Combined MC traffic of SA1 and SA2 decreases below threshold

The MC traffic rate from SA1 remains at 150 kbps. The MC traffic rate from SA2 decreases to 375 kbps. The measured cumulative MC traffic rate from SA1 and SA2 for G2 is 150 + 375 = 525 kbps < 1000 kbps.

PE-1 generates an S-PMSI A-D unreachable for the (SA1,G2) SMET from PE-2 and for the (*,G2) SMET from PE-3. PE-2 and PE-3 leave the specific S-PMSI trees and receive MC traffic from the wildcard S-PMSI tree again.

Conclusion

SR OS supports S-PMSI A-D routes in EVPN OISM networks and in VPLS networks with EVPN proxy.

EVPN Sticky ECMP for IP Prefix Routes

This chapter provides information about EVPN sticky ECMP for IP prefix routes.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and the configuration in this chapter are based on SR OS Release 25.3.R1. Sticky ECMP for BGP routes is supported in SR OS Release 19.10 and later. Sticky ECMP for EVPN IFL and EVPN IFF routes is supported in SR OS Release 23.10 and later.

EVPN sticky ECMP can be combined with weighted ECMP and IP aliasing ECMP. For weighted ECMP, see the EVPN unequal ECMP for RT5 IFL and IFF routes chapter. For IP aliasing ECMP, see the EVPN IP Aliasing for IP Prefix Routes chapter.

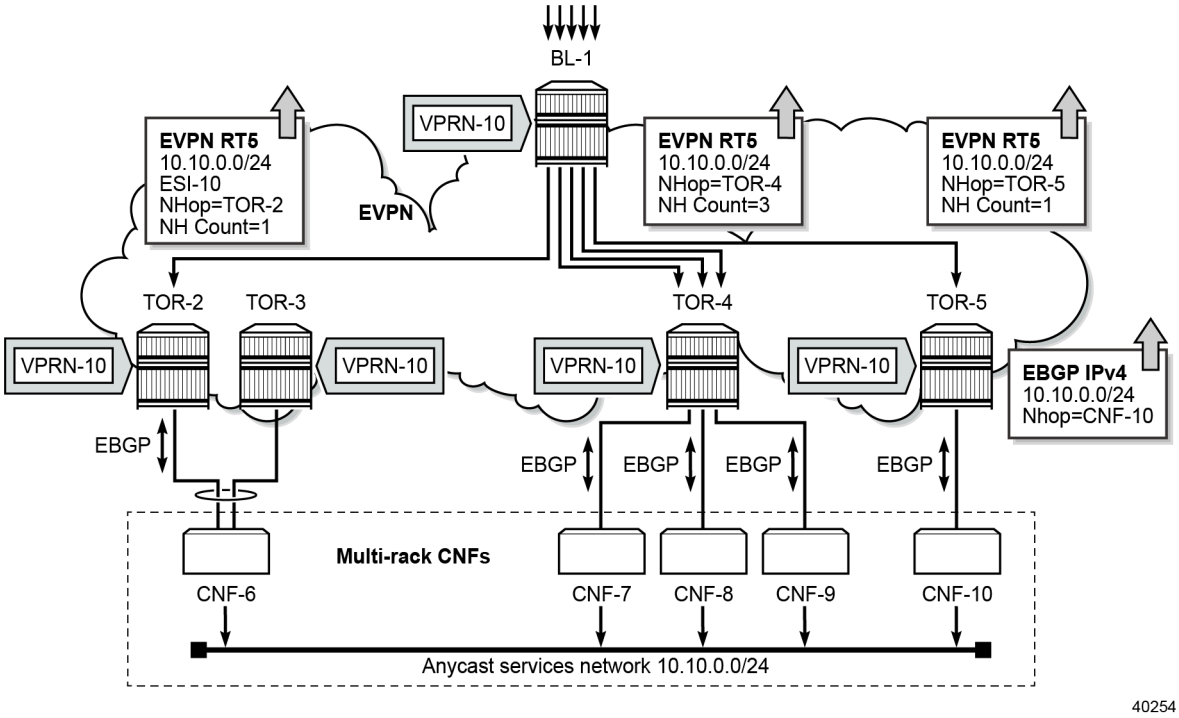
Overview

Figure 130: Weighted traffic distribution toward anycast services network shows the flow distribution in an EVPN network toward an anycast services network. The ECMP distribution of the flows from the border leaf BL-1 toward the Top of Racks (TORs) is weighted. For example, TOR-4 advertises a weight of 3 (expressed as a next-hop count of 3 in the EVPN Link Bandwidth Extended Community), which means it receives three times as many flows as TOR-5 and as the combined total of TOR-2 and TOR-3. CNF-6 has an EBGP session with TOR-2, but not with TOR-3. With IP aliasing ECMP configured between TOR-2 and TOR-3, TOR-3 forwards traffic to CNF-6 without tromboning via TOR-2.

Note: CNF stands for Containerized Network Function. In this example, the CNFs are simulated by SR OS nodes.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

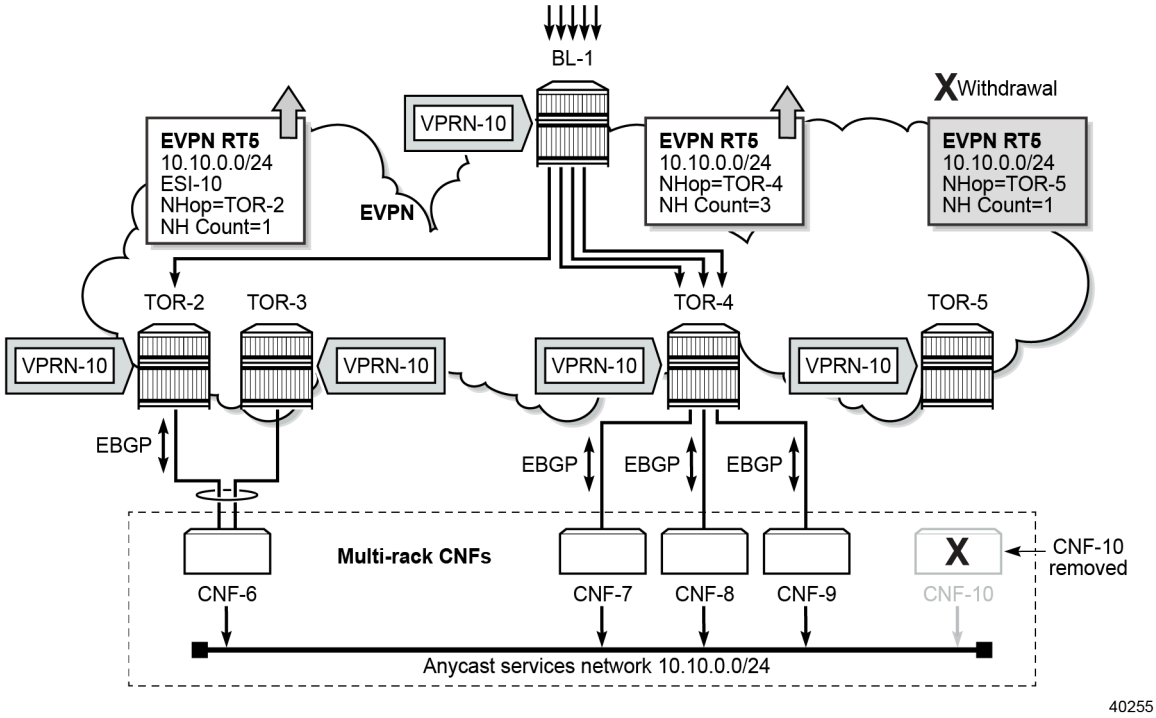
Figure 130: Weighted traffic distribution toward anycast services network



Sticky ECMP is implemented in software and—for FP-based platforms—each sticky route takes 64 next-hop hashing buckets in the data path. When CNF-10 is removed or a network failure causes CNF-10 to be unreachable, TOR-5 withdraws the IP prefix route for prefix 10.10.0.0/24 and the flows are redistributed over the remaining next-hops according to the weighted ECMP set. Existing flows to TOR-2, TOR-3, or TOR-4 may be affected and the potential applications' TCP sessions to the CNFs too. When sticky ECMP is configured, the existing flows via TOR-2, TOR-3, or TOR-4 remain unchanged; only the flows via TOR-5 are affected and must be redistributed over the remaining routes that are shown in Figure 131: Redistributed traffic flows after CNF-10 is removed. Table Table 11: Sticky ECMP flow distribution when one next-hop is removed for 10.10.0.0/24 in the Appendix shows the distribution over the internal hashing buckets.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 131: Redistributed traffic flows after CNF-10 is removed



The same issue arises when an additional CNF is added. When initially all flows are distributed over TOR-2, TOR-3, and TOR-4, and CNF-10 is added afterward, only a subset of the flows is affected. The total ECMP weight is initially 1 + 3 = 4 and after CNF-10 is added, the total ECMP weight becomes 1 + 3 + 1 = 5. This implies that 80% of the existing flows via TOR-2, TOR-3, or TOR-4 remain unchanged, while 20% of the flows moves to CNF-10 with TOR-5 as next-hop, see Table 12: Sticky ECMP flow distribution when one next-hop is added for 10.10.0.0/24 in the Appendix.

The **sticky-ecmp** command enables stickiness and is configurable in policy actions.

```
[ex:/configure policy-options]
A:admin@BL-1# tree flat detail | match sticky-ecmp
policy-statement <string> default-action sticky-ecmp <boolean>
policy-statement <string> entry <number> action sticky-ecmp <boolean>
policy-statement <string> named-entry <string> action sticky-ecmp <boolean>
```

The **sticky-ecmp** command only has effect in a BGP import policy applied to one or more BGP peers in the base router or in a service; it has no effect in a BGP export policy.

Configuration

The following examples are described in this section;

- Sticky ECMP for EVPN IFL over MPLS
- Sticky ECMP for EVPN IFL over SRv6
- Sticky ECMP for EVPN IFF over VXLAN

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Sticky ECMP can be combined with regular ECMP, weighted ECMP, and IP aliasing ECMP. In all examples in the following sections, weighted ECMP is enabled on BL-1 and all TORs; IP aliasing ECMP is configured on TOR-2 and TOR-3.

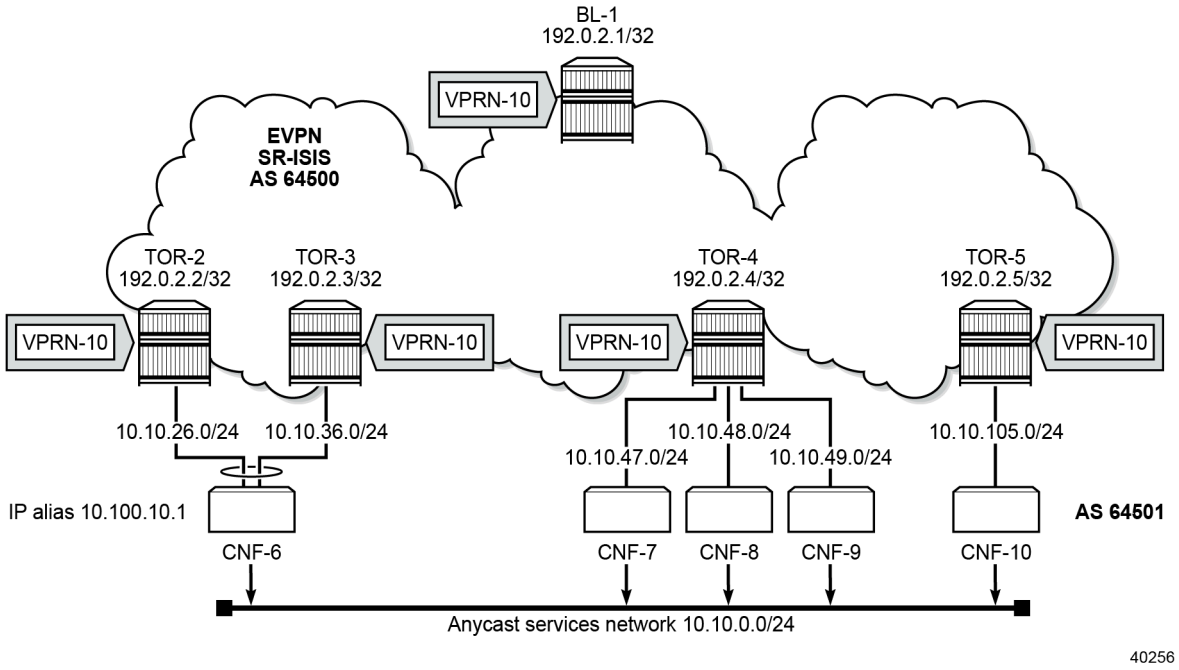
Sticky ECMP for EVPN IFL over MPLS

Figure 132: Example topology - IFL EVPN-MPLS shows the example topology with an EVPN-MPLS network in autonomous system (AS) 64500 with border leaf BL-1 and four TORs:

- TOR-2 and TOR-3 are both connected to CNF-6 and have IP aliasing ECMP
- TOR-4 is connected to CNF-7, CNF-8, and CNF-9
- TOR-5 is connected to CNF-10

The CNFs in AS 64501 connect to an anycast services network. The ECMP distribution of the flows from the BL to the TORs are weighted based on the number of CNFs advertising the same anycast network to the TORs, so TOR-4 receives three times as many flows as TOR-5 or the combination of TOR-2 and TOR-3.

Figure 132: Example topology - IFL EVPN-MPLS



Configuration

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- SR-ISIS on the router interfaces in AS 64500

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- IBGP between route reflector (RR) BL-1 and each TOR for the EVPN address family

Sticky ECMP is only configured on BL-1 using the following policy which adds stickiness to prefix 10.10.0.0/24 in VPRN-10:

```
# on BL-1:
configure {
    policy-options {
        community "comm-10" {
            member "target:64500:10" { }
        }
        prefix-list "cnf_ips-10" {
            prefix 10.10.0.0/24 type longer {
            }
        }
        policy-statement "import-add-stickiness-vprn-10" {
            entry 10 {
                from {
                    prefix-list ["cnf_ips-10"]
                    community {
                        name "comm-10"
                    }
                }
                action {
                    action-type accept
                    sticky-ecmp true     # add stickiness
                }
            }
            entry 11 {
                from {
                    community {
                        name "comm-10"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

The **sticky-ecmp** command only has effect in import policies. It suffices to configure this policy on one BGP peer in the base router on BL-1, as follows. For the same destination 10.10.0.0/24, the router programs the next-hops (192.0.2.2, 192.0.2.3, 192.0.2.4, and 192.0.2.5) as sticky even if only BGP peer 192.0.2.2 is configured with this import policy.

```
# on RR BL-1:
configure {
    router "Base" {
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "TORs" {
                type internal
                peer-as 64500
                family {
                    evpn true
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                cluster {
                    cluster-id 192.0.2.1
                }
            }
            neighbor "192.0.2.2" {
                group "TORs"
                import {
                    policy ["import-add-stickiness-vprn-10"]
                }
            }
            neighbor "192.0.2.3" {
                group "TORs"
            }
            neighbor "192.0.2.4" {
                group "TORs"
            }
            neighbor "192.0.2.5" {
                group "TORs"
            }
```

Alternatively, the import policy can also be configured at service level, see further.

On the TORs, the BGP configuration does not include such import policy:

```
# on TOR-2, TOR-3, TOR-4, TOR-5:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            rapid-update {
                evpn true
            }
            group "BL" {
                type internal
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "BL"
            }
        }
```

The configuration of VPRN-10 on BL-1 is as follows:

```
# on BL-1:
configure {
    service {
        vprn "VPRN-10" {
            admin-state enable
            description "EVPN-MPLS IFL VPRN-10"
            service-id 10
            customer "1"
            ecmp 10
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.1:10"
                    evi 10
```

                }
            }
        }
```

The service configuration on TOR-2 is as follows. The Ethernet segment is configured on TOR-2 and TOR-3 for IP aliasing ECMP. EBGP is configured in VPRN-10 with neighbor CNF-6 on TOR-2 only, not on TOR-3.

```
# on TOR-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ES-10" {               # same on TOR-3
                        admin-state enable
                        type virtual
                        esi 00:00:00:00:00:23:23:23:10:00
                        multi-homing-mode all-active
                        association {
                            vprn-next-hop 10.100.10.1 {     # IP alias on CNF-6
                                virtual-ranges {
                                    evi 10 { }
                                }
                            }
                        }
                    }
                }
            }
        }
        vprn "VPRN-10" {
            admin-state enable

```
            }
        }
```

The nodes in AS 64500 exchange EVPN IFL routes for VPRN-10, while the EBGP sessions between VPRN-10 on the TORs and the base router on the CNFs exchange BGP IPv4 routes. The export policy "export-evpn-ifl-bgp" in VPRN-10 on the TORs is needed to export BGP routes for the corresponding EVPN IFL routes:

```
# on TOR-2, TOR-3, TOR-4, TOR-5:
configure {
    policy-options {
        policy-statement "export-evpn-ifl-bgp" {
            description "export from EVPN-IFL to BGP"
            entry 10 {
                from {
                    protocol {
                        name [evpn-ifl]
                    }
                }
                to {
                    protocol {
                        name [bgp]
                    }
                }
                action {
                    action-type accept
                }
            }
```

On TOR-4, VPRN-10 is configured as follows:

```
# on TOR-4:
configure {
    service {
        vprn "VPRN-10" {
            admin-state enable
            description "EVPN-MPLS IFL VPRN-10"
            service-id 10
            customer "1"
            autonomous-system 64500
            ecmp 10
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.4:10"
                    evi 10
                    vrf-target {

                }
            }
        }
```

For VPRN-10, TOR-5 only has neighbor CNF-10 and the configuration is as follows:

```
# on TOR-5:
configure {
    service {
        vprn "VPRN-10" {
            admin-state enable
            description "EVPN-MPLS IFL VPRN-10"
            service-id 10
            customer "1"
            autonomous-system 64500
            ecmp 10
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.5:10"
                    evi 10
                    vrf-target {
                        community "target:64500:10"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise {
                        }
                    }
                }
            }
            bgp {
                rapid-withdrawal true
                split-horizon true
                ebgp-default-reject-policy {
                    import false
                }
                group "PE-CE-10" {
                    type external
                    peer-as 64501
                    family {
                        ipv4 true
                    }
                    export {
                        policy ["export-evpn-ifl-bgp"]
                    }
                }
                neighbor "10.10.105.2" {
                    group "PE-CE-10"
                    evpn-link-bandwidth {
                        add-to-received-bgp 1
                    }
                }
            }
            interface "int-VPRN10-TOR-5-CNF-10" {
                ipv4 {
                    primary {
                        address 10.10.105.1
                        prefix-length 24
```

```
                    }
                }
                sap 1/1/c3/1:10 {
                }
            }
        }
```

The BGP configuration on the corresponding CNF-10 is as follows:

```
# on CNF-10 (simulated by SR OS node):
configure {
    policy-options {
        community "comm-10" {
            member "target:64500:10" { }
        }
        prefix-list "anycast-ip-10" {
            prefix 10.10.0.0/24 type exact {
            }
        }
        policy-statement "export-anycast-ip-10" {
            entry 10 {
                from {
                    prefix-list ["anycast-ip-10"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                    community {
                        add ["comm-10"]      # for VPRN-10 on TORs
                    }
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64501
        bgp {
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
            }
            group "PE-CE-10" {
            }
            neighbor "10.10.105.1" {
                group "PE-CE-10"
                type external
                peer-as 64500
                local-as {
                    as-number 64501
                }
                export {
                    policy ["export-anycast-ip-10"]
                }
            }
        }
```

The configuration on the other CNFs is similar. The BGP configuration of CNF-6 uses the alias IP 10.100.10.1, as follows:

```
# on CNF-6 (simulated by SR OS node):
configure {
    router "Base" {
        bgp {
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
            }
            group "PE-CE-10" {
            }
            neighbor "10.100.10.2" {    # neighbor reachable via static route
                group "PE-CE-10"
                local-address 10.100.10.1
                type external
                peer-as 64500
                local-as {
                    as-number 64501
                }
                export {
                    policy ["export-anycast-ip-10"]
                }
            }
        }
```

Verification

BL-1 has stickiness applied for destination 10.10.0.0/24 on IBGP peer 192.0.2.2. For the same destination 10.10.0.0/24, BL-1 programs the next-hops as sticky even if only one of them is configured with sticky ECMP. The following route table for prefix 10.10.0.0 in VPRN-10 shows that sticky ECMP is not only requested for the EVPN IFL route with next-hop 192.0.2.2, but also for the EVPN IFL routes with next-hops 192.0.2.3, 192.0.2.4, or 192.0.2.5, as indicated with **[S]**:

```

```

Stickiness is applied for all routes to the same destination, regardless of the weight of these routes.

On BL-1, the extensive route table for prefix 10.10.0.0 shows that sticky ECMP is enabled (**Sticky ECMP: Yes**). The ECMP weight is different for the different next-hops, but the stickiness applies to all next-hops.

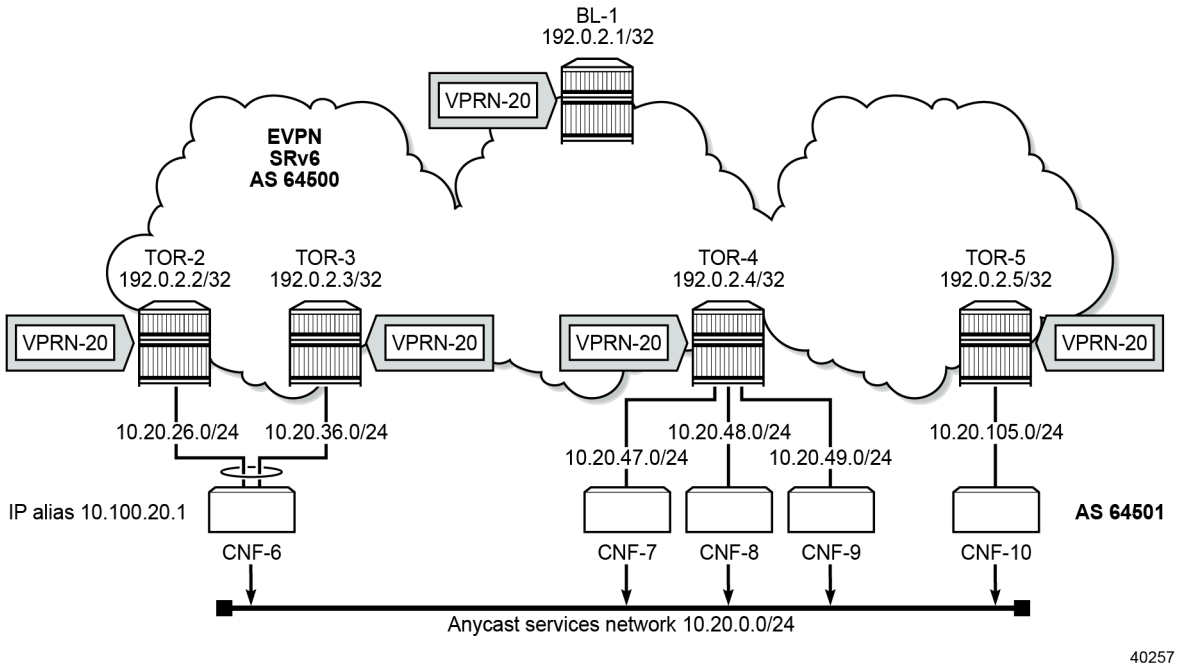
Sticky ECMP for EVPN IFL over SRv6

Figure 133: Example topology - IFL EVPN-SRv6 shows the topology with VPRN-20 in an EVPN SRv6 network.

Figure 133: Example topology - IFL EVPN-SRv6



Configuration

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on the router interfaces of BL-1 and the TORs, except for the router interfaces between TORs and CNFs
- SRv6 on BL-1 and the TORs
- IBGP on BL-1 and the TORs with BL-1 acting as RR

On BL-1, the policy "add-stickiness-vprn-20" can be applied at BGP peer level or at service level. In the following configuration, the policy is applied as vrf-import policy in VPRN-20:

```
# on BL-1:
configure {
    policy-options {
        community "comm-20" {
            member "target:64500:20" { }
        }
        prefix-list "cnf_ips-20" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            prefix 10.20.0.0/24 type longer {
            }
        }
        policy-statement "AS-20" {
            entry 1 {
                action {
                    action-type accept
                    as-path-prepend {
                        as-path 64503
                    }
                    community {
                        add ["comm-20"]
                    }
                }
            }
        }
        policy-statement "add-stickiness-vprn-20" {
            entry 12 {
                from {
                    prefix-list ["cnf_ips-20"]
                    community {
                        name "comm-20"
                    }
                }
                action {
                    action-type accept
                    sticky-ecmp true
                }
            }
            entry 13 {

```
                    source-address 2001:db8::2:1
                    evi 20
                    vrf-target {
                        community "target:64500:20"
                    }
                    vrf-import {
                        policy ["add-stickiness-vprn-20"]
                    }
                    vrf-export {
                        policy ["AS-20"]
                    }
                    srv6 {
                        instance 1
                        default-locator "BL1-loc"
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise {
                        }
                    }
                }
            }
            interface "test-20" {
                ipv4 {
                    primary {
                        address 172.20.20.1
                        prefix-length 30
                    }
                }
                sap 1/1/c10/1:20 {
                }
            }
```

The configuration of VPRN-20 on the TORs is similar, but without the stickiness. IP aliasing ECMP is implemented on TOR-2 and TOR-3 in a similar way as in Sticky ECMP for EVPN IFL over MPLS. The configuration of the CNFs is also similar.

Verification

On BL-1, the routes for prefix 10.20.0.0 have sticky ECMP enabled for all next-hops, as follows:

```
[/]
A:admin@BL-1# show router service-name "VPRN-20" route-table 10.20.0.0/24

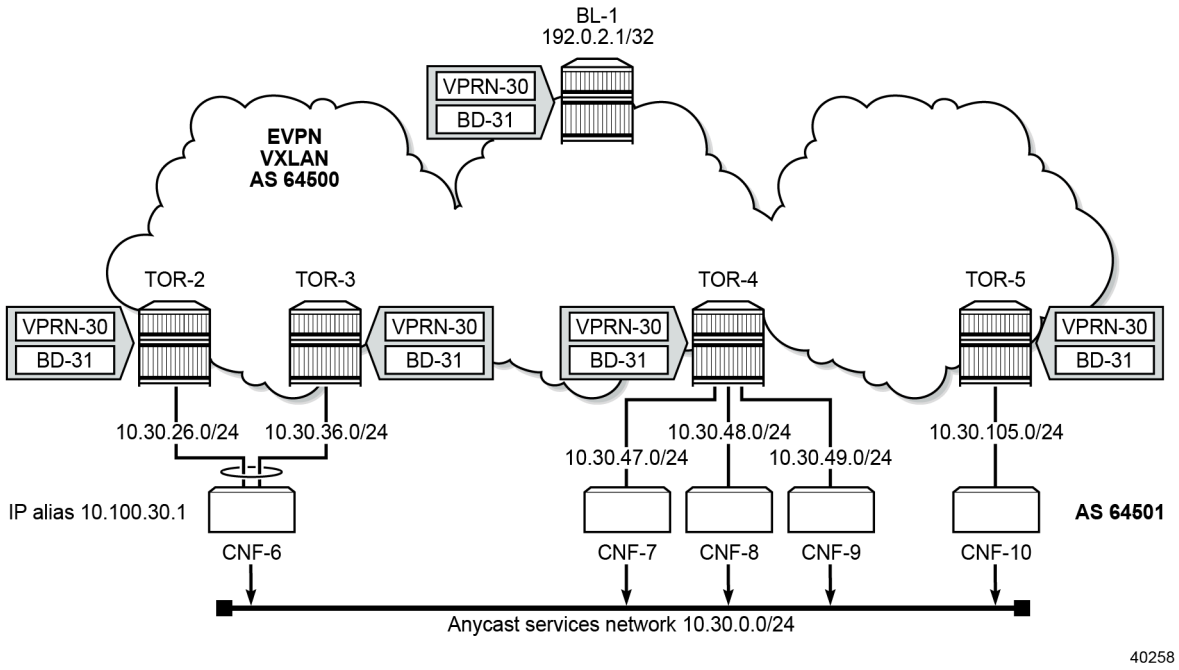
Sticky ECMP for EVPN IFF over VXLAN

Figure 134: Example topology - IFF EVPN-VXLAN shows the topology with R-VPLS BD-31 linked to VPRN-30 in an EVPN-VXLAN network.

Figure 134: Example topology - IFF EVPN-VXLAN



Configuration

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on the router interfaces of BL-1 and the TORs, except for the router interfaces between TORs and CNFs
- IBGP on BL-1 and the TORs with BL-1 acting as RR

On BL-1, the import policy adds ECMP stickiness to R-VPLS BD-31. This import policy is applied as vsi-import in R-VPLS BD-31, but it can also be applied at BGP peer level. The configuration on BL-1 is as follows:

```
# on BL-1:
configure {
    policy-options {
        community "comm-31" {
            member "target:64500:31" { }
        }
        prefix-list "cnf_ips-30" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            prefix 10.30.0.0/24 type longer {
            }
        }
        policy-statement "import-add-stickiness-rvpls-31" {
            entry 10 {
                from {
                    prefix-list ["cnf_ips-30"]
                    community {
                        name "comm-31"
                    }
                }
                action {
                    action-type accept
                    sticky-ecmp true
                }
            }
            entry 11 {
                from {
                    community {
                        name "comm-31"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    service {

                }
            }
            interface "int-VPRN30-TOR-2-to-CNF-6" {
                ipv4 {
                    primary {
                        address 10.30.26.1
                        prefix-length 24
                    }
                }
                sap 1/1/c3/1:30 {
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 10.100.30.2
                        prefix-length 32
                    }
                }
            }
            static-routes {
                route 10.100.30.1/32 route-type unicast {
                    next-hop "10.30.26.2" {
                        admin-state enable
                    }
                }
            }
        }
```

The configuration on the other TORs is similar, but the interface addresses are used instead of the IP alias.

EVPN IFF routes have a default preference of 169, whereas EVPN IFL routes have a default preference of 170. The TORs with EBGP sessions to the CNFs receive the EBGP route for the anycast prefix with default BGP preference 170 and they advertise an EVPN IFF route for the anycast prefix with preference 169. When the TORs receive EVPN IFF routes for the anycast prefix with preference 169, the EVPN IFF routes have preference over the EBGP route. The TORs install the EVPN IFF route in the route table for VPRN-30 and they withdraw their own generated EVPN IFF route, so BL-1 will not have EVPN IFF routes to each TOR. To prefer the EBGP route over the EVPN IFF routes, the preference of the EBGP routes is configured with a value lower than 169.

Verification

TOR-2, TOR-4, and TOR-5 install the prefix 10.30.0.0 in VPRN-30 with the configured preference 168; on TOR-2 as follows:

```
[/]
A:admin@TOR-2# show router 30 route-table 10.30.0.0

The BGP route for prefix 10.30.0.0/24 is preferred over the EVPN IFF routes for the same anycast prefix, so TOR-2, TOR-4, and TOR-5 each generate an EVPN IFF route for prefix 10.30.0.0/24. BL-1 receives the following three IP prefix routes for prefix 10.30.0.0/24:

```
[/]

Conclusion

When EVPN IP prefix routes advertise an additional route with a new next-hop for the same prefix or when an EVPN IP prefix is withdrawn for that prefix, the number of paths changes and therefore, the flow distribution changes. Upon withdrawal of one of the next-hops, sticky ECMP redistributes only the affected flows. When adding a next-hop, sticky ECMP minimizes the impact on existing flows. This way, the number of TCP resets is limited. The stickiness is solely associated with next-hops and not with links at LAG level.

Appendix

The sticky ECMP implementation is based on software. The ECMP behavior is emulated by repeating each ECMP next-hop of the sticky route a number of times, depending on the next-hop normalized weight, in different hashing buckets. The assignment of hashing buckets is not based on the number of existing next-hops for a router, but on the maximum number of internal hashing buckets, which is 64 in FP-based platforms and 16 in IXR platforms.

Note: The closer the number of next-hops to the maximum number of ECMP paths (64 for SR OS), the worse the distribution algorithm works. (In the example, only three next-hops are used for 64 ECMP paths.)

Table 11: Sticky ECMP flow distribution when one next-hop is removed for 10.10.0.0/24 compares the initial sticky ECMP distribution with three next-hops with the sticky ECMP flow distribution when next-hop 3 is removed as in Figure 131: Redistributed traffic flows after CNF-10 is removed. Next-hop 2 has weight 3 while next-hops 1 and 3 have weight 1.

Table 11: Sticky ECMP flow distribution when one next-hop is removed for 10.10.0.0/24

All existing flows with next-hops 1 (TOR-2) or 2 (TOR-4) remain unchanged; only the flows with next-hop 3 (TOR-5) are redistributed over the remaining paths according to the weighted ECMP set.

Similarly, when the initial ECMP distribution has two next-hops (next-hop 1 with weight 1 and next-hop 2 with weight 3) and a third next-hop (next-hop 3 with weight 1) is added, the stickiness ensures that only 20% of the flows is redistributed, as shown in Table 12: Sticky ECMP flow distribution when one next-hop is added for 10.10.0.0/24. The initial situation is different from the preceding table.

Table 12: Sticky ECMP flow distribution when one next-hop is added for 10.10.0.0/24

EVPN unequal ECMP for RT5 IFL and IFF routes

This chapter provides information about EVPN unequal ECMP for IFL and IFF IP prefix routes (RT5) with MPLS, VXLAN, or SRv6 transport.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 24.10.R1.

EVPN unequal ECMP for IFL IP prefix routes with MPLS transport is supported on FP-based platforms in SR OS Release 22.7.R2 and later. EVPN unequal ECMP for IFL IP prefix routes with SRv6 transport is supported on FP4-based platforms in SR OS Release 23.7.R1 and later. EVPN unequal ECMP for IFF IP prefix routes with VXLAN transport is supported on FP-based platforms in SR OS Release 22.7.R2 and later.

Overview

SR OS Release 22.7.R2 and later supports unequal ECMP for EVPN IPv4 and IPv6 prefix routes in the EVPN interface-less (EVPN IFL) and EVPN interface-ful (EVPN IFF) models.

Based on draft-ietf-bess-evpn-unequal-lb, it introduces a new EVPN link bandwidth extended community in the IP prefix routes to indicate a weight that the receiver PE must consider when load balancing traffic to multiple next hops (EVPN or CE).

Figure 135: Example topology is used to illustrate how EVPN unequal ECMP works.

Several multi-rack Container Network Functions (CNFs) are connected to a few Top of Rack (TOR) switches in an EVPN network. Each CNF advertises the anycast IP prefix in a single EBGP PE-CE session to the connected TOR. IPv4 prefix 198.51.100.1/32 is used as an example. An IPv6 prefix is also possible.

Each TOR re-advertises the IP prefix in an EVPN IP prefix route.

Without unequal ECMP, the Border Leaf (BL) creates an ECMP set for the IP prefix and distributes the traffic flows to it equally across the TORs (when the number of TORs is not larger than **ecmp**).

With unequal ECMP, each TOR adds a weight encoded in the EVPN IP prefix route. By default, the (dynamic) weight matches the number of CNFs that are attached to that TOR. The BL creates an ECMP set with the weights taken into account for the IP prefix and distributes the traffic flows to it according to the weights across the CNFs (when the number of TORs is not larger than **ecmp**).

The procedures associated with unequal ECMP for EVPN IPv4 and IPv6 prefix routes can be divided into advertising and receiving procedures.

- advertising procedures can be enabled with:
  - for EVPN-IFL with MPLS transport: **configure service vprn <vprn> bgp-evpn mpls <bgp instance> evpn-link-bandwidth advertise**
  - for EVPN-IFL with SRv6 transport: **configure service vprn <vprn> bgp-evpn segment-routing-v6 <bgp instance> evpn-link-bandwidth advertise**
  - for EVPN-IFF: **configure service vpls <vpls> bgp-evpn routes ip-prefix link-bandwidth advertise**

  These commands trigger the advertisement of the EVPN link bandwidth extended community with a weight that, by default (dynamic), matches the number of CEs/CNFs that advertise the EVPN IP prefix route. The dynamic weight can, optionally, be overridden with: **advertise weight <weight>**
- receiving procedures can be enabled with:
  - for EVPN-IFL with MPLS transport: **configure service vprn <vprn> bgp-evpn mpls <bgp instance> evpn-link-bandwidth weighted-ecmp true**
  - for EVPN-IFL with SRv6 transport: **configure service vprn <vprn> bgp-evpn segment-routing-v6 <bgp instance> evpn-link-bandwidth weighted-ecmp true**
  - for EVPN-IFF: **configure service vpls <vpls> bgp-evpn routes ip-prefix link-bandwidth weighted-ecmp true**

  SR OS supports **weighted-ecmp**:
  - for EVPN-IFL and EVPN-IFF IP prefix routes with dynamic or configured weight. EVPN-IFL IP prefix routes (with a default preference of 170) and EBGP PE-CE routes (with a default preference of 170 too) can be combined in the same ECMP set.
  - for EVPN-IFL IP prefix routes with dynamic or configured weight and **bgp neighbor <EBGP neighbor>** for group **<EBGP group>** configured with **evpn-link-bandwidth add-to-received-bgp <number>**. EVPN-IFF IP prefix routes (with a default preference of 169) are by default preferred over EBGP PE-CE routes (with a default preference of 170).

  When **weighted-ecmp true** is configured, the receiving PE installs IP prefix routes in the VPRN route table with a normalised weight that is derived from the signaled weight and that in SR OS FP based platforms has a non-configurable maximum value of 64 (the maximum number of ECMP next hops). The normalised weight of an ECMP next-hop determines its relative share of the traffic forwarded toward the destination IP prefix.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When a BGP route toward a specific destination IP prefix has N ECMP next hops H[i] with signaled weight S[i] each, the normalised weight W[i] for each next hop H[i] is computed using the following algorithm:

1. Compute the Greatest Common Divisor (GCD) of all S[i] and compute Stotal=(sum of S[i]), for i = 1 to N
2. If (Stotal/GCD) is not larger than 64, the normalised weight W[i] for next hop H[i] is S[i]/GCD
3. Else, the normalised weight W[i] for next hop H[i] is (1 + (the integer result of (S[i]/Stotal * (64 - N)))

- For EVPN-IFL, for unequal ECMP across EVPN next hops and CE next hops:
  - **service vprn <vprn> bgp neighbor <EBGP neighbor> evpn-link-bandwidth add-to-received-bgp <number>** and
  - **service vprn <vprn> bgp eibgp-loadbalance true**

  must be configured.
  For EVPN-IFF, for unequal ECMP across EVPN next hops:
  - **service vprn <vprn> bgp neighbor <EBGP neighbor> evpn-link-bandwidth add-to-received-bgp <number>**

  must be configured. Unequal ECMP for EVPN-IFF can only be applied to EVPN next hops and **service vprn <vprn> bgp eibgp-loadbalance** has no effect.

Configuration

The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IBGP in the EVPN network for the EVPN address family
- IS-IS on the router interfaces in the EVPN network (OSPF or OSPF3 router interfaces are also possible)
- LDP in the EVPN network
- base router SRv6 segment routing (for the SRv6 transport example)

Router configuration

The router configuration on TOR3 is as follows:

```
# On TOR3:
configure {
    router "Base" {
        autonomous-system 64500
        interface "int-TOR3-BL5" {
            port 1/1/c5/1:10
            ipv4 {
                primary {
                    address 192.168.35.1
                    prefix-length 30
                }
            }
            ipv6 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                address 2001:db8::168:35:1 {
                    prefix-length 126
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.3
                    prefix-length 32
                }
            }
            ipv6 {
                address 2001:db8::2:3 {
                    prefix-length 128

The router configuration on TOR4 and TOR1 is similar.

The router configuration on BL5 is as follows:

```
# On BL5:
configure {
    router "Base" {
        autonomous-system 64500
        interface "int-BL5-TOR1" {
            port 1/1/c1/1:10
            ipv4 {
                primary {
                    address 192.168.15.2
                    prefix-length 30
                }
            }
            ipv6 {
                address 2001:db8::168:15:2 {
                    prefix-length 126
                }
            }
        }
        interface "int-BL5-TOR3" {
            port 1/1/c3/1:10
            ipv4 {
                primary {
                    address 192.168.35.2
                    prefix-length 30

                        function {
                            end 1 {
                                srh-mode usp
                            }
                            end-x-auto-allocate usp protection protected { }
                        }
                    }
                }

configure {
    router "Base" isis 0 segment-routing-v6 {
                admin-state enable
                locator "BL5-loc" {
                    level-capability 2
                }
```

The base SRv6 segment routing configuration for TOR1, TOR3, and TOR4 is similar, with different locators and locator prefixes.

Use cases

The following use cases are described in the following sections:

- EVPN-IFL model
- EVPN-IFF model

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

EVPN-IFL model

To advertise the 198.51.100.1/32 prefix, export policy "vrf-1-export-1" for prefix-list "prefix-1" with prefix 198.51.100.1/32 is configured on the CNFs:

```
# On CNF2:
configure {
    policy-options {
        prefix-list "prefix-1" {
            prefix 198.51.100.1/32 type exact { }
        }
        policy-statement "vrf-1-export-1" {
            entry 10 {
                from {
                    prefix-list ["prefix-1"]
                }
                to {
                    protocol {
                        name [bgp]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

The export policy configuration on CNF3, CNF4, CNF5, and CNF1 is identical.

To illustrate SRv6 transport, a similar export policy "vrf-6-export-1" for the same prefix-list is configured on the CNFs.

To advertise prefix 198.51.100.1/32, export policy "vrf-1-export-1" for community "comm-vrf-1" with members "target:64500:1" is configured on BL5:

```
# On BL5:
configure {
    policy-options {
        community "comm-vrf-1" {
            member "target:64500:1" { }
        }
        policy-statement "vrf-1-export-1" {
            entry 10 {
                action {
                    action-type accept
                    as-path-prepend {
                        as-path 64503
                    }
                    community {
                        add ["comm-vrf-1"]
                    }
                }
            }
        }
```

The **as-path-prepend** command ensures that the prefixes are advertised as if they originate in an external autonomous system.

To illustrate SRv6 transport, a similar export policy "vrf-6-export-1" is configured on BL5, but then for community "comm-vrf-6" with members "target:64500:6".

The following cases are described in the following sections:

- IPv4 prefix advertisement from CNFs - MPLS transport
- IPv4 prefix advertisement from CNFs - SRv6 transport
- IPv4 prefix advertisement from CNFs and BL
- EVPN link bandwidth advertisement via policies

IPv4 prefix advertisement from CNFs - MPLS transport

Figure 136: CNF only advertisement illustrates how EVPN-IFL unequal ECMP works when only the CNFs advertise the IPv4 prefix. There are four CNFs (CNF2, CNF3, CNF4, CNF5), two TORs (TOR3, TOR4) and one BL (BL5). TOR3 and TOR4 are connected to BL5. CNF2, CNF3, and CNF4 are connected to TOR3. CNF5 is connected to TOR4. VPRN 1 and VPRN 6 are configured on the CNFs, the TORs, and the BL.

VPRN 1 is configured on the CNFs as follows:

```
# On CNF2:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64501
            bgp {
                rapid-withdrawal true
                ebgp-default-reject-policy {
                    import false
                }
                group "PE-CE" {
                    type external
                    peer-as 64500
                }
                neighbor "10.13.12.1" {
                    group "PE-CE"
                    export {
                        policy ["vrf-1-export-1"]
                    }
                }
            }
            interface "subs-1" {
                loopback true
                ipv4 {
                    primary {
                        address 198.51.100.1
                        prefix-length 32
                    }
                }
            }
            interface "to-TOR3" {
                ipv4 {
                    primary {
                        address 10.13.12.2
                        prefix-length 30
                    }
                }
                sap 1/1/c3/1:10 { }
            }
```

The following cases are described in the following sections:

- Dynamic PE-CE weights (5 cases)
- Configured maximum weight=73 on TOR3
- Configured weight=23 on TOR3
- Reduced ECMP on TOR3 (2 cases)

The configuration, BGP update and **show** command output for all cases is summarised in tables:

- Table 13: TOR3 weights summary - configuration: summarises, for each case, the **evpn-link-bandwidth add-to-received-bgp** values that are configured for each CNF connected to TOR3, and the value that TOR3 advertises for each case (obtained from **EVPN-IP-PREFIX** BGP update messages sent from TOR3)
- Table 14: TOR3 weights summary - route table and FIB: summarises, for each case, the normalised weights in the route table of TOR3 (obtained from: **show router "1" route-table 198.51.100.1/32 extensive**) and the normalised weights in the FIB of TOR3 (obtained from: **show router "1" fib 1 ip-prefix-prefix-length 198.51.100.1/32 extensive**)
- Table 15: BL5 weights summary: summarises, for each case, the weights that BL5 receives from TOR3 and TOR4 (obtained from **EVPN-IP-PREFIX** BGP update messages received on BL5), the normalised weights in the route table of BL5 (obtained from: **show router "1" route-table 198.51.100.1/32 extensive**), and the normalised weights in the FIB of BL5 (obtained from: **show router "1" fib 1 ip-prefix-prefix-length 198.51.100.1/32 extensive**)

The detailed configuration, BGP update, and **show** command output is explicitly included in the further description only for the first two cases.

Table 13: TOR3 weights summary - configuration

		No configured PE-CE weights	Equal configured PE-CE weights (GCD>1)	Different configured PE-CE weights (GCD>1)	Different configured PE-CE weights (GCD=1 and Stotal/GCD≤64)	Different configured PE-CE weights (GCD=1 and Stotal/GCD>64)	Configured maximum weight=73 on TOR3	Configured weight=23 on TOR3	ecmp=2 on TOR3	ecmp=1 on TOR3

Dynamic PE-CE weights

There is one EBGP PE-CE session for each CNF. Each CNF advertises the anycast 198.51.100.1/32 prefix in its specific EBGP PE-CE session to its corresponding TOR. To enable unequal ECMP processing for EVPN-IFL IPv4 prefix routes, the advertising and receiving procedures are configured in the **service vprn <vprn> bgp-evpn mpls <bgp instance>** context on the TORs and on the BL. To indicate with what relative weight the load balancing across the EVPN-IFL IPv4 prefix routes must be executed, the **add-to-received-bgp <number>** is configured for each EBGP PE-CE session in the **service vprn <vprn> bgp neighbor <EBGP neighbor>** context on the TORs.

The following cases are described in the following sections:

- No configured PE-CE weights
- Configured PE-CE weights

No configured PE-CE weights

Initially, **add-to-received-bgp** is not configured. This is the same as if **add-to-received-bgp 1** is configured for each EBGP PE-CE session, so that each EBGP PE-CE session is taken into account equally. Unequal ECMP for EVPN-IFL IPv4 prefix routes then load balances traffic from the BL to the CNFs equally across all CNFs.

VPRN 1 is configured on the TORs as follows:

```
# On TOR3:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64500
            ecmp 3
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.3:1"
                    evi 1
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise { }
                    }
                }
            }
            bgp {
                eibgp-loadbalance true
                rapid-withdrawal true
                multipath {
                    family ipv4 {
                        max-paths 10
                    }
                }
                group "PE-CE" {
```

```
                    type external
                    peer-as 64501
                }
                neighbor "10.13.12.2" {
                    group "PE-CE"
                }
                neighbor "10.13.13.2" {
                    group "PE-CE"
                }
                neighbor "10.13.14.2" {
                    group "PE-CE"
                }
            }
            interface "to-CE2" {
                ipv4 {
                    primary {
                        address 10.13.12.1
                        prefix-length 30
                    }
                }
                sap 1/1/c2/1:10 { }
            }
            interface "to-CE3" {
                ipv4 {
                    primary {
                        address 10.13.13.1
                        prefix-length 30
                    }
                }
                sap 1/1/c3/1:10 { }
            }
            interface "to-CE4" {
                ipv4 {
                    primary {
                        address 10.13.14.1
                        prefix-length 30
                    }
                }
                sap 1/1/c4/1:10 { }
            }
```

The configuration on TOR4 is similar, with only one CNF.

Note: On each TOR, **service vprn <vprn> ecmp** is configured with a value that is not smaller than the number of CNFs that are connected to the TOR.

VPRN 1 is configured on the BL as follows:

```
# On BL5:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64500
            ecmp 3
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.5:1"
                    evi 1
                    vrf-target {
                        community "target:64500:1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise { }
                    }
                }
            }
            bgp { }
```

Note: On the BL, **service vprn <vprn> ecmp** is configured with a value that is not smaller than the number of TORs that are connected to the BL.

On TOR3, each next hop along which prefix 198.51.100.1/32 can be reached is assigned S[i]=1. TOR3 has three such next hops, so GCD=1, Stotal=3, S[i]/GCD=1, Stotal/GCD=3 (not larger than 64), W[i]=1.

TOR3 advertises Stotal=3 for prefix 198.51.100.1/32 and 1 for each next hop prefix, as follows:

```
# On TOR3:

TOR4 has only one such next hop, so GCD=1, Stotal=1, S[1]/GCD=1, Stotal/GCD=1 (not larger than 64), W[1]=1. TOR4 advertises Stotal=1 for prefix 198.51.100.1/32 and 1 for the next hop prefix.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, CNF3, and CNF4, with ECMP weight N/A in the VPRN route table and normalised ECMP weights W[i]=1 in the VPRN FIB:

```

Similarly, TOR4 installs in its VPRN route table and VPRN FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that TOR4 receives via EBGP from CNF5, with ECMP weight N/A in the VPRN route table and normalised ECMP weight W[1]=1 in the VPRN FIB.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=3 and one from TOR4 with S[2]=1. So GCD=1, Stotal=4, S[1]/GCD=3, S[2]/GCD=1, Stotal/GCD=4 (not larger than 64), W[1]=3, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=3 and W[2]=1:

```

Similar for TOR4, with **Community : target:64500:1 evpn-bandwidth:1:1 bgp-tunnel-encap:MPLS**

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The format of **evpn-bandwidth:<units>:<weight>** in the **Community** is as follows:

- **units** is a decimal value [0-255] representing the units. For practical purposes only values 0 and 1 are specified. Only value 1 is supported at the moment.
- **weight** is a decimal value [0-1099511627775] –five octets– encoding either the bandwidth in Mbps (if units=0x00) or the number of BGP paths (if units=0x01). Because only units=0x01 is supported, the weight is always a "Generalised Weight", as described in draft-ietf-bess-evpn-unequal-lb.

By default, each TOR advertises the weight dynamically, based on the number of CNFs (EBGP PE-CE sessions) that advertise the same IPv4 prefix to it. By default, the maximum value for the signaled weight is 128.

```
# On TOR3:
[ex:/configure service vprn "VPRN 1" bgp-evpn mpls 1 evpn-link-bandwidth]
A:admin@TOR3# info detail
    weighted-ecmp true
    advertise {
        weight dynamic
        max-dynamic-weight 128
    }
```

Verifying that the **evpn-link-bandwidth** is enabled for VPRN 1 can be done as follows:

```
[/]
A:admin@TOR3# show service id "1" bgp-evpn

Configured PE-CE weights

A TOR can assign a configured **add-to-received-bgp <number [1-128]>** weight to each EBGP PE-CE session.

Note: The values in the following examples are chosen to illustrate the computation of the normalised weights. In real life NWs, the values are typically less extreme.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following cases are described in the following sections:

- Equal configured PE-CE weights (GCD>1)
- Different configured PE-CE weights (GCD>1)
- Different configured PE-CE weights (GCD=1 and Stotal/GCD≤64)
- Different configured PE-CE weights (GCD=1 and Stotal/GCD>64)

Equal configured PE-CE weights (GCD>1)

VPRN 1 is reconfigured on TOR3 as follows:

```
# On TOR3:
configure {
    service vprn "VPRN 1" {
            ecmp 3
            ---snip---
            bgp-evpn {
                mpls 1 {
                    ---snip---
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise {
                        }
                    }
                }
            }
            bgp {
                ---snip---
                eibgp-loadbalance true
                rapid-withdrawal true
                neighbor "10.13.12.2" {
                    group "PE-CE"
                    evpn-link-bandwidth {
                        add-to-received-bgp 5
                    }
                }
                neighbor "10.13.13.2" {
                    group "PE-CE"
                    evpn-link-bandwidth {
                        add-to-received-bgp 5
                    }
                }
                neighbor "10.13.14.2" {
                    group "PE-CE"
                    evpn-link-bandwidth {
                        add-to-received-bgp 5
                    }
                }
            }
```

Nothing changes on TOR4.

On TOR3, S[i]=5. So, GCD=5, Stotal=15, S[i]/GCD=1, Stotal/GCD=3 (not larger than 64), W[i]=1.

TOR3 advertises Stotal=15 for prefix 198.51.100.1/32, as follows:

```
# On TOR3:
1 2024/12/17 10:40:39.169 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=15 and one from TOR4 with S[2]=1. So GCD=1, Stotal=16, S[1]/GCD=15, S[2]/GCD=1, Stotal/GCD=16 (not larger than 64), W[1]=15, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=15 and W[2]=1:

Different configured PE-CE weights (GCD>1)

VPRN 1 is reconfigured on TOR3 with: S[1]=4, S[2]=8, S[3]=12. So, GCD=4, Stotal=24, S[1]/GCD=1, S[2]/GCD=2, S[3]/GCD=3, Stotal/GCD=6 (not larger than 64), W[1]=1, W[2]=2, W[3]=3.

TOR3 advertises Stotal=24 for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, CNF3, and CNF4, with normalised ECMP weights W[1]=1, W[2]=2, W[3]=3.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=24 and one from TOR4 with S[2]=1. So GCD=1, Stotal=25, S[1]/GCD=24, S[2]/GCD=1, Stotal/GCD=25 (not larger than 64), W[1]=24, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=24 and W[2]=1.

Different configured PE-CE weights (GCD=1 and Stotal/GCD≤64)

VPRN 1 is reconfigured on TOR3 with: S[1]=5, S[2]=17, S[3]=31. So, GCD=1, Stotal=53, S[1]/GCD=5, S[2]/GCD=17, S[3]/GCD=31, Stotal/GCD=53 (not larger than 64), W[1]=5, W[2]=17, W[3]=31.

TOR3 advertises Stotal=53 for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, CNF3, and CNF4, with normalised ECMP weights W[1]=5, W[2]=17, W[3]=31.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=53 and one from TOR4 with S[2]=1. So GCD=1, Stotal=54, S[1]/GCD=53, S[2]/GCD=1, Stotal/GCD=54 (not larger than 64), W[1]=53, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=53 and W[2]=1.

Different configured PE-CE weights (GCD=1 and Stotal/GCD>64)

VPRN 1 is reconfigured on TOR3 with: S[1]=5, S[2]=17, S[3]=59. So, GCD=1, Stotal=81, S[1]/GCD=5, S[2]/GCD=17, S[3]/GCD=59, Stotal/GCD=81 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64:

- W[1]=1+integer(5/81*(64-3))=4
- W[2]=1+integer(17/81*(64-3))=13
- W[3]=1+integer(59/81*(64-3))=45

TOR3 advertises Stotal=81 for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, CNF3, and CNF4, with normalised ECMP weights W[1]=4, W[2]=13, W[3]=45.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=81 and one from TOR4 with S[2]=1. So GCD=1, Stotal=82, S[1]/GCD=81, S[2]/GCD=1, Stotal/GCD=82 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64:

- W[1]=1+integer(81/82*(64-2))=62
- W[2]=1+integer(1/82*(64-2))=1

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=62 and W[2]=1.

Configured maximum weight=73 on TOR3

A TOR can limit the maximum dynamic weight to a value below 128.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VPRN 1 is reconfigured on TOR3 as follows:

```
# On TOR3:
configure {
    service vprn "VPRN 1" bgp-evpn mpls 1 evpn-link-bandwidth {
                          advertise {
                              weight dynamic
                              max-dynamic-weight 73
```

On TOR3, S[1]=5, S[2]=17, S[3]=59. So, GCD=1, Stotal=81, S[1]/GCD=5, S[2]/GCD=17, S[3]/GCD=59, Stotal/GCD=81 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=4, W[2]=13, W[3]=45.

TOR3 advertises min(max-dynamic-weight,Stotal)=73 instead for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, CNF3, and CNF4, with normalised ECMP weights W[1]=4, W[2]=13, W[3]=45.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=73 and one from TOR4 with S[2]=1. So GCD=1, Stotal=74, S[1]/GCD=73, S[2]/GCD=1, Stotal/GCD=74 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=62, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=62 and W[2]=1.

Verifying that the **max-dynamic-weight** is reconfigured for VPRN 1 can be done as follows:

```
[/]
A:admin@TOR3# show service id "1" bgp-evpn

Configured weight=23 on TOR3

A TOR can overwrite the dynamic advertised weight with a configured **weight <weight [1-128]>**. Unequal ECMP for EVPN-IFL IPv4 prefix routes then load balances traffic from the BL to the TOR as if the TOR has <weight> CNFs (EBGP PE-CE sessions) connected to it.

VPRN 1 is reconfigured on TOR3 as follows:

```
# On TOR3:
configure {
    service vprn "VPRN 1" bgp-evpn mpls 1 evpn-link-bandwidth {
                          advertise {
                              max-dynamic-weight 128
                              weight 23
```

On TOR3, S[1]=5, S[2]=17, S[3]=59. So, GCD=1, Stotal=81, S[1]/GCD=5, S[2]/GCD=17, S[3]/GCD=59, Stotal/GCD=81 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=4, W[2]=13, W[3]=45.

TOR3 advertises weight=23 instead for prefix 198.51.100.1/32 and weight=23 for each next hop prefix, as follows:

```
# On TOR3:

Reduced ECMP on TOR3

In the previous scenarios, **service vprn <vprn> ecmp** is configured with a value that is not smaller than the number of CNFs that are connected to the TOR. When **service vprn <vprn> ecmp** is configured with a value **<max-ecmp>** that is smaller than the number of CNFs that are connected to the TOR, only **<max-ecmp>** CNFs are taken into account, with lowest IP first.

The following cases are described in the following sections:

- ecmp=2 on TOR3
- ecmp=1 on TOR3

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

ecmp=2 on TOR3

VPRN 1 is reconfigured on TOR3 with **ecmp 2** and S[1]=5, S[2]=113, S[3]=23.

S[3] is not used in the computation. So, GCD=1, Stotal=118, S[1]/GCD=5, S[2]/GCD=113, Stotal/GCD=S[1]/GCD+S[2]/GCD=118 (larger than 64). The normalised weights are computed, such that (W[1]*GCD+W[2]*GCD) is not larger than 64:

- W[1]=1+integer(5/118*(64-2))=3
- W[2]=1+integer(113/118*(64-2))=60

TOR3 advertises Stotal=118 for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: each EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2 and CNF3, with normalised ECMP weights W[1]=3, W[2]=60.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=118 and one from TOR4 with S[2]=1. So GCD=1, Stotal=119, S[1]/GCD=118, S[2]/GCD=1, Stotal/GCD=119 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=62, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=62 and W[2]=1.

ecmp=1 on TOR3

VPRN 1 is reconfigured on TOR3 with **ecmp 1** and S[1]=109, S[2]=113, S[3]=23.

S[2] and S[3] are not used in the computation. So, GCD=109, Stotal=109, S[1]/GCD=1, Stotal/GCD=S[1]/GCD=1 (not larger than 64). W[1]=1.

TOR3 advertises Stotal=109 for prefix 198.51.100.1/32.

TOR3 installs in its VPRN route table and VPRN FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that TOR3 receives via EBGP from CNF2, with normalised ECMP weight W[1]=1.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=109 and one from TOR4 with S[2]=1. So GCD=1, Stotal=110, S[1]/GCD=109, S[2]/GCD=1, Stotal/GCD=110 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=62, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=62 and W[2]=1.

IPv4 prefix advertisement from CNFs - SRv6 transport

The same scenarios as for MPLS transport apply for SRv6 transport. Only one specific scenario is described here for the same Figure 136: CNF only advertisement: advertising with dynamic weights, using different EBGP PE-CE configured weights S[i] with GCD=1 and Stotal/GCD larger than 128.

There is one EBGP PE-CE session for each CNF. Each CNF advertises the anycast 198.51.100.1/32 prefix in its specific EBGP PE-CE session to its corresponding TOR. To enable unequal ECMP processing for EVPN-IFL IPv4 prefix routes, the advertising and receiving procedures are configured in the **service vprn <vprn> bgp-evpn segment-routing-v6 <bgp instance>** context on the TORs and on the BL. To indicate with what relative weight the load balancing across the EVPN-IFL IPv4 prefix routes must be executed, the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

add-to-received-bgp <number> is configured for each EBGP PE-CE session in the **service vprn <vprn> bgp neighbor <EBGP neighbor>** context on the TORs.

VPRN 6 is configured on the CNFs, the TORs, and the BL.

VPRN 6 is configured on the CNFs as follows:

```
# On CNF2:
configure {
    service vprn "VPRN 6" {
            admin-state enable
            service-id 6
            customer "1"
            autonomous-system 64501
            bgp {
                rapid-withdrawal true
                ebgp-default-reject-policy {
                    import false
                }
                group "PE-CE" {
                    multihop 10
                    type external
                    peer-as 64500
                    local-as {
                        as-number 64501
                    }
                }
                neighbor "10.63.12.1" {
                    group "PE-CE"
                    export {
                        policy ["vrf-6-export-1"]
                    }
                }
            }
            interface "subs-1" {
                loopback true
                ipv4 {
                    primary {
                        address 198.51.100.1
                        prefix-length 32
                    }
                }
            }
            interface "to-TOR3" {
                ipv4 {
                    primary {
                        address 10.63.12.2
                        prefix-length 30
                    }
                }
                sap 1/1/c3/1:60 { }
            }
```

The configuration on CNF3, CNF4, and CNF5 is similar, with CNF5 associated with TOR4.

VPRN 6 is configured on the TORs as follows:

```
# On TOR3:
configure {
    service vprn "VPRN 6" {
            admin-state enable
            service-id 6
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            autonomous-system 64500
            ecmp 3
            segment-routing-v6 1 {
                locator "TOR3-loc" {
                    function {
                        end-dt4 { }
                        end-dt6 { }
                        end-dt46 { }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "6:3"
                    source-address 10:20:1::3
                    evi 6
                    vrf-target {
                        community "target:64500:6"
                    }
                    srv6 {
                        instance 1
                        default-locator "TOR3-loc"
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise { }
                    }
                }
            }
            bgp {

```

The configuration on TOR4 is similar, with only one CNF with **add-to-received-bgp 1**.

VPRN 6 is configured on the BL as follows:

```
# On BL5:
configure {
    service vprn "VPRN 6" {
            admin-state enable
            service-id 6
            customer "1"
            autonomous-system 64500
            ecmp 3
            segment-routing-v6 1 {
                locator "BL5-loc" {
                    function {
                        end-dt4 { }
                        end-dt6 { }
                        end-dt46 { }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "6:5"
                    source-address 10:20:1::5
                    evi 6
                    vrf-target {
                        community "target:64500:6"
                    }
                    srv6 {
                        instance 1
                        default-locator "BL5-loc"
                    }
                    evpn-link-bandwidth {
```

© 2026 Nokia.

```
                        weighted-ecmp true
                        advertise { }
                    }
                }
            }
            bgp { }
```

On TOR3, S[1]=2, S[2]=9, S[3]=120. So, GCD=1, Stotal=131, S[1]/GCD=2, S[2]/GCD=9, S[3]/GCD=120, Stotal/GCD=131 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64:

- W[1]=1+integer(2/131*(64-3))=1
- W[2]=1+integer(9/131*(64-3))=5
- W[3]=1+integer(120/131*(64-3))=56

TOR3 advertises min(max-dynamic-weight,Stotal)=128 for prefix 198.51.100.1/32 and 1 for each next hop prefix, as follows:

```
# On TOR3:

```

Similarly, TOR4 installs in its VPRN route table and VPRN FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that TOR4 receives via EBGP from CNF5, with normalised ECMP weight W[1]=1.

BL5 receives via IBGP two EVPN-IFL routes for prefix 198.51.100.1/32: one from TOR3 with S[1]=128 and one from TOR4 with S[2]=1. So GCD=1, Stotal=129, S[1]/GCD=128, S[2]/GCD=1, Stotal/GCD=129 (larger than 64). The normalised weights are computed, such that sum(W[i]*GCD) is not larger than 64. W[1]=62, W[2]=1.

BL5 installs in its VPRN route table and VPRN FIB: the two received EVPN-IFL routes for prefix 198.51.100.1/32, with normalised ECMP weights W[1]=62 and W[2]=1:

```

IPv4 prefix advertisement from CNFs and BL

Figure 137: CNF and BL advertisement illustrates how EVPN-IFL unequal ECMP works when also the BL (or TORs) advertise the IPv4 prefix. This applies for both the MPLS and the SRv6 transport. Only MPLS transport is illustrated further on. There is one CNF (CNF1), one TOR (TOR1) and one BL (BL5). TOR1 is connected to BL5. CNF1 is connected to TOR1. VPRN 1 is configured on CNF1, TOR1, and BL5.

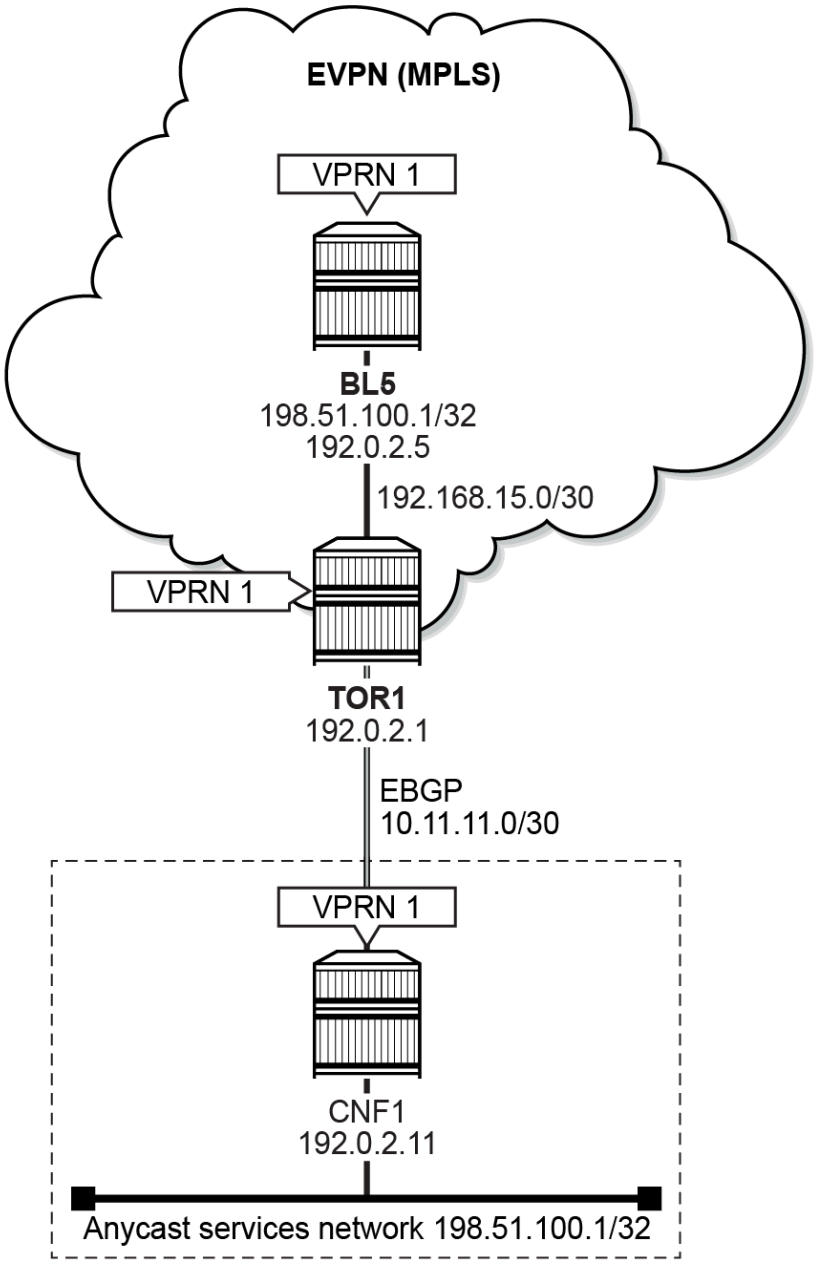
Figure 137: CNF and BL advertisement



40100b

The CNF advertises prefix 198.51.100.1/32 in its specific EBGP PE-CE session to its corresponding TOR. To enable unequal ECMP processing for EVPN-IFL IPv4 prefix routes, the advertising and receiving procedures are configured in the **service vprn <vprn> bgp-evpn mpls <bgp instance>** (or **service vprn <vprn> bgp-evpn segment-routing-v6 <bgp instance>**) context on the TOR and on the BL. To indicate with what relative weight the load balancing across the EVPN-IFL IPv4 prefix routes must be executed, the

add-to-received-bgp <number> is configured for the EBGP PE-CE session in the **service vprn <vprn> bgp neighbor <EBGP neighbor>** context on the TOR.

VPRN 1 is configured on CNF1, TOR1, and BL5.

VPRN 1 is configured on CNF1 as follows:

```
# On CNF1:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64501
            bgp {
                rapid-withdrawal true
                ebgp-default-reject-policy {
                    import false
                }
                group "PE-CE" {
                    type external
                    peer-as 64500
                }
                neighbor "10.11.11.1" {
                    group "PE-CE"
                    export {
                        policy ["vrf-1-export-1"]
                    }
                }
            }
            interface "subs-1" {
                loopback true
                ipv4 {
                    primary {
                        address 198.51.100.1
                        prefix-length 32
                    }
                }
            }
            interface "to-TOR1" {
                ipv4 {
                    primary {
                        address 10.11.11.2
                        prefix-length 30
                    }
                }
                sap 1/1/c1/1:10 { }
            }
```

VPRN 1 is configured on TOR1 as follows:

```
# On TOR1:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64500
            ecmp 3
            bgp-evpn {
                mpls 1 {

                        weighted-ecmp true
                    }
                }
            }
            bgp { }
```

The BL advertises the 198.51.100.1/32 prefix as if it is received from an EBGP session. This requires adding an external community via an export policy.

When **service vprn <vprn> bgp eibgp-loadbalance** is not configured on the TOR, the TOR:

- installs in its VPRN route table and FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that the TOR receives via EBGP from the CNF, with weight 1
- does not install in its VPRN route table and FIB: the EVPN-IFL route for prefix 198.51.100.1/32 that the TOR receives via IBGP from the BL, because EBGP learned routes (PE-CE) have preference over IBGP learned routes (EVPN-IFL).

When **service vprn <vprn> bgp eibgp-loadbalance true** is configured on the TOR, the TOR:

- installs in its VPRN route table and FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that the TOR receives via EBGP from the CNF, with weight 1
- additionally installs in its VPRN route table and FIB: the EVPN-IFL route for prefix 198.51.100.1/32 that the TOR receives via IBGP from the BL, with weight 1, because EBGP learned routes (PE-CE) and IBGP learned routes (EVPN-IFL) are then treated equally, and EVPN-IFL routes have the same preference as EBGP PE-CE routes.

Note: configure router bgp path-selection bgp-ibgp-equal is not needed if **service vprn <vprn> bgp eibgp-loadbalance true** and ecmp>1 are configured under the VRF.

VPRN 1 is reconfigured on TOR1 with:

```
# On TOR1:
configure {
    service vprn "VPRN 1" bgp {
                eibgp-loadbalance true
```

```
[/]

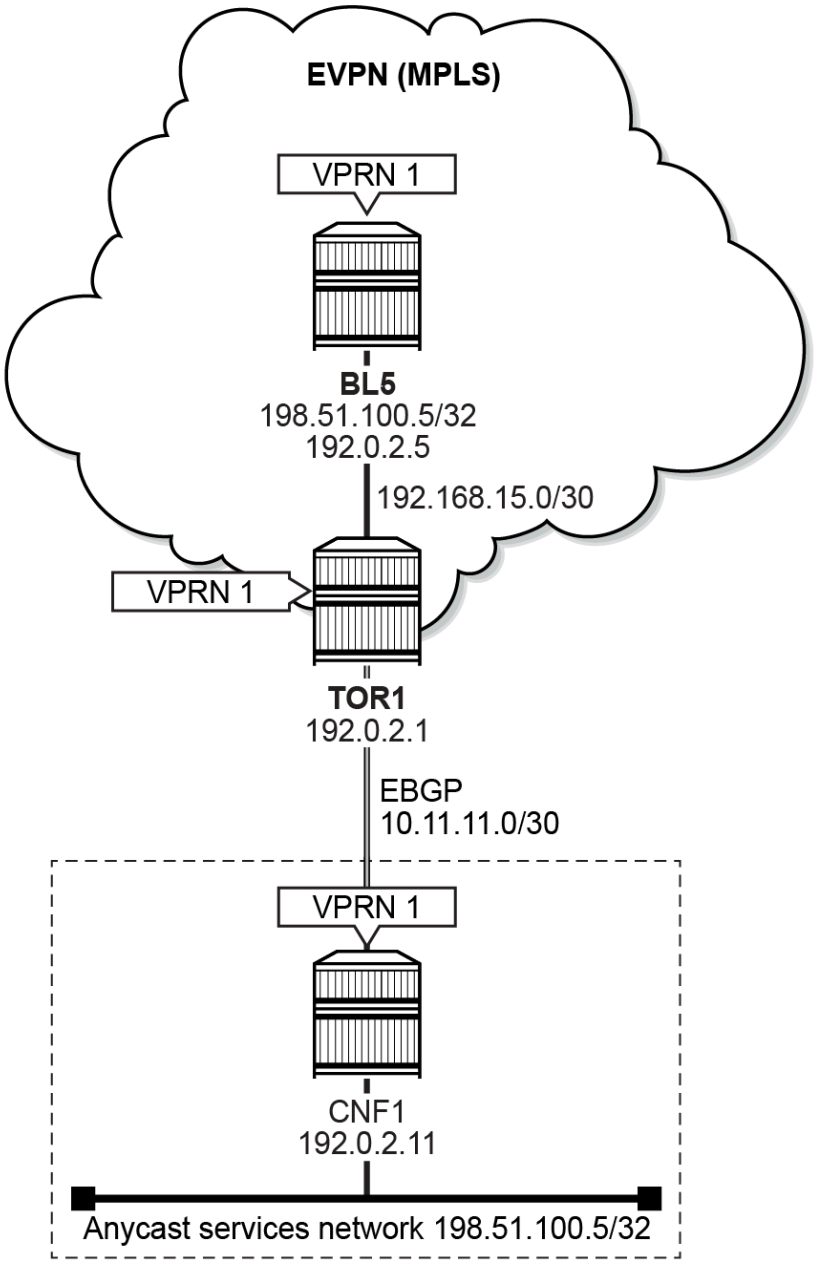
Figure 138: EVPN link bandwidth extended community with policies



40101b

To advertise the 198.51.100.5/32 prefix, the following export policy is configured on CNF1:

```
# On CNF1:
configure {
    policy-options {
        prefix-list "prefix-5" {
            prefix 198.51.100.5/32 type exact { }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        policy-statement "vrf-1-export-5" {
            entry 10 {
                from {
                    prefix-list ["prefix-5"]
                }
                to {
                    protocol {
                        name [bgp]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

VPRN 1 is configured on CNF1, TOR1, and BL5 as follows:

```
# On CNF1:
configure {
    service vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            autonomous-system 64501
            bgp {
                rapid-withdrawal true
                ebgp-default-reject-policy {
                    import false
                }
                group "PE-CE" {
                    type external
                    peer-as 64500
                }
                neighbor "10.11.11.1" {
                    group "PE-CE"
                    export {
                        policy ["vrf-1-export-5"]
                    }
                }
            }
            interface "subs-5" {
                loopback true
                ipv4 {
                    primary {
                        address 198.51.100.5
                        prefix-length 32

                    auto-bind-tunnel {
                        resolution any
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                        advertise { }
                    }
                }
            }
            bgp { }
```

The EVPN link bandwidth extended community has the following fields:

- Type: EVPN (0x06)
- Sub-type: EVPN Link BW (0x10)
- Value Units: encoded as:
  - 0x00 weight expressed using default units of Mbps
  - 0x01 Generalised Weight (supported in SR OS Release 22 and further)
- Value Weight: when Value Units = 0x01, this field encodes the number of PE-CE multi-paths for a specific prefix that is re-advertised into an RT5.

As an example, 0610:010000000002 represents evpn-bandwidth:1:2. When **evpn-link-bandwidth advertise** is not configured on the BL, but an "evpn-link-bw" community with members "ext:0610:010000000002" is configured instead in an EBGP export policy for the BL, the BL advertises the IPv4 prefix together with the additional EVPN link bandwidth extended community evpn-bandwidth:1:2 to the TOR.

To advertise the 198.51.100.5/32 prefix with the EVPN link bandwidth extended community, the following export policy is configured on BL5:

```
# On BL5:
configure {
    policy-options {
        community "comm-vrf-1" {
            member "target:64500:1" { }
        }
        community "evpn-link-bw" {
            member "ext:0610:010000000002" { }
        }
        policy-statement "vrf-1-export-5" {
            entry 10 {
                action {
                    action-type accept
                    as-path-prepend {
                        as-path 64503
                    }
                    community {
                        add ["evpn-link-bw" "comm-vrf-1"]
                    }
                }
            }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **as-path-prepend** command ensures that the prefixes are advertised as if they originate in an external autonomous system.

VPRN 1 is reconfigured on BL5 as follows:

```
# On BL5:
configure {
    service vprn "VPRN 1" {
            autonomous-system 64500
            ecmp 3
            interface "subs-5" {
                loopback true
                ipv4 {
                    primary {
                        address 198.51.100.5
                        prefix-length 32
                    }
                }
            }
            bgp-evpn {
                mpls 1 {
                    route-distinguisher "192.0.2.5:1"
                    evi 1
                    vrf-export {
                        policy ["vrf-1-export-5"]
                    }
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                    evpn-link-bandwidth {
                        weighted-ecmp true
                    }
                }
            }
            bgp { }
```

As for any other transitive extended community, BGP accepts the EVPN link bandwidth extended community from IBGP or EBGP neighbors and re-advertises it to IBGP or EBGP neighbors. As for any other EVPN extended community, the EVPN link bandwidth extended community is not propagated when re-exporting RT5s installed in the VPRN route table into other BGP owners (for example: EVPN-IFF, IFL, VPN-IP, BGP PE-CE).

TOR1 receives a BGP update from BL5 for the EVPN IP prefix route to 198.51.100.5/32, containing the EVPN link bandwidth extended community with the specified weight 2.

```
# On TOR1:

EVPN-IFF model

Figure 139: EVPN-IFF unequal ECMP illustrates how EVPN-IFF unequal ECMP works with VXLAN transport. There is one CNF (CNF1), one TOR (TOR1) and one BL (BL5). TOR1 is connected to BL5. CNF1 is connected to TOR1. VPLS 21 with VXLAN is configured on TOR1 and BL5. VPRN 2 on top of VPLS 21 is configured on TOR1 and BL5. VPRN 2 is configured on CNF1.

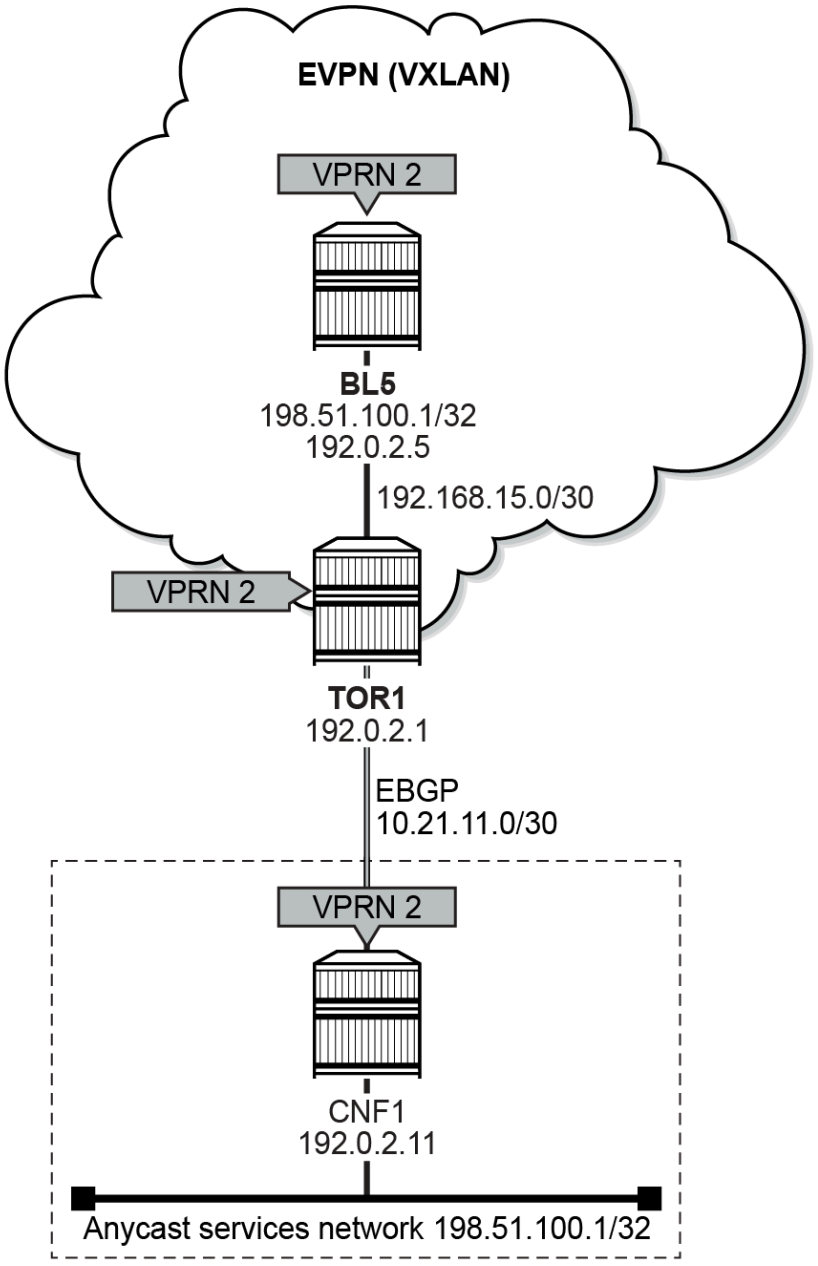
Use subject to Terms available at: www.nokia.com/terms.

Figure 139: EVPN-IFF unequal ECMP



40102b

To advertise the 198.51.100.1/32 prefix, the following export policy is configured on CNF1:

```
# On CNF1:
configure {
    policy-options {
        prefix-list "prefix-1" {
            prefix 198.51.100.1/32 type exact { }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        policy-statement "vrf-2-export-1" {
            entry 10 {
                from {
                    prefix-list ["prefix-1"]
                }
                to {
                    protocol {
                        name [bgp]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

To advertise prefix 198.51.100.1/32, the following export policy is configured on BL5:

```
# On BL5:
configure {
    policy-options {
        community "comm-vrf-2" {
            member "target:64500:2" { }
        }
        policy-statement "vrf-2-export-1" {
            entry 10 {
                action {
                    action-type accept
                    as-path-prepend {
                        as-path 64503
                    }
                    community {
                        add ["comm-vrf-2"]
                    }
                }
            }
        }
```

The **as-path-prepend** command ensures that the prefixes are advertised as if they originate in an external autonomous system.

VPLS 21 is configured on TOR1 and BL5 as follows:

```
# On TOR1 and BL5:
configure {
    service vpls "VPLS 21" {
            admin-state enable
            service-id 21
            customer "1"
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            routed-vpls { }
            bgp 1 { }
            bgp-evpn {
                evi 21
                routes {
                    ip-prefix {
                        advertise true
                        link-bandwidth {
                            weighted-ecmp true
```

```

The following cases are described in the following sections:

- IPv4 prefix advertisement from CNFs
- IPv4 prefix advertisement from CNFs and BL

IPv4 prefix advertisement from CNFs

The CNF advertises prefix 198.51.100.1/32 in its specific EBGP PE-CE session to its corresponding TOR. To enable unequal ECMP processing for EVPN-IFF IPv4 prefix routes, the advertising and receiving procedures are configured in the **service vpls <vpls> bgp-evpn** context on the TOR and on the BL. To

indicate with what relative weight the load balancing across the EVPN-IFF IPv4 prefix routes must be executed, the **add-to-received-bgp <number>** is configured for the EBGP PE-CE session in the **service vprn <vprn> bgp neighbor <EBGP neighbor>** context on the TOR.

TOR1 installs in its VPRN route table and FIB: the EBGP PE-CE route for prefix 198.51.100.1/32 that the TOR receives via EBGP from the CNF, with ECMP weight 1. The Next hop is the interface to the CE. The preference for the PE-CE route route is 170.

```

IPv4 prefix advertisement from CNFs and BL

The CNF advertises prefix 198.51.100.1/32 in its specific EBGP PE-CE session to its corresponding TOR. To enable unequal ECMP processing for EVPN-IFF IPv4 prefix routes, the advertising and receiving procedures are configured in the **service vpls <vpls> bgp-evpn** context on the TOR and on the BL. To indicate with what relative weight the load balancing across the EVPN-IFF IPv4 prefix routes must be executed, the **add-to-received-bgp <number>** is configured for the EBGP PE-CE session in the **service vprn <vprn> bgp neighbor <EBGP neighbor>** context on the TOR. The BL advertises the 198.51.100.1/32 prefix as if it is received from an EBGP session. This requires adding an external community via an export policy.

VPRN 2 is reconfigured on BL5 as follows:

```
# On BL5:
configure {
    service vprn "VPRN 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp-evpn {
                mpls 1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                admin-state enable
                route-distinguisher "192.0.2.5:2"
                vrf-export {
                    policy ["vrf-2-export-1"]
                }
                vrf-target {
                    community "target:64500:2"
                }
            }
        }
        bgp { }
        interface "BD 1" {
            vpls "VPLS 21" {
                evpn-tunnel { }
            }
        }
        interface "subs-1" {
            loopback true
            ipv4 {
                primary {
                    address 198.51.100.1
                    prefix-length 32
                }
            }
        }
```

Irrespective of whether **service vprn <vprn> bgp eibgp-loadbalance** is configured or not on the TOR, the TOR:

- installs in its VPRN route table and FIB: the EVPN-IFF route for prefix 198.51.100.1/32 that it receives via IBGP from the BL, with weight 1, because the EVPN-IFF route has lower priority than the EBGP PE-CE route and always wins. The Next hop is the interface to the VPLS.

Conclusion

SR OS supports unequal ECMP for EVPN IPv4 and IPv6 prefix routes in the EVPN IFL and EVPN IFF models. Traffic from the BL to the anycast IP prefix destination is load balanced according to configurable weights. EVPN-IFL IP prefix routes and EBGP PE-CE routes are combined in the ECMP set for an IP prefix route. EVPN-IFF IP prefix routes are by default preferred over EBGP PE-CE routes in the ECMP set for an IP prefix route.

EVPN VPLS Services Using SRv6 Transport

This chapter provides information about EVPN VPLS using SRv6 transport.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and MD-CLI configuration in this chapter are based on SR OS Release 24.3.R1.

EVPN VPLS services over SRv6 are supported on FP4-based platforms in SR OS Release 22.7.R1 and later. For FP platforms, both all-active and single-active multihoming modes in EVPN VPLS services over SRv6 are supported in SR OS Release 23.10.R1 and later.

For migration scenarios from EVPN MPLS to EVPN SRv6 or from EVPN VXLAN to EVPN SRv6, see the EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 Stitching chapter.

Overview

SRv6 locator and micro-segment locator

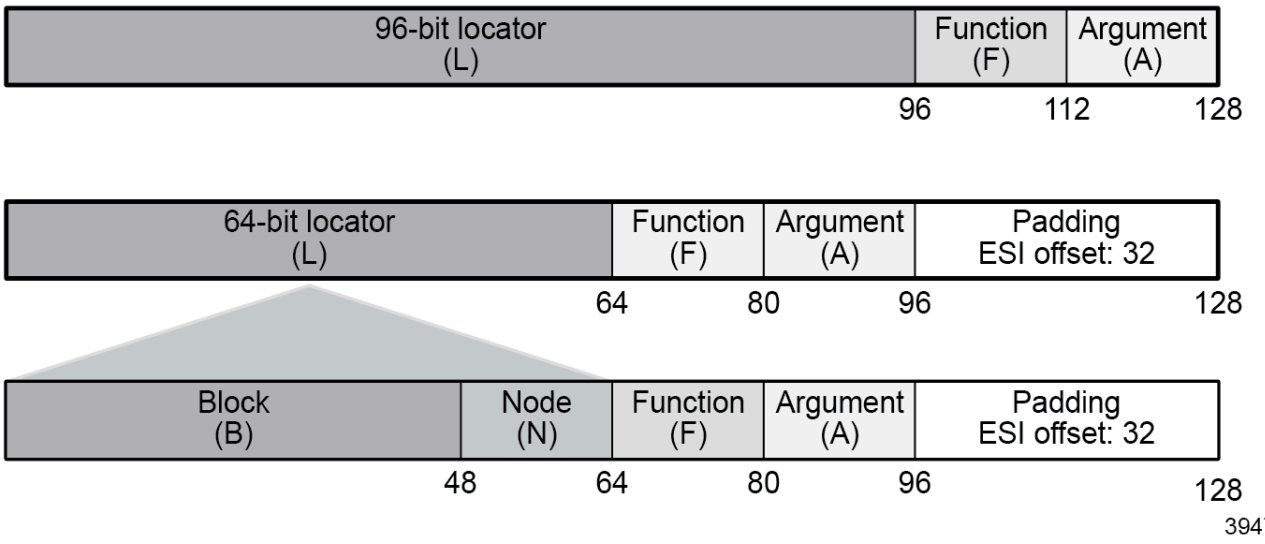
An EVPN VPLS service using SRv6 transport can be configured with a locator for segment identifiers (SIDs) or with a micro-segment locator for micro-SIDs (uSIDs). The micro-SID is an extension of the SRv6 architecture that allows for better efficiency. For micro-SIDs, multiple uSID instructions can be encoded within a single 128-bit SID address, with a maximum of six uSID instructions. Any SID in the destination address or segment routing header can be an SRv6 uSID carrier containing one or more uSIDs.

Locator for SID

Figure 140: SRv6 SID encoding shows two examples of SRv6 SID encoding: one with a 96-bit locator and one with a 64-bit locator. The 64-bit locator contains a 48-bit block address B and a 16-bit node-specific address N.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 140: SRv6 SID encoding



The block length, function length, and argument length can be configured with the following command:

```
[ex:/configure router "Base" segment-routing segment-routing-v6]
A:admin@PE-2# locator "PE2-loc" ?

 locator

 admin-state           - Administrative state of the locator
 algorithm             - IGP flexible algorithm ID
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 argument-length       - SRv6 locator argument length
 block-length          - SRv6 locator block address length
 function-length       - Function length
 label-block           - Reserved label block name for service termination
 prefix                + Enter the prefix context
 static-function       + Enter the static-function context
 termination-fpe       - List of the SRv6 termination FPE
```

The only two possible values for the argument length are 0 (default) and 16, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 locator "PE2-loc"]
A:admin@PE-2# argument-length ?

 argument-length <number>
 <number> - <0,16>
 Default  - 0

    SRv6 locator argument length

    Warning: Modifying this element toggles 'configure router "Base" segment-routing
    segment-routing-v6 locator "PE2-loc" admin-state' automatically for the new value
    to take effect.
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The block length can have any value from 0 to 96, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 locator "PE2-loc"]
A:admin@PE-2# block-length ?

 block-length <number>
 <number> - <0..96>
 Default  - 0

    SRv6 locator block address length

    Warning: Modifying this element toggles 'configure router "Base" segment-routing
    segment-routing-v6 locator "PE2-loc" admin-state' automatically for the new value
    to take effect.
```

The function length can be 16 or any value from 20 to 96, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 locator "PE2-loc"]
A:admin@PE-2# function-length ?

 function-length <number>
 <number>        - <16,20..96>
 Dynamic Default - 20

    Function length

    Warning: Modifying this element toggles 'configure router "Base" segment-routing
    segment-routing-v6 locator "PE2-loc" admin-state' automatically for the new value
    to take effect.
```

For an EVPN VPLS service using SRv6 transport and configured with a locator, the egress PE signals the following functions to the ingress PE:

- End.DT2U for known unicast traffic, encoded in EVPN MAC/IP advertisement routes
- End.DT2M for BUM traffic, encoded in Inclusive Multicast Ethernet Tag (IMET) routes

In EVPN VPLS services, End.DT2U must be configured (with or without a static value) so that MAC/IP routes can be advertised. Similarly, End.DT2M must be configured (with or without a—different—static value) so that IMET routes can be advertised.

Micro-segment locator for micro-SID

A maximum of six 16-bit micro-SID instructions can be encoded within a single 128-bit SID address, as follows:

<32-bit prefix>:<uSID1>:<uSID2>:<uSID3>:<uSID4>:<uSID5>:<uSID6>

The prefix length or block length is 32 in the preceding example, but can be any multiple of 8, with a maximum of 64. Any SRv6 instruction starting with this 32-bit prefix can contain up to six micro-instructions <uSIDx>. In the case that less than six uSIDs are used with this 32-bit prefix, the unused micro-instructions are set to 0x0000.

Figure 141: SRv6 micro-SID encoding shows an example of SRv6 micro-SID encoding with a 32-bit uSID prefix (block B), a 16-bit uSID identifying the node (uN), a 16-bit function, and optionally a 16-bit argument:

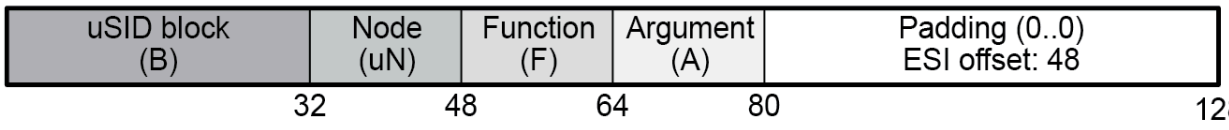
Figure 141: SRv6 micro-SID encoding



39480

Micro-segments can be configured with the following command:

```
[ex:/configure router "Base" segment-routing segment-routing-v6]
A:admin@PE-2# micro-segment ?

 micro-segment

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 argument-length       - Micro-segment argument length
 block                 + Enter the block list instance
 block-length          - Micro-SID block length
 global-sid-entries    - Maximum number of micro-segment locators network wide
 sid-length            - Micro-SID length
```

The argument length is either 0 or 16, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 micro-segment]
A:admin@PE-2# argument-length ?

 argument-length <number>
 <number> - <0,16>
 Default  - 0

    Micro-segment argument length
```

For micro-segments, the block length must be a multiple of 8, with a maximum of 64, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 micro-segment]
A:admin@PE-2# block-length ?

 block-length <number>
 <number> - <8,16,24,32,40,48,56,64>
 Default  - 32

    Micro-SID block length
```

The micro-segment SID length can only be 16, as follows:

```
[ex:/configure router "Base" segment-routing segment-routing-v6 micro-segment]
A:admin@PE-2# sid-length ?

 sid-length <number>
 <number> - <16>
 Default  - 16

    Micro-SID length
```

In the case of a micro-segment locator, the egress PE signals the following functions to the ingress PE:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- End.uDT2U for known unicast traffic
- End.uDT2M for BUM traffic

EVPN VPLS services using SRv6 transport

An EVPN VPLS service using SRv6 can either be configured with a locator or a micro-segment locator, as follows:

```
[ex:/configure service vpls "VPLS-2" segment-routing-v6 1]
A:admin@PE-2# ?

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 locator               + Enter the locator list instance
 micro-segment-        + Enter the micro-segment-locator list instance
  locator
```

The EVPN VPLS can be configured with an SRv6 locator, as follows:

```
[ex:/configure service vpls "VPLS-2" segment-routing-v6 1 micro-segment-locator "PE2-mloc"]
A:admin@PE-2# ?

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 function              + Enter the function context
```

When a locator is configured, the possible functions are End.DT2U for known unicast traffic and End.DT2M for BUM traffic, as follows:

```
[ex:/configure service vpls "VPLS-1" segment-routing-v6 1 locator "PE2-loc"]
A:admin@PE-2# function ?

 function

 end-dt2m              + Enable the end-dt2m context
 end-dt2u              + Enable the end-dt2u context
```

When a micro-segment locator is configured, the functions are End.uDT2U for known unicast traffic and End.uDT2M for BUM traffic, as follows:

```
[ex:/configure service vpls "VPLS-2" segment-routing-v6 1 micro-segment-locator "PE2-mloc"]
A:admin@PE-2# function ?

 function

 udt2m                 + Enable the udt2m context
 udt2u                 + Enable the udt2u context
```

In the **bgp-evpn segment-routing-v6** context, the following can be configured:

```
[ex:/configure service vpls "VPLS-1" bgp-evpn]
A:admin@PE-2# segment-routing-v6 1 ?

 segment-routing-v6

 admin-state           - Administrative state of segment routing over IPv6
 apply-groups          - Apply a configuration group at this level
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
apply-groups-exclude  - Exclude a configuration group at this level
default-route-tag     - Default route tag
ecmp                  - Maximum ECMP value configured on the service
evi-three-byte-auto-  - Auto-derive the BGP EVPN route target
 rt
fdb                   + Enter the fdb context
force-vc-forwarding   - Datapath forwarding to force vlan-vc-type
mh-mode               - Multihoming mode
oper-group            - Operational group
resolution            - Resolution options for routes
route-next-hop        + Enter the route-next-hop context
source-address        - Source IPv6 address
split-horizon-group   - Split horizon group
srv6                  + Enter the srv6 context
```

The following parameters are specific to BGP-EVPN SRv6:

- The **default-route-tag** command is used to match BGP-EVPN routes for the service on export policies, for example, to add or modify BGP attributes.
- The **ecmp** command is used for aliasing on remote SRv6 EVPN Ethernet segment (ES) destinations.
- The **evi-three-byte-auto-rt** command is used to enable or disable 3-byte EVI auto-RT.
- The **force-vc-forwarding {vlan|qinq-c-tag-c-tag|qinq-s-tag-c-tag}** command is used to preserve VLAN tags in the SRv6 tunnel.
- The **mh-mode** option can be configured with the values access or network (needed in the case of multi-instance VPLS services).
- The **oper-group** command is required for fault propagation purposes.
- The **resolution {route-table|tunnel-table|fallback-tunnel-to-route-table}** command allows for setting the resolution of SRv6 routes in the route table or tunnel table (needed for SRv6 policies), and even a fallback from tunnel to route table resolution.
- The **fdb protected-src-mac-violation-action discard** command is required for loop avoidance.
- The **route-next-hop** command controls the BGP next hop used for service routes. The default is system IPv4 address.
- The **source-address** command does not need to be reachable or even exist on a local interface. This is possible because the source address is not looked up in the data path at the remote PE. If not configured, the source address is inherited from the locator's source address.
- The **split-horizon-group** command is used for a seamless integration with spoke SDPs and migration from the EVPN-MPLS services (multi-instance services).

AD per-ES routes in EVPN SRv6 multihoming

An EVPN VPLS service over SRv6 cannot be configured with all-active or single-active multihoming with the ESI label when the SRv6 locator has—the default—argument length 0. The following error is raised when attempting to configure a SAP with a LAG that is associated to an all-active ES in an EVPN VPLS service with SRv6 locator with argument length 0:

```
*[ex:/configure service vpls "VPLS-4" sap lag-1:4]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS-4" sap lag-1:4 description -
locator argument-length must not be default when MH is configured -
configure router "Base" segment-routing segment-routing-v6 locator "PE2-loc-arg0"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
argument-length
```

The arg.fe2 argument is advertised along with the AD per-ES routes for all-active or single-active multihoming with the ESI label. The arg.fe2 argument is used along with the End.DT2M or End.uDT2M functions and supports the transposition into the ESI label extended community label field.

The arg.fe2 argument is dynamically allocated and encoded as follows:

- The allocated arg.fe2 value is encoded in the high-order 16 bits of the ESI label field.
- The SRv6 SID value is always 0.
- The SID structure advertised in the SRv6 SID sub-sub-TLV follows the length of the locator associated with the VPLS (block length, node length, function length).

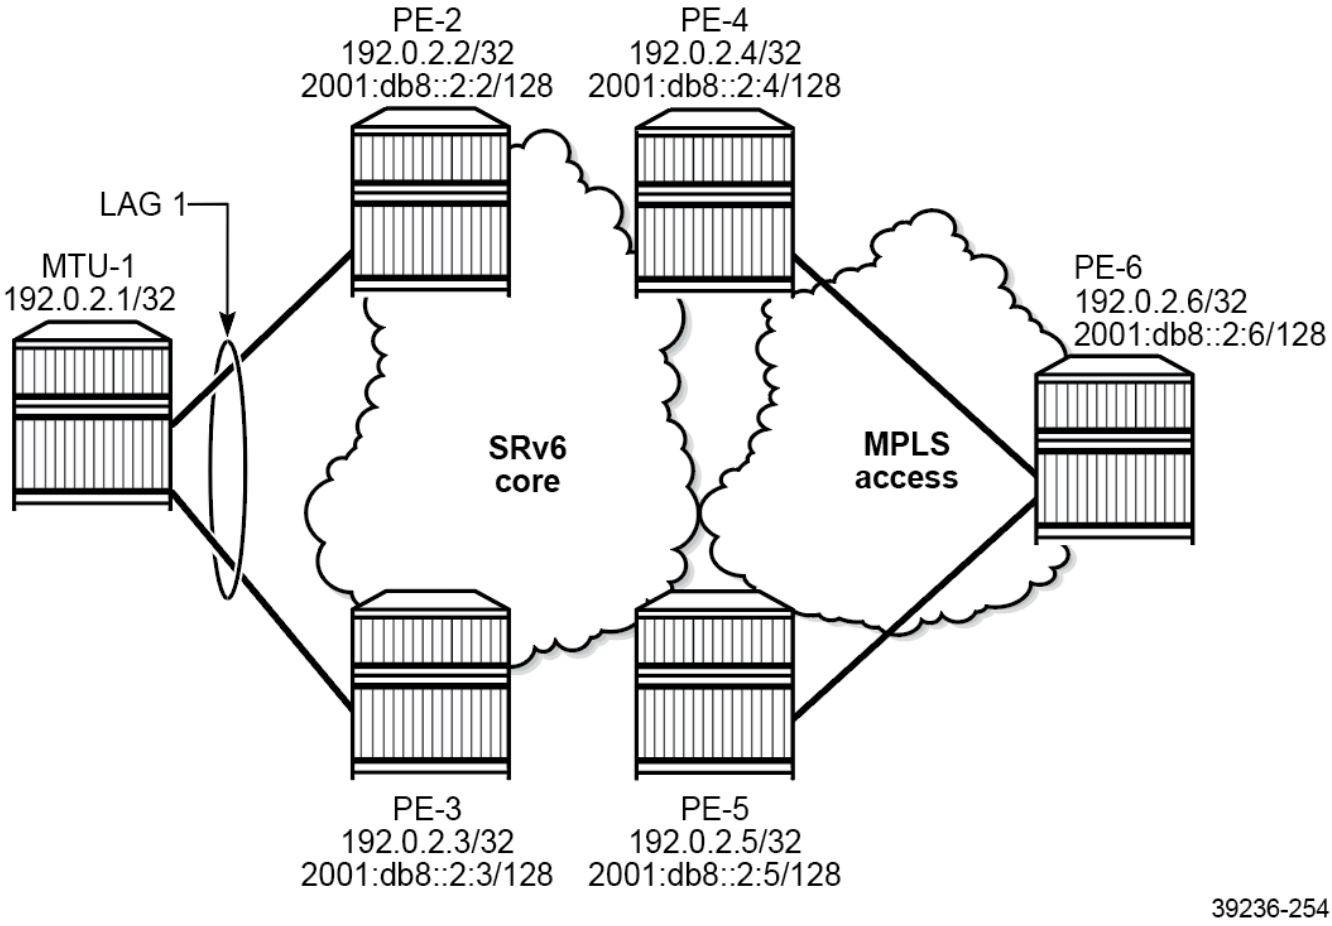
Note: If the ES is configured as **multi-homing single-active no-esi-label**, the AD per-ES routes are advertised with ESI label 3 (for an implicit-null label) and without the arg.fe2 argument.

Configuration

The Figure 142: Example topology shows the topology with six SR OS nodes:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 142: Example topology



The initial configuration includes:

- cards, MDAs, ports
- LAG 1 between MTU-1, PE-2, and PE-3
- router interfaces
- IS-IS on the router interfaces
- BGP for the EVPN address family on PE-2, PE-3, PE-4, and PE-5

As an example, the BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            evpn true
        }
        group "internal" {
            peer-as 64500
            family {
                evpn true
            }
        }
        neighbor "2001:db8::2:3" {
            group "internal"
        }
        neighbor "2001:db8::2:4" {
            group "internal"
        }
        neighbor "2001:db8::2:5" {
            group "internal"
        }
    }
```

Two use cases are described in the following sections:

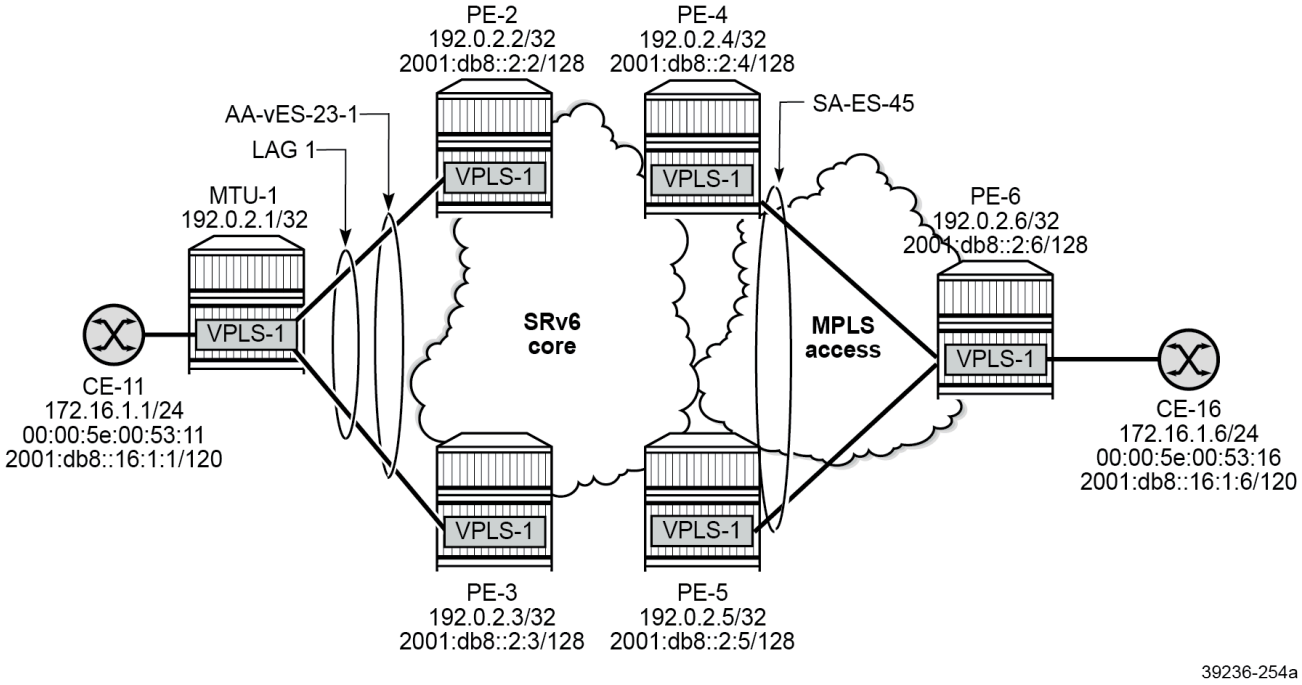
- EVPN VPLS using SRv6 with locator
- EVPN VPLS using SRv6 with micro-segment locator

EVPN VPLS using SRv6 with locator

The core PEs in Figure 143: Example topology with VPLS-1 are connected through an SRv6 network. All-active multihoming applies between PE-2 and PE-3, while single-active multihoming applies between PE-4 and PE-5.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 143: Example topology with VPLS-1



SRv6 configuration with locator

SRv6 is configured on the core PEs. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    card 1 {
        mda 1 {
            xconnect {
                mac 1 {
                    loopback 1 {
                    }
                    loopback 2 {
                    }
                }
            }
        }
    }
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
            application {
                srv6 {
                    type origination
                }
            }
        }
        fpe 2 {
```

                            end 1 {
                                srh-mode usp
                            }
                            end-x-auto-allocate psp protection unprotected { }
                        }
                    }
                }
            }
        }
```

The configuration on the other PEs is similar. On PE-5, no reserved MPLS label block is configured and the labels will be allocated by the system from the dynamic label range. The function length of the locator "PE5-loc" is 24 and the argument length is 16.

EVPN VPLS service configuration

VPLS-1 is configured on all nodes. The configuration on MTU-1 is as follows:

```
# on MTU-1:
configure {
    service {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        vpls "VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/c10/1:1 {
                description "SAP to CE-11"
            }
            sap lag-1:1 {
            }
        }
```

On PE-2 and PE-3, all-active multihoming is configured, as follows:

```
# on PE-2:
configure exclusive
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "AA-vES-23-1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:00:00:01:01
                        orig-ip 2001:db8::2:2                 # on PE-3: 2001:db8::2:3
                        route-next-hop 2001:db8::2:2          # on PE-3: 2001:db8::2:3
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 100                 # on PE-3: value 150
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 1 {
                                            end 4
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "PE2-loc" {    # on PE-3: "PE3-loc"
                    function {
                        end-dt2u {     # label dynamically allocated; label block
                        }
                        end-dt2m {     # label dynamically allocated; label block
                        }
                    }
```

```
            }
        }
        bgp 1 {
        }
        bgp-evpn {
            evi 1
            segment-routing-v6 1 {
                admin-state enable
                ecmp 2
                source-address 2001:db8::2:2           # on PE-3: 2001:db8::2:3
                srv6 {
                    instance 1
                    default-locator "PE2-loc"          # on PE-3: "PE3-loc"
                }
                route-next-hop {
                    ip-address 2001:db8::2:2           # on PE-3: 2001:db8::2:3
                }
            }
        }
        sap lag-1:1 {
        }
    }
```

On PE-4, the function values are manually configured with a value of 10 for End.DT2U and a value of 11 for End.DT2M. The locator "PE4-loc" refers to the MPLS label block and the number of static functions is 16. Single-active multihoming applies between PE-4 and PE-5. The corresponding SDPs use LDP IPv6 tunnels, as follows:

```
# on PE-4:
configure {
    router "Base" {
        segment-routing {
             segment-routing-v6 {
                origination-fpe [1]
                source-address 2001:db8::2:4
                locator "PE4-loc" {
                    admin-state enable
                    block-length 48
                    function-length 16
                    termination-fpe [2]
                    label-block "srv6-labels"
                    argument-length 16
                    prefix {
                        ip-prefix 2001:db8:aaaa:104::/64
                    }
                    static-function {
                        max-entries 16      # for configured function values
                    }
                }
            }
        }
    }
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "SA-ES-45" {
                        admin-state enable

```

ES "SA-ES-45" is configured in a single-active multihoming mode with the ESI label; therefore, PE-5 sends the AD per-ES routes that carry the arg.fe2 value. The SID structure in the SRv6 sub-sub-TLV indicates that the argument length is 16 bits. The 16-bit length of the arg.fe2 value is transposed into the ESI label extended community label field. The transposition length is 16 (argument length 16) and the transposition offset is 88 (block length 48 + node length 16 + function length 24). The SRv6 SID is :: (0).

End.DT2U and End.DT2M functions

On PE-4, function value 10 is configured for End.DT2U and function value 11 for End.DT2M, as follows:

```
[/]
A:admin@PE-4# show router segment-routing-v6 local-sid end-dt2m end-dt2u

===============================================================================

```

EVPN and VPLS integration

EVPN and VPLS integration (RFC 8560) is supported when SRv6 transport is used. SDP bindings signaled by TLDP (manually configured or BGP-AD) or BGP can coexist in VPLS services where EVPN SRv6 is enabled. The SR OS node allows for the creation of an EVPN destination and an SDP binding to the same far end, but the SDP binding is kept operationally down with a flag indicating an EVPN route conflict.

On PE-2 and PE-5, LDP SDPs are created, as follows:

```
# on PE-2:
configure {
    router "Base" {
        ldp {
            interface-parameters {
                interface "int-PE-2-PE-5" {       # on PE-5: "int-PE-5-PE-2"
                    ipv6 {
                        admin-state enable
                    }
                }
            }
        }
    }
    service {
        sdp 25 {                                  # on PE-5: sdp 52
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 2001:db8::2:5          # on PE-5: 2001:db8::2:2
            }
        }
        vpls "VPLS-1" {
            spoke-sdp 25:1 {                      # on PE-5: spoke-sdp 52:1
            }
        }
```

PE-2 still has an SRv6-ISIS tunnel toward 2001:db8:aaaa:105::/64 on PE-5, as follows:

```
[/]
```

-------------------------------------------------------------------------------
2001:db8:aaaa:103::/64                      srv6-isis SRV6  524289    0
  fe80::14:1ff:fe01:1f-"int-PE-2-PE-3"                        10
2001:db8:aaaa:104::/64                      srv6-isis SRV6  524290    0
  fe80::1a:1ff:fe01:b-"int-PE-2-PE-4"                         10
2001:db8:aaaa:105::/64                      srv6-isis SRV6  524291    0
  fe80::1e:1ff:fe01:15-"int-PE-2-PE-5"                        10
-------------------------------------------------------------------------------
Flags: B = BGP or MPLS backup hop available
       L = Loop-Free Alternate (LFA) hop available
       E = Inactive best-external BGP route
       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

The spoke SDP from PE-2 to PE-5 is operationally down and no egress label is allocated, as follows:

```
[/]
A:admin@PE-2# show service id "VPLS-1" sdp 25:1

===============================================================================
Service Destination Point (Sdp Id : 25:1)
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
25:1             Spok                     Up      Down      524282    None
                          2001:db8::2:5
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The reason why the spoke SDP from PE-2 to PE-5 is operationally down is because of an EVPN route conflict, as follows:

```
[/]
A:admin@PE-2# show service id "VPLS-1" sdp 25:1 detail | match Flag post-lines 1
Flags              : NoEgrVCLabel
                     EvpnRouteConflict
```

Tools commands

The following command shows the EVPN usage statistics:

```
[/]
A:admin@PE-2# tools dump service evpn usage

EVPN VPLS using SRv6 with micro-segment locator

Figure 144: Example topology with VPLS-2 shows the topology with VPLS-2. The same nodes and ESs are used, but the VPLS-2 service uses micro-SIDs, whereas VPLS-1 uses regular SIDs. The CEs are different as well.

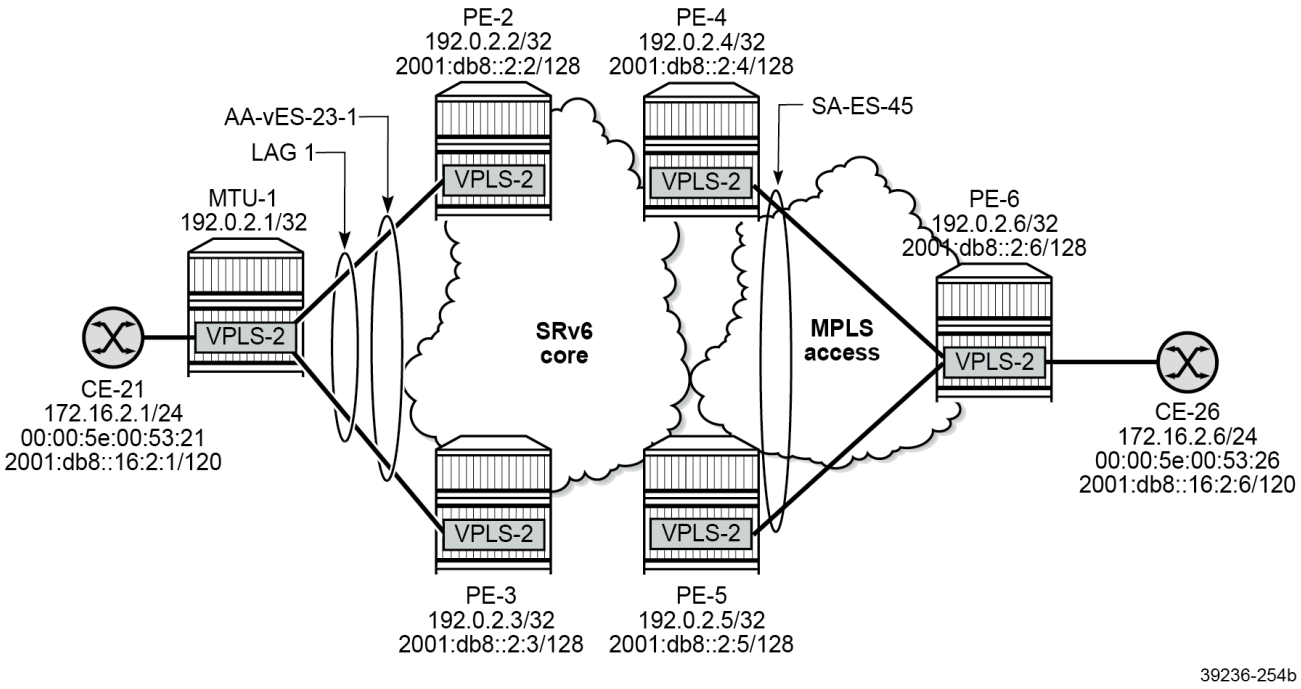
Figure 144: Example topology with VPLS-2



SRv6 micro-segment configuration on core PEs

On all core PEs, a micro-segment and a micro-segment locator are configured on PE-2, as follows:

```
# on PE-2:
configure {
    router "Base" {
        mpls-labels {
            reserved-label-block "res-block1" {
                start-label 19000
                end-label 19999
            }
        }
        isis 0 {
            segment-routing-v6 {
                micro-segment-locator "PE2-mloc" {
                    level 1 {
                    }
                    level 2 {
                    }
                }
            }
        }
        segment-routing {
            segment-routing-v6 {
                origination-fpe [1]
                source-address 2001:db8::2:2
                micro-segment-locator "PE2-mloc" {   # or PE3-mloc, PE4-mloc, PE5-mloc
                    admin-state enable
                    block "PE2-ms-block1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    un {
                        srh-mode usp
                        value 2      # on PE-3: value 3; PE-4: value 4; PE-5: value 5
                    }
                }
                micro-segment {
                    argument-length 16
                    block "PE2-ms-block1" { # PE3-ms-block1, PE4-ms-block1, PE5-ms-block1
                        admin-state enable
                        termination-fpe [2]
                        label-block "res-block1"
                        prefix {
                            ip-prefix 2001:bbbb::/32   # on all PEs; block length 32
                        }
                        static-function {
                            max-entries 16
                        }
                    }
                }
                base-routing-instance {
                    micro-segment-locator "PE2-mloc" {  # or PE3-mloc, PE4-mloc, PE5-mloc
                        function {
                            ua 1 {
                                srh-mode usp
                            }
                            ua-auto-allocate psp protection unprotected { }
                        }
                    }
                }
            }
        }
```

The micro-segment locator contains a micro-segment node value (**un value**) that must be unique network-wide. The **un** function is equivalent to the regular SRv6 End function, but it is configured in the **micro-segment-locator** context instead of the Base instance. The **un value** command creates a node identifier as an IPv6 address that is composed of the block part and followed by a 16-bit SID.

The **ua** micro-SID function encodes the behavior of an adjacency SID.

The following error message is raised when an IP prefix is configured with a length of /48 that is different from the block length of /32:

```
*[ex:/configure router "Base" segment-routing segment-routing-v6 micro-segment
block "PE2-ms-block1" prefix]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure router "Base" segment-routing segment-routing-v6
micro-segment block "PE2-ms-block1" prefix ip-prefix -
prefix-length must be equal to block-length -
configure router "Base" segment-routing segment-routing-v6 micro-segment block-length
```

Service configuration

On MTU-1, VPLS-2 is configured as follows:

```
# on MTU-1:
configure {
    service {
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            customer "1"
            sap 1/1/c10/1:2 {
            }
            sap lag-1:2 {
            }
        }
```

On PE-2 and PE-3, VPLS-2 is configured with all-active multihoming using ES "AA-vES-23-1". The micro-segment locator is configured with the End.uDT2U and End.uDT2M functions, as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            segment-routing-v6 1 {
                micro-segment-locator "PE2-mloc" {            # on PE-3: PE3-mloc
                    function {
                        udt2m {
                        }
                        udt2u {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                segment-routing-v6 1 {
                    admin-state enable
                    ecmp 2
                    source-address 2001:db8::2:2             # on PE-3: 2001:db8::2:3
                    srv6 {
                        instance 1
                        default-locator "PE2-mloc"           # on PE-3: PE3-mloc
                    }
                    route-next-hop {
                        ip-address 2001:db8::2:2             # on PE-3: 2001:db8::2:3
                    }
                }
            }
            sap lag-1:2 {
            }
```

The VPLS-2 configuration on PE-4 uses spoke SDP 46:2, while on PE-5, spoke SDP 56:2 is used, as follows:

```
# on PE-4:
configure {
    service {
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            segment-routing-v6 1 {
                micro-segment-locator "PE4-mloc" {    # on PE-5: PE5-mloc
                    function {
                        udt2m {
                        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        udt2u {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                segment-routing-v6 1 {
                    admin-state enable
                    ecmp 2
                    source-address 2001:db8::2:4      # on PE-5: PE5-mloc; 2001:db8::2:5
                    srv6 {
                        instance 1
                        default-locator "PE4-mloc"    # on PE-5: PE5-mloc
                    }
                    route-next-hop {
                        ip-address 2001:db8::2:4      # on PE-5: 2001:db8::2:5
                    }
                }
            }
            spoke-sdp 46:2 {                          # on PE-5: spoke-sdp 56:2
            }
        }
```

The configuration for VPLS-2 on MTU-6 is as follows:

```
# on MTU-6:
configure {
    service {
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            endpoint "CORE" {
            }
            spoke-sdp 64:2 {
                endpoint {
                    name "CORE"
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 65:2 {
                endpoint {
                    name "CORE"
                }
                stp {
                    admin-state disable
                }
            }
            sap 1/1/c10/1:2 {
            }
        }
```

Verification

PE-2 already had three SRv6-ISIS tunnels to the locators 2001:db8:aaaa:103::/64 on PE-3, 2001:db8:aaaa:104::/64 on PE-4, and 2001:db8:aaaa:105::/64 on PE-5. Now, PE-2 also has SRv6-ISIS tunnels to the micro-segment locators 2001:bbbb:3::/48 on PE-3, 2001:bbbb:4::/48 on PE-4, and 2001:bbbb:5::/48 on PE-5, as follows:

```
[/]
A:admin@PE-2# show router tunnel-table ipv6 protocol srv6-isis

===============================================================================
IPv6 Tunnel Table (Router: Base)
===============================================================================
Destination                                 Owner     Encap TunnelId  Pref

ES "SA-ES-45" is configured in a single-active multihoming mode with the ESI label; therefore, PE-4 sends AD per-ES routes that carry the arg.fe2 value. The SID structure in the SRv6 sub-sub-TLV indicates that the argument length is 16 bits. The 16-bit length of the arg.fe2 value is transposed into the ESI label extended community label field. The transposition length is 16 (argument length 16) and the transposition offset is 64 (block length 32 + node length 16 + function length 16). The SRv6 SID is :: (0).

SRv6 functions and SIDs

The following command on PE-2 shows the SIDs for the End.uDT2U and End.uDT2M functions:

```
[/]
A:admin@PE-2# show router segment-routing-v6 micro-segment-local-sid udt2u udt2m

  1  2001:db8::2:5 (2001:db8::2:5)    2.46 ms  2.89 ms  2.68 ms
```

Conclusion

EVPN VPLS services using SRv6 transport can be configured with locators as well as micro-segment locators. Both all-active and single-active multihoming modes are supported.

EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 Stitching

This chapter provides information about the EVPN VPLS with MPLS to SRv6 or VXLAN to SRv6 stitching.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 23.10.R2. MPLS to SRv6 stitching within an EVPN VPLS is supported in SR OS Release 22.10.R1 and later; VXLAN to SRv6 stitching within an EVPN VPLS is supported in SR OS Release 22.10.R3 and later.

Overview

SRv6 to MPLS stitching or SRv6 to VXLAN stitching is required in hybrid networks where MPLS PEs and SRv6 PEs are both attached to the same EVPN VPLS service. This concept follows the RFC 9014 standard and it is implemented in SR OS by using two EVPN instances in the same EVPN VPLS service. Also, a migration from MPLS tunnels to SRv6 tunnels in EVPN VPLS services requires the support of an SRv6 instance and an MPLS instance in the same EVPN VPLS service. EVPN destinations of different transport types (MPLS, VXLAN, or SRv6) can be placed in the same Split Horizon Groups (SHGs) to avoid loops.

Figure 145: The need for MPLS to SRv6 stitching in an EVPN VPLS shows an EVPN VPLS service configured in all PEs where the gateways (GWs) PE-4 and PE-5 have two service instances in the EVPN VPLS: BGP instance 1 uses MPLS transport and BGP instance 2 uses SRv6. For GW redundancy on PE-4 and PE-5, the anycast multihoming concept is applied.

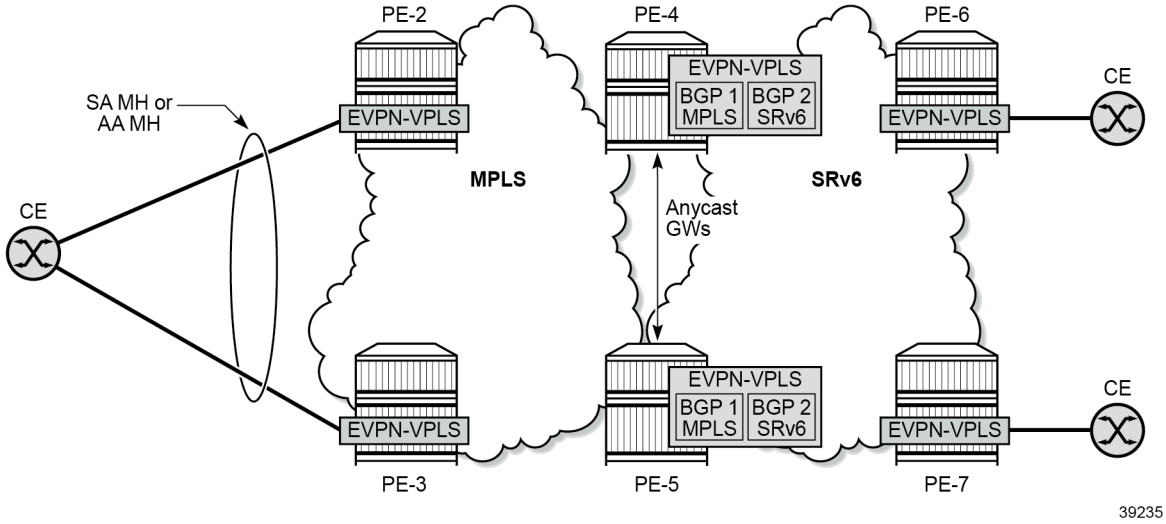
Figure 145: The need for MPLS to SRv6 stitching in an EVPN VPLS



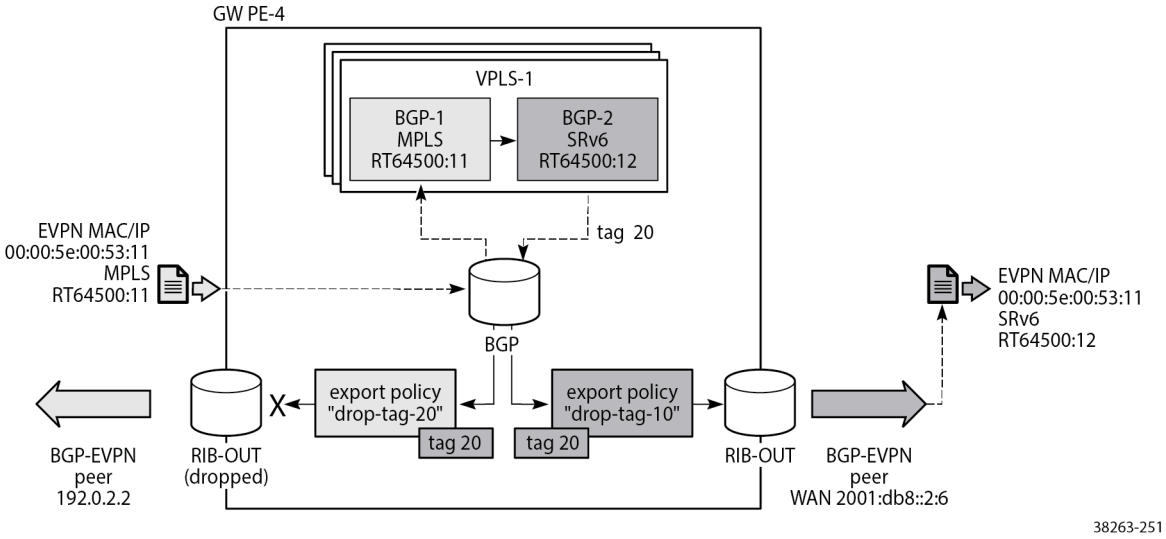
The following applies for multi-instance EVPN VPLS services with SRv6:

- SHGs are supported:
  - EVPN VXLAN cannot be configured with an explicit SHG
  - SHG associated to the EVPN MPLS instance can be the same as or different from the SHG associated to the EVPN SRv6 instance:
    - when the same SHG is configured across two instances, no routes are redistributed between the instances
    - when different SHGs are configured across two instances, routes are redistributed between the instances
- when one of the instances is SRv6, SAPs can be configured only if the two instances are configured with the same explicit SHG
- no SDP bindings are supported on multi-instance VPLS services:
  - the configuration of spoke SDPs or mesh SDPs is blocked
  - BGP VPLS and BGP AD can be configured, but the spoke SDPs are not auto-created
- the **mh-mode access | network** command is supported to configure multihoming:
  - access or network mode can be configured in an SRv6 instance, with network being the default mode
  - the following combinations are supported:
    - SRv6 mh-mode network with MPLS instance mh-mode access
    - SRv6 mh-mode access with MPLS instance mh-mode network (Note: If provider-tunnel is needed on the multi-instance service, the MPLS instance must be configured as mh-mode network)
    - two mh-mode access instances in the same EVPN VPLS are allowed for the combinations VXLAN/MPLS, VXLAN/SRv6, and MPLS/SRv6 (but not for the combination MPLS/MPLS)
- Anycast multihoming can be applied:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- two or more PEs can be configured with the same service parameters as part of the same redundancy group:
  - same Route Distinguisher (RD) for the same BGP instance
  - same Route Target (RT) for the same BGP instance
  - same inclusive multicast originator IP address
- remote PEs set up EVPN destinations to only one PE in the anycast group for a service
- no EVPN BUM destinations are established among the PEs in the anycast group because the received anycast peer inclusive multicast Ethernet tag (IMET) routes have the same inclusive multicast originator IP address
- policies are applied on the GW PEs to avoid loops:
  - export policies add route target and site-of-origin (SOO) extended communities to the redistributed MAC/IP routes and the peer GW PEs drop the routes received with the group SOO
  - default route tags per service instance differentiate the allowed non-redistributed MAC/IP routes from the rest, so that these MAC/IP routes are not advertised between access and network peers, as shown in Figure 146: Default route tags per service instance avoid loops.

Figure 146: Default route tags per service instance avoid loops



The figure shows that an incoming MAC/IP route with RT 64500:11 is accepted in VPLS-1 on GW PE-4 by service instance 1 and passed on to service instance 2 where it gets RT 64500:12 and default route tag 20. Routes with route tag 20 are accepted for routes sent to peer 2001:db8::2:6 in the network, but not for routes sent back to access peer 192.0.2.2. Likewise (but not shown in the figure), routes coming from peer 2001:db8::2:6 with RT 64500:12 are accepted by service instance 2 and passed on to service instance 1 where default route tag 10 is added. Routes with route tag 10 are forwarded to peer 192.0.2.2, but are not sent back to the network peer 2001:db8::2:6.

Configuration

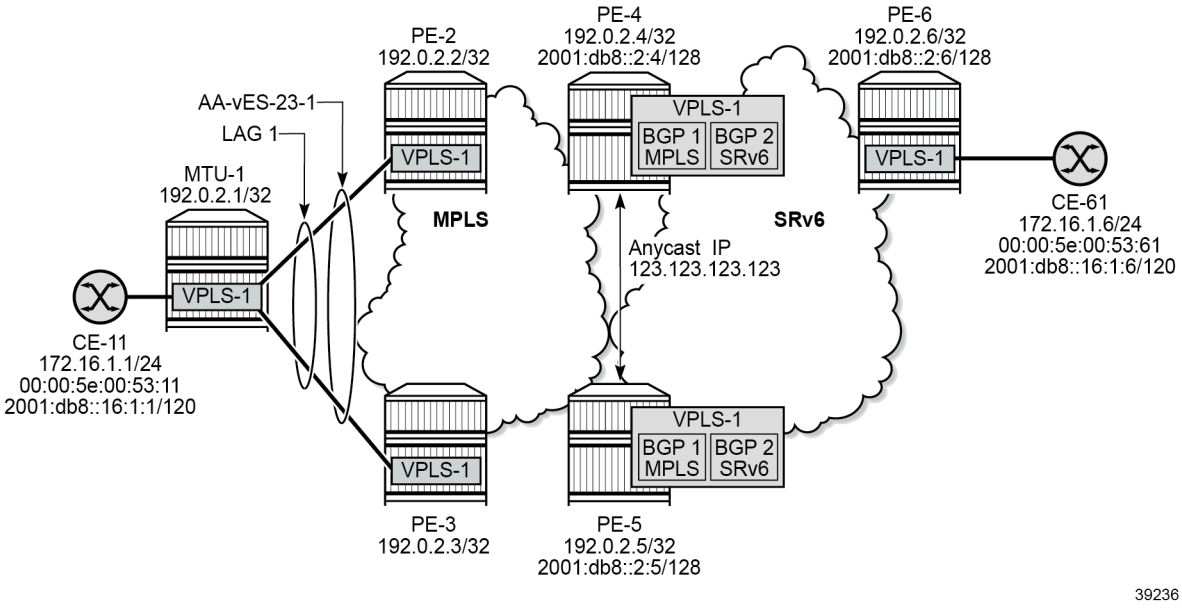
The following use cases are described in this section:

- EVPN VPLS with MPLS to SRv6 stitching
- EVPN VPLS with VXLAN to SRv6 stitching

EVPN VPLS with MPLS to SRv6 stitching

Figure 147: Example topology with VPLS-1 shows the example topology for VPLS-1 with MPLS to SRv6 stitching in the GWs PE-4 and PE-5.

Figure 147: Example topology with VPLS-1



The initial configuration on the nodes includes:

- cards, MDAs, ports, LAG
- router interfaces
- IS-IS as IGP
- LDP between PE-2, PE-3, PE-4, PE-5

SRv6 configuration

The SRv6 configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    card 1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        mda 1 {
            xconnect {
                mac 1 {
                    loopback 1 {
                    }
                    loopback 2 {
                    }
                }
            }
        }
    }
    fwd-path-ext {
        fpe 1 {

The SRv6 configuration on PE-5 and PE-6 is similar.

BGP configuration

In the MPLS access network, PE-2 acts as the route reflector (RR) with clients PE-3, PE-4, and PE-5. The BGP configuration is as follows:

```
# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "access-mpls"
            }
            neighbor "192.0.2.4" {
                group "access-mpls"
            }
            neighbor "192.0.2.5" {
                group "access-mpls"
            }
```

The BGP configuration on PE-3 is as follows:

```
# on PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "access-mpls"
            }
```

In the SRv6 network, PE-6 acts as the RR. The BGP configuration on the GWs PE-4 and PE-5 is as follows. The export policy "drop-tag-10" is used to avoid loops within the core SRv6 network and the export policy "drop-tag-20" is used to avoid loops within the access MPLS network, as shown in Figure 146: Default route tags per service instance avoid loops.

```
# on GWs PE-4 and PE-5:
configure {
    policy-options {
        policy-statement "drop-tag-10" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            description "route tag in VPLSs to avoid loops"
            entry 10 {
                from {
                    tag 10
                }
                action {
                    action-type reject
                }
            }
        }
        policy-statement "drop-tag-20" {
            description "route tag in VPLSs to avoid loops"
            entry 10 {
                from {
                    tag 20
                }
                action {
                    action-type reject
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {

            neighbor "2001:db8::2:5" {
                group "core-srv6"
            }
```

Service configuration

VPLS-1 is configured on all nodes. On PE-2, PE-3, PE-4, and PE-5, service instance 1 of VPLS-1 uses MPLS tunnels. The service configuration on PE-2 and PE-3 is identical, except for the preference value in the all-active Ethernet segment (ES). Route target 64500:11 is accepted in service instance 1 of VPLS-1 on the GW PEs PE-4 and PE-5. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "AA-vES-23-1" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000101
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 100              \# on PE-3: preference 150
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 1 {
                                            end 1
                                        }
                                    }
                                }
                            }
                        }
                    }
```

            }
        }
```

The following configuration on the anycast GW PE-4 shows that the EVPN VPLS is configured with two instances: service instance 1 uses MPLS transport and service instance 2 uses SRv6. The configuration on GW PE-5 is identical with only a different SRv6 locator name. The VSI policies are used to accept EVPN routes with the matching route target and to avoid loops between GWs PE-4 and PE-5 based on the SOO.

```
# on PE-4:
configure {
    policy-options {
        community "RT64500:11" {
            member "target:64500:11" { }
        }
        community "RT64500:12" {
            member "target:64500:12" { }
        }
        community "SOO-45" {
            member "origin:45:45" { }
        }
        policy-statement "vsi-11-export" {
            entry 10 {

                mpls 1 {
                    admin-state enable
                    split-horizon-group "SHG-1"
                    ecmp 2
                    default-route-tag 0xa        # default route tag 10
                    mh-mode access
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            split-horizon-group "SHG-1" {
            }
            split-horizon-group "SHG-2" {
            }
        }
```

The configuration of SHGs is optional. In this example, different SHGs are applied to the two service instances, so the routes can be redistributed between the instances.

In the anycast solution, the RDs, RTs, and the originator IP address must be identical on the GWs PE-4 and PE-5:

- originator IP address: 145.145.145.145
- for instance 1: RD 192.0.2.45:1, RT 64500:11
- for instance 2: RD 192.0.2.54:1, RT 64500:12

Service instance 1 has default route tag 10 and service instance 2 has default route tag 20. These route tags allow to differentiate routes and avoid loops as shown in Figure 146: Default route tags per service instance avoid loops.

The MPLS multihoming mode is access in this example; the SRv6 multihoming mode is network (default).

Show commands

After VPLS-1 is configured on all nodes, traffic is sent between CE-11 and CE-61. The FDB for VPLS-1 on PE-2 is as follows:

```
[/]

The GWs PE-4 and PE-5 redistribute EVPN MAC routes between MPLS and SRv6 domains. The FDB on PE-4 shows that MAC address 00:00:5e:00:53:11 of CE-11 can be reached via the all-active ES with ESI 01:00:00:00:00:23:00:00:01:01, which is in the MPLS domain. MAC address 00:00:5e:00:53:61 of CE-61 can be reached using an SRv6 tunnel to PE-6. The FDB table on PE-5 is similar.

```

The remote PEs, such as PE-2, set up EVPN destinations to only one GW PE in the anycast group for an EVPN VPLS service. The following command on PE-2 shows that two IMET routes with originator IP address 145.145.145.145 are valid, but only the IMET route from PE-4 is used:

```
[/]
A:admin@PE-2# show router bgp routes evpn incl-mcast originator-ip 145.145.145.145

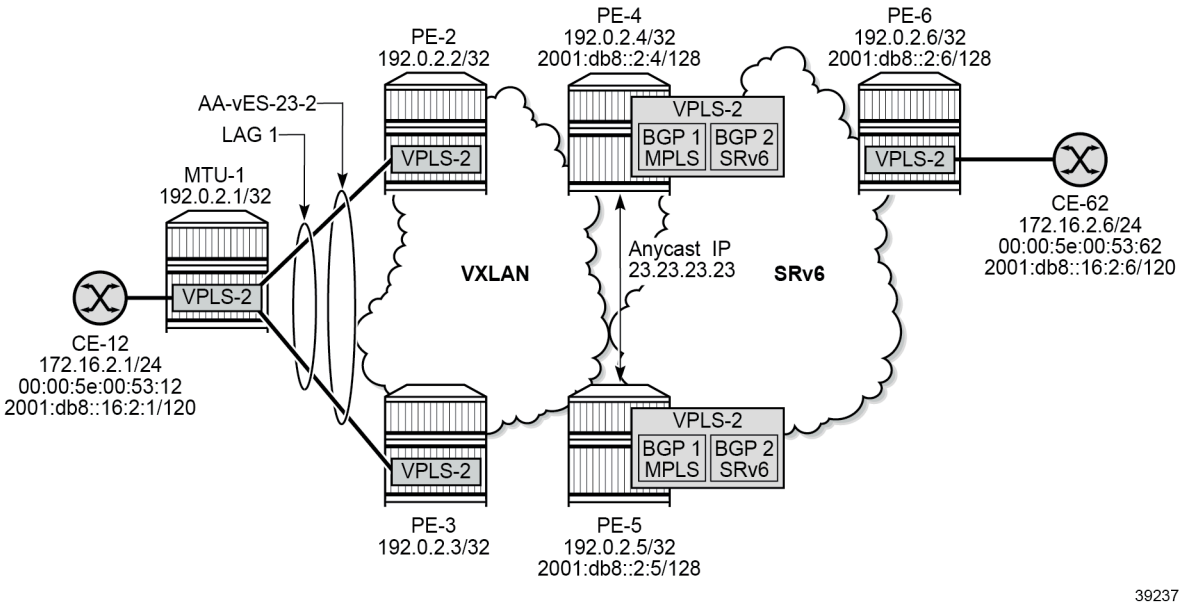
EVPN VPLS with VXLAN to SRv6 stitching

Figure 148: Example topology with VPLS-2 shows the example topology for VPLS-2 with VXLAN to SRv6 stitching in the GWs PE-4 and PE-5.

Figure 148: Example topology with VPLS-2



© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Initial configuration

The initial configuration is similar to the one for EVPN VPLS with MPLS to SRv6 stitching, but LDP is not required between PE-2, PE-3, PE-4, and PE-5. The BGP configuration remains the same with the export policies using route tags to avoid loops.

Service configuration

In the VXLAN domain, all-active multihoming is used between PE-2 and PE-3. The service configuration on PE-2 and PE-3 is identical. Route tag 64500:21 accepted in instance 1 of VPLS-2 on GWs PE-4 and PE-5:

```
#  on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "AA-vES-23-2" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:02:00:01:01
                        multi-homing-mode all-active
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 2 {
                                            end 2
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp 1 {
                route-target {
                    export "target:64500:21"
                    import "target:64500:21"
                }
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                    mh-mode network               # required for VXLAN MH
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    routes {
                        auto-disc {
                            advertise true        # required for VXLAN MH
                        }
                    }
                }
            }
            sap lag-1:2 {
            }
        }
```

In the SRv6 domain, no multihoming is used. The configuration of VPLS-2 on PE-6 is as follows:

```
#  on PE-6:
configure {
    service {
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            segment-routing-v6 1 {
                locator "PE6-loc" {
                    function {
                        end-dt2u {
                        }
                        end-dt2m {
                        }
                    }
                }
            }
            bgp 1 {
                route-target {
                    export "target:64500:22"
                    import "target:64500:22"
                }
            }
            bgp-evpn {
                evi 2
                segment-routing-v6 1 {
                    admin-state enable
                    srv6 {
                        instance 1
                        default-locator "PE6-loc"
                    }
                    route-next-hop {
                        system-ipv6
                    }
                }
            }
            sap 1/1/c10/1:2 {
            }
        }
```

On the GW PEs, service instance 1 uses VXLAN and service instance 2 uses SRv6 transport. VSI policies are used to accept routes with the matching RT and to avoid loops based on the SOO. In the VXLAN service instance, the multihoming mode is access (multihoming mode network is not supported on VXLAN) and no explicit SHG can be configured. For anycast, the same RD and RT values are used on both GW PEs and the originator IP address is 45.45.45.45. The configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    policy-options {
```

Conclusion

SRv6 to MPLS stitching and SRv6 to VXLAN stitching are required to interwork with non-SRv6 networks.

EVPN VPWS Multihoming on PW ports

This chapter provides information about EVPN-VPWS multihoming on PW ports.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 23.10.R1.

Prerequisite reading: EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS) and EVPN VPWS Services with SRv6 Transport.

Overview

Service providers are migrating active/standby pseudowire (PW) aggregation networks to EVPN-VPWS. This architecture is commonly known as "Pseudowire Headend" architecture. In SR OS, the PW headend PE uses PW ports to map ingress traffic from the access into Layer 2 or Layer 3 services in the core. PW ports provide PW termination with the following characteristics:

- provide SAP-based capabilities to a PW which has traditionally been a network-port-based concept within SR OS. PW payload can be extracted onto PW-port-based SAPs with granular queuing capabilities (per SAP).
- look up dot1q and qinq VLAN tags underneath the PW labels and map the traffic to different services.
- terminate subscriber traffic carried within the PW on a Broadband Network Gateway (BNG): PW-port-based SAPs are instantiated under a group interface with Enhanced Subscriber Management (ESM).

PW ports can operate in two modes:

- PW port bound to a specific physical input/output port (I/O port)
- PW port independent of the I/O port on which the PW is terminated: Forwarding Path Extension (FPE) based PW port

In this chapter, FPE-based PW ports are used. The benefit of FPE-based PW ports is that they can provide services when traffic within the PW is rerouted between I/O ports because of a network failure.

Both all-active and single-active EVPN multihoming modes are supported. Figure 149: EVPN-MPLS single-active multihoming on Epipe PW ports shows the example topology with stitching Epipe "Epipe-123" in the access network and single-active multihoming between PE-2 and PE-3. The single-active Ethernet segment (ES) has a PW port associated to it.

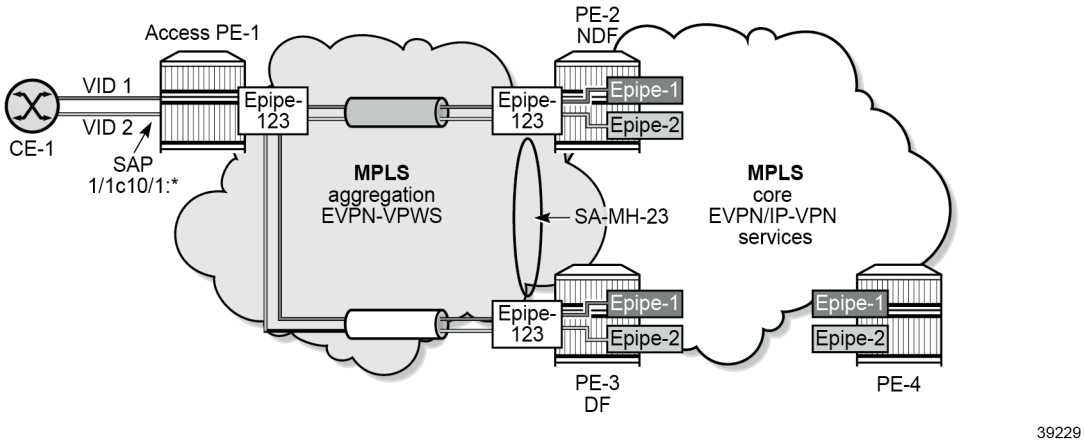
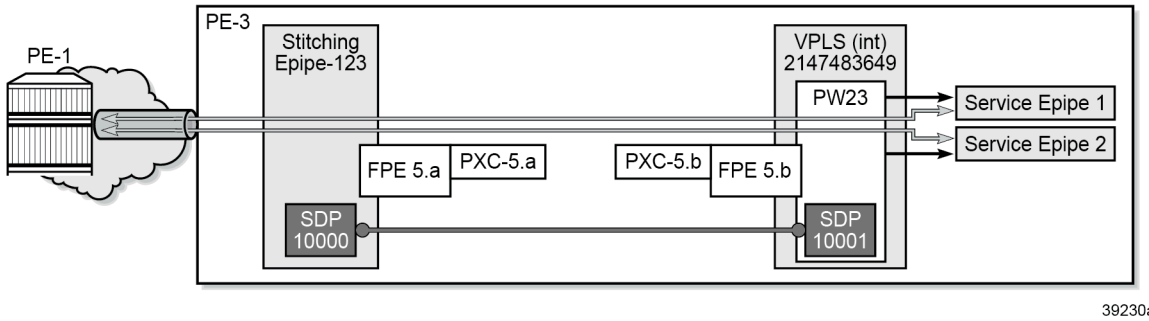
Figure 149: EVPN-MPLS single-active multihoming on Epipe PW ports



In the aggregation network, the stitching EVPN-VPWS "Epipe-123" backhauls the traffic. The SAP of the stitching Epipe on access node PE-1 is 1/1/c10/1:*, so it accepts packets with VID 1 for core service "Epipe-1" and packets with VID 2 for core service "Epipe-2". The stitching between Epipe "Epipe-123" and the service Epipes is done at the Designated Forwarder (DF) PE-3. PE-2 is the Non-Designated Forwarder (NDF) which brings the PW port operationally down due to the MHStandby flag (unless the **oper-up-on-mhstandby** option is enabled). On the NDF PE-2, the PW SAPs pw-23:1 and pw-23:2 (in the core services "Epipe-1" and "Epipe-2") are brought operationally down when the PW port is down. If the PW port is down only due to the MHStandby flag, the AD per-ES route and AD per-EVI route for the service Epipes are still advertised, so PE-1 receives EVPN-AD routes from DF PE-3 and NDF PE-2.

Figure 150: Internal connectivity between switching Epipe and service Epipes shows how internal VPLS "_tmnx_InternalVplsService" with ID 2147483649 is used for the internal cross-connect between the stitching Epipe and the service Epipes.

Figure 150: Internal connectivity between switching Epipe and service Epipes

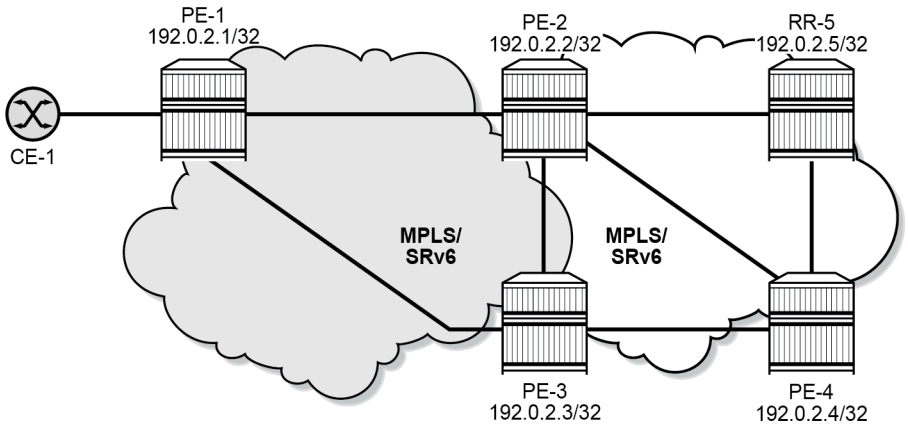


Configuration

Figure 151: Example topology shows the example topology used throughout this section.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 151: Example topology



The initial configuration on the PEs and RR includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on the router interfaces (alternatively, OSPF can be used)

The following scenarios are described in this section:

- EVPN-MPLS all-active multihoming on Epipe PW ports
- EVPN-MPLS single-active multihoming on Epipe PW ports
- EVPN-SRv6 single-active multihoming on Epipe PW ports

In the EVPN-MPLS scenarios, MPLS is used in the aggregation network (between PE-1, PE-2, and PE-3) and in the core network (between PE-2, PE-3, and PE-4). In this example, LDP is applied in the aggregation network and SR-ISIS in the core network.

In the EVPN-MPLS scenarios, the BGP configuration is as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.5" {
                group "internal"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

In the EVPN-MPLS scenarios, the BGP configuration on RR-5 is the following:

```
# on RR-5:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.5
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
```

In all scenarios, FPE 5 is configured with PW port extension on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 5 {
            path {
                pxc 5
            }
            application {
                pw-port-extension {
                }
            }
        }
    }
    port pxc-5.a {
        admin-state enable
    }
    port pxc-5.b {
        admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

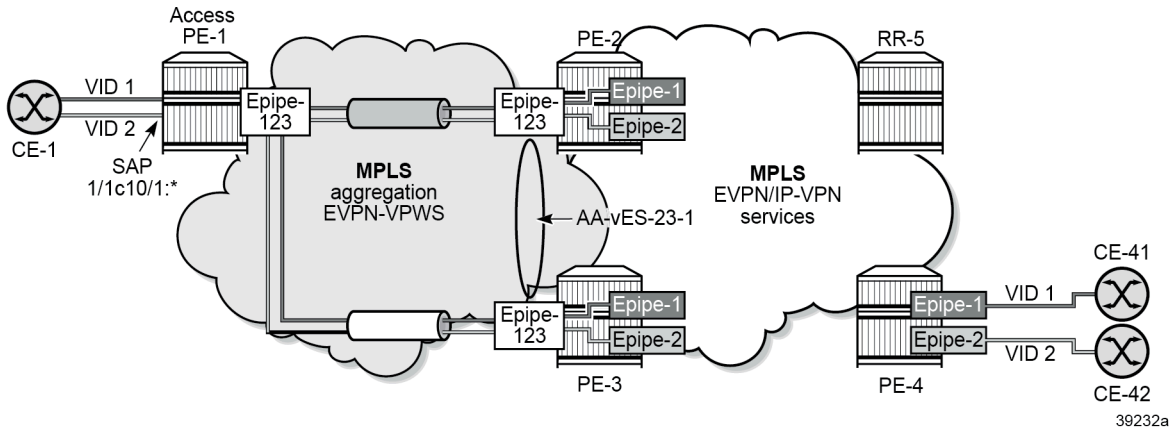
```
    }
    port 1/1/c5/1 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port-xc {
        pxc 5 {
            admin-state enable
            port-id 1/1/c5/1
        }
    }
```

The preceding configuration is similar to the VXLAN FPE configuration, as described in the VXLAN Forwarding Path Extension chapter.

EVPN-MPLS all-active multihoming on Epipe PW ports

Figure 152: EVPN-MPLS all-active multi-homing on Epipe PW ports shows the stitching Epipe in the aggregation network and the core Epipe services in an all-active multihoming scenario.

Figure 152: EVPN-MPLS all-active multi-homing on Epipe PW ports



The stitching EVPN-VPWS service is configured on PE-1, PE-2, and PE-3. The configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:* {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                description "SAP to CEs"
            }
            bgp-evpn {
                evi 123
                local-attachment-circuit "ac-1" {
                    eth-tag 1
                }
                remote-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

CE-1 is connected to this Epipe on PE-1. In this setup, CE-1 is emulated by a VPRN service: on one interface, it sends traffic with VID 1 and an another interface, it sends traffic with VID 2. Both are accepted on SAP 1/1/c10/1:* in EVPN-VPWS "Epipe-123" on PE-1.

The stitching EVPN-VPWS on PE-2 and PE-3 is assigned to FPE-based PW port 23, as follows:

```
# on PE-2, PE-3:
configure {
    pw-port 23 {
        epipe "stitching-Epipe-123" {
            fpe-id 5
        }
    }
    service {
        epipe "stitching-Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 123
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-1" {
                    eth-tag 1
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The aggregation network uses EVPN-VPWS to backhaul the traffic. The network nodes PE-2 and PE-3 apply the same Ethernet tag (23) on the local attachment circuit in the stitching Epipe. Optionally, PE-2 and PE-3 can use the same route distinguisher on the stitching service. AD per-EVI routes for the stitching service are advertised with ESI 0.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The FPE-based PW port is associated to a virtual all-active ES on PE-2 and PE-3. The configuration on PE-2 is as follows; the configuration on PE-3 is identical, but with a different preference value.

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "AA-vES-23-1" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000101
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 100
                                }
                            }
                        }
                        association {
                            pw-port 23 {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 1 {
                                            end 200
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
```

PE-2 and PE-3 receive tagged traffic inside the EVPN-VPWS stitching Epipe and map each tag to a different service in the core, such as ESM services, Epipe services, or VPRN services. In this example, the following services are configured:

```
# on PE-2, PE-3:
configure {
    service {
        epipe "service-Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap pw-23:1 {
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        epipe "service-Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap pw-23:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

These Epipe services are also configured on PE-4:

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:1 {
                description "SAP to CE-41"
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                remote-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:2 {
                description "SAP to CE-42"
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                remote-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

Forwarding from CE-1 to CE-41 or CE-42 works as follows:

- Access node PE-1 forwards traffic based on the best AD per-EVI route advertised by PE-2 and PE-3 for the stitching Epipe. This selection can be either BGP-based if PE-2 and PE-3 use the same route distinguisher (RD) in the stitching service or EVPN-based if different RDs are used. The EVPN-based selection when the RDs are different is based on the lowest IP address of the route. In the example, the RDs are auto-derived, such as 192.0.2.2:123, 192.0.2.3:123.

  Note:
  BGP-based selection is also possible when the RDs are different if the command **configure service system bgp evpn ad-per-evi-routes bgp-path-selection** is configured. For example, in the case of regular BGP best path selection, it is possible to modify the local preference to influence which path is selected.

- When access node PE-1 selects the route to PE-2, PE-2 receives the traffic on the local PW SAP for Epipes "Epipe-1" or "Epipe-2" and forwards it based on the EVPN-VPWS rules in the network to PE-4.

Forwarding from CE-41 or CE-42 to CE-1 works as follows:

- PE-4 forwards the traffic based on the configuration of ECMP and aliasing rules for Epipes "Epipe-1" or "Epipe-2".
- PE-4 may send the traffic to PE-3 and PE-3 to the access node PE-1.

Traffic from the core to the access network may follow an asymmetric path because the multihoming procedures are run on the PW SAPs of the core services, not on the stitching Epipe service. The AD per-EVI routes advertised in the context of the stitching Epipe use ESI 0.

The following command shows that the all-active ES applies to EVI 1 and EVI 2, not to the stitching Epipe with EVI 123:

```
[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "AA-vES-23-1" all
```

```

DF election is not applicable for all-active multihoming in EVPN-VPWS services. For the stitching Epipe, the EVI 123 is not active on the Ethernet segment.

The following VPLS "_tmnx_InternalVplsService" with SDP 10001:100023 on FPE-5.a ensures the internal cross-connect between the stitching Epipe and the core Epipes in PE-2.

```

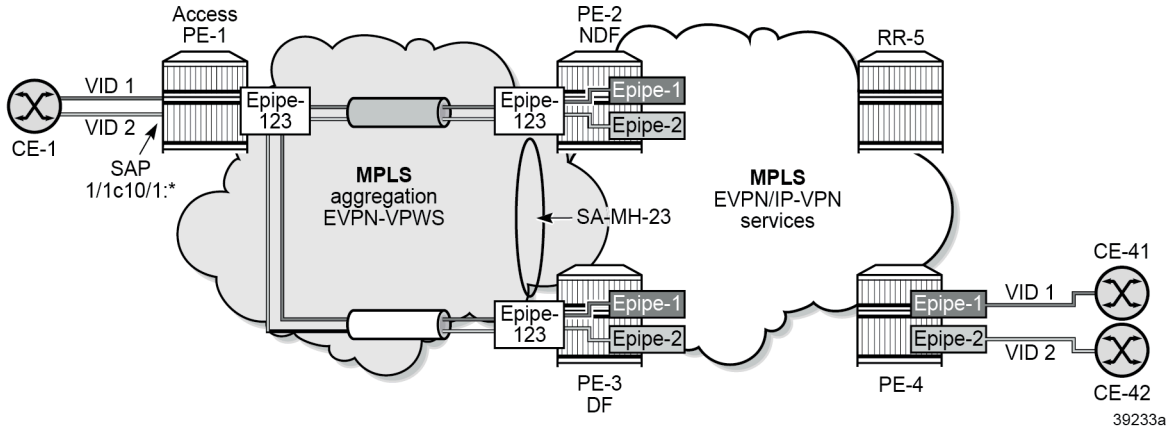
EVPN-MPLS single-active multihoming on Epipe PW ports

EVPN-MPLS single-active multihoming support on Epipe PW ports is supported in SR OS Release 22.2.R1 and later.

Figure 149: EVPN-MPLS single-active multihoming on Epipe PW ports shows the EVPN-MPLS single-active multihoming on Epipe PW ports.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 153: EVPN-MPLS single-active multihoming on Epipe PW ports



Service configuration on PE-2 and PE-3

On PE-2 and PE-3, the stitching Epipe is configured as follows:

```
# on PE-2, PE-3:
configure {
     pw-port 23 {
        epipe "stitching-Epipe-123" {
            fpe-id 5
        }
    }
    service {
        epipe "stitching-Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 123
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-1" {
                    eth-tag 1
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The following (non-virtual) single-active ES is configured on PE-2 and PE-3.

```
# on PE-2, PE-3:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "SA-ES-23" {
                        admin-state enable
                        esi 0x01000000002300000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            pw-port 23 {
                                pw-port-headend true
                            }
                        }
                    }
                }
            }
        }
```

The **pw-headend** keyword allows PW ports to be associated with ESs in single-active mode. The **pw-headend** keyword ensures that the stitching Epipe is running the ES and DF election procedures similar to the mh-mode network in VPLS services. The NDF on the stitching Epipe brings the PW port down with reason MHStandby. The AD per-ES routes and AD per-EVI routes are advertised with the RD and RT of the service Epipe and the configured ESI of the ES associated with the PW port. If the PW port is down only due to MHStandby, the AD per-ES routes and AD per-EVI routes are still advertised. The **oper-up-on-mhstandby** option allows to keep the PW port up on the NDF, which can speed up convergence in case a large number of PW SAPs is configured on the same PW port.

The DF receives tagged traffic inside EVPN-VPWS circuits and maps each tag to a different service in the core network, such as ESM services, Epipe services, or VPRN services. In this example, the following Epipe services are configured with PW SAPs:

```
# on PE-2, PE-3:
configure {
    service {
        epipe "service-Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap pw-23:1 {
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        epipe "service-Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap pw-23:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The configuration on PE-1 and PE-4 is similar to the configuration in the all-active multihoming scenario.

ES and DF election procedures on stitching Epipe

The stitching Epipe associated with the PW port is running the ES and DF election procedures. The following ES command on PE-3 shows the state for the stitching Epipe EVI 123, not for the contained PW SAP services with EVI 1 and EVI 2. PE-3 is the DF.

```
[/]
A:admin@PE-3# show service system bgp-evpn ethernet-segment name "SA-ES-23" all

-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
---snip---
```

The following command shows that PE-2 is NDF for the stitching Epipe:

```
[/]
A:admin@PE-2# show service id 123 ethernet-segment
No sap entries
No sdp entries
No vxlan instance entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
Pw-Port               Eth-Seg                         Status
-------------------------------------------------------------------------------
23                    SA-ES-23                        NDF
===============================================================================
```

The NDF PE-2 will bring the PW port down because of the MHStandby flag, but the AD per-ES route for the stitching Epipe service is still advertised (if MHStandby is the only reason for the PW port to be down). Therefore, PE-1 receives an AD per-ES route for the stitching Epipe from PE-2 and from PE-3:

```

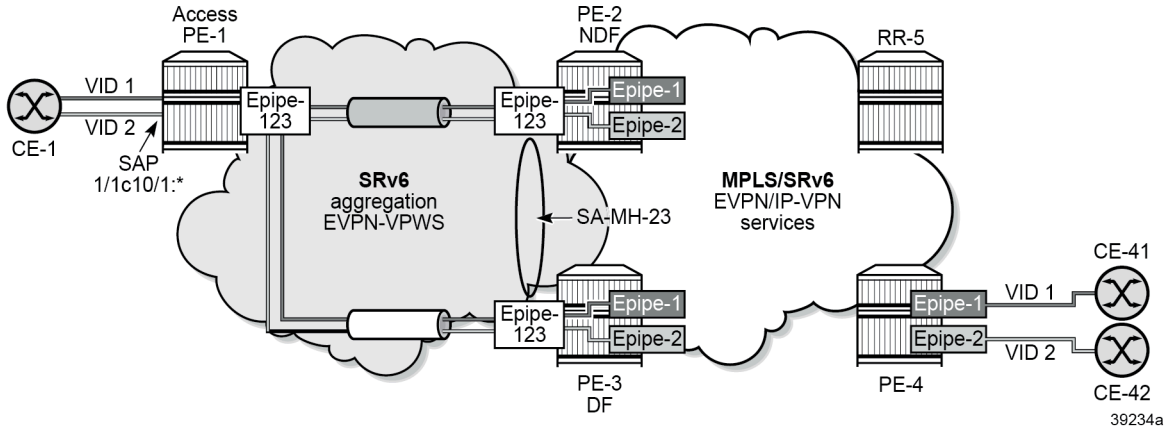
EVPN-SRv6 single-active multihoming on Epipe PW ports

EVPN-SRv6 single-active multihoming support on Epipe PW ports is supported in SR OS Release 22.5.R1 and later.

Figure 154: EVPN-SRv6 single-active multihoming on Epipe PW ports shows the topology with EVPN-SRv6 in the aggregation network and both EVPN-MPLS and EVPN-SRv6 in the core network.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 154: EVPN-SRv6 single-active multihoming on Epipe PW ports



The stitching Epipe in the aggregation network uses SRv6 transport. Epipe 1 in the core network uses SRv6 transport, while Epipe 2 in the core network uses MPLS transport.

SRv6 configuration

The SRv6 configuration is as described in the EVPN VPWS Services with SRv6 Transport chapter:

```
# on PE-2:
configure {
    card 1 {
        mda 1 {
            xconnect {
                mac 1 {
                    loopback 1 {
                    }
                    loopback 2 {
                    }
                }
            }
        }
    }
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
            application {
                srv6 {
                    type origination
                }
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                srv6 {
                    type termination
```

```
                }
                base-routing-instance {
                    locator "loc_Epipe" {
                        function {
                            end 1 {
                                srh-mode usp
                            }
                            end-x-auto-allocate psp protection unprotected { }
                        }
                    }
                }
            }
        }
```

The configuration on the other PEs is similar. IPv6 addresses are configured on all interfaces. The BGP configuration uses IPv6 addresses, as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "2001:db8::2:5" {
                group "internal"
            }
```

```
# on RR-5:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.5
                }
                extended-nh-encoding {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    vpn-ipv4 true
                    ipv4 true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor "2001:db8::2:1" {
                group "internal"
            }
            neighbor "2001:db8::2:2" {
                group "internal"
            }
            neighbor "2001:db8::2:3" {
                group "internal"
            }
            neighbor "2001:db8::2:4" {
                group "internal"
            }
```

Service configuration

On PE-1, the EVPN-VPWS "Epipe-123" is configured as follows:

```
# on access node PE-1:
configure {
    service {
        epipe "Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            sap 1/1/c10/1:* {
                description "SAP to CEs"
            }
            bgp-evpn {
                evi 123
                local-attachment-circuit "ac-1" {
                    eth-tag 1
                }
                remote-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                segment-routing-v6 1 {
                    admin-state enable
                    srv6 {
                        instance 1

On PE-2 and PE-3, the stitching Epipe and the single-active ES are configured as follows:

```
# on PE-2, PE-3:
configure {
    pw-port 23 {
        epipe "stitching-Epipe-123" {
            fpe-id 5
        }
    }
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "SA-ES-23" {
                        admin-state enable
                        esi 0x01000000002300000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            pw-port 23 {
                                pw-port-headend true
                            }
                        }
                    }
                }
            }
        }
        epipe "stitching-Epipe-123" {
            admin-state enable
            service-id 123
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 123

The core service "service-Epipe-1" uses SRv6 transport:

```
# on PE-2, PE-3:
configure {
    service {
        epipe "service-Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            sap pw-23:1 {
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                segment-routing-v6 1 {
                    admin-state enable
                    ecmp 2
                    srv6 {
                        instance 1
                        default-locator "loc_Epipe"
                    }
                }
            }
        }
```

The core service "service-Epipe-2" uses MPLS transport:

```
# on PE-2, PE-3:
configure {
    service {
        epipe "service-Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap pw-23:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                remote-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                mpls 1 {
                    admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

On PE-4, the corresponding Epipe services are configured as follows:

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "loc_Epipe" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            sap 1/1/c10/1:1 {
                description "SAP to CE-41"
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "ac-4" {
                    eth-tag 4
                }
                remote-attachment-circuit "ac-23" {
                    eth-tag 23
                }
                segment-routing-v6 1 {
                    admin-state enable
                    ecmp 2
                    srv6 {
                        instance 1
                        default-locator "loc_Epipe"
                    }
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:2 {
                description "SAP to CE-42"
            }

```
                    eth-tag 23
                }
                mpls 1 {
                    admin-state enable
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

Verification

The stitching Epipe associated with the PW port is running the ES and DF election procedures. The following service configuration output shows that the ES is applied for EVI 123 of the stitching Epipe, not for EVI 1 or EVI 2.

```

PE-1 receives the following AD per-ES route with RD 192.0.2.2:123 of the stitching Epipe on PE-2. This AS per-ES route contains:

- an ESI-label extended community with the multihomed mode (single-active) and an ESI label
- an SRv6 L2 service TLV with:
  - an SRv6 SID value of zero (the locator, function, and argument equal zero)
  - the used endpoint behavior code point 0x18 for End.DT2M

```

The AD per-EVI routes contain an SRv6 L2 service TLV with:

- an SRv6 SID value of 2001:db8:aaaa:103:: with:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - block length (BL) 48
  - node length (NL) 16
  - function length (FL) 20
  - argument length (AL) 0
  - transposition length (TL) 20 (for EVPN and IP-VPN) - transposition of 20 bits of the function field to the ESI label field
  - transposition offset (TO) 0
- the used endpoint behavior code point 0x15 for End.DX2

Conclusion

EVPN-VPWS multihoming on PW ports is supported for all-active and for single-active multihoming. The transport on the stitching (and service) Epipe services can be MPLS or SRv6.

EVPN VPWS Services with SRv6 Transport

This chapter provides information about SRv6 support for EVPN-VPWS overlay services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R2. SRv6 support for EVPN-VPWS overlay services is supported on FP-based platforms with FP4-based network ports in SR OS Release 22.7.R1 and later.

Chapter EVPN for MPLS Tunnels is prerequisite reading.

Overview

Service providers prefer an optimized, standardized, and unified control plane for VPNs. EVPN-VPWS is supported in SRv6 networks that may also run other EVPN-based services, such as EVPN-based VPLS services or Layer 3 EVPN IFL (interface-less) services. From a control plane perspective, EVPN-VPWS is a simplified point-to-point version of RFC 7432, because there is no need to advertise MAC/IP advertisement routes in VPWS. EVPN-VPWS is described in RFC 8214, and the signaling aspects to support SRv6 are specified in RFC 9252.

EVPN-VPWS supports all-active multihoming (per-flow load-balancing multihoming) as well as single-active multihoming (per-service load-balancing multihoming), using the same Ethernet segments (ESs) used for EVPN-based VPLS services. EVPN-VPWS uses route type 1 and route type 4; it does not use route types 2, 3, or 5, because MAC/IP routes, inclusive multicast routes, or IP-prefix routes are not required.

EVPN-VPWS uses AD per-EVI routes, and optionally, if multihoming is used, AD per-ES and ES routes are required:

- route type 1 - Auto-discovery per EVPN instance (AD per-EVI). This route type is used in all EVPN-VPWS scenarios, with or without multihoming. For EVPN-VPWS, the Ethernet tag field is encoded with the local attachment circuit (AC) of the advertising PE. This value is configured using the **configure service epipe** *<service-name>* **bgp-evpn local-attachment-circuit** *<name>* **eth-tag** *<eth-tag>* command. The route distinguisher (RD), label, and the Ethernet segment identifier (ESI) are encoded as for EVPN-based VPLS. The label field is used as service label. In case of multihoming, AD per-EVI routes containing the same ESI are used to provide aliasing and a backup path to the PEs part of the ES. The L2 MTU field is encoded with the service MTU configured in the Epipe. The flags used for EVPN-VPWS are:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

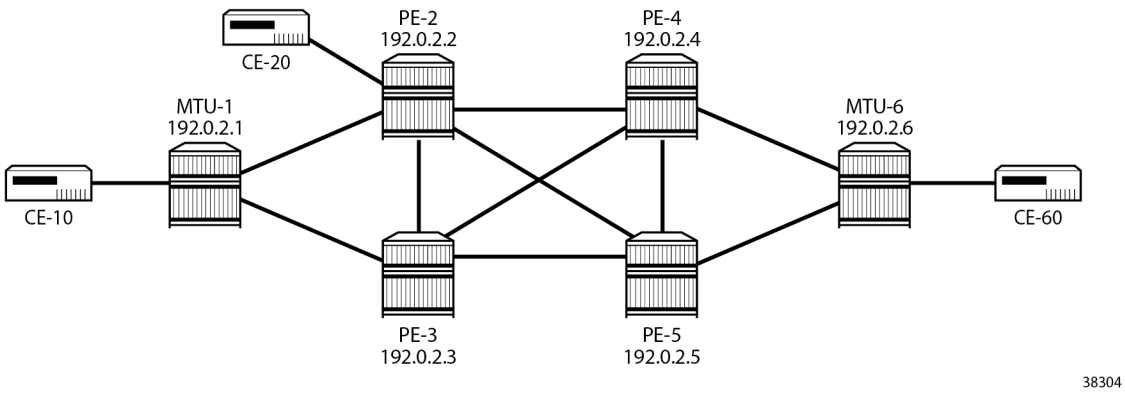
  - Flag C: this flag is set if a control word is configured in the service; however, this does not apply if the transport is SRv6.
  - Flag P: this flag is set if the advertising PE is a primary PE.
    - If no multihoming is used, there is no primary PE (P = 0).
    - In all-active multihoming, all PEs in the ES are primary (P = 1).
    - In single-active multihoming, only one PE per-EVI in the ES is a primary (P = 1).
  - Flag B: this flag is set if the advertising PE is a backup PE.
    - Flag B is only set in case of single-active multihoming and only for one PE, even if more than two PEs are present in the same single-active ES. The backup PE is the winner of the second designated forwarder (DF) election (excluding the DF). The remaining non-DF PEs send B = 0.

  If there is no multihoming, the ESI, flag P, and flag B are set to zero.
- route type 1 - Auto-discovery per Ethernet segment (AD per-ES). This route type has the same encoding as for EVPN-based VPLS. The AD per-ES route is only used in multihoming scenarios where it is advertised from the PE for each ES. This route type carries the ESI label (used for split-horizon, but only for VPLS services and not for Epipe services) and can affect procedures such as the DF election, as well as the aliasing on remote PEs.
- route type 4 - ES route. This route type has the same encoding as for EVPN-based VPLS. The ES route is only used in multihoming scenarios. This route type advertises a local configured ES. The exchange of this route type can discover remote PEs that are part of the same ES and the DF election algorithm among them.

Configuration

Figure 155: EVPN-VPWS example topology shows the example topology that is used throughout this chapter.

Figure 155: EVPN-VPWS example topology



The example topology consists of six SR OS nodes with the following initial configuration:

- Network (or hybrid) ports interconnect the core PEs with configured router interfaces.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MTU-1 is a pure Ethernet aggregator. The ports toward the core PEs are access ports. Likewise, the ports on PE-2 and PE-3 toward MTU-1 are access ports.
- Core PEs and MTU-6 run IS-IS on all interfaces.
- Link LDP is configured between all PEs, and toward and from MTU-6.
- EVPN uses BGP for exchanging reachability information at the service level. Therefore, BGP peering sessions must be established among the core PEs for the EVPN family. Although a separate router is typically used, in this chapter, PE-2 is used as route reflector with the following BGP configuration:

```
[/]
A:admin@PE-2# configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
            vpn-apply-export true
            peer-ip-tracking true
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "gr_v6_internal" {
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
                peer-as 64500
                extended-nh-encoding {
                    ipv4 true
                    vpn-ipv4 true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor 2001:db8::2:3 {
                group "gr_v6_internal"
            }
            neighbor 2001:db8::2:4 {
                group "gr_v6_internal"
            }
            neighbor 2001:db8::2:5 {
                group "gr_v6_internal"
            }
        }
    }
}
```

The BGP configuration on the other PEs is as follows:

```
[/]
A:admin@PE-3#, A:admin@PE-4#,A:admin@PE-5# configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
            vpn-apply-export true
            peer-ip-tracking true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "gr_v6_internal" {
                family {
                    evpn true
                }
                peer-as 64500
                extended-nh-encoding {
                    ipv4 true
                    vpn-ipv4 true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor 2001:db8::2:2 {
                group "gr_v6_internal"
            }
        }
    }
}
```

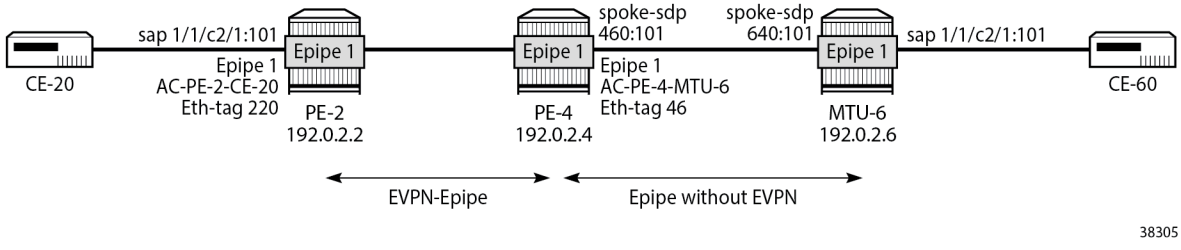
The following sections describe the EVPN-VPWS scenarios:

- SRv6 tunnels in EVPN-VPWS services without multihoming
- SRv6 tunnels in EVPN-VPWS services with all-active multihoming
- SRv6 tunnels in EVPN-VPWS services with single-active multihoming

SRv6 tunnels in EVPN-VPWS services without multihoming

BGP-EVPN can be enabled in Epipe services with either SAPs or spoke SDPs at the access, as shown in Figure 156: Example topology for EVPN-VPWS without multihoming.

Figure 156: Example topology for EVPN-VPWS without multihoming



On PE-2, Epipe 1 is configured as follows:

```
[/]
A:admin@PE-2# configure {
    service {
        epipe "Epipe-1" {
            customer "1"
            service-id 1
            segment-routing-v6 1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                locator "loc_Epipe-1" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                local-attachment-circuit AC-PE-2-CE-20 {
                    eth-tag 220
                }
                remote-attachment-circuit AC-PE-4-MTU-6 {
                    eth-tag 46
                }
                evi 10
                segment-routing-v6 1 {
                    srv6 {
                        instance 1
                        default-locator "loc_Epipe-1"
                    }
                    # source-address 2001:db8::2:2    # defined for SRv6 on router level
                    admin-state enable
                }
            }
            sap 1/1/c2/1:101 {
            }
            admin-state enable
        }
    }
}
```

On PE-4, the service configuration is as follows:

```
[/]
A:admin@PE-4# configure {
    service {
        sdp 460 {
            far-end {
                ip-address 192.0.2.6
            }
            admin-state enable
        }
        epipe "Epipe-1" {
            customer "1"
            service-id 1
            segment-routing-v6 1 {
                locator "loc_Epipe-1" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                local-attachment-circuit AC-PE-4-MTU-6 {
                    eth-tag 46
                }
                remote-attachment-circuit AC-PE-2-CE-20 {
                    eth-tag 220
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
                evi 10
                segment-routing-v6 1 {
                    srv6 {
                        instance 1
                        default-locator "loc_Epipe-1"
                    }
                    # source-address 2001:db8::2:4    # defined for SRv6 on router level
                    admin-state enable
                }
            }
            spoke-sdp 460:101 {
            }
            admin-state enable
        }
    }
}
```

The following commands are relevant for the EVPN-VPWS configuration:

- the **bgp** <*bgp-instance*> command enables the context for the BGP configuration relevant to the service. The **bgp** context configures the common BGP parameters for all BGP families in the service, such as the RD and the route target (RT). Even if the general BGP parameters for the service are auto-derived, the **bgp** context must be enabled.

```
[/]
A:admin@PE-2# configure {
    service {
        epipe "Epipe-1" {
            bgp 1 ?

 bgp

 adv-service-mtu       - Advertised service MTU value
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 pw-template-binding   + Enter the pw-template-binding list instance
 route-distinguisher   - High-order 6 bytes that are used as string to compose VSI-ID for
 use in NLRI
 route-target          + Enter the route-target context
 vsi-export            - VSI export policies
 vsi-import            - VSI import policies
```

- The following parameters can be configured in the **bgp-evpn** context:

```
[/]
A:admin@PE-2# configure {
    service {
        epipe "Epipe-1" {
            bgp-evpn ?

 bgp-evpn

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 evi                   - EVPN ID
 local-attachment-     + Enter the local-attachment-circuit list instance
  circuit
 mpls                  + Enter the mpls list instance
 remote-attachment-    + Enter the remote-attachment-circuit list instance
  circuit
 segment-routing-v6    + Enter the segment-routing-v6 list instance
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
vxlan                + Enter the vxlan list instance
```

– The **evi** command configures a 2-byte or 3-byte EVPN identifier (EVI) used for auto-deriving the service RD, service RT, and for the service carving (or DF election) when multihoming is used. For 2-byte EVIs, the auto-derivation of RD and RT is as follows:

  • RD system-ip:evi

  • RT autonomous-system:evi

  The EVI values must be unique in the system, regardless of the type of service they are assigned to (Epipe or VPLS).

– The **local-attachment-circuit** and **remote-attachment-circuit** commands configure the two attachment circuits connected by the EVPN-VPWS service. The configured Ethernet tag for the local AC is advertised in the Ethernet tag field of the AD per-EVI route for the Epipe, along with the corresponding RD, RT, and label. Both local and remote Ethernet tags are necessary to bring up the Epipe service. If the received Ethernet tag for the Epipe service matches the configured remote AC Ethernet tag, an EVPN-SRv6 destination is created to the next hop.

  The local Ethernet tag cannot be modified without disabling **bgp-evpn segment-routing-v6** in the Epipe, as shown in the following output:

```
[/]
A:admin@PE-2# configure {
    service {
        epipe "Epipe-1" {
            bgp-evpn {
                local-attachment-circuit AC-PE-2-CE-20 {
                    eth-tag 221
                }
            }
        }
    }
}
MINOR: SVCMGR #8036: configure service epipe "Epipe-1" bgp-evpn local-attachment-circuit
 "AC-PE-2-CE-20" - evpn-vpws ac eth-tag not allowed - cannot change while evpn mpls/
vxlan/srv6 is enabled
```

  Unlike local Ethernet tags, remote Ethernet tags can be modified without disabling bgp-evpn.

– The following configuration options are available for Epipes in the **configure service epipe 1 bgp-evpn segment-routing-v6** context:

```
[/]
A:admin@PE-2# configure {
    service {
        epipe "Epipe-1" {
            bgp-evpn {
                segment-routing-v6 1 ?

-------------------------------------------------------------------------------
===============================================================================

===============================================================================
Segment Routing v6 Ethernet Segment Dest
===============================================================================
Instance  Eth SegId                      Num. Macs     Last Change
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

Note:
The egress label for the EVPN-SRv6 destination on PE-4 is 524278. The 24-bit label value in the BGP update debug is 16 (2^4) times as high:

524 278 * 16 = 8 388 448

because the debug message is shown before the router can parse the label field and determine if it corresponds to an MPLS label or a transposed function (20 bits), or to a VXLAN VNI (24 bits).

The BGP AD per-EVI routes for Ethernet tag 46 are shown with the following command:

```
[/]
A:admin@PE-2# show router bgp routes evpn auto-disc tag 46

Note:
Each PE sends its service MTU into the L2 MTU field in the l2-attribute in the AD per-EVI route for the Epipe service. The received L2 MTU is checked. In case of a mismatch between the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

received MTU and the configured service MTU, the router does not set up the EVPN destination and, therefore, the service does not come up.

SRv6 tunnels in EVPN-VPWS services with multihoming

SR OS supports EVPN multihoming as per RFC 8214.

The EVPN multihoming implementation is based on the concept of the ES. An ES is a logical structure that can be defined in one or more PEs and identifies the CE (or access network) multihoming to the EVPN PEs. An ES is associated with a port, LAG, or SDP object, and is shared by all the services defined on those objects. It can also be shared between Epipe and VPLS services.

Each ES has a unique ESI that is 10 bytes and is manually configured. The ESI is advertised in the control plane to all the PEs in an EVPN network; therefore, it is very important to ensure that the 10-byte ESI value is unique throughout the entire network. Single-homing CEs are assumed to be connected to an ES with ESI = 0 (single-homing ESs are not explicitly configured).

The ES is part of the base BGP-EVPN configuration and is not applied to any EVPN-based VPLS service by default. An ES can be shared by multiple services; a specific SAP or spoke SDP is automatically associated with an ES when the SAP is defined in the same LAG or port configured in the ES, or when the spoke SDP is defined in the same SDP configured in the ES.

Regardless of the multihoming mode, the local Ethernet tag values must match on all the PEs that are part of the same ES. The PEs in the ES use the AD per-EVI routes from the peer PEs to validate the PEs as DF election candidates for an EVI. The DF election is only relevant for single-active multihoming ESs. For Epipes defined in an all-active multihoming ES, there is no DF election required, because all PEs are forwarding traffic and all traffic is treated as unicast.

Aliasing is supported when sending traffic to an ES destination. Assuming ECMP is enabled on the ingress PE (and shared queuing or ingress policing are configured), per-flow load-balancing is performed among all the PEs that advertise P = 1. PEs advertising P = 0 are not considered as next hops for an ES destination.

The following sections show the configuration of:

- an all-active multihoming ES with a LAG associated with it
- a single-active multihoming ES linked to an SDP

Figure 157: Example topology EVPN-VPWS with multihoming shows the example topology has an all-active multihoming ES "ESI-23" with a LAG associated with it in PE-2 and PE-3. A single-active multihoming ES "ESI-45" with an SDP associated with it is configured in PE-4 and PE-5.

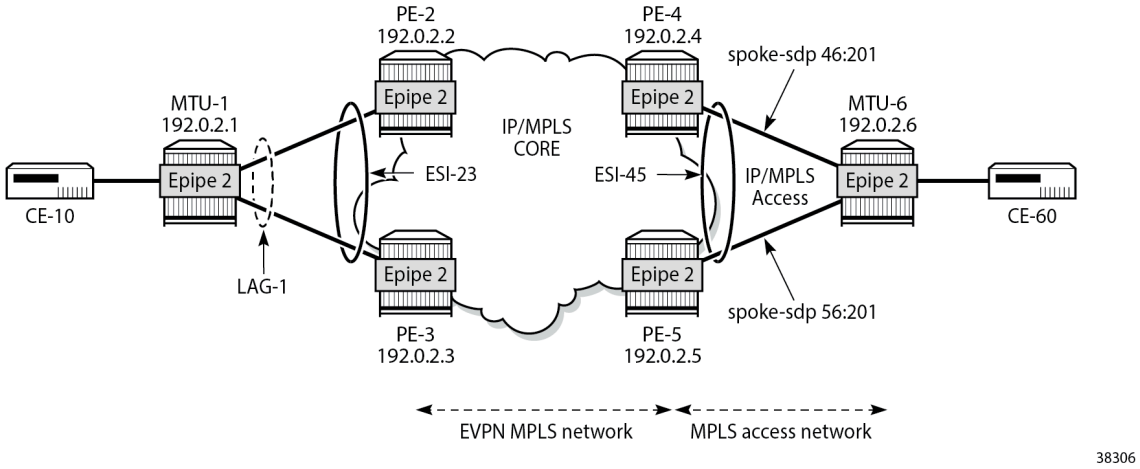
Figure 157: Example topology EVPN-VPWS with multihoming



SRv6 tunnels in EVPN-VPWS services with all-active multihoming

All-active multihoming allows for per-flow load-balancing. Unlike EVPN-based VPLS services, EVPN-VPWS has no DF election in all-active multihoming. All PEs in the ES are active and the remote PE performs per-flow load-balancing. ESI-23 is configured on PE-2 and PE-3 as all-active multihoming and is associated with LAG 1. This LAG is used as a SAP in Epipe 2 on both PE-2 and PE-3. The configuration of the ES and Epipe 2 is identical on PE-2 and PE-3, including the local AC and remote AC names and Ethernet tags:

```
[/]
A:admin@PE-2#, A:admin@PE-3# configure {
    service {
        system {
            bgp {

The ESI label is in the extended community, as well as the indication that the multihoming is all-active. Epipe services do not require ESI labels because BUM traffic is not recognized in EVPN-VPWS services. However, because the ES can be shared by Epipe and VPLS services, the AD per-ES route still includes a non-zero ESI label. In this case, the transport is SRv6, so there are no ESI labels. The label field in the

ESI-label extended community is an implicit-null value (3) and the included SRv6 Services TLV encodes a SID with value 0.

The following two AD per-EVI routes (route type 1) with Ethernet tag 231 sent by RR PE-2 are received and imported on PE-4:

```

* indicates that the corresponding row element may have been truncated.
```

Note:
Even if ECMP is configured, the ingress router (where a SAP is configured) does not load-balance the traffic unless shared queuing or ingress policing is configured in the SAP. This is not specific to EVPN, but is generic to the way Epipes forward traffic.

In all-active multihoming for EVPN-VPWS, there is no DF election and all PEs in the ES are active. For ESI-23, both PE-2 and PE-3 are active primary DF, but there are no DF candidates, because there is no DF election:

```

SRv6 tunnels in EVPN-VPWS services with single-active multihoming

Single-active multihoming allows for per-service load-balancing. Single-active multihoming is configured on PE-4 and PE-5 with ES "ESI-45". Both PEs have an SDP to MTU-6, which is associated with the ES and to the Epipe service. The configuration of the local and remote AC names and Ethernet tags is identical on PE-4 and PE-5.

On PE-4, the service configuration is as follows:

```
[/]
A:admin@PE-4# configure {
    service {
        sdp 46 {
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            ldp true
            admin-state enable
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        esi 01:00:00:00:00:45:00:00:00:01
                        df-election {
                            es-activation-timer 3
                        }
                        multi-homing-mode single-active
                        association {
                            sdp 46 {
                            }
                        }
                        admin-state enable
                    }
                }
            }
        }
        epipe "Epipe-2" {
            customer "1"
            service-id 2
            segment-routing-v6 1 {
                locator "loc_Epipe-2" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                local-attachment-circuit AC-ESI-45-MTU-6 {
                    eth-tag 456
                }
                remote-attachment-circuit AC-ESI-23-MTU-1 {
                    eth-tag 231
                }
                evi 20
                segment-routing-v6 1 {
                    srv6 {
                        instance 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        default-locator "loc_Epipe-2"
                    }
                    ecmp 2
                    # source-address 2001:db8::2:4    # defined for SRv6 on router level
                    admin-state enable
                }
            }
            spoke-sdp 46:201 {
            }
            admin-state enable
        }
    }
}
```

On PE-5, the configuration is similar, but with a different SDP:

```
[/]
A:admin@PE-5# configure {
    service {
        sdp 56 {
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            ldp true
            admin-state enable
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        esi 01:00:00:00:00:45:00:00:00:01
                        df-election {
                            es-activation-timer 3
                        }
                        multi-homing-mode single-active
                        association {
                            sdp 56 {
                            }
                        }
                        admin-state enable
                    }
                }
            }
        }
        epipe "Epipe-2" {
            customer "1"
            service-id 2
            segment-routing-v6 1 {
                locator "loc_Epipe-2" {
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                local-attachment-circuit AC-ESI-45-MTU-6 {

            }
            spoke-sdp 56:201 {
            }
            admin-state enable
        }
    }
}
```

Three route types are exchanged between the core PEs: AD per-EVI, AD per-ES, and ES routes.

As an example, the following is the ES route with originator PE-4 sent by RR PE-2 to PE-5. It contains a target 00:00:00:00:45:00 in the extended community that is derived from the ESI:

```
# on PE-2:
45 2023/01/10 23:29:07.514 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5
"Peer 1: 2001:db8::2:5: UPDATE
Peer 1: 2001:db8::2:5 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 85
    Flag: 0x90 Type: 14 Len: 34 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-ETH-SEG Len: 23 RD: 192.0.2.4:0 ESI: 01:00:00:00:00:45:00:00:00:01, IP-Len:
 4 Orig-IP-Addr: 192.0.2.4
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
        1.1.1.1
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:

        target:00:00:00:00:45:00
"
```

The AD per-ES route has a MAX-ET tag and an ESI label in the extended community. The multihoming mode is single-active. As in the case of all-active multihoming, the ESI label is not used in Epipe services. The following BGP update with originator PE-5 is sent by RR PE-2 to its client PE-4:

```
# on PE-2:
51 2023/01/10 23:29:07.669 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
"Peer 1: 2001:db8::2:4: UPDATE

"
```

The AD per-EVI route contains flags for primary and backup, which are different for routes received from PE-4 and PE-5. In this case, PE-4 is the primary in the single-active multihoming ES (P = 1):

```
# on PE-2:
53 2023/01/10 23:29:10.550 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:5

```

The DF election is key for the forwarding and backup functions in single-active multihoming ESs. The PE elected as DF is the primary for the ES in the Epipe and unblocks its SAP and spoke SDP for upstream and downstream traffic. The rest of the PEs in the ES bring their ES SAPs or spoke SDPs operationally down.

PE-5 is a non-DF, as follows:

```
[/]
A:admin@PE-5# show service system bgp-evpn ethernet-segment name "ESI-45" evi evi-1 20

===============================================================================
EVI DF and Candidate List

-------------------------------------------------------------------------------
Number of entries: 2
===============================================================================
* indicates that the corresponding row element may have been truncated.
```

In single-active multihoming, the service SAP or spoke SDP is brought operationally down on the non-DF, as shown in the following output:

```
[/]
A:admin@PE-5# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
56:201           Spok     192.0.2.6       Up      Down      524275    524275
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The spoke sdp 56:201 is operationally down with a StandbyForMHProtocol flag:

```
[/]
A:admin@PE-5# show service id 2 sdp 56:201 detail | match Flag
Flags              : StandbyForMHProtocol
```

Two consecutive DF elections take place: the first DF election includes all PEs in the ES for that Epipe and determines which PE is the primary PE (flags P = 1, B = 0). The second DF election excludes this DF and determines which PE is the backup (P = 0, B = 1). All other PEs signal flags P = 0 and B = 0.

When the primary PE fails, AD per-ES and AD per-EVI withdrawal messages are sent to the remote PE, which updates its next hop to the backup. The backup PE takes over immediately without waiting for the ES activation timer (configured with the **es-activation-timer** command) to bring up its SAP and spoke SDP.

ES failures

When the SDP toward the primary (DF) fails, the backup PE needs to take over. An SDP failure is emulated and log 99 on PE-4 shows that SDP 46 is operationally down and PE-4 is no longer the DF:

```
191 2023/01/10 23:38:55.867 CET MINOR: SVCMGR #2303 Base
"Status of SDP 46 changed to admin=up oper=down"

193 2023/01/10 23:38:55.868 CET MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-45, EVI:20, Designated Forwarding state changed to:false"
```

Remote PEs receive route withdrawal updates (unreachable NLRI) from the former DF PE-4, for example on PE-2:

```
# on PE-2:
1 2023/01/10 23:38:55.869 CET MINOR: DEBUG #2001 Base Peer 1: 2001:db8::2:4
"Peer 1: 2001:db8::2:4: UPDATE

```

BGP updates are exchanged and the remote PEs resolve the ESI to the TEP address 192.0.2.5. For example, on PE-2:

```
[/]
A:admin@PE-2# show service id 2 segment-routing-v6 esi 01:00:00:00:00:45:00:00:00:01

-------------------------------------------------------------------------------
===============================================================================
* indicates that the corresponding row element may have been truncated.
```

Because of the default DF election algorithm, this process is revertive; as soon as the SDP 46 is operationally up again, a new DF election is triggered with two DF candidates and PE-4 is elected as DF. A non-revertive mode is also available if preference-based DF election is configured.

Troubleshooting and debugging

The following **show** and **debug** commands can be used in EVPN-VPWS:

- **show redundancy bgp-evpn-multi-homing**
- **show router bgp routes evpn** (and filters)
- **show service segment-routing-v6 [**<*ip-address*>**]**
- **show service id** <*service-id*> **bgp-evpn**
- **show service system bgp-evpn**
- **show service system bgp-evpn ethernet-segment** (and modifiers)
- **debug router bgp update**
- **show log log-id** <*log-id*>

Most of these commands have been shown in the preceding sections; some commands are shown in this section.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Information about the configured boot timers (before DF election) and ES activation timer (after the system has been elected DF) is shown as follows:

```
[/]
A:admin@PE-2# show redundancy bgp-evpn-multi-homing

===============================================================================
Redundancy BGP EVPN Multi-homing Information
===============================================================================
Boot-Timer              : 10 secs
Boot-Timer Remaining    : 0 secs
ES Activation Timer     : 3 secs
===============================================================================
```

See chapter EVPN for MPLS Tunnels for a description of these timers.

The following command shows that the BGP route type 4 (ES route) messages are only imported by the PEs in the same ES; for example, on PE-3:

```
[/]
A:admin@PE-3# show router bgp routes evpn eth-seg

===============================================================================
```

In addition to the preceding commands, the following **tools dump** commands may be useful:

- **tools dump service evpn usage** - This command shows the number of EVPN-SRv6 (and EVPN-MPLS and EVPN-VXLAN) destinations in the system.
- **tools dump service system bgp-evpn ethernet-segment** <*name*> **evi** <*evi*> **df** - This command computes the DF election for a specific ESI and EVI. For all-active multihoming, there is no DF election and all PEs forward traffic. For single-active multihoming, one PE is active for a service while another PE is a backup. This command shows the DF (primary), even if it is not the local PE.

The usage of EVPN resources is shown as follows:

```
[/]
A:admin@PE-2# tools dump service evpn usage
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
vxlan-srv6-evpn-mpls usage statistics at 01/10/2023 23:35:05:

MPLS-TEP                                        :             0

SRV6-TEP                                        :             2
Total-TEP                                       :      2/ 16383

Mpls Dests (TEP, Egress Label + ES + ES-BMAC)   :             0
Mpls Etree Leaf Dests                           :             0
Vxlan Dests (TEP, Egress VNI + ES)              :             0
Srv6 Dests (TEP, SID  + ES)                     :             2
Total-Dest                                      :      2/196607

Sdp Bind +  Evpn Dests                          :      2/245759
ES L2/L3 PBR                                    :      0/ 32767
Evpn Etree Remote BUM Leaf Labels               :             0
```

On PE-2, there is one SRv6 TEP (192.0.2.4 in Epipe 1 and in Epipe 2) and there are two SRv6 destinations: 192.0.2.4 and ESI 01:00:00:00:00:45:00:00:00:01. PE-5 is not an SRv6 TEP for PE-2 because it is not a primary and, therefore, is not forwarding any traffic.

In all-active multihoming, the DF election is not applicable:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "ESI-23" evi 20 df

[01/10/2023 23:35:05] All Active VPWS or IP-ALIASING - DF N/A
```

In single-active multihoming, the following command shows which PE is the DF:

```
[/]
A:admin@PE-5# tools dump service system bgp-evpn ethernet-segment "ESI-45" evi 20 df

[01/10/2023 23:35:10] Computed DF: 192.0.2.4 (Remote) (Boot Timer Expired: Yes)
[01/10/2023 23:35:10] Computed Backup: 192.0.2.5 (This Node)
```

The command is launched on PE-5, which is a backup. The computed DF is PE-4 and the boot timer has expired, meaning there is no DF re-election pending.

Conclusion

EVPN-VPWS is a simplified point-to-point version of RFC 7432. EVPN provides a unified control plane mechanism that simplifies the network deployment and operation. Single-active and all-active multihoming can be used in Epipes; EVPN-VPWS is a differentiator of EVPN compared to traditional TLDP or BGP Epipe redundancy mechanisms.

EVPN-IFF BGP Attribute Propagation Between Families

This chapter provides information about EVPN-IFF BGP attribute propagation between families .

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and MD-CLI configuration in this chapter are based on SR OS Release 22.7.R1. EVPN Interface-ful (EVPN-IFF) BGP attribute propagation between BGP families based on uniform propagation is supported in SR OS Release 21.2.R1 and later.

For more information on routed VPLS in EVPN, see chapters EVPN for VXLAN Tunnels (Layer 3) and EVPN for MPLS Tunnels in Routed VPLS .

Overview

SR OS allows multiple BGP owners in the same VPRN service to receive or advertise IP prefixes contained in the VPRN route table. A VPRN route table can simultaneously install and process IPv4 or IPv6 prefixes for the following owners:

- EVPN Interface-ful (EVPN-IFF)
- EVPN Interface-less (EVPN-IFL)
- VPN-IP (also referred to as IP-VPN routes)
- IP (also referred to as BGP PE-CE routes)

EVPN-IFF routes are EVPN IP-prefix routes, otherwise known as route type 5 (RT-5) routes, that are imported and exported based on the configuration of the R-VPLS services attached to the VPRN. To enable the EVPN-IFF model, the command **configure service vpls <..> bgp-evpn routes ip-prefix advertise true** needs to be configured. By default, BGP attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. However, BGP attributes can be used to influence routing (for example, local preference, Autonomous System (AS) path, communities, and so on), and therefore, SR OS supports EVPN-IFF BGP attribute propagation to other BGP families (uniform propagation), as described in *draft-ietf-bess-evpn-ipvpn-interworking*.

The following CLI command is used to enable EVPN-IFF BGP attribute propagation and EVPN-IFF best path selection:

```
[ex:/configure service system bgp evpn]
A:admin@PE-4# ip-prefix-routes ?
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
ip-prefix-routes

d-path-length-ignore  - Ignore D-PATH length for BGP path selection of EVPN-IFF
iff-attribute-        - Enable uniform propagation of BGP attributes
 uniform-propagation
iff-bgp-path-         - Enable BGP path selection for EVPN-IFF routes
 selection
```

The **iff-bgp-path-selection** command cannot be enabled when **iff-attribute-uniform-propagation** is disabled.

When **iff-attribute-uniform-propagation** is enabled on a node:

- the following BGP path attributes are propagated:
  - AS path
  - domain path (D-PATH), supported in SR OS Release 21.10.R1 and later
  - IBGP-only attributes, when advertising to an IBGP neighbor: local preference, originator ID, cluster ID
  - Multiple Exit Discriminator (MED)
  - communities, large communities, extended communities
- the following BGP path attributes are not propagated across families:
  - any type 0x06 extended communities supported by RT-5 routes:
    - MAC mobility extended community
    - EVPN router MAC extended community
  - BGP encapsulation extended community
  - Route Target extended community
  - BGP tunnel encapsulation attribute
  - BGP prefix-SID attribute used in RT-5 routes and VPN-IP routes for Segment Routing over IPv6 dataplane (SRv6) services
- IBGP-only attributes are only propagated to IBGP neighbors; EBGP-only attributes only to EBGP neighbors
- routes received with well-known communities, such as no-advertise or no-export(-subconfed), are sent or not sent depending on the community values
- BGP path attributes are propagated even when doing route leaking between routing instances

If multiple EVPN-IFF routes for the same prefix are received for the same VPRN, they are by default ordered and selected based on the lowest R-VPLS Ifindex, Route Distinguisher (RD), and Ethernet tag.

When **iff-bgp-path-selection** is enabled, EVPN-IFF routes with the same or different RD are selected based on regular BGP path selection rules in the following order:

1. valid route wins over invalid route (invalid routes are looped routes or routes where the originator ID matches the receiving router)
2. lowest origin validation state (origin validation state: valid is preferred to origin validation state: not found; origin validation state: not found is preferred to origin validation state: invalid) – applicable to IPv4, IPv6, or BGP Labeled Unicast (BGP-LU) routes

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

3. lowest Routing Table Manager (RTM) preference
4. highest local preference
5. shortest D-PATH
6. lowest Accumulated Interior Gateway Protocol (AIGP) metric (AIGP is not supported for EVPN-IFL, EVPN-IFF, or IP-VPN routes)
7. shortest AS path
8. lowest origin (origin: IGP is preferred to origin: EGP; origin: EGP is preferred to origin: incomplete)
9. lowest MED (routes without MED are considered as zero or infinity based on the configuration of the **always-compare-med** command)
10. lowest owner type (owner type: BGP-label is preferred to owner type: BGP; owner type: BGP is preferred to owner type: BGP-VPN) with BGP-VPN referring to VPN-IP and EVPN-IFL
11. EBGP wins over IBGP
12. lowest route-table or tunnel-table cost to the next-hop

Note: The **ignore-nh-metric** command is not supported for EVPN-IFF.

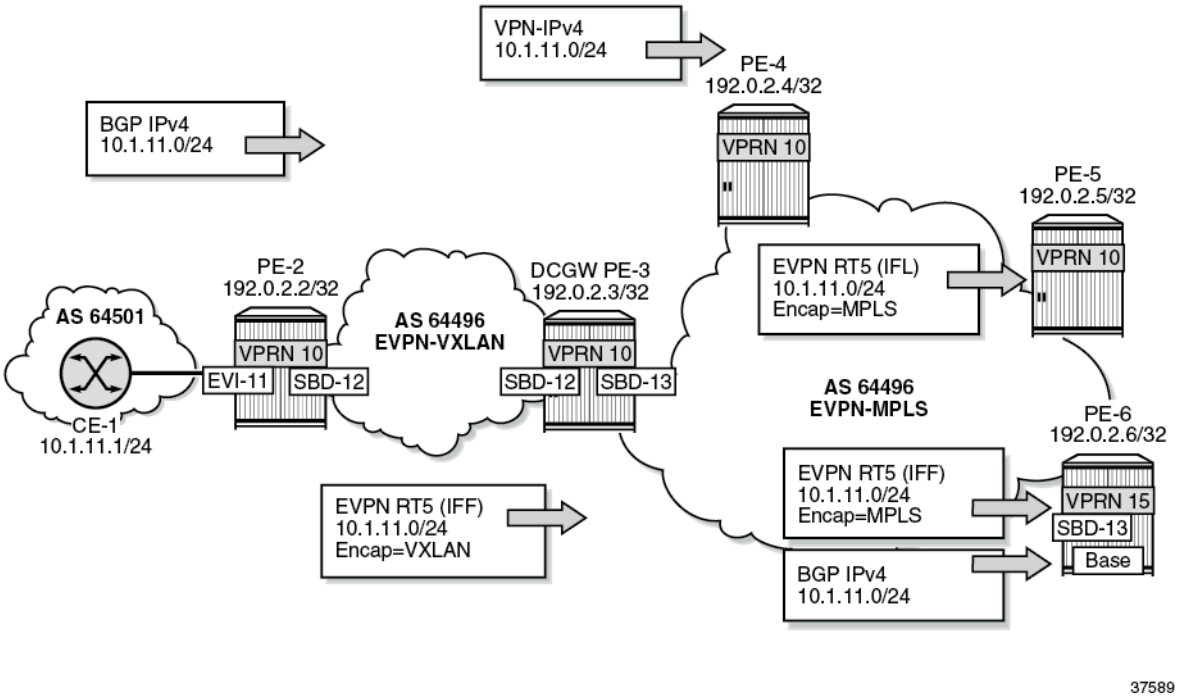
13. lowest next-hop type – a next-hop resolved to a tunnel-table entry is considered as a lower type than a next-hop resolved to a route-table entry
14. lowest router ID – applicable to IBGP peers
15. shortest cluster list length – applicable to IBGP peers
16. lowest IP address – IP address refers to the peer that advertised the route
17. EVPN-IFL wins over IPVPN
18. next-hop check (IPv4 next-hop wins over IPv6, then lowest next-hop wins) - The next-hop check is a tiebreaker if BGP receives the same prefix for VPN-IPv6 and EVPN-IFL. An IPv6 prefix received as VPN-IPv6 has an IPv6 next-hop whereas the same IPv6 prefix received as EVPN-IFL can have an IPv4 next-hop.
19. lowest RD for route-table selection
20. lowest path ID (add-path)

Configuration

Figure 158: Example topology shows the example topology with PE-3 as Data Center Gateway (DCGW) between an EVPN-VXLAN network and an EVPN-MPLS network. Routed VPLS is configured on PE-2, PE-3, and PE-6. Supplementary broadcast domain "SBD-12" is configured in the EVPN-VXLAN network between PE-2 and PE-3; "SBD-13" in the EVPN-MPLS network between PE-3 and PE-6. On PE-2, Ethernet VPN instance "EVI-11" is configured toward CE-1.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 158: Example topology



CE-1 advertises prefix 10.1.11.0/24 to BGP neighbor 10.0.0.2 in VPRN 10 on PE-2. PE-2 sends an EVPN-IFF route to DCGW PE-3. PE-3 forwards the prefix 10.1.11.0/24 as VPN-IPv4 route to PE-4, as EVPN-IFL route to PE-5, as EVPN-IFF route to PE-6, and as IPv4 route to PE-6.

The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces on all PEs
- IS-IS on the router interfaces
- LDP on the router interfaces on PE-3, PE-4, PE-5, and PE-6

On the PEs, BGP is configured for the EVPN address family. Between PE-3 and PE-4, both the VPN-IPv4 and the EVPN address family are configured. The configuration on PE-3 is as follows:

```
# on PE-3:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64496
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "internal1" {
                peer-as 64496
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "internal1"
            }
            neighbor "192.0.2.4" {
                group "internal"
                family {
                    vpn-ipv4 true
                    evpn true
                }
            }
            neighbor "192.0.2.5" {
                group "internal"
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.6" {
                group "internal"
                family {
                    evpn true
                }
            }
        }
```

On CE-1, BGP is configured in VPRN 11 for the IPv4 address family. The export policy adds communities "1:1" and "2:2" and sets the MED to a value of 81.

```
# on CE-1:
configure {
    policy-options {
        community "1:1_2:2" {
            member "1:1" { }
            member "2:2" { }
        }
        policy-statement "export-vnf-to-all" {
            entry 10 {
                from {
                    protocol {
                        name [direct direct-interface]
                    }
                }
                action {
                    action-type accept
                    bgp-med {
                        set 81
                    }
                    community {
                        add ["1:1_2:2"]
                    }
                }
            }
        }
    }
    service {
        vprn "VPRN 11" {
            admin-state enable
            service-id 11
```

                        address 10.0.0.1
                        prefix-length 24
                    }
                }
                sap 1/1/2:11 {
                }
            }
            interface "test" {
                ipv4 {
                    primary {
                        address 10.1.11.1
                        prefix-length 24
                    }
                }
                sap 1/1/2:12 {
                }
            }
```

On PE-2, VPRN 10 has R-VPLS interface "int-EVI-11" toward CE-1 and R-VPLS interface "int-SBD-12" toward PE-3. BGP is configured toward neighbor 10.0.0.1 on CE-1 and the import policy sets the local preference (LP) to 200, as follows:

```
# on PE-2:
configure {
    policy-options {
        policy-statement "local-preference-200" {
            entry 10 {
                action {
                    action-type accept
                    local-preference 200
                }
            }
        }
    }
    service {
        vprn "VPRN 10" {
            admin-state enable
            service-id 10
            customer "1"
            autonomous-system 64496
            bgp {
                split-horizon true
```

                    }
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

On PE-3, VPRN 10 is configured with:

- three interfaces:
  - R-VPLS interface "int-SBD-12" toward PE-2
  - R-VPLS interface "int-SBD-13" toward PE-6
  - interface "int-VPRN10-PE-3-to-PE-6" to the base router of PE-6.
- BGP-IPVPN for the exchange of VPN-IPv4 routes with PE-4
- BGP-EVPN to propagate EVPN-IFL routes to PE-5 and EVPN-IFF routes to PE-6
- BGP to propagate BGP IPv4 routes to the base router on PE-6. The export policy is only required in the BGP configuration.

```
# on PE-3:
configure {
    policy-options {
        prefix-list "10.1.0.0" {
            prefix 10.1.0.0/16 type longer {
            }
        }
        policy-statement "export-bgp" {

```
                }
            }
```

On PE-5, VPRN 10 is configured with BGP-EVPN, as follows:

```
# on PE-5:
configure {
    service {
        vprn "VPRN 10" {
            admin-state enable
            service-id 10
            customer "1"
            bgp-evpn {
                mpls 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.5:10"
                    vrf-target {
                        community "target:64496:10"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            bgp {
            }
```

In the base router of PE-6, BGP is configured to neighbor 10.15.16.3 on PE-3. VPRN 15 is configured with R-VPLS interface "int-SBD-13" toward PE-3. The configuration is as follows:

```
# on PE-6:
configure {
    router "Base" {
        interface "int-PE-6-to-VPRN10-PE-3" {
            port 1/1/1:13
            ipv4 {
                primary {
                    address 10.15.16.6
                    prefix-length 24
                }
            }
        }
        bgp {
            group "PE-6-CE" {
                family {
                    ipv4 true
                }
            }
            neighbor "10.15.16.3" {
                group "PE-6-CE"
                type internal
                peer-as 64496
                local-as {
                    as-number 64496
                }
            }
        }
    }

            customer "1"
            autonomous-system 64502
            interface "int-SBD-13" {
                vpls "SBD-13" {
                    evpn-tunnel {
                    }
                }
            }
        }
```

Default behavior

By default, BGP path attributes are re-originated when a prefix is propagated to and from an EVPN-IFF route. Figure 159: EVPN-IFF BGP path attributes are re-originated by PE-2 and PE-3 shows that PE-2 receives an IPv4 route for prefix 10.1.11.0/24 with non-default BGP path attributes, whereas PE-2 propagates the prefix as an EVPN-IFF route with default path attributes.

Uniform propagation for EVPN-IFF BGP path attributes to different BGP families

Enable **iff-attribute-uniform-propagation** and **iff-best-path-selection** on PE-2 as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ip-prefix-routes
                        iff-attribute-uniform-propagation
                        iff-bgp-path-selection
                    }
                }
            }
```

In a similar configuration, **iff-attribute-uniform-propagation** and **iff-bgp-path-selection** are enabled on the other PEs.

The following command shows that uniform propagation for EVPN-IFF BGP path attributes and BGP path selection are enabled:

```
[/]
A:admin@PE-2# show service system bgp-evpn

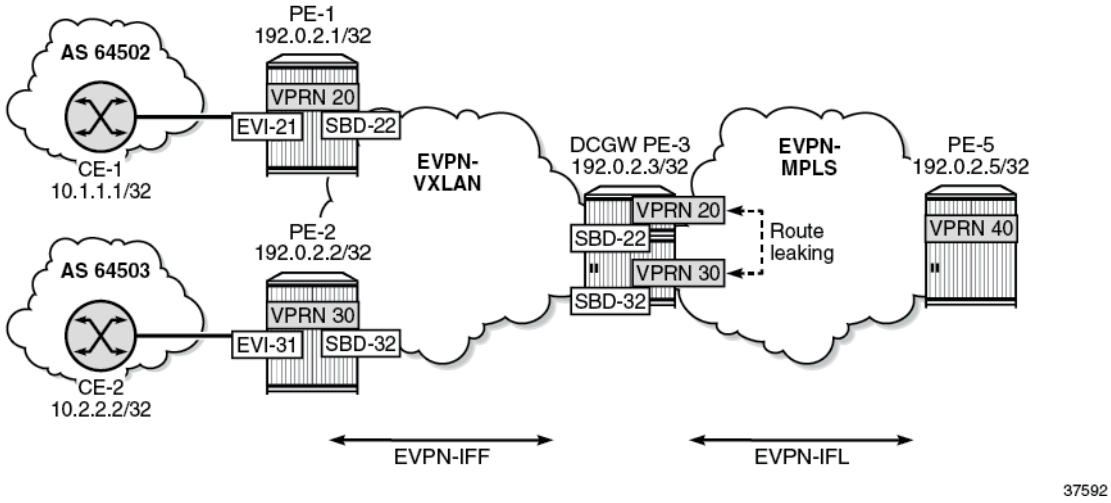
EVPN-IFF BGP path attributes exported to leaked EVPN routes

Figure 161: Example topology shows the example topology with two VPRNs on DCGW PE-3 where routes are leaked.

Figure 161: Example topology

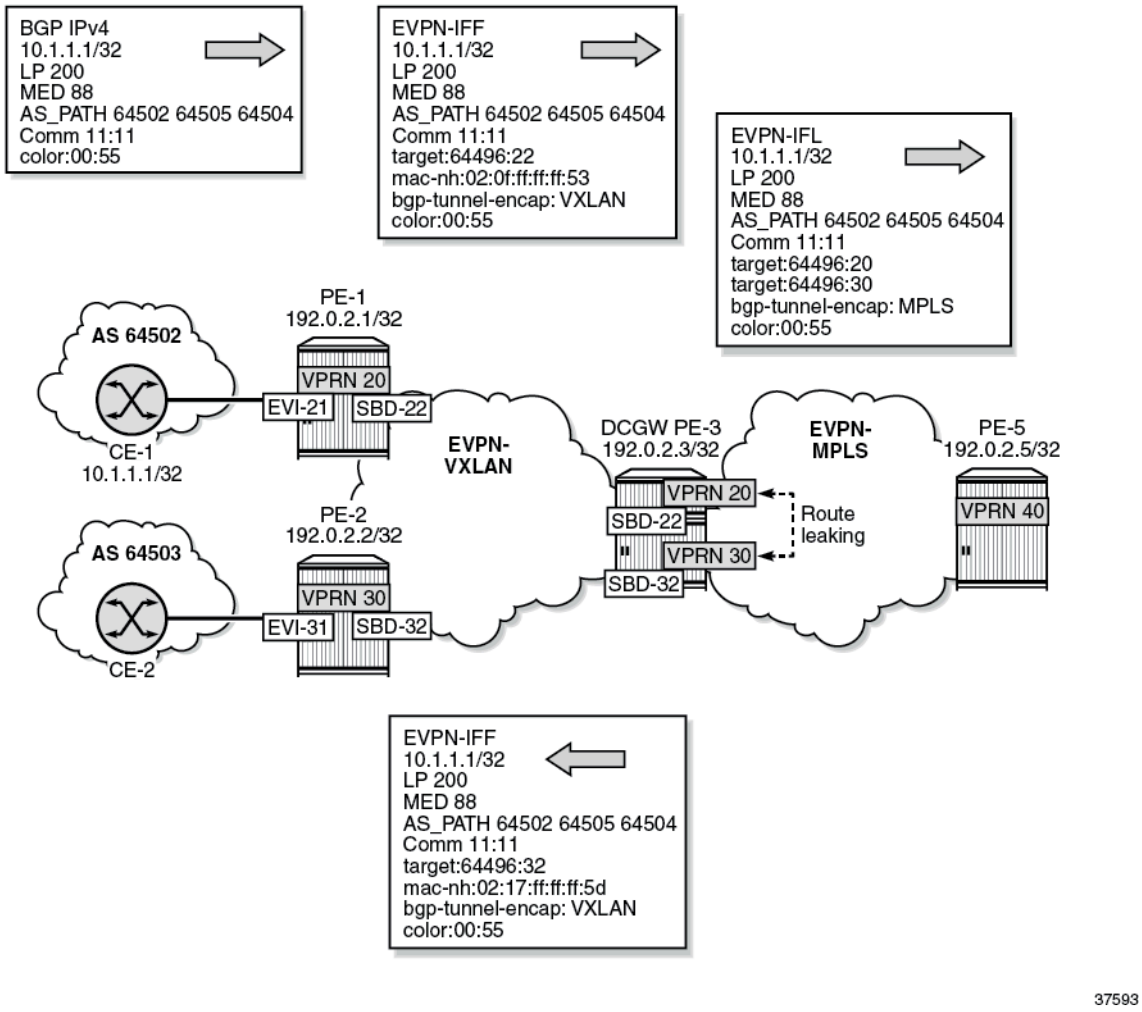


The uniform propagation for EVPN-IFF BGP path attributes is enabled on all PEs.

Figure 162: BGP path attributes are propagated in leaked EVPN routes shows that CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1. This route has non-default BGP attributes; for example, MED 88, AS path 64502 64505 64504, and community "11:11" "color:00:55". PE-1 exports this route as an EVPN-IFF route to PE-3. PE-3 forwards this route as EVPN-IFL route to PE-5. On PE-3, the route is leaked from VPRN 20 to VPRN 30. The BGP path attributes are propagated to the leaked EVPN routes, except those attributes that are not expected to be propagated, such as the router's MAC extended community. PE-3 advertises an EVPN-IFF route for prefix 10.1.1.1/32 to PE-2.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 162: BGP path attributes are propagated in leaked EVPN routes



In a similar way, CE-2 exports IPv4 prefix 10.2.2.2/32 to PE-2 with non-default BGP path attributes. PE-2 advertises this prefix as an EVPN-IFF route with the same BGP path attributes. PE-3 leaks the route from VPRN 30 to VPRN 20 while preserving the BGP path attributes. PE-3 advertises an EVPN-IFF route for prefix 10.2.2.2/32 to PE-1 with the same BGP path attributes. PE-3 also advertises the prefix as EVPN-IFL route to PE-5 with the same BGP path attributes. For brevity, the routes for prefix 10.2.2.2/32 are not shown here.

In this example, VPRN "CE-1" is configured as follows. The export policy sets the MED, prepends some AS numbers to the AS path, and adds the communities "11:11" and "color:00:55".

```
# on CE-1:
configure {
    policy-options {
        community "11:11" {
            member "11:11" { }
        }
        community "color:00:55" {
            member "color:00:55" { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        policy-statement "export-vnf-to-all-2" {
            entry 10 {
                from {
                    protocol {

        }
    }
```

The configuration on PE-2 is similar with VPRN 30, R-VPLS "EVI-31", and R-VPLS "SBD-32".

PE-3 has two VPRNs: "VPRN 20" and "VPRN 30". Export policy "leak-color-55-into-30" is used to leak routes with color community "color:00:55" from VPRN 20 to VPRN 30. The configuration is as follows:

```
# on PE-3:
configure {
    policy-options {
        community "RT64496:20" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            member "target:64496:20" { }
        }
        community "RT64496:30" {
            member "target:64496:30" { }
        }
        community "color:00:55" {
            member "color:00:55" { }
        }

                    admin-state enable
                    route-distinguisher "192.0.2.5:40"
                    vrf-export {
                        policy ["vrf-40-export"]
                    }
                    vrf-import {
                        policy ["vrf-40-import"]
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 10.5.5.5
                        prefix-length 32
                    }
                }
            }
```

CE-1 exports an IPv4 route for prefix 10.1.1.1/32 to PE-1 with community "color:00:55" and other non-default BGP path attributes. The route table for VPRN 20 on PE-1 includes an BGP IPv4 route for prefix 10.1.1.1/32:

```
[/]
A:admin@PE-1# show router 20 route-table 10.1.1.1/32

===============================================================================
Route Table (Service: 20)
===============================================================================

-------------------------------------------------------------------------------
10.1.1.1/32                                   Remote  EVPN-IFL  00h03m59s  170
       192.0.2.3 (tunneled)                                       10
10.2.2.2/32                                   Remote  EVPN-IFL  00h03m56s  170
       192.0.2.3 (tunneled)                                       10
10.5.5.5/32                                   Local   Local     00h04m03s  0
       loopback                                                   0
-------------------------------------------------------------------------------
No. of Routes: 3
```

In a similar way, PE-5 received an EVPN-IFL route for prefix 10.2.2.2/32. Prefix 10.5.5.5/32 is local to VPRN 40 on PE-5 and is advertised to PE-3 as EVPN-IFL route.

On PE-3, routes with community "color:00:55" are leaked between VPRN 20 and VPRN 30. PE-1 and PE-3 have forwarded the route with the original BGP path attributes, so this community is preserved and the route for prefix 10.1.1.1/32 is leaked to VPRN 30, as shown in the following route table. The next hop is R-VPLS "SBD-22" in local VPRN 20.

```
[/]
A:admin@PE-3# show router 30 route-table

===============================================================================
Route Table (Service: 30)
===============================================================================

Conclusion

SR OS nodes can be configured to propagate EVPN-IFF BGP path attributes between families to influence the path selection, as per *draft-ietf-bess-evpn-ipvpn-interworking*.

EVPN-MPLS E-Tree

This chapter provides information about EVPN-MPLS E-Tree.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the CLI in the current edition is based on SR OS Release 23.7.R1. VPLS E-Tree without EVPN is supported in SR OS Release 12.0.R4, and later. EVPN-MPLS E-Tree is supported in SR OS Release 15.0.R1, and later.

Overview

Ethernet Tree (E-Tree) is a rooted multipoint Ethernet service defined by the Metro Ethernet Forum (MEF). E-Tree can be implemented based on the following:

- RFC 7796, *Ethernet-Tree Support in Virtual Private LAN Services* (VPLS E-Tree without EVPN)
- RFC 8317, *E-Tree Support in EVPN and PBB-EVPN* (EVPN-MPLS E-Tree)

VPLS E-Tree without EVPN

The E-Tree implementation is based on RFC 7796 and is supported for unicast and broadcast, unknown unicast, and multicast (BUM) traffic. Interfaces can be defined as root attachment circuit (AC) or leaf AC, or both, as described in Table 16: Interfaces in E-Tree. A VPLS E-Tree can have multiple root ACs. Access and network interfaces are both supported on SAPs and SDP bindings.

Table 16: Interfaces in E-Tree

Interface	Tag
Access interface (user-to-network interface - UNI)	Root tag
	Leaf tag
Network interface (network-to-network interface - NNI)	Root-leaf tag

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On the ingress access interfaces, all frames are tagged and forwarded. On the network interfaces, no traffic is dropped based on the root or leaf tag. On the egress access interfaces, all traffic toward a root AC is forwarded, whereas traffic toward a leaf AC is only forwarded when it originates from a root AC, as summarized in Table 17: E-Tree Forwarding on Access Interfaces. Traffic from leaf AC to leaf AC is blocked.

Table 17: E-Tree Forwarding on Access Interfaces

	To root AC	To leaf AC
From root AC	Allowed	Allowed
From leaf AC	Allowed	Not allowed

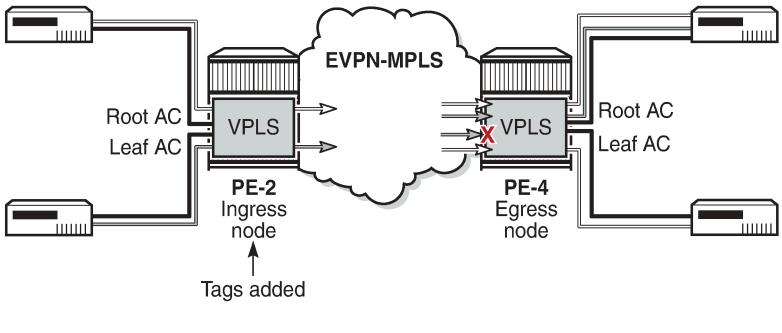
Within an E-Tree, the split horizon group capability is inherent for leaf SAPs and leaf SDP bindings and extends to all the remote nodes that are part of the same VPLS E-Tree service.

Ingress Tagging and Egress Filtering

Figure 163: Frame Forwarding in a VPLS E-Tree without EVPN shows how frames are forwarded in an E-Tree. The ingress node PE-2 knows whether the frame comes from a leaf AC or a root AC and adds a tag indicating "from root" or "from leaf". Specific VLAN IDs are used to indicate "from root" or "from leaf". The egress node PE-4 forwards the frame based on the "from root" or "from leaf" tag, as follows:

- A frame with the "from root" tag can be forwarded to any AC, leaf or root.
- A frame with the "from leaf" tag can only be forwarded to a root AC, not to a leaf AC.

Figure 163: Frame Forwarding in a VPLS E-Tree without EVPN



SAPs and SDP bindings are considered as root AC automatically (in the following example, SAP 1/2/c1/1:4 is a root AC); leaf ACs get the keyword **leaf-ac**, and NNI SAPs and SDP bindings get the keyword **root-leaf-tag**. The root tag equals the service delimiting VLAN ID (VID) in the SAP and the leaf tag can only be configured with a different value.

```
On PE-2:
configure {
    service {
        vpls "VPLS 4" {
            admin-state enable
            service-id 4
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            etree true
            sap 1/2/c1/1:4 { }
            sap 1/2/c3/1:4 {
                etree-leaf true
            }
            sap 1/2/c5/1:4 {
                etree-root-leaf-tag {
                    leaf 44
                }
            }
            spoke-sdp 24:4 {
                etree-root-leaf-tag true
                vc-type vlan
            }
            spoke-sdp 210:4 {
                etree-leaf true
            }
        }
    }
}
```

VLAN ranges are not allowed in a VPLS E-Tree, as shown for the following connection profile VLAN, which is configured on PE-2:

```
On PE-2:
configure {
    connection-profile {
        vlan 10 {
            qtag-range 10 {
                end 19
            }
            qtag-range 110 {
                end 110
            }
        }
    }
}
```

The following error is raised when attempting to configure a SAP with VLAN range cp-10:

```
configure {
    service {
        vpls "VPLS 4" {
            sap 1/2/c3/1:cp-10 { }
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 4" sap 1/2/c3/1:cp-10
 - vlan-range not allowed with etree vpls

configure {
    service {

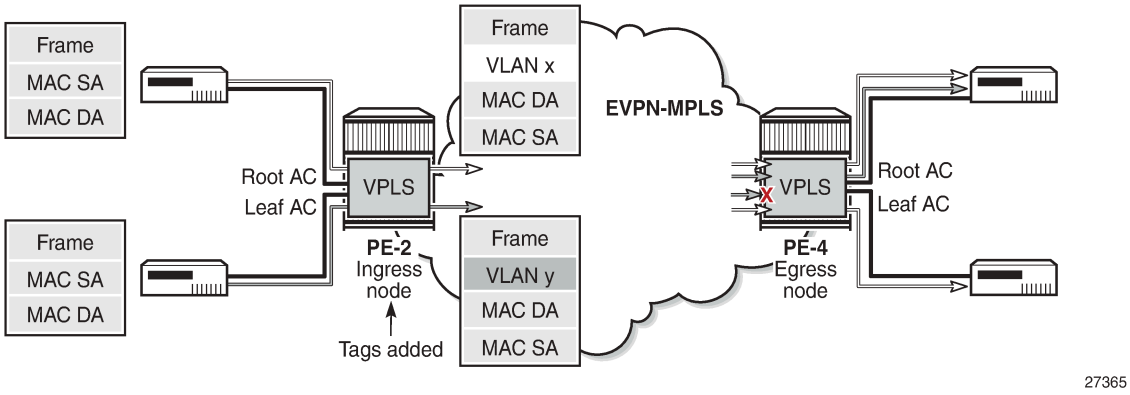
All incoming frames on a SAP or SDP binding in a VPLS have their dot1q/qinq encapsulation removed by the local PE. In a VPLS E-Tree, the local PE then adds a VLAN tag with a dedicated VID indicating whether the frame originates from a root AC or a leaf AC.

- For dot1q/qinq-based L2 services, a VLAN tag with VID x is added for root and VID y for leaf. Frames with VID x are forwarded to any type of AC, while frames with VID y are only forwarded to root ACs at the remote node, as shown in Figure 164: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree.
- For pseudowire-based L2 services, a VLAN tag with VID 1 is hard-coded for frames received on a root AC and a VLAN tag with VID 2 for frames received on a leaf AC.

Figure 164: VLAN Tags Added by Ingress Node and Filtered by Egress Node in VPLS E-Tree



EVPN-MPLS E-Tree

Operators migrate their regular VPLS services to EVPN services because of the advantages offered by EVPN, such as all-active multi-homing, scalability, and easy provisioning. EVPN-MPLS E-Trees block leaf-to-leaf traffic, while allowing all traffic from and to root ACs. The following is a configuration example of an EVPN-MPLS E-Tree. The **evpn-etree-leaf-label** command is only relevant for EVPN E-Tree services and allocates an E-Tree leaf label on the system, which is used for egress filtering of BUM traffic.

```
configure {
    service {
        system {
            bgp {
                evpn {
                    etree-leaf-label true
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            etree true
            bgp 1 { }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/c1/1:1 { }
            sap 1/2/c3/1:1 {
                etree-leaf true
            }
            spoke-sdp 210:1 {
                etree-leaf true
            }
        }
    }
}
```

SAPs or SDP bindings are by default root AC objects. MAC addresses learned on root AC objects are advertised as usual, while MAC addresses learned on a SAP or SDP binding configured as leaf AC are advertised with an BGP EVPN E-Tree extended community with leaf indication bit L=1.

BGP EVPN VXLAN is not supported in E-Tree services; only EVPN-MPLS E-Tree is supported. The following error is raised when attempting to configure VXLAN in an E-Tree enabled service:

```
configure {
    service {
        vpls "VPLS 3" {
            admin-state enable
            service-id 3
            customer "1"
            etree true
            vxlan {
                instance 1
MINOR: MGMT_CORE #2203: configure service vpls "VPLS 3" vxlan instance 1
 - Invalid element - etree or m-vpls must be unset
```

In an EVPN-MPLS E-Tree, it is not required and not even possible to configure the **etree-root-leaf-tag** option on interfaces. The following error is raised when attempting to configure a spoke SDP or SAP with **etree-root-leaf-tag** option:

```
configure {
    service {
        vpls "VPLS 1" {
            spoke-sdp 24:1 {
                etree-root-leaf-tag true
                vc-type vlan
            }
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" spoke-sdp 24:1 etree-root-leaf-tag
 - Not supported with bgp-evpn
 - configure service vpls "VPLS 1" bgp-evpn

configure {
    service {
        vpls "VPLS 1" {
            sap 1/2/c3/1:200 {
                etree-root-leaf-tag {
                    leaf 22
                }
MINOR: SVCMGR #12: configure service vpls "VPLS 1" sap 1/2/c3/1:200 etree-root-leaf-tag

```

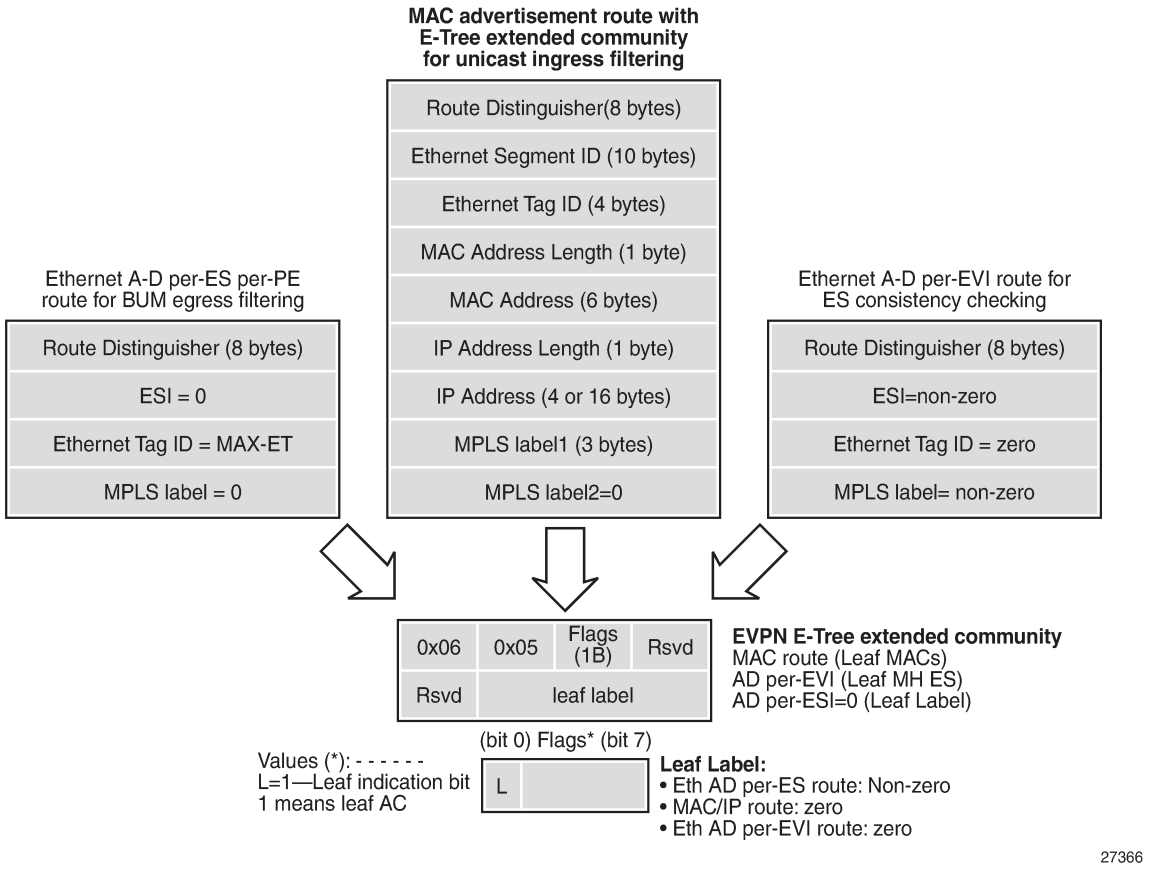
BGP EVPN Control Plane for EVPN E-Tree

No leaf tag needs to be added to frames forwarded to EVPN destinations. Instead, the BGP EVPN control plane for EVPN E-Tree advertises a leaf indication bit and a leaf label in the E-tree extended community, as shown in Figure 165: BGP EVPN Control Plane for EVPN E-Tree.

Figure 165: BGP EVPN Control Plane for EVPN E-Tree



The BGP EVPN control plane is extended with the EVPN E-Tree extended community, as per RFC 8317. The low-order bit of the flags field contains the L-bit (L=1 indicates a leaf AC). The leaf label contains a 20-bit MPLS label that is non-zero for Ethernet Auto Discovery (AD) per Ethernet Segment (per-ES) routes (tag MAX-ET), but it equals zero for MAC/IP routes and Ethernet AD per EVPN Instance (per-EVI) routes (tag 0). The following BGP EVPN AD per-ES route contains an EVPN E-Tree extended community with L=0 and leaf label 524282, and is used for egress BUM filtering. RFC 8317 states that the leaf indication bit L must be ignored on reception and should be zero on transmission.

===============================================================================
```

If receiving the same MAC route as root from PE-1 and as leaf from PE-2, the MAC route from PE-1 is selected: root MAC routes have higher priority than leaf MAC routes. Root static MAC routes take precedence over leaf static MAC routes.

EVPN MAC routes with a higher sequence number have a higher priority than root or leaf MAC routes. MAC mobility procedures take precedence to first identify the location of the MAC before associating that MAC with a root or a leaf site. The EVPN MAC route selection criteria in tie-break order are as follows:

1. Conditional static MACs (local protected MACs)
2. Auto-learned protected MACs (locally learned MACs on SAPs or mesh/spoke SDPs because of the configuration of auto-learn-mac-protect)
3. EVPN ES PBR MACs
4. EVPN static MACs (remote protected MACs)
5. Data plane learned MACs (regular MAC learning on SAPs/SDP-bindings)
6. EVPN MACs with a higher sequence number
7. EVPN E-Tree root MACs
8. Lowest IP (next-hop IP of the EVPN NLRI)
9. Lowest Ethernet tag (Ethernet tag is zero for MPLS and non-zero for VXLAN)
10. Lowest RD

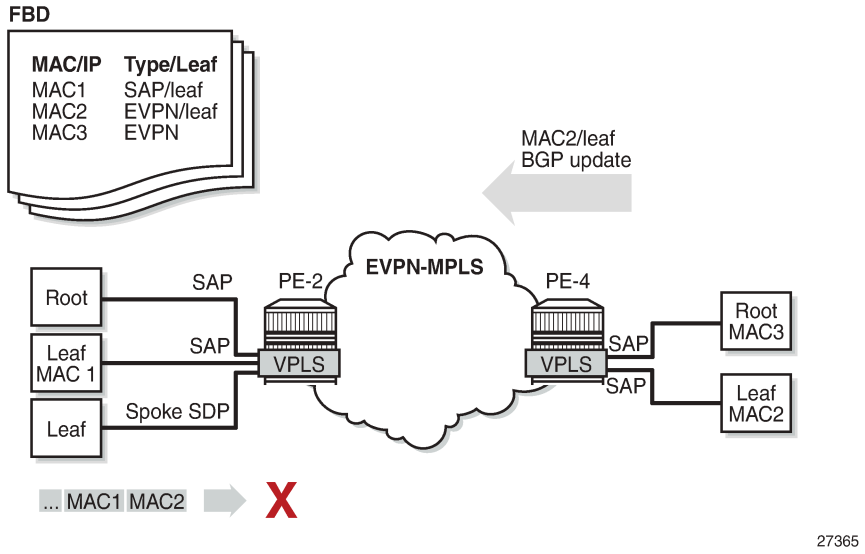
Ingress Leaf Filtering for Unicast Traffic

EVPN-MPLS E-Tree is the only E-Tree technology able to do unicast ingress filtering, as opposed to the usual unicast egress filtering that, for example, VPLS does. Remote MAC addresses are learned in the control plane, so EVPN can optimize the forwarding by filtering known unicast traffic at the ingress:

- Unicast frames entering a root AC at the ingress PE are not filtered. The MAC destination address (DA) is looked up in the FDB and the frames are forwarded. The MAC source address (SA) is learned and advertised in BGP EVPN without the E-Tree extended community.
- Unicast frames entering a leaf AC at the ingress PE are filtered. The MAC DA is looked up in the FDB. When the MAC DA is learned from an EVPN leaf (or a leaf AC), the frame is dropped. When the MAC DA is learned from an EVPN root (or root AC), the frame is forwarded. The MAC SA is learned and advertised in BGP EVPN with leaf indication bit L=1.

Figure 166: Ingress Leaf Filtering for Known Unicast Traffic shows that PE-4 advertises MAC2 with leaf indication bit L=1. When a frame is sent with MAC SA MAC1 on a leaf AC of PE-2, PE-2 does a MAC lookup in the FDB to find out that the DA MAC2 is learned from an EVPN leaf. Therefore, PE-2 does not forward the frame to PE-4, but drops it at the ingress.

Figure 166: Ingress Leaf Filtering for Known Unicast Traffic



The ingress filtering blocks E-Tree leaf-to-leaf traffic and requires the implementation of an extra leaf EVPN-MPLS destination per remote PE containing leaf ACs per E-Tree service. Therefore, a dedicated EVPN-MPLS binding is created per leaf unicast traffic in the service. This additional internal EVPN-MPLS destination is created per remote PE that contains a leaf and that advertises at least one leaf MAC. The MPLS E-Tree leaf destination is created when a MAC route with L=1 is received. Any EVPN E-Tree service could potentially use one additional EVPN-MPLS destination for leaf unicast traffic per remote PE. This additional EVPN-MPLS leaf destination in the E-Tree is only unicast and not part of the flooding list. The EVPN-MPLS leaf destination consumes EVPN resources, as can be verified as follows:

```
[/]
A:admin@PE-2# tools dump service evpn usage | match "Mpls Etree"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Mpls Etree Leaf Dests                          :            1
```

All MAC addresses received with L=1 point to this EVPN-MPLS E-Tree leaf destination, whereas root MAC addresses point to the root destination.

Egress Leaf Filtering for BUM Traffic

Figure 167: Egress Leaf Filtering for BUM Traffic shows that leaf-to-leaf BUM traffic is filtered at the egress, based on the EVPN leaf label advertised in the E-Tree extended community of the zero ESI AD per-ES route (tag=MAX-ET).

- BUM frames that enter a root AC at the ingress PE are not filtered; the BUM frames follow regular EVPN data plane procedures.
- BUM frames that enter a leaf AC at the ingress PE are marked as leaf and forwarded or replicated to the egress IOM. At the egress IOM, the frame is flooded in the default multicast list, subject to the following:
  - Leaf entries are skipped when BUM traffic is forwarded, so no BUM traffic is forwarded to local leaf ACs.
  - BUM traffic to remote BGP EVPN PEs is encapsulated with the EVPN label stack.
    - If the remote PE has advertised an AD per-ES route with E-Tree leaf label L1, this leaf label L1 is added at the bottom of the stack. At the egress PE, when the leaf label L1 matches the leaf label of the PE, the BUM traffic is only forwarded to the root ACs, not to the leaf ACs.
    - If the egress PE does not have any E-Tree enabled service, it has not advertised any AD per-ES route with E-Tree leaf label. The local PE forwards the BUM traffic with BGP EVPN encapsulation, but without an additional label. Even when the egress PE does not have E-Tree enabled, it can still work with the VPLS E-Tree service available in the ingress PE. No traffic is dropped at the egress PE where no E-Tree is configured.

Figure 167: Egress Leaf Filtering for BUM Traffic

The following command is used to monitor the ESI label entries consumed by the EVPN E-Tree application:

```
[/]
A:admin@PE-2# tools dump service evpn usage | match "BUM"
Evpn Etree Remote BUM Leaf Labels              :            1
```

Configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- LDP between the PEs
- BGP for the EVPN address family (between the PEs)

In this section, the following cases are described:

- EVPN-MPLS E-Tree without multi-homing
- EVPN-MPLS E-Tree with all-active and single-active multi-homing

EVPN-MPLS E-Tree without Multi-homing

Figure 168: Example Topology for EVPN-MPLS E-Tree without Multi-homing shows an example topology with two PEs in an EVPN-MPLS network with VPLS 1 configured as E-Tree. CE-6 and CE-8 have root ACs and are able to send and receive traffic to and from all other CEs, whereas CE-7, CE-9, and CE-1 are only able to exchange traffic with CE-6 and CE-8, but not with each other. The video source can be connected to CE-8 (root AC) or CE-9 (leaf AC).

Figure 168: Example Topology for EVPN-MPLS E-Tree without Multi-homing

The service configuration on PE-2 is as follows:

```
On PE-2:
configure {
    service {
        sdp 210 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.10
            }
        }
        system {
            bgp {
                evpn {
                    etree-leaf-label true
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            etree true

            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/c1/1:1 { }
            sap 1/2/c3/1:1 {
                etree-leaf true
            }
            spoke-sdp 210:1 {
                etree-leaf true
            }
        }
    }
}
```

The service configuration on PE-4 is similar, with SAP 1/2/c1/1:1 as root AC and SAP 1/2/c3/1:1 as leaf AC.

The following command on PE-2 shows that SAP 1/2/c1/1:1 is a root AC (default), SAP 1/2/c3/1:1 is a leaf AC (indicated by "L"), and spoke SDP 210:1 is also a leaf AC.

```
[/]
A:admin@PE-2# show service id 1 etree

EVPN E-Tree BUM Egress Filtering

When multicast traffic is sent from a video source via CE-8 (root AC), both CE-6 and CE-7 receive this traffic; for multicast traffic sent via CE-9 (leaf AC), only CE-6 (root AC) receives this traffic. PE-2 received leaf label 524282 in an AD per-ES route from PE-4, as follows:

```
[/]

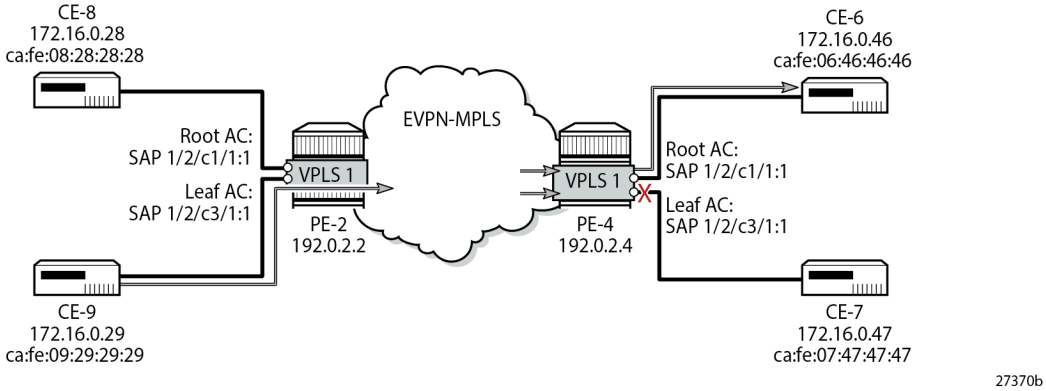
EVPN E-Tree Egress Filtering Based on MAC SA

Egress filtering on MAC SA is required to cover cases when the ingress PE sends traffic received on a leaf AC, but without leaf indication. Figure 169: EVPN E-Tree Egress Filtering Based on MAC SA shows that CE-9 sends traffic with MAC SA ca:fe:09:29:29:29 on a leaf AC.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 169: EVPN E-Tree Egress Filtering Based on MAC SA



When CE-9 sends unicast traffic to CE-6 with root MAC DA ca:fe:06:46:46:46, the ingress PE-2 forwards the frames to this root MAC DA to egress PE-4. However, if PE-4 does not have the MAC DA in its FDB (because of aging or MAC flush and the MAC route has not made it yet to PE-2), it may flood the frame to all the root and leaf ACs, even if the frame originated from a leaf AC. EVPN E-Tree egress filtering based on MAC SA prevents this from happening, so the traffic is only forwarded to the root AC.

The data path does the egress filtering based on MAC SA as follows:

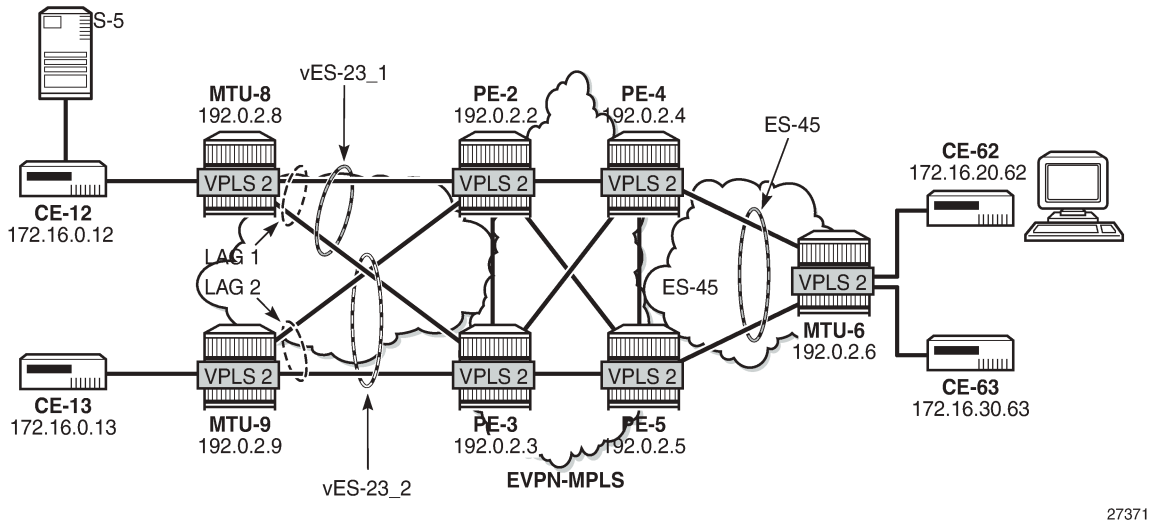
- First, frames are identified as leaf frames in one of the following cases:
  - Frames arriving on a leaf SAP
  - EVPN traffic arriving with a leaf label
  - Frames arriving with a MAC SA that is flagged as being a leaf SA
- At the egress PE, frames identified as leaf are filtered depending on the type of traffic:
  - For known unicast traffic, the FDB is consulted. If the MAC DA FDB entry is marked as being from a leaf, the frame is dropped to prevent leaf-to-leaf forwarding.
  - For BUM traffic, the leaf frames are filtered at the egress IOM to suppress leaf-to-leaf forwarding.

EVPN-MPLS E-Tree with Multi-homing

Figure 170: Example Topology with All-active ESs and Single-active ES shows the example topology with two all-active multi-homing vESs on PE-2 and PE-3 and one single-active multi-homing ES on PE-4 and PE-5.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 170: Example Topology with All-active ESs and Single-active ES



On PE-2, two all-active multi-homing vESs are configured. VPLS 2 is configured as EVPN-MPLS E-Tree with LAG 1 as root AC and LAG 2 as leaf AC. RD 2.2.2.2 is configured and used in the non-zero AD per-ES routes, while the zero ESI routes (AD per-ES) use the IP address 192.0.2.2. The service configuration on PE-2 is as follows:

```
On PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ad-per-es-route {
                        route-target-type evi-route-target-set
                        route-distinguisher-ip-address 2.2.2.2
                    }
                    etree-leaf-label true
                    ethernet-segment "vESI-23_1" {
                        admin-state enable
                        type virtual

The service configuration on PE-3 is identical, but with **evi-rt-set route-distinguisher** 3.3.3.3 instead.

Note:
The command **config service system bgp-evpn ad-per-es-route-target evi-rt-set** is not supported for EVPN E-Tree services. When the command is configured on a router, the AD per-ES routes (with ESI=0) used for EVPN E-Tree services are always advertised with the service route target and route distinguisher, regardless of the **ad-per-es-route-target** configuration. AD per-ES routes for non-zero ESIs (used for regular multi-homing) is usually sent using either **evi-rt-set** or **evi-rt**, based on the router configuration.

It is important that all the ACs in each EVI for an ES must either be root ACs or leaf ACs in both PEs where the ES is defined, not a mix. In this example, SAP lag-1:2 is assigned to vES-23_1 and defined as root AC in both PE-2 and PE-3. Likewise, SAP lag-2:2 is assigned to vES-23_2 and configured as leaf AC in PE-2 and PE-3. However, if the configuration were a mix of root and leaf ACs in different PEs of the same ES, a

remote PE (PE-4 or PE-5) would receive the AD per-EVI routes with inconsistent leaf indication and would treat the AC as root AC.

PE-2 sends the following BGP EVPN AD routes: an AD per-ES route with zero ESI and RD 192.0.2.2:2 (for egress filtering of BUM traffic) and an EVPN AD per-EVI route with non-zero ESI and RD 2.2.2.2:1 (to verify the ES consistency).

```

The following command shows the EVI RT set RD ranging from 2.2.2.2:1 to 2.2.2.2:512. In VPLS VPLS 2, the configured EVI is 2 and needs to be divided by 128, the number of EVI RT sets that are advertised. This value is rounded up to 1; therefore, the RD in the preceding AD per-EVI equals 2.2.2.2:1. The minimum EVI RT set RD equals 2.2.2.2:1 and the maximum is 2.2.2.2:512, because the EVI ranges from 1 to 65535 and 65536/128=512.

The FDB for VPLS 2 on PE-3 shows the same EVPN leaf MAC addresses. For all PEs in the all-active MH ESs, the MAC addresses ca:fe:06:00:20:12 and ca:fe:06:00:30:13 from the locally attached ACs can be learned on the SAPs or via EVPN from the ES peer where they are learned on the SAPs. In this case, they are learned on the SAPs on PE-2 and PE-3.

Egress Filtering for BUM Traffic

Each PE advertises zero ESI AD per-ES routes (with tag MAX-ET) that are needed for egress BUM filtering.

BUM frames received on an ES root AC are flooded to the EVPN, based on regular EVPN procedures. The regular ESI label is sent for split horizon when frames are sent to the DF or NDF PEs in the same ES.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

BUM frames received on an ES leaf AC are flooded in the default multicast list. The egress PE does not forward BUM traffic to any leaf ACs, including the ES leaf ACs. However, in the unlikely event that some ACs in a specific ES for an EVI have an inconsistent E-Tree configuration, these ACs are treated as root ACs, and the traffic is forwarded.

The remote PE-4 receives the following EVPN AD routes from DF PE-2: a zero ESI AD per-ES (tag MAX-ET), two AD per-EVI (tag 0) routes with a non-zero label, and two AD per-ES routes (tag MAX-ET).

Conclusion

E-Trees can be used for enterprise business services, for the distribution of IPTV multicast content, for centralized backup BNGs, and so on. In a VPLS E-Tree, leaf SAPs or leaf SDP bindings cannot exchange traffic with each other, similar to split horizon group behavior. The E-Tree restrictions apply to all remote PEs that are part of the same service. E-Trees can be applied in an EVPN-MPLS VPLS as well as in a regular VPLS.

EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services

This chapter provides information about EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 14.0.R5, but the MD-CLI in the current edition is based on SR OS Release 25.7.R1.

Chapters EVPN for MPLS Tunnels and EVPN for VXLAN Tunnels (Layer 2) are prerequisite reading.

Note:
This chapter was initially written for SR OS Release 14.0.R5 that did not support the creation of ES destinations in VXLAN. The creation of ES destinations in VXLAN is supported in SR OS Release 19 and later; see the EVPN Multi-Homing for VXLAN VPLS Services chapter.

Overview

When EVPN-MPLS is deployed in the WAN, many service providers are looking for a way to integrate existing Layer 2 EVPN-VXLAN based data center services into the WAN, while keeping the end-to-end advantages of EVPN. RFC 9014 describes how to provide Layer 2 connectivity for EVPN-overlay data centers in different ways. This chapter follows section 4.4 of RFC 9014, in which EVPN-MPLS is used in the same VPLS service that terminates overlay (VXLAN) tunnels.

To provide EVPN-MPLS connectivity to VPLS services terminating EVPN-VXLAN, SR OS supports the configuration of BGP-EVPN MPLS and BGP-EVPN VXLAN at the same time by adding two BGP instances to the service. Two BGP instances are supported in the same VPLS at most. BGP-EVPN MPLS and BGP-EVPN VXLAN can both use BGP instance 1 or 2, but they must use different instances.

In a service with EVPN-VXLAN and EVPN-MPLS, the **configure service vpls bgp-evpn mpls 2** command allows the user to associate BGP-EVPN MPLS to BGP instance 2, while BGP-EVPN VXLAN is associated to BGP instance 1, and therefore, have both encapsulations simultaneously enabled in the same service. Either BGP instance 1 or 2 can be associated to BGP-EVPN VXLAN or MPLS, but they must be different. When the two BGP instances are successfully added to the same VPLS service, the service behaves as follows:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MAC/IP routes received on one instance are "consumed" (accepted, imported, and installed in FDB) and re-advertised in the other instance, as long as the route is the best route for a specific MAC or MAC/IP.
- Inclusive multicast routes are independently generated for each BGP instance.
- From a data plane perspective, EVPN-MPLS and EVPN-VXLAN destinations are instantiated in different implicit Split-Horizon Groups (SHGs) so that traffic can be forwarded between the two SHGs, but not between destinations of the same kind. For example, traffic coming from EVPN-MPLS cannot be forwarded to other destinations in the EVPN-MPLS SHG.

The following example shows a VPLS service configured on PE-2 with two BGP instances and both encapsulations, VXLAN and MPLS, configured at the same time:

```
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            description "evpn-mpls and evpn-vxlan in the same service"
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
                route-distinguisher "10:1"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
            }
            bgp 2 {
                route-distinguisher "10:2"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
                mpls 2 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

In the preceding example

- **bgp 1** is the default BGP instance.
- **bgp 2** is the additional instance that is required when both BGP-EVPN VXLAN and BGP-EVPN MPLS are enabled in the service.
- The same commands supported under BGP instance 1 exist for this second BGP instance, with the following considerations:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

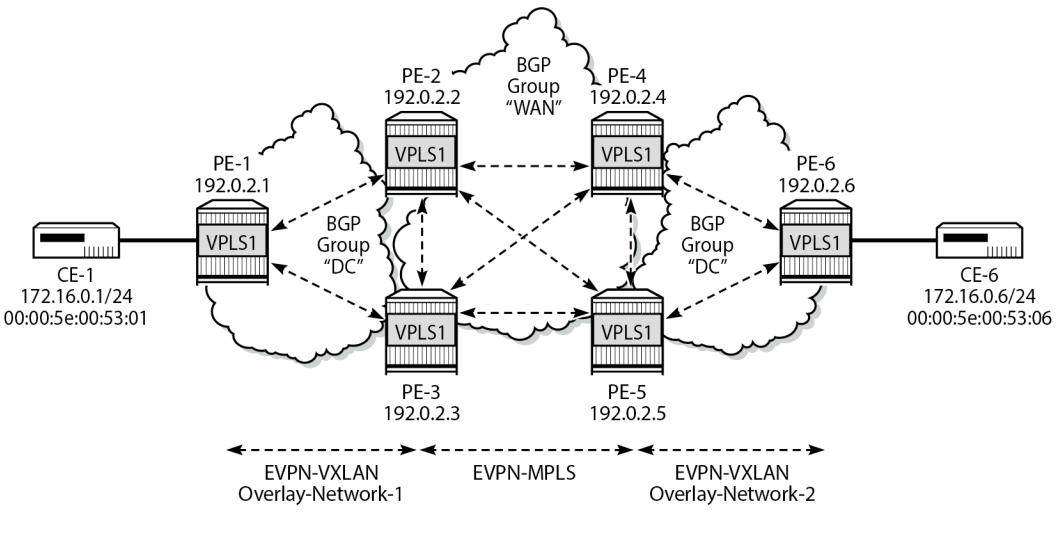
  - **pw-template-binding** – the pseudowire (PW) template binding can only exist in BGP instance 1; it is not supported in BGP instance 2. Because no SDP-bindings can exist in a VPLS service with two BGP instances, the **pw-template-binding** command is ineffective in this configuration.
  - **route-distinguisher** – the route distinguisher in both BGP instances must be different.
  - **route-target** – the route target in both instances can be the same or different.
  - **vsi-import** and **vsi-export** – import and export policies can also be defined for either BGP instance.
- The **mpls 2** command assigns BGP instance 2 to MPLS. The VPLS configuration can only be committed if the BGP instance associated with MPLS has a different route distinguisher than the BGP instance associated with VXLAN.
- The **evi** can still be used for auto-derivation of RD/RT on BGP instance 1 and auto-derivation of RT (not RD) on BGP instance 2. Auto-RD or an explicitly configured RD is needed in BGP instance 2.

Configuration

Figure 171: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the example topology used throughout this chapter, as well as the BGP peering topology. PE-1, PE-2, and PE-3 simulate a data center, shown as Overlay-Network-1, where PE-2 and PE-3 are DC GWs. In the same way, PE-4, PE-5, and PE-6 simulate a remote data center, Overlay-Network-2. Inside each DC, EVPN-VXLAN is used.

The two DC GW pairs are connected by EVPN-MPLS; therefore, CE-1 and CE-6 are end-to-end connected by EVPN without any VLAN or PW hand-off, maintaining all the EVPN advantages across the DC Interconnect (DCI) network.

Figure 171: EVPN-MPLS interconnect for EVPN-VXLAN - example topology



The example topology consists of six 7750 SR routers with the following initial configuration:

- Hybrid ports (they could have been network type too) are interconnecting the six PEs with configured router interfaces.
- The six PEs are running IS-IS and creating point-to-point adjacencies.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Link LDP is configured in the core, among PE-2, PE-3, PE-4, and PE-5, while PE-1 and PE-6 are only running VXLAN.
- EVPN uses MP-BGP for exchanging reachability at service level. Therefore, BGP peering sessions must be established among the PEs for the EVPN family. Figure 171: EVPN-MPLS interconnect for EVPN-VXLAN - example topology shows the peering sessions established among the six PEs. Although usually a Route-Reflector (RR) is used in each DC and another RR in the WAN, in this example, there are direct peering sessions in each DC and in the WAN.

The following output shows the BGP configuration of PE-2. The BGP configuration on the rest of the DC GWs (PE-3, PE-4, and PE-5) is similar:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "DC" {
                type internal
                import {
                    policy ["drop SOO-DCGW-23"]
                }
                export {
                    policy ["allow only vxlan and add SOO"]
                }
            }
            group "WAN" {
                type internal
                import {
                    policy ["drop SOO-DCGW-23"]
                }
                export {
                    policy ["allow only mpls and add SOO"]
                }
            }
            neighbor "192.0.2.1" {
                group "DC"
            }
            neighbor "192.0.2.3" {
                group "DC"
            }
            neighbor "192.0.2.4" {
                group "WAN"
            }
            neighbor "192.0.2.5" {
                group "WAN"
            }
        }
```

Two different BGP groups are configured: DC and WAN. The DC group contains the DC neighbors (including the peer DC GW) and the WAN group contains the WAN neighbors. This grouping makes the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

use of policies easier. These policies are described in the section The mandatory use of BGP policies in the multi-homed anycast solution.

The following output shows the BGP configuration of PE-1. PE-6 has a similar BGP configuration.

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "DC" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "DC"
            }
            neighbor "192.0.2.3" {
                group "DC"
            }
        }
```

VPLS service configuration

After the base infrastructure (interfaces, IGP, LDP in the core, and BGP) is configured, the services can be added. The configuration example in this section uses VPLS 1 as the service to be interconnected across the two DCs.

PE-1 and PE-6 have a regular EVPN-VXLAN configuration; DCI connectivity provided by EVPN-MPLS is completely transparent to them. The configuration of VPLS 1 in PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/1/c10/1:1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
```

See the EVPN for VXLAN Tunnels (Layer 2) chapter for a complete description of the EVPN-VXLAN commands.

The configuration on PE-2, PE-3, PE-4, and PE-5 (see Figure 171: EVPN-MPLS interconnect for EVPN-VXLAN - example topology) enables EVPN-VXLAN and EVPN-MPLS in the same VPLS service. As an example, the VPLS 1 configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
                route-distinguisher "64500:1"
            }
            bgp 2 {
                route-distinguisher "64500:2"
            }
            bgp-evpn {
                evi 1
                incl-mcast-orig-ip 23.23.23.23        # for anycast
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
                mpls 2 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

As described in the Overview section, the preceding configuration enables the router to create EVPN-VXLAN and EVPN-MPLS destinations in the same VPLS service, but in different SHGs. In addition to the **bgp 2** commands already described in the Overview section, the **incl-mcast-orig-ip** command is added in the configuration. If configured, this command changes the originating IP address in the inclusive multicast routes (from the default system IP) for both BGP instances. The section Multi-homed anycast configuration for dual BGP-instance VPLS services describes why this command is added in anycast scenarios.

The following section provides a detailed description of the expected behavior for EVPN routes that are imported and exported on dual BGP instance VPLS services.

EVPN route handling in dual BGP-instance VPLS services

This section describes how the BGP-EVPN routes are processed in dual BGP instance services.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Usually, the router validates the received tunnel encapsulation (from the RFC 5512 Extended Community) with the configured encapsulation of the service/BGP-instance. Therefore, an EVPN-VXLAN route is not imported into the BGP-EVPN MPLS instance and vice-versa. This is also how the different EVPN route types are handled in dual BGP instance services:

Route type 1 - auto-discovery routes

AD per-EVI routes for the VXLAN instance are generated when an Ethernet Segment (ES) is associated with the service. Also, AD per-EVI routes can be received from the EVPN-MPLS peers and are processed as usual. Therefore, a VPLS service with two BGP instances supports aliasing/backup and AD per-ES checking procedures for a remote multi-homed ES, as described in the EVPN for MPLS Tunnels chapter. However, in this chapter, no multi-homed ESs are configured; therefore, no AD per-EVI routes are present in this example. See the Figure 171: EVPN-MPLS interconnect for EVPN-VXLAN - example topology for an example with ESs associated with a dual BGP-instance VPLS service.

Route type 2 - MAC/IP routes

MAC/IP routes received on one of the two BGP instances are imported and the MAC addresses added to the FDB according to the existing selection rules. If the MAC address is active (therefore installed in the FDB), it is re-advertised in the other BGP instance with the BGP attributes of the other BGP instance (new route target if different, new route distinguisher, and so on). The **bgp-evpn routes mac-ip advertise** command governs the advertisement of MAC addresses in either BGP instance.

The MAC/IP route redistribution across BGP instances is performed according to the following rules:

- A MAC route is redistributed only if it is the best route according to the EVPN selection rules in the EVPN for MPLS Tunnels chapter.
- Assuming a specific MAC route is the best one and has to be redistributed, the MAC/IP information along with the sticky bit is propagated in the redistribution.
- A change in the MAC/IP route sequence number or sticky bit in one instance is updated in the other instance, as long as that route is the best MAC route for the route key.
- When a MAC address moves within the EVPN-VXLAN (or the EVPN-MPLS) network, the MAC route is received on the same BGP instance where it was previously received, but now with a higher sequence number. In this case, the MAC route is redistributed with the new sequence number. However, a router with two BGP instances in the same service does not detect any duplicate MAC on the EVPN-VXLAN and EVPN-MPLS networks.

As an example, the following output shows the debug of a MAC/IP route received on PE-2, on the BGP instance for EVPN-VXLAN on VPLS 1, and how the route is re-advertised to the BGP instance used for MPLS (with a different next-hop, route distinguisher, label, and BGP tunnel encapsulation):

```

Route type 3 - inclusive multicast routes

EVPN Inclusive Multicast Ethernet Tag (IMET) routes are generated independently for each BGP instance with the correct BGP tunnel encapsulation extended community and the tunnel type associated with the BGP instance; for example, Ingress Replication (IR), P2MP mLDP, or Assisted Replication (AR):

- On the EVPN-VXLAN BGP instance, IR or AR IMET routes are supported.
  - When **assisted-replication replicator** is enabled and the received VXLAN broadcast and multicast packets contain an IP DA = AR-IP, the DC GW sends the packets back to VXLAN (but not to the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VXLAN termination end-point (VTEP) from where the packet is received) in addition to the EVPN-MPLS destinations.

  - If **assisted-replication replicator** is used on the DC GWs, the AR-IP (**configure service system vxlan assisted-replication ip-address**) must be a loopback different from the router's system IP and the configured **bgp-evpn incl-mcast-orig-ip**. The two AR-IP addresses in the DC GW pair do not need to be the same IP address.

- On the EVPN-MPLS BGP instance, IR, P2MP mLDP, or composite IMET routes are supported.
- Following is the behavior when the **incl-mcast-orig-ip** command is used:
  - The configured IP in the **incl-mcast-orig-ip** command is encoded in the originating IP field of the IMET routes for IR, P2MP, and composite routes for both BGP instances.
  - The originating IP field of the IMET AR routes is still derived from the configured **service system vxlan assisted-replication ip-address** value.
- The received IMET routes is processed in the following way depending on their type:
  - IMET-IR routes: the EVPN destination (MPLS or VXLAN) is set up based on the NLRI next-hop.
  - IMET-P2MP routes: the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PTA) tunnel ID are used to join the mLDP tree (as mLDP FEC in the LDP mapping messages).
  - IMET-P2MP-IR (composite) routes: the PTA tunnel ID is used to join the mLDP tree. The NLRI next-hop is used to build the EVPN destination.
  - IMET-AR routes: the NLRI next-hop is used to build the EVPN-VXLAN destination.
- Upon reception of two IMET routes with similar information, the router behaves as follows:
  - If the router receives two IMET routes with the same originating IP, different RDs, and different NLRI next-hops, it sets up two EVPN destinations, one to each next-hop.
  - If the router gets two IMET routes with the same originating IP, different RDs, but the same next-hop, it sets up only one EVPN destination.
  - The router does not set up an EVPN destination to its DC GW peer if the received originating IP matches its own originating IP, regardless of whether the local RD and the remote RD are the same or different. This enables the use of the redundant anycast solution that is described in the following section: Multi-homed anycast configuration for dual BGP-instance VPLS services.

Route type 4 - ES routes

ESs are supported in routers where dual BGP-instance services exist. However, because dual BGP-instance VPLS services do not support SDP-bindings, ESs and ES routes are not relevant to these types of services.

Route type 5 - IP-prefix routes

IP-prefix routes are neither generated nor processed by the service.

Multi-homed anycast configuration for dual BGP-instance VPLS services

Services with EVPN-MPLS and EVPN-VXLAN SHGs are specified in RFC 9014 and the associated multi-homing solution is also described in RFC 9014. That multi-homing solution is based on an interconnect ES

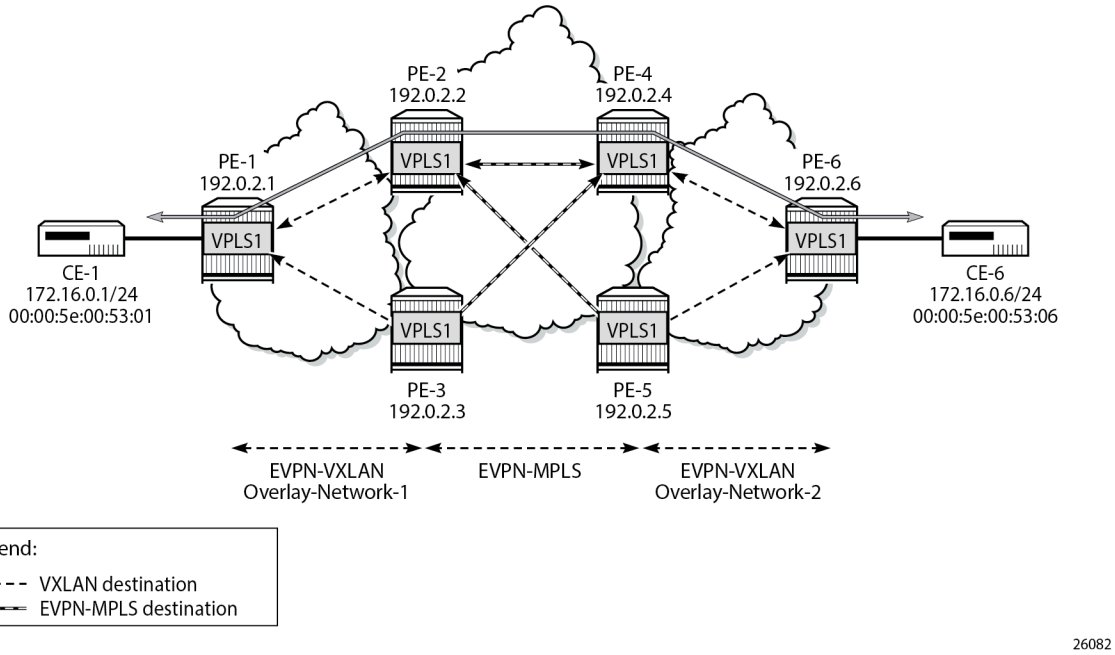
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

that allows all-active and single-active multi-homed EVPN networks as well as local attachment circuits in the DC GWs (SAP/SDP-bindings).

Note:
This chapter was initially written for SR OS Release 14.0.R5 and an anycast solution is used to provide redundancy. This anycast solution is based on the two PE DC GWs in the redundant pair being configured to advertise MAC/IP and IMET routes with the same route key, so that the remote PEs only pick up one of the two anycast DC GWs when sending unicast or BUM traffic, and no loop or packet duplication is created. However, Nokia recommends the use of interconnect ESs over the anycast configuration. See the EVPN Interconnect Ethernet Segments chapter for an example with I-ES.

Figure 172: EVPN destinations created on multi-homed anycast DC GWs is an example of how multi-homing can be achieved for dual BGP-instance VPLS services. The figure also shows the EVPN destinations created and their direction (see the arrows). For instance, only one EVPN multicast destination is created for PE-1, PE-2, or PE-4. Therefore, BUM traffic sent by CE-1 is sent via PE-2, PE-4, and PE-6 only, and no duplication or loops occur.

Figure 172: EVPN destinations created on multi-homed anycast DC GWs



The following output shows the VPLS 1 configuration on PE-2 and PE-3 so that this anycast redundancy can be realized. The route distinguishers as well as the **incl-mcast-orig-ip** addresses must match between the two PEs in the redundant pair. VPLS 1 is configured on PE-2 and PE-3 as follows:

```
# on PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
                route-distinguisher "64500:1"
            }
            bgp 2 {
                route-distinguisher "64500:2"
            }
            bgp-evpn {
                evi 1
                incl-mcast-orig-ip 23.23.23.23        # for anycast
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
                mpls 2 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The VPLS 1 configuration on PE-4 and PE-5 is as follows:

```
# on PE-4, PE-5:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
                route-distinguisher "64501:1"
            }
            bgp 2 {
                route-distinguisher "64501:2"
            }
            bgp-evpn {
                evi 1
                incl-mcast-orig-ip 45.45.45.45         # for anycast
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
                mpls 2 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

Based on the preceding configuration example, the DC GWs behavior in this scenario is as follows:

- PE-2 and PE-3 both send IMET IR routes to the other PEs with the same route key but a different next-hop. The route key in IMET routes comprises [RD, Ethernet tag, originator-IP/length], which in this case is [64500:1, 0, 23.23.23.23/32] for the EVPN-VXLAN IMET routes and [64500:2, 0, 23.23.23.23/32] for the EVPN-MPLS IMET routes.
- In the same way, PE-2 and PE-3 both send MAC/IP routes to the other PEs with the same route key but a different next-hop. The route key comprises [RD, Ethernet tag, MAC/MAC-length, IP/IP-length].

The configuration of the same **incl-mcast-orig-ip** address and RDs in both DC GWs enables the anycast solution as follows:

- The configured originating IP (for example, 23.23.23.23 in PE-2 and PE-3) is not required to be a reachable IP address, which forces the remote PEs (or RRs if they exist) to select only one of the two DC GWs for BUM traffic (based on regular BGP selection). In this example, the remote PEs select the PE-2 IMET route and create only one destination. The following output shows the IMET routes received by PE-1 (only the PE-2 route is used) and the created EVPN-VXLAN destination to PE-2. The same behavior could have been shown in the rest of the PEs.

- Because of the same RD and originating IP configured on PE-2 and PE-3 (similarly in PE-4 and PE-5), the DC GW redundant PEs will never establish an EVPN destination between each other. PE-2 only sets up EVPN multicast destinations to PE-1 and PE-4, as follows:

```

- Likewise, when the two redundant PEs receive the same MAC/IP route, they both re-advertise it with the same route key, forcing the remote PEs to pick up only one of the two (based on regular BGP

selection) and create only one EVPN destination (if different from the multicast destination). In the following example, PE-6 advertised the CE-6 MAC address, that is, re-advertised by PE-4/PE-5 and then by PE-2/PE-3, but only one of the routes is selected at each hop. The following output shows that PE-1 selects the PE-2 MAC/IP route (see the "used" flag) and uses the existing EVPN destination to PE-2:

- As shown in the preceding outputs, the EVPN destinations are always created to the IMET or MAC/IP route's BGP next-hops, which are still the system IP address of the routers (they could have also been a loopback address). The BGP next-hops need to be reachable in their respective network: DC or WAN.

The mandatory use of BGP policies in the multi-homed anycast solution

BGP policies must be configured in a multi-homed anycast solution, such as the one described in the previous section. Without policies, the following undesired behavior would happen:

- IMET routes with VXLAN encapsulation would be sent to the BGP peers in the MPLS network and IMET routes with MPLS encapsulation sent to BGP peers in the DC. The configured BGP policies avoid that and make sure that the VXLAN routes are only sent to the DC and MPLS routes only to the WAN.
- MAC/IP routes received in the VXLAN BGP instance of a DC GW would be re-advertised to the redundant DC GW in the MPLS BGP instance and the redundant DC GW would re-advertise the same MAC again into the VXLAN instance, creating a control plane loop. The same thing would happen for MAC/IP routes received in an MPLS BGP instance. The configured BGP policies prevent a DC GW from re-advertising MAC/IP routes received from the redundant DC GW.

While service-level BGP policies (**configure service vpls bgp vsi-import | configure service vpls bgp vsi-export**) may have been configured to prevent these loops and misbehavior, the use of BGP peer-level policies (**configure router bgp group import | configure router bgp group export**) is recommended because of the following reasons:

- Simplicity - BGP peer-level policies do not require any extra configuration at the service level, only at the BGP level.
- Scalability - BGP peer-level policies scale better than VSI-level policies, because the number of services where the VSI policies must be configured may be significant.

The following policies are configured in the example used in this chapter. No policies are needed in PE-1 and PE-6; only the DC GWs must be configured.

Following are the policies on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
    policy-options {
        community "SOO-DCGW-23" {
            member "origin:64500:23" { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        community "mpls" {
            member "bgp-tunnel-encap:MPLS" { }
        }
        community "vxlan" {
            member "bgp-tunnel-encap:VXLAN" { }
        }

/* "drop SOO-DCGW-23" will drop any EVPN route that is received from PE-3,
the other DC GW in the pair. */

        policy-statement "drop SOO-DCGW-23" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "SOO-DCGW-23"
                    }
                }
                action {
                    action-type reject
                }
            }
        }

/* "allow only mpls and add SOO" has a twofold objective: avoids sending EVPN-VXLAN
routes to the MPLS network and marks the advertised EVPN routes with a Site-Of-Origin
extended community that identifies the DC GW pair. */

        policy-statement "allow only mpls and add SOO" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "vxlan"
                    }
                }
                action {
                    action-type reject
                }
            }
            entry 20 {
                from {
                    family [evpn]
                }
                action {
                    action-type accept
                    community {
                        add ["SOO-DCGW-23"]
                    }
                }
            }
        }

/* In the same way, "allow only vxlan and add SOO" avoids sending EVPN-MPLS routes
to the VXLAN network and marks the EVPN routes with a Site-Of-Origin extended
community that identifies the DC GW pair. */

        policy-statement "allow only vxlan and add SOO" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "mpls"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            action {
                action-type reject
            }
        }
        entry 20 {
            from {
                family [evpn]
            }
            action {
                action-type accept
                community {
                    add ["SOO-DCGW-23"]
                }
            }
        }
    }
```

The policies are applied at BGP group level, as follows:

```
# on PE-2, PE-3:
configure {
    router "Base" {
        bgp {
            ---snip---
            group "DC" {
                type internal
                import {
                    policy ["drop SOO-DCGW-23"]
                }
                export {
                    policy ["allow only vxlan and add SOO"]
                }
            }
            group "WAN" {
                type internal
                import {
                    policy ["drop SOO-DCGW-23"]
                }
                export {
                    policy ["allow only mpls and add SOO"]
                }
            }
            ---snip---
```

PE-4 and PE-5 use the same BGP peer policies, but using a Site Of Origin extended community identifying the PE-4/PE-5 pair instead of the PE-2/PE-3 pair:

```
# on PE-4, PE-5:
configure {
    policy-options {
        community "SOO-DCGW-45" {
            member "origin:64500:45" { }
        }
        community "mpls" {
            member "bgp-tunnel-encap:MPLS" { }
        }
        community "vxlan" {
            member "bgp-tunnel-encap:VXLAN" { }
        }
```

```
---snip---
```

Dual BGP instance VPLS service restrictions

When two BGP instances are enabled on the same VPLS service, the following considerations apply:

- SDP-bindings are not supported (therefore, no pw-template-binding is needed in the service). Any attempt to add an SDP-binding to a service with two BGP instances is blocked by the CLI, as follows:

```
*[ex:/configure service vpls "VPLS 1" spoke-sdp 21:1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" - multiple bgp-evpn instances not
 supported with local mesh or spoke sdp
```

- Services that are not supported: M-VPLS, I-VPLS, B-VPLS, or E-Tree VPLS.
- No IP prefix routes (route type 5) are supported on dual BGP-instance services.

```
*[ex:/configure service vpls "BD 30" bgp-evpn routes]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "BD 30" bgp-evpn routes ip-prefix advertise -
 ip-prefix advertise not supported with multiple bgp-evpn instances - configure service vpls
 "BD 30" bgp-evpn vxlan 1
MINOR: MGMT_CORE #4001: configure service vpls "BD 30" bgp-evpn mpls 2 - ip-prefix advertise
 not supported with non-default bgp instance - configure service vpls "BD 30" bgp-evpn
 routes ip-prefix advertise
```

- Proxy-ARP/ND is not supported.

```
*[ex:/configure service vpls "VPLS 1" proxy-arp]
A:admin@PE-2# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" proxy-arp - multiple bgp-evpn
 instances not supported with proxy-arp
```

- Although the Assisted-Replication feature is supported on dual BGP-instance VPLS services, the Assisted-Replication configuration is only relevant to the VXLAN destinations. See section EVPN route handling in dual BGP-instance VPLS services for some considerations about how EVPN handles IMET AR routes.

In addition to the preceding restrictions, some commands have a specific behavior when two BGP instances are configured:

- **configure service vpls bgp-evpn routes mac-ip advertise <boolean>** enables or disables the re-advertisement of MAC/IP routes in a BGP instance for MAC addresses that have been learned in the other BGP instance in the service.
- **configure service vpls bgp-evpn routes mac-ip unknown-mac <boolean>** enables or disables the advertisement of the unknown MAC route (MAC 00:..:00) on the BGP-EVPN VXLAN instance. The unknown MAC route is never sent to the BGP-EVPN MPLS instance.

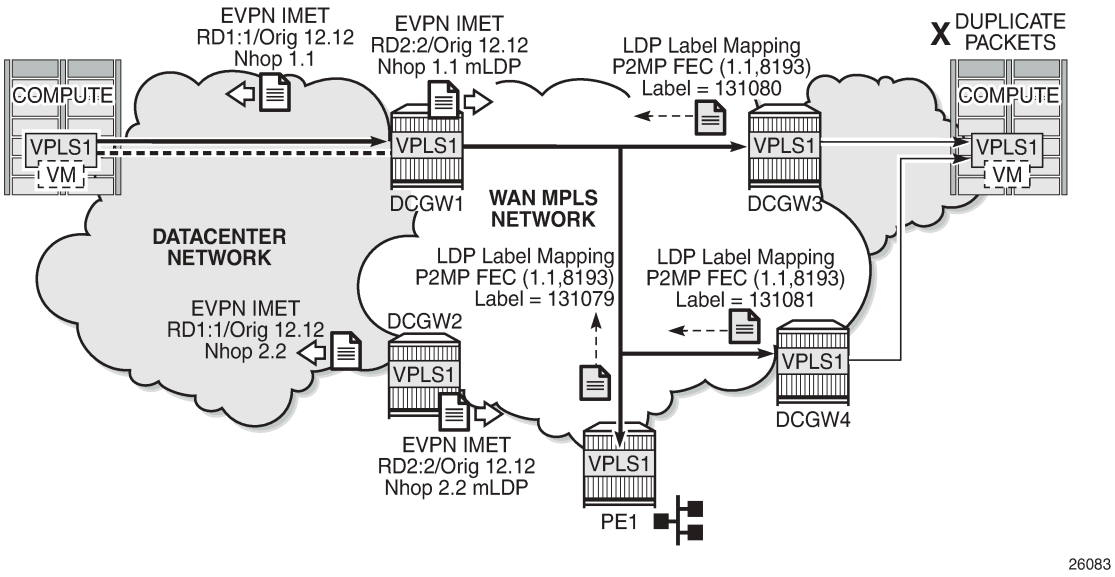
The use of provider tunnels on multi-homed anycast solutions

The use of provider tunnels in dual BGP-instance VPLS services connecting multiple DCs is not recommended. Figure 173: Use of provider-tunnels between anycast DC GWs create packet duplication shows the case where the same BGP-EVPN service is configured in redundant anycast DC GWs and

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

mLDP is used in the MPLS instance. In this case, packet duplication may occur if the configuration is not done carefully.

Figure 173: Use of provider-tunnels between anycast DC GWs create packet duplication



When mLDP is used along with multiple anycast multi-homing DC GWs to send BUM traffic to remote PEs, but no BUM traffic between DCs is needed, the same originating IP must be used on all the DC GWs; otherwise, packet duplication may happen. In the example in Figure 173: Use of provider-tunnels between anycast DC GWs create packet duplication, each pair of DC GWs, DCGW1/DCGW2 and DCGW3/DCGW4, is configured with a different originating IP (**configure service vpls bgp-evpn incl-mcast-orig-ip**):

- DCGW3 and DCGW4 receive the IMET route with the same route key from DCGW1 and DCGW2.
- DCGW3 and DCGW4 select only one route, which usually is the same; for example, the DCGW1 IMET route.
- Because of that, both DCGW3 and DCGW4 join the mLDP tree with root in DCGW1, creating packet duplication when DCGW1 sends BUM traffic.
- Remote PE nodes with a single MPLS instance join the mLDP tree without any issue.

To avoid the packet duplication shown by the example of Figure 173: Use of provider-tunnels between anycast DC GWs create packet duplication, the same originating IP may be configured in the four DCGWs, while the RD is still different per pair. By doing that:

- In the example of Figure 173: Use of provider-tunnels between anycast DC GWs create packet duplication, DCGW3 and DCGW4 never join any mLDP tree sourced from DCGW1 or DCGW2. This prevents any packet duplication because a router ignores IMET routes received with its own originating IP, regardless of the RD.
- PE-1 (a remote EVPN-MPLS PE) still joins the mLDP trees from the two DCs.
- The preceding configuration allows the use of mLDP as long as no BUM traffic is required between the two DCs. If BUM traffic is required between DCs, IR must be used.

Troubleshooting and debugging

The following show and debug commands can be used in dual BGP-instance VPLS services:

- show router bgp routes evpn (and filters)
- show service evpn-mpls [<TEP IP address>]
- show service vxlan [<TEP IP address>]
- show service id bgp-evpn
- show service id evpn-mpls (and modifiers)
- show service id vxlan destinations
- debug router bgp update (in classic CLI)
- show log log-id 99

See chapter EVPN for MPLS Tunnels and EVPN for VXLAN Tunnels (Layer 2) for a detailed description of these commands.

Also, in dual BGP-instance VPLS services, the **show service id bgp <bgp-instance>** command may help see the BGP parameters of each individual BGP instance:

```
[/]
A:admin@PE-2# show service id 1 bgp ?

 bgp [<number>]

 [bgp-instance] <number>
 <number>  - <1..2>

    <number> - <1..2>
```

```
[/]
A:admin@PE-2# show service id "VPLS 1" bgp 1

Conclusion

As service providers deploy EVPN-MPLS in the network for Ethernet local area network (E-LAN) and Ethernet point-to-point (E-Line) services, the use of EVPN-MPLS to interconnect data centers is becoming a popular option. Based on RFC 9014, SR OS supports the connectivity of Layer 2 EVPN-VXLAN services to an EVPN-MPLS network. To implement that EVPN-MPLS Data Center Interconnect (DCI) solution, VPLS services support dual BGP instances, where EVPN-VXLAN and EVPN-MPLS can coexist simultaneously in the same VPLS service. This chapter describes the configuration of such dual BGP-instance VPLS services and how to deploy them in a redundant anycast DC GW configuration.

EVPN-VXLAN VPWS

This chapter provides information about EVPN-VXLAN VPWS.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 16.0.R7, but the MD-CLI in the current edition is based on SR OS Release 21.5.R2.

Overview

Some service providers use VXLAN as a next-generation access technology between Multi-Service Access Node (MSAN) PE and core PE routers. VXLAN allows any IP router in the aggregation core and provides a simple alternative to MPLS. Static VXLAN bindings can be used when the MSAN PEs do not support any control plane. However, EVPN offers a control plane protocol for the VXLAN bindings for faster convergence and fault propagation. In this chapter, the focus is on EVPN-VPWS, which provides a lighter control plane compared to full-blown EVPN when point-to-point services need to be extended to the Data Center (DC).

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, including support of Equal Cost Multi-Path (ECMP), and EVPN All-Active (AA) and Single-Active (SA) Multi-Homing (MH). The configuration resembles the EVPN-MPLS Epipe configuration, as described in the EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS) chapter. As an example, the following configures EVPN-VXLAN Epipe 4 with SA MH.

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ES45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:04
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 460 {
                            }
                        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
    }
    epipe "Epipe-4" {
        admin-state enable
        service-id 4
        customer "1"
        bgp 1 {
        }
        spoke-sdp 460:4 {
        }
        vxlan {
            instance 1 {
                vni 4
            }
        }
        bgp-evpn {
            evi 4
            local-attachment-circuit "AC-45" {
                eth-tag 145
            }
            remote-attachment-circuit "AC-23" {
                eth-tag 123
            }
            vxlan 1 {
                admin-state enable
                vxlan-instance 1
                ecmp 2
            }
        }
    }
    sdp 460 {
        admin-state enable
        description "GRE SDP for SA MH"
        far-end {
            ip-address 192.0.2.6
        }
    }
```

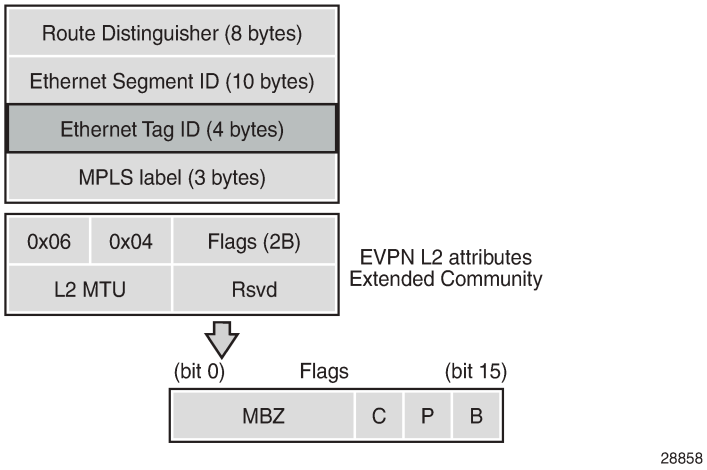
The SDP is a GRE SDP, because no MPLS is configured in the network. The VNI is 4, and the local Attachment Circuit (AC) name is "AC-45" with Ethernet tag 145, whereas the remote AC name is "AC-23" with Ethernet tag 123. An ES can contain up to four nodes. Each of these nodes will have the same local Ethernet tag.

On Epipe services, the BGP instance is 1 and the VXLAN instance is 1. ECMP is configured with a value of 2, so the traffic flows can be sprayed over two paths with equal cost (a value greater than 2 can be configured if aliasing to more than two nodes is needed). By default, **send-tunnel-encap** is enabled, which determines whether the RFC 5512 encapsulation extended community is sent with VXLAN value (if enabled) or not sent.

EVPN-VPWS uses BGP-EVPN route type 1 (autodiscovery (AD) per-EVI routes and AD per-ES routes) and route type 4 (Ethernet Segment (ES) routes); it does not use route types 2 (MAC/IP routes), 3 (Inclusive Multicast routes), or 5 (IP Prefix routes). Figure 174: BGP-EVPN AD per-EVI route shows the fields in a BGP-EVPN AD per-EVI route.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 174: BGP-EVPN AD per-EVI route



The Route Distinguisher (RD) is encoded as specified in RFC 7432; in this example, the system IP address is followed by the service ID, such as 192.0.2.2:1 for Epipe 1 on PE-2. The MPLS label field is encoded as the VXLAN Network Identifier (VNI) and the Ethernet tag field defines the local Attachment Circuit (AC) ID. The ES ID (ESI) is the 10 bytes configured ESI for MH and equals zero for single-homed services.

The EVPN L2 attributes extended community has type 0x06 (EVPN) and subtype 0x04 (EVPN L2 attributes). The flags are defined as follows:

- Flag C (control word) is set if control word is configured in the service. For EVPN-MPLS VPWS, the control word can be configured in the **bgp-evpn>mpls** context, but for EVPN-VXLAN VPWS, the control word cannot be configured in the **bgp-evpn>vxlan** context, so flag C is always zero (C=0).
- Flag P (primary) is set in MH scenarios: all nodes in an AA MH ES send P=1, but in an SA MH ES, only the Designated Forwarder (DF) sends P=1, while the NDFs send P=0. In single-homed scenarios, all nodes send P=0.
- Flag B (backup) is set in SA MH scenarios: the NDF that will take the primary role after the original primary node has failed is the backup, so it sends B=1. All other NDFs have B=0. In AA MH scenarios, all nodes send B=0. Also, in single-homed scenarios, all nodes except for the backup DF send B=0.

If the received L2 MTU does not match the configured service MTU, the EVPN binding is not set up. However, if the received L2 MTU is zero, the MTU is ignored.

AD per-EVI routes are responsible for aliasing. The following BGP update shows an AD per-EVI route received from DF 192.0.2.4 (PE-4) in an SA MH ES with ESI 01:00:00:00:00:45:00:00:00:04, Ethernet tag 145 for the local AC on PE-4, and MPLS label 4 for Epipe 4. The primary flag is set: P=1.

```

```

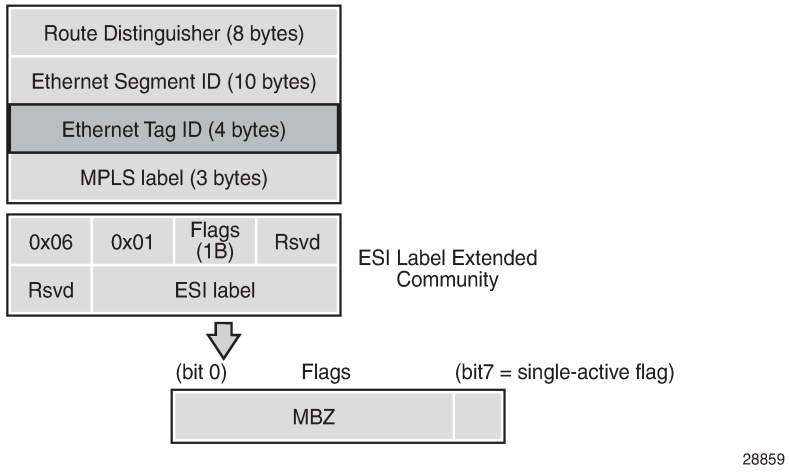
As per RFC 8214, in an AD per-ES route, the Ethernet tag is MAX-ET (all bits are set), the MPLS label is zero, and the BGP extended community contains the single-active flag (1 for SA and 0 for AA) and ESI label. Figure 175: BGP-EVPN AD per-ES route shows the fields in a BGP-EVPN AD per-ES route.

Figure 175: BGP-EVPN AD per-ES route



The following AD per-ES route is received by PE-2 from PE-4, which is in an SA MH ES with ESI 01:00:00:00:00:45:00:00:00:04.

```

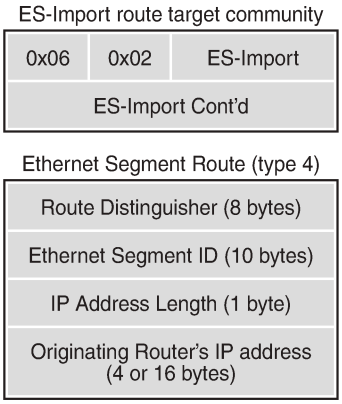
Figure 176: BGP-EVPN ES route shows a BGP-EVPN route type 4 (ES route) that is used for MH ES discovery and DF election.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 176: BGP-EVPN ES route



The RD is taken from the system level RD; by default, the RD is derived as system-IP:0, such as 192.0.2.4:0 for PE-4. The ESI contains the 10-byte identifier as configured in the ES. The ES import route target community has type 0x06 (EVPN) and subtype 0x02 (ES import route target), and is derived from the MAC address portion of the ESI. This extended community is treated as a route target, such as: target:00:00:00:00:45:00. Only the PEs attached to the ES will import the ES route.

The following BGP update shows a BGP-EVPN ES route sent by PE-4. The RD is defined as 192.0.2.4:0, the ESI is 01:00:00:00:00:45:00:00:00:04, and the originating IP address is 192.0.2.4 for PE-4. The ES import route target is target:00:00:00:00:45:00.

```

```

By default, the system IP addresses are used for the VXLAN tunnel termination. However, it is possible to use non-system IPv4 or IPv6 termination for EVPN-VXLAN VPWS, both for single-homed and multi-homed services. In that case, Forwarding Path Extension (FPE) needs to be defined with VXLAN termination, as described in chapter Static VXLAN Termination in Epipe Services.

The following shows the configuration of the single-homed Epipe 2 using non-system IPv4 source VXLAN Tunnel Endpoint (VTEP) 10.0.3.1 on PE-3. Likewise, it is possible to use a non-system IPv6 source VTEP, such as **vxlan>source-vtep 2001::3:1**. Unlike the source VTEP, the egress VTEP cannot be configured when BGP-EVPN is enabled. The egress VTEP is dynamically learned via BGP instead.

```
# on PE-3:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:2 {
            }
            vxlan {
                source-vtep 10.0.3.1
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-3" {
                    eth-tag 103
                }
                remote-attachment-circuit "AC-5" {
                    eth-tag 105
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

Configuration

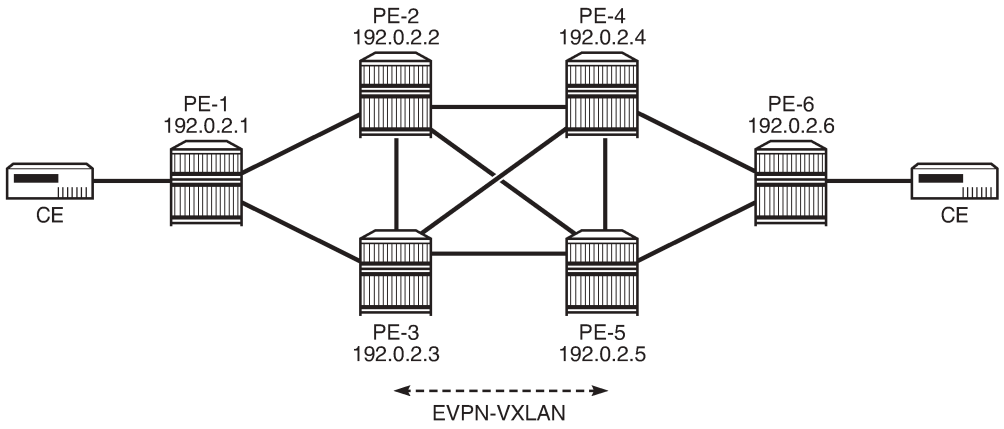
The following use cases are included in the configuration section:

- Single-homed EVPN-VXLAN Epipe using IPv4 system addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using IPv4 system addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses
- AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

Figure 177: Example topology shows the example topology with six PEs. EVPN-VXLAN Epipe services will be configured on the core PEs PE-2, PE-3, PE-4, and PE-5. On the access nodes PE-1 and PE-6, ordinary Epipe services will be configured, without EVPN-VXLAN. The CEs are emulated by VPRN services configured on PE-1 or PE-6.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 177: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS on all router interfaces: level 2 between the core PEs and level 1 in the access networks

No MPLS protocol is configured.

BGP is configured on the core PEs for the EVPN address family with RR PE-2. The BGP configuration on RR PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-update {
                evpn true
            }
            group "iBGP" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "iBGP"
            }
            neighbor "192.0.2.4" {
                group "iBGP"
            }
```

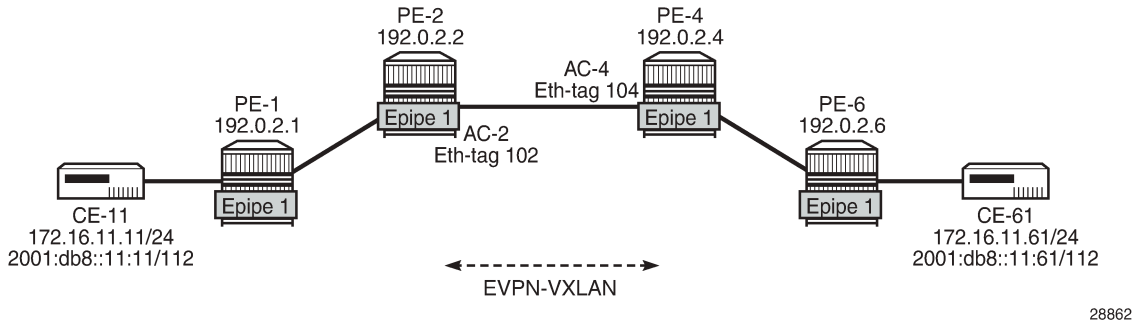
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            neighbor "192.0.2.5" {
                group "iBGP"
            }
```

Single-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 178: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses shows the routers PE-1, PE-2, PE-4, and PE-6 configured with Epipe 1. VXLAN-EVPN is only configured on the core PEs PE-2 and PE-4.

Figure 178: Single-homed EVPN-VXLAN Epipe 1 using system IP addresses



Configuration of Epipe 1

On PE-1, Epipe 1 is configured without EVPN-VXLAN, as follows.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/1:1 {
            }
            sap 1/2/1:1 {
            }
        }
```

On PE-2, Epipe 1 is configured with EVPN-VXLAN. The local AC "AC-2" has Ethernet tag 102 and the remote AC is "AC-4" with Ethernet tag 104, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/2:1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "AC-2" {
                    eth-tag 102
                }
                remote-attachment-circuit "AC-4" {
                    eth-tag 104
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The Epipe configuration on PE-4 is similar, but the local AC and remote AC are swapped, as follows. Instead of a SAP, a spoke-SDP is configured toward PE-6. The SDP itself is GRE-based.

```
# on PE-4:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            spoke-sdp 46:1 {
            }
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "AC-4" {
                    eth-tag 104
                }
                remote-attachment-circuit "AC-2" {
                    eth-tag 102
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 46 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

On PE-6, Epipe 1 is an ordinary Epipe with spoke-SDP 64:1 toward PE-4 and SAP 1/2/1:1 toward a CE, as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 64:1 {
            }
            sap 1/2/1:1 {
            }
        }
        sdp 64 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.4
            }
        }
```

Verification

VPRN 11 on PE-1 and PE-6 simulates the CEs CE-11 and CE-61. The connectivity between the CEs can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.11.61 router-instance "VPRN 11" interval 0.1
                                                              output-format summary
PING 172.16.11.61 56 data bytes
!!!!!
---- 172.16.11.61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.42ms, avg = 5.89ms, max = 10.9ms, stddev = 2.49ms
```

```
[/]
A:admin@PE-1# ping 2001:db8::11:61 router-instance "VPRN 11" interval 0.1
                                                              output-format summary
PING 2001:db8::11:61 56 data bytes
!!!!!
---- 2001:db8::11:61 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.14ms, avg = 5.63ms, max = 11.2ms, stddev = 2.79ms
```

On PE-2, the VXLAN destination for Epipe 1 is the system address of PE-4: 192.0.2.4, as follows. There are no VXLAN ES destinations for Epipe 1, because the service is single-homed.

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

PE-2 has received the following BGP-EVPN AD per-EVI route with RD 192.0.2.4:1 and Ethernet tag 104 from PE-4. Epipe 1 is single-homed, so ESI=0 and there is no primary or backup node (P=B=0). Also, no control word is used, so C=0.

```

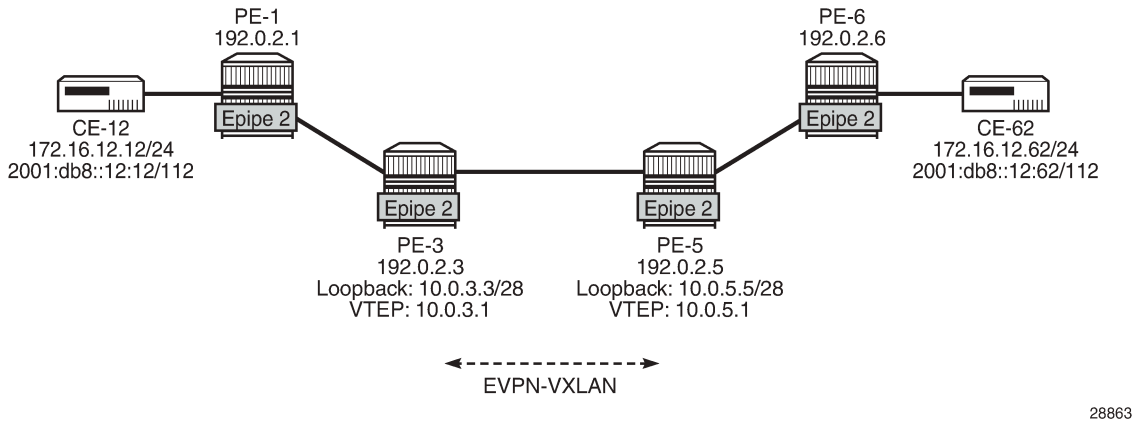
Single-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 179: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses shows the single-homed service Epipe 2 configured on PE-1, PE-3, PE-5, and PE-6. On PE-3, a loopback interface is created in the base router with IPv4 address 10.0.3.3/28. Epipe 2 uses VXLAN termination 10.0.3.1 from the same subnet.

Figure 179: Single-homed EVPN-VXLAN Epipe 2 using non-system IP addresses



Configuration of Epipe 2

On PE-1 and PE-6, the configuration of Epipe 2 is similar to the configuration of Epipe 1.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-3, FPE needs to be configured using PXC, as described in chapter Static VXLAN Termination in Epipe Services. The following configuration is included without further explanation about FPE or PXC. The same configuration is required on PE-5.

```
# on PE-3:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            encap-type dot1q
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port-xc {
        pxc 1 {
            admin-state enable
            port 1/2/5
        }
    }
```

On PE-3, the following loopback interface is created and IS-IS is enabled on it. The subnet must allow multiple IP addresses; one other IP address from the subnet will be defined as VXLAN tunnel termination. The IPv6 address is only required in the next use-case, but this configuration will not be repeated in that section.

```
# on PE-3:
configure {
    router "Base" {
        interface "lo1" {
            loopback
            ipv4 {
                primary {
                    address 10.0.3.3
                    prefix-length 28
                }
            }
            ipv6 {
                address 2001::3:3 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    prefix-length 124
                }
            }
        }
        isis 0 {
            interface "lo1" {
                passive true
            }
        }
```

Up to three VXLAN tunnel terminations can be defined per system. On PE-3, the following two VXLAN tunnel terminations are configured. For Epipe 2, only the first VXLAN tunnel termination is required; the second (IPv6) VXLAN tunnel termination is used in Epipe 3. The VXLAN tunnel termination is used as VXLAN source VTEP in Epipe 2. No egress VTEP can be defined when BGP-EVPN is configured in the service; egress VTEPs are configured in static VXLAN tunnels instead.

```
# on PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.3.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::3:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:2 {
            }
            vxlan {
                source-vtep 10.0.3.1
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-3" {
                    eth-tag 103
                }
                remote-attachment-circuit "AC-5" {
                    eth-tag 105
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration on PE-5 is similar. The following is the service configuration on PE-5.

```
# on PE-5:
configure {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        system {
            vxlan {
                tunnel-termination 10.0.5.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::5:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            spoke-sdp 56:2 {
            }
            vxlan {
                source-vtep 10.0.5.1
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-5" {
                    eth-tag 105
                }
                remote-attachment-circuit "AC-3" {
                    eth-tag 103
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 56 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

It is possible to use a system IPv4 address as a VXLAN tunnel termination on one of the nodes and a non-system IPv4 address on another, but that is not configured here.

Verification

The connectivity between the CEs that are emulated by VPRN 12 can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.12.62 router-instance "VPRN 12" interval 0.1
                                                        output-format summary
PING 172.16.12.62 56 data bytes
!!!!!
---- 172.16.12.62 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
round-trip min = 4.31ms, avg = 4.67ms, max = 5.13ms, stddev = 0.268ms
```

```
[/]
A:admin@PE-1# ping 2001:db8::12:62 router-instance "VPRN 12" interval 0.1
                                                                output-format summary
PING 2001:db8::12:62 56 data bytes
!!!!!
---- 2001:db8::12:62 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 4.39ms, avg = 4.84ms, max = 5.20ms, stddev = 0.276ms
```

On PE-3, the VXLAN destination for Epipe 2 is the non-system address 10.0.5.1 on PE-5, as follows:

```
[/]
A:admin@PE-3# show service id 2 vxlan destinations

Single-homed EVPN-VXLAN Epipe using non-system IPv6 addresses

Figure 180: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses shows the example topology for single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses for VXLAN tunnel termination.

Figure 180: Single-homed EVPN-VXLAN Epipe 3 using non-system IPv6 addresses

Configuration of Epipe 3

The following single-homed Epipe 3 using non-system IPv6 addresses for the VXLAN tunnel terminations is configured on PE-3.

```
# on PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.3.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::3:1 {
                    fpe-id 1
                }
            }
        }
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
            }
            sap 1/1/1:3 {
            }
            vxlan {
                source-vtep 2001::3:1
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-3_v6" {
                    eth-tag 163
                }
                remote-attachment-circuit "AC-5_v6" {
                    eth-tag 165
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The service configuration on PE-5 is similar, as follows:

```
# on PE-5:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.5.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::5:1 {
                    fpe-id 1
                }
            }
```

© 2026 Nokia.

```
        }
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
            }
            spoke-sdp 56:3 {
            }
            vxlan {
                source-vtep 2001::5:1
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-5_v6" {
                    eth-tag 165
                }
                remote-attachment-circuit "AC-3_v6" {
                    eth-tag 163
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
        sdp 56 {
            admin-state enable
            description "GRE SDP for single-homing"
            far-end {
                ip-address 192.0.2.6
            }
        }
```

Verification

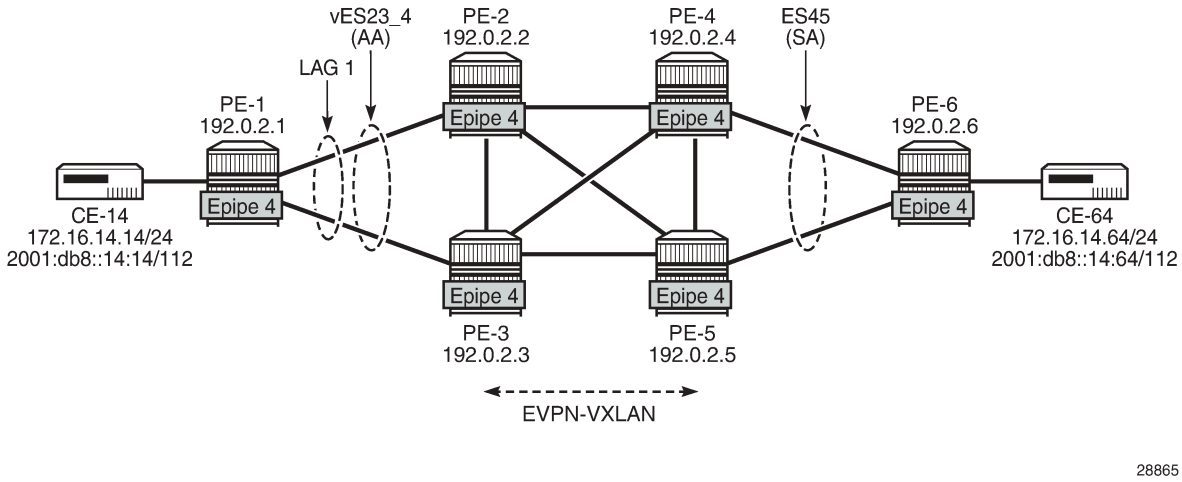
AA and SA multi-homed EVPN-VXLAN Epipe using system IPv4 addresses

Figure 181: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 4 with AA MH ES "vES23_4" between PE-2 and PE-3 and SA MH ES "ES45" between PE-4 and PE-5.

Figure 181: EVPN-VXLAN Epipe 4 with AA MH and SA MH using system IPv4 addresses



Configuration of Epipe 4

On PE-1, Epipe 4 is configured as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            sap 1/2/1:4 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap lag-1:4 {
            }
        }
```

On PE-2 and PE-3, the AA MH ES "vES23_4" is configured as a virtual ES for LAG 1 and dot1q-tag 4, so it only affects Epipe 4.

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_4" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:00:00:00:04
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 4 {
                                            end 4
                                        }
                                    }
                                }
                            }
                        }
                    }
```

On PE-2 and PE-3, Epipe 4 is configured as follows. The system IPv4 address is used as VXLAN termination, the local AC Ethernet tag is 123, and the remote AC Ethernet tag is 145.

```
# on PE-2, PE-3:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
            }
            sap lag-1:4 {
            }
            vxlan {
                instance 1 {
                    vni 4
                }
            }
            bgp-evpn {
                evi 4
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-45" {
                    eth-tag 145
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

On PE-4 and PE-5, the SA MH ES "ES45" is configured with a GRE SDP toward PE-6: SDP 460 on PE-4 and SDP 560 on PE-6. The following is the configuration of "ES45" on PE-4:

```
# on PE-4:
configure {
    service {
        sdp 460 {
            admin-state enable
            description "GRE SDP for SA MH"
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ES45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:04
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 460 {
                            }
                        }
                    }
                }
            }
        }
```

On PE-4, Epipe 4 is configured as follows. The configuration on PE-5 is similar, but with spoke-SDP 560:4 instead.

```
# on PE-4:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
            }
            spoke-sdp 460:4 {
            }
            vxlan {
                instance 1 {
                    vni 4
                }
            }
            bgp-evpn {
                evi 4
                local-attachment-circuit "AC-45" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    eth-tag 145
                }
                remote-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

On PE-6, Epipe 4 is configured as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe-4" {
            admin-state enable
            description "Epipe-4 with active/standby pseudowire"
            service-id 4
            customer "1"
            endpoint "EP" {
            }
            spoke-sdp 640:4 {
                endpoint {
                    name "EP"
                }
            }
            spoke-sdp 650:4 {
                endpoint {
                    name "EP"
                }
            }
            sap 1/2/1:4 {
            }
        }
```

Verification

The connectivity between the CEs emulated by VPRN 14 can be verified as follows:

```
[/]
A:admin@PE-1# ping 172.16.14.64 router-instance "VPRN 14" interval 0.1
                                                              output-format summary
PING 172.16.14.64 56 data bytes
!!!!!

In AA MH ESs, the DF for VPLS services is the forwarder for Broadcast, Unknown unicast, and Multicast (BUM) traffic. In Epipes, however, all traffic is treated as unicast. The following tools commands on PE-2 and PE-3 show that DF is not applicable for AA MH ES "vES23_4.

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vES23_4" evi 4 df

[06/30/2021 17:33:54] All Active VPWS - DF N/A
```

```
[/]
A:admin@PE-3# tools dump service system bgp-evpn ethernet-segment "vES23_4" evi 4 df

[06/30/2021 17:33:56] All Active VPWS - DF N/A
```

The following command on PE-2 shows no DF candidates for ES "vES23_4", even though PE-2 (as well as PE-3) is considered as DF (DF=yes):

```
[/]
A:admin@PE-2# show service system bgp-evpn ethernet-segment name "vES23_4" evi evi-1 4

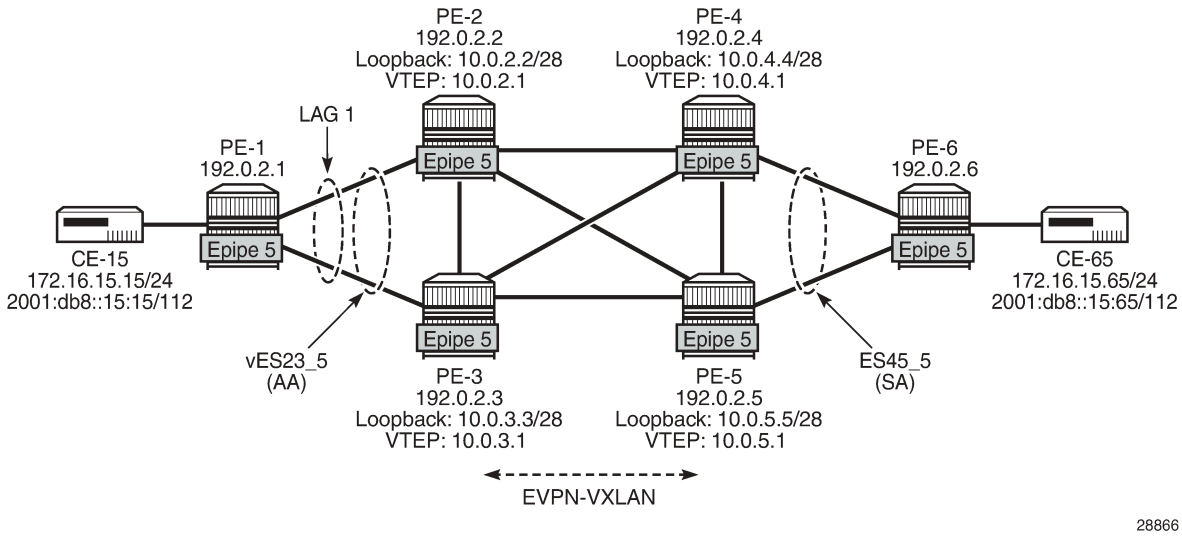
AA and SA multi-homed EVPN-VXLAN Epipe using non-system IPv4 addresses

Figure 182: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses shows the example topology for EVPN-VXLAN Epipe 5 with AA MH ES "vES23_5" between PE-2 and PE-3 and SA MH ES "ES45_5" between PE-4 and PE-5.

Figure 182: EVPN-VXLAN Epipe 5 with AA MH and SA MH using non-system IPv4 addresses



The configuration of Epipe 5 on PE-1 is similar to the configuration of Epipe 4 on PE-1, so it is not shown here. The same applies for Epipe 5 on PE-6.

On PE-2, VTEP 10.0.2.1 is used instead of the system IP address. The ES must include two additional parameters for the DF selection: **orig-ip** and **route-next-hop**, which are both equal to the VTEP. Without these parameters, the DF selection will not work. The **orig-ip** command modifies the originator IP address of the ES route and the **route-next-hop** modifies the next-hop of the AD per-ES routes for the ES. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 10.0.2.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::2:1 {
                    fpe-id 1
                }
            }
            bgp {
                evpn {
                    ethernet-segment "vES23_5" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:00:00:00:05
                        orig-ip 10.0.2.1
                        route-next-hop 10.0.2.1
                        multi-homing-mode all-active
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    dot1q {
                                        q-tag 5 {
                                            end 5
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
        epipe "Epipe-5" {
            admin-state enable
            service-id 5

```
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    ecmp 2
                }
            }
        }
```

The service configuration on PE-3 is similar.

On PE-4, the service configuration is as follows:

```
# on PE-4:
configure {
    service {
        sdp 465 {
            admin-state enable
            description "GRE SDP for SA MH_Epipe5"
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            vxlan {
                tunnel-termination 10.0.4.1 {
                    fpe-id 1
                }
                tunnel-termination 2001::4:1 {
                    fpe-id 1
                }
            }
            bgp {
                evpn {
                    ethernet-segment "ES45_5" {

            }
        }
```

Conclusion

EVPN-VXLAN VPWS is similar to EVPN-MPLS VPWS, and can be used in networks without MPLS.

Flow-Aware Transport (FAT) Label Signaling in L2VPN and EVPN Services

This chapter provides information about Flow-Aware Transport (FAT) label signaling in BGP Layer 2 services and BGP EVPN services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and the configuration in this chapter are based on SR OS Release 24.3.R1. FAT label signaling in BGP VPLS and BGP VPWS is supported in SR OS Release 22.10.R2 and later. FAT label signaling in EVPN VPLS and EVPN VPWS is supported in SR OS Release 23.10.R1 and later.

Overview

Some operators require the use of the FAT label, also known as the hash label, as an alternative to entropy label in order to interoperate with other vendors. The hash label adds entropy to divisible flows and creates load-balancing for unicast flows in the network. The hash label uses only one additional label, whereas the entropy label adds two labels: the entropy label indicator and the entropy label itself, as described in the *Entropy Label* chapter in the *7450 ESS, 7750 SR, 7950 XRS, and VSR MPLS Advanced Configuration Guide for MD CLI*. The hash label is mutually exclusive with the entropy label. The hash label works end-to-end regardless of the transport tunnels. The packet sequencing is preserved because one hash label is used per flow.

Besides the hash label itself, SR OS nodes can signal the capability of transmitting or receiving the hash label using the following control flags:

- the T and R control flags as per RFC 8395 in BGP L2VPN routes
- the F control flag as per RFC 7342bis in BGP EVPN routes.

Hash label signaling in BGP VPLS and BGP VPWS services

Figure 184: Control flags in the layer 2 extended community shows the control flags in the Layer 2 extended community, with T for transmit capability and R for receive capability for the hash label. The C and S control flags are beyond the scope of this chapter.

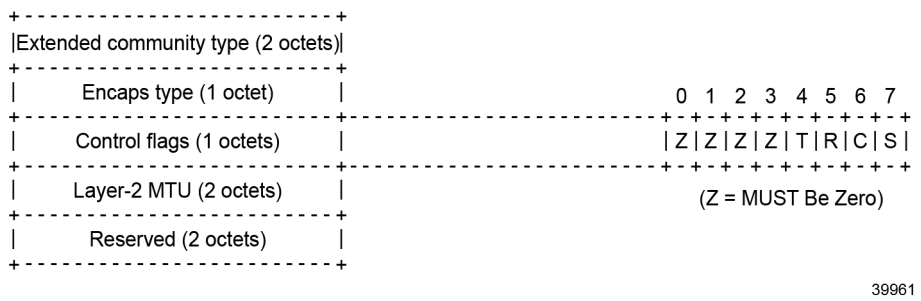
Use subject to Terms available at: www.nokia.com/terms.

Figure 184: Control flags in the layer 2 extended community



RFC 8395 extends the BGP L2VPN route signaling to indicate the capability of a node to send and receive the hash label at the bottom of the stack on a per pseudowire (PW) basis. BGP VPLS and BGP VPWS services use PW templates, that can be configured with the **hash-label** attribute with or without the **signal-capability** option.

```
*[ex:/configure service pw-template "PW-2-hash-label-only"]
A:admin@PE-1# hash-label ?

 hash-label

 signal-capability     - Signal hash label capability to the remote PE
```

Note: The **hash-label [signal-capability]** command is also used to signal the hash label in TLDP SDP bindings, but the scope of this section is hash label signaling in BGP L2VPN routes.

When the PW template is configured with **hash-label** only, the control flags are signaled as T=R=0 (Flags=none) and the hash label is sent and expected to be received in all the packets.

When the PW template is configured with **hash-label signal-capability**, the control flags are signaled as T=R=1. The dynamic signaling of the capability to transmit or receive hash labels is required in mixed environments where different vendors in the same service may support the hash label or not.

For example, PE-1 signals T=R=1 to PE-2 and PE-2 signals T=R=0 to PE-1. When PE-1 receives the information that PE-2 is not capable of transmitting or receiving hash labels, PE-1 sends packets without a hash label to PE-2 and PE-1 expects packets without a hash label from PE-2. If PE-2 sends packets with a hash label while PE-2 signaled T=R=0, PE-1 drops these packets.

In principle, it is possible that a node signals different values for the T and R flag, for example, T=1 and R=0 (or T=0 and R=1), but in either case, no traffic is possible toward such a node. SR OS does not support hash label asymmetry between peers. If peer PE-3 signals R=1 to PE-1, PE-1 sends packets with a hash label to PE-3 and expects packets with hash label from PE-3, regardless of the value of the received T flag. PE-1 drops packets without a hash label received from PE-3. If peer PE-4 signals R=0 to PE-1, PE-1 sends packets without a hash label to PE-4 and PE-1 expects packets without a hash label from PE-4. PE-1 drops packets with a hash label received from PE-4.

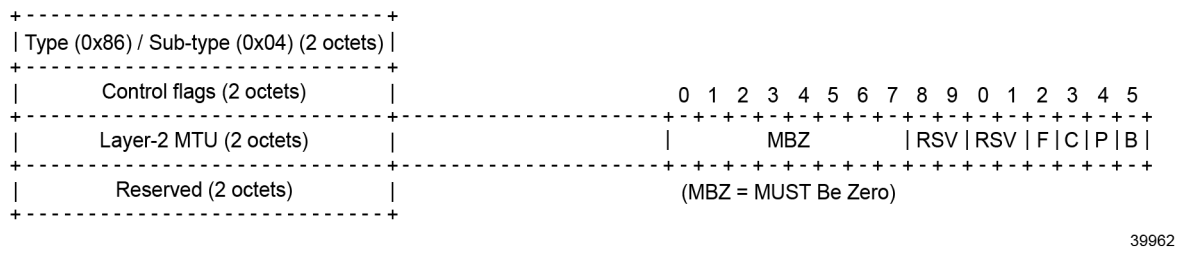
Hash label signaling in EVPN VPLS and EVPN VPWS services

Figure 185: Control flags in the EVPN Layer 2 attributes community shows the control flags in the EVPN Layer 2 attributes community, with F for the presence of a flow label. The C control flag is used for the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

presence of a control word and C=1 in one of the configuration examples in this chapter; the P and B control flags are described in the EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS) chapter.

Figure 185: Control flags in the EVPN Layer 2 attributes community



When the F-bit is set to 1, the PE announces the capability of both sending and receiving hash labels for unicast.

The following command enables the hash label in an EVPN VPWS service:

```
configure {
    service {
        epipe "EVPN-VPWS-4" {
            bgp-evpn {
                mpls 1 {
                    hash-label true
```

The following command enables the hash label in an EVPN VPLS service:

```
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                mpls 1 {
                    ingress-replication-bum-label true
                    hash-label true
```

The following error message is raised when attempting to enable the hash label in an EVPN VPLS service without **ingress-replication-bum-label**:

```
*[ex:/configure service vpls "EVPN-VPLS-3" bgp-evpn mpls 1]
A:admin@PE-1# commit
MINOR: MGMT_CORE #3001: configure service vpls "EVPN-VPLS-3" bgp-evpn mpls 1 ingress-
replication-bum-label - hash-label cannot be configured without ingress-replication-bum-label
```

The **configure service vpls <..> bgp-evpn routes incl-mcast advertise-l2-attributes true** command enables the advertisement of the EVPN Layer 2 attributes enhanced community in Inclusive Multicast Ethernet Tag (IMET) routes for the EVPN VPLS:

```
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-l2-attributes true
                    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
```

For EVPN VPWS services, the Layer 2 attributes are signaled in the AD per-EVI routes. No IMET routes are sent for EVPN VPWS services, so the preceding command is not supported in Epipes.

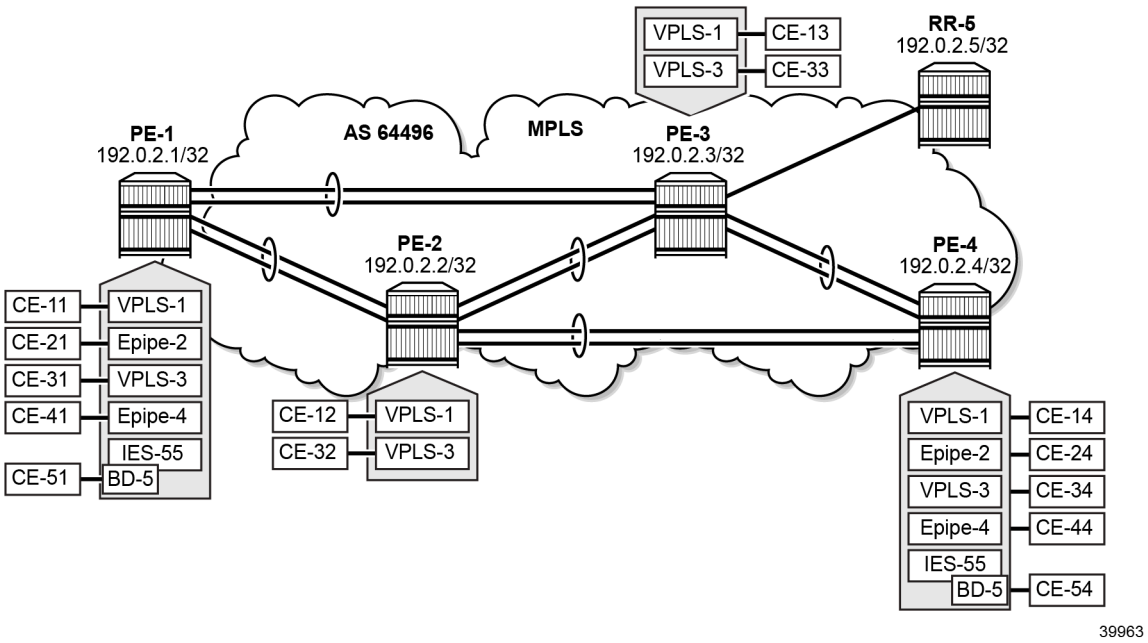
When a node receives an IMET (for EVPN VPLS) or a BGP-EVPN AD per-EVI (for EVPN-VPWS) route that contains the F bit, the node compares the received F bit with the local configuration for the hash label. In case of a mismatch, the node brings down the EVPN destination in case of EVPN VPLS or removes the EVPN destination in case of EVPN VPWS.

Besides the F flag, the Layer 2 attributes community also includes the service MTU and the control word. A node compares the received MTU with the local service MTU. In case of an MTU mismatch, the node brings down the EVPN destination in case of EVPN VPLS or removes the EVPN destination in case of EVPN VPWS, unless the **ignore-mtu-mismatch true** command is configured. The control word flag C is set by the advertising PE when the **control-word true** command is configured in the service. A node compares the received C flag with the local configuration. In case of a mismatch, the node brings down the EVPN destination in case of EVPN VPLS or removes the EVPN destination in case of EVPN VPWS.

Configuration

Figure 186: Example topology shows the example topology with four PEs and one route reflector (RR) in AS 64496.

Figure 186: Example topology



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- ECMP = 2 in the base router of all PEs

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- IS-IS between all nodes
- LDP between all PEs, not toward the RR

In this section, the following will be described:

- Hash label signaling in BGP VPLS and BGP VPWS
  - BGP VPLS "BGP-VPLS-1"
  - BGP VPWS "BGP-VPWS-2"
- Hash label signaling in EVPN VPLS and EVPN VPWS
  - EVPN VPLS "EVPN-VPLS-3
  - EVPN VPWS "EVPN-VPWS-4"
  - EVPN R-VPLS "BD-5" in IES "IES-55"

Hash label signaling in BGP VPLS and BGP VPWS

BGP is configured for the L2VPN address family, as follows:

```
# on PE-1, PE-2, PE-3, PE-4;
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                l2-vpn true
            }
            group "internal" {
                peer-as 64496
            }
            neighbor "192.0.2.5" {    # RR-5
                group "internal"
                family {
                    l2-vpn true
                }
            }
```

In this section, three PW templates are used:

- PW template "PW-1" in BGP VPLS and BGP VPWS without hash label
- PW template "PW-2-hash-label-only" in BGP VPLS and BGP VPWS with hash label only
- PW template "PW-3-hash-label-sign" in BGP VPLS and BGP VPWS with hash label and hash label signaling

All of these PW templates are used on different nodes in Different hash label configuration in BGP-VPLS-1 on different nodes.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

BGP VPLS and BGP VPWS without hash label

PW template "PW-1" is configured with split-horizon-group (SHG) "SHG-1" but without hash label, as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    service {
        pw-template "PW-1" {
            pw-template-id 1
            split-horizon-group {
                name "SHG-1"
            }
        }
```

The following services on PE-1 use PW template "PW-1":

```
# on PE-1:
configure {
    service {
        vpls "BGP-VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"

```

PW template 1 does not have hash label enabled. The following command shows that the hash label is disabled on all SDPs in BGP-VPLS-1:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match Hash
Hash Label         : Disabled                Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Disabled
Hash Label         : Disabled                Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Disabled
Hash Label         : Disabled                Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Disabled
```

The following command shows that the hash label is disabled on the SDP in BGP-VPWS-2:

```
[/]
A:admin@PE-1# show service id 2 sdp detail | match Hash
Hash Label         : Disabled                Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Disabled
```

BGP VPLS and BGP VPWS with hash label only

The following command configures PW template "PW-2-hash-label-only" with SHG and hash label, but without hash label signaling capability:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    service {
        pw-template "PW-2-hash-label-only" {
            pw-template-id 2
            hash-label {
            }
            split-horizon-group {
                name "SHG-1"
            }
        }
```

The following command configures the BGP VPLS and BGP VPWS services with PW template 2 (instead of PW template 1):

```
# on PE-1:
configure {
    service {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        vpls "BGP-VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "192.0.2.1:1"
                route-target {
                    export "target:64496:1"
                    import "target:64496:1"
                }
                pw-template-binding "PW-2-hash-label-only" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 10
                ve {
                    name "PE-1"
                    id 1
                }
            }
            sap 1/1/c10/1:1 {
            }
        }
        epipe "BGP-VPWS-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "192.0.2.1:2"
                route-target {
                    export "target:64496:2"
                    import "target:64496:2"
                }
                pw-template-binding "PW-2-hash-label-only" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"
                    id 1
                }
                remote-ve "PE-4" {
                    id 4
                }
            }
            sap 1/1/c10/1:2 {
            }
        }
```

The configuration on the other PEs is similar. BGP-VPWS-2 is only configured on PE-1 and PE-4.

The following command shows that hash label is enabled, but the hash label signaling capability is disabled. The operational hash label is enabled only when both ends of the SDP have the hash label enabled.

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match Hash
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Enabled
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Enabled
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Enabled
```

```
[/]
A:admin@PE-1# show service id 2 sdp detail | match Hash
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Disabled
Oper Hash Label    : Enabled
```

The hash label signaling capability is disabled, so no T-bit or R-bit is advertised. The following shows that no flags are received in the L2VPN community for BGP-VPLS-1:

```
[/]
A:admin@PE-1# show router bgp routes l2-vpn community target:64496:1 detail | match Community
 post-lines 1
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
Community      : target:64496:1
                 l2-vpn/vrf-imp:Encap=19: Flags=none: MTU=1514: PREF=0
```

Similarly, no flags are received in the L2VPN community for BGP-VPWS-2:

```
[/]
A:admin@PE-1# show router bgp routes l2-vpn community target:64496:2 detail | match Community
 post-lines 1
Community      : target:64496:2
                 l2-vpn/vrf-imp:Encap=5: Flags=none: MTU=1514: PREF=0
Community      : target:64496:2
                 l2-vpn/vrf-imp:Encap=5: Flags=none: MTU=1514: PREF=0
```

BGP VPLS and BGP VPWS with hash label and hash label signaling

The following command configures PW template "PW-3-hash-label-sign" with SHG, hash label, and hash label signal capability. This PW template is applied in BGP-VPLS-1 and BGP-VPWS-2.

```
# on PE-1, PE-4:
configure {
    service {
        pw-template "PW-3-hash-label-sign" {
            pw-template-id 3
            hash-label {
                signal-capability
            }
            split-horizon-group {
                name "SHG-1"
            }
        }
        vpls "BGP-VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
                route-distinguisher "192.0.2.1:1" # on PE-4:192.0.2.4:1
                route-target {
                    export "target:64496:1"
                    import "target:64496:1"
                }
                pw-template-binding "PW-3-hash-label-sign" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 10
                ve {
                    name "PE-1"               # on PE-4: name "PE-4"
                    id 1                      # on PE-4: id 4
                }
            }
            sap 1/1/c10/1:1 {
            }
        }
        epipe "BGP-VPWS-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "192.0.2.1:2" # on PE-4:192.0.2.4:2
                route-target {
                    export "target:64496:2"
                    import "target:64496:2"
                }
                pw-template-binding "PW-3-hash-label-sign" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"               # on PE-4: name "PE-4"
                    id 1                      # on PE-4: id 4
                }
                remote-ve "PE-4" {            # on PE-4: remote-ve "PE-1"
                    id 4                      # on PE-4: id 1
                }
            }
            sap 1/1/c10/1:2 {
            }
        }
```

The configuration on PE-2 and PE-3 is similar for BGP-VPLS-1; BGP-VPWS-2 is only configured on PE-1 and PE-4.

The following shows that hash label and hash label signaling capability is supported on all SDPs in BGP-VPLS-1 on PE-1:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match Hash
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Enabled
Oper Hash Label    : Enabled
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Enabled
Oper Hash Label    : Enabled
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Enabled
Oper Hash Label    : Enabled
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Likewise, hash label and hash label capability signaling is enabled on the SDP in BGP-VPWS-2 on PE-1:

```
[/]
A:admin@PE-1# show service id 2 sdp detail | match Hash
Hash Label         : Enabled                  Hash Lbl Sig Cap  : Enabled
Oper Hash Label    : Enabled
```

PE-1 receives the following BGP L2VPN route for BGP-VPLS-1 with T=R=1 (Flags=-T-R) from PE-4:

```
98 2024/09/18 07:07:43.970 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5

Different hash label configuration in BGP-VPLS-1 on different nodes

BGP-VPLS-1 is reconfigured on PE-2 and PE-3 with different PW templates. The following command configures BGP-VPLS-1 with PW template 1 on PE-2:

```
# on PE-2:
configure {
    service {
        vpls "BGP-VPLS-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "192.0.2.2:1"
                route-target {
                    export "target:64496:1"
                    import "target:64496:1"
                }
                pw-template-binding "PW-1" {    # hash label disabled in PW-1
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 10
                ve {
                    name "PE-2"
                    id 2
                }
            }
            sap 1/1/c10/1:1 {
            }
```

Similarly, BGP-VPLS-1 on PE-3 is reconfigured with PW template 2. As a result, BGP-VPLS-1 has a different hash label configuration on different nodes:

- PW template 3 (hash label with hash label signaling capability) on PE-1 and PE-4
- PW template 1 (no hash label) on PE-2
- PW template 2 (hash label without hash label signaling capability) on PE-3

BGP-VPLS-1 on PE-1 (hash label with hash label signaling capability) has connectivity with BGP-VPLS-1 on PE-2 (no hash label):

```
[/]
A:admin@PE-1# ping 172.16.1.2 router-instance "CE-11" interval 0.1 output-format summary
PING 172.16.1.2 56 data bytes
!!!!!
---- 172.16.1.2 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
round-trip min = 2.71ms, avg = 5.03ms, max = 12.8ms, stddev = 3.90ms
```

BGP-VPLS-1 on PE-2 is configured without hash label, so PE-2 always sends and expects to receive frames without a hash label. Even though BGP-VPLS-1 on PE-1 is configured with hash label and hash label signalling capability, when PE-1 receives T=R=0 (Flags:none) from PE-2, PE-1 adapts to send and expect to receive frames without a hash label to and from PE-2.

BGP-VPLS-1 on PE-1 (hash label with hash label signaling capability) has no connectivity with BGP-VPLS-1 on PE-3 (hash label only):

```
[/]
A:admin@PE-1# ping 172.16.1.3 router-instance "CE-11" interval 0.1 output-format summary
PING 172.16.1.3 56 data bytes
.....
---- 172.16.1.3 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

BGP-VPLS-1 on PE-3 is configured with hash label only, so PE-3 always sends and expects to receive frames with a hash label. PE-3 has no signaling capability, so PE-3 sends T=R=0 (Flags:none). Even though BGP-VPLS-1 on PE-1 is configured with hash label and hash label signalling capability, when PE-1 receives T=R=0 from PE-3, PE-1 adapts to send and expect to receive frames without a hash label to and from PE-3. So, there is a mismatch, causing PE-1 to drop the frames with a hash label from PE-3 and PE-3 to drop the frames without a hash label from PE-1.

From BGP-VPLS-1 on PE-3 (hash label only), there is no connectivity to PE-1 (hash label with hash label signaling capability) or to PE-2 (no hash label):

```
[/]
A:admin@PE-3# ping 172.16.1.1 router-instance "CE-13" interval 0.1 output-format summary
PING 172.16.1.1 56 data bytes
.....
---- 172.16.1.1 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss

[/]
A:admin@PE-3# ping 172.16.1.2 router-instance "CE-13" interval 0.1 output-format summary
PING 172.16.1.2 56 data bytes
.....
---- 172.16.1.2 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss
```

BGP-VPLS-1 on PE-2 is configured without hash label, so PE-2 always sends and expects to receive frames without a hash label. PE-3 is configured with hash label only, so it always sends and expects to receive frames with a hash label. This is a mismatch and the frames are dropped.

Hash label signaling in EVPN VPLS and EVPN VPWS

BGP is configured for the EVPN address family, as follows:

```
# on PE-1, PE-2, PE-3, PE-4:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            evpn true
        }
        group "internal" {
            peer-as 64496
        }
        neighbor "192.0.2.5" {        # RR-5
            group "internal"
            family {
                evpn true
            }
        }
```

This section is divided in the following subsections:

- EVPN VPLS and EVPN VPWS services without hash label where the hash label is disabled
- EVPN VPWS services with hash label and hash label signaling capability where the F flag is set in the AD per-EVI route
- EVPN VPLS services with hash label only where the hash label is enabled, but the F flag is not included in the IMET route
- EVPN VPLS services with hash label and hash label signaling capability where the F flag is set in the IMET route
- Different hash label configuration in EVPN-VPLS-3 on different nodes

EVPN VPLS and EVPN VPWS services without hash label

The following EVPN VPLS and EVPN VPWS services are configured on PE-1:

```
# on PE-1:
configure {
    service {
        vpls "EVPN-VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "192.0.2.1:3"    # on PE-4: 192.0.2.4:3
                route-target {
                    export "target:64496:3"
                    import "target:64496:3"
                }
            }
            bgp-evpn {
                evi 3
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/c10/1:3 {
            }
        }
        epipe "EVPN-VPWS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
```

EVPN VPWS services with hash label and hash label signaling capability

The following command enables the hash label in BGP-VPWS-4:

```
# on PE-1, PE-4:
configure {
    service {
        epipe "EVPN-VPWS-4" {
            bgp-evpn {
                mpls 1 {
                    hash-label true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following shows that the hash label is enabled in BGP-VPWS-4:

```
[/]
A:admin@PE-1# show service id 4 bgp-evpn | match Hash
Hash Label         : Enabled
```

PE-1 receives the following AD per EVI route from originator PE-4:

```
167 2024/09/18 07:50:14.535 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 95
    Flag: 0x90 Type: 14 Len: 36 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.4
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:4 ESI: ESI-0, tag: 4 Label: 8388464 (Raw Label:
 0x7fff70) PathId:
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.4
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
        192.0.2.5
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64496:4
        l2-attribute:MTU: 1514 F: 1 C: 0 P: 0 B: 0
        bgp-tunnel-encap:MPLS
"
```

The L2 attributes community includes the MTU and the control flags. The flow label F flag is set to 1. When the hash label is enabled, it is advertised in the AD per-EVI route.

EVPN VPLS services with hash label only

The hash label is configured in EVPN-VPLS-3 and BD-5, as follows:

```
# on PE-1, PE-4 (on PE-2 and PE-3 only for EVPN-VPLS-3):
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                mpls 1 {
                    ingress-replication-bum-label true    # required for hash label
                    hash-label true
                }
            }
        }
        vpls "BD-5" {
            bgp-evpn {
                mpls 1 {
                    control-word true                       # optional
                    ingress-replication-bum-label true    # required for hash label
                    hash-label true
                }
            }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following shows that the hash label is enabled in EVPN-VPLS-3 and BD-5:

```
[/]
A:admin@PE-1# show service id 3 bgp-evpn | match Hash
Hash Label : Enabled

[/]
A:admin@PE-1# show service id 5 bgp-evpn | match Hash
Hash Label : Enabled
```

The hash label is enabled, but the flow label control flag F is not advertised. The following IMET route for EVPN-VPLS-3 shows that there is no Layer 2 attributes community in the extended community:

```
171 2024/09/18 07:50:14.539 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.5
"Peer 1: 192.0.2.5: UPDATE
Peer 1: 192.0.2.5 - Received BGP UPDATE:

        Tunnel-Endpoint 192.0.2.4
"
```

EVPN VPLS services with hash label and hash label signaling capability

The following command is configured on the PEs to include the Layer 2 attributes community in the IMET routes:

```
# on PE-1, PE-4 (on PE-2 and PE-3 only for EVPN-VPLS-3):
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-l2-attributes true
                    }
                }
            }
        }
        vpls "BD-5" {
            bgp-evpn {
                routes {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    incl-mcast {
                        advertise-l2-attributes true
                    }
                }
            }
```

The Layer 2 attributes community is included in the IMET routes. The flow label control flag is set to 1 for EVPN-VPLS-3, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn incl-mcast community target:64496:3 detail | match
 Community post-lines 2
Community      : target:64496:3

-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The operational flags will indicate which problems occur in case of a mismatch in hash label configuration on the different PEs, as shown in the following section.

Different hash label configuration in EVPN-VPLS-3 on different nodes

The hash label configuration in EVPN-VPLS-3 is removed on PE-2:

```
# on PE-2:
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                mpls 1 {
                    delete hash-label
```

On PE-3, the hash label remains enabled in EVPN-VPLS-3, but the Layer 2 attributes community is not advertised:

```
# on PE-3:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        vpls "EVPN-VPLS-3" {
            bgp-evpn {
                delete routes
```

As a result, EVPN-VPLS-3 has a different hash label configuration on the different PEs:

- on PE-1 and PE-4; hash label enabled and Layer 2 attributes community advertised
- on PE-2: no hash label configured
- on PE-3: hash label enabled, but no Layer 2 attributes community advertised

The following ping commands show that it is only possible to ping between PE-1 and PE-4, but not between PE-1 and PE-2 or between PE-1 and PE-3.

```
[/]
A:admin@PE-1# ping 172.16.3.2 router-instance "CE-31" interval 0.1 output-format summary
PING 172.16.3.2 56 data bytes
.....
---- 172.16.3.2 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss

[/]
A:admin@PE-1# ping 172.16.3.3 router-instance "CE-31" interval 0.1 output-format summary
PING 172.16.3.3 56 data bytes
.....
---- 172.16.3.3 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss

[/]
A:admin@PE-1# ping 172.16.3.4 router-instance "CE-31" interval 0.1 output-format summary
PING 172.16.3.4 56 data bytes
!!!!!
---- 172.16.3.4 PING Statistics ----
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 3.70ms, avg = 3.84ms, max = 4.06ms, stddev = 0.127ms
```

Similarly, it is possible to ping between PE-4 and PE-1, but not between PE-4 and PE-2 or between PE-4 and PE-3.

It is not possible to ping between PE-2 and PE-1, between PE-2 and PE-3, or between PE-2 and PE-4:

```
[/]
A:admin@PE-2# ping 172.16.3.1 router-instance "CE-32" interval 0.1 output-format summary
PING 172.16.3.1 56 data bytes
.....
---- 172.16.3.1 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss

[/]
A:admin@PE-2# ping 172.16.3.3 router-instance "CE-32" interval 0.1 output-format summary
PING 172.16.3.3 56 data bytes
.....
---- 172.16.3.3 PING Statistics ----
5 packets transmitted, 0 packets received, 100% packet loss

[/]
A:admin@PE-2# ping 172.16.3.4 router-instance "CE-32" interval 0.1 output-format summary
PING 172.16.3.4 56 data bytes
.....
---- 172.16.3.4 PING Statistics ----
```

© 2026 Nokia.

```

Conclusion

BGP L2VPN and BGP EVPN support hash label to enable a more efficient load balancing in the MPLS network. BGP L2VPN and BGP EVPN routes can signal the hash label capability dynamically, which is useful in networks where not all nodes support hash label.

Inter-AS Model C for VLL

This chapter describes advanced inter-AS model C for Virtual Leased Line (VLL) configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 8.0.R4. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2.

Overview

SR OS supports RFC 3107, *Carrying Label Information in BGP-4*, including VLL/VPLS. BGP SDPs can also be used with PBB-VPLS services.

Internet service providers are looking for mechanisms to implement the VLL and VPLS services across Autonomous Systems (ASs). Service providers may have inter-AS operation as a consequence of delivering inter-provider VLL/VPLS or because they use multiple ASs as a result of acquisitions and mergers.

The objective of this chapter is to describe the interconnection of VLL services across multiple ASs, using inter-AS model C. Inter-AS Model C involves eBGP redistribution of internal system addresses to the neighboring AS using labeled IPv4 routes.

Example topology

Figure 187: Example topology – Inter-AS model C for VLL shows the example topology used for Inter-AS Model C VLL.

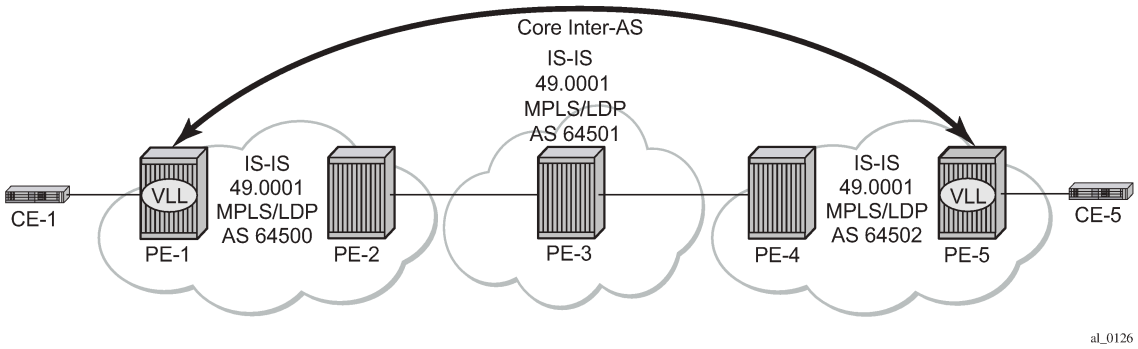
Use subject to Terms available at: www.nokia.com/terms.

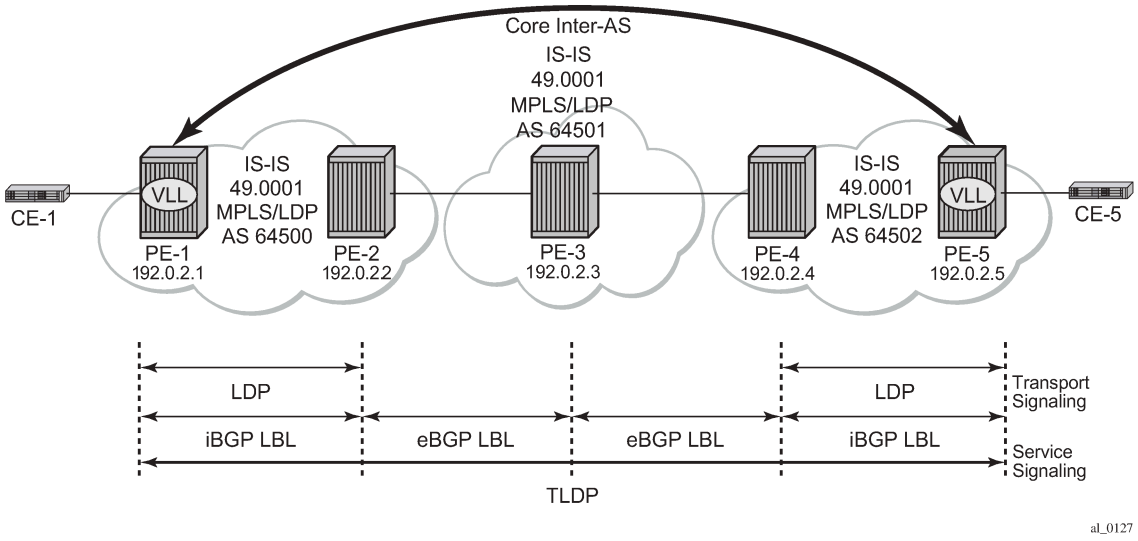
Figure 187: Example topology – Inter-AS model C for VLL



The example topology shown in Figure 187: Example topology – Inter-AS model C for VLL consists of three sites in different ASs with each site using SR OS nodes.

AS 64500 contains PE-1 and PE-2, AS 64501 contains PE-3, and AS 64502 contains PE-4 and PE-5. There is a business customer with two remote locations, Site A and Site B, with Customer Edge (CE) devices CE-1 connected to the AS 64500 via PE-1 and CE-5 connected to the AS 64502 via PE-5. A VLL Epipe service is configured between PE-1 and PE-5 to connect site A and site B.

Figure 188: Inter-AS model C for VLL



Configuration

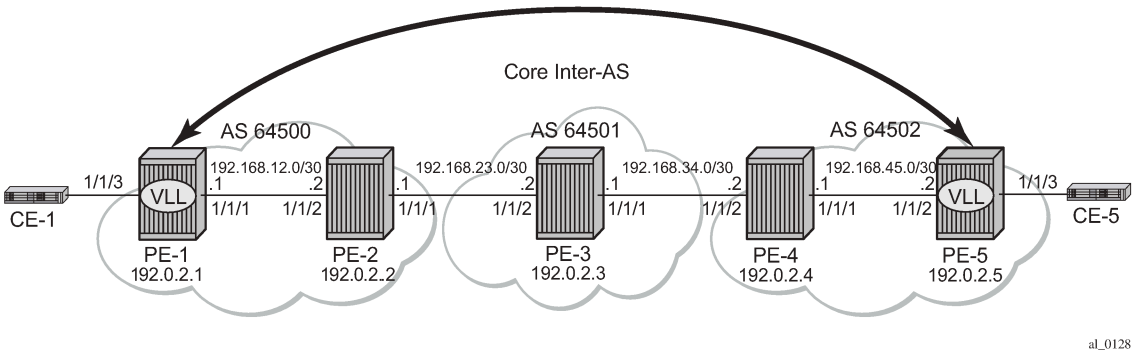
This section describes all of the relevant configuration tasks for the detailed setup shown in Figure 189: Network setup configuration. In this particular example, the following protocols are assumed to be already configured.

- IS-IS as the IGP with all the nodes being level Level1/Level 2.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- LDP as the MPLS protocol to signal the transport tunnels within AS 64500 and AS 64502.

Figure 189: Network setup configuration



BGP configuration

A BGP tunnel must be established between PE-1 and PE-5, therefore, labeled BGP routes must be exchanged for prefixes 192.0.2.1/32 and 192.0.2.5/32 across the ASs. The following shows the BGP configuration — iBGP and eBGP — required for the PE routers to implement an Inter-AS VLL.

The BGP configuration on PE-3 in AS 64501 is as follows:

```
# on PE-3:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64501
                }
            }
            neighbor "192.168.23.1" {
                group "EBGP"
                peer-as 64500
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64500"]
                }
                export {
                    policy ["export-from64502"]
                }
            }
            neighbor "192.168.34.2" {
                group "EBGP"
                peer-as 64502
                family {
                    label-ipv4 true
                }
                import {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    policy ["import-from64502"]
                }
                export {
                    policy ["export-from64500"]
                }
            }
        }
```

The address family **label-ipv4** must be configured so that MPLS labels are carried along with MP-BGP Network Layer Reachability Information (NLRIs), see chapter "Separate BGP RIBs for Labeled Routes" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Unicast Routing Protocols Advanced Configuration Guide for Classic CLI*. The setting **split-horizon** is optional and prevents that a received route is sent back to the originator, which may result in multiple routes for a certain prefix.

To export the prefixes of the nodes where the Epipe is configured (PE-1 and PE-5) to another AS, a common scenario is to advertise the prefix to be exported within the AS as labeled BGP. Therefore, an export policy is defined for prefix192.0.2.1/32 on PE-1 and this prefix will be advertised with community "64500:0" to the ASBR in AS 64500, in this case to PE-2.

On PE-2, the labeled BGP route for prefix 192.0.2.1/32 is inactive, because the IGP route for that prefix is preferred. The setting **advertise-inactive** will allow the inactive labeled BGP routes from AS 64500 to be advertised to PE-3 in AS 64501. However, for EBGP sessions on Autonomous System Border Routers (ASBRs) such as PE-2, RFC 8212 is supported, so that routes are neither imported nor exported unless specifically enabled by configuration. Export policy "export-from64500" exports all routes with community "64500:0" and import policy "import-from64502" imports all routes with community "64502:0" which is the community added by the export policy on PE-5.

On PE-5, an export policy is configured to advertise prefix 192.0.2.5/32 with community "64502:0" to ASBR PE-4 in AS 64502.

On PE-4, BGP is configured with **advertise-inactive** to advertise the labeled BGP route to its EBGP peer, PE-3. Export policy "export-64502:0" exports routes with community "64502:0" to PE-3. Import policy "import-64500:0" imports routes with community "64500:0".

On PE-3, import and export policies are configured toward the EBGP peers. PE-3 imports routes with community "64500:0" from PE-2 and exports these routes to PE-4. Simultaneously, PE-3 imports routes with community "64502:0" from PE-4 and exports these routes to PE-2.

Labeled BGP is used end-to-end between PE-1 and PE-5 and no IGP routes are to be redistributed into BGP, which would be the case if no local BGP labeled routes were advertised within AS 64500 or AS 64502 and only IGP routes were defined within these ASs.

The ASBRs PE-2, PE-3, and PE-4 will swap the BGP labels. PE-3 will advertise the labeled BGP routes learned from AS 64500 to AS 64502 and vice versa and the ASBRs will advertise these labeled routes for remote PE prefixes to their BGP peers. Eventually, PE-1 will have learned a labeled BGP route for prefix 192.0.2.5/32 and PE-5 will have learned a labeled BGP route for prefix 192.0.2.1/32 and a VLL Epipe can be established between PE-1 and PE-5.

The following policies are configured on ASBR PE-2:

```
# on PE-2:
configure {
    policy-options {
        community "64500:0" {
            member "64500:0" { }
        }
        community "64502:0" {
            member "64502:0" { }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        policy-statement "export-from64500" {
            entry 10 {
                from {
                    community {
                        name "64500:0"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
        policy-statement "import-from64502" {
            entry 10 {
                from {
                    community {
                        name "64502:0"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

The BGP configuration of PE-2 in AS 64500 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64500
                }
            }
            group "IBGP" {
            }
            neighbor "192.0.2.1" {
                group "IBGP"
                next-hop-self true
                peer-as 64500
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.23.2" {
                advertise-inactive true
                group "EBGP"
                peer-as 64501
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64502"]
                }
                export {
                    policy ["export-from64500"]
                }
            }
```

© 2026 Nokia.

Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The BGP configuration of ASBR PE-4 in AS 64502 is as follows.The import and export policies are similar to the policies on PE-2.

```
# on PE-4:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "EBGP" {
                local-as {
                    as-number 64502
                }
            }
            group "IBGP" {
            }
            neighbor "192.0.2.5" {
                group "IBGP"
                next-hop-self true
                peer-as 64502
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.34.1" {
                advertise-inactive true
                group "EBGP"
                peer-as 64501
                family {
                    label-ipv4 true
                }
                import {
                    policy ["import-from64500"]
                }
                export {
                    policy ["export-from64502"]
                }
            }
        }
```

PE-1 and PE-5 are the PEs to which the CEs are connected in AS 64500 and AS 64502. PE-1 and PE-5 advertise their system prefixes as labeled BGP routes to their BGP peers within the AS.

The BGP configuration of PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base"{
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "IBGP" {
                export {
                    policy ["export-PE-1"]
                }
            }
            neighbor "192.0.2.2" {
                group "IBGP"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                next-hop-self true
                peer-as 64500
                family {
                    label-ipv4 true
                }
            }
        }
```

The BGP configuration of PE-5 in AS 64502 is as follows:

```
# on PE-5:
configure {
    router "Base" {
        autonomous-system 64502
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "IBGP" {
                export {
                    policy ["export-PEsys"]
                }
            }
            neighbor "192.0.2.4" {
                group "IBGP"
                next-hop-self true
                peer-as 64502
                family {
                    label-ipv4 true
                }
            }
        }
```

Policy configuration

The export policies on PE-1 and PE-5 advertise the system addresses to the remote AS. The added communities are used by the export and import policies on PE-2, PE-3, and PE-4. The export policy on PE-1 has a prefix list that only contains prefix 192.0.2.1/32 as follows:

```
# on PE-1:
configure {
    policy-options {
        community "64500:0" {
            member "64500:0" { }
        }
        prefix-list "PE-1" {
            prefix 192.0.2.1/32 type exact {
            }
        }
        policy-statement "export-PE-1" {
            entry 10 {
                from {
                    prefix-list ["PE-1"]
                }
                action {
                    action-type accept
                    origin igp
                    community {
                        add ["64500:0"]
                    }
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
```

A similar export policy can be configured for prefix 192.0.2.5/32 on PE-5. However, the export policy on PE-5 is slightly different: the policy has a prefix list that can be applied for prefixes on multiple PEs, but in this case, only prefix 192.0.2.5/32 will be exported:

```
# on PE-5:
configure {
    policy-options {
        community "64502:0" {
            member "64502:0" { }
        }
        prefix-list "PEsys" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "export-PEsys" {
            entry 10 {
                from {
                    prefix-list ["PEsys"]
                    protocol {
                        name [direct]
                    }
                }
                action {
                    action-type accept
                    origin igp
                    community {
                        add ["64502:0"]
                    }
                }
            }
        }
```

The same policy could have been applied on PE-1.

Service configuration

Once BGP is configured, the configuration requires the service to be defined (Epipe 1). The focus here is a VLL service, however, it is also possible to have a similar configuration with VPLS services.

The following shows the service level configuration on PE-1:

```
# on PE-1:
configure {
     service {
        epipe "Epipe 1" {
            admin-state enable
            description "Tunnel-PE-1-PE-5"
            service-id 1
            customer "1"
            spoke-sdp 15:1 {
            }
            sap 1/1/3:1 {
            }
        }
        sdp 15 {
            admin-state enable
            delivery-type mpls
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp-tunnel true
            far-end {
                ip-address 192.0.2.5
            }
        }
```

The following CLI shows the service level configuration on PE-5:

```
# on PE-5:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            description "Tunnel-PE-5-PE-1"
            service-id 1
            customer "1"
            spoke-sdp 51:1 {
            }
            sap 1/1/3:1 {
            }
        }
        sdp 51 {
            admin-state enable
            delivery-type mpls
            bgp-tunnel true
            far-end {

            }
        }
```

Show commands and troubleshooting

On PE-5, BGP tunnels exist to the remote AS system addresses that are using LDP as a transport mechanism and the configuration of end-to-end SDPs over which T-LDP service labels are exchanged.

In the following sections, the same commands are launched on the nodes in the following order: first on PE-1 and PE-5; then on PE-3, and finally, on PE-2 and PE-4.

Show commands and troubleshooting on PE-1

The following shows information about SDP 15 on PE-1:

```
[]
A:admin@PE-1# show service sdp

Conclusion

The BGP tunnel-based SDP binding is allowed for VLL and VPLS services, including PBB-VPLS. Using RFC 3107, it is possible to implement inter-AS Model C VLLs.

The example used in this chapter illustrates the configuration of an Inter-AS VLL providing access to CE sites. Troubleshooting commands also have been shown to verify all the procedures.

L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing

This chapter provides information about L2 Multicast in EVPN-MPLS VPRN R-VPLS with All-Active Multi-Homing.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 23.7.R1.

Overview

IPv4 multicast traffic can be forwarded from an EVPN-MPLS service into an attached R-VPLS service in which the receiving devices are using EVPN all-active multi-homing.

The routed service to which the R-VPLS service attaches can be an IES or a VPRN service. In this way, IPv4 multicast traffic can be transported using native IP for the IES case or NG-MVPN technologies for the VPRN case.

This feature requires:

- IGMP support on the R-VPLS IP interface
- Forwarding IPv4 multicast traffic from the IP interface of a VPRN or IES to its EVPN-MPLS R-VPLS service
- IGMP snooping within the VPLS of the R-VPLS service
- IGMP snooping state synchronization based on the ESI label to synchronize the IGMP snooping state between the all-active (R-)VPLS LAG SAPs

The configuration used in this chapter is the NG-MVPN scenario as shown in Figure 190: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing.

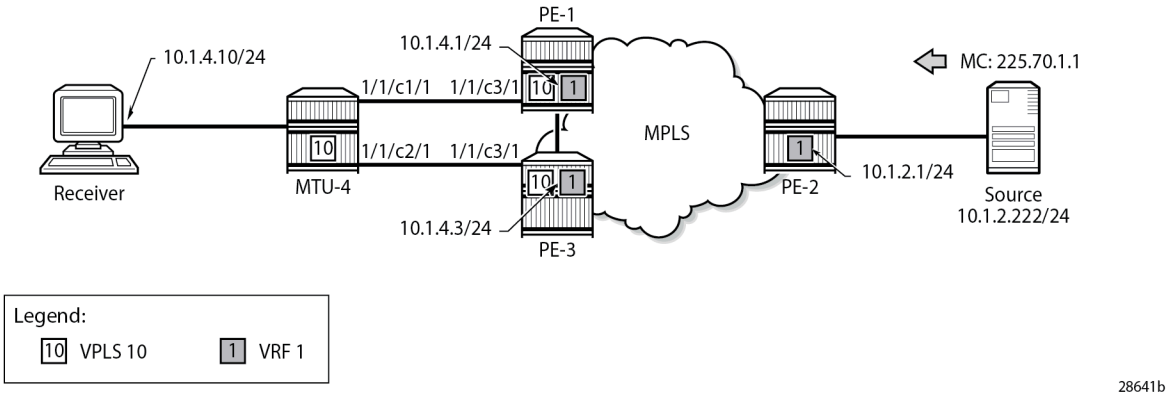
Figure 190: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing



A multicast stream is emitted by the source connected to PE-2 with group address 225.70.1.1. A multicast receiver connected to MTU-4 joins group 225.70.1.1. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. On MTU-4, LAG 1 comprises port 1/1/c1/1 and 1/1/c2/1, and this LAG is used in VPLS 10. On PE-1 and PE-3, VPLS 10 is interconnected with VPRN 1 through an Integrated Routing and Bridging (IRB) interface. VPRN 1 is defined in PE-1, PE-2, and PE-3, and uses NG-MVPN for transporting the multicast traffic through the core of the network. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information about EVPN. See the "NG-MVPN Configuration with MPLS" and "NG-MVPN Configuration with PIM" chapters in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 3 Services Advanced Configuration Guide for MD CLI* for more information about NG-MVPN.

Configuration

The initial configuration on the PE nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be used)
- MPLS tunnels between the PEs: LDP- or RSVP-based

BGP is required at the core of the network, using the VPN IPv4 and MVPN IPv4 address families between all PEs, for supporting unicast and multicast traffic on VPRN services, and additionally using the EVPN address family between PE-1 and PE-3 to support EVPN services. The BGP configurations for PE-1, PE-2, and PE-3 are as follows:

```
# on PE-1:
configure {
    router {
        autonomous-system 64496
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            family {
```

```
        autonomous-system 64496
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            family {
                ipv4 false
                vpn-ipv4 true
                mvpn-ipv4 true
                evpn true
            }
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "iBGP" { }
            neighbor "192.0.2.1" {
                group "iBGP"
                peer-as 64496
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                peer-as 64496
            }
        }
    }
}
```

The receiver connected to MTU-4 joins group 225.70.1.1, and the corresponding multicast stream is emitted by the source that is connected to PE-2. MTU-4 is connected to PE-1 and PE-3 through an all-active multi-homing EVPN Ethernet segment comprising LAG 1. The VPLS and the LAG on MTU-4 are defined as follows:

```
# on MTU-4:
configure {
    service {
        vpls "mcast-vpls" {
            admin-state enable
            service-id 10
            customer "1"
            igmp-snooping {

The all-active multi-homing Ethernet segment esi-13 is configured identically on PE-1 and PE-3, as follows. See the EVPN for MPLS Tunnels and EVPN for MPLS Tunnels in Routed VPLS chapters for more information.

```
# on PE-1 and PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "esi-13" {
                        admin-state enable
                        esi 0x01000000001300000001
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 30
                                }
                            }
                        }
                        association {
                            lag "lag-1" { }
                        }
                    }
                }
            }
        }
    }
}
```

The multi-homed access circuits of esi-13 are located on port 1/1/c3/1 for PE-1 and PE-3, so the LAG is configured identically, as follows:

```
# on PE-1 and PE-3:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        port 1/1/c3/1 { }
    }
}
```

Also, the EVPN VPLS service with ID 10 is configured identically on PE-1 and PE-3, as follows. The *mcast-vpls* name is needed to link VPLS 10 to VPRN 1 at a later stage, without requiring a physical loop or hairpin. The **routed-vpls** command enables the VPLS to become an R-VPLS. The **igmp-snooping** and **mrouter-port true** commands are required for multicast to work correctly in an all-active multi-homed scenario.

```
# on PE-1 and PE-3:
configure {
    service {
        vpls "mcast-vpls" {
            admin-state enable
            service-id 10
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            routed-vpls {
                multicast {
                    ipv4 {
                        igmp-snooping {
                            mrouter-port true
                        }
                    }
                }
                bgp 1 { }
                igmp-snooping {
                    admin-state enable
                }
                bgp-evpn {
                    evi 111
                    mpls 1 {
                        admin-state enable
                        ingress-replication-bum-label true
                        auto-bind-tunnel {
                            resolution any
                        }
                    }
                }
                sap lag-1:10 { }
            }
        }
}
```

The VPRN service with ID 1 provides the connection toward MTU-4 via VPLS 10, through the *int-MCAST-VPLS* interface with address 10.1.4.1/24 on PE-1, and with address 10.1.4.3/24 on PE-3. This L3 interface is linked to VPLS 10 with the **vpls "mcast-vpls" { }** command. The *int-MCAST-VPLS* interface is also included in the IGMP and PIM configurations of VPRN 1. The full configuration of VPRN 1 on PE-1 is as follows. The configuration of VPRN 1 on PE-3 is similar.

```
# on PE-1:
configure {
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp {
                ssm-translate {
                    group-range start 225.70.1.1 end 225.70.255.255 {
                        source 10.1.2.222 { }
                    }
                }
                interface "int-MCAST-VPLS" { }
                interface "int-PE-1-CE-1" { }
            }
            pim {
                interface "int-MCAST-VPLS" { }
                interface "system" { }
            }
            mvpn {
                c-mcast-signaling bgp
                mdt-type receiver-only
                auto-discovery {
                    type bgp
                }
                vrf-target {

The full configuration of VPRN 1 on PE-2 is as follows. The *int-PE-2-CE-2-source* interface provides the connection to the multicast source.

```
# on PE-2:
configure {
    service {
        vprn "VPRN 1" {
            admin-state enable
            service-id 1
            customer "1"
            pim {
                interface "int-PE-2-CE-2-source" { }
                interface "system" { }
            }
            mvpn {
                c-mcast-signaling bgp
                mdt-type sender-only
                auto-discovery {
                    type bgp
                }
                vrf-target {
                    unicast true
                }
                provider-tunnel {
                    inclusive {
                        mldp {
                            admin-state enable
                        }
                    }

A stream with group address 225.70.1.1 is started by the multicast source and joined by the multicast receiver connected to MTU-4. This stream is forwarded from PE-2 to PE-3; PE-1 is not involved in the forwarding.

PE-1 maintains IGMP state for group 225.70.1.1 in VPRN 1, and so does PE-3. PE-1 and PE-3 synchronize IGMP state using a data-driven mechanism. The forwarding list includes the *int-MCAST-VPLS* interface, as follows:

```
[/]
A:admin@PE-1# show router 1 igmp group 225.70.1.1 interfaces
===============================================================================
IGMP Interface Groups
===============================================================================

(*,225.70.1.1)                                          UpTime: 0d 00:01:41
    Fwd List  : int-MCAST-VPLS
-------------------------------------------------------------------------------
Entries : 1
===============================================================================
```

PE-1 maintains PIM state for group 225.70.1.1, as follows. The outgoing interfaces list is empty and the forwarding rate is zero; both are indications that PE-1 is not forwarding any multicast traffic.

```
[/]

```

PE-3 sends this multicast stream to MTU-4, which in turn sends it to the receiver that sent the join, so the path taken by the multicast stream runs via PE-2, PE-3, and MTU-4.

In the example from Figure 190: Multicast From an EVPN-MPLS Service Into an R-VPLS With All-Active EVPN Multi-Homing, and the commands and traces that follow, PE-1 is the active IGMP querier using address 10.1.4.1, sending out the queries across the L2 domain. The group queries are sent by PE-1 to PE-3 across the EVPN-MPLS tunnel because PE-3 is DF for *esi-13*, then forwarded onto MTU-4 to reach the (potential) receiver. MTU-4 relays the IGMP responses from the receiver to one of the links; in this example, the link between MTU-4 and PE-1. When the IGMP response for joining the 225.1.70.1 stream is received on PE-1, this event is signaled across the EVPN-MPLS tunnel because it is received over esi-13. This way, the IGMP state is synchronized between PE-3 and PE-1 in a data-driven way.

The basic IGMP snooping state for VPLS 10 on PE-1 and PE-3 is as follows. The output shows that IGMP snooping is enabled on ports sap:lag-1:10, rvpls, and evpn-mpls.

```

PE-1 sends the IGMP queries on VPRN 1 via the *int-MCAST-VPLS* interface, so the VPLS that is referenced in the *int-MCAST-VPLS* interface registers the ports on which the IGMP queries are received as multicast router ports. EVPN-MPLS tunnels are always multicast router ports. The following output displays the source addresses of the multicast routers:

```

Debug

Debugging is useful for troubleshooting purposes, and the debug configuration used on PE-1 and PE-3 for checking IGMP and IGMP snooping functionalities is as follows:

```
debug {
    router "VPRN 1" {
        igmp {
            packet {
                dropped true
                ingress true
                egress true
            }
        }
    }
    service {
        vpls "mcast-vpls" {
            igmp-snooping {
                packet {
                    dropped true
                    ingress true
                    egress true
                    evpn-mpls true
                    sap lag-1:10 { }
                }
            }
        }
    }
}
```

When group 225.70.1.1 is joined, the trace on PE-1 is as follows. Event 4 is the IGMPv3 join message for group 225.70.1.1 received on SAP lag-1:10 in VPLS 10 from the receiver. The reception of this message is synchronized across the EVPN-MPLS tunnel for VPLS 10, as indicated by event 5. Event 6 is the IGMPv3 join message as received on interface *int-MCAST-VPLS* by VPRN 1.

Similar events are logged when the multicast receiver leaves the 225.70.1.1 group.

Conclusion

By connecting customers to EVPN-MPLS VPRN/IES routed services via an R-VPLS, service providers can offer IPv4 multicast services to customers in an all-active multi-homing scenario.

L2 Services with Auto-GRE Spoke-SDPs

This chapter provides information about L2 Services with Auto-GRE Spoke-SDPs.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 16.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Auto-GRE spoke-SDPs are supported in L2 services in SR OS Release 16.0.R1, and later.

Overview

When the connectivity between nodes is IP-based (not MPLS), VPWS and VPLS services can use manually provisioned or auto-generated GRE transport tunnels. For auto-GRE transport tunnels, the signaling can be BGP or Targeted LDP (T-LDP). BGP signaling is more scalable than T-LDP, because T-LDP requires point-to-point sessions between communicating peers.

Auto-GRE spoke-SDPs can be used in the following services:

- BGP-VPLS with BGP signaling
- LDP VPLS using BGP-AD with T-LDP signaling
- BGP-VPWS with BGP signaling
- Dynamic Multi-segment Pseudowire (MS-PW) spoke-SDP Forwarding Equivalence Class (FEC) 129 with T-LDP signaling (*not* supported in MD-CLI for SR OS Release 21.5.R1)

PW templates for auto-GRE spoke-SDPs are configured with **auto-gre-sdp true**.

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# auto-gre-sdp ?

 auto-gre-sdp <boolean>
 <boolean>  - ([true]|false)
 Default    - false

 'auto-gre-sdp' is: immutable

    Use a GRE tunnel to automatically create an SDP

    Warning: Modifying this element recreates 'configure service pw-template "PW3"'
    automatically for the new value to take effect.
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

The **auto-gre-sdp** parameter can be combined with the parameter **provisioned-sdp prefer**, but not with **provisioned-sdp use** (because that might contradict the use of auto-GRE spoke-SDPs), as follows:

```
*[ex:/configure service pw-template "PW3"]
A:admin@PE-1# commit
MINOR: SVCMGR #5626: configure service pw-template "PW3" auto-gre-sdp - not compatible with
 auto-gre-sdp - auto-gre-sdp is not allowed with used-provisioned-sdp
```

The auto-GRE SDP and SDP binding are created after a matching BGP route has been received. Subsequent requests for an auto-GRE SDP of the same type and to the same destination as an existing auto-GRE SDP will use the existing auto-GRE SDP.

Downstream fragmentation is allowed for auto-GRE SDPs by clearing the Don't Fragment (DF) bit in the GRE IP header. The following command controls fragmentation for a PW template:

```
configure {
    service {
        pw-template "PW40" {
            pw-template-id 40
            allow-fragmentation true
            auto-gre-sdp true
        }
```

The following PW template parameters are not supported with GRE tunnels and will be ignored when a GRE SDP is auto-created:

- Hash label
- Entropy label
- SDP include/exclude (there is no mechanism to configure an SDP admin group for auto-GRE SDPs)

However, these parameters are relevant for provisioned MPLS SDPs when the PW template is configured with **provisioned-sdp prefer**.

The **pw-template-binding** parameter in the **bgp <..>** context of the L2 service allows to configure the PW template to be used. It is possible to define multiple PW template bindings within a service. The mechanism for selecting the PW template is as follows:

- In BGP-VPWS, BGP-VPLS, and BGP-AD services, the PW template binding selection is based on matching the configured import Route Targets (RTs) for a PW template binding with the RTs in the received routes.
- The binding with the first matching RT is chosen. If no import RTs are configured, the lowest PW template binding ID is used.
- It is not possible to add RTs to BGP-VPWS BGP updates using import or export policies, because they are ignored. However, the RT exported to select the destination service can be used on the receiving PE with PW template binding statement to influence the PW template to be selected; see the first use case in the Configuration section.
- If the selected PW template is configured with **provisioned-sdp prefer** and an SDP with a matching far-end address exists, the system chooses the SDP with the lowest metric from the tunnel table. If multiple matching SDPs with the same metric occur, the highest SDP ID that is operationally up is chosen.

Use subject to Terms available at: www.nokia.com/terms.

The following **tools** command allows for PW template bindings to change:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template

 [policy-id] <number>
 <number>  - <1..2147483647>

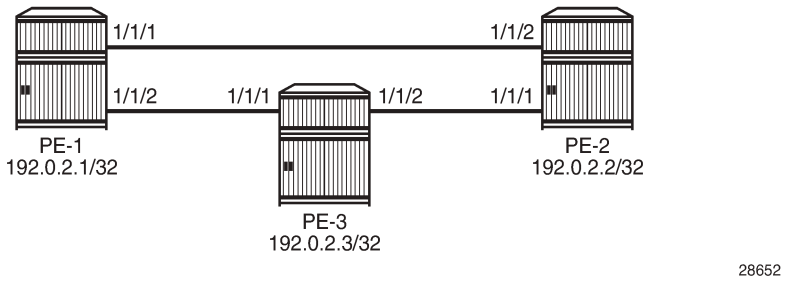
    <number> - <1..2147483647>
```

The policy ID refers to the PW template currently in use. With the **allow-service-impact** option, the current binding will be torn down and re-signaled.

Configuration

Figure 191: Example topology shows the example topology with three PEs in AS 64500. Services will be configured on PE-1 and PE-2, and PE-3 is the route reflector (RR).

Figure 191: Example topology



The initial configuration on the three PEs includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (alternatively, OSPF can be used)

Auto-GRE spoke-SDPs are configured in the following use cases:

1. BGP-VPLS with BGP signaling
2. BGP-AD in VPLS with T-LDP signaling
3. BGP-VPWS with BGP signaling

In these three use cases (BGP-VPLS, BGP-AD, BGP-VPWS), BGP is configured for the L2-VPN address family. In each of the use cases, two L2 services will be configured using different PW templates with **auto-gre-sdp**: one with **provisioned-sdp prefer** and one without.

Auto-GRE spoke-SDPs in BGP-VPLS

Figure 192: BGP-VPLS with auto-GRE spoke-SDPs shows the example topology with BGP-VPLSs 1 and 2 configured on PE-1 and PE-2. BGP is configured for the L2-VPN address family with PE-3 as Route

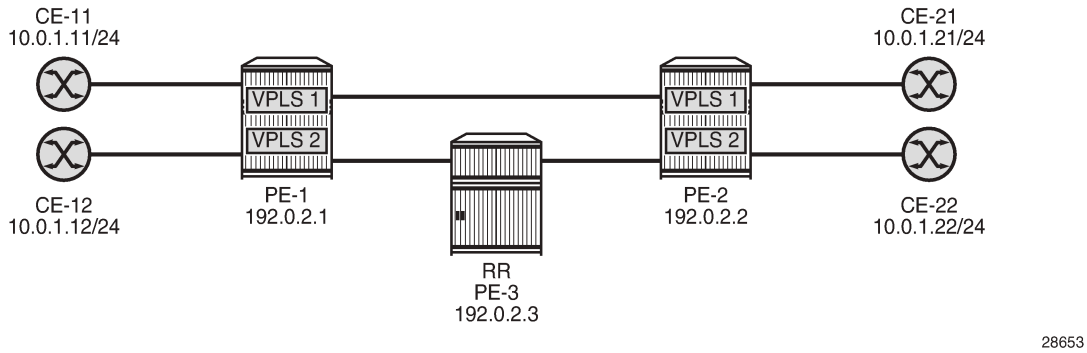
Reflector (RR). The CEs are emulated through VPRNs configured on the PEs and connected to the VPLSs via Port Cross-connect (PXC).

Figure 192: BGP-VPLS with auto-GRE spoke-SDPs



BGP configuration

For the BGP-VPLS, BGP-AD, and BGP-VPWS use cases, BGP is configured with the L2-VPN address family. The BGP configuration on PE-1 and PE-2 is identical, as follows:

```
# on PE-1, PE-2::
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "WAN" {
                type internal
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.3" {
                group "WAN"
            }
```

On RR PE-3, BGP is configured as follows:

```
# on RR PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            group "WAN" {
                type internal
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 192.0.2.3
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            neighbor "192.0.2.1" {
                group "WAN"
            }
            neighbor "192.0.2.2" {
                group "WAN"
            }
```

Service configuration

The configuration of BGP-VPLS services is described in the BGP VPLS chapter.

PW template 10 is configured with **auto-gre-sdp**; PW template 20 is configured with **provisioned-sdp prefer** and **auto-gre-sdp**. Because only IP connectivity is present between the nodes (no MPLS), the provisioned SDP is GRE-based using BGP signaling (no T-LDP). VPLS 1 has PW template bindings with IDs 10 and 20; VPLS 2 is configured with PW template binding 20. The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        sdp 12 {
            admin-state enable
            signaling bgp
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "BGP-VPLS-1" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP"
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "64500:1"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 100
                ve {
                    name "PE-1"
                    id 1
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap pxc-10.a:1 {        # SAP to connect to CE-11
            }
        }
        vpls "BGP-VPLS-2" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP_prefer provisioned SDP"
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "64500:2"
                route-target {
                    export "target:64500:2"
                    import "target:64500:2"
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpls {
                admin-state enable
                maximum-ve-id 100
                ve {
                    name "PE-1"
                    id 1
                }
            }
            sap pxc-10.a:2 {        # SAP to connect to CE-12
            }
        }
```

The service configuration on PE-2 is similar, but the VE name is "PE-2" and the VE ID equals 2 instead, as follows:

```
# on PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        sdp 21 {
            admin-state enable
            signaling bgp
            far-end {
                ip-address 192.0.2.1
            }
        }
        vpls "BGP-VPLS-1" {
            admin-state enable
            description "BGP-VPLS with auto-GRE spoke-SDP"
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "64500:1"
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
```

```

VPLS 2 is configured with PW template binding 20, which prefers provisioned SDPs, so the provisioned SDP 12 is used, as follows:

```
[/]
A:admin@PE-1# show service id 2 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967294    BgpVpls  192.0.2.2       Up      Up        524273    524272
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
===============================================================================
```

In VPLS 1, the PW template binding selection can be changed by configuring a non-matching import RT to PW template 10, as follows:

```
# on PE-1:
configure {
    service {
        vpls "BGP-VPLS-1" {
            bgp 1 {
                pw-template-binding "PW10-auto-GRE" {
                    import-rt ["target:64500:999"]
                }
            }
```

This does not change the selected PW template during service operation and PW template 10 remains in use, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 10
```

The following **tools** command forces the system to re-evaluate the PW template binding:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 10 allow-service-impact
eval-pw-template succeeded for Svc 1 32767:4294967295 Policy 10
```

When the PW template binding is re-evaluated, PW template binding 20 is selected and the provisioned SDP 12 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match "PW-Template"
PW-Template Id     : 20
```

```
[/]
A:admin@PE-1# show service id 1 sdp

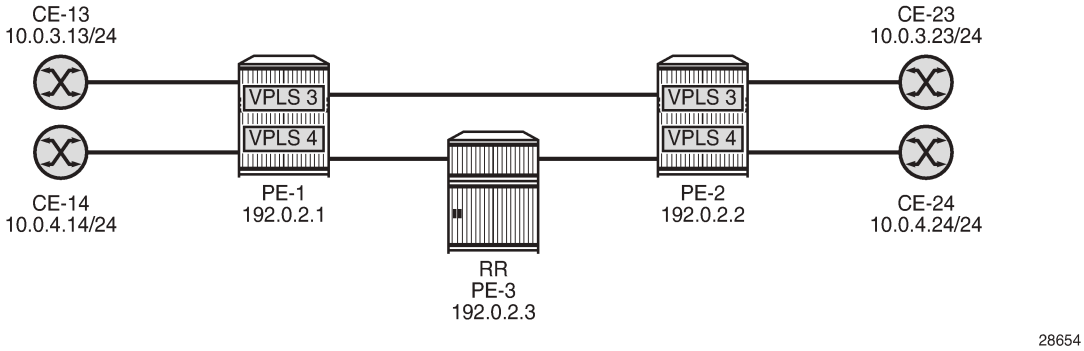
Auto-GRE spoke-SDPs in LDP-VPLS using BGP-AD

Figure 193: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs shows the example topology with VPLSs 3 and 4 configured with BGP-AD on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 193: LDP-VPLS using BGP-AD with auto-GRE Spoke-SDPs



The following T-LDP session is configured between PE-1 and PE-2:

```
# on PE-1:
configure {
    router "Base" {
        ldp {
            targeted-session {
                peer 192.0.2.2 {
                }
            }
```

```
# on PE-2:
configure {
    router "Base" {
        ldp {
            targeted-session {
                peer 192.0.2.1 {
                }
            }
```

The following T-LDP signaled SDP is configured on PE-1 and PE-2:

```
# on PE-1:
configure {
    service {
        sdp 120 {
            admin-state enable
            far-end {
                ip-address 192.0.2.2
            }
        }
```

```
# on PE-2:
configure {
    service {
        sdp 210 {
            admin-state enable
            far-end {
                ip-address 192.0.2.1
            }
        }
```

Use subject to Terms available at: www.nokia.com/terms.

The service configuration on PE-1 and PE-2 is as follows; see chapter LDP VPLS Using BGP Auto-Discovery for a description of BGP-AD in LDP VPLS. PW templates 10 and 20 are the same as in the preceding example.

```
# on PE-1, PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        vpls "BGP-AD VPLS-3" {
            admin-state enable
            description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP"
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "64500:3"
                route-target {
                    export "target:64500:3"
                    import "target:64500:3"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "64500:3"
            }
            sap pxc-10.a:3 {          # SAP to connect to CE-13 (PE-1) or CE-23 (PE-2)
            }
        }
        vpls "BGP-AD VPLS-4" {
            admin-state enable
            description "BGP-AD for LDP VPLS with auto-GRE spoke-SDP pref-prov-SDP"
            service-id 4
            customer "1"

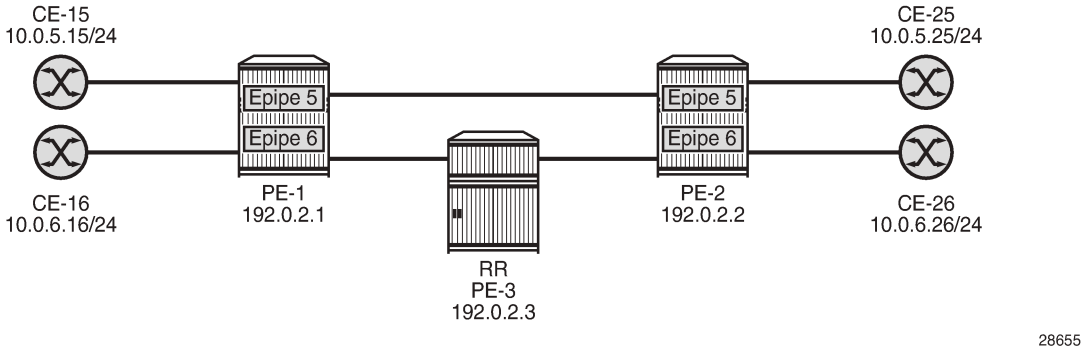
Auto-GRE spoke-SDPs in BGP-VPWS

Figure 194: BGP-VPWS with auto-GRE spoke-SDPs shows the example topology with BGP-VPWS Epipes 5 and 6 on PE-1 and PE-2. The BGP configuration is identical to the one for BGP-VPLS.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 194: BGP-VPWS with auto-GRE spoke-SDPs



Chapter BGP Virtual Private Wire Services describes the configuration of BGP VPWS. The configuration of Epipes 5 and 6 on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        epipe "BGP-VPWS-5" {
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP"
            service-id 5
            customer "1"
            bgp 1 {
                route-distinguisher "64500:5"
                route-target {
                    export "target:64500:5"
                    import "target:64500:5"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"
                    id 1
                }
                remote-ve "PE-2" {
                    id 2
                }
            }
            sap pxc-10.a:5 {        # SAP to connect to CE-15
            }
        }
        epipe "BGP-VPWS-6" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP_prefer provisioned SDP"
            service-id 6
            customer "1"
            bgp 1 {
                route-distinguisher "64500:6"
                route-target {
                    export "target:64500:6"
                    import "target:64500:6"
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-1"
                    id 1
                }
                remote-ve "PE-2" {
                    id 2
                }
            }
            sap pxc-10.a:6 {        # SAP to connect to CE-16
            }
        }
```

The configuration of the Epipes is similar on PE-2, but the VE names and VE IDs are different, as follows:

```
# on PE-2:
configure {
    service {
        pw-template "PW10-auto-GRE" {
            pw-template-id 10
            auto-gre-sdp true
        }
        pw-template "PW20-auto-GRE_prefer-prov" {
            pw-template-id 20
            provisioned-sdp prefer
            auto-gre-sdp true
        }
        epipe "BGP-VPWS-5" {
            admin-state enable
            description "BGP-VPWS with auto-GRE spoke-SDP"
            service-id 5
            customer "1"
            bgp 1 {
                route-distinguisher "64500:5"
                route-target {
                    export "target:64500:5"
                    import "target:64500:5"
                }
                pw-template-binding "PW10-auto-GRE" {
                }
                pw-template-binding "PW20-auto-GRE_prefer-prov" {
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-2"
                    id 2
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                remote-ve "PE-1" {

Conclusion

In IP-based networks, auto-GRE spoke-SDPs can be used in VPWS and VPLS services. Manually configured GRE tunnels are not an option in networks — such as LTE networks — where it is common to assign IP addresses dynamically from a pool of addresses, but auto-GRE spoke-SDPs can be applied instead.

Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication

This chapter provides information about Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3. Layer 2 multicast optimization for EVPN-VXLAN - Assisted Replication (AR) is supported in SR OS Release 14.0.R4, and later.

Overview

Typically, EVPN-VXLAN can use either Ingress Replication (IR) or Protocol Independent Multicast (PIM) for Broadcast, Unknown unicast, and Multicast (BUM) traffic (although SR OS does not support PIM along with EVPN-VXLAN). PIM requires keeping multicast state awareness per subnet per tenant in the core routers, which may not scale. Not all core routers support PIM.

IR inefficiency is usually tolerable in EVPN networks for broadcast and unknown unicast traffic; however, it is not tolerable for multicast traffic:

- Broadcast traffic can be reduced by the proxy-ARP and proxy-ND capabilities supported by EVPN.
- Unknown unicast traffic is greatly reduced in virtualized Data Center (DC) networks where all MAC and IP addresses are learned in the control or management planes. In such cases, unknown MAC addresses are always outside the DC. An **unknown-mac-route** can be enabled to ensure that the unknown unicast traffic is sent only to the DC gateway, which minimizes flooding within the DC.
- Multicast traffic may be an issue for the hypervisors holding the multicast sources, because the hypervisors need to replicate the multicast traffic to the remote VXLAN Tunnel Endpoints (VTEPs). The multicast replication at the hypervisors is a software process and the throughput can be heavily impacted. This is also true when VPLS services are used in the Virtual Service Router (VSR) and many replicas must be done from the VSR. Using a dedicated service node to replicate the multicast traffic on behalf of the hypervisors can help, but the replication capabilities of such service nodes are limited too.

SR OS supports the Assisted Replication (AR) feature for IPv4 VXLAN tunnels (both replicator and leaf functions) in compliance with the non-selective mode described in *draft-ietf-bess-evpn-optimized-ir*. AR is a Layer 2 multicast optimization feature that helps software-based PEs and Network Virtualization Edge

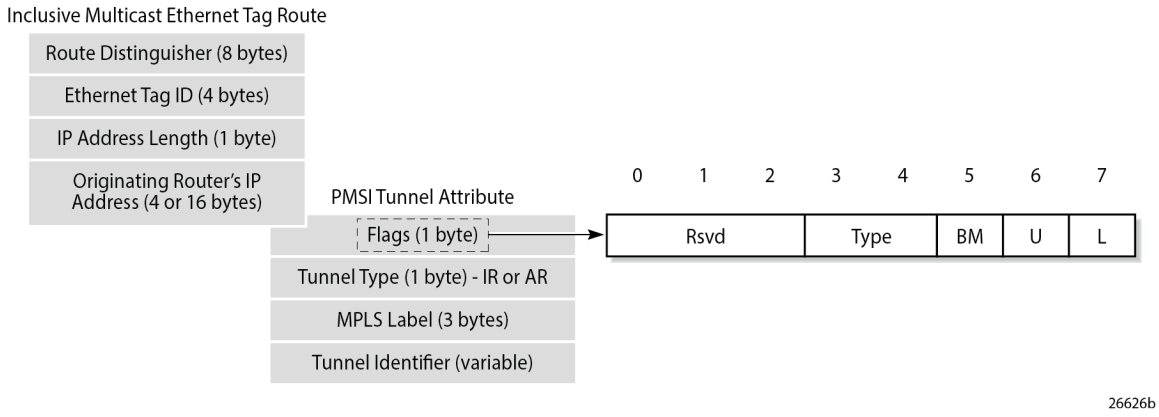
(NVE) devices with low-performance replication capabilities to deliver Broadcast and Multicast (BM) Layer 2 traffic to remote VTEPs in the VPLS.

SR OS nodes support the AR-Replicator (AR-R) and AR-Leaf (AR-L) functions, although not simultaneously on the same service. Nodes configured as AR-L select an AR-R within a service and send all BM packets to this AR-R. AR-Rs replicate traffic to all the VTEPs in the VPLS on behalf of the AR-Ls, so BM traffic is delivered to all VPLS participants without any packet loss caused by performance issues. Unknown unicast packets follow the same path as known unicast packets to avoid packet reordering. Therefore, no AR-R is used for unknown unicast traffic.

When multiple AR-Rs exist in a service, the AR-L performs per-service load-balancing of the BM traffic. The AR-L lists the candidate AR-Rs, ordered by IP address and VXLAN Network Identifier (VNI); candidate 0 having the lowest IP address and VNI. The replicator is selected using a modulo function of the service ID and the number of candidate AR-Rs. For example, assume that VPLS 1 has two candidate AR-Rs: because 1 modulo 2 equals 1, the second AR-R in the list is selected. In case of failure, a new AR-R is selected. If there are no more AR-Rs, the system falls back to IR.

Figure 195: PMSI Tunnel Attribute - Flags shows an EVPN route-type 3, an Inclusive Multicast Ethernet Tag (IMET) route containing a PMSI tunnel attribute with a flags octet. Flag L was already defined in RFC 6514. *Draft-ietf-bess-evpn-optimized-ir* defines additional flags: type, BM, and U. The BM and U flags are used for Pruned Flood Lists (PFL) signaling and they are not supported.

Figure 195: PMSI Tunnel Attribute - Flags



The type field has two bits that define the AR role of the advertising router, as follows:

- Type 00 = Regular Network Virtualization Edge (RNVE) - indicates that AR is not supported and IR is applied instead (for backward compatibility)
- Type 01= AR-R
- Type 10 = AR-L
- Type 11 = reserved

The tunnel type in the PMSI tunnel attribute can be configured with the following options for IR and AR:

- Tunnel type 0x06 = (non-optimized) IR, sent by AR-R and AR-L if **ingress-repl-inc-mcast-advertisement** is enabled, which is the default option
- Tunnel type 0x0A = type AR, originated by AR-R

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

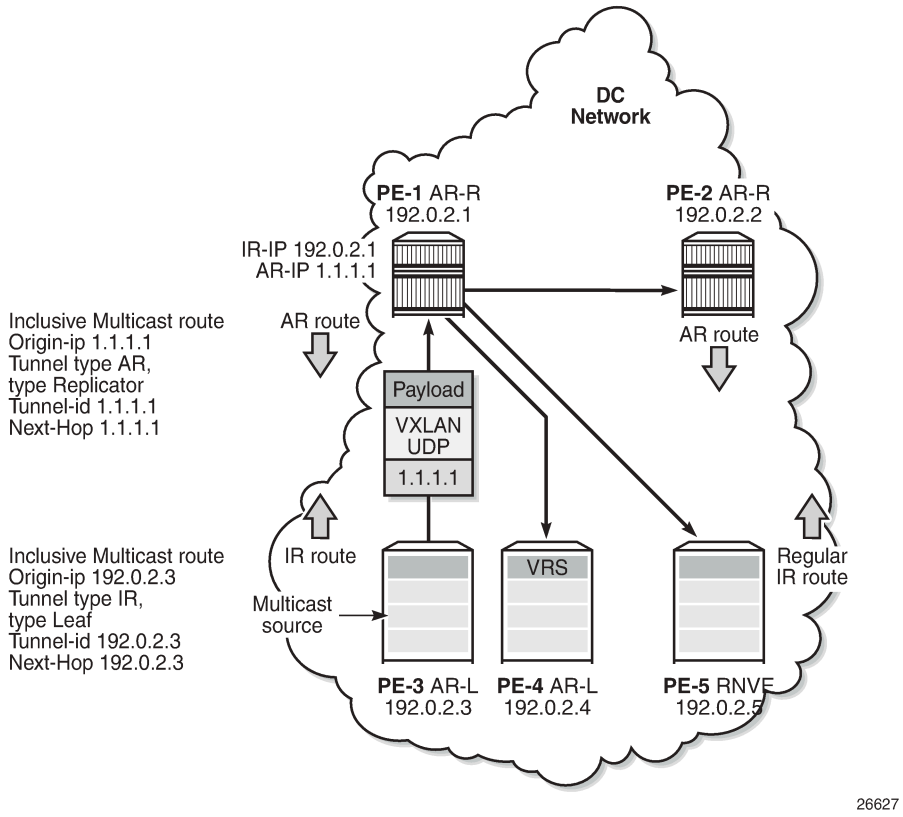
For regular IR routes, the originating router's IP address equals the system IP address. The MPLS label and tunnel identifier must be used as described in RFC 7432. The tunnel identifier is set to a routable address of the PE.

For AR routes, the originating router's IP address and the tunnel identifier are both set to the AR IP address (AR-IP) configured in the **service system vxlan** context. The AR-IP must be previously defined as a loopback interface address in the base router and must be different from the IR IP address (IR-IP).

Note:
If the AR-IP loopback interface is down, the router does not withdraw the AR route. However, the remote AR-Ls is not able to resolve the AR route's BGP next-hop if the AR-IP is no longer propagated in the IGP.

Figure 196: EVPN Assisted Replication for VXLAN shows the example topology with the multicast source connected to a hypervisor PE-3 that acts as AR-L, which sends an IR route containing the system address of PE-3. The AR-R PE-1 sends an AR route that uses AR-IPs instead of IR-IPs; for example, PE-1 has AR-IP 1.1.1.1 and IR-IP 192.0.2.1.

Figure 196: EVPN Assisted Replication for VXLAN



Hypervisor PE-3 sends the BM traffic to the AR-R, which replicates it to all the VTEPs in the VPLS, except to PE-3.

Table 18: Inclusive multicast route information sent by different AR roles shows the inclusive multicast route information sent by each role in an AR-capable service.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Table 18: Inclusive multicast route information sent by different AR roles

AR role	function	inclusive multicast route advertised
AR-R	assists AR-Ls	IR inclusive multicast route (tunnel = 0x06 = IR, IR-IP, type = 0 = none) AR inclusive multicast route (tunnel = 0x0A = AR, AR-IP, type = 1 = AR-R)
AR-L	sends BM only to AR-R	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 2 = AR-L)
RNVE	non-AR support	IR inclusive multicast route (tunnel = 0x06 = IR, IR- IP, type = 0 = none)

Unicast traffic (known or unknown) is processed as normal. For BM traffic, the AR-R uses AR or IR based on the IP destination address (DA):

- If IP DA equals the AR-IP, the AR-R replicates to the VTEPs in the VXLAN service, except for the VTEP over which the BM traffic was received.
- If IP DA equals the IR-IP, normal IR forwarding is done.

Non-optimized-IR nodes are unaware of the PMSI tunnel attribute flag definition with the additional flags for AR, so they ignore the information in the flags field.

The *draft-ietf-bess-evpn-optimized-ir* describes the following three types of IR optimizations:

- Non-selective AR - the chosen AR-R replicates the BM traffic to all NVEs in the Ethernet VPN Instance (EVI) except for the source NVE.
- Selective AR - AR-Rs replicate BM traffic to only their AR-L set and the rest of the AR-Rs. Selective AR allows a "multi-stage" AR replication, as opposed to a "single-stage" AR replication.
- Pruned Flood Lists - AR-Ls can signal PFL flags to be pruned from the flood lists for BM or for unknown unicast traffic. PFL may be used in combination with AR.

This chapter only describes non-selective AR.

Configure AR-R and AR-L

The AR-IP is configured on the AR-R, as follows:

```
configure {
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address ?

 ip-address <unicast-ipv4-address>
 <unicast-ipv4-address> - <d.d.d.d>

    IP address for assisted replication in the router
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The AR-IP is the IPv4 address of a loopback interface in the base router instance. When attempting to configure an AR-IP and the loopback address does not exist, the following error message is raised:

```
configure {
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address 1.1.1.1

MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address
 - loopback interface with address (max prefix) needed for assisted replication
 - configure router "Base"
```

The AR types replicator and leaf are configured in a VPLS with the following command:

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication ?

 assisted-replication

 Choice: role
 leaf                 :+ Enter the leaf context
 replicator           :- AR role as replicator
```

When attempting to configure an AR-R before the AR-IP is set, the following error is raised:

```
configure {
    service {
        vpls "VPLS 10" {
            customer "1"
            service-id 10
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        replicator
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 10" vxlan instance 1 assisted-replication
 replicator
 - assisted-replication ip address needed for replication role
 - configure service system vxlan assisted-replication ip-address
```

The assisted-replication-time can only be configured on leaf nodes. The following error is raised after an attempt to configure the assisted-replication-time on an AR-R:

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    assisted-replication {
                        replicator {
                            acttime 5
MINOR: MGMT_CORE #2201: Unknown element - 'acttime'
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **acttime** can optionally be activated, and works as follows. When the router creates an AR-R destination for the first time, the assisted replication time must expire before this AR-R destination is eligible as candidate AR-R to forward BM traffic. Upon expiration, the router runs the AR-R selection (service ID modulo the number of AR-Rs provides the selected AR-R in the ordered list of candidate AR-Rs). The AR-R EVPN destination is created as "BM" and the destinations to the remaining nodes is shown as "U".

The **acttime** allows the AR-R some time to program the leaf VTEPs in the following cases:

- Configuration of a new AR-R
- AR-R rebooting
- AR-R going operationally down and up again

If the timer is zero (default value), the AR-R may receive packets from a VTEP that has not been programmed yet, in which case the AR-R drops the packets.

With the AR-Rs and AR-Ls configured, IMET AR routes can be exchanged. IR can be enabled or disabled independently of the AR configuration. The following command is required to enable IR inclusive multicast routes, and is enabled by default:

```
configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-ingress-replication true
```

BGP-EVPN routes

By default, IR is enabled in BGP-EVPN. The following IMET IR route is sent from PE-5 (RNVE) to Route Reflector (RR) PE-1. The flags in the PMSI Tunnel Attribute (PTA) indicate that regular IR is used to forward BUM traffic (tunnel type: 0x06). The AR type is "None", because AR is disabled on PE-5. The IR-IP 192.0.2.5 is used as next-hop, originator IP address, and tunnel endpoint. The MPLS label corresponds to the VNI.

```
A:admin@PE-5# //
A:PE-5# show debug
debug
    router "Base"
        bgp
            update
        exit
    exit
exit
A:PE-5# //
```

"
```

The IMET IR routes contain the system IP addresses of the nodes, not the AR-IPs.

The following AR route is advertised from AR-R PE-1. The tunnel type is AR and the flags indicate that PE-1 is configured as AR-R. The AR-IP 1.1.1.1 is the next-hop address, the originator address, and the tunnel endpoint.

```
On PE-1:

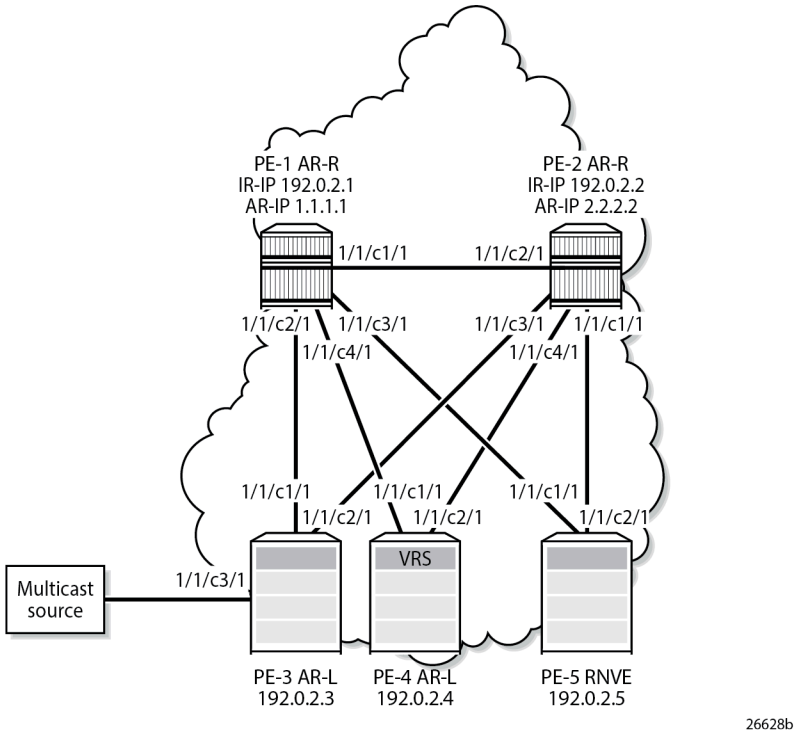
Configuration

Figure 197: Example topology shows the example topology with PE-1 and PE-2 as AR-R nodes, PE-3 and PE-4 as AR-L nodes, and PE-5 as RNVE node. The multicast source is connected to PE-3, which is a low-performance node. PE-1 acts as an RR for all nodes.

Figure 197: Example topology



The initial configuration on the nodes includes:

- Cards, MDAs, ports

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Router interfaces between the nodes
- IS-IS as IGP (alternatively, OSPF can be used)

BGP is configured for address family EVPN with RR PE-1. The BGP configuration on PE-1 is as follows:

```
On PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "DC" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.1
                }
            }
            neighbor "192.0.2.2" {
                group "DC"
            }
            neighbor "192.0.2.3" {
                group "DC"
            }
            neighbor "192.0.2.4" {
                group "DC"
            }
            neighbor "192.0.2.5" {
                group "DC"
            }
        }
```

The BGP configuration on the other nodes is as follows:

```
On the other PEs:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "DC" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "DC"
            }
        }
```

VPLS 10 is configured on all nodes. PE-1 is configured as AR-R with AR-IP 1.1.1.1, which must be configured as loopback IPv4 address in the base router and as AR-IP that can be shared between services. When attempting to configure an AR-IP with an IP address that does not exist in the base router, the following error is raised:

```
configure {
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address 1.1.1.1
MINOR: MGMT_CORE #4001: configure service system vxlan assisted-replication ip-address
 - loopback interface with address (max prefix) needed for assisted replication
 - configure router "Base"
```

First, a loopback interface is configured in the base router. The IP address needs to be routable and, in this example, an export policy exporting this IP address is configured in IS-IS. Alternatively, a static route can be configured or an additional IS-IS passive interface can be configured for the loopback interface. The IP address is then configured as AR-IP in the **service system vxlan** context. PE-1 is configured as AR-R for VPLS 10, as follows:

```
On PE-1:
configure {
    policy-options {
        prefix-list "AR-IP" {
            prefix 1.1.1.1/32 type exact {
            }
        }
        policy-statement "export_AR-IP" {
            entry 10 {
                from {
                    prefix-list ["AR-IP"]
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        interface "AR-IP" {
            loopback
            ipv4 {
                primary {
                    address 1.1.1.1
                    prefix-length 32
                }
            }
        }
        isis 0 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            export-policy ["export_AR-IP"]
        }
    }
    service {
        system {
            vxlan {
                assisted-replication {
                    ip-address 1.1.1.1
                }
            }
        }
        vpls "VPLS 10" {
            customer "1"
            service-id 10
            admin-state enable
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        replicator
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
    }
```

The configuration is similar on PE-2, but with AR-IP 2.2.2.2 instead of 1.1.1.1.

PE-3 and PE-4 are configured as AR-L nodes for VPLS 10. No AR-IP needs to be configured. The configuration of VPLS 10 on PE-3 is as follows:

```
On PE-3:
configure {
    service {
        vpls "VPLS 10" {
            admin-state enable
            service-id 10
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        leaf { }
                    }
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap 1/1/c3/1 {    # sap for ingress traffic from STC
            }
            sap 1/2/c1/1:1 {    # sap for egress traffic to VPLS 10
            }
```

Multicast traffic enters SAP 1/1/c3/1, whereas receiving hosts can be connected to other SAPs, such as SAP 1/2/c1/1:1. The configuration of VPLS 10 on PE-4 is similar, but no multicast source is connected. When a node is configured as AR-L, optionally the **acttime** can be configured to define the waiting time before the leaf can begin sending multicast traffic to a new replicator or a replicator that was rebooted. The default is zero seconds, in which case the AR-L starts sending packets to the AR-R without delay. Nokia recommends configuring a **acttime** value different from zero.

```
configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 1
                    assisted-replication {
                        leaf {
                            acttime ?

 acttime <number>
 <number> - <1..255> - seconds

    Time for the leaf to wait before sending traffic to a new replicator
```

PE-5 is configured as an RNVE node for VPLS 10, as follows:

```
On PE-5:
configure {
    service {
        vpls "VPLS 10" {
            admin-state enable
            service-id 10
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/2/c1/1:1 {    # sap for egress traffic to VPLS 10
            }
```

BGP-EVPN IMET routes are exchanged between the nodes. The following IMET routes are used on AR-L PE-3, with two routes from each AR-R: one IR route with BGP next-hop 192.0.2.x and one AR route with BGP next-hop x.x.x.x (with x equal to 1 or 2).

-------------------------------------------------------------------------------
Routes : 6
===============================================================================
```

When the AR-R has no local attachment circuits, such as SAPs or SDP-bindings, it should not generate regular IR routes. This can be controlled by disabling **advertise-ingress-replication** on PE-1 and PE-2, as follows:

```
On PE-1 and PE-2:
configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                routes {
                    incl-mcast {
                        advertise-ingress-replication false
```

When IR is disabled on the AR-Rs, no IR routes are sent to the other nodes and PE-3 only sees the AR routes from PE-1 and PE-2, as follows:

```
[/]
A:admin@PE-3# show router bgp routes evpn incl-mcast
===============================================================================
 BGP Router ID:192.0.2.3        AS:64500       Local AS:64500

```

PE-3 is configured as AR-L and no **acttime** is defined (default). Four egress VTEPs are listed: the system IP addresses are used for IR routes and the AR-IPs are used for AR routes. All BM traffic is forwarded to AR-IP 1.1.1.1 on PE-1. The AR-R in use is selected by the modulo operation on the service ID (10). In this example, two AR-Rs are available, and the service ID modulo 2 equals zero: 10 mod 2 = 0. This is the lowest possible outcome, so the first AR-R in the ordered candidate list is used. The AR-Rs are ordered by IP and VNI, with candidate 0 the lowest IP and VNI.

```
[/]

-------------------------------------------------------------------------------
Number of entries : 2
-------------------------------------------------------------------------------
===============================================================================
```

Within a service, no load-sharing is done between the AR-Rs. However, different AR-Rs can be used for different services.

- If PE-3 were configured as AR-L in VPLS 11, the calculation would be as follows: 11 mod 2 = 1; therefore, the second AR-R in the list would be selected.
- When three AR-Rs were available for VPLS 11, the calculation would be: 11 mod 3 = 2, so the third AR-R in the list would be used.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In case different VNIs are configured for the AR-Rs, the lowest IP address is always higher in the list, even when the VNI is higher. This can be shown when the VPLS VXLAN configuration on PE-1 is modified with VNI 99 instead of VNI 1, as follows:

```
On PE-1:
configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                delete vxlan 1
            }
            delete vxlan

configure {
    service {
        vpls "VPLS 10" {
            vxlan {
                instance 1 {
                    vni 99
                    assisted-replication {
                        replicator

configure {
    service {
        vpls "VPLS 10" {
            bgp-evpn {
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
```

The list of AR-Rs on PE-3 shows that the first entry is the VTEP with the lowest IP address (1.1.1.1), even though the VNI 99 is higher than 1:

```
[/]
A:admin@PE-3# show service id 10 vxlan assisted-replication replicator

1     2.2.2.2                1        no      yes               0
-------------------------------------------------------------------------------
Number of entries : 2
-------------------------------------------------------------------------------
===============================================================================
```

Note:
If the AR-IP loopback interface is down, BGP does not withdraw the AR route. When the route to the AR-IP is signaled using IGP, the route is removed from the routing table and the AR-L selects another AR-R. However, when a static route is defined for the AR-IP, a black-hole exists when the AR-IP interface is down.

PE-5 is configured as an RNVE node that signals regular IMET IR routes and is unaware of the AR-R and AR-L roles in the EVI. RNVE nodes ignore IMET AR routes. In the example, only PE-3, PE-4, and PE-5 send IMET IR updates, so the list of VTEP addresses on PE-5 only contains PE-3 and PE-4, as follows:

```

```

Verification of multicast traffic

The multicast source connected to PE-3 generates multicast traffic. PE-3 acts as AR-L and forwards the multicast packets to AR-R PE-1. In this example topology, multicast traffic enters port 1/1/c3/1 on PE-3 and is forwarded to egress port 1/1/c1/1 toward PE-1. Port statistics are cleared and traffic is generated, then the port statistics are verified.

===============================================================================
```

Besides the multicast traffic, IGP signaling is sent and received on the network interfaces. This explains why the counters on the network interface 1/1/c1/1 toward PE-1 show a slightly higher value than on the interface 1/1/c3/1 toward the multicast source. No multicast traffic is forwarded to PE-2, which is an AR-R candidate, but not used. AR-L PE-3 selected PE-1 for VPLS 10.

When the AR-R PE-1 receives the multicast traffic from PE-3, it forwards the traffic to PE-4 and PE-5 within the VXLAN service. The VXLAN information for VPLS 10 on PE-1 shows that PE-2 is not in the list of egress VTEPs. The reason is that PE-2 does not have any SAPs or SDP-bindings and no IMET IR route is sent by PE-2 because **advertise-ingress-replication** is disabled.

AR-R PE-1 receives the multicast traffic from PE-3 on port 1/1/c2/1 and forwards it to the egress ports 1/1/c3/1 toward PE-5 and 1/1/c4/1 toward PE-4, as follows. No multicast traffic needs to be forwarded to egress port 1/1/c1/1 toward PE-2. Source squelching ensures that the traffic is not sent back to the originator AR-L PE-3. PE-1 has no local SAPs or SDP-bindings.

```

An egress AR-L or RNVE node performs regular egress BUM forwarding procedures. Packets are replicated to local SAPs or SDP-bindings, but not to VXLAN-bindings.

AR-R failure scenarios

When the AR-IP interface on the used AR-R is down for any kind of reason, the route to this AR-IP is removed from the routing table on AR-L PE-3, and PE-3 selects AR-R PE-2. To simulate an AR-R failure, the AR-IP interface on PE-1 is disabled, as follows:

```
On PE-1:
configure {
    router "Base" {
        interface "AR-IP" {
            admin-state disable
```

After a while, the routing table on PE-3 does not contain an entry for prefix 1.1.1.1/32 anymore, as follows:

```
[/]
A:admin@PE-3# show router route-table 1.1.1.1/32
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```

```

In this case, IR is done for all BUM traffic toward PE-4 and PE-5.

Conclusion

AR uses replicators to forward broadcast and multicast traffic on behalf of less-performing nodes that are configured as AR-Ls. AR is primarily used for L2 multicast optimization in data centers, but may also be used in any network using overlay EVPN-VXLAN tunnels.

LDP VPLS Using BGP Auto-Discovery

This chapter provides information about LDP VPLS using BGP Auto-Discovery.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 9.0.R3. The MD-CLI in this edition is based on SR OS Release 20.10.R2. There are no prerequisites for this configuration.

Knowledge of BGP-auto-discovery RFC 6074 architecture and functionality, RFC 4447 Pseudo-wire set-up using label distribution protocol is assumed throughout this chapter, as well as knowledge of Multi-Protocol BGP (MP-BGP).

Overview

MPLS-based Virtual Private LAN Services (VPLS) may have many different provisioning models to allow the signaling of pseudowires between Provider Edge (PE) routers containing VPLS instances.

Network Management System (NMS) provisioning using Label Distribution Protocol (LDP) signaling is a well understood method of provisioning of Layer 2 VPLS services as described in RFC 4762. This relies on the provisioning of pseudowires between VPLS instances using LDP signaling with a common Virtual Circuit (VC) identifier within the label mapping message to instantiate pseudowires.

Border Gateway Protocol Auto-Discovery (BGP-AD), as specified in RFC 6074, is an alternative method of provisioning of Layer 2 PE routers containing VPLS service instances to those described above where PEs in a common VPLS instance are automatically discovered using BGP-AD techniques.

Each PE router advertises the presence of VPLS instances to other PE routers using defined parameters within a BGP update message.

LDP is used as the pseudowire signaling protocol and relies on the auto-discovery of VPLS endpoints to instantiate pseudowires instead of manually provisioning virtual circuits. Locally configured parameters, along with BGP learned parameters, are used to determine local and remote VPLS endpoints, which are used by LDP to signal service labels to peer routers.

Figure 198: Example topology shows the example topology with six SR OS nodes located in the same autonomous system (AS).There are three PEs and RR-6 acts as a route reflector for the AS. The PE routers are all VPLS-aware. The provider (P) routers are VPLS-unaware and do not take part in the BGP process. A full mesh VPLS between PE-1, PE-2, and PE-3 is described.

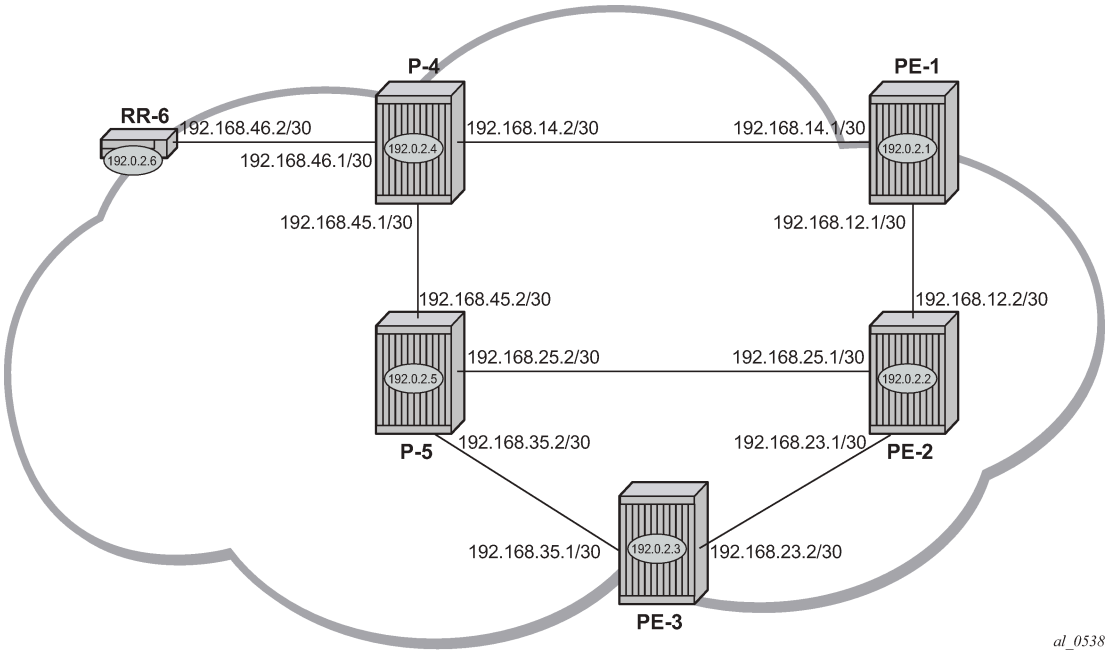
Use subject to Terms available at: www.nokia.com/terms.

Figure 198: Example topology



The following configuration tasks are completed as a prerequisite:

- IS-IS or OSPF is enabled on all network interfaces between each of the PE/P routers and route reflector RR-6.
- MPLS is configured on all interfaces between PE and P routers; MPLS is not required between P-4 and RR-6.
- LDP is configured on interfaces between PE and P routers; LDP is not required between P-4 and RR-6.
- The RSVP protocol must be enabled.

BGP-AD

In this architecture, a VPLS service is a collection of local VPLS instances present on a number of PEs in a provider network. In this context, VPLS-aware devices are PE routers. Each VPLS instance has a unique identifier known as the VPLS identifier (VPLS-ID). All PEs that have this VPLS instance present will have a common VPLS-ID configured.

Each VPLS instance within a PE contains a Virtual Switching Instance (VSI). The VPLS attachment circuits and pseudowires are associated with the VSI. Each VSI within a VPLS has a unique identifier called the VSI identifier (VSI-ID) and is a concatenation of the VPLS-ID plus an IP address, usually the system IP address.

The PEs communicate with each other at the control plane level by means of BGP updates containing BGP Layer 2 Network Layer Reachability Information (NLRI). Each update contains enough information for a PE to determine the presence of other local VPLS instances on peering PEs. In turn, this allows peer PE routers to set up pseudowire connectivity using LDP signaling for data flow between peers containing a local VPLS within the same VPLS instances.

Each update contains parameters usually associated with Multi-Protocol BGP updates:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- NLRI encoded as route target (RT)—usually the VPLS-ID—and PE system address.
- Next-Hop — The system IP address of the sending PE router.
- Extended communities — Contains the RT extended community and the VPLS-ID as community values.

Each VPLS instance is configured with import and export RT extended communities to create the required pseudowire topology by controlling the distribution of each NLRI.

This chapter describes the provisioning of a VPLS instance across three PE routers. A full mesh of pseudowires interconnects the VSI of each PE within the VPLS instance. A single attachment circuit is also configured on each VSI.

Configuration

The first step is to configure an MP-iBGP session using the L2-VPN address family between each of the PEs and the RR.

The configuration on the PEs is as follows:

```
# on PE-1, PE-2, and PE-3:
configure {
    router "Base"
        autonomous-system 65536
        bgp {
            group "internal" {
                peer-as 65536
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
```

The IP addresses can be derived from Figure 198: Example topology.

The configuration for RR-6 is as follows:

```
# on RR-6:
configure {
    router "Base"
        autonomous-system 65536
        bgp {
            group "rr-internal" {
                peer-as 65536
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "rr-internal"
            }
            neighbor "192.0.2.2" {
                group "rr-internal"
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            neighbor "192.0.2.3" {
                group "rr-internal"
            }
```

On PE-1, the BGP session with RR-6 is established with address family L2-VPN capability negotiated, as follows:

```
[]
A:admin@PE-1# show router bgp neighbor 192.0.2.6

===============================================================================
BGP Neighbor
===============================================================================
-------------------------------------------------------------------------------
Peer                 : 192.0.2.6
Description          : (Not Specified)
Group                : internal
-------------------------------------------------------------------------------
Peer AS              : 65536            Peer Port            : 50296
Peer Address         : 192.0.2.6
Local AS             : 65536            Local Port           : 179
Local Address        : 192.0.2.1
Peer Type            : Internal         Dynamic Peer         : No
State                : Established      Last State           : Established
Last Event           : recvOpen
Last Error           : Cease (Connection Collision Resolution)
Local Family         : L2-VPN
Remote Family        : L2-VPN
---snip---
```

On RR-6, the following BGP sessions are established with each PE for the L2-VPN address family:

```
[]
A:admin@RR-6# show router bgp summary all

===============================================================================
BGP Summary
===============================================================================
Legend : D - Dynamic Neighbor
===============================================================================
Neighbor
Description

                      PktSent OutQ
-------------------------------------------------------------------------------
192.0.2.1
Def. Instance  65536       18    0 00h07m44s 0/0/0 (L2VPN)
                           18    0
192.0.2.2
Def. Instance  65536       18    0 00h07m44s 0/0/0 (L2VPN)
                           18    0
192.0.2.3
Def. Instance  65536       18    0 00h07m44s 0/0/0 (L2VPN)
                           18    0

-------------------------------------------------------------------------------
```

A full mesh of RSVP Label Switched Paths (LSPs) is configured between the PE routers. For reference, the MPLS interface configuration and LSPs for PE-1 to PE-2 and PE-3 is as follows:

```
# on PE-1:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    router "Base"
        mpls {
            admin-state enable
            interface "int-PE-1-P-4" {
            }
            interface "int-PE-1-PE-2" {
            }
            path "loose" {
                admin-state enable
            }
            lsp "LSP-PE-1-PE-2" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.2
                primary "loose" {
                }
            }
            lsp "LSP-PE-1-PE-3" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.3
                primary "loose" {
                }
            }
```

VPLS PE configuration

Pseudowire templates

Pseudowire templates are used by BGP to dynamically instantiate service destination point (SDP) bindings. For a given service, pseudowire templates signal the egress service de-multiplexer labels used by remote PEs to reach the local PE.

The template determines the signaling parameters of the pseudowire, control word presence, plus other usage characteristics such as Split Horizon Groups (SHGs), MAC-pinning, filters, and so on.

The MPLS transport tunnel between PE routers can be signaled using either LDP or RSVP.

LDP-based pseudowires can be automatically instantiated; RSVP-based SDPs have to be pre-provisioned.

Pseudowire templates for auto-SDP creation using LDP

In order to use an LDP transport tunnel for data flow between PEs, it is necessary for link layer LDP to be configured between all PEs/Ps so that a transport label for each PE system interface address is available. Using this mechanism, SDPs can be auto-instantiated with SDP-IDs starting at 32767. Any subsequent SDPs created use SDP-IDs decrementing from this value.

A pseudowire template is required which may contain an SHG. Each SDP created with this template is contained within the configured SHG so that traffic cannot be forwarded between them.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            split-horizon-group {
                name "vpls-shg"
            }
        }
```

A pseudowire template can also be created that does not contain a split horizon group. The split horizon group can then be specified when the pw-template is included within the service.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW2" {
            pw-template-id 2
        }
```

Pseudowire templates for provisioned SDPs using RSVP

To use an RSVP tunnel as transport between PEs, it is necessary to bind the RSVP LSPs to the SDPs between each PE.

On PE-1, SDP 12 from PE-1 to PE-2 is configured as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
```

To create an SDP within a service that uses an RSVP transport tunnel, a pseudowire template is required that has the **provisioned-sdp use** parameter.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
provisioned-sdp use
        }
```

Alternatively, the **provisioned-sdp prefer** parameter can be used, see chapter LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP.

VPLS BGP-AD using auto-provisioned SDPs

Figure 199: VPLS instance with auto-provisioned SDPs

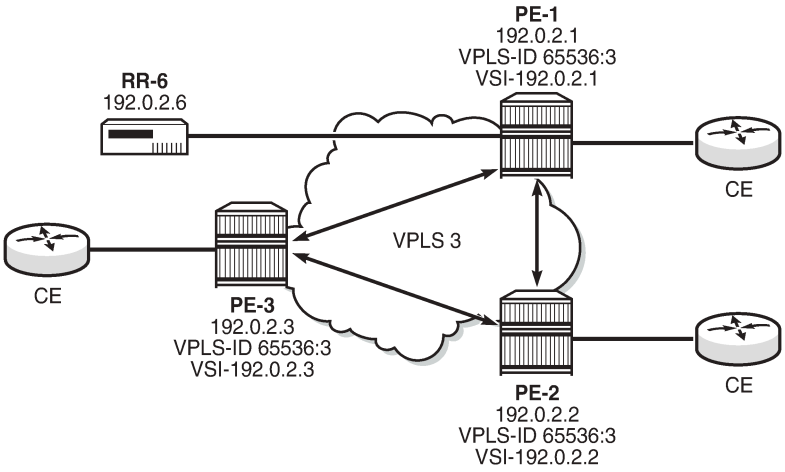

Figure 199: VPLS instance with auto-provisioned SDPs shows a schematic of a VPLS instance where the SDPs are auto-provisioned. SDPs are instantiated by a PE router using LDP signaling upon receipt of BGP Auto-Discovery (BGP-AD) updates from peer PE routers.

PE-1 configuration:

The following output shows the configuration required for a VPLS service using a pseudowire template configured for auto-provisioning of SDPs.

```
# on PE-1:
configure {
    service {
         vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.1
            }
            sap 1/1/4:3.0 {
            }
```

Within the **bgp** context, the pseudowire template is referenced which can be linked to an SHG and an import RT, if required.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Within the **bgp-ad** context, the signaling parameters are configured. These are two parameters used by each PE to determine the presence of a VPLS instance on a PE router. In turn, these are translated into endpoint identifiers for LDP signaling of pseudowires. As previously discussed, these parameters are:

- VPLS-ID — a unique identifier of the VPLS instance. Each PE that is a member of a VPLS must share the same VPLS-ID. This is inserted as an extended community value in the format AS:n. In this case, the VPLS-ID for VPLS 3 is 65536:3. This is a mandatory parameter and if it is not configured, it is not possible to enable BGP-AD (admin-state enable).
- Virtual Switching Instance (VSI) prefix — This identifies a specific instance of the VPLS. This must be unique within the VPLS instance, and is encoded using the 4 byte dotted-decimal notation. Generally, the system address is used as the VSI prefix. If this parameter is not configured, then the system address is used automatically.

The VPLS-ID and VSI prefix for VPLS 3 on each PE is shown in Figure 199: VPLS instance with auto-provisioned SDPs.

The VPLS-ID and VSI prefix are concatenated to form a unique VSI-ID. In this case, PE-1 has a VSI-ID of 65536:3:192.0.2.1. This uniquely identifies the VPLS instance on each individual PE and is advertised as an L2-VPN BGP update.

A BGP-AD update is transmitted to all other PEs via the RR, as follows:

```

-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

The preceding BGP update is transmitted by PE-1 and has route type auto-discovery.

In this L2-VPN update, the VPLS-ID is encoded as the L2-VPN extended community 65536:3.

The VSI is seen as the prefix 192.0.2.1. The combination of the VPLS-ID and the VSI forms the VSI-ID and uniquely identifies the VPLS instance within this PE router.

The next-hop is also encoded as the local system IP address 192.0.2.1, which allows remote PEs to identify a suitable transport tunnel to PE-1 and for the targeted-LDP peer for instantiating the SDP.

As can be seen within the update, the VPLS-ID 65536:3 is also used to determine the RT extended community and the route distinguisher (RD).

PE-2 configuration

On PE-2, VPLS 3 is created using pseudowire template 1, with VPLS-ID 65536:3 and VSI-ID prefix 192.0.2.2 (system IP address), as follows”

```
# on PE-2:
configure {
    service {
        vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.2
            }
            sap 1/1/4:3.0 {
            }
```

PE-3 configuration

On PE-3, VPLS 3 is created using pseudowire template 2, with VPLS-ID 65536:3—identical to the VPLS-ID of PE-1 and PE-2—and VSI-ID 192.0.2.3 (system IP address), as follows:

```
# on PE-3:
configure {
    service {
         vpls "VPLS-3" {
            admin-state enable
            service-id 3
            customer "1"
            bgp 1 {
                route-distinguisher "65536:3"
                route-target {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    export "target:65536:3"
                    import "target:65536:3"
                }
                pw-template-binding "PW2" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:3"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:3"
                vsi-id-prefix 192.0.2.3
            }
            sap 1/1/4:3.0 {
            }
```

PE-1 service operation verification

The following output on PE-1 shows that the VPLS and its objects (SAP and auto-discovered spoke SDPs) are operationally up on PE-1:

```
[]

===============================================================================
* indicates that the corresponding row element may have been truncated.
```

The **SB** flag indicates that the SDP is of type spoke-SDP (S flag) BGP (B flag).

BGP is used to discover the VPLS endpoints and exchange network reachability information. LDP is used to signal the pseudowires between the PEs.

LDP signaling occurs when each PE has discovered the endpoints of the VPLS instance. This compares with the use of the provisioned virtual circuit IDs used in an NMS provisioned VPLS instances as per RFC 4762.

The ability of PE-1 to reach the other PE routers with VSIs within the VPLS instance is verified from the following L2-route table:

```
[]
A:admin@PE-1# show service l2-route-table bgp-ad
```

===============================================================================
```

This output shows the presence of the signaled pseudowire SDPs. SDPs from PE-1 to PE-2 and PE-3 are signaled using LDP Forwarding Equivalence Class (FEC) Element 129.

Each PE router uses targeted LDP to signal the local and remote endpoints. If there is an endpoint match, then SDPs are instantiated. This compares with the use of LDP for NMS provisioned SDPs, which uses virtual circuit IDs to signal pseudowires using LDP FEC Element 128.

In order to signal the SDPs, the following parameters are required:

1. Attachment Group Identifier (AGI): this is used to carry the VPLS-ID of the local PE router VPLS instance. The VPLS-ID must be identical for all PEs in the same VPLS instance.
2. Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII): these use AII type 1 (RFC 4446) and are used to carry the NLRI (VSI-ID minus the RD) of the remote PE router VPLS instance.

The AGI for each PE must be identical. SAII and TAII must be different.

The following shows the service LDP bindings for VPLS 3 on PE-1:

```
[]

BGP AD using pre-provisioned SDPs

It is possible to configure BGP-AD instances that use RSVP transport tunnels. In this case, the LSPs and SDPs must be manually created.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 200: VPLS instance using pre-provisioned SDPs

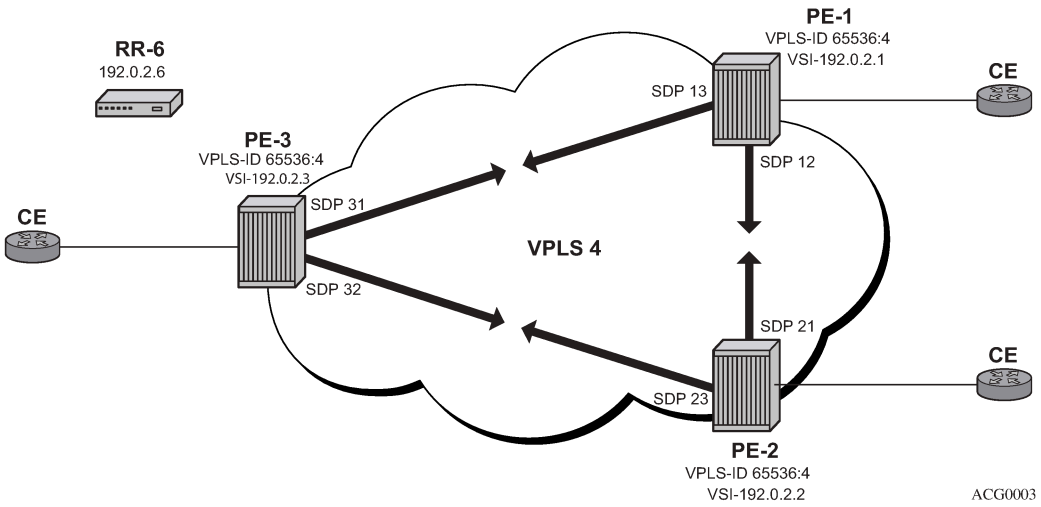

Figure 200: VPLS instance using pre-provisioned SDPs shows a VPLS instance configured across three PE routers as before.

The following SDPs are configured on the three PEs:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
        sdp 13 {
            admin-state enable
            description "RSVP-based SDP from PE-1 to PE-3"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.3
            }
            lsp "LSP-PE-1-PE-3" { }
        }
```

```
# on PE-2:
configure {
    service {
        sdp 21 {
            admin-state enable
            description "RSVP-based SDP from PE-2 to PE-1"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-PE-2-PE-1" { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        sdp 23 {
            admin-state enable
            description "RSVP-based SDP from PE-2 to PE-3"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.3
            }
            lsp "LSP-PE-2-PE-3" { }
        }
```

```
# on PE-3:
configure {
    service {
        sdp 31 {
            admin-state enable
            description "RSVP-based SDP from PE-3 to PE-1"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.1
            }
            lsp "LSP-PE-3-PE-1" { }
        }
        sdp 32 {
            admin-state enable
            description "RSVP-based SDP from PE-3 to PE-2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-3-PE-2" { }
        }
```

The PW template to be used within each VPLS instance must be provisioned on all PEs and must use the keyword provisioned-sdp use, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW3" {
            pw-template-id 3
            provisioned-sdp use
        }
```

The following output shows the configuration required for a VPLS service using a pseudowire template configured for pre-provisioned RSVP SDPs.

```
# on PE-1:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
                vsi-id-prefix 192.0.2.1
            }
            sap 1/1/4:4.0 {
            }
```

Similarly, on PE-2 the configuration is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
                vsi-id-prefix 192.0.2.2
            }
            sap 1/1/4:4.0 {
            }
```

On PE-3, VPLS 4 is configured as follows:

```
# on PE-3:
configure {
    service {
        vpls "VPLS-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp 1 {
                route-distinguisher "65536:4"
                route-target {
                    export "target:65536:4"
                    import "target:65536:4"
                }
                pw-template-binding "PW3" {
                    split-horizon-group "vpls-shg"
                    import-rt ["target:65536:4"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65536:4"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            vsi-id-prefix 192.0.2.3
        }
        sap 1/1/4:4.0 {
        }
```

The following output shows that the service and its objects are operationally up on PE-1.

```

Conclusion

BGP-AD coupled with LDP pseudowire signaling allows the delivery of L2-VPN services to customers where BGP is commonly used. This example shows the configuration of BGP-AD together with the associated show outputs which can be used for verification and troubleshooting.

LDP VPLS Using BGP Auto-Discovery — Prefer Provisioned SDP

This chapter provides information about LDP VPLS using BGP auto-discovery — prefer provisioned SDP.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. BGP Auto-Discovery (BGP-AD) based on RFC 6074 is supported in SR OS Release 6.0, and later. The **provisioned-sdp prefer** option is supported in SR OS Release 14.0.R1, and later.

Overview

As described in chapter LDP VPLS Using BGP Auto-Discovery, BGP-AD based on RFC 6074 can auto-create SDP bindings, but an operator can force the system to use a provisioned SDP by specifying the **provisioned-sdp use** option. This chapter compares the **provisioned-sdp use** option with the **provisioned-sdp prefer** option. The chapter describes a migration scenario for a VPLS service with a pseudowire (PW) template binding, restricted to using provisioned SDPs toward a PW template binding preferring to use provisioned SDPs, but auto-creating SDPs in case there is no suitable manually created SDP available.

PW templates

PW templates can be configured with the following command:

```
[ex:/configure service]
A:admin@PE-1# pw-template "PW 1" ?

 pw-template

 Immutable fields      - pw-template-id, provisioned-sdp, auto-gre-sdp
---snip---
```

When provisioned SDPs are to be used, the **provisioned-sdp** context must be configured:

```
*[ex:/configure service pw-template "PW 1"]
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
A:admin@PE-1# provisioned-sdp ?

 provisioned-sdp <keyword>
 <keyword>  - (use|prefer)

 'provisioned-sdp' is: immutable

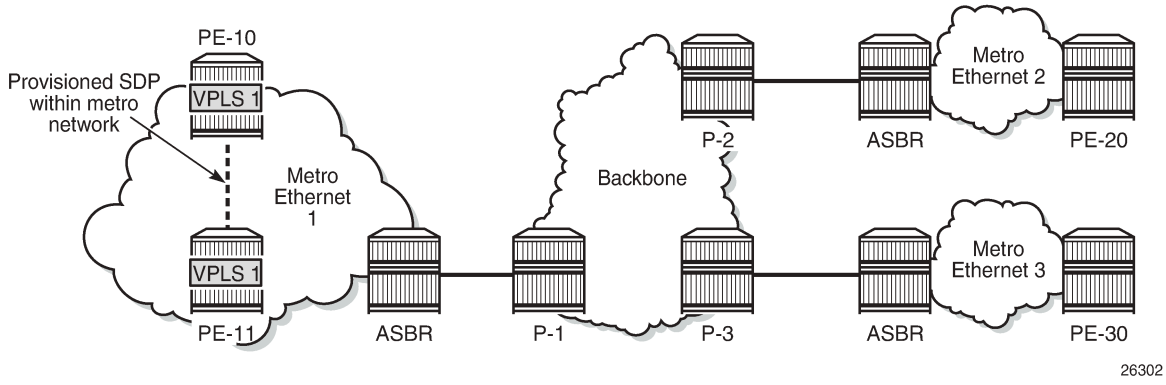
    Provisioned SDP type

    Warning: Modifying this element recreates 'configure service pw-template "PW 1"'
    automatically for the new value to take effect.
```

- When the **provisioned-sdp use** option is configured, the tunnel manager is forced to look for a provisioned and active SDP to the far-end PE. The far-end PE is auto-discovered from the BGP next hop. If multiple SDPs are active to this far-end PE, the tunnel manager chooses the SDP template with the best metric. If there is a tie, the SDP ID is used as a tie-breaker and the highest SDP ID wins. However, if no provisioned SDP exists, the SDP binding will not be instantiated.
- When the **provisioned-sdp prefer** option is configured, the behavior is the same when a provisioned SDP exists. When the tunnel manager finds an existing matching SDP, it will use it even if it is operationally down. Only when no provisioned SDP exists, will the SDP binding be auto-created.
- When a PW template is configured without the **provisioned-sdp use** or **provisioned-sdp prefer** option, the SDP bindings will be auto-created.

Figure 201: LDP VPLS using BGP-AD with provisioned-sdp use option shows the following use case: the metro Ethernet networks were initially built with provisioned SDPs. Intra-metro services are provisioned using provisioned SDPs; for example, customer X has a VPLS service defined in the metro Ethernet networks, using BGP-AD with a PW template to use the provisioned SDPs in the metro Ethernet networks.

Figure 201: LDP VPLS using BGP-AD with provisioned-sdp use option



The service provider initially started with PE-10 and PE-11 in metro Ethernet 1, but now wants to add PE-20 and PE-30 as new sites to the VPLS service. Therefore, the BGP-AD routes should propagate beyond the boundaries of the metro Ethernet network. The backbone network may be in a different AS, but in this example, all networks are in the same AS. VPLS 1 of customer X can have sites added to the service on PEs in different metro Ethernet networks. A new PW template is configured with the **provisioned-sdp prefer** option and applied to the VPLS service.

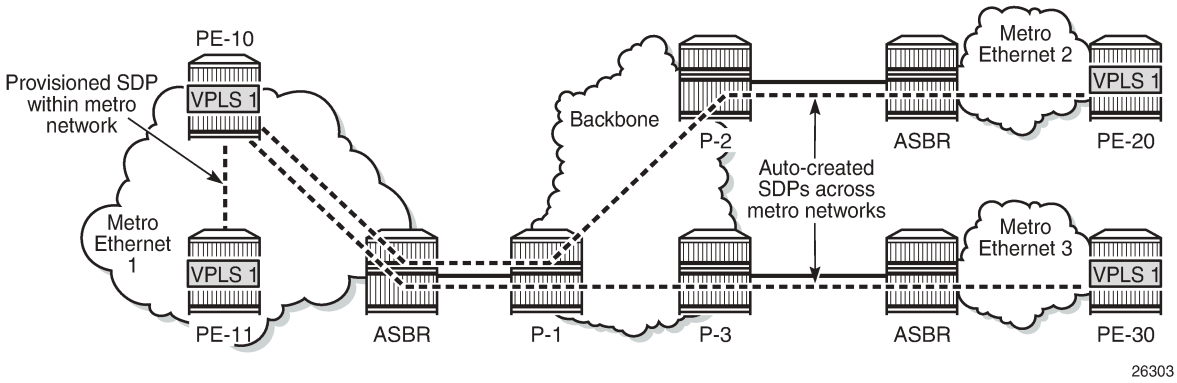
- When a new site within the metro Ethernet network is added, an SDP is already provisioned to this site and this SDP is used for the SDP binding in the VPLS.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- When a new site in a different metro Ethernet network is added, no SDP is available to the site in the remote metro Ethernet network and the SDP binding is auto-created.

Figure 202: LDP VPLS using BGP-AD with provisioned-sdp prefer option shows the SDP bindings in VPLS 1 between PE-10 and the other PEs. For simplicity, the SDP bindings between the other PEs are not shown.

Figure 202: LDP VPLS using BGP-AD with provisioned-sdp prefer option

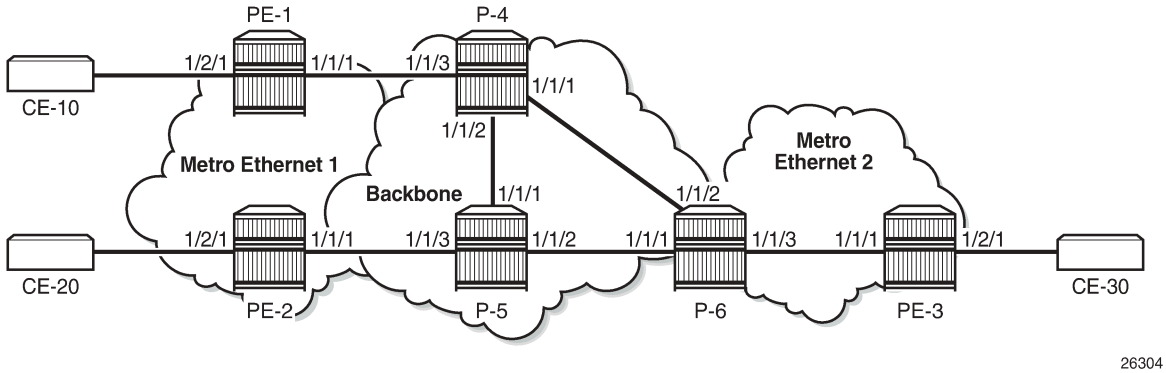


When PW templates are in use, it is not possible to modify the **provisioned-sdp prefer** option to **provisioned-sdp use** and vice versa. To support migration from one PW template to another with minimal service impact, two PW templates can be applied in parallel, as shown in the Configuration section.

Configuration

Figure 203: Example topology shows the example topology. For simplicity, all nodes are in the same AS.

Figure 203: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (or OSPF) on all interfaces

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MPLS and RSVP on all interfaces, except "int-P-4-P-6" and "int-P-5-P-6".
- LDP on all interfaces

BGP is configured on all PE routers for address family l2-vpn, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "internal" {
                peer-as 64496
                family {
                    l2-vpn true
                }
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
        }
```

The BGP configuration on the route reflector (RR) P-6 is as follows:

```
# on P-6:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            group "rr-internal" {
                peer-as 64496
                family {
                    l2-vpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "rr-internal"
            }
            neighbor "192.0.2.2" {
                group "rr-internal"
            }
            neighbor "192.0.2.3" {
                group "rr-internal"
            }
        }
```

On PE-1 and PE-2 in metro Ethernet network 1, an RSVP LSP is created that is used in a manually created SDP. The LSP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        mpls {
            admin-state enable
            path "loose" {
                admin-state enable
            }
            lsp "LSP-PE-1-PE-2" {
                admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                type p2p-rsvp
                to 192.0.2.2
                primary "loose" {
                }
            }
        }
```

On PE-1, SDP 12 is configured as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            description "SDP12 to 192.0.2.2"
            delivery-type mpls
            far-end {
                ip-address 192.0.2.2
            }
            lsp "LSP-PE-1-PE-2" { }
        }
```

The configuration on PE-2 is similar.

LDP VPLS using AD without provisioned-sdp prefer option

Initially, the following two PW templates are configured on all PEs: PW template 1 has the **provisioned-sdp use** option and PW template 2 is configured without any option; therefore, SDP bindings will be auto-created.

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW 1" {
            pw-template-id 1
            provisioned-sdp use
        }
        pw-template "PW 2" {
            pw-template-id 2
        }
```

The following lists the PW templates configured on PE-1:

```
[/]
A:admin@PE-1# show service pw-template

===============================================================================

===============================================================================
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On all PEs, two VPLS services are configured: VPLS 1 with BGP-AD PW template 1 and VPLS 2 with PW template 2, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-distinguisher "64496:1"
                route-target {
                    export "target:64496:1"
                    import "target:64496:1"
                }
                pw-template-binding "PW 1" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "64496:1"
            }
            sap 1/2/1:1 {
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "64496:2"
                route-target {
                    export "target:64496:2"
                    import "target:64496:2"
                }
                pw-template-binding "PW 2" {
                    import-rt ["target:64496:2"]
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "64496:2"
            }
            sap 1/2/1:2 {
            }
        }
```

On PE-1, the following SDP bindings have been created:

```
[/]
A:admin@PE-1# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End              Opr   I.Label E.Label
                                                         State
-------------------------------------------------------------------------------
1          12:4294967295      BgpAd  192.0.2.2            Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3            Up    524278  524280
2          32767:4294967294   BgpAd  192.0.2.2            Up    524279  524279
-------------------------------------------------------------------------------
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Number of SDPs : 3
------------------------------------------------------------------------------
==============================================================================
```

The first SDP binding is created by BGP-AD in VPLS 1 and uses the configured SDP 12 with far-end PE-2; the other two SDP bindings have been auto-created by BGP-AD in VPLS 2 and have far-end PE-2 and PE-3.

The list of SDP bindings on PE-2 looks similar:

```
[/]
A:admin@PE-2# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End              Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
1          21:4294967295      BgpAd  192.0.2.1            Up    524280  524280
2          32766:4294967293   BgpAd  192.0.2.3            Up    524278  524281
2          32767:4294967294   BgpAd  192.0.2.1            Up    524279  524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

On PE-3, there are only two SDP bindings, both in VPLS 2:

```
[/]
A:admin@PE-3# show service sdp-using

===============================================================================
SDP Using
===============================================================================
SvcId      SdpId              Type   Far End              Opr   I.Label E.Label
                                                        State
-------------------------------------------------------------------------------
2          32766:4294967294   BgpAd  192.0.2.2            Up    524281  524278
2          32767:4294967295   BgpAd  192.0.2.1            Up    524280  524278
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

Log "99" on PE-3 shows that the system failed to create a dynamic BGP-L2VPN SDP binding because no provisioned SDP was found, as follows:

```
69 2021/04/01 16:36:44.405 CEST MAJOR: SVCMGR #2322 Base
"The system failed to create a dynamic bgp-l2vpn SDP Bind  in service 1 with SDP pw-template
 policy 1 for the following reason: suitable manual SDP not found."
```

Figure 204: SDP bindings in VPLS 1 with provisioned-sdp use option shows the SDPs used in VPLS 1. PE-1 and PE-2 both used the provisioned SDP. PE-3 has no SDP bindings in VPLS 1.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 204: SDP bindings in VPLS 1 with provisioned-sdp use option

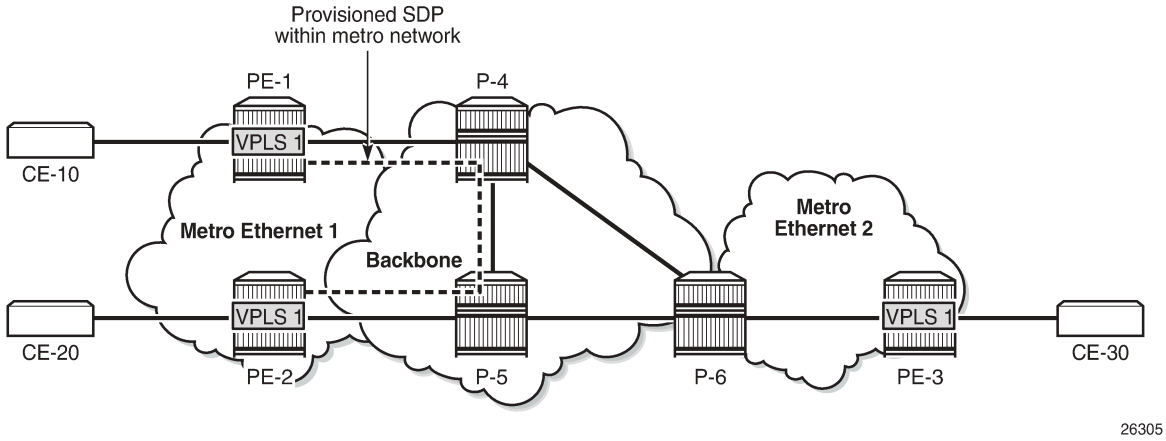

Figure 205: Auto-created SDP bindings in VPLS 2 shows the auto-created SDP bindings in VPLS 2. Each PE has two auto-created SDP bindings to each other PE.

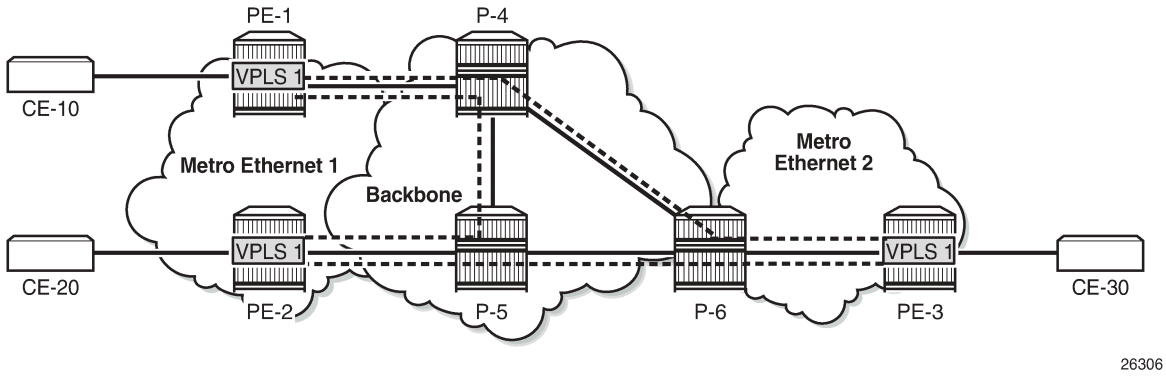
Figure 205: Auto-created SDP bindings in VPLS 2



Migrate VPLS 1 to provisioned-sdp prefer option

VPLS 1 uses PW template 1 with the **provisioned-sdp use** option. This option cannot be modified when the PW template is in use, as follows:

```
[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# provisioned-sdp prefer

*[ex:/configure service pw-template "PW 1"]
A:admin@PE-1# commit
MINOR: SVCMGR #5609: configure service vpls "VPLS 1" bgp 1 pw-template-binding "PW 1" - PW
 Template is in use
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following steps are needed to migrate to another PW template with the **provisioned-sdp prefer** option without service outage:

1. Configure new PW template with **provisioned-sdp prefer** option.
2. Add new PW template binding to VPLS and verify which PW template is used.
3. Modify old PW template binding to make it not usable.
4. Launch tools command to re-evaluate old PW template in the VPLS.
5. When the old PW template is not used anymore, remove PW template binding from the VPLS configuration.

A new PW template with the provisioned-sdp prefer option is configured on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        pw-template "PW 10" {
            pw-template-id 10
            provisioned-sdp prefer
        }
```

An additional PW template binding is configured in VPLS 1 on all PEs, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                pw-template-binding "PW 10" {
                }
            }
        }
```

The configuration of VPLS 1 includes two PW template bindings, as follows:

```
[ex:/configure service vpls "VPLS 1"]
A:admin@PE-1# info
    admin-state enable
    service-id 1
    customer "1"
    bgp 1 {
        route-distinguisher "64496:1"
        route-target {
            export "target:64496:1"
            import "target:64496:1"
        }
        pw-template-binding "PW 1" {
        }
        pw-template-binding "PW 10" {
        }
    }
    bgp-ad {
        admin-state enable
        vpls-id "64496:1"
    }
    sap 1/2/1:1 {
    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following shows that no additional SDP bindings have been created. The only SDP binding in VPLS 1 on PE-1 uses the provisioned SDP 12.

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

The following shows that PW template 1 was used for the creation of the SDP binding:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967295            Type              : BgpAd
PW-Template Id     : 1
```

The PW template 10 has a higher ID than PW template 1 and is not used. Re-evaluating the PW template binding for PW template 1 in VPLS 1 will make no difference if both PW templates are usable. However, PW template 1 can be made unusable by adding a dummy **import-rt** not matching any route in the VPLS, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                pw-template-binding "PW 1" {
                    import-rt "target:111:111"
                }
```

As a result, PW template 10 with the **provisioned-sdp prefer** option is used for the automatic creation of SDP bindings where no provisioned SDP is available, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:4294967295    BgpAd    192.0.2.2       Up      Up        524280    524280
32766:4294967292 BgpAd    192.0.2.3       Up      Up        524277    524279
-------------------------------------------------------------------------------
Number of SDPs : 2
-------------------------------------------------------------------------------
===============================================================================
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

For the first SDP binding, PW template 1 is used, and for the second SDP binding, PW template 10 is used, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967295           Type              : BgpAd
PW-Template Id     : 1
SDP Id             : 32766:4294967292        Type              : BgpAd
PW-Template Id     : 10
```

The following command forces the system to re-evaluate PW template 1 in VPLS 1:

```
[/]
A:admin@PE-1# tools perform service id 1 eval-pw-template 1 allow-service-impact
eval-pw-template succeeded for Svc 1 12:4294967295 Policy 1
```

As a result, only PW template 10 is used for the creation of SDP bindings in VPLS 1, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp detail | match 'SDP Id|PW-Template Id'
SDP Id             : 12:4294967291           Type              : BgpAd
PW-Template Id     : 10
SDP Id             : 32766:4294967292        Type              : BgpAd
PW-Template Id     : 10
```

PW template 1 is not used anymore and can be removed from the VPLS configuration, as follows:

```
# on PE-1, PE-2, PE-3:
configure {
    service {
        vpls "VPLS 1" {
            bgp 1 {
                delete pw-template-binding "PW 1" {
                }
```

The configuration of VPLS 1 on PE-1 contains only a PW template binding for PW template 10, as follows:

```
[ex:/configure service vpls "VPLS 1" bgp 1]
A:admin@PE-1# info
    route-distinguisher "64496:1"
    route-target {
        export "target:64496:1"
        import "target:64496:1"
    }
    pw-template-binding "PW 10" {
    }
```

Figure 206: SDP bindings in VPLS 1 with provisioned-sdp prefer option shows the SDP bindings in VPLS 1 with the **provisioned-sdp prefer** option. Within metro Ethernet network 1, the provisioned SDP is used, and between metro Ethernet networks, auto-created SDP bindings are used.

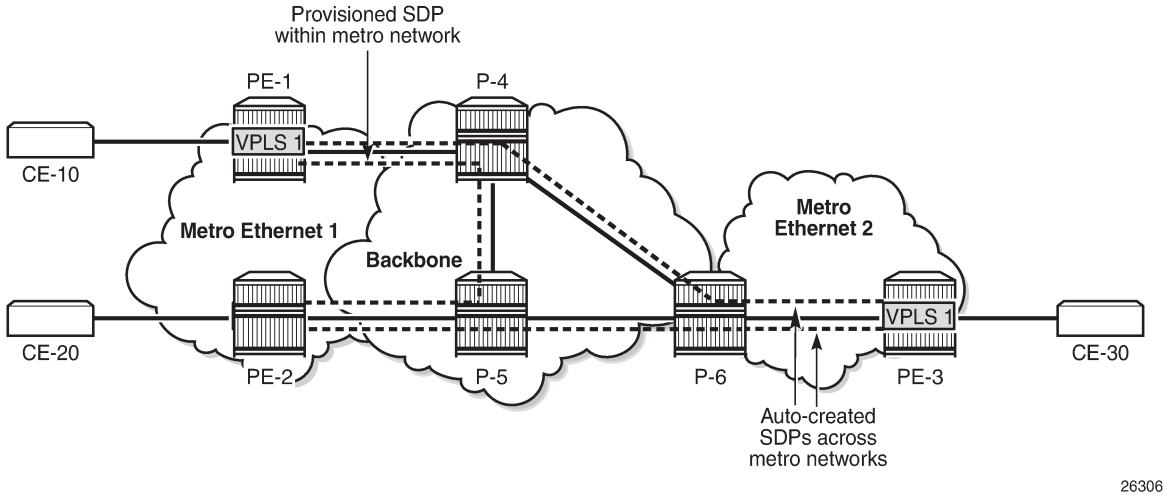
Use subject to Terms available at: www.nokia.com/terms.

Figure 206: SDP bindings in VPLS 1 with provisioned-sdp prefer option



Conclusion

LDP VPLS using BGP-AD allows the creation of SDP bindings that are either auto-created or that use provisioned SDPs. When the **provisioned-sdp prefer** option is used, the tunnel manager will look for a provisioned and active SDP to the far end and use it, if available, even if it is down. When no provisioned SDP is available, the system will auto-create an SDP binding.

Mobility for EVPN Hosts Within an R-VPLS

This chapter provides information about Mobility for EVPN Hosts Within an R-VPLS.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R2. Efficient EVPN host mobility without tromboning or hairpinning in an R-VPLS is supported for IPv4 in SR OS Release 19.10.R3 and later and is supported for IPv6 in SR OS Release 20.5.R1 and later.

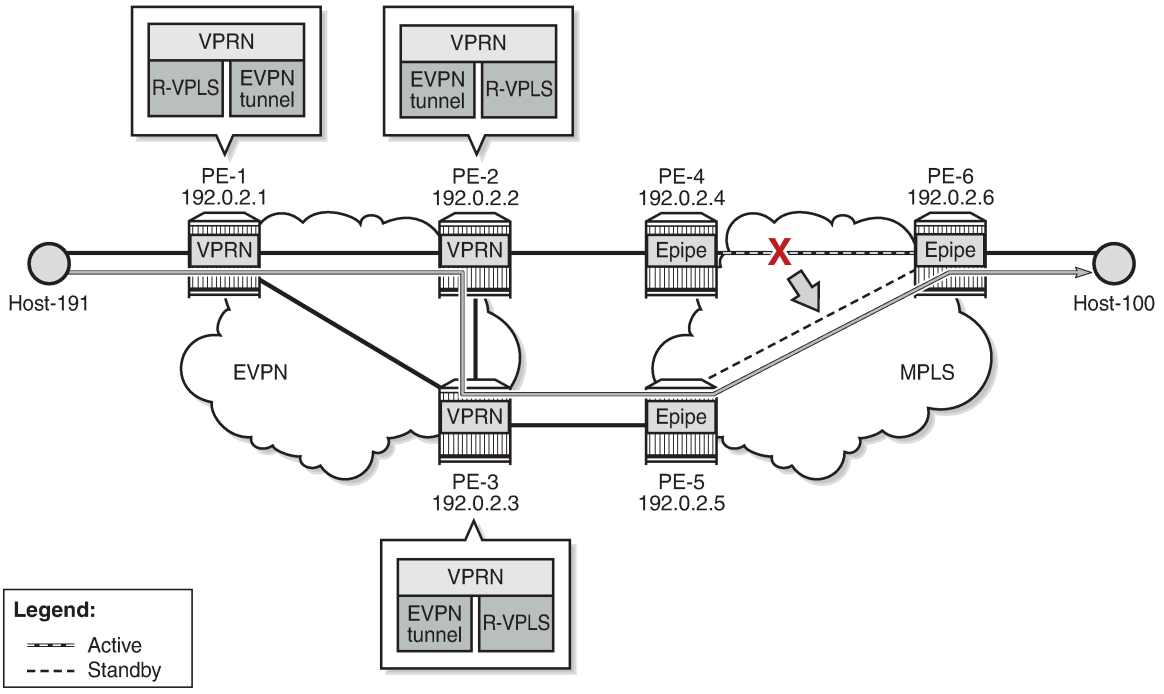
Overview

SR OS can populate a VPRN route table with host routes learned from the IPv4 Address Resolution Protocol (ARP) messages or IPv6 Neighbor Discovery (ND) protocol messages. The host routes can be advertised in the VPRN context as IP-VPN or EVPN route type 5 (RT5), to be used by an IP-VPN or EVPN core network for inter-subnet forwarding. SR OS supports *draft-ietf-bess-evpn-inter-subnet-forwarding* for a dynamic and efficient routing between remote hosts, avoiding hairpinning.

In SR OS releases earlier than Release 19.10.R3, inefficient hairpinning situations may occur when the VPRN is configured to advertise IPv4 host routes as IP-VPN or EVPN RT5 routes. Figure 207: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3 shows hairpinning in an EVPN broadcast domain with PE-1, PE-2, and PE-3.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 207: Hairpinning in a broadcast domain after switchover for SR OS releases earlier than Release 19.10.R3



When host-100 comes up, it sends a Gratuitous Address Resolution Protocol (GARP) message that is then learned on PE-2 and PE-3. PE-2 and PE-3 are configured to advertise host routes, so they generate an RT5 host route for prefix 10.0.0.100/32 of host-100. PE-3 selects its best RT5 for 10.0.0.100/32 and traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-4, and PE-6. However, when the active path between PE-4 and PE-6 fails, the standby path between PE-5 and PE-6 takes over and hairpinning occurs when PE-1 continues selecting PE-2 as the next hop, while a more efficient path is possible via next-hop PE-3. Traffic from host-191 to host-100 uses the path via PE-1, PE-2, PE-3, PE-5, and PE-6.

In SR OS Release 19.10.R3 and later, the more efficient path from host-191 via PE-1, PE-3, PE-5, and PE-6 to host-100 is used, as shown in Figure 208: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later.

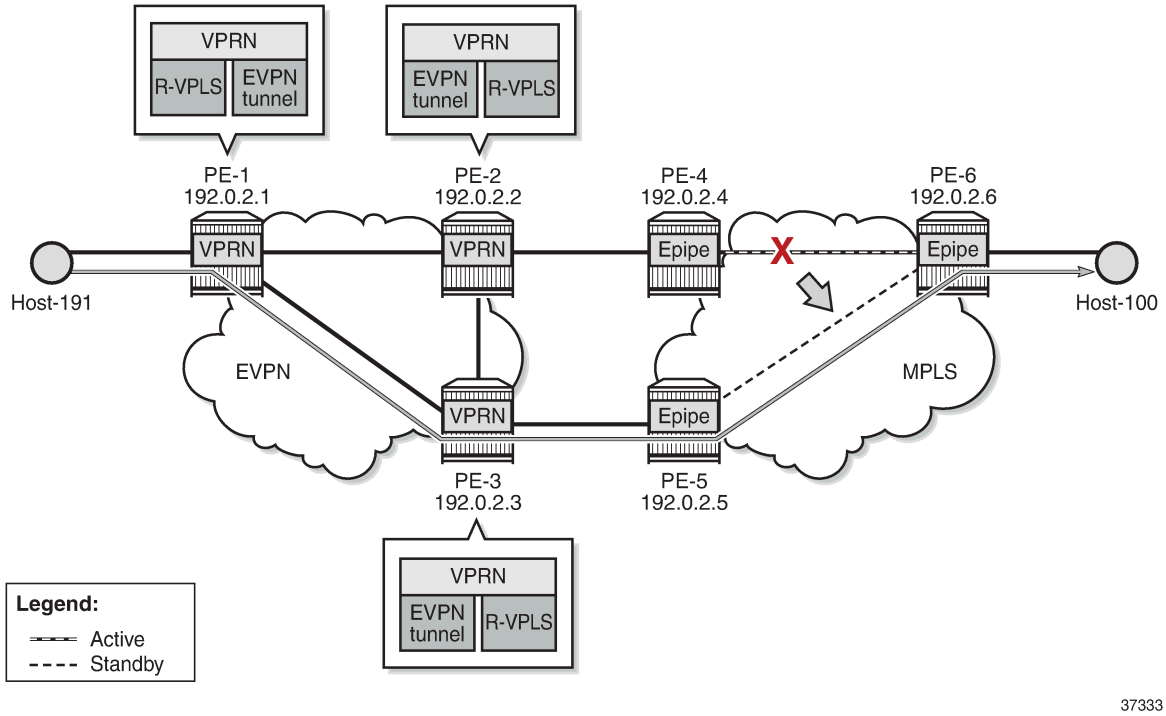
Figure 208: Forwarding in a broadcast domain after switchover for SR OS Release 19.10.R3 and later



In SR OS Release 19.10.R3 and later, EVPN host mobility is supported for IPv4 as described in section "Symmetric and Asymmetric IRB" of *draft-ietf-bess-evpn-inter-subnet-forwarding*. When a host moves from a source PE to a target PE in the same broadcast domain, the behavior for IPv4 hosts is one of the following.

1. The host initiates an ARP request or GARP.
2. The host sends a data packet without first initiating an ARP request or GARP.
3. The host does not send any traffic and the source PE generates an ARP request when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-100 from source PE-2 to target PE-3 is simulated.

For the first of these scenarios, the VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            interface "evi-17" {
                mac 00:00:00:00:2f:17
                ipv4 {
                    primary {
                        address 10.0.0.2
                        prefix-length 24
                    }
                    neighbor-discovery {
                        timeout 300
                        learn-unsolicited true
                        proactive-refresh true
                        local-proxy-arp true
                        host-route {
                            populate dynamic {
                            }
                        }
                    }
                    vrrp 1 {
                        backup [10.0.0.254]
                        passive true
                        ping-reply true
                        traceroute-reply true
                    }
                }
                vpls "evi-17" {
                    evpn {
                        arp {
                            learn-dynamic false
                            flood-garp-and-unknown-req false
                            advertise dynamic {
                            }
                        }
                    }
                }
            }
        }
```

For IPv4, the behavior is controlled by the following commands.

- **ipv4>neighbor-discovery>host-route>populate [dynamic | evpn | static]** configures PE-2 to advertise host routes. The type of ARP entry that can create a host route can be dynamic, EVPN, static, or a combination of these.
- **ipv4>neighbor-discovery>learn-unsolicited** triggers the learning of an ARP entry upon receiving an ARP or GARP message that was not requested by the router.
- **ipv4>neighbor-discovery>proactive-refresh** triggers the refresh of the ARP entry 30 seconds before aging out.
- **ipv4>neighbor-discovery>local-proxy-arp** ensures that PE-2 replies to any received ARP request on behalf of the other hosts in the R-VPLS broadcast domain.
- **vpls>evpn>arp>learn-dynamic** controls whether data path ARP messages received on EVPN connections can populate the ARP tables.
- **vpls>evpn>arp>flood-garp-and-unknown-req** controls the flooding of Control Processing Module (CPM)-generated ARP requests to EVPN destinations.
- **vpls>evpn>arp>advertise [dynamic | static]** enables PE-2 to advertise MAC and IP in EVPN-MAC routes for ARP entries of the dynamic or static type.

For IPv6, the corresponding commands are as follows:

- **ipv6>neighbor-discovery>host-route>populate [dynamic | evpn | static]**

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **ipv6>neighbor-discovery>learn-unsolicited [global | link-local | both]**
- **ipv6>neighbor-discovery>proactive-refresh [global | link-local | both]** triggers the refresh of the ND entry upon aging out.
- **ipv6>neighbor-discovery>local-proxy-nd**
- **vpls>evpn>nd>learn-dynamic**
- **vpls>evpn>nd>advertise [dynamic | static]**

For IPv6, CPM-generated Neighbor Solicitation (NS) messages are always flooded to EVPN destinations. This is not configurable in the **vpls>evpn>nd** context of the VPRN service, in contrast to the **flood-garp-and-unknown-req** command in the **vpls>evpn>arp** context for IPv4.

The behavior for IPv6 hosts when moving from a source PE to a target PE is one of the following.

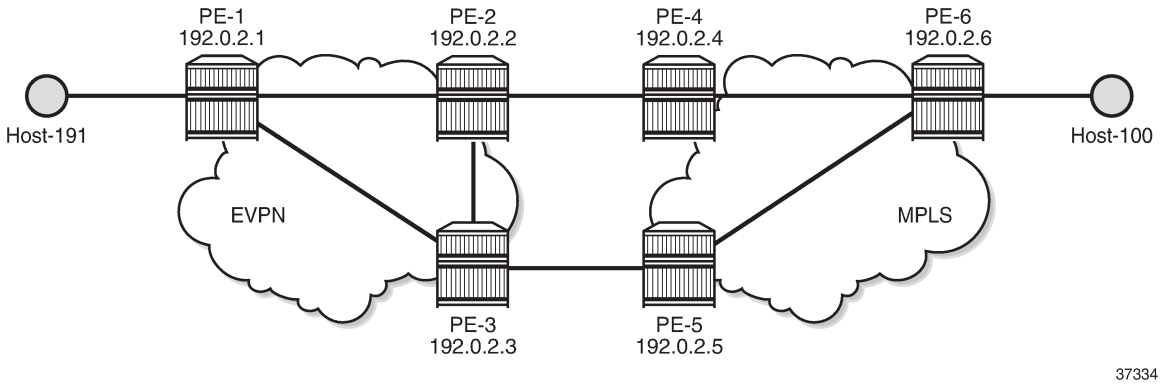
1. The host initiates an unsolicited Neighbor Advertisement (NA).
2. The host sends traffic, without first initiating NA or NS messages.
3. The host does not send any traffic, and the source PE generates an NS message when the MAC address of the host expires and the EVPN-MAC is withdrawn.

All three scenarios are described in more detail later, where the move of host-66 from source PE-2 to target PE-3 is simulated.

Configuration

Figure 209: Example topology with system IP addresses shows the example topology with PE-1, PE-2, and PE-3 in an EVPN-MPLS network and PE-4, PE-5, and PE-6 in an MPLS network.

Figure 209: Example topology with system IP addresses



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- LDP between PE-1, PE-2, PE-3 and between PE-4, PE-5, and PE-6
- BGP configured for the EVPN address family on PE-1, PE-2, and PE-3

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-1, BGP is configured as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "dc" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "dc"
            }
            neighbor "192.0.2.3" {
                group "dc"
            }
        }
```

The BGP configuration is similar on PE-2 and PE-3.

IPv4 host mobility

The following use cases for IPv4 host mobility are described:

1. Host initiates ARP request or GARP after moving
2. Host initiates non-ARP traffic after moving
3. Host does not send any traffic after moving

IPv4 host mobility case 1: host initiates ARP request or GARP after moving

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        vpls "sbd-15" {
            admin-state enable
            description "R-VPLS 15"
            service-id 15
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.1:15"
            }
            bgp-evpn {
                evi 15
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                routes {
                    ip-prefix {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:01
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
            interface "evi-20" {
                mac 00:00:00:00:1e:20
                ipv4 {
                    primary {
                        address 10.0.20.1
                        prefix-length 24
                    }
                }
                vpls "evi-20" {
                }
            }
        }
        vpls "evi-20" {
            admin-state enable
            description "R-VPLS 20"
            service-id 20
            customer "1"
            routed-vpls {
            }
            sap pxc-10.a:20 {
            }
        }
```

VPRN "ip-vrf-16" has two interfaces: interface "evi-15" toward R-VPLS "sbd-15" and interface "evi-20" toward R-VPLS "evi-20". Host-191 is connected to interface "evi-20" of R-VPLS "evi-20".

PE-2 and PE-3 are configured with an anycast gateway, that is, a VRRP passive instance with the same backup IP address 10.0.0.254 on interface "evi-17" in VPRN "ip-vrf-16". The MAC address under VRRP is by default derived from the Virtual Router ID (VRID), so both PE-2 and PE-3 get MAC address 00:00:5E:00:01:01. The service configuration on PE-2 and PE-3 is similar.

```
# on PE-2:
configure {
    service {
        vpls "evi-17" {
            admin-state enable
            description "R-VPLS 17"
            service-id 17
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:17"        # on PE-3: 192.0.2.3:17
            }
            bgp-evpn {
                evi 17
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:17 {                                # on PE-3: sap 1/1/2:17
            }
        }
        vpls "sbd-15" {
            admin-state enable
            description "R-VPLS 15"
            service-id 15
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:15"         # on PE-3: 192.0.2.3:15
            }
            bgp-evpn {
                evi 15
                routes {
                    ip-prefix {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02              # on PE-3: 00:00:00:00:00:03
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
                }
            }
            interface "evi-17" {
                mac 00:00:00:00:2f:17              # on PE-3: 00:00:00:00:3f:17
                ipv4 {
                    primary {
                        address 10.0.0.2           # on PE-3: 10.0.0.3
                        prefix-length 24
                    }
                    neighbor-discovery {
                        timeout 300
                        learn-unsolicited true
                        proactive-refresh true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        local-proxy-arp true
                        host-route {
                            populate dynamic {
                            }
                        }
                    }
                    vrrp 1 {
                        backup [10.0.0.254]      # anycast IP address on PE-2, PE-3
                        passive true
                        ping-reply true
                        traceroute-reply true
                    }
                }
                vpls "evi-17" {
                    evpn {
                        arp {
                            learn-dynamic false
                            flood-garp-and-unknown-req false
                            advertise dynamic {
                            }
                        }
                    }
                }
            }
        }
```

The **ipv4>neighbor-discovery>host-route>populate dynamic** ensures that route-table ARP-ND host routes are created for dynamic entries, not for static or EVPN entries. The **learn-dynamic false** command prevents PE-2 and PE-3 from learning ARP entries from ARP messages received on an EVPN destination. The **flood-garp-and-unknown-req false** command suppresses CPM-generated ARP to reduce unnecessary ARP flooding.

In this sample topology, an Epipe is used where a failover from the primary to the secondary path simulates a move of host-100 from PE-2 to PE-3. SAP 1/1/1:17 in R-VPLS "evi-17" on PE-2 is connected to a SAP of Epipe 17 on PE-4; SAP 1/1/2:17 in R-VPLS "evi-17" on PE-3 to a SAP of Epipe 17 on PE-5. The service configuration on PE-4 is as follows. The configuration on PE-5 is similar.

```
# on PE-4:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 17" {
            admin-state enable
            service-id 17

```

On PE-6, the service configuration is as follows:

```
# on PE-6:
configure {
    service {
        epipe "Epipe 17" {
            admin-state enable
            service-id 17
            customer "1"
            endpoint "EP17" {
            }
            spoke-sdp 64:17 {
                endpoint {
                    name "EP17"
                    precedence primary
                }
            }
            spoke-sdp 65:17 {
                endpoint {
                    name "EP17"
                }
            }
            sap 1/2/1:17 {
            }
        }
        sdp 64 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.4
            }
        }
        sdp 65 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.5
            }
        }
```

Host-100 is connected to SAP 1/2/1:17 in Epipe 17.

On PE-2 and PE-3, debugging is enabled (in classic CLI):

```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-16"
        ip
            arp
            route-table
        exit
    exit
exit
```

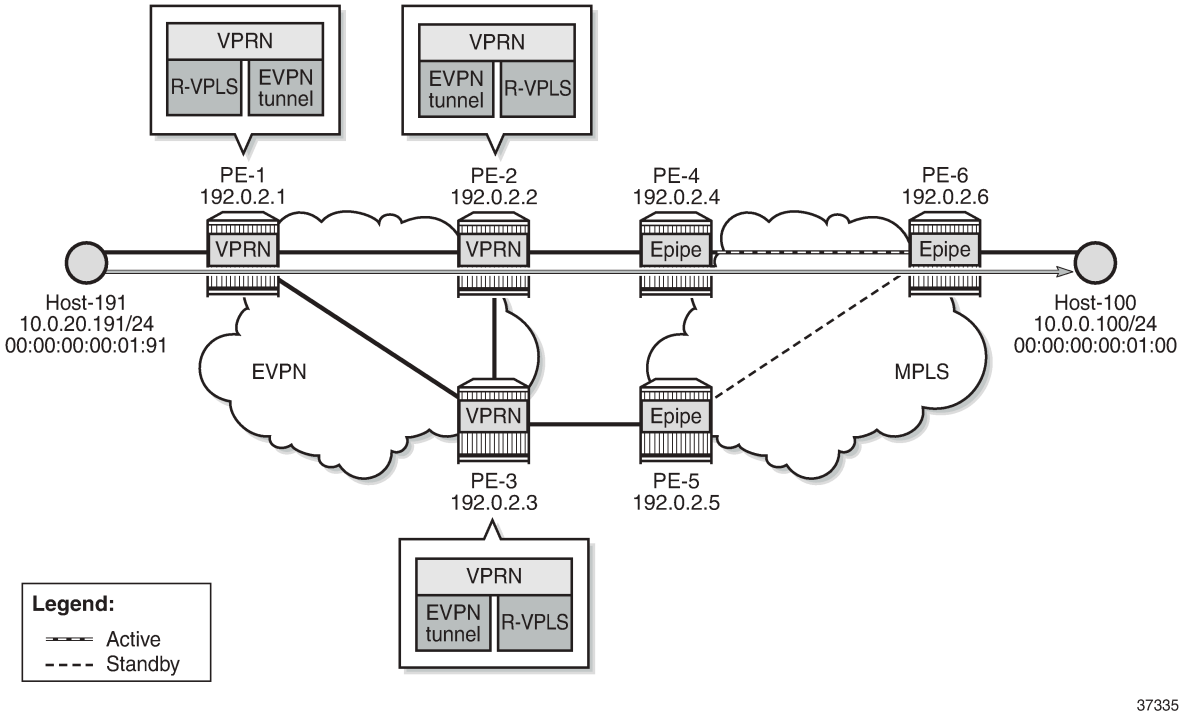
Initial phase

Figure 210: Initial situation with forwarding path via PE-2 shows that traffic from host-191 to host-100 is forwarded via PE-1, PE-2, PE-4, and PE-6.

Figure 210: Initial situation with forwarding path via PE-2



Host-191 sends a traceroute to host-100 via PE-2 (10.0.0.2):

```
[/]
A:admin@PE-1# traceroute 10.0.0.100 router-instance "H-191" source-address 10.0.20.191
traceroute to 10.0.0.100 from 10.0.20.191, 30 hops max, 40 byte packets
  1  10.0.20.1 (10.0.20.1)    3.96 ms  2.27 ms  2.07 ms
  2  10.0.0.2 (10.0.0.2)    2.96 ms  2.95 ms  2.82 ms
  3  10.0.0.100 (10.0.0.100)    10.9 ms  5.54 ms  5.07 ms
```

The ARP table for VPRN "ip-vrf-16" on PE-2 shows that IP address 10.0.0.100 corresponds to MAC address 00:00:00:00:01:00 and is learned dynamically:

```
[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================

===============================================================================
```

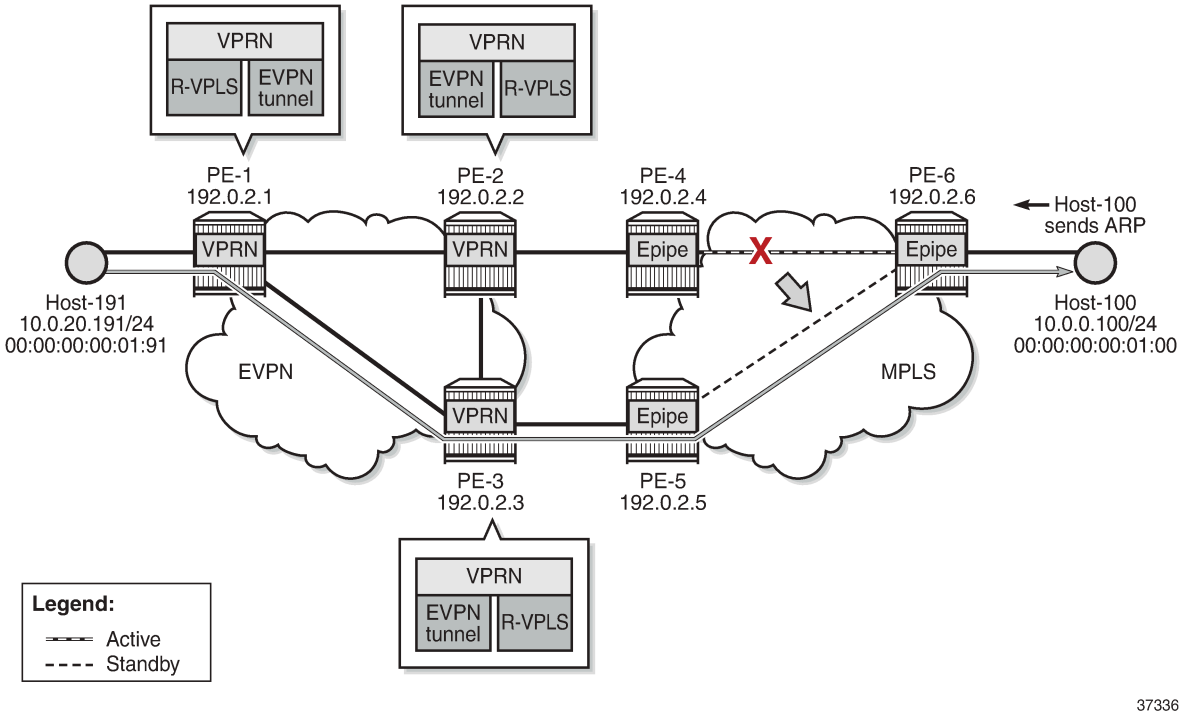
PE-3 receives the IP and MAC addresses of host-100 as EVPN type. PE-3 must not learn these IP and MAC addresses as dynamic because PE-3 must be prevented from advertising an RT5 route. If PE-3 advertised prefix 10.0.0.100, then PE-1 could select PE-3 as next hop to reach host-100, causing an undesired hairpinning forwarding behavior.

Host-100 sends an ARP request or GARP after moving

Figure 211: Host-100 sends an ARP request or GARP after switchover shows a switchover from the active to the standby path where host-100 sends an ARP request or GARP and its IP and MAC addresses are learned on PE-3 instead of PE-2. The failure is simulated by disabling the SDP from PE-4 to PE-6.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 211: Host-100 sends an ARP request or GARP after switchover



Due to the SDP failure on PE-4, the initial path can no longer be used. Host-100 sends an ARP request or GARP with its IP and MAC addresses. In the following example, PE-3 receives the following ARP request and replies to it:

```
1 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP ingressing on evi-17
   Who has 10.0.0.254 ? Tell 10.0.0.100
"
2 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP

ARP egressing on evi-17
   10.0.0.254 is at 00:00:5e:00:01:01
"
```

The Route Table Manager (RTM) for prefix 10.0.0.100 in VPRN "ip-vrf-16" is modified with preference 1 and owner ARP-ND. This behavior is due to the **ipv4>neighbor-discovery>host-route>populate dynamic** command.

```
3 2022/01/28 12:49:45.684 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ROUTE
instance 2 (16), RTM MODIFY event

            Transport:Tnl-Id                         Age
-------------------------------------------------------------------------------
17         00:00:00:00:01:00 mpls-1:                 Evpn     01/28/22 12:49:46
                             192.0.2.3:524283
           ldp:65538
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

On PE-3, the ARP table for VPRN "ip-vrf-16" shows that IP address 10.0.0.100 is learned dynamically on interface "evi-17":

```
[/]
A:admin@PE-3# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h04m40s Dyn[I] evi-17
===============================================================================
```

On PE-2, the ARP table for VPRN "ip-vrf-16" shows that the entry for IP address 10.0.0.100 is updated from dynamic to type EVPN:

```
[/]
A:admin@PE-2# show router 16 arp 10.0.0.100

===============================================================================
ARP Table (Service: 16)
===============================================================================
IP Address      MAC Address       Expiry    Type   Interface
-------------------------------------------------------------------------------
10.0.0.100      00:00:00:00:01:00 00h00m00s Evp[I] evi-17
===============================================================================
```

An ARP entry's change from dynamic to EVPN triggers a CPM-generated ARP request from PE-2, but the configured **flood-garp-and-unknown-req false** command prevents PE-2 from flooding the ARP request to EVPN destinations such as PE-3.

On PE-3, the route table for VPRN "ip-vrf-16" shows an ARP-ND host route for prefix 10.0.0.100:

```
[/]
```

IPv4 host mobility case 2: host sends traffic without first initiating an ARP request or GARP after moving

In use cases 2 and 3, the configuration of VPRN "ip-vrf-16" is modified on PE-2 and PE-3. The only difference from case 1 is that the **flood-garp-and-unknown-req** is configured, which is the default setting. The VPRN configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vprn "ip-vrf-16" {
            admin-state enable
            service-id 16
            customer "1"
            interface "evi-15" {
                mac 00:00:00:00:00:02
                vpls "sbd-15" {
                    evpn-tunnel {
                    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
        interface "evi-17" {
            mac 00:00:00:00:2f:17
            ipv4 {
                primary {
                    address 10.0.0.2
                    prefix-length 24
                }
                neighbor-discovery {
                    timeout 300
                    learn-unsolicited true
                    proactive-refresh true
                    local-proxy-arp true
                    host-route {
                        populate dynamic {
                        }
                    }
                }
                vrrp 1 {
                    backup [10.0.0.254]
                    passive true
                    ping-reply true
                    traceroute-reply true
                }
            }
            vpls "evi-17" {
                evpn {
                    arp {
                        learn-dynamic false
                        flood-garp-and-unknown-req true  # default behavior
                        advertise dynamic {
                        }
                    }
                }
            }
        }
```

Initial forwarding path

The initial forwarding path via PE-2 is restored by enabling the SDP from PE-4 to PE-6. The route table for VPRN "ip-vrf-16" on PE-2 shows the following ARP-ND host route for prefix 10.0.0.100/32:

```
[/]
A:admin@PE-2# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================

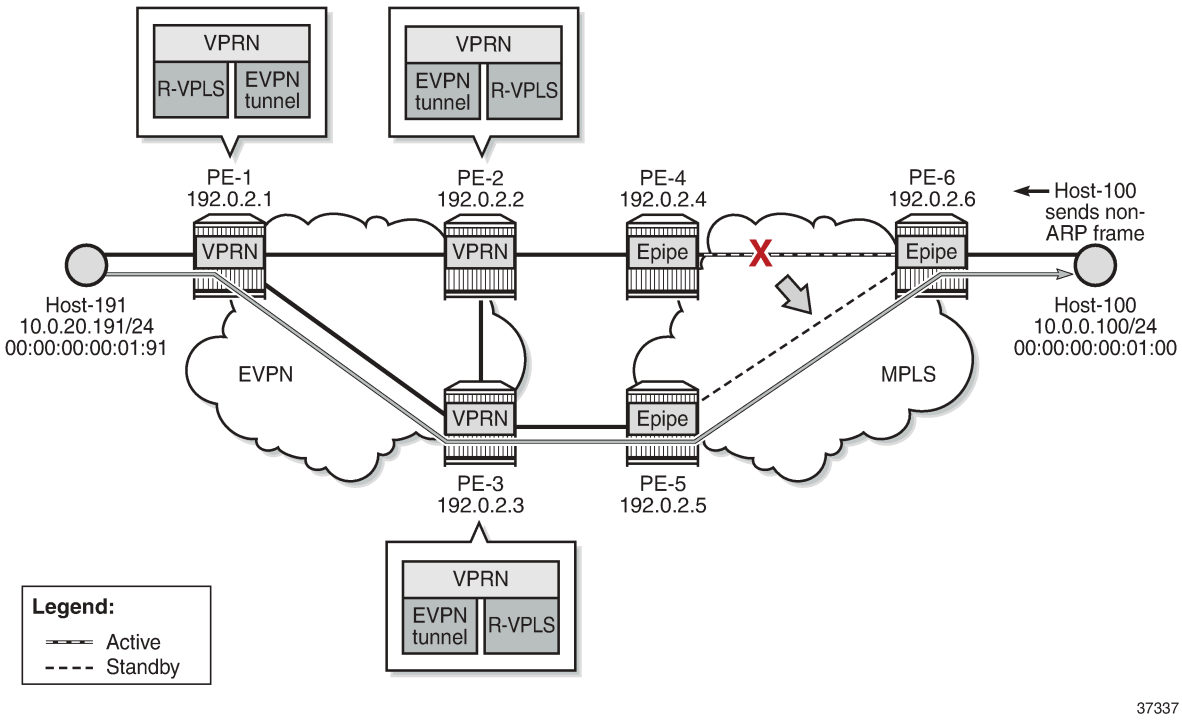
Host-100 generates non-ARP traffic after moving

On PE-4, the SDP from PE-4 to PE-6 is disabled, causing a switchover to the standby path. Figure 212: Host sends non-ARP frame after switchover shows the path after switchover. Host-100 generates non-ARP traffic after moving.

Figure 212: Host sends non-ARP frame after switchover



Host-100 sends a non-ARP frame with MAC source address 00:00:00:00:01:00 to host-191. The following steps occur:

1. PE-3 receives this frame with MAC 00:00:00:00:01:00 and updates its FDB.
2. PE-3 advertises an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address) with a higher sequence number.
3. PE-2 receives this EVPN MAC route, updates its FDB and withdraws its EVPN-MAC routes for MAC 00:00:00:00:01:00.
4. The FDB update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for MAC 00:00:00:00:01:00.
5. PE-2 is configured with **flood-garp-and-unknown-req**, so the ARP request is flooded to the EVPN destinations PE-1 and PE-3. PE-3 floods this ARP request to its SAPs and SDP-bindings; in this case, to SAP 1/1/2:17.
6. When the ARP request reaches host-100, it sends an ARP reply to the anycast IP address 10.0.0.254. This ARP reply is received by PE-3.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

7. When PE-3 receives the ARP reply, it updates the ARP entry for 10.0.0.100 to type dynamic instead of type EVPN.
8. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. Also, MAC 00:00:00:00:01:00 is now learned in ARP as local, so PE-3 sends an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100.
9. PE-2 receives the EVPN routes and updates the ARP entry for prefix 10.0.0.100 from type dynamic to type EVPN. PE-2 also removes its ARP-ND host route from the route table and withdraws its RT5 for prefix 10.0.0.100/32.

On PE-3, the route for prefix 10.0.0.100/32 is an ARP-ND host route:

```
[/]
A:admin@PE-3# show router 16 route-table 10.0.0.100

===============================================================================
Route Table (Service: 16)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.0.100/32                                 Remote  ARP-ND    00h01m05s  1
       10.0.0.100                                                  0
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

IPv4 host mobility case 3: host does not send any traffic after moving

The service configuration on PE-2 and PE-3 remains the same as in use case 2.

The forwarding path is restored by enabling the SDP from PE-4 to PE-6, so the initial situation is the same as in the preceding cases. PE-2 learns MAC address 00:00:00:00:01:00 on its local SAP 1/1/1:17, as follows:

```
[/]
A:admin@PE-2# show service id 17 fdb detail

```
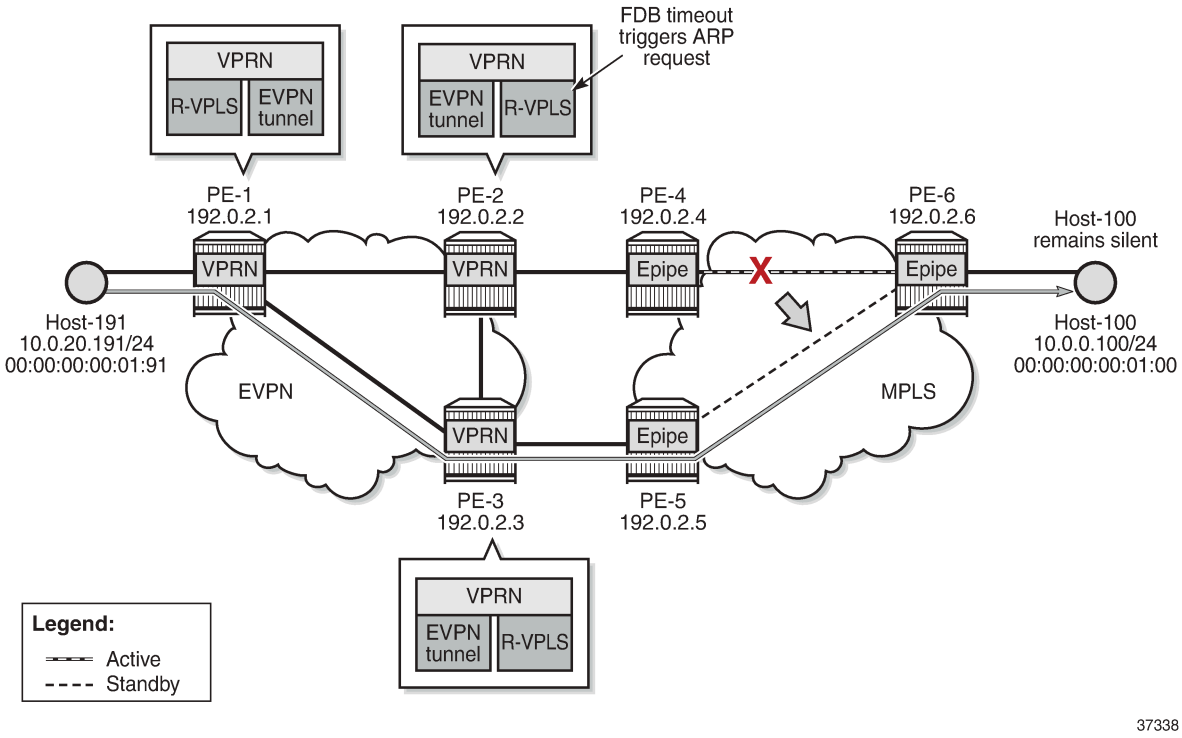
===============================================================================
```

The SDP from PE-4 to PE-6 is disabled and host-100 does not send any traffic, as shown in Figure 213: Host does not send any traffic after switchover.

Figure 213: Host does not send any traffic after switchover



The following steps occur:

1. When MAC 00:00:00:00:01:00 ages out in the FDB of R-VPLS 17 on PE-2, PE-2 withdraws the EVPN-MAC routes for MAC 00:00:00:00:01:00. The update for MAC 00:00:00:00:01:00 triggers PE-2 to send an ARP request for 10.0.0.100.

```
# on PE-2:
99 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 vprn16 PIP
"PIP: ARP
instance 2 (16), interface index 6 (evi-17),
ARP egressing on evi-17
   Who has 10.0.0.100 ? Tell 10.0.0.254
"
```

```
101 2022/01/28 13:12:04.028 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 42
    Flag: 0x90 Type: 15 Len: 38 Multiprotocol Unreachable NLRI:
        Address Family EVPN

```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
"
```

2. PE-2 is configured with **flood-garp-and-unknown-req true**. PE-2 floods the CPM-generated ARP request to PE-3. PE-3 forwards the ARP request to host-100.
3. Host-100 sends an ARP reply that is received by PE-3. PE-3 updates its FDB and ARP tables.
4. The FDB update on PE-3 makes PE-3 advertise an EVPN-MAC route for MAC 00:00:00:00:01:00 (with a null IP address). The ARP update makes PE-3 advertise an EVPN-MAC route with MAC 00:00:00:00:01:00 and IP prefix 10.0.0.100. PE-2 receives two EVPN-MAC routes from PE-3:

```
103 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE

    Flag: 0xc0 Type: 16 Len: 24 Extended Community:
        target:64500:17
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:5
"
```

5. PE-3 is configured with **populate dynamic**, so it advertises an RT5 for prefix 10.0.0.100/32. In the route table for VPRN "ip-vrf-16", the route for IP prefix 10.0.0.100/32 is ARP-ND host route. PE-2 receives the following RT5 route from PE-3:

```
102 2022/01/28 13:12:04.033 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3
"Peer 1: 192.0.2.3: UPDATE
Peer 1: 192.0.2.3 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 90
    Flag: 0x90 Type: 14 Len: 45 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-IP-PREFIX Len: 34 RD: 192.0.2.3:15, tag: 0,
         ip_prefix: 10.0.0.100/32 gw_ip 0.0.0.0 Label: 8388544 (Raw Label: 0x7fffc0)
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 24 Extended Community:

        mac-nh:00:00:00:00:00:03
        bgp-tunnel-encap:MPLS
"
```

6. PE-2 receives the EVPN routes and updates its FDB and ARP tables. When the ARP entry changes its type from dynamic to EVPN, PE-2 withdraws its RT5 route.

On PE-2, the FDB for R-VPLS 17 shows an EVPN route for MAC 00:00:00:00:01:00:

IPv6 host mobility

The following use cases for IPv6 host mobility are described:

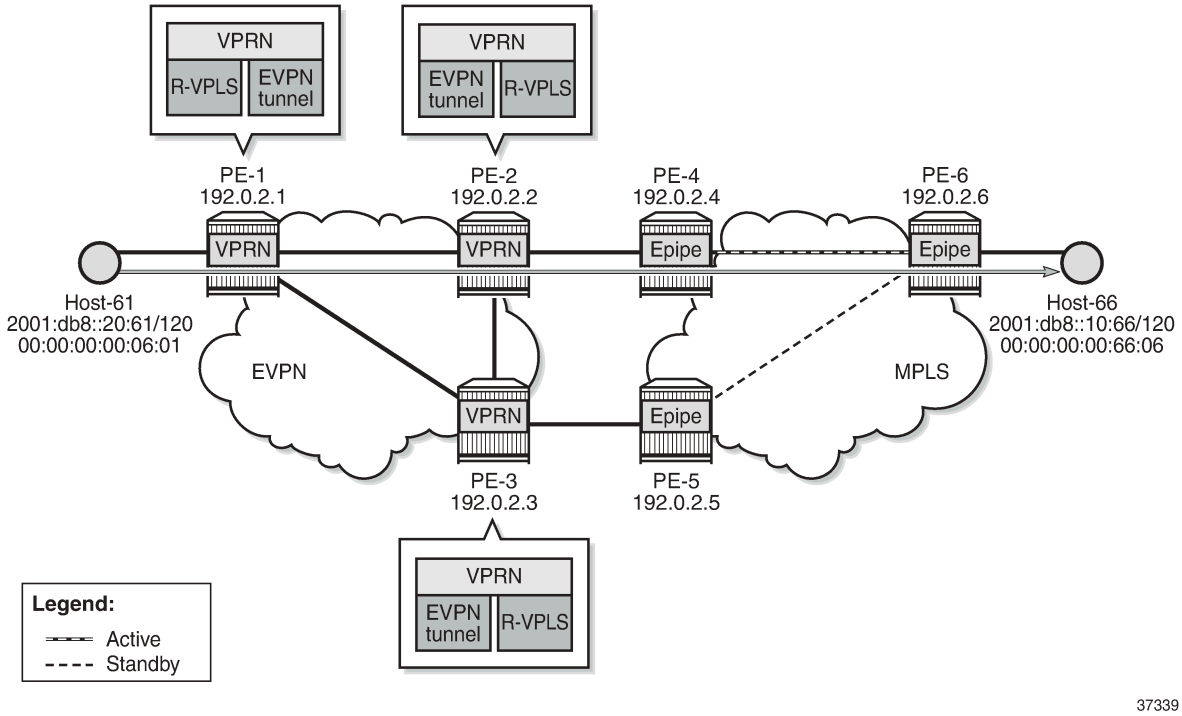
1. Host initiates an unsolicited NA message after moving
2. Host sends non-ND traffic after moving
3. Host does not send any traffic after moving

The configuration is identical in these use cases.

Figure 214: Example topology for initial forwarding path via PE-2 with IPv6 addresses shows the topology with IPv6 addresses for host-61 and host-66.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 214: Example topology for initial forwarding path via PE-2 with IPv6 addresses



The services are the following:

- R-VPLS "sbd-5" on PE-1, PE-2, and PE-3
- VPRN "ip-vrf-6" on PE-1, PE-2, and PE-3
- R-VPLS "evi-10" on PE-1; R-VPLS "evi-7" on PE-2 and PE-3
- Epipe "Epipe 7" on PE-4, PE-5, and PE-6
- Host-61 is connected to R-VPLS "evi-10" on PE-1
- Host-66 is connected to Epipe "Epipe 7" on PE-6

The service configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        vpls "evi-10" {
            admin-state enable
            description "R-VPLS 10"
            service-id 10
            customer "1"
            routed-vpls {
            }
            sap pxc-10.a:10 {
            }
        }
        vpls "sbd-5" {
            admin-state enable
            description "R-VPLS 5"
            service-id 5
```

                mac 00:00:00:06:1e:20
                vpls "evi-10" {
                }
                ipv6 {
                    address 2001:db8::20:1 {
                        prefix-length 120
                    }
                }
            }
            interface "evi-5" {
                mac 00:00:00:00:06:01
                vpls "sbd-5" {
                    evpn-tunnel {
                    }
                }
                ipv6 {
                }
            }
        }
```

The service configuration on PE-2 is as follows. The service configuration on PE-3 is similar.

```
# on PE-2:
configure {
    service {
        vpls "sbd-5" {
            admin-state enable
            description "R-VPLS 5"
            service-id 5
            customer "1"
            routed-vpls {
            }
            bgp 1 {
                route-distinguisher "192.0.2.2:5"         # on PE-3: 192.0.2.3:5
            }
            bgp-evpn {
                evi 5
```

                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:7 {                                # on PE-3: sap 1/1/2:7
            }
        }
```

Debugging is enabled on PE-2 and PE-3 (in classic CLI):

```
# on PE-2, PE-3:
debug
    router "Base"
        bgp
            update
        exit
    exit
    router service-name "ip-vrf-6"
        ip
            route-table
            icmp6 "evi-7"
            neighbor "evi-7"
        exit
    exit
exit
```

Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    1034 ms  2.80 ms  4.17 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.1 ms  5.59 ms  4.95 ms
```

The following route table on PE-2 shows an ARP-ND host route for prefix 2001:db8::10:66/128:

```
[/]
A:admin@PE-2# show router 6 route-table 2001:db8::10:66

```

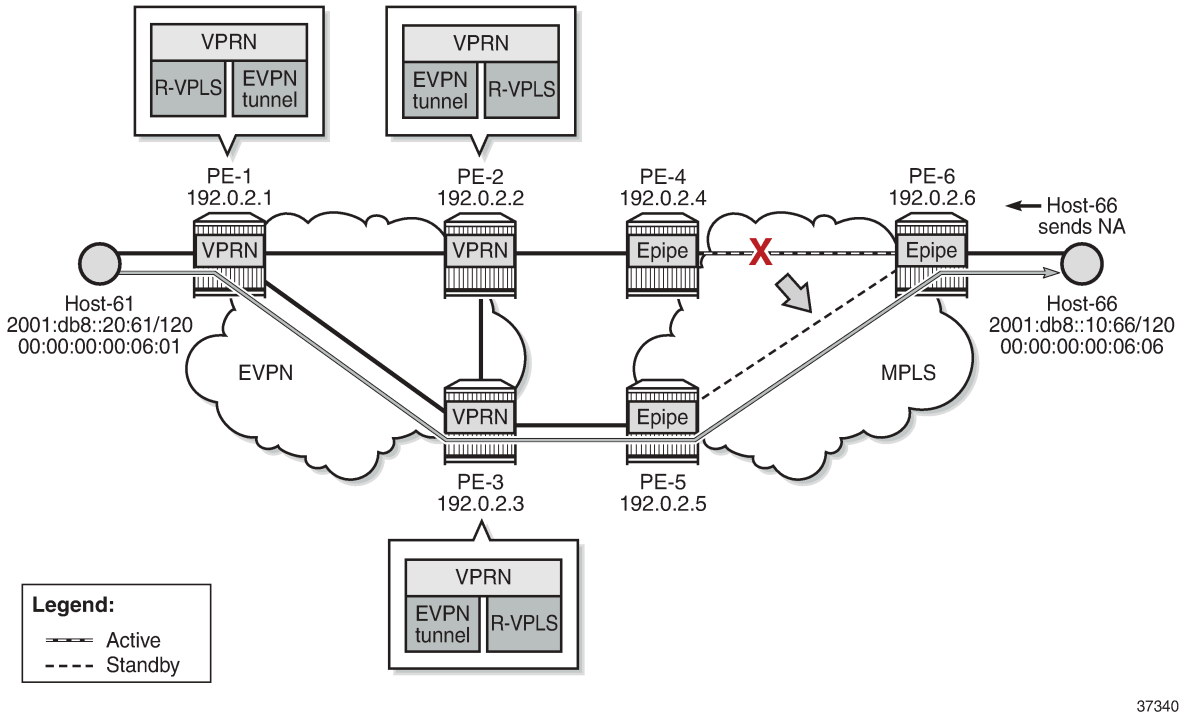
IPv6 host mobility case 1: host initiates an unsolicited NA message after moving

On PE-2 and PE-3, the **learn-unsolicited** command is configured on interface "evi-7" in VPRN "ip-vrf-6". When an unsolicited NA message is received, a stale neighbor is created. If **host-route>populate dynamic** is enabled, a confirmation message is sent for all the neighbor entries created as stale, and if confirmed, the corresponding ARP-ND routes are added to the route table.

Disabling SDP 46 on PE-4 causes a failover from the primary path via PE-4 to the secondary path via PE-5, simulating host-66 moving from PE-2 to PE-3. To trigger an unsolicited NA message from host-66, its MAC address 00:00:00:00:66:06 is replaced by MAC address 00:00:00:00:06:06. Figure 215: Host-66 sends unsolicited NA message after switchover shows that host-66 sends an unsolicited NA message.

Figure 215: Host-66 sends unsolicited NA message after switchover



Host-66 advertises its new MAC address in unsolicited NA messages. PE-3 receives the following NA messages from host-66. PE-2 also receives the NA messages, but it rejects NA messages received on interface "evi-7" when **learn-dynamic false** is configured:

```
# on PE-3:
3 2022/01/28 13:19:55.747 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: ICMP6_PKT
```

-------------------------------------------------------------------------------
7          00:00:00:00:06:06 sap:1/1/2:7             L/90     01/28/22 13:19:56
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

PE-3 sends CPM-generated NS messages that are also flooded to the EVPN destinations. The **learn-dynamic false** command prevents PE-2 from learning MAC addresses dynamically on an EVPN connection.

PE-3 sends an EVPN-MAC update to PE-2 and MAC address 00:00:00:00:06:06 appears in the FDB on PE-2 as an EVPN entry:

```
[/]
A:admin@PE-2# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================
Forwarding Database, Service 7

```

IPv6 host mobility case 2: host sends non-ND traffic after moving,

The service configuration is the same as in the use case 1. The only difference from use case 1 is the type of message that is sent by host-66 after moving.

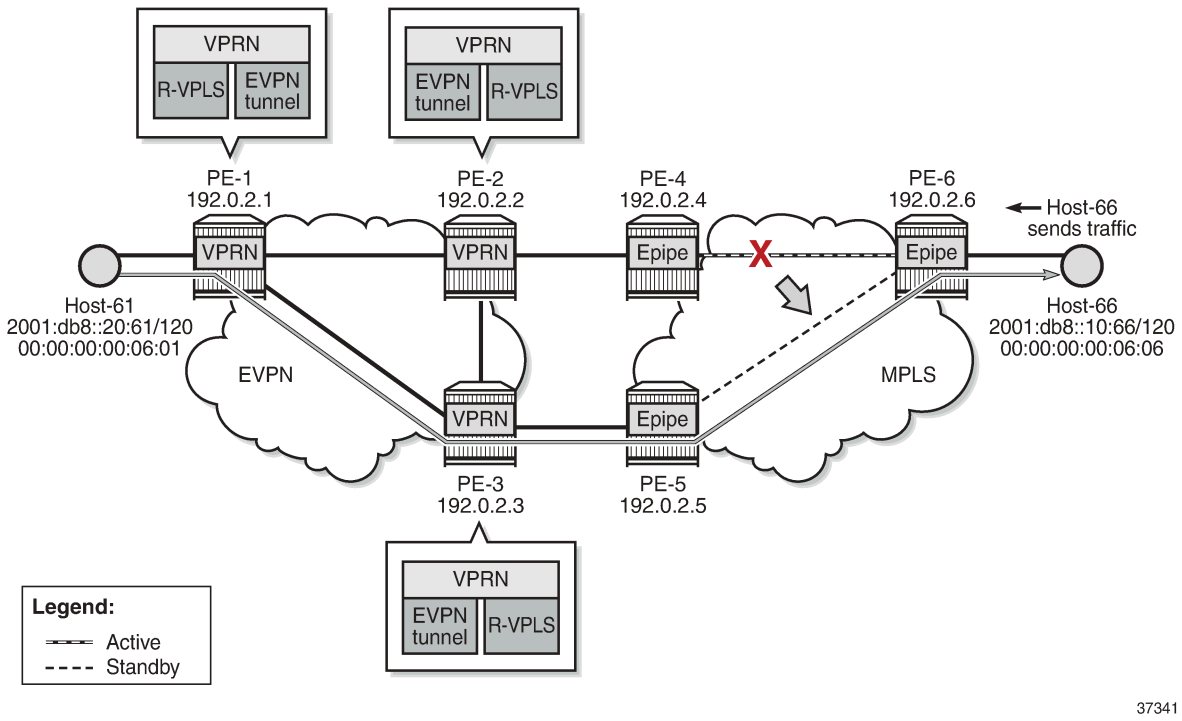
Initially, the traceroute from host-66 to host-61 is via PE-2 (2001:db8::10:2):

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    7.88 ms  3.85 ms  3.67 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    11.0 ms  5.19 ms  5.30 ms
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A switchover from the primary path to the secondary path takes place, so host-66 moves from PE-2 to PE-3. Figure 216: Host generates non-ND traffic after switchover shows that host-66 sends non-ND traffic after moving.

Figure 216: Host generates non-ND traffic after switchover



The traceroute from host-66 to host-61 is via PE-3 (2001:db8::10:3) instead of PE-2, as follows:

```
[/]
A:admin@PE-6# traceroute 2001:db8::20:61 router-instance "H-66"
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:3 (2001:db8::10:3)    7.68 ms  3.84 ms  3.65 ms
  2  ::  * * *
  3  2001:db8::20:61 (2001:db8::20:61)    5.54 ms  5.55 ms  5.64 ms
```

On PE-3, MAC address 00:00:00:00:06:06 from host-66 is learned on the local SAP 1/1/2:17:

```
[/]
A:admin@PE-3# show service id 7 fdb mac 00:00:00:00:06:06

===============================================================================
Forwarding Database, Service 7
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change

```

IPv6 host mobility case 3: host does not send any traffic after moving

The service configuration is the same as use cases 1 and 2. SDP 46 is enabled on PE-4, so host-66 moves back to PE-2. The following traceroute shows that the forwarding path from host-66 to host-61 is via PE-2:

```
[/]
A:admin@PE-6# traceroute router 8 2001:db8::20:61 source 2001:db8::10:66
traceroute to 2001:db8::20:61 from 2001:db8::10:66, 30 hops max, 60 byte packets
  1  2001:db8::10:2 (2001:db8::10:2)    3.76 ms  4.23 ms  4.00 ms
  2  ::  * * *
```

© 2026 Nokia.

```

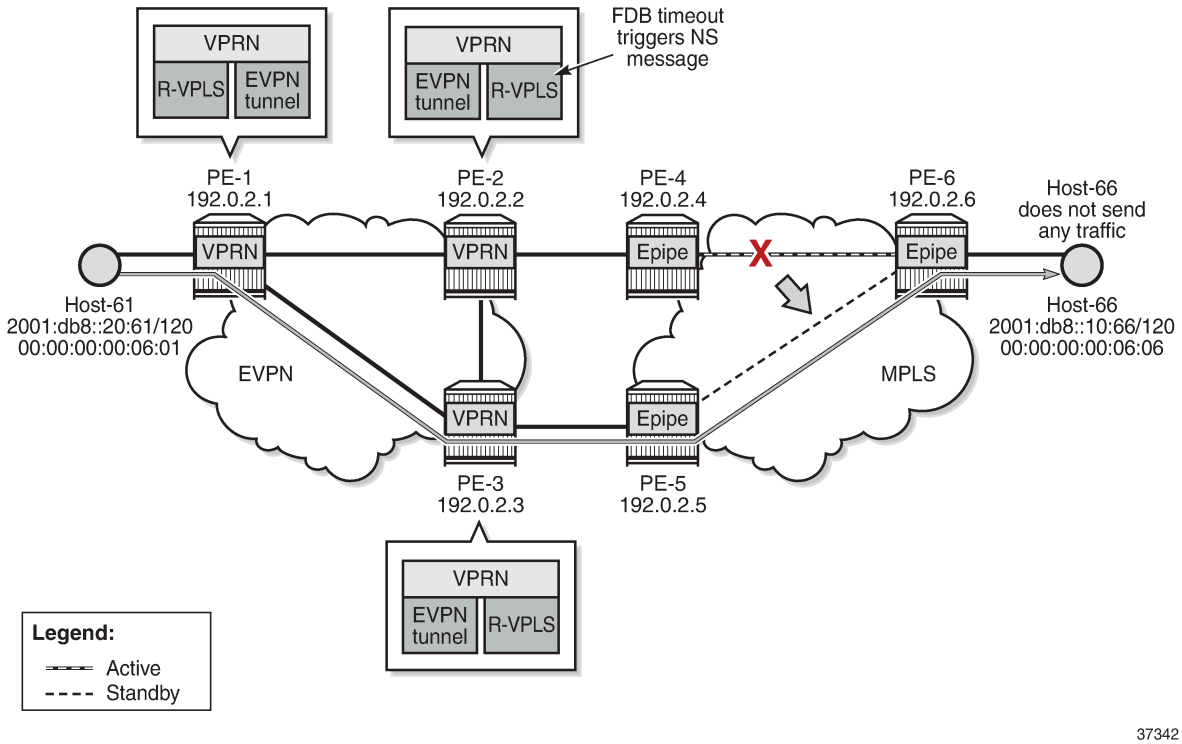
A failure is simulated, causing a failover from the primary path via PE-4 to the secondary path via PE-5. Host-66 does not send any traffic after switchover. Figure 217: Host does not send any traffic after switchover shows that PE-2 sends an NS message when the FDB entry for host-66 ages out.

Figure 217: Host does not send any traffic after switchover



© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-2, MAC address 00:00:00:00:06:06 expires in the FDB for R-VPLS "evi-7", which triggers PE-2 to send an NS message for 2001:db8::10:66. This CPM-generated NS message is flooded to the EVPN destinations PE-1 and PE-3.

```
# on PE-2:
202 2022/01/28 13:37:34.634 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Sending NS for nbr addr 2001:db8::10:66 nbr type dynamic"
```

The NS message reaches host-66, which replies with an NA message. PE-3 receives the NA message and updates its FDB and ND tables. PE-2 also receives the NA message, but it rejects NA messages received on interface "evi-7" when no learn-dynamic is configured:

```
225 2022/01/28 13:37:34.638 UTC MINOR: DEBUG #2001 vprn6 TIP
"TIP: NBR
Ignore NA for target address 2001:db8::10:66 on evpn endpoint evi-7 because learn-dynamic is
 disabled."
```

PE-2 receives the following EVPN-MAC routes from PE-3:

```
237 2022/01/28 13:43:03.001 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.3

```

Conclusion

EVPN host mobility is supported in SR OS as described in draft-ietf-bess-evpn-inter-subnet-forwarding. This chapter describes several cases when a host moves from a source PE to a target PE within the same broadcast domain.

Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire

This chapter provides information about multi-chassis endpoint for VPLS active/standby pseudowire.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 7.0.R6, but the MD-CLI in this edition is based on SR OS Release 23.7.R2.

Overview

When implementing a large VPLS, one of the limiting factors is the number of T-LDP sessions required for the full mesh of SDPs. Mesh-SDPs are required between all PEs participating in the VPLS with a full mesh of T-LDP sessions.

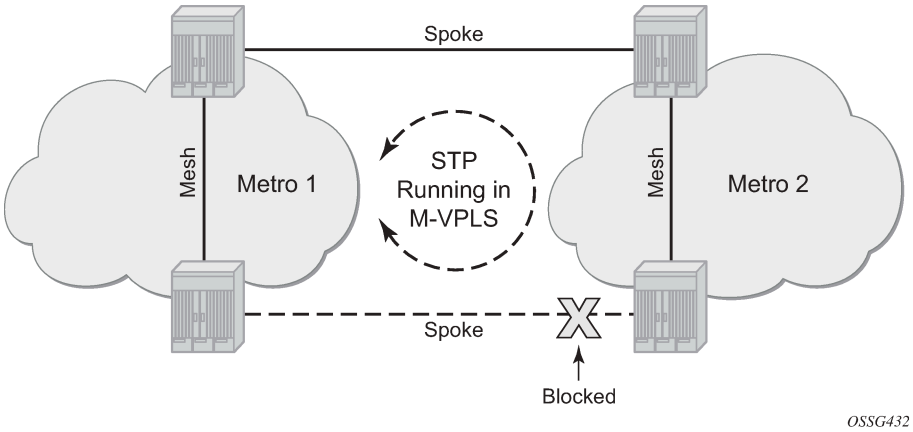
This solution is not scalable, because the number of sessions grows more rapidly than the number of participating PEs. Several options exist to reduce the number of T-LDP sessions required in a large VPLS.

The first option is hierarchical VPLS (H-VPLS) with spoke SDPs. By using spoke SDPs between two clouds of fully meshed PEs, any-to-any T-LDP sessions for all participating PEs are not required.

However, if spoke SDP redundancy is required, STP must be used to avoid a loop in the VPLS. Management VPLS can be used to reduce the number of STP instances and separate customer and STP traffic, as illustrated in Figure 218: H-VPLS with STP.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

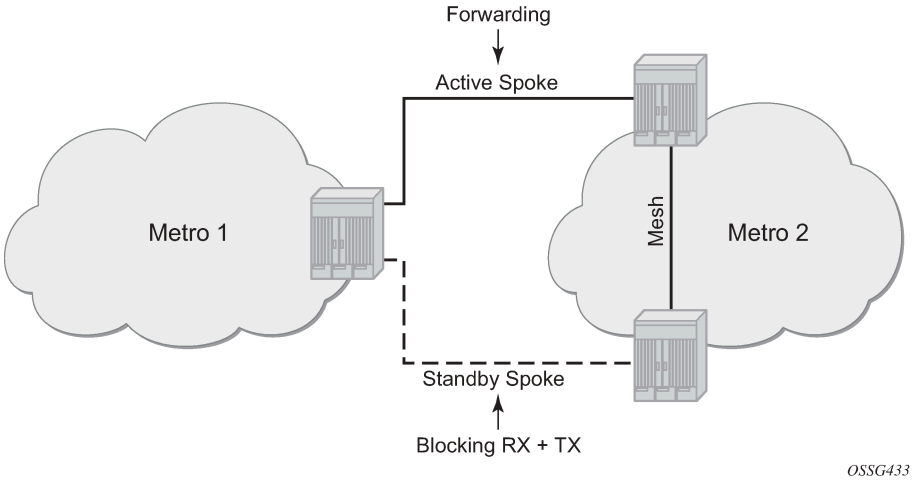
Figure 218: H-VPLS with STP



VPLS pseudowire redundancy provides H-VPLS redundant spoke connectivity. The active spoke SDP is in forwarding state, while the standby spoke SDP is in blocking state. Therefore, STP is not needed anymore to break the loop, as illustrated in Figure 219: VPLS pseudowire redundancy.

However, the PE implementing the active and standby spokes represents a single point of failure in the network.

Figure 219: VPLS pseudowire redundancy



Multi-chassis endpoint (MC-EP) for VPLS active/standby pseudowire expands on the VPLS pseudowire redundancy and allows the removal of the single point of failure.

Only one spoke SDP is in forwarding state; all standby spoke SDPs are in blocking state. Mesh and square resiliency are supported.

Mesh resiliency can protect against simultaneous node failure in the core and in the MC-EP (double failure), but requires more SDPs (and therefore more T-LDP sessions). Mesh resiliency is illustrated in Figure 220: Multi-chassis endpoint with mesh resiliency.

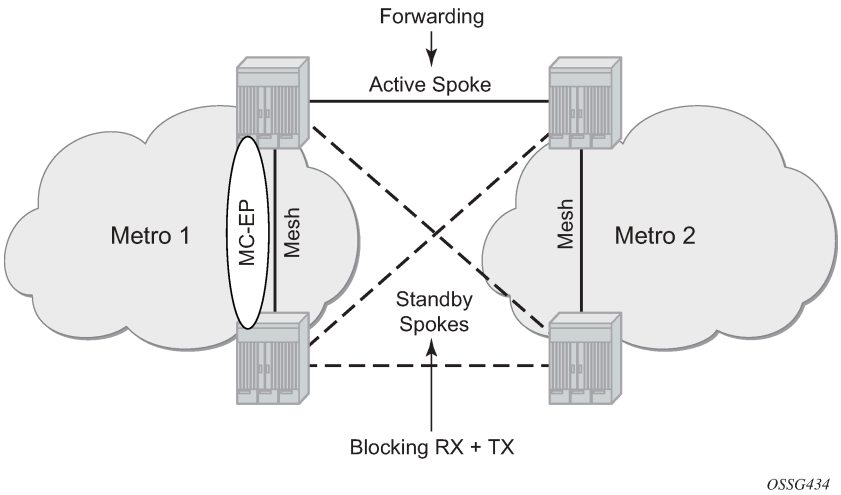
Use subject to Terms available at: www.nokia.com/terms.

Figure 220: Multi-chassis endpoint with mesh resiliency



Square resiliency provides single failure node protection, and requires less SDPs (and thus less T-LDP sessions). Square resiliency is illustrated in Figure 221: Multi-chassis endpoint with square resiliency.

Figure 221: Multi-chassis endpoint with square resiliency

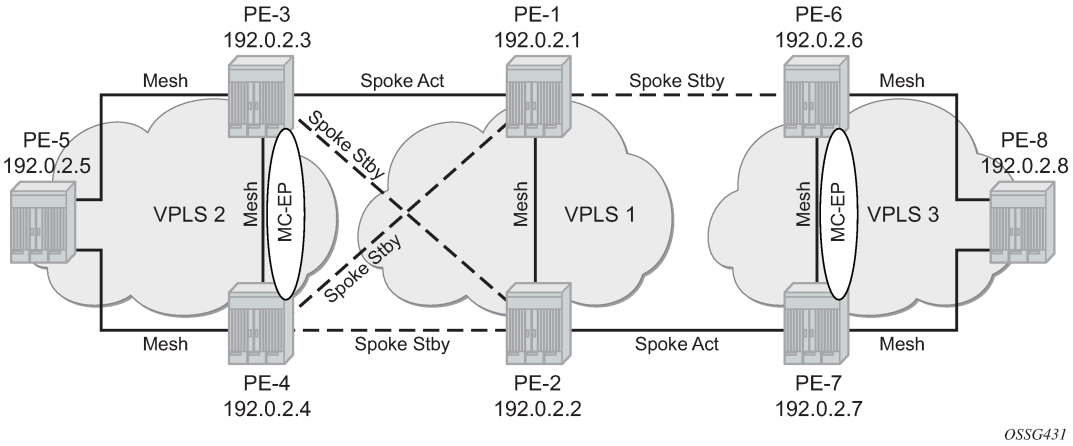
Example topology

Figure 222: Example topology



The network topology is displayed in Figure 222: Example topology.

The setup consists of:

- Two core nodes (PE-1 and PE-2), and three nodes for each metro area (PE-3, PE-4, PE-5 and PE-6, PE-7, PE-8, respectively).
- VPLS "Core VPLS-1" is the core VPLS, used to interconnect the two metro areas represented by VPLSs "Metro 1 VPLS-2" and "Metro 2 VPLS-3".
- VPLS "Metro 1 VPLS-2" is connected to the VPLS "Core VPLS-1" in mesh resiliency.
- VPLS "Metro 2 VPLS-3" is connected to the VPLS "Core VPLS-1" in square resiliency.

Three separate VPLS identifiers are used for clarity. However, the same identifier could be used for each. For interoperation, only the same VC-ID is required to be used on both ends of the spoke SDPs.

The initial configuration includes:

- Cards, MDAs, ports, router interfaces
- IS-IS on all router interfaces (alternatively, OSPF can be configured)
- LDP on all router interfaces (alternatively, RSVP-signaled LSPs can be configured over the paths used for mesh/spoke SDPs)

Configuration

SDP configuration

On each PE, SDPs are created to match the topology described in Figure 222: Example topology.

The convention for the SDP naming is: XY where X is the originating node and Y the target node.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The SDP configuration in PE-3 is as follows:

```
# on PE-3:
configure {
    service {
        sdp 31 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.1
            }
        }
        sdp 32 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        sdp 34 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.4
            }
        }
        sdp 35 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.5
            }
        }
```

The following command shows that the SDPs on PE-3 are operationally up:

```
[/]
A:admin@PE-3# show service sdp

Full mesh VPLS configuration

Three fully meshed VPLS services are configured:

- VPLS "Core VPLS-1" on PE-1 and PE-2
- VPLS "Metro 1 VPLS-2" on PE-3, PE-4, and PE-5
- VPLS "Metro 2 VPLS-3" on PE-6, PE-7, and PE-8

VPLS "Core VPLS-1" is configured on PE-1 as follows. The configuration on PE-2 is similar.

```
# on PE-1:
configure {
    service {
        vpls "Core VPLS-1" {
            admin-state enable
            description "core VPLS"
            service-id 1
            customer "1"
            mesh-sdp 12:1 {
            }
        }
```

VPLS "Metro 1 VPLS-2" is configured on PE-3 as follows. The configuration on PE-4 and PE-5 is similar.

```
# on PE-3:
configure {
    service {
         vpls "Metro 1 VPLS-2" {
            admin-state enable
            description "Metro 1 VPLS"
            service-id 2
            customer "1"
            mesh-sdp 34:2 {
            }
            mesh-sdp 35:2 {
            }
        }
```

VPLS "Metro 2 VPLS-3" is configured on PE-6 as follows. The configuration on PE-7 and PE-8 is similar.

```
# on PE-6:
configure {
    service {
        vpls "Metro 2 VPLS-3" {
            admin-state enable
            description "Metro 2 VPLS"
            service-id 3
            customer "1"
            mesh-sdp 67:3 {
            }
            mesh-sdp 68:3 {
            }
        }
```

Verification of the VPLS:

- The service must be operationally up.
- All mesh SDPs must be up in the VPLS service.

```

Multi-chassis configuration

Multi-chassis is configured on the MC peers PE-3, PE-4 and PE-6, PE-7. The peer system address is configured, and **mc-endpoint** is enabled.

The multi-chassis configuration on PE-3 is as follows. The configuration on PE-4, PE-6, and PE-7 is similar.

```
# on PE-3:
configure {
    redundancy {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                mc-endpoint {
                    admin-state enable
                }
            }
        }
```

The multi-chassis synchronization (MCS) can be verified with the following command:

```
[/]
A:admin@PE-3# show redundancy multi-chassis mc-endpoint peer ip-address 192.0.2.4

===============================================================================
Multi-Chassis MC-Endpoint
===============================================================================
Peer Addr       : 192.0.2.4           Peer Name            :
Admin State     : up                  Oper State           : up
Last State chg  :                     Source Addr          :
System Id       : 02:11:ff:00:00:00   Sys Priority         : 0
Keep Alive Intvl: 10                  Hold on Nbr Fail     : 3
Passive Mode    : disabled            Psv Mode Oper        : No
Boot Timer      : 300                 BFD                  : disabled
Last update     : 10/05/2023 15:21:53 MC-EP Count          : 0
===============================================================================
```

If the MCS fails, both nodes will fall back to single-chassis mode. In that case, two spoke SDPs could become active at the same time. It is important to verify the MCS before enabling the redundant spoke SDPs.

Mesh resiliency configuration

PE-3 and PE-4 are connected to the core VPLS in mesh resiliency.

- First an endpoint is configured.
- The **suppress-standby-signaling false** command is needed to block the standby spoke SDP.
- The multi-chassis endpoint peer is configured. The multi-chassis endpoint ID must match between the two peers.

The configuration on PE-3 and PE-4 is similar, but with a different multi-chassis endpoint peer.

```
# on PE-3:
configure {
    service {
        vpls "Metro 1 VPLS-2" {
            endpoint "CORE" {
                suppress-standby-signaling false
                mc-endpoint 1 {
                    mc-ep-peer {
                        peer-address 192.0.2.4
                    }
                }
            }
```

After this configuration, the MP-EP count in the preceding show command changes to 1, as follows:

```
[/]
```

===============================================================================
```

Two spoke SDPs are configured on each peer of the multi-chassis to the two nodes of the core VPLS (mesh resiliency). Each spoke SDP refers to the endpoint CORE.

The precedence is defined on the spoke SDPs as follows:

- Spoke-SDP 31:1 on PE-3 is configured as primary (= precedence 0) and will be active.
- Spoke-SDP 32:1 on PE-3 is configured with precedence 1 and will be the first backup.
- Spoke-SDP 41:1 on PE-4 is configured with precedence 2 and will be the second backup.
- Spoke-SDP 42:1 on PE-4 is configured with precedence 3 and will be the third backup.

The following spoke SDPs are configured in VPLS "Metro 1 VPLS-2" on PE-3:

```
# on PE-3:
configure {
    service {
        vpls "Metro 1 VPLS-2" {
            spoke-sdp 31:1 {
                endpoint {
                    name "CORE"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 32:1 {
                endpoint {
                    name "CORE"
                    precedence 1
                }
                stp {
                    admin-state disable
                }
            }
```

The following spoke SDPs are configured in VPLS "Metro 1 VPLS-2" on PE-4:

```
# on PE-4:
configure exclusive
    service {
        vpls "Metro 1 VPLS-2" {
            spoke-sdp 41:1 {
                endpoint {
                    name "CORE"
                    precedence 2
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 42:1 {
                endpoint {
                    name "CORE"
                    precedence 3
                }
                stp {
                    admin-state disable
                }
            }
```

The following command is used to verify that the spoke and mesh SDPs in VPLS "Metro 1 VPLS-2" on PE-3 are operationally up:

```
[/]
A:admin@PE-3# show service id "Metro 1 VPLS-2" sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl

31:1             Spok     192.0.2.1       Up      Up        524277    524278
32:1             Spok     192.0.2.2       Up      Up        524276    524278
34:2             Mesh     192.0.2.4       Up      Up        524279    524279
35:2             Mesh     192.0.2.5       Up      Up        524278    524279
-------------------------------------------------------------------------------
Number of SDPs : 4
-------------------------------------------------------------------------------
===============================================================================
```

The endpoints on PE-3 and PE-4 can be verified. One spoke SDP is in Tx-Active mode (31:1 on PE-1 because it is configured as primary).

```
[/]
A:admin@PE-3# show service id "Metro 1 VPLS-2" endpoint CORE | match "Tx Active"
Tx Active (SDP)              : 31:1
Tx Active Up Time            : 0d 00:00:14
Tx Active Change Count       : 1
Last Tx Active Change        : 10/05/2023 15:24:35
```

There is no active spoke SDP on PE-4.

```
[/]
A:admin@PE-4# show service id "Metro 1 VPLS-2" endpoint CORE | match "Tx Active"
Tx Active                    : none
Tx Active Up Time            : 0d 00:00:00
Tx Active Change Count       : 0
Last Tx Active Change        : 10/05/2023 14:46:21
```

On PE-1 and PE-2, the spoke SDPs are operationally up.

```
[/]
A:admin@PE-1# show service id "Core VPLS-1" sdp

===============================================================================
Services: Service Destination Points
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
12:1             Mesh     192.0.2.2       Up      Up        524279    524279
13:1             Spok     192.0.2.3       Up      Up        524278    524277
14:1             Spok     192.0.2.4       Up      Up        524277    524277
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

However, because pseudowire signaling has been enabled, only one spoke SDP will be active, the others are set in standby.

On PE-1, spoke SDP 13:1 is active (no pseudowire bit signaled from peer PE-3) and the spoke SDP 14:1 is signaled in standby by peer PE-4.

```
[/]
A:admin@PE-1# show service id "Core VPLS-1" sdp 13:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : None

[/]
A:admin@PE-1# show service id "Core VPLS-1" sdp 14:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

On PE-2, both spoke SDPs are signaled in standby by peers PE-3 and PE-4.

```
[/]
A:admin@PE-2# show service id "Core VPLS-1" sdp 23:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby

[/]
A:admin@PE-2# show service id "Core VPLS-1" sdp 24:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

There is one active and three standby spoke SDPs.

Square resiliency configuration

PE-6 and PE-7 will be connected to the core VPLS in square resiliency.

- First an endpoint is configured.
- The **suppress-standby-signaling false** command is needed to block the standby spoke SDP.
- The multi-chassis endpoint peer is configured. The multi-chassis endpoint ID must match between the two peers.

On PE-7 and PE-6, one spoke SDP is configured on each peer of the multi-chassis to one node of the core VPLS (square resiliency). Each spoke SDP refers to the endpoint CORE.

```
# on PE-7:
configure {
    service {
        vpls "Metro 2 VPLS-3" {
            endpoint "CORE" {
                suppress-standby-signaling false
                mc-endpoint 1 {
                    mc-ep-peer {
                        peer-address 192.0.2.6
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                }
            }
```

The precedence will be defined on the spoke SDPs as follows:

- Spoke-SDP 72:1 on PE-7 is configured as primary (= precedence 0) and will be active.
- Spoke-SDP 61:1 on PE-6 is configured with precedence 1 and will be the first backup.

On PE-7, spoke SDP 72:1 is configured as primary, as follows:

```
# on PE-7:
configure {
    service {
        vpls "Metro 2 VPLS-3" {
            spoke-sdp 72:1 {
                endpoint {
                    name "CORE"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
```

On PE-6, spoke SDP 61:1 is configured with precedence 1, as follows:

```
# on PE-6:
configure {
    service {
        vpls "Metro 2 VPLS-3" {
            spoke-sdp 61:1 {
                endpoint {
                    name "CORE"
                    precedence 1
                }
                stp {
                    admin-state disable
                }
            }
```

The following command can be used to verify the spoke and mesh SDPs:

```
[/]
A:admin@PE-6# show service id "Metro 2 VPLS-3" sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------
61:1             Spok     192.0.2.1       Up      Up        524277    524276
67:3             Mesh     192.0.2.7       Up      Up        524279    524279
68:3             Mesh     192.0.2.8       Up      Up        524278    524279
-------------------------------------------------------------------------------
Number of SDPs : 3
-------------------------------------------------------------------------------
===============================================================================
```

On PE-6 and PE-7, the spoke SDPs must be up.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The endpoints on PE-7 and PE-6 can be verified. Spoke-SDP 72:1 on PE-7 is configured as primary and is in Tx-Active mode.

```
[/]
A:admin@PE-7# show service id "Metro 2 VPLS-3" endpoint | match "Tx Active"
Tx Active (SDP)             : 72:1
Tx Active Up Time           : 0d 00:00:46
Tx Active Change Count      : 1
Last Tx Active Change       : 10/05/2023 15:27:13
```

There is no active spoke SDP on PE-6.

```
[/]
A:admin@PE-6# show service id "Metro 2 VPLS-3" endpoint | match "Tx Active"
Tx Active                   : none
Tx Active Up Time           : 0d 00:00:00
Tx Active Change Count      : 2
Last Tx Active Change       : 10/05/2023 15:27:13
```

The following output on PE-1 shows that spoke SDP 16:1 is signaled with peer in standby mode.

```
[/]
A:admin@PE-1# show service id "Core VPLS-1" sdp 16:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : pwFwdingStandby
```

The following output on PE-2 shows that the spoke SDP 27:1 is signaled with peer active (no pseudowire bits).

```
[/]
A:admin@PE-2# show service id "Core VPLS-1" sdp 27:1 detail | match "Peer Pw Bits"
Peer Pw Bits       : None
```

There is one active and one standby spoke SDP.

Additional parameters

Multi-chassis

```
[ex:/configure redundancy multi-chassis peer 192.0.2.4 mc-endpoint]
A:admin@PE-3# ?

 admin-state           - Administrative state of the MC-EP
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 bfd                   - Enable BFD detection for the MC-EP peering tunnel
 boot-timer            - Time to attempt connection before declaring failure
 hold-on-neighbor-     - Number of keepalive intervals to wait for packets
  failure
 keep-alive-interval   - Interval for exchange of keepalive messages
 passive-mode          - Enable passive mode for the MC-EP tunnel
 system-priority       - System priority of the MC-EP
```

These parameters will be explained in the following sections.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Peer failure detection

The default mechanism is based on the keep-alive messages exchanged between the peers.

The keep-alive interval is the interval at which keep-alive messages are sent to the MC peer. It is set in tenths of a second from 5 to 500), with a default value of 10.

Hold-on-neighbor failure is the number of keep-alive intervals that the node will wait for a packet from the peer before assuming it has failed. After this interval, the node will revert to single chassis behavior. It can be set from 2 to 25 with a default value of 3.

BFD session

BFD is another peer failure detection mechanism. It can be used to speed up the convergence in case of peer loss.

```
# on PE-3:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                mc-endpoint {
                    admin-state enable
                    bfd true
                }
            }
```

BFD must be enabled on the system interface.

```
# on PE-3:
configure {
    router "Base" {
        interface "system" {
            ipv4 {
                bfd {
                    admin-state enable
                }
                primary {
                    address 192.0.2.3
                    prefix-length 32
                }
            }
```

Verification of the BFD session:

```
[/]
A:admin@PE-3# show router bfd session

===============================================================================

  mcep                                              cpm-np          N/A        N/A
  192.0.2.3
-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
```

Note:
Simulators are used in the test environment. A limitation of working with simulators is that the minimum BFD transmit or receive interval on simulators equals 1000 ms. Therefore, the timer values in the show command may not reflect the configured timer intervals.

Boot timer

The **boot-timer** command specifies the time after a reboot that the node will try to establish a connection with the MC peer before assuming a peer failure. In case of failure, the node will revert to single chassis behavior.

System priority

The system priority influences the selection of the MC master. The lowest priority node will become the primary.

In case of equal priorities, the lowest system ID (that is, the lowest chassis MAC address) will become the primary.

VPLS endpoint and spoke SDP

Ignore standby pseudowire bits

```
[ex:/configure service vpls "Core VPLS-1" spoke-sdp 14:1]
A:admin@PE-1# ?

---snip---
 ignore-standby-       - Ignore standby-bit received from TLDP peers when performing internal
 tasks
  signaling
---snip---
```

The peer pseudowire status bits are ignored and traffic is forwarded over the spoke SDP, which can speed up convergence for multicast traffic in case of spoke SDP failure. Traffic sent over the standby spoke SDP will be discarded by the peer.

In this topology, if the **ignore-standby-signaling** command is enabled on PE-1, it sends MC traffic to PE-3 and PE-4 (and to PE-6). If PE-3 fails, PE-4 can start forwarding traffic in the VPLS as soon as it detects PE-3 being down. There is no signaling needed between PE-1 and PE-4.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Block-on-mesh failure

```
*[ex:/configure service vpls "Metro 1 VPLS-2" endpoint "CORE"]
A:admin@PE-1#  block-on-mesh-failure ?

 block-on-mesh-failure <boolean>
 <boolean> - ([true]|false)
 Default   - false

    Enable blocking after the endpoints are in a down state
```

In case a PE loses all the mesh SDPs of a VPLS, it should block the spoke SDPs to the core VPLS, and inform the MC-EP peer that can activate one of its spoke SDPs.

If **block-on-mesh-failure** is enabled, the PE will signal all the pseudowires of the endpoint in standby.

In this topology, if PE-3 does not have any valid mesh SDP to the VPLS "Metro 1 VPLS-2" mesh, it will set the spoke SDPs under endpoint CORE in standby.

When **block-on-mesh-failure** is activated under an endpoint, it must also be configured under the spoke SDPs belonging to this endpoint.

```
# on PE-3:
configure {
     service {
        vpls "Metro 1 VPLS-2" {
            endpoint "CORE" {
                suppress-standby-signaling false
                block-on-mesh-failure true
                mc-endpoint 1 {
                    mc-ep-peer {
                        peer-address 192.0.2.4
                    }
                }
            }
            spoke-sdp 31:1 {
                block-on-mesh-failure true
                endpoint {
                    name "CORE"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 32:1 {
                block-on-mesh-failure true
                endpoint {
                    name "CORE"
                    precedence 1
                }
                stp {
                    admin-state disable
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Precedence

```
[ex:/configure service vpls "Metro 1 VPLS-2" spoke-sdp 31:1 endpoint]
A:admin@PE-3# ?

 name                  - Name of service endpoint to which SDP bind is attached
 precedence            - Precedence of this SDP bind when there are multiple SDP
                         binds attached to one service endpoint
```

The precedence is used to indicate in which order the spoke SDPs should be used. The value is from 0 to 4 (0 being primary), the lowest having higher priority. The default value is 4.

Revert time

```
[ex:/configure service vpls "Metro 1 VPLS-2"]
A:admin@PE-3# endpoint "CORE" ?

---snip---
 revert-time           - Time to wait before reverting to primary spoke SDP
---snip---
```

If the precedence is equal between the spoke SDPs, there is no revertive behavior. Changing the precedence of a spoke SDP will not trigger a revert.

MAC flush parameters

When a spoke SDP goes from standby to active (due to the active spoke SDP failure), the node will send a flush-all-but-mine message.

After a restoration of the spoke SDP, a new **flush-all-but-mine** message will be sent.

```
# on PE-1:
configure {
    service {
        vpls "Core VPLS-1" {
            mac-flush {
                tldp {
                    propagate true
```

A node configured with **mac-flush tldp propagate true** forwards the flush messages received on the spoke SDP to its other mesh or spoke SDPs.

A node configured with **send-on-failure true** sends a flush-all-from-me message when one of its SDPs goes down.

```
# on PE-1:
configure exclusive
    service {
        vpls "Core VPLS-1" {
            mac-flush {
                tldp {
                    send-on-failure true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Failure scenarios

For the subsequent failure scenarios, the configuration of the nodes is as described in the Configuration section.

Core node failure

When the core node PE-1 fails, the spoke SDPs 31:1 from PE-3 and 41:1 from PE-4 go down.

Because the spoke SDP 31:1 was active, the MC master (PE-3 in this case) will select the next best spoke SDP, which will be 32:1 (precedence 1). See Figure 223: Core node failure.

Multi-chassis communication failure

If the multi-chassis communication is interrupted, both nodes will revert to single chassis mode.

To simulate a communication failure between the two nodes, define a static route on PE-3 that will blackhole the system address of PE-4.

```
# on PE-3:
configure {
    router "Base" {
        static-routes {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            route 192.0.2.4/32 route-type unicast
                blackhole {
                    admin-state enable
                }
            }
```

Verify that the MC synchronization is operationally down.

```
[/]

Last Tx Active Change        : 10/05/2023 15:39:19
```

This can potentially cause a loop in the system. The Passive mode subsection describes how to avoid this loop.

Passive mode

As in the preceding Multi-chassis communication failure subsection, if there is a failure in the multi-chassis communication, both nodes will assume that the peer is down and will revert to single-chassis mode. This can create loops because two spoke SDPs can become active.

One solution is to synchronize the two core nodes, and configure them in passive mode, as illustrated in Figure 225: Multi-chassis passive mode.

In passive mode, both peers will stay dormant as long as one active spoke SDP is signaled from the remote end. If more than one spoke SDP becomes active, the MC-EP algorithm will select the best SDP. All other spoke SDPs are blocked locally (in Rx and Tx directions). There is no signaling sent to the remote PEs.

If one peer is configured in passive mode, the other peer will be forced to passive mode as well.

© 2026 Nokia.

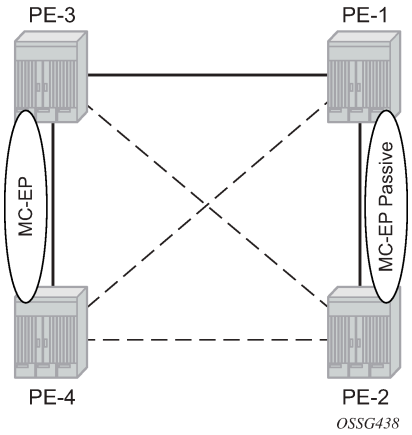
The **suppress-standby-signaling false** and **ignore-standby-signaling false** commands are required.

Figure 225: Multi-chassis passive mode



The following output shows the multi-chassis configuration on PE-1 (similar on PE-2).

```
# on PE-1:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.2 {
                admin-state enable
                mc-endpoint {
                    admin-state enable
                    passive-mode true
                }
            }
        }
```

The following output shows the VPLS spoke SDPs configuration on PE-1 (similar on PE-2)

```
# on PE-1:
configure {
    service {
        vpls "Core VPLS-1" {
            endpoint "METRO1" {
                suppress-standby-signaling false
                mc-endpoint 1 {
                    mc-ep-peer {
                        peer-address 192.0.2.2
                    }
                }
            }
            spoke-sdp 13:1 {
                endpoint {
                    name "METRO1"
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 14:1 {
                endpoint {
                    name "METRO1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
                stp {
                    admin-state disable
                }
            }
```

To simulate a communication failure between the two nodes, a static route is defined on PE-3 that will blackhole the system address of PE-4.

```
# on PE-3:
configure {
    router "Base" {
        static-routes {
            route 192.0.2.4/32 route-type unicast
                blackhole {
                    admin-state enable
                }
            }
```

The spoke SDPs are active on PE-3 and on PE-4.

```
[/]
A:admin@PE-3# show service id "Metro 1 VPLS-2" endpoint | match "Tx Active"
Tx Active (SDP)              : 31:1
Tx Active Up Time            : 0d 00:04:04
Tx Active Change Count       : 8
Last Tx Active Change        : 10/05/2023 15:44:36
```

```
[/]
A:admin@PE-4# show service id "Metro 1 VPLS-2" endpoint | match "Tx Active"
Tx Active (SDP)              : 42:1
Tx Active Up Time            : 0d 00:04:07
Tx Active Change Count       : 4
Last Tx Active Change        : 10/05/2023 15:44:36
```

PE-1 and PE-2 have blocked one spoke SDP which avoids a loop in the VPLS.

```
[/]
A:admin@PE-1# show service id "Core VPLS-1" endpoint | match "Tx Active"
Tx Active (SDP)              : 13:1
Tx Active Up Time            : 0d 00:04:39
Tx Active Change Count       : 5
Last Tx Active Change        : 10/05/2023 15:44:37
```

```
[/]
A:admin@PE-2# show service id "Core VPLS-1" endpoint | match "Tx Active"
Tx Active                    : none
Tx Active Up Time            : 0d 00:00:00
Tx Active Change Count       : 2
Last Tx Active Change        : 10/05/2023 15:44:42
```

The passive nodes do not set the pseudowire status bits; therefore, the nodes PE-3 and PE-4 are not aware that one spoke SDP is blocked.

Conclusion

Multi-chassis endpoint for VPLS active/standby pseudowire allows the building of hierarchical VPLS without single point of failure, and without requiring STP to avoid loops.

Care must be taken to avoid loops. The multi-chassis peer communication is important and should be possible on different interfaces.

Passive mode can be a solution to avoid loops in case of multi-chassis communication failure.

Multi-Instance EVPN VPWS with MPLS to SRv6 Interworking

This chapter provides information about multi-instance EVPN VPWS with MPLS to SRv6 interworking.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

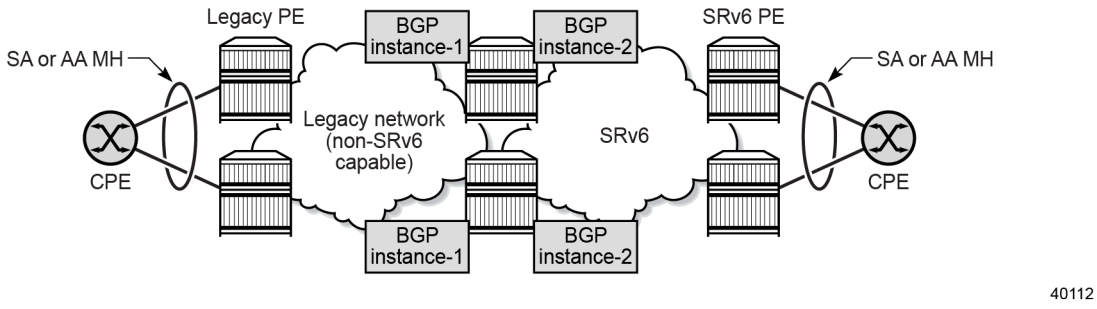
Applicability

The information and the configuration in this chapter are based on SR OS Release 24.10.R1. Multi-instance EVPN VPWS with MPLS to SRv6 interworking is supported in SR OS Release 23.10.R2 and later.

Overview

EVPN is used in most networks. During migration to SRv6, interworking between EVPN MPLS and EVPN SRv6 is required. Also, some MPLS networks do not support SRv6 and yet, end-to-end services are required. This chapter describes the configuration of EVPN VPWS services with MPLS to SRv6 stitching. Multi-instance EVPN VPWS is described in *draft-sr-bess-evpn-vpws-gateway*. Figure 226: EVPN-MPLS to EVPN-SRv6 stitching shows the need for EVPN-MPLS to EVPN-SRv6 stitching between a legacy MPLS network and an SRv6 network: some terminating PEs are legacy PEs attached to an MPLS domain while other terminating PEs are attached to an SRv6 network.

Figure 226: EVPN-MPLS to EVPN-SRv6 stitching



Gateway redundancy is based on an anycast gateway redundant model; Interconnect Ethernet Segments (I-ESs) are not supported in SR OS Release 24.10.R1.

© 2026 Nokia.

An Epipe service can contain two BGP instances. BGP instance 1 and BGP instance 2 can be matched to MPLS, SRv6, or VXLAN. MPLS and SRv6 can be configured in Epipes with one or two instances and they can use either instance 1 or instance 2 interchangeably. The MPLS and SRv6 instances are configured with a multihoming mode. The default multihoming mode is network, but only one instance can be configured with multihoming mode network, so the other instance must have multihoming mode access. A BGP-EVPN instance in multihoming mode access does not participate in multihoming procedures, such as Designated Forwarder (DF) election processing or local bias forwarding.

The use of D-PATH in multi-instance EVPN VPWS services is supported to avoid control plane loops when redistributing EVPN AD per-EVI routes between adjacent domains. For more information about D-PATH, see the Domain Path Attribute for VPRN BGP Routes chapter.

Multi-instance EVPN VPWS is supported for MPLS and SRv6, but not for VXLAN. In SR OS Release 24.10.R1, VXLAN is only supported on Epipes with a single BGP instance, which can be instance 1 or instance 2. Multihoming mode and domain ID cannot be configured in VXLAN instances.

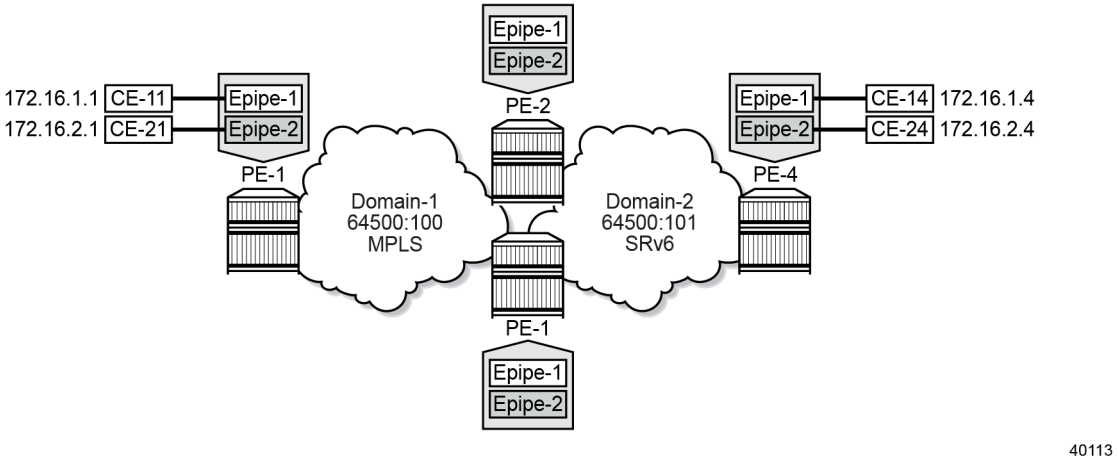
In a multi-instance EVPN VPWS, the local and the remote attachment circuits (ACs) are defined in different BGP instances.

SAPs or SDP bindings are not supported in a multi-instance EVPN VPWS.

Configuration

Figure 227: Example topology shows terminating PE-1 in an MPLS network and terminating PE-4 in an SRv6 network. The Epipes on the gateways PE-2 and PE-3 have two BGP instances.

Figure 227: Example topology



The initial configuration on the PEs includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on all router interfaces; on the gateways PE-2 and PE-3 with different instances: IS-IS 0 in domain 1 and IS-IS 1 in domain 2
- SR-ISIS on PE-1, PE-2, and PE-3

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- SRv6 on PE-2, PE-3, and PE-4

BGP is configured for the EVPN address family with BGP group "mpls" in domain 1 and with BGP group "srv6" in domain 2. The BGP configuration on gateway PE-2 is as follows:

```
#  on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "mpls" {            # similar configuration on PE-1, PE-3
                peer-as 64500
                family {
                    evpn true
                }
            }
            group "srv6" {            # similar configuration on PE-3, PE-4
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "mpls"
            }
            neighbor "192.0.2.3" {
                group "mpls"
            }
            neighbor "2001:db8::2:3" {
                group "srv6"
            }
            neighbor "2001:db8::2:4" {
                group "srv6"
            }
```

Service configuration

In this section, the following EVPN VPWS services are configured between PE-1 and PE-4:

- Epipe-1 with identical route distinguishers (RDs) and with two explicit endpoints on the gateways PE-2 and PE-3
- Epipe-2 with different RDs and with one implicit and one explicit endpoint on the gateways PE-2 and PE-3

For both Epipe-1 and Epipe-2, MPLS uses BGP instance 1 and SRv6 uses BGP instance 2.

On PE-1, the EVPN VPWS services are configured with BGP instance 1, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:1 {
                description "SAP to CE-11"
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "AC-PE-1-1" {
                    eth-tag 11
                }
                remote-attachment-circuit "GW-MPLS-1" {
                    eth-tag 123
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/c10/1:2 {
                description "SAP to CE-21"
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-PE-1-2" {
                    eth-tag 21
                }
                remote-attachment-circuit "GW-MPLS-2" {
                    eth-tag 223
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The local and remote ACs are configured with BGP 1.

On gateway PE-2, the following EVPN VPWS configuration includes two BGP instances: BGP 1 in the MPLS domain and BGP 2 in the SRv6 domain.

```
# on PE-2:
configure {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2        # on PE-3: 192.0.2.3
                community-value {
                    start 60000
                    end 65000
                }
            }
        }
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "PE2-loc" {        # on PE-3: PE3-loc
                    function {
                        end-dx2 {
                        }
                    }
                }
            }
            bgp 1 {
                route-distinguisher "64500:1"     # same RD on PE-2 and PE-3
            }
            bgp 2 {
                route-distinguisher "64500:2"     # same RD on PE-2 and PE-3
            }
            endpoint "MPLS" {
            }
            endpoint "SRv6" {
            }
            bgp-evpn {
                evi 1
                local-attachment-circuit "GW-MPLS-1" {
                    endpoint "MPLS"
                    eth-tag 123
                }
                local-attachment-circuit "GW-SRv6-1" {
                    endpoint "SRv6"

                source-address 2001:db8::2:2       # on PE-3: 2001:db8::2:3
                domain-id "64500:101"
                srv6 {
                    instance 1
                    default-locator "PE2-loc"      # on PE-3: PE3-loc
                }
                route-next-hop {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        system-ipv6
                    }
                }
            }
        }
```

On PE-2 and PE-3, Epipe-1 is configured with two explicit endpoints (endpoint MPLS and endpoint SRv6) while Epipe-2 is configured with one explicit endpoint (endpoint SRv6) in BGP 2 and one implicit endpoint in BGP 1. BGP 1 is used in the MPLS domain while BGP 2 is used in the SRv6 domain. The configuration of the endpoints and the ACs is identical on PE-2 and PE-3.

The Route Distinguisher (RD) for BGP instance 1 can be:

- auto-derived from the default value "system-IP:EVI" , for example, RD 192.0.2.2:2 for BGP 1 in Epipe-2 on PE-2
- manually configured, for example, RD 64500:1 for BGP 1 in Epipe-1 on PE-2 and PE-3
- auto-derived from the configured BGP auto-RD range.

The RD for BGP instance 2 can be:

- manually configured, for example, RD 64500:2 for BGP 2 in Epipe-1 on PE-2 and PE-3
- auto-derived from the configured BGP auto-RD range, for example, RD 192.0.2.2:60000 for BGP 2 in Epipe-2 on PE-2.

For Epipe-1, the RDs 64500:1 for BGP 1 and 64500:2 for BGP 2 are identical on PE-2 and PE-3; for Epipe-2, the RDs are different, for example for BGP-1, the auto-derived RD on PE-2 is 192.0.2.2:2 and the auto-derived RD on PE-3 is 192.0.2.3:2.

On the gateways, multiple AD per-EVI routes with the same expected remote Ethernet tag ID may be received, requiring the selection of one route. If the AD per-EVI route keys of the received routes differ (in EVPN AD per-EVI routes, different route keys mean different RD, Ethernet tag, or ESI), the EVPN application selects the route based on the lowest PE IP address. However, if the route keys are identical, the selection follows the BGP decision process.

The multihoming mode must be different in both instances: one of the two instances—MPLS BGP 1—is configured with **mh-mode access**; the other instance—SRv6 BGP 2—has **mh-mode network**, which is the default multihoming mode.

For Epipe-1 and Epipe-2, the domain ID 64500:100 is configured in the MPLS domain while the domain ID 64500:101 is configured in the SRv6 domain. The D-PATH is supported in AD per-EVI routes to avoid loops on the gateways.

The service configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    policy-options {
        community "comm-epipe-1" {
            member "target:64500:1" { }
        }
        community "low-latency" {
            member "color:01:1" { }
        }
        policy-statement "vsi-export-1" {
            entry 10 {
                action {
                    action-type accept
                    community {
```

© 2026 Nokia.

```
                    eth-tag 24
                }
                remote-attachment-circuit "GW-SRv6-2" {
                    eth-tag 2623
                }
                segment-routing-v6 1 {
                    admin-state enable
                    source-address 2001:db8::2:4
                    srv6 {
                        instance 1
                        default-locator "PE4-loc"
                    }
                    route-next-hop {
                        system-ipv6
                    }
                }
            }
        }
```

The VSI export policy adds a color attribute and a route target.

By default, AD per-EVI routes do not propagate attributes, path selection based on PE IP address is used instead of BGP path selection (unless the route keys are identical), and the D-PATH is taken into account to prevent loops, as follows:

```
[ex:/configure service system bgp evpn ad-per-evi-routes]
A:admin@PE-2# info detail
    d-path-ignore false
    attribute-propagation false
    bgp-path-selection false
```

In a simple example topology with only two different domains, the D-PATH attribute contains maximum one domain ID, therefore, the default settings are used and attributes such as the D-PATH need not be propagated. However, the color attribute will not be propagated either when attribute propagation is disabled, see further.

Verification

Single-instance EVPN VPWS services only generate AD per-EVI routes when they have a local SAP or spoke SDP configured that is operationally up. In this example, Epipe-1 and Epipe-2 generate AD per-EVI routes from PE-1 and from PE-4. In contrast, multi-instance EVPN VPWS services do not allow local SAPs or spoke SDPs, therefore they do not generate AD per-EVI routes for the configured local AC Ethernet tags. The EVPN VPWS services on PE-2 and PE-3 redistribute AD per-EVI routes received in one instance into the other instance. The following redistribution rules apply at the gateways PE-2 and PE-3 as per *draft-sr-bess-evpn-vpws-gateway*:

- An AD per-EVI route received in BGP 1 which does not contain a local domain ID and which is selected to be installed triggers an AD per-EVI route to be redistributed in BGP 2 using the Ethernet tag, RD, route target, and properties of BGP 2.
- Route targets are re-originated in the redistributed AD per-EVI.
- The redistributed AD per-EVI route carries the communities, extended communities, and large communities of the source route only when attribute configuration is enabled. The exceptions are EVPN extended communities and BGP encapsulation extended communities which are never propagated across domains.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The redistributed AD per-EVI route must update the D-PATH attribute of the received AD per-EVI route (when attribute propagation is enabled) or add the D-PATH attribute if the received route does not contain a D-PATH.

This section contains the following subsections:

- AD per-EVI routes
- RDs and route targets in BGP instances
- SRv6 to MPLS interworking
- Attribute propagation
- BGP path selection for equal route key
- BGP path selection enabled for AD per-EVI routes

AD per-EVI routes

AD per-EVI routes are redistributed from the SRv6 domain to the MPLS domain and vice versa. Figure 228: AD per-EVI route from SRv6 domain redistributed into MPLS domain shows an AD per-EVI route sent by PE-4 in domain 64500:101 which is redistributed by PE-2 and PE-3 into domain 64500:100. The gateways add the D-PATH attribute containing domain ID 64500:101 in the redistributed AD per-EVI route.

Figure 228: AD per-EVI route from SRv6 domain redistributed into MPLS domain

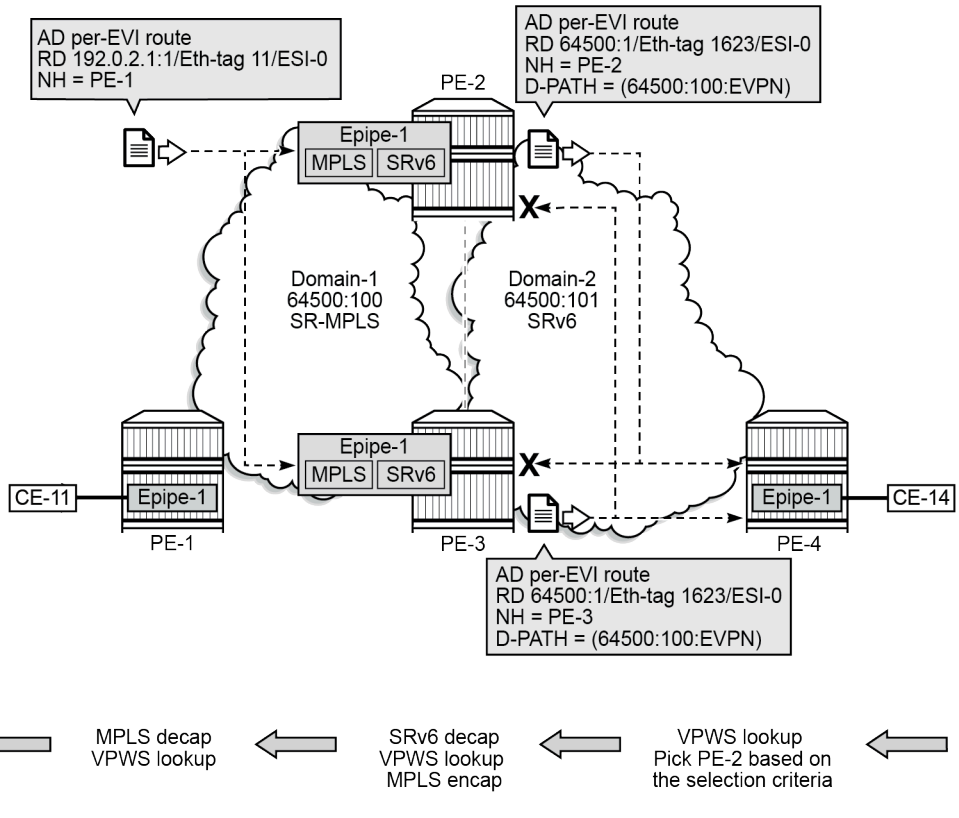
When CE-11 sends traffic to CE-14, a VPWS lookup takes place in PE-1. The packets get an MPLS encapsulation and are forwarded to PE-2 based on the selection criteria. For Epipe-1, the route keys and RDs on the gateways are identical, so the BGP decision process is used instead of the EVPN selection. On gateway PE-2, MPLS is decapsulated, a VPWS lookup takes place, and SRv6 encapsulation is added. The traffic is forwarded to PE-4 where SRv6 is decapsulated, a VPWS lookup takes place, and the packets are forwarded to CE-14.

In this simple example topology with only two domains, attribute propagation is not required for the D-PATH attribute. The D-PATH is added by the gateways PE-2 and PE-3, not propagated. By default, attribute propagation is disabled and the gateways PE-2 and PE-3 drop attributes such as the color attribute in the redistributed AD per-EVI routes.

Similarly, gateways PE-2 and PE-3 add D-PATH attribute with domain ID 64500:100 when redistributing AD per-EVI routes from the MPLS domain in the SRv6 domain, as shown in Figure 229: AD per-EVI route from MPLS domain redistributed into SRv6 domain:

Figure 229: AD per-EVI route from MPLS domain redistributed into SRv6 domain



PE-2 receives the following AD per-EVI route from PE-1 with ESI-0, Ethernet tag 11, and RD 192.0.2.1:1.

For Epipe-1, the anycast redundancy solution is used for the gateways PE-2 and PE-3 that stitch MPLS to SRv6. The service configuration for Epipe-1 has identical RDs on both gateways: RD 64500:1 for BGP 1 and RD 64500:2 for BGP 2. Gateways PE-2 and PE-3 redistribute AD per-EVI routes with the same route key so that PE-1 and PE-4 select one of the two gateways based on BGP best path selection, not on the EVPN selection criteria.

The anycast gateways attached to the two domains redistribute the EVPN AD per-EVI routes between these domains and reset the ESI to zero. The anycast gateways prepend the received D-PATH attribute with source domain ID 64500:101 when redistributing the AD per-EVI route to the MPLS domain. In this simple topology, the D-PATH attribute was not present in the route received from PE-4, so the gateway PE-2 adds the D-PATH attribute to the route. The D-PATH attribute avoids control plane loops: when PE-2 receives an AD per-EVI route redistributed by PE-3 in the MPLS domain and the D-PATH contains domain ID 64500:101 which is local to PE-2, PE-2 does not install this AD per-EVI route. D-PATH is considered in the BGP best path selection unless **d-path-ignore** is configured and **bgp-path-selection** is configured for the AD per-EVI routes. The router compares the D-PATH attribute received in VPWS AD per-EVI routes with the same route key, as follows:

- The routes with the shortest D-PATH are preferred; the other routes are not installed. Routes without D-PATH attributes are considered zero-length D-PATH.
- The routes with the numerically lowest left-most domain ID are preferred; the other routes are not installed.

Note: In this example topology with two domains, the D-PATH (if present) only contains one domain ID. When multiple domains are traversed, the D-PATH attribute needs to be propagated to avoid loops.

RDs and route targets in BGP instances

The following command shows the BGP RDs and route target in Epipe-1 on PE-2. The RD 64500:1 for BGP 1 and the RD 64500:2 for BGP 2 are configured, but the route target 64500:1 is derived from the Autonomous System Number (ASN) 65400 and the EVI 1.

On PE-3, the RDs and route target are identical for Epipe-1.

The following command shows the BGP RDs and route target in Epipe-2 on PE-2. The RD 192.0.2.2:2 for BGP 1 is derived from the system IP address and the EVI 2; the RD 192.0.2.2:60000 for BGP 2 is derived via auto-rd. The route target is derived from the ASN 65400 and the EVI 2: 64500:2.

Verification for the MPLS domain

PE-1 receives the following two AD per-EVI routes for Epipe-1 with the same route key (Ethernet tag 123, ESI-0, RD 64500:1), so the routes are equal and the BGP selection criteria are used. The tiebreaker is the originator with the lowest router ID, so the route received from PE-2 is preferred:

```
[/]
A:admin@PE-1# show router bgp routes evpn auto-disc rd 64500:1
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================

Attribute propagation

By default, attribute propagation is disabled, so attributes such as the color or the D-PATH are not propagated in the redistributed AD per-EVI routes.

Redistributed AD per-EVI routes without attribute propagation

Figure 228: AD per-EVI route from SRv6 domain redistributed into MPLS domain shows the AD per-EVI route originated by PE-4 in the SRv6 domain and redistributed by the gateways PE-2 and PE-3 into the MPLS domain. The AD per-EVI route from PE-4 contains a color attribute that is added by an export policy. PE-2 receives the following AD per-EVI route from PE-4 with color:01:1, Ethernet tag 14, RD 192.0.2.4:1, and SID 2001:db8:aaaa:104:: for Epipe-1:

```
[/]
A:admin@PE-2# show router bgp routes evpn auto-disc tag 14 hunt

Redistributed AD per-EVI routes with attribute propagation

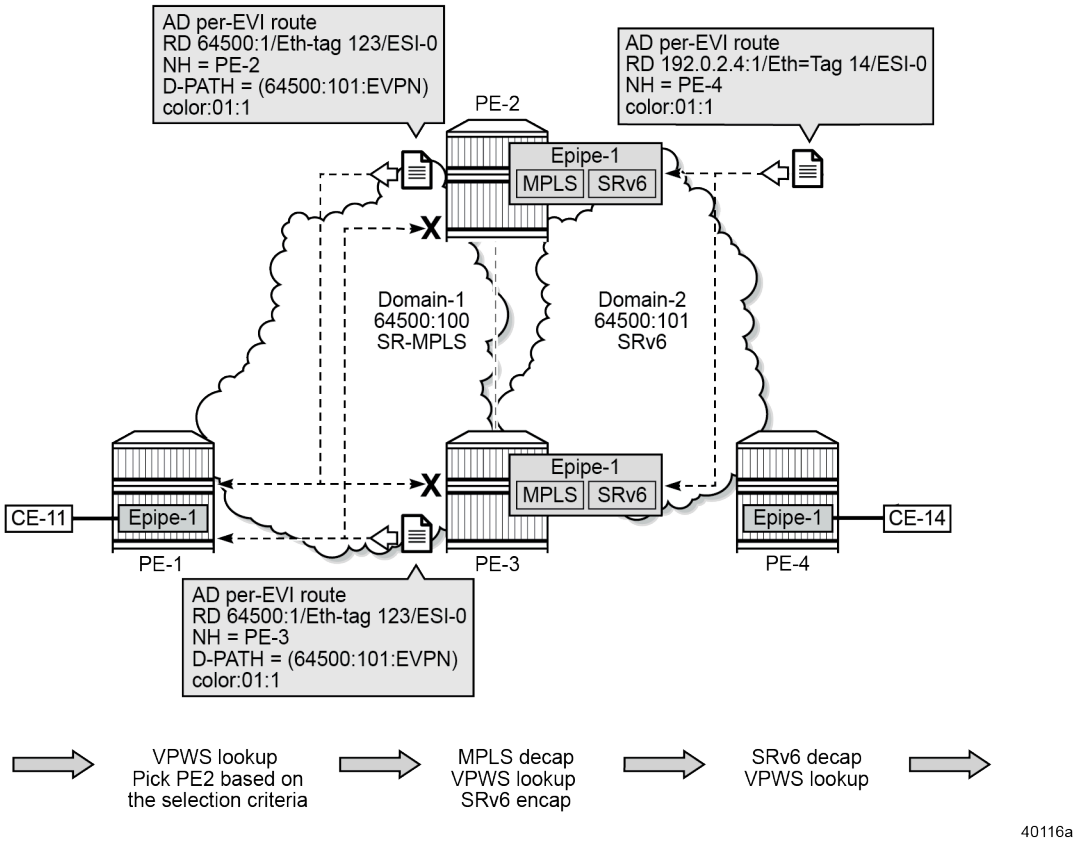
The following command enables attribute propagation and BGP path selection for AD per-EVI routes on the gateways:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ad-per-evi-routes {
                        attribute-propagation true
                    }
                }
            }
```

With **attribute-propagation true**, the gateways propagate all BGP attributes when redistributing the AD per-EVI routes for the VPWS service. Figure 230: Redistributing AD per-EVI routes from the SRv6 domain into the MPLS domain with attribute propagation shows that the color attribute is propagated by the gateways when redistributing the AD per-EVI route in the MPLS domain:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 230: Redistributing AD per-EVI routes from the SRv6 domain into the MPLS domain with attribute propagation



PE-2 receives an AD per-EVI from PE-4 with the color attribute (color:01:1) in the extended community, as follows:

```
[/]
A:admin@PE-2# show router bgp routes evpn auto-disc rd 192.0.2.4:1 hunt | match Community post-
lines 1
Community      : color:01:1 target:64500:1 l2-attribute:MTU: 1514 V: 0 M: 0 F:
                 0 C: 0 P: 0 B: 0
```

Similarly, PE-3 receives the color attribute in the extended community. When PE-2 and PE-3 propagate the attributes, PE-1 receives the color attribute in both AD per-EVI routes, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn auto-disc rd 64500:1 hunt

BGP path selection for equal route key

PE-1 and PE-4 receive two AD per-EVI routes with identical route key (Ethernet tag, ESI-0, RD) for Epipe-1, so the BGP route selection criteria apply. However, for Epipe-2, the RDs are different, so BGP hands over the routes to EVPN and the EVPN application performs the selection (which can be based on a default set of rules or based on BGP best path selection). Both for the BGP selection and for the EVPN selection, the tiebreaker is the IP address of the originator, so the AD per-EVI routes from PE-2 are preferred. However, the BGP selection changes in a topology where the AS path is longer for one of the peers: the BGP decision takes into account the AS path length while the EVPN selection does not.

To illustrate this, a policy is configured on PE-2 to prepend ASN 64999 to the AS path and this export policy is applied for the BGP peers of PE-2.

```
# on PE-2:
configure {
    policy-options {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        policy-statement "prepend ASN" {
            entry 10 {
                from {
                    evpn-type ethernet-auto-discovery
                }
                action {
                    action-type accept
                    as-path-prepend {
                        as-path 64499
                    }
                }
            }
        }
    }
    router "Base"  {
        bgp {
            neighbor 192.0.2.1 {
                export {
                    policy ["prepend ASN"]
                }
            }
            neighbor 2001:db8::2:4 {
                export {
                    policy ["prepend ASN"]
                }
            }
```

PE-4 receives two AD per-EVI routes for Epipe-1 with identical route key, so the BGP selection applies. The following command shows that the route received from PE-3 is preferred over the route received from PE-2:

```
[/]
A:admin@PE-4# show router bgp routes evpn auto-disc rd 64500:2

===============================================================================
```

BGP path selection enabled for AD per-EVI routes

It is possible to configure BGP path selection for all AD per-EVI routes, so that EVPN can also apply BGP best path selection to routes with the same Ethernet Tag ID but different RDs, as follows on PE-4:

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ad-per-evi-routes {
                        attribute-propagation true     # required for bgp-path-selection
                        bgp-path-selection true
                    }
                }
            }
        }
```

The following error is raised when attempting to enable BGP path selection when attribute propagation is disabled:

```
*[ex:/configure service system bgp evpn ad-per-evi-routes]
A:admin@PE-4# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ad-per-evi-routes bgp-path-selection
 - Inconsistent value - bgp-path-selection cannot be enabled when attribute-propagation is
 disabled
```

With BGP path selection enabled for the AD per-EVI routes at the EVPN level, the status of the AD per-EVI routes with different RDs remains the same at BGP level, so both routes from PE-2 and PE-3 are used, as follows.

```
[/]
```

Conclusion

SRv6 to MPLS interworking is required during the migration to SRv6 and also to interwork with non-SRv6 legacy networks. EVPN VPWS services support the stitching of MPLS and SRv6.

Appendix: best path selection rules

This appendix lists the default route selection rules and the BGP selection rules for AD per-EVI routes.

Default EVPN route selection for AD per-EVI routes

When two or more EVPN routes are received at a PE, BGP route selection typically takes place when the route key or the routes are equal. When the route key is different, but the PE has to make a selection, BGP hands over the routes to EVPN and the EVPN application performs the default selection based on the following tie-breaking order:

1. Lowest IP (next-hop IP of the EVPN NLRI).
2. Lowest Ethernet tag.
3. Lowest RD.
4. Lowest BGP instance (this tie-breaking rule is only considered if the service has two BGP instances of the same encapsulation).

BGP best-path selection for AD per-EVI routes

When a BGP router has multiple paths in its RIB for the same NLRI, its BGP decision process is responsible for deciding which path is the best. The best path can be used by the local router and advertised to other BGP peers.

On SR OS routers, the BGP decision process orders received paths based on the following sequence of comparisons. If there is a tie between paths at any step, BGP proceeds to the next step.

1. Highest local preference
2. Shortest D-PATH (if **d-path-ignore** is disabled)
3. Lowest left-most D-PATH domain-id (if **d-path-ignore** is disabled)
4. Shortest AS-PATH
5. Lowest Origin
6. Lowest MED
7. EBGP wins over IBGP
8. Lowest tunnel-table cost to the next-hop
9. Lowest next-hop type wins (resolution in TTM wins over RTM)

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

10. Lowest router ID (applicable to IBGP peers only)
11. Shortest cluster list length (applicable to IBGP peers only)
12. Lowest IP address of the peer that advertised the route
13. Next-hop check (IPv4 next-hop wins, then lowest next-hop wins)
14. Lowest RD
15. Lowest path ID (add-path)

Multi-Instance VPRN with EVPN-IFL Using SRv6 Transport

This chapter provides information about multi-instance VPRN services with EVPN-IFL using SRv6 transport.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 23.10.R2.

Overview

SRv6 transport in VPRN services with EVPN-IFL is supported in SR OS Release 22.5.R1 and later. Maximum two BGP instances per VPRN are supported and these BGP instances can be associated with the same BGP address family or different BGP address families. When configuring a VPRN with EVPN in interface-less mode (EVPN-IFL) over SRv6 transport, the associated SRv6 locator must have the End.DT4, End.DT6, or End.DT46 functions which can be statically configured or dynamically allocated by the router.

BGP path attribute propagation for SRv6 routes does not require a dedicated CLI command. When multiple BGP owners coexist in the same VPRN route table, BGP path propagation is supported in the following cases, regardless of the encapsulation (MPLS or SRv6) of the route:

- between VPN-IPv4/v6 and EVPN-IFL
- between VPN-IPv4/v6 and VPN-IPv4/v6 – when **allow-export-bgp-vpn** is enabled
- between EVPN-IFL and EVPN-IFL – when **allow-export-bgp-vpn** is enabled
- between VPN-IPv4/v6 and IPv4/v6
- between EVPN-IFL and IPv4/v6
- between VPN-IPv4/v6 and EVPN-IFF – when **iff-attribute-uniform-propagation** is enabled
- between EVPN-IFL and EVPN-IFF – when **iff-attribute-uniform-propagation** is enabled

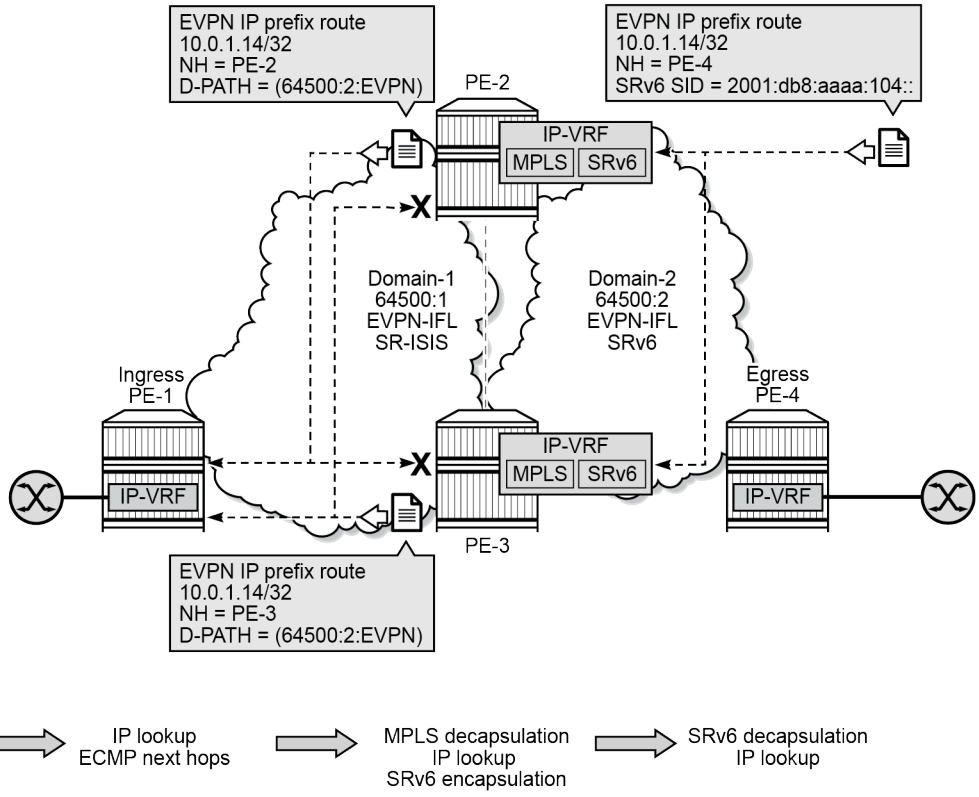
Note:
When a VPRN is configured with **allow-export-bgp-vpn**, the **split-horizon** context is lost. A re-exported route can be easily advertised back to the sending peer unless this is blocked by BGP export policies. This can cause route flaps or similar instability.

In addition, **allow-export-bgp-vpn** must never be used in a VPRN service with a route distinguisher that is used in other PEs attached to the same service. If the same route distinguisher is used in this case, constant route flaps will occur.

Figure 231: EVPN IP prefix routes readvertised between domains shows how an EVPN IP prefix route originating from PE-4 is advertised for a VPRN with EVPN-IFL configured on all nodes. The VPRN with EVPN-IFL uses SRv6 transport in domain 2 and SR-ISIS tunnels in domain 1.

Figure 231: EVPN IP prefix routes readvertised between domains



PE-2 and PE-3 act as service gateways (GWs) that import routes and readvertise them between domains. On the service GWs, the VPRN has two BGP instances that are associated with the EVPN address family. The domain path attribute is used as automated loop prevention, as described in the Domain Path Attribute for VPRN BGP Routes chapter. Each service GW imports the IP prefix route and prepends the domain ID of origin when readvertising these IP prefix routes. When GW PE-2 receives the IP prefix route from PE-4, it prepends domain ID 64500:2 and advertises the IP prefix to PE-1 and PE-3. PE-1 accepts and uses this IP prefix route, but PE-3 does not install this IP prefix route in the VRF because the domain ID 64500:2 is local to PE-3.

Interworking between EVPN-IFL and IP-VPN is supported, as shown in Figure 232: Interworking between EVPN-IFL and IP-VPN.

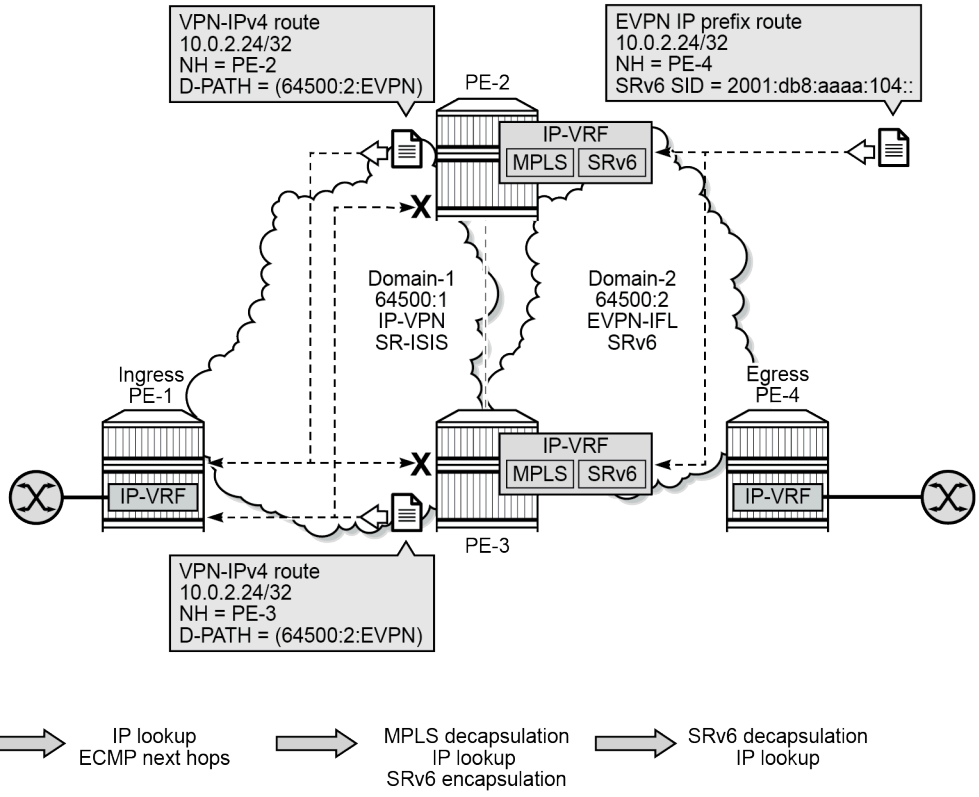
Use subject to Terms available at: www.nokia.com/terms.

Figure 232: Interworking between EVPN-IFL and IP-VPN



On the service GWs PE-2 and PE-3, one BGP instance is associated with the EVPN address family while the other BGP instance is associated with the VPN-IPv4 address family.

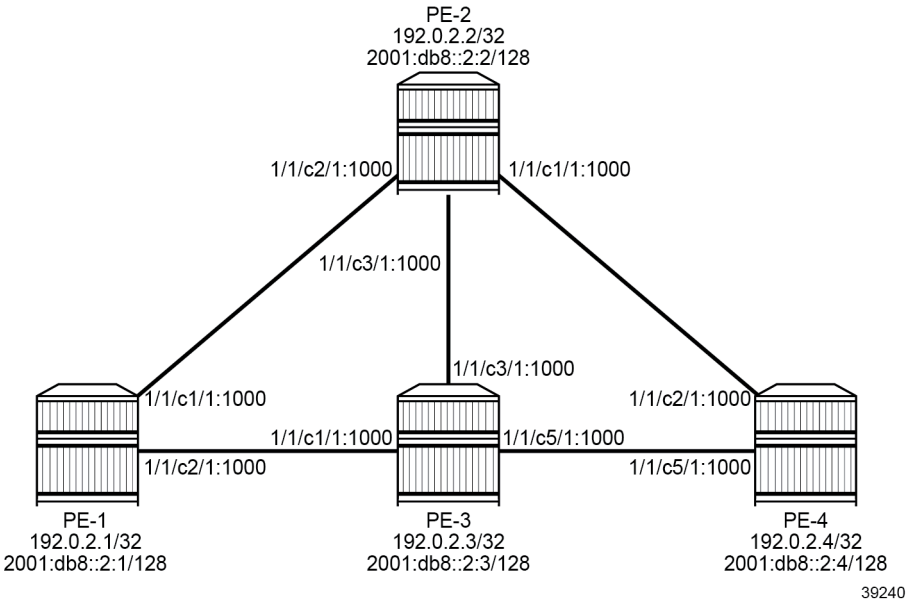
When GW PE-2 receives the IP prefix route from PE-4, it prepends domain ID 64500:2 and advertises the IP prefix 10.0.2.24/32 in a VPN-IPv4 route to PE-1 and PE-3. PE-1 accepts and uses this VPN-IPv4 route, but PE-3 does not install this VPN-IPv4 route in the VRF because the domain ID 64500:2 is local to PE-3.

Configuration

Figure 233: Example topology shows the example topology with four SR OS nodes:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 233: Example topology



The initial configuration on the nodes includes:

- cards, MDAs, ports
- router interfaces
- IS-IS on all router interfaces: IS-IS level 1 between PE-1, PE-2, and PE-3; IS-IS level 2 between PE-2, PE-3, and PE-4
- SR-ISIS between PE-1, PE-2, and PE-3
- SRv6 between PE-2, PE-3, and PE-4

As an example, the initial configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    card 1 {
        mda 1 {
            xconnect {
                mac 1 {
                    loopback 1 {
                    }
                    loopback 2 {
                    }
                }
            }
        }
    }
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
            application {
                srv6 {
                    type origination
```

                        }
                    }
                }
            }
        }
```

The following scenarios are described in this section:

- Multi-instance VPRN with one EVPN-IFL domain using SRv6 transport
  - Multi-instance VPRN with EVPN-IFL over SRv6 and EVPN-IFL over SR-ISIS
  - Multi-instance VPRN with EVPN-IFL over SRv6 and VPN-IPv4/v6 over SR-ISIS
- Multi-instance VPRN with two EVPN-IFL domains using SRv6 transport
  - VPRN with two BGP-EVPN instances pointing at the same SRv6 locator
  - VPRN with two BGP-EVPN instances pointing at different SRv6 locators

Multi-instance VPRN with one EVPN-IFL domain using SRv6 transport

The following two scenarios are described in this section:

- Multi-instance VPRN with EVPN-IFL over SRv6 and EVPN-IFL over SR-ISIS where EVPN-IFL is used in both domains and only the transport is different
- Multi-instance VPRN with EVPN-IFL over SRv6 and VPN-IPv4/v6 over SR-ISIS with interworking between EVPN-IFL and VPN-IPv4/v6 and different transport tunnels in both domains

Multi-instance VPRN with EVPN-IFL over SRv6 and EVPN-IFL over SR-ISIS

BGP configuration

BGP is configured on all nodes for the EVPN address family. The configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "access-mpls"
            }
            neighbor "192.0.2.3" {
                group "access-mpls"
            }
```

The BGP configuration on the service GW PE-2 has two different groups. The BGP configuration for the "access-mpls" group is similar to the BGP configuration on PE-1, whereas the BGP configuration for the "core-srv6" has IPv6 peers and advertises IPv6 next hops for EVPN routes:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            group "core-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            neighbor "192.0.2.1" {
                group "access-mpls"
            }
            neighbor "192.0.2.3" {
                group "access-mpls"
            }
            neighbor "2001:db8::2:3" {
                group "core-srv6"
            }
            neighbor "2001:db8::2:4" {
                group "core-srv6"
            }
```

The BGP configuration on PE-3 is identical, but with different peer addresses.

On PE-4, the BGP configuration is as follows:

```
# on PE-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "core-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor "2001:db8::2:2" {
                group "core-srv6"
            }
            neighbor "2001:db8::2:3" {
                group "core-srv6"
            }
```

Service configuration

VPRN-1 is configured with EVPN-IFL. On PE-1, VPRN-1 has only one BGP instance and MPLS (SR-ISIS) tunnels are used:

```
# on PE-1:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp-evpn {
                mpls 1 {
                    admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    route-distinguisher "192.0.2.1:11"
                    vrf-target {
                        community "target:64500:11"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "loopback" {
                loopback true
                mac 00:00:5e:00:53:11
                ipv4 {
                    primary {
                        address 10.0.1.11
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::1:11 {
                        prefix-length 128
                    }
                }
            }
        }
```

On GW PE-2, the VPRN-1 service is configured as follows. The SRv6 locator from the **router "Base" segment-routing segment-routing-v6** context is used and the End.DT4, End.DT6, and End.DT46 functions are configured for it. EVPN-IFL is used in domain 1 and in domain 2. The **allow-export-bgp-vpn** command is required between two EVPN-IFL instances. The route distinguishers and the route targets have different values in the different domains. The domain IDs are configured on the service GWs to avoid loops. For SRv6, the IPv6 system address is used as source address.

```
# on PE-2:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            allow-export-bgp-vpn true    # required between two EVPN-IFL instances
            segment-routing-v6 1 {
                locator "PE2-loc" {
                    function {
                        end-dt4 {
                        }

                    route-distinguisher "192.0.2.2:12"
                    source-address 2001:db8::2:2
                    domain-id "64500:2"
                    vrf-target {
                        community "target:64500:12"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE2-loc"
                    }
                }
            }
```

The service configuration on PE-3 is similar.

On PE-4, the VPRN-1 service is configured as follows:

```
# on PE-4:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            segment-routing-v6 1 {
                locator "PE4-loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.4:12"
                    source-address 2001:db8::2:4
                    vrf-target {
                        community "target:64500:12"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE4-loc"
                    }
                }
            }
            interface "loopback" {
                loopback true
                mac 00:00:5e:00:53:14
                ipv4 {
                    primary {
                        address 10.0.1.14
                        prefix-length 32
                    }
                }
```

PE-2 readvertises this IP prefix route to PE-1 and PE-3 after prepending the domain ID 64500:2. PE-1 accepts the route, but PE-3 has domain ID 64500:2 locally, so it does not install the IP prefix in its VRF. The following shows that PE-3 does not use the IP prefix route for prefix 10.0.1.14/32 with RD 192.0.2.2:11 and D-path [64500:2:(evpn)] . PE-3 detects a domain path loop in VRF 1.

```

Likewise, when PE-3 receives an IP prefix route for prefix 10.0.1.14/32 from PE-4, it imports the route and it readvertises this IP prefix route to PE-1 and PE-2 after prepending the domain ID 64500:2. PE-1 accepts and uses the route, but PE-2 has domain ID 64500:2 locally, so it does not install the IP prefix route in its VRF. The following shows that PE-2 does not use the IP prefix route for prefix 10.0.1.14/32 with RD 192.0.2.3:11 and D-path [64500:2:(evpn)] . PE-2 detects a domain path loop in VRF 1.

The IPv4 route table for VPRN-1 on PE-1 shows an EVPN-IFL route to 10.0.1.14/32 that uses an SR-ISIS tunnel to PE-2:

```
[/]
A:admin@PE-1# show router service-name "VPRN-1" route-table

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.0.1.11/32                                    Local   Local     00h06m36s  0
       loopback                                                        0
10.0.1.14/32                                    Remote  EVPN-IFL  00h06m11s  170
       192.0.2.2 (tunneled:SR-ISIS:524290)                             10
-------------------------------------------------------------------------------
No. of Routes: 2

```

On PE-4, the route table for VPRN-1 is as follows:

```
[/]
A:admin@PE-4# show router service-name "VPRN-1" route-table

===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.0.1.11/32                                  Remote  EVPN-IFL  00h06m04s  170
       2001:db8:aaaa:102:7fff:c000:: (tunneled:SRV6)                10
10.0.1.14/32                                  Local   Local     00h06m08s  0
       loopback                                                    0
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The IPv6 route tables for VPRN-1 on the different PEs are similar; for example, on PE-2:

```
[/]
A:admin@PE-2# show router service-name "VPRN-1" route-table ipv6

===============================================================================
IPv6 Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
2001:db8::1:11/128                            Remote  EVPN-IFL  00h07m17s  170
       192.0.2.1 (tunneled:SR-ISIS:524290)                         10
2001:db8::1:14/128                            Remote  EVPN-IFL  00h07m03s  170
       2001:db8:aaaa:104:7fff:f000:: (tunneled:SRV6)                10
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

EVPN-IFL IPv4 routes are advertised with End.DT4 or End.DT46 in that preference order and EVPN-IFL IPv6 routes are advertised with End.DT6 or End.DT46 in that preference order. The following command shows the SID values for the End.DT4, End.DT6, and End.DT46 functions on PE-4:

```
[/]
A:admin@PE-4# show service id "VPRN-1" segment-routing-v6 instance 1
```

Multi-instance VPRN with EVPN-IFL over SRv6 and VPN-IPv4/v6 over SR-ISIS

This section describes a use case with interworking between EVPN-IFL and VPN-IPv4.

BGP configuration

Between PE-1, PE-2, and PE-3, BGP is supported for the VPN-IPv4 and VPN-IPv6 address families. The BGP configuration on PE-1 is as follows:

```
#  on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
            neighbor "192.0.2.2" {
                group "access-mpls"
            }
            neighbor "192.0.2.3" {
                group "access-mpls"
            }
```

The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                evpn true
            }
            group "access-mpls" {
                peer-as 64500
                family {
                    vpn-ipv4 true
                    vpn-ipv6 true
                }
            }
            group "core-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "access-mpls"
            }
            neighbor "192.0.2.3" {
                group "access-mpls"
            }
            neighbor "2001:db8::2:3" {
                group "core-srv6"
            }
            neighbor "2001:db8::2:4" {
                group "core-srv6"
            }
```

The BGP configuration on PE-3 is similar.

The BGP configuration on PE-4 remains unchanged.

Service configuration

On PE-1, VPRN-2 is configured as follows:

```
# on PE-1:
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.1:21"
                    vrf-target {
                        community "target:64500:21"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "loopback" {
                loopback true
                mac 00:00:5e:00:53:21
                ipv4 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    primary {
                        address 10.0.2.21
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::2:21 {
                        prefix-length 128
                    }
                }
            }
```

On PE-2, VPRN-2 is configured as follows:

```
# on PE-2:
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            segment-routing-v6 1 {
                locator "PE2-loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.2:22"
                    source-address 2001:db8::2:2
                    domain-id "64500:2"
                    vrf-target {
                        community "target:64500:22"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE2-loc"
                    }
                }
            }
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.2:21"
                    domain-id "64500:1"
                    vrf-target {
                        community "target:64500:21"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

The configuration on PE-3 is similar.

On PE-4, VPRN-2 is configured as follows:

```
# on PE-4:
configure {
    service {
        vprn "VPRN-2" {
            admin-state enable
            service-id 2
            customer "1"
            segment-routing-v6 1 {
                locator "PE4-loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.4:22"
                    source-address 2001:db8::2:4
                    vrf-target {
                        community "target:64500:22"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE4-loc"
                    }
                }
            }
            interface "loopback" {
                loopback true
                mac 00:00:5e:00:53:24
                ipv4 {
                    primary {
                        address 10.0.2.24
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::2:24 {
                        prefix-length 128
                    }
                }
            }
```

Verification

GW PE-2 receives and uses the following IP prefix route from PE-4:

```
[/]
A:admin@PE-2# show router bgp routes evpn ip-prefix rd 192.0.2.4:22
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500
===============================================================================
 Legend -

PE-2 readvertises this prefix in a VPN-IPv4 route to PE-1 and PE-3 after prepending the domain ID 64500:2. PE-1 accepts this route, but PE-3 has domain ID 64500:2 locally, so it does not add this route to its VRF. The following shows that PE-3 does not use the VPN-IPv4 route received from PE-2 and that PE-3 detects a domain path loop in VRF 2:

```

Multi-instance VPRN with two EVPN-IFL domains using SRv6 transport

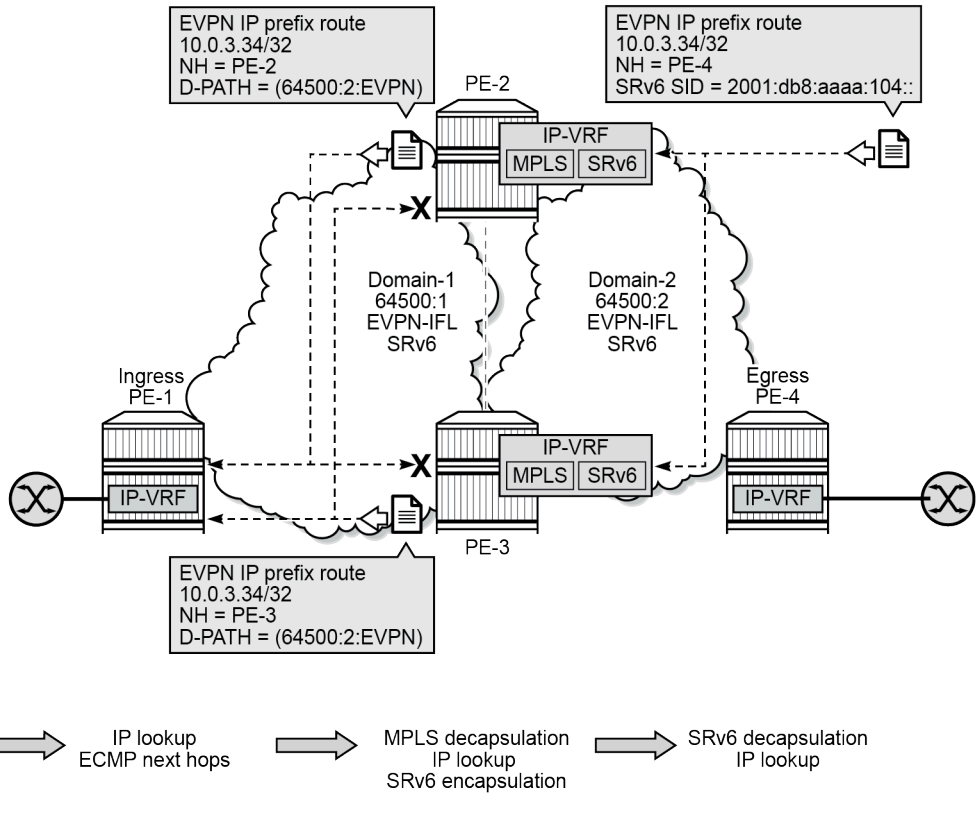
Multi-instance VPRNs with two EVPN-IFL domains using SRv6 transport are supported in SR OS Release 23.10.R1 and later. In this section, the following two scenarios are described:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- VPRN with two BGP-EVPN instances pointing at the same SRv6 locator
- VPRN with two BGP-EVPN instances pointing at different SRv6 locators

Figure 234: EVPN IP prefix routes readvertised between SRv6 domains shows how IP prefix 10.0.3.34/32 is advertised in VPRN-3 with two BGP-EVPN instances pointing at the same SRv6 locator.

Figure 234: EVPN IP prefix routes readvertised between SRv6 domains



For a VPRN with two BGP-EVPN instances pointing at different SRv6 locators, the behavior is identical but the SRv6 SID on PE-4 is different for a different SRv6 locator.

VPRN with two BGP-EVPN instances pointing at the same SRv6 locator

This section describes VPRN-3 which has two BGP-EVPN instances that both use the same locator.

SRv6 configuration

SRv6 was already configured among PE-2, PE-3, and PE-4. In this scenario and the following, SRv6 is also configured among PE-1, PE-2, and PE-3. The IS-IS configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        isis 0 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            admin-state enable
            advertise-passive-only true
            advertise-router-capability as
            ipv6-routing native
            traffic-engineering true
            area-address [49.0001]
            traffic-engineering-options {
                ipv6 true
                application-link-attributes {
                }
            }
            segment-routing-v6 {
                admin-state enable
                locator "PE1-loc" {
                    level-capability 1       # on PE-2, PE-3: level 1/2 (default)
                }
            }
            interface "int-PE-1-PE-2" {
                interface-type point-to-point
                level-capability 1
            }
            interface "int-PE-1-PE-3" {
                interface-type point-to-point
                level-capability 1
            }
            interface "system" {
                passive true
            }
            level 1 {
                wide-metrics-only true
            }
            level 2 {
                wide-metrics-only true
            }
        }
```

On the GWs PE-2 and PE-3, the existing locators "PE2-loc" and "PE3-loc" are used on both SRv6 domains and these SRv6 locators are configured with level-capability 1/2, which is the default value.

BGP configuration

In this example, BGP uses IPv6 peer addresses. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            neighbor "2001:db8::2:2" {
                group "access-srv6"
            }
            neighbor "2001:db8::2:3" {
                group "access-srv6"
            }
```

The BGP configuration on the service GWs PE-2 and PE-3 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "access-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            group "core-srv6" {
                peer-as 64500
                family {
                    evpn true
                }
                advertise-ipv6-next-hops {
                    evpn true
                }
            }
            neighbor "2001:db8::2:1" {
                group "access-srv6"
            }
            neighbor "2001:db8::2:3" {            # on PE-3: 2001:db8::2:2
                group "core-srv6"
            }
            neighbor "2001:db8::2:4" {
                group "core-srv6"
            }
```

The BGP configuration on PE-4 remains the same as in the preceding use cases.

Service configuration

On PE-1 and PE-4, the configuration of VPRN-3 is similar. VPRN-3 is configured on PE-1 as follows:

```
# on PE-1:
configure {
    service {
         vprn "VPRN-3" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            admin-state enable
            service-id 3
            customer "1"
            segment-routing-v6 1 {
                locator "PE1-loc" {             # on PE-4: "PE4-loc"; same functions
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.1:31"         # on PE-4: 192.0.2.4:32
                    source-address 2001:db8::2:1               # on PE-4: 2001:db8::2:4
                    vrf-target {
                        community "target:64500:31"            # on PE-4: target:64500:32
                    }
                    srv6 {
                        instance 1
                        default-locator "PE1-loc"              # on PE-4: "PE4-loc"
                    }
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 10.0.3.31                      # on PE-4: 10.0.3.34
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::3:31 {                   # on PE-4: 2001:db8::3:34
                        prefix-length 128
                    }
                }
            }
```

On GWs PE-2 and PE-3, VPRN-3 has two BGP-EVPN instances that both point to the same locator, as follows:

```
# on PE-2:
configure {
    service {
        vprn "VPRN-3" {
            admin-state enable
            service-id 3
            customer "1"
            allow-export-bgp-vpn true
            segment-routing-v6 1 {
                locator "PE2-loc" {               # on PE-3: "PE3-loc"; same functions
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                }
            }
        }
        bgp-evpn {
            segment-routing-v6 1 {
                admin-state enable
                route-distinguisher "192.0.2.2:31"        # on PE-3: 192.0.2.3:31
                source-address 2001:db8::2:2              # on PE-3: 2001:db8::2:3
                domain-id "64500:1"
                vrf-target {
                    community "target:64500:31"
                }
                srv6 {
                    instance 1
                    default-locator "PE2-loc"             # on PE-3: "PE3-loc"
                }
            }
            segment-routing-v6 2 {
                admin-state enable
                route-distinguisher "192.0.2.2:32"        # on PE-3: 192.0.2.3:32
                source-address 2001:db8::2:2              # on PE-3: 2001:db8::2:3
                domain-id "64500:2"
                vrf-target {
                    community "target:64500:32"
                }
                srv6 {
                    instance 1
                    default-locator "PE2-loc"             # on PE-3: "PE3-loc"
                }
            }
        }
```

Verification

The domain path attribute is used for loop prevention. GW PE-2 does not use the IP prefix routes readvertised by GW PE-3:

```
[/]
A:admin@PE-2# show router bgp routes evpn ip-prefix rd 192.0.2.3:31
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500

       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
```

The behavior is the same as in the preceding use cases. The same **show** commands can be used to verify that.

VPRN with two BGP-EVPN instances pointing at different SRv6 locators

This section describes VPRN-4, which has two BGP-EVPN instances pointing at different locators.

SRv6 locator configuration

On PE-2, PE-3, and PE-4, an additional SRv6 locator is configured. In this example, the only difference is the IP prefix. On PE-2, the "PE2-loc" locator was already configured and the "PE2-loc-2" locator is added:

```
# on PE-2:
configure {
    router "Base" {
        isis 0 {
            segment-routing-v6 {
                admin-state enable
                locator "PE2-loc" {
                }
                locator "PE2-loc-2" {
                }
            }
---snip---
        segment-routing {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            segment-routing-v6 {
                origination-fpe [1]
                source-address 2001:db8::2:2
                locator "PE2-loc" {
                    admin-state enable
                    block-length 48
                    termination-fpe [2]
                    prefix {
                        ip-prefix 2001:db8:aaaa:102::/64
                    }
                }
                locator "PE2-loc-2" {
                    admin-state enable
                    block-length 48
                    termination-fpe [2]
                    prefix {
                        ip-prefix 2001:db8:aaaa:122::/64
                    }
                }
                base-routing-instance {
                    locator "PE2-loc" {
                        function {
                            end 1 {
                                srh-mode usp
                            }
                            end-x-auto-allocate psp protection unprotected { }
                        }
                    }
                    locator "PE2-loc-2" {
                        function {
                            end 1 {
                                srh-mode usp
                            }
                            end-x-auto-allocate psp protection unprotected { }
                        }
                    }
                }
            }
        }
```

Likewise, PE-3 gets additional locator "PE3-loc-2" and PE-4 gets additional locator "PE4-loc-2".

BGP configuration

The BGP configuration is the same as for VPRN-3: BGP is enabled for the EVPN address family and the peer addresses are the IPv6 system addresses.

Service configuration

On PE-1, VPRN-4 is configured as follows:

```
#  on PE-1:
configure {
    service {
        vprn "VPRN-4" {
            admin-state enable
            service-id 4
            customer "1"
            segment-routing-v6 1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                locator "PE1-loc" {
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.1:41"
                    source-address 2001:db8::2:1
                    vrf-target {
                        community "target:64500:41"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE1-loc"
                    }
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 10.0.4.41
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::4:41 {
                        prefix-length 128
                    }
                }
            }
```

On PE-2, VPRN-4 is configured with two SRv6 instances that use different locators, as follows. The configuration on PE-3 is similar.

```
#  on PE-2:
configure {
    service {
        vprn "VPRN-4" {
            admin-state enable
            service-id 4
            customer "1"
            bgp-vpn true
            segment-routing-v6 1 {
                locator "PE2-loc" {           # on PE-3: "PE3-loc"; same functions
                    function {
                        end-dt4 {
                        }
                        end-dt6 {
                        }
                        end-dt46 {
                        }
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            segment-routing-v6 2 {
                locator "PE2-loc-2" {         # on PE-3: "PE3-loc-2"; same functions
                    function {
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.2:41"      # on PE-3: 192.0.2.3:41
                    source-address 2001:db8::2:2            # on PE-3: 2001:db8::2:3
                    domain-id "64500:1"
                    vrf-target {
                        community "target:64500:41"
                    }
                    srv6 {
                        instance 1
                        default-locator "PE2-loc"           # on PE-3: "PE3-loc"
                    }
                }
                segment-routing-v6 2 {
                    admin-state enable
                    route-distinguisher "192.0.2.2:42"      # on PE-3: 192.0.2.3:42
                    source-address 2001:db8::2:2            # on PE-3: 2001:db8::2:3
                    domain-id "64500:2"
                    vrf-target {
                        community "target:64500:42"
                    }
                    srv6 {
                        instance 2
                        default-locator "PE2-loc-2"         # on PE-3: "PE3-loc-2"
                    }
                }
            }
```

On PE-4, VPRN-4 is configured as follows:

```
#  on PE-4:
configure {
    service {
        vprn "VPRN-4" {
            admin-state enable
            service-id 4
            customer "1"
            segment-routing-v6 1 {
                locator "PE4-loc-2" {
                    function {
                        end-dt46 {
                        }
                    }
                }
            }
            bgp-evpn {
                segment-routing-v6 1 {
                    admin-state enable
                    route-distinguisher "192.0.2.4:42"
                    source-address 2001:db8::2:4
                    vrf-target {
                        community "target:64500:42"
                    }
                    srv6 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        instance 1
                        default-locator "PE4-loc-2"
                    }
                }
            }
            interface "loopback" {
                loopback true
                ipv4 {
                    primary {
                        address 10.0.4.44
                        prefix-length 32
                    }
                }
                ipv6 {
                    address 2001:db8::4:44 {
                        prefix-length 128
                    }
                }
            }
```

Verification

The behavior is similar as in the preceding use cases. Loops are prevented using the domain path attribute. The following shows that PE-3 detects a domain path loop in VRF 4 for a route originating from PE-2:

```
[/]

Conclusion

Multi-instance VPRN services with EVPN-IFL can use SRv6 transport as well as MPLS transport. Interworking between EVPN-IFL and IP-VPN is supported. Multi-instance VPRN services can be used as Service Gateways to connect two SRv6 domains together.

OISM to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI

This chapter provides information about Optimized Intersubnet Multicast (OISM) to Multicast VPN/Protocol Independent Multicast (MVPN/PIM) interworking (using the MVPN to EVPN Gateway/PIM to EVPN Gateway (MEG/PEG) functions) with Multicast Label Distribution Protocol (MLDP) Inclusive Provider Multicast Service Interface (I-PMSI).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 24.10.R2. Only on FP-based platforms, SR OS Release 22.2.R2 and later support MLDP I-PMSI.

Overview

SR OS Release 21.10.R1 and later support OISM EVPN interworking with MVPN and PIM networks. Two key interworking functions are used to achieve this interworking:

- MEG (MVPN to EVPN Gateway): Bridges MVPN and EVPN.
- PEG (PIM to EVPN Gateway): Bridges PIM and EVPN.

The system uses a Designated Router (DR) election process to ensure redundancy. This is achieved by:

- Including the Designated Forwarder (DF) Election extended community in the Inclusive Multicast Ethernet Tag (IMET) routes.
- Following the DR selection procedures defined in RFC 8584.

After being elected, the MEG/PEG routers use Ingress Replication (IR) to handle multicast (MC) traffic efficiently within supplementary broadcast domains (SBDs).

In addition to IR and only on FP-based platforms, SR OS Release 22.2.R2 and later also support MLDP root-and-leaf (See P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services for more details) on the SBD of the MEG/PEG routers. On a MEG/PEG router, traffic originating from either the MVPN/PIM domain or the EVPN domain can be forwarded or received by the MEG/PEG DR through an MLDP provider tunnel. The PIM Instance can be in MVPN.

Figure 235: Example topology is used to illustrate the working of OISM EVPN to MVPN/PIM interworking with MLDP I-PMSI.

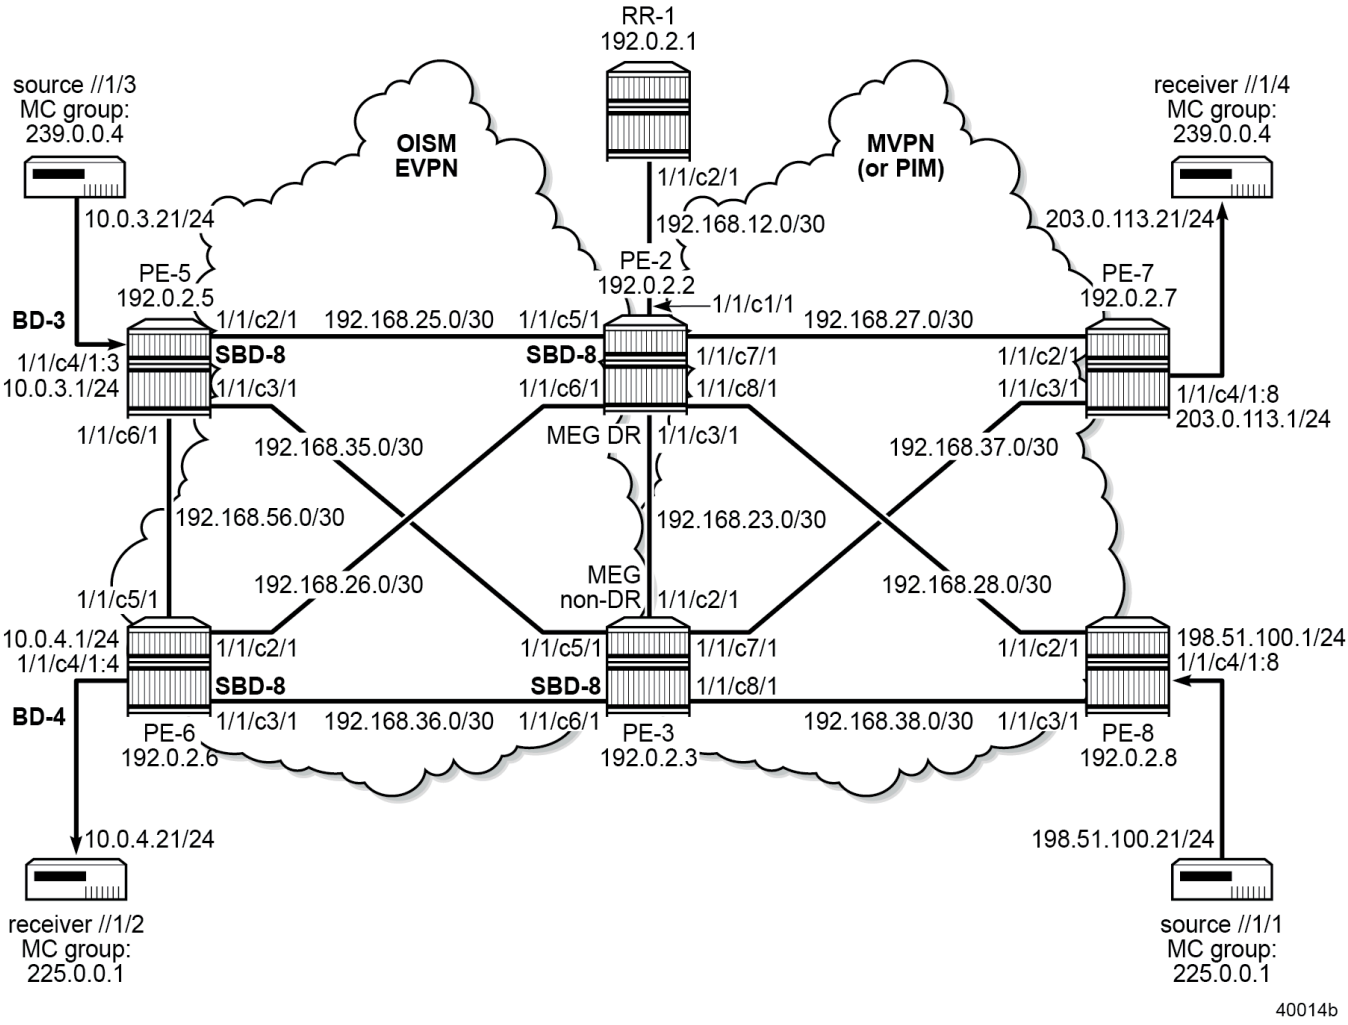
Use subject to Terms available at: www.nokia.com/terms.

Figure 235: Example topology



PE-2 and PE-3 connect an OISM EVPN network hosting PE-5 and PE-6, and an MVPN/PIM network hosting PE-7 and PE-8. PE-2 and PE-3 act as MEG/PEG DR candidates. PE-2 and PE-3 forward traffic into the EVPN using MLDP I-PMSIs. An MC receiver connected to PE-6 in the EVPN network joins MC group 225.0.0.1 of an MC source connected to PE-8 in the MVPN/PIM network to receive MC traffic from the MC source. An MC receiver connected to PE-7 in the MVPN/PIM network joins MC group 239.0.0.4 of an MC source connected to PE-5 in the EVPN network to receive MC traffic from the MC source. All PEs exchange BGP messages via a BGP route reflector RR-1 that is connected to PE-2.

The EVPN MPLS services use **provider-tunnel inclusive**. The **owner** must be configured as **bgp-evpn-mpls**. Other options are **bgp-ad**, **bgp-vpls**, or no **owner** configured (default). If **bgp-evpn-mpls** and **bgp-vpls** are enabled in the same service, they are mutually exclusive with **provider-tunnel**. If **bgp-evpn-mpls** and **bgp-ad** coexist in the same service, only **bgp-evpn-mpls** can be the **provider-tunnel inclusive owner**.

The provider tunnel in the EVPN MPLS services uses the **incl-mcast advertise-ingress-replication** configuration to determine the Inclusive Multicast route PMSI Tunnel Attribute (PTA) type:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **incl-mcast advertise-ingress-replication false**: the PE does not send IMET-IR or IMET-P2MP-IR routes
- **incl-mcast advertise-ingress-replication true** (default)
  - if **root-and-leaf** is not configured or **root-and-leaf false** is configured (default): the PE sends an IMET-IR route
  - if **root-and-leaf true** is configured: the PE sends an IMET-P2MP-IR composite tunnel route

Configuration

The initial configuration includes:

- cards, MDAs, ports
- BGP route reflector (RR)
- router interfaces
- IBGP in the EVPN network for the EVPN address family
- IBGP in the MVPN/PIM network for the VPN IPv4 and MVPN IPv4 address families
- IS-IS on the router interfaces (OSPF or OSPF3 router interfaces are also possible)
- LDP and MPLS in the EVPN and MVPN/PIM networks (not on the RR)

Router configuration

The router configuration on PE-2 is as follows:

```
# On PE-2:
configure {
    router "Base" {
        interface "int-PE-2-PE-3" {
            port 1/1/c3/1
            ipv4 {
                primary {
                    address 192.168.23.1
                    prefix-length 30
                }
            }
            ipv6 {
                address 2001:db8::168:23:1 {
                    prefix-length 126
                }
            }
        }
        interface "int-PE-2-PE-5" {
            port 1/1/c5/1
            ipv4 {
                primary {
                    address 192.168.25.1
                    prefix-length 30
                }
            }
            ipv6 {
                address 2001:db8::168:25:1 {
                    prefix-length 126
```

The router configuration on PE-3, PE-5, PE-6, PE-7 and PE-8 is similar. PE-3, PE-5, PE-6, PE-7 and PE-8 have no interface to RR-1.

RR-1 is the BGP route reflector. RR-1 is connected with PE-2 and runs IS-IS. RR-1 is configured as follows:

```
# On RR-1:
configure {
    router "Base" {
        interface "int-RR-1-PE-2" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
            ipv6 {
                address 2001:db8::168:12:1 {
                    prefix-length 126
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.1
                    prefix-length 32
                }
            }
            ipv6 {
                address 2001:db8::2:1 {
                    prefix-length 128
                }
            }
        }
        isis 0 {
            admin-state enable
            advertise-router-capability as
            ipv6-routing native
            level-capability 2
            traffic-engineering true
            area-address [49.0001]
            traffic-engineering-options {
                ipv6 true
```

```
                application-link-attributes { }
            }
            interface "int-RR-1-PE-2" {
                interface-type point-to-point
            }
            interface "system" { }
            level 2 {
                wide-metrics-only true
            }
        }
```

The IBGP configuration on RR-1 is as follows:

```
# On RR-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            rapid-update {
                vpn-ipv4 true
                mvpn-ipv4 true
                evpn true
            }
            group "IBGP" {
                type internal
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.2" {
                group "IBGP"
                family {
                    vpn-ipv4 true
                    mvpn-ipv4 true
                    evpn true
                }
            }
            neighbor "192.0.2.3" {
                group "IBGP"
                family {
                    vpn-ipv4 true
                    mvpn-ipv4 true
                    evpn true
                }
            }
            neighbor "192.0.2.5" {
                group "IBGP"
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.6" {
                group "IBGP"
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.7" {
                group "IBGP"
                family {
                    vpn-ipv4 true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    mvpn-ipv4 true
                }
            }
            neighbor "192.0.2.8" {
                group "IBGP"
                family {
                    vpn-ipv4 true
                    mvpn-ipv4 true
                }
            }
```

The IBGP configuration on PE-2 is as follows:

```
# On PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            peer-ip-tracking true
            rapid-update {
                vpn-ipv4 true
                mvpn-ipv4 true
                evpn true
            }
            group "IBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "IBGP"
                family {
                    vpn-ipv4 true
                    mvpn-ipv4 true
                    evpn true
                }
            }
        }
```

The IBGP configuration on PE-3, PE-5, PE-6, PE-7, and PE-8 is similar. PE-2 and PE-3 operate in both the EVPN and the MVPN/PIM networks. They support the VPN IPv4, MVPN IPv4, and EVPN address families. PE-5 and PE-6 operate in the EVPN network only. They support only the EVPN address family. PE-7 and PE-8 operate in the MVPN/PIM network only. They support only the VPN IPv4 and MVPN IPv4 address families.

Service configuration in the EVPN network

The initial routed VPLS SBD-8 is configured on all PEs in the EVPN network, as follows. To forward IPv4/IPv6 multicast traffic from the VPLS side of the routed VPLS service to the IP side, **routed-vpls multicast ipv4 forward-to-ip-interface true** and/or **routed-vpls multicast ipv6 forward-to-ip-interface true** must be configured.

```
# On PE-2, PE-3, PE-5, PE-6:
configure {
    service {
        vpls "SBD-8" {
            admin-state enable
            service-id 8
            customer "1"
            routed-vpls {
```

```
                multicast {
                    ipv4 {
                        forward-to-ip-interface true
                    }
                    ipv6 {
                        forward-to-ip-interface true
                    }
                }
            }
            bgp 1 { }
            igmp-snooping {
                admin-state enable
            }
            mld-snooping {
                admin-state enable
            }
            bgp-evpn {
                evi 8
                routes {
                    mac-ip {
                        advertise false
                    }
                    ip-prefix {
                        advertise true
                        domain-id "64500:8"
                    }
                    sel-mcast {
                        advertise true
                    }
                }
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
```

bgp-evpn routes ip-prefix domain-id 64500:8 is needed for loop prevention between EVPN and MVPN/PIM. See Domain Path Attribute for VPRN BGP Routes for the use of this command.

Additionally, PE-2 and PE-3 are configured as MEG/PEG router, as follows:

```
# On PE-2, PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The provider tunnel on the routed VPLS SBD-8 service on PE-2 and PE-3 is additionally configured as **root-and leaf**, as follows:

```
# On PE-2, PE-3:
configure {
    service {
        vpls "SBD-8" {
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
```

The initial VPRN-1 is configured on all PEs, depending on their role in the EVPN or MVPN/PIM networks. PE-2 and PE-3 have identical VPRN-1 configuration (except for their route-distinguisher), as follows:

```
# On PE-2, PE-3:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp {
                interface "int-SBD-8" { }    # to reach EVPN MC receiver
            }
            pim {
                apply-to all
                interface "int-SBD-8" {    # to reach EVPN MC source
                    multicast-senders always
                }
            }
            mvpn {
                c-mcast-signaling bgp
                auto-discovery {
                    type bgp
                }
                vrf-target {
                    unicast true
                }
                provider-tunnel {
                    inclusive {
                        mldp {
                            admin-state enable
                        }
                    }
                }
            }
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.2:1"    # 192.0.2.3:1 for PE-3
                    domain-id "64500:1"
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            interface "int-SBD-8" {
                vpls "SBD-8" {
                    evpn-tunnel {
                        supplementary-broadcast-domain true
                    }
                }
            }
```

VPRN-1 on PE-2 and on PE-3 uses SBD-8 toward the EVPN MC source on PE-5 and toward the EVPN MC receiver on PE-6.

PE-5 and PE-6 have an identical initial VPRN-1 configuration, which uses SBD-8 toward the MEG/PEG routers, as follows. Because an SBD interface does not have IP addresses, **multicast-senders always** must be configured to pass the RPF-check.

```
# On PE-5, PE-6:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp { }
            pim {
                apply-to all
                interface "int-SBD-8" {
                    multicast-senders always
                }
            }
            interface "int-SBD-8" {
                vpls "SBD-8" {
                    evpn-tunnel {
                        supplementary-broadcast-domain true
                    }
                }
            }
```

PE-7 and PE-8 have nearly identical initial VPRN-1, with IGMP on PE-7 on the interface to the directly connected MC receiver and PIM on PE-8 on the interface to the directly connected MC source, as follows:

```
# On PE-7:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp {
                interface "to-receiver" { }
            }
            pim {
                apply-to all
            }
            mvpn {
                c-mcast-signaling bgp
                umh-selection highest-ip    # this is the default
                auto-discovery {
                    type bgp
                }
                vrf-target {
                    unicast true
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                provider-tunnel {
                    inclusive {
                        mldp {
                            admin-state enable
                        }
                    }
                }
            }
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.7:1"
                    vrf-target {
                        community "target:64500:1"
                    }
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            interface "to-receiver" {
                ipv4 {
                    primary {
                        address 203.0.113.1
                        prefix-length 24
                    }
                }
                sap 1/1/c4/1:8 { }
            }
```

```
# On PE-8:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            service-id 1
            customer "1"
            igmp { }
            pim {
                apply-to all
                interface "to-source" { }
            }
            mvpn {
                c-mcast-signaling bgp
                auto-discovery {
                    type bgp
                }
                vrf-target {
                    unicast true
                }
                provider-tunnel {
                    inclusive {
                        mldp {
                            admin-state enable
                        }
                    }
                }
            }
            bgp-ipvpn {
                mpls {
                    admin-state enable
                    route-distinguisher "192.0.2.8:1"
                    vrf-target {
```

```
                    community "target:64500:1"
                }
                auto-bind-tunnel {
                    resolution any
                }
            }
        }
        interface "to-source" {
            ipv4 {
                primary {
                    address 198.51.100.1
                    prefix-length 24
                }
            }
            sap 1/1/c4/1:8 { }
        }
```

Use cases

The following use cases are described in the following sections:

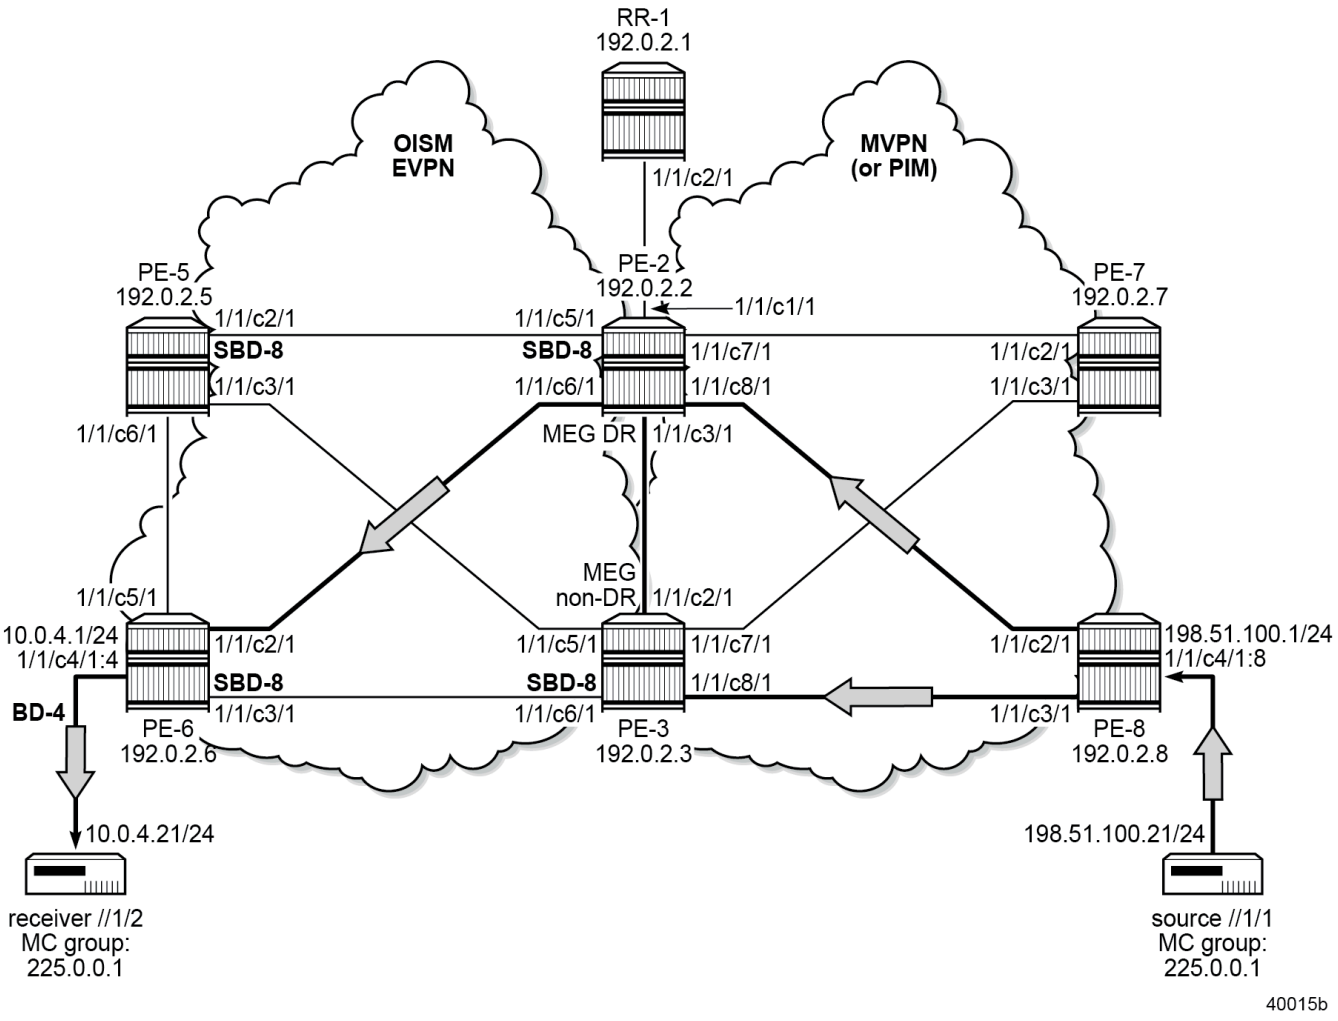
- MC traffic from MC source in MVPN/PIM network to MC receiver in EVPN network
- MC traffic from MC source in EVPN network to MC receiver in MVPN/PIM network
- Delayed MEG/PEG DR election

MC traffic from MC source in MVPN/PIM network to MC receiver in EVPN network

Figure 236: MVPN/PIM MC source - EVPN MC receiver example setup illustrates MVPN/PIM to OISM EVPN interworking.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 236: MVPN/PIM MC source - EVPN MC receiver example setup



The MC source is connected to PE-8 in the MVPN/PIM network. The MC receiver is connected to PE-6 in the EVPN network. The MC source (198.51.100.21) sends MC traffic to the MC receiver (10.0.4.21) that requested group membership for MC group 225.0.0.1.

The following cases are described in the following sections:

- MC source configuration
- MC receiver configuration
- MEG/PEG DR election
- MC traffic verification

MC source configuration

The MC source is directly connected to VPRN-1 on PE-8 and needs no further configuration beyond the initial VPRN-1 configuration.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

MC receiver configuration

The MC receiver is connected to routed VPLS BD-4 on PE-6, as follows:

```
# On PE-6:
configure {
    service {
        vpls "BD-4" {
            admin-state enable
            service-id 4
            customer "1"
            routed-vpls {
                multicast {
                    ipv4 {
                        forward-to-ip-interface true
                    }
                    ipv6 {
                        forward-to-ip-interface true
                    }
                }
            }
            bgp 1 { }
            igmp-snooping {
                admin-state enable
            }
            mld-snooping {
                admin-state enable
            }
            bgp-evpn {
                evi 4
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/c4/1:4 {
                igmp-snooping {
                    fast-leave true
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
```

VPRN-1 on PE-6 uses BD-4 toward the MC receiver (next to SBD-8 toward the MEG/PEG routers) and is additionally configured as follows:

```
# On PE-6:
configure {
    service {
        vprn "VPRN-1" {
            ---snip---
            igmp {
                interface "int-BD-4" { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            interface "int-BD-4" {
                description "to_receiver_OISM"
                ipv4 {
                    primary {
                        address 10.0.4.1
                        prefix-length 24
                    }
                }
                vpls "BD-4" { }
            }
            ---snip---
```

MEG/PEG DR election

PE-2 and PE-3 run the MEG/PEG DR election. The MEG/PEG DR election is based on the default algorithm used for EVPN DF election: modulo function of the EVI and the number of PEs. Result 0 corresponds with the lowest IP, result 1 corresponds with the next-lowest IP, and so on. The MEG/PEG routers build a list of up to 4 MEG/PEG DR candidates using the **orig_addr** field in the IMET routes for SBD-8. PE-2 is elected as MEG/PEG DR:

```

# On PE-3:
16 2025/01/09 13:36:37.181 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Received BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 123
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.2
        Type: EVPN-INCL-MCAST Len: 17 RD: 192.0.2.2:8, tag: 0,
orig_addr len: 32, orig_addr: 192.0.2.2
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0x80 Type: 9 Len: 4 Originator ID: 192.0.2.2
    Flag: 0x80 Type: 10 Len: 4 Cluster ID:
        1.1.1.1
    Flag: 0xc0 Type: 16 Len: 32 Extended Community:
        target:64500:8
        mcast-flags:SBD/MEG/PEG/OISM/NO-MLD-Proxy/NO-IGMP-Proxy
        df-election::DF-Type:Auto/DP:0/DF-Preference:0/AC:0
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 25 PMSI:
        Tunnel-type Composite LDP P2MP IR (130)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label1 Ag  0
        MPLS Label2 IR 8388320
        Root-Node 192.0.2.2, LSP-ID 0x2002
        "
```

The MEG/PEG non-DR is configured such that it does not attract traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        non-dr-attract-traffic none
```

The MEG/PEG non-DR does not send wild card EVPN Selective Multicast Ethernet Tag (**EVPN-SMET**) BGP updates. The MEG/PEG DR does send the wildcard **EVPN-SMET** BGP update and attracts traffic.

MC traffic verification

When the MC source on PE-8 starts sending MC traffic for MC group 225.0.0.1, PE-8 sends out an MVPN **Source-Ad** BGP update in the MVPN/PIM network. PE-2 and PE-3 install the corresponding source-ad route:

```
[/]
A:admin@PE-2# show router bgp routes mvpn-ipv4 type source-ad group-ip 225.0.0.1
===============================================================================

The MEG/PEG DR forwards the MC traffic to the MC receiver on PE-6 in the EVPN network. int-SBD-8 is the Incoming Intf, while the local int-BD-4 is in the Outgoing Intf List:

PE-8 receives MC traffic from the locally connected MC source and forwards it in the MVPN/PIM network. PE-3 (MEG/PEG non-DR) and PE-7 do not forward the MC traffic. PE-2 forwards the MC traffic into the EVPN network. PE-5 has no MC receivers and does not forward the MC traffic. PE-6 forwards the MC traffic to the MC receiver that requested the group membership:

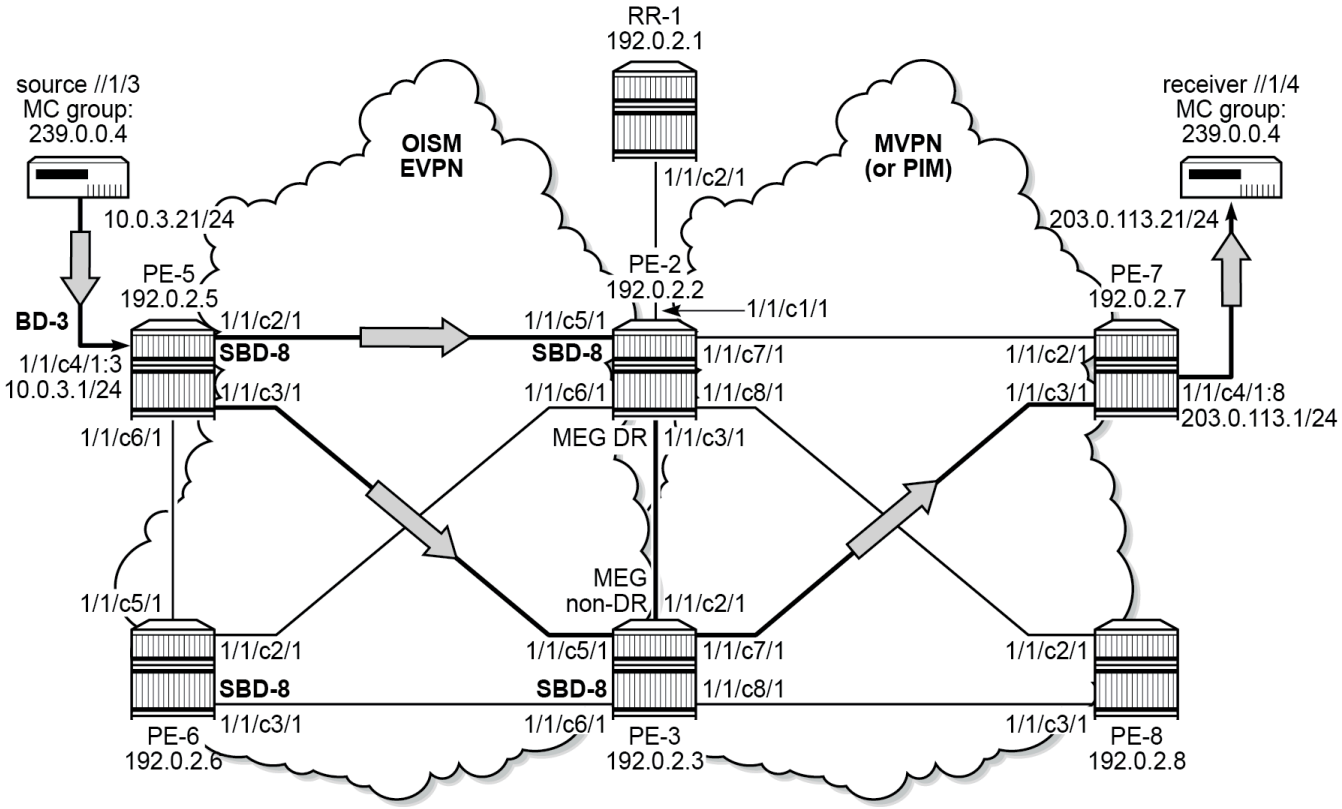
MC traffic from MC source in EVPN network to MC receiver in MVPN/PIM network

Figure 237: EVPN MC source - MVPN/PIM MC receiver example setup, with non-DR as UMH for PE-7 illustrates OISM EVPN to MVPN/PIM interworking.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 237: EVPN MC source - MVPN/PIM MC receiver example setup, with non-DR as UMH for PE-7



40016b

The MC source is connected to PE-5 in the EVPN network. The MC receiver is connected to PE-7 in the MVPN/PIM network. The MC source (10.0.3.21) sends MC traffic to the MC receiver (203.0.113.21) that requested the group membership for MC group 239.0.0.4.

The following cases are described in the following sections:

- MC source configuration
- MC receiver configuration
- MEG/PEG DR election
- MEG/PEG non-DR as upstream multicast hop (UMH)
- MC traffic verification
- MEG/PEG DR as upstream multicast hop (UMH)

MC source configuration

The MC source is connected to routed VPLS BD-3 on PE-5, as follows:

```
# On PE-5:
configure {
    service {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        vpls "BD-3" {
            admin-state enable
            service-id 3
            customer "1"
            routed-vpls {
                multicast {
                    ipv4 {
                        forward-to-ip-interface true
                    }
                    ipv6 {
                        forward-to-ip-interface true
                    }
                }
            }
            bgp 1 { }
            igmp-snooping {
                admin-state enable
            }
            mld-snooping {
                admin-state enable
            }
            bgp-evpn {
                evi 3
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/c4/1:3 { }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
```

VPRN-1 on PE-5 uses BD-3 toward the MC source (next to SBD-8 toward the MEG/PEG routers) and is additionally configured as follows:

```
# On PE-5:
configure {
    service {
        vprn "VPRN-1" {
            ---snip---
            igmp {
                interface "int-SBD-8" { }
            }
            interface "int-BD-3" {

MC receiver configuration

The MC receiver is directly connected to VPRN-1 on PE-7 and needs no further configuration beyond the initial VPRN-1 configuration.

MEG/PEG DR election

MEG/PEG DR election does not change, so PE-3 is MEG/PEG non-DR. The MEG/PEG non-DR is configured with **routed-vpls multicast evpn-gateway non-dr-attract-traffic none**, so it does not send wildcard **EVPN-SMET** BGP update and does not attract traffic. The MEG/PEG DR still sends the wildcard **EVPN-SMET** BGP update and attracts traffic.

```
# On PE-2:
27 2025/01/09 13:36:39.745 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1

        bgp-tunnel-encap:MPLS
"
```

MEG/PEG non-DR as upstream multicast hop (UMH)

Ensure that the connection from PE-7 to PE-2 has a lower IGP cost than the connection from PE-7 to PE-3, as follows:

```
# On PE-7:
configure {
    router "Base" {
        isis 0 {
            interface "int-PE-7-PE-2" {
                interface-type point-to-point
                level 1 {
                    metric 5    # for proof of umh-selection
                }
                level 2 {
                    metric 5    # for proof of umh-selection
                }
```

PE-7 receives two VPN IPv4 routes for the MC source address in the 10.0.3.0/24 address range, one from PE-2 with configured IGP cost 5 and one from PE-3 with default IGP cost 10.

Configure PE-7 with the default **mvpn umh-selection highest-ip** configuration, so that, to select the upstream multicast hop, PE-7 uses the highest next hop IP address and not the lowest IGP cost.

MC traffic verification

Because PE-5 is configured with **root-and-leaf** for BD-3, PE-5 originates a P2MP tunnel in the EVPN network from BD-3 with **LSP-ID** 8193, when BD-3 is enabled. SR OS dynamically assigns the **LSP-ID**. When the same **LSP-ID** is reused on different PEs, they represent different P2MP tunnels.

```

PE-5 receives MC traffic from the locally connected MC source and forwards it to PE-2 and PE-3. PE-2 (MEG/PEG DR) forwards the MC traffic only to PE-3 (MEG/PEG non-DR). PE-3 forwards the MC traffic to PE-2, PE-7 and PE-8. PE-8 has no MC receivers. PE-7 forwards the MC traffic to the MC receiver that requested the group membership.

MEG/PEG DR as upstream multicast hop (UMH)

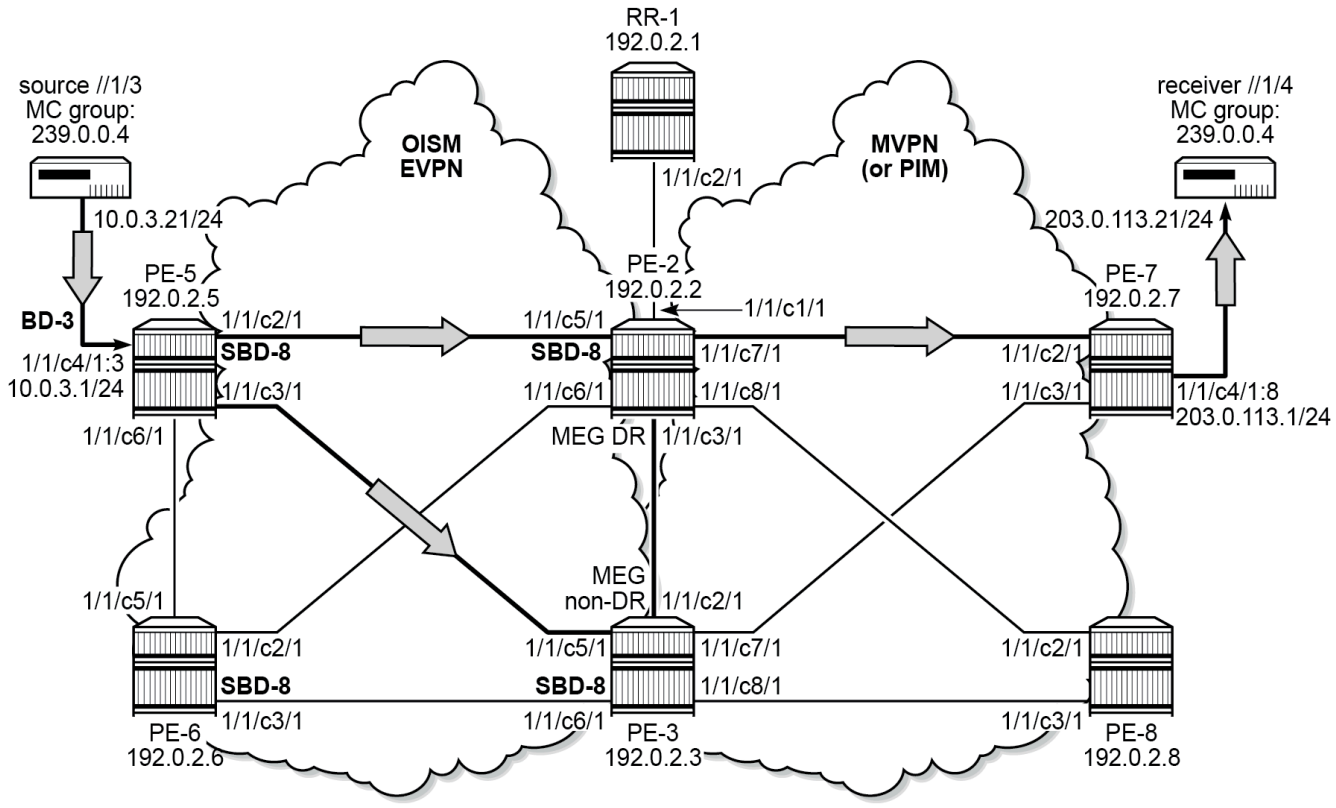
The upstream multicast hop selection for PE-7 is changed to prefer PE-2, as follows:

```
# On PE-7:
configure {
    service {
        vprn "VPRN-1" {
            mvpn {
                umh-selection unicast-rt-pref
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The P2MP tunnels in the EVPN network remain the same. **IngLbl**, **EgrLbl**, and **ldp binding Interface** in the MVPN/PIM network change.

Figure 238: EVPN MC source - MVPN/PIM MC receiver example setup, with DR as UMH for PE-7



40017b

When the MC receiver on PE-7 joins the MC group 239.0.0.4, PE-7 now selects the MEG/PEG DR PE-2 as upstream multicast hop (UMH) for its (S,G) join, because the PE-7 to PE-2 connection has lower IGP cost than the PE-7 to PE-3 connection.

The MEG/PEG DR sends the corresponding (S,G) **EVPN-SMET** BGP update. PE-5 only keeps sbd-mpls:192.0.2.2:524270 toward the MEG/PEG DR in the MFIB at BD-3, only for wildcard joins on the MEG/PEG DR.

PE-5 receives MC traffic from the locally connected MC source and forwards it to PE-2 and PE-3. PE-3 (MEG/PEG non-DR) forwards the MC traffic only to PE-2 (MEG/PEG DR). PE-2 forwards the MC traffic to PE-3, PE-7, and PE-8. PE-8 has no MC receivers. PE-7 forwards the MC traffic to the MC receiver that requested the group membership.

Delayed MEG/PEG DR election

Upon booting up an OISM MEG/PEG router, the advertising of its IMET routes for the SBD and the start of the MEG/PEG DR election are delayed until after the boot timer expires.

The boot timer is configured on the MEG/PEG DR candidate that is expected to become the MEG/PEG DR after MEG/PEG election, as follows:

```
# On PE-2:
[ex:/configure redundancy bgp-evpn ethernet-segment]
A:admin@PE-2#                 boot-timer ?

 boot-timer <number>
 <number> - <0..1800> - seconds
 Default  - 10

    Time before BGP EVPN multi-homing DF election algorithm
```

As an example, the PE-2 configuration is saved, the boot-timer on PE-2 is set to 180 seconds, and PE-2 is rebooted.

```
# On PE-2:
configure {
    redundancy {
        bgp-evpn ethernet-segment {
            boot-timer 180
```

After the reboot, PE-2 waits 180 seconds before advertising its IMET routes and starting the MEG/PEG DR election. During that time, PE-2 is not in the candidate list and PE-3 is the MEG/PEG DR.

Conclusion

SR OS supports the interworking of OISM EVPN networks and MVPN/PIM networks in both directions. The choice for the upstream multicast hop selection can be configured. The start of the MEG/PEG DR election can be configured with the boot timer.

OISM to MVPN/PIM interworking non-DR attract traffic function on MEG/PEG

This chapter provides information about the non-DR attract traffic function on Optimized Intersubnet Multicast (OISM) to Multicast VPN/Protocol Independent Multicast (MVPN/PIM) interworking (MEG/PEG function).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 24.10.R2. Only on FP-based platforms, SR OS Release 22.2.R2 and later support MEG/PEG non-DR attract traffic.

Overview

SR OS Release 21.10.R1 and later support OISM EVPN interworking with MVPN and PIM networks. Two key interworking functions are used to achieve this interworking:

- MEG (MVPN to EVPN Gateway): Bridges MVPN and EVPN.
- PEG (PIM to EVPN Gateway): Bridges PIM and EVPN.

The system uses a Designated Router (DR) election process to ensure redundancy. This is achieved by:

- Including the Designated Forwarder (DF) Election extended community in the Inclusive Multicast Ethernet Tag (IMET) routes.
- Following the DR selection procedures defined in RFC 8584.

After being elected, the MEG/PEG routers use Ingress Replication (IR) to handle multicast (MC) traffic efficiently within supplementary broadcast domains (SBDs).

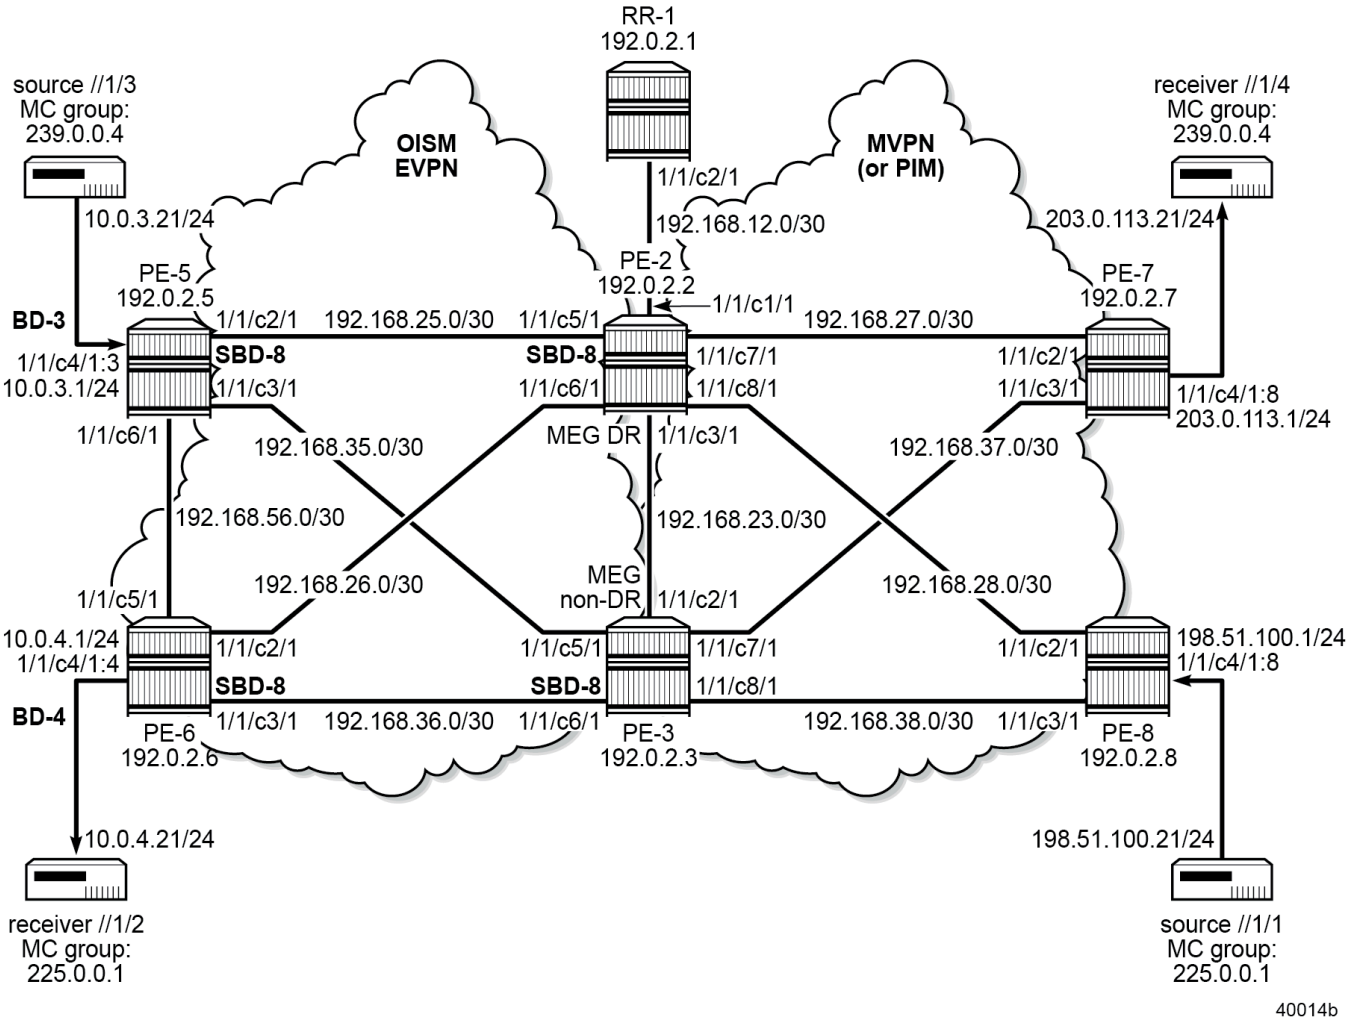
In addition to IR and only on FP-based platforms, SR OSRelease 22.2.R2 and later also support:

- MLDP root-and-leaf (See P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services for more details) on the SBD of the MEG/PEG routers. On a MEG/PEG router, traffic originating from either the MVPN/PIM domain or the EVPN domain can be forwarded or received by the MEG/PEG DR through an MLDP provider tunnel. The PIM Instance can be in MVPN.
- non-DR attract traffic

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 239: Example topology is used to illustrate the working of the OISM EVPN to MVPN/PIM interworking non-DR attract traffic function on MEG/PEG. This is the same topology as for the OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI.

Figure 239: Example topology



PE-2 and PE-3 connect an OISM EVPN network hosting PE-5 and PE-6, and an MVPN/PIM network hosting PE-7 and PE-8. PE-2 and PE-3 act as MEG/PEG DR candidates. PE-2 and PE-3 forward traffic into the EVPN using MLDP I-PMSIs. A MC receiver connected to PE-6 in the EVPN network joins MC group 225.0.0.1 of a MC source connected to PE-8 in the MVPN/PIM network to receive MC traffic from the MC source. A MC receiver connected to PE-7 in the MVPN/PIM network joins MC group 239.0.0.4 of a MC source connected to PE-5 in the EVPN network to receive MC traffic from the MC source.

The **provider-tunnel inclusive**, **owner**, and **ingress-repl-inc-mcast-advertisement** are configured as in OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI.

The MEG/PEG DR translates Selective Multicast Ethernet Tag (SMET) routes into PIM routes and the other way around, depending on where the MC source and the MC receiver are located. Even though

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

the MEG/PEG non-DR also receives SMET routes from a MC receiver that is located in the OISM EVPN network, the MEG/PEG non-DR does not execute this action.

```
# On PE-3#
[ex:/configure service vpls "SBD-8" routed-vpls multicast evpn-gateway]
A:admin@PE-3# non-dr-attract-traffic ?

 non-dr-attract-traffic <keyword>
 <keyword> - (none|from-evpn|from-pim-mvpn|from-evpn-pim-mvpn)
 Default   - from-pim-mvpn

    Multicast traffic attraction option on non-DR router GW

    Warning: Modifying this element toggles
    'configure service vpls "SBD-8" routed-vpls multicast evpn-gateway admin-state'
automatically for the new value to take effect.
```

The **non-dr-attract-traffic** command allows changing the above MEG/PEG non-DR behavior, according to the mode that is selected from the following options:

- **non-dr-attract-traffic none**: the MEG/PEG non-DR does not generate wildcard SMET routes and does generate a PIM/C-multicast join upon receiving a SMET route.

  Note: •The **non-dr-attract-traffic** is changed in SR OSRelease 22.2.R1 in a non-backward compatible manner. When upgrading to SR OSRelease 22.2.R1, the user needs to remove the command **non-dr-attract-traffic** from the configuration, otherwise the upgrade will fail.

- **non-dr-attract-traffic from-pim-mvpn** (default): backward compatible with the behavior in SR OSRelease 21.10 if **non-dr-attract-traffic none** was configured before the upgrade. With this option, the MEG/PEG non-DR does not generate wildcard SMET routes but it generates a PIM/C-multicast join upon receiving a SMET route. Local joins on a non-SBD service generate PIM/C-multicast routes or SMET routes irrespective.
- **non-dr-attract-traffic from-evpn**: the MEG/PEG non-DR generates a wildcard SMET route to attract the multicast traffic from the OISM EVPN domain. No layer-3 IFF or PIM/C-multicast route is triggered from received SMET routes on the MEG/PEG non-DR.
- **non-dr-attract-traffic from-even-pim-mvpn**: the MEG/PEG non-DR behaves as if **non-dr-attract-traffic from-pim-mvpn** and **non-dr-attract-traffic from-evpn** are configured concurrently.

Configuration

The initial configuration is identical to that for OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI.

The initial configuration includes:

- cards, MDAs, ports
- BGP route reflector (RR)
- router interfaces
- IBGP in the EVPN network for the EVPN address family
- IBGP in the MVPN/PIM network for the VPN IPv4 and MVPN IPv4 address families
- IS-IS on the router interfaces (OSPF or OSPF3 router interfaces are also possible)

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- LDP and MPLS in the EVPN and MVPN/PIM networks (not on the RR)
- VPRN service in the EVPN and MVPN/PIM networks
- routed VPLS services in the EVPN network

Router configuration

The router configuration is identical to that for OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI.

Service configuration in the EVPN network

The service configuration is identical to that for OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI.

Use cases

The following use cases are described in the following sections:

- MC traffic from MC source on MVPN/PIM network to MC receiver on EVPN network
- MC traffic from MC source on EVPN network to MC receiver on MVPN/PIM network

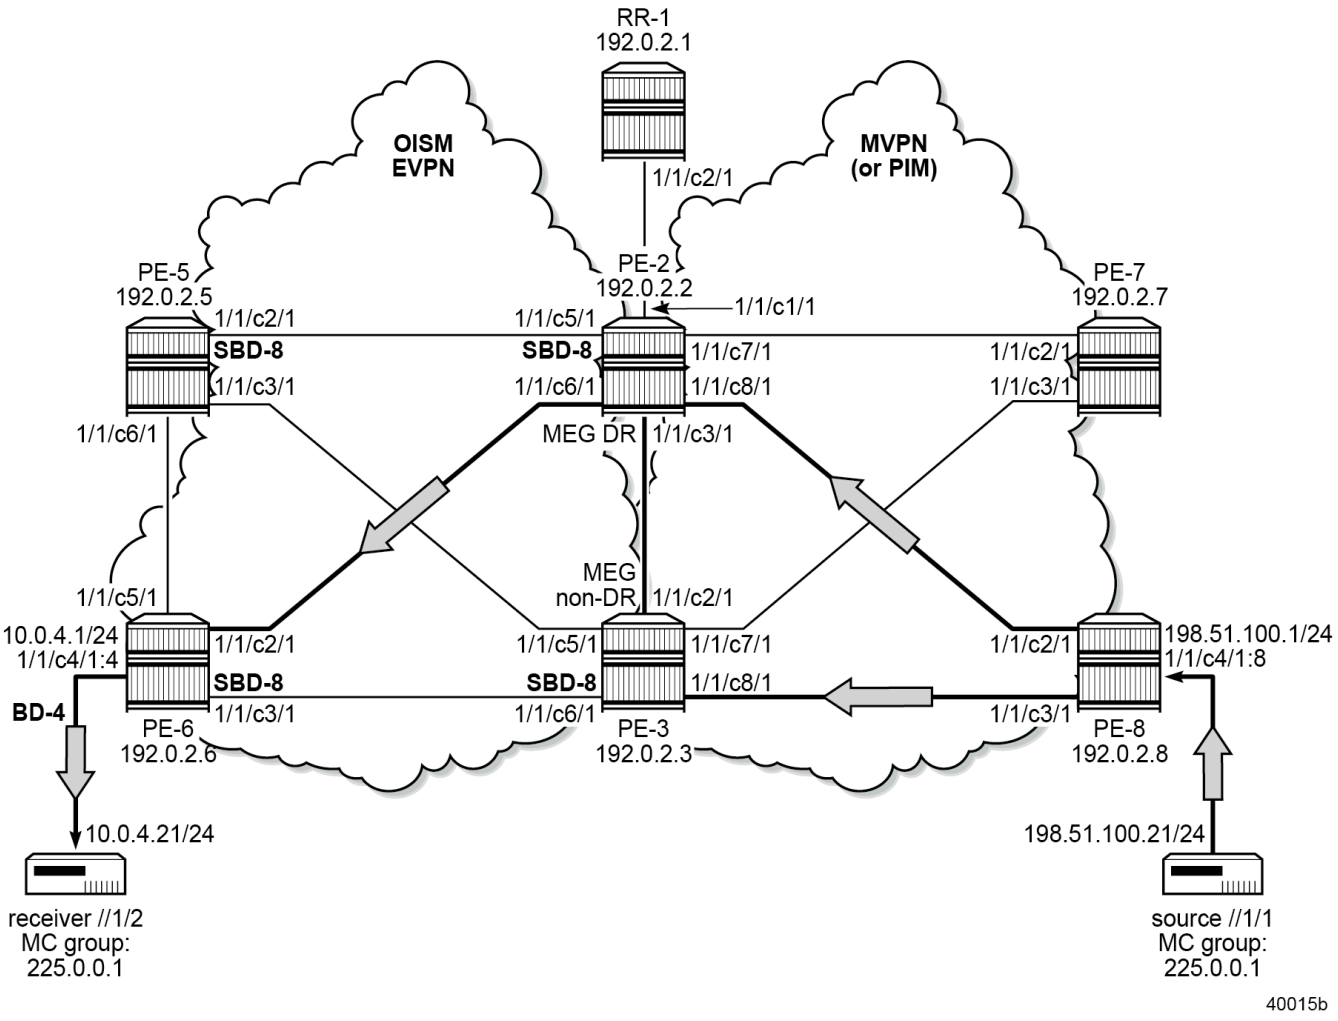
MC traffic from MC source on MVPN/PIM network to MC receiver on EVPN network

Figure 240: MVPN/PIM MC source - EVPN MC receiver example setup illustrates the MEG/PEG non-DR attract traffic function on MEG/PEG for MVPN/PIM to OISM EVPN interworking. This is the same setup as for the OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI for MVPN/PIM to OISM EVPN interworking.

The MC source is connected to PE-8 in the MVPN/PIM network. The MC receiver is connected to PE-6 in the EVPN network. The MC source (198.51.100.21) sends MC traffic to the MC receiver (10.0.4.21) in MC group 225.0.0.1.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 240: MVPN/PIM MC source - EVPN MC receiver example setup



PE-2 is elected as MEG/PEG DR, PE-3 is MEG/PEG non-DR. See OISM to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI for the election procedure.

The following cases are described in the following sections:

- MEG/PEG non-DR does not attract traffic
- MEG/PEG non-DR attracts traffic
- MEG/PEG non-DR stops attracting traffic

MEG/PEG non-DR does not attract traffic

The MEG/PEG non-DR is initially configured such that it does not attract traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic none
```

When the MC receiver on PE-6 joins the MC group 225.0.0.1, PE-6 sends an **EVPN-SMET** BGP update message that is meant for SBD-8:

```
# On PE-6:
2 2025/01/15 15:10:11.813 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE

Because MLDP is used for I-PMSI, MC traffic is sent to all PEs in the same service. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-8 reaches the MEG/PEG DR and the MEG/PEG non-DR. The MEG/PEG DR forwards the MC traffic to PE-6: in the MEG/PEG DR, int-SBD-8 is in the OIL. In the MEG/PEG non-DR, int-SBD-8 is not in the OIL and the MEG/PEG non-DR does not forward the MC traffic:

MEG/PEG non-DR attracts traffic

While MC traffic is being forwarded from the MC source on PE-8 to the MC receiver on PE-6, the MEG/PEG non-DR is reconfigured such that it attracts traffic from the MVPN network, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic from-pim-mvpn    # default
```

To allow the MEG/PEG non-DR to attract traffic, VPRN-1 on the MEG/PEG non-DR needs at least one non-SBD BD-9, as follows:

```
# On PE-3:
configure {
    service {
        vprn "VPRN-1" {
            admin-state enable
            ---snip---
            igmp {
                ---snip---
                interface "int-BD-9" { }
            }
            pim {
                ---snip---
                }
            }
            mvpn {
                ---snip---
            }
            bgp-ipvpn {
                mpls {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    ---snip---
                    }
                }
            }
            ---snip---
            interface "int-BD-9" {
                ipv4 {
                    primary {
                        address 10.0.9.1
                        prefix-length 24
                    }
                }
                vpls "BD-9" { }
            }
```

```
# On PE-3:
configure {
    service {
        vpls "BD-9" {
            admin-state enable
            service-id 9
            customer "1"
            description "non-SBD_attached-VPRN-1"
            routed-vpls { }
            bgp 1 { }
            igmp-snooping {
                admin-state enable
            }
            bgp-evpn {
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

This reconfiguration has no immediate effect: changes to the MC traffic flow are applied only after the MC receiver rejoins the MC group. This is described in the following cases:

- no receiver rejoin
- enforced receiver rejoin

no receiver rejoin

PE-6 does not send a new **EVPN-SMET** BGP update message. So, the **EVPN SMET** routes and the MFIB at SBD-8 remain unchanged on the MEG/PEG DR and the MEG/PEG non-DR.

The MEG/PEG non-DR sends an MVPN-IPv4 **Source-Join** BGP update message too, indicating the MEG/PEG non-DR as next hop. The MVPN-IPv4 **Source-Join** BGP update message is meant for PE-8.

```

-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

Following section 11.1.3 of RFC 6514, the RD of the advertised MCAST-VPN NLRI is set to the RD of the VPN-IP route that contains the address carried in the Multicast Source field, when the local and the upstream PEs are in the same AS. Because the RDs for the two routes are the same, the RR does not forward the newly received MVPN-IPv4 **Source-Join** BGP update message, so PE-8 remains unaware of it.

Because PE-8 does not receive the MVPN-IPv4 **Source-Join** BGP update message from the MEG/PEG non-DR, PE-8 still has only one MVPN-IPv4 **Source-Join** route for MC group 225.0.0.1: toward the MEG/PEG DR.

Note: The exact behavior depends on the BGP configuration. In case of failure of the MEG/PEG DR, the RR advertises the route toward the MEG/PEG non-DR. If there would be a full mesh BGP network instead of a RR, PE-8 would receive the MVPN-IPv4 **Source-Join** BGP update message from the MEG/PEG non-DR and would add a second MVPN-IPv4 **Source-Join** route for MC group 225.0.0.1: toward the MEG/PEG non-DR. This route would be unused until the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

MEG/PEG DR would fail. **add-path** may be configured to advertise multiple copies of the same routes with different next hops.

Because PE-8 does not receive the MVPN-IPv4 **Source-Join** BGP update message from the MEG/PEG non-DR, PE-8 does not send a new MVPN-IPv4 **Source-AD** BGP update message. So, the MVPN-IPv4 **Source-AD** routes for MC group 225.0.0.1 remain unchanged on the MEG/PEG DR and the MEG/PEG non-DR.

Both the MEG/PEG DR and the MEG/PEG non-DR create PIM state at VPRN-1 with a non-empty OIL and start attracting traffic:

```

Because MLDP is used for I-PMSI, MC traffic is sent to all PEs in the same service. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-8 reaches the MEG/PEG DR and the MEG/PEG non-DR. The MEG/PEG DR forwards the MC traffic to PE-6: in the MEG/PEG DR, int-SBD-8 is in the OIL. The MEG/PEG non-DR forwards the MC traffic to PE-3: in the MEG/PEG non-DR, int-BD-9 is in the OIL.

```

The MEG/PEG DR forwards the MC traffic to PE-6 in the OISM EVPN network. On PE-6, int-SBD-8 is the incoming interface, while the local int-BD-4 to the MC receiver is in the OIL:

```

The RR receives the MVPN-IPv4 **Source-Join** BGP update messages and adds MVPN-IPv4 **Source-Join** routes for MC group 225.0.0.1 toward the MEG/PEG DR and toward the MEG/PEG non-DR.

```
[/]
A:admin@RR-1# show router bgp routes mvpn-ipv4 type source-join
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
---snip---

===============================================================================
```

Because MLDP is used for I-PMSI, MC traffic is sent to all PEs in the same service. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-8 reaches the MEG/PEG DR and the MEG/PEG non-DR. The MEG/PEG DR forwards the MC traffic to PE-6: in the MEG/PEG DR, int-SBD-8 is in the OIL. The MEG/PEG non-DR forwards the MC traffic to PE-3: in the MEG/PEG non-DR, int-BD-9 is in the OIL.

MEG/PEG non-DR stops attracting traffic

While MC traffic is being forwarded from the MC source on PE-8 to the MC receiver on PE-6, the MEG/PEG non-DR is reconfigured such that it stops attracting traffic from the MVPN network, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic none
```

This reconfiguration has no immediate effect: changes to the MC traffic flow are applied only after the MC receiver rejoins the MC group. This is described in the following cases:

- no receiver rejoin
- enforced receiver rejoin

no receiver rejoin

PE-6 does not send a new **EVPN-SMET** BGP update message. So, the **EVPN SMET** routes and the MFIB at SBD-8 remain unchanged on the MEG/PEG DR and the MEG/PEG non-DR.

Both the MEG/PEG DR and the MEG/PEG non-DR do not receive an **EVPN-SMET** BGP update message, so they do not send an MVPN-IPv4 **Source-Join** BGP update message. PE-8 does not receive an MVPN-IPv4 **Source-Join** BGP update message, so the MVPN-IPv4 **Source-Join** route for MC group 225.0.0.1 remains unchanged on PE-8.

PE-8 does not send an MVPN-IPv4 **Source-AD** BGP update message, so the MVPN-IPv4 **Source-AD** routes for MC group 225.0.0.1 remain unchanged on the MEG/PEG DR and the MEG/PEG non-DR.

Because MLDP is used for I-PMSI, MC traffic is sent to all PEs in the same service. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-8 reaches the MEG/PEG DR and the MEG/PEG non-DR. The MEG/PEG DR forwards the MC traffic to PE-6: in the MEG/PEG DR, int-SBD-8 is in the OIL. The MEG/PEG non-DR forwards the MC traffic to PE-3: in the MEG/PEG non-DR, int-BD-9 is in the OIL. The system keeps on behaving as before the reconfiguration.

enforced receiver rejoin

With **non-dr-attract-traffic none** still applied, the MC receiver on PE-6 leaves the MC group 225.0.0.1.

PE-6 sends an **EVPN-SMET** unreachable NLRI BGP update message.

The MEG/PEG DR and the MEG/PEG non-DR send an MVPN-IPv4 **Source-Join** unreachable NLRI BGP update message.

PE-8 sends an MVPN-IPv4 **Source-AD** unreachable NLRI BGP update message.

As a result, neither the MEG/PEG DR, nor the MEG/PEG non-DR have PIM state.

After that, the MC receiver on PE-6 joins the MC group 225.0.0.1 again.

PE-6 sends a new **EVPN-SMET** BGP update message that is meant for SBD-8. So, the **EVPN SMET** routes and the MFIB at SBD-8 change accordingly on the MEG/PEG DR and on the MEG/PEG non-DR.

MC traffic from MC source on EVPN network to MC receiver on MVPN/PIM network

Figure 241: EVPN MC source - MVPN/PIM MC receiver example setup, with non-DR as UMH for PE-7 illustrates the MEG/PEG non-DR attract traffic function on MEG/PEG for OISM EVPN to MVPN/PIM interworking. This is the same setup as for the OISM EVPN to MVPN/PIM interworking (MEG/PEG function) with MLDP I-PMSI for OISM EVPN to MVPN/PIM interworking.

The MC source is connected to PE-5 in the EVPN network. The MC receiver is connected to PE-7 in the MVPN/PIM network. The MC source (10.0.3.21) sends MC traffic to the MC receiver (203.0.113.21) in MC group 239.0.0.4.

The following cases are described in the following sections:

- MEG/PEG non-DR is upstream multicast hop
- MEG/PEG DR is upstream multicast hop

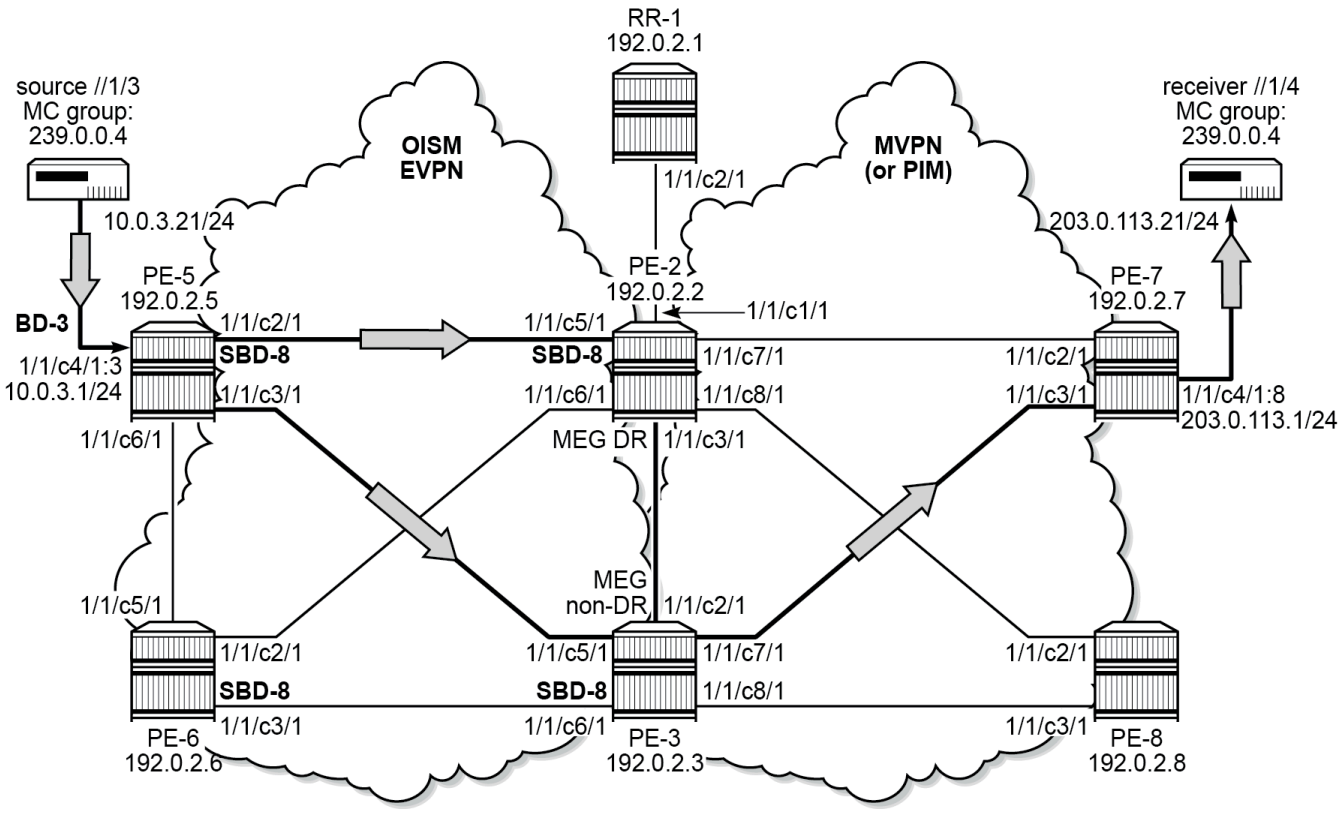
MEG/PEG non-DR is upstream multicast hop

Figure 241: EVPN MC source - MVPN/PIM MC receiver example setup, with non-DR as UMH for PE-7



40016b

The upstream multicast hop (UMH) selection for PE-7 is configured to prefer PE-3 (MEG/PEG non-DR), as follows:

```
# On PE-7:
configure {
    service {
        vprn "VPRN-1" {
            mvpn {
                umh-selection highest-ip    # default
```

The following cases are described in the following sections:

- MEG/PEG non-DR does not attract traffic
- MEG/PEG non-DR attracts traffic
- MEG/PEG non-DR stops attracting traffic

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

MEG/PEG non-DR does not attract traffic

The MEG/PEG non-DR is initially configured such that it does not attract traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic none
```

The MEG/PEG DR is configured with **non-dr-attract-traffic from-pim-mvpn** and generates a wildcard **EVPN SMET** route.

When the MC receiver on PE-7 joins the MC group 239.0.0.4, PE-7 sends an MVPN-IPv4 C-multicast **Source-Join** (S,G)=(10.0.3.21,239.0.0.4) BGP update message that is meant for PE-3 (UMH).

```
# On PE-7:
1 2025/01/15 15:34:15.348 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1

"
```

Both the MEG/PEG DR and the MEG/PEG non-DR receive the MVPN-IPv4 C-multicast **Source-Join** BGP update message.

Only the MEG/PEG non-DR uses the corresponding MVPN-IPv4 **Source-Join** route to PE-7:

```
[/]
A:admin@PE-2# show router bgp routes mvpn-ipv4 type source-join group-ip 239.0.0.4

Because MLDP is used for I-PMSI, MC traffic is sent to every far-end that participates in that I-PMSI. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-5 reaches the MEG/PEG DR and the MEG/PEG non-DR. In the MEG/PEG DR, the MVPN tunnel is not in the OIL and the MEG/PEG DR does not forward the MC traffic. The MEG/PEG non-DR forwards the MC traffic to PE-7: in the MEG/PEG non-DR, the MVPN tunnel is in the OIL:

```

MEG/PEG non-DR attracts traffic

The MEG/PEG non-DR is reconfigured such that it attracts traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic from-evpn
```

This reconfiguration has immediate effect. The **non-dr-attract-traffic from-evpn** command causes the MEG/PEG non-DR to send a wildcard **EVPN-SMET** BGP update message that is meant for SBD-8:

```
# On PE-3:
7 2025/01/15 15:36:20.440 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 68
    Flag: 0x90 Type: 14 Len: 31 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-SMET Len: 20 RD: 192.0.2.3:8, tag: 0,
Mcast-Src-Len: 0, Mcast-Src-Addr: 0.0.0.0,
Mcast-Grp-Len: 0, Mcast-Grp-Addr: 0.0.0.0,
Orig Addr: 192.0.2.3/32, Flags(0x0): IE:0/V3:0/V2:0/V1:0
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:64500:8
        bgp-tunnel-encap:MPLS
"
```

PE-5 receives the wildcard **EVPN-SMET** BGP update message and uses an additional wildcard **EVPN SMET** route to the MEG/PEG non-DR:

```
[/]

                                      sbd-mpls:192.0.2.3:524270    Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 2
===============================================================================
```

Because in the example setup the MC traffic for MC group 239.0.0.4 was already forwarded via the MEG/PEG non-DR, this does not introduce any change in the MC traffic flow, neither immediately upon reconfiguration, nor after a rejoin of the MC receiver on PE-7.

MEG/PEG non-DR stops attracting traffic

The MEG/PEG non-DR is reconfigured such that it stops attracting traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic none
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

This reconfiguration has immediate effect. The **non-dr-attract-traffic none** command causes the MEG/PEG non-DR to send a wildcard **EVPN-SMET** unreachable NLRI BGP update message:

```
# On PE-3:
2 2025/01/15 15:43:55.337 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 29
    Flag: 0x90 Type: 15 Len: 25 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-SMET Len: 20 RD: 192.0.2.3:8, tag: 0,
Mcast-Src-Len: 0, Mcast-Src-Addr: 0.0.0.0,
Mcast-Grp-Len: 0, Mcast-Grp-Addr: 0.0.0.0,
Orig Addr: 192.0.2.3/32, Flags(0x0): IE:0/V3:0/V2:0/V1:0
"
```

PE-5 receives the wildcard **EVPN-SMET** unreachable NLRI BGP update message and removes the wildcard **EVPN SMET** route to the MEG/PEG non-DR:

```
[/]

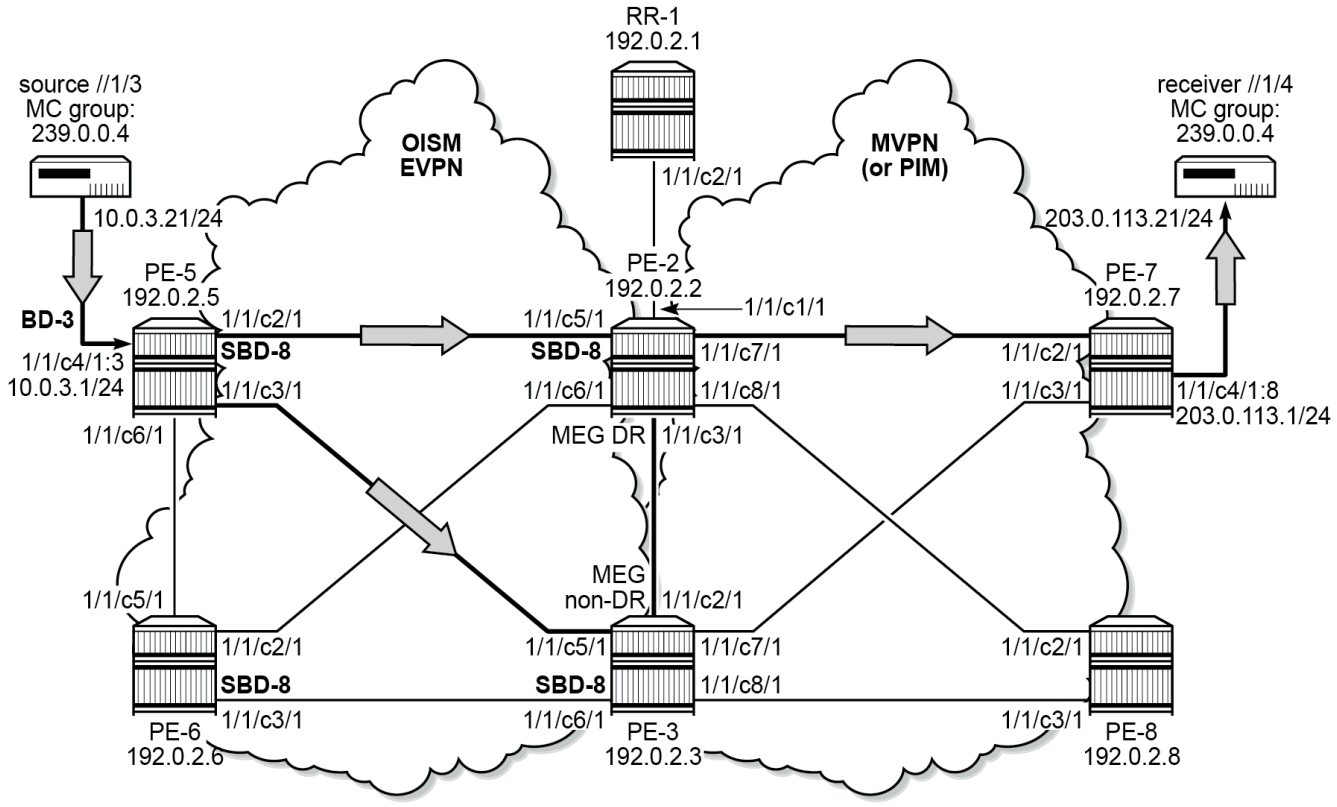
Because in the example setup the MC traffic for MC group 239.0.0.4 was already forwarded via the MEG/PEG non-DR, this does not introduce any change in the MC traffic flow, neither immediately upon reconfiguration, nor after a rejoin of the MC receiver on PE-7.

MEG/PEG DR is upstream multicast hop

Figure 242: EVPN MC source - MVPN/PIM MC receiver example setup, with DR as UMH for PE-7



40017b

The upstream multicast hop selection for PE-7 is reconfigured to prefer PE-2 (MEG/PEG DR), as follows:

```
# On PE-7:
configure {
    service {
        vprn "VPRN-1" {
            mvpn {
                umh-selection unicast-rt-pref
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-7 sends an MVPN-IPv4 C-multicast **Source-join** unreachable NLRI BGP update message and an MVPN-IPv4 C-multicast **Source-join** (S,G)=(10.0.3.21,239.0.0.4) BGP update message that is meant for the MEG/PEG DR (UMH):

```
# On PE-7:

Because MLDP is used for I-PMSI, MC traffic is sent to every far-end that participates in that I-PMSI. Nodes that do not have MC state or connected MC receivers drop the MC traffic that they receive. So, MC traffic from the MC source on PE-5 reaches the MEG/PEG DR and the MEG/PEG non-DR. The MEG/PEG DR forwards the MC traffic to PE-7: the MVPN tunnel is in the OIL. In the MEG/PEG non-DR, the MVPN tunnel is not in the OIL and the MEG/PEG non-DR does not forward the MC traffic.

PE-7 receives MC traffic via the MEG/PEG DR. On PE-7, the MVPN tunnel from the MEG/PEG DR is the incoming interface and the local to-receiver interface is in the OIL:

```

The following cases are described in the following sections:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MEG/PEG non-DR attracts traffic
- MEG/PEG non-DR stops attracting traffic

MEG/PEG non-DR attracts traffic

The MEG/PEG non-DR is reconfigured such that it attracts traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic from-evpn
```

This reconfiguration has immediate effect. The **non-dr-attract-traffic from-evpn** command causes the MEG/PEG non-DR to send a wildcard **EVPN-SMET** BGP update message that is meant for SBD-8:

```
# On PE-3:
7 2025/01/15 15:57:03.540 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 68
    Flag: 0x90 Type: 14 Len: 31 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.3
        Type: EVPN-SMET Len: 20 RD: 192.0.2.3:8, tag: 0,
Mcast-Src-Len: 0, Mcast-Src-Addr: 0.0.0.0,
Mcast-Grp-Len: 0, Mcast-Grp-Addr: 0.0.0.0,
Orig Addr: 192.0.2.3/32, Flags(0x0): IE:0/V3:0/V2:0/V1:0
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100

===============================================================================
Multicast FIB, Service 3
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                         Blk
-------------------------------------------------------------------------------
*               *                     sap:1/1/c4/1:3              Local    Fwd
                                      sbd-mpls:192.0.2.2:524270   Local    Fwd
                                      sbd-mpls:192.0.2.3:524270   Local    Fwd
*               * (mac)               sbd-mpls:192.0.2.2:524270   Local    Fwd
                                      sbd-mpls:192.0.2.3:524270   Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 2
===============================================================================
```

Because in the example setup the MC traffic for MC group 239.0.0.4 was already forwarded via the MEG/PEG DR, this does not introduce any change in the MC traffic flow, neither immediately upon reconfiguration, nor after a rejoin of the MC receiver on PE-7.

MEG/PEG non-DR stops attracting traffic

The MEG/PEG non-DR is reconfigured such that it stops attracting traffic, as follows:

```
# On PE-3:
configure {
    service {
        vpls "SBD-8" {
            routed-vpls {
                multicast {
                    evpn-gateway {
                        admin-state enable
                        non-dr-attract-traffic none
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

This reconfiguration has immediate effect. The **non-dr-attract-traffic none** command causes the MEG/PEG non-DR to send a wildcard **EVPN-SMET** unreachable NLRI BGP update message:

```
# On PE-3:
2 2025/01/15 16:02:45.376 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.1
"Peer 1: 192.0.2.1: UPDATE
Peer 1: 192.0.2.1 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 29
    Flag: 0x90 Type: 15 Len: 25 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-SMET Len: 20 RD: 192.0.2.3:8, tag: 0,
Mcast-Src-Len: 0, Mcast-Src-Addr: 0.0.0.0,
Mcast-Grp-Len: 0, Mcast-Grp-Addr: 0.0.0.0,
Orig Addr: 192.0.2.3/32, Flags(0x0): IE:0/V3:0/V2:0/V1:0
"
```

PE-5 receives the wildcard **EVPN-SMET** unreachable NLRI BGP update message and removes the wildcard **EVPN SMET** route to the MEG/PEG non-DR:

```
[/]
A:admin@PE-5# show router bgp routes evpn smet
===============================================================================
 BGP Router ID:192.0.2.5        AS:64500       Local AS:64500

===============================================================================
```

Because in the example setup the MC traffic for MC group 239.0.0.4 was already forwarded via the MEG/PEG DR, this does not introduce any change in the MC traffic flow, neither immediately upon reconfiguration, nor after a rejoin of the MC receiver on PE-7.

Conclusion

SR OS supports MEG/PEG non-DR attract traffic in the interworking of OISM EVPN networks and OISM MVPN/PIM networks in both directions.

Operational Groups for EVPN-VXLAN VPWS Services

This chapter describes the Operational Groups for EVPN-VXLAN VPWS Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 16.0.R5, but the MD-CLI in the current edition corresponds to SR OS Release 21.7.R1. EVPN-VXLAN VPWS and service-level operational groups for VPWS services are supported in SR OS Release 16.0.R1, or later.

Overview

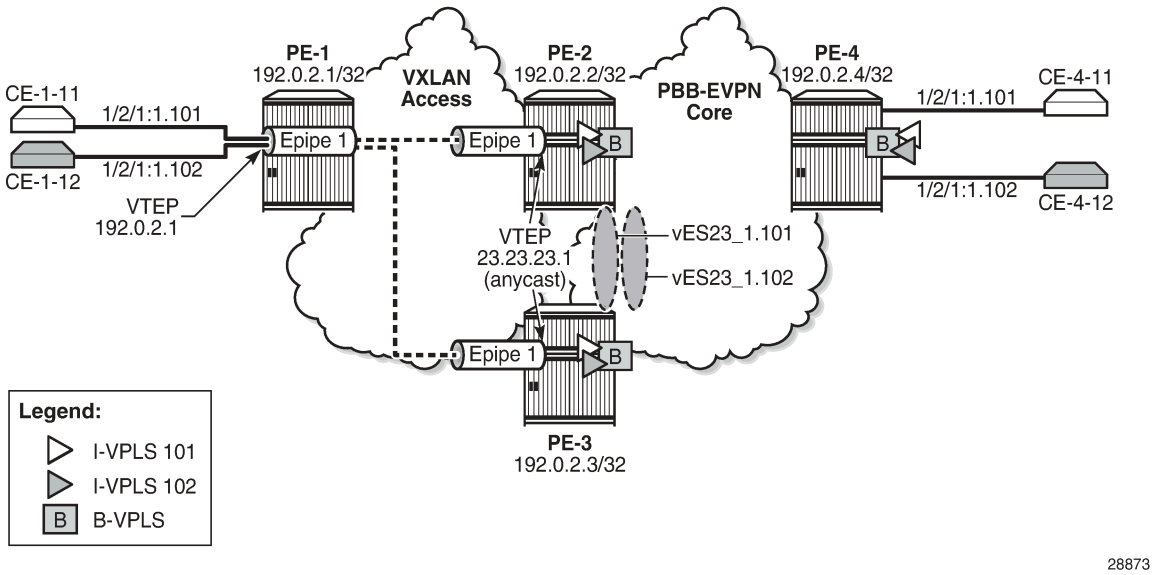
Operational groups on Epipe services are used for fault propagation to other services, such as I-VPLS or R-VPLS services. Epipes with VXLAN destinations are used in some edge PE applications along with port cross-connect (PXC) so that VXLAN networks can be terminated in other VPLS or VPRN services. In such cases, the operational status of the Epipe services terminating VXLAN must override the operational status of the SAPs of the VPLS or VPRN where the Epipe is stitched to.

Operational group on egress VTEP in Epipes with static VXLAN bindings

The Static VXLAN Termination in Epipe Services chapter describes how Epipes with static VXLAN termination are stitched to I-VPLS services. In Epipes with static VXLAN bindings, operational groups can be configured in the egress VTEP context. Figure 243: Epipe with static VXLAN termination shows the example topology with a static VXLAN tunnel between PE-1 and an anycast address on PE-2 and PE-3. The All-Active Multi-Homing Ethernet Segments (AA MH ESs) "vES23_1.101" and "vES23_1.102" are used by the I-VPLSs 101 and 102, which are both stitched to Epipe 1 in PE-2 and PE-3. The SAPs in these I-VPLSs monitor the operational group configured in the egress VTEP context of the Epipe service, so the SAPs will go operationally down when the operational group of the VTEP goes operationally down.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 243: Epipe with static VXLAN termination



On PE-2 and PE-3, Epipe 1 is configured with static VXLAN bindings, as follows. The egress VTEP is 192.0.2.1, which is the system IP address of PE-1. Operational group "op-grp-1" in configured for this egress VTEP. LAG 2 combines PXC ports and is used to stitch Epipe 1 to the I-VPLS services 101 and 102. For a detailed description of the configuration, see the Static VXLAN Termination in Epipe Services chapter.

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap lag-2:1.* {
            }
            vxlan {
                source-vtep 23.23.23.1
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.1
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

For failure propagation to the stitched I-VPLSs, the SAPs in the I-VPLSs can monitor the operational group "op-grp-1", for I-VPLS 101 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap lag-1:1.101 {
                monitor-oper-group "op-grp-1"
            }
        }
```

When the egress VTEP prefix 192.0.2.1 disappears from the global route-table on PE-2, the VXLAN binding goes down, as follows:

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================

===============================================================================
BGP EVPN VXLAN ES Dest
===============================================================================
I Eth Seg Id                    TEP Address       VNI       Last Changed
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

When the egress VTEP 192.0.2.1 goes down, the operational group "op-grp-1" goes down too, as follows:

```
[/]
A:admin@PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

When the operational group "op-grp-1" goes down, the monitoring SAP in I-VPLS 101 goes operationally down with flag OperGroupDown, as follows:

```
[/]
A:admin@PE-2# show service id 101 sap lag-1:1.101 detail | match 'Flags | Oper State'
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Admin State        : Up                        Oper State        : Down
Flags              : OperGroupDown
Stp Admin State    : Up                        Stp Oper State    : Down
```

When this SAP goes down, the entire I-VPLS 101 service goes down on PE-2, as follows:

```
[/]
A:admin@PE-2# show service id 101 base | match 'State'
Admin State       : Up                  Oper State        : Down
```

Epipes with static VXLAN bindings impose the following restrictions, which cannot be overcome unless a control plane protocol such as BGP-EVPN is used for the VXLAN bindings.

- When anycast VTEPs on the PEs are used, a change in the vES preference on the DF PE triggers a DF switchover for the I-VPLS service. However, the access PE (PE-1 in Figure 243: Epipe with static VXLAN termination) is unaware and keeps sending the VXLAN traffic to the same PE, unless a change in DF comes with an automatic change in the underlay IGP metrics, which cannot be easily accomplished.
- Without a control plane, Eth-CFM must be used between PEs and access PEs to detect end-to-end service-level failures.
- Traffic from the access PE is forwarded to the anycast VTEP, based on underlay IGP metrics. There is no control on a per-service basis.
- The architecture does not support AA MH for the Epipe service, so the access PEs always send the traffic to one single PE.

The preceding challenges can be addressed by using different VTEPs on the PEs and adding a BGP-EVPN control plane on the Epipe, as described in the next section.

Operational groups in EVPN-VXLAN Epipes

Figure 244: Epipe 2 with EVPN-VXLAN and all-active multi-homing shows EVPN-VXLAN Epipe 2 stitched to I-VPLSs 201 and 202. AA MH ESs "vES23_2.201" and "vES23_2.202" are used by the I-VPLSs 201 and 202 respectively.

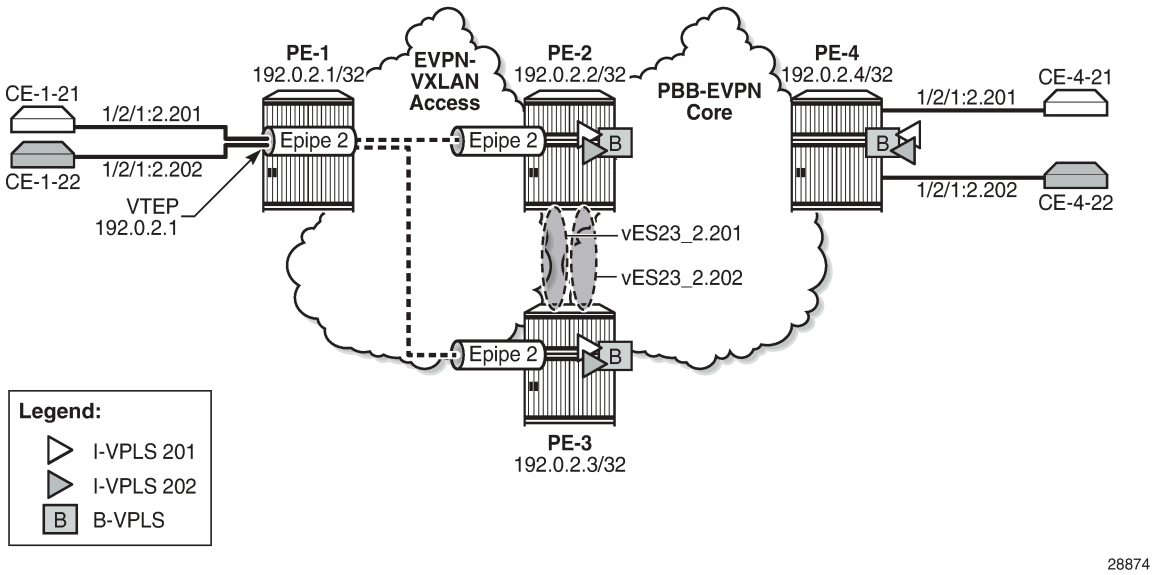
Figure 244: Epipe 2 with EVPN-VXLAN and all-active multi-homing



The EVPN-VXLAN VPWS chapter describes the configuration of Epipes with EVPN-VXLAN bindings instead of static VXLAN bindings. The egress VTEP is not configured manually, but dynamically learned through BGP-EVPN. Therefore, the operational group cannot be configured in the egress VTEP context. However, it is possible to configure an operational group in an Epipe at the service level, as follows:

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-2" {
        }
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            oper-group "op-grp-2"
            bgp 1 {
            }
            sap lag-2:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
        }
```

The following shows the error messages raised when attempting to configure the egress VTEP manually in an Epipe service with BGP-EVPN enabled:

```
[ex:/configure service epipe "Epipe 2" vxlan instance 1 egress-vtep]
A:admin@PE-2# ip-address 192.0.2.1

*[ex:/configure service epipe "Epipe 2" vxlan instance 1 egress-vtep]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 2" vxlan instance 1 egress-vtep ip-address -
 Inconsistent Value error - configuration incompatible with bgp-evpn - configure service epipe
 "Epipe 2" bgp-evpn
MINOR: MGMT_CORE #4001: configure service epipe "Epipe 2" vxlan instance 1 egress-vtep ip-
address - egress vtep not supported with bgp-evpn - configure service epipe "Epipe 2" bgp-evpn
```

An operational group can be associated with the entire Epipe or with specific objects, such as SAPs or spoke-SDPs, but not simultaneously. The following error is raised when attempting to associate the operational group "op-grp-2"—that is already associated with the Epipe with the SAP on PE-2:

```
[ex:/configure service epipe "Epipe 2" sap lag-2:2.*]
A:admin@PE-2# oper-group "op-grp-2"

*[ex:/configure service epipe "Epipe 2" sap lag-2:2.*]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 2" sap lag-2:2.* oper-group - Inconsistent
 Value error - cannot monitor or belong to a service oper-group within the same service -
 configure service epipe "Epipe 2" oper-group
```

The service-level operational group status is derived from the service operational status: when Epipe 2 is operationally down, the operational group "op-grp-2" will be down.

For fault propagation to the stitched I-VPLSs 201 and 202, the SAPs in the I-VPLSs monitor the operational group "op-grp-2", for I-VPLS 201 on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 201" {
            admin-state enable
            service-id 201
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 201
                }
            }
            sap lag-1:2.201 {
                 monitor-oper-group "op-grp-2"
            }
        }
```

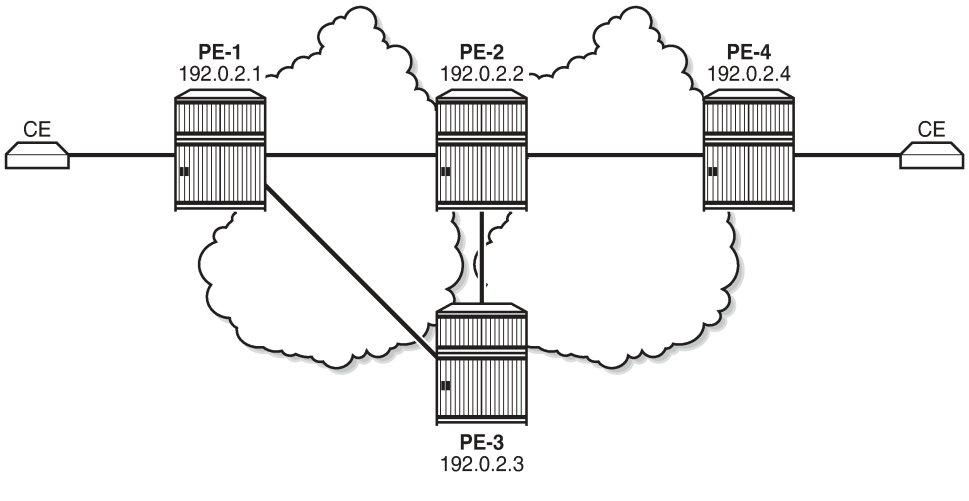
Configuration

In this section, the following use cases are described:

- operational group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using AA MH ESs
- service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLSs using Single-Active (SA) MH ESs

Figure 245: Example topology shows the example topology with four PEs in an autonomous system.

Figure 245: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS as IGP (level capability 2 in the core between PE-2, PE-3, and PE-4; level capability 1 in the access toward PE-1)
- LDP between the core routers PE-2, PE-3, and PE-4

Oper group on egress VTEP in Epipes with static VXLAN bindings stitched to I-VPLSs using AA MH ESs

When static VXLAN bindings are used, no BGP-EVPN is required in the access network to and from PE-1; BGP is only configured in the core network. When PE-2 acts as the route reflector, its BGP configuration is as follows:

```
# on RR PE-2:
configure {
    router "Base" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-update {
                evpn true
            }
            group "CORE" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "CORE"
            }
            neighbor "192.0.2.4" {
                group "CORE"
            }
```

Figure 243: Epipe with static VXLAN termination shows that Epipe 1 is configured in the access network: on PE-1, the VTEP is the system address 192.0.2.1 (default), and on PE-2 and PE-3, the VTEP is a unicast address 23.23.23.1.

On PE-1, Epipe 1 is configured with egress VTEP 23.23.23.1, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 23.23.23.1
                    }
                }
            }
        }
```

On PE-2 and PE-3, the following unicast address is configured:

```
# on PE-2, PE-3:
configure {
    router "Base" {
        interface "lo23" {
            loopback
            ipv4 {
                primary {
                    address 23.23.23.0
                    prefix-length 31
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

On PE-2 and PE-3, three ports are configured as PXC. PXC 1 is used as Forwarding Path Extension (FPE) and the VXLAN tunnel termination 23.23.23.1 is configured with this FPE, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 23.23.23.1 {
                    fpe-id 1
                }
            }
```

PXCs 2 and 3 are used in the internal LAGs that are used to stitch Epipe 1 to I-VPLSs 101 and 102, as follows. LAG "lag-1" will be used in the I-VPLS services; LAG "lag-2" in the Epipe services.

```
# on PE-2, PE-3:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-2.a {
        }
        port pxc-3.a {
        }
    }
    lag "lag-2" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-2.b {
        }
        port pxc-3.b {
        }
    }
```

On PE-2 and PE-3, Epipe 1 is configured with source VTEP 23.23.23.1 and egress VTEP 192.0.2.1, as follows. The operational group "op-grp-1" is associated with the egress VTEP. The SAP stitches Epipe 1 to the I-VPLSs 101 and 102.

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            description "Epipe 1 with static VXLAN bindings"
            service-id 1
            customer "1"
            sap lag-2:1.* {
            }
            vxlan {
                source-vtep 23.23.23.1
                instance 1 {
                    vni 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    egress-vtep {
                        ip-address 192.0.2.1
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

On PE-2, B-VPLS 100 is configured as follows. The configuration is similar on PE-3 and PE-4.

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS-100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 1532
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:02
                    use-es-bmac-lsb true
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

On PE-2, I-VPLS 101 is configured as follows. The SAP monitors the operational group "op-grp-1" that is configured in Epipe 1. The AA MH ES "vES23_1.101" is used. The configuration of I-VPLS 102 is similar, but it uses AA MH ES "vES23_1.102" with preference value 50 instead. On PE-3, the preference values are reversed: preference value 50 for "vES23_1.101" and 100 for "vES23_1.102".

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_1.101" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000111
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 100
                                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        }
                    }
                    association {
                        lag "lag-1" {
                            virtual-ranges {
                                qinq {
                                    s-tag-c-tag 1 c-tag-start 101 {
                                        c-tag-end 101
                                    }
                                }
                            }
                        }
                    }
                    pbb {
                        source-bmac-lsb 0x2311
                    }
                }
            }
        }
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap lag-1:1.101 {
                monitor-oper-group "op-grp-1"
            }
        }
```

On PE-4, I-VPLS 101 is configured as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 101
                }
            }
            sap 1/2/1:1.101 {
            }
        }
```

To emulate a failure that affects the operational state of the egress VTEP (and also of the Epipe service), the SAP of Epipe 1 on PE-2 is disabled, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 1" {
            sap lag-2:1.* {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                admin-state disable
```

When the SAP is operationally down, Epipe 1 goes down, as follows:

```
[/]
A:admin@PE-2# show service id 1 base | match 'State'
Admin State       : Up                 Oper State        : Down
```

The egress VTEP 192.0.2.1 is operationally down, as follows:

```
[/]
A:admin@PE-2# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
192.0.2.1                             1                   Down      static
-------------------------------------------------------------------------------
Number of Egress VTEP, VNI : 1
-------------------------------------------------------------------------------
===============================================================================

===============================================================================
BGP EVPN VXLAN ES Dest
===============================================================================
I Eth Seg Id                    TEP Address       VNI       Last Changed
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

The operational group "op-grp-1" is associated with the egress VTEP, so it goes operationally down, as follows:

```
[/]
A:admin@PE-2# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1
Creation Origin  : manual                          Oper Status: down
Hold DownTime    : 0 secs                          Hold UpTime: 4 secs
Members          : 1                               Monitoring : 2
===============================================================================
```

This operational group is monitored by the SAPs in I-VPLSs 101 and 102, so these SAPs go down with flag OperGroupDown; for example, for I-VPLS 101 on PE-2:

```
[/]
A:admin@PE-2# show service id 101 sap lag-1:1.101 detail | match 'Flags'
Flags              : OperGroupDown
```

When the SAP goes down, the I-VPLS service goes down, as follows:

```
[/]
A:admin@PE-2# show service id 101 base | match 'State'
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
Admin State       : Up                  Oper State        : Down
```

Even though Epipe 1 on PE-2 is operationally down while Epipe 1 on PE-3 is up, PE-1 is unaware because the VXLAN destination in Epipe 1 remains up, as follows:

```
[/]
A:admin@PE-1# show service id 1 vxlan destinations

===============================================================================
Egress VTEP, VNI

Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using AA MH ESs

BGP must be enabled on all nodes for the EVPN address family, also in the access to and from PE-1. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
            vpn-apply-export true
            rapid-update {
                evpn true
            }
            group "ACCESS" {
                type internal
                split-horizon true
                family {
                    evpn true
                }
            }
            neighbor 192.0.2.2 {
                group "ACCESS"
            }
            neighbor 192.0.2.3 {
                group "ACCESS"
            }
```

On PE-1, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 101 and remote Ethernet tag 123.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/2/1:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                remote-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                vxlan 1 {
                    admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    vxlan-instance 1
                }
            }
        }
```

On PE-2, the following EVPN-VXLAN Epipe 2 is configured with local Ethernet tag 123 and remote Ethernet tag 101. The operational group "op-grp-2" is associated with Epipe 2. The configuration on PE-3 is identical.

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-2" {
        }
        epipe "Epipe 2" {
            admin-state enable
            description "Epipe 2 with EVPN-VXLAN"
            service-id 2
            customer "1"
            oper-group "op-grp-2"
            bgp 1 {
            }
            sap lag-2:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration of B-VPLS 100 remains unchanged and the configuration of the I-VPLSs 201 and 202 resembles the configuration of VPLSs 101.

When there is no failure, the egress VTEP for Epipe 2 on PE-1 is 192.0.2.2, which is the system IP address of PE-2, as follows:

```
[/]
A:admin@PE-1# show service id 2 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================

To emulate a failure that affects the operational state of the Epipe service, the SAP in Epipe 2 is disabled, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 2" {
            sap lag-2:2.* {
                admin-state disable
```

When the SAP goes down, the Epipe goes down, as follows:

```
[/]
A:admin@PE-2# show service id 2 base | match 'State'
Admin State       : Up                 Oper State        : Down
```

On PE-1, the egress VTEP for Epipe 2 is 192.0.2.3, which is the system IP address of PE-3, as follows:

```
[/]
A:admin@PE-1# show service id 2 vxlan destinations

===============================================================================

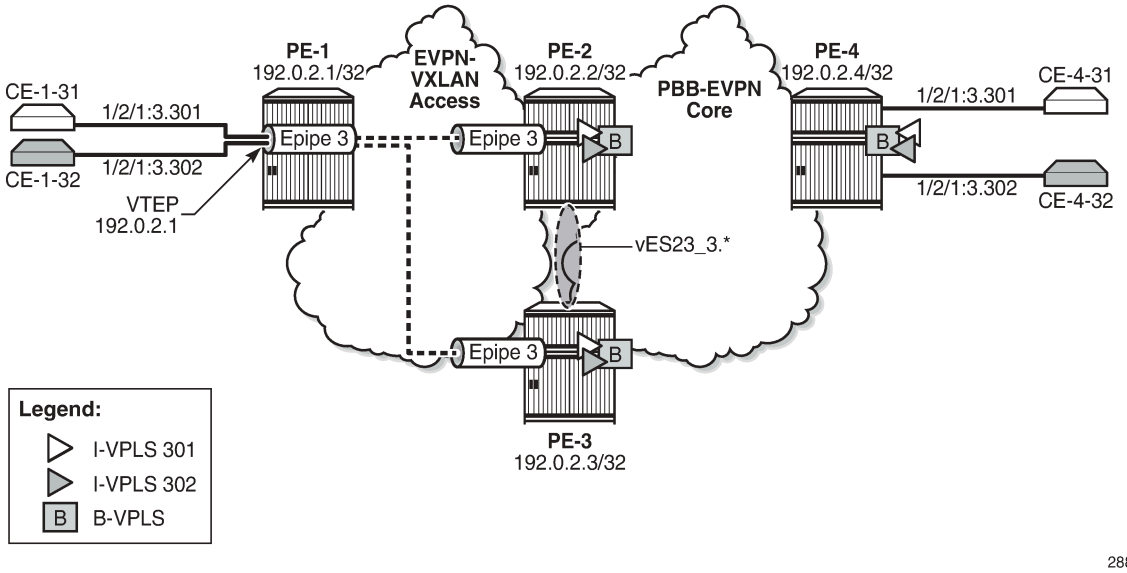
Service-level operational group in EVPN-VXLAN Epipes stitched to I-VPLS using SA MH ESs

Figure 246: Epipe 3 with EVPN-VXLAN and SA MH ES shows the example topology with an SA MH ES used by the I-VPLSs.

Figure 246: Epipe 3 with EVPN-VXLAN and SA MH ES



The configuration of Epipe 3 resembles the configuration of Epipe 2: the same Ethernet tags are used, only the VNI, EVI, and SAPs are different.

On PE-2 and PE-3, PXC 4 is configured to stitch Epipe 3 to I-VPLSs 301 and 302. The PXC port will be used in the SA MH ES.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

On PE-2 and PE-3, Epipe 3 is configured as follows:

```
# on PE-2, PE-3:
configure {
    service {
        oper-group "op-grp-3" {
        }
        epipe "Epipe 3" {
            admin-state enable
            description "EVPN-VXLAN Epipe 3"
            service-id 3
            customer "1"
            oper-group "op-grp-3"
            sap pxc-4.b:3.* {
            }
            vxlan {
                instance 1 {
                    vni 3
                }
            }
            bgp-evpn {
                evi 3
                local-attachment-circuit "AC-23" {
                    eth-tag 123
                }
                remote-attachment-circuit "AC-1" {
                    eth-tag 101
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

On PE-2, I-VPLS 301 uses SA MH ES "vES23_3.*", and is configured as follows.

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-3" {
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "vES23_3.*" {
                        admin-state enable
                        type virtual
                        esi 0x01000000002300000301
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 100
                                }
                            }
                        }
                        association {
                            port pxc-4.a {
                                virtual-ranges {

```
                                    s-tag 3 {
                                        end 3
                                    }
                                }
                            }
                        }
                    }
                    pbb {
                        source-bmac-lsb 0x2334
                    }
                }
            }
        }
        vpls "I-VPLS 301" {
            admin-state enable
            service-id 301
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS-100" {
                    isid 301
                }
            }
            sap pxc-4.a:3.301 {
                monitor-oper-group "op-grp-3"
            }
        }
```

The configuration is similar on PE-3, but with source-bmac-lsb 23-35 and preference 50.

When Epipe 3 on PE-2 is operationally up, the egress VTEP for Epipe 3 on PE-1 is 192.0.2.2, as follows:

```
[/]
A:admin@PE-1# show service id 3 vxlan destinations

===============================================================================

To emulate a failure on PE-2 that affects the operational state of the Epipe service, the SAP in Epipe 3 is disabled, as follows:

```
# on PE-2:
configure {
    service {
        epipe "Epipe 3" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            sap pxc-4.b:3.* {
                admin-state disable
```

When the SAP goes down, Epipe 3 goes down on PE-2, as follows:

```
[/]
A:admin@PE-2# show service id 3 base | match 'State'
Admin State       : Up                 Oper State        : Down
```

When Epipe 3 on PE-2 goes operationally down, the egress VTEP for Epipe 3 on PE-1 is 192.0.2.3, as follows:

```
[/]
A:admin@PE-1# show service id 3 vxlan destinations

Conclusion

Some service providers use VXLAN as a next-generation access technology used between the MSANs (or access PEs) and core PE routers. EVPN-VXLAN Epipes can be stitched using PXC to other services, such as I-VPLS. Operational groups can be defined in the Epipe for fault propagation to the SAPs of the services where the Epipe is stitched to.

Operational Groups in EVPN Services

This chapter provides information about Operational Groups in EVPN Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 21.10.R1. EVPN operational groups are supported in EVPN-VXLAN and EVPN-MPLS VPLS and R-VPLS services in SR OS Release 19.10.R2 and later; in EVPN-MPLS Epipes in SR OS Release 19.5.R1 and later.

Overview

An operational group includes objects and drives the status of service endpoints (such as pseudowires, SAPs, IP interfaces) located in the same or in different service instances. The operational group status is derived from the status of the individual components. Other service objects can monitor the operational group status. The status of the operational group influences the status of the monitoring objects.

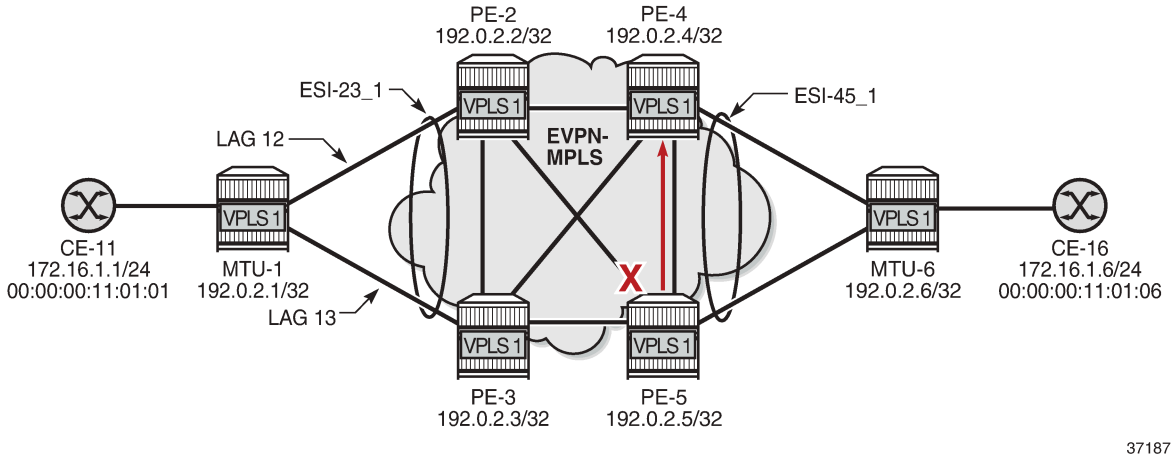
If the operational group goes down, the monitoring objects are also brought operationally down. When one of the objects included in the operational group comes up, the entire operational group comes up, as well as the monitoring objects.

Operational groups for EVPN destinations

Figure 247: EVPN mesh going down triggers DF switchover from PE-5 to PE-4 shows a sample topology with VPLS 1 configured on all nodes. PE-4 and PE-5 share a single-active Ethernet Segment (ES) "ESI-45_1" where PE-5 is the Designated Forwarder (DF).

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 247: EVPN mesh going down triggers DF switchover from PE-5 to PE-4



When the EVPN-VPLS service becomes isolated from the rest of the EVPN network (for example, all EVPN destinations are removed on DF PE-5), an operational group for EVPN destinations is required to trigger a DF switchover and bring the monitoring access SAP (or spoke SDP) down. EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. Ethernet Connectivity Fault Management (ETH-CFM) is enabled on a down Maintenance Endpoint (MEP) configured on the SAP to detect SAP failure. After the remote MEP on MTU-6 detects the failure, MTU-6 redirects its traffic to PE-4. This avoids blackholes when PE-5 is disconnected from the EVPN core.

On PE-5, VPLS 1 is configured with operational group "vpls-1_45" in EVPN-MPLS and SAP 1/1/2:1 monitoring this operational group. The operational group configured under a BGP-EVPN instance cannot be configured under any other object, such as SAPs or SDP-bindings.

```
# on PE-5:
configure {
    service {
        oper-group "vpls-1_45" {
            hold-time {
                down 0
                up 0
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                routes {
                    mac-ip {
                        cfm-mac true
                    }
                }
                mpls 1 {
                    admin-state enable
                    oper-group "vpls-1_45"
                    auto-bind-tunnel {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        resolution any
                    }
                }
            }
            sap 1/1/2:1 {
                description "to MTU-6"
                monitor-oper-group "vpls-1_45"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-11" mep-id 56 {
                        admin-state enable
                        mac-address 00:00:00:00:56:05
                        fault-propagation suspend-ccm
                        ccm true
                    }
                }
            }
        }
```

Using operational groups in the EVPN service, it is possible to monitor if the PE is isolated and, if it is, trigger a Designated Forwarder switchover. The operational group associated with the EVPN-MPLS instance goes down in the following cases:

- bgp-evpn mpls is disabled
- VPLS is disabled
- all EVPN destinations associated with the instance are removed, for example, when:
  - no tunnels are available for auto-bind-tunnel resolution
  - the network ports facing the EVPN ports are down
  - the BGP sessions to the route reflector or PEs are down

Operational groups for Ethernet Segments (Port-active multi-homing)

Operational groups can be configured on single-active ESs that need to function as port-active multi-homing Ethernet Segments. 'Port-active' refers to a special single-active mode where the PE is DF or non-DF for all the services attached to the ES. The configuration of a port-active ES is as follows:

```
# on PE-2:
configure {
    service {
        oper-group "vpls-1_23" {
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23_1" {
                        admin-state enable
                        esi 01:23:00:00:00:00:01:00:00:00
                        multi-homing-mode single-active
                        oper-group "vpls-1_23"
                        ac-df-capability exclude
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                            manual {
                                preference {
                                    value 150              # on PE-3: value 100
                                }
                            }
                        }
                        association {
                            lag "lag-12" {                 # on PE-3: lag 13
                            }
                        }
                    }
                }
            }
        }
```

This ES operational group "vpls-1_23" can be monitored on the LAG:

```
# on PE-2:
configure {
    lag "lag-12" {
        admin-state enable
        description "to MTU-1"
        encap-type dot1q
        mode access
        standby-signaling lacp                        # default value
        monitor-oper-group "vpls-1_23"
        max-ports 64
        lacp {
            mode active
            system-id 00:00:00:01:02:01
            system-priority 1
            administrative-key 1
        }
        port 1/1/2 {
        }
    }
```

When the operational group is configured on the ES and monitored on the associated LAG:

- The status of the ES operational group is driven by the ES DF status.
  - When a node becomes NDF, the ES operational group goes down and all the SAPs in the ES go down.
- The ES operational group goes down when all the SAPs in the ES go down.
  - When all SAPs in the ES go down, the operational group goes down and the node becomes NDF.

The monitoring LAG goes down when the ES operational group is down. The LAG signals the LAG standby state to the access node. The LAG standby signaling can be configured as **lacp** or **power-off.**

```
*[ex:/configure lag "lag-12"]
A:admin@PE-2# standby-signaling ?

 standby-signaling <keyword>
 <keyword>  - (lacp|power-off)
Default    - lacp

    Way of signaling a member port to the remote side
```

- **standby-signaling lacp** signals LACP out-of-sync to the CE when the application layer instructs the LAG to become standby

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **standby-signaling power-off** brings the LAG members down, and hence the access SAPs down

The ES and AD routes for the ES are not withdrawn because the router recognizes that the LAG becomes standby due to the ES operational group.

Some restrictions:

- Multi-chassis LAG and ES are mutually exclusive:

```
*[ex:/configure redundancy multi-chassis peer 192.0.2.2 mc-lag lag "lag-13"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure lag "lag-13" - invalid combination mc-lag <-> monitor-
oper-group
```

- LAG sub-groups are blocked:

```
*[ex:/configure lag "lag-13" port 1/1/1]
A:admin@PE-3# sub-group 2

*[ex:/configure lag "lag-13" port 1/1/1]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure lag "lag-13" port 1/1/1 - invalid combination port sub-
group <-> monitor-oper-group - configure lag "lag-13" monitor-oper-group
```

- Only LAGs in access mode can monitor operational groups:

```
*[ex:/configure lag "lag-3"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #3001: configure lag "lag-3" mode - monitor-oper-group not allowed when lag
 is not access
```

- Operational groups cannot be assigned to virtual ESs:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" association lag "lag-5"
 virtual-ranges dot1q q-tag 1]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "vESI-23_1" oper-
group - Inconsistent Value error - ethernet-segment oper-group not supported with virtual
 ethernet-segment
```

- Operational groups cannot be assigned to all-active ESs:

```
*[ex:/configure service system bgp evpn]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "AA_ESI-23_1" oper-
group - Inconsistent Value error - all-active multi-homing not supported with ethernet-
segment oper-group
```

- Operational groups cannot be assigned to ESs with service-carving auto:

```
*[ex:/configure service system bgp evpn]
A:admin@PE-3# commit
MINOR: SVCMGR #12: configure service system bgp evpn ethernet-segment "ESI-23_auto" oper-
group - Inconsistent Value error - ethernet-segment oper-group not supported with service-
carving-mode auto
```

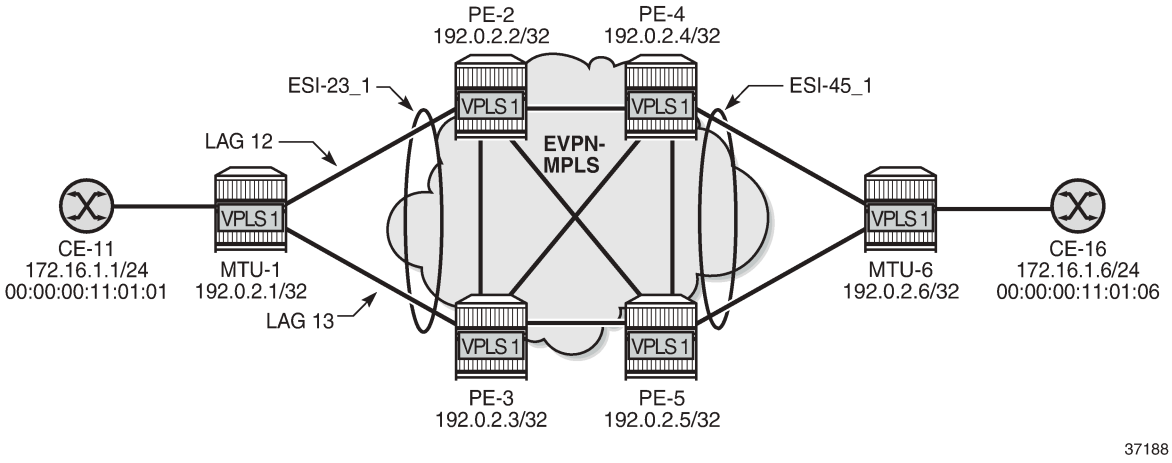
Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM. However, not all access nodes support ETH-CFM and, in that case, LAG **standby-signaling lacp** or **power-off** can be used instead.

Configuration

Figure 248: Sample topology with VPLS 1 shows the sample topology with VPLS 1 configured on all nodes.

Figure 248: Sample topology with VPLS 1



The initial configuration includes:

- Cards, MDAs, ports
- LAG 12 between PE-1 and PE-2; LAG 13 between PE-1 and PE-3
- Router interfaces between PE-2, PE-3, PE-4, and PE-5
- IS-IS on all router interfaces
- LDP between PE-2, PE-3, PE-4, and PE-5
- BGP between PE-2, PE-3, PE-4, and PE-5

For BGP, PE-2 acts as route reflector and the configuration is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

Operational groups for EVPN destinations

On PE-4, single-active ES "ESI-45_1" is configured with service carving auto. Operational group "vpls-1_45" is associated with EVPN-MPLS in VPLS 1 and SAP 1/1/1:1 is monitoring that operational group. ETH-CFM is enabled on a down MEP configured on the SAP to detect SAP failures. The service configuration is as follows:

```
# on PE-4:
configure {
    service {
        oper-group "vpls-1_45" {
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45_1" {
                        admin-state enable
                        esi 01:45:00:00:00:00:01:00:00:00
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            port 1/1/1 {
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
```

Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                routes {
                    mac-ip {
                        cfm-mac true
                    }
                }
                mpls 1 {
                    admin-state enable
                    oper-group "vpls-1_45"
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/1:1 {
                description "to MTU-6"
                monitor-oper-group "vpls-1_45"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-10" mep-id 46 {
                        admin-state enable
                        mac-address 00:00:00:00:46:04
                        ccm true
                    }
                }
            }
        }
```

The configuration on PE-5 is similar.

On MTU-6, VPLS 1 is configured with three SAPs: SAP 1/1/2:1 toward PE-4, SAP 1/1/1:1 toward PE-5, and SAP 1/2/1:1 toward CE-16. ETH-CFM MEPs are configured on SAP 1/1/1:1 and SAP 1/1/2:1. The service configuration is as follows:

```
# on MTU-6:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/1/1:1 {
                description "to PE-5"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-11" mep-id 65 {
                        admin-state enable
                        mac-address 00:00:00:00:65:06
                        ccm true
                    }
                }
            }
            sap 1/1/2:1 {
                description "to PE-4"
                eth-cfm {
                    mep md-admin-name "domain-1" ma-admin-name "association-10" mep-id 64 {
                        admin-state enable
                        mac-address 00:00:00:00:64:06
                        ccm true
                    }
                }
            }
```

Avoiding blackholes when EVPN destinations are removed

On PE-5, a failure is simulated by disabling LDP:

```
# on PE-5:
configure exclusive
    router "Base" {
        ldp {
            admin-state disable
            commit
```

With LDP disabled, PE-5 has no tunnels available for auto-bind-tunnel in VPLS 1 and all EVPN destinations are removed, as follows:

```
[/]
A:admin@PE-5# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address                   Egr Label     Num.   Mcast Last Change

```

Finally, the failure is restored by re-enabling LDP on PE-5:

```
# on PE-5:
configure exclusive
    router "Base" {
        ldp {
            admin-state enable
            commit
```

Operational groups for ES (Port-Active Multi-Homing)

On PE-2 and PE-3, operational group vpls-1_23 is configured and associated with ES " ESI-23_1", but not configured or monitored in VPLS 1. The service configuration on PE-3 is as follows:

```
# on PE-3:
configure {
    service {
        oper-group "vpls-1_23" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            hold-time {
                down 0
                up 0
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23_1" {
                        admin-state enable
                        esi 01:23:00:00:00:00:01:00:00:00
                        multi-homing-mode single-active
                        oper-group "vpls-1_23"
                        ac-df-capability exclude
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 100           # on PE-2: value 150
                                }
                            }
                        }
                        association {
                            lag "lag-13" {
                            }
                        }
                    }
                }
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-13:1 {                          # on PE-2: sap lag-12:1
                description "to MTU-1"
            }
        }
```

LAG 12 on PE-2 and LAG 13 on PE-3 monitor operational group "vpls-1_23". The **monitor-oper-group** command can be added to the LAG:

```
# on PE-3:
configure {
    lag "lag-13" {
        admin-state enable
        description "to MTU-1"
        encap-type dot1q
        mode access
        standby-signaling lacp      # default value
        monitor-oper-group "vpls-1_23"
```

```
        max-ports 64
        lacp {
            mode active
            system-id 00:00:00:01:03:01
            system-priority 1
            administrative-key 1
        }
        port 1/1/1 {
        }
```

Note:
In this example, MTU-1 is connected to PE-2 and PE-3 through two different LAGs, however, this port-active multi-homing mode also supports the use of a single LAG on MTU-1. If a single LAG was used on MTU-1, the LAG ports on PE-2 and PE-3 must be configured with the same LACP parameters (administrative-key, system-id and system-priority) to ensure that PE-2 and PE-3 show themselves as a single system to MTU-1.

EVPN single-active multi-homing PEs that are elected as NDF must notify their attached access nodes to prevent these from sending traffic to the NDF. In this port-active multi-homing mode, ETH-CFM is not used, and other notification mechanisms are needed, such as LAG standby signaling (**lacp** or **power-off**). When the EVPN application layer instructs the LAG to become standby as a result of the NDF status, the behavior is as follows:

- the **lacp** option signals LACP out-of-sync to MTU-1
- the **power-off** option brings down the LAG ports connected to MTU-1

MTU-1 is connected to PE-2 and PE-3 using two different access LAGs with encapsulation dot1q and at least one port in each LAG. Any encapsulation type is supported in the LAGs. The LAG configuration is as follows:

```
# on MTU-1:
configure {
    lag "lag-12" {
        admin-state enable
        description "to PE-2"
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32768
        }
        port 1/1/1 {
        }
    }
    lag "lag-13" {
        admin-state enable
        description "to PE-3"
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32769
        }
        port 1/1/2 {
        }
    }
```

On MTU-1, VPLS 1 is configured as follows:

```
# on MTU-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/2/1:1 {
                description "to CE-11"
            }
            sap lag-12:1 {
                description "to PE-2"
            }
            sap lag-13:1 {
                description "to PE-3"
            }
        }
```

Initial situation without failures

PE-2 is DF for VPLS 1:

```

DF switchover

To trigger a DF switchover, the preference value is modified on PE-2, as follows:

```
# on PE-2:
configure exclusive
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-23_1" {
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 50
                                }
                            }
                        }
```

Figure 249: DF switchover in single-active ESI-23_1 shows a DF switchover from PE-2 to PE-3. PE-2 becomes the NDF and LAG 12 is in standby.

© 2026 Nokia.

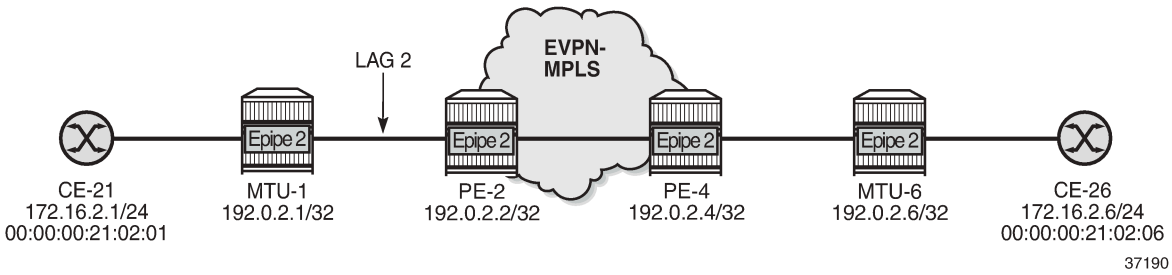
Link Loss Forwarding in EVPN-VPWS

Fault propagation in EVPN-VPWS services is supported using ETH-CFM, but also using LAG **standby-signaling lacp** or **power-off**.

Figure 250: Sample topology with Epipe 2 shows the sample topology with Epipe 2.

Figure 250: Sample topology with Epipe 2



The configuration on MTU-1 is as follows:

```
# on MTU-1:
configure {
    lag "lag-2" {
        admin-state enable
        encap-type dot1q
        mode access
        max-ports 64
        lacp {
            administrative-key 32770
        }
        port 1/1/5 {
        }
    }
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            sap 1/2/1:2 {
            }
            sap lag-2:2 {
            }
        }
```

On PE-2, operational group "llf-1" is configured and associated to EVPN-MPLS. LAG 2 monitors this operational group.

```
# on PE-2:
configure {
    lag "lag-2" {
        admin-state enable
        encap-type dot1q
        mode access
        standby-signaling lacp
        monitor-oper-group "llf-1"
        max-ports 64
        lacp {
            mode active

            system-priority 1
            administrative-key 2
        }
        port 1/1/5 {
        }
    }
    service {
        oper-group "llf-1" {
            hold-time {
                down 0
                up 0
            }
        }
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap lag-2:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-1_2" {
                    eth-tag 12
                }
                remote-attachment-circuit "ac-6_2" {
                    eth-tag 62
                }
                mpls 1 {
                    admin-state enable
                    oper-group "llf-1"
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

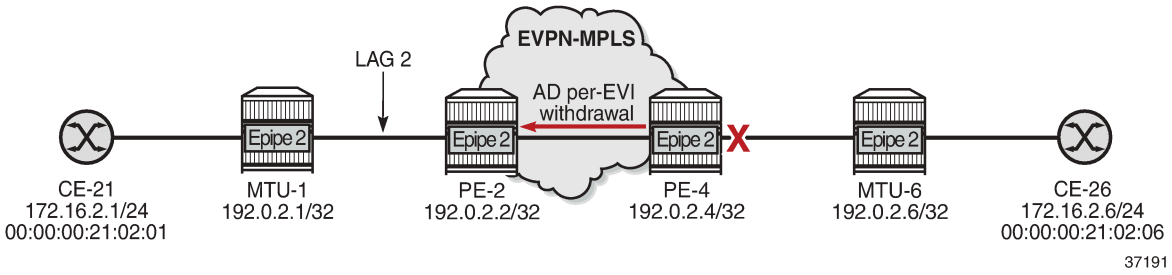
The configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            sap 1/1/5:2 {
            }
            bgp-evpn {
                evi 2
                local-attachment-circuit "ac-6_2" {
                    eth-tag 62
                }
                remote-attachment-circuit "ac-1_2" {
                    eth-tag 12
                }
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

Figure 251: LLF in Epipe 2 - PE-4 failure shows when a failure occurs on PE-4.

Figure 251: LLF in Epipe 2 - PE-4 failure



The failure is simulated on PE-4 by disabling port 1/1/5 toward MTU-6.

```
# on PE-4:
configure exclusive
    port 1/1/5 {
        admin-state disable
        commit
```

When the link between PE-4 and MTU-6 fails, PE-4 withdraws the AD per-EVI route for Epipe 2. PE-2 receives the following AD per-EVI withdrawal from PE-4:

```
155 2021/12/23 17:18:37.217 CET MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Received BGP UPDATE:
    Withdrawn Length = 0
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    Total Path Attr Length = 34
    Flag: 0x90 Type: 15 Len: 30 Multiprotocol Unreachable NLRI:
        Address Family EVPN
        Type: EVPN-AD Len: 25 RD: 192.0.2.4:2 ESI: ESI-0, tag: 62
              Label: 0 (Raw Label: 0x0) PathId:
"
```

Upon receiving this AD per-EVI route, Epipe 2 goes operationally down on PE-2:

```
[/]
A:admin@PE-2# show service id 2 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

Operational group "llf-1" goes down when the Epipe is operationally down:

```
[/]
A:admin@PE-2# show lag 2 detail | match "per group"
Monitor oper group  : llf-1
Oper group status   : down
```

On PE-2, the detailed information for operational group "llf-1" shows that the operational group and the monitoring LAG are down.

```

PE-2 signals the fault based on the configuration of the LAG standby signaling:

- If the LAG standby signaling is power-off, PE-2 brings down the ports in the LAG.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- If the LACP standby signaling is configured, PE-2 signals an LACP out-of-sync on the LAG ports.

In either case, MTU-1 stops forwarding traffic to PE-2.

The following debug message in log 99 on MTU-1 shows that MTU-1 received an LACP out-of-sync message for port 1/1/5 of LAG 2:

```
154 2021/12/23 17:18:37.216 CET WARNING: LAG #2007 Base LAG
"LAG lag-2 : partner oper state bits changed on member 1/1/5 : [sync TRUE -> FALSE] [collecting
 TRUE -> FALSE]"
```

The following debug messages in log 99 on MTU-1 show that LAG 2 and interface 1/1/5 are not operational:

```
156 2021/12/23 17:18:37.217 CET WARNING: SNMP #2004 Base lag-2
"Interface lag-2 is not operational"

155 2021/12/23 17:18:37.216 CET WARNING: SNMP #2004 Base 1/1/5
"Interface 1/1/5 is not operational"
```

On MTU-1, LAG 2 is operationally down:

```
[/]
A:admin@MTU-1# show lag 2

===============================================================================

    lag-2
===============================================================================
```

Conclusion

Operational groups can be useful in EVPN services to avoid blackholes when a PE is disconnected from the EVPN core. Failures can be propagated by the PEs to access nodes, either by ETH-CFM or LAG standby signaling.

P2MP mLDP FEC Resolution for BGP-LU in EVPN

This chapter provides information about P2MP mLDP FEC Resolution for BGP-LU in EVPN.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 16.0.R3, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Recursive and non-recursive multicast Label Distribution Protocol (mLDP) Forwarding Equivalence Class (FEC) resolution for BGP Labeled Unicast (BGP-LU) is supported in SR OS Release 15.0.R1 or later; see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

In SR OS Release 15.0.R4, and later, a leaf node in an MVPN can generate non-recursive mLDP mapping messages even if the root IP address is resolved using BGP-LU, without the need to leak BGP routes to IGP and LDP. In SR OS Release 16.0.R1, this is also supported for EVPN-MPLS services.

Overview

In inter-AS and intra-AS scenarios, recursive and non-recursive FEC label mapping messages can be used to set up the mLDP tree. In the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter, recursive and non-recursive mLDP FEC resolution is documented for inter-AS model C.

This chapter describes the following use cases for recursive and non-recursive mLDP FEC resolution for BGP-LU:

- P2MP mLDP FEC resolution for inter-AS model C
- P2MP mLDP FEC resolution for seamless MPLS

Some routers do not support recursive mLDP FEC, so basic non-recursive mLDP FEC is used instead. The non-recursive mLDP FEC resolution does not require the root IP address to be leaked from BGP to IGP and LDP. This is different from the configuration in the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

Figure 252: Example topology for inter-AS model C shows the example topology for inter-AS model C with the configured protocols (IGP, LDP, BGP). Root node PE-1 is situated in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are AS Border Routers (ASBRs) that are configured with next-hop-self (NHS). VPLS 1 is configured on root node PE-1 and leaf node PE-4, and is EVPN-MPLS enabled. The example topology for seamless MPLS is similar, but P-2 and P-3 will then act as Area Border Routers (ABRs) and IGP instance 0 is configured between them.

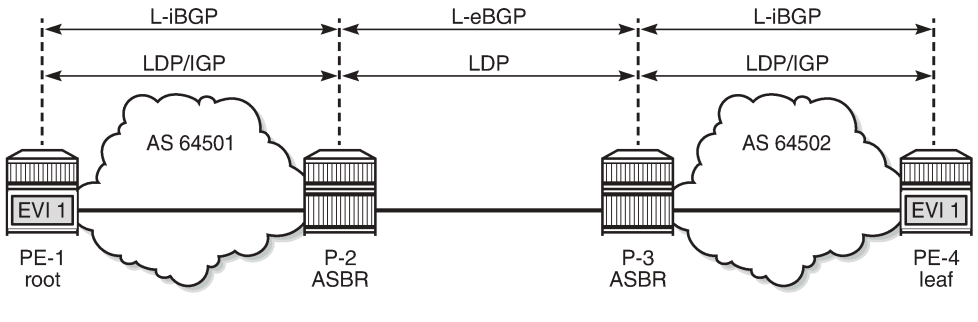
Use subject to Terms available at: www.nokia.com/terms.

Figure 252: Example topology for inter-AS model C

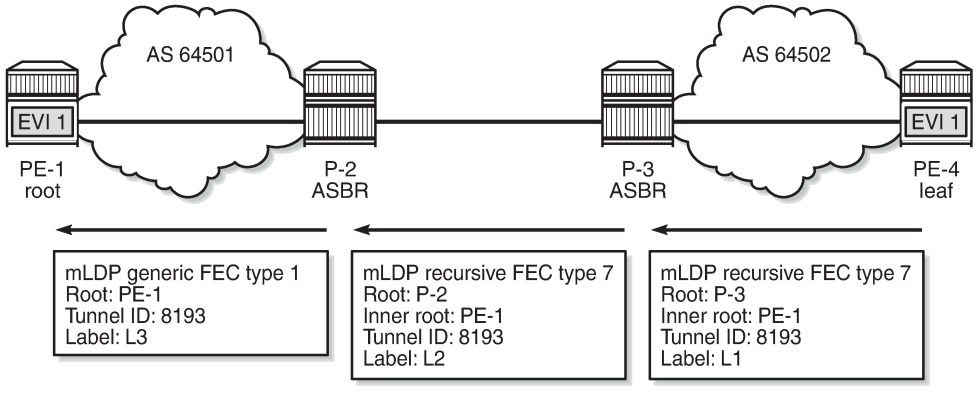


Recursive mLDP FEC resolution requires the nodes in a remote AS (or remote area in case of seamless MPLS) to support GRT recursive FEC type 7 to join the root node.

- PE-4 has a labeled BGP route to root PE-1 with next-hop P-3 in its route table. If PE-4 supports it, it sends a GRT recursive FEC type 7 label mapping message with inner root PE-1 and root P-3.
- P-3 has a labeled BGP route to PE-1 with next-hop P-2. When P-3 receives the mLDP label mapping message from PE-4, it generates its own GRT recursive FEC type 7 message with inner root PE-1 and root P-2.
- P-2 has an IGP route to root PE-1. When P-2 receives the mLDP label mapping message from P-3, it generates a non-recursive FEC type 1 message with root PE-1.

Figure 253: mLDP FEC label mapping messages for inter-AS model C shows the mLDP label mapping messages for inter-AS model C.

Figure 253: mLDP FEC label mapping messages for inter-AS model C



However, if the leaf node PE-4 does not support GRT recursive FEC type 7, it is possible to generate a non-recursive FEC type 1 label mapping message with root PE-1 to the local ASBR that supports GRT recursive FEC type 7. The following command generates only generic FEC type 1 label mapping messages with PE-1 as the root, on the leaf node PE-4:

```
# on PE-4:
configure {
    router "Base" {
        ldp {
```

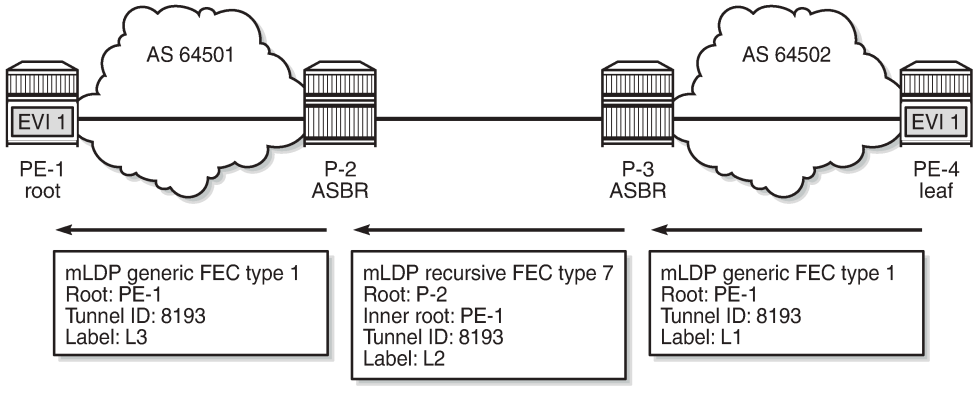
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            generate-basic-fec-only true
```

Note:
SR OS always generates a recursive FEC if the root node is resolved via BGP; if the root node is resolved via IGP, basic FEC is generated instead. The only way to not generate a recursive FEC when the root is resolved via BGP is by configuring the **generate-basic-fec-only** command.

Figure 254: Non-recursive mLDP FEC for inter-AS model C shows the non-recursive mLDP label mapping messages for inter-AS model C.

Figure 254: Non-recursive mLDP FEC for inter-AS model C

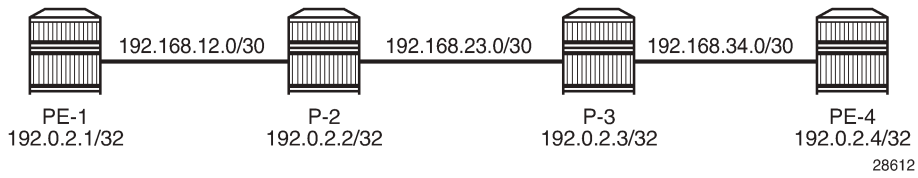


It is also possible that the ASBR routers do not support GRT recursive FEC either. The same **generate-basic-fec-only** command can be configured on all these nodes, which will then generate basic FEC type 1 label mapping messages with root address 192.0.2.1 to the next-hop.

Configuration

Figure 255: Example topology shows the example topology with four nodes.

Figure 255: Example topology



The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Inter-AS model C

Figure 252: Example topology for inter-AS model C showed the example topology for inter-AS model C. The following is configured for that topology. For a detailed explanation of the configuration, see the P2MP mLDP Inter-AS Model C for EVPN-MPLS Services chapter.

- Within each AS, OSPF is configured as IGP (alternatively, IS-IS can be used).
- LDP is enabled within each AS.
- LDP is enabled between the ASBRs using the interface IP addresses 192.168.23.x.
- On the ASBRs, a static route 192.168.23.y/32 for the interface IP address on the ASBR peer is configured (with mask /32 instead of /30). When a label mapping message is received for an LDP FEC prefix, the next-hop for a FEC prefix is resolved using the routing table. The FEC is installed in the Label Information Base (LIB) if the next-hop matches a /32 route entry.
- BGP is configured on all nodes for the labeled IPv4 address family. An export policy exports the system IP addresses of the root and leaf nodes PE-1 and PE-4.
- A multi-hop BGP session is established between PE-1 and PE-4 for the EVPN address family, allowing inclusive multicast EVPN routes to be exchanged.
- EVPN-MPLS VPLS 1 is configured on PE-1 and PE-4 with mLDP enabled. PE-1 is configured as root node.

The BGP configuration on PE-1 is as follows. The BGP configuration on PE-4 is similar, but with different neighbors and AS numbers. The export policy is identical.

```
# on PE-1:
configure {
    policy-options {
        prefix-list "sysPE" {
            prefix 192.0.2.0/29 type longer {
            }
        }
        policy-statement "PE-sys-to-labeled-BGP" {
            entry 10 {
                from {
                    prefix-list ["sysPE"]
                    protocol {
                        name [direct]
                    }
                }
                to {
                    protocol {
                        name [bgp-label]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "eBGP" {
                multihop 10
```

© 2026 Nokia.

```
                type external
                peer-as 64502
                family {
                    evpn true
                }
                ebgp-default-reject-policy {
                    import false
                    export false
                }
            }
            group "iBGP" {
                type internal
            }
            neighbor 192.0.2.2 {
                group "iBGP"
                family {
                    label-ipv4 true
                }
                export {
                    policy ["PE-sys-to-labeled-BGP"]
                }
            }
            neighbor "192.0.2.4" {
                group "eBGP"
            }
```

On PE-1, VPLS 1 is configured as follows. The service configuration on PE-4 is similar, but with different RT values and without the **root-and-leaf** parameter.

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer 1
            bgp 1 {
                route-target {
                    export target:64501:1
                    import target:64502:1
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true     # PE-1 is configured as root node
                    mldp
                }
            }
        }
```

On P-2, the following static route with mask /32 is configured for the interface IP address of the peer ASBR. The configuration on P-3 is similar.

```
# on P-2:
configure {
    router "Base" {
        static-routes {
            route 192.168.23.2/32 route-type unicast {
                next-hop 192.168.23.2 {
                    admin-state enable
                }
            }
```

On P-2, the BGP and LDP configuration is as follows. The configuration on P-3 is similar.

```
# on P-2:
configure {
    policy-options {
        community "64501:0" {
            member "64501:0" { }
        }
        community "64502:0" {
            member "64502:0" { }
        }
        policy-statement "export-bgp" {
            entry 10 {
                from {
                    protocol {
                        name [bgp-label]
                    }
                }
                action {
                    action-type accept
                    origin igp
                    community {
                        add ["64501:0"]
                    }
                }
            }
        }
        policy-statement "import-bgp" {
            entry 10 {
                from {
                    community {
                        name "64502:0"
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "eBGP" {
                type external
                import {
                    policy ["import-bgp"]
                }
                export {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    policy ["export-bgp"]
                }
            }
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.168.23.2" {
                advertise-inactive true
                group "eBGP"
                next-hop-self true
                peer-as 64502
                family {
                    label-ipv4 true
                }
            }
        }
        ldp {
            interface-parameters {
                interface "int-P-2-P-3" {
                    ipv4 {
                        admin-state enable
                        local-lsr-id {
                            interface-name "int-P-2-P-3"
                        }
                    }
                }
                interface "int-P-2-PE-1" {
                    ipv4 {
                        admin-state enable
                    }
                }
            }
```

Leaf node PE-4 has a labeled BGP route toward root node PE-1 using next-hop 192.0.2.3, as follows:

```
[/]
A:admin@PE-4# show router route-table

===============================================================================
Route Table (Router: Base)

```

Recursive mLDP FEC resolution for inter-AS model C

With the preceding configuration, leaf node PE-4 sends a recursive mLDP FEC label mapping message with PE-1 as inner root and P-3 as root. On PE-4, the number of GRT recursive mLDP bindings is 1, as follows:

```

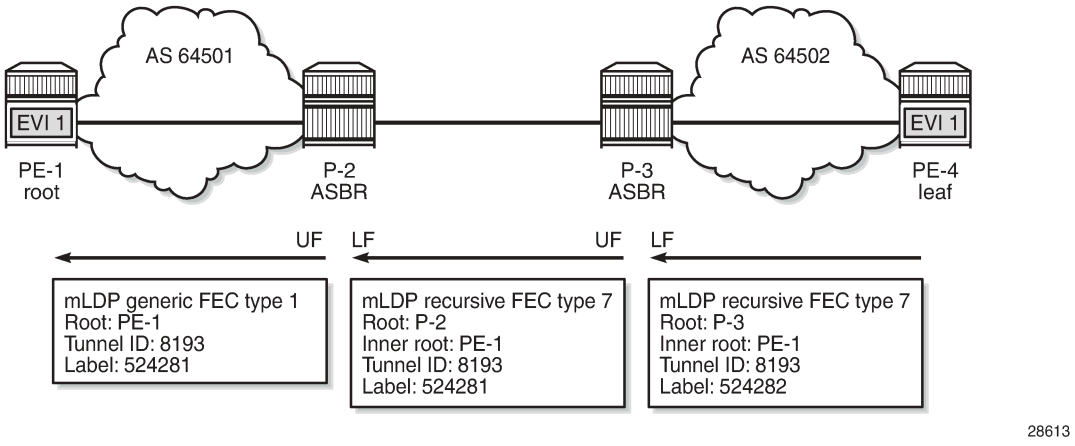
Figure 256: Recursive mLDP FEC for inter-AS model C



Non-recursive mLDP FEC resolution for inter-AS model C

Some routers may not support GRT recursive FEC type 7. In that case, the router generates a non-recursive FEC type 1 with root PE-1 to the next-hop P-3. In this example, leaf node PE-4 does not support GRT recursive FEC type 7 and is configured to only send basic FEC type 1 messages. ASBR P-3 supports GRT recursive type 7 and sends similar messages as in the preceding scenario. However, it is possible that none of the routers supports GRT recursive FEC type 7. In that case, the **generate-basic-fec-only** command is configured on all nodes.

The following command is configured on leaf node PE-4 to make the system send only basic FEC type 1 messages:

```
# on PE-4:
configure {
    router "Base" {
        ldp {
            generate-basic-fec-only true
```

When PE-4 is configured to only generate basic FEC type 1, PE-4 withdraws the GRT recursive type 7 (T:7) label mapping message with PE-1 as inner root and P-3 as root and sends a non-recursive generic type 1 (T:1) label mapping message with PE-1 as root instead. When debugging is enabled on PE-4 for LDP label mapping messages between P-3 and PE-4, the following messages are logged:

```
# on PE-4:
1 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Withdraw packet (msgId 96) to 192.0.2.3:0
Protocol version = 1
Label 524282 withdrawn for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"

2 2021/06/17 08:44:52.342 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP

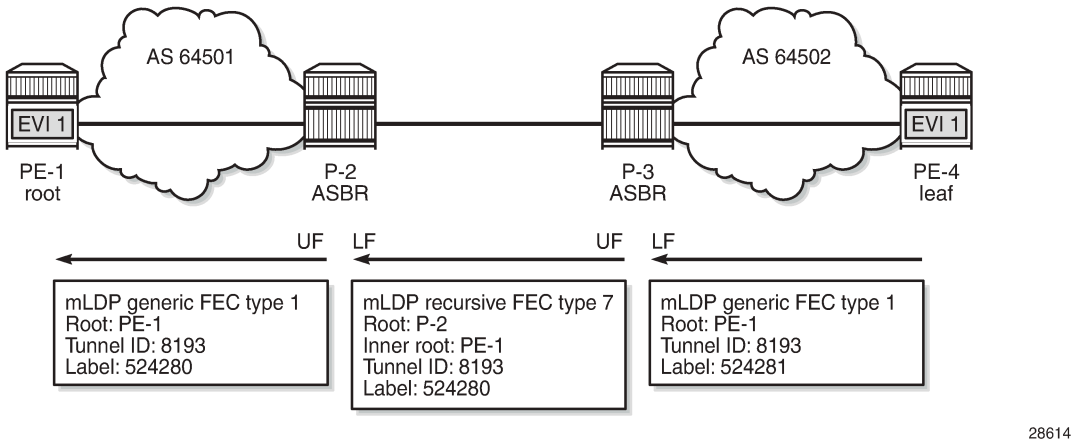
On P-2 and PE-1, the mLDP bindings are similar to the preceding scenario, but the labels are different. Figure 257: Non-recursive mLDP FEC for inter-AS model C shows the label mapping messages with label 524280 between PE-1 and P-2 and label 524280 between P-2 and P-3; label 524281 is used between P-3 and PE-4.

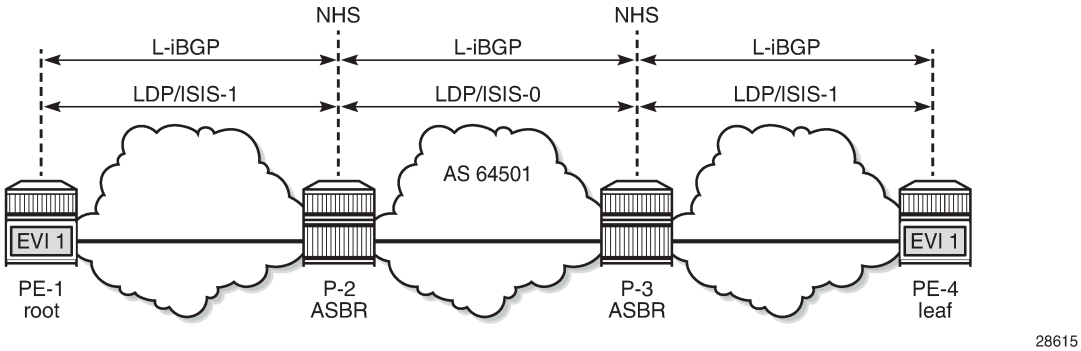
Figure 257: Non-recursive mLDP FEC for inter-AS model C



Seamless MPLS

Figure 258: Example topology for seamless MPLS shows the example topology for seamless MPLS.

Figure 258: Example topology for seamless MPLS



The configuration is according to the *Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP* chapter in the *7450 ESS, 7750 SR, 7950 XRS, and VSR MPLS Advanced Configuration Guide for Classic CLI*.

IS-IS is configured as IGP. IS-IS instance 0 is configured between P-2 and P-3, whereas IS-IS instance 1 is configured between P-2 and PE-1 and between P-3 and PE-4. On P-2, IS-IS is configured as follows:

```
# on P-2:
configure {
    router "Base" {
        isis 0 {
            admin-state enable
            level-capability 2
            area-address [49.0001]
            interface "int-P-2-P-3" {
                interface-type point-to-point
            }
            interface "system" {
            }
        }
        isis 1 {
            admin-state enable
            level-capability 2
            area-address [49.0001]
            interface "int-P-2-PE-1" {
                interface-type point-to-point
            }
            interface "system" {
            }
        }
```

Other characteristics of this example are as follows:

- Unlike the preceding use case for inter-AS model C, no static route is required between P-2 and P-3.
- LDP is configured on all interfaces.
- VPLS 1 is configured as before, but the route target is identical for import and export, and equal to 64501:1.
- All nodes are in AS 64501, so only iBGP is configured.

On PE-1, BGP is configured as follows, using the same policy as for inter-AS model C. The BGP configuration on PE-4 is similar, but the neighbors are different.

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
                export {
                    policy ["PE-sys-to-labeled-BGP"]
                }
            }
            neighbor "192.0.2.4" {
                group "iBGP"
                family {
                    evpn true
```

```
                }
            }
        }
```

On P-2, the BGP configuration is as follows. The ABRs are configured with **next-hop-self** in both directions. The BGP configuration is similar on P-3.

```
# on P-2:
configure {
    router "Base" {
        autonomous-system 64501
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "iBGP"
                next-hop-self true
                family {
                    label-ipv4 true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.3" {
                advertise-inactive true
                group "iBGP"
                next-hop-self true
                family {
                    label-ipv4 true
                }
            }
        }
```

The following route table on PE-4 shows a labeled BGP route to root node PE-1 with P-3 as the next-hop:

```
[/]
A:admin@PE-4# show router route-table 192.0.2.1

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                  Remote  BGP_LABEL 00h00m47s  170
       192.0.2.3 (tunneled)                                       10

```

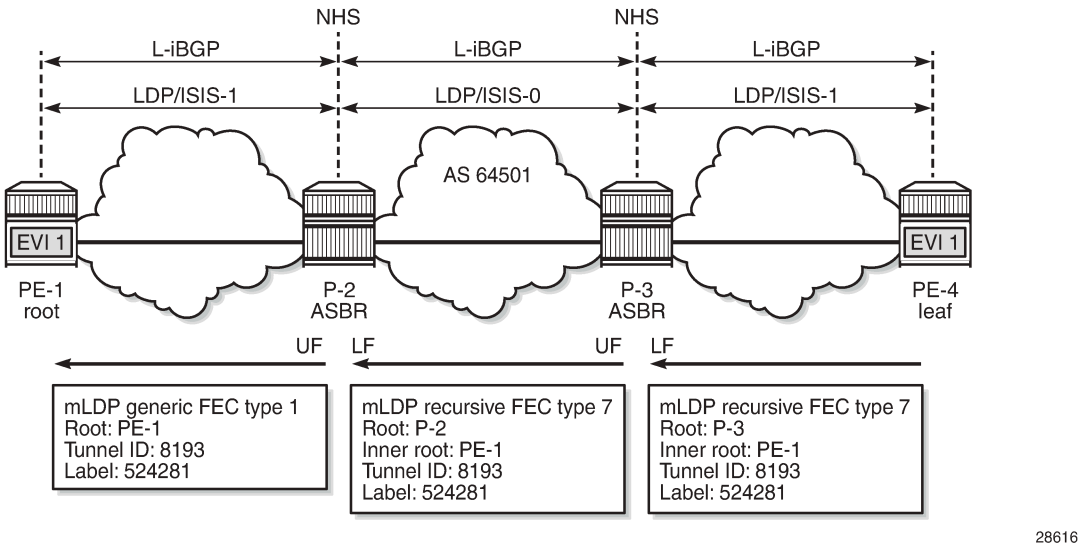
P-2 has one GRT recursive FEC binding with inner root PE-1 and root P-2 (LF). P-2 also has one non-recursive FEC binding with root PE-1 (UF). PE-1 only has a non-recursive FEC binding with root PE-1. Figure 259: Recursive mLDP FEC for seamless MPLS shows the mLDP label mapping messages that all have label 524281 in this example.

Figure 259: Recursive mLDP FEC for seamless MPLS



Non-recursive mLDP FEC resolution for seamless MPLS

For nodes that do not support GRT recursive mLDP FEC type 7, the following command ensures that only non-recursive mLDP type 1 label mapping messages will be sent. In this example, it is assumed that only PE-4 does not support GRT recursive mLDP FEC type 7.

```
# on PE-4:
configure {
    router "Base" {
        ldp {
            generate-basic-fec-only true
```

PE-4 sends a non-recursive mLDP label mapping message with PE-1 as the root to its peer P-3, as follows:

```
[/]
A:admin@PE-4# show router ldp bindings p2mp opaque-type generic detail ipv4

===============================================================================
```

===============================================================================
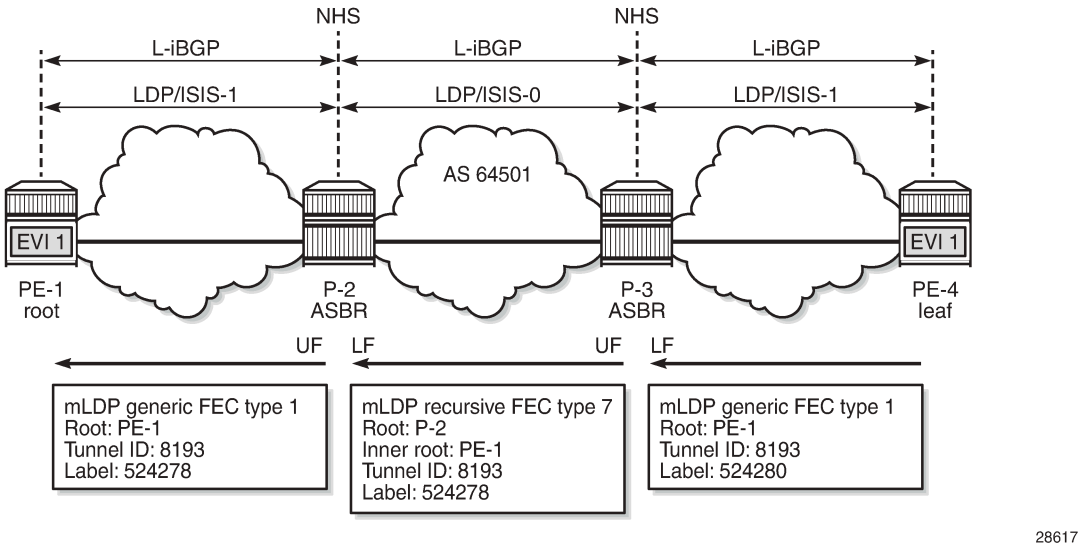
No. of Generic IPv4 P2MP Bindings: 1
===============================================================================
```

Figure 260: Leaf node sends basic FEC in seamless MPLS shows the label mapping messages when leaf node PE-4 only generates basic FEC type 1 messages.

Figure 260: Leaf node sends basic FEC in seamless MPLS



It is possible that ABR routers do not support GRT recursive either. The same command is configured on P-2 and P-3, as follows:

```
# on P-2, P-3:
configure {
    router "Base" {
        ldp {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            generate-basic-fec-only true
```

When **generate-basic-fec-only** is enabled in the ABRs, P-2 and P-3 will only generate basic FEC messages. On P-3, there are no GRT recursive mLDP bindings anymore, as follows:

```
[/]
A:admin@P-3# show router ldp bindings p2mp summary ipv4
 No. of Generic IPv4 P2MP Bindings: 2
 No. of In-Band-SSM IPv4 P2MP Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Bindings: 0
 No. of Recursive with In-Band-SSM IPv4 P2MP Bindings: 0
 No. of VPN Recursive with Generic IPv4 P2MP Bindings: 0
 No. of GRT Recursive with Generic IPv4 P2MP Bindings: 0
```

The two generic mLDP bindings on P-3 have root address 192.0.2.1, as follows. There is no UF or LF.

```
[/]
A:admin@P-3# show router ldp bindings p2mp opaque-type generic detail ipv4

===============================================================================

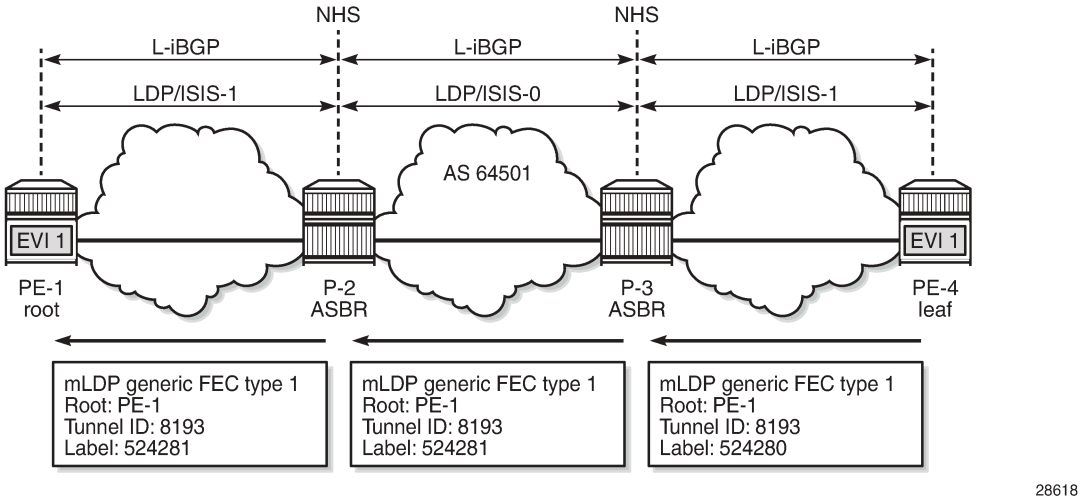
Figure 261: ABRs and leaf node send basic FEC in seamless MPLS



Conclusion

In inter-AS and intra-AS scenarios, mLDP trees can be set up using recursive or non-recursive label mapping messages. Routers not supporting recursive FEC can generate only non-recursive FEC, even if the system address of the root node is resolved via BGP. This feature is supported in MVPN and in EVPN.

P2MP mLDP Inter-AS Model C for EVPN-MPLS Services

This chapter provides information about P2MP mLDP Inter-AS Model C for EVPN-MPLS Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 15.0.R5, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1.

Point-to-Multipoint Multicast Label Distribution Protocol (P2MP mLDP) for Broadcast, Unknown Unicast, and Multicast (BUM) traffic in EVPN-MPLS networks is supported in SR OS Release 14.0.R1, and later. EVPN with P2MP mLDP LSPs is supported in a seamless MPLS or inter-AS model C scenario in SR OS Release 15.0.R1, and later. This chapter describes the inter-AS model C scenario, but the configuration for seamless MPLS is similar.

Overview

Chapter P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services describes P2MP mLDP within an Autonomous System (AS). PEs configured with **root-and-leaf true** can send BUM traffic over P2MP mLDP tunnels; PEs configured with root-and-leaf false (that is, leaf-only) can only send BUM traffic over Ingress Replication (IR) tunnels. Both types of PEs (root-and-leaf and leaf-only) can receive BUM traffic over either P2MP mLDP tunnels or IR tunnels.

When **provider-tunnel inclusive mldp** is enabled in an EVPN-MPLS service in combination with **root-and-leaf true** and **bgp-evpn>mpls>ingress-replication-bum-label true**, the system will send an Inclusive Multicast Ethernet Tag (IMET) route with a composite tunnel type (IMET-P2MP-IR) in the provider tunnel attributed.

Inter-AS VPN model C is described in chapters "Inter-AS VPRN Model C" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 3 Services Advanced Configuration Guide for MD CLI* and Inter-AS Model C for VLL. Labeled IPv4 unicast BGP is used to provide inter-AS connectivity. The system IP addresses within each AS are exported by the Autonomous System Border Routers (ASBRs) and a multi-hop BGP session is established between root node and leaf node for address family EVPN. The root node advertises a composite IMET-P2MP-IR route to the leaf nodes and the leaf nodes advertise an IMET-IR route to the root node. Figure 262: Inter-AS Model C for P2MP mLDP shows an example topology with root node PE-1 in AS 64501 and leaf node PE-4 in AS 64502. P-2 and P-3 are ASBRs.

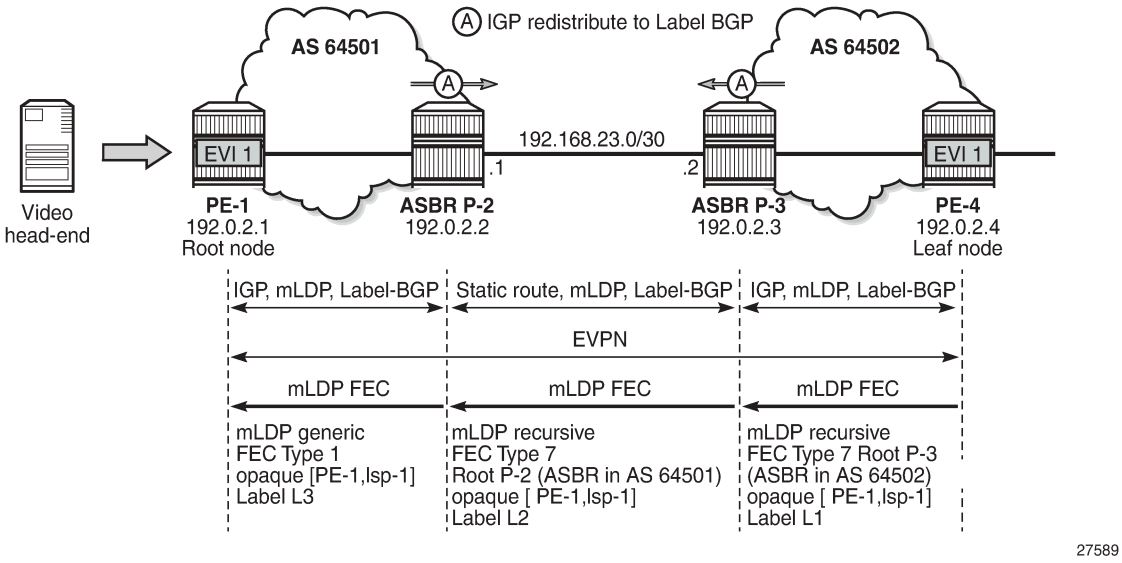
Use subject to Terms available at: www.nokia.com/terms.

Figure 262: Inter-AS Model C for P2MP mLDP



The composite IMET-P2MP-IR route received by leaf node PE-4 contains the root node (192.0.2.1) and the LSP ID (0x2001) that will be used by the nodes to set up a P2MP mLDP tree toward the root.

"
```

The Provider Multicast Service Interface (PMSI) tunnel attribute for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 always equals zero in SR OS Release 21.5.R1, because SR OS does not support aggregated P2MP tunnels. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388544 needs to be divided by 16 to get the MPLS label value: 8388544/16 = 524284. This is due to the debug message being shown before the router can parse the label field and see whether it corresponds to an

```

The use of mLDP with recursive opaque values is specified in RFC 6512.

When the leaf node PE-4 receives the composite IMET-P2MP-IR route from the root node PE-1, a P2MP mLDP tree needs to be established from the leaf node to the root node. Leaf node PE-4 resolves the IP address of PE-1 to a labeled BGP route with next-hop ASBR P-3. PE-4 then sends an mLDP FEC with root node ASBR P-3 and an opaque value containing the root PE-1 and an LSP ID that was advertised in the IMET-P2MP-IR route, as follows:

```
# on PE-4:
4 2021/06/02 08:31:13.915 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 40) to 192.0.2.3:0
Protocol version = 1
Label 524283 advertised for the following FECs
P2MP: root = 192.0.2.3, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

T: 7 indicates the MLDP recursive FEC type 7. The tunnel ID 8193 corresponds to the hexadecimal value 0x2001 sent by the root node PE-1, which is the inner root 192.0.2.1 in the recursive opaque value.

When ASBR P-3 receives this mLDP FEC, it identifies itself as root node and resolves the recursive opaque value (PE-1, LSP ID) and creates a new mLDP FEC element with root node ASBR P-2 and an identical opaque value (PE-1, LSP ID). The following mLDP FEC is sent to ASBR P-2:

```
# on P-3:
4 2021/06/02 08:32:36.794 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 34) to 192.168.23.1:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.168.23.1, T: 7, L: 17 (InnerRoot: 192.0.2.1 T: 1, L: 4, TunnelId: 8193)
"
```

ASBR P-2 receives the mLDP FEC and finds that it is the root node. P-2 creates a new mLDP FEC, but no recursion is required because P-2 knows the IP address of PE-1 through the IGP. P-2 sends the following mLDP FEC with root node PE-1, LSP ID 8193, and mLDP FEC type 1.

```
# on P-2:
6 2021/06/02 08:32:36.814 UTC MINOR: DEBUG #2001 Base LDP
```

Label 524279 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"
```

Configuration

The example topology was already shown in Figure 262: Inter-AS Model C for P2MP mLDP. The initial configuration includes the following:

- Cards, MDAs, ports
- Router interfaces
- OSPF as IGP within each AS (alternatively, IS-IS can be used)
- LDP enabled within each AS

The following two scenarios are configured:

- Inter-AS model C for mLDP
- Optimized inter-AS model C for mLDP

Inter-AS Model C for mLDP

The initial BGP configuration on the PEs only includes a label-IPv4 peering with the ASBRs. The BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        bgp {
            split-horizon true
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.2" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
            }
```

On the ASBRs, BGP is configured for address family label-IPv4, both internal to PE-1 and external to the peer ASBR. A policy exports the system prefixes as label-IPv4 routes to the eBGP peer. The BGP configuration on P-2 is as follows:

```
# on P-2:
configure {
    policy-options {
        prefix-list "sysPE" {
            prefix 192.0.2.0/24 type longer {
            }
        }
        policy-statement "PE-sys-to-labeled-BGP" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            entry 10 {
                from {
                    prefix-list ["sysPE"]
                }
                to {
                    protocol {
                        name [bgp-label]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
    }
    router "Base" {
        bgp {
            ebgp-default-reject-policy {
                import false
            }
            group "eBGP" {
                type external
            }
            group "iBGP" {
                type internal
            }
            neighbor "192.0.2.1" {
                group "iBGP"
                family {
                    label-ipv4 true
                }
            }
            neighbor "192.168.23.2" {
                split-horizon true
                group "eBGP"
                peer-as 64502
                family {
                    label-ipv4 true
                }
                local-as {
                    as-number 64501
                }
                export {
                    policy ["PE-sys-to-labeled-BGP"]
                }
            }
```

The BGP configuration on ASBR P-3 is similar, but the IP addresses are different and the local AS and peer AS are swapped. The export policy is identical on both ASBRs P-2 and P-3.

When a P2MP mLDP tree must be established across ASs, LDP needs to be enabled on the interface between the ASBRs with **local-lsr-id>interface-name <..>** instead of the default value "system". The LDP configuration on P-2 is as follows:

```
# on P-2:
configure {
    router "Base" {
        ldp {
            interface-parameters {
                interface "int-P-2-P-3" {
                    ipv4 {
                        local-lsr-id {
                            interface-name "int-P-2-P-3"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                }
            }
```

With this LDP configuration, a link adjacency will be established toward the interface IP address instead of the system address, as follows:

```
[/]
A:admin@P-2# show router ldp session ipv4

===============================================================================
LDP IPv4 Sessions
===============================================================================
Peer LDP Id         Adj Type  State         Msg Sent  Msg Recv  Up Time
-------------------------------------------------------------------------------
192.0.2.1:0         Link      Established   100       101       0d 00:04:05
192.168.23.2:0      Link      Established   16        18        0d 00:00:20
-------------------------------------------------------------------------------
No. of IPv4 Sessions: 2
===============================================================================
```

However, this LDP configuration is insufficient for the resolution of mLDP FEC as link LSR ID. LDP needs a /32 route instead of a /30 route, so the following /32 static route is configured on P-2:

```
# on P-2:
configure {
    router "Base" {
        static-routes {
            route 192.168.23.2/32 route-type unicast {
                next-hop "192.168.23.2" {
                    admin-state enable
                }
            }
```

The configuration on ASBR P-3 is similar for static route 192.168.23.1/32. When this static route is not configured, no mLDP label mapping message will be sent from P-3 to P-2, so the mLDP P2MP tree cannot be established.

On PE-1, VPLS 1 is configured with mLDP root-and-leaf, as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-target {
                    export "target:64501:1"
                    import "target:64502:1"
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
        }
```

On PE-4, VPLS 1 is configured with mLDP leaf-only (no root-and-leaf, which is default), as follows:

```
# on PE-4:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
                route-target {
                    export "target:64502:1"
                    import "target:64501:1"
                }
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
        }
```

The Route Distinguisher (RD) is auto-derived from EVI 1, but the route target (RT) should not be auto-derived, because the export RT on PE-1 must match the import RT on PE-4, and vice versa. It is an option to configure an identical RT on all PEs, such as 1:1, but in this example, the export RT on PE-1 is 64501:1, which equals the import RT on PE-4. When the RTs do not match, the BGP routes will be received at the PE in the peer AS, but they will not become active and no mLDP P2MP tree can be established.

Multi-hop BGP peering is configured between PE-1 and PE-4 for address family EVPN. The external BGP configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        bgp {
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            group "eBGP" {
                multihop 10
                peer-as 64502
                family {
                    evpn true
                }
                local-as {
                    as-number 64501
                }
            }
            neighbor "192.0.2.4" {
                group "eBGP"
            }
```

The external BGP configuration on PE-4 is similar, but the local AS and peer AS are swapped, and the neighbor IP address is different.

Inter-AS Model C for mLDP - Verification

The following BGP summary shows that P-2 has sent and received two prefixes with its eBGP peer P-3 and has advertised two prefixes to its iBGP peer PE-1:

```
[/]

       k = RIB-API or Forwarding Policy backup hop
===============================================================================
```

The tunnels toward P-3 and PE-4 are BGP tunnels. The SDP in the list is auto-created on the root node by mLDP. The output of these show commands on PE-4 is similar, but no SDP will be created on a leaf-only node.

The route-table on ASBR P-2 includes tunneled routes toward P-3 and PE-4 and a static route to 192.168.23.2/32, as follows:

```
[/]
A:admin@P-2# show router route-table

===============================================================================

```

Optimized Inter-AS Model C for mLDP

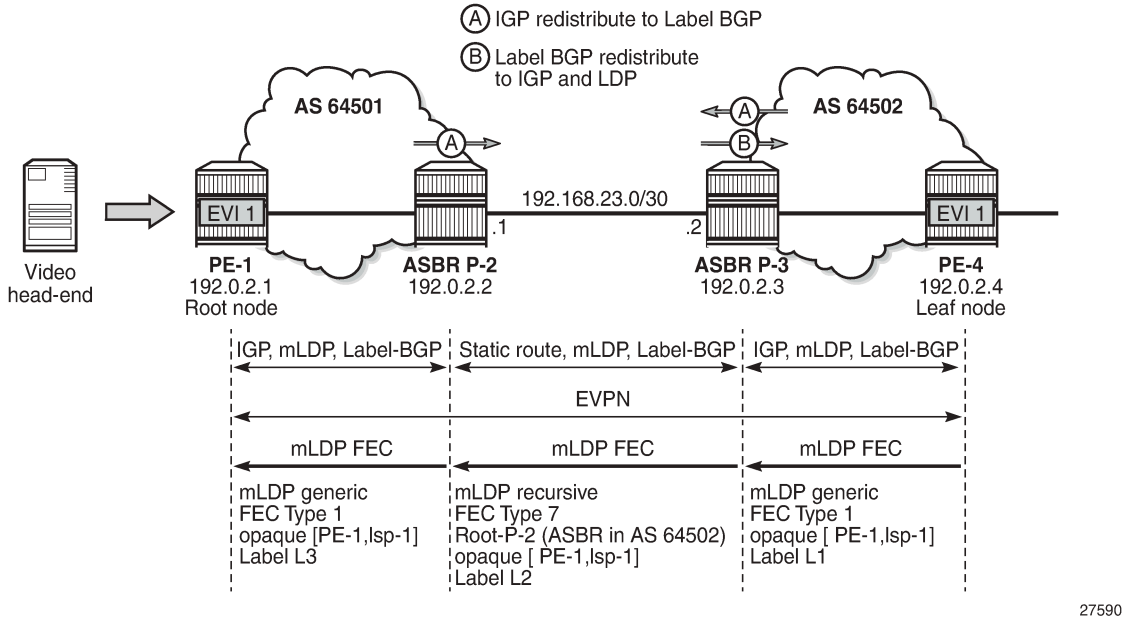
When some leaf nodes do not support labeled BGP routes or recursive opaque mLDP label mapping, the ASBR in the AS where the leaf nodes are situated needs to leak the root IP address into the leaf PE

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

IGP, which allows the leaf node PE-4 to send a generic FEC type 1 to join the root. The recursive opaque functionality is pushed to the local ASBR P-3.

Figure 263: Example topology for optimized Inter-AS Model C for mLDP shows the example topology for the optimized inter-AS model C for mLDP.

Figure 263: Example topology for optimized Inter-AS Model C for mLDP



The configuration starts with the configuration in the preceding section Inter-AS Model C for mLDP. The policy to export system prefixes from the ASs to labeled BGP is already configured and applied on both ASBRs. The following additional policies are defined on ASBR P-3 in the AS of the leaf node to export labeled BGP routes to OSPF and to LDP.

```
# on ASBR P-3:
configure {
    policy-options {
        policy-statement "bgpToLdp" {
            entry 10 {
                from {
                    protocol {
                        name [bgp-label]
                    }
                }
                to {
                    protocol {
                        name [ldp]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
        policy-statement "bgpToOspf" {
            entry 10 {
                from {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    protocol {
                        name [bgp-label]
                    }
                }
                to {
                    protocol {
                        name [ospf]
                    }
                }
                action {
                    action-type accept
                }
            }
        }
```

Policy "bgpToOspf" is configured in the OSPF context and policy "bgpToLdp" in the **ldp** context, as follows:

```
# on ASBR P-3:
configure {
    router "Base" {
        ldp {
            export-tunnel-table ["bgpToLdp"]
        }
        ospf 0 {
            export-policy ["bgpToOspf"]
        }
```

Optimized Inter-AS Model C for mLDP - Verification

The prefixes from AS 64501 are now exported to OSPF and LDP in AS 64502; therefore, leaf node PE-4 will no longer use the labeled BGP routes to a node in AS 64501.

```

Root node PE-1 will send an IMET-P2MP-IR route to leaf node PE-4. PE-4 will send an mLDP label mapping message type 1 instead of type 7, because there is an LDP tunnel toward PE-1 instead of a BGP tunnel. The only P2MP mLDP binding on leaf node PE-4 is a generic P2MP binding, as follows:

```
[/]
A:admin@PE-4# show router ldp bindings p2mp summary ipv4
 No. of Generic IPv4 P2MP Bindings: 1
 No. of In-Band-SSM IPv4 P2MP Bindings: 0
 No. of In-Band-VPN-SSM IPv4 P2MP Bindings: 0
 No. of Recursive with In-Band-SSM IPv4 P2MP Bindings: 0
 No. of VPN Recursive with Generic IPv4 P2MP Bindings: 0
 No. of GRT Recursive with Generic IPv4 P2MP Bindings: 0
```

PE-4 sends the following mLDP label mapping message type 1 with root address 192.0.2.1 (PE-1) to its peer P-3.

```
15 2021/06/02 08:39:21.702 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 100) to 192.0.2.3:0
Protocol version = 1
Label 524279 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 8193
"
```

The following generic P2MP mLDP binding for root address 192.0.2.1 is seen on PE-4:

```

```

The P2MP mLDP bindings on P-2 and PE-1 are the same as in the previous non-optimized inter-AS model C for mLDP scenario. P-2 has one GRT recursive mLDP binding to P-3 and one generic mLDP binding to root node PE-1, whereas PE-1 only has a generic mLDP binding to P-2.

The following command on root node PE-1 shows that an EVPN-MPLS destination is created to the leaf node PE-4. This EVPN destination runs over a BGP tunnel and can transport multicast (BUM) traffic. However, as discussed in the preceding section, the EVPN destination is used for BUM traffic only in the case where the provider tunnel goes operationally down.

```
[/]
A:admin@PE-1# show service id 1 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest
===============================================================================
TEP Address     Egr Label     Num. MACs   Mcast           Last Change
                Transport:Tnl                             Sup BCast Domain
```

© 2026 Nokia.

-------------------------------------------------------------------------------
192.0.2.1       524284        0           bum             06/02/2021 08:31:14
                ldp:65538                                 No
-------------------------------------------------------------------------------
Number of entries : 1
-------------------------------------------------------------------------------
===============================================================================
---snip---
```

The other **show** commands in the Inter-AS Model C for mLDP section have an identical output for both scenarios.

Conclusion

P2MP mLDP is supported in inter-AS model C for EVPN-MPLS services with or without optimization. Optimization in this chapter refers to the ability to set up an end-to-end mLDP tunnel without the need for recursive opaque mLDP FECs on the leaf nodes. A similar configuration is applied in the case of seamless MPLS across different areas.

P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services

This chapter provides information about P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 14.0.R4, but the CLI in the current edition is based on SR OS Release 23.3.R3.

Point-to-Multipoint (P2MP) multicast Label Distribution Protocol (mLDP) tunnels for Broadcast, Unknown unicast, and Multicast (BUM) traffic in Ethernet Virtual Private Network Multiprotocol Label Switching (EVPN-MPLS) networks are supported in SR OS Release 14.0.R1, and later. Internet Group Management Protocol (IGMP) snooping support for EVPN-MPLS services is supported in SR OS Release 14.0.R4, and later.

Overview

Service providers are moving their existing VPN services to EVPN. Providers using P2MP LSPs for VPLS services expect the same capabilities in EVPN. Before SR OS Release 14.0.R1, only Ingress Replication (IR) was supported. This works well for broadcast and unknown unicast traffic, but it is inefficient for multicast. Ingress replication does not use a multicast mechanism. Instead, the parent node makes n individual copies and unicasts each copy through an MPLS or IP tunnel to each child node.

BUM traffic is sent from a root node to a number of leaf nodes, but leaf nodes are also allowed to send BUM traffic to root nodes. If most BUM traffic is flowing from a few root nodes to leaf nodes, it would be inefficient to promote all leaf nodes to root-and-leaf nodes because of the amount of P2MP tunnels that would need to be set up. Another solution is to use a combination of P2MP mLDP and ingress replication (IR) tunnels in the service. The root nodes send BUM traffic using P2MP tunnels while the leaf nodes use IR tunnels to send BUM traffic to the root nodes. This avoids the need to set up a P2MP tree from each leaf, while it still allows leaf nodes to send BUM traffic to the root nodes.

Figure 264: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a multicast mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7.

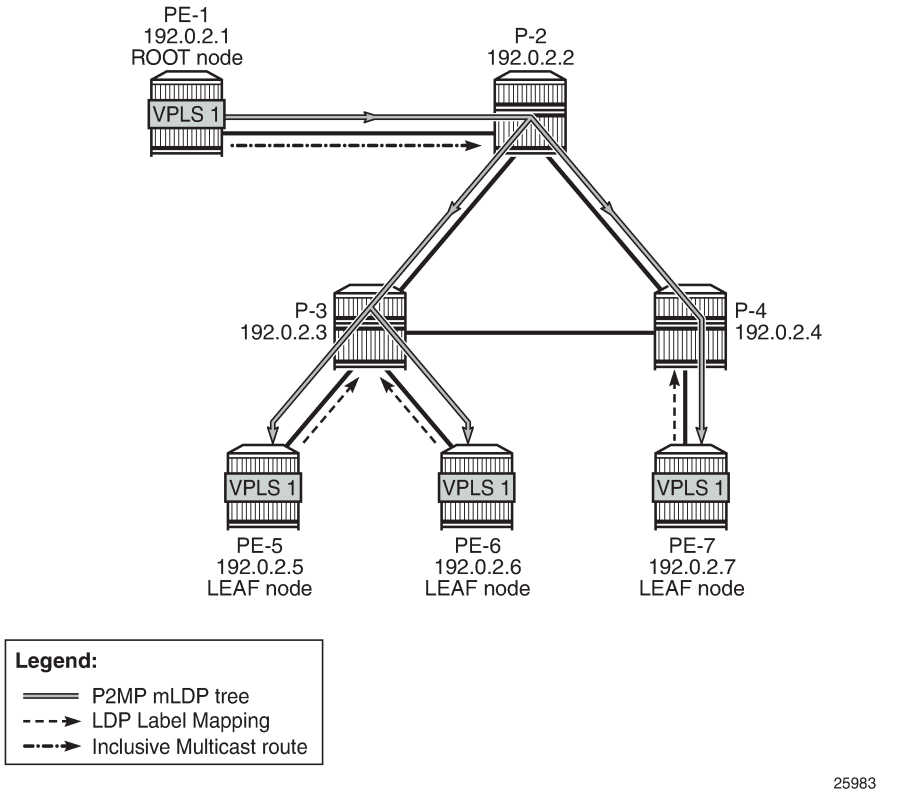
Figure 264: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7



The Inclusive Multicast Ethernet Tag (IMET) route (EVPN route type 3) sent by root node PE-1 contains the required information to set up an mLDP tree, such as the root node IP address and an opaque value. As described in chapter "Multicast Label Distribution Protocol" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR MPLS Advanced Configuration Guide for Classic CLI*, the mLDP tree is set up from the leaf nodes toward the root.

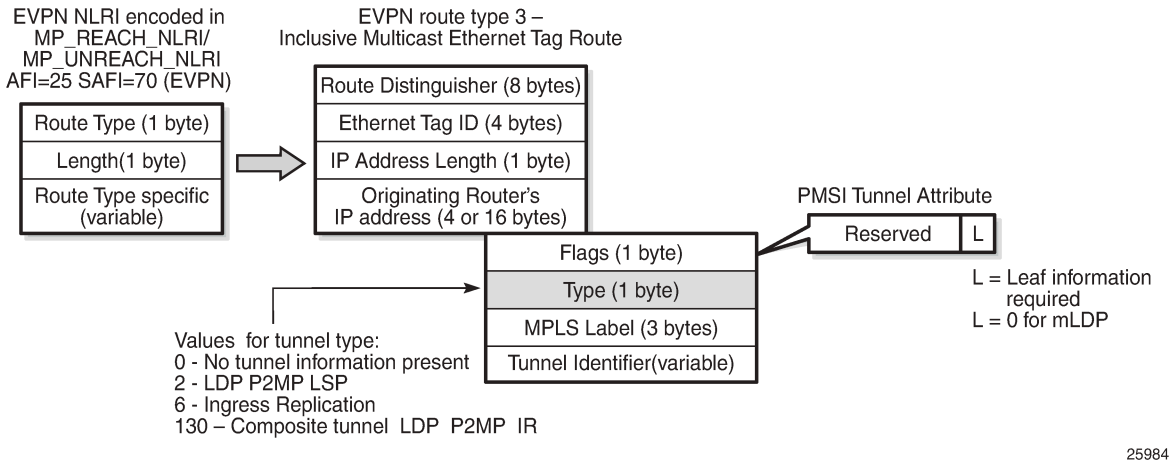
The LDP label mapping message contains the root node address, an opaque value, and an MPLS label. The leaf nodes send an LDP label mapping message to their upstream next hop toward the root node of the tree. Each transit node that has received such LDP label mapping message generates a new LDP label mapping message to its upstream next hop toward the root. This is repeated until the root node receives an LDP label mapping message and the multicast tree is completed.

Figure 264: P2MP mLDP tree with root node PE-1 and leaf nodes PE-5, PE-6, and PE-7 shows a P2MP mLDP tree rooted in PE-1, which is optimal for multicast traffic. However, no P2MP mLDP tree needs to be rooted in PE-5, PE-6, and PE-7 for the reverse direction. These three PEs can use IR to send traffic to the root (and to the other leaf nodes if needed).

EVPN route type 3 is used for setting up the flooding tree for a specified VPLS service. EVPN route type 3 includes the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PMSI Tunnel Attribute = PTA), which can have different formats depending on the tunnel type; see Figure 265: BGP-EVPN route type 3 with PTA.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 265: BGP-EVPN route type 3 with PTA



The following route values are used for EVPN-MPLS services:

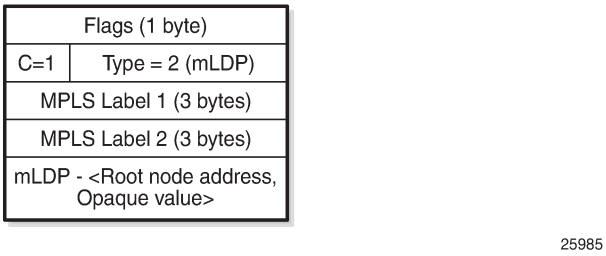
- The route distinguisher (RD) is taken from the RD of the VPLS service, which can be configured in the BGP context or auto-derived from the BGP-EVPN EVPN Instance (EVI) value. In this case, the RD is auto-derived from the EVI, resulting in a value of 192.0.2.1:1 for VPLS 1 on PE-1.
- The Ethernet tag ID equals 0.
- The IP address length equals 32.
- The originating router's IP address carries the IPv4 system address.
- The PTA can have different formats depending on the tunnel type enabled in the service. The SR OS EVPN-MPLS implementation supports the following tunnel types (SR OS supports different tunnel types for EVPN-VXLAN):
  - Tunnel type 2 - P2MP mLDP
    - The route is referred to as an Inclusive Multicast Ethernet Tag Point-to-Multipoint (IMET-P2MP).
    - Flags: leaf not required.
    - The MPLS label is zero.
    - The tunnel identifier includes the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join to the mLDP P2MP tree.
  - Tunnel type 6 - Ingress Replication (IR)
    - The route is referred to as an Inclusive Multicast Ethernet Tag Ingress Replication (IMET-IR).
    - Flags: leaf not required.
    - The MPLS label is a non-zero, downstream allocated label. This MPLS label is allocated to the service and is the same for unicast MAC/IP routes for the same service, unless **ingress-replication-bum-label** is configured in the service.
    - The tunnel identifier is the tunnel endpoint and is equal to the originating IP address.
  - Tunnel type 130 - Composite tunnel: Type: C-bit (composite) + type 2 (mLDP)
    - The route is referred to as an IMET-P2MP-IR.
    - Flags: leaf not required.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MPLS label 1 equals zero.
- MPLS label 2 is a non-zero, downstream allocated label (as any other IR label). The leaf nodes use the label to set up an EVPN-MPLS binding to the root and add it to the default multicast list.
- The mLDP tunnel identifier is the root node address and an opaque number. This is the tunnel identifier that the leaf nodes use to join the mLDP P2MP tree.

Figure 266: PTA for composite tunnel IMET-P2MP-IR shows the PTA for tunnel type 130.

Figure 266: PTA for composite tunnel IMET-P2MP-IR



The composite bit C is set, indicating that the PTA identifies two tunnels: the transmit tunnel is a P2MP mLDP tunnel and the receive tunnel is an IR tunnel.

IMET-P2MP-IR routes

The composite tunnel type is an optimized solution that combines mLDP and IR within the same EVPN service so that each root node sends BUM traffic using the P2MP tunnel whereas each leaf-only node sends BUM traffic to the root node using IR.

- PEs configured with **root-and-leaf** can send all BUM traffic over P2MP mLDP tunnels while they receive BUM traffic either over P2MP mLDP tunnels (from other root-and-leaf nodes) or over ingress-replication tunnels (from leaf-only nodes).
- PEs configured without **root-and-leaf** (default setting) can use IR to send BUM traffic to root nodes and other leaf-only nodes, while receiving BUM traffic over either P2MP mLDP tunnels (from root nodes) or ingress-replication tunnels (from leaf-only nodes).

The root PEs signal an IMET-P2MP-IR route, indicating that they intend to transmit BUM traffic using an mLDP P2MP tunnel, while they can receive traffic over an IR EVPN-MPLS binding. Composite tunnels reduce the number of P2MP mLDP tunnels that the PE/P routers in the EVI need to handle, because no full mesh of P2MP tunnels among all the PEs in the EVI is required. This is important (in terms of scaling) in services where there are just a pair of root nodes sending BUM in P2MP tunnels and hundreds of leaf nodes that only need to send BUM traffic to the root nodes using IR tunnels.

Configuration

Initial configuration

The PE and P nodes have the following initial configuration:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The ports between the routers are configured as network ports and have router interfaces configured.
- IS-IS is enabled on all the router interfaces.
- LDP is enabled on all the router interfaces.
- BGP is enabled on all PEs with route reflector (RR) P-2. The BGP configuration on RR P-2 is as follows:

```
# On P-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-import true
            vpn-apply-export true
            peer-ip-tracking true
            rapid-withdrawal true
            split-horizon true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
            neighbor "192.0.2.6" {
                group "internal"
            }
            neighbor "192.0.2.7" {
                group "internal"
            }
        }
    }
```

Configure EVPN P2MP mLDP in VPLS Service

On the root node PE-1, VPLS 1 is configured as follows:

```
# On PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
            sap 1/2/c3/1 {    # sap for ingress traffic from STC
            }
        }
    }
```

The configuration options in the **bgp-evpn** context of the VPLS are as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            bgp-evpn ?
*[ex:/configure service vpls "VPLS 1"]
A:admin@PE-1#             bgp-evpn ?

 bgp-evpn

 accept-ivpls-evpn-    - Accept and process non-zero ethernet-tag MAC routes
  flush
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 evi                   - EVPN ID
 ignore-mtu-mismatch   - Ignore MTU mismatch
 incl-mcast-orig-ip    - Originating IP address
 isid-route-target     + Enter the isid-route-target context
 mac-duplication       + Enter the mac-duplication context
 mpls                  + Enter the mpls list instance
 routes                + Enter the routes context
 segment-routing-v6    + Enter the segment-routing-v6 list instance
 vxlan                 + Enter the vxlan list instance
```

By default, the advertisement of the inclusive multicast route with IR is enabled (**ingress-repl-inc-mcast-advertisement**). However, if it is disabled, the router does not send the IMET-IR or IMET-P2MP-IR routes, regardless of the service being enabled for BGP EVPN-MPLS or BGP EVPN-VXLAN.

For information about the other parameters in the **bgp-evpn** context of the VPLS, see chapters EVPN for VXLAN Tunnels (Layer 2) and EVPN for MPLS Tunnels.

The configuration options in the **provider-tunnel inclusive** context are as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            provider-tunnel {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
               inclusive ?
*[ex:/configure service vpls "VPLS 1" provider-tunnel]
A:admin@PE-1#                inclusive ?

 inclusive

 admin-state           - Administrative state of P2MP LSP as the I-PMSI
 data-delay-interval   - I-PMSI data delay timer
 owner                 - Configure provider-tunnel owner
 root-and-leaf         - Configure whether the provider tunnel acts as a leaf or both a root
 and leaf

 Choice: ipmsi
 mldp                 :- Enable/Disable MLDP
 rsvp                 :+ Enter the rsvp context
```

- The **data-delay-interval** is configured in seconds in the range from 3 to 180 seconds. A node configured with **root-and-leaf** sends all BUM packets (data plane and control plane: ARP, CCMs, and so on) to its provider tunnel after the delay-data-interval has expired. This timer keeps the provider tunnel operationally down until its expiration, and, during that time, the router can use the EVPN-MPLS destinations typically used for IR.
- mLDP is enabled by adding the keyword **mldp** and enabling the provider tunnel (**admin-state enable**).
- The owner must be **bgp-evpn-mpls** if MPLS is enabled in the EVPN.

```
configure {
    service {
        vpls "VPLS 1" {
            provider-tunnel {
                inclusive {
                    owner ?
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
A:admin@PE-1#                    owner ?

 owner <keyword>
 <keyword> - (bgp-ad|bgp-vpls|bgp-evpn-mpls)
```

Only one of the three possible owner protocols supports the provider tunnel in the service and needs to be set before the provider tunnel can be enabled. By default, no owner is configured. The following error is raised when a user wants to enable the provider tunnel without an owner:

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
MINOR: SVCMGR #12: configure service vpls "VPLS 1" provider-tunnel inclusive admin-state
 - Inconsistent Value error
 - no owner configured for the provider tunnel
```

After the provider tunnel has an owner and is enabled, the owner can only be changed when the provider tunnel is disabled.

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" provider-tunnel inclusive owner
 - the enabled provider-tunnel cannot have owner set to bgp-vpls when evpn-mpls is enabled
 - configure service vpls "VPLS 1" bgp-evpn mpls 1 admin-state
```

After the owner is set, the corresponding protocol is checked to see if it is enabled in the service configuration.

```
*[ex:/configure service vpls "VPLS 1" provider-tunnel inclusive]
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
MINOR: SVCMGR #12: configure service vpls "VPLS 1" provider-tunnel inclusive admin-state
 - Inconsistent Value error
 - bgp-vpls must be configured when the provider tunnel with owner bgp-vpls is enabled
 - configure service vpls "VPLS 1"
```

- If **ingress-repl-inc-mcast-advertisement** is enabled and the PE is configured with **root-and-leaf**, the router sends an IMET-P2MP-IR route; if the PE is configured without **root-and-leaf** (default), the router sends an IMET-IR route. However, if **ingress-repl-inc-mcast-advertisement** is disabled and the PE is configured with **root-and-leaf**, the router only sends IMET-P2MP routes. Leaf-only nodes do not send any IMET routes at all in case no IR multicast advertisement is allowed.

  Root-and-leaf nodes only send BUM traffic to the P2MP tunnel as long as it is active. If the P2MP tunnel goes operationally down, it starts sending BUM traffic to IR tunnels (EVPN-MPLS destinations shown in the **show service id 1 evpn-mpls** command).
- If a provider tunnel is configured on a node, the router can join P2MP trees as a leaf, by generating an LDP label mapping message including the corresponding P2MP mLDP FEC. If no provider tunnel is configured, the node does not join P2MP mLDP trees, and can only use IR for BUM.
- If one node is configured as root, all other nodes must be configured with provider tunnels; otherwise, they do not receive BUM traffic sent on P2MP tunnels. The configuration of leaf-only node PE-5 is as follows, the main difference with the configuration for the root being the absence of **root-and-leaf** (default setting):

```
# On PE-5:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {

            }
        }
    }
```

As described, the tunnel types for BUM traffic are controlled by **ingress-repl-inc-mcast-advertisement** and the **provider-tunnel** context (**root-and-leaf**). The IMET route sending behavior is summarized in Table 19: IMET routes and Tunnel Types advertised based on the configuration .

```

Note:
The same IMET-P2MP route cannot be imported by two services at the same time. If two VPLS services (where a provider tunnel is enabled) have the same import route-target, only one service joins the mLDP tree (whichever comes first).

EVPN P2MP mLDP operation

After the root node and leaf nodes are configured as shown, the root node sends BGP EVPN composite IMET-P2MP-IR routes, as follows:

```
# On PE-1:
2 2023/07/03 22:26:27.189 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

        MPLS Label1 Ag  0
        MPLS Label2 IR 8388480
        Root-Node 192.0.2.1, LSP-ID 0x2001
"
```

The PTA for tunnel type 130 (composite tunnel) has two MPLS labels, of which MPLS label 1 equals zero. MPLS label 2 is used by the downstream nodes to set up the EVPN-MPLS destination to the root node and add it to the default multicast list. The actual MPLS label only uses the high-order 20 bits out of the 24 bits advertised in the MPLS label. Therefore, the value 8388480 needs to be divided by 16 to have the MPLS label: 8388480/16 = 524280. This is because the debug message is shown before the router can parse the label field and see whether it corresponds to an MPLS label (20 bits) or a VXLAN VNI (24 bits).

The tunnel identifier field contains the root node address 192.0.2.1 and the opaque value 0x2001, which corresponds to decimal value 8193. With this tunnel identifier, the leaf nodes can join the mLDP multicast tree toward the root node by sending LDP label mapping messages that contain the root node IP address and the opaque value.

Note:
When static P2MP mLDP tunnels and dynamic P2MP mLDP tunnels used by BGP-EVPN coexist on the same router,Nokia recommends that the static tunnels use a tunnel ID less than 8193. If a tunnel ID is statically configured with a value equal to or greater than 8193, BGP-EVPN may attempt to use the same tunnel ID for services with an enabled provider tunnel and fail to set up an mLDP tunnel.

The root node PE-1 receives IMET-IR routes from all leaf nodes, as shown for the BGP update sent by leaf node PE-5 (via RR P-2):

```
# On PE-1:
3 2023/07/03 22:28:45.189 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

The PTA tunnel type 6 for IR has only one MPLS label, which corresponds to the MPLS label 524280 allocated for the service. The tunnel identifier is the tunnel endpoint 192.0.2.5, which is the system address of the originating leaf node.

On leaf node PE-5, three BGP EVPN inclusive multicast routes have been learned and are used, as follows:

```
[/]
A:admin@PE-5# show router bgp routes evpn incl-mcast

The MPLS label is 524280, as described. The LSP ID equals 8193, which corresponds to the hexadecimal value 0x2001 in the preceding BGP update message sent by the root node PE-1.

To set up the mLDP tree, leaf node PE-5 has generated an LDP label mapping message to the next hop router toward the root, P-3. The label mapping message includes the root address 192.0.2.1, the opaque value 8193, and MPLS label 524279, as follows:

```

VPLS 1 Inclusive Provider Tunnels Terminating
===============================================================================
ipmsi (LDP)                                     P2MP-ID  Root-Addr
-------------------------------------------------------------------------------
                                                8193    192.0.2.1

-------------------------------------------------------------------------------
---snip---
```

The inclusive provider tunnels are identified by the combination of the P2MP ID (opaque value) and the root address. These parameters are in every label mapping message and they are included in the PTA tunnel identifier for tunnel type 130 (IMET-P2MP-IR) and for tunnel type 2 (IMET-P2MP).

In VPLS 1 on root node PE-1, an SDP of type VplsPmsi is auto-created, as follows:

```
[/]
A:admin@PE-1# show service id 1 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl
-------------------------------------------------------------------------------

IGMP snooping

When IGMP snooping is disabled and a multicast stream enters VPLS 1 on the root node, this stream is sent to all the leaf nodes, even if no receivers join the multicast group on the leaf nodes. In this example, a receiver connected to PE-5 joins a multicast group, but there are no receivers for any multicast group on PE-6 and PE-7. By default, IGMP is disabled and the multicast stream is flooded to all leaf PEs, as can be verified with the following monitor command on PE-6 where no receivers have joined any multicast stream:

```
[/]
A:admin@PE-6# monitor port all-ethernet-rates repeat 15 interval 4

=======================================================================
Monitor statistics for all Ethernet Port Rates

This implies that bandwidth is wasted, which can be prevented by enabling IGMP snooping. IGMP snooping ensures that multicast traffic is only sent to the receivers that joined a multicast group. IGMP snooping can be enabled in VPLS 1 on all PEs, as follows:

```
configure {
    service {
        vpls "VPLS 1" {
            igmp-snooping {
                admin-state enable
            }
```

A receiver connected to PE-5 has sent an IGMP report whereas PE-6 has no receivers that joined a multicast group. The traffic counters are monitored on the outgoing port to the (potential) receivers. On PE-5, traffic is sent to the receiver, as follows:

```
[/]
A:admin@PE-5# monitor port all-ethernet-rates repeat 15 interval 4

IGMP snooping can be enabled in EVPN-MPLS services with IR or provider-tunnel mLDP trees. When IGMP snooping is enabled on the VPLS, all the EVPN-MPLS destinations are added to the MFIB as a single router interface. IGMP queries and reports are properly forwarded to and from EVPN-MPLS destinations.

The following shows the EVPN-MPLS destinations as part of the MFIB when IGMP snooping is enabled:

```
[/]
A:admin@PE-5# show service id 1 mfib

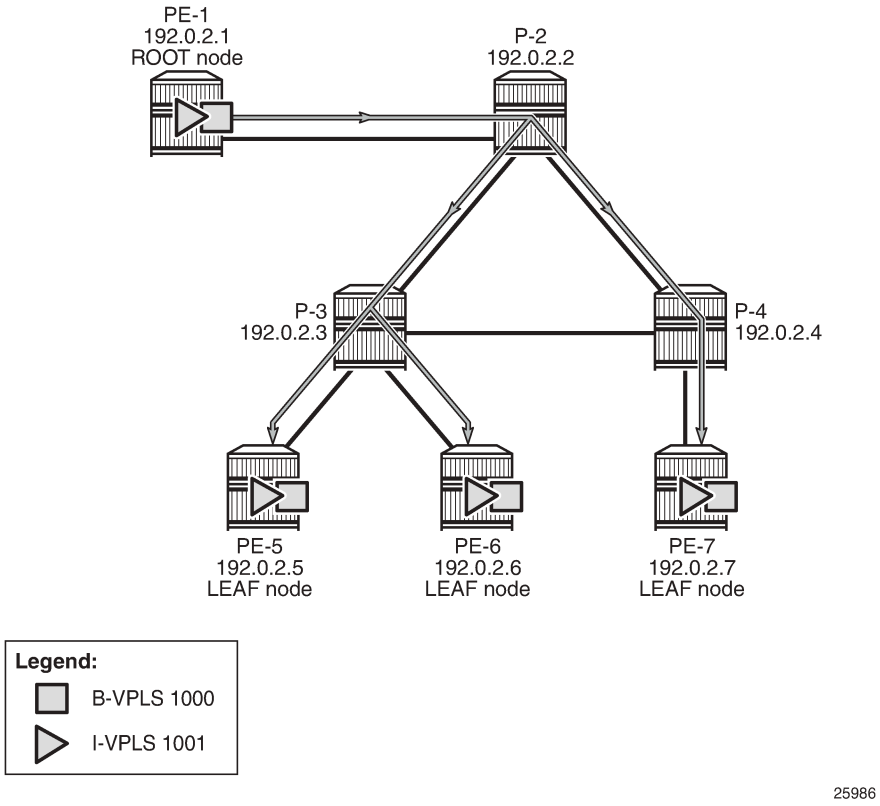
PBB-EVPN and P2MP mLDP

Provider Backbone Bridging (PBB) EVPN is described in chapter EVPN for PBB over MPLS (PBB-EVPN).

Figure 267: P2MP mLDP in PBB-EVPN shows the setup for P2MP mLDP in PBB-EVPN.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 267: P2MP mLDP in PBB-EVPN



P2MP mLDP tunnels can also be used in PBB-EVPN services. In Release 14.0, the use of **provider-tunnel inclusive mldp** is only for the default multicast list; no per-ISID IMET-P2MP routes are supported.

The Backbone (B) -VPLS still uses Multicast Forwarding Information Bases (MFIBs) for ISIDs using IR.

If an ISID policy is configured in the B-VPLS, a range of ISIDs configured with **use-def-mcast** use the P2MP tree, and a range of ISIDs configured with **advertise-local** make the router advertise IMET-IR routes for the local ISIDs in the range.

PE-1 is configured with **root-and-leaf**. The configuration for B-VPLS and I-VPLS is as follows:

```
# On PE-1:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                }
            }
            bgp 1 {
            }
            bgp-evpn {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
            isid-policy {
                entry 10 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 1001
                        end 2000
                    }
                }
            }
        }
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            sap 1/2/c3/1 {    # sap for ingress traffic from STC
            }
        }
    }
```

In this example, ISIDs in the range from 1001 to 2000 use the P2MP tree (**use-def-mcast**) and the router does not advertise the IMET-IR routes for the local ISIDs included in that range (**no advertise-local**). Any other local ISID advertises an IMET-IR and uses the MFIB to forward BUM packets to the remote EVPN-MPLS bindings created by IMET-IR routes.

The configuration on the leaf nodes PE-5, PE-6, and PE-7 is similar to the one for the root node, except for the absence of the **root-and-leaf** setting (which is default), as follows:

```
# On PE-5:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:05
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
            isid-policy {
                entry 10 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 1001
                        end 2000
                    }
                }
            }
        }
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            sap 1/2/c1/1:1001 {    # sap for egress traffic to VPLS 1001
            }
        }
    }
```

A VPLS-PMSI SDP is auto-created in the B-VPLS at the root node, as follows:

```
[/]
A:admin@PE-1# show service id 1000 sdp

===============================================================================
Services: Service Destination Points
===============================================================================
SdpId            Type     Far End addr    Adm     Opr       I.Lbl     E.Lbl

32767:4294967292 VplsPmsi not applicable  Up      Up        None      3
-------------------------------------------------------------------------------
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The default multicast list for the B-VPLS 1000 can be retrieved on root node and leaf nodes, for instance for leaf node PE-5, as follows:

```
[/]
A:admin@PE-5# tools dump service id 1000 evpn-mpls default-multicast-list
-------------------------------------------------------------------------
TEP Address                           Egr Label
                                      Transport
-------------------------------------------------------------------------
192.0.2.1                             524283
                                      ldp
192.0.2.6                             524286
                                      ldp
192.0.2.7                             524281
                                      ldp
-------------------------------------------------------------------------
```

IGMP snooping can be enabled in the I-VPLS 1001 on all PEs, as follows:

```
configure {
    service {
        vpls "I-VPLS 1001" {
            igmp-snooping {
                admin-state enable
            }
```

After IGMP snooping is enabled, the multicast stream is not flooded anymore to any receivers until they send an IGMP report for the multicast stream.

On each PE, the logical interface B-EVPN-MPLS is added as a single IGMP snooping interface and treated as an mrouter, as follows:

```
[/]
A:admin@PE-5# show service id 1001 igmp-snooping base

===============================================================================
IGMP Snooping Base info for service 1001
===============================================================================

===============================================================================
```

PE-5 has a receiver that sent an IGMP report for a multicast group in I-VPLS 1001 on SAP 1/2/c1/1:1001 and this SAP is an mrouter port. On PE-6, there is no receiver that sent IGMP reports; therefore, the only mrouter port corresponds to the B-EVPN-MPLS logical interface, as follows:

```
[/]
A:admin@PE-6# show service id 1001 igmp-snooping base

===============================================================================
```

-------------------------------------------------------------------------------
Number of mrouters: 1
===============================================================================
```

Conclusion

Service providers are migrating their existing VPN services to EVPN and expect at least the same capabilities in EVPN, including the forwarding of BUM traffic. Ingress replication is a good mechanism for broadcast and unknown unicast traffic in EVPN networks, but not efficient for multicast applications. EVPN P2MP mLDP offers efficiency for multicast, using composite tunnels combining the benefits of P2MP mLDP and IR.

PBB-Epipe

This chapter provides information about Provider Backbone Bridging (PBB) — Ethernet Virtual Leased Line in an MPLS-based network which is applicable to SR OS.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 7.0.R5. The MD-CLI in the current edition corresponds to SR OS Release 20.10.R2. There are no specific prerequisites.

Overview

RFC 7041, *Extensions to VPLS PE model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

The PBB model is organized around a B-component (backbone instance) and an I-component (customer instance). In Nokia's implementation of the PBB model, the use of an Epipe as I-component is allowed for point-to-point services. Multiple I-VPLS and Epipe services can be all mapped to the same B-VPLS (backbone VPLS instance).

The use of Epipe scales the E-Line services because no MAC switching, learning, or replication is required in order to deliver the point-to-point service. All packets ingressing the customer SAP are PBB-encapsulated and unicasted through the B-VPLS tunnel using the backbone destination MAC of the remote PBB PE. All the packets egressing the B-VPLS destined for the Epipe are PBB de-encapsulated and forwarded to the customer SAP.

Some use cases for PBB-Epipe are:

- Get a more efficient and scalable solution for point-to-point services:
  - Up to 8K VPLS services per box are supported (including I-VPLS or B-VPLS) and using I-VPLS for point-to-point services takes VPLS resources as well as unnecessary customer MAC learning. A better solution is to connect a PBB-Epipe to a B-VPLS instance, where there is no customer MAC switching/learning.
- Take advantage of the pseudowire aggregation in the M:1 model:
  - Many Epipe services may use only a single service and set of pseudowires over the backbone.
- Have a uniform provisioning model for both point-to-point (Epipe) and multipoint (VPLS) services.

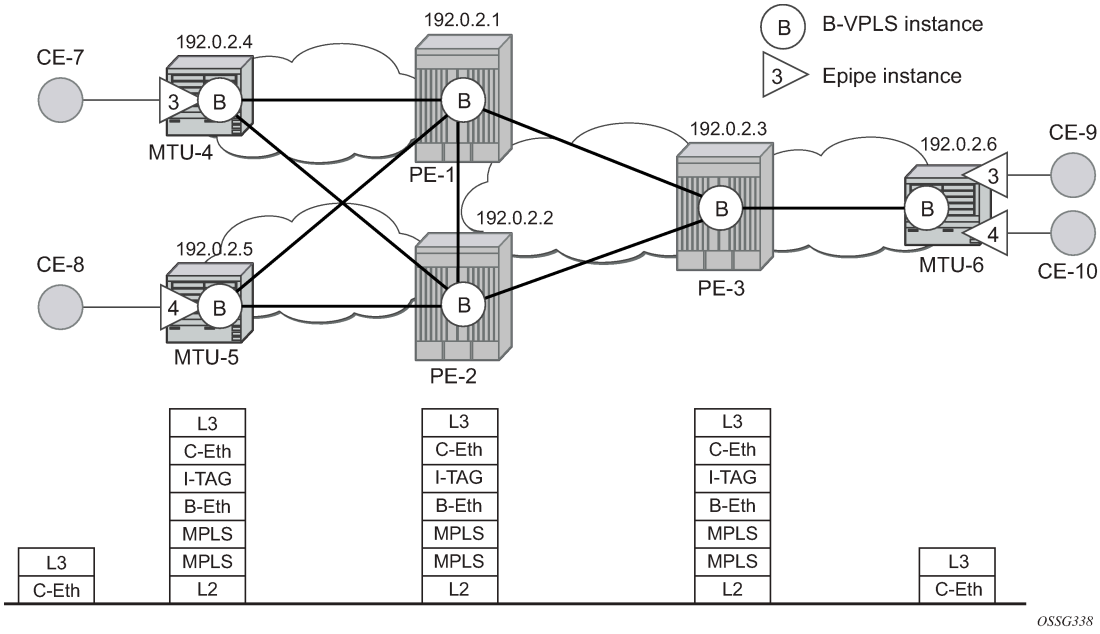
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

– Using the PBB-Epipe, the core MPLS/pseudowire infrastructure does not need to be modified: the new Epipe inherits the existing pseudowire and MPLS structure already configured on the B-VPLS and there is no need for configuring new tunnels or pseudowire switching instances at the core.

Knowledge of the PBB-VPLS architecture and functionality on the service router family is assumed throughout this section. For additional information, see the relevant Nokia user documentation.

Figure 268: Example topology shows the example topology that is used throughout the rest of the chapter.

Figure 268: Example topology



The setup consists of a three SR OS routers in the core (PE-1, PE-2, and PE-3) core and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 101) will be defined in all the six nodes, whereas two Epipe services will be defined as illustrated in Figure 268: Example topology (Epipe 3 in nodes MTU-4 and MTU-6, Epipe 4 in nodes MTU-5 and MTU-6). Those Epipe services will be multiplexed into the common B-VPLS 101, using the I-Service ID (ISID) field within the I-TAG as the demultiplexer field required at the egress MTU to differentiate each specific customer. I-VPLS and Epipe services can be mapped to the same B-VPLS.

The B-VPLS domain constitutes a H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby (A/S) spoke-SDPs can be used from the MTUs to the PEs (like in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (like MTU-6).

The protocol stack being used along the path between the CEs is represented in Figure 268: Example topology.

Configuration

This section describes all the relevant PBB-Epipe configuration tasks for the setup shown in Figure 268: Example topology. The appropriate B-VPLS and associated IP/MPLS configuration is out of the scope of this document. In this particular example, the following protocols will be configured beforehand in the core:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

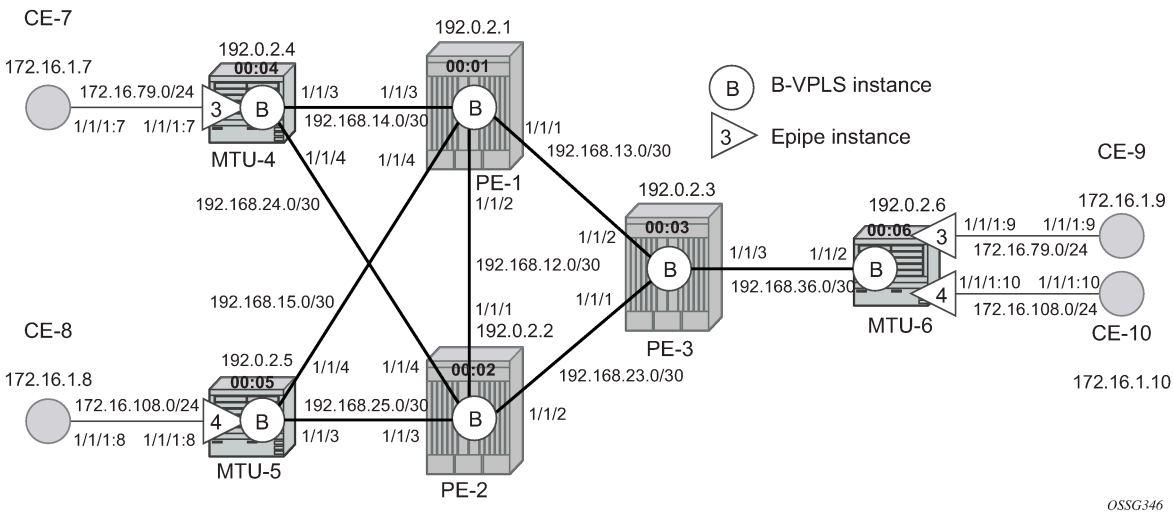
- ISIS-TE as IGP with all the interfaces being level-2. Alternatively, OSPF could have been used.
- RSVP-TE as the MPLS protocol to signal the transport tunnels.
- LSPs between core PEs will be fast re-route protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.
- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the A/S pseudowire protection configured in the B-VPLS.
- BGP is configured for auto-discovery—BGP-AD (Layer 2 VPN family), because FEC 129 will be used to establish the pseudowires between PEs in the core (FEC 128 between MTU and PE nodes).

Once the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB Epipe service configuration

Figure 269: Setup detailed view shows an example where the Epipes 3 and 4 are using the B-VPLS 101 in the core. The same B-VPLS which is multiplexing the Epipe services into a common service provider infrastructure can also be used to connect the I-VPLS instances existing in the network for multipoint services.

Figure 269: Setup detailed view



B-VPLS and PBB configuration

First, configure the B-VPLS instance that will carry the PBB traffic. There is no specific requirement on the B-VPLS to support Epipes. The following shows the B-VPLS configuration on MTU-4 and PE-1.

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:04:04:04:04:04
                }
            }
            endpoint "core" {
                suppress-standby-signaling false
            }
            spoke-sdp 41:101 {
                endpoint {
                    name "core"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 42:101 {
                endpoint {
                    name "core"
                }
                stp {
                    admin-state disable
                }
            }
        }
```

```
# on PE-1:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
            provisioned-sdp use
            split-horizon-group {
                name "CORE"
            }
        }
        vpls "B-VPLS 101" {
            admin-state enable
            service-id 101
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:01:01:01:01:01
                }
            }
            bgp 1 {
                route-target {
                    export "target:65000:101"
                    import "target:65000:101"
                }
                pw-template-binding "PW1" {
                }
            }
            bgp-ad {
                admin-state enable
                vpls-id "65000:101"
            }
            spoke-sdp 14:101 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            spoke-sdp 15:101 {
            }
        }
```

- The B-VPLS service MTU must be at least 18 bytes greater than the Epipe MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1514 bytes), therefore, any MTU equal or greater than 1532 bytes must be configured. In this particular example, an MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.
- The source B-MAC is the MAC that will be used as a source when the PBB traffic is originated from that node. It is possible to configure a source B-MAC per B-VPLS instance (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. A common B-MAC is configured as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
        }
```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported.
  - Default SAP types are blocked in the CLI for the B-VPLS SAP.
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowire, the outgoing PBB frame on an SDP (for example, Bpseudowire) contains a BVID q-tag only if the pseudowire type is Ethernet VLAN (vc-type=vlan). If the pseudowire type is Ethernet (vc-type=ether), the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS, therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group has been configured to emulate the behavior of mesh SDPs in the core.
- While Multiple MAC Registration Protocol (MMRP) is useful to optimize the flooding in the B-VPLS domain and build a flooding tree on a per I-VPLS basis, it does not have any effect for Epipes because the destination B-MAC used for Epipes is always the destination B-MAC configured in the Epipe and never the group B-MAC corresponding to the ISID.
- If a local Epipe instance is associated with the B-VPLS, local frames originated or terminated on local Epipe(s) are PBB encapsulated or de-encapsulated using the PBB Etype provisioned under the related port or SDP component.

By default, the PBB Etype is 0x88e7 (which is the standard one defined in the 802.1ah, indicating that there is an I-TAG in the payload) but this PBB Etype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
[ex:configure port 1/1/3 ethernet]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 <number> - <0x600..0xffff>
 Default  - 35047

    Ethertype for PBB encapsulation on the Ethernet port
```

```
[ex:configure service sdp 41]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 0x88E7

    Ethertype used in frames sent out on this SDP when VC type is 'vlan' for
    Provider Backbone Bridging frames
    as 0xXXYY with range 0x0600-0xFFFF.
```

The following commands are useful to check the actual PBB Etype.

```
[]
A:admin@MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                   PBB Etype          : 0x88e7
```

```
[]
A:admin@MTU-4# show port 1/1/3 | match PBB
PBB Ethertype      : 0x88e7
```

Before configuring the Epipe itself, the operator can optionally configure MAC names under the PBB context. MAC names will simplify the Epipe provisioning later on and in case of any change on the remote node MAC address, only one configuration modification is required as opposed as one change per affected Epipe (potentially thousands of Epipes which are terminated onto the same remote node). The MAC names are configured in the service PBB CLI context:

```
[ex:configure service pbb]
A:admin@MTU-4# mac ?

 [name] <string>
 <string> - <1..32 characters>

    MAC address name
```

The MAC names of the MTUs are configured on all nodes, as follows:

```
# on all nodes:
configure {
    service {
        pbb {
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
```

It is not required to configure a node with its own MAC address, so on MTU-4, the line defining the mac-name MTU-4 can be omitted.

Use subject to Terms available at: www.nokia.com/terms.

Epipe configuration

Once the common B-VPLS is configured, the next step is the provisioning of the customer Epipe instances. For PBB-Epipes, the I-component or Epipe is composed of an I-SAP and a PBB tunnel endpoint which points to the backbone destination MAC address (B-DA).

The following outputs show the relevant CLI configuration for the two Epipe instances represented in Figure 269: Setup detailed view. The Epipe instances are configured on the MTU devices, whereas the core PEs are kept as customer-unaware nodes.

Epipes 3 and 4 are configured on MTU-6 as follows:

```
# on MTU-6:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-4"
                }
            }
            sap 1/1/1:9 {
            }
        }
        epipe "Epipe 4" {
            admin-state enable
            description "pbb epipe number 4"
            service-id 4
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 4
                    backbone-dest-mac-name "MTU-5"
                }
            }
            sap 1/1/1:10 {
            }
        }
```

The following shows the Epipe configuration on MTU-4 and MTU-5.

```
# on MTU-4:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-6"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            sap 1/1/1:7 {
            }
        }
```

```
# on MTU-5:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            description "pbb epipe number 4"
            service-id 4
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 4
                    backbone-dest-mac-name "MTU-6"
                }
            }
            sap 1/1/1:8 {
            }
        }
```

All Ethernet SAPs supported by a regular Epipe are also supported in the PBB Epipe. spoke-SDPs are not supported in PBB-Epipes, for example, no spoke-SDP is allowed when PBB tunnels are configured on the Epipe.

The PBB tunnel links the SAP configured to the B-VPLS 101 existing in the core. The following parameters are accepted in the PBB tunnel configuration:

```
[ex:configure service epipe "Epipe 4" pbb]
A:admin@MTU-5# tunnel ?

 tunnel

 Immutable fields     - backbone-vpls-service-name, isid

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 backbone-vpls-        ^ Backbone VPLS service
  service-name
 isid                  ^ Service instance ID

 Mandatory choice: backbone-mac
 backbone-dest-mac    :- Backbone Destination MAC address
 backbone-dest-mac-   :- Name for backbone Destination MAC address
  name
```

Where:

- The backbone VPLS service name matches the B-VPLS name, in this case, "B-VPLS 101".
- The backbone destination can be configured by a MAC name (as in the configuration example, with MAC name "MTU-6") or the MAC address itself. It is recommended to use MAC names, as explained in the previous section.
- The ISID corresponds to the Epipe service ID and must be specified.

Flood avoidance in PBB-Epipes

As already discussed in the previous section, when provisioning a PBB Epipe, the remote backbone destination MAC (MAC name or MAC address) must be explicitly configured on the PBB tunnel so that the ingress PBB node can build the 802.1ah encapsulation.

If the configured remote backbone destination MAC address is not known in the local FDB, the Epipe customer frames will be 802.1ah encapsulated and flooded into the B-VPLS until the MAC address is learned. As previously stated, MMRP does not help to minimize the flooding because the PBB Epipes always use the configured backbone destination MAC for flooding traffic as opposed to the group B-MAC derived from the ISID.

Flooding could be indefinably prolonged in the following cases:

- Configuration mistake of the backbone destination MAC (either MAC name or MAC address). The service will not work, but the operator will not detect the mistake, because the customer traffic is not dropped at the source node. Every single frame is turned into an unknown unicast PBB frame and therefore flooded into the B-VPLS domain.
- Change the backbone source MAC in the remote PE B-VPLS instance.
- There is only unidirectional traffic in the Epipe service. In this case, the backbone destination MAC address will never be learned in the local FIB and the frames will always be flooded into the B-VPLS domain.
- The remote node owning the backbone destination MAC simply goes down.

In any of those cases, the operator can easily check whether the PBB Epipe is flooding into the B-VPLS domain, just by looking at the flood flag in the following command output:

```
[]
A:admin@MTU-4# show service id 3 base

In this particular example, the PBB Epipe 3 is flooding into the B-VPLS 101, as the flood flag indicates. The operator can also confirm that the operational destination B-MAC for the PBB tunnel, MTU-6, has not been learned in the B-VPLS FDB:

```
[]
A:admin@MTU-4# show service id 101 fdb pbb

===============================================================================
Forwarding Database, b-Vpls Service 101
===============================================================================
MAC               Source-Identifier     iVplsMACs  Epipes     Type/Age
-------------------------------------------------------------------------------
No Matching Entries
===============================================================================
```

In small B-VPLS environments (up to 20 B-VPLSs, each with 10 MC-LAGs), it is possible to configure the PBB V-VPLS MAC notification mechanism to send notification messages at regular intervals (using the renotify parameter), rather than being only event-driven. This can avoid flooding into the B-VPLS.

Flooding cases 1 and 2 — Wrong backbone destination MAC

Flooding cases 1 and 2 should be fixed after detecting the flooding (see previous commands) and checking the FDBs and PBB tunnel configurations.

Flooding case 3 — Unidirectional traffic: virtual MEP and CCM configuration

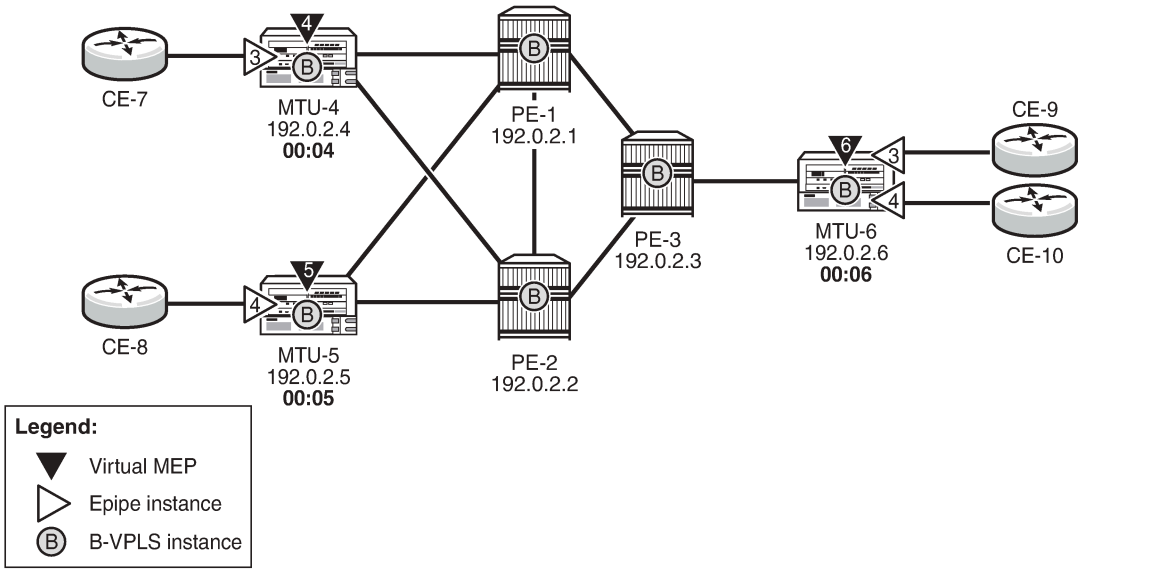
For flooding case 3 (unidirectional traffic), Nokia recommends the use of ETH-CFM (802.1ag/Y.1731 Connectivity Fault Management) virtual Maintenance End Points (MEPs). By defining a virtual MEP per node terminating a PBB Epipe, configuring the MEP MAC address to be the source BMAC value and activating continuity check messages (CCM), a twofold effect is achieved:

- The PBB tunnel backbone destination MAC address will always be learned at the local FDB, as long as the remote virtual MEP is active and sending CC messages. As a result, there will not be flooding even if we have unidirectional traffic.
- An automatic proactive OAM mechanism exists to detect failures on remote nodes, which ultimately cause unnecessary flooding in the B-VPLS domain.

Figure 270: Virtual MEPs for flooding avoidanceshows an example where the virtual MEPs MEP4, MEP5, and MEP6 are configured in B-VPLS 101:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 270: Virtual MEPs for flooding avoidance



The following configuration example uses MTU-4. First, the general ETH-CFM configuration is made, as follows:

```
# on MTU-4:
configure {
    eth-cfm {
        domain "domain-1" {
            level 3
            name "domain-1"
            md-index 1
            association "assoc-1" {
                icc-based "B-VPLS-000101"
                ma-index 1
                bridge-identifier "B-VPLS 101" {
                }
                remote-mep 5 {
                }
                remote-mep 6 {
                }
            }
```

Then the actual virtual MEP configuration is made:

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 101" {
            eth-cfm {
                mep md-admin-name "domain-1" ma-admin-name "assoc-1" mep-id 4 {
                    admin-state enable
                    mac-address 00:04:04:04:04:04
                    ccm true
                }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
```

The MAC address configured for the MEP4 matches the MAC address configured as the **source-bmac** on MTU-4, which is the **backbone-destination-mac** configured on the Epipe 3 PBB tunnel on MTU-6. The source-BMAC address on MTU-4 is 00:04:04:04:04:04, as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
```

In Epipe 3 on MTU-6, the configured backbone destination MAC name is MAC name "MTU-4", which corresponds to MAC address 00:04:04:04:04:04, as follows:

```
# on MTU-6:
configure {
    service {
        pbb {
            source-bmac {
                address 00:06:06:06:06:06
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
        epipe "Epipe 3" {
            admin-state enable
            description "pbb epipe number 3"
            service-id 3
            customer "1"
            pbb {
                tunnel {
                    backbone-vpls-service-name "B-VPLS 101"
                    isid 3
                    backbone-dest-mac-name "MTU-4"
                }
            }
            sap 1/1/1:9 {
            }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Once MEP4 has been configured, check that MTU-6 is receiving CC messages from MEP4 with the following command:

```
[]
A:admin@MTU-6# show eth-cfm mep 6 domain 1 association 1 all-remote-mepids

================================================================================
Eth-CFM Remote-Mep Table
================================================================================
R-mepId AD Rx CC RxRdi Port-Tlv If-Tlv Peer Mac Addr     CCM status since
--------------------------------------------------------------------------------
4          True  False Absent   Absent 00:04:04:04:04:04 01/11/2021 16:26:59
5          True  False Absent   Absent 00:05:05:05:05:05 01/11/2021 16:26:59
================================================================================
Entries marked with a 'T' under the 'AD' column have been auto-discovered.
```

As a result of the CC messages coming from MEP4, the MTU-4 MAC is permanently learned in the B-VPLS 101 FDB on node MTU-6 and no flooding takes place. The following output shows that the flooding flag is not set.

```
[]
A:admin@MTU-6# show service id 3 base

```

Flooding case 4 — Remote node failure

If the node owner of the backbone destination MAC fails or gets isolated, the node where the PBB Epipe is initiated will not detect the failure; that is, if MTU-4 fails, the Epipe 3 remote end will also fail, but MTU-6 will not detect the failure and, as a result of that, MTU-6 will flood the traffic to the network (flooding will occur after MTU-4 MAC is removed from the B-VPLS FDBs, due to either the B-VPLS flushing mechanisms or aging).

In order to avoid/reduce flooding in this case, the following mechanisms are recommended:

- Provision virtual MEPs in the B-VPLS instances terminating PBB Epipes, as already explained. This will guarantee there is no unknown B-MAC unicast being flooded under normal operation.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- CCM timers should be provisioned based on how long the service provider is willing to accept flooding.

```
[ex:configure eth-cfm domain "domain-1" association "assoc-1"]
A:admin@MTU-6# ccm-interval ?

 ccm-interval <keyword>
 <keyword> - (10ms|100ms|1s|10s|60s|600s)
 Default   - 10s

    CCM transmission interval for all MEPs in the association
```

- It is possible to provision **discard-unknown** in the B-VPLS, so that flooded traffic due to the destination MAC being unknown in the B-VPLS is discarded immediately. This can be configured on the PEs and the MTUs. On the MTUs, it is important to configure this in conjunction with the CC messages from the virtual MEPs to ensure that the remote B-MACs are learned in both directions. If, for any reason, the remote B-MACs are not in the MTU B-VPLS, no traffic will be forwarded at all on the PBB-Epipe.

```
configure {
    service {
        vpls "B-VPLS 101" {
            fdb {
                discard-unknown true
            }
```

  As soon as the MTU node recovers, it will start sending CC messages and the backbone MAC address will be learned on the backbone nodes and MTU nodes again.

With the recommended configuration in place, in case MTU-4 fails, the backbone destination MAC configured on the PBB tunnel for Epipe 3 on MTU-6 will be removed from the B-VPLS 101 on all the nodes (either by MAC flush mechanisms on the B-VPLS or by aging). From that point on, traffic originated from CE-9 will be discarded at MTU-6 and won't be flooded further.

As soon as MTU-4 comes back up, MEP4 will start sending CCM and as such the MTU-4 MAC will be learned throughout the B-VPLS 101 domain and in particular in PE-1, PE-3, and MTU-6 (CCM PDUs use a multicast address). From the moment MTU-4 MAC is known on the backbone nodes and MTU-6, the traffic will not be discarded any more, but forwarded to MTU-4.

PBB-Epipe show commands

The following commands can help to check the PBB Epipe configuration and their related parameters.

For the B-VPLS service:

```
[]

```

CCMs are no longer received from virtual MEP 6 (the one defined in MTU-6) since 01/11/2021 16:43:56. This conveys which node has failed and when it failed.

Conclusion

Point-to-Point Ethernet services can use the same operational model followed by PBB VPLS for multipoint services. In other words, Epipes can be linked to the same B-VPLS domain being used by I-VPLS instances and use the existing H-VPLS network infrastructure in the core. The use of PBB Epipes reduces dramatically the number of services and pseudowires in the core and therefore allows the service provider to scale the number of E-Line services in the network.

The example used in this document shows the configuration of the PBB Epipes as well as all the related features which are required for this environment. Show commands have also been suggested so that the operator can verify and troubleshoot the service.

PBB-EVPN ISID-based CMAC Flush

This chapter provides information about PBB-EVPN ISID-based CMAC Flush.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 15.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. PBB-EVPN ISID-based CMAC flush is supported on the following objects in an I-VPLS:

- SAPs in a BGP multi-homing site (no Ethernet Segment (ES))-supported in SR OS Release 14.0.R4, and later
- SAPs in ESs or virtual ESs (vESs)-SR OS Release 15.0.R1, and later
- Spoke-SDPs (that may be part of an ES/vES or not)-SR OS Release 15.0.R4, and later.

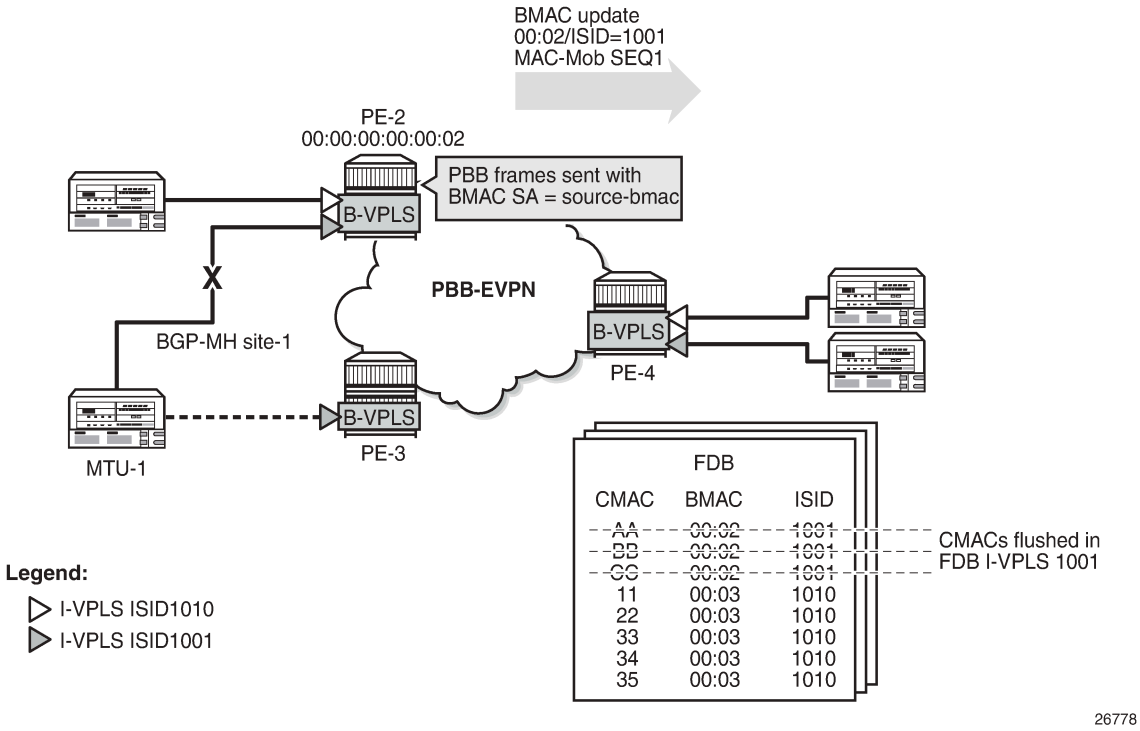
Chapter EVPN for PBB over MPLS (PBB-EVPN) is prerequisite reading.

Overview

Figure 271: CMAC flush when SAP in BGP multi-homing site fails shows an example topology with PBB-EVPN where a CMAC flush is triggered after a SAP in a BGP multi-homing site fails.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 271: CMAC flush when SAP in BGP multi-homing site fails



I-VPLS 1001 is configured in PE-2 and PE-3 with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** and connected to MTU-1. In the example, the SAP goes operationally down in I-VPLS 1001 on PE-2. To speed up convergence without flushing CMAC addresses in other I-VPLS services, PE-2 sends a BGP-EVPN BMAC route for ISID 1001 with increased sequence number to trigger a MAC-flush for I-VPLS 1001 on the remote PEs. All CMAC addresses in the FDB for other I-VPLS services, such as I-VPLS 1010 in this example, will be preserved. When PE-4 needs to send traffic to one of the flushed CMAC addresses in I-VPLS 1001, it will flood the frames until the CMAC address is learned again (via PE-3).

When SAPs or SDP-bindings-associated with ESs, vESs, or BGP-MH sites-in an I-VPLS service fail, a BGP-EVPN BMAC route (route type 2) can trigger an ISID-based CMAC flush on the remote PEs. For the CMAC addresses to be flushed from the FDB of the I-VPLS, the existing EVPN BMAC routes will be used with the Ethernet tag equal to the ISID. Figure 272: EVPN BMAC route with ISID indication shows the EVPN BMAC route with ISID indication (BMAC/ISID). A BMAC/ISID update may trigger a selective MAC-flush for a specific I-VPLS, whereas a BMAC/0 update (BMAC/ISID route where ISID=0) may trigger a MAC-flush for all I-VPLS services. This procedure is based on *draft-snr-bess-pbb-evpn-isid-cmacflush*.

© 2026 Nokia.

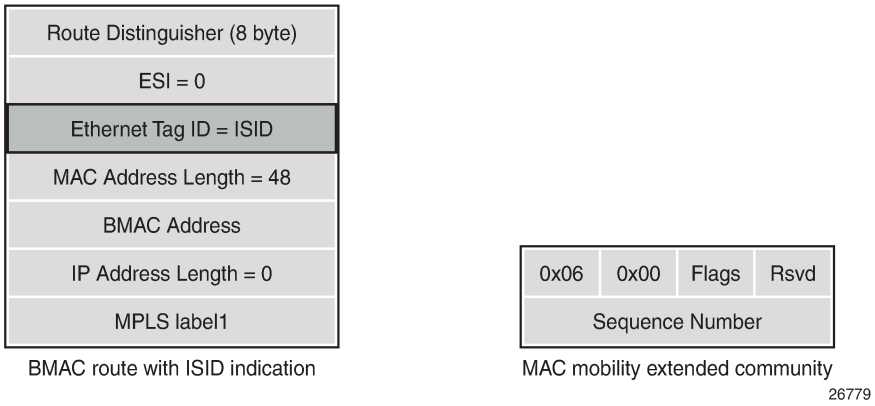
Figure 272: EVPN BMAC route with ISID indication



By default, ISID-based CMAC flush is disabled: no I-VPLS will send a B-VPLS EVPN flush message and no B-VPLS will accept any I-VPLS EVPN flush messages. The router only installs CMAC entries corresponding to a zero Ethernet tag and ignores non-zero Ethernet tag MAC routes. However, when the B-VPLS is configured to accept BMAC/ISID routes, non-zero Ethernet tag BMAC routes can be processed for CMAC flush. The CMAC flush trigger will be an EVPN BMAC/ISID route with a sequence number that is higher than before. The receiving PE will then flush all CMACs associated with this BMAC address in the I-VPLS.

The first time that a BMAC/ISID route is received, it is added to the database as a baseline. It does not cause a CMAC flush. Only subsequent BMAC/ISID updates with increased sequence number or withdrawals will cause CMAC flush.

The following command shows that B-VPLS 1000 does not accept any I-VPLS EVPN flush messages. This is the default behavior.

```
[/]
A:admin@PE-2# show service id 1000 bgp-evpn | match "Accept IVPLS Flush"
Accept IVPLS Flush : Disabled
```

At the receiving node, B-VPLS 1000 will accept BMAC/ISID routes when the following command is configured:

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS 1000" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
```

By default, I-VPLS 1001 will not send any B-VPLS EVPN flush messages, as follows:

```
[/]
A:admin@PE-2# show service id 1001 base | match SendBvplsEvpnFlush
SendBvplsEvpnFlush: Disabled
```

The following configuration allows I-VPLS 1001 to send B-VPLS EVPN flush messages when a SAP or SDP-binding fails:

```
# on PE-2:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        vpls "I-VPLS 1001" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
```

When enabled, the I-VPLS will send a BMAC/ISID route and subsequent updates with a higher sequence number whenever a SAP fails in the I-VPLS on the node. The default setting for a SAP allows a B-VPLS EVPN flush message to be sent (when enabled in the I-VPLS itself):

```
[/]
A:admin@PE-2# show service id 1001 sap 1/2/1:1001 detail | match SendBvplsEvpnFlush
SendBvplsEvpnFlush : Enabled
```

When no alternative route via another node is available for specific SAPs (single-homed SAPs), no CMAC flush should be triggered. When no B-VPLS EVPN flush messages need to be sent from PE-4 when SAP 1/2/1:1001 goes down, the configuration is as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1001" {
            sap 1/2/1:1001 {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls false
```

The router only installs the BMACs received in MAC routes that have Ethernet tag zero. When CMAC flush is enabled, MAC routes with Ethernet tag equal to the ISID (always non-zero) are for CMAC flush, but not for installing the conveyed BMACs.

BMAC/ISID routes have the following characteristics:

- BMAC/ISID routes are sent with the static bit flag set as for any other BMAC route. The static bit is ignored at reception because this route is never used to install a BMAC in the FDB.
- BMAC/ISID routes received with non-zero ESI and non-zero Ethernet tag are treated as withdraw by the router at application level. Route Reflectors (RRs) treat such BMAC/ISID routes as valid routes that can be forwarded.
- BMAC/ISID routes are shown as valid in the **show router bgp routes evpn mac** commands, as in the following output, even though they are not used to populate the FDB. This shows that BGP is sending the routes to the application layer for CMAC flush processing. The BMAC/0 route should be sent before the BMAC/ISID routes for the same BMAC. Also, when the B-VPLS goes operationally down, the BMAC/0 should be withdrawn before the BMAC/ISID routes.

When **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** is configured in an I-VPLS that is associated with a B-VPLS, BGP-EVPN BMAC/ISID updates will be sent when certain events take place in the I-VPLS or B-VPLS. Table 20: CMAC flush transmission behavior shows the CMAC flush transmission behavior at the egress PE.

Table 20: CMAC flush transmission behavior

Local Event	pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	sap>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	Action
Reconfigure I-VPLS: enable or disable send-to-bvpls	true or false	N/A	Send update/withdraw source BMAC/ISID with Seq=0
Associate/disassociate I-VPLS to/from B-VPLS	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
I-VPLS oper-up/oper-down	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
B-VPLS oper-up/oper-down	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0 Note: All BMACs are also advertised/withdrawn.
B-VPLS bgp-evpn mpls enabled/disabled	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Local Event	pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	sap>i-vpls-mac-flush>bgp-evpn>send-to-bvpls	Action
B-VPLS operational source BMAC change	true	N/A	Send update/withdraw source BMAC/ISID with Seq=0
SAP oper-up	true	N/A	No operation
SAP oper-down	true	true	Send update source BMAC/ ISID Seq=Seq+1
	true	false	No operation

Table 21: CMAC flush reception behavior shows the reception behavior at the ingress PE. For the CMAC flush triggered by a BMAC/ISID update with increased sequence number, the B-VPLS in the receiving PE must be configured with **accept-ivpls-evpn-flush true**. BMAC/0 refers to a BMAC route where the Ethernet Tag is 0.

Table 21: CMAC flush reception behavior

Received route	Action
BMAC/0 withdraw	Flush all CMACs for that BMAC
BMAC/ISID withdraw	Flush all CMACs for that BMAC and ISID
BMAC/0 update + Seq change	Flush all CMACs for that BMAC
BMAC/ISID update + Seq change	Flush all CMACs for that BMAC and ISID
BMAC/0 update + PE (NHop) change	No CMAC-flush
BMAC/ISID update + PE (NHop) change	Flush all CMACs for that BMAC and ISID

BMAC/ISID updates will trigger CMAC flush procedures regardless of the Termination Endpoint (TEP) or Route Distinguisher (RD) with which the update is received. CMAC flush will be processed even if the BMAC-ISID comes from a TEP or RD different from the BMAC/0 route. Even when the sequence number is the same as in the previous BMAC/ISID update, CMAC flush will happen when the TEP is different. When the same BMAC/ISID is received from two PEs, both are accepted and any change in sequence number causes a MAC flush. However, when the same BMAC/ISID route is received from two PEs with the same RD, BGP will select only one, so the router only sees one.

CMAC flush for ES/vES

RFC 7623 (PBB-EVPN) defines the following CMAC Flush notification mechanisms for single-active multi-homing. These notifications do not include the local ISIDs:

- When ES-BMACs are used and the ES goes operationally down, the ES-BMAC will be withdrawn.
- When source-BMACs are used and the ES goes operationally down, a BGP-EVPN BMAC/0 is sent with a higher sequence number.

Figure 273: ISID-independent CMAC flush when ES fails shows the following two scenarios for ISID-independent CMAC flush that are supported in SR OS Release 13.0.R4, and later:

- PBB frames are sent with the source-BMAC. When the ES goes operationally down, a BMAC update is sent with an increased sequence number, triggering a CMAC flush for all CMAC addresses associated with the BMAC address in I-VPLS, regardless of the ISID.
- PBB frames are sent with the ES-BMAC address. When the ES goes operationally down, a BMAC withdraw message is sent, triggering the remote PEs to flush all CMAC addresses associated to the ES-BMAC address, regardless of the ISID.

Figure 273: ISID-independent CMAC flush when ES fails

Use subject to Terms available at: www.nokia.com/terms.

In addition to the preceding ISID-independent CMAC flush mechanisms, ISID-based CMAC flush is also supported in I-VPLS services with SAP or spoke-SDPs that are part of an ES or vES. ISID-based CMAC flush is enabled in the I-VPLS with the **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** command. An I-VPLS that is configured with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** requires one of the following conditions to be met:

- The SAP or spoke-SDP has **i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** configured.
- The SAP or spoke-SDP has **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured (default) and one of the following conditions is met:
  - The SAP or spoke-SDP is not on an ES.
  - The SAP or spoke-SDP is on an ES or vES with no **src-bmac-lsb** configured.
  - The B-VPLS has **pbb>source-bmac>use-es-bmac-lsb false** configured.

For ES SAPs with **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** in I-VPLS services that have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured, the ISID-based CMAC flush replaces the RFC 7623-based CMAC flush mechanism.

For each ES/vES and B-VPLS, the system will check whether all I-VPLS services in the ES/B-VPLS have ISID-based MAC-flush enabled.

- If all I-VPLSs have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured:
  - No BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Only BMAC/ISID updates with increased sequence number will be sent when the I-VPLS attachment circuit goes operationally down.
- If at least one I-VPLS has **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** configured:
  - BMAC/0 updates with increased sequence number will be triggered when the ES/vES goes operationally down.
  - Also, BMAC/ISID updates with increased sequence number will be generated for those I-VPLS services that have **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured.

The number of CMAC addresses that may be flushed at the remote nodes can be reduced by enabling ISID-based MAC-flush for all the I-VPLS services in the ES/vES.

When attempting to set **use-es-bmac-lsb true** in B-VPLS 1000 on PE-4 when the SAP/SDP-binding has default settings (and **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** in the I-VPLS), the following error is raised:

```
[ex:/configure service vpls "B-VPLS 1000" pbb source-bmac]
A:admin@PE-4# use-es-bmac-lsb true

*[ex:/configure service vpls "B-VPLS 1000" pbb source-bmac]
A:admin@PE-4# commit

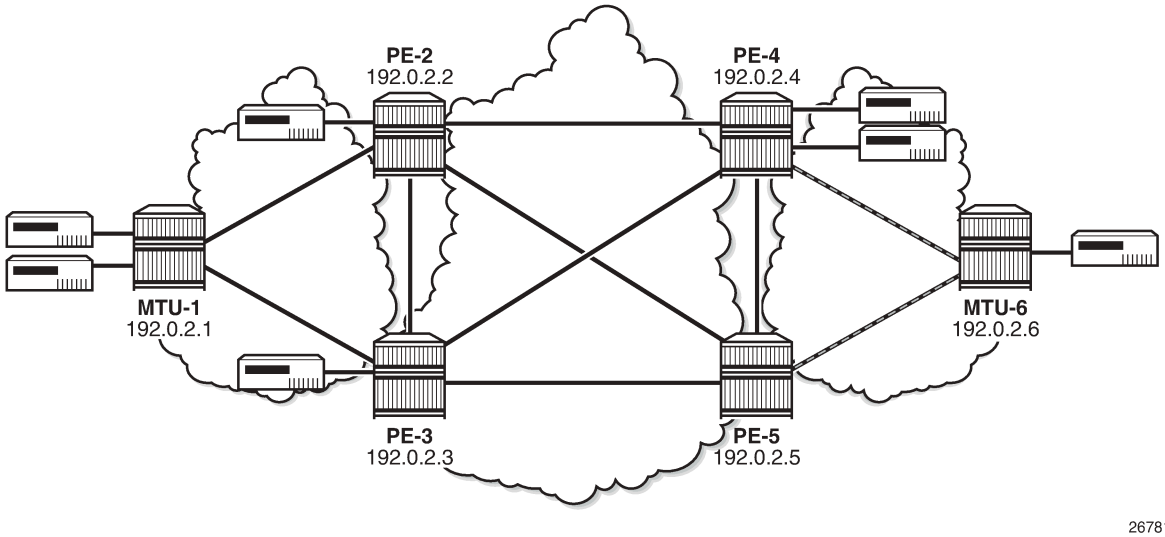
Configuration

Figure 274: Example topology shows the example topology.

Figure 274: Example topology



The initial configuration includes the following:

- Cards, MDAs
- Ports: the ports between the MTUs and the PEs are hybrid or access ports with dot1q encapsulation; the ports between the PEs are network ports with null encapsulation
- Router interfaces
- IS-IS on all router interfaces (alternatively, OSPF could be used)
- LDP on all router interfaces

The following use cases are described in this section:

- ISID-based CMAC flush for BGP non-EVPN multi-homing (no ES)

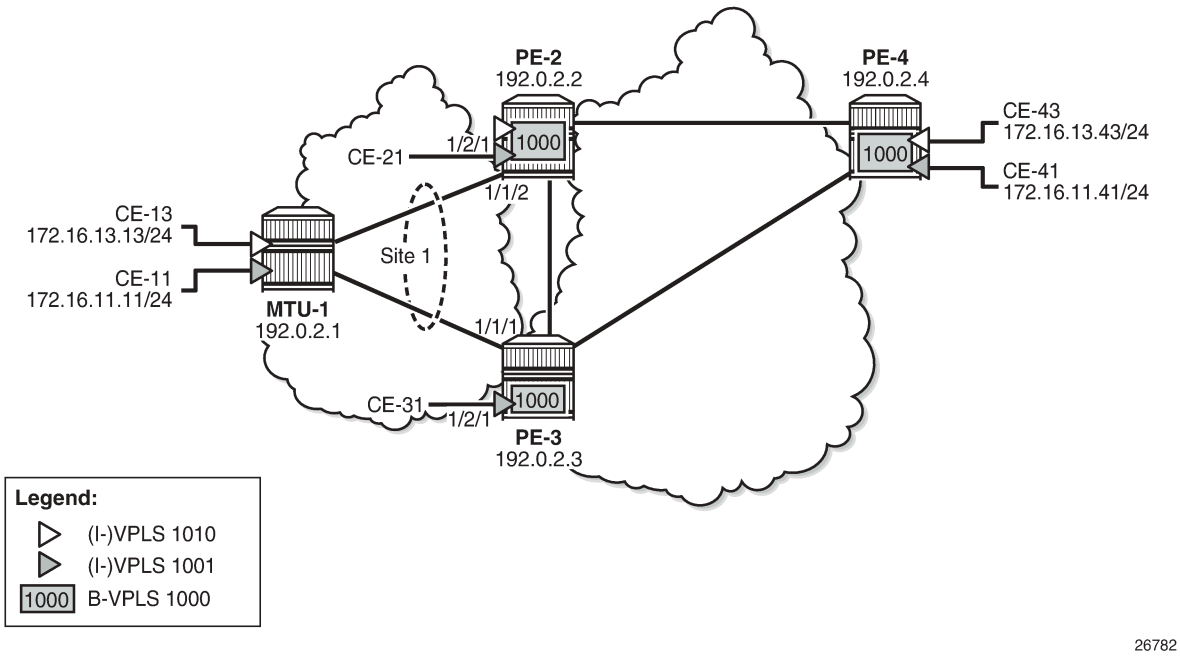
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- ISID-based CMAC flush for BGP-EVPN in a single-active ES

ISID-based CMAC flush for BGP multi-homing

Figure 275: Example topology with BGP multi-homing shows the example topology with BGP multi-homing site 1 between PE-2 and PE-3. B-VPLS 1000 is configured on all the core nodes (PEs) and I-VPLS 1001 and I-VPLS 1010 are associated with this B-VPLS in the PEs. On MTU-1, regular VPLSs are configured. For more information about BGP non-EVPN multi-homing, see chapter BGP Multi-Homing for VPLS Networks.

Figure 275: Example topology with BGP multi-homing



BGP is configured for address family EVPN on all PEs with PE-2 as RR. For BGP multi-homing, address family L2-VPN is enabled between PE-2 and PE-3. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base"
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                l2-vpn true
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
                family {
                    l2-vpn true
                    evpn true
                }
            }
            neighbor "192.0.2.4" {
                group "internal"
                family {
                    evpn true
                }
            }
        }
```

The BGP configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    router "Base"
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
        }
```

The configuration of B-VPLS 1000 and I-VPLS 1001 on PE-2 is as follows. ISID-based CMAC flush is disabled by default. BGP multi-homing site "MH-site-1" is configured on PE-2 with SAP 1/1/2:1001 associated with it, whereas SAP 1/2/1:1001 is not associated to the MH site. CE-21 is attached to I-VPLS 1001 with SAP 1/2/1:1001.

```
# on PE-2:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2
                community-value {
                    start 1
                    end 999
                }
```

            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1010
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                route-target {
                    export "target:64500:1010"
                    import "target:64500:1010"
                }
            }
            sap 1/1/2:1010 {
            }
        }
```

I-VPLS 1010 is configured without multi-homing. The configuration of VPLS 1001 on PE-3 is similar, but without I-VPLS 1010.

ISID-based CMAC flush is not enabled yet. The PEs exchange BGP-EVPN MAC routes with Ethernet tag zero. PE-3 has received BMAC/0 routes from PE-2 and PE-4, as follows:

```
[/]
A:admin@PE-3# show router bgp routes evpn mac

-------------------------------------------------------------------------------
Routes : 2
===============================================================================
```

PE-2 and PE-4 have also received BMAC/0 routes from the other PEs.

ISID-based CMAC flush is enabled in I-VPLS 1001 on PE-2 and PE-3. PE-4 has no multi-homing in I-VPLS 1001, so it should not send any CMAC flush. I-VPLS 1010 has no multi-homing in any PE, so ISID-based MAC-flush should not be enabled in I-VPLS 1010.

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 1001" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-2 and PE-3 will send BMAC/1001 updates with sequence number 0 to the other two PEs. As an example, the following EVPN-MAC route for BMAC 00:00:00:00:00:03 with tag 1001 is sent by PE-3:

```
22 2021/04/15 08:07:57.818 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

```

When a failure occurs on PE-2, PE-3 and PE-4 should accept the BMAC/ISID with increased sequence number; for a failure on PE-3, PE-2 and PE-4 should accept the BMAC/ISID update. Therefore, the B-VPLS on all PEs should accept the CMAC flush message for ISID 1001, and this is configured as follows:

```
# on PE-2, PE-3, PE-4:
configure {
    service {
        vpls "B-VPLS 1000" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
```

The FDB for VPLS 1001 on PE-4 includes MAC address 00:00:11:11:11:11 with source-identifier 192.0.2.2:524282, so PE-4 will forward traffic toward that MAC address to PE-2.

```

```

A failure is simulated on SAP 1/1/2:1001 in multi-homing site 1 on PE-2 as follows:

```
# on PE-2:
configure {
    service {
        vpls "I-VPLS 1001" {
            sap 1/1/2:1001 {
                admin-state disable
```

SAP 1/1/2:1001 has the default **i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** and I-VPLS 1001 is configured with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true**, so PE-2 will send BMAC/ISID updates for BMAC 00:00:00:00:00:02, ISID 1001, and sequence number 1 to its BGP peers. The following BGP update is sent by PE-2 to PE-4:

```
# on PE-2:
64 2021/04/15 08:12:55.058 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

        target:64500:1000
        bgp-tunnel-encap:MPLS
        mac-mobility:Seq:1/Static
"
```

This BMAC/ISID with sequence number 1 triggers a CMAC flush in the FDB for VPLS 1001, so the entry for 00:00:11:11:11:11 will be flushed, along with all other MAC addresses associated with BMAC 00:00:00:00:00:02. The FDB on PE-4 does not contain any entries with source-identifier BMAC 00:00:00:00:00:02, as follows:

```
[/]
A:admin@PE-4# show service id 1001 fdb detail

===============================================================================

```

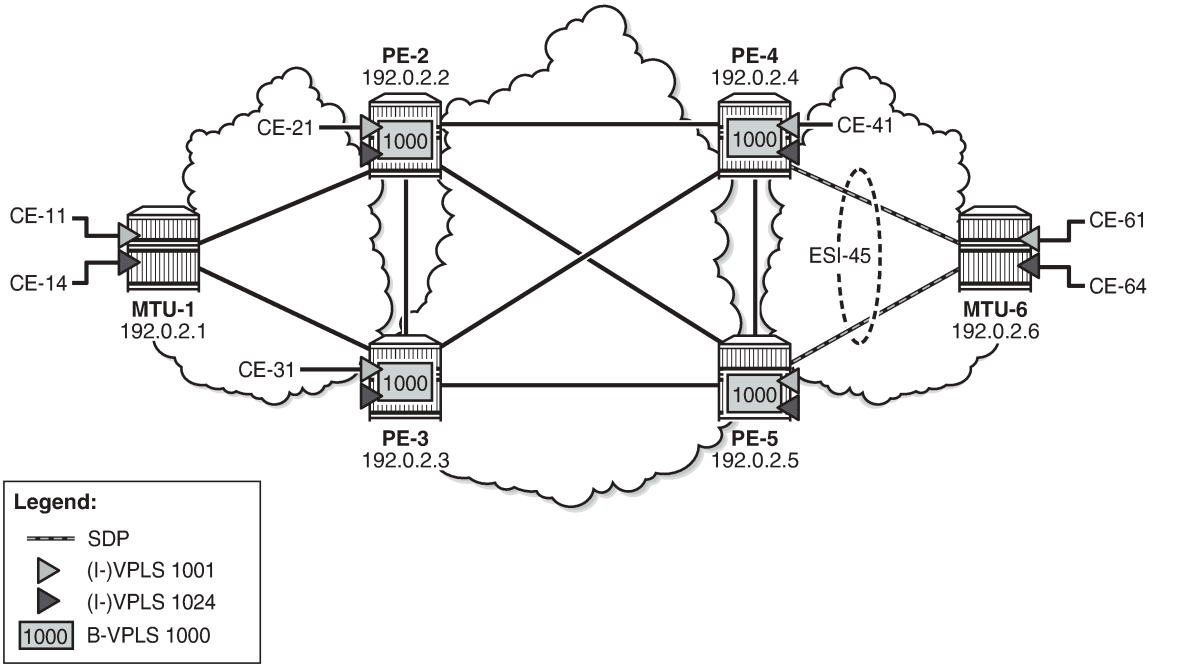
ISID-based CMAC flush in single-active ES

CMAC flush only makes sense for single-active multi-homing. Also, CMAC flush only works for single-active multi-homing; not for all-active multi-homing, because ES-BMAC is required in all-active multi-homing. Figure 276: Example topology with single-active ES shows the example topology with a single-active ES "ESI-45" configured in PE-4 and PE-5.

Figure 276: Example topology with single-active ES



The multi-homing configuration has been removed from PE-2 and PE-3, so no CMAC flush should be sent by PE-2 or PE-3. VPLS 1001 is configured as follows on PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    service {
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1001"
                    import "target:64500:1001"
                }
            }
            sap 1/2/1:1001 {
            }
            sap lag-1:1001 {
            }
        }
```

SDPs are configured between PE-4 and MTU-6, and between PE-5 and MTU-6. These SDPs are associated with the single-active ES "ESI-45".

The configuration of B-VPLS 1000 on PE-4 is as follows. The B-VPLS configuration on the other PEs is similar, but with a different source BMAC.

```
# on PE-4:
configure {
    service {
        vpls "B-VPLS 1000" {
            admin-state enable
            service-id 1000
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:04
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                accept-ivpls-evpn-flush true
                evi 1000
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

The service configuration on PE-4 includes an SDP toward PE-6 and a single-active multi-homing ES, as follows:

```
# on PE-4:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-45" {
                        admin-state enable
                        esi 01:00:00:00:00:45:00:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 46 {
                            }
                        }
                        pbb {
                            source-bmac-lsb 45-04
                        }
                    }
                }
            }
        }
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
```

The configuration on PE-5 is similar. The configuration of B-VPLS 1000 is similar to the one for PE-2, with only a different BMAC. The configuration of I-VPLS 1001 on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1001" {
            admin-state enable
            service-id 1001
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1001
                }
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1001"
                    import "target:64500:1001"
                }
            }
            spoke-sdp 46:1001 {
            }
            sap 1/2/1:1001 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
        }
```

ISID-based MAC-flush is enabled in B-VPLS 1000 and I-VPLS 1001 on all PEs.

I-VPLS 1024 is also associated with B-VPLS 1000 and contains one object (SAP or spoke-SDP) in each PE. The configuration of I-VPLS 1024 is identical on PE-2 and PE-3, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 1024" {
            admin-state enable
            service-id 1024
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1024
                }
            }
            sap lag-1:1024 {
            }
        }
```

The configuration of I-VPLS 1024 on PE-4 has **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls true** configured and contains a spoke-SDP instead of a SAP, as follows. The configuration on PE-5 is similar, but with a different SDP.

```
# on PE-4:
configure {
    service {
        vpls "I-VPLS 1024" {
            admin-state enable
            service-id 1024
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1024
                }
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
            spoke-sdp 46:1024 {
            }
        }
```

ISID-based MAC-flush is enabled on PE-4 and PE-5 for both I-VPLS 1001 and I-VPLS 1024, and BMAC/ISID updates are sent for ISID 1001 and ISID 1024, as follows:

```

```

PE-5 is the DF for VPLS 1001 in "ESI-45". A failure is simulated by disabling the SDP toward PE-5 on MTU-6, as follows:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state disable
```

PE-5 sends the following BMAC/ISID with increased sequence number for ISID 1001 to the RR PE-2:

```
50 2021/04/15 08:24:35.567 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

```
"
```

When PE-3 receives this BMAC/ISID, all MAC routes with next-hop PE-5 are flushed and the FDB will contain the following MAC entries:

```
[/]
A:admin@PE-3# show service id 1001 fdb detail

===============================================================================
Forwarding Database, Service 1001
===============================================================================
ServId     MAC               Source-Identifier       Type     Last Change
           Transport:Tnl-Id                          Age
-------------------------------------------------------------------------------
1001       00:00:11:11:11:11 sap:lag-1:1001          L/0      04/15/21 08:19:47
1001       00:00:41:41:41:41 b-mpls:                 L/0      04/15/21 08:19:47
                             192.0.2.4:524282
           ldp:65538
-------------------------------------------------------------------------------
No. of MAC Entries: 2
-------------------------------------------------------------------------------
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
===============================================================================
```

If MAC address 00:00:61:61:61:61 is learned again, the next hop will be PE-4 instead of PE-5.

The configuration is restored as follows:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state enable
```

No CMAC/ISID update will be sent when the last SAP/SDP-binding in a service goes operationally down. VPLS 1024 only has one SAP/SDP-binding in DF PE-4: spoke-SDP 46:1024. A failure of the spoke-SDP is simulated as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state disable
```

When the last SAP/SDP-binding is down, the service will be operationally down, as follows:

```
[/]
A:admin@PE-4# show service id 1024 base | match "Oper State"
Admin State       : Up                 Oper State        : Down
```

PE-4 sends the following withdrawal message instead of a CMAC/ISID:

```
56 2021/04/15 08:26:10.691 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE
Peer 1: 192.0.2.2 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 61
    Flag: 0x90 Type: 15 Len: 57 Multiprotocol Unreachable NLRI:

```
                              orig_addr len: 32, orig_addr: 192.0.2.4
        Type: EVPN-MAC Len: 33 RD: 192.0.2.4:1000 ESI: ESI-0, tag: 1024, mac len: 48
                       mac: 00:00:00:00:00:04, IP len: 0, IP: NULL, label1: 0
"
```

The configuration is restored as follows:

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state enable
```

ISID-based and regular CMAC flush in ES

When ISID-based CMAC flush is not enabled in all I-VPLS services using the ES, a failure in the ES will trigger BMAC/0 updates and BMAC/ISID updates with increased sequence number. An additional I-VPLS is configured on the nodes with **pbb>i-vpls-mac-flush>bgp-evpn>send-to-bvpls false** (default). The configuration of I-VPLS 1021 on PE-5 is as follows:

```
# on PE-5:
configure {
    service {
        vpls "I-VPLS 1021" {
            admin-state enable
            service-id 1021
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 1000" {
                    isid 1021
                }
            }
            spoke-sdp 56:1021 {
            }
            sap 1/2/1:1021 {
            }
        }
```

The configuration on PE-4 is similar; PE-2 and PE-3 have SAP lag-1:1021 instead of the spoke-SDP.

On MTU-6, SDP 65 is disabled, which will cause an ES failure on PE-5:

```
# on MTU-6:
configure {
    service {
        sdp 65 {
            admin-state disable
```

The following BMAC updates are sent by PE-5:

- BMAC/0 with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for all I-VPLS services (ISID-independent)
- BMAC/ISID with increased sequence number, which will trigger a CMAC flush for all entries received from PE-5 for VPLS 1001

```

```

Conclusion

ISID-based MAC-flush speeds up convergence after a SAP or spoke-SDP failure, triggering a selective CMAC flush on the receiving nodes, which flushes all CMAC entries associated with that ISID and BMAC. The feature can be enabled per I-VPLS and disabled for those SAPs or spoke-SDPs for which no alternative route is available, or for those SAPs that are contained in an all-active Ethernet Segment. The BMAC/ISID update always contains the source-BMAC, not the ES-BMAC. CMAC flush based on ES-BMAC is not performed per ISID.

PBB-EVPN ISID-based Route Targets

This chapter provides information about PBB-EVPN ISID-based Route Targets.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.5.R1. PBB-EVPN ISID-based route targets are supported in SR OS Release 15.0.R1, and later.

Overview

The following BGP-EVPN routes are used in PBB-EVPN according to RFC 7623:

- B-MAC routes—based on BGP-EVPN route type 2—are sent with the B-VPLS Route Target (RT), so they are sent to all the PEs where the B-VPLS is defined.
- Ethernet Segment (ES) routes—route type 4—are used for multi-homing. ES routes are sent with an RT auto-derived from the ES Identifier (ESI). If the RT-constraint is enabled, the routes are sent to only those PEs that are part of the ES.
- Inclusive Multicast Ethernet Tag (IMET) routes—route type 3—are used for the setup of per-ISID flooding domains and can be sent with a B-VPLS RT or with an ISID-based RT.
  - IMET routes are, by default, sent with a B-VPLS RT (referred to as IMET/0 routes), so they are imported by all the PEs where the B-VPLS is defined, as per RFC 7623, and supported in SR OS Release 13.0.R4, and later.
  - IMET routes with an ISID-based RT (referred to as IMET/ISID routes) are imported by only the PEs where the ISID is defined. RFC 7623 recommends these routes for deployments where the ISIDs are sparsely distributed in the network. This is supported in SR OS Release 15.0.R1, and later. The service ISID is encoded in the Ethernet tag field.

Figure 277: PBB-EVPN B-VPLS-based RT shows how the B-MAC and IMET routes with a B-VPLS RT sent by PE-1 are advertised to all other PEs (via the Route Reflector (RR)), regardless of the ISID.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 277: PBB-EVPN B-VPLS-based RT

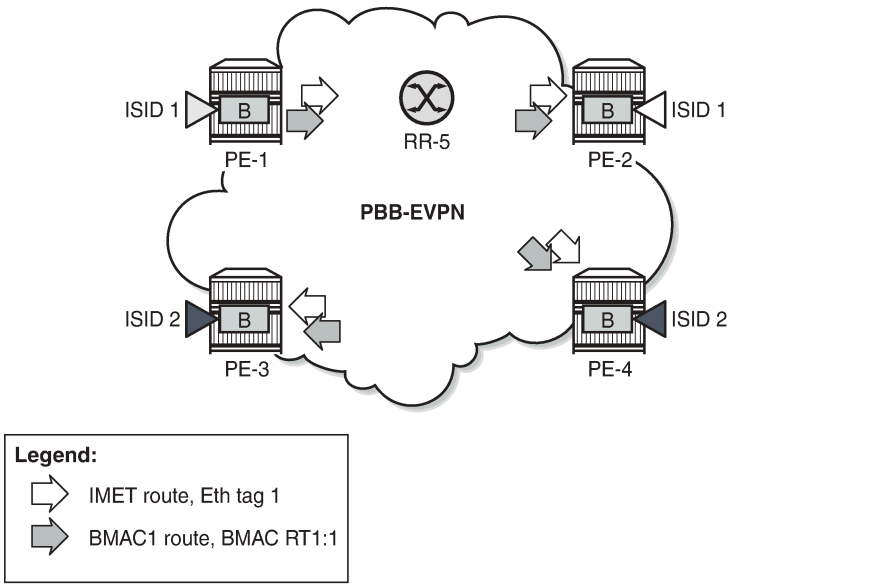

Figure 278: PBB-EVPN ISID-based RT shows how the B-MAC routes are sent to all PEs within the B-VPLS, whereas the IMET routes sent by PE-1 are selectively reflected by the RR (due to RT-constraints) and only sent to PE-2, which is the only PE with the same ISID.

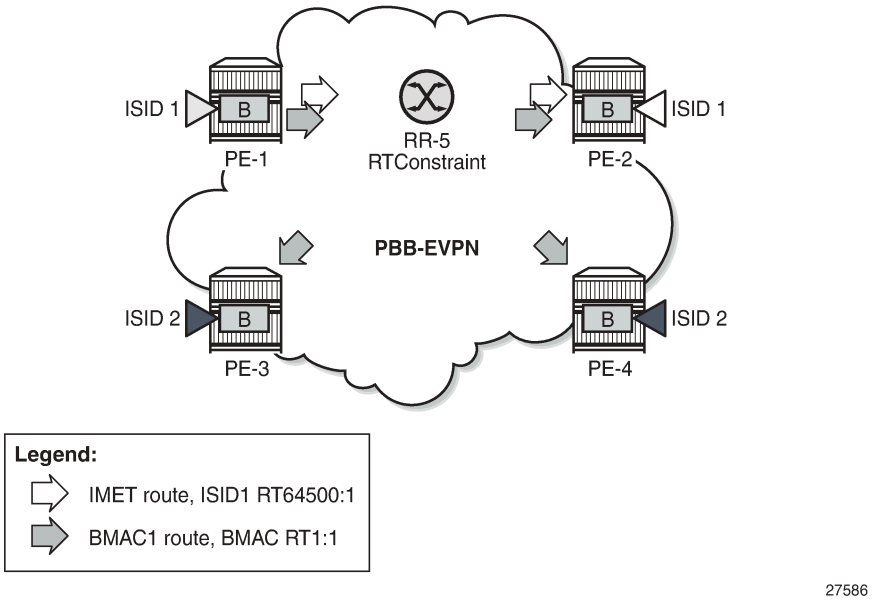
Figure 278: PBB-EVPN ISID-based RT



IMET routes with ISID-based RTs (IMET/ISID) can significantly reduce the number of IMET/ISID routes distributed by the RRs. The RT for the IMET/ISID route can be auto-derived from the corresponding Ethernet tag (ISID).

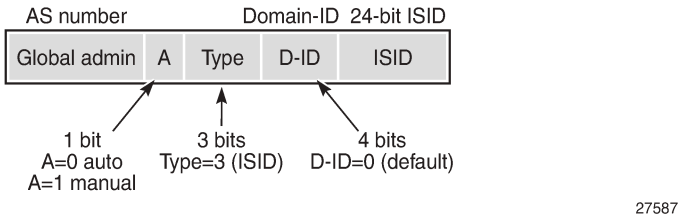
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In addition to RFC 7623, the ISID-derived RTs can be used for BMAC/ISID routes if ISID-based CMAC flush is enabled, as per *draft-snr-bess-pbb-evpn-isid-cmacflush*. The service ISID is encoded in the Ethernet tag field.

PBB-EVPN ISID-based RT format

Figure 279: PBB-EVPN ISID-based RT format shows the ISID-based RT format:

Figure 279: PBB-EVPN ISID-based RT format



For an auto-derived ISID-based RT, the values are as follows:

- The Autonomous System (AS) number is obtained from the **config>router>autonomous-system** command:
  - Value = 2-byte AS number
  - For AS numbers with more than 2 bytes, the low-order 16-bit value is used.
- A = 0 for auto-derivation
- Type = 011 = 3 for ISID-based RT
- Domain ID = 0000 (default)
- ISID value

The auto-derived RT will be AS:00110000+ISID = AS:0x30+ISID Hex.

The type and sub-type of the BGP extended community is 0x00 and 0x02.

Enabling ISID-based RT

The following command is used to enable ISID-based RT for specific ISID ranges for IMET/ISID and BMAC/ISID routes.

```
*[ex:/configure service vpls "B-VPLS 100" bgp-evpn]
A:admin@PE-1# isid-route-target ?

 isid-route-target

 range                 + Enter the range list instance
```

The ISID range is configured as follows:

```
[ex:/configure service vpls "B-VPLS 100" bgp-evpn isid-route-target]
A:admin@PE-1# range ?
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 [start] <number>
 <number>  - <1..16777215>

    Starting value of the isid-range entry
```

```
[ex:/configure service vpls "B-VPLS 100" bgp-evpn isid-route-target range 1]
A:admin@PE-1# end ?

 end <number>
 <number>  - <1..16777215>

 'end' is: mandatory

    Ending value of the isid-range entry
```

The RT to be used for the I-VPLS can be auto-derived (default) or explicitly configured. The following configures an ISID range from 20 to 29 with auto-derived RT (default: type auto), whereas ISID 30 has a manually configured RT of 64500:30.

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 20 {
                        end 29
                        # type auto   # default
                    }
                    range 30 {
                        end 30
                        type configured
                        route-target "target:64500:30"
                    }
                }
```

If **isid-route-target** is enabled, the IMET/ISID and BMAC/ISID route processing is modified in the export and import directions:

- "Exported IMET/ISID and BMAC/ISID routes:
  - IMET/ISID routes are sent with an ISID-based RT for the local I-VPLS ISIDs and static ISIDs, unless the ISID is contained in an ISID policy for which **advertise-local false** is configured.
  - When **isid-route-target** and **ivpls-mac-flush>bgp-evpn>send-to-bvpls** are both enabled for an I-VPLS, the BMAC/ISID route will also be sent with the ISID-based RT instead of the B-VPLS-based RT.
  - The **isid-route-target** command has impact only on IMET/ISID and BMAC/ISID, not on IMET/0, BMAC/0, or ES routes.
  - When a new ISID-based RT is added for an I-VPLS, a BGP update is sent for the existing IMET/ISID and BMAC/ISID routes. The new RT will be added when the routes are advertised.
- Imported IMET/ISID and BMAC/ISID routes:
  - When **isid-route-target** is enabled for an I-VPLS, BGP will start importing IMET/ISID routes and—if **ivpls-mac-flush>bgp-evpn>send-to-bvpls** is enabled—BMAC/ISID routes with ISID-based RTs.
  - ISID-based RTs are added for import operations when the I-VPLS is associated with the B-VPLS (regardless of the operational state of the I-VPLS) and/or when the static ISID has been added.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - Ensure that the ISID-based RTs are configured consistently in the network. The system does not keep a mapping of RTs and ISIDs for imported routes.
  - The system will not check the format of the received auto-derived RTs. Routes will be imported when the RT is on the list of RTs for the B-VPLS.
- When **isid-route-target** is configured for an I-VPLS, VSI import/export policies are blocked in the B-VPLS, whereas BGP import/export policies are allowed and matching on the export ISID-based RT is supported.

Some other considerations:

- ISID ranges cannot overlap within a B-VPLS, but they can overlap across different B-VPLSs.
- The explicitly configured RT is meant to be used in two cases:
  - ISID aggregation - when multiple ISIDs are using the same ISID RT
  - Interoperability - in case the peer sends an RT in a different format

ISID-based RTs and RT-constraint

The use of the RT-constraint feature (BGP family route-target) maximizes the benefits of using different RTs per ISID; therefore, service providers are expected to enable both ISID-based RTs and RT-constraint. RT-constraint is enabled by adding the BGP address family route-target in the general BGP settings, per group, or per neighbor, as follows:

```
configure {
    router "Base" {
        bgp {
            family {
                route-target true
                ---snip---

            group "internal" {
                family {
                    route-target true
                    ---snip---

            neighbor 192.0.2.4 {
                family {
                    route-target true
                    ---snip---
```

The system will advertise the RT-constraint route when the I-VPLS is associated with the B-VPLS, regardless of the operational state of the I-VPLS. However, the IMET/ISID and the BMAC/ISID routes are sent based on the I-VPLS operational state.

Configuration

Figure 280: Example topology shows the example topology with three PEs and an RR.

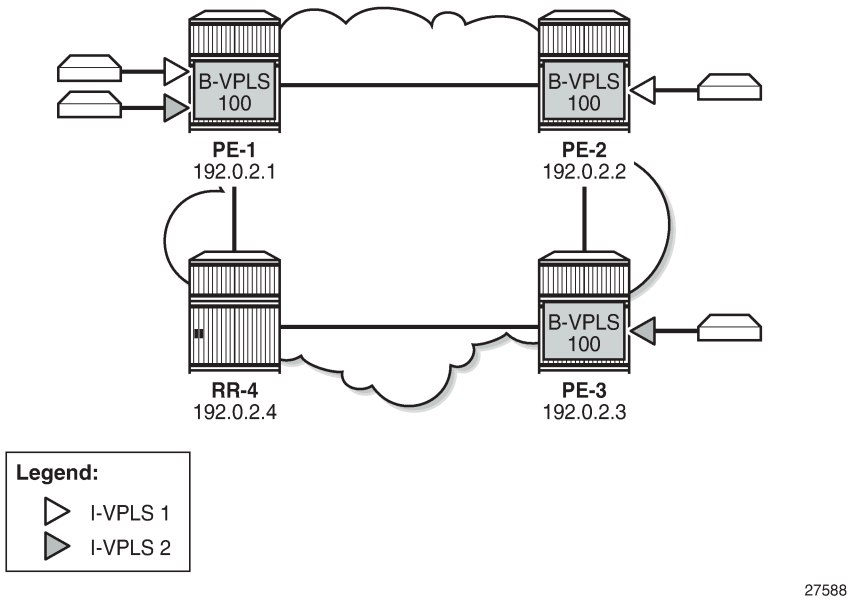
Figure 280: Example topology



Initial configuration

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on all router interfaces (alternatively, OSPF could be used)
- SR-ISIS enabled on the PEs (but disabled on the RR)

BGP is configured on all PEs for address family EVPN, as follows.

```
# on PE-1, PE-2, PE-3:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

On RR-4, BGP is configured as follows:

```
# on RR-4:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            family {
                ipv4 false
                evpn true
            }
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
        }
```

For the RT-constraint feature, the route-target address family can be configured in combination with the EVPN address family; see section ISID-based RTs and RT-constraint.

The initial service configuration on PE-1 without ISID-based RTs is as follows:

```
# on PE-1:
configure {
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.1
                community-value {
                    start 10
                    end 99
                }
            }
        }
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:1"
                    import "target:64500:1"
                }
            }
            sap 1/2/1:1 {
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
                route-target {
                    export "target:64500:2"
                    import "target:64500:2"
                }
            }
            sap 1/2/1:2 {
            }
        }
```

The service configuration on PE-2 is similar, but only I-VPLS 1 is configured. On PE-3, only I-VPLS 2 is configured.

PE-1 sends the following default BGP-EVPN IMET/0 update to the RR:

```
# on PE-1:
2 2021/05/28 08:55:18.406 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

```
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
```

In the preceding output, each of the four inclusive multicast routes occurs twice: the first time with the original attributes, the second time with the modified attributes, but in this example, the attribute did not change.

For the EVPN MAC routes, the output is similar. ISID-based CMAC flush is not enabled yet, so there are only BMAC/0 routes, no BMAC/ISID routes, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn mac

Use subject to Terms available at: www.nokia.com/terms.

ISID-based RTs

On the PEs, B-VPLS 100 is configured with ISID-based RTs, but initially without ISID-based CMAC flush, as follows:

```
# on PE-1, PE-2:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 1 {
                        end 2
                    }
                    range 10 {
                        end 11
                        type configured
                        route-target "target:64500:10"
                    }
                }
            }
```

B-VPLS 100 has two ISID-ranges configured:

- For ISIDs 1 and 2, the RT is auto-derived. The hexadecimal value for ISID 1 is 0x30000001, which corresponds to decimal value 805306369. The hexadecimal value for ISID 2 is 0x30000002 (decimal value 805306370). For ISID 1, the RT is 64500: 805306369; for ISID 2, the RT is 64500: 805306370.
- For ISIDs 10 and 11, the RT is manually configured as 64500:10.

The configuration is identical on PE-2. On PE-3, only ISID range 2 is configured, as follows:

```
# on PE-3:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 2 {
                        end 2
                    }
                }
            }
```

On PE-1, the same four BGP-EVPN IMET routes are shown, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn incl-mcast
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================

u*>i  192.0.2.3:100       192.0.2.3
      0                   192.0.2.3

u*>i  192.0.2.3:100       192.0.2.3
      2                   192.0.2.3

-------------------------------------------------------------------------------
Routes : 4
```

The IMET route with Ethernet tag 1 now has RT 64500:805306369 (ISID 1) and the IMET route with Ethernet tag 2 has RT 64500:805306370 (ISID 2), as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn incl-mcast detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
```

Again, each route has two identical entries in the preceding command: one with the original attributes and another with the modified attributes.

The following BGP-EVPN IMET/ISID route is sent by PE-1 for ISID 1. The Ethernet tag is 1 and the RT is 64500:805306369.

```

        Tunnel-Endpoint 192.0.2.1
"
```

When a SAP (or SDP binding) is added with static ISID 11, RT 64500:10 will be added. The service configuration on PE-1 is modified as follows:

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                isid-route-target {
                    range 1 {
                        end 2
                    }
                    range 10 {
                        end 11
                        type configured
                        route-target "target:64500:10"
                    }
                }
            }
            sap 1/1/1:100 {
                static-isid {
                    range 1 {
                        start 11
                        end 11
                    }
                }
            }
            isid-policy {
                entry 10 {
                    range {
                        start 11
                        end 11
                    }
                }
            }
```

Use subject to Terms available at: www.nokia.com/terms.

The configuration is similar on PE-2. Only on PE-1 and PE-2, SAPs are configured, with static ISID 11. The following IMET/ISID route with RT 64500:10 is sent by PE-1:

```
# on PE-1:
13 2021/05/28 08:59:47.251 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 77
    Flag: 0x90 Type: 14 Len: 28 Multiprotocol Reachable NLRI:
        Address Family EVPN
        NextHop len 4 NextHop 192.0.2.1
        Type: EVPN-INCL-MCAST Len: 17 RD: 192.0.2.1:100, tag: 11, orig_addr len: 32,
                              orig_addr: 192.0.2.1
    Flag: 0x40 Type: 1 Len: 1 Origin: 0
    Flag: 0x40 Type: 2 Len: 0 AS Path:
    Flag: 0x40 Type: 5 Len: 4 Local Preference: 100
    Flag: 0xc0 Type: 16 Len: 16 Extended Community:
        target:64500:10
        bgp-tunnel-encap:MPLS
    Flag: 0xc0 Type: 22 Len: 9 PMSI:
        Tunnel-type Ingress Replication (6)
        Flags: (0x0)[Type: None BM: 0 U: 0 Leaf: not required]
        MPLS Label 8388560
        Tunnel-Endpoint 192.0.2.1
"
```

This RT 64500:10 is not auto-derived, but configured manually for ISID range 10 to 11.

ISID-based CMAC flush

ISID-based CMAC flush is described in chapter PBB-EVPN ISID-based CMAC Flush and requires the following configuration on PE-1:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
        }
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    bgp-evpn {
                        send-to-bvpls true
                    }
                }
            }
        }
        vpls "B-VPLS 100" {
            bgp-evpn {
                accept-ivpls-evpn-flush true
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The configuration on PE-2 and PE-3 is similar, but only needs to be applied for I-VPLS 1 on PE-2 (I-VPLS 2 is not configured on PE-2) and for I-VPLS 2 on PE-3. The configuration for B-VPLS 100 is the same on all PEs.

When ISID-based CMAC flush is enabled on the PEs, additional BGP-EVPN MAC routes are sent by PE-1 for ISIDs 1 and 2:

```
# on PE-1:
27 2021/05/28 09:02:38.769 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4

-------------------------------------------------------------------------------
Routes : 4
===============================================================================
```

The BMAC/0 routes have an RT based on the B-VPLS, whereas the BMAC/ISID routes have an RT derived from the ISID, as follows:

```
[/]
A:admin@PE-1# show router bgp routes evpn mac detail | match Community
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:805306369 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:100 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
Community      : target:64500:805306370 bgp-tunnel-encap:MPLS
```

ISID-based RTs and RT-constraint

To show that RT BGP updates are sent when the I-VPLS is associated with the B-VPLS, the I-VPLSs are initially disassociated from B-VPLS 100 on PE-1, as follows:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                delete backbone-vpls "B-VPLS 100"
            }
        }
        vpls "I-VPLS 2" {
            pbb {
                delete backbone-vpls "B-VPLS 100"
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The BGP configuration is modified on all nodes to include address families route-target and EVPN, as follows:

```
# on PE-1, PE-2, PE-3, RR-4:
configure {
    router "Base" {
        bgp {
            family {
                route-target true
                evpn true
            }
```

The following RT-constraint route is sent by PE-1 after I-VPLS 1 is associated with B-VPLS 100. The RT is auto-derived from the ISID 1:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
        }
        vpls "I-VPLS 2"
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
        }
```

```
# on PE-1:
73 2021/05/28 09:09:34.587 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

"
```

The RT-constraint route is withdrawn when the I-VPLS is disassociated from B-VPLS 100, as follows:

```
# on PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            pbb {
                delete backbone-vpls "B-VPLS 100"
```

```
# on PE-1:
84 2021/05/28 09:11:28.205 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE
Peer 1: 192.0.2.4 - Send BGP UPDATE:
    Withdrawn Length = 0
    Total Path Attr Length = 20
    Flag: 0x90 Type: 15 Len: 16 Multiprotocol Unreachable NLRI:
        Address Family RTC_V4
        [RT-Const-V4] origin-as 64500, Target target:64500:805306369
"
```

Conclusion

PBB-EVPN ISID-based RTs, in combination with RT-constraint, reduce the number of advertised IMET routes to only those nodes where the ISID is configured. The ISID-based RT can be auto-derived from the ISID or configured manually. When ISID-based CMAC flush is also enabled, the BMAC/ISID routes will contain the same auto-derived RT.

PBB-VPLS

This chapter provides information about Provider Backbone Bridging (PBB) in a Multi-Protocol Label Switching (MPLS) based network.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was initially written for SR OS Release 7.0.R6. The MD-CLI in the current edition is based on SR OS Release 20.10.R2.

Note:
Although it can be used in an MPLS-based PBB network as described in this document, the MAC notification feature for dual-homed access is normally used in native PBB networks.

Overview

RFC 7041, *Extensions to the Virtual Private LAN Service (VPLS) Provider Edge (PE) Model for Provider Backbone Bridging*, describes the PBB-VPLS model supported by SR OS. This model expands the VPLS PE model to support PBB as defined by the IEEE 802.1ah.

PBB-VPLS combines the best of the PBB and VPLS technologies to deliver the most scalable multi-point Layer 2 VPN in the market. PBB-VPLS inherits all the benefits derived from MPLS (for example, sub-50ms Fast Reroute (FRR) protection, Traffic Engineering (TE), no need for Multiple Spanning Tree Protocol (MSTP) in the backbone) while greatly increasing the scalability of the network by providing MAC hiding, service multiplexing, and pseudowire aggregation.

The SR OS PBB-VPLS implementation also includes support for:

- Multiple MAC Registration Protocol (MMRP), application within IEEE 802.1ak for flood containment in the backbone instances, as specified in Section 6 of RFC 7041.
- Extensions to LDP signaling for PBB-VPLS, according to *draft-balus-l2vpn-pbb-ldp-ext-00*. These extensions avoid network black-hole issues, as described in the Section 3 of the mentioned draft.

This chapter describes how to configure and troubleshoot a PBB-VPLS network.

Knowledge of the VPLS and H-VPLS (RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*) architecture and functionality is assumed throughout this chapter. The most relevant concepts are briefly described in this chapter. For further information, see the relevant Nokia documentation.

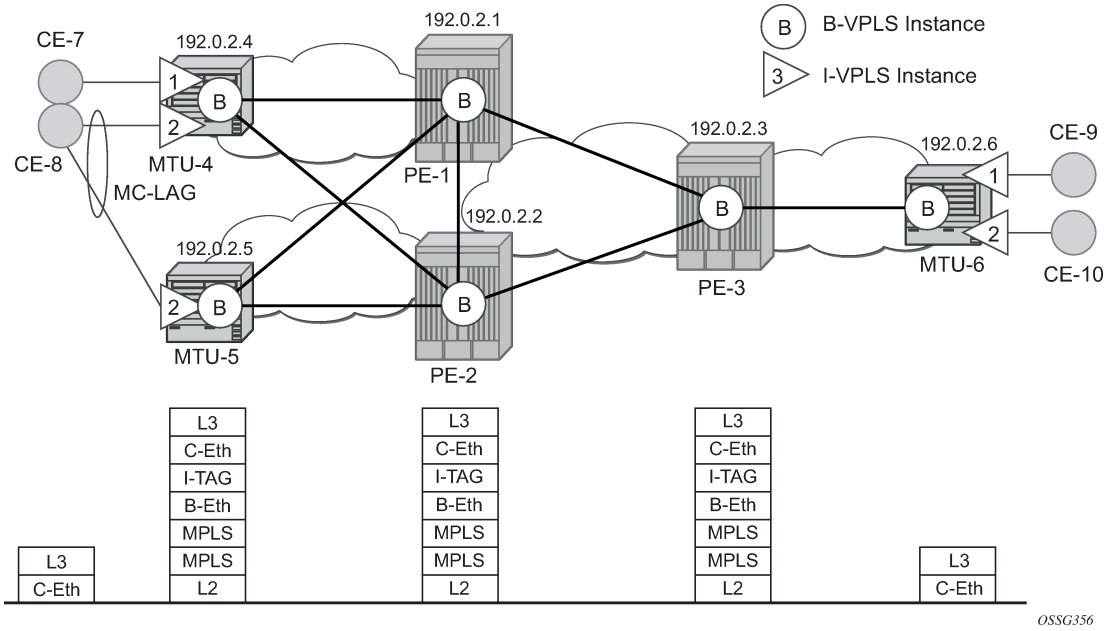
Figure 281: Example topology including B-VPLS, I-VPLSs, and protocol stacks shows the example topology that are used throughout the rest of the chapter, together with the protocol stack used along the path between the CEs.

Figure 281: Example topology including B-VPLS, I-VPLSs, and protocol stacks



The topology consists of three core nodes (PE-1, PE-2, and PE-3) and three Multi-Tenant Unit (MTU) nodes connected to the core. A backbone VPLS instance (B-VPLS 100) will be defined in all the six nodes, whereas a few customer I-VPLS instances will be defined on the three MTU nodes.

Those I-VPLS instances will be multiplexed into the common B-VPLS, using the ISID field within the I-TAG as the demultiplexer field at the egress MTU to differentiate each specific customer.

The B-VPLS domain constitutes an H-VPLS network itself, with spoke-SDPs from the MTUs to the core PE layer. Active/standby spoke-SDPs can be used from the MTUs to the PEs (for example, in the MTU-4 and MTU-5 cases) or single non-redundant spoke-SDPs (for example, MTU-6). CE-8 is dual-connected to the service provider network through MC-LAG.

Configuration

This section describes all the relevant PBB-VPLS configuration tasks for the setup shown in Figure 281: Example topology including B-VPLS, I-VPLSs, and protocol stacks. The appropriate associated IP/MPLS configuration is out of the scope of this example. In this particular example, the following protocols will be configured beforehand:

- ISIS-TE as IGP with all the interfaces being Level-2 (OSPF-TE could have been used instead).
- RSVP-TE as the MPLS protocol to signal the transport tunnels (LDP could have been used instead).
- LSPs between core PEs will be fast reroute protected (facility bypass tunnels) whereas LSP tunnels between MTUs and PEs will not be protected.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The protection between MTU-4, MTU-5 and PE-1, PE-2 will be based on the active/standby pseudowire protection configured in the B-VPLS.
- BGP is configured for auto-discovery (Layer 2-VPN family), because FEC 129 will be used for the pseudowires between PEs in the core.

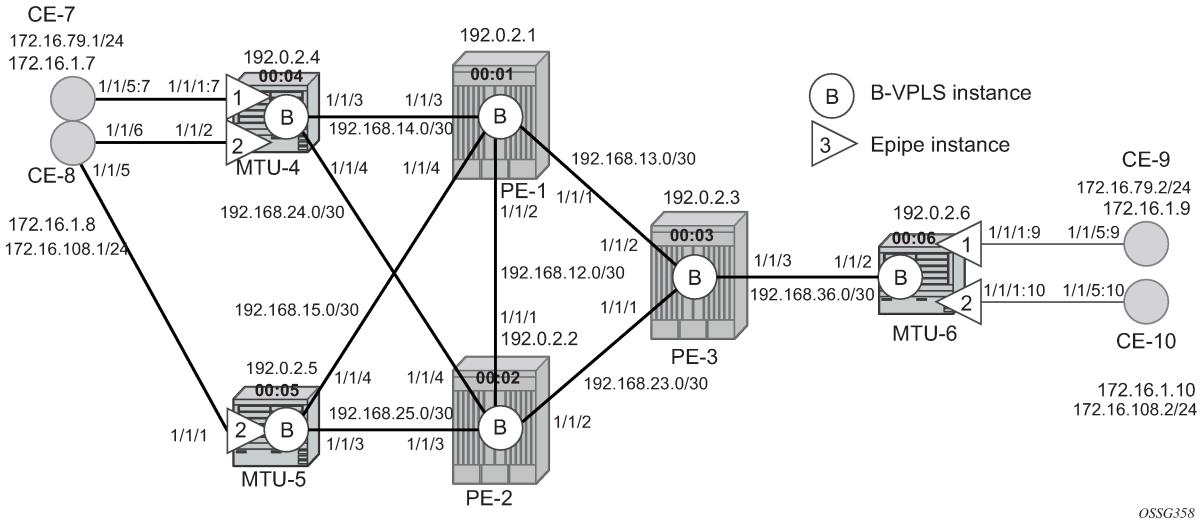
When the IP/MPLS infrastructure is up and running, the service configuration tasks described in the following sections can be implemented.

PBB-VPLS M:1 service configuration

This section describes the process to configure PBB-VPLS services in a M:1 fashion, M being the number of customer I-VPLS services multiplexed into the same B-VPLS instance (instance 100). An alternative configuration is 1:1, where each customer I-VPLS has its own B-VPLS. MTU-4 and PE-1 will be picked to show the relevant CLI configuration commands. The bold digits separated by colons **00:xx** are abbreviations for the backbone MAC addresses.

Figure: Example topology with port numbers and IP addresses shows the example topology with the used IP addresses.

Figure 282: Example topology with port numbers and IP addresses



B-VPLS configuration

The first step is to configure the B-VPLS instance that will carry the PBB traffic. The following shows the B-VPLS configuration on MTU-4 and PE-1. The configuration on MTU-5 and MTU-6 resembles the configuration on MTU-4; the configuration on PE-2 and PE-3 resembles the configuration on PE-1.

The configuration for B-VPLS 100 on MTU-4 is as follows:

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:04:04:04:04:04
                }
            }
            endpoint "core" {
                suppress-standby-signaling false
            }
            spoke-sdp 41:100 {
                endpoint {
                    name "core"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 42:100 {
                endpoint {
                    name "core"
                }
                stp {
                    admin-state disable
                }
            }
        }
```

On PE-1, B-VPLS 100 is configured as follows:

```
# on PE-1:
configure {
    service {
        pw-template "PW1" {
            pw-template-id 1
            provisioned-sdp use
            split-horizon-group {
                name "CORE"
            }
        }
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:01:01:01:01:01
                }
            }
            bgp 1 {
                route-target {
                    export "target:65000:100"
                    import "target:65000:100"
                }
                pw-template-binding "PW1" {
                }
            }
            bgp-ad {
                admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vpls-id "65000:100"
            }
            spoke-sdp 14:100 {
            }
            spoke-sdp 15:100 {
            }
        }
```

The B-VPLS is a regular VPLS instance in terms of configuration, with the following exceptions:

- The B-VPLS service MTU must be at least 18 bytes greater than the I-VPLS MTU of the multiplexed instances. In this example, the I-VPLS instances will have the default service MTU (1500 bytes); therefore, any MTU equal to or greater than 1518 bytes must be configured. In this particular example, a MTU of 2000 bytes is configured in the B-VPLS instance throughout the network.
- The source B-MAC is the MAC address that will be sourced when the PBB traffic is originated from that node. A source B-MAC per B-VPLS instance can be configured (if there are more than one B-VPLS) or a common source B-MAC that will be shared by all the B-VPLS instances in the node. If no specific source B-MAC is provisioned, the system MAC address is used as the source B-MAC. When using the access multi-homing feature for native PBB, the source B-MAC must be a configured one and never the chassis MAC address. The way to configure a common B-MAC for all the B-VPLS instances on MTU-4 is as follows:

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
```

The following considerations will be taken into account when configuring the B-VPLS:

- B-VPLS SAPs:
  - Ethernet null, dot1q, and qinq encapsulations are supported
  - Default SAP (:*) types are blocked in the CLI for the B-VPLS SAP
- B-VPLS SDPs:
  - For MPLS, both mesh and spoke-SDPs with split-horizon groups are supported.
  - Similar to regular pseudowires, the outgoing PBB frame on an SDP (for example, B-pseudowire) contains a BVID qtag only if the pseudowire type is Ethernet VLAN. If the pseudowire type is **Ethernet**, the BVID q-tag is stripped before the frame goes out.
  - BGP-AD is supported in the B-VPLS; therefore, spoke-SDPs in the B-VPLS can be signaled using FEC 128 or FEC 129. In this example, BGP-AD and FEC 129 are used. A split-horizon group (SHG) has been configured to emulate the behavior of mesh-SDPs in the core.
- If a local I-VPLS instance is associated with the B-VPLS, local frames originated/terminated on local I-VPLS(s) are PBB encapsulated/de-encapsulated using the PBB Ethertype provisioned under the related port or SDP component.

By default, the PBB Ethertype is 0x88e7 (which is the standard one defined in 802.1ah for the I-TAG) but this PBB Ethertype can be changed if required due to interoperability reasons. This is the way to change it at port and/or SDP level:

```
[ex:configure port 1/1/3 ethernet]
A:admin@MTU-4# pbb-etype ?
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 35047

    Ethertype for PBB encapsulation on the Ethernet port
```

```
[ex:configure service sdp 41]
A:admin@MTU-4# pbb-etype ?

 pbb-etype <number>
 <number> - <0x600..0xffff>
 Default  - 0x88E7

    Ethertype used in frames sent out on this SDP when VC type is 'vlan' for
    Provider Backbone Bridging frames as 0xXXYY with range 0x0600-0xFFFF.
```

The following commands are useful to check the actual PBB Ethertype:

```
[]
A:admin@MTU-4# show port 1/1/3 | match PBB
PBB Ethertype      : 0x88e7
```

```
[]
A:admin@MTU-4# show service sdp 41 detail | match PBB
Bw BookingFactor     : 100                   PBB Etype          : 0x88e7
```

I-VPLS configuration

When the common B-VPLS is configured, the next step is to provision the customer I-VPLS instances. The following shows the relevant configuration on MTU-4 for the two I-VPLS instances represented in Figure 282: Example topology with port numbers and IP addresses. The I-VPLS instances are configured on the MTU devices, whereas the core PEs are customer-unaware nodes.

```
# on MTU-4:
configure {
    service {
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            sap 1/1/1:7 {
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
            }
            sap lag-1 {
            }
        }
```

The I-VPLS instance has to be linked to its corresponding transport B-VPLS instance. That link is specified by the **backbone-vpls <b-vpls> isid <isid>** command. The ISID is mandatory when configuring the backbone VPLS.

The following considerations will be taken into account when configuring the I-VPLS:

- I-VPLS SAPs:
  - SAPs can be defined on ports with any Ethernet encapsulation type (null, dot1q, and qinq)
  - The I-VPLS SAPs can coexist on the same port with SAPs for other business services, for example, VLL and VPLS SAPs.
- I-VPLS SDPs:
  - GRE and MPLS SDPs are supported.
  - No mesh-SDPs are supported, only spoke-SDP. Mesh-SDPs can be emulated by using SHGs.

Existing SAP processing rules still apply for the I-VPLS case; the SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service that the packet belongs to:

- Null encapsulation defined on ingress — Any VLAN tags are ignored and the packet goes to a default service for the SAP.
- Dot1q encapsulation defined on ingress — only first VLAN tag is considered.
- QinQ encapsulation defined on ingress — both VLAN tags are considered; wildcard for the inner VLAN tag is supported.
- For dot1q/qinq encapsulations, traffic encapsulated with VLAN tags for which there is no definition is discarded.
- Any VLAN tag used for service selection on the I-SAP is stripped before the PBB encapsulation is added. Appropriate VLAN tags are added at the remote PBB PE when sending the packet out on the egress SAP.

MMRP for flooding optimization

When the M:1 model is used (as in this example), any I-VPLS broadcast, unknown unicast, or multicast (BUM) frame is flooded throughout the B-VPLS domain regardless of the nodes where the originating I-VPLS is defined. In other words, in our example in Figure 281: Example topology including B-VPLS, I-VPLSs, and protocol stacks, any BUM frame coming from CE-7 would be flooded in the B domain and would reach PE-2 and MTU-5, even though that traffic only needs to go to PE-3 and MTU-6. To build customer-based flooding trees and optimize the flooding, Multiple MAC Registration Protocol (MMRP) must be configured on the B-VPLS.

MMRP can be enabled with its default settings just by executing the following command on all nodes:

```
# on all nodes:
configure {
    service {
        vpls "B-VPLS 100" {
            mrp {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                admin-state enable
```

There are specific B-VPLS MRP settings that can be modified. These are the default values:

```
[ex:configure service vpls "B-VPLS 100" mrp]
A:admin@MTU-4# info detail
    admin-state enable
    mmrp {
        admin-state enable
        end-station-only false
     ## flood-time
        attribute-table {
            high-wmark 95
            low-wmark 90
            size 2048
        }
    }
```

These attributes can be changed to control the number of MMRP attributes per B-VPLS and optimize the convergence time in case of failures in the B-VPLS:

- Controlling the number of attributes per B-VPLS

  The MMRP exchanges create one entry per attribute (group B-MAC) in the B-VPLS where MMRP protocol is running. PBB uses a group B-MAC address—built using a specific OUI (00:1e:83) with the multicast bit set, and the ISID value for the last 24 bits—as a destination MAC address for flooding any BUM frame into the B-domain.

  When the first registration is received for an attribute, an MFIB entry is created for it. The **attribute-table size** allows the user to control the number of MMRP attributes (group B-MACs) created on a per B-VPLS basis, between 1 and 2048. Based on the configured size, high and low watermarks can be set (in percentage) so that alarms can be triggered upon exceeding the watermarks. This ensures that no B-VPLS will take up all the resources from the total pool. The maximum number of attributes per B-VPLS is 2048 and 4000 can be configured globally on the system.

- Optimizing the convergence time

  Assuming that MMRP is used in a certain B-VPLS, under failure conditions, the time it takes for the B-VPLS forwarding to resume may depend on the data plane and control plane convergence plus the time it takes for MMRP exchanges to stabilize the flooding trees on a per ISID basis. In order to minimize the convergence time, the PBB SR OS implementation offers the selection of a mode where B-VPLS forwarding reverts for a short time to flooding so that MMRP has enough time to converge. This mode can be selected through configuration using the **flood-time <value>** command where value represents the amount of time in seconds (between 3 and 600) that flooding will be enabled. If this behavior is selected, the forwarding plane starts with B-VPLS flooding for a configurable time period, then it reverts back to the MFIB entries installed by MMRP. The following B-VPLS events initiate the switch from per I-VPLS (MMRP) MFIB entries to B-VPLS flooding:

  – Reception or local triggering of a Spanning Tree Topology Change Notification (TCN)

  – B-SAP failure

  – Failure of a B-SDP binding

  – Pseudowire activation in a primary/standby H-VPLS resiliency solution

  – SF/CPM switchover due to STP reconvergence

The IEEE 802.1ak standard, which defines MRP, requires the implementation of different state machines with associated timers that can be tuned. A full MRP participant maintains the following state machines:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Registrar state machine
- Applicant state machine
- LeaveAll state machine
- PeriodicTransmission state machine

The two first state machines are maintained for each attribute in which the participant is interested, whereas the two latter are global to all the attributes.

The job of the registrar function is to record declarations of the attribute made by other participants on the LAN. A registrar does not send any protocol messages, because the applicant looks after the interests of all would-be participants.

The job of the applicant is twofold: first, to ensure that this participant's declaration is correctly registered by other participants' registrars, and next, to prompt other participants to register again after one withdraws a declaration.

The associated timers can be tuned on a per SAP/SDP basis:

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 41:100]
A:admin@MTU-4# mrp ?

 mrp

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 join-time             - Set the maximum rate for attribute join messages to be sent
                         on the SDP.
 leave-all-time        - Set the frequency where all attribute declarations on the
                         SDP are refreshed.
 leave-time            - Set the time an attribute is held in leave state before
                         registration is removed.
 periodic-time         - Set the freqeuency of retransmission of attribute
                         declarations.
 periodic-timer        - Enable/Disable retransmission of attribute declarations.
 policy                - Specify they MRP policy to control which Group BMAC
                         attributes will advertise on the egress SDP Bind.
```

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 41:100 mrp]
A:admin@MTU-4# info detail
 ## apply-groups
 ## apply-groups-exclude
    join-time 2
    leave-time 30
    leave-all-time 100
    periodic-time 10
    periodic-timer false
 ## policy
```

A brief description of the MRP SAP/SDP attributes follows:

- **Join-time** — This command controls the interval between transmit opportunities that are applied to the applicant state machine. An instance of this join period timer is required on a per-port, per-MRP participant basis. For more information, see IEEE 802.1ak-2007 section 10.7.4.1.
- **Leave-time** — This command controls the period of time that the registrar state machine will wait in the leave state before transitioning to the MT state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The leave period timer is set to the value leave-time when it is started. A registration is normally in "in" state where there is an MFIB entry and traffic being forwarded. When a "leave all" is performed (periodically around every 10-15 seconds per

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

SAP/SDP binding – see leave-all-time below), a node sends a message to its peer indicating a leave all is occurring and puts all of its registrations in leave state. The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations. See IEEE 802.1ak-2007 section 10.7.4.2.

- **Leave-all-time** — This command controls the frequency with which the leaveall state machine generates leaveall PDUs. The timer is required on a per-port, per-MRP participant basis. The leaveall period timer is set to a random value, T, in the range leavealltime<T<1.5*leave-all-time when it is started. See IEEE 802.1ak-2007, section 10.7.4.3.
- **Periodic-time** — This command controls the frequency the periodic transmission state machine generates periodic events if the periodic transmission timer is enabled. The timer is required on a per-port basis. The periodic transmission timer is set to one second when it is started.
- **Periodic-timer** — This command enables or disables the periodic transmission timer.

The following command shows the MRP configuration and statistics on a per SAP/SDP basis within the B-VPLS:

In the example throughout the chapter, as soon as MMRP is enabled, an optimized flooding tree will be built for ISID 1, because the I-VPLS 1 is only defined in MTU-4 and MTU-6, but not in MTU-5. A good way to track the flooding tree for a particular ISID is the following command:

```
[]
A:admin@MTU-4# show service id 100 mmrp mac
-------------------------------------------------------------------------------
SAP/SDP                               MAC Address       Registered  Declared

Number of Entries=2 SAPs=0 SDPs=2
-------------------------------------------------------------------------------
```

The group B-MAC ending in **01** corresponds to the I-VPLS 1 whereas the one ending in **02** to the I-VPLS 2. MMRP PDUs for the two attributes are sent throughout the loop-tree topology (not over STP blocked ports or standby spoke-SDPs and observing the split-horizon rules). The two attributes are registered on every B-VPLS virtual port; however, the tree is only built on those ports where the attribute is also declared, and not only registered. For instance, the spoke-SDP 52:100 in MTU-5 will not be part of the ISID 1 or ISID 2 flooding trees. Neither attribute is declared because I-VPLS 1 does not exist on MTU-5 and I-VPLS 2 is operationally down on MTU-5 (MC-LAG SAP is in standby state, so the I-VPLS is down).

As soon as a group B-MAC attribute is registered on a particular port, an MFIB entry is added for that B-MAC on that port, regardless of the declaration state for that attribute on the port. For instance, neither

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

B-MAC is declared on MTU-5, however, the two MFIB entries are created as soon as the attributes are registered:

```

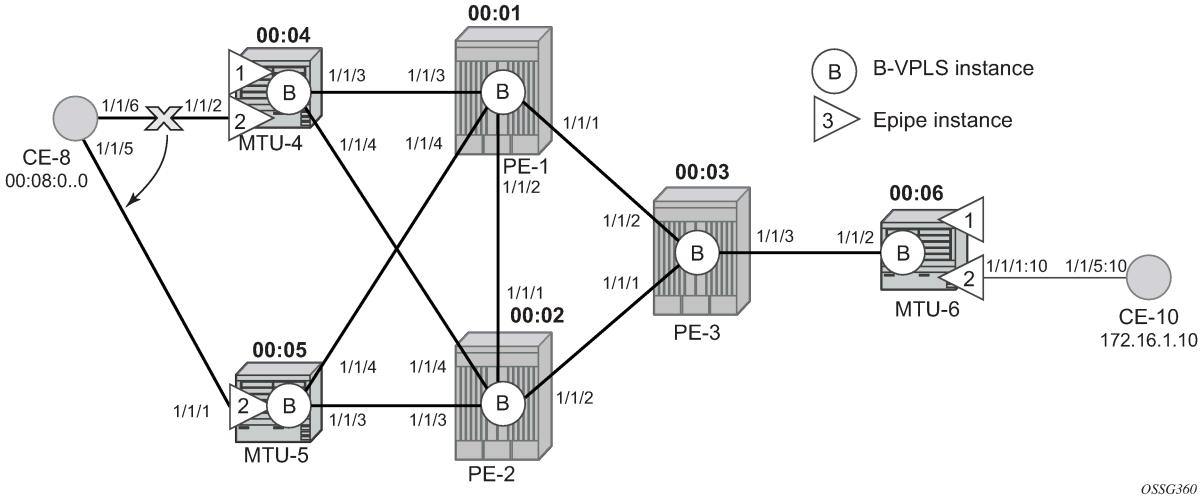
```

MAC flush: avoiding black-holes

Both the I-VPLS and B-VPLS components inherit the MAC flush capabilities of a regular VPLS clearing the related C-MAC and respectively B-MAC FIBs. All types of MAC flush—all-but-mine and all-from-me—are supported together with the related CLI. In addition to these features, some extensions have been added so that MAC flush can be triggered on the B-VPLS based on some events happening on the I-VPLS. Figure: Black-hole shows a potential scenario where black-holes can occur if the correct configuration is not added.

Figure 283: Black-hole



Under normal conditions, the I-VPLS 2 FIB on MTU-6 shows that CE-8 MAC address is learned through B-MAC 00:04 of MTU-4:

```
[]
A:admin@MTU-6# show service id 2 fdb pbb

```
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:04:04:04:04:04 L/60
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/60
===============================================================================
```

When a failure happens in the CE-8 MC-LAG active link, the link to MTU-5 takes over. However, the FIB on MTU-6 still points at the BMAC of MTU-4 and that will still be the B-MAC used in the PBB encapsulation. Therefore, a black-hole occurs until either bidirectional traffic is sent or the FIB aging timer expires.

The configuration in the I-VPLS can be modified to trigger a MAC flush in the B-VPLS with the following command:

```
[ex:configure service vpls "I-VPLS 2" pbb i-vpls-mac-flush tldp]
A:admin@MTU-4# send-to-bvpls ?

 send-to-bvpls

 all-but-mine          - Generate LDP MAC withdraw message to b-VPLS
 all-from-me           - Generate LDP MAC withdraw all from me message to b-VPLS
```

The following command is executed on all MTUs to solve the black-hole:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    tldp {
                        send-to-bvpls {
                            all-from-me true
                        }
                    }
                }
            }
```

By configuring **send-to-bvpls all-from-me true** on I-VPLS 2, a failure on the MC-LAG active link on I-VPLS 2 will trigger an LDP MAC **flush-all-from-me** into the B-VPLS that will flush the FIB in MTU-6 for I-VPLS 2, avoiding the black-hole. A MC-LAG failure is emulated by disabling the LAG on MTU-4, as follows:

```
# on MTU-4:
configure {
    lag 1 {
        admin-state disable
    }
```

MTU-4 sends the following LDP MAC flush for all MAC addresses learned from MTU-4:

```
1 2021/01/12 17:02:25.211 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Address Withdraw packet (msgId 263) to 192.0.2.1:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
ISID 1 = 2
Number of Path Vectors : 1
Path Vector(  1) = 192.0.2.4
"
```

On MTU-6:

```
1 2021/01/12 17:02:25.227 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Address Withdraw packet (msgId 206) from 192.0.2.3:0
Protocol version = 1
MAC Flush (All MACs learned from me)
Service FEC PWE3: ENET(5)/100 Group ID = 0 cBit = 0
Number of PBB-BMACs = 1
BMAC 1 = 00:04:04:04:04:04
Number of PBB-ISIDs = 1
ISID 1 = 2
Number of Path Vectors : 3
Path Vector(  1) = 192.0.2.4
Path Vector(  2) = 192.0.2.1
Path Vector(  3) = 192.0.2.3
```

Immediately after receiving the MAC flush, the CE-8 MAC is flushed. The CE-8 MAC is learned again, but this time linked to the B-MAC 00:05, which is the B-MAC of MTU-5:

```
[]
A:admin@MTU-6# show service id 2 fdb pbb

===============================================================================
Forwarding Database, i-Vpls Service 2
===============================================================================
MAC               Source-Identifier     B-Svc     b-Vpls MAC        Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:08:00:00:00:00 b-sdp:63:100          100       00:05:05:05:05:05 L/0
00:10:00:00:00:00 sap:1/1/1:10          100       N/A               L/120
===============================================================================
```

The following I-VPLS events are propagated into the B-VPLS depending on the all-but-mine or all-from-me keywords used in the configuration:

If the all-but-mine keyword is configured (positive flush), the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. TCN event in one or more of the related I-VPLS/M-VPLS.
2. Pseudowire/SDP binding activation with active/standby pseudowire (standby to active or down to up).
3. Reception of an LDP MAC withdraw flush-all-but-mine in the related I-VPLS.

If the all-from-me keyword is configured (negative flush) the following events in the I-VPLS trigger a MAC flush into the B-VPLS:

1. MC-LAG active link failure (in our example).
2. Failure of a local SAP – requires **mac-flush>tldp>send-on-failure true** to be enabled in I-VPLS.
3. Failure of a local pseudowire/SDP binding – requires **mac-flush>tldp>send-on-failure true** to be enabled in I-VPLS.
4. Reception of an LDP MAC withdraws flush-all-from-me in the related I-VPLS.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In addition to this and regardless of what type, MAC flush has been optimized to avoid flushing in the core PEs, flushing only the C-MACs mapped to a specific B-MAC (belonging to a specific ISID FIB) and the ability to indicate to core PEs which messages should always be forwarded endpoint-to-endpoint toward all PBB PEs regardless of the propagate-mac-flush setting in B-VPLS. All of this is implemented without the need of any additional CLI commands and it is part of **draft-balus-l2vpn-pbb-ldp-ext-00**.

Another extension supported to avoid black-holes within this mix of I- and B-VPLS environments is the **block-on-mesh-failure** feature in PBB. When the VPLS mesh exists only in I-VPLS or in B-VPLS, and the **block-on-mesh-failure** feature is enabled, the regular VPLS behavior will apply (when all the mesh-SDPs go down an LDP notification with pseudowire status bits = 0x01—Pseudo Wire Not Forwarding—is sent over the spoke-SDPs). When the active/standby pseudowire resiliency is implemented in I-VPLS such that the PBB PE performs the role of a PE-rs, the B-VPLS core replaces the pseudowire (SDP binding) mesh. The block-on-mesh notification (LDP notification indicating pseudowire not forwarding) will be sent to the MTUs only when the related B-VPLS is operationally down. The B-VPLS core is operationally down only when all of its SAPs and SDPs are down.

The final feature that can be enabled in an I-VPLS with CLI is the **send-on-bvpls-failure** feature, as follows:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "I-VPLS 2" {
            pbb {
                i-vpls-mac-flush {
                    tldp {
                        send-on-bvpls-failure true
                        }
                    }
```

This feature is required to avoid black-holes when there is a full mesh of pseudowires in the I-VPLS domain and the B-VPLS instance can go operationally down. Figure 284: Send flush on B-VPLS failure example shows a typical scenario where this feature is needed (normally when PBB-VPLS and multi-chassis end point are combined together).

Figure 284: Send flush on B-VPLS failure example

Access dual-homing and MAC notification

Although this section is focused on PBB in a MPLS based network, the Nokia PBB implementation also allows the operator to use a native Ethernet infrastructure in the PBB core. Native Ethernet tunneling can be emulated using Ethernet SAPs to interconnect the related B-VPLS instances. In those cases, there is no LDP signaling available; therefore, there is no MAC flush sent when the active link in a multi-homed access device fails.

The SR OS supports a mechanism to avoid potential black-holes in native Ethernet PBB networks. In addition to the source B-MAC associated with each B-VPLS, an additional B-MAC is associated with each MC-LAG supporting Multi-homed I-VPLS SAPs. The nodes that are in a multi-homed MC-LAG configuration share a common B-MAC on the related MC-LAG interfaces. When the MAC notification is enabled, an Ethernet CFM notification message is sent from the node holding the active link. That message will be flooded in the B-VPLS domain using the MC-LAG SAP B-MAC as the source MAC address. The remote nodes will learn the customer MAC addresses behind the MC-LAG and will link them to this new SAP B-MAC. MC-LAG will keep track of the active link for each particular LAG associated with a SAP B-MAC. Should MC-LAG detect any new active link in a node, a new CFM notification message will be flooded from the new active node.

The following restrictions and considerations must be taken into account:

- Only MC-LAG is supported as dual-home mechanism.
- This mechanism is supported for native PBB and/or MPLS-based PBB-VPLS. Although it is mostly beneficial when native PBB is used in the core, it can also help to optimize the re-learning process in a MPLS-based core in case of MC-LAG failures, in addition to the existing LDP MAC flush procedures.

The example of this configuration shows the setup being used in this configuration example. MAC-notification will be configured in MTU-4 and MTU-5 for the dual-homed CE-8.

The first step is to configure the SAP B-MAC that will be used for the MAC notification messages. The **source-bmac-lsb** (source backbone MAC least significant bits) command has been added to the MC-LAG branch so that the operator can decide the two last octets to be used in the SAP B-MAC. Those two last octets can be derived from the LACP key (if the **use-lacp-key** statement is used) or can be specifically defined.

```
[ex:configure redundancy multi-chassis peer 192.0.2.5 mc-lag]
A:admin@MTU-4# lag 1 ?

 lag

 Immutable fields      - lacp-key, system-id, system-priority
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 lacp-key              - Key based on the remote MC-LAG
 remote-lag            - Lag ID of the remote MC-LAG
 source-bmac-lsb       - MAC address value to apply to all ingress traffic
 system-id             - ID based on the remote MC-LAG
 system-priority       - Priority based on the remote MC-LAG
```

There must be a different SAP B-MAC per MC-LAG. The use of the LACP key as a default for two least significant octets makes the operations simpler. In this example, the last two octets of the SAP BMAC will come from the lacp-key. The configuration on MTU-4 is as follows:

```
# on MTU-4:
configure {
    redundancy {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        multi-chassis {
            peer 192.0.2.5 {
                admin-state enable
                mc-lag {
                    admin-state enable
                    lag 1 {
                        lacp-key 15
                        system-id 00:00:00:00:00:01
                        system-priority 65535
                        source-bmac-lsb use-lacp-key
                    }
                }
            }
        }
```

Therefore, the SAP B-MAC will be formed in the following way:

[SAP BMAC = 4 first bytes of the source BMAC + 2 bytes from source-bmac-lsb]

MAC notification in B-VPLS 100 is enabled on all MTUs, as follows:

```
# on MTU-4, MTU-5, MTU-6:
configure {
    service {
        vpls "B-VPLS 100"
            pbb {
                mac-notification {
                    admin-state enable
                }
```

The **mac-notification** command activates the described mechanism and has the following parameters:

```
[ex:configure service vpls "B-VPLS 100" pbb]
A:admin@MTU-4# mac-notification ?

 mac-notification

 admin-state          - Administrative state of MAC notification
 count                - MAC notification messages count
 interval             - Interval for MAC notification messages
 renotify             - Re-notify interval for MAC-notification messages
```

Where:

- interval <value> controls how often the subsequent MAC notification messages are sent. Default = 100 ms. Required values: 100 ms – 10 sec, in increments of 100 ms.
- count <value> controls how often the MAC notification messages are sent. Default: 3. Range: 1–10.

The "count" and "interval" parameters can also be configured at the service context. The settings configured at the B-VPLS service context take precedence though.

```
[ex:configure service pbb]
A:admin@MTU-4# mac-notification ?

 mac-notification

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 count                 - MAC notification messages count
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 interval              - Interval for MAC-notification messages
```

Finally, the B-VPLS is instructed to use the SAP B-MAC. The **use-mclag-bmac-lsb** statement enables the use of the source B-MAC allocated to the multi-homed SAPs (assigned to the MC-LAG) in the related I-VPLS service (could be Epipe service as well). The command will fail if the value of the source B-MAC assigned to the B-VPLS is the hardware (chassis) B-MAC. In other words, the source B-MAC must be a configured one. The **use-mclag-bmac-lsb** statement is by default false.

```
# on MTU-4:
configure {
    service {
        vpls "B-VPLS 100"
            pbb {
                source-bmac {
                    address 00:aa:aa:aa:aa:04
                    use-mclag-bmac-lsb true
                }
```

```
# on MTU-5:

===============================================================================
```

As soon as MAC notification is enabled, an Ethernet CFM notification message is sent from MTU-4, which is the node where the active MC-LAG link resides. The CFM message will have the source MAC address "00:aa:aa:aa:00:0f" (4 first bytes of the configured source BMAC + 2 bytes from the configured source-bmac-lsb, which is 15 in hex) and will be flooded throughout the B-VPLS domain. Should the link between CE-8 and MTU-4 fail, the MC-LAG protocol will activate the redundant link and MTU-5 will immediately issue a CFM message with the shared sourced SAP B-MAC that will be flooded in the B-VPLS domain.

PBB and IGMP snooping

IGMP snooping can be enabled on I-VPLS SAPs and SDPs (it cannot be enabled on B-VPLS). SR OS can keep track of IGMP joins received over individual B-SDPs or B-SAPs, and it starts flooding the multicast group (and only the multicast group) to all B-components (using the group B-MAC for I-SID) as soon as the first IGMP join for that multicast group is received in one of the B-SAP/SDP components.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The first IGMP join message received over the local B-VPLS will add all the B-VPLS SAP/SDP components into the related multicast table associated with the I-VPLS context. When the querier is connected to a remote I-VPLS instance, over the B-VPLS infrastructure, its location is identified by the B-VPLS SDP/SAP on which the query was received and also by the source B-MAC address used in the PBB header for the query message, the B-MAC associated with the B-VPLS instance on the remote PBB PE.

The following configuration on MTU-4 enables IGMP snooping in I-VPLS 1 and adds some static groups on a SAP. The location of the querier is configured by adding the B-MAC where the querier is connected to (in this example, MTU-6) and adding the two B-VPLS spoke-SDPs as mrouter ports (B-VPLS mrouter ports are added in the I-VPLS backbone-vpls context).

The **mac** command translates MAC address into strings so that the names can be used instead of typing the entire MAC address every time we need to.

```
# on MTU-4:
configure {
    service {
        pbb {
            source-bmac {
                address 00:04:04:04:04:04
            }
            mac "MTU-4" {
                address 00:04:04:04:04:04
            }
            mac "MTU-5" {
                address 00:05:05:05:05:05
            }
            mac "MTU-6" {
                address 00:06:06:06:06:06
            }
        }
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                    igmp-snooping {
                        mrouter-destination "MTU-6" { }
                    }
                    spoke-sdp 41:100 {
                        igmp-snooping
                            mrouter-port true
                        }
                    }
                    spoke-sdp 42:100 {
                        igmp-snooping
                            mrouter-port true
                        }
                    }
                }
            }
            igmp-snooping
                admin-state enable
            }
            sap 1/1/1:7 {
                igmp-snooping {
                    static {
                        group 228.0.0.1 {
                            starg
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        }
                        group 228.0.0.2 {
                            starg
                        }
                        group 239.0.0.1 {
                            source 172.16.99.99 { }
                        }
                    }
                }
            }
```

As in regular VPLS instances, mrouter ports are added to all the multicast groups:

```

MMRP policies and ISID-based filtering for PBB inter-domain expansion

As described in the MMRP for flooding optimization section, MMRP is used in the backbone VPLS instances to build per I-VPLS flooding trees. Each I-VPLS has an associated group B-MAC in the B-VPLS, which is derived from the ISID, and is advertised by MMRP throughout the whole B-VPLS context, regardless of whether a specific I-VPLS is present in one or all the B-VPLS PEs.

In an inter-domain environment, the same B-VPLS can be defined in different domains and therefore MMRP will advertise all the group B-MACs in every domain. The group B-MACs are consuming resources in all the PEs no matter if a particular ISID—and therefore its group B-MAC—is required in one of the domains or not. When MMRP is enabled in a particular PE, data plane and control plane resources are consumed and they must be taken into consideration when designing PBB-VPLS networks:

- Control plane – MRRP processing takes CPU cycles and the number of attributes that can be advertised is not unlimited
- Data plane – each group B-MAC registration takes one MFIB entry (the MFIB is shared between MMRP and IGMP/PIM snooping)

SR OS routers support MMRP policies and ISID-based filters so that control plane and data plane resources can be saved when I-VPLS instances are not defined in all the domains.

Figure 285: Inter-domain B-VPLS and MMRP policies/ISID-based filters example illustrates an example of usage for MMRP policies and ISID-based filters that will be configured in this section. "Domain 1" and "domain 2" will have a range of local ISIDs each and a range of "inter-domain" ISIDs:

- Domain 1 local ISIDs: from 1 to 100
- Domain 2 local ISIDs: from 101 to 200
- Inter-domain ISIDs: from 1000 to 2000

By applying the MMRP policies indicated in Figure 285: Inter-domain B-VPLS and MMRP policies/ISID-based filters example, domain 1 attributes will be prevented from being declared and registered in domain 2 and the other way around, domain 2 attributes from being declared and registered in domain 1. The egress MAC filters will drop any traffic sourced from a local ISID preventing it to be transmitted to the remote domain.

Figure 285: Inter-domain B-VPLS and MMRP policies/ISID-based filters example

MMRP policies

The following shows the MMRP policy configuration on node PE-1. This policy will block any registration/declaration except those for ISIDs 1000-2000. Packets will be compared against the configured matching ISIDs as long as the PBB Etype matches the one configured on the port or SDP.

```
# on PE-1:
configure {
    service {
        mrp {
            policy "mrp_policy_1" {
                description "allow-inter-domain-isids"
                default-action block
                entry 10 {
                    action allow
                    match {
                        isid 1000 {
                            higher-value 2000
                        }
                    }
                }
            }
```

After the MMRP policy is configured, it must be applied on the corresponding SAP or SDP-binding. An MRP policy can be applied to a B-VPLS SAP, B-VPLS spoke-SDP or B-VPLS mesh-SDP:

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            spoke-sdp 14:100 {
                mrp {
                    policy "mrp_policy_1"
                }
            }
            spoke-sdp 15:100 {
                mrp {
                    policy "mrp_policy_1"
                }
            }
```

In the same way, mrp_policy_3 will be configured in PE-3.

Some additional considerations about the MMRP policies:

- Different entries within the same MRP policy can have overlapping ISID ranges. The entries will be evaluated in the order of their IDs and the first match will cause the implementation to execute the associated action for that entry and then to exit the MRP policy.
- If no ISID is specified in the match condition then:
  - If the action is "end-station", no entry is added and the action is block.
  - If the action is different from "end-station", every ISID is considered for that action.
- The MRP policy specifies either a forward or a drop action for the group B-MAC attributes associated with the ISIDs specified in the match criteria.

```
[ex:configure service mrp policy "mrp_policy_1" entry 10]
A:admin@PE-1# action ?
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
action <keyword>
<keyword>  - (block|allow|end-station)

   Specify the action to take for packets that match this mrp-policy entry
```

- There is an additional action called end-station. This action specifies that an end-station emulation is present on the SAP/SDP-binding where the policy has been applied. The matching ISIDs will not get declared/registered in the SAP/SDP-binding (just like the block action). However, those attributes will get mapped as static MMRP entries on the SAP/SDP-binding, which implicitly get instantiated in the data plane as MFIB entries associated with that SAP/SDP-binding for the related group B-MAC. When the action is "end-station", the default action must be block:

```
*[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# default-action allow

*[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service mrp policy "mrp_policy_3" entry 10 action -
Mrp-policy default-action must be block when end-station action exists - configure
 service mrp policy "mrp_policy_3" default-action
```

- The end-station action can be used in the inter-domain gateways when, for instance, we do not want MMRP control plane exchanges between domains. The following output shows how to define the static MMRP entries 1000-2000 in PE-3 without receiving any declaration for any of those attributes or having any of those locally configured.

```
# on PE-3:
configure {
    service {
        mrp {
             policy "mrp_policy_3" {
                default-action block
                entry 10 {
                    action end-station
                    match {
                        isid 1000 {
                            higher-value 2000
                        }
                    }
                }
            }
```

```

```

- The MRP policy can be applied to multiple B-VPLS services as long as the scope of the policy is template (the scope can also be exclusive).
- Any changes made to the existing policy will be applied immediately to all services where this policy is applied. For this reason, when many changes are required on a MRP policy, Nokia recommends copying the policy to a work-in-progress policy. That work-in-progress policy can be modified until complete and then written over the original MRP policy. You can use the **configure service mrp copy** command to work with the policies in this manner.

```
[ex:configure service mrp]
A:admin@PE-1# copy policy "mrp_policy_3" to policy ?

 [policy-name] <string>
 <string>  - <1..32 characters>

    Specify the policy name associated with the MRP
```

The **rename** command can help to change the entries sequence order.

```
[ex:configure service mrp policy "mrp_policy_3"]
A:admin@PE-3# rename entry 10 to ?

 [entry-id] <number>
 <number>  - <1..65535>

    Sepcify an id for the MRP policy entry
```

An MRP policy cannot be deleted until it is removed from all the SAPs/SDP-bindings where it is applied.

ISID-based filters

The MMRP policies help to control the exchange of group B-MAC attributes across domains. Based on the registration state of a specific group B-MAC on a SAP/SDP-binding, the BUM traffic for a particular I-VPLS will be allowed or dropped. However, to avoid that any local ISID packet is flooded to the remote B-VPLS domain, all the packets tagged with the local ISIDs at the gateway PEs need to be filtered at the data plane. ISID-based filters will prevent the local ISIDs from sending any packet with unicast B-MAC to the remote domain. This is particularly useful for PBB-Epipe services across domains, where all the frames use unicast B-MACs and MMRP policies cannot help because they only act on group B-MAC packets.

The following CLI output shows how to configure an ISID-based filter that drops all the traffic sourced from the local ISIDs on PE-1 (the default action is drop and it does not show up in the configuration).

```
# on PE-1:
configure {
    filter {
        mac-filter "MAC 1" {
            description "drop_local_isids"
            type isid
            filter-id 1
            entry 10 {
                log 101
                match {
                    frame-type 802dot3
                    isid {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        range {
                            start 1000
                            end 2000
                        }
                    }
                }
                action {
                    accept
                }
            }
```

Once the filter is configured, it must be applied on a B-VPLS SAP or SDP-binding and always at egress.

```
# on PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            spoke-sdp 14:100 {
                egress {
                    filter {
                        mac "MAC 1"
                    }
                }
            }
            spoke-sdp 15:100 {
                egress {
                    filter {
                        mac "MAC 1"
                    }
                }
            }
```

Some additional comments about ISID-based filters:

- The **type isid** statement must be added when ISIDs are defined in the match command, otherwise the system will show an error, as follows:

```
*[ex:configure filter mac-filter "MAC 2"]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure filter mac-filter "MAC 2" entry 10 match isid value
 - The match criteria entered are not compatible with the Mac filter type - Allowed
only with mac-filter type ISID - configure filter mac-filter "MAC 2" type
```

- When the operator sets the "type isid", the filter cannot be applied at ingress. Only egress ISID-based filters are allowed:

```
[ex:configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress filter]
A:admin@PE-1# mac "MAC 1"

*[ex:configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress filter]
A:admin@PE-1# commit
MINOR: SVCMGR #2050: configure service vpls "B-VPLS 100" spoke-sdp 14:100 ingress
 filter mac - Can not apply filter of type 'isid' on ingress - configure filter
 mac-filter "MAC 1" type
```

- Like any filter or MMRP policy, the filter can be applied to multiple B-VPLS services as long as the scope of the policy is "template" (the scope can also be "exclusive").

Use subject to Terms available at: www.nokia.com/terms.

```
                event
                exit
                packet
                    init detail
                    label detail
                exit
            exit
        exit
    exit
exit
```

The following debug commands (in classic CLI) can help the operator to troubleshoot MMRP.

```
A:MTU-4# debug service id 100 mrp ?
  - mrp
  - no mrp

      all-events      - Enable/disable MRP debugging for all events
 [no] applicant-sm    - Enable/disable MRP debugging for applicant state machine
                        changes
 [no] leave-all-sm    - Enable/disable MRP debugging for leave all state machine
                        changes
 [no] mmrp-mac        - Enable/disable MRP debugging for a particular MAC address
 [no] mrpdu           - Enable/disable MRP debugging for Rx/Tx MRP PDUs
 [no] mvrp-vlan       - Enable/disable debugging for a particular vlan
 [no] periodic-sm     - Enable/disable MRP debugging for periodic state  machine
                        changes
 [no] registrant-sm   - Enable/disable MRP debugging for registrant state machine
                        changes
 [no] sap             - Enable/disable MRP debugging for a particular SAP
 [no] sdp             - Enable/disable MRP debugging for a particular SDP
```

Conclusion

PBB-VPLS allows the service providers to scale VPLS services by multiplexing customer I-VPLS instances into one or more B-VPLS instances. This multiplexing dramatically reduces the number of services, pseudowires, and MAC addresses in the core and therefore allows the service provider to scale Layer 2 multi-point networks and provide services across international backbones.

The example used in this chapter shows the configuration of the customer and backbone VPLS instances as well as all the related features which are required for this environment. Show and debug commands have also been suggested so that the operator can verify and troubleshoot the service.

PIM Snooping for IPv4 in EVPN-MPLS Services

This chapter provides information about PIM snooping for IPv4 in EVPN-MPLS services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

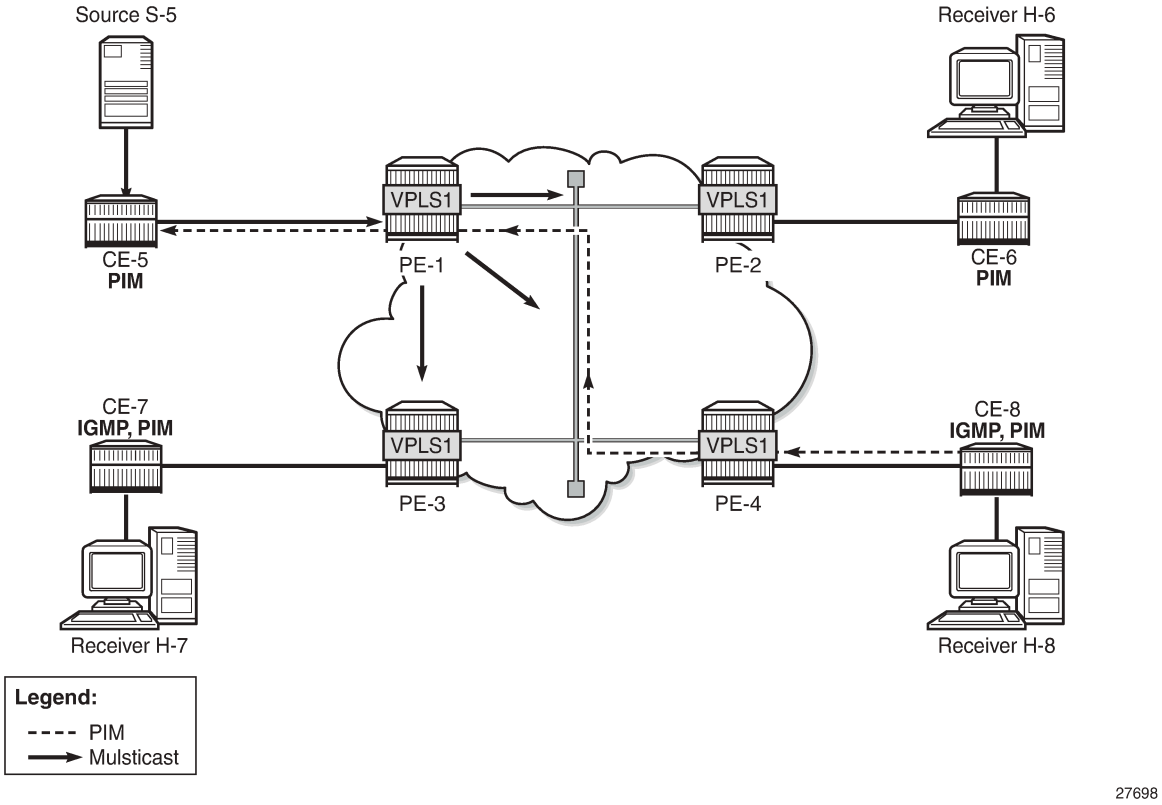
This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. PIM snooping for IPv4 is supported in EVPN-MPLS services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing mode without ESI label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active multi-homing mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping in all-active multi-homing mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

Figure 286: Multicast in VPLS without PIM Snooping shows the example topology with four CEs that have IGMP and PIM enabled (L3) and four PEs configured with VPLS 1 (L2). Source-specific multicast is used in this example. The following description applies to all VPLSs, with or without EVPN.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 286: Multicast in VPLS without PIM Snooping



The VPLS emulates a LAN interconnecting sites with L3-capable devices that use PIM to join or leave multicast groups. When receiver H-8 sends an IGMP report message to join a multicast group, CE-8 sends a PIM join message to CE-5. The PEs forward the PIM message without learning any PIM-related information, such as which CE sent the PIM join and for which multicast group.

The source S-5 is sending the multicast stream to CE-5. When CE-5 receives a PIM join message for this multicast group from CE-8, it forwards the multicast stream to CE-8. By default, all PEs flood the multicast stream on all their connections in the VPLS domain, regardless of whether a PIM join was received from that connection. L2 flooding is not aware of the PIM join/prune messages from the L3 edge routers, resulting in an inefficient use of network resources. To avoid this L2 flooding, PIM snooping can be enabled in the VPLS by the following command:

```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping ?

 pim-snooping

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 group-policy          - Group policy name
 hold-time             - Duration that allows the PIM-snooping switch to snoop all the PIM
 states in the VPLS
 ipv4                  + Enter the ipv4 context
 ipv6                  + Enter the ipv6 context
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping {
            ipv4 ?

 ipv4

 admin-state           - Administrative state of snooping for multicast traffic
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
```

The default mode is proxy, but PIM snooping can also use snooping mode, depending on the information in the received PIM hello messages. In snooping mode, the PE does not modify the PIM messages; in proxy mode, the PE terminates incoming PIM messages and generates its own PIM messages.

PIM snooping is used for router multicast registration, whereas IGMP snooping is used for host/client multicast registration. IGMP snooping in EVPN-MPLS services is described in chapter P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services. Optionally, PIM snooping and IGMP snooping can be enabled simultaneously.

With PIM enabled, the CEs send PIM hello messages to the well-known multicast address for PIM, 224.0.0.13. PIM hello messages are used to form PIM neighbors and can be used to form the Forwarding Database (FDB). With PIM snooping enabled in the VPLS in the PEs, the PEs snoop PIM messages. The PEs only forward multicast traffic downstream when required, as determined from the received PIM messages. This provides a more efficient use of network resources.

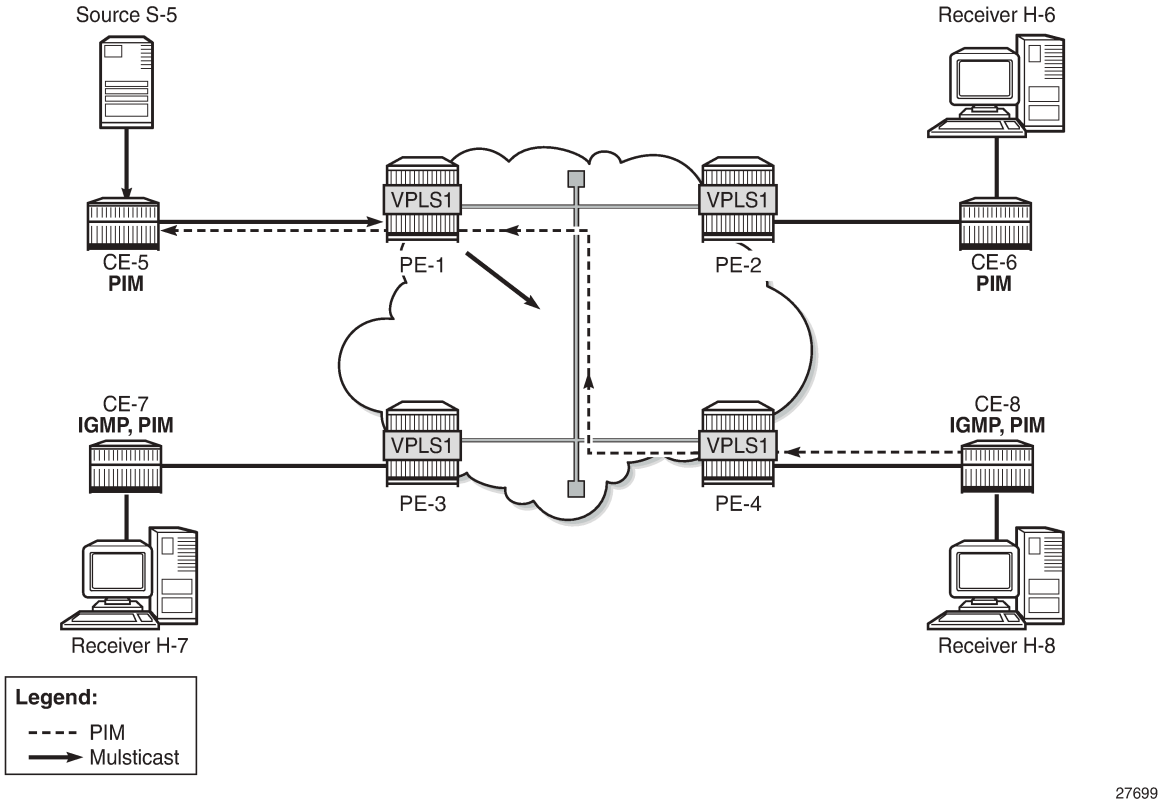
PIM snooping states in a PE are maintained per VPLS instance. When PIM snooping is enabled, IP multicast traffic to a multicast group that is not learned via snooping is dropped by default, unless it is received from a directly connected source.

PIM Snooping in Snooping Mode

Figure 287: Multicast in VPLS with PIM Snooping in Snooping Mode shows that the multicast stream is not flooded in PE-1 when PIM snooping is enabled and operating in snooping mode.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 287: Multicast in VPLS with PIM Snooping in Snooping Mode



When H-8 sends an IGMP report message to join the multicast stream from source S-5 to CE-8, CE-8 sends a PIM join message to CE-5. PE-4 snoops the PIM join message and builds the FDB. PE-4 forwards the PIM join message to PE-1 by matching the upstream neighbor address in the join with the neighbor database. PE-1 snoops the PIM join message, builds its Multicast Forwarding Information Base (MFIB), and performs a similar lookup in its FDB. PE-1 forwards the PIM join to CE-5. The Source Path Tree (SPT) between receiver CE-8 and sender CE-5 is now built and CE-5 forwards multicast data frames to CE-8. PE-1 does not flood multicast frames, but forwards them to CE-8 only, based on the MFIB.

Figure 288: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs shows how the number of PIM messages in the control plane increases when multiple client CEs are connected to PE-4.

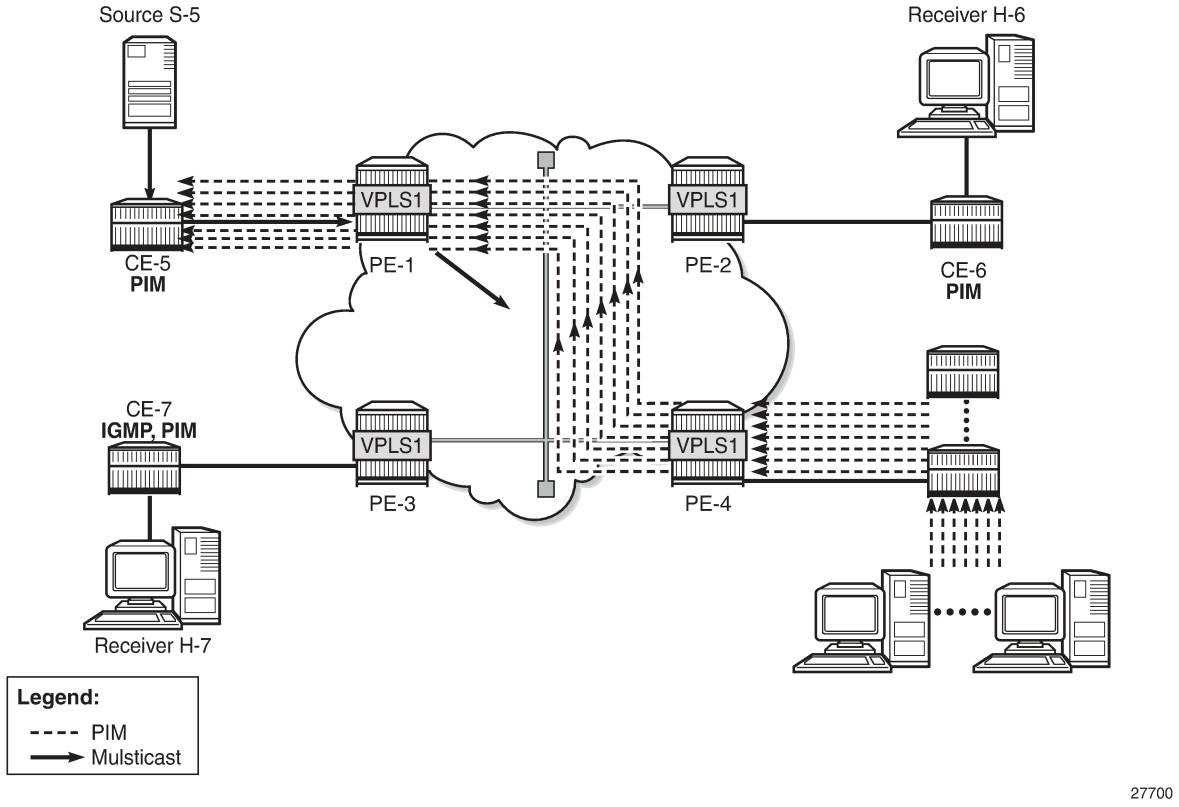
Figure 288: Multicast in VPLS with PIM Snooping in Snoop Mode – Multiple CEs



PIM Snooping in Proxy Mode

When H-8 sends an IGMP report message to join a multicast stream, CE-8 again sends a PIM join message to CE-5. PE-4 terminates the incoming PIM join message and generates its own PIM join message using CE-5 as the source address, learned from the PIM hello messages. PE-4 builds its MFIB and sends a new PIM join message to S-5. PE-1 terminates the incoming PIM join message and builds its MFIB. PE-1 generates its own PIM join message using CE-5 as the source address. PE-1 forwards the PIM join to CE-5. The SPT between CE-8 and CE-5 is now built and the multicast stream flows from source S-5 to receiver H-8. No multicast traffic is sent to CE-6 and CE-7, because they do not have receivers attached that joined the multicast stream.

The default mode for PIM snooping is proxy mode.

Figure 289: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs shows that the number of PIM messages in the control plane does not increase when multiple client CEs are connected to PE-4, compared to snooping mode.

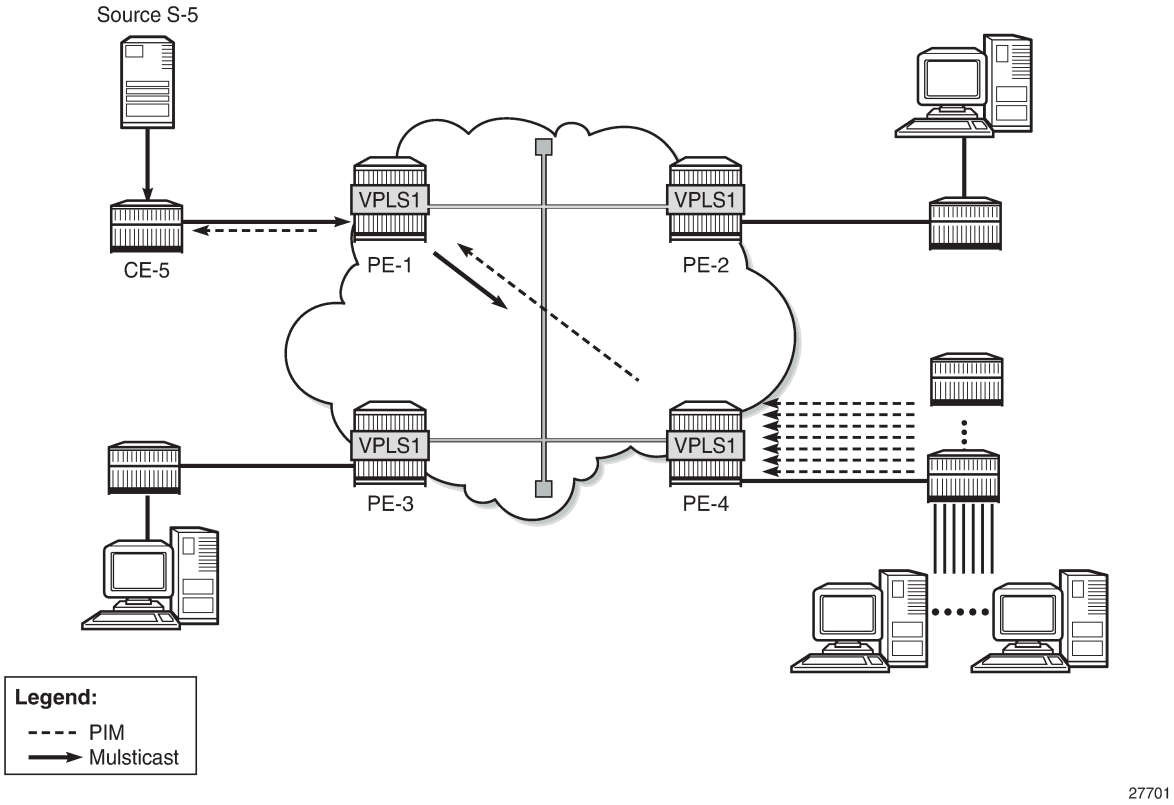
Use subject to Terms available at: www.nokia.com/terms.

Figure 289: Multicast in VPLS with PIM Snooping in Proxy Mode - Multiple CEs



PIM snooping in proxy mode can be configured with a delay to avoid existing traffic interruption. PIM snooping in proxy mode does not program the MFIB until a hold timer has expired. This hold time is useful in the following cases:

- PIM snooping being enabled on the VPLS
- PIM snooping states being manually cleared by an operator

When the hold timer is started, but not expired yet, multicast traffic is flooded in the VPLS as if PIM snooping was not enabled. VPLS flooding ensures flow delivery during the hold time.

PIM Snooping in VPLS with EVPN-MPLS

PIM snooping in an EVPN-MPLS service supports the following:

- Regular PIM snooping on SAPs/SDP-bindings
  - PIM messages received on EVPN-MPLS endpoints are forwarded to SAPs/SDP-bindings.
  - IP multicast traffic received on an EVPN-MPLS binding is forwarded to SAPs/SDP-bindings from which a PIM join was received, or to ports configured as mrouter ports.
- The EVPN-MPLS endpoints are treated as a single PIM interface:
  - IP multicast traffic and PIM messages received on an EVPN-MPLS endpoint are not forwarded to other EVPN-MPLS endpoints (split-horizon).

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - Hello and join/prune messages from SAPs/SDP-bindings are forwarded to all EVPN-MPLS destinations.
  - When a hello message is received from one PIM neighbor on an EVPN-MPLS destination, the single interface representing all EVPN-MPLS destinations has that neighbor.
    - Individual destinations appear in the MFIB, but the information for each EVPN-MPLS destination entry is identical.
- If a Point-to-Multipoint (P2MP) mLDP provider tunnel is configured:
  - If the PE is the root node of a P2MP LSP that is up, PIM messages and IP multicast traffic are only forwarded over the P2MP Label Switched Path (LSP) instead of being sent to the EVPN-MPLS endpoints. Therefore, the P2MP leaves must match the EVPN-MPLS endpoints, in this case, PE-2, PE-3, and PE-4.
  - If the PE is a leaf node of a P2MP LSP, it sends PIM messages and IP multicast traffic over its EVPN-MPLS endpoints.
  - The PEs can expect to receive IP multicast traffic and PIM messages from leaf nodes over their EVPN-MPLS endpoints, or over the P2MP LSPs for traffic from root nodes.
- PIM snooping is supported in inter-AS model B and inter-AS model C, as for IGMP snooping.
- All-active and single-active EVPN multi-homing are supported.
- Multi-chassis Synchronization (MCS) of PIM snooping state is supported on SAPs and spoke-SDPs in dual-homing.
  - The active (Designated Forwarder (DF)) PE sends the PIM states to the backup non-DF (NDF) PE.
  - In case of failure, the backup PE has the PIM states already, and the multicast traffic path can be re-established fast without any need to wait for PIM states to be snooped.
  - A sync-tag is configured on the ports or SDPs that need to be synchronized on both PEs.
  - MCS PIM snooping is restricted to two peers, even though MCS supports more peers for other types of information. An error is raised when attempting to configure a sync-tag on the same port or SDP to more than one peer.
- PIM snooping is supported for both IPv4 and IPv6 multicast. PIM snooping for IPv6 uses MAC-based forwarding by default, and can be configured to use (S,G)-based forwarding.
- PIM snooping is transparent to the underlying tunnel. PIM snooping works with RSVP, LDP, SR-ISIS, SR-OSPF, SR-TE, BGP, and MPLSoUDP.
- PIM snooping is not supported with routed VPLS with EVPN-MPLS, and its configuration is blocked.

Configuration

Figure 290: Example Topology shows the example topology. Source S-5 sends multicast streams to CE-5, which forwards those only after a PIM join message has been received. An mLDP P2MP LSP is used to distribute the multicast from the root node PE-1 to the other PEs. All CEs have PIM enabled and the receiving CEs (CE-6, CE-7, and CE-8) have IGMP configured on the interface toward the receivers (H-6, H-7, and H-8). EVPN-MPLS VPLS 1 is configured on the PEs. Initially, PIM snooping is disabled in the VPLS. Receiver H-8 joins multicast group 232.1.1.1 from source S-5.

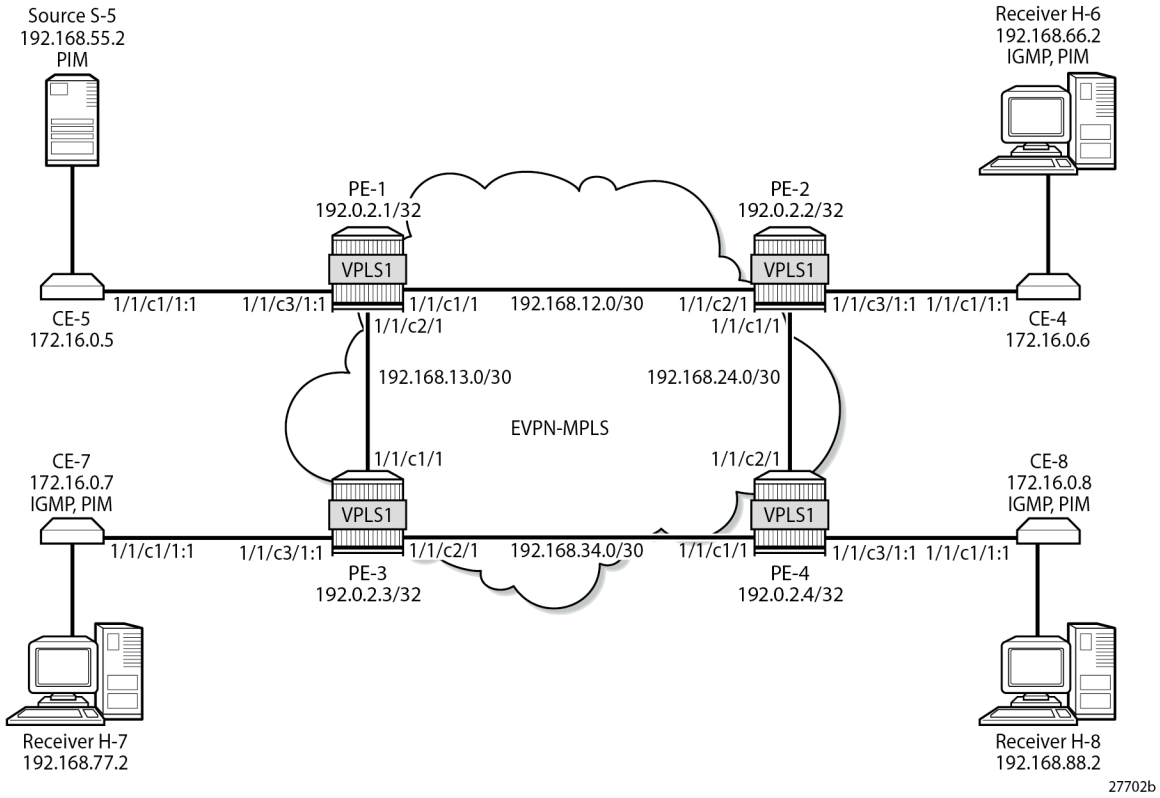
Figure 290: Example Topology



The initial configuration includes the following:

- Cards, MDAs
- Ports
  - Ports between PEs are network ports with null encapsulation
  - Ports between CEs and PEs are hybrid ports with dot1q encapsulation
- IS-IS as IGP between the PEs (alternatively, OSPF can be used)
- LDP between the PEs
- BGP with address family EVPN between the PEs. PE-2 is the route reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
On PE-2:
configure {
    router "Base" {
        autonomous-system 64496
        bgp {
            rapid-withdrawal true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            group "INTERNAL" {
                type internal
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.1" {
                group "INTERNAL"
            }
            neighbor "192.0.2.3" {
                group "INTERNAL"
            }
            neighbor "192.0.2.4" {
                group "INTERNAL"
            }
        }
    }
}
```

EVPN-MPLS VPLS without PIM Snooping

VPLS 1 is configured with EVPN-MPLS in the PEs. By default, PIM snooping is disabled. PE-1 is configured as **root-and-leaf** node for the P2MP mLDP multicast tree, while the other three PEs have the default **no root-and-leaf** configured, so they are leaf-only nodes. The configuration of VPLS 1 on PE-1 is as follows:

```
On PE-1:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 { }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/c3/1:1 { }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    root-and-leaf true
                    mldp
                }
            }
        }
    }
}
```

===============================================================================
```

When a P2MP mLDP provider tunnel is configured, the root node forwards PIM messages and IP multicast traffic over the provider tunnel instead of over the EVPN-MPLS endpoints. However, the leaf nodes of a P2MP mLDP provider tunnel send PIM messages and IP multicast traffic over the EVPN-MPLS endpoints.

The following P2MP mLDP bindings are active on root node PE-1: one toward PE-2 via port 1/1/c1/1 and one toward PE-3 via port 1/1/c2/1.

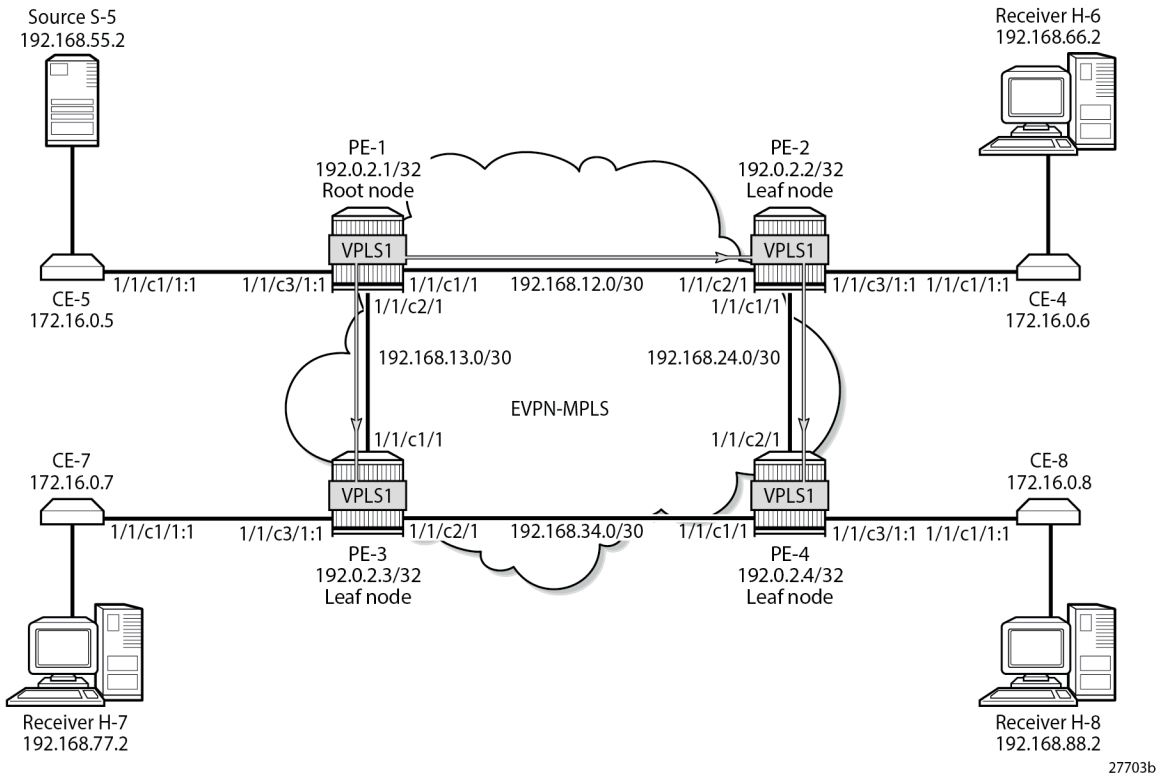
Figure 291: P2MP mLDP Multicast Tree shows the mLDP multicast tree. Multicast traffic from source S-5 uses the mLDP multicast tree from PE-1 to both PE-2 and PE-3. PE-2 is a transit node for multicast traffic to PE-4, and also a leaf node. PE-3 and PE-4 are leaf nodes.

Figure 291: P2MP mLDP Multicast Tree



CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. The configuration on CE-8 is as follows:

```
On CE-8:
configure {
    router "Base" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        interface "int-CE-8-H-8" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.88.1
                    prefix-length 24
                }
            }
        }
        interface "int-CE-8-PE-4" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.8
                    prefix-length 16
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.8
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.55.0/30 route-type unicast {
                next-hop "172.16.0.5" {
                    admin-state enable
                }
            }
        }
        pim {
            apply-to all
        }
        igmp {
            interface "int-CE-8-H-8" { }
        }
    }
}
```

The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure {
    router "Base" {
        interface "int-CE-5-PE-1" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.5
                    prefix-length 16
                }
            }
        }
        interface "int-CE-5-S-5" {
            port 1/1/c3/1
            ipv4 {
                primary {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    address 192.168.55.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.5
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.66.0/24 route-type unicast {

Figure 292: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled shows that receiver H-8 sends an IGMP report to CE-8 and CE-8 sends a PIM join message to CE-5 via PE-4. PE-4 floods the PIM join message to all PEs, and the message is not snooped by any intermediate PE.

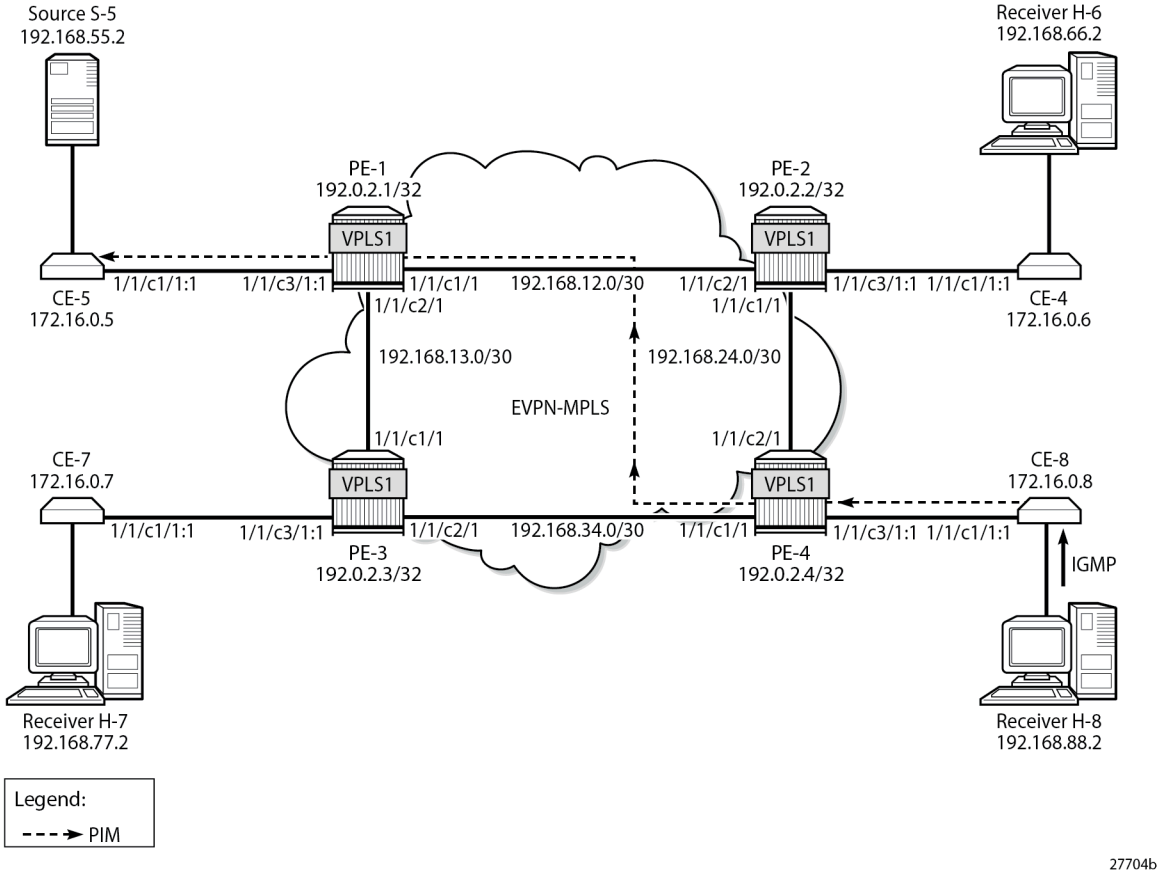
Figure 292: H-8 Joins Group (192.168.55.2, 232.1.1.1) and PIM Snooping is Disabled



Alternatively, a static multicast group can be configured on IGMP interface int-CE-8-H-8 for multicast group (192.168.55.2, 232.1.1.1), as follows:

```
On CE-8:
configure {
    router "Base" {
        igmp {
            interface "int-CE-8-H-8" {
                ssm-translate {
                    group-range start 232.0.0.0 end 232.255.255.255 {
                        source 192.168.55.2 { }
                    }
                }
                static {
                    group 232.1.1.1 {
                        source 192.168.55.2 { }
                    }
                }
            }
        }
    }
}
```

"
```

Multicast stream 232.1.1.1 is sent from source S-5 to CE-5. When CE-5 has received the PIM join message, it floods the multicast stream to PE-1. Root node PE-1 sends the multicast stream to both PE-2 and PE-3. PE-2 forwards the multicast stream to PE-4 and to CE-6; PE-3 forwards the stream to CE-7, and PE-4 forwards to CE-8. The following PIM group for group address 232.1.1.1 is joined on CE-8:

```

===============================================================================
```

Besides the multicast traffic, signaling messages (such as IS-IS or BGP) are sent, which explains the other counters on the ports being different from zero.

A similar result occurs on PE-2, where incoming traffic from PE-1 is forwarded to PE-4 and to CE-6.

The following port statistics on CE-6 show that the incoming traffic on port 1/1/c1/1 from PE-2 is not forwarded to port 1/1/c2/1 to H-6:

```

```

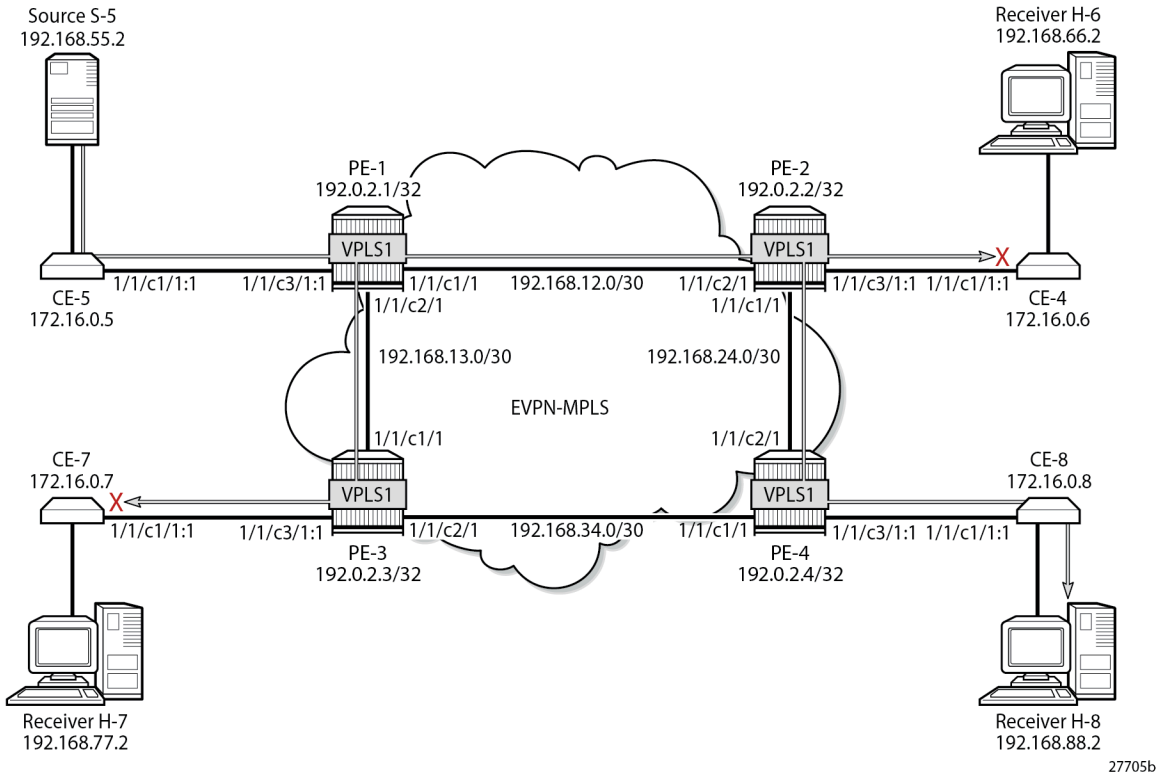
Without PIM snooping, multicast streams are forwarded to CEs that drop them, which wastes resources. Figure 293: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled shows the multicast data streams with receiver H-8 joined and PIM snooping disabled.

Figure 293: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Disabled



EVPN-MPLS VPLS with PIM Snooping Enabled

PIM snooping is enabled on all PEs as follows:

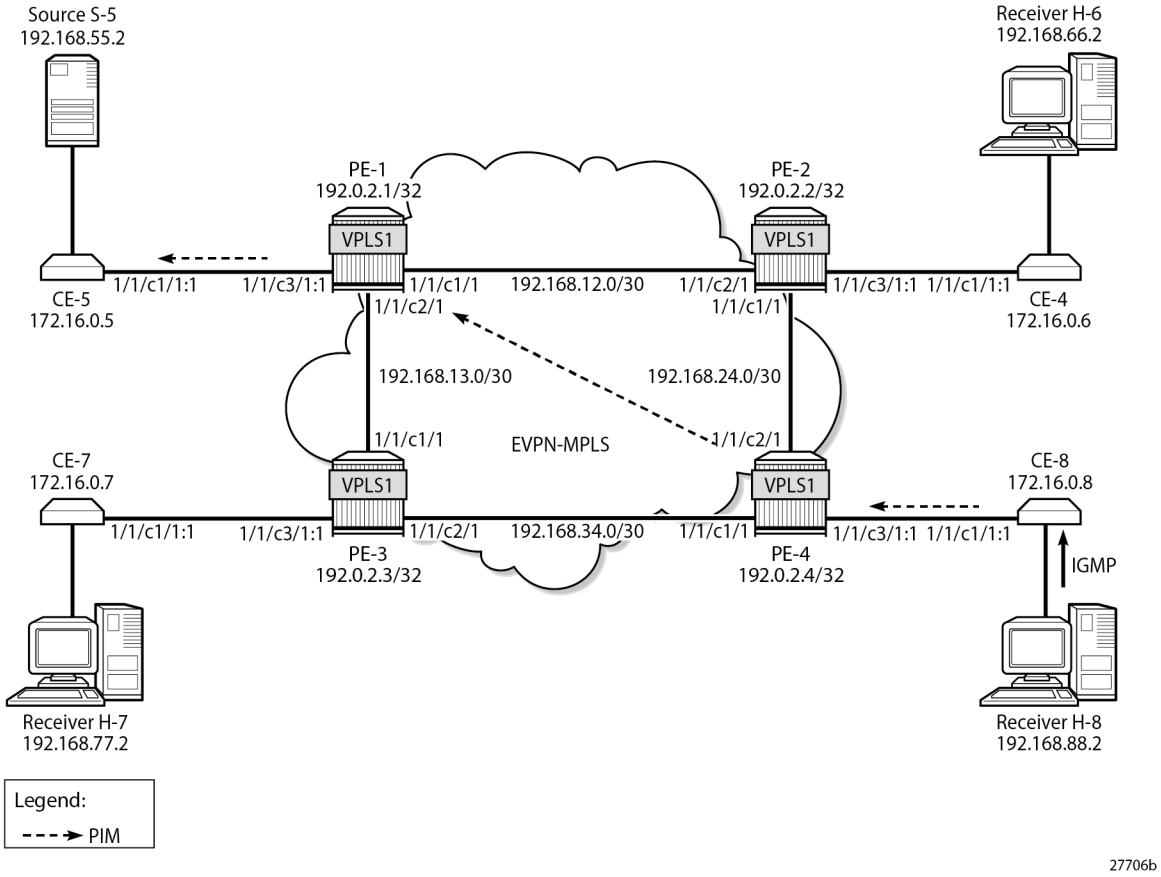
```
configure {
    service {
        vpls "VPLS 1" {
            pim-snooping { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
}
```

The default mode for PIM snooping is proxy mode, which allows the intermediate PEs to terminate the incoming PIM join or prune messages and create their own PIM join or prune message to be sent toward CE-5, as shown in Figure 294: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode:

Figure 294: H-8 Joins (192.168.55.2, 232.1.1.1) and PIM Snooping is Enabled in Proxy Mode



PE-4 receives the following PIM join message for multicast group (192.168.55.2, 232.1.1.1) from CE-8 to CE-5 on SAP 1/1/c3/1:1:

```
17 2023/08/10 22:59:27.162 CEST MINOR: DEBUG #2001 Base PIM[vpls 1 ]
"PIM[vpls 1 ]: Join/Prune
[000 00:24:58.740] PIM-RX ifId 1 ifName SAP:1/1/c3/1:1 172.16.0.8 -> 224.0.0.13 Length: 34

The following **show** command of the PIM group snooped on PE-1 shows the SAP toward the source as incoming interface, and the EVPN-MPLS interface as outgoing interface (traffic coming in from the source is not sent back to the SAP toward the source):

```

The following identical **show** command of the PIM group snooped on PE-4 shows the EVPN-MPLS interface as incoming interface. Even though the EVPN-MPLS interface is also listed as outgoing interface, traffic coming from that interface is not forwarded on that interface (all EVPN-MPLS destinations are treated as one single EVPN-MPLS interface), so the traffic is forwarded to the SAP toward the receiving CE only.

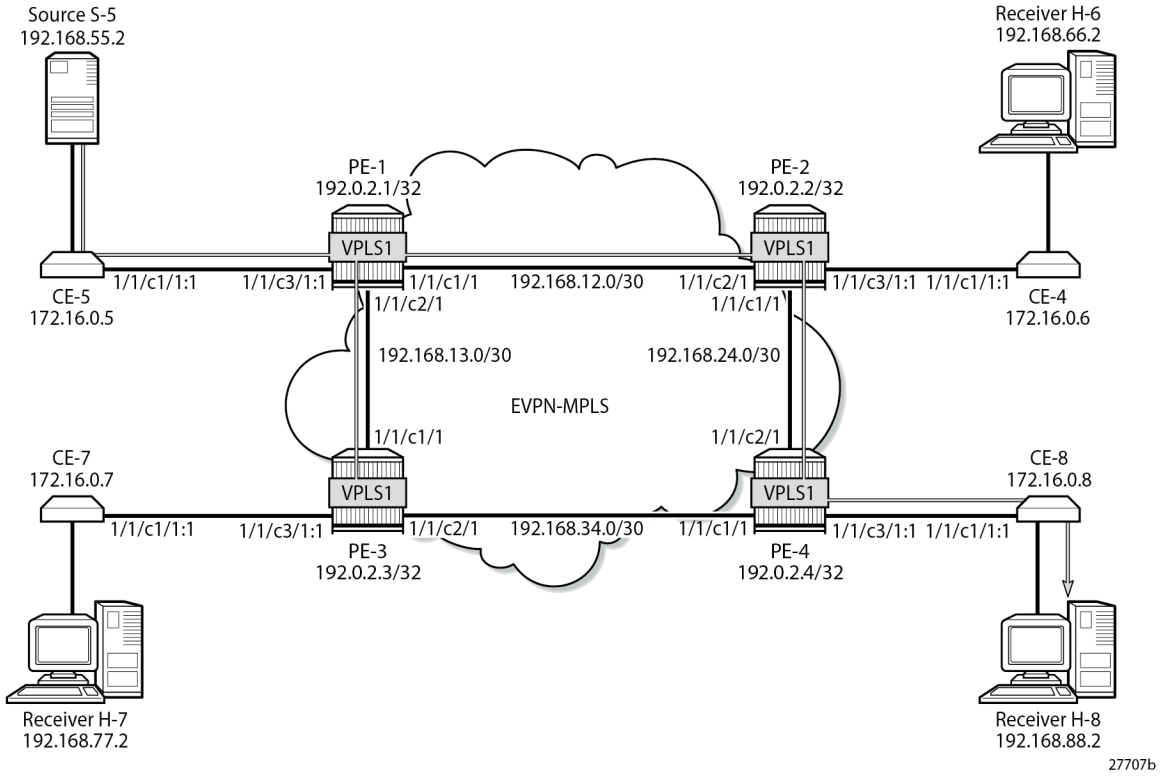
Figure 295: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled shows that the multicast stream still flows from the source S-5 to the receiver H-8, but is not forwarded to CE-6 and CE-7 when PIM snooping is enabled. The root node PE-1 sends the multicast traffic received on the SAP to all EVPN-MPLS destinations over the P2MP mLDP provider tunnel. The EVPN-MPLS interface is treated as a single interface.

Figure 295: Multicast Stream (192.168.55.2, 232.1.1.1) with PIM Snooping Enabled



Multi-homed EVPN-MPLS VPLS without PIM Snooping

When CE-5 receives a PIM join message, it forwards the multicast stream to PE-1. All multicast traffic in VPLS 2 is sent to all receiving CEs, regardless of the received PIM join messages.

Figure 296: Example Topology with Multi-homing ESs shows the example topology with an all-active multi-homing virtual Ethernet Segment (ES) "ESI-34_2" between PE-3 and PE-4 using a LAG, and a single-active multi-homing ES "ESI-24" between PE-2 and PE-4 using SDPs.

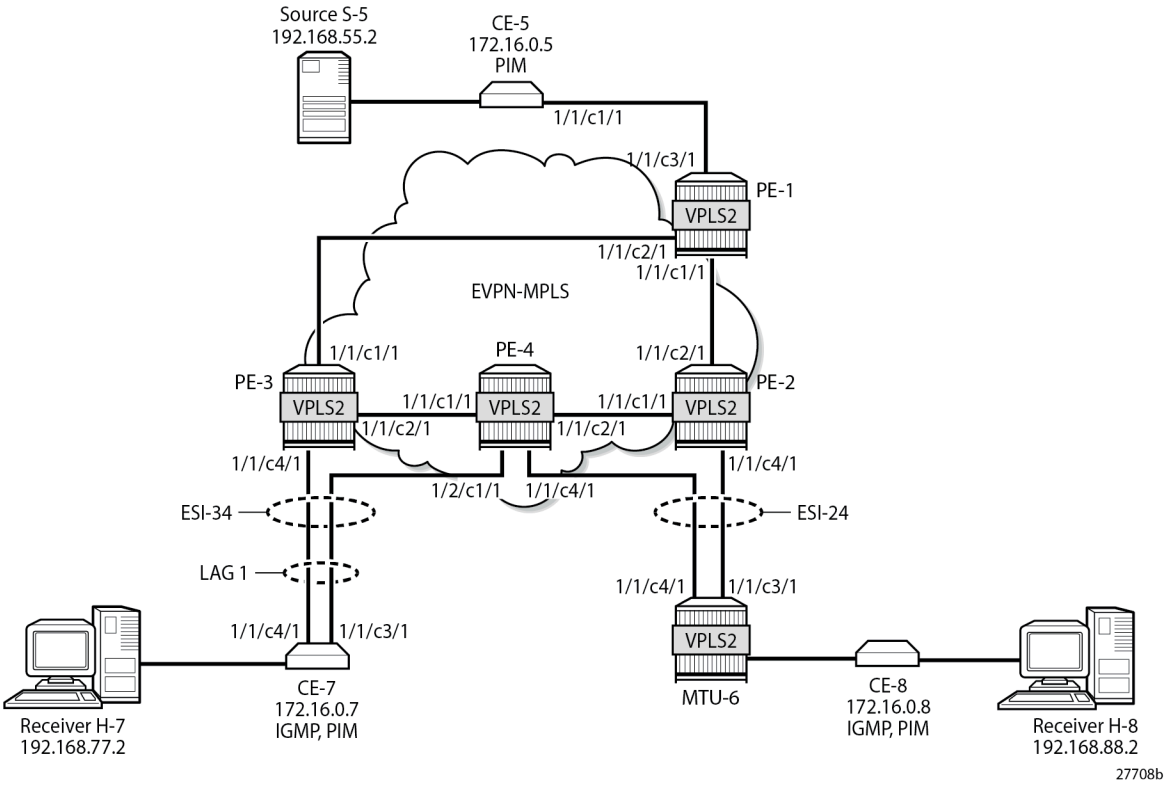
Use subject to Terms available at: www.nokia.com/terms.

Figure 296: Example Topology with Multi-homing ESs



The configuration of VPLS 2 is similar to the configuration of VPLS 1 on all PEs. An identical P2MP mLDP provider tunnel is established on the PEs for VPLS 2: PE-1 is the root node, PE-2 is a leaf node and a transit node, PE-3 is a leaf node, and PE-4 is also a leaf node.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active multi-homing ES "ESI-24". Spoke-SDP 26:2 is associated with VPLS 2.

```
On PE-2:
configure {
    service {
        sdp 26 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 { }
            bgp-evpn {
                evi 2
                mpls 1 {
                    admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            spoke-sdp 26:2 { }
            provider-tunnel {
                inclusive {
                    admin-state enable
                    owner bgp-evpn-mpls
                    mldp
                }
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 10000
                                }
                            }
                        }
                        association {
                            sdp 26 { }
                        }
                    }
                }
            }
        }
    }
}
```

The same ES is configured on PE-4, together with another ES-an all-active multi-homing virtual ES that applies to VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 5000 (which is lower than the preference 10000 on PE-3); see chapter Preference-based and Non-revertive EVPN DF Election. VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure exclusive
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
```

For VPLS 2, PE-2 is the DF in ES "ESI-24", as follows:

```
[/]
A:admin@PE-2# show service id 2 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
26:2                 ESI-24                           DF
===============================================================================
No vxlan instance entries
```

PE-3 is the DF in ES "ESI-34_2", as follows:

```
[/]
A:admin@PE-3# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
lag-1:2              ESI-34_2                         DF
===============================================================================
No sdp entries
No vxlan instance entries
```

PE-4 is NDF for both ESI-24 and ESI-34_2, as follows:

```
[/]
A:admin@PE-4# show service id 2 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================

===============================================================================
No vxlan instance entries
```

When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tree to PE-2, PE-3, and PE-4. The DF PE-2 forwards the traffic to MTU-6, and DF PE-3 forwards it to CE-7, even though a PIM join for this group has not been received from CE-7. PE-4 is NDF, so it does not forward the traffic to MTU-6 or CE-7. MTU-6 forwards the traffic to CE-8, which sends it to H-8. CE-7 drops the multicast traffic because no attached receiver has joined the multicast group. Figure 297: EVPN-MPLS with Multi-homing – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

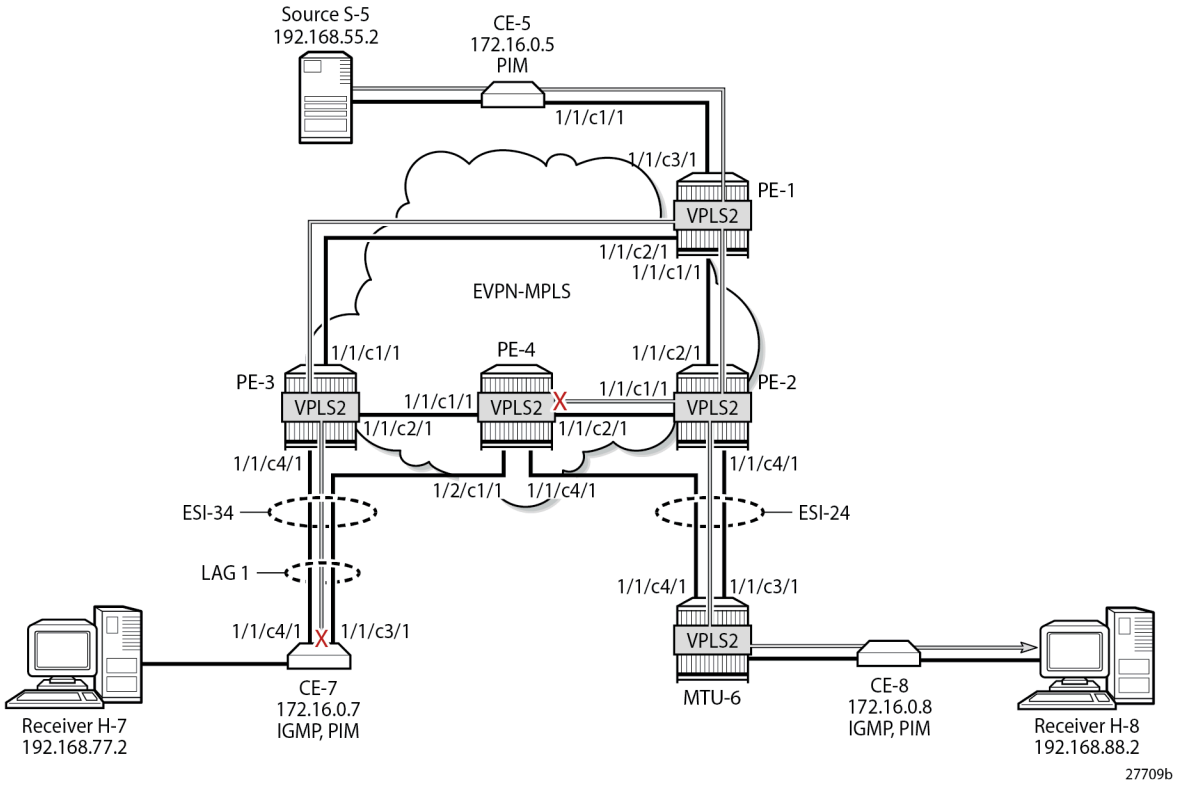
Use subject to Terms available at: www.nokia.com/terms.

Figure 297: EVPN-MPLS with Multi-homing – Receiver H-8 Joined



The static IGMP multicast is removed to emulate an IGMPv3 report from receiver H-8 to exclude multicast group 232.1.1.1 from source 192.168.55.2, as follows:

```
On CE-8:
configure {
    router "Base" {
        igmp {
            interface "int-CE-8-H-8" {
                static {
                    delete group 232.1.1.1
                }
            }
        }
    }
}
```

Multi-homed EVPN-MPLS VPLS with PIM Snooping

PIM snooping is enabled in VPLS 2 on all PEs, including PE-1, which is not part of an ES-with the following command:

```
configure {
    service {
        vpls "VPLS 2" {
            pim-snooping { }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
}
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
[/]
A:admin@PE-1# show service id 2 pim-snooping neighbor

===============================================================================
PIM Snooping Neighbors ipv4
===============================================================================
Port Id                 Nbr DR Prty     Up Time       Expiry Time     Hold Time
  Nbr Address

  172.16.0.8
EVPN-MPLS               1               0d 00:01:15   0d 00:01:30     105
  172.16.0.5
EVPN-MPLS               1               0d 00:01:17   0d 00:01:27     105
  172.16.0.7
-------------------------------------------------------------------------------
Neighbors : 3
===============================================================================
```

PE-3 and PE-4 also have these three CEs as PIM snooping neighbors.

All-active MH EVPN-MPLS VPLS with PIM Snooping

On CE-7, the following static IGMP membership is configured on interface int-CE-7-H-7:

```
On CE-7:
configure {
    router "Base" {
        igmp {
            interface "int-CE-7-H-7" {
                ssm-translate {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    group-range start 232.0.0.0 end 232.255.255.255 {
                        source 192.168.55.2 { }
                    }
                }
                static {
                    group 232.1.1.1 {
                        source 192.168.55.2 { }
                    }
                }
            }
        }
    }
}
```

When H-7 joins the multicast group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2, with four port IDs: the local SAP to CE-5 and the EVPN-MPLS destinations, as follows:

```
[/]
A:admin@PE-1# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1             sap:1/1/c3/1:2              Local    Fwd
                                      mpls:192.0.2.2:524280       Local    Fwd
                                      mpls:192.0.2.3:524280       Local    Fwd
                                      mpls:192.0.2.4:524280       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

The MFIB on PE-2 is empty because no locally attached node has sent a PIM join for any multicast group:

```
[/]
A:admin@PE-2# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                        Blk
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Number of entries: 0
===============================================================================
```

The MFIB on PE-3 contains an entry for the (S,G) with the local SAP lag-1:2 and the EVPN-MPLS destination, as follows:

```
[/]
A:admin@PE-3# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
```

                                     mpls:192.0.2.1:524280       Local    Fwd
                                     mpls:192.0.2.2:524280       Local    Fwd
                                     mpls:192.0.2.4:524280       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

Data-driven PIM state synchronization between PE-3 and PE-4 in the ESI-34_2 results in the following MFIB entry on PE-4:

```
[/]
A:admin@PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================
Source Address  Group Address         Port Id                     Svc Id   Fwd
                                                                            Blk
-------------------------------------------------------------------------------
192.168.55.2    232.1.1.1            sap:lag-1:2                 Local    Fwd
                                     mpls:192.0.2.1:524280       Local    Fwd
                                     mpls:192.0.2.2:524280       Local    Fwd
                                     mpls:192.0.2.3:524280       Local    Fwd
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
```

When debugging is enabled on the PEs as follows, the synchronization between peers in ES "ESI-34_2" is logged:

```
debug {
    service {
        vpls "VPLS 2" {
            pim-snooping {
                events {
                    port {
                        evpn-mpls
                    }
                    jp { }
                }
                packet {
                    packet-types {
                        jp true
                    }
                }
            }
        }
    }
}
```

For example, PE-4 sends the following PIM message to its remote peer PE-3 in ESI-34_2:

```
82 2023/08/10 23:13:20.784 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimVplsFwdJPToEvpn
Forwarding to remote peer on bgp-evpn ethernet-segment ESI-34_2"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

PE-3 receives the following PIM message from its remote peer PE-4 in ESI-34_2:

```
74 2023/08/10 23:13:20.786 CEST MINOR: DEBUG #2001 Base PIM[vpls 2 ]
"PIM[vpls 2 ]: pimProcessPdu
Received from remote peer on bgp-evpn ethernet-segment ESI-34_2, will be applied on lag-1:2
"
```

On PE-1, the PIM snooping group (192.168.55.2, 232.1.1.1) has incoming interface SAP 1/1/c3/1:2 toward CE-5 and the EVPN-MPLS interface as outgoing interface, as follows:

```

===============================================================================
```

On PE-3, the same PIM snooping group has the EVPN-MPLS as incoming interface and the SAP lag-1:2 as outgoing interface. The split-horizon mechanism ensures that the multicast traffic that enters through the EVPN-MPLS interface is not forwarded on the EVPN-MPLS interface, which is regarded as a single interface.

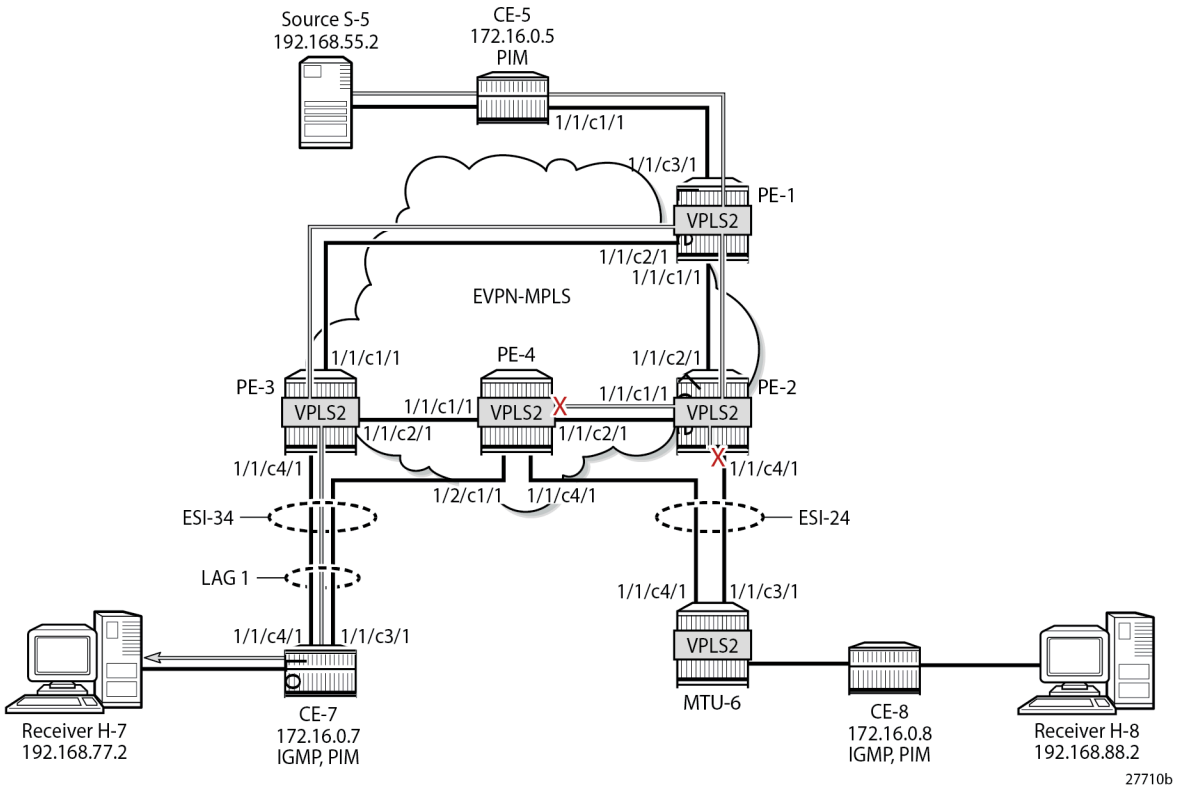
Figure 298: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined shows how the multicast traffic is forwarded when H-7 joins the multicast group and PIM snooping is enabled. DF PE-3 forwards the traffic toward CE-7. The multicast stream also reaches PE-2 and PE-4, where it is dropped.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 298: EVPN-MPLS with All-active Multi-homing and PIM Snooping Enabled – Receiver H-7 Joined



H-7 leaves the multicast group and H-8 joins it instead.

Single-active MH EVPN-MPLS VPLS with PIM Snooping

When H-8 joins the multicast group and PIM snooping is enabled, only DF PE-2 forwards traffic from the EVPN-MPLS toward a receiver. PE-3 does not forward traffic to CE-7 because no PIM join message was received from CE-7. Figure 299: EVPN-MPLS with Single-active Multi-homing and PIM Snooping Enabled – Receiver H-8 Joined shows how the multicast traffic is forwarded when H-8 joins the multicast group and PIM snooping is enabled.

```

PIM state synchronization is data-driven, so the PIM states are not stored in a database. Therefore, the ESs must be configured as **non-revertive** to avoid reverting back to the preferred PE while this PE is unaware of the PIM states.

PIM Snooping with Multi-chassis Synchronization

Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later. The ES must be configured as non-revertive, so that after a failover, the new DF remains the DF even when the original DF is operational again. When data-driven PIM state synchronization cannot be used, for example, when the service carving is configured in auto mode, or when the SR OS Release is an earlier release of 15.0, Multi-chassis synchronization (MCS) can be configured for a faster failover. MCS of the PIM snooping state on SAPs and spoke-SDPs is supported between an active and a standby PE and the PIM states are stored in a synchronization database. This can be configured in case of single-active multi-homing (MH), for example on PE-2 for peer PE-4, with PIM snooping on spoke-SDPs, as follows:

```
On PE-2:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 26 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                            }
                        }
                    }
                }
            }
        }
    }
}
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.2 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 46 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
        }
    }
}
```

When H-8 joins the multicast group, the following entries are in the MCS synchronization database of the PEs. The MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
[/]
A:admin@PE-2# tools dump redundancy multi-chassis sync-database detail

If no entries are present for an application, no detail will be displayed.

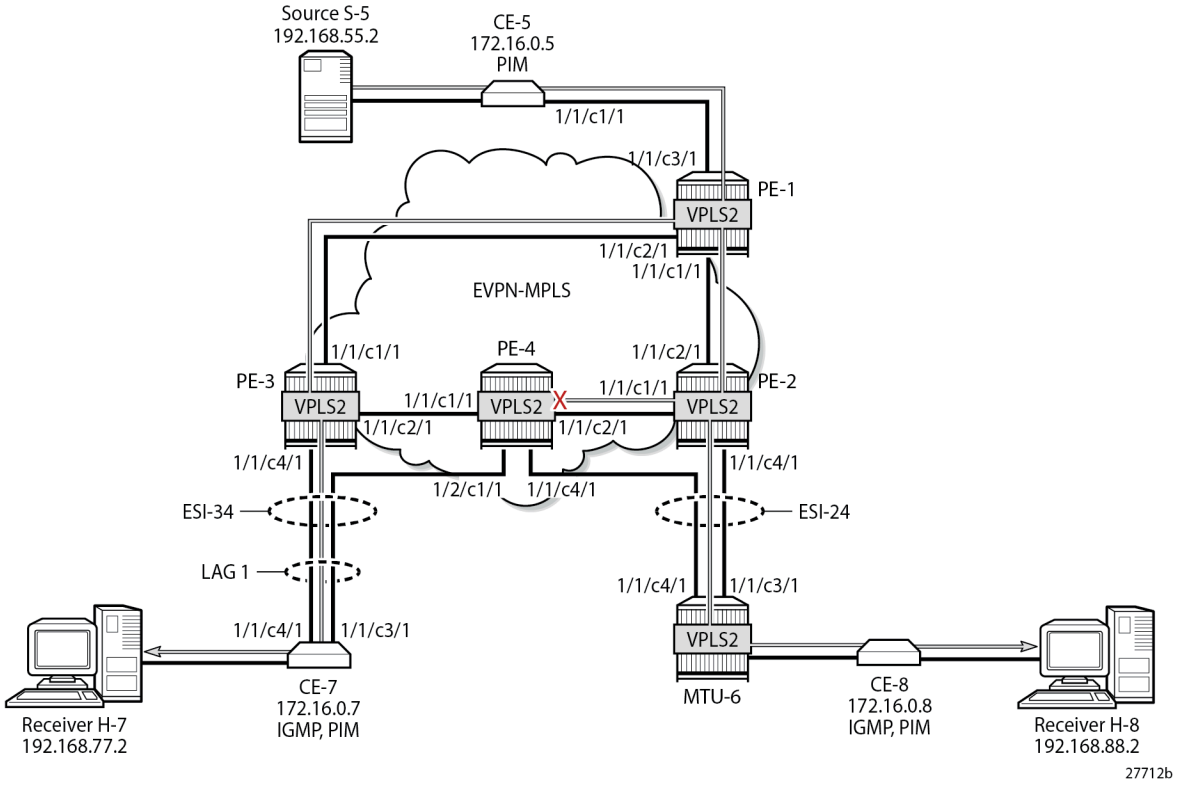
Failover

Figure 300: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined shows the multicast traffic flow in the case where both receivers H-7 and H-8 joined multicast group 232.1.1.1 from source 192.168.55.2 and no failures have occurred. For SR OS Release 15.0.R4, and later, MCS need not be configured for faster failover in single-active MH when the ES is non-revertive.

Figure 300: EVPN-MPLS with Multi-homing and PIM Snooping - Receivers H-7 and H-8 Joined



NDF PE-4 has an MFIB table with the required information for a fast failover, as follows:

```
[/]
A:admin@PE-4# show service id 2 mfib

===============================================================================
Multicast FIB, Service 2
===============================================================================

```

The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. On MTU-6, SDP 62 is disabled, as follows:

```
configure {
    service {
        sdp 62 {
            admin-state disable
        }
    }
}
```

On CE-7, port 1/1/c4/1 toward PE-3 is disabled, as follows:

```
configure {
    port 1/1/c4/1 {
        admin-state disable
    }
}
```

Log 99 on PE-3 shows that the DF state in ESI-34_2 changed to false:

```
172 2023/08/10 23:18:51.662 CEST MINOR: SVCMGR #2094 Base
"Ethernet Segment:ESI-34_2, EVI:2, Designated Forwarding state changed to:false"
```

PE-4 becomes the DF for both ESs, as follows:

```

===============================================================================
```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. CE-7 forwards the traffic to H-7. PE-3 drops the multicast traffic because LAG-1 is down because of the failure that was introduced at CE-7 (port disabled).

Conclusion

PIM snooping in EVPN-MPLS services results in a more efficient use of network resources because multicast traffic no longer needs to be flooded. PIM snooping can be used in EVPN-MPLS services with all-active and single-active multi-homing with data-driven PIM state synchronization. Alternatively, MCS synchronization of the PIM snooping state on SAPs and spoke-SDPs is supported with single-active MH.

PIM Snooping for IPv4 in PBB-EVPN Services

This chapter describes PIM Snooping for IPv4 in PBB-EVPN Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R5, but the CLI in the current edition corresponds to SR OS Release 23.7.R1. Protocol Independent Multicast (PIM) snooping for IPv4 is supported in Provider Backbone Bridging - Ethernet Virtual Private Network (PBB-EVPN) services in SR OS Release 15.0.R1, and later. PIM snooping in single-active multi-homing (MH) mode without Ethernet Segment Identifier (ESI) label is supported in SR OS Release 15.0.R1, and later, whereas PIM snooping in single-active MH mode with ESI label is supported in SR OS Release 15.0.R4, and later. PIM snooping for IPv4 in all-active MH mode is supported in SR OS Release 15.0.R4, and later. Data-driven PIM state synchronization is supported in SR OS Release 15.0.R4, and later.

Overview

PBB-EVPN services have EVPN-MPLS enabled in the B-VPLS. PIM snooping in PBB-EVPN I-VPLS provides the following:

- PIM snooping in SAPs and SDP-bindings: PIM messages received from SAPs, SDP-bindings, or the B-VPLS are forwarded to SAPs or SDP-bindings according to the PIM snooping.
- Multicast flooding between I-VPLS and B-VPLS is the same for a PBB-EVPN B-VPLS as for a B-VPLS without EVPN. The first PIM join message received over the local B-VPLS from a B-VPLS SAP/SDP-binding or EVPN endpoint results in adding the B-VPLS SAP/SDP-binding or EVPN interface into the Multicast Forwarding Information Base (MFIB) associated with the I-VPLS context. Multicast traffic is flooded throughout the B-VPLS on a per-ISID single tree.
- When the PIM router is connected to a remote I-VPLS instance over the B-VPLS infrastructure, its location is identified by the B-VPLS SAP/SDP-binding or by the set of all EVPN endpoints on which PIM hellos are received. The location is also identified by the source BMAC address in the PBB header for the PIM hello message, which is the BMAC address associated with the B-VPLS instance on the remote PBB PE.
- The set of all EVPN endpoints in the B-VPLS is treated as a single PIM interface.
  - Hello and join/prune messages from I-VPLS SAPs/SDP-bindings are always sent to all B-VPLS PBB-EVPN destinations.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

  - When a hello message is received from one B-VPLS PBB-EVPN destination PIM neighbor, the single interface representing all B-VPLS PBB-EVPN destinations will have that PIM neighbor.
  - All individual B-VPLS PBB-EVPN destinations appear in the MFIB, but the information for each B-VPLS PBB-EVPN destination entry is identical.
  - The EVPN split-horizon logic ensures that IP multicast traffic and PIM messages received on a PBB-EVPN endpoint are not forwarded back to other PBB-EVPN endpoints.
- When a point-to-multipoint (P2MP) mLDP provider tunnel is configured in the B-VPLS, the provider tunnel only works for the default multicast list. Ingress Replication (IR) is used for the per-ISID MFIB trees. ISID policies can be configured to specify ISID ranges that will use the default multicast list. ISID policies can help reduce the per-ISID MFIB resources used.
- PIM snooping for IPv4 within a PBB-EVPN I-VPLS is supported with single-active MH and with all-active MH in the associated I-VPLS.
- Data-driven PIM state synchronization between remote peers in an all-active MH Ethernet Segment (ES) is supported.
- Multi-Chassis Synchronization (MCS) of PIM snooping state on SAPs and spoke-SDPs is supported in active/standby scenarios.

The following command enables PIM snooping in an I-VPLS:

```
configure {
    service {
        vpls "I-VPLS 1" {
            pim-snooping { }
        }
```

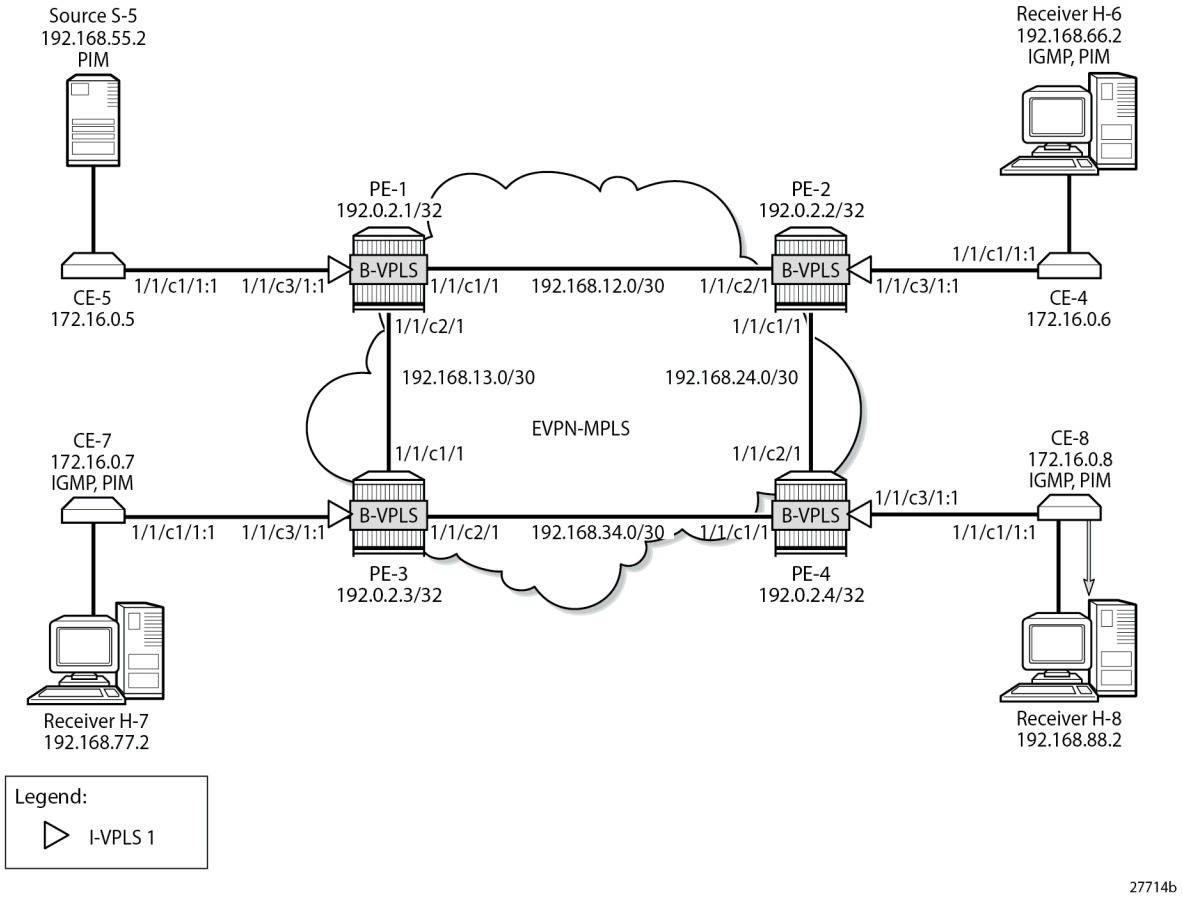
The default PIM snooping mode is proxy mode, which implies that the PE will terminate the PIM join/prune messages and generate its own PIM join/prune messages with the same (S,G). The advantage is that the number of PIM messages to be sent can be reduced: regardless of the number of PIM join messages received for a certain (S,G), the node only needs to send one PIM join message toward the source. PIM snooping can also use snooping mode based on the information in the received PIM hello messages; in snooping mode, the PE does not modify the PIM messages.

Configuration

Figure 302: Example Topology for PBB-EVPN without MH shows the example topology with source S-5 and receivers H-6, H-7, and H-8 attached to CEs that are connected to PEs. On the PEs, B-VPLS 100 is configured and I-VPLS 1 is associated with it. B-VPLS 100 has EVPN-MPLS enabled. An mLDP P2MP provider tunnel is used to distribute multicast traffic from PE-1 to the other PEs.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 302: Example Topology for PBB-EVPN without MH



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS enabled on the PEs (alternatively, OSPF can be used)
- LDP enabled on the PEs

BGP is configured on the PEs with address family EVPN, and PE-2 is configured as route reflector (RR). The BGP configuration on PE-2 is as follows:

```
On PE-2:
configure {
    router "Base" {
        bgp {
            rapid-withdrawal true
            ebgp-default-reject-policy {
                import false
                export false
            }
            rapid-update {
                evpn true
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "INTERNAL" {
                type internal
                family {
                    evpn true
                }
                cluster {
                    cluster-id 192.0.2.2
                }
            }
            neighbor "192.0.2.1" {
                group "INTERNAL"
            }
            neighbor "192.0.2.3" {
                group "INTERNAL"
            }
            neighbor "192.0.2.4" {
                group "INTERNAL"
            }
        }
```

PBB-EVPN without MH – No PIM Snooping

B-VPLS 100 is configured with EVPN-MPLS enabled on all PEs. Multicast LDP is configured in B-VPLS 100 with PE-1 as the P2MP tunnel root node (**root-and-leaf**) and the other PEs as leaf nodes (**no root-and-leaf** is default). An (optional) ISID policy defines that the default multicast tree -which is used by the P2MP mLDP tunnel- is used for ISIDs 1 and 2 (range 1 to 2). The configuration of B-VPLS 100 on PE-1 is as follows:

```
On PE-1:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            description "B-VPLS 100"
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:01
                    use-es-bmac-lsb true
                }
            }
            bgp 1 { }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    split-horizon-group "CORE"
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            split-horizon-group "CORE" { }
            provider-tunnel {
                inclusive {
                    admin-state enable

                }
            }
        }
```

The configuration of B-VPLS on the other PEs is similar, but without the root-and-leaf option.

In B-VPLS 100 on root node PE-1, the following mLDP provider tunnel is created with Provider Multicast Service Interface (PMSI) owner bgpEvpnMpls. PE-1 is configured as root-and-leaf node.

```
[/]
A:admin@PE-1# show service id 100 provider-tunnel

When the B-VPLS is created, I-VPLS 1 can be associated with it, as follows:

```
On PE-1:
configure {
    service {
        vpls "I-VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 1
                }
            }
            sap 1/1/c3/1:1 { }
        }
}
```

The configuration of I-VPLS 1 on the other PEs is identical.

CE-6, CE-7, and CE-8 have IGMP enabled on the interface toward the receiver and PIM enabled on all interfaces. Source-specific multicast is used in this example. The configuration on CE-8 is as follows:

```
On CE-8:
configure {
    router "Base" {
        interface "int-CE-8-PE-4" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.8
                    prefix-length 16
                }
            }
        }
        interface "int-CE-8-H-8" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.88.1
                    prefix-length 24
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.8
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.55.0/30 route-type unicast {
                next-hop "172.16.0.5" {
                    admin-state enable
                }
            }
        }
        igmp {
            interface "int-CE-8-H-8" { }
        }
        pim
            apply-to all
        }
    }
```

The static route is required on the receiving CEs for the PIM join/prune messages to reach the multicast source S-5 with IP address 192.168.55.2; only IP subnet 172.16.0.0/16 can be reached via the VPLS.

CE-5 has PIM enabled and static routes configured to reach the receiving hosts, as follows:

```
On CE-5:
configure {
    router "Base" {
        interface "int-CE-5-PE-1" {
            port 1/1/c1/1:1
            ipv4 {
                primary {
                    address 172.16.0.5
                    prefix-length 16
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        interface "int-CE-5-S-5" {
            port 1/1/c3/1
            ipv4 {
                primary {
                    address 192.168.55.1
                    prefix-length 30
                }
            }
        }
        interface "system" {
            ipv4 {
                primary {
                    address 192.0.2.5
                    prefix-length 32
                }
            }
        }
        static-routes {
            route 192.168.66.0/24 route-type unicast {
                next-hop "172.16.0.6" {
                    admin-state enable
                }
            }
            route 192.168.77.0/24 route-type unicast {
                next-hop "172.16.0.7" {
                    admin-state enable
                }
            }
            route 192.168.88.0/24 route-type unicast {
                next-hop "172.16.0.8" {
                    admin-state enable
                }
            }
        }
        pim {
            apply-to all
        }
    }
```

When receiver H-8 sends an IGMP report to join multicast group (S,G), CE-8 sends a PIM join message to CE-5. This PIM join message is flooded by the PEs. When CE-5 receives the PIM join message, it forwards the multicast stream to receiver H-8. PIM snooping is disabled by default and the MFIB on each of the PEs remains empty, so the multicast stream is not only sent to CE-8, but also to CE-6 and CE-7. CE-6 and CE-7 drop this stream when no receiver is active, while CE-8 forwards the multicast stream to receiver H-8, as shown in Figure 303: Multicast Stream to Receiver H-8 with PIM Snooping Disabled.

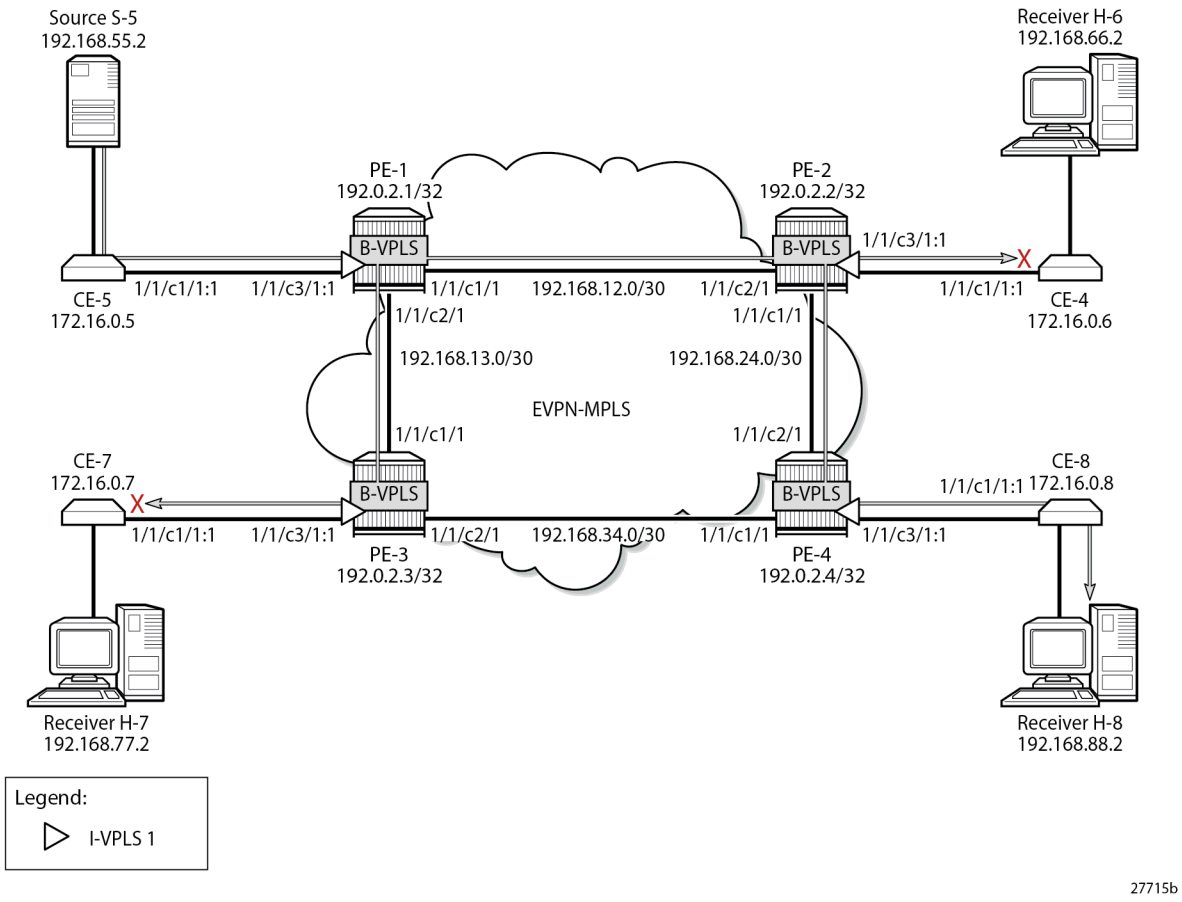
Use subject to Terms available at: www.nokia.com/terms.

Figure 303: Multicast Stream to Receiver H-8 with PIM Snooping Disabled



PBB-EVPN without MH – PIM Snooping for IPv4 Enabled

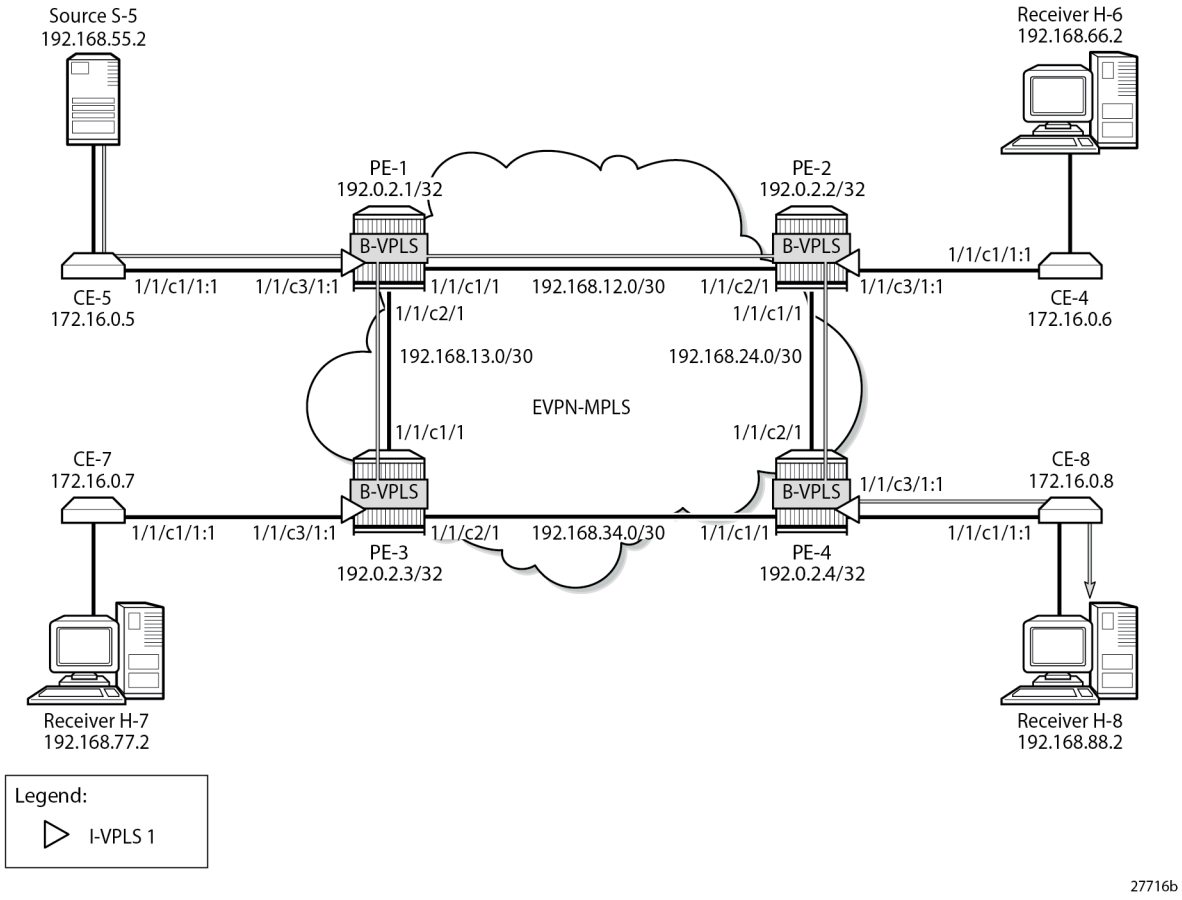
PIM snooping for IPv4 is enabled in I-VPLS 1 on all PEs as follows:

```
On all PEs:
configure {
    service {
        vpls "I-VPLS 1" {
            pim-snooping { }
        }
```

When PIM snooping for IPv4 is enabled, the PEs only forward the multicast traffic to those CEs that have sent PIM join messages for that multicast group. This implies that PE-2 and PE-3 do not forward traffic to the CEs; only PE-4 forwards traffic toward CE-8 and CE-8 forwards to receiver H-8, as shown in Figure 304: Multicast Stream to Receiver H-8 with PIM Snooping Enabled.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 304: Multicast Stream to Receiver H-8 with PIM Snooping Enabled



When PIM snooping for IPv4 is enabled, PE-1 has the following two PIM snooping ports: the SAP toward the source and the backbone b-EVPN-MPLS interface, which is treated as one entity for all PBB-EVPN destinations.

```
[/]

The following shows that PE-2 receives the multicast packets on port 1/1/c2/1 and forwards them to PE-4 on port 1/1/c1/1. With PIM snooping for IPv4 enabled, PE-2 does not forward the traffic to CE-6 on port 1/1/c3/1 because no PIM join message was received from CE-6. Besides the multicast traffic, some signaling

© 2026 Nokia.

The following PIM snooping group with group address 232.1.1.1 and source address 192.168.55.2 is shown on PE-1. The incoming interface is the SAP toward CE-5 and the outgoing interface is the b-EVPN-MPLS interface. A single b-EVPN-MPLS interface is shown in the outgoing interface list, regardless of the B-VPLS PBB-EVPN destination. The split-horizon mechanism ensures that all traffic from the incoming interface SAP 1/1/c3/1:1 is only forwarded on the b-EVPN-MPLS interface, not sent back on the SAP.

On PE-2 and PE-3, there are no PIM snooping groups.

On PE-4, the PIM snooping group with group address 232.1.1.1 and source address 192.168.55.2 has the b-EVPN-MPLS interface as incoming interface and SAP 1/1/c3/1:1 toward CE-8 as outgoing interface, as follows. The split-horizon mechanism ensures that traffic received from the b-EVPN-MPLS interface is not forwarded on the b-EVPN-MPLS interface to the other PEs, so it is only forwarded on the SAP 1/1/c3/1:1 toward CE-8.

PBB-EVPN with MH – No PIM Snooping

Figure 305: Example Topology for PBB-EVPN with MH shows the example topology with CE-7 attached to MTU-9, which is connected to both PE-3 and PE-4 via LAG lag-1. Virtual ES (vES) ESI-34_2 is configured in all-active MH mode using lag-1 for dot1q value 2. MTU-6 is connected to PE-2 and PE-4 with SDPs. These SDPs are associated with a single-active MH ES ESI-24.

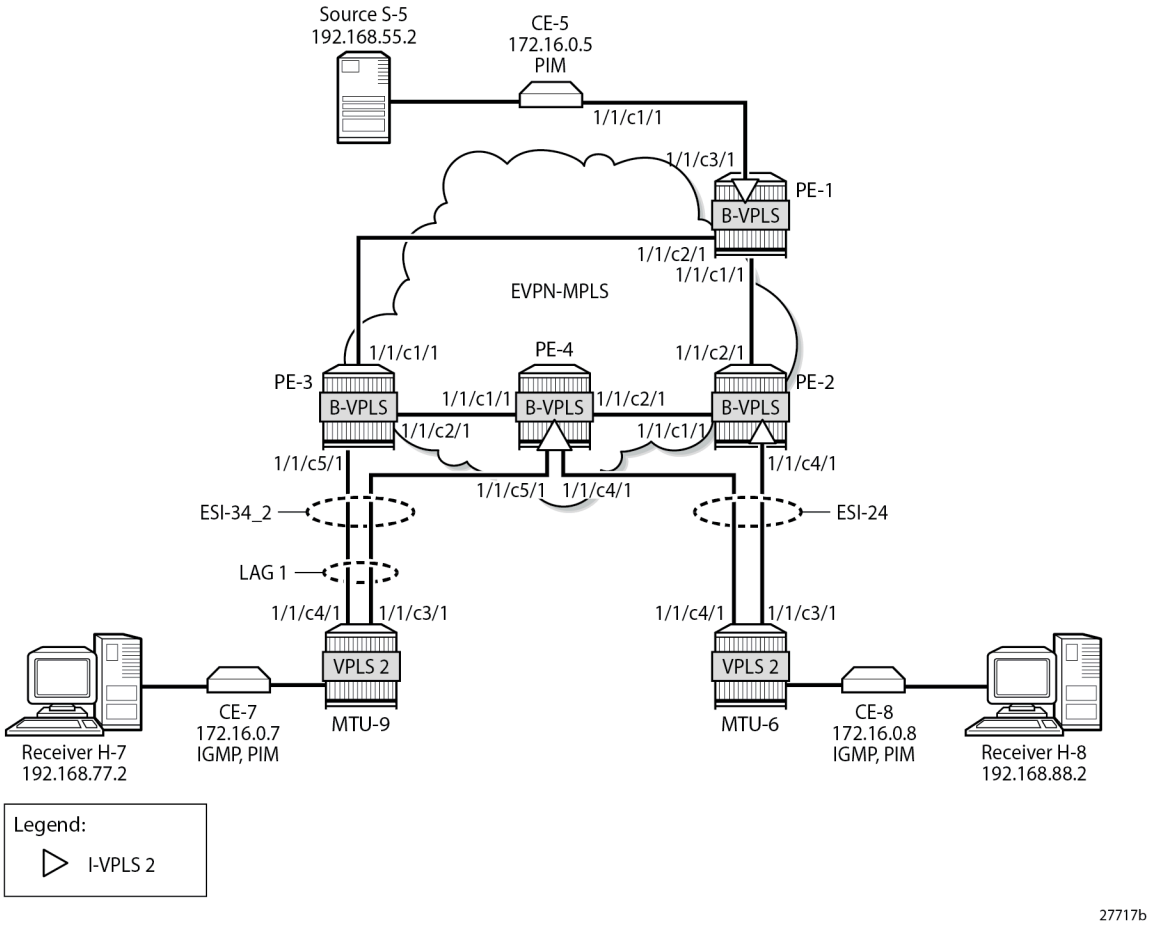
Figure 305: Example Topology for PBB-EVPN with MH



The configuration of I-VPLS 2 is similar to the preceding configuration of I-VPLS 1 on all PEs.

On PE-2, PE-3, and PE-4, one or more ESs are configured. The service configuration on PE-2 is as follows. An SDP is configured toward MTU-6 that is associated with a single-active MH ES ESI-24, that is non-restrictive -after failover, it does not restore to the initial designated forwarder (DF) if available again; see chapter Preference-based and Non-revertive EVPN DF Election. The manually configured preference is 200 on PE-2, which is higher than preference 50 at PE-3, so PE-2 is the DF when no failover has occurred. Spoke-SDP 26:2 is associated with I-VPLS 2. The B-VPLS 100 remains unchanged and is not repeated here.

```
On PE-2:
configure {
    service {
        sdp 26 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
```

© 2026 Nokia.

```
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 200
                                }
                            }
                        }
                        association {
                            sdp 26 { }
                        }
                        pbb {
                            source-bmac-lsb 0x2402
                        }
                    }
                }
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            spoke-sdp 26:2 { }
        }
        vpls "B-VPLS 100" {
            pbb {
                source-bmac {
                    use-es-bmac-lsb true
                }
            }
        }
    }
```

On PE-4, lag-1 is configured in access mode with dot1q encapsulation on the port to MTU-9, as follows. The LAG configuration is similar on PE-3.

```
On PE-4:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type dot1q
        mode access
        lacp {
            mode active
            system-id 00:00:00:00:01:34
            administrative-key 1
        }
        port 1/1/c5/1 { }
    }
```

Single-active ES ESI-24 is configured on PE-4, together with a virtual ES ESI-34_2, which is an all-active MH virtual ES that applies to lag-1 for I-VPLS 2 only (**q-tag-range 2**); see chapter Virtual Ethernet Segments. The preference for the DF election is configured manually to a value of 50 (which is lower than preference 200 on the remote peer in the ES). I-VPLS 2 has a SAP and a spoke-SDP configured. The service configuration on PE-4 is as follows:

```
On PE-4:
configure {
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-24" {
                        admin-state enable
                        esi 0x01000000002400000001
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 50
                                }
                            }
                        }
                        association {
                            sdp 46 { }
                        }
                        pbb {
                            source-bmac-lsb 0x2404
                        }
                    }
                    ethernet-segment "ESI-34_2" {
                        admin-state enable

```
                                    }
                                }
                            }
                        }
                        pbb {
                            source-bmac-lsb 0x3434
                        }
                    }
                }
            }
        }
        vpls "I-VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 2
                }
            }
            spoke-sdp 46:2 { }
            sap lag-1:2 { }
        }
        vpls "B-VPLS 100" {
            pbb {
                source-bmac {
                    use-es-bmac-lsb true
                }
            }
        }
    }
```

On PE-4, the source BMAC in the all-active MH ESI-34_2 is identical to the source BMAC on remote peer PE-3, but in the single-active MH ESI-24, the source BMAC must be different. Remote PEs might send traffic to the NDF PE based on the shared source BMAC, which is fine for all-active MH ESs, but not for single-active MH ESs.

The following service configuration on PE-3 includes an all-active virtual ES ESI-34_2 with preference 200, which makes PE-3 the DF for ESI-34_2 when no failover has occurred. After failover, PE-4 becomes DF, and it does not revert to PE-3 when available.

```
On PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "ESI-34_2" {
                        admin-state enable
                        type virtual
                        esi 0x01000000003402000001
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 200
                                }
                            }
```

When H-8 sends an IGMP report to join multicast group 232.1.1.1 from source 192.168.55.2, CE-5 forwards the multicast stream after receiving the corresponding PIM join message. PE-1 forwards the multicast traffic on the P2MP mLDP tunnel to all EVPN-MPLS destinations: PE-2, PE-3, and PE-4. PE-2 is the DF for ESI-24 and forwards the traffic to MTU-6, which forwards it to CE-8, where it is sent to the attached receiver H-8 that joined the multicast group. PE-3 is the DF for ESI-34_2 and sends the multicast stream to MTU-9, which forwards it to CE-7, where it is dropped because no attached receiver has joined the multicast group. PE-4 is the NDF for both ESs, so it does not forward the traffic to MTU-6 or MTU-9. Figure 306: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined shows how this multicast is forwarded when PIM snooping is disabled.

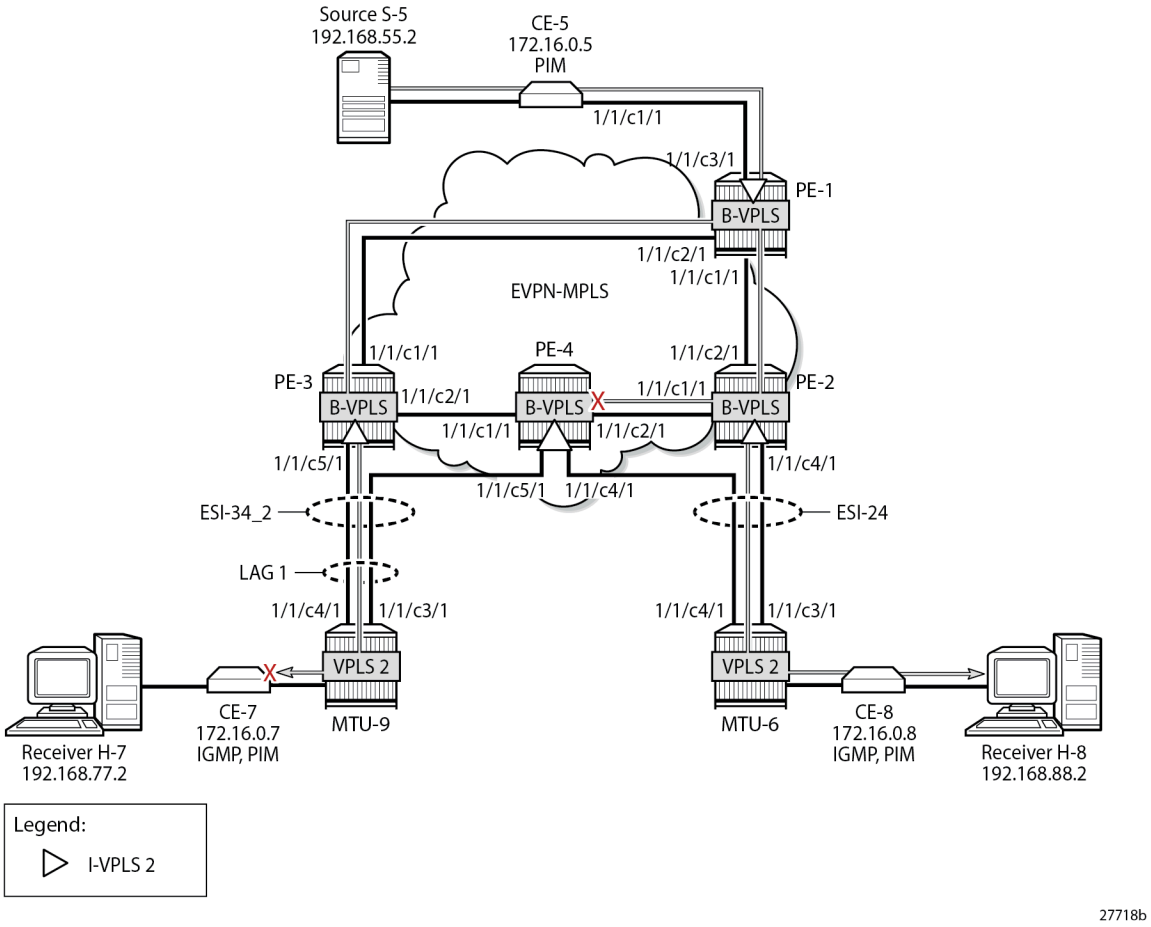
Figure 306: EVPN-MPLS with MH - PIM Snooping Disabled – Receiver H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 Enabled

PIM snooping for IPv4 is enabled in I-VPLS 2 on all PEs with the following command:

```
On all PEs:
configure {
    service {
        vpls "I-VPLS 2" {
            pim-snooping { }
        }
```

All PEs have three PIM snooping neighbors: CE-5, CE-7, and CE-8. The list of PIM snooping neighbors on PE-1 is as follows:

```
[/]
A:admin@PE-1# show service id 2 pim-snooping neighbor

================================================================================

When H-7 and H-8 join the group 232.1.1.1 via source 192.168.55.2, the PIM join messages are snooped by the PEs and the MFIB is built. The MFIB on PE-1 contains one entry for group address 232.1.1.1 and source address 192.168.55.2 with four port IDs: the local SAP to CE-5 and the B-VPLS PBB-EVPN destinations, as follows:

```
[/]
A:admin@PE-1# show service id 2 mfib

Furthermore, data-driven PIM state synchronization between PEs in an all-active MH ES allows the NDF PE-4 to build its MFIB, even when the NDF does not forward multicast traffic to the receivers. When the NDF has the MFIB information, the failover is faster and the loss of traffic is limited. For data-driven PIM state synchronization, the source BMAC must be identical within the ES, so it only works for all-active MH in PBB-EVPN, not for single-active MH. The MFIB on PE-4 contains the SAP from the all-active MH ESI-34_2, but not the spoke-SDP from the single-active MH ESI-24, as follows:

```

With the PIM snooping group information available on the NDF, the traffic loss is limited when the NDF PE-4 becomes the DF after failover. Data-driven PIM state synchronization does not store PIM states in a database, so the DF election in the ES should be configured as non-revertive, to prevent that when the preferred DF is restored after a failover, the system would revert to a DF that is unaware of the PIM state.

PE-4 is also NDF in the single-active MH ES ESI-24, but it received no PIM state synchronization information from DF PE-2. Data-driven PIM state synchronization is not supported for single-active MH in PBB-EVPN services, because it is not allowed to have two PEs in a single-active MH ES using the same source BMAC, with the potential risk of traffic sent by remote PEs to the NDF PE (based on it sending to the shared source BMAC) being dropped. However, for a faster failover in single-active MH, multi-chassis synchronization (MCS) can be configured, as described in the next section.

Figure 307: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined shows the multicast traffic flow when PIM snooping is enabled and both receivers H-7 and H-8 have joined the multicast group. All PEs receive the multicast traffic on the P2MP tunnel, but only DF PE-2 and DF PE-3 forward the multicast traffic to the MTUs, which forward the traffic to the CEs, where it is forwarded to the receivers.

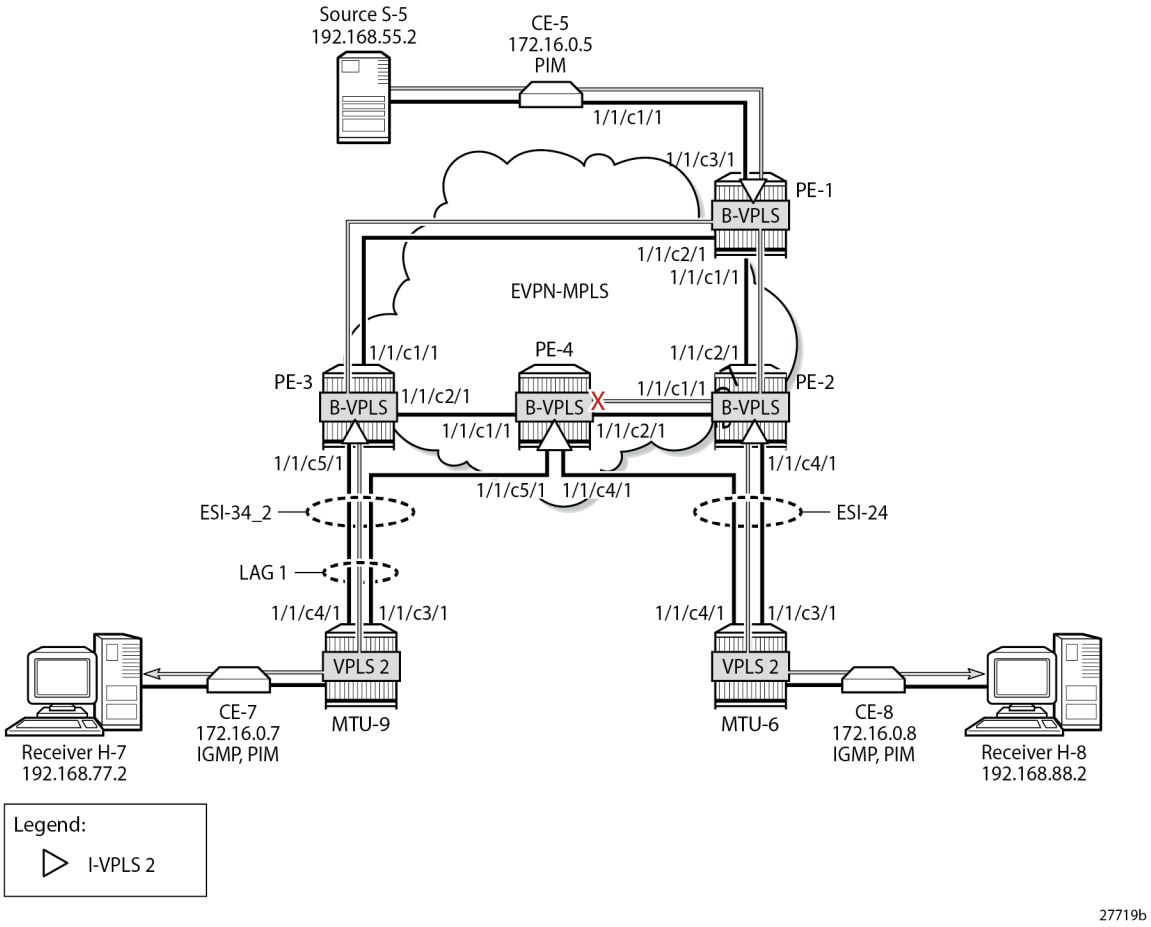
Figure 307: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined



PBB-EVPN with MH – PIM Snooping for IPv4 with MCS

MCS of the IPv4 PIM snooping state for SAPs and spoke-SDPs can optionally be configured in the case of MH. MCS reduces the failover time when data-driven PIM state synchronization is not supported; for example, for single-active MH in PBB-EVPN services. The synchronization information is stored in an MCS synchronization DB. MCS is configured on PE-2, identifying the peer (PE-4), with PIM snooping for spoke-SDPs as MCS client application and the list of spoke-SDPs, as follows:

```
On PE-2:
configure {
    redundancy {
        multi-chassis {
            peer 192.0.2.4 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    tags {
                        sdp 26 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
```

On PE-4, MCS is configured for peer PE-2, as follows:

```
On PE-4:
configure exclusive
    redundancy {
        multi-chassis {
            peer 192.0.2.2 {
                admin-state enable
                sync {
                    admin-state enable
                    pim-snooping {
                        spoke-sdps true
                    }
                    tags {
                        sdp 46 {
                            range start 2 end 2 {
                                sync-tag "syncSA"
                            }
                        }
                    }
                }
            }
```

When H-8 has joined the multicast group, the MCS sync-database on PE-2 shows the PIM snooping entries on the spoke-SDP 26:2 of the single-active MH ESI-24, as follows:

```
[/]
A:admin@PE-2# tools dump redundancy multi-chassis sync-database detail

The following command on PE-4 shows that the incoming PIM interface is the B-VPLS EVPN-MPLS interface and the spoke-SDP is the outgoing interface. Again, the split-horizon mechanism prevents traffic received from the B-VPLS EVPN-MPLS interface from being forwarded on the B-VPLS EVPN-MPLS interface.

However, PE-4 remains the NDF for both ESs and does not forward any traffic from the B-VPLS EVPN-MPLS interface to the spoke-SDP. Figure 308: PBB-EVPN with MH and PIM Snooping – Receiver H-8 Joined shows the multicast traffic flow when PIM snooping is enabled and receiver H-8 has joined.

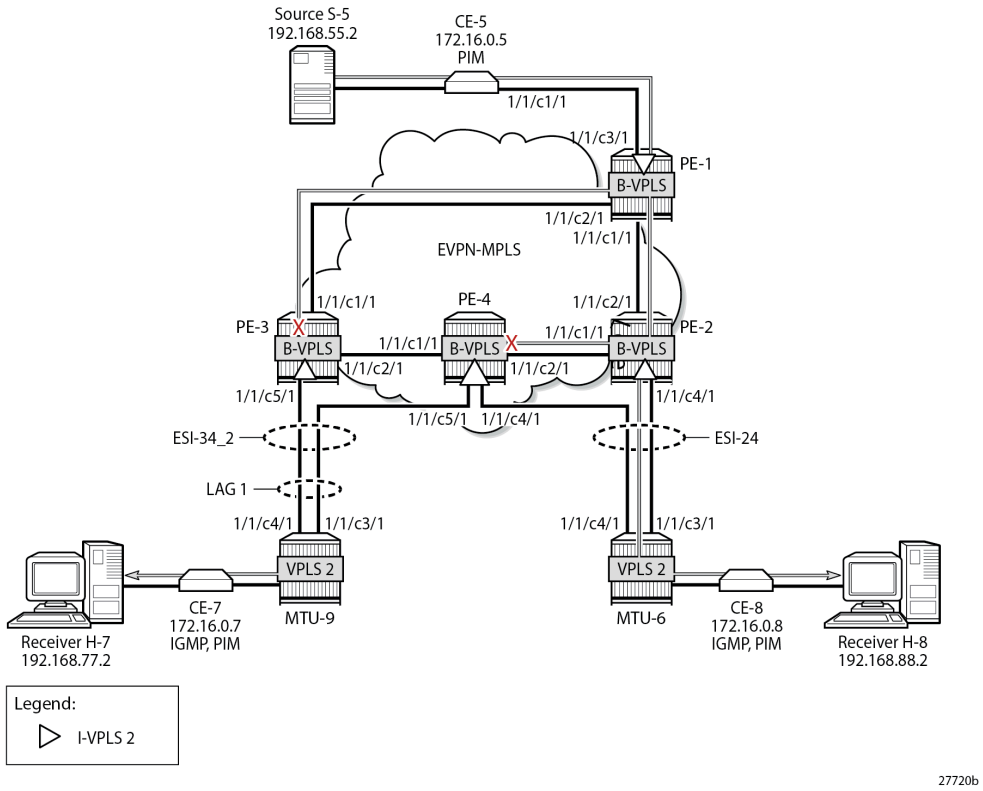
Figure 308: PBB-EVPN with MH and PIM Snooping – Receiver H-8 Joined



Failover

Figure 307: EVPN-MPLS with MH and PIM Snooping – Receivers H-7 and H-8 Joined showed the multicast traffic flow when both H-7 and H-8 have joined the multicast group. PE-2 is the DF for ESI-24 and PE-4 is the DF for ESI-34_2. The following failures are introduced to force a failover from PE-2 to PE-4 and from PE-3 to PE-4. Data-driven PIM state synchronization is used for all-active MH; MCS is configured for fast failover in the single-active MH ES ESI-24.

On MTU-6, SDP 62 is disabled, as follows:

```
On MTU-6:
configure {
    service {
        sdp 62 {
            admin-state disable
        }
```

On MTU-9, port 1/1/c3/1 toward PE-3 is disabled, as follows:

```
On MTU-9:
configure {
    port 1/1/c3/1 {
        admin-state disable
    }
```

===============================================================================
```

MTU-6 forwards the traffic to CE-8, which forwards it to H-8. MTU-9 forwards the traffic to CE-7, which sends it to H-7. PE-3 drops the multicast traffic because lag-1 is down because of the failure that was introduced at MTU-9 (port disabled).

Conclusion

PIM snooping reduces flooding of multicast traffic in L2 services and can be used in PBB-EVPN I-VPLSs in the same way as in I-VPLSs using B-VPLS without EVPN. PIM snooping can be used in all-active and single-active MH scenarios with data-driven state synchronization and MCS, respectively.

Preference-based and Non-revertive EVPN DF Election

This chapter provides information about Preference-based and Non-revertive EVPN DF Election.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R3, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2. Preference-based and non-revertive EVPN Designated Forwarder (DF) election is supported in SR OS Release 15.0.R1, and later. This mechanism works for Ethernet Segments (ESs) and virtual ESs (vESs).

Overview

RFC 7432 defines the Designated Forwarder (DF) in (PBB-)EVPN networks as the PE that will forward the following packets to a multi-homed node:

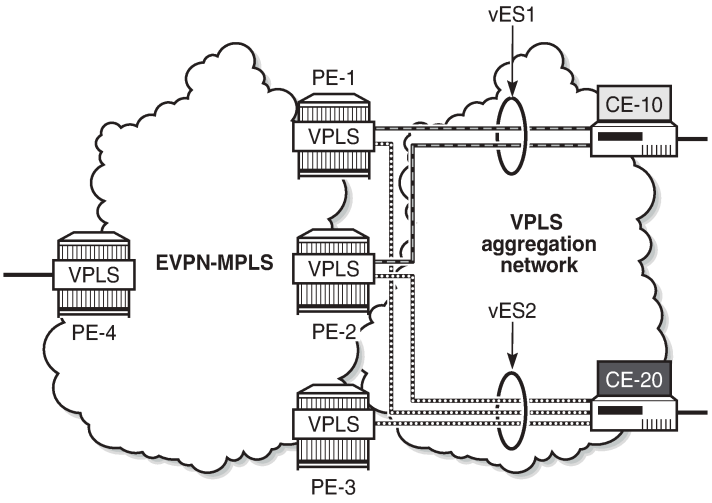
- Broadcast, Unknown unicast, and Multicast (BUM) traffic in an all-active multi-homing Ethernet Segment (ES)
- BUM and unicast in a single-active multi-homing ES

For more information about vESs, see chapter Virtual Ethernet Segments.

Figure 310: Virtual Ethernet Segments shows a topology with two vESs.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 310: Virtual Ethernet Segments

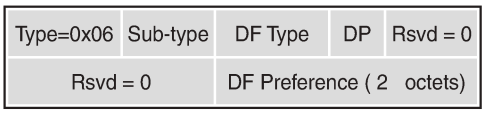


Taking the Ethernet VPN Identifier (EVI) or ISID and the number of PEs in the ES as input, the RFC 7432 service-carving algorithm elects the DF from the list of candidate PEs that advertise the ES identifier (ESI). While this algorithm provides an automated and fair DF distribution across services in the ES, it does not allow the operator to control what PE is the DF for which service. In addition, in case of a DF failure, when the former DF comes back up, a new DF switchover will cause unnecessary packet loss (this mode of operation is called revertive). SR OS implements *draft-ietf-bess-evpn-pref-df* to give more control to the operator on the DF election and avoid the revertive mode.

In SR OS, in addition to the automated service-carving, the DF election can also be controlled by configuring a preference manually. Also, it is possible to force an on-demand DF switchover without reconfiguring the PEs in the ES. Furthermore, the non-revertive option prevents an automatic switchover when a new active PE can preempt the existing DF PE. The non-revertive option avoids service impact when an ES comes back up.

Figure 311: BGP-EVPN extended community for DF election shows the BGP-EVPN extended community defined for DF election and the different values described in draft-ietf-bess-evpn-pref-df.

Figure 311: BGP-EVPN extended community for DF election



Type=0x06	Sub-type	DF Type	DP	Rsvd = 0
Rsvd = 0		DF Preference (2 octets)		

DP = Do not preempt (non-revertive)
DF = Designated forwarder
- Type 0 – Default, modulo-based DF election (RFC7432)
- Type 1 – Highest Random Weight (HRW) algorithm
- Type 2 – Preference algorithm

26787

The "Do not preempt" (DP) bit is set to enable the non-revertive option. When preference-based service carving is configured in the ES, DF type 2 is advertised along with a 2-byte preference value, which is 32767 by default.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Service carving can be configured in auto mode or manual mode. The preference can only be configured in manual mode.

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election]
A:admin@PE-2# service-carving-mode ?

 service-carving-mode <keyword>
 <keyword>  - (auto|manual|off)
 Default    - auto

    Mode of service carving enabled per EVPN associated with this Ethernet segment entry
```

When manual mode is enabled, the following parameters can be configured to control which PE will be elected as DF:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election]
A:admin@PE-2# manual ?

 manual

 evi                   + Enter the evi list instance
 isid                  + Enter the isid list instance
 preference            + Enable the preference context
```

The EVI and ISID ranges configured in the service-carving context do not need to be consistent with any ranges configured for virtual ESs.

When preference is configured manually, the mode can be configured as revertive (default) or non-revertive:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_1" df-election manual
 preference]
A:admin@PE-2# mode ?

 mode <keyword>
 <keyword>  - (revertive|non-revertive)
 Default    - revertive

 'mode' is: immutable

    Method used to elect the DF

    Warning: Modifying this element recreates 'configure service system bgp evpn
    ethernet-segment "vESI-23_1" df-election manual preference' automatically for the
    new value to take effect.
```

The preference-based EVPN DF election is as follows:

- By default, all SAPs and spoke-SDPs on the configured ES select the highest-preference PE as DF; however, when the EVI or ISID ranges are configured in the ES, the lowest-preference PE is selected.
- When the preference is equal, the DP bit is the tiebreaker: DP=1 wins over DP=0.
- For equal preference and DP, the PE IP address is the tiebreaker: the lowest IP address wins.

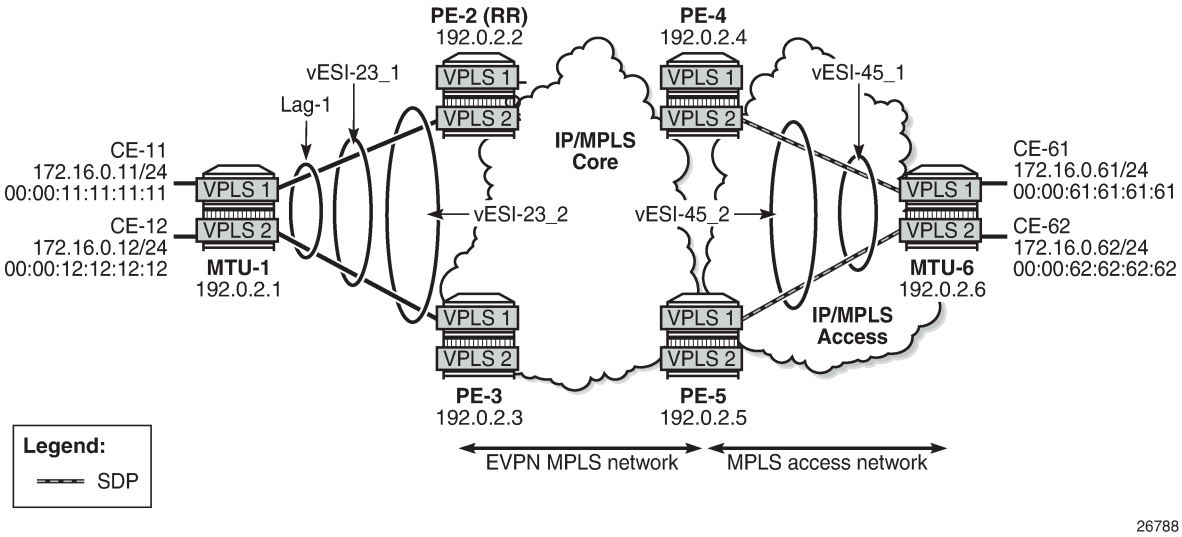
Use subject to Terms available at: www.nokia.com/terms.

Configuration

Figure 312: Example topology with all-active and single-active vESs shows the example topology with six nodes. EVPN-MPLS is configured between the core PE nodes. All-active vESs are configured between PE-2 and PE-3 and single-active vESs are configured between PE-4 and PE-5.

Figure 312: Example topology with all-active and single-active vESs



The initial configuration includes:

- Cards, MDAs, ports
- LAG 1 between MTU-1, PE-2, PE-3
- Router interfaces
- IS-IS (alternatively, OSPF could be used)
- LDP

BGP is configured on the four core PEs with PE-2 as Route Reflector (RR). The BGP configuration on RR PE-2 is as follows:

```
# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

VPLS 1 and VPLS 2 are configured on each node. The PEs have EVPN-MPLS enabled. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:1.1 {
            }
        }
        vpls "VPLS 2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap lag-1:2.1 {
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
```

The configuration on the other PEs is similar; PE-4 and PE-5 have a spoke-SDP configured instead of a SAP. For an explanation of the configuration, see chapter EVPN for MPLS Tunnels.

Service carving: auto mode

On PE-2 and PE-3, the following all-active multi-homing vESs are configured:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:01:00:00:01
                        multi-homing-mode all-active

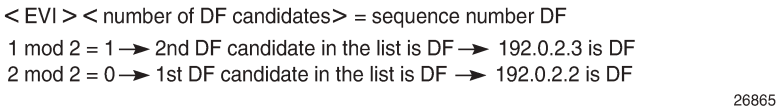
The service carving mode is set to **auto**, so the DF election is based on a modulo function of the EVI and the number of DF candidates. In the vES "vESI-23_1", there are two DF candidates, PE-2 and PE-3, listed in that order because PE-2 has the lower system IP address, as follows:

```
[/]
A:admin@PE-3# show service system bgp-evpn ethernet-segment name "vESI-23_1" all
                                          | match "EVI Information" post-lines 19
EVI Information
===============================================================================
EVI                 SvcId               Actv Timer Rem      DF
-------------------------------------------------------------------------------
1                   1                   0                   yes
-------------------------------------------------------------------------------
Number of entries: 1
===============================================================================
-------------------------------------------------------------------------------
DF Candidate list
-------------------------------------------------------------------------------
EVI                                     DF Address
-------------------------------------------------------------------------------
1                                       192.0.2.2
1                                       192.0.2.3
-------------------------------------------------------------------------------
Number of entries: 2
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
===============================================================================
```

The first DF candidate from the list will be selected when the result of the modulo function equals 0; the second DF candidate when the result equals 1. The calculation is as follows:



The following shows that PE-2 is not the DF for VPLS 1, but it is the DF for VPLS 2:

```
[/]
A:admin@PE-2# show service id 1 ethernet-segment

Instead of the preceding show commands, the following tools commands can be used:

```
[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_1"  evi 1 df

[04/26/2021 09:19:25] Computed DF: 192.0.2.3 (Remote) (Boot Timer Expired: Yes)

[/]
A:admin@PE-2# tools dump service system bgp-evpn ethernet-segment "vESI-23_2"  evi 2 df

[04/26/2021 09:19:25] Computed DF: 192.0.2.2 (This Node) (Boot Timer Expired: Yes)
```

Service carving: preference-based manual mode

To have more control, the vES can be configured in manual mode. The following reconfigures the vES "vESI-23_1" in manual mode, preference-based and revertive with preference value 32767 (default) on PE-2 and 5000 on PE-3, whereas vES "vESI-23_2" is preference-based and non-revertive with preference value 15000 on PE-2 and 20000 on PE-3.

An EVI range is configured for ES "vESI-23_2", but not for ES "vESI-23_1". When no EVI range is configured, the highest preference wins; for configured EVI ranges, the lowest preference wins. When there are no failures, PE-2 will be the DF for "vESI-23_1" (highest preference) and for "vESI-23_2" (lowest preference for configured EVI 2).

On PE-2, the ESs are reconfigured as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_2" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 15000
                                }
                            }
                        }
                    }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                }
```

The **non-revertive** mode is configured for vES "vESI-23_2", but not for vES "vESI-23_1".

On PE-3, the ES configuration is modified as follows:

```
# on PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 5000
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_2" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 20000
                                }
                            }
                        }
                    }
                }
```

For the single-active multi-homing vESs on PE-4 and PE-5, the same preferences are configured manually. The ES configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:01:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                }
                            }
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
```

                            manual {
                                evi 2 {
                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 15000
                                }
                            }
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
                                    vc-id 2 {
                                        end 2
                                    }
                                }
                            }
                        }
                    }
                }
```

The ES configuration on PE-5 is as follows:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        admin-state enable
                        type virtual

                                    end 2
                                }
                                preference {
                                    mode non-revertive
                                    value 20000
                                }
                            }
                        }
                        association {
                            sdp 56 {
                                virtual-ranges {
                                    vc-id 2 {
                                        end 2
                                    }
                                }
                            }
                        }
                    }
                }
```

The preference configuration must be consistent across the PEs in the ES (manual or auto), otherwise the system reverts to the modulo-based DF election.

With preference-based DF election configured with default preference value 32767 and revertive, PE-4 sends the following BGP-EVPN update to the RR PE-2. The **df-election** extended community shows the DP=0 (revertive) and DF preference 32767.

```
# on PE-4:

It is important to note that a router will prune a remote PE from the DF candidate list for an ES if it does not receive the corresponding Auto Discovery (AD) per-EVI and AD per-ES routes for that PE. A remote PE will not be shown in the DF Candidate list if its AD per-ES route is withdrawn. This is only true for EVPN. In PBB-EVPN, there are no AD routes, therefore the DF Candidate list is built out of the ES routes only.

DF election: higher preference prevails for non-configured EVI ranges

The PEs run the DF election per PE per EVI, and the elected DF for a service will activate the SAP/Spoke-SDP when the es-activation-timer expires. PE-4 is the DF in "vESI-45_1" used in VPLS 1, as follows. The EVI is not configured in ES "vESI-45_1", so the higher preference prevails. The ES "vESI-45_1" has (default) preference 32767 on PE-4 (DF) and preference 5000 on PE-5 (Non-Designated Forwarder (NDF)).

```

The preference value can be modified on the fly on an active ES. This allows the user to force a new DF for the ES for maintenance operations on the former DF or other reasons.

DF election: lowest preference prevails for configured EVI ranges

ES "vESI-45_2" is configured with EVI 2, so the lowest preference prevails. The admin preference value is 15000 on PE-4 and 20000 on PE-5. Both PE-4 and PE-5 are DF candidates, but PE-4 has the lowest preference, so it will be the DF, as follows:

```

DF election: DP prevails when preferences are equal

The service carving in the ES is configured with default preference and non-revertive option, as follows:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    delete value    # default value: 32767
                                }
                            }
                        }
```

The ES configuration on PE-4 remains unchanged, so the behavior is revertive. PE-4 and PE-5 have the same preference (default 32767), but PE-5 is non-revertive and becomes the DF, as follows:

```
[/]
A:admin@PE-5# show service id 1 ethernet-segment
No sap entries
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------

===============================================================================
No vxlan instance entries
```

DF election: lowest IP address prevails when preferences and DP are equal

The vES configuration on PE-4 is modified by enabling the non-revertive option, as follows:

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            manual {
                                preference {
                                    mode non-revertive
                                }
                            }
                        }
```

PE-4 and PE-5 have an equal preference (default value = 32767) and non-revertive behavior. The tiebreaker for the DF selection is the IP address. PE-4 has the lower IP address and becomes the DF, as follows:

```
[/]
A:admin@PE-4# show service id 1 ethernet-segment
No sap entries

===============================================================================
SDP Ethernet-Segment Information
===============================================================================
SDP                  Eth-Seg                          Status
-------------------------------------------------------------------------------
46:1                 vESI-45_1                        DF
===============================================================================
No vxlan instance entries
```

Service-carving configuration must be consistent

When the service carving on one of the PEs in the ES is configured in auto mode while one of the other PEs in the ES is configured in manual mode, the system reverts to modulo-based auto mode. The configuration of ES "vESI-45_1" remains unchanged on PE-4, but is modified on PE-5, as follows:

```
# on PE-5#
configure {
    service {
        system {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode auto
                            delete manual
                        }
```

ES "vESI-45_1" will operate in auto mode on PE-4 and on PE-5. The following **show** command on PE-4 shows that the ES is configured in manual mode, but operates in auto mode:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"

===============================================================================
```

For the remainder of the chapter, the vES configuration for "vESI-45_1" on PE-4 and PE-5 is restored to the initial settings. On PE-4, vESI-45_1" is configured with manual service-carving mode, reversive, and with default preference value (32767):

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    delete mode     # default mode: revertive
                                }
                            }
```

On PE-5, "vESI-45_1" is configured with manual service-carving mode, reversive, and with preference value 5000:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-45_1" {
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    value 5000
                                }
                            }
```

When there are no failures, PE-4 is the DF, because it has a higher preference.

Revertive behavior

When SDP 64 fails on MTU-6, PE-4 becomes the NDF for ES "vESI-45_1" and PE-5 will be the DF instead, as follows. The failure is emulated by disabling the SDP on MTU-6.

```
# on MTU-6:
configure {
    service {
        sdp 64 {
            admin-state disable
```

When the PE is not a candidate DF because it cannot be used, the operational preference value equals 0, as follows:

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_1"
                                           | match "DF Pref Election" post-lines 6
```

===============================================================================
No vxlan instance entries
```

Non-revertive behavior

When no failures have occurred, PE-4 is the DF for "vESI-45_2" because the lowest preference prevails for the configured EVI 2. The preference of PE-4 is 15000, which is lower than PE-5's preference of 20000.

```

The operational preference value on NDF PE-4 equals the preference value on DF PE-5, as follows. In this example, EVI 2 is included in the configured EVI range, so the lowest preference wins. To avoid the system reverting to the lower preference of 15000, the operational preference is raised to the value of 20000, which equals the preference of the current DF PE-5.

```
[/]
A:admin@PE-4# show service system bgp-evpn ethernet-segment name "vESI-45_2"
                                            | match "DF Pref Election" post-lines 6

non-revertive  15000          04/26/2021 09:21:41      20000          Disabled
-------------------------------------------------------------------------------
```

PE-4 checks its own administrative preference and compares it with the one of the Highest-PE and Lowest-PE that have DP=1 in their ES routes.

- The Highest-PE is the PE with higher preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.
- The Lowest-PE is the PE with lower preference, using the DP bit (with DP=1 being better) and, after that, the lower PE-IP address as tie-breakers.

Depending on this comparison, PE-4 will send the ES route with a preference and DP that may be different from its administrative values.

- If PE-4's preference value is higher than the Highest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Highest-PE's and DP=0.
- If PE-4's preference value is lower than the Lowest-PE's, PE-4 will send the ES route with an 'in-use' operational preference equal to the Lowest-PE's and DP=0.
- If PE-4's preference value is neither higher nor lower than the Highest-PE's or the Lowest-PE's respectively, PE-4 will send the ES route with its administrative [preference,DP]=[15000,1].

In this example, NDF PE-4 sends operational preference 20000 and DP=0, because its admin preference value was lower than the Lowest-PE's (PE-5), as follows:

```
# on PE-4:
148 2021/04/26 09:43:17.492 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2

"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

With equal operational preference, the current DF PE-5 sends DP=1, which is preferred over DP=0. The following output shows the BGP extended community of the ES routes for "vESI-45_2" in the RIB-In (received ES route from PE-5) and RIB-Out (sent ES route) on PE-4:

```
[/]
A:admin@PE-4# show router bgp routes evpn eth-seg hunt
                                    | match "target:00:00:00:00:45:02" pre-lines 2
Community      :                                  # in RIB-In
                  df-election::DF-Type:Preference/DP:1/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
Community      :                                  # in RIB-Out
                  df-election::DF-Type:Preference/DP:0/DF-Preference:20000/AC:1
                  target:00:00:00:00:45:02
```

Either of the following events cause PE-4 to re-advertise its admin preference 15000 and DP=1:

- DF PE-5 withdraws its ES route.
- The admin preference for ES "vESI-45_2" on DF PE-5 is modified by configuration to a value preferred over PE-4's admin preference; in this case, to a value lower than 15000.

The admin preference value can be modified on ES "vESI-45_2" on DF PE-5, as follows:

```
# on PE-5:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_2" {
                        df-election {
                            manual {
                                preference {
                                    mode non-revertive
                                    value 10000
                                }
                            }
```

The preference value 10000 is lower than 15000 and, therefore, preferred when the lowest preference wins. PE-5 remains DF, but now there is no need to modify the preference of PE-4, because the system does not need to revert. Therefore, PE-4 can send the admin preference 15000 and configured DP=1, as follows:

```
# on PE-4:
151 2021/04/26 09:47:45.433 CEST MINOR: DEBUG #2001 Base Peer 1: 192.0.2.2
"Peer 1: 192.0.2.2: UPDATE

Conclusion

Preference-based DF election offers more control over the DF Election and applies to regular ESs and vESs, either in single-active or in all-active multi-homing mode, in VPLS, I-VPLS, or Epipe services. The DF election is by default revertive, but when preference mode is chosen, it can be configured as non-revertive to reduce service impact.

Proxy-ARP/ND MAC List for Dynamic Entries

This chapter provides information about Proxy-ARP/ND MAC List for Dynamic Entries.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. Proxy-Address Resolution Protocol/Neighbor Discovery (proxy-ARP/ND) MAC list for dynamic entries is supported in SR OS Release 15.0.R1, and later.

Overview

In some EVPN networks, the use of static proxy-ARP/ND entries is preferred to dynamically learned entries. For example, this is the case with some Internet eXchange Points (IXPs) that use EVPN and proxy-ARP/ND technologies. The MAC address in the static entry can be a MAC address from a list of n preregistered MAC addresses. The advantage is that—in case of a router or card failure—the hardware can be replaced, and no reconfiguration is required if the new MAC address is within a list of allowed MAC addresses.

In SR OS, these allow lists are called MAC lists. The associated proxy-ARP/ND entries will not be added upon configuration, but dynamically through a resolve procedure. This follows *draft-ietf-bess-evpn-proxy-arp-nd*.

- When the dynamic proxy-ARP/ND IP address with its associated MAC list is configured, the system sends a resolve message to all its non-EVPN peers.
- The resolve message is an ARP request for IPv4, or a Neighbor Solicitation (NS) message for IPv6.
- The resolve message is sent at a configurable interval between 1 and 60 minutes; the default is 5 minutes.
- The system keeps sending resolve messages until a dynamic entry is created for the proxy-ARP/ND IP address. This entry is only created when two conditions are met:
  - An ARP/Gratuitous Address Resolution Protocol (GARP) or Neighbor Advertisement (NA) is received for the configured IP address.
  - The associated MAC address belongs to the MAC list configured for the IP address. If the MAC list is empty or not configured, the system will never create an entry for the IP address.

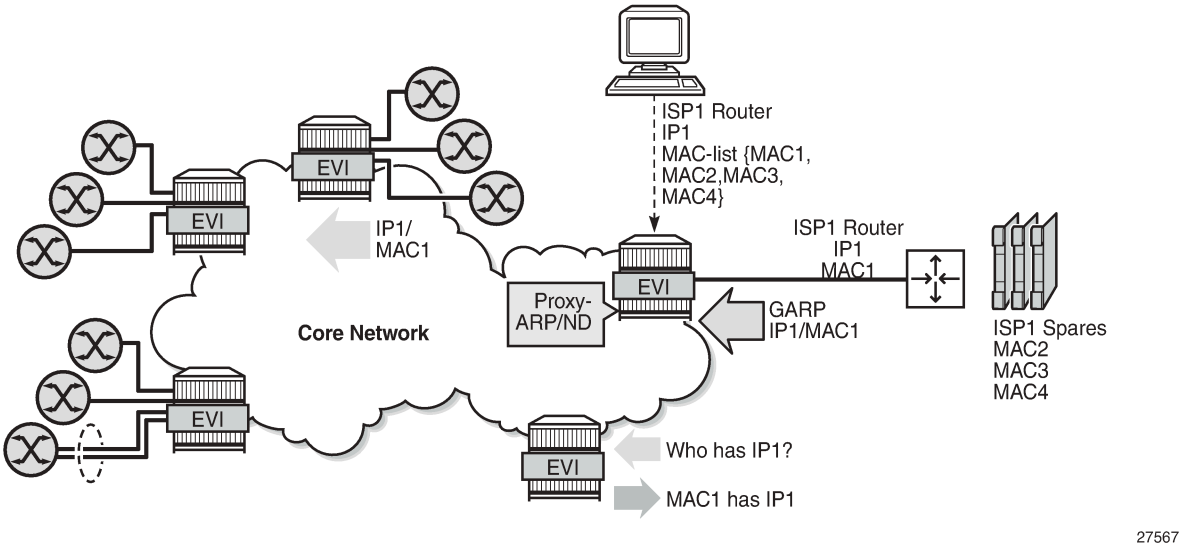
When the dynamic proxy-ARP/ND IP entry is created, the system advertises an EVPN-MAC update to its EVPN peers. The sticky bit will be set depending on how the corresponding MAC address is learned. If the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

MAC address is learned on a SAP/SDP-binding with Auto-Learn MAC Protect (ALMP) enabled, the EVPN-MAC route will be advertised as static.

Figure 313: IXP with proxy-ARP/ND MAC list for dynamic entries shows an example of an IXP network that uses proxy-ARP/ND and a MAC list.

Figure 313: IXP with proxy-ARP/ND MAC list for dynamic entries



The ISP1 router with IP1 and MAC1 is connected to a PE in the core network that has proxy-ARP/ND enabled and a list of allowed MAC addresses. This MAC list contains four MAC addresses: MAC1 (for the hardware that is currently in use) and three MAC addresses for spares: MAC2, MAC3, and MAC4. The proxy-ARP/ND table will be populated as follows:

- The PE floods a resolve message for the configured IP address for proxy-ARP/ND to its non-EVPN peers.
- The ISP1 router that is connected to the network sends a GARP or ARP Reply message with IP1 and MAC1 that will be snooped by the PE.
- The PE checks whether IP1 is configured as a dynamic proxy-ARP/ND entry and MAC1 is in the MAC list assigned to proxy-ARP/ND entry IP1.
  - If true, the IP1/MAC1 entry is created in the proxy-ARP/ND table and advertised in EVPN.
  - If the GARP message contains MAC5, which is not in the MAC allow list, no proxy-ARP/ND entry is created, and IP/MAC is not advertised. If **proxy-arp>evpn>flood>gratuitous-arp false** is configured, the GARP containing MAC5 will be discarded.

If after the proxy-ARP/ND creation, the corresponding MAC address is flushed from the Forwarding Database (FDB), the entry goes inactive. After the age-time, the inactive entry will age out and the resolve process will restart.

MAC lists are configured with the following command:

```
[ex:/configure service proxy-arp-nd mac-list]
A:admin@PE-2# list "ISP1" ?

 list
```

```
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 mac                   - Add a list entry for mac
```

The MAC list contains the allowed MAC addresses and can be associated in one or more services with a proxy-ARP/ND IP address. A MAC list is associated with dynamic proxy-ARP IP 1.1.1.1 with the following command:

```
[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp]
A:admin@PE-2# ip-address 1.1.1.1 ?

 ip-address

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 mac-list              - MAC list for the dynamic entry
 resolve-retry-time    - Frequency at which the resolve messages are sent
```

The configuration for proxy-ND is similar:

```
[ex:/configure service vpls "EVI-1" proxy-nd dynamic-neighbor]
A:admin@PE-2# ip-address 2001:db8::99 ?

 ip-address

 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 mac-list              - MAC list for the dynamic entry
 resolve-retry-time    - Frequency at which the resolve messages are sent
```

- The MAC list can be associated with multiple configured dynamic IP addresses:
  - In different services
  - In the same service, for proxy-ARP and proxy-ND
- An empty MAC list can be configured and applied, but no proxy-ARP/ND entries will be created when the PE receives a GARP message containing a MAC address that is not in the allow list.
- MAC lists can be modified at any time: MAC addresses can be added or removed even when the MAC lists are associated with configured dynamic IP addresses. If the MAC list changes, all the IP addresses associated with that MAC list will delete the proxy entries and restart the resolve process.

An existing dynamic proxy-ARP/ND entry IP1/MAC1 can be overridden when the system receives a GARP/ARP/NA for IP1 with another MAC address from the MAC list (IP1/MAC2). The system will first send a confirm message to check whether the old IP1/MAC1 is still reachable. Only when there is no answer, the entry IP1/MAC1 is replaced by IP1/MAC2. The existing duplicate-detect and confirm procedures are only applied for MAC address changes within the MAC list.

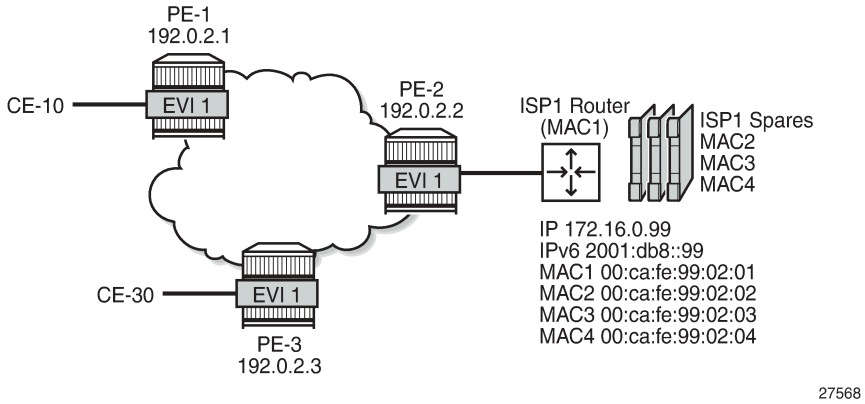
An existing dynamic proxy-ARP/ND entry IP1/MAC1 will be deleted when the system receives a GARP/ARP/NA IP1/MAC5 with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message will be discarded and the resolve procedure is restarted.

Configuration

Figure 314: Example topology shows the example topology with three PEs. ISP router 1 is connected to PE-2. MAC1 is used; MAC2, MAC3, and MAC4 correspond to spares.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 314: Example topology



The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS between the PEs (alternatively, OSPF can be used)
- LDP between the PEs

BGP is enabled between the PEs for address family EVPN. The BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.1" {
                group "internal"
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
        }
```

VPLS 1 is configured on PE-2 as follows. The configuration on the other PEs is similar.

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/2/1:1 {
            }
            sap 1/2/1:3 {
            }
        }
```

MAC list

The following MAC lists are configured on PE-2: ISP1 is an empty list; ISP2 is a MAC list containing four MAC addresses.

```
# on PE-2:
configure {
    service {
        proxy-arp-nd {
            mac-list {
                list "ISP1" {
                }
                list "ISP2" {
                    mac 00:ca:fe:99:02:01 { }
                    mac 00:ca:fe:99:02:02 { }
                    mac 00:ca:fe:99:02:03 { }
                    mac 00:ca:fe:99:02:04 { }
                }
            }
```

The following command shows the configured MAC lists on PE-2, with the number of MAC addresses and the number of associations. None of the MAC lists has been associated with a proxy-ARP/ND IP entry, so the number of associations is zero.

```
[/]
A:admin@PE-2# show service proxy-arp-nd mac-list

MAC list associated with proxy-ARP/ND in VPLS

MAC lists can be associated with one or more services. An empty MAC list—such as ISP1—can be associated, but it is impossible to associate a non-existing MAC list with a service. The following error is raised when attempting to associate the non-existing MAC list ISP3 with proxy-ARP IP 1.1.1.1 in VPLS 1 on PE-2:

```
*[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1]
A:admin@PE-2# mac-list "ISP3"

*[ex:/configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1]
A:admin@PE-2# commit
MINOR: MGMT_CORE #224: configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address 1.1.1.1
 mac-list - Entry does not exist - configure service proxy-arp-nd mac-list list "ISP3"
```

MAC list ISP2 is associated with proxy-ARP IP 172.16.0.99 and with proxy-ND IP 2001:db8::99 in VPLS 1 on PE-2, as follows:

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            proxy-arp {
                admin-state enable
                dynamic-populate true
                dynamic-arp {
                    ip-address 172.16.0.99 {
                        mac-list "ISP2"
                        resolve-retry-time 1
                    }
                }
            }
            proxy-nd {
                admin-state enable
                dynamic-populate true
                dynamic-neighbor {
                    ip-address 2001:db8::99 {
                        mac-list "ISP2"
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    }
                }
            }
```

For proxy-ARP IP 172.16.0.99, the resolve interval is 1 minute, which is the minimum; for proxy-ND IP 2001:db::99, the resolve interval is the default of 5 minutes. In scaled environments, Nokia recommends using the default interval, or even configuring a longer interval. The proxy-ARP and proxy-ND tables can be populated with dynamic entries (**dynamic-populate true**).

The following command shows all associations for MAC list ISP2: two associations are defined in VPLS 1: one for IP address 172.16.0.99 and another for IP address 2001:db8::99.

```
[/]
A:admin@PE-2# show service proxy-arp-nd mac-list name "ISP2" associations

===============================================================================

```

Different dynamic proxy-ARP/ND entries

A distinction is made between regular dynamic entries and configured dynamic entries:

- No IP address needs to be configured for regular dynamic proxy-ARP/ND entries. What only needs to be configured, is the option **dynamic-populate true**.
- IP address and MAC list need to be defined for configured proxy-ARP/ND entries.

Configured dynamic entries can override static and regular dynamic entries.

Regular dynamic proxy-ARP/ND entries can override configured dynamic entries.

EVPN entries cannot override configured dynamic entries, even though they can override regular dynamic entries.

Likewise, static entries can override regular dynamic entries, but they cannot override dynamic configured entries. The following error is raised when attempting to configure a static proxy-ARP entry for IP 172.16.0.99, which has already been configured as dynamic and associated with a MAC list.

```
*[ex:/configure service vpls "EVI-1" proxy-arp static-arp ip-address 172.16.0.99]A:admin@PE-2#
 commit
MINOR: MGMT_CORE #258: configure service vpls "EVI-1" proxy-arp dynamic-arp ip-address
 172.16.0.99 - Unique values required - configure service vpls "EVI-1" proxy-arp static-arp ip-
address 172.16.0.99
```

Debugging

Debugging for both proxy-ARP/ND IP entries is enabled—in classic CLI—on PE-2 as follows:

```
# on PE-2:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
debug
    service
        id 1
            proxy-arp ip 172.16.0.99
            proxy-nd ip 2001:db8::99
        exit
    exit
exit
```

When the dynamic proxy-ARP IP 172.16.0.99 is configured with MAC list "ISP2", PE-2 floods a resolve message—in this case, an ARP request—to all its EVPN peers. Router ISP1 replies. PE-2 advertises an EVPN-MAC update to its EVPN peers PE-1 and PE-3. PE-2 adds a dynamic proxy-ARP entry for 172.16.0.99 with MAC address 00:ca:fe:99:02:01. Router ISP1 sends a GARP message. The following messages are logged:

```
29 2021/05/11 14:11:39.920 CEST MINOR: DEBUG #2001 Base proxy arp
"proxy arp:
svc: 1 ip: 172.16.0.99 flood resolve"

Tools command to trigger resolve procedure

The following tools command can be used to force the system to send a resolve message to its non-EVPN peers. The **force** option will trigger the resolve process even for existing entries in the proxy-ARP/ND table.

```
[/]
A:admin@PE-2# tools perform service id 1 proxy-arp dynamic-resolve ?

 dynamic-resolve all [force]
 dynamic-resolve <IP address> [force]

 [ip-address] (<ipv4-address> | <ipv6-address>)
 <ipv4-address>  - <d.d.d.d>
 <ipv6-address>  - (<x:x:x:x:x:x:x:x>|<x:x:x:x:x:x:d.d.d.d>)

 [ip-address]          - ipv4 address '<d.d.d.d>' or ipv6 address
 '(<x:x:x:x:x:x:x:x>|<x:x:x:x:x:x:d.d.d.d>)'

By default, aging is disabled, and the entries remain in the inactive status until the MAC address is learned again. However, if aging is enabled, the inactive proxy-ARP/ND entry will age out. After the entry is

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

deleted, the system sends a resolve message. When the ISP1 router replies, the entry is created again in the proxy-ARP/ND table. The age time is configured in seconds with the following command:

```
[ex:/configure service vpls "EVI-1" proxy-arp]
A:admin@PE-2# age-time ?

 age-time (<number> | <keyword>)
 <number>   - <60..86400>  - seconds
 <keyword>  - never        - seconds
 Default    - never

    Aging timer for proxy entries, where entries are flushed upon timer expiry
```

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            proxy-arp {
                age-time 60
            }
            proxy-nd {
                age-time 60
            }
```

The following debug messages for proxy ARP IP 172.16.0.99 show that an EVPN-MAC withdraw message is sent (when the MAC address is flushed from the FDB) and—after time-out—the proxy-ARP entry is deleted. PE-2 sends a resolve message to all its non-EVPN peers. Router ISP1 replies and the proxy-ARP entry is created again; an EVPN-MAC update is sent to the EVPN peers. Similar debug messages occur for proxy-ND.

```
57 2021/05/11 14:16:48.589 CEST MINOR: DEBUG #2001 Base proxy arp

MAC address replacement

When the system receives a GARP/ARP/NA for the same IP address, but with another MAC address from the MAC list, it will first send a confirm message to ensure that the old MAC address is not used anymore for the IP address. If the existing proxy-ARP/ND entry is IP1/MAC1 and a GARP/ARP/NA message is received for IP1/MAC4, the system sends an EVPN-MAC withdraw message for MAC1 and changes MAC1 to MAC4 for proxy-ARP/ND IP1, but the status is pending (pendng), as follows:

```
[/]A:admin@PE-2# show service id 1 proxy-arp detail | match 172.16.0.99 pre-lines 6
                                                                        post-lines 3

```

The system sends a confirm message (unicast ARP request) for the old entry IP1/MAC1 to ensure that there is no duplication. When there is no reply from MAC1, there is no duplication. An EVPN-MAC route is advertised for MAC4. The status of the proxy-ARP entry IP1/MAC4 changes to active. The following debug messages are logged for proxy-ARP 172.16.0.99:

```
151 2021/05/11 14:23:29.394 CEST MINOR: DEBUG #2001 Base proxy arp
"proxy arp:

-------------------------------------------------------------------------------
172.16.0.99         00:ca:fe:99:02:04   dyn       active    05/11/2021 14:24:34
-------------------------------------------------------------------------------
Number of entries : 1
===============================================================================
```

The mechanism is similar for proxy-ND.

The behavior is different when the system receives a GARP/ARP/NA for the IP address with a MAC address that is not contained in the MAC list. The GARP/ARP/NA message is discarded and the proxy-ARP/ND entry deleted. The resolve procedure gets restarted.

Modified MAC list

MAC lists can be modified at any time, as follows:

```
# on PE-2:
configure {
    service {
        proxy-arp-nd {
            mac-list {
                list "ISP2" {
                    mac 00:ca:fe:99:02:05 { }
```

```
[/]A:admin@PE-2# show service proxy-arp-nd mac-list name "ISP2"

195 2021/05/11 14:25:23.420 CEST MINOR: DEBUG #2001 Base proxy nd
"proxy nd:
svc: 1 ip: 2001:db8::99 type: Dyn mac: 00:ca:fe:99:02:04 Gratuitous Update"
```

Conclusion

MAC lists can be associated with configured dynamic proxy-ARP/ND IP addresses. The actual proxy entries will only be created after a GARP/ARP/NA message is received for the IP address and one of the MAC addresses from the MAC list.

This tool complements the SR OS EVPN proxy-ARP/ND solution for providers present at IXPs.

Shortest Path Bridging for MAC

This chapter describes advanced shortest path bridging for MAC configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 11.0.R4, but the MD-CLI in the current edition is based on SR OS Release 23.7.R2.

Overview

SPB enables a next generation control plane for Provider Backbone Bridges (PBB) and PBB-VPLS that adds the stability and efficiency of link state to unicast and multicast services (Epipes and I-VPLSs). In addition, SPBM provides resiliency, load balancing, and multicast optimization without the need for any other control plane in the B-VPLS (for example, there is no need for spanning tree, or G.8032, or Multiple MAC Registration Protocol (MMRP)).

SPBM exploits the complete knowledge of backbone addressing, which is a key consequence of the PBB hierarchy, by advertising and distributing the backbone MAC addresses (BMACs) through a link-state protocol, namely IS-IS. An immediate effect of this is that the old "flood-and-learn" can at last be turned off in the backbone and every B-VPLS node in the network will know what destination BMAC addresses are expected and valid. As a result of that, receiving an unknown unicast BMAC on a B-VPLS SAP or PW is indicative of an error, whereupon the frame is discarded (due to the Reverse Path Forwarding Check (RPFC) performed in SPBM) instead of flooded. Furthermore, SPBM allows condensing all the relevant information distribution (unicast and multicast) into a single control protocol: IS-IS.

SPBM can be easily enabled on the existing B-VPLS instances being used for multiplexing I-VPLS and Epipe services, providing the following benefits:

- Per-service flood containment (for I-VPLS services) without the need for an additional protocol such as MMRP,
- Loop avoidance in the B-VPLS domain without the need for MSTP or other technologies,
- No unknown BMAC flooding in the B-VPLS domain,
- No need for MAC notification mechanisms or vMEPs in the B-VPLS to update the B-VPLS forwarding databases (FDBs) (vMEPs can still be configured though for OAM purposes).

Some other characteristics of the SPB implementation in the SR OS are:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The SR OS SPB implementation always uses Multi-Topology (MT) topology instance zero. However, up to four logical instances (that is, SPB instances in different B-VPLS services) are supported if different topologies are required for different services.
- Area addresses are not used and SPB is assumed to be a single area. SPB must be consistently configured on nodes in the system. SPB regions information and IS-IS hello logic that detect mismatched configuration are not supported. IS-IS area is always zero.
- SPB uses all-intermediate systems 09-00-2B-00-00-05 destination MAC to communicate.
- SPB source ID is always zero.
- SPB uses a separate instance of IS-IS from the base IP IS-IS. IS-IS for SPB is configured in the SPB context under the B-VPLS component. Up to four ISIS-SPB instances are supported, where the instance identifier can be any number between 1024 and 2047. The instance number is not in TLVs.
- Two Equal Cost Tree (ECT) algorithms (IEEE 802.1aq) per SPB instance are supported: low-path-id and high-path-id algorithms.
- SPB link state protocol data units (link state packets) contain BMACs, ISIDs (for multicast services) and link and metric information for an IS-IS database.
  - Epipe ISIDs are not distributed in SR OS SPB allowing high scalability of PBB Epipes.
  - I-VPLS ISIDs are distributed in SR OS SPB and the respective multicast group addresses (composed of PBB-OUI plus ISID) are automatically populated in a manner that provides automatic pruning of multicast to the subset of the multicast tree that supports an I-VPLS with a common ISID. This replaces the function of MMRP and is more efficient than MMRP.
- Multiple ISIS-SPB adjacencies between two nodes are not supported as per the IEEE 802.1aq standard specification. If multiple links between two nodes exist, LAG must be used.

Configuration

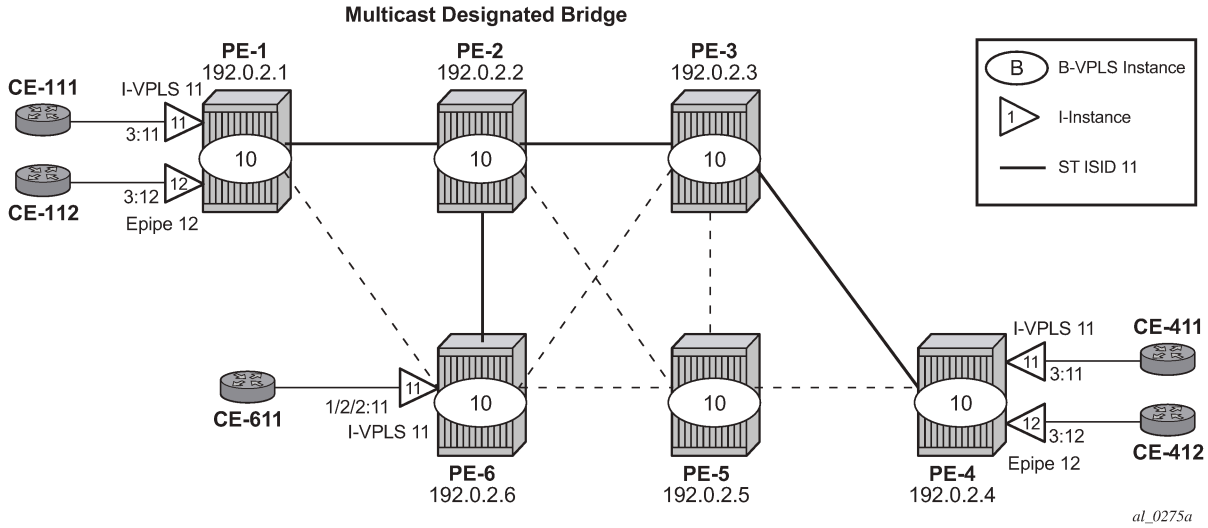
This section describes the configuration of SPBM on SR OS as well as the available troubleshooting commands.

Basic SPBM configuration

Figure 315: Basic SPBM topology shows the topology used as an example of a basic SPBM configuration.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 315: Basic SPBM topology



Assume the following protocols and objects are configured beforehand:

- The six PEs shown in Figure 315: Basic SPBM topology are running IS-IS for the global routing table with all the interfaces being level-2.
- LDP is used as the MPLS protocol to signal transport tunnel labels.
- LDP SDPs are configured among the six PEs, as shown in Figure 315: Basic SPBM topology (dashed lines and bold lines among PEs).

Once the network infrastructure is properly running, the actual service configuration can be carried out. In the example, B-VPLS-10 will provide backbone connectivity for the services I-VPLS-11 and Epipe-12.

The SPBM configuration is only relevant to the B-VPLS instance and can be added to an existing B-VPLS, assuming that such a B-VPLS does not contain any non-SPB-compatible configuration parameters. The following parameters are not supported in SPB-enabled B-VPLS instances:

- Mesh SDPs (only SAPs or spoke-SDPs are supported in SPB-enabled B-VPLS)
- Spanning tree protocol (STP)
- Split-horizon groups
- Non-conditional static-MAC addresses (configured under SAPs or spoke-SDPs, see the Static BMACs and static ISIDs configuration section)
- G.8032
- mac-flush tldp propagate and mac-flush tldp send-on-failure (because failures within the B-VPLS are handled by SPB)
- Maximum number of MAC addresses (fdb maximum-mac-addresses)
- Bridge Protocol Data Unit (BPDU) translation
- Layer 2 Protocol Termination (L2PT)
- MAC-pinning
- Operational groups

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MAC-move
- Any BGP, BGP auto-discovery (BGP-AD), or BGP virtual private LAN services (BGP-VPLS) parameters
- Endpoints
- Local/remote age
- MAC notification
- MAC protect
- Multiple MAC Registration Protocol (MMRP)
- Provider tunnel
- Temporary flooding

Assuming all the parameters mentioned are not configured in the B-VPLS (B-VPLS-10 in the example), SPBM can be enabled. The SPBM parameters are all configured in the **configure service vpls(b-vpls) spb** and **configure service vpls(b-vpls) spoke-sdp/sap spb** contexts:

```

metric                - Metric
```

The parameters configured in the **spb** context refer to the SPB IS-IS and they should be configured following the same considerations as for the IS-IS base instance:

- spb
  - isis-instance <isis-instance[1024..2047]> identifies the SPB IS-IS process. Up to four different IS-IS SPB processes can be run in a system.
  - forwarding identifier <fid> identifies the standard SPBM B-VID which is signaled in IS-IS with each advertised BMAC. Each B-VPLS has a single configurable FID.
  - lsp-lifetime <seconds> : [350..65535]
  - lsp-refresh-interval <seconds> : [150..65535]
  - overload [timeout <seconds>] : [60..1800]
  - overload-on-boot [timeout <seconds>] : [60..1800]
  - timers
    - lsp-wait
      - max-wait : [10..120000] in milliseconds
      - initial-wait : [10..100000] in milliseconds
      - second-wait : [10..100000] in milliseconds
    - spf-wait
      - max-wait : [10..120000] in milliseconds
      - initial-wait : [10..100000] in milliseconds
      - second-wait : [10..100000] in milliseconds
- spoke-sdp/sap
  - spb
    - lsp-pacing-interval <milli-seconds> : [0..65535]
    - retransmit-interval <seconds> : [1..65535]
      - level 1

        Under retransmit-interval <seconds> : [1..20000]

        Under hello-multiplier <multiplier> : [2..100]

In the same way, lsp-wait (initial-wait) and spf-wait (initial-wait) can be tuned in the base router IS-IS instance to minimize the convergence time (to 0 and 10 respectively), the equivalent SPB IS-IS parameters should also be adjusted so that failover time is minimized at the service level.

The following parameters are specific to SPBM (note that only IS-IS level 1 is supported for SPB):

- **spb level 1 bridge-priority <bridge-priority> : [0..15]**

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

This parameter influences the election of the multicast designated bridge through which all the Single Trees (STs) for the multicast traffic are established. The default value will be lowered on that node where the multicast designated bridge function is desired, normally because that node is the best connected node. In the example, PE-2 is the multicast designated bridge for B-VPLS-10 and therefore, PE-2 will be the root of the STs for the I-VPLS instances in that B-VPLS. Default value = 8.

- **spb level 1 ect-high-path-fid <fid>**

  Two ECT algorithms are supported: low-path-id and high-path-id. They can provide the required path diversity for an efficient load balancing in the B-VPLS. By default, the low-path-id ECT algorithm applies for all FIDs from 1 to 4095. The **ect-high-path-fid <fid>** command defines for which FID values the high-path-id ECT algorithm is used.

- **spb level 1 forwarding-tree topology {spf|st}**

  This command configures the type of tree to be used for unicast traffic: shortest path tree or single tree. The multicast traffic (that encapsulated I-VPLS Broadcast, Unknown unicast, and Multicast (BUM) traffic always uses the ST path. Using SPF for unicast traffic can produce some packet re-ordering for unicast traffic compared to BUM traffic because different trees are used, therefore, when the B-VPLS transports I-VPLS traffic and the unicast and multicast trees do not follow the same path, it is recommended to use ST paths for unicast and multicast. Default value = spf.

- **spoke-sdp/sap spb level 1 metric <number> : [1..16777215]**

  This command configures the metric for each SPB interface (spoke-SDP or SAP). This value helps influence the SPF calculation in order to pick a certain path for the traffic to a remote system BMAC.When the SPB link metric advertised by two peers is different, the maximum value is chosen according to the RFC 6329. Default value = 0 (no metric).

As an example, the following CLI output shows the relevant configuration of PE-1 and PE-2 (the multicast designated bridge). SPB has to be created and enabled at B-VPLS service level first and then created and enabled under every SAP or spoke-SDP in the B-VPLS. Non-SPB-enabled SAPs or spoke-SDPs can exist in the SPB B-VPLS only if conditional static-MACs are configured for them (see the Static BMACs and static ISIDs configuration section). As for regular B-VPLS services, the service MTU has to be changed from the default value (1500) to a number 18 bytes greater than the I-VPLS service MTU in order to allow for the PBB encapsulation.

```
# on PE-1:
configure {
    service {
        pbb {
            source-bmac {
                address 00:00:5e:00:53:01
            }
            mac "PE-1" {
                address 00:00:5e:00:53:01
            }
            mac "PE-2" {
                address 00:00:5e:00:53:02
            }
            mac "PE-3" {

        }
```

As discussed, the **bridge-priority** influences the election of the multicast designated bridge. By making PE-2's bridge-priority zero, it ensures that PE-2 becomes the root of all the STs for B-VPLS-10 as long as the priority for the rest of the PEs is larger than zero. In case of a tie, the PE owning the lowest system BMAC will be elected as multicast designated bridge. Figure 315: Basic SPBM topology shows the ST for I-VPLS-11 (see a thicker continuous line representing the ST). PE-2 is the root of the ST tree.

```
# on PE-2:
configure {
    service {
        pbb {
            source-bmac {
                address 00:00:5e:00:53:02
            }
            mac "PE-1" {
                address 00:00:5e:00:53:01
            }
            mac "PE-2" {
                address 00:00:5e:00:53:02
            }
            mac "PE-3" {
                address 00:00:5e:00:53:03
            }
            mac "PE-4" {

                    admin-state enable
                }
            }
            spoke-sdp 26:10 {
                spb {
                    admin-state enable
                }
            }
        }
```

The rest of the nodes is configured accordingly. SPB instance 1024 will set up shortest path first (SPF) trees for unicast traffic and a single tree (ST) per ISID with PE-2 as the root bridge (because it has the lowest bridge priority 0 configured) for BUM traffic. The ECT algorithm chosen for the B-VPLS FID (10) is the low-path-id (default).

Once SPBM is configured on all the six nodes, the six system BMAC addresses and the ISID 11 will be advertised by SPB IS-IS.

The following show commands can help understand the IS-IS configuration for SPB 1024 and the BMAC addresses populated by IS-IS:

- **show service id "B-VPLS-10" spb base** provides the SPB configuration and parameters for a particular SPB B-VPLS.

```
[/]
A:admin@PE-1# show service id "B-VPLS-10" spb base

The preceding output shows that the unicast (SPF) tree and the multicast (ST) tree differ with respect to PE-6.

The following commands help check the unicast and multicast topology for B-VPLS-10:

- **show service id "B-VPLS-10" spb routes** provides a detailed view of the unicast and multicast routes computed by SPF. As shown in the following command, the SPB unicast and multicast routes match on PE-2 because this node is the multicast designated bridge. Unicast and multicast routes will differ on most other nodes.

```
[/]
A:admin@PE-2# show service id "B-VPLS-10" spb routes

SPB multicast trees (STs) are pruned for each particular I-VPLS ISID, based on the advertisement of I-VPLS ISIDs in SPB IS-IS by each individual PE. Multicast B-VPLS traffic not belonging to any particular I-VPLS follows the default tree. The default tree is an ST for the B-VPLS which is not pruned and therefore

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

reaches all the PE nodes in the B-VPLS. For instance, Ethernet-CFM CCM messages sent from vMEPs configured on the SPB B-VPLS will use the default tree. The default tree does not consume MFIB entries and can be checked in each node through the use of the following command:

```
[/]
A:admin@PE-5# tools dump service id 10 spb default-multicast-list
saps : { }
spoke-sdps : { 52:10 }
```

PE-5 is not part of the tree for I-VPLS-11. However, as with any SPB node part of B-VPLS-10, PE-5 is part of the default tree. Refer to Configuration of ISID policies in SPB B-VPLS to see more use cases for the default tree.

The following tools commands allow the operator to easily see the forwarding path (unicast and multicast) followed by the traffic to a remote node, with the aggregate metric from the source.

```
[/]
A:admin@PE-1# tools dump service id 10 spb fid 10 forwarding-path destination PE-4 forwarding-
tree unicast

```

In large networks or networks where IP multicast, PBB, and PBB-SPB services coexist, the data plane MFIB entries is a hardware resource that should be periodically checked. The **tools dump service vpls-mfib-stats** command shows the total number of hardware MFIB entries (in this case, 40959 entries) and the entries being used by IP multicast or PBB (MMRP or SPB) (in this case, 16383 entries). The **tools dump service vpls-pbb-mfib-stats** shows the breakdown between MFIB entries populated by MMRP, SPB, or by EVPN, and the individual limits, system-wide, and per service:

```

Control and user B-VPLS configuration

The SR OS implementation of SPB allows a single SPB IS-IS instance to control the paths and FDBs of many B-VPLS instances. This is done by using the control B-VPLS, user B-VPLS, and fate-sharing concepts.

The control B-VPLS will be SPB-enabled and configured with all the related SPB IS-IS parameters. Although the control B-VPLS might or might not have I-VPLSs or Epipes directly attached, it must be configured on all the nodes where SPB forwarding is expected to be active. SPB uses the logical instance and a forwarding ID (FID) to identify SPB locally on the node. That FID must be consistently configured on all the nodes where the B-VPLS exists. User B-VPLS are other instances of B-VPLS that are usually configured to separate the traffic for manageability reasons, QoS, or ECT different treatment.

Figure 316: Control and user B-VPLS example topology illustrates the control B-VPLS "control B-VPLS-20" and user B-VPLS "user B-VPLS-21" concept. In this example, there is only one user B-VPLS, but there can be several user B-VPLSs sharing fate with the same control B-VPLS. The control B-VPLS and the user B-VPLS must share the same topology and both B-VPLSs must share exactly the same interfaces. The user B-VPLS, which is linked to the control B-VPLS by its FID, follows—that is, inherits the state of—the control B-VPLS, but may use a different ECT path in case of equal metric paths, like in this example: FID 20, that is, the control B-VPLS, follows the low-path-id ECT, whereas FID 21, for example, the user B-VPLS, follows the high-path-id ECT.

```

If there is a mismatch between the topology of a user B-VPLS and its control B-VPLS, only the user B-VPLS links and nodes that are in common with the control B-VPLS will function.

User B-VPLS instances supporting only unicast services (PBB-Epipes) may share the FID with the other B-VPLS (control or user). This is a configuration shortcut that reduces the LSP advertisement size for B-VPLS services but results in the same separation for forwarding between the B-VPLS services. In the case of PBB-Epipes, only BMACs are advertised per FID, but BMACs are populated per B-VPLS in the FIB. If I-VPLS services are to be supported on a B-VPLS, that B-VPLS must have an independent FID.

Although user B-VPLS-21 does not have any SPB setting (other than the **spbm-control-vpls**), the spoke-SDPs use the same SDPs as the parent control B-VPLS-20. The **show service id <user b-vpls> spb fate-sharing** command shows the control spoke-SDP/SAPs that control the user spoke-SDP/SAPs.

```

SPBM access resiliency configuration

The following example shows how to configure an I-VPLS or Epipe attached to an SPB-enabled B-VPLS when access resiliency is used.

Multi-Chassis LAG (MC-LAG) is the only resiliency mechanism supported for PBB-Epipes. The MC-LAG active node will advertise the MC-LAG BMAC (or SAP BMAC) in SPB IS-IS. In case of failure, when the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

standby node takes over, it will advertise the MC-LAG SAP BMAC. Without SPB, the MC-LAG solution for PBB-Epipe required the use of MAC notification and periodic MAC notification. SPB provides a faster and more efficient solution without the need for any extra MAC notification mechanism. In the example described in this section, Epipe 31 uses MC-LAG access resiliency to get connected to the B-VPLS-30 on nodes PE-2 and PE-6.

As far as I-VPLS access resiliency is concerned, the same mechanisms supported for regular B-VPLS are supported for SPB-enabled B-VPLS, except for G.8032. A very important aspect of the I-VPLS resiliency is a proper MAC flush propagation when there is a failure at the I-VPLS access links.

If the SPB-enabled B-VPLS uses B-SAPs for its connectivity to the backbone, there is no MAC flush propagation (because there is no TLDP). In this case, if MC-LAG is used and there is an MC-LAG switchover, the new active chassis will keep using the same source BMAC, such as the SAP BMAC, and it will advertise it in the B-VPLS domain so that the remote FDBs can be properly updated. No MAC flush is required in this case.

When the B-VPLS uses spoke-SDPs for its backbone connectivity, the traditional LDP MAC flush propagation mechanisms and commands can be used as follows:

- **mac-flush tldp send-on-failure** works as expected when SPB is used at the B-VPLS. When configured, a flush-all-from-me event is triggered upon a SAP or spoke-SDP failure in the I-VPLS.
- **pbb i-vpls-mac-flush tldp send-to-bvpls** works as expected when SPB is used at the B-VPLS. Two variants are configurable: all-from-me/all-but-mine. Any I-VPLS SAP or spoke-SDP failure is propagated to the I-VPLS on the peers to flush their respective customer MAC addresses (CMACs). It works only in conjunction with **mac-flush tldp send-on-failure** configuration on I-VPLS. The associated ISID list is passed along with the LDP MAC flush message, which is flushed or retained according to the **all-from-me**/**all-but-me** flag.
- **pbb i-vpls-mac-flush tldp send-on-bvpls-failure** works as expected when SPB is used at the B-VPLS. A local B-VPLS failure is propagated to the I-VPLS, which then triggers a LDP MAC flush if it has any spoke SDP on it.
- **pbb i-vpls-mac-flush tldp propagate-from-bvpls** does not work when SPB is used at the B-VPLS (because failures within the B-VPLS are handled by SPB) and its configuration is blocked.

In the example described later in this section, I-VPLS-32 uses active/standby spoke-SDP resiliency to get connected to the B-VPLS-30 on nodes PE-3 and PE-5.

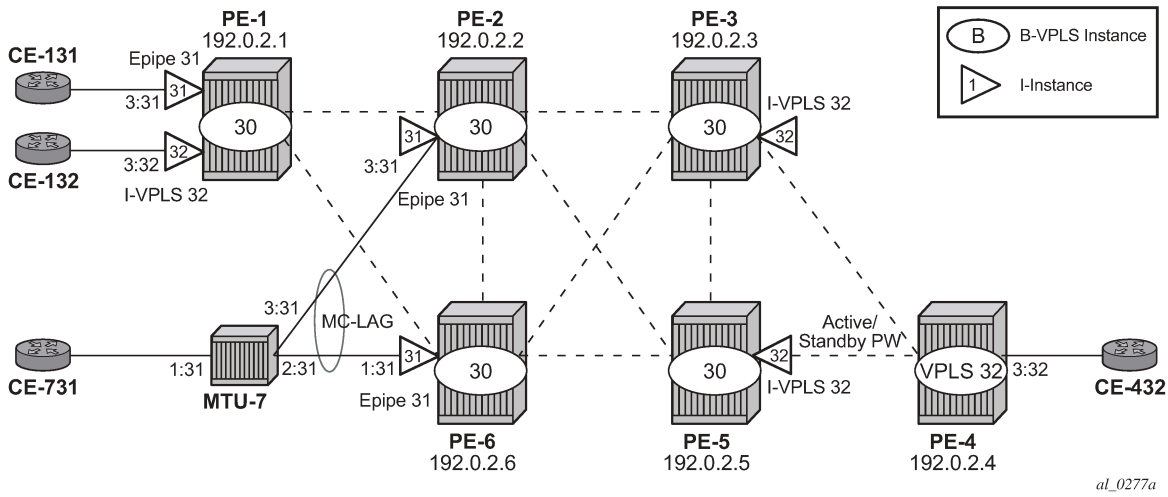
Figure 317: Access resiliency example topology



As an example of MC-LAG connectivity, the Epipe-31 configuration is shown. Just like for regular PBB-VPLS, a SAP BMAC is used as source BMAC for the Epipe traffic from PE-2 or PE-6 to PE-1. A SAP BMAC is a virtual BMAC formed from the configured source BMAC plus the MC-LAG LACP-key (if configured this way) and owned by the MC-LAG active chassis.

The following shows the configuration of MC-LAG as well as the generation of the SAP BMAC. Once it is properly configured and the MC-LAG and Epipe are up and running, SPB IS-IS will distribute the SAP BMAC throughout the B-VPLS, as it does for the system BMACs and OAM vMEP MACs. In this example, PE-2 is the MC-LAG active node, therefore the SAP BMAC for Epipe 31 is generated from PE-2.

```

The VPLS configuration on PE-4 and PE-3 is as follows.

```
# on PE-4:
configure {
    service {
        vpls "VPLS-32" {                          # Ordinary VPLS, no I-VPLS
            admin-state enable
            service-id 32
            customer "1"
            endpoint "CORE" {
                suppress-standby-signaling false
            }
            spoke-sdp 43:32 {
                endpoint {
                    name "CORE"
                    precedence primary
                }
                stp {
                    admin-state disable
                }
            }
            spoke-sdp 45:32 {
                endpoint {
                    name "CORE"
                }
                stp {
                    admin-state disable
                }
            }
            sap 1/1/c3/1:32 {
            }
        }
```

```
# on PE-3:
configure {
    service {
        vpls "B-VPLS-30" {
            admin-state enable
            service-id 30
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            spb {
                admin-state enable
                isis-instance 1026
                fid 30
            }
            spoke-sdp 32:30 {
```

Use subject to Terms available at: www.nokia.com/terms.

```
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 35:30 {
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 36:30 {
                spb {
                    admin-state enable
                }
            }
        }
        vpls "I-VPLS-32" {
            admin-state enable
            service-id 32
            customer "1"
            pbb-type i-vpls
            mac-flush {
                tldp {
                    send-on-failure true
                }
            }
            pbb {
                backbone-vpls "B-VPLS-30" {
                    isid 32
                }
                i-vpls-mac-flush {
                    tldp {
                        send-to-bvpls {
                            all-from-me true
                        }
                    }
                }
            }
            spoke-sdp 34:32 {
            }
        }
```

As discussed, **mac-flush tldp send-on-failure true** and **i-vpls-mac-flush tldp send-to-bvpls all-from-me** are configured in the I-VPLS. When the active spoke-SDP goes down on PE-3, a flush-all-from-me message will be propagated through the backbone and will flush the corresponding CMACs associated to I-VPLS-32 in node PE-1. MAC flush-all-from-me messages are automatically propagated in the core up to the remote I-VPLS-32 on node PE-1 (there is no need for any mac-flush propagate in the intermediate nodes).

Static BMACs and static ISIDs configuration

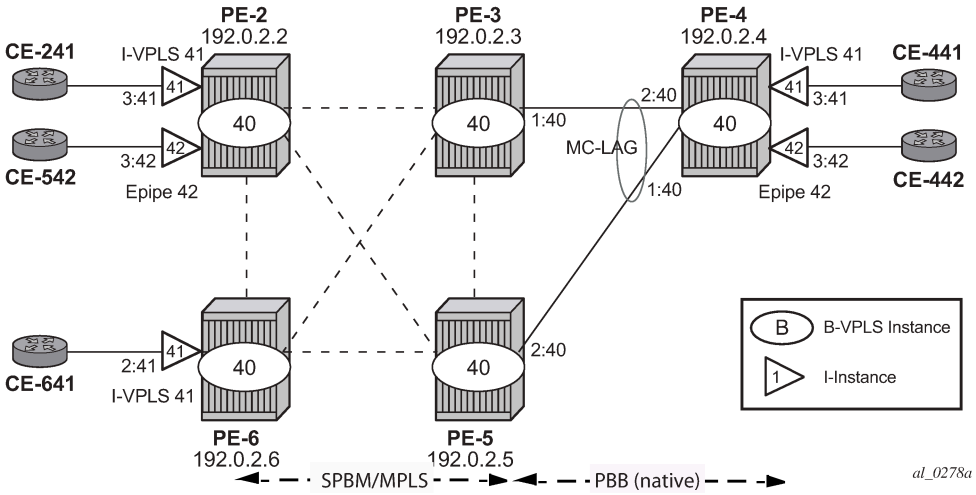
SR OS supports the interworking between SPB-enabled B-VPLS and non-SPB B-VPLS instances. SPB networks can be connected to non-SPB capable nodes, for example third party vendor PBB switches or 7210 SAS nodes. This is possible through the use of conditional static BMACs and static ISIDs on the nodes doing the interworking function. Conditional static BMACs and static ISIDs can be associated to non-SPB B-VPLS SAPs or spoke-SDPs.

The following example shows an SPB-enabled B-VPLS (B-VPLS-40) on nodes PE-2, PE-6, PE-3, and PE-5. Node PE-4 supports PBB, but not SPB and it is connected by a MC-LAG to nodes PE-3 and PE-5. Services I-VPLS-41 and Epipe-42 have endpoints on node PE-4. In this example, nodes PE-3 and PE-5

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

are acting as interworking nodes. They will be configured with the BMAC of PE-4 so that the MC-LAG active node advertises the non-SPB capable node BMAC into SPB IS-IS. The BMAC will be configured as a conditional static BMAC so that an SPB node, such as PE-3 or PE-5, will only advertise PE-4's BMAC if its connection to PE-4 is active. Besides the conditional static BMAC, nodes PE-3 and PE-5 should advertise the I-VPLS ISIDs defined in PE-4. Epipe ISIDs are not advertised in SPB IS-IS, therefore, it is not necessary to create a static ISID for Epipe-42.

Figure 318: Access resiliency example topology



The commands to configure conditional static BMACs and static ISIDs are as follows.

```
[ex:/configure service vpls "B-VPLS-40" fdb static-mac]
A:admin@PE-3# mac ?

 [mac-address] <unicast-mac-address-no-zero>
 <unicast-mac-address-no-zero> - <xx:xx:xx:xx:xx:xx>

    Static MAC address to SAP/SDP-binding or black-hole
```

```
[ex:/configure service vpls "B-VPLS-40" sap lag-1:40]
A:admin@PE-3# static-isid range ?

 [range-id] <number>
 <number> - <1..8191>

    Range ID for static ISID
```

The **monitor forward-status** attribute identifies this to be a conditional MAC and is mandatory for static BMAC addresses. This parameter instructs SR OS to advertise the BMAC only if the corresponding SAP or spoke-SDP is in forwarding state.

```
[ex:/configure service vpls "B-VPLS-40" fdb static-mac mac 00:00:5e:00:53:04]
A:admin@PE-3# monitor ?

 monitor <keyword>
 <keyword> - (none|forward-status)
 Default   - none

 'monitor' is: immutable
```

Use subject to Terms available at: www.nokia.com/terms.

```
    Entity to be monitored to decide whether this entry can be installed in the FDB

    Warning: Modifying this element recreates
    'configure service vpls "B-VPLS-40" fdb static-mac mac 00:00:5e:00:53:04' automatically for
 the new
    value to take effect.
```

The configuration of the conditional static BMAC and static ISID is as follows. The values for **spf-wait** are the default ones.

```
# on PE-3:
configure {
     service {
        vpls "B-VPLS-40" {
            admin-state enable
            service-id 40
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            fdb {
                static-mac {
                    mac 00:00:5e:00:53:04 {
                        sap lag-1:40
                        monitor forward-status
                    }
                }
            }
            spb {
                admin-state enable
                isis-instance 1027
                fid 40
            }
            spoke-sdp 32:40 {
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 35:40 {
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 36:40 {
                spb {
                    admin-state enable
                }
            }
            sap lag-1:40 {
            }
        }
```

```
# on PE-5:
configure {
    service {
        vpls "B-VPLS-40" {
            admin-state enable
            service-id 40
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            fdb {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                static-mac {
                    mac 00:00:5e:00:53:04 {
                        sap lag-1:40
                        monitor forward-status
                    }
                }
            }
            spb {
                admin-state enable
                isis-instance 1027
                fid 40
            }
            spoke-sdp 52:40 {
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 53:40 {
                spb {
                    admin-state enable
                }
            }
            spoke-sdp 56:40 {
                spb {
                    admin-state enable
                }
            }
            sap lag-1:40 {
            }
        }
```

The conditional static BMAC is added to the FDB based on the forwarding state of the SAP or SDP-binding. The following shows that the LAG is active on PE-3:

```
[/]
A:admin@PE-3# show lag 1

===============================================================================
Lag Data
===============================================================================
Lag-id         Adm     Opr     Weighted Threshold Up-Count MC Act/Stdby
    name
-------------------------------------------------------------------------------
1              up      up      No       0         1        active
    lag-1
===============================================================================
```

On PE-3, where the forwarding state of SAP lag-1:40 is active, the conditional static BMAC is tagged in the FDB as *CStatic*, for Conditional Static, as follows:

```
[/]
A:admin@PE-3# show service id 40 fdb pbb

===============================================================================
Forwarding Database, b-Vpls Service 40
===============================================================================
MAC               Source-Identifier     iVplsMACs  Epipes     Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:00:5e:00:53:02 sdp:32:40             0          0          Spb
00:00:5e:00:53:04 sap:lag-1:40          0          0          CStatic
00:00:5e:00:53:05 sdp:35:40             0          0          Spb
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
00:00:5e:00:53:06 sdp:36:40             0          0          Spb
===============================================================================
```

On PE-5, the LAG is in standby, as follows:

```
[/]
A:admin@PE-5# show lag 1

===============================================================================
Lag Data
===============================================================================
Lag-id         Adm     Opr     Weighted Threshold Up-Count MC Act/Stdby
    name
-------------------------------------------------------------------------------
1              up      down    No       0         0        standby
    lag-1
===============================================================================
```

On PE-5, SAP lag-1:40 in B-VPLS-40 is not forwarding any traffic. The FDB for B-VPLS-40 on PE-5 does not contain any conditional static MAC addresses, even though the static MAC address is configured. In the FDB for B-VPLS-40 on PE-5, this MAC address is assigned to SDP 53:40 (type SPB), as follows:

```
[/]
A:admin@PE-5# show service id 40 fdb pbb

===============================================================================
Forwarding Database, b-Vpls Service 40
===============================================================================
MAC               Source-Identifier     iVplsMACs  Epipes     Type/Age
 Transport:Tnl-Id
-------------------------------------------------------------------------------
00:00:5e:00:53:02 sdp:52:40             0          0          Spb
00:00:5e:00:53:03 sdp:53:40             0          0          Spb
00:00:5e:00:53:04 sdp:53:40             0          0          Spb
00:00:5e:00:53:06 sdp:56:40             0          0          Spb
===============================================================================
```

The **static-isid** command identifies a set of ISIDs for I-VPLS services that are external to SPBM. These ISIDs are advertised as supported locally on this node unless altered by an ISID policy. Although the preceding example shows the use of the static ISID associated to a MC-LAG SAP, regular SAPs or spoke-SDPs are also supported. ISIDs declared in this way become part of the ISID multicast and consume MFIBs. Multiple SPBM static-ISID ranges are allowed under a SAP or spoke-SDP. ISIDs are advertised as if they were attached to the local BMAC. Only remote I-VPLS ISIDs need to be defined. In the MFIB, the backbone group MAC addresses are then associated with the active SAP or spoke-SDP.

Once the conditional static BMAC for PE-4 and the static ISID 41 (for I-VPLS-41) are configured as described, the advertised BMAC and ISID can be checked in the remote SPB nodes:

```
[/]
A:admin@PE-6# show service id 40 spb fdb

Configuration of ISID policies in SPB B-VPLS

ISID policies are an optional aspect of SPBM which allow additional control of the advertisement of ISIDs and creation of MFIB entries for I-VPLS (Epipe services do not trigger ISID advertisements or the creation of MFIB entries). By default, if no ISID policies are used, SPBM automatically advertises and populates MFIB entries for I-VPLS and static ISIDs. ISID policies can be used on any SPB-enabled node with locally defined I-VPLS instances or static ISIDs. The ISID policy parameters are as follows:

```
[ex:/configure service vpls "B-VPLS-40" isid-policy]
A:admin@PE-3# entry 10 ?

 entry

 advertise-local       - Advertise locally-defined I-VPLS ISIDs or static ISIDs
 apply-groups          - Apply a configuration group at this level
 apply-groups-exclude  - Exclude a configuration group at this level
 range                 + Enter the range context
 use-def-mcast         - Use default multicast tree to propagate ISIS range
```

Where:

- **advertise-local** defines whether the local ISIDs (I-VPLS ISIDs linked to the B-VPLS) or static ISIDs contained in the configured range are advertised in SPBM.
- **use-def-mcast** controls whether the ISIDs contained in the range use MFIB entries (if **use-def-mcast false** is used) or just the default tree which does not use any MFIB entry.

The ISID policy becomes active as soon as it is defined, as opposed to other policies in SR OS, which require the policy itself to be applied within the configuration.

The typical use of ISID policies is to reduce the number of ISIDs being advertised and to save MFIB space (in deployments where MFIB space is shared with MMRP and IP multicast). The use of ISID policies is recommended for I-VPLS where most of the traffic is unicast or for I-VPLS where the ISID endpoints are present in all the backbone edge bridges (BEBs) of the SPB network. In both cases, advertising ISIDs or consuming MFIB entries for those I-VPLSs has little value because no multicast (first case) or the default tree (second case) are as efficient as using MFIB entries.

The following configuration example will use the example topology in Figure 318: Access resiliency example topology. In this case, the objective of the ISID policy will be to use the default tree for all the I-VPLS services with ISIDs between 41 and 100, excluding the range 80-90. The following example shows the policy configuration in the SPB nodes PE-2, PE-3, PE-5, and PE-6:

```
# on PE-2, PE-3, PE-5, PE-6:
configure {
    service {
        vpls "B-VPLS-40" {
            isid-policy {
                entry 10 {
                    range {
                        start 80
                        end 90
                    }
                }
                entry 20 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 41
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        end 79
                    }
                }
                entry 30 {
                    advertise-local false
                    use-def-mcast true
                    range {
                        start 91
                        end 100
                    }
                }
            }
```

The **advertise-local false** option can only be configured if the **use-def-mcast true** option is also configured.

```
[ex:/configure service vpls "B-VPLS-40" isid-policy entry 40]
A:admin@PE-3# advertise-local false

[ex:/configure service vpls "B-VPLS-40" isid-policy entry 40]
A:admin@PE-3# commit
MINOR: MGMT_CORE #3001: configure service vpls "B-VPLS-40" isid-policy entry 40 advertise-local
 -
 advertise-local or use-def-mcast option must be specified
```

Overlapping ISID values can be configured as long as the actions are consistent for the same ISID. Conflicting actions are shown in the CLI.

```
[ex:/configure service vpls "B-VPLS-40" isid-policy entry 40]
A:admin@PE-3# commit
MINOR: MGMT_CORE #5001: configure service vpls "B-VPLS-40" isid-policy entry 40 -
Range 82..95 is overlaping with entry 10 range 80..90 and advertise-local use-def-mcast
 conflicts
```

The ISID policy configured for B-VPLS-40 in all the four nodes makes the SPB network to use the default tree for ISIDs 41-79 and 91-100 and not advertise those ISIDs in SPB ISIS even if the ISID is locally defined (as in the case for ISIDs 41-100 in PE-3). As discussed in Basic SPBM configuration , the default tree path can be checked from each node by using the **tools dump service id 40 spb default-multicast-list** command.

Due to entry 10 in the policy, ISIDs 80-90 will be advertised by PE-3 (active MC-LAG node). However, nodes PE-2 and PE-6 will not create any MFIB entry for those ISIDs until the corresponding I-VPLS ISIDs are locally created (or configured through static-ISIDs). The following command executed on PE-2 proves that ISIDs 80-90 are indeed being advertised by PE-3:

```

The **mfib** parameter in the **show service id "B-VPLS-40" sap lag-1:40 static-isids mfib** command can help understand the state of the MFIB entries added (or not) by the configured static ISID. The following possible states can be shown:

- If the static ISID is configured and programmed in the MFIB, the status is shown as:
  - ok
- If the static ISID is not configured and not programmed in the MFIB, the reasons can be (order of priority):
  - useDefMCTree - ISID policy is applied on the service for the ISID.
  - sysMFibLimit - system MFIB limit has been exceeded
  - addPending - adding pending due to processing delays
- If the static ISID is not configured, but present in the MFIB:
  - delPending - cleanup pending due to processing delays.

The following output shows the status of the static ISIDs:

```
[/]
A:admin@PE-5# show service id 40 sap lag-1:40 static-isids mfib

Conclusion

SR OS supports an efficient SPBM implementation in the context of a B-VPLS, where system BMACs, vMEP OAM BMACs, and SAP BMACs are advertised in SPB IS-IS. SPBM provides a simple solution where no other control plane protocol is required in the B-VPLS to take care of the resiliency, load-balancing, and multicast optimization. The SPBM implementation in the SR OS provides scale optimization through the use of control and user B-VPLSs, allows the interworking between SPB networks and PBB networks, as well as the optimization of the MFIB resources and advertisement of ISIDs through the use of ISID policies.

SR-TE Weighted ECMP for EVPN Layer 2 Services

This chapter provides information about Segment Routing with Traffic Engineering (SR-TE) Weighted Equal Cost Multipath (ECMP) for EVPN Layer 2 services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 24.7.R2.

SR-TE Weighted ECMP for EVPN Layer 2 services is supported on FP4-based platforms in SR OS Release 22.7.R1 and later.

Overview

Weighted ECMP can be configured for auto-bind tunnels in EVPN Layer 2 services (Epipe and VPLS), with the following parameters:

- the **auto-bind-tunnel ecmp** parameter: **configure service epipe|vpls <service name> bgp-evpn mpls <instance number> auto-bind-tunnel ecmp <maximum number of auto bind tunnel ECMP routes>**
- the **auto-bind-tunnel weighted-ecmp** parameter: **configure service epipe|vpls <service name> bgp-evpn mpls <instance number> auto-bind-tunnel weighted-ecmp**

ECMP then refers to spraying data traffic across multiple named SR-TE tunnels (or RSVP-TE tunnels) within the same ECMP set.

Weighted ECMP is applied only when all tunnels in an ECMP set have the same type (all SR-TE or all RSVP-TE). When ECMP is configured for several tunnel types, only one specific tunnel type is selected, according to partially configurable preference rules. The tunnel type selection for a specific tunnel destination (or endpoint) in the IPv4 or IPv6 tunnel table is based on the following criteria:

1. tunnel type preference parameter **tunnel-table-pref**, applied from lowest to highest.

Note: The **tunnel-table-pref** default value can be changed for all tunnel types, except for the SR policy tunnel type. Nokia recommends to avoid configuring different tunnel types with the same **tunnel-table-pref** value, because that can cause preference to be given to a tunnel type that has been introduced first in the history of SR OS: RSVP-TE, LDP, SR-OSPF/SR-OSPF3/SR-ISIS, SR-TE, regardless of the LSP metric and tunnel ID.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note: The SR policy tunnel type has a tunnel table preference that cannot be configured, because it always wins over other tunnel types when the service or routing context BGP route has a color attribute.

2. When multiple tunnels exist for a selected tunnel type, the following applies:
   - RSVP-TE LSP <key={destination address, admin-tags}>: preference for tunnels with the lowest LSP metric, then the lowest tunnel ID.
   - SR-TE LSP <key={destination address, admin-tags}>: preference for tunnels with the lowest LSP metric, then the lowest tunnel ID.
   - LDP or BGP <key={destination address}>: one tunnel always exists (best route).
   - SR-OSPF/SR-OSPF3/SR-ISIS <key={destination address, SR algorithm}> : preference for tunnels with the lowest IGP instance ID.
   - MPLS forwarding policy <key={endpoint, admin-tags}>: one tunnel always exists (the lowest policy preference which is different from the parameter **tunnel-table-pref**).
   - SR policy <key={endpoint, color}>: one tunnel always exists (the highest policy preference which is different from the parameter **tunnel-table-pref**).

Note: The preceding bullet list does not imply an order of tunnel type preference.

When multiple tunnels of the selected tunnel type are operational, data traffic is sprayed across them. The maximum number of tunnels of this type that can be used is configured with the **auto-bind-tunnel ecmp** parameter. When the number of SR-TE or RSVP-TE tunnels that are operational exceeds this maximum, only tunnels of the selected tunnel type (SR-TE LSP or RSVP-TE LSP) with the same lowest LSP metric can be part of the ECMP set. The LSP metric is configured with the LSP metric parameter: **configure router "Base" mpls lsp <LSP name> metric <metric value>**. When the number of tunnels in this ECMP set still exceeds the value configured in the **auto-bind-tunnel ecmp** parameter, the lowest tunnel ID tunnels are selected first.

When **weighted-ecmp** is configured, the spraying across the tunnels in the retained ECMP set is performed according to the per-LSP weight, as configured in the LSP load balancing weight parameter: **configure router "Base" mpls lsp <LSP name> load-balancing-weight <weight value>**. For each tunnel in the retained ECMP set, the actually used weight is normalised from the configured weights, as follows:

```
normalised weight of an LSP =
configured weight of the LSP / (sum of the configured weights of all used LSPs in the retained
 ECMP set)
```

When the LSP load balancing weight parameter is not configured for at least one tunnel in the retained ECMP set, regular ECMP spraying across the tunnels in the retained ECMP set is used.

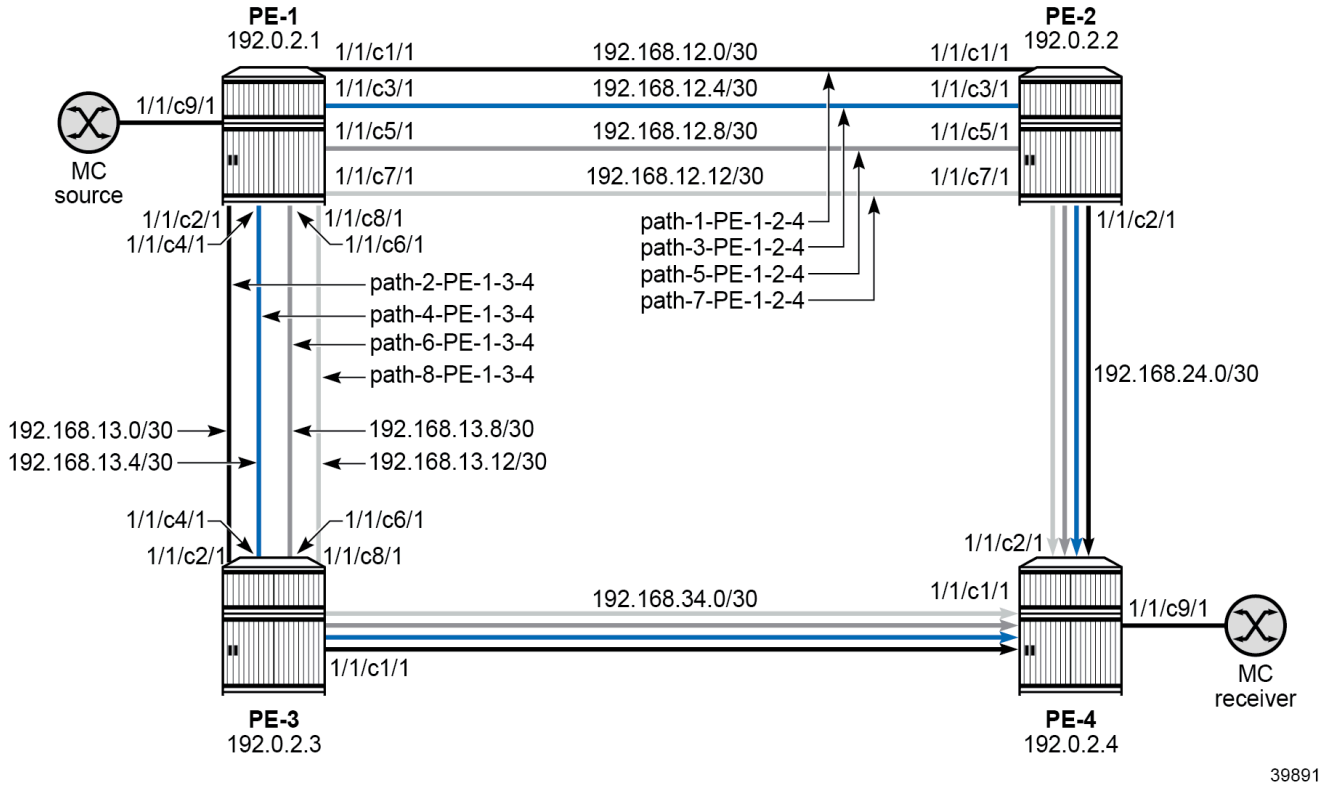
For shortest path tunnels, such as LDP, SR-OSPF, SR-OSPF3, SR-ISIS, and UDP tunnels, the maximum number of tunnels in the ECMP set is configured in the ECMP parameter: **configure router "Base" ecmp <maximum number of ECMP routes>**.

Configuration

The Figure 319: Example topology shows the topology with four SR OS nodes:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 319: Example topology



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- BGP for the EVPN address family
- IS-IS or OSPF or OSPF3, MPLS, RSVP, and LDP on the router interfaces. OSPF and OSPF3 are not used in this chapter.
- RSVP-TE, SR-TE, LDP, and SR-ISIS tunnels. UDP tunnels are not used in this chapter.
- an EVPN VPLS service on PE-1 and PE-4 that can make use of these tunnels.

Router configuration

To allow multiple different MPLS paths from PE-1 to PE-4, four router interfaces are configured between PE-1 and PE-2, and between PE-1 and PE-3.

The configuration on PE-1 is as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        interface "int-PE-1-PE-2-1" {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            port 1/1/c1/1
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-2-2" {
            port 1/1/c3/1
            ipv4 {
                primary {
                    address 192.168.12.5
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-2-3" {
            port 1/1/c5/1
            ipv4 {
                primary {
                    address 192.168.12.9
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-2-4" {
            port 1/1/c7/1
            ipv4 {
                primary {
                    address 192.168.12.13
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-3-1" {
            port 1/1/c2/1
            ipv4 {
                primary {
                    address 192.168.13.1
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-3-2" {
            port 1/1/c4/1
            ipv4 {
                primary {
                    address 192.168.13.5
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-3-3" {
            port 1/1/c6/1
            ipv4 {
                primary {
                    address 192.168.13.9
                    prefix-length 30
                }
            }
        }
        interface "int-PE-1-PE-3-4" {
            port 1/1/c8/1
```

The configuration of PE-2, PE-3, and PE-4 is similar.

MPLS paths as in Table 22: Configured MPLS Paths are configured from PE-1 to PE-4, over the interfaces to PE-2 and PE-3 respectively, as follows:

```
# on PE-1:
configure {
    router "Base" mpls {
            path "path-1-PE-1-2-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.12.2
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-2-PE-1-3-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.13.2
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-3-PE-1-2-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.12.6
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-4-PE-1-3-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.13.6
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-5-PE-1-2-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.12.10
                    type strict
                }
                hop 2 {
```

```
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-6-PE-1-3-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.13.10
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-7-PE-1-2-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.12.14
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
            path "path-8-PE-1-3-4" {
                admin-state enable
                hop 1 {
                    ip-address 192.168.13.14
                    type strict
                }
                hop 2 {
                    ip-address 192.0.2.4
                    type loose
                }
            }
```

Table 22: Configured MPLS Paths

Path	Via Interface
"path-1-PE-1-2-4"	"int-PE-1-PE-2-1"
"path-2-PE-1-3-4"	"int-PE-1-PE-3-1"
"path-3-PE-1-2-4"	"int-PE-1-PE-2-2"
"path-4-PE-1-3-4"	"int-PE-1-PE-3-2"
"path-5-PE-1-2-4"	"int-PE-1-PE-2-3"
"path-6-PE-1-3-4"	"int-PE-1-PE-3-3"
"path-7-PE-1-2-4"	"int-PE-1-PE-2-4"
"path-8-PE-1-3-4"	"int-PE-1-PE-3-4"

While not strictly needed, similar MPLS paths are configured from PE-4 to PE-1, over the interfaces to PE-2 and PE-3 respectively.

MPLS tunnels as in Table 23: Configured MPLS Tunnels that make use of these paths are configured on PE-1, with LSP type, LSP tunnel ID, LSP metric, and LSP load balancing weight, as follows:

```
# on PE-1:
configure {
    router "Base" mpls {
# SR-TE LSPs
            lsp "lsp-sr-te-1-PE-1-2-4" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.4
                metric 10
                load-balancing-weight 60
                path-computation-method local-cspf
                primary "path-1-PE-1-2-4" { }
            }
            lsp "lsp-sr-te-2-PE-1-3-4" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.4
                metric 10
                load-balancing-weight 120
                path-computation-method local-cspf
                primary "path-2-PE-1-3-4" { }
            }
            lsp "lsp-sr-te-3-PE-1-2-4" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.4
                metric 8
                load-balancing-weight 1
                path-computation-method local-cspf
                primary "path-3-PE-1-2-4" { }
            }
            lsp "lsp-sr-te-4-PE-1-3-4" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.4
                metric 10
                load-balancing-weight 180
                path-computation-method local-cspf
                primary "path-4-PE-1-3-4" { }
            }
            lsp "lsp-sr-te-5-PE-1-2-4" {
                admin-state enable
                type p2p-sr-te
                to 192.0.2.4
                metric 10
                load-balancing-weight 120

                path-computation-method local-cspf
                primary "path-1-PE-1-2-4" { }
            }
            lsp "lsp-rsvp-te-2-PE-1-3-4" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.4
                metric 12
                load-balancing-weight 3
                path-computation-method local-cspf
                primary "path-2-PE-1-3-4" { }
            }
            lsp "lsp-rsvp-te-3-PE-1-2-4" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.4
                metric 14
                load-balancing-weight 2
                path-computation-method local-cspf
                primary "path-3-PE-1-2-4" { }
            }
            lsp "lsp-rsvp-te-4-PE-1-3-4" {
                admin-state enable
                type p2p-rsvp
                to 192.0.2.4
                metric 12
                load-balancing-weight 1
                path-computation-method local-cspf
                primary "path-4-PE-1-3-4" { }
            }
```

The **metric** and **load-balancing-weight** options can be configured with the following commands:

```
# on PE-1:
configure {
    router "Base" mpls lsp "lsp-sr-te-1-PE-1-2-4" metric ?

 metric <number>
 <number>        - <0..16777215>
 Dynamic Default - 0
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    LSP metric that forces to a constant value
```

```
# on PE-1:
configure {
    router "Base" mpls lsp "lsp-sr-te-1-PE-1-2-4" load-balancing-weight ?

 load-balancing-weight <number>
 <number> - <1..4294967295>

    Load balancing weight for an MPLS LSP
```

Table 23: Configured MPLS Tunnels

LSP Name	LSP Type	LSP Tunnel ID	LSP Metric	LSP Load Balancing Weight	Primary Path
"lsp-sr-te-1-PE-1-2-4"	SR-TE	655362	10	60	"path-1-PE-1-2-4-"
"lsp-sr-te-2-PE-1-3-4"	SR-TE	655363	10	120	"path-2-PE-1-3-4"
"lsp-sr-te-3-PE-1-2-4"	SR-TE	655364	12	1	"path-3-PE-1-2-4"
"lsp-sr-te-4-PE-1-3-4"	SR-TE	655365	10	180	"path-4-PE-1-3-4"
"lsp-sr-te-5-PE-1-2-4"	SR-TE	655366	10	120	"path-5-PE-1-2-4"
"lsp-sr-te-6-PE-1-3-4"	SR-TE	655367	12	3	"path-6-PE-1-3-4"
"lsp-sr-te-7-PE-1-2-4"	SR-TE	655368	10	60	"path-7-PE-1-2-4"
"lsp-sr-te-8-PE-1-3-4"	SR-TE	655369	11	5	"path-8-PE-1-3-4"
"lsp-rsvp-te-1-PE-1-2-4"	RSVP-TE	1	12	4	"path-1-PE-1-2-4"
"lsp-rsvp-te-2-PE-1-3-4"	RSVP-TE	2	12	3	"path-2-PE-1-3-4"
"lsp-rsvp-te-3-PE-1-2-4"	RSVP-TE	3	14	2	"path-3-PE-1-2-4"
"lsp-rsvp-te-4-PE-1-3-4"	RSVP-TE	4	12	1	"path-4-PE-1-3-4"

While not strictly needed, similar MPLS tunnels are configured on PE-4.

The SR OS automatically generates the SR-TE tunnel IDs (and RSVP-TE tunnel IDs) in the order in which the SR-TE tunnels (and RSVP-TE tunnels) are added. The SR OS also automatically generates the tunnel IDs for the other tunnel protocols.

The binding between MPLS paths and MPLS tunnels can be verified with the following **show** command:

```
[/]
A:admin@PE-1# show router mpls path lsp-binding

===============================================================================
MPLS Path:   Bindings
===============================================================================
Path Name                       Opr  LSP Name                         Binding
-------------------------------------------------------------------------------
path-1-PE-1-2-4                 Up   lsp-rsvp-te-1-PE-1-2-4           Primary
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                                Up   lsp-sr-te-1-PE-1-2-4            Primary
path-2-PE-1-3-4                 Up   lsp-rsvp-te-2-PE-1-3-4          Primary

Service configuration

EVPN VPLS 14 is configured on PE-1 and PE-4, as follows:

```
# on PE-1:
configure {
    service vpls "VPLS 14" {
            admin-state enable
            service-id 14
            customer "1"
            bgp 1 { }
            bgp-evpn {
                evi 14
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution filter
                        ecmp 3
                        weighted-ecmp true
                        resolution-filter {
                            ldp true
                            rsvp true
                            sr-isis true
                            sr-te true
                            udp true
                        }
                    }
                }
            }
            sap 1/1/c9/1:100 { }
```

The **resolution-filter**, **ecmp**, and **weighted-ecmp** options can be configured with the following commands:

```
# on PE-1:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel resolution-filter ?

 resolution-filter

 bgp                   - Use BGP tunneling for next-hop resolution
 ldp                   - Use LDP tunneling for next-hop resolution
 mpls-fwd-policy       - Use MPLS forwarding policy for next-hop resolution
 rib-api               - Use RIB API gRPC service for next-hop resolution
 rsvp                  - Use RSVP tunneling for next-hop resolution
 sr-isis               - Use IS-IS SR tunneling for next-hop resolution
 sr-ospf               - Use OSPF SR tunneling for next-hop resolution
 sr-ospf3              - Use OSPFv3 SR tunneling for next-hop resolution
 sr-policy             - Use SR policies for next-hop resolution
 sr-te                 - Use SR-TE tunneling for next-hop resolution
 udp                   - Use MPLS over UDP tunneling for next-hop resolution
```

```
# on PE-1:
configure {
    service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel ecmp ?

 ecmp <number>
 <number> - <1..32>
 Default  - 1

    Maximum ECMP routes information
```

```
# on PE-1:
configure {
    service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel weighted-ecmp ?

 weighted-ecmp <boolean>
 <boolean> - ([true]|false)
 Default   - false

    Allow weighted load balancing

 allow-flex-algo-      - Enable flexible algorithm fallback
  fallback
 ecmp                  - Maximum ECMP routes information
 enforce-strict-       - Enable/disable enforcement of strict tunnel tagging
  tunnel-tagging
 resolution            - Resolution method for tunnel selection
 resolution-filter     + Enter the resolution-filter context
```

When **ecmp 3** is configured, the EVPN VPLS supports the establishment of a maximum of three RSVP-TE, SR-TE, LDP, (SR-OSPF, SR-OSPF3), SR-ISIS, or UDP tunnels with per-LSP load balancing of the data traffic from PE-1 to PE-4. This can be verified with the following **show** command:

```
[/]
A:admin@PE-1# show service id 14 bgp-evpn

Use cases

The following use cases are described in the following sections:

- Tunnel selection with preference for SR-TE
  - LSP load balancing weights configured on all selected SR-TE tunnels
  - LSP load balancing weight not configured on at least one selected SR-TE tunnel
  - Maximum number of tunnels increased but below the possible number of tunnels
  - Maximum number of tunnels exceeding the possible number of tunnels
  - Minimum LSP metric values configured on SR-TE tunnels with a higher tunnel ID
- SR-TE tunnel type no longer supported
- Also RSVP-TE tunnel type no longer supported
- Also LDP tunnel type no longer supported

To verify the operation in these use cases, UDP data traffic is launched at a rate of 2000 packets per second from a test source connected to PE-1 to a test destination connected to PE-4.

Tunnel selection with preference for SR-TE

The Table 24: Default tunnel table preferences table shows the default tunnel table preference value for different tunnel protocols. SR OS prefers a lower preference value over a higher one. By default, operational RSVP-TE tunnels are preferred. SR-OSPF and SR-OSPF3 are not used in this chapter.

Table 24: Default tunnel table preferences

Tunnel Protocol	Preference
RSVP-TE	7
SR-TE	8
LDP	9

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Tunnel Protocol	Preference
SR-OSPF/SR-OSPF3	10
SR-ISIS	11

The **tunnel-table-preference** for different tunnel protocols can be configured with the following commands:

```
# on PE-1:
configure {
    router "Base" mpls tunnel-table-pref ?

 tunnel-table-pref

 rsvp-te               - RSVP-TE tunnel table preference
 sr-te                 - SR-TE tunnel table preference

configure {
router "Base" mpls tunnel-table-pref rsvp-te ?

 rsvp-te <number>
 <number> - <1..255>
 Default  - 7

    RSVP-TE tunnel table preference

configure {
    router "Base" mpls tunnel-table-pref sr-te ?

 sr-te <number>
 <number> - <1..255>
 Default  - 8

    SR-TE tunnel table preference
```

```
# on PE-1:
configure {
    router "Base" ldp tunnel-table-pref ?

 tunnel-table-pref <number>
 <number> - <1..255>
 Default  - 9

    Tunnel table preference value for address FECs
```

```
# on PE-1:
configure {
    router "Base" ospf segment-routing tunnel-table-pref ?

 tunnel-table-pref <number>
 <number> - <1..255>
 Default  - 10

    Preference of SR tunnels created by the IGP instance
```

```
# on PE-1:
configure {
    router "Base" ospf3 segment-routing tunnel-table-pref ?

 tunnel-table-pref <number>
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 <number> - <1..255>
 Default  - 10

    Preference of SR tunnels created by the IGP instance
```

```
# on PE-1:
configure {
    router "Base" isis segment-routing tunnel-table-pref ?

 tunnel-table-pref <number>
 <number> - <1..255>
 Default  - 11

    Preference of SR tunnels created by the IGP instance
```

The Table 25: Tunnel table preferences to prefer SR-TE table shows the modified tunnel preference table with SR-TE as the preferred tunnel type.

```
# on PE-1:
configure {
    router "Base" mpls tunnel-table-pref {
                sr-te 1
```

Table 25: Tunnel table preferences to prefer SR-TE

Tunnel Protocol	Preference
SR-TE	8 → 1
RSVP-TE	7
LDP	9
SR-OSPF/SR-OSPF3	10
SR-ISIS	11

LSP load balancing weights configured on all selected SR-TE tunnels

As can be derived from the Table 23: Configured MPLS Tunnels table, there are eight possible SR-TE tunnels, of which only five have the lowest LSP metric value of 10, leading to Table 26: Configured SR-TE Tunnels. This can be verified with the output of the following **show** command, that also contains the configured RSVP-TE tunnels, and the automatically generated LDP and SR-ISIS tunnels:

```
[/]

-------------------------------------------------------------------------------
---snip---
===============================================================================
```

Table 26: Configured SR-TE Tunnels

LSP Name	LSP Type	LSP Tunnel ID	LSP Metric	LSP Load Balancing Weight	Primary Path
"lsp-sr-te-1-PE-1-2-4"	SR-TE	655362	10	60	"path-1-PE-1-2-4"
"lsp-sr-te-2-PE-1-3-4"	SR-TE	655363	10	120	"path-2-PE-1-3-4"
"lsp-sr-te-4-PE-1-3-4"	SR-TE	655365	10	180	"path-4-PE-1-3-4"
"lsp-sr-te-5-PE-1-2-4"	SR-TE	655366	10	120	"path-5-PE-1-2-4"
"lsp-sr-te-7-PE-1-2-4"	SR-TE	655368	10	60	"path-7-PE-1-2-4"

Only the first three SR-TE tunnels with the lowest metric (10) and the lowest tunnel IDs (655362, 655363, and 655365) are selected. With the LSP load balancing weight for each LSP configured as in Table 26: Configured SR-TE Tunnels, the following applies:

- "lsp-sr-te-1-PE-1-2-4" carries 60/(60+120+180)=60/360=16.67% of the data traffic via "path-1-PE-1-2-4"
- "lsp-sr-te-2-PE-1-3-4" carries 120/360=33.33% of the data traffic via "path-2-PE-1-3-4"
- "lsp-sr-te-4-PE-1-3-4" carries 180/360=50% of the data traffic via "path-4-PE-1-3-4"

PE-1 receives 2000 packets per second on port 1/1/c9/1 and sends out 336 packets per second on 1/1/c1/1 (~16.67%; "lsp-sr-te-1-PE-1-2-4"), 671 packets per second on 1/1/c2/1 (~33.33%; "lsp-sr-te-2-PE-1-3-4"), and 997 packets per second on 1/1/c4/1 (~50%; "lsp-sr-te-4-PE-1-3-4"). This can be verified with the output of the following **monitor** command. The same **monitor** command can be used on PE-2, PE-3, and PE-4 to verify how the data traffic is further transported, as follows:

```
[/]
A:admin@PE-1# monitor port all-ethernet-rates interval 3 repeat 5

===============================================================================
Monitor statistics for all Ethernet Port Rates
===============================================================================
Port-Id          D                Bits    Packets     Errors    Util
-------------------------------------------------------------------------------

1/1/c1/1         I                 736          1          0    0.00
                 0              391592        336          0    0.00
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
1/1/c2/1          I                824          1          0    0.00
                  0             783576        671          0    0.00

1/1/c3/1          I                168          0          0    0.00
                  O               1016          1          0    0.00

1/1/c4/1          I               1144          1          0    0.00
                  0            1164024        997          0    0.00

---snip---

1/1/c9/1          I            2048000       2000          0    0.00
                  O                  0          0          0    0.00

===============================================================
```

Note: The measured values may not exactly correspond with the theoretically expected values, because of signaling overhead, the burstiness of the source traffic within the monitoring interval, or the lack of sufficiently high entropy in the source traffic to guarantee an even traffic load balance.

The following **show** command confirms that the selected tunnel type is indeed SR-TE, with (first) the lowest LSP metric (as from Table 23: Configured MPLS Tunnels) and (second) the lowest tunnel ID.

```
[/]
A:admin@PE-1# show service id 14 evpn-mpls

================================================================================
BGP EVPN-MPLS Dest (Instance 1)
================================================================================
TEP Address                     Transport:Tnl     Egr Label  Oper  Mcast  Num
                                                             State        MACs
--------------------------------------------------------------------------------
192.0.2.4                       sr-te:655362      524276     Up    bum    0
---snip---
```

Note: This command shows only the first tunnel in the ECMP set.

LSP load balancing weight not configured on at least one selected SR-TE tunnel

When the LSP load balancing weight value is removed from "lsp-sr-te-4-PE-1-3-4", the same three SR-TE tunnels are still selected, but each SR-TE tunnel carries 1/3=33.33% of the data traffic.

```
# on PE-1:
configure {
    router "Base" mpls lsp "lsp-sr-te-4-PE-1-3-4" {
                delete load-balancing-weight
```

With the LSP load balancing weight not configured on "lsp-sr-te-4-PE-1-3-4", the following applies:

- "lsp-sr-te-1-PE-1-2-4" carries 33.33% of the data traffic via "path-1-PE-1-2-4"
- "lsp-sr-te-2-PE-1-3-4" carries 33.33% of the data traffic via "path-2-PE-1-3-4"
- "lsp-sr-te-4-PE-1-3-4" carries 33.33% of the data traffic via "path-4-PE-1-3-4"

                                                             State        MACs
-------------------------------------------------------------------------------
192.0.2.4                       sr-te:655362      524276     Up    bum    0
---snip---
```

Maximum number of tunnels increased but below the possible number of tunnels

When the LSP load balancing weights are configured on all selected SR-TE tunnels, the LSP load balancing weight value of 180 is configured again on "lsp-sr-te-4-PE-1-3-4", and the maximum number of tunnels is increased to 4 (<5), the first four SR-TE tunnels with the lowest metric (10) and the lowest tunnel IDs (655362, 655363, 655365, and 655366) are selected.

```
# on PE-1:
```

Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    router "Base" mpls lsp "lsp-sr-te-4-PE-1-3-4" {
                load-balancing-weight 180
```

```
# on PE-1:
configure {
    service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel {
                        ecmp 4
```

With the LSP load balancing weight for each LSP configured as in Table 26: Configured SR-TE Tunnels, the following applies:

- "lsp-sr-te-1-PE-1-2-4" carries 60/(60+120+180+120)=60/480=12.5% of the data traffic via "path-1-PE-1-2-4"
- "lsp-sr-te-2-PE-1-3-4" carries 120/480=25% of the data traffic via "path-2-PE-1-3-4"
- "lsp-sr-te-4-PE-1-3-4" carries 180/480=37.5% of the data traffic via "path-4-PE-1-3-4"
- "lsp-sr-te-5-PE-1-2-4" carries 120/480=25% of the data traffic via "path-5-PE-1-2-4"

PE-1 receives 2000 packets per second on port 1/1/c9/1 and sends out 250 packets per second on 1/1/c1/1 (~12.5%; "lsp-sr-te-1-PE-1-2-4"), 502 packets per second on 1/1/c2/1 (~25%; "lsp-sr-te-2-PE-1-3-4"), 751 packets per second on 1/1/c4/1 (~37.5%; "lsp-sr-te-4-PE-1-3-4"), and 503 packets per second on 1/1/c5/1 (~25%; "lsp-sr-te-5-PE-1-2-4").

The following **show** command confirms that the selected tunnel type is indeed SR-TE, with (first) the lowest LSP metric (as from Table 23: Configured MPLS Tunnels) and (second) the lowest tunnel ID.

```
[/]
A:admin@PE-1# show service id 14 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest (Instance 1)
===============================================================================
TEP Address                     Transport:Tnl     Egr Label  Oper  Mcast  Num
                                                             State        MACs
-------------------------------------------------------------------------------
192.0.2.4                       sr-te:655362      524276     Up    bum    0
---snip---
```

Maximum number of tunnels exceeding the possible number of tunnels

When the LSP load balancing weights are configured on all selected SR-TE tunnels and the maximum number of tunnels is increased to 20 (>5), all five SR-TE tunnels with the lowest metric (10) and the lowest tunnel IDs (655362, 655363, 655365, 655366, and 655368) are selected.

```
# on PE-1:
configure {
    service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel {
                        ecmp 20
```

With the LSP load balancing weight for each LSP configured as in Table 26: Configured SR-TE Tunnels, the following applies:

- "lsp-sr-te-1-PE-1-2-4" carries 60/(60+120+180+120+60)=60/540=11.11% of the data traffic via "path-1-PE-1-2-4"
- "lsp-sr-te-2-PE-1-3-4" carries 120/540=22.22% of the data traffic via "path-2-PE-1-3-4"
- "lsp-sr-te-4-PE-1-3-4" carries 180/540=33.33% of the data traffic via "path-4-PE-1-3-4"
- "lsp-sr-te-5-PE-1-2-4" carries 120/540=22.22% of the data traffic via "path-5-PE-1-2-4"
- "lsp-sr-te-7-PE-1-2-4" carries 60/540=11.11% of the data traffic via "path-7-PE-1-2-4"

Even though there are five more SR-TE tunnels, those are not selected because they do not have the lowest LSP metric value of 10.

PE-1 receives 2000 packets per second on port 1/1/c9/1 and sends out 220 packets per second on 1/1/c1/1 (~11.11%; "lsp-sr-te-1-PE-1-2-4"), 438 packets per second on 1/1/c2/1 (~22.22%; "lsp-sr-te-2-PE-1-3-4"), 663 packets per second on 1/1/c4/1 (~33.33%; "lsp-sr-te-4-PE-1-3-4"), 455 packets per second on 1/1/c5/1 (~22.22%; "lsp-sr-te-5-PE-1-2-4"), and 231 packets per second on 1/1/c7/1 (~11.11%; "lsp-sr-te-7-PE-1-2-4").

Table 27: Configured SR-TE Tunnels

LSP Name	LSP Type	LSP Tunnel ID	LSP Metric	LSP Load Balancing Weight	Primary Path
"lsp-sr-te-3-PE-1-2-4"	SR-TE	655364	12 → 8	1	"path-3-PE-1-2-4"
"lsp-sr-te-6-PE-1-3-4"	SR-TE	655367	12 → 8	3	"path-6-PE-1-3-4"

Only the two SR-TE tunnels with the lowest metric (8) and the lowest tunnel IDs (655364 and 655367) are selected. With the LSP load balancing weight for each LSP configured as in Table 27: Configured SR-TE Tunnels, the following applies:

- "lsp-sr-te-3-PE-1-2-4" carries 1/(1+3)=1/4=25% of the data traffic via "path-3-PE-1-2-4"
- "lsp-sr-te-6-PE-1-3-4" carries 3/4=75% of the data traffic via "path-6-PE-1-3-4"

PE-1 receives 2000 packets per second on port 1/1/c9/1 and sends out 497 packets per second on 1/1/c3/1 (~25%; "lsp-sr-te-3-PE-1-2-4") and 1504 packets per second on 1/1/c6/1 (~75%; "lsp-sr-te-6-PE-1-3-4").

                 O                    0         0          0    0.00

===============================================================================
```

The following **show** command confirms that the selected tunnel type is indeed SR-TE, with (first) the lowest LSP metric (as from Table 23: Configured MPLS Tunnels) and (second) the lowest tunnel ID.

```
[/]
A:admin@PE-1# show service id 14 evpn-mpls

===============================================================================
BGP EVPN-MPLS Dest (Instance 1)
===============================================================================
TEP Address                     Transport:Tnl     Egr Label  Oper  Mcast  Num
                                                             State        MACs
-------------------------------------------------------------------------------
192.0.2.4                       sr-te:655364      524276     Up    bum    0
---snip---
```

SR-TE tunnel type no longer supported

When the **sr-te** option is removed from the **auto-bind-tunnel resolution-filter**, RSVP-TE tunnels are preferred, in accordance with Table 25: Tunnel table preferences to prefer SR-TE.

```
# on PE-1:
configure service vpls "VPLS 14" bgp-evpn mpls 1 auto-bind-tunnel resolution-filter {
                           delete sr-te
```

As can be derived from the Table 23: Configured MPLS Tunnels table, there are four possible SR-TE tunnels, of which only three have the lowest LSP metric value of 12, leading to Table 28: Configured RSVP-TE Tunnels. This can be verified with the output of the following **show** command, that also contains the configured SR-TE tunnels, and the automatically generated LDP and SR-ISIS tunnels:

Table 28: Configured RSVP-TE Tunnels

LSP Name	LSP Type	LSP Tunnel ID	LSP Metric	LSP Load Balancing Weight	Primary Path
"lsp-rsvp-te-1-PE-1-2-4"	RSVP-TE	1	12	4	"path-1-PE-1-2-4"
"lsp-rsvp-te-2-PE-1-3-4"	RSVP-TE	2	12	3	"path-2-PE-1-3-4"
"lsp-rsvp-te-3-PE-1-2-4"	RSVP-TE	3	14	2	"path-3-PE-1-2-4"
"lsp-rsvp-te-4-PE-1-3-4"	RSVP-TE	4	12	1	"path-4-PE-1-3-4"

Only the three RSVP-TE tunnels with the lowest metric (12) and the lowest tunnel IDs (1, 2, and 4) are selected. With the LSP load balancing weight for each LSP configured as in Table 28: Configured RSVP-TE Tunnels, the following applies:

- "lsp-rsvp-te-1-PE-1-2-4" carries 4/(4+3+1)=4/8=50% of the data traffic via "path-1-PE-1-2-4"
- "lsp-rsvp-te-2-PE-1-3-4" carries 3/8=37.5% of the data traffic via "path-2-PE-1-3-4"
- "lsp-rsvp-te-4-PE-1-3-4" carries 1/8=12.5% of the data traffic via "path-4-PE-1-3-4"

PE-1 receives 2000 packets per second on port 1/1/c9/1 and sends out 1001 packets per second on 1/1/c1/1 (~50%; "lsp-rsvp-te-1-PE-1-2-4"), 749 packets per second on 1/1/c2/1 (~37.5%; "lsp-rsvp-te-2-PE-1-3-4"), and 253 packets per second on 1/1/c4/1 (~12.5%; "lsp-rsvp-te-4-PE-1-3-4").

Conclusion

SR OS supports weighted ECMP with per-LSP load balancing across multiple auto-bind SR-TE tunnels in EVPN Layer 2 services. The selection of a single tunnel type and the load balancing are configurable.

Static VXLAN Termination in Epipe Services

This chapter provides information about Static VXLAN Termination in Epipe Services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 15.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.5.R1. Static VXLAN termination for Epipe services is supported in SR OS Release 15.0.R1, and later.

Overview

Static Virtual eXtensible Local Area Network (VXLAN) termination on non-system IP addresses of the PEs is supported in VPLS services, as described in chapter VXLAN Forwarding Path Extension, and in Epipe services, as described in this chapter. Whereas VPLSs using VXLAN require BGP-EVPN control plane in the current release, Epipe services using VXLAN do not. This implies that only the configured values are used because no auto-discovery of the remote Termination Endpoints (TEPs) can be done without BGP-EVPN.

This chapter describes the configuration and use of static VXLAN as an access tunneling mechanism to a PBB-EVPN network. This is a design deployed in some service provider networks where the aggregation network is a non-MPLS IP network.

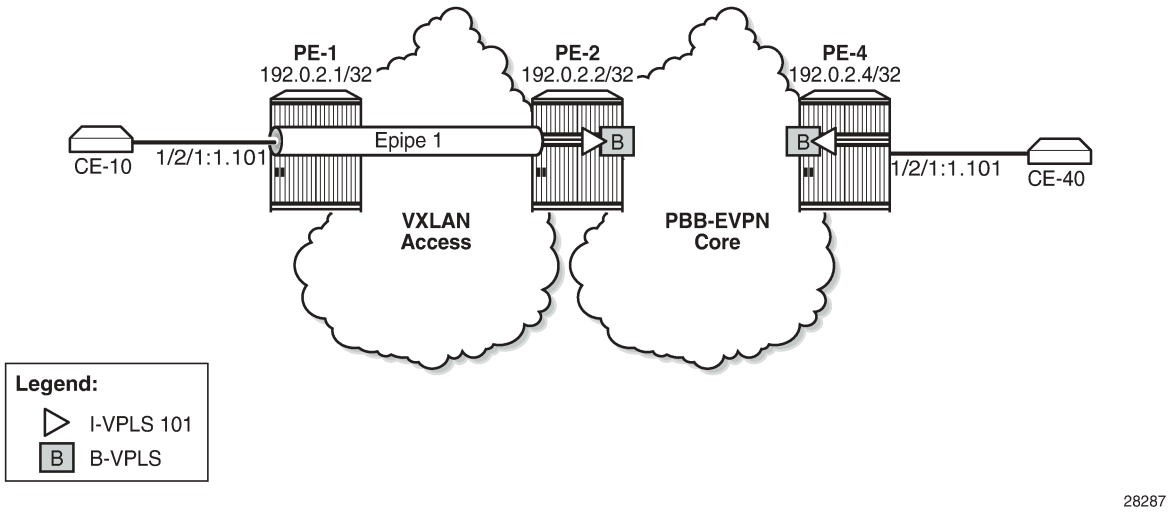
Static VXLAN termination for Epipe services can be applied on system IP addresses or non-system IP addresses.

Static VXLAN termination on system IP addresses

Figure 320: Static VXLAN termination on system IP addresses shows an example topology with three PEs and two CEs. Epipe 1 is configured on PE-1 and PE-2. PE-2 and PE-4 are part of a PBB-EVPN network. On PE-2, a port cross-connect (PXC) is configured to connect the SAP in Epipe 1 and the SAP in I-VPLS 101. CE-10 and CE-40 can send traffic to each other.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 320: Static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VXLAN Termination Endpoint (VTEP) 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows:

```
# on PE-1:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.2
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

where:

- The configured VXLAN Virtual Network Identifier (VNI) is used by the system as follows:
  - As the egress VNI when sending VXLAN packets for the Epipe service
  - As the source VNI that identifies the VXLAN packet to be part of the Epipe
  - Unique in the system, so it can only be configured in one service, either VPLS or Epipe

  The configuration of the VXLAN VNI in an Epipe is similar to the configuration of the VXLAN VNI in a VPLS, except that in a VPLS, the VNI is only used as the source VNI, because the egress VNI is learned from BGP-EVPN. However, in Epipe services with static VXLAN, the egress VNI is also the configured VNI.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The egress VTEP is the system IP address of the remote PE. The system will add the configured egress VTEP IP address as the remote VTEP when encapsulating the frames into VXLAN packets. Only the egress VTEP is configured, not the source VTEP. The PE receiving VXLAN packets will not check the source VTEP.
- The egress VTEP IP address must be in the Routing Table Manager (RTM). An oper-group is associated with the egress VTEP IP address, so that when the egress VTEP disappears from the base route table, the oper-group is brought operationally down, which propagates the failure to other objects that have this oper-group associated. The status of the oper-group and the service will be as follows:
  - When the egress VTEP disappears from the RTM, the VXLAN binding goes operationally down and the oper-group associated with the egress VTEP goes operationally down.
  - When the Epipe SAP goes down, the service goes down too.
  - When the VXLAN binding goes down, the service remains up as long as the access SAP is up.
  - When the service is disabled, the VXLAN binding and the oper-group associated with the egress VTEP are both brought operationally down.
- Only SAPs can be associated with the Epipe; no spoke-SDPs are supported in SR OS Release 21.5.R1, as follows. Regular SAPs and PXC SAPs are supported.

```
*[ex:/configure service epipe "Epipe 1" spoke-sdp 11:1]
A:admin@PE-1# commit
MINOR: SVCMGR #12: configure service epipe "Epipe 1" vxlan instance 1 egress-vtep ip-address -
 Inconsistent Value error - vxlan-egr-vtep not supported with spoke-sdps in service - configure
 service epipe "Epipe 1" spoke-sdp 11:1
```

Frame encapsulation and forwarding

Incoming traffic in the PEs is treated as follows:

- For frames received from the SAPs, a SAP lookup identifies all frames matching the configured SAP (on PE-1, SAP 1/2/1:1.*). The matching frames will be encapsulated into VXLAN IPv4 packets with the following fields:
  - Source VTEP = system IP address
  - Destination VTEP = configured address in **egress-vtep**
  - VNI = configured VXLAN VNI
  - Source and destination UDP ports will be populated as per the existing VXLAN implementation VPLS services, with the source UDP port populated with the result of a hash on the ingress packets.
- For VXLAN frames received from the VXLAN network, a VNI lookup is done for packets with IP DA = system IP address. Frames with the configured VNI 1 are assigned to Epipe 1. The VXLAN encapsulation is removed and the frames are forwarded to the SAP.

Per-service hashing is not supported in Epipe-VXLAN services; only regular hashing and spraying in LAG/ECMP is supported as in any Epipe.

Static VXLAN termination on IPv6 or non-system IPv4 addresses

The non-system IPv4 or IPv6 VXLAN termination on Epipe services is configured in the same way as for VPLS services and described in the VXLAN Forwarding Path Extension chapter, using the FPE function for additional processing. The following steps are required for configuring the FPE for VXLAN termination:

1. Create FPE.
2. Associate FPE with VXLAN termination.
3. Configure the loopback router interface subnet for VXLAN termination and its advertisement into the routing protocol. The subnet can be IPv4 or IPv6.
4. Configure the loopback address for VXLAN termination.
5. Add the service configuration.

Configuration

In this section, static VXLAN termination for Epipe services is configured for the following cases:

- VXLAN termination on system IP addresses
- VXLAN termination on non-system IPv4 addresses
- VXLAN termination on IPv6 addresses
- Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing

Static VXLAN termination on system IP addresses

Figure 321: Example topology for static VXLAN termination on system IP addresses shows the example topology for static VXLAN termination on system IP addresses. The initial configuration of the PEs includes the cards, MDAs, ports, router interfaces, and IGP. BGP is not required on PE-1; on PE-2 and PE-4, BGP is configured for address family EVPN.

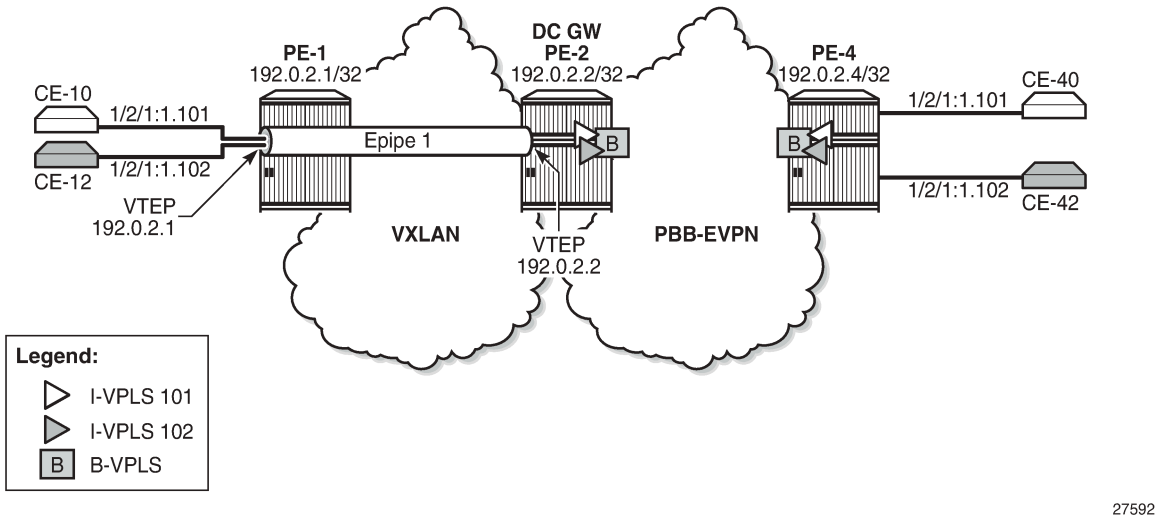
Figure 321: Example topology for static VXLAN termination on system IP addresses



On PE-1, Epipe 1 is configured with egress VXLAN VNI 1, egress VTEP 192.0.2.2, oper-group op-grp-1, and a SAP toward CE-10, as follows. This configuration was explained in the text under Figure 320: Static VXLAN termination on system IP addresses.

```
# on PE-1:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap 1/2/1:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
                    egress-vtep {
                        ip-address 192.0.2.2
                        oper-group "op-grp-1"
                    }
                }
            }
        }
```

On PE-2, BGP is configured for address family EVPN, as follows:

```
# on PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
        }
```

There is a PXC configured on port 1/2/1 that will connect SAP pxc-21.a:1.* in Epipe 1, SAP pxc-21.b:1.101 in I-VPLS 101, and SAP pxc-21.b:1.102 in I-VPLS 102. The PXC is configured on PE-2 as follows. See the "Port Cross-Connect (PCX)" chapter in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Advanced Configuration Guide for Classic CLI* for more information.

```
# on PE-2:
configure {
    port-xc {
        pxc 21 {
            admin-state enable
            port-id 1/2/1
        }
    }
    port pxc-21.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-21.b {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port 1/2/1 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
```

The service configuration on PE-2 includes Epipe 1, B-VPLS 100, and I-VPLSs 101-102, as follows:

```
# on PE-2:
configure {
    service {
        oper-group "op-grp-1" {
        }
        epipe "Epipe 1" {
            admin-state enable
            service-id 1
            customer "1"
            sap pxc-21.a:1.* {
            }
            vxlan {
                instance 1 {
                    vni 1
```

```
                egress-vtep {
                    ip-address 192.0.2.1
                    oper-group "op-grp-1"
                }
            }
        }
    }
    vpls "B-VPLS 100" {
        admin-state enable
        service-id 100
        customer "1"
        service-mtu 2000
        pbb-type b-vpls
        pbb {
            source-bmac {
                address 00:00:00:00:00:02
            }
        }
        bgp 1 {
        }
        bgp-evpn {
            evi 100
            mpls 1 {
                admin-state enable
                ingress-replication-bum-label true
                auto-bind-tunnel {
                    resolution any
                }
            }
        }
    }
    vpls "I-VPLS 101" {
        admin-state enable
        service-id 101
        customer "1"
        pbb-type i-vpls
        pbb {
            backbone-vpls "B-VPLS 100" {
                isid 101
            }
        }
        sap pxc-21.b:1.101 {
        }
    }
    vpls "I-VPLS 102" {
        admin-state enable
        service-id 102
        customer "1"
        pbb-type i-vpls
        pbb {
            backbone-vpls "B-VPLS 100" {
                isid 102
            }
        }
        sap pxc-21.b:1.102 {
        }
    }
```

The service configuration on PE-4 is similar for the B-VPLS and the I-VPLSs, but Epipe 1 is not configured on PE-4.

The oper-group with member egress VTEP 192.0.2.2 cannot be monitored on a SAP in the same Epipe. The following error is raised when attempting to configure the same oper-group for the SAP in Epipe 1 on PE-1:

```
[ex:/configure service epipe "Epipe 1" sap 1/2/1:1.*]
A:admin@PE-1# oper-group "op-grp-1"

*[ex:/configure service epipe "Epipe 1" sap 1/2/1:1.*]
A:admin@PE-1# commit
MINOR: MGMT_CORE #5001: configure service epipe "Epipe 1" sap 1/2/1:1.* - Oper-group has an Egr
Vtep member, no other members allowed
```

The following ports on PE-2 are disabled to make the destination VTEP unreachable from PE-1:

```
# on PE-2:
configure {
    port 1/1/1 {
        admin-state disable
    }
    port 1/1/2 {
        admin-state disable
    }
```

When the destination VTEP disappears from the RTM, the oper-group op-grp-1 goes down and the VXLAN binding in Epipe 1 goes down, while the Epipe service remains up, as follows:

```
[/]
A:admin@PE-1# show service oper-group "op-grp-1"

===============================================================================
Service Oper Group Information
===============================================================================
Oper Group       : op-grp-1

-------------------------------------------------------------------------------
sap:1/2/1:1.*                            qinq         1578    1578    Up   Up
===============================================================================
```

The output is similar on PE-2. The ports are re-enabled on PE-2, which will cause the VXLAN binding and the oper-group to be operationally up again:

```
# on PE-2:
configure {
    port 1/1/1 {
        admin-state enable
    }
    port 1/1/2 {
        admin-state enable
    }
```

The preceding example proved that the Epipe service remains up when the VXLAN binding goes down. The following example shows that the Epipe service goes down when the SAP goes down. On PE-1, port 1/2/1 is disabled, as follows:

```
# on PE-1:
configure {
    port 1/2/1
        admin-state disable
```

The following command shows that SAP 1/2/1:1.* and Epipe 1 are down on PE-1:

```
[/]
A:admin@PE-1# show service id 1 base

===============================================================================

The port is re-enabled and SAP 1/2/1:1 and service Epipe 1 will be up again.

```
# on PE-1:
configure {
    port 1/2/1 {
        admin-state enable
```

When the service is disabled (**admin-state disable**), the SAP goes down, the VXLAN binding goes down, and the oper-group goes down, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 1" {
            admin-state disable
```

```

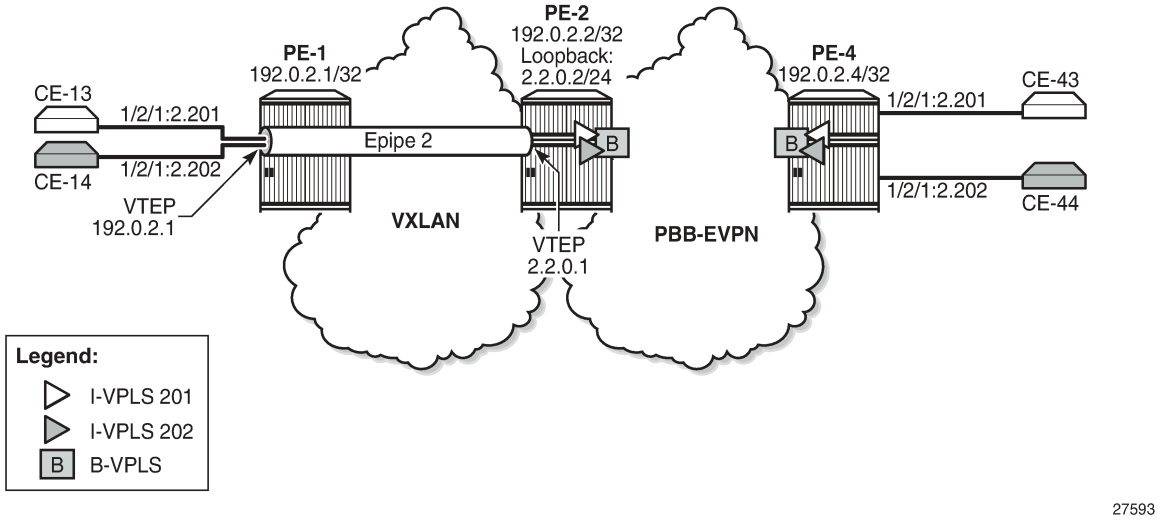
Static VXLAN termination on non-system IPv4 addresses

Non-system IP VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 322: Example topology for static VXLAN termination on non-system IPv4 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The non-system loopback address on PE-2 will be used for VXLAN termination, whereas the system IP address will be used on PE-1.

Figure 322: Example topology for static VXLAN termination on non-system IPv4 addresses



Create FPE

FPE uses the back-to-back PXC, either a PXC port or a LAG-based PXC. PXC 1 is created on PE-2:

```
# on PE-2:
configure {
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/5
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
```

```
[/]
A:admin@PE-2# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPE uses the PXC:

```
# on PE-2:
configure {
    fwd-path-ext {
        fpe 1 {
            path {
                pxc 1
            }
```

The following shows that FPE 1 uses PXC 1 and has no VXLAN termination associated:

```
[/]
A:admin@PE-2# show fwd-path-ext fpe 1

===============================================================================

Associate FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-2:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
```

When attempting to associate the FPE with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*[ex:/configure fwd-path-ext fpe 1 application vxlan-termination]
A:admin@PE-2# commit
MINOR: FPE #1021: configure fwd-path-ext fpe 1 - sdp-id-range is not configured - configure
 fwd-path-ext sdp-id-range
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs; see the VXLAN Forwarding Path Extension chapter for more information about the use of SDP IDs. The application for FPE 1 is VXLAN termination.

```
[/]
A:admin@PE-2# show fwd-path-ext

===============================================================================
FPE Info
===============================================================================
FPE Id                  Path                          Application

```
   IP-Address                                                    PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                  PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                  PREFERRED
---snip---
```

Configure router loopback interface

The following loopback interface is configured in PE-2 and added to the IS-IS context. The IPv6 address is not required yet.

```
# on PE-2:
configure {
    router "Base" {
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 2.2.0.2
                    prefix-length 24
                }
            }
            ipv6 {
                address 220::2 {
                    prefix-length 120
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
        }
```

A subnet must be assigned to the loopback interface, but not a /32 or /128 subnet mask, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 2.2.0.0/24 can be used for VXLAN tunnel termination, except for 2.2.0.2. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127.

Configure non-system VTEP addresses

On PE-2, non-system IP address 2.2.0.1 in the subnet of the loopback address 2.2.0.2/24 is configured as VTEP, as follows. Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs.

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 2.2.0.1 {
                    fpe-id 1
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

No non-system VTEP addresses need to be configured on PE-1.

When the non-system VTEP address is configured, an internal loopback interface _tmnx_vli_vxlan_1_131075 with VTEP address 2.2.0.1/32 is auto-created that can respond to ICMP requests.

```
[/]
A:admin@PE-2# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                  PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                PREFERRED
_tmnx_vli_vxlan_1_131075         Up        Up/Up       Network loopback
   2.2.0.1/32                                                  n/a
   fe80::13:ffff:fe00:0/64                                     PREFERRED
---snip---
```

The system does not verify if there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding ICMP for that address, regardless of the presence of a loopback in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the services

Epipe 2 is configured on PE-1 as follows. By default, the system IP address will be used as source VTEP of the VXLAN-encapsulated frames. The non-system IP address 2.2.0.1 is used as egress VTEP.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap 1/2/1:2.* {
            }
            vxlan {
                instance 1 {
                    vni 2
                    egress-vtep {
                        ip-address 2.2.0.1
                    }
                }
            }
        }
```

The configuration of Epipe 2 on PE-2 defines the non-system IP address 2.2.0.1 as source VTEP, as follows. The egress VTEP is 192.0.2.1, the system IP address of PE-1. The configuration of the B-VPLS

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

is the same as in the preceding example; the configuration of the I-VPLSs 201 and 202 is similar to the configuration of I-VPLS 101 in the preceding example.

```
# on PE-2:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            sap pxc-21.a:2.* {
            }
            vxlan {
                source-vtep 2.2.0.1
                instance 1 {
                    vni 2
                    egress-vtep {
                        ip-address 192.0.2.1
                    }
                }
            }
        }
```

The following **show** command on PE-1 shows that no VXLAN source VTEP IP address is configured:

```
[/]
A:admin@PE-1# show service id 2 vxlan
===============================================================================
Vxlan Src Vtep IP: N/A
===============================================================================

===============================================================================
Vxlan Instance
===============================================================================
VXLAN Instance               VNI                     Oper-flags
-------------------------------------------------------------------------------
1                            2                       none
-------------------------------------------------------------------------------
Number of Entries : 1
-------------------------------------------------------------------------------
===============================================================================
```

The following shows that the egress VTEP is 2.2.0.1, which is a non-system VTEP on PE-2. The VXLAN tunnel is operationally up.

```
[/]

Static VXLAN termination on IPv6 addresses

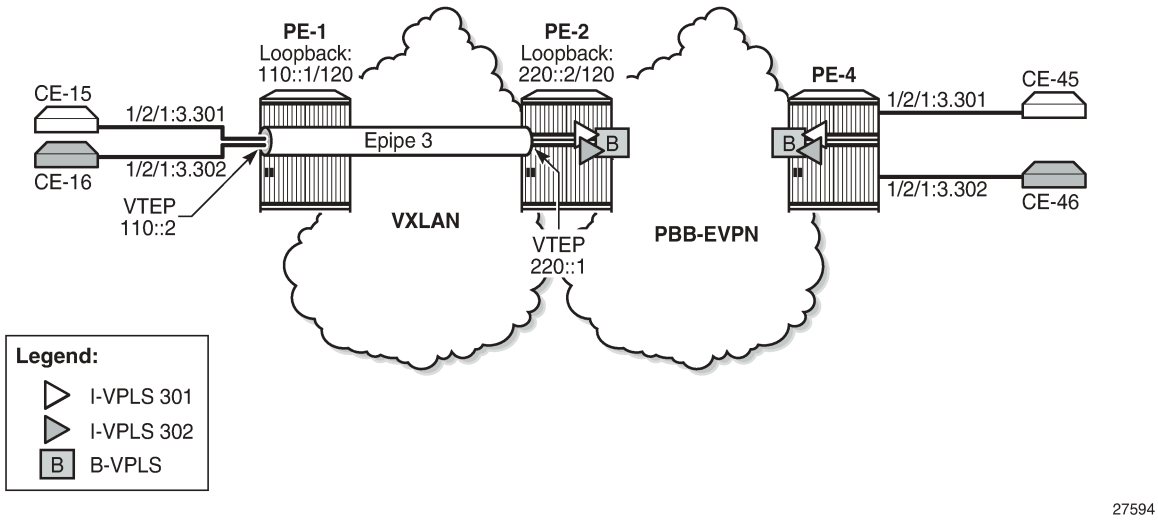
IPv6 VXLAN termination is provisioned as follows:

1. Create FPE
2. Associate FPE with VXLAN termination
3. Configure router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Figure 323: Example topology for static VXLAN termination on IPv6 addresses shows the example topology with PE-1 and PE-2 in a VXLAN network. The loopback addresses on PE-1 and PE-2 will be used for IPv6 VXLAN termination. The existing PXC 1 on PE-2 is reused for FPE; only an IPv6 VTEP address needs to be added.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 323: Example topology for static VXLAN termination on IPv6 addresses



For IPv6 routing, the following option is configured for IS-IS on all nodes:

```
# on all PEsL
configure {
    router "Base" {
        isis 0 {
            ipv6-routing native
```

Create FPE

The following PXC is created on PE-1; PXC 1 will be used for FPE:

```
# on PE-1:
configure {
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/5
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port 1/2/5 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    }
```

```
[/]
A:admin@PE-1# show port pxc 1

===============================================================================
```

Configure FPE with VXLAN termination

The following command associates FPE 1 with VXLAN termination:

```
# on PE-1:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
```

The following shows the range of SDP IDs for FPE and the list of configured FPEs. The application for FPE 1 is VXLAN termination.

```
[/]
A:admin@PE-1# show fwd-path-ext

===============================================================================
FPE Info
===============================================================================
FPE Id                  Path                          Application
                        pxc/xc-a, xc-b
-------------------------------------------------------------------------------

```
A:admin@PE-1# show fwd-path-ext fpe 1

===============================================================================
FPE Id: 1
===============================================================================
Description        : (Not Specified)
Path               : pxc 1
Pw Port            : Disabled                          Oper     : down
Sub Mgmt Extension : Disabled                          Oper     : N/A
Vxlan Termination  : Router: Base                      Oper     : up
Segment-Routing V6 : Disabled
===============================================================================
```

After the FPEs are associated with VXLAN termination, the system creates two internal router interfaces per FPE, one per PXC sub-port, as follows:

```
[/]
A:admin@PE-1# show router interface

===============================================================================
Interface Table (Router: Base)
===============================================================================
Interface-Name                   Adm       Opr(v4/v6)  Mode    Port/SapId
   IP-Address                                                   PfxState
-------------------------------------------------------------------------------
_tmnx_fpe_1.a                    Up        Up/Up       Network pxc-1.a:1
   fe80::100/64                                                 PREFERRED
_tmnx_fpe_1.b                    Up        Up/Up       Network pxc-1.b:1
   fe80::101/64                                                 PREFERRED
---snip---
```

Configure router loopback interface

The following loopback interface is configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure {
    router "Base" {
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 1.1.0.1
                    prefix-length 24
                }
            }
            ipv6 {
                address 110::1 {
                    prefix-length 120
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
        }
```

All IPv6 addresses in the 110::/120 subnet can be used for VXLAN tunnel termination, except for 110::1.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Configure non-system VTEP addresses

On PE-1, IPv6 address 110::2 in the subnet of the loopback address 110::1/120 is configured as VTEP, as follows:

```
# on PE-1:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 110::2 {
                    fpe-id 1
                }
            }
```

On PE-2, IPv6 address 220::1 in the subnet of the loopback address 220::2/120 is configured as VTEP, as follows:

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 220::1 {
                    fpe-id 1
                }
            }
```

When the IPv6 VTEP address is configured on PE-1, an internal loopback interface _tmnx_vli_vxlan_1_131075 is created, as follows.

```
[/]
A:admin@PE-1# show router interface

===============================================================================

```

Configure the services

Epipe 3 is configured on PE-1 with **source-vtep** 110::2, which is the VTEP address configured in the preceding step (VXLAN tunnel termination). The egress VTEP is 220::1, which is the VXLAN termination configured on PE-2.

```
# on PE-1:
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            service-id 3
            customer "1"
            sap 1/2/1:3.* {
            }
            vxlan {
                source-vtep 110::2
                instance 1 {
                    vni 3
                    egress-vtep {
                        ip-address 220::1
                    }
                }
            }
        }
```

Epipe 3 on PE-2 has VXLAN source VTEP 220::1 and egress VTEP 110::2.

```
# on PE-2:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    service {
        epipe "Epipe 3" {
            admin-state enable
            service-id 3
            customer "1"
            sap pxc-21.a:3.* {
            }
            vxlan {
                source-vtep 220::1
                instance 1 {
                    vni 3
                    egress-vtep {
                        ip-address 110::2
                    }
                }
            }
        }
```

The configuration of the B-VPLS is the same as in the preceding example. The configuration of I-VPLS 302 is similar.

```
# on PE-2:
configure {
    service {
        vpls "I-VPLS 301" {
            admin-state enable
            service-id 301
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 301
                }
            }
            sap pxc-21.b:3.301 {
            }
        }
```

The following **show** commands on PE-1 show that the VXLAN source VTEP IP address is 110::2 and the egress VTEP is 220::1. The VXLAN tunnel is operationally up.

```

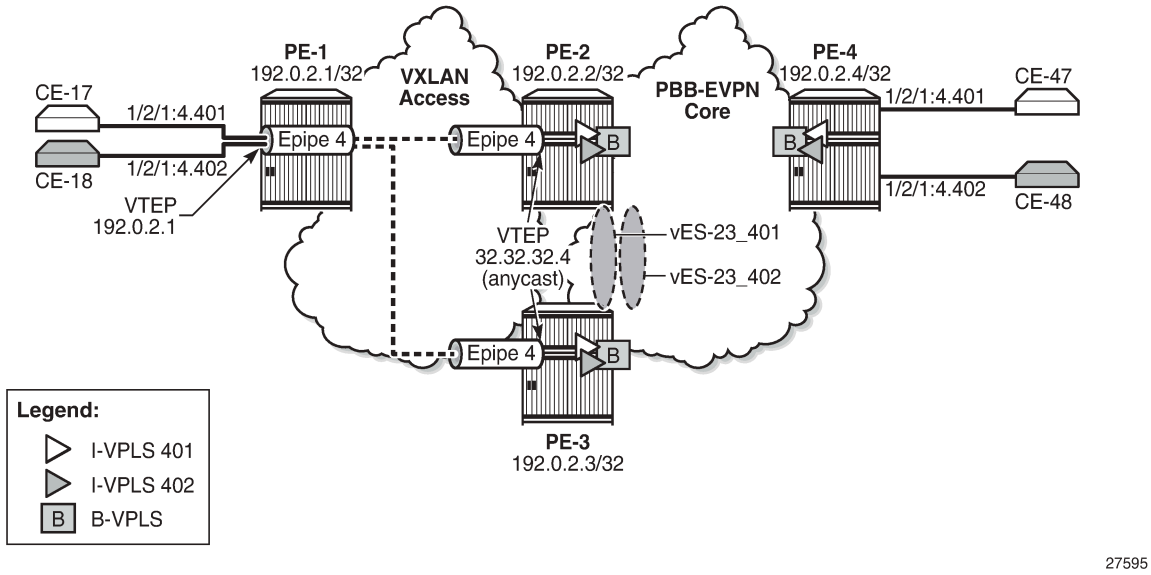
Static VXLAN used as access network for PBB-EVPN core: all-active multi-homing and anycast VTEPs

Figure 324: Example topology for static VXLAN termination using anycast shows the example topology with PE-1, PE-2, and PE-3 in the VXLAN access network. Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, the system IP address 192.0.2.1 is used as source VTEP, while (anycast) IP address 23.23.23.4 is used as source VTEP on PE-2 and PE-3.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In the PBB-EVPN core network, all-active multi-homing virtual Ethernet segments vES-23_401 and vES-23_402 are configured on PE-2 and PE-3.

Figure 324: Example topology for static VXLAN termination using anycast



VXLAN access network

On PE-2 and PE-3, PXC ports are configured: PXC 2 will be used as FPE, whereas PXC-3 and PXC-4 will be used to make a LAG for the PXC between Epipe and I-VPLS services. The PXC sub-ports for FPE have dot1q encapsulation whereas the PXC sub-ports for port cross-connect have qinq encapsulation. The configuration of the PXC ports and sub-ports is as follows:

```
# on PE-2, PE-3:
configure {
    port 1/2/6 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/7 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/8 {
        admin-state enable
        ethernet {
            mode hybrid
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port pxc-3.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-3.b {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-4.a {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port pxc-4.b {
        admin-state enable
        ethernet {
            encap-type qinq
        }
    }
    port-xc {
        pxc 2 {
            admin-state enable
            port-id 1/2/6
        }
        pxc 3 {
            admin-state enable
            port-id 1/2/7
        }
        pxc 4 {
            admin-state enable
            port-id 1/2/8
        }
    }
```

On PE-2 and PE-3, FPE 2 is configured. FPE 2 is associated with VXLAN termination and two internal interfaces will be auto-created: _tmnx_fpe_2.a and _tmnx_fpe_2.b.

```
# on PE-2, PE-3:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 2 {
            path {
                pxc 2
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            application {
                vxlan-termination {
                }
            }
        }
```

```
[/]
A:admin@PE-2# show router interface

===============================================================================

   fe80::200/64                                                 PREFERRED
_tmnx_fpe_2.b                    Up        Up/Up       Network pxc-2.b:1
   fe80::201/64                                                 PREFERRED
---snip---
```

A router loopback interface with IP address 23.23.23.2/24 is created on PE-2, and on PE-3 with IP address 23.23.23.3/24:

```
# on PE-2:
configure {
    router "Base" {
        interface "loopback2" {
            loopback
            ipv4 {
                primary {
                    address 23.23.23.2
                    prefix-length 24
                }
            }
        }
        isis 0 {
            interface "loopback2" {
            }
        }
```

On PE-2 and PE-3, the VTEP 23.23.23.4 is configured for FPE 2, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 23.23.23.4 {
                    fpe-id 2
                }
            }
        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The following command shows an additional VTEP 23.23.23.4 to the existing router interface _tmnx_vli_vxlan_1_131075 on PE-2:

```
[/]
A:admin@PE-2# show router interface "_tmnx_vli_vxlan_1_131075"

===============================================================================

===============================================================================
```

On PE-2 and PE-3, the VXLAN Epipe 4 uses LAG 4 (composed of pxc-3.b and pxc-4.b) to extend the VXLAN toward the I-VPLSs 401 and 402. The I-VPLS SAPs use LAG 3 (composed of pxc-3.a and pxc-4.a). The PXC LAGs provide higher bandwidth and better resiliency. The LAGs are configured as follows on both PE-2 and PE-3:

```
# on PE-2, PE-3:
configure {
    lag "lag-3" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-3.a {
        }
        port pxc-4.a {
        }
    }
    lag "lag-4" {
        admin-state enable
        encap-type qinq
        mode hybrid
        max-ports 64
        port pxc-3.b {
        }
        port pxc-4.b {
        }
    }
```

Epipe 4 is configured on PE-1, PE-2, and PE-3. On PE-1, no FPE is required because the system IP address is used as VTEP. Epipe 4 is configured on PE-1 with egress VTEP 23.23.23.4, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            service-id 4
            customer "1"
            sap 1/2/1:4.* {
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            vxlan {
                instance 1 {
                    vni 4
                    egress-vtep {
                        ip-address 23.23.23.4
                    }
                }
            }
        }
```

Epipe 4 is configured on PE-2 and PE-3 with source VTEP 23.23.23.4 and egress VTEP 192.0.2.1, as follows. The SAP uses LAG 4, which is composed of PXC sub-ports pxc-3.b and pxc-4.b.

```
# on PE-2, PE-3:
configure {
    service {
        epipe "Epipe 4" {
            admin-state enable
            service-id 4
            customer "1"
            sap lag-4:4.* {
            }
            vxlan {
                source-vtep 23.23.23.4
                instance 1 {
                    vni 4
                    egress-vtep {
                        ip-address 192.0.2.1
                    }
                }
            }
```

The following command on PE-1 shows that the egress VTEP in Epipe 4 equals 23.23.23.4.

```
[/]
A:admin@PE-1# show service id 4 vxlan destinations

===============================================================================
Egress VTEP, VNI
===============================================================================
VTEP Address                          Egress VNI          Oper      Vxlan
                                                          State     Type
-------------------------------------------------------------------------------
23.23.23.4                            4                   Up        static

```

PBB-EVPN core network

Two all-active multi-homing virtual ESs are configured on PE-2 and PE-3. The preference for the DF election is configured manually, with opposite preference values for the vESs so that DF load balancing is achieved. While vES-23_401 has preference 5000 on PE-2 and preference 10000 on PE-3, vES-23_402 has preference 10000 on PE-2 and preference 5000 on PE-3. When no event has occurred that caused a DF switchover, PE-2 is DF for vES-23_402 and PE-3 is DF for vES-23_401. Both vESs use LAG 3, which is composed of pxc-3.a and pxc-4.a. For vES-23_401, the qinq encapsulation must match S-tag 4 and C-

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

tag 401; for vES-23_402, the S-tag must be 4 and the C-tag 402. On PE-2, the vESs are configured as follows.

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vES-23_401" {
                        admin-state enable
                        type virtual
                        esi 0x01000000230401000001
                        multi-homing-mode all-active
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 5000
                                }
                            }
                        }
                        association {
                            lag "lag-3" {
                                virtual-ranges {
                                    qinq {
                                        s-tag-c-tag 4 c-tag-start 401 {
                                            c-tag-end 401
                                        }
                                    }
                                }
                            }
                        }
                        pbb {
                            source-bmac-lsb 0x2341
                        }
                    }
                    ethernet-segment "vES-23_402" {
                        admin-state enable
                        type virtual
                        esi 0x01000000230402000001
                        multi-homing-mode all-active
                        df-election {
                            service-carving-mode manual
                            manual {
                                preference {
                                    mode non-revertive
                                    value 10000
                                }
                            }
                        }
                        association {
                            lag "lag-3" {
                                virtual-ranges {
                                    qinq {
                                        s-tag-c-tag 4 c-tag-start 402 {
                                            c-tag-end 402
                                        }
                                    }
                                }
                            }
                        }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        pbb {
                            source-bmac-lsb 0x2342
                        }
                    }
                }
            }
        }
```

The B-VPLS 100 is configured to use the ES-BMAC. On PE-2, the B-VPLS is configured as follows.

```
# on PE-2:
configure {
    service {
        vpls "B-VPLS 100" {
            admin-state enable
            service-id 100
            customer "1"
            service-mtu 2000
            pbb-type b-vpls
            pbb {
                source-bmac {
                    address 00:00:00:00:00:02
                    use-es-bmac-lsb true
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 100
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

On PE-4, the following configuration sets ECMP to a value of 2 in the **bgp-evpn mpls** context of the B-VPLS, so that aliasing is possible.

```
# on PE-4:
configure {
    service {
        vpls "B-VPLS 100" {
            bgp-evpn {
                mpls 1 {
                    ecmp 2
                }
            }
```

On PE-2 and PE-3, the I-VPLSs are configured with SAP LAG 3, which is composed of pxc-3.a and pxc-4.a, as follows. The qinq encapsulation 4.401 in I-VPLS 401 matches the condition in vES-23_401, whereas qinq 4.402 in I-VPLS 402 matches vES-23_402.

```
# on PE-2, PE-3:
configure {
    service {
        vpls "I-VPLS 401" {
            admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            service-id 401
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 401
                }
            }
            sap lag-3:4.401 {
            }
        }
        vpls "I-VPLS 402" {
            admin-state enable
            service-id 402
            customer "1"
            pbb-type i-vpls
            pbb {
                backbone-vpls "B-VPLS 100" {
                    isid 402
                }
            }
            sap lag-3:4.402 {
            }
        }
```

With the preceding configuration, PBB-EVPN all-active multi-homing and the anycast VTEP at the access VXLAN network can be combined for an efficient and fully redundant network. PE-4 can alias the known unicast traffic to PE-2 and PE-3 on a per-flow basis, whereas if ECMP (and shared queuing) is enabled on PE-1, traffic can also be load-balanced to PE-2 and PE-3. BUM traffic sent from PE-4 will be forwarded by the corresponding DF for the ES.

See chapter EVPN for PBB over MPLS (PBB-EVPN) for more information about PBB-EVPN and all-active multi-homing.

Verification

The following command shows that PE-2 is NDF in vES-23_401 in I-VPLS 401:

```
[/]
A:admin@PE-2# show service id 401 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
SAP                   Eth-Seg                         Status
-------------------------------------------------------------------------------
lag-3:4.401           vES-23_401                      NDF
===============================================================================
No sdp entries
No vxlan instance entries
```

For I-VPLS 402, PE-2 is DF, as follows:

```
[/]
A:admin@PE-2# show service id 402 ethernet-segment

===============================================================================
SAP Ethernet-Segment Information
===============================================================================
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
SAP                   Eth-Seg                          Status
-------------------------------------------------------------------------------
lag-3:4.402           vES-23_402                       DF
===============================================================================
No sdp entries
No vxlan instance entries
```

For PE-3, the reverse is true: PE-3 is DF in vES-23_401 for I-VPLS 401 and NDF in vES-23_402 for I-VPLS 402.

Within B-VPLS 100, the BMAC addresses are advertised via BGP-EVPN. On PE-2, the following FDB for B-VPLS 100 contains the BMAC addresses of PE-3 and PE-4, which are advertised via BGP-EVPN:

```
[/]

When a ping is initiated from CE-17 to CE-47, the ICMP packets are forwarded from PE-1 to PE-2, because the best route to 23.23.23.4 is via PE-2. PE-2 learns MAC address ca:fe:01:17:17:17 of CE-17 on the local I-VPLS SAP. PE-2 forwards the ICMP packets through I-VPLS 401 and B-VPLS 100 toward PE-4. PE-4 learns MAC ca:fe:01:17:17:17 of CE-17 via the ES-BMAC. When the reply is sent, PE-4 learns MAC address ca:fe:04:47:47:47 of CE-47 on the local SAP.

The FDB for I-VPLS 401 on PE-2 shows that MAC ca:fe:04:47:47:47 is learned on the local SAP and MAC ca:fe:04:47:47:47 can be reached via the B-VPLS to PE-4.

Conclusion

VXLAN FPE is required to terminate non-system IPv4/IPv6 VXLAN tunnels. The examples in this chapter show how VXLAN FPE can be applied in Epipe services, to stitch static VXLAN to other services, such as I-VPLS services.

Three-byte EVI in EVPN Services

This chapter provides information about the three-byte EVI in EVPN services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter are based on SR OS Release 22.10.R1. The three-byte EVI is supported in EVPN services in SR OS Release 21.10.R1 and later. Three-byte EVI values can be configured in VPLS, R-VPLS, B-VPLS, and Epipe services for MPLS, VXLAN, and SRv6 instances.

Overview

In SR OS implementations earlier than SR OS Release 21.10.R1, the EVPN instance (EVI) is defined as a two-byte integer value, providing up to 65535 unique identifiers. The EVI is a unique value per service that can be used for three purposes:

- service route target (RT) auto-derivation – autonomous system number (ASN):EVI; for example, 64496:10
- service route distinguisher (RD) auto-derivation – system IP address:EVI; for example, 192.0.2.1:10
- designated forwarder (DF) election, as described in the Preference-based and Non-revertive EVPN DF Election chapter

However, in large networks, more than 65535 EVI values are required if the EVI is desired to be unique network-wide. The three-byte EVI provides up to 16777215 values and is supported in SR OS Release 21.10.R1 and later.

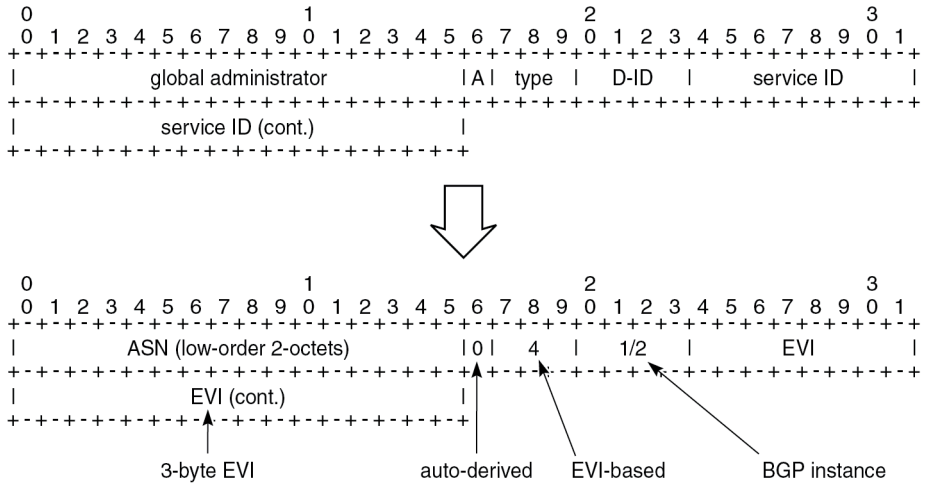
All DF election procedures support the extended EVI range. The RD auto-derivation is only possible for the two-byte EVI; the RT auto-derivation for the three-byte EVI can be enabled with the **evi-three-byte-auto-rd** command.

Auto-derived RT

The figure Figure 325: Auto-derived RT in RFC 8365shows the RT auto-derivation for configured EVI values in the range up to 16777215.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 325: Auto-derived RT in RFC 8365



For three-octet EVI values, the fields in the RT format are:

- the global administrator field, which contains (the lower two octets of) the autonomous system number (ASN)
- the single-bit field A, which indicates if the RT is auto-derived: A=0 for auto-derivation
- the three-bit type field, which indicates the space in which the three-byte service ID is defined:
  - 0: VID (802.1Q VLAN ID)
  - 1: VXLAN
  - 2: NVGRE
  - 3: I-SID
  - **4: EVI**
  - 5: dual-VID (QinQ VLAN ID)
- the four-bit D-ID field, which encodes the domain ID. For type 4 (EVI), the D-ID corresponds to the BGP instance ID in the EVPN service.
- the three-octet service ID, which is set to the EVI (for type 4)

As an example, in a dual-instance EVPN-VPLS service with the following characteristics:

- ASN 64496
- EVI 100002 (0x186A2)
- BGP 1 for EVPN-VXLAN; BGP 2 for EVPN-MPLS
- **evi-three-byte-auto-rt** enabled

The two auto-derived RTs are:

- 64496:1090619042 (0x4**1**0186A2) for BGP 1
- 64496:1107396258 (0x4**2**0186A2) for BGP 2

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The RT can also be configured manually, for example, 64496:100002. A manually configured RT has precedence over an auto-derived RT.

Auto-derived RD

Each BGP instance in an EVPN service has an RD. Only for EVI values smaller than or equal to 65535, the RD for BGP instance 1 can be auto-derived out of the system IP address and the EVI, for example, 192.0.2.2:10. EVI values greater than 65535 do not generate RDs automatically.

The VPLS RD is selected based on the following precedence order:

- manually configured RD or auto-RD take precedence when configured,
- if there is no manual RD or auto-RD configuration, the RD is derived from the **bgp-ad>vpls-id**,
- if there is no manual RD, auto-RD, or VPLS ID configuration, the RD is derived from the EVI for EVI values up to 65535 and except for **bgp-mh** which does not support EVI-derived RD,

The Epipe RD is determined in a similar way, but there is no VPLS ID in Epipes.

The following error messages are raised when attempting to enable **bgp-evpn** with an EVI value greater than 65535 without having configured a manual RD, auto-RD, or BGP-AD VPLS ID:

```
*[ex:/configure service vpls "VPLS-99"]

evpn evi to derive RD or RT - configure service vpls "VPLS-99" bgp-evpn evi
```

The RD configuration can be changed dynamically. When the RD changes, the active routes for the service are withdrawn and readvertised with the new RD.

EVI RT set for AD per-ES routes

As described in the EVPN for MPLS Tunnels chapter, Auto-discovery per Ethernet Segment (AD per-ES) routes carry the ESI label and the multi-homing mode. When multiple EVIs are defined in an ES, the AD per-ES routes can be aggregated.

EVI RT set for AD per-ES routes with two-byte EVI

The following command enables the aggregation of AD per-ES routes for two-byte EVI values:

```
configure {
    service {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        system {
            bgp {
                evpn {
                    ad-per-es-route {
                        route-target-type evi-route-target-set
                        route-distinguisher-ip-address <ip-address>
                    }
```

The RD is specific for this EVI RT set feature. If enabled, a single AD per-ES route with the associated RD and a set of maximum 128 EVI RTs can be advertised. The EVI RTs are distributed in routes with the RD configured in the preceding command and one of the following *comm-val* values (the *comm-val* range is not configurable):

- EVIs from 1 to 128 – *comm-val* = 1
- EVIs from 129 to 256 – *comm-val* = 2
- ...
- EVIs from 65409 to 65535 – *comm-val* = 512

EVI RT set for AD per-ES routes with three-byte EVI

The command to enable AD per-ES route aggregation with extended EVI range is:

```
configure {
    service {
        system {
            bgp {
                evpn {
                    ad-per-es-route {
                        route-target-type evi-route-target-set
                        route-distinguisher-ip-address <ip-address>
                        extended-evi-range true
                    }
```

For three-byte EVIs, the *comm-val* range is extended from 512 to 65535 and the maximum number of AD per-ES routes that can be aggregated is increased from 128 to 257. The 257 RTs per route packing is done for any configured EVI, regardless of the value being greater than 65535 or not.

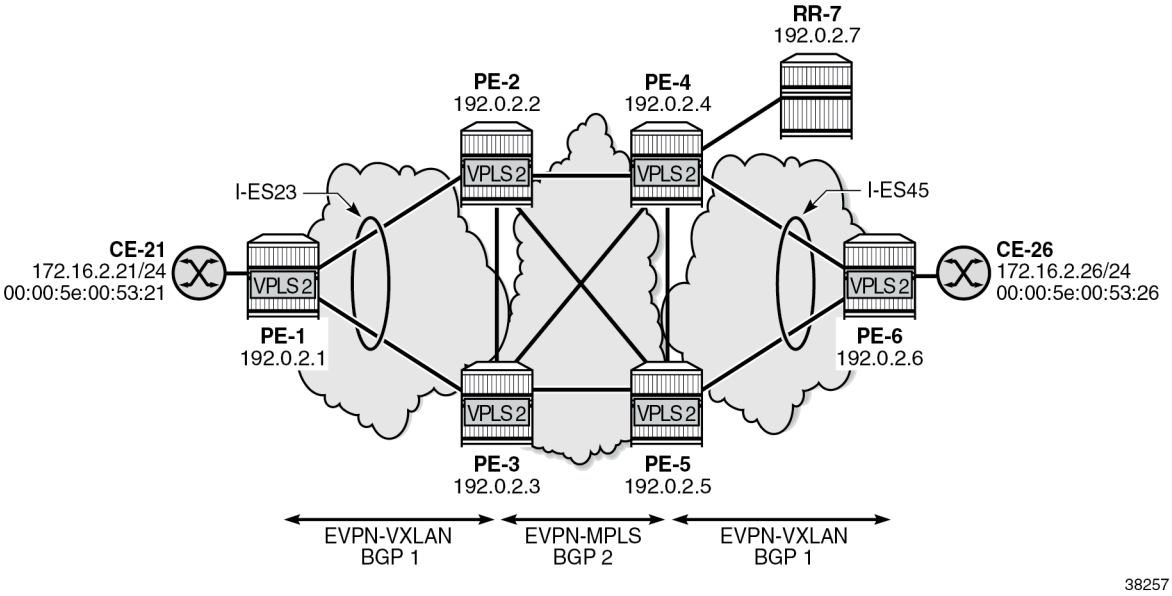
- EVIs from 1 to 257 – *comm-val* = 1
- EVIs from 258 to 514 – *comm-val* = 2
- ...
- EVIs from 16776961 to 16777215 – *comm-val* = 65281

Configuration

The figure Figure 326: Example topology with dual-instance VPLS shows the example topology with dual-instance VPLS 2: VXLAN is used between PE-1, PE-2, PE-3 and also between PE-4, PE-5, and PE-6. MPLS is used between the core PEs PE-2, PE-3, PE-4, and PE-5.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 326: Example topology with dual-instance VPLS



The initial configuration includes:

- cards, MDAs, ports
- router interfaces
- IS-IS level 2 between core PEs PE-2, PE-3, PE-4, PE-5, and RR-7
- IS-IS level 1 between PE-1, PE-2, and PE-3
- IS-IS level 1 between PE-6, PE-4, and PE-5
- SR-ISIS between core PEs PE-2, PE-3, PE-4, and PE-5

The BGP configuration and the used policies for dual-instance VPLSs in ESs are described in the EVPN Interconnect Ethernet Segmentschapter. Policies are required to prevent loops. RR-7 acts as route reflector for the core PEs PE-2, PE-3, PE-4, and PE-5. The policy and BGP configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    policy-options {
        community "SOO-DCGW-23" {
            member "origin:64500:23" { }
        }
        community "vxlan" {
            member "bgp-tunnel-encap:VXLAN" { }
        }
        policy-statement "add SOO to vxlan routes" {
            entry 10 {
                from {
                    family [evpn]
                    community {
                        name "vxlan"
                    }
                }
                action {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                    action-type accept
                    community {
                        add ["SOO-DCGW-23"]
                    }
                }
            }
            default-action {
                action-type accept
            }
        }
        policy-statement "allow only mpls" {
            entry 10 {
                from {

                group "WAN"
            }
```

The all-active interconnect ES "I-ES23" is configured on PE-2 and PE-3; the single-active interconnect ES "I-ES45" is configured on PE-4 and PE-5. VPLS 1 with EVI 1 (0x1) and VPLS 2 with EVI 100002 (0x186A2) are configured on all PEs. Both VPLSs have BGP 1 for VXLAN and BGP 2 for MPLS (SR-ISIS) in the core. For VPLS 1, no extended EVI range is required. The RD can be auto-derived for BGP instance 1, but not for BGP instance 2. For VPLS 2, the EVI is greater than 65535, so the RD must always be configured (manual configuration or auto-RD). The RT is auto-derived in VPLS 1 and VPLS 2. For VPLS 2, the **evi-three-byte-auto-rt** command is configured to enable auto-derivation of RTs for EVI values up to 16777215. On all core PEs, **evi-route-target-set** is enabled for the aggregation of AD per-ES routes. The service configuration on PE-2 is as follows:

```
# on PE-2:
configure exclusive
    service {
        system {
            bgp-auto-rd-range {
                ip-address 192.0.2.2
                community-value {
                    start 2000
                    end 2999
                }
            }
            bgp {
                evpn {
                    ethernet-segment "I-ES23" {
                        admin-state enable
                        type virtual
                        esi 00:00:00:00:00:23:23:00:00:01

```
        vpls "VPLS-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                instance 1 {
                    vni 2
                }
            }
            bgp 1 {
                route-distinguisher auto-rd    # RD cannot be auto-derived from EVI
            }
            bgp 2 {
                route-distinguisher auto-rd
            }
            bgp-evpn {
                evi 100002
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    evi-three-byte-auto-rt true
                }
                mpls 2 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    evi-three-byte-auto-rt true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
        }
```

When configuring the **evi-route-target-set** command, the RD must be different from the RD in the auto-rd range. If not, the following error message is raised:

```
*[ex:/configure service system bgp evpn ad-per-es-route]
A:admin@PE-2# route-distinguisher-ip-address 192.0.2.2

*[ex:/configure service system bgp evpn ad-per-es-route]
A:admin@PE-2# commit
MINOR: SVCMGR #12: configure service system bgp-auto-rd-range ip-address - Inconsistent Value
 error - cannot be the same as ad-per-es-route/route-distinguisher-ip-address - configure
 service system bgp evpn ad-per-es-route route-distinguisher-ip-address
```

The following command shows the RD and RT values for both BGP instances in VPLS 1 on PE-2:

```
[/]
A:admin@PE-2# show service id 1 bgp

ADV Service MTU      : -1

PW-Template Id       : None
-------------------------------------------------------------------------------
===============================================================================
```

RD 192.0.2.2:1 for BGP instance 1 is auto-derived whereas RD 192.0.2.2:2000 for BGP instance 2 is the result of auto-RD. RT 64496:1 is auto-derived based on the system IP address and the EVI. It is possible to configure **evi-three-byte-auto-rt true** in VPLS 1, even though the EVI value is smaller than 65535.

```
# on PE-2:
configure {
    service {
        vpls "VPLS-1" {
            bgp-evpn {
                vxlan 1 {
                    evi-three-byte-auto-rt true
                }
                mpls 2 {
                    evi-three-byte-auto-rt true
                }
            }
```

In this case, the auto-derivation is based on RFC 8365 and the value is 64496:1090519041 (0x41000001) for BGP 1 and 64496:1107296257 (0x42000001) for BGP 2.

```

The auto-derived RTs on the other nodes are the same as on PE-2 when the BGP instance is the same. On PE-2, PE-3, PE-4, and PE-5, BGP 1 is for VXLAN and BGP 2 is for MPLS in the core. That way, EVPN messages can be exchanged in BGP instance 2 between the core PEs.

AD per-ES aggregation is enabled on the core nodes. The following command on PE-2 shows one AD per-ES with RD 10.0.2.4:390 (10.0.2.4 is the RD configured for **evi-route-target-set** and 390 is the *comm-val* value for the EVI range from 99974 to 100230) and one AD per-EVI with RD 192.0.2.4:2002 (auto-RD).

The figure Figure 327: Example topology with VPLS 4 and Epipe 5 shows an example topology with EVPN-MPLS in the core, all-active ES "vESI-23" on PE-2 and PE-3, and single-active ES "vESI-45" on PE-4 and PE-5. VPLS 4 with EVI 100004 is configured on all PEs with manually configured RD and RT.

Instead of VXLAN or MPLS, SRv6 can be used too. As an example,VPLS 6 with EVI 100006 (0x186A6) is configured on PE-1, PE-2, PE-4, and PE-6. SRv6 is configured between PE-4 and PE-6, as described in the *Segment Routing over IPv6* chapter. The configuration on PE-2 is as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS-6" {
            admin-state enable
            service-id 6
            customer "1"
            vxlan {
                instance 1 {
                    vni 6
                }
            }
            segment-routing-v6 1 {
                locator "PE-2_loc" {
                    function {
                        end-dt2u {
                        }
                        end-dt2m {
                        }
                    }
                }
            }
            bgp 1 {
                route-distinguisher auto-rd
            }
            bgp 2 {
                route-distinguisher auto-rd
            }
            bgp-evpn {
                evi 100006
                segment-routing-v6 2 {
                    admin-state enable
                    ecmp 2
                    evi-three-byte-auto-rt true
                    srv6 {
                        instance 1
                        default-locator "PE-2_loc"
                    }
                }
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                    evi-three-byte-auto-rt true

```

Conclusion

In large networks, a three-byte EVI can be required as a unique identifier for services. RTs can be auto-derived based on a three-byte EVI, but RDs cannot be auto-derived that way.

VCCV BFD for Epipe Services

This chapter describes the VCCV BFD for Epipe services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R7. The MD-CLI in the current edition corresponds to SR OS Release 23.7.R1.

Overview

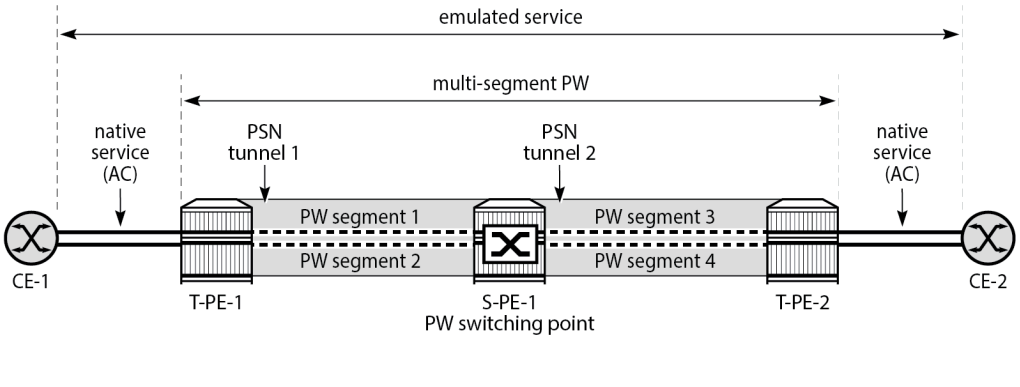
Virtual circuit connectivity verification (VCCV) is defined by RFC 5085. Bidirectional forwarding detection (BFD) is defined by RFC 5880.

VCCV is an end-to-end fault-detection tool for testing pseudowires (PWs), and typically requires an operator to take manual actions. The PWs can be used for virtual leased line (VLL), virtual private LAN service (VPLS), and Internet enhanced service (IES)/virtual private routed network (VPRN) services with Epipe or Ipipe spoke-SDPs.

SR OS supports RFC 5885 which specifies a method for carrying BFD messages in a PW-associated channel and is referred to as VCCV BFD in SR OS. Because the associated channel shares fate with the data plane, VCCV BFD monitors the PW between two terminating PEs (T-PEs), regardless of the number of provider routers or switching PEs (S-PEs) the PW may traverse; see Figure 328: PW reference model. When enabled, faults in individual PWs can be detected quickly, whether or not other provider routers or S-PEs also carry other PWs. VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in a minimum amount of time is critical.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 328: PW reference model



VCCV BFD avoids manual hop-by-hop troubleshooting of each element along the path of the PW, which minimizes the probability of not detecting silent failures on intermediate routers.

VCCV BFD sessions run end-to-end on a switched or single-hop PW, from T-PE to T-PE. They do not terminate on an intermediate S-PE; therefore, the TTL of the PW label on VCCV BFD packets is always set to 255, to ensure that the packets reach the far-end T-PE of a multi-segment PW.

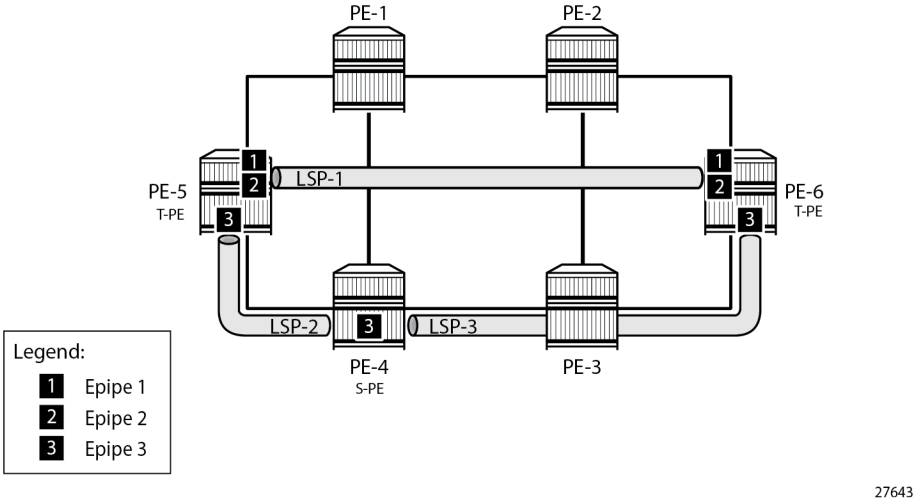
BFD is only used for fault detection. While RFC 5885 provides a mode in which VCCV BFD can be used to signal PW status, this mode is only applicable for PWs that have no other status signaling mechanism in use. LDP status and static PW status signaling always take precedence over BFD-signaled PW status, and BFD-signaled PW status is not used on PWs that use LDP status or static PW status signaling mechanisms.

Configuration

Figure 329: Example topology shows the example topology with Epipes "Epipe-1" and "Epipe-2" using LSP "lsp-1" between PE-5 and PE-6 and Epipe "Epipe-3" using LSP "lsp-2" between PE-5 and S-PE PE-4 and LSP "lsp-3" between PE-4 and PE-6.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 329: Example topology



The initial configuration includes:

- Cards, MDAs, and ports
- Router interfaces
- IS-IS as IGP on all interfaces (alternatively, OSPF can be used), with traffic engineering enabled
- MPLS paths and LSPs:
  - LSP "lsp-1" configured on PE-5 with primary path "path-5-1-2-6" and on PE-6 with primary path "path-6-2-1-5"
  - LSP "lsp-2" configured on PE-5 with primary path "path-5-4" and on PE-4 with primary path "path-4-5"
  - LSP "lsp-3" configured on PE-4 with primary path "path-4-3-6" and on PE-6 with primary path "path-6-3-4"

VCCV BFD configuration

Three steps are needed when configuring VCCV BFD:

1. Configure the BFD template
2. Apply the BFD template
3. Enable BFD

Step 1: configure BFD template

The **bfd-template** command provides the control packet timer values for the BFD.

The general command to define a BFD template is as follows:

```
configure {
    bfd {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        bfd-template <name> {
            echo-receive <echo-interval>
            multiplier <multiplier>
            receive-interval <receive-interval>
            transmit-interval <transmit-interval>
            type {cpm-np}
```

However, network processor BFD (cpm-np) is not supported for VCCV, and the minimum supported receive or transmit timer interval is 100 ms. An error is generated if a user tries to apply a BFD template with the **type cpm-np** command or any unsupported transmit or receive interval value. An error is also generated when the user attempts to commit changes to a BFD template that is already bound to a spoke-SDP.

Steps 2 and 3: apply BFD template and enable BFD

To apply and enable the BFD template to a spoke-SDP where LDP is used as the SDP signaling protocol for a service, the following command can be used, depending on the service:

```
configure {
    service {
        [epipe|cpipe|ipipe|vpls|ies|vprn] <name> {
            spoke-sdp <sdp-binding-id> {
                bfd {
                    bfd-template <name>
                    bfd-liveness {
                    }
```

If BGP is used as the SDP signaling protocol, the following command is used:

```
configure {
    service {
        [epipe|vpls] <name> {
            bgp 1 {
                pw-template-binding <reference> {
                    bfd 1 {
                        bfd-template <name>
                        bfd-liveness true
```

In this example, the following BFD templates are configured on PE-5 and PE-6:

```
# on PE-5, PE-6:
configure {
    bfd {
        bfd-template "bfdt-1" {
            multiplier 5
            receive-interval 2000
            transmit-interval 2000
        }
        bfd-template "bfdt-2" {
            receive-interval 1000
            transmit-interval 1000
        }
```

These BFD templates are used in the Epipe services configured in the next section.

Service configuration

LDP VLL "Epipe-1"

The service "Epipe-1" is an LDP VLL running between PE-5 and PE-6, and uses manually configured SDP 56 on PE-5 and SDP 65 on PE-6, respectively, so the signaling is set to T-LDP. On PE-5, the spoke-SDP 56:1 has BFD template *bfdt-2* applied, and BFD is enabled. The configuration on PE-6 is similar.

```
# on PE-5:
configure {
    service {
        epipe "Epipe-1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 56:1 {
                bfd {
                    bfd-template "bfdt-2"
                    bfd-liveness {
                    }
                }
            }
            sap 1/1/c4/1:1 {
            }
        }
        sdp 56 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            lsp "lsp-1" { }
        }
```

Log 99 indicates the local discriminator value used for the VCCV BFD session, as follows:

```
95 2023/08/21 08:23:10.590 CEST MINOR: VRTR #2070 Base 127.0.0.1
"The vccv BFD session with Local Discriminator 1 on Svc 1 SdpBind 56:1 is up"
```

Configuring the spoke-SDP with a template with an invalid type (for example, type "cpm-np") or with invalid transmit or receive intervals leads to errors, as follows:

```
[ex:/configure service epipe "Epipe-1" spoke-sdp 56:1 bfd]
A:admin@PE-5# bfd-template "bfdt-cpm-np-50ms"

*[ex:/configure service epipe "Epipe-1" spoke-sdp 56:1 bfd]
A:admin@PE-5# commit
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
- bfd-template transmit-interval must be minimum 100 for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" transmit-interval
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
- bfd-template receive-interval must be minimum 100 for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" receive-interval
MINOR: MGMT_CORE #4001: configure service epipe "Epipe-1" spoke-sdp 56:1 bfd
bfd-template
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
- bfd-template type is not valid for this application
- configure bfd bfd-template "bfdt-cpm-np-50ms" type
```

BGP VPWS "Epipe-2"

The service "Epipe-2" is a BGP VPWS, also running between PE-5 and PE-6, using the manually configured SDPs 561 and 651 with the signaling set to BGP, as follows. Again, BFD template *bfdt-2* is used, but now the BFD template is referred to from the **pw-template-binding** context. See the BGP Virtual Private Wire Services chapter for more information.

```
# PE-5:
configure {
    service {
        pw-template "1" {
            provisioned-sdp prefer
        }
        epipe "Epipe-2" {
            admin-state enable
            service-id 2
            customer "1"
            bgp 1 {
                route-distinguisher "65545:2"
                route-target {
                    export "target:65545:2"
                    import "target:65545:2"
                }
                pw-template-binding "1" {
                    bfd-template "bfdt-2"
                    bfd-liveness true
                }
            }
            bgp-vpws {
                admin-state enable
                local-ve {
                    name "PE-5"
                    id 5
                }
                remote-ve "PE-6" {
                    id 6
                }
            }
            sap 1/1/c4/1:2 {
            }
        }
        sdp 561 {
            admin-state enable
            delivery-type mpls
            signaling bgp
            far-end {
                ip-address 192.0.2.6
            }

LDP VLL "Epipe-3" with switching node PE-4

The service "Epipe-3" is another LDP VLL running between PE-5 and PE-6, but switched at PE-4. It uses the manually configured SDPs 54 and 45 between PE-5 and PE-4, and SDPs 46 and 64 between PE-4 and PE-6. All these SDPs are using T-LDP for the signaling. On PE-5, the spoke-SDP 54:3 has BFD template "bfdt-1" applied, and **control-word** is active. This ensures that BFD packets get into the PW mapping to that spoke-SDP and that these packets are forwarded between the VC-switched spoke-SDPs at PE-4. The configuration on PE-6 is similar.

```
# on PE-5:
configure {
    bfd {
        bfd-template "bfdt-1" {
            multiplier 5
            receive-interval 2000
            transmit-interval 2000
        }
    }
    service {
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            spoke-sdp 54:3 {
                control-word true
                bfd {
                    bfd-template "bfdt-1"
                    bfd-liveness {
                    }
                }
            }
            sap 1/1/c4/1:3 {
            }
        }
        sdp 54 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.4
            }
            lsp "lsp-2" { }
        }
```

For PE-4 to switch traffic from one VC to another, **vc-switching true** is configured in the Epipe, as follows:

```
# on PE-4:
configure {
    service {
        epipe "Epipe-3" {
            admin-state enable
            service-id 3
            customer "1"
            vc-switching true      # S-PE
            spoke-sdp 45:3 {
            }
            spoke-sdp 46:3 {
            }
        }
        sdp 45 {
            admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            delivery-type mpls
            far-end {
                ip-address 192.0.2.5
            }
            lsp "lsp-2" { }
        }
        sdp 46 {
            admin-state enable
            delivery-type mpls
            far-end {
                ip-address 192.0.2.6
            }
            lsp "lsp-3" { }
        }
```

VCCV BFD verification

The following command shows that BFD template "bfdt-2" is applied to SDP 56:1 in the "Epipe-1" service and to SDP 561:4294967295 in the "Epipe-2" service:

```
[/]
A:admin@PE-5# show router bfd bfd-template "bfdt-2"

SvcId               Sdp Bind                      BFD Enable     BFD Encap
-------------------------------------------------------------------------------
1                   56:1                          yes            ipv4
2                   561:4294967295                yes            ipv4
===============================================================================
```

The BFD configuration for SDP 56:1 on the "Epipe-1" service is listed in the detailed output for the SDP, as follows. The BFD template used is *bfdt-2*, BFD is enabled, and the BFD encapsulation used is IPv4. The peer VCCV CV bits indicate that the remote end supports LSP ping as well as BFD fault detection.

-------------------------------------------------------------------------------
===============================================================================
```

Conclusion

VCCV BFD can monitor specific high-value services, where detecting forwarding failures (and potentially recovering from them) in the minimal amount of time is critical. VCCV BFD complements other on-demand tools such as VCCV ping and VCCV trace by providing proactive detection of faults. VCCV ping and VCCV trace can later be used to localize and diagnose the root cause of the fault.

Virtual Ethernet Segments

This chapter provides information about Virtual Ethernet Segments.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

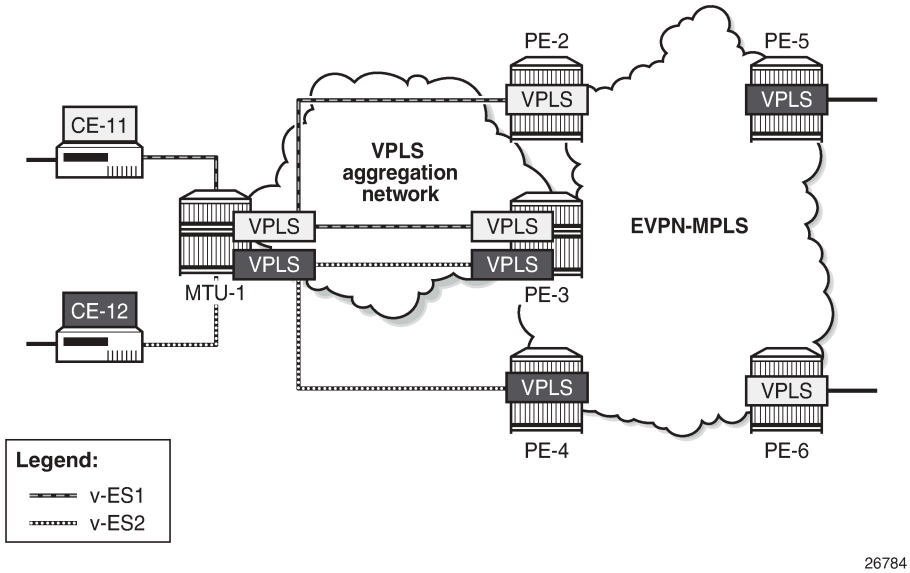
This chapter was initially written based on SR OS Release 15.0.R3, but the MD-CLI in the current edition is based on SR OS Release 21.2.R2. Virtual Ethernet segments are supported in SR OS Release 15.0.R1, and later.

Overview

RFC 7432 describes the use and procedures for Ethernet segments (ESs) that can be associated with physical Ethernet ports and LAGs. The SR OS implementation also allows an ES to be associated with SDPs. ESs meet the redundancy requirements of directly connected CEs. However, ESs will not work when an aggregation network exists between CEs and ES PEs, which requires different ESs to be defined for the port, LAG, or SDP. *Draft-ietf-bess-evpn-virtual-eth-segment* describes how virtual ESs (vESs) can be defined with an Attachment Circuit (AC) level granularity. Figure 330: vESs for PWs shows an example where vES definition at the pseudowire (PW) granularity level is required:

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 330: vESs for PWs



When a Layer 2 aggregation network is used to get access to EVPN, the association of ACs that belong to the same ES and physical ports or SDPs can be arbitrary. For example, the SDP between MTU-1 and PE-3 (Figure 330: vESs for PWs) cannot be associated with only one ES, because it is being used by two different CEs that require different ESs. The association must be at spoke-SDP level. The RFC 7432 port/lag-based ES definition is not sufficient, so vESs need to be defined. Virtual ESs can be configured with up to eight ranges of one or more:

- VC-IDs (spoke-SDPs)
- Q-tags (dot1q)
- S-tags (qinq)
- C-tags for a fixed S-tag (qinq)

Mesh-SDPs are not allowed for an SDP used by a vES.

Virtual ESs are configured as Ethernet segments of type virtual:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-1"]
A:admin@PE-2# type ?

 type <keyword>
 <keyword>  - (none|virtual)
 Default    - none

 'type' is: immutable

    Type of the ethernet segment.

    Warning: Modifying this element recreates
    'configure service system bgp evpn ethernet-segment "ESI-1"' automatically for the
 new value to take effect.
```

Virtual ES "vESI-23_600" is associated with LAG 1 and one service-delimiting VLAN range is defined for the S-tag, as follows:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_600" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:06:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 600 {
                                            end 602
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
```

The configured ES will match all the SAPs for which the top (outer) service-delimiting tag is within the 600 to 602 range.

When the ES is created as virtual, a port, LAG, or SDP needs to be created before any VLAN or VC-ID can be associated.

- For VC-ID, only spoke-SDPs are allowed, no mesh-SDPs. Manual spoke-SDP VC-IDs and BGP-AD VC-IDs can be included in the range.
- For dot1q, only those SAPs that match the service-delimiting VLAN range will be associated with the vES
- For qinq, the following two commands can be configured, with a mutually exclusive S-tag:
  - **s-tag <qtag1> end <qtag1>** - associates all qinq SAPs with outer tag between the configured qtags.
  - **s-tag-c-tag <qtag1> c-tag-start <qtag2> c-tag-end <qtag2>** - associates all qinq SAPs with outer qtag1 and inner qtag between the configured qtag2 values to the vES

  A mutually exclusive S-tag means that a value for the S-tag can be configured in either of the two commands, but not in both.

Table 29: Supported examples for Q-tag values between 1 and 4094 shows the supported examples for qtag values between 1 and 4094; Table 30: Supported examples for Q-tag values 0, *, and null shows the supported examples for qtag values 0, *, and null:

Table 29: Supported examples for Q-tag values between 1 and 4094

vES configuration for port 1/1/1	SAP association
dot1q qtag 100	1/1/1:100
dot1q qtag-range 100 to 102	1/1/1:100, 1/1/1:101, 1/1/1:102
qinq s-tag 100 c-tag 200	1/1/1:100.200
qinq s-tag 100 c-tag-range 200 to 202	1/1/1:100.200, 1/1/1:100.201, 1/1/1:100.202
qinq s-tag 100	All SAPs 1/1/1:100.x (x being 1 to 4094, 0, or *)
qinq s-tag-range 100 to 102	All SAPs 1/1/1:100.x, 1/1/1:101.x, 1/1/1:102.x (x being 1 to 4094, 0, or *)

*Table 30: Supported examples for Q-tag values 0, *, and null*

vES configuration for port 1/1/1	SAP association
dot1q qtag 0	1/1/1:0
dot1q qtag *	1/1/1:*
qinq s-tag 0 c-tag *	1/1/1:0.*
qinq s-tag * c-tag *	1/1/1:*.*
qinq s-tag * c-tag null	1/1/1:*.null

Considerations:

- The ranges can be modified on the fly for qtag, s-tag/c-tag, or vc-id.
- For port-based vESs, PXC sub-ports are supported. For more information about PXC, see the "Port Cross-Connect (PCX)" chapter in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Advanced Configuration Guide for Classic CLI*.
- Virtual ESs are supported in EVPN-MPLS, PBB-EVPN, and EVPN-VPWS
- Virtual ESs are supported in single-active and all-active EVPN multi-homing
  - Two all-active vESs must use different ES-BMAC addresses, even if they are defined in the same LAG.
- Virtual ESs implement CMAC flush procedures described in RFC 7623. Optionally, ISID-based CMAC-flush can be used where the single-active vES does not use ES-BMAC allocation. See chapter PBB-EVPN ISID-based CMAC Flush.
- Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. For more information about CP-SAPs, see chapter VLAN Range SAPs for VPLS and Epipe Services.

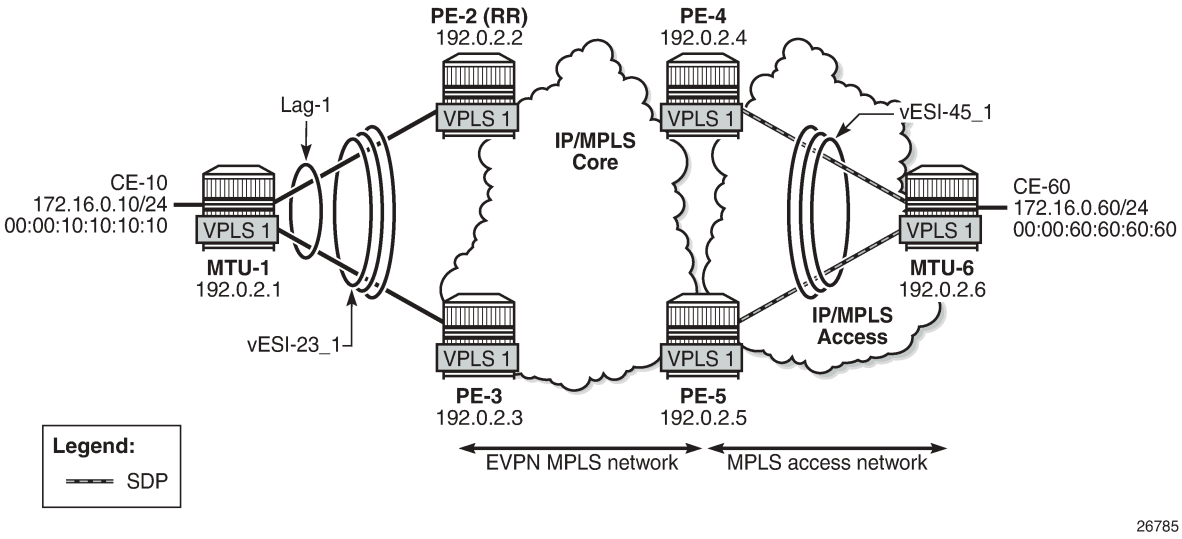
Configuration

Figure 331: Example topology shows the example topology with four core PEs in an EVPN-MPLS network and two MTUs. VPLS 1 is configured in all the nodes. EVPN is configured on the core PEs, not on the MTUs. LAG 1 is configured on MTU-1, PE-2, and PE-3 and associated with an all-active vES "ESI-23_1" on PE-2 and PE-3. A single-active vES "ESI-45_1" is configured on PE-4 and PE-5, associated with SDPs.

Figure 331: Example topology



The configuration is similar to the one in chapter EVPN for MPLS Tunnels, where the parameters are described in detail.

The initial configuration on the nodes includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (alternatively, OSPF can be configured)
- LDP in the IP/MPLS core and IP/MPLS access network

LAG 1 is configured with qinq encapsulation. The LAG configuration on MTU-1 is as follows:

```
# on MTU-1:
configure {
    lag "lag-1" {
        admin-state enable
        encap-type qinq
        mode access
        max-ports 64
        lacp {
            mode active
            administrative-key 32768
        }
        port 1/1/1 {
        }
        port 1/1/2 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
    }
```

BGP is configured on all PEs for address family EVPN. PE-2 is the Route Reflector (RR) and is configured as follows.

```
# on RR PE-2:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            vpn-apply-export true
            vpn-apply-import true
            rapid-withdrawal true
            peer-ip-tracking true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
                cluster {
                    cluster-id 1.1.1.1
                }
            }
            neighbor "192.0.2.3" {
                group "internal"
            }
            neighbor "192.0.2.4" {
                group "internal"
            }
            neighbor "192.0.2.5" {
                group "internal"
            }
        }
```

VPLS 1 is configured on all nodes. On the PEs, BGP-EVPN is enabled for MPLS. The following is configured on PE-2:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            sap lag-1:1.1 {
            }
        }
```

The configuration on the other PEs is similar, but on PE-4 and PE-5, a spoke-SDP is configured instead of a SAP. The service configuration on PE-4 is as follows:

```
# on PE-4:
configure {
    service {
        sdp 46 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.6
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    ecmp 2
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            spoke-sdp 46:1 {
            }
        }
```

Virtual ESs must be configured with type **virtual**; if not, the following error is raised after an attempt to define virtual ranges:

```
*[ex:/configure service system bgp evpn ethernet-segment "ESI-3" association lag "lag-1"]
A:admin@PE-2# virtual-ranges {
MINOR: MGMT_CORE #2203: configure service system bgp evpn ethernet-segment "ESI-3" association
 lag "lag-1" virtual-ranges - Invalid element - virtual-ranges allowed only on virtual
 ethernet-segments
```

On PE-2 and PE-3, the two following two all-active multi-homing vESs are created, each with a unique ESI:

```
# on PE-2, PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:01:00:00:01
                        multi-homing-mode all-active
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag-c-tag 495 c-tag-start 100 {
                                            c-tag-end 102
                                        }
                                        s-tag 1 {
                                            end 1
                                        }
                                        s-tag 500 {
                                            end 501
                                        }
                                    }
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-23_600" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:06:00:00:01
                        multi-homing-mode all-active
                        df-election {
                            es-activation-timer 3
                            service-carving-mode manual
                            manual {
                                evi 2 {
                                    end 2
                                }
                            }
                        }
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 600 {
                                            end 602
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
```

When attempting to configure another vES with the ESI of an existing ES/vES, the following error is raised:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_610"]
A:admin@PE-2# esi 01:00:00:00:00:23:06:00:00:01

*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_610"]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_610" -
 Inconsistent value - esi 01:00:00:00:00:23:06:00:00:01 in use by ethernet segment vESI-23_600
```

Multiple vESs can be defined on the same LAG. However, the ranges should not overlap. The following error is raised after attempting to configure an additional range in vES "ESI-23_600" that uses S-tag 600 in combination with a range of C-tags. S-tag 600 is already included in the first range: **s-tag 600 end 602**.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The error message points out that this range is of a different type: the existing range defines only S-tags, whereas the new range defines a range of C-tags for S-tag 600.

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_600" association lag "lag-1"
 virtual-ranges qinq s-tag-c-tag 600 c-tag-start 100]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_600"
 association lag "lag-1" virtual-ranges qinq s-tag-c-tag 600 c-tag-start 100 - Inconsistent
 value - range overlaps with range of a different type in this ethernet-segment
```

When attempting to define **s-tag 1** in "vESI-23_2", when S-tag 1 is already defined in "vESI-23_1", the following error is raised:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_600" association lag "lag-1"
 virtual-ranges qinq s-tag 1]
A:admin@PE-2# commit
MINOR: SVCMGR #1003: configure service system bgp evpn ethernet-segment "vESI-23_600"
 association lag "lag-1" virtual-ranges qinq s-tag 1 - Inconsistent value - range overlaps with
 range in ethernet-segment vESI-23_1
```

On PE-4, the following single-active multi-homing vESs are configured. The configuration on PE-5 contains a different SDP.

```
# on PE-4:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-45_1" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:01:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            sdp 46 {
                                virtual-ranges {
                                    vc-id 1 {
                                        end 1
                                    }
                                    vc-id 500 {
                                        end 501
                                    }
                                }
                            }
                        }
                    }
                    ethernet-segment "vESI-45_2" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:45:02:00:00:01
                        multi-homing-mode single-active

```

The ranges in the vES can be modified while the vES is operationally up, for example, an S-tag range can be added as follows:

```
# on PE-2:
configure {
    service {
        system {
            bgp {
                evpn
                    ethernet-segment "vESI-23_1" {
                        association {
                            lag "lag-1" {
                                virtual-ranges {
                                    qinq {
                                        s-tag 10 {
                                            end 10
                                        }
                                    }
```

```

Connection-profile-vlan SAPs (CP-SAPs) cannot be associated with a vES and cannot be configured on ports where vESs are defined. CP-SAP 10 is created on PE-3, as follows:

```
# on PE-3:
configure {
    connection-profile vlan 10 {
        qtag-range 5 {
            end 100
        }
        qtag-range 495 {
            end 495
        }
```

The following vES is configured on PE-3:

```
# on PE-3:
configure {
    service {
        system {
            bgp {
                evpn {
                    ethernet-segment "vESI-23_10" {
                        admin-state enable
                        type virtual
                        esi 01:00:00:00:00:23:10:00:00:01
                        multi-homing-mode single-active
                        df-election {
                            es-activation-timer 3
                        }
                        association {
                            port 1/2/3 {
                                virtual-ranges {
                                    qinq {
                                        s-tag 100 {
                                            end 100
                                        }
                                    }
                                }
                            }
                        }
                    }
```

© 2026 Nokia.

This vES can only be configured when no CP-SAPs are defined on port 1/2/3. The following error message is raised when a CP-SAP is configured on port 1/2/3 already and the vES is configured afterward:

```
*[ex:/configure service system bgp evpn ethernet-segment "vESI-23_10" association port 1/2/3
 virtual-ranges qinq s-tag 100]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/3:100.cp-10 - connection
 profile saps not allowed on port/lags associated with evpn ethernet-segments - configure
 service system bgp evpn ethernet-segment "vESI-23_10" association
```

When attempting to configure CP-SAP 1/2/3:cp-10 in VPLS 1 with port 1/2/3 associated with a vES, the following error message is raised.

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/3:100.cp-10]
A:admin@PE-3# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/3:100.cp-10 - connection
 profile saps not allowed on port/lags associated with evpn ethernet-segments - configure
 service system bgp evpn ethernet-segment "vESI-23_10" association
```

Conclusion

Regular ESs and vESs can be associated with ports, LAGs, and SDPs; in case of vES, ranges of Q-tags, S-tags, C-tags, or VC-IDs can be defined. The granularity for vES is per AC. Multiple vESs with different ESIs can be defined on the same port, LAG, or SDP.

VLAN Range SAPs for VPLS and Epipe Services

This chapter provides information about VLAN range SAPs for VPLS and Epipe services.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS Release 14.0.R6, but the MD-CLI in the current edition is based on SR OS Release 21.2.R1. Connection-Profile VLAN SAPs (CP SAPs) are supported in SR OS Release 14.0.R1, and later.

Overview

Backhaul services through metro Ethernet networks require bundled interface support. In SR OS terminology, bundling refers to Connection-Profile VLAN SAPs (CP SAPs)—special SAPs that capture the traffic of a range of CE VLAN IDs (VIDs) entering an Ethernet port. CP SAPs are fully compatible with Metro Ethernet Forum (MEF) 10.3 bundling service attributes and RFC 7432 EVPN VLAN bundle service interfaces. CP SAPs are supported in Layer 2 services only, and can be configured together with other SAPs and/or SDP-bindings.

For frames with an ingress VID contained in the range configured in the SAP's CP, the behavior is similar to default SAPs, such as 1/1/1:*, where "*" spans the entire VID range from 0 to 4095 and serves as a wildcard. However, unlike a default SAP, a CP SAP cannot co-exist with a VLAN SAP that is in the same range and on the same port or LAG. For example, 1/1/1:* and 1/1/1:100 can co-exist whereas 1/1/2:cp-1 (where cp-1 corresponds to the VLAN range from 1 to 200) and 1/1/2:100 cannot co-exist.

The VLAN manipulation between VLAN SAPs, default SAPs, and CP SAPs is compared in Table 31: VLAN manipulation in SAPs .

Table 31: VLAN manipulation in SAPs

	VLAN SAP	Default SAP	CP SAP
Service-delimiting VLAN	Yes For example: VLAN 100 in 1/1/1:100	No	No
Push/pop VLAN tags in egress/ ingress frames	Yes	No	No

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

	VLAN SAP	Default SAP	CP SAP
VLAN translation	Yes	No	No

Figure 332: Customer VID is popped and pushed by VLAN SAPs - VLAN translation shows how dot1q VLAN SAPs pop the customer VLAN tag in ingress frames and push the VLAN tag in egress frames. Therefore, frames are untagged between PE-1 and PE-2. VLAN translation is possible when the VIDs in the VLAN tags that are popped or pushed at the SAPs are different at ingress and egress, as follows.

Figure 332: Customer VID is popped and pushed by VLAN SAPs - VLAN translation

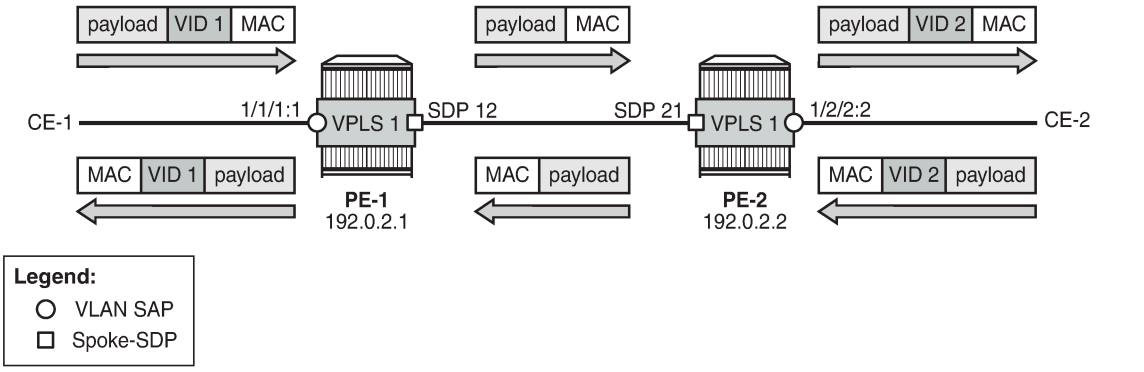

Figure 333: Customer VID is preserved between dot1q CP SAPs - no VLAN translation shows that dot1q CP SAPs do not pop or push the CE VID. Frames keep the same tag end-to-end; therefore, VLAN translation is not possible.

Figure 333: Customer VID is preserved between dot1q CP SAPs - no VLAN translation

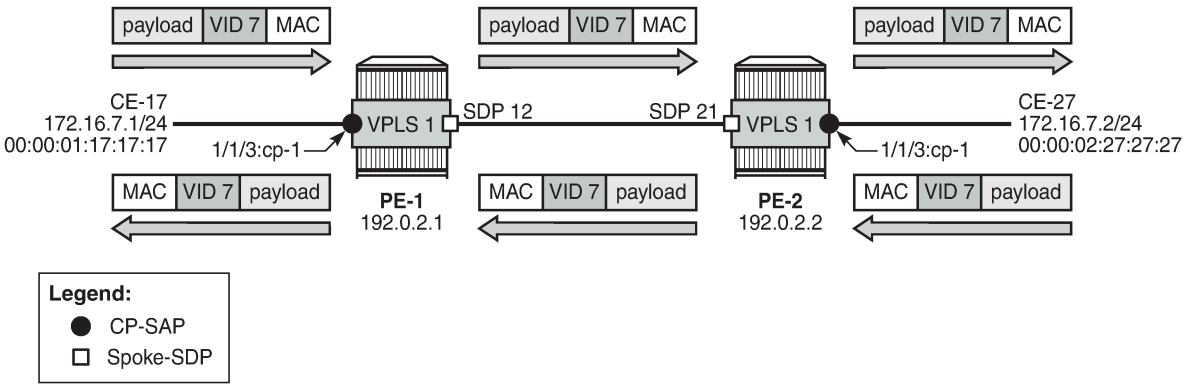

Figure 334: Customer VID is preserved between QinQ CP SAPs - no VLAN translation shows that QinQ CP SAPs only pop or push the service delimiting VID (VID 100), but not the customer VID in the CP range, as follows:

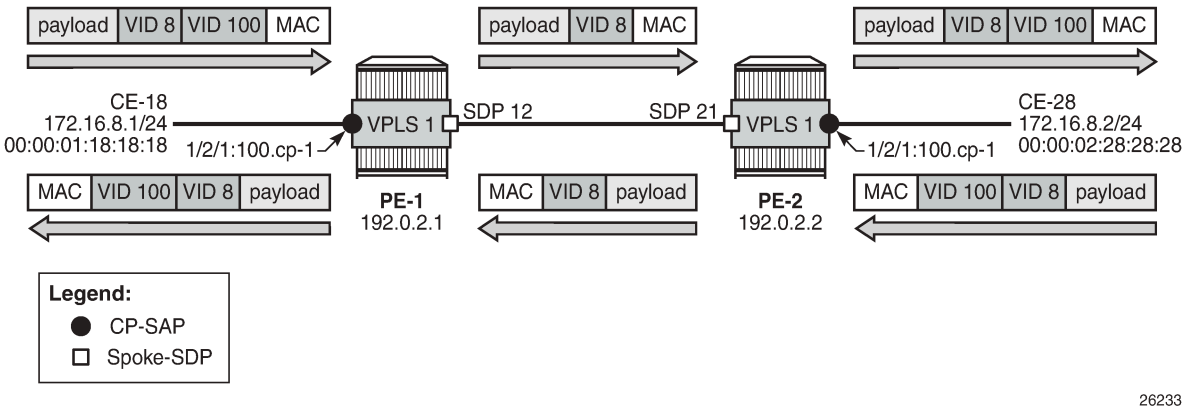
© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 334: Customer VID is preserved between QinQ CP SAPs - no VLAN translation



VID 100 is service delimiting and can be different in both SAPs, but the customer VID in the VLAN range of the CP is not.

Connection profile VLAN

Note:
The **connection-profile>vlan** context is different from the connection-profile used for ATM connectivity.

CP SAPs refer to connection profiles that can contain up to 32 ranges of customer VIDs. Connection profiles are configured with the following command:

```
[ex:/configure connection-profile]
A:admin@PE-1# vlan ?

 [connection-profile-id] <number>
 <number>  - <1..8000>

    Identifier of this connection profile
```

VLAN ranges in a CP contain one or more consecutive VIDs, as follows:

```
*[ex:/configure connection-profile vlan 10]
A:admin@PE-1# qtag-range ?

 [start] <number>
 <number>  - <1..4094>

    Lower bound of VLAN range for connection profile
```

```
*[ex:/configure connection-profile vlan 10]
A:admin@PE-1# qtag-range 150 ?

 qtag-range

 Immutable fields      - end

 apply-groups          - Apply a configuration group at this level
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
 apply-groups-exclude  - Exclude a configuration group at this level
 end                   - Upper bound of VLAN range for connection profile
```

Following is an example of a CP configuration containing three non-overlapping VLAN ranges:

```
configure {
    connection-profile {
        vlan 10 {
            qtag-range 5 {
                end 100
            }
            qtag-range 150 {
                end 300
            }
            qtag-range 350 {
                end 350
            }
        }
```

Overlapping ranges are not allowed within the same CP. The following error is raised when attempting to add a VLAN range from 7 to 9 to the preceding CP.

```
*[ex:/configure connection-profile vlan 10 qtag-range 7]
A:admin@PE-1# commit
MINOR: SVCMGR #9012: configure connection-profile vlan 10 - Overlapping range - configure
 connection-profile vlan 10 qtag-range 7 end
```

Additional VLAN ranges can be configured to the CP defined in an existing and operationally up SAP. The CP's VLAN ranges can also be removed on the fly. When a user wants to extend a VLAN range, for example, VLAN range 350 becoming a range from 350 to 400, the existing VLAN range is overwritten, as follows:

```
[ex:configure connection-profile vlan 10]
A:admin@PE-1# qtag-range 350 {

[ex:configure connection-profile vlan 10 qtag-range 350]
A:admin@PE-1# end 400

*[ex:configure connection-profile vlan 10 qtag-range 350]
A:admin@PE-1# }

*[ex:configure connection-profile vlan 10]
A:admin@PE-1# commit

[ex:configure connection-profile vlan 10]
A:admin@PE-1# info
    qtag-range 5 {
        end 100
    }
    qtag-range 150 {
        end 300
    }
    qtag-range 350 {
        end 400
    }
```

The following example shows three VLAN ranges in CP 10, with a timestamp of the last change for each VLAN range:

```
[/]
```

===============================================================================
===============================================================================
```

If a VLAN tag combination matches different SAPs, the highest priority SAP will be picked regardless of the operational status. For completeness, the following two tables show the SAP lookup matching order for dot1q and QinQ ports.

Table 32: SAP lookup order for dot1q ports

Incoming frame qtag VID value	**SAP lookup precedence order (:0 and :* are mutually exclusive on the same port)**			
	:X	**:CP**	**:0**	**:***
X (belongs to the CP range)	1st	1st		2nd
0			1st	1st
<untagged>			1st	1st

Table 33: SAP lookup order for QinQ ports

Incoming frame qtag1.qtag2	**System/port settings = new-qinq-untagged-sap SAP lookup precedence order (assumption: X and Y are defined in CP ranges)**							
	:X.Y	**:X.0**	**:X.CP**	**:CP.***	**:X.***	**:0.***	**:*.null**	**:*.***
X.Y	1st		1st	2nd	2nd			3rd
X.0		1st		2nd	2nd			3rd
0.Y						1st		2nd
0.0						1st		2nd
X		1st		2nd	2nd		3rd	4th
0						1st	2nd	3rd

Incoming frame qtag1.qtag2	System/port settings = new-qinq-untagged-sap SAP lookup precedence order (assumption: X and Y are defined in CP ranges)							
	:X.Y	:X.0	:X.CP	:CP.*	:X.*	:0.*	:*.null	:*.*
<untagged>						1st	2nd	3rd

For example, ingress frames with VIDs 100.20 are classified as part of CP SAP 1/2/1:100.cp-10, not of CP SAP 1/2/3:cp-10.*. Only when SAP 1/2/1:100.cp-10 is removed from the configuration, frames with VIDs 100.20 will go to SAP 1/2/3:cp-10.*.

Assign CP SAPs to VPLS or Epipe services

Like ordinary SAPs, CP SAPs can be assigned to VPLS or Epipe services, as follows. The VPLS and Epipe can be EVPN services or not. In the following example, VPLS 1 has BGP-EVPN enabled, whereas Epipe 2 does not:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            spoke-sdp 12:2 {
            }
            sap 1/2/1:200.cp-10 {
            }
        }
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                mpls 1 {
                    admin-state enable
                    ingress-replication-bum-label true
                    auto-bind-tunnel {
                        resolution any
                    }
                }
            }
            sap 1/1/3:cp-10 {
            }
            sap 1/2/1:1.11 {
            }
            sap 1/2/1:100.cp-10 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            }
            sap 1/2/3:cp-10.* {
            }
        }
```

CP SAPs are configured in the same way as VLAN SAPs and default SAPs, with the following restrictions:

- A CP can be defined for inner or outer tags as shown in the preceding configuration, but not both at the same time, as follows:

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:cp-3.cp-10]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/1:cp-3.cp-10 - SAP and port
 encapsulation values are incompatible - configure port 1/2/1 ethernet encap-type
```

- If a CP is defined for the outer VID, the inner VID cannot be a specific VID, as follows. The inner VID can only be a "*" (where the inner tag can have any value) or a "0" (where the inner tag can be 0 or null).

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:cp-3.4]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service vpls "VPLS 1" sap 1/2/1:cp-3.4 - SAP and port
 encapsulation values are incompatible - configure port 1/2/1 ethernet encap-type
```

- No VLAN SAP can be added on a port in dot1q (or a combination of port and service-delimiting VLAN in case of QinQ) when the VLAN is included in the VLAN range in a CP SAP on the same port. One of the VLAN ranges in CP 10 contains all VIDs from 5 to 100. Therefore, it is not allowed to configure a VLAN SAP with VID 100 on port 1/1/3, where a CP SAP is configured with CP 10, as follows:

```
*[ex:/configure service vpls "VPLS 1" sap 1/1/3:100]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:100 - Configuration change
 failed validation - sap conflicts with connection-profile-vlan 10
```

- No CP SAPs can be added with overlapping VLAN ranges on the same port for dot1q (or on the same port- and service-delimiting tag for QinQ), as follows. CP 1 contains VLAN range from 7 to 9, which overlaps with VLAN range from 5 to 100 in CP 10.

```
# on PE-1:
configure {
    connection-profile {
        vlan 1 {
            qtag-range 7 {
                end 9
            }
```

```
*[ex:/configure service vpls "VPLS 1" sap 1/1/3:cp-1]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:7 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:8 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
```

© 2026 Nokia.

```
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/1/3:cp-1 - Configuration change
 failed validation - a sap 1/1/3:9 in the connection-profile-vlan conflicts with connect-
profile-vlan 10
```

```
*[ex:/configure service vpls "VPLS 1" sap 1/2/1:100.cp-1]
A:admin@PE-1# commit
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.7 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.8 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
MINOR: COMMON #238: configure service vpls "VPLS 1" sap 1/2/1:100.cp-1 - Configuration
 change failed validation - a sap 1/2/1:100.9 in the connection-profile-vlan conflicts with
 connect-profile-vlan 10
```

However, the CP can be referred to by SAPs on other ports for dot1q or for QinQ on other combinations of port and service-delimiting VLAN.

- CP SAPs can be added when they contain non-overlapping VLAN ranges on the same port, as follows. CP 3 contains one VLAN range with only one VID: 3. This VLAN range (3) does not overlap with any VLAN range in the CP SAPs assigned to VPLS 1.

```
# on PE-1:
configure {
    connection-profile {
        vlan 3 {
            qtag-range 3 {
                end 3
            }
        }
    }
    service {
        vpls "VPLS 1" {
            sap 1/1/3:cp-3 {
            }
            sap 1/2/1:100.cp-3 {
            }
```

VPLS 1 contains the following SAPs. There is no overlap between the VLAN ranges on a port (or port and service-delimiting tag for QinQ).

```
[/]

Regular and default SAPs consume one SAP instance each, whereas CP SAPs consume a number of SAP instances equal to the number of VLANs in the range. The following shows that there are ten SAP entries (in this example, nine SAPs in VPLS 1 and one SAP in Epipe 2), which can be regular, default, or CP SAP entries:

```
[/]

===============================================================================
```

However, the number of SAP instances consumed for card 1 FP 1 exceeds the number of SAP entries in the system, as follows:

```
[/]
A:admin@PE-1# tools dump resource-usage card 1 fp 1

===============================================================================
Resource Usage Information for Card Slot #1 FP #1
===============================================================================
                                                 Total   Allocated        Free
-------------------------------------------------------------------------------
---snip---
                              SAP Instances |      63999       1497      62502
---snip---
===============================================================================
```

The calculation of the number of SAP instances is as follows. In this example, CP 10 is used in five SAPs (four in VPLS 1 and one in Epipe 2) and contains the following VLAN ranges:

```
[/]
A:admin@PE-1# show connection-profile-vlan 10

5                   100                           03/31/2021 09:11:59
150                 300                           03/31/2021 09:11:59
350                 400                           03/31/2021 09:12:08
===============================================================================
===============================================================================
```

The number of VLANs in the VLAN ranges of CP 10 equals 298. For each of the five SAP entries with CP 10, 298 SAP instances are used, for a total of 1490. As well, there is one CP SAP using CP 1 with three VLANs in the VLAN range from 7 to 9 (for three more SAP instances). Three CP SAPs use CP 3 with only VID 3 in the VLAN range (for three more SAP instances), and one SAP is a regular SAP that consumes one SAP instance. Therefore, the total number of SAP instances is 1497.

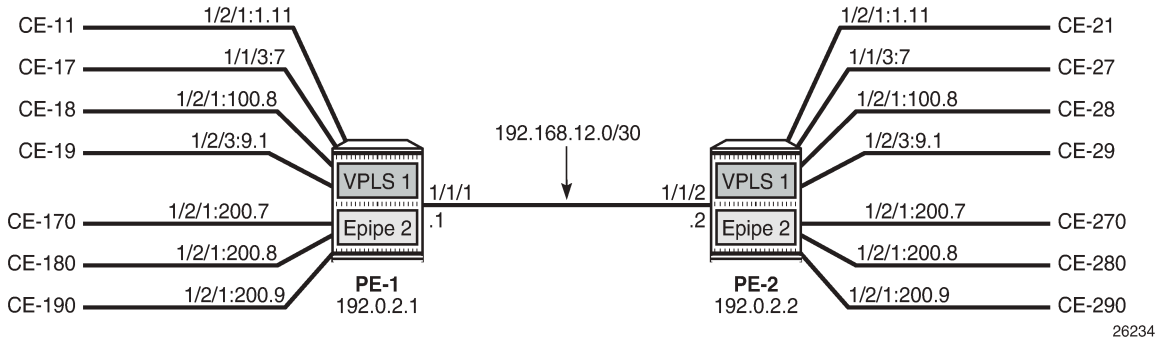
Configuration

Figure 335: Example topology shows the example topology used in this chapter.

Figure 335: Example topology



The initial configuration on the PEs includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS (or OSPF) between the PEs
- LDP between the PEs

In this example, no BGP is configured and no BGP-EVPN will be configured in the VPLS and Epipe services. However, VLAN ranges can be applied in EVPN VPLS and EVPN Epipe services.

VLAN ranges in VPLS services

Figure 336: Example topology for VLAN ranges in VPLS 1 shows the example topology for VPLS 1 with a combination on VLAN SAPs and CP SAPs. The port:VID represents the port to which the CE is connected and the VID sent by the CE; for example, CE-17 is connected to port 1/1/3 on PE-1 and sends frames with VID 7. When VLAN ranges are used, the port:VID 1/1/3:7 does not represent the configured SAP, which is 1/1/3:cp-1.

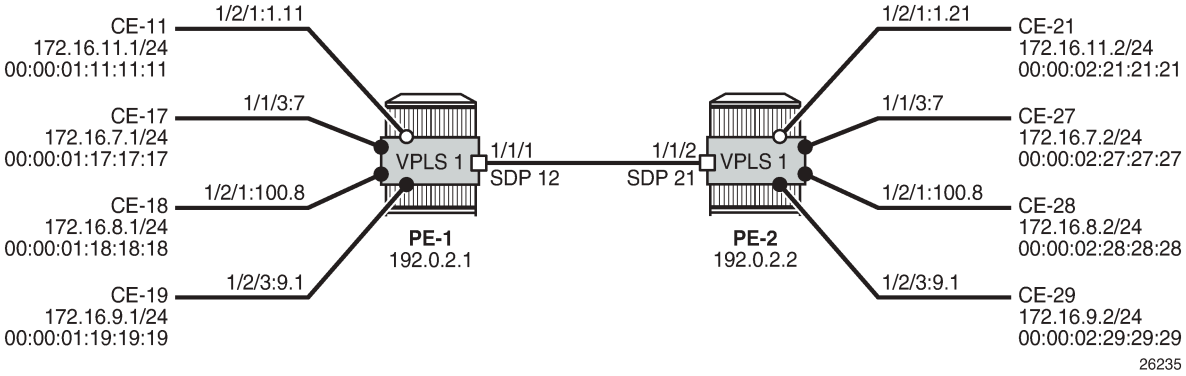
Use subject to Terms available at: www.nokia.com/terms.

Figure 336: Example topology for VLAN ranges in VPLS 1



The service configuration for VPLS 1 on PE-1 is as follows:

```
# on PE-1:
configure {
    service {
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
        vpls "VPLS 1" {
            admin-state enable
            service-id 1
            customer "1"
            spoke-sdp 12:1 {
            }
            sap 1/1/3:cp-1 {
            }
            sap 1/2/1:1.11 {
            }
            sap 1/2/1:100.cp-1 {
            }
            sap 1/2/3:cp-1.* {
            }
        }
```

The configuration of VPLS 1 on PE-2 is as follows:

```
‘# on PE-2:
configure {
    service {
        sdp 21 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.1
            }
        }
        vpls "VPLS 1" {
            admin-state enable
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            service-id 1
            customer "1"
            spoke-sdp 21:1 {
            }
            sap 1/1/3:cp-1 {
            }
            sap 1/2/1:1.21 {
            }
            sap 1/2/1:100.cp-1 {
            }
            sap 1/2/3:cp-1.* {
            }
        }
```

When the CEs send traffic to each other, such as ICMP echo requests, the MAC addresses are learned in the SAPs, and the forwarding database (FDB) on PE-1 is as follows:

```
[/]
A:admin@PE-1# show service id 1 fdb detail

===============================================================================

VLAN manipulation in dot1q SAPs

Figure 337: Customer VIDs are popped and pushed by dot1q VLAN SAPs shows the VLAN manipulation for VLAN SAPs. CE-17 and CE-18 are connected to VLAN SAPs, where the VLAN tag with VID 7 will be popped or pushed. VLAN translation is possible, but does not apply. The configuration of the SAPs in VPLS 1 on PE-1 and PE-2 is modified as follows:

```
# on PE-1, PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:cp-1
            sap 1/1/3:7 {
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 337: Customer VIDs are popped and pushed by dot1q VLAN SAPs

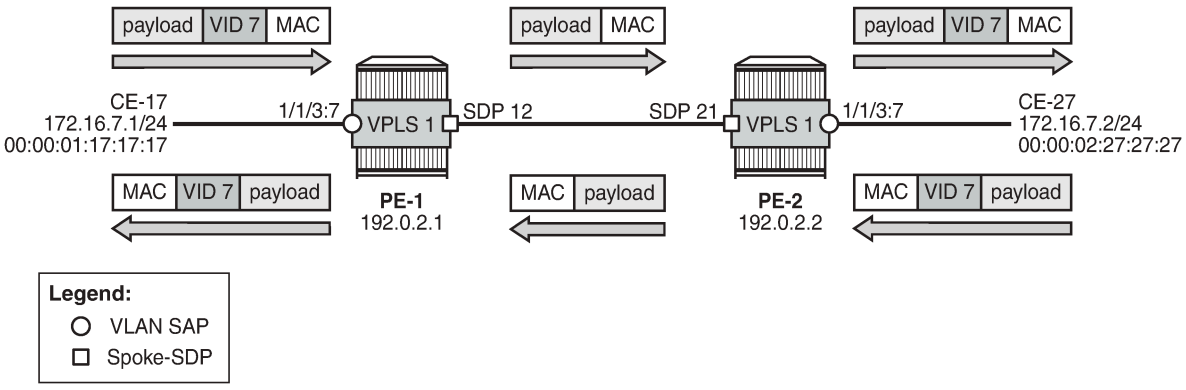

Figure 338: Customer VID is preserved between two dot1q CP SAPs shows how the customer VID 7 is preserved between CE-17 and CE-27 when CP SAPs are used instead of VLAN SAPs. The configuration for the SAPs is modified as follows:

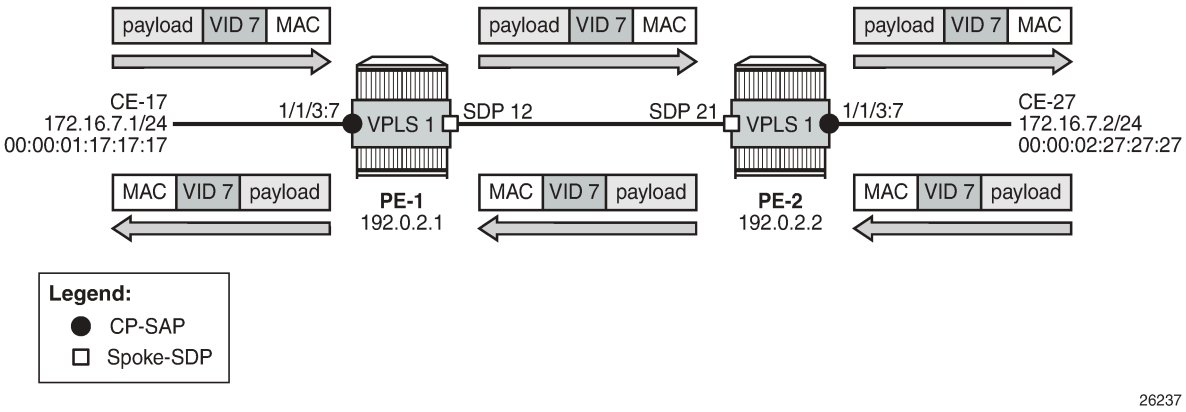
```
# on PE-1, PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:7
            sap 1/1/3:cp-1 {
            }
```

CE-17 sends frames with VID 7 to dot1q CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1, and this CP SAP preserves the VLAN tag. When the frames with VID 7 reach the egress CP SAP 1/1/3:cp-1 of VPLS 1 on PE-2, the egress CP SAP preserves the VID, and the frames are forwarded to CE-27. Traffic in the opposite direction is treated in the same way: the customer VID is preserved between the CEs.

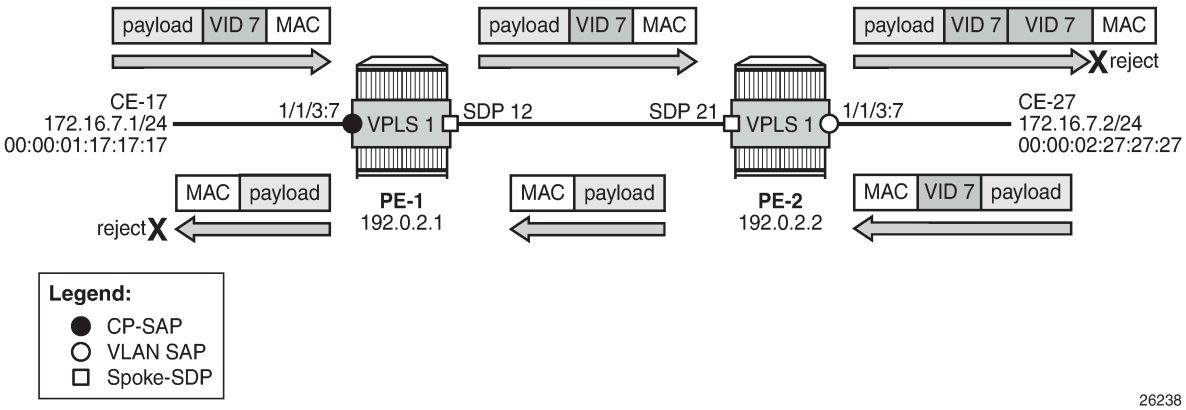
Figure 338: Customer VID is preserved between two dot1q CP SAPs



No traffic is possible between a CP SAP in VPLS 1 on PE-1 and a VLAN SAP in VPLS 1 on PE-2, as shown in Figure 339: No traffic between dot1q CP SAP and dot1q VLAN SAP.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 339: No traffic between dot1q CP SAP and dot1q VLAN SAP



The CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 remains unchanged, whereas the SAP in VPLS 1 on PE-2 is reconfigured as VLAN SAP 1/1/3:7 for VLAN 7, as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/1/3:cp-1
            sap 1/1/3:7 {
            }
```

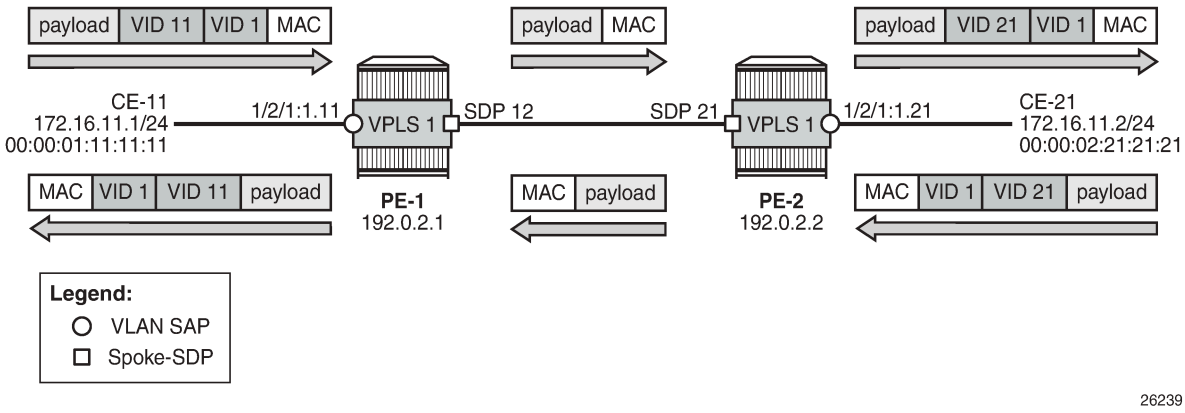
Frames from CE-17 are forwarded by CP SAP 1/1/3:cp-1 in VPLS 1 on PE-1 without any changes to the VLAN tag. The tagged frames reach the VLAN SAP 1/1/3:7, where another VLAN tag with VID 7 is pushed onto the frame. The receiver CE-27 rejects the double-tagged frame. When CE-27 sends traffic to CE-17, the VLAN SAP 1/1/3:7 in VPLS 1 on PE-2 pops the VLAN tag and the frame is forwarded untagged to PE-1. The CP SAP 1/1/3:cp-1 on PE-1 does not push any VLAN tag and the frame is forwarded untagged to CE-17, where it is rejected.

VLAN manipulation in QinQ SAPs

Figure 340: Traffic between two QinQ VLAN SAPs - VLAN translation shows the VLAN manipulation in QinQ VLAN SAPs that pop and push the VLAN labels. In the example, the customer VID is translated.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 340: Traffic between two QinQ VLAN SAPs - VLAN translation



CE-11 sends double-tagged traffic to QinQ VLAN SAP 1/2/1:1.11 in VPLS 1 on PE-1. This VLAN SAP pops both labels and forwards the frame untagged to PE-2. The egress VLAN SAP 1/2/1:1.21 in VPLS 1 on PE-2 pushes a label stack with two labels: the inner label with VID 21 and the outer label with VID 1. Both VIDs can be translated, but in this example, only the inner label gets another VID.

Figure 341: No traffic between two QinQ CP SAPs - VLAN translation not supported shows that VLAN translation is not possible between two QinQ CP SAPs. In the example, the outer tag with VID 1 is popped by the CP SAPs (VLAN translation is possible for this VLAN tag, but not done here) and the inner tag with VID 11 or 21 is preserved by the CP SAPs, which implies that the received frames will be rejected.

In this example, CP 2 is configured on both PE-1 and PE-2 with one VLAN range with one VID (11 or 21), as follows:

```
# on PE-1:
configure {
    connection-profile {
        vlan 2 {
            qtag-range 11 {
                end 11
            }
```

```
# on PE-2:
configure {
    connection-profile {
        vlan 2 {
            qtag-range 21 {
                end 21
            }
```

The VLAN SAP 1/2/1:1.11 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

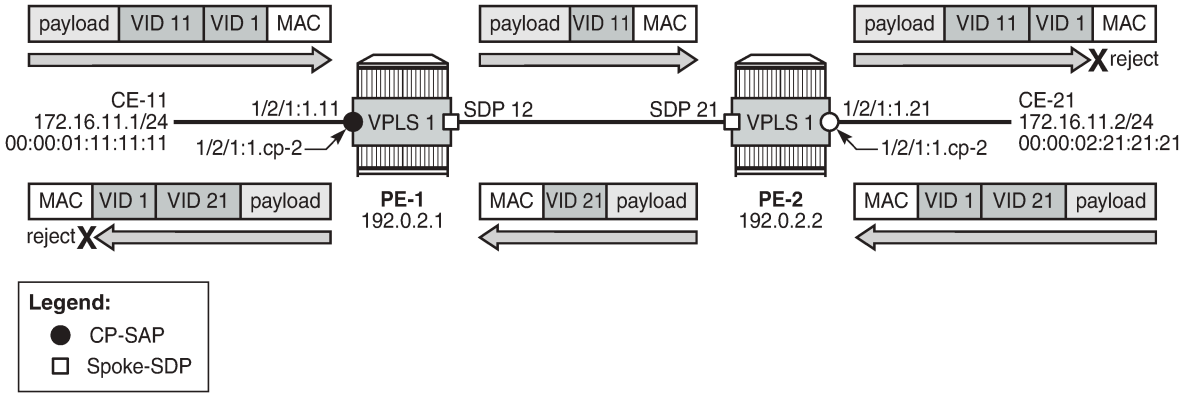
```
# on PE-1:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/2/1:1.11
            sap sap 1/2/1:1.cp-2 {
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Likewise, the VLAN 1/2/1:1.21 is replaced by CP SAP 1/2/1:1.cp-2, as follows:

```
# on PE-2:
configure {
    service {
        vpls "VPLS 1" {
            delete sap 1/2/1:1.21
            sap sap 1/2/1:1.cp-2 {
            }
```

Figure 341: No traffic between two QinQ CP SAPs - VLAN translation not supported



CE-11 sends double-tagged frames to SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1. This CP SAP pops the outer tag with VID 1, but preserves the VLAN tag with VID 11. The single-tagged frame is sent to PE-2 where CP SAP 1/2/1:1.cp-2 pushes an outer tag with VID 1 onto the frame. This double-tagged frame is sent to CE-12 where it is rejected, because an inner label with VID 21 is expected.

When CE-21 sends frames to CE-11, the frames will be double-tagged with inner tag VID 21 and outer tag 1. The outer tag is popped by the ingress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-2, but the inner tag is preserved. The egress SAP 1/2/1:1.cp-2 in VPLS 1 on PE-1 preserves the inner tag with VID 21 and pushes an outer tag with VID 1. This double-tagged frame is rejected by CE-11, because another inner tag is expected, with VID 11 instead of VID 21.

Figure 342: Traffic between two QinQ CP SAPs - no VLAN translation shows how traffic is sent between two QinQ CP SAPs without VLAN translation. Both CE-18 and CE-28 send double-tagged frames with inner tag VID 8 and outer tag VID 100. The tag with VID 100 need not be the same on both CEs, because it is popped and pushed by the CP SAPs; only the tag with VID 8 from the VLAN range must be unchanged.

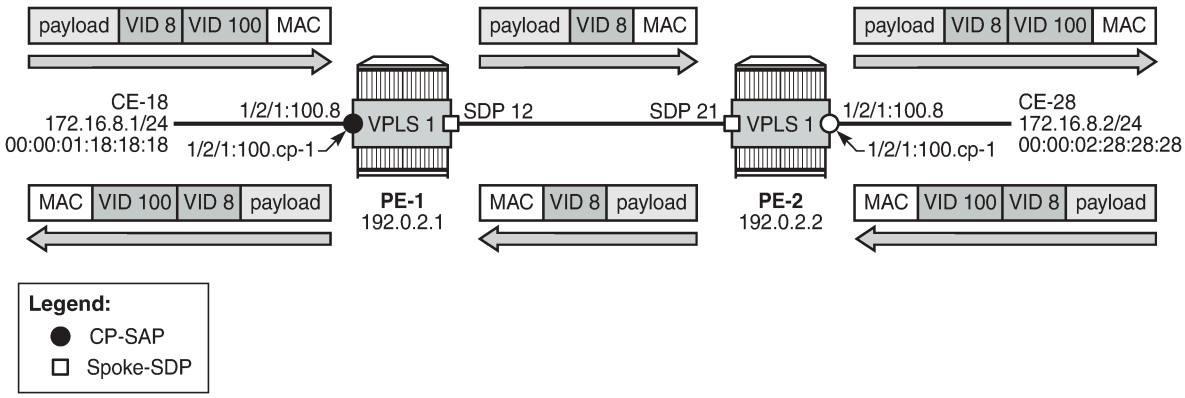
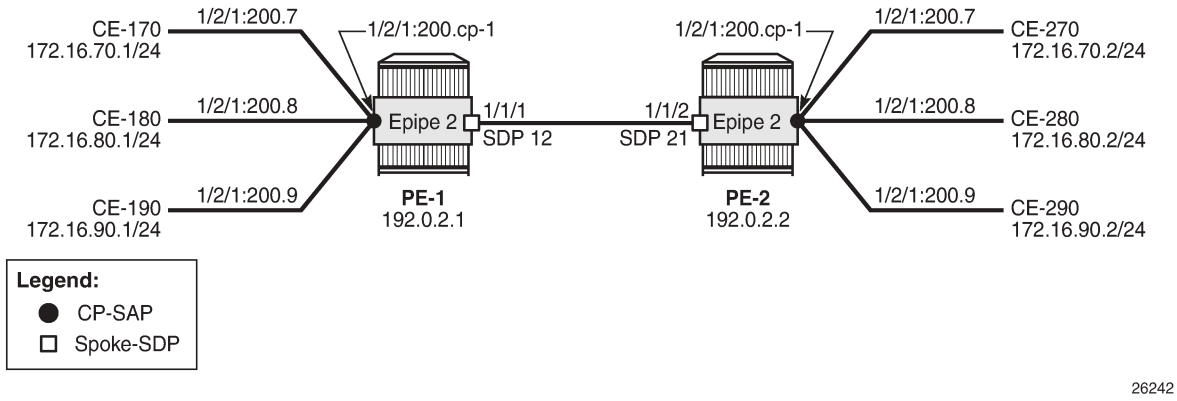
Figure 342: Traffic between two QinQ CP SAPs - no VLAN translation



VLAN ranges in Epipe services

Figure 343: Example topology for VLAN ranges in Epipe 2 shows the example topology for VLAN ranges in Epipe 2.

Figure 343: Example topology for VLAN ranges in Epipe 2



Epipe 2 is configured with one CP SAP and a spoke-SDP, as follows:

```
# on PE-1:
configure {
    service {
        epipe "Epipe 2" {
            admin-state enable
            service-id 2
            customer "1"
            spoke-sdp 12:2 {
            }
            sap 1/2/1:200.cp-1 {
            }
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
        }
        sdp 12 {
            admin-state enable
            delivery-type mpls
            ldp true
            far-end {
                ip-address 192.0.2.2
            }
        }
```

CE-170 and CE-270 send double-tagged frames with inner VID 7 and outer VID 200. The inner VID 7 is preserved by the CP SAPs; therefore, CE-170 can only communicate with CE-270, not with any other CE at the other end, because they have different customer VIDs.

Conclusion

CP SAPs can be used to build services that can be bundled as per MEF 10.3 and RFC 7432. Multiple customer VIDs can be mapped to one CP-SAP.

VXLAN Forwarding Path Extension

This chapter provides information about VXLAN Forwarding Path Extension.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written based on SR OS Release 15.0.R4, but the MD-CLI in the current edition corresponds to SR OS Release 21.2.R2. Virtual eXtensible Local Area Network (VXLAN) Forwarding Path Extension (FPE) is supported in SR OS Release 14.0.R4, and later. IPv6 addresses are supported for EVPN-VXLAN BGP peering in SR OS release 15.0.R1, and later.

Overview

Use cases

VXLAN Forwarding Path Extension (FPE) is an SR OS feature that enables VXLAN tunnels to terminate on non-system IPv4 and IPv6 Destination Addresses (DAs). The non-system IPv4/IPv6 VXLAN termination feature can be applied in the following use cases:

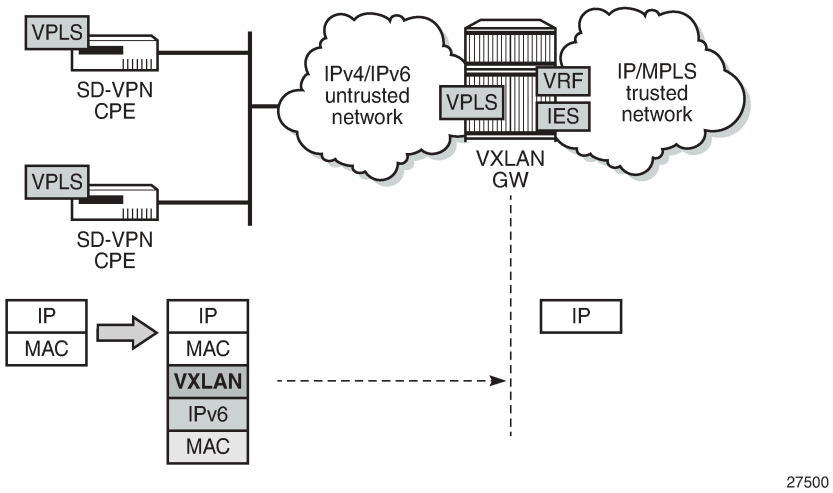
- VXLAN Gateway (GW) in Software-Defined VPNs (SD-VPNs)
- VXLAN IPv6 underlay for Data Centers (DCs)

VXLAN GW in SD-VPNs

Traffic transported on a VXLAN is usually connected to a trusted environment through a VPRN running in a private IP/MPLS network. The VXLAN GW system IP address is used for all internal management and MPLS termination in the trusted network. However, in this use case, SR OS routers are expected to be used as a VXLAN GW in SD-VPNs where the VXLAN GW terminates untrusted VXLAN tunnels initiated on the SD-VPN CPEs and forwards packets to a trusted IP/MPLS network, as shown in Figure 344: VXLAN GW in an SD-VPN.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 344: VXLAN GW in an SD-VPN

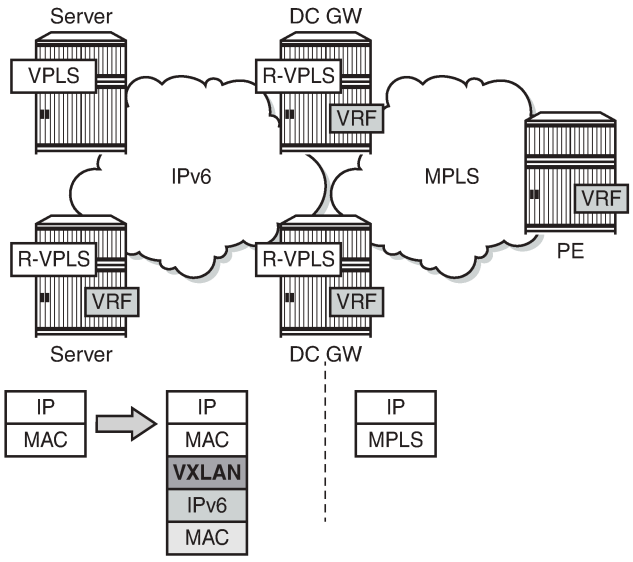


For security reasons, service providers will not expose system IP addresses to the untrusted IP network. Therefore, an IPv4 or IPv6 loopback address will be defined and used for VXLAN termination. The VXLAN tunnel can be terminated in a VPLS, an Epipe, or an R-VPLS service connected to a VPRN.

VXLAN IPv6 underlay for DCs

Some service providers migrate their entire network infrastructure to IPv6, including the DC network, so the DC GW must be able to terminate a VXLAN over an IPv6 infrastructure. Layer 2 (VPLS termination) and Layer 3 (R-VPLS termination) DC interconnect are both supported. Figure 345: VXLAN IPv6 underlay for DC shows the VXLAN IPv6 underlay for DC.

Figure 345: VXLAN IPv6 underlay for DC



© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

VXLAN FPE function

The following applies to VXLAN FPE:

- In an SR OS node, VXLAN tunnels can be terminated in four different VXLAN Tunnel Endpoints (VTEPs):
  - System IPv4 address
  - Up to three non-system IPv4/IPv6 addresses

  This limit is based on the number of supported source IP addresses that can be used for VXLAN encapsulation.
- The preceding four terminating IP addresses can be used in addition to the Assisted Replication IP address (AR IP). The AR IP does not count against this limit of four VTEPs. See chapter Layer 2 Multicast Optimization for EVPN-VXLAN — Assisted Replication"Layer 2 Multicast Optimization for EVPN-VXLAN - Assisted Replication" for more information about AR.
- VXLAN FPE requires PXC ports; see the "Port Cross-Connect (PCX)" chapter in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Advanced Configuration Guide for MD CLI*.
  - Ingress traffic from a VXLAN with an IP DA equal to a loopback address will be redirected to the PXC port where the IP header will get additional processing.
  - Usually, only the ingress traffic from the VXLAN is redirected to the PXC port. The egress traffic to the VXLAN tunnel can go straight out of the egress network port, except for R-VPLS traffic toward an IPv6 VXLAN that is redirected to the PXC port.
- The VPLS/R-VPLS functionality is not impacted by the choice of VTEP termination (system IP address or not).

Provisioning model

Non-system IP VXLAN termination and VXLAN IPv6 underlay are both provisioned as per the following steps:

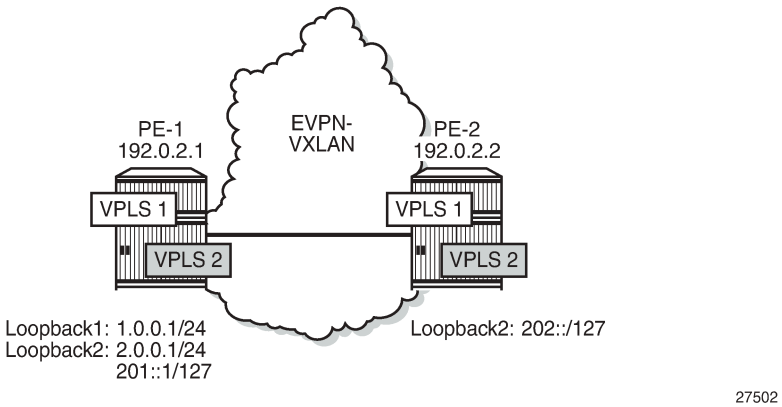
1. Create an FPE
2. Associate the FPE with VXLAN termination
3. Configure a router loopback interface
4. Configure non-system VXLAN termination VTEP addresses
5. Add the service configuration

Configuration

Figure 346: Example topology for VXLAN FPE shows the example topology with two PEs in an EVPN-VXLAN network. The loopback addresses in the base router will be used for non-system IP VXLAN termination.

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Figure 346: Example topology for VXLAN FPE



The initial configuration includes the cards, MDAs, ports, router interfaces and IGP. BGP is configured for address family EVPN, for example on PE-1 as follows:

```
# on PE-1:
configure {
    router "Base" {
        autonomous-system 64500
        bgp {
            rapid-withdrawal true
            split-horizon true
            rapid-update {
                evpn true
            }
            group "internal" {
                peer-as 64500
                family {
                    evpn true
                }
            }
            neighbor "192.0.2.2" {
                group "internal"
            }
        }
```

In this example, the BGP peering is IPv4-based, but EVPN-VXLAN routes can also be exchanged between IPv6 BGP peers.

Non-system IP VXLAN termination

Create FPEs

PXC is used as a simple back-to-back cross-connect. An FPE uses the PXC ports assigned in the FPE path, either a PXC port or a LAG-based PXC. For non-system IP VXLAN terminations between VPLSs, the PXC is only required on the ingress (from VXLAN, or from PE-1 to GW PE-2). PXC 1 and PXC 2 are created on PE-1, as follows:

```
# on PE-1:
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
configure {
    port 1/2/1 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port 1/2/2 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    port pxc-1.a {
        admin-state enable
    }
    port pxc-1.b {
        admin-state enable
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port-xc {
        pxc 1 {
            admin-state enable
            port-id 1/2/1
        }
        pxc 2 {
            admin-state enable
            port-id 1/2/2
        }
    }
```

The sub-ports of PXC 1 are operationally up, as follows.

```
[/]
A:admin@PE-1# show port pxc 1

===============================================================================
Ports on Port Cross Connect 1
===============================================================================
Port          Admin Link Port    Cfg  Oper LAG/ Port Port Port   C/QS/S/XFP/
Id            State      State   MTU  MTU  Bndl Mode Encp Type   MDIMDX
-------------------------------------------------------------------------------
pxc-1.a       Up    Yes  Up      1574 1574    - hybr dotq xgige
pxc-1.b       Up    Yes  Up      1574 1574    - hybr dotq xgige
===============================================================================
```

The following FPEs use the PXCs.

```
# on PE-1, PE-2:
configure {
    fwd-path-ext {
        fpe 1 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
            path {
                pxc 1
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
        }
```

These FPEs are created without defining a range of SDP IDs. SDP IDs are required in case of R-VPLS services terminating IPv6 VXLAN tunnels, where the FPE is also used at the egress and an internal static SDP is created to allow for the required extra processing.

When the FPE has no VXLAN termination associated, no internal router interfaces are created, so the only router interfaces are the system interface and the interface between PE-1 and PE-2, as follows.

```
[/]
A:admin@PE-1# show router interface

===============================================================================
Interface Table (Router: Base)

===============================================================================
```

Associate the FPEs with VXLAN termination

The following command associates the FPEs with VXLAN termination.

```
# on PE-1, PE-2:
configure {
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 1 {
            path {
                pxc 1
            }
            application {
                vxlan-termination {
                }
            }
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                vxlan-termination {
```

```
                }
            }
        }
```

When attempting to associate the FPEs with VXLAN termination without configuring a range of SDP IDs for FPE, the following error is raised:

```
*[ex:/configure fwd-path-ext fpe 1 application vxlan-termination]
A:admin@PE-1# commit
MINOR: FPE #1021: configure fwd-path-ext fpe 1 - sdp-id-range is not configured - configure
 fwd-path-ext sdp-id-range
```

After the FPEs are associated with VXLAN terminations, the system creates two internal router interfaces per FPE, one per PXC sub-port:

```
[/]
A:admin@PE-1# show router interface

```

Configure router loopback interfaces

The following loopback interfaces are configured in PE-1 and added to the IS-IS context:

```
# on PE-1:
configure {
    router "Base"
        interface "loopback1" {
            loopback
            ipv4 {
                primary {
                    address 1.0.0.1
                    prefix-length 24
                }
            }
        }
        interface "loopback2" {
            loopback
            ipv4 {
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                primary {
                    address 2.0.0.1
                    prefix-length 31
                }
            }
            ipv6 {
                address 201:: {
                    prefix-length 127
                }
            }
        }
        isis 0 {
            interface "loopback1" {
            }
            interface "loopback2" {
            }
        }
```

A non /32 or /128 subnet must be assigned to the loopback interface, because the system cannot terminate VXLAN on a local interface address. In the preceding example, all addresses in the subnet 1.0.0.0/24 can be used for VXLAN tunnel termination, except for 1.0.0.1. The subnet will be advertised by the IGP. The subnet can be as small as /31 or /127, as for example for interface "loopback2".

In this scenario, only one loopback interface with an IPv4 address is sufficient: interface "loopback1" with IPv4 address 1.0.0.1/24. There is no need to configure loopback interfaces in the GW PE-2, because VXLAN FPE is only required in the ingress (from VXLAN to GW).

Configure non-system VTEP addresses

Up to three non-system VTEP addresses can be configured to terminate VXLAN tunnels and their corresponding FPEs; on PE-1 as follows:

```
# on PE-1:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 1.0.0.2 {
                    fpe-id 1
                }
                tunnel-termination 2.0.0.2 {
                    fpe-id 2
                }
                tunnel-termination 201::1 {
                    fpe-id 2
                }
```

No non-system VTEP addresses need to be configured on PE-2.

When attempting to configure the IP address of the loopback interface as a VXLAN tunnel termination, the following error is raised:

```
*[ex:/configure service system vxlan tunnel-termination 1.0.0.1]
A:admin@PE-1# commit
MINOR: MGMT_CORE #4001: configure service system vxlan tunnel-termination 1.0.0.1 - IP address
 matches a local interface IP address
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When attempting to configure more than three non-system VTEP addresses, the following error is raised:

```
*[ex:/configure service system vxlan tunnel-termination 1.0.0.100]A:admin@PE-1# commit
MINOR: MGMT_CORE #232: configure service system vxlan tunnel-termination 1.0.0.100 - Reached
 maximum number of entries - maximum is 3 but has 4
```

When the non-system VTEP addresses are configured, an internal loopback interface "_tmnx_vli_vxlan_1_131077" is created that can respond to ICMP requests.

```
[/]
A:admin@PE-1# show router interface

Interfaces : 9
===============================================================================
```

The system does not verify whether there is a local base router loopback interface with a subnet corresponding to the VTEP address. If a tunnel termination address is configured and the FPE is up, the system will start terminating VXLAN traffic and responding using ICMP for that address, regardless of the presence of a loopback interface in the base router. It is also possible that a non-loopback interface has an IP address in the configured subnet.

Configure the VPLS

A VPLS will be configured with EVPN-VXLAN enabled. By default, the system IP address will be used as the source VTEP of the VXLAN-encapsulated frames. This default behavior can be overruled by the

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

source-vtep command in the VPLS. The IP address corresponds to the non-system VTEP address configured in the preceding step (VXLAN tunnel termination). VPLS 1 is configured on PE-1 as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                source-vtep 1.0.0.2
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
            sap 1/1/2:1 {
            }
```

When attempting to configure an IP address different from the VTEP addresses, the following error is raised:

```
[ex:/configure service vpls "EVI-1" vxlan]
A:admin@PE-1# source-vtep 1.0.0.99

*[ex:/configure service vpls "EVI-1" vxlan]
A:admin@PE-1# commit
MINOR: MGMT_CORE #224: configure service vpls "EVI-1" vxlan source-vtep - Entry does not
 exist - configure service system vxlan tunnel-termination 1.0.0.99
```

A different VTEP address can be configured as **source-vtep** in different services on the same PE, as follows:

```
# on PE-1:
configure {
    service {
        vpls "EVI-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 201::1
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
```

© 2026 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The configuration of VPLS 1 on PE-2 does not include any VTEP address, because it is not required in the egress, as follows:

```
# on PE-2:
configure {
    service {
        vpls "EVI-1" {
            admin-state enable
            service-id 1
            customer "1"
            vxlan {
                instance 1 {
                    vni 1
                }
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 1
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

When a source VTEP is configured in VPLS 1 on PE-1, this VTEP address will be used as the IP source VTEP for VPLS 1 and BGP will use this VTEP to the BGP NLRI next-hop, as shown in the following BGP route update messages.

The following BGP EVPN inclusive multicast route sent by PE-1 shows the configured source VTEP address 1.0.0.2 as NLRI next-hop, as originator address, and as tunnel endpoint.

```
# on PE-1:

Underlay IPv6 VXLAN termination

The configuration for underlay IPv6 VXLAN termination is similar to the non-system IP VXLAN termination. In the following example, R-VPLS 2 is configured; therefore, non-system VTEP addresses are configured in PE-2 as well as in PE-1. The changes required in PE-1 are as follows.

- IPv6 must be enabled on the router interfaces
- IPv6 native routing is configured in IS-IS
- IPv6 addresses are loopback address 201::/127 and VTEP address 201::1

```
# on PE-1:
configure {
    port-xc {
        pxc 2 {
            admin-state enable
            port-id 1/2/2
        }
    }
    port pxc-2.a {
        admin-state enable
    }
    port pxc-2.b {
        admin-state enable
    }
    port 1/2/2 {
        admin-state enable
        ethernet {
            mode hybrid
            dot1x {
                tunneling true
            }
        }
    }
    fwd-path-ext {
        sdp-id-range {
            start 10000
            end 10127
        }
        fpe 2 {
            path {
                pxc 2
            }
            application {
                vxlan-termination {
                }
            }
        }
    }
    router "Base" {
        interface "int-PE-1-PE-2" {
            port 1/1/1
            ipv4 {
                primary {
                    address 192.168.12.1
                    prefix-length 30
                }
            }
            ipv6 {
            }
        }
```

```
        interface "loopback2" {
            loopback
            ipv4 {
                primary {
                    address 2.0.0.1
                    prefix-length 31
                }
            }
            ipv6 {
                address 201:: {
                    prefix-length 127
                }
            }
        }
        isis 0 {
            ipv6-routing native
            interface "loopback2" {
            }
        }
    }
    service {
        system {
            vxlan {
                tunnel-termination 201::1 {
                    fpe-id 2
                }
            }
        }
        vpls "EVI-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 201::1
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The service configuration on PE-2 is as follows.

```
# on PE-2:
configure {
    service {
        system {
            vxlan {
                tunnel-termination 202:: {
                    fpe-id 2
                }
            }
        }
```

```
        vpls "EVI-2" {
            admin-state enable
            service-id 2
            customer "1"
            vxlan {
                source-vtep 202::
                instance 1 {
                    vni 2
                }
            }
            routed-vpls {
            }
            bgp 1 {
            }
            bgp-evpn {
                evi 2
                vxlan 1 {
                    admin-state enable
                    vxlan-instance 1
                }
            }
        }
```

The routing table for IPv6 on PE-1 shows that an internal static route is configured for the source VTEP 201::1 using the FPE internal interface "_tmnx_fpe_2.a". The route to egress VTEP 202:: is an IS-IS route.

```
[/]
A:admin@PE-1# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
201::/127                                     Local   Local     00h16m34s  0
       loopback2                                                    0
201::1/128                                    Remote  Static    00h11m53s  5
       fe80::201-"_tmnx_fpe_2.a"                                    1
202::/127                                     Remote  ISIS      00h00m06s  15
       fe80::14:1ff:fe01:1-"int-PE-1-PE-2"                          10
-------------------------------------------------------------------------------
No. of Routes: 3
```

Likewise, the routing table for IPv6 on PE-2 shows an internal static route for source VTEP 202:: using the FPE internal interface "_tmnx_fpe_2.a":

```
[/]
A:admin@PE-2# show router route-table ipv6

===============================================================================
IPv6 Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
201::/127                                     Remote  ISIS      00h00m06s  15
       fe80::10:1ff:fe01:1-"int-PE-2-PE-1"                          10
202::/127                                     Local   Local     00h00m12s  0
       loopback2                                                    0
202::/128                                     Remote  Static    00h00m13s  5
       fe80::201-"_tmnx_fpe_2.a"                                    1
```

```
-------------------------------------------------------------------------------
No. of Routes: 3
```

When non-system IPv6 VTEP addresses are used in an R-VPLS, VTEP addresses need to be configured on ingress and egress VXLAN. The system creates an internal SDP binding for the egress processing. A range of SDP IDs has been configured from 10000 to 10127. The following command lists all SDP bindings for FPE:

```
[/]
A:admin@PE-2# show service sdp-using | match "Fpe"
2          10002:2            Fpe    fpe_2.b             Up    524287  524287
```

The internal SDP has ID 10002 and the far-end is fpe_2.b. The following command shows that the SDP source is FPE.

```
[/]
A:admin@PE-2# show service sdp 10002 detail | match "Sdp" pre-lines 4 post-lines 10

===============================================================================
Service Destination Point (Sdp Id : 10002) Details
===============================================================================
-------------------------------------------------------------------------------
 Sdp Id 10002  -fpe_2.b
-------------------------------------------------------------------------------
Description           : (Not Specified)
SDP Id                : 10002SDP Source         : fpe

Conclusion

VXLAN FPE is required to terminate VXLAN tunnels on non-system IPv4/IPv6 addresses and to configure IPv6 underlay.
