example user-db"
            ipoe
                match-list mac
                host "default" create
                    address pool "pool4-1"
                    no shutdown
                exit
                host "entry-11" create
                    host-identification
                        mac 00:00:00:11:11:11
                    exit
                    address 10.1.1.211
                    ---snip---
```

```
                        no shutdown
                    exit
                    ---snip---
                exit
                ppp
                    match-list username
                    host "entry-55" create
                        host-identification
                            username "sub55@domain1"
                        exit
                        password chap sub55
                        address 10.1.2.252
                        ---snip---
                        no shutdown
                    exit
                    ---snip---
                exit
                no shutdown
            exit
```

IPoE hosts

IPoE host entry lookup using a MAC-address only is triggered with following **tools** command.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-1" ipoe
                                        host-lookup mac 00:00:00:11:11:11
===============================================================================
IPoE Host Lookup results
===============================================================================
Result               : Success
Matched Host Name    : entry-11
Admin State          : Up
Last Mgmt Change     : 11/20/2018 11:25:10

Host Identification
 Circuit Id          : N/A

```

The following command triggers the lookup of a non-existing MAC-address, leading to a host not found message.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-1" ipoe
                                            host-lookup mac 00:00:00:12:34:56
===============================================================================
IPoE Host Lookup results
===============================================================================
Result               : host not found
*A:BNG-1#
```

The host not found message is also confirmed by the debug output.

```
3 2018/11/20 11:43:30.351 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup success - host not found
  mac: 00:00:00:12:34:56

  Host not found in user data base ludb-1"
```

To allow IPoE users with unknown MAC-addresses to successfully connect, a default host can be created, at which time an informational message is returned:

```
*A:BNG-1# configure subscriber-mgmt local-user-db "ludb-1" ipoe host "default" create
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host# address pool pool4-1
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host# no shutdown
INFO: DHCPS #1138 This host will be considered as the default host
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host# exit all
*A:BNG-1#
```

After the previous commands are executed, devices with MAC-addresses not explicitly listed in the LUDB can also connect.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-1" ipoe
                                     host-lookup mac 00:00:00:12:34:56

```
================================================================================
*A:BNG-1#
```

Similar to the IPoE host lookup, the lookup of a non-existing user fails if no default entry is defined for PPP.
In this case, a default host can be defined.

Example 2: Multiple match criteria

The following shows an excerpt from ludb-2, with multiple match criteria.

The match-list includes mac, circuit-id, and remote-id, in this sequence.

```
configure
    subscriber-mgmt
        local-user-db "ludb-2" create
            ipoe
                match-list mac circuit-id remote-id
                host "entry-11" create
                    host-identification
                        mac 00:00:00:11:11:11
                    exit
                    address 10.1.1.111
                    ---snip---
                    no shutdown
                exit
                host "entry-12" create
                    host-identification
                        circuit-id string "11"
                        mac 00:00:00:11:11:11
                    exit
                    address 10.1.1.112
                    ---snip---
                    no shutdown
                exit
                host "entry-13" create
                    host-identification
                        circuit-id string "11"
                        mac 00:00:00:11:11:11
                        remote-id string "AA"
                    exit
                    address 10.1.1.113
                    ---snip---
                    no shutdown
                exit
                host "entry-14" create
                    host-identification
                        circuit-id string "11"
                        remote-id string "AA"
                    exit
                    address 10.1.1.114
                    ---snip---
                    no shutdown
                exit
```

The following **tools** command uses a MAC-address only, with entry-11 being matched.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-2"

  Host entry-111 found in user data base ludb-3"
```

Example 4: Masking (2)

The following shows an excerpt from ludb-4, applying masks.

The match-list includes the username, circuit-id, and remote-id, in this sequence. Masking applies to both the username and the circuit-id. The username has everything before the @-sign and the trailing .org stripped. The circuit-id has the trailing 11 characters stripped.

```
configure
    subscriber-mgmt
        local-user-db "ludb-4" create
            ppp
                match-list username circuit-id remote-id
                mask type circuit-id suffix-length 11
                mask type username prefix-string "*@" suffix-string ".org"
                host "entry-11" create
                    host-identification
                        username domain1
                        circuit-id string "BSAN-2"
                    exit
                    address pool "pool4-1"
```

```
                         identification-strings 254 create
                             sla-profile-string "sla-prof-1"
                             sub-profile-string "sub-prof-2"
                         exit
                         no shutdown
                  exit
                  ---snip---
            exit
            no shutdown
      exit
      ---snip---
```

The following **tools** command does not result in a match, which is not the intention.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-4" ppp host-lookup
               user-name sub11@domain1.org circuit-id "BSAN-2|100|1/2/1:111"
===============================================================================
PPP host Lookup results
===============================================================================
Result                : host not found
*A:BNG-1#
```

The debug output shows the original and the masked value of the user-name and the circuit-id; the remote-id was not provided.

```
14 2018/11/20 11:57:45.554 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup success - host not found
  user-name:
    original:  sub11@domain1.org
    masked:    domain1
  circuit-id:
    original:  BSAN-2|100|1/2/1:111
    masked:    BSAN-2|10
  remote-id:

  Host not found in user data base ludb-4"
```

The preceding output shows that three more characters (the |10) must be stripped to have a successful lookup, and following configuration changes are needed.

```
configure
    subscriber-mgmt
        local-user-db "ludb-4" create
            ppp
                mask type circuit-id suffix-length 14
```

Modifying the mask results in host entry-11 being matched.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-4" ppp host-lookup
               user-name sub11@domain1.org circuit-id "BSAN-2|100|1/2/1:111"
===============================================================================

Matched Objects       : userName circ-id
---snip---
===============================================================================
*A:BNG-1#
```

The debug output shows the effect of the modified mask.

```
15 2018/11/20 11:58:29.339 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup success - host found
  user-name:
    original:  sub11@domain1.org
    masked:    domain1
  circuit-id:
    original:  BSAN-2|100|1/2/1:111
    masked:    BSAN-2
  remote-id:

  Host entry-11 found in user data base ludb-4"
```

Example 5: VLAN range

LUDB matching also supports the use of encap-tag-range. Host-identification then needs a start and an end for the range, which both use the following format:

```
dot1q          - qtag1
    qinq           - (qtag1.qtag2 | qtag1.* | *.qtag2)
    atm            - (vpi/vci | vpi/* | */vci)
      qtag1          - [0..4094]
      qtag2          - [0..4094]
      vpi            - [0..4095] (NNI)
                       [0..255] (UNI)
      vci            - [1..65535]
```

For VLAN tagging, the Ethernet frames could be single- or dual- tagged. For ATM, a virtual path identifier (VPI) and a virtual circuit identifier (VCI) can be defined. The asterisk (*) serves as a wildcard, meaning that the parameter is ignored.

The system validates, at configuration time, the values of the start-tag and the end-tag, applying following rules:

- The start-tag must be lower than the end-tag.

- When using the asterisk, it should be present in both the start-tag and the end-tag, as either the inner or the outer tag:

  - *.10 - *.100 — the outer tag is ignored

  - 201.* - 299.* — the inner tag is ignored

- The encapsulation type for start-tag and end-tag must be the same.

- Overlapping ranges (while on the same port) are not allowed.

The following shows an excerpt from ludb-5, using vlan-ranges.

```
configure
    subscriber-mgmt
        local-user-db "ludb-5" create
            description "example for vlan ranges"
            ipoe
                match-list encap-tag-range
                host "range-1" create
                    host-identification
                        encap-tag-range start-tag *.1 end-tag *.50
                    exit
                    address pool "pool4-3"
                    ---snip---
                    no shutdown
                exit
                host "range-2" create
                    host-identification
                        encap-tag-range start-tag *.51 end-tag *.100
                    exit
                    address pool "pool4-4"
                    ---snip---
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

The following **tools** command specifies a sap-id including an outer and an inner tag, matching host range-1.

```
*A:BNG-1# tools perform subscriber-mgmt local-user-db "ludb-5"
                                        ipoe host-lookup sap-id 1/1/1:50.4

```

Operational considerations

Following operational considerations should be kept in mind:

- Names of LUDBs and LUDB entries cannot be changed.

- Modification of the host identification fields is possible only when the host-entry is put in the shutdown state. Modifying output fields does not require the host-entry to be in the shutdown state.

```
*A:BNG-1>config>subscr-mgmt>...>ppp>host>host-ident# circuit-id string x-y-z
MINOR: DHCPS #1133 Not allowed. Host is not shutdown
```

- Modifying a match-list requires the LUDB to be in the shutdown state.

- Modifying a match-list results in a re-evaluation of all host entries of the LUDB block, so that the lookup database and the unmatched host list are re-populated.

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe# match-list circuit-id
INFO: DHCPS #1107 Host could not be inserted in lookup database
- lookup database constructed, 1 hosts not inserted: 1 no match, 0 duplicate
```

Modifying the match-list also imposes the risk of a default entry with host-identification fields suddenly not being the fallback (default) entry anymore, which is why defining a default entry with host-identification fields is not recommended.

- Modifying one or more mask types does not require the LUDB to be in the shutdown state.

- Deletion of an LUDB requires that the LUDB is not referenced and the LUDB is in the shutdown state. Use caution: the status of the individual entries is not taken into account when deleting an LUDB.

```
*A:BNG-1>config>subscr-mgmt# no local-user-db "ludb-1"
MINOR: DHCPS #1103 User data base still referenced

*A:BNG-1>config>subscr-mgmt# no local-user-db "ludb-11"
MINOR: DHCPS #1104 Not allowed when user db admin state is up
```

Troubleshooting and debugging LUDBs

The **tools** command can also be used for troubleshooting; the example is not repeated for brevity.

Show commands

The following command shows which LUDBs are available in the system, including the administrative state and the host count. The host count equals the total number of configured ipoe and ppp entries, regardless of their administrative state (shutdown/no shutdown).

```
*A:BNG-1# show subscriber-mgmt local-user-db

Debugging commands

The following configuration enables debugging for both ludb-1 and for ludb-2.

```
debug
    subscriber-mgmt
        local-user-db "ludb-1"
            detail all
        exit
        local-user-db "ludb-2"
            detail all
        exit
    exit
exit
```

To ensure that the debug output is sent to the console, the following additional configuration is needed.

```
configure
    log
        log-id 1
            from debug-trace
            to session
            no shutdown
        exit
    exit
```

After the preceding configuration, debug output appears as part of the session.

```
2 2018/11/20 11:42:27.965 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup success - host found
  mac: 00:00:00:11:11:11

   masked:    AA

 Host not found in user data base ludb-2"
```

```
37 2018/11/20 12:18:59.141 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup failed
 Problem: user db is shutdown"
```

Conclusion

In this chapter general LUDB concepts are explained. LUDBs are defined and host entries for both IPoE as well as for PPP are described. The different match criteria are explained and demonstrated by means of examples, including the use of single and multiple match criteria. Match criteria are handled left to right, in sequence, so that a natural priority is taken care of. Debugging aids are provided through **show**, **debug** and **tools** commands.

Local User Database for DHCPv4 Server

This chapter provides information about local user database (LUDB) for DHCPv4 server.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 13.0.R1, but the information and configuration in the current edition are based on SR OS Release 16.0.R4.

Basic LUDB knowledge is a prerequisite for understanding this chapter.

Overview

In SR OS, a local DHCPv4 server can be assigned a local user database (LUDB).

Assigning an LUDB to a DHCPv4 server allows the server to:

- control IP address assignment; for example, by assigning a fixed IP address based on the user's MAC address.
- control DHCPv4 options for native as well as for simulated DHCPv4 clients used by PPP. In the case of PPP, users are identified to the DHCPv4 server using the DHCPv4 Vendor-Specific Information Sub-option [82,9][6] in the DHCPv4 discover/request messages.
- provide ESM strings (referred to as identification-strings in CLI) using a user-defined unassigned DHCPv4 option (option 254 is provided as default).

Introduction

A local DHCPv4 server can be used for IPoE users as well as for PPP users (see Figure 128: LUDB access via a DHCPv4 server).

When a DHCPv4 user connects, the typical discover, offer, request, and acknowledge (DORA) message sequence running between the DHCPv4 client and the DHCPv4 server also passes through a relay agent.

When a PPP user connects through LCP/IPCP, an internal DHCPv4 client manages the communication toward the DHCPv4 server, on the condition that the relay agent also has relaying enabled for PPP applications. This internal DHCPv4 client is also referred to as a local (DHCPv4) client.

The DHCPv4 server can be located in the same node as the relay agent and the local client, but that is not required.

Figure 128: LUDB access via a DHCPv4 server

DORA- Discover, Offer, Request, Acknowledge

al_0811
The relay agent must be configured correctly in order to forward the messages toward a DHCPv4 server. The DHCPv4 server IP address is defined. The relay agent can include following configurable options and sub-options to be used by the DHCPv4 server:

- [82,1] Agent circuit ID sub-option
- [82,2] Agent remote ID sub-option
- [82,9] Vendor-specific information sub-option (VSO)
  - [1] system ID
  - [2] client MAC address
  - [3] service ID (IES/VPRN service ID)
  - [4] SAP ID
  - [5] string
  - [13] pool name

The local client uses the same DHCPv4 server IP address as the preceding relay agent, and can include its own set of (unconfigurable) options and sub-options to be used by the DHCPv4 server:

- [60] vendor class (fixed string: ALU7XXXSBM)
- [82,1] Agent circuit ID sub-option
- [82,2] Agent femote ID sub-option
- [82,6] Subscriber ID sub-option (equals PPPoE username)
- [82,9] Vendor-specific information sub-option
  - [1] system ID (not included in a redundant node)
  - [2] client MAC address
  - [3] service ID (IES/VPRN service ID)
  - [4] SAP ID (not included for retail VPRN and redundant node)

- [6] client type (1=PPP)

- [13] pool name

- [14] service name (PPPoE tag service name)

- [17] session ID (PPPoE session ID)

When one or more of these options and sub-options are included, the DHCPv4 server can use them while accessing the LUDB, for selection of the section (client type 1 is the PPP section), and the host entry in that section. For example, not including the service ID VSO [82,9][3] to the DHCPv4 server, when LUDB host identification needs the MAC address and service ID, will result in an LUDB lookup failure on the DHCPv4 server and a silent drop of the DHCPv4 discover message.

LUDB input parameters

The following IPoE host identification fields are supported when accessing an LUDB from a DHCPv4 server:

- circuit-id

- encap-tag-range

- mac

- option60

- remote-id

- sap-id

- service-id

- string

- system-id

The LUDB lookup process can match up to four IPoE match-criteria, as defined by the IPoE match-list.

The following PPP host identification fields are supported when accessing an LUDB from a DHCPv4 server:

- circuit-id

- encap-tag-range

- mac

- remote-id

- sap-id

- service-name

- username

The LUDB lookup process can match up to three PPP match-criteria, as defined by the PPP match-list.

LUDB output parameters

Addressing information

The host entry address field has the following configuration options when the LUDB is associated with a DHCPv4 server:

- no address

  Host access is not allowed. The clients mapping to this host entry will not get an IP address.

  ```
  23 2018/11/21 13:20:09.958 CET MINOR: DEBUG #2001 Base DHCP server
  "DHCP server:  dhcp4-srv
  DISCOVER dropped: host=entry-66, host found but no valid address info
  ```

- address *<ip-address>*

  A fixed IP address is offered to the client and should not overlap with the address ranges configured in the local DHCP server.

- address pool *<pool-name>* [secondary-pool *<sec-pool-name>*]

  The DHCPv4 server allocates an address from one of the subnets in that pool on the condition that the DHCPv4 server is configured to use pool names for address selection. Optionally, a secondary pool can be defined, to be used in case the primary pool is exhausted.

  Pool-name addressing is useful when the subscriber management node is not capable of inserting the pool-name VSO [82,9][13] or when a specific host requires a specific pool-name different from the pool-name included by the subscriber management node.

- address gi-address [scope <subnet | pool>]

  When the scope is set to subnet, the DHCPv4 server allocates an address from the subnet that includes the Gi address. When the scope is set to pool, the DHCPv4 server allocates an address from the subnet that includes the Gi address, or from the other subnets belonging to the same pool. Gi-addressing is useful when the subnet that the Gi address belongs to is exhausted.

- address use-pool-from-client [delimiter *<delimiter>*]

  The DHCPv4 server allocates an address from one of the subnets in the pool, as indicated by the pool-name VSO [82,9][13]. If two pools are available in this VSO, the configured delimiter distinguishes the first pool-name from the second pool-name.

Identification strings

An LUDB can optionally return identification strings (also known as ESM strings). The DHCPv4 server returns them in a user-defined DHCPv4 option (default: 254) to the requesting entity (the relay agent or the local client). The identification strings, in alphabetical order, are:

- ancp-string
- app-profile-string
- category-map-name
- inter-dest-id

- sla-profile-string

- sub-profile-string

- subscriber-id

Options

An LUDB can return options to be used by the relay agent, the internal client, or the end-user device.

The IPoE user options configurable by option-name are:

- default-router

- dns-server

- domain-name

- lease-rebind-timer

- lease-renew-timer

- lease-time

- netbios-name-server

- netbios-node-type

- subnet-mask

The PPP user options configurable by option-name are:

- dns-server

- netbios-name-server

Additional options, configurable by option-number, can be configured for both IPoE and PPP users by using the **custom-option** command.

```
*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host>options# custom-option ?
  - custom-option <option-number> address [<ip-address>...(upto 4 max)]
  - custom-option <option-number> hex <hex-string>
  - custom-option <option-number> string <ascii-string>
  - no custom-option <option-number>

<option-number>     : [1..254]
<ip-address>        : a.b.c.d
<ascii-string>      : [127 chars max]
<hex-string>        : [0x0..0xFFFFFFFF...(max 254 hex nibbles)]

*A:BNG-1>config>subscr-mgmt>loc-user-db>ipoe>host>options#
```

The encoding of these custom options is either in hexadecimal, ASCII, or IP address format. In debug output, these custom options are indicated as *Unknown options* and presented in Type-Length-Value (TLV) format.

Options and custom options can be configured at three different levels:

- LUDB host entry level

- DHCPv4 server pool level

- DHCPv4 server subnet level

Options and custom options defined at the host entry level overrule options defined at either of the server levels.

Other parameters

All other parameters in the host entry definition are silently ignored (for example, IPv6 related parameters, msap-defaults, retail-service-id, and so on) because they are not applicable for a DHCPv4 server-associated LUDB.

Configuration

Figure 129: Example configuration shows the example configuration used in this chapter.

Figure 129: Example configuration
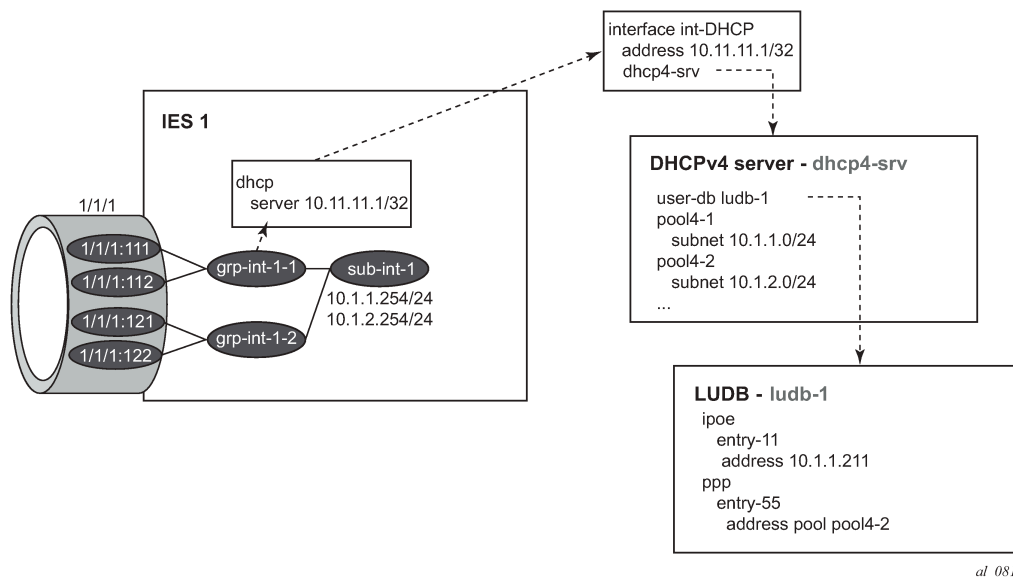

An LUDB can be associated with a DHCPv4 server in the base router instance or in a VPRN service instance using the following commands:

```
configure router dhcp local-dhcp-server <name> user-db <name>
configure service vprn <service-id> dhcp local-dhcp-server <name> user-db <name>
```

The following example has the DHCPv4 server created in the base router instance.

```
configure
    router
        dhcp
            local-dhcp-server "dhcp4-srv" create
                user-db "ludb-1"
                use-gi-address
                use-pool-from-client
                pool "pool4-1" create
                    subnet 10.1.1.0/24 create
```

```
                        options
                            subnet-mask 255.255.255.0
                            default-router 10.1.1.254
                        exit
                        address-range 10.1.1.1 10.1.1.100
                    exit
                exit
                pool "pool4-2" create
                    subnet 10.1.2.0/24 create
                        options
                            subnet-mask 255.255.255.0
                            default-router 10.1.2.254
                        exit

                        address-range 10.1.2.1 10.1.2.254
                    exit
                exit
                ---snip---
                no shutdown
            exit
        exit
```

The server is then associated with the loopback interface at address 10.11.11.1, as follows:

```
configure
    router
        interface "int-DHCP"
            address 10.11.11.1/32
            loopback
            local-dhcp-server "dhcp4-srv"
            no shutdown
        exit
    exit
```

The following is a partial configuration of service IES 1. Note that the DHCPv4 relay agent is configured to include the service-ID VSO [82,9][3] because this option is used in the LUDB for matching purposes.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.1.1.254/24
                address 10.1.2.254/24
                group-interface "grp-int-1-1" create
                    arp-populate
                    dhcp
                        option
                            action replace
                            circuit-id
                            remote-id
                            vendor-specific-option
                                pool-name
                                service-id
                            exit
                        exit
                        server 10.11.11.1
                        trusted
                        lease-populate 100
                        client-applications dhcp ppp
                        gi-address 10.1.1.254
                        no shutdown
                    exit
```

```
                    sap 1/1/1:111 create
                        sub-sla-mgmt
                            def-sub-profile "sub-prof-1"
                            def-sla-profile "sla-prof-1"
                            sub-ident-policy "sub-id-pol-1"
                            multi-sub-sap
                            no shutdown
                        exit
                    exit
                    ---snip---
                    pppoe
                        session-limit 100
                        sap-session-limit 100
                        no shutdown
                    exit
                exit
            exit
```

In the following example, IPoE users are matched against the service-id, the MAC address and option 60.
Host *entry-11* returns a fixed IP address, three identification strings, and a set of options. PPP users are
matched against the MAC address. Host *entry-55* returns an address-pool, two identification strings, and
two DNS servers as options.

```
configure
    subscriber-mgmt
        local-user-db "ludb-1" create
            description "example user-db"
            ipoe
                match-list service-id mac option60
                host "entry-11" create

                        custom-option 251 hex 0x010203
                    exit
                    no shutdown
                exit
                ---snip---
            exit
            ppp
                match-list mac
                host "entry-55" create
                    host-identification
                        mac 00:00:00:55:55:55
                    exit
                    address pool "pool4-2"
                    identification-strings 254 create
```

```
                        subscriber-id "sub-55"
                        sla-profile-string "sla-prof-3"
                        sub-profile-string "sub-prof-3"
                    exit
                    options
                        dns-server 2.2.2.2 2.2.2.1
                    exit
                    ---snip---
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

Entry-11 defines a fixed IP address in one of the subnets allowed on the group interface *grp-int-1-1* on IES 1, but out of the range defined in the DHCPv4 server.

Debugging

The following example debugs the local DHCP server and the LUDB *ludb-1*.

```
debug
    router "Base"
        local-dhcp-server "dhcp4"
            detail-level medium
            mode egr-ingr-and-dropped
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-1"
            detail all
        exit
    exit
exit
```

The following additional configuration ensures that the debug output is sent to the current login session.

```
configure
    log
        log-id 1
            from debug-trace
            to session
            no shutdown
        exit
    exit
exit
```

IPoE users verification

The following command shows the DHCPv4 server lease state record for LUDB host *entry-11*. The address type is set to *fixed* because *ludb-1* returns a fixed IP address.

```
*A:BNG-1# show router dhcp local-dhcp-server "dhcp4-srv" leases 10.1.1.211 detail

===============================================================================
*A:BNG-1#
```

The debug output on the DHCPv4 server and the LUDB *ludb-1* shows that the LUDB is accessed for every incoming message. The identification-strings are returned to the relay agent in the Offer and Acknowledge messages through option [254]; see Figure 130: Decoding the ESM user option for the decoding.

    [255] End
"
```

The user-defined option value for carrying the ESM strings and taken from the LUDB (identification-strings)
should match the value defined in the strings-from-option parameter (value 254 in the following example)
referenced in the subscriber identification policy on the relaying node.

```
configure
```

```
        subscriber-mgmt
            sub-ident-policy "sub-id-pol-1" create
                sub-profile-map
                    use-direct-map-as-default
                exit
                sla-profile-map
                    use-direct-map-as-default
                exit
                strings-from-option 254
            exit
```

The DHCP options in the debug output match the definition of the options in the LUBD.

Figure 130: Decoding the ESM user option
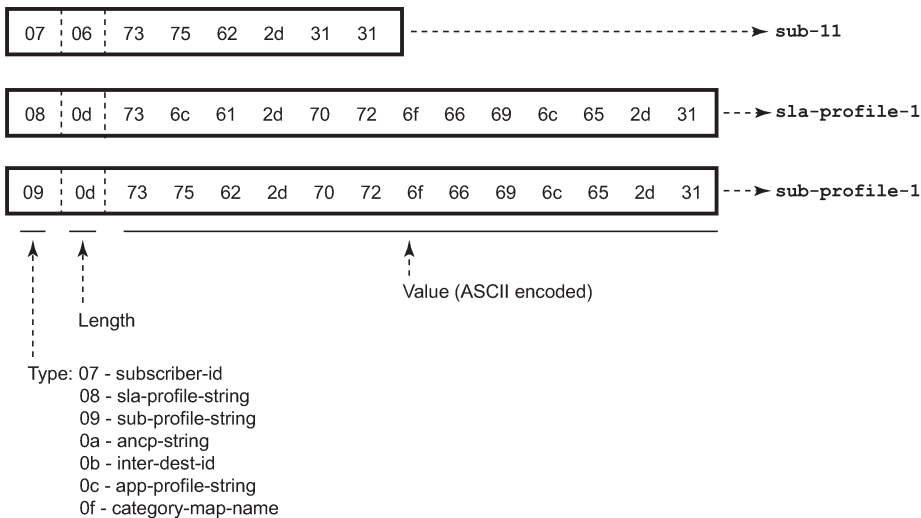

PPP users verification

The following command shows the DHCPv4 server lease state record for LUDB host *entry-55*. The client type is set to ppp, and the address type is set to dynamic as *ludb-1* returns address-pool *pool4-2* for this host.

```

Operational considerations

A DHCPv4 server with an LUDB cannot be used for supporting Local Address Assignment (LAA) scenarios. LAA can be used when the DHCPv4 relay agent and the DHCPv4 server are in the same node, and where IP address assignment for PPP users happens through the API directly into the local DHCPv4 server. See the ESM SLAAC Prefix Assignment via Local Address Server chapter for details on this topic.

Conclusion

This chapter explained and demonstrated the use of an LUDB in combination with a DHCPv4 server. For the DHCPv4 server to find matching entries in the LUDB, the relay agent has to be configured with the correct options and sub-options so that entries can be matched in the LUDB. It was noted that the DHCPv4 server does not require the relaying function to be located in the same node. The input and the output parameters of a DHCPv4 server-attached LUDB were listed. Carrying over the identification/ESM strings in a user-defined DHCP option was configured and demonstrated, and the decoding of this option was explained.

Local User Database for Enhanced Subscriber Management

This chapter provides information about local user database for enhanced subscriber management.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 13.0.R6. The CLI in the current edition corresponds to SR OS Release 16.0.R4.

Having knowledge of ESM Basics, the Routed CO model, and Local User Database Basics are prerequisites for understanding this chapter.

Overview

A local user database (LUDB) is a data source providing enhanced subscriber management (ESM) data so that subscribers and subscriber hosts can be instantiated when end-users connect their devices. ESM data includes identification strings, IP address/prefix, profiles, and so on. See the ESM Basics chapter for more information.

LUDBs offer a self-contained method for providing the ESM data, so that no additional ESM data sources are needed.

Alternative ESM data sources are: RADIUS, Diameter NASREQ, Diameter Gx, DHCP-server, Python, and defaults.

Mixed scenarios, where part of the data is provided by an LUDB and the remaining part is provided through RADIUS, are the subject of the Flexible Authentication Model in ESM chapter.

LUDBs can be used for the following applications:

- assisting a DHCPv4 server in assigning fixed IP addresses to dedicated devices; see the Local User Database for DHCPv4 Server chapter.
- authenticating devices, so that ESM hosts and subscribers can be instantiated. This is supported for the Routed CO model only.
- authenticating devices as a fallback for RADIUS authentication, in case the RADIUS server is not available. This is supported for the Routed CO model only.

This chapter describes the use of LUDBs for authentication, including:

- parameters that can be returned by LUDBs
- contexts where LUDBs can be applied in the system

LUDB authentication is supported:

- for IPoE as well as for PPP
- for regular SAPs as well as for capture and managed SAPs
- for the proxy scenario as well as for the relay scenario

LUDB authentication can be started directly through one of the following protocol triggers; see Figure 131: LUDB authentication:

- DHCPv4 Discover
- DHCPv6 Solicit
- PPPoE PADI
- PPPoA Conf Req
- Router Solicit [RS]

Figure 131: LUDB authentication
(*) – indirect trigger only, via RADIUS fallback

25536

When triggered, ESM can directly access an LUDB because the LUDB is applied to the service directly (through one of its sub-contexts), or indirectly as a fallback action for RADIUS (through the authentication policy); see Figure 132: Direct and indirect LUDB authentication. ARP requests can only trigger LUDB authentication indirectly.

> **Note:**
> An authentication policy can be referenced from a group interface and a capture SAP, or from an LUDB.

Figure 132: Direct and indirect LUDB authentication
Three ESM scenarios in which an LUDB is accessed are as follows:

- ESM gets all the data needed for host creation directly from the LUDB.

- ESM gets some data from the LUDB and the remaining data from an AAA server (RADIUS, NASREQ, Gx). This requires the LUDB to provide an authentication or a Diameter application policy, and no authentication or Diameter policy at the group interface level.

- ESM tries to fetch the data from a RADIUS server, but because this server is not reachable, ESM falls back to an LUDB.

The examples in the Configuration section of this chapter describe the first and the last scenario. The second scenario is described in the Flexible Authentication Model in ESM chapter.

LUDB input and output parameters

As described in the Local User Database Basics chapter, when processing an LUDB lookup request, the input parameters are filtered and optionally masked before searching through the entries in the database. Every entry, except for the default, contains one or more host-identification fields that are used for matching purposes. As a result of the lookup process, these output parameters are then used for host creation.

The following IPoE host-identification fields are supported when accessing an LUDB for ESM; see Figure 133: LUDB parameters for IPoE:

- mac

- circuit-id + remote-id

- option60 (excluded for the IPoE session model)

- sap-id + encap-tag-range

- service-id

- string

- system-id

The LUDB lookup process can take up to four IPoE match-criteria into account, as defined by the IPoE match-list.

The following PPP host-identification fields are supported when accessing an LUDB for ESM; see Figure 134: LUDB parameters for PPPoE:

- mac

- circuit-id + remote-id

- sap-id + encap-tag-range

- service-name (PPPoE tag: service name)

- username (excluded for the RADIUS fallback scenario)

The LUDB lookup process can take up to three PPP match-criteria into account, as defined by the PPP match-list.

The fields output from the lookup process include the identification strings, options, and others.

See Figure 133: LUDB parameters for IPoE and Figure 134: LUDB parameters for PPPoE for the full list of input and output parameters for IPoE and PPPoE, respectively.

Figure 133: LUDB parameters for IPoE

Applying an LUDB for ESM

LUDB authentication for regular SAPs requires an LUDB to be applied at the group interface level in the Layer 3 service (VPRN or IES); see Figure 135: LUDB authentication for regular SAPs. All the SAPs on that group interface share the same authentication configuration. See the Local User Database for DHCPv4 Server chapter for the scenario where a user database is attached to a DHCPv4 server.

Figure 135: LUDB authentication for regular SAPs
LUDB authentication for capture and managed SAPs requires an LUDB to be assigned at capture SAP level in the Layer 2 service (capture-VPLS), and at the group interface level in the Layer 3 service (VPRN or IES). Because the trigger messages to create the managed SAPs are received on the capture SAP and subsequent messages on the managed SAP, the authentication configurations for the Layer 2 and the Layer 3 service must align, including the LUDBs; see Figure 136: LUDB authentication for capture and managed SAPs.

Figure 136: LUDB authentication for capture and managed SAPs
The following CLI commands are available for applying LUDBs:

```
configure service vprn | ies subscriber-interface <x> group-interface <y>
    dhcp user-db <local-user-db-name>
    ipoe-session user-db <local-user-db-name>
    ipv6 dhcp6 user-db <local-user-db-name>
    ipv6 router-solicit user-db <local-user-db-name>
    ppp user-db <local-user-db-name>
    pppoe user-db <local-user-db-name>
    wpp user-db <local-user-db-name>
```

```
configure service vpls <x> sap  <y>
    dhcp-user-db <local-user-db-name>
    dhcp6-user-db <local-user-db-name>
    ipoe-session user-db <local-user-db-name>
    ppp-user-db <local-user-db-name>
    pppoe-user-db <local-user-db-name>
    rtr-solicit-user-db <local-user-db-name>
```

An LUDB can be assigned in different contexts, and can be reused. Assuming an LUDB contains both IPoE as well as PPP entries, this LUDB is likely to be assigned in a dhcp context as well as in a ppp or a pppoe context.

Configuration guidelines

The following rules have to be observed when configuring authentication for regular, capture, and managed SAPs:

- If an authentication policy is applied at the capture SAP or group interface level, that authentication policy has priority, no matter whether or in which other sub-contexts an LUDB is assigned. Only when the AAA/RADIUS server referenced from the authentication policy is not available, can the SR OS rely on a fallback LUDB if configured. In that case, only a limited set of parameters are returned; see Figure 133: LUDB parameters for IPoE and Figure 134: LUDB parameters for PPPoE.

  This means that for an LUDB to provide ESM data, no authentication policy may be applied at the capture SAP or group interface level, provided that the LUDB is in the no shutdown state.

- An LUDB can return an authentication policy so that the ESM data can be partially provided by the LUDB, and partially by an AAA/RADIUS server. For this mixed scenario, RADIUS fallback is only possible for PPP, PPPoE, DHCPv4, IPoE sessions, and WPP, but not for DHCPv6 and IPv6 router solicitation. For more information, see the Flexible Authentication Model in ESM chapter. When the AAA/RADIUS server is defined but not available, the SR OS can rely on a fallback LUDB if configured.

- LUDB authentication for RADIUS fallback requires an LUDB to be applied to an authentication policy as a fallback action:

```
configure subscriber-mgmt authentication-policy <name>
               fallback-action user-db <local-user-db-name>
```

- The DHCPv4 server referenced from a group interface in the dhcp context (for supporting the relay scenario) can have an LUDB assigned; see the Local User Database for DHCPv4 Server chapter. See Figure 133: LUDB parameters for IPoE and Figure 134: LUDB parameters for PPPoE for the parameters that this LUDB can return to the DHCPv4 server.

  An LUDB cannot be assigned to a DHCPv6 server.

- If an LUDB is applied in the ipoe-session context of a group interface or capture SAP, the LUDBs assigned in the dhcp, dhcp6, and router-solicit contexts of the same group interface or capture SAP are ignored.

  This avoids accessing the LUDB on every DHCPv4 DORA or DHCPv6 SARR message, which is the case when no IPoE sessions are used.

  For IPoE sessions, the LUDB host identification cannot be based on option 60. Entries in the LUDB with host-identification option 60 strings are ignored. All the other LUDB entry match criteria are allowed.

- If an LUDB is applied in the ppp or pppoe context of a group interface or capture SAP, PAP or CHAP authentication is based on the password configured in the entry. If no password is required, the password parameter in the LUDB entry must be explicitly set to ignore.

  A password verification failure leads to a setup failure.

Configuration

Figure 137: Baseline setup shows the baseline configuration used in this chapter. Dual and single stack end-user devices supporting IPoE and PPPoE connect to the SAPs of IES-1. Different LUDBs are added to this baseline configuration later in this chapter, depending on the scenario.

Figure 137: Baseline setup
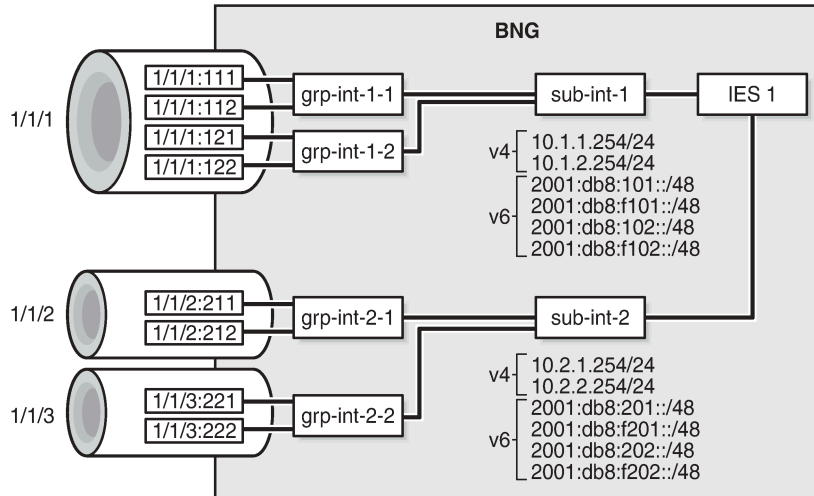

The following partial configuration applies to IES-1. This service is provisioned with ESM enabled on all of its SAPs, and supports proxy and relay scenarios on all group interfaces for both IPv4 and IPv6. Only the part relevant to subscriber interface *sub-int-1* and group interface *grp-int-1-1* is shown. The configurations for the other subscriber and group interfaces are similar. Check the ESM Basics and Routed CO chapters for more information.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1" create
                address 10.1.1.254/24
                ---snip---

                            multi-sub-sap
                            no shutdown
                        exit
                    exit
                    ---snip---
                exit
            exit
            ---snip---
```

For brevity, the configurations of the local DHCPv4 and DHCPv6 servers are not shown.

An excerpt from the LUDB *ludb-rsap* follows. Host *entry-11* defines the settings for a dual stack IPoE host, and host *entry-55* the settings for a dual stack PPPoE host. For both hosts, the LUDB provides all the data needed to ensure host instantiation.

```
configure
    subscriber-mgmt
        local-user-db "ludb-rsap" create
            description "LUDB for Regular SAPs"
            ipoe

```

IPoE authentication - session model

In this example, the LUDB *ludb-rsap* is applied to the group interface in the ipoe-session context. This is
the Nokia recommended way for supporting IPoE subscribers through an LUDB.

```
configure
    service
        ies 1 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    ipoe-session
                        ipoe-session-policy "ipoe-sess-1"
```

```
                        session-limit 100
                        user-db "ludb-rsap"
                        no shutdown
                   exit
```

Use the following debug configuration for troubleshooting connection issues.

```
debug
    router "Base"
        ip
            dhcp
                detail-level low
                mode egr-ingr-and-dropped
            exit
            dhcp6
                mode egr-ingr-and-dropped
                detail-level low
            exit
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-rsap"
            detail all
        exit
    exit
exit
```

The following trace appears when the user with MAC address 00:00:00:11:11:11 first connects using DHCPv4 and subsequently connects using DHCPv6 without removing the DHCPv4 connection. The LUDB is accessed just once, immediately after the DHCPv4 Discover message.

```

```

IPoE authentication - host model

In this example, the LUDB *ludb-rsap* is applied to the group interface in the dhcp6, router-solicit, and dhcp contexts, but not in the ipoe-session context.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    ipv6
                        dhcp6
                            user-db "ludb-rsap"
```

```
                            exit
                            router-solicit
                                user-db "ludb-rsap"
                                no shutdown
                            exit
                    exit
                    dhcp
                        user-db "ludb-rsap"
                        no shutdown
                    exit
                exit
```

With the same debug configuration as for the IPoE session model, the LUDB is accessed multiple times
when devices connect, as shown in the following trace.

```
13 2018/11/22 12:50:55.275 CET MINOR: DEBUG #2001 Base PIP

22 2018/11/22 12:51:20.261 CET MINOR: DEBUG #2001 Base TIP
"TIP: DHCP6_PKT
    Incoming DHCP6 Msg : REQUEST (3)
    on itf grp-int-1-1"

23 2018/11/22 12:51:20.261 CET MINOR: DEBUG #2001 Base LUDB
"LUDB: User lookup success - host found
  mac: 00:00:00:11:11:11

  Host entry-11 found in user data base ludb-rsap"

24 2018/11/22 12:51:20.262 CET MINOR: DEBUG #2001 Base TIP
"TIP: DHCP6_PKT
    Outgoing DHCP6 Msg : REPLY (7)
    to itf grp-int-1-1"
```

The LUDB is accessed for every incoming message. In a proxy case, the LUDB is accessed two times per host because the downstream messages (Offer and Reply for IPv4, Solicit and Reply for IPv6) are generated by ESM. In a relay case, where an IP address or an IP prefix is allocated by the DHCP server, the LUDB is accessed four times per host.

The command to list the active subscriber hosts is the same as for the IPoE session model, and is not repeated here. The same applies to the other commands providing origin codes.

PPPoE authentication

In this example, the LUDB *ludb-rsap* is applied to the group interface in the pppoe context.

```
configure
    service
```

```
            ies 1
                subscriber-interface "sub-int-1"
                    group-interface "grp-int-1-1"
                        pppoe
                            user-db "ludb-rsap"
                            no shutdown
                        exit
                    exit
```

The following debug configuration applies for this example.

```
debug
    service
        id 1
            ppp
                packet
                    mode egr-ingr-and-dropped
                    detail-level high
                    discovery
                    ppp
                    dhcp-client
                exit
            exit
        exit
    exit
    subscriber-mgmt
        local-user-db "ludb-rsap"
            detail all
        exit
    exit
exit
```

The trace shows that the LUDB *ludb-rsap* is accessed once when user *sub55@domain1* connects. In this example, the LUDB is accessed in the middle of the CHAP authentication.

Regular SAPs versus capture and managed SAPs

When an LUDB is to be used for regular SAPs, the LUDB must be assigned at the group interface level of a Layer 3 service (IES or VPRN). This LUDB is then used for all SAPs on that group interface, as described in the section Applying an LUDB for ESM.

When an LUDB is to be used for capture and managed SAPs, the LUDB must be assigned at the capture SAPs of the Layer 2 (VPLS) service and at the group interface level of the corresponding Layer 3 service (IES or VPRN).

Because the managed SAPs are dynamically created at the group interface of a Layer 3 service, this service must have its authentication configuration aligned with the Layer 2 service; see Figure 136: LUDB authentication for capture and managed SAPs.

Capture and managed SAPs support IPoE (session and host model) and PPP.

The capture VPLS is defined as follows.

```
configure
    service
        vpls 3 customer 1 create
            stp
                shutdown
            exit
            sap 1/1/2:* capture-sap create
                trigger-packet arp dhcp dhcp6 pppoe rtr-solicit
                dhcp-user-db "ludb-cmsap"
                pppoe-user-db "ludb-cmsap"
                ipoe-session
                    ipoe-session-policy "ipoe-sess-1"
                    user-db "ludb-cmsap"
                    no shutdown
                exit
                msap-defaults
                    group-interface "grp-int-1-1"
                    policy "msap-pol-1"
                    service 2
                exit
            exit
            no shutdown
        exit
```

The VPRN on which the managed SAPs are created is defined as follows.

```
configure
    service
        vprn 2 customer 1 create
            ---snip---
            subscriber-interface "sub-int-1" create
                address 10.111.1.254/24
                ipv6
                    delegated-prefix-len 56
                    subscriber-prefixes
                        prefix 2001:db8:901::/48 wan-host
                        prefix 2001:db8:f901::/48 pd
                    exit
                exit
                group-interface "grp-int-1-1" create
                    ---snip---
                    ipoe-session
                        ipoe-session-policy "ipoe-sess-1"
                        sap-session-limit 100
                        user-db "ludb-cmsap"
                        no shutdown
                    exit
                    oper-up-while-empty
                    pppoe
                        session-limit 100
                        user-db "ludb-cmsap"
                        no shutdown
                    exit
                exit
            exit
```

```
            exit
```

The msap-defaults needed for creation of the managed SAPs can be taken from the capture SAP, but can also be obtained from an LUDB, as the following example shows. In that case, they overrule the capture SAP msap-defaults.

```
configure
    subscriber-mgmt
        local-user-db "ludb-cmsap" create
            description "LUDB for capture/managed SAPs"
            ipoe
                match-list mac
                host "entry-1" create
                    host-identification
                        mac 00:00:00:01:01:01
                    exit
                    address 10.111.1.101
                    identification-strings 254 create
                        subscriber-id "sub-priv-1"
                        sla-profile-string "sla-prof-3"
                        sub-profile-string "sub-prof-4"
                    exit
                    msap-defaults
                        group-interface "grp-int-1-1"
                        policy "msap-pol-1"
                        service 2
                    exit
                    options
                        subnet-mask 255.255.255.0
                    exit
                    ipv6-address 2001:db8:901:11::11
                    ipv6-delegated-prefix 2001:db8:f901:1100::/56
                    ipv6-delegated-prefix-len 56

                    ipv6-address 2001:db8:901:5::5
                    ipv6-delegated-prefix 2001:db8:f901:500::/56
                    ipv6-delegated-prefix-len 56
                    no shutdown
                exit
            exit
```

Detailed information on managed and capture SAPs is in the Managed SAPs with Routed CO chapter.

The commands to display the subscribers, lease, and session states with the origin codes are the same as in the section PPPoE authentication, so these are not repeated.

LUDB for ESM as RADIUS fallback

RADIUS fallback can be triggered in the following situations; see also Figure 135: LUDB authentication for regular SAPs and Figure 136: LUDB authentication for capture and managed SAPs:

- with the authentication policy directly assigned at the group interface level
- with the authentication policy referenced from an LUDB

For the second case, first-level authentication is performed by the LUDB, and second-level authentication should be performed by the RADIUS server. For both cases, when the RADIUS server is not reachable, fallback happens.

> **Note:**
> RADIUS fallback is not supported when the LUDB is attached to the group interface or capture SAP via the ipv6 dhcp6 and rtr-solicit contexts.

Although RADIUS fallback applies to both IPoE and PPP, only IPoE is shown in the example that follows.

To demonstrate the use of an LUDB for RADIUS fallback, the configuration of the previous example with capture and managed SAPs is modified, as follows.

```
# the (capture-)VPLS
configure
    service
        vpls 3 customer 1 create
            sap 1/1/2:* capture-sap create
                authentication-policy "auth-pol-1"
                exit
            exit
        exit
    exit
```

```
# the VPRN
configure
    service
        vprn 2 customer 1 create
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1-1"
                    authentication-policy "auth-pol-1"
                exit
            exit
        exit
    exit
```

The authentication policy is applied in the VPLS at the SAP level, and in the VPRN at the group interface level. Even with LUDBs assigned in other contexts at that group interface, the authentication policy takes higher priority.

The LUDB used for RADIUS fallback is defined as follows, and both the ipoe and the ppp sections contain a default host entry.

```
configure
    subscriber-mgmt
        local-user-db "ludb-radiusfb" create
```

```
                    description "LUDB for RADIUS fallback"
                    ipoe
                        match-list mac
                        host "default" create
                            msap-defaults
                                group-interface "grp-int-1-1"
                                policy "msap-pol-1"
                                service 2
                            exit
                            no shutdown
                        exit
                    exit
                    ppp
                        match-list username
                            host "default" create
                            msap-defaults
                                group-interface "grp-int-1-1"
                                policy "msap-pol-1"
                                service 2
                            exit
                            no shutdown
                        exit
                    exit
                    no shutdown
                exit
```

The authentication policy from which this LUDB is referenced is defined as follows.

```
configure
    subscriber-mgmt
        authentication-policy "auth-pol-1" create
            fallback-action user-db "ludb-radiusfb"
            radius-server-policy "rsp-1"
        exit
```

The definition of the RADIUS server policy is not relevant so it is not shown.

The following debug configuration applies.

```
debug
    router "Base"
        radius
            packet-type authentication accounting coa
            detail-level high
        exit
    exit
    router "2"
        ip
            dhcp
                detail-level medium
                mode egr-ingr-and-dropped
            exit
        exit
    exit
    service
        id 3
            dhcp
                mode egr-ingr-and-dropped
            exit
        exit
    exit
    subscriber-mgmt
```

```
            local-user-db "ludb-radiusfb"
                detail all
            exit
        exit
    exit
```

The following partial debug output shows that when a DHCPv4 user connects, the LUDB *ludb-radiusfb* is accessed after failing to connect to the RADIUS server. Similar debug output appears when connecting through DHCPv6 via IPoE sessions, or PPP.

```
62 2018/11/22 13:03:15.510 CET MINOR: DEBUG #2001 Base SVCMGR

   [51] Lease time: 864000
   [1] Subnet mask: 255.255.255.0
   [255] End"
```

In this example, the LUDB accessed (on RADIUS fallback) defines a default host for ipoe as well as for ppp with msap-defaults only, which means relaying applies where the DHCPv4 and DHCPv6 servers provide the IP addresses and prefixes.

See Figure 133: LUDB parameters for IPoEand Figure 134: LUDB parameters for PPPoE for the list of supported parameters for IPoE and PPP in the RADIUS fallback scenario.

Operational considerations and remarks

The operational considerations listed in the Local User Database Basics chapter still apply.

To maintain backward compatibility with previous software releases, LUDB informational and error messages are sent to the error logs as if they are originating from the DHCPS application (DHCPS #xyz in the preceding outputs).

Conclusion

LUDBs offer a self-contained method of providing ESM data locally stored on the router, so that no external database is needed for supporting authentication. In case authentication relies on an AAA/RADIUS server that fails, an LUDB can provide the ESM data instead through RADIUS fallback. LUDBs can be used on regular, managed, and capture SAPs.

Managed SAPs with Routed CO

This chapter provides information about Managed SAPs with Routed CO.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and was initially written for Release 8.0.R1. The CLI in this edition corresponds to Release 15.0.R2.

Overview

Managed SAPs (MSAP) are SAPs dynamically created after the reception of a trigger packet on a capture SAP. The creation of the MSAP is controlled through an MSAP policy, which is defined during the authentication phase along with the subscriber host parameters required for host instantiation.

Following trigger packet types can lead to the creation of an MSAP:

- arp
- dhcp
- dhcp6
- rtr-solicit
- pppoe
- ppp
- data

Multiple trigger packet types can be enabled for a single capture SAP.

MSAP creation takes several steps:

- Reception of a trigger packet on the capture SAP.
- Authentication, for example via RADIUS, LUDB, NASREQ, etc.

  Authentication provides the MSAP policy and the target service context required in the next step.

- The actual creation of the MSAP in the service defined during the authentication step, taking the MSAP policy into account.

MSAPs are supported in the Bridged Central Office model and the Routed Central Office (RCO) model. For the bridged model, the service context returned by authentication is the service ID of a VPLS. For the

routed model, the service context is the service ID of a routed service (IES or VPRN) plus the name of a group-interface in the target service. Only the RCO model is explained in this chapter.

The capture SAP receives trigger packets and initiates authentication. The capture SAP is defined in a VPLS, and does not forward traffic.

The MSAP is created in the target service, and the VLAN of the MSAP is the same as the VLAN of the trigger packet. The MSAP behaves as a regular SAP, but its configuration is not user editable and not maintained in the configuration file. The MSAP remains active as long as the session is active. MSAPs and regular SAPs can co-exist on the same port and in the same service.

MSAPs can be created in a wholesale VPRN service while the corresponding subscriber host or session is terminated in a retail VPRN or IES service. Both wholesale MSAP data (service, group-interface, and policy) and retail service id must be provided during authentication.

Knowledge of TPSDA (Triple Play Service Delivery Architecture) and functionality is assumed throughout this chapter.

Capture SAP

The IOM classifies traffic based on the tags present in the incoming packets, and sends traffic to existing SAPs if the tag or tag combination in the incoming packet is known to the IOM.

The capture SAP is used if a more specific match for the Q or Q-in-Q tags is not found by the traffic classification on the IOM.

Trigger packets received on the capture SAP are sent to the CPM, non-trigger packets received on the capture SAP are dropped.

Following formats are allowed on the capture SAP:

SAP 1/2/2:*	for dot1Q
SAP 1/2/2:*.*	for QinQ
SAP 1/2/2:Q1.*	for QinQ
SAP 1/2/2:*.Q1	for QinQ (inverse capture SAP)

By default, the MSAP created will have one q-tag (for dot1q) or two q-tags (for qinq), and these are taken from the original trigger packet. The optional **allow-dot1q-msaps** command additionally enables single tagged trigger packet support for QinQ capture SAPs. See the user manual for a full description.

MSAP with Redundant Configurations

MSAPs are High Availability (HA) enabled (there is no service impact following a CPM failover). In addition, the MSAPs are also stored in the subscriber management persistence file (if enabled), allowing the MSAPs to be recreated after a reboot.

MSAPs can be used in dual-homed BNG scenarios with multi-chassis LAG, multi-chassis ring and subscriber router redundancy protocol.

RADIUS Authentication and Vendor Specific Attributes (VSAs) for MSAP

The Alc-MSAP-Serv-Id attribute returned by the RADIUS server defines the service in which the MSAP must be created.

In the RCO scenario, the MSAP is created in a group-interface context. The Alc-MSAP-Interface attribute returned by the RADIUS server defines the group-interface where the MSAP must be installed, and must exist in the target service.

The Alc-MSAP-Policy attribute returned by the RADIUS server defines the MSAP parameters required for creating the MSAP.

Topology

The network topology is displayed in Figure 138: Network Topology. This chapter uses the RCO model with PPPoE, IPv4, and RADIUS authentication for demonstrating MSAPs.

Figure 138: Network Topology
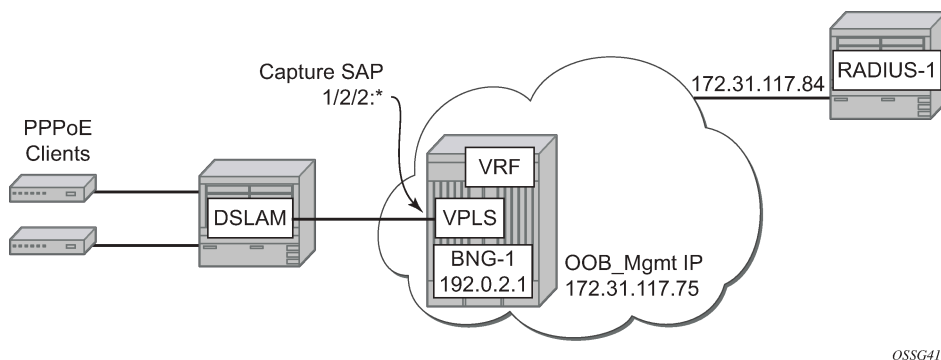

Configuration

RADIUS

In this chapter the management router is used for RADIUS communication, and the configuration used is as follows:

```
configure
    router "management"
        radius-server
            server "radius-138.203.10.250" address 172.31.117.84
                                           secret vsecret1 create
                description "Management router is used for RADIUS"
                accept-coa
            exit
        exit
    exit
```

```
    exit
```

```
configure
    aaa
        radius-server-policy "rad-serv-pol-1" create
            servers
                router "management"
                source-address 172.31.117.75
                server 1 name "radius-172.31.117.84"
            exit
        exit
    exit
exit
```

```
configure
    subscriber-mgmt
        authentication-policy "authentication-1" create
            description "RADIUS authentication policy"
            password "letmein"
            pppoe-access-method pap-chap
            include-radius-attribute
                remote-id
                nas-identifier
                mac-address
            exit
            radius-server-policy "rad-serv-pol-1"
        exit
    exit
exit
```

The value of the secret is defined as *vsecret1*. The secret is a case sensitive character string of 20 characters maximum, which must be configured in the clients.conf file on the RADIUS server.

The management routing instance with the out-of-band 172.31.117.75 IP address is used as the source to communicate authentication messages between the BNG and the RADIUS server. The RADIUS server IP address is 172.31.117.84. Up to sixteen servers can be configured in the RADIUS server policy. When multiple servers are defined, the access algorithm can be set to **direct**, or **round-robin**.

The authentication method used in this example is PAP/CHAP, so the pap-chap value is used for the pppoe-access-method.

The user's remote-id and mac-address are included with the nas-identifier into the access request message sent to the RADIUS.

QoS SAP Policies

The following QoS SAP ingress and egress policies are used later in this chapter. The dot1p and dscp values used are examples:

```
configure
    qos
        sap-ingress 20 create
            description "64K_upstream"
            queue 1 create
                rate 64
            exit
            queue 11 multipoint create
            exit
```

```
            exit
        ---snip---
        sap-egress 50 create
            description "2M_downstream"
            queue 1 create
                rate 2048
            exit
            fc be create
                queue 1
                dot1p 3
                dscp cs1
            exit
        exit
    exit
exit
```

Enhanced Subscriber Management Parameters

SLA profiles are configured where the downstream speed is four times the upstream speed and the SLA profile will be named with the downstream speed. A subscriber profile is configured to initiate RADIUS accounting. A subscriber identification profile is configured for direct mapping subscriber and SLA profiles, as follows:

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-1M" create
            ingress
                qos 40 shared-queuing
                exit
            exit
            egress
                qos 40
                exit
                no qos-marking-from-sap
            exit
        exit
        ---snip---
        sub-profile "sub-profile-default" create
            radius-accounting
                policy "accounting-11"
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
        sub-ident-policy "sub-id-default" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
```

MSAP Policy

MSAP policies contain the parameters which are used for MSAP creation and the information required to complete the subscriber identification process.

Creation of an MSAP requires an MSAP policy. The MSAP policy to be used can be defined during authentication. If authentication does not return an MSAP policy, then the default MSAP policy configured in the capture-sap as msap-defaults is used instead.

```
configure
    subscriber-mgmt
        msap-policy "msap-ISP1" create
            sub-sla-mgmt
                def-sub-id use-sap-id
                def-sub-profile "sub-profile-default"
                def-sla-profile "sla-profile-512K"
                sub-ident-policy "sub-id-default"
                single-sub-parameters
                    profiled-traffic-only
                exit
            exit
        exit
        msap-policy "msap-default" create
            sub-sla-mgmt
                def-sub-id use-sap-id
                def-sub-profile "sub-profile-default"
                def-sla-profile "sla-profile-256K"
                sub-ident-policy "sub-id-default"
                single-sub-parameters
                    profiled-traffic-only
                exit
            exit
        exit
    exit
exit
```

If managed routes are required for some subscribers, then the anti-spoof command is required in the msap-policy. The default value for anti-spoof is **ip-mac**. Managed routes are out of the scope of this chapter.

```
configure
    subscriber-mgmt
        msap-policy "msap-ISP1" create
            ies-vprn-only-sap-parameters
                anti-spoof nh-mac
            exit
        exit
    exit
exit
```

VPLS Service with a Capture SAP

Configure a VPLS service with capture SAP and define the triggering packet types. The **trigger-packet** is mandatory. In case of RADIUS authentication, an **authentication-policy** is required. Additionally, the **cpu-protection** command can be added to enable CPU protection policies, as follows:

```
configure
    service
        vpls 1 customer 1 create
            description "VPLS for Capture SAPs"
            stp
                shutdown
            exit
            sap 1/2/2:* capture-sap create
                description "capture SAP for MSAP creation on port 1/2/2"
                trigger-packet arp dhcp pppoe
                msap-defaults
                    policy "msap-default"
                exit
                authentication-policy "authentication-1"
            exit
            no shutdown
        exit
    exit
exit
```

Verify the details of capture SAP:

```
*A:BNG-1# show service id 1 sap 1/2/2:* detail

===============================================================================
Service Access Points(SAP)
===============================================================================

*A:BNG-1#
```

The Sap Statistics section provides statistics for the capture SAP per trigger type, which can help troubleshooting the service. The dropped packet counter indicates the amount of non triggering packets received on the capture SAP. No SAP queues are instantiated for a capture SAP.

VPRN Service - VLAN-Per-Subscriber (PPPOE)

The following output shows an RCO configuration example. No static SAPs are defined in this example, but it is allowed.

```
configure
    service
        vprn 2 customer 1 create
            route-distinguisher 64496:2
            subscriber-interface "sub-int-1" create
                address 10.255.255.254/8
                group-interface "grp-int-1" create
                    description "ROUTED CO MSAP VLAN X"
                    authentication-policy "authentication-1"
                    pppoe
                        session-limit 2000
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Initially, no MSAPs are present, so the operational state of both the subscriber interface and group interface context are down.

```
*A:BNG-1# show router 2 interface

===============================================================================
Interface Table (Service: 2)
===============================================================================
Interface-Name                   Adm         Opr(v4/v6)  Mode      Port/SapId
   IP-Address                                                      PfxState
-------------------------------------------------------------------------------
grp-int-1                        Up          Down/Down   VPRN G* n/a
sub-int-1                        Up          Down/Down   VPRN S* subscriber
   10.255.255.254/8                                                n/a
-------------------------------------------------------------------------------
Interfaces : 2
===============================================================================
* indicates that the corresponding row element may have been truncated.
*A:BNG-1#
```

To allow the subscriber interface to consider this group interface to be operationally enabled without any active MSAPs, the following command can be added to the configuration (this would be useful in order to propagate the subnet interface address into a routing protocol):

```
configure
    service
        vprn 2
            subscriber-interface "sub-int-1"
                group-interface "grp-int-1"
```

```
                    oper-up-while-empty
                exit
            exit
        exit
    exit
exit
```

The status of the interfaces then is as follows:

```
*A:BNG-1# show router 2 interface

===============================================================================
Interface Table (Service: 2)
===============================================================================
Interface-Name                   Adm        Opr(v4/v6)  Mode     Port/SapId
    IP-Address                                                   PfxState
-------------------------------------------------------------------------------
grp-int-1                        Up         Down/Down   VPRN G* n/a
sub-int-1                        Up         Up/Down     VPRN S* subscriber
    10.255.255.254/8                                             n/a
-------------------------------------------------------------------------------
Interfaces : 2
===============================================================================
* indicates that the corresponding row element may have been truncated.
*A:BNG-1#
```

Check the status of the group interface once the first MSAP is created.

RADIUS User File

The following entry is an example of a user entry in the RADIUS users file for the FreeRadius server:

```
"user1@ISP1.com" Cleartext-Password := "letmein"
        Alc-Subsc-ID-Str := "%{ADSL-Agent-Remote-Id}",
        Alc-SLA-Prof-Str == "sla-profile-2M",
        Alc-MSAP-Serv-ID = 2,
        Alc-MSAP-Policy == "msap-ISP1",
        Alc-MSAP-Interface == "grp-int-1",
        Framed-IP-Address = 10.255.0.1,
        Alc-Primary-DNS = 172.31.31.31,
        Alc-Secondary-DNS = 172.31.31.32,
```

So when the PPPoE user sends the correct username and password, the RADIUS accepts the access message and returns the correct VPRN service id 2, the correct group interface *group-int-1*, the MSAP policy to use *msap-ISP1*.

In case no MSAP policy is returned by the RADIUS server, the default MSAP policy *msap-default* under the capture SAP is used instead.

In the preceding entry, the PPPoE user will have its IP address and DNS assigned by RADIUS as well.

Connect PPPoE user

Connect PPPoE user *user1*, initiate a PPPoE session on VLAN 1, and verify PPPoE session establishment.

```
*A:BNG-1# show service id 2 pppoe session
```

```
===============================================================================
PPPoE sessions for svc-id 2
===============================================================================
Sap Id               Mac Address       Sid   Up Time        Type
    IP/L2TP-Id/Interface-Id                                 MC-Stdby
-------------------------------------------------------------------------------
[1/2/2:1]            00:00:00:01:01:01 1     0d 00:01:12    local
    10.255.0.1
-------------------------------------------------------------------------------
Number of sessions   : 1
===============================================================================
*A:BNG-1#
```

The PPPoE session is established successfully and the IP address and subscriber strings obtained from the RADIUS server are used.

In order to differentiate between the MSAP and the normal SAP, the MSAP will be shown between square brackets [1/2/2:1] in the show commands.

Verify Subscriber Values

Verify subscriber values returned from RADIUS for user1.

```
*A:BNG-1# show service id 2 pppoe session ip-address 10.255.0.1 detail

===============================================================================

*A:BNG-1#
```

Where, the subscriber id is *user1*, and the subscriber profile is *sub-profile-default*.

Because the RADIUS server did not return a subscriber profile string, the system uses the **def-sub-profile** configured under the msap-policy *msap-ISP1*.

Another command can also be used to show less detail in a hierarchical form.

```
*A:BNG-1# show service active-subscribers hierarchy subscriber "user1"

```

The default QoS policy associated with MSAPs can be changed:

- To save queue resources when profiled-traffic-only cannot be used, for example when more than one subscriber is active on an MSAP. See further.

- To provide adequate QoS treatment for multicast traffic in a per MSAP replication mode.

  Egress multicast traffic in per MSAP replication mode is forwarded via the MSAP queues or policers. Multicast traffic can be mapped into a dedicated queue or policer. The MSAP queue can be port-parented to provide scheduling priority at port level. The QoS policies associated with an MSAP are configured in the MSAP policy.

QoS Egress Remarking

For remarking to apply to MSAP egress traffic the SLA profile must include the **no qos-marking-from-sap** command, as follows:

```
configure
    subscriber-mgmt
        sla-profile "sla-profile-512K" create
            ---snip---
            egress
                qos 30
                exit
                no qos-marking-from-sap
```

```
            exit
        exit
    exit
exit
```

By default, the egress QoS marking for subscriber-host traffic is derived from the SAP-egress QoS policy associated with the corresponding SAP rather than the SLA profile associated with the corresponding subscriber-host. As a consequence, no egress QoS marking (for example, dot1p marking was set to 0, DSCP/PREC field is unchanged) is performed for traffic transmitted on an MSAP because by default, SAP-egress policy one (1) was attached to every MSAP.

MSAP Queue Optimization

For single subscriber SAPs, where the multi-sub-sap limit equals 1, the SAP queues will not be instantiated when using the **profiled-traffic-only** option in the msap-policy. This parameter is ignored when the multi-sub-sap limit is different from 1.

```
configure
    subscriber-mgmt
        msap-policy "msap-ISP1" create
            sub-sla-mgmt
                def-sub-id use-sap-id
                def-sub-profile "sub-profile-default"
                def-sla-profile "sla-profile-512K"
                sub-ident-policy "sub-id-default"
                single-sub-parameters
                    profiled-traffic-only
                exit
            exit
        exit
    exit
exit
```

For multi subscriber MSAPs, a QoS policy can be associated with an MSAP in which all forwarding classes are mapped to a policer. In that case, a single ingress and egress policer is instantiated per MSAP (instead of ingress and egress queues). QoS policies associated with an MSAP are configured in the MSAP policy:

```
configure
    subscriber-mgmt
        msap-policy "msap-ISP2" create
            ies-vprn-only-sap-parameters
                egress
                    qos 10
                exit
                ingress
                    qos 10 shared-queuing
                exit
            exit
        exit
    exit
exit
```

Troubleshooting

The authentication policy used on the capture SAP must be the same as the policy used on the managed SAP.

The managed SAP will not be created if the authentication policy on the group-interface is different from the authentication policy defined on the capture SAP.

```
configure
    service
        vpls 1
            ---snip---
            sap 1/2/2:* capture-sap create
                ---snip---
                authentication-policy "authentication-1"
            exit
            no shutdown
        exit

configure
    service
        vprn 2
            subscriber-interface "sub-int-1"create
                ---snip---
                group-interface "group-int-1" create
                    authentication-policy "authentication-2"
                    ---snip---
                exit
            exit
            no shutdown
        exit
```

This can be seen in log 99:

```
*A:BNG-1# show log log-id 99

                    packet
                        mode egr-ingr-and-dropped
                        detail-level medium
                        discovery
                        ppp
                    exit
                exit
            id 2
                ppp
                    packet
                        mode egr-ingr-and-dropped
                        detail-level medium
                        discovery
                        ppp
                        dhcp-client
                    exit
                exit
            exit
        exit
exit
```

```
configure
    log
        log-id 1
            from debug-trace
            to session
        exit
    exit
exit
```

Disconnect/connect *user1*, then check the RADIUS access request/accept and accounting messages from the debug output.

```

Conclusion

MSAP allows dynamic creation of SAPs which results in:

- Less provisioning.
- Less possibility for introducing provisioning errors.
- Reduced configuration file size.

Multi-Chassis Ring Layer 2 with Enhanced Subscriber Management

This chapter provides information about MC-ring layer 2 with enhanced subscriber management (ESM).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS Release 7.0.R5.

Overview

Multi-Chassis Ring (MC-ring) is an extension for dual homing support in TPSDA (Triple Play Service Delivery Architecture) networks based on Layer 2 CO (Layer 2 Central Office) model. The extension addresses networks where multiple access nodes (for example, DSLAMs, GPON OLT) are connected in a single ring.

MC Ring Layer 2 ESM is considered an extension or evolution for ring topologies of the Multi-Chassis LAG dual-homing solution used for directly connected access nodes.

MC Ring Layer 2 CO is documented in the Triple Play Enhanced Subscriber Management / Dual Homing section of the 7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide.

MC-Ring

Figure 139: MC-Ring Layer 2 CO Dual Homing shows a typical ring-based configuration of network model based on the Layer 2 CO model.

Individual rings of access nodes are aggregated at the Broadband Service Aggregator (BSA) level in one (or multiple) Virtual Private LAN Service (VPLS) service(s). At higher aggregation levels, Broadband Service Router (BSR) individual BSAs are connected to a Layer 3 interface (Internet Enhanced Service (IES) or Virtual Private Routed Network (VPRN)) by means of a spoke SDP (service destination point) termination. Every Layer 3 interface at the BSR level aggregates all subscribers in one or more subnets. ESM is performed in the BSAs.

Figure 139: MC-Ring Layer 2 CO Dual Homing
The key functional components of the MC-Ring Layer 2 CO dual-homing redundancy solution are:

1. Mirroring of the subscriber state between the two BSAs performing subscriber management using the multi-chassis synchronization (MCS) protocol (BSA-1 and BSA-2 in Figure 139: MC-Ring Layer 2 CO Dual Homing).

2. Ring control between the two BSAs, using the following mechanisms:

   • In-band bi-directional forwarding detection (BFD) between the BSAs over the ring to monitor ring integrity and detect failures. A BFD session between BSA-1 and BSA-2 runs through the access ring using a dedicated IES/VPRN interface configured on both BSAs. This connection uses a separate VLAN throughout the ring (access nodes provide transparent bridging for this VLAN).

   • Out-of-band communication between the BSA nodes to exchange information about the reachability of individual access nodes, and to verify the configuration consistency of the ring. The information on configuration is synchronized through MCS (this use of MCS is related to, but independent to, MCS for subscriber-state synchronization mentioned above).

3. Ring Node Connectivity Verification (RNCV). Each BSA uses RNCV to detect the reachability of individual Access Nodes. It is used after a ring failure to determine which BSA should handle the traffic of each Access Node. RNCV uses ARP requests to "ping" individual ANs, which must be configured with an IP address for this purpose.

4. Per-subscriber attribute (intermediate destination ID) for the BSA to know the Access Node each subscriber is connected to (assigned through RADIUS or DHCP/Python).

5. VRRP in the BSRs to provide a redundant default gateway to the CPEs/Home Gateways. BSRs do not perform any subscriber management functions.

The operation of dual homing at the BSA level will be covered based on two underlying mechanisms.

MC-Ring Layer 2 CO Operation

To describe the functional behavior and operation of the dual-homing concept in a ring, it is best to sub-divide the description into the following three parts:

- Steady-state operation with ring fully closed

- Transition to ring-broken state

- Transition from ring-broken to steady state operation

Steady-State Operation of Dual-Homed Ring

Figure 140: Dual homing Under Steady-State Condition illustrates the detailed operation of the dual-homed ring. The steady-state is achieved under following conditions:

- Both nodes are configured in a consistent way

- The MCS peering relation is up

- In-Band Ring Control Connection (IB-RCC) is in an operationally UP state.

> **Note:**
> This connection is set-up using BFD session between IP interfaces on BSA-1 and BSA-2

Figure 140: Dual homing Under Steady-State Condition
Under the above conditions, the ring is fully closed and every access node (the **ring-node**) has two possible paths toward the VPLS core. Figure 140: Dual homing Under Steady-State Condition refers to them as **path-a** and **path-b**. In order to avoid the loop created by the ring, only one of the paths may be used by any given ring-node for any given VLAN. The assignment of the individual VLANs to path-a or path-b, respectively, has to be provisioned on both BSAs in a consistent manner. The BSA with a lower IP address in the interface used for BFD will be the master for the VLANs associated with path-a and standby for the VLANs associated with path-b.

The following summarizes the behavior of the master and standby BSA for a given path (a or b) and the VLANs configured for that path:

Master BSA for the VLANs/SAPs associated with a given path (a or b):

- SAPs associated with the path are operationally up and FDB entries for sub-hosts point to the corresponding SAP

- Master BSA for a path performs RNCV checks to all ring nodes. RNCV failures trigger an alarm but do **not** trigger a switchover

- The ARP reply agent replies to ARP requests for subscriber-hosts associated with ring-nodes for which the BSA is master

Standby BSA:

- All SAPs associated with the path for which the BSA is standby will be operationally down and all FDB entries of subscriber hosts associated with those SAPs will point towards an SDP connecting to the master BSA.

Broken-Ring Operation and the Transition to this State

Figure 141: Broken Ring State illustrates the scenario with the broken ring (link failure or ring-node failure). This state is reached under following conditions:

- Both nodes are configured in a consistent way

- The MCS peering relation is up

- IB-RCC is in operationally down state

In this situation, every ring node has only one access path towards the VPLS core and hence the path-a and path-b notion has no real meaning in this situation.

From a functional point of view, both BSAs are now the master for the ring-nodes they can reach. For all hosts behind unreachable ring-nodes, the corresponding subscriber host FDB (Forwarding DataBase) entries will point to SDP pointing to the other head-end ring PE.

Figure 141: Broken Ring State

OSSG426
Transition from Broken to Closed Ring State

MC-ring operates in a revertive mode. This means that whenever the ring connectivity is restored, the BSA with the lower IP address in the IB-RCC communication channel will become master of path-a and slave for ring-b with vice versa operations on the other BSA.

The actions in this case are straightforward. After restoration of BFD session, the master functionality is assumed by respective BSAs. The FDB tables are updated according to the master/standby role of the given BSA and FDB population messages will be sent accordingly.

Configuration

Figure 142: Network Topology
The network topology is displayed in Figure 142: Network Topology. The setup consists of two BSA nodes (PE-1 and PE-2), two BSR nodes (PE-3, PE-4) and another PE router (PE-5). A setup with one BSR node and two BSA nodes can also be used, but in this example, two (2) BSR nodes were used to show the typical Layer 2-CO setup with VRRP and Protocol Independent Multicast (PIM) on the BSRs. The access ring consists of four CE nodes.

Base Topology

This section assumes that the following base configuration has been implemented on the PE:

- Cards, MDAs and ports configured
- Interfaces configured
- IGP (Interior Gateway Protocol) configured and converged LDP (Label Distribution Protocol) configured on the interfaces between PE-3-PE-1, PE-1-PE-2 and PE-2-PE-4
- T-LDP (Targeted-LDP) configured on PE-1, PE-2, PE-3, PE-4

• SDPs configured between PE-3-PE-1, PE-1-PE-2 and PE-2-PE-4

> **Note:**
> You can choose between OSPF and IS-IS as the IGP. Both LDP and RSVP (Resource
> Reservation Protocol) can be used for signaling the transport MPLS labels. Alternatively, GRE
> (Generic Routing Encapsulation) can be used for the transport tunnels. In this example, OSPF is
> configured and LDP SDPs are used.

7750 SR routers are used as ring-nodes to simulate Access Nodes. Ring-nodes can be any L2 device that
support VLANs and have the ability to connect an IP interface to one VLAN (required for RNCV).

NTP Configuration

Time must be the same on the redundant NSAs (PE-1 and PE-2); otherwise, the lease times will be
different on both nodes. NTP can be used:

```
configure system time
            ntp
                server 10.30.30.30 prefer
                no shutdown
            exit
exit all
```

MC-Ring Configuration

Configure a VPLS service on the CE routers for the In-Band Ring Control connection (BFD packets
between PE-1 and PE-2 traversing the ring). This VPLS service will also be used for RNCV.

> **Note:**
> An Epipe service can also be used in case the service is only used for BFD. In that case, a
> separate service is required for the RNCV.

In this example, QinQ encapsulation is used and BFD and RNCV packets will use VLAN tag 1. Note that
dot1q encapsulation can also be used.

The configuration of CE-1 is shown below. A similar configuration is required on the other CE routers.

```
configure
    port 1/1/1
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    port 1/1/2
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    service
        vpls 1 customer 1 create
            interface "lo1" create
```

```
                    address 172.16.0.1/24
                exit
                sap 1/1/1:1.0 create
                exit
                sap 1/1/2:1.0 create
                exit
                no shutdown
        exit
 exit all
```

An interface *lo1* is created in the VPLS. This interface will be used for RNCV.

On the BSA nodes (PE-1 and PE-2), configure an IES services that will originate BFD and RNCV
messages. On PE-1:

```
configure
    port 1/1/1
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    service
        ies 1 customer 1 create
            interface "bfd-rncv1" create
                address 172.16.0.251/24
                bfd 100 receive 100 multiplier 3
                sap 1/1/1:1.0 create
                exit
            exit
            no shutdown
        exit
 exit all
```

On PE-2:

```
configure
    port 1/1/2
        ethernet
            mode access
            encap-type qinq
        exit
        no shutdown
    exit
    service
        ies 1 customer 1 create
            interface "bfd-rncv1" create
                address 172.16.0.252/24
                bfd 100 receive 100 multiplier 3
                sap 1/1/2:1.0 create
                exit
            exit
            no shutdown
        exit
 exit all
```

In-Band Ring Control Connection BFD is always originated on an IES or VPRN service on the BSA nodes.
RNCV messages can be originated from the same IES/VPRN service or from a separate service.

Configure Multi-Chassis Synchronization (MCS) on the BSA nodes. Enable MCS for **igmp-snooping**, **mc-ring** and **sub-mgmt**. The configuration of PE-1 is shown below. The configuration of PE-2 is similar.

```
configure redundancy multi-chassis peer 192.0.2.2 create
            sync
                igmp-snooping
                mc-ring
                sub-mgmt
                port 1/1/1 sync-tag "l2ring1" create
                exit
                no shutdown
            exit
            no shutdown
exit all
```

Add the MC-ring configuration on the BSA nodes and link the Ring Control Connection BFD session to the IES service created before.

```
configure redundancy multi-chassis peer 192.0.2.2 create
            mc-ring
                ring "l2ring1" create
                    in-band-control-path
                        service-id 1
                        interface "bfd-rncv1"
                        dst-ip 172.16.0.252
                    exit
                    no shutdown
                exit
            exit
            no shutdown
exit all
```

Note that the ring name is exactly the same as the sync-tag already configured.

At this moment, the MC-ring should be up:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2 ring l2ring1 detail
===============================================================================
Multi-Chassis MC-Ring Detailed Information
===============================================================================
Peer          : 192.0.2.2
Ring Type     : Layer 2
Sync Tag      : l2ring1
Port ID       : 1/1/1
Admin State   : inService
Oper State    : connected
Admin Change  : 11/05/2009 21:17:54
Oper Change   : 11/05/2009 21:17:54
Failure Reason : None
Control B Path : No
    -------------------------------------------------------------------------
In Band Control Path
    -------------------------------------------------------------------------
Service ID    : 1
Interface Name : bfd-rncv1
Oper State    : connected
Dest IP       : 172.16.0.252
Src  IP       : 172.16.0.251
...
```

Next, configure under MCS the ring nodes on PE-1 and PE-2. This configuration will be used for the RNCV. The ring node configuration for CE-1 is shown below:

```
configure redundancy multi-chassis peer 192.0.2.2 mc-ring ring l2ring1
                      ring-node "CE-1" create
                          connectivity-verify
                              dst-ip 172.16.0.1
                              interval 1
                              service-id 1
                              vlan 1
                              no shutdown
                          exit
                      exit
exit all
```

Note:
The **interval** parameter is the interval used to check the reachability of the CE nodes (configurable from 1 to 6000 minutes). A BFD failure will also be a trigger for a reachability check.

The configuration on PE-2 is identical and the configuration of the other ring nodes is similar.

Configure VLAN 3 to take path-b (default is path-a).

```
configure redundancy multi-chassis peer 192.0.2.2 mc-ring ring l2ring1
                      path-b
                          range 3-3
                      exit
exit all
```

MC-Ring Verification

Verify that MCS is up and running:

```
A:PE-1# show redundancy multi-chassis all
===============================================================================
Multi-Chassis Peers
===============================================================================
Peer IP         Src IP          Auth       Peer Admin   MC-Ring Oper MC-EP Adm
  MCS Admin       MCS Oper        MCS State  MC-LAG Adm   MC-LAG Oper
-------------------------------------------------------------------------------
192.0.2.2       192.0.2.1       None       Enabled      inService    --
  Enabled         Enabled         inSync     Disabled     Disabled
===============================================================================
```

The output shows that MCS is administrative and operational up and that both peers are synchronized. MC-ring is operational in service.

The following output shows more detailed information about the configured ring:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2 ring l2ring1 detail
===============================================================================
Multi-Chassis MC-Ring Detailed Information
===============================================================================

-------------------------------------------------------------------------------
no range
```

The output above shows that the ring *l2ring1* on port 1/1/1 is in service and connected. Ring-node Connectivity Check (BFD) is running on **interface bfd-rncv1** in service *1*. All VLANs on port 1/1/1 use path-a (default) except VLAN 3, which uses path-b.

The BSA peer with the lower IP address (the master) will put the SAPs configured for path-a in operational up state while the SAPs configured in path-b will be put in operational down state. The other BSA peer will do the reverse. This is done to prevent loops in the ring.

> **Note:**
> No VLANs are configured to be excluded from the paths. If a VLAN is configured to be excluded from the paths, the respective SAPs of this VLAN on both BSA nodes will be operationally up.

Check which ring-nodes are configured and connected:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2 ring l2ring1 ring-node
===============================================================================
MC-Ring Node entries
===============================================================================
Name                           Loc Oper St.    Failure Reason
  In Use                         Rem Oper St.
-------------------------------------------------------------------------------
CE-1                           connected       None
  No                             notTested
CE-2                           connected       None
  No                             notTested
```

```
CE-3                                    connected          None
  No                                      notTested
CE-4                                    connected          None
  No                                      notTested
-------------------------------------------------------------------------
No. of MC-Ring Node entries: 4
=========================================================================
A:PE-1#
```

The output above shows that four ring-nodes are connected. Only the master will send RNCV messages to the ring-nodes. As soon as a ring failure occurs, the BFD session goes down and both BSA nodes send out RNCV messages to see which ring-nodes are connected.

> **Note:**
> When the reachability of the CE nodes is determined, the RNCV messages will be sent at a continuous interval (see above).

More detail about each ring-node can be provided with following command:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2 ring l2ring1 ring-node CE-1

Unicast Services Configuration

Figure 143: Unicast Services — Logical Topology shows the logical setup of the services that will be created. A mesh SDP is used between PE-1 and PE-2. A spoke SDP could also be used.

Figure 143: Unicast Services — Logical Topology
In this setup, two unicast services (VPLS 2 and VPLS 3) are created. VPLS 2 uses path-a and VPLS 3 uses path-b.

The services use a mesh SDP between PE-1 and PE-2 and a spoke-SDP between PE-1/PE-3 and another spoke SDP between PE-2/PE-4. On PE-3 and PE-4 a spoke SDP terminated IES is configured with a VRRP default gateway address. The VRRP packets are switched through the BSAs.

IGMP snooping and ESM are configured on both services. ESM is required since the BSA node must know which ring-node each subscriber is connected to. In this setup, the intermediate destination identifier (int_dest_id) will be returned by Option 254 in x Dynamic Host Control Protocol (DHCP). ESM configuration details are outside the scope of this document. Refer to the 7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide.

The following output shows the configuration of VPLS 2 on PE-1:

```
configure service
      vpls 2 customer 1 create
            description "VLAN_2"
            split-horizon-group "RSHG" residential-group create
            exit
            sap 1/1/1:2.* split-horizon-group "RSHG" create
                  dhcp
                        snoop
                        lease-populate 10
                        no shutdown
                  exit
                  anti-spoof ip-mac
                  sub-sla-mgmt
                        def-sub-profile "initial"
                        def-sla-profile "initial"
```

```
                sub-ident-policy "speedy"
                multi-sub-sap 10
                no shutdown
            exit
        exit
        mesh-sdp 12:2 create
            dhcp
                snoop
            exit
        exit
        spoke-sdp 13:2 create
            dhcp
                snoop
            exit
        exit
        no shutdown
    exit
exit all
```

The configuration of VPLS 3 is similar. The configuration of VPLS 2 and 3 are similar on PE-2.

The output below shows the subscriber management configuration on PE-1. Similar configuration is required on PE-2.

```
configure subscriber-mgmt
        sla-profile "initial" create
        exit
        sub-profile "initial" create
        exit
        sub-ident-policy "speedy" create
            strings-from-option 254
        exit
exit all
```

Also, configure VLAN 2 and 3 on all the ring-nodes. This configuration is straightforward. Below is an example of the VLAN 2 configuration on CE-1. In this example, the client is connect to port 1/1/3 and should send packets with an outer tag of 2:

```
configure service
        vpls 2 customer 1 create
            sap 1/1/1:2.* create
            exit
            sap 1/1/2:2.* create
            exit
            sap 1/1/3:2.* create
            exit
            no shutdown
        exit
exit all
```

In the example, VLAN 2.* and 3.* is used to allow for transparent transport of the customer VLAN.

The IES service where VPLS 2 terminates looks like this on BSR PE-3:

```
configure service
        ies 2 customer 1 create
            interface "VLAN_2" create
                address 10.0.2.3/24
                dhcp
                    server 10.10.10.10
                    trusted
```

```
                    no shutdown
            exit
            ip-mtu 1500
            vrrp 2
                backup 10.0.2.254
                ping-reply
            exit
            local-proxy-arp
            spoke-sdp 31:2 create
            exit
        exit
        no shutdown
    exit
exit all
```

And on PE-4:

```
configure service
        ies 2 customer 1 create
            interface "VLAN_2" create
                address 10.0.2.4/24
                dhcp
                    server 10.10.10.10
                    trusted
                    no shutdown
                exit
                ip-mtu 1500
                vrrp 2
                    backup 10.0.2.254
                    ping-reply
                exit
                local-proxy-arp
                spoke-sdp 42:2 create
                exit
            exit
            no shutdown
        exit
exit all
```

Notice that the ip-mtu must be set to match the vc-mtu signaled by the other side of the spoke-SDP. Otherwise, the service will be operationally down with a ServiceMTUMismatch.

Note also in the configuration that DHCP relay is done by configuring a DHCP server under the IES interface.

The configuration of IES 3 on PE-3 and PE-4 is similar..

On PE-5 an IES interface is configured to the DHCP-server. The interface is configured with a Dot1Q encapsulated port because this port will be also be used for an interface to the multicast server.

```
configure service
        ies 2 customer 1 create
            interface "dhcp-server" create
                address 192.168.6.1/30
                sap 1/1/3:2 create
                exit
            exit
            no shutdown
        exit
exit all
```

Unicast Services Verification

Request an IP address on VLAN 2 on CE-1. On BSA routers PE-1 and PE-2 following DHCP info can be checked:

```
A:PE-1# show service id 2 dhcp lease-state
===============================================================================
DHCP lease state table, service 2
===============================================================================
IP Address      Mac Address      Sap/Sdp Id           Remaining  Lease   MC
                                                       LifeTime   Origin  Stdby
-------------------------------------------------------------------------------
10.0.2.107      00:00:64:01:01:02 1/1/1:2.*            09d07h38m  DHCP
-------------------------------------------------------------------------------
Number of lease states : 1
===============================================================================
```

ESM show commands can be used to obtain the subscriber identity, IP address, MAC address and SLA-profile:

```
A:PE-1# show service active-subscribers
===============================================================================
Active Subscribers
===============================================================================
-------------------------------------------------------------------------------
Subscriber subscriber_1_vlan_2 (initial)
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
(1) SLA Profile Instance sap:1/1/1:2.* - sla:initial
-------------------------------------------------------------------------------
IP Address      MAC Address      PPPoE-SID Origin
----------------------------------------------------
10.0.2.107      00:00:64:01:01:02 N/A       DHCP

-------------------------------------------------------------------------------
Number of active subscribers : 1
===============================================================================
```

The following command gives more information about a specific subscriber:

```
A:PE-1# show service active-subscribers subscriber subscriber_1_vlan_2 detail

===============================================================================
Active Subscribers
===============================================================================
-------------------------------------------------------------------------------
Subscriber subscriber_1_vlan_2 (initial)
-------------------------------------------------------------------------------
I. Sched. Policy : N/A
E. Sched. Policy : N/A                            E. Agg Rate Limit: Max
Q Frame-Based Ac*: Disabled
Acct. Policy    : N/A                             Collect Stats    : Disabled
Rad. Acct. Pol.  : N/A
Dupl. Acct. Pol. : N/A
ANCP Pol.        : N/A
HostTrk Pol.     : N/A
Sub. ANCP-String : "subscriber_1_vlan_2"
Sub. Int Dest Id : "CE-1"

```

```
--------------------------------------------------------------------
(1) SLA Profile Instance
    - sap:1/1/1:2.* (VPLS 2)
    - sla:initial
--------------------------------------------------------------------
Description          : (Not Specified)
Host Limit           : No Limit
Ingress Qos-Policy   : 1                       Egress Qos-Policy : 1
Ingress Queuing Type : Service-queuing
Ingress Filter-Id    : N/A                     Egress Filter-Id  : N/A
Ingress Report-Rate  : N/A
Egress Report-Rate   : N/A
Egress Remarking     : from Sap Qos
Credit Control Pol.  : N/A
    ----------------------------------------------------------------
    ----------------------------------------------------------------
IP Address      MAC Address       PPPoE-SID Origin
    ------------------------------------------------------------
10.0.2.107      00:00:64:01:01:02 N/A         DHCP
```

The output above gives more details about which ring-node the customer is connected to (Sub. Int Dest Id :
CE-1), which QoS policies are applied, statistics of each queue,

MCS Verification

Check if the two redundant peers are in sync and check the detailed MCS info:

```
A:PE-1# show redundancy multi-chassis sync peer 192.0.2.2
===============================================================================
Multi-chassis Peer Table
===============================================================================
Peer
-------------------------------------------------------------------------------

Rem Alarm Entries       : 0
-------------------------------------------------------------------------
Application             : subHostTrk
Num Entries             : 0
Lcl Deleted Entries     : 0
Alarm Entries           : 0
-------------------------------------------------------------------------
Rem Num Entries         : 0
Rem Lcl Deleted Entries : 0
Rem Alarm Entries       : 0
```

```
    --------------------------------------------------------------------------
    ==========================================================================
    A:PE-1#
```

The output shows that both MCS peers are in sync and that entries are populated for MC-ring and Subscriber Management (DHCP lease states).

Notice that the lease states are also populated on PE-2:

```
A:PE-2# show service id 2 dhcp lease-state
===============================================================================
DHCP lease state table, service 2
===============================================================================
IP Address      Mac Address        Sap/Sdp Id          Remaining  Lease   MC
                                                        LifeTime   Origin  Stdby
-------------------------------------------------------------------------------
10.0.2.107      00:00:64:01:01:02 1/1/2:2.*            09d06h16m  DHCP    Yes
-------------------------------------------------------------------------------
Number of lease states : 1
===============================================================================
A:PE-2#
```

The output is similar to the output on PE-1 except that on PE-2 the flag MC-Stdby is set to yes, which implies that this node is in standby mode for this VLAN.

This can be verified by looking at the status of the SAP on PE-1 and PE-2. On PE-1 the SAP is operationally up:

```
A:PE-1# show service id 2 sap 1/1/1:2.*
===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 2
SAP                : 1/1/1:2.*            Encap            : qinq
QinQ Dot1p         : Default
Description        : (Not Specified)
Admin State        : Up                  Oper State       : Up
Flags              : None
Multi Svc Site     : None
Last Status Change : 11/06/2009 17:17:26
Last Mgmt Change   : 11/04/2009 22:51:15
===============================================================================
```

On PE-2 the situation is different:

```
A:PE-2# show service id 2 sap 1/1/2:2.*
===============================================================================
Service Access Points(SAP)
===============================================================================
Service Id         : 2
SAP                : 1/1/2:2.*            Encap            : qinq
QinQ Dot1p         : Default
Description        : (Not Specified)
Admin State        : Up                  Oper State       : Down
Flags              : StandByForMcRing
Multi Svc Site     : None
Last Status Change : 11/06/2009 18:07:30
Last Mgmt Change   : 11/04/2009 23:43:16
===============================================================================
```

Notice that the SAP on PE-2 is operationally down and that a flag is set: StandByForMcRing.

The situation is reversed for VLAN 3 since it was configured for path-b; here the SAP on PE-1 is operationally down and the SAP on PE-2 is operationally up.

Ring Failure Verification

In case a ring failure occurs (either ring link failure or ring-node failure), the IB-RCC BFD session between PE-1 and PE-2 will go down and both nodes will put the SAP in operational up state.

Break the link between CE-2 and CE-1.

Observe that the ring is now in a *broken* state:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2
===============================================================================
MC-Ring entries
===============================================================================
Sync Tag                       Oper State      Failure Reason
-------------------------------------------------------------------------------
l2ring1                        broken          None
-------------------------------------------------------------------------------
No. of MC-Ring entries: 1
===============================================================================
```

The following command shows the BSA to ring nodes connections:

```
A:PE-1# show redundancy multi-chassis mc-ring peer 192.0.2.2 ring l2ring1 ring-node
===============================================================================
MC-Ring Node entries
===============================================================================
Name                           Loc Oper St.    Failure Reason
  In Use                         Rem Oper St.
-------------------------------------------------------------------------------
CE-1                           connected       None
   Yes                            disconnected
CE-2                           disconnected    None
   No                             connected
CE-3                           disconnected    None
   No                             connected
CE-4                           disconnected    None
   No                             connected
-------------------------------------------------------------------------------
No. of MC-Ring Node entries: 4
===============================================================================
```

The output shows that CE-1 is connected to PE-1. CE-2, CE-3 and CE4 are connected to PE-2.

Notice that the SAPs on both PE-1 and PE-2 are now operationally up. This can be checked with the **show service id 2 sap 1/1/1:2.*** command on PE1 and the **show service id 2 sap 1/1/2:2.*** command on PE2.

Following the ring failure, the BSA nodes send a MAC address withdrawal message to all the SDP peers configured in the VPLS.

Multicast Service Configuration

In general, BTV (Broadcast TV) services are delivered to the DSLAM on a different VLAN using a different VPLS service. The DSLAM can send/relay IGMP group membership messages if it wants to receive a multicast stream. At the BSA level (PE-1 and PE-2), IGMP snooping is configured. At the BSR level (PE-3,

PE-4) and the PE where the video source is located, PIM is configured and IGMP is configured on the IES service facing the BSA ring. The BSA ring consists of concatenated spoke SDPs. The spoke SDP ring is not closed between PE-3 and PE-4 to avoid a loop. Figure 144: Multicast Service — Logical Setup shows the logical setup for the multicast service with a MC-ring.

Figure 144: Multicast Service — Logical Setup
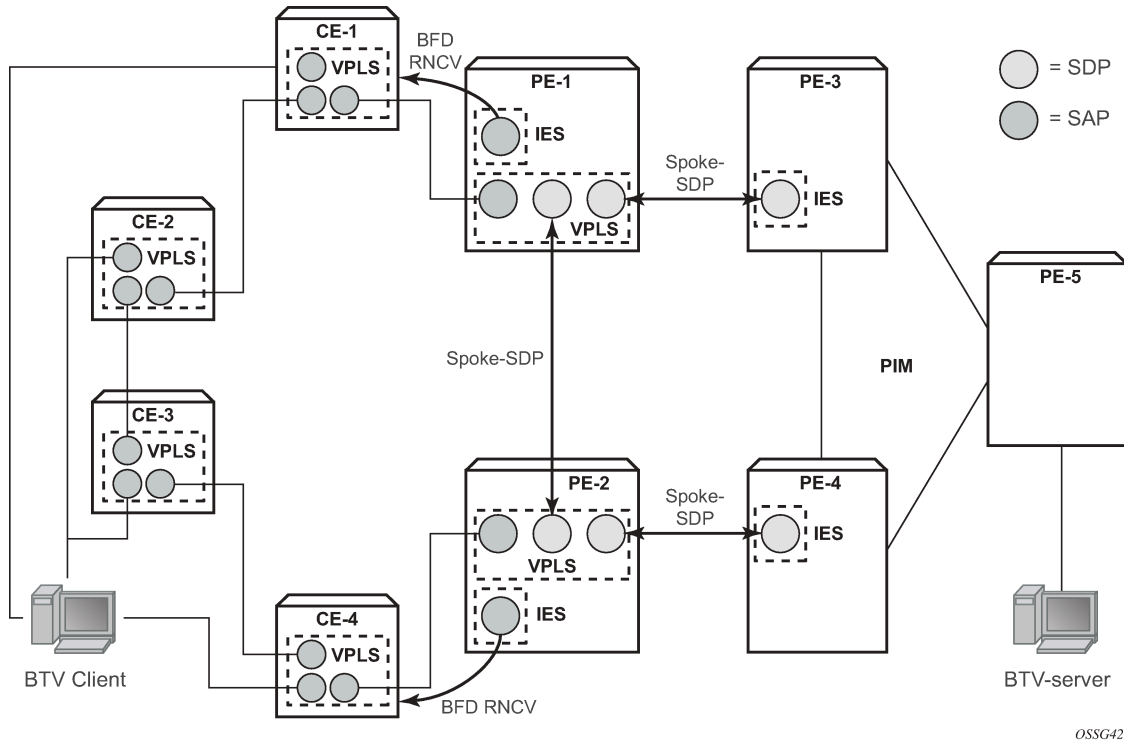

Configure an interface to the multicast server on PE-5:

```
configure service
        ies 3 customer 1 create
            interface "mcast-server" create
                address 192.168.7.1/30
                sap 1/1/3:3 create
                exit
            exit
            no shutdown
        exit
exit all
```

Configure a VPLS service on PE-1 and PE-2. The configuration on PE-1 is shown below. The VPLS configuration on PE-2 is similar.

```
configure service
        vpls 4 customer 1 create
            description "Multicast VLAN"
            igmp-snooping
                no shutdown
            exit
            sap 1/1/1:4.* create
            exit
```

```
            spoke-sdp 12:4 create
                igmp-snooping
                    mrouter-port
                exit
            exit
            spoke-sdp 13:4 create
                igmp-snooping
                    mrouter-port
                exit
            exit
            no shutdown
        exit
 exit all
```

Notice that igmp-snooping has been enabled and that the spoke SDPs are configured as mrouter-ports in order to forward the IGMP joins to the BSRs.

Configure a spoke SDP terminated IES service on PE-3:

```
configure service
        ies 4 customer 1 create
            interface "btv-dst" create
                address 10.0.4.3/24
                ip-mtu 1500
                spoke-sdp 31:4 create
                exit
            exit
            no shutdown
        exit
exit all
```

On PE-4:

```
configure service
        ies 4 customer 1 create
            interface "btv-dst" create
                address 10.0.4.4/24
                ip-mtu 1500
                spoke-sdp 42:4 create
                exit
            exit
            no shutdown
        exit
exit all
```

Notice that also here the **ip-mtu** must be configured to bring the service up. The **ip-mtu** is required to have an MTU match on the spoke SDP between the IES service and the VPLS service.

Configure PIM on PE-3, PE-4 and PE-5. The configuration on PE-3 is shown below. The PIM configuration on PE-4 and PE-5 is similar.

```
configure router pim
            interface "system"
            exit
            interface "int-PE-3-PE-4"
                priority 10
            exit
            interface "int-PE-3-PE-5"
            exit
            interface "btv-dst"
            exit
```

```
            rp
                static
                    address 192.0.2.5
                        group-prefix 224.0.0.0/4
                    exit
                exit
            exit
exit all
```

> **Note:**
> PE-5 is statically configured as the RP. This is just an example. Different configurations can be
> used.

Configure IGMP on PE-3/PE-4:

```
configure router igmp interface btv-dst no shutdown
```

The service should also be configured on all ring nodes. Below, the configuration on CE-2 is shown. Similar
configurations are required on the other ring-nodes.

```
configure service
        vpls 4 customer 1 create
            sap 1/1/1:4.* create
            exit
            sap 1/1/2:4.* create
            exit
            sap 1/1/3:4.* create
            exit
            no shutdown
        exit
exit all
```

Multicast Service Verification

Configure the multicast server to send one or more multicast streams. Have the BTV client connected to
CE-2 send an IGMP join message for this multicast stream.

On the BSA routers (PE-1/PE-2), IGMP snooping can be checked:

```
A:PE-1# show service id 4 mfib
===============================================================================
Multicast FIB, Service 4
===============================================================================
Source Address  Group Address       Sap/Sdp Id           Svc Id   Fwd/Blk
-------------------------------------------------------------------------------
*               *                   sdp:12:4             Local    Fwd
                                    sdp:13:4             Local    Fwd
*               225.1.1.1           sap:1/1/1:4.*        Local    Fwd
                                    sdp:12:4             Local    Fwd
                                    sdp:13:4             Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 2
===============================================================================
```

On PE-3/PE-4 the IGMP groups can be checked:

```
A:PE-3# show router igmp group
```

```
===============================================================================
IGMP Groups
===============================================================================

(*,225.1.1.1)                            Up Time : 0d 00:01:03
    Fwd List  : btv-dst
-------------------------------------------------------------------------------
(*,G)/(S,G) Entries : 1
===============================================================================
```

Following command shows that the MCS peers are synchronized and that there is one IGMP entry on both peers:

```
A:PE-1# show redundancy multi-chassis sync peer 192.0.2.2 detail
===============================================================================
Multi-chassis Peer Table
===============================================================================
Peer
-------------------------------------------------------------------------------

===========================================================================
```

If a failure occurs in the ring-node, the IB-RCC BFD session between PE-1 and PE-2 will go down and the
SAP on both PE-1 and PE-2 will be put in operational up state.

Configuration Notes

RNCV (used for ring-node connectivity check) and BFD (used for ring control connection) can either run on
the same VLAN in the same IES or VPRN service or can run on different VLAN.

MCS for IGMP or DHCP states on a MC-ring requires ESM since the BSA nodes must know which ring
node a subscriber is connected to in case a ring failure occurs. The ring-node name is returned through a
Python script, a RADIUS server or through a local user database. This string (int_dest_id) must match one
of the ring nodes defined in the redundancy configuration.

Convergence time after a ring failure should be 3 * BFD timer + MCS convergence time. Convergence time
after a BSA failure should be likewise.

Note that a debounce timer runs on the MC-ring peers. After a ring failure, the MC-ring converges
immediately (after the BFD session times out) and the debounce timer is started. After the ring is fixed and
the BFD session is up the MC-ring converges immediately again. If another ring failure occurs before the
debounce timer expires, convergence will be slowed down by two (2) seconds. If a third ring failure occurs
before the debounce timer expires, four second delays are introduced. In case of a fourth failure, an eight
second delay is introduced. 200 seconds of delay is the maximum. The debounce timer can be configured
under the MC-ring.

Conclusion

This chapter covers an extension of dual homing support in TPSDA networks based on Layer 2 CO model.
The extension addresses networks where multiple access nodes (for example, DSLAMs) are connected
in a single ring. The examples show the use of a ring with four access nodes in a ring. The behavior is
described in normal operation and in case a failure occurs in the access ring.

Python Cache Support for ESM Applications

This chapter provides information about Python cache support for ESM applications.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS Release 12.0.R4.

Overview

SR OS sports an embedded Python scripting engine which can be used to manipulate selected messages of protocols including DHCPv4, DHCPv6, RADIUS and Diameter.

Python cache provides a central key-value memory cache with a set of APIs allowing Python scripts to store and retrieve strings across different runs of the same or even different Python scripts.

The following are some basic concepts of Python cache:

- Multiple Python policies can be defined, and each Python policy has a separate cache; only scripts configured in the Python policy can access and share that policy's cache.
- A cache entry consists of a key and a value, both of them being strings. The key is used to search and fetch the cache entry.
- A cache entry has a lifetime and the system automatically removes expired entries.

The following are the Python cache APIs:

- alc.cache.save(val,key): Save the value identified by the key into the cache.
- alc.cache.retrieve(key): Return the cached entry's value identified by the key.
- alc.cache.clear(key): Remove the entry identified by the key from the cache.
- cache.get_lifetime(key): The system returns an integer indicating the remaining lifetime of the specified entry expressed in seconds.
- cache.set_lifetime(key,new_lifetime): new_lifetime is an integer; the system sets the remaining lifetime of the specified entry (in seconds).

Configuration

The test topology is shown in .

Figure 145: Test topology
The example shows how the Python cache can be used to store multiple class attributes from the RADIUS access-accept packets and reflect them into RADIUS accounting request packets (start/interim-update/stop).

Test setup:

- A PC is used as DHCPv4 host, connect to SAP 1/1/9 of BNG-1

- SAP 1/1/9 is attached to group interface grp-int-1, which is under subscriber interface sub-int-1 of IES 1

- DHCP host is authenticated via RADIUS server, which resides in management routing instance of BNG-1

- A Python script python-script-1 stores all class attributes in access-accept and add stored attributes into RADIUS accounting requests.

- RADIUS user-name is used as cache key, which is the MAC address of the PC.

The Python cache configuration commands are shown below.

```
config>python>py-policy>
    [no] cache [create]
            [no] entry-size <size>
            [no] max-entries <count>
            [no] max-entry-lifetime [days <days>] [hrs <hours>]
                                    [min <minutes>] [sec <seconds>]
            [no] mcs-peer <ip-address> sync-tag <[32 chars max]>
            [no] minimum-lifetimes
                [no] high-availability <seconds>
                [no] multi-chassis-redundancy <seconds>
                [no] persistence <seconds>
            [no] persistence
            [no] shutdown

config>system>persistence>
    python-policy-cache
        [no] description <desc>
        [no] location <cflash-id>

config>redundancy>multi-chassis>peer>sync>
    [no] python
```

Refer to the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* for details of above commands. The basic configuration of the Python cache is the **cache create** statement in the python-policy as shown below:

```
config>python>py-policy>
---------------------------------------------
            cache create
                no shutdown
            exit
            radius access-accept direction ingress script "python-script-1"
            radius accounting-request direction egress script "python-script-1"
---------------------------------------------
```

The **cache create** configuration enables the cache support for the Python policy. The system's behavior can be tuned in the following aspects:

- Configure **entry-size** and **max-entries** to limit the memory usage.

- Configure **max-entry-lifetime** to specify the maximum lifetime.

- Enable **persistence** to make cache entries persistent across reboot.

- Configure **mcs-peer** to enable Multi-Chassis Synchronization.

In this example only the basic cache configuration is used.

Step 0. Configuring ESM

As a prerequisite ESM must be enabled and as such BNG-1 is configured as follows:

- An **authentication-policy radius-auth-policy-1** is used to authenticate DHCPv4 hosts on group interface grp-int-1.

- A **radius-accounting-policy radius-acct-policy-1** is configured in the **sub-profile sub-profile-1** to enable RADIUS accounting.

- The **user-name** is included in *radius-acct-policy-1* since the User-Name is used as cache entry key.

- Interim-update is enabled in the *radius-acct-policy-1* with an interval 5 minutes.

- The local DHCPv4 server *dhcpv4-svr* is used to assign address to hosts.

```
    #-------------------------------------------------
    echo "Management Router Configuration"
    #-------------------------------------------------
        router management
            radius-server
                server "radius-svr-1" address 192.168.1.1 secret
                                      "iaCuILBunKirJurE4jK2URAnzip6nK32" hash2 create
                exit
            exit
        exit
    #-------------------------------------------------
    echo "Router (Network Side) Configuration"
    #-------------------------------------------------

    exit
```

1. Create the Python script file.

   A Python script is created and stored on the local storage, for example as CF3:\python_cache.py. This script handles the RADIUS packets listed below:

   • Access-Accept — All class attributes from the access-accept packets are stored in the cache by combining them into a single string. The user-name (MAC address) is used as the key, and the format of this string is:

     – 1st byte is the number of class attributes in this string

     – 2nd – nth bytes: each byte holds the number of bytes for class-n attributes

     – Rest of bytes: combined string of class-1 to class-n

   • Acct-Start — Retrieves the stored combined class string using the user name as key. The combined string is parsed and split into the individual class attributes and then inserted into the packet.

   • Interim-Update — The cached entry is parsed and the stored class attributes are inserted, then the lifetime is reset to 15 minutes. This is greater than the interim-update interval (5 minutes) so the cached entry will not expire before next interim-update arrives.

   • Acct-Stop — The cached entry is parsed and the stored class attributes are inserted, then the cached entry is removed.

   > **Note:**
   > There is some error checking and exception handling logic in the script which causes the script to drop the packet if certain errors occur. This script is only an overview example so the error handling logic should be added according to real application requirements. In addition to the exception handling logic included in the script, the **action-on-fail** command could be used in the **python-script** command to define system's action upon failed execution, for example when an un-captured exception is encountered.

```
#------------------------------------------------------------------------------
# Name:      Nokia SR OS Python Cache Support Example
# Purpose:   This script is used to demonstrate SR OS python cache support for
#            the following use case:
#               RADIUS sever returns multiple Class attributes in
#               access-accept, these Class attributes need to be reflected
#               in accounting request packets
```

```
#-----------------------------------------------------------------------
from alc import cache
from alc import radius
import struct
def main():
    radius_header = radius.header()
    if radius_header['code'] == 2: # in case of access-accept
        entry_key = radius.attributes.get(1) # use user-name as the cache entry
                                             # key
        if entry_key == "": #drop the packet if there is no user-name present
            radius.drop()
            return
        class_list = radius.attributes.getTuple(25) # get a list of Class
                                                    # attributes
        if class_list == (): #drop the packet if there is no class present
            radius.drop()
            return
        class_len_str = ''
        class_str = ''
        class_count = 0
        for radius_class in class_list:
            class_len_str += chr(len(radius_class))
            class_str += radius_class
            class_count += 1
        entry_val = chr(class_count)+class_len_str+class_str
        try:
            cache.save(entry_val,entry_key)
        except:
            radius.drop() #drop the packet if cache.save fails
            return

    elif radius_header['code'] == 4: # in case of acct-request
        entry_key = radius.attributes.get(1)
        if entry_key == "": #drop the packet if there is no user-name present
            radius.drop()
            return
        try:
            entry_val = cache.retrieve(entry_key)
        except:#drop the packet if cache.retrieve fails
            radius.drop()
            return
        class_count = ord(entry_val[0])
        pos = class_count+1
        class_list = []
        for i in range(class_count):
            class_len = ord(entry_val[i+1])
            class_list.append(entry_val[pos:pos+class_len])
            pos += class_len
        radius.attributes.set(25,tuple(class_list))
        acct_type=struct.unpack('>I',radius.attributes.get(40))[0]
        if acct_type == 2: # in case of acct-stop
            cache.clear(entry_key) # remove the cache entry
        elif acct_type == 3: # in case of interim-update
            try:
                cache.set_lifetime(entry_key,900) # reset the lifetime
            except:#drop the packet if cache.set_lifetime fails
                radius.drop()
                return

main()
```

2. Configure **python-script** and **python-policy**.

- Enable *python-script-1* to process received (ingress) access-accept packets and transmitted (egress) accounting-request packets.
- Enable the Python cache by configuring **cache create** in *python-policy-1.*
- Reference *python-policy-1* in the *radius-server-policy-1*.

```
#--------------------------------------------------
echo "PYTHON Configuration"
#--------------------------------------------------
    python
        python-script "python-script-1" create
            primary-url "cf3:/python_cache.py"
            no shutdown
        exit
        python-policy "python-policy-1" create
            cache create
                no shutdown
            exit
            radius access-accept direction ingress script "python-script-1"
            radius accounting-request direction egress script "python-script-1"
        exit
exit
#--------------------------------------------------
echo "AAA Configuration"
#--------------------------------------------------
    aaa
        radius-server-policy "radius-svr-policy-1" create
            python-policy "python-policy-1"
```

3. Configure the RADIUS server so that:

- The DHCP host is authenticated via its MAC address.
- The RADIUS server returns the following class attributes and values in access-accept packets:
  - "Class-1"
  - "Class-22"
  - "Class-333"

4. Enable debug on BNG-1 to observe the Python cache in action.

- Enable the following debug on BNG-1:

```
debug
    router "Base"
        ip
            dhcp
                detail-level low
                mode egr-ingr-and-dropped
            exit
        exit
    exit
    router "management"
        radius
            packet-type authentication accounting coa
            detail-level medium
        exit
    exit
    python
```

```
        python-script "python-script-1"
            script-all-info
        exit
    exit
exit

A:BNG-1>config>log# info
----------------------------------------------
        log-id 10
            from debug-trace
            to session
        exit
----------------------------------------------
```

5. Initiate DHCPv4 on the PC.

   - Initiate the DHCPv4 process on the PC. When the PC sends out a DHCPv4 discover message, BNG-1 contacts the RADIUS server to authenticate the user and a DHCPv4 ESM host is created.

   - RADIUS accounting-start will be sent upon host creation and interim-update will be sent every 5 minutes.

   The following describes the debug output:

   - The system initiates RADIUS authentication upon receipt of a DHCP discovery message.

   - The RADIUS server returns an access-accept with the three class attributes.

   - The system executes python-script-1, stores the three class attributes.

   - After the DHCP host is created, the system sends RADIUS accounting-start and interim-update messages in which python-script-1 adds the three stored class attributes.

```

===============================================================================
```

6. Release DHCPv4 lease on the PC

   • Release DHCPv4 lease on the PC which is sent to BNG-1.

- DHCPv4 release message from the PC will trigger BNG-1 to remove the ESM host on BNG-1.

- BNG-1 will send an accounting-stop packet to the RADIUS server.

The following is the debug output:

```
"Python Output: python-script-1
"

67 2014/06/26 03:26:14.84 UTC MINOR: DEBUG #2001 Base Python Result

    CLASS [25] 7 0x436c6173732d31
    CLASS [25] 8 0x436c6173732d3232
    CLASS [25] 9 0x436c6173732d333333
"

69 2014/06/26 03:26:14.85 UTC MINOR: DEBUG #2001 management RADIUS
"RADIUS: Receive
  Accounting-Response(5) id 13 len 20 from 192.168.1.1:1813 vrid 4095 pol radius
-svr-policy-1
"

70 2014/06/26 03:26:14.85 UTC MINOR: DEBUG #2001 management RADIUS
"RADIUS: Script
  Accounting-Response(5) id 13 len 20 from 192.168.1.1:1813 policy python-policy
-1 status success
"
```

As the debug output shows, *python-script-1* inserts three RADIUS class attributes in the accounting-stop message.

The **tools dump python python-policy** *<name>* **cache** command can be used to verify the cached entry has been removed:

```
A:BNG-1# tools dump python python-policy "python-policy-1" cache
===============================================================================
Python policy cache "python-policy-1" entries
===============================================================================
===============================================================================
```

7. Manually change the lifetime of a cached entry (optional).

A **tools** command can be used to manually change the lifetime of an existing cached entry, with following syntax:

```
tool perform python-policy <name> cache {hex-key <hex-str>|string-key <str>} set-lifetime
 <newlifetime>
```

However, manually changing the lifetime might cause issues with the Python script (for example, if reducing the lifetime causes the entry to expire) that needs the cached entry so it should be used with caution.

To demonstrate this recreate the cached entry by initiating a DHCPv4 discover from the PC (see Step 5, 5), then change the lifetime to 20 minutes.

```
A:BNG-1# tools dump python python-policy "python-policy-1" cache
===============================================================================
Python policy cache "python-policy-1" entries
===============================================================================
Key       : 00:20:fc:1e:cd:53
Value     : (hex) 03 07 08 09 43 6c 61 73 73 2d 31 43 6c 61 73 73 2d 32 43 6c 61 73 73 2d
 33 33 33
Time Left : 0d 00:09:48
DDP Key   : N/A
===============================================================================
A:BNG-1# tools perform python-policy "python-policy-1" cache string-key "00:20:fc:1e:cd:53"
 set-lifetime 1200
A:BNG-1# tools dump python python-policy "python-policy-1" cache

===============================================================================
Python policy cache "python-policy-1" entries
===============================================================================
Key       : 00:20:fc:1e:cd:53
Value     : (hex) 03 07 08 09 43 6c 61 73 73 2d 31 43 6c 61 73 73 2d 32 43 6c 61 73 73 2d
 33 33 33
Time Left : 0d 00:19:57
DDP Key   : N/A
===============================================================================
```

8. Manually remove a cached entry (optional).

Manually removing an existing cached entry can be done using a clear command with following syntax:

```
clear python python-policy <name> cache {hex-key <hex-str>|string-key <str>}
```

Manually removing a cached entry can result in unexpected results (for example, if a script expects an entry to exist but it has been removed), so this should be used with caution.

The following command sequence demonstrates the effect of the clear command after initiating a DHCPv4 discover from the PC to recreate the cached entry (see Step 5, 5).

```
A:BNG-1# tools dump python python-policy "python-policy-1" cache

===============================================================================
Python policy cache "python-policy-1" entries
===============================================================================
Key       : 00:20:fc:1e:cd:53
Value     : (hex) 03 07 08 09 43 6c 61 73 73 2d 31 43 6c 61 73 73 2d 32 43 6c 61 73 73 2d
 33 33 33

===============================================================================
Python policy cache "python-policy-1" entries
===============================================================================
===============================================================================
```

Configuration and Operational Guidelines

The following is a list of configuration and operational guidelines that a user should follow when using the Python cache:

- SR OS has a limit on the total amount of memory used for the python cache since the python cache can be demanding with respect to memory usage. The maximum memory allocated for the cache system wide is restricted to 256MB. However, it is good practice to configure per python-policy limits using the **entry-size** and **max-entries** commands; by doing this, one python-policy's cache will not impact another python-policy's cache memory usage.

- For applications needing a cache entry for the entire lifetime of an ESM host, lifetime management is essential. If the lifetime is too long then unneeded entries might reside in the system, wasting memory; if the lifetime is too short then entries might expire while they are still needed. One way to address this is by initially setting a relative short lifetime and then using the RADIUS interim-update message as a trigger to reset a new lifetime. This new lifetime should be larger than the interim-update interval. Then the entry should be removed by a script when an accounting-stop message is sent.

- With MCS enabled, each python cached entry will have a corresponding MCS record, resulting in each python cache entry consuming twice amount of memory. For example, 256MB cached entries would consume additional 256MB memory for MCS records.

- Choosing the right key is important, a network designer needs to choose the key meeting the application requirement in terms of their uniqueness. For example: if an application needs to store per-host information then the key for that host must be unique (for example, its MAC address or remote-id). The key must be derived from the trigger packet. For example: if an application needs to store information on DHCP discovery and retrieve it on receiving a RADIUS accounting-request message for the same host, then the script needs to be able derive the same key from both the DHCP discovery as well as from the RADIUS accounting-request message.

- Using tools or clear commands to manually change cached entries could cause problems if the entries are needed by a script. Only use these commands when it is absolutely necessary.

- The minimum-lifetimes exist to make the system more efficient in handling system memory before a cache entry could be synced or made persistent (e.g. when a new entry is created or when MCS is enabled). The cache entry's lifetime must be equal or larger than the configured minimal-lifetime listed below for that function to occur.

  1. high-availability — The minimum lifetime of a cache entry for it to be synchronized from the active CPM to the standby CPM.

     The default is 0 seconds, resulting in all entries being synchronized.

  2. multi-chassis-redundancy — The minimum lifetime of a cache entry for it to be synchronized between chassis.

     The default is 0 seconds, resulting in all entries being synchronized.

  3. persistence — The minimum lifetime of a cache entry for it to be written to the persistency file.

     The default is 0 seconds, resulting in all entries will be synchronized.

Conclusion

The Python cache provides a very powerful and flexible way to share information across different Python scripts in SR OS.

RADIUS-Triggered Dynamic Data Service Provisioning

This chapter describes advanced RADIUS-triggered dynamic data service provisioning configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration are based on SR OS Release 11.0.R2.

Overview

RADIUS-triggered dynamic data services enables a zero touch, single-ended provisioning model for business services on the basis of Enhanced Subscriber Management functionality.

Triggered by the authentication of a single or dual stack PPPoE or IPoE session or a single stack IPv4 host as the "control channel" from the business CPE, parameters are passed in a RADIUS Access Accept or Change of Authorization (CoA) message to set up one or multiple Layer 2 or Layer 3 data services.

This concept removes the need to have an Operations Support System (OSS) responsible for the service provisioning and is particularly beneficial in a highly dynamic network environment, where physical network topologies – especially in the access – change frequently. With a regular service provisioning, frequent changes would be hard to keep track of. In the RADIUS-based model the service gets instantiated wherever it "pops-up" in the network. Even planned customer moves to a different office would not require advanced notifications and lead times but could be instantaneous, assuming the pure physical connectivity is given.

A variation of the current service offering will only require one or a few modified service parameters in the RADIUS user database and does not require timely and costly IT changes (for RADIUS those service parameters are just attributes; the RADIUS server does not check the logic). This speeds up the time-to-market for new service offerings, which is another big advantage.

Taking this logic to its full extent, it becomes immediately clear that the managed business CPE terminating the carrier service (and being responsible for the PPP or DHCP control channel) also needs to be provisioned in the most flexible way. Through the control channel or a dedicated management channel instantiated as the first dynamic data service, the business CPE should get its full configuration from a configuration server via a pre-populated configuration file. The details of the CPE provisioning are outside of the scope of this example and therefore not discussed further.

As the whole approach is centered around the principle of "highly flexible in a highly dynamic environment", it is naturally required to maintain as little state information about connections in the RADIUS parameter attributes as possible. For example, fixed remote peer IP-addresses for the SDPs used in a VPLS service

in the RADIUS parameter lists would remove all the flexibility and would not allow access services to be moved dynamically. As such the data services for this functionality focuses on those types where a control protocol like BGP is used to exchange VPN membership information. Dynamic data services supported include local Epipe VLL services, Epipe VLL services with dynamic Multi-Segment PseudoWires (MS-PWs) (FEC129) or spoke SDP, VPLS services with BGP-AD PWs or mesh/spoke SDPs, IES, and VPRN services.

To display the complete white list of dynamic data services CLI configuration commands, use the **tools dump service dynamic-services command-list** CLI command.

A Python script interface adds a flexible abstraction layer so that only the business user specific service parameters (service type, IP address, QoS and filter parameters, etc.) are required from RADIUS and are then used in a CLI template to set up the target service.

The setup sequence is shown in Figure 146: Principle Model of Dynamic Data Services with the example of a VPLS service.

Figure 146: Principle Model of Dynamic Data Services
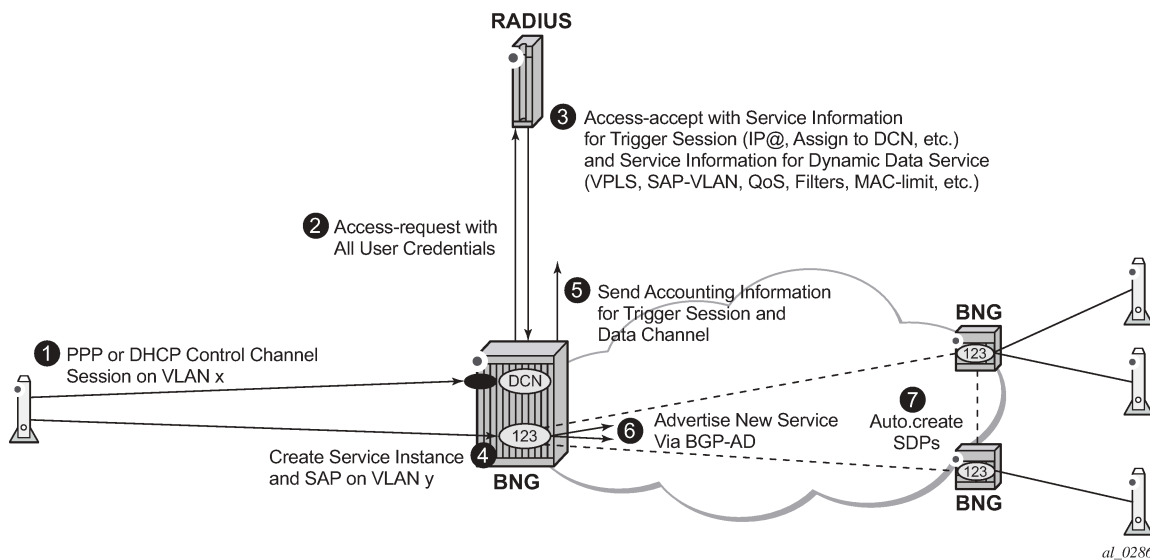

1. Business CPE initiates a PPP or DHCP "control channel" session. This session is important to let the BNG and RADIUS understand the existence of a new access circuit and the location of the service endpoint.

2. BNG sends an Access-Request with all user credentials to RADIUS.

3. RADIUS replies using an Access-Accept with attributes for the PPP/DHCP control channel and attributes for the dynamic data service (Service-type, SAP-VLAN, QoS, Filter, etc.).

4. BNG creates a dynamic data service instance (if it is first access-circuit for this service) and a SAP, thus completing the service configuration.

5. BNG sends an Accounting Start for PPP/DHCP control channel session and also for the dynamic data service session (and subsequently interim accountings and accounting stop for both).

6. BNG advertises VPLS instance-ID (123) via BGP-AD to other PEs/BNGs.

7. PEs/BNGs with same service instance will auto-establish SDPs to the BNG.

The result is a fully functional service which is the same as a traditionally configured service.

The lifetime of the dynamic data services are bound to the existence of the control channel session. If, for whatever reason, the control channel session is torn down all associated dynamic data services will also be terminated.

Dynamic data service SAPs have to be located on dot1q or qinq encapsulated Ethernet ports and can be part of a LAG.

Both XML accounting and RADIUS accounting can be enabled on a dynamic data service SAP. The RADIUS accounting data can be sent to up to two different RADIUS servers.

There is a strict separation of services created by dynamic service provisioning and services created via the CLI or through other standard mechanisms (5620 SAM, SNMP). It is therefore not allowed to:

- create a dynamic services object in a local provisioned CLI/SNMP context (e.g. create a dynamic SAP in a local provisioned VPLS).
- create a local provisioned object in a dynamic service context (e.g. create a SAP via CLI/SNMP in a dynamic VPLS service).
- change parameters in a local provisioned CLI/SNMP context using the dynamic services model (change system name with dynamic services provisioning).
- change parameters with the CLI/SNMP in a dynamically created context.
- delete a local provisioned object using dynamic provisioning model.
- delete a dynamic provisioning object using the CLI/SNMP.
- create a reference to a dynamic services object in a local provisioned CLI/SNMP context (reference to dynamic interface in **router ospf**)

A special command exists to overcome some of the above rules. This command is designed to ease Python script creation and testing and not for normal operations. This is discussed in Configuration.

Configuration

It is assumed that the reader is familiar with the regular Enhanced Subscriber Management (ESM) functionality as well as with general service related configurations. Furthermore certain knowledge about Python programming is also assumed.

The test topology is shown in Figure 147: Test Topology.

Figure 147: Test Topology
al_0287

The pure service setup can be tested with a single node acting as BNG. However an Epipe service between two nodes will not normally become status "up" with only one endpoint in an up state. As such, for packets should be sent through the established dynamic data service, a remote PE could also be configured. The remote PE could have its data service configured in a regular fashion, meaning via CLI/SNMP or 5620 SAM.

The required functionality on the BNG is divided into multiple building blocks. The following sections discuss each building block in detail.

Figure 148: Building Blocks of Dynamic Data Services
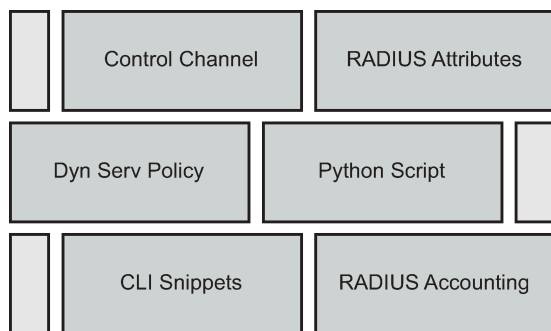

al_0288

Based on a PPP or DHCP control session, RADIUS will return the required parameters for the dynamic data service via dedicated Vendor Specific Attributes (VSAs). The existence of those attributes in the RADIUS Accept message will trigger the relaying of the parameters relating to those attributes towards the Python script defined in the dynamic service policy, which will process them to generate the regular CLI output for the various service types (IES, VPRN, Epipe, VPLS).

For efficiency and flexibility the Python script needs to be structured into different parts per service which then reference each other internally. Those parts are called snippets.

Finally, as the services are initiated from RADIUS, RADIUS accounting messages per dynamic data service will be sent to the RADIUS server as a necessary feedback mechanism to inform the RADIUS server about a successful or failed service setup.

Building Block: Control Channel

The configuration to authenticate and instantiate a dynamic data service control channel is identical to a residential Enhanced Subscriber Management (ESM) configuration. Examples for this can be found in other chapters of the advanced configuration guide and will not be covered here in detail.

Building Block: Dynamic Services Policy

The dynamic services parameters are configured under the **configure service dynamic-services** CLI context. The following output shows two policy examples.

```
configure service dynamic-services
            dynamic-services-policy "dynamic-services-1" create
              accounting-1
                  server-policy "radius-server-policy-1"
                  update-interval min 5
              exit
              accounting-2
                  server-policy "radius-server-policy-2"
                  stats-type time
                  update-interval min 5
                  update-interval-jitter absolute 10
              exit
              cli-user "dynuser"
              description "Dynamic Service Policy #1"
              sap-limit 4000
              script-policy "script-policy-1"
          exit
          dynamic-services-policy "dynamic-services-2" create
              accounting-1
                  server-policy "radius-server-policy-2"
              stats-type volume-time
                  update-interval min 30
                  update-interval-jitter absolute 20
              exit
              accounting-2
                  server-policy "radius-server-policy-2"
                  stats-type time
                  update-interval min 5
                  update-interval-jitter absolute 10
              exit
              cli-user "dynuser"
              description "Dynamic Service Policy #2"
              sap-limit 100
              script-policy "script-policy-2"
          exit
          service-range 1000 10000
          timers
              setup-timeout access-accept 3
          exit
```

Details of each command and the possible parameters can be found in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* in the RADIUS Triggered Dynamic Data Services section.

On the top command level under the dynamic-services sub-tree there are three options:

- dynamic-services-policy
- service-range
- timers

The setup-timeout value under **timers** is used to limit the maximum delay allowed for a dynamic data service setup. In addition, it also protects the node during times where there is a high load on the CPU. If a requested dynamic data service cannot be established in the specified time the request will be dropped.

Dynamic data services are not preferred over regular ESM subscribers. As such, given a BNG with a mix of residential ESM subscribers and business customers with dynamic data services, all compete for the same CPU resources to establish the connections.

However, dynamic data services are expected to have a very long lifetime compared to potentially very dynamic lifetimes for residential subscribers. In a regular operating mode the amount of additional setup requests for dynamic data services should be relatively small. Only in the event of a node reboot will all users again compete to gain access, where longer setup-times are inevitable.

The service-range value reserves a certain amount of service IDs for the use of dynamic data services. The configured range is no longer available for regular provisioned services configured via the CLI/SNMP.

The dynamic-services-policy contains a CLI-user identifier, SAP-limits, accounting parameters and reference to a Python script policy which is used when creating a dynamic data service. Multiple dynamic services policies can be created to enable different profiles to be used for different users/customers or services (as an example, two different departments within the service provider, one responsible for Layer 2 services, one for Layer 3 services). The policy used for a dynamic data service is determined from the Alc-Dyn-Serv-Policy [26-6527-167] RADIUS attribute. If the attribute is not present and a policy named *default* exists, then the *default* policy is used, otherwise the dynamic data service creation fails.

Up to two accounting server policies can be defined. This allows the use of separate RADIUS accounting servers independent from the accounting servers used for residential services. The parameters defined in the accounting sections are the default values which are used if no specific values are sent via RADIUS VSAs.

As the service is established via RADIUS, a feedback mechanism towards RADIUS is most likely required which would be at least RADIUS start and stop messages per service/session. In addition performance counters (with a fixed set of parameters) can also be included in the RADIUS messages. It is also possible to use the standard service-accounting under the service instance and remove any counters from the RADIUS accounting messages.

The specification of a CLI user allows linking of the dynamic data service to a specific user-profile. In addition, this facilitates limiting of the scope of allowed service configurations even further, based on the specified context under the user profile.

The CLI-user needs to be configured locally on the node and needs to have a local user profile (remote authorization via TACACS/RADIUS is not possible).

The radius-script-policy is configured under the **configure aaa** CLI context.

```
configure aaa
radius-script-policy "script-policy-2"
    action-on-fail passthrough
            primary
                script-url "cf3:/scripts/dyn_services.py"
                no shutdown
```

```
            exit
            secondary
                script-url ftp://user*:*pwd@10.255.137.80/scripts/dyn_services.py"
                no shutdown
            exit
    exit
exit
```

The parameters are no different to what have been defined generally for the use of Python scripting on the BNG.

When the very first session request arrives, the Python script is loaded into memory and executed. For all subsequent session requests the script is executed without the need for a reload. It is possible for both primary and secondary locations to be FTP sites (the small transfer delay for the first session is acceptable), however, it is recommended to have a compact-flash (cf1 or cf2) as the primary location and a remote location as backup.

Building Block: RADIUS Attributes

A series of vendor specific attributes (VSAs) have been defined to setup, teardown or modify dynamic data services from RADIUS.

The VSAs and their meaning are as follows:

- Alc-Dyn-Serv-SAP-Id [26-6527-164], type "string"

  This attribute identifies the dynamic service SAP. The format can be any valid Ethernet SAP format (dot1q or qinq encapsulation), including LAGs. A wildcard ("#") can be specified for the port field and optionally for one of the tag fields of a qinq interface. To define the dynamic data service SAP-ID, the wildcard fields are replaced with the corresponding field from the Control Channel SAP-ID.

  Examples: "1/2/7:10.100" or "#:#.100"

- Alc-Dyn-Serv-Script-Action [26-6527-166], type "integer"

  A mandatory VSA in a COA to the control channel accounting session ID or the accounting session ID of the dynamic data service (only applicable for modify or teardown). Tells the system what script action is required: setup, modify or teardown of a dynamic data service.

  Values: 1=setup, 2=modify, 3=teardown

- Alc-Dyn-Serv-Policy [26-6527-167], type "string"

  Specifies the dynamic service policy to use for provisioning the dynamic service. The policy must be configured in the "configure service dynamic-services dynamic-services-policy < dynsrv-policy-name>" CLI context.

- Alc-Dyn-Serv-Script-Params [26-6527-165], type "string"

  This VSA contains parameters that can be used by the Python script to setup or modify a dynamic data service. The parameters can be split into multiple instances of the same attribute, linked together by the same tag, that is, the parameters can cross an attribute boundary. The concatenation of all "Alc-Dyn-Serv-Script-Params" attributes with the same tag in a single message must be formatted as "function-key = {dictionary}" where function-key specifies which Python functions will be called and {dictionary} contains the actual parameters in a Python dictionary structure format.

  Example: "business_1 = { 'as_id' : '100', 'comm_id' : '200', 'if_name' : 'itf1', 'ipv4_address' : '172.16.1.1', 'egr_ip_filter' : '100' , 'routes' : [{'to' : '172.16.100.0/24', 'next-hop' : '172.16.1.2'}, {'to' : '172.16.200.0/24', 'next-hop' : '172.16.1.2'}]}

The above example shows each parameter with a keyword and the associated value. Alternatively only the parameter values can be sent with a pre-defined (and always constant) sequence.

Example: "business_1 = {"t": '100', '200', 'itf1', '172.16.1.1', '100', '172.16.100.0/24', '172.16.1.2', '172.16.200.0/24', '172.16.1.2'}.

- Alc-Dyn-Serv-Acct-Interim-Ivl-1 [26-6527-168], type "integer"

  This VSA defines the number of seconds between each accounting interim update message for the primary accounting server. It overrides the local configured "update-interval" value in the dynamic services policy "accounting-1" CLI context. A value of 0 (zero) corresponds to no accounting interim update messages. A value [1..299] seconds is rounded to 300s (min. CLI value) and a value above 15552000 seconds (180 days, maximum CLI value) is rounded to the maximum CLI value.

  Range = 0 | [300 - 15552000].

- Alc-Dyn-Serv-Acct-Interim-Ivl-2 [26-6527-169], type "integer"

  Same function and values as Alc-Dyn-Serv-Acct-Interim-Ivl-1 [26-6527-168], for the second accounting server. It overrides the locally configured "update-interval" value in the dynamic services policy "accounting-2" CLI context.

- Alc-Dyn-Serv-Acct-Stats-Type-1 [26-6527-170], type "integer"

  Enable or disable dynamic data service accounting to the primary accounting server and specify the type of statistics that should be reported: volume and time or time only. It overrides the locally configured value in the dynamic services policy "accounting-1" CLI context.

  Values: 1=off, 2=volume-time, 3=time

- Alc-Dyn-Serv-Acct-Stats-Type-2 [26-6527-171], type "integer"

  Enable or disable dynamic data service accounting to the secondary accounting server and specify the type of statistics that should be reported: volume and time or time only. It overrides the locally configured "stats-type" value in the dynamic services policy "accounting-2" CLI context.

  Values: 1=off, 2=volume-time, 3=time

All VSAs are tagged to enable manipulation of up to 32 (tag values 0..31) dynamic data services in a single RADIUS message. VSAs with an identical tag belong to the same dynamic data service.

The use of the VSAs in RADIUS Access-Accept, CoA and Disconnect Messages is detailed in Table 31: Dynamic Service Attribute List for Setup, Modify and Teardown . An Access-Accept message can only contain dynamic data service setup requests. A CoA can be used to setup, modify or terminate a dynamic data service. A Disconnect Message can only be used to terminate a dynamic data service.

Table 31: Dynamic Service Attribute List for Setup, Modify and Teardown

Attribute Name	Access Accept	CoA			Disc. Message	Comment
	Setup	Setup	Modify	Teardown	Teardown	
Acct-Session-Id	N/A	M	M	M	M	Acct-Session-Id of the Control Channel or in case of a CoA: any other valid CoA key for ESM hosts/ sessions.

Attribute Name	Access Accept	CoA			Disc. Message	Comment
	Setup	Setup	Modify	Teardown	Teardown	
Alc-Dyn-Serv-SAP-Id	M	M(*)	M(*)	M(*)	N/A	Identifies the dynamic data service
Alc-Dyn-Serv-Script-Params	O	M(*)	M(*)	N/A	N/A	For a Modify, the script parameters represent the new parameters required for the change.
Alc-Dyn-Serv-Script-Action	O	M(*)	M(*)	M(*)	N/A	Must be "setup" if specified in an access-accept.
Alc-Dyn-Serv-Policy	O	O	O	O	N/A	The *default* policy used when not specified for create. In CoA, must be same as used for Setup if Specified for Modify or Teardown.
Alc-Dyn-Serv-Acct-Interim-Ivl-1	O	O	X(**)	X(**)	N/A	
Alc-Dyn-Serv-Acct-Interim-Iv2	O	O	X(**))	X(**))	N/A	
Alc-Dyn-Serv-Acct-Stats-Type-1	O	O	X(**)	X(**))	N/A	
Alc-Dyn-Serv-Acct-Stats-Type-2	O	O	X(**))	X(**))	N/A	
M = Mandatory, O= Optional, X = May not, N/A = Not Applicable (ignored)						
(*) = CoA Nak'd, if not specified (Error Cause: 402 - Missing Attribute)						
(**) = CoA Nak'd if specified (Error Cause:405 - Unsupported Service)						

To summarize, Table 32: Dynamic Service Actions on Control- and Data-Channel shows resulting dynamic service script actions as function of the RADIUS message (Access-Accept, CoA or DM) and the target (Control Channel or Dynamic Service SAP).

Table 32: Dynamic Service Actions on Control- and Data-Channel

Target	RADIUS Message	Dynamic Service Script Action	Comments
Control Channel	Access-Accept	Setup	Up to 32 dynamic data services in single message.

Target	RADIUS Message	Dynamic Service Script Action	Comments
			Alc-Dyn-Serv-Script-Action VSA optional.
		Modify/Teardown	Not supported.
	CoA (acct-session-id or any other valid CoA key for ESM hosts/sessions)	Create/Modify/ Teardown	Cannot be mixed with session/post parameter changes in the same RADIUS message (results in CoA NAK). Up to 32 dynamic data services in single message. Alc-Dyn-Serv-Script-Action VSA mandatory.
	Disconnect	N/A	Teardown the Control Channel session and all associated dynamic data services.
Dynamic Service	CoA (acct-session-id of the dynamic data service sap)	Modify/Teardown	Only single dynamic data service per message (Acct-Session-Id). Alc-Dyn-Serv-Script-Action VSA mandatory.
		Setup	Not supported.
	Disconnect (acct-session-id of the dynamic data service sap)	N/A	Teardown the corresponding dynamic data service.

Building Block: Python Script

Dynamic data services scripts are built using a Python script engine. The following dedicated functions are available in the alc.dyn module:

- dyn.reference(function-key, reference-id string, dictionary)

This function creates a dynamic reference to another function in the script. This function eases the creation of N:1 relationships in the script. For more information about use cases, see Building Block: CLI Snippets. The function-key specifies the key in the action dictionary to find the corresponding setup/ modify/teardown function calls.

The reference-id (typically derived from a parameter specified from RADIUS, for example: service-name) specifies a unique instance string that identifies this reference.

The dictionary specifies a dictionary with parameters that can be used in the parent function to generate CLI script output.

- dyn.action(d)

When called, the dyn.action will take the "function-key" string specified in the Alc-Dyn-Serv-Script-Params attribute, and perform a lookup in the specified dictionary d to find the corresponding Python function to execute. The format of the dictionary is d = {key-1 : (Setup-1, Modify-1, Revert-1, Teardown-1), …, key-n : (Setup-n, Modify-n, Revert-n, Teardown-n) }. If the function-key matches, for example, key-1 and the corresponding Alc-Dyn-Script-Action is "setup", then the function specified as

"Setup-1" will be executed. Setup and teardown functions are mandatory. Modify and revert functions are optional. If a modify function is defined, a corresponding revert function must also be defined. If no modify/revert function is required, the keyword **None** should be used instead.

- dyn.add_cli(string)

This function is used to generate CLI output in the Python script. The use of dyn.add_cli ("""") allows the specification of strings spanning multiple lines, which drastically improves the readability of the script.

A subset of all available CLI commands is currently enabled for dynamic data services. The command "tools dump service dynamic-services command-list" provides a complete overview of all available CLI nodes for dynamic data services. In the allowed nodes section, all CLI nodes are listed that can be navigated to and where attributes can be modified. The pass through nodes section shows CLI nodes that can be navigated to but no attribute changes are allowed. For example, it is not allowed to change the autonomous system of a router (configure router autonomous-system <autonomous-system>) because "configure router" is a "pass through node". However, you can navigate to configure router, because you can add a static route: "/configure router static-route 0.0.0.0/0 next-hop 192.168.1.1" is part of the "allowed nodes".

- dyn.select_free_id("service-id")

This function is used to select a free service ID within the service ID range defined under dynamic-services context. An automatic assignment of the service id is one option, but it is also possible to provide the service id as one of the parameters in the "Alc-Dyn-Serv-Script-Params" list from RADIUS.

The service-ID is a node-internal attribute. As such it is valid to let the node select the ID itself. However, in a network with multiple BNGs and a single customer service spanning two or more BNGs, a network administrator may actually prefer to use the same service-id for this customer service on all nodes for better visibility, which cannot be guaranteed if the automatic option is chosen. 5620 SAM is also using the service-ID as one attribute in addition to others to discover service-entities across the whole network. If SAM is in use for general management and service assurance, it is advised to manually specify the service-ID and not to use the automatic selection.

In any case, the administrator needs to make a choice between the automatic ID assignment and the specific assignment for all dynamic data services, as a mix between both is not recommended.

When the automatic assignment is chosen, there is no "binding/memory" of a service ID to a provisioned service, which means a service that may have service ID xyz initially may get another service ID the next time it comes up. In other words, as soon as a service is disconnected, the service ID is freed up for the next activated service.

- dyn.get_sap()

This function returns the value of the evaluation of the "Alc-Dyn-Serv-SAP-Id" attribute as a string. Wildcards ("#") in the Alc-Dyn-Serv-SAP-Id are replaced with the corresponding port/vlan information of the control channel SAP-ID. So if, for example, the "Alc-Dyn-Serv-SAP-Id" contains "#:#.1" and the control channel SAP ID is "1/1/5:100.100", the resulting SAP for the data service would be "1/1/5:100.1".

- dyn.get_circuit_id()

This function returns a string which is equal to the Control Channel Circuit-ID (from the DHCP relay agent option 82 or PPP tags). This function may be useful, for example, to use the circuit id in the SAP description.

- dyn.get_remote_id()

This function returns a string which is equal to the Control Channel Remote-ID (from the DHCP relay agent option 82 or PPP tags). This function may be useful, for example, to use the remote id in the SAP description.

In addition to the RADIUS dictionary, the node will also store service-related parameters in a service-specific dictionary. The information in the RADIUS messages or in the stored dictionary are used for the various functions as outlined in Table 33: Function and Dictionary Relationship :

Table 33: Function and Dictionary Relationship

Function Name	Input	Returns
setup dynsvc(rd*)	**rd:** radius dictionary in the parameter list in Alc-Dyn-Serv-Script-Params. VSA Passed to setup function.	A dictionary that will be stored for the lifetime of the dynamic service (sd).
modify_dynsvc(rd,sd**)	**rd:** radius dictionary in the parameter list in Alc-Dyn-Serv-Script-Params. VSA passed to modify function. **sd:** previously stored dictionary of the setup/ previous modify functions.	Updated stored dictionary (sd)
revert_dynsvc(rd, sd)	**rd:** radius dictionary in the parameter list in Alc-Dyn-Serv-Script-Params. VSA passed to revert function. **sd:** previously stored dictionary of the setup/ previous modify function.	The function does not return (store) any information. The previously stored dictionary (sd) is kept.
teardown_dynsvc(sd)	**sd:** previously stored dictionary by the setup function or a previous modify function are passed to the teardown function.	The function does not return (store) any information. The stored dictionary (sd) is deleted.
(*) rd = radius dictionary		
(**) sd = stored dictionary. sd is required for modifies, reverts and teardowns.		

Building Block: CLI Snippets

The necessary functional parts of a service configuration cannot typically be put into one large script (one single actionable function). This is best described with a small and simple example:

Imagine a single script where the setup action creates both the service instance and the SAP, and the teardown action removes the service instance and the SAP. For a service with just one SAP per service instance this may work fine, however, in a multi SAP service like a VPLS this will cause problems, especially during the service teardown action. This is because if multiple SAPs have been instantiated in a single service, the disconnect of just one SAP would trigger the teardown action which would try to remove the SAP (still ok) but then would try to remove the service instance. This action would fail as other SAPs still exist in the service. As such the script execution would fail.

It is therefore necessary to structure the whole required configuration into individual actionable pieces which are referenced by each other with specific reference-IDs. Those actionable pieces are called "snippets".

Referenced snippets may or may not be executed depending on whether the functional instance exists already or not. As shown on the left of the picture below, the action to create a SAP references the creation of a service and then to the creation of a customer. For the very first business site to come up all three

snippets will be executed. For any further business site to come up in the same service the script to create the SAP will be executed, the referenced service script and subsequently the customer script will not be executed again as those instances already exist. The same logic applies during the teardown action. Only when the last SAP in a service is removed is the service-instance itself removed, and potentially also the customer (unless it too is associated with other services).

Figure 149: Hierarchy of Snippets
The implementation supports a three level hierarchy of snippets for high flexibility as shown in the picture. A reference to the fourth level as shown on the right side would result in an error.

Furthermore, snippets can be scaled "horizontally", so from one level multiple references to other snippets are possible. An example for that would be the creation of a SAP triggers the creation of a service as well as the creation of an Ethernet CFM association for that SAP.

Identifiers are needed for the referencing. The same identifier can be used on the "horizontal" level, but not on the vertical level between the same pair of snippets, also shown above.

Snippets are heavily used in the service examples in Bringing it all together where the logic and the referencing are described with real data.

Building Block: RADIUS Accounting

As dynamic data services are instantiated through RADIUS, it is also typically required to provide feedback to the RADIUS server for service establishment and teardown. This is achieved via RADIUS accounting records for the dynamic data channels in addition to the accounting messages for the PPP or DHCP control channel.

Up to two dedicated accounting destinations can be defined within the dynamic services policy. Thus, the accounting for the dynamic data services can be handled by an independent set of accounting servers (from the accounting for general ESM subscribers). But the same servers can also be used.

Each dynamic data service has its own accounting start/stop/interim messages based on a unique accounting session ID. In addition, the accounting packets contain a multi-session ID which is identical to the accounting session ID of the control channel and is therefore displayed in show commands as Acct-Session-ID-Ctrl as shown below.

```
A:BNG-1# show service dynamic-services saps summary
===============================================================================

-------------------------------------------------------------------------------
No. of SAP's: 5
===============================================================================
```

The Accounting Session ID (in the centre above) is the one for the dynamic data service itself, the one on the right is from the control-channel. The above example clearly shows that the last 4 dynamic services all belong to the same control channel, as they all have the same Acct-Session-ID-Ctrl.

If the accounting stats-type is set to "volume-time", the interim and stop accounting messages will also contain counters for the data traffic through the service. With the accounting stats-type "time", no counters are included, only session time is reported.

As a dynamic data service is functionally no different from a regular data service, traffic volumes can also be gathered by assigning accounting policies within the service for file-based XML accounting.

Bringing it all together

This section gives examples of all of the above parameters and will also cover show, log and debug information.

In the given example, a single user in the database has four different associated data services. Not only are the data service types all different, but also other aspects of the parameter set, this has an effect on how the data is entered in the RADIUS VSAs and how the Python script is constructed. More detail is given below. The different models for specifying parameters are presented to show the flexibility. An operator typically chooses a single model and uses that for all its services.

As all of the information for these four services will potentially be sent in one RADIUS message, the VSAs need to be tagged so that the BNG can link the appropriate VSAs to each other and differentiate the services. For better visibility, the different sections in the RADIUS users file are displayed with bold black and dark grey text.

The freeradius users file format is used for this example.

```
1.    "subscriber12@domain2.com" Cleartext-Password := "ALU"
2.        Alc-Subsc-ID-Str := "pppoe-user12",
3.        Framed-IP-Address = 10.2.1.200,
4         Alc-Dyn-Serv-SAP-Id:1  = "#:#.1",
```

```
5.          Alc-Dyn-Serv-Script-Params:1 = "business_epipe={'t':('EPipe-
6.              CustomerName','CustomerName-Circuit-1','3','3','64496',
7.              '192.0.2.5','192.0.2.1','3333')}",
8.          Alc-Dyn-Serv-Policy:1 =  "dynamic-services-2",
9.          Alc-Dyn-Serv-SAP-Id:2 += "#:#.2",
10.         Alc-Dyn-Serv-Script-Params:2 += "business_vprn={'t':('9999',
11.             'VPRN-CustomerName','64497','100000','CustomerName-Circuit-
12.             1','172.16.10.1/30','3','1','3','2','172.16.100.0/24',
13.             '172.16.10.2','100')}",
14.         Alc-Dyn-Serv-Acct-Interim-Ivl-1:2 += "600",
15.         Alc-Dyn-Serv-Acct-Interim-Ivl-2:2 += "0",
16.         Alc-Dyn-Serv-Policy:2  +=  "dynamic-services-2",
17.         Alc-Dyn-Serv-SAP-Id:3  += "#:#.3",
18.         Alc-Dyn-Serv-Script-Params:3 += "business_vpls={'inst':
19.             'VPLS-CustomerName','if_name':'CustomerName-Circuit-1','ing_qos':'3',
20.             'egr_qos':'3','imp_comm_val':'10000','exp_comm_val':'10000',
21.             'rt':'64498','rd':'64498'}",
22.         Alc-Dyn-Serv-Policy:3 +=  "dynamic-services-2",
23.         Alc-Dyn-Serv-Acct-Interim-Ivl-1:3 += "0",
24.         Alc-Dyn-Serv-Acct-Interim-Ivl-2:3 += "0",
25.         Alc-Dyn-Serv-Acct-Stats-Type-1:3 += off,
26.         Alc-Dyn-Serv-Acct-Stats-Type-2:3 += off,
27.         Alc-Dyn-Serv-SAP-Id:4  += "#:#.4",
28.         Alc-Dyn-Serv-Script-Params:4 += "business_ies={'t':
29.             ('IES-CustomerName','CustomerName-Circuit-1','172.16.11.1/30',
30.             '2001:db8:5100:1000::1/64','5','1','1','6','2','2','5','25',
31.             'cfm-Mep-to-CPE','100',",
32.         Alc-Dyn-Serv-Script-Params:4 += "[{'to':'172.16.110.0/24',
33.             'n-h':'172.16.11.2'},{'to':'2001:db8:bbbb::/56',
34.             'n-h':'2001:db8:5100:1000::2'}])}",
35.         Alc-Dyn-Serv-Policy:4 +=  "dynamic-services-2",
36.         Alc-Dyn-Serv-Acct-Interim-Ivl-1:4 += "600",
37.         Alc-Dyn-Serv-Acct-Interim-Ivl-2:4 += "0",
38.         Alc-Dyn-Serv-Acct-Stats-Type-1:4 += "3",
39.         Alc-Dyn-Serv-Acct-Stats-Type-2:4 += "2",
```

The first section (lines 1 — 3) shows a minimal parameter set for the (PPP) control channel. As the focus of this example is on the dynamic data services, all default parameters will be used for the control-session which are defined under the msap.

The second section (lines 4 — 8, attributes with tag ":1") shows a possible parameter set for an Epipe service. Only the absolutely minimum set of VSAs is used (see Table 31: Dynamic Service Attribute List for Setup, Modify and Teardown). Furthermore, all service parameters are listed without keywords in a pre-defined order. No service ID number is specified in "Alc-Dyn-Serv-Script-Params", hence the Python script should dynamically select the next free ID.

The third section (lines 9 — 16, attributes with tag ":2") shows a possible parameter set for a VPRN service. A few more VSAs are defined, thus some of the default parameters in the dynamic service policy are overwritten for this service. The first entry in the "Alc-Dyn-Serv-Script-Params" attribute specifies the Service-ID number for this service, so the Python script should not select a service ID automatically. Furthermore, static-routing information towards the CPE is added as normal attributes at the end of the list.

The fourth section (line 17 — 26, attributes with tag ":3") shows a possible parameter set for a VPLS service. Notice the difference with the first two services in the "Alc-Dyn-Serv-Script-Params" part: now all parameters are given their specific keyword. As such, the sequence of those parameters is not important. The effect on the Python script is shown further down.

The fifth section (lines 27 — 39, attributes with tag ":4") finally shows a possible parameter set for an IES service. All of the required parameters for this service do not fit into a single "Alc-Dyn-Serv-Script-Params" attribute anymore (limited to 247 bytes). As is shown, multiple VSAs can be "concatenated" by simply splitting the attributes. It is important that the order in which the different "Alc-Dyn-Serv-Script-Params"

attributes with the same tag is received can be guaranteed. Furthermore the second appearance of this VSA shows a different way of provisioning static-routing information towards the CPE.

To better understand the details it is necessary to take a closer look into the active Python script. The first important part is the section with the dynamic actions.

```
---snip---

d = {
"vprn": (setup_vprn, None, None, teardown_vprn),
"ies": (setup_ies, None, None, teardown_ies),
"vpls": (setup_vpls, None, None, teardown_vpls),
"epipe": (setup_epipe, None, None, teardown_epipe),
"ethcfm" : (setup_ethcfm_domain, None, None, teardown_ethcfm_domain),
"business_vprn" : (setup_business_vprn, None, None, teardown_business_vprn),
"business_ies" : (setup_business_ies, None, None, teardown_business_ies),
"business_vpls" : (setup_business_vpls, None, None, teardown_business_vpls),
"business_epipe" : (setup_business_epipe, modify_business_epipe,
                    revert_business_epipe, teardown_business_epipe)}
dyn.action(d)
```

The function-key string specified at the start of the "Alc-Dyn-Serv-Script-Params" (for example Alc-Dyn-Serv-Script-Params:1 = "business_epipe={…}") has a 1:1 mapping with the keys of the dictionary "d" in the highlighted section of the above sample (for example d = { …, "business_epipe" : (…)}. For services, different values for setup, modify, revert and teardown are given which point to other sections in the Python script (see below). Setup and teardown functions are mandatory, whereas modify and revert functions are optional.

In the unbolded text of the previous example, there are other actions defined that are not contained in the RADIUS attributes (for example d = { "vprn": (…) , …). Those actions are referenced by the four main functions.

In the next part, there is more detail presented in each service example and maps it to the corresponding Python function.

It is advisable to read through all examples, as only the deltas between each service are explicitly explained.

Example 1 – Epipe service

```
# copy of the RADIUS attributes from above
---snip---
        Alc-Dyn-Serv-SAP-Id:1   = "#:#.1",
        Alc-Dyn-Serv-Script-Params:1 = "business_epipe={'t':
            ('EPipe-CustomerName','CustomerName-Circuit-1','3','3','64496'
             ,'192.0.2.5','192.0.2.1','3333')}",
        Alc-Dyn-Serv-Policy:1 =   "dynamic-services-2",

""" % d)
---snip---
```

Based on the dictionary specified in the dyn.action(d) call, the function definition "setup_business_epipe" in the Python script corresponds with the function that will be called if the function-key "business-epipe" is specified in the "Alc-Dyn-Serv-Script-Params" attribute as dictionary name and if a setup action is required. The dictionary containing the parameters in the RADIUS VSA "Alc-Dyn-Serv-Script-Params" has a single key-value pair, with the parameters stored in a tuple. The individual parameters cannot be identified with a keyword hence the order in which they are specified in the RADIUS VSA should match the order in which they are extracted in the Python script. The first two lines in this part of the script extract the parameters out of the array "t" and link them to unique keywords, which are used for the rest of the script.

The parameter "inst" is important in this logic, as it defines whether access circuits belong to the same service-instance or different instances (the RADIUS VSAs for two SAPs belonging to the same service therefore need to have the same "inst" value). If you look at the CLI of the "setup_business_epipe" function, you can see that it creates the SAP and all related attributes, but not the service itself. It is the "ref_d = dyn.reference("epipe", d['inst'], d)" that references a part in the script to create the actual service-instance. The referenced function is found by using the first parameter in the dyn.reference call ("epipe") as a function-key lookup in the dictionary specified in the dyn.action(d) and finding the corresponding setup function: d = { …, "epipe" : (setup_epipe, …), …}. The second parameter ("d['inst']") is used as unique identification of the service instance. The last parameter ("d") is a dictionary with parameters that can be used by the references function. When the first customer endpoint with a new "inst" name comes up, the service itself gets created.

By looking at "def setup_epipe(d):" the first line "d['svc_id'] = dyn.select_free_id("service-id")" of the script automatically picks a free service-id out of the range defined in the dynamic service policy, as no service ID was provided in the RADIUS parameters. The rest of this function creates the service instance. Service attributes that were provided by RADIUS and are placed in a service specific dictionary are available to this function via the third parameter in the dyn.reference call. The newly generated service ID is returned to the calling script by the "return {'svc_id':d['svc_id']}" command at the end of the function. The service specific dictionary (as explained in the Python Script Building Block) is updated with the appropriate information.

Back to "def setup_business_epipe(d):", the service ID together with the SAP ID and the parameters from the Alc-Dyn-Serv-Script-Params VSA are used to create the appropriate CLI code for the SAP and the SDP within the service.

Similar to the setup, there is also a teardown part for both service and SAP. The teardown function is called either through the termination of the control-channel, through a COA with Alc-Dyn-Script-Action = teardown or through a disconnect message. The CLI for the teardown script must be written in the correct sequence as applied by the SR OS CLI logic so that SAP(s) and service(s) are removed in the correct order.

Example 2 – VPRN service

```
RADIUS-part from above
---snip---
      Alc-Dyn-Serv-SAP-Id:2 += "#:#.2",
      Alc-Dyn-Serv-Script-Params:2 += "business_vprn={'t':
          ('9999','VPRN-CustomerName','64497','100000',
           'CustomerName-Circuit-1','172.16.10.1/30','3','1','3','2',
           '172.16.100.0/24','172.16.10.2','100')}",

In this example of a VPRN service two additional RADIUS VSAs are used to overwrite the accounting interim update intervals for the two RADIUS Accounting servers that are specified in the dynamic services policy. The Stats-Type configuration (time or volume-time) is obtained from the dynamic services policy as no RADIUS VSA is provided for that.

The beginning of the "setup_business_vprn" definition is identical to the earlier Epipe service example. This time a service identifier is provided as part of the parameter list. The referenced function to create the VPRN service (def setup_vprn) does not need the line to auto-generate the service ID.

At the end of the setup-procedure there is a basic example to add static-route information in case they are needed for PE-CE communication. Later on, in the IES service example, a more flexible alternative is shown.

Example 3 – VPLS service

---snip---
```

In the VPLS example the "Alc-Dyn-Serv-Acct-Stats-Type" is set to "off" for both RADIUS accounting destinations, meaning RADIUS accounting is switched off, even if it is enabled in the dynamic data services policy. In the script you can see that this service uses XML-accounting on the SAP instead ("collect-stats" and "accounting-policy 10").

The dictionary containing the parameters in the RADIUS VSA "Alc-Dyn-Serv-Script-Params" has a key-value pair for each parameter. In the Python script the individual parameters can be identified immediately with the dictionary key. The order in which they are specified in the RADIUS VSA does not have to be strictly defined. The drawback of this approach is that the length of the parameter VSA increases. A single parameter VSA is limited to a length of 246 bytes and the total length of all parameter VSAs for a single service is limited to 1000 bytes.

Example 4 – IES service

```
RADIUS-part from above

```

The IES example has the most attributes. The maximum length of a tagged RADIUS VSA is 246 bytes. If the amount of data is too big to fit into one attribute, simply add a second or third one in the syntax shown above in the RADIUS part. There is no need to separate the attributes exactly at 246 bytes; it can be cut at any position in the list (preferably between two attributes for better readability). Note also that all the parameter VSAs that belong to the same service should have the same tag (":4" in this example).

In case of multiple parameter VSAs, the order in which they are specified is important and must be guaranteed as the concatenation of all the attributes must result in a Python dictionary in the form: "dictionary-name = {…}". The Python script is not aware that multiple attributes were used.

Another difference to the previous examples is that there is not only a reference to the function for the service creation, but also a similar reference to a function for Ethernet Connectivity Fault Management (CFM). Considering that you may want to put all of the Eth-CFM endpoints under the same domain within unique associations, the Eth-CFM domain needs to be created first and torn down as last.

Finally, a different way to provide static-route information is shown at the end of the "setup_business_ies" definition (starting with "for route in d['routes']:"). Also note the difference in how this information is implemented at the end of the "Alc-Dyn-Serv-Script-Params" list. The static routes themselves are defined as a dictionary and thus as many routes as required can be added with this method. Compare this to the VPRN example where a more basic mechanism was used.

As outlined before, dynamic data services can be triggered during the Access-Accept for the control channel but also through a CoA to the control channel Accounting Session ID.

Example 5 – modify an Epipe service using CoA

So far the focus was on service establishment and teardown. It is also possible to change a running dynamic data service using the "modify" function. This will be explained with the previously configured Epipe service.

```
RADIUS attributes in the COA message
    Acct-Session-Id = D6E559000000BD5166BF34 #
    Alc-Dyn-Serv-SAP-Id:1  = "#:#.1",
    Alc-Dyn-Serv-Script-Params:1 = "business_epipe={'ing_qos':'4','egr_qos':'4'}",
    Alc-Dyn-Serv-Script-Action:1 = modify,
    Alc-Dyn-Serv-Policy:1 =  "dynamic-services-2",

Python-part
d = {
---snip---
"business_epipe" : (setup_business_epipe, modify_business_epipe, revert_business_epipe,
 teardown_business_epipe)}
dyn.action(d)
---snip---
def modify_business_epipe(d, sd):
    sd['ing_qos'] = d['ing_qos']
    sd['egr_qos'] = d['egr_qos']
    dyn.add_cli("""
configure
    service
       epipe %(svc_id)s
           sap %(sap_id)s
             ingress
                qos %(ing_qos)s
             exit
             egress
                qos %(egr_qos)s
             exit
           exit
        exit
    exit
exit
"""% sd)
    return sd

def revert_business_epipe(d, sd):
    dyn.add_cli("""
configure
    service
      epipe %(svc_id)s
        sap %(sap_id)s
          ingress
             qos %(ing_qos)s
          exit
          egress
             qos %(egr_qos)s
          exit
        exit
      exit
    exit
exit
""" % sd)
---snip---
```

Through the function-key in the parameter list (Alc-Dyn-Serv-Script-Params:1 = "business_epipe= …) and the action attribute of "modify" (Alc-Dyn-Serv-Script-Action:1 = modify), the script will identify the relevant routine to be invoked for the modification (modify_business_epipe). If a modify function is defined, there must also be a definition for a revert function. A revert function cannot be initiated from RADIUS, but it is automatically executed to restore the initial configuration in case the modify script execution fails.

A modify action for an existing service is triggered with a CoA message. For this CoA, either the Accounting Session ID (ASID) of the control channel or the Accounting Session ID of the dynamic data channel can be used. In case the ASID of the control channel is used, the "Alc-Dyn-Serv-SAP-Id" can contain wildcards, as the appropriate port and VLAN information will be taken from the control channel. If the ASID of the dynamic data channel itself is used, the "Alc-Dyn-Serv-SAP-Id" needs to be fully specified, without wildcards. Otherwise the script execution will fail.

For a modify action, the "Alc-Dyn-Serv-Script-Params" only contains the parameters to be changed and does not need any further service identifying information. The service is identified based on the ASID and the "Alc-Dyn-Serv-SAP-Id". Parameters which have been previously received by the setup or an earlier modify function are available in the stored dictionary (sd). Those are combined with the dictionary in the RADIUS message (d). Service modifications which relate to subsequent modifications, or for the service teardown, need to be updated in the stored dictionary so that they can be used in those later actions. This is achieved by the "return sd" command.

As with "manual" provisioned services, the new QoS settings from our example take effect immediately.

A dynamic data service can also be disconnected using a RADIUS Disconnect Message containing the Accounting Session ID of the dynamic data service, or indirectly via a RADIUS Disconnect Message containing the Accounting Session ID of the control channel which would result in a teardown of all associated dynamic data services.

Debugging

It is obvious that the Python scripts need extensive testing in the lab before they are deployed in the field. This testing may require a number of iterations: write the script, testing, verification, improvement and testing again. Every time there is a change in the Python script the node needs to reload the script. This is achieved by a **shutdown** and **no shutdown** of the active script using the command:

configure aaa radius-script-policy <script-policy-name> <primary/secondary> shutdown

configure aaa radius-script-policy <script-policy-name> <primary/secondary> no shutdown

Testing the script may result in some problems if certain aspects may not work as expected (see also debug functions later in this section). It can be that a dynamically created service cannot be removed properly because the teardown script contains errors and the whole service, or fragments of that service, may still exist on the node.

Dynamic data services cannot be edited in normal CLI mode as it may potentially make a later removal of that service through the script impossible. For troubleshooting there is a procedure to manipulate those services during the testing phase, thus avoiding the need to reboot the box to clear the state. The **enable-dynamic-services-config** command allows for the editing dynamic services just like normal services. As this is an action that should only be executed by authorized personnel, the activation of this command is protected by the use of a password, defined under **configure system security password dynsvc-password**.

The **show users** command has been extended to visualize the respective mode ('D' indicates a user is in dynamic service edit mode). A user in dynamic services edit mode cannot modify regular services.

no enable-dynamic-services-config returns the user to normal mode.

To support the creation and the troubleshooting during the test phase the SR OS debug functions have been extended extensively to allow for a detailed review of what is happening in the script and on the CLI.

```
debug dynamic-services
debug dynamic-services scripts
debug dynamic-services scripts event
debug dynamic-services scripts event cli
debug dynamic-services scripts event errors
debug dynamic-services scripts event executed-cmd
debug dynamic-services scripts event state-change
debug dynamic-services scripts event warnings
debug dynamic-services scripts instance
debug dynamic-services scripts instance event
debug dynamic-services scripts instance event cli
debug dynamic-services scripts instance event errors
debug dynamic-services scripts instance event executed-cmd
debug dynamic-services scripts instance event state-change
debug dynamic-services scripts instance event warnings
debug dynamic-services scripts script
debug dynamic-services scripts script event
debug dynamic-services scripts script event cli
debug dynamic-services scripts script event errors
debug dynamic-services scripts script event executed-cmd
debug dynamic-services scripts script event state-change
debug dynamic-services scripts script event warnings
```

It is advised to enable all debug options when starting and then remove more and more debugs options as the script becomes more complete and stable. The debug output gives clear indications about errors in the script or its execution in case something goes wrong.

An additional aid is the use of "print" commands in the Python script itself for certain attributes during the execution of the script. The print output will appear in the debug log. "Print" commands in the Python script should only be used during the testing phase and not in the normal operations mode.

The following command allows the execution of a dynamic services Python script without the need for RADIUS interaction:

tools perform service dynamic-services evaluate-script sap <sap-id> control-session <acct-session-id> action <script-action> [dynsvc-policy <name>]

show service dynamic-services script statistics provides general statistics about script execution.

show service dynamic-services script snippets displays the individual service configuration parts and allows to check if all "snippets" are actually referenced (the counter will increment/decrement with every function call).

In the case of a failed script action a SAP may not be deleted properly and it remains in the configuration as an "orphaned" object.

An orphaned object no longer has any references, which can be seen using **show service dynamic-services root-objects** command where the snippet name and snippet instance is set to "N/A".

Complete setup flow example

To finalize the section about the interaction between RADIUS and the Python script, the complete setup flow for the Epipe example is shown using extracts from the debug output (any missing sequence numbers in the flow below are simple acknowledge messages from RADIUS and are left out to focus on the important information). The debug settings to be used for this output are the following.

```
*A:BNG-1# show debug
debug
```

```
        router "Base"
            radius
                packet-type authentication accounting coa
                detail-level medium
            exit
        exit
        router "management"
            radius
                packet-type authentication accounting coa
                detail-level medium
            exit
        exit
        dynamic-services
            scripts
                event
                    cli
                exit
                instance "dynamic-services-1"
                    event
                        cli
                    exit
                exit
            exit
        exit
exit
```

The first sequence in the flow is the Access-Request to the RADIUS server for the control channel. The information provided is that configured as part of the regular ESM configuration.

```

```

The "Stats-Type" in the dynamic service policy (or obtained via RADIUS in a VSA) defines what information is sent back to the accounting server (per server). In this example one was set to Stats-Type "time" and the other to "volume-time". The first accounting message displays the content of "volume-time". A full set of statistics counters per service class are provided for the dynamic service. This is equivalent to the extended accounting statistics also provided in the ESM context. The second accounting message shows the content of "time". No volume statistics counters are provided in this case.

Once the dynamic data services are instantiated they can be displayed with the regular show commands.

```
A:BNG-1# show service service-using

The description at the end of this show command explains how the dynamic services SAPs are displayed. Note that there are managed SAPs created for the control channel as well as dynamic data services SAPs.

If only the SAPs for dynamic data services should be displayed, the command **show service sap-using dyn-script** can be used.

```

Dynamic data services CLI is not saved as part of the configuration file. The active dynamic data services configuration is hidden in the output of the "admin display-config" CLI command. To display the dynamic services configuration, use:

- "info" in a configuration CLI context for SR OS Releases prior to 14.0.R1

- "info include-dynamic" in a configuration context for SR OS Release 14.0.R1 or later

Conclusion

RADIUS-based dynamic data services provide an innovative way for business service provisioning. They are created both automatically and instantaneously.

Raw Formatting of DHCPv4/v6 Options in ESM

This chapter provides information about raw formatting of DHCPv4/v6 options in ESM.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This example is applicable to DHCPv4/v6 subscriber-hosts using the routed central office ESM model.

A local DHCPv4/v6 server is used for address/prefix assignment, which implies a DHCP *relay* scenario (as opposed to a DHCP *proxy* scenario where the IP address/prefix is assigned via a RADIUS server or an LUDB).

The information and configuration in this chapter is based on a single homed environment using SR OS Release 12.0.R4.

Overview

An SR OS node supports IP address assignment to its DHCP clients via two IP address assignment authorities:

- DHCP server — In this model the SR OS node behaves as a DHCP relay between the DHCP client and the DHCP server.
- RADIUS/LUDB — In this model the IP address/prefix is assigned via a RADIUS server or an LUDB and the SR OS node internal or external behaves as a proxy between the DHCP client and the non-DHCP aware RADIUS/LUDB.

> **Note:** The term proxy can also refer to the functionality where the DHCP server is used for address assignment. In this case, the SR OS node would hide the DHCP server from the client and pretend to be the DHCP server to the client, passing the DHCP parameters between the client and the server (lease times, etc).

Within these two fundamental address assignment models, there are several mechanisms available on the SR OS node by which DHCP parameters (DHCP options and various parameters within the options) can be passed to the DHCP client during the address assignment phase.

For example, in the RADIUS/LUDB address assignment model, the DHCP parameters can be supplied via RADIUS, LUDB and Python, while in the DHCP server model, the DHCP parameters can also be also supplied via the DHCP server itself (in addition to RADIUS, LUDB and Python).

Some of the more commonly used DHCP parameters have their own RADIUS and CLI constructs. For example, a default router has its own RADIUS attributes:

```
Alc-Default-Router (26-6527-18)
```

or even its own CLI keyword:

```
config>router>dhcp>server>pool>subnet>options# default-router
config>service>router>dhcp>server>pool>subnet>options# default-router
config>subscr-mgmt>ludb>ipoe>host>options# default-router
```

Other less common DHCP options can be defined and inserted by the DHCP relay agent using the pre-formatted (IP address, domain, or string) or the non-formatted (hex) custom-option CLI command:

```
config>router>dhcp>server>pool>options# custom-option
config>router>dhcp>server>pool>subnet>options# custom-option
config>router>dhcp6>server>pool>options# custom-option
config>router>dhcp6>server>pool>prefix>options# custom-option
config>service>vprn>dhcp>server>pool>options# custom-option
config>service>vprn>dhcp>server>pool>subnet>options# custom-option
config>service>vprn>dhcp6>server>pool>options# custom-option
config>service>vprn>dhcp6>server>pool>prefix>options# custom-option
config>subscriber-mgmt>ludb>ipoe>host>options# custom-option
```

The most flexible way of configuring DHCP parameters is by means of 'raw' (or hexadecimal) formatting. Any DHCP option can be hexadecimally (raw) formatted via the following RADIUS attributes:

```
Alc-ToClient-Dhcp-Options
Alc-ToClient-Dhcp6-Options
```

and/or via the custom-options CLI commands as outlined above. These options are then passed on to the DHCP client via the DHCP relay agent in the SR OS node.

In addition to raw formatting via RADIUS or CLI, Python scripting can be used to intercept DHCP messages and modify their content.

The focus of this example is to demonstrate how the **raw** DHCP options are formatted via RADIUS. The messages can be optionally pre/post-processed by a Python script in the SR OS node before they are passed on to the DHCP client.

In this example, the following DHCP parameters are passed to the DHCP client using the **Alc-ToClient-Dhcp-Options** and the **Alc-ToClient-Dhcp6-Options** RADIUS attributes:

Table 34: RADIUS inserted raw options

RADIUS	
DHCPv4 **ToClient-Dhcp-Options**	**DHCPv6** **ToClient-Dhcp6-Options**
(default-)router [3] = 10.10.10.254	DNS server [23] = 2001:db8:1:1:1:1:1:1 2001:db8:1:1:1:1:1:2
DNS server [6] = 172.22.250.250	Domain search list [24] =

RADIUS	
DHCPv4 **ToClient-Dhcp-Options**	**DHCPv6** **ToClient-Dhcp6-Options**
172.22.250/251	'Nokia.com' 'test.com'
Domain name [15] = 'alcatel.com'	Vendor specific-option [17] = 'custom-test-option'
Custom option [230] = 'custom test option'	
Renew time [58] = 5 min (300sec)	
Rebind time [59] = 6min 40sec (400sec)	

The DHCP parameters in the following DHCP messages are altered by a Python script:

Table 35: Python Modified DHCP Fields

Python	
DHCPv4 (DHCP Request)	**DHCPv6 (LDRA DHCP Request)**
Lease-time [51] = 8min 20sec (500sec)	IA-NA Preferred-Lifetime = 66min 40sec (4000sec)
	IA-NA Valid-Lifetime = 66min 40sec (4000sec)
	IA-NA Renew-Time (T1) = 33min 20sec (2000sec)
	IA-NA Rebind-Time (T2) = 50min (3000sec)
	IA-PD Preferred-Lifetime = 66min 40sec (4000sec)
	IA-PD Valid-Lifetime = 66min 40sec (4000sec)
	IA-PD Renew-Time (T1) = 33min 20sec (2000sec)
	IA-PD Rebind-Time (T2) = 50min (3000sec)

The following DHCP parameters are configured via CLI in the SR OS node DHCPv4/v6 server:

Table 36: CLI Inserted DHCP Options

CLI DHCP Server Pool/prefix Options	
DHCPv4	**DHCPv6**
DNS server [6] = 172.22.250.253	DNS server [23] = 2001:db8:1:1:1:1:1:3
Custom option [231] = 'dhcp injected custom option 231'	Custom option [232]= 'v6 custom option 232'

CLI DHCP Server Pool/prefix Options	
DHCPv4	**DHCPv6**
	IA-NA Preferred-Lifetime = 20min (1200sec)
	IA-NA Valid-Lifetime = 20min (1200sec)
	IA-NA Renew-Time (T1) = 10 min (600 sec)
	IA-NA Rebind-Time (T2) = 15min (900 sec)
	IA-PD Preferred-Lifetime = 20min (1200sec)
	IA-PD Valid-Lifetime = 20min (1200sec)
	IA-PD Renew-Time (T1) = 10min (600 sec)

The RADIUS injected raw options are prepended by the DHCP relay agent in the SR OS node to any existing DHCP options already present in the DHCP message before being sent to the client. The existing options could be generated by the DHCP server (internal or external) or by the LUDB. No check is performed on the outgoing DHCP message towards the client in order to verify whether any of the RADIUS inserted options are already present in the DHCP message. This could potentially lead to duplication of DHCP options in the outgoing DHCP messages in case that the same option is inserted via the DHCP server and via RADIUS. To prove the point, this example supplies the same DHCP option (with different values) via multiple sources (RADIUS and CLI).

Configuration of DHCP lease related times requires closer examination. In DHCPv4, the DHCP lease-time option (51) is always supplied by the DHCPv4 server (this cannot be disabled). In case the lease-time is also supplied via RADIUS in an Alc-ToClient-Dhcp-Options VSA, the client would receive two lease-times for the same IP address. This can lead to unpredictable behavior not only on the client side but also on the SR OS node DHCPv4 server side since the DHCPv4 server (and the SR OS node DHCPv4 relay agent) creates the lease state only for the lease-time supplied by the DHCP server, and ignores the one supplied via RADIUS or LUDB. This scenario is shown in Figure 150: DHCPv4 Lease-Time Inserted by RADIUS and DHCPv4 Server:

1. DHCP Discover arrives.

2. Radius authentication is triggered.

3. RADIUS returns lease-time value 'B' (Alc-ToClient-DHCP-Option) in Authentication-Accept message.

4. DHCP Discover is forwarded by the DHCP relay agent to the DHCP server.

5. DHCP server offers an IP lease with the configured lease-time of 'A'.

6. The DHCP offer is sent to the DHCP relay agent.

7. The DHCP relay agent appends the lease-time 'B' supplied by RADIUS to the DHCP message.

8. The DHCP relay forwards the message to the DHCP client with both lease-times 'A' and 'B'.

Note that the example in Figure 150: DHCPv4 Lease-Time Inserted by RADIUS and DHCPv4 Server does not represent a typical deployment case. This example is solely chosen to clarify the behavior in SR OS nodes.

Figure 150: DHCPv4 Lease-Time Inserted by RADIUS and DHCPv4 Server
To ensure DHCPv4 lease time unambiguity, the lease-time should be supplied by a single source, in this case by the DHCPv4 server.

Since this eliminates RADIUS as a source of the DHCPv4 lease-time, an alternate method operating on the *raw level* is used to influence the automatic selection of the lease-time in the DHCPv4 server. This alternate method relies on the fact that the DHCPv4 server accepts hints received from the client as to what the desired lease-time should be. In other words, if the client sends the option 51 (lease-time) with a specific value, the SR OS node DHCPv4 server will honor this hint, as long as this value is within the configured range of values specified in the DHCP server. To demonstrate this behavior, a Python script is invoked upon receipt of a DHCPv4 Request message during the IP address assignment process (DORA – Discover-Offer-Request-Ack). The Python script inserts a new option 51 with the desired value for the lease-time. The DHCPv4 server honors this hint from the client and it returns the requested lease-time back to the client. This scenario is shown in Figure 151: Python Injected Hint for Lease-Time:.

1. DHCP Discover arrives.

2. DHCP Discover is intercepted by the Python processing engine and the lease-time 'B' is inserted in DHCP Discover message. This is then used as a hint to the DHCP server.

3. DHCP Discover message is sent to the DHCP relay agent.

4. RADIUS authentication is triggered.

5. User is authenticated. This time lease-time is not returned via RADIUS.

6. DHCP Discover is forwarded to the DHCP server.

7. The DHCP server honors the hint from the DHCP Discover and offers lease-time 'B', even though the server is configured with lease-time 'A'.

8. The DHCP server replies with a DHCP Offer message.

9. DHCP Offer is forwarded by the DHCP relay agent to the client.

Figure 151: Python Injected Hint for Lease-Time
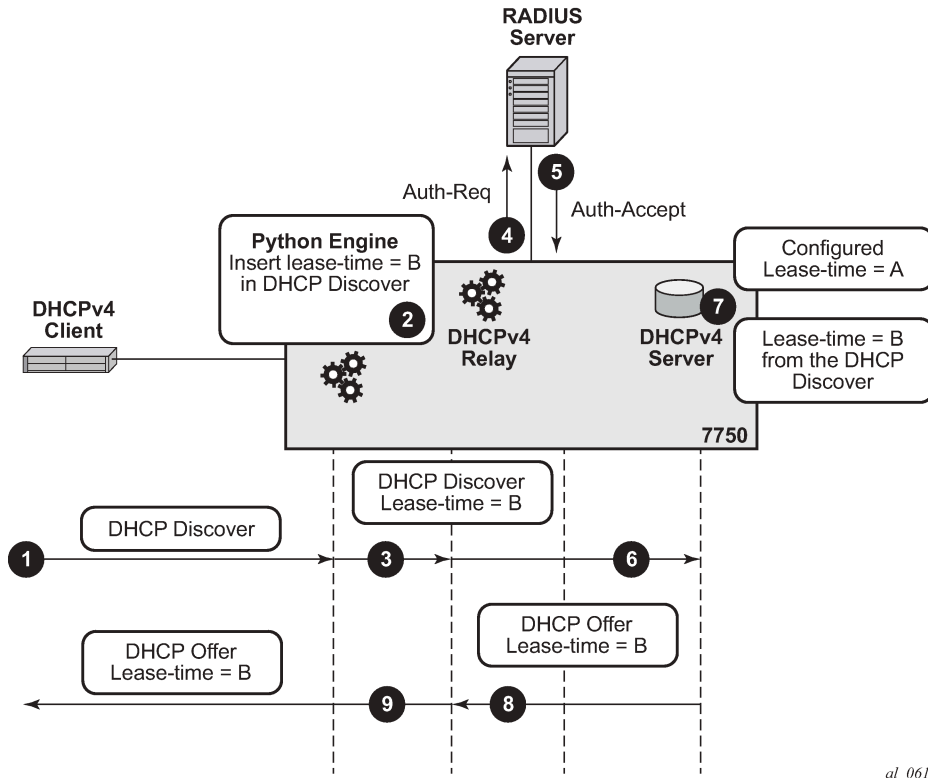

al_0614

By default the local DHCP server does **not** inject Renew (T1) and Rebind (T2) times so these two timers can still be supplied via RADIUS without duplication by the local DHCP server.

When it comes to lease-time related parameters, the behavior of the DHCPv6 server is different from the behavior of the DHCPv4 server.

DHCPv6 lease related timers are **not** DHCP options. Instead, they are parameters within the IPv6 addressing option. An IPv6 address or prefix is assigned to the client via the IA-NA or IA-PD option, which contains additional parameters (which are not considered options) such as the IP address/prefix and the lease related timers. Figure 152: Format of the IA-NA Option shows the IA-NA option that carries the T1/T2 parameters.

Figure 152: Format of the IA-NA Option
al_0615

The format of the IA address option is shown in Figure 153: Format of the IA Address Option. This option carries preferred and valid lifetimes.

Figure 153: Format of the IA Address Option
al_0616

In this example, the IPv6 address/prefix is provided by the local DHCPv6 server and as such, RADIUS cannot modify the parameters within the DHCPv6 options supplied by the DHCP server. Therefore, the desired IPv6 lease timers (preferred-life time, valid-lifetime, renew-time[T1], rebind-time[T2]) are part of the IPv6 pool configuration in the DHCPv6 server.

Alternatively Python can be used to intercept the outgoing DHCPv6 message and then change the timers within the IA-NA and IA-PD options. Although this would configure the lease timers for the client, the action of modifying the outgoing DHCP6 message occurs after the DHCPv6 server processing. This would result in different lease times in the client and the DHCPv6 server, without any intermediary between them (such as a DHCPv6 Proxy) to deal with the differences.

For consistency purposes with the DHCPv4 example, a Python script processes the incoming DHCPv6 message (DHCPv6 Request) altering the lease timers (preferred/valid/renew/rebind) as a hint to the DHCPv6 server to request those values. However, the SR OS node DHCPv6 server does not honor those hints and uses its own values (default or configured) instead.

Configuration

The topology is shown in .

Figure 154: Topology
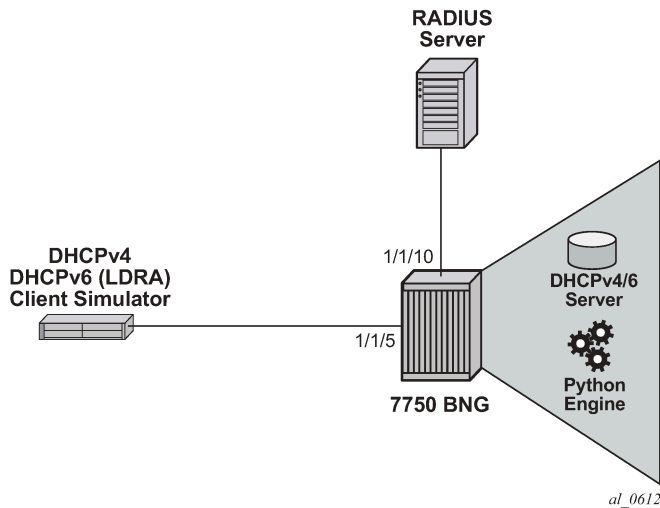

Access Ethernet Port with QinQ Encapsulation

```
configure port 1/1/5
    ethernet
            mode access
          encap-type qinq
    exit
     no shutdown
```

Capture SAP

A capture SAP is used to dynamically detect VLAN ID(s) in incoming DHCP (trigger) packets. This example uses RADIUS authentication along with Python scripting for DHCP message processing and therefore the authentication and Python policies must be configured under the capture SAP.

```
configure service vpls 10
    sap 1/1/5:1.* capture-sap create
        description "circuit-id authentication"
        trigger-packet dhcp dhcp6
        dhcp-python-policy "acg"
        dhcp6-python-policy "acg"
        authentication-policy "rad"
```

MSAP-Policy Configuration

The MSAP-policy defines the anti-spoofing mode which is set to next-hop MAC (nh-mac) in this example. It also defines the default subscriber management parameters in case that they are not supplied via LUDB or RADIUS.

MSAP-policy configuration is mandatory when a capture-SAP is deployed. In this example, the MSAP-policy name is supplied via RADIUS:

```
Alc-MSAP-Policy = "msaps"

configure subscriber-mgmt msap-policy "msaps"
    sub-sla-mgmt
        sub-ident-policy "sub_ident_pol"
        multi-sub-sap limit 500
    exit
    ies-vprn-only-sap-parameters
        anti-spoof nh-mac
    exit
```

Subscriber-Interface and Group-Interface Configuration

In this example the subscriber-interface is a 'numbered interface' in which the interface IPv4 address and the interface IPv6 prefixes are explicitly configured. The IPv4 address is used as the default-gateway by the IPoE attached clients. The IPv4 subnet to which this address belongs and the configured IPv6 prefixes are used for routing aggregation and are treated as local subnets/prefixes in the SR OS node routing table.

The managed (dynamic) SAPs are created under the group-interface which contains the reference to the authentication-policy name, the Python script, the v4/6 policy names and the DHCPv4/v6 relay related configuration settings (for example, a reference to DHCP servers). Both the authentication-policy name and the Python policy name referenced under the group-interface must match those configured under the capture-SAP.

```
configure service vprn 1
    subscriber-interface "int1-1" create
    address 10.10.10.254/24  # Numbered IPv4 subscriber interface.
    ipv6
        delegated-prefix-len 54
        subscriber-prefixes
            prefix 2001:db8:3::/48 pd       # Numbered IPv6 subscriber interface.
            prefix 2001:db8:4::/48 wan-host # Numbered IPv6 subscriber interface.
        exit
    exit
    group-interface "g1-1" create
        ipv6
            router-advertisements
                no shutdown
            exit
            dhcp6
                python-policy "acg"  # Python script for DHCPv6 messages.
                relay
                    server 2001:db8::1001 # IPv6 address of the DHCPv6 server.
                    client-applications dhcp
                    no shutdown
                exit
            exit
        exit
```

© 2024 Nokia.

Use subject to Terms available at: www.nokia.com/terms.

```
        dhcp
            python-policy "acg"              # Python script for DHCPv4 messages.
            option
                action keep              # Keep option82 in the received DHCP packet.
                vendor-specific-option
                    pool-name # Pool-name obtained via RADIUS (or LUDB) will be passed
                                # via DHCP relay to the local DHCP server.  This name
                                # will be used for pool selection in DHCPv4 server.
                exit
            exit
            server 192.168.100.1 # IPv4 address of the DHCPv4 server.
            lease-populate 100   # Maximum number of DHCPv4 lease under each
                                # SAP of the group-interface.
            client-applications dhcp
            no shutdown
        exit
        authentication-policy "rad" # RADIUS authentication policy.
    exit
exit
```

Loopback (DHCP) Interface Configuration

The loopback interface is used for the DHCPv4/v6 server binding. It is configured with the IPv4/IPv6 addresses which are referenced from the DHCP relay configuration under the group-interface.

```
configure service vprn 1
    interface "loopback1-1" create
        address 192.168.100.1/32         # IPv4 address of the DHCPv4 server.
        ipv6
            address 2001:db8::1001/128  # IPv6 address of the DHCPv6 server.
            local-dhcp-server "v6"       # Binding of the DHCPv6 server
                                         # to this interface.
        exit
        local-dhcp-server "v4"           # Binding of the DHCPv4 server
                                         # to this interface.

        loopback
    exit
```

DHCPv4/6 Server Configuration

The local DHCP server configuration contains the pool selection method, pool information and DHCP options which are passed to the DHCP client at IP address/prefix assignment time.

```
configure service vprn 1
    dhcp
        local-dhcp-server "v4"
            use-pool-from-client  # Pool-name received in the DHCP messages
                                  # sent by the DHCP relay. The pool-name
                                  # is used in pool selection.
            pool "non-shared-left"
                options
                    dns-server 172.22.250.253  # DHCPv4 option passed on to the client.
                    custom-option 231 string "dhcp server injected custom option 231"
                exit                            # DHCPv4 option passed on to the client.
                subnet 10.10.10.0/24 create
                    address-range 10.10.10.5 10.10.10.100 # IPv4 address range available
                                                           # for address allocation.
```

```
                    exit
                exit
            exit
        exit
        dhcp6
            local-dhcp-server "v6"
                use-pool-from-client
                pool "pd-left" create
                    options
                        dns-server 2001:db8:1:1:1:1:1:3
                        custom-option 232 string "v6 custom option 232"
                    exit
                    prefix 2001:db8:4::/48 pd    # IPv6 prefix range available for delegated
                                                 # prefix allocation by this DHCPv6 server.
                        preferred-lifetime min 20 # Preferred lifetime of the allocated
                                                 # delegated prefix.
                        rebind-timer min 15      # Rebind (T2) time of the allocated
                                                 # delegated prefix.
                        renew-timer min 10       # Renew (T1) time of the allocated
                                                 # delegated prefix.
                        valid-lifetime min 20    # Valid lifetime of the allocated

                exit
                no shutdown
            exit
        exit
```

RADIUS Authentication-Policy Configuration

The RADIUS authentication-policy is referenced under the capture-sap and under the group-interface
configuration.

```
authentication-policy "rad" create
    password "ALU" hash2
      radius-authentication-server
      router "Base"
          server 1 address 192.168.114.1 secret "ALU" hash2
    exit
    user-name-format circuit-id
    include-radius-attribute
        circuit-id
        remote-id
        nas-port-id
        nas-identifier
```

```
    exit
exit
```

Subscriber-Identification Policy

The subscriber-identification policy in this example defines a mapping method between the subscriber strings and the predefined subscriber profiles (*sub* and *sla*) locally configured on the SR OS node. In our example the subscriber strings (*sub* and *sla*) are provided via RADIUS and are directly mapped to the preconfigured sub-profiles and sla-profiles with the matching names.

The subscriber-identification policy can be configured with default subscriber profiles in case the strings are not explicitly obtained via other means (RADIUS, LUSB, Python or statically provisioned). Subscriber-identification policy configuration is mandatory.

```
sub-ident-policy "sub_ident_pol" create
    sub-profile-map
        use-direct-map-as-default
    exit
    sla-profile-map
        use-direct-map-as-default
    exit
```

Sla-Profile and Sub-Profile Configuration

The following is the configuration of the sub-profile and the sla-profile which are used to setup the subscriber-host. The sla and sub profiles are mandatory when creating subscriber-hosts in SR OS node.

```
sla-profile "sla-profile-1" create
    ingress
        qos 2
        exit
    exit
     egress
        qos 2
        exit
    exit
exit

sub-profile "sub-profile-1" create
exit
```

Python-Policy Configuration

The python-policy defined below is applied under the capture-sap and under the group-interface. It references the python-script command which defines the location of the script. A python-policy specifies the DHCP messages along with the direction to which the script processing applies.

The DHCPv4 script in this example is applied to incoming DHCPv4 Request messages. The python script inserts the lease-time option in the DHCPv4 Request message as a hint to the DHCPv4 server.

Similar logic is applied to the incoming Lightweight DHCPv6 Relay Agent

(LDRA) DHCPv6 messages where IA-NA and IA-PD related lease times are altered. Note that in the DHCPv6 case the local DHCPv6 server does not honor the hint and therefore the lease related times are explicitly configured in the DHCPv6 server.

```
python-script "acg" create
    action-on-fail passthrough #In case of python script failure, do not drop the
                  message but instead continue with message processing
        in 7750.
    primary-url "ftp://a.b.c.d/pub/configs/alu/SIMS/acg.py"
    no shutdown
exit
python-script "acg6" create
    action-on-fail passthrough
    primary-url "ftp://a.b.c.d/pub/configs/alu/SIMS/acg6.py"
    no shutdown
exit
python-policy "acg" create  #Python policy that is applied under the capture-sap and
                             under the group-interface.
    dhcp request direction ingress script "acg"
    dhcp6 relay-forward direction ingress script "acg6"
exit
```

Python Script Configuration

In this example the Python script is located in an external location and downloaded to the SR OS node once the python-script CLI node is enabled (**no shutdown**).

The DHCPv4 Python script has exception code included (try/except statements). This makes script debugging easier in case one of the commands in the script fails.

For simplicity reasons, the exception code is removed from the DHCPv6 Python script. Note that in real deployments it is recommended for the exception code to be included in all Python scripts.

DHCPv4 Python Script:

```
from alc import dhcpv4
try:
    myopt = dhcpv4.getOptionList()
    if myopt != []:
        print "option-list ", repr(myopt)
        print "\n"
except Exception:
    print "Can't retrieve DHCP options"
#lease 500s 8min 20sec
try:
    dhcpv4.set(51,('\x00\x00\x01\xf4', #Insert the lease-time (opt51) in the incoming
                                DHCPv4 request as a hint to the DHCPv4 server.
except Exception:
    print "Can't set time lease"
```

DHCPv6 Python Script:

```
from alc import dhcpv6
import struct
packet = dhcpv6.get_relaymsg()# Extract the original DHCPv6 packet within LDRA.

msgType = ord(packet.msg_type) # Get the message type.
ia_na = packet.get_iana()    # Store the IA-NA option for further processing later on.
ia_pd = packet.get_iapd()    # Store the IA-PD option for further processing later on.
```

```
if msgType == 3: # If the message in the LDRA packet is DHCPv6 Request, insert the lease
 related times in address/prefic options.

    ia_na[0][1] = '\x00\x00\x07\xd0'# Set the renew time (T1) in IA-NA to 2000sec.
    ia_na[0][2] = '\x00\x00\x0b\xb8'# Set the rebind time (T2) in IA-NA to 3000sec.
    ia_na[0][3][5][0][1] = '\x00\x00\x0f\xa0'  # Set the preferred time in IA-NA to
                                               # 4000sec.
    ia_na[0][3][5][0][2] = '\x00\x00\x0f\xa0'# Set the valid time in IA-NA to 4000sec.
    packet.set_iana(ia_na) # Update the stored packet with the new values for IA-NA.

    ia_pd[0][1] = '\x00\x00\x07\xd0'# Set the renew time (T1) in IA-PD to 2000sec.
    ia_pd[0][2] = '\x00\x00\x0b\xb8'# Set the rebind time (T2) in IA-PD to 3000sec.
    ia_pd[0][3][26][0][0] = '\x00\x00\x0f\xa0' # Set the preferred time in IA-PD to
                                               # 4000sec.
    ia_pd[0][3][26][0][1] = '\x00\x00\x0f\xa0'# Set the valid time in IA-PD to 4000sec.
    packet.set_iapd(ia_pd) # Update the stored packet with the new values for IA-PD.
    dhcpv6.set_relaymsg(packet) # Insert the packet in the LDRA message.
```

RADIUS Access-Accept

Upon authentication, RADIUS returns the Access-Accept message with the following attributes:

```
Sending Access-Accept of id 66 to 192.168.114.2 port 64384
    Alc-Subsc-Prof-Str = "sub-profile-1"
    Alc-SLA-Prof-Str = "sla-profile-2"
    Alc-MSAP-Interface = "g1-1"
    Alc-MSAP-Policy = "msaps"
    Alc-MSAP-Serv-Id = 1
    Framed-Pool = "non-shared-left"
    Framed-IPv6-Pool = "wan-left"
    Alc-Delegated-IPv6-Pool = "pd-left"
    Alc-ToClient-Dhcp-Options += 0x03040a0a0afe
    Alc-ToClient-Dhcp-Options += 0x0608ac16fafaac16fafb
    Alc-ToClient-Dhcp-Options += 0x0f0b616c636174656c2e636f6d
    Alc-ToClient-Dhcp-Options += 0xe612637573746f6d2074657374206f7074696f6e
    Alc-ToClient-Dhcp-Options += 0x3a040000012c
    Alc-ToClient-Dhcp-Options += 0x3b0400000190

Alc-ToClient-Dhcp6-Options +=   0x0018001e0e616c636174656c2e6c7563656e7403636f6d00047465737403636f6d0   domain list (24) = Nokia.com test.com [formatting as described in section 3.1 of RFC 1035 (as referenced by RFC 4704 and RFC 3315)].

Results and Verification

The results are verified via debug output and show commands on the SR OS node, and also via pcap (Wireshark® packet capture) files on the DHCP client side.

Debug output on the SR OS node is enabled for DHCPv4/6 messages and for the Python script.

The DHCP debug output shows the options sent to the client in the DHCPv4/6 Ack/Reply messages.

The following commands enables debugging information to be sent to the current telnet/ssh session:

```
*A:BNG1# configure  log
*A:BNG1>config>log# info
---------------------------------------------
        log-id 50 # Capturing and displaying debug output is configured via log.
            from debug-trace # Capture debug output.
            to session     # Output the debug to the current tcp/ssh session.
        exit
---------------------------------------------
```

The following commands enable DHCP related debugging:

```
*A:BNG1>config>log# show debug
```

```
debug
    router "1"
        ip
            dhcp
                detail-level high
                mode egr-ingr-and-dropped
            exit
            dhcp6
                mode egr-ingr-and-dropped
                detail-level high
            exit
        exit
        local-dhcp-server "v4"
            detail-level high
            mode egr-ingr-and-dropped
        exit
        local-dhcp-server "v6"
            detail-level high
            mode egr-ingr-and-dropped
        exit
    exit
```

DHCPv4 Results

The following output displays the DHCPv4 Request message as it was received by the SR OS node DHCP server.

This message has been modified by the Python script on ingress and the lease-time option [51] has been inserted as a hint to the DHCPv4 server.

Option [82] is partially added by the **access-node** (relay-agent —> circuit-id and remote-id) and partially by the internal SR OS node DHCP-relay (pool name).

```
32830 2014/07/24 03:02:46.44 WEST MINOR: DEBUG #2001 vprn1 DHCP server
"DHCP server:  v4
Rx DHCP Request

  ciaddr: 0.0.0.0          yiaddr: 0.0.0.0
  siaddr: 0.0.0.0          giaddr: 10.10.10.254
  chaddr: 00:00:65:01:03:01    xid: 0x159dd536

  DHCP options:
  [82] Relay agent information: len = 42
     [1] Circuit-id: ds-left
     [2] Remote-id: remote0
     [9] Vendor-Specific info: len = 22
         Enterprise [6527] : len = 17
         [13] dhcpPool: non-shared-left
  [53] Message type: Request
  [54] DHCP server addr: 192.168.100.1
  [50] Requested IP addr: 10.10.10.34
  [51] Lease time: 500
  [255] End
```

The next output captures the DHCPv4 ACK message (within the SR OS node) that is on its way to the client.

It can be observed that the DHCPv4 server inserted options are listed first:

- Opt[82] is echoed back by SR OS node DHCPv4 server

- Opt[53], [54], [51] and [1] are by default inserted by the local DHCPv4 server and they cannot be disabled. The value for the lease-time [51] is set by the Python script.

- The next two options ([6] and [231]) are the options configured explicitly in the DHCPv4 server (Table 36: CLI Inserted DHCP Options).

The remaining options (with the exception of the **end** [255] option) are provided by RADIUS and they appear in the exact same order as they appear in the RADIUS Alc-ToClient-Dhcp-Options attributes (Table 34: RADIUS inserted raw options).

There are two options [6] since they are inserted by both DHCP and RADIUS server.

Custom options [231] and [230] are decoded in Table 34: RADIUS inserted raw options and Table 36: CLI Inserted DHCP Options .

```

DHCPv6 Results

The DHCPv6 server receives the DHCPv6 Request message with Python modified lease times (preferred, valid, renew and rebind) for IA-NA and IA-PD.

```

```

The **hinted** DHCPv6 lease-times are not honored by the SR OS node DHCPv6 server and instead the SR
OS node DHCPv6 server default values are inserted in the outgoing DHCPv6 Reply message towards the
client as shown in the output below.

The explicitly configured DHCPv6 options are inserted by the DHCPv6 server first (Table 36: CLI Inserted
DHCP Options) followed by the RADIUS supplied options inserted by the DHCPv6 relay (Table 34:
RADIUS inserted raw options).

There are two DNS options [23] since they are supplied via two sources (DHCPv6 server and RADIUS Alc-
ToClient-DHCP-Option VSA).

```

Python Debug Output

DHCPv4

For debugging purpose a line is added to the Python script printing all DHCP option numbers present in the incoming DHCP packets.

It can also be observed that all Python induced modifications to the original DHCP message are also displayed in the debugging output (inserting option [51] in this case).

Python script:

```
from alc import dhcpv4
myopt = dhcpv4.getOptionList()
print "option-list =", repr(myopt)
#lease 500s 8min 20sec
dhcpv4.set(51,('\x00\x00\x01\xf4',))
```

Debug Output:

```
32826 2014/07/24 03:02:46.44 WEST MINOR: DEBUG #2001 Base Python Output
"Python Output: acg
option-list  (53, 54, 50, 82, 255)
"
32827 2014/07/24 03:02:46.44 WEST MINOR: DEBUG #2001 Base Python Result
"Python Result: acg
DHCPv4 Option 51, SET
        '\x00\x00\x01\xf4'
"
```

DHCPV6

Also the DHCPv6 Python script has some lines added to demonstate Python debugging capabilities. The new lines print assigned values to the debugging output.

DHCPv6 script

```
from alc import dhcpv6
import struct
packet = dhcpv6.get_relaymsg()
msgTop = ord(dhcpv6.msg_type)
msgBot = ord(packet.msg_type)
ia_na = packet.get_iana()
ia_pd = packet.get_iapd()
print 'ia-na = ', ia_na
print '\n'
print 'ia-pd = ', ia_pd
print '\n'
print 'msg type Top = ', msgTop
```

```
print 'msg type Bot = ', msgBot

msgType = struct.unpack('B',packet.msg_type)[0]
print "relay packet: ", msgType

# in relay request insert DHCPv6 lease times
if msgBot == 3:

        ia_na[0][1] = '\x00\x00\x07\xd0'
        ia_na[0][2] = '\x00\x00\x0b\xb8'
        ia_na[0][3][5][0][1] = '\x00\x00\x0f\xa0'
        ia_na[0][3][5][0][2] = '\x00\x00\x0f\xa0'
        packet.set_iana(ia_na)
        ia_pd[0][1] = '\x00\x00\x07\xd0'
        ia_pd[0][2] = '\x00\x00\x0b\xb8'
        ia_pd[0][3][26][0][0] = '\x00\x00\x0f\xa0'
        ia_pd[0][3][26][0][1] = '\x00\x00\x0f\xa0'
        packet.set_iapd(ia_pd)
        dhcpv6.set_relaymsg(packet)
```

Python debugging output

```

Conclusion

The most common DHCP options that need to be passed by the SR OS node to the clients can be directly configured in CLI with a DHCP option specific command (such as DNS or a router option in IPv4). The DHCP option specific commands hide the complexity of the option encoding from the operator.

Less common options can be configured via a custom-option command in CLI. This scenario requires the operator to be familiar with the encoding of the option.

Similarly, RADIUS provides the means to pass the DHCP options destined to the client in the form of option specific RADIUS attributes (lease-time, etc). For less common options, two RADIUS attributes are provided: **Alc-ToClient-Dhcp-Options** and **Alc-ToClient-Dhcp6-Options**. These two attributes allow the operator to encode client destined DHCP options using hexadecimal notation. Although this process requires manual encoding it provides a very flexible way of providing options to the client.

The custom options supplied via LUDB or RADIUS are appended by the SR OS node DHCP-relay agent to any existing options that may have been already inserted by the DHCP server in the DHCP packet.

Python processing can additionally assist in DHCP message processing where the options or the parameters within the existing options can be added, removed or modified.

Routed CO

This chapter provides information about Routed Central Office (Routed CO) configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS 11.0.R4.

Overview

In the Routed Central Office (Routed CO) model, subscriber management features are implemented on a Layer 3 subscriber interface, available in a VPRN or an IES service. Compared to regular Layer 3 interfaces, a subscriber interface supports multiple SAPs, see later.

Customer originated traffic enters an Access Node (AN) and can be aggregated via either a Layer 2 or a Layer 3 aggregation network before being handled by a Broadband Network Gateway (BNG). Alternatively, an AN can be directly connected to the BNG.

Routed CO supports numbered, unnumbered, and hybrid (combined numbered/unnumbered) subscriber interface configurations.

Enhanced Subscriber Management (ESM) is not mandatory for IPoEv4 in Routed CO, but is mandatory for PPPoE and all IPoEv6 scenarios.

The numbered and unnumbered scenarios in this example use an IES service with:

- Dual Stack IPoEv4 + IPoEv6
- Single stack PPPoEv4

General knowledge of Triple Play Service Delivery Architecture is assumed throughout this chapter. Refer to the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide*.

The Routed CO model offers through the subscriber and group interface construct:

- Flexible subnet management
  - Subnets can be shared across multiple access nodes.
- Support for different deployment models, for example:
  - VLAN/service model.
  - VLAN/subscriber model.

- – VLAN/service/subscriber model.
- – VLAN/access node model.

- Per group-interface load balancing in multi-chassis redundancy configurations. Redundancy is out of the scope of this example.

The components needed in the Routed CO model are depicted in Figure 155: Components of the Routed CO Model.

For the Routed CO model two interface types are needed:

- First, one or more subscriber interfaces must be created.

- Second, one or more group interfaces must be created within the subscriber interface context.

Figure 155: Components of the Routed CO Model
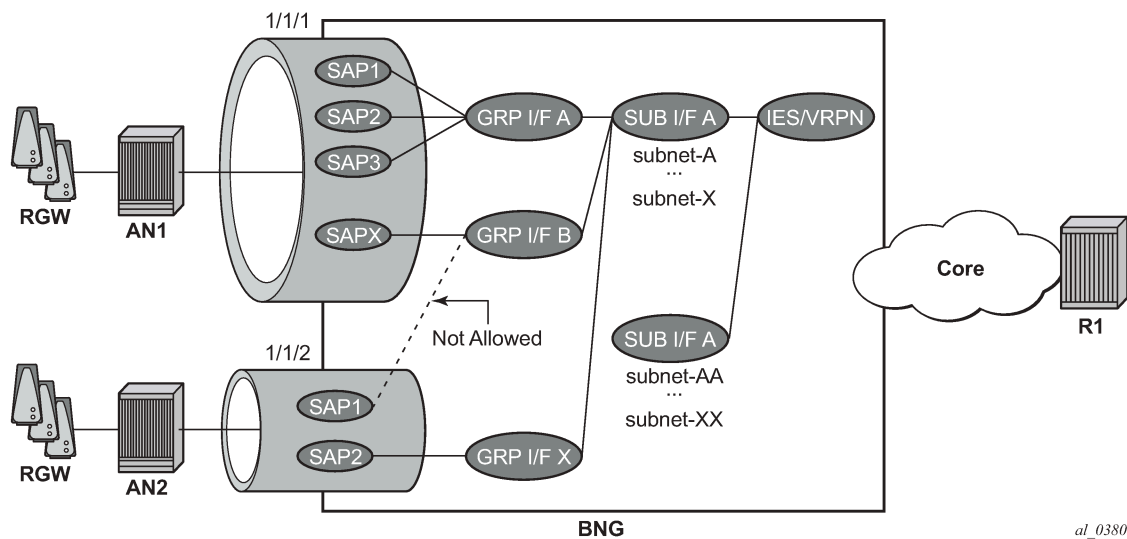

Subscriber Interface

A subscriber interface is a set of one or more group interfaces and identified by name.

A subscriber interface is created under an IES or VPRN service context, and supports up to 256 subnets (sum of IPv4 subnets and IPv6 prefixes).

Three types of subscriber interface configurations are available:

- Numbered subscriber interface.

- Unnumbered subscriber interface.

- Hybrid subscriber interface (numbered and unnumbered combined).

Subnet/Prefix Assignment

For the numbered scenario, the subscriber interface is configured with

- One or more IPv4 subnets.

- One or more IPv6 subscriber prefixes:

    - For WAN-hosts, using the DHCPv6 Identity Association for Non-temporary Addresses (IA_NA) option or Stateless Address Auto Configuration (SLAAC) and the prefix length is /64.

    - For Prefix Delegation-hosts (PD-hosts), using the DHCPv6 Identity Association for Prefix Delegation (IA_PD) option and the prefix length is defined by the Delegated Prefix Length (DPL).

This allows for subscriber-host address assignment in these subnets/prefixes only.

For the unnumbered scenario, the subscriber interface is configured with:

- IPv4:

    - No IPv4 subnets.

    - The keyword **unnumbered** plus an interface in the same routing instance (for example the system interface). The IP address of the interface referenced in the unnumbered command is used in IPCP negotiation.

- IPv6:

    - No IPv6 prefixes.

    - **allow-unmatching-prefixes**.

This allows for subscriber-host address assignment in any subnet/prefix. For IPv4, the keywords **unnumbered** and **allow-unmatching-subnets** are mutually exclusive.

For the hybrid scenario the subscriber interface is configured with:

- One or more IPv4 subnets and/or IPv6 subscriber prefixes.

- For IPv4: the keyword **allow-unmatching-subnets**.

- For IPv6: the keyword **allow-unmatching-prefixes**.

This allows for both subscriber-host address assignment within and outside of these subnets/prefixes.

Host IP Reachability

For the numbered scenario, host IP reachability requires:

- Adding the subscriber interfaces to the Interior Gateway Protocol (IGP).

- Or an export policy matching the subscriber interface subnets/prefixes.

For the unnumbered scenario, host IP reachability requires:

- An export policy matching the addresses of all individual subscriber hosts (from protocol sub-mgmt).

For the hybrid scenario, host IP reachability requires:

- An export policy matching both the subscriber interface subnets/prefixes as well as all individual subscriber hosts addresses.

Detailed examples of numbered/unnumbered/hybrid scenarios, including host IP reachability are included below.

Group Interface

A group interface is a set of one or more SAPs belonging to the same port and identified by name.

Configuration

This section covers:

- The definition of subscriber and group interfaces.

- A description of the numbered, unnumbered and hybrid scenarios.

- Options ensuring host IP reachability throughout the network.

Subscriber Interface

The configuration of the subscriber interface appears as follows.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                address 10.1.1.254/24
                address 10.1.2.254/24
                ipv6
                    delegated-prefix-len 56
                    link-local-address FE80::EA:48:FF
                    subscriber-prefixes
                        prefix 2001:DB8:101::/48 wan-host
                        prefix 2001:DB8:102::/48 pd
                        prefix 2001:DB8:F101::/48 wan-host
                        prefix 2001:DB8:F102::/48 pd
                    exit
                exit
            exit
            subscriber-interface "sub-int-2" create
                address 10.2.1.254/24
                address 10.2.2.254/24
                ipv6
                    delegated-prefix-len 56
                    link-local-address FE80::EA:48:FF
                    subscriber-prefixes
                        prefix 2001:DB8:201::/48 wan-host
                        prefix 2001:DB8:202::/48 pd
                        prefix 2001:DB8:F201::/48 wan-host
                        prefix 2001:DB8:F202::/48 pd
                    exit
                exit
            exit
```

Notice that once a subnet/prefix is assigned to a subscriber interface, the subnet/prefix is tied to that interface, meaning that the same subnet/prefix cannot be used on another subscriber interface or regular interface in the same routing instance. When using VPRN for the Routed CO model, overlapping subnets/prefixes are allowed when on different VPRN services.

As long as no group interfaces are configured within the subscriber interface context, the subscriber interfaces are in the operationally down state as shown in the following output. The subscriber-interfaces, sub-int-1 and sub-int-2, are operational down since no group-interfaces have been assigned at this stage.

*A:BNG#
```

No subscriber interface subnets/prefixes are present in the IPv4 and the IPv6 routing table as the subscriber interfaces are operational down.

Group Interface

A group interface is created under the subscriber-interface hierarchy.

```
configure
    service
        ies 1
            subscriber-interface "sub-int-1" create
                group-interface "grp-int-1-1" create
                    ipv6
                    exit
                    sap 1/1/1:111 create
                    exit
                    sap 1/1/1:112 create
                    exit
                exit
                group-interface "grp-int-1-2" create
                    ipv6
                    exit
                    sap 1/1/1:121 create
                    exit
                exit
            exit
            subscriber-interface "sub-int-2" create
                group-interface "grp-int-2-1" create
                    ipv6
                    exit
                    sap 1/1/2:211 create
                    exit
                exit
                group-interface "grp-int-2-2" create
                    ipv6
                    exit
                    sap 1/1/3:221 create
                    exit
                    sap 1/1/3:222 create
                    exit
                exit
            exit
        exit
```

Static SAPs are created manually under the group-interface context. Managed SAPs (MSAPs) are dynamically created when a trigger packet (DHCP, DHCPv6, ARP, PPPoE) is successfully authenticated,

which eliminates the provisioning of static SAPs. The creation and use of capture and managed SAPs (MSAPs) is explained in the example on Managed SAPs with Routed CO.

A group interface is operationally up when at least one of its statically configured SAPs is operationally up or when no static SAPs are configured while the parameter **oper-up-while-empty** under the group-interface context is enabled. The following output shows all group interfaces are operationally up.

```
*A:BNG# show router "Base" interface ipv4

Numbered Scenario

Figure 156: Numbered Scenario For IES 1 depicts the numbered scenario outlined below, including the connecting subscribers and subscriber hosts. Subscribers sub-11 and sub-44 are using PPPv4 hosts, and subscribers sub-22 and sub-33 are using dual stack DHCP hosts. Their VLANs and the MAC addresses are shown, as are the IP addresses and prefixes assigned once they are connected.

Figure 156: Numbered Scenario For IES 1
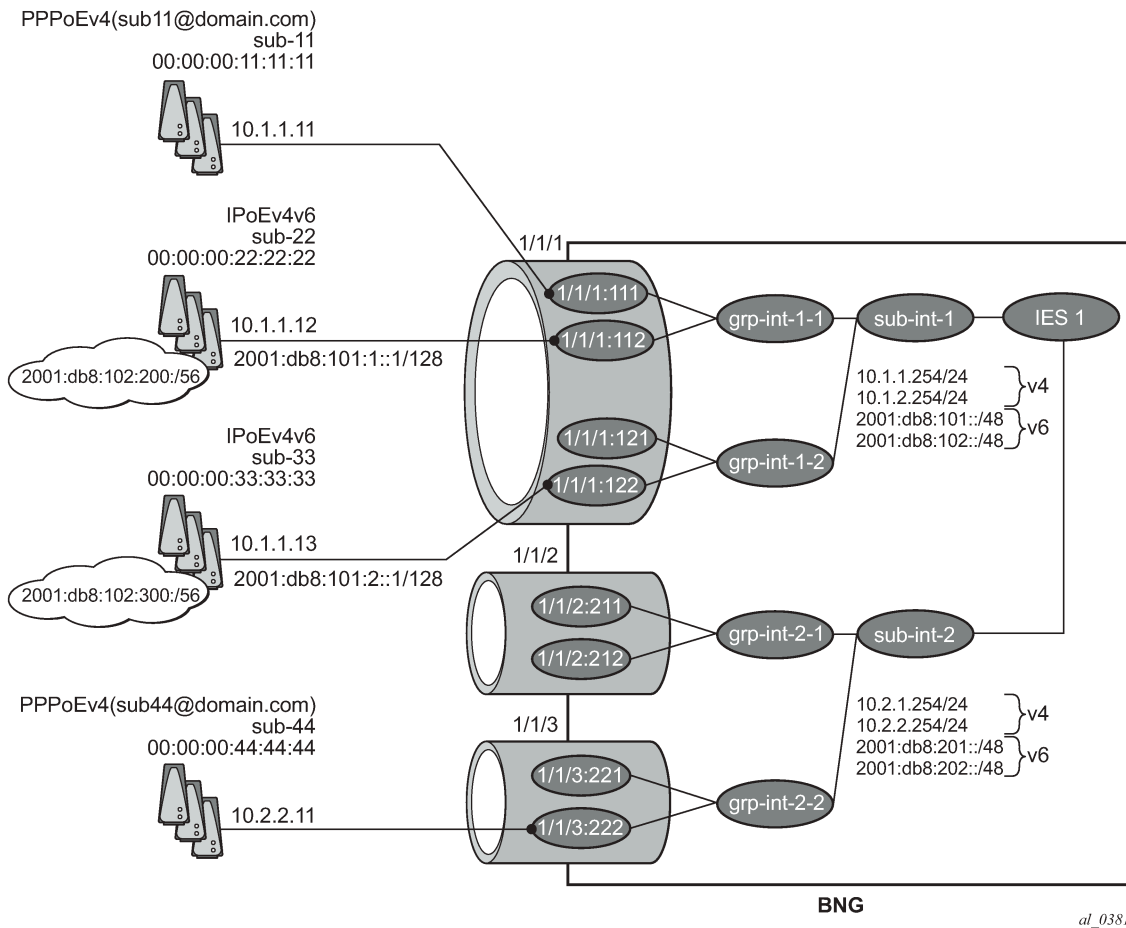

The configuration for the numbered scenario is shown below. Only the configuration items specific to the numbered scenario are shown.

In the numbered scenario the subscriber interfaces have following configuration:

- IPv4
  - Subnets.
  - **no allow-unmatching-subnets**.
  - **no unnumbered**.
- IPv6
  - A delegated prefix length.
  - subscriber prefixes.
  - **no allow-unmatching-prefixes**.

                        exit
                exit
        exit
        no shutdown
```

The following parameters are mandatory for the routed CO model:

- **lease-populate** — DHCPv4 lease state population is enabled by default on a group-interface with DHCPv4 configured as **no shutdown**. The number of leases allowed on each SAP of the group-interface must be configured. By default one single DHCPv4 host is allowed on each SAP. This parameter enables the creation of an ESM host table entry for each DHCPv4 lease. For DHCPv6 the ESM host table entry creation is implicit: no CLI parameter is required.

- **arp-populate** — The ARP table is populated with dynamically learned entries from the DHCP lease state table or static entries from the static host table. The BNG does not send downstream ARPs for those managed ARP table entries.

- **local-proxy-arp** — Enables user to user traffic in a split-horizon environment. The BNG responds with its own MAC address to ARP requests targeting subnets configured on the subscriber interface. If the ARP request is targeting a host of the same subscriber on the same SAP, the ARP request is silently discarded. This prevents traffic within a single bridged home to be attracted to the BNG. Local-proxy-arp is enabled by default.

- **anti-spoof** — Checks the source MAC and/or source IP of the upstream subscriber traffic. This parameter is configured at the SAP level with values **ip-mac** (default), **ip** or **nh-mac**. With ESM enabled, anti-spoof must include the source mac (values **ip-mac** or **nh-mac**).

Optional settings are:

- **description** — Can be used to assign a descriptive text to the item and used for administrative reasons.

- **delayed-enable** — To be used in redundant configurations. It is expressed in seconds and defines the additional time the BNG waits before the interface is enabled.

Verification

The interfaces on the BNG are listed using following command. Notice that all subscriber and group interfaces are operational up for IPv4 and IPv6.

```
A:BNG# show router "Base" interface

A:BNG#
```

Manually cross-referencing the SAPs from this output with the actual configuration shows the following for IPv4, and is depicted in Figure 156: Numbered Scenario For IES 1.

- Sub-11 and sub-22 are connected to the same subscriber and group interface (sub-int-1 and grp-int-1-1) but via different SAPs (1/1/1:111 and 1/1/1:112) and are sharing the same IPv4 subnet.

- Sub-33 is also connected to the same subscriber interface (sub-int-1) but via a different group-interface (grp-int-1-2). Sub-33 shares the same IPv4 subnet as sub-11 and sub-12, showing that the same subnet is shared across multiple group-interfaces.

- Sub-44 is connected to a different subscriber and group interface, and does not share a subnet with the other subscribers.

An alternative way to find where, for example, subscriber sub-33 is connected is shown below.

```
*A:BNG# show service active-subscribers subscriber "sub-33" detail

*A:BNG#
```

For IPv6, the situation is as follows:

- Sub-22 and sub-33 are connected to the same subscriber interface (sub-int-1) but to different group interfaces. Both subscribers share the same IPv6 prefix for prefix-delegation (PD) and wan-host.

With these subscriber hosts connected, the IPv4 routing table (RIB) for the base router looks as follows.

```
*A:BNG# show router "Base" route-table ipv4

```

The addresses of the individual subscriber hosts show up in the RIB but they do not show up in the FIB.

- /32 for IPv4-hosts.

- /DPL (Delegated Prefix Length) for IPv6 DP hosts, /56 in this example.

- /128 or /64 for IPv6 wan host.

Downstream traffic is forwarded based on a subscriber host table lookup. For specific network designs, subscriber host IPv4 addresses can optionally be included in the FIB with the populate-host-routes statement added to the subnet configuration. This is out of scope of this example.

Unnumbered Scenario

Figure 157: Unnumbered Scenario for IES 1 depicts the unnumbered scenario outlined below, including the connecting subscribers and subscriber hosts. Sub-11 and sub-44 are using single stack PPPoEv4 hosts, and sub-22 and sub-33 are using dual stack DHCP hosts. Their VLANs and the MAC addresses are shown, as are the IP addresses and prefixes assigned once they are connected.

Figure 157: Unnumbered Scenario for IES 1
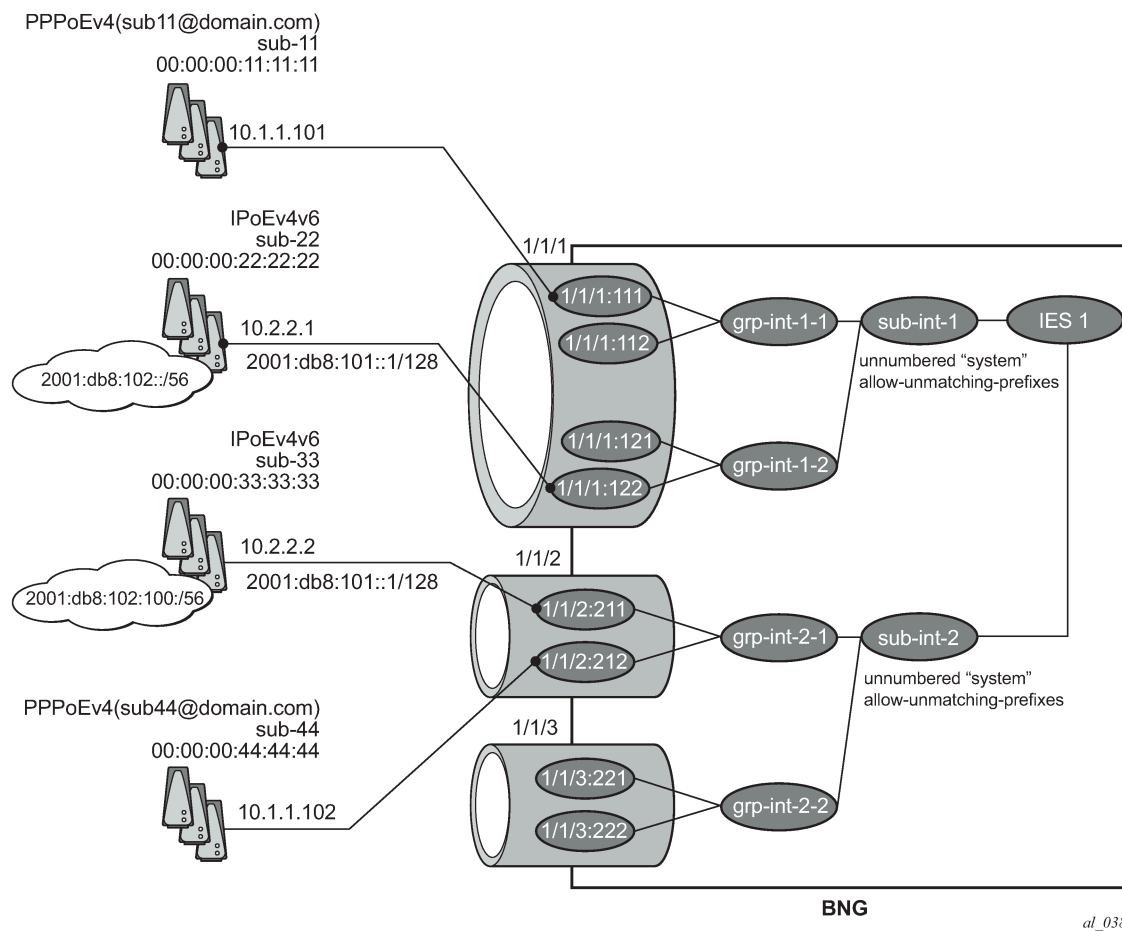

The configuration for the unnumbered scenario is show below. Only the configuration items specific to the unnumbered scenario are shown.

In the unnumbered scenario the subscriber interfaces have following properties:

- IPv4:
  - No subnets configured.

- – **unnumbered**, with an IPv4 interface or an IPv4 address used for IPCP negotiation.

  – **no allow-unmatching-subnets**.

- IPv6:

  – No subscriber prefixes configured.

  – **allow-unmatching-prefixes**.

*A:BNG#
```

Manually cross-referencing the SAPs from this output with the actual configuration shows the following for IPv4, and is represented in Figure 157: Unnumbered Scenario for IES 1.

- Sub-11 and sub-44 share the same IPv4 subnet even though they are connected to different subscriber interfaces.

- Sub-22 and sub-33 share the same subnet even though they are connected to different subscriber interfaces.

For IPv6 the situation is as follows:

- Sub-22 and sub-33 are in different subscriber interfaces and do not share IPv6 prefixes in this example.

With these subscriber hosts are connected, the IPv4 RIB for the base router looks as follows.

```
A:BNG# show router "Base" route-table ipv4

The addresses of the individual subscriber hosts appear in the RIB and the FIB, which is the main difference with the numbered model. The forwarding plane here needs the individual addresses to forward the traffic towards the individual subscriber hosts.

Hybrid Scenario

An alternative to the scenarios described above does exist in the form of a mixed numbered/unnumbered (hybrid) scenario as depicted in Figure 158: Hybrid Configuration.

The subscriber interface is configured with

- One or more IPv4 subnets and/or IPv6 subscriber prefixes.
- For IPv4: the keyword **allow-unmatching-subnets**.
- For IPv6: the keyword **allow-unmatching-prefixes**.

No explicit configuration is shown as it is a mix of the numbered and the unnumbered scenario described above, and as such the behavior is mixed.

Figure 158: Hybrid Configuration
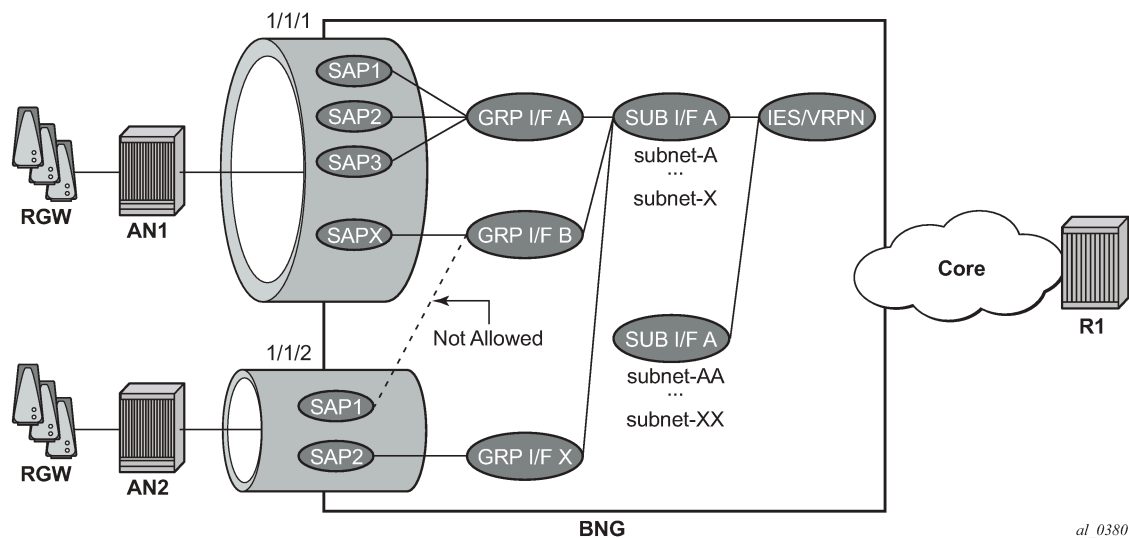

Host IP Reachability

To ensure reachability to the individual subscriber hosts, the subnets and prefixes of the subscriber interfaces/subscriber hosts need to be distributed to other routers in the network.

Three options are available:

- Without an export policy.
- With an export policy using, for example, from protocol direct.
- With an export policy using, for example, from protocol sub-mgmt.

Option 1 – No Export Policy

The key properties for the first option are:

- Subscriber interface subnets and prefixes are distributed into the network by adding the subscriber interfaces as passive interfaces to the routing protocol.

- It is used in combination with IGP based route distribution.

- It works with the numbered model only.

In this option the BNG uses IS-IS as IGP and no export policy is needed.

```
configure
    router
        isis
                area-id 48.0001
                multi-topology
                    ipv6-unicast
                exit
                interface "system"
                    no shutdown
                exit
                interface "sub-int-1"
                    passive
                    no shutdown
                exit
                interface "sub-int-2"
                    passive
                    no shutdown
                exit
                interface "toR1"
                    interface-type point-to-point
                    no shutdown
                exit
                no shutdown
        exit
```

The corresponding IPv4 RIB on router R1 (from Figure 155: Components of the Routed CO Model) lists the subscriber-interface subnets, not the individual subscriber host addresses.

```

===============================================================================
A:R1#
```

Alternatively the same result can be achieved with OSPF/OSPFv3.

Option 2 – Export Policy (from protocol direct)

The key properties for the second option are:

- Subscriber interface subnets and prefixes are distributed into the network by applying an export policy.

- It is most typically used in combination with BGP based route distribution.

- It works with the numbered model only.

The following export policy is used for this example.

```
configure
    router
        policy-options
            policy-statement "local-subnets-out"
                entry 10
                    from
                        protocol direct
                    exit
                    action accept
                    exit
                exit
            exit
```

In this option the BNG relies on BGP using the policy local-subnets-out as an export policy. The neighbor address is the IPv4 system address of router R1.

```
configure
    router
        autonomous-system 65536
        bgp
            group "grp-1"
                family ipv4 ipv6
                export "local-subnets-out"
                peer-as 65536
                neighbor 192.0.2.76
                    advertise-label ipv6
                exit
            exit
            no shutdown
        exit
```

The following command shows the IPv4 routes advertised by applying the local-subnets-out policy. The subscriber interface subnets are advertised, as are some other local subnets.

```
*A:BNG# show router bgp neighbor 192.0.2.76 advertised-routes ipv4

*A:R1# #
```

The same export policy can be used in combination with IGP based route distribution. However, when IGP
based route distribution is needed option 1 is the preferred method.

Option 3 – Export Protocol (from protocol sub-mgmt)

The key properties for the third option are:

- Host addresses and prefixes are distributed into the network by applying an export policy.

- It is most typically used in combination with BGP based route distribution, as IGP based route distribution does not scale for a large number of subscribers.

- It is most typically used for the unnumbered model, and in some cases for the numbered model.

The following export policy is used for this option.

```
configure
    router
        policy-options
            policy-statement "subsc-hosts-out"
                entry 10
                    from
                        protocol sub-mgmt
                    exit
                    action accept
                    exit
                exit
            exit
```

In this option the BNG relies on BGP using the policy subsc-hosts-out as an export policy.

```
configure
    router
        autonomous-system 65536
        bgp
            group "grp-1"
                family ipv4 ipv6
                export "subsc-hosts-out"
                peer-as 65536
                neighbor 192.0.2.76
                    advertise-label ipv6
                exit
            exit
            no shutdown
        exit
```

The following command shows the IPv4 routes advertised by applying the subsc-hosts-out policy. Now the subscriber host addresses are advertised individually.

```

Conclusion

This example explains how to configure and use the Routed CO model. The subscriber and the group interfaces were configured for the numbered, unnumbered and hybrid scenario, showing the flexibility of the Routed CO model in terms of subnet/prefix assignment as well as the impact on the forwarding and the reachability to and from the subscriber hosts.

Subscriber Redundancy for Routed CO

This chapter provides information about Subscriber Redundancy for Routed CO (SRRP).

Topics in this chapter include:

Applicability

This chapter is applicable to SR OS routers and was initially based on Release 7.0.R5. The CLI is updated to Release 16.0.R6.

Overview

This chapter focuses on the delivery of redundant services in an enhanced subscriber management (ESM) routed CO environment using Internet enhanced service (IES) or virtual private routed network (VPRN).

It is applicable to delivering high speed Internet (HSI), voice-over-IP (VoIP) and video-on-demand (VoD) to subscribers.

Redundancy is provided at two levels:

- system redundancy

- network redundancy

The system redundancy is based on the high availability features of the SR OS routers, such as component redundancy (power, fans, control processor modules, and so on) and software redundancy (service and protocol redundancy and non-stop-routing), which are not discussed here.

The network redundancy for subscriber access in an ESM routed CO environment requires that each broadband service access node (BSAN) is dual-homed to two SR OS routers, either in a point-to-point fashion with the BSANs having direct physical connectivity to the SR OS routers, or by having Layer 2 aggregation between the BSANs and the SR OS routers.

This connection will operate in a primary-standby relationship providing both link and system redundancy for the subscribers on the BSAN when accessing the configured services.

Subscriber redundancy for routed-CO aims to minimize the outage due to a failure.

This chapter provides configuration and troubleshooting commands for SRRP with **static-host ip-mac**.

Knowledge of the triple play service delivery architecture (TPSDA) concepts is assumed throughout this document.

There are three components on SR OS routers to implement network redundancy:

1. Redundant access from the BSANs to two SR OS routers provided by the SRRP.

2. Mirroring of subscriber state between two SR OS routers is achieved through the multi-chassis synchronization (MCS) protocol.

3. Backup spoke SDP traffic path between two SR OS peers.

These components are shown in Figure 159: Network Redundancy Components for ESM Routed CO.

Figure 159: Network Redundancy Components for ESM Routed CO
The following configuration tasks should be done first and are not explained in this chapter:

- Basic service router configuration (system interface, IGP, MPLS, BGP)
- Routed CO service topology: VPRN or IES service with subscriber and group interface on broadband network gateways (BNGs)
- ESM configuration
- Static host configuration

This chapter will focus on SRRP in a VPRN service subscriber-interface on BNG (routed-CO). In case of routed CO, it is also possible to configure SRRP in the base routing instance using an IES service.

SRRP Protocol

The SRRP protocol operates on a specific SAP within the group interface under the subscriber-interface of an IES/VPRN service. Through a method similar to the virtual router redundancy protocol (VRRP), it provides a set of default gateways to the subscribers on the BSAN. These are active on the SR OS router in the master state (primary) and inactive on the router in the backup state. Upstream and downstream traffic is forwarded through the master. If the backup loses connectivity with the primary (for example, fails to receive SRRP messages from the primary), it transitions to the master state and takes over the ownership of the default gateways and the responsibility for forwarding traffic to and from the subscriber. This provides redundancy from the BSAN toward the provider network.

If an SRRP fail over were to occur, it is important that the subscriber state (IP/MAC addresses, QOS profiles, etc.) be immediately available on the new SRRP primary; otherwise, subscriber traffic will be dropped due to the anti-spoofing security. The subscriber state is synchronized through the MCS protocol, which mirrors the subscriber state between the two peers. This allows both peers to know the details of the active subscribers and therefore forward traffic on their behalf with the correct QOS actions both to and from the BSAN if that peer is the SRRP primary.

The last topic relates to the forwarding from the provider network to the subscribers. If the IP routing causes this traffic to forward through the SRRP primary, then the traffic will automatically be forwarded to the subscriber. However, if the provider routing scheme causes traffic destined to a subscriber to arrive at the router in the SRRP backup state for that subscriber, it will be dropped as the backup does not forward traffic out of the subscriber SAPs.

To avoid this, a redundant interface is configured between the two SR OS routers under the subscriber/group-interfaces. Any traffic arriving on the router for an active subscriber, where its associated SRRP instance is in the backup state, will be forwarded through the redundant interface to the SRRP primary, which in turn forwards the traffic to the subscriber.

In addition to successful forwarding the traffic, this operation also maintains the subscriber QOS compliance as all traffic for a given subscriber enters and exits the routed-CO interface through a single SAP, allowing the associated IOM hardware to perform the correct QOS actions.

Configuration

Subscriber Interface Configuration

Redundant Default Gateway

The redundant default gateway IP addresses must be configured under the subscriber-interface (within the IES/VPRN service) for each subnet defined.

Three subnets are configured under the subscriber-interface sub-int-1, each with a **gw-ip-address** which is used as the default gateway by the subscribers in that subnet.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            ---snip---
            subscriber-interface "sub-int-1" create
                address 10.2.0.2/16 gw-ip-address 10.2.0.254
                address 10.3.0.2/16 gw-ip-address 10.3.0.254
                address 10.4.0.2/16 gw-ip-address 10.4.0.254
                ---snip---
            exit
        exit
    exit
exit
```

The **gw-ip-address** could be a virtual (unused) address in this subnet or the address of one of the actual subscriber-interfaces on the two routers, but it must not be used as a subscriber address.

If DHCP were to be used, the associated subscriber-interface address should be used as the gi-address configured for DHCP under the group-interface (will not be covered here as static host is used). This ensures that the offer returned from the DHCP server and arriving at the SRRP backup (rather than primary) will be forwarded by the backup SRRP router to the primary SRRP router through the redundant interface.

In environments where there are many subscribers, it will take time to synchronize the subscriber state between the peers when the subscriber-interface is enabled (perhaps, after a reboot). In order to ensure that the state has time to get synchronized, a hold timer can be applied to the subscriber interface. The optional **init-only** parameter can be added to use this timer only after a reboot.

```
*A:BNG-2>config>service>vprn>red-if>hold-time#
 [no] down             - Configure the hold time when the interface is coming up
 [no] up               - Configure the hold time when the interface is going down

*A:BNG-2>config>service>vprn>red-if>hold-time#
```

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                hold-time
                    down ip 1200 init-only
                exit
            exit
        exit
    exit
```

Group Interface Configuration

The group interface *group-int-1* providing connectivity to the BSAN is configured under the subscriber interface:

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                ---snip---
            exit
        exit
    exit
exit
```

Static Host Configuration

First enable the sub-sla-mgmt and sub-ident-policy *sub-id-default* under **sap 1/1/3:1**, then define a static host (ip-mac) with **sla-profile sla-profile-1**, **sub-profile sub-profile-1** and **subscriber static-host-routed-10.2.0.3**.

```
# on BGG-2
configure
```

```
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    sap 1/1/3:1 create
                        sub-sla-mgmt
                            sub-ident-policy "sub-id-default"
                            multi-sub-sap
                            no shutdown
                        exit
                        static-host ip 10.2.0.3 mac 00:00:00:00:00:01 create
                            sla-profile "sla-profile-1"
                            sub-profile "sub-profile-1"
                            subscriber "static-host-routed-10.2.0.3"
                            no shutdown
                        exit
                    exit
                exit
            exit
        exit
    exit
exit
```

SRRP Configuration

In order for the redundant gateway information to be used by subscribers through SAPs belonging to a
particular group-interface, an SRRP instance must be added in the group interface context.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    srrp 1 create
                        ---snip---
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

At this point, any subscriber ARPing for the gw-ip-address will receive a response from the SRRP
primary with a source MAC of 00-00-5E-00-01-<xx>, where <xx> is the first byte of the SRRP identifier in
hexadecimal, so in this case for SRRP=1 the source MAC will be 00-00-5E-00-01-01.

The redundant default gateway MAC address could be explicitly configured, if desired, by use of the **gw-mac** parameter.

```
*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp# gw-mac
  - gw-mac <mac-address>
  - no gw-mac

 <mac-address>         : xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp#
```

There can be only one SRRP instance per group-interface and all SRRP identifiers must be unique per system.

When an SRRP instance is enabled, or when there is an SRRP failover from one device to another, gratuitous ARPs are sent on all VLANs associated with this instance for all gw-ip-addresses (for example, on all subscriber SAPs and on the SRRP message path SAP in the associated group interface). This allows all downstream devices to relearn the path to the new primary.

The SRRP messages are normally forwarded through the BSAN, thereby verifying the connectivity from one router through the BSAN to the other router. In order to achieve this, a non-subscriber SAP must be configured under the **group-interface** which is referenced in the SRRP configuration by the **message-path** parameter. This not only selects the SAP to be used for the SRRP messages but also avoids the subscriber anti-spoofing from automatically dropping the received messages (as there would be no subscriber IP-to-MAC entry corresponding to the received information) and causing both peers to become primary.

The message-path SAP configuration effectively disables IP-MAC anti-spoofing on that SAP.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    ----snip---
                    sap 1/1/3:2 create
                    exit
                    srrp 1 create
                        message-path 1/1/3:2
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The SRRP messages are then not sent on the same SAP as the subscriber data traffic, under the assumption that the path traversed by the SRRP messages is the same as the path for the subscriber data; if this is not the case, then the SRRP state would not necessarily reflect a failure in the data path.

The primary of the SRRP instance generates advertisement messages at the keep-alive-interval (which is encoded in the message) ranging from one (1) to 100 in multiples of 100ms with a default of 10 (for example, 1 second). The SRRP backup will monitor the reception of these messages and assume the role of the primary if three consecutive messages are not received.

At all times the keep-alive-interval of the primary is used.

```
*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp# keep-alive-interval
  - keep-alive-interval <interval>
  - no keep-alive-interval

 <interval>               : [1..100] tenths of a second

*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp#
```

Only two devices can participate in an SRRP protocol exchange for a given SRRP instance, this being another difference from VRRP which allows more potential backup devices. This is a consequence of the direct relationship between the SRRP instance and the associated redundant interface and MCS peering.

This protocol exchange is also used for the primary/backup election, based on the priority (1 to 254) configured in the SRRP instance. The device with the highest priority will become primary.

```
*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp# priority
  - no priority
  - priority <priority>

 <priority>           : [1..254]

*A:BNG-2>config>service>vprn>sub-if>grp-if>srrp#
```

The message source IP address (system IP address) is used as a tie break when the priorities are the same (the lower IP address becomes the primary). The primary/backup status is per SRRP instance (not per IP address). For example, the primary is the active gateway for all gw-ip-addresses under the subscriber interface for the associated group-interface (this is true even if the backup is the IP address owner for one of the gw-ip-addresses). Priority 0 is sent by the primary when it is transitioning to the backup role due to the appearance of a high priority peer. Higher priority backups always preempt a lower priority primary.

A basic form of load distribution can be achieved by having the primary SRRP for some group-interfaces on one peer and the primary for other group interfaces on the other peer. Clearly, a failure may cause all primary SRRPs to be active on a single peer, which must be taken into account when designing the network.

The minimum keep-alive-timer of 1 is configured, together with the message-path defining the SAP to be used for the SRRP messages. The priority is set to 250 (default is 100) in order to force this peer to be the SRRP primary when both peers are active.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                ---snip---
                srrp 1 create
                    keep-alive-interval 1
                    message-path 1/1/3:2
                    priority 250
                    no shutdown
                exit
            exit
        exit
```

SRRP Configuration Notes

A VRRP policy statement can be added to the SRRP instance definition in order to dynamically adjust the SRRP priority based on certain non-SRRP related events occurring (for example, port down, LAG degrade, host unreachable or route unknown).

The gw-ip-addresses are accessible by active subscribers, for example, regardless which peer is the primary, an active subscriber can ping or telnet to its associated gw-ip-address (clearly, filters can be configured to control this).

Bi-directional Forwarding Detection

Bi-directional forwarding detection (BFD) can be configured with SRRP to speed up the convergence.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                ---snip---
                    srrp 1 create
                        ---snip---
                        bfd-enable 2 interface "bfd-1" dst-ip 10.1.1.1
                        no shutdown
                    exit
                exit
            exit
        exit
    exit
exit
```

An IES service needs to be created for the BFD session.

```
# on BNG-1
configure
    service
        ies 2 customer 1 create
            interface "bfd-1" create
                address 10.1.1.1/31
                bfd 100 receive 100 multiplier 3
                sap 1/1/3:3 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Monitoring In-Band Communications Path

In order to monitor the in-band communications path between the subscribers and two routers, SRRP uses a slightly modified VRRP advertisement message.

The SRRP message destination IP address (224.0.0.18) and IP protocol number (112) are the same as for VRRP but there are changes in the following areas:

- The source IP address of the message is the system IP address, as opposed to the interface IP address.

- The protocol version has been set to eight (8) (the current version of VRRP is two (2)).

- The source MAC address is included instead of the virtual router IP addresses (this being 00-00-5E-00-01-<xx>, where <xx> is the first byte of the SRRP identifier in hexadecimal).

Synchronizing the SRRP Peer State

In order to troubleshoot an SRRP environment, the state of each peer is synchronized with the other peer through multi-chassis synchronization (MCS). MCS is a proprietary protocol used for synchronizing application state between two peers. SRRP will function without synchronizing its state but this synchronization allows for the current state of both the local and remote peers to be displayed and appropriate error messages to be reported when the peer state is not correct. It also allows the primary SRRP subscriber-interface to be pinged through the backup peer (through the redundant interface).

To link information being mirrored between two routers, a **sync-tag** value is configured to correspond to either an entire port/LAG or under a port/LAG for a VLAN range. This allows each router to know exactly which information should be in sync on each device. The sync-tag must be unique on the two peers involved.

This example configuration shows only the SRRP aspects. The SRRP instance has been configured for MCS peer 192.0.2.1 using VLANs 1-2 on port 1/1/3. Here, a sync-tag is associated with the SRRP instance.

```
# on BNG-2
configure
    redundancy
        multi-chassis
            peer 192.0.2.1 create
                authentication-key "sync-testing"
                sync
                    srrp
                    sub-mgmt ipoe
                    port 1/1/3 "st1" create
                        range 1-2 sync-tag "st1"
                    exit
                    no shutdown
                exit
                no shutdown
            exit
```

Alternatively, if the information needs to be synchronized for all VLANs on port 1/1/3, then the following port command could be used instead of the preceding port-plus-ranges shown.

```
# on BNG-2
configure
    redundancy
        multi-chassis
            peer 192.0.2.1 create
                authentication-key "sync-testing"
                sync
                    srrp
                    sub-mgmt ipoe
                    port 1/1/3 sync-tag "st1" create
                    exit
                    no shutdown
                exit
                no shutdown
            exit
```

The VLANs used within the group interfaces must match between the two peers, clearly the physical ports identifiers may differ.

Multi-Chassis Synchronization

Multi-chassis synchronization (MCS) is a general propriety protocol used to synchronize information between two peers. It can be used for the several applications, such as:

- IGMP

- IGMP snooping

- Subscriber management

- Subscriber router redundancy protocol

This chapter only covers the subscriber management and SRRP applications.

Subscriber Management Synchronization

In order to ensure that the QOS defined for a subscriber is adhered to, all traffic for a given subscriber needs to be forwarded by a single port. When an MSAN is dual-homed to two routers, this is achieved using the SRRP protocol (described above) and the redundant interface (described below); specifically, the traffic is forwarded through the SRRP primary of the related group-interface.

When a subscriber is created on the primary SRRP, a host route (/32) for its IP address is inserted in the FIB pointing towards the appropriate group-interface.

The same subscriber on the backup peer will have a host route in the IP FIB pointing to the redundant interface. On the backup peer, this requires the subscriber subnet to also be present in the FIB, which in turn requires one of the following:

- The local subscriber-interface is up.

- The subscriber subnets are learned from the active broadband network gateway (BNG) through the routing protocol.

- Forcing the subscriber-interface to stay up by creating a dummy group interface with the **oper-up-when-empty** command.

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            subscriber-interface "sub-int-1" create
                group-interface "group-int-1" create
                    oper-up-while-empty
                    sap 1/1/3:1 create
                        ---snip---
                    exit
                exit
            exit
        exit
    exit
exit
```

Redundant Interface

The requirement for the redundant interface stems from the situation where traffic destined to a subscriber arrives on the router where the associated SRRP state is not primary.

When the SRRP state is backup for a particular group-interface, subscriber traffic is normally not forwarded in/out of the associated subscriber SAPs. Also traffic could arrive where the specific group-interface for that subscriber is down. These situations could occur due to the regular routing within the provider network or temporarily during an SRRP failover. Note that as the subscriber subnets are configured under the subscriber-interface, it is not possible to stop advertising these subnets into the provider core in the case where only a subset of the group interfaces are down or the associated SRRP instances are in backup. The advertisement of the subscriber subnet could therefore attract traffic to the router, while not being the SRRP primary.

In these cases, traffic must be sent to the active SRRP router in order to be forwarded to the subscriber. This is achieved through the configuration of a redundant interface between two SRRP peers, protecting against failures of related group interfaces.

The redundant interface is configured under the IES/VRPN service. It must use a single pseudowire, configured as a spoke SDP, to provide connectivity to the peer router. This is essential as it avoids any possibility of the traffic being misrouted by any other system between the two peers. It can either use a /31 IP subnet mask or a longer mask with the remote IP being explicitly specified.

```
# on BRG-2
configure
    service
        vprn 1 customer 1 create
            ---snip---
            redundant-interface "bng-2-bng-1-vprn-1" create
                address 192.168.4.1/31
                spoke-sdp 21:1 create
                exit
            exit
            ---snip---
        exit
    exit
exit
```

If a non /31 address is used, the remote IP address will be required.

```
*A:BNG-2>config>service>vprn# redundant-interface "bng-2-bng-1-vprn-1"
*A:BNG-2>config>service>vprn>red-if# address 192.168.4.1/30
INFO: PIP #1399 Invalid or unspecified remote IP address - Non /31 address requires remote IP
 address
```

The remote-ip address can be defined by the following command:

```
*A:BNG-2>config>service>vprn>red-if# address 192.168.4.1/30 remote-ip 192.4.1.2
```

Then each group-interface must be assigned a redundant interface, as follows:

```
# on BNG-2
configure
    service
        vprn 1 customer 1 create
            ---snip---
            subscriber-interface "sub-int-1" create
```

```
                    ---snip---
                group-interface "group-int-1" create
                    redundant-interface "bng-2-bng-1-vprn-1"
                    oper-up-while-empty
                    ---snip---
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Only one redundant interface is required for a given IES/VPRN service on each peer, though it is possible to create multiple redundant interfaces and assign group interfaces to each individually. Clearly, each redundant interface needs to terminate on a matching redundant interface in the corresponding peer service.

When traffic arrives from the core network for an active subscriber on a SAP in group-interface *group-int-1*, and if the associated SRRP instance is in the backup state, then this traffic will be forwarded over the **redundant-interface bng-2-bng-1-vprn-1** to the peer router. It will then be forwarded to the subscriber as the associated SRRP instance will be in the primary state.

The information about the redundant interfaces is mirrored through MCS as part of the SRRP synchronization.

> **Note:**
> When changing the local and remote redundant-interface addresses afterward, **shutdown** and **no shutdown** of the redundant interface on one side is required in order to guarantee subscriber-interface IP reachability.

Show and Debug Commands

Routing Table Related Information

A host route (/32) for the static host is inserted in the FIB pointing toward the appropriate group-interface.

```
*A:BNG-2# show router 1 route-table protocol sub-mgmt

*A:BNG-2#
```

Also shown are the port/VLANs synchronized with their respective sync-tags.

To further troubleshoot and debug this configuration, there are commands to both dump the sync and SRRP MCS information and to dump the SRRP database:

```
tools dump redundancy multi-chassis sync-database [application {sub-mgmt|srrp}]
```

The command provides the same information as the equivalent show commands. However, the detailed version gives more information about the contents of the sync-database.

For SRRP, there are entries for the base configuration, group interface and subnet information for each of the SRRP instances. This should show corresponding entries for the local and remote peer. Specifying the **sync-tag st1** shows only the information for SRRP instance 1.

```
*A:BNG-2# tools dump redundancy multi-chassis sync-database application srrp
                                                      sync-tag st1 detail

If no entries are present for an application, no detail will be displayed.

Monitoring the Traffic on Redundant Interface

The Oper State reflects both the state of the SRRP instance and its action with respect to the redundant interface. Specifically, when the peer is SRRP primary the operational state is always primary – traffic is sent directly to the subscriber over its associated SAP. If the peer is SRRP backup and the redundant interface is Up then the Oper State will be backupShunt, if the redundant interface is down then the Oper State is *backupRouting*. In the *backupShunt* state, traffic to the subscriber is shunted (for example, forwarded) across the redundant interface to the peer (to the primary) in order to be forwarded to the subscriber.

When in the *backupRouting* state, the SRRP instance is in backup but the redundant interface is down, so the traffic is forwarded directly to the subscriber through its associated SAP.

A useful command to see the traffic on the redundant interface is:

```
*A:BNG-2# monitor service id 1 sdp 21:1 rate interval 11 repeat 3

```

SRRP Debug Commands

There are debug command to show the SRRP protocol events and packets.

```
*A:BNG-2# debug router 1 srrp events
*A:BNG-2# debug router 1 srrp packets
```

To display the debugging information, a dedicated log should be created:

```
configure
    log
        log-id 1
            from debug-trace
            to memory 3000
            no shutdown
        exit
    exit
exit
```

The following output displays a sample SRRP debug log:

```
2558 2019/04/05 13:57:55.104 CEST MINOR: DEBUG #2001 vprn1 SRRP
"SRRP: Receiving Pkt

Version (SRRP)     : 8

    Checksum: 0x0001 [correct]
```

As an example, in the following output BNG-2 is the SRRP primary for instance 1 and sends SRRP advertisement messages. Then BNG-2 receives an SRRP message with a higher priority (254) from its peer BNG-1. This causes an event *Become Pending-Backup Shunt* where BNG-2 prepares to transition to the backup state. To achieve this, BNG-2 sends and SRRP message with priority 0. If BNG-2 continues to receive priority 254 SRRP messages from its peer BNG-1, it passes into the backup state with the event *Become Backup Shunt*.

```

Where DSCP 0x30=48 (DSCP value). This can be changed to EF, for example, using the following command:

```
*A:BNG-2# configure service vprn 1 sgt-qos application srrp dscp ef
```

Conclusion

This chapter provides configuration and troubleshooting commands for SRRP with static (IP-MAC) host in a Layer 3 Routed-CO (IES/VPRN subscriber interface) context.

Virtual Residential Gateway Authentication Scenarios

This chapter describes virtual residential gateway authentication scenarios.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 14.0.R3.

Overview

In the virtual residential gateway (vRGW) model, the Layer 3 (L3) functions are moved out of the traditional residential gateway (RGW) and into the network. The Virtual Residential Gateway Home Pool Management chapter provides the rationale for this scenario, and describes how services must be configured for the service router to support this model.

The home network can be self-managed through a service portal, where end users can connect and change home-specific settings; see Figure 160: BRG and home device management. The portal logic is implemented in a controlling entity providing a RESTful interface. A protocol conversion and mediation platform (PCMP) is needed to translate the RESTful interface into RADIUS (and SNMP), and vice versa. The PCMP operates in conjunction with the 5620 SAM. In the remainder of this chapter, PCMP and the controller are represented as a single component.

Managing individual BRGs requires the vRGW to maintain a context for every BRG, so each BRG is identified through the BRG ID. This context is created when authenticating the BRG, and stores the home-level settings. The BRG context is deleted when the BRG is not deemed alive anymore.

The BRG ID can be derived from any of the parameters in the RADIUS Access-Request message, such as the SAP, tunnel-source, or called-station ID by a controlling entity; see the Implicit authentication and Explicit authentication sections that follow in this chapter. Typically, the MAC address of the BRG serves as the BRG ID, and that is what is used throughout this chapter.

Figure 160: BRG and home device management
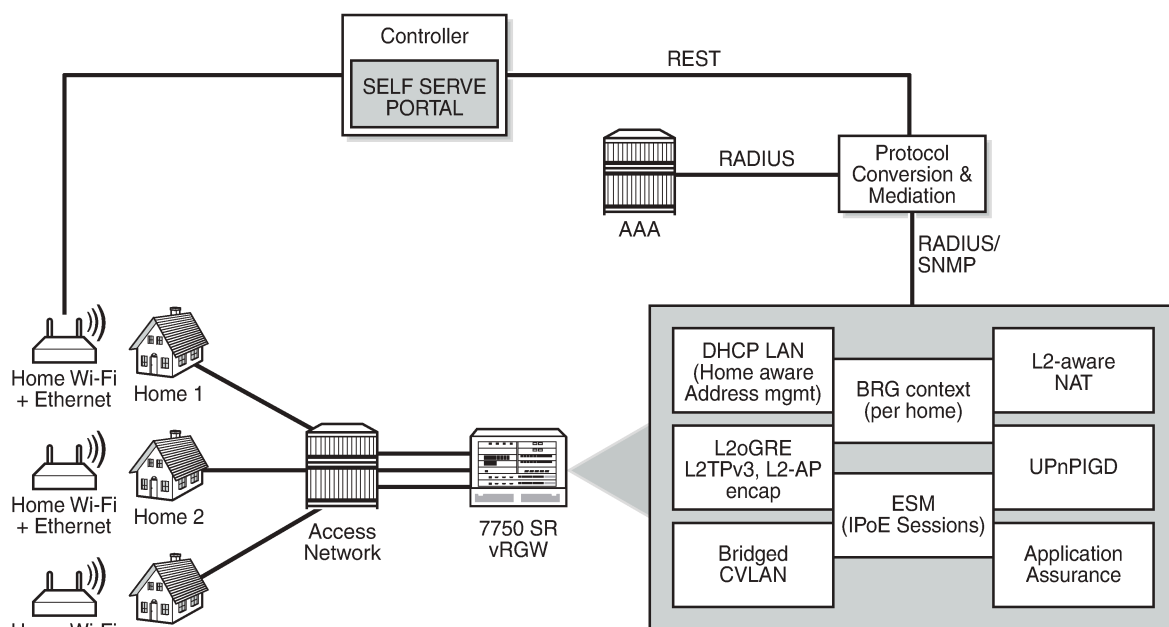

The vRGW supports two scenarios for authenticating bridged gateways and their hosts:

- Explicit authentication
- Implicit authentication

Explicit authentication

Two main phases are distinguished in the explicit authentication scenario; see Figure 161: Explicit BRG authentication. The first phase is the BRG authentication phase, the second phase is the device authentication phase. The example in Figure 161: Explicit BRG authentication uses IPv4, but also works with IPv6.

Figure 161: Explicit BRG authentication
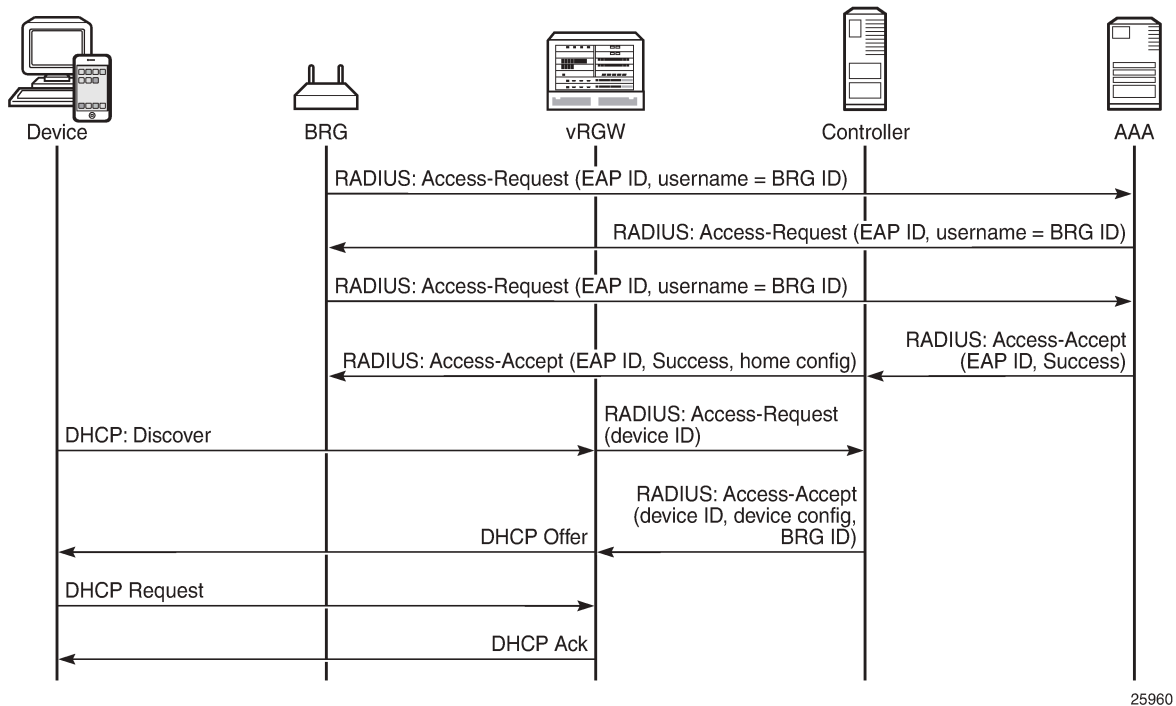

The first message in the first phase is an Access-Request message sent by the BRG toward the AAA/ RADIUS server, and uses the extensible authentication protocol (EAP). This message is proxied by the vRGW as well as by the controller to the AAA server, and the BRG ID is used as the username. The last message of the first phase is the Access-Accept message. When the controller receives this message from the AAA server, it fetches and adds the per-home configuration parameters to the Access-Accept message before forwarding this message to the vRGW.

The second phase starts with the Discover message of a typical Discover-Offer-Request-Ack (DORA) message sequence. The vRGW then initiates device authentication toward the controller, which returns the BRG ID and, optionally, device-specific configuration data in an Access-Accept message. The controller usually will not proxy device authentication toward the AAA server. Typically, the RADIUS protocol is used between the vRGW and the controller. As such, the vRGW will send an Access-Request message to the controller for every new device, including static devices, to get the per-device configuration.

Usually, the vRGW combines the home-specific data with the device-specific data, where the more specific device data overrules the home-specific data. The combined data is then used to create the corresponding ESM hosts and IPoE sessions.

If the home-specific data includes Alc-Reserved-Addresses attributes defining static devices, these devices are authenticated automatically as soon as at least one dynamic device is connected.

The explicit authentication scenario requires the BRG profile to include a RADIUS proxy server; see the Configuration section in this chapter for a practical example.

Implicit authentication

In the implicit authentication scenario, the BRG is authenticated when the first device connects to the vRGW; see Figure 162: Implicit BRG authentication for an example.

Figure 162: Implicit BRG authentication
In Figure 162: Implicit BRG authentication, the Discover message triggers the vRGW to send an Access-Request message toward the controller. The controller returns device-specific data including the BRG ID. Because there is no context for this BRG yet, the vRGW starts BRG authentication toward the AAA/RADIUS server. The controller proxies this message, and on return adds the home-specific data to the Access-Accept message. The overall result is that the vRGW now knows the home- and device-specific data.

As with the explicit authentication scenario, the combined data is then used to create the corresponding ESM hosts and IPoE sessions.

No separate BRG authentication is required when subsequent devices connect and device authentication returns a BRG ID that is already known to the vRGW.

As with the explicit authentication scenario, if the home-specific data includes Alc-Reserved-Addresses attributes defining static home devices, the static devices are authenticated automatically when at least one dynamic device is connected.

The implicit authentication scenario requires the BRG profile to include a RADIUS authentication context defining a RADIUS server policy and a password; see the Configuration section in this chapter for an example.

Connectivity verification and BRG deletion

For the purpose of clearing resources when these resources are not needed anymore, the vRGW performs the BRG connectivity verification and deletion process. When BRG connectivity is considered lost, the BRG and its hosts are deleted automatically.

Parameters controlling the BRG connectivity verification and deletion process are located in the BRG profile context:

```
*A:BNG>config>subscr-mgmt>brg-profile#
   connectivity-verification count 3 timeout 30 retry-time 900
     count <nr-of-attempts>    : [1..5]      — default: 3
     timeout <timeout-seconds>  : [5..60]      — default: 30
     retry-time <retry-seconds> : [300..3600]  — default: 300
   hold-time <seconds> [30..86400]            - default: no hold-time
   initial-hold-time <seconds> [0..900]       - default: 300
```

When the last dynamic host associated with a BRG is deleted, while at the same time connectivity-verification is enabled, the vRGW starts a liveliness test toward the BRG through ICMP (v4 or v6) messages. These messages are sent to either the BRG tunnel source IP address or the BRG RADIUS source IP address. If the BRG has neither of these addresses (for example, because each BRG is managed through a unique VLAN in the implicit authentication scenario), connectivity verification is not executed and only the hold-timer applies. If no answer is returned by the BRG in time (timeout), the vRGW considers the BRG in a failed state, and tries again (retry-time) for some maximum number of times (count).

The vRGW starts the hold-timer when the maximum number of tries is reached, or when connectivity verification is disabled (no connectivity verification). When the hold-timer expires, the BRG context is deleted together with the associated hosts.

The initial-hold-timer is required in the scenario where operators want to use explicit authentication without connectivity-verification, and with no hold-timer defined. In this scenario, defining a non-zero initial-hold-timer value avoids BRG contexts from being deleted immediately after their creation.

If a new dynamic host connects while executing the liveliness test or while the hold-timer or the initial-hold-timer is running, the connectivity verification and BRG deletion process is canceled.

The hold-timer is ignored when manually clearing BRGs and related hosts with the following command.

```
clear subscriber-mgmt brg gateway
    brg-id <brg-ident>
        host <ieee-address>
        all-hosts
        idle-bindings
    all-gateways
```

Configuration

The services configuration shown in Figure 163: Example service configuration for explicit and implicit BRG authentication applies to the examples throughout this chapter. Because the main focus of this chapter is on BRG and home device authentication, the detailed configuration of VPLS 10 containing the capture SAP and of VPRN-2 containing the outside L2-aware NAT range is not repeated here. See the Virtual Residential Gateway Home Pool Management chapter for those configurations.

In summary, VPRN-1 provides the connection toward the customer premises, and hosts the NAT inside addresses. VPRN-2 provides the connection toward the Internet, and hosts the NAT outside addresses. Also, VPRN-3 provides connection to the management interfaces of the BRGs, and is used for the explicit BRG authentication scenario.

Figure 163: Example service configuration for explicit and implicit BRG authentication
Service configuration

An excerpt of the configuration of VPRN-1 follows. The group interface *grp-int-1-1* has RADIUS authentication enabled through authentication policy *radius-AUTH*, and BRG authentication through the default BRG profile *brg-prof-1*.

```
configure
    service
        vprn 1 customer 1 create
            ---snip---
            subscriber-interface "sub-int-1" create
                address 198.51.100.254/24
                address 192.168.1.1/24
                ---snip---
            group-interface "grp-int-1-1" create
                ipv6
                    ---snip---
                    ipoe-bridged-mode
                exit
                ---snip---
                authentication-policy "radius-AUTH"
                ipoe-session
                    ipoe-session-policy "sess-pol-SAP-MAC"
                    sap-session-limit 128
                    no shutdown
                exit
                brg
                    default-brg-profile "brg-prof-1"
                    no shutdown
```

```
                    exit
                    oper-up-while-empty
                exit
            exit
            nat
                inside
                    l2-aware
                        address 192.168.0.1/16
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

BRG profile

The BRG profile *brg-prof-1* is defined in the subscriber management context and provides an SLA profile, a subscriber profile, a DHCP pool, a RADIUS server policy plus the corresponding password, and a RADIUS proxy server.

For explicit BRG authentication, the RADIUS proxy server is used; for implicit BRG authentication, the RADIUS server policy and password defined in the RADIUS authentication context are used.

```
configure
    subscriber-mgmt
        ---snip---
        brg-profile "brg-prof-1" create
            description "default BRG-profile, demo purposes"
            sla-profile-string "sla-prof-1"
            sub-profile-string "sub-prof-1"
            dhcp-pool
                subnet 192.168.1.1/24 start 192.168.1.2 end 192.168.1.254
            exit
            radius-authentication
                password letmein
                radius-server-policy "rad-serv-pol-RSP"
            exit
            radius-proxy-server router 3 name "rad-prox-RPROX"
        exit
    exit
exit
```

RADIUS proxy configuration

VPRN-3 is defined for supporting explicit BRG authentication via a RADIUS proxy. The *int-BRG* interface is on SAP 1/1/1:1, and provides connectivity to the management interface of the physical BRGs. The RADIUS proxy listens on the *int-LB-PROXY* interface, and directs the incoming RADIUS messages to the server, as defined by the default authentication-server policy.

```
configure
    service
        vprn 3
            route-distinguisher 64496:3
            interface "int-LB-PROXY" create
                address 10.33.33.1/32
```

```
                    loopback
                exit
                interface "int-BRG" create
                    address 10.1.0.254/24
                    sap 1/1/1:1 create
                    exit
                exit
                radius-proxy
                    server "rad-prox-RPROX" purpose authentication create
                        default-authentication-server-policy "rad-serv-pol-RSP"
                        interface "int-LB-PROXY"
                        secret vsecret1
                        no shutdown
                    exit
                exit
                no shutdown
            exit
        exit
exit
```

RADIUS policies

The RADIUS authentication and accounting policies are defined as follows, so authentication and accounting happens via the base router instance.

```
configure
    router
        radius-server
            server "radius-172.16.1.2" address 172.16.1.2 secret vsecret1 create
                accept-coa
            exit
        exit
    exit
exit

configure
    aaa
        radius-server-policy "rad-serv-pol-RSP" create
            servers
                router "Base"
                source-address 192.0.2.1
                server 1 name "radius-172.16.1.2"
            exit
        exit
    exit
exit

configure
    subscriber-mgmt
        authentication-policy "radius-AUTH" create
            description "RADIUS authentication policy"
            password letmein
            radius-server-policy "rad-serv-pol-RSP"
        exit
        radius-accounting-policy "radius-ACCT" create
            update-interval 5
            include-radius-attribute
                mac-address
                nat-port-range
                subscriber-id
            exit
```

```
            radius-accounting-server
                source-address 192.0.2.1
                router "Base"
                server 1 address 172.16.1.2 secret vsecret1
            exit
        exit
    exit
exit
```

RADIUS user configuration

Although a PCMP will be used in conjunction with an external controller, for demonstration purposes, this chapter relies on a RADIUS server only.

A sample RADIUS user configuration follows. MAC addresses are used for authentication. MAC address 00:0c:29:00:00:10 identifies the BRG. The addresses ranging from 00:0c:29:00:00:11 to 00:0c:29:00:00:1f identify the home devices connected to that BRG so they all return the same Alc-BRG-Id.

```
00:0c:29:00:00:10       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",
                        Framed-IPv6-Prefix = 2001:db8:101:1010::/64,
                        Alc-DMZ-address = 192.168.1.254,
                        Alc-Home-Aware-Pool =
                                "192.168.1.1/24 192.168.1.100-192.168.1.254",
                        Alc-Reserved-Addresses =
                                "sticky 00:0c:29:00:00:11 192.168.1.110",
                        Alc-Reserved-Addresses +=
                                "static 00:0c:29:00:00:1f 192.168.1.254",
                        Alc-Reserved-Addresses +=
                                "static 00:0c:29:00:00:1e 198.51.100.110",
                        Alc-Portal-Url = "http://11.11.11.11",
                        Alc-Primary-Dns = 1.1.1.1,
                        Alc-Secondary-Dns = 1.1.2.2,
                        Alc-Primary-Nbns = 2.2.1.1,
                        Alc-Secondary-Nbns = 2.2.2.2,
                        Alc-Ipv6-Primary-DNS = 2001:db8:dddd:1::1,
                        Alc-Ipv6-Secondary-DNS = 2001:db8:dddd:2::1,

00:0c:29:00:00:11       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",

00:0c:29:00:00:12       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",

00:0c:29:00:00:13       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",

00:0c:29:00:00:14       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",
                        Alc-Primary-Dns = 1.1.3.3,
```

Debug configuration

The following debug configuration can be used for troubleshooting purposes.

```
debug
    router "Base"
```

```
            radius
                packet-type authentication accounting coa
                detail-level high
            exit
        exit
        router "1"
            ip
                dhcp
                    detail-level medium
                    mode egr-ingr-and-dropped
                exit
                icmp6
            exit
        exit
        router "3"
            radius-proxy
                server "rad-prox-RPROX"
                    detail-level high
                    direction both
                    packet-type access-request access-accept access-reject
                                access-challenge accounting-request
                                accounting-response other
                exit
            exit
        exit
exit
```

Explicit authentication

In the explicit authentication scenario, the BRG is authenticated before any home device attempts to connect. The following trace shows that the RADIUS proxy server in router 3 receives an Access-Request from BRG with BRG ID 00:0c:29:00:00:10, and passes this to the AAA/RADIUS server, which returns the BRG specific data. Two static addresses and one sticky address are associated with this BRG.

```

===============================================================================
*A:BNG#
```

When the first device connects, in this example using DHCPv4 (DORA), this device is authenticated using RADIUS, and the controller returns the corresponding BRG ID and device-specific primary DNS server (messages 7 and 8). Because the BRG has two static addresses associated with it, at the same time these are also authenticated (messages 12 and 15 for the first static host, 13 and 16 for the second static host). The device with MAC address 00:0c:29:00:00:14 has a dedicated primary DNS server, which overrules the primary DNS server defined at BRG level (messages 8, 10, and 14).

No. of BRG hosts: 2
===============================================================================
*A:BNG#
```

As long as the BRG is still alive, these hosts will remain, and so will the BRG context. For that reason, the vRGW might start connectivity verification and eventually delete the BRG and its hosts, depending on the configuration.

The BRG context can also be cleared manually using the following command, after which the BRG and the associated hosts are deleted.

```
*A:BNG# clear subscriber-mgmt brg gateway brg-id "00:0c:29:00:00:10"

*A:BNG# show subscriber-mgmt brg gateway brg-id "00:0c:29:00:00:10" hosts
No entries found.

*A:BNG# show subscriber-mgmt brg gateways
No entries found.
*A:BNG#
```

Implicit authentication

In the implicit authentication scenario, the BRG is authenticated when the first host is authenticated, which requires two phases. In the first phase, the RADIUS server is accessed for authenticating the device (00:0c:29:00:00:11), returning the device-specific data including the BRG ID. In the second phase, the RADIUS server is accessed for authenticating the BRG (00:0c:29:00:00:10), returning the home-specific data. Because the RADIUS server returns two reserved static addresses, SR OS additionally authenticates the static devices.

----------------------------------------------------------------------
No. of BRG hosts: 4
======================================================================
*A:BNG#
```

Releasing both dynamic devices results in all BRG hosts being deleted, including the static hosts.

```
*A:BNG# show subscriber-mgmt brg gateway brg-id "00:0c:29:00:00:10" hosts
No entries found.
*A:BNG#
```

Also, the BRG is deleted automatically.

```
*A:BNG# show subscriber-mgmt brg gateways
No entries found.
*A:BNG#
```

Conclusion

This chapter describes the explicit and the implicit authentication models for the BRG. The explicit authentication model requires the BRG to contain an embedded RADIUS client, and offers better security in comparison with the implicit model, which does not require an embedded RADIUS client.

Virtual Residential Gateway Home LAN Extension

This chapter describes the home LAN extension of the Virtual Residential Gateway.

Topics in this chapter include:

Applicability

The information and configuration in this chapter are based on SR OS Release 15.0.R6. Hardware that supports the Wireless LAN Gateway (WLAN-GW) must be used (ISA1/ISA2 cards).

Overview

With Virtual Residential Gateway (vRGW), all L3 routing and services (DHCP server, NAT, firewall, Application Assurance (AA), and so on) are moved out of the home CPE to the service provider network.

The home CPE (known as Bridged Residential Gateway (BRG)) runs in a bridged mode and acts as an L2 switch between all connected home devices and the vRGW. Therefore, in-home traffic will be switched locally while other traffic will be sent to the vRGW.

However, there are some services/applications implemented on the cloud (for example, Data Center (DC)) that need to appear as if they are on the same home LAN and need L2 bridged access, so they need a Home LAN Extension (HLE).

Examples:

- Digital Living Network Alliance (DLNA) server in the cloud for media streaming

- Storage server in the cloud, discoverable via Server Message Block (SMB) protocol

HLE provides the capability to deploy new services in a DC that require L2 reachability to the home and being reachable on L2 to each individual host at home.

A unique per-home Bridge Domain (BD) is created on the WLAN-GW ISA1/ISA2. This acts as an L2 switch before any IP routing functionality is performed.

By using BGP-EVPN VPLS services, a BD is extended via a Virtual Extensible Local Area Network (VXLAN) tunnel to a virtual machine (VM) in a DC. Access from the home CPE can be a soft-GRE or an L2 Tunnel Protocol version 3 (L2TPv3) tunnel or Native VLAN terminated on the WLAN-GW group ISA via L2 Access Point (L2-AP). The HLE network side relies on MP-BGP for the control plane, whereas the data plane is based on VXLAN; see Figure 164: vRGW-HLE.

Figure 164: vRGW-HLE
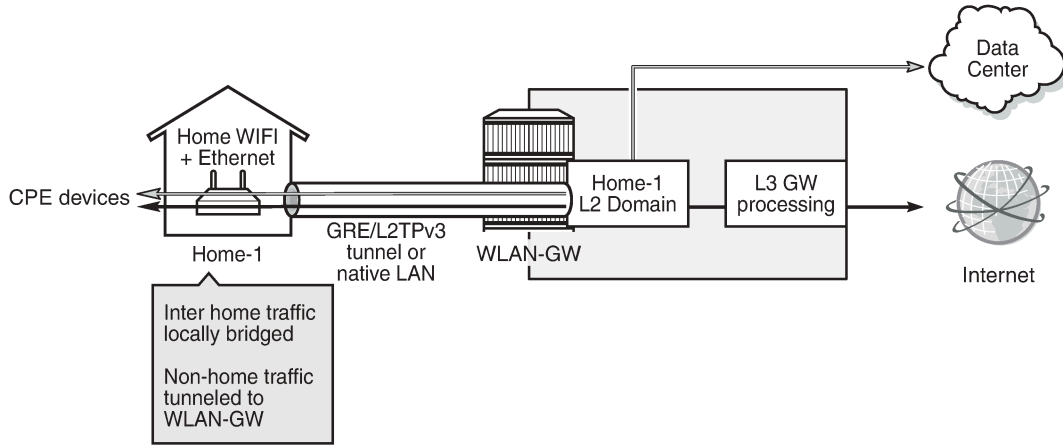

Bridge Domain Characteristics

The BD bridges traffic between the following connections:

- access-facing connection (for example, home) - GRE/L2TPv3/L2-AP
- network-facing connection (for example, DC) - VXLAN tunnel
- ESM SAP-facing connection - each home has its own ESM SAP

Figure 165: BD Connections in the Data Plane shows the BD connections in the data plane.

Figure 165: BD Connections in the Data Plane
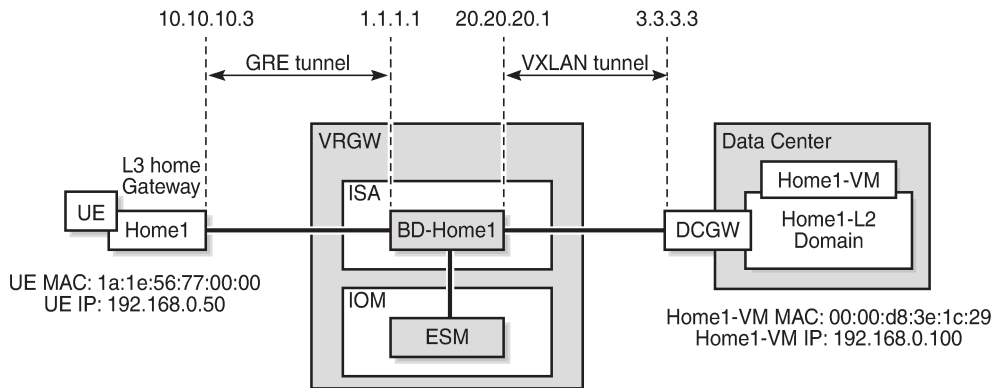

With HLE services, each home host constitutes a WLAN-GW User Equipment (UE) object and an ESM host object. Each network host (such as a VM in a DC) constitutes a WLAN-GW UE object but not an ESM host.

Each BD maintains the following tables:

- MAC table: this table contains the learned MAC address by access and network connections

- flood table: this table contains flood destinations for broadcast, unknown unicast, multicast (BUM) traffic; these are typically the access and network connections

- IPv4 ARP table: this table contains learned ARP entries by access and network connections. The ARP and neighbor tables are populated when Assistive Address Resolution (AAR) is enabled (see the Assistive Address Resolution section for more information).

- IPv6 neighbor table: this table contains learned neighbor entries by access and network connections.

Configuration

vRGW Configuration

The following prerequisite configurations are based on vRGW, in the order to be created.

WLAN-GW Group

```
configure wlan-gw-group <wlan-gw-group-id> [create] [redundancy <unit>]

 <wlan-gw-group-id>   : [1..4]
 <create>             : keyword
 <unit>               : iom|mda

configure
    isa
        wlan-gw-group 1 create redundancy mda
            active-mda-limit 1
            mda 3/1
            no shutdown
        exit
    exit
exit
```

RADIUS Policies

ISA RADIUS Policy

```
configure
    aaa
        isa-radius-policy "isa-rad-pol-1" create
            password nokia
            servers
                router "Base"
                source-address-range 44.44.44.44
                server 1 create
                    authentication
                    coa
                    ip-address 192.77.77.2
                    secret Nokia123
```

```
                    no shutdown
                exit
            exit
        exit
    exit
exit
```

RADIUS Server Policy

```
configure
    router
        radius-server
            server "FreeRadius" address 192.77.77.2 secret Nokia123 create
                accept-coa
            exit
        exit
    exit
exit
```

```
configure
    aaa
        radius-server-policy "rad-serv-pol-1" create
            servers
                router "Base"
                source-address 10.10.10.4
                server 1 name "FreeRadius"
            exit
        exit
    exit
exit
```

RADIUS Accounting Policy

```
configure
    subscriber-mgmt
        radius-accounting-policy "rad-acc-pol-1" create
            ---snip---
            radius-server-policy "rad-serv-pol-1"
        exit
    exit
```

L2-Aware NAT

```
configure
    service
        vprn 333 customer 1 create
            nat
                inside
                    l2-aware
                        address 192.168.0.101/24
                    exit
                exit
                outside
                    pool "nat-pool-1" nat-group 1 type l2-aware create
```

```
                                    port-reservation blocks 1
                                    address-range 120.1.0.1 120.1.0.100 create
                                    exit
                                    no shutdown
                            exit
                        exit
                    exit
            exit
            nat
                nat-policy "nat-pol-1" create
                    pool "nat-pool-1" router 333
                exit
            exit
        exit
exit
```

Subscriber Management Parameters

```
configure
    subscriber-mgmt
        authentication-policy "auth-pol-1" create
        exit
        sla-profile "sla-prof-def" create
        exit
        sub-profile "sub-prof-def" create
            nat-policy "nat-pol-1"
            radius-accounting
                policy "rad-acc-pol-1"
            exit
        exit
        sub-ident-policy "sub-ident-pol-def" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
    exit
exit
```

BRG Profile

```
configure
    subscriber-mgmt
        vrgw
            brg
                brg-profile "brg-prof-1" create
                    dhcp-pool
                        subnet 192.168.0.1/24 start 192.168.0.50 end 192.168.0.99
                    exit
                    radius-authentication
                        password nokia
                        radius-server-policy "rad-serv-pol-1"
                    exit
                exit
            exit
        exit
```

```
    exit
exit
```

vRGW BRG Service

A service can be either an IES or a VPRN; in this example, a VPRN is shown.

```
*A:SR7-CMPT-vRGW# configure service vprn 333
*A:SR7-CMPT-vRGW>config>service>vprn# info
----------------------------------------------
                route-distinguisher 333:333
                subscriber-interface "sub-int-1" create
                    allow-unmatching-subnets
                    address 192.168.1.1/24
                    group-interface "grp-int-1" wlangw create
                        sap-parameters
                            sub-sla-mgmt
                                def-sla-profile "sla-prof-def"
                                def-sub-id use-auto-id
                                def-sub-profile "sub-prof-def"
                                sub-ident-policy "sub-ident-pol-def"
                            exit
                        exit
                        dhcp
                            proxy-server
                                emulated-server 192.168.1.1
                                no shutdown
                            exit
                            trusted
                            lease-populate 1000
                            gi-address 192.168.1.1
                            no shutdown
                        exit
                        authentication-policy "auth-pol-1"
                        wlan-gw
                            gw-address 1.1.1.1
                            learn-ap-mac
                            router "Base"
                            wlan-gw-group 1
                            l2-access-points
                                l2-ap 4/2/1 create
                                    encap-type dot1q
                                    no shutdown
                                exit
                            exit
                            vlan-tag-ranges
                                range default
                                    authentication
                                        authentication-policy "isa-rad-pol-1"
                                    exit
                                    authenticate-on-dhcp
                                    vrgw
                                        brg
                                            default-brg-profile "brg-prof-1"
                                            no shutdown
                                        exit
                                    exit
                                exit
                            exit
                            no shutdown
                        exit
```

```
                    exit
                exit
                nat
                    ---snip---
                exit
                no shutdown
    --------------------------------------------
```

BGP Configuration

Because HLE is based on BGP-EVPN, the operator needs to configure BGP with address family EVPN and define the corresponding neighbors, where a neighbor can, for example, be a Nuage Virtualized Service Controller (VSC) in a DC, a DC Gateway (DCGW), or a Route Reflector (RR) to avoid full mesh iBGP between iBGP speakers.

```
configure
    router
        bgp
            min-route-advertisement 1
            rapid-withdrawal
            rapid-update evpn
            group "EVPN"
                family vpn-ipv4 evpn
                type internal
                neighbor 10.10.10.3
                exit
            exit
            no shutdown
        exit
    exit
exit
```

HLE RADIUS Attributes and User Configuration

Each BD has a unique ID, which is an integer returned by the RADIUS server as the mandatory attribute [241.26.6527.9] **Alc-Bridge-Id** during BRG and device authentication. The returned value must be equal on both authentication levels.

The Alc-Bridge-Id is the ID of the per-subscriber BD on the ISA. It is different from the Alc-BRG-ID, which is the ID of the BRG.

Optional attributes can be returned by the RADIUS server during BRG authentication, which are used for BGP-EVPN VPLS to extend the BD to the remote network in the DC:

- HLE BGP-EVPN route target (RT): [241.26.6527.14] **Alc-RT**, which defines which BD the route belongs to. If not returned, the system defines the RT as "target:<configured_lanext_as>:<Alc-Bridge-Id>". Configuring LANEXT AS will be covered in the VXLAN/EVPN Parameters section later in this chapter.

- HLE BGP-EVPN route distinguisher (RD): [241.26.6527.15] **Alc-RD**; if not returned, the system defines the RD as "<configured_lanext_as>:<Alc-Bridge-Id>"

- HLE BGP-EVPN VXLAN VNI: [241.26.6527.10] **Alc-Vxlan-VNI** (VXLAN Virtual Network Identifier), which is encoded in the MPLS label field in the EVPN routes, and is used to demux the VXLAN packet into the correct BD. If not returned, the system automatically assigns a VNI.

Examples for user entries on RADIUS server (FreeRadius) follow:

Device (Host) authentication

```
1a:1e:56:55:00:00  Cleartext-Password := "nokia"
        Alc-Subsc-ID-str := "BRG-ID-5",
        Alc-Bridge-Id := 555
```

Home (BRG) authentication

```
BRG-ID-5  Cleartext-Password := "nokia"
        Alc-Bridge-Id := 555,
        Alc-RT := target:100:555,
        Alc-RD := 100:555,
        Alc-Vxlan-VNI := 3
```

For accounting, in addition to the previous attributes, the operator can add the following attribute into accounting messages sent to the accounting server:

[241.26.6527.28] **Alc-HLE-Device-Type** to indicate the type of HLE host; the value is fixed to " home".

An example RADIUS accounting policy including LANEXT attributes follows:

```
configure
    subscriber-mgmt
        radius-accounting-policy "rad-acc-pol-1" create
            ---snip---
            include-radius-attribute
                ---snip---
                lanext-bridge-id
                lanext-device-type
                lanext-route-distinguisher
                lanext-route-target
                lanext-vni
                ---snip---
            exit
            radius-server-policy "rad-serv-pol-1"
        exit
    exit
exit
```

VXLAN/EVPN Parameters

```
A:WLANGW# configure router vrgw lanext
  - lanext
 [no] vxlan-port      - Configure the remote VXLAN UDP port
 [no] vxlan-vtep-ran* - Configure a range of VXLAN VTEP addresses
 [no] wlan-gw-group   - Configure the ISA WLAN Gateway group
 [no] shutdown        - Enable/disable the Home LAN Extension functionality
```

Where:

```
  - vxlan-port <4789|8472>                   # default is 4789
  - vxlan-vtep-range start <ip-address|ipv6-address> end <ip-address|ipv6-address>
  - wlan-gw-group <wlan-gw-group-id>       # value configured in previous step
```

Example:

```
configure
```

```
      router
          vrgw
              lanext
                  vxlan-vtep-range start 20.20.20.1 end 20.20.20.20
                  wlan-gw-group 1
                  no shutdown
              exit
          exit
      exit
exit
```

HLE is enabled on the Base routing instance.

As mentioned, RT is derived from the target:LANEXT_AS:bridge-id.

The LANEXT Autonomous System (AS) number can be configured in the following context:

```
A:WLANGW# configure subscriber-mgmt vrgw lanext router-target-as-number
  - router-target-as-number <as-number>

 <as-number>          : [1..65535]
```

Example:

```
configure
    subscriber-mgmt
        vrgw
            lanext
                router-target-as-number 100
            exit
        exit
    exit
exit
```

If the router AS number is not configured on the WLAN-GW, it must be returned from RADIUS in both Alc-RT & Alc-RD attributes during BRG authentication; otherwise, the host DHCP fails and the system shows the following error message in log 99.

```
53 2018/01/03 15:48:53.236 PST WARNING: DHCP #2005 vprn333 Lease State Population
Error
"Lease state table population error on SAP 3/1/nat-out-ip:2145.22 in service 333 - Could not
 link IPoE session (3/1/nat-out-ip:2145.22 - 1a:1e:56:77:00:00) with BRG BRG-ID-7: Router AS
 number is not configured"
```

BD-related Settings

On the group-interface level, the overall number of allowed BDs created can be limited. By default, the limit is zero, but it can be set between 1 and 131 071.

```
A:WLANGW>config>service>vprn>sub-if>grp-if>wlan-gw# max-lanext-bd
  - max-lanext-bd <[1..131071]>
```

When HLE is enabled (under the VLAN vRGW LANEXT hierarchy) and **max-lanext-bd** on the group-interface level is zero, the following error message is displayed when the WLAN-GW is enabled in the **group-interface** context:

```
*A:WLANGW>config>service>vprn>sub-if>grp-if>wlan-gw# no shutdown
```

```
MINOR: SVCMGR #8456 The group-interface's max-lanext-bd must be greater than 0 to enable lanext
 in the VLAN range - VLAN range 4096-4096
```

If the number of BDs reaches that limit, the following message is displayed in log 99:

```
114 2018/01/03 16:04:14.215 PST WARNING: DHCP #2029 Base Miscellaneous DHCP Problem
"Failed to create bridge domain: max-lanext-bd limit reached - Bridge ID: 555, MAC:
 1a:1e:56:55:00:00"
```

BD Access-Side Settings

The **max-mac** parameter in the **access** context is used to limit the number of MAC addresses learned from home devices:

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# access
  - access

 [no] max-mac        - Configure maximum number of MAC entries in bridged domain
 [no] multi-access   - Allow multiple access
```

The **max-mac** ranges between 1 and 128, with a default value of 20.

The **multi-access** parameter is used for Multi-Dwelling Unit (MDU) scenarios.

To override the default parameters, the vRGW LANEXT hierarchy should be in the shutdown state; an error is raised when trying to configure these parameters when LANEXT is enabled.

```
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext>access# max-mac 128
MINOR: SVCMGR #8452 Not allowed when lanext is no shut

*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext>access# multi-access
MINOR: SVCMGR #8452 Not allowed when lanext is no shut
```

BD Network-Side Settings

The **max-mac** parameter in the **network** context is used to limit the number of MAC addresses learned from EVPN/DC.

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# network
  - network

 [no] max-mac        - Configure maximum number of VM MAC entries in bridged domain
 [no] shutdown       - Enable/disable data center connections
```

The **max-mac** ranges between 1 and 64, with a default value of 20. LANEXT is by default enabled (no shutdown).

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext>network# max-mac
<[1..64]>
```

The operator can shut down the network side to disable the connection to the DC.

To override the default configuration, LANEXT should be shut down, as follows:

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext>network# max-mac 64
```

```
MINOR: SVCMGR #8452 Not allowed when lanext is no shut

*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext>network# shutdown
MINOR: SVCMGR #8452 Not allowed when lanext is no shut
```

Finally, the LANEXT functionality is enabled under the following context:

```
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext#
[no] shutdown          - Enable/disable the Home LAN Extension functionality
```

ARP/ND Handling and MAC Advertisement Optimizations

Assistive Address Resolution

AAR is an optional HLE feature used to avoid sending ARP/ND requests from the home across a WAN to a remote network, or sending ARP/ND requests from the remote network across an access network to a home. The system responds to the ARP/ND request from the network or home with the learned ARP/ND entries, instead of flooding them.

With AAR enabled, the system populates the ARP and neighbor tables with the learned ARP and neighbor entries via either:

- BGP EVPN MAC routes that contain an IP address, or
- (G)ARP/ND/NS packets

AAR Disabled

AAR is disabled by default. With AAR disabled, the ARP request is flooded from one side to the other; see Figure 166: ARP Requests Flooded with AAR Disabled. The BD ARP table will only be populated for the GW address and any IP/MAC learned via BGP EVPN MAC routes that contain an IP address.

Figure 166: ARP Requests Flooded with AAR Disabled
AAR Enabled

To enable AAR, **assistive-address-resolution** is configured in the **lanext** context, as follows:

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext#
[no] assistive-addr* - Enable/disable assistive address resolution in bridged domains
```

AAR can only be enabled when **lanext** is shut down, as follows:

```
A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# assistive-address-resolution
MINOR: SVCMGR #8452 Not allowed when lanext is no shut
```

In Figure 167: No ARP Request Flooding with AAR Enabled, when an ARP request is received, the ISA performs a lookup in the ARP table with the IP address as a key, and if found, it answers without flooding to the other side.

Figure 167: No ARP Request Flooding with AAR Enabled
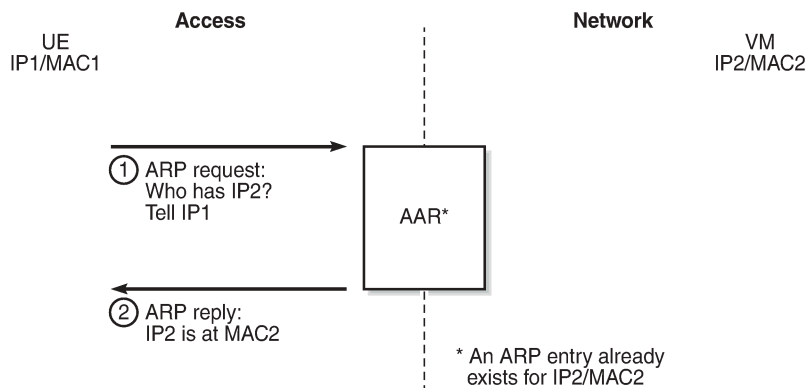

MAC Address Translation

MAC Address Translation (MAT) is an optional HLE feature that translates the host MAC address of a subscriber into a single BD MAC address. This feature decreases the number of BGP EVPN MAC routes to advertise per subscriber to one, and prevents BGP sending update messages when hosts are created and removed, which increases BGP stability.

MAT is performed on traffic in both directions:

- traffic from access to network - the system changes the source MAC address to BD MAC address, as shown in Figure 168: MAT - Access to Network Direction.

Figure 168: MAT - Access to Network Direction
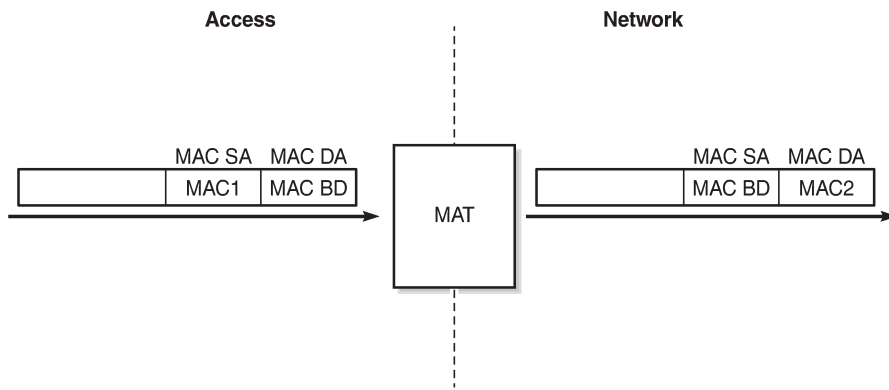

• traffic from network to access - the system changes the destination MAC address (BD MAC) to the real host MAC address based on the ARP table or neighbor table lookup using the IP address as key, as shown in Figure 169: MAT - Network to Access Direction.

Figure 169: MAT - Network to Access Direction
MAT is disabled by default. MAC is enabled by configuring **mac-translation** and **bd-mac-prefix** under the **lanext** context, as follows.

```
*A:SR7-CMPT-vRGW>grp-if>wlan-gw>ranges>range>vrgw>lanext#
 [no] assistive-addr* - Enable/disable assistive address resolution in bridged domains
 [no] bd-mac-prefix   - Configure MAC translation prefix in bridged domains
 [no] mac-translation - Enable/disable MAC translation in bridged domains
```

To configure MAT, the following conditions apply:

• Assistive address resolution must be enabled

```
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# no shutdown
MINOR: SVCMGR #8455 mac-translation requires assistive-address-resolution
```

- **lanext** context must be shut down

```
A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# mac-translation
MINOR: SVCMGR #8452 Not allowed when lanext is no shut
```

- BD-MAC-Prefix must be configured

```
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# shutdown
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# mac-translation
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext# no shutdown
MINOR: SVCMGR #8454 mac-translation requires a bd-mac-prefix to be set
*A:WLANGW>grp-if>wlan-gw>ranges>range>vrgw>lanext#
```

When MAT is configured, the BD ARP table will use a system-generated MAC address with MAC prefix as the configured BD-MAC-prefix, instead of the group-interface MAC address for the default GW entry.

This MAC address will be advertised toward the network as a BGP EVPN MAC route (route type 2), and used for MAC translation, as shown in Figure 168: MAT - Access to Network Direction and Figure 169: MAT - Network to Access Direction.

> **Note:**
> - When MAT is disabled (default), ARP replies contain the real MAC address, in case there is an existing entry in the ARP table; otherwise, the ARP requests are flooded to the other side. Data traffic will contain the real MAC destination address (DA).
> - When MAT is enabled, ARP replies use the BD MAC address in both directions. No MAC routes from the host side are learned at the network side. Data traffic will contain the BD MAC DA.
> - For two hosts within the same BD, and for traffic in the network to access direction, the ISA does a lookup for ARP entries with the IP DA as a key. If the IP DA is found, the MAC DA is replaced by the MAC DA of the corresponding host.

Table 38: ARP/MAT/BD-MAC-Prefix Possible Combinations shows possible combinations for ARP/MAT/BD-MAC-Prefix, where Combo1 is the default combination.

Table 38: ARP/MAT/BD-MAC-Prefix Possible Combinations

vRGW lanext	Combo1	Combo2	Combo3	Combo4	Combo5
assistive-address-resolution	Disabled	Disabled	**Enabled**	**Enabled**	**Enabled**
bd-mac-prefix	Disabled	**Enabled**	Disabled	**Enabled**	**Enabled**
mac-translation	Disabled	Disabled	Disabled	Disabled	**Enabled**

Show Commands

The following command displays BD info, or a specific BD:

```
show subscriber-mgmt vrgw lanext bd [<bridge-id>]

A:WLANGW# show subscriber-mgmt vrgw lanext bd 555

Tools Commands

The following lists **tools** commands dump info regarding BD data plane tables, as well as BD statistics:

```
*A:WLANGW# tools dump wlan-gw lanext bd
  - bd <bridge-id>

      arp-table      - Dump bridge domain ARP table
      flood-table    - Dump bridge domain flood table
      mac-table      - Dump bridge domain MAC table
      neighbor-table - Dump bridge domain neighbor table
      statistics     - Dump bridge domain statistics
```

The following **tools** command is used to clear ARP/MAC/Neighbor table entries, as well as BD statistics:

```
*A:WLANGW# tools perform wlan-gw lanext bd
  - bd <bridge-id>

      clear-arp      - Clear bridge domain ARP table
      clear-mac      - Clear bridge domain MAC table
      clear-neighbor - Clear bridge domain neighbor table
      clear-statisti* - Clear bridge domain statistics
```

ARP Table

The following **tools** command shows the ARP table when AAR is disabled and ARP requests are flooded when the ARP table does not contain an entry for the IP DA:

```
A:WLANGW# tools dump wlan-gw lanext bd 777 arp-table

===============================================================================
Matched 2 ARP entries for Bridge Domain 777 on Slot #3 MDA #1
===============================================================================

```

Where:

- Upstream direction means traffic coming from the DC or home going toward the BD.

- Downstream direction means traffic coming from the Internet toward the BD.

Conclusion

This chapter describes HLE based on vRGW and BGP EVPN to extend home LAN to DC VMs via VXLAN, for different access models (softGRE and VLAN L2-AP).

Virtual Residential Gateway Home Pool Management

This chapter describes virtual residential gateway home pool management.

Topics in this chapter include:

* Applicability
* Overview
* Configuration
* Conclusion

Applicability

The information and configuration in this chapter are applicable to SR OS Release 14.0.R3.

Overview

In the virtual residential gateway model, the Layer 3 (L3) functions are moved out of the traditional residential gateway (RGW) and into the network; see Figure 170: Virtual Residential Gateway in the Network with Bridged Residential Gateway at Home. Examples of L3 functions moved to the network are:

* DHCPv4
* Network Address Translation (NAT)
* Firewalling
* Universal Plug and Play

The in-home equipment interconnecting all devices in the home is referred to as the bridged residential gateway (BRG). The BRG only handles Layer 2 (L2) connectivity (for example, Ethernet and WiFi) and is always operating in bridged mode. The BRG has an L2 uplink connecting it to the virtual residential gateway (vRGW), either through a direct link or through tunneling technology. The vRGW handles all L3 connectivity.

For the vRGW to offer IPv4 connectivity to the devices in the home network, the vRGW provides the following features:

* Private addresses from a single home address pool are offered. The address pools can overlap between homes.
* Sticky or static addresses provide a fixed device to IP mapping.
* Public addresses can be assigned, to enable home servers to be publicly accessible.
* A demilitarized (DMZ) host can be defined.

Because multiple homes are allowed to use the same private subnet, the vRGW requires L2-aware NAT. L2-aware NAT is handled in the "L2-aware NAT (with dNAT and MNPs)" chapter in *7450 ESS, 7750 SR, and VSR Multiservice ISA and ESA Advanced Configuration Guide for Classic CLI*.

For the vRGW to offer IPv6 connectivity to the devices in the home network, the vRGW provides the following features:

- A /64 SLAAC prefix is assigned per home.

- IA_NA address allocation using DHCPv6 relay or proxy is supported, following standard ESM rules.

- Prefix Delegation (PD) is not supported.

Using the vRGW model, the ISP now has visibility on the MAC and IP addresses used by the in-home devices.

Figure 170: Virtual Residential Gateway in the Network with Bridged Residential Gateway at Home
DHCP and IP Address Management

The vRGW has the following characteristics for DHCPv4:

- One pool per home

- IP overlap between homes

- Sticky IP addresses

Sticky IP addresses are DHCPv4 addresses assigned to devices that need to have the same address all the time and are provided through the DHCP protocol. Home servers, network-attached storage (NAS), and network printers are examples of devices that typically are configured with sticky IP addresses. The vRGW sets a flag indicating that the IP address is reserved, to avoid assigning the sticky address to devices that do not have this requirement.

Static IP addresses can be used and configured for devices that do not use or support the DHCP protocol, and are configured manually on the device. The static IP address used can be a public or a private address. Traffic to and from private addresses undergoes NAT, whereas traffic to and from public addresses does not undergo NAT. The vRGW drops DHCP messages originating from devices that are considered to be static.

The vRGW requires the use of IPoE sessions for supporting BRGs, and creates an IPoE session per device. Static devices require at least one dynamic host to be created first so that the associated SAP or tunnel can be defined to send traffic over. Each static device is authenticated individually using RADIUS to retrieve the per-device parameters.

The vRGW has the following characteristics for IPv6:

- Both SLAAC and IA_NA allocation are supported.

- Static IPv6 addresses are not supported. However, a static IPv4 device can get an IPv6 SLAAC prefix if IPoE-linking is enabled.

- No per-home pool is supported for IA_NA, but DHCPv6 can be relayed to an external or local DHCPv6 server.

The vRGW only operates in IPoE bridged mode, so that multiple hosts on the same BRG share the same SLAAC/64 prefix. Only one SLAAC prefix per BRG is supported.

Prefix delegation (PD) is not supported in the vRGW.

Demilitarized Zone (DMZ)

When a DMZ host is specified within a home, all downstream traffic not matching an existing flow or port forwarding rule is sent to that host. Without a DMZ host, this traffic is dropped. DMZ requires a single port-reservation block to be defined on the outside L2-aware NAT range.

Configuration

The services configuration overview shown in Figure 171: Services Configuration Overview applies to the examples used throughout this chapter. For L2-aware NAT, two routed services are configured. In this example, VPRN-1 provides the connection toward the customer premises, and hosts the NAT inside addresses. VPRN-2 provides the connection toward the Internet, and hosts the NAT outside addresses. Addresses from the documentation range as defined in RFC 5737 are used for the public addresses.

The examples in this chapter use capture and managed SAPs. The capture SAP is created manually on VPLS-10, and the managed SAPs are created dynamically on VPRN-1. Also, static SAPs can be used to support BRGs, but in that case the configuration file can grow rapidly when many SAPs are required.

Figure 171: Services Configuration Overview

Services Configuration

An excerpt of the configuration of VPRN-1 follows. This VPRN contains subscriber interface *sub-int-1* with group interface *grp-int-1-1*, thereby using the routed central office (CO) model. No static SAPs are configured; managed SAPs will be created when triggers are received on VPLS-10. The IPoE session policy required for the vRGW is *sess-pol-SAP-MAC*, and the default BRG profile used is *brg-prof-1*.

Relay and proxy scenarios are configured for DHCPv4 and DHCPv6. SLAAC prefixes are taken from the wan-host prefix range, and must be advertised to devices using router-advertisement (RA) messages in response to router-solicit (RS) messages. For that purpose, group interface *grp-int-1-1* is configured in its IPv6 context to support router advertisement and router solicitation. Also IPoE bridged mode is enabled in this context, so that the same SLAAC prefix can be allocated multiple times to the same SAP.

RADIUS authentication is enabled through authentication policy *radius-AUTH*. The inside L2-aware NAT range is 192.168.0.1/16, and the DHCP pool subnets defined in the BRG profile must belong to that range; see the ESM Configuration part in this chapter.

                exit
            exit
            nat
                inside
                    l2-aware
                        address 192.168.0.1/16
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

VPRN-2 defines an interface to the outside world, *int-VPRN2-INTERNET*, as well as the outside L2-aware
NAT range, which is 203.0.113.1 up to 203.0.113.10. Port-reservation blocks is set to 1, to ensure a unique
outside IP per subscriber (home) and correct operation of the DMZ feature.

```
configure
    service
        vprn 2 customer 1 create
            route-distinguisher 64496:2
            interface "int-VPRN2-INTERNET" create
                ---snip---
            exit
            nat
                outside
                    pool "nat-outside-1" nat-group 1 type l2-aware create
                        port-reservation blocks 1
                        address-range 203.0.113.1 203.0.113.10 create
                        exit
                        no shutdown
                    exit
                exit
            exit
            no shutdown
        exit
    exit
```

```
            exit
```

VPLS-10 defines the capture SAP on port 1/1/1. The triggers configured are dhcp, dhcp6, and rtr-solicit.
The authentication policy and the IPoE session policy used are the same as the ones used on VPRN-1,
and are *radius-AUTH* and *sess-pol-SAP-MAC*, respectively. The MSAP defaults indicate that the managed
SAPs must be created on service 1, group interface *grp-int-1-1*, using MSAP policy *msap-pol-MSAP*.

```
configure
    service
        vpls 10 customer 1 create
            description "VPLS for capture SAPs - BRG-demo"
            stp
                shutdown
            exit
            sap 1/1/1:* capture-sap create
                description "capture SAP for MSAP creation on 1/1/1"
                trigger-packet dhcp dhcp6 rtr-solicit
                ipoe-session
                    ipoe-session-policy "sess-pol-SAP-MAC"
                    no shutdown
                exit
                msap-defaults
                    group-interface "grp-int-1-1"
                    policy "msap-pol-MSAP"
                    service 1
                exit
                authentication-policy "radius-AUTH"
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

RADIUS User Configuration

Although a protocol conversion and mediation platform (PCMP) will be used in conjunction with an external
controller, for demonstration purposes this chapter relies on a RADIUS server only.

A sample RADIUS user configuration follows. The user's MAC address is used for authenticating
purposes. MAC address 00:0c:29:00:00:10 identifies the BRG. The addresses ranging from
00:0c:29:00:00:11 to 00:0c:29:00:00:1f identify the home devices connected to the same BRG so they
all return the same Alc-BRG-Id. For the BRG, RADIUS provides primary and secondary DNS and NBNS
servers, a set of reserved addresses, a DMZ address, a framed IPv6 prefix (used for SLAAC), a home-
aware pool, and the BRG profile. The home pool subnet must be a subnet of the L2-aware inside subnet.

```
00:0c:29:00:00:10       Cleartext-Password := "letmein"
                        Alc-BRG-Id = "00:0c:29:00:00:10",
                        Alc-BRG-Profile = "brg-prof-1",
                        Framed-IPv6-Prefix = 2001:db8:101:1010::/64,
                        Alc-DMZ-address = 192.168.1.254,
                        Alc-Home-Aware-Pool =
                                "192.168.1.1/24 192.168.1.100-192.168.1.254",
                        Alc-Reserved-Addresses =
                                "sticky 00:0c:29:00:00:11 192.168.1.110",
                        Alc-Reserved-Addresses +=
                                "static 00:0c:29:00:00:1f 192.168.1.254",
                        Alc-Reserved-Addresses +=
```

```
                                "static 00:0c:29:00:00:1e 198.51.100.110",
                    Alc-Portal-Url = "http://11.11.11.11",
                    Alc-Primary-Dns = 1.1.1.1,
                    Alc-Secondary-Dns = 1.1.2.2,
                    Alc-Primary-Nbns = 2.2.1.1,
                    Alc-Secondary-Nbns = 2.2.2.2,
                    Alc-Ipv6-Primary-DNS = 2001:db8:dddd:1::1,
                    Alc-Ipv6-Secondary-DNS = 2001:db8:dddd:2::1,

00:0c:29:00:00:11       Cleartext-Password := "letmein"
                    Alc-BRG-Id = "00:0c:29:00:00:10",

00:0c:29:00:00:14       Cleartext-Password := "letmein"
                    Alc-BRG-Id = "00:0c:29:00:00:10",
                    Alc-Primary-Dns = 1.1.3.3,
---snip---
```

The RADIUS server is allowed to return a SLAAC pool name using the **Alc-SLAAC-IPv6-Pool** attribute, but in that case local address assignment needs to be configured on the vRGW. See the ESM SLAAC Prefix Assignment via Local Address Server chapter for more information.

ESM Configuration

The subscriber management policies and profiles are defined as follows. The BRG profile *brg-prof-1* provides an SLA profile, a sub-profile, a RADIUS server policy, plus the corresponding password, a RADIUS proxy server, and a DHCP pool. The DHCP pool is within the inside L2-aware NAT range defined for VPRN-1.

```
configure
    subscriber-mgmt
        ipoe-session-policy "sess-pol-SAP-MAC" create
        exit
        sla-profile "sla-prof-1" create
        exit
        sub-profile "sub-prof-1" create
            nat-policy "nat-pol-1"
        exit
        sub-ident-policy "sub-ident-DIRECT" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
        msap-policy "msap-pol-MSAP" create
            sub-sla-mgmt
                def-sub-id use-sap-id
                def-sub-profile "sub-prof-1"
                def-sla-profile "sla-prof-1"
                sub-ident-policy "sub-ident-DIRECT"
            exit
        exit
        brg-profile "brg-prof-1" create
```

```
            description "default BRG-profile, demo purposes"
            sla-profile-string "sla-prof-1"
            sub-profile-string "sub-prof-1"
            dhcp-pool
                subnet 192.168.1.1/24 start 192.168.1.2 end 192.168.1.254
            exit
            radius-authentication
                password letmein
                radius-server-policy "rad-serv-pol-RSP"
            exit
        exit
    exit
exit
```

The RADIUS authentication and accounting policies are defined as follows.

```
configure
    router
        radius-server
            server "radius-172.16.1.2" address 172.16.1.2 secret vsecret1 create
                accept-coa
            exit
        exit
    exit
exit

configure
    aaa
        radius-server-policy "rad-serv-pol-RSP" create
            servers
                router "Base"
                source-address 192.0.2.1
                server 1 name "radius-172.16.1.2"
            exit
        exit
    exit
exit

configure
    subscriber-mgmt
        authentication-policy "radius-AUTH" create
            description "Radius authentication policy"
            password letmein
            radius-authentication-server
                source-address 192.0.2.1
            exit
            radius-server-policy "rad-serv-pol-RSP"
        exit
        radius-accounting-policy "radius-ACCT" create
            update-interval 5
            include-radius-attribute
                mac-address
                nat-port-range
                subscriber-id
            exit
            radius-accounting-server
                source-address 192.0.2.1
                router "Base"
                server 1 address 172.16.1.2 secret vsecret1
            exit
        exit
    exit
exit
```

NAT Policy configuration

The NAT policy used in support for the BRGs is *nat-pol-1*, and refers to the outside address pool defined in VPRN-2.

```
configure
    service
        nat
            nat-policy "nat-pol-1" create
                pool "nat-outside-1" router 2
            exit
        exit
    exit
exit
```

Operation and Verification

The following command shows the current BRG hosts. Six hosts are connected. The first host has a sticky address, the third a plain dynamic address, the fifth a public static address, and the last a private static address. The second and the fourth hosts correspond to the SLAAC hosts, and their allocation type is "not-applicable". For the static hosts, no DHCP lease information is maintained.

```
*A:BNG# show subscriber-mgmt brg brg-hosts

No. of BRG hosts: 6
===============================================================================
*A:BNG#
```

The following command shows the active BRGs. Because all the hosts from the previous command
belong to the same BRG, only a single BRG gateway exists. The SLAAC prefix, subnet, start address, end
address, DMZ address, DNS addresses for IPv4 and IPv6, NBNS-1 and NBNS-2 addresses, and IPv4 and
IPv6 portal addresses are obtained from the RADIUS server. "DMZ address in use" is set to "yes" because
RADIUS returned the Alc-DMZ-address, and the outside L2 NAT pool has a single port-reservation block
configured (ref. VPRN-2).

```
*A:BNG# show subscriber-mgmt brg gateways

Conclusion

Using a BRG in the home network instead of a full-fledged L3 RGW offers network operators a view on the IP addresses and MAC addresses used by home devices, enabling them to provide per-device service offerings. Integrating BRGs in their networks can help the operators to optimize the revenue stream.

WiFi Aggregation and Offload — Basic Open SSID

This chapter provides information about WiFi Aggregation and Offload — Basic Open SSID.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 12.0.R5.

Overview

WiFi Aggregation and Offload functionality for the 7750 SR is supported on SR OS 10.0.R3 or later. The functionality includes a RADIUS proxy server with a RADIUS proxy cache and support for soft-GRE tunnels.

WLAN-GW subscribers are implemented using Enhanced Subscriber Management (ESM) on the Control Processing Module (CPM), to benefit from the extensive ESM features available on the 7750 SR platform. Many different WiFi Offload configurations are possible, with the two most versatile configurations being open and secure Service Set Identifier (SSID).

This configuration should be used as a starting point for operators who need to offer an open SSID, where any client can connect to an Access Point (AP) and obtain an IP address without authentication. In most cases, operators want users to go through an authentication process before allowing full Internet access using the open SSID; therefore, this configuration also includes a web portal.

IP address assignment and Internet connectivity can be achieved using various methods in SR OS. In this configuration, a local DHCP server provides IP addresses to the User Equipment (UE) and routing to the Internet is performed using Global Routing Table (GRT) leaking.

Several considerations typically affect the choice of a WiFi Offload solution:

- Access can be free or paid.
- Equipment can be preconfigured or users can bring their own WiFi device.

When there is no pre-existing subscription, an open SSID is the most obvious solution. To provide a paywall or to have the user acknowledge certain terms of use due to legal reasons, a web portal may also be required.

When a web portal is implemented, users who connect to the open SSID which are not yet authenticated have all their web traffic redirected to the web portal landing page. This is performed using an http-redirect filter applied to the initial (limited) Service Level Agreement (SLA) profile assigned to the UE. Typically, the operating system of the UE will detect the presence of the web portal and automatically open the login

page for the user. When the user logs in, the web portal sends a RADIUS Change of Authorization (CoA) request to the WLAN-GW, changing the SLA profile to one that does not contain an http-redirect filter.

Besides authentication, a major consideration is the method used to achieve Internet connectivity. Will the users require public addresses or are private addresses sufficient? In case few public IP addresses are available, private IP addresses can be assigned to UEs and the WLAN-GW can perform a Network Address Translation (NAT) function. If public routable IP addresses can be made available to all UEs, traffic from the UEs can be routed by the WLAN-GW to the Internet.

When a UE connects to an open SSID (as shown in Figure 172: Call Flow for Open SSID), typically the UE attempts to obtain an IP address using Dynamic Host Configuration Protocol (DHCP). The WLAN-GW can serve as a DHCP relay or proxy and may obtain the IP address from an external source, or use a local DHCP server function. A DHCP Discover or Request packet from a UE will trigger a form of authentication where the WLAN-GW requests information about the UE, such as SLA profile or DHCP local pool name. This authentication is separate from the web portal authentication and occurs immediately when a UE connects.

In summary:

- DHCP Discover triggering RADIUS authentication
- DHCP completes and UE has SLA profile with limited access
- UE logs into a web portal
- Successful login causes the portal to send a RADIUS CoA which assigns an SLA profile with full access

Figure 172: Call Flow for Open SSID
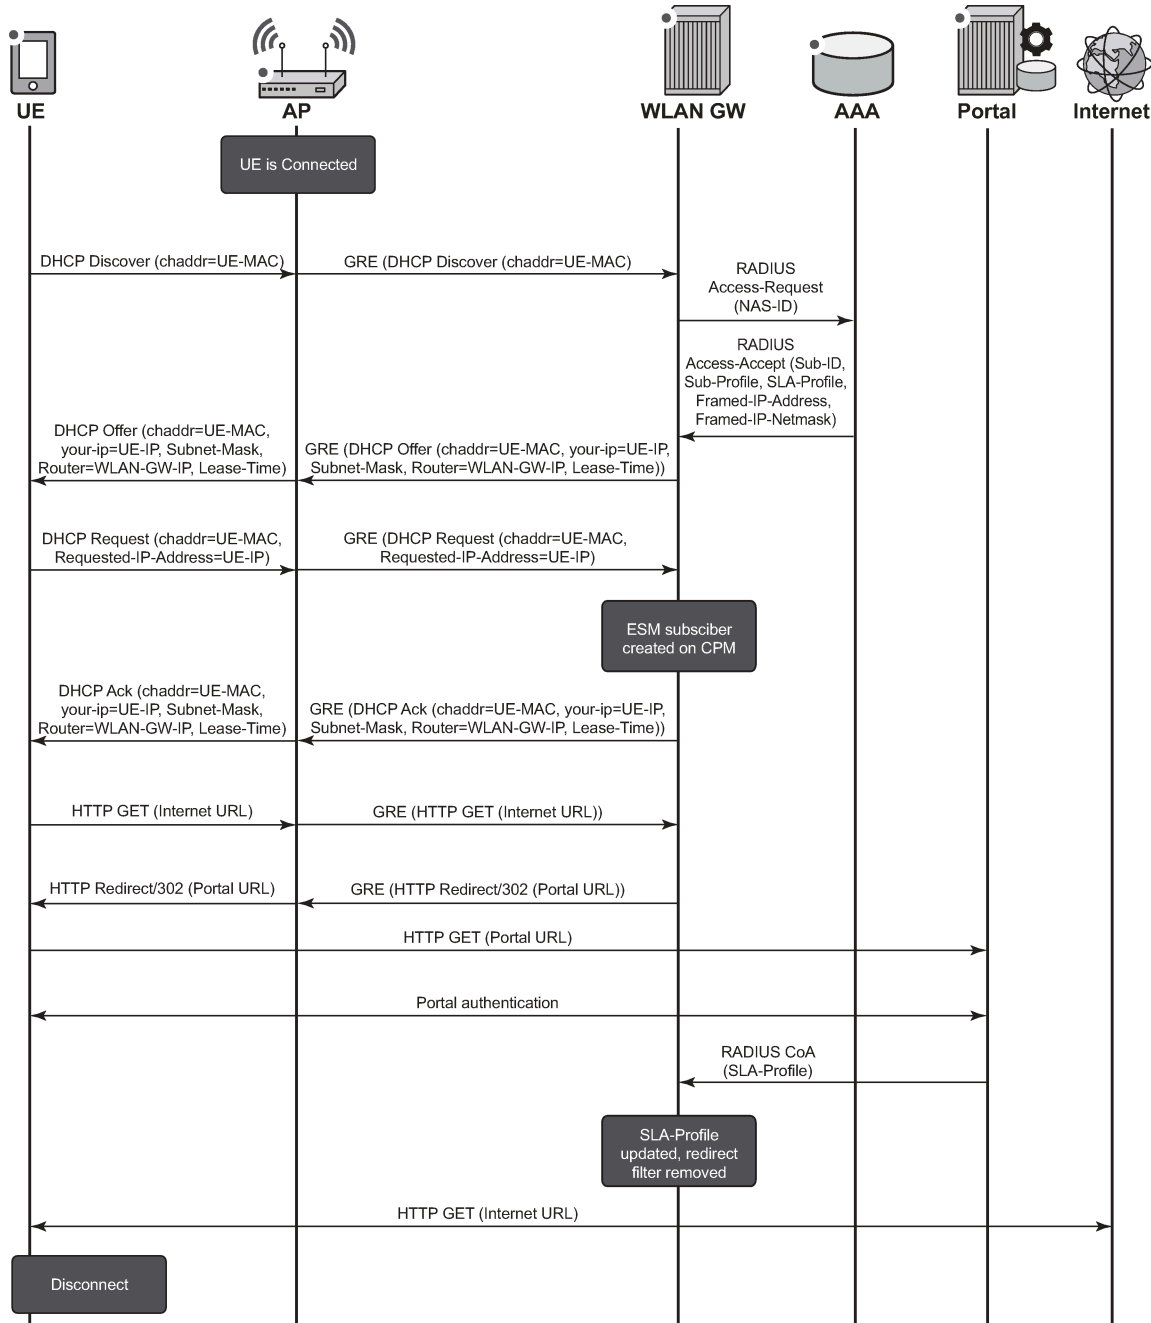

al_0831

The SR OS is flexible in allowing the operator to separate the various WiFi Offload functions between different routing instances. All functions can be configured in the same routing instance, or as shown in Figure 173: WiFi Offload Scenario with Open SSID and Local DHCP Server, the connectivity to the APs (and soft-GRE tunnels) can be provided in one Virtual Private Routed Network (VPRN), the users can be instantiated in another VPRN, and Authentication, Authorization and Accounting (AAA) access can be

provided in yet another routing instance (in this case, the Base router). This clear separation of functions can enhance security; for example, by separating user traffic from authentication traffic.

Configuration

The WiFi offload scenario shown in Figure 173: WiFi Offload Scenario with Open SSID and Local DHCP Server has following characteristics:

- Open SSID with web portal authentication
- Local breakout to Internet using GRT leaking, routing through Base routing instance
- Same private IP address assigned to all UEs, with L2-aware NAT
- AP access in VPRN 1000
- UEs terminated in VPRN 2005
- Local DHCP server assigning public IP addresses

Figure 173: WiFi Offload Scenario with Open SSID and Local DHCP Server
WLAN-GW

Note that the uplink interface, Interior Gateway Protocol (IGP), and system configuration is outside the scope of this document.

The following card and Media Dependent Adapter (MDA) configuration shows only the WLAN-Input/Output Module (IOM). An IOM card containing two Multi-Service Integrated Service Adapter (MS-ISA) cards provides the WLAN-GW functionality. The MDA type for the ISA cards is isa-bb, the same type that is used for NAT.

```
*A:WLAN-GW# /configure card 2
*A:WLAN-GW>config>card# info
-------------------------------------------
        card-type iom3-xp-b
        mda 1
            mda-type isa-bb
            no shutdown
```

© 2024 Nokia.

Use subject to Terms available at: www.nokia.com/terms.

```
        exit
        mda 2
            mda-type isa-bb
            no shutdown
        exit
        no shutdown
-----------------------------------------------
```

The following ISA configuration defines a wlan-gw-group referencing the IOM in slot two which hosts the two MS-ISA cards and providing the WLAN-GW functions.

```
A:WLAN-GW# /configure isa
A:WLAN-GW>config>isa# info
-----------------------------------------------
        wlan-gw-group 1 create
            active-iom-limit 1
            iom 2
            no shutdown
        exit
-----------------------------------------------
```

The following is a RADIUS server configuration, where the secret must match the secret configured on the external RADIUS server. The accept-coa option must be configured to allow the change of SLA profile by the web portal using a CoA request.

```
*A:WLAN-GW# /configure router radius-server
*A:WLAN-GW>config>router>radius-server# info
-----------------------------------------------
        server "Server2" address 10.43.186.2 secret "zmLYVgt8UOLypJamceNSSHDWbZproq7Y"
 hash2 create
            accept-coa
        exit
-----------------------------------------------
```

The following AAA configuration contains a RADIUS server policy used in the authentication policy. The source address must match the IP address configured for this client on the RADIUS server.

```
*A:WLAN-GW# /configure aaa
*A:WLAN-GW>config>aaa# info
-----------------------------------------------
        radius-server-policy "RS_5" create
            servers
                router "Base"
                source-address 10.10.10.165
                server 1 name "Server2"
            exit
        exit
-----------------------------------------------
```

The following policy configuration is used for exporting routes so that they are reachable by the public network. These policies are used for exporting UE routes in subsequent configuration sections.

```
*A:WLAN-GW# /configure router policy-options
*A:WLAN-GW>config>router>policy-options# info
-----------------------------------------------
        prefix-list "WiFi-clients"
            prefix 10.165.0.0/16 longer
        exit
        policy-statement "WiFi-clients"
            entry 10
```

```
                        from
                            prefix-list "WiFi-clients"
                        exit
                        action accept
                        exit
                    exit
                exit
    -----------------------------------------------
```

The uplink network configuration is outside the scope of this document. However, note that the IGP (here ISIS) must be aware of the UE addresses so that they are accessible from the Internet.

```
*A:WLAN-GW# /configure router isis
*A:WLAN-GW>config>router>isis# info
-----------------------------------------------
        export "WiFi-clients"
-----------------------------------------------
```

The following IP filter redirects all HTTP traffic to the web portal. The filter should also allow DNS and potentially other traffic, so the entry that allows TCP port 80 traffic to the web portal address must be placed before the entry that redirects all traffic to that portal; otherwise, there will be a redirect loop.

The HTTP redirect URL also includes a parameter that provides the MAC address of the UE to the web portal. In this configuration, either $MAC or $SUB can be used since both variables contain the MAC address of the UE. The web portal can reply with a CoA request specifying this particular UE MAC as the Subscriber ID after successful login. The URL also returns the IP address of the WLAN-GW to the web portal, so that the portal knows which WLAN-GW to send the CoA request to.

```
*A:WLAN-GW# /configure filter
*A:WLAN-GW>config>filter# info
-----------------------------------------------
        ip-filter 2005 create
            default-action forward
            entry 70 create
                match protocol udp
                    dst-port eq 53
                exit
                action forward
            exit
            entry 80 create
                match protocol icmp
                exit
                action forward
            exit
            entry 90 create
                match protocol tcp
                    dst-ip 10.43.186.2/32
                    dst-port eq 80
                exit
                action forward
            exit
            entry 100 create
                match protocol tcp
                    dst-port eq 80
                exit
                action http-redirect "http://portal2.3ls.net/portal-no-login.php?gw=
10.10.10.165&mac=$SUB"
            exit
        exit
```

The following is a subscriber management configuration, with the RADIUS authentication policy used to authenticate DHCP requests, including the accept-authorization-change option to allow for SLA profile change after portal authentication. This DHCP authentication request also sends the NAS ID attribute that allows the RADIUS server to match on the configuration for this particular SSID. All UEs will be authenticated with their MAC address as user name, and *alcatel* as their password (any DHCP request will result in a successful authentication).

Two SLA profiles are required: profile SLAP_5_portal is initially used for each UE and refers to the portal redirect filter, while profile SLAP is applied using a CoA request after the user successfully authenticates on the web portal. A subscriber identity policy is also required.

```
configure subscriber-mgmt
        authentication-policy "WiFi-165-5-auth-policy" create
            password alcatel
            accept-authorization-change
            include-radius-attribute
                nas-identifier
            exit
            radius-server-policy "RS_5"
        exit
        sla-profile "SLAP" create
        exit
        sla-profile "SLAP_5_portal" create
            ingress
                    ip-filter 2005
            exit
        exit
        sub-profile "SUBP" create
        exit
        sub-ident-policy "SIP" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
```

The following VPRN 1000 configuration contains the interface to the AP, and has GRT lookup with export-grt configured to allow APs to be managed from the Base routing instance.

```
*A:WLAN-GW# /configure service vprn 1000
*A:WLAN-GW>config>service>vprn# info
----------------------------------------------
        route-distinguisher 65400:1000
        interface "toAP3" create
            address 10.1.3.1/24
            sap 1/1/10 create
            exit
        exit
        grt-lookup
            enable-grt
                static-route 0.0.0.0/0 grt
            exit
            export-grt "WiFi-APs"
        exit
        no shutdown
----------------------------------------------
```

VPRN 2005 is used for UE termination and contains:

- A local DHCP server with a single pool of addresses that are assigned to UEs.

- A loopback interface used by the DHCP server.

- A subscriber interface and group interface of type **wlangw** (called softgre prior to Release 12.0).

- Subscriber parameters.

- The authentication policy, which will run each time a UE requests a DHCP address.

- The host-connectivity-verify function, which periodically checks the presence of UEs and quickly removes disconnected UEs even before their DHCP lease expires; the WLAN-GW has no other way of knowing when a UE has disconnected from the AP.

- The wlan-gw CLI-node (called soft-gre prior to Release 12.0), including the wlan-gw GRE tunnel end-point address,and the routing instance where AP traffic is terminated, the ISA WLAN-GW group, and mobility parameters, which allow the UE state to be kept if the UE moves between two APs broadcasting the same SSID.

- GRT lookup with export-grt configured to allow UE traffic to be routed to the Internet.

```
*A:WLAN-GW# /configure service vprn 2005
*A:WLAN-GW>config>service>vprn# info

                no shutdown
```

Freeradius

This simple default configuration section matches on any host. During the DHCP authentication phase, RADIUS returns the DHCP pool name *pool1* informing the WLAN-GW DHCP server which pool to assign the UE IP address from:

```
/etc/freeradius/users
DEFAULT          Auth-Type := Local, User-Password := "alcatel", user-name=~""
                    Alc-Subsc-ID-Str = "%{User-Name}",
                    Framed-Pool = "pool1",
```

In /etc/freeradius/clients.conf, the secret must match the secret configured in the WLAN-GW RADIUS server configuration.

```
client 10.10.10.165 {
        secret      = alcatel
        shortname   = WLAN-GW
}
```

The RADIUS CoA sent during successful portal login allows this UE full access, by applying SLA profile SLAP which does not have an http-redirect filter.

```
echo "ALC-Subsc-Id-Str='68:7f:74:8b:3d:d7',ALC-Subsc-Prof-Str='SUBP_5',ALC-SLA-Prof-Str=
'.SLAP',Alc-Primary-Dns = '10.43.186.43'" | /usr/bin/radclient -x -r 1 -t 2 '10.10.10.165' coa
  'alcatel'
```

Access Points

At a minimum, the following must be configured on the Access Point:

- IP address 10.1.3.10/24

- Default route to 10.1.3.1

- Open SSID WiFi-165-5 mapped to VLAN 50

- Soft-GRE tunnel with destination 192.5.5.5, with VLAN 50 mapped to this tunnel

Show Commands

The following show commands reflect the status of the router after the UE has connected and obtained an IP address using DHCP.

The following output displays the UEs presently connected.

```
*A:WLAN-GW# show subscriber-mgmt wlan-gw ue

Debug

The following is a complete debug of a UE connecting and logging in to the portal. Shortly after logging in, the UE disconnects from the SSID and the subscriber is removed by host-connectivity-verify.

The following debug configuration applies:

```
debug
    router "Base"
        radius
            packet-type authentication accounting coa
            detail-level medium
        exit
    exit
    router "2005"
        ip
            dhcp
                detail-level medium
                mode egr-ingr-and-dropped
            exit
        exit
        local-dhcp-server "local_dhcp_2005"
            detail-level medium
            mode dropped-only
        exit
    exit
    service
        id 2005
            host-connectivity-verify
                mac 68:7f:74:8b:3d:d7
            exit
        exit
    exit
exit
```

The WLAN-GW is notified of the UE after receiving the first DHCP packet.

```
1 2014/09/22 10:47:58.46 EDT MINOR: DEBUG #2001 vprn2005 PIP

Conclusion

The 7750 SR WLAN-GW can support many WiFi Offload architectures, including open SSID with portal authentication. WiFi Offload functions such as terminating GRE tunnels or subscribers can be performed in separate routing instances, if required. IP addresses can be assigned from an external or local source and routing can be performed using NAT, by connecting the UE routing instance directly to the Internet, or by leaking routes to other routing instances. Using http-redirect, a web portal can be used to allow users to log in to a paid service or to accept the terms of service for a free WiFi service. Several show commands and debug options are available to help the operator monitor and troubleshoot the solution.

WiFi Aggregation and Offload — Basic Secure SSID with Distributed RADIUS Proxy

This chapter provides information about WiFi Aggregation and Offload — Basic Secure SSID with Distributed RADIUS Proxy.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 13.0.R3.

WiFi Aggregation and Offload functionality has been supported in SR OS 10.0.R3, and later. This includes a RADIUS proxy server and support for soft-GRE tunnels.

Overview

WLAN-GW subscribers can be implemented using Enhanced Subscriber Management (ESM) on the CPM in order to benefit from the extensive ESM features available on the SR OS nodes. Many different WiFi Offload configurations are possible, with two versatile categories being open and secure SSID.

Starting from SR OS Release 12.0.R4, distributed RADIUS-proxy functionality (DRP) has been added to the MS-ISA. This feature allows running a high-performance proxy over multiple MS-ISA cards instead of being limited to a single CPM, greatly increasing scalability.

This chapter can be used as a starting point for operators who wish to configure a secure SSID scenario using DRP and ESM. In a secure SSID scenario, the Access Point (AP) uses 802.1x and Extensible Authentication Protocol (EAP) to authenticate the UE. The EAP method used is transparent to the WLAN-GW. In this chapter, PEAP/EAP-MSCHAPv2 is used to associate with the SSID by entering a user name and password, but other methods such as EAP-Subscriber Identity Module (EAP-SIM) can also be used without any configuration change on the WLAN-GW.

IP address assignment and Internet connectivity can be achieved by using various methods on the SR OS node. In this scenario, the RADIUS server provides the IP addresses to the User Equipment (UEs). The same IP private address is assigned to every UE and L2-aware Network Address Translation (NAT) is used to provide a public IP address on the Internet.

For a WiFi Offload solution where the service provider has a record of their users, that is, where users have login accounts, the provider may consider offering a secure SSID as a more convenient and secure alternative to an open SSID with a web portal. In a secure SSID scenario, all user traffic is encrypted between the UE and the AP, and UEs are only granted access if they authenticate successfully. This

makes attacks more difficult and blocks non-paying users who only connect to test if they can get free access.

Authentication in this case requires a centralized Authentication, Authorization and Accounting (AAA) which keeps track of the user accounts. The user is granted full access immediately after connecting to the secure SSID. One drawback is that WiFi clients may need some configuring by the user before they are able to connect to the SSID using the correct EAP method. In the case of EAP-SIM, users do not need to know their user name and password because authentication is done based on credentials contained in the SIM card, but the SSID configuration may need to be preloaded by the operator on the mobile device or provided to the user ahead of time. For other EAP methods such as PEAP/EAP-MSCHAPv2, users need to supply the correct user name and password, without the help of a portal or any instructions to guide them.

An operator offering Internet access to a large number of users while only a limited number of public IP addresses are available will likely use Network Address Translation (NAT) in order to conserve public IP addresses. NAT typically maps a few public IP addresses and ports to a large number of inside (private) IP addresses and ports. The WLAN-GW supports several NAT configurations including L2-aware NAT, where the MAC address of the UE is also used when creating the mapping between the inside IP/port and the outside IP/port. Therefore with L2-aware NAT, the same private IP address can be assigned to all UEs because the unique MAC address for each UE allows the WLAN-GW to distinguish between each UE. This greatly simplifies IP address assignment; the RADIUS server can assign the same private IP address to all UEs and there is no DHCP server required. Using a RADIUS server for IP address assignment means DHCP proxy needs to be configured on the WLAN-GW.

The SR OS platform is flexible in terms of allowing the operator to separate the various WiFi Offload functions between different routing instances. All functions can be configured in the same routing instance, or as shown in the following configuration, the connectivity to the APs (and soft-GRE tunnels) can be provided in one Virtual Private Routed Network (VPRN), the users can be instantiated in another VPRN, and AAA access can be provided in yet another routing instance (in this example the Base router). This provides a clear separation of functions and can enhance security, by separating user traffic from authentication and management traffic.

Configuration

The WiFi offload scenario with SSID and L2-aware NAT shown in Figure 174: WiFi Offload Scenario with Secure SSID and L2-Aware NAT has following characteristics:

• Secure SSID with EAP authentication

• Local breakout to Internet, routing through the Base routing instance

• Same private IP address assigned to all UEs by RADIUS

• L2-aware NAT

• AP access in VPRN 1000

• UEs terminated in VPRN 2001

Figure 174: WiFi Offload Scenario with Secure SSID and L2-Aware NAT
WLAN-GW

Note that configuring the uplink interface, Interior Gateway Protocol (IGP) and system configuration is outside the scope of this chapter and only partial configuration is provided.

Card and Media Dependent Adapter (MDA) configuration showing only the WLAN-IOM. An IOM card containing two MS-ISA cards provides the WLAN-GW functionality. The MDA type for the ISA cards is isa-bb, the same type that is used for NAT.

```
*A:WLAN-GW# /configure card 2
*A:WLAN-GW>config>card# info
----------------------------------------------
        card-type iom3-xp-b
        mda 1
            mda-type isa-bb
            no shutdown
        exit
        mda 2
            mda-type isa-bb
            no shutdown
        exit
        no shutdown
----------------------------------------------
```

The ISA configuration contains a wlan-gw-group referencing the IOM in slot 2, which hosts the two MS-ISA cards providing the WLAN-GW functions.

```
A:WLAN-GW# /configure isa
A:WLAN-GW>config>isa# info
----------------------------------------------
        wlan-gw-group 1 create
            active-iom-limit 1
            iom 2
            no shutdown
        exit
----------------------------------------------
```

The AAA configuration contains an ISA RADIUS policy used for authentication requests. The source address range configures the source address of the first MS-ISA in the wlan-gw-group. The second MS-ISA card gets the next consecutive IP address and so on. All the IP addresses assigned this way to MS-ISA cards must be configured as clients on the RADIUS server. The secret here must match the secret configured on the RADIUS server.

```
A:WLAN-GW# /configure aaa
A:WLAN-GW>config>aaa# info
----------------------------------------------
        isa-radius-policy "IRS_1" create
            servers
                router "Base"
                source-address-range 10.10.165.1
                server 1 create
                    authentication
                    ip-address 10.93.186.2
                    secret "7USmr6f7JkxaGnDDq1uqwEAJKGbhZr5i" hash2
                    no shutdown
                exit
            exit
        exit
----------------------------------------------
```

The following policy shows the two routes that must be exported for this scenario to work: UE NAT outside routes (NAT is configured in the next step), to make UEs reachable on the Internet, and MS-ISA RADIUS source address routes, in order for the MS-ISAs to be reachable from the RADIUS server. This policy should be used for export in the IGP configuration (not shown).

```
A:WLAN-GW# /configure router policy-options
A:WLAN-GW>config>router>policy-options# info
----------------------------------------------
            prefix-list "WiFi"
                prefix 10.10.165.0/24 longer
                prefix 10.165.0.0/16 longer
            exit
            policy-statement "WiFi"
                entry 10
                    from
                        prefix-list "WiFi"
                    exit
                    action accept
                    exit
                exit
            exit
----------------------------------------------
```

The following configures L2-aware NAT by creating an outside NAT pool with a public IP address range. The private inside address used by the UE will be mapped to an outside IP address routable on the Internet. NAT port mapping parameters can be set in this configuration, controlling how many outside ports can be used by each UE. Details of NAT configuration are outside the scope of this document.

```
A:WLAN-GW# /configure router nat
A:WLAN-GW>config>router>nat# info
----------------------------------------------
            outside
                pool "WiFi-165-1" nat-group 1 type l2-aware create
                    address-range 10.165.1.0 10.165.1.255 create
                    exit
                    no shutdown
                exit
```

```
            exit
-----------------------------------------------
```

The following configures a NAT policy under services, linking this policy with the outside NAT pool. When
the NAT policy is invoked for a subscriber, this associates the subscriber with the correct outside pool.

```
A:WLAN-GW# /configure service nat
A:WLAN-GW>config>service>nat# info
-----------------------------------------------
            nat-policy "WiFi-165-1" create
                pool "WiFi-165-1" router Base
            exit
-----------------------------------------------
```

The following subscriber management configuration includes an SLA profile, a subscriber identity policy,
and the subscriber profile that makes use of the previously defined NAT policy. This allows subscriber
traffic to be forwarded to the Internet through the Base routing instance where the outside NAT pool exists.

A dummy authentication-policy is required for the CPM to handle the DHCP Discover messages forwarded
by the MS-ISA cards.

```
A:WLAN-GW# /configure subscriber-mgmt
A:WLAN-GW>config>subscr-mgmt# info
-----------------------------------------------
        authentication-policy "dummy-auth-policy" create
        exit
        sla-profile "SLAP_1" create
        exit
        sub-profile "SUBP_1" create
            nat-policy "WiFi-165-1"
        exit
        sub-ident-policy "SIP" create
            sub-profile-map
                use-direct-map-as-default
            exit
            sla-profile-map
                use-direct-map-as-default
            exit
        exit
-----------------------------------------------
```

VPRN 1000 contains the interface to the AP as well as the distributed RADIUS proxy server RP_1. The
RADIUS proxy wlan-gw address configures a special NAT route in VPRN 1000 that forwards RADIUS
packets from the AP to the correct MS-ISA. That address is known to the AP as the RADIUS server
address it uses for EAP authentication for this SSID. The secret configured here has to match the RADIUS
secret configured on the AP.

The RADIUS proxy is configured to create cache entries based on attribute 31 in RADIUS access-request
packets (Calling-Station-ID), which contains the MAC address of the UE. These cache entries will be
stored temporarily and used to authenticate DHCP packets from the UE. The **track-accounting start**
parameter allows mobility to be triggered for a UE upon receiving an accounting-start message. The
UE's associated tunnel will be moved to the IP address indicated by the NAS-IP-Address. The **track-accounting stop** parameter allows the UE session to be terminated immediately when the AP sends a
RADIUS accounting-stop for the UE, when this UE disconnects from the SSID.

The default-authentication-server-policy links the RADIUS proxy with the isa-radius-policy that
authenticates the UEs. If accounting is required, the accounting policy can be specified in this configuration
and can be the same as or different from the isa-radius-policy. The send-accounting-response option

makes the WLAN-GW acknowledge (and then discard) the RADIUS accounting messages from the AP, instead of proxying the accounting messages to the external RADIUS server.

```
A:WLAN-GW# /configure service vprn 1000

```

VPRN 2001 is used for UE termination and contains:

- A subscriber interface and group interface of type **wlangw** (**soft-gre** prior to Release 12.0).

- Default subscriber parameters assigned to every UE.

- DHCP proxy, which allows the RADIUS-assigned IP address parameters stored in the DRP cache during authentication to be passed to the UE.

- A dummy authentication policy which allows the CPM to handle the DHCP Discover passed on by the MS-ISA.

- The **wlan-gw** node (**soft-gre** prior to Release 12.0), which includes:

    – The gw-address that is the end-point of the GRE tunnel

    – The routing instance where AP traffic is terminated

    – The ISA wlan-gw-group, which associates this WLAN-GW configuration with a set of IOMs

    – Mobility parameters, which allow the UE state to be kept if the UE moves between two APs broadcasting the same SSID

    – The authenticate-on-dhcp option required for the CPM to instantiate ESM UEs when using DRP

    – The L2-aware address/subnet used for L2-aware NAT. This address matches the default gateway assigned to the UEs.

```

Freeradius

This part of the user's configuration file matches on the user name entered by the UE while connecting
to this secure SSID. If the password entered is correct, RADIUS returns the IP addressing parameters
configured as follows. The same IP address 192.168.1.9 is assigned to every user on this SSID, but the
L2-aware NAT on the WLAN-GW can distinguish between all the UEs based on their L2 MAC address.

```
/etc/freeradius/users:
"user1"              User-Password := "alcatel"
                     Alc-Subsc-ID-Str = "%{User-Name}",
                     Alc-Default-Router = 192.168.1.1,
                     Alc-Primary-Dns = 10.43.186.43,
                     Framed-IP-Address = 192.168.1.9,
```

```
                        Framed-IP-Netmask = 255.255.255.0,
```

In /etc/freeradius/clients.conf the secret matches the one configured in the WLAN-GW isa-radius-policy configuration. Since there are only two MS-ISA cards in the wlan-group used in this example, two clients are configured.

```
client 10.10.165.1 {
        secret      = alcatel
        shortname   = WLAN-GW-ISA1
}
client 10.10.165.2 {
        secret      = alcatel
        shortname   = WLAN-GW-ISA2
}
```

Access Points

The following must be configured on the Access Point as a minimum:

- IP address 10.1.3.10/24

- Default route to 10.1.3.1

- Secure SSID WiFi-165-1 mapped to VLAN 10, using WPA2 with EAP/802.1x authenticating against RADIUS server 192.11.11.11, with RADIUS accounting enabled

- Soft-GRE tunnel with destination 192.1.1.1, with VLAN 10 mapped to this tunnel

Show Commands

The following show commands reflect the status of the WLAN-GW after the UE has connected and obtained and IP address using DHCP.

The following output displays the connected UEs:

```
A:WLAN-GW# show subscriber-mgmt wlan-gw ue

Call Flow

Figure 175: Call Flow for Secure SSID with DSM shows the call flow for a secure SSID with DRP. The main steps are:

- EAP authentication using DRP on MS-ISA placing UE authorized-only state

- UE sends DHCP Discover which is forwarded by the MS-ISA to the CPM

- CPM places UE in ESM-user state

- Upon disconnect, the AP sends a RADIUS accounting-stop which clears the UE context on the WLAN-GW

Figure 175: Call Flow for Secure SSID with DSM
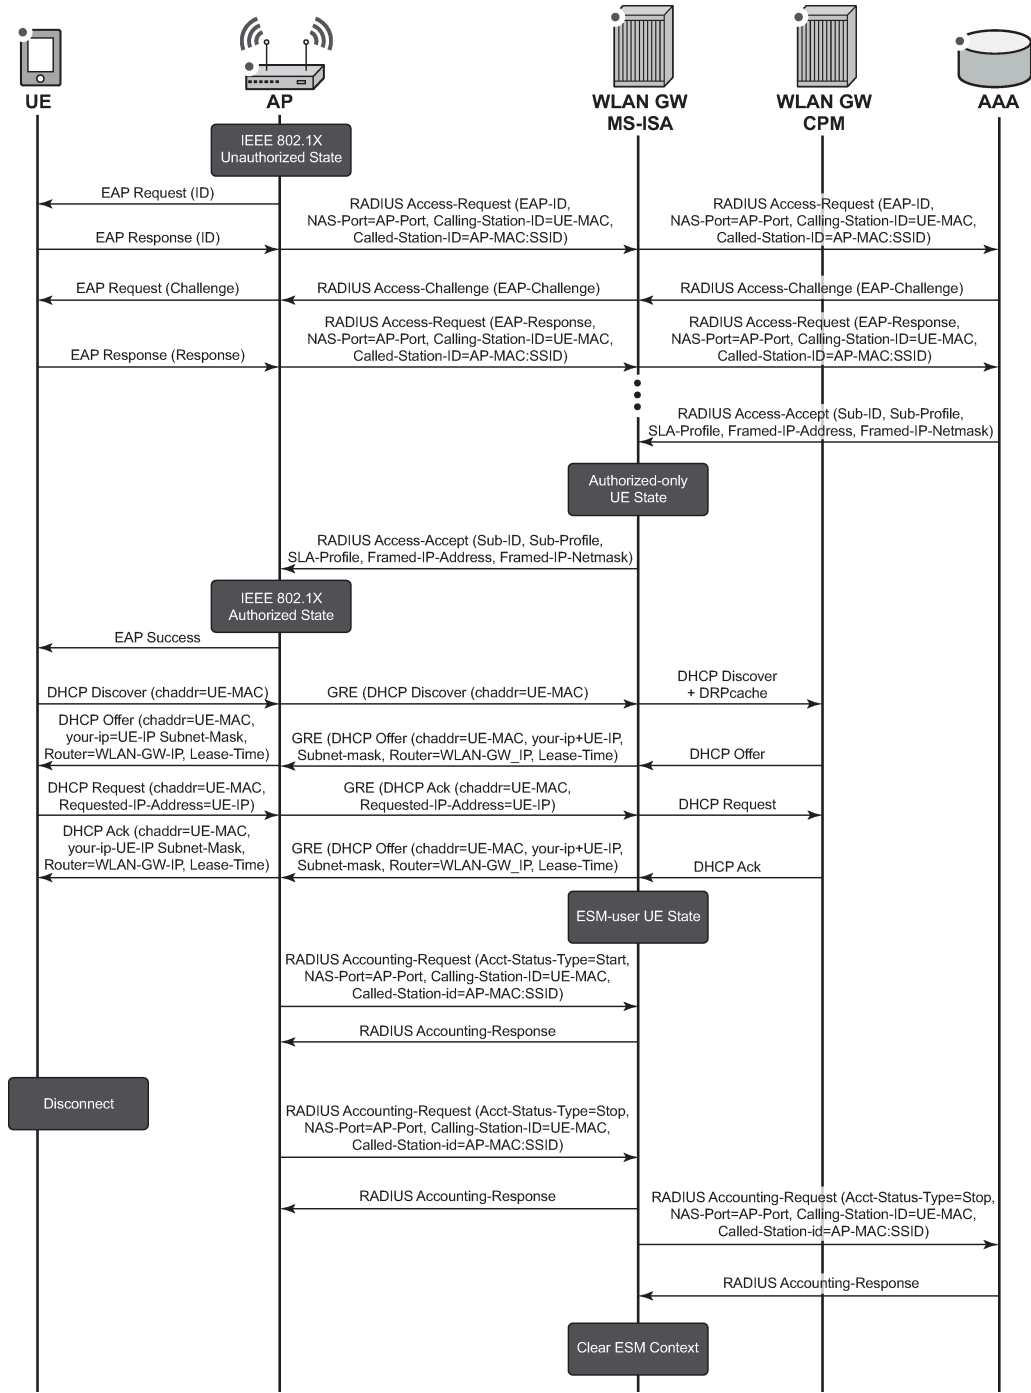

Debug

In this example, the following debug configuration is used (note that some default options are automatically added and do not need to be entered manually, e.g. mode under dhcp). For DRP, only a limited number of UEs can be debugged at a time and their MAC address have to be specified.

```
debug

The following is a partial debug of a UE connecting to the SSID and authenticating with the RADIUS server. Shortly after logging in the UE disconnects from the SSID and the subscriber is removed on reception of the RADIUS accounting-stop message.

As soon as the UE attempts to connect to the secure SSID, the WLAN-GW distributed RADIUS proxy in VPRN 1000 receives the first Access-Request packet from the AP. Note that the CALLING STATION ID [31] attribute contains the MAC address of the UE, and that the AP sends the SSID name in the NAS IDENTIFIER [32] attribute.

```

Many RADIUS Access-Request and Access Challenge messages are exchanged, which encapsulate the
EAP authentication between the UE and the RADIUS server. At the end of the exchange, for a successful
authentication, the WLAN-GW receives an Access-Accept message (for a failed authentication it would
receive an Access-Reject).

This removes the subscriber from the WLAN-GW, clears the DHCP state, and also removes the GRE
tunnel if this UE is the last one on the tunnel.

Conclusion

The WLAN-GW can support many WiFi Offload architectures including secure SSID with various types of
EAP authentication. WiFi Offload functions such as terminating GRE tunnels, NAT, and RADIUS server
connectivity can be performed in separate routing instances if required. UE IP addresses can be assigned
locally or from an external source such as RADIUS, and routing to the Internet can be performed in various
ways, including NAT. Several show commands and debug options are available to help the operator
monitor and troubleshoot the solution.

WiFi Aggregation and Offload — IPv4/v6 Dual-Stack UEs

This chapter provides information about WiFi aggregation and offload IPv4/v6 dual-stack UEs.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 13.0.R3.

WiFi Aggregation and Offload functionality is supported on SR OS 10.0.R3 or later. The functionality includes enhanced subscriber management (ESM) for user equipment (UE) that gains network access via a WiFi service.

Overview

This chapter provides a functional description of the WLAN-GW features related to IPv4/v6 dual-stack UEs, as well as the related configuration.

Because IP address demand is mainly due to mobile devices, the support of IPv6 on mobile devices is a major requirement to manage IPv4 address depletion.

However, IPv6 on mobile devices is currently considered as an add-on rather than a replacement of IPv4, so the demand is for IPv4/v6 dual-stack UEs.

The basic concepts of ESMv6 for IPoE dual-stack hosts also apply to dual-stack UEs. However, WLAN-GW operates in a bridged environment where the Access Point (AP) performs L2 forwarding of Ethernet frames between the IEEE 802.11 air interface and the soft-GRE, soft-L2TPv3, or VLAN tunnel. Therefore, a WLAN-GW treats each UE as an individual subscriber who connects to the WiFi service. This contrasts with ESMv6 IPoE hosts behind a routed residential gateway (RG), where multiple hosts connect via the RG and the BNG treats the RG as the subscriber.

Depending on the type of UE, it may be allocated an IPv4 address through DHCPv4 and an IPv6 address through Stateless Address Auto-Configuration (SLAAC), or DHCPv6, or both (not all UEs have support for DHCPv6). Therefore, a UE can instantiate up to three IPoE hosts: a DHCPv4 host, a SLAAC host, and a DHCPv6 host.

Authentication and authorization depend on whether the UE connects to a WiFi with open or closed SSID. With an open SSID, authentication and authorization are performed when the first packet is received from the UE (typically a DHCPv4 Discover, an ICMPv6 Router-Solicit, or a DHCPv6 Solicit), similar to the routed RG model. Upon successful authentication, the Access-Accept is stored for 10 s on the WLAN-GW, so

for a dual-stack IPv4/v6 UE, two or three authentication rounds can be avoided if DHCPv4, SLAAC, and DHCPv6 are started within this 10 s interval.

When the UE has successfully authenticated with the portal, a CoA-Request may lift the HTTP redirect filter by changing the SLA profile and, optionally, the subscriber profile. If the CoA-Request contains the subscriber ID, the CoA-Request applies to both the DHCPv4 host and the SLAAC and/or DHCPv6 host. See the RADIUS attributes reference guide for more information about alternative subscriber host identification in RADIUS CoA-Request messages.

Figure 176: DHCPv4 + SLAAC/64 — Open SSID

al_0818

With a closed SSID, there is a separation between the authentication and authorization phases. When a UE connects to a WiFi with closed SSID in WPA-Enterprise mode, also known as WPA-802.1X mode, the UE initiates authentication before it obtains an IP address. The WLAN-GW is aware of the successful authentication when it receives the DHCPv4 Discover, the ICMPv6 Router-Solicit, or the DHCPv6 Solicit.

As with ESMv6, the WLAN-GW supports SLAAC/64 and DHCPv6/128 Identity Association for Non-temporary Addresses (IA_NA). DHCPv6 Identity Association for Prefix Delegation (IA_PD) is not supported because the UEs are considered as individual hosts that have direct Layer 2 connectivity with the WLAN-GW. Devices that use the UE as an IPv6 gateway are currently not supported.

For SLAAC/64 hosts, the DNS information can be advertised with the recursive DNS server (RDNSS) option [RFC 6106] via SLAAC or via stateless DHCPv6 [RFC 3736]. For DHCPv6/128 hosts, the DNS information is advertised via DNS options for DHCPv6 [RFC3646]. If the AP supports a Lightweight DHCPv6 Relay Agent (LDRA), the WLAN-GW can learn the AP MAC address and the SSID that the UE connects to if the DHCPv6 Interface-Id option is in the format *<ap-mac>:<ssid>:{o (open) | s (secure)}* This information can then be used in subsequent accounting messages.

The following three IPv4/v6 dual-stack UE IP address assignment models are available:

- DHCPv4 + SLAAC/64
- DHCPv4 + SLAAC/64 with DHCPv4 linking
- DHCPv4 + DHCPv6/128 IA_NA

In the DHCPv4 + SLAAC/64 model, DHCPv4 DORA and SLAAC/64 are processed independently of each other. If successful, two IPoE hosts are instantiated on the WLAN-GW for a particular UE: a DHCPv4 IPoE host and an IPv6 SLAAC/64 host.

Figure 177: DHCPv4 + SLAAC/64 model — closed SSID
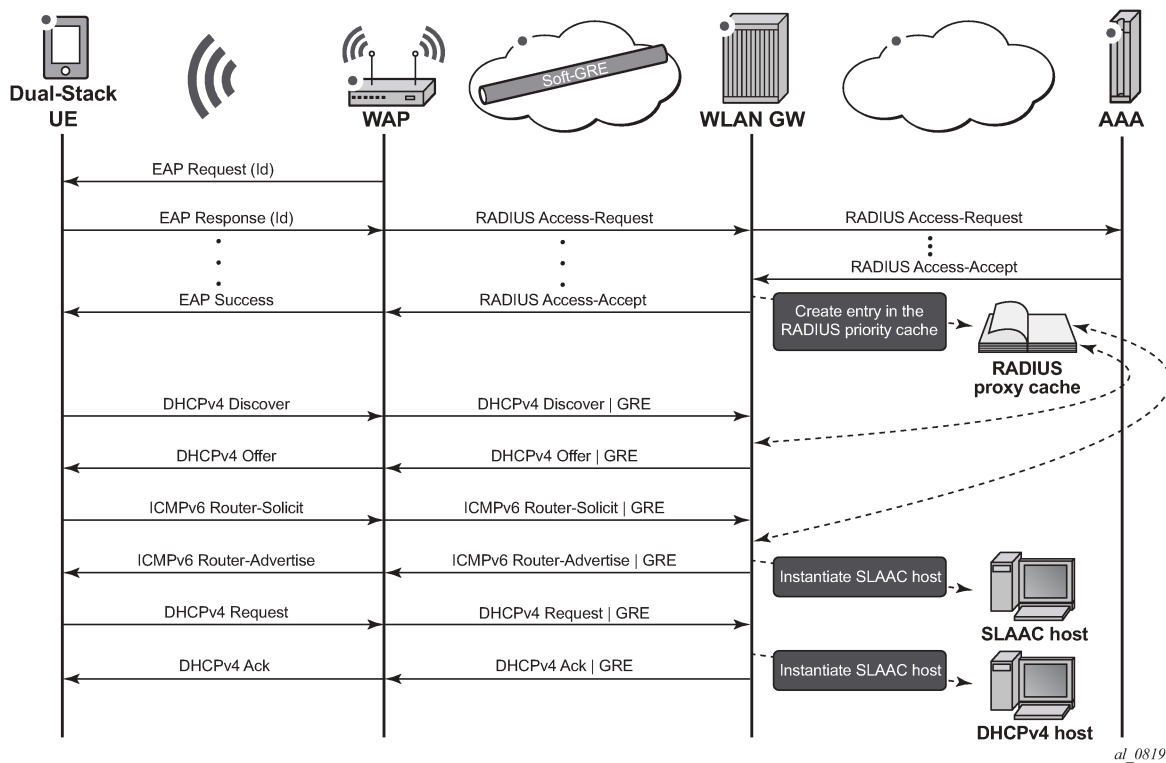

When the AP sends a RADIUS Accounting-Stop for a particular UE while track-accounting is enabled for Accounting-Stop messages, both the DHCPv4 IPoE host and the IPv6 SLAAC/64 host will be removed.

However, it is not always possible for the AP to send RADIUS accounting messages (for example, in the case of an open SSID). Because SLAAC has no renew or release mechanism, the only way to delete a SLAAC host is to determine which UE was stopped using the SLAAC prefix; for example, by using idle-timeout and/or by periodic Subscriber Host Connectivity Verification (SHCV).

In the DHCPv4 + SLAAC/64 with DHCPv4 linking model, a SLAAC/64 host is instantiated when a DHCPv4 host is instantiated. The state of the SLAAC/64 host is linked to the state of the DHCPv4 host. This is useful to speed up the removal of the SLAAC host in cases where the AP does not send RADIUS accounting messages. With DHCPv4 linking, when the DHCPv4 host is removed, also the SLAAC/64 host is removed.

Figure 178: DHCPv4 + SLAAC/64 with DHCPv4 linking model — closed SSID
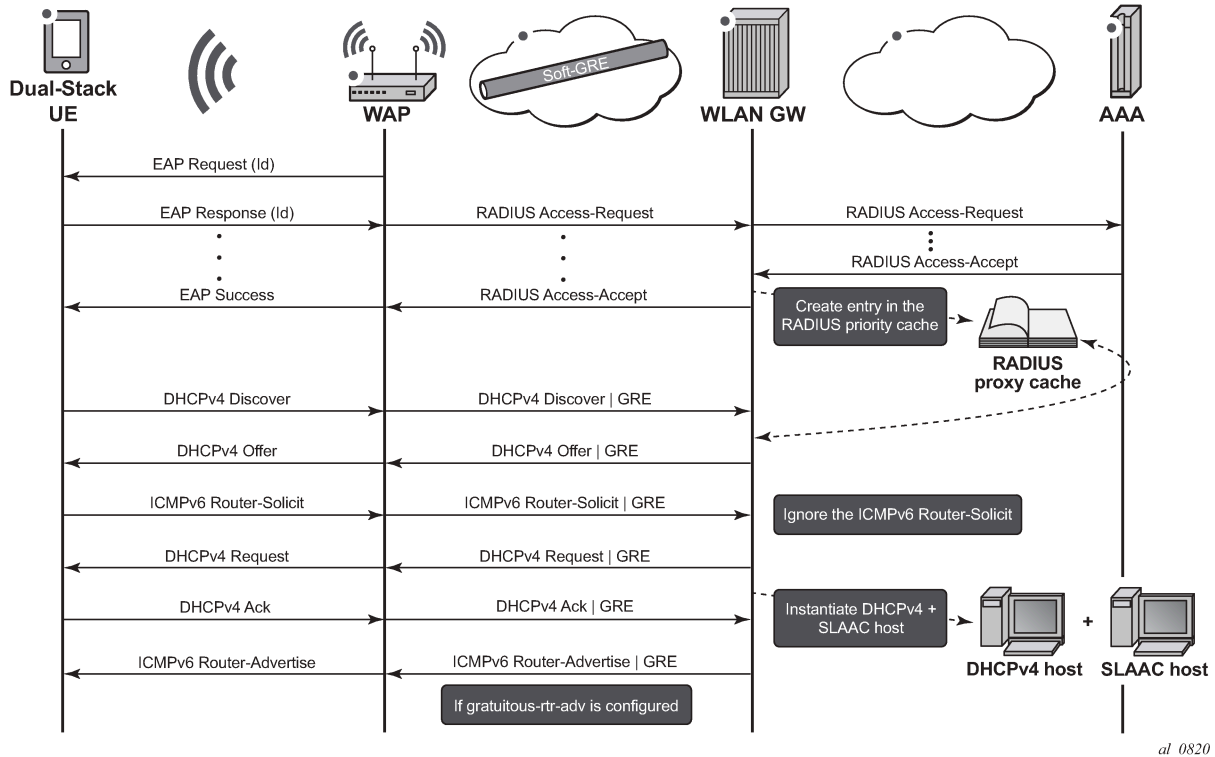

In the DHCPv4 + DHCPv6/128 IA_NA model, similar to the DHCPv4 + SLAAC/64 model, DHCPv4 DORA and DHCPv6/128 IA_NA are processed independently of each other. SLAAC/64 is optional in this model although it is typically enabled because some UEs do not support DHCPv6.

UEs that do support stateful address auto-configuration only initiate DHCPv6 when they receive an ICMPv6 Router-Advertisement with the M-bit set (RFC 2462, *IPv6 Stateless Address Autoconfiguration*). Because the WLAN-GW does not know whether the UE supports DHCPv6, the WLAN-GW must include a SLAAC/64 prefix in the ICMPv6 Router-Advertisement, also for UEs that do support DHCPv6. Therefore, for a UE that does support DHCPv6, three IPoE hosts are instantiated in the WLAN-GW. To avoid this, the WLAN-GW can be configured to flush the SLAAC/64 host when a DHCPv6/128 IA_NA host is established. The UE should always prefer the DHCPv6/128 IA_NA address for sending data traffic above the IPv6 address derived from the SLAAC/64 prefix.

Figure 179: DHCPv4 + DHCPv6/128 IA_NA model — closed SSID
As with ESMv6, the SLAAC/64 prefix could come from the Local User Database (LUDB); this is typically not used because it requires configuring individual UE MAC addresses with their associated SLAAC/64 prefix. Alternatively, the SLAAC/64 prefix could come from RADIUS via the Framed-IPv6-Prefix attribute, or from a local SLAAC prefix pool that is referenced in the LUDB or from RADIUS via the Alc-SLAAC-IPv6-Pool attribute.

The DHCPv6/128 prefix comes from a DHCPv6 server that could be local (collocated with the WLAN-GW) or external, or from RADIUS via the Alc-IPv6-Address attribute. When a DHCPv6 server is used, the WLAN-GW relays the DHCPv6 messages between the UE and the local or external DHCPv6 server. If the DHCPv6/128 prefix comes from RADIUS/LUDB, the WLAN-GW must be configured as a DHCPv6 proxy server.

Note that IPv6 for WLAN-GW UEs is not supported in combination with certain other features, which include GPRS Tunneling Protocol (GTP(v2)) offload, migrant UEs, and data-triggered authentication (DTA).

Data-triggered authentication is not supported for IPv6 hosts, which means that an IPv6 packet from a UE for which no ESM context exists will not trigger RADIUS authentication. However, by using SLAAC/64 with DHCPv4 linking, the SLAAC host will be created together with the DHCPv4 host by successful completion of IPv4 data-triggered authentication. This requires the RADIUS Access-Accept to contain the necessary DHCPv4 and SLAAC/64 attributes.

Figure 180: DHCPv4 + SLAAC/64 with DHCPv4 linking model — DTA
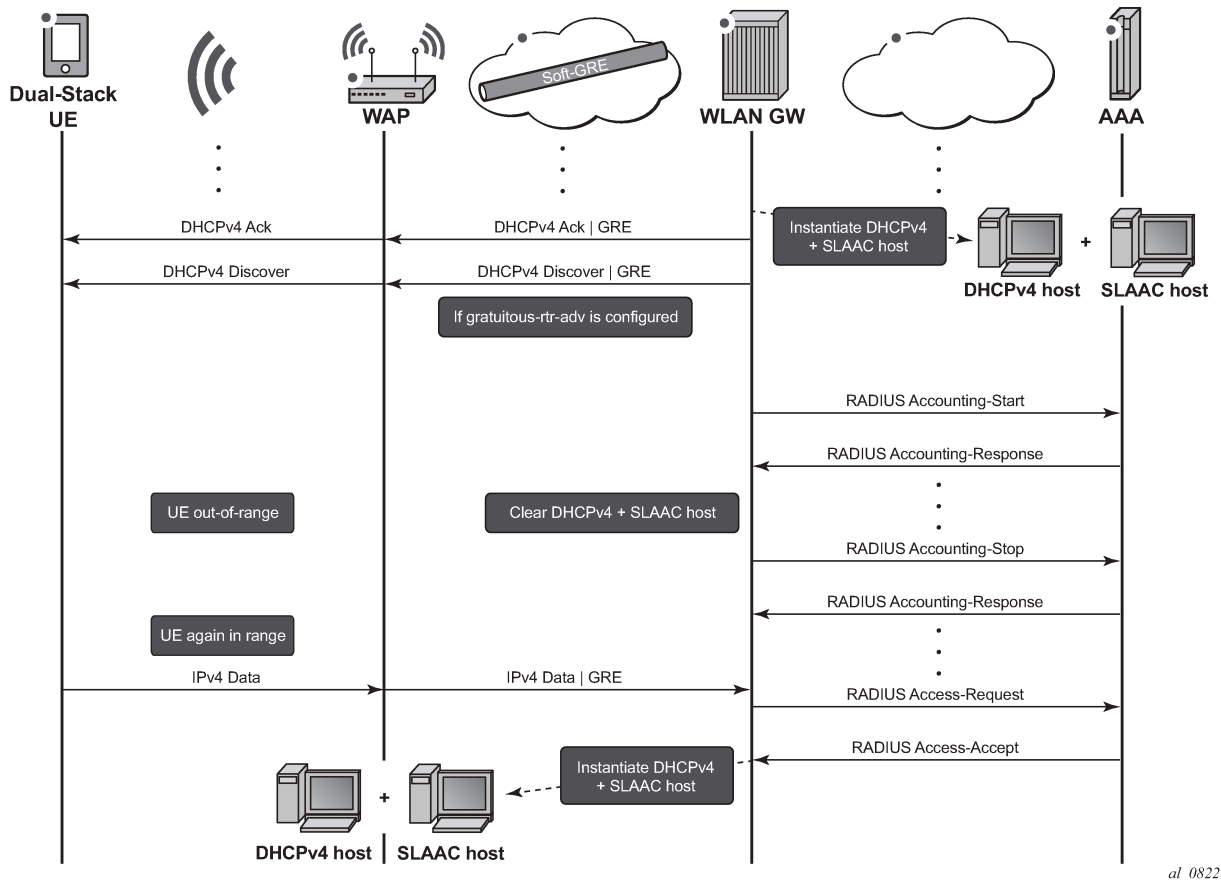

IPv6 is also not supported for migrant UEs, which means that ICMPv6 Router-Solicitation and DHCPv6 Solicit messages will be dropped by the WLAN-GW as long as the UE is in a migrant state. However, by using SLAAC/64 with DHCPv4 linking, when the UE becomes an ESM subscriber and a DHCPv4 host is created, a SLAAC/64 host is also created.

Configuration

Open versus closed SSID

The configuration examples in this chapter always refer to a closed SSID scenario. With an open SSID, the lookup in the RADIUS proxy cache is typically not configured. Instead, an authentication policy is directly referenced.

```
configure service vprn 2 customer 1 create
    subscriber-interface "sub-int-1" create
        group-interface "group-int-1" wlangw create
            authentication-policy "auth-pol-1"
            dhcp
                no user-db
```

```
                exit
            exit
        exit
 exit
```

DHCPv4 + SLAAC/64 model

In this model, DHCPv4 and SLAAC/64 are enabled independently of each other. The autonomous flag tells the UE that the IPv6 prefix in the ICMPv6 Router-Advertisement can be used for SLAAC. The no on-link configuration commands the UE to always perform neighbor discovery for the WLAN-GW, even for destinations within the IPv6 prefix.

```
configure service vprn 2 customer 1 create
    subscriber-interface "sub-int-1" create
        address 10.255.255.254/8
        ipv6
            subscriber-prefixes
                prefix 2001:db8:ffff::/48 wan-host
            exit
        exit
        group-interface "group-int-1" wlangw create
            ipv6
                router-advertisements
                    no managed-configuration
                    no other-stateful-configuration
                    dns-options
                        include-dns
                    exit
                    prefix-options
                        autonomous
                        no on-link
                    exit
                    no shutdown
                exit
                router-solicit
                    user-db "ludb-1"
                    no shutdown
                exit
            exit
            ipoe-linking
                shutdown
            exit
            sap-parameters
                sub-sla-mgmt
                    def-sub-id use-auto-id
                    sub-ident-policy "policy-sub-ident-1"
                exit
            exit
            dhcp
                proxy-server
                    emulated-server 172.16.0.1
                    no shutdown
                exit
                lease-populate 10000
                user-db "ludb-1"
                no shutdown
            exit
            ip-mtu 1454
            wlan-gw
                gw-address 172.16.74.244
```

```
                    gw-ipv6-address 2001:db8::1:1
                    router 1
                    tcp-mss-adjust 1400
                    wlan-gw-group 1
                    no shutdown
                exit
            exit
        exit
        no shutdown
exit
```

The SLAAC/64 prefix can come from the RADIUS server, as in the following RADIUS users file:

```
"user-1" Cleartext-Password := "pass-1"
        Alc-Subsc-ID-Str := "user-1",
        Alc-Subsc-Prof-Str := "sub-profile-1",
        Alc-SLA-Prof-Str := "sla-profile-1",
        Framed-IP-Address := 10.255.0.1,
        Alc-Primary-DNS := 67.138.54.100,
        Framed-IPv6-Prefix := 2001:db8:ffff::/64,
        Alc-IPv6-Primary-Dns := 2001:db8::8:8:8:8,
        Alc-IPv6-Secondary-Dns := 2001:db8::8:8:4:4
```

If the UE is successfully connected, two IPoE hosts will exist on the WLAN-GW.

```
*A:WLAN-GW # show service active-subscribers
===============================================================================
Active Subscribers
===============================================================================
-------------------------------------------------------------------------------
Subscriber user-1 (sub-profile-1)
-------------------------------------------------------------------------------

(1) SLA Profile Instance sap:[4/2/nat-out-ip:2049.4] - sla:sla-profile-1
-------------------------------------------------------------------------------
IP Address
               MAC Address       PPPoE-SID Origin
----------------------------------------------------------
10.255.0.1
               b0:9f:ba:b9:40:f8 N/A       DHCP
2001:db8:ffff::/64
               b0:9f:ba:b9:40:f8 N/A       IPoE-SLAAC
-------------------------------------------------------------------------------
Number of active subscribers : 1
-------------------------------------------------------------------------------
```

The trigger that created the SLAAC host and the origin is shown by issuing:

```
*A:WLAN-GW # show service id 2 slaac host detail
===============================================================================
SLAAC hosts for service 2
===============================================================================
Service ID          : 2
Prefix              : 2001:db8:ffff::/64
Interface Id        : N/A
Mac Address         : b0:9f:ba:b9:40:f8
Subscriber-interface : sub-int-1
Group-interface     : group-int-1
SAP                 : [4/2/nat-out-ip:2049.4]
Creation Time       : 2015/07/09 11:24:19
Persistence Key     : N/A
```

```
IPoE Trigger        : rtr-solicit
Last Auth Time      : 2015/07/09 11:24:19
Inactivity Timer    : 0d 00:03:59

Sub-Ident           : "user-1"
Sub-Profile-String  : "sub-profile-1"
SLA-Profile-String  : "sla-profile-1"
App-Profile-String  : ""
ANCP-String         : ""
Int Dest Id         : ""
Category-Map-Name   : ""

Info origin         : radius
Pool                : ""

Primary-Dns         : 2001:db8::8:8:8:8
Secondary-Dns       : 2001:db8::8:8:4:4

Circuit Id          : N/A
Remote Id           : N/A
-------------------------------------------------------------------------------
Number of hosts : 1
===============================================================================
```

The SLAAC/64 prefix can also come from a local SLAAC prefix pool:

```
configure service vprn 2 customer 1 create
    dhcp6
        local-dhcp-server "local-dhcp-server-1" create
            use-pool-from-client
            pool "slaac-prefix-pool-1" create
                prefix 2001:db8:ffff:ffff::/64 wan-host create
                    options
                        dns-server 2001:db8::8:8:8:8
                    exit
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The subscriber interface must then be configured with local-address-assignment enabled:

```
configure service vprn 2 customer 1 create
    subscriber-interface "sub-int-1" create
        group-interface "group-int-1" wlangw create
            local-address-assignment
                ipv6
                    client-application ipoe-slaac
                    server "local-dhcp-server-1"
                exit
                no shutdown
            exit
        exit
    exit
exit
```

The origin of the SLAAC host then changes to:

```
*A:WLAN-GW # show service id 2 slaac host detail | match origin
Info origin         : localPool
```

```
DHCPv4 + SLAAC/64 with DHCPv4 linking model
```

In this model, DHCPv4 linking instantiates a SLAAC/64 host when a DHCPv4 host is instantiated. This requires **ipoe-linking** to be configured:

```
configure service vprn 2 customer 1 create
    subscriber-interface "sub-int-1" create
        address 10.255.255.254/8
        ipv6
            subscriber-prefixes
                prefix 2001:db8:ffff::/48 wan-host
            exit
        exit
        group-interface "group-int-1" wlangw create
            ipv6
                router-advertisements
                    no managed-configuration
                    no other-stateful-configuration
                    dns-options
                        include-dns
                    exit
                    prefix-options
                        autonomous
                        no on-link
                    exit
                    no shutdown
                exit
                router-solicit
                    shutdown
                exit
            exit
            ipoe-linking
                gratuitous-rtr-adv
                no shutdown
            exit
            sap-parameters
                sub-sla-mgmt
                    def-sub-id use-auto-id
                    sub-ident-policy "policy-sub-ident-1"
                exit
            exit
            dhcp
                proxy-server
                    emulated-server 172.16.0.1
                    no shutdown
                exit
                lease-populate 10000
                user-db "ludb-1"
                no shutdown
            exit
            ip-mtu 1454
            wlan-gw
                gw-address 172.16.74.244
                gw-ipv6-address 2001:db8::1:1
                router 1
                tcp-mss-adjust 1400
                wlan-gw-group 1
                no shutdown
            exit
        exit
    exit
    no shutdown
```

```
exit
```

Note that DHCPv4 linking is mutually exclusive with ICMPv6 Router-Solicit handling. Configuring DHCPv4 linking while ICMPv6 Router-Solicit handling is still enabled results in the following error:

```
*A:WLAN-GW # configure service vprn 2 subscriber-interface "sub-int-1" group-interface "group-
int-1" ipoe-linking no shutdown
MINOR: SVCMGR #1543 Can't enable linking if router solicit authentication is enabled
```

Similarly, enabling ICMPv6 Router-Solicit handling while DHCPv4 linking is still enabled, results in the following error:

```
*A:WLAN-GW # configure service vprn 2 subscriber-interface "sub-int-1" group-interface "group-
int-1" ipv6 router-solicit no shutdown
MINOR: SVCMGR #1544 Can't enable router solicit authentication if linking is enabled
```

As with the DHCPv4 + SLAAC/64 model without DHCPv4 linking, if the UE is successfully connected, two IPoE hosts will exist on the WLAN-GW:

```
*A:WLAN-GW # show service active-subscribers
===============================================================================
Active Subscribers
===============================================================================
-------------------------------------------------------------------------------
Subscriber user-1 (sub-profile-1)
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
(1) SLA Profile Instance sap:[4/2/nat-out-ip:2049.4] - sla:sla-profile-1
-------------------------------------------------------------------------------
IP Address
              MAC Address      PPPoE-SID Origin
-----------------------------------------------------------
10.255.0.1
              b0:9f:ba:b9:40:f8 N/A        DHCP
2001:db8:ffff::/64
              b0:9f:ba:b9:40:f8 N/A        IPoE-SLAAC
-------------------------------------------------------------------------------
Number of active subscribers : 1
-------------------------------------------------------------------------------
```

The trigger that created the SLAAC host and the origin is shown by issuing:

```
*A:WLAN-GW # show service id 2 slaac host detail
===============================================================================
SLAAC hosts for service 2
===============================================================================
Service ID          : 2

```

DHCPv4 + DHCPv6/128 IA_NA model

Because some UEs do not support DHCPv6, this model configures DHCPv4 + DHCPv6/128 IA_NA with SLAAC/64 enabled. To avoid having two IPv6oE hosts set up for the UEs that do support DHCPv6, the **allow-multiple-wan-addresses** and **override-slaac** parameters are both configured. The allow-multiple-wan-addresses allows handling of DHCPv6 when a SLAAC host exists already, and the **override-slaac** parameter removes the SLAAC host after successful assignment of an IPv6 address via DHCPv6:

```
configure service vprn 2 customer 1 create
    subscriber-interface "sub-int-1" create
        address 10.255.255.254/8
        ipv6
            subscriber-prefixes
                prefix 2001:db8:ffff::/48 wan-host
            exit
        exit
        group-interface "group-int-1" wlangw create
            ipv6
                allow-multiple-wan-addresses
                router-advertisements
                    managed-configuration
                    other-stateful-configuration
                    dns-options

```

Conclusion

The WLAN-GW supports IPv4/v6 dual-stack UEs. Although the IPv6 support for UEs can handle single-stack IPv6-only UEs, the UEs only have IPv6 support as an add-on to IPv4.

WiFi Aggregation and Offload — Migrant User Support

This chapter provides information about WiFi aggregation and offload for migrant user support configurations.

Topics in this chapter include:

Applicability

The information and configuration in this chapter is based on SR OS Release 11.0.R4.

Overview

The term "Migrant user" refers to user equipment (UEs) that connects to a WiFi network service set identification (SSID) but moves out of the range of the access point before initiating or completing authentication. For open-SSIDs, a migrant user may stay in the range of the access point just long enough to get a DHCP lease from the WLAN-GW. In actual WiFi deployments with portal authentication, it has been observed that a large percentage of users are migrant such that they get a DHCP lease but do not initiate or complete authentication.

Prior to this feature, an Enhanced Subscriber Management (ESM) host is created when the DHCP process completes. This results in the consumption of resources on both the CPM and IOM, limiting the ESM scale and performance for fully authenticated active users. This feature adds support to create an ESM host only after a user has been fully authenticated, either via a web portal or with an AAA server based on completing EAP exchange. In addition, with this feature L2-aware NAPT is required, such that each UE gets the same shared configured inside IP address from the ISA via DHCP. Until a user is authenticated, forwarding of user traffic is constrained (via policy) to DNS and portal server access only.

Each user is allocated a small number of configured NAT outside ports to minimize public IP address consumption for unauthenticated users. Once the user is successfully authenticated, as indicated via a RADIUS Change of Authorization (COA) on successful portal authentication, an ESM host is created, and the L2-aware NAT is applied via a normal per-subscriber NAT policy. The inside IP address of the user does not change. The outside IP pool used is as per the NAT policy, and the L2-aware NAT could be 1:1 or NAPT with larger number of outside ports than in the un-authenticated phase. If a user is already pre-authenticated (for example if the RADIUS server remembers the MAC address of the UE from a previous successful portal authentication) then the initial access-accept from RADIUS will trigger the creation of the ESM host.

Migrant user support for open SSID based on portal authentication

Sequence of events

1. DHCP is received from UE on ISA

   Based on the DHCP and L2-aware NAT configuration on the ISA, an IP address is assigned to the user via DHCP. The DHCP and L2-aware NAT configuration is under the soft-gre node under the group-interface, or under vlan-tag range under the soft-gre node on the group-interface.

   A different DHCP lease-time can be configured for an un-authenticated user (initial-lease-time) and an authenticated user (active-lease-time) for which an ESM host has been created. It is suggested that the initial lease be configured to a smaller value while the UE is migrant so that resources can be reclaimed quickly for a truly migrant user that will not complete authentication.

   In addition to lease-times, DHCP return options, for example primary and secondary DNS and NBNS server addresses, that can be configured. This configuration can be per soft-GRE group interface or per VLAN range (where a VLAN tag corresponds to an SSID).

   Up to 512 bytes of received DHCP options from clients are stored on the ISA. Once the DHCP ACK is sent back to the UE from the ISA, the UE will be created on the ISA in "migrant (or unauthenticated) state".

   A configured L2-aware IP address is returned to each UE and a temporary L2-aware host is created on the anchor ISA for the UE. The NAT policy applicable to this L2-aware NAT for UE in migrant state is also configured under the group-interface (under soft-gre node or under vlan-tag range).

   ARP requests coming from the UE in migrant state will be responded to from the ISA. The authentication to RADIUS is triggered on receiving the first Layer 3 data packet as opposed to on a DHCP DISCOVER.

2. Layer 3 data packet received on the ISA

   The first Layer 3 packet (other than DHCP) will trigger RADIUS authentication from the ISA based on configured **isa-radius-policy** in the **configure>aaa** context. The user-name in the access-request is as per the user-name-format configured in the isa-radius-policy. By default it is the MAC address of the UE. The isa-radius-policy can be configured as the authentication policy under the soft-gre group-interface, or under specific VLAN tag ranges on the soft-gre group-interface. The latter allows for the use of a different authentication policy per SSID.

   The RADIUS packets from the ISA are sourced with the IP address owned by the ISA. Each ISA in the WLAN-GW group gets an IP address from a set of contiguous addresses, the start of which is configurable in isa-radius-policy. The nas-ip-address sent in access-request message is configurable in the isa-radius-policy as the ISA's local IP address or the system IP address. In case the RADIUS server is behind a load-balancer which updates the source IP address of the RADIUS messages, the RADIUS server may use nas-ip-address to route the RADIUS response back. In this case the nas-ip-address should be configured as the ISA's IP address otherwise the response would incorrectly be routed to the CPM instead of the ISA.

   The following debug output shows a RADIUS accept-request being sent to the RADIUS server on reception of first Layer 3 packet. The debug can be enabled by issuing:

```
debug router "management" radius packet-type authentication | accounting | coa

253 2013/08/07 20:58:35.53 UTC MINOR: DEBUG #2001 Base WLAN-GW

      CHADDR [27] 17 00:0a:0a:00:01:00
"
```

Received Layer 3 packets from the UE are handled as per the redirect-policy configured under the soft-gre group-interface or under applicable VLAN tag range on the soft-gre interface.

The redirect-policy is an IP ACL that should contain one more "forward rules" for traffic that should be forwarded while the UE is pending portal authentication. This typically should include traffic to and from DNS and web portal and is subjected to temporary L2-aware NAT. The redirect-policy also specifies the URL for redirecting triggered by http packets. The redirect-policy and/or the redirect URL can also be overridden via the RADIUS access-accept. Any other non-http traffic that does not match the forward rules is dropped.

While a UE is pending portal authentication no accounting messages are sent to the AAA server. Disconnect-Message from AAA server is supported while the UE is pending authentication.

3. Access-accept from RADIUS

The access-accept is received on the ISA from which the access-request was generated. The initial access-accept from RADIUS can indicate if a user needs to be authenticated by the portal or is a pre-authenticated user. The indication is based on inclusion of a "redirect policy" applicable to the user in a vendor specific attribute (VSA) (Alc-Wlan-Portal-Redirect, type = string) received from the RADIUS server. The access-accept can also include a redirect URL VSA (Alc-Wlan-Portal-Url, type = string) for the user. An empty Alc-Wlan-Portal_redirect VSA forces the use of the redirect policy that is locally specified under the soft-gre interface or under vlan-tag ranges on soft-gre interface. The redirect-policy is created under sub-mgmt node.

The UE state is changed to "portal" to indicate the UE is pending portal authentication and has limited access.

The following debug output shows the RADIUS accept-request being received from the RADIUS server and being processed by the WLAN-GW.

```
255 2013/08/07 20:58:35.61 UTC MINOR: DEBUG #2001 Base WLAN-GW
"WLAN-GW: MDA 2/1, SeqNo 11831
   Info:     anchor ingressing frame

```

If neither of the two redirect related VSAs are included in access-accept, then this indicates a "pre-authenticated user", and an ESM host is created for the subscriber with a subscriber-profile and other subscriber configuration from access-accept; from here normal ESM based forwarding occurs for the subscriber.

If a user is determined as a "pre-authenticated user", a message is generated to the CPM to create an ESM host. The information received from RADIUS in the access-accept message (for example subscriber-profile, app-profile etc) and the information from DHCP (for example the DHCP options) are passed in this message.

- COA from RADIUS

  When user's credentials entered on the portal are successfully verified, the portal triggers the AAA server to generate COA to WLAN-GW. The COA serves as a trigger to create an ESM host. The COA MUST contain the subscriber-id and user-name, which are used as a key to identify the UE pending portal authentication.

  The following shows an example debug of a COA being received from the AAA server.

```
248 2013/08/07 19:12:38.29 UTC MINOR: DEBUG #2001 Base RADIUS
"RADIUS: Transmit
  Change of Authorization(43) 192.0.2.3:36776 id 124 len 96 vrid 1
    VSA [26] 19 Alcatel(6527)
      SUBSC ID STR [11] 17 00:0a:0a:00:01:00
    USER NAME [1] 17 00:0a:0a:00:01:00
    VSA [26] 10 Alcatel(6527)
      SLA PROF STR [13] 8 sla-profile-1
    VSA [26] 10 Alcatel(6527)
      SUBSC PROF STR [12] 8 sub-profile-1
  "
```

When the COA is received and successfully processed, a COA-ACK is sent back to the AAA server. The COA message is passed to the CPM to create an ESM host. The information received in the COA, as well as stored information from DHCP (for example the DHCP options) are passed in this message. Once the ESM host is successfully created, the state of the UE on the ISA is changed accordingly to "ESM-user", and can be seen in the output of **tools dump WLAN-GW UE** command, as shown below.

The UE now has full access (and is not restricted by the original redirect-policy). The COA provides a reference to a subscriber profile that contains the NAT policy for an authenticated UE. The UE continues to keep the same inside L2-aware IP address that was provided originally via DHCP on the ISA. However, the NAT for an authenticated user could be an L2-aware 1:1 NAT or NAPT with a different outside pool and outside ports than the UE in migrant state. The ESM host that is created as described above will also result in the creation of a normal L2-aware host. The original temporary L2-aware host is retained for 10 seconds (and then deleted) to ensure the http response from the portal can be successfully routed back to the UE on the existing connection.

```

```

If UE goes out of range such that the idle timeout expires, the ESM host is deleted and an accounting-stop is sent to the AAA server. If a UE then comes back, and still has a valid DHCP lease, it may not send DHCP DISCOVER or REQUEST and continue to send data. The **data-triggered-ue-creation** command can be configured under soft-gre node on the group-interface (or under vlan-tag ranges on the group-interface) to trigger authentication and recreation of the ESM host for this UE.

The overall sequence of events to take a UE from migrant to authenticated state, where the forwarding of UE traffic is not restricted, is shown in Figure 181: Sequence of events to establish and authenticate a migrant User.

Figure 181: Sequence of events to establish and authenticate a migrant User
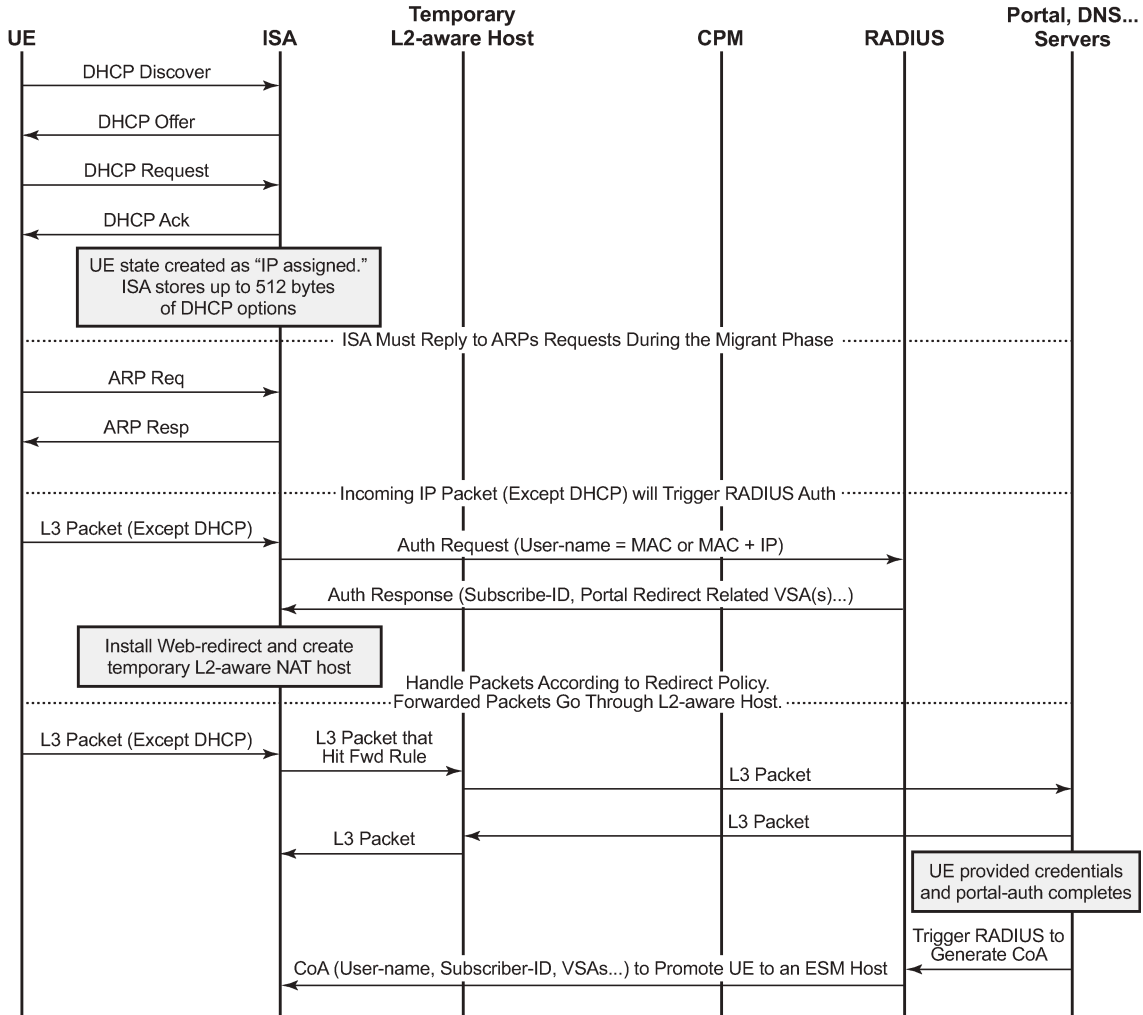

Figure 182: Sequence of events to establish and authenticate a migrant user (continued)

Configuration

The authentication-policy as shown below is used to configure a RADIUS server, and is applicable to the UEs in authenticated state.

```
subscriber-mgmt
    authentication-policy "authentication-1" create
     password "E40PedK6aqrEIpr2DEoJyVR8PQ3XkFF7" hash2
       radius-authentication-server
                source-address 192.0.2.1
                router "management"
                server 1 address 192.0.2.3 secret "6uuGli25Vtl49q0." hash2
       exit
       accept-authorization-change
       include-radius-attribute
                acct-session-id
                circuit-id
                remote-id
                nas-port-id
                nas-identifier
                nas-port-type
                pppoe-service-name
                dhcp-options
                dhcp-vendor-class-id
                access-loop-options
                mac-address
                called-station-id
                calling-station-id sap-string
```

```
                 tunnel-server-attrs
```

An isa-radius-policy is required for authentication from the ISA, as below – this contains the attributes to be
sent in the access request message to the RADIUS server, which is also configured in this policy.

```
aaa
    isa-radius-policy "isa-policy-1" create
        nas-ip-address-origin isa-ip
        password "CA06ALDnhyBJERE4xnXoW15MQ/hu74x5nDE7F.OJxHM" hash2
        auth-include-attributes
            called-station-id
            calling-station-id
            circuit-id
            dhcp-options
            dhcp-vendor-class-id
            mac-address
            nas-identifier
            nas-port-id
            nas-port-type
            remote-id
        exit
        servers
            router 1
            source-address-range 192.168.0.2
            server 1 create
                authentication
                coa
                ip-address 192.0.2.3
                secret "CA06ALDnhyBJERE4xnXoW15MQ/hu74x5nDE7F.OJxHM" hash2
                no shutdown
            exit
        exit
    exit
exit
```

The HTTP redirect policy is shown below, this is enforced on ISA while a UE is migrant and contains the
configurations defining the forwarding of traffic in this state.

```
subscriber-mgmt
    http-redirect-policy "redirect-policy-1" create
 url "http://66.185.84.163"
 forward-entries
     dst-ip 192.168.1.1 protocol udp dst-port 53
     dst-ip 192.168.1.2 protocol udp dst-port 53
     dst-ip 66.185.84.163 protocol tcp dst-port 80
     dst-ip 10.0.0.1 protocol udp dst-port 67
     dst-ip 10.0.0.1 protocol udp dst-port 68
  exit
     exit
exit
```

The NAT pool configuration for migrant and authenticated UEs is shown below.

```
vprn 10 customer 1 create
    nat
        inside
            l2-aware
                address 10.0.0.1/24
            exit
        exit
        outside
```

```
            pool "migrant-pool-1" nat-group 1 type wlan-gw-anchor create
                address-range 192.168.2.0 192.168.2.255 create
                exit
                no shutdown
            exit
            pool "auth-pool-1" nat-group 1 type l2-aware create
                address-range 192.168.3.0 192.168.3.255 create
                exit
                no shutdown
            exit
        exit
    exit
exit
```

The NAT policy for migrant UEs is as follows.

```
service
    nat
        nat-policy "migrant-policy" create
            pool "migrant-pool-1" router 1
            timeouts
                tcp-established min 1
            exit
        exit
    exit
exit
```

Below is the NAT policy for authenticated UEs.

```
service
    nat
        nat-policy "nat-auth-policy-1" create
            pool "auth-pool-1" router 10
        exit
    exit
exit
```

The migrant user configuration under the soft-gre group-interface within the VPRN service is shown below. This includes configuration for authentication, DHCP, and forwarding from the ISA, as defined in the sections above. The migrant user related configuration can be specified per VLAN tag (or range) under soft-gre interface, where each VLAN tag represents an SSID.

```
vprn 1 customer 1 create
    subscriber-interface "sub-int-1" create
        address 10.0.0.1/24
        group-interface "soft-gre-1" softgre create
            sap-parameters
                sub-sla-mgmt
                    def-sla-profile "sla-profile-1"
                    def-sub-id use-auto-id
                    def-sub-profile "sub-profile-1"
                    sub-ident-policy "sub_ident"
                exit
            exit
            dhcp
                proxy-server
                    emulated-server 10.0.0.1
                    lease-time hrs 1
                    no shutdown
                exit
                trusted
```

```
                            lease-populate 32767
                            gi-address 10.0.0.1
                            no shutdown
                        exit

                        authentication-policy "authentication-1"

                                        authentication-policy "isa-policy-1"
                                    exit
                                    data-triggered-ue-creation
                                    dhcp
                                        active-lease-time min 12
                                        initial-lease-time min 5
                                        l2-aware-ip-address 10.0.0.10
                                        primary-dns 192.168.1.1
                                        secondary-dns 192.168.1.2
                                        no shutdown
                                    exit
                                    http-redirect-policy "redirect-policy-1"
                                    nat-policy "migrant-policy"
                                exit

                        exit
                        no shutdown
                    exit
                exit
            exit
        exit
```

Conclusion

Migrant user support is a useful feature that optimizes system resources (public IP addresses, ESM hosts, CPU processing, etc.) to provide the scale and performance required in live hot-spot and home-spot WiFi deployments at peak times.

WiFi Aggregation and Offload — Open SSID with DSM and Lawful Intercept

This chapter provides information about WiFi Aggregation and Offload — Open SSID with DSM and Lawful Intercept.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 12.0.R4.

Overview

WiFi Aggregation and Offload functionality for the 7750 SR has been supported in SR OS 10.0.R1 and later. This includes a RADIUS proxy server with RADIUS proxy cache and support for soft-GRE tunnels.

Initially, WLAN-GW subscribers were implemented using Enhanced Subscriber Management (ESM) on the Control Processing Module (CPM). To achieve higher scalability, subscribers can be implemented using Distributed Subscriber Management (DSM) on the Multi-Service Integrated Service Adapter (MS-ISA) cards, as described in this chapter.

Law enforcement agencies often require operators to provide a method of intercepting traffic from specific User Equipment (UE). This chapter describes a method of configuring Lawful Intercept (LI) for a DSM UE.

Starting with Release 12.0.R4, DSM can be used for higher scalability by instantiating subscribers on the MS-ISA cards, even after authentication, instead of creating them on the CPM as when using ESM. Therefore, the maximum number of UEs per WLAN-GW, and other performance factors such as setup rate, are higher. When using DSM, commands that are different from those used with ESM are used to monitor the UEs. These commands are similar to those used by the previously available migrant users feature, which only instantiated the users on the MS-ISA cards prior to their authentication.

Lawful intercept can also be configured to intercept traffic to and from a UE. For security reasons, the configuration for LI can be kept separate and invisible to the regular admin user of the 7750 SR, even if this admin user has full admin access. In this situation, any information about the intercept is only available to the LI user. An example LI configuration is shown in this document, with the intercept configured using CLI. It is also possible to trigger DSM LI using RADIUS (in Access-Accept or Change of Authorization (CoA) messages). The RADIUS attributes are encrypted so that knowledge of the intercept cannot be gained by examining a packet capture.

Configuration

The WiFi offload scenario with open SSID, DSM and LI shown in has following characteristics:

- Open SSID with web portal authentication
- DSM with fixed IPv4 address for all UEs, with L2-aware NAT
- Access Point (AP) access in Virtual Private Routed Network (VPRN) 1000
- UEs terminated in VPRN 2004
- Lawful Intercept with separate user account for monitoring or configuring intercepts using the CLI

Figure 183: WiFi Offload Scenario with Open SSID, DSM and LI
WLAN-GW

Note that the uplink interface, Interior Gateway Protocol (IGP), and system configuration is outside the scope of this document.

The following Card and Media Dependent Adapter (MDA) configuration only shows the WLAN-Input/Output Module (IOM). An IOM card containing two MS-ISA cards provides the WLAN-GW functionality. The MDA type for the ISA cards is isa-bb, the same type that is used for NAT.

```
*A:WLAN-GW# /configure card 3
*A:WLAN-GW>config>card# info
--------------------------------------------
        card-type iom3-xp
        mda 1
            mda-type isa-bb
            no shutdown
        exit
        mda 2
            mda-type isa-bb
```

```
                no shutdown
            exit
        no shutdown
-----------------------------------------------
```

The following ISA configuration applies.

```
*A:WLAN-GW# /configure isa
*A:WLAN-GW>config>isa# info
-----------------------------------------------
        wlan-gw-group 1 create
            active-iom-limit 1
            iom 3
            no shutdown
        exit
-----------------------------------------------
```

The following NAT configuration provides an outside pool of type wlan-gw-anchor required to support DSM.

```
*A:WLAN-GW# /configure router nat
*A:WLAN-GW>config>router>nat# info
-----------------------------------------------
            outside
                pool "WiFi-4-dsm" nat-group 1 type wlan-gw-anchor create
                    port-reservation ports 15
                    address-range 10.0.40.0 10.0.40.255 create
                    exit
                    no shutdown
                exit
            exit
-----------------------------------------------

*A:WLAN-GW# /configure service nat
*A:WLAN-GW>config>service>nat# info
-----------------------------------------------
            nat-policy "WiFi-4-dsm" create
                pool "WiFi-4-dsm" router Base
            exit
-----------------------------------------------
```

The following Authentication, Authorization and Accounting (AAA) configuration contains an isa-radius-policy. The nas-ip-address-origin parameter selects the IP address sent as the Network Access Server (NAS) IP Address attribute in the ISA RADIUS requests. The source-address-range configures the IP address used by the first MS-ISA card on this WLAN-GW to send and receive RADIUS messages. Other WLAN IOM MS-ISA cards will get consecutive IP addresses in order of slot number. The password and secret configured here have to match the RADIUS server configuration.

```
*A:WLAN-GW# /configure aaa
*A:WLAN-GW>config>aaa# info
-----------------------------------------------
        isa-radius-policy "IRS_4" create
            nas-ip-address-origin isa-ip
            password "7USmr6f7JkxD5zb3MeEZnjf1BSqaZkcH" hash2
            servers
                access-algorithm round-robin
                router "Base"
                source-address-range 10.10.186.1
                server 1 create
                    authentication
                    coa
                    ip-address 10.43.186.1
```

```
                    secret "7USmr6f7JkxD5zb3MeEZnjf1BSqaZkcH" hash2
                    no shutdown
                exit
            exit
        exit
-----------------------------------------------
```

The following subscriber management configuration contains the http-redirect-policy for redirecting newly
connected UEs to the web portal, and allowing only traffic to the web portal IP address and the Domain
Name Server (DNS) server.

```
*A:WLAN-GW# /configure subscriber-mgmt
*A:WLAN-GW>config>subscr-mgmt# info
-----------------------------------------------
        http-redirect-policy "WiFi-4-dsm-redirect" create
            url "http://portal1.3ls.net/portal4.php?mac=$MAC"
            forward-entries
                dst-ip 10.43.186.1 protocol tcp dst-port 80 prefix-length 32
                dst-ip 10.43.186.43 protocol udp dst-port 53 prefix-length 32
            exit
        exit
-----------------------------------------------
```

The following policy configuration is used for exporting required routes, including the address of the APs,
the outside NAT prefixes, and the ISA RADIUS source IP addresses.

```
*A:WLAN-GW# /configure router policy-options
*A:WLAN-GW>config>router>policy-options# info
-----------------------------------------------
            prefix-list "WiFi"
                prefix 10.0.0.0/16 longer
                prefix 10.10.186.0/24 longer
            exit
            prefix-list "WiFi-APs"
                prefix 10.1.0.0/16 longer
            exit
            policy-statement "toisis"
                entry 10
                    from
                        prefix-list "WiFi" "WiFi-APs"
                    exit
                    action accept
                    exit
                exit
            exit
            policy-statement "WiFi-APs"
                entry 10
                    from
                        prefix-list "WiFi-APs"
                    exit
                    action accept
                    exit
                exit
            exit
-----------------------------------------------
```

The following configuration is used for exporting the outside NAT prefixes and the ISA RADIUS source IP
addresses to ISIS.

```
*A:WLAN-GW# /configure router isis
*A:WLAN-GW>config>router>isis# info
```

```
        -----------------------------------------
            export "toisis"
        -----------------------------------------
```

The following configures VPRN 1000 for AP connectivity, where the AP prefix is exported to the Global
Route Table (GRT) so that it can be managed from servers reachable through the Base router.

```
*A:WLAN-GW# /configure service vprn 1000
*A:WLAN-GW>config>service>vprn# info
        -----------------------------------------
            route-distinguisher 65400:1000
            interface "toAP" create
                address 10.1.0.1/24
                sap 1/1/7 create
                exit
            exit
            grt-lookup
                enable-grt
                    static-route 0.0.0.0/0 grt
                exit
                export-grt "WiFi-APs"
            exit
        -----------------------------------------
```

The following configures VPRN 2004 for UE termination, with distributed-sub-mgmt enabled and the ISA
RADIUS policy configured under vlan-tag-ranges.

```
*A:WLAN-GW# /configure service vprn 2004
*A:WLAN-GW>config>service>vprn# info
        -----------------------------------------
            description "Open WiFi with DSM"
            route-distinguisher 65400:2004

echo "LI Filter Lock State Configuration"
#-------------------------------------------------
        li-filter-lock-state locked
#-------------------------------------------------
echo "LI Mirror Source Configuration"
#-------------------------------------------------
```

```
            li-source 199
                wlan-gw
                    dsm-subscriber mac 68:7f:74:8b:3d:d7
                        intercept-id 1
                        session-id 199
                    exit
                exit
                no shutdown
            exit
----------------------------------------------
```

Freeradius

This default configuration section sets the VSA Alc-Wlan-Ue-Creation-Type with value 1, which triggers the creation of a DSM host (value 0 is ESM). The Nas-Ip-Address is returned in the Alc-Wlan-Portal-URL to tell the web portal which MS-ISA address should receive the RADIUS CoA request:

```
/etc/freeradius/users:

DEFAULT         Auth-Type := Local, User-Password := "alcatel", user-name=~"^.*$"
                    Alc-Subsc-ID-Str = "%{User-Name}",
                    Alc-Wlan-Ue-Creation-Type = 1,
                    Alc-Wlan-Portal-Redirect = "WiFi-4-dsm-redirect",
                    Alc-Wlan-Portal-URL = "http://portal1.3ls.net/portal4.php?nas=%{Nas-Ip-
Address}&mac=%{User-Name}&ssid=WiFi-4",
```

As an alternative to configuring the LI for the UE in the CLI, the following RADIUS attributes can be sent in the Access-Accept and CoA.

```
                    Alc-LI-Action = "enable",
                    Alc-LI-Destination = "199",
                    Alc-LI-Intercept-Id = 1,
```

In /etc/freeradius/clients.conf, each ISA is a client.

```
client 10.10.186.1 {
        secret      = alcatel
        shortname   = WLAN-GW-ISA1
}
client 10.10.186.2 {
        secret      = alcatel
        shortname   = WLAN-GW-ISA2
}
```

A RADIUS CoA sent during a successful portal login makes the following UE a DSM subscriber with full access.

```
echo "User-Name='.$mac.',Alc-Wlan-Ue-Creation-Type="1",Alc-Subsc-Prof-Str="SUBP_4",Alc-SLA-
Prof-Str=SLAP_4,Alc-Primary-Dns = 10.43.186.43," | /usr/bin/radclient -x -r 1 -t 2 '.$nas.' coa
 alcatel
```

Access Points

The following must be configured on the Access Point as a minimum:

- IP address 10.1.1.10/24

- Default route to 10.1.1.1

- Open SSID WiFi-4 mapped to VLAN 40

- Soft-GRE tunnel with destination 192.4.4.4, with VLAN 40 mapped to this tunnel

Show Commands

The following commands show the status of the UEs. For DSM users, the UEs are displayed using a tools command. Before portal authentication, the UE is in Portal state.

```
*A:WLAN-GW# /tools dump wlan-gw ue

Debug

In this example, the following debug configuration applies.

```
debug
    mirror-source 99
        port 1/1/7 egress ingress
        port 1/1/9 egress ingress
        no shutdown
    exit
    wlan-gw
        group 1
            ue 68:7f:74:8b:3d:d7 packet dhcp radius
        exit
    exit
exit

The debug trace starts with DHCP.

    VSA [26] 6 Alcatel(6527)
      PRIMARY DNS [9] 4 10.43.186.43
"
```

Finally the UE is in DSM state with unrestricted access.

Conclusion

The 7750 SR WLAN-GW, with Open SSID, can support WiFi Offload users as DSM subscribers instantiated on MS-ISA cards. This allows the support of a greater number of UEs on a single system when a full ESM feature set is not required. DSM UEs, just as ESM UEs, can have their traffic intercepted using LI.
