Table of Contents

1	Getting Started	27
1.1	About This Guide.....	27
1.2	Nokia SR OS Services Configuration Process.....	28
2	Introduction to Triple Play	29
2.1	In This Section.....	29
2.2	Nokia's Triple Play Service Delivery Architecture.....	30
2.2.1	Introduction to Triple Play.....	30
2.2.2	Blueprint for Optimizing Triple Play Service Infrastructures	30
2.2.3	Architectural Foundations.....	31
2.2.4	Optimizing Triple Play Service Infrastructures.....	33
2.2.4.1	Distributed Service Edges	34
2.2.4.2	Service Differentiation, QoS Enablement.....	36
2.2.4.3	Virtual MAC Subnetting for VPLS.....	40
2.3	Services.....	43
2.3.1	Service Types.....	43
2.3.2	Service Policies	44
2.4	Nokia Service Model.....	45
2.4.1	Introduction.....	45
2.4.2	Service Entities.....	46
2.4.3	Customers	47
2.4.4	Service Access Points (SAPs).....	47
2.4.4.1	SAP Encapsulation Types and Identifiers	48
2.4.4.2	Ethernet Encapsulations.....	48
2.4.4.3	SAP Considerations	49
2.4.5	Service Distribution Points (SDPs)	50
2.4.5.1	SDP Binding	51
2.4.5.2	Spoke and Mesh SDPs	51
2.4.5.3	SDP Encapsulation Types.....	52
2.4.5.4	SDP Keepalives.....	53
2.5	Epipe Service Overview	54
2.6	VPLS Service Overview	55
2.6.1	Split Horizon SAP Groups and Split Horizon Spoke SDP Groups	55
2.6.1.1	Residential Split Horizon Groups.....	56
2.7	IES Service Overview.....	56
2.7.1	IP Interface	57
2.8	VPRN Service Overview.....	58
2.9	Deploying and Provisioning Services	58
2.9.1	Phase 1: Core Network Construction	59
2.9.2	Phase 2: Service Administration.....	59
2.9.3	Phase 3: Service Provisioning.....	59
2.10	Configuration Notes.....	59
2.10.1	General.....	60
2.11	Configuring Triple Play Services with CLI	61
2.11.1	Configuring VPLS Residential Split Horizon Groups	61

2.11.1.1	Configuring Static Hosts	62
2.12	Triple Play Services Command Reference	69
2.12.1	Command Hierarchies	69
2.12.1.1	IES Triple Play Commands	70
2.12.1.2	VPLS Triple Play Commands	72
2.12.1.3	Service DHCP and Anti-Spoof Filtering Commands	76
2.12.1.4	Triple Play ARP Commands	78
2.12.1.5	Triple Play Multicast Commands	79
2.12.1.6	Show Commands	81
2.12.1.7	Clear Commands	83
2.12.1.8	Tools Commands	84
2.12.2	Command Descriptions	85
2.12.2.1	Global Commands	85
2.12.2.2	Service Commands	87
2.12.2.3	Show Commands	242
2.12.2.4	Clear Commands	356
2.12.2.5	Debug Commands	366
2.12.2.6	Tools Commands	369
3	DHCP Management	371
3.1	In This Chapter	371
3.2	DHCP Principles	372
3.3	DHCP Features	375
3.3.1	DHCP Relay	375
3.3.2	DHCPv4 Relay Proxy	376
3.3.3	Subscriber Identification Using Option 82 Field	383
3.3.3.1	Trusted and Untrusted	384
3.3.4	DHCP Snooping	385
3.3.5	DHCP Lease State Table	386
3.3.6	DHCP and Layer 3 Aggregation	389
3.3.6.1	DHCPv4 Snooping	389
3.3.6.2	DHCPv6 Snooping	390
3.3.7	Local DHCP Servers	392
3.3.7.1	Overview	392
3.3.7.2	Local DHCP Server Support	394
3.3.8	DHCPv6	395
3.3.8.1	DHCPv6 Relay Agent	395
3.3.8.2	DHCPv6 Prefix Options	396
3.3.8.3	Neighbor Resolution via DHCPv6 Relay	396
3.3.8.4	DHCPv6 Lease Persistency	396
3.3.8.5	Local Proxy Neighbor Discovery	396
3.3.8.6	IPv6oE Hosts Behind Bridged CPEs	397
3.3.8.7	IPv6 Link-Address Based Pool Selection	397
3.3.8.8	IPv6 Address/Prefix Stickiness	397
3.3.8.9	IPv4/v6 Linkage for Dual-Stack Hosts or Layer 3 RGs	398
3.3.8.10	Host Connectivity Checks for IPv6	398
3.3.9	Lease Query	398
3.3.10	DHCPv6 to Server Option	399

3.3.11	Flexible Host Identification in LUDB Based on DHCPv4/v6 Options	399
3.3.12	DHCP Caching	400
3.3.13	Flexible Creation of DHCPv4/6 Host Parameters	401
3.3.14	Python DTC Variables and API	401
3.3.14.1	DTC Debugging Facility.....	406
3.3.15	Virtual Subnet for DHCPv4 Hosts.....	406
3.3.16	Address Reservation for Sticky Leases.....	407
3.4	Proxy DHCP Server.....	408
3.4.1	Local DHCP Servers	413
3.4.1.1	Terminology	413
3.4.1.2	Overview.....	414
3.4.1.3	DHCP Lease Synchronization	418
3.4.1.4	Intercommunication Link Failure Detection	419
3.4.1.5	DHCP Server Failover States	420
3.4.1.6	Lease Time Synchronization	421
3.4.1.7	Maximum Client Lead Time (MCLT).....	423
3.4.1.8	Sharing IPv4 Address-Range or IPv6 Prefixes.....	426
3.4.1.9	Fast-Switchover of IP Address/Prefix Delegation.....	430
3.5	Local Address Assignment.....	432
3.5.1	Stateless Address Auto-configuration	432
3.6	Configuring DHCP with CLI	433
3.7	Common Configuration Tasks	433
3.7.1	Enabling DHCP Snooping	433
3.7.2	Configuring Option 82 Handling	434
3.7.3	Enabling DHCP Relay	435
3.7.4	Configuring Local User Database Parameters	436
3.8	Triple Play DHCP Command Reference	445
3.8.1	Command Hierarchies.....	445
3.8.1.1	Global DHCP Commands.....	445
3.8.1.2	Router DHCP Local User Database Commands.....	446
3.8.1.3	Service Commands	449
3.8.1.4	Local User Database Commands.....	461
3.8.1.5	Show Commands	468
3.8.1.6	Tools Commands	470
3.8.1.7	Clear Commands.....	471
3.8.1.8	Debug Commands.....	472
3.8.2	Command Descriptions	473
3.8.2.1	Triple Play DHCP Configuration Commands.....	473
3.8.2.2	Show Commands	577
3.8.2.3	Tools Commands	609
3.8.2.4	Clear Commands.....	616
3.8.2.5	Debug Commands.....	621
4	SLAAC	623
4.1	In This Chapter	623
4.2	Stateless Address Auto-configuration (SLAAC) Management	624
4.3	SLAAC Principles	624
4.4	Configuration Overview	624

4.5	Router-Solicit Trigger.....	624
4.6	SLAAC Address Assignment.....	625
4.7	Static SLAAC Prefix Assignment.....	625
4.8	Dynamic SLAAC Prefix Assignment.....	625
5	Point-to-Point Protocol over Ethernet Management	627
5.1	In This Chapter	627
5.2	PPPoE	627
5.2.1	PPPoE Authentication and Authorization	631
5.2.1.1	General Flow	631
5.2.1.2	RADIUS	632
5.2.1.3	Local User Database Directly Assigned to PPPoE Node	633
5.2.1.4	Subscriber per PPPoE Session Index	634
5.2.1.5	Local DHCP Server with Local User Database	637
5.2.2	Multiple Sessions Per MAC Address	638
5.2.3	Private Retail Subnets	639
5.2.4	IPCP Subnet Negotiation.....	640
5.2.4.1	Numbered WAN Support for Layer 3 RGs	641
5.2.5	IES as Retail Service for PPPoE Host.....	641
5.2.6	Unnumbered PPPoX	641
5.3	MLPPPoE, MLPPP(oE)oA with LFI on LNS	643
5.3.1	Terminology.....	643
5.3.2	LNS MLPPPoX.....	643
5.3.3	MLPPP Encapsulation.....	644
5.3.4	MLPPPoX Negotiation.....	645
5.3.5	Enabling MLPPPoX.....	646
5.3.6	Link Fragmentation and Interleaving (LFI).....	647
5.3.6.1	MLPPPoX Fragmentation, MRRU and MRU Considerations	648
5.3.7	LFI Functionality Implemented in LNS	650
5.3.7.1	Last Mile QoS Awareness in the LNS	652
5.3.7.2	BB-ISA Processing	654
5.3.7.3	LNS-LAC Link.....	655
5.3.7.4	AN-RG Link	656
5.3.7.5	Home Link	656
5.3.7.6	Optimum Fragment Size Calculation by LNS	656
5.3.8	Upstream Traffic Considerations	659
5.3.9	Multiple Links MLPPPoX With No Interleaving.....	659
5.3.10	MLPPPoX Session Support.....	660
5.3.11	Session Load Balancing Across Multiple BB-ISAs	663
5.3.12	BB-ISA Hashing Considerations.....	663
5.3.13	Last Mile Rate and Encapsulation Parameters	664
5.3.14	Link Failure Detection.....	667
5.3.15	CoA Support.....	667
5.3.16	Accounting	668
5.3.17	Filters and Mirroring.....	669
5.3.18	PTA Considerations.....	669
5.3.19	QoS Considerations	669
5.3.19.1	Dual-Pass	669
5.3.19.2	Traffic Prioritization in LFI.....	670

5.3.19.3	Shaping Based on the Last Mile Wire Rates	671
5.3.19.4	Downstream Bandwidth Management on Egress Port.....	673
5.3.20	Sub/Sla-Profile Considerations	673
5.3.21	Example of MLPPPoX Session Setup Flow	674
5.3.22	Other Considerations.....	676
5.4	Configuration Notes.....	676
5.5	PPP Command Reference	679
5.5.1	Command Hierarchies.....	679
5.5.1.1	PPPoE Policy Configuration Commands.....	679
5.5.1.2	PPPoE Service Commands.....	680
5.5.1.3	PPPoE Local User Database Commands	682
5.5.1.4	MLPPP on LNS Commands	684
5.5.1.5	Show Commands	686
5.5.2	Command Descriptions	687
5.5.2.1	PPP Configuration Commands.....	687
5.5.2.2	Show Commands	719
5.5.2.3	Clear Commands.....	725
5.5.2.4	Debug Commands.....	726
6	L2TP	729
6.1	In This Chapter	729
6.2	L2TP	729
6.2.1	Terminology.....	729
6.2.2	LAC DF Bit.....	730
6.2.3	Handling L2TP Tunnel/Session Initialization Failures	730
6.2.3.1	L2TP Tunnel/Session Initialization Failover Mechanisms on LAC	730
6.2.3.2	Peer Blacklist.....	731
6.2.3.3	Tunnel Blacklists.....	732
6.2.3.4	Tunnel Selection Mechanism	734
6.2.3.5	Tunnel Probing	735
6.2.3.6	Controlling the Size of Blacklist	735
6.2.3.7	Displaying the Content of a Blacklist	735
6.2.3.8	Generating Trap when the Blacklist is Full	736
6.2.3.9	Premature Removal of Blacklisted Entries	737
6.2.3.10	Manual Purging of Entities within the Blacklist	737
6.2.4	CDN Result Code Overwrite.....	738
6.2.5	LNS Proxy	738
6.3	L2TP LAC VPRN	740
6.3.1	Per-ISP Egress L2TP DSCP Reclassification	742
6.4	L2TP Tunnel RADIUS Accounting.....	743
6.4.1	Accounting Packets List	744
6.5	RADIUS Attributes Value Considerations.....	748
6.5.1	Other Optional RADIUS Attributes	748
6.5.2	RADIUS VSA to Enable L2TP Tunnel Accounting	749
6.5.3	MLPPP on the LNS Side	749
6.5.4	LNS Reassembly.....	749
6.6	L2TP Command Reference.....	751
6.6.1	Command Hierarchies.....	751
6.6.1.1	L2TP Configuration Commands	751

6.6.1.2	L2TP Tunnel RADIUS Accounting Commands	753
6.6.1.3	Show Commands	754
6.6.1.4	Clear Commands.....	754
6.6.1.5	Debug Commands.....	754
6.6.1.6	Tools Commands	756
6.6.2	Command Descriptions	757
6.6.2.1	L2TP Configuration Commands	757
6.6.2.2	Show Commands	775
6.6.2.3	Debug Commands.....	783
7	Triple Play Security	785
7.1	In This Chapter	785
7.2	Triple Play Security Features	785
7.2.1	Anti-Spoofing Filters	785
7.2.1.1	Anti-spoofing Filter Types.....	786
7.2.1.2	Filtering Packets	787
7.2.2	Layer 2 Triple Play Security Features	787
7.2.2.1	MAC Pinning.....	788
7.2.2.2	MAC Protection	788
7.2.2.3	DoS Protection	789
7.2.2.4	VPLS Redirect Policy	791
7.2.3	ARP Handling	792
7.2.3.1	ARP Reply Agent.....	792
7.2.3.2	Dynamic ARP Table Population	793
7.2.3.3	Local Proxy ARP	793
7.2.4	Web Portal Redirect	794
7.3	Configuring Triple Play Security with CLI	797
7.3.1	Common Configuration Tasks	797
7.3.1.1	Configuring Anti-Spoofing Filters.....	797
7.3.1.2	Configuring Triple Play Security features	798
7.3.1.3	Configuring ARP Handling.....	801
7.3.1.4	Configuring Web Portal Redirect.....	804
7.4	Triple Play Security Command Reference	807
7.4.1	Command Hierarchies.....	807
7.4.1.1	Anti-Spoofing Commands.....	807
7.4.1.2	Layer 2 Security Commands	807
7.4.1.3	ARP Handling Commands.....	808
7.4.1.4	Tools Commands	808
7.4.2	Command Descriptions	809
7.4.2.1	Triple Play Security Configuration Commands.....	809
7.4.2.2	Show Commands	820
7.4.2.3	Tools Commands	821
8	Triple Play Multicast	825
8.1	In This Chapter	825
8.2	Introduction to Multicast.....	826
8.3	Multicast in the Broadband Service Router	827
8.3.1	Internet Group Management Protocol	827
8.3.1.1	IGMP Versions and Interoperability Requirements	827

8.3.1.2	IGMP Version Transition	828
8.3.2	Multicast Listener Discovery	829
8.3.2.1	MLD Versions and Interoperability Requirements	829
8.3.2.2	Source Specific Multicast Groups	830
8.3.3	Protocol Independent Multicast Sparse Mode (PIM-SM)	830
8.3.4	Ingress Multicast Path Management (IMPM) Enhancements	831
8.4	Multicast in the BSA	832
8.4.1	IGMP Snooping	833
8.4.1.1	IGMP/MLD Message Processing	834
8.4.1.2	IGMP Message Processing	834
8.4.1.3	MLD Message Processing	836
8.4.1.4	IGMP/MLD Filtering	836
8.4.2	Multicast VPLS Registration (MVR)	836
8.4.3	Layer 3 Multicast Load Balancing	837
8.4.4	IGMP State Reporter	839
8.4.4.1	IGMP Data Records	840
8.4.4.2	Transport Mechanism	843
8.4.4.3	HA Compliance	843
8.4.4.4	QoS Awareness	843
8.4.4.5	Hardware Support	844
8.4.4.6	IGMP Reporting Caveats	844
8.5	Multicast Support over Subscriber Interfaces in Routed CO Model	845
8.5.1	Hardware Support	847
8.5.2	Multicast Over IPoE	847
8.5.2.1	Per SAP Replication Mode	848
8.5.2.2	Per Subscriber Host Replication Mode	857
8.5.3	Multicast Over PPPoE	861
8.5.4	IGMP Flooding Containment	862
8.5.5	IGMP/MLD Timers	862
8.5.6	IGMP/MLD Query Intervals	863
8.5.7	HQoS Adjustment	864
8.5.7.1	Host Tracking (HT) Considerations	869
8.5.7.2	HQoS Adjust Per Vport	870
8.5.8	Redirection	874
8.5.9	Hierarchical Multicast CAC (H-MCAC)	875
8.5.9.1	MCAC Bundle Bandwidth Limit Considerations	878
8.5.10	Determining MCAC Policy in Effect	883
8.5.11	Multicast Filtering	883
8.5.12	Joining the Multicast Tree	884
8.5.13	Wholesale/Retail Requirements	884
8.5.14	QoS Considerations	885
8.5.15	Redundancy Considerations	886
8.5.15.1	Redirection Considerations	889
8.5.16	Query Intervals for Multicast	889
8.5.16.1	ESM Host-based Queries	890
8.5.16.2	Group Interface-based Queries	891
8.6	Configuring Triple Play Multicast Services with CLI	893
8.6.1	Configuring IGMP Snooping in the BSA	894
8.6.1.1	Enabling IGMP Snooping in a VPLS Service	894

8.6.1.2	With IGMPv3 Multicast Routers.....	894
8.6.1.3	With IGMPv1/2 Multicast Routers.....	894
8.6.1.4	Modifying IGMP Snooping Parameters	895
8.6.1.5	Modifying IGMP Snooping Parameters for a SAP or SDP	895
8.6.2	Configuring Static Multicast Groups on a SAP or SDP	897
8.6.2.1	Enabling IGMP Group Membership Report Filtering	898
8.6.3	Configuring Multicast VPLS Registration (MVR)	900
8.6.4	Configuring IGMP, MKD, and PIM in the BSR	901
8.6.4.1	Enabling IGMP	902
8.6.4.2	Configuring IGMP Interface Parameters	902
8.6.4.3	Configuring Static Parameters.....	903
8.6.4.4	Configuring SSM Translation.....	904
8.6.4.5	Enabling MLD	905
8.6.4.6	Configuring MLD Interface Parameters	905
8.6.4.7	Configuring Static Parameters.....	905
8.6.4.8	Configuring SSM Translation.....	906
8.6.4.9	Configuring PIM.....	907
8.6.4.10	Configuring Bootstrap Message Import and Export Policies	913
8.7	Triple Play Multicast Command Reference	915
8.7.1	Command Hierarchies.....	915
8.7.1.1	MCAST Management Commands.....	915
8.7.1.2	Multicast Info Policy Bundle Commands	916
8.7.1.3	Triple Play Multicast Service Commands	918
8.7.1.4	Ingress Multicast Path Management Commands.....	921
8.7.1.5	Multicast Redirection	922
8.7.1.6	Multicast Query Timer Commands	923
8.7.1.7	Show Commands	924
8.7.1.8	Clear Commands.....	925
8.7.1.9	Debug Commands.....	925
8.7.2	Command Descriptions	927
8.7.2.1	Multicast Management Configuration Commands.....	927
9	Triple Play Enhanced Subscriber Management.....	967
9.1	In This Section.....	967
9.2	Uniform RADIUS Server Configuration	968
9.2.1	RADIUS Server Configuration	968
9.2.1.1	Uniform RADIUS Server Configuration (Preferred).....	968
9.2.1.2	Legacy RADIUS Server Configuration	971
9.3	RADIUS Authentication of Subscriber Sessions	973
9.3.1	RADIUS Authentication Extensions.....	974
9.3.1.1	Triple Play Network with RADIUS Authentication.....	975
9.3.2	RADIUS Authorization Extensions	976
9.3.2.1	Calling-Station-ID	977
9.3.2.2	Subscriber Session Timeout.....	977
9.3.2.3	RADIUS Reply Message for PPPoE PAP/CHAP	980
9.3.2.4	SHCV Policy	980
9.3.3	radius-server-policy Retry Attempt Overview	980
9.3.4	AAA RADIUS Server Operation Status	981
9.3.5	AAA RADIUS Accounting Server Stickiness	983

9.3.6	AAA RADIUS Authentication Fallback Action.....	983
9.3.7	AAA Test User Account.....	984
9.3.8	Troubleshooting the RADIUS Server.....	985
9.3.9	Provisioning of Enhanced Subscriber Management (ESM) Objects	986
9.3.9.1	Provisioning IP Configuration of the Host.....	987
9.3.9.2	RADIUS Based Authentication in Wholesale Environment	988
9.3.9.3	Change of Authorization and Disconnect-Request.....	988
9.3.9.4	RADIUS-Based Accounting.....	992
9.3.9.5	RADIUS Accounting Terminating Cause.....	997
9.3.9.6	Accounting Modes Of Operation	998
9.3.9.7	Per Session Accounting	1001
9.3.9.8	RADIUS Session Accounting with PD as a Managed Route.....	1002
9.3.9.9	No Host-Accounting.....	1005
9.3.9.10	Host-Accounting Enabled	1006
9.3.9.11	Reduction of Host Updates for Session Accounting Start and Stop	1008
9.3.9.12	Accounting Interim Update Message Interval.....	1008
9.3.9.13	CoA Triggered Accounting Interim Update.....	1009
9.3.9.14	Class Attribute	1009
9.3.9.15	User Name	1010
9.3.9.16	Accounting-On and Accounting Off	1010
9.3.9.17	RADIUS Accounting Message Buffering	1014
9.3.9.18	Multiple Accounting Policies	1017
9.3.9.19	Sending an Accounting Stop Message upon a RADIUS Authentication Failure of a PPPoE Session	1017
9.4	Enhanced Subscriber Management Overview	1019
9.4.1	Enhanced Subscriber Management Basics.....	1019
9.4.1.1	Standard and Enhanced Subscriber Management.....	1019
9.4.2	ESM for IPv6	1026
9.4.2.1	Models	1026
9.4.2.2	Setup	1028
9.4.2.3	Behavior	1029
9.4.2.4	Delegated-Prefix-Length.....	1030
9.4.2.5	DHCPv6 Relay Agent.....	1032
9.4.2.6	DHCPv6 Relay to Third Party DHCPv6 External Server	1034
9.4.2.7	DHCPv6 Local Server	1034
9.4.3	Dynamic Subscriber Host Processing	1036
9.4.3.1	Dynamic Tables.....	1036
9.4.4	Enhanced Subscriber Management Entities	1039
9.4.4.1	Instantiating a New Host.....	1040
9.4.4.2	Packet Processing for an Existing Host.....	1041
9.4.5	ESM Host Lockout	1041
9.4.5.1	Functionality	1042
9.4.6	ANCP and GSMP	1042
9.4.6.1	ANCP.....	1043
9.4.6.2	General Switch Management Protocol Version 3 (GSMPv3)	1045
9.4.6.3	DHCP Release Messages.....	1046
9.4.6.4	DHCP Client Mobility	1046
9.4.6.5	DHCP Lease Control	1047

9.4.7	Using Scripts for Dynamic Recognition of Subscribers	1047
9.4.7.1	Python Language and Programmable Subscriber Configuration Policy (PSCP).....	1047
9.4.7.2	Determining the Subscriber Profile and SLA Profile of a Host	1048
9.4.7.3	Determining the Subscriber Profile	1049
9.4.7.4	Determining the SLA Profile	1051
9.4.8	Auto-Sub ID	1054
9.4.8.1	Sub-id Identifiers.....	1058
9.4.8.2	Dual Stack Hosts	1058
9.4.8.3	Mixing Hosts with Auto-Generated IDs and non Auto-Generated IDs	1059
9.4.8.4	PPPoA/PPPoEoA Considerations	1059
9.4.8.5	Deployment Considerations	1059
9.4.8.6	Caveats	1061
9.4.9	Limiting Subscribers and Hosts on a SAP.....	1061
9.4.10	Static Subscriber Hosts	1062
9.4.11	QoS for Subscribers and Hosts	1062
9.4.11.1	QoS Parameters in Different Profiles	1062
9.4.11.2	QoS Policy Overrides	1063
9.4.12	ESM Subscriber Hierarchical Traffic Control	1063
9.4.12.1	Subscriber HQoS.....	1063
9.4.12.2	Subscriber CFHP.....	1067
9.4.12.3	ATM/Ethernet Last-Mile Aware QoS for Broadband Network Gateway	1069
9.4.13	Subscriber Volume Statistics.....	1091
9.4.13.1	IP (Layer 3) Volume Accounting.....	1091
9.4.13.2	Separate IPv4 and IPv6 Counters.....	1092
9.4.14	Configuring IP and IPv6 Filter Policies for Subscriber Hosts.....	1098
9.4.14.1	IP Filter Attribute Format Details	1106
9.4.14.2	Checking Filter Policy Details	1110
9.4.15	ESM PPPoA/PPPoEoA	1111
9.4.15.1	PPPoA	1111
9.4.15.2	PPPoEoA.....	1113
9.4.15.3	Hardware Support	1114
9.4.15.4	Termination Points within 7450 ESS and 7750 SR	1115
9.4.15.5	PPPoA Encapsulation	1116
9.4.15.6	Encapsulation Summary.....	1120
9.4.15.7	Concurrent Support for Different Service Types on the Same Port	1121
9.4.15.8	Restrictions in Scaled ATM MDA Mode	1121
9.4.15.9	QoS Implementation.....	1123
9.4.15.10	Association Between the Subscriber and ATM VC Traffic Descriptor (QoS).....	1124
9.4.15.11	Per VP Shaping	1127
9.4.15.12	ATM/IOM QoS Integration	1130
9.4.15.13	Subscriber Instantiation Use Cases	1139
9.4.15.14	Authentication	1143
9.4.15.15	LUDB Access via Capture SAP.....	1144
9.4.15.16	Encapsulation Autosensing	1145
9.4.15.17	SAP Autoprovisioning.....	1145

9.4.15.18	PPP Nodes and ppp-policy.....	1147
9.4.15.19	MTU Considerations.....	1147
9.4.16	Multi-Chassis Synchronization	1150
9.4.16.1	Overview.....	1150
9.4.17	Subscriber Routed Redundancy Protocol (SRRP)	1152
9.4.17.1	SRRP Messaging	1152
9.4.17.2	SRRP and Multi-Chassis Synchronization	1154
9.4.17.3	SRRP Instance	1154
9.4.17.4	Subscriber Subnet Owned IP Address Connectivity	1158
9.4.17.5	Subscriber Subnet SRRP Gateway IP Address Connectivity.....	1158
9.4.17.6	Receive SRRP Advertisement SAP and Anti-Spoof.....	1158
9.4.18	PPPoE MC Redundancy	1158
9.4.18.1	Hardware Support	1159
9.4.18.2	SRRP Considerations for PPPoE.....	1159
9.4.18.3	State Synchronization.....	1161
9.4.18.4	Traffic Control and Redundant Interface	1163
9.4.18.5	MSAP Considerations	1167
9.4.18.6	Unnumbered Interface Support	1168
9.4.18.7	Compatibility with MC-LAG.....	1169
9.4.18.8	IPv6 Support.....	1169
9.4.18.9	Considerations with Local DHCP Server	1171
9.4.18.10	Redundant Interface Considerations	1172
9.4.19	Routed Central Office (CO)	1173
9.4.19.1	Layer 3 Subscriber Interfaces.....	1173
9.4.19.2	Wholesale Retail Routed CO.....	1180
9.4.19.3	Routed Subscriber Hosts.....	1186
9.4.20	Dual Homing	1196
9.4.20.1	Dual Homing to Two PEs (Redundant-Pair Nodes) in Triple Play Aggregation	1196
9.4.20.2	Steady-State Operation of Dual-homed Ring	1199
9.4.20.3	Broken-Ring Operation and the Transition to this State	1201
9.4.20.4	Transition from Broken to Closed Ring State	1203
9.4.20.5	Provisioning Aspects and Error Cases	1203
9.4.20.6	Dual Homing to Two BSR Nodes	1204
9.4.20.7	MC Services	1205
9.4.20.8	Routed CO Dual Homing.....	1207
9.4.20.9	SRRP and Multi-Chassis Synchronization	1213
9.4.20.10	Dual Homing and ANCP.....	1213
9.4.21	SRRP Enhancement	1214
9.4.21.1	SRRP Fate Sharing	1215
9.4.21.2	Fate Sharing Algorithm.....	1221
9.4.21.3	SRRP Aware Routing - IPv4/IPv6 Route Advertisement Based on SRRP State	1223
9.4.21.4	SRRP in Conjunction with a PW in ESM Environment – Use Case	1228
9.4.21.5	Group Monitor.....	1229
9.4.22	Subscriber Override.....	1233
9.4.23	Dual Stack Lite	1235
9.4.23.1	IP-in-IP.....	1236
9.4.23.2	Configuring Dual Stack Lite	1237

9.4.23.3	L2TP over IPv6.....	1237
9.5	L2TP Tunnel RADIUS Accounting.....	1239
9.5.1	Accounting Packets List	1240
9.5.2	RADIUS Attributes Value Considerations.....	1244
9.5.3	Other Optional RADIUS Attributes	1244
9.5.4	RADIUS VSA to Enable L2TP Tunnel Accounting	1244
9.5.5	MLPPP on the LNS Side	1245
9.6	RADIUS Route Download	1245
9.7	Managed SAP (MSAP).....	1247
9.7.1	Sticky MSAP	1254
9.7.2	ESM Identification Process.....	1255
9.7.2.1	SAP-ID ESM Identifier	1255
9.7.2.2	DSLAM-ID	1255
9.7.3	Default-Subscriber.....	1256
9.7.4	Multicast Management	1256
9.7.5	Subscriber Mirroring	1256
9.8	Volume and Time Based Accounting	1257
9.8.1	Metering.....	1257
9.8.1.1	Categories Map and Categories.....	1257
9.8.1.2	Quota Consumption.....	1259
9.8.1.3	Minimum Credit Control Quota Values	1259

1 Getting Started

1.1 About This Guide

This guide describes details pertaining to Triple Play Services Delivery Architecture (TPSDA) support provided by the operating system and presents examples to configure and implement various protocols and services.

This guide is organized into functional chapters and provides concepts and descriptions of the implementation flow, as well as Command Line Interface (CLI) syntax and command usage.

The topics and commands described in this document apply to the:

- 7450 ESS
- 7750 SR

[Table 1](#) lists the available chassis types for each SR OS router.

Table 1 Supported SR OS Router Chassis Types

7450 ESS	7750 SR
<ul style="list-style-type: none">• 7450 ESS-6/6v• 7450 ESS-7/12 running in standard mode (not mixed-mode)	<ul style="list-style-type: none">• 7450 ESS-7/12 running in mixed-mode (not standard mode)• 7750 SR-a4/a8• 7750 SR-c4/c12• 7750 SR-1e/2e/3e• 7750 SR-7/12• 7750 SR-12e

For a list of unsupported features by platform and chassis, refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000x TQZZA.

Command outputs shown in this guide are examples only; actual displays may differ depending on supported functionality and user configuration.

Note: This guide generically covers Release 14.0 content and may contain some content that will be released in later maintenance loads. Please refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000x TQZZA, for information on features supported in each load of the Release 14.0 software.

1.2 Nokia SR OS Services Configuration Process

[Table 2](#) lists the tasks necessary to configure TPSDA entities. Each section describes a software area and provides CLI syntax and command usage to configure parameters for a functional area.

Table 2 Configuration Process

Area	Task	Chapter	Supported Platform
Introduction	Overview	Introduction to Triple Play	7750 SR, 7450 ESS
DHCP	Theory, configuration	DHCP Management	7750 SR, 7450 ESS
Security	Anti-spoofing, MAC pinning, MAC protection, DoS protection VPLS redirect policies, Web portal redirect, ARP handling	Triple Play Security	7750 SR, 7450 ESS
PPPoE	Theory, configuration	Point-to-Point Protocol over Ethernet Management	7750 SR, 7450 ESS
Multicast	Multicast, IGMP, SSM, PIM	Triple Play Multicast	7750 SR, 7450 ESS
Enhanced Subscriber management	RADIUS authentication, ESM entities, Routed CO, M-SAP	Triple Play Enhanced Subscriber Management	7750 SR, 7450 ESS
	Python Scripting	Python Script Support for ESM	7750 SR, 7450 ESS
Reference	List of IEEE, IETF, and other proprietary entities.	Standards and Protocol Support	7750 SR, 7450 ESS

2 Introduction to Triple Play

2.1 In This Section

This section provides an overview of the 7450 ESS and 7750 SR OS services, service model and service entities used in conjunction with Triple Play services only to the relevant service types. Details about services, configurations, and CLI syntax can be found in the 7450 ESS and 7750 Services Overview Guide.

Topics in this section include:

- [Nokia's Triple Play Service Delivery Architecture](#)
 - [Introduction to Triple Play](#)
 - [Blueprint for Optimizing Triple Play Service Infrastructures](#)
 - [Architectural Foundations](#)
 - [Optimizing Triple Play Service Infrastructures](#)
- [Services](#)
 - [Service Types](#)
 - [Service Policies](#)
- [Nokia Service Model](#)
 - [Service Entities](#)
 - [Customers](#)
 - [Service Access Points \(SAPs\)](#)
 - [Service Distribution Points \(SDPs\)](#)
- [Epipe Service Overview](#)
- [VPLS Service Overview](#)
 - [Split Horizon SAP Groups and Split Horizon Spoke SDP Groups](#)
- [IES Service Overview](#)
 - [IP Interface](#)
- [VPRN Service Overview](#)

2.2 Nokia's Triple Play Service Delivery Architecture

2.2.1 Introduction to Triple Play

For more than a decade, telephony service providers have considered offering video services to residential customers. However, in the past it was not economically nor technically feasible to launch the implementation on a large scale.

Recently, several technical trends and evolutions have propelled video delivery to the foreground, including:

- Technical improvements in areas such as real-time MPEG encoding and compression.
- Widespread deployment of High Speed Internet (HSI) over broadband access (ADSL and cable modems).
- Decreased cost of high-bandwidth infrastructure (typically Ethernet-based) as well as storing, converting, and delivering video content.
- Increased competition between telephony and cable operators. This is partly due to changes in regulations.

Traditional cable operators began offering television services and later added Internet access and telephony to their offerings. Conversely, traditional telephony operators such as RBOCS, PTTs, have also added Internet access, and many are now in the process of also adding video delivery.

This bundling of video, voice, and data services to residential subscribers is now commonly known as Triple Play services. The video component always includes linear programming (broadcast television), but often also has a non-linear Video on Demand (VoD) component.

2.2.2 Blueprint for Optimizing Triple Play Service Infrastructures

Nokia's TPSDA allows network operators to progressively integrate their HSI, voice, and video services within a unified and homogeneous Ethernet-based aggregation network environment. The key benefits of the proposed service infrastructure include cost optimization, reduced risk, and accelerated time to market for new services.

At a high level, TPSDA implements:

- Ethernet-based service architecture — Solves bandwidth bottlenecks and exponential capital expenditure and operating expenses issues in the second mile by leveraging the efficiency of this technology.
- Multiple distributed service edges — Allows service providers to achieve faster times to market for new services while retaining the existing Broadband Remote Access Server (BRAS) / Point-to-Point Protocol over Ethernet (PPPoE) mode of operation for wholesale and retail HSI.
- Distributed multicasting functions in access and aggregation networks — Enables service providers to optimize bandwidth and content delivery mechanisms, based on densities and penetration rates. It is also essential to subscriber and service scaling, and optimizes the bandwidth required in the aggregation network.
- Carrier video and Voice over Internet Protocol (VoIP) services using Dynamic Host Configuration Protocol (DHCP) — Enables service providers to introduce plug-and-play services delivered through set-top boxes and VoIP devices, which are designed for use with the DHCP.
- Flexible deployment models — The architecture allows data, video, and VoIP services to be rapidly rolled out without any lock-in to specific operational models. It allows service providers to maximize flexibility and minimize financial and technological risks by allowing all modes of operation, including:
 - Copper (DSL/DSLAM) and fiber-based (FTTx) deployments in the first mile.
 - Single or multiple last mile circuits.
 - Bridged or routed home gateways.
 - Single or multiple IP address deployment models.

2.2.3 Architectural Foundations

With the SR OS, the architectural foundations of Nokia's TPSDA established in previous releases is reinforced while its applicability is expanded to encompass many new deployment models and support Any Mode of Operation (AMO). Through these enhancements, TPSDA becomes more universally deployable and flexible in addressing the specifics of any provider's network/rollout.

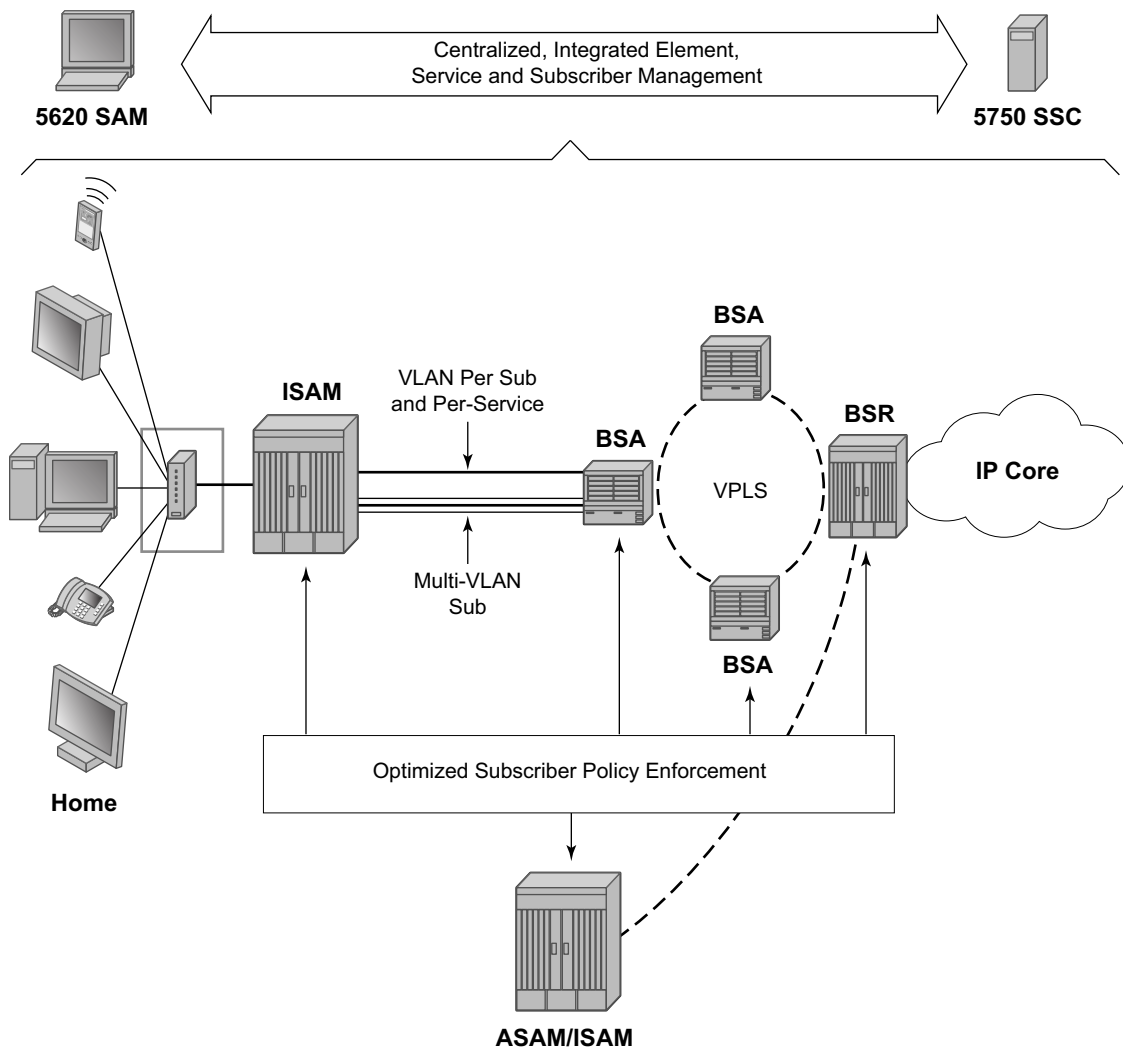

Nokia has defined new terminologies that have been adopted industry-wide, including:

- Broadband Service Access Node (BSAN)
- Broadband Service Aggregator (BSA)

- Broadband Service Router (BSR)

Figure 1 depicts TPSDA's centralized, integrated element, service and subscriber management architecture.

Figure 1 Triple Play Service Delivery Architecture

OSSG091

2.2.4 Optimizing Triple Play Service Infrastructures

More than a branding exercise, new terminologies signal a significant shift from “best effort” and traditional DSLAMs, Ethernet switches and BRASs, in the sense that they capture a shift in required characteristics and capabilities for a new generation of service rollouts, including:

- High-availability for non-stop service delivery (non-stop unicast and multicast routing, non-stop services, etc.).
- Multi-dimensional scale (such as the ability to scale performance, bandwidth, services, and subscribers concurrently).
- Ethernet — Optimization (leading density, capacity, scaling, performance).
- Optimal system characteristics (optimal delay/jitter/loss characteristics, and so on).
- Rich service capabilities with uncompromised performance.

Nokia’s Triple Play Service Delivery Architecture (TPSDA) advocates the optimal distribution of service intelligence over the BSAN, BSA and BSR, rather than concentrating on fully centralized or decentralized BRAS models which artificially define arbitrary policy enforcement points in the network. With the SR OS, the optimized enforcement of subscriber policies across nodes or over a single node (as dictated by evolving traffic patterns), allows a more flexible, optimized, and cost-effective deployment of services in a network, guaranteeing high quality and reliable delivery of all services to the user.

Table 3 **Nokia’s TPSDA**

Entity	Description
Subscriber Management	Centralized and fully integrated with element and services management across the infrastructure end-to-end solution (through the Nokia 5750 SSC).
Policy Enforcement	Optimally distributed, based on actual traffic patterns. Maximized flexibility, minimized risk of architectural lock-in. Optimized cost structure.
Support for “Any Mode of Operation”	With TPSDA, network economics, subscriber density, network topologies and subscriber viewership patterns define the optimal policy enforcement point for each policy type (security, QoS, multicasting, anti-spoofing, filtering etc.). The SR OS capabilities allow service providers to support any mode of operation, including any combination of access methods, home gateway type, and policy enforcement point (BSAN, BSA or BSR or a combination of the three).

All of the SR OS and Nokia’s 5750 SSC’s subscriber policy enforcement and management capabilities described in this section build upon Nokia’s TPSDA extensive capabilities and provide key capabilities in the following areas:

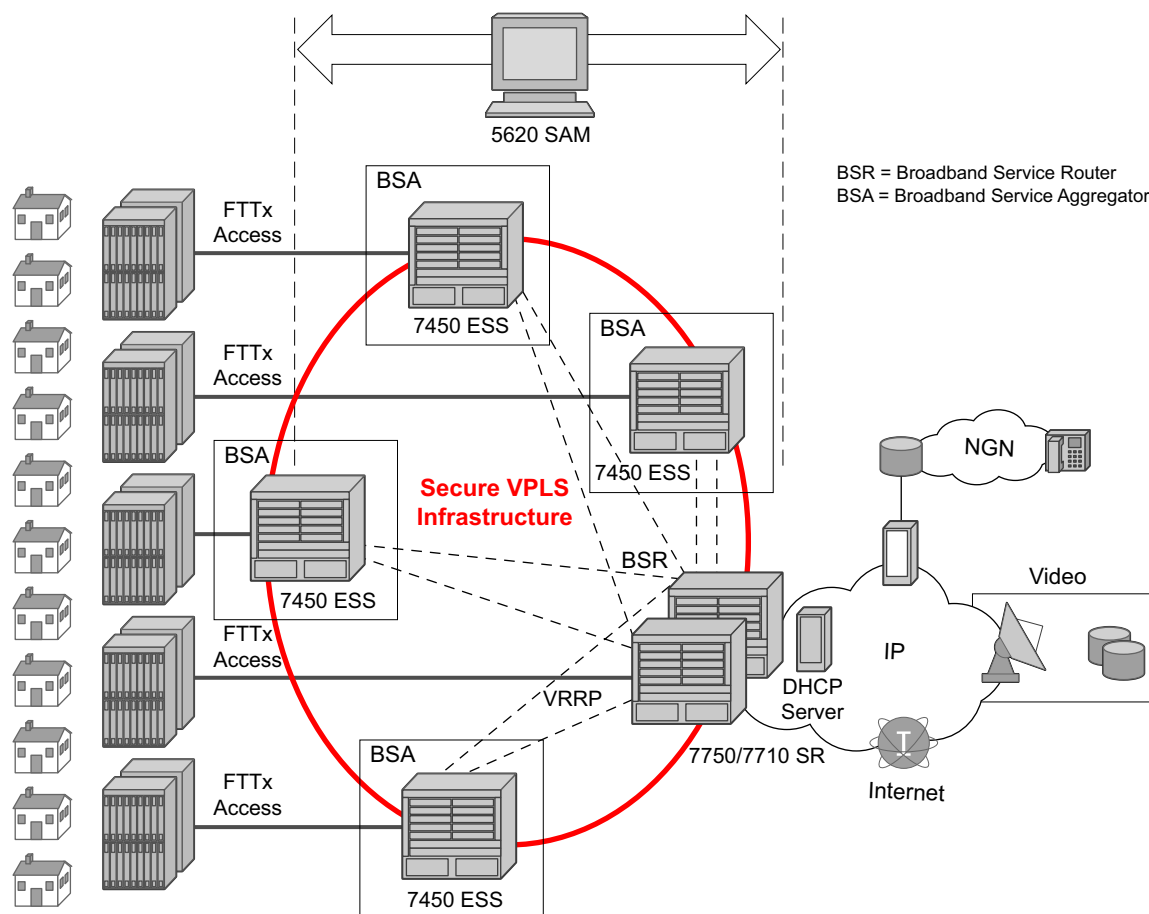

- Operationalization of Triple Play Services (AAA, subscriber policy enforcement, etc.)
- Service Assurance and Control
- Non-stop Video Service Delivery

2.2.4.1 Distributed Service Edges

The TPSDA architecture ([Figure 2](#)), is based on two major network elements optimized for their respective roles, the Broadband Service Aggregator (BSA) and the Broadband Service Router (BSR). An important characteristic of BSAs and BSRs is that they effectively form a distributed virtual node with the BSAs performing subscriber-specific functions where the various functions scale, and the BSRs providing the routing intelligence where it is most cost-effective.

The Nokia 7450 ESS and 7750 SR OS, respectively, provide the BSA and BSR functionalities in TPSDA. Both are managed as a single virtual node using Nokia's 5620 Service Aware manager (SAM), which provides a unified interface for streamlined service and policy activation across the distributed elements of the TPSDA architecture, including VPLS, QoS, multicasting, security, filtering and accounting.

Figure 2 Nokia's Triple Play Service Delivery Architecture

OSSG069A

Digital subscriber line access multiplexers (DSLAMs) or other access nodes are connected to Ethernet access ports on the BSA. Typically a single VLAN per subscriber is configured between the access node and the BSA. A VLAN per subscriber provides a persistent context against which per-subscriber policies (QoS, filtering, accounting) can be applied in the BSA.

Scaling of traffic and services is achieved by dividing the Layer 2 and Layer 3 functions between the BSA and BSR and by distributing key service delivery functions. BSAs are more distributed than BSRs, cost-effectively scaling per-subscriber policy enforcement.

The BSA is a high-capacity Ethernet-centric aggregation device that supports hundreds of Gigabit Ethernet ports, tens of thousands of filter policies, and tens of thousands of queues. The BSA incorporates wire speed security, per-subscriber service queuing, scheduling, accounting, and filtering.

BSAs aggregate traffic for all services towards the BSR. The BSR terminates the Layer 2 access and routes over IP/MPLS (Multi Protocol Label Switching) with support for a full set of MPLS and IP routing protocols, including multicast routing. The BSR supports hundreds of ports and sophisticated QoS for per-service and per-content/source differentiation.

The connectivity between BSAs and BSRs is a Layer 2 forwarding model shown in [Figure 2](#) above as a secure VPLS infrastructure. This refers to the fact that the BSA-BSR interconnections form a multipoint Ethernet network with security extensions to prevent unauthorized communication, denial of service, and theft of service. One of the advantages of using VPLS for this application is that VPLS instances can be automatically established over both 'hub and spoke' and ring topologies providing sub-50 ms resilience. Regardless of the fiber plant layout, VPLS enables a full mesh to be created between BSA and BSR nodes, ensuring efficient traffic distribution and resilience to node or fiber failure.

Other unique features of the BSA and BSR that contribute to this secure VPLS infrastructure are:

1. Using Residential Split Horizon Groups (RSHG), direct user-user bridging is automatically prohibited, without the need for address-specific ACLs;
2. RSHG combined with the ARP reply agent perform ARP and broadcast suppression to ensure that addressing information is restricted;
3. Protection against theft of service and denial of service is provided by MAC and/or IP filters automatically populated using DHCP snooping, and by MAC pinning;
4. Using the RADIUS interface, is possible to perform RADIUS authentication of users before allowing a DHCP discover to progress into the network.

2.2.4.2 Service Differentiation, QoS Enablement

Nokia's TPSDA approach provides a model based on call admission for video and VoIP, with the need to guarantee delay/jitter/loss characteristics once the service connection is accepted. The architecture also meets the different QoS needs of HSI, namely per-subscriber bandwidth controls, including shaping and policing functions that have little or no value for video and VoIP services. In conjunction with the architecture's support for content differentiation, this enables differentiated service pricing within HSI.

The distribution of QoS policy and enforcement across BSA and BSR allows the service provider to implement meaningful per-subscriber service level controls. Sophisticated and granular QoS in the BSA allows the service provider to deliver truly differentiated IP services based on the subscriber as well as on the content.

The BSR performs service distribution routing based on guarantees required to deliver the service and associated content, rather than on individual subscribers. The BSR only needs to classify content based on the required forwarding class for a given BSA to ensure that each service's traffic receives the appropriate treatment towards the BSA.

The diagram illustrates a multi-service network architecture. On the left, a DSL remote connects to a network edge (GE). This edge is associated with 'Per-sub Rate-limited HSI', 'Per-sub QoS Policy', and 'Per-Service Priority/Delay/Loss'. Traffic then flows through a central BSA (Bandwidth Service Agent) to another network edge (GE). This second edge is associated with 'Per-Service Priority/Delay/Loss' and 'Content Differentiation in HSI'. The traffic then passes through a BSR (Bandwidth Service Router) and enters an IP cloud, which connects to a destination IP address. The network is divided into four sections labeled A, B, C, and D. Section A shows the DSL remote and the first GE. Section B shows the BSA and the second GE. Section C shows the BSR and the IP cloud. Section D shows the destination IP address. The traffic flow is indicated by arrows pointing from left to right.

Key	Description
A	Per-subscriber queuing and PIR/CIR policing/shaping for HSI. HSI service classified on source IP range. Per-service prioritization for VoIP and video. VoIP is prioritized over video. Destination IP and/or DSCP classification. 802.1 marking for prioritization in the access and home.
B	VoIP and video queued and prioritized on per-VLAN QoS policy basis. HSI content differentiation based on DSCP. Each queue may have individual CIR/PIR and shaping. Optical overall subscriber rate limiting on VLAN (H-QoS).
C	For HSI, content differentiation queuing for gold/silver/bronze based on DSCP classification. Optional overall subscriber rate limiting on VLAN.

Table 4 Downstream QoS Enablement (Continued)

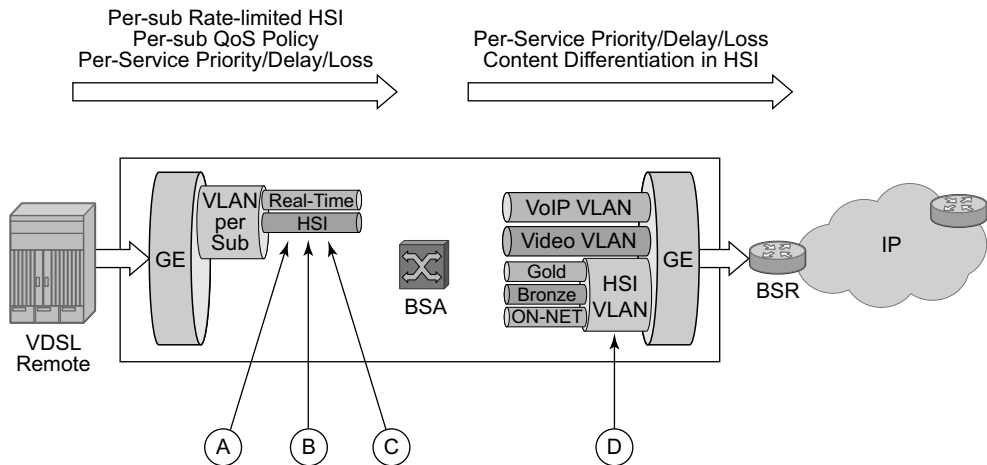

Key	Description
D	Preferred content marked (DSCP) of trusted ingress points of IP network.

In the upstream direction (BSA to BSR, [Figure 4](#)), traffic levels are substantially lower. Class-based queuing is used on the BSA network interface to ensure that video control traffic is propagated with a minimal and consistent delay, and that preferred data/HSI services receive better treatment for upstream/peering service traffic than the best effort Internet class of service.

Note: The IP edge is no longer burdened with enforcing per-subscriber policies for hundreds of thousands of users. This function is now distributed to the BSAs, and the per-subscriber policies can be implemented on the interfaces directly facing the access nodes.

Figure 4 Upstream QoS Enablement

OSSG079

Table 5 Upstream QoS Enablement

Key	Description
A	HSI: Per-subscriber queuing with PIR/CIR policy/shaping.
B	VoIP/Video: Shared queuing for prioritization of real-time traffic over HSI. Upstream video is negligible.
C	Per-subscriber QoS/Content classification for content differentiation.

Table 5 Upstream QoS Enablement (Continued)

Key	Description
D	Video/VoIP: Policy defines priority aggregate CIR/PIR. HSI: QoS policy defines priority and aggregate CIR/PIR. Content differentiation based on ingress classification. DSCP is marked.

The BSA is capable of scheduling and queuing functions on a per-service, per-subscriber basis, in addition to performing wire-speed packet classification and filtering based on both Layer 2 and Layer 3 fields.

Each subscriber interface provides at least three dedicated queues. TPSDA makes it possible to configure these queues such that the forwarding classes defined for all services can all be mapped to one service VLAN upstream. In the BSA, assuming hundreds of subscribers per Gigabit Ethernet interface, this translates to a thousand or more queues per port.

In addition to per-service rate limiting for HSI services, each subscriber's service traffic can be rate limited as an aggregate using a bundled service policy. This allows different subscribers to receive different service levels independently and simultaneously.

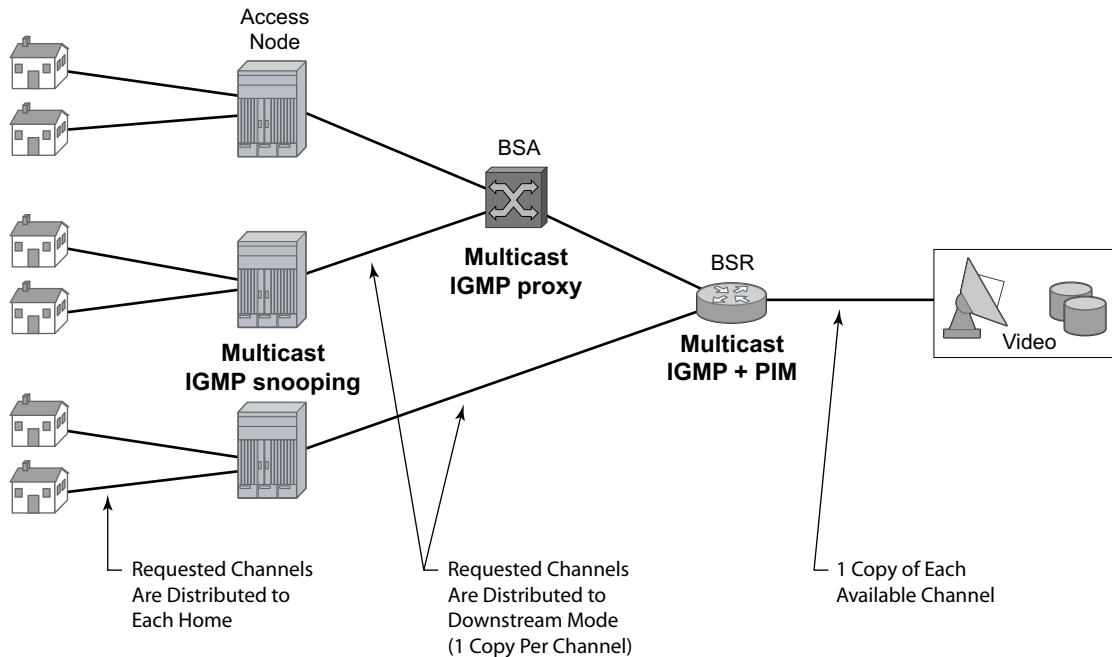

Distributed multicasting today's predominant video service is broadcast TV, and will likely remain significant for a long time. As video services are introduced, it is sensible to optimize investments by matching resources to the service model relevant at the time. Consequently, the objective of the service infrastructure should be to incorporate sufficient flexibility to optimize for broadcast TV in the short term, yet scale to support a full unicast (VoD) model as video service offerings evolve.

Optimizing for broadcast TV means implementing multicast packet replication throughout the network. Multicast improves the efficiency of the network by reducing the bandwidth and fiber needed to deliver broadcast channels to the subscriber. A multicasting node can receive a single copy of a broadcast channel and replicate it to any downstream nodes that require it, substantially reducing the required network resources. This efficiency becomes increasingly important closer to the subscriber. Multicast should be performed at each or either of the access, aggregation, and video edge nodes.

Multicasting as close as possible to the subscriber has other benefits since it enables a large number of users to view the content concurrently. The challenges of video services are often encountered in the boundary cases, such as live sports events and breaking news, for which virtually all the subscribers may be watching just a few channels. These exceptional cases generally involve live content, which is true broadcast content. Multicasting throughout the network makes it possible to deliver content under these circumstances while simplifying the engineering of the network.

Efficient multicasting requires the distribution of functions throughout the access and the aggregation network to avoid overloading the network capacity with unnecessary traffic. TPSDA realizes efficient multicasting by implementing IGMP snooping in the access nodes, IGMP snooping in the BSA and multicast routing in the BSR (Figure 5).

Figure 5 Distributed Multicasting in TPSDA

OSSG079

2.2.4.3 Virtual MAC Subnetting for VPLS

This feature allows, at the VPLS instance level, MAC subnetting, such as learning and switching based on a configurable number of bits from the source MAC address and from the destination MAC, respectively. This considerably reduces the VPLS FIB size.

MAC scalability involving MAC learning and switching based on the first x bits of a virtual MAC address is suitable in an environment where some MAC addresses can be aggregated based on a common first x bits, for example 28 out of 48. This can be deployed in a TPSDA environment where the VPLS is used for pure aggregation (there is no subscriber management) between the DSLAM and BRAS devices. The DSLAMs must be able to map customer MAC addresses to a pool of internal virtual

MAC addresses where the first bits (28, for example) identify the DSLAM with the next 20 bits identifying, the DSLAM slot, port number, and customer MAC station on that port. The VPLS instance(s) in the PE distinguishes only between different DSLAMs connected to it. They need to learn and switch based only on the first 28 bits of the MAC address allowing scaling of the FIB size in the PE.

Figure 6 Subnetting Topology

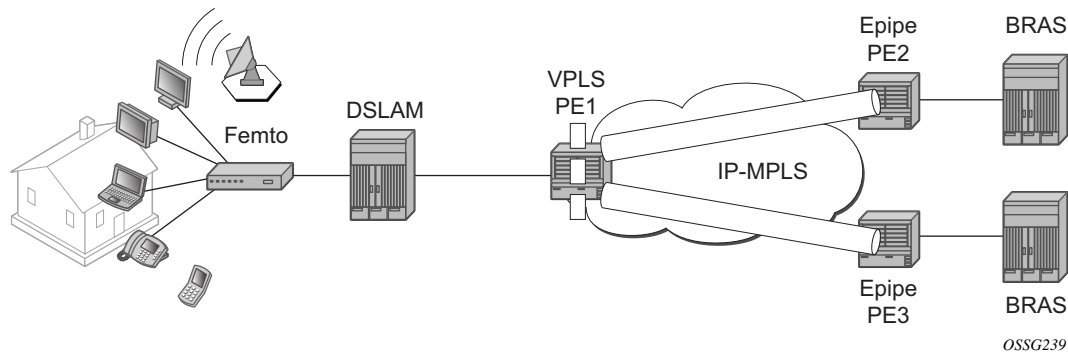

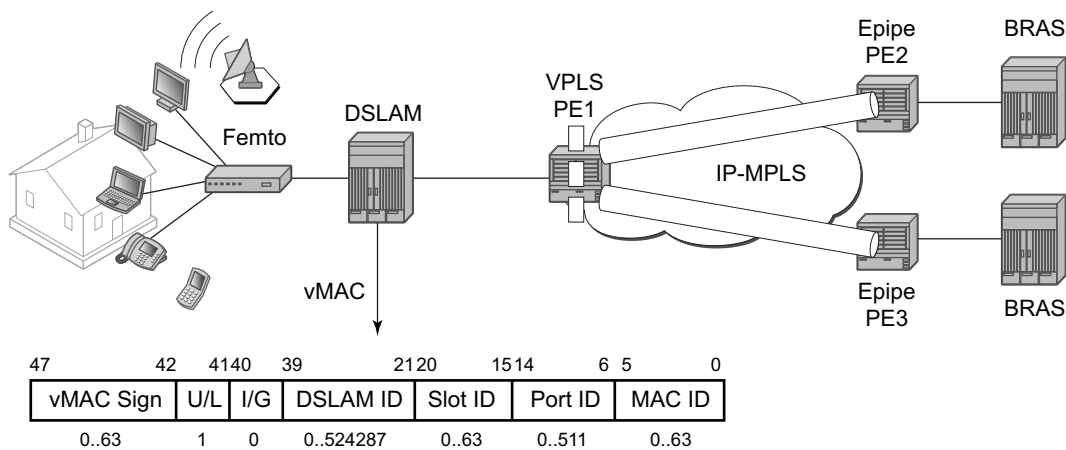

Figure 6 displays a Layer 2 PE network (such as the ESS-Series) aggregating traffic from DSLAMs (Nokia) to BRAS devices. The VPLS service is running in the PEs directly connected to the DSLAMs (VPLS PE1) while the PEs connected to the BRAS devices are running a point-to-point Layer 2 service (Epipe).

Nokia DSLAMs have the capability to map every customer MAC to a service provider MAC using the virtual MAC addressing scheme depicted in Figure 7.

Figure 7 VMAC Subnetting Topology

OSSG240

As the packet ingresses the DSLAM from the residential customer, the source MAC address (a customer MAC for one of its terminals/routers) is replaced by the DSLAM with a virtual MAC using the format depicted in Figure 7.

- The U/L bit is the seventh bit of the first byte and is used to determine whether the address is universally or locally administered. The U/L bit is set to 1 to indicate the address is locally administered.
- The following bits are used to build the VMAC address: DSLAM ID bits 39 — 21, slot ID bits 20 — 15, port ID bits 14-6 and the customer station ID bits 5 — 0.

Based on this scheme, it is apparent that the VMACs from one DSLAM have bits 47-21 in common.

The VPLS instance in PE1 only learns the first part of the MAC (bits 47 — 21) and, as the packets arrive from the BRAS device, switches based only on these bits in the destination MAC address to differentiate between the connected DSLAMs. Once the packet arrives at the DSLAM, the entire destination MAC is checked to determine the slot, port and which specific customer station the packet is destined to. As the packet is sent to the customer, the DSLAM replaces the destination MAC address with the actual customer MAC corresponding to the customer station.

The following are VPLS features not supported when the VMAC subnetting feature is enabled:

- Blocked features — CLI consistency checked provided
- Residential Split Horizon Groups

- BGP AD
- TPSDA (subscriber management) features
- PBB
- VPLS OAM (MAC populate, MAC ping, MAC trace, CPE Ping)

2.3 Services

A service is a globally unique entity that refers to a type of connectivity service for either Internet or VPN connectivity. Each service is uniquely identified by a service ID within a service area. The service model uses logical service entities to construct a service. In the service model, logical service entities are provide a uniform, service-centric configuration, management, and billing model for service provisioning.

Services can provide Layer 2/bridged service or Layer3/IP routed connectivity between a service access point (SAP) on one router and another service access point (a SAP is where traffic enters and exits the service) on the same (local) or another 7450 ESS or 7750 SR OS (distributed). A distributed service spans more than one router.

Distributed services use service distribution points (SDPs) to direct traffic to another 7450 ESS or 7750 SR OS through a service tunnel. SDPs are created on each participating 7450 ESS or 7750 SR OS, specifying the origination address (the router participating in the service communication) and the destination address of another 7450 ESS or 7750 SR OS. SDPs are then bound to a specific customer service. Without the binding process, far-end 7450 ESS and 7750 SR devices are not able to participate in the service (there is no service without associating an SDP with a service).

2.3.1 Service Types

The 7450 ESS and 7750 SR OS offers the following types of subscriber services which are described in more detail in the referenced chapters:

- Virtual Leased Line (VLL) services:
 - Ethernet pipe (Epipe) — A Layer 2 point-to-point VLL service for Ethernet frames.
 - ATM VLL (Apipe) — A point-to-point ATM service between users connected to 7750 nodes on an IP/MPLS network.

- Frame-Relay (Fpipe) — A point-to-point Frame Relay service between users connected to 7750 nodes on the IP/MPLS network.
- IP Pipe (Ipipe) — Provides IP connectivity between a host attached to a point-to-point access circuit (FR, ATM, PPP) with routed IPv4 encapsulation and a host attached to an Ethernet interface.
- Virtual Private LAN Service (VPLS) — A Layer 2 multipoint-to-multipoint VPN. VPLS includes Hierarchical VPLS (H-VPLS) which is an enhancement of VPLS which extends Martini-style signaled or static virtual circuit labeling outside the fully meshed VPLS core.
- Internet Enhanced Service (IES) — A direct Internet access service where the customer is assigned an IP interface for Internet connectivity.
- Virtual Private Routed Network (VPRN) — Layer 3 IP multipoint-to-multipoint VPN service as defined in RFC 2547bis. VPRN is supported on the 7750 SR only.

2.3.2 Service Policies

Common to all 7450 ESS and 7750 SR connectivity services are policies that are assigned to the service. Policies are defined at a global level and then applied to a service on the router. Policies are used to define service enhancements. The types of policies that are common to all 7450 ESS and 7750 SR connectivity services are:

- SAP Quality of Service (QoS) policies which allow for different classes of traffic within a service at SAP ingress and SAP egress.

QoS ingress and egress policies determine the QoS characteristics for a SAP. A QoS policy applied to a SAP specifies the number of queues, queue characteristics (such as forwarding class, committed, and peak information rates, etc.) and the mapping of traffic to a forwarding class. A QoS policy must be created before it can be applied to a SAP. A single ingress and a single egress QoS policy can be associated with a SAP.

- Filter policies allow selective blocking of traffic matching criteria from ingressing or egressing a SAP.

Filter policies, also referred to as access control lists (ACLs), control the traffic allowed in or out of a SAP based on MAC or IP match criteria. Associating a filter policy on a SAP is optional. Filter policies are identified by a unique filter policy ID. A filter policy must be created before it can be applied to a SAP. A single ingress and single egress filter policy can be associated with a SAP.

- Scheduler policies define the hierarchy and operating parameters for virtual schedulers. Schedulers are divided into groups based on the tier each scheduler is created under. A tier is used to give structure to the schedulers within a policy and define rules for parent scheduler associations.

- Accounting policies define how to count the traffic usage for a service for billing purposes.

The 7450 ESS and 7750 SR OS provide a comprehensive set of service-related counters. Accounting data can be collected on a per-service, per-forwarding class basis, which enables network operators to accurately measure network usage and bill each customer for each individual service using any of a number of different billing models.

2.4 Nokia Service Model

Topics in this section:

- [Service Entities](#)
- [Customers](#)
- [Service Access Points \(SAPs\)](#)
- [Service Distribution Points \(SDPs\)](#)

2.4.1 Introduction

In the 7450 ESS and 7750 SR service model, the service edge routers are deployed at the provider edge. Services are provisioned on the routers and transported across an IP and/or IP/MPLS provider core network in encapsulation tunnels created using Generic Router Encapsulation (GRE) or MPLS Label Switched Paths (LSPs).

The service model uses logical service entities to construct a service. The logical service entities are designed to provide a uniform, service-centric configuration, management, and billing model for service provisioning. Some benefits of this service-centric design include:

- Many services can be bound to a single customer.
- Many services can be bound to a single tunnel.
- Tunnel configurations are independent of the services they carry.
- Changes are made to a single logical entity rather than multiple ports on multiple devices. It is easier to change one tunnel rather than several services.
- The operational integrity of a logical entity (such as a service tunnel and service end points) can be verified rather than dozens of individual services improving management scaling and performance.

- A failure in the network core can be correlated to specific subscribers and services.
- QoS policies, filter policies, and accounting policies are applied to each service instead of correlating parameters and statistics from ports to customers to services.

Service provisioning uses logical entities to provision a service where additional properties can be configured for bandwidth provisioning, QoS, security filtering, accounting/billing to the appropriate entity.

2.4.2 Service Entities

The basic logical entities in the service model used to construct a service are:

- Customers
- Service Access Points (SAPs)
- Service Distribution Points (SDPs) (for distributed services only)

Figure 8 **Nokia's Service Entities**

2.4.3 Customers

The terms customers and subscribers are used synonymously. The most basic required entity is the customer ID value which is assigned when the customer account is created. To provision a service, a customer ID must be associated with the service at the time of service creation.

2.4.4 Service Access Points (SAPs)

Each subscriber service type is configured with at least one service access point (SAP). A SAP identifies the customer interface point for a service on an Nokia 7450 ESS or 7750 SR OS (Figure 9). The SAP configuration requires that slot, MDA, and port/channel (7750 SR) information be specified. The slot, MDA, and port/channel parameters must be configured prior to provisioning a service (see the Cards, MDAs, and Ports section of the Interface Configuration Guide).

A SAP is a local entity to the 7450 ESS and 7750 SR and is uniquely identified by:

- The physical Ethernet port or SONET/SDH port or TDM channel (7750 SR)
- The encapsulation type
- The encapsulation identifier (ID)

Depending on the encapsulation, a physical port or channel can have more than one SAP associated with it. SAPs can only be created on ports or channels designated as “access” in the physical port configuration. SAPs cannot be created on ports designated as core-facing “network” ports as these ports have a different set of features enabled in software.

Figure 9 Service Access Point (SAP)

OSSG002

2.4.4.1 SAP Encapsulation Types and Identifiers

The encapsulation type is an access property of a service Ethernet port or SONET/SDH or TDM channel (the TDM channel applies to the 7750 SR). The appropriate encapsulation type for the port or channel depends on the requirements to support multiple services on a single port/channel on the associated SAP and the capabilities of the downstream equipment connected to the port/channel. For example, a port can be tagged with IEEE 802.1Q (referred to as dot1q) encapsulation in which each individual tag can be identified with a service. A SAP is created on a given port or channel by identifying the service with a specific encapsulation ID.

2.4.4.2 Ethernet Encapsulations

The following lists encapsulation service options on Ethernet ports:

1. Null — Supports a single service on the port. For example, where a single customer with a single service customer edge (CE) device is attached to the port. The encapsulation ID is always 0 (zero).
2. Dot1q — Supports multiple services for one customer or services for multiple customers ([Figure 10](#)). For example, the port is connected to a multi-tenant unit (MTU) device with multiple downstream customers. The encapsulation ID used to distinguish an individual service is the VLAN ID in the IEEE 802.1Q header.
3. Q-in-Q — The q-in-q encapsulation type adds a IEEE 802.1Q tag to the 802.1Q tagged packets entering the network to expand the VLAN space by tagging tagged packets, producing a double tagged frame.

Note: The SAP can be defined with a wildcard for the inner label. (e.g. “100:*”). In this situation all packets with an outer label of 100 will be treated as belonging to the SAP. If, on the same physical link there is also a SAP defined with q-in-q encap of 100:1 then traffic with 100:1 will go to that SAP and all other traffic with 100 as the first label will go to the SAP with the 100:* definition.

In the dot1q and q-in-q options, traffic encapsulated with tags for which there is no definition are discarded.

Figure 10 Multiple SAPs on a Single Port/Channel

2.4.4.3 SAP Considerations

When configuring a SAP, consider the following:

- A SAP is a local entity and only locally unique to a given device. The same SAP ID value can be used on another 7450 ESS or 7750 SR.
- There are no default SAPs. All SAPs must be created.
- The default administrative state for a SAP at creation time is administratively enabled.
- When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Ethernet Service (IES), the IP interface must be shutdown before the SAP on that interface may be removed.
- A SAP is owned by and associated with the service in which it is created in each 7450 ESS or 7750 SR.
- A port/channel with a dot1q or BCP-dot1q encapsulation type means the traffic for the SAP is identified based on a specific IEEE 802.1Q VLAN ID value. The VLAN ID is stripped off at SAP ingress and the appropriate VLAN ID placed on at SAP egress. As a result, VLAN IDs only have local significance, so the VLAN IDs for the SAPs for a service need not be the same at each SAP.
- If a port/channel is administratively shutdown, all SAPs on that port/channel will be operationally out of service.
- A SAP cannot be deleted until it has been administratively disabled (shutdown).
- Each SAP can be configured with only the following:
 - Ingress or egress filter policy
 - Ingress or egress QoS policy

- Accounting policy
- Ingress or egress scheduler policy

2.4.5 Service Distribution Points (SDPs)

A service distribution point (SDP) acts as a logical way to direct traffic from one 7450 ESS or 7750 SR to another 7450 ESS or 7750 SR through a uni-directional (one-way) service tunnel. The SDP terminates at the far-end router which directs packets to the correct service egress SAPs on that device. A distributed service consists of a configuration with at least one SAP on a local node, one SAP on a remote node, and an SDP binding the service to the service tunnel.

An SDP has the following characteristics:

- An SDP is locally unique to a participating 7450 ESS or 7750 SR. The same SDP ID can appear on other 7450 ESS or 7750 SR OS.
- An SDP uses the system IP address to identify the far-end 7450 ESS or 7750 SR edge router.
- An SDP is not specific to any one service or any type of service. Once an SDP is created, services are bound to the SDP. An SDP can also have more than one service type associated with it.
- All services mapped to an SDP use the same transport encapsulation type defined for the SDP (either GRE or MPLS).
- An SDP is a management entity. Even though the SDP configuration and the services carried within are independent, they are related objects. Operations on the SDP affect all the services associated with the SDP. For example, the operational and administrative state of an SDP controls the state of services bound to the SDP.

An SDP from the local device to a far-end 7450 ESS or 7750 SR requires a return path SDP from the far-end router back to the local router. Each device must have an SDP defined for every remote router to which it wants to provide service. SDPs must be created first, before a distributed service can be configured.

2.4.5.1 SDP Binding

To configure a distributed service from ALA-A to ALA-B, the SDP ID (4) (Figure 11) must be specified in the service creation process in order to “bind” the service to the tunnel (the SDP). Otherwise, service traffic is not directed to a far-end point and the far-end 7450 ESS and 7750 SR device(s) cannot participate in the service (there is no service).

Figure 11 A GRE Service Distribution Point (SDP) pointing from ALA-A to ALA-B

OSSG004

2.4.5.2 Spoke and Mesh SDPs

When an SDP is bound to a service, it is bound as either a spoke SDP or a mesh SDP. The type of SDP indicates how flooded traffic is transmitted.

A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.

All mesh SDPs bound to a service are logically treated like a single bridge “port” for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke SDPs and SAPs) and not transmitted on any mesh SDPs.

2.4.5.3 SDP Encapsulation Types

The Nokia service model uses encapsulation tunnels through the core to interconnect 7450 ESS and 7750 SR service edge routers. An SDP is a logical way of referencing the entrance to an encapsulation tunnel.

The following encapsulation types are supported:

- Layer 2 within Generic Routing Encapsulation ([GRE](#))
- Layer 2 within RSVP signaled, loose hop non-reserved MPLS LSP
- Layer 2 within RSVP signaled, strict hop non-reserved MPLS LSP
- Layer 2 within RSVP-TE signaled, bandwidth reserved MPLS LSP

2.4.5.3.1 GRE

GRE encapsulated tunnels have very low overhead and are best used for Best-Effort class of service. Packets within the GRE tunnel follow the Interior Gateway Protocol (IGP) shortest path from edge to edge. If a failure occurs within the service core network, the tunnel will only converge as fast as the IGP itself. If Equal Cost Multi-Path (ECMP) routing is used in the core, many loss-of-service failures can be minimized to sub-second timeframes.

2.4.5.3.2 MPLS

Multi-Protocol Label Switching (MPLS) encapsulation has the following characteristics:

- LSPs (label switched paths) are used through the network, for example, primary, secondary, loose hop, etc. These paths define how traffic traverses the network from point A to B. If a path is down, depending on the configuration parameters, another path is substituted.
Paths can be manually defined or a constraint-based routing protocol (e.g., OSPF-TE or CSPF) can be used to determine the best path with specific constraints.
- The 7450 ESS and 7750 SR OS support both signaled and non-signaled LSPs through the network.
- Non-signaled paths are defined at each hop through the network.
- Signaled paths are communicated via protocol from end to end using Resource Reservation Protocol (RSVP).

Because services are carried in encapsulation tunnels and an SDP is an entrance to the tunnel, an SDP has an implicit Maximum Transmission Unit (MTU) value. The MTU for the service tunnel can affect and interact with the MTU supported on the physical port where the SAP is defined.

2.4.5.4 SDP Keepalives

SDP keepalives are a way of actively monitoring the SDP operational state using periodic Nokia SDP Ping Echo Request and Echo Reply messages. Nokia SDP Ping is a part of Nokia's suite of Service Diagnostics built on an Nokia service-level OA&M protocol. When SDP Ping is used in the SDP keepalive application, the SDP Echo Request and Echo Reply messages are a mechanism for exchanging far-end SDP status.

Configuring SDP keepalives on a given SDP is optional. SDP keepalives for a particular SDP have the following configurable parameters:

- AdminUp/AdminDown State
- Hello Time
- Message Length
- Max Drop Count
- Hold Down Time

SDP keepalive Echo Request messages are only sent when the SDP is completely configured and administratively up and SDP keepalives is administratively up. If the SDP is administratively down, keepalives for the SDP are disabled.

SDP keepalive Echo Request messages are sent out periodically based on the configured Hello Time. An optional Message Length for the Echo Request can be configured. If Max Drop Count Echo Request messages do not receive an Echo Reply, the SDP will immediately be brought operationally down.

If a keepalive response is received that indicates an error condition, the SDP will immediately be brought operationally down.

Once a response is received that indicates the error has cleared and the Hold Down Time interval has expired, the SDP will be eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP will enter the operational state.

2.5 Epipe Service Overview

An Epipe service is Nokia's implementations of an Ethernet VLL based on the IETF Martini Drafts (draft-martini-l2circuit-trans-mpls-08.txt and draft-martini-l2circuit-encapmpls-04.txt) and the IETF Ethernet Pseudo-wire Draft (draft-so-pwe3-ethernet-00.txt).

An Epipe service is a Layer 2 point-to-point service where the customer data is encapsulated and transported across a service provider's IP or MPLS network. An Epipe service is completely transparent to the subscriber's data and protocols. The 7450 ESS and 7750 SR Epipe service does not perform any MAC learning. A local Epipe service consists of two SAPs on the same node, whereas a distributed Epipe service consists of two SAPs on different nodes. SDPs are not used in local Epipe services.

Each SAP configuration includes a specific port/channel (applies to the 7750 SR) on which service traffic enters the router from the customer side (also called the access side). Each port is configured with an encapsulation type. If a port is configured with an IEEE 802.1Q (referred to as dot1q) encapsulation, then a unique encapsulation value (ID) must be specified.

Figure 12 Epipe/VLL Service

2.6 VPLS Service Overview

Virtual Private LAN Service (VPLS) as described in Internet Draft *draft-ietf-ppvpn-vpls-ldp-01.txt*, is a class of virtual private network service that allows the connection of multiple sites in a single bridged domain over a provider-managed IP/MPLS network. The customer sites in a VPLS instance appear to be on the same LAN, regardless of their location. VPLS uses an Ethernet interface on the customer-facing (access) side which simplifies the LAN/WAN boundary and allows for rapid and flexible service provisioning.

VPLS offers a balance between point-to-point Frame Relay service and outsourced routed services (VPRN). VPLS enables each customer to maintain control of their own routing strategies. All customer routers in the VPLS service are part of the same subnet (LAN) which simplifies the IP addressing plan, especially when compared to a mesh constructed from many separate point-to-point connections. The VPLS service management is simplified since the service is not aware of nor participates in the IP addressing and routing.

A VPLS service provides connectivity between two or more SAPs on one (which is considered a local service) or more (which is considered a distributed service) routers. The connection appears to be a bridged domain to the customer sites so protocols, including routing protocols, can traverse the VPLS service.

Other VPLS advantages include:

- VPLS is a transparent, protocol-independent service.
- There is no Layer 2 protocol conversion between LAN and WAN technologies.
- There is no need to design, manage, configure, and maintain separate WAN access equipment, thus, eliminating the need to train personnel on WAN technologies such as Frame Relay.

For details on VPLS, including a packet walkthrough, refer to VPLS section in the SR-OS Services Guide.

2.6.1 Split Horizon SAP Groups and Split Horizon Spoke SDP Groups

Within the context of VPLS services, a loop-free topology within a fully meshed VPLS core is achieved by applying split-horizon forwarding concept that packets received from a mesh SDP are never forwarded to other mesh SDPs within the same service. The advantage of this approach is that no protocol is required to detect loops within the VPLS core network.

In applications such as DSL aggregation, it is useful to extend this split-horizon concept also to groups of SAPs and/or spoke SDPs. This extension is referred to as a split horizon SAP group or residential bridging.

Traffic arriving on a SAP or a spoke SDP within a split horizon group will not be copied to other SAPs and spoke SDPs in the same split horizon group (but will be copied to SAPs/spoke SDPs in other split horizon groups if these exist within the same VPLS).

2.6.1.1 Residential Split Horizon Groups

To improve the scalability of a SAP-per-subscriber model in the broadband services aggregator (BSA), the 7450 ESS and 7750 SR support a variant of split horizon groups called residential split horizon groups (RSHG).

A RSHG is a group of split horizon group SAPs with following limitations:

- Downstream broadcast traffic is not allowed.
- Downstream multicast traffic is allowed when IGMP snooping is configured in the VPLS.
- STP is not supported.

Spoke SDPs can also be members of a RSHG VPLS. The downstream multicast traffic restriction does not apply to spoke SDPs.

2.7 IES Service Overview

Internet Enhanced Service (IES) is a routed connectivity service where the subscriber communicates with an IP router interface to send and receive Internet traffic. An IES has one or more logical IP routing interfaces each with a SAP which acts as the access point to the subscriber's network. IES allow customer-facing IP interfaces to participate in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber be unique between other provider addressing schemes and potentially the entire Internet.

While IES is part of the routing domain, the usable IP address space may be limited. This allows a portion of the service provider address space to be reserved for service IP provisioning, and be administered by a separate but subordinate address authority.

IP interfaces defined within the context of an IES service must have a SAP associated as the access point to the subscriber network. Multiple IES services are created to segregate subscriber-owned IP interfaces.

Figure 13 Internet Enhanced Service

OSSG023

The IES service provides Internet connectivity. Other features include:

- Multiple IES services are created to separate customer-owned IP interfaces.
- More than one IES service can be created for a single customer ID.
- More than one IP interface can be created within a single IES service ID. All IP interfaces created within an IES service ID belong to the same customer.

2.7.1 IP Interface

IES customer IP interfaces can be configured with most of the same options found on the core IP interfaces. The advanced configuration options supported are:

- VRRP (for IES services with more than one IP interface)
- Cflowd (supported on the 7750 SR only)
- Secondary IP addresses
- ICMP options

Configuration options found on core IP interfaces not supported on IES IP interfaces are:

- Unnumbered interfaces
- NTP broadcast receipt

2.8 VPRN Service Overview

VPRN service is supported on the 7750 SR only.

RFC2547bis is an extension to the original RFC 2547, which details a method of distributing routing information and forwarding data to provide a Layer 3 Virtual Private Network (VPN) service to end customers.

Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via MP-BGP peering. Each route exchanged via the MP-BGP protocol includes a Route Distinguisher (RD), which identifies the VPRN association.

The service provider uses BGP to exchange the routes of a particular VPN among the PE routers that are attached to that VPN. This is done in a way which ensures that routes from different VPNs remain distinct and separate, even if two VPNs have an overlapping address space. The PE routers distribute routes from other CE routers in that VPN to the CE routers in a particular VPN. Since the CE routers do not peer with each other there is no overlay visible to the VPN's routing algorithm.

When BGP distributes a VPN route, it also distributes an MPLS label for that route. On a SR-Series, a single label is assigned to all routes in a VPN.

Before a customer data packet travels across the service provider's backbone, it is encapsulated with the MPLS label that corresponds, in the customer's VPN, to the route which best matches the packet's destination address. The MPLS packet is further encapsulated with either another MPLS label or GRE tunnel header, so that it gets tunneled across the backbone to the proper PE router. Each route exchanged by the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association. Thus the backbone core routers do not need to know the VPN routes.

2.9 Deploying and Provisioning Services

The service model provides a logical and uniform way of constructing connectivity services. The basic steps for deploying and provisioning services can be broken down into three phases.

2.9.1 Phase 1: Core Network Construction

Before the services are provisioned, the following tasks should be completed:

- Build the IP or IP/MPLS core network.
- Configure routing protocols.
- Configure MPLS LSPs (if MPLS is used).
- Construct the core SDP service tunnel mesh for the services.

2.9.2 Phase 2: Service Administration

Perform preliminary policy and SDP configurations to control traffic flow, operator access, and to manage fault conditions and alarm messages, the following tasks should be completed:

- Configure group and user access privileges.
- Build templates for QoS, filter and/or accounting policies needed to support the core services.

2.9.3 Phase 3: Service Provisioning

- Provision customer account information.
- If necessary, build any customer-specific QoS, filter or accounting policies.
- Provision the customer services on the 7450 ESS or 7750 SR service edge routers by defining SAPs, binding policies to the SAPs, and then binding the service to appropriate SDPs as necessary.

2.10 Configuration Notes

This section describes service configuration caveats.

2.10.1 General

Service provisioning tasks can be logically separated into two main functional areas, core tasks and subscriber tasks and are typically performed prior to provisioning a subscriber service.

Core tasks include the following:

- Create customer accounts
- Create template QoS, filter, scheduler, and accounting policies
- Create LSPs
- Create SDPs

Subscriber services tasks include the following:

- Create VLL, VPLS, IES, or VPRN services (VPRN is supported on the 7750 SR only)
- Configure interfaces (where required) and SAPs
- Bind SDPs
- Create exclusive QoS and filter policies

2.11 Configuring Triple Play Services with CLI

This section provides information to configure Residential Broadband Aggregation services using the command line interface. It is assumed that the reader is familiar with basic configuration of VPLS, IES and VPRN services (VPRN is supported on the 7750 SR only).

Topics in this section include:

- [Configuring VPLS Residential Split Horizon Groups](#)
- [Configuring Static Hosts](#)
- [Configuring Static Hosts on an VPLS SAP](#)
- [Configuring Static Hosts on an IES SAP](#)
- [Configuring Static Hosts on an VPRN SAP](#)

2.11.1 Configuring VPLS Residential Split Horizon Groups

To configure a group of SAPs in a VPLS service as a Residential Split Horizon Group (RSHG), add the residential-group parameter when creating the split horizon group. Traffic arriving on a SAP within an RSHG will not be copied to other SAPs in the same split horizon group.

Note: The split horizon group must be created before it can be applied.

The following example displays a VPLS configuration with split horizon enabled:

```
*A:ALA-48>config>service>vpls# info
-----
split-horizon-group "DSL-group2" residential-group create
description "split horizon group for DSL - no broadcast supported"
exit
stp
shutdown
exit
sap 2/1/4:100 split-horizon-group "DSL-group2" create
description "SAP in RSHG"
exit
sap 2/1/4:200 split-horizon-group "DSL-group2" create
description "another SAP in the RSHG"
exit
no shutdown
-----
```

```
*A:ALA-48>config>service>vpls#
```

2.11.1.1 Configuring Static Hosts

In order for the static host to be operational, forwarding traffic bi-directional, the mac address of the host must be learned or configured. Learning the MAC of the static host is different for IPv4 or IPv6.

If an IPv4 static host MAC is not specified

- The system will learn respective MAC address dynamically from ARP packets (arp-request or gratuitous-arp) generated by the host with the specified IP address.
- On a VPLS service, this can occur if arp-reply-agent function is enabled on a given SAP. On Layer 3 services, such as IES or VPRN, the ARP packets are always examined so no further conditions are applicable.

If an IPv6 static host MAC is not specified

- The system learns the MAC address depending on the type of host configured such as: IPv6 prefix host or IPv6 address host.
 - A SAP can be specified as a single-MAC and it implies that there is only a single device attached to the SAP. It changes the MAC learning behavior on the SAP for IPv6 host only. Firstly, all IPv6 hosts will share the same learned MAC. Secondly, the MAC address is learned from the host's router solicits and neighbor discoveries.
 - For static host with an address, upon shutdown, a RS for the clients IPv6 address is sent towards the host and the MAC is learned upon the RA reply
 - For static host with an address, SHCV will send the RS, and the MAC is learned from the RA
 - For static host with an address, the OAM command can trigger a RS and the MAC is learned from the RA
 - For static host with either a prefix or an address, linking the IPv6 host to an IPv4 host will copy the IPv4 host MAC address to the IPv6 host and vice versa.

The learned MAC address will be handled as a MAC address of static host with explicitly defined mac-address. Meaning:

- The MAC address will not be aged by the mac-aging or any other aging timers.

- The MAC address will not be moved to a new SAP as a consequence of relearning event. A relearning event is a learning request for the same MAC address which comes from a new SAP.
- The MAC address will not be flushed from FDB due to SAP failure or STP flush messages.

Every time the given static-host uses different MAC address in its ARP request, the dynamic MAC learning process will be performed. The old MAC address will be overwritten by a new MAC address.

The learned MAC address will not be made persistent (a static host is not a part of the persistency file). A service discontinuity of such a host could be proportional to its arp-cache timeout.

The following interactions are described:

- Antispoof (all services) — In case a static IP-only host is configured on a given SAP, anti-spoof types, IP, NH MAC, and IP MAC are supported. Static hosts for which MAC address is not known will not have any antispoof entry. This will be added only after the corresponding MAC has been learned. As a consequence, all traffic generated by the host before the MAC is learned are dropped.
- MAC-linking (IES and VPRN service only) — the MAC address can be learned from either the IPv4 or IPv6 host. Once learned it is copied over to the host of the other address family
- Single-MAC (IES and VPRN service only) — This specifies that there is only one single subscriber (MAC) on the SAP and any ICMP6 message from the SAP can be assumed to be the subscriber MAC address. This does not apply to IPv4 host.
- Enhanced subscriber management (all services) — ESM is supported in a combination with a static ip-only host. It is assumed that ip-mac antispoofing is enabled. The resources (queues, etc.) are allocated at the time such a host is configured, although they will be effectively used only after antispoof entry has been installed.
- Dual-homing (for IPv4 host only) — It is assumed that static host is configured on both chassis. The dynamic mac-address learning event will be then synchronized (also, if the members are on two different nodes) and corresponding anti-spoof entries will be installed on both chassis.
- MAC-pinning (for VPLS services only) — The dynamically learned MAC address of the static-host will be considered as a static-mac and is not affected by the no mac-pinning command.

- ARP-reply-agent (VPLS services only) — It is possible to enable arp-reply-agent on a SAP where static host with ip-only configured. Besides the regular arp-reply-agent functionality (reply to all arp-requests targeting the given host's IP address) learning of the host's MAC address will be performed. As long as no MAC address have been learned no ARP replies on behalf of such host should be expected. Enabling of arp-reply-agent is optional for SAP with ip-only static hosts.

2.11.1.1.1 BNG Learning IP-Only Static Host's MAC Address

Before an IP-only static host can forward or receive traffic, the MAC of the host must be learned by the BNG. The learned MAC is used to fill in the anti-spoof entry for the static host. [Table 6](#) summarizes the different methods that the BNG could use to learn the IP only static host MAC address.

Table 6 Methods to Learn IP-Only Static Host MAC Addresses

Number of Host(s) on SAP	IPv4 Static Host	IPv6 Numbered Static Host	IPv6 Prefix Only Host (unnumbered)	Dual Stack Host
1	Host's ARP Triggered SHCV Data packet OAM SHCV	Auto populate RS/NS MAC GUA based NS Triggered SHCV Data packet OAM SHC V	Auto populate RS/NS MAC GUA based NS Data packet	IPv4: Via IPv6 static host MAC (if available) and mechanisms listed for IPv4 static host IPv6 numbered host: Via IPv4 static host MAC (if available) and mechanisms listed for IPv6 numbered static host IPv6 prefix only host: Via IPv4 static host MAC (if available) and mechanism listed for IPv6 prefix only host

Table 6 Methods to Learn IP-Only Static Host MAC Addresses (Continued)

Number of Host(s) on SAP	IPv4 Static Host	IPv6 Numbered Static Host	IPv6 Prefix Only Host (unnumbered)	Dual Stack Host
N	Host's ARP Triggered SHCV Data packet OAM SHCV	GUA based NS SHCV Data packet OAM SHCV	GUA based NS Data packet	IPv4 Via IPv6 static host MAC (if available) and mechanism listed for IPv4 static host IPv6 numbered host: Via IPv4 static host MAC (if available) and mechanism listed for IPv6 numbered static host IPv6 prefix only host: Via IPv4 static host MAC (if available) and mechanism listed for IPv6 prefix only host

IP-only static hosts without a MAC address are put into a “non-forwarding” state and are not be able to send or receive traffic. The BNG must populate the MAC address using the methods described in the table above to put the host into a “forwarding” state. If the IPv4 static host sends an ARP, then the IPv4 address along with Ethernet header source MAC can populate the IP-only host MAC address. For IPv6, the subscriber must send in a NS using the GUA to allow the BNG to resolve the MAC address. If the IP-only host is an IPv6 prefix, NS using the GUA can also resolve the static host MAC address, provided that the GUA is within the subnet of the prefix. n IPv6 prefix host can only have one MAC association, multiple bridged hosts using a single IPv6 prefix is not supported. To support multiple bridge hosts on a SAP, individual /128 host must be configured along with enabling **ipoe-bridge-mode**.

2.11.1.1.2 Static Host Learning the IPv6 Default Gateway Address

Static hosts also need to resolve the default gateway and MAC in order to forward traffic. Static hosts can learn the BNG MAC using the following methods.

1. If the static host can use the BNG link-local as the default gateway, then the exchange of router solicit and advertisement should be able to populate the default route for the static host.
2. If the static host can use the BNG link-local as the default gateway but only through neighbor solicit, the BNG will respond to NS only if the source address is the GUA of the host.
3. If the static host can only use a GUA as the default gateway, then the subscriber interface must be configured with an IPv6 address instead of a prefix.

A host's RS/NS messages might use link-local as the source address. The host's link-local addresses are unknown to the BNG, since the BNG only knows static hosts by their GUA. By default, unknown host's RS/NS messages are dropped. Therefore, static hosts cannot resolve their default gateway/MAC address. There are two different methods to enable the BNG to respond to static host's RS/NS messages. The first solution is to declare the SAP as a single-mac. When a SAP is configured as a "single-mac", it is declaring that only a single host is expected on the SAP and any RS/NS sent by the host will automatically populate the MAC table. The BNG in return will also respond to the static host's RS/NS. The second solution is for cases where multiple hosts are on the SAP. RS/NS might not provide enough information to populate the subscriber host's MAC because the source IP are link-local addresses. The BNG anti-spoof will only reply to known hosts RS/NS; therefore, these static hosts' RS/NS are dropped. The group interface has a configuration option to auto-reply to any RS/NS, which will allow the static host to resolve their default gateway/route. Afterwards, the static host can send traffic to the BNG, which the BNG can use for MAC learning. To use data packets for MAC learning, the BNG has a "data-trigger" learning option for static hosts.

2.11.1.1.3 Configuring Static Hosts on an VPLS SAP

The following example displays a static host on a VPLS SAP configuration:

```
*A:ALA-48>config>service# info
-----
vpls 800 customer 6001 create
  description "VPLS with residential split horizon for DSL"
  stp
    shutdown
  exit
  sap 1/2/7:100 split-horizon-group "DSL-group2" create
    description "SAP for RSHG"
    static-host ip 10.1.1.1
  exit
  no shutdown
-----
*A:ALA-48>config>service#
```

2.11.1.1.4 Configuring Static Hosts on an IES SAP

The following displays a static host on an IES SAP:

```
*A:ALA-49>config>service>ies>sub-if>grp-if# info
-----
  sap 7/1/5 create
  description "IES with static host"
    static-host ip 10.1.1.1 create
    static-host ip 2001::1/128 create
```

```
static-host ip 2001:1::/64 create
exit
-----
*A:ALA-49>config>service>ies#
```

2.11.1.1.5 Configuring Static Hosts on an VPRN SAP

The following displays a static host on a VPRN SAP:

```
*A:ALA-49>config>service>vprn>sub-if>grp-if# info
-----
description "VPRN service with static host"
sap 7/1/5 create
description "IES with static host"
static-host ip 10.1.1.1 create
static-host ip 2001::1/128 create
static-host ip 2001:1::/64 create
exit
-----
*A:ALA-49>config>service>vprn#
```

2.12 Triple Play Services Command Reference

2.12.1 Command Hierarchies

Note: The command trees in this section are limited to those commands specific to Triple Play services. For the full command trees for a specific service type refer to the appropriate section in the Services Overview Guides.

2.12.2 Command Descriptions

2.12.2.1 Global Commands

description

Syntax	description <i>description-string</i> no description
Context	config>service>vpls config>service>vpls>igmp-snooping>mvr config>service>vpls>split-horizon-group config>service>vpls>sap config>service>ies>if>sap config>service>vprn config>service>vprn>sub-if config>service>vprn>sub-if>group-interface config>service>vprn>sub-if>grp-if>dhcp config>service>vprn>sub-if>grp-if>srrp config>service>vpls>sap>dhcp config>service>vpls>mld-snooping>mvr
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The no form of this command removes the string from the configuration.</p>
Default	n/a
Parameters	<i>description-string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown

```

Description This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.

The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described below in Special Cases.

The **no** form of this command places the entity into an administratively enabled state.

Special Cases **Service Admin State** — Bindings to an SDP within the service will be put into the out-of-service state when the service is shutdown. While the service is shutdown, all customer packets are dropped and counted as discards for billing and debugging purposes.

Service Operational State — A service is regarded as operational providing that two SAPs or if one SDP are operational.

SDP (global) — When an SDP is shutdown at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.

SDP (service level) — Shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.

SDP Keepalives — Enables SDP connectivity monitoring keepalive messages for the SDP ID. Default state is disabled (shutdown) in which case the operational state of the SDP-ID is not affected by the keepalive message state.

VPLS SAPs and SDPs — SAPs are created in a VPLS and SDPs are bound to a VPLS in the administratively up default state. The created SAP will attempt to enter the operationally up state. An SDP will attempt to go into the in-service state once bound to the VPLS.

2.12.2.2 Service Commands

ies

Syntax	ies <i>service-id</i> customer <i>customer-id</i> vpn <i>vpn-id</i> ies <i>service-id</i> no ies <i>service-id</i>
Context	config>service
Description	This command creates or edits an IES service instance.

The **ies** command is used to create or maintain an Internet Ethernet Service (IES). If the *service-id* does not exist, a context for the service is created. If the *service-id* exists, the context for editing the service is entered.

IES services allow the creation of customer facing IP interfaces in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.

While IES is part of the routing domain, the usable IP address space may be limited. This allows a portion of the service provider address space to be set aside for service IP provisioning, becoming administered by a separate but subordinate address authority. This feature is defined using the **config router service-prefix** command.

IP interfaces defined within the context of an IES service ID must have a SAP created as the access point to the subscriber network. This allows a combination of bridging and IP routing for redundancy purposes.

When a service is created, the **customer** keyword and *customer-id* must be specified and associates the service with a customer. The *customer-id* must already exist having been created using the **customer** command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified will result in an error.

Multiple IES services are created to separate customer owned IP interfaces. More than one IES service may be created for a single customer ID. More than one IP interface may be created within a single IES service ID. All IP interfaces created within an IES service ID belongs to the same customer.

By default, no IES service instances exist until they are explicitly created.

The **no** form of this command deletes the IES service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces defined within the service ID have been shutdown and deleted.

Parameters	<p><i>service-id</i> — The unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every router on which this service is defined.</p>
	<p>Values <i>service-id</i>: 1 to 214748364 <i>svc-name</i>: A string up to 64 characters in length.</p>
	<p>customer <i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p>
	<p>Values 1 to 2147483647</p>
	<p>vpn <i>vpn-id</i> — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.</p>
	<p>Values 1 to 2147483647</p>
	<p>Default null (0)</p>

vpls

Syntax	<p>vpls <i>service-id</i> customer <i>customer-id</i> vpn <i>vpn-id</i> [m-vpls] vpls <i>service-id</i> no vpls <i>service-id</i></p>
Context	config>service
Description	<p>This command creates or edits a Virtual Private LAN Services (VPLS) instance. The vpls command is used to create or maintain a VPLS service. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>A VPLS service connects multiple customer sites together acting like a zero-hop, layer 2 switched domain. A VPLS is always a logical full mesh.</p> <p>When a service is created, the create keyword must be specified if the create command is enabled in the environment context.</p> <p>When a service is created, the customer keyword and <i>customer-id</i> must be specified and associates the service with a customer. The <i>customer-id</i> must already exist having been created using the customer command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.</p> <p>To create a management VPLS, the m-vpls keyword must be specified. See section Hierarchical VPLS Redundancy for an introduction to the concept of management VPLS.</p>

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified will result in an error.

More than one VPLS service may be created for a single customer ID.

By default, no VPLS instances exist until they are explicitly created.

The **no** form of this command deletes the VPLS service instance with the specified *service-id*. The service cannot be deleted until all SAPs and SDPs defined within the service ID have been shutdown and deleted, and the service has been shutdown.

Parameters *service-id* — The unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every router on which this service is defined.

Values *service-id*: 1 to 214748364
svc-name: A string up to 64 characters in length.

customer *customer-id* — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn *vpn-id* — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default null (0)

m-vpls — Specifies a managed VPLS.

vpn

Syntax **vpn** *service-id* [**customer** *customer-id*]
no vpn *service-id*

Context config>service

Description This command creates or edits a Virtual Private Routed Network (VPRN) service instance.

If the *service-id* does not exist, a context for the service is created. If the *service-id* exists, the context for editing the service is entered.

VPRN services allow the creation of customer-facing IP interfaces in the same routing instance used for service network core routing connectivity. VPRN services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.

IP interfaces defined within the context of an VPRN service ID must have a SAP created as the access point to the subscriber network.

When a service is created, the **customer** keyword and *customer-id* must be specified and associates the service with a customer. The *customer-id* must already exist having been created using the customer command in the service context. When a service is created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.

When a service is created, the use of the **customer** *customer-id* is optional to navigate into the service configuration context. If attempting to edit a service with the incorrect *customer-id* results in an error.

Multiple VPRN services are created to separate customer-owned IP interfaces. More than one VPRN service can be created for a single customer ID. More than one IP interface can be created within a single VPRN service ID. All IP interfaces created within an VPRN service ID belongs to the same customer.

The **no** form of the command deletes the VPRN service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces and all routing protocol configurations defined within the service ID have been shutdown and deleted.

Default n/a

Parameters *service-id* — The unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every 7750 SR on which this service is defined.

Values

service-id: 1 to 2147483648
svc-name: 64 characters maximum

customer *customer-id* — Specifies an existing customer identification number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

service-name

Syntax **service-name** *service-name*
no service-name

Context config>service>epipe
config>service>ies
config>service>vpls
config>service>vprn

Description	<p>This command configures an optional service name, up to 64 characters in length, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider/administrator to identify and manage services within the 7750 SR and 7450 ESS platforms.</p> <p>All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.</p>
Parameters	<p><i>service-name</i> — Specifies a unique service name to identify the service. Service names may not begin with an integer (0 to 9).</p>

disable-aging

Syntax	[no] disable-aging
Context	<p>config>service>vpls</p> <p>config>service>vpls>spoke-sdp</p> <p>config>service>vpls>sap</p>
Description	<p>This command disables MAC address aging across a VPLS service or on a VPLS service SAP or spoke SDP.</p> <p>Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the VPLS forwarding database (FDB). The disable-aging command turns off aging for local and remote learned MAC addresses.</p> <p>When no disable-aging is specified for a VPLS, it is possible to disable aging for specific SAPs and/or spoke SDPs by entering the disable-aging command at the appropriate level.</p> <p>When the disable-aging command is entered at the VPLS level, the disable-aging state of individual SAPs or SDPs will be ignored.</p> <p>The no form of this command enables aging on the VPLS service.</p>
Default	no disable-aging

disable-learning

Syntax	<p>disable-learning</p> <p>no disable-learning</p>
Context	<p>config>service>vpls</p> <p>config>service>vpls>sap</p>

```
config>service>vpls>spoke-sdp
```

Description This command enables learning of new MAC addresses in the VPLS forwarding database (FDB) for the service instance, SAP instance or spoke SDP instance.

When **disable-learning** is enabled, new source MAC addresses will not be entered in the VPLS service forwarding database. This is true for both local and remote MAC addresses.

When **no disable-learning** is specified for a VPLS on a 7450 ESS, it is possible to disable learning for specific SAPs and/or spoke SDPs by entering the **disable-learning command at the appropriate level**.

When disabled, new source MAC addresses will be learned and entered into the VPLS forwarding database. When the **no disable-learning** command is entered on VPLS level on a 7450 ESS, the **disable-learning** state of individual SAPs or spoke SDPs will be ignored.

This parameter is mainly used in conjunction with the **discard-unknown** command.

The **no** form of this command enables learning of MAC addresses meaning that normal MAC learning is enabled.

Default no disable-learning

discard-unknown

Syntax [no] discard-unknown

Context config>service>vpls

Description By default, packets with unknown destination MAC addresses are flooded. If discard-unknown is enabled at the VPLS level, packets with unknown destination MAC address will be dropped instead (even when configured FIB size limits for VPLS or SAP are not yet reached).

The **no** form of this command allows flooding of packets with unknown destination MAC addresses in the VPLS.

Default no discard-unknown

fdb-table-high-wmark

Syntax [no] fdb-table-high-wmark *high-water-mark*

Context config>service>vpls

Description This command specifies the value to send logs and traps when the threshold is reached.

Default 95

Parameters *high-water-mark* — When to send logs and traps.
Values 0 to 100

fdb-table-low-wmark

Syntax **[no] fdb-table-low-wmark** *low-water-mark*
Context config>service>vpls
Description This command specifies the value to send logs and traps when the threshold is reached.
Default 90
Parameters *low-water-mark* — When to send logs and traps.
Values 0 to 100

fdb-table-size

Syntax **fdb-table-size** *table-size*
no fdb-table-size [*table-size*]
Context config>service>vpls
Description This command specifies the maximum number of MAC entries in the forwarding database (FDB) for the VPLS instance on this node.

The **fdb-table-size** specifies the maximum number of forwarding database entries for both learned and static MAC addresses for the VPLS instance.

The **no** form of this command returns the maximum FDB table size to default.

Default **250** to Forwarding table of 250 MAC entries.
Parameters *table-size* — The number of entries permitted in the forwarding database for this VPLS instance.
The following values apply only to the 7750 SR:
Values Chassis-mode A or B limit: 131071
Chassis-mode D limit: 511999

local-age

Syntax **local-age** *seconds*
no local-age
Context config>service>vpls

Description Specifies the aging time for locally learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance.

In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The **local-age** timer specifies the aging time for local learned MAC addresses.

The **no** form of this command returns the local aging timer to the default value.

Default **local age 300** to Local MACs aged after 300 seconds.

Parameters *seconds* — The aging time for local MACs expressed in seconds.

Values 60 to 86400

remote-age

Syntax **remote-age** *seconds*
no remote-age

Context config>service>vpls

Description Specifies the aging time for remotely learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance.

In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Like in a layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The **remote-age** timer specifies the aging time for remote learned MAC addresses. To reduce the amount of signaling required between switches configure this timer larger than the **local-age** timer.

The **no** form of this command returns the remote aging timer to the default value.

Default **remote age 900** to Remote MACs aged after 900 seconds.

Parameters *seconds* — The aging time for remote MACs expressed in seconds.

Values 60 to 86400

service-mtu

Syntax	service-mtu <i>octets</i> no service-mtu
Context	config>service>vpls
Description	This command configures the service payload (Maximum Transmission Unit – MTU), in bytes, for the service. This MTU value overrides the service-type default MTU.

The **service-mtu** defines the payload capabilities of the service. It is used by the system to validate the SAP and SDP binding's operational state within the service.

The service MTU and a SAP's service delineation encapsulation overhead (i.e., 4 bytes for a Dot1q tag) is used to derive the required MTU of the physical port or channel on which the SAP was created. If the required payload is larger than the port or channel MTU, then the SAP will be placed in an inoperative state. If the required MTU is equal to or less than the port or channel MTU, the SAP will be able to transition to the operative state.

When binding an SDP to a service, the service MTU is compared to the path MTU associated with the SDP. The path MTU can be administratively defined in the context of the SDP. The default or administrative path MTU can be dynamically reduced due to the MTU capabilities discovered by the tunneling mechanism of the SDP or the egress interface MTU capabilities based on the next hop in the tunnel path. If the service MTU is larger than the path MTU, the SDP binding for the service will be placed in an inoperative state. If the service MTU is equal to or less than the path MTU, then the SDP binding will be placed in an operational state.

In the event that a service MTU, port or channel MTU, or path MTU is dynamically or administratively modified, then all associated SAP and SDP binding operational states are automatically re-evaluated.

The **no** form of this command returns the default **service-mtu** for the indicated service type to the default value.

Default VPLS: 1514

The following table displays MTU values for specific VC types.

Table 7 MTU values for specific VC types

VC-Type	Example Service MTU	Advertised MTU
Ethernet	1514	1500
Ethernet (with preserved dot1q)	1518	1504
VPLS	1514	1500
VPLS (with preserved dot1q)	1518	1504

Table 7 MTU values for specific VC types (Continued)

VC-Type	Example Service MTU	Advertised MTU
VLAN (dot1p transparent to MTU value)	1514	1500
VLAN (QinQ with preserved bottom Qtag)	1518	1504

Parameters *octets* — The size of the MTU in octets, expressed as a decimal integer.

Values 1 to 9194

split-horizon-group

Syntax `[no] split-horizon-group [group-name] [residential-group]`

Context `config>service>vpls`

Description This command creates a new split horizon group for the VPLS instance. Traffic arriving on a SAP or spoke SDP within this split horizon group will not be copied to other SAPs or spoke SDPs in the same split horizon group.

A split horizon group must be created before SAPs and spoke SDPs can be assigned to the group.

The split horizon group is defined within the context of a single VPLS. The same group-name can be re-used in different VPLS instances.

Up to 30 split horizon groups can be defined per VPLS instance.

The **no** form of the command removes the group name from the configuration.

Default A split horizon group is by default not created as a residential-group.

Parameters *group-name* — Specifies the name of the split horizon group to which the SDP belongs.

residential-group — Defines a split horizon group as a residential split horizon group (RSHG). Doing so entails that:

- a. SAPs which are members of this Residential Split Horizon Group will have:
 - Double-pass queuing at ingress as default setting (can be disabled)
 - STP disabled (can not be enabled)
 - ARP reply agent enabled by default (can be disabled)
 - MAC pinning enabled by default (can be disabled)
 - broadcast packets are discarded, blocking unknown, flooded traffic
- b. Spoke SDPs which are members of this Residential Split Horizon Group will have:
 - Downstream multicast traffic supported

- Double-pass queuing is not applicable
- STP is disabled (can be enabled)
- ARP reply agent is not applicable (dhcp-lease-states are not supported on spoke SDPs)
- MAC pinning enabled per default (can be disabled)

2.12.2.2.1 SAP Commands

sap

Syntax [no] sap *sap-id* [create]

Context config>service>ies>if
config>service>ies>sub-if>grp-if
config>service>vprn>if
config>service>vprn>sub-if>grp-if

Description This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique.

All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.

Enter an existing SAP without the **create** keyword to edit SAP parameters. The SAP is owned by the service in which it was created.

A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the **config interface port-type port-id mode access** command.

If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.

Note: You can configure an IES interface as a loopback interface by issuing the **loopback** command instead of the **sap sap-id** command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For IES, the IP interface must be shutdown before the SAP on that interface may be removed.

Default n/a

Special Cases **IES** — IES SAP can be defined with Ethernet or SONET/SDH ports on the 7450 ESS. A SAP is defined within the context of an IP routed interface. Each IP interface is limited to a single SAP definition. Attempts to create a second SAP on an IP interface will fail and generate an error; the original SAP will not be affected.

sap

Syntax	<p>sap <i>sap-id</i> [split-horizon-group <i>group-name</i>][capture-sap] [create] [eth-ring <i>ring-index</i>] [root-leaf-tag leaf-ac] no sap <i>sap-id</i></p>
Context	config>service>vpls
Description	<p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the 7450 ESS or 7750 SR. Each SAP must be unique. All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the create keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the config interface <i>port-type</i> <i>port-id</i> mode access command. Channelized TDM ports are always access ports (TDM applies to the 7750 SR only).</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The no form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Ethernet Service (IES), the IP interface must be shutdown before the SAP on that interface may be removed.</p>
Default	n/a
Special Cases	<p>VPLS SAP — A VPLS SAP can be defined with Ethernet ports, SONET/SDH or TDM channels (TDM is supported on the 7750 SR only).</p> <p>A default SAP has the following format: <i>port-id</i>.*. This type of SAP is supported only on Ethernet MDAs and its creation is allowed only in the scope of Layer 2 services (Epipe and VPLS). This type of SAP is mutually exclusive with a SAP defined by explicit null encapsulation (for example, 1/1/1:0).</p>
Parameters	<p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p> <p><i>port-id</i> — Specifies the physical port ID in the <i>slot/mda/port</i> format.</p> <p>If the card in the slot has Media Dependent Adapters (MDAs) installed, the <i>port-id</i> must be in the <i>slot_number</i>/<i>MDA_number</i>/<i>port_number</i> [<i>.channel</i>] format. For example 6/2/3 specifies port 3 on MDA 2 in slot 6.</p> <p>The <i>port-id</i> must reference a valid port type. When the <i>port-id</i> parameter represents SONET/SDH and TDM channels, the port ID must include the channel ID. A period “.” separates the physical port from the <i>channel-id</i>. The port must be configured as an access port.</p>

If the SONET/SDH port is configured as clear-channel then only the port is specified.

split-horizon-group *group-name* — Specifies the name of the split horizon group to which the SAP belongs. This parameter applies to the 7450 ESS or 7750 SR only.

capture-sap — Specifies a capturing SAP in which triggering packets will be sent to the CPM. Non-triggering packets captured by the capture SAP will be dropped. This parameter applies to the 7450 ESS or 7750 SR only.

create — Keyword used to create a SAP instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

root-leaf-tag — Specifies a SAP as a root leaf tag SAP. Only SAPs of the form dot1q (for example, 1/1/1:X) or qinq (for example, 1/1/1:X.Y, 1/1/1:X.*) are supported. The default E-Tree SAP type is a root AC, if *root-leaf-tag* (or *leaf-ac*) is not specified at SAP creation. This option is only available when the VPLS is designated as an E-Tree VPLS.

leaf-tag-vid — Specified after *root-leaf-tag* to replace the outer SAP-ID for leaf traffic. The leaf tag VID is only significant between peering VPLS but the values must be consistent on each end.

leaf-ac — Specifies a SAP as a leaf access (AC) SAP. The default E-Tree SAP type is root AC if *leaf-ac* (or *root-leaf-tag*) is not specified at SAP creation. This option is only available when the VPLS is designated as an E-Tree VPLS.

sap

Syntax	[no] sap <i>sap-id</i>
Context	config>service>vprn>if
Description	<p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique.</p> <p>All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the create keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the config interface port-type port-id mode access command. Channelized TDM ports are always access ports.</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p>

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted.

Default No SAPs are defined.

Parameters *sap-id* — Specifies the physical port identifier portion of the SAP definition.

port-id — Specifies the physical port ID in the *slot/mda/port* format.

If the card in the slot has Media Dependent Adapters (MDAs) installed, the *port-id* must be in the *slot_number/MDA_number/port_number* format. For example 6/2/3 specifies port 3 on MDA 2 in slot 6.

The *port-id* must reference a valid port type. When the *port-id* parameter represents SONET/SDH and TDM channels the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

If the SONET/SDH port is configured as clear-channel then only the port is specified.

create — Keyword used to create a SAP instance.

accounting-policy

Syntax **accounting-policy** *acct-policy-id*
no accounting-policy

Context config>service>vpls>sap
config>service>vpls>spoke-sdp
config>service>vpls>mesh-sdp
config>service>ies>if>sap
config>service>ies>sub-if>grp-if>sap

Description This command creates the accounting policy context that can be applied to a SAP or SDP.

An accounting policy must be defined before it can be associated with a SAP or SDP.

If the *policy-id* does not exist, an error message is generated.

A maximum of one accounting policy can be associated with a SAP or SDP at one time. Accounting policies are configured in the **config>log** context.

The **no** form of this command removes the accounting policy association from the SAP or SDP, and the accounting policy reverts to the default.

Default Default accounting policy.

Parameters *acct-policy-id* — Enter the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

collect-stats

Syntax	[no] collect-stats
Context	config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp config>service>ies>if>sap
Description	<p>This command enables accounting and statistical data collection for either the SAP or SDP, network port, or IP interface. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.</p> <p>When the no collect-stats command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent collect-stats command is issued then the counters written to the billing file include all the traffic while the no collect-stats command was in effect.</p>
Default	collect-stats

limit-mac-move

Syntax	limit-mac-move [blockable non-blockable] no limit-mac-move
Context	config>service>vpls>sap config>service>vpls>spoke-sdp
Description	This command indicates whether or not the mac-move agent, when enabled using config>service>vpls>mac-move or config>service>epipe>mac-move , will limit the MAC re-learn (move) rate on this SAP.
Default	SAPs and spoke SDPs are blockable
Parameters	<p>blockable — the agent will monitor the MAC re-learn rate on the SAP, and it will block it when the re-learn rate is exceeded.</p> <p>non-blockable — When specified, this SAP will not be blocked, and another blockable SAP will be blocked instead.</p>

mac-pinning

Syntax	[no] mac-pinning
Context	config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp

Description Enabling this command will disable re-learning of MAC addresses on other SAPs within the VPLS. The MAC address will remain attached to a given SAP for the duration of its age-timer.

The age of the MAC address entry in the FIB is set by the age timer. If **mac-aging** is disabled on a given VPLS service, any MAC address learned on a SAP/SDP with **mac-pinning** enabled will remain in the FIB on this SAP/SDP forever.

Every event that would otherwise result in re-learning will be logged (MAC address, original-SAP, new-SAP).

Note: MAC addresses learned during DHCP address assignment (DHCP snooping enabled) are not impacted by this command. MAC-pinning for such addresses is implicit.

Default When a SAP or spoke SDP is part of a Residential Split Horizon Group (RSHG), MAC pinning is activated at creation of the SAP. Otherwise MAC pinning is not enabled by default.

managed-vlan-list

Syntax **managed-vlan-list**

Context config>service>vpls>sap

Description This command enters the context for configuring VLAN ranges to be managed by a management VPLS. The list indicates, for each SAP, the ranges of associated VLANs that will be affected when the SAP changes state.

This command is only valid when the VPLS in which it is entered was created as a management VPLS.

range

Syntax [**no**] **range** *vlan-range*

Context config>service>vpls>sap>managed-vlan-list

Description This command configures a range of VLANs on an access port that are to be managed by an existing management VPLS.

This command is only valid when the VPLS in which it is entered was created as a management VPLS, and when the SAP in which it was entered was created on an Ethernet port with encapsulation type of dot1q or qinq, or on a SONET/SDH port with encapsulation type of bcp-dot1q.

To modify the range of VLANs, first the new range should be entered and afterwards the old range removed.

Default	n/a
Parameters	<i>vlan-range</i> — Specify the VLAN start value and VLAN end value. The end-vlan must be greater than start-vlan. The format is <start-vlan>-<end-vlan>
Values	start-vlan: 1 to 4094 end-vlan: 1 to 4094

track-srrp

Syntax	track-srrp <i>srrp-id</i> no track-srrp
Context	config>service>vpls>sap
Description	<p>This is a capture SAP level command. This command is important in PPPoE deployments with MSAPs. PPPoE operation requires that the MAC address learned by the client at the very beginning of the session negotiation phase remains unchanged for the lifetime of the session (RFC 2516). This command will ensure that the virtual MAC address used during the PPPoE session negotiation phase on the capture SAP is the same virtual MAC address that is used by the SRRP on the group-interface on which the session is established. Therefore, it is mandated that the SRRP instance (and implicitly the group-interface) where the session belongs to is known in advance. If the group-interface name for the session is returned by the RADIUS, it must be ensured that this group-interface is the one on which the tracked SRRP instance is configured. PPPoE sessions on the same capture SAP cannot be shared across multiple group-interfaces, but instead they all must belong to a single group-interface that is known in advance.</p> <p>The same restrictions will apply to IPoE clients in MC Redundancy scenario if they are to be supported concurrently on the same capture SAP as PPPoE.</p> <p>The supported capture SAP syntax is this:</p> <p>sap <port-id>:X.* capture-sap</p> <p>The capture SAP syntax that is NOT supported is this:</p> <p>sap <port-id>:*. * capture-sap</p>
Default	n/a
Parameters	<i>srrp-id</i> — Specify the SRRP instance number.
Values	1to4294967295

2.12.2.2.2 SAP Subscriber Management Commands

Subscriber management commands are also described in the Triple Play Services Command Reference section.

sub-sla-mgmt

Syntax	[no] sub-sla-mgmt
Context	config>service>vpls>sap config>service>ies>sub-if>sap config>service>ies>if>sap
Description	This command enables the context to configure subscriber management parameters for this SAP.
Default	no sub-sla-mgmt

def-sla-profile

Syntax	def-sla-profile <i>default-sla-profile-name</i> no def-sla-profile
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt
Description	<p>This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sla-profile context.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.</p> <p>The no form of the command removes the default SLA profile from the SAP configuration.</p>
Default	no def-sla-profile
Parameters	<i>default-sla-profile-name</i> — Specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sla-profile context.

def-sub-profile

Syntax	def-sub-profile <i>sub-profile-name</i>
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt
Description	<p>This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sub-profile context.</p> <p>A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.</p> <p>The no form of the command removes the default SLA profile from the SAP configuration.</p>
Parameters	<i>sub-profile-name</i> — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sub-profile context.

sub-ident-policy

Syntax	sub-ident-policy <i>sub-ident-policy-name</i>
Context	config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt
Description	<p>This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sub-ident-policy context.</p> <p>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.</p> <p>For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.</p> <p>When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.</p>

The **no** form of the command removes the default subscriber identification policy from the SAP configuration.

Default	no sub-ident-policy
Parameters	<p><i>sub-ident-policy-name</i> — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the config>subscr-mgmt>sub-ident-policy context.</p> <p><i>subscriber sub-ident-string</i> — Specifies a subscriber identification profile to be associated with the static subscriber host. The subscriber information is used by the SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.</p> <p>For VPLS SAPs with arp-reply-agent enabled with the optional <i>sub-ident</i> parameter, the static subscriber host's sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the destinations.</p> <p>If the static subscriber host's <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. (ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.)</p> <p>If <i>sub-ident</i> is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.</p> <p>ARP requests are never forwarded back to the same SAP or within the receiving SAP's Split Horizon Group.</p>

profiled-traffic-only

Syntax	[no] profiled-traffic-only
Context	<pre>config>service>vpls>sap>sub-sla-mgmt config>service>ies>if>sap>sub-sla-mgmt>single-sub config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt</pre>
Description	<p>This command enables profiled traffic only for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the sla-profile and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1).</p> <p>The no form of the command disables the command.</p>

non-sub-traffic

Syntax	non-sub-traffic sub-profile <i>sub-profile-name</i> sla-profile <i>sla-profile-name</i> [subscriber <i>sub-ident-string</i>] no non-sub-traffic
Context	config>service>ies>if>sap>sub-sla-mgmt>single-sub config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub
Description	<p>This command configures non-subscriber traffic profiles. It is used in conjunction with the profiled-traffic-only on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.</p> <p>The no form of the command removes the profiles and disables the feature.</p>
Parameters	<p>sub-profile <i>sub-profile-name</i> — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the config>subscr-mgmt>sub-profile context.</p> <p>sla-profile <i>sla-profile-name</i> — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the config>subscr-mgmt>sla-profile context.</p> <p>subscriber <i>sub-ident-string</i> — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the config>subscr-mgmt>sub-ident-policy context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.</p> <p>For SAPs with arp-reply-agent enabled with the optional <i>sub-ident</i> parameter, the static subscriber host's <i>sub-ident-string</i> is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the destinations.</p> <p>If the static subscriber host's <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. (ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.)</p> <p>If <i>sub-ident</i> is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.</p> <p>ARP requests are never forwarded back to the same SAP or within the receiving SAP's Split Horizon Group.</p>

profiled-traffic-only

Syntax	[no] profiled-traffic-only
---------------	-----------------------------------

Context config>service>ies>if>sap>sub-sla-mgmt>single-sub
 config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub

Description This command enables profiled traffic only for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the sla-profile and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1).

The **no** form of the command disables the command.

2.12.2.2.3 Triple Play Multicast Commands

igmp-snooping

Syntax	igmp-snooping
Context	config>service>vpls config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp
Description	This command enables the Internet Group Management Protocol (IGMP) snooping context.
Default	n/a

fast-leave

Syntax	[no] fast-leave
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	<p>This command enables fast leave.</p> <p>When IGMP fast leave processing is enabled, the 7450 ESS or 7750 SR will immediately remove a SAP or SDP from the IP multicast group when it detects an IGMP 'leave' on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a 'leave' from the forwarding table without first sending out group-specific queries to the SAP or SDP, and thus speeds up the process of changing channels ('zapping').</p> <p>Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.</p> <p>When fast leave is enabled, the configured last-member-query-interval value is ignored.</p>
Default	no fast-leave

from-vpls

Syntax	from-vpls <i>vpls-id</i> no from-vpls
Context	config>service>vpls>sap>snooping>mvr config>service>vpls>sap>mld-snooping>mvr

Description	This command configures the VPLS from which multicast traffic is copied upon receipt of an IGMP join request. IGMP snooping must be enabled on the MVR VPLS.
Default	no from-vpls
Parameters	<i>vpls-id</i> — Specifies the MVR VPLS from which multicast channels should be copied into this SAP.

group

Syntax	[no] group <i>grp-address</i>
Context	config>service>vpls>sap>snooping>static config>service>vpls>spoke-sdp>snooping>static config>service>vpls>mesh-sdp>snooping>static
Description	This command adds a static multicast group either as a (*, g) or as one or more (s,g) records. When a static IGMP group is added, multicast data for that (*,g) or (s,g) is forwarded to the specific SAP or SDP without receiving any membership report from a host.
Default	n/a
Parameters	<i>grp-address</i> — Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.

group-policy

Syntax	group-policy <i>policy-name</i> no group-policy
Context	config>service>vpls>snooping>mvr config>service>vpls>mld-snooping>mvr
Description	Identifies filter policy of multicast groups to be applied to this MVR VPLS. The sources of the multicast traffic must be a member of the MVR VPLS The no form of the command removes the MVR policy association from the VPLS.
Default	n/a
Parameters	<i>policy-name</i> — The routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context. The router policy must be defined before it can be imported.

import

Syntax	import <i>policy-name</i> no import
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	<p>This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a single SAP at any time.</p> <p>The no form of the command removes the policy association from the SAP or SDP.</p>
Default	n/a
Parameters	<i>policy-name</i> — The routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context The router policy must be defined before it can be imported.

last-member-query-interval

Syntax	last-member-query-interval <i>tenths-of-seconds</i> no last-member-query-interval
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	<p>This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between 2 consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.</p> <p>The configured last-member-query-interval is ignored when fast-leave is enabled on the SAP or SDP.</p>
Default	10

Parameters	<i>seconds</i> — Specifies the frequency, in tenths of seconds, at which query messages are sent.
Values	1 to 50

max-num-groups

Syntax	max-num-groups <i>count</i> no max-num-groups
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	This command defines the maximum number of multicast groups that can be joined on this SAP or SDP. If the 7450 ESS or 7750 SR receives an IGMP join message that would exceed the configured number of groups, the request is ignored.
Default	no max-num-groups
Parameters	<i>count</i> — Specifies the maximum number of groups that can be joined on this SAP or SDP.
Values	1 to 1000

mcac

Syntax	mcac
Context	config>service>pw-template>igmp-snooping config>service>vpls>mesh-sdp>snooping
Description	This command configures multicast CAC policy and constraints for this interface.
Default	n/a

mld-snooping

Syntax	mld-snooping
Context	config>service>vpls config>service>vpls>sap
Description	This command configures MLD snooping parameters.

mrouter-port

Syntax	[no] mrouter-port
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping
Description	<p>This command specifies whether a multicast router is attached behind this SAP or SDP.</p> <p>Configuring a SAP as an mrouter-port will have a double effect. Firstly, all multicast traffic received on another SAP or SDP will be copied to this SAP or SDP. Secondly, IGMP reports generated by the system as a result of someone joining or leaving a multicast group, will be sent to this SAP or SDP.</p> <p>If two multicast routers exist in the network, one of them will become the active querier. While the other multicast router (non-querier) stops sending IGMP queries, it should still receive reports to keep its multicast trees up to date. To support this, the mrouter-port should be enabled on all SAPs or SDPs connecting to a multicast router.</p> <div style="display: flex; align-items: flex-start; margin-top: 10px;"> <div style="margin-right: 10px; text-align: center;">  </div> <div> <p>Note: The IGMP version to be used for the reports (v1, v2 or v3) can only be determined after an initial query has been received. Until such time no reports are sent on the SAP or spoke SDP, even if mrouter-port is enabled.</p> </div> </div> <p>If the send-queries command is enabled on this SAP or spoke SDP, the mrouter-port parameter can not be set.</p>
Default	no mrouter-port

mvr

Syntax	mvr
Context	config>service>vpls>snooping config>service>vpls>mld-snooping config>service>vpls>sap>snooping
Description	This command enables the context to configure Multicast VPLS Registration (MVR) parameters.

policy

Syntax	policy <i>policy-name</i> no policy
Context	config>service>pw-template>igmp-snooping>mcac

```
config>service>vpls>mesh-sdp>snooping>mcac
```

Description This command configures the multicast CAC policy name.

Parameters *policy-name* — The multicast CAC policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

query-interval

Syntax **query-interval** *seconds*
no query-interval

Context config>service>vpls>snooping
config>service>vpls>sap>snooping
config>service>vpls>spoke-sdp>snooping
config>service>vpls>mesh-sdp>snooping
config>service>vpls>mld-snooping
config>service>vpls>sap>mld-snooping
config>service>vpls>spoke-sdp>mld-snooping
config>service>vpls>mesh-sdp>mld-snooping

Description If the **send-queries** command is enabled, this parameter specifies the interval between two consecutive general queries sent by the system on this SAP or SDP.

The configured query-interval must be greater than the configured query-response-interval.

If send-queries is not enabled on this SAP or SDP, the configured query-interval value is ignored.

Default 125

Parameters *seconds* — Specifies the time interval, in seconds, that the router transmits general host-query messages.

Values 2 to 1024

report-src-ip

Syntax **report-src-ip** *ip-address*
no report-src-ip

Context config>service>vpls>igmp-snooping

Description This parameters specifies the source IP address used when generating IGMP reports. According the IGMPv3 standard, a zero source address is allowed in sending IGMP reports. However, for interoperability with some multicast routers, the source IP address of IGMP group reports can be configured using this command.

Default	0.0.0.0
Parameters	<i>ip-address</i> — Specifies the source IP source address in transmitted IGMP reports.

robust-count

Syntax	robust-count <i>robust-count</i> no robust-count
Context	config>service>vpls>snooping config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	<p>If the send-queries command is enabled, this parameter allows tuning for the expected packet loss on a SAP or SDP. The robust-count variable allows tuning for the expected packet loss on a subnet and is comparable to a retry count. If this SAP or SDP is expected to be 'lossy', this parameter may be increased. IGMP snooping on this SAP or SDP is robust to (robust-count-1) packet losses.</p> <p>If send-queries is not enabled, this parameter will be ignored.</p>
Default	2
Parameters	<i>robust-count</i> — Specifies the robust count for the SAP or SDP.
Values	2 to 7

unconstrained-bw

Syntax	unconstrained-bw <i>bandwidth</i> mandatory-bw <i>mandatory-bw</i> no unconstrained-bw
Context	config>service>vpls>mesh-sdp>snooping>mcac config>service>vpls>spoke-sdp>snooping>mcac config>service>vpls>sap>igmp-snooping>mcac
Description	This command configures the bandwidth for the interface's multicast CAC policy traffic. When disabled (no unconstrained-bw) there will be no checking of bandwidth constraints on the interface level. When enabled and a policy is defined, enforcement is performed. The allocated bandwidth for optional channels should not exceed the unconstrained-bw minus the mandatory-bw and the mandatory channels have to stay below the specified value for the mandatory-bw . After this interface check, the bundle checks are performed.

Parameters	<p><i>bandwidth</i> — The bandwidth assigned for interface's MCAC policy traffic, in kilo-bits per second (kbps).</p> <p>Values 0 to 2147483647</p> <p>mandatory-bw <i>mandatory-bw</i> — Specifies the bandwidth pre-reserved for all the mandatory channels on a given interface in kilo-bits per second (kbps).</p> <p>If the <i>bandwidth</i> value is 0, no mandatory channels are allowed. If <i>bandwidth</i> is not configured, then all mandatory and optional channels are allowed.</p> <p>If the value of <i>mandatory-bw</i> is equal to the value of <i>bandwidth</i>, then all the unconstrained bandwidth on a given interface is allocated to mandatory channels configured through multicast CAC policy on that interface and no optional groups (channels) are allowed.</p> <p>The value of <i>mandatory-bw</i> should always be less than or equal to that of <i>bandwidth</i>. An attempt to set the value of <i>mandatory-bw</i> greater than that of <i>bandwidth</i>, will result in inconsistent value error.</p> <p>Values 0 to 2147483647</p>
-------------------	--

query-src-ip

Syntax	<p>query-src-ip <i>ipv6-address</i></p> <p>no query-src-ip</p>
Context	<p>config>service>vpls>mld-snooping</p> <p>config>service>vpls>igmp-snooping</p>
Description	This command configures the IP source address used in IGMP or MLD queries.
Parameters	<p><i>ipv6-address</i> — IPv6 address in the form:</p> <p style="margin-left: 40px;">x:x:x:x:x:x:x:x:x:x:d.d.d.d</p> <p style="margin-left: 40px;">where:</p> <p style="margin-left: 40px;">x - [0 to FF]</p> <p style="margin-left: 40px;">d - [0 to 255]</p>

query-response-interval

Syntax	query-response-interval <i>seconds</i>
Context	<p>config>service>vpls>sap>snooping</p> <p>config>service>vpls>spoke-sdp>snooping</p> <p>config>service>vpls>mesh-sdp>snooping</p> <p>config>service>vpls>sap>mld-snooping</p> <p>config>service>vpls>spoke-sdp>mld-snooping</p> <p>config>service>vpls>mesh-sdp>mld-snooping</p>

Description	<p>If the send-queries command is enabled, this parameter specifies the maximum response time advertised in IGMPv2/v3 queries.</p> <p>The configured query-response-interval must be smaller than the configured query-interval.</p> <p>If send-queries is not enabled on this SAP or SDP, the configured query-response-interval value is ignored.</p>
Default	10
Parameters	<p><i>seconds</i> — Specifies the length of time to wait to receive a response to the host-query message from the host.</p> <p>Values 1 to 1023</p>

send-queries

Syntax	[no] send-queries
Context	<pre>config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping</pre>
Description	<p>This command specifies whether to send IGMP general query messages on the SAP or SDP.</p> <p>If mrouter-port is enabled on this SAP or spoke SDP, the send-queries command parameter can not be set.</p>
Default	no send-queries

source

Syntax	[no] source <i>ip-address</i>
Context	<pre>config>service>vpls>sap>snooping>static>group config>service>vpls>spoke-sdp>snooping>static>group config>service>vpls>mesh-sdp>snooping>static>group</pre>
Description	<p>This command adds a static (s,g) entry to allow multicast traffic for the corresponding multicast group from that specific source. For the same multicast group, more than one source can be specified.</p> <p>Static (s,g) entries can not be entered when a starg is already created.</p> <p>Use the no form of the command to remove the source from the configuration.</p>

Default	n/a
Parameters	<i>ip-address</i> — Specifies the IPv4 unicast address.

starg

Syntax	[no] starg
Context	config>service>vpls>sap>snooping>static>group config>service>vpls>spoke-sdp>snooping>static>group config>service>vpls>mesh-sdp>snooping>static>group
Description	This command adds a static (*,g) entry to allow multicast traffic for the corresponding multicast group from any source. This command can only be enabled if no existing source addresses for this group are specified. The no form of the command removes the starg entry from the configuration.
Default	no starg

static

Syntax	static
Context	config>service>vpls>sap>snooping config>service>vpls>spoke-sdp>snooping config>service>vpls>mesh-sdp>snooping config>service>vpls>sap>mld-snooping config>service>vpls>spoke-sdp>mld-snooping config>service>vpls>mesh-sdp>mld-snooping
Description	This command enables access to the context to configure static group addresses. Static group addresses can be configured on a SAP or SDP. When present either as a (*, g) or a (s,g) entry, multicast packets matching the configuration will be forwarded even if no join message was registered for the specific group.
Default	n/a

to-sap

Syntax	to-sap sap-id no to-sap
Context	config>service>vpls>sap>snooping>mvr
Description	In some situations, the multicast traffic should not be copied from the MVR VPLS to the SAP on which the IGMP message was received (standard MVR behavior) but to another SAP.

This command configures the SAP to which the multicast data needs to be copied.

Default no to-sap

Parameters *sap-id* — Specifies the SAP to which multicast channels should be copied.

2.12.2.2.4 VPLS SAP ATM Commands

Note: The commands described in this section apply only to the 7750 SR.

atm

Syntax	atm
Context	config>service>vpls>sap
Description	<p>This command enables access to the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supports ATM functionality such as:</p> <ul style="list-style-type: none"> • Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality • Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality. <p>If ATM functionality is not supported for a given context, the command returns an error.</p>

egress

Syntax	egress
Context	config>service>vpls>sap>atm
Description	This command enables the context to configure egress ATM attributes for the SAP.

encapsulation

Syntax	encapsulation <i>atm-encap-type</i>
Context	config>service>vpls>sap>atm
Description	<p>This command specifies the data encapsulation for an ATM PVCC delimited SAP. The definition references RFC 2684, <i>Multiprotocol Encapsulation over ATM AAL5</i>, and to the ATM Forum LAN Emulation specification.</p> <p>Ingress traffic that does not match the configured encapsulation will be dropped.</p>
Default	<p>The encapsulation is driven by the services for which the SAP is configured.</p> <p>For IES and VPRN service SAPs, the default is aal5snap-routed.</p>

Parameters	<i>atm-encap-type</i> — Specify the encapsulation type.
Values	<p>aal5snap-routed — Routed encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.</p> <p>aal5mux-ip — Routed IP encapsulation for VC multiplexed circuit as defined in RFC 2684</p>

ingress

Syntax	ingress
Context	config>service>vpls>sap>atm
Description	This command enables the context to configure ingress ATM attributes for the SAP.

traffic-desc

Syntax	traffic-desc <i>traffic-desc-profile-id</i> no traffic-desc
Context	config>service>vpls>sap>atm>ingress config>service>vpls>sap>atm>egress
Description	<p>This command assigns an ATM traffic descriptor profile to a given context (for example, a SAP).</p> <p>When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction.</p> <p>When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.</p> <p>The no form of the command reverts the traffic descriptor to the default traffic descriptor profile.</p>
Default	The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.
Parameters	<i>traffic-desc-profile-id</i> — Specify a defined traffic descriptor profile (see the QoS atm-td-profile command).

oam

Syntax	oam
Context	config>service>vpls>sap>atm

Description This command enables the context to configure OAM functionality for a PVCC delimiting a SAP.

The ATM-capable MDAs support F5 end-to-end OAM functionality (AIS, RDI, loopback):

- ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance Principles and Functions version 11/95
- GR-1248-CORE - Generic Requirements for Operations of ATM Network Elements (NEs). Issue 3 June 1996
- GR-1113-CORE - Bellcore, Asynchronous Transfer Mode (ATM) and ATM Adaptation Layer (AAL) Protocols Generic Requirements, Issue 1, July 1994

alarm-cells

Syntax [no] alarm-cells

Context config>service>vpls>sap>atm

Description This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.

When alarm-cells functionality is enabled, PVCC's operational status is affected when a PVCC goes into AIS or RDI state because of an AIS/RDI processing (i.e. assuming nothing else affects PVCC's operational status, PVCC goes DOWN, when it enters a fault state and comes back UP, when it exits that fault state) and RDI cells are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state; however, if as result of an OAM state change, the PVCC changes operational status; then a trap is expected from an entity the PVCC is associated with (for example a SAP).

The no command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, PVCC's operational status is no longer affected by PVCC's OAM state changes due to AIS/RDI processing and RDI cells are not generated as result of PVCC going into an AIS or RDI state; however, PVCC's OAM status will record OAM faults as described above.

Note: When alarm-cells is disabled, a PVCC will change operational status to UP, if it was DOWN because of the alarm-cell processing.

Default Enabled for PVCCs delimiting VPLS SAPs

2.12.2.2.5 Service DHCP and Anti-Spoof Filtering Commands

anti-spoof

Syntax	anti-spoof {ip mac ip-mac} no anti-spoof
Context	config>service>vpls>sap config>service>ies>sap
Description	<p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (ip, mac, ip-mac) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The no form of the command disables anti-spoof filtering on the SAP.</p>
Default	no anti-spoof
Parameters	<p>ip — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof ip command will fail.</p> <p>mac — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. If a static host exists on the SAP without a specified MAC address, the anti-spoof mac command will fail.</p> <p>ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. For information about static host configuration, see sections Configuring Static Hosts and BNG Learning IP-Only Static Host's MAC Address.</p>

authentication-policy

Syntax	authentication-policy <i>name</i> no authentication-policy
Context	config>service>vpls>sap
Description	<p>This command defines which subscriber authentication policy must be applied when a DHCP message is received on the interface. The authentication policies must already be defined. The policy will only be applied when DHCP snooping is enabled on the SAP on Layer 2 interfaces.</p>
Parameters	<i>name</i> — Specifies a unique authentication policy name.

arp-host

Syntax	arp-host
Context	config>service>vpls>sap
Description	This command enables the context to configure ARP host parameters.

diameter-auth-policy

Syntax	diameter-auth-policy <i>name</i> no diameter-auth-policy
Context	config>service>vpls>sap
Description	This command is used to configure the Diameter NASREQ application policy to use for authentication.
Parameters	<i>name</i> — Specifies the name of the Diameter NASREQ application policy to use for authentication.

host-limit

Syntax	host-limit <i>max-num-hosts</i> no host-limit
Context	config>service>vpls>sap>arp-host
Description	This command configures the maximum number of ARP hosts. The no form of the command returns the value to the default.
Default	1
Parameters	<i>max-num-hosts</i> — Specifies the maximum number of ARP hosts allowed on this SAP.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

min-auth-interval

Syntax **min-auth-interval** *min-auth-interval*

no min-auth-interval

Context	config>service>vpls>sap>arp-host
Description	This command configures the minimum authentication interval. The no form of the command returns the value to the default.
Default	15
Parameters	<i>min-auth-interval</i> — Specifies the minimum authentication interval, in minutes. Values 1 to 6000

arp-reply-agent

Syntax	arp-reply-agent [sub-ident] no arp-reply-agent
Context	config>service>vpls>sap
Description	<p>This command enables a special ARP response mechanism in the system for ARP requests destined to static or dynamic hosts associated with the SAP. The system responds to each ARP request using the hosts MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header.</p> <p>ARP replies and requests received on a SAP with arp-reply-agent enabled will be evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP will be discarded when anti-spoof filtering is enabled.</p> <p>The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke-SDP or mesh-SDP) associated with the VPLS instance of the SAP.</p> <p>A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.</p> <p>Static hosts can be defined on the SAP using the host command. Dynamic hosts are enabled on the system by enabling the lease-populate command in the SAP's dhcp context. In the event that both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. In the event that both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.</p> <p>The arp-reply-agent command will fail if an existing static host on the SAP does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the SAP without both an IP address and MAC address will fail.</p> <p>The ARP-reply-agent may only be enabled on SAPs supporting Ethernet encapsulation.</p>

The **no** form of the command disables ARP-reply-agent functions for static and dynamic hosts on the SAP.

Default	not enabled
Parameters	<p><i>sub-ident</i> — Configures the arp-reply-agent to discard ARP requests received on the SAP that are targeted for a known host on the same SAP with the same subscriber identification.</p> <p>Hosts are identified by their subscriber information. For DHCP subscriber hosts, the subscriber hosts, the subscriber information is configured using the optional subscriber parameter string.</p> <p>When arp-reply-agent is enabled with sub-ident:</p> <ul style="list-style-type: none"> • If the subscriber information for the destination host exactly matches the subscriber information for the originating host and the destination host is known on the same SAP as the source, the ARP request is silently discarded. • If the subscriber information for the destination host or originating host is unknown or undefined, the source and destination hosts are not considered to be the same subscriber. The ARP request is forwarded outside the SAP's Split Horizon Group. • When sub-ident is not configured, the arp-reply-agent does not attempt to identify the subscriber information for the destination or originating host and will not discard an ARP request based on subscriber information.

calling-station-id

Syntax	[no] calling-station-id {mac remote-id sap-id sap-string}
Context	<pre>config>service>ies>if>sap config>service>ies>sub-if>grp-if config>service>vpls>sap config>service>vprn>if config>service>vprn>sub-if>grp-if config>subscr-mgmt>auth-plcy>include-radius-attribute</pre>
Description	This command enables the inclusion of the calling-station-id attribute in RADIUS authentication requests and RADIUS accounting messages.
Default	no calling-station-id
Parameters	<p>mac — Specifies that the mac-address will be sent.</p> <p>remote-id — Specifies that the remote-id will be sent.</p> <p>sap-id — Specifies that the sap-id will be sent.</p> <p>sap-string — Specifies that the value is the inserted value set at the SAP level. If no calling-station-id value is set at the SAP level, the calling-station-id attribute will not be sent.</p>

mac-linking

Syntax	mac-linking <i>ip-address</i> no mac-linking
Context	config>service>ies>sub-if>grp-if>sap>static-host config>service>vprn>sub-if>grp-if>sap>static-host
Description	This command associates this IPv6 host to the specified IPv4 host through the learned MAC address. A learned MAC from the IPv6 host will be associated with the IPv4 host and vice versa.
Default	n/a

rip-policy

Syntax	rip-policy <i>rip-policy-name</i> no rip-policy
Context	config>service>ies>sub-if>grp-if>sap>static-host
Description	This command specifies the name of the RIP policy up to 32 characters in length. The no form of the command removes the policy name from the static-host configuration.
Default	n/a

igmp-host-tracking

Syntax	igmp-host-tracking
Context	config>service>vprn>sub-if>grp-if>sap
Description	This command enables the context to configure IGMP host tracking parameters.

disable-router-alert-check

Syntax	[no] disable-router-alert-check
Context	config>service>vprn>sub-if>grp-if>sap>igmp-host-tracking
Description	This command enables the IGMP router alert check option. The no form of the command disables the router alert check.

expiry-time

Syntax	expiry-time <i>expiry-time</i> no expiry-time
Context	config>service>vprn>sub-if>grp-if>sap>igmp-snooping
Description	This command configures the time that the system continues to track inactive hosts. The no form of the command removes the values from the configuration.
Default	no expiry-time
Parameters	<i>expiry-time</i> — Specifies the time, in seconds, that this system continues to track an inactive host. Values 1 to 65535

import

Syntax	import <i>policy-name</i> no import
Context	config>service>vprn>sub-if>grp-if>sap>igmp-snooping
Description	This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a single SAP at any time. The no form of the command removes the policy association from the SAP or SDP.
Default	no import
Parameters	<i>policy-name</i> — The routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context The router policy must be defined before it can be imported.

max-num-group

Syntax	max-num-groups <i>max-num-groups</i> no max-num-groups
Context	config>service>vprn>sub-if>grp-if>sap>igmp-snooping
Description	This command configures the maximum number of multicast groups allowed to be tracked. The no form of the command removes the values from the configuration.

Default	no max-num-groups
Parameters	<i>max-num-groups</i> — Specifies the maximum number of multicast groups allowed to be tracked.
Values	1 to 196607

max-num-sources

Syntax	max-num-sources <i>max-num-sources</i> no max-num-sources
Context	config>service>vprn>sub-if>grp-if>sap>igmp-snooping
Description	This command configures the maximum number of multicast sources allowed to be tracked per group. The no form of the command removes the value from the configuration.
Parameters	<i>max-num-sources</i> — Specifies the maximum number of multicast sources allowed to be tracked per group.
Values	1 to 1000

max-num-grp-sources

Syntax	[no] max-num-grp-sources
Context	config>service>vprn>sub-if>grp-if>sap>igmp-snooping
Description	This command configures the maximum number of group sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed. When this object has a value of 0, there is no limit to the number of group sources. The no form of the command removes the value from the configuration.
Default	no max-num-grp-sources
Parameters	1 to 32000 — Specifies the maximum number of multicast sources allowed to be tracked per group.

2.12.2.2.6 Filter and QoS Policy Commands

egress

Syntax	egress
Context	config>service>vpls>sap config>service>vpls>mesh-sdp config>service>ies>if>sap
Description	This command enables the context to configure egress Quality of Service (QoS) policies and filter policies. If no QoS policy is defined, the system default QoS policy is used for egress processing. If no egress filter is defined, no filtering is performed.

ingress

Syntax	ingress
Context	config>service>vpls>sap>egress config>service>vpls>mesh-sdp config>service>vpls>spoke-sdp config>service>ies>if>sap
Description	This command enables the context to configure ingress Quality of Service (QoS) policies and filter policies. If no QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter is defined, no filtering is performed.

filter

Syntax	filter ip <i>ip-filter-id</i> filter ipv6 <i>ipv6-filter-id</i> filter mac <i>mac-filter-id</i> no filter no filter [ip <i>ip-filter-id</i>] [mac <i>mac-filter-id</i>] [ipv6 <i>ipv6-filter-id</i>]
Context	config>service>vpls>sap>egress config>service>vpls>sap>ingress config>service>vpls>mesh-sdp config>service>vpls>spoke-sdp config>service>ies>if>spoke-sdp>egress config>service>ies>if>spoke-sdp>ingress

Description	<p>This command associates an IP filter policy or MAC filter policy with an ingress or egress Service Access Point (SAP) or IP interface.</p> <p>Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.</p> <p>The filter command is used to associate a filter policy with a specified <i>filter ID</i> with an ingress or egress SAP. The <i>filter ID</i> must already be defined before the filter command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.</p> <p>The no form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.</p>
Special Cases	VPLS — Both MAC and IP filters are supported on a VPLS service SAP.
Parameters	<p>ip <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.</p> <p>Values 1 to 65535</p> <p>ipv6 <i>ipv6-filter-id</i> — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters (applies only to the 7750 SR).</p> <p>Values 1 to 65535</p> <p>mac <i>mac-filter-id</i> — Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.</p> <p>Values 1 to 65535</p>

agg-rate

Syntax	[no] agg-rate
Context	<pre>config>service>vprn>sub-if>grp-if>sap>egress config>service>ies>sub-if>grp-if>sap>egress</pre>
Description	<p>This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: rate, limit-unused-bandwidth, and queue-frame-based-accounting.</p>

rate

Syntax	rate {max rate} no rate
Context	config>service>vprn>sub-if>grp-if>sap>egress>agg-rate config>service>ies>sub-if>grp-if>sap>egress>agg-rate
Description	This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, VPORT etc.).

limit-unused-bandwidth

Syntax	[no] limit-unused-bandwidth
Context	config>service>vprn>sub-if>grp-if>sap>egress>agg-rate config>service>ies>sub-if>grp-if>sap>egress>agg-rate
Description	This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

queue-frame-based-accounting

Syntax	[no] queue-frame-based-accounting
Context	config>service>vprn>sub-if>grp-if>sap>egress>agg-rate
Description	This command is used to enabled (or disable) frame based accounting on all policers and queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSMDA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured, however the offsets are applied to the statistics.

filter

Syntax	filter ip <i>ip-filter-id</i> filter ipv6 <i>ipv6-filter-id</i> no filter [ip <i>ip-filter-id</i>] [ipv6 <i>ipv6-filter-id</i>] no filter [ip <i>ip-filter-id</i>]
Context	config>service>ies>if>sap>egress config>service>ies>if>sap>ingress config>service>ies>sub-if>grp-if>sap>egress config>service>ies>sub-if>grp-if>sap>ingress config>service>vprn>sub-if>grp-if>sap>egress

```
config>service>vprn>sub-if>grp-if>sap>ingress
```

Description This command associates an IP filter policy with an ingress or egress Service Access Point (SAP). Filter policies control the forwarding and dropping of packets based on the matching criteria. MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.

The **filter** command is used to associate a filter policy with a specified *filter ID* with an ingress or egress SAP. The *filter policy* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to the match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Special Cases **IES** — Only IP filters are supported on an IES IP interface, and the filters only apply to routed traffic.

Parameters **ip** *ip-filter-id* — Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

ipv6 *ipv6-filter-id* — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters ().

Values 1 to 65535

qinq-mark-top-only

Syntax [no] qinq-mark-top-only

Context config>service>vprn>if>sap>egress
config>service>vprn>sub-if>grp-if>sap>egress

Description When enabled (the encapsulation type of the access port where this SAP is defined as qinq), the **qinq-mark-top-only** command specifies which P-bits to mark during packet egress. When disabled, both set of P-bits are marked. When the enabled, only the P-bits in the top Q-tag are marked.

Default no qinq-mark-top-only

multicast-group

Syntax	multicast-group <i>group-name</i> no multicast-group
Context	config>service>vpls>sap>egress
Description	This command places a VPLS Ethernet SAP into an egress multicast group. The SAP must comply with the egress multicast group's common requirements for member SAPs. If the SAP does not comply, the command will fail and the SAP will not be a member of the group. Common requirements for an egress multicast group are listed below:

- If an egress-filter is specified on the egress multicast group, the SAP must have the same egress filter applied.
- If an egress-filter is not defined on the egress multicast group, the SAP cannot have an egress filter applied.
- If the egress multicast group has an encap-type set to null, the SAP must be defined on a port with the port encapsulation type set to null.
- If the egress multicast group has an encap-type set to dot1q, the SAP must be defined on a port with the port encapsulation type set to dot1q and the port's dot1q-etype must match the dot1q-etype defined on the egress multicast group.
- The access port the SAP is created on cannot currently be an egress mirror source.

Once a SAP is a member of an egress multicast group, the following rules apply:

- The egress filter defined on the SAP cannot be removed or modified. Egress filtering is managed at the egress multicast group for member SAPs.
- If the encapsulation type for the access port the SAP is created on is set to dot1q, the port's dot1q-etype value cannot be changed.
- Attempting to define an access port with a SAP that is currently defined in an egress multicast group as an egress mirror source will fail.

Once a SAP is included in an egress multicast group, it is then eligible for efficient multicast replication if the egress forwarding plane performing replication for the SAP is capable. If the SAP is defined as a Link Aggregation Group (LAG) SAP, it is possible that some links in the LAG are on forwarding planes that support efficient multicast replication while others are not. The fact that some or all the forwarding planes associated with the SAP cannot perform efficient multicast replication does not affect the ability to place the SAP into an egress multicast group.

A SAP may be a member of one and only one egress multicast group. If the multicast-group command is executed with another egress multicast group name, the system will attempt to move the SAP to the specified group. If the SAP is not placed into the new group, the SAP will remain a member of the previous egress multicast group. Moving a SAP into an egress multicast group may cause a momentary gap in replications to the SAP destination while the move is being processed.

The **no** form of the command removes the SAP from any egress multicast group in which it may currently have membership. The SAP will be removed from all efficient multicast replication chains and normal replication will apply to the SAP. A momentary gap in replications to the SAP destination while it is being moved is possible. If the SAP is not currently a member in an egress multicast group, the command has no effect.

Default no multicast-group

Parameters *group-name* — The *group-name* is required when specifying egress multicast group membership on a SAP. An egress multicast group with the specified egress-multicast-group-name must exist and the SAP must pass all common requirements or the command will fail.

Values Any valid egress multicast group name.

Default n/a, an egress multicast group name must be explicitly specified.

qos

Syntax **qos** *policy-id*
no qos

Context config>service>vpls>sap>egress
config>service>vpls>sap>ingress
config>service>ies>if>sap>egress
config>service>ies>if>sap>ingress
config>service>vprn>if>sap>egress
config>service>vprn>sub-if>grp-if>sap>egress

Description This command associates a Quality of Service (QoS) policy with an ingress or egress Service Access Point (SAP) or IP interface.

QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the *policy-id* does not exist, an error will be returned.

The **qos** command is used to associate both ingress and egress QoS policies. The **qos** command only allows ingress policies to be associated on SAP or IP interface ingress and egress policies on SAP or IP interface egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.

By default, no specific QoS policy is associated with the SAP or IP interface for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.

Parameters	<i>policy-id</i> — The ingress/egress policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.
Values	1 to 65535
	shared-queuing — Specify the ingress shared queue policy used by this SAP. When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.

queue-override

Syntax	[no] queue-override
Context	config>service>ies>if>sap>egress config>service>ies>if>sap>ingress
Description	This command enables the context to configure override values for the specified SAP egress QoS queue. These values override the corresponding ones specified in the associated SAP egress QoS policy.

queue

Syntax	[no] queue <i>queue-id</i>
Context	config>service>ies>if>sap>egress>queue-override config>service>ies>if>sap>ingress>queue-override
Description	This command specifies the ID of the queue whose parameters are to be overridden.
Parameters	<i>queue-id</i> — The queue ID whose parameters are to be overridden.
Values	1 to 32

adaptation-rule

Syntax	adaptation-rule [pir {max min closest}] [cir {max min closest}] no adaptation-rule
Context	config>service>ies>if>sap>egress>queue-override>queue config>service>ies>if>sap>ingress>queue-override>queue
Description	This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

The **no** form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

Default	no adaptation-rule
Parameters	<p>pir — The pir parameter defines the constraints enforced when adapting the PIR rate defined within the queue queue-id rate command. The pir parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the rate command is not specified, the default applies.</p> <p>max — The max (maximum) option is mutually exclusive with the min and closest options. When max is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the rate command.</p> <p>min — The min (minimum) option is mutually exclusive with the max and closest options. When min is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the rate command.</p> <p>closest — The closest parameter is mutually exclusive with the min and max parameter. When closest is defined, the operational PIR for the queue will be the rate closest to the rate specified using the rate command.</p> <p>cir — The cir parameter defines the constraints enforced when adapting the CIR rate defined within the queue queue-id rate command. The cir parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the cir parameter is not specified, the default constraint applies.</p>

avg-frame-overhead

Syntax	avg-frame-overhead <i>percent</i> no avg-frame-overhead
Context	config>service>ies>if>sap>egress>queue-override config>service>ies>if>sap>ingress>queue-override
Description	<p>This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).</p> <p>When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:</p> <ul style="list-style-type: none"> • Offered-load to The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.

- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000×0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50×20 or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be $1000 / 10000$ or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500×1.1 or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- Frame based PIR — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500×1.1 or 8250 octets.

- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to figure the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default 0

Parameters *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Values 0 to 100

cbs

Syntax **cbs** *size-in-kbytes*
no cbs

Context config>service>ies>if>sap>egress>queue-override>queue
config>service>ies>if>sap>ingress>queue-override>queue

Description This command can be used to override specific attributes of the specified queue's CBS parameters.

It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS settings into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

The **no** form of this command returns the CBS size to the default value.

Default	no cbs
Parameters	<i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).
Values	0 to 1048576 or default

high-prio-only

Syntax	high-prio-only <i>percent</i> no high-prio-only
Context	config>service>ies>if>sap>egress>queue-override>queue config>service>ies>if>sap>ingress>queue-override>queue
Description	This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The high-prio-only command configures the percentage of buffer space for the queue, used exclusively by high priority packets.

The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The **high-prio-only** parameter is used to override the default value derived from the **network-queue** command.

The defined **high-prio-only** value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the **high-prio-only** value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command restores the default high priority reserved size.

Parameters	<i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.
Values	0 to 100 default

mbs

Syntax	mbs { <i>size-in-kbytes</i> default } no mbs
Context	config>service>ies>if>sap>egress>queue-override>queue config>service>ies>if>sap>ingress>queue-override>queue
Description	<p>This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.</p> <p>The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packets RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The no form of this command returns the MBS size assigned to the queue.</p>
Default	default
Parameters	<p><i>size-in-kbytes</i> — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.</p> <p>Values 0 to 1073741824 or default</p>

rate

Syntax	rate <i>pir-rate</i> [<i>cir cir-rate</i>] no rate
Context	config>service>ies>if>sap>egress>queue-override>queue config>service>ies>if>sap>ingress>queue-override>queue
Description	This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.

The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.

The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile, then out-of-profile, packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.

The CIR can be used by the queue's parent commands *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

Default	rate max cir 0 — The max default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The max value is mutually exclusive to the pir-rate value.
Parameters	<p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the rate command is executed, a valid PIR setting must be explicitly defined. When the rate command has not been executed, the default PIR of max is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's adaptation-rule parameters and the actual hardware where the queue is provisioned.</p> <p>Values 1 to 2000000000</p> <p>Default max</p> <p>cir <i>cir-rate</i> — The cir parameter overrides the default administrative CIR used by the queue. When the rate command is executed, a CIR setting is optional. When the rate command has not been executed or the cir parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer. The sum keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.</p> <p>Values 0 to 2000000000, max, sum</p> <p>Default 0</p>

scheduler-policy

Syntax	scheduler-policy <i>scheduler-policy-name</i>
---------------	--

no scheduler-policy

Context	<pre> config>service>vpls>sap>ingress config>service>vpls>sap>egress config>service>ies>if>sap>egress config>service>ies>if>sap>ingress config>service>vprn>if>sap>egress config>service>vprn>sub-if>grp-if>sap>egress config>service>vprn>if>sap>ingress config>service>vprn>sub-if>grp-if>sap>ingress </pre>
Description	<p>This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the config>qos>scheduler-policy <i>scheduler-policy-name</i> context.</p> <p>The no form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the ingress SAP queues and egress SAP policers and queues associated with the customer site. Policers and queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have policers or queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more policers or queues. When the no scheduler-policy command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.</p>
Parameters	<p><i>scheduler-policy-name</i> — The <i>scheduler-policy-name</i> parameter applies an existing scheduler policy that was created in the config>qos>scheduler-policy <i>scheduler-policy-name</i> context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.</p>
Values	Any existing valid scheduler policy name.

block-on-mesh-failure

Syntax	[no] block-on-mesh-failure
Context	config>service>vpls>spoke-sdp
Description	<p>This command enables blocking (bring the spoke SDP to an operationally down state) after all configured mesh SDPs are in operationally down state. This event is signaled to corresponding T-LDP peer by withdrawing service label (status-bit-signaling non-capable peer) or by setting "PW not forwarding" status bit in T-LDP message (status-bit-signaling capable peer).</p>
Default	disabled

max-nbr-mac-addr

Syntax	max-nbr-mac-addr <i>table-size</i> no max-nbr-mac-addr
Context	config>service>vpls>sap config>service>vpls>spoke-sdp
Description	<p>This command specifies the maximum number of FDB entries for both learned and static MAC addresses for this SAP or spoke SDP.</p> <p>When the configured limit has been reached, and discard-unknown-source has been enabled for this SAP or spoke SDP (see the discard-unknown-source command), packets with unknown source MAC addresses will be discarded.</p> <p>The no form of the command restores the global MAC learning limitations for the SAP or spoke SDP.</p>
Default	no max-nbr-mac-addr
Parameters	<i>table-size</i> — The maximum number of MAC entries in the FDB from this SAP. Values 1 to 511999 for the 7750 SR 1 to 131071 for the 7450 ESS

multi-service-site

Syntax	multi-service-site <i>customer-site-name</i> no multi-service-site
Context	config>service>vpls>sap config>service>ies>sap config>service>ies>sub-if>grp-if>sap config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap
Description	<p>This command associates the SAP with a <i>customer-site-name</i>. If the specified <i>customer-site-name</i> does not exist in the context of the service customer ID an error occurs and the command will not execute. If <i>customer-site-name</i> exists, the current and future defined queues on the SAP (ingress and egress) will attempt to use the scheduler hierarchies created within <i>customer-site-name</i> as parent schedulers.</p> <p>This command is mutually exclusive with the SAP ingress and egress scheduler-policy commands. If a scheduler-policy has been applied to either the ingress or egress nodes on the SAP, the multi-service-site command will fail without executing. The locally applied scheduler policies must be removed prior to executing the multi-service-site command.</p> <p>The no form of the command removes the SAP from any multi-service customer site the SAP belongs to. Removing the site can cause existing or future policers and queues to enter an orphaned state.</p>

Default	n/a
Parameters	<p><i>customer-site-name</i> — The customer-site-name must exist in the context of the customer-id defined as the service owner. If customer-site-name exists and local scheduler policies have not been applied to the SAP, the current and future policers queues defined on the SAP will look for their parent schedulers within the scheduler hierarchies defined on customer-site-name.</p> <p>Values Any valid customer-site-name created within the context of the customer-id.</p>

retail-service-id

Syntax	retail-svc-id <i>service-id</i> no retail-svc-id
Context	config>service>ies>sub-if>grp-if>sap>static-host config>service>vprn>sub-if>grp-if>sap>static-host
Description	This command specifies the service id of the retailer IES/VP RN service to which the static IPv6 host belongs. A corresponding retailer subscriber interface must exist in the specified service.
Default	no retail-svc-id
Parameters	<i>service-id</i> — Specifies the retailer service id. <p>Values 1 to 2148007978 or service name up to 64 characters in length</p>

static-host

Syntax	static-host ip <i>ip-address</i> [mac <i>ieee-address</i>] [create] static-host mac <i>ieee-address</i> [create] no static-host ip <i>ip-address</i> [mac <i>ieee-address</i>] no static-host all [force] no static-host ip <i>ip-address</i>
Context	config>service>ies>if>sap config>service>vpls>sap config>service>ies>sub-if>grp-if>sap config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap
Description	This command creates a static subscriber host for the SAP. Static subscriber hosts may be used by the system for various purposes. Applications within the system that make use of static host entries include anti-spoof, ARP reply agent and source MAC population into the VPLS forwarding database.

Multiple static hosts may be defined on the SAP. Each host is identified by either a source IP address, a source MAC address or both a source IP and source MAC address. Every static host definition must have at least one address defined, IP or MAC.

Static hosts can exist on the SAP even with anti-spoof and ARP reply agent features disabled. When enabled, each feature has different requirements for static hosts.

Use the **no** form of the command to remove a static entry from the system. The specified *ip-address* and *mac-address* must match the host's exact IP and MAC addresses as defined when it was created. When a static host is removed from the SAP, the corresponding anti-spoof filter entry and/or FDB entry is also removed.

- Parameters**
- ip** *ip-address* — Specify this optional parameter when defining a static host. The IP address must be specified for **anti-spoof ip**, **anti-spoof ip-mac** and **arp-reply-agent** (**arp-reply-agent** is supported by the 7450 ESS only). Only one static host may be configured on the SAP with a given IP address.
- mac** *mac-address* — Specify this optional parameter when defining a static host. The MAC address must be specified for **anti-spoof mac**, and **anti-spoof ip-mac** and **arp-reply-agent** (**arp-reply-agent** is supported by the 7450 ESS only). Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address.
- Every static host definition must have at least one address defined, IP or MAC.
- force** — Specifies the forced removal of the static host addresses.

ancp-string

- Syntax** **ancp-string** *ancp-string*
no ancp-string
- Context** config>service>ies>if>sap>static-host
config>service>vpls>sap>static-host
config>service>ies>sub-if>grp-if>sap>static-host
config>service>vprn>if>sap
config>service>vprn>sub-if>grp-if>sap
- Description** This command specifies the ANCP string associated to this SAP host.
- Parameters** *ancp-string* — Specifies the ANCP string up to 63 characters in length.

app-profile

- Syntax** **app-profile** *app-profile-name*
no app-profile
- Context** config>service>ies>if>sap>static-host
config>service>vpls>sap>static-host

```
config>service>ies>sub-if>grp-if>sap>static-host
config>service>vprn>if>sap
config>service>vprn>sub-if>grp-if>sap
```

Description This command specifies an application profile name.

Parameters *app-profile-name* — Specifies the application profile name up to 32 characters in length.

inter-dest-id

Syntax **inter-dest-id** *intermediate-destination-id*
no inter-dest-id

Context config>service>ies>if>sap>static-host
config>service>vpls>sap>static-host
config>service>vprn>if>sap>static-host
config>service>vprn>sub-if>grp-if>sap>static-host

Description This command specifies to which intermediate destination (for example a DSLAM) this host belongs.

Parameters *intermediate-destination-id* — Specifies the intermediate destination ID.

managed-routes

Syntax **managed-routes**

Context config>service>ies>sub-if>grp-if>sap>static-host
config>service>vprn>sub-if>grp-if>sap>static-host

Description This command configures managed routes.

route

Syntax **route** {*ip-prefix/length* | *ip-prefix netmask*} [**create**]
no route {*ip-prefix/length* | *ip-prefix netmask*} [**metric** *metric-value*]

Context config>service>ies>sub-if>grp-if>sap>static-host>managed-routes
config>service>vprn>sub-if>grp-if>sap>static-host>managed-routes

Description This command assigns managed-route to a given subscriber-host. As a consequence, a static-route pointing subscriber-host ip address as a next hop will be installed in FIB. Up to 16 managed routes per subscriber-host can be configured.

The **no** form of the command removes the respective route. Per default, there are no managed-routes configured.

- Parameters** *ipv6-prefix/length | ipv6-prefix netmask* — This parameter associates an IPv6 managed route to the IPv6 static host. The IPv6 managed routes can overlap with the static host IPv6 address.
- ipv4-prefix/length | ipv6-prefix netmask* — This parameter associates an IPv4 managed route to the IPv4 static host.

Note: A maximum of 16 managed routes can be associated to a static host. IPv4 hosts can only have IPv4 managed routes and IPv6 hosts can only have IPv6 managed routes.

metric *metric-value* — A metric can be associated with the provisioned managed route.

sla-profile

- Syntax** **sla-profile** *sla-profile-name*
no sla-profile
- Context** config>service>ies>if>sap>static-host
 config>service>vpls>sap>static-host
 config>service>ies>sub-if>grp-if>sap>static-host
 config>service>vprn>if>sap>static-host
 config>service>vprn>sub-if>grp-if>sap>static-host
- Description** This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.
- Parameters** *sla-profile-name* — Specifies the SLA profile name.

sub-profile

- Syntax** **sub-profile** *sub-profile-name*
no sub-profile
- Context** config>service>ies>if>sap>static-host
 config>service>vpls>sap>static-host
 config>service>ies>sub-if>grp-if>sap>static-host
 config>service>vprn>if>sap>static-host
 config>service>vprn>sub-if>grp-if>sap>static-host
- Description** This command specifies an existing subscriber profile name to be associated with the static subscriber host.
- Parameters** *sub-profile-name* — Specifies the sub-profile name.

subscriber

Syntax	subscriber <i>sub-ident</i> no subscriber
Context	config>service>ies>if>sap>static-host config>service>vpls>sap>static-host config>service>ies>sub-if>grp-if>sap>static-host config>service>vprn>if>sap>static-host config>service>vprn>sub-if>grp-if>sap>static-host
Description	This command specifies an existing subscriber identification profile to be associated with the static subscriber host.
Parameters	<i>sub-ident</i> — Specifies the subscriber identification.

subscriber-sap-id

Syntax	[no] subscriber-sap-id
Context	config>service>ies>if>sap>static-host config>service>vpls>sap>static-host config>service>ies>sub-if>grp-if>sap>static-host config>service>vprn>if>sap>static-host config>service>vprn>sub-if>grp-if>sap>static-host
Description	This command enables using the SAP ID as subscriber id.
Parameters	subscriber-sap-id — Specifies to use the sap-id as the subscriber-id.

static-host-mgmt

Syntax	static-host-mgmt
Context	config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	This command enables the context to configure common parameters for IPv6 static hosts.

mac-learning-options

Syntax	[no] mac-learning-options
Context	config>service>ies>sub-if>grp-if>sap>static-host-mgmt config>service>vprn>sub-if>grp-if>sap>static-host-mgmt

Description	This command configures additional methods by which the BNG will learn the subscriber host MAC.
--------------------	---

data-triggered

Syntax	[no] data-triggered
Context	config>service>ies>sub-if>grp-if>sap>static-host-mgmt>mac-learning-options config>service>vprn>sub-if>grp-if>sap>static-host-mgmt>mac-learning-options
Description	This command enables learning of MAC addresses from data packets. The no form of the command disables learning of MAC addresses from data packets.
Default	no data-triggered

single-mac

Syntax	[no] single-mac
Context	config>service>ies>sub-if>grp-if>sap>static-host-mgmt>mac-learning-options config>service>vprn>sub-if>grp-if>sap>static-host-mgmt>mac-learning-options
Description	This command controls how the SAP will learn the IPv6 static host MAC address. Enabling this command indicates that this particular SAP will only have one subscriber and will only have one MAC address for all hosts. With this parameter enabled, the subscriber's NS and RS source MAC address is used to automatically populate the subscriber MAC address. To allow this auto-populate behavior, the subscriber's NS and RS source IP must be of type link local address.
Default	no single-mac

static-mac

Syntax	[no] static-mac <i>ieee-mac-address</i>
Context	config>service>vpls>sap config>service>vpls>mesh-sdp config>service>vpls>spoke-sdp
Description	This command creates a remote static MAC entry in the Virtual Private LAN Service (VPLS) forwarding database (FDB) associated with the Service Distribution Point (SDP). In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Remote static MAC entries create a permanent MAC address to SDP association in the forwarding database for the VPLS instance so that MAC address will not be learned on the edge device.

Note: Static MAC definitions on one edge device are not propagated to other edge devices participating in the VPLS instance, that is, each edge device has an independent forwarding database for the VPLS.

Only one static MAC entry (local or remote) can be defined per MAC address per VPLS instance.

By default, no static MAC address entries are defined for the SDP.

The **no** form of this command deletes the static MAC entry with the specified MAC address associated with the SDP from the VPLS forwarding database.

Parameters *ieee-mac-address* — Specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

2.12.2.2.7 SDP Commands

mesh-sdp

Syntax	mesh-sdp <i>sdp-id[:vc-id]</i> [vc-type { ether vlan }] no mesh-sdp <i>sdp-id[:vc-id]</i>
Context	config>service>vpls config>service>vpls>mesh-sdp
Description	This command binds a VPLS service to an existing Service Distribution Point (SDP). Mesh SDPs bound to a service are logically treated like a single bridge “port” for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke SDPs and SAPs) and not transmitted on any mesh SDPs.

 **Note:** This command creates a binding between a service and an SDP. The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.

The SDP must already be defined in the **config>service>sdp** context in order to associate the SDP with an Epipe or VPLS service. If the **sdp sdp-id** is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end router devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

Default	No <i>sdp-id</i> is bound to a service.
Special Cases	VPLS — Several SDPs can be bound to a VPLS. Each SDP must be destined to a different router. If two <i>sdp-id</i> bindings terminate on the same router, an error occurs and the second SDP binding is rejected.
Parameters	<i>sdp-id</i> — The SDP identifier. Values 1 to 17407 <i>vc-id</i> — The virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID. Values 1 to 4294967295 vc-type — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the vc-type command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the binding's VC type causes the binding to signal the new VC type to the far end when signaling is enabled. VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i> . The VC type value for Ethernet is 0x0005. The VC type value for an Ethernet VLAN is 0x0004. ether — Defines the VC type as Ethernet. The vlan keyword is mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing no vc-type and restores the default VC type for the spoke SDP binding. (hex 5) vlan — Defines the VC type as VLAN. The ethernet keyword is mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings.

spoke-sdp

Syntax	spoke-sdp <i>sdp-id</i> [: <i>vc-id</i>] [vc-type { ether vlan }] [split-horizon-group <i>group-name</i>] no spoke-sdp <i>sdp-id</i> [: <i>vc-id</i>]
---------------	---

Context	config>service>vpls
Description	<p>This command binds a service to an existing Service Distribution Point (SDP).</p> <p>A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the config>service>sdp context in order to associate an SDP with a VPLS service. If the sdp sdp-id is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end 7450 ESS or 7750 SR devices can participate in the service.</p> <p>The no form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p>
Default	No <i>sdp-id</i> is bound to a service.
Special Cases	VPLS — Several SDPs can be bound to a VPLS service. Each SDP must use unique <i>vc-ids</i> . An error message is generated if two SDP bindings with identical <i>vc-ids</i> terminate on the same router. Split horizon groups can only be created in the scope of a VPLS service.
Parameters	<p><i>sdp-id</i> — The SDP identifier.</p> <p>Values 1 to 17407</p> <p><i>vc-id</i> — The virtual circuit identifier.</p> <p>Values 1 to 4294967295</p> <p>vc-type — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the vc-type command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the binding’s VC type causes the binding to signal the new VC type to the far end when signaling is enabled.</p> <p>VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i>.</p> <p>The VC type value for Ethernet is 0x0005.</p> <p>The VC type value for an Ethernet VLAN is 0x0004.</p> <p>Values ether, vlan</p>

ether — Defines the VC type as Ethernet. The **ethernet**, **vlan**, and **vpls** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke SDP binding. (hex 5)

vlan — Defines the VC type as VLAN. The **ethernet**, **vlan**, and **vpls** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings.
The VLAN VC-type requires at least one dot1Q tag within each encapsulated Ethernet packet transmitted to the far end.

split-horizon-group *group-name* — Specifies the name of the split horizon group to which the SDP belongs.

spoke-sdp

Syntax	spoke-sdp <i>sdp-id[:vc-id]</i> no spoke-sdp <i>sdp-id[:vc-id]</i>
Context	config>service>ies>if
Description	<p>This command binds a service to an existing Service Distribution Point (SDP).</p> <p>A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the config>service>sdp context in order to associate an SDP with an IES service. If the sdp sdp-id is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.</p> <p>The no form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router. The spoke SDP must be shut down first before it can be deleted from the configuration.</p>
Default	No <i>sdp-id</i> is bound to a service.
Special Cases	IES — At most, only one <i>sdp-id</i> can be bound to an IES service.
Parameters	<i>sdp-id</i> — The SDP identifier. Allowed values are integers in the range of 1 and 17407 for existing SDPs.

vc-id — The virtual circuit identifier.

Values 1 to 4294967295

egress

Syntax	egress
Context	config>service>vpls>mesh-sdp config>service>vpls>spoke-sdp config>service>ies>if>spoke-sdp
Description	This command configures the egress SDP context.

ingress

Syntax	ingress
Context	config>service>vpls>mesh-sdp config>service>vpls>spoke-sdp config>service>ies>if>spoke-sdp
Description	This command configures the ingress SDP context.

vc-label

Syntax	[no] vc-label <i>egress-vc-label</i>
Context	config>service>vpls>mesh-sdp>egress config>service>vpls>spoke-sdp>egress config>service>ies>if>spoke-sdp>egress
Description	This command configures the egress VC label.
Parameters	<i>vc-label</i> — A VC egress value that indicates a specific connection. Values 16 to 1048575

vc-label

Syntax	[no] vc-label <i>ingress-vc-label</i>
Context	config>service>vpls>mesh-sdp>ingress config>service>vpls>spoke-sdp>ingress config>service>ies>if>spoke-sdp>ingress

Description	This command configures the ingress VC label.
Parameters	<i>vc-label</i> — A VC ingress value that indicates a specific connection.
Values	2048 to 18431

vlan-vc-tag

Syntax	vlan-vc-tag <i>vlan-id</i> no vlan-vc-tag [<i>vlan-id</i>]
Context	config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp
Description	<p>This command specifies an explicit dot1q value used when encapsulating to the SDP far end. When signaling is enabled between the near and far end, the configured dot1q tag can be overridden by a received TLV specifying the dot1q value expected by the far end. This signaled value must be stored as the remote signaled dot1q value for the binding. The provisioned local dot1q tag must be stored as the administrative dot1q value for the binding.</p> <p>When the dot1q tag is not defined, the default value of zero is stored as the administrative dot1q value. Setting the value to zero is equivalent to not specifying the value.</p> <p>The no form of this command disables the command.</p>
Default	no vlan-vc-tag
Parameters	<i>vlan-id</i> — Specifies a valid VLAN identifier to bind an 802.1Q VLAN tag ID.

avg-frame-overhead

Syntax	avg-frame-overhead <i>percent</i> no avg-frame-overhead
Context	config>service>vpls>sap>egress>queue-override>queue
Description	<p>This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).</p> <p>When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:</p>

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queues current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000×0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50×20 or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queues offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be $1000 / 10000$ or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queues configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500×1.1 or 550 octets.
- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queues frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port schedulers within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queues configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500×1.1 or 8250 octets.

- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to figure the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default 0

Parameters *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Values 0 to 100

queue-override

Syntax [no] queue-override

Context config>service>vpls>sap>egress
config>service>vpls>sap>ingress

Description This command enables the context to configure override values for the specified SAP egress or ingress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy.

queue

Syntax	[no] queue <i>queue-id</i>
Context	config>service>vpls>sap>egress>queue-override config>service>vpls>sap>ingress>queue-override
Description	This command specifies the ID of the queue whose parameters are to be overridden.
Parameters	<i>queue-id</i> — The queue ID whose parameters are to be overridden.
Values	1 to 32

adaptation-rule

Syntax	adaptation-rule [pir { max min closest }] [cir { max min closest }] no adaptation-rule
Context	config>service>vpls>sap>egress>queue-override>queue config>service>vpls>sap>ingress>queue-override>queue
Description	<p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> <p>The no form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific adaptation-rule is removed, the default constraints for rate and cir apply.</p>
Default	no adaptation-rule
Parameters	<p><i>pir</i> — The pir parameter defines the constraints enforced when adapting the PIR rate defined within the queue <i>queue-id</i> rate command. The pir parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the rate command is not specified, the default applies.</p> <p><i>max</i> — The max (maximum) option is mutually exclusive with the min and closest options. When max is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the rate command.</p> <p><i>min</i> — The min (minimum) option is mutually exclusive with the max and closest options. When min is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the rate command.</p> <p><i>closest</i> — The closest parameter is mutually exclusive with the min and max parameter. When closest is defined, the operational PIR for the queue will be the rate closest to the rate specified using the rate command.</p>

cir — The **cir** parameter defines the constraints enforced when adapting the CIR rate defined within the **queue queue-id rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

cbs

Syntax	cbs <i>size-in-kbytes</i> no cbs
Context	config>service>vpls>sap>egress>queue-override>queue config>service>vpls>sap>ingress>queue-override>queue
Description	<p>This command can be used to override specific attributes of the specified queue's CBS parameters.</p> <p>It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS settings into the defined reserved total.</p> <p>When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.</p> <p>The no form of this command returns the CBS size to the default value.</p>
Default	no cbs
Parameters	<p><i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).</p> <p>Values 0 to 1048576 or default</p>

high-prio-only

Syntax	high-prio-only <i>percent</i> no high-prio-only
Context	config>service>vpls>sap>egress>queue-override>queue config>service>vpls>sap>ingress>queue-override>queue

Description	<p>This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The high-prio-only command configures the percentage of buffer space for the queue, used exclusively by high priority packets.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The high-prio-only parameter is used to override the default value derived from the network-queue command.</p> <p>The defined high-prio-only value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.</p> <p>The no form of this command restores the default high priority reserved size.</p>
Parameters	<p><i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.</p> <p>Values 0 to 100 default</p>

mbs

Syntax	mbs { <i>size-in-kbytes</i> default } no mbs
Context	config>service>vpls>sap>ingress>queue-override>queue config>service>vpls>sap>egress>queue-override>queue
Description	<p>This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueueing packets. Once the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.</p> <p>The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packets RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The defined high-prio-only value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.</p>

The **no** form of this command returns the MBS size assigned to the queue to the default value.

Default default

Parameters *size-in-kbytes* — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.

Values 0 to 1073741824 or default

rate

Syntax **rate** *pir-rate* [**cir** *cir-rate*]
no rate

Context config>service>vpls>sap>egress>queue-override>queue
config>service>vpls>sap>ingress>queue-override>queue

Description This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.

The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.

The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile, then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.

The CIR can be used by the queue's parent commands *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at anytime, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

Default **rate max cir 0** — The **max** default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The **max** value is mutually exclusive to the **pir-rate** value.

Parameters *pir-rate* — Defines the administrative PIR rate, in kilobits, for the queue. When the **rate** command is executed, a valid PIR setting must be explicitly defined. When the **rate** command has not been executed, the default PIR of **max** is assumed. Fractional values are not allowed and must be given as a positive integer.

The actual PIR rate is dependent on the queue's **adaptation-rule** parameters and the actual hardware where the queue is provisioned.

Values 1 to 2000000000

Default max

cir-rate — The **cir** parameter overrides the default administrative CIR used by the queue. When the **rate** command is executed, a CIR setting is optional. When the **rate** command has not been executed or the **cir** parameter is not explicitly specified, the default CIR (0) is assumed.

Fractional values are not allowed and must be given as a positive integer.

Values 0 to 2000000000, max

Default 0

scheduler-override

Syntax [no] scheduler-override

Context config>service>vpls>sap>egress
config>service>vpls>sap>ingress

Description This command specifies the set of attributes whose values have been overridden via management on this virtual scheduler. Clearing a given flag will return the corresponding overridden attribute to the value defined on the SAP's ingress scheduler policy.

scheduler

Syntax scheduler scheduler-name
no scheduler scheduler-name

Context config>service>vpls>sap>egress>sched-override

Description This command can be used to override specific attributes of the specified scheduler name.

A scheduler defines a bandwidth control that limits each child (other schedulers, policers and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have policers, queues or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier, except for schedulers created in tier 1). A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.

Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If *scheduler-name* already exists within the policy tier level (regardless of the inclusion of the keyword **create**), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause policers, queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).

If the *scheduler-name* exists within the policy on a different tier (regardless of the inclusion of the keyword **create**), an error occurs and the current CLI context will not change.

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

- Step 1.** The maximum number of schedulers has not been configured.
- Step 2.** The provided *scheduler-name* is valid.
- Step 3.** The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.

Parameters *scheduler-name* — The name of the scheduler.

Values Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

Default n/a. Each scheduler must be explicitly created.

create — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given *scheduler-name*. If the **create** keyword is omitted, **scheduler-name** is not created when the system environment variable **create** is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists.

rate

Syntax **rate** *pir-rate* [**cir** *cir-rate*]
 no rate

Context config>service>vp1s>sap>egress>sched-override>scheduler

Description This command can be used to override specific attributes of the specified scheduler rate. The **rate** command defines the maximum bandwidth that the scheduler can offer its policers, child queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase.

The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child queues and schedulers to operate at their maximum rates.

The **no** form of this command returns all queues created with this *queue-id* by association with the QoS policy to the default PIR and CIR parameters.

Parameters *pir-rate* — The **pir** parameter accepts a step multiplier value that specifies the multiplier used to determine the PIR rate at which the queue will operate. A value of 0 to 100000000 or the keyword **max** is accepted. Any other value will result in an error without modifying the current PIR rate.

To calculate the actual PIR rate, the rate described by the queue's **rate** is multiplied by the *pir-rate*.

The SAP ingress context for PIR is independent of the defined forwarding class (fc) for the queue. The default **pir** and definable range is identical for each class. The PIR in effect for a queue defines the maximum rate at which the queue will be allowed to forward packets in a given second, thus shaping the queue's output.

The PIR parameter for SAP ingress queues do not have a negate (**no**) function. To return the queue's PIR rate to the default value, that value must be specified as the PIR value.

Values 1 to 100000000, **max**

Default **max**

cir *cir-rate* — The **cir** parameter accepts a step-multiplier value that specifies the multiplier used to determine the CIR rate at which the queue will operate. A value of 0 to 250 or the keyword **max** is accepted. Any other value will result in an error without modifying the current CIR rate.

To calculate the actual CIR rate, the rate described by the **rate** **pir** *pir-rate* is multiplied by the *cir* *cir-rate*. If the **cir** is set to **max**, then the CIR rate is set to infinity.

The context for CIR is dependent on the defined forwarding class (fc) for the queue. The default CIR and definable range is different for each class. The CIR in effect for a policer or queue defines both its profile (in or out) marking level as well as the relative importance compared to other queues for scheduling purposes during congestion periods.

Values 0 to 10000000, **max**, **sum**

Default sum

match-qinq-dot1p

Syntax **match-qinq-dot1p** {**top** | **bottom**}
no match-qinq-dot1p

Context config>service>vpls>sap>ingress
config>service>ies>if>sap>ingress
config>service>vprn>sub-if>grp-if>sap>ingress

Description This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

The **no** form of the command restores the default dot1p evaluation behavior for the SAP.

By default, the bottom-most service delineating Dot1Q tag's Dot1P bits are used. [Table 8](#) defines the default behavior for Dot1P evaluation when the **match-qinq-dot1p** command is not executed.

Table 8 Default QinQ and TopQ SAP Dot1P Evaluation

Port / SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits

Table 8 Default QinQ and TopQ SAP Dot1P Evaluation (Continued)

Port / SAP Type	Existing Packet Tags	PBits Used for Match
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

Default no match-qinq-dot1p (no filtering based on p-bits)

(top or bottom must be specified to override the default QinQ dot1p behavior)

Parameters **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 9](#) defines the dot1p evaluation behavior when the top parameter is specified.

Table 9 Top Position QinQ and TopQ SAP Dot1P Evaluation

Port / SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / QinQ	TopQ BottomQ	TopQ PBits

bottom — The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 10](#) defines the dot1p evaluation behavior when the bottom parameter is specified.

Table 10 Bottom Position QinQ and TopQ SAP Dot1P Evaluation

Port / SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	BottomQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	BottomQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

discard-unknown-source

Syntax [no] discard-unknown-source

Context config>service>vpls>sap
config>service>vpls>spoke-sdp

Description When this command is enabled, packets received on a SAP or on a spoke SDP with an unknown source MAC address will be dropped only if the maximum number of MAC addresses for that SAP or spoke SDP (see [max-nbr-mac-addr](#)) has been reached. If max-nbr-mac-addr has not been set for the SAP or spoke SDP, enabling discard-unknown-source has no effect.

When disabled, the packets are forwarded based on the destination MAC addresses.

The **no** form of this command causes packets with an unknown source MAC addresses to be forwarded by destination MAC addresses in VPLS.

Default no discard-unknown

Parameters **ima** — Specifies Inverse Multiplexing over ATM. An IMA Group is a collection of physical links bundled together and assigned to an ATM Port (applies only the 7750 SR).

qtag1, *qtag2* — Specifies the encapsulation value used to identify the SAP on the port or sub-port. If this parameter is not specifically defined, the default value is 0.

Values

qtag1: 0 to 4094
qtag2: *, 0 to 4094

The values depends on the encapsulation type configured for the interface. The following table describes the allowed values for the port and encapsulation types.

Table 11 Allowed Values For Port And Encapsulation Types

Port Type	Encap-Type	Allowed Values	Comments
Ethernet	Null	0	The SAP is identified by the port.
Ethernet	Dot1q	0 to 4094	The SAP is identified by the 802.1Q tag on the port. Note that a 0 qtag1 value also accepts untagged packets on the dot1q port.
Ethernet	QinQ	qtag1: 0 to 4094 qtag2: 0 to 4094	The SAP is identified by two 802.1Q tags on the port. Note that a 0 qtag1 value also accepts untagged packets on the dot1q port.
SONET/SDH	IPCP	-	The SAP is identified by the channel. No BCP is deployed and all traffic is IP.
SONET/SDH TDM	BCP-Null	0	The SAP is identified with a single service on the channel. Tags are assumed to be part of the customer packet and not a service delimiter.
SONET/SDH TDM	BCP-Dot1q	0 to 4094	The SAP is identified by the 802.1Q tag on the channel.
SONET/SDH TDM	Frame Relay	16 to 991	The SAP is identified by the data link connection identifier (DLCI).
SONET/SDH ATM	ATM	vpi (NNI) 0 to 4095 vpi (UNI) 0 to 255 vci 1, 2, 5 to 65535	The SAP is identified by the PVC identifier (vpi/vci).

create — Keyword used to create a SAP instance.

split-horizon-group *group-name* — Specifies the name of the split horizon group to which the SAP belongs.

bpdu-translation

Syntax	bpdu-translation { auto auto-rw pvst pvst-rw stp } no bpdu-translation
Context	config>service>vpls>sap config>service>vpls>spoke-sdp
Description	<p>This command enables the translation of BPDUs to a given format, meaning that all BPDUs transmitted on a given SAP or spoke SDP will have a specified format.</p> <p>The no form of this command reverts to the default setting.</p>
Default	no bpdu-translation
Parameters	<p>auto — Specifies that appropriate format will be detected automatically, based on type of BPDUs received on such port.</p> <p>pvst-rw — Specifies the BPDU format as PVST and the rewrite of the VLAN-ID will occur when:</p> <ul style="list-style-type: none">• The BPDU sent on the dot1Q SAP egress will contain the VLAN ID of the SAP in the BDPU-PVID TLV• The BPDU sent on the default QinQ SAP egress will contain the outer VLAN ID of the SAP in the BDPU-PVID TLV• The BPDU sent on the QinQ SAP egress will contain the inner VLAN ID of the SAP in the BDPU-PVID TLV <p>pvst — Specifies the BPDU format as PVST.</p>

Note: The correct VLAN tag is included in the payload (depending on encapsulation value of outgoing SAP).

auto-rw — Specifies that the appropriate format will be detected automatically and the rewrite of the VLAN-ID will occur when:

- The BPDU sent on the dot1Q SAP egress will contain the VLAN ID of the SAP in the BDPU-PVID TLV
- The BPDU sent on the default QinQ SAP egress will contain the outer VLAN ID of the SAP in the BDPU-PVID TLV
- The BPDU sent on the QinQ SAP egress will contain the inner VLAN ID of the SAP in the BDPU-PVID TLV

stp — Specifies the BPDU-format as STP.

I2pt-termination

Syntax	[no] I2pt-termination
---------------	------------------------------

Context	config>service>vpls>sap config>service>vpls>spoke-sdp
Description	This commands enables L2PT termination on a given SAP or spoke SDP. L2PT termination will be supported only for STP BPDUs. PDUs of other protocols will be discarded. This feature can be enabled only if STP is disabled in the context of the given VPLS service.
Default	no l2pt-termination

def-mesh-vc-id

Syntax	[no] def-mesh-vc-id <i>vc-id</i>
Context	config>service>vpls
Description	This command configures the value used by each end of a tunnel to identify the VC. If this command is not configured, then the service ID value is used as the VC-ID. This VC-ID is used instead of a label to identify a virtual circuit. The VC-ID is significant between peer routers on the same hierarchical level. The value of a VC-ID is conceptually independent from the value of the label or any other datalink specific information of the VC. The no form of this command disables the VC-ID.
Default	n/a
Parameters	<i>vc-id</i> — Specifies the value used by each end of a tunnel to identify the VC. Values 1 to 4294967295

mac-move

Syntax	[no] mac-move
Context	config>service>vpls
Description	This command enables the context to configure MAC move attributes. A sustained high re-learn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the mac-move feature is an alternative way to protect your network against loops. When enabled in a VPLS, mac-move monitors the re-learn rate of each MAC. If the rate exceeds the configured maximum allowed limit, it disables the SAP where the source MAC was last seen. The SAP can be disabled permanently (until a shutdown/no shutdown command is executed) or for a length of time that grows linearly with the number of times the given SAP was disabled. You have the option of marking a SAP as non-blockable in the config>service>vpls>sap>limit-mac-move or config>service>vpls>spoke-sdp>limit-mac-move contexts. This means that when the re-learn rate has exceeded the limit, another

(blockable) SAP will be disabled instead.

The **mac-move** command enables the feature at the service level for SAPs and spoke SDPs, as only those objects can be blocked by this feature. Mesh SDPs are never blocked, but their re-learn rates (sap-to-mesh/spoke-to-mesh or vice versa) are still measured.

The operation of this feature is the same on the SAP and spoke SDP. For example, if a MAC address moves from SAP to SAP, from SAP to spoke SDP, or between spoke SDPs, one will be blocked to prevent thrashing. If the MAC address moves between a SAP and mesh SDP or spoke SDP and mesh SDP combinations, the respective SAP or spoke SDP will be blocked.

The re-learn rate is computed as the number of times a MAC moves in a 5 second interval. Therefore, the fastest a loop can be detected and broken is 5 seconds.

The **no** form of this command disables MAC move.

Default not enabled

mac-protect

Syntax **mac-protect**

Context config>service>vpls

Description This command indicates whether or not this MAC is protected. When enabled, the agent will protect the MAC from being learned or re-learned on a SAP that has restricted learning enabled.

Default disabled

mac

Syntax [**no**] **mac** *ieee-address*

Context config>service>vpls>mac-protect

Description This command specifies the 48-bit IEEE 802.3 MAC address.

Parameters *ieee-address* — Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers.

mac-subnet-length

Syntax **mac-subnet-length** *subnet-length*
no mac-subnet-length

Context	config>service>vpls
Description	This command specifies the number of bits to be considered when performing MAC learning (MAC source) and MAC switching (MAC destination). Specifically, this value identifies how many bits, starting from the beginning of the MAC address are used. For example, if the mask-value of 28 is used, MAC learning will only do a lookup for the first 28 bits of the source MAC address when comparing with existing FIB entries. Then, it will install the first 28 bits in the FIB while zeroing out the last 20 bits of the MAC address. When performing switching in the reverse direction, only the first 28 bits of the destination MAC address will be used to perform a FIB lookup to determine the next hop. The no form of this command switches back to full MAC lookup.
Parameters	<i>subnet-length</i> — Specifies the number of bits to be considered when performing MAC learning or MAC switching. Values 24 to 48

mcr-default-gtw

Syntax	mcr-default-gtw
Context	config>service>vpls
Description	This command enables the context to configure the default gateway information when using Dual Homing in L2-TPSDA. The IP and MAC address of the default gateway used for subscribers on an L2 MC-Ring are configured in this context. After a ring heals or fails, the system will send out a gratuitous ARP on an active ring SAP in order to attract traffic from subscribers on the ring with connectivity to that SAP.

ip

Syntax	ip address no ip
Context	config>service>vpls>mcr-default-gtw
Description	This command relates to a system configured for Dual Homing in L2-TPSDA. It defines the IP address used when the system sends out a gratuitous ARP on an active SAP after a ring heals or fails in order to attract traffic from subscribers on the ring with connectivity to that SAP.
Default	no ip
Parameters	<i>address</i> — Specifies the IP address in a.b.c.d. format.

mac

Syntax	mac <i>ieee-address</i> no mac
Context	config>service>vpls>mcr-default-gtw
Description	This command relates to a system configured for Dual Homing in L2-TPSDA. It defines the MAC address used when the system sends out a gratuitous ARP on an active SAP after a ring heals or fails in order to attract traffic from subscribers on the ring with connectivity to that SAP.
Default	no mac
Parameters	<i>ieee-address</i> — Specifies the address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros).

move-frequency

Syntax	move-frequency <i>frequency</i> no move-frequency
Context	config>service>vpls>mac-move
Description	<p>This object indicates the maximum rate at which MAC's can be re-learned in the VPLS service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MAC's.</p> <p>The rate is computed as the maximum number of re-learns allowed in a 5 second interval. For example, the default rate of 10 relearns per second corresponds to 50 relearns in a 5 second period.</p> <p>The no form of the command reverts to the default value.</p>
Default	2 (when mac-move is enabled)
Parameters	<i>frequency</i> — Specifies the rate, in 5-second intervals for the maximum number of relearns.
Values	1 to 100

retry-timeout

Syntax	retry-timeout <i>timeout</i> no retry-timeout
Context	config>service>vpls>mac-move

Description	<p>This object indicates the time in seconds to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>A zero value indicates that the SAP will not be automatically re-enabled after being disabled. If, after the SAP is re-enabled it is disabled again, the retry timeout is increased with the provisioned retry timeout in order to avoid thrashing. For example, when retry-timeout is set to 15, it increments (15, 30, 45, 60, and so on).</p> <p>The no form of the command reverts to the default value.</p>
Default	10 (when mac-move is enabled)
Parameters	<p><i>timeout</i> — Specifies the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>Values 0 to 120</p>

mfib-table-high-wmark

Syntax	[no] mfib-table-high-wmark <i>high-water-mark</i>
Context	config>service>vpls
Description	This command specifies the multicast FIB high watermark. When the percentage filling level of the multicast FIB exceeds the configured value, a trap is generated and/or a log entry is added.
Parameters	<p><i>high-water-mark</i> — Specifies the multicast FIB high watermark as a percentage.</p> <p>Values 1 to 100</p> <p>Default 95%</p>

mfib-table-low-wmark

Syntax	[no] mfib-table-low-wmark <i>low-water-mark</i>
Context	config>service>vpls
Description	This command specifies the multicast FIB low watermark. When the percentage filling level of the Multicast FIB drops below the configured value, the corresponding trap is cleared and/or a log entry is added.
Parameters	<p><i>low-water-mark</i> — Specifies the multicast FIB low watermark as a percentage.</p> <p>Values 1 to 100</p> <p>Default 90%</p>

mfib-table-size

Syntax	mfib-table-size <i>size</i> no mfib-table-size
Context	config>service>vpls
Description	<p>This command specifies the maximum number of (s,g) entries in the multicast forwarding database (MFIB) for this VPLS instance.</p> <p>The <i>mfib-table-size</i> parameter specifies the maximum number of multicast database entries for both learned and static multicast addresses for the VPLS instance.</p> <p>When a table-size limit is set on the mfib of a service which is lower than the current number of dynamic entries present in the mfib then the number of entries remains above the limit.</p> <p>The no form of this command removes the configured maximum MFIB table size.</p>
Default	n/a
Parameters	<p><i>size</i> — The maximum number of (s,g) entries allowed in the Multicast FIB.</p> <p>Values 1 to 16383</p>

send-flush-on-failure

Syntax	[no] send-flush-on-failure
Context	config>service>vpls
Description	<p>This command enables sending out “flush-all-from-ME” messages to all LDP peers included in affected VPLS, in the event of physical port failures or “oper-down” events of individual SAPs. This feature provides an LDP-based mechanism for recovering a physical link failure in a dual-homed connection to a VPLS service. This method provides an alternative to RSTP solutions where dual homing redundancy and recovery, in the case of link failure, is resolved by RSTP running between a PE router and CE devices.</p> <p>This feature cannot be enabled on management VPLS.</p>
Default	no send-flush-on-failure

2.12.2.2.8 DHCP Commands

dhcp

Syntax	dhcp
---------------	-------------

Context config>service>vpls>sap
 config>service>vpls>spoke-sdp
 config>service>vpls>mesh-sdp
 config>service>ies>if
 config>service>vprn>if
 config>service>ies>sub-if>group-interface
 config>service>ies>sub-if

Description This command enables the context to configure DHCP parameters.

gi-address

Syntax **gi-address** *ip-address* [*src-ip-addr*]
no gi-address

Context config>service>ies>if>dhcp
 config>service>vprn>if>dhcp
 config>service>ies>sub-if>grp-if>dhcp
 config>service>ies>sub-if>dhcp

Description This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the **group interface dhcp** context or **subscriber-interface dhcp** context in order for DHCP to function.

Default no gi-address

Parameters *ip-address* — Specifies the host IP address to be used for DHCP relay packets.
src-ip-address — Specifies that this GI address is to be the source IP address for DHCP relay packets.

lease-populate

Syntax **lease-populate** [*nbr-of-leases*]
lease-populate [*nbr-of-leases*] **l2-header** [*mac ieee-address*]
no lease-populate

Context config>subscr-mgmt>msap-policy>vpls-only>dhcp
 config>service>vpls>sap>dhcp
 config>service>ies>if>dhcp
 config>service>vprn>if>dhcp
 config>service>ies>sub-if>grp-if>dhcp

	<pre>config>service>vprn>sub-if>grp-if>dhcp config>service>vprn>sub-if>dhcp</pre>
Description	<p>This command enables and disables dynamic host DHCPv4 lease state management for SAPs.</p> <p>For VPLS, DHCP snooping must be explicitly enabled (using the snoop command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.</p> <p>The optional number-of-entries parameter defines the number lease state table entries allowed.</p> <ul style="list-style-type: none">• for this SAP in case of a VPLS service• for this interface in case of an IES or VPRN interface• for each SAP in case of an IES or VPRN group-interface• for this interface in case of an IES or VPRN retail subscriber interface <p>If number-of-entries is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.</p> <p>The retained lease state information representing dynamic hosts may be used to:</p> <ul style="list-style-type: none">• Populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.• Populate the system's ARP cache based on the arp-populate configuration. Applicable to IES and VPRN interfaces or group-interfaces.• Populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address• Generate dynamic ARP replies if arp-reply-agent is enabled. Applicable to VPLS service SAPs
Default	no lease-populate
Parameters	<i>nbr-of-leases</i> — Specifies the number of DHCPv4 leases allowed.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071
 1 to 500000 (retail subscriber interface)

I2-header — Indicates a mode of operation where anti-spoof entry associated with the given DHCP state is created based on the MAC address from the Layer 2 header. The Layer 2 header flag is not set by default. This parameter is only applicable for group-interfaces.

mac — Specifies that the provisioned ieee-address will be used in the anti-spoofing entries for this SAP. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a tools perform command is issues for the lease. This parameter is only applicable for group-interfaces.

match-circuit-id

Syntax	<code>[no] match-circuit-id</code>
Context	<code>config>service>ies>sub-if>grp-if>dhcp</code>
Description	<p>This command enables Option 82 circuit ID on relayed DHCP packet matching.</p> <p>For Routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked. When get a response back from the server the virtual router ID, transaction ID, and client HW MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client HW MAC address are not guaranteed to be unique.</p> <p>When the match-circuit-id command is enabled this part of the key is used to guarantee correctness in our lookup. This is really only needed when dealing with an IP aware DSLAM that proxies the client HW mac address.</p>
Default	<code>no match-circuit-id</code>

option

Syntax	<code>[no] option</code>
Context	<code>config>service>vpls>sap>dhcp</code> <code>config>service>ies>if>dhcp</code> <code>config>service>vprn>if>dhcp</code> <code>config>service>ies>sub-if>grp-if>dhcp</code>

Description This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options.

The **no** form of this command returns the system to the default.

Default no option

action

Syntax **action** {**replace** | **drop** | **keep**}
no action

Context config>service>vpls>sap>dhcp>option
config>service>ies>if>dhcp>option
config>service>vprn>if>dhcp>option
config>service>ies>sub-if>grp-if>dhcp

Description This command configures the Relay Agent Information Option (Option 82) processing.

The **no** form of this command returns the system to the default value.

Default The default is to keep the existing information intact.

Parameters **replace** — In the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).

drop — The DHCP packet is dropped if an Option 82 field is present, and a counter is incremented.

keep — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is forwarded towards the client.

circuit-id

Syntax **circuit-id** [ascii-tuple | vlan-ascii-tuple]
no circuit-id

Context config>service>vpls>sap>dhcp>option

Description When enabled, the router sends an ASCII-encoded tuple in the **circuit-id** sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by “|”.

If disabled, the **circuit-id** sub-option of the DHCP packet will be left empty.

The **no** form of this command returns the system to the default.

Default	circuit-id
Parameters	<p>ascii-tuple — Specifies that the ASCII-encoded concatenated tuple consisting of the access-node-identifier, service-id, and interface-name is used.</p> <p>vlan-ascii-tuple — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p>

circuit-id

Syntax	circuit-id [ascii-tuple ifindex sap-id vlan-ascii-tuple] no circuit-id
Context	config>service>ies>if>dhcp>option config>service>vprn>if>dhcp>option config>service>vprn>sub-if>grp-if>dhcp>option
Description	<p>When enabled, the router sends an ASCII-encoded tuple in the circuit-id sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by “ ”.</p> <p>If disabled, the circuit-id sub-option of the DHCP packet will be left empty.</p> <p>The no form of this command returns the system to the default.</p>
Default	circuit-id
Parameters	<p>ascii-tuple — Specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “ ”.</p> <p>ifindex — Specifies that the interface index will be used. (The If Index of a router interface can be displayed using the command show>router>interface>detail)</p> <p>sap-id — Specifies that the SAP identifier will be used.</p> <p>vlan-ascii-tuple — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q-encapsulated ports only. Thus, when the option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p>

remote-id

Syntax	remote-id [mac string <i>string</i>] no remote-id
Context	config>service>vpls>sap>dhcp>option config>service>ies>if>dhcp>option

```
config>service>vprn>if>dhcp>option
config>service>ies>sub-if>grp-if>dhcp
config>subscr-mgmt>msap-policy>vpls-only>dhcp>option
```

Description This command specifies what information goes into the remote-id sub-option in the DHCP Relay packet.

If disabled, the **remote-id** sub-option of the DHCP packet will be left empty.

The **no** form of this command returns the system to the default.

Default remote-id

Parameters **mac** — This keyword specifies the MAC address of the remote end is encoded in the sub-option.

string *string* — Specifies the remote-id.

snoop

Syntax [no] snoop

Context config>service>vpls>sap>dhcp -
config>service>vpls>spoke-sdp>dhcp
config>service>vpls>mesh-sdp>dhcp

Description This command enables DHCP snooping of DHCP messages on the SAP or SDP. Enabling DHCP snooping on interfaces (SAPs and SDP bindings) is required where DHCP messages important to lease state table population are received, or where Option 82 information is to be inserted. This includes interfaces that are in the path to receive messages from either DHCP servers or from subscribers.

Use the **no** form of the command to disable DHCP snooping on the specified VPLS SAP or SDP binding.

Default no snoop

server

Syntax **server** *server1* [*server2*...(up to 8 max)]

Context config>service>ies>if>dhcp
config>service>vprn>if>dhcp
config>service>ies>sub-if>grp-if>dhcp

Description This command specifies a list of servers where requests will be forwarded. The list of servers can be entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list.

There can be a maximum of 8 DHCP servers configured.

Default	no server
Parameters	<i>server</i> — Specify the DHCP server IP address.

trusted

Syntax	[no] trusted
Context	config>service>ies>if>dhcp config>service>vpn>if>dhcp config>service>ies>sub-if>grp-if>dhcp
Description	According to RFC 3046, <i>DHCP Relay Agent Information Option</i> , a DHCP request where the giaddr is 0.0.0.0 and which contains a Option 82 field in the packet, should be discarded, unless it arrives on a “trusted” circuit. If trusted mode is enabled on an IP interface, the Relay Agent (the router) will modify the request's giaddr to be equal to the ingress interface and forward the request.

Note: This behavior only applies when the action in the Relay Agent Information Option is “keep”. In the case where the option 82 field is being replaced by the Relay Agent (action = “replace”), the original Option 82 information is lost anyway, and there is thus no reason for enabling the trusted option.

The **no** form of this command returns the system to the default.

Default	not enabled
----------------	-------------

2.12.2.2.9 Egress Multicast Group Commands

egress-multicast-group

Syntax	egress-multicast-group <i>egress-multicast-group-name</i> no egress-multicast-group <i>group-name</i>
Context	config>service
Description	This command creates an egress multicast group (EMG) context. An EMG is created as an object used to group VPLS SAPs that are allowed to participate in efficient multicast replication (EMR). EMR is a method to increase the performance of egress multipoint forwarding by sacrificing some destination-based features. Eliminating the requirement to perform unique features for each destination allows the egress forwarding plane to chain together multiple destinations into a batch replication process. In order to perform this batch replication function, similar characteristics are required on each SAP within the EMG.

Only SAPs defined on Ethernet access ports are allowed into an egress-multicast-group.

In order to understand the purpose of an egress-multicast-group, an understanding of the system's use of flooding lists is required. A flooding list is maintained at the egress forwarding plane to define a set of destinations to which a packet must be replicated. Multipoint services make use of flooding lists to enable forwarding a single packet to many destinations. Examples of multipoint services that use flooding lists are VPLS, IGMP snooping and IP multicast routing. Currently, the egress forwarding plane will only use efficient multicast replication for VPLS and IGMP snooping flooding lists.

In VPLS services, a unique flooding list is created for each VPLS context. The flooding list is used when a packet has a broadcast, multicast or unknown destination MAC address. From a system perspective, proper VPLS handling requires that a broadcast, multicast or unknown destined packet be sent to all destinations that are in the forwarding state. The ingress forwarding plane ensures the packet gets to all egress forwarding planes that include a destination in the VPLS context. It is the egress forwarding plane's job to replicate the packet to the subset of the destinations that are reached through its interfaces and each of these destinations are included in the VPLS context's flooding list.

For IGMP snooping, a unique flooding list is created for each IP multicast (s,g) record. This (s,g) record is associated with an ingress VPLS context and may be associated with VPLS destinations in the source VPLS instance or other VPLS instances (in the case of MVR). Again, the ingress forwarding plane ensures that an ingress IP multicast packet matching the (s,g) record gets to all egress forwarding planes that have a VPLS destination associated with the (s,g) record. The egress forwarding plane uses the flooding list owned by the (s,g) record to replicate the packet to all VPLS destinations in the flooding list. The IGMP Snooping function identifies which VPLS destinations should be associated with the (s,g) record.

With normal multicast replication, the egress forwarding plane examines which features are enabled for each destination. This includes ACL filtering, mirroring, encapsulation and queuing. The resources used to perform this per destination multicast processing are very expensive to the egress forwarding plane when high replication bandwidth is required. If destinations with similar egress functions can be grouped together, the egress forwarding plane can process them in a more efficient manner and maximize replication bandwidth.

The egress-multicast-group object is designed to allow the identification of SAPs with similar egress characteristics. When a SAP is successfully provisioned into an egress-multicast-group, the system is ensured that it may be batched together with other SAPs in the same group at the egress forwarding plane for efficient multicast replication. A SAP that does not meet the common requirements is not allowed into the egress-multicast-group.

At the forwarding plane level, a VPLS flooding list is categorized into chainable and non-chainable destinations. Currently, the only chainable destinations are SAPs within an egress-multicast-group. The chainable destinations are further separated by egress-multicast-group association. Chains are then created following the rules below:

- A replication batch chain may only contain SAPs from the same egress-multicast-group
- A replication batch chain length may not exceed the dest-chain-limit of the egress-multicast-group to which the SAPs are members

Further subcategories are created for an IGMP (s,g) flooding list. A Layer 2 (s,g) record is created in a specific VPLS instance (the instance the (s,g) flow ingresses). SAPs within that VPLS context that join the (s,g) record are considered native SAPs within the flooding list. SAPs that join the (s,g) flooding list through the multicast VPLS registration process (MVR) from another VPLS context using the **from-vpls** command are considered alien SAPs. The distinction between native and alien in the list is maintained to allow the forwarding plane to enforce or suspend split-horizon-group (SHG) squelching. When the source of the (s,g) matching packet is in the same SHG as a native SAP, the packet must not be replicated to that SAP. For a SAP in another VPLS context, the source SHG of the packet has no meaning and the forwarding plane must disregard SHG matching between the native source of the packet and the alien destination. Because the SHG squelch decision is done for the whole chain based on the first SAP in the chain, all SAPs in the chain must be all native or all alien SAPs. Chains for IGMP (s,g) flooding lists are created using the following rules:

1. A replication batch chain may only contain SAPs from the same egress-multicast-group.
2. A replication batch chain may only contain all alien or all native SAPs.
3. A replication batch chain length may not exceed the dest-chain-limit of the egress-multicast-group to which the SAPs are members

When a packet associated with a flooding list is received by the egress forwarding plane, it processes the packet by evaluating each destination on the list sequentially in a replication context. If the current entry being processed in the list is a non-chained destination, the forwarding plane processes the packet for that destination and then moves on to process other packets currently in the forwarding plane before returning to process the next destination in the list. If the current entry being processed is a chained destination, the

forwarding plane remains in the replication context until it has forwarded to each entry in that chain. Once the replication context finishes with the last entry in the chain, it moves on to process other packets waiting for egress processing before returning to the replication context. Processing continues in this manner until the packet has been forwarded to all destinations in the list.

Batch chain processing of a chain of SAPs improves replication efficiency by bypassing the functions that perform egress mirroring decisions on SAPs within the chain and making a single ACL filtering decision for the whole chain. Each destination in the chain may have a unique egress QoS policy and per destination queuing is still performed for each destination in the chain. Also, while each SAP in the chain must be on access ports with the same encaps-type, if the encaps-type is dot1q, each SAP may have a unique dot1q tag.

One caveat to each SAP having a unique egress QoS policy in the chain is that only the Dot1P marking decisions for the first SAP in the list is enforced. If the first SAP's QoS policy forwarding class action states that the packet should not be remarked, none of the replicated packets in the chain will have the dot1P bits remarked. If the first SAP's QoS policy forwarding class action states that the packet should be remarked with a specific dot1P value, all the replicated packets for the remaining SAPs in the chain will have the same dot1P marking.

While the system supports 32 egress multicast groups, a single group would usually suffice. An instance where multiple groups would be needed is when all the SAPs requiring efficient multicast replication cannot share the same common requirements. In this case, an egress multicast group would be created for each set of common requirements. An egress multicast group may contain SAPs from many different VPLS instances. It should be understood that an egress multicast group is not equivalent to an egress forwarding plane flooding list. An egress multicast group only identifies which SAPs may participate in efficient multicast replication. As stated above, entries in a flooding list are populated due to VPLS destination creation or IGMP snooping events.

The **no** form of the command removes a specific egress multicast group. Deleting an egress multicast group will only succeed when the group has no SAP members. To remove SAP members, use the **no multicast-group group-name** command under each SAP's egress context.

Note: Efficient multicast replication will only be performed on IOMs that support chassis mode b. If an IOM does not support mode b operation, egress-multicast-group membership is ignored on that IOM's egress forwarding planes. The chassis need not be placed into mode b for efficient multicast replication to be performed on the capable IOMs.

Parameters	<i>group-name</i> — Multiple egress multicast groups may be created on the system. Each must have a unique name. The egress-multicast-group-name is an ASCII string up to 16 characters in length and follows all the naming rules as other named policies in the system. The group's name is used throughout the system to uniquely identify the Egress Multicast Group and is used to provision a SAP into the group.
Values	Up to 32 egress multicast groups may be created on the system.
Default	n/a, each egress multicast group must be explicitly configured.

description

Syntax	description <i>description-string</i> no description
Context	config>service>egress-multicast-group
Description	This command defines an ASCII string associated with egress-multicast-group-name. The no form of the command removes an existing description string from egress-multicast-group.
Default	n/a
Parameters	<i>description-string</i> — The description command accepts a description-string parameter. The description-string parameter is an ASCII string of up to 80 characters in length. Only printable 127 bit ASCII characters are allowed. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.
Values	An ASCII string up to 80 characters in length.

dest-chain-limit

Syntax	dest-chain-limit <i>destinations per pass</i> no dest-chain-limit
Context	config>service>egress-multicast-group
Description	This command defines the maximum length of an egress forwarding plane efficient multicast replication chain for an egress-multicast-group. Varying the maximum length of chains created for an egress multicast group has the effect of efficient multicast batched chain replication on other packets flowing through the egress forwarding plane. While replicating for the SAPs within a replication chain, other packets are waiting for the forwarding plane to finish. As the chain length increases, forwarding latency for the other waiting packets may increase. When the chain length decreases, a loss of efficiency in the replication process will be observed.

The **no** form of the command restores the default value of 10 to the **dest-chain-limit** parameter for the **egress-multicast-group**.

Default no dest-chain-limit

Parameters *destinations per pass* — This parameter must be specified when executing the **dest-chain-limit** command. When executed, the command will use the **number-of-destinations** parameter to reorganize all efficient multicast SAP chains that contain members from the **egress-multicast-group**.

The *destinations per pass* parameter can be modified at any time. Be aware that when changing the maximum chain length, the system will rebuild the chains according to the new limit. When this happens, it is possible that packets will not be replicated to a destination while it is being reorganized in the flooding lists' chains. Only the chains associated with the **egress-multicast-group** context the command is executed in will be affected by changing the parameter.

It is expected that the optimal replication chain length will be between 10 and 16. Since so many variables affect efficient multicast (i.e. ingress packet rate, number of chains, size of replicated packets), only proper testing in the environment that replication will be performed will identify the best **dest-chain-limit** value for each Egress Multicast Group.

Setting the *destinations per pass* parameter to a value of 0 has the effect of removing from all egress forwarding planes all chains with members from the **egress-multicast-group**. Replication to each destination SAP from the group is performed using the normal method (non-efficient replication). The value 0 is not considered a normal value for **dest-chain-limit** and is provided for debugging purposes only. Setting the value to 0 is persistent between reboots of the system.

Setting the *destinations per pass* parameter to a value of 1 has the effect of placing each **egress-multicast-group** member SAP into a chain with a single SAP. The value 1 is not considered a normal value for the **dest-chain-limit** and is provided for debugging purposes only. Setting the value to 1 is persistent between reboots of the system.

Values 0 to 255

Default 10

sap-common-requirements

Syntax sap-common-requirements

Context config>service>egress-multicast-group

Description This command configures the common SAP parameter requirements. The SAP common requirements are used to evaluate each SAP for group membership. If a SAP does not meet the specified requirements, the SAP is not allowed into the **egress-multicast-group**. Once a SAP is a member of the group, attempting to change the parameters on the SAP will fail.

egress-filter

Syntax	egress-filter [ip <i>ip-filter-id</i>] egress-filter [ipv6 <i>ipv6-filter-id</i>] egress-filter [mac <i>mac-filter-id</i>] no egress-filter [ip <i>ip-filter-id</i>] [ipv6 <i>ipv6-filter-id</i>][mac <i>mac-filter-id</i>]
Context	config>service>egress-multicast-group>sap-common-requirements
Description	<p>This command identifies the type of filter and actual filter ID that must be provisioned on the SAP prior to the SAP being made a member of the egress-multicast-group. If the SAP does not have the specified filter applied, the SAP cannot be provisioned into the group. It is important that the egress filter applied to each SAP within the egress-multicast-group be the same since the batch replication process on an efficient multicast replication chain will apply the first SAP's ACL decision to all other SAPs on the chain.</p> <p>Once the SAP is made a member of the egress-multicast-group, the SAP's egress filter cannot be changed on the SAP.</p> <p>Changing the egress-filter parameters within the sap-common-requirements node automatically changes the egress filter applied to each member SAP. If the filter cannot be changed on the SAP due to resource constraints, the modification will fail.</p> <p>The specified egress-filter does not contain an entry that is defined as an egress mirror-source. Once the filter is associated with the egress-multicast-group, attempting to define one of its entries as an egress mirror source will fail.</p> <p>The no form of the command removes the egress-filter from each member SAP. The no egress-filter command specifies that an egress filter (IP, IPv6 or MAC) is not applied to a new member SAP within the egress-multicast-group (IPv6 applies to the 7750 SR).</p>
Default	no filter. The egress filter ID must be defined with the associated ip or mac keyword. If an egress-filter is not specified or the no egress-filter command is executed in the sap-common-requirements node, a new member SAP does not have an egress IP or MAC filter defined.
Parameters	<p>ip <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.</p> <p>Values 1 to 65535</p> <p>ipv6 <i>ipv6-filter-id</i> — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters (applies only to the 7750 SR).</p> <p>Values 1 to 65535</p> <p>mac <i>mac-filter-id</i> — Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.</p> <p>Values 1 to 65535</p>

encap-type

Syntax	encap-type {dot1q null} no encap-type
Context	config>service>egress-multicast-group>sap-common-requirements
Description	<p>This command specifies the encapsulation type that must exist on the SAP's access port to allow the SAP membership within the egress-multicast-group. The config>port>ethernet>access>encap-type command is used to define the encapsulation type for the Ethernet port. The allowed encapsulation type values are dot1q and null. If the SAP does not exist on a port with the specified encap-type, it will not be allowed into the egress-multicast-group.</p> <p>If at least one SAP is currently a member of the efficient-multicast-group, the encap-type cannot be changed within the sap-common-requirements node. If the efficient-multicast-group does not contain any member SAPs, the encap-type may be changed at anytime.</p> <p>There is no interaction between an efficient-multicast-group and the corresponding access ports associated with its members since all SAPs must be deleted from a port before its encap-type can be changed. When the SAPs are deleted from the port, they are also automatically deleted from the efficient-multicast-group.</p> <p>The no form of the command returns the egress-multicast-group required encapsulation type for SAPs to dot1q. If the current encap-type is set to null, the command cannot be executed when SAPs exist within the egress-multicast-group.</p>
Default	dot1q — For an egress-multicast-group. null — If member SAPs are on a null encapsulated access port.
Parameters	<p>null — The null keyword is mutually exclusive with the dot1q keyword. When the encap-type within the sap-common-requirements is specified to be null, the encapsulation type for the access ports associated with all SAPs within the egress-multicast-group must be set to null.</p> <p>dot1q — The dot1q keyword is mutually exclusive with the null keyword. When the encap-type within the sap-common-requirements is specified to be dot1q, the encapsulation type for the access ports associated with all SAPs within the egress-multicast-group must be set to dot1q.</p>

dot1q-etype

Syntax	[no] dot1q-etype
Context	config>service>egress-multicast-group>sap-common-requirements

Description	<p>This command specifies the dot1q EtherType that must exist on the SAP's access port to allow the SAP membership within the egress-multicast-group. The config>port>ethernet>access>dot1q-etype command is used to define the EtherType used when encapsulating a packet with a dot1q tag on the Ethernet port. Any valid EtherType is allowed on the port.</p> <p>If the current encap-type for the egress-multicast-group is set to null, the dot1q-etype EtherType is ignored when evaluating SAP membership in the group. If the encap-type is set to dot1q (the default), a member SAP's access port must be configured with the same dot1q-etype EtherType as the egress-multicast-group.</p> <p>If at least one SAP is currently a member of the efficient-multicast-group, the dot1q-etype value cannot be changed within the sap-common-requirements node. If the efficient-multicast-group does not contain any member SAPs, the dot1q-etype value may be changed at anytime.</p> <p>If an access port currently has SAPs associated with it that are defined within an egress-multicast-group and the port is currently set to encap-type dot1q, the dot1q-etype value defined on the port cannot be changed.</p> <p>The no form of the command returns the egress-multicast-group dot1q EtherType to the default value of 0x8100. If the current encap-type is set to a value other than 0x8100, the command cannot be executed when SAPs exist within the egress-multicast-group.</p>
Default	The default dot1q-etype is 0x8100 for an egress-multicast-group.
Parameters	<p><i>ethertype</i> — Defines the dot1q EtherType that must be associated with a SAP's access port when the encap-type is set to dot1q. Any valid EtherType may be specified.</p> <p>Values [0x0600 to 0xffff]: [1536 to 65535] in decimal or hex</p> <p>Default 0x8100</p>

qinq-etype

Syntax	[no] qinq-etype
Context	config>service>egress-multicast-group>sap-common-requirements
Description	This command specifies the Ethertype used for QinQ encapsulation.
Default	no qinq-etype
Parameters	<p>0x0600 to 0xffff — Defines the dot1q Ethertype that must be associated with a SAP's access port when the encap-type is set to dot1q. Any valid Ethertype may be specified.</p> <p>Values [0x0600 to 0xffff]: [1536 to 65535] in decimal or hex</p>

qinq-fixed-tag-value

Syntax	qinq-fixed-tag-value <i>tag-value</i> no qinq-fixed-tag-value
Context	config>service>egress-multicast-group>sap-common-requirements
Description	This command configures the fixed tag value used for QinQ encapsulation.
Default	no qinq-fixed-tag-value
Parameters	<i>tag-value</i> — Specifies the provisioned common value of the fixed 802.1Q tag of all the QinQ SAPs in this egress multicast group. The value 0 is used to indicate that the actual value of the fixed tag will be defined implicitly by the corresponding tag of the first SAP added to this egress multicast group.
Values	0, 1 to 4094

2.12.2.2.10 Interface Commands

interface

Syntax	interface <i>ip-int-name</i> no interface <i>ip-int-name</i>
Context	config>service>ies config>service>vprn
Description	This command creates a logical IP routing interface for a Virtual Private Routed Network (VPRN). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within VPRN service IDs. The **interface** command can be executed in the context of an VPRN service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config router interface** and **config service vprn interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

The available IP address space for local subnets and routes is controlled with the **config router service-prefix** command. The **service-prefix** command administers the allowed subnets that can be defined on service IP interfaces. It also controls the prefixes that may be learned or statically defined with the service IP interface as the egress interface. This allows segmenting the IP address space into **config router** and **config service** domains.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All VPRN IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shutdown before issuing the **no interface** command.

For VPRN services, the IP interface must be shutdown before the SAP on that interface may be removed. VPRN services do not have the **shutdown** command in the SAP CLI context. VPRN service SAPs rely on the interface status to enable and disable them.

Parameters *ip-int-name* — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service vprn interface** commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

address

Syntax **address** {*ip-address/mask* | *ip-address netmask*} [**broadcast all-ones** | **host-ones**] [**track-srrp** *srrp-instance*]
no address

Context config>service>ies>if
 config>service>vprn>if

Description This command assigns an IP address, IP subnet, and broadcast address format to an IES IP router interface. Only one IP address can be associated with an IP interface.

An IP address must be assigned to each IES IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

The local subnet that the **address** command defines must be part of the services' address space within the routing context using the **config router service-prefix** command. The default is to disallow the complete address space to services. Once a portion of the address space is allocated as a service prefix, that portion can be made unavailable for IP interfaces defined within the **config router interface** CLI context for network core connectivity with the **exclude** option in the **config router service-prefix** command.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down.

Table 12 Address Admin and Operational States

Address	Admin State	Oper State
No address	up	down
No address	down	down
1.1.1.1	up	up
1.1.1.1	down	down

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

Parameters *ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

/ — The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the “/” and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.

mask-length — The subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask-length* parameter. The mask length parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Allowed values are integers in the range 0 – 31.

Note: A mask length of 32 is reserved for loopback addresses (includes system addresses).

mask — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical ‘AND’ function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

broadcast — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**. The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

Default host-ones

all-ones — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

host-ones — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

allow-directed-broadcast

Syntax	[no] allow-directed-broadcast
Context	config>router>interface config>service>ies>if config>service>vpn>if
Description	<p>This command enables the forwarding of directed broadcasts out of the IP interface.</p> <p>A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The allow-directed-broadcasts command on an IP interface enables or disables the transmission of packets destined to the subnet broadcast address of the egress IP interface.</p>

When enabled, a frame destined to the local subnet on this IP interface will be sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks.

When disabled, directed broadcast packets discarded at this egress IP interface will be counted in the normal discard counters for the egress SAP.

By default, directed broadcasts are not allowed and will be discarded at this egress IP interface.

The **no** form of this command disables the forwarding of directed broadcasts out of the IP interface.

Default **no allow-directed-broadcasts** — Directed broadcasts are dropped

cflowd

Syntax **cflowd {acl | interface}**
no cflowd

Context config>service>ies>if

Description This command enables **cflowd** to collect traffic flow samples through a router for analysis.

cflowd is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement. When **cflowd** is enabled at the interface level, all packets forwarded by the interface are subjected to analysis according to the **cflowd** configuration.

Default no cflowd

Parameters **acl** — **cflowd** configuration associated with a filter.

interface — **cflowd** configuration associated with an IP interface.

loopback

Syntax **[no] loopback**

Context config>service>ies>if
config>service>vprn>if

Description This command specifies that the associated interface is a loopback interface that has no associated physical interface. As a result, the associated IES/VPRN interface cannot be bound to a SAP.

Note: You can configure an IES interface as a loopback interface by issuing the **loopback** command instead of the **sap sap-id** command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.

Default n/a

mac

Syntax **mac** *ieee-address*
no mac

Context config>service>ies>if
config>service>ies>sub-if>grp-if

Description This command assigns a specific MAC address to an IES IP interface.

The **no** form of the command returns the MAC address of the IP interface to the default value.

Default The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).

Parameters *ieee-address* — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

authentication-policy

Syntax **authentication-policy** *name*
no authentication-policy

Context config>service>ies>sub-if>grp-if
config>service>vprn>sub-if>grp-if

Description This command defines which subscriber authentication policy must be applied when a DHCP message is received on the interface. The authentication policies must already be defined. The policy will only be applied when DHCP snooping is enabled on the SAP on Layer 2 interfaces.

Parameters *name* — Specifies a unique authentication policy name.

root-guard

Syntax	[no] root-guard
Context	config>service>vpls>sap>stp
Description	This command specifies whether this port is allowed to become an STP root port. It corresponds to the restrictedRole parameter in 802.1Q. If set, it can cause lack of spanning tree connectivity.
Default	no root-guard

secondary

Syntax	secondary { <i>ip-address/mask</i> <i>ip-address netmask</i> } [broadcast all-ones host-ones] [igp-inhibit] no secondary <i>ip-address</i>
Context	config>service>ies>if
Description	This command assigns a secondary IP address/IP subnet/broadcast address format to the interface.
Default	n/a
Parameters	<p><i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>mask</i> — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the <i>ip-address</i> from a traditional dotted decimal mask. The <i>mask</i> parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.</p>

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

netmask — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.

broadcast — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface. (*Default: host-ones*)

all-ones — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

host-ones — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

igp-inhibit — The optional **igp-inhibit** parameter signals that the given secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the specified secondary IP interfaces will not be injected and used as passive interfaces and will not be advertised as internal IP interfaces into the IGP's link state database. For RIP, this means that these secondary IP interfaces will not source RIP updates.

tos-marking-state

Syntax	tos-marking-state {trusted untrusted} no tos-marking-state
Context	config>service>ies>if config>service>ies>sub-if>grp-if
Description	<p>This command is used to change the default trusted state to a non-trusted state. When unset or reverted to the trusted default, the ToS field will not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set, in which case the egress network interface treats all IES and network IP interfaces as untrusted.</p> <p>When the ingress interface is set to untrusted, all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface. The egress network remarking rules also apply to the ToS field of IP packets routed using IGP shortcuts (tunneled to a remote next-hop). However, the tunnel QoS markings are always derived from the egress network QoS definitions.</p>

Egress marking and remarking is based on the internal forwarding class and profile state of the packet once it reaches the egress interface. The forwarding class is derived from ingress classification functions. The profile of a packet is either derived from ingress classification or ingress policing.

The default marking state for network IP interfaces is trusted. This is equivalent to declaring no tos-marking-state on the network IP interface. When undefined or set to tos-marking-state trusted, the trusted state of the interface will not be displayed when using show config or show info unless the detail parameter is given. The **save config** command will not store the default tos-marking-state trusted state for network IP interfaces unless the detail parameter is also specified.

The **no** tos-marking-state command is used to restore the trusted state to a network IP interface. This is equivalent to executing the tos-marking-state trusted command.

Default	trusted
Parameters	<p>trusted — The default prevents the ToS field to not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set.</p> <p>untrusted — Specifies that all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface.</p>

address

Syntax	address { <i>ip-address/mask</i> <i>ip-address netmask</i> } [gw-ip-address <i>ip-address</i>] [track-srrp <i>srrp-inst</i>] [holdup-time <i>msec</i>] no address
Context	config>service>ies>sub-if config>service>vprn>sub-if
Description	This command will configure the subscriber interface address along with additional parameters related to multi-chassis redundancy.
Default	n/a
Parameters	<p><i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>/</i> — The forward slash is a parameter delimiter and separates the <i>ip-address</i> portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the <i>"/"</i> and the <i>mask-length</i> parameter. If a forward slash is not immediately following the <i>ip-address</i>, a dotted decimal mask must follow the prefix.</p>

mask — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical AND function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

netmask — The subnet mask in dotted decimal notation.

Values 0.0.0.0 - 255.255.255.255

track-srrp *srrp-inst* — This command will enable the subscriber interface route to track the SRRP state of the specified SRRP instance. The route will update its state attribute to reflect the *state* of SRRP instance:

- Master = srrp-master
- Any other = srrp-non-master

Routing policy can be applied towards the state attribute in order to customize the advertisement of the route. Only one SRRP instance can be tracked per subscriber interface route. Tracked SRRP instance can be part of the Fate Sharing Group. This command can be enabled at any time.

holdup-time *msec* — Time to wait for the route before it accepts the new state attribute. This timer is used to prevent fluctuations in route advertisement caused by short lived SRRP instabilities, in the case that such condition arises.

Values *msec* [100...5000] msec

link-local-address

Syntax	link-local-address <i>ipv6-address</i> no link-local-address
Context	config>service>ies>sub-if>ipv6 config>service>vpn>sub-if>ipv6
Description	This command will configure the IPv6 Link Local address that will be used as a virtual SRRP IPv6 address by the Master SRRP node. This address will be sent in the Router Advertisements initiated by the Master SRRP node. Clients will use this address as IPv6 default-gateway. Both SRRP nodes, Master and Backup, must be configured with the same Link Local address.
Default	n/a
Parameters	<i>ipv6-address</i> — IPv6 address in the form: <div>x:x:x:x:x:x:x:x:x:x:d.d.d.d</div>

where:

x - [0 to FF]

d - [0 to 255]

monitor-oper-group

Syntax	monitor-oper-group <i>name</i> priority-step <i>step</i> no monitor-oper-group
Context	config>service>ies>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>srrp
Description	This command will configure the association between the SRRP instance in a Fate Sharing Group and the operational-group that contains messaging SAPs. A state transition of a messaging SAP within an operational-group will trigger calculation of the priority for all SRRP instances that are associated with that operational-group.
Default	n/a
Parameters	<i>name</i> — Name of the operational-group that is tracking operational state of SRRP messaging SAPs priority-step — The priority step for which the priority of an SRRP instance will be changed. If a messaging SAP within an operational-group transition to a non-UP state, the priority will be decreased by the step value. If the messaging SAP within the operational-group transition into the UP state, the priority of the SRRP instance will be increased by the step value. <i>step</i> — The step for which the SRRP priority is modified expressed as a decimal integer. Values 0 to 253

oper-group

Syntax	oper-group <i>name</i> no oper-group
Context	config>service>epipe>spoke-sdp config>service>ies>sub-if>grp-if>sap config>service>vprn>sub-if>grp-if>sap
Description	This command will configure an epipe or a (messaging) SAP to be the member of the oper-group. Epipe:

The epipe status can be monitored by the SRRP messaging SAP. The messaging SAP will transition into the DOWN state if the epipe is either DOWN or has a STANDBY status. In order for the messaging SAP to assume the DOWN state, both RX and TX side of the PW must be shut. In other words, a PW in standby mode also must have the local TX disabled by the virtue of the 'slave' flag (standby-signaling-slave command under the spoke-sdp hierarchy). Without the TX disabled, the SAP monitoring the PW would not transition in the down state. The messaging SAP will be in the UP state if the epipe is in the UP state (Active status).

(SRRP messaging) SAP:

The state of the messaging SAPs will be monitored by SRRP instances in a Fate Sharing Group. A state change of any of the messaging SAPs defined under the *group-interface* and within the oper-group will trigger recalculation of SRRP priority.

Default	n/a
Parameters	<i>name</i> — Specify name of the operational-group that contains the member epipe.

srrp-enabled-routing

Syntax	srrp-enabled-routing [<i>hold-time decisec</i>] no srrp-enabled-routing
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command will enable SRRP state tracking by managed (IPv4 only) and subscriber-routes. Managed and subscriber-routes that are installed in the Route Table Manager (RTM) would be modified by the source (SRRP would update the route's <i>state</i> attribute - srrp-master, srrp-non-master) and this would trigger policy reevaluation with the corresponding action.
Default	n/a
Parameters	hold-time — Waiting period before which the route's state attribute is updated. The purpose of this command is to avoid propagation of quick successive SRRP state transitions into the routing. <i>decisec</i> — Specify in deci seconds Values 1 to 50

track-srrp

Syntax	track-srrp <i>srrp-id</i> no track-srrp
Context	config>service>vpls>sap>

Description This is a capture SAP level command and applies only to the 7750 SR. This command is important in PPPoE deployments with MSAPs. PPPoE operation requires that the MAC address learned by the client at the very beginning of the session negotiation phase remains unchanged for the lifetime of the session (RFC 2516). This command will ensure that the virtual MAC address used during the PPPoE session negotiation phase on the capture SAP is the same virtual MAC address that is used by the SRRP on the group-interface on which the session is established. Therefore, it is mandated that the SRRP instance (and implicitly the group-interface) where the session belongs to is known in advance. If the group-interface name for the session is returned by the RADIUS, it must be ensured that this group-interface is the one on which the tracked SRRP instance is configured. PPPoE sessions on the same capture SAP cannot be shared across multiple group-interfaces, but instead they all must belong to a single group-interface that is known in advance.

The same restrictions will apply to IPoE clients in MC Redundancy scenario if they are to be supported concurrently on the same capture SAP as PPPoE.

The supported capture SAP syntax is this:

```
sap <port-id>:X.* capture-sap
```

The capture SAP syntax that is NOT supported is this:

```
sap <port-id>:.*.* capture-sap
```

Default n/a

Parameters *srrp-id* — Specify SRRP instance number.

Values 1 to 4294967295

srrp

Syntax **[no]** *srrp srrp-id*

Context config>service>ies>sub-if>grp-if
config>service>vprn>sub-if>grp-if

Description This command creates a Subscriber Router Redundancy Protocol (SRRP) instance on a group IP interface. An SRRP instance manages all subscriber subnets within the group interfaces subscriber IP interface or other subscriber IP interfaces that are associated through a wholesale/retail relationship. Only one unique SRRP instance can be configured per group interface.

The **no** form of the command removes an SRRP instance from a group IP interface. Once removed, the group interface ignores ARP requests for the SRRP gateway IP addresses that may exist on subscriber subnets associated with the group IP interface. Then the group interface stops routing using the redundant IP interface associated with the group IP interface and will stop routing with the SRRP gateway MAC address. Ingress packets destined to the SRRP gateway MAC will also be silently discarded. This is the same behavior as a group IP interface that is disabled (shutdown).

Default	no srrp
Parameters	<p><i>srrp-id</i> — Specifies a 32 bit instance ID that must be unique to the system. The instance ID must also match the instance ID used by the remote router that is participating in the same SRRP context. SRRP is intended to perform a function similar to VRRP where adjacent IP hosts within local subnets use a default gateway to access IP hosts on other subnets.</p> <p>Values 1 to 4294967295</p>

bfd-enable

Syntax	[no] bfd-enable [<i>service-id</i>] interface <i>interface-name</i> dst-ip <i>ip-address</i>
Context	<p>config>service>ies>sub-if>grp-if>srrp</p> <p>config>service>vprn>sub-if>grp-if>srrp</p>
Description	<p>This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface.</p> <p>The no form of this command removes BFD from the configuration.</p>
Default	n/a
Parameters	<p><i>service-id</i> — Specifies the service ID of the interface running BFD.</p> <p>Values <i>service-id</i>: 1 to 214748364 <i>svc-name</i>: A string up to 64 characters in length.</p> <p>interface <i>interface-name</i> — Specifies the name of the interface running BFD.</p> <p>dst-ip <i>ip-address</i> — Specifies the destination address of the interface running BFD.</p>

gw-mac

Syntax	<p>gw-mac <i>mac-address</i></p> <p>no gw-mac</p>
Context	<p>config>service>ies>sub-if>grp-if>srrp</p> <p>config>service>vprn>sub-if>grp-if>srrp</p>

Description	<p>This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.</p> <p>One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.</p> <p>The no form of the command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.</p>
Parameters	<p><i>mac-address</i> — Specifies a MAC address that is used to override the default SRRP base MAC address</p> <p>Values Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.</p> <p>If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.</p>

keep-alive-interval

Syntax	<p>keep-alive-interval <i>interval</i></p> <p>no keep-alive-interval</p>
Context	<p>config>service>ies>sub-if>grp-if>srrp</p> <p>config>service>vpn>sub-if>grp-if>srrp</p>
Description	<p>This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.</p> <p>When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.</p> <p>The keep-alive-interval may be changed at anytime, but will have no effect until the SRRP instance is in the master state.</p> <p>The no form of the command restores the default interval.</p>

Parameters	<i>interval</i> — Specifies the interval between SRRP advertisement messages sent when operating in the master state.
Values	1 to 100 hundreds of milli-seconds
Default	10

message-path

Syntax	message-path <i>sap-id</i> no message-path
Context	config>service>ies>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>srrp
Description	This command defines a specific SAP for SRRP in-band messaging. A message-path SAP must be defined prior to activating the SRRP instance. The defined SAP must exist on the SRRP instances group IP interface for the command to succeed and cannot currently be associated with any dynamic or static subscriber hosts. Once a group IP interface SAP has been defined as the transmission path for SRRP Advertisement messages, it cannot be administratively shutdown, will not support static or dynamic subscriber hosts and cannot be removed from the group IP interface.

The SRRP instance message-path command may be executed at anytime on the SRRP instance. Changing the message SAP will fail if a dynamic or static subscriber host is associated with the new SAP. Once successfully changed, the SRRP instance will immediately disable anti-spoof on the SAP and start sending SRRP Advertisement messages if the SRRP instance is activated.

Changing the current SRRP message SAP on an active pair of routers should be done in the following manner:

1. Shutdown the backup SRRP instance.
2. Change the message SAP on the shutdown node.
3. Change the message SAP on the active master node.
4. Re-activate the shutdown SRRP instance.

Shutting down the backup SRRP instance prevents the SRRP instances from becoming master due to temporarily using differing message path SAPs.

If an MCS peering is operational between the redundant nodes and the SRRP instance has been associated with the peering, the designated message path SAP will be sent from each member.

The **no** form of the command can only be executed when the SRRP instance is shutdown. Executing no message-path allows the existing SAP to be used for subscriber management functions. A new message-path SAP must be defined prior to activating the SRRP instance.

Parameters	<i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.
-------------------	---

one-garp-per-sap

Syntax	[no] one-garp-per-sap
Context	config>service>ies>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>srrp
Description	This command is applicable to PPPoE only deployments in which there are multiple subnets under the subscriber interface. In such case, if the switchover occurs, it will be sufficient to send a single Gratuitous ARP on every VLAN to update the Layer 2 forwarding path in the access aggregation network. This single gratuitous ARP will contain the IP address of the first GW address found under the subscriber interface address.

prefix

Syntax	prefix <i>ipv6-address/prefix-length</i> [pd] [wan-host] track-srrp <i>srrp-instance</i> [holdup-time <i>milli-seconds</i>] no prefix
Context	config>service>vprn>sub-if>ipv6>sub-pfx config>service>ies>sub-if>ipv6>sub-pfx
Description	This command will configure the IPv6 subscriber interface address along with additional parameters related to multi-chassis redundancy.
Default	n/a
Parameters	<p><i>ip-address</i> — Specifies the IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>/</i> — The forward slash is a parameter delimiter and separates the <i>ip-address</i> portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the <i>ip-address</i>, the <i>/</i> and the <i>mask-length</i> parameter. If a forward slash is not immediately following the <i>ip-address</i>, a dotted decimal mask must follow the prefix.</p> <p><i>mask</i> — Specifies the subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the <i>ip-address</i> from a traditional dotted decimal mask. The <i>mask</i> parameter indicates the complete mask that will be used in a logical AND function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.</p>

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

netmask — The subnet mask in dotted decimal notation.

Values 0.0.0.0 - 255.255.255.255

track-srrp *srrp-inst* — This command will enable the subscriber interface IPv6 route to track the SRRP state of the specified SRRP instance. The route will update its state attribute to reflect the state of SRRP instance:

Master = srrp-master

Any other = srrp-non-master

Routing policy can be applied towards the state attribute in order to customize the advertisement of the route. Only one SRRP instance can be tracked per subscriber interface route. Tracked SRRP instance can be part of the Fate Sharing Group. This command can be enabled at any time.

holdup-time *msec* — Time to wait for the route before it accepts the new state attribute. This timer is used to prevent fluctuations in route advertisement caused by short lived SRRP instabilities, in the case that such condition arises.

msec [100 to 5000] msec

policy

Syntax [no] **policy** *vrrp-policy-id*

Context config>service>ies>sub-if>grp-if>srrp
config>service>vprn>sub-if>grp-if>srrp

Description This command associates one or more VRRP policies with the SRRP instance. A VRRP policy is a collection of connectivity and verification tests used to manipulate the in-use priorities of VRRP and SRRP instances. A VRRP policy can test the link state of ports, ping IP hosts, discover the existence of routes in the routing table or the ability to reach L2 hosts. When one or more of these tests fail, the VRRP policy has the option of decrementing or setting an explicit value for the in-use priority of an SRRP instance.

More than one VRRP policy may be associated with an SRRP instance. When more than one VRRP policy is associated with an SRRP instance the delta decrement of the in-use priority is cumulative unless one or more test fail that have explicit priority values. When one or more explicit tests fail, the lowest priority value event takes effect for the SRRP instance. When the highest delta-in-use-limit is used to manage the lowest delta derived in-use priority for the SRRP instance.

VRRP policy associations may be added and removed at anytime. A maximum of two VRRP policies can be associated with a single SRRP instance.

The **no** form of the command removes the association with *vrrp-policy-id* from the SRRP instance.

Parameters *vrrp-policy-id* — Specifies one or more VRRP policies with the SRRP instance.

Values 1 to 9999

preempt

Syntax	[no] preempt
Context	config>service>ies>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>srrp
Description	<p>When preempt is enabled, a newly initiated SRRP instance can overrides an existing Master SRRP instance if its priority value is higher than the priority of the current Master.</p> <p>If preempt is disabled, an SRRP instance only becomes Master if the master down timer expires before an SRRP advertisement message is received from the adjacent SRRP enabled node.</p>
Default	preempt

priority

Syntax	priority <i>priority</i> no priority
Context	config>service>ies>sub-if>grp-if>srrp config>service>vprn>sub-if>grp-if>srrp
Description	<p>This command overrides the default base priority for the SRRP instance. The SRRP instance priority is advertised by the SRRP instance to its neighbor router and is compared to the priority received from the neighbor router. The router with the best (highest) priority enters the master state while the other router enters the backup state. If the priority of each router is the same, the router with the lowest source IP address in the SRRP advertisement message assumes the master state.</p> <p>The base priority of an SRRP instance can be managed by VRRP policies. A VRRP policy defines a set of connectivity or verification tests which, when they fail, may lower an SRRP instances base priority (creating an in-use priority for the instance). Every time an SRRP instances in-use priority changes when in master state, it sends an SRRP advertisement message with the new priority. If the dynamic priority drops to zero or receives an SRRP Advertisement message with a better priority, the SRRP instance transitions to the <i>becoming backup</i> state.</p> <p>When the priority command is not specified, or the no priority command is executed, the system uses a default base priority of 100. The priority command may be executed at anytime.</p> <p>The no form of the command restores the default base priority to the SRRP instance. If a VRRP policy is associated with the SRRP instance, it will use the default base priority as the basis for any modifications to the SRRP instances in-use priority.</p>

Parameters	<i>priority</i> — Specifies a base priority for the SRRP instance to override the default.
Values	1 to 254
Default	100

arp-populate

Syntax	[no] arp-populate
Context	config>service>ies>if config>service>ies>sub-if>grp-if config>service>vprn>if config>service>vprn>sub-if>grp-if
Description	<p>This command, when enabled, disables dynamic learning of ARP entries. Instead, the ARP table is populated with dynamic entries from the DHCP Lease State Table (enabled with lease-populate), and optionally with static entries entered with the host command.</p> <p>Enabling the arp-populate command will remove any dynamic ARP entries learned on this interface from the ARP cache.</p> <p>The arp-populate command will fail if an existing static ARP entry exists for this interface.</p> <p>The arp-populate command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.</p> <p>Once arp-populate is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.</p> <p>When arp-populate is enabled, the system will not send out ARP requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with arp-populate enabled. The arp-populate command can only be enabled on IES and VPRN interfaces supporting Ethernet encapsulation.</p> <p>Use the no form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information for this interface will be removed from the system's ARP cache.</p>
Default	not enabled

arp-timeout

Syntax	arp-timeout <i>seconds</i> no arp-timeout
Context	config>service>ies>if config>service>vprn>if config>service>ies>sub-if>grp-if

config>service>vprn>sub-if>grp-if

Description	<p>This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If arp-timeout is set to a value of zero seconds, ARP aging is disabled.</p> <p>When the arp-populate and lease-populate commands are enabled on an IES interface, the ARP table entries will no longer be dynamically learned, but instead by snooping DHCP ACK message from a DHCP server. In this case the configured arp-timeout value has no effect.</p> <p>The default value for arp-timeout is 14400 seconds (4 hours).</p> <p>The no form of this command restores arp-timeout to the default value.</p>
Default	14400 seconds
Parameters	<p><i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.</p> <p>Values 0 to 65535</p>

host-connectivity-verify

Syntax	host-connectivity-verify [source { vrrp interface }] [interval <i>interval</i>] [action { remove alarm }] [timeout <i>retry-timeout</i>] [retry-count <i>retry-count</i>]
Context	config>service>ies>if config>service>vprn>if
Description	This command enables subscriber host connectivity verification for all hosts on this interface. This tool will periodically scan all known hosts (from dhcp-state) and perform UC ARP requests. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.
Default	no host-connectivity-verify
Parameters	source { vrrp interface } — Specifies the source to be used for generation of subscriber host connectivity verification packets. The vrrp keyword specifies that the VRRP state should be used to select proper IP and MAC (active uses VRID, back-up uses interface addresses). The interface keyword forces the use of the interface mac and ip addresses.

Note: There are up to 256 possible subnets on a given interface, therefore the subscriber host connectivity verification tool will use always an address of the subnet to which the given host is pertaining. In case of group-interfaces, one of the parent subscriber interface subnets (depending on host's address) will be used.

action {remove | alarm} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, etc.). The **alarm** keyword raises an alarm indicating that the host is disconnected.

interval interval — The interval, expressed in minutes, which specifies when all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000

Note: A zero value can be used by the SNMP agent to disable host-connectivity-verification.

timeout retry-timeout — Specifies the timeout in seconds before a connectivity check retransmission.

Values 10 to 60 seconds

retry-count retry-count — Specifies the number of connectivity check retransmissions.

Values 2 to 29

icmp

Syntax	icmp
Context	config>service>ies>if config>service>ies>sub-if>grp-if config>service>vprn>if
Description	This command enables the context to configure Internet Control Message Protocol (ICMP) parameters on a service.

ip-mtu

Syntax	ip-mtu octets no ip-mtu
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	<p>This command specifies the maximum size of IP packets on this group-interface. Packets larger than this will be fragmented.</p> <p>The ip-mtu applies to all IPoE host types (DHCP, ARP, static). For PPP/L2TP sessions, the ip-mtu is not taken into account for the mtu negotiation; the ppp-mtu in the ppp-policy should be used instead.</p>

The **no** form of the command removes the octets value from the configuration.

Default	n/a
Parameters	<i>octets</i> — Specifies the largest frame size (in octets) that this interface can handle.
Values	512 to 9000

private-retail-subnets

Syntax	[no] private-retail-subnets
Context	config>service>vprn>sub-if
Description	<p>This command controls the export of retail subnets and prefixes to the wholesale forwarding service. When this attribute is configured, subnets and prefixes configured on the retail subscriber interface will no longer be exported to the associated wholesale VPRN and will remain private to the retail VPRN. This is useful in a PPPoE business service context as it allows retail services to use overlapping IP address spaces even if these services are associated with the same wholesale service. PPPoE sessions are actually terminated in the retail service although their traffic transits on a SAP belonging to the wholesale service.</p> <p>Configuring private retail subnets is not supported for IPoEv4 host management (DHCPv4, IPv4 static-host and ARP-host). If PPPoE sessions need to coexist with IPoEv4 hosts, then this attribute should not be configured on the retail subscriber interface.</p> <p>This command will fail if the subscriber interface is not associated with a wholesale service.</p> <p>If the retail VPRN is of the type hub, this attribute is mandatory. In this case, private retail subnets will be enabled by default and it will not be possible to deconfigure it.</p>

unnumbered

Syntax	unnumbered [<i>ip-int-name</i> <i>ip-address</i>] no unnumbered
Context	config>service>vprn>sub-if config>service>ies>sub-if
Description	<p>This command can be configured only for subscriber interfaces that do not have an IPv4 address explicitly configured and is therefore operationally in a DOWN state. By configuring this command, the subscriber interface will borrow the IPv4 address from the referenced interface (directly or indirectly via IP address) that must be operationally UP and located in the same routing instance as the subscriber interface. This will allow the subscriber interface to become operationally UP and consequently allow forwarding of the subscriber traffic.</p> <p>Such interface is referred as unnumbered interface, since it does not have explicitly configured a unique IP address. Subscriber-hosts under the unnumbered subscriber interface are installed in the fib as /32 hosts.</p>

Without this command the subscriber interface is operationally DOWN and subscriber-host instantiation is not possible.

This command is mutually exclusive with the allow-unmatched-subnets command under the same CLI hierarchy.

The operation of IPv6 host is not affected by this command.

Default	no unnumbered
Parameters	<i>ip-int-name</i> — Specifies the interface name from which an IPv4 address will be borrowed. <i>ip-address</i> — The IP address from an optionally up interface that will be used for subscriber interface.

ipv6

Syntax	ipv6
Context	config>service>ies>sub-if config>service>ies>sub-if>grp-if config>service>vprn>sub-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to enable IPv6 IPoE bridged mode.

ipoe-bridged-mode

Syntax	[no] ipoe-bridged-mode
Context	config>service>ies>sub-if>ipv6 config>service>ies>sub-if>grp-if>ipv6 config>service>vprn>sub-if>ipv6 config>service>vprn>sub-if>grp-if>ipv6
Description	This command enters the context to enable IPv6 IPoE bridged mode. The no form of the command disables the IPv6 IPoE bridged mode.

allow-multiple-wan-addresses

Syntax	[no] allow-multiple-wan-addresses
Context	config>service>ies>sub-if>ipv6 config>service>ies>sub-if>grp-if>ipv6 config>service>vprn>sub-if>ipv6

```
config>service>vprn>sub-if>grp-if>ipv6
```

Description This command enables host to have two WAN addresses, one from DHCP IA_NA and one from SLAAC assignment.

Default no allow-multiple-wan-addresses

nd

Syntax nd

Context config>service>ies>sub-if>grp-if>ipv6
config>service>vprn>sub-if>grp-if>ipv6

Description This command enables the context to configure neighbor discovery parameters.

dad-snooping

Syntax [no] dad-snooping

Context config>service>ies>sub-if>grp-if>ipv6>nd
config>service>vprn>sub-if>grp-if>ipv6>nd

Description This command allows the router to populate the neighbor discovery table through snooping subscribers' duplicate address detection messages.

Default no dad-snooping

neighbor-limit

Syntax [no] neighbor-limit

Context config>service>ies>sub-if>grp-if>ipv6>nd
config>service>vprn>sub-if>grp-if>ipv6>nd

Description This command configures the maximum number of neighbors learned.

Parameters 1 to 8 — Specifies the maximum number of neighbors learned.

router-advertisements

Syntax [no] router-advertisements

Context config>service>ies>sub-if>ipv6
config>service>ies>sub-if>grp-if>ipv6
config>service>vprn>sub-if>ipv6

```
config>service>vprn>sub-if>grp-if>ipv6
```

Description This command configures IPv6 router advertisements for this interface.

current-hop-limit

Syntax [no] **current-hop-limit** *limit*

Context config>router>router-advert>if
config>service>ies>sub-if>ipv6>rtr-adv
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>router-advert>if
config>service>vprn>sub-if>ipv6>rtr-adv

Description This command configures the hop-limit advertised for this interface.

Default 64

Parameters *limit* — Specifies the default value to be placed in the current hop limit field in router advertisements sent from this interface.

Values 0 to 255

dns-options

Syntax [no] **dns-options**

Context config>router>router-advert
config>router>router-advert>if
config>service>ies>sub-if>ipv6>rtr-adv
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>router-advert
config>service>vprn>router-advert>if
config>service>vprn>sub-if>ipv6>rtr-adv
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

Description This command enables the context to configure IPv6 DNS options for SLAAC hosts

include-dns

Syntax [no] **include-dns**

Context config>router>rtr-adv>if>dns-opt
config>service>ies>sub-if>ipv6>rtr-adv>dns-opt
config>service>ies>sub-if>grp-if>ipv6>rtr-adv>dns-opt
config>service>vprn>rtr-adv>if>dns-opt
config>service>vprn>sub-if>ipv6>rtr-adv>dns-opt

```
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>dns-opt
```

Description This command specifies to include the Recursive DNS Server (RDNSS) Option as defined in RFC 6106 in IPv6 Router Advertisements for DNS name resolution of IPv6 SLAAC hosts

Default no include-dns

rdnss-lifetime

Syntax **rdnss-lifetime** *seconds*
rdnss-lifetime infinite
no rdnss-lifetime

Context config>router>rtr-adv>dns-opt
 config>router>rtr-adv>if>dns-opt
 config>service>ies>sub-if>ipv6>rtr-adv>dns-opt
 config>service>ies>sub-if>grp-if>ipv6>rtr-adv>dns-opt
 config>service>vprn>rtr-adv>dns-opt
 config>service>vprn>rtr-adv>if>dns-opt
 config>service>vprn>sub-if>ipv6>rtr-adv>dns-opt
 config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>dns-opt

Description Specify the maximum time in seconds that the RDNSS address may be used for name resolution.

Default rdnss-lifetime 3600

Parameters *seconds* — Specifies the time in seconds.

Values 900 to 3600

infinite — The RDNSS address can be used permanently.

force-mcast

Syntax **force-mcast** [*ip*] [*mac*]
no force-mcast

Context config>service>ies>sub-if>ipv6>rtr-adv
 config>service>ies>sub-if>grp-if>ipv6>rtr-adv
 config>service>vprn>sub-if>ipv6>rtr-adv
 config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

Description This command configures the multicast router advertisements on this interface, either IP or MAC.

managed-configuration

Syntax	[no] managed-configuration
Context	<pre>config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv</pre>
Description	This command sets or resets managed address configuration flag for this group-interface.

max-advertisement

Syntax	max-advertisement <i>seconds</i> no max-advertisement
Context	<pre>config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv</pre>
Description	This command specifies the maximum time allowed between sending unsolicited router advertisements from this interface.
Parameters	<i>seconds</i> — Specifies the maximum advertisement interval in seconds for this group-interface. Values 900 to 11800

min-advertisement

Syntax	min-advertisement <i>seconds</i> no min-advertisement
Context	<pre>config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv</pre>
Description	This command specifies the minimum time allowed between sending unsolicited router advertisements from this interface.

Parameters *seconds* — Specifies the minimum advertisement interval in seconds for this group-interface.

Values 900 to 1350

mtu

Syntax *mtu bytes*
no mtu

Context config>router>router-advert>if
config>service>ies>sub-if>ipv6>rtr-adv
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>router-advert>if
config>service>vprn>sub-if>ipv6>rtr-adv
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

Description This command specifies the value to be placed in link MTU options sent by the router on this interface.

Parameters *bytes* — Sets the advertised MTU value in bytes for this group-interface.

Values 1280 to 9212

other-stateful-configuration

Syntax [no] **other-stateful-configuration**

Context config>router>router-advert>if
config>service>ies>sub-if>ipv6>rtr-adv
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>router-advert>if
config>service>vprn>sub-if>ipv6>rtr-adv
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

Description This command sets and resets the other-stateful-configuration flag for this group-interface.

prefix-options

Syntax [no] **prefix-options**

Context config>service>ies>sub-if>ipv6>rtr-adv
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>sub-if>ipv6>rtr-adv
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

Description This command enables the context to configure prefix options for this group-interface.

autonomous

Syntax	[no] autonomous
Context	config>service>ies>sub-if>ipv6>rtr-adv>pfx-opt config>service>ies>sub-if>grp-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>pfx-opt
Description	This command enables or disables the option that determines whether or not the prefix can be used for stateless address autoconfiguration.

on-link

Syntax	[no] on-link
Context	config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv>pfx-opt config>service>ies>sub-if>grp-if>ipv6>rtr-adv>pfx-opt config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>pfx-opt
Description	This command specifies whether the prefix will be assigned to an interface on the specified link.

preferred-lifetime

Syntax	preferred-lifetime <i>seconds</i> preferred-lifetime <i>infinite</i> no preferred-lifetime
Context	config>service>ies>sub-if>ipv6>rtr-adv>pfx-opt config>service>ies>sub-if>grp-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>pfx-opt
Description	This command specifies the remaining time for this prefix to be preferred, thus time until deprecation.
Default	3600 seconds
Parameters	<i>seconds</i> — Specifies the time for the prefix to remain preferred on this interface in seconds. Values 0 to 4294967295 infinite — Specifies that the remaining time will never expire.

reachable-time

Syntax	reachable-time <i>milli-seconds</i> no reachable-time
Context	config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv
Description	This command configures the value to be placed in the reachable time field in router advertisement messages sent from this interface.
Default	0
Parameters	<i>milli-seconds</i> — Specifies the reachable time in seconds for advertisements from this interface. Values 0 to 3600000

retransmit-time

Syntax	retransmit-time <i>milli-seconds</i> no retransmit-time
Context	config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv
Description	This command configures the value to be placed in the retransmit timer field in router advertisements sent from this interface.
Default	0
Parameters	<i>milli-seconds</i> — Specifies the retransmit time in milli-seconds for advertisement from this group-interface. Values 0 to 1800000

router-lifetime

Syntax	router-lifetime <i>seconds</i> router-lifetime no-default-router no router-lifetime
---------------	--

Context	config>router>router-advert>if config>service>ies>sub-if>ipv6>rtr-adv config>service>ies>sub-if>grp-if>ipv6>rtr-adv config>service>vprn>router-advert>if config>service>vprn>sub-if>ipv6>rtr-adv config>service>vprn>sub-if>grp-if>ipv6>rtr-adv
Description	This command configures the value to be placed in the router lifetime field of router advertisements sent from this interface.
Default	4500
Parameters	<i>seconds</i> — Specifies the router lifetime in seconds for this group-interface. Values 2700 to 9000 no-default-router — Specifies that the router is not to be used as a default router.

router-solicit

Syntax	router-solicit
Context	config>service>ies>sub-if>grp-if>ipv6 config>service>vprn>sub-if>grp-if>ipv6 config>service>vprn>sub-if>ipv6 config>service>ies>sub-if>ipv6
Description	This command enables the context to configure parameters used for router-solicit based authentication.

inactivity-timer

Syntax	inactivity-timer [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] no inactivity-timer
Context	config>service>ies>sub-if>ipv6>rtr-sol config>service>ies>sub-if>grp-if>ipv6>rtr-sol config>service>vprn>sub-if>ipv6>rtr-sol config>service>ies>sub-if>grp-if>ipv6>rtr-sol
Description	This command specifies the time before an inactive host is removed.
Default	no interactive-timer
Parameters	infinite — An idle host is never removed. days <i>days</i> — An idle host is removed if idle within the number of specified days. hrs <i>hours</i> — An idle host is removed if idle within the number of specified hours. min <i>minutes</i> — An idle host is removed if idle within the number of specified minutes.

sec seconds — An idle host is removed if idle within the number of specified seconds.

min-auth-interval

Syntax	min-auth-interval [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] no min-auth-interval
Context	config>service>ies>sub-if>grp-if>ipv6>rtr-sol config>service>ies>sub-if>grp-if>ipv6>rtr-sol
Description	This command specify the minimum interval between two consecutive authentication attempts from the same host.
Default	no min-auth-interval
Parameters	days <i>days</i> — The number of days that a user must wait for the next authentication attempt. hrs <i>hours</i> — The number of hours that a user must wait for the next authentication attempt. min <i>minutes</i> — The number of minutes that a user must wait for the next authentication attempt. sec <i>seconds</i> — The number of seconds that a user must wait for the next authentication attempt.

user-db

Syntax	[no] user-db
Context	config>service>ies>sub-if>grp-if>ipv6>rtr-sol config>service>ies>sub-if>grp-if>ipv6>rtr-sol
Description	This command enables the use of the local-user-database for authentication.
Default	no user-db
Parameters	<i>local-user-db-name</i> — Specifies the name of the local-user-database to authenticate the router-solicit. The local-user-database can also return a static prefix or a pool name for address assignment.

shutdown

Syntax	[no] shutdown
Context	config>service>ies>sub-if>grp-if>ipv6>rtr-sol config>service>ies>sub-if>grp-if>ipv6>rtr-sol

Description	This command enables or disables SLAAC triggered host creation.
Default	no shutdown

local-proxy-arp

Syntax	[no] local-proxy-arp
Context	config>service>ies>if config>service>ies>sub-if>grp-if config>service>vpn>if
Description	<p>This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet.</p> <p>When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked.</p>
Default	no local-proxy-arp

mask-reply

Syntax	[no] mask-reply
Context	config>service>ies>if>icmp config>service>ies>sub-if>grp-if config>service>vpn>if
Description	<p>This command enables responses to Internet Control Message Protocol (ICMP) mask requests on the router interface.</p> <p>If a local node sends an ICMP mask request to the router interface, the mask-reply command configures the router interface to reply to the request.</p> <p>By default, the router instance will reply to mask requests.</p> <p>The no form of this command disables replies to ICMP mask requests on the router interface.</p>
Default	mask-reply

proxy-arp-policy

Syntax	[no] proxy-arp-policy <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)]
Context	config>service>ies>if

	<pre>config>service>ies>sub-if>grp-if config>service>vpn>if</pre>
Description	<p>This command configures a proxy ARP policy for the interface.</p> <p>The no form of this command disables the proxy ARP capability.</p>
Default	no proxy-arp-policy
Parameters	<p><i>policy-name</i> — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>The specified name(s) must already be defined.</p>

redirects

Syntax	<pre>redirects [<i>number seconds</i>]</pre> <p>no redirects</p>
Context	<pre>config>service>ies>if>icmp config>service>ies>sub-if>grp-if config>service>vpn>if</pre>
Description	<p>This command configures the rate for Internet Control Message Protocol (ICMP) redirect messages issued on the router interface.</p> <p>When routes are not optimal on this router and another router on the same subnetwork has a better route, the router can issue an ICMP redirect to alert the sending node that a better route is available.</p> <p>The redirects command enables the generation of ICMP redirects on the router interface. The rate at which ICMP redirects is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of redirect messages that can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP redirect messages is enabled at a maximum rate of 100 per 10 second time interval. (<i>Default: redirects 100 10</i>)</p> <p>The no form of this command disables the generation of icmp redirects on the router interface.</p>
Default	redirects 100 10 — Maximum of 100 redirect messages in 10 seconds.
Parameters	<p><i>number</i> — The maximum number of ICMP redirect messages to send. This parameter must be specified with the <i>second</i> parameter.</p> <p>Values 10 to 1000</p>

seconds — The time frame in seconds used to limit the *number* of ICMP redirect messages that can be issued.

Values 1 to 60

remote-proxy-arp

Syntax	[no] remote-proxy-arp
Context	config>service>ies>if config>service>vpn>if config>service>ies>sub-if>grp-if
Description	<p>This command enables remote proxy ARP on the interface.</p> <p>Remote proxy ARP is similar to proxy ARP. It allows the router to answer an ARP request on an interface for a subnet that is not provisioned on that interface. This allows the router to forward to the other subnet on behalf of the requester. To distinguish remote proxy ARP from local proxy ARP, local proxy ARP performs a similar function but only when the requested IP is on the receiving interface.</p>
Default	no remote-proxy-arp

static-arp

Syntax	static-arp <i>ip-address ieee-mac-address</i> no static-arp <i>ip-address ieee-mac-address</i>
Context	config>service>ies>if config>service>vpn>if
Description	<p>This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP will appear in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface.</p> <p>If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.</p> <p>The no form of this command removes a static ARP entry.</p>
Default	n/a
Parameters	<i>ip-address</i> — Specifies the IP address for the static ARP in IP address dotted decimal notation.

ieee-mac-address — Specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

ttl-expired

Syntax	ttl-expired <i>number seconds</i> no ttl-expired
Context	config>service>ies>if>icmp
Description	<p>This command configures the rate Internet Control Message Protocol. (ICMP) TTL expired messages are issued by the IP interface.</p> <p>By default, generation of ICMP TTL expired messages is enabled at a maximum rate of 100 per 10 second time interval.</p> <p>The no form of this command disables the limiting the rate of TTL expired messages on the router interface.</p>
Default	ttl-expired 100 10
Parameters	<p><i>number</i> — The maximum number of ICMP TTL expired messages to send, expressed as a decimal integer. This parameter must be specified with the <i>seconds</i> parameter.</p> <p>Values 10 to 1000</p> <p><i>seconds</i> — The time frame in seconds used to limit the <i>number</i> of ICMP TTL expired messages that can be issued, expressed as a decimal integer.</p> <p>Values 1 to 60</p>

unreachables

Syntax	unreachables [<i>number seconds</i>] no unreachables
Context	config>service>ies>if>icmp
Description	<p>This command configures the rate for ICMP host and network destination unreachable messages issued on the router interface.</p> <p>The unreachables command enables the generation of ICMP destination unreachables on the router interface. The rate at which ICMP unreachables is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of destination unreachable messages which can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP destination unreachables messages is enabled at a maximum rate of 100 per 10 second time interval.</p>

The **no** form of this command disables the generation of icmp destination unreachables on the router interface.

Default **unreachables 100 10**

Parameters *number* — The maximum number of ICMP unreachable messages to send. This parameter must be specified with the *seconds* parameter.

Values 10 to 1000

seconds — The time frame in seconds used to limit the *number* of ICMP unreachable messages that can be issued.

Values 1 to 60

2.12.2.2.11 Interface IPv6 Commands

ipv6

Syntax **[no] ipv6**

Context config>service>ies>if
 config>service>ies>sub-if>grp-if

Description This command enables the context to configure IPv6 for an interface.

address

Syntax **address** *ipv6-address/prefix-length* **[eui-64]**
 no address *ipv6-address/prefix-length*

Context config>service>ies>if>ipv6

Description This command assigns an IPv6 address to the IES interface.

Parameters *ipv6-address/prefix-length* — Specify the IPv6 address on the interface.

Values

ipv6-address	x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:d.d.d.d
	x [0 to FFFF]H
	d [0 to 255]D
prefix-length	1 to 128

eui-64 — When the **eui-64** keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the Base MAC address of the chassis is used.

default-dns

Syntax	default-dns <i>ipv6-address</i> [secondary <i>ipv6-address</i>] no default-dns
Context	config>service>ies>sub-if>ipv6 config>service>vprn>sub-if>ipv6
Description	Configure last resort IPv6 DNS addresses that can be used for name resolution by IPoEv6 hosts (IA_NA, IA_PD and SLAAC) and PPPoEv6 hosts (IA_NA, IA_PD and SLAAC).
Default	no default-dns
Parameters	<i>ipv6-address</i> — s - IPv6 address of the primary DNS server. secondary <i>ipv6-address</i> — IPv6 address of the secondary DNS server (optional).

address

Syntax	address <i>ipv6-address/prefix-length</i> [pd] [wan-host] [track-srrp <i>srrp-instance</i>] [holdup-time <i>milli-seconds</i>] no address <i>ipv6-address/prefix-length</i>
Context	config>service>ies>sub-if>ipv6 config>service>vprn>sub-if>ipv6
Description	This command assigns an IPv6 address/subnet to the subscriber interface.

Note: SRRP is not supported for IPv6 subscriber interface.

Default	n/a
Parameters	<i>ipv6-address</i> — Specifies the 128-bit IPv6 address. Values 128-bit hexadecimal IPv6 address in compressed form. <i>prefix-length</i> — Specifies the length of any associated aggregate prefix. Values 32-63 pd — Specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation.

wan-host — Specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 addresses or by a routing gateway's WAN interface.

allow-unmatching-prefixes

Syntax	[no] allow-unmatching-prefixes
Context	config>service>vprn>sub-if>ipv6 config>service>ies>sub-if>ipv6
Description	<p>This command allows address assignments for IPoEv6 and PPPoEv6 hosts in cases where the subscriber host assigned IPv6 address or prefix falls outside of the subscriber-prefix range explicitly configured for the subscriber interface (config>service>vprn/ies>sub-if>ipv6> or the subscriber-prefix is not configured at all.</p> <p>SLAAC hosts will be installed in the FIB as /64 entries, the length of the installed DHCP-PD prefix will be dictated by the prefix-length and the DHCP-NA host will be installed as /128 entries.</p> <p>IPv4 subscriber hosts are unaffected by this command.</p>
Default	no allow-unmatching-prefixes

auto-reply

Syntax	[no] auto-reply
Context	config>service>vprn>sub-if>grp-if>ipv6 config>service>ies>sub-if>grp-if>ipv6
Description	<p>This command assists IP-only static hosts to resolve their default gateway and MAC. By default, the BNG anti-spoof filter drops packets from unknown hosts. The auto-reply features first allow hosts to resolve their default gateway and afterwards allow them to forward traffic. Using the data traffic, the BNG can utilize the data-trigger mechanism to learn the host's MAC and populate the full IP+MAC static host entry.</p>
Default	no auto-reply

neighbor-solicitation

Syntax	[no] neighbor-solicitation
Context	config>service>vprn>sub-if>grp-if>ipv6>auto-reply config>service>ies>sub-if>ipv6>auto-reply
Description	This command enables auto-reply for neighbor solicitation.

The **no** form of the command disables auto-reply.

router-solicitation

Syntax	[no] router-solicitation
Context	config>service>vprn>sub-if>grp-if>ipv6>auto-reply config>service>ies>sub-if>grp-if>ipv6>auto-reply
Description	This command enables auto-reply router solicitation. The no form of the command disables router-solicitation.

delegated-prefix-length

Syntax	delegated-prefix-length <i>bits</i> delegated-prefix-length <i>variable</i> no delegated-prefix-length
Context	config>service>ies>sub-if>ipv6 config>service>vprn>sub-if>ipv6
Description	This command configures the subscriber interface level setting for delegated prefix length. The delegated prefix length for a subscriber- interface can be either set to a fixed value that is explicitly configured under the subscriber interface CLI hierarchy or a variable value that can be obtained from various sources. This command can be changed only when no IPv6 prefixes are configured under the subscriber-interface context.
Default	no delegated-prefix-length This means that the delegated prefix length is 64.
Parameters	<p><i>bits</i> — The delegated prefix length in bits. This value will be applicable to the entire subscriber interface. In case that the delegated prefix length is also supplied via other means (LUDB, RADIUS or DHCP Server), such supplied value must match the value configured under the subscriber-interface context. Otherwise the prefix instantiation in the router will fail.</p> <p>Values 48 to 64</p> <p>variable — The delegated prefix value can be of any length between 48 to 64. The value itself can vary between the prefixes and it will be provided at the time of prefix instantiation. The order of priority for the source of the delegated prefix length is:</p> <ul style="list-style-type: none"> • LUDB • RADIUS • DHCPv6 server

subscriber-prefixes

Syntax	[no] subscriber-prefixes
Context	config>services>ies>sub-if>ipv6 config>services>vprn>sub-if>ipv6
Description	This command specifies aggregate off-link subscriber prefixes associated with this subscriber interface. Individual prefixes are specified under the prefix context list aggregate routes in which the next-hop is indirect via the subscriber interface.

prefix

Syntax	prefix <i>ipv6-address/prefix-length</i> [pd] [wan-host] no prefix <i>ipv6-address/prefix-length</i>
Context	config>services>ies>sub-if>ipv6>sub-prefixes config>services>vprn>sub-if>ipv6>sub-prefixes
Description	This command allows a list of prefixes (using the prefix command multiple times) to be routed to hosts associated with this subscriber interface. Each prefix will be represented in the associated FIB with a reference to the subscriber interface. Prefixes are defined as being for prefix delegation (pd) or use on a WAN interface or host (wan-host).
Parameters	<p><i>ipv6-address</i> — Specifies the 128-bit IPv6 address.</p> <p>Values 128-bit hexadecimal IPv6 address in compressed form.</p> <p><i>prefix-length</i> — Specifies the length of any associated aggregate prefix.</p> <p>Values 32-63</p> <p>pd — Specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation.</p> <p>wan-host — Specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface.</p>

dhcp6-relay

Syntax	[no] dhcp6-relay
Context	config>service>ies>if>ipv6
Description	<p>This command enables the context to configure DHCPv6 relay parameters for the IES interface.</p> <p>The no form of the command disables DHCP6 relay.</p>

lease-populate

Syntax	lease-populate [<i>nbr-of-leases</i>] lease-populate [<i>nbr-of-leases</i>] route-populate [pd] na [ta] lease-populate [<i>nbr-of-leases</i>] route-populate pd [na] [ta] [exclude] lease-populate [<i>nbr-of-leases</i>] route-populate [pd] [na] ta no lease-populate
Context	config>service>ies>if>ipv6>dhcp6-relay config>service>vprn>if>ipv6>dhcp6-relay
Description	<p>This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.</p> <p>Optionally, by specifying “route-populate” parameter, system could:</p> <ul style="list-style-type: none"> • Create routes based on the IA_PD/IA_NA/IA_TA prefix option in relay-reply message. • Create black hole routes based on OPTION_PD_EXCLUDE in IA_PD in relay-reply message. <p>These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in “from protocol”:</p> <ul style="list-style-type: none"> • dhcpv6-pd • dhcpv6-na • dhcpv6-ta • dhcpv6-pd-excl <p>The no form of the command disables dynamic host lease state management.</p>
Default	no lease-populate
Parameters	<p><i>nbr-of-leases</i> — Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP6 ACK messages are discarded.</p> <p>Values 1 to 8000</p> <p>route-populate — Create routes based on options in relay-reply messages.</p> <p>Values pd/na/ta — Create route based on specified option. exclude — Create blackhole route based on OPTION_PD_EXCLUDE</p>

neighbor-resolution

Syntax	[no] neighbor-resolution
Context	config>service>ies>if>ipv6>dhcp6-relay

config>service>vprn>if>ipv6>dhcp6-relay

Description This command enables neighbor resolution with DHCPv6 relay.

The **no** form of the command disables neighbor resolution.

remote-id

Syntax [no] remote-id

Context config>service>ies>if>ipv6>dhcp6>option
config>service>vprn>if>ipv6>dhcp6>option

Description This command enables the sending of remote ID option in the DHCPv6 relay packet.

The client DHCP Unique Identifier (DUID) is used as the remote ID.

option

Syntax [no] option

Context config>service>ies>if>ipv6>dhcp6-relay
config>service>vprn>if>ipv6>dhcp6-relay

Description This command enables the context to configure DHCPv6 relay information options.

The **no** form of the command disables DHCPv6 relay information options.

interface-id

Syntax interface-id
interface-id ascii-tuple
interface-id ifindex
interface-id sap-id
interface-id string *string*
no interface-id

Context config>service>ies>if>ipv6>dhcp6>option
config>service>vprn>if>ipv6>dhcp6>option

Description This command enables the sending of interface ID options in the DHCPv6 relay packet.

The **no** form of the command disables the sending of interface ID options in the DHCPv6 relay packet

- Parameters**
- ascii-tuple** — Specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “|”.
 - ifindex** — Specifies that the interface index will be used. (The If Index of a router interface can be displayed using the command `show>router>interface>detail`)
 - sap-id** — Specifies that the SAP identifier will be used.
The **no** form of the command disables the sending of remote ID option in the DHCPv6 relay packet.

icmp6

- Syntax** **icmp6**
- Context** `config>service>ies>if>ipv6`
- Description** This command configures ICMPv6 parameters for the interface.

packet-too-big

- Syntax** **packet-too-big** [*number seconds*]
no packet-too-big
- Context** `config>service>ies>if>ipv6>icmp6`
- Description** This command specifies whether “packet-too-big” ICMP messages should be sent. When enabled, ICMPv6 “packet-too-big” messages are generated by this interface.

The **no** form of the command disables the sending of ICMPv6 “packet-too-big” messages.
- Default** 100 10
- Parameters** *number* — Specifies the number of “packet-too-big” ICMP messages to send in the time frame specified by the *seconds* parameter.
- Values** 10 to 1000
 - Default** 100
- seconds* — Specifies the time frame in seconds that is used to limit the number of “packet-too-big” ICMP messages issued.
- Values** 1 to 60
 - Default** 10

param-problem

Syntax	param-problem [<i>number seconds</i>] no packet-too-big
Context	config>service>ies>if>ipv6>icmp6
Description	<p>This command specifies whether “parameter-problem” ICMP messages should be sent. When enabled, “parameter-problem” ICMP messages are generated by this interface.</p> <p>The no form of the command disables the sending of “parameter-problem” ICMP messages.</p>
Default	100 10
Parameters	<p><i>number</i> — Specifies the number of “parameter-problem” ICMP messages to send in the time frame specified by the <i>seconds</i> parameter.</p> <p>Values 10 to 1000</p> <p>Default 100</p> <p><i>seconds</i> — Specifies the time frame in seconds that is used to limit the number of “parameter-problem” ICMP messages issued.</p> <p>Values 1 to 60</p> <p>Default 10</p>

redirects

Syntax	redirects [<i>number seconds</i>] no redirects
Context	config>service>ies>if>ipv6>icmp6
Description	<p>This command configures ICMPv6 redirect messages. When enabled, ICMPv6 redirects are generated when routes are not optimal on this router and another router on the same subnetwork has a better route in order to alert that node that a better route is available.</p> <p>When disabled, ICMPv6 redirects are not generated.</p>
Default	100 10
Parameters	<p><i>number</i> — Specifies the number of version 6 redirects are to be issued in the time frame specified by the <i>seconds</i> parameter.</p> <p>Values 10 to 1000</p> <p>Default 100</p>

seconds — Specifies the time frame in seconds that is used to limit the number of version 6 redirects issued.

Values 1 to 60

Default 10

time-exceeded

Syntax **time-exceeded** [*number seconds*]
no time-exceeded

Context config>service>ies>if>ipv6>icmp6

Description This command specifies whether “time-exceeded” ICMP messages should be sent. When enabled, ICMPv6 “time-exceeded” messages are generated by this interface.

When disabled, ICMPv6 “time-exceeded” messages are not sent.

Default 100 10

Parameters *number* — Specifies the number of “time-exceeded” ICMP messages are to be issued in the time frame specified by the *seconds* parameter.

Values 10 to 1000

Default 100

seconds — Specifies the time frame in seconds that is used to limit the number of “time-exceeded” ICMP message to be issued.

Values 1 to 60

Default 10

unreachables

Syntax **unreachables** [*number seconds*]
no unreachables

Context config>service>ies>if>ipv6>icmp6

Description This command specifies that ICMPv6 host and network unreachable messages are generated by this interface.

When disabled, ICMPv6 host and network unreachable messages are not sent.

Default 100 10

Parameters *number* — Specifies the number of destination unreachable ICMPv6 messages are issued in the time

frame specified by the *seconds* parameter.

Values 10 to 1000

Default 100

seconds — Specifies the time frame in seconds that is used to limit the number of destination unreachable ICMPv6 messages to be issued.

Values 1 to 60

Default 10

local-proxy-nd

Syntax [no] **local-proxy-nd**

Context config>service>ies>if>ipv6

Description When this command is enabled, the interface will reply to neighbor solicitation requests when both the hosts are on the same subnet. In this case, ICMP redirects will be disabled. When this command is disabled, the interface will not reply to neighbor solicitation requests if both the hosts are on the same subnet.

Default disabled

neighbor

Syntax **neighbor** *ipv6-address mac-address*
no neighbor *ipv6-address*

Context config>service>ies>if>ipv6

Description This command configures IPv6-to-MAC address mapping on the IES interface.

Parameters *ipv6-address* — The IPv6 address of the interface for which to display information.

Values x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x: [0 to FFFF]H
d: [0 to 255]D
prefix-length [1 to 128]

mac-address — Specifies the 48-bit MAC address for the IPv6-to-MAC address mapping in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

proxy-nd-policy

Syntax	proxy-nd-policy <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no proxy-nd-policy
Context	config>service>ies>if>ipv6
Description	<p>This command configures a proxy neighbor discovery policy for the interface. This policy determines networks and sources for which proxy ND will be attempted, when local proxy neighbor discovery is enabled.</p> <p>The no form of this command reverts to the default value.</p>
Default	no proxy-nd-policy
Parameters	<p><i>policy-name</i> — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> <p>The specified name(s) must already be defined.</p>

2.12.2.3 Show Commands

Note: The command outputs in this section are examples only; actual displays may differ depending on supported functionality and user configuration

egress-label

Syntax	egress-label <i>egress-label1</i> [<i>egress-label2</i>]
Context	show>service
Description	<p>Display services using the range of egress labels.</p> <p>If only the mandatory <i>egress-label1</i> parameter is specified, only services using the specified label are displayed.</p> <p>If both <i>egress-label1</i> and <i>egress-label2</i> parameters are specified, the services using the range of labels X where <i>egress-label1</i> <= X <= <i>egress-label2</i> are displayed.</p> <p>Use the show router ldp bindings command to display dynamic labels.</p>

Parameters *egress-label1* — The starting egress label value for which to display services using the label range. If only *egress-label1* is specified, services only using *egress-label1* are displayed.

Values 0, 2049 to 131071

egress-label2 — The ending egress label value for which to display services using the label range.

Values 2049 to 131071

Default The *egress-label1* value.

Output Show Service Egress Command Output

The following table describes show service egress label output fields.

Table 13 Service Egress Label Output Field Descriptions

Label	Description
Svc Id	The ID that identifies a service.
Sdp Id	The ID that identifies an SDP.
Type	Indicates whether the SDP binding is a spoke or a mesh.
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP.
E. Lbl	The VC label used by this device to send packets to the far-end device in this service by the SDP.
Number of bindings found	The total number of SDP bindings that exist within the specified egress label range.

Sample Output

```
A:ALA-12# show service egress-label 0 10000
```

```

fdb-info

Syntax **fdb-info**

Context show>service

Description This command displays global FDB usage information.

Output Show FDB-Info Command Output

The following table describes show FDB-Info command output.

Table 14 **Show FDB-Info Command Output Field Descriptions**

Label	Description
Service ID	The ID that identifies a service.
Mac Move	Indicates the administrative state of the MAC movement feature associated with the service.
Mac Move Rate	The maximum rate at which MACs can be re-learned in this service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MACs. The rate is computed as the maximum number of re-learns allowed in a 5 second interval: for example, the default rate of 10 re-learns per second corresponds to 50 re-learns in a 5 second period.
Mac Move Timeout	Indicates the time in seconds to wait before a SAP that has been disabled after exceeding the maximum re-learn rate is re-enabled. A value of zero indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.
Table Size	The maximum number of learned and static entries allowed in the FDB.
Total Count	The current number of entries (both learned and static) in the FDB.

Table 14 Show FDB-Info Command Output Field Descriptions (Continued)

Label	Description (Continued)
Learned Count	The current number of learned entries in the FDB.
Static Count	The current number of static entries in the FDB.
Remote Age	The number of seconds used to age out FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs.
Local Age	The number of seconds used to age out FDB entries learned on local SAPs.
High WaterMark	The utilization of the FDB table of this service at which a 'table full' alarm is raised by the agent.
Low WaterMark	The utilization of the FDB table of this service at which a 'table empty' alarm is raised by the agent.
Mac Learning	Specifies whether the MAC learning process is enabled in this service.
Discard Unknown	Specifies whether frames received with an unknown destination MAC are discarded in this service.
MAC Aging	Specifies whether the MAC aging process is enabled in this service.
MAC Pinning	Specifies whether MAC Pinning is enabled in this service.
Relearn Only	When enabled, indicates that either the FDB table of this service is full or that the maximum system-wide number of MACs supported by the agent has been reached, and thus MAC learning is temporary disabled, and only MAC re-learns can take place.
Total Service FDBs	The current number of service FDBs configured on this node.
Total FDB Size	The sum of configured FDBs.
Total FDB Entries In Use	The total number of entries (both learned and static) in use.

Sample Output

```
A:ALA-12# show service fdb-info

ingress-label

Syntax **ingress-label** *ingress-label1* [*ingress-label2*]

Context show>service

Description Display services using the range of ingress labels.

If only the mandatory *ingress-label1* parameter is specified, only services using the specified label are displayed.

If both *ingress-label1* and *ingress-label2* parameters are specified, the services using the range of labels X where *ingress-label1* <= X <= *ingress-label2* are displayed.

Use the **show router vprn-service-id ldp bindings** command to display dynamic labels.

Parameters *ingress-label1* — The starting ingress label value for which to display services using the label range. If only *ingress-label1* is specified, services only using *ingress-label1* are displayed.

Values 0, 2048 to 131071

ingress-label2 — The ending ingress label value for which to display services using the label range.

Values 2048 to 131071

Default The *ingress-label1* value.

Output Show Service Ingress Label

The following table describes show service ingress label output fields:

Table 16 Show Service Ingress Label Field Descriptions

Label	Description
Svc ID	The value that identifies a specific service.
SDP Id	The SDP identifier.
Type	Indicates whether the SDP is a spoke or a mesh.
I.Lbl	The ingress label used by the far-end device to send packets to this device in this service by the SDP.
E.Lbl	The egress label used by this device to send packets to the far-end device in this service by the SDP.
Number of Bindings Found	The number of SDP bindings within the label range specified.

Sample Output

sap-using

Syntax

```

sap-using [sap sap-id]
sap-using interface [ip-address | ip-int-name]
sap-using [ingress | egress] atm-td-profile td-profile-id
sap-using [ingress | egress] filter filter-id
sap-using [ingress | egress] qos-policy qos-policy-id
sap-using authentication-policy auth-plcy-name

```

Context show>service

Description Displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs.

The optional parameters restrict output to only SAPs matching the specified properties.

Parameters **ingress** — Specifies matching an ingress policy.

egress — Specifies matching an egress policy.

qos-policy *qos-policy-id* — The ingress or egress QoS Policy ID for which to display matching SAPs.

Values 1 to 65535

atm-td-profile *td-profile-id* — Displays SAPs using this traffic description (applies only to the 7750 SR).

filter *filter-id* — The ingress or egress filter policy ID for which to display matching SAPs.

Values 1 to 65535

authentication *auth-plcy-name* — The session authentication policy for which to display matching SAPs.

sap-id — Specifies the physical port identifier portion of the SAP definition.

interface — Specifies matching SAPs with the specified IP interface.

ip-addr — The IP address of the interface for which to display matching SAPs.

Values 1.0.0.0 to 223.255.255.255

ip-int-name — The IP interface name for which to display matching SAPs.

Output Show Service SAP

The following table describes show service SAP output fields:

Table 17 Show Service SAP Field Descriptions

Label	Description
Port ID	The ID of the access port where the SAP is defined.
Svc ID	The service identifier.
SapMTU	The SAP MTU value.
I.QoS	The SAP ingress QoS policy number specified on the ingress SAP.
I.MAC/IP	The MAC or IP filter policy ID applied to the ingress SAP.
E.QoS	The SAP egress QoS policy number specified on the egress SAP.
E.Mac/IP	The MAC or IP filter policy ID applied to the egress SAP
A.Pol	The accounting policy ID assigned to the SAP.
Adm	The administrative state of the SAP.
Opr	The operational state of the SAP.

Sample Output

sdp

Syntax **sdp** [*sdp-id* | **far-end** *ip-addr*] [**detail**]

Context show>service>id

Description Displays information for the SDPs associated with the service.

If no optional parameters are specified, a summary of all associated SDPs is displayed.

Parameters *sdp-id* — Displays only information for the specified SDP ID.

Values 1 to 17407

Default All SDPs

far-end *ip-addr* — Displays only SDPs matching with the specified far-end IP address.

Default SDPs with any far-end IP address.

detail — Displays detailed SDP information.

Output Show Service-ID SDP

The following table describes show service-id SDP output fields:

Table 18 Show Service-ID SDP Field Descriptions

Label	Description
Sdp Id	The SDP identifier.
Type	Indicates whether the SDP is a spoke or a mesh.
Split Horizon Group	Name of the split horizon group that the SAP belongs.
VC Type	Displays the VC type: ether, vlan, or vpls.
VC Tag	Displays the explicit dot1Q value used when encapsulating to the SDP far end.
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP.
Admin Path MTU	The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case.)

Table 18 Show Service-ID SDP Field Descriptions (Continued)

Label	Description (Continued)
Oper Path MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Far End	Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.
Delivery	Specifies the type of delivery used by the SDP: GRE or MPLS.
Admin State	The administrative state of this SDP.
Oper State	The current status of the KeepAlive protocol.
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP.
Egress Label	The label used by this device to send packets to the far-end device in this service by the SDP.
Last Changed	The date and time of the most recent change to the SDP.
Signaling	Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.
Admin State	The administrative state of the keepalive process.
Oper State	The operational state of the keepalive process.
Hello Time	Specifies how often the SDP echo request messages are transmitted.
Max Drop Count	Specifies the maximum number of consecutive SDP echo request messages that can be unacknowledged before the keepalive protocol reports a fault.
Hello Msg Len	Specifies the length of the transmitted SDP echo request messages.
Hold Down Time	Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.
I. Fwd. Pkts.	Specifies the number of forwarded ingress packets.
I. Dro. Pkts	Specifies the number of dropped ingress packets.
E. Fwd. Pkts.	Specifies the number of forwarded egress packets.
E. Fwd. Octets	Specifies the number of forwarded egress octets.

Table 18 Show Service-ID SDP Field Descriptions (Continued)

Label	Description (Continued)
Associated LSP List	When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far end field. If the SDP type is GRE, then the following message displays: SDP delivery mechanism is not MPLS

sdp-using

- Syntax** **sdp-using** [*sdp-id*[:*vc-id*] | far-end *ip-address*]
- Context** show>service
- Description** This command displays services using SDP or far-end address options.
- Parameters** *sdp-id* — Displays only services bound to the specified SDP ID.
Values 1 to 17407
vc-id — The virtual circuit identifier.
Values 1 to 4294967295
far-end ip-address — Displays only services matching with the specified far-end IP address.
Default Services with any far-end IP address.
- Output** Show Service SDP Using X
- The following table describes **sdp-using** output fields.

Table 19 Show Service SDP Using Field Descriptions

Label	Description
Svc ID	The value identifying a service.
Spd ID	The SPD identifier.
Type	Type of SDP: Spoke or Mesh.
Far End	The far-end address of the SDP.
Oper State	The operational state of the service.
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP.
Egress Label	The label used by this device to send packets to the far-end device in this service by this SDP.

Sample Output

```

credit-control

Syntax **credit-control** [**subscriber** *sub-ident-string*]
 credit-control out-of-credit [**action** *action*] [**summary**]
 credit-control extended-failure-handling [*state*] [**summary**]

Context show>service>active-subscribers

Description This command displays active subscriber credit control information. Without additional filters, the output lists information for all active subscribers.

The output of this command can be filtered:

- per subscriber by specifying the optional **subscriber** *sub-ident-string* parameter
- per all subscribers that are out of credit by specifying the **out-of-credit** parameter with the optional **action** *action* parameter
- per subscribers that have a Diameter Gy session with Extended Failure Handling (EFH) enabled by specifying the **extended-failure-handling** parameter with the optional *state* parameter

Parameters **subscriber** *sub-ident-string* — Displays credit control information for the specified subscriber

Values 32 character subscriber identification string

out-of-credit [**action** *action*] — Displays credit control information for subscribers that are out of credit and, optionally, have the specified out of credit action enabled

Values continue, block-category, change-service-level

extended-failure-handling [*state*] — Displays credit control information for subscribers with a Diameter Gy session with EFH enabled. The optional *state* parameter lists subscribers for which the Diameter Gy session EFH is active, inactive, or both (all).

Values active, inactive, all

summary — Lists the number of matching entries for the specified filter

Output [Table 21](#) describes the **show service active-subscribers credit-control** command output fields for Diameter credit control.

Table 21 show service active-subscribers credit-control Field
Descriptions for Diameter Credit Control

Label	Description
Credit Control Policy	The credit control policy name in use for this subscriber session
Category Map	The active category map in use for this subscriber session
Diameter Session Gy	The Diameter Gy session ID
CC Failure Handling	The current value for Credit Control Failure Handling (CCFH) as configured in the Diameter Gy application policy or as received in an Answer message from the Online Charging Server (OCS) in the CCFH AVP Values: terminate, continue, or retry-and-terminate
Extended Failure Handling (EFH) - State ⁽¹⁾	The EFH state: active—EFH is enabled and currently active inactive—EFH is enabled and currently inactive
EFH - Attempts ^{(1) (2)}	The number of times interim credit is assigned to all rating groups followed by an attempt to establish a new Diameter Gy session with the Online Charging Server (OCS), or credit control server
EFH - Maximum Attempts ^{(1) (2)}	The configured maximum attempts value in the Diameter application policy When an attempt to establish a new Diameter Gy session with the OCS continues to fail after the maximum attempts value is reached, then the user session is terminated (the subscriber hosts are deleted from the system).
EFH - Active Time ^{(1) (2)}	The time since the EFH state became active for this subscriber session
EFH - Total Active Time ⁽¹⁾	The accumulated time of all occurrences that EFH was active during the lifetime of this subscriber session
EFH - Total Active Count ⁽¹⁾	The number of times that EFH was active during the lifetime of this subscriber session
Category - Category Name	The name of the category as configured in the category map
Category - Ingress Queues	The ingress queues for which credit control is applied in this category as configured in the category map

Table 21 show service active-subscribers credit-control Field
Descriptions for Diameter Credit Control (Continued)

Label	Description
Category - Egress Queues	The egress queues for which credit control is applied in this category as configured in the category map
Category - Ingress Policers	The ingress policers for which credit control is applied in this category as configured in the category map
Category - Egress Policers	The egress policers for which credit control is applied in this category as configured in the category map
Category - Credit Volume Used	The used total octets counter (ingress and egress combined) since the last usage reporting of this rating group
Category - Credit Volume Avail.	The remaining total granted octets available before a new credit negotiation is triggered for this rating group (category) or the out of credit action is triggered
Category - Credit Volume Thres.	The volume quota threshold in octets as received from the OCS When the Credit Volume Available octets fall below the Credit Volume Threshold, a new credit negotiation is triggered for this rating group (category). The Credit Volume Threshold value is set to Expired and Credit Negotiating is set to True.
Category - Credit Time Used	The number of seconds passed since the last reporting of this rating group
Category - Credit Time Avail.	The remaining number of seconds before a new credit negotiation is triggered for this rating group (category) or the out of credit action is triggered
Category - Credit Time Thres.	The time quota threshold in seconds as received from the OCS When the Credit Time Available falls below the Credit Time Threshold, a new credit negotiation is triggered for this rating group (category). The Credit Time Threshold value is set to Expired and Credit Negotiating is set to true.
Category - Credit Expired	The credit expired value: False—Negotiated credit is still available True—All granted credit is exhausted; either new credit is being negotiated with the OCS or the out of credit action is activated.

Table 21 show service active-subscribers credit-control Field
Descriptions for Diameter Credit Control (Continued)

Label	Description
Category - Credit Negotiating	The credit negotiating value: False—There is no credit being requested to the OCS True—New credit is being requested to the OCS
Category - Out Of Credit Action	The out of credit action value: None—Out-of-credit action is not active When the out-of-credit action is active, the value is set to one of: ChangeServiceLevel, BlockCategory, Continue, or DisconnectHost
Category - Quota Holding Time	The Idle timeout associated with the granted quota. When no traffic associated with the quota is observed for the time specified, a credit negotiation is triggered with the OCS.
Category - Validity Time Used	The number of seconds passed since the Validity Time was installed
Category - Validity Time Avail.	The remaining number of seconds of the Validity Time before a new usage reporting is triggered for this rating group (category)
Category - EFH Unreported Credit - Current Volume ⁽¹⁾ ⁽²⁾	The unreported volume credit for the current occurrence of EFH in an active state. This counter includes the unreported used volume credit for the initial Diameter Gy session that caused the active EFH state and the unreported volume interim credit for previous attempts. Used interim credit for the current attempt is shown in the Credit Volume Used counter.
Category - EFH Unreported Credit - Total Volume ⁽¹⁾	The accumulated total unreported volume credit for the previous occurrences of EFH in an active state. The total counter is updated when the EFH state toggles from active to inactive. When interim credit reporting is enabled, the counters are reset to zero when the actual usage reporting for this rating group (category) occurs. When interim credit reporting is disabled, the counters accumulate the total unreported volume credit during the lifetime of the subscriber session.

Table 21 show service active-subscribers credit-control Field
Descriptions for Diameter Credit Control (Continued)

Label	Description
Category - EFH Unreported Credit - Current Time ⁽¹⁾ ⁽²⁾	The unreported time credit for the current occurrence of EFH in an active state. This counter includes the unreported used time credit for the initial Diameter Gy session that caused the active EFH state and the unreported time interim credit for previous attempts. Used interim credit for the current attempt is shown in the Credit Time Used counter.
Category - EFH Unreported Credit - Total Time ⁽¹⁾	The accumulated total unreported time credit for the previous occurrences of EFH in an active state. The total counter is updated when the EFH state toggles from active to inactive. When interim credit reporting is enabled, the counters are reset to zero when the actual usage reporting for this rating group (category) occurs. When interim credit reporting is disabled, the counters accumulate the total unreported time credit during the lifetime of the subscriber session.

⁽¹⁾ These fields are only shown when EFH is enabled in the Diameter application policy. EFH is enabled using the **configure subscriber-mgmt diameter-application-policy gy extended-failure-handling no shutdown** command.

⁽²⁾ These fields are only shown when the EFH state is active.

filter

Syntax **filter** [**subscriber** *sub-ident-string*] [**origin** *origin*]

Context show>service>active-subscribers

Description This command displays active subscriber filter information.

hierarchy

Syntax	hierarchy [subscriber <i>sub-ident-string</i>]
Context	show>service>active-subscribers
Description	This command displays active subscriber hierarchy information. To display an IPoE/PPP session, the group of hosts within the session is visually indented. Additional information related to the session is also shown. For PPPoE, the circuit ID and remote ID if used is shown. For IPoE, the key used to group the session is shown (for example, the circuit ID). The command also display PD host which are modeled as a managed route. The PD managed route is directly underneath and points to the host that it is using as the next hop. The PD managed route forwarding status is also shown, where (N) indicates that the route is not forwarding.

Output

Sample Output

```
*A:Dut-C# show service active-subscribers hierarchy

=====
```

radius-acct

Syntax	radius-acct
Context	show>service>active-subscribers>hierarchy
Description	This command provides information about subscriber RADIUS accounting sessions including: the accounting policy name, the accounting mode, the interim intervals, the accounting session ID, and the multi-session ID. If there are no RADIUS accounting sessions enabled for subscribers, this command will still show the session ID that can be used by CoA.

PD hosts modeled as routes are not considered hosts, and therefore, are not shown in the output of this command.

This command only shows a numeric RADIUS session ID even if the RADIUS accounting policy is configured using the descriptive format.

Output

Sample Output

```
A:BNG # show service active-subscribers hierarchy radius-acct

id

Syntax	id service-id
Context	show>service
Description	Enables the context to display information for a particular service-id.
Parameters	<p>service-id — The unique service identification number that identifies the service in the service domain.</p> <p>all — Displays detailed information about the service.</p> <p>arp — Displays ARP entries for the service.</p> <p>arp-host — Displays ARP host related information.</p> <p>base — Displays basic service information.</p> <p>fdb — Displays FDB entries.</p> <p>host — Displays static hosts configured on the specified service.</p> <p>labels — Displays labels being used by this service.</p> <p>sap — Displays SAPs associated to the service.</p> <p>sdp — Displays SDPs associated with the service.</p> <p>split-horizon-group — Display split horizon group information.</p> <p>stp — Displays STP information.</p>

all

Syntax	all
Context	show>service>id

Description Displays detailed information for all aspects of the service.

Output Show All Service-ID Output

The following table describes the show all service-id command output fields:

Table 22 Show All Service-ID Output Field Descriptions

Label	Description
Service Id	The value that identifies a service.
VPN Id	The number that identifies the VPN.
Service Type	Specifies the type of service.
SDP Id	The SDP identifier.
Description	Text string describing general information about the service.
Customer Id	The customer identifier.
Last Mgmt Change	The date and time of the most recent management-initiated change to this customer.
SAP Count	The number of SAPs specified for this service.
SDP Bind Count	The number of SDPs bound to this service.
Split Horizon Group	Name of the split horizon group for this service.
Description	Text string describing the split horizon group.
Last Changed	The date and time of the most recent management-initiated change to this split horizon group.
SDP Id	The SDP identifier.
Type	Indicates whether this Service SDP binding is a spoke or a mesh.
Admin Path MTU	The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Oper Path MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Delivery	Specifies the type of delivery used by the SDP: GRE or MPLS.
Admin State	The administrative state of this SDP.
Oper State	The operational status of the KeepAlive protocol.

Table 22 Show All Service-ID Output Field Descriptions (Continued)

Label	Description (Continued)
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP.
Egress Label	The label used by this device to send packets to the far-end device in this service by this SDP.
Ingress Filter	The ID of the ingress filter policy.
Egress Filter	The ID of the egress filter policy.
Far End	Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.
Last Changed	The date and time of the most recent change to this customer.
Signaling	Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.
Admin State	Specifies the operating status of the SDP.
Oper State	The operational state of the SDP.
Hello Time	Specifies how often the SDP echo request messages are transmitted on this SDP.
Hello Msg Len	Specifies the length of the SDP echo request messages transmitted on this SDP.
Max Drop Count	Specifies the maximum number of consecutive SDP echo request messages that can be unacknowledged before the keepalive protocol reports a fault.
Hold Down Time	Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.
SDP Delivery Mechanism	When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the Far End field. If the SDP type is GRE, then the following message displays: SDP Delivery Mechanism is not MPLS
Number of SDPs	The total number SDPs applied to this service ID.
Service Access Points	
Service Id	The value that identifies a service.
Port Id	The ID of the access port where this SAP is defined.
Description	Generic information about the SAP.

Table 22 Show All Service-ID Output Field Descriptions (Continued)

Label	Description (Continued)
Encap Value	The value of the label used to identify this SAP on the access port.
Admin State	The desired state of the SAP.
Oper State	The operating state of the SAP.
Last Changed	The date and time of the last change.
Admin MTU	The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Oper MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Ingress qos-policy	The SAP ingress QoS policy ID.
Egress qos-policy	The SAP egress QoS policy ID.
Ingress Filter-Id	The SAP ingress filter policy ID.
Egress Filter-Id	The SAP egress filter policy ID.
Multi Svc Site	Indicates the multi-service site in which the SAP is a member.
Ingress sched-policy	Indicates the ingress QoS scheduler for the SAP.
Egress sched-policy	Indicates the egress QoS scheduler for the SAP.
Acct. Pol	Indicates the accounting policy applied to the SAP.
Collect Stats	Specifies whether accounting statistics are collected on the SAP.
Dropped	The number of packets or octets dropped.
Offered Hi Priority	The number of high priority packets, as determined by the SAP ingress QoS policy.
Offered Low Priority	The number of low priority packets, as determined by the SAP ingress QoS policy.
Forwarded In Profile	The number of in-profile packets or octets (rate below CIR) forwarded.
Forwarded Out Profile	The number of out-of-profile packets or octets (rate above CIR) forwarded.
Dropped In Profile	The number of in-profile packets or octets discarded.
Dropped Out Profile	The number of out-of-profile packets or octets discarded.

Table 22 Show All Service-ID Output Field Descriptions (Continued)

Label	Description (Continued)
Forwarded In Profile	The number of in-profile packets or octets (rate below CIR) forwarded.
Forwarded Out Profile	The number of out-of-profile packets or octets (rate above CIR) forwarded.
Ingress Queue 1	The index of the ingress QoS queue of this SAP.
High priority offered	The packets or octets count of the high priority traffic for the SAP.
High priority dropped	The number of high priority traffic packets/octets dropped.
Low priority offered	The packets or octets count of the low priority traffic.
Low priority dropped	The number of low priority traffic packets/octets dropped.
In profile forwarded	The number of in-profile packets or octets (rate below CIR) forwarded.
Out profile forwarded	The number of out-of-profile octets (rate above CIR) forwarded.
Egress Queue 1	The index of the egress QoS queue of the SAP.
In profile forwarded	The number of in-profile packets or octets (rate below CIR) forwarded.
In profile dropped	The number of in-profile packets or octets dropped for the SAP.
Out profile forwarded	The number of out-of-profile packets or octets (rate above CIR) forwarded.
Out profile dropped	The number of out-of-profile packets or octets discarded.
State	Specifies whether DHCP relay is enabled on this SAP.
Info Option	Specifies whether Option 82 processing is enabled on this SAP.
Action	Specifies the Option 82 processing on this SAP or interface: keep, replace or drop.
Circuit ID	Specifies whether the If index is inserted in Circuit ID sub-option of Option 82.
Remote ID	Specifies whether the far-end MAC address is inserted in remote ID sub-option of Option 82
Managed by Service	Specifies the service-id of the management VPLS managing this SAP.
Managed by SAP	Specifies the sap-id inside the management VPLS managing this SAP.

Table 22 Show All Service-ID Output Field Descriptions (Continued)

Label	Description (Continued)
Prune state	Specifies the STP state inherited from the management VPLS.
Managed by Service	Specifies the service-id of the management VPLS managing this spoke SDP.
Managed by Spoke	Specifies the sap-id inside the management VPLS managing this spoke SDP.
Prune state	Specifies the STP state inherited from the management VPLS.

Sample Output

```

arp

- Syntax** **arp** [*ip-address*] | [**mac** *ieee-address*] | [**sap** *sap-id*] | [**interface** *ip-int-name*]
- Context** show>service>id
- Description** Displays the ARP table for the IES instance.
- Parameters** *ip-address* — Displays only ARP entries in the ARP table with the specified IP address.
Default All IP addresses.
mac ieee-address — Displays only ARP entries in the ARP table with the specified 48-bit MAC address. The MAC address can be expressed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers.
Default All MAC addresses.
sap sap-id — Displays SAP information for the specified SAP ID.
ip-int-name — The IP interface name for which to display matching ARPs.
- Output** Show Service-ID ARP
- The following table describes show service-id ARP output fields.

Table 23 Show Service-ID ARP Field Descriptions

Label	Description
Service ID	The value identifying the service.
MAC	The specified MAC address
Source-Identifier	The location the MAC is defined.
Type	Static FDB entries created by management.
	Learned Dynamic entries created by the learning process.
	OAM Entries created by the OAM process.
Age	The time lapsed since the service was enabled.
Interface	The interface applied to the service.
Port	The port where the SAP is applied.

Sample Output

```

A:ALA-12# show service id 2 arp

base

Syntax	base
Context	show>service>id
Description	This command displays basic information about the service ID including service type, description, SAPs and SDPs.
Output	Show Service-ID Base

The following table describes show service-id base output fields:

Table 24 Show Service-ID Base Field Descriptions

Label	Description
Service Id	The service identifier.
Vpn Id	Specifies the VPN ID assigned to the service.
Service Type	The type of service.
Description	Generic information about the service.
Customer Id	The customer identifier.

Table 24 Show Service-ID Base Field Descriptions (Continued)

Label	Description (Continued)
Last Mgmt Change	The date and time of the most recent management-initiated change to this customer.
Adm	The administrative state of the service.
Oper	The operating state of the service.
Mtu	The largest frame size (in octets) that the service can handle.
Def. Mesh VC Id	This object is only valid in services that accept mesh SDP bindings. It is used to validate the VC ID portion of each mesh SDP binding defined in the service.
SAP Count	The number of SAPs defined on the service.
SDP Bind Count	The number of SDPs bound to the service.
Identifier	Specifies the service access (SAP) and destination (SDP) points.
Type	Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP.
AdmMTU	Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end ESR, without requiring the packet to be fragmented.
OprMTU	Specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end ESR, without requiring the packet to be fragmented.
Opr	The operational state of the SDP.

labels

Syntax	labels
Context	show>service>id
Description	Displays the labels being used by the service.
Output	Show Service-ID Labels

The following table describes show service-id labels output fields:

Table 25 Show Service-ID Labels Field Descriptions

Label	Description
Svc Id	The service identifier.
Sdp Id	The SDP identifier.
Type	Indicates whether the SDP is a spoke or a mesh.

Table 25 Show Service-ID Labels Field Descriptions (Continued)

Label	Description (Continued)
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP.
E. Lbl	The VC label used by this device to send packets to the far-end device in this service by the SDP.

Sample Output

```

A:ALA-12# show service id 1 labels

mfib

Syntax **mfib brief**
mfib [group grp-address]
mfib statistics [group grp-address]

Context show>service>id

Description This command displays the multicast FIB on the VPLS service.

Parameters **group grp-ip-address** — Displays the multicast FIB for a specific multicast group address.
statistics — Displays statistics on the multicast FIB.

Output Show Output

The following table describes the command output fields:

Table 26 Triple Play Mfib Output Field Descriptions

Label	Description
Source Address	IPv4 unicast source address.
Group Address	IPv4 multicast group address.
SAP/SDP ID	Indicates the SAP/SDP to which the corresponding multicast stream will be forwarded/blocked.
Forwarding/Blocking	Indicates whether the corresponding multicast stream will be blocked/forwarded.
Number of Entries	Number of entries in the MFIB.
Forwarded Packets	Indicates the number of multicast packets forwarded for the corresponding source/group.
Svc ID	Indicates the service to which the corresponding multicast stream will forwarded/blocked. Local means that the multicast stream will be forwarded/blocked to a SAP or SDP local to the service.

Sample Output

The following is an example for the 7450 ESS:

```

mstp-configuration

Syntax	mstp-configuration
Context	show>service>id
Description	This command displays the MSTP specific configuration data. This command is only valid on a management VPLS.

sap

Syntax	sap sap-id [detail]
Context	show>service>id
Description	<p>This command displays information for the SAPs associated with the service.</p> <p>If no optional parameters are specified, a summary of all associated SAPs is displayed.</p>
Parameters	<p>sap-id — The ID that displays SAP information.</p> <p>detail — Displays detailed information for the SAP.</p>
Output	Show Service-ID SAP

The following table describes show service SAP fields:

Table 27 **Show Service-ID SAP Field Descriptions**

Label	Description
Service Id	The service identifier.
SAP	The SAP and qtag.
Encap	The encapsulation type of the SAP.
Ethertype	Specifies an Ethernet type II Ethertype value.
Admin State	The administrative state of the SAP.
Oper State	The operational state of the SAP.
Flags	Specifies the conditions that affect the operating status of this SAP.
Last Status Change	Specifies the time of the most recent operating status change to this SAP
Last Mgmt Change	Specifies the time of the most recent management-initiated change to this SAP.
Admin MTU	The desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.
Oper MTU	The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.
Ingress qos-policy	The ingress QoS policy ID assigned to the SAP.
Egress qos-policy	The egress QoS policy ID assigned to the SAP.
Ingress Filter-Id	The ingress filter policy ID assigned to the SAP.
Egress Filter-Id	The egress filter policy ID assigned to the SAP.
Acct. Pol	The accounting policy ID assigned to the SAP.
Collect Stats	Specifies whether collect stats is enabled.
Dropped	The number of packets and octets dropped due to SAP state, ingress MAC or IP filter, same segment discard, bad checksum, etc.
Off. HiPrio	The number of high priority packets and octets, as determined by the SAP ingress QoS policy, offered by the Pchip to the Qchip.

Table 27 Show Service-ID SAP Field Descriptions (Continued)

Label	Description (Continued)
Off. LowPrio	The number of low priority packets and octets, as determined by the SAP ingress QoS policy, offered by the Pchip to the Qchip.
Off. Uncolor	The number of uncolored packets and octets, as determined by the SAP ingress QoS policy, offered by the Pchip to the Qchip.
Dro. HiPrio	The number of high priority packets and octets, as determined by the SAP ingress QoS policy, dropped by the Qchip due to: MBS exceeded, buffer pool limit exceeded, etc.
Dro. LowPrio	The number of low priority packets and octets, as determined by the SAP ingress QoS policy, dropped by the Qchip due to: MBS exceeded, buffer pool limit exceeded, etc.
Dro. InProf	The number of in-profile packets and octets discarded by the egress Qchip due to MBS exceeded, buffer pool limit exceeded, etc.
Dro. OutProf	The number of out-of-profile packets and octets discarded by the egress Qchip due to MBS exceeded, buffer pool limit exceeded, etc.
For. InProf	The number of in-profile packets and octets (rate below CIR) forwarded by the egress Qchip.
For. OutProf	The number of out-of-profile packets and octets (rate above CIR) forwarded by the egress Qchip.

*A:ALA-48>show>service>id#

```

sdp

Syntax	sdp [<i>sdp-id</i> <i>far-end ip-addr</i>] [<i>detail</i>]
Context	show>service>id
Description	Displays information for the SDPs associated with the service. If no optional parameters are specified, a summary of all associated SDPs is displayed.
Parameters	<i>sdp-id</i> — Displays only information for the specified SDP ID. <div> Values 1 to 17407 </div> <div> Default All SDPs. </div>

far-end *ip-addr* — Displays only SDPs matching with the specified far-end IP address.

Default SDPs with any far-end IP address.

detail — Displays detailed SDP information.

Output Show Service-ID SDP

The following table describes show service-id SDP output fields:

Table 28 Show Service-ID SDP Field Descriptions

Label	Description
Sdp Id	The SDP identifier.
Type	Indicates whether the SDP is a spoke or a mesh.
Split Horizon Group	Name of the split horizon group that the SAP belongs to.
VC Type	Displays the VC type: ether, vlan, or vpls.
VC Tag	Displays the explicit dot1Q value used when encapsulating to the SDP far end.
I. Lbl	The VC label used by the far-end device to send packets to this device in this service by the SDP.
Admin Path MTU	The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case.)
Oper Path MTU	The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.
Far End	Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.
Delivery	Specifies the type of delivery used by the SDP: GRE or MPLS.
Admin State	The administrative state of this SDP.
Oper State	The current status of the SDP.
Ingress Label	The label used by the far-end device to send packets to this device in this service by this SDP.

gsmp

Syntax	gsmp
Context	show>service>id
Description	This enables the command to display GSMP information.

neighbors

Syntax	neighbors group [<i>name</i>] [<i>ip-address</i>]
Context	show>service>id>gsmp
Description	This command display GSMP neighbor information.
Parameters	group — A GSMP group defines a set of GSMP neighbors which have the same properties. <i>name</i> — Specifies a GSMP group name is unique only within the scope of the service in which it is defined. <i>ip-address</i> — Specifies the ip-address of the neighbor.
Output	Show Service-ID GSMP Neighbors Group

The following table describes show service-id gsmp neighbors group output fields:

Table 29 Show Service-ID GSMP Neighbors Group Field Descriptions

Label	Description
Group	Displays the group name.
Neighbor	Displays the neighbor IP address.
AdminState	Displays the administrative state of the neighbor.
Sessions	Displays the number of sessions (open TCP connections) for each configured neighbor.

Sample Output

These commands show the configured neighbors per service, regardless that there exists an open TCP connection with this neighbor. The admin state is shown because for a neighbor to be admin enabled, the service, gsmp node, group node and the neighbor node in this service must all be in 'no shutdown' state. Session gives the number of session (open TCP connections) for each configured neighbor.

sessions

- Syntax** **sessions** [**group** *name*] [**neighbor** *ip-address*] [**port** *port-number*] [**association**] [**statistics**]
- Context** show>service>id>gsmp
- Description** This command displays GSMP sessions information.
- Parameters**

group — A GSMP group defines a set of GSMP neighbors which have the same properties.

name — Specifies a GSMP group name is unique only within the scope of the service in which it is defined.

ip-address — Specifies the ip-address of the neighbor.

port — Specifies the neighbor TCP port number use for this ANCP session.

Values 0 to 65535

association — Displays to what object the ANCP-string is associated.

statistics — Displays statistics information about an ANCP session known to the system.
- Output**

Show Service-ID GSMP sessions

The following table describes service ID GSMP sessions output fields:

Table 30 Show Service-ID GSMP Sessions Field Descriptions

Label	Description
Port	Displays the port ID number.
Ngbr-IpAddr	Displays the neighbor IP address.
GsmP-Group	Displays the GSMP group ID.
State	The GSMP state of this TCP connection.
Peer Instance	Together with the peer port and peer name output, displays a unique GSMP ID for each end of the GSMP connection.
Peer Port	Together with the peer instance and peer name output, displays a unique GSMP ID for each end of the GSMP connection.
Peer Name	Together with the peer port and peer instance output, displays a unique GSMP ID for each end of the GSMP connection.
timeouts	Displays the number of successive timeouts for this session.
Peer Timer	Displays the GSMP keepalive timer.
Capabilities	Displays the ANCP capabilities negotiated for this session.
Conf Capabilities	Displays the ANCP capabilities configured for this session.
Priority Marking	Displays the priority marking configured for this session.
Local Addr	Displays the IP address used by the box's side of the TCP connection.
Conf. Local Addr.	Displays the configured IP address used by the box's side of the TCP connection.
Sender Instance	The instance sent to the neighbor in this session.
Sender Port	The port sent to the neighbor in this session.
Sender Name	The name sent to the neighbor in this session.
Max. Timeouts	The maximum number of successive timeouts configured for this session.
Sender Timer	Indicates the timeout value that will be announced towards the neighbor. The neighbor uses this timeout value while waiting for an acknowledgment from this system.

Sample Output

This show command gives information about the open TCP connections with DSLAMs.

stp

Syntax **stp** [**detail**]

Context show>service>id

Description Displays information for the spanning tree protocol instance for the service.

Parameters **detail** — Displays detailed information.

Output Show Service-ID STP Output

The following table describes show service-id STP output fields:

Table 31 Show Service-ID STP Output Field Descriptions

Label	Description
RSTP Admin State	Indicates the administrative state of the Rapid Spanning Tree Protocol instance associated with this service.
Core Connectivity	Indicates the connectivity status to the core.

Table 31 Show Service-ID STP Output Field Descriptions (Continued)

Label	Description (Continued)
RSTP Oper State	Indicates the operational state of the Rapid Spanning Tree Protocol instance associated with this service. This field is applicable only when STP is enabled on the router.
Bridge-id	Specifies the MAC address used to identify this bridge in the network.
Hold Time	Specifies the interval length during which no more than two Configuration BPDUs shall be transmitted by this bridge.
Bridge fwd delay	Specifies how fast a bridge changes its state when moving toward the forwarding state.
Bridge Hello time	Specifies the amount of time between the transmission of Configuration BPDUs.
Bridge max age	Specifies the maximum age of spanning tree protocol information learned from the network on any port before it is discarded. This is the actual value that this bridge is currently using.
Bridge priority	Defines the priority of the spanning tree protocol instance associated with this service.
Topology change	Specifies whether a topology change is currently in progress.
Last Top. change	Specifies the time (in hundredths of a second) since the last time a topology change was detected by the Spanning Tree Protocol instance associated with this service.
Top. change count	Specifies the total number of topology changes detected by the Spanning Tree Protocol instance associated with this service since the management entity was last reset or initialized.

Sample Output

```
A:ALA-12# show service id 1 stp

subscriber-hosts

- Syntax** **subscriber-hosts** [**sap** *sap-id*] [**ip** *ip-address[/mask]*] [**mac** *ieee-address*] [**sub-profile** *sub-profile-name*] [**sla-profile** *sla-profile-name*] [**detail**] **statistics**
- Context** show>service>id
- Description** This command displays subscriber host information.
- Parameters**
- sap** *sap-id* — specifies the physical port identifier portion of the SAP definition
 - ip** *ip-address[/mask]* — shows information for the specified IP address and mask
 - mac** *ieee-address* — displays information only for the specified 48-bit MAC address. The MAC address can be expressed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers.
 - profile** *sub-profile-name* — displays an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.
 - sla-profile** *sla-profile-name* — displays this optional parameter to specify an existing SLA profile name
 - detail** — displays detailed information
 - statistics** — displays the HTTP redirect statistics for the host. The redirect statistics is divided into HTTP GET and HTTP response for redirection.

Output Show Service-ID subscriber hosts

The following table describes show service-id subscriber hosts output fields:

Table 32 Show Service-ID Subscriber Hosts Field Descriptions

Label	Description

Context show>service>sdp

Description This command displays SDP information.

If no optional parameters are specified, a summary SDP output for all SDPs is displayed.

Parameters *sdp-id* — The SDP ID for which to display information.

Values 1 to 17407

Default All SDPs.

pw-port *pw-port-id* — Displays the SAP identifier for PW-SAPs.

Values 1 to 10239

far-end *ip-address* — Displays only SDPs matching with the specified far-end IP address.

Default SDPs with any far-end IP address.

detail — Displays detailed SDP information.

Default SDP summary output.

keep-alive-history — Displays the last fifty SDP keepalive events for the SDP.

Default SDP summary output.

subscriber-using

- Syntax** **subscriber-using** [**service-id** *service-id*] [**sap-id** *sap-id*] [**interface** *ip-int-name*] [**ip** *ip-address[/mask]*] [**mac** *ieee-address*] [**sub-profile** *sub-profile-name*] [**sla-profile** *sla-profile-name*] [**app-profile** *app-profile-name*] [**port** *port-id*] [**no-inter-dest-id** | **inter-dest-id** *intermediate-destination-id*]
- Context** show>service
- Description** This command displays selective subscriber information using specific options.
- Parameters** **service-id** *service-id* — Displays information for the specifies ID that uniquely identifies a service.
- sap-id** *sap-id* — Displays the physical port identifier portion of the SAP definition.
- interface** *ip-int-name* — Shows DHCP statistics on the specified interface.

port *port-id* — Indicates the SAP or SDP for which this entry contains information.

ip *ip-address[/mask]* — Shows information for the specified IP address and mask.

mac *ieee-address* — Displays information only for the specified 48-bit MAC address.
The MAC address can be expressed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers.

sub-profile *sub-profile-name* — Displays an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context. *sla-profile-name*

sla-profile — Displays this optional parameter to specify an existing SLA profile name.

app-profile — Displays the application specified profile.

inter-dest-id *intermediate-destination-id* — Indicates the intermediate destination identifier received from either the DHCP or the RADIUS server or the local user database.

mc-ipsec

Syntax	mc-ipsec peer <i>addr</i> [tunnel-group <i>group-id</i>]
Context	show>redundancy>multi-chassis
Description	This command displays the IPsec multi-chassis states. Optionally, only the states of the specified tunnel-groups will be displayed.
Parameters	<i>addr</i> — Specifies the address of the peer. <i>group-id</i> — Specifies the tunnel-group ID.
Output	

Sample Output

```

mc-ring

- Syntax** **mc-ring peer** *ip-address* **statistics**
mc-ring peer *ip-address* [**ring** *sync-tag* [**detail|statistics**]]
mc-ring peer *ip-address* **ring** *sync-tag* **ring-node** [*ring-node-name* [**detail|statistics**]]
mc-ring global-statistics
- Context** show>redundancy>multi-chassis
- Description** This command displays multi-chassis ring information.
- Parameters** *ip-address* — Specifies the address of the multi-chassis peer to display.
ring *sync-tag* — Specifies a synchronization tag to be displayed that was used while synchronizing this port with the multi-chassis peer.
node *ring-node-name* — Specifies a ring-node name.
global-statistics — Displays global statistics for the multi-chassis ring.
detail — Displays detailed peer information for the multi-chassis ring.
- Output** Show mc-ring peer ip-address ring Output
- The following table describes mc-ring peer ip-address ring output fields.

Table 33 Show mc-ring peer ip-address ring Output Field Descriptions

Label	Description
Sync Tag	Displays the synchronization tag that was used while synchronizing this port with the multi-chassis peer.
Oper State	noPeer The peer has no corresponding ring configured.
	connected The inband control connection with the peer is operational.
	broken The inband control connection with the peer has timed out.
	conflict The inband control connection with the peer has timed out but the physical connection is still OK; the failure of the inband signaling connection is caused by a misconfiguration. For example, a conflict between the configuration of this system and its peer, or a misconfiguration on one of the ring access node systems.

Table 33 Show mc-ring peer ip-address ring Output Field Descriptions

Label	Description (Continued)
Oper State (Cont)	testingRing The inband control connection with the peer is being set up. Waiting for result.
	waitingForPeer Verifying if this ring is configured on the peer.
	configErr The ring is administratively up, but a configuration error prevents it from operating properly.
	halfBroken The inband control connection indicates that the ring is broken in one direction (towards the peer).
	localBroken The inband control connection with the peer is known to be broken due to local failure or local administrative action.
	shutdown The ring is shutdown.
Failure Reason	Displays the failure reason.
No. of MC Ring entries	Displays the number of MC ring entries.

Sample Output

```

show redundancy multi-chassis ring peer statistics Output

The following table describes multi-chassis ring peer output fields

Table 34 Multi-chassis Ring Peer Output Field Descriptions

Label	Description
Message	Displays the message type.
Received	Indicates the number of valid MC-Ring signaling messages received from the peer.
Transmitted	Indicates the number of valid MC-Ring signaling messages transmitted from the peer.
MCS ID Request	Displays the number of valid MCS ID requests were received from the peer.
MCS ID Response	Displays the number of valid MCS ID responses were received from the peer.
Ring Exists Request	Displays the number of valid 'ring exists' requests were received from the peer.
Ring Exists Response	Displays the number of valid ring exists' responses were received from the peer.

Table 34 Multi-chassis Ring Peer Output Field Descriptions (Continued)

Label	Description (Continued)
Keepalive	Displays the number of valid MC-Ring control packets of type 'keepalive' were received from the peer.

show mc-ring ring-node Output**Table 35** Show mc-ring ring-node Output Field Descriptions

Label	Description
Oper State	Displays the state of the connection verification (both local and remote).
	notProvisioned Connection verification is not provisioned.
	configErr Connection verification is provisioned but a configuration error prevents it from operating properly.
	notTested Connection verification is administratively disabled or is not possible in the current situation.
	testing Connection Verification is active, but no results are yet available.
	connected The ring node is reachable.

Table 35 Show mc-ring ring-node Output Field Descriptions (Continued)

Label	Description (Continued)
Oper State (Cont)	disconnected Connection verification has timed out.
In Use	Displays "True" if the ring node is referenced on an e-pipe or as an inter-dest-id on a static host or dynamic lease.

show mc-ring global-statistics Output**Table 36 Show mc-ring global-statistics Output Field Descriptions**

Label	Description
Rx	Displays the number of MC-ring signaling packets were received by this system.
Rx Too Short	Displays the number of MC-ring signaling packets were received by this system that were too short.
Rx Wrong Authentication	Displays the number of MC-ring signaling packets were received by this system with invalid authentication.
Rx Invalid TLV	Displays the number of MC-ring signaling packets were received by this system with invalid TLV.
Rx Incomplete	Displays the number of MC-ring signaling packets were received by this system that were incomplete.
Rx Unknown Type	Displays the number of MC-ring signaling packets were received by this system that were of unknown type.
Rx Unknown Peer	Displays the number of MC-ring signaling packets were received by this system that were related to an unknown peer.
Rx Unknown Ring	Displays the number of MC-ring signaling packets were received by this system that were related to an unknown ring.
Rx Unknown Ring Node	Displays the number of MC-ring signaling packets were received by this system that were related to an unknown ring node.
Tx	Displays the number of MC-ring signaling packets were transmitted by this system.
Tx No Buffer	Displays the number of MC-ring signaling packets could not be transmitted by this system due to a lack of packet buffers.
Tx Transmission Failed	Displays the number of MC-ring signaling packets could not be transmitted by this system due to a transmission failure.

Table 36 Show mc-ring global-statistics Output Field Descriptions

Label	Description (Continued)
Tx Unknown Destination	Displays the number of MC-ring unknown destination signaling packets were transmitted by this system.
Missed Configuration Events	Displays the number of missed configuration events on this system.
Missed BFD Events	Displays the number of missed BFD events on this system.

Sample Output

lease-state

Syntax **lease-state** [**wholesaler** *service-id*] [**sap** *sap-id* | **sdp** *sdp-id:vc-id*] **interface** *interface-name* [**ip-address** *ip-address[/mask]* | **chaddr** *ieee-address* | **mac** *ieee-address* | {[**port** *port-id*] [**no-inter-dest-id** | **inter-dest-id** *inter-dest-id*]}] [**session** {**none** | **ipoe**}] [**detail**]

Context show>service>id>dhcp

Description This command displays DHCP lease state information.

Note: The **wholesaler** *service-id* parameter is applicable only in the VPRN context (VPRN is supported by the 7750 SR only).

- Parameters**
- wholesaler** *service-id* — The service ID of the wholesaler. When specified in this context, SAP, SDP, interface, IP address and MAC parameters are ignored. This parameter only applies to the 7750 SR.
 - Values**
 - service-id*: 1 to 214748364
 - svc-name*: A string up to 64 characters in length.
 - sap** *sap-id* — Specifies the physical port identifier portion of the SAP definition.
 - sdp** *sdp-id* — The SDP identifier.
 - Values** 1 to 17407
 - vc-id* — The virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID.
 - Values** 1 to 4294967295
 - interface** *interface-name* — Specifies the interface name up to 32 characters in length.
 - ip** *ip-address[/mask]* — Shows information for the specified IP address and mask.
 - port** *port-id* — The DHCP lease state local specifies that the DHCP lease state is learned by either a SAP or SDP. When the value is SAP, the value indicates the SAP for which this entry contains information.
 - chaddr** — Specifies the MA address of the DHCP lease state.
 - interface** *interface-name* — Shows information for the specified IP interface.
 - detail** — Displays detailed lease state information.
 - inter-dest-id** — Indicates the intermediate destination identifier received from either the DHCP or the RADIUS server or the local user database.
 - session** — Shows DHCPv4 lease states for hosts that are associated with an IPoE session or for hosts that are not associated with an IPoE session.
 - Values** none, ipoe
 - detail** — Displays detailed information.

lease-state

Syntax	lease-state [detail] [wholesaler <i>service-id</i>] [session {none ipoe ppp}] lease-state [detail] interface <i>interface-name</i> [wholesaler <i>service-id</i>] [session {none ipoe ppp}] lease-state [detail] <i>ipv6-address</i> <i>ipv6-prefix</i> [/ <i>prefix-length</i>] [wholesaler <i>service-id</i>] [session {none ipoe ppp}] lease-state [detail] mac <i>ieee-address</i> [wholesaler <i>service-id</i>] [session {none ipoe ppp}]
Context	show>service>id>dhcp6
Description	This command displays DHCP6 lease state information.

Note: The **wholesaler** *service-id* parameter is applicable only in the VPRN context.

Parameters	wholesaler <i>service-id</i> — The service ID of the wholesaler. When specified in this context, SAP, SDP, interface, IP address and MAC parameters are ignored. This parameter only applies to the 7750 SR. Values <i>service-id</i> : 1 to 214748364 <i>svc-name</i> : A string up to 64 characters in length. sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. sdp <i>sdp-id</i> — The SDP identifier. Values 1 to 17407 <i>vc-id</i> — The virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID. Values 1 to 4294967295
------------	--

interface *interface-name* — Specifies the interface name up to 32 characters in length.

ipv6 *ipv6-address[/mask]* — Shows information for the specified IPv6 address and mask.

port *port-id* — The DHCP6 lease state local specifies that the DHCP lease state is learned by either a SAP or SDP. When the value is SAP, the value indicates the SAP for which this entry contains information.

chaddr — Specifies the MA address of the DHCP6 lease state.

interface *interface-name* — Shows information for the specified IP interface.

detail — Displays detailed lease state information.

inter-dest-id — Indicates the intermediate destination identifier received from either the DHCP6 or the RADIUS server or the local user database.

session — Shows DHCPv6 lease states for clients that are associated with an IPE session or for clients that are associated with a PPP session or for clients that are not associated with an IPE session.

Values none, ipoe, ppp

detail — Displays detailed information.

statistics

Syntax	statistics [[sap <i>sap-id</i>][sdp <i>sdp-id:vc-id</i>]][interface <i>interface-name</i>]]
Context	show>service>id>dhcp
Description	This command displays DHCP relay statistics.
Parameters	<p>interface <i>ip-int-name</i> — Display DHCP statistics on the specified interface.</p> <p>interface <i>interface-name</i> — Displays DHCP statistics for the specified interface name.</p> <p>sap <i>sap-id</i> — Displays DHCP statistics for the specified SAP.</p>

Output

Sample Output

statistics

- Syntax** **statistics** [**interface** *ip-int-name* | *ip-address*]
- Context** show>router>dhcp
- Description** This command displays statistics for DHCP relay and DHCP snooping. If no IP address or interface name is specified, then all configured interfaces are displayed. If an IP address or interface name is specified, then only data regarding the specified interface is displayed.
- Parameters** **interface** *ip-int-name* | *ip-address* — Displays statistics for the specified IP interface or IP address.
- Output** Show DHCP Statistics Output

The following table describes the output fields for DHCP statistics.

Table 37 Show DHCP Statistics Output Field Descriptions

Label	Description
Received Packets	The number of packets received from the DHCP clients.
Transmitted Packets	The number of packets transmitted to the DHCP clients.
Received Malformed Packets	The number of malformed packets received from the DHCP clients.
Received Untrusted Packets	The number of untrusted packets received from the DHCP clients.
Client Packets Discarded	The number of packets received from the DHCP clients that were discarded.
Client Packets Relayed	The number of packets received from the DHCP clients that were forwarded.
Client Packets Snooped	The number of packets received from the DHCP clients that were snooped.
Server Packets Discarded	The number of packets received from the DHCP server that were discarded.
Server Packets Relayed	The number of packets received from the DHCP server that were forwarded.
Server Packets Snooped	The number of packets received from the DHCP server that were snooped.

Table 37 Show DHCP Statistics Output Field Descriptions (Continued)

Label	Description (Continued)
Client packets proxied (RADIUS)	The number of packets that were generated from RADIUS data and not relayed from a server
Client packets proxied (Lease-Split)	Indicates the total number of client packets proxied by the DHCP relay agent based on data received from a RADIUS server
DHCP RELEASEs spoofed	Indicates the total number of DHCP release messages spoofed by the DHCP relay agent to the DHCP server.
DHCP FORCERENEWs spoofed	The number of DHCP force-renew packets sent to DHCP clients.

Sample Output

```

2.12.2.3.1 IGMP Snooping Show Commands**igmp-snooping**

Syntax	igmp-snooping
Context	show>service>id>
Description	This command enables the context to display IGMP snooping information.

all

Syntax	all
Context	show>service>id>igmp-snooping
Description	Displays detailed information for all aspects of IGMP snooping on the VPLS service.
Output	Show All Service-ID

The following table describes the show all service-id command output fields:

Table 39 IGMP Snooping Show All Service-ID Field Descriptions

Label	Description
Admin State	The administrative state of the IGMP instance.
Querier	Displays the address of the IGMP querier on the IP subnet to which the interface is attached.
Sap/Sdp Id	Displays the SAP and SDP IDs of the service ID.
Oper State	Displays the operational state of the SAP and SDP IDs of the service ID.
Mrtr Port	Specifies where the port is a multicast router port.
Send Queries	Specifies whether the send-queries command is enabled or disabled.
Max Num Groups	Specifies the maximum number of multicast groups that can be joined on this SAP or SDP.
MVR From VPLS	Specifies MVR from VPLS.
Num Groups	Specifies the actual number of multicast groups that can be joined on this SAP or SDP.

Sample Output

mrollers

- Syntax** **mrollers [detail]**
- Context** show>service>id>igmp-snooping
- Description** Displays all multicast routers.
- Parameters** **detail** — Displays detailed information.
- Output** Show igmp-snooping mrollers

The following table describes the show igmp-snooping mrollers output fields:

Table 40 IGMP Snooping Mrollers Field Descriptions

Label	Description
MRouter	Specifies the multicast router port.
Sap/Sdp Id	Specifies the SAP and SDP ID multicast router ports.
Up Time	Displays the length of time the mrouter has been up.
Expires	Displays the amount of time left before the query interval expires.
Version	Displays the configured version of IGMP running on this interface.

Sample Output

```

*A:ALA-48# show service id 700 igmp-snooping mrollers
=====
IGMP Snooping Multicast Routers for service 700

mvr

Syntax	mvr
Context	show>service>id>igmp-snooping
Description	Displays Multicast VPLS Registration (MVR) information.
Output	Show igmp-snooping mvr

The following table describes the show igmp-snooping mvr output fields:

Table 41 IGMP Snooping Mvr Field Descriptions

Label	Description
IGMP Snooping Admin State	Displays the IGMP snooping administrative state.
MVR Admin State	Displays the MVR administrative state.
MVR Policy	Displays the MVR policy name.
Svc ID	Displays the service ID.
Sap/SDP	Displays the SAP/SDP ID.
Oper State	Displays the operational state.
From VPLS	Displays the originating VPLS name.
Num Local Groups	Displays the number of local groups.

Sample Output

```

port-db

Syntax

```

port-db sap sap-id [detail]
port-db sap sap-id group grp-address
port-db sdp sdp-id:vc-id [detail]
port-db sdp sdp-id:vc-id group grp-address

```

Context show>service>id>igmp-snooping

Description This command displays information on the IGMP snooping port database for the VPLS service.

Parameters

- group** *grp-ip-address* — Displays the IGMP snooping port database for a specific multicast group address.
- sap** *sap-id* — Displays the IGMP snooping port database for a specific SAP.
- sdp** *sdp-id* — Displays only IGMP snooping entries associated with the specified mesh SDP or spoke SDP. For a spoke SDP, the VC ID must be specified; for a mesh SDP, the VC ID is optional.

Values 1 to 17407

vc-id — The virtual circuit ID on the SDP ID for which to display information.

Values 1 to 4294967295

Default For mesh SDPs only, all VC IDs

group *grp-address* — Displays IGMP snooping statistics matching the specified group address.

source *ip-address* — Displays IGMP snooping statistics matching one particular source within the multicast group.

Output

Syntax	tunnel-interface
Context	show>router>igmp
Description	This command displays IGMP tunnel-interface information.

2.12.2.4 Clear Commands

id

Syntax	id <i>service-id</i>
Context	clear>service clear>service>statistics
Description	This command clears the identification for a specific service.
Parameters	<i>service-id</i> — The ID that uniquely identifies a service. Values service-id: 1 to 214748364 svc-name: A string up to 64 characters in length.

arp-host

Syntax	arp-host arp-host { mac <i>ieee-address</i> sap <i>sap-id</i> ip-address <i>ip-address</i> [/ <i>mask</i>] } arp-host [port <i>port-id</i>] [inter-dest-id <i>intermediate-destination-id</i> no-inter-dest-id] arp-host statistics [sap <i>sap-id</i> interface <i>interface-name</i>]
Context	clear>service>id
Description	This command clears ARP host data.

authentication

Syntax	authentication
Context	clear>service>id
Description	This command enters the context to clear session authentication information.

msap

Syntax	msap { <i>msap-id</i> idle-only }										
Context	clear>service>id										
Description	<p>This command clears Managed SAP (MSAP) information.</p> <p>This command can remove an MSAP with active subscribers still associated with the MSAP. You can specify the idle-only parameter to clear only MSAPs in an idle state; MSAPs with active subscribers will not be cleared.</p>										
Parameters	<p><i>msap-id</i> — Specifies a Managed SAP ID.</p> <table><tr><th colspan="2">Values</th></tr><tr><td>dot1q</td><td>[port-id lag-id]:qtag1</td></tr><tr><td>qinq</td><td>[port-id lag-id]:qtag1.qtag2</td></tr><tr><td>qtag1</td><td>0 to 4094</td></tr><tr><td>qtag2</td><td>0 to 4094</td></tr></table> <p>idle-only — Specifies to clear only MSAPs in an idle state.</p>	Values		dot1q	[port-id lag-id]:qtag1	qinq	[port-id lag-id]:qtag1.qtag2	qtag1	0 to 4094	qtag2	0 to 4094
Values											
dot1q	[port-id lag-id]:qtag1										
qinq	[port-id lag-id]:qtag1.qtag2										
qtag1	0 to 4094										
qtag2	0 to 4094										

msap-policy

Syntax	msap-policy <i>msap-policy-name</i>
---------------	--

Context	clear>service>id
Description	This command clears Managed SAPs created by the Managed SAP policy.
Parameters	<i>msap-policy-name</i> — Specifies an existing MSAP policy.

statistics

Syntax	statistics
Context	clear>service>id>authentication
Description	This command clears session authentication statistics for this service.

statistics

Syntax	statistics
Context	clear>service
Description	This command clears the statistics for a service.

subscriber

Syntax	subscriber <i>sub-ident-string</i>
Context	clear>service>statistics
Description	This command clears the statistics for a particular subscriber.
Parameters	<i>sub-ident-string</i> — Clears statistics for the specified subscriber identification string.

fdb

Syntax	fdb { all mac <i>ieee-address</i> sap <i>sap-id</i>] mesh-sdp <i>sdp-id[:vc-id]</i> spoke-sdp <i>sdp-id:vc-id</i> }
Context	clear>service>id
Description	This command clears FDB entries for the service.
Parameters	<p>all — Clears all FDB entries.</p> <p>mac <i>ieee-address</i> — Clears only FDB entries in the FDB table with the specified 48-bit MAC address. The MAC address can be expressed in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i>, <i>bb</i>, <i>cc</i>, <i>dd</i>, <i>ee</i> and <i>ff</i> are hexadecimal numbers.</p> <p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p>

mesh-sdp — Clears only service FDB entries associated with the specified mesh SDP ID. For a mesh SDP, the VC ID is optional.

spoke-sdp — Clears only service FDB entries associated with the specified spoke SDP ID. For a spoke SDP, the VC ID must be specified.

sdp-id — The SDP ID for which to clear associated FDB entries.

vc-id — The virtual circuit ID on the SDP ID for which to clear associated FDB entries.

Values	sdp-id[:vc-id]	<i>sdp-id</i>	1 to 17407
		<i>vc-id</i>	1 to 4294967295
	sdp-id:vc-id	<i>sdp-id</i>	1 to 17407
		<i>vc-id</i>	1 to 4294967295

mesh-sdp

Syntax	mesh-sdp <i>sdp-id[:vc-id]</i> ingress-vc-label
Context	clear>service>id
Description	Clears and resets the mesh SDP bindings for the service.
Parameters	<i>sdp-id</i> — The mesh SDP ID to be reset. Values 1 to 17407 <i>vc-id</i> — The virtual circuit ID on the SDP ID to be reset. Values 1 to 4294967295 Default All VC IDs on the SDP ID.

spoke-sdp

Syntax	spoke-sdp <i>sdp-id:vc-id</i> ingress-vc-label
Context	clear>service>id
Description	Clears and resets the spoke SDP bindings for the service.
Parameters	<i>sdp-id</i> — The spoke SDP ID to be reset. Values 1 to 17407 <i>vc-id</i> — The virtual circuit ID on the SDP ID to be reset. Values 1 to 4294967295

sap

Syntax	sap <i>sap-id</i> { all counters stp }
Context	clear>service>statistics
Description	Clears SAP statistics for a SAP.
Parameters	<i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. all — Clears all SAP queue statistics and STP statistics. counters — Clears all queue statistics associated with the SAP. stp — Clears all STP statistics associated with the SAP.

sdp

Syntax	sdp <i>sdp-id</i> [keep-alive]
Context	clear>service>statistics
Description	Clears keepalive statistics associated with the SDP ID.
Parameters	<i>sdp-id</i> — The SDP ID for which to clear statistics. Values 1 to 17407 keep-alive — Clears the keepalive history.

counters

Syntax	counters
Context	clear>service>statistics>id
Description	Clears all traffic queue counters associated with the service ID.

sap

Syntax	sap <i>sap-id</i> { all counters stp }
Context	clear>service>statistics>id
Description	Clears statistics for the SAP bound to the service.
Parameters	<i>sap-id</i> — Specifies the SAP ID for which to clear statistics. all — Clears all queue statistics and STP statistics associated with the SAP. counters — Clears all queue statistics associated with the SAP.

stp — Clears all STP statistics associated with the SAP.

spoke-sdp

Syntax	spoke-sdp <i>sdp-id[:vc-id]</i> { all counters stp }
Context	clear>service>statistics>id
Description	Clears statistics for the spoke SDP bound to the service.
Parameters	<i>sdp-id</i> — The spoke SDP ID for which to clear statistics. Values 1 to 17407 <i>vc-id</i> — The virtual circuit ID on the SDP ID to be reset. Values 1 to 4294967295 all — Clears all queue statistics and STP statistics associated with the SDP. counters — Clears all queue statistics associated with the SDP. stp — Clears all STP statistics associated with the SDP.

stp

Syntax	stp
Context	clear>service>statistics>id
Description	Clears all spanning tree statistics for the service ID.

detected-protocols

Syntax	detected-protocols { all sap <i>sap-id</i> spoke-sdp <i>sdp-id[:vc-id]</i> }
Context	clear>service>id>stp
Description	RSTP automatically falls back to STP mode when it receives an STP BPDU. The clear detected-protocols command forces the system to revert to the default RSTP mode on the SAP or spoke SDP.
Parameters	all — Clears all detected protocol information. <i>sap-id</i> — Clears the specified lease state SAP information. <i>sdp-id</i> — The SDP ID to be cleared. Values 1 to 17407

vc-id — The virtual circuit ID on the SDP ID to be cleared.

Values 1 to 4294967295

lease-state

Syntax **lease-state** [**no-dhcp-release**]
lease-state [**port** *port-id*] [**inter-dest-id** *intermediate-destination-id*] [**no-dhcp-release**]
lease-state [**port** *port-id*] **no-inter-dest-id** [**no-dhcp-release**]
lease-state **ip-address** *ip-address*[/*mask*] [**no-dhcp-release**]
lease-state **mac** *ieee-address* [**no-dhcp-release**]
lease-state **sap** *sap-id* [**no-dhcp-release**]
lease-state **sdp** *sdp-id*[:*vc-id*] [**no-dhcp-release**]

Context clear>service>id>dhcp

Description Clears DHCP lease state information for this service.

Parameters **no-dhcp-release** — Specifies that the node will clear the state without sending the DHCP release message.

port *port-id* — The DHCP lease state local specifies that the DHCP lease state is learned by either a SAP or SDP. When the value is SAP, the value indicates the SAP for which this entry contains information.

ip-address — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

ieee-address — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

intermediate-destination-id — Specifies the intermediate destination identifier which is encoded in the identification strings.

Values Up to 32 characters maximum

sap-id — Clears the specified lease state SAP information.

sdp-id — The SDP ID to be cleared.

Values 1 to 17407

vc-id — The virtual circuit ID on the SDP ID to be cleared.

Values 1 to 4294967295

statistics

Syntax	statistics [sap <i>sap-id</i> sdp [<i>sdp-id</i> [: <i>vc-id</i>]]
Context	clear>service>id>dhcp
Description	Clears DHCP statistics for this service.

port-db

Syntax	port-db { sap <i>sap-id</i> sdp <i>sdp-id</i> [: <i>vc-id</i>]} [group <i>grp-address</i> [source <i>ip-address</i>]]
Context	clear>service>id>igmp-snooping
Description	Clears the information on the IGMP snooping port database for the VPLS service.
Parameters	<p>sap <i>sap-id</i> — Clears IGMP snooping statistics matching the specified SAP ID and optional encapsulation value.</p> <p>sdp <i>sdp-id</i> — Clears only IGMP snooping entries associated with the specified mesh SDP or spoke SDP. For a spoke SDP, the VC ID must be specified; for a mesh SDP, the VC ID is optional.</p> <p>Values 1 to 17407</p> <p><i>vc-id</i> — The virtual circuit ID on the SDP ID for which to clear information.</p> <p>Values 1 to 4294967295</p> <p>Default For mesh SDPs only, all VC IDs.</p> <p>group <i>grp-address</i> — Clears IGMP snooping statistics matching the specified group address.</p> <p>source <i>ip-address</i> — Clears IGMP snooping statistics matching one particular source within the multicast group.</p>

querier

Syntax	querier
Context	clear>service>id>igmp-snooping
Description	Clears the information on the IGMP snooping queriers for the VPLS service.

statistics

Syntax	statistics { all sap <i>sap-id</i> sdp <i>sdp-id</i> [: <i>vc-id</i>]}
Context	clear>service>id>igmp-snooping

Description	Clears IGMP snooping statistics for the VPLS service.
Parameters	<p>sap <i>sap-id</i> — Clears IGMP snooping statistics matching the specified SAP ID and optional encapsulation value.</p> <p>sdp <i>sdp-id</i> — Clears only IGMP snooping entries associated with the specified mesh SDP or spoke SDP. For a spoke SDP, the VC ID must be specified, for a mesh SDP, the VC ID is optional.</p> <p>Values 1 to 17407</p> <p><i>vc-id</i> — The virtual circuit ID on the SDP ID for which to clear statistics.</p> <p>Values 1 to 4294967295</p> <p>Default For mesh SDPs only, all VC IDs</p>

mfib

Syntax	mfib
Context	clear>service>id
Description	Enter the context to clear multicast FIB info for the VPLS service.

statistics

Syntax	statistics {all group <i>grp-address</i>}
Context	clear>service>id>mfib
Description	Clears multicast FIB statistics for the VPLS service.
Parameters	<i>grp-address</i> — Specifies an IGMP multicast group address that receives data on an interface.

mld-snooping

Syntax	mld-snooping
Context	clear>service>id
Description	This command enables the context to clear MLD snooping-related data.

port-db

Syntax	port-db sap <i>sap-id</i> [group <i>grp-ipv6-address</i>]
---------------	--

```
port-db sap sap-id group grp-ipv6-address source src-ipv6-address  
port-db sdp sdp-id:vc-id [group grp-ipv6-address]  
port-db sdp sdp-id:vc-id group grp-ipv6-address source src-ipv6-address
```

Context clear>service>id>mld-snooping

Description This command clears MLD snooping port-db group data.

querier

Syntax **querier**

Context clear>service>id>mld-snooping

Description This command clears MLD snooping querier information.

statistics

Syntax **statistics all**
statistics sap *sap-id*
statistics sdp *sdp-id:vc-id*

Context clear>service>id>mld-snooping

Description This command clears MLD snooping statistics.

Parameters **all** — Clears all MLD snooping statistics
sap *sap-id* — Clears all MLD snooping SAP statistics.
sdp *sdp-id:vc-id* — Clears all MLD snooping SDP statistics.

arp

Syntax **arp** {**all** | *ip-address*}
arp interface [*ip-int-name* | *ip-address*]

Context clear>router

Description This command clears all or specific ARP entries. The scope of ARP cache entries cleared depends on the command line option(s) specified.

Parameters **all** — Clears all ARP cache entries.
ip-address — Clears the ARP cache entry for the specified IP address.
interface *ip-int-name* — Clears all ARP cache entries for the IP interface with the specified name.

interface *ip-addr* — Clears all ARP cache entries for the specified IP interface with the specified IP address.

dhcp

Syntax **dhcp**

Context clear>router

Description This command enables the context to clear and reset DHCP entities.

statistics

Syntax **statistics** [**interface** *ip-int-name* | *ip-address*]

Context clear>router>dhcp

Description Clears DHCP statistics.

2.12.2.5 Debug Commands

mcast-reporting-dest

Syntax [**no**] **mcast-reporting-dest** [*dest-name*]

Context debug>mcast-mgmt

Description This command debugs multicast path management reporting destinations and applies only to the 7750 SR.

igmp

Syntax [**no**] **igmp** [**host** *ip-address*] [**group** *grp-address*]

Context debug>mcast-mgmt>mcast-rprt-dest

Description This command sets mcast reporting dest debug filtering options and applies only to the 7750 SR.

arp-host

Syntax	[no] arp-host
Context	debug>service>id
Description	This command enables and ARP host debugging. The no form of the command disables ARP host debugging

mld-snooping

Syntax	[no] mld-snooping
Context	debug>service>id
Description	This command enables and configures MLD-snooping debugging. The no form of the command disables MLD-snooping debugging

detail-level

Syntax	detail-level {low medium high} no detail-level
Context	debug>service>id>mld
Description	This command enables and configures the MLD tracing detail level. The no form of the command disables the MLD tracing detail level.

mac

Syntax	[no] mac <i>ieee-address</i>
Context	debug>service>id>mld
Description	This command shows MLD packets for the specified MAC address. The no form of the command disables the MAC debugging.

mode

Syntax	mode {dropped-only ingr-and-dropped egr-ingr-and-dropped} no mode
---------------	---

Context debug>service>id>mld

Description This command enables and configures the MLD tracing mode.
The **no** form of the command disables the configures the MLD tracing mode.

sap

Syntax [**no**] **sap** *sap-id*

Context debug>service>id>mld

Description This command shows MLD packets for a specific SAP.
The **no** form of the command disables the debugging for the SAP.

sdp

Syntax [**no**] **sdp** *sdp-id:vc-id*

Context debug>service>id>mld

Description This command shows MLD packets for a specific SDP.
The **no** form of the command disables the debugging for the SDP.

2.12.2.6 Tools Commands

msap

Syntax	msap [service <i>service-id</i>]
Context	tools>dump>service
Description	This command provides MSAP-related statistics for the chassis and tracks the number of sticky MSAPs. The statistics include the total number of MSAPs, sticky MSAPs, and idle MSAPs. When a subscriber disconnects from a sticky MSAP, it transitions to an idle MSAP. The idle MSAP transitions back to a sticky MSAP when the subscriber reconnects. A large number of idle MSAPs during peak network hours indicate that an idle MSAP cleanup is required. The total MSAP statistic counts both the total number of traditional MSAPs (non-sticky) and total number of sticky MSAPs. Idle MSAPs are counted towards the total number of sticky MSAPs.
Parameters	<i>service-id</i> — Specifies the service for which to show the MSAP-related statistics. The service is indicated in the chassis.

3 DHCP Management

3.1 In This Chapter

This chapter provides information about using DHCP, including theory, supported features and configuration process overview.

Topics in this chapter include:

- [DHCP Principles](#)
- [DHCP Features](#)
 - [DHCP Relay](#)
 - [Subscriber Identification Using Option 82 Field](#)
 - [DHCP Snooping](#)
 - [DHCP Lease State Table](#)
 - [DHCPv6](#)
 - [DHCPv4 Relay Proxy](#)
 - [Virtual Subnet for DHCPv4 Hosts](#)
- [Proxy DHCP Server](#)
- [Local Address Assignment](#)
- [Configuring DHCP with CLI](#)

3.2 DHCP Principles

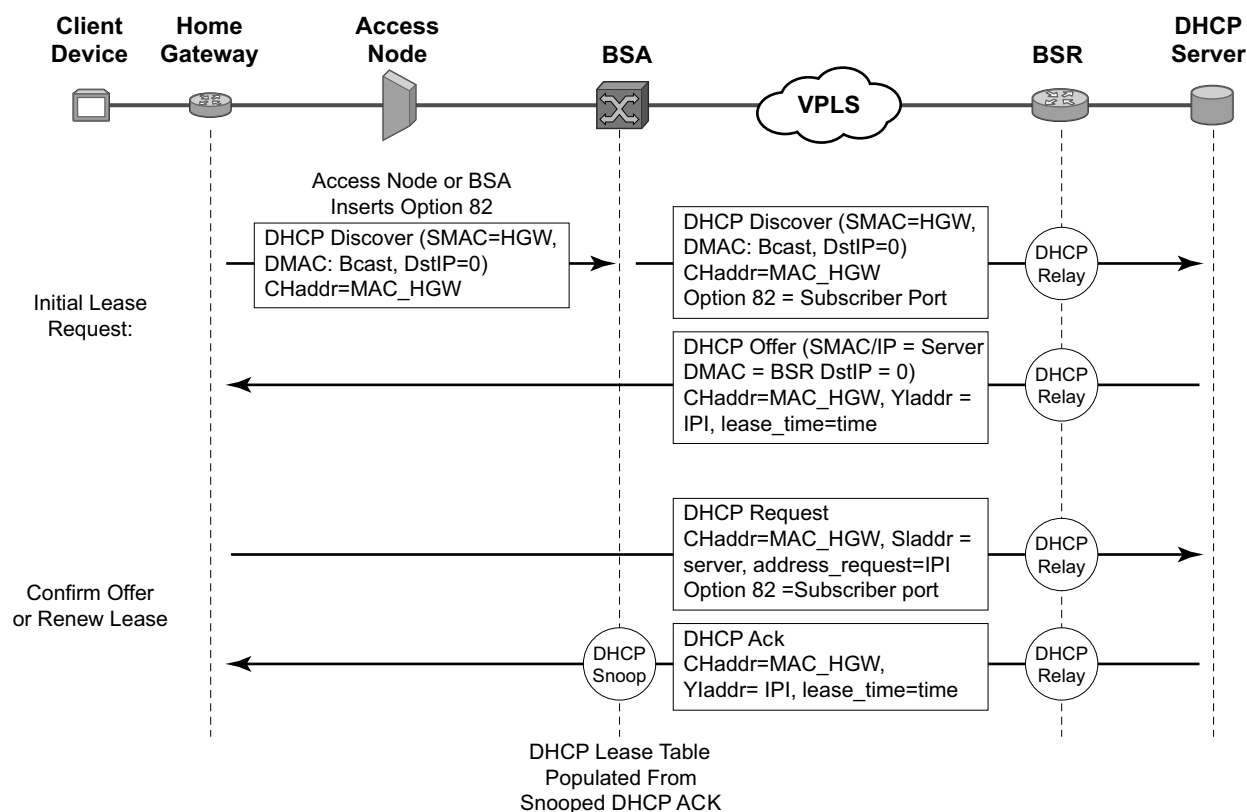

In a Triple Play network, client devices (such as a routed home gateway, a session initiation protocol (SIP) phone or a set-top box) use Dynamic Host Configuration Protocol (DHCP) to dynamically obtain their IP address and other network configuration information.

DHCP is defined and shaped by several RFCs and drafts in the IETF DHC working group including the following:

- RFC 1534, *Interoperation Between DHCP and BOOTP*
- RFC 2131, *Dynamic Host Configuration Protocol*
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 3046, *DHCP Relay Agent Information Option*

The DHCP operation is illustrated in [Figure 14](#).

Figure 14 IP Address Assignment with DHCP

OSSG068

1. During boot-up, the client device sends a DHCP discover message to get an IP address from the DHCP Server. The message contains:

- Destination MAC address — broadcast
- Source MAC address — MAC of client device
- Client hardware address — MAC of client device

If this message passes through a DSLAM or other access node, typically the Relay information option (Option 82) field is added, indicating shelf, slot, port, VPI, VCI etc. to identify the subscriber.

DHCP relay is enabled on the first IP interface in the upstream direction. Depending on the scenario, the DSLAM, BSA or the BSR will relay the discover message as a unicast packet towards the configured DHCP server. DHCP relay is configured to insert the giaddr in order to indicate to the DHCP server in which subnet an address should be allocated.

2. The DHCP server will lookup the client MAC address and Option 82 information in its database. If the client is recognized and authorized to access the network, an IP address will be assigned and a DHCP offer message returned. The BSA or BSR will relay this back to the client device.
3. It is possible that the discover reached more than one DHCP server, and thus that more than one offer was returned. The client selects one of the offered IP addresses and confirms it wants to use this in a DHCP request message, sent as unicast to the DHCP server that offered it.
4. The DHCP server confirms that the IP address is still available, updates its database to indicate it is now in use, and replies with a DHCP ACK message back to the client. The ACK will also contain the Lease Time of the IP address.

3.3 DHCP Features

- [DHCP Relay](#)
- [DHCPv4 Relay Proxy](#)
- [Subscriber Identification Using Option 82 Field](#)
- [DHCP Snooping](#)
- [DHCP Lease State Table](#)

3.3.1 DHCP Relay

Since DHCP requests are broadcast packets that normally will not propagate outside of their IP subnet, a DHCP relay agent intercepts such requests and forwards them as unicast messages to a configured DHCP server.

When forwarding a DHCP message, the relay agent sets the giaddr (gateway IP address) in the packet to the IP address of its ingress interface. This allows DHCP clients to use a DHCP server on a remote network. From both a scalability and a security point of view, it is recommended that the DHCP relay agent is positioned as close as possible to the client terminals.

DHCP relay is used in a Layer 3 environment, and thus is only supported in IES services and VPRN services. VPRN is supported on the 7750 SR only.

When DHCP clients and servers are in different VPRN routing instances of which one is the Base routing instance, route leaking (GRT-leaking) should be used to relay DHCPv4 and DHCPv6 messages between a VPRN and the Global Routing Table (GRT).

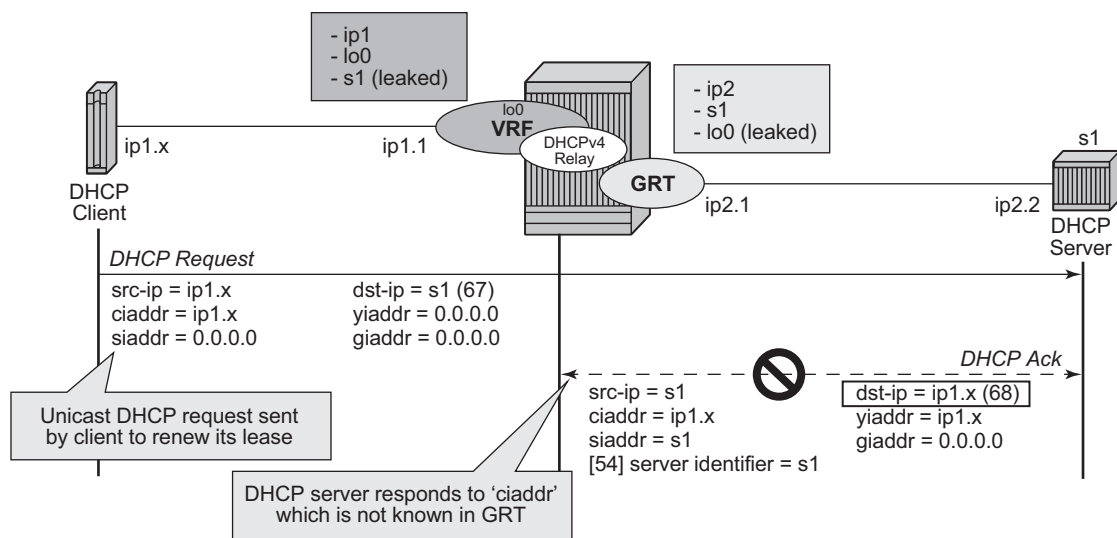

While DHCP relay is not implemented in a VPLS, it is still possible to insert or modify Option 82 information.

In a Routed CO environment in the 7750 SR, the subscriber interface's group interface DHCP relay is stateful.

3.3.2 DHCPv4 Relay Proxy

In network deployments where DHCPv4 client subnets cannot be leaked in the DHCPv4 server routing instance, unicast renewal messages (DHCP ACKs) cannot be routed in the DHCPv4 server routing instance, as illustrated in [Figure 15](#). The DHCP server sets the destination IP address of the DHCP ACK to the Client IP address (ciaddr) as received in the DHCP REQUEST message. Because there is no route available for the client subnet in the DHCP server routing instance, the DHCP ACK cannot be delivered.

Figure 15 Unicast Renewal Routing Problem

al_0114

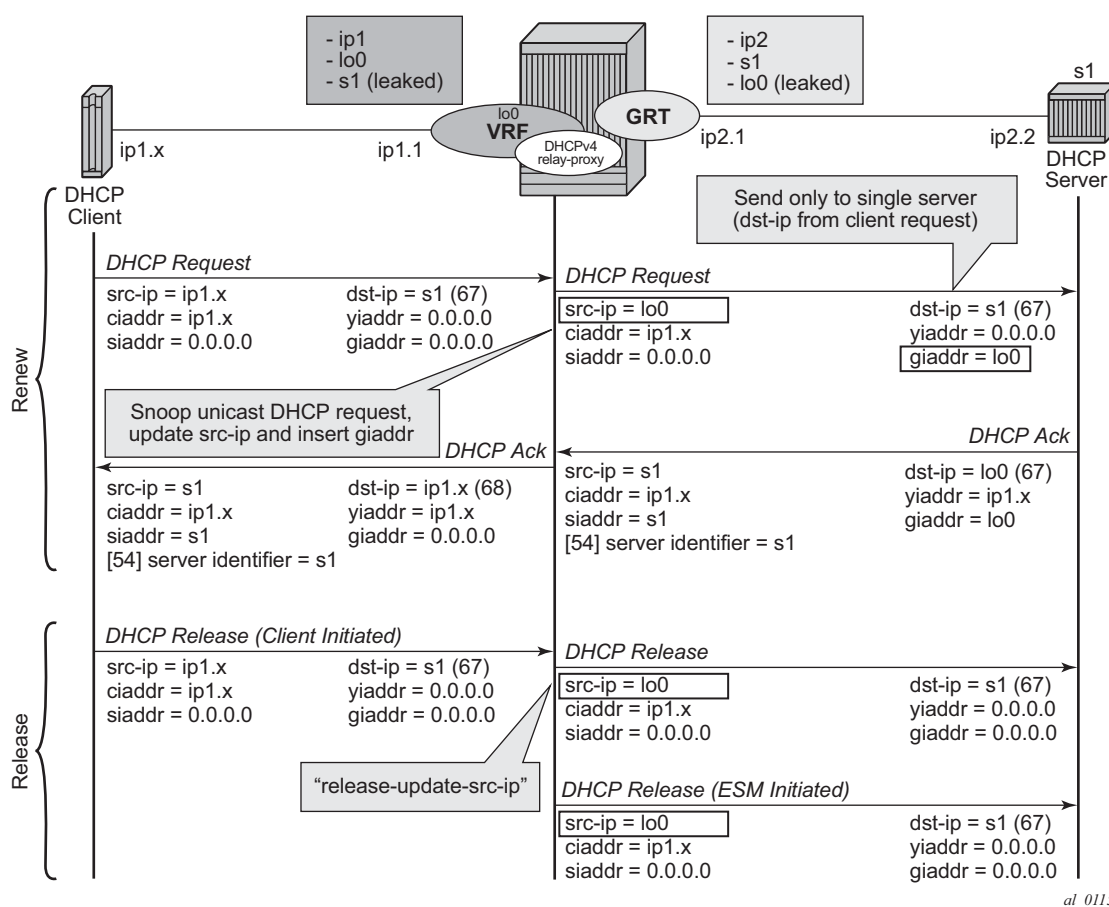

The unicast renewal routing problem illustrated in [Figure 15](#) can be solved with a relay proxy function that enhances the DHCPv4 relay. With the **relay-proxy** command in the DHCPv4 relay on a regular interface or group-interface, the unicast renewals are now also relayed to the DHCPv4 server, as described below and illustrated in [Figure 16](#):

- In the client to server direction, the source IP address is updated and the gateway IP address (gi-address) field is added before sending the message to the intended DHCP server (the message is not broadcasted to all configured DHCP servers).
- In the server to client direction, the gi-address field is removed and the destination IP address is updated with the value of the your IP address (yiaddr) field.

When **relay-proxy** is enabled, the gi-address can be configured to any local address that is configured in the same routing instance. The gi-address is the only address that must be leaked in the DHCPv4 server routing instance because a DHCPv4 server always sends the response on a relayed packet to the relay agent using the gi-address as the destination IP address.

By default, unicast DHCPv4 RELEASE messages are forwarded transparently by a relay proxy function. The optional **release-update-src-ip** flag updates the source IP address with the value that is used for all relayed DHCPv4 messages, as shown in Figure 16.

Figure 16 Relay Unicast Messages

al_0115

The **relay-proxy** command can also be used to hide the DHCPv4 server address for DHCP clients. This prevents the client from learning the DHCPv4 server infrastructure details such as the IP address and number of servers. Hiding infrastructure details helps in Denial of Service (DoS) prevention.

The optional **siaddr-override** *ip-address* parameter in **relay-proxy** enables DHCPv4 server IP address hiding towards the client. The client interacts with the relay proxy as if it is the DHCP server. In addition to the relay proxy functions as described earlier, the following actions are performed when DHCPv4 server IP address hiding is configured:

- In all DHCP messages to the client, the value of following header fields and DHCP options containing the DHCP server IP address is replaced with the configured *<ip-address>*:
 - the source IP address
 - the siaddr field in the DHCPv4 header if it is not equal to zero in the message received from the server
 - the Server Identification option (DHCPv4 option 54) if present in the original server message
- The DHCP OFFER selection during initial binding. Only the first DHCP OFFER message is forwarded to the client. Subsequent DHCP OFFER messages from different servers are silently dropped.

The **siaddr-override** *ip-address* parameter can be any local address in the same routing instance. If DHCP relay lease split is enabled, **siaddr-override** *ip-address* has priority over the **emulated-server** *ip-address* configured in the proxy-server and will be used as the source IP address.

The active DHCPv4 server IP address obtained from the DHCP OFFER selection is required for the IP address hiding function and is stored in the lease state record. Therefore **lease-populate** must be enabled on the interface when **siaddr-override** *ip-address* is configured.

[Figure 17](#) shows the initial lease binding phase of a relay proxy with DHCP server address hiding enabled. In the absence of a DHCP lease state in the initial lease binding phase, the DHCP server IP address resulting from the OFFER selection is stored in a DHCP transaction cache. After successful lease binding, the DHCP server IP address is added to the lease state record.

In a host creation failure scenario, if no transaction cache or lease state is available when a DHCP REQUEST message is received, then the DHCP REQUEST is silently dropped. The drop reason can be found by enabling DHCP debug.

Figure 17 DHCP Server IP Address Hiding/Initial Binding

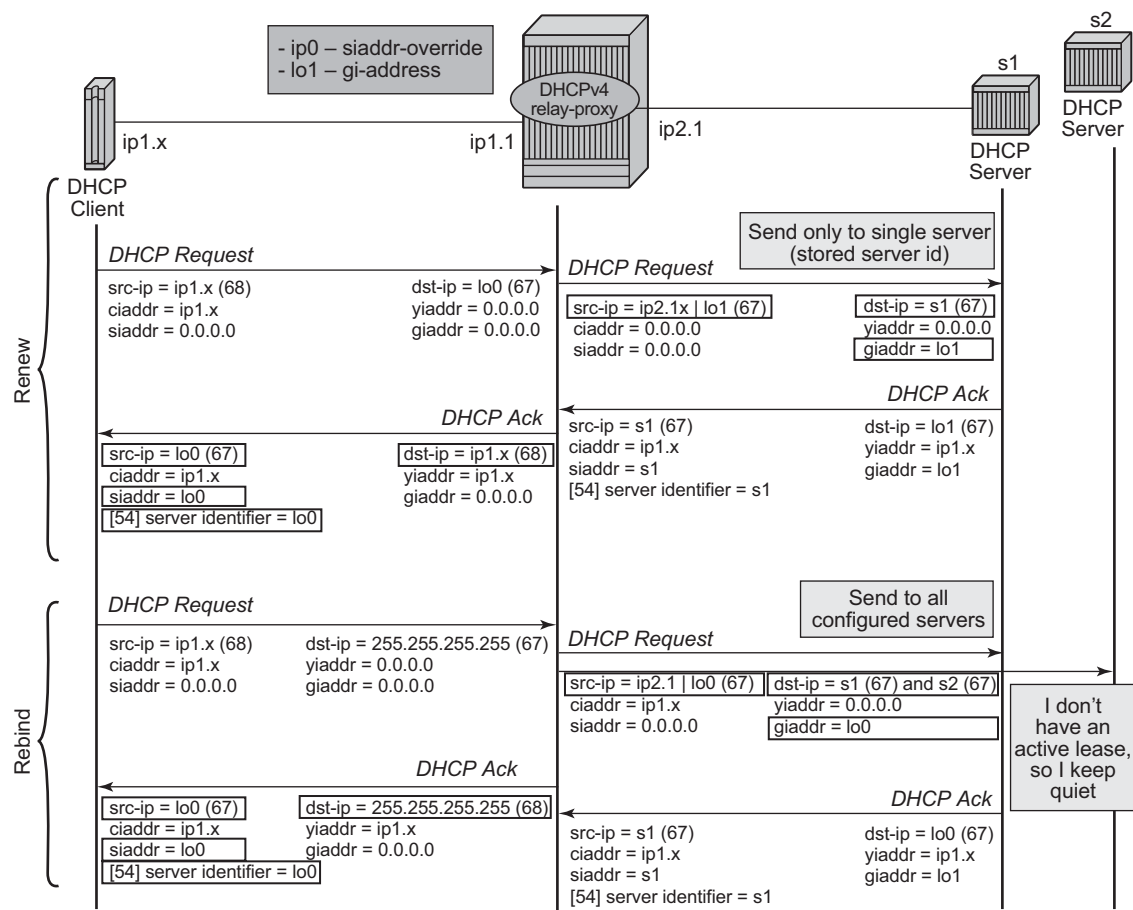

Figure 18 shows the lease renewal phase of a relay proxy with DHCP server address hiding enabled. A unicast REQUEST (renew) is relayed only to the DHCP server owning the lease. A broadcast REQUEST (rebind) is relayed to all configured DHCP servers.

During lease renewal, the DHCP server IP address can be updated in the lease state if the DHCP ACK is received from a different server. This optimizes the DHCP proxy relay operation in a DHCP server failover scenario. This is depicted in Figure 19.

Figure 18 DHCP Server IP Address Hiding/Lease Renewal

0932

Figure 19 DHCP Server IP Address Hiding, Lease Renewal With Active Server Failure

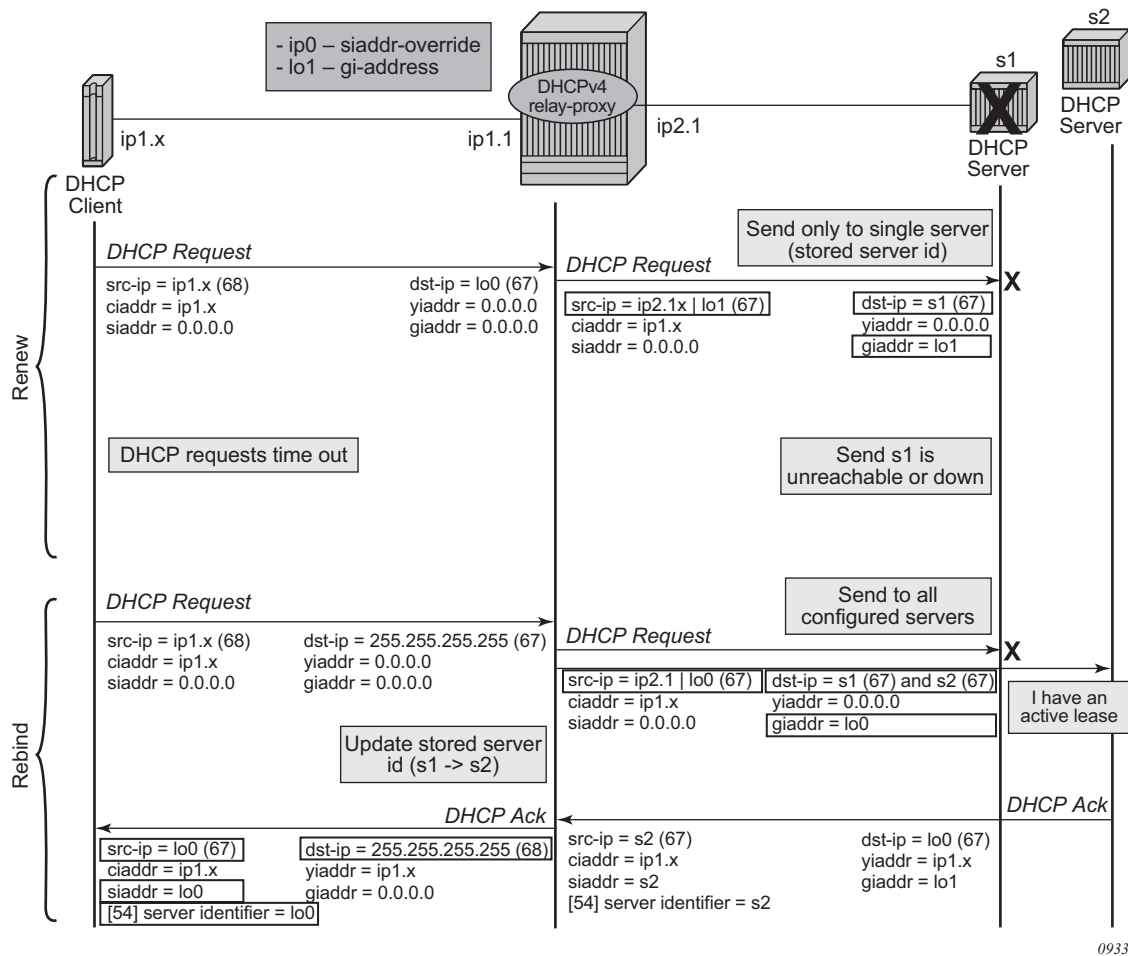

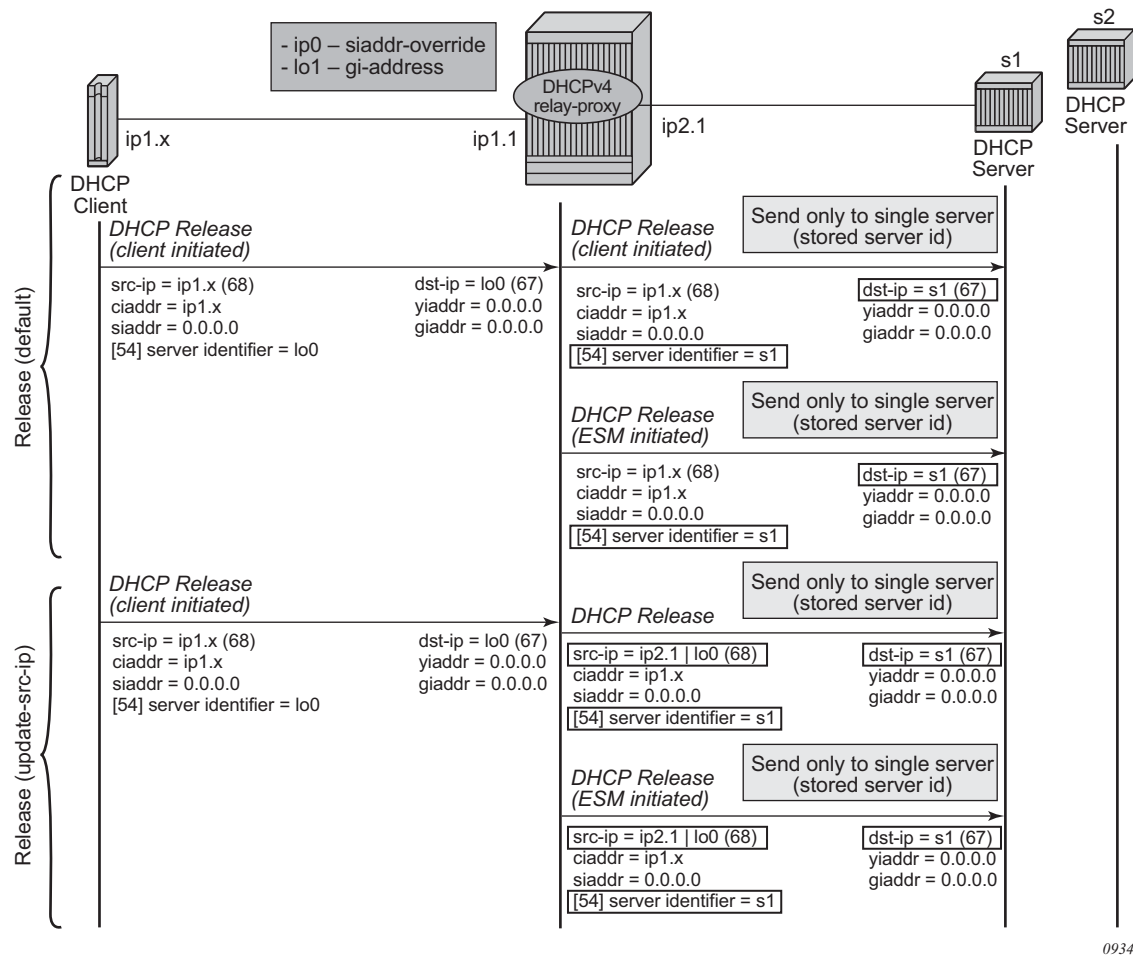

Figure 20 shows the release in a relay proxy scenario with DHCP server address hiding enabled. The RELEASE message is sent only to the DHCP server owning the lease. Optionally, the source Ip address can be updated.

Figure 20 DHCP Server IP Address Hiding, Release

0934

Relay proxy can be enabled on subscriber group-interfaces and regular interfaces in an IES or VPRN service.

For retail subscriber interfaces, **relay-proxy** is configured at the subscriber-interface dhcp CLI context, as shown in the example that follows.

A relay proxy function is not supported in combination with a double DHCPv4 relay (L3 DHCPv4 relay in front of a 7750 DHCPv4 relay with **relay-proxy** enabled).

Configuration example

```
config>service>vpn>
  interface "lo0" create
    address 192.0.2.10/32
    loopback
  exit
  interface "lo1" create
    address 192.0.2.11/32
    loopback
  exit
  subscriber-interface "sub-int-1" create
    address 10.1.0.254/24
    group-interface "group-int-1-1" create
      dhcp
        server 172.16.1.1
        lease-populate 32767
        relay-proxy release-update-src-ip siaddr-override 192.0.2.10
        gi-address 192.0.2.11 src-ip-addr
        no shutdown
      exit
    exit
  exit
exit
```

3.3.3 Subscriber Identification Using Option 82 Field

Option 82, or the relay information option is specified in RFC 3046, *DHCP Relay Agent Information Option*, and allows the router to append some information to the DHCP request that identifies where the original DHCP request came from.

There are two sub-options under Option 82:

- *Agent Circuit ID Sub-option* (RFC 3046, section 3.1): This sub-option specifies data which must be unique to the box that is relaying the circuit.
- *Remote ID Sub-option* (RFC 3046 section 3.2): This sub-option identifies the host at the other end of the circuit. This value must be globally unique.

Both sub-options are supported and can be used separately or together.

Inserting Option 82 information is supported independently of DHCP relay. However in a VPLS (when DHCP Relay is not configured), DHCP snooping must be enabled on the SAP to be able to insert Option 82 information.

When the **circuit id sub-option** field is inserted, it can take following values:

- *sap-id*: The SAP index (only under a IES or VPRN service)
- *ifindex*: The index of the IP interface (only under a IES or VPRN service)

- *ascii-tuple*: An ASCII-encoded concatenated tuple, consisting of [system-name|service-id|interface-name] (for VPRN or IES) or [system-name|service-id|sap-id] (for VPLS).
- *vlan-ascii-tuple*: An ASCII-encoded concatenated tuple, consisting of the ascii-tuple followed by Dot1p bits and Dot1q tags.

For VPRN, the ifindex is unique only within a VRF. The DHCP relay function automatically prepends the VRF ID to the ifindex before relaying a DHCP Request. VPRN is supported on the 7750 SR only.

When a DHCP packet is received with Option 82 information already present, the system can do one of three things. The available actions are:

- **Replace** — On ingress the existing information-option is replaced with the **information-option** parameter configured. On egress (towards the customer) the information option is stripped (per the RFC).
- **Drop** — The DHCP packet is dropped and a counter is incremented.
- **Keep** — The existing information is kept on the packet and the router does not add any additional information. On egress the information option is not stripped and is sent on to the downstream node.

In accordance with the RFC, the default behavior is to keep the existing information; except if the giaddr of the packet received is identical to a local IP address on the router, then the packet is dropped and an error incremented regardless of the configured action.

The maximum packet size for a DHCP relay packet is 1500 bytes. If adding the Option 82 information would cause the packet to exceed this size, the DHCP client packet will be discarded. This packet size limitation exists to ensure that there will be no fragmentation on the end Ethernet segment where the DHCP server attaches.

In the downstream direction, the inserted Option 82 information should not be passed back towards the client (as per RFC 3046, *DHCP Relay Agent Information Option*). To enable downstream stripping of the option 82 field, DHCP snooping should be enabled on the SDP or SAP connected to the DHCP server.

3.3.3.1 Trusted and Untrusted

There is a case where the relay agent could receive a request where the downstream node added Option 82 information without also adding a giaddr (giaddr of 0). In this case the default behavior is for the router to drop the DHCP request. This behavior is in line with the RFC.

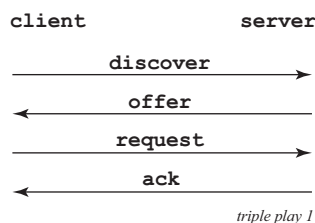

The **trusted** command is supported which allows the router to forward the DHCP request even if it receives one with a giaddr of 0 and Option 82 information attached. This could occur with older access equipment. In this case the relay agent would modify the request's giaddr to be equal to the ingress interface. This only makes sense when the action in the information option is keep, and the service is IES or VPRN. In the case where the Option 82 information gets replaced by the relay agent, either through explicit configuration or the VPLS DHCP Relay case, the original Option 82 information is lost, and the reason for enabling the trusted option is lost.

3.3.4 DHCP Snooping

This section discusses the Nokia routers acting as a Broadband Subscriber Aggregator (BSA) with Layer 2 aggregation towards a Broadband Subscriber Router (BSR).

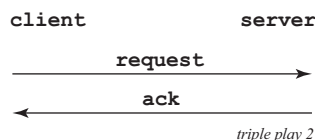

A typical initial DHCP scenario is described in [Figure 21](#).

Figure 21 Initial DHCP Scenario

But, when the client already knows its IP address, it can skip the discover, as shown in [Figure 22](#).

Figure 22 DHCP Scenario with Known IP Address

The BSA can copy packets designated to the standard UDP port for DHCP (port 67) to its control plane for inspection, this process is called DHCP snooping.

DHCP snooping can be performed in two directions:

1. From the client to the DHCP server (Discover or Request messages):

- to insert Option 82 information (when the system is not configured to do DHCP Relay), see [Subscriber Identification Using Option 82 Field](#);
- to forward DHCP requests to a RADIUS server first, and not send them to the DHCP server unless the RADIUS server confirms positive identification.

For these applications, DHCP snooping must be enabled on the SAP towards the subscriber;

2. From the DHCP server (ACK messages):

- to remove the Option 82 field toward the client
- to build a dynamic DHCP lease state table for security purposes, see section [DHCP Lease State Table](#)
- to perform Enhanced Subscriber Management, see section [Triple Play Enhanced Subscriber Management](#)

For these applications, DHCP snooping must be enabled on both the SAP or SDP towards the network and the SAP towards the subscriber.

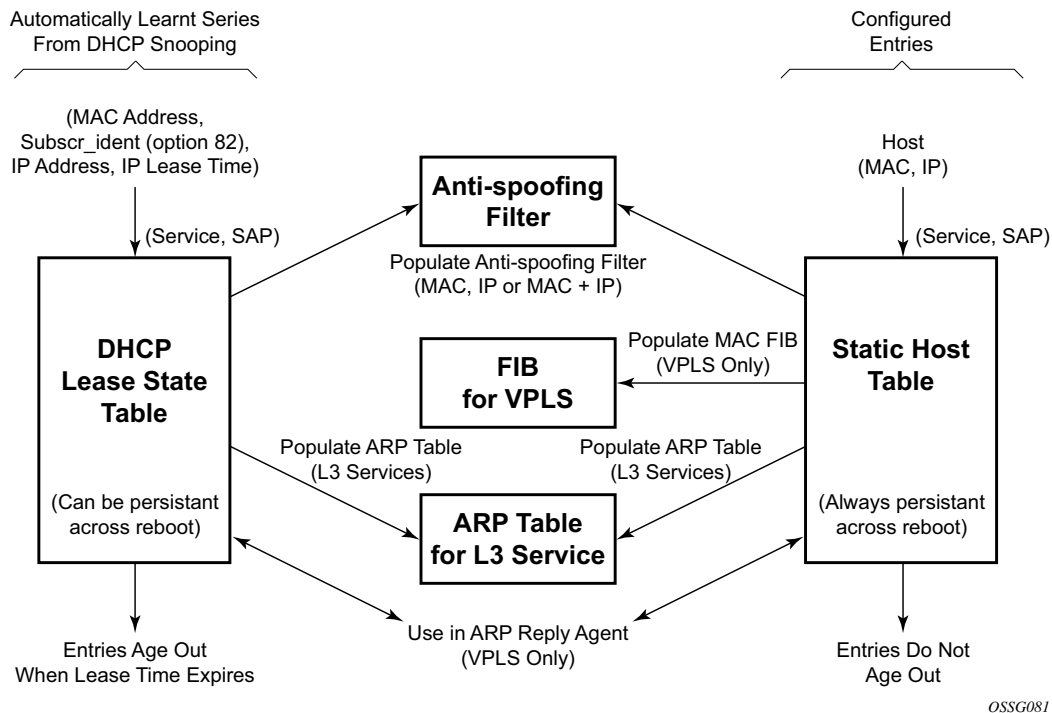

A major application for DHCP response snooping in the context of Triple Play is security: A malicious user A could send an IP packet (for example, requesting a big video stream) with as source the IP address of user B. Any return packets would be sent to B, and thus potentially jam the connection to B.

As the snooped information is coming straight from the operator's DHCP server, it is considered reliable. The BSA and BSR can use the snooped information to build anti-spoofing filters, populate the ARP table, send ARP replies, etc.

3.3.5 DHCP Lease State Table

The DHCP lease state table has a central role in the BSA operation ([Figure 23](#)). For each SAP on each service it maintains the identities of the hosts that are allowed network access.

Figure 23 DHCP Lease State Table

When the command **lease-populate** is enabled on a SAP, the DHCP lease state table is populated by snooping DHCP ACK messages on that SAP, as described in the [DHCP Snooping](#) section above.

Entries in the DHCP lease state table remain valid for the duration of the IP address lease. When a lease is renewed, the expiry time is updated. If the lease expires and is not renewed, the entry is removed from the DHCP lease state table.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) on the SAP and/or SDP where DHCP messages requiring snooping ingress the VPLS instance. For IES interfaces and VPRN IP interfaces (VPRN is supported on the 7750 SR only), using the **lease-populate** command also enables DHCP snooping for the subnets defined under the IP interface. Lease state information is extracted from snooped or relayed DHCP ACK messages to populate DHCP lease state table entries for the SAP or IP interface.

For IES and VPRN services, if ARP populate is configured, no statics ARPs are allowed. For IES and VPRN services, if ARP populate is not configured, then statics ARPs are allowed.

The retained DHCP lease state information representing dynamic hosts can be used in a variety of ways:

- To populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering — Anti-spoof filtering is only available on VPLS SAPs, or IES IP or VPRN IP interfaces terminated on a SAP.
- To populate a VPLS SAP-based arp-reply-agent table to provide dynamic ARP replies using the dynamic hosts IP assigned IP address and learned MAC address — ARP reply agent functionality is only available for static and dynamic hosts associated with a VPLS SAP. arp-reply-agent is supported on the 7450 ESS only.
- To populate the system's ARP cache using the **arp-populate** feature — **arp-populate** functionality is only available for static and dynamic hosts associated with IES and VPRN SAP IP interfaces.
- To populate managed entries into a VPLS forwarding database — When a dynamic host's MAC address is placed in the DHCP lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent learning of the MAC on another interface (implicit MAC Pinning on the 7450 ESS). Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the DHCP lease state associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance can be created while a dynamic host exists associated with the static MAC address. To support the Routed CO model, see [Routed Central Office \(CO\)](#).
- To support enhanced Subscriber management, see section [RADIUS Authentication of Subscriber Sessions](#).

Note that if the system is unable to execute any of these tasks, the DHCP ACK message is discarded without adding a new lease state entry or updating an existing lease state entry; and an alarm is generated.

3.3.6 DHCP and Layer 3 Aggregation

3.3.6.1 DHCPv4 Snooping

The default mode of operation for DHCP snooping is that the DHCP snooping agent instantiates a DHCP lease state based on information in the DHCP packet, the client IP address and the client hardware address.

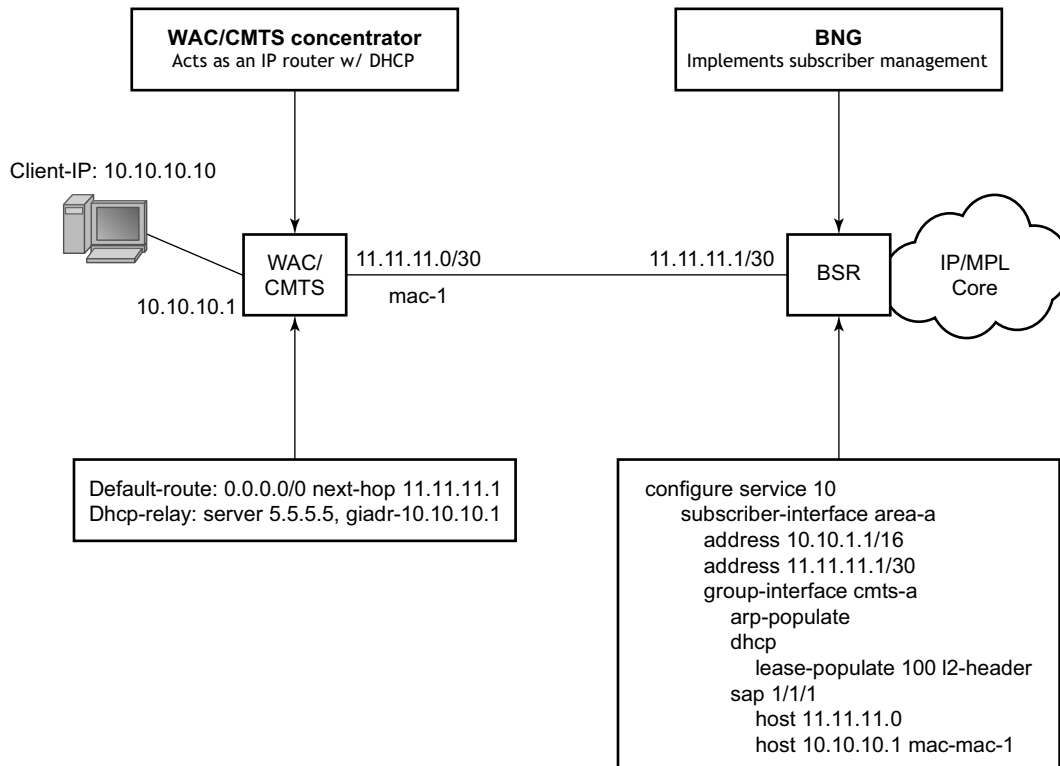

The mode of operation can be changed for DHCP snooping so that the Layer 2 header MAC address is used instead of the client hardware address from the DHCP packet for the DHCP lease state instantiation. This mode is selected by enabling **I2-header** in the **lease-populate** configuration command at the DHCP level. Because SR-Series routers do not have the ability to verify the DHCP information (both the **src-ip** and **src-mac** of the packet will be those of the previous relay point) anti-spoofing must be performed at the access node prior to the SR-Series routers. This mode provides compatibility with MAC concentrator devices, and cable modem termination system (CMTS) and WiiMAX Access Controller (WAC).

A configuration example of a cable/wireless network together with subscriber management is shown in [Figure 24](#). The subnet used to connect to the CMTS/WAC must be defined as a subnet in the subscriber interface of the Layer 3 CO model under which the hosts will be defined. This means that all subscriber lease states instantiated on BSR must be from a “local” subscriber-subnet, even if those are behind the router, as there will be no additional layer 3 route installed pointing to them.

The important items to notice are static hosts at the subscriber interface side:

- IP-only static host pointing to CMTS/WAC WAN link is needed to allow BSR to reply to ARP requests originated from CMTS/WAC.
- IP-MAC static host pointing to CMTS/WAC access-facing interface is required to provide BSR with an arp entry for the DHCP relay address.

When dual-homing is used the CMTS/WAC may be configured with the same MAC for both upstream interfaces. If that is not possible the BSR can be configured with an optional MAC address. The BSR will then use the configured MAC address when instantiating the DHCP lease states.

Figure 24 CMTS/WAC Network Configuration Example

Fig_34

3.3.6.2 DHCPv6 Snooping

Similar to DHCPv4, the subscriber interface SAP must be on the data path between the subscriber host and the DHCPv6 server. The SAP snoops the DHCPv6 message exchanged between the server and the client. An ESM host is created upon snooping a “reply” message from the DHCPv6 server.

DHCPv6 messages differ from a DHCPv4 messages because it is not mandatory to have the client MAC inside the header or options. The DUID in the DHCPv6 option can be a random generated number instead of the subscriber host’s MAC. The source MAC of the DHCPv6 Ethernet header cannot be used either, because a Layer 3 aggregation network will replace the client’s MAC via routing. From the perspective of the BNG, all DHCPv6 message from the same downstream router will have the same source MAC. By default, the BNG utilizes the DHCPv6 Ethernet header source MAC as a host entry identifier. Therefore, it is mandatory to use the interface-id in

addition to the source MAC to identify a host individually. If the interface-id is unavailable, it is possible to use python to copy another unique ID, such as DUID or remote-id, into the interface id. The interface-id option must be on the same level as the relay-forward header. Together, the interface-id and the DHCP relay MAC address will be used as an identifier internally in the BNG.

If the interface-id option is on the subscriber native DHCP message (such as solicit), it is simply ignored.

The downstream router must resolve the BNG MAC before it is able to route traffic to the BNG. Traditionally, a BNG sends router advertisement to directly connected hosts to help them resolve their default gateway and MAC address. However, routers differ from hosts and neighbor advertisements are used to resolve the neighbor's MAC instead. The downstream router has two options when programming the BNG as the next hop. It can either use the BNG subscriber interface link-local address or the subscriber interface GUA address. If an IPv6 prefix was configured on the BNG subscriber interface, then the downstream router must use the BNG link local as the next hop. If the subscriber interface is configured as an IPv6 address, then the downstream router can configure the GUA or the link-local as the next hop. In order to forward traffic bidirectionally, the downstream router interface MUST be modeled as a static host with both IP and MAC. IP-only static host is not supported.

The DHCP relay agent use one of its interface as a IP source address in the DHCP relay-forward message. The BNG forwards a DHCP relay-reply message from the DHCP server back to the relay agent using that exact same source IP address. There are restrictions for the IP source address used by the DHCP relay agent and it depends if the relay agent is a few hops way or is directly connected to the BNG. In the case where relay agent is a few hops away, the source address used by the relay agent must not fall under the subnet or prefix range configured on the subscriber interface. For example, the loopback or the egress interface address of the DHCP relay agent can be used instead. To forward the DHCP6 relay-forward message back to the relay agent, simply add a static route for the relay agent source IP address. The static route will have the static IPv6 host as the next hop. In the case where the relay agent is directly connected to the BNG, there are two options. In the first option, the IPv6 static host configured on the BNG is actually an interface on the relay agent. If the relay agent use this as the relay-forward source address, no additional configuration is required on the BNG to forward relay-reply back to the relay-agent. The other option is to use an interface address on the relay agent which does not fall under the subnet or prefix under the subscriber interface. Similar to the scenario where the relay-agent is a few hops away, a static route is required to forward the DHCP relay-reply message back to the relay agent. Again the static route must use the IPv6 static host as the next hop.

A default host is supported for IPv6 host as well. It is generally used as a failover mechanism where the host can continue to forward traffic without a host entry on the backup BNG.

For IPv6 ESM host, it is mandatory that each host have a unique /64 prefix. Service providers who wish to share the /64 prefix among multiple WAN host can utilize the DHCPv6 filter **bypass-host-creation na**” option. All bypass hosts in general require a default host creation as well.

While ESM hosts are subject to QoS and filters rules specified in sub-profile and sla-profile, default-host follows the QoS and filters specified directly on the subscriber SAP.

DHCP6 filters perform actions based on the options inside the relay-forward DHCP message. The options must be set on the innermost level, such as, DHCP solicit. The filter will ignore options set on relay-forward levels.

ESMv6 host created via DHCP snooping is not supported with the following:

- WLAN-GW
- DHCPv6 Proxy
- Wholesale/Retail
- SHCV
- L2-aware NAT
- GRT leaking/Extranet

3.3.7 Local DHCP Servers

3.3.7.1 Overview

The local-dhcp-server functions only if there is a relay (gateway) in front of it. Either a GI address is needed to find a subnet or Option 82, which is inserted by the relay, to perform authentication in the local-user-db.

A local DHCP server functions only if there is a relay agent (gateway) in front of it. The local DHCP server must be configured to assign addresses in one of the following ways:

1. Use a local user database authentication (**user-db** *local-user-db-name*)

The host is matched against the specified local user database. A successful user lookup should return information on one of the following valid addresses:

- A fixed IP address — The IP address should not overlap with the address ranges configured in the local dhcp server.
- A pool name — A free address of any subnet in that pool is offered.

- **use-gi-address** [scope <subnet | pool>] — The gi address is used to find a matching subnet. When scope is subnet, an address is allocated in the same subnet as the GI address only. When scope is pool, an address is allocated from any subnet within a local pool once that pool has been selected based on matching the “giaddr” field in the DHCP message with any of the configured subnets in the pool.
- **use-pool-from-client** — The pool name specified in the DHCP client message options and added by the DHCP relay agent is used. A free address of any subnet in that pool is offered.

When no valid address information is returned from the local user database lookup, no IP address is offered to the client.

2. without local user database authentication (no user-db)

One or both address assignment options must be configured:

- Use a pool name (**use-pool-from-client**)
The pool name specified in the DHCP client message options and added by the DHCP relay agent is used. A free address of any subnet in that pool is offered.
- Use the gi address (**use-gi-address** [**scope** <**subnet** | **pool**>])
The gi address is used to find a matching subnet. When scope is subnet, an address is allocated in the same subnet as the GI address only. When scope is pool, an address is allocated from any subnet within a local pool once that pool has been selected based on matching the “giaddr” field in the DHCP message with any of the configured subnets in the pool.

When both options are configured and a pool name is specified in the DHCP client message options, then the **use-pool-from-client** option has precedence over the **use-gi-address** option.

Note: Note: The local DHCP server will not allocate any address if none of the above options are configured (no user-db, no use-gi-address, no use-pool-from-client).

Options and identification strings can be defined on several levels. In principle, these options are copied into the DHCP reply, but if the same option is defined several times, the following precedence is taken:

1. user-db host options
2. Subnet options
3. Pool options
4. From the client DHCP request.

A local DHCP server must be bound to a specified interface by referencing the server from that interface. The DHCP server will then be addressable by the IP address of that interface. A normal interface or a loopback interface can be used.

A DHCP client is defined by the MAC address and the circuit-id. This implies that for a certain combination of MAC and circuit-id, only one IP-address can be returned. If you ask 1 more, you get same address again. The same address will be returned if a re-request is made.

Typically, the DHCP server can be configured to perform as follows:

- • When a user-db is specified, a host lookup is performed in the local-user-db and the local user-db host defines how to get the IP-address or pool to get the IP-address from:
 - A fixed IP-address.
 - A pool — A free address of any subnet in that pool is offered.
 - use-pool-from-client — The pool name is taken from Option 82 vendor-specific suboption. (If not present, proceed to the next bullet.)
 - use-gi-address — The gi-address is used to find a matching subnet.
- • If no IP-address, subnet, or pool is found in the first 2 bullets (above), no IP-address is offered to the client. If a subnet is found, an available address from the subnet is offered to the client. If a pool is found, an available address from any subnet of the pool is offered to the client.

Note: When the no use-gi, no use-pool-from-client and no user-db commands are specified, the DHCP server does not act.

3.3.7.2 Local DHCP Server Support

Local DHCP servers provide a standards-based full DHCP server implementation which allows a service provider the option of decentralizing the IP address management into the network. Local DHCP servers are supported on 7750 SR-7, and 7750 SR-12 models. Note that the 7450 ESS-Series routers use DHCP relay and proxy DHCP server functionality.

Three applications are targeted for the local DHCP server:

- Subscriber aggregation in either a single node (routed CO) or TPSDA.

- Business services — A server can be defined in a VPRN service and associated with different interfaces. Locally attached hosts can get an address directly from the servers. Routed hosts will receive addresses through a relay point in the customer's network. This option is supported for the 7750 SR only.
- PPP clients — Either in a single node or a separate PPPoE server node and a second DHCP server node. The PPPoE server node may be configured to query the DHCP server node for an address and options to provide to the PPPoE client. The PPPoE server will provide the information in PPP format to the client.

DHCP server scenarios include:

- DHCP servers can be integrated with Enhanced Subscriber Management (ESM) for DHCP clients, DHCP relays and PPPoE clients.
- A stand-alone DHCP server can support DHCP clients and DHCP relays.
- IPv4 is supported. DHCP servers provide increased management over the IPv4 address space across its subscriber base, with support for public and private addressing in the same router, including overlapped private addressing in the form of VPRNs in the same SR-series router.

DHCP servers are configurable and can be used in the bridged CO, routed CO, VPRN wholesaler, and dual-homing models.

3.3.8 DHCPv6

In the stateful auto-configuration model, hosts obtain interface addresses and/or configuration information and parameters from a server. Servers maintain a database that keeps track of which addresses have been assigned to which hosts. The stateful auto-configuration protocol allows hosts to obtain addresses, other configuration information or both from a server.

3.3.8.1 DHCPv6 Relay Agent

When the server unicast option is present in a DHCP message from the server, the option is stripped from the message before sending to the clients.

3.3.8.2 DHCPv6 Prefix Options

The prefix delegation options described in RFC 3633, *IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6*, provide a mechanism for automated delegation of IPv6 prefixes using DHCP. This mechanism is intended for delegating a long-lived prefix from a delegating router to a requesting router, across an administrative boundary, where the delegating router does not require knowledge about the topology of the links in the network to which the prefixes will be assigned. For example, the delegating router can get a /48 prefix via DHCPv6 and assign /64 prefixes to multiple requesting routers. Prefix delegation is supported for the delegating router (not the requesting router).

3.3.8.3 Neighbor Resolution via DHCPv6 Relay

This is similar to ARP populate for IPv4. When it is turned on, an SR OS needs to populate the link-layer address to IPv6 address mapping into the neighbor database based on the DHCPv6 lease information received.

If the IPv6 address of the host doesn't belong to the subnets of the interface, such a neighbor record should not be created. This could happen when there is a downstream DHCPv6 relay router or prefix delegation requesting router.

3.3.8.4 DHCPv6 Lease Persistency

DHCPv6 lease persistency is supported.

The following features are enabled:

- DHCPv6 lease information is reconciled to the standby.
- DHCPv6 lease information can be stored on a flash card.
- When rebooted, DHCPv6 lease information stored on a flash card can be used to re-populate the DHCPv6 table as well as the neighbor database if neighbor-resolution is enabled.

3.3.8.5 Local Proxy Neighbor Discovery

Local proxy neighbor discovery is similar to local proxy ARP. It is useful in the residential bridging environment where end users are not allowed to talk to each other directly.

When local proxy ND is turned on for an interface, the router:

- Responds to all neighbor solicitation messages received on the interface for IPv6 addresses in the subnet(s) unless disallowed by policy.
- Forwards traffic between hosts in the subnet(s) of the interface.
- Drops traffic between hosts if the link-layer address information for the IPv6 destination has not been learned.

3.3.8.6 IPv6oE Hosts Behind Bridged CPEs

This feature adds support for dual-stack IPoE hosts behind bridged clients, receiving globally-routable address using SLAAC or DHCPv6. The feature also provides configurable support for handing out /128 addresses to bridged hosts from same /64 prefix or a unique /64 prefix per host. Bridged hosts that share the same /64 prefix are required to be all SLAAC hosts or DHCPv6 hosts, and are required to be associated with the same SAP. For SLAAC based assignment, downstream neighbor-discovery is automatically enabled to resolve the assigned address.

3.3.8.7 IPv6 Link-Address Based Pool Selection

This feature provides the capability to select prefix pools for WAN or PD allocations based on configured Link-Address. The scope of selection is the pool or a prefix range within the pool.

3.3.8.8 IPv6 Address/Prefix Stickiness

This feature extends lease identification criterion beyond DUID (default) for DHCPv6 leases held in the lease database for a configured period after the lease times out. DHCPv6 leases can be held in the lease database for a configurable period of time, after the lease time has expired. A large configured timeout value allows for address and prefix “stickiness”. When a subscriber requests a lease via DHCPv6 (IA_NA or PD), existing lease is looked-up and handed out. The lease identification match criterion has been extended beyond DUID to also include interface-id or interface-id and link-local address.

3.3.8.9 IPv4/v6 Linkage for Dual-Stack Hosts or Layer 3 RGs

In case of dual-stack Layer 3 RGs or dual-stack hosts behind Layer 2 CPEs, it is beneficial to have the ability to optionally link Ipv6oE host management to DHCP state for v4. This feature provides configurable support to use circuit-id in DHCPv4 option-82 to authenticate DHCPv6. Also, a SLAAC host is created based on DHCPv4 authentication if RADIUS returns IPv6 framed-prefix. IPv6oE host is deleted when the linked IPv4oE host is deleted. In addition, with v4 and v6 linkage configured, sending of unsolicited unicast RA towards the client can be configured when v4 host state is created and IPv6 is configured for the client. The linkage between IPv4 and IPv6 is based on SAP and MAC address. The sharing of circuit-id from DHCPv4 for authentication of DHCPv6 (or SLAAC) allows the SR series router to work around lack of support for LDRA on Access-nodes.

3.3.8.10 Host Connectivity Checks for IPv6

This feature provides support to perform SHCV checks on the global unicast address (assigned via SLAAC or DHCPv6 IA_NA) and link-local address of a L3 RG or a bridged host. SHCV uses IPv6 NS and NA messages. The configuration is similar to IPv4 support in SHCV. The **host-connectivity-check** command is extended to be configured for IPv6 or both IPv4 and IPv6.

3.3.9 Lease Query

A lease query by client-id as defined in RFC 5007, *DHCPv6 Lease Query*, is supported for Local DHCPv6 servers. For security reasons this must be explicitly enabled via the CLI flag `allow-lease-query`. The user identification option must be set to DUID (default value) for lease-query to work. Lease query by address is not supported. It is not possible to filter out leases with the link address, the server will always return all addresses for a client. The Relay Data and Client Link options are not supported and will not be returned.

3.3.10 DHCPv6 to Server Option

A DHCPv6-relay **user-db** can be configured on an IES or VPRN IP interface. This allows the insertion of a **to-client** and **to-server** option on the client's DHCPv6 message. The VPRN or IES IP interface must be the first relay agent for the subscriber. The interface must also have **lease-populate** enabled. The interface can store up to eight leases per DHCPv6 (relay) reply. If the interface contains both RADIUS and user-db, RADIUS will always take precedence. The **to-client** and **to-server** option will be inserted in the inner most level of the DHCPv6 packet.

ESM IPoE subscriber can also utilize the **user-db** to insert **to-server** option. IPoE ESM subscribers are not limited to only **to-client** and **to-server** option, and can utilize all other parameters configurable under **config>subscr-mgmt>loc-user-db>ipoe>host>** in LUDB.

3.3.11 Flexible Host Identification in LUDB Based on DHCPv4/v6 Options

Host identification plays a critical role during the assignment of the parameters to the host via LUDB. The parameters that can be assigned to the subscriber host can range from the IP addressing parameters and the subscriber identification string all the way to the parameters that define the service to which the subscriber is entitled.

LUDB access in the context of IPoE hosts is triggered by DHCP messages passing through the interface on which the LUDB access is configured. This is true regardless of the direction of the DHCP message flow (ingress/egress).

The parameters that define the characteristics of the host will be represented by an LUDB host *entry*. The parameters in the LUDB entry can be unique for each individual host, or they can be shared for a group of hosts. In the former case, the identification field for the LUDB host entry must be host specific while in the latter case the identification field for LUDB host entry could be derived from DHCP options that are common to a set of host.

The host identification in the LUDB can be based on a fixed set of predefined fields within the 7750 SR and 7450 ESS. If this predefined set of fields is not flexible enough, a custom identification field can be constructed from the DHCP options that are processed by the Python script. Once this custom identifier is constructed, its value can be preserved for the duration of the DHCP transaction and it is used by the LUDB for the host identification.

An example of how this can be used is the following:

A Python script is installed in 7750 SR and 7450 ESS. This Python script will intercept incoming DHCP messages on the access side (Discover/Solicit/Request/Renew/Rebind) and it will consequently create a host identification string based on DHCP options in the packet. This string will then be cached and used for host identification in LUDB in both directions (access ingress and network ingress).

This functionality is supported for DHCPv4/DHCPv6 hosts.

3.3.12 DHCP Caching

Subscriber host **identification** via LUDB is performed upon the arrival of the incoming DHCP messages on both, the access and the network side, while the host **instantiation and ESM string assignment** is performed only during the processing of the DHCP ACK/Reply messages. In other words, if Python without the caching is used for subscriber host identification and classification (into proper service class by means of deriving ESM strings), the DHCP options required for host identification must be present in all DHCP messages – even the ones sent by the DHCP servers. However, DHCP servers are not required to echo DHCP options sent by the clients and relay-agents. Consequently, the missing options from the server side would cause the subscriber host instantiation to fail.

To remedy this situation and cover all deployments models (even the ones where the DHCP options are not echoed back by the DHCP servers), a **caching** mechanism is introduced whereby the results of the Python processing on ingress access are locally stored in 7750 SR and 7450 ESS. This will ensure that the information about the subscriber host is readily available when the DHCP packet from the DHCP server arrives. Furthermore, since we already have the cached information, no additional Python processing on the network ingress is needed.

The caching is performed in a *DHCP Transaction Cache (DTC)*, which is accessible to Python and to the ESM module. Python will write the result of its processing to it and the Enhanced Subscriber Management (ESM) module within 7750 SR and 7450 ESS will be able to access those results.

The cache entries are relatively short lived, with the lifetime of a *DHCP transaction*. *DHCP transaction* is defined as a pair of DHCP messages that have the same DHCP transaction-id number (<Discover, Offer>, <Request, Ack>, <Solicit, Advertize>, <Request, Reply>, <Renew, Ack>, etc).

3.3.13 Flexible Creation of DHCPv4/6 Host Parameters

One of the facilities for flexible creation and assignment of subscriber host parameters is through Python scripting.

There are two models that allow assignment of the subscriber hosts parameters based on the Python processing, one without the utilizing the internal cache (DTC) and the other with the internal cache (DTC).

- Without utilizing the DTC, Python can process options in DHCP ACK message, derive the subscriber host parameters based on those options and consequently insert those parameters in a pre-configured DHCP option (defined in *sub-ident-policy*). The ESM module can be then instructed to extract those parameters and consequently instantiate the host with proper service levels. The drawback of this solution is that the DHCP server may not return all DHCP (v4 and v6) options that clients and relay-agents originally transmitted. Since those options are needed for subscriber parameter determination (but may be absent in the DHCP ACK/REPLY messages when the Python script is run), this solution falls short of covering all deployment cases. In addition, the range of parameters that can be assigned to a subscriber host in this fashion is smaller than the set of parameters utilizing the DTC.
- The internal cache (DTC) allows us to store the result of Python processing. The result is stored during the lifetime of the DHCP transaction. This method of string assignment does not rely on the DHCP server ability to return client's options, DHCPv4 and DHCPv6.

Parameters (ESM strings, IP addresses, etc.) present in the DTC will have priority over any other source that is providing overlapping parameters when it comes to ESM processing. In other words, if the same parameter is provided via DTC (Python), LUDB and RADIUS, the one provided via DTC will be in effect. This prioritization will occur automatically without the need for any additional CLI.

For example, if the IPv4 address is provided via DTC during DHCP Discovery processing, then the mode of operation for this host will be proxy-to-dhcp (ESM will terminate DHCP, without going to the server), regardless of whether the IP address is also provided via LUDB or RADIUS.

This functionality is supported for DHCPv4/DHCPv6 hosts.

3.3.14 Python DTC Variables and API

The following are the Python variables and APIs related to DTC:

Subscriber Host Identification

alc.dtc.derivedId — A read/write (from the Python perspective) string to store the LUDB lookup key for subscriber host identification. This key is derived from the contents of the packet. This string will be used as a *match* criteria in LUDB. The derived-id can only be used when the lookup is performed in ESM. If the LUDB is attached to the local DHCP server, then the lookup based on the derived-id cannot be performed as the DHCP server has no means to derive such an ID from the DHCP message.

Caching Any Data During the Lifetime of a Transaction

alc.dtc.store(key,value) => the operator can store any data he desires in one or more entries. The key can be any arbitrary string (printable ASCII characters), up to 32 bytes in length. The value part is 'unlimited' (memory permitting) in size.

alc.dtc.retrieve(key) => retrieve data from the DTC. The key must be an existing key, which is a string consisting of printable ASCII characters, up to 32 bytes in length.

For example, this can be used to cache the DHCP options that the client inserts but the server does not echo back. Those options can still be retrieved in 7750 SR and 7450 ESS via cache in case that their presence is needed for any reason.

The lifespan of the cached data is tied to a DHCP transaction (a pair or corresponding DHCP messages flowing in opposite direction).

ESM Related Parameters (ESM strings, routing context, etc.)

DTC provides an API to supply a subset of configuration parameters that can otherwise come from RADIUS and LUDB and are used by the ESM code to setup the subscriber host.

DTC parameters as defined below should NOT be considered as DHCP options that can be blindly returned to the DHCP client, but instead they should be considered as real configuration settings. For example, the lease-time option is used in LUDB to enforce the lease time for the client. As such, the ESM keeps state of the lease-time. The following parameters can be used to setup a subscriber host:

alc.dtc.setESM (key-from-below, value) => store data that is used by ESM. This data is write-only.

The keys will be predefined (**only** these can be used) and are shown in [Table 42](#). These keys are read-only static variables.

The LUDB column indicates the configuration option under the **config>subscriber-mgmt>loc-user-db>ipoe>host** context in LUDB.

Table 42 ESM-Related Python Variables

DTC Variable	Type	LUDB	RADIUS Attribute	Comment
alc.dtc.subIdent	string	identification-strings >subscriber-id	Alc-Subsc-ID-Str	
alc.dtc.subProfileString	string	identification-strings >sub-profile-string	Alc-Subsc-Prof-Str

Table 42 ESM-Related Python Variables (Continued)

DTC Variable	Type	LUDB	RADIUS Attribute	Comment
alc.dtc.dhcpv6RebindTimer	integer	ipv6-lease-times>rebind-timer	Alc-Dhcp6-Rebind-Time	
alc.dtc.dhcpv6RenewTimer	integer	ipv6-lease-times>renew-timer	Alc-Dhcp6-Renew-Time	
alc.dtc.dhcpv6ValidLifetime	integer	ipv6-lease-times>valid-lifetime	Alc-v6-Valid-Lifetime	

For example, an IP address is assigned to a DTC variable as a string:

alc.dtc.ipAddress = "192.168.0.10" — This is performed through the following ALU API: **alc.dtc.setESM(alc.dtc.ipAddress, '192.168.0.10')**. The DTC logic then parses this variable and converts it into appropriate format for consumption by ESM code.

The values defined above are the ones that are mostly defined in the LUDB. Main use, however, is assigning ESM strings for the subscriber host instantiation phase during the processing of DHCP ACK/Reply messages. Consequently the Python script needs to be run only on DHCP Request messages (no need to run it on Discoveries for ESM string assignment, unless the LUDB derived-id is also needed).

DHCP options that are blindly returned to the DHCP client without the ESM code being aware of them cannot be configured via DTC. Such options should be configured via RADIUS (Alc-ToClient-Dhcp-Options – IPv4 only) or they can be inserted directly into DHCP messages via Python (bypassing DTC).

Other possible uses for DTC variables are:

- Assigning routing context information via Python (service-id, msap, msap-policy, retail service-id, etc). For example AN can insert certain 'hints' in various DHCP options that would suggest to us (via Python) in which service context to place the subscriber-host.
- IP address assignment via Python (DTC). This would address the DTC-to-DHCP-Proxy case where Python script is invoked on DHCP Discovery/Solicit. For example:
 - Discover arrives
 - Python generates an IP address, for example based on some DHCP options
 - The script stores the IP address by using `alc.dtc.setEsm(alc.dtc.ipAddress, "10.0.1.2");`

- After the script is finished, ESM starts processing the packet (no LUDB/RADIUS authentication configured)
- ESM finds the IP address already in DTC and decides to handle all DHCP and execute proxy function instead of relay
- ESM sends an offer with the address that python generated
- DHCP options should be provided as well in this case (lease-times, etc.)
- The same applies to the DHCP Request

3.3.14.1 DTC Debugging Facility

DTC debugging is part of the generic DHCP debugging facility that is enabled by the following commands:

debug router <router-id> **ip dhcp** --> Enable DHCP debug on Layer 3 interfaces, including subscriber-interfaces.

debug service id <service-id> **dhcp** --> Enable DHCP debugging on capture SAP.

If the DTC cache is populated via Python, the corresponding DTC entries will be shown as part of the matching DHCP message debug.

3.3.15 Virtual Subnet for DHCPv4 Hosts

The **virtual-subnet** command in the **sub-if>dhcp** context allows the system to snoop and record the default router address in DHCP ACK messages for a DHCPv4 ESM host. The system can answer ping or traceroute request even if the default router address is not configured on the subscriber-interface.

This feature eliminates the need to configure every default-gw address on subscriber interface. Beside default router address, the system will also calculate host's subnet by using an assigned address and the subnet mask option in ACK. Both recorded default router address and the subnet can be displayed with the **show service id virtual-subnet** command.

Every ESM subscriber only has one set of default router address and subnet.

3.3.16 Address Reservation for Sticky Leases

Address reservation for sticky leases adds support in local DHCP servers to provide IP address reservation for the assignment of sticky leases. These leases are pre-provisioned in the server (via SNMP or CLI) with a given set of user-identification parameters. This set of parameters must be unique for each pool to avoid duplicate leases. For management purposes, these leases also have an additional *hostname* parameter to easily retrieve them via SNMP. When a sticky lease is created, the corresponding requested IP address is allocated from the specified pool and this address afterwards can only be used by DHCP if they match the specified user identification parameters. It is not possible to make an existing DHCP lease sticky.

Sticky leases are persistent but not synchronized in multi-chassis synchronization. To support multi-chassis redundancy, a management system can allocate the lease on one 7750 SR, immediately retrieve the lease and populate it again on the redundant router. For this to work sticky leases should not be combined with any other allocation method (for example, regular DHCP leases, or Local Address Assignment because these methods can already allocate the address on the standby node).

This feature targets two scenarios

- Simplified IP address reservation. It is not necessary to provision LUDB entries and exclude ranges for sticky leases. Once the lease is reserved in the local DHCP server (triggered by an external system via SNMP or CLI), the external system can then subsequently assign the corresponding IP address to a DHCP client that matches the configured lease. A use case of this related to virtual residential gateway (vRGW) application and is described in the vRGW section.
- Pool management without DHCP. In pure management cases, this provides an easy method to perform pool management without implementing DHCP-specific configurations. For example, a management platform can allocate an IP address from a pool via the sticky lease mechanism and then assign this to a static host without risking overlap.

3.4 Proxy DHCP Server

This section describes the implementation of a proxy DHCP server capability provide a standards- based DHCP server which will front end to downstream DHCP client and DHCP relay enabled devices and interface with RADIUS to authenticate the IP host and subscriber and will obtain the IP configuration information for DHCP client devices.

The proxy DHCP server is located between an upstream DHCP server and downstream DHCP clients and relay agents when RADIUS is not used to provide client IP information.

Service providers can introduce DHCP into their networks without the need to change back-end subscriber management systems that are typically based around RADIUS (AAA). Service providers can support the use of DHCP servers and RADIUS AAA servers concurrently to provide IP information for subscriber IP devices.

Figure 25 Typical DHCP Deployment Scenarios

DHCP is the predominant client-to-server based protocol used to request IP addressing and necessary information to allow an IP host device to connect to the network.

By implementing DHCP, the complexity of manually configuring every IP device that requires connectivity to the network is avoided. IP devices with DHCP can dynamically request the appropriate IP information to enable network access.

DHCP defines three components that are implemented in a variety of device types:

- The DHCP client allows an IP device (host) to request IP addressing information from a DHCP server to enable access to IP based networks. This is typically found in:
 - End user notebooks, desktops and servers
 - Residential gateways and CPE routers
 - IP phones

- Set-top boxes
- Wireless access points
- The DHCP relay agent passes (relays) DHCP client messages to pre-configured DHCP servers where a DHCP server is not on the same subnet as the IP host. This feature optionally adds information into DHCP messages (Option 82) which is typically used for identifying attaching IP devices and their location as part of subscriber management. This is typically found in:
 - Residential gateways and CPE routers
 - DSLAMs
 - Edge aggregation routers
- The DHCP server receives DHCP client messages and is responsible for inspecting the information within the messages and determining what IP information if any is to be provided to a DHCP client to allow network access. This is typically found in:
 - Dedicated stand alone servers
 - Residential gateways and CPE routers
 - Edge aggregation routers
 - Centralized management systems

DHCP is the predominant address management protocol in the enterprise community, however in the provider market PPP has traditionally been the means by which individual subscribers are identified, authenticated and provided IP addressing information.

The use of DHCP in the provider market is a growing trend for managing subscriber IP addressing, as well as supporting newer devices such as IP-enabled IP phones and set-top boxes. The majority of subscriber management systems rely heavily on RADIUS (RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*) as the means for identifying and authorizing individual subscribers (and devices), deciding whether they will be allowed access to the network, and which policies should be put in place to control what the subscriber can do within network.

The proxy DHCP server capability enables the deployment of DHCP into a provider network, by acting as a proxy between the downstream DHCP devices and the upstream RADIUS based subscriber management system.

- Interact with downstream DHCP client devices and DHCP relay Agents in the path
- Interface with RADIUS to authenticate DHCP requests
- Receive all the necessary IP information to properly respond to a DHCP client
- Ability to override the allocate IP address lease time, for improved IP address management.

Figure 26 Aggregation Network With DHCP to RADIUS Authentication

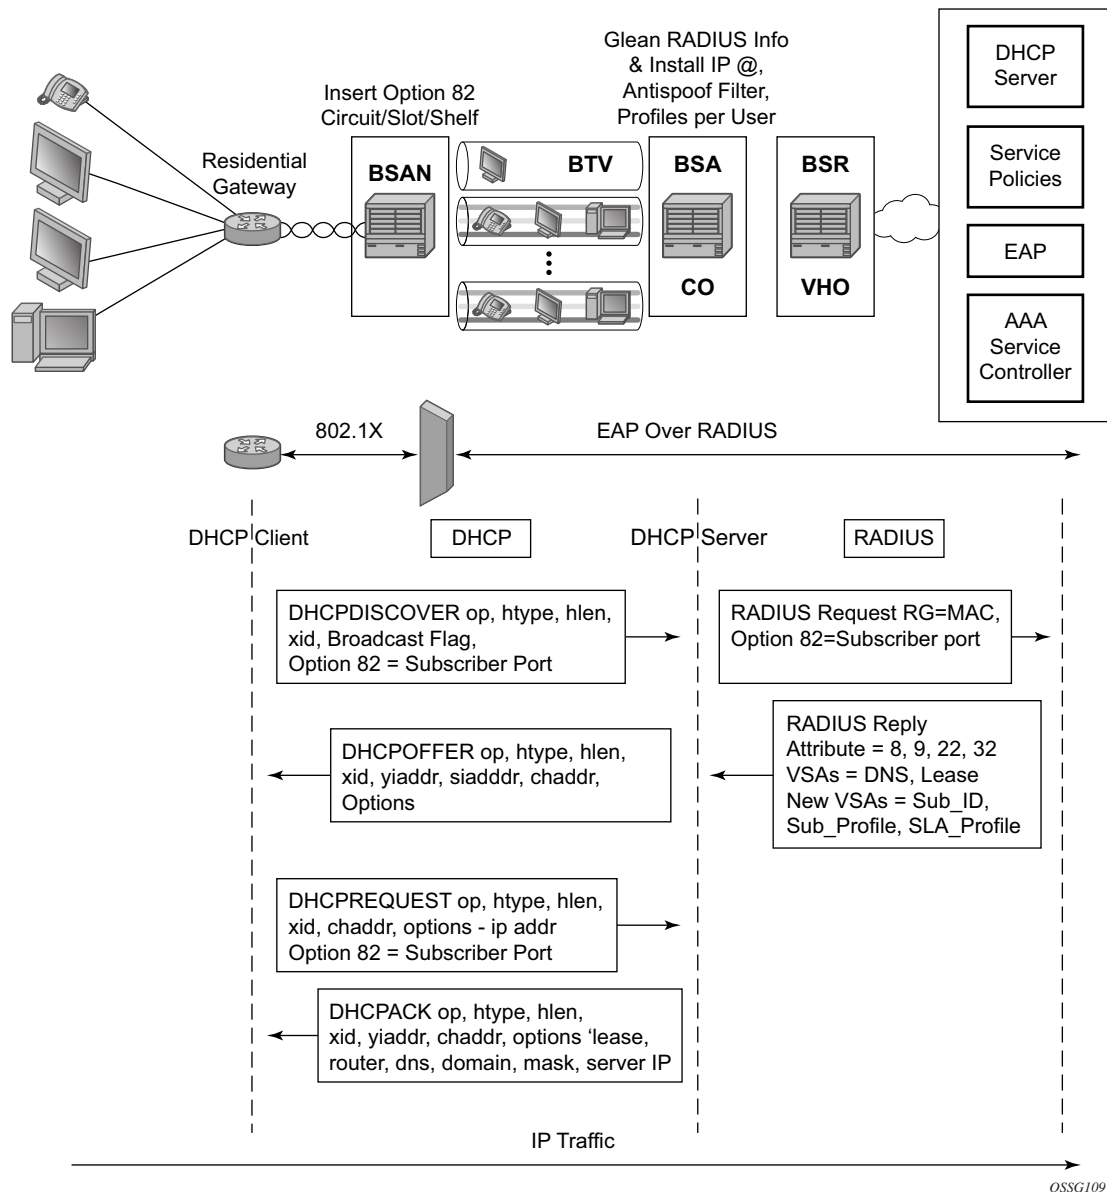

Figure 26 displays a typical DHCP initial boot-up sequence with the addition of RADIUS authentication. The proxy DHCP server will interface with downstream DHCP client devices and then authenticate upstream using RADIUS to a providers subscriber management system.

In addition to granting the authentication of DHCP hosts, the RADIUS server can include RADIUS attributes (standard and vendor-specific attributes (VSAs)) which are then used by the edge router to:

- Provision objects related to a given DHCP host — Subscriber and SLA policy
- Provide IP addressing information to a DHCP client
- Support the features that leverage DHCP lease state
 - Dynamic ARP population
 - ARP reply agent
 - Anti-spoofing filters
 - MAC pinning
- Leverage host-connectivity-verify to determine the state of a downstream IP host

This feature offers the ability for a customer to integrate DHCP to the subscriber while maintaining their existing subscriber management system typically based around RADIUS. This provides the opportunity to control shifts to an all DHCP environment or to deploy a mixed DHCP and RADIUS subscriber management system.

In order to maximize its applicability VSAs of legacy BRAS vendors can be accepted so that a network provider is not forced to reconfigure its RADIUS databases (or at least with minimal changes).

To receive data from the RADIUS server the following are supported:

- Juniper (vendor-id 4874) attributes 4 (Primary DNS server) and 5 (Secondary DNS server)
- Redback (vendor-id 2352) attributes 1 (Primary DNS) and 2 (Secondary DNS).
- Juniper attributes 6 and 7 (Primary and Secondary NetBIOS nameserver).
- Redback attributes 99 and 100 (Primary and Secondary NetBIOS nameserver).

The following attributes can be sent to RADIUS:

- Sending authentication requests: (from the DSL Forum) (vendor-id 3561), attributes 1 (Circuit ID) and 2 (Remote ID).
- DSL Forum attributes 129 and 130 (Actual Data Rate Upstream and Downstream), 131 and 132 (Minimum Data Rate Upstream and Downstream) and 144 (Access Loop Encapsulation).

The complete list of Nokia VSAs is available on a file included on the compact flash shipped with the image.

3.4.1 Local DHCP Servers

3.4.1.1 Terminology

- **Local 7750 SR and 7450 ESS DHCP Server** – DHCP server instantiated on the local 7750 SR and 7450 ESS node.
- **Remote 7750 SR and 7450 ESS DHCP Server** – DHCP server instantiated on the remote 7750 SR and 7450 ESS node (external to the local 7750 SR and 7450 ESS node).
- **3rd party DHCP server** – DHCP server external to any 7750 SR and 7450 ESS node and implemented outside of 7750 SR and 7450 ESS.
- **Intercommunication link** – the logical link between dual-homed 7750 SR and 7450 ESS DHCP servers used for synchronizing DHCP lease states. Multi-chassis Synchronization (MCS) protocol runs over this link. Once this link is interrupted, synchronization of the leases between redundant DHCP servers is impaired. This link should be well protected with multiple underlying physical paths.
- **Local IP address-range/prefix** – refers to the local failover mode in which the IP address-range/prefix is configured in dual-homed DHCP environment. The local keyword does not refer to the locality (local vs remote) of the server on which the IP address-range/prefix is configured, but rather refers to the ownership of the IP address-range/prefix. The DHCP server on which the local IP address-range/prefix is configured, owns this IP address-range/prefix and consequently is allowed to delegate the IP addresses/prefixes from it at any time, regardless of the state of the intercommunication link.
- **Remote IP address-range/prefix** – refers to the remote failover mode in which the IP address-range/prefix is configured in dual-homed DHCP environment. The remote keyword does not refer to the locality of the server on which the IP address-range/prefix is configured, but rather refers to the ownership of the IP address-range/prefix. The DHCP server on which the remote IP address-range/prefix is configured, but does not own this IP address-range/prefix during normal operation and consequently is NOT allowed to delegate the IP addresses/prefixes from it. Only when the intercommunication link between the two nodes transition into particular (failed) state, the DHCP server is allowed to start delegating new IP addresses from the remote IP address-range/prefix.
- **IP address-range/prefix ownership** – 7750 SR and 7450 ESS DHCP server can delegate new leases from an IP address-range/prefix that it owns. For example, an IP address-range/prefix designated as remote is not owned by the DHCP server on which it is configured unless certain conditions are met. Those conditions are governed by the state of the intercommunication link.

- **IP address-range/prefix takeover** – a 7750 SR and 7450 ESS DHCP server that does not own an IP address-range/prefix can take over the ownership of this IP address-range/prefix under certain conditions. Once the ownership is taken, the new IP addresses can start being delegated from this IP address-range/prefix. Only the remote IP address-range/prefix can be taken over. Note that the takeover of an IP address-range/prefix has only local significance – in other words, the ownership is not taken away from some other DHCP server that has the same IP address-range/prefix designated as local. It only means that IP address-range/prefix that is configured as remote is available to takeover for new IP address delegation.
- **Local PPPoX Address Pools** – this term refers to the method of accessing an IPv4/v6 address pool in 7750 SR and 7450 ESS DHCP4/6 server. For PPPoX clients, the IPv4/v6 addresses are allocated from those pools without the need for an intermediate DHCP relay-agent (7750 SR and 7450 ESS internal DHCP relay-agent). Although those pools are part of the local DHCP server in 7750 SR and 7450 ESS, the method of accessing them is substantially different than accessing local DHCP address pools for IPoE (DHCP) clients. IPoE (DHCP) and PPPoX hosts can share the same pool and yet each client type can access them in their own unique way:
 - IPoE client via DHCP messaging
 - PPPoE via internal API calls
- **Local PPPoX Pool Management** – IPv4 address allocation/management for PPPoX clients independent of DHCP process (DHCP lease state). An IPv4 address allocated via local PPPoX Pool Management is tied to the PPPoX session. It is without the need for an internal DHCP relay-agent.

3.4.1.2 Overview

7750 SR and 7450 ESS DHCP server multi-homing will ensure continuity of IP address/prefix assignment/renewal process in case that an entire 7750 SR and 7450 ESS DHCP server fails or in case of a failure of the active link that connects clients to one of the 7750 SR and 7450 ESS DHCP servers in the access part of the network. DHCP server multi-homing is an integral part of the overall subscriber management multi-chassis protection scheme.

DHCP server multi-homing can be implemented outside of the BNG, without subscriber management enabled. However, in the following text, it is assumed that the subscriber management multi-homing (SRRP/MC-LAG, subscriber synchronization) is deployed along with DHCP server multi-homing.

Although the subscriber synchronization process and the DHCP lease states synchronization process use the same synchronization infrastructure within 7750 SR and 7450 ESS (Multi Chassis Redundancy protocol), they are in essence two separate processes that are not aware of each other. As such, the mechanisms that drive their switchover are different. For example, the mechanism that drives subscriber switchover from one node to the other is driven by the access protection mechanism (SRRP/MC-LAG) while the switchover (or takeover) of the IP address-range/prefixes in a DHCP pool is driven by the state of the intercommunication link over which the leases are synchronized. The failure of an entire node makes those differences irrelevant since the access-link failure coincides with the intercommunication link failure and vice versa. However, link-only failures become critical when it comes to their interpretation by the protection mechanisms (SRRP/MC-LAG/DHCP server multi-homing). Regardless of nature of the failure, overall DHCP server multi-chassis protection scheme must be devised in such fashion that the two 7750 SR and 7450 ESS DHCP servers never allocate the same IP address/prefix to two different clients. Otherwise IP address/prefix duplication will ensue. Unique IP address/prefix allocation is achieved by making only one 7750 SR and 7450 ESS DHCP server responsible for IP address/prefix delegation out of the shared IP address-range/prefix.

There are two basic models for DHCP server dual-homing:

- Shared IP address-range/prefix is designated as local on one 7750 SR and 7450 ESS DHCP server and as remote on the other.

In this case, the dhcp-relays must point to both DHCP servers; the one configured with the local IP address-range/prefix as well as the one with the remote IP address-range/prefix.

Under normal circumstances, the new IP addresses/prefixes can be only allocated from the DHCP server configured with the local IP address-range/prefix.

The DHCP server configured with the remote IP address-range/prefix will start delegating new lease from it only when it declares that the redundant peer with the local IP address-range/prefix becomes unavailable.

Detection of the peer unavailability is triggered by the failure of the intercommunication link which can be caused either by the nodal failure or simply by the loss of connectivity between the two nodes protecting each other. Thus, the loss of intercommunication link does not necessarily mean that the peering node is truly gone. It can simply mean that the two nodes became isolated and unable to synchronize their DHCP leases between each other. In such environment, both nodes can potentially allocate the same IP address at the same time. To prevent this, additional intercommunication link states and associated timers are introduced to give the chance the operator ample time to fix the problem.

For example, the DHCP server will take over the remote IP address-range/prefix once the MCLT period expires while the intercommunication link is in PARTNER-DOWN state. The PARTNER-DOWN state is entered after a preconfigured timer (partner-down-delay) expires. The consequence of these two additional timers (partner-down-delay and MCLT) is that the new IP address delegation from the remote (shared) IP address-range/prefix will not be possible until the preset timers expire. This is needed and justified in case that the intercommunication link is interrupted, the nodes become isolated and consequently the DHCP lease state synchronization becomes impaired. On the other hand, if the DHCP server with local IP address-range/prefix becomes truly unavailable, those additional restoration times will cause interruption in service since the new IP addresses from the remote IP address-range/prefix will not be immediately available for delegation.

Note that only new IP address delegation from the remote IP address-range/prefix is affected by this behavior. The existing IP leases can be extended on both nodes at any time irrespective of whether the configured address-range/prefix is designated as local or remote.

To ensure uninterrupted service even for new lease delegation in this model (local-remote), two approaches can be adopted:

- Segment the IP address/prefix space so that each node has an IP address-range/prefix designated as local.
For example, instead of designating IP address-range 10.10.10.0/24 as local on DHCP server A and as remote on DHCP server B, the 10.10.10.0/24 IP address will be split into two: 10.10.10.0/25 and 10.10.10.128/25. The 10.10.10.0/25 would be designated as local on the DHCP server A and as remote on DHCP server B. The 10.10.10.128/25 would be designated as remote on the DHCP server A and as local on DHCP server B. In this fashion, one node will always be available to assign new leases without any overlap.
- In case that only one shared IP address-range/prefix is deployed, the operator can bypass the timers (partner-down-delay and MCLT) that are put in place in case that DHCP server nodes become isolated. This bypass of the timers can be achieved via configuration. In this case, a safe operation is warranted only if the operator is certain that the intercommunication link failure will be caused by the nodal failure, and not the physical link failure between the two nodes.
- Shared IP address-range/prefix is designated as access-driven on both 7750 SR and 7450 ESS DHCP servers.

In this scenario, the shared IP address-range/prefix is owned by both nodes and the ownership is not driven by the state of the intercommunication link.

To avoid IP address duplication, only one DHCP server at any given time must be responsible for IP address assignment from this shared IP address-range/prefix.

This will be ensured by the access protection mechanism (SRRP/MC-LAG) that will provide a single active path from the clients to the one of the DHCP servers.

In case that clients have access to the same IP address-range/prefix on both DHCP servers at the same time, the IP address duplication may occur.

Consider the following case:

Two DHCP clients send DHCP Discovers in the following fashion:

- DHCP client A sends DHCP Discover to the DHCP server A
- DHCP client B sends DHCP Discover to the DHCP server B
- DHCP server A assigns IP address 10.10.10.10 to the DHCP client A
- DHCP server B assigns IP address 10.10.10.10 to the DHCP client B
- This is a legitimate scenario since the DHCP lease states are not synchronized until the DHCP lease assignment is completed.
- Just before the DHCP ACK is sent to the respective clients from both nodes, the DHCP lease sync messages are exchanged between the peers.
- DHCP servers do not wait for the reply to the sync message before they send the DHCP Ack to the client.
- Once the DHCP syn message is received from the peer, the DHCP server will realize that the IP lease already exist. In this case, the newer IP lease will override the older.
- The result is that clients A and B use the same IP address and consequently the forwarding of the traffic will be impaired.

In access-driven model, the ESM subscriber host must be collocated with the DHCP server. In other words, the DHCP server must be instantiated in redundant BNGs. The dhcp-relays must point to the respective local DHCP servers. There must be no cross-referencing of DHCP servers in this model. In addition, the IP address that the DHCP servers are associated with, must be the same on both DHCP servers. This is necessary to ensure uninterrupted service levels once the switchover in the access occurs.

For example:

- DHCP server A on BNG A is associated with the IP address 1.1.1.1 (for example loopback interface A on BNG A)
- DHCP server B on the peering BNG B is associated with the IP address 1.1.1.1 (configured in BNG B under loopback interface B)
- Dhcp-relay on BNG A points to the IP address 1.1.1.1—DHCP server in BNG A
- Dhcp-relay on BNG B points to the IP address 1.1.1.1—DHCP server in BNG B.

Consider the following when contemplating deployment of the two described models:

- Local-remote model is agnostic of the access protection mechanism. In fact, the access protection mechanism is not needed at all for safe operation.

Fast takeover of the single shared (remote) IP address-range/prefix can be provided only in cases where the operator can guarantee that the intercommunication link failure is caused by the nodal failure (entire DHCP server node becomes unavailable). Fast takeover is provided by bypassing the partner-down-timer and MCLT.

In case that multiple IP address-ranges/prefixes are deployed, bypass of the timers is not needed since the local IP address-ranges/prefixes are available on both nodes.

- Access-driven model allows a single IP address-range/prefix to be shared across the redundant DHCP server nodes. The access to the single DHCP server node from the client side is ensured by the protection mechanism deployed in the access part of the network (SRRP or MC-LAG).

3.4.1.3 DHCP Lease Synchronization

DHCP server leases are synchronized over Multi-Chassis Synchronization (MCS) protocol. A DHCP lease synchronization message is sent to the peering node just before the DHCP ACK/Reply is sent to the client.

For example, the message flow for DHCPv4 lease establishment is the following:

DHCP Discover	; DHCP client — DHCP server
DHCP Offer	; DHCP server — DHCP client
DHCP Request	; DHCP client — DHCP server
DHCP Sync Message	; DHCP server — via MCS to the peering DHCP server
DHCP Ack	; DHCP server— DHCP client

DHCP server failover mechanism in the local-remote IP address-range/prefix model relies on the detection of the failure of the link over which DHCP states are synchronized (via MCS protocol). This link is normally disjoint from the access links towards the clients. MCS protocol normally runs over a direct link between the two redundant nodes (1) or over backbone links (2) in case that the direct link is not present.

Figure 27 Redundancy Model

In the access-driven IP address-range/prefix model, the DHCP server address-ranges/prefixes are not tied to the state of the intercommunication link. Instead, the DHCP server selection for IP address assignment is only governed by the path selected by the path protection mechanism (SRRP/MC-LAG) deployed in the access part of the network.

3.4.1.4 Intercommunication Link Failure Detection

7750 SR and 7450 ESS DHCP Server is a client of Multi-chassis Synchronization (MCS) application with 7750 SR and 7450 ESS. Once MCS transitions into out-of-sync state, the 7750 DHCP server redundancy assumes that there is a failure in the network. In essence, the DHCP server failure in dual-chassis configuration relies on the failure detection mechanism of MCS.

MCS runs over TCP, port 45067 and it is using either data traffic or keepalives to detect failure on the communication link between the two nodes. In the absence of any MCS data traffic for more than 0.5sec, MCS will send its own keepalive to the peer. If a reply is NOT received within 3sec, MCS will declare its operational state as DOWN and the DB Sync state as out-of-sync. MCS will consequently notify its clients (DHCP Server being one of them) of this condition.

In essence, it can take up to 3 seconds before the DHCP client realizes that the interclasses communication link failed.

MCS Clients (applications) can optimally send their own proprietary keepalive messages to its partner over MCS to detect failure. DHCP Server does not utilize this method and it strictly relies on the failure notifications by MCS.

Note that the intercommunication link failure does not necessarily assume the same failed fate for the access links. In other words, it is perfectly possible (although unlikely) that both access links are operational while the inter-chassis communication link is broken.

The failure detection of the intercommunication link will lead to certain failover state transitions on the DHCP server. The DHCP lease handling in the local-remote model will depend on the particular failover state on the DHCP server and the duration of each failover state is determined by preconfigured timers.

3.4.1.5 DHCP Server Failover States

DHCP Server when paired in redundant fashion can transition through several states:

- TRANSITION
- SHUTDOWN
- INIT
- STARTUP
- NORMAL – In this state, the 7750 SR and 7450 ESS DHCP Server is serving all IP leases from the local and access-driven IP addresses-ranges/prefixes (assigning new leases and extending existing ones). Remote IP addresses-ranges/prefixes are not served (new or existing ones).
- COMMUNICATION INTERRUPTED – IP addresses/prefixes under the local and access-driven IP address-range/prefix are served in the same fashion as in the NORMAL state. The IP addresses/prefixes under the remote IP address-range/prefix will be renewed. However, the new address/prefix from the remote address-range/prefix will not be allocated until the partner-down timer expires,

the failover state consequently transitions into PARTNER DOWN and the MCLT timer while in the PARTNER-DOWN state expires. This is necessary in case that the failure occurred only on the intercommunication link while the access link is still operational (DHCP server nodes become isolated).

COMMUNICATION INTERRUPTED state indicates that there is a failure of some kind, but it cannot be determined whether an entire node failed or only the inter-chassis link. The access layer may still be fully operational, but the new leases (including RENEWS/REBINDS) cannot be synchronized between the two peers.

- PARTNER DOWN – Once the DHCP Server reaches this state, the remote IP address-range/prefix is taken over and after an additional time period of MCLT (Maximum Client Lead Time), the new IP addresses/prefixes from it can be delegated to clients. PARTNER-DOWN state is an indication (and assumption at the same time) that the remote node is truly down.

Otherwise, the IP address duplication may occur in case that all of the following conditions are met:

- the DHCP server nodes become isolated
- the failover state is PARTNER-DOWN
- DHCP/PPPoX clients have simultaneous access to the same IP address-range/prefix on the both DHCP servers.

3.4.1.6 Lease Time Synchronization

7750 SR and 7450 ESS DHCP server state synchronization is different from the lease state synchronization of the subscriber host itself.

- Each subscriber host lease state is synchronized via sub-mgmt client application. The host lease state can be seen via the output of following CLI command:

show service id *id* dhcp lease-state

The output of this command represents the state of our internal DHCP relay (client).

- On the other hand, the DHCP server lease states can be observed via the following CLI command:

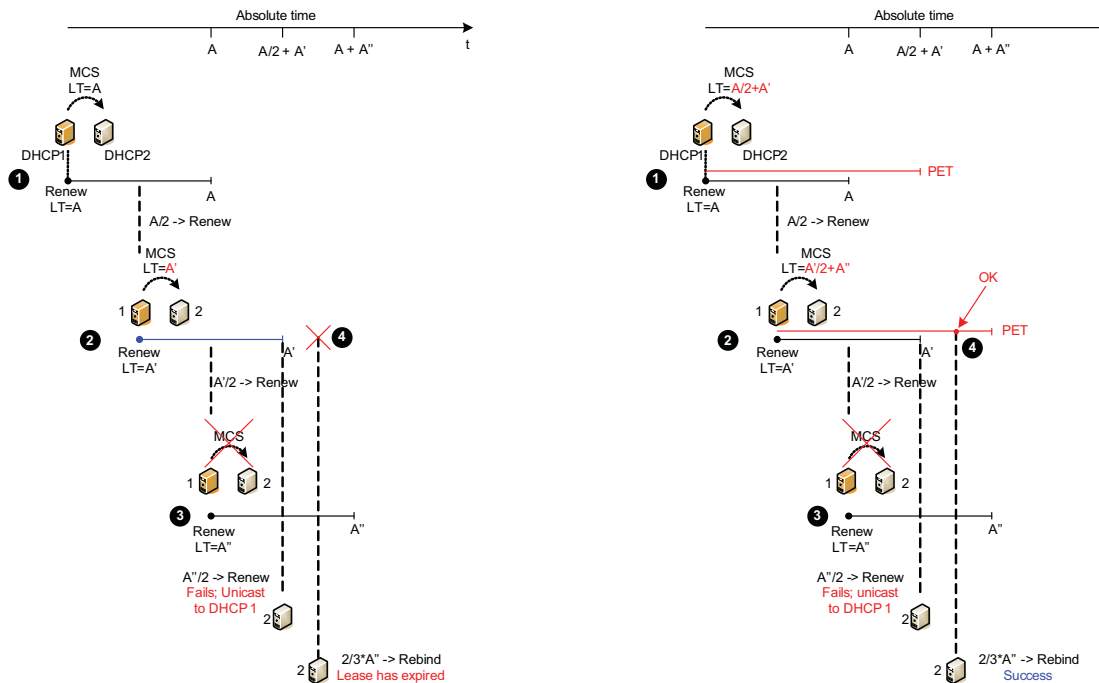

show routed id dhcp local-dhcp-server *name* lease

The concern is with the latter, the 7750 SR and 7450 ESS DHCP server lease state synchronization. To ensure un-interrupted IP lease renewal process after a failure in the network, the DHCP server lease time that is synchronized between the 7750 SR and 7450 ESS DHCP servers must always lead the currently assigned lease time for the period of the anticipated lease time in the next period.

For comparison purposes the two flow diagrams are juxtaposed in [Figure 28](#):

- The right side does not include any lead time during synchronization
- The left side includes the lead time during synchronization

Figure 28 Potential Expiration Time

On the left side of the graph, the lease time is synchronized to the same value to which it was renewed.

In point 3, the primary DHCP server renews the lease time but fails to synchronize it due to its own failure (crash). The secondary server (2) has the old lease time A' in its database. The next time the client tries to REBIND its address/prefix, the lease in the secondary server will be expired (4). As a result, the IP address/prefix will not be renewed.

To remedy this situation, the primary server must synchronize the lease time as the current RENEW time + the next lease-time. In this fashion, as depicted in point 3, when the REBIND reaches server 2, the lease in its DB will still be active (4) and the server 2 will be able to extend the lease for the client.

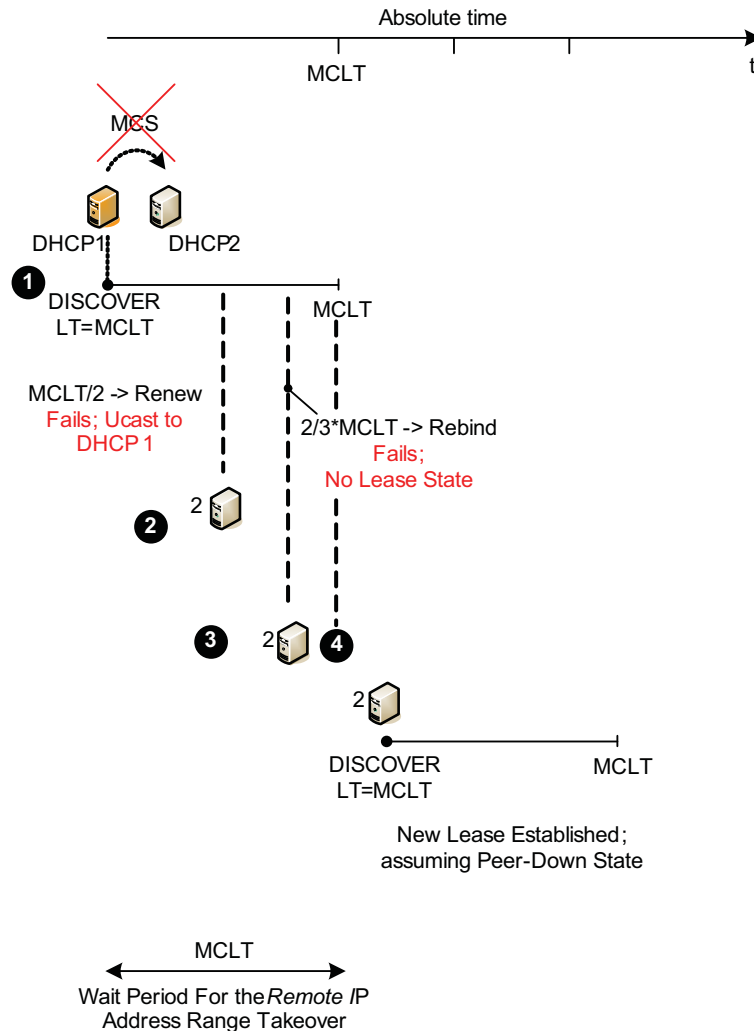

3.4.1.7 Maximum Client Lead Time (MCLT)

Maximum Client Lead Time (MCLT) is the maximum time that the 7750 SR and 7450 ESS DHCP Server can extend the lease time to its clients beyond the lease time currently known by the 7750 SR and 7450 ESS DHCP partner node. By default this time is relatively short (10min).

The purpose of the MCLT is explained in the following scenario:

The local DHCP server assigns a new IP lease to the client but it crashes before it sends a sync update to the partner server. Because of the local DHCP server failure, the remote DHCP server is not aware of the IP address/prefix that has been allocated on the local DHCP server. This condition creates the possibility that the remote DHCP server allocates the same address/prefix to another client. This would cause IP address/prefix duplication. MCLT is put in place to prevent this scenario.

MCLT based solution is shown in [Figure 29](#).

Figure 29 Address/Prefix Allocation without Synchronization

The sequence of events is the following:

1. DHCP Server 1 is the local DHCP server (with the local address-range/prefix) that creates the IP lease state for a new client. The initial lease-time assigned to the client is MCLT which is normally shorter than the requested lease time. This DHCP server fails before it gets a chance to synchronize the lease state with the DHCP Server 2 (remote DHCP server with the remote address-range/prefix).

2. The remote DHCP server transitions into the PARTNER-DOWN state (assuming that the partner-down timer is 0). In this state the remote DHCP server can extend the lease time to the existing clients but it can NOT assign a new lease for a period of MCLT. In MCLT/2 a new RENEW request is sent directly to the local DHCP server. This server is DOWN and therefore it cannot reply.
3. The client broadcasts a REBIND request that reaches the remote DHCP server. The remote DHCP server has no knowledge of the requested lease and therefore it does not reply.
4. The lease for the client will expire and the client will have to reinitiate the IP address/prefix assignment process.

Since the remote DHCP server is not aware of the lease state that was assigned by the local DHCP server, there is a chance that the remote DHCP server assigns to the new client the same IP address/prefix already allocated by the local DHCP server just before it crashed. This is why the remote DHCP server needs to wait for the MCLT time to expire so that the IP addresses/prefixes allocated (but never synchronized) by the local DHCP server can time out.

When the communication channel between the chassis is interrupted, two scenarios are possible:

1. The entire node becomes unavailable. In this case the redundant node takes over and it starts reducing the lease time until the lease time reaches MCLT.
 - COMMUNICATION-INTERRUPTED
The remote DHCP server only renews the leases but does not delegate new ones (primary is DOWN).
The local DHCP server renews the leases (which eventually trickle down to MCLT) and delegates the new ones with the lease time of MCLT (secondary is down).
 - PARTNER-DOWN
The remote DHCP server starts delegating new IP addresses/prefixes from the remote address-range/prefix after MCLT (primary is down). The lease time of the new clients is MCLT. A lease cannot be assigned for a period longer than what is agreed with the peer incremented with the MCLT. As for a “new” lease nothing is agreed yet so the sum falls back to the MCLT itself.
2. The communication channel is down but the remote DHCP server is not (meaning that the clients have still access to both servers). The behavior in this case is following:
 - COMMUNICATION-INTERRUPTED

The remote DHCP server keeps renewing existing leases but it does not delegate the new leases. The chances that this will happen are low as the clients will keep sending RENEWS via unicast to the local DHCP server which is still active. The non-synched leases in the remote DHCP server will time out. The local DHCP server will start trickling down the lease time to MCLT.

The local DHCP server will keep delegating the new leases, although with the MCLT lease time.

– PARTNER-DOWN State

The local DHCP server will keep extending the existing leases but it will also start delegating new IP leases once the initial MCLT elapses.

Note that both local and remote DHCP server will delegate new leases in PARTNER-DOWN state (although the remote DHCP server in PARTNER-DOWN state will have to wait an additional MCLT period before it can start delegating new leases).

3.4.1.8 Sharing IPv4 Address-Range or IPv6 Prefixes

Access-driven DHCP server redundancy model will ensure uninterrupted IP address assignment service from a single IP address-range/prefix in case that an access link forwards BNG fails. To avoid duplicate address allocation, there MUST be a single active path available from the clients to only one of the 7750 SR and 7450 ESS DHCP servers in redundant configuration. This single active path is ensured via a protection mechanism in dual-homed environment in the access side of the network. The supported protection mechanisms in the access in 7750 SR and 7450 ESS are SRRP or MC-LAG.

In access-driven DHCP redundancy model, the DHCP relay in each 7750 SR and 7450 ESS node must point only to the IP address of the local DHCP server. In other words, the DHCP messages received on one DHCP server should never be relayed to the other. Since the IP address-ranges/prefixes are shared between the DHCP servers, accessing both DHCP servers with the same DHCP request can cause DHCP lease duplication. Moreover, the IP addresses of both DHCP servers must be the same in both nodes. Otherwise the DHCP renew process would fail.

Granting new leases out of the shared IP address-ranges or prefixes that are configured as access-driven is not dependent on the state of the inter-chassis communication link (MCS). Instead, the new leases can be granted from both nodes simultaneously and it is the role of the protection mechanism in the access to ensure that a single path to either server is always active.

This model will allow the newly active node, after a SRRP/MC-LAG switchover, to be able to serve new clients immediately from the same (shared) IP range or prefix. At the same time, upon the switchover, the corresponding subscriber-interface route is re-evaluated for advertisement with a higher routing metric to the network side via SRRP awareness. The end result is that by aligning the subscriber-interface routes or prefixes with access-driven DHCP address ranges or prefixes in DHCP server, the IP address ranges or prefixes will be advertised to the network side only from the actively serving node (SRRP Master or active MC-LAG node). This will be performed indirectly via the corresponding subscriber-interface route that is aligned (by configuration) with the DHCP address range or prefix in access-driven mode.

In case that SRRP or MC-LAG is not deployed in conjunction with the access-driven configuration option, the IP address duplication could occur.

Note that multi-chassis redundancy relies on MCS to synchronize various client applications. (subscriber states, DHCP states, IGMP states, etc) between the two chassis. Therefore the links over which MCS peering session is established must be highly redundant. Failed MCS peering session will render dual-chassis redundancy non-operational. Considering this fact, the DHCP failover scenario with SRRP/MC-LAG and shared IP address range should be evaluated considering the following cases:

Table 43 DHCP Failover Scenarios

Access Related Failure	Inter-Chassis Link State	Number of Failures	Action
None	None	None	Only the MASTER SRRP BNG will grant IP leases. The subnet tied to the SRRP instance is advertised to the network side on the MASTER SRRP node.
None	COMM-INT	Possibly multiple	Only the MASTER SRRP BNG will grant IP leases. Communication link between the two chassis has failed and the DHCP states cannot be synchronized. Operator is required to restore the links between the chassis.
None	PARTNER-DOWN	Possibly multiple	Same as above. The premise of this deployment model in general (SRRP/MC-LAG + access-driven) is that there is only one path leading to the DHCP server active. This path is governed by SRRP. Therefore there is no change in behavior between the PARTNER-DOWN and COMM-INT states in this particular scenario.

Table 43 DHCP Failover Scenarios (Continued)

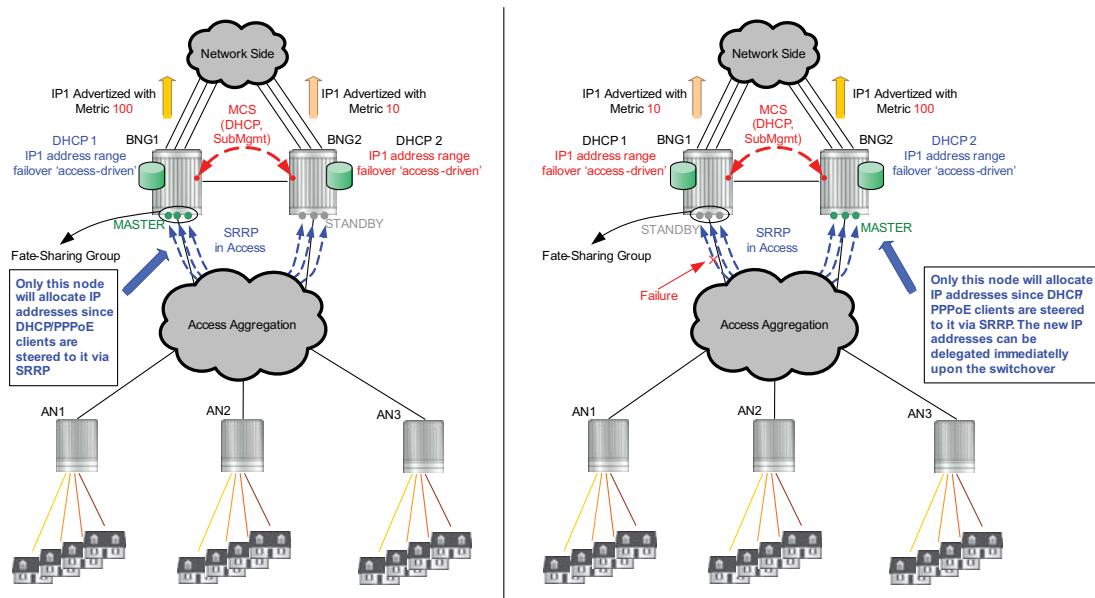

Access Related Failure	Inter-Chassis Link State	Number of Failures	Action
Access Link Towards the Master SRRP	NORMAL	Single	SRRP will switch over. The new IP lease grants will continue from new SRRP Master using the same IP address range. IP leases will be synched OK. Subnets will be advertised from new Master via SRRP awareness.
Access Link Towards the Master SRRP	COMM-INT	Multiple	<p>SRRP will switch over. The new leases can be handed from the DHCP server on the newly SRRP Master node. However, this DHCP server may not have its lease state table up to date since the inter-chassis communication link is non-operational.</p> <p>Consequently, new SRRP Master node may start handing out leases that are already allocated on the node with the failed link. In this case, IP address duplication would ensue.</p> <p>This is why it of utmost importance that the intercommunication chassis link is well protected and the only event that causes it to go down is when the entire node goes down. Otherwise the nodes becomes isolated from each other and synchronization becomes non-operational.</p>
Access Link Towards the Master SRRP	PARTNER-DOWN	Multiple	Same as above.
Access Link Towards the Standby SRRP	NORMAL	Single	No effect on the operation since everything is active on the Master SRRP node anyway.
Access Link Towards the Standby SRRP	COMM-INT	Multiple	Intercommunication link is broken. The Master SRRP node will continue handing out the new leases and renewing the old ones. However, they will not be synchronized to the peering node.
Access Link Towards the Standby SRRP	PARTNER-DOWN	Multiple	Same as above.

Table 43 DHCP Failover Scenarios (Continued)

Access Related Failure	Inter-Chassis Link State	Number of Failures	Action
Entire Master Node	COMM-INT	Single	SRRP will switch over. However, lease duplication may occur on the newly Master since the intercommunication link is broken and this newly SRRP Master is not aware of DHCP leases that the peer (failed node) may have allocated to the clients while the intercommunication-link was broken.
Entire Master Node	PARTNER-DOWN	Single	Same as above.
Entire Standby Node	COMM-INT	Single	Operation continues OK but multi-chassis redundancy is lost.
Entire Standby Node	PARTNER-DOWN	Single	Same as above.

A possible deployment scenario is shown in [Figure 30](#).

Figure 30 Failover Scenario with SRRP and DHCP in Access-Driven Mode

3.4.1.9 Fast-Switchover of IP Address/Prefix Delegation

Some deployments require that the remote IP address/prefix range starts delegating new IP addresses/prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.

In other words, the takeover of the remote IP address-range/prefix should follow the failure of the intercommunication link, without any significant delays.

This can be achieved by configuring both of the following two items under the dhcp failover CLI hierarchy:

- The partner-down-delay must be set to 0. This will cause the intercommunication link to bypass the COMM-INT state upon the failure and transition straight into the PARTNER-DOWN state. The remote IP address-range/prefix can be taken over only in PARTNER-DOWN state, once the MCLT expires.
- The ignore-mclt-on-takeover flag must be enabled. With this flag enabled, remote IP address/prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the MCLT to expire. Note that by setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times will be set to MCLT. This behavior remains the same as originally intended for MCLT. This functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (partner-down-delay and MCLT) would ensure that during their duration, the new IP addresses/prefixes are delegated only from one node – the one with local IP address-range/prefix. The drawback is of course that the new IP address delegation is delayed and thus service is impacted.

But if one could ensure that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. This is why it is of utmost importance that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses/prefixes.

3.4.1.9.1 DHCP Server Synchronization and Local PPPoX Pools

Since there is no classical DHCP lease state maintained for local PPPoX pools, the IP addresses will not be synchronized via DHCP Server. Instead they will be synchronized via PPPoX clients. Once the PPPoX subscriber is synchronized, the respective IP address lease will be updated in the respective local pool.

For example:

- A PPPoE client is created on 7750 SR and 7450 ESS 'A'.
- The IP address is assigned from the local pool on 7750 SR and 7450 ESS 'A'.
- The PPPoE client will be synchronized to the peering node 7750 SR and 7450 ESS 'B'.
- Once the client is synchronized in 7750 SR and 7450 ESS 'B', the IP address assignment will be synchronized by our internal PPPoE process on 7750 SR and 7450 ESS 'B' with the local pool.

One artifact of this behavior (IP address assignment in local DHCP pools is synchronized via PPPoX clients and not via DHCP server synchronization mechanism) is that during the node boot, the DHCP server must wait for the completion of PPPoX subscriber synchronization via MCS so that it learns which addresses/prefixes are already allocated on the peering node. Since the DHCP server can theoretically start assigning IP addresses before the PPPoX sync is completed, a duplicate address assignment may occur. For example an IP address lease can be granted via DHCP local pools while PPPoX sync is still in progress. Once the PPPoX sync is completed, the DHCP server may discover that the granted IP lease has already been allocated by the peering node. The most recent lease will be kept and the other will be removed from both systems. To prevent this scenario, a configurable timer can be set to an arbitrary value that will render sub-if non-operational until the timer expires. The purpose of this timer is to allow the PPPoX sync to complete before subscribers under the sub-intf can be served.

3.5 Local Address Assignment

3.5.1 Stateless Address Auto-configuration

In the stateless auto-configuration model, hosts can be assigned address statically or dynamically. For static prefix assignment, LUDB and RADIUS can be used. For dynamic assignment, a pool name returned from LUDB or RADIUS and the local DHCPv6 server is used for address management. Although, the DHCPv6 server is used there are no lease time associated with the SLAAC prefix assigned to hosts. To utilize the local pool for SLAAC prefix assignment, the command **local-address-assignment** is used under group-interface. The client-application type **ppp-slaac** and/or **ipoe-slaac** must first be specified. Afterwards, the server name of the local-address-server must also be provisioned.

3.6 Configuring DHCP with CLI

This section provides information to configure DHCP using the command line interface.

- [Common Configuration Tasks](#)
 - [Enabling DHCP Snooping](#)
 - [Configuring Option 82 Handling](#)
 - [Enabling DHCP Relay](#)
 - [Configuring Local User Database Parameters](#)

3.7 Common Configuration Tasks

Topics in this section are:

- [Enabling DHCP Snooping](#)
- [Configuring Option 82 Handling](#)
- [Enabling DHCP Relay](#)
- [Configuring Local User Database Parameters](#)

3.7.1 Enabling DHCP Snooping

DHCP snooping is the process of copying DHCP packets and using the contained information for internal purposes. The BSA and BSR can use the snooped DHCP information to build anti-spoofing filters, populate the ARP table, send ARP replies, and so on.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) on the SAP or SDP where DHCP messages ingress the VPLS instance. It is recommended to enable snooping on both the interface to the DHCP server (to snoop ACK messages) and the interface to the subscriber (to snoop RELEASE messages).

For IES and VPRN IP interfaces (VPRN is supported on the 7750 SR only), lease-populate enables DHCP snooping for the subnets defined under the IP interface. The number of allowed simultaneous DHCP sessions on a SAP or interface can be limited using the lease-populate command with the parameter number-of-entries specified. Enabling lease-populate and snoop commands is effectively enabling “standard subscriber management” as described in [Standard and Enhanced Subscriber Management](#).

The following output displays an example of a partial BSA configuration with DHCP snooping enabled in a service:

```
*A:ALA-48>config>service# info
-----
...
    vpls 600 customer 701 create
        sap 1/1/4:100 split-horizon-group "DSL-group2" create
            description "SAP towards subscriber"
            dhcp
                lease-populate 1
                option
                    action replace
                    circuit-id
                    no remote-id
                exit
            no shutdown
        exit
    exit
    mesh-sdp 2:800 create
        dhcp
            snoop
        exit
    exit
    no shutdown
exit
...
-----
*A:ALA-48>config>service#
```

3.7.2 Configuring Option 82 Handling

Option 82, or “Relay Information Option” is a field in DHCP messages used to identify the subscriber. The Option 82 field can already be filled in when a DHCP message is received at the router, or it can be empty. If the field is empty, the router should add identifying information (circuit ID, remote ID or both). If the field is not empty, the router can decide to replace it.

The following example displays an example of a partial BSA configuration with Option 82 adding on a VPLS service. Snooping must be enabled explicitly on a SAP.

```
A:ALA-1>config>service>vpls#
```

```

-----
no shutdown
description "Default tls description for service id 1"
sap 1/1/11 split-horizon-group "2dslam" create
dhcp
  no description
  snoop
  no lease-populate
  option
    action replace
    circuit-id ascii-tuple
    no remote-id
  exit
  no shutdown
exit
exit
-----
A:ALA-1>config>service>vpls#

```

3.7.3 Enabling DHCP Relay

Lease populate and DHCP relay are different features in which are not both required to be enabled at the same time. DHCP relay can be performed without populating lease tables.

The following example displays DHCP relay configured on an IES interface:

```

A:ALA-48>config>service>ies>if# info
-----
address 10.10.42.41/24
local-proxy-arp
proxy-arp
  policy-statement "ProxyARP"
exit
sap 1/1/7:0 create
  anti-spoof ip
exit
arp-populate
dhcp
  description "relay_ISP1"
  server 10.200.10.10 10.200.10.20
  lease-populate 1
  no shutdown
exit
-----
A:ALA-48>config>service>ies>if#

```

3.7.4 Configuring Local User Database Parameters

A local user data base defines a collection of host entries. There are two types of hosts: PPP and IPoE. A local user database can be used to:

- Authenticate PPP clients. For this only the host entries configured in the **ppp** CLI are matched.
- Authenticate IPoE hosts (DHCPv4, DHCPv6 IA-NA/IA-PD, SLAAC). The host entries configured in the **ipoe** CLI context are matched.
- Perform authentication and address management for the local DHCPv4 server. For this, both PPP and IPoE sections can be used depending on the client type indicated by a vendor-specific suboption inside Option 82 of the DHCPv4 message.

Each host can be identified by a set of values. However, at any point in time only four of these values are taken into account for IPoE as defined by the **ipoe match-list** option and only three are considered for PPP as defined in the **ppp match-list** option.

When trying to find a matching host entry, attempts are made to match as many items as possible. If several hosts match an incoming IPoE packet, the one with most match criteria is taken.

One host entry can map on several physical clients. For instance, when using a circuit ID, by masking when the interface-id is used, the host-entry is used for all the clients on that same interface.

IPoE host identification includes:

- Circuit ID; this field also matches the DHCPv6 interface-id field
- MAC address
- Remote ID — Matches on the remote-id sub-option in option 82 for DHCPv4 clients and on the remote-id option (including enterprise-id field) for DHCPv6 clients
- Option 60 from DHCPv4 message; only first 32 bytes are looked at
- SAP ID
- Service ID
- String from vendor-specific suboption of Option 82
- System ID
- derived-id — A string provided via a DHCP Python script

- dual-stack-remote-id — Matches on the remote-id sub-option in option 82 for DHCPv4 clients and on the remote-id field in the remote-id option (without enterprise-id) for DHCPv6 clients
- encap-tag-range — Matches on VLAN tag ranges
- IP — Matches on the source IPv4/IPv6 address of a data-trigger packet

PPP host identification includes:

- Circuit ID
- MAC address
- Remote id
- User name, either complete user name, domain part only, or host part only
- Derived ID — A string provided by Python script

When a host cannot be inserted in the lookup database, it will be placed in an unmatched-hosts list. This can occur due to:

- Another host with the same host-identification exists. Only the host-identification that is specified in the match-list is taken into account for this.
- A host has no host-identification specified in the match-list.

When used for PPPoE-authentication, the fields are used as follows:

- password — Verifies the PPPoE user password. This is mandatory. If no password is required then it must be explicitly set to **ignore**.
- address:
 - no address — No address information. The address must be obtained by other means, either RADIUS or DHCP server.
 - gi-address — No meaning in this context. The address must be obtained by other means, either RADIUS or DHCP server.
 - use-pool-from-client — No meaning in this context, address must be obtained by other means, either RADIUS or DHCP server.
 - pool-name — The address must be obtained by other means, either RADIUS or a DHCP-server. When a DHCP server is used, this pool-name will be included in Option 82 vendor-specific suboption.
 - ip-address — This ip-address will be offered to the client.
- Identification-strings — Returns the strings used for enhanced subscriber management (ESM).
- Options — Only DNS servers and NBNS server are used, others are ignored.

When used from the DHCP server, the following applies:

- password — Not used.
- address — Defines how the address should be allocated for this host.
 - no address — The host is not allowed. The clients mapping to this host will not get an IP address.
 - gi-address — Finds the matching subnet and an IP address is taken from that subnet.
 - pool-name — A free IP address is taken from that pool.
 - ip-address — This ip-address will be offered to the client.
 - use-pool-from-client — Use the **poolname** in the Option 82 vendor-specific suboption. If no **poolname** is provided there, falls back to the DHCP server default (none or use-gi-address).
- identification-strings — The operator can specify subscriber management strings and in which option the strings are sent back in dhcp-offer and dhcp-ack messages.
- options — The operator defines which options specific to this host should be sent back in the dhcp-offer and dhcp-ack messages. The options defined here override options defined on the pool-level and subnet-level inside the local DHCP server.

The circuit ID from PPPoE or from Option 82 in IPoE messages can be masked in following ways:

- prefix-length — Drop a fixed number of bytes at the beginning of the circuit-id.
- suffix-length — Drop a fixed number of bytes at the end of the circuit-id.
- prefix-string — The matching string will be dropped from the beginning of the circuit-id. The matching string can contain wildcards (*). For example: incoming circuit-id "mybox|3|my_interface|1/1/1:22" masked with "*|*|" will leave "my_interface|1/1/1:22".
- suffix-string — The matching string will be dropped at the end of the circuit-id. For example: incoming circuit-id "mybox|3|my_interface|1/1/1:22" masked with "|*" will result in "mybox|3|my_interface".

The following is an example of a local user database used for PPPoE authentication:

```
*A:ALA-48>config>subscr-mgmt# info
-----
...
    local-user-db "pppoe user db"
        description "pppoe authentication data base"
        ppp
            match-list username circuit-id
            mask prefix-string "*|*|" suffix-string "|*"
            host "john" create
            host-identification
                username "john" no-domain
```

```

        exit
        password pap "23T8yPoe0w1R.BPGHB98i0qhJf7ZlZGctXBKGnjrIrA" hash2
        no shutdown
    exit
    host "test.com" create
        host-identification
            username "test.com" domain-only
        exit
        password ignore
        no shutdown
    exit
    host "john@test.com" create
        host-identification
            username "john@test.com"
        exit
        password pap "23T8yPoe0w0Tlfl1yCb4hskknvTYLqA2avvBB567g3eQ" hash2
        identification-strings 122 create
            subscriber-id "john@test.com"
            sla-profile-string "sla prof1"
            sub-profile-string "subscr profile 1"
            ancp-string "ancp string"
            inter-dest-id "inter dest"
        exit
        no shutdown
    exit
    host "john@test.com on interface group-if"
        host-identification
            circuit-id string "group-if"
            username "john@test.com"
        exit
        password pap "23T8yPoe0w1R.BPGHB98i0qhJf7ZlZGctXBKGnjrIrA" hash2
        address 10.1.2.3
        no shutdown
    exit
exit
no shutdown
exit
...
-----
*A:ALA-48>config>subscr-mgmt#

```

The following are some examples when a user tries to set up PPPoE:

- john@test.com tries to setup PPPoE with circuit-id "pe_23|3|group-if|1/1/1": host "john@test.com on interface group-if" will match, the PAP password is checked and the IP address 10.1.2.3 is given to PPPoE to use for this host.
- john@test.com (on another interface): host "john@test.com" will match, the PAP password is checked, and identification strings are returned to PPPoE.
- nokie@test.com: host "test.com" will match, no password check, the user is allowed.
- john@nokie.com: host "john" will match and the password will be checked.
- anybody@anydomain: will not match and will not be allowed.

The following is an example of a local user database used for DHCP server for IPoE clients:

```
*A:ALA-50>config>subscr-mgmt# info
-----
...
    local-user-db "dhcp server user db"
        description "dhcp server user data base"
        ipoe
            match-list circuit-id mac
            mask prefix-string "*"|"*" suffix-string "|"*"
            host "mac 3 on interface" create
                host-identification
                    circuit-id string "group-if"
                    mac 00:00:00:00:00:03
                exit
                address 10.0.0.1
                no shutdown
            exit
            host "maskedCircId" create
                host-identification
                    circuit-id string "group-if"
                exit
                address pool "pool 1"
                identification-strings 122 create
                    subscriber-id "subscriber 1234"
                    sla-profile-string "sla prof 1"
                    sub-profile-string "sub prof 1"
                    ancp-string "ancpstring"
                    inter-dest-id "inter dest id 123"
                exit
                options
                    netbios-name-server 1.2.3.4
                    lease-time min 2
                exit
                no shutdown
            exit
        exit
    exit
no shutdown
exit
...
-----
*A:ALA-50>config>subscr-mgmt#
```

The following is an access example:

- MAC 00:00:00:00:00:03 on circuit-id "pe5|3|group-if|1/1/1": host "mac 3 on interface" is matched and address 10.0.0.1 is offered to the IPoE client.
- Another MAC on circuit-id "pe5|3|group-if|2/2/2": host "maskedCircId" is matched and an address is taken from "pool1" (defined in the DHCP server). The identification-strings will be copied to Option 122 in the dhcp-offer and dhcp-ack messages. The options defined here will also be copied into dhcp-offer and dhcp-ack messages.

- The circuit-id "pe5|3|other_group_if|1/1/3": no host is matched. The client will only get an IP address if on DHCP server level you defined the use-gi-address parameter and the gi-address matches a subnet.

The following is an example of a local user database used for a DHCP server, only for PPPoE clients:

If PPPoE does not get an IP address from RADIUS or the local-user-db used for authentication, the internal dhcp-client will be used to access a DHCP server which can be in the same node or in another node. These request are identified by inserting Option 82 suboption client-id in the dhcp-discover and dhcp-request messages. When the DHCP server receives this request and has a user-db connected to it, then the PPPoE section of that user-db is accessed.

```
*A:ALA-60>config>subscr-mgmt# info
-----
...
    local-user-db "pppoe user db"
        description "pppoe authentication data base"
        ppp
            match-list username
            host "internet.be" create
                host-identification
                    username "internet.com" domain-only
                exit
                address "pool_1"
                no shutdown
            exit
            host "john@internet.com" create
                host-identification
                    username "john@internet.com"
                exit
                identification-strings 122 create
                    subscriber-id "john@test.com"
                    sla-profile-string "sla prof1"
                    sub-profile-string "subscr profile 1"
                    ancp-string "ancp string"
                    inter-dest-id "inter dest"
                exit
                address use-gi
                no shutdown
            exit
            host "malicious@internet.com"
                host-identification
                    circuit-id string "group-if"
                    username "internet@test.com"
                exit
                no shutdown
            exit
        exit
        no shutdown
    exit
...
-----
*A:ALA-60>config>subscr-mgmt#
```

The following is an access example:

- john@internet.com: GI is used to find a subnet and a free address will be allocated from that subnet. Identification strings are returned in Option 122.
- anybody@internet.com: pool_1 will be used to find a free IP address.
- malicious@internet.com: no address is defined. This user will not get an IP address.

The following is an example of associating a local user database to PPPoE for authentication for the 7750 SR.

```
A:pe5>config>service>vprn#
-----
        subscriber-interface "tomylinux" create
        address 10.2.2.2/16
        group-interface "grp_pppoe3" create
        pppoe
        e "pppoe"
        exit
    exit
-----
A:pe5>config>service>vprn#
```

The following is an example of associating a local user database to a local DHCP server.

```
A:pe7>config>router>dhcp#
-----
        local-dhcp-server my_server
        description "my dhcp server"
        user-db "data base 1"
        ...
    exit
-----
A:pe7>config>router>dhcp#
```

In PPPoE access scenarios without access node or with access nodes that do not insert PPPoE vendor specific tags "Circuit-ID" and/or "Remote-ID", it may be required to configure this information in the local user database so that they can be picked up in pre-authentication phase and used for RADIUS authentication and reporting in RADIUS accounting messages. For example:

```
config>subscr-mgmt

        local-user-db "ludb-1" create
        ppp
        match-list username
        host "host-1" create
        access-loop-information
            circuit-id string "LUDB inserted circuit-id"
            remote-id string "LUDB inserted remote-id"
```

```
        exit
        host-identification
            username "cpe-1@domain1.com"
        exit
        auth-policy "auth-policy-1"
        password ignore
        no shutdown
    exit
exit
```

In the case of PPPoE, when the system accesses a LUDB during a discovery phase, a matched host could return a second LUDB via a “user-db” configuration under the LUDB host context. This second database will be accessed again during the PAP/CHAP phase. The following is an example:

```
local-user-db "padi-db" create
    ppp
        match-list derived-id
        host "testuser" create
            host-identification
                derived-id "testuser"
            exit
            msap-defaults
                group-interface "g1"
                service 500
            exit
            user-db "chap-db"
            no shutdown
        exit
    exit
    no shutdown
exit
local-user-db "chap-db" create
    ppp
        match-list derived-id username
        host "testuser" create
            host-identification
                derived-id "testuser"
                username "testuser"
            exit
            password chap "cYhRmQYWOkLW3s0LrtEnBjWlAwFa/1Kx" hash2
            identification-strings 254 create
                sla-profile-string "sla-2"
            exit
            no shutdown
        exit
    exit
    no shutdown
exit
```

3.8.2 Command Descriptions

3.8.2.1 Triple Play DHCP Configuration Commands

Note: For the 7450 ESS configurations, the DHCP6 and IPv6 ESM commands apply only when in mixed-mode.

3.8.2.1.1 Global Commands

description	
Syntax	description <i>description-string</i> no description
Context	config>filter>dhcp-filter config>service>vpls>sap>dhcp config>service>vpls>sap>dhcp6 config>service>vpls>sap>ipoe-session config>service>ies>if>dhcp config>service>ies>if>ipv6>dhcp6-relay config>service>vprn>if>dhcp config>router>dhcp>server config>router>dhcp>server>pool config>subscr-mgmt>loc-user-db config>service>vprn>sub-if>ipv6>dhcp6>relay config>service>ies>sub-if>ipv6>dhcp6>relay
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The no form of this command removes the string from the configuration.</p>
Default	No description associated with the configuration context.

Parameters	<i>description-string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.
-------------------	---

shutdown

Syntax	[no] shutdown
Context	<pre>config>service>ies>if>dhcp config>service>vpls>sap>dhcp config>service>vpls>sap>dhcp6 config>service>vpls>sap>dhcp>option>vendor config>service>vpls>sap>ipoe-session config>service>vprn>if>dhcp config>service>vprn>if>dhcp>proxy-server config>subscr-mgmt>loc-user-db config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host config>router>dhcp6>server>failover config>router>dhcp>server>failover</pre>
Description	<p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.</p> <p>The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.</p> <p>The no form of this command places the entity into an administratively enabled state.</p>

3.8.2.1.2 Global DHCP Commands

dhcp

Syntax	dhcp
Context	config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp config>service>ies>interface config>service>vprn config>service>vprn>interface config>service>vprn>sub-if config>service>vprn>sub-if>grp-if config>service>ies>sub-if>grp-if config>service>ies>sub-if config>service>ies>sub-if>grp-if
Description	This command enables the context to configure DHCP parameters.

adv-noaddrs-global

Syntax	adv-noaddrs-global [esm-proxy] [esm-relay] [relay] [server] no adv-noaddrs-global
Context	config>system>dhcp6
Description	<p>This command configures the different DHCPv6 applications to send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the global DHCP message level.</p> <p>By default, all applications send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the IA_NA Option level.</p> <p>Different applications for which NoAddrsAvail Status-Code in DHCPv6 Advertise messages can be configured at the global DHCP message level.</p> <p>The only valid combination in current SROS is “adv-noaddrs-global esm-relay server”.</p>
Default	no adv-noaddrs-global. All applications send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the IA_NA Option level.
Parameters	<p>esm-proxy — Specifies the DHCPv6 proxy server on subscriber group-interfaces. Not supported in current SR OS.</p> <p>esm-relay — Specifies the DHCPv6 relay on subscriber group-interfaces. Must be enabled together with the DHCPv6 server (server) application.</p> <p>relay — Specifies the DHCPv6 relay on regular IES/VP RN interfaces. Not supported in current SR OS.</p>

server — Specifies the DHCPv6 server. Must be enabled together with the DHCPv6 relay on subscriber interfaces (esm-relay) application.

dhcp-filter

Syntax	dhcp-filter <i>filter-id</i> [create] no dhcp-filter
Context	config>filter
Description	This command creates a configuration context for the specified DHCP filter policy if it does not exist and enables the context to configure the specified DHCP filter policy.
Default	no dhcp-filter
Parameters	<i>filter-id</i> — specifies the DHCP filter policy ID expressed as a decimal integer Values 1 to 65535 create — Keyword required to create the configuration context

dhcp6-filter

Syntax	dhcp6-filter <i>filter-id</i> [create] no dhcp6-filter
Context	config>filter
Description	This command creates a configuration context for the specified DHCPv6 filter policy if it does not exist and enables the context to configure the specified DHCPv6 filter policy.
Default	no dhcp6-filter
Parameters	<i>filter-id</i> — specifies the DHCPv6 filter policy ID expressed as a decimal integer Values 1 to 65535 create — Keyword required to create the configuration context

default-action

Syntax	default-action { bypass-host-creation drop } no default-action
Context	config>filter>dhcp-filter config>filter>dhcp6-filter
Description	This command specifies the default action when no entries match.

Parameters **bypass-host-creation** — Specifies to bypass ESM host creation options.
 drop — Specifies to drop and not process the DHCP6 message.

entry

Syntax **entry** *entry-id* [**create**]
 no entry *entry-id*

Context config>filter>dhcp-filter
 config>filter>dhcp6-filter

Description This command configures DHCP filter entries.

 The **no** form of the command removes the entry from the configuration.

Parameters *entry-id* — Specifies the entry ID.

Values 1 to 65535

create — This keyword is required when first creating the DHCP filter entry. Once the context is created, it is possible to navigate into the context without the **create** keyword.

action

Syntax **action bypass-host-creation**
 action drop
 no action

Context config>filter>dhcp-filter>entry
 config>filter>dhcp6-filter>entry

Description This command specifies the action to take on DHCP host creation when the filter entry matches.

 The **no** form of the command reverts to the default wherein the host creation proceeds as normal.

Default no action

Parameters **bypass-host-creation** — specifies that the host creation is bypassed
 drop — specifies that the DHCP message is dropped

option

Syntax **option** *dhcp-option-number* {**present** | **absent**}

	option <i>dhcp-option-number</i> match hex <i>hex-string</i> [exact] [invert-match] option <i>dhcp-option-number</i> match string <i>ascii-string</i> [exact] [invert-match] no option
Context	config>filter>dhcp-filter>entry config>filter>dhcp6-filter>entry
Description	This command configures the match criteria for the DHCP filter policy entry. The no form of the command reverts to the default.
Default	no option
Parameters	<i>dhcp-option-number</i> — specifies the DHCP option number Values 0 to 255 present — specifies that the related DHCP option must be present absent — specifies that the related DHCP option must be absent match hex <i>hex-string</i> — The option must (partially) match a specified hex string. Values 0x0 to 0xFFFFFFFF...(max 254 hex nibbles) match string <i>ascii-string</i> — The option must (partially) match a specified ASCII string. Values Up to 127 characters exact — This option requires an exact match of a hex or ascii string. invert-match — Requires the option not to (partially) match.

3.8.2.1.3 Router DHCP Commands

local-dhcp-server

Syntax	local-dhcp-server <i>server-name</i> [create] no local-dhcp-server <i>server-name</i>
Context	config>router>dhcp config>service>vprn>dhcp
Description	This command instantiates a local DHCP server. A local DHCP server can serve multiple interfaces but is limited to the routing context it was which it was created.
Default	none
Parameters	<i>server-name</i> — Specifies the name of local DHCP server. create — Keyword used to create the local DHCP server. The create keyword requirement can be enabled/disabled in the environment>create context.

allow-lease-query

Syntax	[no] allow-lease-query
Context	config>router>dhcp6>server config>service>vprn>dhcp6>server
Description	If enabled, the local DHCPv6 server will handle and reply to lease query messages. The no form of the command disables lease query support.
Default	no allow-lease-query

failover

Syntax	failover
Context	config>router>dhcp>server config>service>vprn>dhcp>server
Description	This command enables the context to configure failover parameters.

ignore-mclt-on-takeover

Syntax	[no] ignore-mclt-on-takeover
---------------	-------------------------------------

Context	<pre> config>router>dhcp>server>failover config>router>dhcp>server>pool>failover config>router>dhcp6>server>failover config>router>dhcp6>server>pool>failover config>service>vprn>dhcp>server>failover config>service>vprn>dhcp>server>pool>failover config>service>vprn>dhcp6>server>failover config>service>vprn>dhcp6>server>pool>failover </pre>
Description	<p>With this flag enabled, the remote IP address/prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the MCLT to expire. By setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times will be set to MCLT. This behavior remains the same as originally intended for MCLT.</p> <p>Some deployments require that the remote IP address/prefix range starts delegating new IP addresses/prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.</p> <p>This can be achieved by enabling the ignore-mclt-on-takeover flag and by configuring the partner-down-delay to 0.</p> <p>Enabling this functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (partner-down-delay and MCLT) would ensure that during their duration, the new IP addresses/prefixes are delegated only from one node, the one with local IP address-range/prefix. The drawback is of course that the new IP address delegation is delayed and thus service is impacted.</p> <p>But if one could ensure that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. This is why it is of utmost importance that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses/prefixes.</p>
Default	no ignore-mclt-on-takeover

maximum-client-lead-time

Syntax	maximum-client-lead-time [<i>maximum-client-lead-time</i>] no maximum-client-lead-time
Context	<pre> config>router>dhcp>server>failover config>router>dhcp>server>pool>failover config>service>vprn>dhcp>server>failover </pre>

```
config>service>vprn>dhcp>server>pool>failover
config>router>dhcp6>server>failover
config>router>dhcp6>server>pool>failover
config>service>vprn>dhcp6>server>failover
config>service>vprn>dhcp6>server>pool>failover
```

Description The **maximum-client-lead-time** (MCLT) is the maximum time that a DHCP server can extend client’s lease time beyond the lease time currently known by the DHCP partner node. In dual-homed environment, the initial lease time for all DHCP clients is by default restricted to MCLT. Consecutive DHCP renewals are allowed to extend the lease time beyond the MCLT.

The MCLT is a safeguard against IP address/prefix duplication in cases of a lease synchronization failure when local-remote failover model is deployed

Once the intercommunication link failure between the redundant DHCP servers is detected, the DHCP IP address range configured as remote will not be allowed to start delegating new leases until the MCLT + partner-down-delay intervals expire. This is to ensure that the new lease that was delegated from the ‘local’ IP address-range/prefix on one node, but was never synchronized due to the intercommunication link failure, will expire before the same IP address/prefix is allocated from the remote IP address-range/prefix on the other node.

However, the already existing (and synchronized) lease times can be renewed from the remote IP address range at any time, regardless of the state of the intercommunication link (operational or failed).

Lease synchronization failure can be caused either by a node failure, or a failure of the link over which the DHCP leases are synchronized (intercommunication link). Synchronization failure detection can take up to 3 seconds.

During the failure, the DHCP lease time for the new clients will be restricted to MCLT while for the existing clients the lease time will over time (by consecutive DHCP renewals) be gradually reduced to the MCLT.

Default 10 minutes

Parameters *maximum-client-lead-time* — Specifies the maximum client lead time.

Values		
hrs	<i>hours</i>	0 to 23
min	<i>minutes</i>	0 to 59
sec	<i>seconds</i>	0 to 59

partner-down-delay

Syntax **partner-down-delay** [*partner-down-delay*]
 no partner-down-delay

Context config>router>dhcp>server>failover
 config>router>dhcp>server>pool>failover

```
config>service>vprn>dhcp>server>failover
config>service>vprn>dhcp>server>pool>failover
config>router>dhcp6>server>failover
config>router>dhcp6>server>pool>failover
config>service>vprn>dhcp6>server>failover
config>service>vprn>dhcp6>server>pool>failover
```

Description Since the DHCP lease synchronization failure can be caused by the failure of the intercommunication link (and not necessary the entire node), there is a possibility the redundant DHCP servers become isolated in the network. In other words, they can serve DHCP clients but they cannot synchronize the lease. This can lead to duplicate assignment of IP addresses, since the servers have configured overlapping IP address ranges but they are not aware of each other's leases.

The purpose of the partner-down-delay is to prevent the IP lease duplication during the intercommunication link failure by not allowing new IP addresses to be assigned from the remote IP address range. This timer is intended to provide the operator with enough time to remedy the failed situation and to avoid duplication of IP addresses/prefixes during the failure.

During the partner-down-delay time, the prefix designated as remote will be eligible only for renewals of the existing DHCP leases that have been synchronized by the peering node. Only after the sum of the partner-down-delay and the maximum-client-lead-time will the prefix designated as remote be eligible for delegation of the new DHCP leases. When this occurs, we say that the remote IP address range has been taken over.

It is possible to expedite the takeover of a remote IP address range so that the new IP leases can start being delegated from that range shortly after the intercommunication failure is detected. This can be achieved by configuring the partner-down-delay timer to 0 seconds, along with enabling the ignore-mclt-on-takeover CLI flag. Caution must be taken before enabling this functionality. It is safe to bypass safety timers (partner-down-delay + MCLT) only in cases where the operator is certain that the intercommunication between the nodes has failed due to the entire node failure and not due to the intercommunication (MCS) link failure. Failed intercommunication due to the nodal failure would ensure that only one node is present in the network for IP address delegation (as opposed to two isolated nodes with overlapping IP address ranges where address duplication can occur). For this reason, the operator must ensure that there are redundant paths between the nodes to ensure uninterrupted synchronization of DHCP leases.

In access-driven mode of operation, partner-down-delay has no effect.

Default 23 hours, 59 minutes and 59 seconds

Parameters *partner-down-delay* — Specifies the partner down delay time.

Values		
hrs	<i>hours</i>	0 to 23
min	<i>minutes</i>	0 to 59
sec	<i>seconds</i>	0 to 59

peer

Syntax	peer <i>ip-address</i> tag <i>sync-tag</i> no peer
Context	config>router>dhcp>server>failover config>router>dhcp>server>pool>failover config>router>dhcp6>server>failover config>router>dhcp6>server>pool>failover
Description	<p>DHCP leases can be synchronized per DHCP server of DHCP pool. The pair of synchronizing servers or pools is identified by a tag. The synchronization information is carried over the Multi-Chassis Synchronization (MCS) link between the two peers. MCS link is a logical link (IP, or MPLS).</p> <p>MCS runs over TCP, port 45067 and it is using either data traffic or keepalives to detect failure on the communication link between the two nodes. In the absence of any MCS data traffic for more than 0.5sec, MCS will send its own keepalive to the peer. If a reply is not received within three sec, MCS will declare its operation state as DOWN and the DB Sync state as out-of-sync. MCS will consequently notify its clients (DHCP Server being one of them) of this. It can take up to three seconds before the DHCP client realizes that the inter-chassis communication link has failed.</p> <p>The inter-chassis communication link failure does not necessarily assume the same failed fate for the access links. In other words the two redundant nodes can become isolated from each other in the network. This would occur in cases where only the intercommunication (MCS) link fails. It is of utmost importance that this MCS link be highly redundant.</p>
Default	none
Parameters	<i>ip-address</i> — Specifies the IPv4 address of the peer. tag <i>sync-tag</i> — Specifies a tag that will identify synchronizing DHCP servers or pools.

startup-wait-time

Syntax	[no] startup-wait-time [min <i>minutes</i>] [sec <i>seconds</i>]
Context	config>router>dhcp>server>failover config>router>dhcp>server>pool>failover config>router>dhcp6>server>failover config>router>dhcp6>server>pool>failover
Description	This command enables startup-wait-time during which each peer waits after the initialization process before assuming the active role for the prefix designated as local or access-driven. This is to avoid transient issues during the initialization process.
Default	2 minutes

Parameters	min — Specifies the startup wait time in minutes. Values 1 to 10
	sec — Specifies the startup wait time in seconds. Values 1 to 59

force-renews

Syntax	[no] force-renews
Context	config>router>dhcp>server config>service>vpn>server
Description	This command enables the sending of sending forcerenew messages. The no form of the command disables the sending of forcerenew messages.
Default	no force-renews

ignore-rapid-commit

Syntax	[no] ignore-rapid-commit
Context	config>router>dhcp6>server config>service>vpn>dhcp6>server
Description	This command enables the Rapid Commit Option. The no form of the command disables the Rapid Commit Option.

interface-id-mapping

Syntax	[no] interface-id-mapping
Context	config>router>dhcp6>server config>service>vpn>dhcp6>server
Description	If enabled, this command enables the behavior where unique /64 prefix is allocated per interface-id, and all clients having the same interface-id get an address allocated out of this / 64 prefix. This is relevant for bridged clients behind the same local-loop (and same SAP), where sharing the same prefix allows communication between bridged clients behind the same local-loop to stay local. For SLAAC based assignment, downstream neighbor-discovery is automatically enabled to resolve the assigned address.
Default	no interface-id-mapping

lease-hold-time

Syntax	lease-hold-time [<i>lease-hold-time</i>] no lease-hold-time
Context	config>service>vprn>dhcp>server config>router>dhcp>server config>service>vprn>dhcp6>server config>router>dhcp6>server
Description	<p>This command configures the time to remember this lease. This lease-hold-time is for unsolicited release conditions such as lease timeout and normal solicited release from DHCP client.</p> <p>The no form of the command reverts to the default.</p>
Default	sec 0
Parameters	<i>lease-hold-time</i> — Specifies the amount of time to remember the lease.
	Values
	days <i>days</i> 0 to 3650
	hrs <i>hours</i> 0 to 23
	min <i>minutes</i> 0 to 59
	sec <i>seconds</i> 0 to 59

lease-hold-time-for

Syntax	[no] lease-hold-time-for
Context	config>service>vprn>dhcp6>server config>router>dhcp6>server config>service>vprn>dhcp>server config>router>dhcp>server
Description	<p>This command enables the context to configure lease-hold-time-for parameters which defines additional types of lease or triggers that cause system to hold up leases.</p> <p>Use the lease-hold-time command to enable or disable lease hold up on the server level.</p>
Default	lease-hold-time-for

internal-lease-ipsec

Syntax	[no] internal-lease-ipsec
Context	config>service>vprn>dhcp6>server>lease-hold-time-for config>router>dhcp6>server> lease-hold-time-for

	config>service>vprn>dhcp>server config>router>dhcp>server
Description	This command enables the server to hold up the lease of local IPsec clients. The no form of the command disables the ability of the server to hold up the lease of local IPsec clients.
Default	no internal-lease-ipsec

solicited-release

Syntax	[no] solicited-release
Context	config>service>vprn>dhcp6>server>lease-hold-time-for config>router>dhcp6>server> lease-hold-time-for config>service>vprn>dhcp>server config>router>dhcp>server
Description	This command enables the server to hold up a lease even in case of solicited release; for example, when the server receives a normal DHCP release message. The no form of the command disables the ability of the server to hold up a lease when a solicited release is received.
Default	no solicited-release

pool

Syntax	pool <i>pool-name</i> [create] no pool <i>pool-name</i>
Context	config>router>dhcp>server config>router>dhcp6>server config>service>vprn>dhcp>server config>service>vprn>dhcp6>server
Description	This command configures a DHCP address pool on the router.
Default	none
Parameters	<i>pool name</i> — Specifies the name of this IP address pool. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. create — Keyword used to create the pool. The create keyword requirement can be enabled/disabled in the environment>create context.

delegated-prefix-length

Syntax	delegated-prefix-length <i>bits</i> [minimum <i>prefix-length</i>] [maximum <i>prefix-length</i>] no delegated-prefix-length
Context	config>router>dhcp6>server>pool config>service>vpn>dhcp6>server>pool
Description	<p>This command configures the delegated prefix length that will be used if the DHCPv6 client does not specify a prefix length hint.</p> <p>The DHCPv6 client prefix length hint is limited by the range specified by the minimum and maximum parameters. If the hint is smaller than the minimum, the allocated prefix length will be equal to the minimum length. If the hint is larger than the maximum, the allocated prefix length will be equal to the maximum length.</p> <p>The no form of the command reverts to the default.</p>
Default	delegated-prefix-length 64 minimum 48 maximum 64
Parameters	<p><i>bits</i> — The delegated prefix length, in bits.</p> <p>Values 48 to 127</p> <p><i>prefix-length</i> — The minimum or maximum allowed prefix length, in bits.</p> <p>Values 48 to 127</p>

exclude-prefix

Syntax	[no] exclude-prefix <i>ipv6-prefix/prefix-length</i>
Context	config>router>dhcp6>server>pool
Description	<p>This command defines a prefix that to be excluded from available prefix in the pool. The typical use case is to exclude the interface address.</p> <ul style="list-style-type: none">• A held lease will be deleted if it got excluded by an exclude prefix.• An exclude range can never exclude only a part of an existing lease. If for example a /63 PD is assigned, an exclude of /64 which belongs to this /63 can NOT be configured.• A single exclude prefix can never exclude a whole include prefix.• When applying or removing an exclude prefix, the threshold stats are adjusted to reflect the actual address space and its usage.
Default	none
Parameters	<i>ipv6-prefix/prefix-length</i> — Specifies an IPv6 prefix and prefix length.
	Values
	ipv6-prefix x::x::x::x::x::x::x::x (eight 16-bit pieces)

	x - [0 to FFFF]H
	d - [0 to 255]D
prefix-length	[0 to 128]

max-lease-time

Syntax	max-lease-time [<i>max-lease-time</i>] no max-lease-time												
Context	config>router>dhcp>server>pool												
Description	This command configures the maximum lease time. The no form of the command returns the value to the default.												
Default	10 days												
Parameters	<i>time</i> — Specifies the maximum lease time. Values <table><tr><td>days</td><td><i>days</i></td><td>0 to 3650</td></tr><tr><td>hrs</td><td><i>hours</i></td><td>0 to 23</td></tr><tr><td>min</td><td><i>minutes</i></td><td>0 to 59</td></tr><tr><td>sec</td><td><i>seconds</i></td><td>0 to 59</td></tr></table>	days	<i>days</i>	0 to 3650	hrs	<i>hours</i>	0 to 23	min	<i>minutes</i>	0 to 59	sec	<i>seconds</i>	0 to 59
days	<i>days</i>	0 to 3650											
hrs	<i>hours</i>	0 to 23											
min	<i>minutes</i>	0 to 59											
sec	<i>seconds</i>	0 to 59											

min-lease-time

Syntax	min-lease-time [<i>min-lease-time</i>] no min-lease-time
Context	config>router>dhcp>server>pool config>service>vpn>dhcp>server>pool
Description	This command configures the minimum lease time. The no form of the command returns the value to the default.
Default	10 minutes
Parameters	<i>time</i> — Specifies the minimum lease time.
	Values
	days <i>days</i> 0 to 3650
	hrs <i>hours</i> 0 to 23
	min <i>minutes</i> 0 to 59
	sec <i>seconds</i> 0 to 59

minimum-free

Syntax	minimum-free <i>minimum-free</i> [percent] [event-when-depleted] no minimum-free
Context	config>router>dhcp>server>pool config>router>dhcp6>server>pool
Description	This command specifies the desired minimum number of free addresses in this pool. The no form of the command reverts to the default.
Default	1
Parameters	<i>minimum-free</i> — Specifies the minimum number of free addresses. 0 to 255 percent — Specifies that the value indicates a percentage. event-when-depleted — This parameter enables a system-generate event when all available addresses in the pool/subnet of local DHCP server are depleted.

nak-non-matching-subnet

Syntax	[no] nak-non-matching-subnet
Context	config>router>dhcp>server>pool
Description	With this command, if the local DHCPv4 server receives a DHCP request with option 50 (means client try to request a previous allocated message as described in section 3.2 of RFC 2131, <i>Dynamic Host Configuration Protocol</i>) and the address allocation algorithm ends up using a pool and the address in option50 is not in pool, then system will return a DHCP NAK, otherwise system just drop the DHCP packet.
Default	no nak-non-matching-subnet

offer-time

Syntax	offer-time [min <i>minutes</i>] [sec <i>seconds</i>] no offer-time
Context	config>router>dhcp>server>pool config>service>vpn>dhcp>server>pool
Description	This command configures the offer time. The no form of the command returns the value to the default.
Default	1 minute

Parameters	<i>time</i> — Specifies the offer time.		
	Values		
	min	<i>minutes</i>	0 to 10
	sec	<i>seconds</i>	0 to 59

options

Syntax	options
Context	config>router>dhcp>server>pool config>router>dhcp>server>pool>subnet config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host config>router>dhcp6>server>pool config>router>dhcp6>server>pool>prefix
Description	This command enables the context to configure pool options. The options defined here can be overruled by defining the same option in the local user database.
Default	none

custom-option

Syntax	custom-option <i>option-number</i> address [<i>ip-address...</i> (up to 4 max)] custom-option <i>option-number</i> hex <i>hex-string</i> custom-option <i>option-number</i> string <i>ascii-string</i> no custom-option <i>option-number</i>
Context	config>router>dhcp>server>pool>options config>router>dhcp>server>pool>subnet>options config>subscr-mgmt>loc-user-db>ipoe>host>options config>subscr-mgmt>loc-user-db>ppp>host>options config>router>dhcp6>server>pool>options config>router>dhcp6>server>pool>prefix>options
Description	This command configures specific DHCP options. The options defined here can overrule options in the local user database. The no form of the removes the option from the configuration.
Default	none
Parameters	<i>option-number</i> — specifies the option number that the DHCP server uses to send the identification strings to the DHCP client. Values 1 to 254 address <i>ip-address</i> — Specifies the IP address of this host.

hex *hex-string* — Specifies the hex value of this option.

Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)

string *ascii-string* — Specifies the value of this option.

Values Up to 127 characters maximum.

dns-server

Syntax	dns-server address [<i>ip-address...</i> (up to 4 max)] no dns-server
Context	config>router>dhcp>server>pool>options config>subscr-mgmt>loc-user-db>ipoe>host>options config>subscr-mgmt>loc-user-db>ppp>host>options config>router>dhcp6>server>pool>prefix>options
Description	This command configures the IP address of the DNS server.
Default	none
Parameters	<i>ipv6-address</i> — Specifies the IPv4 address of the DNS server. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

dns-server

Syntax	dns-server ipv6-address [<i>ipv6-address...</i> (up to 4 max)] no dns-server
Context	config>router>dhcp6>server>pool>options config>router>dhcp6>server>pool>prefix>options config>subscr-mgmt>loc-user-db>ppp>host>options6 config>subscr-mgmt>loc-user-db>ipoe>host>options6
Description	This command configures IPv6 DNS server addresses that can be used for name resolution
Default	no dns-server
Parameters	<i>ipv6-address</i> — Specifies the IPv6 address of the a DNS server.

domain-name

Syntax	domain-name domain-name no domain-name
Context	config>router>dhcp>server>pool>options

```
config>subscr-mgmt>loc-user-db>ipoe>host>options
config>router>dhcp6>server>pool>options
config>router>dhcp6>server>pool>prefix>options
config>service>vprn>dhcp>server>pool>options
config>service>vprn>dhcp6>server>pool>options
config>service>vprn>dhcp6>server>pool>prefix>options
```

Description This command configures the default domain for a DHCP client that the router uses to complete unqualified host names (without a dotted-decimal domain name).

The **no** form of the command removes the name from the configuration.

Default none

Parameters *domain-name* — Specifies the domain name for the client.

Values Up to 127 characters

lease-rebind-time

Syntax **lease-rebind-time** [*lease-rebind-time*]
no lease-rebind-time

Context config>router>dhcp>server>pool>options
config>subscr-mgmt>loc-user-db>ipoe>host>options
config>service>vprn>dhcp>server>pool>options

Description This command configures the time the client transitions to a rebinding state.

The **no** form of the command removes the time from the configuration.

Default none

Parameters *time* — Specifies the lease rebind time.

Values

days <i>days</i>	0 to 3650
hrs <i>hours</i>	0 to 23
min <i>minutes</i>	0 to 59
sec <i>seconds</i>	0 to 59

lease-renew-time

Syntax **lease-renew-time** [*lease-renew-time*]
no lease-renew-time

Context config>router>dhcp>server>pool>options
config>subscr-mgmt>loc-user-db>ipoe>host>options
config>service>vprn>dhcp>server>pool>options

Description This command configures the time the client transitions to a renew state.
The **no** form of the command removes the time from the configuration.

Default none

Parameters *time* — Specifies the lease renew time.

Values

days:	0 to 3650
hours:	0 to 23
minutes:	0 to 59
seconds	0 to 59

lease-time

Syntax **lease-time** [*lease-time*]
no lease-time

Context config>router>dhcp>server>pool>options
config>subscr-mgmt>loc-user-db>ipoe>host>options
config>service>vprn>dhcp>server>pool>options

Description This command configures the amount of time that the DHCP server grants to the DHCP client permission to use a particular IP address.

The **no** form of the command removes the lease time parameters from the configuration.

Default none

Parameters *time* — Specifies the lease time.

Values

days <i>days</i>	0 to 3650
hrs <i>hours</i>	0 to 23
min <i>minutes</i>	0 to 59
sec <i>seconds</i>	0 to 59

netbios-name-server

Syntax **netbios-name-server ip-address** [*ip-address...*(up to 4 max)]
no netbios-name-server

Context config>router>dhcp>server>pool>options
config>subscr-mgmt>loc-user-db>ppp>host>options
config>subscr-mgmt>loc-user-db>ipoe>host>options
config>service>vprn>dhcp>server>pool>options

Description	This command configures up to four Network Basic Input/Output System (NetBIOS) name server IP addresses.
Default	none
Parameters	<i>ip-address</i> — The IP address of the NetBIOS name server. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

netbios-node-type

Syntax	netbios-node-type <i>netbios-node-type</i> no netbios-node-type		
Context	config>router>dhcp>server>pool>options config>subscr-mgmt>loc-user-db>ipoe>host>options config>service>vprn>dhcp>server>pool>options		
Description	This command configures the Network Basic Input/Output System (NetBIOS) node type.		
Default	none		
Parameters	<i>netbios-node-type</i> — Specifies the netbios node type. <table> <tr> <td>Values</td><td> <p>B — Broadcast node uses broadcasting to query nodes on the network for the owner of a NetBIOS name.</p> <p>P — Peer-to-peer node uses directed calls to communicate with a known NetBIOS name server for the IP address of a NetBIOS machine name.</p> <p>M — Mixed node uses broadcast queries to find a node, and if that fails, queries a known P-node name server for the address.</p> <p>H — Hybrid node is the opposite of the M-node action so that a directed query is executed first, and if that fails, a broadcast is attempted.</p> </td></tr> </table>	Values	<p>B — Broadcast node uses broadcasting to query nodes on the network for the owner of a NetBIOS name.</p> <p>P — Peer-to-peer node uses directed calls to communicate with a known NetBIOS name server for the IP address of a NetBIOS machine name.</p> <p>M — Mixed node uses broadcast queries to find a node, and if that fails, queries a known P-node name server for the address.</p> <p>H — Hybrid node is the opposite of the M-node action so that a directed query is executed first, and if that fails, a broadcast is attempted.</p>
Values	<p>B — Broadcast node uses broadcasting to query nodes on the network for the owner of a NetBIOS name.</p> <p>P — Peer-to-peer node uses directed calls to communicate with a known NetBIOS name server for the IP address of a NetBIOS machine name.</p> <p>M — Mixed node uses broadcast queries to find a node, and if that fails, queries a known P-node name server for the address.</p> <p>H — Hybrid node is the opposite of the M-node action so that a directed query is executed first, and if that fails, a broadcast is attempted.</p>		

msap-defaults

Syntax	msap-default
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures MSAP authentication defaults.

group-interface

Syntax	group-interface <i>ip-int-name</i> [prefix { <i>port-id</i> }] [suffix { <i>port-id</i> }] no group-interface
Context	config>subscr-mgmt>loc-user-db>ipoe>host>msap-defaults config>subscr-mgmt>loc-user-db>ppp>host>msap-defaults
Description	This command configures the group interface.
Parameters	<i>ip-int-name</i> — Specifies the IP interface name. Values 32 chars max (must start with a letter) prefix { <i>port-id</i> } — Specifies the port ID as the prefix to the specified ip-int-name. suffix { <i>port-id</i> } — Specifies the port ID as the suffix to the specified ip-int-name.

policy

Syntax	policy <i>msap-policy-name</i> no policy
Context	config>subscr-mgmt config>subscr-mgmt>loc-user-db>ipoe>host>msap-defaults config>subscr-mgmt>loc-user-db>ppp>host>msap-defaults
Description	This command configures the MSAP policy.
Parameters	<i>msap-policy-name</i> — Specifies the policy name.

service

Syntax	service <i>service-id</i> no service
Context	config>subscr-mgmt>loc-user-db>ipoe>host>msap-defaults config>subscr-mgmt>loc-user-db>ppp>host>msap-defaults
Description	This command sets default service for all subscribers created based on trigger packets received on the given capture SAP in case the corresponding VSA is not included in the RADIUS authentication response. This command is applicable to capture SAP only.
Parameters	<i>service-id</i> — Specifies the service ID as an integer. Values 1-2147483648

retail-service-id

Syntax	[no] retail-service-id <i>service-id</i>
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command sets the retail-service ID for a given subscriber host.
Default	no retail-service-id

prefix

Syntax	prefix <i>ipv6-addr/prefix-length</i> [failover { local remote access-driven }] [pd] [wan-host] [create] no prefix <i>ipv6-addr/prefix-length</i>
Context	config>router>dhcp6>server>pool config>service>vpn>dhcp6>server>pool
Description	This command allocates a prefix to a pool from which Prefix Delegation prefixes and or wan addresses can be assigned.
Default	None
Parameters	<i>prefix ipv6-addr/prefix-length</i> — Specifies the prefix.

Values

ipv6-address	x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:d.d.d.d
	x [0 to FFFF]H
	d [0 to 255]D
prefix-length	[1 to 128]

failover {local | remote | access-driven} — This command designates a prefix as local, remote, or access-driven. This is used when multi-chassis synchronization is enabled.

Values

local — (default) A prefix designated as local is always used to renew the existing addresses/prefixes or to assign a new one.

remote — A prefix designated as remote is used only to renew the existing DHCP leases. The new leases will be assigned from it only after the maximum-client-lead-time + partner-down-delay time elapses.

access-driven — A prefix designated as access-driven is similar to local (a new prefix assignment as well as a renewal). However, as the prefix is shared between the redundant server pair, the following additional conditions should be met to avoid duplicate address allocations:

- A dual home access protection mechanism such as srrp or mc-lag must ensure a single active path from the dhcp client to the server.
- The dhcp relay should point to the local server only.

pd — (default) When configured, IA-PD prefixes may be allocated from this prefix.

wan-host — (default) When configured, IA-NA addresses and/or SLAAC prefixes (local-address-assignment) may be allocated from this prefix.

create — Keyword used to create the prefix configuration. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

thresholds

Syntax	thresholds
Context	config>service>vprn>dhcp6>server>pool config>router>dhcp6>server>pool
Description	This command enables the context to configure pool level thresholds.
Default	thresholds

thresholds

Syntax	thresholds
Context	config>service>vprn>dhcp6>server>pool>prefix config>router>dhcp6>server>pool>prefix
Description	This command enables the context to configure prefix level thresholds.
Default	thresholds

minimum-free

Syntax	[no] minimum-free prefix-length [<i>prefix-length</i>]
Context	config>service>vprn>dhcp6>server>pool>thresholds config>router>dhcp6>server>pool>thresholds

Description	<p>This command creates a threshold for a given prefix length on the pool level. Up to 128 thresholds could be created. For example, with minimum-free prefix-length 64, then the usage of /64 prefix in the pool is counted.</p> <p>There are two types of thresholds that could be defined at the pool level:</p> <ul style="list-style-type: none"> • Depleted — The system sends out a warning when the prefix with the configured length is no long available in the pool. • Minimum free — A percentage-based threshold which represents the minimal available percentage of prefix with the configured length in the pool. The system will send out warning if the actual percentage is lower than the configured percentage <p>Configuration of this command also enables the system stats collection for configure prefix length, which could be displayed via the show router <router-id>dhcp6 local-dhcp-server "d6" pool-threshold-stats command.</p>
Default	none
Parameters	<p><i>prefix-length</i> — Specifies the IPv6 prefix length.</p> <p>Values 1 to 128</p>

depleted-event

Syntax	[no] depleted-event
Context	config>service>vprn>dhcp6>server>pool>thresholds>minimum-free config>router>dhcp6>server>pool>thresholds>minimum-free
Description	This command enables the system to send out warnings when the prefix with the configured length is no long available in the pool.
Default	none

depleted-event

Syntax	[no] depleted-event
Context	config>service>vprn>dhcp6>server>pool>prefix>thresholds>minimum-free config>router>dhcp6>server>pool>prefix>thresholds>minimum-free
Description	<p>This command enables the system to send out a warning when the prefix with a configured length is no long available in the provisioned prefix.</p> <p>For example:</p> <pre>prefix 2001:0:0:ffe0::/50 pd wan-host create thresholds minimum-free prefix-length 64</pre>

depleted-event

With the above configuration, the system will send out a warning when there is no available /64 that can be allocated out of 2001:0:0:ffe0::/50.

Default none

minimum

Syntax **minimum percent** [*percent*]
no minimum

Context config>service>vprn>dhcp6>server>pool>thresholds>minimum-free
config>router>dhcp6>server>pool>thresholds>minimum-free

Description This command specifies a percentage based threshold which represent the minimal available percentage of the prefix with configured length in the pool. The system will send out a warning if the actual percentage is lower than the configured percentage.

Default none

Parameters **percent percent** — Specifies the percentage of used prefixes with the minimum free threshold length in the pool compared to the number of provisioned prefixes.

Values 0 to 100

minimum

Syntax **minimum** [**percent** [*percent*]] [**number** [*number*]]
no minimum

Context config>service>vprn>dhcp6>server>pool>prefix>thresholds>minimum-free
config>router>dhcp6>server>pool>prefix>thresholds>minimum-free

Description This command configures a percentage-based or number-based threshold which represents the minimal available percentage or number of the prefix with a configured length in the provisioned prefix. The system will send out a warning if the actual percentage or number is lower than the configured threshold.

For example:

```
prefix 2001:0:0:ffe0::/50 pd wan-host create
  thresholds
    minimum-free prefix-length 64
    minimum number 3
```

With the above configuration, the system will send a warning when the number of available / 64 in prefix 2001:0:0:ffe0::/50 is less than 3.

Default	none
Parameters	<p>percent [<i>percent</i>] — Specifies the percentage of used prefixes with the minimum free threshold length in the pool compared to the number of provisioned prefixes.</p> <p>Values 0 to 100</p> <p>number [<i>number</i>] — Specifies the number of prefixes.</p> <p>Values 0 to 4294967295</p>

to-client-options

Syntax	to-client-options
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the DHCP options to send to the client.

user-db

Syntax	user-db <i>name</i> no user-db
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	<p>This command specifies local user database for PPP PAP/CHAP access.</p> <p>With this configuration, system will access the specified DB again during PPP PAP/CHAP phase.</p> <p>This configuration only becomes effective when system is accessing parent DB during PPPoE discovery phase.</p>
Default	none
Parameters	<i>name</i> — Specifies the name of the local user database for PAP/CHAP access.

custom-option

Syntax	<p>custom-option <i>option-number</i> address [<i>ip-address...</i>(up to 4 max)]</p> <p>custom-option <i>option-number</i> hex <i>hex-string</i></p> <p>custom-option <i>option-number</i> string <i>ascii-string</i></p> <p>no custom-option <i>option-number</i></p>
Context	config>router>dhcp>server>pool>options config>router>dhcp>server>pool>subnet>options

	config>service>vprn>dhcp>server>pool>options
Description	<p>This command configures specific DHCP options. The options defined here can overrule options in the local user database.</p> <p>The no form of the removes the option from the configuration.</p>
Default	none
Parameters	<p><i>option-number</i> — specifies the option number that the DHCP server uses to send the identification strings to the DHCP client.</p> <p>Values 1 to 254</p> <p>address <i>ip-address</i> — Specifies the IP address of this host.</p> <p>hex <i>hex-string</i> — Specifies the hex value of this option.</p> <p>Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)</p> <p>string <i>ascii-string</i> — Specifies the value of this option.</p> <p>Values Up to 127 characters maximum.</p>

option

Syntax	<p>option <i>option-number</i> address <i>ipv4-address</i> [<i>ipv4-address...</i>(up to 4 max)]</p> <p>option <i>option-number</i> hex <i>hex-string</i></p> <p>option <i>option-number</i> string <i>ascii-string</i></p> <p>no option <i>option-number</i></p>
Context	<p>config>subscr-mgmt>loc-user-db>ipoe>host>to-client-options>ipv4</p> <p>config>subscr-mgmt>loc-user-db>ppp>host>to-client-options>ipv4</p>
Description	<p>This command configures DHCPv4 options via LUDB that will be passed in all DHCP messages to the client. The options will be blindly appended to any options already present in the DHCP message. In other words, there is no intelligent merging of the options where overlapping options from different sources are further evaluated to determine whether only one option or multiple options should be returned to the client.</p> <p>Multiple DHCP options can be configured at the same time although each option requires its own option statement. Those options are equivalent to RADIUS VSAs Alc-ToClient-Dhcp4-Options.</p> <p>DHCPv4 options can be provided via DHCPv4 server in the relay case. In addition, DHCPv4 options provided via LUDB or RADIUS can be supplied and consequently appended to the already existing options. In case that DHCPv4 options are provided simultaneously via LUDB and RADIUS, the RADIUS as a source of DHCPv4 option will be blocked and the options supplied via LUDB will be passed to the client. This is valid for the relay and proxy case.</p> <p>Any DHCP option may be encoded in the option statement. An example of the option statement for DHCPv4 default-gateway is given below:</p>

option 3 192.168.1.254

DHCPv4 options may be fixed length or variable length. They are appended at the end of DHCPv4 messages. All options begin with a tag octet, which uniquely identifies the option. Fixed-length options without data consist of only a tag octet. Only options 0 and 255 are fixed length. All other options are variable-length.

Default no option

Parameters *option-number* — Number of the option. This can be a well known option, or a an anonymous option.

address *ipv4-address* — Specifies an IPv4 address as an option.

hex *hex-string* — Specifies options coded as Hex characters.

string *ascii-string* — Specifies options coded as an ASCII string.

subnet

Syntax **subnet** {*ip-address/mask* | *ip-address netmask*} [**create**]
no subnet {*ip-address/mask* | *ip-address netmask*}

Context config>router>dhcp>server>pool
config>service>vprn>dhcp>server>pool

Description This command creates a subnet of IP addresses to be served from the pool. The subnet cannot include any addresses that were assigned to subscribers without those addresses specifically excluded. When the subnet is created no IP addresses are made available until a range is defined.

Default none

Parameters *ip-address* — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

mask — The subnet mask in dotted decimal notation. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252.

Note: A mask of 255.255.255.255 is reserved for system IP addresses.

netmask — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.

create — Keyword used to create the subnet. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

address-range

Syntax	[no] address-range <i>start-ip-address end-ip-address</i> [failover { local remote }]
Context	config>router>dhcp>server>pool>subnet config>service>vprn>dhcp>server>pool
Description	This command configures a range of IP addresses to be served from the pool. All IP addresses between the start and end IP addresses will be included (other than specific excluded addresses).
Default	none
Parameters	<p><i>start-ip-address</i> — Specifies the start address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>end-ip-address</i> — Specifies the end address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p>failover local — Specifies that the DHCP server failover control type is in control under normal operation.</p> <p>failover remote — Specifies that the remote DHCP server failover system is in control under normal operation.</p>

drain

Syntax	[no] drain
Context	config>service>vprn>dhcp>server>pool>subnet
Description	<p>This command subnet draining which means no new leases can be assigned from this subnet and existing leases are cleaned up upon renew/rebind.</p> <p>The no form of the command means the subnet is active and new leases can be assigned from it.</p>

exclude-addresses

Syntax	[no] exclude-addresses <i>start-ip-address</i> [<i>end-ip-address</i>]
Context	config>router>dhcp>server>pool>subnet config>service>vprn>dhcp>server>pool>subnet
Description	This command specifies a range of IP addresses that excluded from the pool of IP addresses in this subnet.

Default	none
Parameters	<p><i>start-ip-address</i> — Specifies the start address of this range to exclude. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>end-ip-address</i> — Specifies the end address of this range to exclude. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p>

maximum-declined

Syntax	maximum-declined <i>maximum-declined</i> no maximum-declined
Context	config>router>dhcp>server>pool>subnet config>service>vprn>dhcp>server>pool>subnet
Description	This command configures the maximum number of declined addresses allowed.
Default	64
Parameters	<p><i>maximum-declined</i> — Specifies the maximum number of declined addresses allowed.</p> <p>Values 0 to 4294967295</p>

minimum-free

Syntax	minimum-free <i>minimum-free</i> [percent] [event-when-depleted] no minimum-free
Context	config>router>dhcp>server>pool>subnet config>router>dhcp6>server>pool>subnet config>service>vprn>dhcp>server>pool>subnet config>service>vprn>dhcp6>server>pool>subnet
Description	This command configures the minimum number of free addresses in this subnet. If the actual number of free addresses in this subnet falls below this configured minimum, a notification is generated.
Default	1
Parameters	<p><i>minimum-free</i> — Specifies the minimum number of free addresses in this subnet.</p> <p>Values 0 to 255</p> <p>percent — Specifies that the value indicates a percentage.</p>

event-when-depleted — This parameter enables a system-generate event when all available addresses in the pool/subnet of local DHCP server are depleted.

default-router

Syntax	default-router <i>ip-address</i> [<i>ip-address...</i> (up to 4 max)] no default-router
Context	config>router>dhcp>server>pool>subnet>options config>subscr-mgmt>loc-user-db>ipoe>host>options config>service>vprn>dhcp6>server>pool>subnet
Description	<p>This command configures the IP address of the default router for a DHCP client. Up to four IP addresses can be specified.</p> <p>The no form of the command removes the address(es) from the configuration.</p>
Default	none
Parameters	<i>ip-address</i> — Specifies the IP address of the default router. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

subnet-mask

Syntax	subnet-mask <i>ip-address</i> no subnet-mask
Context	config>router>dhcp>server>pool>subnet>options config>subscr-mgmt>loc-user-db>ipoe>host>options
Description	<p>This command specifies the subnet-mask option to the client. The mask can either be defined (for supernetting) or taken from the pool address.</p> <p>The no form of the command removes the address from the configuration.</p>
Default	none
Parameters	<i>ip-address</i> — Specifies the IP address of the subnet mask. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

use-gi-address

Syntax	use-gi-address [scope <i>scope</i>]
Context	config>router>dhcp>server

```
config>service>vprn>dhcp>server
```

Description This command enables the use of gi-address matching. If the gi-address flag is enabled, a pool can be used even if a subnets is not found. If the local-user-db-name is not used, the gi-address flag is used and addresses are handed out by GI only. If a user must be blocked from getting an address the server maps to a local user database and configures the user with no address.

A pool can include multiple subnets. Since the GI is shared by multiple subnets in a subscriber interface the pool may provide IP addresses from any of the subnets included when the GI is matched to any of its subnets. This allows a pool to be created that represents a sub-int.

Default no use-gi-address

Parameters **scope** *scope* — Specifies if addresses are handed out for a certain subnet where the gi-address belongs to only or for all subnets part of the pool.

Values **subnet** — Addresses are only handed out for the subnet where the gi-address is part of
pool — All subnets part of the pool which contain subnet where the gi-address is part of can hand out addresses.

use-pool-from-client

Syntax **use-pool-from-client** *delimiter delimiter*
use-pool-from-client
no use-pool-from-client

Context config>router>dhcp>server
config>service>vprn>dhcp>server

Description This command enables the use of the pool indicated by DHCP client. When enabled, the IP address pool to be used by this server is the pool is indicated by the vendor-specific sub-option 13 of the DHCP option 82. When disabled or if there is no sub-option 13 in the DHCP message, the pool selection falls back to the “use-gi-address” configuration.

Default no use-pool-from-client

Parameters **delimiter** *delimiter* — A single ASCII character specifies the delimiter of separating primary and secondary pool names in Option82 VSO.

user-ident

Syntax **user-ident** *user-ident*
no user-ident

Context config>router>dhcp>server

	config>service>vprn>dhcp>server
Description	This command configures the user identification method for the DHCPv4 server.
Default	mac-circuit-id
Parameters	<i>user-ident</i> — Specifies the user identification method
Values	client-id — Specifies to use the DHCPv4 client identifier as the user identification method circuit-id — Specifies to use the circuit identifier of the DHCPv4 client as the user identification method mac — Specifies to use the MAC address of the DHCPv4 client as the user identification method mac-circuit-id — Specifies to use the MAC address and circuit identifier of the DHCPv4 client as the user identification method remote-id — Specifies to use the MAC address of the remote end as the user identification method

user-ident

Syntax	user-ident <i>user-ident</i> no user-ident
Context	config>router>dhcp6>server config>service>vprn>dhcp6>server
Description	This command configures the keys for identification of the DHCPv6 lease being held in the lease-database (for configured period after lease timeout). Subscriber requesting a lease via DHCPv6 that matches an existing lease based on this configured key is handed the matched prefix or address. This allows address and prefix “stickiness” for DHCPv6 assigned prefixes (IA_NA or PD).
Default	duid
Parameters	<i>user-ident</i> — Specifies the user identification method
Values	duid — Specifies the IPv6 DHCP unique identifier from DHCPv6. interface-id — Specifies the IPv6 interface-id option. interface-id-link-local — Specifies the interface-id and link-local address.

use-link-address

Syntax	use-link-address [scope <i>scope</i>] no use-link-address
Context	config>router>dhcp6>server config>service>vprn>dhcp6>server
Description	If configured, local pool selection for v6 address or prefix assignment will use the configured link-address under relay configuration. The selected pool will contain a prefix covering the link-address. The scope option defines the scope for the match. With scope subnet , the prefix or address selection is limited to the prefix in the pool that covers the link-address. With scope pool , all the prefixes in the selected pool are eligible for assignment.
Default	scope subnet
Parameters	scope <i>scope</i> — Specifies the scope of the IP address selection. Values subnet — Specifies that the prefix or address selection is limited to the prefix in the pool that covers the link address. pool — Specifies that all prefixes in the selected pool are eligible for assignment.

user-db

Syntax	user-db <i>local-user-db-name</i> [create] no user-db
Context	config>router>dhcp>server config>subscr-mgmt
Description	This command configures a local user database for authentication.
Default	not enabled
Parameters	<i>local-user-db-name</i> — Specifies the name of a local user database. create — Keyword used to create the local user database. The create keyword requirement can be enabled/disabled in the environment>create context.

3.8.2.1.4 Service Commands

dhcp6

Syntax	dhcp6
Context	<pre> config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp config>service>ies>interface config>system config>service>vprn config>service>vprn>interface config>service>vprn>sub-if config>service>vprn>sub-if>grp-if config>service>ies>sub-if>group-grp-if config>service>vprn>sub-if>grp-if>ipv6 config>service>ies>sub-if>grp-if>ipv6 config>service>ies>sub-if config>service>ies>sub-if>grp-if </pre>
Description	This command enables the context to configure DHCP6 parameters.

relay

Syntax	[no] relay
Context	<pre> config>service>vprn>sub-if>grp-if>ipv6>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6 config>service>vprn>sub-if>ipv6>dhcp6 config>service>ies>sub-if>ipv6>dhcp6 </pre>
Description	This command enables the context to configure DHCPv6 relay parameters for this interface.

client-applications

Syntax	client-applications {[dhcp] [ppp]} no client-applications
Context	<pre> config>service>vprn>sub-if>dhcp config>service>ies>sub-if>dhcp config>service>vprn>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>dhcp config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy config>service>vprn>sub-if>grp-if>ipv6>dhcp6>relay config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy </pre>

```

config>service>ies>sub-if>grp-if>ipv6>dhcp6>relay
config>service>vprn>sub-if>ipv6>dhcp6>proxy
config>service>vprn>sub-if>ipv6>dhcp6>relay
config>service>ies>sub-if>ipv6>dhcp6>proxy
config>service>ies>sub-if>ipv6>dhcp6>relay

```

Description	<p>This command enables DHCP relay and proxy-server for the configured client types.</p> <p>The no form of the command resets the default client application (dhcp).</p>
Default	client-applications dhcp
Parameters	<p>dhcp — Enables IPoE clients to use the DHCP relay or proxy-server</p> <p>ppp — Enables PPPoE clients to use the DHCP relay or proxy-server that PPPoE will attempt to request an IP address for a PPPoE client from the DHCP server(s) assigned to PPPoE node.</p>

match-circuit-id

Syntax	[no] match-circuit-id
Context	<pre> config>service>ies>sub-if>grp-if>dhcp config>service>vprn>sub-if>dhcp config>service>vprn>sub-if>grp-if>dhcp </pre>
Description	<p>This command enables matching Option 82 circuit ID on relayed DHCP packet matching.</p> <p>For Routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked. When a response is received from the server the virtual router ID, transaction ID, and client HW MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client HW MAC address are not guaranteed to be unique.</p> <p>When the match-circuit-id command is enabled this part of the key is used to guarantee correctness in the lookup. This is only needed when are dealing with an IP aware DSLAM that proxies the client HW mac address.</p>
Default	no match-circuit-id

lease-populate

Syntax	<p>lease-populate [<i>nbt-of-entries</i>]</p> <p>no lease-populate</p>
Context	<pre> config>service>vpls>if>dhcp>option config>service>ies>if>dhcp>option config>subscr-mgmt>msap-policy>vpls-only>dhcp </pre>

```
config>service>vpls>sap>dhcp
config>service>ies>if>dhcp
config>service>vprn>if>dhcp
config>service>ies>sub-if>grp-if>dhcp
config>service>vprn>sub-if>grp-if>dhcp
config>service>vprn>sub-if>dhcp
```

Description This command enables dynamic host lease state management for SAPs.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the MSAP.

The optional number-of-entries parameter is used to define the number lease state table entries allowed for an MSAP or IP interface. If number-of-entries is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- Populate an MSAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.
- Generate dynamic ARP replies if **arp-reply-agent** is enabled.

The **no** form of the command disables dynamic host lease state management for the MSAP.

Default no lease-populate

lease-populate

Syntax **lease-populate** [*nbr-of-leases*]
lease-populate [*nbr-of-leases*] **I2-header** [*mac ieee-address*]
no lease-populate

Context config>subscr-mgmt>msap-policy>vpls-only>dhcp
config>service>vpls>sap>dhcp
config>service>ies>if>dhcp
config>service>vprn>if>dhcp
config>service>ies>sub-if>grp-if>dhcp
config>service>vprn>sub-if>grp-if>dhcp
config>service>vprn>sub-if>dhcp

Description This command enables and disables dynamic host DHCPv4 lease state management for SAPs.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.

The optional number-of-entries parameter defines the number lease state table entries allowed.

- for this SAP in case of a VPLS service
- for this interface in case of an IES or VPRN interface
- for each SAP in case of an IES or VPRN group-interface
- for this interface in case of an IES or VPRN retail subscriber-interface

If number-of-entries is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- Populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.
- Populate the system's ARP cache based on the arp-populate configuration. Applicable to IES and VPRN interfaces or group-interfaces.
- Populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address
- Generate dynamic ARP replies if **arp-reply-agent** is enabled. Applicable to VPLS service SAPs

Default no lease-populate

Parameters *nbr-of-leases* — Specifies the number of DHCPv4 leases allowed.

Values 1 to 32767
 1 to 65535 (chassis-mode d, SF/CPM-4 or later)
 1 to 1262143 (chassis-mode d, SF/CPM-4 or later, retail
 subscriber interfaces only)

l2-header — Indicates a mode of operation where anti-spoof entry associated with the given DHCP state is created based on the MAC address from the Layer 2 header. The Layer 2 header flag is not set by default. This parameter is only applicable for group-interfaces.

mac — Specifies that the provisioned ieee-address will be used in the anti-spoofing entries for this SAP. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a tools perform command is issues for the lease. This parameter is only applicable for group-interfaces.

option

Syntax	[no] option
Context	config>service>vpls>sap>dhcp config>service>vpls>sap>dhcp6 config>service>ies>if>dhcp config>service>vprn>if>dhcp config>service>vprn>sub-if>dhcp config>service>vprn>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>dhcp
Description	This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options. The no form of this command returns the system to the default.
Default	no option

action

Syntax	action {replace drop keep} no action
Context	config>service>ies>if>dhcp>option config>service>ies>sub-if>grp-if>dhcp config>service>vpls>sap>dhcp>option config>service>vprn>if>dhcp>option config>service>vprn>sub-if>grp-if>dhcp>option
Description	This command configures the Relay Agent Information Option (Option 82) processing. The no form of this command returns the system to the default value.
Default	The default is to keep the existing information intact.

- Parameters**
- replace** — In the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).
 - drop** — The DHCP packet is dropped if an Option 82 field is present, and a counter is incremented.
 - keep** — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is forwarded towards the client.
 In Vendor-Specific Options (VSOs) scenarios, the behavior is slightly different. Even with the action=keep, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.
 If no Option 82 field is present, the router will not create the Option 82 field - in that case, no VSO will be added to the message.

circuit-id

- Syntax** **circuit-id [ascii-tuple | vlan-ascii-tuple]**
no circuit-id
- Context** config>service>vpls>sap>dhcp>option
- Description** When enabled, the router sends an ASCII-encoded tuple in the **circuit-id** sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by "|".
- In order to send a tuple in the circuit ID, the **action replace** command must be configured in the same context.
- If disabled, the **circuit-id** sub-option of the DHCP packet will be left empty.
- The **no** form of this command returns the system to the default.
- Default** circuit-id
- Parameters**
- ascii-tuple** — Specifies that the ASCII-encoded concatenated tuple consisting of the access-node-identifier, service-id, and interface-name is used.
 - vlan-ascii-tuple** — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.

circuit-id

- Syntax** **circuit-id [ascii-tuple | ifindex | sap-id | vlan-ascii-tuple]**

no circuit-id

Context	config>service>ies>if>dhcp>option config>service>ies>sub-if>grp-if>dhcp>option config>service>vprn>if>dhcp>option config>service>vprn>sub-if>grp-if>dhcp>option
Description	<p>When enabled, the router sends an ASCII-encoded tuple in the circuit-id sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by " ".</p> <p>In order to send a tuple in the circuit ID, the action replace command must be configured in the same context.</p> <p>If disabled, the circuit-id sub-option of the DHCP packet will be left empty.</p> <p>The no form of this command returns the system to the default.</p>
Default	circuit-id
Parameters	<p>ascii-tuple — Specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by " ".</p> <p>ifindex — Specifies that the interface index will be used. (The If Index of a router interface can be displayed using the command show>router>interface>detail)</p> <p>sap-id — Specifies that the SAP identifier will be used.</p> <p>vlan-ascii-tuple — Specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q-encapsulated ports only. Thus, when the option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p>

remote-id

Syntax	remote-id [mac string <i>string</i>] no remote-id
Context	config>service>ies>if>dhcp>option config>service>ies>sub-if>grp-if>dhcp>option config>service>ies>sub-if>grp-if>dhcp>option config>service>vpls>sap>dhcp>option config>service>vprn>if>dhcp>option config>subscr-mgmt>msap-policy>vpls-only>dhcp>option
Description	<p>This command specifies what information goes into the remote-id sub-option in the DHCP relay packet.</p> <p>If disabled, the remote-id sub-option of the DHCP packet will be left empty.</p> <p>The no form of this command returns the system to the default.</p>

Default	remote-id
Parameters	mac — This keyword specifies the MAC address of the remote end is encoded in the sub-option. string <i>string</i> — Specifies the remote-id.

vendor-specific-option

Syntax	[no] vendor-specific-option
Context	config>service>vpls>sap>dhcp>option config>service>ies>if>dhcp>option config>service>vprn>if>dhcp>option config>service>ies>sub-if>grp-if>dhcp>option config>service>vprn>sub-if>grp-if>dhcp>option
Description	This command configures the Nokia vendor-specific sub-option of the DHCP relay packet.

client-mac-address

Syntax	[no] client-mac-address
Context	config>service> ies>if>dhcp>option>vendor config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor
Description	This command enables the sending of the MAC address in the Nokia vendor-specific sub-option of the DHCP relay packet. The no form of the command disables the sending of the MAC address in the Nokia vendor-specific sub-option of the DHCP relay packet.

pool-name

Syntax	[no] pool-name
Context	config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor
Description	This command sends the pool name in the Nokia vendor specific suboption of the DHCP relay packet. The no form of the command disables the sending.

sap-id

Syntax	[no] sap-id
Context	<pre>config>service>vpls>sap>dhcp>option>vendor config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor</pre>
Description	<p>This command enables the sending of the SAP ID in the Nokia vendor-specific sub-option of the DHCP relay packet.</p> <p>The no form of the command disables the sending of the SAP ID in the Nokia vendor-specific sub-option of the DHCP relay packet.</p>

service-id

Syntax	[no] service-id
Context	<pre>config>service>vpls>sap>dhcp>option>vendor config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor</pre>
Description	<p>This command enables the sending of the service ID in the Nokia vendor-specific sub-option of the DHCP relay packet.</p> <p>The no form of the command disables the sending of the service ID in the Nokia vendor-specific sub-option of the DHCP relay packet.</p>

string

Syntax	[no] string <i>text</i>
Context	<pre>config>service>vpls>sap>dhcp>option>vendor config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor</pre>
Description	<p>This command specifies the string in the Nokia vendor-specific sub-option of the DHCP relay packet.</p> <p>The no form of the command returns the default value.</p>
Parameters	<p><i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" ").</p>

system-id

Syntax	[no] system-id
Context	config>service>vpls>sap>dhcp>option>vendor config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor config>service>ies>sub-if>grp-if>dhcp>option>vendor
Description	This command specifies whether the system-id is encoded in the Nokia vendor-specific sub-option of Option 82.

filter

Syntax	filter filter-id no filter
Context	config>service>ies>sub-if>grp-if>ipv6>dhcp6 config>service>vprn>sub-if>grp-if>ipv6>dhcp6
Description	This command assigns a DHCP6 filter to the group-interface.
Default	no filter
Parameters	<i>filter-id</i> — Specifies the DHCP6 filter ID. Values 1 to 65535

override-slaac

Syntax	[no] override-slaac
Context	config>service>vprn>sub-if>ipv6>dhcp6 config>service>ies>sub-if>ipv6>dhcp6 config>service>vprn>sub-if>grp-if>ipv6>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6
Description	This command allows a DHCP IA_NA address to override and replace a host existing SLAAC address. When this feature is enabled, a subscriber SLAAC address is removed once the DHCP IA_NA address assignment is completed. If used with conjunction with the allow-multiple-wan-address command, the DHCP IA_NA address will also override the SLAAC address.

pd-managed-route

Syntax	pd-managed-route [next-hop {ipv4 ipv6}] no pd-managed-route
---------------	--

Context config>service>vprn>sub-if>ipv6>dhcp6
 config>service>ies>sub-if>ipv6>dhcp6
 config>service>vprn>sub-if>grp-if>ipv6>dhcp6
 config>service>ies>sub-if>grp-if>ipv6>dhcp6

Description This command enables DHCP IA-PD (delegated prefix) to be modeled as managed (framed) route instead of as a subscriber-host. Antispoof filtering for the subscriber host associated with the IA-PD route must be set to **nh-mac**. The subscriber specific parameters (such as **sla-profile** or **sub-profile**) will be ignored during the authentication phase because IA-PD is not modeled as a subscriber host. Other subscriber host-specific functions (for example, host overrides via CoA or host accounting) are not possible with a PD as the managed route.

By default, or when configured with the **next-hop ipv6** parameter, the next-hop for PD managed route is an IPv6 WAN sub-host (DHCP IA-NA or SLAAC) with the same mac address as the one in the DHCP lease state for the managed IA-PD. The DHCP IA-NA next-hop host will always override the SLAAC next-hop host if both are available. If the IPv6 next-hop is not present when the framed IA-PD is instantiated, the IA-PD will be set up but the PD managed route will not be installed in the IPv6 route table and the DHCPv6 lease state for the IA-PD will have the managed route status (DHCP6 MRt Status) set to “noNextHop”.

When configured with the **next-hop ipv4** parameter the next-hop for PD managed route is a DHCPv4 sub-host that belongs to the same IPoE session or PPPoE session. For IPoE, **ipoe-session** must be enabled on the group-interface. If **ipoe-session** is disabled, an IPv4 next-hop will not be found. If the IPv4 next-hop is not found or not present at the time when the framed IA-PD is instantiated, the IA-PD will be set up but the PD managed route will not be installed in the IPv6 route table. In this case, the DHCPv6 lease state for the IA-PD will have the managed route status (DHCP6 MRt Status) set to “noNextHop”.

Note: IPv6 filters, QoS IPv6 criteria, and IPv6 multicast are not supported for DHCPv6 IA-PD as managed route pointing to an IPv4 subscriber host as next-hop.

The DHCP IA-PD modeled as a route is displayed differently than regular subscriber hosts in **show** commands related to subscriber host state. The PD managed route is always shown directly below the host it is using as the next hop. The forwarding status of the PD managed route is also shown, where (N) indicate that the PD managed route is not forwarding. In addition, DHCP IA-PD route is displayed as a managed route for the corresponding IPv6 subscriber host (DHCP IA-NA or SLAAC) or DHCPv4 subscriber host.

DHCP IA-PD information for managed IA-PD route is still maintained in the DHCPv6 lease state.

Default no pd-managed-route

Parameters	next-hop {ipv4 ipv6} — Specifies the next-hop type for the DHCP IA-PD managed route.
Values	<p>ipv4 - The next-hop for PD managed route is a DHCPv4 sub-host that belongs to the same IPoE session (based on the IPoE session key which is sap-mac by default). IPoE session must be enabled on the group-interface.</p> <p>ipv6 - The next-hop for PD managed route is an IPv6 WAN sub-host (DHCP IA-NA or SLAAC) with the same MAC address as the one in the DHCP lease state for the managed IA-PD. This is the default when no next-hop is specified.</p>

enable-ingress-stats

Syntax	[no] enable-ingress-stats
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	<p>This command enables the collection of ingress interface IP stats. This command is only applicable to IP statistics, and not to uRPF statistics.</p> <p>If enabled, then the following statistics are collected:</p> <ul style="list-style-type: none"> • IPv4 offered packets • IPv4 offered octets • IPv6 offered packets • IPv6 offered octets <p>Octet statistics for IPv4 and IPv6 bytes at IP interfaces include the Layer 2 frame overhead.</p>
Default	no enable-ingress-stats

duid

Syntax	duid <i>duid</i> [<i>iaid</i> <i>iaid</i>] no duid
Context	config>service>ies>if>ipv6>dhcp6>pfx-delegate>prefix
Description	This command configures the DHCP Unique Identifier (DUID) of the DHCP client.
Parameters	<i>duid</i> — Specifies the ID of the requesting router. If set to a non zero value the prefix defined will only be delegated to this router. If set to zero, the prefix will be delegated to any requesting router.

iaid *iaid* — Specifies the identity association identification (IAID) from the requesting router that needs to match in order to delegate the prefix defined in this row. If set to 0 no match on the received IAID is done.

preferred-lifetime

Syntax	preferred-lifetime [days <i>days</i>] [hrs <i>hours</i>] [min <i>minutes</i>] [sec <i>seconds</i>] preferred-lifetime infinite no preferred-lifetime								
Context	config>service>ies>if>ipv6>dhcp6>pfx-delegate>prefix config>service>vprn>if>ipv6>dhcp6>pfx-delegate>prefix config>service>vprn>sub-if>ipv6>dhcp6>proxy config>service>ies>sub-if>ipv6>dhcp6>proxy config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy								
Description	This command configures the IPv6 prefix/mask preferred life time. The preferred-lifetime value cannot be bigger than the valid-lifetime value. The no form of the command reverts to the default value.								
Default	604800 seconds (7 days)								
Parameters	<i>preferred-lifetime</i> — Specifies the preferred lifetime. Values <table><tr><td>days <i>days</i></td><td>0 to 3650</td></tr><tr><td>hrs <i>hours</i></td><td>0 to 23</td></tr><tr><td>min <i>minutes</i></td><td>0 to 59</td></tr><tr><td>sec <i>seconds</i></td><td>0 to 5</td></tr></table>	days <i>days</i>	0 to 3650	hrs <i>hours</i>	0 to 23	min <i>minutes</i>	0 to 59	sec <i>seconds</i>	0 to 5
days <i>days</i>	0 to 3650								
hrs <i>hours</i>	0 to 23								
min <i>minutes</i>	0 to 59								
sec <i>seconds</i>	0 to 5								

infinite — Specifies that the remaining time will never expire.

Note: The value **4294967295** seconds is interpreted as infinite.

preferred-lifetime

Syntax	preferred-lifetime <i>seconds</i> preferred-lifetime infinite no preferred-lifetime
Context	config>service>ies>sub-if>grp-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>pfx-opt

	config>service>ies>sub-if>ipv6>rtr-adv>pfx-opt config>service>vprn>sub-if>ipv6>rtr-adv>pfx-opt
Description	This command specifies the remaining time for this prefix to be preferred, thus time until deprecation.
Default	3600
Parameters	<i>seconds</i> — Specifies the time for the prefix to remain preferred on this group-interface in seconds. Values 0 to 4294967295 <i>infinite</i> — Specifies that the remaining time will never expire.

Note: The value **4294967295** seconds is interpreted as infinite.

valid-lifetime

Syntax	valid-lifetime <i>seconds</i> valid-lifetime <i>infinite</i> no valid-lifetime
Context	config>service>ies>if>ipv6>dhcp6>pfx-delegate>prefix config>service>vprn>sub-if>grp-if>ipv6>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6
Description	This command configures the time, in seconds, that the prefix is valid. The maximum value 4294967295 is considered equal to infinity. The no form of the command reverts to the default value.
Default	2592000 seconds (30 days)
Parameters	<i>seconds</i> — Specifies the time, in seconds, that this prefix remains valid. Values 1 to 4294967294 <i>infinite</i> — Specifies that this prefix remains valid infinitely.

valid-lifetime

Syntax	valid-lifetime <i>seconds</i> valid-lifetime <i>infinite</i> no valid-lifetime
Context	config>service>ies>sub-if>ipv6>rtr-adv>pfx-opt

```
config>service>ies>sub-if>grp-if>ipv6>rtr-adv>pfx-opt
config>service>vprn>sub-if>ipv6>rtr-adv>pfx-opt
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv>pfx-opt
```

Description	This command specifies the remaining time for this prefix to be valid for the purpose of on-link determination.
Default	86400 seconds
Parameters	<i>seconds</i> — Specifies the time for the prefix to remain valid on this interface in seconds. Values 0 to 4294967295 <i>infinite</i> — Specifies that the remaining time will never expire.

valid-lifetime

Syntax	valid-lifetime [<i>valid-lifetime</i>]								
Context	config>service>vprn>dhcp6>local-dhcp-server>pool>prefix								
Description	This command configures the valid lifetime for the IPv6 prefix or address in the option.								
Default	1 day								
Parameters	<i>valid-lifetime</i> — Specifies the valid lifetime. Values <table><tr><td>days <i>days</i></td><td>0 to 3650</td></tr><tr><td>hrs <i>hours</i></td><td>0 to 23</td></tr><tr><td>min <i>minutes</i></td><td>0 to 59</td></tr><tr><td>sec <i>seconds</i></td><td>0 to 5</td></tr></table>	days <i>days</i>	0 to 3650	hrs <i>hours</i>	0 to 23	min <i>minutes</i>	0 to 59	sec <i>seconds</i>	0 to 5
days <i>days</i>	0 to 3650								
hrs <i>hours</i>	0 to 23								
min <i>minutes</i>	0 to 59								
sec <i>seconds</i>	0 to 5								

python-policy

Syntax	python-policy <i>name</i> no python-policy
Context	config>service>ies>if>dhcp config>service>vprn>if>dhcp>
Description	This command specifies the python-policy to be used for DHCPv4 relay.
Parameters	<i>name</i> — Specifies the name of an existing python script up to 32 characters in length.

python-policy

Syntax	python-policy <i>name</i>
---------------	----------------------------------

no python-policy

Context	config>service>vprn>sub-if config>service>vprn>sub-if>ipv6>dhcp6 config>service>ies>sub-if>ipv6>dhcp6 config>service>ies>if>ipv6>dhcp6-relay config>service>vprn>if>ipv6>dhcp6-relay
Description	This command specifies the python-policy to be used for DHCPv6 relay.
Parameters	<i>name</i> — Specifies the name of an existing python script up to 32 characters in length.

emulated-server

Syntax	emulated-server <i>ip-address</i> no emulated-server
Context	config>service>vpls>sap>dhcp>proxy-server config>service>ies>if>dhcp>proxy-server config>service>ies>sub-if>grp-if>dhcp>proxy-server config>service>vprn>dhcp>proxy config>service>vprn>sub-if>grp-if>dhcp config>service>vprn>if>dhcp>proxy
Description	<p>This command configures the IP address which will be used as the DHCP server address in the context of the SAP. Typically, the configured address should be in the context of the subnet represented by the service.</p> <p>The no form of this command reverts to the default setting. The local proxy server will not become operational without the emulated-server address being specified.</p>
Parameters	<i>ip-address</i> — Specifies the emulated server's IP address. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

lease-time

Syntax	lease-time [<i>lease-time</i>] [override] no lease-time
Context	config>service>vpls>sap>dhcp>proxy-server config>service>ies>if>dhcp>proxy-server config>service>ies>sub-if>grp-if>dhcp>proxy-server config>service>vprn>if>dhcp>proxy config>service>vprn>sub-if>grp-if>dhcp>proxy-server

Description	<p>This command defines the length of lease-time that will be provided to DHCP clients. By default the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server.</p> <p>The no form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.</p>								
Default	7 days 0 hours 0 seconds								
Parameters	<p>override — Specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients.</p> <p>radius-override — Supported only in the config>service>vpls>sap>dhcp>proxy-server context, specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients.</p> <p><i>lease-time</i> — Specifies the length of lease-time that will be provided to DHCP clients</p> <table><tr><td>days <i>days</i></td><td>0 to 3650</td></tr><tr><td>hrs <i>hours</i></td><td>0 to 23</td></tr><tr><td>min <i>minutes</i></td><td>0 to 59</td></tr><tr><td>sec <i>seconds</i></td><td>0 to 5</td></tr></table>	days <i>days</i>	0 to 3650	hrs <i>hours</i>	0 to 23	min <i>minutes</i>	0 to 59	sec <i>seconds</i>	0 to 5
days <i>days</i>	0 to 3650								
hrs <i>hours</i>	0 to 23								
min <i>minutes</i>	0 to 59								
sec <i>seconds</i>	0 to 5								

snoop

Syntax	snoop no snoop
Context	config>service>vpls>sap>dhcp config>service>vpls>sap>dhcp6 config>service>vpls>spoke-sdp>dhcp config>service>vpls>mesh-sdp>dhcp config>service>vprn>if>dhcp>option
Description	<p>This command enables DHCP snooping of DHCP messages on the SAP or SDP. Enabling DHCP snooping on interfaces (SAPs and SDP bindings) is required where DHCP messages important to lease state table population are received, or where Option 82 information is to be inserted. This includes interfaces that are in the path to receive messages from either DHCP servers or from subscribers.</p> <p>Use the no form of the command to disable DHCP snooping on the specified SAP or SDP binding.</p>
Default	no snoop dhcp6

dhcp-user-db

Syntax	dhcp-user-db <i>local-user-db</i> no dhcp-user-db
Context	config>service>vpls>sap
Description	This command enabled access to LUDB for DHCPv4 hosts under the capture SAP. The name of this local user database must match the name of local user database configured under the config>service>vprn/ies>subscr-intf>group-intf>dhcp hierarchy.
Default	no dhcp-user-db
Parameters	<i>local-user-db</i> — Specifies the name of the local-user-database up to 32 characters max.

dhcp-python-policy

Syntax	dhcp-python-policy <i>policy-name</i> no dhcp-python-policy
Context	config>service>vpls>sap
Description	This command specifies the name of the Python policy. The Python policy is created in the config>python>python-policy <i>name</i> context. The no form of the command reverts to the default.
Default	none
Parameters	<i>policy-name</i> — Specifies a Python policy name up to 32 characters in length.

dhcp6

Syntax	dhcp6
Context	config>service>vpls>sap config>service>ies>sub-if>grp-if>ipv6 config>service>vprn>sub-if>grp-if>ipv6
Description	This command configures DHCP6 parameters for this SAP.

interface-id

Syntax	interface-id interface-id <i>ascii-tuple</i> no interface-id
---------------	---

Context	config>service>ies>if>ipv6>dhcp6>option config>service>vprn>if>ipv6>dhcp6>option config>service>vpls>sap>dhcp6>option
Description	This command configure the interface-id suboption of the DHCP6 Relay packet The no form of the command disables the sending of interface ID options in the DHCPv6 relay packet
Parameters	ascii-tuple — Specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “ ”. mac — This keyword specifies the MAC address of the remote end is encoded in the sub-option.

remote-id

Syntax	remote-id remote-id mac remote-id string [32 chars max] no remote-id
Context	config>service>ies>if>ipv6>dhcp6>option config>service>vprn>if>ipv6>dhcp6>option config>service>vpls>sap>dhcp6>option
Description	This command enables the sending of remote ID option in the DHCPv6 relay packet. The client DHCP Unique Identifier (DUID) is used as the remote ID. The no form of the command disables the sending of remote ID option in the DHCPv6 relay packet.

interface-id

Syntax	interface-id interface-id ascii-tuple no interface-id
Context	config>service>vpls>sap>dhcp6>option
Description	This command configures the interface-id suboption of the DHCP6 relay packet. The no form of the command reverts to the default.
Default	none

Parameters **ascii-tuple** — Specifies that the ASCII-encoded concatenated tuple consisting of the access-node-identifier, service-id, and interface-name is used.

dhcp6-user-db

Syntax **dhcp6-user-db** *local-user-db*
no dhcp6-user-db

Context config>service>vpls>sap

Description This command enabled access to LUDB for DHCPv6 hosts under the capture SAP. The name of this ludb must match the name of ludb configured under the **config>service>vprn/ies>subscr-intf>group-intf>dhcp** hierarchy.

Default no dhcp6-user-db

Parameters *local-user-db* — Specifies the name of the local-user-database up to 32 characters max.

ppp-user-db

Syntax **ppp-user-db** *local-user-db-name*
no ppp-user-db

Context config>service>vpls

Description This command enabled access to LUDB for PPPoE and PPPoEoA v4and v6 hosts under the capture SAP. The name of this local user database must match the name of local user database configured under the **config>service>vprn/ies>subscr-intf>group-intf>pppoe** hierarchy.

Default no pppoe-user-db

Parameters *local-user-db* — Specifies the name of the local-user-database up to 256 characters max.

pppoe-user-db

Syntax **pppoe-user-db** *local-user-db-name*
no pppoe-user-db

Context config>service>vpls

Description This command enabled access to LUDB for PPPoE and PPPoEoA v4and v6 hosts under the capture SAP. The name of this ludb must match the name of ludb configured under the **config>service>vprn/ies>subscr-intf>group-intf>pppoe** hierarchy.

Default no pppoe-user-db

Parameters	<i>local-user-db</i> — Specifies the name of the local-user-database up to 256 characters max.
-------------------	--

filter

Syntax	filter <i>filter-id</i> no filter
Context	config>service>ies>sub-if>grp-if>dhcp config>service>vprn>sub-if>grp-if>dhcp
Description	This command assigns a DHCP filter to the group-interface. This feature is used where the SR7750 is the second DHCP relay or where DHCP messages are snooped for subscriber management. The filter can be used to bypass host creation, drop DHCP message, or perform no action.
Default	no filter

gi-address

Syntax	gi-address <i>ip-address</i> [<i>src-ip-addr</i>] no gi-address
Context	config>service>ies>if>dhcp config>service>vprn>if>dhcp config>service>vprn>sub-if>dhcp config>service>ies>sub-if>grp-if>dhcp config>service>ies>sub-if>dhcp
Description	<p>This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.</p> <p>By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the group interface DHCP context or subscriber-interface DHCP context in order for DHCP to function.</p>
Default	no gi-address
Parameters	<i>ip-address</i> — Specifies the host IP address to be used for DHCP relay packets. <i>src-ip-address</i> — Specifies that this GI address is to be the source IP address for DHCP relay packets.

gi-address

Syntax	gi-address <i>ipv4-address</i> no gi-address
Context	config>subscr-mgmt>loc-user-db>ipoe>host
Description	<p>This command allows selection of gi-addresses based on the host entry in LUDB.</p> <p>The gi-address must be a valid address (associated with an interface) within the routing context that received the DHCP message on the access side.</p>
Default	no gi-address
Parameters	<i>ipv4-address</i> — Specifies the IPv4 gi-address.

relay-plain-bootp

Syntax	[no] relay-plain-bootp
Context	config>service>ies>if>dhcp
Description	<p>This command enables the relaying of plain BOOTP packets.</p> <p>The no form of the command disables the relaying of plain BOOTP packets.</p>

relay-proxy

Syntax	relay-proxy [release-update-src-ip] [siaddr-override <i>ip-address</i>] no relay-proxy
Context	config>service>ies>if>dhcp config>service>ies>sub-if>dhcp config>service>ies>sub-if>grp-if>dhcp config>service>vprn>if>dhcp config>service>vprn>sub-if>dhcp config>service>vprn>sub-if>grp-if>dhcp
Description	<p>This command enables the DHCPv4 relay proxy function on the interface. The command has no effect when no dhcp servers are configured (DHCPv4 relay not configured). By default, unicast DHCPv4 release messages are forwarded transparently. The optional “release-update-src-ip” flag, updates the source IP address with the value used for relayed DHCPv4 messages. Additionally when the optional flag “relay-unicast-msg” is enabled, then the gi address and source IP address of relayed DHCPv4 messages can be configured to any local configured IP address in the same routing instance.</p> <p>A relay proxy enhances the relay such that it also relays unicast client DHCPv4 REQUEST messages (lease renewals).</p>

- In the upstream direction, update the source IP address and add the gateway IP address (gi-address) field before sending the message to the intended DHCP server (the message is not broadcasted to all configured DHCP servers).
- In the downstream direction, remove the gi-address and update the destination IP address to the address of the yiaddr (your IP address) field.

The optional **release-update-src-ip** parameter updates the source IP address of a DHCP RELEASE message with the address used for relayed DHCPv4 messages.

The optional **siaddr-override** *<ip-address>* parameter enables DHCP server IP address hiding towards the client. This parameter requires that **lease-populate** is enabled on the interface. The DHCP server ip address is required for the address hiding function and is stored in the lease state record. The client interacts with the relay proxy as if it is the DHCP server. In all DHCP messages to the client, the value of following header fields and DHCP options containing the DHCP server IP address is replaced with the configured *<ip-address>*:

- the “source IP address” field in the IP DHCPv4 packet header
- the “siaddr” field in the DHCPv4 header if not equal to zero in the message received from the server
- the Server Identification option (DHCPv4 option 54) if present in the original server message
- the source IP address field in the IP packet header

DHCP OFFER selection during initial binding is done in the relay-proxy. Only the first DHCP OFFER message is forwarded to the client. Subsequent DHCP OFFER messages from different servers are silently dropped.

Default no relay-proxy

Parameters **release-update-src-ip** — Updates the source IP address of a DHCP RELEASE message with the address used for relayed DHCPv4 messages.

siaddr-override *<ip-address>* — Enables DHCPv4 server address hiding towards the DHCPv4 client and activates DHCPv4 OFFER selection in case multiple DHCP servers are configured. The *<ip-address>* can be any local address in the same routing instance. If DHCP relay lease-split is enabled, **siaddr-override** *<ip-address>* has priority over the **emulated-server** *<ip-address>* configured in the proxy-server and will be used as the source IP address.

server

Syntax **server** *ipv6z-address* [*ipv6z-address...*(up to 8 max)]

Context config>service>ies>if>ipv6>dhcp6

Description This command specifies a list of servers where DHCP6 requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP6 relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list.

There can be a maximum of 8 DHCP6 servers configured.

Default	no server
Parameters	<i>ipv6z-address</i> — Specifies a non-global IPv4 address including a zone index as defined by the InetAddressIPv4z textual convention. Up to 8 addresses can be specified.
Values	ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x: [0 to FFFF]H d: [0 to 255]D

virtual-subnet

Syntax	[no] virtual-subnet
Context	config>service>ies>sub-if>dhcp config>service>vprn>sub-if>dhcp
Description	This command enables a virtual-subnet for DHCPv4 hosts under the subscriber-interface. With this command configured, the system will snoop and record the default router address in the DHCP ACK message for the DHCPv4 ESM host. The system could answer ping or traceroute request even if the default router address is not configured on the subscriber-interface.
Default	none

server

Syntax	server <i>server1</i> [<i>server2</i> ...(up to 8 max)]
Context	config>service>ies>if>dhcp config>service>vprn>if>dhcp config>service>ies>sub-if>grp-if>dhcp
Description	<p>This command specifies a list of servers where requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list.</p> <p>There can be a maximum of 8 DHCP servers configured.</p>
Default	no server
Parameters	<i>server</i> — Specify the DHCP server IP address.

relay-plain-bootp

Syntax	[no] relay-plain-bootp
Context	config>service>vprn>if>dhcp
Description	This command enables the relaying of plain BOOTP packets. The no form of the command disables the relaying of plain BOOTP packets.

use-arp

Syntax	[no] use-arp
Context	config>service>vprn>if>dhcp
Description	This command enables the use of ARP to determine the destination hardware address. The no form of the command disables the use of ARP to determine the destination hardware address

trusted

Syntax	[no] trusted
Context	config>service>ies>if>dhcp config>service>vprn>if>dhcp config>service>vprn>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>dhcp
Description	This command enables relaying of untrusted packets. The no form of this command disables the relay.
Default	not enabled

host-connectivity-verify

Syntax	host-connectivity-verify [interval <i>interval</i>] [action {remove alarm}]
Context	config>service>vprn>if>sap config>service>vprn>sub-if>grp-if config>service>vprn>sub-if>grp-if>dhcp
Description	This command enables subscriber host connectivity verification on a given SAP within a service.

This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.

Default no host-connectivity-verify

Parameters **interval** *interval* — The interval, expressed in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000 (A zero value can be used by the SNMP agent to disable host-connectivity-verify.)

action {remove | alarm} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, etc.). DHCP-RELEASE will be signaled to corresponding DHCP server. Static hosts will never be removed. The **alarm** keyword raises an alarm indicating that the host is disconnected.

dhcp

Syntax dhcp

Context config>service>vprn>interface
config>service>vprn>
config>service>vprn>sub-if>grp-if

Description This command enables the context to configure DHCP parameters.

action

Syntax action {replace | drop | keep}
no action

Context config>service>vprn>if>dhcp>option
config>service>vprn>sub-if>grp-if>dhcp>option

Description This command configures the processing required when the SR-Series receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet.

The **no** form of this command returns the system to the default value.

Default Per RFC 3046, *DHCP Relay Agent Information Option*, section 2.1.1, *Reforwarded DHCP requests*, the default is to keep the existing information intact. The exception to this is if the giaddr of the received packet is the same as the ingress address on the router. In that case the packet is dropped and an error is logged.

Parameters	<p>replace — In the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).</p> <p>drop — The packet is dropped, and an error is logged.</p> <p>keep — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on towards the client.</p> <p>The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.</p> <p>If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.</p>
-------------------	---

match-circuit-id

Syntax	[no] match-circuit-id
Context	config>service>vprn>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>dhcp
Description	<p>This command enables Option 82 circuit ID on relayed DHCP packet matching. For routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked.</p> <p>When a response is received from the server the virtual router ID, transaction ID, and client hardware MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client hardware MAC address are not guaranteed to be unique.</p> <p>When the match-circuit-id command is enabled this part of the key is used to guarantee correctness in our lookup. This is really only needed when dealing with an IP aware DSLAM that proxies the client hardware MAC address.</p>
Default	no match-circuit-id

option

Syntax	[no] option
Context	config>service>vprn>if>dhcp config>service>vprn>sub-if>dhcp config>service>vprn>sub-if>grp-if>dhcp config>service>vpls>sap>dhcp config>service>ies>if>dhcp

```
config>service>ies>sub-if>grp-if>dhcp
```

Description This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options.

The **no** form of this command returns the system to the default.

Default no option

vendor-specific-option

Syntax **[no] vendor-specific-option**

Context config>service>vprn>if>dhcp>option
config>service>vprn>sub-if>grp-if>dhcp>option

Description This command configures the Nokia vendor specific suboption of the DHCP relay packet.

client-mac-address

Syntax **[no] client-mac-address**

Context config>service>vprn>if>dhcp>option
config>service>vprn>if>dhcp>option>vendor
config>service>vprn>sub-if>grp-if>dhcp>option>vendor

Description This command enables the sending of the MAC address in the Nokia vendor specific suboption of the DHCP relay packet.

The **no** form of the command disables the sending of the MAC address in the Nokia vendor specific suboption of the DHCP relay packet.

sap-id

Syntax **[no] sap-id**

Context config>service>vprn>if>dhcp>option>vendor
config>service>vprn>sub-if>grp-if>dhcp>option>vendor

Description This command enables the sending of the SAP ID in the Nokia vendor specific suboption of the DHCP relay packet.

The **no** form of the command disables the sending of the SAP ID in the Nokia vendor specific suboption of the DHCP relay packet.

service-id

Syntax	[no] service-id
Context	config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor
Description	This command enables the sending of the service ID in the Nokia vendor specific suboption of the DHCP relay packet. The no form of the command disables the sending of the service ID in the Nokia vendor specific suboption of the DHCP relay packet.

string

Syntax	[no] string <i>text</i>
Context	config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor
Description	This command specifies the vendor specific suboption string of the DHCP relay packet. The no form of the command returns the default value.
Parameters	<i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" ").

system-id

Syntax	[no] system-id
Context	config>service>vprn>if>dhcp>option>vendor config>service>vprn>sub-if>grp-if>dhcp>option>vendor
Description	This command specifies whether the system-id is encoded in the Nokia vendor specific suboption of Option 82.
Default	None

proxy-server

Syntax	proxy-server
Context	config>service>vpls>sap>dhcp config>subscr-mgmt>msap-policy>vpls-only>dhcp config>service>vprn>if>dhcp

```

config>service>ies>if>dhcp
config>service>vprn>sub-if>grp-if>dhcp
config>service>ies>sub-if>grp-if>dhcp
config>service>vprn>sub-if>dhcp
config>service>vprn>sub-if>grp-if>ipv6>dhcp6
config>service>ies>sub-if>grp-if>ipv6>dhcp6
config>service>vprn>sub-if>ipv6>dhcp6
config>service>ies>sub-if>ipv6>dhcp6

```

Description This command configures the DHCP proxy server.

server

Syntax **server** *server1* [*server2...*(up to 8 max)]

Context config>service>vprn>if>dhcp
config>service>vprn>sub-if>grp-if>dhcp

Description This command specifies a list of servers where requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list. There can be a maximum of 8 DHCP servers configured.

The flood command is applicable only in the VPLS case. There is a scenario with VPLS where the VPLS node only wants to add Option 82 information to the DHCP request to provider per-subscriber information, but it does not do full DHCP relay. In this case, the server is set to "flood". This means the DHCP request is still a broadcast and is sent through the VPLS domain. A node running at L3 further upstream then can perform the full L3 DHCP relay function.

Default no server

Parameters *server* — Specify the DHCP server IP address.

host-connectivity-verify

Syntax **host-connectivity-verify source-ip** *ip-address* [**source-mac** *ieee-address*] [**interval** *interval*] [**action** {**remove** | **alarm**}] [**timeout** *retry-timeout*] [**retry-count** *count*]

Context config>service>vpls
config>service>vpls>sap

Description This command enables subscriber host connectivity verification on a given VPLS SAP or within a VPLS service.

This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.

Default	no host-connectivity-verify
Parameters	<p>source-ip <i>ip-address</i> — Specify an unused IP address in the same network for generation of subscriber host connectivity verification packets.</p> <p>source-mac <i>ieee-address</i> — Specifies the source MAC address to be used for generation of subscriber host connectivity verification packets.</p> <p>interval <i>interval</i> — The interval, in minutes, which specifies the time interval in which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p>Values 1 to 6000 Note that a zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p>action {remove alarm} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The remove keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, etc.). DHCP release will be signaled to corresponding DHCP server. Static host will be never removed. The alarm keyword raises an alarm indicating that the host is disconnected.</p> <p>timeout <i>retry-timeout</i> — Specifies the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>Values 0 to 120</p> <p>retry-count <i>count</i> — Specifies the number of connectivity check retransmissions.</p> <p>Values 10 to 60 seconds</p>

source-address

Syntax	source-address <i>ipv6-address</i> no source-address
Context	config>service>ies>if>ipv6>dhcp6>relay config>service>ies>sub-if>ipv6>dhcp6>relay config>service>ies>sub-if>grp-if>ipv6>dhcp6>relay config>service>vprn>if>ipv6>dhcp6>relay config>service>vprn>sub-if>ipv6>dhcp6>relay config>service>vprn>sub-if>grp-if>ipv6>dhcp6>relay
Description	This command configures the source IPv6 address of the DHCPv6 relay messages.

Parameters *ipv6-address* — Specifies the source IPv6 address of the DHCPv6 relay messages.

Values

ipv6-address: x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:x.d.d.d.d
 x: [0 to FFFF]H
 d: [0 to 255]D

user-db

Syntax **user-db** *local-user-db-name*
[no] user-db

Context config>service>ies>if>ipv6>dhcp6-relay
 config>service>vprn>if>ipv6>dhcp6-relay

Description This command enables access to the LUDB for DHCPv6 messages under a routed interface. The name of this LUDB must match the name of the LUDB configured by the **config>sub-gmt>localuser-db** command.

Default **no user-db**

Parameters *local-user-db-name* — Specifies the name of the local user database up to 32 character maximum.

dhcp6-server

Syntax **[no] dhcp6-server**

Context config>service>ies>if>ipv6

Description This command enables the context to configure DHCPv6 server parameters for the IES interface.

The **no** form of the command disables the DHCP6 server.

max-nbr-of-leases

Syntax **max-nbr-of-leases** *max-nbr-of-leases*
no max-nbr-of-leases

Context config>service>ies>if>ipv6>dhcp6-server

Description This command configures the maximum number of lease states installed by the DHCP6 server function allowed on this interface.

The **no** form of the command returns the value to the default.

Default	8000
Parameters	<i>max-nbr-of-leases</i> — Specifies the maximum number of lease states installed by the DHCP6 server function allowed on this interface.
Values	0 to 8000

prefix-delegation

Syntax	[no] prefix-delegation
Context	config>service>ies>if>ipv6>dhcp6-server
Description	<p>This command configures prefix delegation options for delegating a long-lived prefix from a delegating router to a requesting router, where the delegating router does not require knowledge about the topology of the links in the network to which the prefixes will be assigned.</p> <p>The no form of the command disables prefix-delegation.</p>

prefix

Syntax	[no] prefix <i>ipv6-address/prefix-length</i>
Context	config>service>ies>if>ipv6>dhcp6-server>pfx-delegate
Description	This command specifies the IPv6 prefix that will be delegated by this system.
Parameters	<i>ipv6-address/prefix-length</i> — Specify the IPv6 address on the interface.
Values	<div> <div> <div> <div>ipv6-address/prefix:</div> <div>ipv6-address</div> <div> x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x [0 to FFFF]H d [0 to 255]D </div> </div> <div> <div>prefix-length</div> <div>1 to 128</div> </div> </div> </div>

Interface Commands**local-proxy-arp**

Syntax	[no] local-proxy-arp
Context	config>service>vprn>interface config>service>vprn>sub-if>grp-if
Description	This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked.
Default	no local-proxy-arp

mac

Syntax	[no] mac <i>ieee-mac-address</i>
Context	config>service>vprn>interface config>service>vprn>if>vrrp config>service>vprn>sub-if>grp-if
Description	This command assigns a specific MAC address to a VPRN IP interface. The no form of this command returns the MAC address of the IP interface to the default value.
Default	The physical MAC address associated with the Ethernet interface that the SAP is configured on.
Parameters	<i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i> , <i>bb</i> , <i>cc</i> , <i>dd</i> , <i>ee</i> and <i>ff</i> are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

proxy-arp-policy

Syntax	[no] proxy-arp <i>policy-name</i> [<i>policy-name...</i>(up to 5 max)]
Context	config>service>vprn>interface config>service>vprn>sub-if>grp-if
Description	This command enables a proxy ARP policy for the interface. The no form of this command disables the proxy ARP capability.

Default	no proxy-arp
Parameters	<i>policy-name</i> — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. The specified name(s) must already be defined.

redundant-interface

Syntax	redundant-interface <i>red-ip-int-name</i> no redundant-interface
Context	config>service>vprn config>service>vprn>sub-if>grp-if
Description	This command configures a redundant interface used for dual homing.
Parameters	<i>red-ip-int-name</i> — Specifies the redundant IP interface name.

remote-proxy-arp

Syntax	[no] remote-proxy-arp
Context	config>service>vprn>interface config>service>vprn>sub-if>grp-if
Description	This command enables remote proxy ARP on the interface. Remote proxy ARP is similar to proxy ARP. It allows the router to answer an ARP request on an interface for a subnet that is not provisioned on that interface. This allows the router to forward to the other subnet on behalf of the requester. To distinguish remote proxy ARP from local proxy ARP, local proxy ARP performs a similar function but only when the requested IP is on the receiving interface.
Default	no remote-proxy-arp

Subscriber Interface Commands

subscriber-interface

Syntax	[no] subscriber-interface <i>ip-int-name</i>
Context	config>service>ies

config>service>vprn

Description This command allows the operator to create special subscriber-based interfaces. It is used to contain multiple group interfaces. Multiple subnets associated with the subscriber interface can be applied to any of the contained group interfaces in any combination. The subscriber interface allows subnet sharing between group interfaces.

Use the **no** form of the command to remove the subscriber interface.

Parameters *ip-int-name* — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

group-interface

Syntax [no] **group-interface** *ip-int-name*

Context config>service>ies>sub-if

Description This command enables the context to configure a group interface. A group interface is an interface that may contain one or more SAPs. This interface is used in triple-play services where multiple SAPs are part of the same subnet.

Default none

Parameters *ip-int-name* — Configures the interface group name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

authentication-policy

Syntax **authentication-policy** *name*
no authentication-policy

Context config>service>ies>sub-if>grp-if

Description This command assigns a RADIUS authentication policy to the interface.

The **no** form of this command removes the policy name from the group interface configuration.

Default no authentication-policy

Parameters *name* — Specifies the authentication policy name.

3.8.2.1.5 Local User Database Commands

IPoE Commands

local-user-db

Syntax	local-user-db <i>local-user-db-name</i> [create] no local-user-db <i>local-user-db-name</i>
Context	config>subscr-mgmt
Description	This command enables the context to configure a local user database.
Default	not enabled
Parameters	<i>local-user-db-name</i> — Specifies the name of a local user database.

snooping

Syntax	[no] snooping
Context	config>service>ies>sub-if>grp-if>ipv6>dhcp6 config>service>vprn>sub-if>grp-if>ipv6>dhcp6
Description	This command enables the group-interface to snoop DHCPv6 relay messages exchange between the subscriber host and the DHCPv6 server. A successful DHCPv6 address assignment will trigger ESM DHCPv6 host creation and a release of the lease will trigger host deletion. This feature is for ESMv6 applications where a Layer 3 aggregation network is upstream from the BNG.

user-db

Syntax	user-db <i>local-user-db-name</i> no user-db
Context	config>service>ies>sub-if>grp-if>dhcp config>service>ies>sub-if>grp-if>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6 config>service>ies>sub-if>grp-if>ipv6>dhcp6
Description	This command assigns a local user database.
Default	not enabled
Parameters	<i>local-user-db-name</i> — Specifies the name of a local user database.

user-ident

Syntax	user-ident <i>user-ident</i> no user-ident
Context	config>service>ies>sub-if>grp-if>ipv6>dhcp6> config>service>vprn> sub-if>grp-if>ipv6>dhcp6>
Description	This feature is only applicable when DHCPv6-snooping is enabled. The Ethernet header MAC address on DHCPv6 is used as the default key host identification. This command allows addition the keys for identifying the DHCPv6 host. The interface-id can be included in addition to the MAC key to further differentiate each DHCPv6 host.
Default	user-ident mac
Parameters	<i>user-ident</i> — Specifies the DHCP6 user-identification for this interface. Values mac — Specifies to use only the Ethernet MAC of the DHCPv6 message to identify the host. mac-interface-id — Specifies to additionally use the interface-id to identify the DHCPv6 host.

ipoe

Syntax	ipoe
Context	config>subscr-mgmt>loc-user-db
Description	This command configures IPE host parameters.

ppp

Syntax	ppp
Context	config>subscr-mgmt>loc-user-db
Description	This command configures PPP host parameters.

mask

Syntax	mask type <i>dhcp-match-type</i> {[prefix-string <i>prefix-string</i> prefix-length <i>prefix-length</i>] [suffix-string <i>suffix-string</i> suffix-length <i>suffix-length</i>]} no mask type <i>dhcp-match-type</i>
Context	config>subscr-mgmt>loc-user-db>ipoe config>subscr-mgmt>loc-user-db>ppp

config>subscr-mgmt>loc-user-db>ipoe

Description This command configures the mask.

Parameters *dhcp-match-type* — Specifies up to four matching types to identify a host.

Values DHCP: circuit-id, option60, remote-id, sap-id, string,
system-id
PPP: circuit-id, remote-id, service-name, username

Values *prefix-string prefix-string*

Specifies a substring that is stripped of the start of the incoming circuit ID before it is matched against the value configured in the DHCP or PPPOE circuit ID.

This string can only contain printable ASCII characters. The “*” character is a wildcard that matches any substring. If a “\” character is masked, use the escape key so it becomes “\\”.

Values 127 characters maximum, * is wildcard.

prefix-length *prefix-length* — Specifies the number of characters to remove from the start of the incoming circuit ID before it is matched against the value configured in the DHCP circuit ID.

Values 1 to 127

suffix-string *suffix-string* — Specifies a substring that is stripped of the end of the incoming circuit ID before it is matched against the value configured in DHCP circuit ID.

This string can only contain printable ASCII characters. The “*” character is a wildcard that matches any substring. If a “\” character is masked, use the escape key so it becomes “\\”.

Values 127 characters maximum

suffix-length *suffix-length* — Specifies the number of characters to remove from the end of the incoming circuit ID before it is matched against the value configured in the DHCP circuit ID.

Values 1 to 127

host

Syntax **host** *host-name* [create]
no host *host-name*

Context config>subscr-mgmt>loc-user-db>ipoe
config>subscr-mgmt>loc-user-db>ppp

Description This command defines a DHCP or PPP subscriber.

Parameters *host-name* — Specifies the host name.

create — Keyword used to create the host name. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

access-loop-encapsulation

Syntax	[no] access-loop-encapsulation
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command enables access loop information.

encap-offset

Syntax	encap-offset [type type] no encap-offset
Context	config>subscr-mgmt>loc-user-db>ppp>host>ale
Description	This command configures the egress encapsulation offset.
Parameters	type type — Selects the encap type.
Values	pppoa-llc, pppoa-null, pppoeoa-llc, pppoeoa-llc-fcs, pppoeoa-llc-tagged, pppoeoa-llc-tagged-fcs, pppoeoa-null, pppoeoa-null-fcs, pppoeoa-null-tagged, pppoeoa-null-tagged-fcs, ipoa-llc, ipoa-null, ipoeoa-llc, ipoeoa-llc-fcs, ipoeoa-llc-tagged, ipoeoa-llc-tagged-fcs, ipoeoa-null, ipoeoa-null-fcs, ipoeoa-null-tagged, ipoeoa-null-tagged-fcs, pppoe, pppoe-tagged, ipoe, ipoe-tagged

rate-down

Syntax	rate-down rate no rate-down
Context	config>subscr-mgmt>loc-user-db>ppp>host>ale
Description	This command configures the last mile link downstream rate in the access loop.
Parameters	rate — Specifies the last mile link downstream rate needed for proper (shaping) rate calculations and interleaving delay in the access loop.
Values	1 to 100000 kbps

access-loop-information

Syntax	access-loop-information
Context	config>subscr-mgmt>loc-user-db>ppp>host>ali
Description	This command enables the context to configure access loop information in the local user database

circuit-id

Syntax	circuit-id sap-id circuit-id string <i>ASCII string</i> no circuit-id
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command specifies a circuit-id for PPPoE hosts. A circuit-id received in PPPoE tags has precedence over the ludb specified circuit-id.
Default	no circuit-id
Parameters	sap-id — Specifies to use the SAP ID of the PPPoE session as the circuit ID. <i>string ASCII string</i> Specifies the circuit-id as a string, up to 63 characters. in length.

remote-id

Syntax	remote-id string mac remote-id string <i>ASCII string</i> no remote-id
Context	config>subscr-mgmt>loc-user-db>ppp>host>ali
Description	This command specifies a remote-id for PPPoE hosts. A remote-id received in PPPoE tags has precedence over the ludb specified remote-id.
Default	no remote-id
Parameters	<i>string ASCII string</i> — specifies the circuit-id as a string, up to 63 characters. in length. mac — specifies MAC address of the PPPoE session as the remote ID.

acct-policy

Syntax	acct-policy <i>acct-policy-name</i> [duplicate <i>acct-policy-name</i>] no acct-policy
---------------	--

Context	config>subscr-mgmt>loc-user-db>ppp>host config>subscr-mgmt>loc-user-db>ipoe>host
Description	<p>This command specifies the accounting policy used for sending an Accounting Stop message to report RADIUS authentication failures of PPPoE sessions. A duplicate policy can be specified if a copy of the Accounting Stop message must be sent to another destination.</p> <p>Reporting RADIUS authentication failures with an Accounting Stop message must be enabled in the RADIUS authentication policy ("send-acct-stop-on-fail")</p> <p>A duplicate RADIUS accounting policy can be specified if the accounting stop resulting from a RADIUS authentication failure must also be sent to a second RADIUS destination.</p>
Default	no acct-policy
Parameters	<i>acct-policy-name</i> — Specifies the name of a RADIUS accounting policy up to 32 characters in length.

address

Syntax	address gi-address [scope scope] address ip-address[/prefix-length] address pool pool-name [secondary-pool sec-pool-name] [delimiter delimiter] address use-pool-from-client [delimiter delimiter] no address
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	<p>This command configures how the IP address is defined for this host.</p> <p>When the user-db is used from a local-dhcp-server, then this command defines how to define the IP address the server will "offer" to the DHCP-client.</p> <p>When the user-db is used for PPPoE authentication, the gi-address parameter cannot be used. A fixed IP address will then cause PPPoE to use this IP address. If no IP address is specified, the PPPoE will look for IP address by other means (DHCP). If a pool name is given, this pool will be sent in the DHCP request so that it can be used in by the DHCP server to determine which address to give to the host.</p> <p>The no form of the command causes no IP address to be assigned to this host. In a user-db referred to from a local-dhcp-server, creating a host without address information will cause the matching client never to get an IP address.</p>
Default	no address
Parameters	gi-address — When specified, the gi-address of the DHCP message is taken to look for a subnet in the local DHCP server. The first available free address of the subnet is taken and "offered" to the host. When local-user-db is used for PPPoE authentication, this has the same result as no address .

ip-address — Specifies the fixed IP address to use for this host.

pool-name/sec-pool-name — Specifies the primary (and secondary) pool (in the local DHCP server) to use to look for an available address. The first available IP address from any subnet in the pool will be used. When the local user database is used for PPPoE authentication, this causes the specified pool name to be sent to the DHCP server in a vendor-specific suboption under Option 82

use-pool-from-client — Use the pool-name in the Option 82 vendor-specific sub-option.

delimiter *delimiter* — A single ascii character specifies the delimiter of separating primary and secondary pool names in option82 VSO.

auth-domain-name

Syntax	auth-domain-name <i>domain-name</i> no auth-domain-name
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the authentication policy of this host.

auth-policy

Syntax	auth-policy <i>policy-name</i> no auth-policy
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the authentication policy of this host and PPPoE hosts. This authentication policy is only used if no authentication policy is defined at the interface level. For DHCP hosts, the host entry should not contain any other information needed for setup of the host (IP address, ESM strings, and so on.). For PPPoE hosts, the authentication policy configured here must have its pppoe-authentication-method set to pap-chap , otherwise the request will be dropped.
Parameters	<i>policy-name</i> — Specifies the authentication policy name.

force-ipv6cp

Syntax	[no] force-ipv6cp
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command specifies if the IPv6 control protocol should be negotiated after PPP reaches the Network-Layer Protocol phase.

diameter-application-policy

Syntax	diameter-application-policy <i>policy-name</i> no diameter-application-policy
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command configures the Diameter application policy.
Parameters	<i>policy-name</i> — Specifies the Diameter application policy name.

diameter-auth-policy

Syntax	diameter-auth-policy <i>name</i> no diameter-auth-policy
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command is used to configure the Diameter NASREQ application policy to use for authentication.
Parameters	<i>name</i> — Specifies the name of the Diameter NASREQ application policy to use for authentication.

auth-domain-name

Syntax	auth-domain-name <i>domain-name</i> no auth-domain-name
Context	config>subscr-mgmt>loc-user-db>ipoe>host
Description	This command sets the domain name which can be appended to user-name in RADIUS-authentication-request message for the given host.
Parameters	<i>domain-name</i> — Specifies the domain name to be appended to user-name in RADIUS-authentication-request message for the given host.

host-identification

Syntax	host-identification
---------------	----------------------------

Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command enables the context to configure host identification parameters.

server

Syntax	server <i>ip-address</i> no server
Context	config>subscr-mgmt>loc-user-db>ipoe>host
Description	<p>This command configures the IP address of the DHCP server to relay to.</p> <p>The no form of the command removes the DHCP server IP address from the configuration.</p> <p>The configured DHCP server IP address must reference one of the addresses configured under the DHCP CLI context of an IES/VPDN subscriber or group interface.</p>
Default	no server
Parameters	<i>ip-address</i> — Specifies the IP address of the DHCP server.

circuit-id

Syntax	circuit-id string <i>ascii-string</i> circuit-id hex <i>hex-string</i> no circuit-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident config>subscr-mgmt>loc-user-db>ppp>host>host-ident
Description	This command specifies the circuit-id to match.
Parameters	<i>ascii-string</i> — specifies the circuit ID from the Option 82. <i>hex-string</i> — Specifies the circuit ID in hexadecimal format from the Option 82. Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)

derived-id

Syntax	derived-id <i>derived-id-string</i> no derived-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident

Description	This command configures an ASCII string that uniquely identifies a host, and is derived by a Python script from packet content available during a DHCP transaction.
Parameters	<i>derived-id-string</i> — Specifies the host ID to be derived by a python script from DHCP packets during a DHCP transaction up to 255 characters in length.

encap-tag-range

Syntax	encap-tag-range start-tag start-tag end-tag end-tag no encap-tag-range
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident config>subscr-mgmt>loc-user-db>ppp>host>host-ident
Description	<p>This command specifies a range of encapsulation tag as the host identifications. The encapsulation tag is dot1q or qinq on Ethernet port; VPI/VCI on ATM port.</p> <p>For dot1q, the start/end-tag is single number, range from 0-4094; for QinQ, the start/end-tag format is x.y, x or y could be “*”, which means ignore inner or outer tag;</p> <p>For ATM the start/end-tag format is vpi/vci, vpi or vci could be “*”, which means ignore VPI or VCI.</p>

Note: This command will only be used when **encap-tag-range** is configured as one of the match-list parameters.

The **no** form of the command removes the values from the configuration.

Default	none																								
Parameters	start-tag <i>start-tag</i> — Specifies the value of the start label in the range of SAP's allowed on this host.																								
	Values																								
	<table><tr><td><i>start-tag</i></td><td>dot1q</td><td>qtag1</td></tr><tr><td></td><td>qinq</td><td>(qtag1.qtag2 qtag1.* *.qtag2)</td></tr><tr><td></td><td>atm</td><td>(vpi/vci vpi/* */vci)</td></tr><tr><td></td><td></td><td>qtag1 [0 to 4094]</td></tr><tr><td></td><td></td><td>qtag2 [0 to 4094]</td></tr><tr><td></td><td></td><td>vpi [0 to 4095] (NNI)</td></tr><tr><td></td><td></td><td>[0 to 255] (UNI)</td></tr><tr><td></td><td></td><td>vci [1 to 65535]</td></tr></table>	<i>start-tag</i>	dot1q	qtag1		qinq	(qtag1.qtag2 qtag1.* *.qtag2)		atm	(vpi/vci vpi/* */vci)			qtag1 [0 to 4094]			qtag2 [0 to 4094]			vpi [0 to 4095] (NNI)			[0 to 255] (UNI)			vci [1 to 65535]
<i>start-tag</i>	dot1q	qtag1																							
	qinq	(qtag1.qtag2 qtag1.* *.qtag2)																							
	atm	(vpi/vci vpi/* */vci)																							
		qtag1 [0 to 4094]																							
		qtag2 [0 to 4094]																							
		vpi [0 to 4095] (NNI)																							
		[0 to 255] (UNI)																							
		vci [1 to 65535]																							

end-tag *end-tag* — Specifies the value of the end label in the range of SAP's allowed on this host.

Values	
<i>end-tag</i>	dot1q qinq atm
	qtag1 (qtag1.qtag2 qtag1.* *.qtag2) (vpi/vci vpi/* */vci) qtag1 [0 to 4094] qtag2 [0 to 4094] vpi [0 to 4095] (NNI) [0 to 255] (UNI) vci [1 to 65535]

ip-prefix

Syntax	ip-prefix ip-prefix/ip-prefix-length no ip-prefix
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident
Description	This command specifies the source IPv4/IPv6 address/prefix of the data trigger packet as the host identification.
Default	no ip-prefix
Parameters	<i>ip-prefix/ip-prefix-length</i> — Specifies the IPv4 address, IPv6 address, or IPv6 prefix
Values	ipv4-prefix a.b.c.d ipv4-prefix-length [0 to 32] ipv6-prefix x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x to [0 to FFFF]H d to [0 to 255]D ipv6-prefix-length [0 to 128]

mac

Syntax	mac <i>ieee-address</i> no mac
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident config>subscr-mgmt>loc-user-db>ppp>host>host-ident
Description	This command specifies the MAC address to match.

Parameters *ieee-address* — Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers.

options6

Syntax **options6**

Context config>subscr-mgmt>loc-user-db>ppp>host
config>subscr-mgmt>loc-user-db>ipoe>host

Description This command enables the context to configure IPv6 DNS server information in the local user database

option60

Syntax **option60** *hex-string*
no option60

Context config>subscr-mgmt>loc-user-db>ipoe>host>host-ident

Description This command specifies the Vendor-Identifying Vendor Option to match. Option 60 is encoded as Type-Length-Value (TLV). The *hex-string* portion of Option 60 in the received DHCP request is used for matching. Only the first 32 bytes can be defined here. If Option 60 from the message is longer, those bytes are ignored.

Default no option60

Parameters *hex-string* — Specifies the hex value of this option.

Values 0x0 to 0xFFFFFFFF(maximum 254 hex nibbles)

remote-id

Syntax **remote-id** *hex-string*
remote-id *ascii-string*
no remote-id

Context config>subscr-mgmt>loc-user-db>ipoe>host>host-ident
config>subscr-mgmt>loc-user-db>ppp>host>host-ident

Description This command specifies the remote id of this host.

The **no** form of this command returns the system to the default.

Default no remote-id

Parameters *remote-id* — Specifies the remote-id.

service-name

Syntax	service-name <i>service-name</i> no service-name
Context	config>subscr-mgmt>loc-user-db>ppp>host>host-ident
Description	This command specifies the service-name tag in PADI and/or PADR packets to match for PPPoE hosts.
Parameters	<i>service-name</i> — Specifies a PPPoE service name, up to 255 characters maximum.

sap-id

Syntax	sap-id <i>sap-id</i> no sap-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident
Description	This command specifies the SAP ID from the Nokia vendor-specific sub-option in Option 82 to match.
Parameters	<i>sap-id</i> — Specifies a SAP ID, up to 255 characters maximum.

service-id

Syntax	service-id <i>service-id</i> no service-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident
Description	This command specifies an existing service ID from the Nokia vendor-specific sub-option in Option 82 to match.
Parameters	<i>service-id</i> — Specifies an existing service ID. Values 1 to 2147483647

string

Syntax	string <i>string</i> no string
Context	config>subscr-mgmt>loc-user-db>ipoe>host>host-ident
Description	This command specifies the string from the Nokia vendor-specific sub-option in Option 82 to match.

Parameters *string* — Specifies the string, up to 255 characters maximum.

system-id

Syntax **system-id** *system-id*
 no system-id

Context config>subscr-mgmt>loc-user-db>ipoe>host>host-ident

Description This command specifies the system ID from the Nokia vendor-specific sub-option in Option 82 to match.

Parameters *system-id* — Specifies the system ID, up to 255 characters maximum.

username

Syntax **username** *user-name*
 username *user-name* [**no-domain**]
 username *user-name* **domain-only**
 no username

Context config>subscr-mgmt>loc-user-db>ppp>host>host-ident

Description This command specifies how the username is specified.

Parameters *username* — Specifies the user name of this host.
 no-domain — No username is specified.
 domain-only — Only the domain part of the username is specified, for example,
 nokia.com.

identification-strings

Syntax **identification-strings** *option-number* [**create**]
 no identification-strings

Context config>subscr-mgmt>loc-user-db>ipoe>host
 config>subscr-mgmt>loc-user-db>ppp>host

Description	This command specifies identification strings for the subscriber. This is useful when the server is centralized with Enhanced Subscriber Management (ESM) in a lower level in the network. These strings will be parsed by a downstream Python script or they can be used literally if the “strings-from-option” option in the config>subscr-mgmt>sub-ident-policy context is set to this option number. In this case, the option number may be set to any allowed number (between 224 and 254 is suggested, as these are not dedicated to specific purposes). If the option number is not given, a default value of 254 is used. For PPPoE only, if the local user database is attached to the PPPoE node under the group interface and not to a local DHCP server, the strings will be used internally so the option number is not used.
Default	254
Parameters	<i>option-number</i> — Specifies identification strings for the subscriber Values 1 to 254

ancp-string

Syntax	ancp-string <i>ancp-string</i> no ancp-string
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the ANCP string which is encoded in the identification strings.
Parameters	<i>ancp-string</i> — Specifies the ANCP string, up to 63 characters, maximum.

app-profile-string

Syntax	app-profile-string <i>app-profile-string</i> no app-profile-string
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the application profile string which is encoded in the identification strings.
Parameters	<i>app-profile-string</i> — Specifies the application profile string, up to 16 characters, maximum.

category-map

Syntax	category-map <i>category-map-name</i> no category-map <i>category-map-name</i>
---------------	---

Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the category map name.
Default	none
Parameters	<i>category-map-name</i> — Specifies an existing category map name up to 32 characters in length.

inter-dest-id

Syntax	inter-dest-id <i>intermediate-destination-id</i> no inter-dest-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the intermediate destination identifier which is encoded in the identification strings.
Parameters	<i>intermediate-destination-id</i> — Specifies the intermediate destination identifier, up to 32 characters, maximum.

sla-profile-string

Syntax	sla-profile-string <i>sla-profile-string</i> no sla-profile-string
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the SLA profile string which is encoded in the identification strings.
Parameters	<i>sla-profile-string</i> — Specifies the SLA profile string, up to 16 characters, maximum.

sub-profile-string

Syntax	sub-profile-string <i>sub-profile-string</i> no sub-profile-string
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings config>subscr-mgmt>loc-user-db>ppp>host>ident-strings
Description	This command specifies the subscriber profile string which is encoded in the identification strings.

Parameters *sub-profile-string* — Specifies the subscriber profile string, up to 16 characters, maximum.

subscriber-id

Syntax **subscriber-id** *sub-ident-string*
no subscriber-id

Context config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings
config>subscr-mgmt>loc-user-db>ppp>host>ident-strings

Description This command specifies the subscriber ID which is encoded in the identification strings.

Parameters *sub-ident-string* — Specifies the subscriber ID string, up to 32 characters, maximum.

ignore-df-bit

Syntax [no] **ignore-df-bit**

Context config>subscr-mgmt>loc-user-db>ppp>host

Description When the ignore-df-bit command is enabled for a subscriber host, then the do-not-fragment (DF) bit in the IPv4 header for frames egressing the subscriber interface is ignored: the frames are fragmented according the applicable egress MTU; the DF bit is reset for frames that are fragmented.

This command applies to PPPoE PTA and L2TP LNS frames only. It is not applicable for L2TP LAC frames.

Default no ignore-df-bit

interface

Syntax **interface** *ip-int-name* **service-id** *service-id*
no interface

Context config>subscr-mgmt>loc-user-db>ppp>host

Description This command configures the interface where PPP sessions are terminated.

The no form of the command reverts to the default.

Default none

Parameters *ip-int-name* — Specifies the name of the group interface where the PPP sessions are established

service-id *service-id* — Specifies the service ID of the service where the PPP sessions are established.

ipv6-address

Syntax	ipv6-address <i>ipv6-address</i> no ipv6-address
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures static DHCPv6 IA-NA address for the host. This address is delegated to the client as /128 via DHCPv6 proxy function within the router. This IP address must not be part of any DHCP pool within internal DHCP server. The no form of the command removes the IPv6 address from the host configuration.
Parameters	<i>ipv6-address</i> — Specifies the IPv6 address. Values ipv6-address: ipv6-prefix x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x [0 to FFFF]H d [0 to 255]D

ipv6-delegated-prefix

Syntax	ipv6-delegated-prefix <i>ipv6-prefix/prefix-length</i> no ipv6-delegated-prefix
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures static DHCPv6 IA-PD prefix for the host. This prefix can be further delegated by the host itself to its clients. The prefix length is restricted to 48 to 64 bits. This prefix must not be part of any DHCP pool within internal DHCP server.
Default	no ipv6-delegated-prefix
Parameters	<i>ipv6-address</i> — Specifies the IPv6 address. Values ipv6-address: ipv6-prefix x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x [0 to FFFF]H d [0 to 255]D prefix-length [48 to 64]

ipv6-delegated-prefix-pool

Syntax	ipv6-delegated-prefix-pool <i>pool-name</i> no ipv6-delegated-prefix-pool
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the pool name that will be used in DHCPv6 server for DHCPv6 IA-PD prefix selection. The no form of the command removes the pool name from the configuration.
Parameters	<i>pool-name</i> — Specifies the pool name to be assigned to the delegated prefix pool.

ipv6-slaac-prefix

Syntax	ipv6-slaac-prefix <i>ipv6-prefix/prefix-length</i> no ipv6-slaac-prefix
Context	config>subscr-mgmt>loc-user-db>ppp>host config>subscr-mgmt>loc-user-db>ipoe>host
Description	This command configures static IPv6 SLAAC prefix (PIO) for the host. The host will assign an IPv6 address to itself based on this prefix. The prefix length is 64 bits. The no form of the command removes the static IPv6 SLAAC prefix (PIO) for the host from the configuration.
Default	no ipv6-slaac-prefix
Parameters	<i>ipv6-prefix/prefix-length</i> — Specifies the IPv6 address and prefix length.

Values

<ipv6-prefix/prefi*> : ipv6-prefix x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x [0 to FFFF]H
 d [0 to 255]D
 prefix-length 64

ipv6-slaac-prefix-pool

Syntax	ipv6-slaac-prefix-pool <i>pool</i> no ipv6-slaac-prefix-pool
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host

Description This command configures the IPv6 slaac prefix pool of this host.

ipv6-delegated-prefix-length

Syntax **ipv6-delegated-prefix-length** *bits*
no ipv6-delegated-prefix-length

Context config>subscr-mgmt>loc-user-db>ipoe>host
 config>subscr-mgmt>loc-user-db>ppp>host

Description This command allows configuration of delegated prefix length via local user database.

Default no ipv6-delegated-prefix-length

Parameters *bits* — Specifies the delegated prefix length in bits.

Values 48 to 64

ipv6-wan-address-pool

Syntax **ipv6-wan-address-pool** *pool-name*
no ipv6-wan-address-pool

Context config>subscr-mgmt>loc-user-db>ipoe>host
 config>subscr-mgmt>loc-user-db>ppp>host

Description This command configures the pool name that will be used in DHCPv6 server for DHCPv6 IA-PA address selection.

The **no** form of the command removes the pool name from the configuration.

Default no ipv6-wan-address-pool

Parameters *pool-name* — Specifies the WAN address pool up to 32 characters in length.

link-address

Syntax **link-address** *ipv6-address*
no link-address

Context config>subscr-mgmt>loc-user-db>ipoe>host

config>service>ies>if>ipv6>dhcp6>relay
 config>service>ies>sub-if>ipv6>dhcp6>relay
 config>service>ies>sub-if>grp-if>ipv6>dhcp6>relay
 config>service>vprn>if>ipv6>dhcp6>relay
 config>service>vprn>sub-if>ipv6>dhcp6>relay

```
config>service>vprn>sub-if>grp-if>ipv6>dhcp6>relay
```

Description This command configures the link address used for prefix selection at the DHCP server.

The link-address is a field in DHCP6 Relay-Forward message that is used in DHCP6 server to select the IPv6 address (IA-NA) or IPv6 prefix (IA-PD) from a pool with configured prefix range covering the link-address. The selection scope is the pool or a prefix range within the pool.

Parameters *ipv6-address* — Specifies the link-address.

Values

<ipv6-address> *ipv6-address* - x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x - [0 to FFFF]H
d - [0 to 255]D

match-radius-proxy-cache

Syntax **match-radius-proxy-cache**

Context config>subscr-mgmt>loc-user-db>ipoe>host

Description This command enables the context to configure RADIUS proxy cache match parameters.

fail-action

Syntax **fail-action {continue | drop}**
no fail-action

Context config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache

Description This command specifies the action to take when no match is found in the cache.

The no form of the command reverts to the default.

Default drop

mac-format

Syntax **mac-format *mac-format***
no mac-format

Context config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache

Description This command specifies how a MAC address is represented.

match

Syntax	match { circuit-id mac remote-id } match option [<i>number</i>] [option6 [<i>number</i>]] match option6 [<i>number</i>] no match
Context	config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache
Description	This command specifies in what DHCPv6 option to retrieve the value to be used as lookup key in the RADIUS proxy cache. The no form of the command reverts to the default.
Default	no match
Parameters	circuit-id — Specifies to use the circuit Id to match against. mac — Specifies the MAC address to match against. remote-id — Specifies the remote ID to match against. option <i>number</i> — Specifies the option number that the DHCP server uses to send the identification strings to the client. Values 1 to 124 option6 <i>number</i> — Specifies the DHCPv6 option to retrieve the value to be used as lookup key in the RADIUS Proxy cache. Values 1 to 65535

server

Syntax	server [service <i>service-id</i>] name <i>server-name</i>] no server
Context	config>subscr-mgmt>loc-user-db>ipoe>host>match-radprox-cache
Description	This command specifies the RADIUS proxy server.

ipv6-lease-times

Syntax	[no] ipv6-lease-times
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the lease times for DHCPv6.

preferred-lifetime

Syntax	preferred-lifetime [days <i>days</i>] [hrs <i>hrs</i>] [min <i>min</i>] [sec <i>sec</i>] preferred-lifetime <i>infinite</i> no preferred-lifetime								
Context	config>service>vprn>sub-if>ipv6>dhcp6>proxy config>service>ies>sub-if>ipv6>dhcp6>proxy config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy								
Description	<p>This command configures the preferred-lifetime for DHCPv6 leases (address/prefix) in a proxy-scenario (For example address/prefix obtained from Radius)</p> <p>Preferred lifetime is the length of time that a valid address/prefix is preferred (for example, the time until deprecation).</p>								
Default	hrs 1								
Parameters	<p><i>infinite</i> — Specifies that the valid lifetime is infinite.</p> <p>preferred-lifetime — Specifies the preferred lifetime.</p> <p>Values</p> <table><tr><td>days <i>days</i></td><td>0 to 7</td></tr><tr><td>hrs <i>hours</i></td><td>0 to 23</td></tr><tr><td>min <i>minutes</i></td><td>0 to 59</td></tr><tr><td>sec <i>seconds</i></td><td>0 to 5</td></tr></table>	days <i>days</i>	0 to 7	hrs <i>hours</i>	0 to 23	min <i>minutes</i>	0 to 59	sec <i>seconds</i>	0 to 5
days <i>days</i>	0 to 7								
hrs <i>hours</i>	0 to 23								
min <i>minutes</i>	0 to 59								
sec <i>seconds</i>	0 to 5								

rebind-timer

Syntax	rebind-timer [<i>rebind-timer</i>] no rebind-timer
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ipv6-lease-times config>subscr-mgmt>loc-user-db>ppp>host>ipv6-lease-times config>service>ies>sub-if>ipv6>dhcp6>proxy config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server config>service>vprn>sub-if>ipv6>dhcp6>proxy config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server
Description	<p>This command configures the lease rebind timer (T2) via LUBD.</p> <p>The T2 time is the time at which the client contacts any available addressing authority to extend the lifetimes of DHCPv6 leases. T2 is a time duration relative to the current time expressed in units of seconds.</p>

The IP addressing authority controls the time at which the client contacts the addressing authority to extend the lifetimes on assigned addresses/prefixes through the T1 and T2 parameters assigned to an IA. At time T1 for an IA, the client initiates a Renew/Reply message exchange to extend the lifetimes on any addresses in the IA. The client includes an IA option with all addresses/prefixes currently assigned to the IA in its Renew message. Recommended values for T1 and T2 are .5 and .8 times the shortest preferred lifetime of the addresses/prefixes in the IA that the addressing authority is willing to extend, respectively.

The configured rebind timer should always be longer than or equal to the renew timer.

The T1 and T2 are carried in the IPv6 address option that is within the IA.

Default rebind-timer min 48

Parameters *rebind-timer* — Specifies the preferred lifetime.

Values

days	<i>days</i>	0 to 7
hrs	<i>hours</i>	0 to 23
min	<i>minutes</i>	0 to 59
sec	<i>seconds</i>	0 to 5

renew-timer

Syntax **renew-timer** [*renew-timer*]
no renew-timer

Context config>subscr-mgmt>loc-user-db>ipoe>host>ipv6-lease-times
config>subscr-mgmt>loc-user-db>ppp>host>ipv6-lease-times
config>service>ies>sub-if>ipv6>dhcp6>proxy
config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server
config>service>vprn>sub-if>ipv6>dhcp6>proxy
config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server

Description This command configures the lease renew time (T1) via LUDB.

The T1 is the time at which the client contacts the addressing authority to extend the lifetimes of the DHCPv6 leases (addresses/prefixes). T1 is a time duration relative to the current time expressed in units of seconds.

The IP addressing authority controls the time at which the client contacts the addressing authority to extend the lifetimes on assigned addresses through the T1 and T2 parameters assigned to an IA. At time T1 for an IA, the client initiates a Renew/Reply message exchange to extend the lifetimes on any addresses in the IA. The client includes an IA option with all addresses currently assigned to the IA in its Renew message. Recommended values for T1 and T2 are .5 and .8 times the shortest preferred lifetime of the addresses in the IA that the addressing authority is willing to extend, respectively.

The configured renew timer should always be smaller than or equal to the rebind timer.

The T1 and T2 are carried in the IPv6 address option that is within the IA.

Default	renew-timer min 30
Parameters	<i>renew-timer</i> — Specifies the preferred lifetime.
Values	
days <i>days</i>	0 to 7
hrs <i>hours</i>	0 to 23
min <i>minutes</i>	0 to 59
sec <i>seconds</i>	0 to 5

server-id

Syntax	server-id duid-en hex <i>hex-string</i> server-id duid-en string <i>ascii-string</i> server-id duid-ll no server-id
Context	config>service>ies>sub-if>ipv6>dhcp6>proxy-server config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server config>service>vprn>sub-if>ipv6>dhcp6>proxy config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server
Description	This command allows operator to customize the “server-id” attribute of a DHCPv6 message from the DHCPv6 proxy server (such as DHCPv6 advertise and reply). By default, the server-id uses DUID-ll derive from the chassis link-layer address. Operators have the option to use a unique identifier by using DUID-en (vendor based on enterprise number). There is a maximum length associated with the customizable hex-string and ascii-string.
Default	server-id duid-ll
Parameters	duid-en hex <i>hex-string</i> — Specifies a DUID system ID in a hex format. Values 0x0 to 0xFFFFFFFF (max 116 hex nibbles) duid-en string <i>ascii-string</i> — Specifies a DUID system ID in an ASCII format up to 58 characters. duid-ll — Specifies that the DUID system ID is derived from the system link layer address.

valid-lifetime

Syntax	valid-lifetime [<i>valid-lifetime</i>] valid-lifetime <i>infinite</i> no valid-lifetime
Context	config>subscr-mgmt>loc-user-db>ipoe>host>ipv6-lease-times

```
config>subscr-mgmt>loc-user-db>ppp>host>ipv6>lease-times
config>service>ies>sub-if>ipv6>dhcp6>proxy
config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server
config>service>vprn>sub-if>ipv6>dhcp6>proxy
config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server
```

Description	<p>This command configured valid-lifetime for DHCPv6 lease (address/prefix).</p> <p>Valid lifetime is the length of time an address/prefix remains in the valid state (i.e., the time until invalidation). The valid lifetime must be greater than or equal to the preferred lifetime. When the valid lifetime expires, the address/prefix becomes invalid and must not be used in communications. RFC 2461, sec 6.2.1 recommends default value of 30 days.</p> <p>Each address/prefix assigned to the client has associated preferred and valid lifetimes specified by the address assignment authority (DHCP Server, Radius, ESM). To request an extension of the lifetimes assigned to an address, the client sends a Renew message to the addressing authority. The addressing authority sends a Reply message to the client with the new lifetimes, allowing the client to continue to use the address/prefix without interruption.</p> <p>The lifetimes are transmitted from the addressing authority to the client in the IA option on the top level (not the address or prefix level).</p>		
Default	valid-lifetime days 1		
Parameters	<i>infinite</i> — Specifies that the valid lifetime is infinite.		
	Values	0xffffffff	
	<i>valid-lifetime</i> — Specifies the preferred lifetime.		
	Values		
	days	days	0 to 7
	hrs	hours	0 to 23
	min	minutes	0 to 59
	sec	seconds	0 to 5

l2tp

Syntax	l2tp
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures L2TP for the host.

group

Syntax	group <i>tunnel-group-name</i> [service-id <i>service-id</i>] no group
--------	--

Context	config>subscr-mgmt>loc-user-db>ppp>host>l2tp
Description	This command configures the L2TP tunnel group. The tunnel-group-name is configured in the config>router>l2tp context. Refer to the Router Configuration Guide.
Parameters	<i>tunnel-group-name</i> — Specifies an existing tunnel L2TP group up to 63 characters in length. service-id <i>service-id</i> — Specifies an existing service ID or service name.
Values	service-id: 1 to 214748364 svc-name: A string up to 64 characters in length.

authentication-policy

Syntax	authentication-policy <i>policy-name</i> no authentication-policy
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the authentication policy for the host. A host name with name “default” will be matched when all other hosts do not match.

pado-delay

Syntax	pado-delay <i>deci-seconds</i> no pado-delay
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the delay timeout before sending a PPPoE Active Discovery Offer. (PADO)
Parameters	<i>deci-seconds</i> — Specifies the delay timeout before sending a PADO.
Values	1 to 30

mask

Syntax	mask type <i>ppp-match-type</i> {[prefix-string <i>prefix-string</i> prefix-length <i>prefix-length</i>] [suffix-string <i>suffix-string</i> suffix-length <i>suffix-length</i>]} no mask type <i>ppp-match-type</i> mask type <i>dhcp-match-type</i> {[prefix-string <i>prefix-string</i> prefix-length <i>prefix-length</i>] [suffix-string <i>suffix-string</i> suffix-length <i>suffix-length</i>]} no mask type <i>dhcp-match-type</i>
Context	config>subscr-mgmt>loc-user-db>ppp config>subscr-mgmt>loc-user-db>ipoe

Description	This command configures the mask.
Parameters	<p><i>ppp-match-type</i> — Specifies the sub-option inserted by the PPPoE intermediate agent.</p> <p>Values circuit-id, remote-id, service-name, username</p> <p><i>dhcp-match-type</i> — The data type represents the type of matching done to identify a DHCP host.</p> <p>Values circuit-id, option60, remote-id, sap-id, string, system-id</p> <p>prefix-string <i>prefix-string</i> — Specifies a substring that is stripped of the start of the incoming circuit ID before it is matched against the value configured in the DHCP or PPPOE circuit ID.</p> <p>This string can only contain printable ASCII characters. The "*" character is a wildcard that matches any substring. If a "\" character is masked, use the escape key so it becomes "\\".</p> <p>Values 127 characters maximum, "*"</p> <p>prefix-length <i>prefix-length</i> — Specifies the number of characters to remove from the start of the incoming circuit ID before it is matched against the value configured in the circuit ID.</p> <p>Values 1 to 127</p> <p>suffix-string <i>suffix-string</i> — Specifies a substring that is stripped of the end of the incoming circuit ID before it is matched against the value configured in circuit ID.</p> <p>This string can only contain printable ASCII characters. The "*" character is a wildcard that matches any substring. If a "\" character is masked, use the escape key so it becomes "\\".</p> <p>Values 127 characters maximum</p> <p>suffix-length <i>suffix-length</i> — Specifies the number of characters to remove from the end of the incoming circuit ID before it is matched against the value configured in the circuit ID.</p> <p>Values 1 to 127</p>

match-list

Syntax	match-list <i>match-type-1</i> [<i>match-type-2</i> ...(up to 4 max)] no match-list
Context	config>subscr-mgmt>loc-user-db>ppp config>subscr-mgmt>loc-user-db>ipoe
Description	This command specifies the type of matching done to identify a host. There are different match-types for PPPoE or IPoE hosts of which a maximum of 4 can be specified.
Default	no match-list

Parameters	<i>match-type-x</i> — Specifies up to four matching types to identify a host.
Values	circuit-id, derived-id, dual-stack-remote-id, encap-tag-range, ip, mac, option60, remote-id, sap-id, service-id, string, system-id
circuit-id	— Specifies the DHCP4 option (82,1) or DHCP6 option 18.
mac	— Specifies the MAC address of the client. Chaddr in DHCP4 and DUID in IPv6.
option60	— Specifies the DHCP4 option 60.
remote-id	— Specifies the DHCP4 option (82,2) or DHCP6 option 37

Note: The format of remote-id in IPv6 is different that the format of remote-id in IPv4; IPv6 remote-id contains enterprise-id field that is also honored in matching.

dual-stack-remote-id — Specifies the enterprise-id in v6 Remote-id will be stripped off before LUDB matching is performed. Processing of IPv4 Remote-id remains unchanged. This will allow a single host entry in LUDB for dual-stack host where host identification is performed based on the Remote-id field.

sap-id — Specifies the SAP ID on which DHCPv4 packet are received. The sap-id is inserted as ALU VSO (82,9,4) by the DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. Since the dhcp-relay configuration is enabled under the group-interface CLI hierarchy, the group-interface and the service-id must be known before the sap-id can be used for LUDB match.

encap-tag-range — Specifies the VLAN tags.

ip — Specifies the source IPv4/IPv6 address of a data-trigger packet.

service-id — Specifies the service-id of the ingress SAP for DHCPv4 packets. The service-id is inserted as ALU VSO (82,9,3) by the DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay.

string — Specifies the custom string configured under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. The string is inserted as ALU VSO (82,9,5) by the DHCPv4 relay in router. Since the dhcp-relay configuration is enabled under the group-interface CLI hierarchy, the group-interface and the service-id must be known before the string can be used for LUDB match.

system-id — Specifies the system-id of the node name configured under the **system>name** CLI hierarchy. The system-id is inserted as ALU VSO (82,9,1) by the DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. Since the dhcp-relay configuration is enabled under the group-interface CLI hierarchy, the group-interface and the service-id must be known before the system-id can be used for LUDB match.

derived-id — Specifies the value extracted by Python script during processing of DHCP Discover/Solicit/Request/Renew/Rebind Messages (client to server bound messages). The value is stored in the DHCP Transaction Cache (DTC) in a variable named `alc.dtc.derivedId`. This value has a lifespan of a DHCP transaction (a single pair of messages exchanged between the client and the server; for example DHCP Discover and DHCP Offer).

password

Syntax	password { ignore chap <i>string</i> pap <i>string</i> } [hash hash2] no password
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command specifies a password type or configures password string for pap or chap . The pap and chap passwords are stored in a hashed format in the config files. The hash hash2 optional keywords are used for config execution. This command will only be interpreted if the local user database is connected directly to the PPPoE node under the VPRN/IES group interface. It is not used if the local user database is accessed by a local DHCP server.
Parameters	ignore — Specifies that the password will be ignored, in which case authentication will always succeed, independent of the password used by the PPPoE client. The client must still perform authentication. chap <i>string</i> — Specifies that the password for Challenge-Handshake Authentication Protocol (CHAP) is used. Only a password received with the CHAP protocol will be accepted. pap <i>string</i> — Specifies that the Password Authentication Protocol (PAP) is used. Only a password received with the PAP protocol will be accepted, even though the CHAP protocol will be proposed to the client first because it is unknown at the time of the offer which password type will be allowed to the client. hash hash2 — Specifies hashing scheme.

pre-auth-policy

Syntax	pre-auth-policy <i>policy-name</i> no pre-auth-policy
Context	config>subscr-mgmt>loc-user-db>ppp>host
Description	This command configures the pre-authentication policy of this host.

to-server-options

Syntax	[no] to-server-options
Context	config>subscr-mgmt>loc-user-db>ipoe>host
Description	This command configures the DHCP options to send to the server.

option

Syntax	option <i>option-number</i> address [<i>ip-address</i>] no option <i>option-number</i>
Context	config>subscr-mgmt>loc-user-db>ipoe>host>to-server-options>ipv6
Description	This command specifies the DHCPv6 options to send to the server. There are four options: option <i>option-number</i> hex <i>hex-string</i> option <i>option-number</i> string <i>ascii-string</i> option <i>option-number</i> domain <i>domain-name</i> no option <i>option-number</i>
Default	None
Parameters	<i>option-number</i> — Specifies the option number and the identification string that will be inserted in the DHCP client message to the server. Values 1 to 65535 <i>ip-address</i> — Specifies the IPv6 address. <i>hex-string</i> — Specifies the hex value of the option. Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles) <i>ascii-string</i> — Specifies the string value of the option. Values 127 character max <i>domain-name</i> — Specifies the domain as in RFC 1035 section 3.1.

retail-service-id

Syntax	retail-service-id <i>service-id</i> no retail-service-id
Context	config>subscr-mgmt>loc-user-db>ipoe>host config>subscr-mgmt>loc-user-db>ppp>host

Description	<p>This command indicates the service ID of the retailer VPRN service to which this session belongs. If the value of this object is non-zero, the session belongs to a retailer VPRN.</p> <p>The no form of the command removes the service ID from the configuration.</p>						
Default	no retail-service-id						
Parameters	<p><i>service-id</i> — Specifies the retailer service ID.</p> <table><tr><td colspan="2">Values</td></tr><tr><td>service-id:</td><td>1 to 2147483647</td></tr><tr><td>service-name:</td><td>Service name up to 64 characters in length.</td></tr></table>	Values		service-id:	1 to 2147483647	service-name:	Service name up to 64 characters in length.
Values							
service-id:	1 to 2147483647						
service-name:	Service name up to 64 characters in length.						

server6

Syntax	server6 <i>ipv6-address</i> no server6				
Context	config>subscr-mgmt>loc-user-db>ipoe>host				
Description	<p>This command allows DHCP6 server selection based on the host entry in LUDB.</p> <p>The configured DHCP6 server IP address must reference one of the v6 addressees configured under the config>service>vprn>sub-if>grp-if>ipv6>dhcipv6>relay or config>service>ies>sub-if>grp-if>ipv6>dhcipv6>relay context.</p>				
Default	no server6				
Parameters	<p><i>ipv6-address</i> — Specifies the retailer service ID.</p> <table><tr><td colspan="2">Values</td></tr><tr><td><ipv6-address></td><td>: ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D</td></tr></table>	Values		<ipv6-address>	: ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D
Values					
<ipv6-address>	: ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D				

3.8.2.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

dhcp

Syntax	dhcp
Context	show>router show>service>id
Description	This command displays DHCP related information.

lease-state

Syntax	lease-state [wholesaler <i>service-id</i>] [sap <i>sap-id</i>] sdp <i>sdp-id:vc-id</i> interface <i>interface-name</i> ip-address <i>ip-address[/mask]</i> chaddr <i>ieee-address</i> mac <i>ieee-address</i> {[port <i>port-id</i>] [no-inter-dest-id inter-dest-id <i>inter-dest-id</i>]} [session { none ipoe }] [detail]
Context	show>service>id>dhcp
Description	This command displays DHCP lease state information. The wholesaler <i>service-id</i> parameter is applicable only in the VPRN context.
Parameters	<p>wholesaler <i>service-id</i> — The service ID of the wholesaler. When specified in this context, SAP, SDP, interface, IP address and MAC parameters are ignored. This parameter applies only to the 7750 SR.</p> <p>Values <i>service-id</i>: 1 to 214748364 <i>svc-name</i>: A string up to 64 characters in length.</p> <p>sap <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p> <p>sdp <i>sdp-id</i> — The SDP identifier.</p> <p>Values 1 to 17407</p> <p><i>vc-id</i> — The virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID.</p> <p>Values 1 — 4294967295</p> <p>interface <i>interface-name</i> — Specifies the interface name up to 32 characters in length.</p> <p>ip <i>ip-address[/mask]</i> — Shows information for the specified IP address and mask.</p>

- port** *port-id* — The DHCP lease state local specifies that the DHCP lease state is learned by either a SAP or SDP. When the value is SAP, the value indicates the SAP for which this entry contains information.
- chaddr** — Specifies the MA address of the DHCP lease state.
- interface** *interface-name* — Shows information for the specified IP interface.
- detail** — Displays detailed lease state information.
- inter-dest-id** — Indicates the intermediate destination identifier received from either the DHCP or the RADIUS server or the local user database.
- session** — Shows DHCPv4 lease states for hosts that are associated with an IPoE session or for hosts that are not associated with an IPoE session.
- Values** none, ipoe
- detail** — Displays detailed information.

Output

declined-addresses

Syntax	declined-addresses <i>ip-address[/mask]</i> [detail] declined-addresses pool <i>pool-name</i>
Context	show>router>dhcp>server
Description	This command display information about declined addresses.
Parameters	pool <i>pool-name</i> — Specifies a DHCP pool name on the router. <i>ip-address</i> — Specifies the IP address of the DNS server. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). detail — Displays detailed information.
Output	

Sample Output

```
*A:ALA-48>show>router>dhcp>server# declined-addresses pool test

free-addresses

Syntax **free-addresses** *ip-address[/mask]*
free-addresses summary [**subnet** *ip-address[/mask]*]
free-addresses pool *pool-name*

Context show>router>dhcp>local-dhcp-server

Description This command displays the free addresses in a subnet.

Parameters **pool** *pool-name* — Specifies a DHCP pool name on the router.
subnet *subnet* — Specifies a subnet of IP addresses that are served from the pool.
summary — Displays summary output of the free addresses.

Output

Sample Output

```

*A:ALA-48>show>router>dhcp>local-dhcp-server# free-addresses pool test subnet

Context show>router>dhcp>local-dhcp-server

Description This command displays the DHCP leases.

Parameters *ip-address* — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

 mask — The subnet mask in dotted decimal notation.

Values 0 to 32

address-from-user-db [**detail**] — Displays only leases that have ip-addresses from the local-user-db.

dhcp-host *dhcp-host-name* [**detail**] — Shows all leases that match a certain DHCP host from the local-user-db.

ppp-host *ppp-host-name* [**detail**] — Displays all leases that match a certain PPPoE host from the local-user-db.

detail — Displays detailed information of all leases that fall into the indicated subnet. The command with no parameters will show all leases from the local-user-db.

Output

Sample Output

```
*A:ALA-48>show>router>dhcp>local-dhcp-server# leases ip-address 1.0.0.4
=====
Leases for DHCP server test router Base
=====
IP Address      Lease State      Mac Address      Remaining Clnt
  PPPoE user name/Opt82 Circuit Id      LifeTime  Type
-----
No leases found
*A:ALA-48>show>router>dhcp>local-dhcp-server#
```

pool-ext-stats

Syntax	pool-ext-stats [<i>pool-name</i>]
Context	show>router>dhcp>server
Description	This command displays extended statistics per DHCPv4 pool in local DHCPv4 server.

The following statistics are included in output:

- The number of stable leases in the pool
- The number of provisioned address in the pool
- The number of used address in the pool
- The number of free address in the pool
- The percentage of used address
- The percentage of free address

For each statistic (except for Provisioned Addresses), there is current value and peak value, peak value is the highest value since pool creation or last reset via the **clear router *rt-id* dhcp local-dhcp-server *svr-name* pool-ext-stats** command.

Parameters *pool-name* — Specify the name of DHCPv4 local server pool.

Output

Sample Output

```
show router 500 dhcp local-dhcp-server "d4" pool-ext-stats "pool-1"
=====
Extended pool statistics for server "d4"

subnet-ext-stats

Syntax **subnet-ext-stats** *ip-address[/mask]*
subnet-ext-stats pool *pool-name*

Context show>router>dhcp>server

Description This command displays extended statistics per DHCPv4 subnet in local DHCPv4 server.

The following statistics are included in output:

- The number of stable leases in the subnet
- The number of provisioned address in the subnet
- The number of used address in the subnet
- The number of free address in the subnet
- The percentage of used address
- The percentage of free address

For each statistic (except for Provisioned Addresses), there is current value and peak value, peak value is the highest value since subnet creation or last reset via the **clear router rt-id dhcp local-dhcp-server svr-name subnet-ext-stats** command.

When parameter pool is used, the statistics of each subnet in the pool will be displayed.

Parameters *ip-address[/mask]* — Specifies the subnet.
pool-name — The name of local DHCPv4 server pool

Output

Sample Output

```
show router 500 dhcp local-dhcp-server "d4" subnet-ext-stats 220.10.10.0/24
=====

statistics

- Syntax** **statistics** [**sap** *sap-id*] | [**sdp** [*sdp-id*[:*vc-id*]] | **interface** *ip-int-name*]]
- Context** show>router>dhcp
show>service>id>dhcp
- Description** This command displays statistics for DHCP relay and DHCP snooping.
- If no IP address or interface name is specified, then all configured interfaces are displayed.
- If an IP address or interface name is specified, then only data regarding the specified interface is displayed.
- Parameters** **sap-id** — Specifies the physical port identifier portion of the SAP definition.
sdp-id — The SDP ID to be shown.
Values 1 to 17407
vc-id — The virtual circuit ID on the ID to be shown.
Values 1 to 4294967295
ip-int-name | *ip-address* — Displays statistics for the specified IP interface.
- Output** **Show DHCP Statistics Output**
- The following table describes the output fields for DHCP statistics.

Table 44 DHCP Statistics Output Fields

Label	Description
Received Packets	The number of packets received from the DHCP clients.
Transmitted Packets	The number of packets transmitted to the DHCP clients.
Received Malformed Packets	The number of malformed packets received from the DHCP clients.
Received Untrusted Packets	The number of untrusted packets received from the DHCP clients.
Client Packets Discarded	The number of packets received from the DHCP clients that were discarded.
Client Packets Relayed	The number of packets received from the DHCP clients that were forwarded.

Table 44 DHCP Statistics Output Fields (Continued)

Label	Description (Continued)
Client Packets Snooped	The number of packets received from the DHCP clients that were snooped.
Server Packets Discarded	The number of packets received from the DHCP server that were discarded.
Server Packets Relayed	The number of packets received from the DHCP server that were forwarded.
Server Packets Snooped	The number of packets received from the DHCP server that were snooped.

Sample Output

leases

Syntax	leases [<i>ipv6-address/prefix-length</i>] [<i>type</i>] [<i>state</i>] [detail]
Context	show>router>dhcp6>local-dhcp-server
Description	This command displays the DHCP6 leases.
Parameters	<i>ipv6-address</i> — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). <i>mask</i> — The subnet mask in dotted decimal notation. Values 0 to 32

type — Displays the lease type.

Values pd, wan-host

state — Displays the state of the lease.

Values advertised, remove-pending, held

detail — Displays detailed information of all leases that fall into the indicated subnet.

The command with no parameters will show all leases from the local-user-db.

Output

pool-ext-stats

Syntax **pool-ext-stats** [*pool-name*]

Context show>router>dhcp6>server

Description This command displays extended statistics per DHCPv6 pool in local DHCPv6 server.

The following statistics are included in output:

- The number of stable leases in the pool
- The number of provisioned /64 address block in the pool
- The number of used /64 address block in the pool
- The number of free /64 address block in the pool
- The percentage of used address (with /64 address block)
- The percentage of free address (with /64 address block)

For each statistic (except for Provisioned Addresses), there is current value and peak value, peak value is the highest value since pool creation or last reset via command “clear router <rt-id> dhcp6 local-dhcp-server <svr-name> pool-ext-stats”.

Parameters *pool-name* — Specifies the name of DHCPv6 local server pool.

Output

Sample Output

```

pool-threshold-stats

Syntax

pool-threshold-stats [*pool-name*] **detail** [**format** {**exact** | **scientific**}]
pool-threshold-stats [*pool-name*]

Context

show>router>dhcp6>server

Description

This commands displays pool level threshold stats of local DHCPv6 server. A minimum-free threshold needs to be configured before system collects threshold stats for the prefix.

The stats for each threshold are calculated based on the configured minimum-free prefix length.

For example, a /59 prefix is provision in the local DHCPv6 server, and the server allocated two PD leases, one /62 and one /63. And there is a /63 minimum threshold configured. So the threshold stats are calculated based on /63 as the base unit(block). So the value of “current used block” would be 3 because there is one /62 lease and one /63 lease, so it equals to total three /63.

Parameters

pool-name — Specifies the name of the pool in local DHCPv6 server.

detail — Displays detailed output.

format — Specifies the format in the display to be either **exact** or **scientific**.

Output

Sample Output

```

show router 500 dhcp6 local-dhcp-server "d6" pool-threshold-stats "1"
=====
Server "d6"
=====
  Operational state      : inService
-----

-----
  Threshold   Used   Peak   Too low   Depleted   Peak timestamp
-----
  /62         25%    25%    N         N         01/21/2015 21:52:12
  /63         19%    19%    N         N         01/21/2015 21:52:12

```

The command shown above displays an overview of pool level thresholds in the specified pool:

- The **Peak** field indicates the peak value of used
- The **Too low** field indicate if the configured minimum-free threshold is exceed
- The **Depleted** field indicate if there is no available prefix with the length in the provisioned prefix
- The **Peak timestamp** field indicates the time of peak used value

```

```

The above command displays detailed statistics of all pool level thresholds in the specified pool:

- **Blks** in the output means the minimum free prefix length.
- **Valid Data** output indicates whether the data you see is valid or not. The data is invalid when a background stats update is scheduled or busy.

prefix-ext-stats

Syntax	prefix-ext-stats <i>ipv6-address/prefix-length</i> prefix-ext-stats pool <i>pool-name</i>
Context	show>router>dhcp6>server
Description	This command displays extended statistics per DHCPv6 prefix in local DHCPv6 server.

The following statistics are included in output:

- The number of stable leases in the prefix
- The number of provisioned /64 address block in the prefix
- The number of used /64 address block in the prefix
- The number of free /64 address block in the prefix
- The percentage of used address (with /64 address block)
- The percentage of free address (with /64 address block)

For each statistic (except for “Provisioned Addresses”), there is current value and peak value, peak value is the highest value since prefix creation or last reset via command “clear router <rt-id> dhcp6 local-dhcp-server <svr-name> prefix-ext-stats”.

When parameter “pool” is used, the statistics of each prefix in the pool will be displayed.

Parameters *ipv6-address/prefix-length* — Specifies the IPv6 prefix
 pool-name — The name of DHCPv6 local server pool

Output

Sample Output

```
show router 500 dhcp6 local-dhcp-server "d6" prefix-ext-stats 2001:ABCD::/62
=====
Extended statistics for prefix 2001:ABCD::/62

prefix-stats

Syntax **prefix-stats** *ipv6-address/prefix-length*
 prefix-stats pool *pool-name*

Context show>router>dhcp6>local-dhcp-server

Description This command displays prefix statistics.

Parameters *ipv6-address* — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

pool-name — The name of DHCPv6 local server pool.

prefix-threshold-stats

Syntax **prefix-threshold-stats pool** *pool-name* **detail** [**format** {**exact**|**scientific**}]

prefix-threshold-stats pool *pool-name*

prefix-threshold-stats *ipv6-address/prefix-length* **detail** [**format** {**exact**|**scientific**}]

prefix-threshold-stats *ipv6-address/prefix-length*

Context show>router>dhcp6>server

Description This commands displays prefix level threshold stats of local DHCPv6 server prefix. A minimum-free threshold needs to be configured before system collects threshold stats for the prefix.

 The stats for each threshold are calculated based on the configured minimum-free prefix length.

 For example, a /59 prefix is provision in the local DHCPv6 server, and the server allocated two PD leases, one /62 and one /63. And there is a /63 minimum threshold configured. So the threshold stats are calculated based on /63 as the base unit(block). So the value of “current used block” would be 3 because there is one /62 lease and one /63 lease, so it equals to total three /63.

Parameters **pool** *pool-name* — Specifies the name of the pool in local DHCPv6 server up to 32 characters in length.

detail — Displays detailed output statistics.

format — Specifies that the number format in the display will be either **exact** or **scientific**

ipv6-address/prefix-length — Specifies the IPv6 prefix with prefix length

Values

ipv6-address x:x:x:x:x:x:x (eight 16-bit pieces)

 x:x:x:x:x:x.d.d.d.d

 x [0 to FFFF]H

 d [0 to 255]D

 prefix-length [1 to 128]

Output

Sample Output

```

virtual-subnet

Syntax **virtual-subnet subscriber** *sub-ident*
virtual-subnet [*sap sap-id*]

Context show>service>id

- Description** This command displays currently recorded default gateway and subnets for all virtual subnets enabled for DHCPv4 hosts in the specified service.
- Parameters** **subscriber** *sub-ident* — Displays information relating to the specified subscriber ID.
sap *sap-id* — Displays information relating to the specified SAP ID.

Output**Sample Output**

```
show service id 500 virtual-subnet
=====
Virtual subnets in service 500
=====
Subscriber                : 00:20:fc:1e:cd:52|1/1/9:200

```

lease-state

- Syntax** **lease-state** [**detail**] [**wholesaler** *service-id*] [**session** {**none**|**ipoe**|**ppp**}]|
lease-state [**detail**] **interface** *interface-name* [**wholesaler** *service-id*] [**session** {**none**|**ipoe**|**ppp**}]|
lease-state [**detail**] *ipv6-address ipv6-prefix[/prefix-length]* [**wholesaler** *service-id*] [**session** {**none**|**ipoe**|**ppp**}]|
lease-state [**detail**] **mac** *ieee-address* [**wholesaler** *service-id*] [**session** {**none**|**ipoe**|**ppp**}]
- Context** show>service>id>dhcp6
- Description** This command displays DHCP6 lease state information. The **wholesaler** *service-id* parameter is applicable only in the VPRN context.
- Parameters** **wholesaler** *service-id* — The service ID of the wholesaler. When specified in this context, SAP, SDP, interface, IP address and MAC parameters are ignored. This parameter applies only to the 7750 SR.
- Values** service-id: 1 to 214748364
svc-name: A string up to 64 characters in length.
- sap** *sap-id* — Specifies the physical port identifier portion of the SAP definition.
- sdp** *sdp-id* — The SDP identifier.
- Values** 1 to 17407

vc-id — The virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID.

Values 1 to 4294967295

interface *interface-name* — Specifies the interface name up to 32 characters in length.

ipv6 *ipv6-address[/mask]* — Specifies the IPv6 address and mask.

port *port-id* — The DHCP6 lease state local specifies that the DHCP lease state is learned by either a SAP or SDP. When the value is SAP, the value indicates the SAP for which this entry contains information.

chaddr — Specifies the MA address of the DHCP6 lease state.

interface *interface-name* — Shows information for the specified IP interface.

detail — Displays detailed lease state information.

inter-dest-id — Indicates the intermediate destination identifier received from either the DHCP6 or the RADIUS server or the local user database.

session — Shows DHCPv6 lease states for clients that are associated with an IPoE session or for clients that are associated with a PPP session or for clients that are not associated with an IPoE session.

Values none, ipoe, ppp

detail — Displays detailed information.

3.8.2.3 Tools Commands

tools

Syntax	tools
Context	<root>
Description	This command enables the context to enable useful tools for debugging purposes.
Default	none
Parameters	dump — Enables dump tools for the various protocols. perform — Enables tools to perform specific tasks.

subscriber-mgmt

Syntax	subscriber-mgmt
Context	tools tools>perform
Description	This command enables tools to control subscriber management.

remap-lease-state

Syntax	remap-lease-state old-mac <i>ieee-address</i> mac <i>ieee-address</i> remap-lease-state sap <i>sap-id</i> [mac <i>ieee-address</i>]
Context	tools>perform>subscr-mgmt
Description	This command allows the remapping of all existing hosts if network card on CMTS/WAC side is changed is required.

When this command is executed, the following restrictions apply

- When **sap** is taken, all leases associated with the SAP are re-written.
 - For a SAP with a configured MAC in lease-populate command, this MAC will be taken.
 - For a SAP without a configured MAC the MAC from tools command will be taken.
 - For a SAP without a configured MAC and no MAC in tools command no action will be perform.
- When using the **old-mac** option, providing a new MAC *ieee-address* is mandatory.

This command is applicable only when dealing with DHCP lease states which were instantiated using I2header mode of DHCP operation.

- Parameters**
- old-mac** *ieee-address* — specifies the old MAC address to remap.
 - mac** *ieee-address* — Specifies that the provisioned MAC address will be used in the anti-spoofing entries for this SAP when I2-header is enabled. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a **tools perform** command is issued for the lease.
 - sap** *sap-id* — Specifies the physical port identifier portion of the SAP definition.
When configured, the SAP parameter will remap all MAC addresses of DHCP lease states on the specified SAP. When no optional MAC parameter is specified, the **sap sap-id** command remaps all MAC addresses of lease states towards the MAC address specified in the I2-header configuration.

perform

- Syntax** perform
- Context** tools
- Description** This command enables the context to enable tools to perform specific tasks.
- Default** none

edit-ppp-session

- Syntax** **edit-ppp-session sap** *sap-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*] [**app-profile-string** *app-profile-string*]
edit-ppp-session svc-id *service-id* [**user-name** *user-name*] [**mac** *mac-address*] [**session-id** *session-id*] [**ip** *ip-address*] [**subscriber** *sub-ident-string*] [**sub-profile-string** *sub-profile-string*] [**sla-profile-string** *sla-profile-string*] [**app-profile-string** *app-profile-string*] [**inter-dest-id** *intermediate-destination-id*] [**ancp-string** *ancp-string*]
- Context** tools>perform>subscr-mgmt
- Description** This command modifies PPP session information.
- Parameters**
- sap-id** — Specifies the physical port identifier portion of the SAP definition.
 - ip-address* — Specifies the IP address.
 - sub-ident-string* — Specifies a subscriber identification profile.
 - sub-profile-string* — Specifies the subscriber profile string, up to 16 characters, maximum.

service-id — The service identification number that identifies the service in the domain.

intermediate-destination-id — Specifies the intermediate destination identifier which is encoded in the identification strings.

ancp-string *ancp-string* — Specifies the ASCII string of the DSLAM circuit ID name.

app-profile-string — Specifies an application profile string.

eval-lease-state

Syntax	eval-lease-state [svc-id <i>service-id</i>] [sap <i>sap-id</i>] [subscriber <i>sub-ident-string</i>] [ip <i>ip-address</i>] [mac <i>mac-address</i>]
Context	tools>perform>subscr-mgmt
Description	This command evaluates lease state.
Parameters	sap-id — Specifies the physical port identifier portion of the SAP definition. <i>ip-address</i> — Specifies the a server's IP address. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). <i>sub-ident-string</i> — Specifies the subscriber ID string, up to 32 characters, maximum. <i>service-id</i> — Specifies an existing service ID. Values 1 to 2147483647

local-user-db

Syntax	local-user-db <i>local-user-db-name</i>
Context	tools>perform>subscr-mgmt
Description	This command enables tools for controlling the local user database.
Parameters	<i>local-user-db-name</i> — Specifies the name of a local user database.

ipoe

Syntax	ipoe
Context	tools>perform>subscr-mgmt>loc-user-db
Description	This command contains the tools used to control IPoE entries in the local user database.

ipoe

Syntax	ipoe
Context	tools>perform>subscr-mgmt>loc-user-db
Description	This command contains the tools used for controlling IPoE entries in the local user database.

authentication

Syntax	authentication user-name <i>user-name</i> password <i>password</i> [circuit-id <i>circuit-id</i>] [circuit-id-hex <i>circuit-id-hex</i>] [mac <i>ieee-address</i>] [remote-id <i>remote-id</i>] [derived-id <i>derived-id</i>] [mac <i>ieee-address</i>] [remote-id-hex <i>remote-id-hex</i>] [sap-id <i>sap-id</i>] [service-name <i>service-name</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ppp
Description	This command authenticates PPP user name. As local user database PAP/CHAP authentication can only be used when the local user database is connected to the PPP node under the group interface, the user lookup will be performed with match-list username.
Parameters	<p>password <i>password</i> — specifies the password of this host up to 32 characters in length.</p> <p>mac <i>ieee-address</i> — Specifies information about the MAC address of the PPP session.</p> <p><i>remote-id</i> — specifies what information goes into the remote-id sub-option in the DHCP relay packet.</p> <p>Values Up to 255 characters maximum</p> <p><i>circuit-id</i> <i>circuit-id</i> — specifies the circuit ID from the Option 82.</p> <p>circuit-id-hex <i>circuit-id-hex</i> — Specifies the circuit ID in hexadecimal format from the Option 82.</p> <p>Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)</p> <p>user-name <i>user-name</i> — Specifies the PPP user name.</p> <p>service-name <i>service-name</i> — Specifies the service name.</p>

host-lookup

Syntax	host-lookup [mac <i>ieee-address</i>] [remote-id <i>remote-id-ascii</i>] [sap-id <i>sap-id</i>] [service-id <i>service-id</i>] [string <i>vso-string</i>] [system-id <i>system-id</i>] [option60 <i>option-60-ascii</i>] [circuit-id <i>circuit-id-ascii</i>] [circuit-id-hex <i>circuit-id-hex</i>] [option60-hex <i>option60-hex</i>] [remote-id-hex <i>remote-id-hex</i>] [derived-id <i>derived-id</i>] [ip-prefix <i>ip-prefix/ip-prefix-length</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ipoe
Description	This command performs a lookup in the local user database. This command looks up the host with the match-list configured in the local user database.

Parameters	<p>mac <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><i>remote-id</i> — specifies what information goes into the remote-id sub-option in the DHCP relay packet.</p> <p>Values Up to 255 characters maximum</p> <p>sap-id — Specifies a SAP identifier to be used.</p> <p><i>service-id</i> — Specifies an existing subscriber service ID.</p> <p>Values 1 to 2147483647</p> <p><i>vso-string</i> — Specifies a Vendor Specific Option (VSO) string.</p> <p><i>system-id</i> — Specifies the system ID.</p> <p>Values up to 255 characters maximum.</p> <p>option60 <i>hex-string</i> — Specifies the content of option 60 for this lookup.</p> <p>Values 0x0 to 0xFFFFFFFF (maximum 64 hex nibbles)</p> <p><i>circuit-id circuit-id</i> — specifies the circuit ID from the Option 82.</p> <p>circuit-id-hex <i>circuit-id-hex</i> — Specifies the circuit ID in hexadecimal format from the Option 82.</p> <p>Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)</p> <p>sap-id <i>sap-id</i> — Specifies a SAP ID, up to 255 characters maximum.</p> <p>option60 <i>option-60-ascii</i> — Specifies the Vendor-Identifying Vendor Option to match against. Option 60 is encoded as Type - Length - Value and must be formatted in ASCII.</p> <p>option60-hex <i>option-60-hex</i> — Specifies the Vendor-Identifying Vendor Option to match against. Option 60 is encoded as Type - Length - Value and must be formatted in HEX.</p>
-------------------	--

ppp

Syntax	ppp
Context	tools>perform>subscr-mgmt>loc-user-db
Description	This command contains the tools used to control PPP entries in the local user database.

host-lookup

Syntax	host-lookup [circuit-id <i>circuit-id</i>] [circuit-id-hex <i>circuit-id-hex</i>] [derived-id <i>derived-id</i>] [mac <i>ieee-address</i>] [remote-id <i>remote-id</i>] [remote-id-hex <i>remote-id-hex</i>] [sap-id <i>sap-id</i>] [service-
---------------	---

	name <i>service-name</i>] [user-name <i>user-name</i>]
Context	tools>perform>subscr-mgmt>loc-user-db>ppp
Description	This command performs a lookup in the local user database.
Parameters	<p>mac <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p>remote-id <i>remote-id</i> — specifies what information goes into the remote-id sub-option in the DHCP relay packet.</p> <p>Values Up to 255 characters maximum</p> <p>user-name <i>user-name</i> — Specifies a user name up to 128 characters in length.</p> <p>service-name <i>service-name</i> — Specifies a PPP service name, up to 255 characters maximum.</p> <p><i>circuit-id</i> <i>circuit-id</i> — specifies the circuit ID from the Option 82.</p> <p>circuit-id-hex <i>circuit-id-hex</i> — Specifies the circuit ID in hexadecimal format from the Option 82.</p> <p>Values 0x0 to 0xFFFFFFFF (maximum 254 hex nibbles)</p> <p>derived-id <i>derived-id</i> — Specifies an ASCII string that uniquely identifies a host, and is derived by a Python script from packet content available during a DHCP transaction.</p>

pool

Syntax	pool <i>pool-name</i>
Context	tools>perform>router>dhcp>server
Description	This command performs local DHCP server IP address pool tasks.
Parameters	<i>pool-name</i> — Specifies the pool name.

create-sticky-lease

Syntax	create-sticky-lease <i>host-name</i> [mac <i>ieee-address</i>] [circuit-id <i>circuit-id</i>] [client-id <i>client-id</i>] [requested-ip-address <i>ip-address</i>] [circuit-id-hex <i>circuit-id-hex-string</i>] [client-id-hex <i>client-id-hex-string</i>]
Context	tools>perform>router>dhcp>server>pool

Description	<p>This command tries to create a lease-state in the specified local-dhcp-server pool with the supplied parameters. The hostname will uniquely identify this lease for subsequent operations. <i>mac/circuit-id</i> and <i>client-id</i> should also have a unique combination of values according to the configured user-ident variables.</p> <p>If the <i>requested-ip-address</i> is provided the server will try to create a lease with this address. If this address is not available in the pool, the command will fail.</p>
Parameters	<p><i>host-name</i> — Specifies a string to identify the lease up to 32 characters in length. If not specified, it can be internally generated based on <i>MAC@</i> or other key (in future).</p> <p>mac <i>ieee-address</i> — Specifies the MAC address in <i>xx:xx:xx:xx:xx:xx</i> or <i>xx-xx-xx-xx-xx-xx</i> format.</p> <p>circuit-id <i>circuit-id</i> — Specifies the circuit-id string up to 255 characters in length.</p> <p>client-id <i>client-id</i> — Specifies the client-id string up to 255 characters in length.</p> <p>requested-ip-address <i>ip-address</i> — Specifies the IPv4 address in dotted notation <i>a.b.c.d</i>.</p>

3.8.2.4 Clear Commands

dhcp

Syntax	dhcp
Context	clear>router
Description	This command enables the context to clear and reset DHCP entities.

local-dhcp-server

Syntax	local-dhcp-server <i>server-name</i>
Context	clear>router>dhcp clear>router>dhcp6
Description	This command clears DHCP server data.
Parameters	<i>server-name</i> — Clears data for the specified local DHCP server.

declined-addresses

Syntax	declined-addresses <i>ip-address[/mask]</i> declined-addresses pool <i>pool-name</i>
Context	clear>router>dhcp>local-dhcp-server
Description	This command clears declined DHCP addresses.
Parameters	<i>pool-name</i> — Specifies the declined pool name. <i>ip-address[/mask]</i> — Specifies the declined IP address and mask.

failover-pool-stats

Syntax	failover-pool-stats [<i>pool-name</i>]
Context	clear>router>dhcp>local-dhcp-server clear>router>dhcp6>local-dhcp-server
Description	This command clears failover pool statistics.
Parameters	<i>pool-name</i> — Specifies the pool name which is defined in the system.

leases

Syntax	leases <i>ip-address[/mask]</i> [<i>state</i>] leases all [<i>state</i>]
Context	clear>router>dhcp>local-dhcp-server clear>router>dhcp6>local-dhcp-server
Description	This command clears DHCP leases.
Parameters	<i>ip-address[/mask]</i> — Clears the specified IP address and mask. state — Clears the state of the lease to be removed. Values offered, stable, force-renew-pending, remove-pending, held, internal, internal-orphan, internal-held, sticky

pool-ext-stats

Syntax	pool-ext-stats [<i>pool-name</i>]
Context	clear>router>dhcp>local-dhcp-server clear>router>dhcp6>local-dhcp-server
Description	This command clears extended pool statistics.
Parameters	<i>pool-name</i> — Specifies the pool name.

server-stats

Syntax	server-stats
Context	clear>router>dhcp>local-dhcp-server
Description	This command clears all server statistics.

subnet-ext-stats

Syntax	subnet-ext-stats <i>ip-address[/mask]</i> subnet-ext-stats pool <i>pool-name</i>
Context	clear>router>dhcp>local-dhcp-server
Description	This command clears extended subnet statistics.

statistics

Syntax	statistics [<i>ip-int-name</i> <i>ip-address</i>]
Context	clear>router>dhcp
Description	This command clears DHCP statistics.
Parameters	<i>ip-int-name</i> — Clears DHCP statistics for the specified interface name. <i>ip-address</i> — Clears DHCP statistics for the specified IP address.

dhcp6

Syntax	dhcp6
Context	clear>router
Description	This command enables the context to clear and reset DHCP6 entities.

lease-state

Syntax	lease-state [ip-address <i>ipv6-address/prefix-length</i>] [mac <i>ieee-address</i>]
Context	clear>service>id>dhcp6
Description	This command clears DHCP6 lease state information.
Parameters	ip-address <i>ipv6-address</i> — Clears the DHCP6 IP address lease state information. The <i>ipv6-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IPv6 addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). mac <i>ieee-address</i> — Clears DHCP6 MAC address lease state information. The 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

statistics

Syntax	statistics [<i>ip-int-name</i> <i>ip-address</i>]
Context	clear>service>id>dhcp
Description	This command clears DHCP statistics.
Parameters	<i>ip-int-name</i> — Clears DHCP statistics for the specified interface name.

ip-address — Clears DHCP statistics for the specified IP address.

leases

Syntax	leases [<i>ipv6-address/prefix-length</i>] [<i>type</i>] [<i>state</i>] leases all [<i>type</i>] [<i>state</i>]
Context	clear>router>dhcp6>server
Description	This command removes the specified leases in the specified local DHCPv6 server.
Parameters	<i>ipv6-address/prefix-length</i> — The prefix of the leases to be removed. <i>type</i> — The type of the lease to be remove. Values pd, slaac, wan-host <i>state</i> — The state of the lease to be removed. Values advertised, remove-pending, held, internal, internal-orphan, internal-offered all — Remove all leases of specified type and(or) state.

pool-threshold-stats

Syntax	pool-threshold-stats [<i>pool-name</i>]
Context	clear>router>dhcp6>server
Description	This commands resets the peak stats in the pool level threshold stats in the specified pool. If the pool name is not specified, then the peak stats in all pools in the server will be reset.
Parameters	<i>pool-name</i> — The name of the local DHCPv6 server pool

prefix-ext-stats

Syntax	prefix-ext-stats <i>ipv6-address/prefix-length</i> prefix-ext-stats pool <i>pool-name</i>
Context	clear>router>dhcp6>server
Description	This command reset the begin time of peak values in output of the show router <i>rt-id</i> dhcp6 local-dhcp-server <i>svr-name</i> prefix-ext-stats command/
Parameters	<i>ipv6-address/prefix-length</i> — Specify the IPv6 prefix. <i>pool-name</i> — The name of the local DHCPv6 server pool

prefix-threshold-stats

Syntax	prefix-threshold-stats <i>ipv6-address/prefix-length</i> prefix-threshold-stats pool <i>pool-name</i>
Context	clear>router>dhcp6>server
Description	This commands resets the peak stats in the prefix level threshold stats in the specified provision prefix or pool.
Parameters	<i>pool-name</i> — Specifies the name of the pool in local DHCPv6 server. <i>ipv6-address/prefix-length</i> — Specifies the name of the IPv6 prefix with prefix length.

server-stats

Syntax	server-stats
Context	clear>router>dhcp6>server
Description	This command reset all stats of the specified local DHCPv6 server.

statistics

Syntax	statistics
Context	clear>router>dhcp6
Description	This command clears DHCP6 statistics.

3.8.2.5 Debug Commands

dhcp

Syntax	[no] dhcp [interface <i>ip-int-name</i>]
Context	debug>router>ip
Description	This command enables DHCP debugging. The no form of the command disables debugging.
Parameters	<i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

detail-level

Syntax	detail-level { low medium high } no detail-level
Context	debug>router>ip>dhcp debug>router>ip>dhcp6 debug>router>local-dhcp-server
Description	This command debugs the DHCP tracing detail level.
Parameters	low — Displays a low detail level for DHCP debugging. medium — Displays a medium detail level for DHCP debugging. high — Displays a high detail level for DHCP debugging.

local-dhcp-server

Syntax	[no] local-dhcp-server <i>server-name</i> [lease-address <i>ip-address</i>] [no] local-dhcp-server <i>server-name</i> [mac <i>ieee-address</i>]
Context	debug>router
Description	This command enables, disables or configures debugging for a local DHCP server.
Parameters	<i>server-name</i> — Specifies an existing local DHCP server name. lease-address <i>ip-address</i> — Specifies the IP address of the lease address to debug. mac <i>ieee-address</i> — Specifies that the provisioned MAC address for the local DHCP server.

mode

Syntax	mode { dropped-only ingr-and-dropped egr-ingr-and-dropped } no mode
Context	debug>router>ip>dhcp debug>router>ip>dhcp6 debug>router>local-dhcp-server
Description	This command debugs the DHCP tracing detail level.
Parameters	dropped-only — Only displays dropped packets. ingr-and-dropped — Only displays ingress packet and dropped packets. egr-ingr-and-dropped — Displays ingress, egress and dropped packets.

dhcp6

Syntax	dhcp6 [<i>ip-int-name</i>] no dhcp6
Context	debug>router>ip
Description	This command enables DHCP debugging The no form of the command disables debugging.
Parameters	<i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

4 SLAAC

4.1 In This Chapter

This chapter provides information about using SLAAC, including theory, supported features and configuration process overview.

Note: The information in this section applies only to the 7750 SR.

Topics in this chapter include:

- [Stateless Address Auto-configuration \(SLAAC\) Management](#)
- [SLAAC Principles](#)
- [Configuration Overview](#)
- [Router-Solicit Trigger](#)
- [SLAAC Address Assignment](#)
- [Static SLAAC Prefix Assignment](#)
- [Dynamic SLAAC Prefix Assignment](#)

4.2 Stateless Address Auto-configuration (SLAAC) Management

4.3 SLAAC Principles

In a Triple Play network, client devices can use SLAAC to dynamically obtain their IP address and other network configuration information.

1. During boot-up, the client sends a Router Solicit (RS) message to get an IP prefix.
2. The BNG address server can assign a prefix statically to the subscriber through Radius or LUDB. Or, dynamically through the use of the local-address-server.
3. The BNG address server will reply to the client with a Router Advertisement which contains a /64 prefix.

4.4 Configuration Overview

The ICMP6 Router Solicit is the primary trigger for SLAAC host creation. It is also possible to use the DHCPv4 message to trigger a SLAAC host creation using the “IPoE-linking” feature. The SLAAC host can use RADIUS or LUDB authentication, as well as bypass authentication. Address assignment can be assigned statically or dynamically. Static prefix assignment is accomplished through RADIUS or LUDB. Dynamic prefix assignment requires the use of the local-address-server (reusing the local DHCPv6 server), and a pool name returned from RADIUS or LUDB. The DHCPv6 server for SLAAC is used for address management only, there are no lease state associated with SLAAC users. The DHCPv6 server can be shared with regular DHCPv6 users as well.

4.5 Router-Solicit Trigger

The following example shows a router-solicit triggered configuration.

```
*A:eng-BNG-2>config>service>vprn>sub-if>grp-if>ipv6# info
-----
router-solicit
no shutdown
exit
```

To add authentication to the above configuration, there are two options.

- For RADIUS authentication, similar to DHCP and PPP authentication, add a RADIUS policy under the group interface.
- For LUDB, add the following to the **router-solicit** configuration.

```
*A:eng-BNG-2>config>service>vprn>sub-if>grp-if>ipv6# info
-----
router-solicit
  user-db "slaac-users"
  no shutdown
exit
```

4.6 SLAAC Address Assignment

After a RS is received to trigger the creation of a SLAAC host, address assignment can be provided statically or dynamically.

4.7 Static SLAAC Prefix Assignment

If using RADIUS, the attribute “framed-ipv6-prefix” VSA is used. The attribute must be a /64 prefix.

```
*A:eng-BNG-2>config>subscr-mgmt>loc-user-db>ipoe>host# info
-----
ipv6-slaac-prefix 2001::/64
```

4.8 Dynamic SLAAC Prefix Assignment

SLAAC prefix can be dynamically assigned to a user at real time. Prefixes are assignment through the local DHCPv6 pool. Therefore a DHCPv6 pool must be defined first. The following displays an example configuration.

```
*A:eng-BNG-2>config>service>vprn>dhcp6# info
-----
local-dhcp-server "dhcp6-server" create
  use-pool-from-client
  pool "pool-01" create
```

```
        prefix 2001::/32 wan-host create
        exit
    exit
exit
```

To associate the DHCPv6 server for SLAAC address assignment, the following configuration is used. Notice the server name configured under **local-address-assignment dhcp6-server** matches the name configured under the DHCPv6 pool.

```
*A:eng-BNG-2>config>service>vprn>sub-if>grp-if# info
-----
    local-address-assignment
        ipv6
            client-application ppp-slaac ipoe-slaac
            server "dhcp6-server"
        exit
        no shutdown
    exit
```

In order to specify the pool to be used for SLAAC prefix assignment, the pool name can either be returned from LUDB or RADIUS.

If using RADIUS, the attribute "Alc-slaac-ipv6-pool" is used.

If using LUDB, the following configuration is used.

```
*A:eng-BNG-2>config>subscr-mgmt>loc-user-db>ipoe>host# info
-----
    ipv6-slaac-prefix-pool "pool-01"
```

In this example, the pool named "pool-01" provisioned in the LUDB or returned from RADIUS will match the pool name configured in the DHCP6 server. A prefix from the 2001::/32 pool will be assigned to the SLAAC subscribers.

5 Point-to-Point Protocol over Ethernet Management

5.1 In This Chapter

This chapter provides information about using Point-to-Point Protocol over Ethernet (PPPoE), including theory, supported features and configuration process overview.

Note: The information in this section applies only to the 7750 SR.

Topics in this chapter include:

- [PPPoE](#)
 - [PPPoE Authentication and Authorization](#)
 - [General Flow](#)
 - [RADIUS](#)
 - [Local User Database Directly Assigned to PPPoE Node](#)
 - [Local DHCP Server with Local User Database](#)
 - [Multiple Sessions Per MAC Address](#)
 - [Private Retail Subnets](#)
- [MLPPPoE, MLPPP\(oE\)oA with LFI on LNS](#)

5.2 PPPoE

A Broadband Remote Access Server (BRAS) is a device that terminates PPPoE sessions. PPPoE sessions are supported on Nokia Broadband Services Router (BSR) on IOM2. The Point-to-Point Protocol (PPP) is used for communications between a client and a server. Point-to-Point Protocol over Ethernet (PPPoE) is a network protocol used to encapsulate PPP frames inside Ethernet frames.

Ethernet networks are packet-based, unaware of connections or circuits. Using PPPoE, Nokia users can dial from one router to another over an Ethernet network, then establish a point-to-point connection and transport data packets over the connection. In this application subscriber hosts can connect to the router using a PPPoE tunnel. There are two command available under PPPoE to limit the number of PPPoE hosts, one to set a limit that is applied on each SAP of the group-interface and one to set the limit per group-interface.

PPPoE is commonly used in subscriber DSL networks to provide point-to-point connectivity to subscriber clients running the PPP protocol encapsulated in Ethernet. IP packets are tunneled over PPP using Ethernet ports to provide the client's software or RG the ability to dial into the provider network. Most DSL networks were built with the use of PPPoE clients as a natural upgrade path from using PPP over dial-up connections. Because the PPP packets were used, many of the client software was reusable while enhancements were made such that the client could use an Ethernet port in a similar manner as it did a serial port. The protocol is defined by RFC 2516, *A Method for Transmitting PPP Over Ethernet (PPPoE)*.

PPPoE has two phases, the discovery phase and the session phase.

- Discovery: The client identifies the available servers. To complete the phase the client and server must communicate a session-id. During the discovery phase all packets are delivered to the PPPoE control plane (CPM or MDA). The IOM identifies these packets by their ethertype (0x8863).
 - PPPoE Active Discovery Initiation (PADI). This broadcast packet is used by the client to search for an active server (Access Concentrator) providing access to a service.
 - PPPoE Active Discovery Offer (PADO): If the access server can provide the service it should respond with a unicast PADO to signal the client it may request connectivity. Multiple servers may respond and the client may choose a server to connect to.
 - PPPoE Active Discovery Request (PADR): After the client receives a PADO it will use this unicast packet to connect to a server and request service.
 - PPPoE Active Discovery Session-confirmation (PADS) A server may respond to the client with this unicast packet to establish the session and provide the session-id. Once the PADS was provided the PPP phase begins.
- Session: Once the session ID is established connectivity is available for the duration of the session, using ethertype 0x8864. Either client or server can terminate a session.

During the life of the session the packets may be uniquely identified by the client's MAC address and session-id. The session can terminate either by PADT sent by the client or server or by an LCP Terminate-Request packet.

During session creation, the following occurs:

- PADI (control packet upstream): This packet is delivered to the control plane. The control plane checks the service tag for service name. In the case multiple nodes are in the same broadcast domain the service tag can be used to decide whether to respond to the client. A relay tag can also be present.
- PADO (control packet downstream): The packet is generated by the control plane as response to the PADI message. The packet is forwarded to the client using the unicast packet directed at the client's MAC address. The node populates the AC-name tag and service tag. The packet sources the forwarding Ethernet MAC address of the node. In the case SRRP is used on the interface, it uses the gateway address as the source MAC. When in a backup state, the packet is not generated.
- PADR (control packet upstream): This packet is delivered to the control plane. The packet is destined to the node's MAC address. The control plane then generates the PADS to create the session for this request.
- PADS: (control packet downstream): The control plane prepares for the session creation and sends it to the client using the client's MAC address. The session-id (16-bit value) is unique per client. The session-id is populated in the response. Once a session-id is generated, the client uses it in all packets. In cases that the server does not agree with the client's populated service tags, the PADS can be used to send a service error tag with a zero session-id to indicate the failure.
- PADT (control packet upstream/downstream): The packet is used to terminate a session. It can be generated by either the control plane or the client. The session-id must be populated. The packet is a unicast packet.
- PPP session creation supports the LCP authentication phase.

During a session, the following forwarding actions occur:

- Upstream, in the PPPoE before PPP phase, there is no anti-spoofing. All packets are sent to the CPM. During anti-spoof lookup with IP and MAC addressing, regular filtering, QoS and routing in context continue. All unicast packets are destined to the node's MAC address. Only control packets (broadcast) are sent to the control plane. Keep-alive packets are handled by the CPM.
- Downstream, packets are matched in the subscriber lookup table. The subscriber information provides queue and filter resources. The subscriber information also provides PPPoE information, such as the dest-mac-address and session-id, to build the packet sent to the client.

PPPoE-capable interfaces can be created in a subscriber interface in both IES and VPRN services (VPRN is supported on the 7750 SR only). Each SAP can support one or more PPPoE sessions depending on the configuration. A SAP can simultaneously have static hosts, DHCP leases and PPPoE sessions. The number of PPPoE sessions is limited per SAP, SLA profile or subscriber profile.

RADIUS can be used for authentication. IP addresses can be provided by both RADIUS and the local IP pool, with the possibility of choosing the IP pool through RADIUS.

DHCP clients and PPPoE clients are allowed on a single SAP or group interface. If DHCP clients are not allowed, the operator should not enable lease-populate and similarly if PPPoE clients are not allowed, the operator should not enable the PPPoE node.

Note: The DHCP node can be enabled when only PPPoE clients are allowed since the DHCP relay function can be used for IP retrieval.

The DHCP lease-populate is for DHCP leases only. A similar command host-limit is made available under PPPoE for limits on the number of PPPoE hosts. The existing per sla-profile instance host limit is for combined DHCP and PPPoE hosts for that instance.

- For authentication, local and RADIUS are supported.
 - RADIUS is supported through an existing policy. A username attribute has been added.
 - For PAP/CHAP, a local user database is supported and must be referenced from the interface configuration.
- The host configuration can come directly from the local user database or from the RADIUS or DHCP server. A local host configuration is allowed through a local DHCP server with a local user database.
- IP information can be obtained from the local user database, RADIUS, a DHCP server, or a local DHCP server.

If IP information is returned from a DHCP server. PPPoE options such as the DNS name are retrieved from the DHCP ACK and provided to the PPPoE client. An open authentication option is maintained for compatibility with existing DHCP-based infrastructure.

The DHCP server can be configured to run on a loopback address with a relay defined in the subscriber or group interfaces. The DHCP proxy functionality that is provided by the DHCP relay (getting information from RADIUS, lease-split, option 82 rewriting) cannot be used for requests for PPPoE clients.

5.2.1 PPPoE Authentication and Authorization

5.2.1.1 General Flow

When a new PPPoE session is setup, the authentication policy assigned to the group interface is examined to determine how the session should be authenticated.

If no authentication policy is assigned to the group interface or the **pppoe-access-method** is set to **none**, the local user database assigned to the PPPoE node under the group interface is queried either during the PADI phase or during the LCP authentication phase, depending on whether the match-list of the local user database contains the requirement to match on username. If the match-list does not contain the username option, PADI authentication will be performed and it is possible to specify an authentication policy in the local user database host for an extra RADIUS PAP-CHAP authentication point.

If an authentication policy is assigned and the pppoe-access-method is set to PADI, the RADIUS server will be queried for authenticating the session based on the information available when the PADI packet is received (any PPP user name and password are not known here). When it is set to PAP-CHAP, the RADIUS server will be queried during the LCP authentication phase and the PPP user name and password will be used for authentication instead of the user name and password configured in the authentication policy.

If this authentication is successful, the data returned by RADIUS or the local user database is examined. If no IP address was returned, the DHCP server is now queried for an IP address and possibly other information, such as other DHCP options and ESM strings.

The final step consists of complementing the available information with configured default values (ESM data), after which the host is created if sufficient information is available to instantiate it in subscriber management (at least subscriber ID, subscriber profile, SLA profile, and IP address).

The information that needs to be gathered is divided in three groups, subscriber ID, ESM strings, and IP data. Once one of the data sources has offered data for one of these groups, the other sources are no longer allowed to overwrite this data (except for the default ESM data). For example, if RADIUS provides an SLA profile but no subscriber ID and IP address, the data coming from the DHCP server (either through Python or directly from the DHCP option) can no longer overwrite any ESM string, only the subscriber ID and IP data. However, after the DHCP data is processed, a configured default subscriber profile will be added to the data before instantiating the host.

5.2.1.2 RADIUS

The following attributes are sent to the RADIUS server for PPPoE authentication (optional attributes can be configured under the **config>subscr-mgmt>auth-plcy>include-radius-attribute** context):

- WT-101 access loop options, DSL-Forum VSAs (optional):
 - Actual data rate Upstream (129)
 - Actual data rate Downstream (130)
 - Minimum data rate Upstream (131)
 - Minimum data rate Downstream (132)
 - Access loop encapsulation (144)
- Circuit-ID, DSL-Forum VSA 1 (optional)
- Remote-ID, DSL-Forum VSA 2 (optional)
- MAC address, Nokia VSA 27 (optional)
- PPPoE-Service-Name, Nokia VSA 35 (optional)
- Port identification attributes (optional)
 - NAS-Port-Id (87) — This attribute can optionally be prefixed by a fixed string and/or suffixed by the circuit-ID or remote-ID given in the PPPoE requests. If either the circuit-ID or remote-ID suffix are given, but the corresponding information is not available, the value 0/0/0/0/0 will be suffixed.
 - NAS-Port-Type (61). Values: 32 (null encap), 33 (dot1q), 34 (qinq), 15 (DHCP hosts), specified value (0 — 255)
- NAS identifier, attribute 32 (optional)
- User-Name, attribute 1
- User-Password, attribute 2
- Service-Type, attribute 6
- Framed-Protocol, attribute 7

In the reply from the RADIUS server, the following authorization attributes are accepted back for PPPoE hosts:

- Calling-station-id (optional)
- Framed-IP-Address, attribute 8
- Session-Timeout, attribute 27
- PADO-delay, Nokia VSA 34
- Framed-Pool, attribute 88 — If a DHCP request is done, this pool will be sent to the DHCP server in a vendor-specific sub-option under Option82 to indicate the pool from which the address from the client should be taken.

- Primary DNS, Nokia VSA 9
- Secondary DNS, Nokia VSA 10
- Primary NBNS, Nokia VSA 29
- Secondary NBNS, Nokia VSA 30
- Subscriber ID string, Nokia VSA 11
- Subscriber profile string, Nokia VSA 12
- SLA profile string, Nokia VSA 13
- ANCP string, Nokia VSA 16
- Intermediate Destination ID, Nokia VSA 28
- Application-profile string, Nokia VSA 45
- Service-Type, attribute 6 (must be correct if returned)
- Framed-Protocol, attribute 7 (must be correct if returned)
- PPPoE-Service-Name, Nokia VSA 35
- Reply-message, attribute 18
- Acct-Interim-Interval, attribute 85

For more information about Vendor-Specific Attributes and the Nokia dictionary, refer to the SR OS RADIUS Attributes Reference Guide.

5.2.1.3 Local User Database Directly Assigned to PPPoE Node

The following are relevant settings for a local user database directly assigned to PPPoE node:

- Host identification parameters (user name only)
- Username
- Password
- Address
- DNS servers (under DHCP options)
- NBNS servers (under DHCP options)
- Identification (ESM) strings

Incoming PPPoE connections are always authenticated through the PPPoE tree in the local user database.

The match list for a local user database that is assigned directly to the PPPoE node under the group interface is always **user-name**, independent of the match list setting in the database.

For user-name matching, the incoming user name (user[@domain]) is always first converted to a user and a domain entity by splitting it on the first @-sign. If the no-domain parameter to the user name is given, the user component should be equal to the given user name, if the domain-only portion of the user name is given, the domain entity should be equal to the given user name and if no extra parameters are given, the user and domain components are concatenated again and compared to the given user name.

The option number for the identification strings is not used if the local user database is assigned directly to the PPPoE node (it is only necessary if it is connected to a local DHCP server). Any valid value may be chosen in this case (if omitted, the default value chosen will be 254).

If a pool name is given for the address, this pool name will be sent to the DHCP server in a vendor-specific sub-option of Option 82 to indicate from which pool the server should take the address. If the gi-address option is given for the address, this will be interpreted as if no address was given.

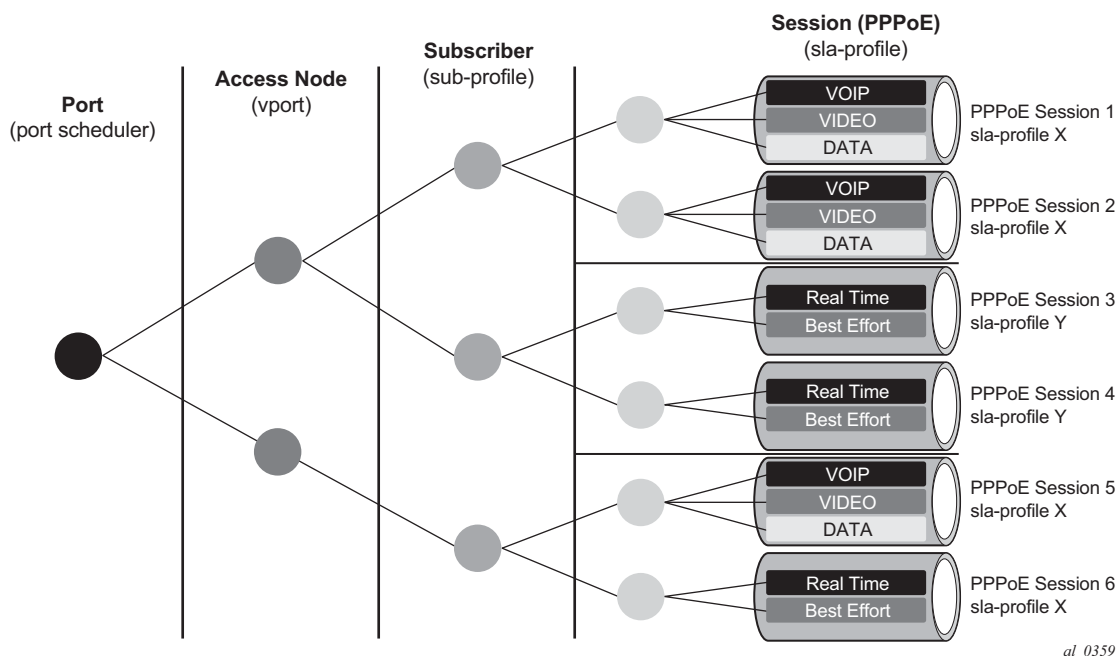

5.2.1.4 Subscriber per PPPoE Session Index

The system will keep track of the number of PPPoE sessions active on a given SAP and assign a per SAP session index to each such that always the lowest free index is assigned to the next active PPPoE session. When PAP/CHAP RADIUS authentication is used, the PPPoE SAP session index can be sent to, and received from, the RADIUS server using the following VSA:

ATTRIBUTE Alc-SAP-Session-Index 180 integer

This is supported for all PPPoE sessions, including those using LAC and LNS, but is not supported in a dual-homing topology. It should only be used in a subscriber per VLAN model as the session index is per SAP.

The intended use of the SAP session index is to provide the ability for PPPoE sessions to have their own set of queues (for QoS and accounting purposes) when using the same SLA profile name received from a RADIUS server. An example of this with multiple levels of HQoS egress scheduling is shown in [Figure 31](#).

Figure 31 Egress QoS per PPPoE Session

This requires a set of identical SLA profiles to be configured which only differ by an index being, for example, appended to their name. The SAP session index must be sent to RADIUS in the Access-Request message, which is achieved by configuring the RADIUS authentication policy to include it as follows:

```
configure subscriber-mgmt authentication-policy name
include-radius-attribute
[no] sap-session-index
```

The RADIUS server must then reflect the SAP session index back to the system in the RADIUS Access-Accept message together with the SLA profile name.

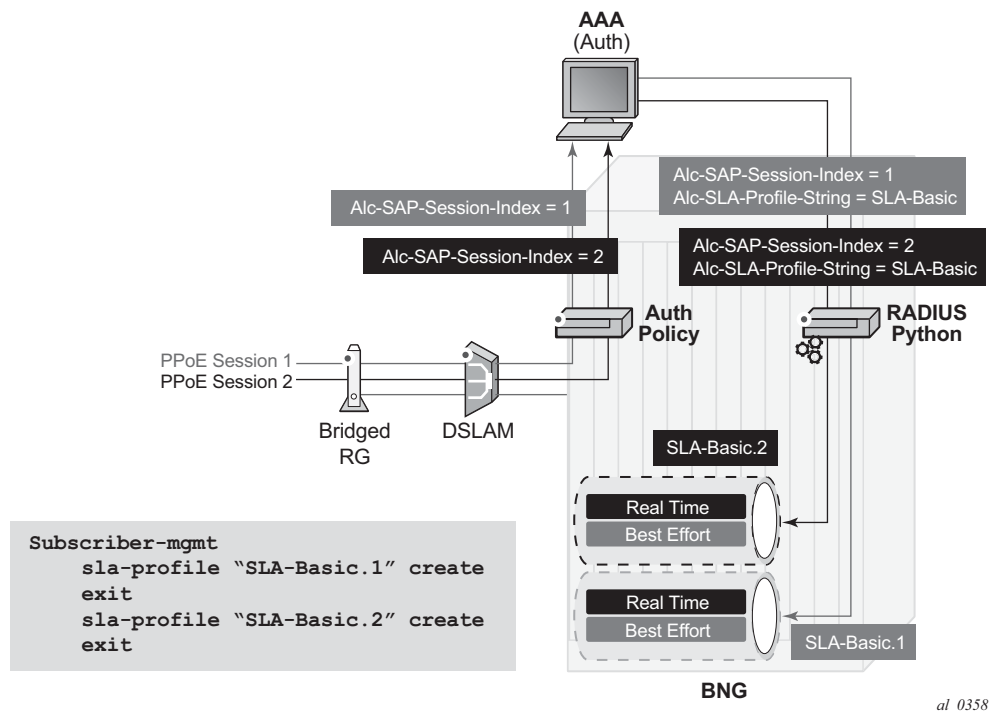

A Python script processes the RADIUS Access-Accept message to append the SAP session index to the SLA profile name to create the unique SLA profile name, in this example with the format:

sla-profile *sla-profile-name.suffix*

The exact format (for example, the separator used) is not fixed and just needs to match the pre-provisioned SLA profiles, while not exceeding 16 characters. This ensures that each PPPoE session is given its own SLA profile and consequently its own set of queues.

This processing is shown in [Figure 32](#).

Figure 32 Per PPPoE Session SLA Profile Selection

Below is an example Python script for this purpose:

```
import alc
import struct
from alc import radius
from alc import sub_svc

PROXY_STATE = 33
ALU = 6527
SLA_PROF_STR = 13
SAP_SESSION_INDEX = 180

#####
## QoS for Multiple PPPoE Sessions
# This script checks if a sap-session-
# index (sid) is included in the authentication
# accept. If present, the sla-profile-string (sla) is adapted to "sla.sid"

if alc.radius.attributes.isVSASet(ALU, SLA_PROF_STR):
    sla = alc.radius.attributes.getVSA(ALU, SLA_PROF_STR)
    if alc.radius.attributes.isVSASet(ALU, SAP_SESSION_INDEX):
        ssi = alc.radius.attributes.getVSA(ALU, SAP_SESSION_INDEX)
        suffix = "" .join(["%x" % ord(x) for x in ssi])
        alc.radius.attributes.setVSA(ALU, SLA_PROF_STR, sla + '.' + "%d" %
int(suffix,16))
```

In order to use a COA to change the SLA profile used, the new SLA profile name must be constructed with the same suffix (in this example) as that used for the current SLA profile. This is necessary in order to ensure unique use of a given provisioned SLA profile. This mandates that the SAP session index is included in the COA information. Two options are proposed to achieve this:

- The COA can specify a new SLA profile name and include the SAP session index. A Python script would then process the COA and construct the new SLA profile name to be used by appending the suffix in the same way as was done with the RADIUS Access-Accept.
- The COA could be using a RADIUS proxy which might make the first option unattractive. An alternative solution would be to use a Python script to append the suffix to the acct-session-id in all messages sent so that the suffix can be identified when a COA is received that uses the acct-session-id(+suffix) for session identification. This would need to be performed for all messages sent that include the acct-session-id. COAs would reference the session using the acct-session-id+suffix. A Python script would be required to remove the suffix and append it to the new SLA profile name. All messages received with the acct-session-id+suffix would be processed by the Python script to remove the suffix before sending the acct-session-id to the system.

In order to ensure that the acct-session-id sent in RADIUS accounting messages is updated with the suffix, the user must configure include-radius-attribute sla-profile in the RADIUS accounting policy to be applied. The Python script needs to remove the suffix from the SLA profile and add it to the acct-session-id for all messages sent. Clearly the acct-session-id used by any external server would then be different to that seen on the system.

5.2.1.5 Local DHCP Server with Local User Database

If a DHCP server is queried for IP or ESM information, the following information is sent in the DHCP request:

- Option 82 sub-options 1 and 2 (Circuit-ID and Remote-ID): These options contain the Circuit-ID and Remote-ID that were inserted as tags in the PPPoE packets).
- Option 82 sub-option 9 vendor-id 6527 VSO 6 (client type): this value is set to 1 to indicate that this information is requested for a PPPoE client. The local DHCP server uses this information to match a host in the list of PPPoE users and not in the DHCP list.
- Option 82 sub-option 6 (Subscriber-ID): This option contains the user name that was used if PAP/CHAP authentication was performed on the PPPoE connection.

- Option 82 sub-option 13 (DHCP pool): This option indicates to the DHCP server that the address from the client should be taken from the specified pool. The local DHCP server will only honor this request if the **use-pool-from-client** option is given in the server configuration.
- Option 82 sub-option 14 (PPPoE Service-Name): This option contains the service name that was used in the PADI packet during PPPoE setup.
- Option 60 (Vendor class ID): This option contains the string “ALU7XXXSBM” to identify the DHCP client vendor.
- The WT-101 access loop options are not sent for PPPoE clients

Local user database settings relevant to PPPoE hosts when their information is retrieved from the local DHCP server using this database:

- Host identification parameters (including user name)
- Address
- DNS servers (under DHCP options)
- NBNS servers (under DHCP options)
- Identification (ESM) strings

For user name matching, the incoming user name (user[@domain]) is always first converted to a user and a domain entity by splitting it on the first @-sign. If the no-domain parameter to the user name is given, the user component should be equal to the given user name, if the domain-only portion of the user name is given, the domain entity should be equal to the given user name and if no extra parameters are given, the user and domain components are concatenated again and compared to the given user name.

To prevent load problems, if DHCP lease times of less than 10 minutes are returned, these will not be accepted by the PPPoE server.

5.2.2 Multiple Sessions Per MAC Address

To support MAC-concentrating network equipment, which translates the original MAC address of a number of subscribers to a single MAC address towards the PPPoE service, the 77x0 supports at most 1023 PPPoE sessions per MAC address. Each of these sessions will be identified by a unique combination of MAC address and PPPoE session ID.

To set up multiple sessions per MAC, the following limits should be set sufficiently high:

- Maximum sessions per MAC in the PPPoE policy

- The PPPoE interface session limit in the PPPoE node of the group interface
- The PPPoE SAP session limit in the PPPoE node of the group interface
- The multiple-subscriber-sap limit in the subscriber management node of the SAP

If host information is retrieved from a local DHCP server, care must be taken that, although a host can be identified by MAC address, circuit ID, remote ID or user name, a lease in this server is only indexed by MAC address and circuit ID. For example, multiple sessions per MAC address are only supported in this scenario if every host with the same MAC address has a unique Circuit-ID value.

5.2.3 Private Retail Subnets

PPPoE is commonly used in residential networks and has expanded into business applications. PPPoE session management allows PPPoE to be used for business VPRN access (VPRN is supported on the 7750 SR only).

PPPoE provides the following:

- Control over the session
- De-muxing based on the session ID provides the ability for the SAP and the Layer 2 network to be common to all VPRNs.

The PPPoE subscriber host will terminate in a retail VPRN and provide a routed path to the customer site. The customer site may be connected to more than one 7750 SR for dual homing purposes. In such a network routing between the two BNGs is required and can be performed with either a direct spoke SDP between the two nodes or by MPBGP route learning.

Since the PPPoE session will terminate in the retail VPRN the node must learn which VPRN service ID will carry it. Both PADI and PAP/CHAP authentication are supported. If the local user database is used, the host configuration provides a reference to the VPRN service ID that will be used. If RADIUS is used, it returns the service ID VSA. The retail interface is determined by the connection between the wholesale and retail subscriber interfaces.

The PPPoE session is negotiated with the parameters defined by the retail VPRN interface. Because the IP address space of the sub-mgmt host may overlap between VPRN services the node must anti-spoof the packets at access ingress with the session-id.

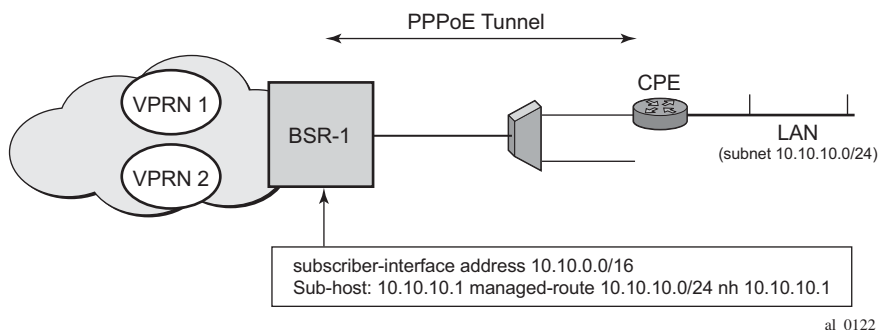

When the **config>service>vprn>sub-if>private-retail-subnets** command is enabled on the subscriber interface, the node will not push the defined subnets in the retail context to the wholesale context. This allows IP overlap between PPPoE sessions. If an operator requires both residential and business services, two VPRNs connected to the same wholesaler can be created and use the flag in only one of them.

5.2.4 IPCP Subnet Negotiation

This feature enables negotiation between Broadband Network Gateway (BNG) and customer premises equipment (CPE) so that CPE is allocated both ip-address and associated subnet.

Some CPEs use the network up-link in PPPoE mode and perform dhcp-server function for all ports on the LAN side. Instead of wasting one subnet for P2P uplink, CPEs use allocated subnet for LAN portion as shown in [Figure 33](#).

Figure 33 CPEs Network Up-link Mode

From a BNG perspective, the given PPPoE host is allocated a subnet (instead of /32) by RADIUS, external dhcp-server, or local-user-db. And locally, the host is associated with managed-route. This managed-route will be subset of the subscriber-interface subnet, and also, subscriber-host ip-address will be from managed-route range. The negotiation between BNG and CPE allows CPE to be allocated both ip-address and associated subnet.

5.2.4.1 Numbered WAN Support for Layer 3 RGs

Numbered WAN interfaces on RGs is useful to manage v6-capable RGs. Dual-stack RGs can be managed via IPv4. However, with v6-only RGs or with dual-stack RGs with private only v4 address, RGs require a globally routable v6 WAN prefix (or address) for management. This feature provides support to assign WAN prefix to PPP based Layer 3 RG using SLAAC. The feature also adds a new RADIUS VSA (Alc-PPP-Force-IPv6CP, Boolean) to control triggering of IPv6CP on completion of PPP LCP. RA messages are sent as soon as IPv6CP goes into open state, and the restriction to hold off on sending RAs until DHCP6-PD is complete in case of dual-stack PPP is no longer applicable.

5.2.5 IES as Retail Service for PPPoE Host

In this application, the PPPoE subscriber host terminates in a retail IES, the IES service ID can be obtained by either of following:

- Alc-Retail-Serv-Id attribute in radius access-accept packet.
- or retail-service-id config in local-user-db pppoe host if local user DB is used.

If MSAP is used then the SAP will be created in the wholesale VPRN.

The PPPoE session will be negotiated with the parameters defined by the wholesale VPRN group interface. The connectivity to the retailer will be done using the linkage between the two interfaces.

Due to the nature of IES service, there will be no IP address overlapping between different IES retails services, so the private-retail-subnets flag is not needed in this case.

5.2.6 Unnumbered PPPoX

Note: Unnumbered subscriber-interfaces are supported only for PPPoE, PPPoA and PPPoEoA (v4 and v6) hosts.

Unlike regular IP routes which are mainly concerned with next-hop information, subscriber-hosts are associated with an extensive set of parameters related to filtering, qos, stateful state (PPPoE/DHCP), antispoofing etc. Forwarding Information Base (fib) is not suitable to maintain all this information. Instead, each subscriber host record is maintained in separate set of subscriber-host tables.

By pre-provisioning the IP prefix (IPv4 and IPv6) under the subscriber-interface and subscriber-interface>ipv6 CLI hierarchy, only a single prefix aggregating the subscriber host entries is installed in the fib. This fib entry points to the corresponding subscriber-host tables that contain subscriber-host records.

In case that IPv4/IPv6 prefix is not pre-provisioned, or the subscriber-hosts falls out of pre-provisioned prefix, each subscriber-host will be installed in the fib. The result of the subscriber-host fib lookup will point to the corresponding subscriber-host record in the subscriber-host table. This scenario is referred to as “unnumbered subscriber-interfaces”

Unnumbered does not mean that the subscriber hosts do not have an IP address or prefix assigned. It only means that the IP address range out of which the address or prefix is assigned to the host does not have to be known in advance via configuration under the **subscriber-interface** or **subscriber-interface>ipv6** node.

An IPv6 example would be:

```
configure
  router/service
    subscriber-interface <name>
      ipv6
        [no] allow-unmatching-prefixes
        delegated-prefix-length <bits>
        subscriber-prefixes
```

This CLI indicates the following:

- There is no need for any indication of anticipated IPv6 prefixes in CLI.
- However, the **delegated-prefix-length** (DPL) command is required. The DPL (or the length of the prefix assigned to each Residential Gateway) must be known in advance. All Residential Gateways (or subscribers) under the same **subscriber-interface** share this pre-configured DPL.
- The DPL range is 48 — 64.
- If the prefix length in the received PD (via DHCP server, RADIUS or LUDB) and the DPL do not match, the host creation will fail.
- In case that the assigned IP prefix/address (DHCP server, RADIUS, LUDB) for the host falls outside of the CLI defined prefixes AND the **allow-unmatching-prefixes** command is configured, then the new address/prefix will be automatically installed in the FIB.

5.3 MLPPPoE, MLPPP(oE)oA with LFI on LNS

MLPPPoX is generally used to address bandwidth constraints in the last mile. The following are other uses for MLPPPoX:

- To increase bandwidth in the access network by bundling multiple links/VCs together. For example it is less expensive for a customer with an E1 access to add another E1 link in order to increase the access b/w, rather than to upgrade to the next circuit speed (E3).
- LFI on a single link to prioritize small packet size traffic over traffic with large size packets. This is needed in the upstream and downstream direction.

PPPoE and PPPoEoA/PPPoA v4/v6 host types are supported.

5.3.1 Terminology

The term MLPPPoX is used to reference MLPPP sessions over ATM transport (oA), Ethernet over ATM transport (oEoA) or Ethernet transport (oE). Although MLPPP in subscriber management context is not supported natively over PPP/HDLC links, the terms MLPPP and MLPPPoX terms can be used interchangeably. The reason for this is that link bundling, MLPPP encapsulation, fragmentation and interleaving can be in a broader scope observed independently of the transport in the first mile. However, MLPPPoX terminology will be prevailing in this document in an effort to distinguish MLPPP functionality on ASAP MDA (outside of ESM) and MLPPPoX in LNS (inside of ESM).

Terms speed and rate are interchangeably used throughout this section. Usually speed refers to the speed of the link in general context (high or low) while rate usually quantitatively describes the link speed and associates it with the specific value in bps.

5.3.2 LNS MLPPPoX

This functionality is supported through LNS on BB-ISA. LNS MLPPPoX can be used then as a workaround for PTA deployments, whereby LAC and LNS can be run back-to-back in the same system (connected via an external loop or a VSM2 module), and thus locally terminate PPP sessions.

MLPPPoX can:

- Increase bandwidth in the last mile by bundling multiple links together.
- LFI/reassembly over a single MLPPPoX capable link (plain PPP does not support LFI).

Figure 34 Typical MLPPPoA Deployment

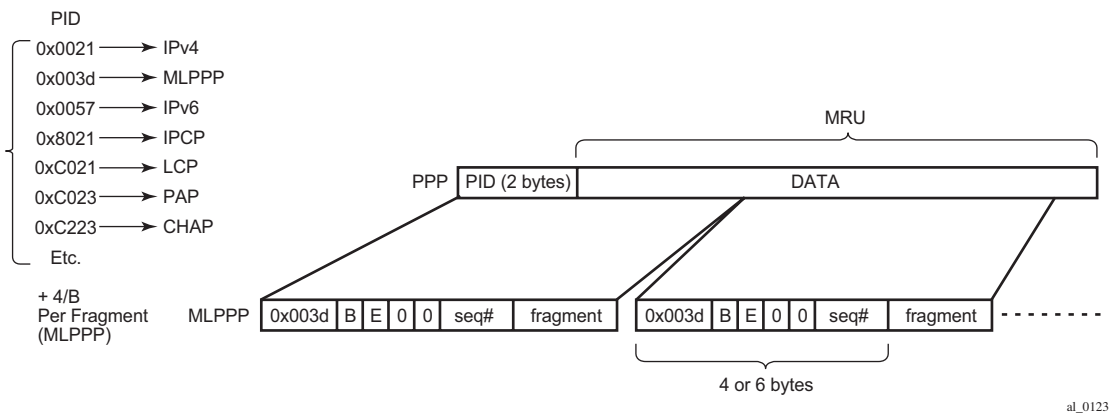

5.3.3 MLPPP Encapsulation

Once the MLPPP bundle is created in the 7750 SR, traffic can be transmitted by using MLPPP encapsulation. However, MLPPP encapsulation is not mandatory over an MLPPP bundle.

MLPPP header is primarily required for sequencing the fragments. But in case that a packet is not fragmented, it can be transmitted over the MLPPP bundle using either plain PPP encapsulation or MLPPP encapsulation. MLPPP encapsulation for fragmented traffic is shown in [Figure 35](#).

Figure 35 MLPPP Encapsulation

5.3.4 MLPPPoX Negotiation

MLPPPoX is negotiated during the LCP session negotiation phase by the presence of the Max-Received-Reconstructed Unit (MRRU) field in the LCP ConfReq. MRRU option is a mandatory field required in MLPPPoX negotiation. It represents the maximum number of octets in the Information field (Data part in [Figure 35](#)) of a reassembled packet. The MRRU value negotiated in the LCP phase must be the same on all member links and it can be greater or lesser than the PPP negotiated MRU value of each member link. This means that the reassembled payload of the PPP packet can be greater than the transmission size limit imposed by individual member links within the MLPPPoX bundle. Packets will always be fragmented so that the fragments are within the MRU size of each member link.

Another field that could be optionally present in an MLPPPoX LCP Conf Req is an Endpoint Discriminator (ED). Along with the authentication information, this field can be used to associate the link with the bundle.

The last MLPPPoX negotiated option is the Short Sequence Number Header Format Option which allows the sequence numbers in MLPPPoX encapsulated frames/fragments to be 12-bit long (instead 24-bit long, by default).

Once the multilink capability is successfully negotiated via LCP, PPP sessions can be bundled together over MLPPPoX capable links.

The basic operational principles are:

- LCP session is negotiated on each physical link with MLPPPoX capabilities between the two nodes.

- Based on the ED and/or the authentication outcome, a bundle is created. A subsequent IPCP negotiation is conveyed over this bundle. User traffic is sent over the bundle.
- If a new link tries to join the bundle by sending a new MLPPPoX LCP Conf Request, the LCP session will be negotiated, authentication performed and the link will be placed under the bundle containing the links with the same ED and/or authentication outcome.
- IPCP/IPv6CP will be in the whole process negotiated only once over the bundle. This negotiation will occur at the beginning, when the first link is established and MLPPPoX bundle created. IPCP and IPc6CP messages are transmitted from the 7750 SR LNS without MLPPPoX encapsulation, while they can be received as MLPPPoX encapsulated or non-MLPPPoX encapsulated.

5.3.5 Enabling MLPPPoX

The lowest granularity at which MLPPPoX can be enabled is an L2TP tunnel. An MLPPPoX enabled tunnel is not limited to carrying only MLPPPoX sessions but can carry normal PPP(oE) sessions as well.

In addition to enabling MLPPPoX on the session terminating node LNS, MLPPPoX can also be enabled on the LAC via PPP policy. The purpose of enabling MLPPPoX on the LAC is to negotiate MLPPPoX LCP parameters with the client. Once the LAC receives the MRRU option from the client in the initial LCP ConfReq, it will change its tunnel selection algorithm so that all sessions of an MLPPPoX bundle are mapped into the same tunnel.

The LAC will negotiate MLPPPoX LCP parameters regardless of the transport technology connected to it (ATM or Ethernet). LCP negotiated parameters are passed by the LAC to the LNS via Proxy LCP in ICCN message. In this fashion the LNS has an option to accept the LCP parameters negotiated by the LAC or to reject them and restart the negotiation directly with the client.

The LAC will transparently pass session traffic handed to it by the LNS in the downstream direction and the MLPPPoX client in the upstream direction. The LNS and the MLPPPoX client will perform all data processing functions related to MLPPPoX such as fragmentation and interleaving.

Once the LCP negotiation is completed and the LCP transition into an open state (configuration ACKs are sent and received), the Authentication phase on the LAC will begin. During the Authentication phase the L2TP parameters will become known (l2tp group, tunnel, and so on), and the session will be extended by the LAC to the LNS via L2TP. In case that the Authentication phase does not return L2TP

parameters, the session will be terminated because the 7750 SR does not support directly terminated MLPPPoX sessions.

In the case that MLPPPoX is not enabled on the LAC, the LAC will negotiate plain PPP session with the client. In case that the client accepts plain PPP instead of MLPPPoX as offered by the LAC, when the session is extended to the LNS, the LNS will re-negotiate MLPPPoX LCP with the client on a MLPPPoX enabled tunnel. The LNS will learn about the MLPPPoX capability of the client via Proxy LCP message in ICCN (first Conf Req received from the client is also send in Proxy LCP). If there is no indication of the MLPPPoX capability of the client, the LNS will establish a plain PPP(oE) session with the client.

Note: There is no dependency between ATM autosensing on LAC and MLPPPoX since autosensing operates on a lower layer than PPP (LCP).

5.3.6 Link Fragmentation and Interleaving (LFI)

The purpose of LFI is to ensure that short high priority packets are not delayed by the transmission delay of large low priority packets on slow links.

For example it takes ~150ms to transmit a 5000B packet over a 256Kbps link, while the same packet is transmitted in only 40us over a 1G link (~4000 times faster transmission). To avoid the delay of a high priority packet by waiting in the queue while the large packet is being transmitted, the large packet can be segmented into smaller chunks. The high priority packet can be then interleaved with the smaller fragments. This approach can significantly reduce the delay of high priority packets.

The interleaving functionality is only supported on MLPPPoX bundles with a single link. If more than one link is added into a interleaving capable MLPPPoX bundle, then interleaving will be internally disabled and the `tmnxMlpppBundleIndicatorsChange` trap will be generated.

With interleaving enabled on an MLPPPoX enabled tunnel, the following session types are supported:

- Multiple LCP sessions tied into a single MLPPPoX bundle. This scenario assumes multiple physical links on the client side. Theoretically it would be possible to have multiple sessions running over the same physical link in the last mile. For example, two PPPoE sessions going over the same Ethernet link in the last mile, or two ATM VCs o2q1231qa23n the same last mile link. Whichever the case might be, the LAC/LNS is unaware of the physical topology in the last mile (single or multiple physical links). Interleaving functionality will be internally disabled on such MLPPPoX bundle.

- A single LCP session (including dual stack) over the MLPPPoX bundle. This scenario assumes a single physical link on the client side. Interleaving will be supported on such single session MLPPPoX bundle as long as the conditions for interleaving are met. Those conditions are governed by max-fragment-delay parameter and calculation of the fragment size as described in subsequent sections.
- An LCP session (including dual stack) over a plain PPP/PPPoE session. This type of session is a regular PPP(oE) session outside of any MLPPPoX bundle and therefore its traffic is not MLPPPoX encapsulated.

Packets on an MLPPPoX bundle are MLPPPoX encapsulated unless they are classified as high priority packets when interleaving is enabled.

5.3.6.1 MLPPPoX Fragmentation, MRRU and MRU Considerations

MLPPPoX in the 7750 SR is concerned with two MTUs:

- **bundle-mtu** determines the maximum length of the original IP packet that can be transmitted over the entire bundle (collection of links) before any MLPPPoX processing takes place on the transmitting side. This is also the maximum size of the IP packet that the receiving node can accept once it de-encapsulates and assembles received MLPPPoX fragments of the same packet. Bundle-mtu is relevant in the context of the collection of links.
- **link-mtu** determines the maximum length of the payload before it is PPP encapsulated and transmitted over an individual link within the bundle. Link-mtu is relevant in the context of the single link within the bundle.

Assuming that the CPE advertised MRRU and MRU values are smaller than any configurable mtu on MLPPPoX processing modules in 7750 SR (carrier IOM and BB-ISA), the bundle-mtu and the link-mtu will be based on the received MRRU and MRU values, respectively. For example, the bundle-mtu will be set to the received MRRU value while link-bundle will be set to the MRU value minus the MLPPPoX encapsulation overhead (4 or 6 bytes).

In addition to mtu values, fragmentation requires a fragment length value for each MLPPP bundle on LNS. This fragment length value is internally calculated according to the following parameters;

- Minimum desired transmission delay in the last mile.
- Fragment “payload to encapsulation overhead” efficiency ratio.
- Various MTU sizes in the 7750 SR dictated mainly by received MRU, received MRRU and configured PPP MTU under the following hierarchy:
 - configure subscriber-mgmt ppp-policy ppp-mtu (ignored on LNS)

- configure service vprn l2tp group ppp mtu
- configure service vprn l2tp group tunnel ppp mtu
- configure router l2tp group ppp mtu
- configure router l2tp group tunnel ppp mtu

The decision whether to fragment and encapsulate a packet in MLPPPoX will depend on the mode of operation, the packet length and the packet priority as follows:

LFI Case — When Interleave is enabled in a bundle, low priority packets will always be MLPPPoX encapsulated. If a low-priority packet's length exceeds the internally calculated Fragment Length, the packet will be MLPPPoX fragmented and encapsulated. High priority packets whose length is smaller than the link-mtu will be PPP encapsulated and transmitted without MLPPP encapsulation.

Non-LFI Case — When Interleave is disabled in a bundle, all packets will be MLPPPoX encapsulated. If a packet's length exceeds the internally calculated fragment length, the packet will be MLPPPoX fragmented and encapsulated.

A packet of the size greater than the link-mtu cannot be natively transmitted over an MLPPPoX bundle. Such packet will be MLPPPoX encapsulated and consequently fragmented. This is irrespective of the priority of the packet in interleaving case or whether the fragmentation is enabled or disabled.

In cases where MLPPPoX fragmentation is disabled with the no max-fragment-delay command, it is expected that packets are not MLPPPoX fragmented but rather only MLPPPoX encapsulated in order to be load balanced over multiple physical links in the last mile. However, even if MLPPPoX fragmentation is disabled, it is possible that fragmentation occurs under certain circumstances. This behavior is related to the calculation of the MTU values on an MLPPPoX bundle.

Consider an example where received MRRU value sent by CPE is 1500B while received MRU is 1492B. In this case, our bundle-mtu will be set to 1500B and our link-mtu will be set to 1488B (or 1486B) to allow for the additional 4/6B of MLPPPoX encapsulation overhead. Consequently, IP payload of 1500B can be transmitted over the bundle but only 1488B can be transmitted over any individual link. In case that an IP packet with the size between 1489B and 1500B needs to be transmitted from 7750 SR towards the CPE, this packet would be MLPPPoX fragmented in 7750 SR as dictated by the link-mtu. This is irrespective of whether MLPPPoX fragmentation is enabled or disabled (as set by no max-fragment-delay flag).

To entirely avoid MLPPPoX fragmentation in this case, the received MRRU sent by CPE should be lower than the received MRU for the length of the MLPPPoX header (4 or 6 bytes). In this case, for IP packets larger than 1488B, IP fragmentation would occur (assuming that DF flag in the IP header allows it) and MLPPPoX fragmentation would be avoided.

On the 7750 SR side, it is not possible to set different advertised MRRU and MRU values with the ppp-mtu command. Both MRRU and MRU advertised values adhere to the same configured ppp mtu value.

5.3.7 LFI Functionality Implemented in LNS

As mentioned in the previous section, LFI on LNS is implemented only on MLPPPoX bundles with a single LCP session.

There are two major tasks (Most of this is also applicable to non-lfi case. The only difference between lfi and non-lfi is that there is no artificial delay performed in non-lfi case) associated with LFI on the LNS:

- Executing subscriber QoS in the carrier IOM based on the last mile conditions. The subscriber QoS rates are the last mile on-the-wire rates. Once traffic is QoS conditioned, it is sent to the BB-ISA for further processing.
- Fragmentation and artificial delay (queuing) of the fragments so that high priority packets can be injected in-between low priority fragments (interleaved). This operation is performed by the BB-ISA.

Examine an example to further clarify functionality of LFI. The parameters, conditions and requirements that will be used in our example to describe the desired behavior are the following:

- High priority packets must NOT be delayed for more than 50ms in the last mile due to the transmission delay of the large low priority packets. Considering that tolerated end-to-end VoIP delay must be under 150ms, limiting the transmission delay to 50ms on the last mile link is a reasonable choosing.
- The link between the LNS and LAC is 1Gbps Ethernet.
- The last mile link rate is 256kbps.
- Three packets arrive back-to-back on the network side of the LNS (in the downstream direction). The large 5000B low priority packet P1 arrives first, followed by two smaller high priority packets P2 and P3, each 100B in length.

Note: Packets P1, P2 and P3 can be originated by independent sources (PCs, servers, etc.) and therefore can theoretically arrive in the LNS from the network side back-to-back at the full network link rate (10Gbps or 100Gbps).

- The transmission time on the internal 10G link between the BB-ISA and the carrier IOM for the large packet (5000B) is 4us while the transmission time for the small packet (100B) is 80ns.

- The transmission time on the 1G link (LNS->LAC) for the large packet (5000B) is 40us while the transmission time for the small packet (100B) is 0.8us.
- The transmission time in the last mile (256 kbps) for the large packet is ~150ms while the transmission time for the small packet on the same link is ~3ms.
- Last mile transport is ATM.

To satisfy the delay requirement for the high priority packets, the large packets will be fragmented into three smaller fragments. The fragments will be carefully sized so that their individual transmission time in the last mile does not exceed 50ms. After the first 50ms interval, there will be window of opportunity to interleave the two smaller high priority packets.

This entire process is further clarified by the five points (1-5) in the packet route from the LNS to the Residential Gateway (RG) as depicted in [Figure 36](#).

The five points are:

1. [Last Mile QoS Awareness in the LNS](#)
2. [BB-ISA Processing](#)
3. [LNS-LAC Link](#)
4. [AN-RG Link](#)
5. [Home Link](#)

Figure 36 Packet Route from the LNS to the RG

5.3.7.1 Last Mile QoS Awareness in the LNS

By implementing MLPPPoX in LNS, we are effectively transferring the traffic treatment functions (QoS/LFI) of the last mile to the node (LNS) that is multiple hops away.

The success of this operation depends on the accuracy at which we can simulate the last mile conditions in the LNS. The assumption is that the LNS is aware of the two most important parameters of the last mile:

- The last mile encapsulation — This is needed for the accurate calculation of the overhead associated of the transport medium in the last mile for traffic shaping and interleaving.
- The last mile link rate — This is crucial for the creation of artificial congestion and packet delay in the LNS.

The subscriber QoS in the LNS is implemented in the carrier IOM and is performed on a per packets basis before the packet is handed over to the BB-ISA. Per packet, rather than per fragment QoS processing will ensure a more efficient utilization of network resources in the downstream direction. Discarding fragments in the LNS would have detrimental effects in the RG as the RG would be unable to reconstruct a packet without all of its fragments.

High priority traffic within the bundle is classified into the high priority queue. This type of traffic is not MLPPPoX encapsulated unless its packet size exceeds the link MTU as described in [MLPPPoX Fragmentation, MRRU and MRU Considerations](#). Low priority traffic is classified into a low priority queue and is always MLPPPoX encapsulated. In case that the high priority traffic becomes MLPPPoX encapsulated/fragmented, the MLPPPoX processing module (BB-ISA) will consider it as low-priority. The assumption is that the high priority traffic is small in size and consequently MLPPPoX encapsulation/fragmentation an degradation in priority can be avoided. The aggregate rate of the MLPPPoX bundle is on-the-wire rate of the last mile as shown in Figure 3.

ATM on-the-wire overhead for non-MLPPPoX encapsulated high priority traffic will include:

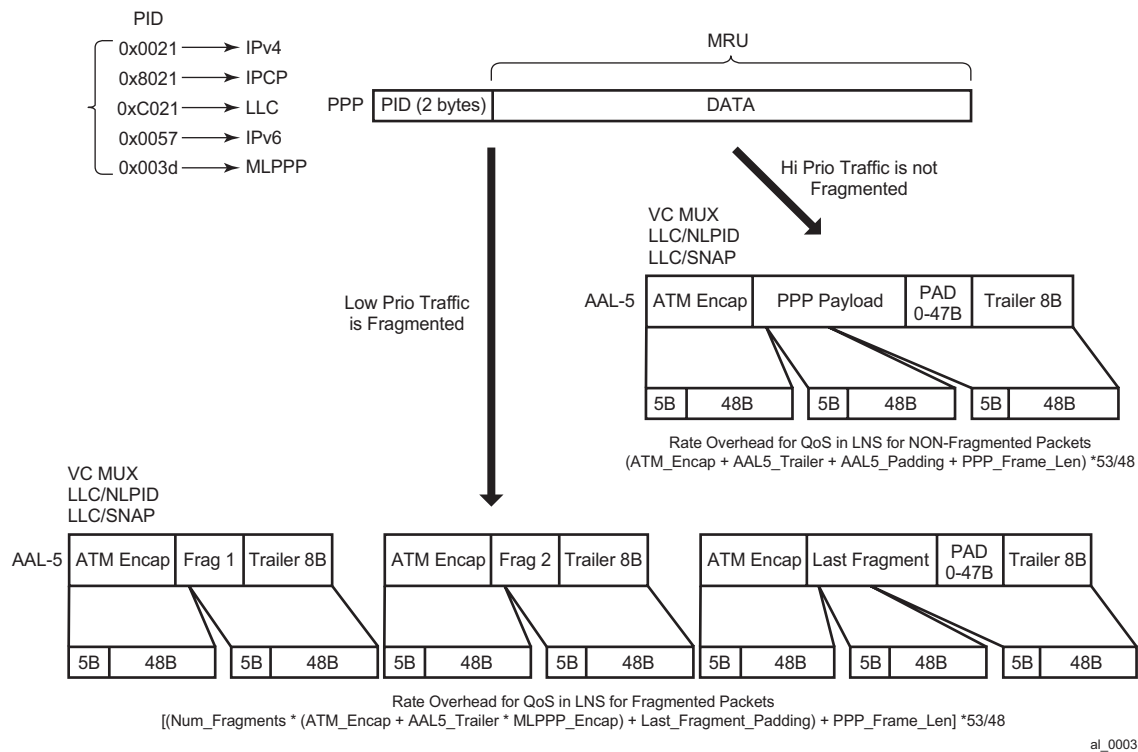

- ATM encapsulation (VC-MUX, LLC/NLPID, LLC/SNAP).
- AAL5 trailer (8B).
- AAL5 padding to 48B cell boundary (this makes the overhead dependent on the packet size).
- Multiplication by 53/48 to account for the ATM cell headers.

For low priority traffic which is always MLPPPoX encapsulated, an additional overhead related to MLPPPoX encapsulation and possibly fragmentation must be added (blue arrow in Figure 3). In other words, each fragment carries ATM+MLPPPoX overhead.

Note: We can avoid the 48B boundary padding for all fragments except the last one. This can be done by choosing the fragment length so that it is aligned on the 48B boundary (rounded down if based on max-fragment-delay or rounded up if based on the encapsulation/utilization).

Figure 37 Last Mile Encapsulation

For Ethernet in the last mile, our implementation always assures that the fragment size plus the encapsulation overhead is always larger or equal to the minimum Ethernet packet length (64B).

5.3.7.2 BB-ISA Processing

MLPPPoX encapsulation, fragmentation and interleaving are performed by the LNS in BB-ISA. If we refer to our example, a large low priority packet (P1) is received by the BB-ISA, immediately followed by the two small high priority packets (P2 and P3). Since our requirement stipulates that there is no more than 50ms of transmission delay in the last mile (including on-the-wire overhead), the large packet must be fragmented into three smaller fragments each of which will not cause more than 50ms of transmission delay.

The BB-ISA would normally send packets/fragments to the carrier IOM at the rate of 10Gbps. In other words, by default the three fragments of the low priority packet would be sent out of the BB-ISA back-to-back at the very high rate before the high priority packets even arrive in the BB-ISA. In order to interleave, the BB-ISA must simulate the last mile conditions by delaying the transmission of the fragments. The fragments will be paced out of the BB-ISA (and out of the box) at the rate of the last mile. High priority packets will get the opportunity to be injected in front of the fragments while the fragments are being delayed.

In [Figure 36](#) (point 2) the first fragment F1 is sent out immediately (transmission delay at 10G is in the 1us range). The transmission of the next fragment F2 is delayed by 50ms. While the transmission of the second fragment F2 is being delayed, the two high priority packets (P1 and P2 in red) are received by the BB-ISA and are immediately transmitted ahead of fragments F2 and F3. This approach relies on the imperfection of the IOM shaper which is releasing traffic in bursts (P2 and P3 right after P1). The burst size is dependent on the depth of the rate token bucket associated with the IOM shaper.

Note: By the time the second fragment F2 is transmitted, the first fragment F1 has traveled a long way (50ms) on high rate links towards the Access Node (assuming that there is no queuing delay along the way), and its transmission on the last mile link has already begun (if not already completed).

This is not applicable for this discussion, but nonetheless worth noticing is that the LNS BB-ISA also adds the L2TP encapsulation to each packet/fragment. The L2TP encapsulation is removed in the LAC before the packet/fragment is transmitted towards the AN.

5.3.7.3 LNS-LAC Link

This is the high rate link (1Gbps) on which the first fragment F1 and the two consecutive high priority packets, P2 and P3, are sent back-to-back by the BB-ISA (BB-ISA->carrier IOM->egress IOM-> out-of-the-LNS).

The remaining fragments (F2 and F3) are still waiting in the BB-ISA to be transmitted. They are artificially delayed by 50ms each.

Additional QoS based on the L2TP header can be performed on the egress port in the LNS towards the LAC. This QoS is based on the classification fields inside of the packet/fragment headers (DSCP, dot1.p, EXP).

Note: The LAC-AN link is not really relevant for the operation of LFI on the LNS. This link can be either Ethernet (in case of PPPoE) or ATM (PPPoE or PPP). The rate of the link between the LAC and the AN is still considered a high speed link compared to the slow last mile link.

5.3.7.4 AN-RG Link

Finally, this is the slow link of the last mile, the reason why LFI is performed in the first place. Assuming that LFI played its role in the network as designed, by the time the transmission of one fragment on this link is completed, the next fragment arrives just in time for unblocked transmission. In between the two fragments, we can have one or more small high priority packets waiting in the queue for the transmission to complete.

Note: On the AN-RG link in [Figure 36](#) that packets P2 and P3 are ahead of fragments F2 and F3. Therefore the delay incurred on this link by the low priority packets is never greater than the transmission delay of the first fragment (50ms). The remaining two fragments, F2 and F3, can be queued and further delayed by the transmission time of packets P2 and P3 (which is normally small, in our example 3ms for each).

Note: If many low priority packets are waiting in the queue, then they would have caused delay and would have further delayed the fragments that are in transit from the LNS to the LAC. This condition is normally caused by bursts and it should clear itself out over time.

5.3.7.5 Home Link

High priority packets P2 and P3 are transmitted by the RG into the home network ahead of the packet P1 although the fragment F1 has arrived in the RG first. The reason for this is that the RG must wait for the fragments F2 and F3 before it can re-assemble packet P1.

5.3.7.6 Optimum Fragment Size Calculation by LNS

Fragmentation in LFI is based on the optimal fragment size. LNS implementation calculates the two optimal fragment sizes, based on two different criteria:

- Optimal fragment size based on the payload efficiency of the fragment given the fragmentation/transportation header overhead associated with the fragment ?encapsulation based fragment size.
- Optimal fragment size based on the maximum transmission delay of the fragment set by configuration ?delay based fragment size.

At the end only one optimal fragment size will be selected. The actual fragments length will be of the optimal fragment size.

- The parameters required to calculate the optimal fragment sizes are known to the LNS either via configuration or via signaling. These, in-advance known parameters are:
- Last mile maximum transmission delay (max-fragment-delay obtained via CLI)
- Last mile ATM Encapsulation (in our example the last mile is ATM but in general it can be Ethernet for MLPPPoE)
- MLPPP encapsulation length (depending on the fragment sequence number format)
- The last mile on-the-wire rate for the MLPPPoX bundle

Examine closer each of the two optimal fragment sizes.

5.3.7.6.1 Encapsulation Based Fragment Size

One needs to be mindful of the fact that fragmentation may cause low link utilization. In other words, during fragmentation a node may end up transporting mainly overhead bytes in the fragment as opposed to payload bytes. This would only intensify the problem that fragmentation is intended to solve, especially on an ATM access link that tend to carry larger encapsulation overhead.

To reduce the overhead associated with fragmentation, the following is enforced in the 7750 SR:

The minimum fragment payload size will be at least 10times greater than the overhead (MLPPP header, ATM Encapsulation and AAL5 trailer) associated with the fragment.

The optimal fragment length (including the MLPPP header, the ATM Encapsulation and the AAL5 trailer) is a multiple of 48B. Otherwise, the AAL5 layer would add an additional 48B boundary padding to each fragment which would unnecessarily expand the overhead associated with fragmentation. By aligning all-but-last fragments to a 48B boundary, only the last fragment will potentially contain the AAL5 48B boundary padding which is no different from a non-fragmented packet. For future reference we will refer to all fragments except for the last fragment as non-padded fragments. The last fragment will obviously be padded if it is not already natively aligned to a 48B boundary.

As an example, calculate the optimal fragment size based on the encapsulation criteria with the maximum fragment overhead of 22B. To achieve >10x transmission efficiency the fragment payload size must be 220B ($10 \times 22\text{B}$). To avoid the AAL5 padding, the entire fragment (overhead + payload) will be rounded UP on a 48B boundary. The final fragment size will be 288B [$22\text{B} + 22\text{B} \times 10 + 48\text{B}_{\text{alignment}}$].

In conclusion, an optimal fragment size was selected that will carry the payload with at least 90% efficiency. The last fragment of the packet cannot be artificially aligned on a 48B boundary (it is a natural reminder), so it will be padded by the AAL5 layer. Therefore the efficiency of the last fragment will probably be less than 90% in our example. In the extreme case, the efficiency of this last fragment may be only 2%.

Note: The fragment size chosen in this manner is purely chosen based on the overhead length. The maximum transmission delay did not play any role in the calculations.

For Ethernet based last mile, the CPM always makes sure that the fragment size plus encapsulation overhead is larger or equal to the minimum Ethernet packet length of 64B.

5.3.7.6.2 Fragment Size Based on the Max Transmission Delay

The first criterion in selecting the optimal fragment size based on the maximum transmission delay mandates that the transmission time for the fragment, including all overheads (MLPPP header, ATM encapsulation header, AAL5 overhead and ATM cell overhead) must be less than the configured max-fragment-delay time.

The second criterion mandates that each fragment, including the MLPPP header, the ATM Encapsulation header, the AAL5 trailer and the ATM cellification overhead be a multiple of 48B. The fragment size is rounded down to the nearest 48B boundary during the calculations in order to minimize the transmission delay. Aligning the fragment on the 48B boundary eliminates the AAL5 padding and therefore reduces the overhead associated with the fragment. The overhead reduction will not only improve the transmission time but it will also increase the efficiency of the fragment.

Given these two criteria along with the configuration parameters (ATM Encapsulation, MLPPP header length, max-fragment-delay time, rate in the last mile), the implementation calculates the optimal non-padded fragment length as well as the transmission time for this optimal fragment length.

5.3.7.6.3 Selection of the Optimum Fragment Length

So far the implementation has calculated the two optimum fragment lengths, one based on the length of the MLPPP/transport encapsulation overhead of the fragment, the other one based on the maximum transmission delay of the fragment. Both of them are aligned on a 48B boundary. The larger of the two is chosen and the BB-ISA will perform LFI based on this selected optimal fragment length.

5.3.8 Upstream Traffic Considerations

Fragmentation and interleaving is implemented on the originating end of the traffic. In other words, in the upstream direction the CPE (or RG) is fragmenting and interleaving traffic. There is no interleaving or fragmentation processing in the upstream direction in the 7750 SR. The 7750 SR will be on the receiving end and is only concerned with the reassembly of the fragments arriving from the CPE. Fragments will be buffered until the packet can be reconstructed. If all fragments of a packet are not received within a preconfigured timeframe, the received fragments of the partial packet will be discarded (a packet cannot be reconstructed without all of its fragments). This time-out and discard is necessary in order to prevent buffer starvation in the BB-ISA. Two values for the time-out can be configured: 100ms and 1s.

5.3.9 Multiple Links MLPPPoX With No Interleaving

Interleaving over MLPPPoX bundles with multiple links will not be supported. However, fragmentation is supported.

In order to preserve packet order, all packets on an MLPPPoX bundle with multiple links will be MLPPPoX encapsulated (monotonically increased sequence numbers).

We will not support multiclass MLPPP (RFC 2686, *The Multi-Class Extension to Multi-Link PPP*). Multiclass MLPPP would require another level of intelligent queuing in the BB-ISA which we do not have.

5.3.10 MLPPPoX Session Support

The following session types in the last mile will be supported:

- MLPPPoE — Single physical link or multilink. The last mile encapsulation is Ethernet over copper (This could be Ethernet over VDSL or HSDSL). The access rates (especially upstream) are still limited by the xDSL distance limitation and as such interleaving is required on a slow speed single link in the last mile. It is possible that the last mile encapsulation is Ethernet over fiber (FTTH) but in this case, users would not be concerned with the link speed to the point where interleaving and link aggregation is required.

Finally, this is the slow link of the last mile, the reason why LFI is performed in the first place. Assuming that LFI played its role in the network as designed, by the time the transmission of one fragment on this link is completed, the next fragment arrives just in time for unblocked transmission. In between the two fragments, we can have one or more small high priority packets waiting in the queue for the transmission to complete.

We can see on the AN-RG link in Figure 2 that packets P2 and P3 are ahead of fragments F2 and F3. Therefore the delay incurred on this link by the low priority packets is never greater than the transmission delay of the first fragment (50ms). The remaining two fragments, F2 and F3, can be queued and further delayed by the transmission time of packets P2 and P3 (which is normally small, in our example 3ms for each).

Note: If many low priority packets were waiting in the queue, then they would have caused delay for each other and would have further delayed the fragments in transit from the LNS to the LAC. This condition is normally caused by bursts and it should clear itself out over time.

Figure 38 MLPPPoE — Multiple Physical Links

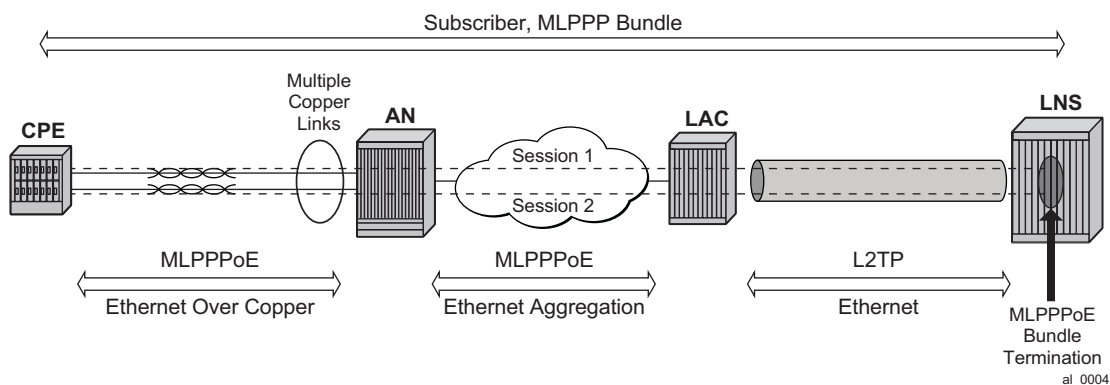

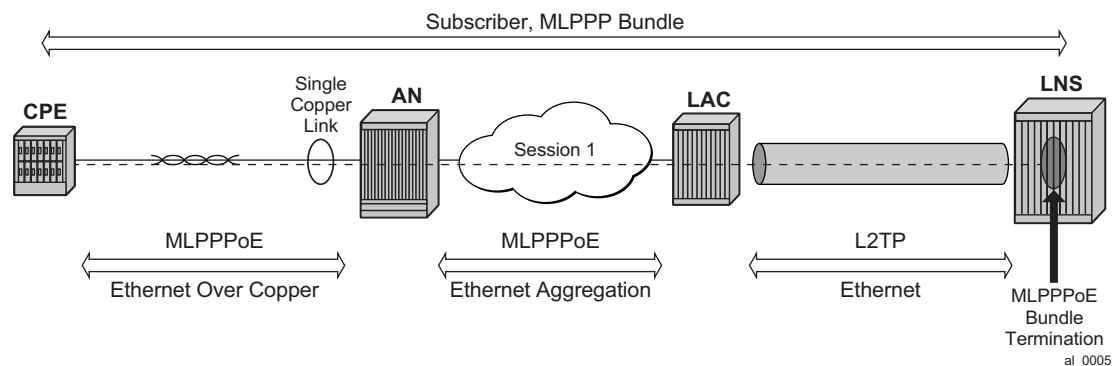

Figure 39 MLPPPoE — Single Physical Link

- MLPPP(oEo)A — A single physical link or multilink. The last mile encapsulation is ATM over xDSL.

Figure 40 MLPPP(oE)oA — Multiple Physical Links

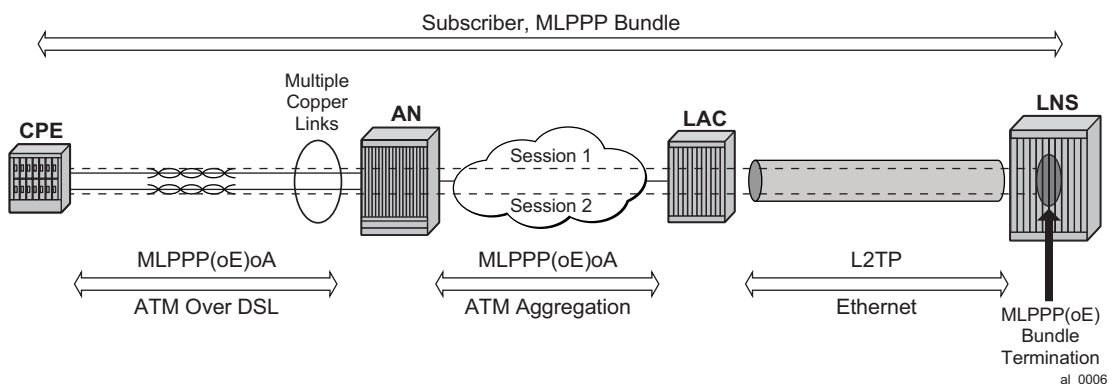

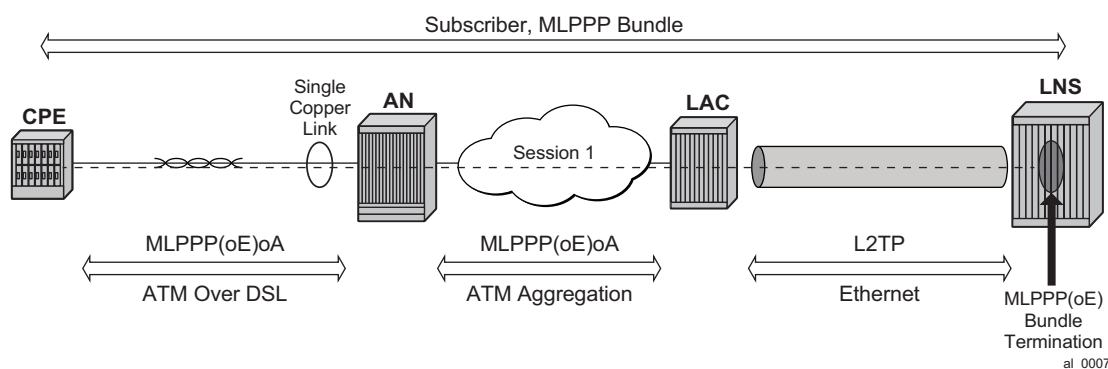

Figure 41 MLPPP(oE)oA — Single Physical Link

Some other combinations are also possible (ATM in the LAST mile, Ethernet in the aggregation) but they all come down to one of the above models that are characterized by:

- Ethernet or ATM in the last mile.
- Ethernet or ATM access on the LAC.
- LPPP/PPPoE termination on the LNS

5.3.11 Session Load Balancing Across Multiple BB-ISAs

PPP/PPPoE sessions are by default load balanced across multiple BB-ISAs (max 6) in the same group. The load balancing algorithm considers the number of active session on each BB-ISA in the same group. The load balancing algorithm does not take into account the number of queues consumed on the carrier IOM. Therefore a session can be refused if queues are depleted on the carrier IOM even though the BB-ISA may be lightly loaded in terms of the number of sessions that is hosting.

With MLPPPoX, it is important that multiple sessions per bundle be terminated on the same LNS BB-ISA. This can be achieved by per tunnel load balancing mode where all sessions of a tunnel are terminated in the same BB-ISA. Per tunnel load balancing mode is mandatory on LNS BB-ISAs that are in the group that supports MLPPPoX.

On the LAC side, all sessions in an MLPPPoX bundle are automatically assigned to the same tunnel. In other words an MLPPPoX bundle is assigned to the tunnel. There can be multiple tunnels created between the same pair of LAC/LNS nodes.

5.3.12 BB-ISA Hashing Considerations

All downstream traffic on an MLPPPoX bundle with multiple links is always MLPPPoX encapsulated. Some traffic is fragmented and served in a octet oriented round robin fashion over multiple member links. However, fragments are never delayed in case that the bundle contains multiple links.

In a per fragment/packet load sharing algorithm, there is always the possibility that there is uneven load utilization between the member links. A single link overload will most likely go unnoticed in the network all the way to the Access Node. The access node is the only node in the network that actually has multiple physical links connected to it. All other session-aware nodes (LAC and LNS) only see MLPPPoX as a bundle with multiple sessions without any mechanism to shape traffic per physical link. Other nodes in this case being 7750 SRs. Other vendors may have the ability to condition (shape) traffic per session.

If one of the member sessions is perpetually overloaded by the LNS, traffic will be dropped in the last mile since the corresponding physical link cannot absorb traffic beyond its physical capabilities. This would have detrimental effects on the whole operation of the MLPPPoX bundle. To prevent this perpetual overloading of the member links that can be caused by per packet/fragment load balancing scheme, the

load balancing scheme that takes into account the number of octets transmitted over each member link. The octet counter of a new link will be initialized to the lowest value of any existing link counter. Otherwise the load balancing mechanism would show significant bias towards the new link until the byte counter catches up with the rest of the links.

5.3.13 Last Mile Rate and Encapsulation Parameters

The last mile rate information along with the encapsulation information is used for fragmentation (to determine the maximum fragment length) and interleaving (delaying fragments in the BB-ISA). In addition, the aggregate subscriber rate (aggregate-rate-limit) on the LNS is automatically adjusted based on the last mile link rate and the number of links in the MLPPPoX bundle.

Downstream Data Rate in the Last Mile

The subscriber aggregate rates (agg-rate-limit) used in (H)QoS on the carrier IOM and in the BB-ISA (for interleaving) must be wire based in the last mile. This rule applies equally to both, the LAC and LNS.

The last mile on-the-wire rates of the subscriber can be submitted to the LAC and the LNS via various means. Here is the break down on how the last mile wire rates will be passed to each entity:

LAC

The last mile link rate is taken via the following methods in the order of listed priority:

- LUDB — rate-down command under the host hierarchy in LUDB.
- RADIUS Alc-Access-Loop-Rate-Down VSA. Although this VSA is stored in the state of plain PPP(oE) sessions (MLPPPoX bundled or not), it is applicable only to MLPPPoX bundles.
- PPPoE tags — Vendor Specific Tags (RFC 2516, *A Method for Transmitting PPP Over Ethernet (PPPoE)*; tag type 0x0105; tag value is Enterprise Number 3561 followed by the TLV sub-options as specified in TR-101 -> Actual Data Rate Downstream 0x82)

As long as the link rate information is available in the LAC, it will always be passed to the LNS in the ICRQ message using the standard L2TP encoding. This cannot be disabled.

In addition, an option is available to control the source of the rate information can be conveyed to the LNS via TX Connect Speed AVP in the ICCN message. This can be used for compatibility reasons with other vendors that can only use TX Connect Speed to pass the link rate information to the LNS. By default, the maximum port speed (or the sum of the maximum speeds of all member ports in the LAG) will be reported in TX Connect Speed. Unlike the rate conveyed in ICRQ message, The TX Connect Speed content is configurable via the following command:

```
config>subscriber-management>  
    sla-profile <name>  
        egress  
            report-rate agg-rate-limit | scheduler <scheduler-name> | pppoe-actual-  
rate | rfc5515-actual-rate
```

The report-rate configuration option will dictate which rate will be reported in the TX Connect Speed as follows:

- agg-rate-limit => statically configured agg-rate-limit value or RADIUS QoS override will be reported
- scheduler <scheduler-name> => virtual schedulers are not supported in MLPPPoX
- pppoe-actual-rate => rate taken from PPPoE Tags will be reported.

Note: Rate reported via RFC5515 can still be different if the source for both methods is not the same.

- rfc5515-actual-speed => the rate is taken from RFC5515.

The RFC 5515 relies on the same encoding as PPPoE tags (vendor id is ADSL Forum and the type for Actual Data Rate Downstream is 0x82).

Note: The two methods of passing the line rate to the LNS are using different message types (ICRQ and ICCN).

The LAC on the 7750 SR is not aware of MLPPPoX bundles. As such, the aggregate subscriber bandwidth on the LAC is configured statically via usual means (sub-profile, scheduler-policy) or dynamically modified via RADIUS. The aggregate subscriber (or MLPPPoX bundle) bandwidth on the LAC is not automatically adjusted according to the rates of the individual links in the bundle and the number of the links in the bundle. As such, an operator must ensure that the statically provided rate value

for aggregate-rate-limit is the sum of the bandwidth of each member link in the MLPPPoX bundle. The number of member links and their bandwidth must be therefore known in advance. The alternative is to have the aggregate rate of the MLPPPoX bundle set to a high value and rely on the QoS treatment performed on the LNS.

LNS

The sources of information for the last mile link rate on the LNS will be taken in the following order:

- LUDB (during user authentication phase, same as in LAC)
- RADIUS (same as in LAC)
- ICRQ message — Actual Data Downstream Rate (RFC 5515)
- ICCN message — TX Connect Speed

There will be no configuration option to determine the priority of the source of information for the last mile link rate. TX Connect Speed in ICCN message will only be taken into consideration as a last resort in absence of any other source of last mile rate information.

Once the last mile rate information is obtained, the subscriber aggregate rate (aggregate-rate-limit) will be automatically adjusted to the minimum value of:

- The smallest link speed in the MLPPPoX bundle multiplied by the number of links in the bundle.
- Statically configured aggregate-rate-limit

The link speed of each link in the bundle must be the same, i.e. different link speeds within the bundle are not supported. In the case that we receive different link speed values for last mile links within the bundle, we will adopt the minimum received speed and apply it to all links.

In case that the obtained rate information from the last mile for a session within the MLPPP bundle is out of bounds (1Kbps to 100Mbps), the session within the bundle will be terminated.

Encapsulation

Wire-rates are dependent on the encapsulation of the link to which they apply. The last mile encapsulation information can be extracted via various means.

LAC

- Static configuration via LUDB.
- RADIUS — Alc-Access_Loop-Encap-Offset VSA.

- PPPoE tags — Vendor Specific Tags (RFC 2516; tag type 0x0105; tag value is Enterprise Number 3561 followed by the TLV sub-options as specified in TR-101 -> Actual Data Rate Downstream 0x82).

The LAC will pass the line encapsulation information to the LNS via ICRQ message using the encoding defined in the RFC 5515.

LNS

The LNS will extract the encapsulation information in the following order:

- Static configuration via LUDB.
- RADIUS — Alc-Access-Loop-Encap-Offset VSA.
- ICRQ message (RFC 5515)

In case that the encapsulation information is not provided by any of the existing means (LUDB, RADIUS, AVP signaling, PPPoE Tags), then by default pppoa-null encapsulation will be in effect. This applies to LAC and LNS.

5.3.14 Link Failure Detection

The link failure in the last mile is detected via the expiration of session keepalives (LCP). The LNS will tear down the session over the failed link and notify the LAC via a CDN message.

5.3.15 CoA Support

CoA request for the subscriber aggregate-rate-limit change is honored on the LAC and the LNS.

CoA for the rate change of an individual link within the bundle is supported through the same VSA that can be used to initially assign the rate parameter to each member link. This is supported only on LNS. The rate override via CoA is applied to all active link members within the bundle.

Change of the access link parameters via CoA is supported in the following fashion:

- Change of access loop encap: refused (NAK)
- Change of access loop rate down:

- On L2TP LAC session: refused (NAK). On LAC the access loop rate down is not locally used for any rate limiting function but instead it is just passed to the LNS at the beginning when the session is first established. Mid-session changes on LAC via CoA are not propagated to the LNS.
- On L2TP LNS session:
 - Plain session: ignored. The rate is stored in the MIB table but no rate limiting action is taken. In other words, this parameter is internally excluded from rate calculations and advertisements. However, it is shown in the output of the relevant show commands.
- Bundle session: applied on all link sessions. The aggregate rate limit of the bundle is set to the minimum of the:
- CoA obtained local loop down rate multiplied by the number of links in the bundle
- The aggregate rate limit configured statically or obtained via CoA.
- Fragment length will be affected by this change. In case that interleaving is enabled on a single link bundle, the interleave interval will be affected.
- Non-L2TP: ignored. The rate is stored in the MIB table but no rate limiting action is taken. In other words, this parameter is internally excluded from rate calculations and advertisements. However, it will be shown in the output of the relevant show commands.

Similar behavior is exhibited if at mid session, the parameters are changed via LUDB with the exception of the rate-down parameter in LAC. If this parameter is changed on the LAC, all sessions are disconnected.

5.3.16 Accounting

Accounting counters on the LNS include all packet overhead (wire overhead from the last mile). There is only one accounting session per bundle.

On the LAC, there is one accounting session per pppoe session (link).

In tunnel-accounting mode there is one accounting session per link.

On LNS only the stop-link of the last link of the bundle will carry all accounting data for the bundle.

5.3.17 Filters and Mirroring

Filters and mirrors (LI) are not supported on an MLPPPoX bundle on LAC. However, filters and ip-only mirror type are supported on the LNS.

5.3.18 PTA Considerations

Locally terminated MLPPPoX (PTA) solution is offered based on the LAC and the LNS hosted in the same system. An external loop (or VSM2) is used to connect the LAC to the LNS within the same box. The subscribers will be terminated on the LNS.

5.3.19 QoS Considerations

5.3.19.1 Dual-Pass

HQoS and LFI are performed in two stages that involve double traversal (dual-pass) of traffic through the carrier IOM and the BB-ISA. The following are the functions performed in each pass:

- In the first pass through the carrier IOM, traffic is marked (dot1p bits) as high or low priority. This will play crucial role in the execution of LFI in the BB-ISA.
- In the first pass through the BB-ISA this prioritization from the 1st step, will be an indication (along with the internally calculated fragment size) of whether the traffic will be interleaved (non MLPPP encapsulated) or not (MLPPP encapsulated). Consequently the BB-ISA will add the necessary padding related to last mile wire overhead to each packet. This padding will be used in the second pass on the carrier IOM to perform last mile wire based QoS functions.
- In the second pass through the carrier IOM, the last mile wire based HQoS will be performed based on the padding added in the first pass through the BB-ISA.
- In the second pass through the BB-ISA, previously added overhead will be stripped off and LFI/MLPPP encapsulation functions will be performed.

5.3.19.2 Traffic Prioritization in LFI

The delivery of high priority traffic within predefined delay bounds on a slow speed last mile link is ensured by proper QoS classification and prioritization. High priority traffic will be interleaved with low priority fragments on a single link MLPPPoX bundle with LFI enabled. The classification of traffic into proper (high or low priority) forwarding class is performed on the downstream ingress interface. However, traffic can be re-classified (re-mapped into another forwarding class) on the egress access interface of the carrier IOM, just before packets are transmitted to the BB-ISA for MLPPPoX processing. This can be achieved via QoS sap-egress policy referenced in the LNS sla-profile.

The priority of the forwarding class in regular QoS (on IOM) is determined by the properties of the queue to which the forwarding class is mapped. Expedited, non-expedited queue type, CIR and PIR rates. In contracts, traffic prioritization in LFI domain (in BB-ISA) is determined by the outer dot1p bits that are set by the carrier IOM while transmitting packets towards the BB-ISA. The outer dot1p bits are marked based on the forwarding class information determined by classification/re-classification on ingress/carrier IOM. This marking of outer dot1p bits in the Ethernet header between the carrier IOM and the BB-ISA is fixed and defined in the default sap-egress LNS ESM policy 65537. The marking definition is as follows:

```
FC be -> dot1p 0
FC l2 -> dot1p 1
FC af -> dot1p 2
FC l1 -> dot1p 3
FC h2 -> dot1p 4
FC ef -> dot1p 5
FC h1 -> dot1p 6
FC nc -> dot1p 7
```

In LFI (on BB-ISA), dot1p bits [0,1,2 and 3] are considered low priority while dot1p bits (4,5,6 and 7) are considered high priority. Consequently, forwarding classes BE, L2, AF and L1 are considered low priority while forwarding classes H2, EF, H1 and NC are considered high priority. High priority traffic will be interleaved with low priority traffic. Assuming that the packet size does not exceed maximum fragment size.

The following describes the reference points in traffic prioritization for the purpose of LFI in the 7750 SR:

- Classification on downstream ingress interface (entrance point into the 7750 SR) - packets can be classified into one of the following eight forwarding classes: be, l2, af, l1, h2, ef, h1 and nc. Depending on the type of the ingress interface (access or network), traffic can be classified based on dot1p, exp, DSCP, TOS bits or ip-match criteria (dscp, dst-ip, dst-port, fragment, src-ip, src-port and protocol-id).

- Re-classification on downstream access egress interface between the carrier IOM and the BB-ISA - in the carrier IOM, downstream traffic can be re-classified into another forwarding class, just before it is forwarded to the BB-ISA. Re-classification on access egress is based on the same fields as on ingress except for the dot1p and exp bits since Ethernet or MPLS headers from ingress are not carried from ingress to egress.
- Marking on downstream access egress interface between the carrier IOM and the BB-ISA - once the forwarding class is available on the carrier IOM in the egress direction (towards BB-ISA), it will be used to mark outer dot1p bits in the new Ethernet header that will be used to transport the frame from the carrier IOM to the BB-ISA. The marking of the dot1p bits on the egress SAP between the carrier IOM and the BB-ISA cannot be changed for MLPPPoX even if the no qos-marking-from-sap command is configured under the sla-profile on egress.

5.3.19.3 Shaping Based on the Last Mile Wire Rates

Accurate QoS, amongst other things, require that the subscriber rates in the first mile on an MLPPPoX bundle be properly represented in the LNS. In other words, the rate limiting functions in the LNS must account for the last mile on-the-wire encapsulation overhead. The last mile encapsulation can be Ethernet or ATM.

For ATM in the last mile, the LNS will account for the following per fragment overhead:

- PID
- MLPPP encapsulation header
- ATM Fixed overhead (ATM encap + fixed AAL5 trailer)
- 48B boundary padding as part of AAL5 trailer
- 5B per each 48B of data in ATM cell.

In case of Ethernet encapsulation in the last mile, the overhead will be:

- PID
- MLPPP header per fragment
- Ethernet Header + FCS per fragment
- Preamble + IPG overhead per fragment

The encap-offset command under the sub-profile egress CLI node will be ignored in case of MLPPPoX. MLPPPoX rate calculation will be by default always based on the last mile wire overhead.

Figure 42 **QoS Enforcement Points in the LNS**

Issue: 01

5.3.19.4 Downstream Bandwidth Management on Egress Port

Bandwidth management on the egress physical ports (Physical Port 1 and Physical Port 2 in Figure 8) is performed at the egress port itself on the egress IOM instead on the carrier IOM. By default, the forwarding class (FC) information is preserved from network ingress to network egress. However, this can be changed via QoS configuration applied to the egress SAP of the carrier IOM towards the BB-ISA.

L2TP traffic originated locally in LNS can be marked via the router/service vprn->sgt-qos hierarchy.

5.3.20 Sub/Sla-Profile Considerations

Sub-profile

In the MLPPPoX case on LNS, multiple sessions are tied into the same subscriber aggregate-rate-limit via a sub-profile. The consequence is that the aggregate rate of the subscriber can be adjusted dynamically depending on the advertised link speed in the last mile and the number of links in the bundle.

Note: Shaping in the LNS is performed per the entire MLPPPoX bundle (subscriber) rather than per individual member links within the bundle. The exception is obviously a MLPPPoX bundle with the single member link (interleaving case) where the relationship between the session and the MLPPPoX bundle is 1:1.

In the LAC, the subscriber aggregate rate cannot be dynamically changed based on the number of links in the bundle and their rate. The LAC has no notion of MLPPPoX bundles. However, multiple sessions that in reality belong to an MLPPPoX bundle under the subscriber are shaped as an aggregate (agg-rate-limit under the sub-profile). This in essence yields the same shaping behavior as on LNS.

Sla-profile

Sessions within the MLPPPoX bundle in LNS share a single sla-profile instances (queues).

In the LAC, as long as the sessions within the subscriber6 are on the same SAP, they can also share the same sla-profile. This will be the case in MLPPPoX.

The manner in which sub/sla-profile are applied to MLPPPoX bundles and the individual sessions within results in aggregate shaping per MLPPPoX bundle as well as allocation of unique set of queues per MLPPPoX bundle. This is valid irrespective of the location where shaping is executed (LAC or LNS). Other vendors may have implemented shaping per session within the bundle and this is something that needs to be taken into consideration during the migration process.

5.3.21 Example of MLPPPoX Session Setup Flow

LAC behavior

- A new PPP(oEoA) session request will arrive to the LAC (PADI or LCP Conf Req).
- The LAC will negotiate PADx session if applicable.
- The LAC may negotiate MLPPPoX LCP phase with its own endpoint discriminator, or it may reject MLPPPoX specific options in LCP if MLPPPoX on the LAC is disabled (i.e. no accept-mrru in the LAC's ppp-policy). If MLPPPoX options (seq num header format, ED, MRRU) are rejected, the assumption is that the client will renegotiate plain PPP(oEoA) session with the LAC.
- Once LCP (MLPPPoX capable or not) is negotiated, the session will be authenticated (PAP/CHAP).
- Upon successful authentication, an L2TP tunnel will be identified to which the session belongs.
- If the session is a non-L2TP session (PTA MLPPPoX capable session for which the tunnel cannot be determined), the session will be terminated.
- Otherwise, the QoS constructs will be created for the subscriber hosts: the session will be assigned to a sub/sla-profiles.
- The session LCP parameters will be sent to the LNS via call management messages.

Note: If another LCP session is requested on the same bundle, the LAC will create a new LCP session and join this session to the existing subscriber as another host. In other words, the LAC is bundle agnostic and the two sessions will appear as two hosts under the same subscriber.

The following assumes that MLPPPoX is configured on the LNS under the L2TP group or the tunnel hierarchy.

LNS behavior

- The LNS have the option to accept the LCP parameters or to reject them and start renegotiating LCP parameters directly with the client.
- If the LNS choose to renegotiate LCP parameters with the client directly, this renegotiation will be completely transparent to the LAC by the means of a T-bit (control vs. data) in the L2TP header. LCP will be renegotiated on the LNS with all the options necessary to support MLPPPoX.

Note: Endpoint Discriminator is not mandatory in the MLPPPoX negotiation. If the client rejects it, the LNS must still be able to negotiate MLPPPoX capable session (same is valid for the LAC). If the client's endpoint discriminator is invalid (bad format, invalid class, etc.), the 7750 SR will not negotiate MLPPPoX and instead a plain PPP session will be created.

- If the LNS is configured to accept the LCP Proxy parameters, the LNS will determine the capability of the client.

If there is no indication of MLPPPoX capability in the Proxy LCP (not even in the original ConfReq), the LNS may accept plain (non MLPPPoX capable) LCP session or renegotiate from scratch the non MLPPPoX capable session.

If there is an indication of MLPPPoX capability in the Proxy LCP (either completely negotiated on the LAC or at least attempted from the client), the LNS will try to either accept the MLPPPoX negotiated session by the LAC or renegotiate the MLPPPoX capable session directly with the client.

If the LCP Proxy parameters with MLPPPoX capability are accepted by the LNS then the endpoint as negotiated on the LAC will also be accepted.

- Once the MLPPPoX capable LCP session is negotiated or accepted, authentication can be performed on the LNS. Authentication on the LNS can be restarted (CHAP challenge/response with the client), or accepted (chap challenge/response accepted and verified by the LNS via RADIUS).

Note: chap-challenge length is configurable in LNS.

- If the authentication is successful, depending on the evaluation of the parameters negotiated up to this point a new MLPPPoX bundle will be created or an existing MLPPPoX bundle will be joined. In case that a new bundle is established, the QoS constructs for the subscriber(-host) will be created (sub/sla-profile). Session negotiation will advance to IPCP phase.
- The decision whether a new session should join an existing MLPPPoX bundle, or trigger creation of a new one is governed by RFC 1990, *The PPP Multilink Protocol (MP)*, section 5.1.3, page 16, cases 1,2,3, and 4.

Note: Interleaving is supported only on MLPPPoX bundles with single session in them.

5.3.22 Other Considerations

- IPv6 is supported.
- AA is supported at LNS where full IP packets can be redirected via AA policies.
- Intra-chassis redundancy is supported:
 - CPM stateful failover
 - BB-ISA — non-stateful failover

5.4 Configuration Notes

MLPPP in subscriber management context is supported only over ATM, Ethernet over ATM or plain Ethernet transport (MLPPPoX). Native MLPPP over PPP/HDLC links is supported outside of the subscriber management context on the ASAP MDA.

MLPPPoX is supported only on LNS.

Interleaving is supported only on MLPPPoX bundles with a single member link. If more than one link is present in an MLPPPoX bundle, the interleaving will be automatically disabled and a SNMP trap will be generated. The MIB for this even is defined as `tmnxMlpppBundleIndicatorsChange`.

If MLPPPoX is enabled on LNS, the load balancing mode between the BB-ISAs within the group should be set to per tunnel. This will ensure that all sessions of the same MLPPPoX bundle are terminated on the same BB-ISA. On the LAC, sessions of the same bundle are setup in the same tunnel.

Virtual schedulers are not supported on MLPPPoX tunnels on LNS. However, aggregate-rate-limit is supported.

The aggregate-rate-limit on LNS will be automatically adjusted to the minimum value of:

- configured aggregate-rate-limit
- minimum last mile rate (obtained via LUDB, RADIUS or PPPoE tags) multiplied by the number of links in the bundle.

The aggregate-rate-limit on the LAC is not adjusted automatically. Therefore, if configured it should be set to a high value and thus the traffic treatment should rely on QoS performed on the LNS.

The rate (rate-down information) of the member links within the bundle must be the same. Otherwise the lowest rate is selected and applied to all member links.

A single CoA for a rate change (Alc-Access-Loop-Rate-Down) of an individual link in an MLPPPoX bundle will modify rates of all links in the bundle. This is applicable on LNS only.

The range of supported last mile rate (rate-down information) for the member links on an MLPPPoX session is 1kbps — 100mbps. On the LNS the last mile rate can be obtained:

- From the LAC via Tx-Connect-Speed AVP or by standard L2TP encoding as described in the RFC 5515, *Layer 2 Tunneling Protocol (L2TP) Access Line Information Attribute Value Pair (AVP) Extensions*.
- From the LAC via LUDB or RADIUS
- Directly on the LNS via LUDB or RADIUS.

The session will fail to come up if the obtained rate-down information is outside of the allowable range (1kbps — 100mbps).

A session within the MLPPPoX bundle will be terminated if the rate-down information for the session is out of bounds (1Kbps — 100Mbps).

If a member link in the last mile fails, traffic will be blackholed until the LNS is notified of this failure. The failure detection in the LNS relies on PPP keepalives.

Shaping is performed per MLPPPoX bundle and not individually per member links.

If encapsulation overhead associated with fragmentation is too large in comparison to payload, the fragments will be sized based on the encapsulation overhead (to increase link efficiency) rather than on maximum transmission delay.

There can be only a single MLPPPoX bundle per subscriber.

MLPPPoX bundles and non-MLPPPoX (plain L2TP PPPoE) sessions cannot coexist under the same subscriber.

Filters and mirrors (LI) are not supported on MLPPPoX bundles on LAC.

ip-only type mirrors are supported on MLPPPoX bundles.

In MLPPP scenario, downstream traffic is traversing Carrier IOM and BB-ISA twice. This is referred to as dual-pass and effectively cuts the throughput for MLPPP in half (for example, 5Gbps of MLPPP traffic on a 10Gbps capable BB-ISA).

5.5.1.5 Show Commands

```
show
  — router
    — l2tp
      — peer ip-address [udp-port port]
      — peer ip-address statistics [udp-port port]
      — peer [draining] [blacklisted | selectable | unreachable]
```

5.5.2 Command Descriptions

5.5.2.1 PPP Configuration Commands

description

Syntax	description <i>description-string</i> no description
Context	config>subscr-mgmt>pppoe-policy config>service>ies>sub-if>grp-if>pppoe config>service>vprn>sub-if>grp-if>pppoe
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The no form of this command removes the string from the configuration.</p>
Default	no description
Parameters	<i>description-string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	config>service>ies>sub-if>grp-if>pppoe config>service>vprn>sub-if>grp-if>pppoe
Description	<p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.</p> <p>The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.</p> <p>The no form of this command places the entity into an administratively enabled state.</p>

ppp-policy

Syntax	ppp-policy <i>ppp-policy-name</i> [create] no ppp-policy <i>ppp-policy-name</i>
Context	config>subscr-mgmt
Description	This command configures a PPP policy. These policies are referenced from interfaces configured for PPP. Multiple PPP policies may be configured. This default policy cannot be modified nor deleted.
Default	default
Parameters	<i>ppp-policy-name</i> — Specifies the PPP policy name up to 32 characters in length. create — Keyword used to create the entity. The create keyword requirement can be enabled/disabled in the environment>create context.

default-pap-password

Syntax	default-pap-password <i>password</i> [hash hash2] no default-pap-password
Context	config>subscr-mgmt>ppp-policy
Description	This command configures the default PAP password for RADIUS authentication when the Password-Length=0 in the PAP Authenticate-Request. RADIUS authentication cannot be initiated when the Password-Length=0 in the PAP Authenticate-Request and no default-pap-password is configured. The PPP session terminates in this case.
Default	no default-pap-password
Parameters	<i>password</i> — Specifies a default PAP password up to 64 characters in length. hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.

default-user-name

Syntax	default-user-name <i>ppp-username</i> no default-user-name
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command configures the default username for authentication when not provided in PAP/CHAP authentication (no Name field in CHAP Response message or Peer-Id-Length=0 in PAP Authenticate-Request).</p> <p>The PPP session terminates when no username is provided in PAP/CHAP authentication and no default-user-name is configured.</p>
Default	no default-user-name
Parameters	<i>ppp-username</i> — Specifies a default username up to 253 characters.

disable-cookies

Syntax	[no] disable-cookies
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command disables the use of cookies.</p> <p>The no form of the command enables cookies.</p>
Default	no disable-cookies

force-ppp-mtu-gt-1492

Syntax	[no] force-ppp-mtu-gt-1492
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command enables PPPoE Maximum-Receive-Unit (MRU) negotiations greater than 1492 bytes without the need to receive a “PPP-Max-Payload” tag in PADI/PADR from the client as defined in RFC 4638, <i>Accommodating a Maximum Transit Unit/Maximum Receive Unit (MTU/MRU) Greater Than 1492 in the Point-to-Point Protocol over Ethernet (PPPoE)</i>.</p> <p>The MRU send in the initial LCP Config Request is determined by the port mtu and ppp-policy ppp-mtu parameters.</p>
Default	no force-ppp-mtu-gt-1492

keepalive

Syntax	keepalive <i>seconds</i> [hold-up-multiplier <i>multiplier</i>] no keepalive
Context	config>subscr-mgmt>ppp-policy
Description	This command defines the keepalive interval and the number of keepalives that can be missed before the session is declared down for this PPP policy. The no form of the command reverts to the default value.
Default	30 seconds 3 multiplier
Parameters	<i>seconds</i> — Specifies the keepalive interval in seconds. Values 10 to 300 <i>hold-up-multiplier multiplier</i> — Specifies the number of keepalives that can be missed. Values 1 to 5

ipcp-subnet-negotiation

Syntax	[no] ipcp-subnet-negotiation
Context	config>subscr-mgmt>ppp-policy
Description	This command enables subnet negotiation using PPP IPCP Subnet-Mask option (0x90) if requested by the client. The subnet can be obtained from RADIUS (Framed-IP-Netmask attribute) or local user database. The subnet is installed as a managed route of the PPP session. This requires the anti-spoof type on the SAP to be configured to nh-mac. By default, an IPCP Config Request with IPCP Subnet-Mask option (0x90) is rejected.
Default	no ipcp-subnet-negotiation

lcp-ignore-magic-numbers

Syntax	[no] lcp-ignore-magic-numbers
Context	config>subscr-mgmt>ppp-policy
Description	This command enables the PPP session to stay established when an LCP peer magic number mismatch is detected. By default, the PPP session is terminated when an LCP peer magic number mismatch is detected.

Default no lcp-ignore-magic-numbers

max-sessions-per-mac

Syntax	max-sessions-per-mac <i>sessions</i> [allow-same-circuit-id-for-dhcp] no max-sessions-per-mac
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command sets the maximum PPP sessions that can be opened for a given MAC address.</p> <p>To enable IPv4 address allocation using the internal dhcpv4 client for multiple PPPoE sessions on a single SAP and having the same MAC address and circuit-ID, the optional cli flag “allow-same-circuit-id-for-dhcp” should be added. The SROS local-dhcp-server will detect the additional vendor-specific options inserted by the internal dhcpv4 client and use an extended unique key for lease allocation.</p> <p>The no form of the command reverts to the default value.</p>
Default	1
Parameters	<p><i>sessions</i> — Specifies the maximum PPP sessions that can be opened for the given MAC address.</p> <p>Values 1 to 8191</p> <p><i>allow-same-circuit-id-for-dhcp</i> — (optional) Enables support for IPv4 address allocation using the internal dhcpv4 client for multiple PPPoE sessions on a single SAP that have the same MAC address and circuit-ID.</p>

pado-ac-name

Syntax	pado-ac-name <i>name</i> no pado-ac-name
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command configures the Access Concentrator name that is used in the PPPoE PADO message.</p> <p>By default, the system name or if not configured, the chassis Serial Number is used.</p>
Default	no pado-ac-name
Parameters	<p><i>name</i> — Specifies the string up to 128 characters to be used as AC name in the PPPoE PADO message.</p>

pado-delay

Syntax	pado-delay <i>deci-seconds</i> no pado-delay
Context	config>subscr-mgmt>ppp-policy
Description	This command configures the delay timeout before sending a PPP Active Discovery Offer (PADO) packet.
Default	no pado-delay
Parameters	<i>deci-seconds</i> — Specifies the delay timeout before sending a PADO. Values 1 to 30

ppp-authentication

Syntax	ppp-authentication { pap chap pref-chap pref-pap } no ppp-authentication
Context	config>subscr-mgmt>ppp-policy
Description	This command configures the PPP protocol used to authenticate the PPP session.
Default	ppp-authentication pref-chap
Parameters	pap — Specifies to always use PAP to authenticate the sessions. chap — Specifies to always use CHAP to authenticate the sessions. pref-chap — Specifies to attempt to use CHAP and if it fails, use PAP. pref-pap — Specifies to attempt to use PAP and if it fails, use CHAP.

ppp-chap-challenge-length

Syntax	ppp-chap-challenge-length min <i>minimum-length</i> max <i>maximum-length</i> no ppp-chap-challenge-length
Context	config>subscr-mgmt>ppp-policy
Description	This command configures the minimum and maximum length of a PPP Chap Challenge. When the Chap Challenge is exactly 16 bytes, it is send in the [60] CHAP-Challenge RADIUS attribute and also copied in the RADIUS Authenticator field from the RADIUS Access Request.
Default	ppp-chap-challenge-length min 32 max 64

Parameters **min** *minimum-length* — Specifies the minimum PPP CHAP challenge length.
 Values 8 to 64
 max *maximum-length* — Specifies the maximum PPP CHAP challenge length.
 Values 8 to 64

ppp-initial-delay

Syntax **[no] ppp-initial-delay**
Context config>subscr-mgmt>ppp-policy
Description This command delays the sending of an LCP-configure request after the discovery phase by 40 – 60 milliseconds.
Default no ppp-initial-delay

ppp-mtu

Syntax **ppp-mtu** *mtu-bytes*
 no ppp-mtu
Context config>subscr-mgmt>ppp-policy
Description This command configures the maximum PPP MTU size.
Default no ppp-mtu
Parameters *mtu-bytes* — Specifies the maximum PPP MTU size.
 Values 512 to 9212

ppp-options

Syntax **ppp-options**
Context config>subscr-mgmt>pppoe-policy
Description This command enables the context to configure PPP options.
Default ppp-options

custom-option

Syntax **custom-option** *protocol option-number address ip-address*

custom-option *protocol option-number hex hex-string*
custom-option *protocol option-number string ascii-string*
no custom-option *protocol option-number*

Context config>subscr-mgmt>pppoe-policy>ppp-options
Description This command provides the ability to configure custom PPP options.

Note: Standard options such as the DNS name will be returned from DHCP or RADIUS and be converted to PPP automatically. Compression is not supported.

The no form of the command removes the custom options from the configuration.

Parameters *protocol* — Specifies a protocol for the custom option.
Values lcp, ipcp
option-number — Assigns an identifying number for the custom option.
Values 0 to 255
ip-address —
ascii-string — Specifies an ASCII format string for the custom option up to 127 characters long.
hex-string — Specifies a hex value for the custom option.
Values [0x0 to 0xFFFFFFFF (max 254 hex nibbles)]

re-establish-session

Syntax **re-establish-session** *padr*
no re-establish-session
Context config>subscr-mgmt>pppoe-policy
Description This command enables/disables host to reconnect and override existing session.

If disabled and a subscriber abruptly terminates a PPP sessions without sending a PADT to the BNG, the BNG will deny any reconnect attempts until the stale PPP session has expired. With this, enabled re-establish-session will eliminate the waiting period by allowing immediate PPP reconnection attempts

Default no re-establish-session

reject-disabled-ncp

Syntax [**no**] **reject-disabled-ncp**

Context	config>subscr-mgmt>pppoe-policy
Description	<p>This command forces an LCP Protocol Reject when receiving an IPv6CP Configure Request message while IPv6 is not configured.</p> <p>By default, an IPv6CP Configure Request message is silently ignored when IPv6 is not configured.</p>
Default	no reject-disabled-ncp

reply-on-padt

Syntax	[no] reply-on-padt
Context	config>subscr-mgmt>pppoe-policy
Description	<p>Some of the PPPoE clients expect reply on PPPoE Active Discovery Terminate (PADT) message before the context of the session is cleared up. To support such client, a command enabling reply to PADT is provided.</p>
Default	no reply-on-padt

session-timeout

Syntax	session-timeout <i>timeout</i> no session-timeout
Context	config>subscr-mgmt>ppp-policy
Description	<p>This command defines the time in seconds between 1 and 360 days before the PPP session will be terminated. The default value is unlimited session timeout.</p> <p>A RADIUS specified session-timeout (attribute [27] Session-Timeout) overrides the CLI configured value.</p>
Default	no session-timeout
Parameters	<i>timeout</i> — Specifies the session timeout in seconds.
Values	1 to 31104000

unique-sid-per-sap

Syntax	unique-sid-per-sap [per-msap] no unique-sid-per-sap
Context	config>subscr-mgmt>ppp-policy

Description	<p>This command assigns a unique session ID to each PPPoE session with different MAC addresses that are active on a single SAP.</p> <p>On a capture-sap, a unique session ID is assigned per MSAP. Multiple sessions with different MAC addresses that are active on the same MSAP have the same session ID.</p> <p>With the optional parameter per-msap, a unique session id is assigned for each session with different MAC address that is active on the same MSAP.</p> <p>The maximum session ID range is 1 to 8191.</p> <p>By default, all PPPoE sessions with different MAC address on a given SAP or MSAP have session-id 1.</p>
Default	no unique-sid-per-sap
Parameters	per-msap — Assigns a unique session id for each session with different MAC address that is active on the same MSAP. This parameter has no effect on regular SAPs.

5.5.2.1.1 MLPPP on LNS Commands

accept-mrru

Syntax	[no] accept-mrru
Context	config>subscr-mgmt>ppp-policy>mlppp
Description	<p>This command is applicable only to LAC. MRRU option is an indication that the session is of MLPPPoX type. The 7750 SR LAC will never initiate MRRU option in LCP negotiation process. However, it will respond to MRRU negotiation request by the client.</p> <p>This command provides an option to specifically enable or disable negotiation of MLPPPoX on a capture SAP level or on a group interface level.</p> <p>The no form of the command causes the MRRU option in LCP will not be negotiated by LAC.</p>
Default	no accept-mrru

admin-state

Syntax	admin-state {up down} no admin-state
Context	config>router>l2tp>group>tunnel>mlppp config>service>vprn>l2tp>group>tunnel>mlppp
Description	<p>This command is applicable only to LNS.</p> <p>The tunnel can be explicitly activated (assuming that the parent group is in a no shutdown state) or deactivated by the up and down keywords.</p> <p>If case that there is no admin-state configured, the tunnel will inherit its administrative state from its parent (group).</p> <p>The no form of the command causes the tunnel administrative state to be inherited from the group.</p>
Default	no admin-state
Parameters	<p>up — Specifies that the tunnel is to be administratively up.</p> <p>down — Specifies that the tunnel is to be administratively down.</p>

encap-offset

Syntax	encap-offset [type <i>encap-type</i>]
---------------	--

no encap-offset

Context	config>subscriber-mgmt>loc-user-db>ppp>host>access-loop																
Description	<p>This command is applicable within the LAC/LNS context. It provides the last mile link encapsulation information that is needed for proper (shaping) rate calculations and interleaving delay in the last mile.</p> <p>The encapsulation value will be taken from the following sources in the order of priority:</p> <ul style="list-style-type: none"> • Statically provisioned value in local user database (LUDB). • RADIUS • PPPoE tags on LAC or ICRQ message (RFC 5515) on LNS <p>In case that the encapsulation information is not provided by any of the existing means (LUDB, RADIUS, AVP signaling, PPPoE Tags), then by default pppoea-null encapsulation will be in effect.</p> <p>The following values are supported encapsulation values on LNS in the 7750 SR.</p> <p>encap-type:</p> <table> <tr> <td>pppoa-llc</td><td>LLC (NLPID) PPPoA encapsulation.</td></tr> <tr> <td>pppoa-null</td><td>VC-MUX PPPoA encapsulation.</td></tr> <tr> <td>pppoeoa-llc</td><td>LLC/SNAP based bridged Ethernet PPPoEoA encapsulation without FCS.</td></tr> <tr> <td>pppoeoa-llc-fcs</td><td>LLC/SNAP based bridged Ethernet PPPoEoA encapsulation with FCS.</td></tr> <tr> <td>pppoeoa-null</td><td>VC-MUX PPPoEoA encapsulation without FCS.</td></tr> <tr> <td>pppoeoa-null-fcs</td><td>VC-MUX PPPoEoA encapsulation with FCS.</td></tr> <tr> <td>pppoe</td><td>PPPoE encapsulation.</td></tr> <tr> <td>pppoe-tagged</td><td>Tagged PPPoE Encapsulation.</td></tr> </table>	pppoa-llc	LLC (NLPID) PPPoA encapsulation.	pppoa-null	VC-MUX PPPoA encapsulation.	pppoeoa-llc	LLC/SNAP based bridged Ethernet PPPoEoA encapsulation without FCS.	pppoeoa-llc-fcs	LLC/SNAP based bridged Ethernet PPPoEoA encapsulation with FCS.	pppoeoa-null	VC-MUX PPPoEoA encapsulation without FCS.	pppoeoa-null-fcs	VC-MUX PPPoEoA encapsulation with FCS.	pppoe	PPPoE encapsulation.	pppoe-tagged	Tagged PPPoE Encapsulation.
pppoa-llc	LLC (NLPID) PPPoA encapsulation.																
pppoa-null	VC-MUX PPPoA encapsulation.																
pppoeoa-llc	LLC/SNAP based bridged Ethernet PPPoEoA encapsulation without FCS.																
pppoeoa-llc-fcs	LLC/SNAP based bridged Ethernet PPPoEoA encapsulation with FCS.																
pppoeoa-null	VC-MUX PPPoEoA encapsulation without FCS.																
pppoeoa-null-fcs	VC-MUX PPPoEoA encapsulation with FCS.																
pppoe	PPPoE encapsulation.																
pppoe-tagged	Tagged PPPoE Encapsulation.																

The following are not supported encapsulation values on LNS in the 7750 SR.

- pppoeoa-llc-tagged
- pppoeoa-llc-tagged-fcs
- pppoeoa-null-tagged
- pppoeoa-null-tagged-fcs
- ipoa-llc
- ipoa-null
- ipoeoa-llc
- ipoeoa-llc-fcs
- ipoeoa-llc-tagged

- ipoeoa-llc-tagged-fcs
- ipoeoa-null
- ipoeoa-null-fcs
- ipoeoa-null-tagged
- ipoeoa-null-tagged-fcs
- ipoe
- ipoe-tagged

Default no encap-offset No offset is configured.

endpoint

Syntax **endpoint ip** *ip-address*
endpoint mac *ieee-address*
endpoint system-ip
endpoint system-mac
no endpoint

Context config>router>l2tp>group>mlppp
config>router>l2tp>group>tunnel>mlppp
config>service>vpn>l2tp>group>mlppp
config>service>vpn>l2tp>group>tunnel>mlppp
config>subscr-mgmt>ppp-plcy>mlppp

Description When configured under the l2tp hierarchy, this command is applicable to LNS.

Within the ppp-policy, this command is applicable only to LAC.

The endpoint, according to RFC 1990, represents the system transmitting the packet. It is used during MLPPPoX negotiation phase to distinguish this peer from all others.

In the case that the client rejects the endpoint option during LCP negotiation, the LAC and the LNS must be able to negotiate the LCP session without the endpoint option.

The **no** form of this command disables sending endpoint option in LCP negotiation.

Default no endpoint

Parameters **ip** *ip-address* — Specifies the IPv4 address (class 2)
system-ip — Specifies to use the system IPv4 address (class 2)
mac *ieee-address* — Specifies the MAC address of the interface (class 3).
system-mac — Specifies to use the MAC address of the system (class 3)

interleave

Syntax	[no] interleave
Context	config>router>l2tp>group>mlppp config>service>vprn>l2tp>group>mlppp
Description	<p>This command is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving will be automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) will be generated.</p> <p>The minimum supported rate of the link on which interleaving is performed is 1kbps.</p> <p>If configured at this level, interleaving will be enabled on all tunnels within the group, unless it is explicitly disable per tunnel.</p>
Default	no interleave — Interleaving per group is disabled.

interleave

Syntax	interleave {always never} no interleave
Context	config>router>l2tp>group>tunnel>mlppp config>service>vprn>l2tp>group>tunnel>mlppp
Description	<p>This command is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving will be automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) will be generated.</p> <p>The minimum supported rate of the link on which interleaving is performed is 1kbps.</p> <p>Interleaving configured on this level will overwrite the configuration option under the group hierarchy. If the no form of the command is configured for interleaving at this level, the interleaving configuration will inherit the configuration option configured under the l2tp group.</p>
Default	no interleave — Interleaving configuration is inherited from the group.
Parameters	<p>always — Always perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.</p> <p>never — Never perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.</p>

load-balance-method

Syntax	load-balance-method {session tunnel}
---------------	---

	no load-balance-method
Context	<pre>config>router>l2tp>group config>router>l2tp>group>tunnel config>service>vprn>l2tp>group config>service>vprn>l2tp>group>tunnel</pre>
Description	<p>This command is applicable only to LNS. By default traffic load balancing between the BB-ISAs is based on sessions. Each session is individually assigned to an BB-ISA during session establishment phase.</p> <p>By introducing MLPPPoX, all sessions of a bundle must be terminated on the same LNS BB-ISA. This is necessary for two reasons:</p> <ul style="list-style-type: none"> • QoS in the carrier IOM has a uniform view of the subscriber • a single BB-ISA is responsible for MLPPPoX encapsulation/fragmentation for a given bundle. <p>Therefore, if fragmentation is enabled, load-balancing per tunnel must be configured. In the per tunnel load-balancing mode, all sessions within the same tunnel are terminated on the same LNS BB-ISA.</p> <p>In the case that we have MLPPPoX sessions with a single member link, both load-balancing methods are valid.</p> <p>The no form of this command sets the per session load balancing.</p>
Default	session — The per session load balancing is enabled by default.
Parameters	<p>session — The traffic load balancing between the LNS BB-ISAs is based on individual PPPoE sessions.</p> <p>tunnel — The traffic load balancing between the LNS BB-ISAs is based on tunnels.</p>

max-fragment-delay

Syntax	max-fragment-delay <i>delay</i> no max-fragment-delay
Context	<pre>config>router>l2tp>group>mlppp config>router>l2tp>group>tunnel>mlppp config>service>vprn>l2tp>group>mlppp config>service>vprn>l2tp>group>tunnel>mlppp</pre>
Description	<p>This command is applicable only to LNS. It determines the maximum fragment delay caused by the transmission that will be imposed on a link.</p> <p>Fragmentation can be used to interleave high priority packet in-between low priority fragments on a MLPPPoX session with a single link or on a MLPPPoX session with multiple links to better load balance traffic over multiple member links.</p>

Default	no max-fragment-delay — Fragmentation is disabled.
Parameters	<i>delay</i> — Specifies the interval in milliseconds.
Values	5 to 1000ms

max-link

Syntax	max-links <i>max-links</i> no max-links
Context	config>router>l2tp>group>mlppp config>router>l2tp>group>tunnel>mlppp config>service>vprn>l2tp>group>mlppp config>service>vprn>l2tp>group>tunnel>mlppp
Description	<p>This command is applicable only to LNS. It determines the maximum number of links that can be put in a bundle.</p> <p>Any attempt of a session to join a bundle that is above the max-link limit will be rejected.</p> <p>If interleaving is configured, it is recommended that max-links be set to 1 or a version of the command is used (no max-links). Both have the same effect.</p> <p>The configuration under the tunnel hierarchy will override the configuration under the group hierarchy.</p> <p>The no form of this command limits the number of links in the bundle to 1.</p>
Default	no max-links — A single link per bundle is allowed.
Parameters	<i>max-links</i> — Specifies the maximum number of links in a bundle.
Values	1 to 8

reassembly-timeout

Syntax	reassembly-timeout { <i>timeout</i> } no reassembly-timeout
Context	config>router>l2tp>group>mlppp config>router>l2tp>group>tunnel>mlppp config>service>vprn>l2tp>group>mlppp config>service>vprn>l2tp>group>tunnel>mlppp

Description	<p>This command is applicable only to LNS. It determines the time during which the LNS keeps fragments of the same packet in the buffer before it discards them. The assumption is that if the fragments do not arrive within certain time, the chance is that they were lost somewhere in the network. In this case the partial packet cannot be reassembled and all fragments that has arrived up to this point and are stored in the buffer will be discarded in order to free up the buffer. Otherwise, a condition will arise in which partial packets will be held in the buffer until the buffer is exhausted.</p> <p>The configuration under the tunnel hierarchy will override the configuration under the group hierarchy.</p> <p>The no form of this command sets the timeout to 1000ms.</p>
Default	1000
Parameters	<i>timeout</i> — Specifies the reassembly timeout value.
	Values 100, 1000 milliseconds

rate-down

Syntax	rate-down <i>rate</i> no rate-down
Context	config>subscriber-mgmt>loc-user-db>ppp>host>access-loop
Description	<p>This command is applicable to LAC and LNS. It provides the last mile link rate in the downstream direction that is needed for proper shaping and calculating the interleaving delay.</p> <p>The rate information in the last mile will be taken from the following sources in the order of priority:</p> <ul style="list-style-type: none">• Statically provisioned value in local user database (LUDB).• RADIUS.• PPPoE tags on LAC or ICRQ message (RFC 5515) /ICCN message (TX Connect Seed) on LNS.
Default	no rate-down
Parameters	<i>rate</i> — Specifies last mile link downstream rate in the access loop.
	Values 1 to 100000 kbps

short-sequence-numbers

Syntax	[no] short-sequence-numbers
Context	config>subscr-mgmt>ppp-policy>mlppp

Description	This command enables a peer request to send short sequence numbers. This command is applicable to LAC and LNS. By default, MLPPPoX will negotiate 24bit long sequence numbers. This command allows this to be changed to shorter, 12-bit sequence numbers.
Default	short-sequence-numbers

5.5.2.1.2 PPP/PPPoE Service Commands

ppp

Syntax	[no] ppp
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command configures PPP parameters. The no form of the command reverts all PPP parameters from the PPP context to their defaults.
Default	ppp

pppoe

Syntax	[no] pppoe
Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables the context to configure PPPoE parameters. The no form of the command reverts all PPPoE parameters from the PPPoE context to their defaults.
Default	pppoe

anti-spoof

Syntax	anti-spoof <i>pppoe-anti-spoofing-type</i> no anti-spoof
Context	config>service>ies>sub-if>grp-if>pppoe config>service>vprn>sub-if>grp-if>pppoe
Description	This command specifies the type of PPPoE anti-spoof filtering to use.
Default	mac-sid
Parameters	<i>pppoe-anti-spoofing-type</i> — Specifies the PPPoE anti-spoof filtering. Values mac-sid, mac-sid-ip

dhcp-client

Syntax	dhcp-client
Context	config>service>vprn>sub-if>grp-if>pppoe config>service>ies>sub-if>grp-if>pppoe
Description	This command enables the context to configure the PPPoE-to-DHCP options.

ccag-use-origin-sap

Syntax	[no] ccag-use-origin-sap
Context	config>service>vprn>sub-if>grp-if>pppoe>dhcp-client config>service>ies>sub-if>grp-if>pppoe>dhcp-client
Description	This command enables the original VPLS SAP to be included in the circuit-id option to send to the DHCP server (in case this interface is connected to a VPLS by a CCA MDA). The no form of the command disables the feature.
Default	no ccag-use-origin-sap

policy

Syntax	policy <i>ppp-policy-name</i> no policy
Context	config>service>vprn>sub-if>grp-if>pppoe config>service>ies>sub-if>grp-if>pppoe
Description	This command specifies the PPPoE policy on this interface.
Parameters	<i>ppp-policy-name</i> — Specifies the PPP policy name up to 32 characters in length.

include-option

Syntax	include-option <i>string text</i> no include-option
Context	config>service>vprn>sub-if>grp-if>pppoe>dhcp-client config>service>ies>sub-if>grp-if>pppoe>dhcp-client
Description	This command allows the configuration of a vendor-specific sub-option string in a DHCP message.

Parameters *string text* — Specifies a vendor-specific string inside-option 82, sub-option 9, sub-option5.

sap-session-limit

Syntax **sap-session-limit** *sap-session-limit*
no sap-session-limit

Context config>service>ies>sub-if>grp-if>pppoe
config>service>vprn>sub-if>grp-if>pppoe

Description This command specifies the number of PPPoE hosts per SAP allowed for this group-interface.

Default 1

Parameters *sap-session-limit* — Specifies the number of PPPoE hosts per SAP allowed.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

session-limit

Syntax **session-limit** *session-limit*
no session-limit

Context config>service>ies>sub-if>grp-if>pppoe
config>service>vprn>sub-if>grp-if>pppoe
config>service>ies>sub-if>pppoe
config>service>vprn>sub-if>pppoe

Description This command specifies the number of PPPoE hosts allowed for this group interface.

Default 1

Parameters *session-limit* — Specifies the number of PPPoE hosts allowed.

Note: The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

1 to 262143 (retail subscriber interface)

user-db

Syntax	user-db <i>local-user-db-name</i> no user-db
Context	config>service>ies>sub-if>grp-if>pppoe config>service>vprn>sub-if>grp-if>pppoe
Description	This command configures the local user database to use for PPP PAP/CHAP authentication
Parameters	<i>local-user-db-name</i> — Specifies the local user database name up to 32 characters in length.

5.5.2.1.3 RADIUS Attribute Commands

acct-authentic

Syntax	[no] acct-authentic
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the acct-authentic RADIUS attribute.

acct-delay-time

Syntax	[no] acct-delay-time
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the acct-delay-time RADIUS attribute.

called-station-id

Syntax	[no] called-station-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command includes called station id attributes.

The **no** form of the command excludes called station id attributes.

calling-station-id

Syntax	calling-station-id calling-station-id { mac remote-id sap-id sap-string } no calling-station-id
Context	config>service>ies>if>sap config>service>ies>sub-if>grp-if>sap config>service>vpls>sap config>service>vprn>if>sap config>service>vprn>sub-if>grp-if>sap config>subscr-mgmt>auth-plcy>include-radius-attribute config>subscr-mgmt>acct-plcy>include>include-radius-attribute
Description	This command enables the inclusion of the calling-station-id attribute in RADIUS authentication requests and RADIUS accounting messages. The value inserted is set at the SAP level. If no calling-station-id value is set at the SAP level, the calling-station-id attribute will not be sent.
Default	no calling-station-id
Parameters	mac — Specifies that the mac-address will be sent. remote-id — Specifies that the remote-id will be sent. sap-id — Specifies that the SAP ID will be sent. sap-string — Specifies that the value is the inserted value set at the SAP level. If no calling-station-id value is set at the SAP level, the calling-station-id attribute will not be sent.

circuit-id

Syntax	[no] circuit-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the agent-circuit-id for RADIUS.
Default	no circuit-id

delegated-ipv6-prefix

Syntax	[no] delegated-ipv6-prefix
---------------	-----------------------------------

Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the delegated-ipv6-prefix RADIUS attribute. The no form of the command disables the generation of the delegated-ipv6-prefix RADIUS attribute.
Default	no delegated-ipv6-prefix

framed-interface-id

Syntax	[no] framed-interface-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the framed-interface-id RADIUS attribute. The no form of the command disables the framed-interface-id RADIUS attribute.
Default	no framed-interface-id

framed-ip-addr

Syntax	[no] framed-ip-addr
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the inclusion of the framed-ip-addr attribute. The no form of the command disables the inclusion of the framed-ip-addr attribute.
Default	no framed-ip-addr

framed-ip-netmask

Syntax	[no] framed-ip-netmask
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the inclusion of the framed-ip-netmask attribute. The no form of the command disables the inclusion of the framed-ip-netmask attribute.
Default	no framed-ip-netmask

framed-ipv6-prefix

Syntax	[no] framed-ipv6-prefix
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the framed-ipv6-prefix RADIUS attribute. The no form of the command disables the generation of the framed-ipv6-prefix RADIUS attribute.
Default	no framed-ipv6-prefix

ipv6-address

Syntax	[no] framed-ipv6-address
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the ipv6-address RADIUS attribute. The no form of the command disables the generation of the ipv6-address RADIUS attribute.
Default	no ipv6-address

mac-address

Syntax	[no] mac-address
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the client MAC address RADIUS attribute. The no form of the command disables the generation of the client MAC address RADIUS attribute.
Default	no mac-address

nas-identifier

Syntax	[no] nas-identifier
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute

Description	This command enables the generation of the nas-identifier RADIUS attribute. The no form of the command disables the generation of the nas-identifier RADIUS attribute.
Default	no nas-identifier

nas-port

Syntax	[no] nas-port <i>bit-specification binary-spec</i>
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-port RADIUS attribute. You enter decimal representation of a 32-bit string that indicates your port information. This 32-bit string can be compiled based on different information from the port (data types). By using syntax number-of-bits data-type you indicate how many bits from the 32 bits are used for the specific data type. These data types can be combined up to 32 bits in total. In between the different data types 0's and/or 1's as bits can be added. The no form of this command disables the nas-port configuration.
Default	no nas-port
Parameters	<i>bit-specification binary-spec</i> — Specifies the NAS-Port attribute

Values

binary-spec	<bit-specification> <binary-spec>
bit-specification	0 1 <bit-origin>
bit-origin	*<number-of-bits><origin>
number-of-bits	1 to 32
origin	o i s m p o outer VLAN ID i inner VLAN ID s slot number m MDA number p port number or lag-id

Output

Sample

```
*12o*12i00*2s*2m*2p => 0000 0000 0000 1111 1111 1111 00ss mmpp
If outer vlan = 0 & inner vlan = 1 & slot = 3 & mda = 1 & port = 1
=> 0000 0000 0000 0000 0000 0001 0011 0101 => nas-port = 309
```

nas-port-id

Syntax	[no] nas-port-id [prefix-string <i>string</i>] [suffix <i>suffix-option</i>]
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command enables the generation of the nas-port-id RADIUS attribute. Optionally, the value of this attribute (the SAP ID) can be prefixed by a fixed string and suffixed by the circuit-id or the remote-id of the client connection. If a suffix is configured, but no corresponding data is available, the suffix used will be 0/0/0/0/0/0.</p> <p>The no form of the command disables the generation of the nas-port-id RADIUS attribute.</p>
Default	no nas-port-id
Parameters	<p>prefix-string <i>string</i> — Specifies that a user configurable string will be added to the RADIUS NAS port attribute, up to 8 characters in length.</p> <p>suffix <i>suffix-option</i> — Specifies the suffix type to be added to the RADIUS NAS port attribute.</p> <p>Values circuit-id, remote-id</p>

nas-port-type

Syntax	nas-port-type nas-port-type <i>value</i> no nas-port-type
Context	config>subscr-mgmt>auth-plcy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command enables the generation of the nas-port-type RADIUS attribute. If set to nas-port-type, the following will be sent: values: 32 (null-encap), 33 (dot1q), 34 (qinq), 15 (DHCP hosts). The nas-port-type can also be set as a specified value, with an integer from 0 to 255.</p> <p>The no form of the command disables the generation of the nas-port-type RADIUS attribute</p>
Default	no nas-port-type
Parameters	<p><i>value</i> — Specifies an enumerated integer that specifies the value that will be put in the RADIUS nas-port-type attribute.</p> <p>Values</p>

nat-port-range

Syntax	[no] nat-port-range
---------------	----------------------------

Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the of nat-port-range attribute. The no form of the command disables the generation of the nat-port-range attribute.
Default	no nat-port-range

remote-id

Syntax	[no] remote-id
Context	config>subscr-mgmt>auth-policy>include-radius-attribute config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command enables the generation of the agent-remote-id for RADIUS. The no form of the command disables the generation of the agent-remote-id for RADIUS.
Default	no remote-id

sap-session-index

Syntax	[no] sap-session-index
Context	config>subscr-mgmt>auth-policy>include-radius-attribute
Description	This command includes sap-session-index attributes. The no form of the command excludes sap-session-index attributes.
Default	no sap-session-index

sla-profile

Syntax	[no] sla-profile
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	This command specifies that SLA profile attributes should be included into RADIUS accounting messages. The no form of the command excludes SLA profile attributes into RADIUS accounting messages.
Default	no sla-profile

sub-profile

Syntax	[no] sub-profile
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command specifies that subscriber profile attributes should be included into RADIUS accounting messages.</p> <p>The no form of the command excludes subscriber profile attributes into RADIUS accounting messages.</p>
Default	no sub-profile

subscriber-id

Syntax	[no] subscriber-id
Context	config>subscr-mgmt>acct-plcy>include-radius-attribute
Description	<p>This command specifies that subscriber ID attributes should be included into RADIUS accounting messages.</p> <p>The no form of the command excludes subscriber ID attributes into RADIUS accounting messages.</p>
Default	no subscriber-id

radius-accounting-server

Syntax	radius-accounting-server
Context	config>app-assure>rad-acct-plcy config>aaa>l2tp-tunnel-acct-plcy
Description	This command creates the context for defining RADIUS accounting server attributes under a given session authentication policy.

access-algorithm

Syntax	access-algorithm {direct round-robin}
Context	config>app-assure>rad-acct-plcy>server
Description	This command configures the algorithm used to access the list of configured RADIUS servers.

Default	direct
Parameters	direct — Specifies that the first server will be used as primary server for all requests, the second as secondary and so on. round-robin — Specifies that the first server will be used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

retry

Syntax	retry <i>count</i>
Context	config>app-assure>rad-acct-plcy>server
Description	This command configures the number of times the router attempts to contact the RADIUS server for authentication.

Note: The retry count includes the first attempt.

Default	3 (the initial attempt as well as two retried attempts)
Parameters	<i>count</i> — Specifies the retry count. Values 1 to 10

router

Syntax	router <i>router-instance</i> router service-name <i>service-name</i> no router
Context	config>app-assure>rad-acct-plcy>server
Description	This command specifies the number of times the router attempts to contact the RADIUS server for authentication, if not successful the first time. The no form of the command reverts to the default value.
Default	no router

server

Syntax	server <i>server-index</i> address <i>ip-address</i> secret <i>key</i> [hash hash2] [port <i>port</i>] [create]
---------------	--

	no server <i>server-index</i>
Context	config>app-assure>rad-acct-plcy>server
Description	<p>This command adds a RADIUS server and configures the RADIUS server IP address, index, and key values.</p> <p>Up to five RADIUS servers can be configured at any one time. RADIUS servers are accessed in order from lowest to highest index for authentication requests until a response from a server is received. A higher indexed server is only queried if no response is received from a lower indexed server (which implies that the server is not available). If a response from a server is received, no other RADIUS servers are queried.</p> <p>The no form of the command removes the server from the configuration.</p>
Default	no server
Parameters	<p><i>server-index</i> — The index for the RADIUS server. The index determines the sequence in which the servers are queried for authentication requests. Servers are queried in order from lowest to highest index.</p> <p>Values 1 to 16 (a maximum of 5 accounting servers)</p> <p><i>address ip-address</i> — The IP address of the RADIUS server. Two RADIUS servers cannot have the same IP address. An error message is generated if the server address is a duplicate.</p> <p>secret key — The secret key to access the RADIUS server. This secret key must match the password on the RADIUS server.</p> <p>Values secret-key — A string up to 20 characters in length. hash-key — A string up to 33 characters in length. hash2-key — A string up to 55 characters in length.</p> <p>hash — Specifies the key is entered in an encrypted form. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified</p> <p>hash2 — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the hash2 encrypted variable cannot be copied and pasted. If the hash or hash2 parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash or hash2 parameter specified.</p> <p><i>port</i> — Specifies the UDP port number on which to contact the RADIUS server for authentication.</p> <p>Values 1 to 65535</p>

source-address-range

Syntax	source-address-range <i>start-ip-address end-ip-address</i> no source-address
Context	config>app-assure>rad-acct-plcy>server
Description	This command configures the source address range of the RADIUS messages. The no form of the command reverts to the default value.
Default	systemIP address
Parameters	<i>start-ip-address</i> — Specifies the start of the range of source addresses to be used for NAT RADIUS accounting. <i>end-ip-address</i> — Specifies the end of the range of source addresses to be used for NAT RADIUS accounting.

timeout

Syntax	timeout <i>seconds</i>
Context	config>app-assure>rad-acct-plcy>server
Description	This command configures the number of seconds the router waits for a response from a RADIUS server. The no form of the command reverts to the default value.
Default	5
Parameters	<i>seconds</i> — Specifies the time the router waits for a response from a RADIUS server. Values 1 to 90

5.5.2.2 Show Commands

Note: Command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

ppp-policy

Syntax	ppp-policy [<i>ppp-policy-name</i> [<i>association</i>]]
Context	show>subscr-mgmt
Description	This command displays PPP policy information.
Parameters	<i>ppp-policy-name</i> — Specifies an existing PPP policy association — Displays the object the PPP policy is associated.
Output	

```
*A:ALA-49>show>subscr-mgmt# pppoe-policy policy1

pppoe

Syntax	pppoe
Context	show>service>id
Description	This command enables the context to display PPPoE information.

session

Syntax	session [interface <i>ip-int-name</i> <i>ip-address</i> sap <i>sap-id</i>] [session-id <i>session-id</i>] [mac <i>ieee-address</i>] [ip-address <i>ip-address[/mask]</i>] [port <i>port-id</i>] [no-inter-dest-id inter-dest-id <i>intermediate-destination-id</i>] [detail statistics] session <i>l2tp-connection-id connection-id</i> [detail statistics]
Context	show>service>id>pppoe
Description	This command displays PPPoE session information.
Parameters	interface <i>ip-int-name</i> — Displays the IP interface name. <i>ip-address</i> — Displays information about the IP address of the PPPoE session. sap <i>sap-id</i> — Displays information about the specified SAP ID. session-id <i>session-id</i> — Displays information about the ID of the PPPoE session. mac <i>ieee-address</i> — Displays information about the MAC address of the PPPoE session. port <i>port-id</i> — Displays information about the specified port ID. no-inter-dest-id — Displays the information about no intermediate destination ID. inter-dest-id <i>intermediate-destination-id</i> — Displays information about the specified intermediate destination ID. detail — Displays detailed information. statistics — Displays statistics about the PPPoE session.

Output

```
*A:ALA-49#show service id 20 pppoe session

summary

Syntax	summary
Context	show>service>id>pppoe
Description	This command displays PPPoE summary information

5.5.2.3 Clear Commands

pppoe

Syntax	pppoe
Context	clear>service>id
Description	This command enables the context to clear PPPoE-related data for the specified service.

session

Syntax	session all [no-padt] session {interface <i>ip-int-name</i> <i>ip-address</i> sap <i>sap-id</i>} [mac <i>ieee-address</i>] [session-id <i>session-id</i>] [ip-address <i>ip-address</i>[/<i>mask</i>]] [port <i>port-id</i>] [no-inter-dest-id inter-dest-id <i>intermediate-destination-id</i>] [no-padt]
Context	clear>service>id>ppoe
Description	This command clears PPPoE sessions.

statistics

Syntax	statistics [{sap <i>sap-id</i> interface <i>ip-int-name</i> <i>ip-address</i>}]
Context	clear>service>id>ppoe
Description	This command clears PPPoE statistics.

5.5.2.4 Debug Commands

ppp

Syntax	[no] ppp
Context	debug>service>id
Description	This command enables and configures PPP debugging.

event

Syntax	[no] event
Context	debug>service>id>ppp
Description	This command enables debugging for specific PPPoE events.

dhcp-client

Syntax	dhcp-client [terminate-only] no dhcp-client
Context	debug>service>id>ppp>event
Description	This command enables debugging for specific DHCP client events.

ppp

Syntax	ppp [terminate-only] no ppp
Context	debug>service>id>ppp>event
Description	This command enables debugging for specific PPP events.

mac

Syntax	[no] mac <i>ieee-address</i>
Context	debug>service>id>ppp
Description	This command shows PPP packets for a particular MAC address.

packet

Syntax	[no] packet
Context	debug>service>id>ppp
Description	This command enables debugging for specific PPPoE packets.

detail-level

Syntax	detail-level {low medium high} no detail-level
Context	debug>service>id>ppp>packet
Description	This command configures the PPP packet tracing detail level.

dhcp-client

Syntax	[no] dhcp-client
Context	debug>service>id>ppp>packet
Description	This command enables debugging for specific DHCP client packets.

discovery

Syntax	discovery [padi] [pado] [padr] [pads] [padt] no discovery
Context	debug>service>id>ppp>packet
Description	This command enables debugging for specific PPP discovery packets.

mode

Syntax	mode {dropped-only ingr-and-dropped egr-ingr-and-dropped} no mode
Context	debug>service>id>ppp>packet
Description	This command configures the PPP packet tracing mode.

ppp

Syntax	ppp [lcp] [pap] [chap] [ipcp] no ppp
Context	debug>service>id>ppp>packet
Description	This command enables debugging for specific PPP packets

sap

Syntax	[no] sap <i>sap-id</i>
Context	debug>service>id>ppp
Description	This command displays PPP packets for a particular SAP.

6 L2TP

6.1 In This Chapter

This chapter provides information about using L2TP, including theory, supported features and configuration process overview.

Note: The information in this section applies only to the 7750 SR.

Topics in this chapter include:

- [L2TP](#)
 - [Terminology](#)
 - [CDN Result Code Overwrite](#)
- [L2TP LAC VPRN](#)
 - [Per-ISP Egress L2TP DSCP Reclassification](#)
- [L2TP Tunnel RADIUS Accounting](#)
 - [Accounting Packets List](#)
- [RADIUS Attributes Value Considerations](#)
 - [Other Optional RADIUS Attributes](#)
 - [RADIUS VSA to Enable L2TP Tunnel Accounting](#)
 - [MLPPP on the LNS Side](#)

6.2 L2TP

6.2.1 Terminology

- **Tunnel spec** — Describes the requirements for a tunnel and is defined as a set of parameters that will be used in tunnel setup/selection process. The tunnel-spec is defined in the CLI or can be supplied through RADIUS.

- Tunnel (instance) — A run-time object with a unique id terminating at a specific peer. Any change in the tunnel spec once the tunnel has been created has no bearings on the tunnel itself. The list of tunnels can be obtained using the **show router l2tp tunnel** command.
- Peer — A run-time object that is defined by a *ip-address/port* combination. Multiple tunnels can be terminated on the same peer. The list of peers can be obtained using the **show router l2tp peer** command.

6.2.2 LAC DF Bit

The LAC DF bit is configurable, but by default, it sends all L2TP packets with the DF bit set to 1. Clearing the DF bit will allow downstream routers to fragment the L2TP packets. The LAC itself will not fragment L2TP packets. L2TP packets that have a larger MTU size than what the LAC egress ports allows are dropped. The DF bit can also be configured via RADIUS attribute **Alc-Tunnel-DF-bit**.

6.2.3 Handling L2TP Tunnel/Session Initialization Failures

6.2.3.1 L2TP Tunnel/Session Initialization Failover Mechanisms on LAC

In deployment scenarios with multiple LNS nodes, a list of those LNS nodes can be presented to the LAC during the L2TP session instantiation process (either through CLI or RADIUS). An example of this would be a RADIUS Accept message with a list of tunnel peers:

```
tunnel.com Auth-Type := Local, Password == "tunnel1"
Tunnel-Type:1 += L2TP,
    Tunnel-Medium-Type:1 += IP,
    Tunnel-Client-Auth-Id:1 += lns_tun,
    Tunnel-Assignment-Id:1 += 1,
    Tunnel-Client-Endpoint:1 += 10.0.0.1,
    Tunnel-Server-Endpoint:1 += 10.0.0.2,
    Tunnel-Password:1 += TUNNELPASS,

    Tunnel-Type:2 += L2TP,
    Tunnel-Medium-Type:2 += IP,
    Tunnel-Client-Auth-Id:2 += lns_tun,
    Tunnel-Assignment-Id:2 += 2,
    Tunnel-Client-Endpoint:2 += 10.0.0.1,
    Tunnel-Server-Endpoint:2 += 10.0.0.3,
    Tunnel-Password:2 += TUNNELPASS,

    Tunnel-Type:3 += L2TP,
    Tunnel-Medium-Type:3 += IP,
    Tunnel-Client-Auth-Id:3 += lns_tun,
    Tunnel-Assignment-Id:3 += 3,
    Tunnel-Client-Endpoint:3 += 10.0.0.1,
    Tunnel-Server-Endpoint:3 += 10.0.0.4,
    Tunnel-Password:3 += TUNNELPASS,
    Tunnel-Type:4 += L2TP,

    Tunnel-Medium-Type:4 += IP,
    Tunnel-Client-Auth-Id:4 += lns_tun,
    Tunnel-Assignment-Id:4 += 4,
    Tunnel-Client-Endpoint:4 += 10.0.0.1,
    Tunnel-Server-Endpoint:4 += 10.0.0.5,
    Tunnel-Password:4 += TUNNELPASS
```

In case that the tunnel or the session establishment attempt fails for any reason, a search for additional operational facilities (tunnels or peers) will be made in order to complete the establishment of the tunnel/session that failed in the previous attempt. Moreover, sometimes it is required to go beyond this automatic search for the new facilities and place the tunnel/peer in question into a blacklist. A tunnel timeout will always force the corresponding peer and the tunnel into the blacklist. In addition, a tunnel can be forced into the blacklist by certain explicit error codes (CDN, and Stop-CCN) during the tunnel/session initialization phase. A peer is never forced on a blacklist as a consequence of explicit Result-Code sent by LNS.

Blacklisted peers and tunnels are not eligible to serve new incoming L2TP session until they are removed from the blacklist. The exception case is when all tunnel specs evaluate into a blacklisted item. In this case a blacklisted item (tunnel) will be tried.

6.2.3.2 Peer Blacklist

A peer is always placed into the blacklist if:

- An attempt to establish a new tunnel fails due to a time out (SCCRQ and SCCN timeouts)
- The timeout occurs on any control packet within an already established tunnel. All sessions on such tunnel are terminated (PADT is sent toward the clients, StopCCN is sent toward the LNS). Other tunnels that are terminated on the same peer will timeout on their own (if the peer is indeed non-operational), for example, the 7750 SR will not explicitly tear them down based on the timeout of a single tunnel. The timeout of an existing tunnel is caused by lack of acknowledgments to transmitted control packets (ICRQ, ICCN, CDN, Hello).

A tunnel timeout will occur if an acknowledgment is not received after max-retries-established (on an established tunnel) or max-retries-not-established (for the tunnel in the process of being established) retries.

Although there is no configuration option that would control whether a peer can or cannot be blacklisted (it is always blacklisted on tunnel timeout), the amount of time that a peer remains in the blacklist is configurable within the **tunnel-selection-blacklist** CLI node.

6.2.3.3 Tunnel Blacklists

A tunnel spec (that evaluates into a tunnel) is temporary unusable in case that corresponding peer or the tunnel is blacklisted. The following events will trigger placement of the tunnel into the blacklist:

1. Explicit termination of the L2TP session that is in the process of being established within this tunnel. The following CDN Result Codes will place a tunnel to a blacklist (text in red are CLI keywords that will enable specific Result Codes as triggers and [rx,tx] is direction of the messages from the LAC perspective):
 - 02 DisconnectedSeeErrorCode, rx (cdn-err-code)
 - 04 TempMissingFacilities, rx (cdn-tmp-no-facilities)
Transmit CDN when no session can be allocated
Audit not yet complete
 - 05 PermanentMissingFacilities, rx (cdn-perm-no-facilities)
No result code available
 - 06 InvalidDestination, rx(cdn-inv-dest)
Tunnel is not usable (for example lns-group is not configure on LNS)
 - 10 NotEstablishedInAllotedTime, tx(tx-cdn-not-established-in-time)

2. Explicit termination of the L2TP tunnel in the process of establishment via Stop-CCN Result-Codes:

- (1) General request to clear control connection, rx (stop-ccn-other)
- (2) General error, rx (stop-ccn-err-code)
- (4) Requester is not authorized to establish a control channel, rx, tx (stop-ccn-other)
- (5) Protocol version not supported, rx, tx(stop-ccn-other)
- (6) Requester is being shutdown, rx (stop-ccn-other)

Error messages identified by the received Result-Codes can be interpreted as the inability of the LNS to accept additional L2TP sessions within the tunnel (for example due to resource depletion) or to accept additional new tunnels.

The following statements further describe behavior related to the placement of tunnels into the blacklist:

- A new L2TP session establishment attempt will not be triggered on the tunnel that is in the blacklist. Instead, another tunnel will be searched according to the configured preference model.
- The tunnel/session initialization failure will always trigger the selection mechanism for another tunnel. However, it is possible to control via configuration whether to blacklist or not the tunnel for which the L2TP initialization process failed due to certain Result Codes in CDN and/or Stop CCN messages.
- Once the L2TP tunnel/session is established, no events other than the timeout can force the tunnel (and the peer) into the blacklist. In other words, a tunnel Stop or Call disconnect message for a stable tunnel/session will not force the tunnel into the blacklist.
- Existing sessions within the L2TP tunnel will not be purposefully terminated in case that the tunnel is forced into the blacklist due to an explicit reply from LNS indicating the tunnel/session initialization failure. In other words, although the L2TP tunnel might be blacklisted and therefore prevented from serving new L2TP sessions, the existing L2TP session over this tunnel will not be affected.
- A peer will NOT be forced into the blacklist in case of the explicit failure response from that particular peer. Only tunnels will be blacklisted in that case, assuming that the configuration trigger is enabled. Peers are blacklisted only based on timeouts and not explicit responses.

In case that the end-point is not in the routing table (unreachable via routing), the end-point is marked as permanently unavailable (removed from the L2TP process). Such end-point will never be blacklisted.

6.2.3.3.1 Tunnel Timeout Due to the Peer IP Address Change

In case that the peer address is changed mid-session (for example, from configured IP@ 1.1.1.1 to the new IP@ 2.2.2.2), and then subsequently the tunnel times-out, the new peer 2.2.2.2 would be placed in the blacklist by default. The tunnel itself would not be placed in the blacklist since it is originally tied to a different peer address that it is not in the blacklist. As such it would be eligible for selection the next time a new session request for it arrives. To block selection of this failed tunnel, we can optionally (by configuration) force it into the blacklist.

This behavior can be enabled with the following CLI:

```
configure router l2tp
configure service vprn <id> l2tp
  tunnel-selection-blacklist
    add-tunnel on <reason> [<reason>... (upto 7 max)]
<reason> : cdn-err-code|cdn-inv-dest|cdn-tmp-no-facilities|cdn-perm-no-
facilities|tx-cdn-not-established-in-time|stop-ccn-err-code|stop-ccn-other|addr-
change-timeout
```

6.2.3.4 Tunnel Selection Mechanism

Once the L2TP tunnel failover is triggered (timeout or specific L2TP session/tunnel setup error message), a new tunnel spec in the list of available tunnel specs will be selected. This tunnel selection mechanism can be controlled via CLI so that the new tunnel-spec is selected from the next preference level. Alternatively the tunnel selection mechanism can be set to a mode where once all the possibilities within the same preference are exhausted, tunnel specs on a higher preference level will be tried.

```
configure router l2tp
configure service vprn <id> l2tp
  next-attempt same-preference-level | next-preference-level
```

In case that ALL tunnels on a given preference levels are blacklisted, then the behavior will depend on the configuration option as per the following:

- next-attempt = next-preference - only one tunnel spec from the current preference level will be tried before switching to the next preference level.
- next-attempt = same-preference – all tunnel specs will be tried before switching to the next preference level.

6.2.3.5 Tunnel Probing

Tunnel probing refers to the mechanism where the blacklisted tunnel or an end-point can be selected to serve only a single L2TP session initialization request. Only in case that this single L2TP session is successfully established over the selected tunnel, the tunnel can be removed from the blacklist and consequently can serve new L2TP sessions. The tunnel is eligible for probing once its preconfigured time in the blacklist has expired.

This behavior will ensure that the new session initialization requests are not buffered while waiting for the tunnel to transition into operational state. Buffering would incur session setup delay and in the worst case it would cause session timeout in case that the L2TP tunnel cannot be established.

Without tunnel probing enabled, tunnels will be automatically removed from the blacklist upon the expiry of the preconfigured timer. New consecutive L2TP session initialization requests for such tunnels will always be buffered.

6.2.3.6 Controlling the Size of Blacklist

The size of the blacklist and the time that an item remains ineligible for selection within the blacklist, is configurable.

```
configure router l2tp
configure service vprn <id> l2tp tunnel-selection-blacklist
    max-time 1..60 (minutes)
    max-list-length unlimited | 1..65535
```

6.2.3.7 Displaying the Content of a Blacklist

The content of a blacklist along with the remaining time that each entity is confined to the blacklist can be displayed with the following command:

```
show router <id> l2tp peer blacklisted|not-blacklisted|selectable
```

Example:

```
show router l2tp peer 10.100.0.2
=====

6.2.3.8 Generating Trap when the Blacklist is Full

A log is generated when the blacklist reaches its max limit of items. The log event is `tmnxL2tpTunnelSelectionBlacklistFull`.

6.2.3.9 Premature Removal of Blacklisted Entries

In case that the total number of supported tunnels and peers in blacklist and in the LAC in general has reached its maximum, then on the new session initialization request, the oldest tunnel entry in the blacklist will be removed from the blacklist irrespective of whether their blacklist max-time has expired or not.

6.2.3.10 Manual Purging of Entities within the Blacklist

The items can be manually purged from the blacklist using the following commands.

```
clear router <id> l2tp tunnel-selection-blacklist
clear router <id> l2tp peer <ip-address> [udp-port <port>] tunnel-selection-
blacklist
clear router <id> l2tp group <tunnel-group-name> [tunnel <tunnel-name>] tunnel-
selection-blacklist
clear router <id> l2tp tunnel <connection-id> tunnel-selection-blacklist
```

6.2.4 CDN Result Code Overwrite

When the number of L2TP sessions reaches the configured maximum value, the LNS sends an out-of-resource Result Code (4 or 5) in a CDN (Call-Disconnect-Notify) message to the LAC. This would trigger the LAC to fail over to another LNS that has the resources available. Similarly, when the tunnel is not usable due to the invalid destination CDN error, the Result-Code 6 will be sent from the LNS.

Certain third-party LAC implementations will trigger tunnel failover only when they receive Result Code 2 in CDN messages (and not 4,5 or 6). In order to support those scenarios, the LNS in the 7750 SR can overwrite result codes 4, 5 and 6 with result code 2 just before they are sent to the LAC. Result Codes can be overwritten only during the L2TP session initialization phase. These codes have the following meanings and are described in RFC 2661, 4.4.2:

- 2 — Call disconnected for the reason indicated in error code
- 4 — Call failed due to lack of appropriate facilities being available (temporary condition)
- 5 — Call failed due to lack of appropriate facilities being available (permanent condition)
- 6 — Invalid Destination

This functionality will be enabled on LNS via the following CLI hierarchy:

```
configure router l2tp
configure service vprn <id> l2tp
  replace-result-code {cdn-tmp-no-facilities | cdn-prem-no-facilities | cdn-inv-
dest}
  no replace-result-code
```

6.2.5 LNS Proxy

LNS offers a proxy LCP (via the **proxy-lcp** command) function where LCP-related information is cached temporarily in the LNS during the ICCN phase where L2TP control messages are exchanged between the LAC and LNS. The LNS can then use the cached information to bypass the LCP negotiation and immediately start the authentication state with the client. Furthermore, proxy authentication (via the **proxy-authentication** command) can also be enabled on the LNS to bypass authentication and the client can immediately start the IPCP negotiation phase.

If the proxy LCP information conflicts from the LNS configuration, then the LNS will force the client to re-start LCP negotiation. LCP negotiation will not be restarted in the proxy LCP mode when:

- MRU is missing in the LastTxLcpConfReq AVP
- The magic number is missing in LastTxLcpConfReq AVP
- Async-Control-Character-Map (ACCM) with value = 0x00000000 is present in LastTxLcpConfReq and LastRxLcpConfReq AVP's
- Address-and-Control-Field-Compression (ACFC) is present in LastTxLcpConfReq and LastRxLcpConfReq. Note that PPP frames with and without address and control field (0xFF03) in the PPP header are accepted. LCP frames without 0xFF03 are also accepted as valid frames.

Also similarly, proxy-authentication that fails will then force the client to re-start the LCP negotiation again.

6.3 L2TP LAC VPRN

Layer 2 Tunneling Protocol (L2TP) allows for PPP sessions to be carried over an IP network.

Each L2TP session transports PPP frames, irrespective of link-layer encapsulation, allows the LNS to terminate PPP sessions that were either PPPoE or PPPoA. L2TP is carried over IPv4 packets in UDP datagrams (default port 1701).

If session data is not reliably delivered, that is, if there is a packet loss, there is no retransmission, a sequence numbers is used within each L2TP session to identify packet loss and re-ordering.

L2TP is comprised of the following concepts:

- L2TP tunnels- L2TP tunnel is a connection between one LAC (L2TP Access Concentrator) and one LNS (L2TP Network Serve) that share a common control channel.
- L2TP sessions -Within each L2TP tunnel, there exists one or more L2TP sessions (one PPP session corresponds to exactly one L2TP session)

L2TP tunnels provide an IP transport for PPP frames between LAC and LNS. In some existing networks, BGP/MPLS VPNs (VPRN in SR-OS) are used to contain the L2TP traffic (and the routes associated with the LAC and LNS) into a dedicated routing instance.

Similar to the LNS implementation, L2TP LAC in a VPRN allows L2TP control and data traffic to be sourced from and received by any valid IP interface within the VPRN (including loopback and interface addresses). L2TP frames may ingress a network port (with up to five MPLS tags) or access ports with SAPs associated with the VPRN IP interfaces.

Non-hitless multi-chassis LAC resiliency

In dual-homed PPPoEv4/v6 wholesale/retail environment over L2TP, the subscriber-hosts are synchronized via Multi-Chassis Synchronization (MCS) protocol. The failover detection mechanism might be implemented via SRRP or Layer 3 MC-LAG with SRRP. When an interface or an entire node fails, the newly selected Master sends PADT to all sessions that were moved over from the failed node.

In case of interface-only failure, CDN is sent towards the LNS to terminate sessions on the LNS.

The PPPoE sessions will be reestablished on the newly selected Master, but because PADT was sent to clients the recovery time is faster (no need to wait for PPPoE session timeout). On the network side (towards the LNS) an existing tunnel towards the LNS can be used to re-establish the sessions or in case that none exists, a new tunnel will be established. There is no need for redundant interface in this case.

Note: The L2TP tunnel carrying the sessions must always be terminated on the Master LAC.

In case of nodal failure, the sessions within the old tunnel on the LAC will time out (CDN cannot be sent from the new Master since there is no tunnel state preserved across redundant LAC nodes). During the time-out period, the LNS will have to maintain double the amount of failed sessions (stale ones plus the new ones). This model is shown in [Figure 43](#).

Figure 43 Non-Hitless Interface/Node Protection on the LAC

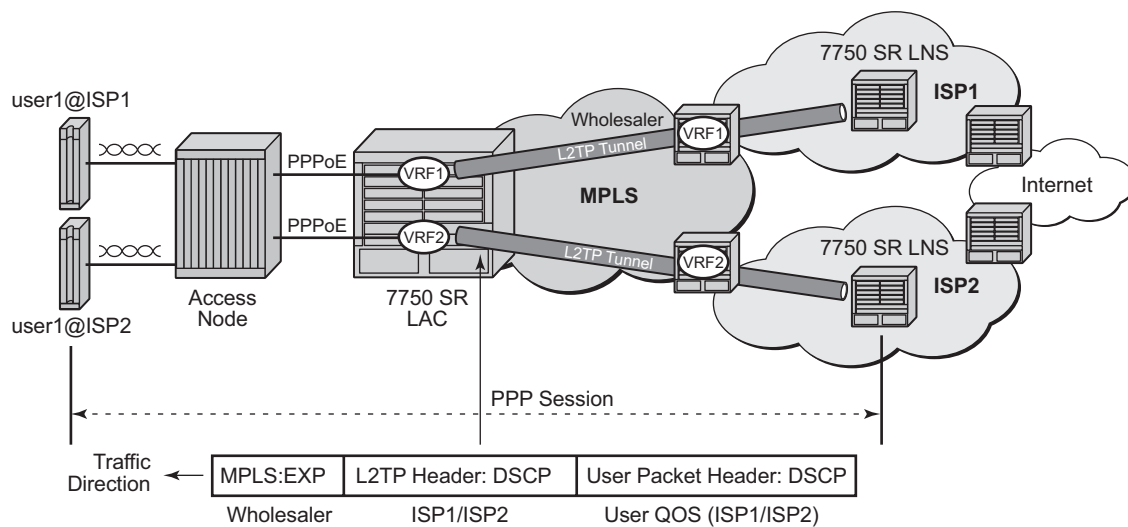

al_0020

6.3.1 Per-ISP Egress L2TP DSCP Reclassification

Wholesale providers can deliver Internet access to directly connected PPP users through third party ISPs. This involves the users connecting to an L2TP Access Concentrator (LAC) with their traffic being tunneled to and from an L2TP Network Server (LNS) in their ISP.

If there is a requirement to support per-ISP (and per-subscriber host) QoS control for downstream traffic on the LAC towards the users based on the DSCP marking in the L2TP header, the command **use-ingress-l2tp-dscp** must be configured within the sla-profile selected for the users.

Figure 44 ISP Internet Access through Wholesale Provider

al_0121

An example topology is shown in Figure 44 in which the downstream traffic arrives at the LAC with:

- An MPLS header (because of the VRF encapsulation). This contains EXP bits which are set based on the wholesale provider's QoS scheme.
- An L2TP header (because of the L2TP tunnel to the ISP). This contains DSCP bits in its IP header which are set by the originating ISP.
- A user IP packet header. This contains DSCP bits which could be set by the ISP or by the originating Internet application.

The network ingress on the LAC would normally use the MPLS EXP bits for traffic QoS classification, however, this matches the wholesale provider's QoS scheme.

It would be possible to apply the **ler-use-dscp** parameter at the LAC network ingress to classify based on the L2TP header DSCP, but this would require the QoS schemes used by all ISPs, and the wholesale provider, to have a consistent interpretation of the DSCP bits.

If the standard egress IP reclassification is used, the QoS would be dependent on the DSCP in the user packet.

Configuring the parameter **use-ingress-l2tp-dscp** in the sla-profile of the ISP1 and ISP2 users will force the egress QoS control to be based on the DSCP from the L2TP header received on the LAC (which is set by ISP1/ISP2). This provides per-ISP (and per-subscriber host) QoS control for downstream traffic on the LAC towards the users.

6.4 L2TP Tunnel RADIUS Accounting

Figure 45 L2TP Tunnel Accounting

When L2TP tunnel accounting is enabled, except for **host** or **sla-profile**-based accounting packets and attributes, the following are additional accounting packets and attributes:

- Accounting packets: tunnel-start/stop/reject; tunnel-link-start/stop/reject — There are no interim updates for L2TP tunnel/session accounting.
- RADIUS accounting attributes:
 - Tunnel-Assignment-Id (LAC only)
 - Acct-Tunnel-Connection
 - Acct-Tunnel-Packets-Lost

These attributes were added into current account-start/stop/interim-update packets (host accounting/sla-profile accounting)

Tunnel level accounting and session level accounting can be enabled or disabled independently.

New accounting packets and related RADIUS attribute list are described in [Table 47](#).

Some considerations of RADIUS attributes are described in [RADIUS Attributes Value Considerations](#).

6.4.1 Accounting Packets List

[Table 47](#) describes L2TP tunnel accounting behavior along with some key RADIUS attributes (apply for both LAC and LNS):

Table 47 L2TP Tunnel Accounting Behavior

Act-Packet	When	Key Attributes	Remark
Tunnel-Start	A new L2TP tunnel is created	Acct-Session-ID	—
		Event-Timestamp	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Tunnel-Server-Auth-Id:0	—

Table 47 L2TP Tunnel Accounting Behavior (Continued)

Act-Packet	When	Key Attributes	Remark
Tunnel-Reject	A new L2TP tunnel creation failed	Acct-Session-Id	—
		Event-Timestamp	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Acct-Terminate-Cause	—
Tunnel-Stop	An established L2TP tunnel is removed	Acct-Session-Id	—
		Event-Timestamp	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Tunnel-Server-Auth-Id:0	—
		Acct-Session-Time	—
		Acct-Input-Gigawords	—
		Acct-Input-Octets	—
		Acct-Output-Gigawords	—
		Acct-Output-Octets	—
		Acct-Input-Packets	—
		Acct-Output-Packets	—
		Acct-Terminate-Cause	—

Table 47 L2TP Tunnel Accounting Behavior (Continued)

Act-Packet	When	Key Attributes	Remark
Tunnel-Link-Start	An L2TP session is created	User-Name	—
		Acct-Session-Id	This is the same as Acct-Session-id in access-request of host auth
		Event-Timestamp	—
		Service-Type	Framed
		Class	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Tunnel-Server-Auth-Id:0	—
		Acct-Tunnel-Connection	See RADIUS Attributes Value Considerations
Tunnel-Link-Reject	A new L2TP session creation is failed	Acct-Session-Id	Should be as same as Acct-Session-id in access-request of host auth
		Event-Timestamp	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Acct-Terminate-Cause	—
		Acct-Tunnel-Connection	—

Table 47 L2TP Tunnel Accounting Behavior (Continued)

Act-Packet	When	Key Attributes	Remark
Tunnel-Link-Stop	A established L2TP session is removed	User-Name	—
		Acct-Session-Id	Should be as same as Acct-Session-id in access-request of host auth
		Event-Timestamp	—
		Service-Type	Framed
		Class	—
		Tunnel-Type:0	—
		Tunnel-Medium-Type:0	—
		Tunnel-Assignment-Id:0	—
		Tunnel-Client-Endpoint:0	—
		Tunnel-Client-Auth-Id:0	—
		Tunnel-Server-Endpoint:0	—
		Tunnel-Server-Auth-Id:0	—
		Acct-Tunnel-Connection	—
		Acct-Session-Time	—
		Acct-Input-Gigawords	—
		Acct-Input-Octets	—
		Acct-Output-Gigawords	—
		Acct-Output-Octets	—
		Acct-Input-Packets	—
		Acct-Output-Packets	—
		Acct-Tunnel-Packets-Lost	—
		Acct-Terminate-Cause	—

Notes:

- Errors will occur if there are multiple hosts sharing the same sla-profile instance and then these hosts go to different tunnel.

- 7750 SRs have an internal limitation of 500 pps for accounting messages. This feature shares the same limitation

6.5 RADIUS Attributes Value Considerations

- The value of Acct-Tunnel-Connection uniquely identify a L2TP session, and in order to match LAC and LNS accounting record, the value of Acct-Tunnel-Connection is determined by a method shared by LAC and LNS. This means for a given L2TP session, Acct-Tunnel-Connection from the LAC and LNS are the same.
- Current ESM stats are used in Tunnel-Link and tunnel level accounting. This applies for both standard attribute and the 7750 SR's own VSA.
- Tunnel level accounting stats need to aggregate all sessions stats that belong to the tunnel.

Note: There could be sessions come and go before tunnel is down, so system need to remember the stats of every session that has been created within the tunnel.

This applies for both standard attribute and 7750 SR's own VSA.

- The value of Acct-Tunnel-Packets-Lost is the aggregation of all discarded packets on both ingress and egress.

6.5.1 Other Optional RADIUS Attributes

Table 48 lists the optional attributes that could be optionally included in tunnel accounting packet, some of them are applied for link level accounting only.

Table 48 Optional RADIUS Attributes

Attribute	Tunnel/Link
nas-identifier	Both
nas-port	Link level only
nas-port-id	Link level only
nas-port-type	Link level only

6.5.2 RADIUS VSA to Enable L2TP Tunnel Accounting

In order to support pure RADIUS-enabled L2TP tunnel accounting on LAC side, the following RADIUS VSA are supported:

Table 49 Supported RADIUS VSAs

VSA	Type	Value
ALC-Tunnel-Accounting-Policy	String	Policy-name; if the name is disable then this means L2TP tunnel accounting is disabled for this tunnel

Note: ALC-Tunnel-Accounting-Policy takes precedence over what has been defined in CLI when Alc-Tunnel-Group is also returned.

6.5.3 MLPPP on the LNS Side

With MLPPP, the counter on LNS side is only available for the bundle, not for each link, so the SR OS's behavior is:

- For each new link session system sends a tunnel-link-start.
- For each link session that is deleted system sends a tunnel-link-stop.
- For all link sessions except the last one system reports 0 for all counters.
- For the last link session, system reports the actual counters for the bundle.

6.5.4 LNS Reassembly

LNS reassembly is supported in the BB-ISA. Fragments are collected and reassembled. Once the entire L2TP packet is reassembled, the packet will either be de-capsulated or sent to the CPM as is.

The delivery of the L2TP packets to the BB-ISA depends on the certain fields in the L2TP header. The forwarding decision on the ingress LNS side in the upstream direction (LAC->LNS) is based on the tunnel-id/session-id combination and the T-bit (message type bit – control or data) in L2TP header.

Control type messages are delivered directly to the CPM. CPM performs L2TP de-capsulation and processes the message (tunnel or session setup/teardown related messages or tunnel hellos). The CPM provides forwarding information to the forwarding plane (ingress/egress IOM and the carrier IOM) and to the BB-ISA (tunnel-src + tunnel-id/session-id + generated-mac-addr and SAP).

Data type messages are delivered directly to the BB-ISA. The BB-ISA de-capsulates the L2TP packets and forwards them to the carrier IOM as a quasi-PPPoE frame (ESM forwarding module).

Since the LAC fragments the packets in the upstream direction, the L2TP header is preserved only in the first fragment. Therefore, the crucial forwarding information needed by LNS is lost in all consecutive fragments. If a fragment ends up in the wrong BB-ISA with no reassembly context for the fragment, the fragment will be dropped.

Similarly, the information whether to forward the fragment to the BB-ISA (data packet) or the CPM (control packet) is lost.

In order to support LSN reassemble, the following configuration limitations are imposed:

- Only one pair of active/standby BB-ISAs are supported. This way all fragments will be forwarded to the same active BB-ISA that maintains all reassembly contexts for all fragments.
- All fragments, regardless of the packet type, are forwarded to the active BB-ISA. Once the L2TP packet is reassembled, it will be determined whether the packet is:
 - A data packet — The packet will be de-capsulated and a quasi PPPoE packet will be forwarded to the carrier IOM (ESM function).
 - A control packet — The packet will not be de-capsulated but instead it will be forwarded as L2TP packet to the CPM.

The **Ins-reassembly** commands that inform the ingress forwarding plane that all L2TP packets should be sent to the BB-ISA are configured in the **config>router>l2tp** and **config>service>vprn>l2tp** contexts.

6.6.2 Command Descriptions

6.6.2.1 L2TP Configuration Commands

6.6.2.1.1 Global Commands

description

Syntax	description <i>description-string</i> no description
Context	config>aaa>l2tp-acct-plcy
Description	<p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The description command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The no form of this command removes the string from the configuration.</p>
Default	No description associated with the configuration context.
Parameters	<i>description-string</i> — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

shutdown

Syntax	[no] shutdown
Context	config>aaa>l2tp-acct-plcy
Description	<p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.</p> <p>The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.</p> <p>The no form of this command places the entity into an administratively enabled state.</p>

6.6.2.1.2 L2TP Tunnel Account Commands

next-attempt

Syntax	next-attempt { same-preference-level next-preference-level } no next-attempt
Context	config>router>l2tp config>service>vprn>l2tp
Description	This command enables tunnel selection algorithm based on the tunnel preference level.
Parameters	<p>same-preference-level — In case that the tunnel-spec selection algorithm evaluates into a tunnel that is currently unavailable (for example tunnel in a blacklist) then the next elected tunnel, if available, it will be chosen within the same preference-level as the last attempted tunnel. Only when all tunnels within the same preference level are exhausted, the tunnel selection algorithm will move to the next preference level.</p> <p>In case that a new session setup request is received while all tunnels on the same preference level are blacklisted, the L2TP session will try to be established on blacklisted tunnels before the tunnel selection moves to the next preference level.</p> <p>next-preference-level — In case that the tunnel-spec selection algorithm evaluates into a tunnel that is currently unavailable (for example tunnel in a blacklist) then the selection algorithm will try to select the tunnel from the next preference level, even though the tunnels on the same preference level might be available for selection.</p> <p>Default next-preference-level</p>

replace-result-code

Syntax	replace-result-code <i>code</i> [code...(up to 3 max)] no replace-result-code
Context	config>router>l2tp config>service>vprn>l2tp
Description	This command will replace CDN Result-Code 4, 5 and 6 on LNS with the Result Code 2. This is needed for interoperability with some implementation of LAC which only take action based on CDN Result-Code 2, while ignore CDN Result-Code 4, 5 and 6.
Default	no replace-result-code
Parameters	<p><i>code</i> — Specifies the L2TP Result codes that need to be replaced.</p> <p>Values</p> <p>cdn-tmp-no-facilities — CDN Result-Code 4 on LNS will be replaced with the result code 2 before it is sent to LAC.</p> <p>cdn-prem-no-facilities — CDN Result-Code 5 on LNS will be replaced with the result code 2 before it is sent to LAC.</p>

cdn-inv-dest — CDN Result-Code 6 on LNS will be replaced with the result code 2 before it is sent to LAC.

df-bit-lac

Syntax	df-bit-lac {always never} no df-bit-lac
Context	config>router>l2tp config>service>vpn>l2tp
Description	By default, the LAC df-bit-lac is always set and sends all L2TP packets with the DF bit set to 1. The DF bit is configurable to allow downstream routers to fragment the L2TP packets. The LAC itself will not fragment L2TP packets. L2TP packets that have a larger MTU size than what the LAC egress ports allows are dropped.
Default	df-bit-lac always
Parameters	always — Specifies that the LAC will send all L2TP packets with the DF bit set to 1. never — Specifies that the LAC will send all L2TP packets with the DF bit set to 0.

df-bit-lac

Syntax	df-bit-lac {always never default} no df-bit-lac
Context	config>router/service>vpn>l2tp>group config>router/service>vpn>l2tp>group>tunnel
Description	By default, the LAC df-bit-lac is set to default and sends all L2TP packets with the DF bit set to 1. The DF bit is configurable to allow downstream routers to fragment the L2TP packets. The LAC itself will not fragment L2TP packets. L2TP packets that have a larger MTU size than what the LAC egress ports allows are dropped. The configuration of the df-bit can be overridden at different levels: l2tp, tunnel, and group. The configuration at the tunnel level overrides the configuration on both the group and l2tp levels. The configuration at the group level overrides the configuration on l2tp.
Default	df-bit-lac default
Parameters	always — Specifies that the LAC will send all L2TP packets with the DF bit set to 1. never — Specifies that the LAC will send all L2TP packets with the DF bit set to 0. default — Follows the DF-bit configuration specified on upper levels.

ignore-avps

Syntax	ignore-avps [sequencing-required] no ignore-avps
Context	config>router>l2tp config>service>vprn>l2tp
Description	This command specifies the L2TP AVPs that should be ignored in L2TP session control.
Default	no ignore-avps
Parameters	sequencing-required — Ignores the [39] Sequencing Required AVP on LNS when present in the L2TP ICCN message received from LAC. By default, the session at LNS would be disconnected, in this case with the Call Disconnect Notify (CDN) error code unknownMandatoryReceive(8). Note that when configured, to ignore the Sequencing Required AVP there will be no Sequence Numbers inserted into the data channel.

group

Syntax	group tunnel-group-name [create] no group tunnel-group-name
Context	config>router>l2tp config>service>vprn>l2tp
Description	This command configures an L2TP tunnel group.
Parameters	<i>tunnel-group-name</i> — Specifies a name string to identify a L2TP group up to 63 characters in length. create — This keyword is mandatory when creating a tunnel group name. The create keyword requirement can be enabled/disabled in the environment>create context.

tunnel

Syntax	tunnel tunnel-name [create] no tunnel tunnel-name
Context	config>router>l2tp>group config>service>vprn>l2tp>group
Description	This command configures an L2TP tunnel. A tunnel exists between a LAC-LNS pair and consists of a Control Connection and zero or more L2TP sessions. The tunnel carries encapsulated PPP datagrams and control messages between the LAC and the L2TP Network Server (LNS).
Parameters	<i>tunnel-name</i> — Specifies a valid string to identify a L2TP up to 32 characters in length.

create — mandatory while creating a new tunnel

tunnel-selection-blacklist

Syntax	tunnel-selection-blacklist
Context	config>router>l2tp
Description	This command enables the context to configure L2TP Tunnel Selection Blacklist parameters.

add-tunnel

Syntax	add-tunnel never add-tunnel on <i>reason</i> [<i>reason...</i> (up to 8 max)] no add-tunnel
Context	config>router>l2tp>tunnel-selection-blacklist config>service>vprn>l2tp>tunnel-selection-blacklist
Description	This command will force the tunnel to the blacklist and render it unavailable for new sessions for the duration of pre-configured time. Peers are always forced to the black list in case that they time out (failure to receive response to control packets). In addition to time outs, certain events can be used to trigger placement of the tunnel on the black list.
Parameters	<i>reason</i> — Specifies the return codes or events that determine which tunnels are added to the blacklist Values cdn-err-code — A tunnel will be forced to the blacklist in case that CDN message with the Result Code 2 (Call disconnected for the reasons indicated in error code) is received. cdn-inv-dest — A tunnel will be forced to the blacklist in case that CDN message with the Result Codes 6 (Invalid destination) is received. cdn-tmp-no-facilities — A tunnel will be forced to the blacklist in case that CDN message with the Result Code 4 is received (Call failed due to lack of appropriate facilities being available - temporary condition) is received. cdn-perm-no-facilities — A tunnel will be forced to the blacklist in case that CDN message with the Result Codes 5 (Call failed due to lack of appropriate facilities being available - permanent condition) is received. tx-cdn-not-established-in-time — A tunnel will be forced to the blacklist in case that CDN message with the Result Code 10 (Call was not established within time allotted by LAC) is sent from the LAC to the LNS.

stop-ccn-err-code — A tunnel will be forced to the blacklist in case that StopCCN message with the Result Code 2 (General error – Error Code indicates the problem) is sent or received.

stop-ccn-other — A tunnel will be forced to the blacklist in case that StopCCN message with the following Result Codes is received:

- (1) General request to clear control connection
- (4) Requestor is not authorized to establish a control channel
- (5) Protocol version not supported
- (6) Requestor is being shutdown

Or in the case that the StopCCN with the following result codes is transmitted:

- (4) Requestor is not authorized to establish a control channel.
- (5) Protocol version not supported

The receipt of the following Result Codes will NEVER blacklist a tunnel:

- (0) Reserved
- (3) Control channel already exist
- (7) Finite state machine error
- (8) Undefined

Transmission of the following Result Codes will NEVER blacklist a tunnel:

- (1) General request to clear control connection
- (3) Control channel already exist
- (6) Requestor is being shutdown
- (7) Finite state machine error

addr-change-timeout — A timed-out tunnel for which the peer IP address has changed mid-session (from the one that is provided initially during configuration) will be forced to the blacklist. In absence of this configuration option, only the configured peer for the tunnel will be blacklisted, but not the tunnel itself which now has a different peer address than the one initially configured.

never — When specified, no tunnels will be placed on blacklist under any circumstance. This parameter will be available to preserve backward compatibility.

max-list-length

Syntax	max-list-length unlimited max-list-length <i>count</i> no max-list-length
Context	config>router>l2tp>tunnel-selection-blacklist config>service>vprn>l2tp>tunnel-selection-blacklist
Description	This command configured the maximum length of the peer/tunnel blacklist.

This command specifies how many items (tunnels or peers) can be in the tunnel-selection-blacklist. If a tunnel or peer needs to be added to the tunnel-selection-blacklist and the tunnel-selection-blacklist is full, the system will remove the item (tunnel or peer) from the blacklist that was in this blacklist for the longest time.

Default	unlimited
Parameters	unlimited — Specifies there is no limit. count — Specifies how many items (tunnels or peers) can be in the tunnel-selection-blacklist. Values 1 to 65635

max-time

Syntax	max-time <i>minutes</i> no max-time
Context	config>router>l2tp>tunnel-selection-blacklist config>service>vpn>l2tp>tunnel-selection-blacklist
Description	This command configures time for which an entity (peer or a tunnel) are kept in the blacklist.
Default	5 minutes
Parameters	<i>minutes</i> — Specifies the maximum time a tunnel or peer may remain in the blacklist, Values 1 to 60

timeout-action

Syntax	timeout-action <i>action</i> no timeout-action
Context	config>router>l2tp>tunnel-selection-blacklist config>service>vpn>l2tp>tunnel-selection-blacklist
Description	This command defines an action that will be executed on the entity (peer/tunnel) in the blacklist once the entity becomes eligible for selection again.
Default	remove-from-blacklist

Parameters	<i>action</i> — Specifies the Action to be taken when a tunnel or peer has been in the blacklist for the max-period of time.
Values	remove-from-blacklist — The peer or tunnel in the blacklist will be removed completely from the blacklist and made eligible for the selection process once the max-time expires. In this mode of operation, multiple new sessions can be mapped into the same, newly released tunnel from the blacklist. The first such session will try to setup the tunnel, while the other will be buffered until the tunnel establishment process is completed. In case that the tunnel remains unavailable, it will be placed in the blacklist again. Consequently all new sessions will have be re-negotiated over an alternate tunnel. try-one-session — Once the max-time expired, the peer or tunnel in the blacklist is made available for selection only to a single new session request. Only upon successful tunnel establishment will the incoming new sessions be eligible to be mapped into this tunnel. This behavior will avoid session establishment delays in case that the tunnel just removed from the blacklist is still unavailable.

non-multi-chassis-tunnel-id-range

Syntax	non-multi-chassis-tunnel-id-range start <i>l2tp-tunnel-id</i> end <i>l2tp-tunnel-id</i> non-multi-chassis-tunnel-id-range default no non-multi-chassis-tunnel-id-range
Context	config>system>l2tp
Description	This command sets the tunnel-id range that will be used to allocate a new tunnel-id for a tunnel for which no multi-chassis redundancy is configured.
Default	Sets the tunnel-id range to the full tunnel-id range available on this system The default for start <i>l2tp-tunnel-id</i> is 1. No tunnel-ids are available for which no multi-chassis redundancy is configured when set to 0. The default for end <i>l2tp-tunnel-id</i> is the maximum tunnel-id allowed on this system. The end <i>l2tp-tunnel-id</i> must be set to 0 when the start <i>l2tp-tunnel-id</i> is set to 0 and vice versa.

track-srrp-instances

Syntax	track-srrp-instances
Context	config>redundancy>multi-chassis>peer>sync
Description	This command enables the context to configure

track-srrp

Syntax	[no] track-srrp [<i>srrp-instance</i>]
Context	config>redundancy>multi-chassis>peer>sync>track-srrp-instances
Description	This command configures a tracked SRRP instance. The no form of the command reverts to the default.
Parameters	<i>srrp-instance</i> — Indicates the unique identifier of the tracked SRRP instance. Values 1 to 4294967295

l2tp-tunnel-id-range

Syntax	l2tp-tunnel-id-range start <i>l2tp-tunnel-id</i> end <i>l2tp-tunnel-id</i> no l2tp-tunnel-id-range
Context	config>redundancy>multi-chassis>peer>sync>track-srrp-instances>track-srrp
Description	This command sets the tunnel-id range that will be used to allocate a new tunnel-id for a tunnel for which multi-chassis redundancy is configured to this MCS peer.
Default	Makes the tunnel ID empty.
Parameters	start <i>l2tp-tunnel-id</i> — Specifies the start of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS). Values 1 to 16383 end <i>l2tp-tunnel-id</i> — Specifies the end of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS). Values 1 to 16383

recovery-max-session-lifetime

Syntax	recovery-max-session-lifetime <i>minutes</i> no recovery-max-session-lifetime
Context	config>router>l2tp>failover
Description	This command configures the sub-set of sessions that this system attempts to synchronize in the Session State Synchronization phase as described in RFC 4951, Fail Over Extensions for Layer 2 Tunneling Protocol (L2TP). The no form of the command reverts to the default.

Default	2
Parameters	<i>minutes</i> — Specifies the sub-set of sessions to recover.
Values	2 to 4294967295

recovery-method

Syntax	recovery-method <i>method</i> no recovery-method
Context	config>router>l2tp>failover config>service>vpn>l2tp>failover config>router>l2tp>group>failover config>service>vpn>l2tp>group>failover config>router>l2tp>group>tunnel>failover config>service>vpn>l2tp>group>tunnel>failover
Description	This command sets the recovery method to be used for newly created tunnels.
Default	mcs on config>router>l2tp>failover default on config>service>vpn>l2tp>failover default on config>router>l2tp>group>tunnel>failover default on config>service>vpn>l2tp>group>failover default on config>service>vpn>l2tp>group>tunnel>failover
Parameters	method — Describes how a pair of redundant LAC peers recover tunnel and session state (sequence numbers, for example) immediately after a failover.

Note: While failover is enabled, the tunnels and sessions proper are always kept synchronized between the redundant pair, regardless of the recovery method for the sequence numbers when a failover really occurs.

Values	mcs — Specifies that the stateful information is recovered from the failover peer directly, using Multi-Chassis Redundancy Synchronization (MCS). recovery-tunnel — Specifies that the stateful information is recovered as described in RFC 4951, <i>Fail Over Extensions for Layer 2 Tunneling Protocol (L2TP)</i> . This method uses a recovery tunnel to the L2TP peer to pass the stateful information.
--------	---

default — Specifies that the actual value must be derived from another object of the same type with a wider scope. Takes the value of the next higher level (not available in **config>router>l2tp>failover** and **config>service>vpn>l2tp>failover**).

recovery-time

Syntax	recovery-time <i>seconds</i> no recovery-time
Context	config>router>l2tp>failover config>service>vpn>l2tp>failover config>router>l2tp>group>failover config>service>vpn>l2tp>group>failover config>router>l2tp>group>tunnel>failover config>service>vpn>l2tp>group>tunnel>failover
Description	This command sets the recovery time to be negotiated via RFC 4951. It represents the extra time this L2TP peer (LAC or LNS) needs to recover all its tunnels.
Default	0 on config>router>l2tp>failover config>service>vpn>l2tp>failover
Parameters	<i>seconds</i> — The period of time, expressed in seconds, an endpoint asks its peer to wait before assuming the recovery process has failed. Values 0 to 900

track-srrp

Syntax	track-srrp <i>srrp-instance</i> peer <i>ip-address</i> sync-tag <i>sync-tag</i> no track-srrp <i>srrp-instance</i>
Context	config>router>l2tp>failover config>service>vpn>l2tp>failover
Description	This command sets the sync-tag to be used to synchronize the tunnels with track-srrp <srrp-id> to MCS peer <IP-@>. The same sync-tag should be configured on the MCS peer.
Default	Removes the sync-tag for the indicated track-srrp.
Parameters	<i>srrp-instance</i> — Specifies the Simple Router Redundancy Protocol (SRRP) instance used for Multi-Chassis redundancy failover that is associated with this Layer Two Tunneling Protocol Tunnel. sync-tag <i>sync-tag</i> — Specifies a synchronization tag to be used while synchronizing with the peer.

tunnel

Syntax	tunnel <i>tunnel-name</i> [create] no tunnel <i>tunnel-name</i>
Context	config>router>l2tp>group
Description	This command configures an L2TP tunnel.
Parameters	<i>tunnel-name</i> — Specifies a string to identify a L2TP tunnel up to 32 characters in length.

6.6.2.1.3 L2TP Tunnel RADIUS Accounting Commands

l2tp-accounting-policy

Syntax	l2tp-policy <i>policy-name</i> [create] no l2tp-policy
Context	config>aaa
Description	This command enables the L2TP accounting. The no form of this command disables accounting.
Default	None
Parameters	<i>name</i> — The name of L2TP tunnel accounting policy. create — Mandatory keyword to create a policy name.

accounting-type

Syntax	accounting-type [session] [tunnel] no accounting-type
Context	config>aaa>l2tp-acct-plcy
Description	This command specifies the accounting type for the L2TP tunnel accounting policy. The no form of the command reverts to the default.
Default	session tunnel
Parameters	session — Enables tunnel level accounting, including: Tunnel-Link-Start Tunnel-Link-Stop Tunnel-Link-Reject tunnel — Enables link level accounting, including: Tunnel-Start Tunnel-Stop Tunnel-Reject

include-radius-attribute

Syntax	[no] include-radius-attribute
---------------	--------------------------------------

Context	config>aaa>l2tp-acct-plcy
Description	This command enables the context to specify the RADIUS parameters that the system should include into RADIUS authentication-request messages. The no form of the command disables

nas-identifier

Syntax	[no] nas-identifier
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-identifier RADIUS attribute.

nas-port

Syntax	[no] nas-port <i>bit-specification binary-spec</i>										
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute										
Description	This command enables the generation of the nas-port RADIUS attribute. You enter decimal representation of a 32-bit string that indicates your port information. This 32-bit string can be compiled based on different information from the port (data types). By using syntax number-of-bits data-type you indicate how many bits from the 32 bits are used for the specific data type. These data types can be combined up to 32 bits in total. In between the different data types 0's and/or 1's as bits can be added. The no form of this command disables your nas-port configuration.										
Parameters	<i>bit-specification binary-spec</i> — Specifies the NAS-Port attribute										
Values	<table><tr><td>binary-spec</td><td><bit-specification> <binary-spec></td></tr><tr><td>bit-specification</td><td>0 1 <bit-origin></td></tr><tr><td>bit-origin</td><td>*<number-of-bits><origin></td></tr><tr><td>number-of-bits</td><td>1 to 32</td></tr><tr><td>origin</td><td>o i s m p outer VLAN ID i inner VLAN ID s slot number m MDA number p port number or lag-id</td></tr></table>	binary-spec	<bit-specification> <binary-spec>	bit-specification	0 1 <bit-origin>	bit-origin	*<number-of-bits><origin>	number-of-bits	1 to 32	origin	o i s m p outer VLAN ID i inner VLAN ID s slot number m MDA number p port number or lag-id
binary-spec	<bit-specification> <binary-spec>										
bit-specification	0 1 <bit-origin>										
bit-origin	*<number-of-bits><origin>										
number-of-bits	1 to 32										
origin	o i s m p outer VLAN ID i inner VLAN ID s slot number m MDA number p port number or lag-id										

Output

Sample

```
*12o*12i00*2s*2m*2p => 0000 0000 0000 iiii iiii iiii 00ss mmpp
If outer vlan = 0 & inner vlan = 1 & slot = 3 & mda = 1 & port = 1
=> 0000 0000 0000 0000 0000 0001 0011 0101 => nas-port = 309
```

nas-port-id

Syntax	nas-port-id nas-port-id [prefix-string <i>string</i>] [suffix <i>suffix-option</i>] no nas-port-id
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-port-id RADIUS attribute. Optionally, the value of this attribute (the SAP-id) can be prefixed by a fixed string and suffixed by the circuit-id or the remote-id of the client connection. If a suffix is configured, but no corresponding data is available, the suffix used will be 0/0/0/0/0/0.
Parameters	prefix-string <i>string</i> — Specifies that a user configurable string will be added to the RADIUS NAS port attribute, up to 8 characters in length. suffix <i>suffix-option</i> — Specifies the suffix type to be added to the RADIUS NAS port attribute. Values circuit-id, remote-id

nas-port-type

Syntax	nas-port-type nas-port-type [<i>type</i>] no nas-port-type
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute
Description	This command enables the generation of the nas-port-type RADIUS attribute. If set to nas-port-type , the following will be sent: values: 32 (null-encap), 33 (dot1q), 34 (qinq), 15 (DHCP hosts). The nas-port-type can also be set as a specified value, with an integer from 0 to 255. The no form of the command reverts to the default.
Default	no nas-port-type
Parameters	<i>type</i> — Specifies an enumerated integer that specifies the value that will be put in the RADIUS nas-port-type attribute. Values 0 to 255

radius-accounting-server

Syntax	radius-accounting-server
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute
Description	This command creates the context for defining RADIUS accounting server attributes under a given session authentication policy.

access-algorithm

Syntax	access-algorithm {direct round-robin} no access-algorithm
Context	config>aaa>l2tp-acct-plcy>include-radius-attribute
Description	This command configures the algorithm used to access the list of configured RADIUS servers.
Default	direct
Parameters	direct — Specifies that the first server will be used as primary server for all requests, the second as secondary and so on. round-robin — Specifies that the first server will be used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

retry

Syntax	retry count
Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command configures the number of times the router attempts to contact the RADIUS server for authentication.

Note: The retry count includes the first attempt.

The **no** form of the command reverts to the default value.

Default	3 (the initial attempt as well as two retried attempts)
Parameters	count — Specifies the retry count. Values 1 to 10

router

Syntax	router <i>router-instance</i> router service-name <i>service-name</i> no router
Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command specifies the number of times the router attempts to contact the RADIUS server for authentication, if not successful the first time. The no form of the command reverts to the default value.

server

Syntax	server <i>server-index</i> address <i>ip-address</i> secret <i>key</i> [hash hash2] [port <i>port</i>] [create] no server <i>server-index</i>
Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command adds a RADIUS server and configures the RADIUS server IP address, index, and key values. Up to five RADIUS servers can be configured at any one time. RADIUS servers are accessed in order from lowest to highest index for authentication requests until a response from a server is received. A higher indexed server is only queried if no response is received from a lower indexed server (which implies that the server is not available). If a response from a server is received, no other RADIUS servers are queried. The no form of the command removes the server from the configuration.
Default	none
Parameters	<i>server-index</i> — The index for the RADIUS server. The index determines the sequence in which the servers are queried for authentication requests. Servers are queried in order from lowest to highest index. Values 1 to 16 (a maximum of 5 accounting servers) <i>address ip-address</i> — The IP address of the RADIUS server. Two RADIUS servers cannot have the same IP address. An error message is generated if the server address is a duplicate. secret key — The secret key to access the RADIUS server. This secret key must match the password on the RADIUS server. Values <i>secret-key</i> — A string up to 20 characters in length. <i>hash-key</i> — A string up to 33 characters in length. <i>hash2-key</i> — A string up to 55 characters in length.

hash — Specifies the key is entered in an encrypted form. If the hash parameter is not used, the key is assumed to be in a non-encrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the hash parameter specified.

hash2 — Specifies the key is entered in a more complex encrypted form. If the hash2 parameter is not used, the less encrypted hash form is assumed.

port — Specifies the UDP port number on which to contact the RADIUS server for authentication.

Values 1 to 65535

source-address

Syntax	source-address <i>ip-address</i> no source-address
Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command configures the source address of the RADIUS messages. The no form of the command reverts to the default value.
Default	system IP address
Parameters	<i>ip-address</i> — Specifies the source address to be used for NAT RADIUS accounting.

timeout

Syntax	timeout <i>seconds</i>
Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command configures the number of seconds the router waits for a response from a RADIUS server. The no form of the command reverts to the default value.
Default	5
Parameters	<i>seconds</i> — Specifies the time the router waits for a response from a RADIUS server. Values 1 to 90

request-script-policy

Syntax	request-script-policy <i>radius-script-policy-name</i> no request-script-policy
---------------	--

Context	config>aaa>l2tp-acct-plcy>radius-acct-server
Description	This command specifies the RADIUS script policy to be used for accounting-request packets. The no form of the command removes the policy from the configuration.
Parameters	<i>radius-script-policy-name</i> — Configures a Python script policy name to modify Access-Request messages.

6.6.2.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

peer

Syntax	peer <i>ip-address</i> [udp-port <i>port</i>] peer <i>ip-address</i> statistics [udp-port <i>port</i>] peer [draining] [blacklisted selectable unreachable]										
Context	show>router>l2tp										
Description	This command displays L2TP peer operational information/										
Parameters	<i>ip-address</i> — Specifies the IP dress for the L2TP peer. Values <table><tr><td><i>ip-address</i></td><td>ipv4-address - a.b.c.d</td></tr><tr><td><i>ipv6-address</i></td><td>x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D</td></tr><tr><td>draining</td><td>keyword</td></tr><tr><td>statistics</td><td>keyword</td></tr><tr><td><i>port</i></td><td>[1 to 65535]</td></tr></table>	<i>ip-address</i>	ipv4-address - a.b.c.d	<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D	draining	keyword	statistics	keyword	<i>port</i>	[1 to 65535]
<i>ip-address</i>	ipv4-address - a.b.c.d										
<i>ipv6-address</i>	x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d x - [0 to FFFF]H d - [0 to 255]D										
draining	keyword										
statistics	keyword										
<i>port</i>	[1 to 65535]										

Output

6.6.2.3 Debug Commands

assignment-id

Syntax	assignment-id <i>assignment-id</i>
Context	debug>router>l2tp
Description	This command enables and configures debugging for the L2TP tunnel with a given assignment-id.
Parameters	<i>assignment-id</i> — Specifies a string that distinguishes this L2TP tunnel.

event

Syntax	[no] event
Context	debug>router>l2tp debug>router>l2tp>assignment-id debug>router>l2tp>group debug>router>l2tp>peer debug>router>l2tp>tunnel
Description	This command configures an L2TP debugging event.

group

Syntax	group <i>tunnel-group-name</i>
Context	debug>router>l2tp
Description	This command enables and configures debugging for an L2TP group.
Parameters	<i>tunnel-group-name</i> — Specifies the tunnel group name up to 63 characters in length.

peer

Syntax	peer <i>ip-address</i> [udp-port <i>port</i>]
Context	debug>router>l2tp
Description	This command enables and configures debugging for an L2TP peer.
Parameters	<i>ip-address</i> — Specifies the IP address of the session.

Values <ip-address> : ipv4-address - a.b.c.d

ipv6-address - x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x - [0 to FFFF]H
d - [0 to 255]D

udp-port *port* — Specifies the local UDP port of this L2TP.

Values 1 to 65535

tunnel

Syntax	tunnel <i>connection-id</i>
Context	debug>router>l2tp
Description	This command enables and configures debugging for an L2TP tunnel.
Parameters	<i>connection-id</i> — Specifies the connection ID of the L2TP session associated with this session.
Values	1 to 4294967295

recovery

Syntax	[no] recovery
Context	debug>router>l2tp>assignment-id>event debug>router>l2tp>event debug>router>l2tp>group>event debug>router>l2tp>peer>event debug>router>l2tp>tunnel>event
Description	This command configures L2TP LAC state recovery event debugging.

recovery-failed

Syntax	[no] recovery-failed
Context	debug>router>l2tp>assignment-id>event debug>router>l2tp>event debug>router>l2tp>group>event debug>router>l2tp>peer>event debug>router>l2tp>tunnel>event
Description	This command configures L2TP LAC state recovery failed event debugging.

7 Triple Play Security

7.1 In This Chapter

This chapter provides information about configuring specific security aspects for Triple Play services, including configuration process overview, and application notes.

Note: The 7450 ESS and 7750 SR support many additional security features, which are described in the System Management Guide.

Topics in this chapter include:

- [Triple Play Security Features](#)
 - [Anti-Spoofing Filters](#)
 - [Layer 2 Triple Play Security Features](#)
 - [MAC Pinning](#)
 - [MAC Protection](#)
 - [DoS Protection](#)
 - [VPLS Redirect Policy](#)
 - [ARP Handling](#)
 - [Web Portal Redirect](#)
- [Configuring Triple Play Security with CLI](#)
- [Common Configuration Tasks](#)

7.2 Triple Play Security Features

7.2.1 Anti-Spoofing Filters

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA).

Anti-spoofing is useful to prevent certain packets gaining unauthorized network access. Such packets originate from within a network and with an invalid source address.

Enabling anti-spoof filtering on a subscriber-facing SAP causes the anti-spoof table to be populated with all static and dynamic host information available on the SAP. Enabling anti-spoof filtering on the SAP will fail if any static hosts are defined without the proper addresses specified for the selected anti-spoof filter type.

When enabled, forwarding IP packets that ingress the SAP is dependent on a successful anti-spoof table match with an entry in the table. DHCP and non-IP packets (including ARP) are not subject to anti-spoof filtering. If an entry does not match the ingress packet, the packet will be silently discarded while incrementing the SAP discard counter.

Anti-spoof filtering is only allowed on VPLS SAPs, IES SAP-based IP interfaces, and VPRN SAP-based IP interfaces. Anti-spoof filtering is not available on IES or VPRN SDP bound IP interfaces. Anti-spoof filtering is not supported on Epipe and other VLL type services. Support for anti-spoofing is dependent on SAP based service interfaces. Note VPRN and VLL are supported on the 7750 SR only.

Note: Anti-spoofing filters, with type **ip-mac**, must be enabled to do Enhanced Subscriber Management (as described in section [Triple Play Enhanced Subscriber Management](#)).

Topics in this section are:

- [Anti-spoofing Filter Types](#)
- [Filtering Packets](#)

7.2.1.1 Anti-spoofing Filter Types

A SAP or interface that supports anti-spoof filtering can be configured to use one of three types of anti-spoof tables. The type of table used by the SAP is dependent on the type of anti-spoof filtering desired, only one anti-spoofing table type is supported per SAP:

- When only the incoming source MAC address is to be verified, the source MAC table must be defined (anti-spoof type = **mac**).
- When only the incoming source IP address is to be verified, the source IP table must be defined (anti-spoof type = **ip**).

- When both the incoming source MAC and source IP addresses are to be verified, the combination source IP and source MAC table must be defined (anti-spoof type = **ip-mac**).

Note: Setting the anti-spoof filter type for the SAP is dependent on pre-existing static host definitions, for example, attempting to set the SAP anti-spoof filtering to mac will fail if any static hosts exist that do not have a defined MAC address.

The anti-spoof table of a SAP or interface will be populated from the DHCP lease state table and from any statically defined hosts on the SAP or interface.

7.2.1.2 Filtering Packets

Packets from a client that match an anti-spoof filter entry when anti-spoof filtering is enabled are allowed to be further processed by the system. The matching packet is still subject to other forwarding criteria including potentially ACL filtering.

All packets that are not exempt from anti-spoofing and do not match a entry in the anti-spoof table are discarded. Every discard event will increment the SAP discard packet counter. The discard event is not logged or alarmed, but a threshold alarm could be configured for the counter (see Configuring System Monitoring Thresholds in the Basic System Configuration Guide).

Not all ingress packets are subject to the anti-spoof filtering when enabled. Non-IP packets are exempt for anti-spoof filter lookups and are allowed to be further processed by the system. This includes ARP requests and replies, as well as PPPoE packets. The only IP packets exempt from anti-spoof filtering are DHCP packets destined to the server UDP port 67. DHCP packets destined to the client UDP port number (port 68) are not exempt.

7.2.2 Layer 2 Triple Play Security Features

Topics in this section include:

- [MAC Pinning](#)
- [MAC Protection](#)
- [DoS Protection](#)
- [VPLS Redirect Policy](#)

7.2.2.1 MAC Pinning

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA).

DHCP snooping and IP/MAC auto-filters can be employed to prevent Theft of Service (by a malicious user spoofing another user's address). However, these auto-filters do not discard non-IP packets such as PPPoE packets, thus potentially allowing a MAC address to be relearned on another SAP. MAC pinning closes this loophole, by not allowing a MAC address to be relearned on another SAP.

When MAC pinning is enabled, a MAC address learned on one SAP or SDP can not be re-learned on another SAP or SDP in the same VPLS, until the FIB entry for the MAC address times out. (Note that in case MAC aging is disabled, MAC entries on a SAP/SDP with MAC pinning enabled will effectively become permanent.)

MAC pinning is implicitly enabled when DHCP auto-filters are enabled, and cannot be disabled. For MAC addressing learned during DHCP address assignment (when DHCP snooping function is active at least on one port of the VPLS), the MAC address is tied to a given SAP for the duration of the DHCP lease.

When a SAP or spoke SDP is part of a Residential Split Horizon Group (RSHG), MAC pinning is automatically enabled at creation of the SAP, but can be disabled if desired.

7.2.2.2 MAC Protection

In a Layer 2 environment, a malicious subscriber could create a denial-of-service attack by sending Ethernet frames, with as source MAC address the address of a gateway (for example, the IP next hop upstream). As MAC learning is typically enabled, this would move the learned gateway MAC from the uplink SAP or SDP to the subscriber's SAP, causing all communication to the gateway to be disrupted. If a local content server is attached to the same VPLS, a similar attack could be launched against it.

Communication between subscribers can be disallowed using Split Horizon Groups, but this by itself will not be sufficient to prevent such an attack.

The solution is to create a mechanism to explicitly protect some MAC addresses against being relearned on other SAPs.

The **mac-protect** feature on the 7450 ESS and 7750 SR allows a list of special MAC addresses to be configured in a VPLS. Two checks can then be made on incoming packets against these protected MAC addresses:

- **[no] auto-learn-mac-protect**: Used to enable the automatic protection of source MAC addresses learned on the associated object. MAC protection is used in conjunction with restrict-protected-src, restrict-unprotected-dst and mac-protect. When this command is applied or removed, the MAC addresses are cleared from the related object.
- **restrict-protected-src**: Used to prevent denial-of-service attacks. If the source MAC address of a packet from a subscriber matches a protected entry, it is probable that this subscriber tried to impersonate the gateway or server. If no parameter is specified, such packets are discarded, a trap is generated, and the SAP on which it arrived is placed operationally down. If the **alarm-only** parameter is specified, the packet is forwarded, and an alarm is generated but the source MAC is not learned. If the **discard-frame** parameter is specified, the packet is discarded and an alarm generated.
- **restrict-unprotected-dst**: Used to force traffic from subscribers to only go towards a few defined destinations (the gateways or servers). Any packet from a subscriber whose destination MAC address does not match a protected entry is discarded.

7.2.2.3 DoS Protection

This section describes the mechanisms and limitations of DoS protection related to subscriber management snooping functions. This feature is only supported on 7750 SR-Series and 7450 ESS-Series redundant chassis models. In subscriber aggregation networks, these routers play an active role in several protocols. Subscribers either intentionally or unknowingly interfere with the operation of the node's processing capacity (for example, excessive ARP handling) or other user traffic.

Routing protocols such as OSPF and ISIS could also be a threat as packets can be injected by customers (erroneously or maliciously) which could cause high CPM overload. Service providers are concerned about DoS protection including DoS attacks when acting as a subscriber aggregation device and guarding against DoS attacks using unprovisioned protocols.

7.2.2.3.1 Subscriber Aggregation Network

In a subscriber aggregation network, multiple devices such as the 7750 SR or 7450 ESS routers provide access to a DHCP or a RADIUS server. These servers usually do not scale high enough to provide the means to control access to snooping functions through a controlled queue. It is possible, under severe conditions, that the network could become unavailable if the node cannot handle requests from subscribers.

Because the IOMs cannot be scaled to provide a per-subscriber queue to control traffic, a monitoring function, handled by the CPM, is provided. With this monitoring system, the CPM tracks the number of control plane messages set per subscriber and limits the rate to a specified level and provides feedback using event generation to alert a centralized system of a possible DoS attack.

The CPM provides a prioritized access to the CPU. Since the number of control packets expected from a subscriber should have a low rate, and under normal conditions, the system will provide a rate limit on a per subscriber/MAC basis and will drop a subscriber control packet before it is queued or processed by the CPU. The system will be configured with expected arrival rate of per MAC/subscriber control packet rates and optionally total rate per interface/SAP.

The system maintains a per-second running rate monitor per SAP and per MAC. If an entry is using more than the configured rate, the system will not forward that packet to be queued. Every existing subscriber host will be monitored. A subscriber host will be flagged and the system observed with an excessive rate of control packets. In the case of PPPoE, the CPM will monitor subscriber hosts before the IP address is provided by the SAP/MAC/session-id combination.

The control protocols affected by this mechanism include:

- ARP (in arp-reply-agent)
- DHCP (for discover and renew)
- ICMP
- PPPoE
- IGMP

7.2.2.3.2 Network Control Filtering

The 7750 SR or 7450 ESS can block network control traffic for unconfigured protocols. For example, if OSPF is not configured on an IP interface, all OSPF-related traffic should be dropped before the traffic reaches the CPU.

Protocols are blocked based on whether that particular protocol is configured to run on the given IP interface. It is not required to re-configure the permitted protocols.

Protocol traffic control by this mechanism includes:

- OSPFv2
- OSPFv3
- IS-IS
- RSVP-TE
- LDP
- RIP
- PIM
- MLD
- IGMP
- BGP
- BFD
- L2PT
- PPP
- DHCP

7.2.2.4 VPLS Redirect Policy

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA) with Layer 2 aggregation towards a Broadband Subscriber Router (BSR).

In a Triple Play network it may be desired to route some traffic from/to subscribers through a Deep Packet Inspection (DPI) device, for example, to limit peer-to-peer traffic. However such a DPI device typically has limited bandwidth available, so only those packets that need inspection should be sent to it.

In a Layer 3 network, such policy-based redirection can be achieved using “next-hop redirect” ACL entries. In a layer 2 (VPLS) aggregation network, the same result can be achieved using “redirect to SAP” or “redirect to SDP” policy.

Refer to the ACL Next-Hop for VPLS section in the Services Overview Guide.

7.2.3 ARP Handling

7.2.3.1 ARP Reply Agent

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA).

In Triple Play networks, typically downstream broadcast is not allowed on subscriber SAPs. As a result, subscribers can not receive ARP requests from the network. Instead, the 7450 ESS or 7750 SR will respond to ARP requests from the network, with information from the DHCP lease state table.

In the upstream direction (towards the network), the ARP reply agent intercepts ARP Requests on subscriber SAPs, and checks them against the DHCP lease state table. The purpose is to prevent a malicious subscriber spoofing ARP Request or ARP reply messages and thus populating the upstream router's ARP table with incorrect entries.

When the keyword **sub-ident** is added in the ARP reply agent configuration, also the subscriber identity is checked. If an upstream ARP request is targeted to the same subscriber, it is dropped. Otherwise, it is flooded to all VPLS interfaces outside the received Split Horizon Group (SHG).

Static hosts can be defined on the SAP using the **host** command. Dynamic hosts are enabled on the system by enabling the **lease-populate** command in the SAP's **dhcp** context. In the event that both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. In the event that both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.

In brief, the ARP Replay Agent operation is as follows:

- For ARP request received from a customer SAP:
 - first check in DHCP lease state table - if no match: discard
 - if (**sub-ident** enabled) and (destination = same subscriber): discard
 - otherwise: flood to all SAPs/SDPs outside this SHG
- For ARP request received from the network:
 - lookup IP address in DHCP lease state table - if no match: discard
 - otherwise: respond with MAC address from the DHCP lease state table

7.2.3.2 Dynamic ARP Table Population

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA) with Layer 3 forwarding towards the network.

In an IES service, the system's ARP table can be populated dynamically using entries in the DHCP lease state table (in turn populated from snooping DHCP ACK messages (see [DHCP Snooping](#))), and from static hosts defined on the SAP. In the router ARP table these are indicated with state managed.

In the event that both a static host is created with the same IP and MAC address as an existing managed entry, creation will fail and a trap is generated.

In the event that a DHCP Lease needs to be populated with the same IP and MAC address as an existing static host entry, creation will fail and a trap is generated.

No **static-arp** creation is possible when combined with **arp-populate**.

7.2.3.3 Local Proxy ARP

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA) with Layer 3 forwarding towards the network.

Local proxy ARP allows the 7450 ESS or 7750 SR to respond to ARP requests received on an interface, for an IP address which is part of a subnet assigned to the interface. When the local proxy ARP feature is enabled, the switch responds to all ARP requests for IP addresses belonging to the subnet with the MAC address of the interface, and forwards all traffic between hosts in the subnet.

This feature is intended to be used in situations (such as DSL aggregation networks) when hosts belonging to the same subnet are prevented from directly communicating with each other over the subnet by the configuration of the switch (or DSLAM) to which they are connected.

Note: When local-proxy-arp is enabled under a IES service, all ICMP redirects on the ports associated with the service are automatically blocked. This prevents users from learning each other's MAC address (from ICMP redirects).

The implementation of proxy ARP with support for local proxy ARP allows the router to respond to ARP requests in the subnet assigned to an IES or VPRN interface, thus allowing multiple customers to share the same IP subnet.

7.2.4 Web Portal Redirect

This section describes the 7450 ESS or 7750 SR acting as a Broadband Subscriber Aggregator (BSA).

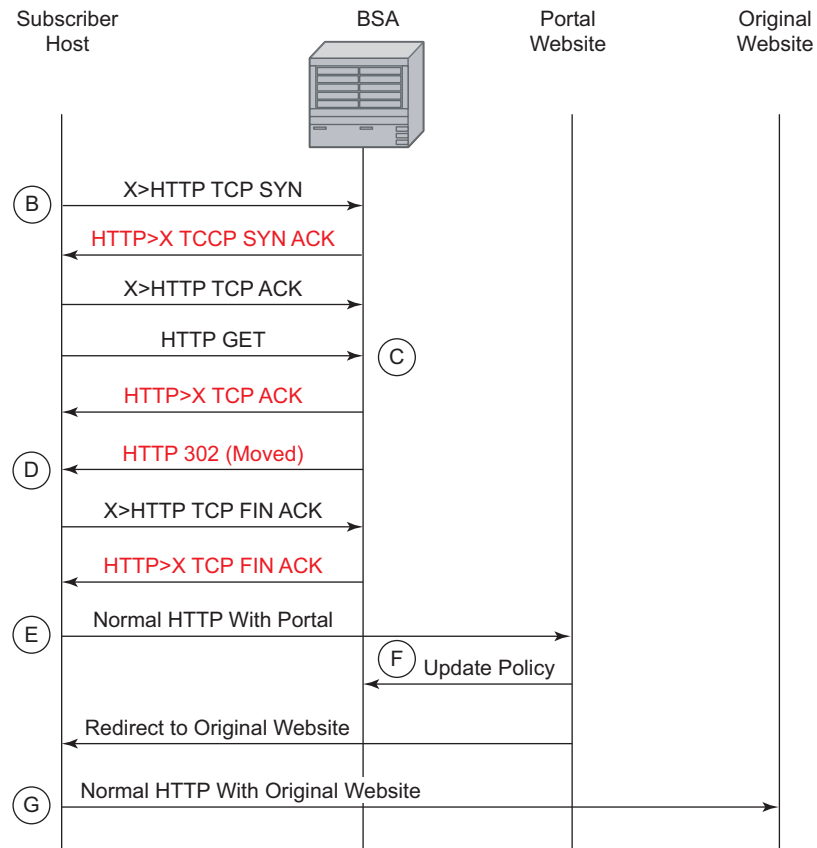

In a Triple Play network it may not be desired (or feasible) to perform manual provisioning of new services and service changes. The ideal way of working is automatic provisioning, with the end-user supplying his details at a retailer, or (if physical connectivity is already present through an on-line customer portal).

The 7450 ESS and 7750 SR support a special ACL that automatically redirects subscribers to a predefined URL. This is done by sending a HTTP 302 (moved) message to the subscriber, regardless of the requested URL.

The message flow is as follows (see [Figure 46](#) below):

- a. The subscriber gets an IP address using DHCP (if the customer is trying to use a static IP he will be blocked by the anti-spoofing filter).
- b. The subscriber tries to connect to a website (TCP SYN, TCP ACK, HTTP GET).
- c. The 7450 ESS or 7750 SR intercepts the HTTP GET request and discards it.
- d. The 7450 ESS or 7750 SR then responds to the subscriber with a HTTP 302 message (service temporarily unavailable/moved), containing a new target URL (that of the portal) configured by the operator. This target URL can include the subscriber's IP and MAC addresses as part of the portal's URL string.
- e. The subscriber's web browser will close the original TCP connection and open a new connection to the web portal, where the subscriber can sign up or change his/her service Profile.
- f. After approving the changes, the web portal updates the ACL (directly or through another system such as the Nokia 5750 SSC) to remove the redirection policy.
- g. The subscriber can now connect to the original site.

Figure 46 IP Illustration of Message Flow in Web Portal Redirect

OSSG0824

The items in red text in [Figure 46](#) are messages the 7450 ESS or 7750 SR will send (masquerading as the destination), regardless of the destination IP address or type of service.

The following displays information that can optionally be added as variables in the portal URL (http-redirect url):

- \$IP – Customer's IP address
- \$MAC – Customer's MAC address
- \$URL – Original requested URL
- \$SAP – Customer's SAP
- \$SUB – Customer's subscriber identification string
- \$CID – string that represents the circuit-id or interface-id of the subscriber host (hexadecimal format)

- \$RID – string that represents the remote-id of the subscriber host (hexadecimal format)

Note: The subscriber's IP and MAC address variables are populated from the anti-spoofing list, and thus anti-spoofing must be enabled (see section [Anti-Spoofing Filters](#)).

Since most web sites are accessed using the domain name, the 7450 ESS or 7750 SR will need to allow DNS queries, and an ACL entry to this effect should be included in the filter (see example in section [Configuring Web Portal Redirect](#)).

7.3 Configuring Triple Play Security with CLI

This section provides information to configure Residential Broadband Aggregation services using the command line interface. It is assumed that the reader is familiar with VPLS, IES and VPRN (VPRN is supported on the 7750 SR only) services.

Topics in this section include:

- [Common Configuration Tasks](#)
 - [Configuring Anti-Spoofing Filters](#)
 - [Configuring Triple Play Security features](#)
 - [Configuring ARP Handling](#)
 - [Configuring Web Portal Redirect](#)

7.3.1 Common Configuration Tasks

Topics in this section are:

- [Configuring Anti-Spoofing Filters](#)
- [Configuring Triple Play Security features](#)
 - [Configuring MAC Pinning](#)
 - [Configuring MAC Protection](#)
 - [Configuring VPLS Redirect Policy](#)
 - [Configuring VPLS Redirect Policy](#)
- [Configuring ARP Handling](#)
- [Configuring Web Portal Redirect](#)

7.3.1.1 Configuring Anti-Spoofing Filters

Anti-spoofing filters are used to prevent malicious subscribers sending IP packets with a forged IP or MAC address, and thus mis-directing traffic. The anti-spoofing filter is populated from the DHCP lease state table, and DHCP snooping must be enabled on the SAP.

There are three types of filters (MAC, IP and IP+MAC), one type is allowed per SAP.

The following displays an IES service interface configuration with anti-spoofing.

```
A:ALA-48>config>service>ies# info
-----
        interface "test123" create
            address 10.10.42.41/24
            local-proxy-arp
            proxy-arp
                policy-statement "ProxyARP"
            exit
            sap 1/1/7:0 create
                anti-spoof ip
            exit
            arp-populate
            dhcp
                lease-populate 1
                no shutdown
            exit
        exit
        no shutdown
-----
A:ALA-48>config>service>ies#
```

7.3.1.2 Configuring Triple Play Security features

Topics in this section are:

- [Configuring MAC Pinning](#)
- [Configuring MAC Protection](#)
- [Configuring VPLS Redirect Policy](#)
- [Configuring VPLS Redirect Policy](#)

7.3.1.2.1 Configuring MAC Pinning

The following example displays a partial BSA configuration with MAC pinning enabled on a SAP:

```
A:ALA-48>config>service# info
-----
vpls 800 customer 6001 create
    description "VPLS with residential split horizon for DSL"
    stp
        shutdown
    exit
    sap 2/1/4:100 split-horizon-group "DSL-group2" create
        description "SAP for RSHG"
        mac-pinning
    exit
    no shutdown
-----
A:ALA-48>config>service#
```

7.3.1.2.2 Configuring MAC Protection

Preventing Access By Residential Subscribers Using Protected (Gateway) MAC Addresses

The first step is to create a list of MAC addresses to be protected, the second step is to prevent access using these source addresses inside an SHG or a SAP.

The following example displays a partial BSA configuration with some protected MAC addresses on any SAP created inside the SHG:

```
A:ALA-48>config>service# info
-----
vpls 800 customer 6001 create
  no shutdown
  split-horizon-group "mygroup" create
    restrict-protected-src
  exit
  description "VPLS with residential split horizon for DSL"
  mac-protect
    mac 00:00:17:FE:82:D8
    mac 93:33:00:00:BF:92
  exit
-----
A:ALA-48>config>service#
```

Restricting Access By Residential Subscribers To a Small List Of Upstream MAC Addresses:

The first step is to create a list of MAC addresses to be protected, the second step is to restrict access to these addresses only from an SHG or a SAP. (If the MAC address of an upstream server is not known, it can be discovered using e.g. the cpe-ping OAM tool.)

The following example displays a partial BSA configuration with restricted access to some MAC addresses from a specified SAP (an unrestricted access from any other SAP within the VPLS):

```
A:ALA-48>config>service# info
-----
vpls 800 customer 6001 create
  no shutdown
  description "VPLS with restricted access on a SAP"
  mac-protect
    mac 00:00:17:FE:82:D8
    mac 93:33:00:00:BF:92
  exit
  sap 1/1/4:30 create
    restrict-unprotected-dst
```

```

exit
-----
A:ALA-48>config>service#

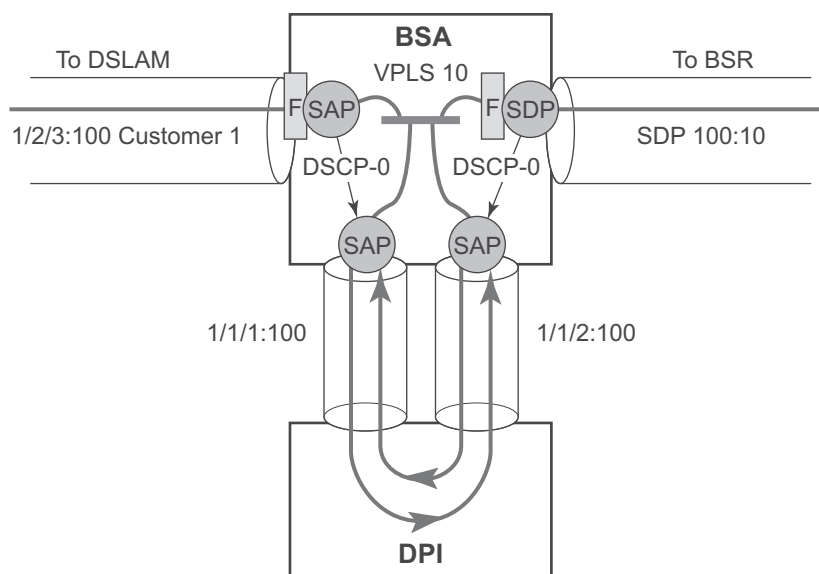

```

7.3.1.2.3 Configuring VPLS Redirect Policy

- [Creating the Filter](#)
- [Applying the Filter to a VPLS Service](#)

Figure 47 displays an IP filter entry configuration for VPLS redirect policy.

Figure 47 VPLS Redirect Policy Example

OSSG0834

Information about defining and applying IP and MAC filters is described in the Router Configuration Guide.

Creating the Filter

The following displays a redirect filter entry:

```

A:ALA-A>config>filter# info
-----
ip-filter 10
  default-action forward
  entry 10
    match
      dscp be

```

```
        exit
        action forward next-hop sap 1/1/1:100
        exit
    exit
exit
ip-filter 11
    default-action forward
    entry 10
        match
            dscp be
        exit
        dscp be
        exit
        action forward next-hop sap 1/1/2:100
    exit
exit
-----
A:ALA-A>config>filter#
```

Applying the Filter to a VPLS Service

The following displays how the redirection filter configured above is assigned to the ingress SAP from the DSLAM, and the ingress SDP from the BSR:

```
A:ALA-A>config>service>vpls# info
-----
    vpls 10 customer 1 create
        description "vpls10"
        sap 1/2/3:100 create
            ingress ip filter 10
        exit
        sap 1/1/1:100 create
        exit
        sap 1/1/2:100 create
        exit
        mesh-sdp 100:10 create
            ingress ip filter 11
        exit
    exit
exit
-----
A:ALA-A>config>service>vpls#
```

7.3.1.3 Configuring ARP Handling

Topics in this section are:

- [Configuring Proxy ARP](#)
- [Configuring Local Proxy ARP](#)
- [Configuring ARP Reply Agent in a VPLS Service](#)

- [Configuring Automatic ARP Table Population in an IES or VPRN Interface](#)

7.3.1.3.1 Configuring Proxy ARP

The implementation of proxy ARP with support for local proxy ARP allows the 7450 ESS or 7750 SR to respond to ARP requests in the subnet assigned to an IES or VPRN interface.

Configuring this command will allow multiple customers to share the same IP subnet.

The following example displays an IES proxy ARP configuration:

```
A:ALA-48>config>service>ies# info
-----
      interface "test123" create
        address 10.10.42.41/24
        local-proxy-arp
        proxy-arp-policy "ProxyARP"
        exit
      exit
    no shutdown
-----
A:ALA-48>config>service>ies#
```

7.3.1.3.2 Configuring Local Proxy ARP

When local proxy ARP is enabled on an IP interface, the 7450 ESS or 7750 SR responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and forwards all traffic between hosts in that subnet. Local proxy ARP is disabled by default.

Note: When local-proxy-arp is enabled under a IES or VPRN service, all ICMP redirects on the ports associated with the service are automatically blocked. This prevents users from learning each other's MAC address (from ICMP redirects).

The following example displays a local proxy ARP IES configuration:

```
A:ALA-A>config>service>ies# info
-----
      interface "test" create
        shutdown
        address 10.10.36.2/24
        local-proxy-arp
        exit
-----
A:ALA-A>config>service>ies#
```

7.3.1.3.3 Configuring ARP Reply Agent in a VPLS Service

When ARP reply agent is enabled, the 7450 ESS or 7750 SR will respond to ARP requests from the network, with information from the DHCP lease state table.

In the upstream direction (towards the network), the ARP reply agent intercepts ARP requests on subscriber SAPs, and checks them against the DHCP lease state table. The purpose is to prevent a malicious subscriber spoofing ARP request or ARP reply messages and thus populating the upstream router's ARP table with incorrect entries.

The following example displays a partial BSA configuration with ARP Reply Agent enabled on a SAP:

```
A:ALA-48>config>service# info
-----
...
    vpls 800 customer 6001 create
        description "VPLS with ARP Reply Agent active"
        sap 2/1/4:100 split-horizon-group "DSL-group2" create
        arp-reply-agent sub-ident
        exit
        sap 3/1/4:200 split-horizon-group "DSL-group2" create
        arp-reply-agent sub-ident
        exit
        no shutdown
    ...
-----
A:ALA-48>config>service#
```

7.3.1.3.4 Configuring Remote Proxy ARP

The following example displays the IES configuration to enable remote proxy ARP:

```
A:ALA-49>config>service>ies# info
-----
        interface "test-1A" create
            address 10.10.26.3/24
            remote-proxy-arp
        exit
        no shutdown
-----
A:ALA-49>config>service>ies#
```

7.3.1.3.5 Configuring Automatic ARP Table Population in an IES or VPRN Interface

The following example displays the IES DHCP configuration to enable automatic population of the ARP table using snooped DHCP information on an IES or VPRN (VPRN is supported on the 7750 SR only) interface:

```
A:ALA-1>config>service>ies>if# info
-----
      arp-populate
      dhcp
        description "snooping_only"
        lease-populate 1
        no shutdown
      exit
-----
A:ALA-1>config>service>ies>if#

A:ALA-1>config>service>vprn>if# info
-----
      dhcp
        description "test"
        lease-populate 1
        no shutdown
      exit
-----
A:ALA-1>config>service>ies>if#
```

7.3.1.3.6 Configuring CPU Protection

CPU Protection can be used to protect the SR OS in subscriber management scenarios. Refer to the SR OS System Management Guide for information about CPU Protection operation and configuration.

7.3.1.4 Configuring Web Portal Redirect

The generic CLI structure for defining and applying IP and MAC filters is described in the Router Configuration Guide.

The following example displays an IP filter entry configuration for web-portal redirect:

```
A:ALA-A>config>filter# info
-----
      ip-filter 10 create
        description "filter to forward DNS and web traffic to my portal; redirect al
1
other web traffic to the portal and drop everything else"
        default-action drop
```

```
entry 10 create
    description "allows DNS traffic"
    match protocol 17
    dst-port 53
    exit
    action forward
exit
entry 20 create
    description "allows web traffic destined to portal (IP address 10.0.0.1)"
"
    match protocol 6
    dst-port eq 80
    dst-ip 10.0.0.1
    exit
    action forward
exit
entry 30
    description "redirects all web traffic to portal"
    match protocol 6
    dst-port eq 80
    exit
    action http-redirect http://www.myportal.com/defaultportal
/login.cgi?ip=$IP&mac=$MAC&orig_url=$URL&usb=$SUB
    exit
exit
-----
A:ALA-A>config>filter#
```

- Filter entry 10 in the example output allows the customer to access DNS to get the IP address of the original website they are trying to view.
- Entry 20 allows HTTP packets destined to the captive portal itself to be forwarded.

Note: The actual IP address (a.b.c.d) needs to be entered, not the DNS name ("www.myportal.com"). The IP address can be easily resolved from the 7450 ESS or 7750 SR CLI using the "ping" command.

- Entry 30 (which is the last option that does not drop the customer packets) checks for HTTP protocol and then starts the redirection process:
 - The 7450 ESS or 7750 SR will intercept the HTTP GET from the subscriber and respond with an HTTP 302 (temporarily moved) with the URL configured in the filter entry. This URL can contain some variables, notably the customer IP and MAC addresses to allow the portal to create an entry for the customer. The original requested URL is also included to redirect the client site back to the original requested site when the process is done.
 - The client will then close the connection with the original IP address and open a connection to the redirected server. Entry 20 will allow this connection.

The following displays how the redirection filter configured above is assigned to an ingress SAP:

```
A:ALA-A>config>service>vpls# info
-----
vpls 3 customer 6 create
  description "VPLS with web portal redirection filter applied"
  sap 2/1/5:0 create
    ingress
      filter ip 10
    exit
  exit
  no shutdown
exit
-----
A:ALA-A>config>service>vpls#
```

7.4 Triple Play Security Command Reference

7.4.1 Command Hierarchies

- [Anti-Spoofing Commands](#)
- [Layer 2 Security Commands](#)
- [ARP Handling Commands](#)
- [Tools Commands](#)

Note: This command tree is limited to those commands specific to Triple Play security. For the full command trees of a particular service type, consult the Services Overview Guide.

7.4.1.1 Anti-Spoofing Commands

```
config
  — service
    — vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls]
      — sap sap-id [split-horizon-group group-name]
        — anti-spoof {ip | mac | ip-mac}
        — no anti-spoof
```

```
config
  — service
    — ies service-id [customer customer-id] [vpn vpn-id]
      — [no] interface ip-int-name
        — sap sap-id
          — anti-spoof {ip | mac | ip-mac}
          — no anti-spoof
      — subscriber-interface
        — group-interface ip-int-name
          — sap sap-id
            — anti-spoof {ip | ip-mac}
            — no anti-spoof
```

7.4.1.2 Layer 2 Security Commands

```
config
  — service
    — [no] vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls]
      — mac-protect
```

- [no] **mac** *[ieee-mac-address]*
- [no] **split-horizon-group** *[group-name]* [residential-group]
 - [no] **restrict-protected-src** [alarm-only | discard-frame]
 - [no] **restrict-unprotected-dst**
- **mesh-sdp** *sdp-id[:vc-id]* [vc-type {ether | vlan}]
 - [no] **mac-pinning**
 - [no] **restrict-protected-src** [alarm-only | discard-frame]
 - [no] **restrict-unprotected-dst**
- **spoke-sdp** *sdp-id[:vc-id]* [vc-type {ether | vlan | vpls}] [split-horizon-group group-name]
 - [no] **mac-pinning**
 - [no] **restrict-protected-src** [alarm-only | discard-frame]
 - [no] **restrict-unprotected-dst**

7.4.1.3 ARP Handling Commands

```

config
— service
    — [no] vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls]
    — sap sap-id
        — arp-reply-agent [sub-ident]
        — no arp-reply-agent

config
— service
    — ies service-id [customer customer-id] [vpn vpn-id]
    — [no] interface ip-int-name
        — [no] arp-populate
        — arp-timeout seconds
        — no arp-timeout
        — [no] local-proxy-arp
        — proxy-arp-policy policy-name [policy-name...(up to 5 max)]
        — no proxy-arp-policy

7.4.2 Command Descriptions

7.4.2.1 Triple Play Security Configuration Commands

Topics in this section include:

- [Triple Play Anti-Spoofing Commands](#)
- [Triple Play Layer 2 Security Commands](#)
- [ARP Handling Commands](#)
- [Show Commands](#)

7.4.2.1.1 Triple Play Anti-Spoofing Commands

anti-spoof

Syntax	anti-spoof {ip mac ip-mac} no anti-spoof
Context	config>service>ies>if>sap config>service>vpls>sap config>service>vprn>if>sap
Description	<p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (ip, mac, ip-mac) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The no form of the command disables anti-spoof filtering on the SAP.</p>
Default	no anti-spoof
Parameters	<p>ip — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof ip command will fail.</p> <p>mac — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. If a static host exists on the SAP without a specified MAC address, the anti-spoof mac command will fail.</p> <p>ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup.</p>

anti-spoof

Syntax	anti-spoof {ip ip-mac} no anti-spoof
Context	config>service>ies>>sub-if>grp-if>sap
Description	<p>This command enables anti-spoof filtering and optionally change the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (ip, ip-mac) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The no form of the command disables anti-spoof filtering on the SAP.</p>
Default	no anti-spoof
Parameters	<p>ip — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof ip command will fail.</p> <p>ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup.</p>

7.4.2.1.2 Triple Play Layer 2 Security Commands

split-horizon-group

Syntax	[no] split-horizon-group <i>[group-name]</i> <i>[residential-group]</i>
Context	config>service>vpls
Description	<p>This command creates a new split horizon group for the VPLS instance. Traffic arriving on a SAP or spoke SDP within this split horizon group will not be copied to other SAPs or spoke SDPs in the same split horizon group.</p> <p>A split horizon group must be created before SAPs and spoke SDPs can be assigned to the group.</p> <p>The split horizon group is defined within the context of a single VPLS. The same group-name can be re-used in different VPLS instances.</p> <p>Up to 30 split horizon groups can be defined per VPLS instance.</p> <p>The no form of the command removes the group name from the configuration.</p>
Default	A split horizon group is by default not created as a residential-group.

Parameters	<p><i>group-name</i> — Specifies the name of the split horizon group to which the SDP belongs.</p> <p><i>residential-group</i> — Defines a split horizon group as a residential split horizon group (RSHG). Doing so entails that:</p> <ol style="list-style-type: none"> SAPs which are members of this Residential Split Horizon Group will have: <ul style="list-style-type: none"> Double-pass queuing at ingress as default setting (can be disabled) STP disabled (can not be enabled) ARP reply agent enabled per default (can be disabled) MAC pinning enabled per default (can be disabled) Besides the multicast downstream also broadcast packets are discarded thus also blocking the unknown, flooded traffic. Spoke SDPs which are members of this Residential Split Horizon Group will have: <ul style="list-style-type: none"> Downstream multicast traffic supported Double-pass queuing is not applicable STP is disabled (can be enabled) ARP reply agent is not applicable (dhcp-lease-states are not supported on spoke SDPs) MAC pinning enabled per default (can be disabled)
-------------------	--

mac-protect

Syntax	mac-protect
Context	config>service>vpls
Description	This command indicates whether or not this MAC is protected on the MAC protect list. When enabled, the agent will protect the MAC from being learned or re-learned on a SAP, spoke SDP or mesh-SDP that has restricted learning enabled. The MAC protect list is used in conjunction with restrict-protected-src , restrict-unprotected-dst and auto-learn-mac-protect .
Default	disabled

mac

Syntax	[no] mac <i>ieee-address</i>
Context	config>service>vpls>mac-protect
Description	This command specifies the 48-bit IEEE 802.3 MAC address.
Parameters	<i>ieee-address</i> — Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers.

auto-learn-mac-protect

Syntax	[no] auto-learn-mac-protect
Context	config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp config>service>vpls>split-horizon-group config>service>vpls>endpoint config>service>pw-template config>service>pw-template>split-horizon-group
Description	<p>This command enables the automatic protection of source MAC addresses learned on the associated object. MAC protection is used in conjunction with restrict-protected-src, restrict-unprotected-dst and mac-protect. When this command is applied or removed, the MAC addresses are cleared from the related object.</p> <p>When the auto-learn-mac-protect is enabled on an SHG the action only applies to the associated SAPs (no action is taken by default for spoke SDPs in the SHG). In order to enable this function for spoke SDPs within a SHG, the auto-learn-mac-protect must be enabled explicitly under the spoke SDP. If required, auto-learn-mac-protect can also be enabled explicitly under specific SAPs within the SHG.</p>
Default	no auto-learn-mac-protect

restrict-protected-src

Syntax	restrict-protected-src [alarm-only discard-frame] no restrict-protected-src
Context	config>service>vpls>sap config>service>vpls>spoke-sdp config>service>vpls>mesh-sdp config>service>vpls>split-horizon-group config>service>vpls>endpoint config>service>pw-template> config>service>pw-template>split-horizon-group
Description	<p>This command indicates how the agent will handle relearn requests for protected MAC addresses, either manually added using the mac-protect command or automatically added using the auto-learn-mac-protect command. While enabled all packets entering the configured SAP, spoke SDP, mesh SDP, or any SAP that is part of the configured split horizon group (SHG) will be verified not to contain a protected source MAC address. If the packet is found to contain such an address, the action taken depends on the parameter specified on the restrict-protected-src command, namely:</p> <ul style="list-style-type: none">• No parameter

The packet will be discarded, an alarm will be generated and the SAP, spoke-SDP or mesh-SDP will be set operationally down. The SAP, spoke-SDP or mesh-SDP must be shutdown and enabled (no shutdown) for this state to be cleared.

- alarm-only

The packet will be forwarded, an alarm will be generated but the source MAC is not learned on the SAP/spoke-SDP/mesh-SDP.

- discard-frame

The packet will be discarded and an alarm generated. The frequency of alarm generation is fixed to be at most one alarm per MAC address per FP2 per 10 minutes in a given VPLS service. This parameter is only applicable to automatically protected MAC addresses.

When the **restrict-protected-src** is enabled on an SHG the action only applies to the associated SAPs (no action is taken by default for spoke SDPs in the SHG) and is displayed in the SAP show output as the oper state unless it is overridden by the configuration of **restrict-protected-src** on the SAP itself. In order to enable this function for spoke SDPs within a SHG, the **restrict-protected-src** must be enabled explicitly under the spoke SDP. If required, **restrict-protected-src** can also be enabled explicitly under specific SAPs within the SHG.

When this command is applied or removed, with either the **alarm-only** or **discard-frame** parameters, the MAC addresses are cleared from the related object.

The use of **restrict-protected-src discard-frame** is mutually exclusive with the configuration of manually protected MAC addresses within a given VPLS.

The **discard-frame** parameter can only be enabled on SAPs on FP2 or later hardware, or on SDPs where all network interfaces are on FP2 or later hardware.

The **alarm-only** parameter is not supported on the 7750 SR-a, 7750 SR-1e/2e/3e.

Default no restrict-protected-src

Parameters **alarm-only** — Specifies that the packet will be forwarded, an alarm will be generated but the source MAC is not learned on the SAP/spoke-SDP/mesh-SDP.

Default no alarm-only

discard-frame — Specifies that the packet will be discarded and an alarm generated. The frequency of alarm generation is fixed to be at most one alarm per FP2 per MAC address per 10 minutes within a given VPLS service.

Default no discard-frame

restrict-unprotected-dst

Syntax **restrict-unprotected-dst**
no restrict-unprotected-dst

Context config>service>pw-template>split-horizon-group

```
config>service>vpls>split-horizon-group
config>service>vpls>sap
```

Description This command indicates how the system will forward packets destined to an unprotected MAC address, either manually added using the `mac-protect` command or automatically added using the `auto-learn-mac-protect` command. While enabled all packets entering the configured SAP or SAPs within a `split-horizon-group` (but not spoke or mesh-SDPs) will be verified to contain a protected destination MAC address. If the packet is found to contain a non-protected destination MAC, it will be discarded. Detecting a non-protected destination MAC on the SAP will not cause the SAP to be placed in the operationally down state. No alarms are generated.

If the destination MAC address is unknown, even if the packet is entering a restricted SAP, with `restrict-unprotected-dst` enabled, it will be flooded.

Default no restrict-unprotected-dst

mac-pinning

Syntax [no] **mac-pinning**

Context config>service>vpls>sap
config>service>vpls>spoke-sdp
config>service>vpls>mesh-sdp

Description Enabling this command will disable re-learning of MAC addresses on other SAPs within the VPLS. The MAC address will remain attached to a given SAP for duration of its age-timer.

The age of the MAC address entry in the FIB is set by the age timer. If **mac-aging** is disabled on a given VPLS service, any MAC address learned on a SAP/SDP with **mac-pinning** enabled will remain in the FIB on this SAP/SDP forever.

Every event that would otherwise result in re-learning will be logged (MAC address; original-SAP; new-SAP).

Note: MAC addresses learned during DHCP address assignment (DHCP snooping enabled) are not impacted by this command. MAC-pinning for such addresses is implicit.

Default When a SAP or spoke SDP is part of a Residential Split Horizon Group (RSHG), MAC pinning is activated at creation of the SAP. Otherwise MAC pinning is not enabled by default.

7.4.2.1.3 ARP Handling Commands

arp-reply-agent

Syntax	arp-reply-agent [sub-ident] no arp-reply-agent
Context	config>service>vpls>sap
Description	<p>This command enables a special ARP response mechanism in the system for ARP requests destined to static or dynamic hosts associated with the SAP. The system responds to each ARP request using the host's MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header.</p> <p>ARP replies and requests received on a SAP with arp-reply-agent enabled will be evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP will be discarded when anti-spoof filtering is enabled.</p> <p>The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke-SDP or mesh-SDP) associated with the VPLS instance of the SAP.</p> <p>A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.</p> <p>Static hosts can be defined on the SAP using the host command. Dynamic hosts are enabled on the system by enabling the lease-populate command in the SAP's dhcp context. In the event that both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. In the event that both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.</p> <p>The arp-reply-agent command will fail if an existing static host on the SAP does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the SAP without both an IP address and MAC address will fail.</p> <p>The ARP-reply-agent may only be enabled on SAPs supporting Ethernet encapsulation.</p> <p>The no form of the command disables ARP-reply-agent functions for static and dynamic hosts on the SAP.</p>
Default	not enabled
Parameters	<i>sub-ident</i> — Configures the arp-reply-agent to discard ARP requests received on the SAP that are targeted for a known host on the same SAP with the same subscriber identification.

Hosts are identified by their subscriber information. For DHCP subscriber hosts, the subscriber hosts, the subscriber information is configured using the optional subscriber parameter string.

When arp-reply-agent is enabled with **sub-ident**:

- If the subscriber information for the destination host exactly matches the subscriber information for the originating host and the destination host is known on the same SAP as the source, the ARP request is silently discarded.
- If the subscriber information for the destination host or originating host is unknown or undefined, the source and destination hosts are not considered to be the same subscriber. The ARP request is forwarded outside the SAP's Split Horizon Group.
- When **sub-ident** is not configured, the arp-reply-agent does not attempt to identify the subscriber information for the destination or originating host and will not discard an ARP request based on subscriber information.

arp-populate

Syntax [no] arp-populate

Context config>service>ies>interface
config>service>ies>subscriber-int

Description This command, when enabled, disables dynamic learning of ARP entries. Instead, the ARP table is populated with dynamic entries from the DHCP lease state table (enabled with **lease-populate**), and optionally with static entries entered with the **host** command.

Enabling the **arp-populate** command will remove any dynamic ARP entries learned on this interface from the ARP cache.

The **arp-populate** command will fail if an existing static ARP entry exists for this interface.

The **arp-populate** command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.

Once **arp-populate** is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.

When **arp-populate** is enabled, the system will not send out ARP requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with **arp-populate** enabled. The **arp-populate** command can only be enabled on IES and VPRN interfaces supporting Ethernet encapsulation (VPRN is supported by the 7750 SR only).

Use the **no** form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information for this interface will be removed from the system's ARP cache.

Default not enabled

arp-timeout

Syntax	arp-timeout <i>seconds</i> no arp-timeout
Context	config>service>ies>interface config>service>ies>sub-if>grp-if
Description	<p>This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If arp-timeout is set to a value of zero seconds, ARP aging is disabled.</p> <p>When the arp-populate and lease-populate commands are enabled on an IES interface, the ARP table entries will no longer be dynamically learned, but instead by snooping DHCP ACK message from a DHCP server. In this case the configured arp-timeout value has no effect.</p> <p>The default value for arp-timeout is 14400 seconds (4 hours).</p> <p>The no form of this command restores arp-timeout to the default value.</p>
Default	14400 seconds
Parameters	<i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.
Values	0 — 65535

authentication-policy

Syntax	authentication-policy <i>name</i> no authentication-policy
Context	config>service>ies>sub-if>grp-if
Description	<p>This command assigns a RADIUS authentication policy to the interface.</p> <p>The no form of this command removes the policy name from the group interface configuration.</p>
Default	no authentication-policy
Parameters	<i>name</i> — Specifies the authentication policy name.

host-connectivity-verify

Syntax	host-connectivity-verify [<i>interval interval</i>] [<i>action {remove alarm}</i>] [<i>timeout retry-timeout</i>] [<i>retry-count count</i>] [<i>family family</i>]
---------------	--

Context	config>service>ies>sub-if>grp-if config>service>vprn>sub-if>grp-if
Description	This command enables subscriber host connectivity verification for all hosts on this interface. This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.
Default	no host-connectivity-verify
Parameters	<p>interval <i>interval</i> — The interval, expressed in minutes, which specifies the time interval at which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p>Values 1 — 6000 A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p>timeout <i>retry-timeout</i> — Specifies the timeout, in seconds, before a retransmission in the periodic connectivity verification.</p> <p>Values 10 — 60 A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p>retry <i>count</i> — Specifies the number of retransmissions in a periodic connectivity verification.</p> <p>Values 2 — 29 A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p>action {remove alarm} — Defines the action taken on a subscriber host connectivity verification failure for a given host. The remove keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries and etc.). DHCP release will be signaled to corresponding DHCP server. Static hosts will be never removed. The alarm keyword raises an alarm indicating that the host is disconnected.</p> <p>family <i>family</i> — The family configuration allows the host connectivity checks to be performed for IPv4 endpoint, IPv6 endpoint or both. With family IPv6 configured, host connectivity checks will be performed on the global unicast address (assigned via SLAAC or DHCPv6 IA_NA) and link-local address of a Layer 3 RG or bridged hosts. In case of SLAAC assignment, host connectivity can only be performed if the /128 is known (via downstream ND). DHCPv6 PD assigned prefixes will be removed if link-local address is determined to be unreachable via “host connectivity check”. Reachability checks for GUA and link-local address will be done simultaneously.</p>

local-proxy-arp

Syntax [no] local-proxy-arp

Context	config>service>ies>interface config>service>ies>sub-if>grp-if
Description	This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked.
Default	no local-proxy-arp

remote-proxy-arp

Syntax	[no] remote-proxy-arp
Context	config>service>ies>interface
Description	This command enables or disables remote proxy ARP on the interface.
Default	no remote-proxy-arp

qos-route-lookup

Syntax	[no] qos-route-lookup
Context	config>service>ies>sub-if>grp-if config>service>ies>sub-if>grp-if>ipv6
Description	This command enables or disables QoS route lookup for the interface.

proxy-arp-policy

Syntax	proxy-arp-policy <i>policy-name</i> [<i>policy-name...</i> (up to 5 max)] no proxy-arp-policy
Context	config>service>ies>interface config>service>ies>sub-if>grp-if
Description	This command specifies an existing policy-statement to analyze match and action criteria that controls the flow of routing information to and from a given protocol, set of protocols, or a particular neighbor.
Default	none

Parameters *policy-name* — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

The specified name(s) must already be defined.

static-arp

Syntax **static-arp** *ip-address* *ieee-mac-address*
no static-arp *ip-address* [*ieee-mac-address*]

Context config>service>ies>interface

Description This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP appears in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface.

If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.

The **no** form of the command removes a static ARP entry.

Default None

Parameters *ip-address* — Specifies the IP address for the static ARP in IP address dotted decimal notation.

ieee-mac-address — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

7.4.2.2 Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

arp

Syntax **arp**

Context show>service>id

Description This command displays the ARP cache entries for this service.

Output Show All Service-ID Output

The following table describes the show command output fields:

Table 50 Security ARP Field Descriptions

Label	Description
IP Address	Specifies the IP address of the ARP cache entry.
MAC Address	Specifies the MAC address associated with the IP address.
Type	Other Learned through normal ARP queries.
	Static Configured by static-arp commands.
	Managed Learned from DHCP snooping or configured by host commands.
Age	Indicates age of the ARP entry.
Interface	Indicates the name of the IP interface.
Port	Indicates the port that the entry was learned on.

Sample Output

7.4.2.3 Tools Commands

authentication-server-check

Syntax **authentication-server-check server-address** *ip-address* [**port** *port*] {{**user-name** *user-*

name **password** *password*} | **attr-from-file** *file-url*} **secret** *key* [**source-address** *ip-address*] [**timeout** *seconds*] [**router** *router-instance*] | **service-name** *service-name*] [**debug**]

Context tools>perform>security

Description This command is used to perform an authentication check on the RADIUS server.

Parameters **server-address** *ip-address* — the IP address of the RADIUS server
port — the port of the RADIUS server

Values 1 to 65535

user-name — the user name, up to 253 characters

password — the user password, up to 64 characters

file-url — specifies to attach additional VSAs from a file

Values

local-url: [*clflash-id*] [*file-path*]

200 characters maximum, including clflash-id directory length maximum 99 characters each

remote-url: [{ftp://|tftp://}<login>:<pswd>@<remote-locn>/][<file-path>]

255 characters maximum, directory length maximum 99 characters each

remote-locn: [<hostname> | <ipv4-address> | <ipv6-address>]

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x[-interface]

x:x:x:x:x:d.d.d.d[-interface]

x - [0..FFFF]H

d - [0..255]D

interface - 32 chars max, for link local addresses

clflash-id: cf1:, cf1-A:, cf1-B:, cf2:, cf2-A:, cf2-B:, cf3:, cf3-A:, cf3-B:

key — the secret key shared between the RADIUS client and server, up to 20 characters

source address *ip-address* — the source address used for the access-request message

Values

ipv4-address a.b.c.d

ipv6-address x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

seconds — the time to wait for the RADIUS server response

Values 1 to 90

router-instance — the router instance that should be used by the access request message

Values

router-name | *vprn-svc-id*

router-name Base, management

Default - Base

vprn-svc-id 1 to 2147483647

service-name — the service name that should be used by the access request message, up to 64 characters

debug — specifies to display the full debug message, including all VSAs and full hex sting, of the RADIUS reply message

8 Triple Play Multicast

8.1 In This Chapter

This chapter provides information about Triple Play Multicast aspects, including configuration process overview, and implementation notes.

Topics in this chapter include:

8.2 Introduction to Multicast

IP multicast provides an effective method of many-to-many communication. Delivering unicast datagrams is fairly simple. Normally, IP packets are sent from a single source to a single recipient. The source inserts the address of the target host in the IP header destination field of an IP datagram, intermediate routers (if present) simply forward the datagram towards the target in accordance with their respective routing tables.

Sometimes distribution needs individual IP packets be delivered to multiple destinations (like audio or video streaming broadcasts). Multicast is a method of distributing datagrams sourced from one (or possibly more) host(s) to a set of receivers that may be distributed over different (sub) networks. This makes delivery of multicast datagrams significantly more complex.

Multicast sources can send a single copy of data using a single address for the entire group of recipients. The routers between the source and recipients route the data using the group address route. Multicast packets are delivered to a multicast group. A multicast group specifies a set of recipients who are interested in a particular data stream and is represented by an IP address from a specified range. Data addressed to the IP address is forwarded to the members of the group. A source host sends data to a multicast group by specifying the multicast group address in datagram's destination IP address. A source does not have to register in order to send data to a group nor do they need to be a member of the group.

Routers and Layer 3 switches use the Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) to manage membership for a multicast session. When a host wants to receive one or more multicast sessions, it will send a join message for each multicast group it wants to join. When a host wants to leave a multicast group, it will send a leave message.

8.3 Multicast in the Broadband Service Router

This section describes the multicast protocols employed when a Nokia router is used as a Broadband Service Router (BSR) in a Triple Play aggregation network.

The protocols used are:

- Internet Group Management Protocol ([Internet Group Management Protocol](#))
- Multicast Listener Discovery ([Multicast Listener Discovery](#))
- Source Specific Multicast Groups ([Internet Group Management Protocol](#))
- Protocol Independent Multicast (Sparse Mode) ([Protocol Independent Multicast Sparse Mode \(PIM-SM\)](#))

8.3.1 Internet Group Management Protocol

Internet Group Management Protocol (IGMP) is used by IPv4 hosts and routers to report their IP multicast group memberships to neighboring multicast routers. A multicast router keeps a list of multicast group memberships for each attached network, and a timer for each membership.

Multicast group memberships include at least one member of a multicast group on a given attached network, not a list of all of the members. With respect to each of its attached networks, a multicast router can assume one of two roles, querier or non-querier. There is normally only one querier per physical network.

A querier issues two types of queries, a general query and a group-specific query. General queries are issued to solicit membership information with regard to any multicast group. Group-specific queries are issued when a router receives a leave message from the node it perceives as the last group member remaining on that network segment.

Hosts wanting to receive a multicast session issue a multicast group membership report. These reports must be sent to all multicast enabled routers.

8.3.1.1 IGMP Versions and Interoperability Requirements

If routers run different versions of IGMP, they will negotiate the lowest common version of IGMP that is supported on their subnet and operate in that version.

Version 1 — Specified in RFC-1112, *Host extensions for IP Multicasting*, was the first widely deployed version and the first version to become an Internet standard.

Version 2 — Specified in RFC-2236, *Internet Group Management Protocol*, added support for low leave latency, that is, a reduction in the time it takes for a multicast router to learn that there are no longer any members of a particular group present on an attached network.

Version 3 — Specified in RFC-3376, *Internet Group Management Protocol*, adds support for source filtering, that is, the ability for a system to report interest in receiving packets only from specific source addresses, as required to support Source-Specific Multicast (See Source Specific Multicast (SSM)), or from all but specific source addresses, sent to a particular multicast address.

IGMPv3 must keep state per group per attached network. This group state consists of a filter-mode, a list of sources, and various timers. For each attached network running IGMP, a multicast router records the desired reception state for that network.

8.3.1.2 IGMP Version Transition

Nokia's SRs are capable of interoperating with routers and hosts running IGMPv1, IGMPv2, and/or IGMPv3. *Draft-ietf-magma-igmpv3-and-routing-0x.txt* explores some of the interoperability issues and how they affect the various routing protocols.

IGMP version 3 specifies that if at any point a router receives an older version query message on an interface that it must immediately switch into a compatibility mode with that earlier version. Since none of the previous versions of IGMP are source aware, should this occur and the interface switch to Version 1 or 2 compatibility mode, any previously learned group memberships with specific sources (learned from the IGMPv3 specific INCLUDE or EXCLUDE mechanisms) MUST be converted to non-source specific group memberships. The routing protocol will then treat this as if there is no EXCLUDE definition present.

8.3.2 Multicast Listener Discovery

Multicast Listener Discovery (MLD) is used by IPv6 hosts and routers to report their IP multicast group memberships to neighboring multicast routers. A multicast router keeps a list of multicast group memberships for each attached network, and a timer for each membership. Multicast group memberships include at least one member of a multicast group on a given attached network, not a list of all of the members. With respect to each of its attached networks, a multicast router can assume one of two roles, querier or non-querier. There is normally only one querier per physical network.

A querier issues two types of queries, a general query and a group-specific query. General queries are issued to solicit membership information with regard to any multicast group. Group-specific queries are issued when a router receives a leave message from the node it perceives as the last group member remaining on that network segment.

Hosts wanting to receive a multicast session issue a multicast group membership report. These reports must be sent to all multicast enabled routers.

8.3.2.1 MLD Versions and Interoperability Requirements

If routers run different versions of MLD, they will negotiate the lowest common version of MLD that is supported on their subnet and operate in that version.

Version 1 — Specified in RFC 2710, *Multicast Listener Discovery (MLD) for IPv6*, was the first deployed version and included low leave latency, that is, a reduction in the time it takes for a multicast router to learn that there are no longer any members of a particular group present on an attached network.

Version 2 — Specified in RFC 3810, *Multicast Listener Discovery Version 2 (MLDv2) for IPv6*, adds support for source filtering, that is, the ability for a system to report interest in receiving packets only from specific source addresses, as required to support Source-Specific Multicast.

Multicast (SSM)), or from all but specific source addresses, sent to a particular multicast address. MLDv2 must keep state per group per attached network. This group state consists of a filter mode, a list of sources, and various timers. For each attached network running MLD, a multicast router records the desired reception state for that network.

8.3.2.2 Source Specific Multicast Groups

IGMPv3 and MLDv2 permits a receiver to join a group and specify that it only wants to receive traffic for a group if that traffic comes from a particular source. If a receiver does this, and no other receiver on the LAN requires all the traffic for the group, then the Designated Router (DR) can omit performing a (*,G) join to set up the shared tree, and instead issue a source-specific (S,G) join only.

For IPv4, the range of multicast addresses from 232.0.0.0 to 232.255.255.255 is currently set aside for source-specific multicast. For groups in this range, receivers should only issue source specific IGMPv3 joins. If a PIM router receives a non-source-specific join for a group in this range, it should ignore it.

For IPv6, the multicast prefix FF3x::/32 is currently set aside for source-specific multicast. For groups in this range, receivers should only issue source specific MLDv2 joins. If a PIM router receives a non-source-specific join for a group in this range, it should ignore it.

A Nokia PIM router must silently ignore a received (*, G) PIM join message where G is a multicast group address from the multicast address group range that has been explicitly configured for SSM. This occurrence should generate an event. If configured, the IGMPv2 (MLDv1 for IPv6) request can be translated into IGMPv3 (MLDv2 for IPv6). The SR allows for the conversion of an IGMPv2 (*,G) request into a IGMPv3 (S,G) request based on manual entries. A maximum of 32 SSM ranges is supported.

IGMPv3 and MLDv2 also permits a receiver to join a group and specify that it only wants to receive traffic for a group if that traffic does not come from a specific source or sources. In this case, the DR will perform a (*,G) join as normal, but can combine this with a prune for each of the sources the receiver does not wish to receive.

8.3.3 Protocol Independent Multicast Sparse Mode (PIM-SM)

PIM-SM leverages the unicast routing protocols that are used to create the unicast routing table: OSPF, IS-IS, BGP, and static routes. Because PIM uses this unicast routing information to perform the multicast forwarding function it is effectively IP protocol independent. Unlike DVMRP, PIM does not send multicast routing tables updates to its neighbors.

PIM-SM uses the unicast routing table to perform the Reverse Path Forwarding (RPF) check function instead of building up a completely independent multicast routing table.

PIM-SM only forwards data to network segments with active receivers that have explicitly requested the multicast group. PIM-SM in the ASM model initially uses a shared tree to distribute information about active sources. Depending on the configuration options, the traffic can remain on the shared tree or switch over to an optimized source distribution tree. As multicast traffic starts to flow down the shared tree, routers along the path determine if there is a better path to the source. If a more direct path exists, then the router closest to the receiver sends a join message toward the source and then reroutes the traffic along this path.

As stated above, PIM-SM relies on an underlying topology-gathering protocol to populate a routing table with routes. This routing table is called the Multicast Routing Information Base (MRIB). The routes in this table can be taken directly from the unicast routing table, or it can be different and provided by a separate routing protocol such as MBGP. Regardless of how it is created, the primary role of the MRIB in the PIM-SM protocol is to provide the next hop router along a multicast-capable path to each destination subnet. The MRIB is used to determine the next hop neighbor to whom any PIM join/prune message is sent. Data flows along the reverse path of the join messages. Thus, in contrast to the unicast RIB that specifies the next hop that a data packet would take to get to some subnet, the MRIB gives reverse-path information, and indicates the path that a multicast data packet would take from its origin subnet to the router that has the MRIB.

8.3.4 Ingress Multicast Path Management (IMPM) Enhancements

Refer to the SR OS Advanced Configuration Guide for more information on IMPM as well as detailed configuration examples.

Ingress multicast path management (IMPM) allows the system to dynamically manage Layer 2 and Layer 3 IP multicast flows into the available multicast paths through the switch fabric. The ingress multicast manager understands the amount of available multicast bandwidth per path and the amount of bandwidth used per IP multicast stream.

Two policies define how each path should be managed, the bandwidth policy, and how multicast channels compete for the available bandwidth, the multicast information policy.

Chassis multicast planes should not be confused with IOM/IMM multicast paths. The IOM/IMM uses multicast paths to reach multicast planes on the switch fabric. An IOM/IMM may have less or more multicast paths than the number of multicast planes available in the chassis.

Each IOM/IMM multicast path is either a primary or secondary path type. The path type indicates the multicast scheduling priority within the switch fabric. Multicast flows sent on primary paths are scheduled at multicast high priority while secondary paths are associated with multicast low priority.

The system determines the number of primary and secondary paths from each IOM/IMM forwarding plane and distributes them as equally as possible between the available switch fabric multicast planes. Each multicast plane may terminate multiple paths of both the primary and secondary types.

The system ingress multicast management module evaluates the ingress multicast flows from each ingress forwarding plane and determines the best multicast path for the flow. A particular path may be used until the terminating multicast plane is “maxed” out (based on the rate limit defined in the **per-mcast-plane-capacity** commands) at which time either flows are moved to other paths or potentially blackholed (flows with the lowest preference are dropped first). In this way, the system makes the best use of the available multicast capacity without congesting individual multicast planes.

The switch fabric is simultaneously handling both unicast and multicast flows. The switch fabric uses a weighted scheduling scheme between multicast high, unicast high, multicast low and unicast low when deciding which cell to forward to the egress forwarding plane next. The weighted mechanism allows some amount of unicast and lower priority multicast (secondary) to drain on the egress switch fabric links used by each multicast plane. The amount is variable based on the number of switch fabric planes available on the amount of traffic attempting to use the fabric planes. The **per-mcast-plane-capacity** commands allows the amount of managed multicast traffic to be tuned to compensate for the expected available egress multicast bandwidth per multicast plane. In conditions where it is highly desirable to prevent multicast plane congestion, the **per-mcast-plane-capacity** commands should be used to compensate for the non-multicast or secondary multicast switch fabric traffic.

8.4 Multicast in the BSA

IP Multicast is normally not a function of the Broadband Service Aggregator (BSA) in a Triple Play aggregation network being a Layer 2 device. However, the BSA does use IGMP snooping to optimize bandwidth utilization.

8.4.1 IGMP Snooping

For most Layer 2 switches, multicast traffic is treated like an unknown MAC address or broadcast frame, which causes the incoming frame to be flooded out (broadcast) on every port within a VLAN. While this is acceptable behavior for unknowns and broadcasts, as IP Multicast hosts may join and be interested in only specific multicast groups, all this flooded traffic results in wasted bandwidth on network segments and end stations.

IGMP snooping entails using information in layer 3 protocol headers of multicast control messages to determine the processing at layer 2. By doing so, an IGMP snooping switch provides the benefit of conserving bandwidth on those segments of the network where no node has expressed interest in receiving packets addressed to the group address.

On the 7450 ESS and 7750 SR, IGMP snooping can be enabled in the context of VPLS services. The IGMP snooping feature allows for optimization of the multicast data flow for a group within a service to only those Service Access Points (SAPs) and Service Distribution Points (SDPs) that are members of the group. In fact, the 7450 ESS and 7750 SR implementation performs more than pure snooping of IGMP data, since it also summarizes upstream IGMP reports and responds to downstream queries.

The 7450 ESS and 7750 SR maintain a number of multicast databases:

- A port database on each SAP and SDP lists the multicast groups that are active on this SAP or SDP.
- All port databases are compiled into a central proxy database. Towards the multicast routers, summarized group membership reports are sent based on the information in the proxy database.
- The information in the different port databases is also used to compile the multicast forwarding information base (MFIB). This contains the active SAPs and SDPs for every combination of source router and group address (S,G), and is used for the actual multicast replication and forwarding.

When the router receives a join report from a host for a particular multicast group, it adds the group to the port database and (if it is a new group) to the proxy database. It also adds the SAP or SDP to existing (S,G) in the MFIB, or builds a new MFIB entry.

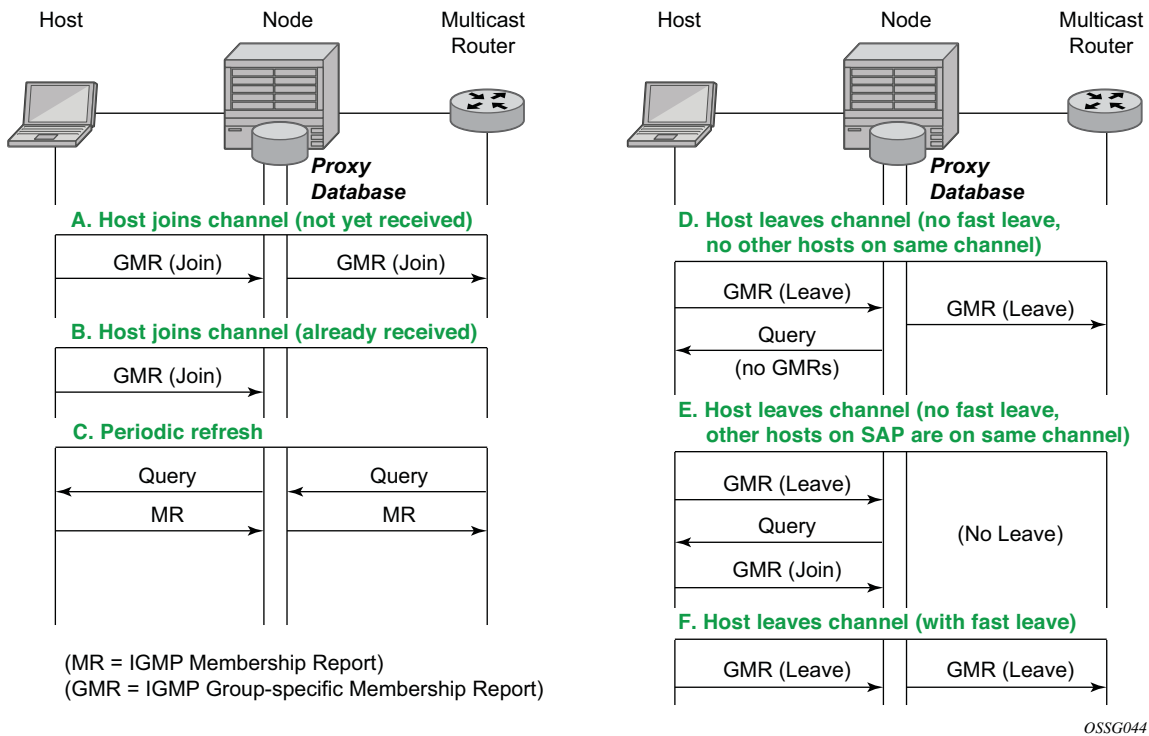

When the router receives a leave report from a host, it first checks if other devices on the SAP or SDP still want to receive the group (unless fast leave is enabled). Then it removes the group from the port database, and from the proxy database if it was the only receiver of the group. The router also deletes entries if it does not receive periodic membership confirmations from the hosts.

The fast leave feature finds its use in multicast TV delivery systems, for example. Fast Leave speeds up the membership leave process by terminating the multicast session immediately, rather than the standard procedure of issuing a group specific query to check if other group members are present on the SAP or SDP.

8.4.1.1 IGMP/MLD Message Processing

Figure 48 illustrates the basic IGMP message processing in several situations.

Figure 48 IGMP/MLD Message Processing

8.4.1.2 IGMP Message Processing

Scenario A: A host joins a multicast group (TV channel) which is not yet being received by other hosts on the router, and thus is not yet present in the proxy database. The 7450 ESS or 7750 SR adds the group to the proxy database and sends a new IGMP Join group-specific membership report upstream to the multicast router.

Scenario B: A host joins a channel which is already being received by one or more hosts on the router, and thus is already present in the proxy database. No upstream IGMP report is generated by the router.

Scenario C: The multicast router will periodically send IGMP queries to the router, requesting it to respond with generic membership reports. Upon receiving such a query, the router will compile a report from its proxy database and send it back to the multicast router.

In addition, the router will flood the received IGMP query to all hosts (on SAPs and spoke SDPs), and will update its proxy database based on the membership reports received back.

Scenario D: A host leaves a channel by sending an IGMP leave message. If fast-leave is not enabled, the router will first check whether there are other hosts on the same SAP or spoke SDP by sending a query. If no other host responds, the 7450 ESS or 7750 SR removes the channel from the SAP. In addition, if there are no other SAPs or spoke SDPs with hosts subscribing to the same channel, the channel is removed from the proxy database and an IGMP leave report is sent to the upstream Multicast Router.

Scenario E: A host leaves a channel by sending an IGMP leave message. If fast-leave is not enabled, the router will check whether there are other hosts on the same SAP or spoke SDP by sending a query. Another device on the same SAP or spoke SDP still wishes to receive the channel and responds with a membership report. Thus the router does not remove the channel from the SAP.

Scenario F: A host leaves a channel by sending an IGMP leave report. Fast-leave is enabled, so the router will not check whether there are other hosts on the same SAP or spoke SDP but immediately removes the group from the SAP. In addition, if there are no other SAPs or spoke SDPs with hosts subscribing to the same group, the group is removed from the proxy database and an IGMP leave report is sent to the upstream multicast router.

8.4.1.3 MLD Message Processing

MLD message processing differs from IGMP. An IPv6 host can have two WAN IPv6 addresses and an IPv6 prefix. MLD messages source address are link local addresses. This makes it difficult to know if the originating host is a WAN host or a PD host. By default, all requested IPv6 (s,g) are first associated with a WAN host. If this particular WAN host disconnects or ends its IPv6 session, the (s,g) is then associated with the remaining WAN host. If there are no more WAN hosts, the (s,g) is then associated with the remaining PD host. The (s,g) is always transferred to the remaining IPv6 host until there are no more report replies to corresponding to the queries. Scenarios A — F will not differ for IPv6 hosts.

8.4.1.4 IGMP/MLD Filtering

A provider may want to block receive or transmit permission to individual hosts or a range of hosts. To this end, the 7450 ESS and 7750 SR support IGMP/MLD filtering. Two types of filter can be defined:

- Filter IGMP/MLD membership reports from a particular host or range of hosts. This is performed by importing an appropriately defined routing policy into the SAP or spoke SDP.
- Filter to prevent a host from transmitting multicast streams into the network. The operator can define a data-plane filter (ACL) which drops all multicast traffic, and apply this filter to a SAP or spoke SDP.

8.4.2 Multicast VPLS Registration (MVR)

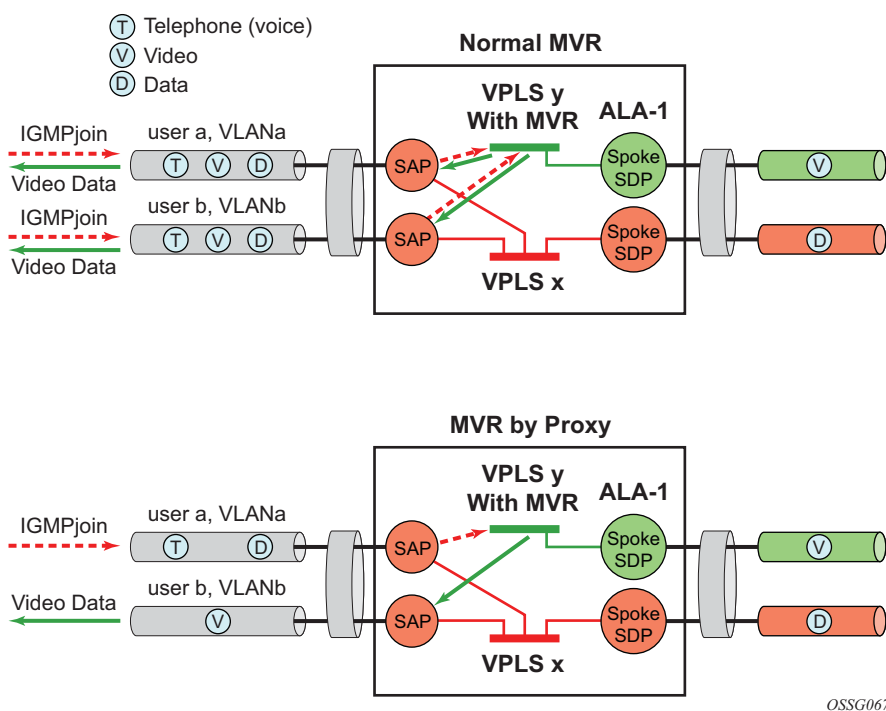

Multicast VPLS Registration (MVR) is a bandwidth optimization method for multicast in a broadband services network. MVR allows a subscriber on a port to subscribe and unsubscribe to a multicast stream on one or more network-wide multicast VPLS instances.

MVR assumes that subscribers join and leave multicast streams by sending IGMP join and leave messages. The IGMP leave and join message are sent inside the VPLS to which the subscriber port is assigned. The multicast VPLS is shared in the network while the subscribers remain in separate VPLS services. Using MVR, users on different VPLS cannot exchange any information between them, but still multicast services are provided.

On the MVR VPLS, IGMP snooping must be enabled. On the user VPLS, IGMP snooping and MVR work independently. If IGMP snooping and MVR are both enabled, MVR reacts only to join and leave messages from multicast groups configured under MVR. Join and leave messages from all other multicast groups are managed by IGMP snooping in the local VPLS. This way, potentially several MVR VPLS instances could be configured, each with its own set of multicast channels.

MVR by proxy — In some situations, the multicast traffic should not be copied from the MVR VPLS to the SAP on which the IGMP message was received (standard MVR behavior) but to another SAP. This is called MVR by proxy.

Figure 49 MVR and MVR by Proxy

8.4.3 Layer 3 Multicast Load Balancing

Layer 3 multicast load balancing establishes a more efficient distribution of Layer 3 multicast data over ECMP and LAG links. Operators have the option to redistribute multicast groups over ECMP and/or LAG links if the number of links changes either up or down.

When implementing this feature, there are several considerations. When multicast load balancing is not configured, the distribution remains as is. Multicast load balancing is based on the number of “s,g” groups. This means that bandwidth considerations are not taken into account. The multicast groups are distributed over the available links as joins are processed. When link failure occurs, the load is distributed on the failed channel to the remaining channels so multicast groups are evenly distributed over the remaining links. When a link is added (or failed link returned) all multicast joins on the added link(s) are allocated until a balance is achieved.

When multicast load balancing is configured, but the channels are not found in the multicast-info-policy, then multicast load balancing is based on the number of “s,g” groups. This means that bandwidth considerations are not taken into account. The multicast groups are distributed over the available links as joins are processed. The multicast groups are evenly distributed over the remaining links. When link failure occurs, the load is distributed on the failed channel to the remaining channels. When a link is added (or failed link returned) all multicast joins on the added link(s) are allocated until a balance is achieved. A manual redistribute command enables the operator to re-evaluate the current balance and, if required, move channels to different links to achieve a balance. A timed redistribute parameter allows the system to automatically, at regular intervals, redistribute multicast groups over available links. If no links have been added or removed from the ECMP/LAG interface, then no redistribution is attempted.

When multicast load balancing is configured, multicast groups are distributed over the available links as joins are processed based on bandwidth configured for the specified group address. If the bandwidth is not configured for the multicast stream then the configured default value is used.

If link failure occurs, the load is distributed on the failed channel to the remaining channels. The bandwidth required over each individual link is evenly distributed over the remaining links.

When an additional link is available for a given multicast stream, then it is considered in all multicast stream additions applied to the interface. This multicast stream is included in the next scheduled automatic rebalance run. A rebalance run re-evaluates the current balance with regard to the bandwidth utilization and if required, move multicast streams to different links to achieve a balance.

A rebalance, either timed or executing the **mc-ecmp-rebalance** command, should be administered gradually in order to minimize the effect of the rebalancing process on the different multicast streams. If multicast re-balancing is disabled and subsequently (re)enabled, keeping with the rebalance process, the gradual and least invasive method is used to minimize the effect of the changes to the customer.

By default multicast load balancing over ECMP links is enabled and set at 30 minutes.

The rebalance process can be executed as a low priority background task while control of the console is returned to the operator. When multicast load rebalancing is not enabled, then ECMP changes will not be optimized, however, when a link is added occurs an attempt is made to balance the number of multicast streams on the available ECMP links. This however may not result in balanced utilization of ECMP links.

Only a single **mc-ecmp-rebalance** command can be executed at any given time, if a rebalance is in progress and the command is entered, it is rejected with the message saying that a rebalance is already in progress. A low priority event is generated when an actual change for a given multicast stream occurs as a result of the rebalance process.

8.4.4 IGMP State Reporter

The target application for this feature is linear TV delivery. In some countries, wholesale Service Providers are obligated by the government regulation to provide information about channel viewership per subscriber to retailers.

A service provider (wholesaler or retailer) may use this information for:

- billing purposes
- market research/data mining to gain view into the most frequently watched channels, duration of the channel viewing, frequency of channel zapping by the time of the day, etc.

The information about channel viewership is based on IGMP states maintained per each subscriber host. Each event related to the IGMP state creation is recorded and formatted by the IGMP process. The formatted event is then sent to another task in the system (Exporter), which allocates a TX buffer and start a timer.

The event is then be written by the Exporter into the buffer. The buffer in essence corresponds to the packet that will contain a single event or a set of events. Those events are transported as data records over UDP transport to an external collector node. The packet itself has a header followed by a set of TLV type data structures, each describing a unique field within the IGMP event.

The packet is transmitted when it reaches a preconfigured size (1400bytes), or when the timer expires, whichever comes first.

Note: The timer started when the buffer was initially created.

The receiving end (collector node) accepts the data on the destination UDP port. It must be aware of the data format so that it can interpret incoming data accordingly. The implementation details of the receiving node are outside of the scope of this description and are left to the network operator.

The IGMP state recording per subscriber host must be supported for hosts which are replicating multicast traffic directly as well as for those host that are only keeping track of IGMP states for the HQoS Adjustment purpose. The latter will be implemented via redirection and not the Host Tracking (HT) feature as originally proposed. The IGMP reporting must differentiate events between direct replication and redirection.

It further distinguish events that are related to denial of IGMP state creation (due to filters, MCAC failure, etc.) and the ones that are related to removal of an already existing IGMP state in the system.

8.4.4.1 IGMP Data Records

Each IGMP state change generates a data record that is formatted by the IGMP task and written into the buffer. IGMP state transitions configured statically through CLI are not reported.

In order to minimize the size of the records when transported over the network, most fields in the data record are HEX coded (as opposed to ASCII descriptive strings).

Each data record has a common header as shown in [Figure 50](#):

Figure 50 Common IGMP Data Record Header

0983

Application:

- 0x01 - IGMP

- 0x02 - IGMP Host Tracking Event:

Event:

- Related to denial of a new state creation:
 - 0x01 – Join
 - 0x02 – (Join_Deny_Filter) Join denied due to filtering via an import policy
 - 0x03 – (Join_Deny_CAC) Join denied due to MCAC
 - 0x04 – (Join_Deny_MaxGrps) Join denied due to maximum groups per host limit reached
 - 0x05 – (Join_Deny_MaxSrcs) Join denied due to maximum sources limit reached
 - 0x06 - Join (Join_Deny_SysErr) Join denied due to an internal error (for example: out of memory)
- Related to removal of an existing IGMP state:
 - 0x07 - (Drop_Leave_Rx) IGMP state is removed due to the Leave message
 - 0x08 - (Drop_Expiry) IGMP state is removed due to time out (by default $2 * \text{query_interval} + \text{query_response_interval} = 260\text{sec}$)
 - 0x09 - (Drop_Filter) IGMP state is removed due to filter (import policy) change
 - 0x0A - (Drop_CfgChange) IGMP state is removed due to configuration change (clear grp, intf shutdown, PPPoE session goes unexpectedly down)
 - 0x0B - (Drop_CAC) an existing stream is stopped due to configuration change in MCAC

Length:

- The length of the entire data record (including the header and TLVs) in octets.

16 bit Sequence Number

- Since IGMP Reporting is based on connectionless transport (UDP), a 16 bit sequence numbers are used in each data record so that data loss in the network can be tracked.
- The 16 bit sequence number is located after the timestamp field. The sequence numbers will increase sequentially from 0 — 65535 and then rollover back to 0.

Timestamp:

- Timestamp is in Unix format (32 bit integer in seconds since 01/01/1970) plus an extra 8 bits for 10msec resolution.

TLVs describing the IGMP state record will have the following structure:

Figure 51 Data Record Field TLV Structure

Table 51 Data Record Field Description

Type	Description	Encoding/Length	Mandatory/Optional
0x02	Subscriber ID	ASCII	M
0x03	Sub Host IP	4 Bytes IPv4	M
0x04	Mcast Group IP	4 Bytes IPv4	M
0x05	Mcast Source IP	4 Bytes IPv4	M
0x06	Host MAC	6 Bytes	M
0x07	PPPoE Session-ID	2 Bytes	M
0x08	Service ID	4 Bytes	M
0x09	SAP ID	ASCII	M
0x0A	Redirection vRtrId	4 Bytes	M
0x0B	Redirection ifIndex	4 Bytes	M

The *redirection destination* TLV is a mandatory TLV that is sent only in cases where redirection is enabled. It contains two 32 bit integer numbers. The first number identifies the VRF where IGMPs are redirected; the second number identifies the interface index.

Optional fields can be included in the data records according to the configuration.

In IGMPv3, if an IGMP message (Join or Leave) contains multiple multicast groups or a multicast group contains multiple IP sources, only a single event is generated per group-source combination. In other words, data records are transmitted with a single source IP address and multiple mcast group addresses or a single multicast group address with multiple source IP addresses, depending on the content of the IGMP message. (*,G)

8.4.4.2 Transport Mechanism

Data is transported via UDP socket. Destination IP address, the destination port and the source IP address are configurable. The default UDP source and destination port number is 1037.

Upon the arrival of an IGMP event, the Exporter allocates a buffer for the packet (if not already allocated) and starts writing the events into the buffer (packet). Along with the initial buffer creation, a timer is started. The trigger for the transmission of the packet is either the TX buffer being filled up to 1400B (hard coded value), or the timer expiry, whichever comes first.

The source IP address is configurable within GRT (by default system IP), and the destination IP address can be reachable only via GRT. The source IP address is modified via **system>security>source-address>application** CLI hierarchy.

The receiving end (the collector node) collects the data and process them according to the formatting rules defined in this document. The capturing and processing of the data on the collector node is outside of the context of this description.

It should be noted that the processing node will need to have sufficient resources to accept and process packets that contain information about every IGMP state change for every host from a set of network BRASes that are transporting data to this particular collector node.

Multicast Reporter traffic will be marked as BE (all 6 DSCP bits are set to 0) exiting our system.

8.4.4.3 HA Compliance

IGMP Events are synchronized between two CPMs before they are transported out of the system.

8.4.4.4 QoS Awareness

IGMP Reporter is a client of sgt-qos so that DSCP/dot1p bits can be appropriately be marked when egressing the system.

8.4.4.5 Hardware Support

The following hardware is supported on the 7750 platform.

IOM support: IOM3, HSMDAv2, Ethernet based non HS-MDAs

Chassis mode: B, C, and D.

8.4.4.6 IGMP Reporting Caveats

The following are not supported:

- Regular (non-subscriber) interfaces
- SAM support as the collector device

8.5 Multicast Support over Subscriber Interfaces in Routed CO Model

Applications for multicast over Subscriber Interfaces in Routed CO ESM model can be divided in two main categories:

Residential customers where the driver applications are:

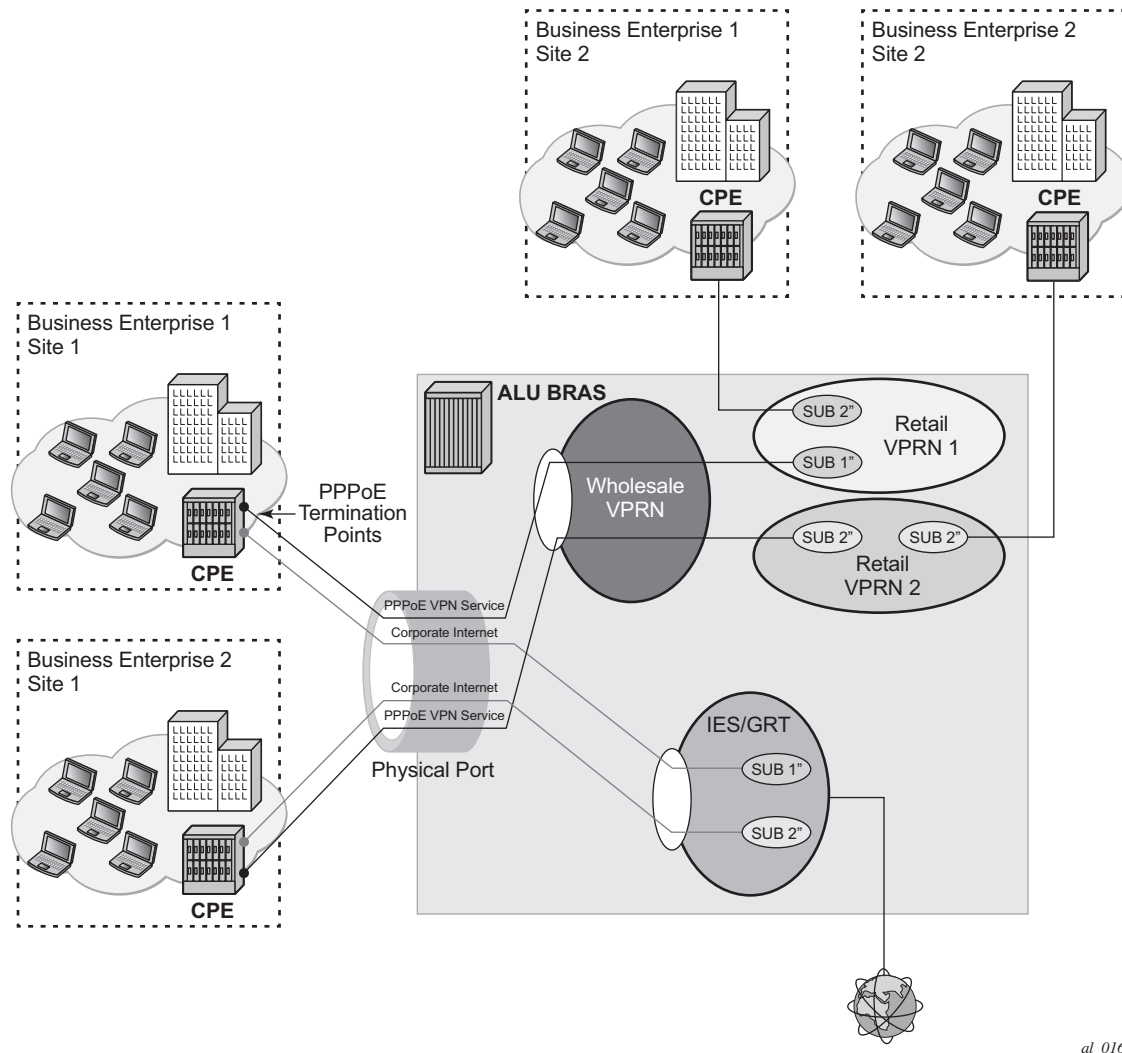

- IPTV in an environment with legacy non-multicasting DSLAMs
- Internet multicast where users connect to a multicast stream sourced from the Internet.

For the business customers, the main drivers are enterprise multicast and Internet multicast applications.

On multicast-capable ANs, a single copy of each multicast stream is delivered over a separate regular IP interface. AN would then perform the replication. This is how multicast would be deployed in Routed CO environment with the 7750 SR and 7450 ESS.

On legacy, non-multicast ANs, or in environments with low volume multicast traffic where it is not worth setting up a separate multicast topology (from BNG to AN), multicast replication is performed via subscriber-interfaces in the 7750 SR and 7450 ESS. There are differences in replicating multicast traffic on IPoE vs PPPoX which will be described in subsequent sessions.

An example of a business connectivity model is shown in [Figure 52](#).

Figure 52 A Typical Business Connectivity Model

al_0169

In this example, HSI is terminated in a Global Routing Table (GRT) whereas VRPN services are terminated in Wholesale/Retail VRPN fashion, with each customer using a separate VRPN.

The actual connectivity model that will be deployed depends on many operational aspects that are present in the customer environment.

Multicast over subscriber-interfaces in a Routed CO model is supported for both types of hosts, IPoE and PPPoE which can be simultaneously enabled on a shared SAP.

There are some fundamental differences in multicast behavior between two host types (IPoE and PPPoX). The differences will be discussed further in the next sections.

8.5.1 Hardware Support

Multicast over subscriber interfaces is supported on all FP2 based hardware that supports Routed CO model. This includes:

- 7750 SR-7/12
- 7750 SR-c4/12
- 7450 ESS in mixed mode

Chassis modes B, C and D are supported.

8.5.2 Multicast Over IPoE

There are several deployment scenarios for delivering multicast directly over subscriber hosts:

- 1:1 model (subscriber per VLAN/SAP) with the Access Node (AN) that is not IGMP/MLD aware.
- N:1 model (service per VLAN/SAP) with the AN in the Snooping mode.
- N:1 model with the AN in the Proxy mode.
- N:1 model with the AN that is not IGMP/MLD aware.

There are two modes of operation for subscriber multicast that can be chosen to address the above mentioned deployment scenarios:

1. Per SAP replication — A single multicast stream per group is forwarded on any given SAP. Even if the SAP has a multicast group (channel) that is registered to multiple hosts, only a single copy of the multicast stream is forwarded over this SAP. The multicast stream will have a multicast destination MAC address (as opposed to unicast). IGMP/MLD states will be maintained per host. This is the default mode of operation.

2. Per subscriber host replication in this mode of operation, multicast is replicated per subscriber host even if this means that multiple copies of the same stream will be forwarded over the same SAP. For example, if two hosts on the same SAP are registered to receive the same multicast group (channel), then this multicast channel will be replicated twice on the same SAP. The streams will have a unique unicast destination MAC address (otherwise it would not make sense to replicate the streams twice).

In all deployment scenarios and modes of operation the IGMP/MLD states per source IP address of the incoming IGMP/MLD message is maintained. This source IP address might represent a subscriber hosts or the AN (proxy mode).

For MLD, the source IP address is the host link local address. Therefore, the MLD message is associated with all IP address/prefix of the host.

8.5.2.1 Per SAP Replication Mode

In the per SAP replication mode a single copy of the multicast channel is forwarded per SAP. In other words, if a subscriber (in 1:1 mode) or a group of subscribers (in N:1 mode) have multiple hosts and all of them are subscribed to the same multicast group (watching the same channel), then only a single copy of the multicast stream for that group will be sent. The destination MAC address will always be a multicast MAC (there will be no conversion to unicast mac address).

IGMP/MLD states are maintained per subscriber host and per SAP.

8.5.2.1.1 Per SAP Queue

Multicast traffic over subscribers in a per SAP replication mode is flowing via a SAP queue which is outside of the subscriber queues context. Sending the multicast traffic over the default SAP queue is characterized by:

- The inability to classify multicast traffic into separate subscriber queues and therefore include it natively in HQoS. However, multicast traffic can be classified into a specific SAP queues, assuming that such queues are enabled via SAP based QoS policy. While multiple SAP queues can be defined under static SAPs, the dynamic SAPs (MSAPs) are limited to a single SAP queue defined in the default egress-sap policy. This default egress-sap policy under MSAP cannot be replaced or modified.

- Redirection of multicast traffic via internal queues in case that the SAP queue in subscriber environment is disabled (**sub-sla-mgmt>single-sub-parameters>profiled-traffic-only**). This is applicable only to 1:1 subscriber model.
- A possible necessity for HQoS Adjustment as multicast traffic is flowing outside of the subscriber queues.
- De-coupling of the multicast forwarding statistics from the overall subscriber forwarding statistics obtained via subscriber specific show commands.

8.5.2.1.2 IPoE 1:1 Model (Subscriber per VLAN/SAP) — No IGMP/MLD in AN

This model is shown in [Figure 53](#). The AN is not IGMP/MLD aware, all replications are performed in the BNG. From the BNG perspective this deployment model has the following characteristics:

- IGMP/MLD states are kept per hosts and SAPs. Each host can be registered to more than one group.
- MLD utilize link-local as source address, which makes it difficult to associate with the originating host. MLD (S,G) are always first associated with a IPv6 WAN host if available. If this WAN host terminate its IPv6 session (via lease expiry, session terminate, etc.), the (S,G) is then associated to any remaining WAN host. Only when there are no more WAN hosts available will the (S,G) be associated to the PD host, if any.
- IGMP/MLD Joins will be accepted only from the active subscriber hosts as dictated by antispoofing.
- IGMP/MLD statistics can be displayed per host or per group.
- Multicast traffic for the subscriber is forwarded through the egress SAP queue. In case that the SAP queue is disabled (profiled-traffic-only command), multicast traffic will flow via internal queues outside of the subscriber context.
- A single copy of any multicast stream is generated per SAP. This can be viewed as replication per unique multicast group per SAP, rather than the replication per host. In other words, the number of multicast streams on this SAP is equal to the number of unique groups across all hosts on this SAP (subscriber).
- Traffic statistics are kept per the SAP queue. Consequently multicast traffic stats will be shown outside of the subscriber context.
- HQoS Adjustment might be necessary.
- Traffic cannot be explicitly classified (forwarding classes and queue mappings) inside of the subscriber queues.
- Redirection to the common multicast VLAN (or Layer 3 interface) is supported.
- Multicast streams have multicast destination MAC.

- MLD utilize link-local as source address, which makes it difficult to associate with the originating host. MLD (s,g) is associated with the IPv6 host. Therefore, if any WAN host or PD host end their IPv6 session (via lease expire, etc.), the (s,g) is associated with the remaining host address/prefix. The (s,g) will be delivered to the subscriber as long as a IPv6 address or prefix remains.

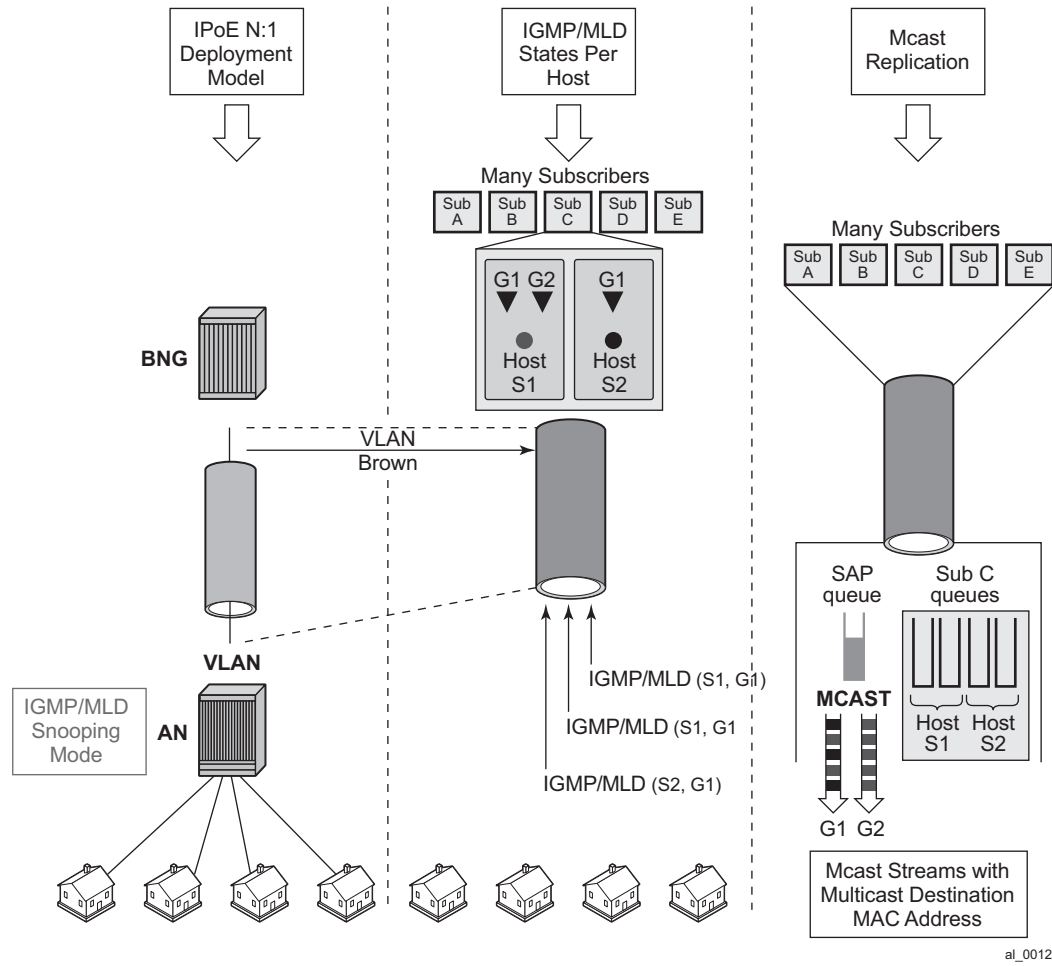

Figure 53 1:1 Model

8.5.2.1.3 IPoE N:1 Model (Service per VLAN/SAP) — IGMP/MLD Snooping in the AN

This model is shown in [Figure 54](#). The AN is IGMP/MLD aware and is participating in multicast replication. From the BNG perspective this deployment model has the following characteristics:

- IGMP/MLD states are kept per hosts and SAPs. Each host can be registered to more than one group.
- IGMP/MLD Joins are accepted only from the active subscriber hosts as dictated by antispoofing.

- IGMP/MLD statistics are displayed per host, per group or per subscriber.
- Multicast traffic for ALL subscribers on this SAP is forwarded through the egress SAP queues.
- A single copy of any multicast stream is generated per SAP. This can be viewed as the replication per unique multicast group per SAP, rather than the replication per host or subscriber. In other words, the number of multicast streams on this SAP is equal to the number of unique groups across all hosts and subscribers on this SAP.
- The AN will receive a single multicast stream and based on its own (AN) IGMP/MLD snooping information, it will replicate the mcast stream to the appropriate subscribers.
- Traffic statistics are kept per the SAP queue. Consequently multicast traffic stats will be shown on a per SAP basis (aggregate of all subscribers on this SAP).
- Traffic cannot be explicitly classified (forwarding classes and queue mappings) inside of the subscriber queues.
- Redirection to the common multicast VLAN is supported.
- Multicast streams have multicast destination MAC.
- IGMP Joins are accepted (src IP address) only for the sub hosts that are already created in the system. IGMP Joins coming from the hosts that are nonexistent in the system will be rejected, unless this functionality is explicitly enabled by the sub-hosts-only command under the IGMP group-int CLI hierarchy level.
- MLD utilize link-local as source address, which makes it difficult to associate with the originating host. MLD (S,G) are always first associated with a IPv6 WAN host, if available. If this WAN host terminate its IPv6 session (via lease expiry, session terminate, etc), the (S,G) is then associated to any remaining WAN host. Only when there are no more WAN hosts available, will the (S,G) be associated to the PD host, if any.
- MLD join are only accepted if it matches the subscriber host link local address. MLD Joins coming from the hosts that are nonexistent in the system will be rejected, unless this functionality is explicitly enabled by the sub-hosts-only command under the MLD group-int CLI hierarchy level.

Figure 54 - N:1 Model - AN in IGMP Snooping Mode

8.5.2.1.4 IPoE N:1 Model (Service per VLAN/SAP) — IGMP/MLD Proxy in the AN

This model is shown in [Figure 55](#). The AN is configured as IGMP/MLD Proxy node and is participating in downstream multicast replication.

For IPv4, IGMP messages from multiple sources (subscribers hosts) for the same multicast group are consolidated in the AN into a single IGMP messages. This single IGMP message has the source IP address of the AN.

For IPv6, MLD messages from multiple sources (subscribers hosts) for the same multicast group are consolidated in the AN into a single MLD messages. This single MLD message has the link-local IP address of the AN.

From the BNG perspective this deployment model has the following characteristics:

- Subscriber IGMP/MLD states are maintained in the AN.
- IGMP Joins are accepted from the source IP address that is different from any of the subscriber' IP addresses already existing in the BNG. This will be controlled via an IGMP filter on a per group-interface level assuming that the IGMP processing for subscriber hosts is disabled with the **no sub-hosts-only** command under the router/service **vprn>igmp>group-interface** CLI hierarchy. In this case all IGMP messages that cannot be related to existing hosts will be treated in the context of the sap while IGMP messages from the existing hosts will be treated in the context of the subscriber hosts.
- MLD Joins are only accepted if the link-local address matches the subscriber' link local address. To allow processing of foreign link-local address such as the AN link local address, the MLD processing for subscriber hosts should be disabled with the **no sub-hosts-only** command under the **router/service vprn>mld>group-interface** CLI hierarchy. In this case all MLD messages that cannot be related to existing hosts will be treated in the context of the sap while MLD messages from the existing hosts will be treated in the context of the subscriber hosts.
- IGMP/MLD statistics can be displayed per group-interface.
- Multicast traffic for all subscribers on this SAP is forwarded through the egress SAP queue.
- A single copy of any multicast stream is generated per SAP.
- The AN will receive a single multicast stream. Based on the IGMP/MLD proxy information, the AN will replicate the mcast stream to the appropriate subscribers.
- Traffic statistics are maintained per SAP queue.
- HQoS Adjustment is not useful because the per host/subscriber IGMP/MLD granularity is lost. IGMP/MLD states are aggregated per AN.
- Traffic can be explicitly classified into a specific SAP queues via a QoS policy applied under the SAP.
- Multicast streams have multicast destination MAC.

In the following example, IGMPs from the source IP address <ip> is accepted even though there is no subscriber-host with that IP addresses present in the system. An IGMP state will be created under the sap context (service per vlan, or N:1 model) for the group <pref-definition>. All other IGMP messages originated from non-subscriber hosts will be rejected. IGMP messages for subscriber hosts will be processed according to the igmp-policy applied to each subscriber host.

```

configure
  service vprn <id>
    igmp
      group-interface <name>
        import <policy-name>

configure
  router
    policy-options
      begin
        prefix-list <pref-name>
          prefix <pref-definition>

        policy-statement proxy-policy
          entry 1
            from
              group-address <pref-name>
              source-address <ip>
              protocol igmp
            exit
          action accept
          exit
        exit
        default-action reject

```

This functionality (accepting IGMP from non-subscriber hosts) can be disabled with the following flag.

```

configure
  service vprn <id>
    igmp
      group-interface <name>
        sub-host-only

```

In this case only per host IGMP processing will be allowed.

In the following example, MLDs with foreign link-local-address is accepted even though there is no subscriber-host with that link local addresses present in the system. An MLD state will be created under the sap context (service per vlan, or N:1 model) for the group <pref-definition>. All other MLD messages originated from non-subscriber hosts will be rejected. MLD messages for subscriber hosts will be processed according to the igmp-policy applied to each subscriber host.

```

configure
  service vprn <id>
    mld
      group-interface <name>
        import <policy-name>

configure
  router
    policy-options
      begin

```

```
prefix-list <pref-name>
  prefix <pref-definition>

policy-statement proxy-policy
entry 1
  from
    group-address <pref-name>
    source-address <ip>
    protocol igmp
  exit
  action accept
  exit
exit
default-action reject
```

This functionality (accepting MLD from non-subscriber hosts) can be disabled with the following flag.

```
configure
  service vprn <id>
    mld
      group-interface <name>
        sub-host-only
```

In this case only per host MLD processing will be allowed.

Figure 55 N:1 Model - AN in Proxy mode

8.5.2.2 Per Subscriber Host Replication Mode

In this mode a multicast stream is transmitted per subscriber hosts for each registered multicast group (channel). As a result, multiple copies of the same multicast stream destined to different destinations can be transmitted over the same SAP. In this case traffic flows within the subscriber queues and consequently it is accounted in HQoS. As a result, HQoS Adjustment is not needed. Each copy of the same multicast stream have a unique unicast destination MAC addresses. The per host unicast MAC destination addresses are necessary to differentiate multiple copies between different receivers on the same SAP.

Per host replication mode can be enabled on a subscriber basis with the **per-host-replication** command in the **config>subscriber-management>igmp-policy** context.

For IPv6, the command is in the **config>subscriber-management>mld-policy** context.

8.5.2.2.1 IPoE 1:1 Model (Subscriber per VLAN/SAP) — No IGMP/MLD in AN

This model is shown in [Figure 56](#). The AN is not IGMP/MLD aware and multicast replication is performed in the BNG. Multicast streams are sent directly to the hosts using their unicast MAC addresses. HQoS adjustment is not needed as multicast traffic is flowing through subscriber queues. From the BNG perspective this deployment model has the following characteristics:

- IGMP/MLD states are kept per hosts. Each host can be registered to multiple IGMP/MLD groups.
- MLD utilize link-local as source address, which makes it difficult to associate with the originating host. MLD (S,G) are always first associated with a IPv6 WAN host if available. If this WAN host terminate its IPv6 session (via lease expiry, session terminate, etc), the (S,G) is then associated to any remaining WAN host. Only when there are no more WAN hosts available, will the (S,G) be associated to the PD host, if any.
- IGMP/MLD Joins will be accepted only from the active subscriber hosts. In other words antispoofing is in effect for IGMP/MLD messages.
- IGMP/MLD statistics can be displayed per host, per group or per subscriber.
- Multicast traffic is forwarded through subscriber queues using unicast destination MAC address of the destination host.

- Multiple copies of the same multicast stream can be generated per SAP. The number of copies depends on the number of hosts on the SAP that are registered to the same multicast group (channel). In other words, the number of multicast streams on the SAP is equal to the number of groups registered across all hosts on this SAP.
- Traffic statistics are kept per the host queue. In case that multicast statistics need to be separated from unicast, the multicast traffic should be classified in a subscriber separate queue.
- HQoS Adjustment is not needed as traffic is flowing within the subscriber queues and is automatically accounted in HQoS.
- Multicast traffic can be explicitly classified into forwarding classes and consequently directed into desired queues.
- MCAC is supported.
- profiled-traffic-only mode defined under sub-sla-mgmt is supported. This mode (profiled-traffic-only) is used to save the number of queues in 1:1 model (sub-sla-mgmt-> no multi-sub-SAP) by preventing the creation of the SAP queues. Since multicast traffic is not using the SAP queue, enabling this feature will not have any effect on the multicast operation.

Figure 56 1:1 Model

8.5.2.2.2 IPoE N:1 Model (Service per VLAN/SAP) — No IGMP/MLD in the AN

This model is shown in [Figure 57](#). The AN is not IGMP/MLD aware and is not participating in multicast replication. From the BNG perspective this deployment model has the following characteristics:

- IGMP/MLD states are kept per hosts. Each host can be registered to multiple multicast groups.

- MLD utilize link-local as source address, which makes it difficult to associate with the originating host. MLD (S,G) are always first associated with a IPv6 WAN host if available. If this WAN host terminate its IPv6 session (via lease expiry, session terminate, etc), the (S,G) is then associated to any remaining WAN host. Only when there are no more WAN hosts available, will the (S,G) be associated to the PD host, if any.
- IGMP/MLD Joins will be accepted only from the active subscriber hosts, subject to antispoofing.
- IGMP/MLD statistics can be displayed per host, per group or per subscriber.
- Multicast traffic is forwarded through subscriber queues using unicast destination MAC address of the destination host.
- Multiple copies of the same multicast stream can be generated per SAP. The number of copies depends on the number of hosts on the SAP that are registered to the same multicast group (channel). In other words, the number of multicast streams on the SAP is equal to the number of groups registered across all hosts on this SAP.
- Traffic statistics are kept per the host queue. In case that multicast statistics need to be separated from unicast, the multicast traffic should be classified in a separate subscriber queue.
- HQoS Adjustment is NOT needed as traffic is flowing within the subscriber queues and is automatically accounted in HQoS.
- Multicast traffic can be explicitly classified into forwarding classes and consequently directed into desired queues.
- MCAC is supported.

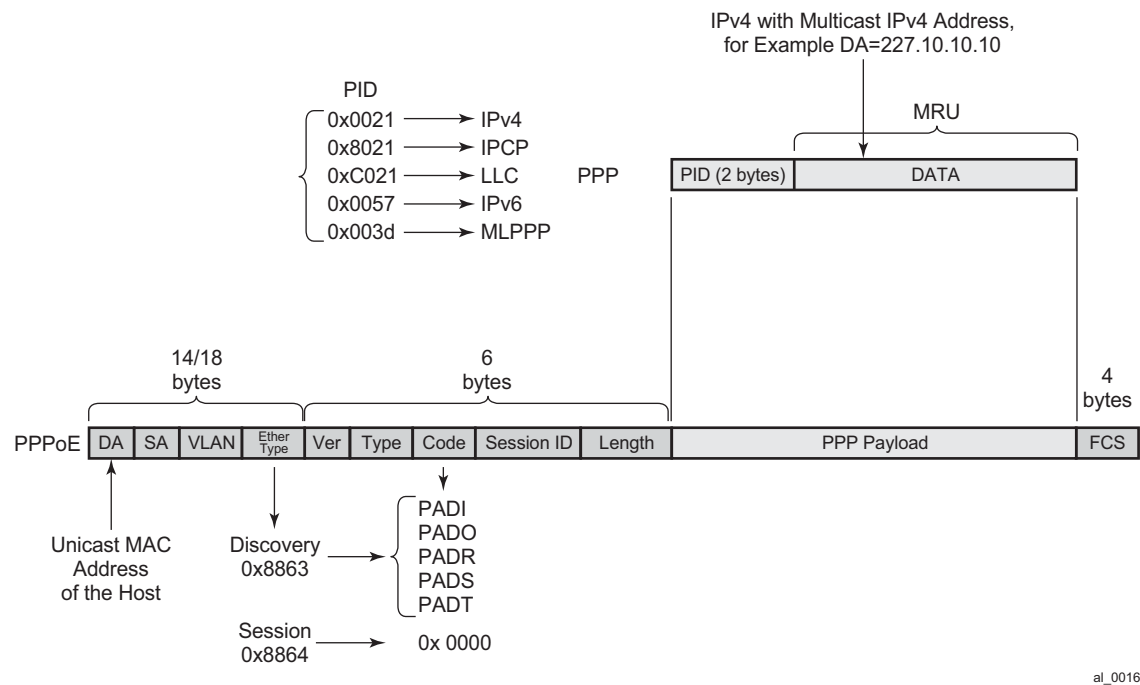

Figure 57 N:1 Model — No IGMP/MLD in the AN

8.5.3 Multicast Over PPPoE

In a PPPoE environment, multicast replication is performed per session (host) regardless of whether those sessions are shared per SAP or they reside on individual SAPs. This is due to the point-to-point nature of PPPoE sessions. There will be no need for HQoS adjustment as multicast is part of the PPPoE session traffic that is flowing via subscriber queues. Multicast packets are sent with unicast MAC address to each CPE. PPP protocol field is set to IP and the destination IP address is the multicast group address for each unique session ID ([Figure 58](#)).

Figure 58 Multicast IPv4 Address and Unicast MAC Address in PPPoE Subscriber Multicast

8.5.4 IGMP Flooding Containment

The query function in IGMP can cause some unintended flooding in N:1 IPoE deployment model with AN in the IGMP snooping mode. By maintaining IGMP session states per host, it is assumed that the IGMP interaction between multicast receivers and the BNG will be on a one-to-one basis. Upon arrival of an IGMP leave from a host for a specific multicast group, the IGMP querier would normally multicast a group-specific query (fast-leave). In N:1 model with SAP replication mode enabled, the 7750 SR and 7450 ESS will send a group-specific query (fast-leave) only when it receives the IGMP leave message for the last group shared amongst all subscribers on this SAP.

8.5.5 IGMP/MLD Timers

IGMP/MLD timers are maintained under the following hierarchy:

IPv4:

```
configure>router>igmp
```

```
configure>service vprn>igmp
```

IPv6:

```
configure>router>mld
```

```
configure>service vprn>mld
```

As it can be seen, the IGMP/MLD timers are controlled on a per routing instance (VRF or GRT) level.

The timer values are used to:

- Determine the interval at which queries are transmitted (query-interval).
- To determine the amount of time after which a join will time out.

However, the timers can be different for hosts and redirected interface in case that redirection between VRFs is enabled.

8.5.6 IGMP/MLD Query Intervals

IGMP/MLD query related intervals (query-interval, query-last-member-interval, query-response-interval, robust-count) are configured on a global router/vprn IGMP/MLD level. They are used to determine the IGMP/MLD timeout states and the rates at which queries are transmitted.

In case of redirection, the subscriber-host IGMP/MLD state will determine the IGMP/MLD state on the redirected interface, assuming that IGMP/MLD messages are not directly received on the redirected interface (for example from the AN performing IGMP/MLD forking). For example if the redirected interface is not receiving IGMP/MLD messages from the downstream node, then the IGMP/MLD state under redirected interface will be removed simultaneously with the removal of the IGMP/MLD state for the subscriber host (due to leave or a timeout).

In case that the redirected interface is receiving IGMP/MLD message directly from the downstream node, the IGMP/MLD states on that redirected interface will be driven by those direct IGMP/MLD messages.

For example, an IGMP/MLD host in VRF1 has an expiry time of 60 seconds and the expiry time defined under the VRF2 where multicast traffic is redirected is set to 90 seconds. The IGMP/MLD state will time out for the host in VRF1 after 60s, and if no host has joined the same multicast group in VRF2 (where redirected interface resides), the IGMP state will be removed there too.

If a join was received directly on the redirection interface in VRF2, the IGMP/MLD state for that group will be maintained for 90s, regardless of the IGMP/MLD state for the same group in VRF1.

8.5.7 HQoS Adjustment

HQoS Adjustment is required in the scenarios where subscriber multicast traffic flow is disassociated from subscriber queues. In other words, the unicast traffic for the subscriber is flowing through the subscriber queues while at the same time multicast traffic for the same subscriber is explicitly (through redirection) or implicitly (per-sap replication mode) redirected through a separate non-subscriber queue. In this case HQoS Adjustment can be deployed where preconfigured multicast bandwidth per channel is artificially included in HQoS. For example, bandwidth consumption per multicast group must be known in advance and configured within the 7450 ESS and 7750 SR. By keeping the IGMP state per host, the bandwidth for the multicast group (channel) to which the host is registered is known and is deducted as consumed from the aggregate subscriber bandwidth.

The multicast bandwidth per channel must be known (this is always an approximation) and provisioned in the BNG node in advance.

In PPPoE and in IPoE per host replication environment, HQoS Adjustment is not needed as multicast traffic is unicasted to each subscriber and therefore is flowing through subscriber queues.

For HQoS Adjustment, the channel bandwidth definition and association with an interface is the same as in the MCAC case. This is a departure from the legacy HT channel bandwidth definition which is done via multicast-info-policy.

Example of HQoS adjustment:

Channel definition:

```
configure
  router
    mcac
      policy <name>
        <channel definition>
```

Channel bandwidth definition policy can be applied under:

- group-interface

```
configure
  service vprn <id>
    igmp
      group-interface <grp-if-name>
        mcac
          policy <mcac-policy-name>
```

- plain interface

```
configure
  router/service vprn
    igmp
      interface <name>
        mcac
          policy <mcac-policy-name>
```

- retailer group-interface:

```
configure
  service vprn <id>
    igmp
      group-interface fwd-service <svc-id> <grp-if-name>
        mcac
      policy <mcac-policy-name>
```

Enabling HQoS adjustment:

```
configure
  subscriber-management
    igmp-policy <name>
      egress-rate-modify [egress-aggregate-rate-limit | scheduler <name>]
```

Applying HQoS adjustment to the subscriber:

```
configure
  subscriber-management
    sub-profile <name>
      igmp-policy <name>
```

In order to activate HQoS adjustment on the subscriber level, the sub-mcac-policy must be enabled under the subscriber via the following CLI:

```
configure
  subscriber-management
    sub-mcac-policy <pol-name>
      no shutdown

configure
  subscriber-management
    sub-profile <name>
      sub-mcac-policy <pol-name>
```

The adjusted bandwidth during operation can be verified with the following commands (depending whether agg-rate-limit or scheduler-policy is used):

```
*B:BNG-1# show service active-subscribers subscriber "sub-1" detail
=====
Active Subscribers
=====
-----
Subscriber sub-1

8.5.7.1 Host Tracking (HT) Considerations

HT is a light version of HQoS Adjustment feature. The use of HQoS Adjustment functionality in place of HT is strongly encouraged.

When HT is enabled, the AN will fork off (duplicate) the IGMP messages on the common mcast SAP to the subscriber SAP. IGMP states will not be fully maintained per sub-host in the BNG, instead they will be only tracked (less overhead) for bandwidth adjustment purposes.

Example of HT

Channel Definition:

```
configure
  mcast-management
    multicast-info-policy <name>
      <channel to b/w mapping definition>
```

Applying channel definition policy on a router/VRN global level:

```
configure>router>multicast-info-policy <name>
configure>service>vrn>multicast-info-policy <name>
```

Defining the rate object on which HT will be applied:

```
configure
  subscriber-management
    host-tracking-policy <name>
      egress-rate-modify [agg-rate-limit | scheduler <sch-name>]
```

Applying the HT to the subscriber:

```
configure
  subscriber-management
    sub-profile <name>
      host-tracking-policy <name> => mutually exclusive with igmp-policy
```

8.5.7.2 HQoS Adjust Per Vport

HQoS adjust per Vport can be used in environments where Vport represents a physical medium over which traffic for multiple subscribers is shared. Typical example of this scenario is shown in [Figure 59](#). Multicast traffic within the router is taking a separate path from unicast traffic, only for the two traffic flows to merge later in the PON (represented by a Vport) and ONT (represented by the subscriber in the 7450 ESS and 7750 SR).

Figure 59 HQoS Adjustment per Subscriber and Vport

al_0166

A single copy of each channel is replicated on the PON as long as there is at least one subscriber on that PON interested in this channel (has joined the IGMP/MLD group).

The 7450 ESS and 7750 SR monitors IGMP/MLD Joins at the subscriber level and consequently the channel bandwidth is subtracted from the current Vport rate limit only in the case that this is the first channel flowing through the corresponding PON. Otherwise, the Vport bandwidth is not modified. Similarly, when the channel is removed from the last subscriber on the PON, the channel bandwidth is returned to the VPort.

Association between the Vport and the subscriber is performed via inter-destination-string or svlan during the subscriber setup phase. Inter-destination-string can be obtained either via Radius or LUDB. In case that the association between the Vport and the subscriber is performed based on the svlan (as specified in sub-sla-mgmt under the sap/msap), then the destination string under the Vport must be a number matching the svlan.

The mcac-policy (channel definition bandwidth) can be applied on the group interface under which the subscribers are instantiated or in case of redirection under the redirected-interface.

In a LAG environment, the Vport instance is instantiated per member LAG link on the IOM. For accurate bandwidth control, it is prerequisite for this feature that subscriber traffic hashing is performed per Vport.

The CLI structure is as follows.

```
configure
  port <port-id>
    ethernet
      access
        egress
          vport <name>
            egress-rate-modify
            agg-rate
            host-match <destination-string>
            port-scheduler-policy <port-scheduler-policy-name>

configure
  port <port-id>
    sonnet-sdh
      path [<sonnet-sdh-index>]
        access
          egress
            vport <name>
              egress-rate-modify
              agg-rate
              host-match <destination-string>
              port-scheduler-policy <port-scheduler-policy-name>
```

The Vport rate that will be affected by this functionality depends on the configuration:

- In case the agg-rate-limit within the Vport is configured, its value will be modified based on the IGMP activity associated with the subscriber under this Vport.
- In case that the port-scheduler-policy within the Vport is referenced, the max-rate defined in the corresponding port-scheduler-policy will be modified based on the IGMP activity associated with the subscriber under this Vport.

Note: HQoS adjust is not supported when a scheduler policy is configured under the VPORT.

The Vport rates can be displayed with the following two commands:

show port 1/1/5 vport *name*

qos scheduler-hierarchy port *port-id* vport *vport-name*

As an example:

```
*A:system-1# show port 1/1/7 vport
=====
Port 1/1/7 Access Egress vport
=====
VPort Name      : isaml
Description     : (Not Specified)
Sched Policy    : 1
Rate Limit      : Max
Rate Modify     : enabled
Modify delta    : -14000
```

In this case, the configured Vport aggregate-rate-limit max value has been reduced by 14Mbps.

Similarly, if the Vport had a port-scheduling-policy applied, the max-rate value configured in the port-scheduling-policy would have been modified by the amount shown in the Modify delta output in the above command.

8.5.7.2.1 Multi-Chassis Redundancy

Modified Vport rate synchronization in multi-chassis environment relies on the synchronization of the subscriber IGMP/MLD states between the redundant nodes. Upon the switchover, the Vport rate on the newly active node is adjusted according to the current IGMP/MLD state of the subscribers associated with the Vport.

8.5.7.2.2 Scalability Considerations

It is assumed that the rate of the IGMP/MLD state change on the Vport level is substantially lower than on the subscriber level.

The reason for this is that the IGMP/MLD Join/Leaves are shared amongst subscribers on the same Vport (PON for example) and thus the IGMP/MLD state on the VPort level is changed only for the first IGMP/MLD Join per channel and the last IGMP/MLD leave per channel.

8.5.8 Redirection

Two levels of MCAC can be enabled simultaneously and in such case this is referred as Hierarchical MCAC (H-MCAC). In case that redirection is enabled, H-MCAC per subscriber and the redirected interface is supported. However, mcac per group-interface in this case is not supported. Channel definition policy for the subscriber and the redirected interface is in this case referenced under the **igmp->interface** (redirected interface) CLI or for IPv6 **mld->interface**.

In case that redirection is disabled, H-MCAC for both, the subscriber and the group-interface is supported. The channel definition policy is in this case configured under the **config>router>igmp>group interface** context or for IPv6 **config>router>mld>group interface**.

There are two options in multicast redirection. The first option is to redirect all subscriber multicast traffic to a dedicated redirect interface.

Example:

Defining redirection action:

```
configure
router
  policy-options
  begin
  policy-statement <name>
    default-action accept
    multicast-redirection [fwd-service <svc id>] <interface name>
  exit
  exit
exit
exit
```

The second option is to redirect only specific multicast groups to the redirect interface while the remaining groups remains on the subscriber SAP. This is applicable for both IPv4 and IPv6. For IPv6 host-ip for a policy statement is not supported.

Example:

Defining redirection action:

```
configure
router
  policy-options
  begin
  prefix-list <name>
    prefix <IPv4 multicast groups>
    prefix <IPv4 multicast groups>
  exit
  policy-statement <name>
    entry 1
      from
        group-address <prefix-list name>
      action accept
      multicast-redirection [fwd-service <svc id>] <interface name>
    exit
  exit
exit
```

Applying redirection to the subscriber for IGMP and MLD respectively.

```
configure
  subscr-mgmt
  igmp-policy <name>
    redirection-policy <name>
  exit
  exit
  mld-policy <name>
    redirection-policy <name>
```

Redirection that cross-connects GRT and VPRN is not supported. Redirection can be only performed between interfaces in the GRT, or between the interfaces in any of the VPRN (cross connecting VPRNs is allowed).

Redirection is also supported in a wholesaler/retailer VPRN model where redirected Layer 3 interface resides in the retailer VPRN.

8.5.9 Hierarchical Multicast CAC (H-MCAC)

MCAC is supported on three levels:

- per subscriber
- per group-interface
- per redirected interface

Two levels of MCAC can be enabled simultaneously and in such case this is referred as Hierarchical MCAC (H-MCAC). In case that redirection is enabled, H-MCAC per subscriber and the redirected interface is supported. However, MCAC per group-interface in this case is not supported. Channel definition policy for the subscriber and the redirected interface is in this case referenced under the **config>router>igmp->interface** (redirected interface) CLI hierarchy or IPv6 **config>router>mld->interface**.

In case that redirection is disabled, H-MCAC for both, the subscriber and the group-interface is supported. The channel definition policy is in this case configured under the **config>router>igmp>group-interface** CLI hierarchy or IPv6 **config>router>mld>group- interface**.

Examples

Note: The same channel definition and association with interfaces is used for MCAC/H-MCAC and HQoS Adjustment.

Channel definition:

```
configure
  router
    mcac
      policy <mcac-pol-name>
        bundle <bundle-name>
          bandwidth <kbps>
          channel <start-address> <end-
address> bw <bw> [class {high|low}] [type {mandatory|optional}]
          :
          :
```

Channel bandwidth definition policy can be referenced under the:

- **group-interface** — This is used for subscribers when redirection is disabled.

```
configure
  service vprn <id>
    igmp/mld
      group-interface <grp-if-name>
        mcac
          policy <mcac-policy-name>
          policy <mcac-policy-name>
```

- **plain interface**

```
configure
  router
    igmp/mld
      interface <name>
        mcac
          policy <mcac-policy-name>
```

```
configure
  service vprn <id>
    igmp/mld
      interface <if-name>
        mcac
          unconstrained-bw <bandwidth> mandatory-bw <mandatory-bw>
```

- retailer's VPRN reference the group-interface in the wholesaler's VPRN

```
configure
  service vprn <id>
    igmp/mld
      group-interface fwd-service <svc-id> <grp-if-name>
        mcac
          policy <mcac-policy-name>
```

Enabling MCAC per subscriber:

```
configure
  subscr-mgmt
    sub-mcac-policy <name>
      unconstrained-bw <bandwidth> mandatory-bw <mandatory-bw>

configure
  subscr-mgmt
    sub-profile <name>
      sub-mcac-policy <name>
```

Enabling MCAC per-group-interface

```
configure
  service vprn <id>
    igmp/mld
      group-interface <grp-if-name>
        mcac
          unconstrained-bw <bandwidth> mandatory-bw <mandatory-bw>
```

Enabling MCAC per redirected interface

```
configure
  router
    igmp/mld
      interface <if-name>
        mcac
          unconstrained-bw <bandwidth> mandatory-bw <mandatory-bw>

configure
  service vprn <id>
    igmp/mld
      interface <if-name>
        mcac
          unconstrained-bw <bandwidth> mandatory-bw <mandatory-bw>
```

8.5.9.1 MCAC Bundle Bandwidth Limit Considerations

In addition to multicast bandwidth limit that can be imposed on subscribers, group-interfaces or regular interfaces, there is another multicast bandwidth limit that can be imposed on a group of channels (channel bundle).

The MCAC policy, aside from the channel bandwidth definitions, could optionally contain this bandwidth cap for the group of channels:

```
config>router>mcac# info
-----
policy "test"
  bundle "test" create
    bandwidth 100000
    channel 225.0.0.10 225.0.0.10 bw 10000 type mandatory
    channel 225.0.0.11 225.0.0.15 bw 5000 type mandatory
    channel 225.0.0.20 225.0.0.30 bw 5000 type optional
  exit
exit
```

This can be used to prevent a single set of channels from monopolizing MCAC bandwidth allocated to the entire interface. The bandwidth of each individual bundle will be capped to some value below the interface MCAC bandwidth limit, allowing each bundle to have its own share of the interface MCAC bandwidth.

In most cases, the bandwidth limit per bundle is not necessary to configure. The aggregate limit per all channels as defined under the subscriber/interface will cover majority of scenarios. In case that one wants to explore the bundle bandwidth limits and how they affect MCAC behavior, the following text will help understanding this topic.

To further understand how various MCAC bandwidth limits are applied, one need to understand the concept of the mandatory bandwidth that is pre-allocated in the following way:

- Bandwidth of each mandatory channel in a bundle is pre-allocated. The artifacts of this are:

- The total mandatory bandwidth in the bundle cannot exceed the bundle cap. For the sake of deterministic behavior, the configured bandwidth of each mandatory channel in the bundle is counted towards the total mandatory bandwidth only once. This means that only one replication of each mandatory channel is assumed. This is normal behavior on a regular interface with a single SAP under it. More than one replication of the same channel per regular interface (or sap) would lead to packet duplication.
- Optional (non-mandatory) channels can use only the difference in bandwidth between the bundle cap and total pre-allocated mandatory bandwidth. They can NOT use more bandwidth than that even if the total pre-allocated mandatory bandwidth is not used up (mandatory channels are not being replicated).
- Mandatory bandwidth under the interface is pre-allocated and subtracted from the unconstrained bandwidth. In the configuration example below, 2mbps is pre-allocated (guaranteed for mandatory channels) and the remaining 8mbps can be used by the optional channels on a first come first serve basis.

```
config>router>igmp# info
-----
      interface "ge-1/1/1"
          mcac
          unconstrained-bw 10000 mandatory-bw 2000
          exit
      exit
```

The bundle bandwidth limit poses a problem when the MCAC policy is applied under the group-interface. The reason is that the group-interface represents the aggregation point for the subscribers and their bandwidth. As such it is natural that the any aggregated bandwidth limit under the group interface be larger than the bandwidth limit applied to any individual subscriber under it. Since the MCAC policy, along with the bundle bandwidth limit, is inherited by all subscribers under the group-interface, the exhaustion of the bundle bandwidth limit under the group interface will coincide with the exhaustion of the bundle bandwidth limit of any individual subscriber. This will result in a single subscriber starving out of multicast bandwidth the remaining subscribers under the same group-interface. While it is perfectly acceptable for the subscribers to inherit the multicast channel definition from the group-interface, for the above reasons it is not acceptable that the subscriber inherit the bandwidth cap from the group-interface.

To remedy this situation, the MCAC bandwidth limits are independently configured under the group-interface level (aggregated level) and the subscriber level via the command `unconstrained-bw <kbps> mandatory-bw <kbps>`. The undesired bundle bandwidth cap in the MCAC policy will be ignored under the group-interface AND under the subscriber. However, the bundle bandwidth cap will be applied automatically to each SAP under the group interface. A SAP is a natural place for a bundle bandwidth limit since each channel on a SAP can be replicated only once and

therefore the amount of pre-allocated mandatory bandwidth can be pre-calculated. This is obviously not the case for the group interface where single channel can be replicated multiple times (one per each SAP under the grp-if). Similarly, the same channel can be replicated multiple times for the same subscriber in per-host replication mode. Only subscribers in per-sap replication mode will warrant a single replication per channel. Therefore, if bundle cap is configured, it will be applied to limit the bandwidth of the bundle that is applied to a subscriber in a per-sap replication mode.

Figure 60 depicts MCAC related inheritances and MCAC bandwidth allocation model in per-sap replication mode. The MCAC policy is applied to the group interface and inherited by each subscriber as well as each SAP under the same group interface. However, the bundle bandwidth limit in the MCAC policy is ignored on the group-interface and under the subscriber (denoted by the red X in the figure). The bundle limit is applied only to each sap under the group-interface.

Overall (non-bundle) MCAC bandwidth limits are independently applied to the group-interface and the subscribers. According to our example, 20mbps of multicast bandwidth in total is allocated per group-interface. 6mbps of the 20mbps is allocated for mandatory channels. This leaves 14mbps of multicast bandwidth for the optional channels combined served on a first come first serve basis. Each physical replication (multiple replications of the same channel can occur, one per each SAP), counts towards the respective group-interface bandwidth limits.

Similar logic applies to the subscriber MCAC bandwidth limits which are applied per sub-profile.

Finally, each SAP can optionally contain the bundle bandwidth limit.

Note: In a hierarchical MCAC fashion, if either of the bandwidth checks fails (SAP, sub or grp-if) the channel admission for the subscriber also fails.

In our example, 6 subscriber hosts watch the same channel but there are only 3 active replications (one per SAP). This would yield:

- 14mbps of available multicast bandwidth under the group-interface. This bandwidth can be used for optional channels on a first come first serve basis. No reserved bandwidth is left.
- Subscriber A — 3mbps is still reserved for mandatory channels and 5mbps is available for optional channels (first come first serve). All this assume that the SAP and the grp-if bandwidth checks pass.
- Subscriber B — 2 mbps is still reserved for mandatory channels and 6mbps is available for optional channels (first come first serve). All this assume that the SAP and the grp-if bandwidth checks pass.

- Subscriber C — No reserved bandwidth for mandatory channels is left. 3 mbps is still left for optional channels. All this assume that the SAP and the grp-if bandwidth checks pass.
- SAPs — Considering that 2mbps are currently replicating (ch A, each SAP can still accept 1 mbps of the mandatory bandwidth (channel B and 7 mbps of the remaining optional channels.

Figure 60 MCAC Policy Inheritance in Per-SAP Replication Mode

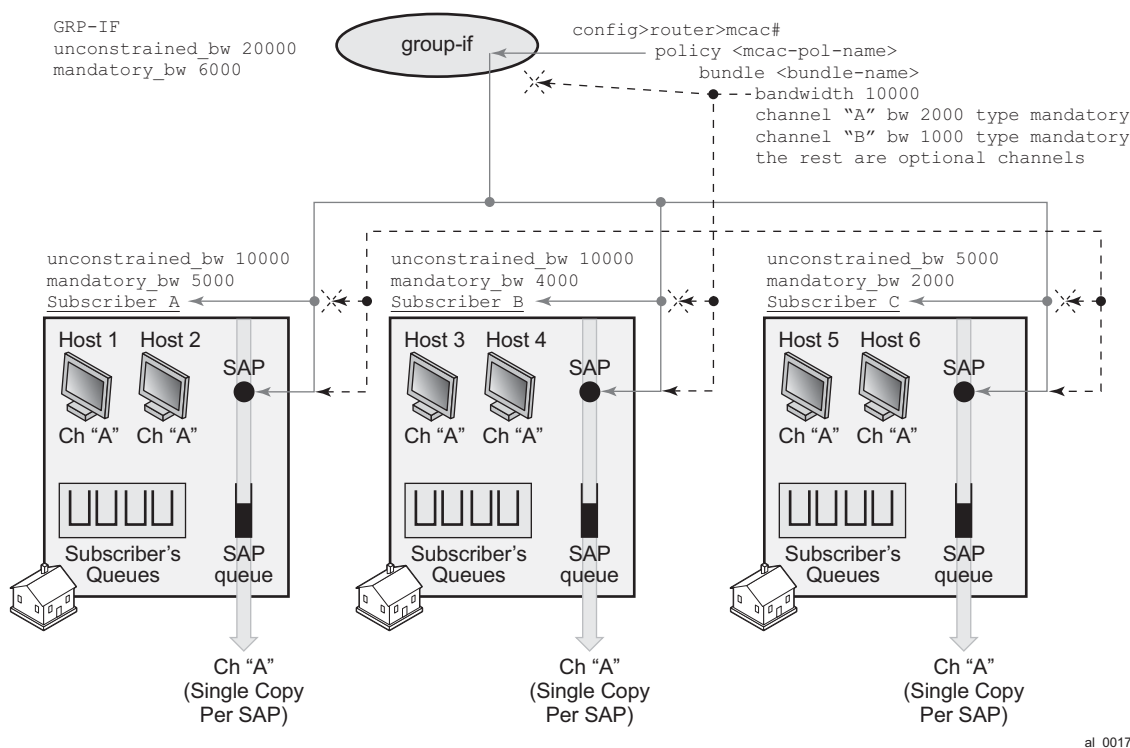

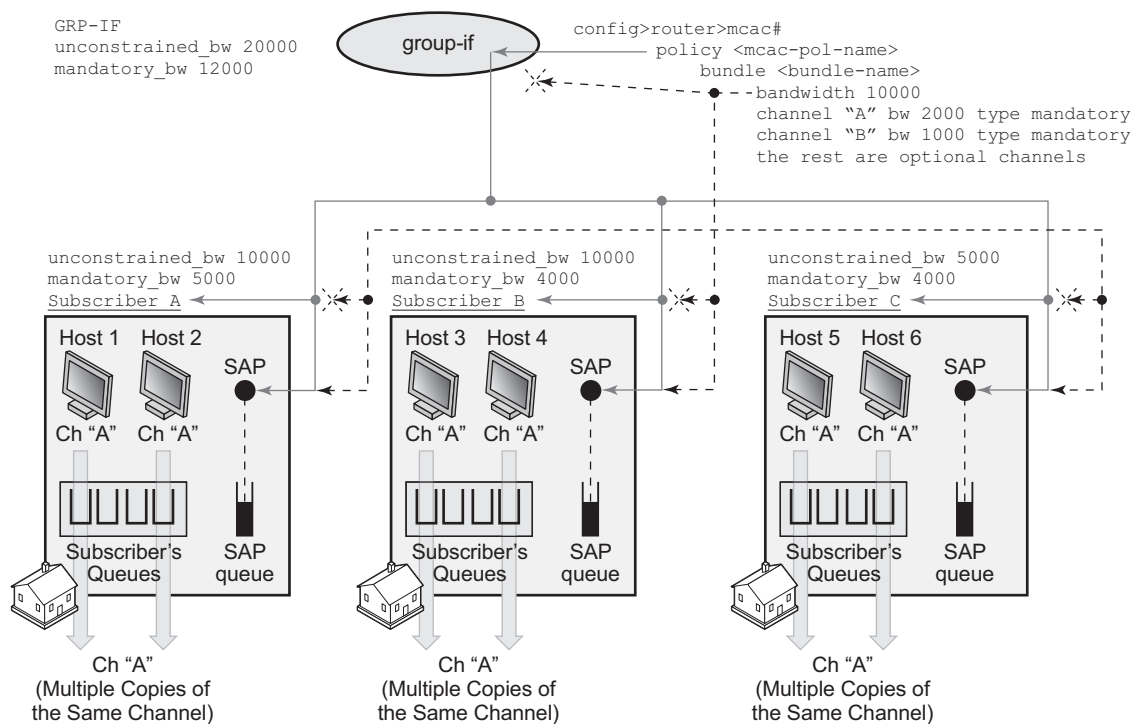

Figure 61 depicts behavior in per-host replication mode. MCAC policy inheritance flow is the same as in the previous example with the difference that the bundle limit has NO effect at all. Each host generates its own copy of the same multicast stream that is flowing via subscriber queues and not the SAP queue. Since each of the copies counts towards the subscriber or group-interface bandwidth limits, the multicast bandwidth consumption is higher in this example. This needs to be reflected in the configured multicast bandwidth limits. For example, the group-interface mandatory bandwidth limit is increased to 12mbps.

In our example, 6 subscriber hosts are still watching the same channel but now the number of replications is doubled from previous example. So the final tally for our MCAC bandwidth limit is as follows:

- Subscriber A - 1 mbps is still reserved for mandatory channels and 5mps for optional channels (first come first serve). All this assume that SAP and grp-if bandwidth checks pass.
- Subscriber B - No reserved mandatory bandwidth is left. 6 mps is still left for optional channels (first come first serve). All this assume that SAP and grp-if bandwidth checks pass.
- Subscriber C - No reserved mandatory bandwidth is left. 1 mps is still left for optional channels (first come first serve). All this assume that SAP and grp-if bandwidth checks pass.
- No reserved bandwidth is left under the group-interface. 8 mbps of available multicast bandwidth under the group-interface is still left for optional channels on a first come first serve basis
- Bundle limit on a SAP is irrelevant in this case.

Figure 61 MCAC Policy Inheritance in Per-HOST Replication Mode

al 0018

8.5.10 Determining MCAC Policy in Effect

Channel bandwidth definition (via MCAC policy) can be applied under the interface level (group-interface or regular interface):

configure>router/service>igmp/mld>interface/grp-if

The following configuration options can lead to the confusion as to which MCAC policy is in effect:

- The MCAC policy (channel bandwidth definition) can be applied under two different places (grp-if and/or regular intf).
- The same policy is used for (H)MCAC and HQoS Adjust with redirection enabled/disabled.

The general rule is that the MCAC policy under the group-interface will always be in effect in cases where redirection is disabled. This is valid for subscriber or group-interface MCAC, hMCAC (subscriber and group-interface) and HQoS Adjust in per SAP replication mode.

If redirection is enabled, the MCAC policy under the group-interface will be ignored.

If redirection is enabled, but there is no MCAC policy applied under the redirected interface (Redirected interface is the interface to which IGMP/MLD Joins are redirected from subscriber hosts), regardless of whether the MCAC policy under the group-interface is applied or not, then:

- HQoS Adjust will have no effect.
- MCAC will have no effect not only per redirected interface but also per subscriber.

8.5.11 Multicast Filtering

Multicast filtering must be done per session (host) for IPoE and PPPoE. There are two types of filters that are supported:

1. IGMP filters on access ingress. Those filters control the flow of IGMP messages between the host and the BNG. They are applied via the import statement in the igmp-policy. The same filters are used for multicast-redirection policy:

For IPv4

```
configure
  subscr-mgmt
    igmp-policy <name>
```

```
import <policy-name>
```

For IPv6

```
configure
  subscr-mgmt
    mld-policy <name>
    import <policy-name>
```

An example of the filter definition is given below:

```
configure
  router
    policy-options
      begin
      prefix-list <pref-name>
        prefix <pref-definition>
      policy-statement <name>
        entry 1
          from
            group-address <pref-name>
            source-address <ip>
            protocol igmp
          exit
          action accept
          exit
        exit
      default-action reject
```

2. Regular traffic filters where control multicast traffic flow can be controlled in both directions (ingress/egress). This is supported through ip-filters under the SLA profile.

8.5.12 Joining the Multicast Tree

The delivery of multicast to the subscribers-interface in a VPRN environment depends on the multicast deployment model (PIM, mBGP). In each model, a subscriber-interface is treated as a regular CE-PE interface that has registered v4 multicast listeners.

8.5.13 Wholesale/Retail Requirements

Multicast support on subscriber interfaces is supported in both wholesale/retail models:

- Wholesale/retail VPRN (IPoE and PPPoE)
- LAC/LNS (PPPoE only)

Figure 62 Wholesale/Retail Multicast Support

al_0019

The distinction between these two models is that in the case of LAC/LNS, the replication will be done further up in the network on an LNS node. This means that the traffic between LAC and LNS will be multiplied by the amount of replications.

8.5.14 QoS Considerations

In per-sap replication mode (which is applicable only to IPoE subscribers), multicast traffic is forwarded through the SAP queue which is outside of the subscribers queues and therefore not accounted in subscriber aggregate rate limit. HQoS Adjust is used to remedy this situation.

In case that the SAP queue is removed from the static SAP in IPoE 1:1 model (with profiled-only-traffic command), multicast traffic will flow via internal queues which cannot be tied into a port-scheduler as part of HQoS. Consequently, the port-scheduler max-rate as defined in the port-scheduler-policy will be used only to rate limit unicast traffic. In other words, the max-rate value in port-scheduler-policy must be lowered for the amount of anticipated multicast traffic that will flow via the port where port-scheduler-policy is applied.

A similar logic applies to per-sap replication mode on dynamic SAPs (MSAPs) even if the SAP queue is not removed. Although the multicast traffic is flowing via the SAP queue in this case, the SAP qos policy on MSAP cannot be changed from the default one. The default QoS policy on a SAP contains a single queue that is not parented by the port-scheduler.

Those restrictions do not apply to static SAPs where the SAP QoS policy can be customized and its queues consequently tied to the port-scheduler.

8.5.15 Redundancy Considerations

The subscriber can receive multicast content through the subscriber SAP, the redirected interface, or a combination of both.

Multicast redundancy is only supported on a MC-LAG topology. Multicast traffic can be delivered over the subscriber SAP, the redirected interface, or a combination of both.

Subscriber IGMP states can be synchronized across multiple 7450 ESS and 7750 SR nodes in order to ensure minimal interruption of (video delivery) service during network outages. The IGMP/MLD state of a subscriber-host in a 7450 ESS and 7750 SR node is tied to the state of the underlying MC-LAG protection mechanism. For example, IGMP states will be activated only for subscribers that are anchored under the group-interfaces with master SRRP state or under an active MC-LAG port.

For multicast redirection on a MC-LAG topology, it must be ensured that the redirected interface (the interface to which multicast forwarding is redirected) is under the same MC-LAG as the subscriber. Otherwise, IGMP states on the redirected interface will be derived independently of the IGMP states for the subscriber from which IGMP/MLD messages are redirected.

The IGMP/MLD synchronization process in conjunction with underlying access protection mechanisms will work as follows:

- IGMP/MLD states for the subscriber will be updated only if IGMP/MLD messages (Joins/Leaves/Reports, etc.) are received:
 - Directly from the downstream node on an active MC-LAG link. This is valid irrespective of the IGMP querier status for the subscriber.

In all other cases, assuming that some protection mechanism in the access is present, the IGMP/MLD messages are discarded and consequently no IGMP/MLD state is updated. Similar logic applies to regular Layer 3 interfaces, where SRRP is replaced with VRRP.

- Once the subscriber IGMP/MLD state is updated as a result of directly received IGMP/MLD message on an active subscriber (SRRP master of active MC-LAG), the sync IGMP/MLD message is sent to the standby subscriber over the Multi-Chassis Synchronization protocol. Synchronized IGMP states will be populated in Multi-chassis Synchronization (MCS) DB in all pairing 7450 ESS and 7750 SR nodes.
- In case that a IGMP/MLD sync (MCS) message is received from the peering node, the IGMP state for the standby subscriber is updated in the MCS DB but it is not downloaded into the forwarding plane unless there is a switchover. In case that the IGMP/MLD sync message is received for the active subscriber, the message will be discarded.
- IGMP/MLD queries are sent out only by IGMP/MLD querier. In a MC-LAG environment, it is the node with the active MC-LAG link.

Note: MC-LAG is usually configured with SRRP and the SRRP state is derived from the MC-LAG.

- IGMP/MLD states from the MCS DB will be:
 - Activated on non-querier subscriber in case that neither SRRP nor MC-LAG is deployed. It is assumed that the querier subscriber has received the original IGMP/MLD message and consequently sent the IGMP/MLD MCS Sync to the non-querier (standby). Non-querier interface will accept the MCS sync message and also it will propagate the IGMP/MLD states to PIM.

The querier subscriber will not accept the IGMP/MLD update from the MCS database.

- Aware of the state of MC-LAG. As soon as the standby MC-LAG becomes active, the IGMP/MLD states will be activated and they will be propagated to PIM. Traffic will be forwarded as soon as multicast streams are delivered to the node and the IGMP states under the subscriber are activated. On a standby MC-LAG, IGMP states will not be propagated from the MCS DB to PIM and consequently subscribers.

- Aware of the SRRP state. Since the subscriber with SRRP Master state is considered active, the states will be propagated to PIM as well. On standby SRRP, IGMP states will not be propagated from MCS DB to PIM and consequently to subscribers.
- For MC-lag setups, once the switchover is triggered via MC-LAG or SRRP, the IGMP/MLD states from MCS DB on the newly active MC-LAG node or subscriber under the newly SRRP Master will be sent to PIM and consequently to the forwarding plane effectively turning on multicast forwarding.

An active and standby subscriber refers to the state of underlying protection mechanism (active MC-LAG).

Note: The subscribers themselves are always instantiated (or active) on both nodes. However, traffic forwarding over those subscribers will be driven by the state of the underlying protection mechanism (MC-LAG). Hence the terms active and standby subscriber.

Note: In subscriber environment, SRRP should be always activated in dual-homing scenario. SRRP in subscriber environment will ensure that downstream traffic is forwarded via the same node that is forwarding upstream traffic. In this fashion, accounting and QoS for the subscriber are consolidated within a single node.

To summarize, in multi-chassis environment with subscribers, IGMP synchronization enabled and an access layer protection mechanism in place (MC-LAG), the behavior for is the following:

- IGMP/MLD states are synchronized between the chassis.
- On a MC-LAG setup, only the SRRP master or active MC-LAG will forward downstream multicast traffic.
- Length of outage during the switchover is determined by the detection and recovery of the underlying protection mechanism (MC-LAG or MCS) in addition to local propagation of IGMP/MLD states from MCS DB to PIM and consequently to forwarding plane.

Note: IGMP/MLD states can be statically configured on both redundant nodes in order to attract multicast traffic from upstream and therefore minimize outage during the switchover.

8.5.15.1 Redirection Considerations

The redirection policy has two options: to redirect only a certain set of multicast groups to the redirect interface or redirect all multicast to the redirect interface. The redirect policy is source agnostic.

On a MC-LAG setup, for redirection and MCS to work simultaneously in predictable manner, the redirected interface and the corresponding subscribers have to be protected by the same MC-LAG. This binds the redirected interfaces and the subscriber-hosts to the same physical port(s).

The following describe some guidelines for a MC-LAG setup:

- The active subscriber will replicate its received IGMP/MLD message to the redirected Layer 3 interface. The Layer 3 redirected interface will accept this message:
 - Independently of the corresponding VRRP state if MC-LAG is not used.
 - Only if the Layer 3 interface is IGMP querier.
 - MC-LAG is used and in active state.
- In all other cases the IGMP message under the Layer 3 redirected interface will be rejected.

Note: Layer 3 redirected interface can also receive IGMP message directly from the downstream node in case that IGMP forking in the access node is activated.

- The Layer 3 redirected interface will NOT accept the IGMP state update from the MCS DB unless the Layer 3 interface is a non-querier.
- In case that the Layer 3 redirected interface is part of MC-LAG, the IGMP state update sent to it via MCS DB will be accepted only during the transitioning phase from standby to active MC-LAG state.

Briefly, IGMP states on Layer 3 interface are not VRRP aware. However, they are MC-LAG aware.

8.5.16 Query Intervals for Multicast

The query interval commands—**query-interval**, **query-last-listener-interval**, **query-last-member-interval**, and **query-response-interval** are configurable in the following command contexts:

- router and VPRN service IGMP and MLD command contexts

- router and VPRN service IGMP and MLD group interface command contexts
- IGMP policy and MLD policy command contexts

The IGMP policy and MLD policy query intervals are only applicable to ESM host-based queries. Group interface query intervals are only applicable when the **no sub-hosts-only** command is configured. This triggers all group interface SAP(s) to send multicast queries. IGMP policy, MLD policy, and group interface timers use the router IGMP and MLD timers as a default fallback (see [ESM Host-based Queries](#) and [Group Interface-based Queries](#)).

For IGMP, the **query-interval** must be configured to be longer than the **query-last-member-interval** and **query-response-interval**. For MLD, the **query-interval** must be configured to be longer than the **query-last-listener-interval** and **query-response-interval**.

8.5.16.1 ESM Host-based Queries

An ESM host associated with an IGMP policy or an MLD policy will be sent host-based queries. A host-based query uses the intervals defined under the IGMP policy or MLD policy first, and if none are configured, it uses the interval values configured under the router IGMP or MLD context as a fallback. The router IGMP and MLD interval values are set to default values if none are configured. It is possible for the IGMP or MLD policy to only configure some of the query intervals while leaving other query intervals to use the values configured under the router IGMP or MLD context. For example, if the IGMP policy only has the **query-interval** configured to 11, the remaining **query-last-member-interval** and **query-response-interval** configurations will use values 1 and 10, respectively, defined under **router igmp**. It is also possible to configure an invalid combination of query timers when using both the IGMP policy configured intervals and intervals under **router igmp**. Using the example above, if the IGMP policy only sets the **query-interval** to 5, while the **query-response-interval** under **router igmp** is set to 10, this becomes an invalid combination because the response interval is longer than the query interval. When the system detects an invalid combination, it will fall back and use all interval values configured under the **router igmp** or **router mld** context and will ignore the interval configured under the IGMP or MLD policy. It is highly recommended that all three query intervals be configured together under the IGMP or MLD policy. To see the active values that each host is using for queries, use the **show router igmp hosts detail** or **show router mld host** command.

8.5.16.2 Group Interface-based Queries

When the group interface is configured with **no sub-hosts-only** (applicable only to IPoE multicast), each SAP configured under that group interface will send out SAP-based queries. In this case, a single query is sent out of the SAP. The query intervals will use the values configured under the group interface. If there are no values configured under the group interface, the router IGMP or MLD values will be used. When using the **no sub-hosts-only** command, IGMP and MLD policy are not required. To see the active values for the SAP-based queries, use the **show router igmp group-interface detail** or **show router mld group-interface detail** command.

8.6 Configuring Triple Play Multicast Services with CLI

This section provides information to configure multicast parameters in a Triple Play network using the command line interface.

Topics in this section include:

- [Configuring IGMP Snooping in the BSA](#)
 - [Enabling IGMP Snooping in a VPLS Service](#)
 - [Modifying IGMP Snooping Parameters](#)
 - [Configuring Static Multicast Groups on a SAP or SDP](#)

8.6.1 Configuring IGMP Snooping in the BSA

- [Enabling IGMP Snooping in a VPLS Service](#)
- [Configuring Static Multicast Groups on a SAP or SDP](#)
- [Enabling IGMP Group Membership Report Filtering](#)
- [Enabling IGMP Traffic Filtering](#)
- [Configuring Multicast VPLS Registration \(MVR\)](#)

8.6.1.1 Enabling IGMP Snooping in a VPLS Service

- [With IGMPv3 Multicast Routers](#)
 - [With IGMPv3 Multicast Routers](#)
 - [With IGMPv1/2 Multicast Routers](#)
- [Modifying IGMP Snooping Parameters](#)
- [Modifying IGMP Snooping Parameters for a SAP or SDP](#)

8.6.1.2 With IGMPv3 Multicast Routers

When multicast routers use IGMPv3, it is sufficient to just enable IGMP snooping, without any further modification of parameters.

The following displays an example of an IGMP snooping configuration:

```
A:ALA-48>config>service>vpls# info
-----
      igmp-snooping
      no shutdown
      exit
      no shutdown
-----
A:ALA-48>config>service>vpls#
```

8.6.1.3 With IGMPv1/2 Multicast Routers

When the multicast routers don't support IGMPv3, some timing parameters need to be configured locally in the SR-series routers.

Note: All routers in the multicast network must use the same values for these parameters.

The following displays an example of a modified IGMP snooping configuration:

```
A:ALA-48>config>service>vpls# info
-----
      stp
        shutdown
      exit
    igmp-snooping
      query-interval 60
      robust-count 5
      no shutdown
    exit
  no shutdown
-----
A:ALA-48>config>service>vpls#
```

8.6.1.4 Modifying IGMP Snooping Parameters

For interoperability with some multicast routers, the source IP address of IGMP group reports can be configured. Use the following CLI syntax to customize this IGMP snooping parameter:

The following displays an example of a modified IGMP snooping configuration:

```
A:ALA-48>config>service>vpls# info
-----
      stp
        shutdown
      exit
    igmp-snooping
      query-interval 60
      robust-count 5
      report-src-ip 10.20.20.20
      no shutdown
    exit
  no shutdown
-----
A:ALA-48>config>service>vpls#
```

8.6.1.5 Modifying IGMP Snooping Parameters for a SAP or SDP

Use the following CLI syntax to customize IGMP snooping parameters on an existing SAP. Commands for spoke or mesh SDPs are identical.

CLI Syntax:

```
config>service# vpls service-id
sap sap-id
    igmp-snooping
        fast-leave
        import policy-name
        last-member-query-interval interval
        max-num-groups max-num-groups
        mrouter-port
        query-interval interval
        query-response-interval interval
        robust-count count
        send-queries
```

To enable and customize sending of IGMP queries to the hosts:

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/3:0
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>snooping# send-queries
config>service>vpls>sap>snooping# query-interval 100
config>service>vpls>sap>snooping# query-response-
interval 60
config>service>vpls>sap>snooping# robust-count 5
config>service>vpls>sap>snooping# exit
config>service>vpls>sap# no shutdown
```

To customize the leave delay:

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:1
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>snooping# last-member-query-
interval 10
config>service>vpls>sap>snooping# no fast-leave
config>service>vpls>sap>snooping# exit
config>service>vpls>sap# exit
```

To enable Fast Leave:

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:1
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>snooping# no last-member-query-
interval
config>service>vpls>sap>snooping# fast-leave
config>service>vpls>sap>snooping# exit
config>service>vpls>sap# exit
```

To limit the number of streams that a host can join:

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:1
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>snooping# max-num-groups 4
config>service>vpls>sap>snooping# exit
config>service>vpls>sap# exit
```

To enable sending group reports on a SAP to standby multicast routers:

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:1
config>service>vpls>sap# igmp-snooping
config>service>vpls>sap>snooping# mrouter-port
config>service>vpls>sap>snooping# exit
config>service>vpls>sap# exit
```

The following example displays the modified IGMP snooping configuration on a SAP:

```
A:ALA-48>config>service>vpls>sap>snooping# info detail
-----
no fast-leave
no import
max-num-groups 4
last-member-query-interval 10
no mrouter-port
query-interval 100
query-response-interval 60
robust-count 5
send-queries
-----
A:ALA-48>config>service>vpls>sap>snooping#
```

8.6.2 Configuring Static Multicast Groups on a SAP or SDP

Use the following CLI syntax to add static group membership entries on an existing SAP (commands for spoke or mesh SDPs are identical):

The following displays an example of a static IGMP snooping configuration on a SAP:

```
A:ALA-48>config>service>vpls>sap# info
-----
max-nbr-mac-addr 4
igmp-snooping
fast-leave
mrouter-port
```

```

        static
        group 224.0.10.10
        source 10.10.10.1
        source 10.10.10.2
        exit
    exit
exit
-----
A:ALA-48>config>service>vpls>sap#

```

8.6.2.1 Enabling IGMP Group Membership Report Filtering

Routing policies can be defined to limit the multicast channels that can be joined by a host. For example, it is possible to define a policy listing a group of multicast streams (for example, 'basic' containing a basic set of TV channels or 'extended' containing a more extended set of TV channels), and to apply this policy to subscribers of IGMP snooping (SAPs and/or SDPs).

The following displays an example of a configuration to import a routing policy on a SAP:

```

A:ALA-48>config>service>vpls# info
-----
    stp
    shutdown
    exit
    igmp-snooping
    query-interval 60
    robust-count 5
    report-src-ip 10.20.20.20
    no shutdown
    exit
    sap 1/1/3:0 create
    igmp-snooping
    query-interval 100
    query-response-interval 60
    robust-count 5
    send-queries
    exit
    exit
    sap 1/1/3:22 create
    max-nbr-mac-addr 4
    igmp-snooping
    fast-leave
    import "test_policy"
    mrouter-port
    static
    group 224.0.10.10
    source 10.10.10.1
    source 10.10.10.2
    exit
    exit
    exit

```

```
        exit
        no shutdown
-----
A:ALA-48>config>service>vpls#
```

For details configuring a routing policy, see the Configuring Route Policies section in the Router Configuration Guide.

The following shows a sample routing policy configuration accepting IGMP messages for only five multicast channels:

```
A:ALA-48>config>router>policy-options# info
-----
    prefix-list "basic_channels"
        prefix 224.10.0.1/32 exact
        prefix 224.10.0.2/32 exact
        prefix 224.10.0.3/32 exact
        prefix 224.10.0.4/32 exact
        prefix 224.10.0.5/32 exact
    exit
    policy-statement "test_policy"
        description "basic set of 5 multicast channels"
        entry 1
            from
                group-address "basic_channels"
            exit
            action accept
            exit
        exit
        default-action reject
    exit
-----
A:ALA-48>config>router>policy-options#
```

8.6.2.1.1 Enabling IGMP Traffic Filtering

For security, it might be advisable to only allow multicast traffic into the SR-series routers from recognized multicast routers and servers. Multicast packets arriving on other interfaces (for example, customer-facing SAPs or spoke SDPs) can be filtered out by defining an appropriate IP filter policy.

For details on how to configure a filter policy, see section Creating an IP Filter Policy in the Router Configuration Guide.

The following example shows a sample IP filter policy configuration dropping all multicast traffic:

```
A:ALA-48>config>filter>ip-filter# info
-----
    ip-filter 1 create
        entry 1 create
```

```

        match
        dst-ip 224.0.0.0/24
        exit
        action accept
    exit
    entry 2 create
        match
        dst-ip 224.0.0.0/4
        exit
        action drop
    exit
exit
-----
A:ALA-48>config>filter>ip-filter#

```

The following example shows how to apply this sample IP filter policy to a SAP:

```

A:ALA-48>config>service>vpls # info
-----
    sap 1/1/1:1
        ingress
            filter ip 1
        exit
    exit
exit
-----
A:ALA-48>config>service>vpls>snooping#

```

8.6.3 Configuring Multicast VPLS Registration (MVR)

Use the following CLI syntax to configure Multicast VPLS Registration. The first step is to register a VPLS as a multicast VPLS.

CLI Syntax:

```

config>service# vpls service-id
igmp-snooping
    mvr
        no shutdown
        description description
        group-policy policy-name

```

Example:

```

config>service# vpls 1000
config>service>vpls# igmp-snooping
config>service>vpls>snooping# mvr
config>service>vpls>snooping>mvr# no shutdown
config>service>vpls>snooping>mvr# description "MVR VPLS"
config>service>vpls>snooping>mvr# group-policy
    "basic_channels_policy"

```

The second step is to configure a SAP to take the multicast channels from the registered multicast VPLS.

CLI Syntax:

```
config>service# vpls service-id
sap sap-id
    igmp-snooping
        mvr
            from-vpls vpls-id
```

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:100
config>service>vpls>sap# igmp-snooping
config>service>vpls>snooping# mvr
config>service>vpls>snooping>mvr# from-vpls 1000
```

For MVR by proxy also the destination SAP for the multicast channels should be configured.

CLI Syntax:

```
config>service# vpls service-id
sap sap-id
    igmp-snooping
        mvr
            from-vpls vpls-id
            to-sap sap-id
```

Example:

```
config>service# vpls 1
config>service>vpls# sap 1/1/1:100
config>service>vpls>sap# igmp-snooping
config>service>vpls>snooping# mvr
config>service>vpls>snooping>mvr# from-vpls 1000
config>service>vpls>snooping>mvr# to-sap 1/1/1:200
```

8.6.4 Configuring IGMP, MKD, and PIM in the BSR

Note: Configuring IGMP, MKD, and PIM in the BSR is supported by the 7750 SR only.

Refer to the Multicast Routing Protocols Guide for information about multicast and the commands required to configure basic IGMP and PIM parameters.

8.6.4.1 Enabling IGMP

The following displays an example of enabled IGMP.

```
A:LAX>>config>router/service>vprn info detail
...
#-----
echo "IGMP Configuration"
#-----
      igmp
        query-interval 125
        query-last-member-interval 1
        query-response-interval 10
        robust-count 2
        no shutdown
      exit
#-----
...
A:LAX>>config>system#
```

8.6.4.2 Configuring IGMP Interface Parameters

The following example displays an IGMP configuration:

```
A:LAX>config>router/service>vprn>igmp# info
-----
    interface "lax-sjc"
    exit
    interface "lax-vls"
    exit
    group-interface "Mcast-subscribers"
    exit
-----
A:LAX>config>router>igmp# exit
```

8.6.4.3 Configuring Static Parameters

The following example displays a configuration to add IGMP a static multicast source::

```
A:LAX>config>router/service>vprn>igmp# info
-----
    interface "lax-sjc"
    exit
    interface "lax-vls"
        static
            group 229.255.0.2
            source 172.22.184.197
        exit
    exit
    exit
    ggroup-interface "mcast-subscribers"
    interface "lax-vls"
        static
            group 229.255.0.2
            source 172.22.184.197
        exit
    exit
    exit
    exit
    exit-----
A:LAX>config>router>igmp#
```

The following example displays the configuration to add a IGMP static starg entry:

```
A:LAX>config>router/service>vprn>igmp# info
-----
    interface "lax-sjc"
        static
            group 230.1.1.1
            starg
        exit
    exit
    exit
    interface "lax-vls"
        static
            group 229.255.0.2
```

```
        source 172.22.184.197
    exit
    exit
    exit
    group-interface "mcast-subscribers"
    static
    group 230.1.1.1
    starg
    exit
    exit
    exit
    exit
-----
A:LAX>config>router>igmp#
```

8.6.4.4 Configuring SSM Translation

The following displays an SSM translation configuration:

```
A:LAX>config>router/service>vprn>igmp# info
-----
    ssm-translate
    grp-range 229.255.0.1 231.2.2.2
    source 10.1.1.1
    exit
    exit
    interface "lax-sjc"
    static
    group 230.1.1.1
    starg
    exit
    exit
    exit
    interface "lax-vls"
    static
    group 229.255.0.2
    source 172.22.184.197
    exit
    exit
    exit
    group-interface "mcast-subscribers"
    static
    group 230.1.1.1
    starg
    exit
    exit
    exit
    exit
-----
A:LAX>config>router/service>vprn>igmp# exit
```

8.6.4.5 Enabling MLD

The following displays an example of enabled MLD.

```
A:LAX>>config>router/service>vprn # info detail
#-----
echo "MLD Configuration"
#-----
mld
query-interval 125
query-last-member-interval 1
query-response-interval 10
robust-count 2
no shutdown
exit
#-----
...
A:LAX>>config>router/service>vprn #
```

8.6.4.6 Configuring MLD Interface Parameters

The following example displays an MLD configuration:

```
A:LAX>config>router/service>vprn>mld# info
-----
interface "lax-sjc"
exit
interface "lax-vls"
exit
group-interface "mcast-subscribers"
exit
-----
A:LAX>config>router/service>vprn>mld#exit
```

8.6.4.7 Configuring Static Parameters

The following example displays a configuration to add MLD a static multicast source:

```
A:LAX>config>router/service>vprn>mld# info
-----
interface "lax-sjc"
exit
interface "lax-vls"
    static
        group ffe8::1
        source 2001::1
    exit
exit
```

```

exit
group-interface "mcast-subscribers"
  static
    group ffe8::1
    source 2001::1
    exit
  exit
exit
-----
A:LAX>config>router/service>vprn>mld#

```

The following example displays the configuration to add a MLD static starg entry:

```

A:LAX>config>router/service>vprn>mld# info
-----
interface "lax-sjc"
  static
    group ffe8::2
    starg
    exit
  exit
interface "lax-vls"
  static
    group ffe8::1
    source 2001::1
    exit
  exit
group-interface "mcast-subscribers"
  static
    group ffe8::2
    starg
    exit
  exit
exit

8.6.4.8 Configuring SSM Translation

The following displays an SSM translation configuration:

```

A:LAX>config>router/service>vprn>mld# info
-----
ssm-translate
  grp-range ff31::1 ff32::1
  source 2001::2
  exit
exit
interface "lax-sjc"
  static

```

```
        group ffe8::2
            starg
            exit
        exit
    exit
interface "lax-vls"
    static
        group ffe8::1
            source 2001::1
            exit
        exit
    exit
group-interface "mcast-subscribers"
    static
        group ff31::20
            starg
            exit
        exit
    exit
exit
-----
A:LAX>config>router/service>vprn>mld# exit
```

8.6.4.9 Configuring PIM

8.6.4.9.1 Enabling PIM

When configuring PIM, make sure to enable PIM on all interfaces for the routing instance, otherwise multicast routing errors can occur.

The following example displays detailed output when PIM is enabled.

```
A:LAX>>config>router# info detail
...
#-----
echo "PIM Configuration"
#-----
    pim
        no import join-policy
        no import register-policy
        apply-to none
        rp
            no bootstrap-import
            no bootstrap-export
            static
            exit
            bsr-candidate
                shutdown
                priority 0
                hash-mask-len 30
                no address
```

```

        exit
        rp-candidate
            shutdown
            no address
            holdtime 150
            priority 192
        exit
    exit
    no shutdown
exit
#-----

```

8.6.4.9.3 Importing PIM Join/Register Policies

The import command provides a mechanism to control the (*,g) and (s,g) state that gets created on a router. Import policies are defined in the **config>router>policy-options** context. See [Configuring PIM Join/Register Policies](#).

Note: In the import policy, if an action is not specified in the entry then the default-action takes precedence. If no entry matches then the default-action also takes precedence. If no default-action is specified, then the default default-action is executed.

The following example displays the command usage to apply the policy statement will not allow join messages for group 229.50.50.208/32 and source 192.168.0.0/16 but allows join messages for 192.168.0.0/16, 229.50.50.208:

Example:

```
config>router# pim
config>router>pim# import join-policy "foo"
config>router>pim# no shutdown
```

The following example displays the PIM configuration:

```
A:LAX>config>router>pim# info
-----
import join-policy "foo"
interface "system"
exit
interface "lax-vls"
exit
interface "lax-sjc"
exit
interface "pl-ix"
exit
rp
static
address 2.22.187.237
group-prefix 224.24.24.24/3
exit
address 10.10.10.10
exit
exit
bsr-candidate
shutdown
exit
rp-candidate
shutdown
exit
exit
-----
A:LAX>config>router>pim#
```

8.6.4.9.4 Configuring PIM Join/Register Policies

Join policies are used in Protocol Independent Multicast (PIM) configurations to prevent the transportation of multicast traffic across a network and the dropping of packets at a scope at the edge of the network. PIM Join filters reduce the potential for denial of service (DoS) attacks and PIM state explosion—large numbers of Joins forwarded to each router on the RPT, resulting in memory consumption.

*,g or s,g is the information used to forward unicast or multicast packets.

- **group-address** matches the group in join/prune messages
group-address 229.55.150.208/32 exact
- **source-address** matches the source in join/prune messages
source-address 192.168.0.0/16 longer
- **interface** matches any join message received on the specified interface
interface port 1/1/1
- **neighbor** matches any join message received from the specified neighbor
neighbor 1.1.1.1

The following configuration example will not allow join messages for group 229.50.50.208/32 and source 192.168.0.0/16 but allows join messages for 192.168.0.0/16, 229.50.50.208.

```
A:ALA-B>config>router>policy-options# info
-----
...
    policy-statement "foo"
    entry 10
    from
    group-address "229.50.50.208/32"
    source-address 192.168.0.0
    exit
    action reject
    exit
exit
policy-statement "reg-pol"
entry 10
from
group-address "224.0.0.0/8"
exit
action accept
exit
exit
exit
exit
...
-----
A:ALA-B>config>router>policy-options#
```

8.6.4.10 Configuring Bootstrap Message Import and Export Policies

Bootstrap import and export policies are used to control the flow of bootstrap messages to and from the RP.

The following configuration example specifies that no BSR messages received or sent out of interface port 1/1/1.

```
:A:ALA-B>config>router>policy-options# policy-statement pim-import
:A:ALA-B>config>router>policy-options>policy-statement$ entry 10
:A:ALA-B>config>router>policy-options>policy-statement>entry$ from
:A:ALA-B>config>router>policy-options>policy-statement>entry>from$ interface port1/
1/1/
:A:ALA-B>config>router>policy-options>policy-statement>entry>from$ exit
:A:ALA-B>config>router>policy-options>policy-statement>entry# action reject
:A:ALA-B>config>router>policy-options>policy-statement>entry# exit
:A:ALA-B>config>router>policy-options>policy-statement# exit

:A:ALA-B>config>router>policy-options# policy-statement pim-export
:A:ALA-B>config>router>policy-options>policy-statement$ entry 10
:A:ALA-B>config>router>policy-options>policy-statement>entry$ to
:A:ALA-B>config>router>policy-options>policy-statement>entry>to$
```

| <b>Description</b> | <p>This command creates a text description stored in the configuration file for a configuration context.</p> <p>The <b>description</b> command associates a text string with a configuration context to help identify the context in the configuration file.</p> <p>The <b>no</b> form of this command removes any description string from the context.</p>                                                  |
| <b>Default</b>     | No description is associated with the configuration context.                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>description-string</i> — A text string describing the entity. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                     |

##### shutdown

|                |                                                                                     |
|----------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] shutdown</b>                                                                |
| <b>Context</b> | config>card>mda>ingress>mcast-mgmt<br>config>card>mda>ingress>mcast-path-management |

config>mcast-mgmt>mcast-rprt-dest

**Description** The shutdown command is used to disable ingress multicast path management for a forwarding plane or MDA. The default state is shutdown. When the no shutdown command is executed, ingress multicast path management is enabled and the system will evaluate all multicast channels on the MDA or forwarding plane based on the default or explicit bandwidth policy applied and multicast information policies associated with the channels.

The **no** form of the command is used to enable ingress multicast path management on the MDA or forwarding plane.

8.7.2.1.2 Multicast Management Commands

mcast-management

**Syntax** mcast-management

**Context** config

**Description** The mcast-management CLI node contains the bandwidth-policy and multicast-info-policy definitions. The bandwidth-policy is used to manage the ingress multicast paths into the switch fabric. The multicast-info-policy defines how each multicast channel is handled by the system. The policy may be used by the ingress multicast bandwidth manager, the ECMP path manager and the egress multicast CAC manager.

The mcast-management node always exists and contains the default bandwidth-policy and the default multicast-info-policy. Enter the mcast-management node when editing, deleting or creating a bandwidth-policy or multicast-info-policy. The default bandwidth-policy and multicast-info-policy cannot be edited or deleted.

A chassis-level node within multicast-management is used to control the switch fabric multicast planes replication limits. The switch fabric multicast planes are the individual multicast spatial replication contexts available in the system.

mcast-reporting-dest

**Syntax** mcast-reporting-dest dest-name [create]  
no mcast-reporting-dest dest-name

**Context** config>mcast-management

**Description** This command will create a Multicast Reporting Destination hierarchy in CLI under which parameters defining this destination can be specified. The destination refers to an external node that will collect and analyze IGMP events.

The Multicast Reporting Destination is associated with a name that each subscriber can reference in order to send the IGMP related events.

It can be also referenced in the Host Tracking Policy in case that IGMP events are related to Host Tracking feature.

|                   |                                                    |
|-------------------|----------------------------------------------------|
| <b>Default</b>    | No mcast-reporting-dest is defined.                |
| <b>Parameters</b> | <i>dest-name</i> — Specifies the destination name. |

## dest-ip-address

|                    |                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dest-ip-address</b> <i>ip-addr</i><br><b>no dest-ip-address</b>                                                                                                                                |
| <b>Context</b>     | config>mcast-mgmt>mcast-reporting-dest                                                                                                                                                            |
| <b>Description</b> | This command specifies the IP address of the external node to which IGMP events will be exported. The destination IP address can only be reachable from the global routing table (no vrf access). |
| <b>Default</b>     | No IP address is configured.                                                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-addr</i> — Specifies the IP address.                                                                                                                                                        |

## max-tx-delay

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-tx-delay</b> <i>deci-seconds</i><br><b>no max-tx-delay</b>                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>mcast-mgmt>mcast-reporting-dest                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command specifies the time interval before the packet starts transmitting towards the destination. When an IGMP event is encoded and ready to be transported, a buffer for the packet will be allocated (if not already existent). The events will be written into this buffer. Along with the initial buffer creation, a timer is started. The trigger for the transmission of the packet is either the TX buffer being filled up to 1400B, or the timer expiry, whichever comes first. |
| <b>Default</b>     | no max-tx-delay. This indicates there is no delay. Events are transported immediately.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>deci-seconds</i> — Specifies the deci-seconds.<br><b>Values</b> 0 to 100                                                                                                                                                                                                                                                                                                                                                                                                                   |

---

## udp-dst-port

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>udp-dst-port</b> <i>port</i><br><b>no udp-dst-port</b>                                                   |
| <b>Context</b>     | config>mcast-mgmt>mcast-reporting-dest                                                                      |
| <b>Description</b> | This command specifies the UDP destination port of the external node to which IGMP events will be exported. |
| <b>Default</b>     | No UDP port is configured.                                                                                  |
| <b>Parameters</b>  | <i>port</i> — Specifies the port number.<br><b>Values</b> 1 to 65535                                        |

### 8.7.2.1.3 Bandwidth Policy Commands

## bandwidth-policy

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>mcast-mgmt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command creates a multicast bandwidth policy. Bandwidth policies are used to manage the ingress multicast path bandwidth. Each forwarding plane supports multicast forwarding paths into the switch fabric. By default, two paths are available; the multicast high priority path and the multicast low priority path. Multicast packets are forwarded on either path based on the expedited or non-expedited (best-effort) nature of the queue the packets are scheduled from. The ingress forwarding plane uses the classification rules to determine the forwarding class of each multicast packet and uses the forwarding class to queue mapping to decide which ingress multipoint queue will forward the packet. When multicast path management has been enabled on an ingress forwarding plane, the multicast bandwidth manager adds a third path for ingress multicast forwarding (ancillary path) and changes the way multicast packets are mapped to the three paths. This new forwarding plane behavior only applies to Layer 2 snooped or Layer 3 routed IP multicast forwarding. VPLS broadcast and unknown or non-snooped flooding is not affected.</p> <p>When multicast path management is enabled, the ingress forwarding plane allows IP multicast snooped or routed packets to be placed on to the three multicast paths independently of the ingress classification rules. The high priority multicast path is treated as the primary path and the low priority multicast path is treated as the secondary path. The ancillary path is the point-to-point bandwidth unused by switch fabric point-to-point traffic. The ingress bandwidth manager evaluates each multicast FIB (M-FIB) record to determine which path is best based on ingress bandwidth, number of switch fabric destinations and the fill level of each path. Explicit path association is also supported.</p> |

### Dynamic Bandwidth Activity Monitoring

When ingress multicast path management is enabled on an MDA, the system monitors the in-use bandwidth associated with each Layer 2 and Layer 3 ingress multicast record. When records are first populated by static, snooping or routing protocols, they are first assumed to be inactive. An inactive record is not considered to be currently consuming ingress multicast path bandwidth.

Within the multicast-info-policy, the bandwidth activity of the new record was configured to be either managed based on an administrative bandwidth, or based on the dynamic bandwidth rate table. The bandwidth-policy associated with ingress MDA contains the configuration parameters for creating the dynamic bandwidth rate table. The purpose of the table is to allow for the system to monitor the bandwidth activity associated with a multicast record and compare the current rate against a number of rate thresholds. Rate thresholds are used to allow a multicast streams rate to fluctuate between a given range while keeping the managed rate at a certain level. Multiple dynamic managed rates are supported in the table to allow monitoring of different types of multicast traffic. Each rate threshold is associated with a rising and falling threshold that defines when the specified rate should be used and when the next lower rate should be used.

Once a record's monitored current rate rises to the first dynamic rising threshold, the record is considered to be active and the system will then manage the bandwidth the record represents based on the parameters associated with the record in the records multicast-info-policy and the configured path information in the MDAs associated bandwidth-policy.

### Ingress Multicast Path Parameters

The bandwidth-policy also contains the configuration parameters for each of the managed ingress multicast paths. Each path may be configured with a path-limit rate used to override a specific paths default rate. Also, forwarding on each path is managed through an ingress path queue. The queue default parameters may be overridden for each path.

### Default Bandwidth Policy

A bandwidth policy with the name 'default' always exists and is used as the default bandwidth policy when ingress multicast path management is enabled without an explicit bandwidth policy defined on an MDA. The default policy cannot be deleted or edited.

The **no** form of the command removes the specified bandwidth policy from the system. The bandwidth policy associations must be removed from MDA configurations before it can be removed.

**Parameters**     *policy-name* — Specifies the name of the bandwidth policy, up to 32 characters in length. Each bandwidth policy must be uniquely named within the system. 32 policies can be configured per system.

**create** — The create keyword is required if creating a new bandwidth policy when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the bandwidth policy name already exists.

## admin-bw-threshold

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>mcast-management>bandwidth-policy                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command defines at which bandwidth rate a multicast channel configured to use an administrative rate will start and stop using that rate as the in-use ingress bandwidth when managing ingress multicast paths. This parameter only applies to channels that are configured to use the admin-bw rate with the bw-activity use-admin-bw command (both are configured in the multicast-info-policy associated with the channel context). |

To be effective, the admin-bw-threshold must be less than the channels configured admin-bw. If the administrative bandwidth configured on the channel is less than the administrative bandwidth threshold defined in the bandwidth policy, the admin-bw value is ignored for ingress multicast path management and the system continually uses the dynamic ingress bandwidth associated with the channel. Since the admin-bw-threshold is defined in the bandwidth-policy and the channel admin-bw value is defined in the multicast-info-policy, it is not possible to pre-determine that a given administrative bandwidth value is less than an administrative bandwidth threshold. Since a typical administrative bandwidth threshold will be set significantly lower than any administrative bandwidth values, this corner case is not expected to be prevalent. However, if the case does arise in a production environment, no ill behavior is expected as the threshold is simply a tuning parameter used to detect when the bandwidth associated with a channel has risen above any OAM or background type traffic.

While a channel that is configured to use-admin-bw (in the bw-activity command) current bandwidth is less than the admin-bw-threshold, the system treats the channel as a dynamic type channel. Once the threshold is crossed, the system immediately allocates the full admin-bw value to the channel and manages the ingress multicast path accordingly. If the bandwidth monitored on the channel rises above the admin-bw value, the system reverts to dynamic bandwidth management operation. If the bandwidth drops below the admin-bw value, but is above the admin-bw-threshold, the system uses the admin-bw value. If the bandwidth drops below the admin-bw-threshold, the system goes back to dynamic bandwidth management operation.

This command has no effect on multicast ECMP or egress CAC management operations.

The no form of the command restores the default threshold value of 10 Kbps.

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>kilobits-per-second</i> — The kilobits-per-second parameter must follow the admin-bw-threshold command and defines rate at which channels configured to use administrative bandwidths change from dynamic bandwidth management to using the channels configured administrative bandwidth. The parameter is expressed as an integer value and represents multiples of 1,000 bits per second. A value of 3000 indicates 3,000,000 bits per second. |
| <b>Values</b>     | 1 to 40,000,000                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>    | 10                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## primary-path

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>primary-path</b>                                                    |
| <b>Context</b>     | config>mcast-mgmt>bandwidth-policy                                     |
| <b>Description</b> | This command enables the context to configure primary path parameters. |

## ancillary-path

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancillary-path</b>                                                                                                                           |
| <b>Context</b>     | config>mcast-mgmt>bandwidth-policy                                                                                                              |
| <b>Description</b> | This command overrides the default path limit for the ancillary path, which is one of the three ingress multicast paths into the switch fabric. |

## t2-paths

|                    |                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>t2-paths</b>                                                                                                                                                                   |
| <b>Context</b>     | config>mcast-management>bandwidth-policy                                                                                                                                          |
| <b>Description</b> | The t2-paths CLI node contains the primary and secondary path CLI nodes for IOM-3s. The commands within this context are ignored when the policy is applied to an IOM-1 or IOM-2. |

## secondary-path

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-path</b>                                                                                                                           |
| <b>Context</b>     | config>mcast-mgmt>bandwidth-policy<br>config>mcast-mgmt>bw-plcy>t2-paths                                                                        |
| <b>Description</b> | This command overrides the default path limit for the secondary path, which is one of the three ingress multicast paths into the switch fabric. |

number-paths

|                    |                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>number-paths</b> <i>number-of-paths</i> [ <b>dual-sfm</b> <i>number-of-paths</i> ]                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>mcast-management>bandwidth-policy>t2-paths>secondary-paths>queue-parameters                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | This command is used to explicitly provision the number of secondary paths (and imply the number of primary paths) supported by the T2 TChip based forwarding plane the bandwidth policy is managing. The default (and minimum) number of secondary paths is 1 and the maximum configurable is 15. The number of primary paths is total number of available paths minus the number of secondary paths. |

Secondary paths are used by:

- Expedited VPLS, IES and VPRN service ingress multipoint queues
- Expedited network ingress multipoint queues
- Managed multicast explicit path primary channels (using the primary paths managed multipoint queue)
- All managed multicast dynamic path channels when the primary paths or multicast planes are not at their limit (using the primary paths managed multipoint queue)
- Highest preference managed multicast dynamic path channels when the primary paths or multicast planes are at their limit (using the primary paths managed multipoint queue)

Secondary paths are used by:

- Best-Effort VPLS, IES and VPRN service ingress multipoint queues
- Best-Effort network ingress multipoint queues
- Managed multicast explicit path secondary channels (using the secondary paths managed multipoint queue)
- Lower preference managed multicast dynamic path channels when the primary paths or multicast planes are at their limit (using the secondary paths managed multipoint queue)

The number of secondary paths should be increased from the default value of 1 when a single secondary path is insufficient for the amount of explicit secondary path managed traffic or the amount of best-effort multipoint non-managed queue traffic.

The **no** form of the command restores the default number of secondary paths.

|                   |                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>number-of-paths</i> — The number-paths parameter specifies the number of secondary paths when only one switch fabric is active, while the dual-sfm parameter specifies the same value when two switch fabrics are active. |
| <b>Values</b>     | 1 to 15                                                                                                                                                                                                                      |
| <b>Default</b>    | 1                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command is used to individually override the default path limit for each of the three ingress multicast paths into the switch fabric on an IOM-1 or IOM-2. When the bandwidth policy is applied to an IOM-3, the path-limit commands are ignored. The configured path limit may be less than, equal to or greater than the terminating switch fabric multicast plane limit.</p> <p>The system will not violate the configured path limit or the multicast plane limits. The system uses all bandwidth limits and record preferences when determining which records should be allowed on which path, which records should be moved and which records should be placed in the black-hole state.</p> <p>Changing a paths bandwidth limit causes the system to immediately reevaluate each record on the path. For dynamic path records, this could cause records to be moved to other paths and records on other paths to be placed in the black-hole state.</p> <p>Changing a path-limit value within the bandwidth policy affects all MDAs where the policy is applied. The policy derived path limit may be overridden on each MDA using the primary-override, secondary-override or ancillary-override nodes in the MDA context.</p> <p>The <b>no</b> form of the command returns the default path bandwidth limit for the ingress multicast path. The command has no effect for MDAs with a path override in effect for the given path.</p> |               |       |                |       |                 |       |
| <b>Default</b>     | no path-limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |               |       |                |       |                 |       |

**Description**

This command defines the individual parameters for the queues through which multicast packets are forwarded into the switch fabric on each path.

The individual path queues may be viewed as shared queues. All multicast packets forwarded through the switch fabric associated with one of the paths traverses bypass the normal queuing behavior. Instead of being forwarded through the normal service or network multicast queue, a single queue associated with the multicast path is used. In order to retain billing and diagnostic information, the forwarding and discard statistics for the service or network queue the packet would have traversed without ingress multicast management is used to account for each packets behavior.

**Note:** Any ingress scheduling policy functions attempting to manage the service or network multicast queues will only be able to read the statistics of the multicast queues and will not be able to manage the queues dynamic rate since the packets are flowing through different, non-managed queues. Since this is the case, multicast queues parented to a scheduling policy should be parented to the root scheduler at the highest priority without any rate limitation. Any ingress rate limiting for multicast traffic will be preformed by the multicast path bandwidth manger based on each records priority and a possible “black-hole” rate threshold.

All queues created for ingress multicast path management are automatically created by the system out of the system reserved queue space. Each queue is created as an expedited queue.

When forwarding through the queues, each packets forwarding class is ignored. However, the forwarding class is retained for proper egress processing. The packets expressed or implied profile is also ignored within the ingress path queues. A packets congestion priority is derived from the records cong-priority-threshold evaluation result as indicated by the policy or multicast-info-policy. The cong-priority-threshold sets the high or low congestion priority of a record based on the records preference value. Within each multicast information policy bundle the cong-priority-threshold is set with a value from 0 to 7 and defines the threshold at which all records with a preference equal to or higher than the defined preference will be treated as congestion priority high. Multicast records with a preference lower than the defined class threshold will be treated as congestion priority low. Low priority packets use the low priority MBS threshold of the queue while high priority packets use the standard MBS value. In the event of path congestion, low priority packets are discarded first, leaving room for the higher priority packets.

For the primary and secondary paths, a single queue exists for each path and every packet forwarded through the path by the bandwidth manager uses that queue. For the ancillary path, a single queue exists for each switch fabric destination. Ancillary path packets are replicated to each switch fabric destination. The replication process places a copy of the packet in the correct ancillary path queue that forwards to that destination.

| <b>Description</b> | <p>This command overrides the default Committed Buffer Size (CBS) for each individual path's queue. The queues CBS threshold is used when requesting buffers from the systems ingress buffer pool to indicate whether the requested buffer should be removed from the reserved portion of the buffer pool or the shared portion. When the queue's fill depth is below or equal to the CBS threshold, the requested buffer comes from the reserved portion. Once the queues depth exceeds the CBS threshold, buffers come from the shared portion.</p> <p>The <b>cbs</b> <i>percent-of-resv-cbs</i> parameter is defined as a percentage of the reserved portion of the pool. The system allows the sum of all CBS values to equal more than 100% allowing for oversubscription of the reserved portion of the pool. If the reserved portion is oversubscribed and the queues are currently using more reserved space than provisioned in the pool, the pool automatically starts using the shared portion of the pool for within-CBS buffer allocation. On the shared early detection slopes could assume more buffers exist within the shared portion than actually do which may cause the early detection function to fail.</p> <p>For the primary-path and secondary-path queues, the percentage is applied to a single queue for each path. For the ancillary-path, multiple queues are required. The <b>cbs</b> <i>percent-of-resv-cbs</i> is divided between all ancillary path queues. For example, if primary is given 10 percent, the primary path queues CBS is set to 10% of the reserved portion of the buffer pool. If ancillary is given 50 percent and 10 ancillary path queues exist, each ancillary queue gets 5%. The number of path queues required depends on the available chassis slots and the provisioned IOM types. 7450 ESS-6 chassis have 4 slots, 7450 ESS-7 and 7750 SR-7 have 5 and the 7450 ESS-12 and 7750 SR-12 have 10. An IOM-1 or IOM-2 on a slot has two switch fabric destinations.</p> <p>The <b>no</b> form of the command restore the path queues default CBS value.</p> |                 |   |                   |    |                   |    |
| <b>Parameters</b>  | <p><i>percent-of-resv-cbs</i> — The percent of buffers reserved from the total buffer pool space, expressed as a decimal integer. If 10 MB is the total buffers in the buffer pool, a value of 10 would reserve 1MB (10%) of buffer space for the forwarding class queue. The value 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can be applied for scheduling purposes).</p> <p><b>Values</b>      0 to 100</p> <p><b>Default</b></p> <table><tr><td><b>Primary:</b></td><td>5</td></tr><tr><td><b>Secondary:</b></td><td>30</td></tr><tr><td><b>Ancillary:</b></td><td>65</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <b>Primary:</b> | 5 | <b>Secondary:</b> | 30 | <b>Ancillary:</b> | 65 |

| <b>Description</b> | <p>This command overrides the default percentage value used to determine the low priority MBS value for the queue. By default, 10 percent of the queue depth is reserved for high congestion priority traffic. When specified, the high-prior-only percentage value is applied to the queues MBS threshold. The resulting value is subtracted from the MBS to derive the low priority MBS threshold maintained by the queue. The low priority MBS threshold defines the point at which all low congestion priority packets destined for the queue will be discarded based on queue depth. Low and high congestion priority is derived from the multicast records preference value compared to the record's bundle priority-threshold.</p> <p>The <b>no</b> form of this command restores the default value.</p> |
| <b>Parameters</b>  | <p><i>percent-of-mbs</i> — The percentage parameter is required when specifying high-prior-only.</p> <p><b>Values</b>      0 to 100</p> <p>0 specifies that the MBS and LP-MBS thresholds will be set to the same value resulting in high and low congestion priority packets being treated equally.</p> <p>100 specifies that the LP-MBS threshold will be set to 0, resulting in a discarded of all low congestion priority packets.</p> <p>Values in between 0 and 100 result in a corresponding differential between the MBS and LP-MBS threshold values.</p>                                                                                                                                                                                                                                               |

config>mcast-management>bandwidth-policy>t2-paths>secondary-paths>queue-parameters

**Description** This command is used to override the default Maximum Buffer Size (MBS) for each individual path's queue. The queues MBS threshold defines the point at which all packets destined for the queue will be discarded based on queue depth. The defined threshold also provides context for the queues high-prior-only parameter.

The mbs *percent-of-pool* parameter is defined as a percentage of the total pool size. The system allows the sum of all MBS values to equal more than 100% allowing for oversubscription of the pool.

For the primary-path and secondary-path queues, the mbs percent is applied to a single queue for each path. For the ancillary-path, multiple queues are required. The mbs percentage is divided between all ancillary path queues. For example, if primary is given 10 percent, the primary path queues MBS is set to 10% of the buffer pool. If ancillary is given 50 percent and 10 ancillary path queues exist, each ancillary queue gets 5%. The number of path queues required depends on the available chassis slots and the provisioned IOM types. ESS-6 chassis have 4 slots, ESS/SR-7 have 5 and ESS/SR-12 have 10. An IOM-1 or IOM-2 on a slot has two switch fabric destinations while an IOM-3 has one.

The **no** form of the command is used to restore the path queues default MBS value.

**Parameters** *percent-of-pool* — The percent of buffers from the total buffer pool space for the maximum amount of buffers, expressed as a decimal integer. If 10 MB is the total buffers in the buffer pool, a value of 10 would limit the maximum queue size to 1MB (10%) of buffer space for the forwarding class queue. If the total size is increased to 20MB, the existing value of 10 would automatically increase the maximum size of the queue to 2MB.

**Values** 0 to 100

**Default**

|                           |    |
|---------------------------|----|
| <b>Primary Default:</b>   | 7  |
| <b>Secondary Default:</b> | 40 |
| <b>Ancillary Default:</b> | 80 |

**Default** 10

falling-percent-reset

**Syntax** **falling-percent-reset** *percent-of-highest*  
**no falling-percent-reset**

**Context** config>mcast-mgmt>bw-plcy

### Description

The falling-percent-reset command is used to configure the percentage of bandwidth decrease that must occur to reset the dynamic bandwidth monitoring function for a multicast channel. When a channel is configured to use the ingress dynamic bandwidth as the in-use bandwidth for ingress multicast path management, the system maintains a sliding window in time that defines how long the last highest bandwidth value associated with the channel should be used. The sliding window duration is derived from the channels bw-activity dynamic falling-delay parameter within the multicast information policy. Each time the system detects a current bandwidth for a channel that is equal to or greater than the current highest bandwidth for the channel, the sliding window is reset and the highest value is used when managing the ingress multicast paths. If the system does not detect a higher or equal bandwidth value for the channel within the window period, the system resets the sliding window and uses the next highest rate seen during the duration of the window period. In this way, the system delays relinquishing bandwidth for a dynamic bandwidth channel for a configurable period of time. If a momentary fluctuation (decrease) in ingress bandwidth occurs, the system ignores the bandwidth change.

While this is useful for momentary fluctuations in bandwidth, it may be desirable to react faster when the current bandwidth monitored for a channel drops significantly relative to the currently in-use bandwidth. When the bandwidth decrease is equal to or greater than the falling-percent-reset value, the system immediately stops using the highest bandwidth and starts using the current bandwidth while resetting the sliding window.

If falling-percent-reset is set to 50%, when the current ingress dynamic bandwidth is 50% of the current in-use highest bandwidth, the system will immediately use the current dynamic ingress bandwidth as the highest bandwidth for the channel.

By default falling-percent-reset is 50% when a new bandwidth policy is created. The default bandwidth policy also has a hard configured value of 50%. Setting falling-percent-reset to 100 is equivalent to specifying no falling-percent-reset.

The **no** form of the command restores the default value of 50%.

## Parameters

*percent-of-highest* — The percent-of-highest parameter is required and defines the percentage of decline between the current ingress dynamic bandwidth and the current in-use highest bandwidth at which the system will reset the dynamic ingress bandwidth monitoring for the channel. When reset in this case, the system uses the current ingress dynamic bandwidth as the highest rate and continues monitoring. The parameter must be defined as an integer value representing a percentage.

**Values** 1 to 100 percent

|                |     |
|----------------|-----|
| <b>Default</b> | 100 |
|----------------|-----|

## Output

### Sample Output

The following output displays an example of bandwidth policy defaults.

```
*A:PE-1# configure mcast-management bandwidth-policy test create
*A:PE-1>config>mcast-mgmt>bw-plcy$ exit all
```

```
*A:PE-1# show mcast-management bandwidth-policy "test" detail

| <b>Description</b> | This command configures the ingress multicast path management buffer pool. The pool is used by the primary, secondary and ancillary path queues through which all ingress managed multicast traffic must flow. The parameters may be used to configure the size of the pool relative to the total ingress buffer space, the amount of reserved CBS buffers within the pool and the slope policy used to manage early congestion detection functions in the shared portion of the pool. |

Care should be taken when managing the buffer pool space as changes to the systems buffer pool behavior can have negative effects on multicast and unicast forwarding.

### Sizing the Pool

The percent-of-total command defines how much of the total ingress buffer pool space for the MDA is dedicated for multicast channels managed by the bandwidth policy. Since multicast typically has a higher scheduling priority through the switch fabric, the buffer pool does not need to be large. By default, the system reserves 10% of the buffers on the ingress side of the MDA once multicast path management is enabled.

**Reserved CBS Portion of the Pool**

The multicast pool is divided into two portions; reserved and shared. The reserved portion is used by the multicast path queues until they cross their individual CBS thresholds. Since the CBS thresholds are configured as percents and the percents are allowed to oversubscribe the reserved portion of the pool, it is possible for some of the queues CBS buffer allocation to be met by the shared portion of the pool. By default, 50% of the pool is defined as reserved. This may be changed using the resv-cbs percentage parameter.

**Shared Portion WRED Slopes**

The shared portion of the buffer pool is used by queues that have crossed over their CBS thresholds. Since the total MBS values for the multicast path queues may oversubscribe the pool size, a buffer congestion control mechanism is supported within the pool in the form of two WRED slopes. The slope-policy parameter defines how the slopes are configured and whether they are activated. Each packet entering a path queue is defined as high or low priority within the queue based on the channels preference value relative to the cong-priority-threshold command. When getting a shared buffer of a high priority packet, the high WRED slope is used. Low priority packets use the low WRED slope.

The **no** form of the command returns the managed multicast path pool to its default settings.

|            |                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameters | <b>percent-of-total</b> <i>percent-of-buffers</i> — The percent-of-total keyword is required when executing the mcast-pool command and must be followed by a percent-of-buffers parameter expressed as an integer and representing the percentage of ingress buffers that will be allocated to the multicast pool.                             |
|            | <b>Values</b> 1 to 50                                                                                                                                                                                                                                                                                                                          |
|            | <b>Default</b> 10                                                                                                                                                                                                                                                                                                                              |
|            | <b>resv-cbs</b> <i>percent-of-pool</i> — The resv-cbs keyword is required when executing the mcast-pool command and must be followed by a percent-of-pool parameter expressed as an integer and representing the percentage of the pool that will be reserved for multicast path queues within their CBS threshold.                            |
|            | <b>Values</b> 1 to 100                                                                                                                                                                                                                                                                                                                         |
|            | <b>Default</b> 50                                                                                                                                                                                                                                                                                                                              |
|            | <b>slope-policy</b> <i>slope-policy-name</i> — The slope-policy keyword is required when executing the mcast-pool command and must be followed by a valid slope-policy-name. The named policy will be used to configure the WRED slopes within the multicast pool. Once a slope policy is associated with a buffer pool, it cannot be deleted. |
|            | <b>Default</b> default                                                                                                                                                                                                                                                                                                                         |

8.7.2.1.4 Multicast Info Policy Commands

multicast-info-policy

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Description | This command configures a multicast information policy. Multicast information policies are used to manage parameters associated with Layer 2 and Layer 3 multicast records. Multiple features use the configured information within the policy. The multicast ingress path manager uses the policy to decide the inactive and active state behavior for each multicast record using the ingress paths to the switch fabric. The system’s multicast ECMP join decisions are influenced by the channel information contained within the policy. |

Multicast Bundles:

A multicast information policy consists of one or multiple named bundles. Multicast streams are mapped to a bundle based on matching the destination address of the multicast stream to configured channel ranges defined within the bundles. Each policy has a bundle named ‘default’ that is used when a destination address does not fall within any of the configured channel ranges.

Each bundle has a set of default parameters used as the starting point for multicast channels matching the bundle. The default parameters may be overridden by optional exception parameters defined under each channel range. Further optional parameter overrides are possible under explicit source address contexts within each channel range.

Default Multicast Information Policy

A multicast information policy always exists with the name ‘default’ and cannot be edited or deleted. The following parameters are contained in the default multicast information policy:

|                                    |                                              |
|------------------------------------|----------------------------------------------|
| Policy Description:                | Default policy, cannot be edited or deleted. |
| Bundle:                            | default                                      |
| Bundle Description:                | Default Bundle, cannot be edited or deleted. |
| Congestion-Priority-Threshold:     | 4                                            |
| ECMP-Optimization-Limit-Threshold: | 7                                            |
| <b>Bundle Defaults:</b>            |                                              |
| Administrative Bandwidth:          | 0 (undefined)                                |
| Preference:                        | 0                                            |
| CAC-Type:                          | Optional                                     |
| Bandwidth Activity:                | Dynamic with no black-hole rate              |

Explicit Ingress SF Path:       None (undefined)

Configured Channel Ranges: None

The default multicast information policy is applied to all VPLS and VPRN services and all routing contexts until an explicitly defined multicast information policy has been mapped.

### Explicit Multicast Information Policy Associations

Each VPLS service and each routing context (including VPRN routing contexts) supports an explicit association with an pre-existing multicast information policy. The policy may need to be unique per service or routing context due to the fact that each context has its own multicast address space. The same multicast channels may be and most likely will be used for completely different multicast streams and applications in each forwarding context.

### Interaction with Ingress Multicast Path Management

When ingress multicast path management is enabled on an MDA, the system automatically creates a bandwidth manager context that manages the multicast path bandwidth into the switch fabric used by the ingress ports on the MDA. As routing or snooping protocols generate L2 or L3 multicast FIB records that will be populated on the MDA's forwarding plane, they are processed though the multicast information policy that is associated with the service or routing context associated with the record. The policy will return the following information for the record to be used by the ingress bandwidth manager:

- The records administrative bandwidth ('0' if undefined)
- Preference level (0 to 7 with 7 being highest)
- Bandwidth activity monitoring setting (use admin bw or dynamic monitoring)  
If admin bw is indicated, will also return active and inactive thresholds
- Initial switch fabric multicast path (primary, secondary or ancillary)  
If ancillary path is indicated, will also return an SF destination threshold
- Explicit switch fabric multicast path (primary, secondary, ancillary or none)

### Interaction with Multicast ECMP Optimization

The multicast information policy is used by the multicast ECMP optimization function to derive each channels administrative bandwidth. The ECMP function tallies all bandwidth information for channels joined and attempts to equalize the load between the various paths to the sender. The multicast information policy returns the following information to the ECMP path manager:

- Administrative bandwidth ('0' if undefined)
- Preference (0 to 7 with 7 the highest preference value)

#### Parameters

*policy-name* — Identifies the name of the policy to be either created or edited. Each multicast information policy must be uniquely named within the system. Names of up to 32 ASCII characters are supported with the normal character restrictions.

**create** — The create keyword is required if creating a new multicast information policy when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the multicast information policy name already exists.

## multicast-info-policy

|----------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>bundle</b> <i>bundle-name</i> [ <b>create</b> ]<br><b>no bundle</b> <i>bundle-name</i> |
| <b>Context</b> | config>mcast-mgmt>mcast-info-plcy                                                         |

**Description** The bundle command is used to create or edit channel bundles within a multicast information policy. Bundles are used for two main purposes. First, bundles are used by the multicast CAC function to group multicast channels into a common bandwidth context. The CAC function limits the ability for downstream nodes to join multicast channels based on the egress interfaces ability to handle the multicast traffic. Bundling allows multicast channels with common preference or application to be managed into a certain percentage of the available bandwidth.

The second function of bundles is to provide a simple provisioning mechanism. Each bundle within a multicast information policy has a set of default channel parameters. If each channel provisioned in to the bundle is able to use the default parameters for the bundle, the provisioning and configuration storage requirements are minimized.

Up to 31 explicit bundles may be defined within a multicast information policy (32 including the default bundle).

Once a bundle is created, the default channel parameters should be configured and the individual channel ranges should be defined. Within each channel range, override parameters may be defined that override the default channel parameters. Further overrides are supported within the channel range based on explicit source overrides.

A bundle may be deleted at anytime (except for the default bundle). When a bundle is deleted, all configuration information within the bundle is removed including multicast channel ranges. Any multicast records using the bundle should be reevaluated. Multicast CAC and ECMP managers should also be updated.

#### Default Bundle

Each multicast information policy contains a bundle named **default**. The default bundle cannot be deleted. Any multicast channel that fails to match a channel range within an explicit bundle is automatically associated with the default bundle.

The **no** form of the command removes a bundle from the multicast information policy. The default bundle cannot be removed from the policy.

**Default** default

**Parameters** *bundle-name* — Specifies bundle expressed as an ASCII string with up to 16 characters and must follow normal naming conventions. If bundle-name already exists, the system will enter the bundle context for editing purposes. If bundle-name does not exist, the system will create the defined bundle in the policy and enter the bundle context for editing purposes.

**create** — The create keyword is required if creating a new multicast information policy bundle when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the bundle name already exists.

| Description | <p>This command defines explicit channels or channel ranges that are associated with the containing bundle. A channel or channel range is defined by their destination IP addresses. A channel may be defined using either IPv4 or IPv6 addresses. If a channel range is being defined, both the start and ending addresses must be the same type.</p> <p>A specific channel may only be defined within a single channel or channel range within the multicast information policy. A defined channel range cannot overlap with an existing channel range.</p> <p>If a channel range is to be shortened, extended, split or moved to another bundle, it must first be removed from its existing bundle.</p> <p>Each specified channel range creates a containing context for any override parameters for the channel range. By default, no override parameters exist.</p> <p>The <b>no</b> form of the command removes the specified multicast channel from the containing bundle.</p>                                                                                                                                                                                                                                                                                                                                                                |
| Parameters  | <p><b>start-channel-ip-address</b> [<b>end-channel-ip-address</b>] — The <b>start-channel-ip-address</b> parameter and optional <b>end-channel-ip-address</b> parameters define the starting and ending destination IP addresses for a channel range.</p> <p>If only the <b>start-channel-ip-address</b> parameter is given, the channel ranges comprises of a single multicast channel.</p> <p>If both the starting and ending address are specified, all addresses within the range including the specified address are part of the channel range.</p> <p>IPv4 or IPv6 addresses may be defined. All specified addresses must be valid multicast destination addresses. The starting IP address must be numerically lower than the ending IP address.</p> <p><b>Values</b> Any valid IP multicast destination address</p> <p><b>Default</b> None</p> <p><b>create</b> — The create keyword is required if creating a new multicast channel range when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the specified channel range already exists.</p> |

| <b>Description</b>       | <p>This command specifies an administrative bandwidth for multicast channels.</p> <p>The specified bandwidth rate may be used by the multicast ingress path manger, multicast CAC manager or multicast ECMP manager.</p> <p>The admin-bw value is closely tied to the bw-activity command. When the bw-activity command is set to use-admin-bw, the multicast ingress path manager uses the configured administrative bandwidth value as the managed ingress bandwidth. The admin-bw value must be defined for the <b>bw-activity use-admin-bw</b> command to succeed. Once the bw-activity command is set to use the admin-bw value, the value cannot be set to 0 and the no admin-bw command will fail. Setting the bw-activity command to dynamic (the default setting), breaks the association between the commands.</p> <p>The <b>no</b> form of the command restores the default value for admin-bw. If the command is executed in the <b>channel</b> context, the channels administrative bandwidth value is set to null. If the command is executed in the <b>source-override</b> context, the source override administrative bandwidth value is set to null.</p> |               |                    |                 |   |                  |                  |                          |                  |
| <b>Default</b>           | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |               |                    |                 |   |                  |                  |                          |                  |

| Description              | <p>This command defines how the multicast ingress path manager determines the amount of bandwidth required by a multicast channel. The default setting is <b>dynamic</b> which causes the bandwidth manager to use the bandwidth policies dynamic rate table entries to determine the current rate. The alternative setting is <b>use-admin-bw</b> which causes the bandwidth manager to use the configured admin-bw associated with the channel. The <b>use-admin-bw</b> setting also requires an active and inactive threshold to be defined which allows the bandwidth manager to determine when the channel is actively using ingress path bandwidth and when the channel is idle.</p> <p>The <b>use-admin-bw</b> setting requires that the channel be configured with an admin-bw value that is not equal to 0 in the same context as the <b>bw-activity</b> command using the setting. Once a context has <b>use-admin-bw</b> configured, the context's admin-bw value cannot be set to 0 and the <b>no admin-bw</b> command will fail.</p> <p>This command also supports an optional <b>black-hole-rate</b> <i>kbps</i> command that defines at which current rate a channel should be placed in the black-hole state. This is intended to provide a protection mechanism against multicast channels that exceed a reasonable rate and cause outages in other channels.</p> <p>The <b>no</b> form of the command restores the default bandwidth activity monitoring setting (dynamic or null depending on the context).</p> |        |            |         |    |                 |         |                  |                  |                          |                  |
| Default                  | no bw-activity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |            |         |    |                 |         |                  |                  |                          |                  |
| Parameters               | <p><b>use-admin-bw   dynamic</b> — The <b>use-admin-bw</b> and <b>dynamic</b> keywords are mutually exclusive and one must be specified when executing the <b>bw-activity</b> command. The <b>use-admin-bw</b> keyword indicates the channels current ingress bandwidth should be derived from the <b>admin-bw</b> setting. The <b>admin-bw</b> setting must not currently be set to 0 for the <b>use-admin-bw</b> setting to succeed.</p> <p>The <b>dynamic</b> keyword indicates that the multicast ingress path manager should use the dynamic rate table (as defined in the bandwidth-policy) to derive the channels current ingress rate.</p> <p><b>falling-delay</b> <i>seconds</i> — Specifies the value the bandwidth manager uses the falling-delay threshold to hold on to the previous highest bandwidth until the delay time has expired while operating in dynamic bandwidth mode. This allows the bandwidth manager to ignore momentary drops in channel bandwidth.</p> <table><tr><td>Values</td><td>10 to 3600</td></tr><tr><td>Default</td><td>30</td></tr><tr><td>Bundle default:</td><td>dynamic</td></tr><tr><td>Channel default:</td><td>Null (undefined)</td></tr><tr><td>Source-override default:</td><td>Null (undefined)</td></tr></table>                                                                                                                                                                                                                                                                | Values | 10 to 3600 | Default | 30 | Bundle default: | dynamic | Channel default: | Null (undefined) | Source-override default: | Null (undefined) |

**black-hole-rate** *kbps* — Specifies a rate at which a channel will be placed in the black-hole state. The kilobits-per-second parameter is expressed as an integer and represents multiples of 1,000 bits per second.

**Values** 0 to 40000000

**Default** None

## cac-type

| <b>Description</b> | This command defines the channels multicast CAC channel type, either <b>mandatory</b> or <b>optional</b> . The <b>cac-type</b> command is supported for future interaction with the egress multicast CAC manager policy. The multicast CAC manager always reserves egress bandwidth for mandatory channels within a bundle, while optional channels are only given bandwidth when a join is received. |
| <b>Parameters</b>  | <b>mandatory</b> — This keyword is mutually exclusive with the <b>optional</b> keyword and specifies the channels multicast CAC channel type.<br><br><b>optional</b> — This keyword is mutually exclusive with the <b>mandatory</b> keyword and specifies the channels multicast CAC channel type.                                                                                                    |

| <b>Description</b> | This command defines an explicit ingress switch fabric multicast path assigned to a multicast channel. When defined, the channel is setup with the explicit path as its inactive path. When an explicit path is not defined, all multicast channels are initialized on the secondary path and when they start to consume bandwidth, they are moved to the appropriate path based on the channel attributes and path limitations. Explicit path channels are not allowed to move from their defined path.<br><br>The <b>explicit-sf-path</b> command in the bundle context defines the initial path for all channels associated with the bundle unless the channel has an overriding explicit-sw-path defined in the channel context. The channel context may also be overridden by the explicit-sf-path command in the source-override context. The channel and source-override explicit-sf-path settings default to null (undefined) and have no effect unless explicitly set. |

The **no** form of the command restores default path association behavior (dynamic or null depending on the context).

| <b>Description</b> | <p>This command configures the keepalive timer override. The PIM (S,G) Keepalive Timer (KAT) is used to maintain the (S,G) state when (S,G) join is not received. Expiry of the KAT causes the (S,G) entry to be removed.</p> <p>The KAT override configuration is performed with an multicast information policy, which must be applied to the related PIM routing instance. When a KAT override is configured under a channel (a group or a group range), it applies to all (S,G) entries that fall under it, except when the source-override is configured and a KAT override is also configured under the source-override. In this scenario, the specific KAT override must be used for the (S,G) entries that fall under the source-override, while other (S,G) entries under the bundle use the KAT override configured under the channel.</p> |

| <b>Description</b> | <p>This command sets the relative preference level for multicast channels. The preference of a channel specifies its relative importance over other multicast channels. Eight levels of preference are supported; 0 through 7. Preference value 7 indicates the highest preference level.</p> <p>When the multicast ingress path manager is congested on one or more of the switch fabric multicast paths, it uses the preference values associated with each multicast record to determine which records will be allowed on the path and which records should be placed in a black-hole state.</p> <p>The preference value is also compared to the bundles cong-priority-threshold setting to determine the congestion priority of the channel. The result also dictates the channels multicast CAC class level (high or low). When the channels preference value is less than the congestion priority threshold, it is considered to have a congestion priority and CAC class value equal to low. When the channels preference value is equal to or greater than the threshold, it is considered to have a congestion priority and a CAC class value equal to high.</p> <p>The preference value is also compared to the bundles ecmp-opt-threshold setting to determine whether the channel is eligible for ECMP path dynamic optimization. If the preference value is equal to or less than the threshold, the channel may be optimized. If the preference value is greater than the threshold, the channel will not be dynamically optimized.</p> <p>The preference command may be executed in three contexts; bundle, channel and source-override. The bundle default preference value is 0. The channel and source-override preference settings are considered overrides to the bundle setting and have a default value of null (undefined).</p> <p>The <b>no</b> form of the command restores the default preference value (0 or null depending on the context).</p> |
| <b>Parameters</b>  | <i>preference-level</i> — The preference-level parameter is required and defines the preference value of the channel. It is represented by an integer value between 0 and 7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Description | <p>This command allows the user to define a bundle in the multicast-info-policy and specify channels in the bundle that must be received from the primary tunnel interface associated with an RSVP P2MP LSP. The multicast info policy is applied to the base router instance.</p> <p>The egress LER will be able to accept multicast packets via two different methods. The regular RPF check on unlabeled IP multicast packets, which is based on routing table lookup. The static assignment which specifies the receiving of a multicast group &lt;*,G&gt; or a specific &lt;S,G&gt; from a primary tunnel-interface associated with an RSVP P2MP LSP.</p> <p>One or more primary tunnel interfaces in the base router instance can be configured. That is, the user will be able to specify to receive different multicast groups, &lt;*,G&gt; or specific &lt;S,G&gt;, from different P2MP LSPs. This assumes that there are static joins configured for the same multicast groups at the ingress LER to forward over a tunnel interface associated with the same P2MP LSP.</p> <p>At any given time, packets of the same multicast group can be accepted from either the primary tunnel interface associated with a P2MP LSP or from a PIM interface. These are mutually exclusive options. As soon as a multicast group is configured against a primary tunnel interface in the multicast info policy, it is blocked from other PIM interfaces.</p> <p>A multicast packet received on a tunnel interface associated with a P2MP LSP can be forwarded over a PIM or IGMP interface which can be an IES interface, a spoke SDP terminated IES interface, or a network interface.</p> <p>The <b>no</b> form of the command removes the static RPF check.</p> |

| <b>Description</b> | This command defines a multicast channel parameter override context for a specific multicast sender within the channel range. The specified senders IP address must be of the same type (IPv4 or IPv6) as the containing channel range.<br><br>The <b>no</b> form of the command removes the specified sender override context from the channel range. |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies either an IPv4 or IPv6 address and it must be the same type as the containing channel range.<br><br><b>Values</b><br>ipv4-address      a.b.c.d<br>ipv6-address      x:x:x:x:x:x:x (eight 16-bit pieces)<br>x:x:x:x:x:d.d.d.d<br>x - [0 to FFFF]H<br>d - [0 to 255]D                                                      |

**create** — The **create** keyword is required if creating a new source override when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the specified source override IP address already exists.

## cong-priority-threshold

| Description | <p>This command defines the preference level threshold where records change from low congestion priority to high congestion priority. Congestion priority is used by the ingress multicast path queues to map packets entering the queue to either the low priority MBS (LP-MBS) or the MBS tail-drop threshold. In the event that congestion happens on the queue, the queue depth increases. As the queue depth increases beyond the low priority MBS, packets with low priority congestion priority are discarded. This leaves room in the queue for packets with high congestion priority until the queue reaches the MBS threshold.</p> <p>The default congestion priority threshold is 4. This means that multicast channels with a preference level of 0 to 3 will be treated as having low congestion priority and channels with preference level of 4 to 7 will be treated as having a high congestion priority. The <b>cong-priority-threshold</b> command can be used to change the default threshold. Any multicast channel with a preference equal to or higher than the configured threshold will be treated with high congestion priority.</p> <p>The <b>cong-priority-threshold</b> value is also used by the multicast CAC manager to derive the class of a channel matched by the multicast information policy. Channels with a preference less than the configured threshold will be treated as low class and channels with a preference equal to or greater than the threshold will be treated as high class.</p> <p>Changing the <b>cong-priority-threshold</b> value causes all channels congestion priority to be reevaluated. Both the ingress multicast path managers and multicast CAC managers must be updated.</p> <p>The <b>no</b> form of the command restores the default congestion priority preference threshold value.</p> |        |        |         |   |
| Default     | 4                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |        |        |         |   |

| Context     | config>mcast-mgmt>mcast-info-plcy>bundle                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Description | <p>This command defines the preference level threshold where multicast ECMP path management is allowed to dynamically optimize channels based on topology or bandwidth events. If the channels preference is equal to or less than the ecmp-opt-threshold, ECMP is allowed to move the channel between ECMP paths when bandwidth distribution events happen. Channels with a preference level higher than the threshold will not be moved during these events.</p> |

The default ECMP optimization limit threshold is 7. This means that multicast channels with a preference level of 0 to 7 (all channels) will be allowed to move between ECMP paths. The `ecmp-opt-threshold` command can be used to change the default threshold.

Changing the threshold causes all channels ECMP optimization eligibility to be reevaluated.

The **no** form of the command restores the default ECMP optimization preference threshold value.

| <b>Description</b> | This command enables multicast balancing of traffic over ECMP links considering multicast bandwidth. When enabled, every multicast stream that needs to be forwarded over an ECMP link will be evaluated for the sum total multicast utilization currently using the ECMP interface in question. |

**Note:** A given interface can be shared between multiple (partially overlapping) ECMP sets. This is taken into consideration and a complete balance is attempted.

ECMP load balancing helps to avoid loss of unicast traffic over ECMP links as it will load balance over ECMP links and if multicast is not balanced then it is possible that a given link does not have sufficient bandwidth to pass its allotted unicast traffic portion.

In order to achieve a proper balance, multicast groups and their bandwidth should be configured in the config **mcast-management** context.

If the bandwidth is not configured, then the default value applies, and for the purpose of ECMP load balancing, the net effect will be that the balance achieved reflects a balance of the number of multicast groups traversing over the ECMP link. The bandwidth used in this policy is the configured value, not the actual bandwidth.

If **mc-ecmp-balance** is enabled, a redistribution may be triggered whenever a interface is added to an ECMP link.

If **mc-ecmp-balance** is enabled, a period re-balance may be configured that re-optimizes the distribution as some multicast streams may have been removed from the ECMP link.

If mc-ecmp-balance is enabled, then a threshold (ecmp-opt-threshold) can be configured to avoid moving multicast streams where interruption should be avoided.

The ecmp-opt-threshold is used to define the preference level threshold where multicast ECMP path management is allowed to dynamically optimize channels based on topology or bandwidth events. If the channels preference is equal to or less than the ecmp-opt-threshold, ECMP is allowed to move the channel between ECMP paths when bandwidth distribution events happen. Channels with a preference level higher than the threshold will not be moved during these events.

Changing the ecmp-opt-threshold causes all channels ECMP optimization eligibility to be reevaluated.

The **no** form of the command removes the re-balancing capability from the configuration.

| <b>Context</b>     | config>router>policy-options>policy-statement>entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command creates the context to configure actions to take for routes matching a route policy statement entry.</p> <p>This command is required and must be entered for the entry to be active.</p> <p>Any route policy entry without the <b>action</b> command will be considered incomplete and will be inactive.</p> <p>The <b>no</b> form of the command deletes the action context from the entry.</p>                                                                                                                                                                                                     |
| <b>Default</b>     | <b>no action</b> — No action is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>accept</b> — Specifies routes matching the entry match criteria will be accepted and propagated.</p> <p><b>next-entry</b> — Specifies that the actions specified would be made to the route attributes and then policy evaluation would continue with next policy entry (if any others are specified).</p> <p><b>next-policy</b> — Specifies that the actions specified would be made to the route attributes and then policy evaluation would continue with next route policy (if any others are specified).</p> <p><b>reject</b> — Specifies routes matching the entry match criteria would be rejected.</p> |

#### interface

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>interface</b> <i>port:tags</i>                                       |
| <b>Context</b>     | config>router>igmp<br>config>services>ies<br>config>services>vprn       |
| <b>Description</b> | This command enables IGMP (or MLD) on the multicast redirect interface. |

### 8.7.2.1.7 Multicast Query Timer Commands

---

## disable-router-alert-check

|                    |                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-router-alert-check</b>                                                                                                                         |
| <b>Context</b>     | config>router>igmp>group-interface<br>config>router>mld>group-interface<br>config>service>vprn>igmp>group-interface<br>config>service>vprn>mld>group-interface |
| <b>Description</b> | This command disables router alert checking for IGMP/MLD messages received on this interface. The <b>no</b> form of the command enables router alert checking. |

## query-interval

|                    |                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-interval</b> <i>seconds</i><br><b>no query-interval</b>                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>router>igmp>group-interface<br>config>router>mld>group-interface<br>config>service>vprn>igmp>group-interface<br>config>service>vprn>mld>group-interface                                                                                                                                                                                         |
| <b>Description</b> | This command configures the query interval when the group interface is configured with <b>no sub-hosts-only</b> . If nothing is configured, by default, the <b>query-interval</b> takes the value defined in the <b>config&gt;router&gt;igmp</b> (or <b>mld</b> ) context or in the <b>config&gt;service&gt;vprn&gt;igmp</b> (or <b>mld</b> ) context. |
| <b>Parameters</b>  | <i>seconds</i> — specifies the frequency, in seconds, at which the router transmits general host-query messages<br><br><b>Values</b> 2 to 1024                                                                                                                                                                                                         |

## query-last-listener-interval

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-last-listener-interval</b> <i>seconds</i><br><b>no query-last-listener-interval</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>router>mld>group-interface<br>config>service>vprn>mld>group-interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures the frequency at which the querier router sends a group-specific query messages, including the messages sent in response to leave-group messages and is only applicable when the group interface is configured with the <b>no sub-hosts-only</b> command. The shorter the interval, the faster the loss of the last listener of a group can be detected. If nothing is configured, by default, the <b>query-last-listener-interval</b> takes the value defined in the <b>config&gt;router&gt;mld</b> context or in the <b>config&gt;service&gt;vprn&gt;mld</b> context. |

| <b>Context</b>     | config>router>igmp>group-interface<br>config>service>vprn>igmp>group-interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | This command configures the frequency at which the querier router sends group-specific query messages, including the messages sent in response to leave-group messages and is only applicable when the group interface is configured with <b>no sub-hosts-only</b> . The shorter the interval, the faster the loss of the last member of a group can be detected. If nothing is configured, by default, the <b>query-last-member-interval</b> takes the value defined in the <b>config&gt;router&gt;igmp</b> context or in the <b>config&gt;service&gt;vprn&gt;igmp</b> context. |
| <b>Parameters</b>  | <i>seconds</i> — specifies the frequency, in seconds, at which query messages are sent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Values</b>      | 1 to 1024                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## query-response-interval

|                    |                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>The fp CLI node contains the multicast path management configuration commands for IOM-3 ingress multicast management. Ingress multicast management manages multicast switch fabric paths which are forwarding plane specific. On IOM-1 and IOM-2, each MDA has a dedicated forwarding plane and so have dedicated multicast paths to the switch fabric allowing the multicast management to be defined per MDA. IOM-3 has a single forwarding plane shared by two MDAs making the previous model of managing multicast at the MDA level problematic. The fp node has been added to simplify ingress multicast management on IOM-3.</p> <p>In subsequent releases, the fp node will be moved to IOM-1 and IOM-2 and the multicast path management commands will be consistent for all IOM types. Other forwarding plane resource configuration commands (i.e. buffer pool management) are expected to also move to the fp node.</p> <p>While IOM-3 only has a single forwarding plane, other IOMs that will use the node in the future will have multiple (i.e. IOM-1 and IOM-2). To accommodate multiple forwarding planes, each forwarding plane is assigned a number. The default forwarding plane is 1. When entering the fp node, if the forwarding plane number is omitted, the system will assume forwarding plane number 1. All show and save configuration output must include the forwarding plane number.</p> |               |   |                |   |
| <b>Parameters</b>  | <p><i>fp-number</i> — The fp-number parameter is optional following the fp command. If omitted, the system assumes forwarding plane number 1. More than a single forwarding plane will be supported in the future when IOMs other than IOM-3 are supported.</p> <table><tr><td><b>Values</b></td><td>1</td></tr><tr><td><b>Default</b></td><td>1</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <b>Values</b> | 1 | <b>Default</b> | 1 |

| <b>Description</b> | The multicast-path-management CLI node contains the forwarding plane or MDA settings for ingress multicast path management. Enter the node to configure the bandwidth-policy, the individual path bandwidth overrides and the administrative state of ingress multicast path management. |

## bandwidth-policy

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                                    |                |         |

| <b>Description</b> | The path-limit command is used to override the path limits contained in the bandwidth policy associated with the MDA. The path limits are used to give the upper limit that multicast channels may use on each path.<br><br>The path-limit commands are not supported on IOM-3.<br><br>The no form of the command removes a path limit override from an ingress multicast path and restore the path limit defined in the bandwidth policy associated with the MDA. |
| <b>Parameters</b>  | <i>megabits-per-second</i> — The megabits-per-second parameter is required when executing the path-limit command and is expressed as an integer representing multiples of 1,000,000 bits per second.<br><br><b>Values</b> Primary-override:1 to 2000<br>Secondary-override:1 to 2000<br>Ancillary-override:1 to 5000<br><br><b>Default</b> None                                                                                                                    |

## 9 Triple Play Enhanced Subscriber Management

### 9.1 In This Section

This section describes features which provide Enhanced Subscriber Management functions for Triple Play services.

Topics in this section include:

- [Uniform RADIUS Server Configuration](#)
- [RADIUS Authentication of Subscriber Sessions](#)
- [radius-server-policy Retry Attempt Overview](#)
- [Enhanced Subscriber Management Overview](#)
- [L2TP Tunnel RADIUS Accounting](#)
- [RADIUS Route Download](#)
- [Managed SAP \(MSAP\)](#)
- [Volume and Time Based Accounting](#)
- [Subscriber Host Idle Timeout](#)
- [Web Authentication Protocol \(WPP\)](#)
- [One-time HTTP Redirection Overview](#)
- [ESM over MPLS Pseudowires](#)
- [Logical Link Identifier \(LLID\)](#)
- [Open Authentication Model for DHCP and PPPoE Hosts](#)
- [Flexible Subscriber-Interface Addressing \(Unnumbered Subscriber-Interfaces\)](#)
- [uRPF for Subscriber Management](#)
- [IPoE Sessions](#)
- [Data-triggered Subscriber Management](#)
- [RADIUS Subscriber Services](#)
- [Residential Gateway Replacement](#)
- [ESM Troubleshooting Show Command](#)
- [Hybrid Access](#)

## 9.2 Uniform RADIUS Server Configuration

### 9.2.1 RADIUS Server Configuration

The following two configuration methods co-exist but are mutually exclusive:

- [Uniform RADIUS Server Configuration \(Preferred\)](#)
- [Legacy RADIUS Server Configuration](#)

#### 9.2.1.1 Uniform RADIUS Server Configuration (Preferred)

This configuration method is preferred as it can be re-used amongst multiple applications (Subscriber authentication and accounting, L2TP tunnel accounting, WLAN gateway RADIUS proxy,) and enables additional functionality not available in the legacy configuration method. For example:

- A RADIUS server policy operational state can be controlled by reception of accounting on/off responses.
- Buffering of accounting messages: When all servers in a **radius-server-policy** are unreachable, it is possible to buffer the acct-stop and acct-interim-update messages for up to 25 hours. When a RADIUS server becomes reachable again then the messages in the buffer are retransmitted.
- A configurable hold down time for accounting servers that are marked down and during which no new communication attempts will be made (hold-down-time).
- A configurable maximum number of outstanding RADIUS requests for accounting servers (pending-requests-limit).
- Increased retry and timeout values for unsuccessful RADIUS communication.
- Enhanced RADIUS server statistics
- IPv6 RADIUS server

**Note:** A RADIUS server is marked down if it detects a number of consecutive timeouts independent of transaction-id or origin of request.

Where a number of consecutive timeouts is defined by the number of retries configured below the radius-server-policy servers.

The default number of retries is 3, meaning 1 initial try and 2 retries.

If, for example, the RADIUS server has “2 timeouts, 1 reply, 1 timeouts”, whereby the timeouts are originated for the same host, the server is not marked down since intermediate replies were received.

To attach a RADIUS server policy to an authentication policy:

For example,

```
configure
 subscriber-mgmt
 authentication-policy "auth-policy-1" create
 radius-server-policy "aaa-server-policy-1"
 exit
exit
```

**Note:**

- To avoid conflicts, the following CLI commands are ignored in the authentication policy when a **radius-server-policy** is attached:
  - All commands in the **radius-authentication-server** context
  - **accept-authorization-change**
  - **coa-script-policy**
  - **accept-script-policy**
  - **request-script-policy**
- The **fallback-action** command specifies the action when no RADIUS server is available is configured direct in the **config>subscr-mgmt>auth-plcy** CLI context.

To attach a RADIUS server policy to a RADIUS accounting policy:

For example:

```
configure
 subscriber-mgmt
 radius-accounting-policy "acct-policy-1" create
 radius-server-policy "aaa-server-policy-1"
 exit
exit
```

**Note:** To avoid conflicts, the following CLI commands are ignored in the RADIUS accounting policy when a **radius-server-policy** is attached:

- All commands in the **radius-accounting-server** context
- **acct-request-script-policy**

To configure the RADIUS servers in a RADIUS server policy:

For example:

```
configure
aaa
 radius-server-policy "aaa-server-policy-1" create
 description "Radius AAA server policy"
 accept-script-policy "script-policy-2"
 acct-on-off oper-state-change
 acct-request-script-policy "script-policy-3"
 auth-request-script-policy "script-policy-1"
 no python-policy
 servers
 access-algorithm direct
 hold-down-time sec 30
 no ipv6-source-address
 retry 3
 router "Base"
 no source-address
 timeout sec 5
 buffering
 acct-interim min 60 max 3600 lifetime 5
 acct-stop min 60 max 3600 lifetime 5
 exit
server 1 name "server-1"
server 2 name "server-2"
exit
exit
exit
```

To configure the RADIUS servers in the routing instance:

- In the Base routing instance: **config>router>radius-server.**
- In a VPRN routing instance: **config>service>vprn 10>radius-server.**
- In the management routing instance (out of band): **config>router management>radius-server.**

For example:

```
configure
router
 radius-server
 server "server-1" address 172.16.1.1 secret <shared secret> hash2 create
 accept-coa
 coa-script-policy "script-policy-4"
 description "Radius server 1"
 pending-requests-limit 4096
 acct-port 1813
 auth-port 1812
 exit
 server "server-2" address 172.16.1.2 secret <shared secret> hash2 create
 accept-coa
```

```
 coa-script-policy "script-policy-4"
 description "Radius server 2"
 pending-requests-limit 4096
 acct-port 1813
 auth-port 1812
 exit
exit
exit
```

**Note:** To configure RADIUS CoA servers for use in Enhanced Subscriber Management, the server must be configured in the corresponding routing instance with the **accept-coa** command enabled.

### 9.2.1.2 Legacy RADIUS Server Configuration

**Note:** It is recommended to migrate to the uniform RADIUS server configuration as described above to have additional functionality enabled.

To configure a RADIUS server in an authentication policy:

```
configure
 subscriber-mgmt
 authentication-policy "auth-policy-1" create
 radius-authentication-server
 access-algorithm direct
 hold-down-time 30
 retry 3
 no source-address
 timeout 5
 router "Base"
 server 1 address 172.16.1.1 secret <shared secret> hash2 port 1812
 pending-requests-limit 4096
 server 2 address 172.16.1.2 secret <shared secret> hash2 port 1812
 pending-requests-limit 4096
 exit
 accept-authorization-change
 accept-script-policy "script-policy-2"
 coa-script-policy "script-policy-4"
 request-script-policy "script-policy-1"
 exit
exit
```

**Note:** In legacy RADIUS server configuration, to configure RADIUS CoA servers for use in Enhanced Subscriber Management, the server must be configured in the authentication policy with the **accept-authorization-change** command enabled. A CoA only server can be configured with the optional **coa-only** flag.

To configure a RADIUS server in a RADIUS accounting policy:

```
configure
 subscriber-mgmt
 radius-accounting-policy "acct-policy-1" create
 radius-accounting-server
 access-algorithm direct
 retry 3
 timeout 5
 no source-address
 router "Base"
 server 1 address 172.16.1.1 secret <shared secret> hash2 port 1813
 server 2 address 172.16.1.2 secret <shared secret> hash2 port 1813
 exit
 acct-request-script-policy "script-policy-3"
 exit
exit
```

### 9.3 RADIUS Authentication of Subscriber Sessions

This section describes the Nokia router acting as a Broadband Subscriber Aggregator (BSA).

**Note:** In the TPSDA solutions, the Nokia 5750 Subscriber Services Controller (SSC) serves as the policy manager, DHCP and RADIUS server.

In this application, one of the required functions can be to authenticate users trying to gain access to the network. While sometimes the DHCP server (an SSC) can perform authentication, in most cases a RADIUS server (an SSC) is used to check the customer's credentials.

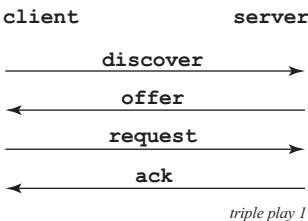

**Note:** Refer to section [DHCP Management](#) for an explanation of DHCP and [DHCP Snooping](#) for an explanation of DHCP snooping.

For information about the RADIUS server selection algorithm, refer to the Security chapter in the OS System Management Guide.

If authentication is enabled, the router will temporarily hold any received DHCP discover message and will send a access-request message to a configured RADIUS server containing the client's MAC address and/or Circuit-ID (from the Option 82 field) as the user name. If and when access is granted by the RADIUS server, the router will then forward or relay the DHCP discover message to the DHCP server and thus allow an IP address to be assigned. If the RADIUS authentication request is denied, the DHCP message is dropped and an event is generated.

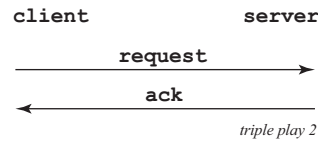

A typical initial DHCP scenario (after client bootup) is shown in [Figure 63](#).

**Figure 63** Initial DHCP Scenario

But, when the client already knows its IP address (when an existing lease is being renewed), it can skip straight to the request/ack phase, as shown in [Figure 63](#).

**Figure 64** DHCP Scenario with Known IP Address

In the first scenario, the DHCP discover triggers an authentication message to RADIUS and the DHCP request also triggers RADIUS authentication. The previous reply is cached for 10 seconds, the second DHCP packet will not result in a RADIUS request.

In the second scenario, the DHCP request triggers an authentication message to RADIUS.

If the optional subscriber management authentication policy **re-authentication** command is enabled, DHCP authentication is performed at every DHCP lease renew request. Only dynamic DHCP sessions are subject to remote authentication. Statically provisioned hosts are not authenticated.

### 9.3.1 RADIUS Authentication Extensions

This section describes an extension to RADIUS functionality in the subscriber management context. As part of subscriber host authentication, RADIUS can respond with access-response message, which, in the case of an accept, can include several RADIUS attributes (standard and vendor-specific) that allow proper provisioning of a given subscriber-host.

Change-of-Authorization (CoA) messages as defined by RFC 3576, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*, are supported. The goal of CoA messages is to provide a mechanism for “mid-session change” support through RADIUS.

### 9.3.1.1 Triple Play Network with RADIUS Authentication

**Figure 65** Triple Play Aggregation Network with RADIUS-Based DHCP Host Authentication

Figure 65 shows a flow of RADIUS authentication of DHCP hosts in the triple play aggregation environment. Besides granting the authentication of given DHCP host, the RADIUS server can include RADIUS attributes (standard and/or Vendor-Specific Attributes (VSAs)) which are then used by the network element to provision objects related to a given DHCP host.

RADIUS is a distributed client/server concept that is used to protect networks against unauthorized access. In the context of the router's subscriber management in TPSDA, the RADIUS client running on nodes sends authentication requests to the SSC.

RADIUS can be used to perform three distinct services:

- Authentication determines whether or not a given subscriber-host is allowed to access a specific service.
- Authorization associates connection attributes or characteristics with a specific subscriber host.
- Accounting tracks service use by individual subscribers.

The RADIUS protocol uses “attributes” to describe specific authentication, authorization and accounting elements in a user profile (which are stored on the RADIUS server). RADIUS messages contain RADIUS attributes to communicate information between network elements running a RADIUS client and a RADIUS server.

RADIUS divides attributes into two groups, standard attributes and Vendor-Specific Attributes (VSAs). VSA is a concept allowing conveying vendor specific configuration information in a RADIUS messages, discussed in RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*. It is up to the vendor to specify the exact format of the VSAs.

Nokia-specific VSAs are identified by vendor-id 6527.

### 9.3.2 RADIUS Authorization Extensions

The following sections define different functional extensions and list relevant RADIUS attributes.

#### Basic Provisioning of Authentication Extensions

In order to comply with RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*, the software includes the following attributes in the authentication-request message:

- agent-circuit-id (as defined by DSL forum)
- agent-remote-id (as defined by DSL forum)

The following attributes can also be included if configured and provided by downstream equipment:

- actual-data-rate-upstream
- actual-data-rate-downstream
- minimum-data-rate-upstream
- minimum-data-rate-downstream
- access-loop-encapsulation

When the node is configured to insert (or replace) Option 82, the above mentioned attributes will have the content after this operation has been performed by the software.

In addition, the following standard RADIUS attributes will be included in authentication request messages (subject to configuration):

- NAS-identifier — string containing system-name

- NAS-port-id
- NAS-port-type — Values: 32 (null encap), 33 (dot1q), 34 (qinq), 15 (DHCP hosts), specified value (0 — 255)
- MAC-address (Nokia VSA 27)
- dhcp-vendor-class-id (Nokia VSA 36)
- calling-station-id

These will only be included in the access-request if they have been configured.

In order to provide the possibility to push new policies for currently active subscribers, the routers support commands to force re-authentication of the given subscriber-host. After issuing such a command, the router will send a DHCP force-renew packet, which causes the subscriber to renew its lease (provided it supports force-renew). The DHCP request and ACK are then authenticated and processed by the routers as they would be during a normal DHCP renew.

### 9.3.2.1 Calling-Station-ID

A **calling-station-id** can be configured at SAP level and can be included in the RADIUS authentication and accounting messages. This attribute is used in legacy BRAS to identify the user (typically phone number used for RAS connection). In the broadband networks this was replaced by circuit-id in Option 82. However, the Option 82 format is highly dependent on access-node vendor, which makes interpretation in management servers (such as RADIUS) troublesome. Some operators use the calling-station-id attribute as an attribute indicating the way the circuit-id should be interpreted. The calling-station-id attribute can be configured as a string which will be configured on the SAP. It can also be configured to use the **sap-id**, **remote-id** or **mac-address**.

### 9.3.2.2 Subscriber Session Timeout

To limit the lifetime of a PPP session or DHCPv4 host to a fixed time interval, a timeout can be specified from RADIUS. By default, a PPP session or DHCPv4 host has no session timeout (infinite).

For PPP sessions, a session-timeout can be configured in the ppp-policy. A RADIUS specified session-timeout overrides the CLI configured value.

```
subscriber-mgmt
 ppp-policy "ppp-policy-1" create
 session-timeout 86400
 exit
```

exit

When the session timeout expires a PPP session is terminated and a DHCPv4 host deleted. For a DHCPv4 host, a DHCP release message is also sent to the server.

The following two attributes can be used in RADIUS Access-Accept and CoA messages to limit the PPP session or DHCPv4 host session time ([Table 52](#)):

**Table 52**      **Subscriber Session Timeout**

| Attribute ID | Attribute Name               | Type    | Limits                    | Purpose and Format                                                                                                       |
|--------------|------------------------------|---------|---------------------------|--------------------------------------------------------------------------------------------------------------------------|
| 27           | Session-Timeout              | integer | 2147483647 seconds        | 0 = infinite (no session-timeout)<br>[1 to 2147483647] in seconds<br>For example:<br>Session-Timeout = 3600              |
| 26-6527-160  | Alc-Relative-Session-Timeout | integer | [0 to 2147483647] seconds | 0 = infinite (no session-timeout)<br>[1 to 2147483647] in seconds<br>For example:<br>Alc-Relative-Session-Timeout = 3600 |

When specified in a RADIUS Access-Accept message, both attributes specify an absolute value for session timeout. When specified in a RADIUS CoA message, attribute [26-6527-160] Alc-Relative-Session-Timeout specifies a relative session timeout value in addition to the current session time while attribute [27] Session-Timeout specifies an absolute session timeout value. If the current session time is greater than the received Session-Timeout, a CoA NAK is sent with error cause "Invalid Attribute Value (407)".

Only one of the above attributes to specify a session timeout can be present in a single RADIUS message. An event is raised when both are specified in a single message.

The output of the show **service id** <service-id> **ppp session detail** CLI command contains following fields related to session timeout for PPP sessions:

- Up Time: the PPP session uptime
- Session Time Left: the remaining time before the session is terminated
- RADIUS Session-TO: the RADIUS received session timeout value.

The output of the "show service id <service-id> dhcp lease-state detail" CLI command contains following fields related to session timeout for DHCPv4 hosts:

- Up Time: the DHCPv4 host uptime
- Remaining Lease Time: the remaining time before the lease expires in the DHCP server. The client should renew its lease before this time.
- Remaining SessionTime: the remaining time before the DHCPv4 host is deleted
- Session-Timeout: the DHCPv4 host is deleted when its uptime reaches the Session-Timeout value.
- Lease-Time: the lease time specified by the DHCPv4 server

**Note:** In a radius-proxy scenario or when a DHCPv4 host is created with a RADIUS CoA message, the RADIUS attribute [26-6527-174] Alc-Lease-Time attribute must be used to specify the lease time. If the [26-6527-174] Alc-Lease-Time is not present in these scenarios, then the RADIUS attribute [27] Session-Timeout is interpreted as DHCPv4 lease time.

#### 9.3.2.2.1 Domain Name in Authentication

In many networks, the user name has specific meaning with respect to the domain (ISP) where the user should be authenticated. In order to identify the user correctly, the user name in an authentication-request message should contain a domain-name. The domain-name can be derived from different places. In PPPoE authentication the domain name is given by the PPPoE client with the user name used in PAP or CHAP authentication. For DHCP hosts similar functionality is implemented by a “pre-authentication” lookup in a local user database before performing the RADIUS request.

For example, it can be derived from option60 which contains the vendor-specific string identifying the ISP the set-box has been commissioned by.

To append a domain name to a DHCP host, the following configuration steps should be taken:

- Under the (group or IP) interface of the service, a local user database should be configured in the DHCP node and no authentication policy should be configured.
- In the local user database, there should be a host entry containing both the domain name to be appended and an authentication policy that should be used for RADIUS authentication of the host. The host entry should contain no other information needed for setting up the host (IP address, ESM string), otherwise the DHCP request will be dropped.
- In the authentication policy, the **user-name-format** command should contain the parameter **append domain-name**.

### 9.3.2.3 RADIUS Reply Message for PPPoE PAP/CHAP

The string returned in a [18] Reply-Message attribute in a RADIUS Access-Accept is passed to the PPPoE client in the CHAP Success or PAP Authentication-Ack message.

The string returned in a [18] Reply-Message attribute in a RADIUS Access-Reject is passed to the PPPoE client in the CHAP Failure or PAP Authentication-Nak message.

When no [18] Reply-Message attribute is available, the SROS default messages are used instead: "CHAP authentication success" or "CHAP authentication failure" for CHAP and "Login ok" or "Login incorrect" for PAP.

### 9.3.2.4 SHCV Policy

SHCV policies are used to control "subscriber host connectivity verification" which verifies the host connectivity to the BNG. There are two types of SHCV: periodic and event triggered. Prior to Release 13.0R4, some event triggered SHCV relied on the reference timer set by the host-connectivity-verify under the group interface while others had hardcoded values. Release 13.0R4 introduced the "SHCV policy" that allows individual configuration of trigger SHCV timers and periodic SHCV timers depending on the application.

## 9.3.3 radius-server-policy Retry Attempt Overview

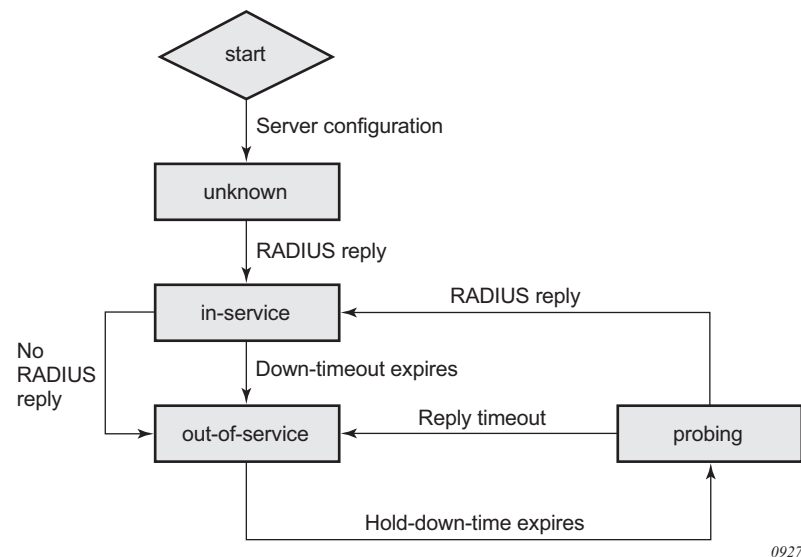

This feature maximizes the use of the remaining healthy RADIUS servers for subscriber authentication and accounting. After the hold-down time expires, a single RADIUS message is used to determine the status of the RADIUS server. If the server remains unresponsive after waiting for a single timeout interval (without any retries), then it is placed back into the hold-down state. If the RADIUS server responds, then it is used for subscriber authentication and accounting with the rest of the healthy servers.

### 9.3.4 AAA RADIUS Server Operation Status

The different operating states of a RADIUS server are shown in [RADIUS Server Operating States](#). When a RADIUS server is first provisioned into the AAA using the **radius-server-policy** command, the operating state is “unknown”. This state indicates that the RADIUS server has yet to receive a RADIUS request message. To send a request message, the **radius-server-policy** command provides three different access algorithms: direct, round-robin, and hash. With the direct algorithm, request messages are always sent to the in-service RADIUS server with the lowest configured server index. With the round-robin algorithm, the RADIUS requests are load-balanced in a round-robin manner. The hash algorithm offers a load-balanced alternative; the 7750 SR generates a hash-key based on the subscriber information, and the RADIUS request is then sent to a particular server based on the hash key. The hash method differs from the round-robin method in that, under normal working conditions, RADIUS requests from a particular subscriber are always forwarded to the same RADIUS server. When a server replies to a RADIUS request, it transitions from the operational state of “unknown” to “in-service”. A server may transition from “unknown” to “out-of-service” if the server fails to respond to the initial RADIUS message.

**Figure 66** RADIUS Server Operating States

A RADIUS server is declared “out-of-service” when the **down-timeout** timer expires. The router starts the **down-timeout** timer when an access-request is sent. The timer only resets to “0” when a reply is received from the RADIUS server. This means that the timer can be reset to “0” if a reply message is received for another subscriber. For example, the RADIUS server may miss a message but stay “in-service” as long as the server responds to another access request from a different subscriber or from a retry of the same subscriber, as long as the reply is received within the **down-timeout** interval.

**Note:** It is highly recommended that the **down-timeout** command be set to its default value, which is **no down-timeout**.

The **down-timeout** default value is the timeout value multiplied by the number of retry attempts. The timeout value is the time that the router waits for the RADIUS server to reply, and the retry value is the number of attempts the 7750 SR will make to contact the RADIUS server after each timeout. If the RADIUS server remains unresponsive, the timer will continue to increment until it reaches the configured **down-timeout** value and the server is declared “out-of-service”.

For RADIUS servers that do not respond to all RADIUS requests, a test user account can be optionally set up to periodically send RADIUS request messages in order to keep the server in service. Typically, a RADIUS server should always respond to all access requests. However, creating a test user account for periodic keep-alive may place an unnecessary load on the processor and may lower the overall scale of the router.

At the start of the out-of-service state, a **hold-down-time** timer starts. The timer holds down the RADIUS server and prevents it from operating; no RADIUS messages are sent to an out-of-service server. This is beneficial for the following reasons.

- The server may be unresponsive due to excessive RADIUS message requests; holding it down allows the server to recover.
- Holding down an unresponsive server allows other healthy RADIUS servers to service new requests promptly.

After the **hold-down-time** timer expires, the server enters into the “probing” state. There must be multiple RADIUS servers and at least one healthy server in order for the server to enter the probing state. Probing is always performed by the test user account; actual subscriber requests are never used during probing. If no test user account exists, an actual subscriber request is used to perform the probe. There are no retry attempts; only a single RADIUS message is used to probe a RADIUS server. If the RADIUS server responds, it is declared “in-service” immediately. If the RADIUS

server fails to respond within the timeout value, it is declared “out-of-service” again and the **hold-down-time** timer restarts. Subscriber RADIUS messages used for probing are not cached, and if the server fails to respond, the subscriber is required to send the RADIUS message again by sending an address request; for example, DHCP, PPP, or SLAAC or by performing a **data-trigger**.

### 9.3.5 AAA RADIUS Accounting Server Stickiness

Stickiness applies to the following subscriber RADIUS accounting sessions: start, interim, and stop. By default, the subscriber sticks with the server that served its last accounting message. For example, if server 1 served the subscriber an accounting start message, then the subsequent interim messages and stop message from the same subscriber will be sent to server 1. If server 1 is out of service, server 2 is used for the subsequent interim and stop messages. When server 1 recovers, the interim and stop messages will stick with server 2. The RADIUS accounting messages will always be forwarded to the server that serviced the subscriber’s last accounting message.

Typically, when using the direct access algorithm, the primary server (lowest configured server index) serves all RADIUS request messages. The other RADIUS servers are used for backup purposes only and might be using a lighter-weight processor. Therefore, it is best to revert to the primary server as soon as it is restored. This can be accomplished by disabling stickiness in direct mode; the RADIUS accounting messages will be forwarded to the primary server once it is restored.

In a round-robin algorithm, while each subscriber session is assigned to a different server in round-robin order, a particular subscriber sticks with a particular server for the entire accounting session. Disabling stickiness will send a subscriber’s RADIUS accounting messages to the list of configured RADIUS servers in a round-robin order.

### 9.3.6 AAA RADIUS Authentication Fallback Action

The fallback action comes into effect when connectivity to all RADIUS servers is lost. The operating state of the RADIUS servers changes to either “out-of-service” or “probing”. There are two configurable fallback actions: **accept** or **user-db**. An accept action without force-probing will automatically accept all authentication requests from all subscribers. A user-db action without force-probing will use the **local-user-db** for subscriber authentication.

Both **accept** and **user-db** can be combined with the **force-probing** command. Force-probing forces the out-of-service server to transition to the probing state immediately, bypassing the **hold-down-time** timer. Force-probing is a mechanism to promptly restore connectivity to a RADIUS server. A test user is not used to perform a force probe; only actual subscriber authentication will be used to test the operating state of the RADIUS server. Probing only occurs when a server is out of service. If all servers are in the probing state, all new incoming authentication requests follow the fallback action immediately.

When probing with an actual subscriber authentication, the 7750 SR will only wait for a reply for one timeout interval without any retries. During the wait, the server will be in a probing state and no other subscribers will be used to probe this server. The subscriber authentication request is not cached when used for probing. Therefore, to trigger authentication again, the subscriber is required to authenticate again with an address request or a data-trigger packet.

### 9.3.7 AAA Test User Account

A test user account is used in the rare case where a RADIUS server ignores RADIUS messages as mentioned in the [AAA RADIUS Server Operation Status](#) section. Consequently, when messages are ignored, the router places the RADIUS server out of service. The test user account can keep a RADIUS server in service by periodically sending RADIUS requests to the server. The RADIUS server, while randomly ignoring other subscriber RADIUS requests, must respond to the test user requests. A RADIUS server is in service if it replies to RADIUS messages before the **down-timeout** timer expires. The default **down-timeout** default value is the timeout value multiplied by the retry value, but it is also configurable. The test user account has a configurable interval value, and it is recommended that this value be configured to be less than the **down-timeout** value for it to be useful. The test user account only applies to RADIUS authentication.

Typically, a RADIUS server always responds to all RADIUS requests, and therefore it is not recommended that a test user account be used unless it is absolutely required for certain types of servers. The test user account creates extra load for the processor and can affect scaling. The test user account can be used with a python script (for example, adding additional attributes to the test user account during an **access-request** operation).

## 9.3.8 Troubleshooting the RADIUS Server

The **tools>perform>security>authentication-server-check** command can be used to troubleshoot a RADIUS server by checking the connectivity and functional status of a RADIUS server for subscriber management operations. The command keyword **debug** can be specified to view additional information on the access request. All VSAs sent and received from the RADIUS server, the hex dump, and all other debug detailed information can be shown without the need to turn on system-wide debugging.

Additional attributes in an Access-Request message can be specified in an attribute file referenced with the command keyword **attr-from-file** *file-url*. Each attribute must be specified on a separate line in the text file in the following format:

**Table 53** authentication-server-check Attribute File Format

| Attribute file format                            | Description                                           |
|--------------------------------------------------|-------------------------------------------------------|
| <type> = <value>                                 | Standard attribute                                    |
| <vendor>, <type> = <value>                       | Vendor Specific Attribute                             |
| e, <type>, <ext-type> = <value>                  | Extended type attribute (RFC 6929)                    |
| evs, <type>, <vendor>, <vendortype><br>= <value> | Extended Vendor Specific attribute<br>(RFC 6929)      |
| le, <type>, <ext-type> = <value>                 | Long Extended type attribute (RFC6929)                |
| evs, <type>, <vendor>, <vendortype><br>= <value> | Long Extended Vendor Specific attribute<br>(RFC 6929) |

### 9.3.9 Provisioning of Enhanced Subscriber Management (ESM) Objects

In the ESM concept on network elements, a subscriber host is described by the following aspects:

- subscriber-id-string
- subscriber-profile-string
- sla-profile-string
- ancp-string
- intermediate-destination-identifier-string
- application-profile-string

This information is typically extracted from DHCP-ACK message using a Python script, and is used to provision subscriber-specific resources such as queues and filter entries. As an alternative to extracting this information from DHCP-ACK packet, provisioning from RADIUS server is supported.

As a part of this feature, the following VSAs have been defined:

- alc-subscriber-id-string — Contains a string which is interpreted as a subscriber-id.
- alc-subscriber-profile-string — Contains a string which is interpreted as a subscriber profile
- alc-sla-profile-string — Contains string which is interpreted as an SLA profile.
- alc-ancp-string — Contains string which is interpreted as an ANCP string.
- alc-int-dest-id-string — Contains a string which is interpreted as an intermediate destination ID
- alc-app-profile-string — Contains a string which is interpreted as an application profile

Note that these strings can be changed in a CoA request.

When RADIUS authentication response messages contain the above VSAs, the information is used during processing of DHCP-ACK message as an input for the configuration of subscriber-host parameters, such as QoS and filter entries.

If ESM is not enabled on a given SAP, information in the VSAs is ignored.

If ESM is enabled and the RADIUS response does not include all ESM-related VSAs (an ANCP string is not considered as a part of ESM attributes), only the subscriber-id is mandatory (the other ESM-related VSAs are not included). The remaining ESM information (sub-profile, sla-profile) will be extracted from DHCP-ACK message according to “normal” flow (Python script, and so on).

If the profiles are missing from RADIUS, they are not extracted from the DHCP data with Python to prevent inconsistent information. Instead, the data will revert to the configured default values.

However, if the above case, a missing subscriber ID will cause the DHCP request to be dropped. The DHCP server will not be queried in that case.

When no DHCP server is configured, DHCP-discover/request messages are discarded.

### 9.3.9.1 Provisioning IP Configuration of the Host

The other aspect of subscriber-host authorization is providing IP configuration (ip-address, subnet-mask, default gateway and dns) through RADIUS directory rather than using centralized DHCP server. In this case, the node receiving following RADIUS attributes will assume role of DHCP server in conversation with the client and provide the IP configuration received from RADIUS server.

These attributes will be accepted only if the system is explicitly configured to perform DHCP-server functionality on a given interface.

The following RADIUS attributes will be accepted from authentication-response messages:

- framed-ip-address — The IP address to be configured for the subscriber-host.
- framed-ip-netmask — The IP network to be configured for the subscriber host. If RADIUS does not return a netmask, the DHCP request is dropped.
- framed-pool — The pool on a local DHCP server from which a DHCP-provided IP address should be selected.
- alc-default-router — The address of the default gateway to be configured on the DHCP client.
- alc-primary-dns — The DNS address to be provided in DHCP configuration.
  - Juniper VSA for primary DNS.
  - Redback VSA for primary DNS.
- alc-secondary-dns
  - Juniper VSA for secondary DNS.

- Redback VSA for secondary DNS.
- alc-lease-time — Defines the lease time.
- session-timeout — Defines the lease time in absence of the alc-lease-time attribute.
- NetBIOS
  - alc-primary-nbns
  - alc-secondary-nbns

### 9.3.9.2 RADIUS Based Authentication in Wholesale Environment

In order to support VRF selection, the following attributes are supported:

- alc-retail-serv-id — Indicates the service-id of the required retail VPRN service configured on the system.

### 9.3.9.3 Change of Authorization and Disconnect-Request

In a typical RADIUS environment, the network element serves as a RADIUS client, which means the messages are originated by a routers. In some cases, such as “mid-session” changes, it is desirable that the RADIUS server initiates a CoA request to impose a change in policies applicable to the subscriber, as defined by RFC 3576.

To configure a RADIUS server to accept CoA and Disconnect Messages is achieved in one of the following ways:

1. Configure up to 64 RADIUS CoA servers per routing instance:

```
config>router>radius-server#
config>service>vprn>radius-server#
server "coa-1" address 10.1.1.1 secret <shared-secret> hash2 create
 accept-coa
exit
```

This is the preferred method.

2. Configure up to 16 RADIUS CoA servers per authentication policy.

```
config>subscr-mgmt>auth-plcy#
accept-authorization-change
```

The UDP port for CoA and Disconnect Messages is configurable per system with the command:

```
config>aaa#
radius-coa-port {1647|1700|1812|3799}
```

**Note:** There is a priority in the functions that can be performed by CoA. The first matching one will be performed:

- If the CoA packet contains a force-renew attribute, the subscriber gets a force-renew DHCP packet. This function is not supported for PPPoE or ARP hosts.
- If the CoA packet contains a create-host attribute, a new lease-state is created. Only DHCP lease-states can be created by a CoA message. PPPoE sessions and ARP hosts cannot be created.
- Otherwise, the ESM strings are updated.

There are several reasons for using RADIUS initiated CoA messages:

1. Changing ESM attributes (SLA or subscriber profiles) or queues/policers/schedulers rates of the given subscriber host — CoA messages containing the identification of the given subscriber-host along with new ESM attributes.
2. Changing (or triggering the change) of IP configuration of the given subscriber-host — CoA messages containing the identification of the given subscriber-host along with VSA indicating request of forcerenew generation.
3. Configuring new subscriber-host — CoA messages containing the full configuration for the given host.

If the changes to ESM attributes are required, the RADIUS sever will send CoA messages to the network element requesting the change in attributes included in the CoA request:

- attribute(s) to identify a single or multiple subscriber host(s): “NAS-Port-Id + IP address/prefix” or “Acct-Session-Id” or “Alc-Subsc-ID-Str”
  - Nas-Port-Id attribute + single IP address/prefix attribute:
    - Framed-IP-Address
    - Alc-lpv6-Address
    - Framed-lpv6-Prefix
    - Delegated-lpv6-Prefix
  - Acct-Session-Id (number format)
  - Alc-Subsc-ID-Str
- alc-subscriber-profile-string
- alc-sla-profile-string
- alc-ancp-string
- alc-app-profile-string
- alc-int-dest-id-string
- alc-subscriber-id-string

- alc-subscriber-qos-override

**Note:** If the subscriber-id-string is changed while the ANCP string is explicitly set, the ANCP-string **must** be changed simultaneously. When changing the alc-subscriber-id-string, the lease state is temporarily duplicated, causing two identical ANCP-strings to be in the system at the same time. This is not allowed.

As a reaction to such message, the router changes the ESM settings applicable to the given host.

If changes to the IP configuration (including the VRF-id in the case of wholesaling) of the given host are needed, the RADIUS server may send a CoA message containing VSA indicating request for forcerenew generation:

- attribute(s) to identify a single or multiple subscriber host(s): “NAS-Port-Id + IP address/prefix” or “Acct-Session-Id” or “Alc-Subsc-ID-Str”:
  - Nas-Port-Id attribute + single IP address/prefix attribute:
    - Framed-IP-Address
    - Alc-Ipv6-Address
    - Framed-Ipv6-Prefix
    - Delegated-Ipv6-Prefix
  - Acct-Session-Id (number format)
  - Alc-Subsc-ID-Str
- alc-force-renew
- alc-force-nak

As a reaction to such message, router will generate a DHCP forcerenew message for the given subscriber host. Consequently, during the re-authentication, new configuration parameters can be populated based on attributes included in Authentication-response message. The force-NAK attribute has the same function as the force-renew attribute, but will cause the ESR to reply with a NAK to the next DHCP renew. This will invalidate the lease state on the ESR and force the client to completely recreate its lease, making it possible to update parameters that cannot be updated through normal CoA messages, such as IP address or address pool.

If the configuration of the new subscriber-host is required, RADIUS server will send a CoA message containing VSA request new host generation along with VSAs specifying all required parameters.

- alc-create-host
- alc-subscriber-id-string — This attribute is mandatory in case ESM is enabled, and optional for new subscriber host creation otherwise.

- **NAS-port-id** — This attribute indicates the SAP where the host should be created.
- **framed-ip-address** — The framed IP address.
- **alc-client-hw-address** — A string in the xx:xx:xx:xx:xx:xx format. This attribute is mandatory for new subscriber-host creation.
- **alc-lease-time** — Specifies the lease time. If both session-timeout and alc-lease-time are not present, then a default lease time of 7 days is used.
- **session-timeout** — Specifies the lease time in absence of the alc-lease-time attribute. If both session-timeout and alc-lease-time are not present, then a default lease time of 7 days is used.
- **alc-retail-svc-id** — This is only used in case of wholesaling for selection of the retail service. Indicates the service-id of the required retail VPRN service configured on the system.
- Optionally other VSAs describing given subscriber host. Obviously, if the ESM is enabled, but the CoA message does not contain ESM attributes the new host will not be created.

After executing the requested action, the router element responds with an ACK or NAK message depending on the success/failure of the operation. In case of failure (and hence NAK response), the element will include the error code in accordance with RFC 3576 definitions if an appropriate error code is available.

Supporting CoA messages has security risks as it essentially requires action to unsolicited messages from the RADIUS server. This can be primarily the case in an environment where RADIUS servers from multiple ISPs share the same aggregation network. To minimize the security risks, the following rules apply:

- Support of CoA messages is disabled by default. They can be enabled on a per RADIUS server or authentication-policy basis.
- When CoA is enabled, the node will listen and react only to CoA messages received from RADIUS servers. In addition, CoA messages must be protected with the key corresponding to the given RADIUS server. All other CoA messages will be silently discarded.

In all cases (creation, modification, forcere-new) subscriber host identification attributes are mandatory in the CoA request: “NAS-Port-Id + IP” or “Acct-Session-Id” or “Alc-Subsc-ID-Str”

- **Nas-Port-Id + single IP address/prefix:**
  - Nas-Port-Id
  - Framed-IP-Address
  - Alc-Ipv6-Address
  - Framed-Ipv6-Prefix

- Delegated-Ipv6-Prefix
- Acct-Session-Id (number format)
- Alc-Subsc-ID-Str

When there are no subscriber host identification attributes present in the CoA, the message will be NAK'd with corresponding error code.

- hosts, meaning only subscriber host to which the given authentication-policy is applicable.
- Receiving CoA message with the same attributes as currently applicable to the given host will be responded to with an ACK message.
- In case of dual homing (through SRRP), the RADIUS server should send CoA messages to both redundant nodes and this with all corresponding attributes (NAS-port-id with its local meaning to corresponding node).
- In the case of change requests, the node which has the given host active (active-sap for master-sap for SRRP) will process the RADIUS message and reply to RADIUS. The standby node will always reply with a NAK.
- In the case of create requests, the active node (the SAP described by NAS-port-id is "active" or "master"). Both nodes will reply, but the standby will NAK the request.

The properties of an existing RADIUS-authenticated PPPoE session can be changed by sending a Change of Authorization (CoA) message from the RADIUS server. Processing of a CoA is done in the same way as for DHCP hosts, with the exception that only the ESM settings can be changed for a PPPoE session (the force-renew attribute is not supported for PPPoE sessions and a Create-Host CoA will always generate a DHCP host.)

For terminating PPPoE sessions from the RADIUS server, the disconnect-request message can be sent from the RADIUS server. This message triggers a shutdown of the PPPoE session. The attributes needed to identify the PPPoE session are the same as for DHCP hosts.

#### 9.3.9.4 RADIUS-Based Accounting

When a router is configured to perform RADIUS-based accounting, at the creation of a subscriber-host, it will generate an accounting-start packet describing the subscriber-host and send it to the RADIUS accounting server. At the termination of the session, it will generate an accounting-stop packet including accounting statistics for a given host. The router can also be configured to send an interim-accounting message to provide updates for a subscriber-host.

The exact format of accounting messages, their types, and communication between client running on the routers and RADIUS accounting server is described in RFC 2866, *RADIUS Accounting*. The following describes a few specific configurations.

In order to identify a subscriber-host in accounting messages different RADIUS attributes can be included in the accounting-start, interim-accounting, and accounting-stop messages. The inclusion of the individual attributes is controlled by the following commands.

```
configure
 subscr-mgmt
 radius-accounting-policy <name>
 include-radius-attribute
 [no] acct-authentic
 [no] acct-delay-time
 [no] called-station-id
 [no] calling-station-id
 [no] circuit-id
 [no] delegated-ipv6-prefix
 [no] dhcp-vendor-class-id
 [no] framed-interface-id
 [no] framed-ip-addr
 [no] framed-ip-netmask
 [no] framed-ipv6-prefix
 [no] framed-route
 [no] framed-ipv6-route
 [no] ipv6-address
 [no] mac-address
 [no] nas-identifier
 [no] nas-port
 [no] nas-port-id
 [no] nas-port-type
 [no] nat-port-range
 [no] remote-id
 [no] sla-profile
 [no] sub-profile
 [no] subscriber-id
 [no] tunnel-server-attrs
 [no] user-name
 [no] wifi-rssi
 [no] alc-acct-triggered-reason
 [no] access-loop-options
 [no] all-authorized-session-addresses
 [no] detailed-acct-attributes
 [no] std-acct-attributes
 [no] v6-aggregate-stats
```

RADIUS volume accounting attributes are depending on the type of volume reporting and can be controlled via an **include-radius-attribute** CLI command. Multiple volume reporting types can be enabled simultaneously:

```
config
 subscr-mgmt
 radius-accounting-policy <name>
```

```
include-radius-attribute
[no] detailed-acct-attributes
[no] std-acct-attributes
[no] v6-aggregate-stats
```

where:

**detailed-acct-attributes** — Report detailed per queue and per policer counters using RADIUS VSAs (enabled by default). Each VSA contains a queue or policer id followed by the stat-mode or 64 bit counter. The VSA's included in the Accounting messages is function of the context (policer or queue, stat-mode, MDA type, an so on):

[26-6527-107] Alc-Acct-I-statmode  
[26-6527-127] Alc-Acct-O-statmode  
[26-6527-19] Alc-Acct-I-Inprof-Octets-64  
[26-6527-20] Alc-Acct-I-Outprof-Octets-64  
[26-6527-21] Alc-Acct-O-Inprof-Octets-64  
[26-6527-22] Alc-Acct-O-Outprof-Octets-64  
[26-6527-23] Alc-Acct-I-Inprof-Pkts-64  
[26-6527-24] Alc-Acct-I-Outprof-Pkts-64  
[26-6527-25] Alc-Acct-O-Inprof-Pkts-64  
[26-6527-26] Alc-Acct-O-Outprof-Pkts-64  
[26-6527-39] Alc-Acct-OC-O-Inprof-Octets-64  
[26-6527-40] Alc-Acct-OC-O-Outprof-Octets-64  
[26-6527-43] Alc-Acct-OC-O-Inprof-Pkts-64  
[26-6527-44] Alc-Acct-OC-O-Outprof-Pkts-64  
[26-6527-69] Alc-Acct-I-High-Octets-Drop\_64  
[26-6527-70] Alc-Acct-I-Low-Octets-Drop\_64  
[26-6527-71] Alc-Acct-I-High-Pack-Drop\_64  
[26-6527-72] Alc-Acct-I-Low-Pack-Drop\_64

[26-6527-73] Alc-Acct-I-High-Octets-Offer\_64  
[26-6527-74] Alc-Acct-I-Low-Octets-Offer\_64  
[26-6527-75] Alc-Acct-I-High-Pack-Offer\_64  
[26-6527-76] Alc-Acct-I-Low-Pack-Offer\_64  
[26-6527-77] Alc-Acct-I-Unc-Octets-Offer\_64  
[26-6527-78] Alc-Acct-I-Unc-Pack-Offer\_64  
[26-6527-81] Alc-Acct-O-Inprof-Pack-Drop\_64  
[26-6527-82] Alc-Acct-O-Outprof-Pack-Drop\_64  
[26-6527-83] Alc-Acct-O-Inprof-Octs-Drop\_64  
[26-6527-84] Alc-Acct-O-Outprof-Octs-Drop\_64  
[26-6527-91] Alc-Acct-OC-O-Inpr-Pack-Drop\_64  
[26-6527-92] Alc-Acct-OC-O-Outpr-Pack-Drop\_64  
[26-6527-93] Alc-Acct-OC-O-Inpr-Octs-Drop\_64  
[26-6527-94] Alc-Acct-OC-O-Outpr-Octs-Drop\_64  
[26-6527-108] Alc-Acct-I-Hiprio-Octets\_64  
[26-6527-109] Alc-Acct-I-Lowprio-Octets\_64  
[26-6527-110] Alc-Acct-O-Hiprio-Octets\_64  
[26-6527-111] Alc-Acct-O-Lowprio-Octets\_64  
[26-6527-112] Alc-Acct-I-Hiprio-Packets\_64  
[26-6527-113] Alc-Acct-I-Lowprio-Packets\_64  
[26-6527-114] Alc-Acct-O-Hiprio-Packets\_64  
[26-6527-115] Alc-Acct-O-Lowprio-Packets\_64  
[26-6527-116] Alc-Acct-I-All-Octets\_64  
[26-6527-117] Alc-Acct-O-All-Octets\_64  
[26-6527-118] Alc-Acct-I-All-Packets\_64

[26-6527-119] Alc-Acct-O-All-Packets\_64

**std-acct-attributes** — Report IPv4 and IPv6 aggregated forwarded counters using standard RADIUS attributes (disabled by default):

[42] Acct-Input-Octets

[43] Acct-Output-Octets

[47] Acct-Input-Packets

[48] Acct-Output-Packets

[52] Acct-Input-Gigawords

[53] Acct-Output- Gigawords

**v6-aggregate-stats** — Report IPv6 aggregated forwarded counters of queues and policers in stat-mode v4-v6 using RADIUS VSAs (disabled by default):

[26-6527-194] Alc-IPv6-Acct-Input-Packets

[26-6527-195] Alc-IPv6-Acct-Input-Octets

[26-6527-196] Alc-IPv6-Acct-Input-GigaWords

[26-6527-197] Alc-IPv6-Acct-Output-Packets

[26-6527-198] Alc-IPv6-Acct-Output-Octets

[26-6527-199] Alc-IPv6-Acct-Output-Gigawords

In addition to accounting-start, interim-accounting, and accounting-stop messages, a RADIUS client on a routers will send also accounting-on and accounting-off messages. An accounting-on message will be sent when a given RADIUS accounting-policy is applied to a given subscriber-profile, or the first server is defined in the context of an already applied policy. The following attributes will be included in such message:

- NAS-identifier
- alc-subscriber-profile-string
- Accounting-session-id
- Event-timestamp

Accounting-off messages will be sent at following events:

- An accounting policy has been removed from a sub-profile.

- The last RADIUS accounting server has been removed from an already applied accounting policy.

These messages contain following attributes:

- NAS-identifier
- alc-subscriber-profile-string
- Accounting-session-id
- Accounting-terminate-cause
- Event-timestamp

In case of dual homing, both nodes will send RADIUS accounting messages for the host, with all attributes as it is locally configured. The RADIUS log files on both boxes need to be parsed to get aggregate accounting data for the given subscriber host regardless the node used for forwarding.

For RADIUS-based accounting, a custom record can be defined to refine the data that is sent to the RADIUS server. Refer to the Configuring an Accounting Custom Record in the OS System Management Guide for further information.

### 9.3.9.5 RADIUS Accounting Terminating Cause

The VSA **acct-terminate-cause** attribute provides some termination information. Two additional attributes: [VSA 227] **alc-error-message** and [VSA 226] **alc-error-code** provide additional information in both string and numeric format about the terminating cause of the subscriber session. The full list of error messages and their corresponding error codes can be viewed using the command **tools>dump>aaa>radius-acct-terminate-cause**.

If required, python can alter the content of both VSAs. The following is a python script example where the error codes are remapped from 123 to 8 and from 124 to 17:

```
import alc
import struct

ALU = 6527
TERM_CAUSE = 49
ALC_ERROR_CODE = 226

if (alc.radius.attributes.isSet(TERM_CAUSE) and
 alc.radius.attributes.isVSASet(ALU, ALC_ERROR_CODE)):

 error_code = alc.radius.attributes.getVSA(ALU, ALC_ERROR_CODE)
 error_code = struct.unpack('!i', error_code)[0]

 term_cause = alc.radius.attributes.get(TERM_CAUSE)
 term_cause = struct.unpack('!i', term_cause)[0]
```

```
#print "error code = ", error_code
#print "term cause = ", term_cause

table with mapping from alc-error-code to the standard terminate cause
if no mapping will be found, no transformation will be done
error_map = {
 123 : 8,
 124 : 17
}

new_term_cause = error_map.get(error_code, term_cause)
#print "new term_cause = ", new_term_cause

alc.radius.attributes.set(TERM_CAUSE, struct.pack('!I', new_term_cause))
```

### 9.3.9.6 Accounting Modes Of Operation

This section is applicable to the 7750 SR or the 7450 ESS in mixed mode. There are three basic accounting models:

- Per queue-instance
- Per Host
- Per Session

Each of the basic models can optionally be enabled to send interim-updates. Inclusion/exclusion of interim-updates will depend on whether volume based (start/interim-updates/stop) or time based (start/stop) accounting is required.

The difference between the three basic accounting models is in its core related to the processing of the acc-session-id for each model. The differences are related to:

- acct-session-id generation within each model.
- outcome in response to the CoA action relative to the targeted acct-session-id.

The counters for volume-based accounting are collected from queues or policers that are instantiated per sla-profile instance (SPI) on non-HSMDA based hardware or per subscriber on HSMDA based hardware. This is true irrespective of which model of accounting (or combination of models) is deployed. Within accounting context, the SPI on non-HSMDA or subscriber on HSMDA equates to queue-instance.

[Table 54](#) summarizes the key differences between various accounting modes of operation that are supported. Interim-updates for each individual mode can be enabled/disabled via configuration (interim-updates keyword as an extension to the commands that enable three basic modes of accounting). This is denoted by the IU-Config keyword under the 'I-U' column in the table. The table also shows that any two combinations of the three basic models (including their variants for volume/time based accounting) can be enabled simultaneously.

**Table 54 Accounting Modes of Operation**

| Accounting Mode                                | Accounting Entity | START | I-U       | STOP | Acct-session-id | Acct-multi-session-id |
|------------------------------------------------|-------------------|-------|-----------|------|-----------------|-----------------------|
| queue-instance-accounting                      | queue-instance    | X     | IU-config | X    | X               |                       |
|                                                | session           |       |           |      |                 |                       |
|                                                | host              |       |           |      |                 |                       |
| session-accounting                             | queue-instance    |       |           |      |                 |                       |
|                                                | session           | X     | IU-config | X    | X               | q-instance            |
|                                                | host              |       |           |      |                 |                       |
| host-accounting                                | queue-instance    |       |           |      |                 |                       |
|                                                | session           |       |           |      |                 |                       |
|                                                | host              | X     | IU-config | X    | X               | queue-instance        |
| queue-instance-accounting + host-accounting    | queue-instance    | X     | IU-config | X    | X               | queue-instance        |
|                                                | session           |       |           |      |                 |                       |
|                                                | host              | X     | IU-config | X    | X               | queue-instance        |
| queue-instance-accounting + session-accounting | queue-instance    | X     | IU-config | X    | X               | queue-instance        |
|                                                | session           | X     | IU-config | X    | X               | queue-instance        |
|                                                | host              |       |           |      |                 |                       |

**Table 54** Accounting Modes of Operation (Continued)

| Accounting Mode                          | Accounting Entity  | START | I-U           | STOP | Acct-session-id | Acct-multi-session-id |
|------------------------------------------|--------------------|-------|---------------|------|-----------------|-----------------------|
| session- accounting +<br>host-accounting | queue-<br>instance |       |               |      |                 | queue-instance        |
|                                          | session            | X     | IU-<br>config | X    | X               |                       |
|                                          | host               | X     |               | X    | X               | SESSION               |

**Note:** Hosts within the targeted CoA entity will be affected as follows:

- If the CoA target is the session, then both constituting members (IPv4 and IPv6) of the dual-stack host will be affected.
- If the CoA target is the queuing-instance, then up to 32 hosts that are sharing that SPI will be affected.

The same principle applies to LI.

The accounting behavior (accounting messages and accounting attributes) in case that the SPI is changed via CoA depends on the accounting mode of operation. On non-HSMDA hardware, the behavior is the following:

- SPI change in conjunction with per queuing instance accounting will trigger a STOP for the old SPI and a START for the new SPI with corresponding counters. Acct-session-id/Acct-Multi-Session-Id will be unique per SPI. Note that Acct-Multi-Session-Id is only generated if per queuing-instance accounting mode of operation is combined with some other mode of operation (host or session).
- SPI change in conjunction with per host or per session accounting (no interim updates for either method) will NOT trigger any new accounting messages. In other words, SPI change will go unnoticed from the perspective of the accounting server until the host/session is terminated. When the host/session is terminated a STOP will be sent with the VSA carrying the latest SPI name and the acct-multi-session-id attribute of the latest SPI. Acct-session-id will stay the same during the lifetime of the host. Counters are not included in STOP (interim-update not enabled).

SPI change in conjunction with per host accounting with interim-updates or per session accounting with interim-updates will trigger two interim-update messages:

- One with the old counters (terminated queues) and the old SPI name VSA. This behavior is similar to the triggered STOP message in per queuing-instance accounting upon SPI change.

- One with the new counters (new queues instantiated), the VSA carrying the new SPI name and the new acct-multi-session-id referencing the new SPI. This behavior is similar to the triggered START message in per queuing-instance when SPI is changed in per queuing-instance accounting.

On HSMDB, no START/STOPS are sent since queues are not re-instantiated on ingress or egress.

### 9.3.9.7 Per Session Accounting

In the per session accounting mode of operation the accounting message stream (START/INTERIM-UPDATE/STOP) is generated per session. The accounting message stream refers to a collection of accounting messages (START/INTERIM-UPDATE/STOP) sharing the same acct-session-id.

- A session is defined for PPPoE hosts for which a state is maintained. The state of the host (single stack or dual-stack) is normally refreshed via PPP keepalives. Each PPPoE host of the same address family (v4 or v6) corresponds to a unique session which is identified by the <session-ID, mac> combination.

In dual-stack PPPoE case, IPv4 and IPv6 hosts are tied to the same (LCP) session. A single authentication request is initiated for such session (triggered by the first host that initiates the session).

For a single stack PPPoE host, the behavior defined in the per session accounting model is indistinguishable from the per host accounting model. The per session accounting model makes difference in behavior only for dual stack PPPoE hosts.

The following are the properties of the Per Session Accounting model:

- A single accounting session ID (acct-session-id) is generated per (PPPoE) session and it can optionally be sent in RADIUS Access-Request message.
- This acct-session-id is synchronized via MCS in dual homing environment.
- The accounting messages (START, INTERIM-UPDATE, STOP) carry the acct-multi-session-id attribute denoting the sla-profile instance with which the session is associated.
- The counters are collected from the queues instantiated through the sla-profile instance. If multiple sessions are sharing the same sla-profile instance, the counters are aggregated. In other words, counters per individual session cannot be extracted from the aggregated count.
- RADIUS triggered changes and LI are applicable per session:
  - Queue/policer RADIUS overrides — Parameters for the referenced queue/policer within the session are changed accordingly.

- Subscriber aggregate rate limits, scheduler rates and arbiter rates are changed accordingly.
- CoA DISCONNECT brings down the entire session.
- LI — Activation based on the session acct-session-id affects the hosts within the session (dual-stack).
- SLA profile instance change affects all hosts (or sessions) sharing the same sla-profile instance (SPI). If the SPI is changed on a non-HSMDA based MDA, then queues are re-instantiated and counters are reset.
- All applicable IP addresses (v4 and v6 – including all v6 attributes – alc-ipv6-address, framed-ipv6-prefix, delegated-ipv6-prefix) are present in accounting messages for the session.

#### **9.3.9.7.1 Caveats**

Per session accounting is supported for entities that have concept of a session. Currently only PPPoE hosts (single or dual-stack) fall into this category.

#### **9.3.9.8 RADIUS Session Accounting with PD as a Managed Route**

The Prefix Delegation (PD) prefix is included in the accounting messages using the VSA [99], Framed-IPv6-Route attribute with the string type “pd-host” appended to differentiate it from a regular framed IPv6 route; for example, FRAMED IPV6 ROUTE [99] 39 2001:1000::/64 :: 0 pref 0 type pd-host. PD as a managed route is applicable to both PPP and IPoE sessions and can point either to an IPv4 host or to an IPv6 WAN host.

[Table 55](#) outlines the RADIUS accounting behavior based on the session type and the next-hop host.

**Table 55** Radius Accounting Behavior

| Session Type and Next-Hop Host                                 | RADIUS Accounting Start                           | RADIUS Accounting Interims                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | RADIUS Accounting Stop                                                                                                                                                                                                                                                                                                                                             |

### RADIUS Per Host Accounting

In SR-OS, the accounting paradigm is based on SLA profile instances yet this is at odds with traditional RADIUS authentication and accounting which is host-centric. In previous SR-OS releases, it was possible to have many hosts sharing a common SLA profile instance, and thus accounting and QoS parameters. Complications would arise with RADIUS accounting because Accounting-Start and Accounting-Stop are a function of sla-profile instance and not the hosts — this meant that some host-specific parameters (like framed-ip-address) would not be consistently included in RADIUS accounting.

Currently, dual-stack subscribers are really two different hosts sharing a single sla-profile instance. A new RADIUS accounting mode has been introduced to support multiple-host environments.

Under accounting-policy, a host-accounting command allows configurable behavior.

#### 9.3.9.9 No Host-Accounting

In prior releases and when no host-accounting is configured, the accounting behavior is as follows:

- A RADIUS accounting start message is sent when the SLA-profile instance is created. It contains accounting (octets/packets) and the framed-ip-address of the host which caused the sla-profile instance to be created.
- Additional hosts may bind to the sla-profile instance at any time, but no additional Accounting messages are sent during these events.
- If the original host disconnects then future Accounting messages will use an IP address of one of the remaining hosts.
- When the final host associated with an sla-profile instance disconnects an Accounting Stop message will be sent.

### 9.3.9.10 Host-Accounting Enabled

When host-accounting is configured, additional RADIUS accounting messages are created for host activity in addition to messages for common queue accounting. The behavior is as follows:

- A RADIUS accounting start message is sent each time a host is authenticated. It contains the framed-ip-address among other things. It does not contain any octet or packet counts.
- A RADIUS accounting start message is sent each time a sla-profile instance is created.
- Whenever a host disconnects a RADIUS accounting stop message is sent for that host.
- If all host associated with an sla-profile instance disconnect, a RADIUS Accounting Stop message is sent for that instance.

This new behavior means certain AVP may be in either host; sla-profile instance or both accounting records.

Note that interim-acct records are not sent for hosts, only the start- and stop-accting messages.

**Table 56**

| RADIUS Accounting AVP | Include-radius-attrs Acct/<br>Auth | Host<br>Accounting | SLA-Profile<br>Accounting |
|-----------------------|------------------------------------|--------------------|---------------------------|
| User-Name             | Yes/No                             | Yes                | No                        |
| NAS-Identifier        | Yes/No                             | Yes                | Yes                       |
| NAS-Ip-Address        | No/No                              | Yes                | Yes                       |
| NAS-Port-Id           | Yes/Yes                            | Yes                | No                        |

| Framed-Ip-Address             | Yes/No                                     | Yes                        | No                                |
| Framed-Ip-Netmask             | Yes/No                                     | Yes                        | No                                |
| Class                         | No/No                                      | Yes                        | No                                |
| Circuit-Id VSA                | Yes/Yes                                    | Yes                        | No                                |
| Called-Station-Id             | Yes/Yes                                    | Yes                        | No                                |
| Calling-Station-Id            | Yes/Yes                                    | Yes                        | No                                |
| MAC-Addr VSA                  | Yes/Yes                                    | Yes                        | No                                |
| Remote-Id VSA                 | Yes/Yes                                    | Yes                        | No                                |
| Acct-Input-Octets             | No/No                                      | No                         | Yes                               |
| Acct-Output-Octets            | No/No                                      | No                         | Yes                               |
| Acct-Input-Gigawords          | No/No                                      | No                         | Yes                               |
| Acct-Output-Gigawords         | No/No                                      | No                         | Yes                               |
| Acct-Session-Id               | No/No                                      | Yes                        | Yes                               |
| Acct-Session-Time             | No/No                                      | Yes                        | Yes                               |
| Acct-Input-Packets            | No/No                                      | No                         | Yes                               |
| Acct-Output-Packets           | No/No                                      | No                         | Yes                               |
| Acct-Multi-Session-Id         | No/No                                      | Yes                        | Yes                               |
| Access-Loop-Encapsulation     | No/Yes                                     | Yes                        | No                                |
| Alc-Subscriber-Id             | Yes/No                                     | Yes                        | Yes                               |
| Alc-Subscriber-Profile-String | Yes/No                                     | Yes                        | Yes                               |
| Alc-Sla-Profile-String        | Yes/No                                     | Yes                        | Yes                               |

### 9.3.9.11 Reduction of Host Updates for Session Accounting Start and Stop

When **host-update** is enabled in session accounting, a dual stack subscriber can generate multiple host update accounting messages at the start and end of a session (for example, one for the IPv4 host and two more for the IPv6 WAN and IPv6 PD hosts). Two features can be used to reduce the number of host update messages per subscriber.

The first feature delays the Start Accounting message by a configurable value and is applicable to both PPPoE and IPoE sessions. The command for configuring this feature is **config>subscr-mgmt>acct-plcy>delay-start-time**. The delay allows the full dual stack address assignment to be completed before triggering the accounting Start message. The Start message reports all the addresses and prefixes assigned to the subscriber at that time. Subsequent new or disconnected hosts will trigger interim host updates if enabled.

The second feature is for PPPoE sessions only and is used to reduce the number of host update messages when a dual stack PPP subscriber disconnects. The command for configuring this feature is **config>subscr-mgmt>sub-prof>rad-acct>session-optimized-stop**. A single accounting Stop message containing all the addresses and prefixes for the subscriber at the time is generated.

### 9.3.9.12 Accounting Interim Update Message Interval

The interval between two RADIUS Accounting Interim Update messages can be configured in the RADIUS accounting policy with the **update-interval** command, for example:

```
config
subscr-mgmt
 radius-accounting-policy "acct-policy-1" create
 update-interval 60
 update-interval-jitter absolute 600
```

A RADIUS specified interim interval (attribute [85] Acct-Interim-Interval) overrides the CLI configured value.

By default, a random delay of 10% of the configured **update-interval** is added to the update-interval between two Accounting Interim Update messages. This jitter value can be configured with the **update-interval-jitter** to an absolute value in seconds between zero and 3600. The effective maximum random delay value is the minimum value of the configured absolute jitter value and 10% of the configured **update-interval**.

A value of zero will send the Accounting Interim Update message without introducing an additional random delay.

### 9.3.9.13 CoA Triggered Accounting Interim Update

The vendor-specific attribute (VSA) [228], Alc-Triggered-Acct-Interim, can be used in a Change of Authorization message to trigger an interim accounting message. This feature requires the accounting mode to have interim updates enabled. You can enable interim updates using, the **config>subscr-mgmt>radius-acct-plcy>host-accounting interim-update** command. The VSA can hold a string of up to 247 characters. The accounting interim echoes this string in the interim message under the same Alc-Triggered-Acct-Interim VSA along with Alc-Acct-Triggered-Reason = CoA-triggered. If the VSA is left blank, it will still trigger the accounting interim message with Alc-Acct-Triggered-Reason = CoA-triggered (18), but without the Alc-Triggered-Acct-Interim attribute. If the subscriber session has multiple accounting policies or modes enabled, multiple interim messages will be generated.

Some CoAs, such as SLA profile or sub-profile changes, will trigger accounting update messages to be generated automatically. These CoAs can automatically generate one or more accounting interim messages. If these CoAs also include the Alc-Triggered-Acct-Interim VSA, no additional interim accounting messages will be generated. The last auto-generated accounting interim message will contain two reasons:

- the reason for the triggered interim message (such as an SLA start)
- the CoA-triggered (18) Alc-Triggered-Acct-Interim attribute that will be echoed on the triggered accounting interim message if the VSA is not empty

### 9.3.9.14 Class Attribute

The RADIUS class attribute helps to aid in user identification.

User identification is used to correlate RADIUS accounting messages with the given user. During the authentication process, the RADIUS authentication server inserts a class attribute into the RADIUS authenticate response message and the router echoes this class attribute in all RADIUS accounting messages.

The 7750 SR can store up to six class attributes for both RADIUS and NASREQ. Each class VSA or AVP can have a maximum of 253 characters. If the VSA or AVP contains more than 253 characters, only the first 253 characters will be stored. If there are more than six VSAs or AVPs, only the first six will be stored. This functionality is also applicable to RADIUS authentication via the ISA.

### 9.3.9.15 User Name

The user-name, which is used for user authentication (user-name attribute in RADIUS authentication request), can be included in RADIUS accounting messages. Per RFC 2865, when a RADIUS server returns a (different) user-name attribute, the changed user name will be used in accounting and not the originally sent user name.

### 9.3.9.16 Accounting-On and Accounting Off

For RADIUS servers configured in a RADIUS server policy, the accounting on/off behavior is controlled via the **acct-on-off** command in the radius-server-policy.

By default, no Accounting-On or Accounting-Off messages are sent (**no acct-on-off**).

With the **acct-on-off** command configured in the radius-server-policy:

- An Accounting-On is sent for the following:
  - When the system is powered on.
  - After a system reboots.
  - When the **acct-on-off** command is added to the **radius-server-policy** configuration.
  - User triggered via CLI: tools perform `aaa acct-on`
- An Accounting-Off is sent for the following:
  - Before a user initiated system reboot.
  - When the **acct-on-off** command is removed from the **radius-server-policy** configuration.
  - User triggered via CLI: tools perform `aaa acct-off`.

The Accounting-On or Accounting-Off message is sent to the servers configured in the radius-server-policy, following the configured access-algorithm until an Accounting Response is received. If the first server responds, no message is sent to the other servers.

The Accounting-On message is repeated until an Accounting Response message is received from a RADIUS server: If after the configured retry/timeout timers for each RADIUS server in the radius-server-policy no response is received then the process starts again after a fixed one minute wait interval.

The Accounting-Off message is attempted once: If after the configured retry/timeout timers for each RADIUS server in the radius-server-policy no response is received then no new attempt is made.

It is possible to block a radius-server-policy until an Accounting Response is received from one of the RADIUS servers in the radius-server-policy that acknowledges the reception of an Accounting-On. The radius-server-policy cannot be used by applications for sending RADIUS messages until the state becomes "Not Blocked". This is achieved with the optional "oper-state-change" flag, for example:

```
config
aaa
 radius-server-policy "aaa-server-policy-1" create
 acct-on-off oper-state-change
 servers
 router "Base"
 server 1 name "server-1"
 exit
exit
exit
```

If multiple radius-server-policies are in use for different applications (for example, authentication and accounting) and an Accounting-On must be send for only one radius-server-policy, it is possible to tie the acct-on-off states of both policies together using an acct-on-off-group. With this configuration, it is possible to block the authentication servers until the accounting servers are available. An acct-on-off-group can be referenced by:

- a single radius-server-policy as controller: the acct-on-off oper-state of the acct-on-off-group is set to the acct-on-off oper-state of the radius-server-policy (acts as master)
- multiple radius-server-policies as monitor: the acct-on-off oper-state of the radius-server-policy is inherited from the acct-on-off oper-state of the acct-on-off group. (acts as a slave)

```
config
aaa
 acct-on-off-group "group-1" create
 description "Grouping of radius-server-policies acct-on-off"
exit
```

```

radius-server-policy "aaa-server-policy-1" create
 acct-on-off oper-state-change group "group-1"
 servers
 router "Base"
 server 1 name "server-1"
 exit
exit
radius-server-policy "aaa-server-policy-2" create
 acct-on-off monitor-group "group-1"
 servers
 router "Base"
 server 1 name "server-2"
 exit
exit

```

It is possible to force an Accounting-On or Accounting-Off message for a radius-server-policy with acct-on-off enabled using following CLI commands:

**tools perform aaa acct-on [radius-server-policy *policy-name*] [force]**

**tools perform aaa acct-off [radius-server-policy *policy-name*] [force] [acct-terminate-cause *number*]**

If an Accounting-On was sent to the radius-server-policy and it was acknowledged with an Accounting Response then a new Accounting-On can only be sent with the “force” flag.

If an Accounting-Off was sent to the radius-server-policy and it was acknowledged with an Accounting Response then a new Accounting-Off can only be sent with the “force” flag. The Acct-Terminate-Cause value in the Accounting-Off can be overwritten.

Use the following CLI command to display the Accounting On/Off information for a radius-server-policy:

```

show aaa radius-server-policy "aaa-server-policy-3" acct-on-off
=====
RADIUS server policy "aaa-server-policy-3" AcctOnOff info
=====
Oper state : on
Session Id : 242FFF0000008F512A3985
Last state change : 02/24/2013 16:06:41
Trigger : startUp
Server : "server-1"
=====

```

The operational state provides following state information: The sending of the Accounting-On or Accounting-Off message is ongoing (sendAcctOn, SendAcctOff), is successfully responded (on, off) or no response received (OffNoResp).

The Session-Id is a unique identifier for each RADIUS server policy accounting Accounting-On/Accounting-Off sequence.

The Trigger field shows what triggered the Accounting On or Accounting Off message. If the radius-server-policy is part of an acct-on-off group then the group name is shown in brackets.

The Server field shows which server in the RADIUS server policy responded to the Accounting-On or Accounting-Off message.

To display the acct-on-off state of a radius-server-policy, use the command, for example:

```
show aaa radius-server-policy "aaa-server-policy-3"
=====
RADIUS server policy "aaa-server-policy-3"
=====
Description : (Not Specified)
Acct Request script policy : script-policy-1
Auth Request script policy : script-policy-1
Accept script policy : script-policy-1
Acct-On-Off : Enabled (state Blocked)

RADIUS server settings

Router : "Base"
Source address : (Not Specified)
Access algorithm : direct
Retry : 3
Timeout (s) : 5
Hold down time (s) : 30
Last management change : 02/20/2013 13:32:05
=====
Servers for "aaa-server-policy-3"
=====
Idx Name Address Port Oper State
 Auth/Acct

1 server-3 172.16.1.10 1812/1813 unknown
=====
```

The Acct-On-Off field indicates if the sending of Accounting-On and Accounting-Off messages is enabled or disabled. If enabled, the oper-state is displayed: state Blocked or state Not Blocked. When Blocked, the radius-server-policy cannot be used to send RADIUS messages.

To display acct-on-off-group information, use following command, for example:

```
show aaa acct-on-off-group "group-1"
=====
Acct-On-Off-Group Information
=====
acct on off group name : group-1
```

- controlling Radius-Server-policy :  
aaa-server-policy-1
- monitored by Radius-Serer-policy :  
aaa-server-policy-2

-----  
Nbr of Acct-on-off-groups displayed : 1  
-----  
=====

### 9.3.9.17 RADIUS Accounting Message Buffering

When all servers in a radius-server-policy are unreachable, it is possible to buffer the Accounting Stop and Accounting Interim-Update messages for up to 25 hours. When a RADIUS server becomes reachable again then the messages in the buffer are retransmitted.

RADIUS Accounting message buffering parameters can be configured per message type, for example:

```
config
aaa
 radius-server-policy "aaa-server-policy-1" create
 servers
 router "Base"
 buffering
 acct-interim min 60 max 3600 lifetime 12
 acct-stop min 60 max 3600 lifetime 12
 exit
 server 1 name "server-1"
 exit
exit
exit
exit
```

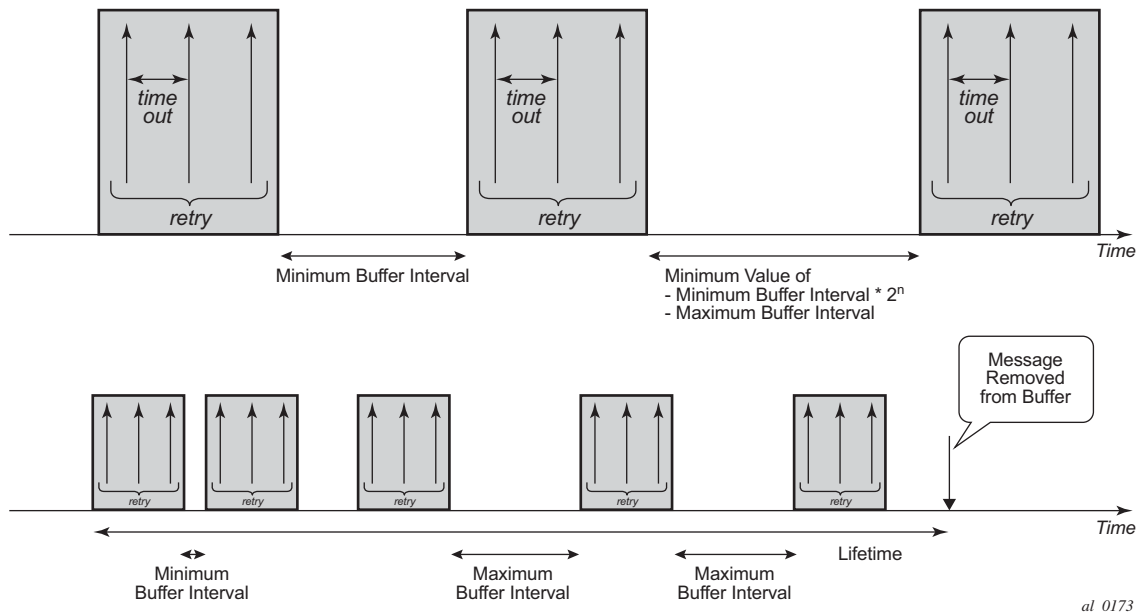

When RADIUS accounting message buffering is enabled:

1. The message is stored in the buffer, a lifetime timer is started and the message is sent to the RADIUS server.
2. If after  $\text{retry} \times \text{timeout}$  seconds no RADIUS accounting response is received for the Accounting Interim Update or Accounting Stop then a new attempt to send the message is started after minimum  $[(\text{min-val} \times 2n), \text{max-val}]$  seconds.
3. Repeat step 2 until:
  - a. RADIUS accounting response is received, or
  - b. the lifetime of the buffered message expires, or
  - c. (if the buffered message is an Accounting Interim-Update only) A new Accounting Interim-Update or an Accounting Stop or for the same accounting session-id and radius-server-policy is stored in the buffer, or

d. the message is manually purged from the message buffer via a clear command

- The message is purged from the buffer as shown in [Figure 67](#).

**Figure 67** Purging Message from Buffer

al\_0173

When Accounting Interim-Update message buffering is enabled, it is recommended to also enable Accounting Stop message buffering. This will guarantee the message ordering per accounting session.

Use following clear command to manually delete messages from the RADIUS accounting message buffer:

```
clear aaa radius-server-policy policy-name msg-buffer [acct-session-id acct-session-id]
```

When specifying the Acct-Session-Id, only that specific message will be deleted from the message buffer. If no Acct-Session-Id is specified, all messages for that radius-server-policy are deleted from the message buffer.

Use the following **show** commands to display the RADIUS accounting message buffer statistics:

```
show aaa radius-server-policy "aaa-server-policy-1" msg-buffer-stats
=====
RADIUS server policy "aaa-server-policy-1" message buffering stats
=====
buffering acct-interim : enabled
min interval (s) : 60
```

```

max interval (s) : 3600
lifetime (hrs) : 12
buffering acct-stop : enabled
min interval (s) : 60
max interval (s) : 3600
lifetime (hrs) : 12

```

## Statistics

```

Total acct-stop messages in buffer : 0
Total acct-interim messages in buffer : 5
Total acct-stop messages dropped (lifetime expired) : 0
Total acct-interim messages dropped (lifetime expired) : 0
Last buffer clear time : N/A
Last buffer statistics clear time : N/A

=====

```

Use following **clear** command to reset the RADIUS accounting message buffer statistics:

**# clear aaa radius-server-policy *policy-name* statistics msg-buffer-only**

Use following **tools** commands to display the RADIUS accounting message buffer content:

**# tools dump aaa radius-server-policy *policy-name* msg-buffer [session-id *acct-session-id*]**

For example:

```

tools dump aaa radius-server-policy "aaa-server-policy-1" msg-buffer
=====
RADIUS server policy "aaa-server-policy-1" message buffering
=====
message type Acct-Session-Id remaining lifetime

acct-interim 242FFF0000009A512B36FC 0d 11:58:54
acct-interim 242FFF0000009B512B36FC 0d 11:58:48
acct-interim 242FFF0000009C512B36FC 0d 11:58:30
acct-interim 242FFF0000009D512B36FC 0d 11:58:29
acct-interim 242FFF0000009E512B36FC 0d 11:59:05

No. of messages in buffer: 5
=====

```

When specifying the Acct-Session-Id, the message details are displayed.

### 9.3.9.18 Multiple Accounting Policies

The subscriber profile allows the user to configure a primary accounting policy with an additional accounting policy. The accounting policies are independent of each other and each policy has its own accounting mode, update interval, and include attributes. The RADIUS VSA [85] Acct-Interim-Interval attribute changes both the primary and the duplicate accounting interim update interval.

### 9.3.9.19 Sending an Accounting Stop Message upon a RADIUS Authentication Failure of a PPPoE Session

In scenarios where RADIUS authentication is used for PPPoE sessions, an accounting stop message can be generated to notify the RADIUS servers in case of an authentication failure.

The failure events are categorized in three categories:

- **“on-request-failure”** — All failure conditions between the sending of an Access-Request and the reception of an Access-Accept or Access-Reject.
- **“on-reject”** — When an Access-Reject is received.
- **“on-accept-failure”** — All failure conditions that appear after receiving an Access-Accept and before successful instantiation of the host or session.

Each of the categories can be enabled separately in the RADIUS authentication policy.

In the Enhanced Subscriber Management (ESM) model, the RADIUS accounting server is found after authentication and host identification as part of the subscriber profile configuration. To report authentication failures to accounting servers, an alternative RADIUS accounting policy configuration is required: local user database pre-authentication can provide the RADIUS authentication policy to be used for authentication and the RADIUS accounting policy to be used for authentication failure reporting. A duplicate RADIUS accounting policy can be specified if the accounting stop resulting from a RADIUS authentication failure must also be sent to a second RADIUS destination.

```
configure
 subscriber-mgmt
 local-user-db "ludb-1" create
 ppp
 match-list username
 host "default" create
 auth-policy "auth-policy-1"
 password ignore
```

```

 acct-policy "acct-policy-1" duplicate "acct-policy-2"
 no shutdown
 exit
 exit
 no shutdown
exit
authentication-policy "auth-policy-1" create
 pppoe-access-method pap-chap
 include-radius-attribute
 - - - snip - - -
 exit
 send-acct-stop-on-fail on-request-failure on-reject on-accept-failure
 radius-server-policy "aaa-server-policy-1"
exit
radius-accounting-policy "acct-policy-1" create
 - - - snip - - -
 radius-server-policy "aaa-server-policy-1"
exit
radius-accounting-policy "acct-policy-2" create
 - - - snip - - -
 radius-server-policy "aaa-server-policy-2"
exit

```

To enable local user database pre-authentication, use the **user-db** configuration in the capture SAP and in the group interface. For example:

```

configure
 service
 vpls 10 customer 1 create
 sap 1/1/1:1.* capture-sap create
 trigger-packet pppoe
 pppoe-policy "ppp-policy-1"
 pppoe-user-db "ludb-1"
 exit
 no shutdown
 exit
 ies 1000 customer 1 create
 subscriber-interface "sub-int-1" create
 - - - snip - - -
 group-interface "group-int-1-1" create
 - - - snip - - -
 pppoe
 policy "ppp-policy-1"
 user-db "ludb-1"
 no shutdown
 exit
 exit
 exit
 no shutdown
exit

```

## 9.4 Enhanced Subscriber Management Overview

### 9.4.1 Enhanced Subscriber Management Basics

In residential broadband networks numerous subscribers can be provisioned that can require significant changes on a daily basis. Manually configuring the applicable parameters for each subscriber would be prohibitive. The Nokia 7450 ESS and 7750 SR have been designed to support fully dynamic provisioning of access, QoS and security aspects for residential subscribers using DHCP to obtain an IP address. Enabling Enhanced Subscriber Management drastically reduces the configuration burden.

Enhanced Subscriber Management in the 7450 ESS and 7750 SR supports many vendor's access nodes and network aggregation models, including VLAN per customer, per service or per access node.

#### 9.4.1.1 Standard and Enhanced Subscriber Management

The system can switch between standard and enhanced subscriber management modes on a per SAP basis. The Enhanced Subscriber Management mode is supported on the SR-7 and SR-12 chassis and on the ESS-7 chassis.

Some functions are common between the standard and enhanced modes. These include DHCP lease management, static subscriber host definitions and anti-spoofing. While the functions of these features may be similar between the two modes, the behavior is considerably different.

- **Standard mode** — The system performs SLA enforcement functions on a per SAP basis, that is, the attachment to a SAP with DHCP lease management capabilities. The node can authenticate a subscriber session with RADIUS based on the MAC address, the circuit-id (from Option 82) or both. It will then maintain the lease state in a persistent manner. It can install anti-spoofing filters and ARP entries based on the DHCP lease state. Static subscriber hosts are not required to have any SLA or subscriber profile associations and are not required to have a subscriber identification string defined.
- **Enhanced mode** — When enabled on a SAP, the system expands the information it stores per subscriber host, allowing SLA enforcement and accounting features on a per subscriber basis. The operator can create a subscriber identification policy that will include a URL to a user-space script that assists with the subscriber host identification process.

- A subscriber host is identified by a subscriber identification string instead of the limited Option 82 values (although, the identification string is normally derived from string manipulation of the Option 82 fields). A subscriber identification policy is used to process the dynamic host DHCP events to manage the lease state information stored per subscriber host. The static subscriber hosts also must have subscriber identification strings associations to allow static and dynamic hosts to be grouped into subscriber contexts.
- Further processing by the subscriber identification policy derives the appropriate subscriber and SLA profiles used to define the hierarchical virtual schedulers for each subscriber and the unique queuing and filtering required for the hosts associated with each subscriber
- The SLA profile information is used to identify which QoS policies and which queues/policers, and also which egress hierarchical virtual schedulers, will be used for each subscriber host (dynamic or static).
- The system performs SLA enforcement functions on a per subscriber SLA profile instance basis. SLA enforcement functions include QoS (classification, filtering and queuing), security (filtering), and accounting.

When the enhanced mode is enabled on a SAP (see [Subscriber SAPs](#)), first, the router ensures that existing configurations on the SAP do not prevent proper enhanced mode operation. If any one of the following requirements is not met, enhanced mode operation is not allowed on the SAP:

- Anti-spoofing filters must be enabled and configured as IP+MAC matching.
- Any existing static subscriber hosts must have:
  - An assigned subscriber identification string.
  - An assigned subscriber profile name.
  - An assigned SLA profile name.
- The system must have sufficient resources to create the required SLA profile instances and schedulers.

When the router successfully enables the enhanced mode, the current dynamic subscriber hosts are not touched until a DHCP message event occurs that allows re-population of the dynamic host information. Thus, over time, the dynamic subscriber host entries are moved from SAP-based queuing and SAP-based filtering to subscriber-based queuing and filtering. In the event that a dynamic host event cannot be processed due to insufficient resources, the DHCP ACK message is discarded and the previous host lease information is retained in the system.

#### 9.4.1.1.1 Subscriber Management Definitions

##### Subscriber

A subscriber is typically defined by a unique subscriber identifier to which an assortment of policies (or subscriber profile) can be applied. A subscriber typically (but not always) maps into a VLAN, a VPI/VCI pair, an "ifentry" (a logical interface such as a SAP), a (source) MAC or IP address or a physical port, which uniquely identify a billable entity for the service provider.

##### Subscriber Management

The management of all services, policies, AAA functions and configurations that relate to the concept of a subscriber. Subscriber management can be configured in a variety of ways, but it is critical that subscriber management integrates seamlessly with element and service management across the broadband infrastructure, via for instance, the 5750 Subscriber Services Controller (SSC). Subscriber management can also be implemented through CLI or scripted commands at the platform level, whereby a network administrator would manually configure the set of QoS, security, AAA or anti-spoofing functions that relate to a particular billable entity or subscriber. Subscriber management is typically centralized and highly integrated with the element, services and middleware management functions for streamlined management, flowthrough provisioning, and accelerated service activation, with minimized operating expenditures.

##### Subscriber Policy Enforcement

Is the set of actual enforcement functions that are implemented relative to a given subscriber, possibly at multiple enforcement points in the infrastructure and as a result of a match between the subscriber profile which was defined by the subscriber management suite (5750 SSC) and actual traffic patterns. Examples include for instance, the shaping, policing or rate limiting of traffic or the traffic of a given subscriber being dropped because it matched or violated any specific rule (packet with a mismatch between MAC and IP address suggesting an address spoof for instance)

##### Subscriber SAPs

A subscriber SAP is a service access point (SAP) where enhanced subscriber management is active. Enhanced subscriber management must be explicitly enabled on a per-SAP basis with the CLI **sub-sla-mgmt** command.

A subscriber SAP can be used by a single subscriber or support multiple subscribers simultaneously. Each subscriber can be represented by one or multiple subscriber hosts on the subscriber SAP. If enhanced subscriber management is enabled on a SAP, any configured QoS and IP filter policies defined on the SAP are ignored. A subscriber SAP must refer to an existing subscriber identification policy.

## Hosts and Subscribers

A host is a device identified by a unique combination of IP address and MAC address. Typically, the term “subscriber host” is used instead of the “host”.

A host can be an end-user device, such as a PC, VoIP phone or a set top box, or it can be the user’s Residential Gateway (RGW) if the RGW is using Network Address Translation (NAT).

Each subscriber host must be either statically provisioned or dynamically learned by the system. The host’s IP address + MAC address are populated in the subscriber host table on the appropriate SAP to allow packets matching the IP address and MAC address access to the provider’s network.

- A dynamic subscriber host is dynamically learned by the system through the DHCP snooping or relay process. Each subscriber SAP created on the system is configured (using the lease-populate command) to monitor DHCP activity between DHCP clients reached through the SAP and DHCP servers. DHCP ACKs from the DHCP server are used to determine that a certain IP address is in use by a specific DHCP client. This client IP address association is treated by the system as a dynamic subscriber host.
- When it is not possible to dynamically learn a subscriber host through DHCP, a static subscriber host can be created directly on a subscriber SAP. Since a subscriber identification policy is not applicable to static subscriber hosts, the subscriber identification string, subscriber profile and SLA profile must be explicitly defined with the hosts IP address and MAC address.

A subscriber (in the context of the router) is a collection of hosts getting common (overall) treatment. It is expected that this group of hosts originate from the same site and all hosts of a subscriber are reached by the same physical path (such as a DSL port).

Once a subscriber host is known by the system, it is associated with a subscriber identifier and an SLA profile instance. Subscriber hosts with a common subscriber identifier are considered to be owned by the same subscriber.

Depending on the network model, hosts associated with a single subscriber can be associated with a single subscriber SAP or spread across multiple subscriber SAPs on the same port.

#### 9.4.1.1.2 Subscriber Identification Policy

The subscriber identification policy contains the URL definitions for the Programmable Subscriber Configuration Policy (PSCP) scripts used for DHCP ACK message processing. Up to three URLs can be defined per subscriber identification policy. These are designated as primary, secondary and tertiary. Each URL can be individually enabled or disabled. Only one script (the URL with the highest priority active script) is used at any one time to process DHCP ACK messages. If the system detects an error with a specified script, the URL is placed in an operationally down state. If the script is shutdown, it is placed in an administratively down state. A script that is operationally or administratively down is considered inactive. The system automatically reverts to the highest priority active script. If a script becomes operationally down, it must be cycled through the administratively down then administratively up states for the system to attempt to reactivate the script.

Multiple subscriber identification policies are provided for the event that access nodes (such as DSLAMs) from different vendors are attached to the same router. Each policy's active script can be explicitly defined to process the various DHCP message formats or idiosyncrasies of each vendor.

If a script is changed, it must be reloaded by disabling and re-enabling any URL which refers to the changed script (a **shutdown** command followed by a **no shutdown** command).

Each subscriber identification policy can also contain a subscriber profile map and/or an SLA profile map. The subscriber profile map creates a mapping between the sub-profile-strings returned from the active script with an existing subscriber profile name. The SLA profile map is used to create a mapping between the sla-profile-strings returned from the active script with an existing SLA profile name.

The subscriber identification policy is designed to accept a DHCP ACK message destined for a subscriber host and return up to three string values to the system;

- The subscriber identification string (mandatory)
- The subscriber profile string (optional)
- The SLA profile string (optional).

These strings are used to derive the subscriber profile and the SLA profile to be used for this host See [Using Scripts for Dynamic Recognition of Subscribers](#).

#### 9.4.1.1.3 Subscriber Identification String

Subscribers are managed by the router through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber.

The subscriber identification string is the index key to any entry in the active subscriber table, and thus must always be available. It is derived as follows:

- For dynamic hosts, the subscriber identification string is derived from the DHCP ACK message sent to the subscriber host.
  - The DHCP ACK message is processed by a subscriber identification script which has the capability to parse the message into an alternative ASCII string value.
  - If enhanced subscriber management is disabled, the default value for the string is the content of the Option 82 circuit-id and remote-id fields interpreted as an octet string.
- For static hosts, the subscriber identification string must be explicitly defined with each static subscriber host.

When multiple hosts are associated with the same subscriber identification string, they are considered to be host members of the same subscriber. Hosts from multiple SAPs can be members of the same subscriber, but for proper virtual scheduling to be performed all hosts of a subscriber must be active on the same IOM.

When the first host (either dynamic or static) is created with a certain subscriber identification string, an entry is created in the active subscriber table. The entries are grouped by their subscriber identification string.

#### **9.4.1.1.4 Subscriber Profile**

The subscriber profile is a template which contains those hierarchical QoS (HQoS) and accounting settings which are applicable to all hosts belonging to the same subscriber. These include:

- Ingress and egress scheduler policy HQoS
- Accounting policy
- RADIUS accounting policy

Subscribers are either explicitly mapped to a subscriber profile template or are dynamically associated with a subscriber profile.

Attempting to delete any subscriber profile (including the profile named 'default') while in use by an existing active subscriber will fail.

#### 9.4.1.1.5 SLA Profile

For the purpose of supporting multiple service types (such as high speed Internet (HSI), voice over IP (VoIP), video on demand (VoD) and Broadcast TV) for a single subscriber, the hosts associated with a subscriber can be subdivided into multiple SLA profiles.

The SLA profile contains those QoS and security settings which are applicable to individual hosts. An SLA profile acts like a template and can be used by many subscribers at one time. Settings in the SLA profile include:

- Egress and ingress QoS settings
- Egress scheduler policy HQoS
- Egress and ingress IP filters
- Host limit

If the SLA profile does not explicitly define an ingress or egress QoS policy, the default SAP ingress or default SAP egress QoS policy is used.

Refer to [Determining the SLA Profile](#) for information on how the SLA profile is determined for dynamic hosts.

#### 9.4.1.1.6 Explicit Subscriber Profile Mapping

An explicit mapping of a subscriber identification string to a specific subscriber profile can be configured.

An explicit mapping overrides all default subscriber profile definitions while processing a DHCP ACK. In an environment where dynamic and static hosts coexist in the context of a single subscriber, care will be taken to not define a subscriber profile in the explicit subscriber map that conflicts with the subscriber profile provisioned for the static host(s). If such a conflict occurs, the DHCP ACKs will be dropped.

An explicit mapping of a subscriber identification string to the subscriber profile name 'default' is not allowed. However, it is possible for the subscriber identification string to be entered in the mapping table without a defined subscriber profile which can result in the explicitly defined subscriber to be associated with the subscriber profile named 'default'.

Attempting to delete a subscriber profile that is currently defined in an explicit subscriber identification string mapping will fail.

The explicit mapping entries can be removed at any time.

## 9.4.2 ESM for IPv6

ESM for IPv6 is supported on 7750 SR chassis with at least IOM3-XP cards or equivalent or in 7450 ESS chassis operating in mixed mode (containing one or more IOM3-XP cards that have the 7750 SR feature set enabled). ESM for IPv6 is supported with RADIUS as the backend authentication and authorization mechanism.

### 9.4.2.1 Models

- [PPPoE Host](#)
- [PPPoE RG](#)
- [IPoE Host/RG](#)

#### 9.4.2.1.1 PPPoE Host

For PPPoE, the ESR suggests the IPv6CP protocol to the client during the session setup phase if the appropriate attributes have been returned by the RADIUS server on authentication. The RADIUS attribute that indicates the setup of a PPPoE host is Framed-IPv6-Prefix, which should contain a /64 prefix for the client.

When a PPPoE host has successfully completed the IPv6CP negotiation, the ESR will transmit a Router Advertisement to the PPPoE host containing the suggested prefix and any other options that are configured. The client may use this information to pick one or more addresses from the suggested prefix; all addresses within the prefix are forwarded towards the client.

Alternatively, the Recursive DNS Server (RDNSS) Option as defined in RFC 6106, *IPv6 Router Advertisement Options for DNS Configuration*, can be included in IPv6 Router Advertisements for DNS name resolution of IPv6 SLAAC hosts. The following CLI command includes the DNS info in IPv6 Router Advertisements for SLAAC hosts and sets the RDNSS lifetime:

```
config>service>ies>sub-if>grp-if>ipv6>rtr-adv
config>service>vprn>sub-if>grp-if>ipv6>rtr-adv

[no] dns-options

[no] include-dns - Set/reset inclusion of the RDNSS server
 option 25 on this group-interface
[no] rdNSS-lifetime - Maximum time the RDNSS address is valid
 in this group-interface
```

The source for DNS information to be included in Router Advertisements for IPv6 SLAAC hosts, can be (listed in priority order):

1. Local User Database IPv6 options:

```
configure subscriber-mgmt local-user-db <ludb-name> dhcp|ppp host <host-name> options6 dns-server <ip-address> [<ip-address>...(up to 4 max)]
```

2. RADIUS attributes [26-6527-105] Alc-Ipv6-Primary-Dns and [26-6527-106] Alc-Ipv6-Secondary-Dns

3. Default IPv6 DNS Server configured at the group interface:

```
configure service ies|vprn <svc-id> subscriber-interface <sub-int-name> ipv6 default-dns <ipv6-address> [secondary <secondary-ipv6-address>]
```

**Note:** A default IPv6 server configuration at the group interface is a last resort IPv6 DNS info that can be used for IPEv6 hosts (IA\_NA, IA\_PD and SLAAC) and PPPoEv6 hosts (IA\_NA, IA\_PD and SLAAC).

#### 9.4.2.1.2 PPPoE RG

Initially, a PPPoE RG follows the same procedure as a PPPoE host: the ESR receives a prefix from RADIUS (in this case through a Delegated-IPv6-Prefix attribute), which is used as a trigger to suggest the IPv6CP protocol to the client. The prefix that is suggested to the client should have the same prefix length as configured under the subscriber interface ipv6 node (delegated-prefix-length). This length should be between 48 and 64 bits, inclusive.

After the IPv6CP protocol has completed, however, the client should run the DHCPv6 protocol over its PPPoE tunnel to receive a Delegated Prefix (IA\_PD) and optionally IPv6 DNS server information. This Delegated Prefix can then be subdivided by the client and distributed over its downstream interfaces. During DHCPv6, no extra RADIUS request will be made; the information is stored during the initial (PPPoE or PPP) authentication until the client starts DHCPv6.

Only after DHCPv6 has completed, the IPv6 subscriber host will be instantiated and the ESR will start sending Router Advertisements (if configured.) The router advertisements will not contain any prefix information, which has already been provided by DHCPv6, but it is used as an indication to the client that its default gateway should be the ESR.

### 9.4.2.1.3 IPoE Host/RG

Similar to an IPv4 DHCP client, a DHCPv6 client is authenticated at its Solicit message, where it can request one or more addresses or prefixes. The address and prefix types supported are IA\_NA (Non-Temporary Address) through the Alc-IPv6-Address RADIUS attribute and IA\_PD (Delegated Prefix) through the Delegated-IPv6-Prefix attribute. Contrary to the IPv4 case, the ESR will always reply to a DHCPv6 request because the client may request more than one address or prefix simultaneously and not all of the requests may be honored.

The DHCPv6 protocol handling and Router Advertisement behavior are similar to the PPPoE RG case above, with the exception that for an IA\_NA address, the entire /64 prefix containing the address is allocated to the client.

For SLAAC prefix assignment, authentication is triggered on router-solicit message. The SLAAC prefix can be assigned statically or dynamically. For a static SLAAC prefix, frame-ipv6-prefix, RADIUS attribute is used. For dynamic SLAAC prefix assignment from a local pool, Alc-slaac-ipv6-pool, RADIUS attribute is used.

### 9.4.2.2 Setup

IPv6 ESM hosts are only supported in the Routed CO model (both VPRN and IES).

At the ipv6 node under the subscriber interface level, the length of the prefixes that are offered is defined through the delegated-prefix-length option. This setting is fixed for the subscriber interface and can not be changed once subscriber prefixes are defined.

Subscriber prefixes define the ranges of addresses that are offered on this subscriber interface. By default only these subscriber prefixes are exported to the routing protocols to keep the routing tables small. There are three types of subscriber interfaces:

- wan-host — A range of prefixes that are assigned to PPPoE hosts and as DHCPv6 IA\_NA addresses. These prefixes are always /64.
- pd — A range of prefixes that are assigned as DHCPv6 IA\_PD prefixes for DHCPv6 IPoE clients and for PPPoE RGs. The length of these prefixes is defined by the delegated-prefix-length.
- both — When both 'wan-host' and 'pd' are defined, the subscriber prefix is a range that can be used for both previous types. However, the delegated-prefix-length is restricted to /64 in this case.

The IPv6 node under the group interface contains the DHCPv6 proxy configuration and the router advertisement configuration.

### 9.4.2.3 Behavior

- [Dual Stack](#)
- [Router Advertisements \(RA\)](#)
- [CoA and Disconnect-Request](#)

#### 9.4.2.3.1 Dual Stack

Clients may support both IPv4 and IPv6 simultaneously (dual stack hosts.) In this case one subscriber host entry will be created for the IPv4 address family and one for the IPv6 instance. The scaling limits apply for all entries, regardless of address type.

For DHCP, these subscriber hosts are fully independent (as they are set up through different protocols), but for PPPoE hosts or RGs, the ESM information in both subscriber host entries is linked together through the PPPoE session.

#### 9.4.2.3.2 Router Advertisements (RA)

RA messages are started immediately after the subscriber host is instantiated and unsolicited messages are sent in the interval defined in the configuration. Apart from unsolicited RAs, the client may also send a router solicitation (RS) to explicitly request the information. RAs are throttled so that they are not sent more often than once every three seconds.

#### 9.4.2.3.3 CoA and Disconnect-Request

For IPv6 subscriber hosts, RADIUS-triggered mid-session changes and session terminations may identify the subscriber host to be changed by the same address or prefix that was originally returned from RADIUS. Only one address attribute (framed-IP-address, framed-IPv6-prefix, delegated-IPv6-prefix or Alc-IPv6-address) may be given in a single request.

For PPPoE clients, changing either the IPv4 or IPv6 information will result in both the v4 and v6 subscriber host being modified (if they are contained within the same PPPoE session.)

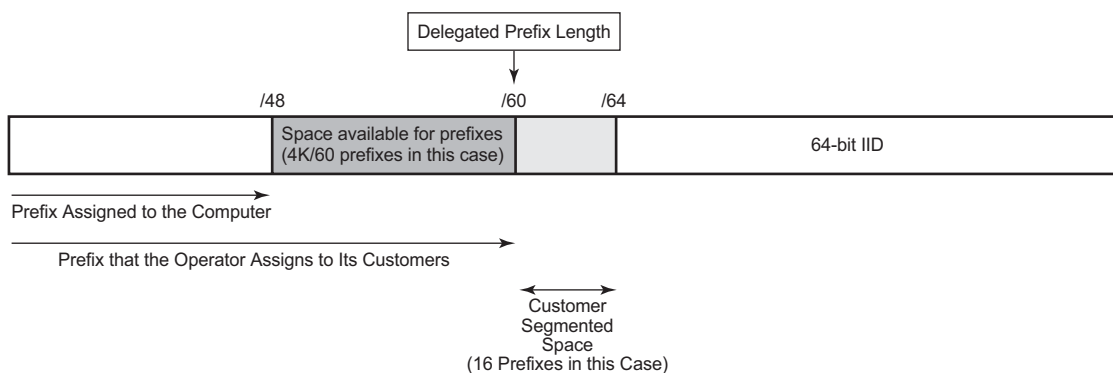

The only CoA action that is allowed for IPv6 hosts is a change of ESM strings; creation of new hosts and forcing a DHCPv6 RENEW is not supported.

### 9.4.2.4 Delegated-Prefix-Length

The delegated prefix length (DPL) is applicable to subscriber-hosts with IPv6 Prefix (IA-PD) assigned via DHCPv6 Server. IPv6 Prefix is more akin to a route than it is to an IP address. The length of the prefix plays crucial role in forwarding decisions, antispoofing, and prefix assignment via DHCPv6 pools in the local DHCPv6 Server.

The structure of an IPv6 prefix is shown in [Figure 68](#).

**Figure 68** IPv6 Prefix

al\_0124

For example, a DHCPv6 server prefix pool contains an aggregated (configured) IPv6 prefix from which the delegated prefixes will be carved out. In [Figure 68](#) this aggregated IPv6 prefix has length of /48. In addition, the DHCPv6 server needs to know the length of the delegated prefix (in the above case /60). These two values are marking the boundary within which a unique delegated prefix will be selected. This is represented by the purple area in [Figure 68](#).

The delegated prefix length can be obtained via:

- RADIUS

- Delegated-IPv6-Prefix attribute that contains the prefix and the length (Delegated-IPv6-Prefix = AAAA:BBBB::/56). The DPL in this case is /56.
- Alc-Delegated-IPv6-Prefix-Length VSA (to be used in conjunction with the DHCPv6 pool name - Alc-Delegated-IPv6-Pool VSA)

- LUDB – configured via LUDB per IPEv6/PPPoEv6 host:

This is to be used along with the DHCPv6 pool name (ipv6-delegated-prefix-pool) defined under the same CLI hierarchy.

```
configure
subscriber-mgmt
 local-user-db <name>
```

```
dhcp | ppp
 host <name>
 ipv6-delegated-prefix-length
 [48 to 64]
```

Alternatively, the entire prefix, including the DPL can be returned via LUDB.

```
configure
 subscriber-mgmt
 local-user-db <name>
 dhcp | ppp
 host <name>
 ipv6-delegated-prefix
 <ipv6-prefix/prefix-
 length>
```

- DHCPv6 server – each DHCPv6 pool can optionally be configured with a DPL:

```
configure
 service/router
 dhcp6
 local-dhcp-server <name>
 pool <pool-name>
 delegated-prefix-length [48 to
 127]
```

- Configured statically under the **ipv6** CLI node of **subscriber-interface**. In this case, the DPL is fixed for all subscriber hosts under the subscriber interface.

```
configure
 service ies/vprn
 subscriber-interface <name>
 ipv6
 delegated-prefix-length [48 to
 64] | variable
```

#### 9.4.2.4.1 Order of Preference for DPL

In case that the DPL is statically provisioned under the subscriber-interface>ipv6> hierarchy, all hosts under this subscriber-interface will inherit this fixed DPL. In case that the DPL is provided via LUDB or RADIUS in addition to static configuration under the subscriber-interface then the LUDB or the RADIUS one MUST match the DPL that is statically provisioned under the subscriber-interface. Otherwise, the prefix instantiation in 7450 ESS and 7750 SR will fail.

Note that the “no delegated-prefix-length” command under the **subscriber-interface>ipv6>** hierarchy means that the DPL is set to a default-value of 64.

When the delegated-prefix-length commands under the **subscriber-interface>ipv6>** hierarchy is set to variable, prefixes under such subscriber-interface can have different lengths and the DPL can be configured via one of the following means:

- LUDB
- RADIUS
- DHCP Server

#### 9.4.2.4.2 DHCP Server Address Utilization and Delegated Prefix Length

In case that the delegated prefix length is variable, for each consecutive address allocation request for the given delegated prefix, the DHCPv6 server will allocate the prefix at the end of the last delegated lease with the same delegated prefix length. This will minimize the address space fragmentation within the configured prefix.

#### 9.4.2.5 DHCPv6 Relay Agent

A DHCPv6 Relay Agent can support a 7450 ESS and 7750 SR DHCPv6 local server (same or remote chassis) and a third party DHCPv6 external server.

An incoming DHCPv6 client message is relayed within the Relay-Forward message specified in RFC 3315. If the server responds with a valid address/prefix, the ESM process attempts to install it. If it fails, the DHCPv6 Relay Agent sends an explicit RELEASE to the server. There is no retransmission of DHCPv6 Relay-Forwards in the case of failure – it requires the client to re-start or re-send the original DHCPv6 message.

A Lightweight DHCPv6 Relay Agent may insert Relay Agent Information including the Interface ID option between the DHCPv6 client and the DHCPv6 Relay Agent.

Additional Relay Agents (non-LDRA) between the DHCPv6 client and the DHCPv6 Relay Agent are not supported.

##### 9.4.2.5.1 Configuring a DHCPv6 Relay Agent

A DHCPv6 Relay Agent is configured in the IPv6 DHCP6 context of a group-interface:

```
config>service>vprn>sub-if>grp-if>ipv6>dhcp6# relay ?
config>service>ies>sub-if>grp-if>ipv6>dhcp6# relay ?
```

```

- no relay
- relay

[no] client-applications - Configure the set of DHCPv6 relay server client
 applications
[no] description - Description for DHCPv6 relay
[no] link-address - Configure the link address of the DHCPv6 relay messages
[no] option + Configure the DHCPv6 Relay information options
[no] server - Configure the DHCPv6 server IPv6 address
[no] shutdown - Administratively enable/disable DHCPv6 relay on this interface
[no] source-address - Configure the source IPv6 address of the DHCPv6 relay messages

```

Up to eight DHCPv6 servers can be provisioned to be served by a DHCPv6 Relay Agent. A Relay-Forward is sent to all servers and the Relay-Replies from all servers are sent to the client.

The “client-applications” parameter specifies if the Relay Agent can be used for IPoE (dhcp) or PPP (ppp) hosts.

Optional configuration parameters:

- description — A free configurable description string.
- link-address — The link address field in the DHCPv6 Relay-Forward message header.

The link address can be configured to enable link-address based pool selection in a 7450 ESS and 7750 SR DHCPv6 local server. The address must be one of the IPv6 prefixes configured at the ipv6 subscriber-prefixes context for a subscriber interface. If not configured, the system selects one of the prefixes.

- option: allows to configure following options to be inserted in the Relay-Forward message:
  - Interface-Id [18] — The interface ID option identifies the interface on which the DHCPv6 client message is received. The format options are the following:
    - ascii-tuple: — *host-name|service-id|group-interface-name|sap-id*
    - ifindex — Interface index for the group-interface
    - sap-id — SAP identifier (port and vlans)
    - string <string>: — A free configurable string (max. 80 chars)
  - Remote-Id [37] — Relay Agent Remote Id option contains the DHCPv6 client DHCP Unique Identifier (DUID).
- source-address: the source-address of the Relay-Forward messages.

If not configured, the outgoing interface IPv6 address is used. The source-address configuration is mandatory for a DHCP Relay Agent in a VPRN service when the DHCPv6 server is reachable via a tunnelled next-hop (MPLS).

### 9.4.2.6 DHCPv6 Relay to Third Party DHCPv6 External Server

When the DHCPv6 Relay Agent is relaying to a third party DHCPv6 external server, following conditions should be met:

- The third party DHCPv6 server must return a unique IA\_PD IPv6 delegated prefix (/64 or lower) for each allocation. The length of the IA\_PD IPv6 delegated prefix must match the delegated-prefix-len configured on the subscriber interface on the 7750 DHCP L3 relay. This length is also included in the Relay-Forward message as PFX\_LEN option (3) in a Vendor-Specific-Information-Option (17).
- For IPv6oE routed CPE's, the 3rd party DHCPv6 server must return a unique IA\_NA IPv6 address (/128) from a different /64 subnet for each allocation.
- For IPv6oE hosts behind bridged CPE's,
  - the third party DHCPv6 server must return a unique IA\_NA IPv6 address (/128) from a different /64 subnet for each allocation (host) that belongs to a different CPE.
  - the third party DHCPv6 server may return a unique IA\_NA IPv6 address (/128) from the same /64 subnet for allocations (hosts) that belong to the same CPE and that are attached to the same vlan (SAP) on the BNG.

Following information is available to the third party DHCPv6 server in a Vendor-Specific-Information-Option (17) included in the Relay-Forward message:

- WAN\_POOL option (1) contains the pool name from which the IA\_NA IPv6 address should be allocated.
- PFX\_POOL option (2) contains the pool name from which the IA\_PD IPv6 delegated prefix should be allocated.
- PFX\_LEN option (3): contains the IA\_PD IPv6 delegated prefix length that should be allocated.

### 9.4.2.7 DHCPv6 Local Server

A local DHCPv6 pool server for both addresses (IA\_NA) and prefixed (IA\_PD) manages the address and prefixes sent to either routing gateways or hosts.

Because IPv6 home networks lack NAT, the IPv6 addresses delegated to a routing gateway are in turn assigned to hosts in the home. These addresses are assigned with reasonably long (but configurable) lifetimes such that the loss of the WAN connection will not result in the IPv6 hosts in the LAN losing their IPv6 addresses. One consequence of these long lifetimes is that the IPv6 hosts will retain any IPv6 address provided the valid-lifetime is greater than zero. Should an operator delegate a prefix and then at a later time delegate a second IPv6 prefix, a host may end up with two or more valid prefixes. This situation plays havoc with IPv6 source address selection and may result in impaired service.

To overcome the problems of multiple IPv6 prefixes in the home, the operator must ensure that the individual subscriber has the same IPv6 prefix even across modem reboots (that is, if a subscriber session is destroyed and later re-created, an attempt should be made to use the previously delegated prefix). In release 8.0, the operator used RADIUS for all address and prefix assignment, but in release 9.0, with the introduction of the local DHCPv6 server, it requires the 7750 to process and maintain some state even after a session disconnects.

For the DHCPv6 local server to function, a DHCPv6 relay or proxy function must also operate alongside ESM. For the purposes of this document, to relay means to implement a DHCPv6 Relay as indicated in RFC 3315 : a relay encapsulates the client DHCP message within a DHCP Relay-Forward message and unicasts it to a specified destination.

A proxy is an internal concept. Unlike a DHCPv6 relay, the DHCPv6 proxy does NOT encapsulate the client message in a Relay-Forward, nor does it send packets towards the Local DHCPv6 Server. The DHCPv6 proxy is exclusively used as an interface between the RADIUS Access-Accept or local user database lookup and the DHCPv6 client in the consumer device.

The use of the DHCPv6 relay or proxy function depends on the attributes returned from authentication phase (RADIUS or LUDB).

1. DHCPv6 Proxy:

- If only IPv6 address/prefix information provided (Framed-IPv6-Prefix, Alc-IPv6-Address or Delegated-IPv6-Prefix).

2. DHCPv6 Relay:

- If no IPv6 address/prefix (Framed-IPv6-Prefix, Alc-IPv6-Address or Delegated-IPv6-Prefix) and no IPv6 pool (Framed-Pool, Delegated-Pool) information provided.
- If no IPv6 address/prefix (Framed-IPv6-Prefix, Alc-IPv6-Address or Delegated-IPv6-Prefix) and IPv6 pool (Framed-Pool, Delegated-Pool) information provided.

3. If both IPv6 address/prefix (Framed-IPv6-Prefix, Alc-IPv6-Address or Delegated-IPv6-Prefix) and IPv6 pool (Framed-Pool, Delegated-Pool) information are present, the DHCP packet is DROPPED.

**Note:** If IPv6 DNS parameters are returned in RADIUS AND a pool is specified then the DNS parameters are ignored. It is the DHCPv6 server that will need to reply with appropriate DNS servers.

## 9.4.3 Dynamic Subscriber Host Processing

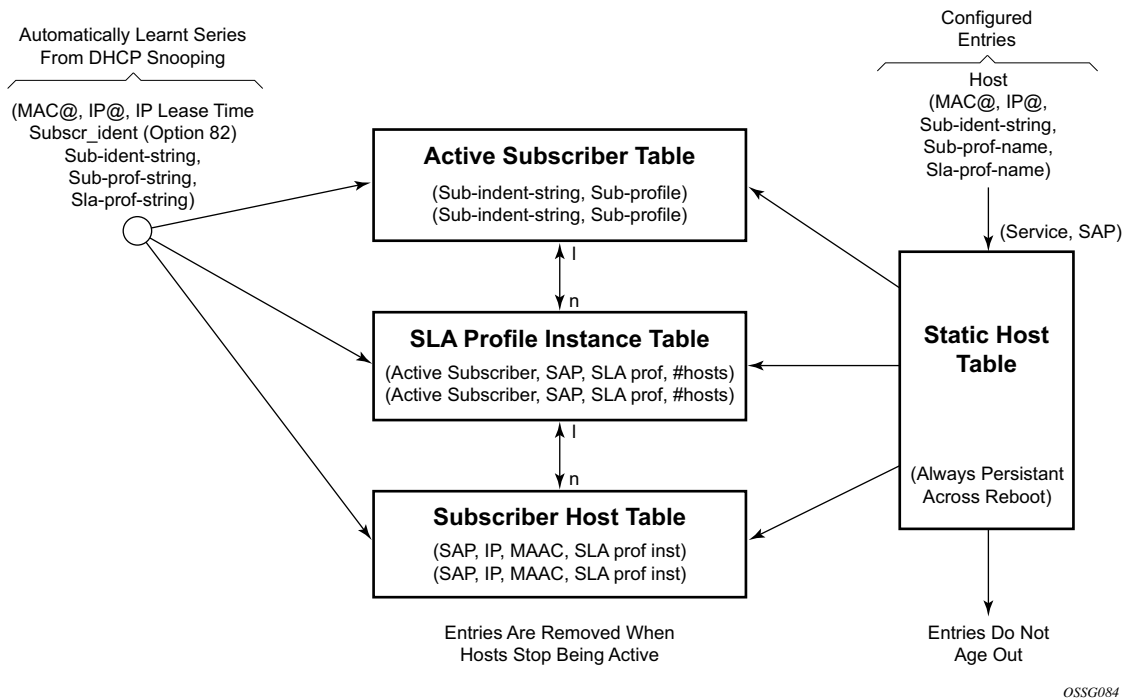

### 9.4.3.1 Dynamic Tables

To support all processing for Enhanced Subscriber Management, several tables are maintained in the router ([Figure 69](#)).

- [Active Subscriber Table](#)
- [SLA Profile Instance Table](#)
- [Subscriber Host Table](#)
- [DHCP Lease State Table](#)

**Figure 69 Enhanced Subscriber Management Dynamic Tables**

#### 9.4.3.1.1 Active Subscriber Table

An entry is created in the active subscriber table when the first host (either dynamic or static) is created with a certain subscriber identification string. The entries are grouped by their subscriber identification string.

Fields for each entry in the active subscriber table include:

- The subscriber identification string (see [Subscriber Identification String](#)).
- In use subscriber profiles (see [Subscriber Profile](#)).

#### 9.4.3.1.2 SLA Profile Instance Table

An entry is created in the SLA profile instance table when the first subscriber host on a certain SAP is created that uses a certain SLA profile. All subsequent hosts of the same subscriber on the same SAP that use the same SLA profile will be associated with this entry. When the last host on this SAP, using this SLA profile disappears, the SLA profile instance is deleted from the table and the associated queues are removed.

SLA profile instances can not span multiple subscriber SAPs. If subscriber hosts from the same subscriber exist on multiple SAPs and are associated with the same SLA profile template, a separate SLA profile instance is created for each SAP.

Fields for each entry in the SLA profile instance table include:

- Active subscriber
- SAP
- SLA profile
- Number of active subscriber hosts that share this instance

#### **9.4.3.1.3 Subscriber Host Table**

An entry is created in the subscriber host table if anti-spoofing is enabled as well as:

- The first host (dynamic or static) with a specific IP and MAC combination is created. If the anti-spoof is IP only, the MAC address is masked to all 0's. If anti-spoof is MAC, only the IP address is 0.0.0.0. All dynamic hosts and static hosts with the same IP and MAC combination will be associated with the same subscriber host entry. If the anti-spoof type includes IP (IP-only or IP/MAC), there can be at most two hosts associated with the entry: one dynamic and one static. If the anti-spoof type is MAC-only, there can be a combination of several dynamic and static hosts associated with the entry.
- The non-prof-traffic is provisioned. Both IP and MAC address are all 0's.

Fields for each entry in the subscriber host table include:

- SAP
- IP address
- MAC address
- SLA profile instance (enhanced mode only)

#### **9.4.3.1.4 DHCP Lease State Table**

An entry in the DHCP lease state table is created for each dynamic host. Fields for each entry in the lease state table include:

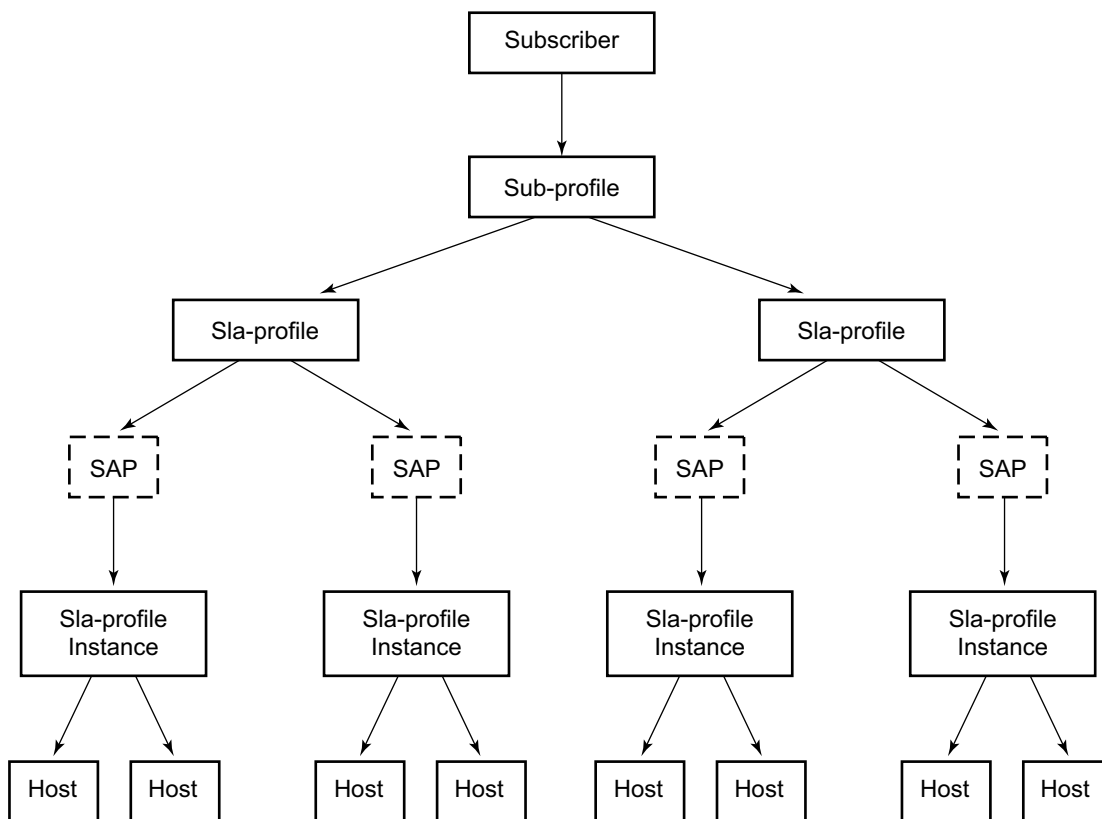

- Assigned IP address
- Assigned MAC address
- Persistence key

## 9.4.4 Enhanced Subscriber Management Entities

Figure 70 illustrates the relationship between the main entities in Enhanced Subscriber Management:

- A subscriber is associated with only one subscriber profile.
- A subscriber can be associated with one or more SLA profile (a VPLS service with 2 different SAPs can have different SLA profiles for the same subscriber).
- A maximum of one SLA profile instance is generated (including ingress and egress queues) per SAP per SLA profile.
- One or more hosts can be assigned to each SLA profile instance (these will share the same queues).

**Figure 70 Relationship Between Enhanced Subscriber Management Entities**

OSSG085

### 9.4.4.1 Instantiating a New Host

When a DHCP ACK is received for a new subscriber host on a particular SAP:

- The ACK message is parsed using the appropriate script.
- An entry is generated in the subscriber host table with indices:
  - The SAP on which the host resides
  - The assigned IP address
  - The assigned MAC address and as lookup parameters:
    - The subscriber profile and
    - The SLA profile to be used (derived from using the script).

If this is the first host of a subscriber, an HQoS scheduler is instantiated using the ingress and egress scheduler policies referred to in the subscriber profile. Otherwise, if the subscriber profile of the new host equals the subscriber profile of the existing subscriber, the new host is linked to the existing scheduler. If the subscriber profile is different from the subscriber profile of the existing subscriber, a new scheduler is created and all the hosts belonging to that subscriber are linked to this new scheduler. Notice that the new subscriber profile will not conflict with the subscriber profile provisioned for a static host or non-sub-traffic under the same SAP.

If this is the first host of a subscriber on a particular SAP using a particular SLA profile, an SLA profile instance is generated and added to the SLA profile instance table. This includes instantiating a number of queues, according to the ingress and egress QoS profiles referred to in SLA profile, optionally with some specific overrides defined in the SLA profile. Otherwise the host is linked to the existing SLA profile instance for this subscriber on this SAP.

**Note:** Any QoS and IP filter policies defined on the SAP are still processed even if Enhanced Subscriber Management is enabled on the SAP. For IPv4 traffic that is dropped due to anti-spoofing, counters, logging, and mirroring can be used. All other Layer 2 traffic that is never blocked by anti-spoofing can be processed by applying a QoS policy on the SAP and can still be classified differently, by the dot1p value.

**Note:** If insufficient hardware resources (queues) or software resources (profile instances) are available to support the new host, the DHCP ACK is dropped and an event is generated.

#### 9.4.4.2 Packet Processing for an Existing Host

Whenever an IP packet arrives on a subscriber-facing SAP on which Enhanced Subscriber Management is enabled, a lookup is done in the subscriber host table using as the index the SAP, source IP address, and source MAC address.

- If there is no entry, this means that the host is not using his assigned IP address, so the packet is dropped;
- If there is an entry, this will refer to the subscriber profile and SLA profile to be used.

#### 9.4.5 ESM Host Lockout

This feature increasingly penalizes hosts that fail repeated login attempts within a configurable time interval. This is done by holding off on creation attempts for these hosts for a configured but adaptable time period. A transient failure, due to a mis-configuration, is quickly corrected and does not prevent the host from logging in within a reasonable amount of time. At the same time, a malicious client or a constantly mis-configured client is locked-out and will not take up resources impacting other clients.

A lockout time per host supports exponential back-off with each retry and failure cycle, starting with a configured minimum value and increasing up to a configured maximum. The lockout time can be reset to the configured minimum value if there is no failed retry within a configured time threshold. The configurable values include:

```
lockout-reset-time seconds
lockout-time [min seconds] [max seconds]
max-lockout-hosts hosts
```

If multiple retries/failure cycles occur within the lockout time, then lockout period is exponentially increased starting from configured minimum value up to the configured maximum value. The lockout is reset to the minimum value if there is no failed retry till this lockout time.

This mechanism is supported for both single and dual-stack PPPoE and IPoE (DHCP) hosts over 1:1 or N:1 static or managed SAPs. The hold-off timer maintenance is on a per host basis (as follows):

- For 1:1 VLAN (PPPoE or IPoE hosts) per <VLAN, MAC address>
- For N:1 VLAN (PPPoE or IPv4oE hosts) per <VLAN, agent-circuit-id, agent-remote-id, MAC@>
- For 1:1 VLAN (IPv6oE hosts) per <VLAN, DUID>

A show lockout state for hosts is supported, given one or more of <SAP, MAC@, agent-circuit-id, agent-remote-id>.

A clear lockout state is supported for hosts given one or more of <SAP, MAC@, agent-circuit-id, agent-remote-id>.

Any changes in configured lockout values will not apply to hosts currently under lockout and will only apply once these hosts are out of lockout.

### 9.4.5.1 Functionality

ESM lockout is supported for dual-stack PPPoE hosts, L2TP LAC hosts, dual-stack IPoE hosts, and ARP hosts. ESM Lockout tracks the following:

- PPPoE PADI and PADR
- DHCPv4 discover, DHCPv4 request, DHCPv6 solicit, DHCPv6 request
- ARP Request
- PPPoE session disconnect after successful session establishment

During lockout, authentication and ESM host creation is suppressed. A lockout context will be created when a client first enters lockout. The context maintains state and timeout parameters for the lockout. If a lockout policy is configured for the underlying SAP for a host that has failed authentication or host creation, the host enters lockout for the configured minimum time (1 to 86400 seconds). When the lockout time expires, normal authentication and ESM host creation will be resumed on relevant PPP or DHCP messages. In case of another failure, the host will again enter the lockout state. The lockout time for the host on each failure will be exponentially increased up to the configured maximum time (1 to 86400 seconds). The lockout time for a client will be reset to the configured minimum value, and the corresponding lockout context will be deleted, if there is no authentication (and host creation) failure within a configured amount of time that needs to elapse after the client initially enters lockout. This time is called the **lockout-reset-time**.

The host identification for lockout includes <SAP, MAC@, circuit ID, remote ID>.

### 9.4.6 ANCP and GSMP

- [ANCP](#)
- [General Switch Management Protocol Version 3 \(GSMPv3\)](#)

### 9.4.6.1 ANCP

Access Node Control Protocol Management (ANCP) can provide the following information to the router:

- ANCP can communicate the current access line rate to the router. This allows the router to adjust the H-QoS subscriber scheduler with the correct rate or potentially change alarm when the rate goes below a set threshold. This allows a policy manager to change the entire policy when the rate drops below a minimal threshold value. The ANCP actual upstream synchronization rate is mapped to the ingress while ANCP actual downstream synchronization rate is mapped to the egress.
- The router can send DSL line OAM commands to complete an OAM test from a centralized point or when operational boundaries prevent direct access to the DSLAM.

When ANCP is used with Enhanced Subscriber Management (ESM), a new string ancp-string can be returned from the Python script or from RADIUS. If not returned it defaults to the subscriber ID.

ANCP version 0x31 and 0x32 are both supported and will be auto detected at the start of each ANCP session. Within version 0x32, partitioning is also supported.

Multiple partitions from the same Access Node are also supported. If partitions are used, they are automatically detected during the start of an ANCP session.

#### 9.4.6.1.1 Static ANCP Management

As depicted in [Figure 71](#), a DSLAM is connected to an aggregation network that is connecting the DSLAM to a BRAS. ANCP is used to provide SAP level rate management. The DSLAM in this application maintains multiple ANCP connections. The primary connection is to the BRAS, providing rate and OAM capabilities while the secondary is to the router to provide rate management.

7750 SR and 7450 ESS:

Figure 71 Static ANCP Management Example

9.4.6.1.2 Enhanced Subscriber Management (ESM) Dynamic ANCP

In this application ANCP is used between the DSLAM and the router to provide line control. There are multiple attributes defined as described below. [Figure 72](#) depicts the connectivity model.

This application is used to communicate the following from the DSLAM to the router (the policy control point):

- Subscriber rate
- OAM

Figure 72 ESM Dynamic ANCP Example

#### 9.4.6.1.3 ANCP String

To support node communication with the access device the line rate, OAM commands, etc. the node can use an “ANCP string” that serves as a key in the out-of-band channel with the access node. The string can be either provisioned in the static case, retrieved from RADIUS or from the Python script.

#### 9.4.6.1.4 ANCP Persistency Support

Persistency is available for subscriber’s ANCP attributes and is stored on the on-board compact flash card. ANCP data will stay persistence during an ISSU as well as nodal reboots. During recovery, ANCP attributes are first restored fully from the persistence file and incoming ANCP sessions are temporarily on hold. Afterwards new ANCP data can overwrite any existing values. This new data is then stored into the compact flash in preparation for the next event.

### 9.4.6.2 General Switch Management Protocol Version 3 (GSMPv3)

General Switch Management Protocol version 3 (GSMPv3) is a generic protocol that allows a switch controller node to establish and maintain connections with one or more nodes to exchange operational information. Several extensions to GSMPv3 exist in the context of broadband aggregation. These extensions were proposed to allow GSMPv3 to be used in a broadband environment as additional information is needed to synchronize the control plane between access nodes (such as DSLAMs) and broadband network gateways (such as BRAS).

In the TPSDA framework, nodes fulfill some BRAS functionality, where per subscriber QoS enforcement is one of the most important aspects. To provide accurate per-subscriber QoS enforcement, the network element not only knows about the subscriber profile and its service level agreement but it is aware of the dynamic characteristics of the subscriber access circuit.

The most important parameters in this context are the subscriber-line capacity (DSL sync-rate) and the subscriber's channel viewership status (the actual number of BTV channels received by the given subscriber in any point in time). This information can be then used to adjust parameters of aggregate scheduling policy.

Besides, the above-mentioned information, GSMPv3 can convey OAM information between a switch controller and access switch. The node can operate in two roles:

- As the intermediate controller — The router terminates a connection from the DSLAM.

- As the terminating controller— The router fulfils full the roll of BRAS.

The DSL forum working documents recommends that a dedicated Layer 2 path (such as, a VLAN in an Ethernet aggregation network) is used for this communication to provide a certain level of security. The actual connection between DSLAM and BRAS is established at TCP level, and then individual messages are transported.

### 9.4.6.3 DHCP Release Messages

The node supports DHCP release messages. A DHCP release message removes state from the DHCP server when the node rejects ACKs or removes hosts.

#### 9.4.6.3.1 DHCP Release

DHCP release messages will be controlled by the node and sent to the DHCP server to clear stale state. There are two examples:

1. If the node drops a DHCP ACK (because of resources, duplicate host or other reasons) the servers state must be cleared and the node will send a DHCP release.
2. When a host state is removed, based on SHCV, ANCP, user clear, etc., the node will send a DHCP release to the server and the MAC will be flushed from SDPs. A new flag will allow the user to elect not to send the release message If when using a clear lease command the host was removed by the user (using a clear command) a new flag will allow the user to elect not to send the release message.

### 9.4.6.4 DHCP Client Mobility

Client mobility allows the node to use host monitoring (SHCV, ANCP, split DHCP) to remove network and server state when a host is removed locally. This allows for MAC addressed learned and pinned to move based on policy parameters.

Subscriber Host Connectivity Verification (SHCV) configuration is mandatory. This allows clients to move from one SAP to another SAP in the same service. This is only applicable in a VPLS service and group interfaces.

The first DHCP message on the new SAP with same MAC address (and IP address for group-interfaces) will trigger SHCV and will always be discarded.

SHCV will check that the host is no longer present on the SAP where the lease is currently populated to prevent spoofing. When SHCV detects that the host is not present on the original SAP, the lease-state will be removed. The next DHCP message on the new SAP can initiate the host.

#### **9.4.6.5 DHCP Lease Control**

DHCP lease control allows the node to be configured to present a different lease to the client. This can be used to monitor the health of the client.

### **9.4.7 Using Scripts for Dynamic Recognition of Subscribers**

Whenever a host belonging to a subscriber is activated (when a PC or set-top box (STB) is turned on), the host will typically request an IP address from the network using DHCP. Refer to [DHCP Management](#) for an explanation of DHCP and DHCP snooping in the router.

The DHCP ACK response from the DHCP server can be parsed and the contents of the message can be used to identify the “class” to which this host belongs, and thus, the QoS and security settings to apply.

The information necessary to select these settings can be codified in, the IP address by the DHCP server and/or the Option 82 string inserted by the DSLAM or other access node.

#### **9.4.7.1 Python Language and Programmable Subscriber Configuration Policy (PSCP)**

PSCP is an identification mechanism using the Python scripting language. The PSCP references a Python script that can use regular expressions to derive the sub-ident-string, sub-profile-string and sla-profile-string from the DHCP response. A tutorial of regular expressions is beyond the scope of this guide, and can be found on the Internet (refer to <http://www.amk.ca/python/howto/regex/>).

A tutorial of Python is beyond the scope of this guide but can be found on the Internet (refer to <http://www.python.org/>).

Example scripts, using some regular expressions, can be found in [Sample Python Scripts](#). Additional information about the service manager scripting language, see [Python Script Support for ESM](#).

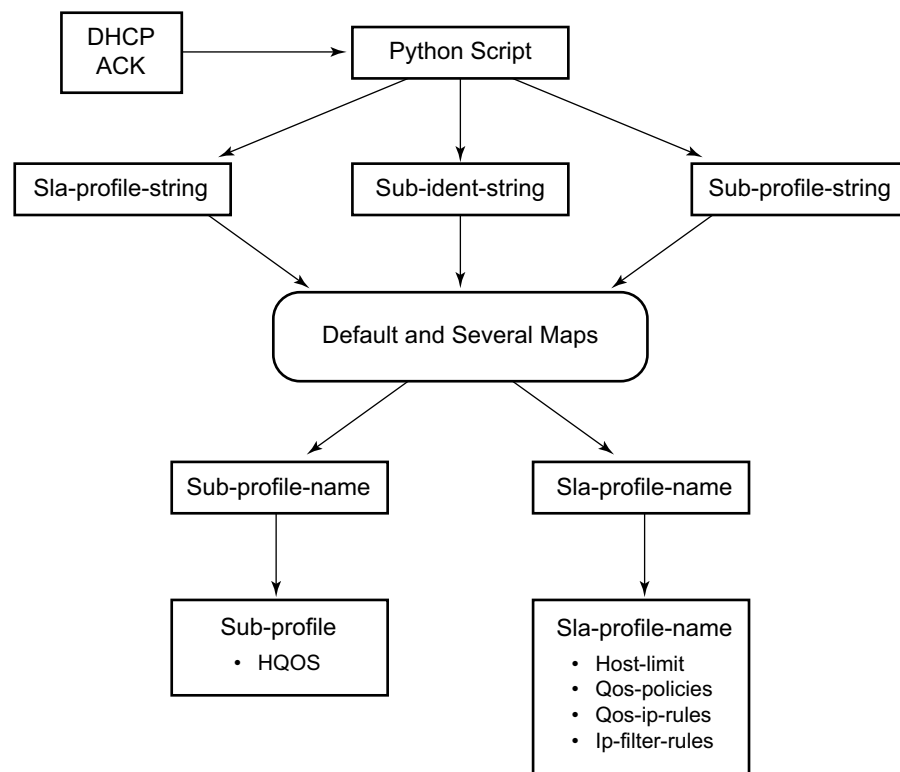

One or more scripts can be written by the operator and stored centrally on a server (in a location accessible by the router). They are loaded into each router at bootup.

Note that if a centrally stored script is changed, it is not automatically re-loaded onto the router. The reload must be forced by executing the **shutdown** / **no shutdown** commands on the affected URL(s).

### 9.4.7.2 Determining the Subscriber Profile and SLA Profile of a Host

[Figure 73](#) describes the data flow while determining which subscriber profile and SLA profile to use for a certain subscriber host based on a snooped/relayed DHCP ACK for that subscriber host.

**Figure 73** Data Flow in Determining Subscriber Profile and SLA Profile

OSSG086

An incoming DHCP ACK (relayed or snooped) is processed by the script provisioned in the sub-ident-policy defined in the SAP on which the message arrived. This script outputs one or more of the following strings:

- sub-ident — Identifies the subscriber (always needed).
- sub-profile — Identifies the subscriber class (optional).
- sla-profile — Identifies the SLA Profile for this subscriber host (optional).

These strings are used for a lookup in one or more maps to find the names of the sub-profile and sla-profile to use. If none of the maps contained an entry for these strings, the names will be determined based on a set of defaults.

Only when the names for both the sub-profile and sla-profile are known, the subscriber host can be instantiated. If even no default is found for either profile, the DHCP ACK is dropped and the host will not gain network access.

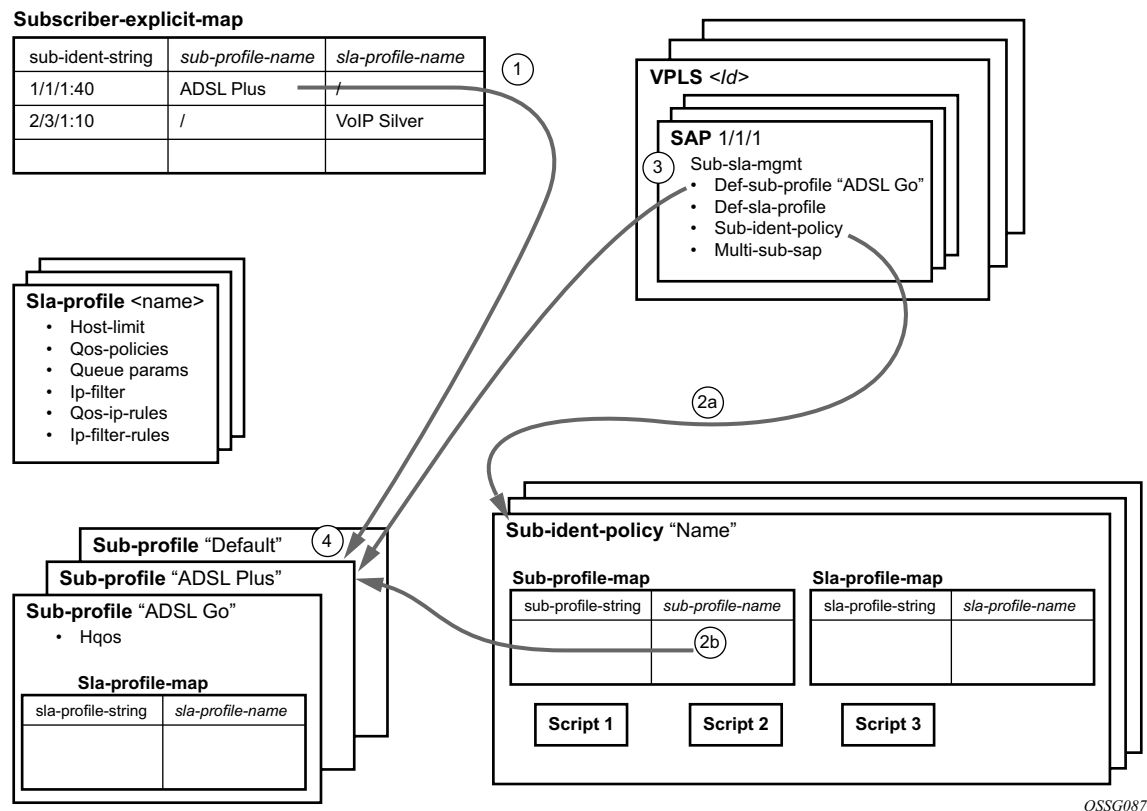

### 9.4.7.3 Determining the Subscriber Profile

All hosts (devices) belonging to the same subscriber will be subject to the same HQoS processing. The HQoS processing is defined in the sub-profile. A sub-profile refers to an existing scheduler policy and offers the possibility to overrule the rate of individual schedulers within this policy.

Because all subscriber hosts of one subscriber use the same scheduler policy instance, they must all reside on the same I/O module.

The figure below shows how the sub-profile is derived, based on the sub-ident string, the sub-profile string and/or the provisioned data structures. The numbers associated with the arrows pointing toward the subscriber profiles indicate the precedence of the checks.

Figure 74 Determining the Subscriber Profile

1. A lookup in the **explicit-subscriber-map** is done with the sub-ident string returned by the script. If a matching entry is found, the sub-profile-name (if defined) is taken. Otherwise:
2. If a **sub-ident-policy** is defined on the SAP, a lookup is done on its **sub-profile-map** with the sub-profile string from the script. The sub-profile-name is taken from the entry.  
If no entry was found, then:
3. If provisioned, the sub-profile-name is taken from the **def-sub-profile** attribute on the SAP. If not provisioned, then:
4. The **sub-profile** with the name "default" is selected (if provisioned). If this is not provisioned, there are no other alternatives, the ACK is dropped, and the host will not gain access.

#### 9.4.7.4 Determining the SLA Profile

For each host that comes on-line, the router also needs to determine which SLA profile to use. The SLA profile will determine for this host:

- The QoS-policies to use:
  - classification
  - queues/policers
  - queue mapping
- The egress scheduling policies to use:
  - egress HQoS
- The IP filter to use.

The SLA profile also has a host-limit attribute which limits the number of hosts (belonging to the same subscriber) on a certain SAP that can be using this SLA profile.

The classification and the queue mapping are shared by all the hosts on the same forwarding complex that use the same QoS policy (by their SLA profile).

The queues/policers are shared by all the hosts (of the same subscriber) on the same SAP that are using the same SLA profile. In other words, queues/policers are instantiated when, on a given SAP, a host of a subscriber is the first to use a certain SLA profile. This instantiation is referred to as an SLA profile instance. Ingress queues can be parented to a scheduler referenced in the ingress of a subscriber profile. Egress policers and queues can be parented to a scheduler referenced in the egress of a subscriber or SLA profile, or to a port scheduler.

A scheduler policy can be applied to the egress an SLA profile, allowing its schedulers to be the parent for its queues and for its tier 1 schedulers to be parented to a scheduler in a scheduler policy applied to the egress of a subscriber profile or a vport, or to a port scheduler applied to a port or vport. Configuring scheduler overrides is allowed for SLA profile egress schedulers. The configuration of a scheduler policy in the egress of an SLA profile is supported for all host types only on Ethernet interfaces on FP2 and higher hardware. It is not supported for ESM over MPLS pseudowires, nor is HQoS adjustment and host tracking supported on its schedulers.

The following show/monitor/clear commands are available related to the SLA profile scheduler:

```
show qos scheduler-hierarchy subscriber sub-ident-string sla-profile sla-profile-
name
sap sap-id [scheduler scheduler-name] [detail]
```

The **show qos scheduler-hierarchy subscriber** command (shown above) displays the scheduler hierarchy with the SLA profile scheduler as the root. Note that if the SLA profile scheduler is orphaned (that is when the scheduler has a parent which does not exist) then the hierarchy is only shown when the **show** command includes the **sla-profile** and **sap** parameters.

**Note:** If the SLA profile scheduler is orphaned (that is when the scheduler has a parent which does not exist) then the hierarchy is only shown when the show command includes the sla-profile and SAP parameters.

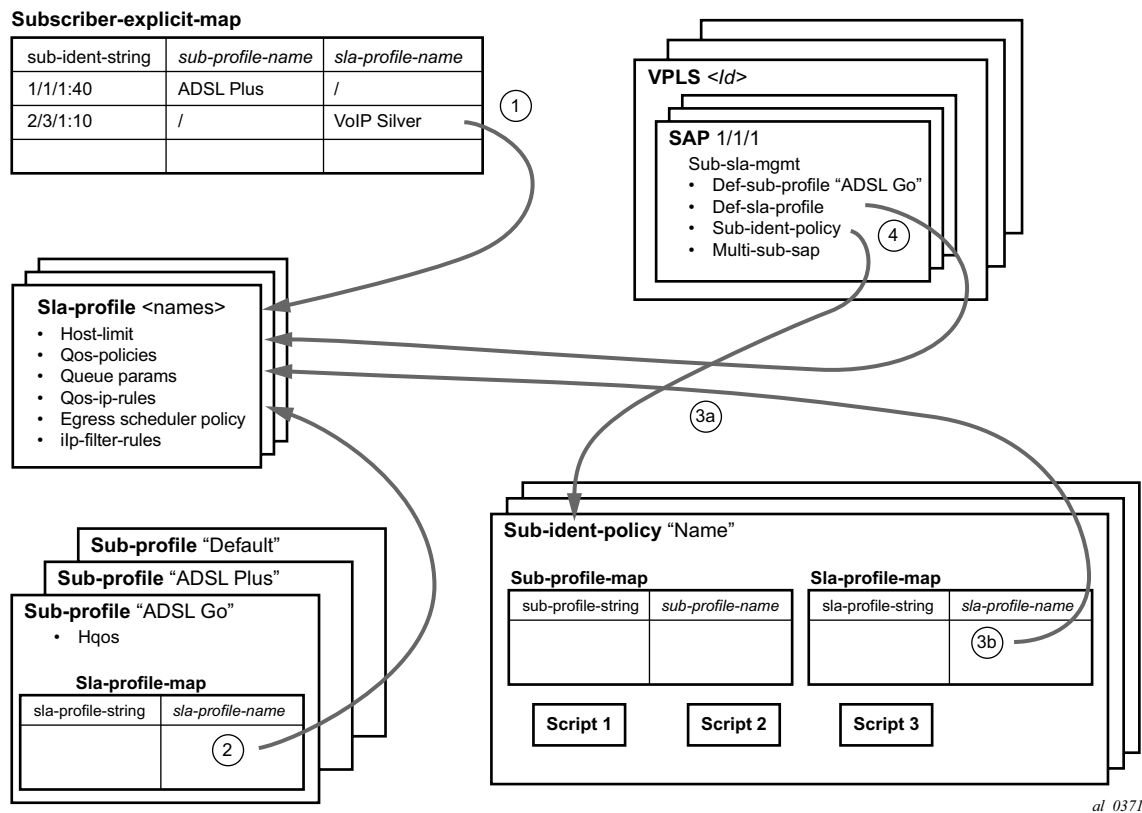

```
monitor qos scheduler-stats subscriber sub-ident-string [interval seconds] [repeat repeat] [absolute|rate] sap sap-id sla-profile sla-profile-name
```

```
show qos scheduler-stats subscriber sub-ident-string sap sap-id sla-profile sla-profile-name [scheduler scheduler-name]
```

```
clear qos scheduler-stats subscriber subscriber sub-ident-string sap sap-id sla-profile sla-profile-name [scheduler scheduler-name]
```

The figure below shows a graphical description of how the SLA profile is derived based on the subscriber identification string, the SLA profile string and the provisioned data structures. The numbers on the arrows towards the SLA profile indicate the *priority* of the provisioning (the lower number means the higher priority).

**Figure 75 Determining the SLA Profile**

1. A lookup is done with the sub-ident string returned by the script in the **explicit-subscriber-map**. If a matching entry is found, the sla-profile-name is taken from it – if defined. Otherwise:
2. A lookup with the sla-profile string from the script is done in the **sla-profile-map** of the sub-profile found earlier. The sla-profile-name from the found entry is taken. If no entry was found, then:
3. A lookup is done with the sla-profile string in the **sla-profile-map** of the **sub-ident-policy** configured on the SAP. The sla-profile-name from the found entry is taken. If no **sub-ident-policy** was configured on the SAP or no entry was found, then:
4. If provisioned, the sla-profile-name is taken from the **def-sla-profile** attribute on the SAP. If not provisioned, there are no more alternatives, the ACK is dropped, and the host will not gain access.

#### 9.4.7.4.1 SLA-Based Egress QoS Marking

The egress QoS marking for subscriber-host traffic is derived from SAP-egress QoS policy associated with a corresponding SAP, rather than from the SLA profile associated with the corresponding subscriber-host. As a consequence, no egress QoS marking (or Dot1p marking is set to 0, the dscp/prec field is kept unchanged) is performed for traffic transmitted on a managed-SAP because per default, sap-egress policy 1 is attached to every managed-SAP.

The default value of the “qos-marking-from-sap” flag is enabled. This means that the qos-marking defined in the SAP egress QoS policy associated with the SAP will be used. The default setting of this flag in a combination with managed-SAP will result in the same behavior as in the current system (dot1p=0, dscp/prec is unchanged).

If “no qos-marking-from-sap” is executed, then both the Dot1p marking (all IOMs) and DSCP marking (IOM2/3 only) are derived from the sla-profile.

Changing the flag setting in the SLA profile being used by any subscriber-hosts (this includes subscriber-hosts on managed-SAPs as well) will be allowed.

The following MC traffic characteristics apply:

- On Layer 3 subscriber-interfaces, MC is not supported so it is impossible to enable it at the SAP level or at the sla-instance level.
- On Layer 2 SAPs IGMP snooping is supported while it is not supported on the sla-instance level. Therefore, any MC traffic transmitted at egress belongs to a SAP (meaning it will use SAP queues), rather than to sla-instance.
- The special case are SAPs with a profiled-traffic-only flag enabled. Although it is possible to define an sla-profile applicable to a Layer 2-host, this will not be taken as reference for marking mc-traffic, but rather SAP settings will be used.

#### 9.4.8 Auto-Sub ID

The subscriber ID name (sub-id) is a mandatory object that binds all hosts of a given subscriber together. Briefly, the sub-id name represents a residential household. Many management/troubleshooting and even billing operations rely on the sub-id name entity. The sub-id name is required for the host creation process, and it can be supplied by RADIUS or LUDB. It is derived from the sap-id or is statically provisioned in the form of a string.

In many ESM deployments with RADIUS, it is desirable that the sub-id is auto-generated within the 7450 ESS and 7750 SR rather than burdening the OSS and the RADIUS server with this function. A typical application for auto sub-id is as follows:

- RADIUS server provides the sla-profile string and the sub-profile string but not the sub-id string.
- The sub-id name is auto-generated and formatted based on the configured options.

The following are the properties of auto sub-id generation:

- The auto-generation of the sub-id name can be based on any combination of the following fields:
  - MAC address
  - sap-id
  - circuit-id
  - remote-id
  - session-id

There can be only a single set of subscriber identification fields defined per host type (IPoE or PPPoE) per chassis. If the combination of the fields must be modified, the existing subscribers with an auto-generated sub-id must be manually terminated. Considering that remote termination of the IPoE subscribers by a DHCP server is not supported by all DHCP client vendors through the FORCERENEW DHCP message (RFC 3203, *DHCP reconfigure extension*), changing the subscriber fields while subscribers with auto generated sub-id are active should be avoided.

The sub-id name generation will take place at the end of the host initiation process (as after the authentication phase is completed) and only in case whereby the sub-id had not been already provided by any other more specific means (RADIUS, LUDB). This means that if the sub-id is supplied by other means (RADIUS, LUDB), then the sub-id name will not be auto-generated.

The format of the sub-id name can be either a random 10 characters encoded string or a user- friendly string based on the subscriber identification fields. Note that the maximum length of the sub-id name is 32 characters.

The sub-id name will not be passed in the Access-Request to the RADIUS server since it is generated after the authentication phase.

The sub-id name can be auto-generated regardless of how the sla/sub-profile strings are obtained (RADIUS, LUDB or static).

The subscriber identification fields used in auto-generation of the sub-id name are enabled on the global level.

```
configure
subscriber-mgmt
 auto-sub-id-key
```

```

ppp-sub-id-key [mac] [sap-id] [circuit-id]
 [remote-id] [session-id]
ipoe-sub-id-key [mac] [sap-id] [circuit-id]
 [remote-id]

```

If no sub-id-key per host type is configured, then the defaults are:

|                  |                           |
|------------------|---------------------------|
| PPPoE host type: | <mac, sap-id, session-id> |
| IPoE host type : | <mac, sap-id>.            |

The order in which the fields are configured is important because the sub-id name will potentially become a concatenated string of the subscriber host identifiers in the order in which they are provisioned. Note that the sub-id cannot be longer than 32 characters.

- In case that the length of the concatenated fields for the sub-id name is larger than 32 characters, the host creation will fail.
- In case that the circuit-id/remote-id is in the key and they contain non-printable characters, their place in sub-id name will be formatted in hex instead of ASCII. ASCII printable characters contain byte values 0x20..0x7E. All other values are ASCII non-printable and thus are formatted in hex characters.

The following would generate a sub-id name: xx:xx:xx:xx:xx:xx|1/1/3:23|44. The length of such sub-id name would be 29B.

- mac: xx:xx:xx:xx:xx:xx
- sap: 1/1/3:23
- session-id: 44 (16bits length)

In case that the key contains the circuit-id as: 0x610163 (3 bytes), then the sub-id name will be formatted as '610161' (hex) since '01' hex is non printable in ASCII. In this case the sub-id name will be of length 6B.

However, if the circuit-id is 0x616263 (3 bytes), then the string will be formatted as ASCII string 'abc' (3 characters). The sub-id name is 3B long.

The assignment of the sub-id to dynamic hosts is as follows:

- From RADIUS (sub-ident-policy including use-direct-map-as-default)
- From LUDB (sub-ident-policy including use-direct-map-as-default)
- Configured (explicit) defaults:
  - use-sap-id: sap-id

- auto-id: combination of sub-id identifiers specified in auto-sub-id-key. The sub-id name will be in a human friendly format, i.e. concatenation of the fields in the pppoe|ipoe-sub-id-key command separated by a “|” character.
- string: custom string
- Non-configured (implicit) defaults:
  - PPPoE host types: random 10 character string based on fields defined in the
    - **ppp-sub-id-key** command. If no such fields are explicitly defined, the default ones will be assumed: <mac, sap-id, session-id>.
    - IPoE host types: random 10 character string based on the **ipoe-sub-id-key** command. If no such fields are explicitly defined, the defaults will be assumed: <mac, sap-id >.

The way in which the default sub-id is generated is configured under the SAP level in the following manner:

```
config
service ies/vprn
 subscriber-interface <sub-if-name>
 group-interface <grp-if-name>
 sap <sap-id>
 sub-sla-mgmt
 def-sub-id use-sap-id|use-
 auto-id|string
```

Under the msap-policy:

```
config
subscriber-mgmt
 msap-policy <name> (msap-policy referenced in msap-
 defaults under the capture sap)
 sub-sla-mgmt
 def-sub-id <use-sap-id|use-auto-id|string
 <sub-id>
```

The **use-auto-id** keyword parameter of the def-sub-id string consists of concatenated auto-sub-id-keys separated by a ‘|’ character. In the absence of the **use-auto-id** keyword, the sub-id name will be a random 10 characters encoded string based on the ipoe|ppp-sub-id-keys. This random encoded 10 character string is unique per chassis as well as in dual-homed environment.

This command will have no effect if it is configured directly under the capture SAPs in VPLS (in the **config>service>vpls>sap>sub-sla-mgmt** context). Managed SAPs in ESM are instantiated by a capture SAP and the msap-policy in this case is mandatory. An auto-id keyword in case of managed SAP will be looked only under the msap-policy.

Static subscribers are required to have the sub-id manually configured.

### 9.4.8.1 Sub-id Identifiers

The sub-id can be based on any combination of the following identifiers:

- The sap-id, in combination with any other allowable identifier, will be used as the search key. This assumes a 1:1 (subscriber per SAP) deployment model.
- The circuit-id, in combination with any other allowable identifier, will be used to identify subscribers. This can be used in 1:1 deployment model, or in service per SAP deployment model. Circuit-id is applicable to IPoE v4 type hosts (option 82), to IPoE v6 type hosts (option 18 – interface-id) and PPPoE hosts (remote agent option signaled by PPPoE tags). The format of circuit-id is identical for IPv4 and IPv6 hosts.
- The remote-id, in combination with any other allowable identifier, will be used to identify subscribers. This can be used in 1:1 deployment model, or in service per SAP deployment model. The remote-id is applicable to IPoE v4 type hosts (option 82), to IPoE v6 type hosts (option 37) and PPPoE hosts (remote agent option signaled via PPPoE tags).
- The mac address (in combination with any other allowable identifier will be used to identify subscribers. This assumes a 1:1 deployment model.
- The PPPoE session id, in combination with any other allowable identifier, is applicable only to PPPoE hosts. The session-id used will be of the first host that is instantiated for the subscriber.

### 9.4.8.2 Dual Stack Hosts

Auto-generation of sub-id names for subscribers with a single dual stack hosts (IPoE and PPPoE) is enabled by default by not explicitly provisioning anything for the def-sub-id. The sub-id name would be semi-randomly generated based on the <mac, sap-id, session-id> for PPPoE hosts and the <mac, sap-id> combination for IPoE host.

### 9.4.8.3 Mixing Hosts with Auto-Generated IDs and non Auto-Generated IDs

Hosts with different sub-id names but identical auto-sub-id keys are not linked into the same subscriber. Such scenarios can arise with hosts with the same auto-sub-id keys but different methods for obtaining the sub-id name. For example, one host relying on auto-generated sub-id name while the other is using explicit configuration methods (sap-id, string, RADIUS or LUDB). If the auto-generated sub-id name and explicit sub-id name are the same, the host will be tied into the same subscriber.

For example:

The default auto-sub-id for the following two hosts are <mac, sap-id>.

Host X on SAP 1/1/1:1 with MAC 00:00:00:00:00:01 obtains sub-id through RADIUS.

Host Y on SAP 1/1/1:1 with MAC 00:00:00:00:00:01 has sub-id auto-generated.

Regardless of which host comes up first, those two hosts at the end will belong two different subscribers as long as their sub-ids are different.

### 9.4.8.4 PPPoA/PPPoEoA Considerations

PPPoA/PPPoEoA hosts will adhere to the same rules as PPPoE. Fields that are supported in PPPoE but not PPPoA/PPPoEoA will be simply ignored.

Fields that are not supported in PPPoA are:

- Remote-id
- Circuit-id
- MAC address

Fields that are most likely not applicable to PPPoEoA are:

- Remote-id
- Circuit-id

### 9.4.8.5 Deployment Considerations

The following is a possible deployment example scenario.

```
config
subscriber-mgmt
 auto-sub-id-key
 ppp-sub-id-key sap-id
 ipoe-sub-id-key mac circuit-id
```

```
config
service vprn 10
 subscriber-interface <sub-if-name>
 authentication-policy <auth-pol-name>
 group-interface <grp-if-name>
 sap 1
 sub-sla-mgmt
 def-sub-id use-sap-id
 sub-ident-policy <ident-pol-name>
 sap 2
 sub-sla-mgmt
 def-sub-id auto-id
 sub-ident-policy <ident-pol-name>
 sap 3
 sub-sla-mgmt
 def-sub-id "sub3"
 sub-ident-policy <ident-pol-name>
 sap 4
 sub-sla-mgmt
 sub-ident-policy <ident-pol-name>
```

Assume the following cases:

1. RADIUS returns the sub-id on all four SAPs.
2. RADIUS does not return the sub-id string on any of the SAPs.

In the first case where RADIUS returns the sub-id string, the following will occur:

- On all 4 SAPs the sub-id string will be assigned by the RADIUS server. Defaults have no effect, and neither do identifiers specified under the auto-sub-id-key node.

In the second case, the effects are the following:

- On SAP1 the sub-id name will be the <sap-id> (1/1/1:3)
- On SAP 2 the sub-id name will be <sap-id> for PPPoE hosts and <mac>-<circuit-id> concatenation for IPoE type hosts.

For example:

1/1/1:100 for PPPoE

AC:AB:AA:AD:AE:AE-AN-id eth 1/1/1/1:2 for IPoE

(circuit-ID format is: Access-Node-Identifier atm slot/port:vpi.vci or Access-Node-Identifier eth slot/port:[vlan-id]).

Note that the circuit-ID can itself be 63B in length whereas the length of the sub-id name is limited to 32 Bytes. So in the above case, the sub-id name length would be 38 Bytes (>32B) and the host instantiation would fail.

- On SAP3 the sub-id name will be the literal 'sub3' for PPPoE and IPoE hosts.
- On SAP4 the sub-id name will be a semi-random value based on <sap-id> for PPPoE hosts and the <mac, circuit-id> combination for IPoE hosts.

#### 9.4.8.6 Caveats

Only a single combination of the subscriber fields used to auto generate sub-id is allowed per host type (IPoE or PPPoE) and per chassis. In case that the combination of the fields needs to be changed, the existing subscribers with an auto-generated sub-id must be manually terminated. Considering that remote termination of the IPoE subscribers by DHCP server is not supported by all DHCP client vendors through FORCERENEW DHCP message (RFC 3203), changing the subscriber fields while subscribers with auto generated sub-id are active should be avoided.

### 9.4.9 Limiting Subscribers and Hosts on a SAP

A number of configuration parameters are available to control the maximum amount of subscribers and/or hosts that can be simultaneously active on a SAP:

- multi-sub-sap — Limits the number of subscribers (dynamic + static) on a SAP
- lease-populate — Limits the number of dynamic hosts on a SAP
- host-limit — Limits the number of hosts (dynamic + static) per SLA profile instance.

If any of these limits are reached, a new host will be denied access. The only exception is when host-limit command is configured with the keyword remove-oldest specified, then the oldest active host is dropped and the new host is granted access. The dynamic host with the least remaining lease time will be considered the oldest host. Note that remove-oldest only applies to DHCP and ARP-host, and it is not for PPPoE or IPv6 ESM hosts.

## 9.4.10 Static Subscriber Hosts

While it is typically preferred to have all hosts provisioned dynamically through DHCP snooping, it may be needed to provide static access for specific hosts (those that do not support DHCP).

Since a subscriber identification policy is not applicable to static subscriber hosts, the subscriber identification string, subscriber profile and SLA profile must be explicitly defined with the host's IP address and MAC address (if Enhanced Subscriber Management is enabled).

If an SLA profile instance associated with the named SLA profile already exists on the SAP for the subscriber, the static subscriber host is placed into that SLA profile instance. If an SLA profile instance does not yet exist, one will be created if possible. If the SLA profile cannot be created, or the host cannot be placed in the existing SLA profile instance (the **host-limit** was exceeded), the static host definition will fail.

## 9.4.11 QoS for Subscribers and Hosts

### 9.4.11.1 QoS Parameters in Different Profiles

QoS aspects for subscribers and hosts can be defined statically on a SAP or dynamically using

Enhanced Subscriber Management. For example, in a VLAN-per-service model, different services belonging to a single subscriber are split over different SAPs, and thus the overall QoS (such as a scheduler policy) of this subscriber must be assigned using Enhanced Subscriber Management.

QoS parameters are shared among the subscriber profile and SLA profile as follows:

- The subscriber profile refers to HQoS ingress and egress scheduler policies which define the overall treatment for hosts of this subscriber when queues are used, or policers managed by HQoS are used at egress. If the subscriber is using policers, the subscriber profile also refers to CFHP ingress and egress policer-control-policies which define the overall treatment for hosts of this subscriber.
- The SLA profile refers to specific queue/policer settings for each host (BT, VoIP, PC) using SAP ingress and SAP egress QoS policies. The SLA profile can also refer to an egress HQoS scheduler policy which defines the scheduling from the queues of the related host.

The primary use of the subscriber profile is to define the ingress and egress scheduler policies/ policer-control-policies used to govern the aggregate SLA for all hosts associated with a subscriber. To be effective, the queues/policers defined in the SLA profile's QoS policies will reference a scheduler/arbitrator from the scheduler policy/policer-control-policy respectively as their parent.

#### **9.4.11.2 QoS Policy Overrides**

Generic QoS queue/policer parameters could be specified for the SAP in a QoS policy and overridden for some customers by queue/policer parameters defined in the SLA profile. This allows for a single SAP ingress and SAP egress QoS policy to be used for many subscribers, while providing individual subscriber parameters for queue/policer operation.

### **9.4.12 ESM Subscriber Hierarchical Traffic Control**

ESM subscribers can make use of both queues and/or policers for both the ingress and egress traffic. The queue and policers are configured within SAP ingress/egress policies applied to the SLA profile. The policers (at egress only) queue can parent to different levels/cir-levels with different weights/cir weights of a virtual scheduler configured within a scheduler policy, and to an egress port scheduler configured in a port scheduler policy, to achieve hierarchical traffic control. The policers can parent to different levels with different weights of an arbitrator configured within a policer control policies to achieve hierarchical traffic control.

#### **9.4.12.1 Subscriber HQoS**

Hierarchical QoS (HQoS) corresponds to scheduling bandwidth distribution to policers, queues and schedulers and is applied using scheduler policies at ingress and egress of the subscriber profile for a subscriber, and at egress in the SLA profile for a host, together with a port scheduler at both the port and vport level.

Each scheduler policy can contain up to three tiers of schedulers with lower level schedulers being able to parent to higher level schedulers in the same scheduler policy.

Policers and queues can parent to any scheduler in their related scheduler policy hierarchy (except vport at egress) and also at the egress to a port scheduler.

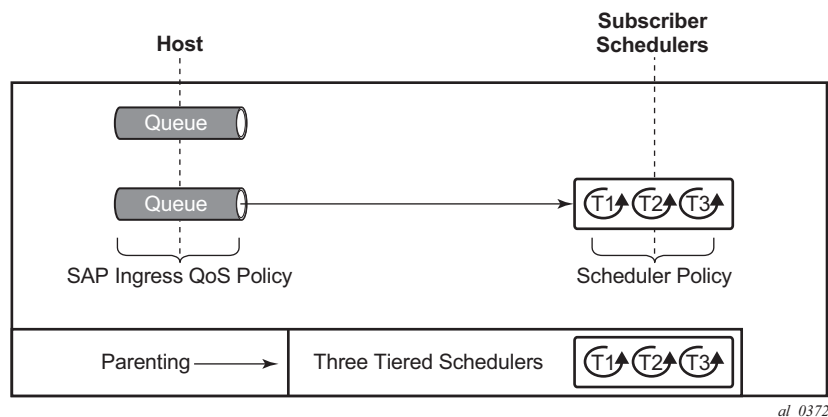

Schedulers can parent to any higher level scheduler in their related scheduler policy hierarchy and, at the egress to a port scheduler configured within the port or vport. When an egress port scheduler is used, an aggregate rate limit can be applied at the subscriber profile and vport levels instead of using a scheduler. To extend the hierarchy further at egress, a tier 1 scheduler within a scheduler policy can parent to any scheduler in a scheduler policy at a higher level.

The scheduling levels are comprised of:

- Ingress and egress queues
- Egress policers
- Egress SLA-profile schedulers
- Ingress and egress subscriber profile schedulers
- Egress vport schedulers
- Port schedulers

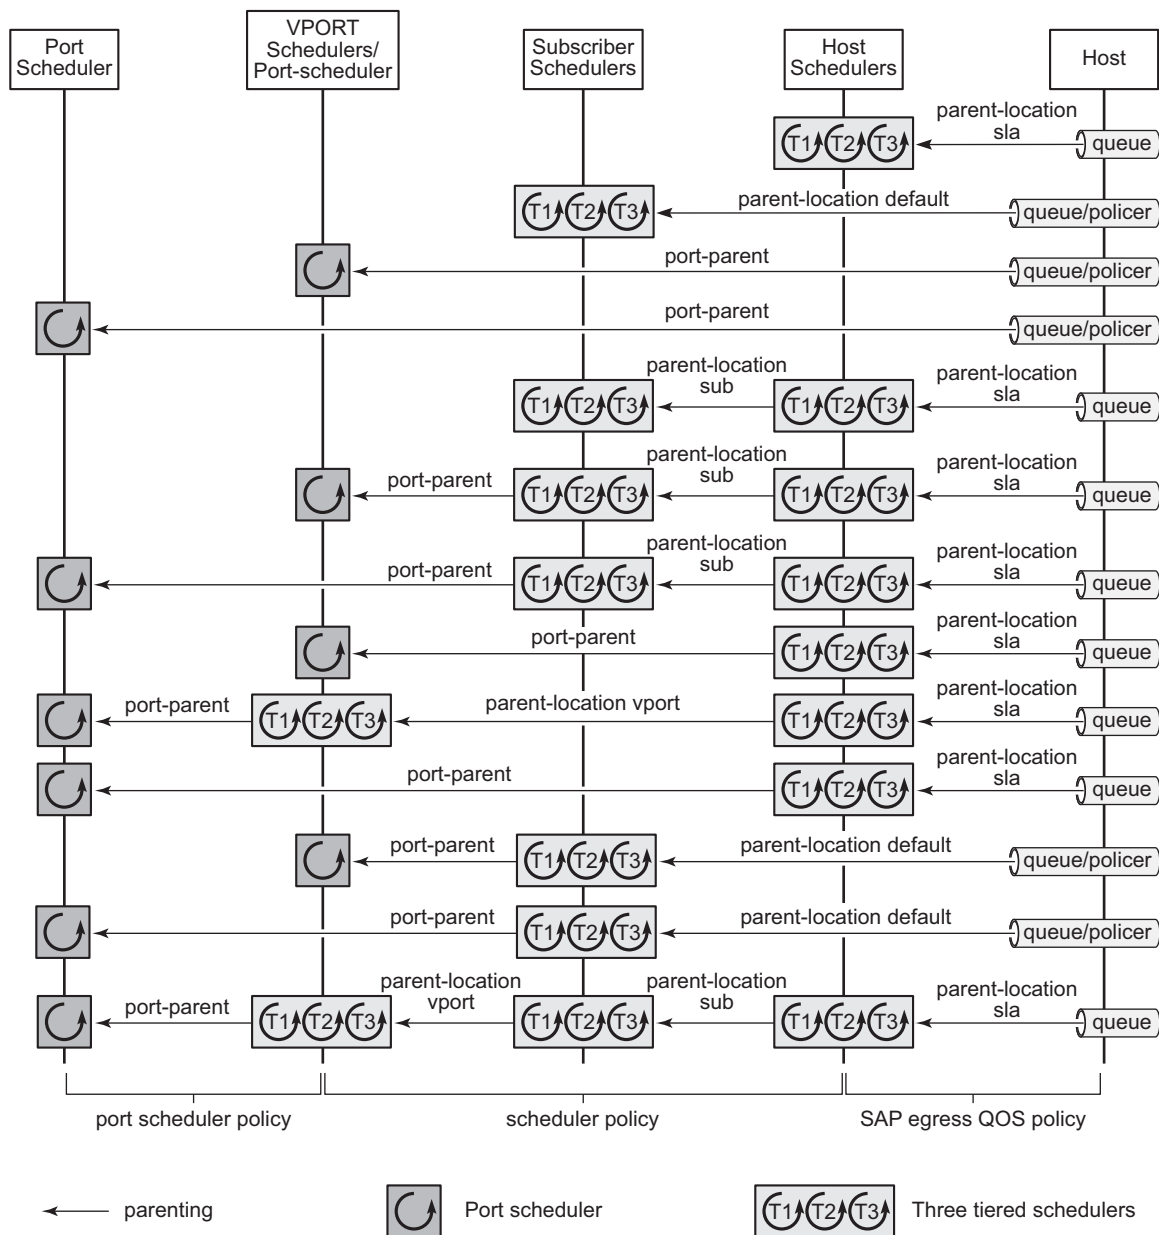

The ingress hierarchical parenting relationship options are shown in [Figure 76](#).

**Figure 76 Ingress Scheduling Hierarchy Options**

The egress hierarchical parenting relationship options are shown in [Figure 77](#). Note that not all combinations can be configured concurrently, and some uses of port parent could be equally achieved using a scheduler parent and a child parent-location.

**Figure 77 Egress Scheduling Hierarchy Options**

No3493

The **parent** command is used to specify the name of the parent scheduler when parenting a queue or scheduler, together with the level/cir-level and weight/cir-weight at which to connect.

```
config>qos>sap-ingress>queue# parent
- parent scheduler-name [weight weight] [level level]
[cir-weight cir-weight] [cir-level cir-level]
```

```
config>qos>sap-egress>queue# parent
- parent scheduler-name [weight weight] [level level]
 [cir-weight cir-weight] [cir-level cir-level]
```

```
config>qos>scheduler-policy>tier>scheduler# parent
- parent scheduler-name [weight weight] [level level]
 [cir-weight cir-weight] [cir-level cir-level]
```

The location of the parent scheduler (in which applied scheduler policy it exists) for a policer or queue defaults to a scheduler in the subscriber ingress or egress scheduler policy. Parents of schedulers themselves must be explicitly configured and by default must be within the same scheduler policy.

At egress, the scheduler parenting relationship is determined using the parent-location command:

By default, egress queues parent to any scheduler in subscriber egress scheduler policy.

```
config>qos>sap-egress# parent-location default
```

Egress queues can parent to any scheduler within the scheduler policy applied to the egress of an SLA profile (this is not supported for policers managed by HQoS).

```
config>qos>sap-egress# parent-location sla
```

By default, a tier 1 scheduler in the scheduler policy is not allowed to be parented to another scheduler.

```
config>qos>scheduler-policy>tier# parent-location none
```

A tier 1 scheduler in the scheduler policy applied to the egress of an SLA profile can parent to a scheduler applied to the egress of a subscriber profile.

```
config>qos>scheduler-policy>tier# parent-location sub
```

A tier 1 scheduler in the scheduler policy applied to the egress of a subscriber profile can parent to a scheduler applied to the egress of a Vport.

```
config>qos>scheduler-policy>tier# parent-location vport
```

The configuration of a **parent-location** and frame-based accounting in a scheduler policy is mutually exclusive in order to ensure consistency between the different scheduling levels.

Note that the parent-location command is supported only on Ethernet interfaces on FP2 and higher hardware. It is not supported for ESM over MPLS pseudowires.

Both egress queues and egress schedulers can port parent using directly to different levels/cir-levels, with different weights/cir weights, to a port egress port scheduler. Egress schedulers can also port parent directly to different levels/cir-levels, with different weights/cir weights, to a vport egress port scheduler.

### 9.4.12.2 Subscriber CFHP

Class Fair Hierarchical Policing (CFHP) corresponds to the policing control of traffic by policers/arbiters. This uses policer control policies and can be applied for ingress and egress capacity control for the subscriber in the subscriber profile.

Each policer control policy can contain up to three tiers of arbiters with lower level arbiters being able to parent to higher level arbiters in the same scheduler policy.

Policers can parent to any arbiter in their related policer control policy hierarchy.

The policing levels are comprised of:

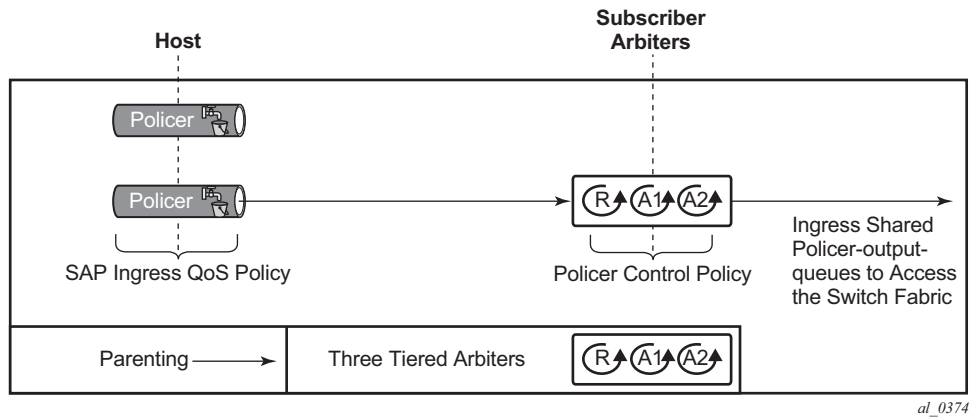

- Ingress and egress policers
- Ingress and egress subscriber arbiters

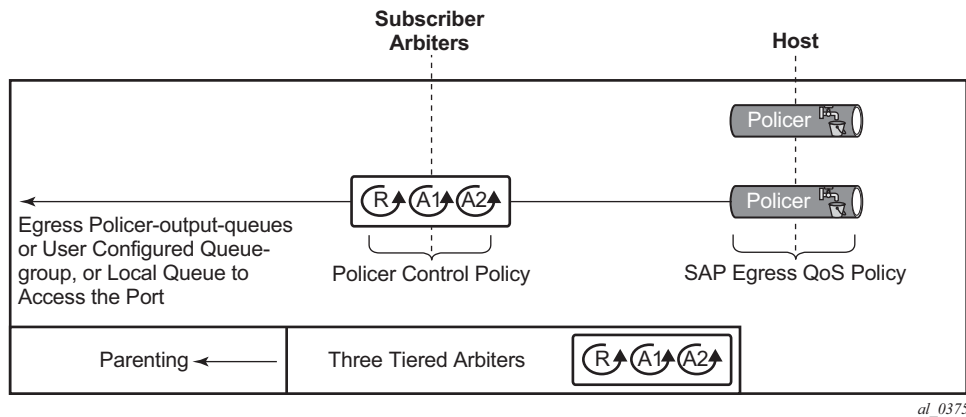

**Note:** Ingress policed traffic uses the shared policer-output-queues to access the switch fabric. At egress, the policed traffic accesses the egress port through a queue group queue (by default the policer-output-queues queue group, though user configurable queue groups can also be used) or a locally configured subscriber queue.

Egress policers can also be managed by HQoS.

The ingress hierarchical parenting relationship options are shown in [Figure 78](#).

**Figure 78 Ingress Policing Hierarchy Options**

The egress hierarchical parenting relationship options are shown in [Figure 79](#).

**Figure 79 Egress Policing Hierarchy Options**

The **parent** command is used to specify the name of the parent arbiter when parenting a policer or arbiter, together with the level and weight at which to connect.

```
config>qos>sap-ingress>policer$ parent
- parent arbiter-name [weight weight-level] [level level]

config>qos>sap-egress>policer$ parent
- parent arbiter-name [weight weight-level] [level level]

config>qos>plcr-ctrl-plcy>tier>arbiter# parent
- parent arbiter-name [weight weight-level] [level level]
```

### **9.4.12.3 ATM/Ethernet Last-Mile Aware QoS for Broadband Network Gateway**

This feature allows the user to perform hierarchical scheduling of subscriber host packets such that the packet encapsulation overhead and ATM bandwidth expansion (when applicable) due to the last mile for each type of broadband session, that is, PPPoEoA LLC/SNAP and VC-Mux, IPoE, IPoEoA LLC/SNAP and VC-Mux, and so on, is accounted for by the 7450 ESS and 7750 SR acting as the Broadband Network Gateway (BNG).

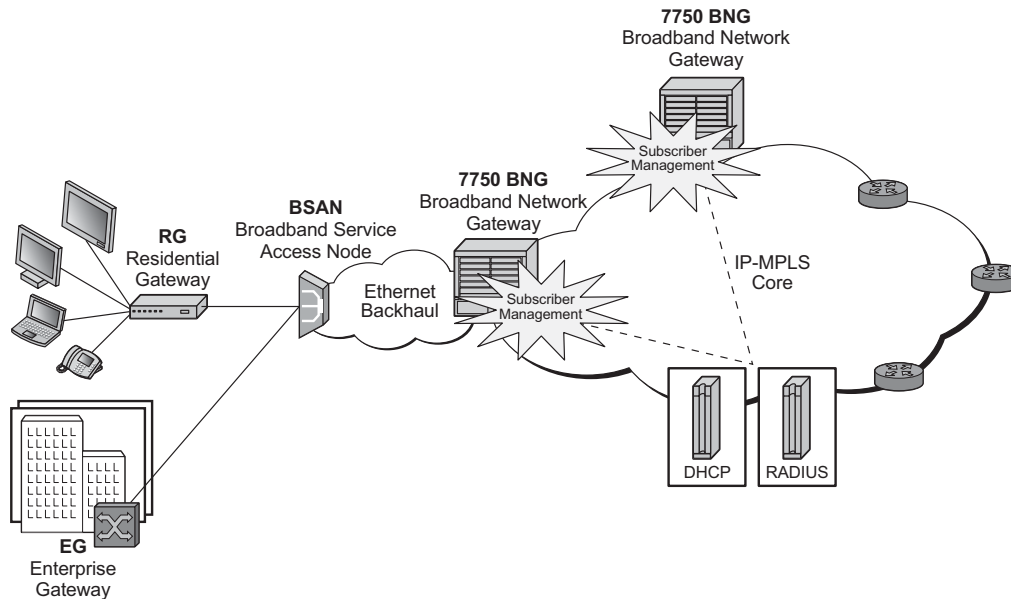

The intent is that the BNG distributes bandwidth among the subscriber host sessions fairly by accounting for the encapsulation overhead and bandwidth expansion of the last mile such that packets are less likely to be dropped downstream in the DSLAM DSL port.

The last mile encapsulation type can be configured by the user or signaled using the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags or DHCP Relay Options as per RFC 4679.

Furthermore, this feature allows the BNG to shape the aggregate rate of each subscriber and the aggregate rate of all subscribers destined to a given DSLAM to prevent congestion of the DSLAM. The subscriber aggregate rate is adjusted for the last mile overhead. The shaping to the aggregate rate of all subscribers of a given destination DSLAM is achieved via a new scheduling object, referred to as Virtual Port or vport in CLI, which represents the DSLAM aggregation node in the BNG scheduling hierarchy

#### **9.4.12.3.1 Broadband Network Gateway Application**

An application of this feature in a BNG is shown in [Figure 80](#).

**Figure 80 BNG Application**

al\_0026

Residential and business subscribers use PPPoEoA, PPOA, IPoA, or IPoEoA based session over ATM/DSL lines. Each subscriber host can use a different type of session. Although Figure 1 illustrates ATM/DSL as the subscriber last mile, this feature supports both ATM and Ethernet in the last mile.

A subscriber SAP is auto-configured via DHCP or RADIUS authentication process, or is statically configured, and uses a Q-in-Q SAP with the inner C-VLAN identifying the subscriber while the outer S-VLAN identifies the Broadband Service Access Node (BSAN) which services the subscriber, i.e., the DSLAM. The SAP configuration is triggered by the first successfully validated subscriber host requesting a session. Within each subscriber SAP, there can be one or more hosts using any of the above session types. The subscriber SAP terminates on an IES or VPRN service on the BNG. It can also terminate on a VPLS instance.

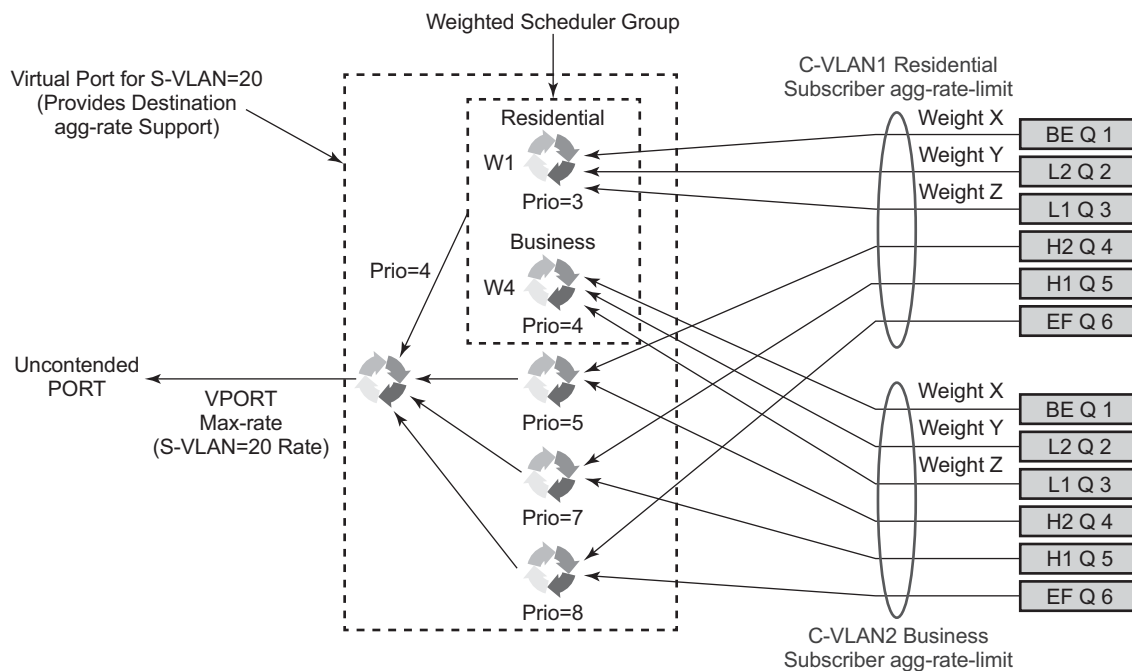

When the 7750 BNG forwards IP packets from the IP-MPLS core network downstream towards the Residential Gateway (RG) or the Enterprise Gateway (EG), it adds the required PPP and Ethernet headers, including the SAP encapsulation with C-VLAN/S-VLAN. When the BSAN node receives the packet, it strips the S-VLAN tag, strips or overwrites the C-VLAN tag, and adds padding to minimum Ethernet size if required. It also adds the LLC/SNAP or VC-mux headers plus the fixed AAL5 trailer and variable AAL5 padding (to next multiple of 48 bytes) and then segments the resulting PDU into ATM cells when the last mile is ATM/DSL. Thus the packet size will undergo a fixed offset due to the encapsulation change and a variable expansion due to the AAL5 padding when applicable. Each type of subscriber host session will

require a different amount of fixed offset and may require a per packet variable expansion depending of the encapsulation used by the session. The BNG node learns the encapsulation type of each subscriber host session by inspecting the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags as specified in RFC 4679. The BNG node must account for this overhead when shaping packets destined to subscriber.

### 9.4.12.3.2 Queue Determination and Scheduling

Figure 81 illustrates the queuing and scheduling model for a BNG using the Ethernet/ATM last-mile aware QoS feature.

**Figure 81 BNG Queuing and Scheduling Model**

al\_0027

A set of per FC queues are applied to each subscriber host context to enforce the packet rate within each FC in the host session as specified in the subscriber's host SLA profile. A packet is stored in the queue corresponding the packet's FC as per the mapping of forwarding class to queue-id defined in the sap-egress QoS policy used by the host SLA profile. In the BNG application however, the host per FC queue packet rate is overridden by the rate provided in the RADIUS access-accept message. This rate represents the ATM rate that will be seen on the last mile, that is, it includes the encapsulation offset and the per packet expansion due to ATM segmentation into cells at the BSAN.

In order to enforce the aggregate rate of each destination BSAN, a scheduling node, referred to as virtual port, and vport is in the CLI. The vport operates exactly like a port scheduler with the difference that multiple vport objects can be configured on the egress context of an Ethernet port. The user adds a vport to an Ethernet port using the following command:

**CLI Syntax:** `config>port>ethernet>access>egress>vport vport-name  
create`

The vport is always configured at the port level even when a port is a member of a LAG. The vport name is local to the port it is applied to but must be the same for all member ports of a LAG. It however does not need to be unique globally on a chassis.

**CLI Syntax:** `config>port>ethernet>access>egress>vport vport-name  
create`

The vport is always configured at the port level even when a port is a member of a LAG. The vport name is local to the port it is applied to but must be the same for all member ports of a LAG. It however does not need to be unique globally on a chassis.

The user applies a port scheduler policy to a vport using the following command:

**CLI Syntax:** `config>port>ethernet>access>egress>vport>port-scheduler-  
policy port-scheduler-policy-name`

A vport cannot be parented to the port scheduler when it is using a port scheduler policy itself. It is thus important the user ensures that the sum of the **max-rate** parameter value in the port scheduler policies of all vport instances on a given egress Ethernet port does not oversubscribe the port's hardware rate. If it does, the scheduling behavior degenerates to that of the H/W scheduler on that port. A vport which uses an agg-rate can be parented to a port scheduler. This is explained in [Applying Aggregate Rate Limit to a Vport](#). Note that the application of the agg-rate rate, port-scheduler-policy and scheduler-policy commands under a vport are mutually exclusive.

Each subscriber host queue is port parented to the vport which corresponds to the destination BSAN using the existing port-parent command:

**CLI Syntax:** `config>qos>sap-egress>queue>port-parent [weight weight]  
[level level] [cir-weight cir-weight] [cir-level cir-level]`

This command can parent the queue to either a port or to a vport. These operations are mutually exclusive in CLI as explained above. When parenting to a vport, the parent vport for a subscriber host queue is not explicitly indicated in the above command. It is determined indirectly. The determination of the parent vport for a given subscriber host queue is described in [Vport Determination and Evaluation](#).

Furthermore, the weight (cir-weight) of a queue is normalized to the sum of the weights (cir-weights) of all active subscriber host queues port-parented at the same priority level of the vport or the port scheduler policy. Since packets of ESM subscriber host queues are sprayed among the link of a LAG port based on the subscriber-id, it is required that all subscribers host queues mapping to the same vport, such as having the same destination BSAN, be on the same LAG link so that the aggregate rate towards the BSAN is enforced. The only way of achieving this is to operate the LAG port in active/standby mode with a single active link and a single standby link.

The aggregate rate of each subscriber must also be enforced. The user achieves this by applying the existing agg-rate-limit command to the egress context of the subscriber profile:

**CLI Syntax:** `config>subscr-mgmt>sub-profile>egress>agg-rate-limit  
agg-rate`

In the BNG application however, this rate is overridden by the rate provided in the RADIUS access-accept message. This rate represents the ATM rate that will be seen on the last mile, that is, it includes the encapsulation offset and the per packet expansion due to ATM segmentation into cells at the BSAN.

#### 9.4.12.3.3 Weighted Scheduler Group

The existing port scheduler policy defines a set of eight priority levels with no ability of grouping levels within a single priority. In order to allow for the application of a scheduling weight to groups of subscriber host queues competing at the same priority level of the port scheduler policy applied to the vport, or to the Ethernet port, a new group object is defined under the port scheduler policy:

**CLI Syntax:** `config>qos>port-scheduler-policy>group group-name rate  
pir-rate [cir cir-rate]`

Up to eight groups can be defined within each port scheduler policy. One or more levels can map to the same group. A group has a rate and optionally a cir-rate and inherits the highest scheduling priority of its member levels. For example, the scheduler group shown in the vport consists of level priority 3 and level priority 4. It thus inherits priority 4 when competing for bandwidth with the standalone priority levels 8, 7, and 5.

In essence, a group receives bandwidth from the port or from the vport and distributes it within the member levels of the group according to the weight of each level within the group. Each priority level will compete for bandwidth within the group based on its weight under congestion situation. If there is no congestion, a priority level can achieve up to its rate (cir-rate) worth of bandwidth.

The mapping of a level to a group is performed as follows:

**CLI Syntax:** `config>qos>port-scheduler-policy>level priority-level  
rate pir-rate [cir cir-rate] group group-name [weight  
weight-in-group]`

**Note:** CLI will enforce that mapping of levels to a group are contiguous. In other words, a user would not be able to add priority level to group unless the resulting set of priority levels is contiguous.

When a level is not explicitly mapped to any group, it maps directly to the root of the port scheduler at its own priority like in existing behavior.

#### 9.4.12.3.4 Queue and Subscriber Aggregate Rate Configuration and Adjustment

Software-Based Implementation (8.0R4)

The subscriber aggregate rate is adjusted and it will be based on an average frame size.

The user enables the use of this adjustment method by configuring the following option in the egress context of the subscriber profile:

**CLI Syntax:** `config>subscr-mgmt>sub-profile>egress>encap-offset  
[type type]`

This command allows the user to configure a default value to be used by all hosts of the subscriber in the absence of a valid signaled value. The following is a list of the configurable values:

**Values:** pppoa-llc, pppoa-null, pppoeoa-llc, pppoeoa-llc-fcs, pppoeoa-llc-tagged, pppoeoa-llc-aggged-fcs, pppoeoa-null, pppoeoa-null-fcs, pppoeoa-null-tagged, pppoeoa-null-tagged-fcs, ipoa-llc, ipoa-null, ipoeoa-llc, ipoeoa-llc-fcs, ipoeoa-llc-tagged, ipoeoa-llc-tagged-fcs, poeoa-null, ipoeoa-null-fcs, ipoeoa-null-tagged, ipoeoa-null-tagged-fcs, pppoe, pppoe-tagged, ipoe, ipoe-tagged

Otherwise, the fixed packet offset will be derived from the encapsulation type value signaled in the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags as explained in Section Signaling of Last Mile Encapsulation Type. Only signaling using PPPoE Tags is supported in the software based implementation. The last signaled valid value is then applied to all active hosts of this subscriber. If no value is signaled in the subscriber host session or the value in the fields of the Access-loop-encapsulation sub-TLV are invalid, then the offset applied to the aggregate rate of this subscriber will use the last valid value signaled by a host of this subscriber if it exists, or the user entered default type value if configured, or no offset is applied.

The user also configures the average frame size value to be used for this adjustment:

**CLI Syntax:** `config>subscr-mgmt>sub-profile>egress>avg-frame-size  
bytes`

The value entered by the user must include the FCS but not the Inter-Frame Gap (IFG) or the preamble. If the user does not explicitly configure a value for the **avg-frame-size** parameter, then it will also be assumed the offset is zero regardless of the signaled or user-configured value.

The computation of the subscriber aggregate rate consists of taking the average frame size, adding the encapsulation fixed offset including the AAL5 trailer, and then adding the variable offset consisting of the AAL5 padding to next multiple of 48 bytes. The AverageFrameExpansionRatio is then derived as follows:

$$\text{AverageFrameExpansionRatio} = (53/48 \times (\text{AverageFrameSize} + \text{FixedEncapOffset} + \text{AAL5Padding})) / (\text{AverageFrameSize} + \text{IFG} + \text{Preamble}).$$

When the last mile is Ethernet, the formula simplifies to:

$$\text{AverageFrameExpansionRatio} = (\text{AverageFrameSize} + \text{FixedEncapOffset} + \text{IFG} + \text{Preamble}) / (\text{AverageFrameSize} + \text{IFG} + \text{Preamble}).$$

The following are the frame size and rate applied to the subscriber queue and scheduler:

Subscriber Host Queue (no change):

Size = ImmediateEgressEncap + Data

Rate = ImmediateEgressEncap + Data

Subscriber Aggregate Rate Scheduler:

Size = ImmediateEgressEncap + Data

Rate = sub-agg-rate / AverageFrameExpansionRatio

Note that the CPM applies the AverageFrameExpansionRatio adjustment to the various components used in the determination of the net subscriber operational aggregate rate. It then pushes these adjusted components to IOM which then makes the calculation of the net subscriber operational aggregate rate.

The formula used by the IOM for this determination is:

$$\text{sub-oper-agg-rate} = \min(\text{sub-policy-agg-rate} / \text{AverageFrameExpansionRatio}, \text{ancp\_rate} / \text{AverageFrameExpansionRatio}) + (\text{igmp\_rate\_delta} / \text{AverageFrameExpansionRatio}),$$

where *sub-policy-agg-rate* is either the value configured in the **agg-rate-limit** parameter in the subscriber profile or the resulting RADIUS override value. In both cases, the CPM uses an internal override to download the adjusted value to IOM.

The value of *sub-oper-agg-rate* is stored in the IOM's subscriber table.

The following are the procedures for handling signaling changes or configuration changes affecting the subscriber profile:

1. If a new RADIUS update comes in for the aggregate subscriber rate, then a new subscriber aggregate ATM adjusted rate is computed by CPM using the last configured **avg-frame-size** and then programmed to IOM.
2. If the user changes the value of the **avg-frame-size** parameter, enables/disables the **encap-offset** option, or changes the parameter value of the **encap-offset** option, the CPM will immediately trigger a re-evaluation of subscribers using the corresponding subscriber profile and an update the IOM with the new subscriber aggregate rate.

3. If the user changes the value of the **agg-rate-limit** parameter in a subscriber profile which has the **avg-frame-size** configured, this will immediately trigger a re-evaluation of subscribers using the corresponding subscriber profile. An update to the subscriber aggregate rate is performed for those subscribers which rate has not been previously overridden by RADIUS.
4. If the user changes the **type** value of the encap-offset command, this will immediately trigger a re-evaluation of subscribers using the corresponding subscriber profile. An update to the subscriber aggregate rate is performed for those subscribers which are currently using the default value.
5. If two hosts of the same subscriber signal two different encapsulation types, the last one signaled gets used at the next opportunity to re-evaluate the subscriber profile.
6. If a subscriber has a DHCP host, a static host or an ARP host, the subscriber aggregate rate will continue to use the user-configured default encapsulation type value or the last valid encapsulation value signaled in the PPPoE tags by other hosts of the same subscriber. If none was signaled or configured, then no rate adjustment is applied.

#### Hardware-Based Implementation

The data path will compute the adjusted frame size real-time for each serviced packet from a queue by adding the actual packet size to the fixed offset provided by CPM for this queue and variable AAL5 padding.

Like in the software based implementation, the user enables the use of the fixed offset and per packet variable expansion by configuring the following option in the egress context of the subscriber profile:

**CLI Syntax:**    `config>subscr-mgmt>sub-profile>egress>encap-offset`  
                  `[type type]`

When this command is enabled, the fixed packet offset will be derived from the encapsulation type value signaled in the Access-loop-encapsulation sub-TLV in the Vendor-Specific PPPoE Tags or DHCP Relay Options as explained in Section Signaling of Last Mile Encapsulation Type.

If the user specifies an encapsulation type with the command, this value will be used as the default value for all hosts of this subscriber until a host session signaled a valid value. The signaled value is applied to this host only and the remaining hosts of this subscriber continue to use the user entered default type value if configured, or no offset is applied. Note however that hosts of the same subscriber using the same SLA profile and which are on the same SAP will share the same instance of FC queues. In this case, the last valid encapsulation value signaled by a host of that same instance of the SAP egress QoS policy will override any previous signaled or configured value.

The procedures for handling signaling changes or configuration changes affecting the subscriber profile are the same as in the Software based implementation with except for the following:

1. The **avg-frame-size** parameter in the subscriber profile is ignored.
2. If the user specifies an encapsulation type with the command, this value will be used as the default value for all hosts of this subscriber until a host session signaled a valid value. The signaled value is applied to this host and other hosts of the same subscriber sharing the same SLA profile and which are on the same SAP. The remaining hosts of this subscriber continue to use the user entered default type value if configured, or no offset is applied.
3. If the user enables/disables the **encap-offset** option, or changes the parameter value of the **encap-offset** option, the CPM will immediately trigger a re-evaluation of subscribers hosts using the corresponding subscriber profile and an update the IOM with the new fixed offset value.
4. If subscriber host session signals an encapsulation type at the session establishment time and subsequently sends a DHCP renewal message using a Layer 2 DHCP relay which does not insert option82 in a unicast message, the encapsulation type for this host will not change. Note that TR-101 states that option82 is mandatory for DHCP broadcast messages).
5. If a subscriber has a static host or an ARP host, the subscriber host will continue to use the user-configured default encapsulation type value or the last valid encapsulation value signaled in the PPPoE tags or DHCP relay options by other hosts of the same subscriber which use the same SLA profile instance. If none was signaled or configured, then no rate adjustment is applied.
6. The encapsulation type value signaled in DHCP relay options or PPPoE tags are not cross-checked against the host type. So, a host signaling PPPoA/LLC encapsulation type via DHCP relay options will be handled as if the packet included a PPPoE header when forwarded over the local Ethernet port. This results in applying an encap-offset in the data path which assumes the PPPoE header is added to forwarded packets over the local Ethernet port.

The **encap-offset** option forces all the rates to be either last-mile frame over the wire or local port frame over the wire, referred to as **LM-FoW** and **FoW** respectively. The system maintains a running average frame expansion ratio for each queue to convert queue rates between these two formats as explained in [Frame Size, Rates, and Running Average Frame Expansion Ratio](#). Here are the details of the queue and scheduler operation:

1. When the **encap-offset** option is configured in the subscriber profile, the subscriber host queue rates, that is, CLI and operational PIR and CIR as well as queue bucket updates, the queue statistics, that is, forwarded, dropped, and HQoS offered counters use the **LM-FoW** format. The scheduler policy CLI and operational rates also use **LM-FoW** format. The port scheduler **max-rate** and

the priority level rates and weights, if a Weighted Scheduler Group is used, are always entered in CLI and interpreted as **FoW** rates. The same is true for an **agg-rate-limit** applied to a vport. Finally the subscriber **agg-rate-limit** is entered in CLI as **LM-FoW** rate. When converting between **LM-FoW** and **FoW** rates, the queue running average frame expansion ratio value is used.

- If the user enabled **frame-based-accounting** in a scheduler policy or **queue-frame-based-accounting** with subscriber **agg-rate-limit** and a port scheduler policy, the queue operational rate will be capped to a user configured **FoW** rate. The scheduler policy operational rates will also be in the **FoW** format. Note that a user configured queue **avg-frame-overhead** value is ignored since the running average frame expansion ratio is what is used when the **encap-offset** option is enabled.
  - If the user configured queue **packet-byte-offset** value, it is ignored and is not accounted for in the net packet offset calculation.
2. When **no encap-offset** is configured in the subscriber profile, that is, default and pre-R9.0 behavior, queue CLI and operational PIR and CIR rates, as well as queue bucket updates, the queue statistics, use data format. The scheduler policy CLI and operational rates also use data format. The port scheduler **max-rate** and the priority level rates and weights, if a Weighted Scheduler Group is used, and the subscriber **agg-rate-limit** are entered in CLI and interpreted as **FoW** rates. When converting between **FoW** and data rates, the queue **avg-frame-overhead** value is used and since this an Ethernet port, it is not user-configurable but constant and is equal to +20 bytes (IFG and preamble).
- If the user enabled **frame-based-accounting** in a scheduler policy or **queue-frame-based-accounting** with subscriber **agg-rate-limit** and a port scheduler policy, the queue operational rate will be capped to a user configured **FoW** rate in CLI which is then converted into a data rate using the queue **avg-frame-overhead** constant value of +20 bytes. The scheduler policy operational rates will also be in the **FoW** format.
  - If the user configured queue **packet-byte-offset** value, it adjusts the immediate packet size. This means that the queue rates, that is, operational PIR and CIR, and queue bucket updates use the adjusted packet size. In addition, the queue statistics will also reflect the adjusted packet size. Scheduler policy rates, which are data rates, will use the adjusted packet size. The port scheduler **max-rate** and the priority level rates and weights, if a Weighted Scheduler Group is used, as well as the subscriber **agg-rate-limit** are always **FoW** rates and thus use the actual frame size. Packet byte offset settings are not included in the applied rate when (queue) frame based accounting is configured, however, the offsets are applied to the statistics.

#### 9.4.12.3.5 Frame Size, Rates, and Running Average Frame Expansion Ratio

The following are the details of the rates and frame sizes applied to the subscriber host queues, the subscriber aggregate rate, and the vport root scheduler for the scheduling model and when the **encap-offset** option is enabled in the subscriber profile.

Subscriber Host Queue:

Size = LastMileFrameOverWireEncap + Data

Rate =  $(48/53)^* \times (\text{LastMileFrameOverWireEncap} + \text{Data})$

\*Applicable to ATM last-mile only.

Subscriber Aggregate Rate:

Size = LastMileFrameOverWireEncap + Data

Rate =  $(48/53)^* \times (\text{LastMileFrameOverWireEncap} + \text{Data})$

\*Applicable to ATM last-mile only.

Vport/Port Port Scheduler and Weighted Scheduler Group

Size = FrameOverWireEncap + Data

Rate = FrameOverWireEncap + Data
